- Substantial revision of BDCP's governance structure is needed. This includes giving full regulatory authority to the POG, while limiting their involvement in implementation.
- To address high uncertainties about project performance and future conditions, instead of a 50-year permit, there should be renewable "no surprises" guarantees issued every ten years based on conditions at the time and prior performance.
- An adaptive management program needs to be developed that has the capacity and authority to conduct adaptive management experiments and effectively use outcomes to revise and improve future actions..
- A well-funded BDCP science program needs to be developed that is integrated with existing Delta science programs. The best opportunity for integration lies with the current efforts to update the Delta Science Program.

Chapter 1: The Bay Delta Conservation Plan and Charge to the Panel

Introduction

The Bay Delta Conservation Plan (BDCP) is being developed to meet endangered species act permit requirements for operations of the Federal Central Valley Project (CVP) and the State Water Project (SWP) within the Sacramento-San Joaquin Delta. The Plan includes proposals for new points of diversion in the North Delta, new operations criteria, extensive floodplain and tidal marsh restoration, and new governance, oversight and adaptive management programs. The Plan applicants are seeking Habitat Conservation Plan (HCP)/Natural Communities Conservation Plan (NCCP) permits that will guide water exports and habitat management for 50 years.

The Bay Delta Conservation Plan is the most complex HCP/NCCP permit application ever attempted. Development of the Plan has been funded principally by state and federal water contractors and has been on-going for more than 5 years. In Spring 2013, select chapters of the Administrative Draft of BDCP were serially released for public review[1]. An Administrative Draft of the EIS/EIR for the Plan was released in May of 2013[2].

At the request of The Nature Conservancy California and American Rivers—two non-governmental organizations engaged in the BDCP process—an independent panel of five experts (Text Box 1.1) was assembled to assist in technical review of BDCP documents. The panel was asked to answer a suite of questions about the Plan to help inform decisionmaking by American Rivers and The Nature Conservancy. The panel was assembled and managed by Saracino & Mount, LLC, under contract from the S.D. Bechtel, Jr. Foundation Water Program. NewFields, Inc. provided support for the panel, including data retrieval, analysis and presentation. This report summarizes the conclusions of the work of this panel.

Guiding Questions

Two planning meetings were held between Saracino & Mount, LLC and staff of American Rivers and The Nature Conservancy. An initial list of more than 40 questions were developed that were germane to decisions that the organizations

---

[1] This report assumes that the reader is familiar with the Sacramento-San Joaquin Delta and on-going efforts to manage water supply and ecosystems to meet the co-equal goals prescribed in the 2009 Delta Reform Act. A summary of conditions in the Delta and other issues can be found at: http://baydeltaconservationplan.com/Home.aspx

[2] http://baydeltaconservationplan.com/Library/DocumentsLandingPage/EIREISDocuments.aspx

needed to make about future engagement with BDCP. These questions were distilled into the following six:

- *Q.1 Do operations of the dual facilities meet the broader goal of taking advantage of wet and above average years for exports while reducing pressure on below average, dry and critically dry years? What substantive changes in operations (and responses, see below) are there both seasonally and interannually?*
- *Q.2 Based on operations criteria, does the Plan properly identify ecological impacts likely to occur adjacent to and in the bypass reach downstream of the new North Delta diversion facilities? If there will be direct and indirect harm to listed species by the facilities, does the Plan prescribe sufficient mitigation measures?*
- *Q.3 Are changes in operations and points of diversion prescribed in the Plan sufficient to significantly improve in-Delta conditions for covered species? The focus is on listed species, including delta and longfin smelt, steelhead, winter and spring run Chinook, and green sturgeon.*
- *Q.4 Are covered pelagic fish like longfin smelt and delta smelt likely to benefit from restoration of floodplain and tidal marsh habitat at the scale proposed by the Plan? Given the current state of knowledge, and assuming that all Plan commitments are met, are these efforts likely to result in relaxed X2 and spring outflow standards?*
- *Q.5 Does the Plan provide achievable, clear and measureable goals and objectives, as well as governance that is transparent and resilient to political and special interest influence?*
- *Q.6 Is there a robust science and adaptive management plan for BDCP? As described, is the proposed "decision tree" likely to resolve major issues regarding Fall X2 and Spring Outflow prior to initial operations?*

Text Box 1.1: Members of the Review Panel.

Jeffrey Mount, Ph.D. (chair), geomorphologist, Professor Emeritus UC Davis, former Chair of the Delta Independent Science Board, and Partner, Saracino & Mount, LLC

William Fleenor, Ph.D. hydrologist and water quality specialist, Research Scientist, UC Davis Center for Watershed Sciences

Brian Gray, J.D. Professor, environmental law, UC Hastings.

Bruce Herbold, Ph.D. retired US Environmental Protection Agency, former Coordinator for the Interagency Ecological Program

Wim Kimmerer, Ph.D. food web ecologist, Researcher, San Francisco State University, Tiburon Center.

Using these questions as guide, the panel reviewed selected chapters within the Plan. The focus of the review was on the biological goals and objectives for species of fish listed as threatened or endangered (BDCP Chapters 1, 2), the conservation measures proposed to meet the biological objectives (BDCP Chapter 3 and appendixes, see Text Box 1.2), and the analysis of the effects of the project on Delta fish species and communities (BDCP Chapter 5 and appendixes). The panel also examined governance, adaptive management and science programs proposed in the

Plan, including the “decision tree” intended to resolve technical disagreements about initial operations (BDCP Chapters 3, 5, 6, 7, 8, 9, 10).

In addition to reviewing BDCP documents and literature, the panel held two meetings with the consultants who prepared the Plan for the project applicants. The consultants answered questions about analyses contained within the Plan and provided or directed panel members to pertinent sources of modeling data.

Text Box 1.2: Conservation Measures Considered by the Panel

There are 22 different conservation measures in BDCP. Since the questions asked were narrowly defined, the Panel focused only on five of the measures. These include:

Conservation Measure 1: Operations and Facilities. This covers the design, implementation and operation of a new North Delta point of diversion and the operation of all SWP and CVP facilities to improve conditions for listed species.

Conservation Measure 2: Yolo Bypass Fisheries Enhancement. The Plan proposes to increase winter flooding in the Yolo Bypass to improve rearing habitat for salmon as well as improve Delta food webs.

Conservation Measure 4: Tidal Natural Communities Restoration. This measure seeks to restore 55,000 acres of tidal freshwater and brackish marsh, with an additional 10,000 acres of transitional habitat. This will improve rearing habitat for several listed species and improve food webs for pelagic fishes.

Conservation Measure 5: Seasonally Inundated Floodplain Restoration. The Plan seeks to restore 10,000 acres of seasonal floodplain outside of the Yolo Bypass. This supports juvenile salmonids and overall food web productivity of the Delta.

Conservation Measure 6: Channel Margin Enhancement. The goal of the Plan is to improve conditions for rearing salmonids along channels of the Delta with close levees. This measure will improve 20 linear miles of channel by creating mudflat, riparian and wetland habitat through levee setbacks.

Basis of Comparison

The Bay Delta Conservation Plan seeks a permit for operation of the SWP and CVP at a future date when new facilities will be constructed. As written, the preferred alternative is to construct a new point of diversion in the North Delta on the Sacramento River near Freeport, with the goal of completion in 2025. This diversion is to have three screened intakes that will divert water into forebays and a pair of tunnels capable of transmitting a maximum of 9000 cfs by gravity feed. These tunnels will link to existing SWP and CVP export facilities located in the South Delta. Permit authority for the construction and combined operations of these facilities—typically referred to as dual facilities—are the foundation of the plan. Construction and operations are paired with extensive conservation measures (see below) to mitigate for impacts of the project and to conserve and recover listed species and their biological communities.

One of the many controversies surrounding the Plan is the establishment of an environmental baseline for comparison of alternatives and analysis of the effects of the project on listed species. The requirements of the Biological Opinions (BiOps) issued by the U.S. Fish and Wildlife Service (USFWS) in 2008 and the National Marine Fisheries Service (NMFS) in 2009 constitute the baseline for the Plan. There is considerable debate between the fish agencies (NMFS and USFWS principally) and the permitees over the provisions of these BiOps, particularly in regard to requirements for high Delta outflows to support longfin smelt in the spring and high outflows to achieve Fall X2 (low salinity zone) provisions to support delta smelt. For this reason, there are two Existing Biological Conditions (EBC) considered by the Plan (Table 1.1): EBC1 includes high spring outflow provisions and EBC2, includes both high spring outflow and the new Fall X2 provisions.

A central requirement of the Plan, and the source of much of its complexity, is to analyze conditions over the 50-year life of the project. The Plan divides future conditions into two classes: Early Long Term (ELT), which captures the initial operating conditions of the project once a new diversion facility has been constructed (approximately 2025), and Late Long Term (LLT) which accounts for full completion of all conservation measures, including restoration of more than 55,000 acres of tidal marsh and floodplain (approximately 2060). Climate change, particularly changes in runoff and sea level, and changes in water demand are incorporated in these projections.

The controversy over spring and fall outflow needs for conservation and recovery of listed species propagates into the assessments of future conditions. Without-project EBC1 and EBC2 are considered for both ELT and LLT. Evaluated starting operations (ESO) of the preferred project and alternatives are presented for ELT and LLT conditions. Two additional future scenarios are evaluated that purport to provide bookends to project operations that dictate future water exports. The first is a High Outflow Scenario (HOS), which is similar to the outflow standards in EBC2 (high spring and fall outflow). The second is a Low Outflow Scenario (LOS), which has reduced outflow standards for both spring and fall. Both the LOS and HOS are considered in the ELT and LLT, with the latter including completion of habitat restoration. The Plan proposes a “decision tree process” be undertaken during construction of the facility that will reduce uncertainties and guide initial project operations, presumably within the bounds of the HOS and LOS (reviewed in Chapter 9).

For the purposes of this review, we simplified our comparison of operations and restoration scenarios to just three. Using simulation data provided by BDCP consultants we examined the HOS and LOS scenarios for ELT. We then used a no-project alternative, NAA ELT, that commonly appears throughout BDCP documentation, particularly in the EIR/EIS. NAA prescribes a high fall outflow to maintain X2 standards for smelt and D-1641 salinity and flow standards required by the State Water Resources Control Board for the remainder of the year.

Table 1.1. Definitions of existing baseline conditions and project conditions simulated in BDCP.

Conditions		**Description**
Existing Biological Conditions	EBC1	Current operations based on BiOps, excluding management of outflows to the Fall X2 provisions of USFWS 2008 BiOp.
	EBC2	Current operations based on BiOps, including management of outflows to meet USFWS Fall X2 provisions from 2008 BiOp.
Projected Future Conditions without the BDCP	EBC2_ELT	EBC2 projected into year 15 (2025) accounting for climate change expected at that time.
	EBC2_LLT	EBC2 projected into year 50 (2060) accounting for climate change expected at that time.
Projected Future Conditions with the BDCP	ESO_ELT	Evaluated starting operations in year 15 assuming new intake facility operational and restoration not fully implemented
	ESO_LLT	Evaluated starting operations in year 50 assuming new intake facility operational and restoration fully implemented.
	HOS_ELT	High-outflow operations during spring and fall in year 15 assuming new intake facility operational and restoration not fully implemented.
	HOS_LLT	High-outflow operations during spring and fall in year 50 assuming new intake facility operational and restoration fully implemented.
	LOS_ELT	Low-outflow operations during spring and fall in year 15 assuming new intake facility operational and restoration not fully implemented.
	LOS_LLT	Low-outflow operations during spring and fall in year 50 assuming new intake facility operational and restoration fully implemented.

It should be noted that the Panel chose not to review LLT scenarios and conditions beyond the question of whether restoration of marsh is likely to benefit listed fishes.

Although it is necessary and useful to consider how the project might operate over the long-term, especially under climate change, the Panel felt that exceptionally high uncertainties made it difficult to offer precise answers within the LLT framework. These uncertainties are associated with our understanding of the Delta, with the models used to simulate future conditions, and with the array of events (biological invasions, floods, droughts, earthquakes, policy changes, lawsuits, etc.) that are likely to occur.

A Note About Hydrologic Modeling Tools and Uncertainties

The basis for the BDCP analysis is hydrologic simulation modeling that provides flow, water elevations, temperature and salinity at various locations throughout the Delta and its upstream areas. Much of the Effects Analysis for aquatic species and all of the export projections are based on outputs from these hydrologic models. BDCP is one of the most complex modeling efforts of its kind and certainly the most complex ever attempted in the Delta. This is a heroic modeling effort.

There are three general categories of uncertainty in the hydrologic model results:

Model uncertainties. This includes how the model simulates hydrology and the hydrologic results of operations, including salinity, temperatures and other water quality parameters. The currently available modeling tools are less than ideal to simulate such a long-term record with dramatic changes in conditions such as sea level rise and introduced sub-tidal and inter-tidal land. The principal issues are summarized in Text Box 1.3.

Future condition uncertainties. There is extensive effort in BDCP to estimate future conditions in the Delta, including sea level rise and changes in temperature and runoff. This is the most comprehensive approach to date. These are described well in Appendix 5A of the Plan and highlight high levels of uncertainty.

Regulatory and behavioral uncertainty. BDCP models assume that flow and water quality standards will remain static during the life of the project. In addition, the models assume uniform behavior of system operators, ignoring real-time operations and adaptations. All of these are highly unlikely to occur.

The hydrologic model results of BDCP are presented as if they are a unique solution. Given the compounding uncertainties, BDCP model results should be considered as scenarios rather than specific outcomes. This issue is often lost in the public debates over BDCP. As discussed later in this report, the model uncertainties significantly impact our confidence in some of our results, particularly our analysis of the response of pelagic fishes to changes in South Delta operations.

Text Box 1.3: Hydrologic Model Uncertainty.

To adapt existing tools to model future conditions under BDCP consultants developed dispersion coefficients with the 3-dimensional UnTRIM model developed by Michael MacWilliams for sea level rise. A similar process was then followed with a 2-dimensional model developed by Research Management Associates to estimate the additional dispersion for the proposed new open tidal areas. Parameters developed from the multi-dimensional efforts were then incorporated into the 1-dimensional DSM2 planning model developed by DWR to simulate a part of the long-term record incorporating sea level rise and tidally restored acreage. The boundary conditions for the DSM2 model, which operates at time steps as short as 15 minutes, was provided by CALSIM, the 1-dimensional system-wide water operations optimization model. CALSIM output occurs on monthly time steps and had to be disaggregated to provide boundary conditions for DSM2. All the results, including the DSM2 results and artificial neural network salinity results, were then used to train the CALSIM model. The CALSIM model was then used to simulate the entire 82-year record that formed the basis for the Effects Analysis. All of these model exchanges, particularly between 1-, 2-, and 3-dimentional models, create error or model bias. To date, there is no assessment of these model biases and how they impact BDCP results.

Organization of This Report

This report is organized into nine chapters followed by a summary of answers to the guiding questions. Chapters 2-9 include:

- *Chapter 2, Overview of the Law Governing BDCP.* Although not specifically requested by TNC and AR, we found it helpful to review key provisions of the HCP/NCCP laws that set standards for recovery of populations of covered fishes.
- *Chapter 3, Water Supply Operations.* This chapter examines how BDCP performs in meeting the goal of increasing water supply reliability. This includes assessment of changes in export volumes, both seasonally and within different year types.
- *Chapter 4, Environmental Flow Performance: Upstream and Inflows.* The new facilities and their operation are supposed to improve flow conditions impacted by the SWP and CVP. This chapter describes flows regulated by project dams, flows past and through the new North Delta facilities, and the overall inflow regime of the estuary.
- *Chapter 5, In-Delta Effects on Pelagic Fishes.* The changes in flow conditions outlined in the previous chapter translate to changes in ecological conditions for listed fish species. This chapter evaluates the likely response of delta smelt and longfin smelt to these changes

- *Chapter 6, Estimated Effects of BDCP Flows on Smelt.* This chapter examines the magnitude of changes in outflow and the likely response of delta and longfin smelt.
- *Chapter 7, Likely Response of Listed Fishes to Habitat Restoration.* A fundamental hypothesis of BDCP is that restoration of physical habitat, particularly tidal marsh, will improve food web conditions for pelagic fishes, aiding their recovery. This chapter evaluates this hypothesis.
- *Chapter 8, Governance and Terms of BDCP*. The 50-year permit for the project, coupled with governance and oversight, are examined in this chapter.
- *Chapter 9, Science and Adaptive Management*. The Plan makes extensive mention of the use of adaptive management supported by robust science to address major uncertainties. The Plan's objectives in this regard are reviewed.
- *Chapter 10*, Summary and Conclusions. This chapter provides a summary of answers to the six questions presented to the panel by American Rivers and The Nature Conservancy. In addition, where appropriate, recommendations are offered for ways to improve the performance of BDCP.

Conclusion

This report is, by design, narrowly focused on a limited set of issues of concern to The Nature Conservancy and American Rivers. It is not intended to serve as a broad review of BDCP, nor is it directed toward a wide audience. In addition, the panel specifically steered away from endorsing or rejecting BDCP, and makes no recommendation on the critical question of whether American Rivers and The Nature Conservancy should support BDCP, support it with modifications, or reject/oppose it. Rather, the observations, analyses and recommendations are solely intended to inform this decision.

Chapter 2: An Overview of the Law Governing the BDCP

Introduction

This chapter provides a brief overview of the law that governs the creation and implementation of the Bay Delta Conservation Plan. It also addresses an important question that has arisen during the BDCP negotiations: May the California Department of Fish and Wildlife (CDFW) approve the BDCP as a natural community conservation plan if the BDCP does not provide for full recovery of the endangered and threatened species covered by the Plan?

Habitat Conservation Planning and Natural Community Conservation Planning Under Federal and California Law

The BDCP is a Habitat Conservation Plan (HCP) authorized by section 10(a) of the federal Endangered Species Act (ESA), 16 U.S.C. § 1539(a), and a Natural Community Conservation Plan (NCCP) authorized by the California Natural Community Conservation Planning Act (NCCPA), California Fish and Game Code §§ 2800-2835. Section 10(a) of the federal ESA allows the U.S. Fish and Wildlife Service (USFWS) and the National Marine Fisheries Service (NMFS) to issue permits that authorize the taking of endangered or threatened species "if such taking is incidental to, and not the purpose of, the carrying out of an otherwise lawful activity" and the proposed activity is governed by an approved HCP. *Id.* § 1539(a)(1)(B) & (2). Similarly, under the NCCPA the California Department of Fish and Wildlife (CDFW) may "authorize by permit the taking of any covered species . . . whose conservation and management is provided for in a natural community conservation plan approved by the department." California Fish & Game Code § 2835.[1]

If approved by the three fish and wildlife agencies, the BDCP will be a legally binding document that defines the terms and conditions under which the U.S. Bureau of Reclamation (USBR) and the California Department of Water Resources (DWR) may construct and operate the proposed new water diversion and transport facilities described in the draft Plan.[2] The BDCP also will serve as "a comprehensive

---

[1] The NCCPA defines "covered species" to include species that are listed for protection under the California Endangered Species Act, California Fish & Game Code §§ 2050-2115.5, and nonlisted species that are "conserved and managed under [another] approved natural community conservation plan and that may be authorized for take." *Id.* § 2805(e).

[2] The complete statutory requirements governing the contents and approval of the BDCP as an HCP and NCCP are set forth respectively in section 10(a)(2)(A) & (B) of the federal Endangered Species Act, 16 U.S.C. § 1539(a)(2)(A) & (B), and sections 2810 and 2820 of the California Fish and Game Code.

conservation strategy for the Sacramento–San Joaquin River Delta (Delta) designed to restore and protect ecosystem health, water supply, and water quality within a stable regulatory framework" (BDCP 1-1)[3].

The BDCP will include "regulatory assurances" that protect the permittees from the financial cost of changes to the BDCP or other regulatory changes needed to protect the species or their habitat[4]. As authorized by federal and state law, these regulatory assurances provide that, if changed circumstances arise that are either unforeseen or not provided for in the Plan, then the fish and wildlife agencies will not require the permittees to devote additional land, water, or financial resources beyond the levels set forth in the BDCP without the consent of the plan participants. Nor will the federal and state regulators impose additional restrictions on project operations without compensating the permittees for the lost water or additional costs.[5]

Both statutes also authorize the fish and wildlife agencies to suspend or revoke the incidental take permits for noncompliance with the terms and conditions of the BDCP or where implementation of the Plan will place the covered species in jeopardy of extinction.[6]

We consider the regulatory assurances, revocation authority, and other aspects of BDCP governance in Chapter 8.

---

[3] In addition, the BDCP will be the basis for a biological assessment that USBR will submit to the USFWS and NMFS prior to consultation under section 7 of the Endangered Species Act. BDCP 1-6. The BDCP thus will help to inform the federal fish and wildlife agencies' analysis of the new facilities and changes in coordinated CVP/SWP operations proposed in the draft Plan. The agencies then will decide whether the BDCP "is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of [the species' critical habitat]." 16 U.S.C. § 1536(a)(2). If the agencies determine that the BDCP *is* likely to jeopardize a listed species or adversely affect critical habitat, the biological opinion that they issue to the Bureau will include "reasonable and prudent alternatives" designed to avoid these consequences, as well as incidental take authorization governing CVP operations. *Id.* § 1536(b)(3) & (4).

[4] The regulatory assurances will apply to all entities that are issued incidental take permits under the BDCP, including DWR and the CVP and SWP contractors if the contractors become permittees. The "no surprises" assurance will not apply, however, to the Bureau of Reclamation. BDCP 6-29.

[5] The USFWS and NMFS adopted the federal "no surprises" policy by rulemaking in 1998. The substantive requirements of these rules may be found at 50 C.F.R. § 17.22(b)(5) & (6) and 50 C.F.R. § 222.307(g), respectively. The state "no surprises" guarantees are set forth in the NCCPA itself. California Fish & Game Code § 2820(f).

[6] The federal suspension and revocation rules are set forth in the Endangered Species Act, 16 U.S.C. § 1539(a)(2)(C), and in the ESA regulations, 50 C.F.R. § 17.22(b)(8). The state law counterparts may be found in California Fish & Game Code § 2820(b)(3).

Conservation and Recovery Requirements Under Federal and State Law

The federal Endangered Species Act and the California Natural Communities Conservation Planning Act differ in their respective conservation and recovery standards. The federal statute provides that the fish and wildlife agencies may not approve the BDCP unless they determine that the incidental take authorized by the permit and HCP "will not appreciably reduce the likelihood of the survival and recovery of the species in the wild." 16 U.S.C. § 1539(a)(2)(B)(iv).

In contrast, the NCCPA states that Department of Fish and Wildlife may approve the BDCP only if it finds *inter alia* that the Plan

> provides for the protection of habitat, natural communities, and species diversity on a landscape or ecosystem level through the creation and long-term management of habitat reserves or other measures that provide equivalent *conservation* of covered species appropriate for land, aquatic, and marine habitats within the plan area.

California Fish & Game Code § 2820(a)(3) (emphasis added). The Act defines "conservation" as "the use of methods and procedures within the plan area that are necessary *to bring any covered species to the point at which the measures provided pursuant to [the California Endangered Species Act] are not necessary.*" *Id.* § 2805(d) (emphasis added).

In other words, the federal Endangered Species Act requires only that habitat conservation plans ensure that the permitted activities do no significant harm to the listed species or to their critical habitats. The California Natural Communities Conservation Planning Act, by comparison, regards proposed projects such as the BDCP as opportunities for more coordinated and cohesive planning to improve the condition of covered species and their habitat, rather than simply being a means to authorize the permitted activities while maintaining the *status quo ante.*

The draft BDCP describes its biological goals and objectives in two different ways. At the "landscape level," the goals include restoration or creation of "ecological processes and conditions that sustain and reestablish natural communities and native species" (BDCP 3.3-5). At the "species level," however, the biological goals refer to *progress toward* the landscape level goal of reestablished and sustainable natural communities and native species.

Thus, the primary biological goals for the Delta Smelt and Longfin Smelt are "increased end of year fecundity and improved survival of adult and juvenile . . . smelt to support increase abundance and long-term population viability" (BDCP 3.3-13 & 3.3-16). Similarly, the principal biological goal for Sacramento Winter-Run Chinook Salmon is "improved survival (to contribute to increased abundance) of immigrating and emigrating . . . salmon through the Plan Area," (BDCP 3.3-16), and for other species of salmon and steelhead the goal is "increased . . . abundance" (BDCP 3.3-17 to 3.3-19).

The draft BDCP explains that the process of developing these species level biological goals "did not assume that the BDCP would be solely responsible for recovery of these species, and so the designated biological goals and objectives did not necessarily match the recovery goals, but instead represented the BDCP's potential to *contribute to recovery* within the Plan Area (BDCP 3.A-14: emphasis added). This decision has become a focal point of debate over the essential purposes and mandates of the NCCPA.

In a July 10, 2013, letter to the Director of CDFW, three environmental organizations challenged the BDCP's proposed adoption of biological goals that do not provide for full recovery of the species, arguing that this "contribution to recovery" standard violates California law:

> Under the plain text of the NCCPA, conservation means recovery, and a Plan is required to contain measures that are sufficient to achieve recovery within the plan area.

The Natural Community Conservation Planning Act is the Foundation for a Successful Bay Delta Conservation Plan, Letter to Charlton H. Bonham, Director of the California Department of Fish and Wildlife, from the Defenders of Wildlife, Natural Resources Defense Council, and the Bay Institute, July 10, 2013, at 5 (citing Fish & Game Code § 2805(c)).

As described in detail in the chapters that follow, the limitations on project operations and other conservation measures set forth in the draft BDCP would not meet the conservation standard proposed by the July 10th letter—*viz.* full recovery of the listed species—though they are likely to contribute to species recovery. The letter thus raises a critical legal question that will have to be resolved by the Director of CDFW, in consultation with the Department's General Counsel and the Attorney General, before the Department decides whether to approve the BDCP.

The answer to this question is not free from doubt, as the Legislature defined the purposes of the NCCPA in terms that stand in some tension to one another. For example, section 2801(i) declares that the "purpose of natural community conservation planning is to *sustain and restore* those species and their habitat . . . that are necessary to maintain the continued viability of those biological communities impacted by human changes to the landscape." California Fish and Game Code § 2801(i) (emphasis added). In contrast, section 2801(g) states that "[n]atural community conservation planning is a mechanism that can provide an early planning framework for proposed development projects . . . in order to avoid, minimize, and compensate *for project impacts to wildlife.*" *Id.* § 2801(g) (emphasis added).

A careful and integrated reading of the text of the substantive provisions of the statute, however, should lead to the conclusion that the Act authorizes the CDFW to approve the BDCP if it concludes that the Plan would protect listed species from the adverse effects of the projects authorized by the Plan (including full mitigation of those effects) *and* would promote the recovery of listed species. Stated differently, we do not believe that the Legislature intended to prohibit the Department from approving the BDCP unless it concludes that the Plan—in isolation both from other existing sources of the species' decline and from other state and federal actions to protect listed species—will achieve full recovery of the species. We reach this conclusion for several reasons.

First, the interpretation of the statute proposed in the July 10th letter is based entirely on the section of the Act that defines the term "conservation." If the Legislature actually intended to require the CDFW to determine that an NCCP would be likely to achieve full recovery of listed species, it would have included this requirement in Section 2820, which governs the Department's approval of proposed NCCPs.

Section 2820(a) lists ten separate findings that are prerequisite to CDFW approval, and section 2820(b) contains nine terms that must be included in the implementation agreements that accompany the NCCPs. None of these mandatory findings and terms includes the requirement proposed in the July 10th letter. We do not believe that the Legislature somehow intended to add a twentieth requirement to these lists—that the NCCP and implementation plan must provide for full species recovery—by implication from the definitions section of the Act.

Second, there are two provisions in section 2820 that expressly link the required conservation measures to the effects of the project authorized by an NCCP. Section 2820(a) states that the CDFW may approve an NCCP only if it finds that the plan

> contains *specific conservation measures that meet the biological needs of covered species and that are based upon* the best available scientific information regarding the status of covered species and *the impacts of permitted activities on those species*. [*Id.* § 2820(a)(6) (emphasis added).]

Section 2820(b) stipulates that implementation agreements must include provisions

> to ensure that *implementation of* mitigation and *conservation measures on a plan basis is roughly proportional in time and extent to the impact on habitat or covered species authorized under the plan*. These provisions shall identify the *conservation measures* . . . that will be maintained or carried out in *rough proportion to the impact on habitat or covered species.* [*Id.* § 2820(b)(9) emphasis added).]

This pairing of conservation and recovery with references to the "impacts of permitted activities," together with the "rough proportionality" limitation on conservation measures, suggests that the Legislature intended to authorize NCCPs as a means of contributing to other state and federal efforts to recover species, but not significantly in excess of the burdens that the project covered by the plan would impose on the species.[7]

Third, there is nothing in the text or legislative history of the NCCPA to indicate that the Legislature intended to force the state to bear programmatic and financial responsibility for full species recovery each time the CDFW approves an NCCP.[8] Conservation measures required to achieve full recovery may extend far beyond the scope of an individual NCCP. Indeed, a requirement of full recovery would be particularly problematic for plans such as the BDCP that involve multiple species (some of which only partly inhabit the program area), multiple sources of stress, and diverse land and water management and regulatory agencies that each have independent obligations to contribute to species conservation and recovery. We do not believe that the Legislature would have assigned such a Herculean obligation to the Department, or imposed such a potentially large financial burden on state taxpayers, without saying so explicitly in the text of the statute.

Finally, an interpretation of the statute that would require the CDFW to make a determination that all proposed NCCPs provide for full recovery of listed species would likely have the unintended and pernicious consequence of deterring the Department from approving future plans. The CDFW might conclude that the scope of the necessary species recovery effort extends beyond the scope of the proposed project and hence beyond the capabilities of the project restrictions and conservation measures that would be included in the individual NCCP. Or it might be reluctant to approve an NCCP in situations where the costs of full recovery of the listed species covered by the plan—which the state would have to bear—significantly exceed the project mitigation costs that may be placed on the project proponents.

Again, these factors are especially pronounced in contexts such as the Delta ecosystem where there are multiple species (some of whose habitat is only partly

---

[7] The July 10th letter acknowledges that the NCCPA contains this "rough proportionality" limitation, but argues that "the concept of 'rough proportionality' is applied only to mitigation measures and not to a plan's conservation measures." Letter to Director Bonham at 7. The text of the Act belies this interpretation, however, as four of the five statutory references expressly apply the "rough proportionality" limitation to the conservation requirements. *See* California Fish & Game Code §§ 2805(g)(3)(C), 2820(b)(3)(B), § 2820(b)(9) & § 2820(c).

[8] The July 10th letter recognizes that the entities that receive incidental take permits under the BDCP may not be required to bear all of the costs of recovery of the various listed species: "[W]hen dividing up the costs of the plan's conservation strategy, the individual developers are only responsible for paying for 'mitigation' and the 'conservation' increment above mitigation is the responsibility of the state." Letter to Director Bonham at 7. Thus, if the costs of recovery exceed the mitigation costs that lawfully may be assigned to the permitted entities, the state must make up the difference: "The BDCP cannot limit its conservation measures to address only those impacts from the covered activities and avoid providing conservation measures sufficient to recover covered species." *Id.* at 8.

within the project area), multiple stressors (many of which are not plan participants), overlapping and sometimes conflicting habitat requirements, and tremendous uncertainty both about the needs of the species and the likelihood of success of recovery strategies. The interpretation of the NCCPA set forth in the July 10th letter therefore poses a significant policy risk of deterring otherwise salutary applications of natural resources conservation planning.

Conclusion

We conclude that the draft BDCP's establishment of biological goals and conservation measures that are based on the Plan's "potential to contribute to recovery" of the covered species complies with the Natural Communities Conservation Planning Act. We also believe that the CDFW may approve the Plan if it determines that the BDCP will ensure the survival of the listed species, fully mitigate the adverse effects of the project on all covered species and their habitat, and further the more general state and federal efforts to recover the species and to restore the favorable conditions of their habitat.

Chapter 3: Water Supply Operations

Introduction

The construction of a new North Delta diversion facility, and the coordinated operation of the North and South Delta facilities constitute the first and most prominent conservation measure (CM#1) of the BDCP. While ostensibly a conservation measure, the new facilities are principally an effort to improve the reliability of exports from the Delta. Their operations, in conjunction with all other conservation measures, are intended to mitigate for impacts of the CVP and SWP, avoid jeopardy and/or to contribute to the recovery of covered species (Chapter 2).

A basic premise of BDCP is that the construction of the new North Delta diversion facility will simultaneously improve water supply reliability while reducing ecosystem impacts. This stems from the increased operational flexibility associated with two points of diversion located in different portions of the Delta. A presumed benefit of this flexibility is the capacity to take advantage of periods of high inflow for exports, allowing for reductions in exports during dry periods when impacts on the ecosystem may be largest. This is consistent with the co-equal goals expressed in the 2009 Delta Reform Act.

This chapter examines the water supply operations proposed under BDCP to evaluate 1) if there are significant changes in supply reliability associated with the project and 2) how these changes apportion exports in wet vs. dry periods. This description is foundational for the assessment of ecological and species-specific consequences of BDCP as described in subsequent chapters.

Proposed Facilities and Operations

There are lengthy descriptions of the design and operation of new and existing water export facilities in the Administrative Drafts of the EIR/EIS and BDCP. The reader is referred to these documents for information. The centerpiece of the plan is the 9000 cfs capacity diversion in the North Delta that conveys water to the SWP and CVP export facilities in the South Delta through two tunnels.

Regulatory Constraints

The operational criteria for the export facilities are both complex and highly constrained (Appendix A). As outlined below, these constraints *significantly reduce the operational flexibility of the facilities*. The current regulatory constraints include but are not limited to:

- SWRCB water rights decision D-1641: this includes standards for minimum monthly Delta outflow, salinity objectives at multiple Delta locations, location of X2 (the position of the 2 ppt salinity near the channel bottom), a maximum export/import ratio objective[1], closures of the Delta Cross Channel (DCC), placement of a barrier at the head of Old River, and flow standards for the San Joaquin River below Vernalis. These standards vary depending upon months of the year and water year type.

- Remanded 2008 USFWS Biological Opinion (BiOp): prescribes restrictions for magnitude and timing of reverse flows in Old and Middle River (OMR) in the South Delta, to protect delta smelt. These vary depending upon time of year, water temperature, flows on the San Joaquin River, and proximity of smelt. This BiOp also calls for higher spring and fall outflows that exceed D-1641 standards. These outflow standards vary on water year type.
- Remanded 2009 NMFS BiOp: has different restrictions on OMR flows than the USFWS BiOp. Reductions in reverse OMR flows are scheduled to protect outmigrating salmonids. These vary depending on temperature and inflow. This BiOp increased San Joaquin River flows and set export/San Joaquin River flow ratios that are more restrictive than D-1641.

There are other regulatory constraints beyond D-1641 and the two remanded BiOps; however, compliance with these regulations appears to dominate water supply export modeling. Additional constraints are based on proposed operating rules for both the North and South Delta facilities. The most significant include:

- Maintenance of minimum flows downstream of the North Delta facility (called "Bypass Flows")
- Restrictions aimed to reduce reverse flows at the confluence between the Sacramento River and Georgiana Slough
- A tiered, three-level pumping regime for December through June that seeks to protect the initial winter flood pulse and spring pulses that affect juvenile salmon outmigration
- Flows with sufficient velocity to reduce impingement of salmonids at diversion screens
- Increased restrictions for reverse Old and Middle River (OMR) flows associated with South Delta exports.

Infrastructure and Inflow Constraints

Infrastructure design and capacity forms another array of constraints. For the purposes of BDCP simulation modeling, south of Delta storage was limited to space within San Luis Reservoir. Operations during wet and above average conditions are often constrained by available space to store water in this facility. Expanding potential storage, particularly groundwater storage, would have created considerably more flexibility in exports, particularly during wet years.

---

[1] BDCP treats the export/import ratio in two ways: 1) counting as "import" all inflows from the San Joaquin and Sacramento Rivers and Delta's tributaries or 2) counting inflows as above, but counting flows below the North Delta facility as inflow. The latter approach seeks to exclude North Delta exports from D-1641 export/import restrictions. From an ecosystem perspective, this makes no sense since the North Delta exports are, in effect, exports from the legal Delta.

The size of the North Delta facility is also a constraint, principally during periods of sustained high flow on the Sacramento River in wet years. The preferred project has shifted from an initial facility size of 15,000 cfs to 9,000 cfs in the current plan. The export, economic and environmental performance of the 9,000 cfs facility is compared to 14 alternatives in Chapter 3 and 5 of the Draft EIS/EIR. These alternatives vary facility size, location and operations in the comparison. A narrative is presented in the EIS/EIR that describes the rationale for rejecting the 14 alternatives and selecting the preferred project[2].

Exports are also naturally constrained by the timing and volume of inflows, with strong seasonal and interannual variation. One of the larger export challenges faced by BDCP is its location at the bottom of the system where flows enter the Delta. Upstream water management and consumptive use dominate inflows to the Delta over most years (Figure 3.1). These abstractions, which consume roughly ¼ of water that would naturally flow to the Delta, are beyond the control of BDCP, yet are the greatest operational influence on Delta inflows. Under BDCP, exports would be roughly equivalent to upstream consumptive use.

In addition, there are important restrictions on reservoir operations that constrain exports. The USACE has congressionally authorized rule curves that dictate Fall, Winter and Spring operations to maintain flood reserves. More importantly, there are BiOps that dictate flow and temperature requirements to meet the life history needs of covered salmon, steelhead and sturgeon below the dams. Meeting these standards, particularly in drier years and under a warming climate, limits the amount and timing of inflows to the Delta. Oroville Reservoir, which has fewer restrictions on flows, becomes the most important for supporting Delta inflows as a result, particularly during drought conditions (see below).

Consequences of Constraints

The above discussion is intended to highlight a conundrum that is not discussed much outside of the BDCP community of experts and is not examined in the Plan: export operations and operations to support conservation are *highly* constrained. These regulatory, operational and infrastructure constraints limit the ability of BDCP to adaptively manage operations to support co-equal export *and* ecosystem objectives. For this reason, the anticipated management associated with the new diversion facility is not fully realized.

---

[2] It is beyond the scope of this review to examine facility size in detail. In general, the analyses offered in the EIR/EIS conclude that the 9000 cfs facility provides the optimal balance of cost and flexibility. The additional capacity of the 15,000 cfs facility is rarely used in the operations that they modeled, leading to a very modest increase (<250 taf) in overall exports. The EIS/EIR did examine smaller facilities with capacities of 6000 and 3000 cfs. However, the operating criteria used to evaluate these two alternatives are not comparable to those of the preferred alternative, making the comparison moot.

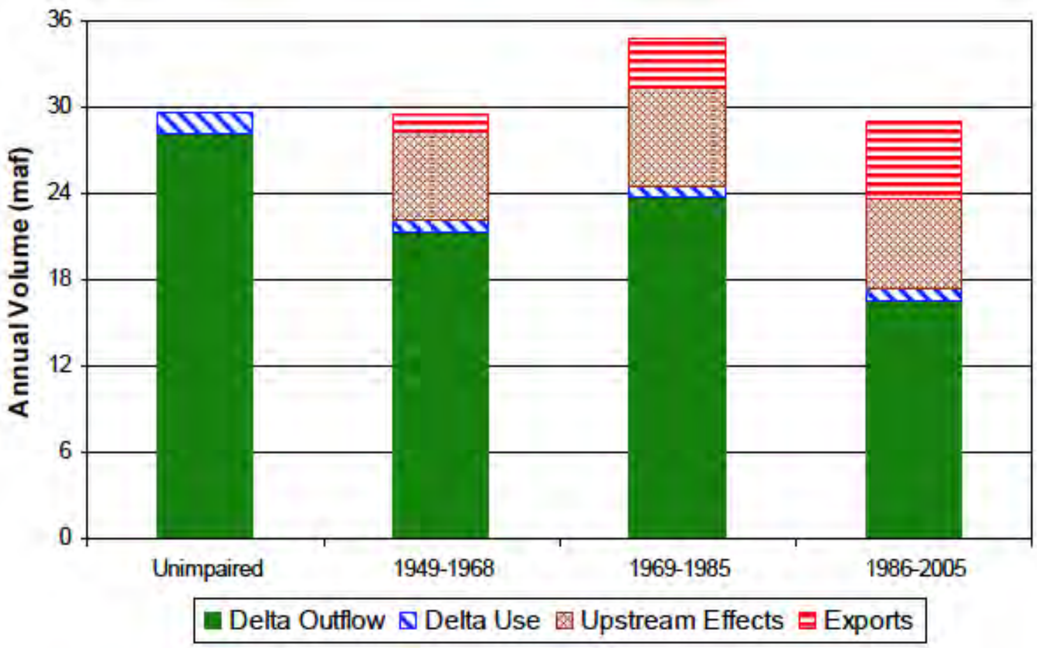

Figure 3.1 Proportional Delta water use. Exports constitute roughly 18% of the total unimpaired flow of the Delta in the 1986-2005 hydrology, with upstream consumptive use approximately 24%. From Fleenor et al. (2010).

This also highlights how flow management in BDCP was developed using system models. As described in Appendix 5C of the Plan, the models sought to meet the requirements of D-1641, the remanded BiOps, reservoir and diversion facility constraints, and south of Delta storage. The objective function was then to maximize Delta exports within those constraints. Although this seems logical, it highlights how CM1 is not a conservation measure, per se. Rather than doing a bottom-up assessment of ecosystem flow needs, as is typically done when setting environmental flows, the modeling sought to meet current regulatory requirements and flow constraints sought by fish agencies. This illustrates one of the key points made by Lund et al. (2010) and Moyle et al. (2012) that multi-objective management of the Delta is likely to require a comprehensive re-evaluation of flow and water quality standards.

Export Reliability

A goal of the BDCP project and the current Delta Plan is to improve reliability of water derived from the Delta for consumptive uses[3]. Using model simulations provided by BDCP consultants, we have evaluated how well BDCP meets the goal of improving export reliability. The most commonly discussed aspect of BDCP—

---

[3] In actuality, the most reliable system would provide a given amount of water each year with the smallest deviation from that amount. Instead, BDCP attempts to produce the most water in any given year under the given regulatory and operational constraints. This produces a more *resilient* water supply systems, whereby the greatest volume is made available, even under the event of catastrophic salinity intrusion into the Delta. The terms resilient and reliable are used interchangeably in BDCP and other documents.

average annual export—is summarized in Figure 3.2, and compares the no-project alternative, NAA with the high outflow scenario, HOS and low outflow scenario, LOS (defined in Chapter 1). This modeling suggests that the HOS and NAA would provide roughly equal average exports, with the LOS providing approximately 700 taf more. However, these figures are an average over an 82-year simulation period and offer little information about reliability.

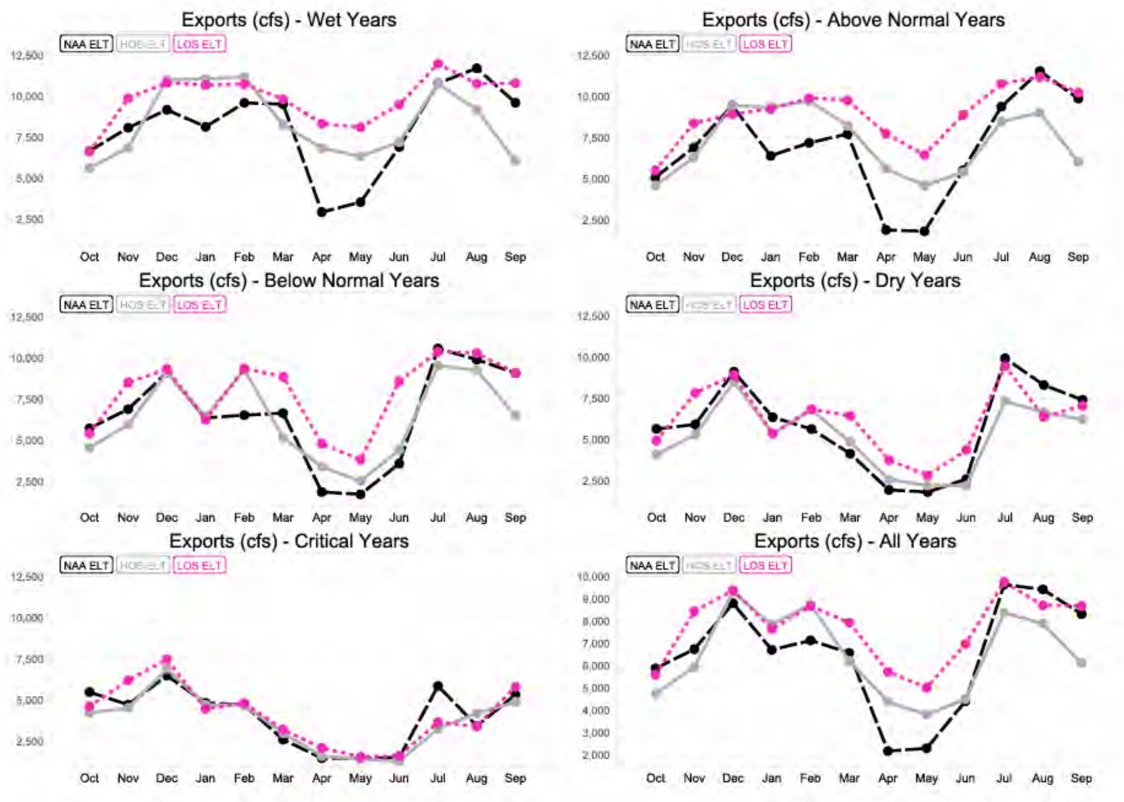

Figure 3.2: Monthly averaged exports for NAA, LOS and HOS under ELT conditions. Based on BDCP CALSIM data.

Exceedance curves (Figure 3.3) give a better indication of reliability. This approach provides the probability that a given export volume will be equaled or exceeded in any given year. For example, for the 50% exceedance probability (meaning one out of every two years), the NAA performs slightly better than the HOS, but much worse than the LOS. Overall, the LOS performs significantly better than NAA in six out of ten years and better than the HOS in eight out of ten. The HOS is outperformed by the NAA in five out of ten years (drier) and appears to only provide significant water supply benefits over the NAA in one out of ten years (wettest). The conclusion is that export reliability for the HOS and NAA are not substantially different, while reliability for the LOS is markedly higher.

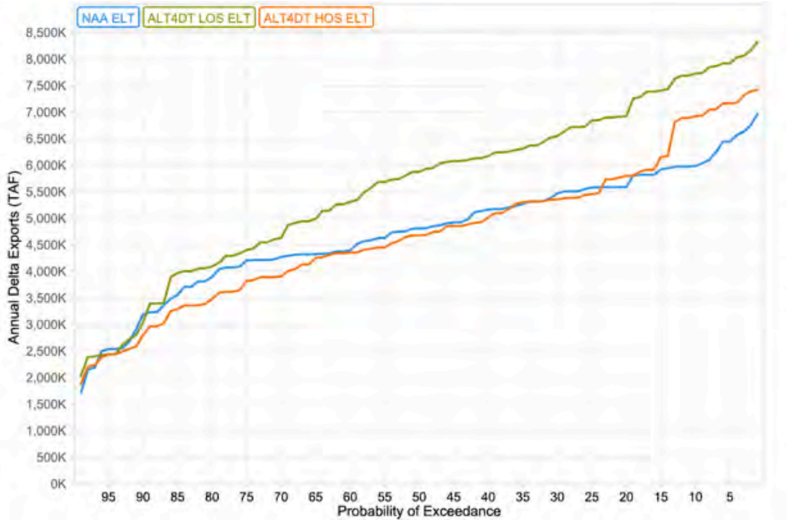

Figure 3.3: Exceedance probabilities for NAA, LOS and HOS exports under ELT conditions. Note that LOS produces higher exports for all probabilities, suggesting that it is the most reliable/resilient of the scenarios.

Water supply reliability curves for SWP and CVP customers are presented in Chapter 5 of the Draft EIS/EIR. These curves indicate that south-of-Delta municipal and farm users would realize considerable increases in overall reliability of supply under the LOS, compared to the NAA and HOS, particularly in above average and wet years. North-of-Delta users of CVP water would likely see a decrease in reliability over the long term, principally due to climate change.

Export Timing

A goal of BDCP and the Delta Plan is to shift exports to wetter years and to reduce pressure on drier years. A comparison of the average exports of NAA, LOS and HOS for all five year-types is presented in Figure 3.2. Based on the modeling data provided, there appears to be a significant increase in LOS exports in above average and wet years as compared to the NAA, with HOS intermediate between the two. This increase is accomplished through increased use of the North Delta facility during winter and spring periods when OMR restrictions most strongly impact South Delta operations.

Below average, dry and critical dry year performance of BDCP is mixed (Figure 3.2). For LOS, overall exports during the drier years are higher than the NAA, while HOS exports are roughly the same as NAA. Exports, on average, for both the LOS and HOS tend to be higher than the NAA in the winter and early spring, and lower during the summer. This minimal change in exports during dry years stems, in comparison to wet years, from the constraints on North Delta facility operations. As is illustrated below, during dry periods the North Delta facility is used very little, creating pressure on South Delta facilities.

In sum, although there are many regulatory and infrastructure constraints, BDCP does make use of the dual points of diversion to create modest increases in wet year exports and, depending on which export scenario is evaluated, equal to or greater exports in drier years. *BDCP therefore does not achieve the broader goal of reducing pressure on the Delta during dry years by shifting exports to wet years*.

Drought Performance

In the draft Plan and EIR/EIS, export performance of BDCP is summarized by presenting averages, typically linked to water year-types based on the Sacramento 40-30-30 index. Averaging fails to fully reflect how the system might be operated, however, because the complex rules governing operation can create significant year-to-year variability in exports (although see concerns over model uncertainties described in Chapter 1). This issue is particularly acute during multi-year droughts, when carryover storage in reservoirs is greatly reduced and demand increases significantly. To better illustrate how this system might perform we examined time series of model outputs during drought periods.

There were two six-year droughts during the 20th Century that fall within the time period used for hydrologic simulations: water years 1929-34 and 1987-92. We focused on the 1987-92 period of record for evaluation because it has historical export data for comparison and facilities that are comparable to today. As shown in Figure 3.4, overall export timing and magnitude during the six-year drought were roughly the same for the NAA, LOS and HOS, with LOS performing marginally better for exports throughout the drought[4]. The significant exception to this pattern is in the one year in that sequence, 1989, where modest inflows to the Delta occurred in the winter. Once bypass flow criteria were met, the flexibility created by the North Delta facility was able to take advantage of these inflows during a period of high restrictions on South Delta pumping to protect smelt.

---

[4] Figure 3.4 highlights one of the issues not discussed in BDCP documentation. The environmental baseline for the BDCP assessment was determined to be the remanded BiOps, with provisions of one of the BiOps (high fall X2 flows in above normal and wet years) yet to be enacted. By choosing this as a baseline, the plan does not provide a comparison with how the project was actually operated under historic conditions. This administrative decision to only compare proposed operations with the remanded BiOps masks the striking differences between historic export operations and those proposed under BDCP.

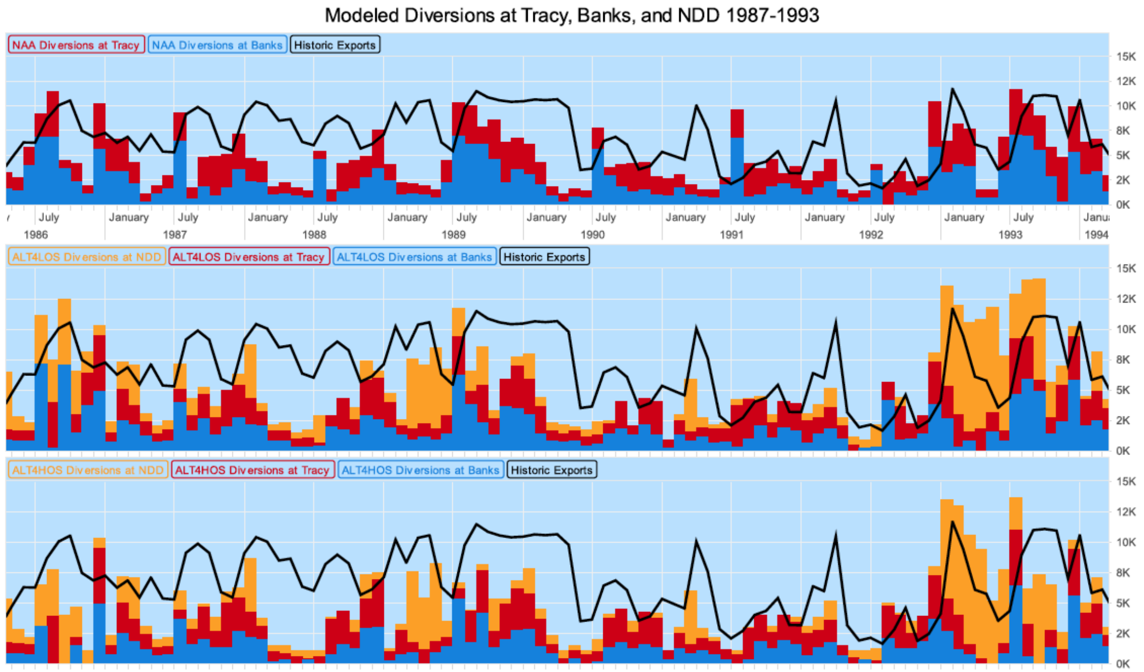

Figure 3.4: Exports for NAA, LOS and HOS under ELT conditions simulated for the 1987-92 drought, with historical exports are plotted for comparison. Important to note that ELT conditions take into account minor changes in climate and sea level rise by 2025 and cannot be compared specifically with historic conditions. In addition, historic conditions reflect human behavior; simulated conditions are guided by algorithms that do not account for human behavior.

Role of Reservoirs in Drought Management

Reservoir storage and operations play a critical role in drought management in California and greatly influence the timing and magnitude of Delta exports. The CALSIM modeling conducted for BDCP manages reservoirs within operational constraints described above and in detail in Chapter 3 of the Plan. The Plan makes it clear that the plan area does not include these reservoirs. Existing and future BiOps will govern their operations, not the terms of the HCP/NCCP permit. Despite this, the plan does envision significant changes to the operations of Oroville Reservoir under BDCP.

The 1987-92 simulated operations of the three most important reservoirs—Shasta, Oroville and Folsom—are shown in Figure 3.5. These simulations have important biological implications that are covered in later chapters. For water supply reliability, there are several important observations:

- As noted by the BDCP documentation, the NAA puts a great deal of pressure on upstream reservoirs to meet flow requirements, with Oroville providing most of the operational flexibility. In comparison to historic operations, the NAA significantly reduces storage, and thus carryover, in Shasta and

Oroville, but has limited impact on Folsom, with the exception of the last two years of drought.

- Under NAA all three reservoirs are at or near dead pool for the last two years of the drought cycle. Had water-year 1989 been closer in runoff to the other drought years, dead pool conditions would have occurred for the last three years of the six-year drought. Although a statement of the obvious, dead pool limits flexibility in managing water supply and ecosystem needs, both immediately downstream and in the Delta. This is likely to be of greatest concern for managing flow and temperature needs of winter- and spring-run Chinook salmon, particularly under warming climate conditions. Changes in flow releases to meet the needs of listed salmon are highly likely to impact export operations during dry periods. BDCP recognizes this as a concern but does not analyze the likely effects.
- A surprising result of the simulations is that HOS drought operating procedures are more protective of reservoir storage than either NAA or LOS. In an extended drought, storage is more aggressively allocated to either outflow (NAA) or exports (LOS), with both increasing the risk of creating dead pool conditions. This suggests that HOS operating criteria designed to protect smelt, may also do a better job of protecting upstream conditions for salmonids and sturgeon by increasing carryover storage. This, in turn may inadvertently improve water supply resiliency during drought.

It is important to note that a time series analysis of one extended drought within a single simulation record does not give guidance on how the system is likely to perform in all future droughts. Each drought is different, with different storage (reservoir and groundwater) conditions at the start, different precipitation and temperature patterns, and different regulatory or operational responses. To test the above observations more thoroughly, a range of six-year drought scenarios, should be simulated and analyzed. Given that most climate models prescribe an increase in frequency and duration of drought, this anecdotal assessment highlights an issue that is likely to occur during the life of the project and have significant impacts on supply as well as ecosystem management.

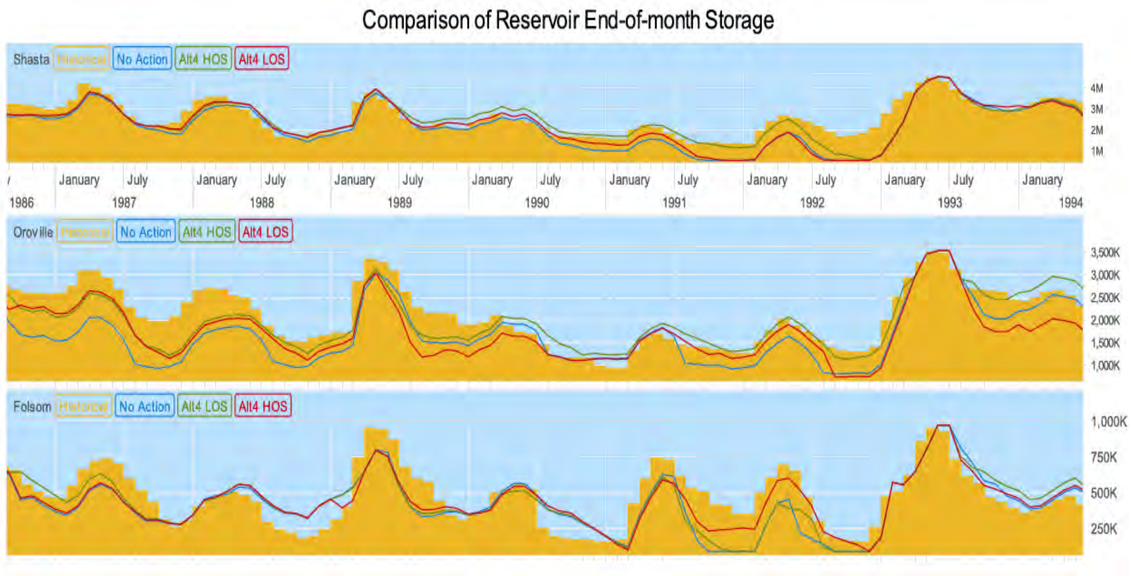

Figure 3.5: End of month storage for HOS, LOS and NAA under ELT conditions simulated for the 1987-92 drought. Historical storage (yellow histogram bars)is plotted for comparison. During the latter stages of the drought, dead pool conditions occur on all three reservoirs. Note that ELT conditions take into account minor changes in climate and sea level rise by 2025 and cannot be compared directly with historical conditions.

Conclusions

The project described in the Draft BDCP and the accompanying Draft EIR/EIR seeks to improve water supply reliability for water exported from the Delta while improving conditions for covered species. An underlying premise for the effort is that adding a second point of diversion, the North Delta facility, operated in conjunction with existing South Delta facilities will allow for more flexible export operations that better support environmental goals and objectives. In concept, this approach appears reasonable and should provide significant flexibility. In practice, however, regulatory and infrastructure constraints, coupled with high upstream consumptive uses of water, severely limits flexibility in operations. These highly constrained operations limit the effectiveness of BDCP in improving water supply reliability.

One of the objectives of BDCP that is in line with those of the Delta Plan is to increase exports during wet periods and decrease them during dry periods when impacts on the ecosystem are greatest. In comparison to the no project alternative, the new facility appears to achieve the former to a modest degree, but it does not significantly reduce pressure on the Delta during drier periods.

The proposed system is particularly vulnerable to extended drought periods (3-6 years). The NAA and LOS lead to dead pool conditions in upstream reservoirs after 3-4 years of drought. This decreases water supply reliability during dry periods and, as discussed in later chapters, places at risk species dependent upon reservoir releases, particularly cold water pool releases. This problem is likely to be particularly acute as climate changes. The surprising result from the model outputs is that the high outflow scenario, principally designed to improve conditions for smelt in the Delta, leads to improved carryover in upstream reservoirs that, in turn, improves year to year water supply reliability and allows for greater flexibility to manage reservoir-dependent species.

The hydrologic modeling effort for BDCP is unprecedented and heroic. However, the tools available for this modeling do not match the information demands. In addition, the plan documents do not do an adequate job of quantifying model uncertainties, particularly those caused by exchanges between 1-, 2- and 3-dimensional models, uncertainties over future conditions, and regulatory behavioral uncertainties . New tools will be needed going forward.

Chapter 4: Environmental Flow Performance: Upstream and Inflows

Introduction

The focus of the BDCP is principally on the legal Delta and adjacent Suisun Bay and Marsh, where export operations have the most direct impact on covered species. As discussed in Chapter 3, upstream management, including reservoir operations, consumptive uses of water, and flood management, play a critical role in inflow timing and volume. In this chapter, we examine how conservation measures #1 (water operations) and #2 (Yolo Bypass fisheries) meet conservation objectives that impact listed aquatic species.

The focus of this chapter is on the environmental performance of proposed flow changes in the Sacramento watershed, including the Sacramento, Feather and American Rivers, and inflows to the Delta through the Yolo Bypass and the Sacramento River. Although inflow from the San Joaquin River is important and a determinant of conditions in the South Delta, BDCP does not envision significant changes in flows. For this reason, our analysis is focused only on the Sacramento watershed.

Performance, as used here, is how well actions proposed by BDCP are likely to meet the goals and objectives of the plan. Although there are many issues discussed in the Plan for the Sacramento system and covered species, there are three central flow performance concerns: changes in reservoir release timing and magnitude and its impact on anadromous fishes; modifications to Fremont Weir and its benefits for floodplain habitat for outmigrating salmonids; and near- and far-field effects of North Delta diversion operations.

Impaired Flow in an Impaired System

One of the objectives of BDCP and the Delta Plan—and a concern of many NGOs--is to produce a flow regime with attributes that better support the life history stages of covered aquatic and riparian species. This objective is supported by a large body of national and international literature that has demonstrated how creating more natural flow regimes in highly regulated systems improves conditions for native species (see recent summary by Arthington, 2012). This issue has been at the forefront of controversial efforts by the SWRCB to develop a basin plan that addresses flows (Fleenor et al., 2010).

A flow regime that mimics natural seasonal variation is also considered by the scientific community in the Delta to be fundamental to better species management (Hanak et al., 2013). Restoring appropriate seasonal and intra-annual variability involves re-establishing flow timing, magnitude, duration, frequency and rates of change that drive key ecosystem attributes that, in turn, support native species (Figure 4.1).

Although restoring elements of the natural flow regime is a worthwhile goal, it should be made clear that in the Delta and its tributaries there is little that remains natural (Bay Institute, 1998; Whipple et al., 2012). Added to these physical changes are profound shifts in biological conditions, including a Delta ecosystem dominated by non-native plants and animals (Lund et al., 2008; Baxter et al., 2010). For this reason, restoring a more naturally variable flow regime in an altered Delta and its watershed, while necessary for improving conditions for covered species, is unlikely to lead, by itself, to their recovery (Mount et al., 2012).

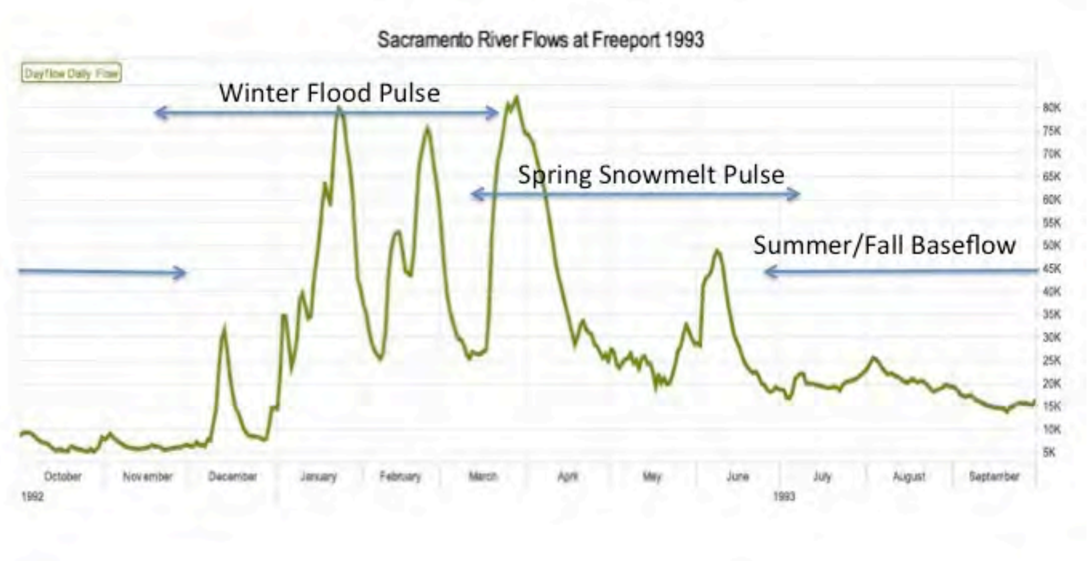

Figure 4.1: Unimpaired Sacramento River flow at Freeport for WY 1992-3 based on DAYFLOW data (DWR). This illustrates the range of natural seasonal variability in flow. Reproduction or migration of aquatic and riparian species are tied to timing, magnitude, frequency, duration and rate of change of flows. Flows, particularly winter and spring flood pulses, are necessary for geomorphic processes that support various life history stages. Flow regulation and land reclamation have significantly altered flow regime (see text for discussion).

In this chapter we sought to evaluate BDCP's potential impact on flow regimes upstream and into the Delta. It is infeasible—if not inappropriate--to reconstruct natural flow in the Central Valley given the significant changes in the landscape. Instead, we use *unimpaired flow* (DWR 2007) as a proxy for a more naturally distributed flow regime[1]. Unimpaired flow is the volume of water that would flow by a given point if no upstream impoundments or diversions were in place. Estimating

---

[1] We focus here principally on the rivers that feed into the Delta rather than the Delta per se. An assessment of changes in outflow that occurs in response to changes in operations is contained in Appendix B.

unimpaired flow is complicated and imprecise, yet is important in setting flow and water quality targets, particularly by the SWRCB. It involves aggregating unimpaired and unregulated runoff from multiple basins that flow to the Delta. Unimpaired flow ignores surface water-groundwater interactions and storage or conveyance of flow in channels, floodplains and wetlands. For this reason, it is not a useful proxy for flow regime on daily time steps, but can be used as an imperfect proxy for annual and monthly flows. We follow that convention in this analysis.

This simplified approach should not be over-interpreted. It is used to assess whether BDCP meets the overall goal of improving ecological conditions by creating a more natural seasonally variable flow regime. It does not address all issues of concern for listed fishes, such as winter- and spring-run Chinook salmon whose primary limitation is due to loss of upstream spawning and rearing habitat and high temperatures in existing channel habitat (Williams, 2006, 2009).

Main Rivers of the Sacramento Valley

Multiple biological goals and objectives of BDCP are associated with flow conditions on the Sacramento River and its two main tributaries, the Feather and American Rivers. All anadromous fishes covered by BDCP rely directly on these river systems for spawning, rearing and migration. As noted in Chapter 1, we focus here principally on winter- and spring-run Chinook since the BiOps that cover their life history needs have the greatest impact on water operations.

With the exception of proposed changes to the Fremont Weir and the Yolo Bypass (CM#2), BDCP does not envision making significant investments in improving physical habitat upstream of the Delta, or addressing other stressors such as hatcheries, contaminants or harvest procedures (see summary in Williams, 2006, 2009). For this reason, most of the impact of BDCP on the Sacramento River and its tributaries upstream of the North Delta facilities will be associated with changes in flow releases from the three major reservoirs: Shasta, Oroville and Folsom.

Simulated average flow conditions affected by changes in reservoir operations under BDCP are summarized in Figure 4.2A-C, including Sacramento River at Red Bluff, Feather River below Oroville Reservoir, and American River below Folsom. These flows, along with all other tributaries, aggregate to form the Freeport flow (Figure 4.2D) and the Yolo Bypass. These results include NAA, LOS and HOS flow scenarios and unimpaired flow under the five year-types based on the Sacramento River wetness index.

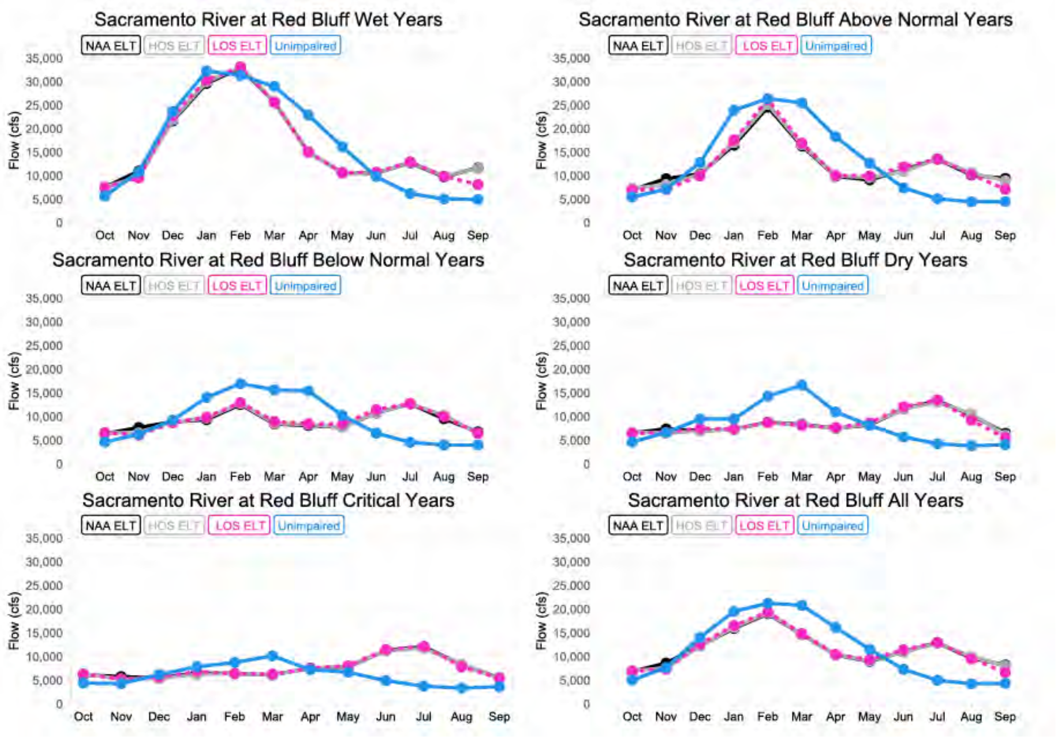

Figure 4.2A: Sacramento River at Red Bluff.

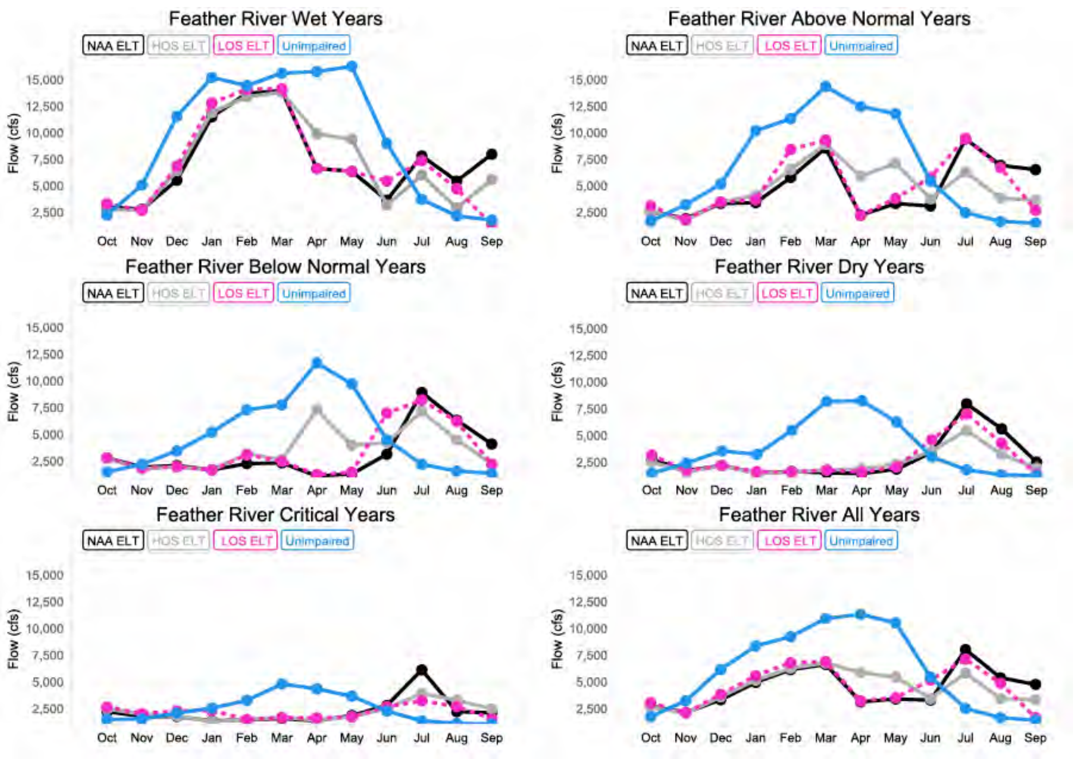

Figure 4.2B: Feather River.

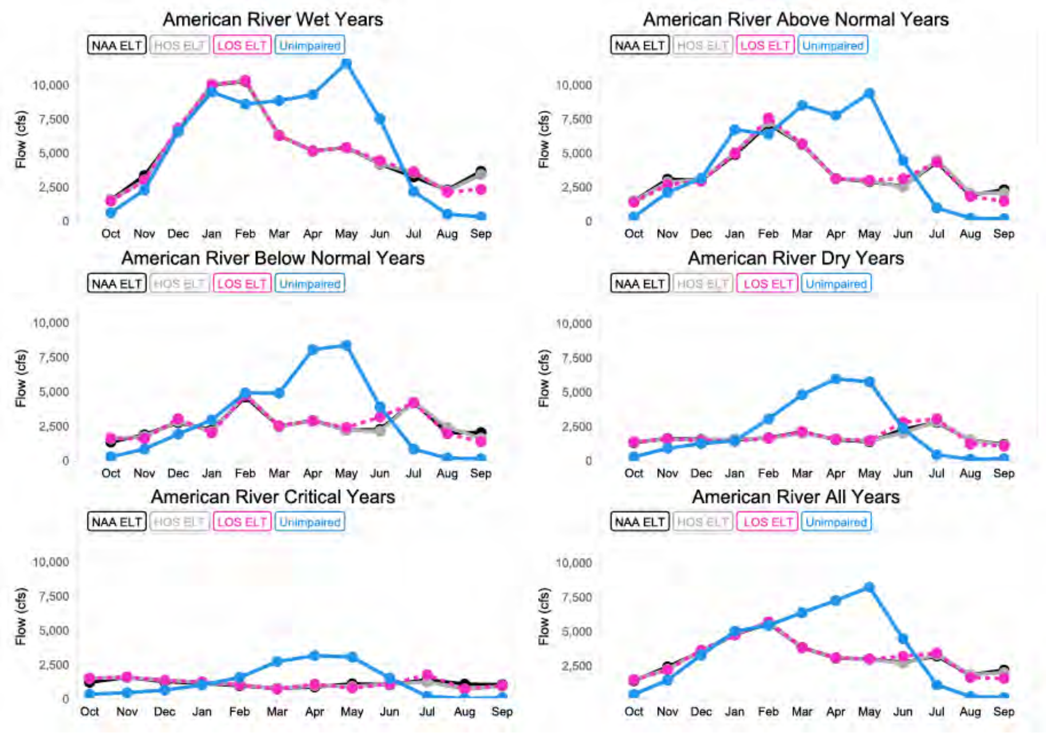

Figure 4.2C: American River.

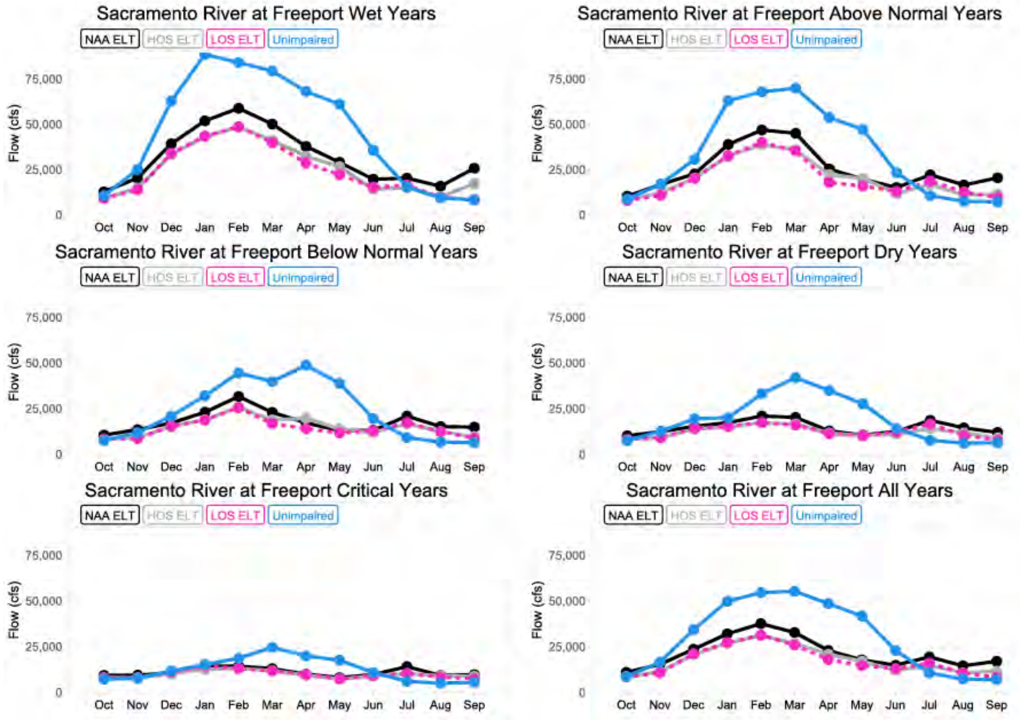

Figure 4.2D: Flow at Freeport. Figures 4.2A-D. Monthly averages sorted by water year types for HOS, LOS, NAA and unimpaired flow. Unimpaired flow is based on current conditions and HOS, LOS and NAA are ELT conditions. See text for discussion. Data from BDCP CALSIM simulations.

As noted in Chapter 3, the constraints on reservoir operations are significant due to temperature and downstream flow requirements, based mostly on the 2009 BiOp. For this reason, the differences between scenarios are not large. However, a comparison of the impaired and unimpaired flow data allows for several general conclusions about the impact of BDCP on key attributes of Sacramento Valley flow regimes:

Winter Flood Pulse. With the exception of the American River, the winter flood pulse is significantly reduced over unimpaired conditions in the Sacramento Valley. The magnitude of this reduction reflects the size and operations of upstream impoundments relative to the total runoff of the watershed. The most dramatic impairment of winter flood pulses occurs on the Feather River where the pulse is virtually eliminated in most years. There are no substantive differences between LOS, HOS and NAA operations for winter flood pulses. The winter flood pulse is marginally higher under NAA at Freeport, but this reflects more frequent flows down the Yolo Bypass.

Spring Snowmelt Pulse. The rise and gradual recession of flow in the spring is, next to low baseflow conditions in the late summer, the most predictable element of the Sacramento Valley flow regime and is of high biological significance. As shown in Figures 4.2A-D, the spring snowmelt pulse is highly impaired due to impoundments and flow diversions. With the exception of the Feather River, there are no substantive differences between HOS, LOS and NAA impacts on the spring snowmelt pulse in the Sacramento Valley. On the Feather, HOS flow operations designed to improve spring outflow in the Delta, lead to significant improvement in spring conditions in all but dry and critical year types.

Summer/Fall Baseflow. The timing and magnitude of reservoir releases dominates the summer/fall flow regime of the basin (Figure 4.2A-D). These releases are to meet the complex array of temperature and flow requirements downstream of the dams, irrigation demands upstream of the Delta, inflows to meet export demands, and outflows to meet water quality and habitat standards. Summer/fall baseflow flow regimes are highly altered with flows three to five times higher than unimpaired flows. With the exception of the Feather River, BDCP does not change summer/fall baseflow conditions. Under HOS and LOS simulations, the summer flows on the Feather are reduced, creating marginal improvement in flow regime.

Main Rivers Summary. The plan area for BDCP is, by design, limited in scope. The same applies to its conservation measures. The project Plan documents make it clear that operations of the CVP and SWP reservoirs are governed by BiOps or FERC licenses, and not BDCP. In addition, they note limited flexibility in reservoir operation due to cold water pool management, particularly on Shasta and Folsom Reservoirs. In this way, the reservoirs are in effect another constraint on BDCP (Chapter 3), rather than an asset for management.

Yet operations of these reservoirs greatly impact winter- and spring-run Chinook habitat downstream. As shown above, these operations contribute to the significant impairment of flows of the Sacramento River and its major tributaries and are a challenge when trying to meet the biological objectives of BDCP. Additionally, these dams block access to holding, spawning and rearing habitat that has far-reaching effects on winter- and spring-run Chinook salmon populations (Williams, 2006, 2009). These dams also support mitigation hatcheries whose operations may be contributing to harm of native salmon (Moyle et al., 2011).

It is unclear to us how to disentangle the relationship between the impacts of BDCP—a project designed to meet CVP and SWP water supply needs and an array of associated biological goals and objectives—and operations of SWP and CVP reservoirs. It seems logical to include these reservoirs in BDCP and operate them, along with the new facilities, under a single HCP/NCCP. The modest improvement in Feather River flows not withstanding, the result of this administrative separation is, in effect, to maintain the status quo for the highly impaired flows of the Sacramento system.

Yolo Bypass Flows

One of the more prominent conservation measures (CM#2) of BDCP is the modification of the Fremont Weir to promote increases in the frequency of winter and early spring inundation of the Yolo Bypass. A well-established and growing body of evidence, involving monitoring data, field experimentation and, to a lesser extent, life cycle models indicate high benefit of floodplain habitat to foraging juvenile salmon (see BDPC documentation for a full summary). This stems from the use of high value, off-channel habitat by juveniles, who, under optimal bioenergetic conditions and low predation pressures grow at high rates, increasing their survivorship through the Delta. Fish that either forage on the Yolo Bypass and/or use it as a migration corridor will not be impacted by near-field effects of the proposed North Delta diversion facilities. Fish using the Bypass are also less likely to enter the interior of the Delta where predation pressures are high. Finally, juveniles that use the Bypass leave the Delta later in the season, increasing the likelihood of arriving at the ocean during higher upwelling periods with better food availability.

Currently flow onto the Yolo Bypass from the Sacramento River only occurs when the Verona gauge exceeds 55,000 cfs. Modifications to the Fremont Weir would allow 1,000 cfs to flow onto the floodplain when flow at Verona exceeds 25,000 cfs. Flow through the Weir would climb to 6000 cfs when the river approaches 55,000 cfs. Above 55,000 cfs flow into the Bypass would be similar to NAA conditions. In addition to allowing flood flows, the weir would be modified to allow 100 cfs attraction flows to a fish ladder to improve upstream passage of adult salmon, steelhead and sturgeon (passage issues not evaluated here).

The average annual flow of the Yolo Bypass is approximately 1.5 maf. Under NAA, HOS and LOS, this amount would not differ significantly since the majority of flow volume on the Bypass occurs when the Sacramento overtops Fremont Weir and the

Sacramento Weir (Figure 4.3). However, the timing, frequency, and duration of floodplain inundation—key elements of the natural flow regime--would change substantially with the proposed modification of Fremont Weir.

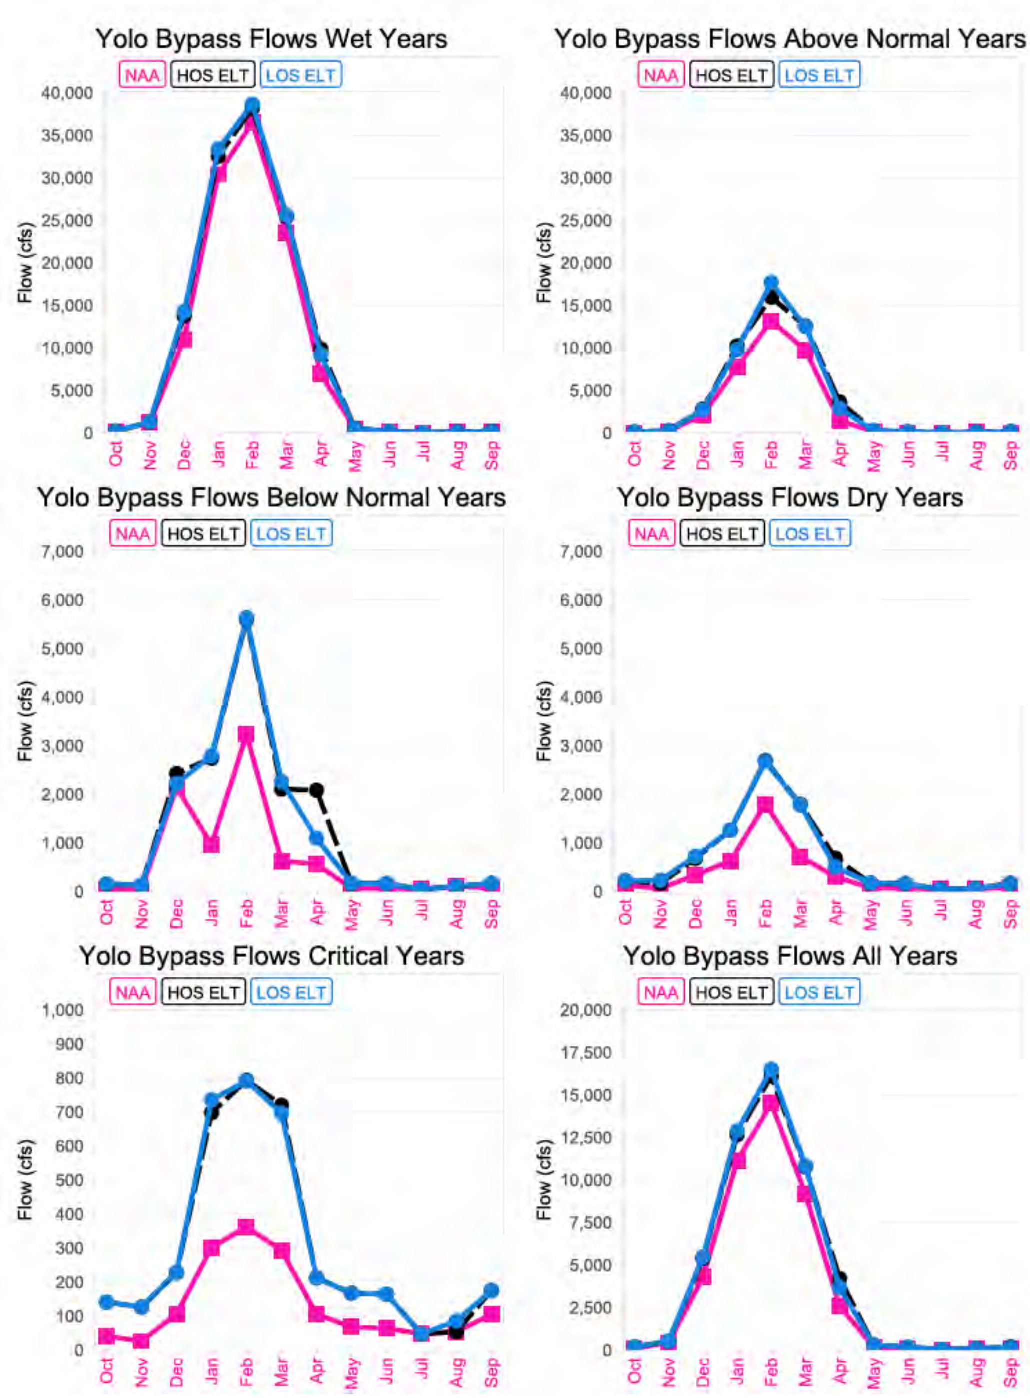

Figure 4.3: Average monthly flows for the Yolo Bypass under HOS, LOS and NAA under ELT conditions for different year types. Note changes in scale.

Flood Frequency. The frequency of inundation of the Bypass increases significantly under BDCP. Under current conditions there is a roughly 40% annual probability of flooding on the Yolo Bypass. Under BDCP this increases to more than 70% annual probability (BDCP statistics). The largest change occurs in drier years (Figure 4.3).

Flood Duration. Multiple studies have shown that flood duration, which allows for nutrient cycling and primary production, is essential for supporting juvenile salmonid foraging (Sommer et al., 2001; Williams, 2006, 2009). Modifications to Fremont Weir increase flood durations with high habitat benefits. Under current operations, flood durations aggregate to an average of 25 days per year. This would not change under NAA in the ELT. Under both HOS and LOS ELT this would increase more than three-fold to an average of 81 days per year.

Flood Timing. In addition to more frequent, longer-lasting flooding conditions, modifications to the Fremont Weir would expand the flood season, particularly in drier years (Figure 4.3). This expansion helps divert early migrants, such as winter-run Chinook salmon and later migrants, such as spring-run and fall-run Chinook, onto the floodplain. For example, based on BDCP data, we estimate that days of flooding above 1000 cfs on the Bypass will more than double in January and triple in April.

Yolo Bypass performance for listed salmon

Although CM#2 achieves the broader objective of improving the amount and quality of floodplain habitat, principally by restoring a more natural flow regime, it's effectiveness in supporting federally listed species of salmon (the focus of this review) is somewhat limited. The BDCP consultants modeled the overall benefits of the Yolo Bypass flows to out-migrating and foraging juveniles. For winter-run Chinook salmon, the benefits were modest with an estimate 1-8% increase in escapement. The limited benefit of the Yolo Bypass is, according to the BDCP model results, due to the small percentage of juveniles likely to be diverted onto the floodplain. This stems from the fact that most migration begins in December and January coincident with the first pulse flows of the season and does not coincide with peak inundation periods of the Bypass.

Greater benefit, albeit still limited, occurs for spring-run Chinook salmon. The bulk of juvenile out-migration takes place during the optimal months for floodplain inundation: February through March. However, two factors reduce the effectiveness of Yolo Bypass for spring-run according to BDCP documents. The majority of spring-run Chinook salmon come from hatcheries in the Feather River. Juveniles leaving the Feather are only diverted onto the Yolo Bypass during rare high flow events, leaving the Sacramento River as their principal migration route to the Delta. Naturally spawned fish in Butte Creek use the Sutter Bypass as their principal migration route. Like Feather River fish, they too only move access the Yolo Bypass during rare high flow events. Naturally spawned spring-run in Battle, Clear, Mill and Deer Creek pass Fremont Weir on their out-migration paths and will benefit most from likely access to the Bypass.

Second, according to BDCP models, most spring-run juveniles reach the Delta, and presumably the Yolo Bypass, as yearling smolts. In this stage, they are presumed by BDCP consultants to not take full advantage of the high quality foraging conditions of the Bypass, but use it principally as a migration corridor. BDCP consultants estimate that 90% of spring-run Chinook in the Yolo Bypass are migrants, rather than foraging fish. The BDCP consultants readily note that this proportion reflects the split between migrants and foraging characteristics in hatchery fish and may not be indicative of proportions of wild fish. Our consultation with several salmon biologists suggests that the distinction between foragers and migrants is arbitrary and likely does not reflect actual behavior of juveniles on the Bypass. In addition, there is emerging evidence that a high percentage of naturally spawned fish move out as fry and migrate during high winter flows (*pers. comm*., P.B. Moyle, 2013).

The BDCP consultants used several approaches to model the effect of the Yolo Bypass on survivorship. They acknowledge that current modeling tools are not well-suited to this kind of analysis. They developed a simple bioenergetic model for floodplain rearing, but told the panel that they felt it did not fully capture the benefits of the Bypass, and that their estimates of survivorship were conservatively low. Despite these limitations the BDCP models along with a growing body of literature suggest that spring-run juveniles as well as winter-run juveniles that access the Bypass are likely to have significantly higher survival rates to Chipps Island and presumably higher adult escapement[2].

Yolo Bypass Summary

CM#2 has high potential to benefit a range of covered species. Its benefit for winter- and spring-run Chinook is muted due to outmigration timing (winter-run) or the structural difficulty in diverting Feather River and Butte Creek fish (spring-run) onto the Bypass. Yet even with these concerns, there are likely to be improvements in survivorship associated with an alternative migration corridor with high value foraging habitat. There is an adaptive management program being developed for the Yolo Bypass that will be incorporated into BDCP. This effort would benefit BDCP objectives by conducting experiments and modeling that test ways to improve access of listed salmon onto the Bypass. This can include modifications to the Fremont Weir or pulse flow releases that improve winter-run diversion. Along with modification of Fremont Weir, this program may also want to consider the potential for using the Sacramento Weir to divert Feather River and Butte Creek fish. Regardless, as outlined below, a more aggressive approach to developing an alternative migration corridor for winter- and spring-run Chinook is likely to be necessary to mitigate the effects of the new North Delta facility.

---

[2] The focus of this chapter is on spring- and winter-run Chinook. There is very significant benefit to other covered species, particularly fall-run Chinook and Sacramento splittail that can take advantage of Yolo Bypass flooding more readily.

North Delta Facility Impacts and Mitigation

The new point of diversion along the Sacramento River is likely to impact all covered fish that either use the main channel of the Sacramento for migration or rearing, or are indirectly affected by downstream changes in flow volume and timing. These impacts are some of the most difficult to assess due to uncertainties about design and operation of the facilities (no comparable facility exists to calibrate models) and the relationship between downstream actions, such as tidal marsh restoration, and flows. This section assesses BDCP's evaluation of near-field (adjacent to the facility) and far-field (downstream from the facility) effects.

Near Field Effects

The preferred project involves the construction of three screened intakes along the left bank of the Sacramento River in the vicinity of the town of Hood. Each screen will be capable of withdrawing up to 3000 cfs. In our view, the BDCP consultants have properly identified the two main sources of near field effects of the facility on out-migrating salmonids: losses due to impingement on the intake screens and losses due to predation near the diversion. However, we are uncertain about the effectiveness of proposed mitigation for these effects.

To mitigate for impingement potential, the consultants propose real-time management of pumping regimes relative to channel flow in order to maintain approach and sweeping velocities that reduce contact with intake screens. This real-time management would be informed by upstream monitoring of outmigrants. This issue remains a high uncertainty for operations of the facility ("low certainty" in the parlance of BDCP). Conceptually, a good adaptive management and research program coupled with real-time management could reduce impacts. However, as of this writing, the specifics of this program are not provided by BDCP (see discussion in Chapters 8, 9 this report) and we are unable to evaluate how effective it might be.

A greater near field effect of the facility is the high likelihood of concentration of predators near the facility, with resulting losses of migrants and foragers due to predation. Predators take advantage of concentrated prey and velocity refugia at physical structures throughout the Delta (Vogel, 2008) and will presumably do the same at the North Delta intake facilities. The BDCP consultants use various modeling approaches to estimate potential predation losses, including comparison with estimates of losses at known structures such as diversion screens of the Glenn-Colusa Irrigation District. Estimated predation losses for juvenile winter run Chinook that pass the facility vary from as low as 1% to as high as 12% (we did not find statistics for spring-run Chinook salmon losses). The higher predation loss values would have significant population-level impacts on winter-run Chinook and would fail to meet objectives of BDCP. The consultants acknowledge high levels of uncertainty about predation effects at the facility. The solution, as with most issues with high uncertainty in BDCP, is to defer this to adaptive management of the project, including unspecified predator control programs and real time management of flows. Based on our experience in the Delta, we consider this to be a significant, unresolved management issue.

Far Field Effects

The North Delta facility is expected to provide an average of roughly half of the exports from the Delta. As outlined in Chapter 3, operations of the facility are highly constrained by flow and water quality regulations, upstream water use, reservoir operations and hydrology. The simulated operations of the North Delta facility are summarized in Figure 4.4, including a measure of the proportion of channel flow that is diverted.

There are significant seasonal and interannual variations in operation of the North Delta facility that will drive far field effects[3]. During wet and above average water years, pumping regimes are most aggressive, particularly during the summer and early fall when 25% to as much as 39% of channel flow is diverted. Diversions, as a percentage of channel flow, decline dramatically in below normal, dry and critical years. In addition, pumping regimes are highly protective of channel flow in December, reflecting the restrictions on exports to protect initial pulse flows for winter-run Chinook. As expected, the HOS scenario, designed to improve Delta outflow, results in the most protective pumping regime for bypass flows at the North Delta facility.

BDCP documents acknowledge that the reductions in bypass flow create multiple far field effects that impact listed salmon. These include reduced attraction flows for migrating adult salmon, increased losses of juvenile salmon migrants and foragers due to longer transit times to the Delta, and diversion into the interior Delta where predation and/or entrainment losses are high. These operations also affect total Delta outflow[4].

The BDCP consultants use multiple modeling approaches to address the far field effects of the North Delta facility. The main model used is the Delta Passage Model (DPM) that tracks smolt survival through the Delta. This model and others summarized in Appendix 5C of the Effects Analysis all draw the same conclusion: there is an increase in losses of winter- and spring-run Chinook salmon migrants associated with reduced flows in the bypass reach from Hood to Rio Vista. The magnitude of this impact varies depending upon year type (wetter years have reduced losses) and magnitude of flow reduction associated with pumping (up to 35% decreases in flows during some migration periods). These results are not surprising since there is a long-established relationship between transit time and

---

[3] We did not evaluate the effects of size of the facility and its level of use. However, it is worth noting in Figure 4.4 how often average monthly exports approach facility capacity. Using a monthly average greater than 8000 cfs as an indicator of periodic use of full capacity, this only occurs in February and March in wet years and March of above average years. This is roughly 5% of the total months, suggesting that operational and regulatory constraints, rather than facility size, determine export volumes.

[4] Appendix B presents a summary of Delta outflow and the magnitude of impairment of flows from the Sacramento Valley. The latter uses a simplified impairment index.

survivorship for smolts leaving the Sacramento River (Newman, 2003; Perry et al., 2010).

Figure 4.4. Average monthly export flows of North Delta diversion facility under HOS and LOS ELT for different year types, and percentage of total bypass channel flow exported.

BDCP proposes to mitigate the increase in losses of smolts associated with far-field effects through six strategies:

- Tiered pumping regimes to reduce withdrawals during the initial winter flood pulse (described in Chapter 3)

- Real-time operational changes that reduce export pumping when monitoring indicates that large numbers of migrants have entered the reach upstream of the facility
- Flow management that reduces tidal reversals at Georgiana Slough, decreasing the likelihood of smolts diverting into the interior of the Delta
- Non-physical barriers at Georgiana Slough
- Reductions in entrainment at the South Delta facility due to reduced export pumping
- Increased diversion of foragers and migrants onto the Yolo Bypass
- Improved channel margin, floodplain and tidal marsh habitat to support foraging juveniles

The benefits of the last of these strategies—habitat restoration—are not captured in the survivorship modeling that was completed by BDCP consultants (see chapter 7 for a discussion). In addition, the models do not incorporate real-time operations adjustments since the scope and terms of these operations have yet to be determined. The remaining strategies are incorporated into models used to assess smolt survivorship. Closely examined, BDCP model results indicate that these measures, in combination, roughly offset the losses created by reductions in flows and increases in predation in the bypass reach, meeting the standard of mitigation. There is no indication that these actions would result in substantial improvement in conditions for listed salmon. This includes the Yolo Bypass, which provides significant benefits for other covered species.

North Delta Facility Summary

We have not had sufficient time or resources to conduct a detailed review of the models used to assess survivorship in the bypass reach and the effectiveness of mitigation efforts. Overall, most of the models used for near and far field impacts are standard Delta models. Model results seem reasonable and fall within the boundaries of current understanding. This suggests that they provide an acceptable first-order approximation useful enough as a basis for further analysis and adaptive management experiments.

We view the efforts to model the effectiveness of predator management and non-physical barriers as having high uncertainty. In addition, as noted, there is insufficient detail on real-time management to assess its likelihood for success. The flow modeling that was done on the bypass reach makes assumptions about tidal marsh restoration in the Cache Slough area. This restoration plays an important role in tidal energy and efforts to manage flow reversals at Georgiana Slough. We are uncertain about both the impact of this tidal marsh restoration and, if modeled correctly, whether the assumed restoration would be completed in the ELT. This same issue applies to the Yolo Bypass. Scheduling contained in BDCP suggests that the Yolo Bypass project would not be complete until after the North Delta facility. This lag in completion hampers efforts to mitigate for the project. At minimum, given the large uncertainties, it seems prudent to have all mitigation efforts in place and tested prior to initiating operation of the diversion facilities.

Conclusion

To meet its biological goals and objectives, BDCP has developed 22 conservation measures. Two of these measures—CM#1, Water Operations, and CM#2, Yolo Bypass—are intended to create significant improvement in conditions for covered fishes by creating more natural flow conditions, improving fish passage and, in the case of the Yolo Bypass, improving floodplain spawning and rearing habitat. We focused our assessment on how CM#1 and CM#2 performed for winter and spring-run Chinook in this regard.

In general, we found that CM#1 does not significantly change the highly impaired flow regime upstream of the Yolo Bypass and Freeport, with the exception of an increase in spring flows on the Feather River under the HOS flow scenario (nor does it change outflows much as shown in Appendix B). BDCP proponents have made the strategic decision to focus principally on the Delta, rather than including CVP and SWP reservoirs that regulate flow into the Delta. This limits BDCP's effectiveness in its conservation measures since it does not address the major risk factors for listed salmon.

We found the increased frequency of flows into the Yolo Bypass to be an important step in restoring floodplain habitat. However, timing of outmigration and current design of CM#2 modifications limit the impact of this effort for listed salmon. The current adaptive management program underway for the Yolo Bypass needs to address this issue, including considering changing reservoir operations and alternative ways to divert fish into the Bypass.

Near field and far field effects of the North Delta facility have the potential to significantly reduce survivorship if not fully mitigated. Uncertainties over mitigation are high and will require a robust adaptive management plan. In our view, the Yolo Bypass program should be viewed as mitigation for the impacts of the North Delta facility on listed salmon. CM#2, along with all other mitigation efforts, need to be in place prior to operation of the facility.

Chapter 5: In-Delta Flow Performance

Introduction

BDCP Conservation Measure #1 (CM#1) aims to restore more natural net flows (i.e. net seaward) within the Delta by adding a point of diversion upstream of the Delta:

> Conservation Measure #1: "Construction and operation of the new north Delta intakes are designed to substantially reduce the incidence of reverse flow (Section 3.4.1.4.3, *Flow Criteria*) and restore a predominantly east-west flow pattern in the San Joaquin River. (Page 3.4-7, emphasis added).

This statement implies two classes of presumed effects that south Delta diversions induce through altered flows: direct effects whereby reversed flows in the south Delta contribute to entrainment of fish at the Delta export facilities, and indirect effects whereby changes in flow in the lower San Joaquin River are believed to alter the survival or migratory success of fish in the affected channels. Both of these presumed effects refer to net flows, which are determined by averaging out the substantial tidal flows that reverse direction twice daily. Although these net flows are small compared to tidal flows in much of the Delta, there is evidence that they can have substantial effects on some fish species.

In this chapter we evaluate changes in net flows in the Delta associated with changes in operations and the construction of the new facility. As in Chapters 3 and 4, we evaluate the differences between HOS and LOS scenarios and compare then to NAA, the no-action alternative. All of these analyses are in the Early Long-Term (ELT) shortly after the beginning of operations of the North Delta facility.

Concerns over modeling

As noted in Chapter 1 of this review, we have concerns over the use and over-interpretation of the modeling data provided to us. In conducting our analysis for this chapter and the following chapter on impacts of outflows on smelt, we have relied on output from CALSIM under various scenarios. Our analysis revealed several apparent anomalies in model output. Although we received clear explanations of the origin of these anomalies from the BDCP consultants, we remain concerned that the model output is unrealistic for projecting actual project operations and the resultant flows. In particular, certain modeled conditions arise through artifact that provide substantial improvements in conditions for delta smelt. Thus, conclusions drawn on the basis of these models rest on an unreliable foundation. These concerns are focused on Delta outflow during fall and southward flow in the southern Delta during winter. These flows have been linked to habitat and survival of delta smelt.

October

The USFWS Biological Opinion for delta smelt includes a fall X2 standard that applies following wet springs. Flows are usually low during this season so small variations in flow can have substantial effects on the location and area of the low salinity zone, and hence potentially on habitat conditions for smelt.

For various reasons X2 calculated by CALSIM differs substantially from that determined from outflow as in Jassby et al. (1995). We therefore focused on outflow as determined by CALSIM, rather than X2 as provided by BDCP modelers.

For this analysis we sorted flow data into a ranked series from lowest to highest values of Delta inflow under NAA. In Octobers of most years in the drier half of the series, outflow under HOS and LOS is up to twice that under NAA (Figure 5.1; median 77% higher for these 41 years). By contrast, during years of high inflow (right-hand half of Figure 5.1), HOS and NAA outflows roughly track each other, while LOS is much lower because the fall X2 requirement does not apply to that scenario. The anomaly occurring under dry conditions is not balanced by flows in other fall months. A few anomalies like those found in October crop up in November, but otherwise in those months either all three outflows track each other or LOS is lower.

To our knowledge there is no regulatory or operational requirement for reduced outflow under NAA or increased outflow under HOS or LOS in dry Octobers. Furthermore, there would be no reason to focus such a requirement in only one month if it were meant to benefit delta smelt, since they are present in the low-salinity zone from summer through fall. Outflow in fall can affect delta smelt recruitment so the modeled outflows can result in considerable differences in predicted recruitment under the three modeled scenarios (Chapter 6). We do not find these differences compelling because of a lack of a regulatory or other basis for the high outflows under HOS and LOS in dry Octobers.

January

January has been the month of greatest adult delta smelt entrainment historically, so the modeled conditions in January can have large impacts on forecasts of adult survival. The CALSIM modeling included a requirement that OMR flows during January be zero in wet years, no more negative than -3500 in above-normal and below-normal years, and no more negative than -5000 in dry and critical years. However, no estimates of current year type are possible in January, and rather than presume perfect foresight or use information available up to that point the modelers chose to operate the simulated system for January using the requirements that applied to the previous year type. Because dry Januaries can follow wet years, this resulted in an anomalous condition in which requirements for wet years applied during dry Januaries.

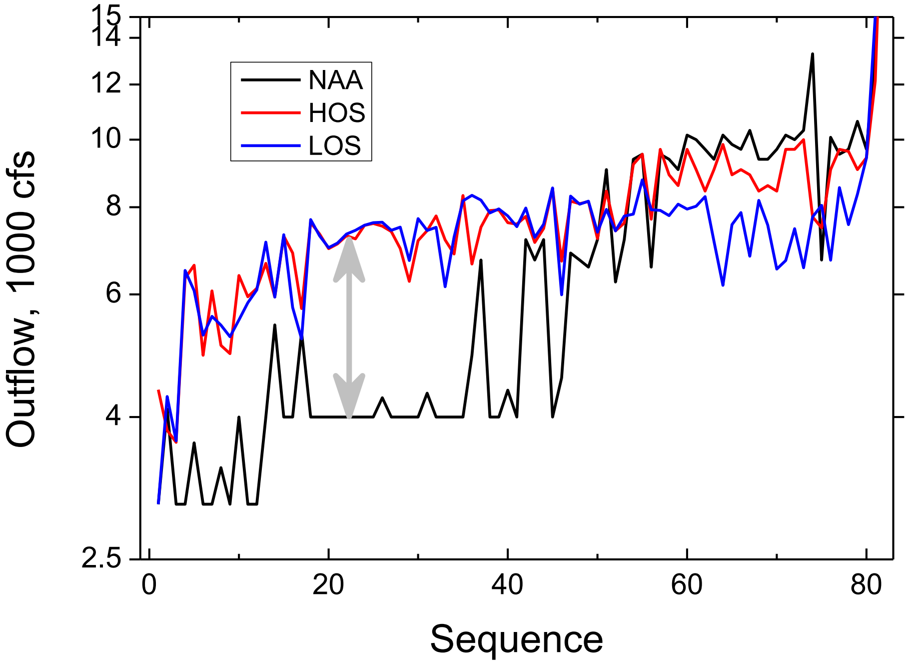

Figure 5.1. Net Delta outflow in October under the three scenarios sorted by inflow as determined by CALSIM under NAA; i.e., sequence 1 is the lowest inflow and 82 the highest. The gray arrow points out the region of interest where outflow under HOS and LOS is as much as double that under NAA. Outflow is plotted on a log scale to show proportional differences among scenarios especially at low flows, and because X2 can be modeled as a function of the log of outflow. The highest two outflows have been cut off to focus the figure on the lower values.

As a result of this anomaly, the modeled scenarios (LOS and HOS) called for reductions in export flows in Januaries following wet years, which substantially increased OMR during many Januaries at the dry end of the historical range for that month (Figure 5.2). This is unrealistic for several reasons. First, the actual values don't conform to the model requirements of 0, -3500 or -5000 cfs, depending on previous year type; instead they are quite variable and achieve zero rarely. Thus, there is no clear regulatory basis for these flows.

Second, the reduction in export flows was sometimes accomplished through increased outflow rather than reduced reservoir releases or increased exports from the North Delta (Figure 5.2). Thus, many January outflows during dry periods were much greater than the corresponding flows of the NAA alternative.

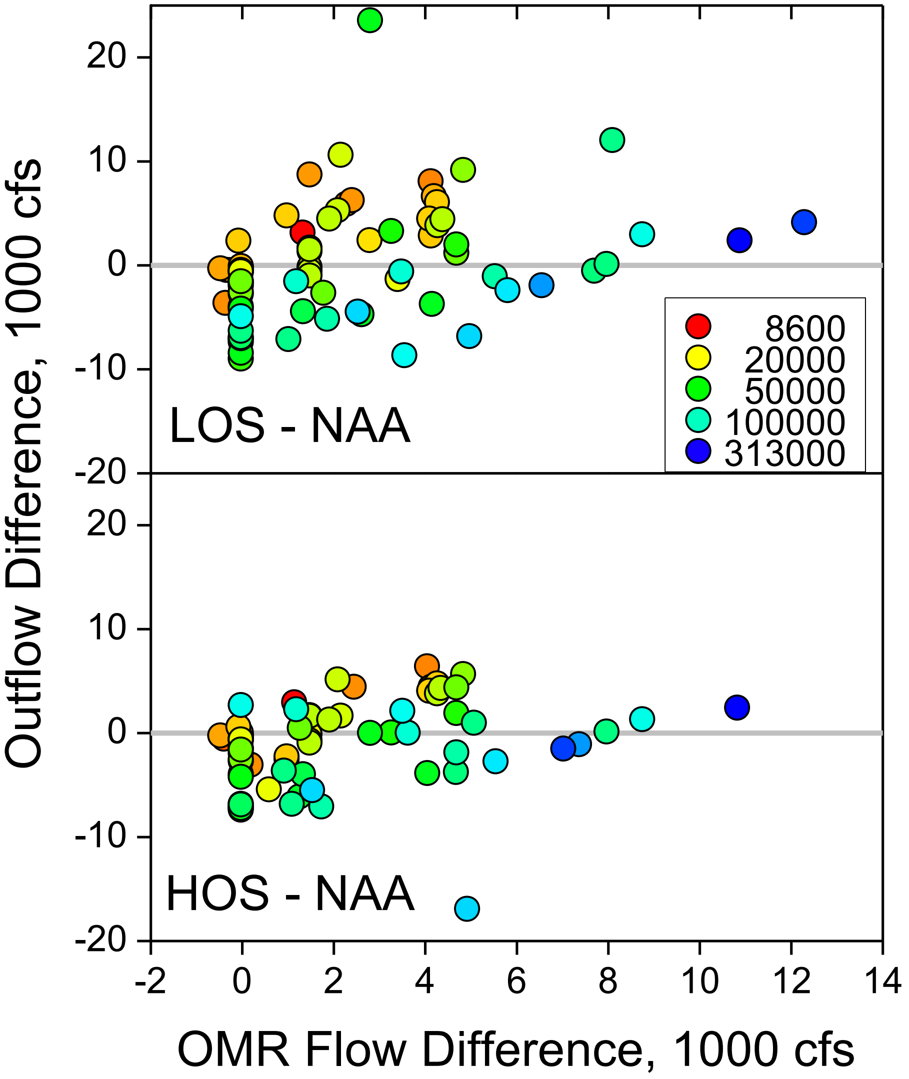

Figure 5.2. January flow conditions compared between the two modeled scenarios (LOS, top; HOS, bottom) as the differences from the flows under NAA. The colors show the range of NAA inflow. Under the LOS there were many Januaries when inflow was low but the outflow and OMR flow were increased by about the same amount over NAA.

Consequences

The anomalies discussed above seem to arise through the application of rules and constraints designed in some cases for real-time operations, using a model with a monthly time step. We understand and appreciate the difficulty in modeling such a complex system and the problems that would arise in attempting to mimic variation on a daily time scale. Furthermore, we trust that the modeling team has made every effort to produce output that conforms to the constraints and the modeled hydrology. Nevertheless, the specific model outputs we focus on above seem unrealistic, particularly since these anomalies are largely confined to October and January. We do not think the system is likely to be operated in real time to achieve the flows shown in model output.

Thus, discussions in this and the next chapter should be accompanied with this caveat: *these apply only if the system were actually to be operated to achieve the flows indicated by the models*. If rules are not in place to ensure these flows are achieved, the benefits to delta smelt (and presumably other species) will not be realized.

Analysis of flows

Construction of a new export facility will not by itself achieve the goals of restoring more natural flow patterns in the Delta; the effects of such a facility are entirely dependent upon its operational rules. We assessed how much the modeled operational scenarios (HOS and LOS) achieve the goals of restoring net natural flow directions within the Delta. In recent years, the Biological Opinions for delta smelt and salmonids have directed attention to net flows in OMR, which are the main channels carrying Sacramento water to the export facilities in the south Delta. OMR flows show relationships with salvage of some fish species at the fish facilities and are presumed to reflect entrainment risk to fish in the Delta, i.e. the direct effects of the projects. In earlier years, focus was on net flows in the lower San Joaquin River (QWEST) as a more general measure of the impacts of water management on net flows in the Delta, which were believed to cause indirect effects on fish populations.

OMR and QWEST flows are two measures for the effectiveness of CM#1 in restoring more seaward flows in the Delta (see Chapter 6 for an estimate of effects of the modeled flows on delta smelt entrainment). Here we examine both the changes in seaward flows and the degree of negative flows as predicted from CALSIM models.

A north Delta diversion will increase the frequency of positive net OMR and QWEST flows and reduce negative values to the extent that exports from the north Delta reduce exports from the south Delta. However, BDCP calls for continued use of south Delta diversion facilities and greatly restricts the operation of the north Delta diversion, particularly in dry periods and early winter. Thus, restoration of seaward flows in the Delta must be viewed in the context of the timing and conditions when the north Delta diversion can be used.

We describe how LOS and HOS alter the incidence and degree of reverse flows during the seasons of sensitivity for the covered fish. For each season of sensitivity, we group results by quartiles of outflow to assess how changes in flows occur under drier vs. wetter conditions. Low flows in the winter and spring are when concern over reverse flows is greatest for most species.

Direct effects

Direct effects are entrainment, or the number of fish diverted into the facilities. This number is not known for any species because substantial numbers of fish are lost in the waterways leading to the fish facilities and through the louvers at the fish facilities. Salvage is therefore a poor measure of entrainment effects, but there are no other direct measures. Estimates of entrainment as a proportion of total population of delta smelt are presented in Chapter 6. Such an analysis has not been developed for any other species of concern. Therefore, to broaden the analysis to all species we examined changes in modeled flow in OMR. This measure has been used in both Biological Opinions. OMR flow is both calculated by models and measured in the field; it is roughly equal to San Joaquin River inflow minus total exports. Because San Joaquin inflows are less than total exports under all but flood conditions, OMR flows are usually negative. We assume OMR is the primary focus of CM #1's goal to "reduce the incidence of reverse flow". To broaden the question we also assess the degree to which flows are made less negative by the alternatives.

Incidence of reverse flow

Because 'incidence' is a measure of frequency, the "Incidence of reverse flows" is the frequency with which OMR is changed from negative under NAA to zero or positive (northward) under the proposed alternatives; because model output is available by month, we examined frequency on a monthly basis (Table 1). The distribution across months of the change in net OMR direction implies that effects on each species will depend on its season of sensitivity.

The results below are consistent with the goal of CM#1 of achieving a greater frequency of positive net flows in Delta channels by shifting exports to the north Delta diversion site. This is true more for HOS than LOS operations.

LOS effects. The LOS reduced the incidence of negative flows by 5% overall (50 months out of the 984 months modeled; Table 1). Under NAA 110 months had positive (northward) OMR flows while 160 months had positive flows under LOS. Positive or zero OMR flows under LOS coincided with negative flows under NAA in all months save August, but most frequently in January – March. There were 21 months when OMR flows were positive under NAA but negative under LOS in April and May (Table 1).

The shift to positive OMR flows under LOS was sometimes quite large (about 6000 cfs) and occurred almost solely under higher river inflows during December through June. The occasions when NAA alone produced positive OMR flow occurred only in April and May and the change in OMR flows between NAA and LOS were small (<1000 cfs).

HOS effects. The HOS had a more substantial effect on the incidence of negative flows than LOS (Table 1). There were only 13 instances when positive OMR flows under NAA were negative under the HOS, and the differences were very small in those cases. As with LOS, the changed OMR status happened in all months save August. The most noticeable difference between HOS and the other two alternatives was in September and November when HOS was northward about a third of the time while NAA was always southward and LOS northward only a few times. The low frequency of northward flows under HOS in October may be related to the anomalies in outflow identified above, but the reasons for the otherwise high frequency of positive OMR flows in fall under HOS are obscure, as they are not called for by regulations and no fishes of concern are vulnerable to export entrainment at that time.

Table 1. Frequency by month of northward (including a few zero flows) or southward flows under NAA vs. LOS, and NAA vs. HOS. Columns in italics indicate those years and months when the direction of flow differed between NAA and the selected scenario. For example, in April there were 47 years when NAA flow was northward, in 5 of which LOS was southward, and 35 years when both flows were southward, out of a total of 82 years.

Magnitude of negative OMR flows

Entrainment rates are a function of population distribution and abundance, season of occurrence in the Delta, and flow conditions including export rates (or OMR conditions). The months of vulnerability for each species of concern were taken from the BDCP documents. For adult longfin and delta smelt the season of vulnerability is from December through March. For juvenile delta smelt the season is from March through June.

The effects of overall flow conditions, i.e. how relatively wet or dry it is, were assessed by grouping the months of vulnerability for all 82 modeled years into quartiles of outflow in the NAA; e.g., for adult delta smelt which are considered vulnerable during December-March, there were 82 months in each quartile of outflow. We examined conditions of OMR, river inflow and outflow under several operational scenarios. We examined differences under four levels of wetness for each month using outflow in the month as a measure of wetness. Historically fish are more often salvaged under drier conditions than under.

In Figure 5.3 we present comparisons of the HOS and LOS scenarios for each quartile of outflow (under the NAA scenario to ensure comparison of the same years in each graph).

Under the HOS and LOS alternatives, OMR differs from NAA during the seasons of sensitivity for adult delta smelt (Dec-Mar) and juvenile delta smelt (April-June).

Three patterns can be seen:

1. In the season of vulnerability for adult smelt (December – March), HOS and LOS both show about a 1000-5000 cfs increase toward positive in OMR under all quartiles of outflow, but all OMR values are strongly negative except in the wettest quartile of the data. Exports in December and January can be high and the use of a north Delta diversion can improve OMR (but see "Concerns over modeling" above). For juvenile smelt, the increase in OMR flow under LOS and HOS is smaller and less consistent. In all cases the level of OMR flow is much less negative than in December – March.
2. The HOS and LOS alternatives differ only slightly except during the drier periods when OMR flow is slightly less negative under HOS than under LOS.
3. Under wetter conditions all alternatives produce median OMR flows in the range targeted as protective in the Biological Opinions (more positive than -5000, but see Modeled Impacts on Delta Smelt in Chapter 6). The use of NDD under high-flow conditions allows the HOS and LOS to avoid the extreme negative OMR values that occur under NAA because of the high south Delta export rates that are possible then.

Thus, in summary, model results suggest that reverse flows in the south Delta become more positive under both LOS and HOS for all quartiles of outflow. These changes can be seen both in the frequency and in the distribution of flows in the two seasons of vulnerability and the four quartiles of NAA outflow. In wetter months the north Delta diversion does not fully replace south Delta exports until river inflows are relatively high, so that OMR remains negative in most months of smelt vulnerability. Changes in OMR during the period of vulnerability of young delta smelt are smaller than those during December – March because all alternatives are constrained by the Biological Opinions to a much higher baseline OMR flow.

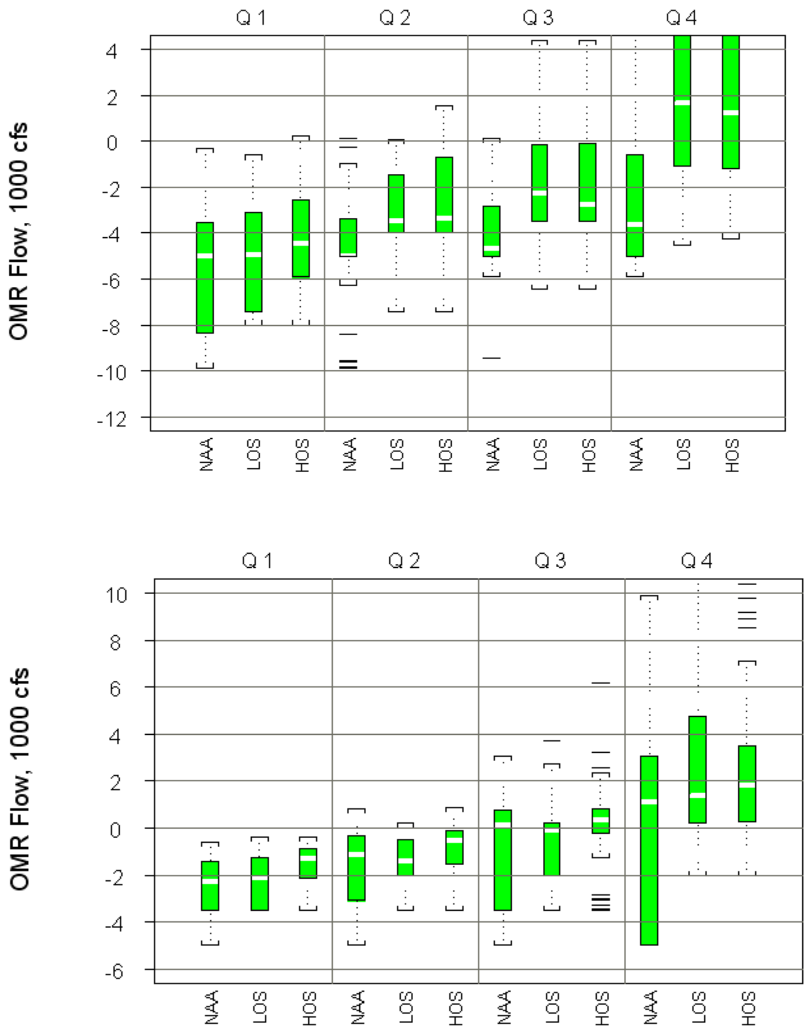

Figure 5.3. Values of OMR under the three alternatives for BDCP shown for quartiles of outflow under the No-Action Alternative. Boxes show first and third quartiles with the median as a white bar. The whiskers encompass points within 1.5 times the interquartile range, and the short lines are outliers. Top, period when adult longfin and delta smelt are vulnerable (Dec-March). Bottom, period when juvenile delta smelt are vulnerable (March-June).

Indirect effects

Net or tidally-averaged flow on the lower San Joaquin River at Jersey Point is parameterized as QWEST. This flow can be negative (i.e., eastward), which is considered an indicator of flow conditions unfavorable to fish. Negative QWEST could alter the speed or path of fish migrating through the Delta, thereby prolonging their migrations or making them susceptible to adverse conditions in the Delta. No field estimates of indirect effects have been made and they are conceptually difficult because the biological effects are difficult to define and because the net flows in the lower San Joaquin River are small compared to tidal flows. Nevertheless, regulatory agencies, particularly the CDFW and the

NMFS, have long expressed concern that negative values of QWEST due to project operations present fish with impediments to their effective migration.

The "east-west flow pattern in the San Joaquin River" referred to in the justification for CM#1 is apparently QWEST. QWEST is calculated in the Dayflow water balance program (http://www.water.ca.gov/dayflow/) as:

QSJR + QCSMR + QMOKE + QMISC + QXGEO - QEXPORTS - QMISDV - 0.65 (QGCD – QPREC),

i.e., the sum of inflows from San Joaquin River, eastside streams, and the Sacramento River via the Cross-Delta Channel and Georgiana Slough, minus south Delta exports, miscellaneous diversions in the Delta, and a fraction of the difference between precipitation and consumptive use within the Delta. However, for CALSIM modeling Delta consumptive use (QGCD), Delta precipitation (QPREC), and Delta miscellaneous diversions (QMISDV) are unavailable so the above equation simplifies to:

QWEST = QSJR + QMOKE + QCSMR + QXGEO – QEXPORTS.

QXGEO increases with Sacramento River flow and also depends on DCC gate operations. Specifically, QXGEO changes as 13.3% of Sacramento River flow with both DCC gates closed and 29.3% with both gates open (Dayflow documentation cited above). Sacramento River flow into the Delta will decrease by the amount diverted in the north Delta. Thus, among the flows controlled under BDCP, QWEST decreases by 100% of south Delta export flows and 13.3% or 29.3% of north Delta diversion flows depending on DCC gate positions.

There are many covered species of fish that migrate through or reside in the central Delta (Table 5.2). At least one of these species is present in the Delta during every month but August. Conditions in the central Delta are important for migratory species that spawn in the San Joaquin or Mokelumne Rivers because the entire population must pass through the central Delta. By contrast, only a fraction (unknown) of Sacramento fish enter the central Delta during migration. To cover the species that would be most affected by changes in flows in the San Joaquin River, we limit discussion to outmigrating salmonid juveniles (February – April) and upmigrating San Joaquin salmon (September – November).

Juvenile salmon

The occasional high springtime flow requirements of HOS (to benefit longfin smelt) coincide with the smolt emigration season (February – April). In drier conditions (the drier two quartiles) there is very little difference between NAA and LOS (Figure 5.4). The occasional occurrence of high flow requirements in HOS produce some differences between LOS and HOS scenarios, but mostly in the second quartile when the high flows are more likely to be triggered than in the driest quartile. All project scenarios diverge from the NAA under the wetter scenarios as more water is diverted from the north Delta and substitutes for high south Delta exports (Figure 5.4). The several thousand cfs differences in wetter months are occurring against baseline flows in the realm of 20000 cfs and greater, whereas the changes in flows in drier conditions are very small because limited North Delta diversion operations at low flows do not affect broad indices of Delta flow such as QWEST.

Table 5.2. Species of fish covered by BDCP that occur within the Central Delta for specific life history stages and the season of sensitivity to changes in flow conditions due to project operations (from various sources).

Species and Life History Stage within the Delta	Timing
Sacramento and San Joaquin steelhead juveniles	February - April
Winter-run Chinook salmon juveniles	November - April
Spring-run Chinook salmon juveniles	March-May
Green sturgeon	November-December
Delta smelt adults	December-March
Delta smelt juveniles	April-June
Longfin smelt adults	December-February
Longfin juveniles	February-March
Upmigrating San Joaquin steelhead	September-April
Upmigrating spring-run Chinook salmon	March-August
Upmigrating winter-run Chinook salmon	January-May
Upmigrating fall-run salmon Chinook salmon	September-November

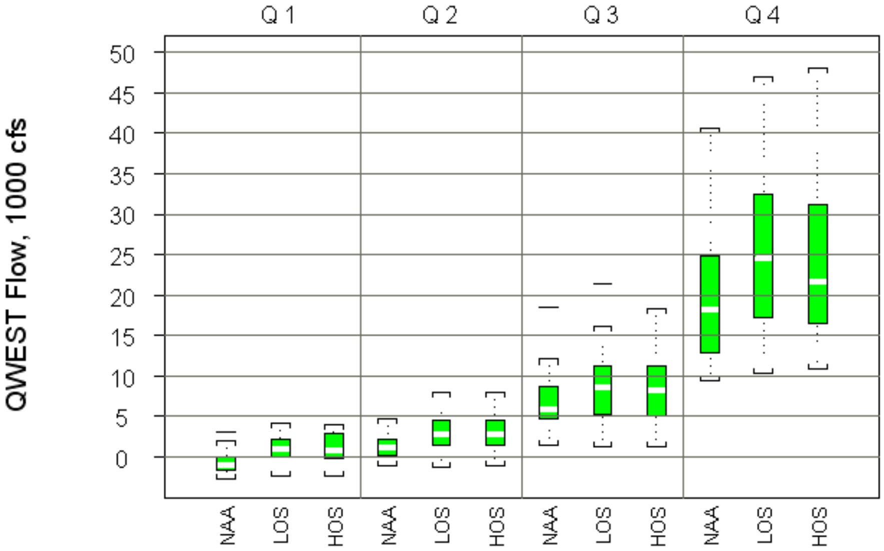

Figure 5.4. Feb-April QWEST flow for NAA and 3 alternative operational scenarios, grouped by quartiles of outflow. Two outliers for each scenario in Quartile 4, with values of 52,000 – 98,000 cfs, were cut off to allow better resolution of the lower values.

Adult San Joaquin fall-run salmon

Upmigrating salmon adults to the San Joaquin River pass through the south Delta and the lower San Joaquin River during September – November. In the fall there is very little difference among the alternatives that is not dwarfed by occasional high inflows due to flood releases or early winter storms (Figure 5.5). However, all alternatives show a general increase in QWEST compared to values for NAA because the use of the North Delta

Diversion is much less restricted and can more often substitute for south Delta diversions that are often operating at maximum flow under NAA.

In summary, project scenarios have small effects on QWEST in any season; changes in QWEST are smaller than those in OMR because use of the North Delta diversion does not translate into direct increases in flow, as it can for OMR. This is true for both the spring and fall. The high flows in HOS produce increases in QWEST in months around median wetness.

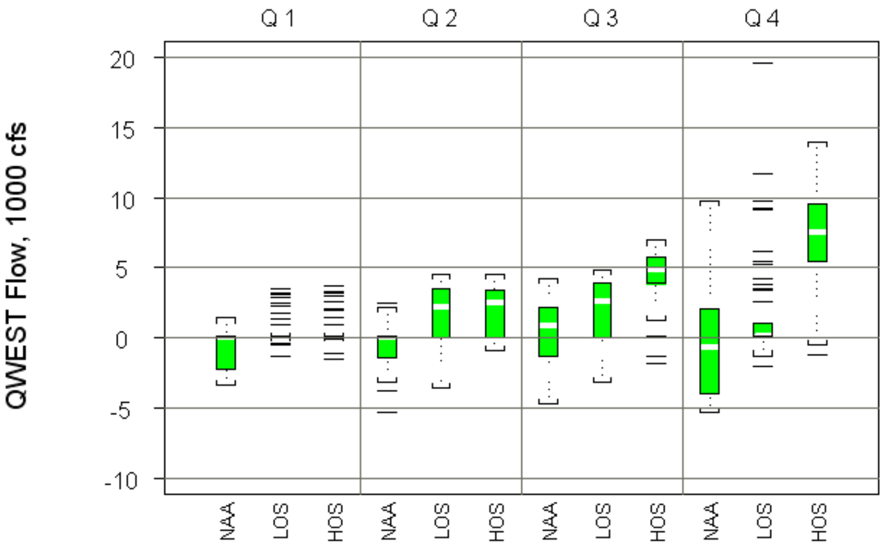

Figure 5.5. QWEST flows for the September-November season grouped by quartile of outflow. One outlier for each scenario in Quartile 4, with values of 22,000 – 30,000 cfs, was cut off to allow better resolution of the lower values.

Conclusion

The analysis presented here demonstrates broad improvement in in-Delta conditions under BDCP, as measured by changes in OMR and QWEST. However, we reiterate our concerns over the likelihood that Delta flows would actually be managed in the manner prescribed by the modeling. Changes in the frequency of reverse flows and their magnitude were somewhat obscured by the high variability among years, even those with similar hydrology. Some of this variability is a consequence of carry-over storage and the specifics of operational rules that may be triggered by conditions in one year but not another even if hydrology is similar. In the context of this variability, the improvements in flow conditions during periods of vulnerability of the smelt and salmon species were modest.

In analyzing model results of the operational scenarios we were surprised to see benefits occurring under dry conditions. The restrictions on North Delta diversions limit its operations to times of substantial river flows, so its ability to substitute for south Delta diversions should be limited to times of high flow. In fact, over a broad range of intermediate flows, the north Delta diversion augmented south Delta exports, rather than substituting for them. Thus, improvements to in-Delta flow conditions happened mostly in the highest quartile of Delta outflow under NAA. The differences between flows under the LOS and HOS were generally rather small.

Chapter 6: Estimated Effects of BDCP Flows on Smelt

Introduction

This chapter takes the model projections for three scenarios discussed in Chapter 5 (NAA, HOS, and LOS) and uses various simple statistical models to estimate the potential effects of these flows on delta and longfin smelt. The principal flows of interest are:

- Winter and spring flows in Old and Middle Rivers, which affect adult and larval to juvenile delta smelt, respectively
- Fall outflow, which may influence extent of habitat and therefore subsequent recruitment of delta smelt
- Spring outflow, which has a statistical relationship with subsequent abundance of young-of-the-year longfin smelt

We did not consider export effects on longfin smelt, for which there is no available statistical model and therefore no method to estimate losses without additional analysis beyond the scope of this review.

In making the calculations presented here we were constrained to use the CALSIM model output for the various flows by month and year. The concerns expressed in Chapter 5 apply here*: we do not believe that the system will actually be operated to obtain monthly patterns of flow like those in the CALSIM output*. This is particularly true in January and October, when wild swings in flows from one year to the next indicate a situation that would be very unlikely in the real system.

Direct Losses of Delta Smelt

Flows in Old and Middle River are related to salvage of delta smelt and other fish at the south Delta fish facilities. Annual salvage in turn is generally assumed to be a small fraction of entrainment losses, particularly for young (small) fish, because of various other losses attributed to export pumping, including predation in the waterways leading to the facilities and inefficient capture of delta smelt by the facilities.

Here we present estimates of export entrainment losses as a fraction of the population of delta smelt during the adult stage and the larval to early juvenile stage, only a small fraction of which is salvaged (Kimmerer 2008). The calculations were based on results of Kimmerer (2008) as amended for adult delta smelt by Kimmerer (2011). The general procedure was to determine a relationship for each of these two life stages between survival and flow variables that were available from CALSIM. Flows used were Old and Middle River flow (OMR) for adults, and net inflow (i.e., inflow less north Delta diversion flow, NDD) and export flow in the south Delta for larvae and juveniles combined.

We modeled the entire period of CALSIM analysis (WY 1922-2003) for the BDCP scenarios, and the historical period (1955-2003) for comparison. We calculated losses as described in

Appendix C for the BDCP scenarios for both time periods, and for the historical period using Dayflow variables and OMR flows from USGS monitoring.

The principal assumptions were:

- The relationships used to calculate survival or recruitment accurately reflected the corresponding population parameters; that is, the confidence intervals of the predictions were assumed to include the true values of the population parameters with 95% probability. Note that these analyses (Kimmerer 2008, 2011) have not been repeated by any analysts, although Miller (2011) provided a detailed critique. This is rather worrisome, because both the BiOP and several published modeling studies rely on the accuracy of those analyses (Maunder and Deriso 2011, Rose et al. 2013a, b).
- Changes due to BDCP actions were cumulative such that each factor could be examined in isolation from the others, and its effect considered separately from the others.
- The only changes considered were those due to the entrainment effects of flow. Long-term changes in sea level, tidal prism, temperature, salinity, and physical configuration of the Delta were neglected, despite their likely influence on the exposure of the smelt population to export entrainment. Exceptions to this were the influences of these factors on flows modeled by CALSIM.
- The flow time-series produced by CALSIM accurately reflected the influence of the various changes (but note concerns expressed above and in previous chapters).
- The broad spatial distributions of delta smelt will not differ substantially from those existing when the above analyses were made. This may not be true if the fraction of the population in the north Delta is higher now and in the future than when the analyses were made (Miller 2011, Kimmerer 2011).

Losses of adult delta smelt were calculated as a linear function of OMR flows. Annual percent loss under each of the three scenarios was similar for the historical and modeled time periods (Figure 6.1). The estimated proportion of adults lost to entrainment was slightly lower for the NAA than for the historical period, reflecting overall lower export flows presumably because some operating rules were not in force during the historical period. The High- and Low-Outflow scenarios (HOS and LOS) both had proportional losses that were ~ half of those under the NAA, or a net change in loss of about 3%/year.

Losses of larval + juvenile smelt were modeled as a function of exports from the south Delta and inflow to the Delta less diversions from the North Delta facility. The patterns for young smelt were somewhat similar to those for adults but with larger differences among scenarios. The NAA had substantially lower losses than the historical condition over the historical period (Figure 6.2). Flows projected for both the HOS and LOS resulted in much lower losses than for the NAA, with losses under the HOS reduced to ~2%/year on average.

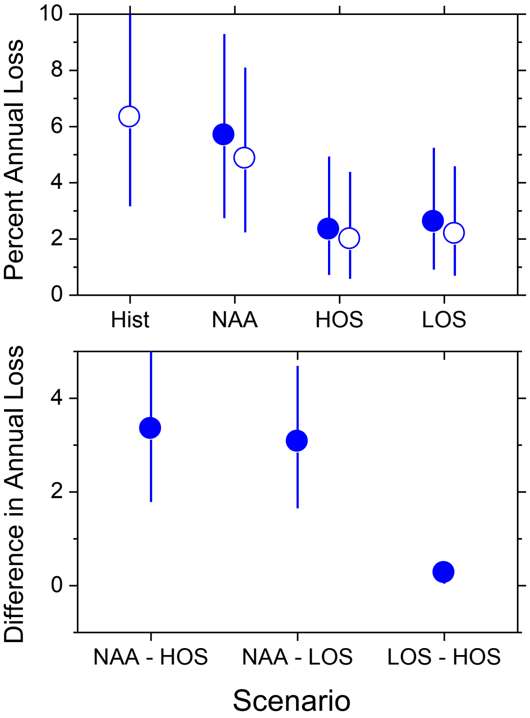

Figure 6.1. Annual percentage of adult delta smelt lost to export pumping for three scenarios and the historical time series. Symbols give means (see text) and error bars give the 95% confidence limit calculated as quantiles of the 1000 simulated samples of the respective distributions. Top panel, percent annual loss for 1922-2003 (filled symbols) and for 1980-2003 (open symbols) including the historical data. Bottom panel, differences between pairs of model scenarios.

We combined results for adults and larvae + juveniles within each calendar year by first calculating the proportion of the population that would remain after 20 years at the mean values in Figures 6.1 and 6.2, then multiplying the proportions remaining to get the influence of these scenarios over both life stages. This is effectively a long-term survival percentage. These are not predictions, and are useful only for examining differences among scenarios. The resulting percentages were 38% for the HOS, 23% for the LOS, and 2% for the NAA (Table 6.1). In other words, the two scenarios with a north Delta diversion resulted in 19- and 11-fold increases in survival over a 20-year period.

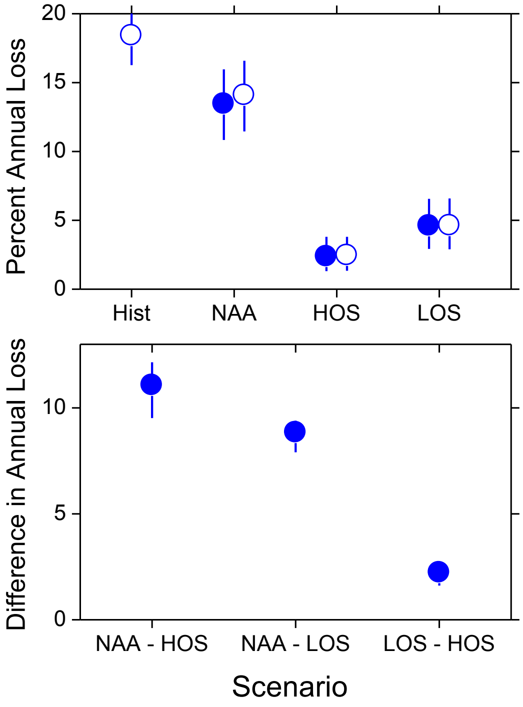

Figure 6.2. As in Figure 6.1 for losses of juvenile delta smelt.

These numbers are highly uncertain, since the value for NAA is so small and variable (Table 6.1). There are indications that losses have been overestimated, especially given the potentially large subpopulation of young delta smelt that may be resident in the Cache Slough complex, where they are immune from effects of export pumping in the south Delta (Miller 2011). Using the upper confidence limits of the projected population size at the end of 20 years (i.e., the lower 95% confidence limits of the loss estimates) the ratios of population remaining after 20 years would have been 14 for HOS and 9 for LOS. These confidence limits do not account for any upward bias in loss estimates, and the loss estimates can and should be refined to reflect current understanding.

Nevertheless, the results of this analysis show a substantial improvement in long-term survival of delta smelt under HOS and to a lesser extent LOS, *provided the water projects are operated in ways that result in flows similar to those in the simulation.* Taken at face value the mean difference in losses between NAA and either of the other scenarios would have roughly sufficed to reverse the decline in delta smelt during the early 2000s.

Table 6.1. Percent of delta smelt population remaining for each of three BDCP scenarios after 20 years of losses at the rates estimated and shown in Figures 1 and 2. Values given with 95% confidence intervals.

	Adults	Juveniles	Combined
NAA	31 ± 22	6 ± 4	2 ± 2
HOS	62 ± 25	62 ± 15	38 ± 19
LOS	59 ± 25	39 ± 15	23 ± 13

Outflow Effects

Two time periods are considered for effects of changed outflow: fall for delta smelt and spring for longfin smelt. These effects are typically cast in terms of X2. For this analysis we calculated X2 from outflow as determined by CALSIM, using the monthly relationship in Jassby et al. (1995), as has been done for all previous analyses of relationships of X2 to abundance indices or habitat of fish (e.g., Feyrer et al. 2007, Kimmerer et al. 2009). CALSIM also produces X2 but it is for the previous month and is somewhat different from that used previously, particularly since it is said to account for sea-level rise and the effects of additional tidal prism due to marsh restoration. Since we were focused on the early long-term (ELT), we elected for now to neglect these considerations and use an X2 value that reflected the anticipated outflows in the same way as in the analyses of X2 effects on fish.

Fall X2 Effects on Delta Smelt

The USFWS Biological Opinion (BiOP) for delta smelt proposes to use X2 in the September-December period as a management tool. The principal basis for this action is the analyses of fall habitat indices (Feyrer et al. 2007, 2011) and an unpublished analysis relating the Summer Townet index to the previous fall Midwater Trawl index and X2:

$$TNS_{y+1} \sim a + bMWT_y + cX2_y + \varepsilon_y \qquad (6.1)$$

where TNS is the summer townet index, MWT the fall midwater trawl index, y is year, ε is error, a, b, and c are fitted parameters, and the time frame was restricted to after 1987 to account for the changes in the foodweb resulting from the introduction of the clam *Potamocorbula amurensis* (See Chapter 7 regarding food limitation of delta smelt).

This model assumes that the main effect of fall X2 on delta smelt is through a combination of survival and growth and therefore population reproduction in the following spring, resulting in effects on abundance in the following summer. Equation 6.1 is somewhat illogical in modeling TNS as an additive function of MWT and X2, and it is also strongly influenced by the data point from 1998, the wettest fall among those included in the analysis. Removing that point weakens that relationship somewhat, although it remains strong. Nevertheless, we fitted an alternative model:

$$\log(TNS_{y+1}) \sim a + b\log(MWT_y) + cX2_y + \varepsilon_y \qquad (6.2)$$

which is more in keeping with the form of the other X2 models (Jassby et al. 1995). This model was fitted to all the data since 1987 using a robust regression method to allow for some over-dispersion in the residuals (function *rlm*, Venables and Ripley 2003). The regression coefficients were a=2.7, b= 0.62 ± 0.22, and c= 0.061 ± 0.55, R^2=0.68, and diagnostic plots revealed that this model was appropriate for the data (Figure 6.3). In particular 1998, and unusually wet year, did not have a strong influence on this relationship.

We extrapolated from this model to the BDCP scenarios using the CALSIM-modeled outflows. The target was the summer townet index, which we examined as a ratio to that predicted under NAA. In contrast to earlier analyses, we did not attempt to relate this to long-term population growth.

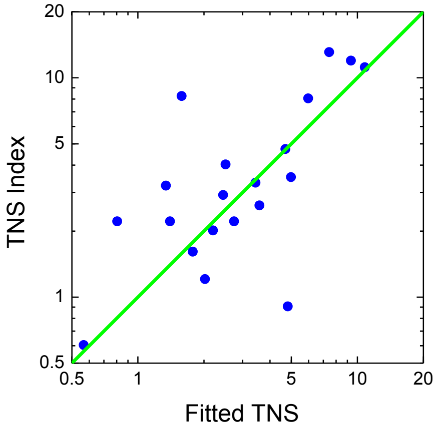

Figure 6.3. Fitted and measured summer townet index (TNS) with a 1:1 line. Values were fitted using Equation 6.2.

The modeled monthly outflow values were converted to X2 according to the monthly equation in Jassby et al. (1995), with the initial value (October 1921) set to the equilibrium X2 for the modeled flow. This was combined with historical monthly mean X2 values and all were averaged over September-December. Equation 6.2 was then used to predict the summer townet index from the mean fall midwater trawl index from 1988 to 2011 and X2 for the three scenarios.

Results showed HOS to have, on average, a slightly higher summer townet index than under NAA (Figure 6.4). The ratio of townet indices determined under HOS to that under NAA was 1.02, i.e., a 2% greater index under HOS, with 10th and 90th percentiles of 0.89 and 1.10 respectively. About a third of the values had lower confidence limits below zero, indicating low confidence that a real increase would be achieved under these conditions.

By contrast, the predicted ratio of townet index for LOS:NAA was about the same as that for HOS:NAA about half of the time, and the other half of the time it was much lower, with large confidence intervals related to the uncertainty in the prediction from the model. The calculated ratio had a median of 0.98 with 10th and 90th percentiles of 0.60 and 1.10. This peculiar pattern arose from the patterns of outflow in the CALSIM output (see Chapter 5). We have very low confidence that these patterns reflect how the system would really be operated, and therefore suggest these results be considered as conditional on proposed operational rules.

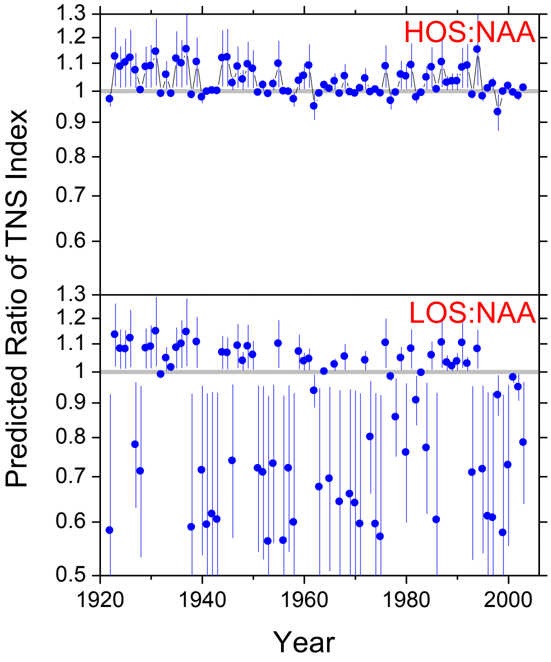

Figure 6.4. Ratios of predicted TNS index by year from HOS (top) and LOS (bottom) to those from NAA.

Spring Outflow/X2 Effects on Longfin Smelt

Longfin smelt has the strongest relationship of abundance index to X2 of any fish (Jassby et al. 1995). The index for a given level of X2 has declined, but the response to flow has not changed. We updated the latest published version of this relationship (Kimmerer et al. 2009) by adding two step changes in time: one in 1987-1988 corresponding to the spread of the clam *Potamocorbula amurensis*, and the other in 2003-2004, the POD decline (Thomson et al. 2010). The statistical model used was

$$\log_{10}(LFS_y) = a_y + bX2_y + \varepsilon_y \qquad 6.3$$

Where LFS is the annual index of longfin smelt abundance from the fall midwater trawl survey, y is year, X2 is monthly values averaged over either January-June (as in Jassby et al. 1995) or March-May, and ε is error. Fitting parameters are *a*, which takes one of three values by year group, and *b*, the slope of the X2 relationship.

The resulting relationship (Figure 6.5) shows both the effect of X2 and the two step-changes in abundance index. Diagnostic statistics showed that the model was appropriate. Since we were interested in the difference between the two alternative flow scenarios and NAA, the only parameter that concerned us here was *b*, which had a value of -0.054 ± 0.005 km^{-1}, essentially identical to previously published values. Averaging X2 over March-May gave a slope of -0.049 ± 0.005 km^{-1}, and the fit was slightly inferior to that of the January-June model.

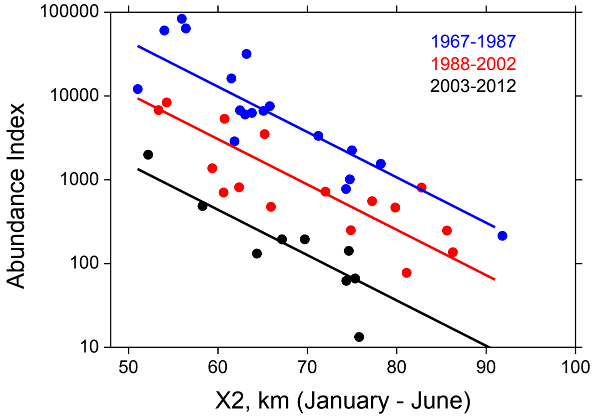

Figure 6.5. Abundance index of longfin smelt vs. X2 averaged over January-June, with step changes between 1987 and 1988 and between 2002 and 2003. Colors of points and lines indicate the time period.

The months selected in the original analysis were based on the assumption that the (unknown) X2 mechanism operated during early life history of longfin smelt, which smelt experts linked to this period. Autocorrelation in the X2 values through months means that statistical analysis provides little guidance for improving the selection of months. A better understanding of the mechanism(s) underlying the relationship would probably allow this period to be narrowed and focused, but for now there is little basis for selecting a narrower period for averaging X2.

The predictions from the above model were then applied to the X2 values calculated from the CALSIM projections of outflow for the 82-year period. We did not attempt to propagate prediction error because it is small compared to variability in outflow. Applying the January-June value for the three selected scenarios resulted in scant differences in predicted abundance indices (Figure 6.6). The median $\log_{10}$ ratio of indices for HOS:NAA was 1.00 (mean 1.05) with 10th and 90th percentiles of 0.91 and 1.27. Corresponding values for LOS:NAA were median 0.92 (mean 0.92) and percentiles of 0.83 and 1.00.

Thus, changes in outflow resulting from the CALSIM projections of spring outflow were small, particularly on the scale of the high variability with X2. HOS provided a minuscule increase in the mean but the median did not change from NAA, indicating that half of the years had higher, and half lower, values under HOS than under NAA. LOS gave values that were ~8% lower than those under NAA.

Although it would be desirable to link such calculations to a population-dynamics model, no such model is available; furthermore, previous analyses have shown that abundance of longfin smelt is highly predictable from X2 and, more recently, groups of years as done above. This does not mean that stock-recruit relationships are unimportant; an alternative analysis models a recruitment index, the log of the ratio of MWT to the MWT value 2 years earlier, as a function of X2 (Nobriga and Rosenfield, in prep.). However, it is unlikely this analysis would indicate a stronger effect of X2 on longfin smelt under BDCP.

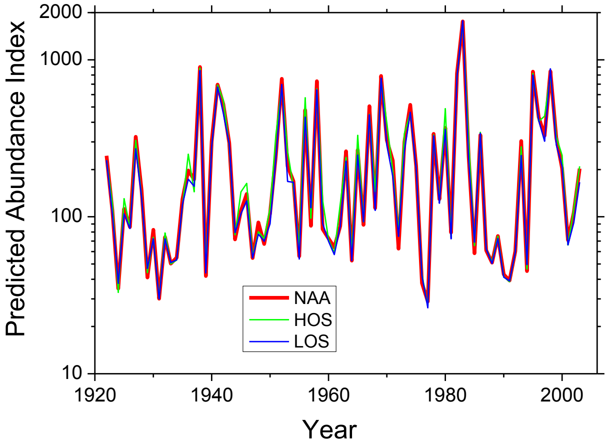

Figure 6.6. Predicted abundance from the model in Figure 6.3 for the three BDCP scenarios. The intercept for the third time period (2003-2012) was used to calculate these indices.

Conclusions

The modeled flow changes under BDCP have mixed effects on the two smelt species. For delta smelt, changes in flow in the south Delta had a marked effect on survival of both adult and young smelt, such that gains of several percent a year would be forecasted for the difference between the NAA and the two with-project alternatives. Effects of outflow on delta smelt were small for HOS compared with NAA, while projections under LOS showed about half the time a marked reduction in predicted summer abundance index compared to NAA. Effects of spring outflow on longfin smelt were not very large.

The results for delta smelt were somewhat surprising, since food supply is clearly an important limitation (Chapter 7) and more likely implicated in the decline than export losses. We nevertheless stand by these results subject to the following contingencies:

- The water projects will be operated to achieve similar flow patterns as in the CALSIM output we used in our analysis.
- Future re-analyses of the influence of export pumping on delta smelt are used to refine these estimates.
- Effects of increasing temperature, introductions of quagga or zebra mussels or other high-impact species, changing flow-X2 relationship, rising sea level, and catastrophic inundation of Delta islands do not materially alter the trajectory of delta smelt.

The last point is presented almost facetiously – things will change, in some ways we can predict and other ways we cannot. The BDCP takes account of some of these changes but others are just as likely over the time frame of the project and should be accounted for

(Chapter 8). Nevertheless, at present we lack the capability to include these factors in a more thorough analysis, but believe it should be done.

Longfin smelt, by contrast, are unlikely to be much affected by BDCP. The anticipated changes in outflow are rather minor, and the flows needed for substantial changes in longfin smelt abundance are likely too great to be practically achieved.

Chapter 7: Likely Response of Listed Fishes to Physical Habitat Restoration

Introduction

This Chapter focuses on the proposed restoration of physical habitat in the Delta and Suisun Marsh. Because of time constraints we have focused on the potential benefits of floodplain and marsh restoration to delta and longfin smelt. These benefits are postulated to occur through expanded physical habitat for the fish, or through export of food from the restored areas to smelt habitat.

Summary of Assessment

The BDCP proposes to restore 55,000 acres of subtidal to intertidal habitat[1] of which 20,600 acres is to be allocated among various Restoration Opportunity Areas (ROAs) in the Delta and Suisun Marsh and the remainder to be allocated later. If completed this restoration will substantially increase the inundated portion of the Plan Area; for example if all 7000 acres assigned to Suisun Marsh were restored it would roughly triple the area exposed to tidal action.

The ROA's include Suisun Marsh, Cache Slough, and the eastern, southern, and western Delta . The documentation is unclear on the depth profiles of these areas and for calculations below we have assumed that about half of each will be intertidal and the remainder subtidal with a mean depth of 2 meters. The document lists the aquatic and terrestrial species expected to benefit from these actions, but here we focus only on their likely effects on the two smelt species.

Our results to date lead to the following preliminary conclusions:

- Delta and longfin smelt are usually food-limited, meaning that population levels would rise if there were more zooplankton in their rearing areas. This limitation is probably stronger in spring-fall than in winter.
- The BDCP is overly optimistic about the likely benefits of tidal marsh restoration to the smelt species, particularly the extent of food production.
- A review of the literature suggests that tidal marshes may either import or export phytoplankton and zooplankton.
- Under highly favorable assumptions about production and export of plankton, restored tidal marshes could make at most a modest contribution to extant plankton production.

---

[1] "Habitat" means the location and conditions in which a population of a species lives; here we follow the BDCP document in using the term to mean a physical space. We likewise use "restore" to mean to prepare that space for the potential occupation of one or more species, irrespective of the previous condition of the space.

- The subpopulation of delta smelt that inhabit the Cache Slough complex through summer may benefit from additional physical space in that area. The same could be true in Suisun Marsh although current use by smelts is low.
- The high level of uncertainty about outcomes points to the use of moderate- to large-scale experimental restoration projects to determine whether the proposed restoration will achieve the food-production goals and, if so, how to design them optimally.

Marsh Restoration

Review of conceptual basis

The BDCP anticipates many benefits to delta and longfin smelt. Although the documentation is unclear on the expected magnitudes of these benefits, it is uniformly optimistic that they will contribute substantially to recovery of the species. Here we focus on two potential benefits to the smelts from the restoration of tidal habitats. First, the restored habitats are expected to provide a food supply that will enhance the food supply available to the smelts. Second, the restored habitats are expected to provide additional physical space, resulting in an increase in smelt abundance. Neither of these proposed benefits is well developed in the documentation, and the literature cited seems to have been selected to support the claims made. The BDCP documentation furthermore contains factual errors and misinterpretations that cast doubt upon the projections that are made, however qualitative. We therefore conducted a reasonably thorough analysis of these specific claims, within the constraints of time available.

The first outcome requires two conditions: 1) that the smelt populations are currently food-limited, meaning that an increase in concentration of food organisms would result in a higher abundance of smelt; and 2) that the restored marshes will produce and export enough food organisms to make a difference to the population status of the smelts.

BDCP Appendix 5E uses “prod-acres” to index the expected productivity of phytoplankton in the restored areas. However, this index is conceptually flawed in two ways. First, it uses an estimate of growth rate rather than production of phytoplankton, which is the product of growth rate and biomass. Second, it assumes implicitly that all phytoplankton growth is available as food for the zooplankton consumed by the smelt species, but analyses published on the San Francisco Estuary and elsewhere show that most of the production is consumed by benthos and by microzooplankton such as ciliates (e.g., Lopez et al. 2006, Lucas and Thompson 2012, Kimmerer and Thompson submitted).

The smelt species are expected to occupy some of the restored habitats. This may provide benefits in the form of increased opportunities for individual fish to find suitable conditions such as spawning substrate, food patches, or shelter from predators. A potential benefit is to diversify the locations in which the smelt species occur, in an attempt to increase resilience of the populations to local perturbations such as high-temperature periods or toxic spills.

Analysis of components

For effects of food production and export we assessed the evidence for food limitation of the smelt populations, and for the amount of food (zooplankton) that restored marshes would export to waters where the smelt species occur. For physical habitat we examined current patterns of occurrence to determine the likely effect of additional physical habitat on the smelt species.

We do not address other potential indirect impacts of marsh restoration, or interactions with other proposed projects. Restoration of extensive areas of marsh will increase the tidal prism in the restored area. This will affect tidal currents and elevations both locally and all the way to Carquinez Strait, and therefore affect salinity penetration and the movement of sediments. The effects on salinity have been included in the modeling presented in BDCP documents, but we did not review this. The U.S. Army Corps of Engineers has proposed a project, now on hold, to deepen the Sacramento Deep-Water Ship Channel, which is currently an important part of the habitat of delta smelt. This and other non-BDCP projects should be taken into account when considering impacts of BDCP.

Are smelt species food-limited?

What is the evidence for and against food limitation in delta and longfin smelt? By food limitation we mean a situation in which an increase in concentration of food organisms would result in a higher abundance of smelt. This does not require that all or even most fish have depressed growth or reproductive rates, only that at least some of them do. Substantial food limitation would require the following to be true:

1. The density of food organisms is too low to support the maximum growth rate of the fish.
2. Therefore some fish are in poorer condition or grow more slowly than under food satiation.
3. Either or both of the following:
    a. Survival over a life stage depends on condition and therefore food supply
    b. Reproductive rate of an adult varies with growth rate during development through its effect on maturity or total eggs per female.
4. Higher reproduction leads to a larger population, all else being equal. We assume this condition must be true as a straightforward consequence of population dynamics.

Food limitation could occur at one or more life stages, which may occupy different parts of the estuary. During spawning and early life delta smelt are mostly in freshwater. During the late larval stage (~July) until the pre-spawning migration in December, part of the population is in the low-salinity zone (LSZ, salinity ~0.5-5), and part is in the Cache Slough-Liberty Island complex in the North Delta (Sommer et al. 2011). Longfin smelt also spawn in freshwater but move earlier and further seaward (Rosenfield and Baxter 2007, Kimmerer et al. 2009). We refer to fish between metamorphosis from the larval stage to their spawning migration as juveniles (i.e., including all fish caught in the fall midwater trawl survey). Both smelt species consume available plankton in their habitat, with the size of prey related to that of the fish.

Food limitation is surprisingly difficult to demonstrate in a fish population. Nearly all populations must be food limited to some degree. However, food limitation of individual fish can be difficult to detect. The prey and the fish are spatially patchy and temporally variable, so the degree of food limitation is sporadic and patchy. Great differences among individuals in feeding success result in differences in growth and survival, such that the survivors are those that have been well fed. Feeding success also interacts with other influences such as predation risk and physiological stress.

The analysis of food limitation relies on a variety of direct and indirect evidence (Details in Appendix D). Some studies suggest food limitation inferred from correlations of abundance or length with measures of food availability, indices of gut fullness and physiological condition of field-caught smelt, and laboratory-derived estimates of feeding rate in relation to food concentration. A few other studies do not support food limitation in these species. However, the weight of evidence suggests that food is limiting the populations of both smelt species.

Export of food from shallow restored areas

One purported benefit to smelts of restored shallow areas is that elevated food production in these areas will be exported as a subsidy to open waters where the smelts are abundant. The implicit conceptual model is that these shallow areas will produce an excess of phytoplankton and zooplankton that will then be exported by stream flow or tidal currents. A subsidy of phytoplankton could stimulate zooplankton production in the open waters, since the zooplankton in this estuary are chronically food-limited in their growth or reproduction (Müller-Solger et al. 2002, Kimmerer et al. 2005). However, grazing by clams is likely to prevent such a subsidy from having much effect on zooplankton production. The alternative subsidy is that of zooplankton grown within the restored areas, including larger forms such as mysids that are consumed by juvenile longfin smelt and adult delta smelt.

The magnitude of any subsidy depends also on the transport process. Where the transport is mediated by tidally-driven currents, the subsidy will be related to the tidal exchange and the difference in biomass between the restored area and the open water. Where it is mediated by river flow, the subsidy will depend on the net flow and the biomass in the restored area.

Here we examine the literature on subsidies from marshes, use a simple model to estimate the magnitude of such a subsidy of either phytoplankton or zooplankton, and estimate the proportional flux from the Suisun Marsh to Suisun Bay using output from a particle-tracking model as a measure of the extant subsidy. Our conclusions are:

- The literature does not support a confident assertion that marshes will subsidize zooplankton of the open waters.
- Calculated subsidies of phytoplankton and zooplankton are modest under optimistic assumptions about in-marsh production and design of restoration sites.

- A subsidy of zooplankton from Suisun Marsh to Grizzly Bay cannot be very large under current conditions, and is unlikely to be much larger with the proposed extent of restoration.

Do shallow areas export phytoplankton or zooplankton?

Marshes can be major producers of organic matter because of their extensive vegetated surface exposed to sunlight, shallow waters leading to light penetration through all or most of the water column, and the continual supply of nutrients from the open waters and from land (Figure 7.1). This appears to be true even for recently restored marshes (Howe and Simenstad 2011). Over the long term, mass must balance, so production in excess of respiration by organisms within the marsh must be either buried or exported as organic matter or organisms to adjacent estuarine waters.

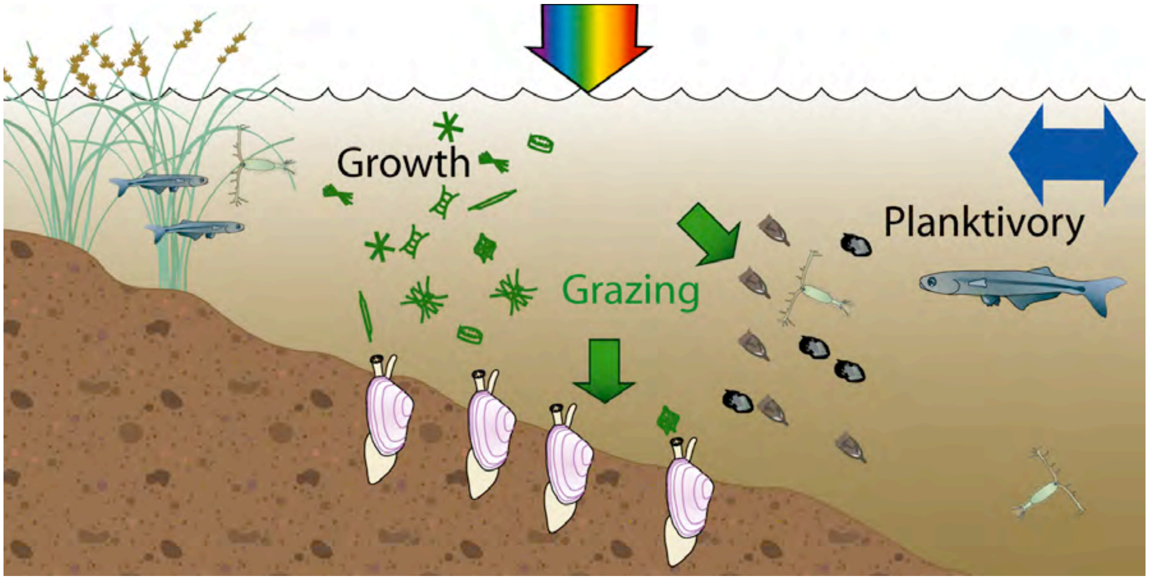

Figure 7.1. Conceptual model of the production of food for pelagic fish in a low-order tidal marsh channel. Because the water is shallow (and may be clearer than in adjacent channels) light penetration is good and growth of phytoplankton and benthic microalgae is high. Losses of phytoplankton occur through benthic grazing and by pelagic grazing, chiefly by microzooplankton but also by larger zooplankton such as copepods that can be consumed by fish. Benthic grazers filter a certain volume of water every day, so the shallower the water the more intensive the grazing on the plankton of the marsh. Small planktivorous fish such as Mississippi silversides seek shelter in the shallowest and vegetated areas; thus consumption of zooplankton is also more focused and more selective for larger organisms in shallow water. Tidal exchange of water with the adjacent higher-order (larger) channel transports nutrients, organic matter, and plankton between marsh and channel, but the direction of transport for zooplankton may be in or out of the marsh depending on the outcomes of the various production and consumption processes.

Export of organic matter from marshes to adjacent estuarine waters was first considered as the "outwelling hypothesis" (Odum 1980, Nixon 1980). This hypothesis holds that the export of labile organic matter provides an important subsidy to nourish adjacent waters of the estuary or continental shelf.

The outwelling hypothesis originated in studies of extensive, rich marshes on the east and Gulf coasts, but even there, quantitative demonstrations of its importance to estuarine or coastal foodwebs were few (Dame et al. 1986). Much of the difficulty arises from the technical challenge of measuring a small net flux in a large tidal signal with high variability (Dame et al. 1986). In addition, dissolved and particulate organic matter produced by rooted vegetation can be highly refractory and therefore largely unavailable to estuarine pelagic foodwebs, which are usually fueled mainly by phytoplankton (Sobczak et al. 2002, 2005).

Marshes can be sites of high productivity by benthic or planktonic microalgae because they are shallow, so waters are well-lit. Therefore a marsh could export organic matter as living phytoplankton. However, the extent of this export depends on consumption within the marsh, including consumption of phytoplankton by benthic grazers in shallow waters, as illustrated for flooded islands in the Delta by Lopez et al. (2006). Often overlooked in attempts at a mass-balance of phytoplankton is the high rate of consumption by microzooplankton, which typically consume about 60% of the production by phytoplankton in estuaries (Calbet and Landry 2004, York et al. 2011). Thus, the production actually available for consumption by mesozooplankton, and for export, is considerably lower than would be expected from estimates of primary production.

For zooplankton the magnitude and direction of the flux depends on behavior and on size- and taxon-specific patterns of mortality. In particular, visual predation by fish can exert strong control on the size distributions, and therefore species distributions, of zooplankton (Brooks and Dodson 1965). Vertical movements of zooplankton and hatching or settlement of larvae can lead to spatial patterns of abundance that do not reflect tidal transport (Houser and Allen 1996). Consumption of zooplankton by small fish that seek food and shelter in shallow areas can reduce zooplankton abundance near shore, and shift the size distribution toward smaller forms, in lakes (Brucet et al. 2005, 2010), lagoons (Badosa et al. 2007), and marshes (Cooper et al. 2012). The outcome can be net fluxes into shallow areas (Carlson 1978, Kimmerer and McKinnon 1989), and marshes can be simultaneously sinks for copepods and areas of aggregation for bottom-oriented larvae (Mazumder et al. 2009).

Thus, marshes may act either as net sources or sinks for plankton in the adjacent waters, depending on the availability of habitat for small fish and the degree of colonization by benthic grazers such as clams. The exact details of the exchange processes depend on the physical configuration of the marsh including permanence of inundation (Brucet et al. 2005), residence time of the water (Lucas and Thompson 2012), and the biological composition, i.e., the kinds and abundance of producers and consumers within the marsh including transient organisms (Kneib 1997). If the excess organic matter is being transported by fish as in some east coast marshes (Kneib 1997), little benefit would accrue to planktivorous fish in the open waters such as the smelts.

Few of these aspects have been examined in marshes of the San Francisco Estuary. Long-term studies of Suisun Marsh have revealed a lot about fish assemblages (e.g., Matern et al. 2002, Feyrer et al. 2003) and medusae and some zooplankton (Wintzer et al. 2011, Meek et al. 2013), and some detailed studies of exchange processes have been undertaken (Culberson et al.2004). Zooplankton abundance is highest in small sloughs of long residence time (P. Moyle, UC Davis, personal communication).

Foodwebs in diverse marshes of the San Francisco Estuary are supported more by local plant production than by estuarine phytoplankton (Howe and Simenstad 2007, 2011). This implies a division of organic-matter sources between those supporting littoral and marsh foodwebs and those supporting pelagic foodwebs (Grimaldo et al. 2009).

Lehman et al. (2010) estimated the fluxes of various substances in and out of Liberty Island, a flooded island in the Cache Slough complex in the northern Delta. They found large seasonal shifts in the magnitude and direction of fluxes. In particular, seasonal chlorophyll flux was into Liberty Island in spring and out in fall, based on point measurements, and into the island in all seasons but more so in spring and summer, based on the continuous measurements. Fluxes of copepods were out during spring and fall, and in during summer, based on a total of six sampling days. Although Lehman et al. (2010) linked fluxes into Liberty Island with storage within the island, it was equally likely to have been a function of consumption, particularly since high inward fluxes of chlorophyll and zooplankton occurred in summer when biological activity would have been high.

A few other marshes and restoration sites in the estuary have been investigated for their potential links to open waters. The South Bay Salt Ponds, which began to be reconnected to the tidal action of the Bay in 2006, are highly productive and may export organic matter to nearby estuarine waters (Thebault et al. 2008). A marsh at China Camp in San Pablo Bay was a net sink for mysids, probably through predation within the marsh (Dean et al. 2005).

Calculated subsidies

Here we assume that the restored areas will actually produce an excess of phytoplankton or zooplankton over adjacent waters, and ask what additional level of food availability to the smelt would result. This is based on a very simple model using data from IEP monitoring, described in detail in Appendix E (See Figure 7.2). The basis of this model is to calculate the subsidy based on high levels of biomass and growth rate in a 2500-acre marsh that is closely connected to smelt habitat and has an optimum rate of exchange with the open water. We assume smelt habitat is represented by the Low-Salinity Zone (LSZ), which has a volume of about 0.5 km^3.

A subsidy is maximized by a large marsh close to the smelt habitat, with tidal exchange close to but not above the net population growth rate of the plankton (Figure 7.3). The subsidy is degraded or even reversed by consumption (clams, planktivorous fish) within the marsh. Water depth may have a positive or negative effect on the subsidy.

The simple model in Appendix E shows that under an extremely favorable set of conditions both within and outside of the marsh, a modest subsidy of phytoplankton is possible.

Phytoplankton input to the LSZ could amount to 16%/day, or about half of the daily net production in the LSZ. However, smelt species do not eat phytoplankton, and the conversion of phytoplankton to zooplankton depends on factors in the open water such as grazing. The direct subsidy of zooplankton would be about 3%/day, also under unrealistically ideal conditions. Although this is not negligible, any reduction in this value would effectively eliminate the subsidy to open water.

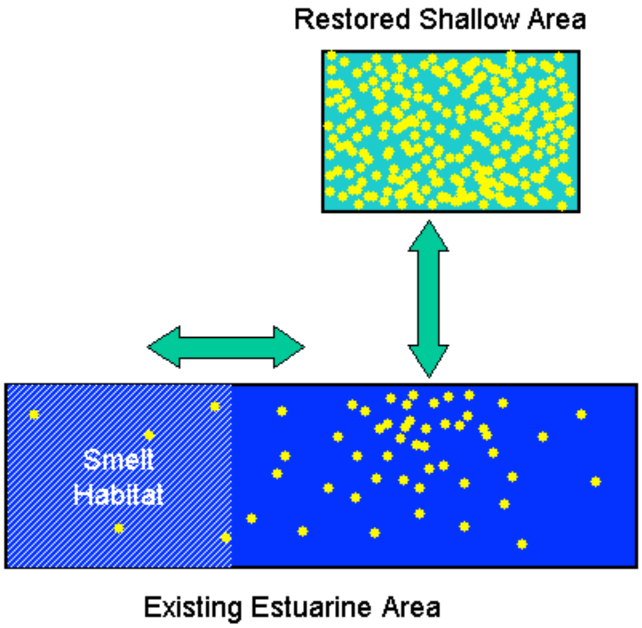

Figure 7.2. Schematic diagram of a subsidy of zooplankton (yellow circles) from a restored tidal marsh or other shallow area to an existing estuarine area. Zooplankton move by dispersion (double-sided arrows) between the restored and existing areas, and within the existing area from the outlet of the restored area to other regions of the estuary including smelt habitat. Advection may alter the flow of zooplankton, for example, if the restored area is on a creek that produces a net flow into the existing area.

Zooplankton export from Suisun Marsh

One of the proposed restoration areas is in the northern end of Suisun Marsh. We estimated the subsidy of copepods to the LSZ from this region using IEP monitoring data and using a particle-tracking model to estimate exchange rate (Appendix E). If the copepods behaved as passive particles, this subsidy would amount to about 2%/d of the population in the LSZ. This is unlikely to produce a noticeable increase in copepod biomass, as their potential population growth rates are on the order of 10%/d. However, particles that migrate to the bottom tidally or remain near the bottom, as most zooplankton do in the estuary (Kimmerer et al. 2002), were essentially trapped within the northern marsh. Behavioral responses to tidal currents, consumption within the marsh, the distance from the mouth of the marsh to the habitat of the smelts, and the operations of the salinity control gate on Montezuma Slough would all reduce or even eliminate this subsidy.

The real world

Several features of the actual restoration site would alter the subsidy to open waters from the analyses above. First, the enlarged restoration area will alter the tidal prism and therefore the exchange rate. The proposed restoration for Suisun Marsh would increase the inundated area 2-3-fold, with a corresponding increase in tidal currents. Since most of the exchange will be mediated by tides, this could substantially increase the exchange rate. Whether this would increase or decrease the subsidy would depend on the net population growth rate achieved in the marsh in relation to the exchange rate. Resolving the change in residence time would require a 3D model with very accurate bathymetry throughout the region. It is impossible to tell with available information whether the stronger tidal connections would result in a greater subsidy from Suisun Marsh, or whether this would be offset by zooplankton behavior or by consumption within the marsh. Such calculations could be done using a hydrodynamic and particle tracking model and some reasonable assumptions about zooplankton behavior.

The BDCP documents acknowledge (but then mostly ignore) that grazing by clams that settle in or near restored subtidal areas may remove all or most of the phytoplankton production and some of the zooplankton. Grazing by clams and zooplankton (including microzooplankton) removed all of the phytoplankton production in the LSZ nearly all the time from late spring through fall during 1988 – 2008 (Kimmerer and Thompson submitted.). Whether clams settle in the newly restored areas is critical in determining whether the area can export any phytoplankton (Lucas and Thompson 2012). At present clams are not abundant in Suisun Marsh except for the larger Suisun and Montezuma Sloughs, where they probably remove a substantial fraction of the phytoplankton and small zooplankton that would otherwise enter Grizzly Bay.

Zooplankton organisms are not passive, and undergo tidal migrations in Suisun Bay (Kimmerer et al. 1998, 2002). It is very likely that they will do so also in marsh channels, which would greatly lengthen the residence time for copepods produced in the marsh, particularly in the far northern area of Suisun Marsh. In addition, several studies have shown that zooplankton organisms may also be consumed by various planktivorous fish within a marsh, resulting in a net flux of zooplankton into the marsh (see literature review above).

Finally, some of the proposed restoration sites are far from the centers of distribution of delta and longfin smelt. Travel times from these sites to where the fish are may be on the order of weeks to months in the dry season or when the North Delta diversions are operating (Kimmerer and Nobriga 2008). A plankton population can double or halve its biomass in a few days depending on local food supply and predation. Thus, any export of zooplankton from a restored area should be assumed to subsidize only the local area.

All of these considerations are based on rather crude models of exchange and population processes. That is appropriate given the level of specificity of the BDCP design.

Nevertheless, this analysis raises significant questions about the putative subsidy from restored areas to estuarine foodwebs. To address this uncertainty, long before any actual restoration takes place a program of analysis, modeling, and experimental restoration should be undertaken.

Likely use of restored areas

Like other fish, smelt use a variety of habitats and appear to explore their environment to find suitable places for spawning, growth, and development. As pelagic fish, their principal habitat is open waters of the estuary, either in freshwater during the larval to early juvenile stages in spring to early summer, or in the low-salinity zone until winter. The low-salinity zone during summer-fall is generally in the western Delta and Suisun Bay, including the channels of Suisun Marsh. Delta smelt appear to be surface-oriented, which would allow them access to shallow areas (Aasen 1999).

The fundamental problem for both smelt species in the open-water, brackish regions of the estuary is the low food supply (discussed above) and possibly also the decreasing turbidity (Kimmerer 2004). Those trends may be difficult to reverse, spelling trouble ahead for the smelts. However, in recent years some proportion of the delta smelt population has remained in freshwater in the Cache Slough complex, despite high temperature there (Sommer and Mejia 2013). This may provide an alternative habitat in which the smelt population can either avoid poor conditions in the LSZ, or hedge its bets on future conditions. Longfin smelt are apparently not very abundant in Cache Slough.

Delta and longfin smelt have been collected in the Suisun Marsh fish survey (Matern et al. 2002). Delta smelt are not common in Suisun Marsh during summer-fall but were formerly common in winter to early spring (Matern et al. 2002) when the fish are migrating and spawning. About 0.7% of 3291 otter trawl samples from the Suisun Marsh survey during May-October of 1982 – 2009 and about 3% of 3320 samples during November – April contained delta smelt, mostly maturing juveniles and adults. The low catches in summer were not due to small size of the fish, since young-of-the-year longfin smelt of the same size range were captured frequently in that program. Temperature in the larger sloughs is ~1°C higher than in Grizzly Bay in July and August, based on IEP and UC Davis monitoring data, but if smelt avoid the warmer water in summer it does not explain the low catches for all of May-October. Longfin smelt are much more abundant in the Suisun Marsh channels than delta smelt, occurring in 8% of samples in May-October and 12% of samples in November-April with no obvious differences among the various sloughs.

The 20mm survey catches smelts during spring-summer in Montezuma Slough in Suisun Marsh and in central Suisun Bay including one station in Grizzly Bay near the major western entrance to the marsh. A graphical comparison of catch per trawl in these locations did not reveal a consistent difference for either species. A similar comparison of catch per trawl between Montezuma Slough and Grizzly Bay in the Fall Midwater Trawl survey also did not reveal a consistent difference, except that delta smelt were somewhat less abundant in the slough than in Grizzly Bay during September. Thus, it appears delta and longfin smelt are roughly as abundant in the larger sloughs of Suisun Marsh as in the open water of the estuary.

The key question for this aspect of restoration is whether additional physical habitat would result in larger populations of smelt. Abundance of delta smelt is related to an index of habitat availability based on salinity and turbidity (Feyrer et al. 2007, 2011, Nobriga et al. 2008). However, the size of the LSZ (volume or area) does not seem to be strongly related to the abundance of either smelt species (Kimmerer et al. 2009, in press). This may be because the LSZ is a contiguous stretch of water whose physical features are ephemeral, and the fish can move around readily within that region. In contrast, shallow tidal areas may offer enough physical structure to provide a wealth of sub-habitats with variable conditions. In that case, having more habitat area could lead to a greater abundance of fish. Note that a relationship between the quantity of habitat and the size of a fish population need not rely on a density-dependent relationship between habitat and the survival or reproduction of individual fish, which seems unlikely for delta smelt at current population levels.

Thus, we are cautiously optimistic that restoration of habitat may result in colonization and subsequent population expansion of delta smelt in the Cache Slough area including the Sacramento Ship Channel (Moyle 2008, Sommer and Mejia 2013). Longfin smelt seem unlikely to benefit from this. We cannot determine whether either species would benefit from similar restoration in the Suisun Marsh or the western Delta. The other restoration sites are too remote from the current population centers to offer much reason for optimism about their colonization by either smelt species.

Floodplain

The BDCP proposes to alter the Fremont Weir at the upstream end of the Yolo Bypass so that the Bypass would flood at lower stages of the Sacramento River. We consider here only the likely effects on the smelt species.

Review of conceptual basis

Although the smelt species do not use floodplain as habitat, elevated production of plankton on the floodplain may provide a subsidy to smelt habitat. This situation differs slightly from that of the potential subsidy from marshes discussed above. First, the floodplain is a flow-through system so that increased biomass of plankton will be transported by the mean, river-derived flow rather than by tidal flow. Second, residence time on a floodplain varies with flow conditions, from hours to a few days under high-flow conditions to effectively infinite in ponds remaining after the floodplain stops draining.

Analysis of components

Apart from its suitability as habitat for fish and other species, the Yolo Bypass may also support foodwebs within the estuary. The mechanism for this would be higher phytoplankton and zooplankton production because of shallow depth and better light penetration than in river channels, as well as higher temperature (Lehman et al. 2007). Whether this translates to zooplankton is uncertain; zooplankton abundance on the Bypass was similar to that in the Sacramento River during 1998-2001 (Sommer et al. 2004). Plankton biomass on a floodplain may increase late in the season as residence time increases and fish switch to larger prey (Grozholz and Gallo 2006), but that was not observed on the Yolo Bypass in most years (Sommer et al. 2004).

At very high flows residence time on the Bypass is probably too short to allow for a buildup of biomass, while at lower flows such a buildup may occur but the rate of export may be low (Schemel et al. 2004). This implies that, as with tidal exchange in marshes (Figure 7.3), there is an intermediate range of flow that maximizes export of plankton.

A subsidy from the Yolo Bypass may be more or less direct to delta smelt habitat, notably in the Cache Slough complex at the southern end of the Bypass. In addition, it may subsidize the low-salinity habitat used by both smelt species in late spring through fall.

In Appendix F we examine the evidence for a subsidy of zooplankton to the open water of the estuary under the current configuration using existing zooplankton data. We do not actually calculate the magnitude of the subsidy, since several factors would intervene to alter conditions. In particular, the Bypass could be flooded later in the year than is now the case, and the greater light penetration and higher temperature would provide for greater plankton production than now occurs. Furthermore, Bypass flow would represent a greater proportion of total inflow to the Delta later in the year, resulting in less dilution of the plankton coming off the Bypass.

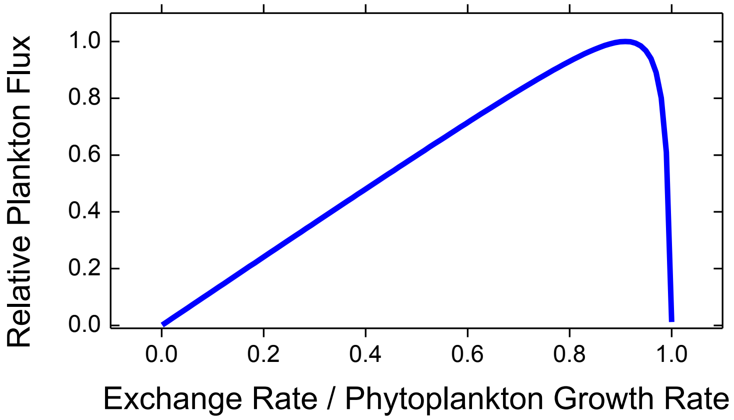

Figure 7.3. Relative magnitude of phytoplankton flux from a tidal marsh as a function of exchange rate, scaled to the growth rate of the phytoplankton. The model is based on a balance among import of nutrients to the marsh, uptake of nutrients to support growth of phytoplankton, and export of phytoplankton. All nutrient uptake is by phytoplankton, there is no consumption, and the phytoplankton concentration in the receiving water is zero.

Our analysis shows no evidence that the open waters of the estuary receive a detectable subsidy of phytoplankton or zooplankton. If anything, plankton abundance is inversely related to Yolo Bypass flow, either during the month of sampling between flow during the winter and zooplankton abundance in the following summer.

Conclusions

There are many reasons for restoring physical habitat in the Delta and Suisun Marsh, and a host of species that are likely to benefit. Among the listed fish species, young salmon use marsh and floodplain during residence, salutatory downstream movement, and active migration. However, it is unclear whether conditions in the Delta have a substantial role in the population dynamics of salmon, and therefore we have elected to focus on the smelt species, for which the Delta is a key part of home (Sommer and Mejia 2013).

The BDCP is overly optimistic about the potential benefits to delta and longfin smelt of physical habitat restoration. Longfin smelt do not appear to use marshes as habitat to any great extent. Delta smelt are also considered pelagic but their persistent abundance in the Cache Slough complex, and greater abundance in shallow rather than deep water, suggests some potential benefit to their population of expanded marsh in that area. The magnitude of this benefit is impossible to predict, as is the degree to which marsh and floodplain restoration might cause an increase, or reverse the decline, in the delta smelt population. Under these conditions it is premature to assert that the restoration activity will have such an effect, until studies including pilot projects and even some smaller full-scale restoration projects can show whether an effect is to be expected.

The idea that restored marsh and floodplain will export substantial amounts of zooplankton to the open waters of the estuary is not tenable. The ecology of shallow waters suggests that shallow areas are more likely to be sinks for zooplankton. Even if they were sources, simple mass-balance considerations indicate that the resulting export would produce at most a small enhancement of extant zooplankton of the open waters. This idea should be dropped from discussions of BDCP, although experimental work should press ahead to determine under what conditions marsh habitats could be sources of significant food for delta and longfin smelt in the open waters.

Chapter 8: Regulatory Oversight and Assurances

Introduction

The previous chapters have demonstrated the relatively high uncertainties associated with proposed conservation actions in BDCP. These uncertainties will likely result in the need to change Plan goals and objectives in the future, along with the prescribed conservation measures to address them.

This chapter addresses the question whether the draft Bay Delta Conservation Plan includes governance policies that are "transparent and resilient to political and special interest influence." We divide our analysis into two parts: (1) analysis of the regulatory oversight of plan implementation and adaptive management; and (2) evaluation of the regulatory assurances and proposed 50-year "no surprises" guarantee.

Regulatory Oversight

Introduction

The draft BDCP vests primary responsibility for implementing the Plan in a Program Manager, who shall "ensure that the BDCP is properly implemented throughout the duration of the Plan" (BDCP 7-2). The Program Manager's authority is broad and includes protection and restoration of habitat, reduction of ecological stressors, management of conserved habitat, coordinated operation of the CVP and SWP, and development of the new facilities authorized by the Plan (BDCP 7-3).[1]

The Program Manager's implementation of the BDCP is subject to oversight by the Authorized Entity Group, which will be comprised of the Director of the California Department of Water Resources as operator of the SWP, the Regional Director of the U.S. Bureau of Reclamation as operator of the CVP, and one representative each of the CVP and SWP contractors if the contractors are issued permits under the Plan (BDCP 7-8).[2] The BDCP also covers certain diversions of water that are not part of CVP or SWP operations and recognizes that these water supply operators may seek incidental take permits under the terms and conditions of the BDCP. If this occurs, these water projects would become Authorized Entities, but would not be members of the Authorized Entity Group (BDCP 7-8).

---

[1] The Program Manager also will have responsibility over the Implementation Office, which will assist the Program Manager in all aspects of implementation of the Plan, BDCP 7-4 to 7-5, and the Science Manager and Adaptive Management Team as described in Chapter 9 of this report.

[2] A question has arisen whether the fish and wildlife agencies legally may grant incidental take permits to the CVP and SWP contractors under the federal Endangered Species Act and the California Natural Community Conservation Planning Act. We address this question in the Appendix G.

The Authorized Entity Group's authority over the BDCP also is broad and multifaceted. The draft BDCP states:

> The Authorized Entity Group will provide oversight and direction to the Program Manager on matters concerning the implementation of the BDCP, provide input and guidance on general policy and program-related matters, monitor and assess the effectiveness of the Implementation Office in implementing the Plan, and foster and maintain collaborative and constructive relationships with the State and federal fish and wildlife agencies, other public agencies, stakeholders and other interested parties, and local government throughout the implementation of the BDCP (BDCP 7-8 to 7-9).

This oversight structure means that the Authorized Entity Group will exercise significant authority over both the coordinated operation of the CVP and SWP and implementation of the BDCP itself. Indeed, the draft Plan declares that the Program Manager "will report to the Authorized Entity Group, and act in accordance with the group's direction" (BDCP 7-2).

The draft Plan vests regulatory responsibility within the BDCP in a "Permit Oversight Group," which is composed of the Regional Director of the U.S. Fish and Wildlife Service, the Regional Administrator of the National Marine Fisheries Service, and the Director of the California Department of Fish and Wildlife (BDCP 7-11). It then states that the three agencies "are expected to issue regulatory authorizations to the Authorized Entities" pursuant to the federal Endangered Species Act and the California Natural Community Conservation Act (BDCP 7-11).

The draft Plan also provides that, "[c]onsistent with their authorities under these laws, the fish and wildlife agencies will retain responsibility for monitoring compliance with the BDCP, approving certain implementation actions, and enforcing the provisions of their respective regulatory authorizations" (BDCP 7-11). This means that, although the USFWS, NMFS, and CDFW will work together as members of the Permit Oversight Group for the purpose of supervising implementation of the BDCP, each agency will retain its independent regulatory powers over the CVP, SWP, and other water users under the federal and state Endangered Species Acts.[3]

This structure is consonant with both the Endangered Species Acts and the California Natural Community Conservation Planning Act, because it separates the regulatory oversight responsibilities of the federal and state fish and wildlife agencies from the operational responsibilities of the Program Manager and the Authorized Entity Group. This structural delineation is undermined, however, by the draft Plan's more detailed definition of the "function" of the Permit Oversight Group, which blurs the distinction between implementation and regulation. It also is undermined by provisions in the draft Plan that grant the Authorized Entity

---

[3] This independent regulatory authority is subject, however, to an important caveat—the draft Plan's requirement of consistency between future section 7 consultations and the BDCP—as described below. *See* pp. 7-8 to 7-9.

Group—rather than the regulatory agencies—veto authority over changes to the conservation measures, biological objectives, and adaptive management strategies, as well as over amendments to the BDCP itself.

Regulatory vs. Programmatic Responsibilities: Implementation

The draft Plan grants the Permit Oversight Group a significant role in implementing the conservation goals and adaptive management strategies of the BDCP:

> The Permit Oversight Group will be involved in certain decisions relating to the implementation of water operations and other conservation measures, actions proposed through the adaptive management program or in response to changed circumstances, approaches to monitoring and scientific research (BDCP 7-11).

It then provides that the Permit Oversight Group "will have the following roles, among others, in implementation matters":

- *Approve, jointly with the Authorized Entity Group,* changes to conservation measures or biological objectives proposed by the Adaptive Management Team.
- *Decide, jointly with the Authorized Entity Group,* all other adaptive management matters for which concurrence has not been reached by the Adaptive Management Team.
- Provide input into the selection of the Program Manager and the Science Manager.
- *Provide input and concur* with the consistency of specified sections of the Annual Work Plan and Budget with the BDCP and with certain agency decisions.
- *Provide input and concur* with the consistency of the Annual Delta Water Operations Plan with the BDCP.
- Provide input and accept Annual Reports.
- *Provide input and approve* plan amendments[4] (BDCP 7-11 to 7-12: emphasis added).

These definitions are poorly drafted, and they assign programmatic authority to the fish and wildlife agencies that may undermine their regulatory responsibilities. We therefore recommend that the draft BDCP be revised in two ways:

First, where the parties to the negotiations want to grant the Permit Oversight Group authority to determine whether certain actions or documents are consistent with the BDCP, the Plan should define its responsibilities more clearly and precisely than does the current language—*e.g.,* "provide input and concur"; "provide input

---

[4] The draft Plan also contains a placeholder "function," which states that the Permit Oversight Group also may play a role in "decision-making regarding real-time operations, consistent with the criteria of *CM1 Water Facilities and Operation* and other limitations set out in the BDCP and annual Delta water operations plans." As the details of this role as still under negotiation, we do not address it here except to note that the role of the Permit Oversight Group should be clearly defined and limited to regulatory oversight as explained in the text.

and accept"; and "provide input and approve." Thus, the draft Plan should be revised to state:

> The Permit Oversight Group shall have exclusive authority to determine whether the Annual Work Plan Budget and Annual Delta Operations Plan are consistent with the BDCP. If the Permit Oversight Group does not issue a determination of consistency, the document in question shall be revised and resubmitted to the Permit Oversight Group for approval or further remission and revision.

Second, the Permit Oversight Group's role should be limited to regulatory oversight. The "functions" listed in the draft Plan conflate the Permit Oversight Group's regulatory responsibilities with the programmatic implementation duties that are best left with the Program Manager and the Authorized Entities Group. Although there is some practical value in collaboration among the regulators and the regulated—*e.g.,* having the fish and wildlife agencies give their "input" during the drafting of annual operations plans—it is better policy to maintain the exclusive regulatory role of the Permit Oversight Group. A regulatory agency that has a stake in the creation of the program and policy decisions that it must ultimately review will not be able to bring its independent judgment to bear in evaluating those same decisions for consistency with the Plan and other applicable laws.

The conflation of regulatory and programmatic responsibilities is especially dangerous in the case of revisions to the biological objectives, conservation measures, and other adaptive management strategies. As currently written, the draft Plan grants the Authorized Entity Group an effective veto over proposed changes to the these programs, even if the Adaptive Management Team, the Science Manager, the Program Manager, and the Permit Oversight Group have concluded that changes are needed to ensure programmatic compliance with the BDCP or to fulfill the requirements of the federal and state Endangered Species Acts (BDCP 7-11).

A better course would be to revise the draft Plan to allow the Science Manager and Adaptive Management Team—subject to oversight and approval from the Program Manager and Authorized Entity Group—to make revisions to the biological objectives, conservation measures, and other adaptive management strategies. These changes then would be submitted to the Permit Oversight Group for review and approval or remission. The Permit Oversight Group also should have independent authority to revise the biological objectives, conservation measures, and other adaptive management strategies if it concludes that the existing programs are inadequate to comply with the BDCP or other governing law.

Regulatory vs. Programmatic Responsibilities: Policy Modifications and Amendments to the BDCP

A similar problem exists for modifications to the BDCP itself. The draft Plan recognizes that "Plan modifications may be needed periodically to clarify provisions or correct unanticipated inconsistencies in the documents" (BDCP 6-45). It then identifies three types of plan modifications: administrative changes, minor modifications, and formal amendments. Only the latter two concern us here.

The draft Plan defines "minor modifications" as including transfers of acreage between Restoration Opportunity Areas or conservation zones and "[a]djustments of conservation measures or biological objectives . . . consistent with the monitoring and adaptive management program and intended to enhance benefits to covered species" (BDCP 6-46). It then describes "formal amendments" as including, but not limited to:

- Changes to the geographic boundary of the BDCP.
- Additions of species to the covered species list.
- Increases in the allowable take limits of covered activities or the addition of new covered activities to the Plan.
- Substantial changes in implementation schedules that will have significant adverse effects on the covered species.
- Changes in water operations beyond those described under *CM1 Water Facilities and Operations*. (BDCP 6-47).

The "minor modifications" and "formal amendments" thus include all aspects of BDCP implementation that will be vital to the success or failure of the BDCP. Yet, the draft Plan expressly provides that the Authorized Entities may veto any such changes.[5] For minor modifications, the draft BDCP states: "If any Authorized Entity disagrees with the proposed minor modification or revision for any reason, the minor modification or revision will not be incorporated into the BDCP" (BDCP 6-46).[6] The draft Plan similarly declares that formal amendments "will be subject to review and approval by the Implementation Office and the Authorized Entities."[7]

The BDCP is fundamentally a set of terms and conditions that allow the principal regulatory agencies—the U.S. Fish and Wildlife Service, the National Marine Fisheries Service, and the California Department of Fish and Wildlife—to authorize the construction and operation of physical improvements to the Delta that will facilitate more reliable (and, one may hope, more environmentally sustainable)

---

[5] Please note that the draft BDCP states that the Authorized Entities—not the Authorized Entity Group—hold this veto power. This may be a typographical error, as the Authorized Entities are not granted implementation decisionmaking authority (except through the Authorized Entity Group) any other place in the document. If it the BDCP negotiators in fact intend to vest veto authority in the Authorized Entities, however, this is especially problematic as the Authorized Entities potentially include water users other than those that comprise the Authorized Entity Group. BDCP 7-8.

[6] By contrast, if any of the fish and wildlife regulatory agencies disagrees with a proposed minor modification, its rights are limited to insisting that the proposal be treated as a formal amendment to the Plan. BDCP 6-46.

[7] At least in the case of formal amendments the draft Plan recognizes a relative parity in the rights of the regulators and the regulated, acknowledging that such amendments "will require corresponding amendment to the authorizations/ permits, in accordance with applicable laws and regulations regarding permit amendments." BDCP 6-47. It also states, however, that the "fish and wildlife agencies will use reasonable efforts to process proposed amendments within 180 days." BDCP 6-46.

exports of water by the CVP and SWP. Although the motivating purpose of the BDCP is to facilitate this water development, the regulatory agencies' foundational responsibility is to ensure that the project does not jeopardize the continued existence of the species that are listed for protection under the federal and state Endangered Species Acts.

To accomplish this essential obligation, the fish and wildlife agencies must both insist on an initial set of biological objectives, conservation measures, and conditions on coordinated project operations that will fulfill this purpose; *and* they must have the means of ensuring that the implementation of the BDCP will continue to achieve that goal throughout its fifty year term.

We do not believe that the draft Plan satisfies this second requirement, as it vests veto authority over necessary changes in the biological objectives, conservation measures, adaptive management strategies, and the terms and conditions of the BDCP itself, not in the regulatory agencies, but in the regulated entities that comprise the Authorized Entity Group. We therefore recommend revision of the draft Plan to require that all "minor modifications" and "formal amendments" to the BDCP be subject to review and approval by the Permit Oversight Group.

As explained above, we also recommend that the draft Plan be revised to authorize the Permit Oversight Group itself to initiate and make changes to the biological objectives, conservation measures, and other adaptive management strategies that the fish and wildlife agencies conclude are needed to ensure the protection and recovery of the species listed under the federal and state Endangered Species Acts. This unilateral authority must extend to all of the identified "minor modifications" and to at least one of the defined "formal amendments"—*viz.* "substantial changes in implementation schedules that will have significant adverse effects on the covered species" (BDCP 6-47).[8]

The other listed "formal amendments"—which include alteration of the geographic boundaries of the Plan and the addition of new species and covered activities—are different, as they include possible changes to the scope and structure of the BDCP, rather than adaptive changes to the implementation and achievement of the goals of the existing BDCP. The draft Plan therefore properly states that formal amendments

---

[8] The governance structure set forth in the current draft Plan also may jeopardize the likelihood that the BDCP will be incorporated into the Delta Plan. *See* California Water Code § 85320-85322. The Delta Reform Act provides:

> The BDCP shall include a transparent, real-time operational decisionmaking process in which *fishery agencies ensure that applicable biological performance measures are achieved in a timely manner with respect to water system operations.* [*Id.* § 85321 (emphasis added).]

The Authorized Entity Group's veto authority over changes to the biological objectives, conservation measures, and adaptive management strategies means that the fish and wildlife agencies would not have the power to ensure that the biological measures will be achieved. The draft Plan therefore violates this statutory mandate, and the CDFW and the Delta Stewardship Council consequently would likely be precluded from incorporating the BDCP into the Delta Plan.

"will involve the same process that was required for the original approval of the BDCP"--i.e., approval of both the Authorized Entities and the Permit Oversight Group (BDCP 6-47).[9]

Regulatory Assurances and the "No Surprises" Policy

Introduction

The draft Plan proposes to create two types of "regulatory assurances." First, it seeks to eliminate the uncertainties associated with consultation under section 7 of the federal Endangered Species Act for coordinated CVP and SWP operations by stipulating that future biological opinions shall be consistent with the terms and conditions of the BDCP. Second, it offers "no surprises" guarantees both for deviations between the biological opinions and the BDCP and for future changes to the BDCP itself. In addition, the draft Plan places difficult scientific, legal, and political burdens on the state and federal governments' power to terminate the incidental take permits and to rescind the BDCP.

In our judgment, these regulatory assurances compound the risks described in the preceding section because they severely constrain the fish and wildlife agencies' ability to respond to inadequacies in the biological objectives, conservation measures, and other adaptive management strategies—even apart from the veto authority that the draft Plan vests in the Authorized Entity Group.

Section 7 Consultation and the BDCP

According to the draft Plan, once the facilities authorized by the BDCP are constructed, the Plan will largely displace the existing section 7 consultation requirements applicable to coordinated CVP and SWP operations: "On the basis of the BDCP and the companion biological assessment, it is expected that USFWS and NMFS will issue a new joint biological opinion (BiOp) that would supersede BiOps existing at that time as they relate to SWP and CVP actions addressed by the BDCP" (BDCP 4-2). The draft Plan then requires that the new biological opinion (as well as any subsequent biological opinions issued during the 50-year term of the BDCP) be consistent with the terms and conditions of the BDCP itself:

> The BDCP is intended to meet the requirements of the ESA and provide the basis for regulatory coverage for a range of activities identified in the Plan. . . .

---

[9] The draft Plan also provides that, "[i]n most cases, an amendment will require public review and comment, CEQA and NEPA compliance, and intra-Service Section 7 consultation," and it requires the fish and wildlife agencies to use "reasonable efforts to process proposed amendments within 180 days." BDCP 6-47. 180 days is probably insufficient time, however, to allow for section 7 consultation, internal agency analysis of the effects of proposed formal amendments on listed species and their habitat, and the drafting, public review, and completion of a new or supplemental EIS/EIR.

It is also worth noting that even this limited "bilateral" approval process for structural amendments to the BDCP may not be consistent with federal law. The ESA rules provide that all incidental take permits "are issued subject to the condition that the National Marine Fisheries Service reserves the right to amend the provisions of a permit for just cause at any time during its term." 50 C.F.R. § 222.306(c).

> Unless otherwise required by law or regulation, in any Section 7 consultation related to a covered activity or associated federal action and covered species, USFWS and NMFS will each ensure that the resulting BiOps are consistent with the integrated BiOp for the BDCP (BDCP 6-44).

We do not necessarily object to this consistency directive. An important goal of the BDCP is to provide all parties—especially the Authorized Entities—with a measure of regulatory and operational certainty that will enable them both to invest in the new facilities and to make water management decisions in their respective service areas in reliance on water deliveries from the CVP and SWP. To the extent that future section 7 consultations conform to the terms of the BDCP, that certainty is enhanced. We also note the first clause of the second sentence quoted above, which expressly reserves the authority of USFWS and NMFS to issue biological opinions that depart from the terms of the BDCP if necessary to comply with the governing law. This law, of course, includes section 7(a)(2) of the federal ESA, which requires all consulting agencies to ensure that their actions are "not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of [critical] habitat." 16 U.S.C. § 1536(a)(2).

We do believe, however, that the proposal to substitute the BDCP for section 7 consultation as the principal means of applying the federal Endangered Species Act to the CVP, SWP, and other Authorized Entities reinforces our recommendations from the preceding section—*viz.* that the Permit Oversight Group must maintain the independent regulatory prerogatives that the fish and wildlife agencies currently possess and must have authority to approve or to deny proposed changes in the biological objectives, conservation measures, and other terms and conditions of the BDCP as required to protect and recover the species covered by the Plan. Our support for the biological opinion/BDCP consistency directive should be read with this caveat.

"No Surprises"

The draft Plan contains two "no surprises" guarantees. The first applies to changes in coordinated CVP and SWP operations or water supply capabilities that may be required by future biological opinions that do not conform to the BDCP. The second is a more general "no surprises" commitment that protects the Authorized Entities from certain changes to the BDCP itself[10].

According to the draft Plan, "Ecological conditions in the Delta are likely to change as a result of future events and circumstances that may occur during the course of the implementation of the BDCP" (BDCP 6-30). The draft then lists seven "Changed Circumstances Related to the BDCP"—levee failures, flooding, new species listings, wildfire, toxic or hazardous spills, nonnative invasive species, and climate change (BDCP 6-31). For each of these "reasonably foreseeable" changes, the draft Plan describes the "planned responses" that BDCP administrators will undertake (BDCP

---

[10] As noted in chapter 2, USBR is not covered by the "no surprises" assurance. BDCP 6-29.

6-31 to 6-42).[11] The draft Plan states that the responses "have been designed to be practical and roughly proportional to the impacts of covered activities on covered species and natural communities, yet sufficient to effectively address such events" (BDCP 6-30). The BDCP budget will include funds to cover the costs of implementing some of the planned responses to "reasonably foreseeable" changed circumstances (BDCP 6-30).[12]

The draft Plan also recognizes that "unforeseen circumstances" may require changes to the biological objectives, conservation measures, adaptive management strategies, or the terms and conditions of the BDCP itself. It defines unforeseen circumstances as "changes in circumstances that affect a species or geographic area covered by an HCP that could not reasonably have been anticipated by the plan participants during the development of the conservation plan, and that result in a substantial and adverse change in the status of a covered species" (BDCP 6-42 citing 50 C.F.R. § 17.3 & 50 C.F.R. § 222.102). The draft Plan contains a similar definition of "unforeseen circumstances" under state law. These are "changes affecting one or more species, habitat, natural community, or the geographic area covered by a conservation plan that could not reasonably have been anticipated at the time of plan development, and that result in a substantial adverse change in the status of one or more covered species" (BDCP 6-43 citing California Fish & Game Code § 2805(k)).

The draft Plan then sets forth the following regulatory assurances under federal and state law:

> Under ESA regulations, if unforeseen circumstances arise during the life of the BDCP, USFWS and/or NMFS may not require the commitment of additional land or financial compensation, or additional restrictions on the use of land, water, or other natural resources other than those agreed to in the plan, unless the Authorized Entities consent (BDCP 6-42).

---

[11] The Implementation Office is charged with identifying the onset of a changed circumstance, working with the Permit Oversight Group to fashion a response, and for implementing and monitoring the responsive actions (BDCP 6-31).

[12] This funding process is described in Chapter 8 of the draft BDCP. *See* BDCP 8-60 to 8-64. The draft states generally that, to "allow for the ability to respond to changed circumstances should they occur, the Implementation Office should maintain a reserve fund for covering costs of changed circumstances" (BDCP 8-61). The draft Plan explains that this is because "the risk of some changed circumstances—*e.g.,* failure of levees attached to tidal marsh and floodplain restoration—and cost of remedial measures increases as greater portions of the conservation strategy are implemented." *Id.*

The draft BDCP only includes levee failure and wildfire damage to preserved lands as possible "changed circumstances for which responses are expected to result in additional implementation costs." *Id.* It omits "changed circumstances related to climate change, flooding, failure of water operations infrastructure, nonnative invasive species, new species listings, and toxic or hazardous spills," explaining that the response costs for these are accounted for in the initial BDCP funding, will be paid by the state and federal governments under the "no surprises" guarantees, or would be the responsibility of a third party. BDCP 8-61 to 8-62.

> In the event of unforeseen circumstances, CDFW will not require additional land, water, or financial compensation or additional restrictions on the use of land, water, or other natural resources without the consent of the plan participants for a period of time specified in the Implementation Agreement (BDCP 6-43).[13]

As noted above, for federal agencies that are subject to section 7 consultation (including consultation for coordinated CVP/SWP operations), the draft Plan contains an additional "no surprises" pledge if new biological opinions contain operational or water supply restrictions that differ from those set forth in the BDCP:

> Furthermore, USFWS and NMFS will not require additional land, water, or other natural resources, or financial compensation or additional restrictions on the use of land, water, or other natural resources regarding the implementation of covered activities beyond the measures provided for under the BDCP, the Implementing Agreement, the incidental take permits, and the integrated BiOp (BDCP 6-44).

The purpose of these regulatory assurances is to exempt the Authorized Entities from any of the costs of complying with the federal and state Endangered Species Acts except as defined in (and funded pursuant to) the terms of the BDCP. These "no surprises" guarantees therefore may place the financial burden of some future changes to the BDCP and project operations exclusively on state and federal taxpayers.

Although both federal Endangered Species Act regulations and the California Natural Community Conservation Planning Act authorize "no surprises" guarantees, we believe, given the uncertainties outlined in the previous chapters, that there is a significant risk that the costs of compensating the projects and their contractors for future "unforeseen" hydrologic, engineering, and operational changes will be excessive. More importantly, we are concerned that the state and federal governments' assumption of liability may deter the fish and wildlife agencies from making changes to future biological opinions or to the BDCP itself that the agencies believe are necessary to protect and recover listed species. The following example focusing on the "reasonably foreseeable" changed circumstance of climate change illustrates our concerns.

The draft Plan defines climate change as "[l]ong-term changes in sea level, watershed hydrology, precipitation, temperature (air or water), or ocean conditions that are of the magnitude or effect assumed for the effects analysis and that adversely affect conservation strategy implementation or covered species are considered a changed circumstance" (BDCP 6-41). It then provides that the

---

[13] The draft Plan notes that, under California law, "such assurances are not applicable in those circumstances in which CDFW determines that the plan is not being implemented in a manner consistent with the substantive terms of the Implementation Agreement." BDCP 6-43 (citing California Fish & Game Code § 2820(f)(2)).

"occurrence of this changed circumstance will be determined jointly by the Implementation Office and fish and wildlife agencies" (BDCP 6-41).[14]

According to the draft Plan, however, alterations in the ecosystem and threats to listed species caused by climate change will not trigger any management or regulatory responses beyond those set forth in the BDCP. "Because the BDCP already anticipates the effects of climate change, no additional actions will be required to remediate climate change effects on covered species and natural communities in the reserve system" (BDCP 6-41). Rather, the Adaptive Management Team will monitor these changes and the Implementation Office will "continually adjust conservation measures to the changing conditions in the Plan Area as part of the adaptive management program" (BDCP 6-42).

The draft Plan also states that all responses to climate change "will be made as part of the adaptive management and monitoring program. Measures beyond those contemplated by the adaptive management and monitoring program are not likely to be necessary because the conservation strategy was designed to anticipate a reasonable worst-case scenario of climate change. *A change in conservation measures in response to climate change beyond that considered in Chapter 3,* Conservation Strategy, *and through the adaptive management and monitoring program is considered an unforeseen circumstance.*" (BDCP 6-42: emphasis added).

There are two serious problems with this changed circumstances strategy:

First, although the "biological goals and objectives [of the BDCP] have been established at the landscape level to take climate change into account during conservation strategy implementation," and the "conservation strategy, monitoring and research program, and adaptive management and monitoring program already include responses to anticipate climate change effects at the landscape, natural community, and species scales" (BDCP 6-42), the draft Plan correctly anticipates that the biological objectives, conservation measures, and other adaptive management strategies are likely to be modified over time as required to respond to the changed conditions brought about by climate change. Yet, as described previously, all such modifications are subject to approval by the Authorized Entities (BDCP 6-46). The fish and wildlife agencies consequently lack independent authority to determine the appropriate policy and management responses to climate change, even within the confines of the defined responses set forth in Chapter 3 of the BDCP.

Second, changes in conservation measures that differ from the defined responses are "unforeseen circumstances," which trigger the "no surprises" guarantee. Again, while the draft Plan anticipates a broad array of ecological changes likely to be caused by climate change, and lays out a detailed set of programmatic responses, it is folly to believe that the BDCP scientists and negotiators have correctly identified

---

[14] We reiterate here the problems that we identified in the preceding section: conflation of the fish and wildlife agencies' regulatory and programmatic roles and the granting of an effective veto to the regulated entities through the Implementation Office.

all of the hydrologic changes, biotic responses, and risks to the ecosystem that will in fact occur over time. As one recent interdisciplinary study of California water policy emphasized:

> New approaches to ecosystem management under changing conditions will require continued, large-scale experimentation aided by computer modeling. This task is complex, because experiments, especially on a large scale, often yield ambiguous results. Also, as with hydrology, the past is not always a good predictor of the future with many ecosystems. Linking human and natural systems, combined with changes in climate and influxes of alien species, creates novel, dynamic ecosystems with no historical analog. Thus, efforts to restore ecosystem functions and attributes involve hitting a moving, only partially visible target. Finally, ecosystem changes are often nonlinear and interrelated. Declines in habitat quality or abundance reduce ecosystem resiliency, with the result that even small changes in conditions can lead to abrupt system collapse and reorganization to a new state. Such thresholds or tipping points are difficult to predict. *Taken together, these factors suggest that efforts to improve conditions for California's native aquatic species will necessarily involve trial and error, and that success is far from guaranteed.*
>
> * * *
>
> The difficulty is compounded by the high uncertainty of success for specific actions, given ecosystem complexity, gaps in knowledge of how to manipulate many key processes, and, most important, continuing change in climate, invasive species, and other conditions in California. *As a result, a flow regime or water quality target that seems adequate today may not provide the same services in 20 to 30 years. Aiming at a moving target in semi-darkness means that there will be many misses.* (From: Hanak et al., 2011: emphasis added).

The potential consequences of the "no surprises" guarantee in this context are troubling. Fisheries biologists generally agree that diminished seasonal outflow and warming water temperatures place several listed species at risk of extinction (see Cloern et al., 2011; Moyle et al., 2013). The projects that would be authorized by the BDCP should reduce some of the sources of stress on these species by reducing entrainment and predation and by creating substitute habitat, but they will not address several other important stressors such as diminished summer and fall outflow and rising water temperatures. Therefore, sometime during the 50-year term of the BDCP, it may be necessary to construct additional upriver storage (*e.g.,* by increasing the capacity of Shasta Reservoir) to enable more sustained cold-water releases to protect salmon spawning and out-migration.

Yet, under the draft Plan, this action would constitute an "unforeseen circumstance," because it falls outside the defined responses to climate change set forth in the BDCP. The consequence would be that the state and federal taxpayers would have to bear all of the costs of constructing and operating the new or expanded storage, even though the fish and wildlife agencies determined that this action is needed to protect one or more listed species from extinction (while maintaining reservoir releases and exports at the levels and timing authorized by the BDCP).

Alternatively, if funding were not available to construct the new storage capacity, and the fish and wildlife agencies made jeopardy findings and issued new biological opinions that altered reservoir release requirements in a manner that reduced water supply or export capacity, the state and federal governments would have to compensate the Authorized Entities for the value of the lost water or the cost of replacement supplies.[15]

For these reasons, we do not believe that the 50-year "no surprises" guarantees are wise or prudent policy. We understand that the Authorized Entities seek to protect their capital investment and obtain maximum security of their water service capabilities, and that a relatively fixed set of biological objectives, conservation measures, and operational constraints help to achieve these goals (BDCP 1-26). But a 50-year commitment is ill-advised in an ecosystem as complex, variable, and scientifically inscrutable as the Delta. As our colleague Peter Moyle has observed, in the Delta Ecosystem, "[o]ver-negotiation of details in advance is unlikely to enable adequate responsiveness and flexibility" and "even the most well-informed, scientifically based management will encounter surprises and make mistakes" (From Moyle et al., 2012).

The parties to the BDCP negotiations therefore should consider separate "no surprises" guarantees—one governing construction of the BDCP projects, and a series of operational "no surprises" commitments that would be reevaluated every

---

[15] During the July 23, 2013, meeting with DWR Director Mark Cowin and CDFW Director Chuck Bonham, Director Cowin stated that it was not the parties' intent to apply the "no surprises" policy to actions taken outside the plan area that may be required to address the effects of climate warming or other changed conditions on listed species. Although we were pleased to learn this, we retain the concerns described in the text for two reasons: First, the draft Plan does not state that new infrastructure or operational changes needed to ensure the survival of species covered by the BDCP are exempt from the "no surprises" guarantee if they are located outside the plan area. Rather, the draft links CVP and SWP facilities and water supply operations upstream of the plan area to the conservation measures that may be required to protect covered species and their downstream habitat (BDCP 1-20). Without an explicit limitation on the "no surprises" guarantee to new, "unforeseen" conservation measures undertaken within the plan area, we believe that there is an unacceptable risk that the Authorized Entities could raise a plausible claim that the "no surprises" policy exempts them from liability for new facilities and operational changes upstream of the plan area that are needed to protect covered species within the plan area.

Second, the draft Plan expressly extends the "no surprises" assurance for future section 7 consultations over new facilities and other changes in CVP operations that are outside the plan area and not part of the BDCP covered activities. The draft Plan stipulates that "USFWS and NMFS will further ensure that the terms of any BiOp issued in connection with projects that are independent of the covered activities and associated federal actions do not create or result in any additional obligation, cost, or expense to the Authorized Entities" (BDCP 6-44).

If the parties to the BDCP negotiations do not intend for the "no surprises" guarantee to cover new construction and project operational changes outside the plan area, then they should revise the draft Plan to say so explicitly and clearly. We also recommend that the sentence quoted above, which exempts the Authorized Entities from all costs associated with section 7 consultations to project facilities and operations other than BDCP covered activities be deleted.

ten years based on *current* information on the appropriateness of the biological objectives, the success or failure of the conservation measures, species survival and recovery, overall ecosystem health, climate change, invasive species, discharges, the effects of authorized project operations, other stressors, and regulatory compliance.

We have chosen ten years for the recommended length of renewable "no surprises" assurances because a ten-year period is likely to include a variety of different types of water years and thus will be sufficiently lengthy to enable BDCP managers and regulators to evaluate how well the biological objectives and conservation measures perform across a spectrum of hydrologic conditions. At the same time, ten years is short enough to minimize the risk that the terms and conditions of the BDCP become antiquated and ineffective in light of the inevitable and unpredictable changes to the ecosystem. Indeed, a series of renewable ten-year "no surprises" guarantees could create a constructive incentive for the parties to the BDCP to monitor progress and achievement of the biological objectives and conservation measures and to make adaptive management changes as required to sustain and recover the covered species and their habitat.[16]

Revocation of Incidental Take Permits and the BDCP

Many of our concerns about the rigidities of the draft Plan and the scope and length of the regulatory assurances would be lessened if there were an effective means of revoking the incidental take permits and thus rescinding the BDCP. But there is not.

As described in the draft Plan, the "Permit Revocation Rule," adopted in 2004, allows the federal fish and wildlife agencies "to nullify regulatory assurances granted under the No Surprises rule and revoke the Section 10 permit only in specified instances, including where continuation of a permitted activity would jeopardize the continued existence of a species covered by an HCP and the impact of the permitted activity on the species has not been remedied in a timely manner" (BDCP 6-48: quoting 69 Fed. Reg. 7172 (Dec. 10, 2004)). The draft Plan states,

---

[16] There is nothing in federal or state law that requires that the term of a "no surprises" guarantee be coextensive with the term of the HCP/NCCP. Indeed, the California Natural Communities Conservation Planning Act requires that the duration of all regulatory assurances be based on a careful assessment of the limits of scientific understanding of the covered species and their habitat. California Fish & Game Code § 2820(f) states that the CDFW's "determination of the level of assurances and the time limits specified in the implementation agreement for assurances may be based on localized conditions and shall consider":

> (A) The level of knowledge of the status of the covered species and natural communities.
>
> (B) The adequacy of analysis of the impact of take on covered species.
>
> (C) The use of the best available science to make assessments about the impacts of take, the reliability of mitigation strategies, and the appropriateness of monitoring techniques.
>
> (D) The appropriateness of the size and duration of the plan with respect to quality and amount of data.
>
> * * *
>
> (H) The size and duration of the plan.

however, that the "USFWS or NMFS will begin the revocation process only if it is determined that the continuation of a covered activity will appreciably reduce the likelihood of survival and recovery of one or more covered species and that no remedy [other than revocation] can be found and implemented" (BDCP 6-49).

Similarly, under the California Natural Communities Conservation Planning Act, the Department of Fish and Wildlife may revoke the state incidental take permit "if necessary to avoid jeopardizing the continued existence of a listed species" (BDCP 6-49: citing California Fish & Game Code § 2820(c)).[17] The federal and state fish and wildlife agencies also may revoke the permits if the Authorized Entities fail to fulfill their obligations under the BDCP, but only following the dispute resolution process set forth in the Implementing Agreement and "providing the Implementation Office and Authorized Entities with a reasonable opportunity to take appropriate responsive action" (BDCP 6-49).

Before the fish and wildlife agencies may revoke the incidental permits, they must follow a variety of procedures and substantive standards. These include determining, in concert with the Implementation Office, "whether changes can be made to the conservation strategy to remedy the situation" and whether "there are additional voluntary implementation actions that the Authorized Entities could undertake to remedy the situation."

More importantly, the draft Plan also requires the federal fish and wildlife agencies to determine whether they or some other agencies can take actions to ensure the survival of the listed species, rather than imposing such burdens on the parties to the Authorized Entities:

> The USFWS or NMFS will determine whether the fish and wildlife agencies or other state and federal agencies can undertake actions that will remedy the situation. The determination must be based on a thorough review of best available practices considering species population status and the effects of multiple federal and nonfederal actions. *It is recognized that the fish and wildlife agencies have available a wide array of authorities and resources that can be used to provide additional protection for the species, as do other state and federal agencies* (BDCP 6-48 & 6-50: emphasis added).

The draft Plan thus makes it difficult for the fish and wildlife agencies to revoke the incidental take permits if the biological objectives, conservation measures, and adaptive management changes do not achieve their primary goal of protecting and recovering the listed species. Procedural and substantive rigor is not in and of itself

---

[17] Section 2820(c) actually addresses a more limited violation of the terms of an NCCP, providing for suspension or revocation if a plan participant fails to "maintain the proportionality between take and conservation measures specified in the implementation agreement and does not either cure the default within 45 days or enter into an agreement with the department within 45 days to expeditiously cure the default." California Fish & Game Code § 2820(c). The more general revocation standard is set forth in section 2820(b)(3)(A)-(D) of the Act.

reason to doubt this last line of defense against extinction. But two additional facts lead us to the conclusion that permit revocation is not likely to be a credible means of ensuring the survival of the species if the BDCP fails its most essential task.

First, neither the federal fish and wildlife agencies nor the California Department of Fish and Wildlife have ever revoked an incidental take permit. Indeed, there is only one case in which a federal incidental take permit has been suspended, and that was for the permittee's violation of the terms and conditions of the habitat conservation plan, rather than because of changes in ecological conditions or the permittee's failure to agree to amendments to the biological objectives and conservation measures[18]. Revocation of the incidental take permits covered by the BCDP therefore would be an unprecedented event.

Second, a decision to revoke the incidental take permits would not be simply a scientific determination that the BDCP—as written today and implemented at some future date during its 50-year existence—is not adequate to ensure the conservation and recovery of the listed species. Although the BDCP assigns the authority to revoke the state incidental take permit to the Director of the California Department of Fish and Wildlife (BDCP 6-50), it stipulates that "[a]ny decision to revoke one or both federal permits must be in writing and must be signed by the Secretary of the Interior or the Secretary of Commerce, as the case may warrant" (BDCP 6-49).[19] In our judgment, this poses an undue risk that the revocation decision would be based on science *and* political considerations. Indeed, there would seem to be no other purpose for elevating the revocation authority from the fish and wildlife agencies to the two Cabinet-level Secretaries.

For these reasons, we do not believe that the state and federal authority to revoke the incidental take permits compensates for the deficiencies in the draft BDCP described above.

Conclusion

We conclude that governance structure set forth in the draft BDCP is neither "transparent [nor] resilient to political and special interest influence." The draft undermines the authority of the federal and state fish and wildlife agencies both by assigning them program responsibilities and by granting the Authorized Entities veto power over changes to the biological objectives, conservation measures, and adaptive management strategies that may be needed to ensure that the Plan achieves its stated goals. To address this deficiency, we recommend that the BDCP be revised to remove the Permit Oversight Group from program decisionmaking and to clarify the regulatory authority of the fish and wildlife agencies both within the BDCP and in their independent roles as principal regulators under the federal and

[19] This would change the process for permit revocation set forth in the federal ESA rules, which vest revocation authority in the Director of the U.S. Fish and Wildlife Service. 50 C.F.R. § 17.22(b)(7).

state Endangered Species Acts and the California Natural Community Conservation Planning Act.

We also believe that the regulatory assurances contained in the draft Plan jeopardize the ability of the fish and wildlife agencies to respond to changed conditions that may require future revisions to the biological objectives and conservation measures of the BDCP. The “no surprises” guarantees—by which the state and federal governments would assume the financial costs of new infrastructure and regulatory changes in CVP/SWP operations needed to address the effects changed circumstances not provided for in the BDCP—are especially troubling. To address this problem, we recommend that the proposed 50-year “no surprises” guarantees be converted into a series of renewable guarantees—the first to cover construction of the projects authorized by the BDCP and the successors to cover project operations for sequential ten-year periods.

Finally, although the fish and wildlife agencies retain the authority to revoke the incidental take permits—and thus to rescind the BDCP—if necessary to avoid jeopardizing any listed species, the draft Plan makes it difficult to do so by requiring the federal agencies to take action against other stressors on the species before determine that it is necessary to revoking the permits. The draft also removes the revocation decision from the federal agencies themselves and places it with the Cabinet-level Secretaries in whose Department the fish and wildlife agencies are located. We believe that these heightened substantive and procedural requirements reduce the likelihood that permit revocation would serve as an effective backstop in the event that the BDCP fails to achieve its overriding purposes of ensuring the survival and contributing to the recovery of the species. Indeed, these limitations on permit revocation strengthen our conclusions that the governance problems described throughout this chapter be repaired so that the fish and wildlife agencies retain the authority to insist on changes to the biological objectives and conservation measures of the BDCP as required to achieve species conservation and recovery.

CHAPTER 9: SCIENCE AND ADAPTIVE MANAGEMENT IN BDCP

Introduction

From the outset BDCP makes it clear that it will be science-based and adhere to the principles of adaptive management. The plan recognizes that all 22 conservation measures that are designed to meet the plan goals and objectives face high levels of uncertainty and that measures used to implement them will inevitably require adjustment and refinement. Indeed, given the unprecedented complexity of BDCP, it will most certainly fail without substantial investments in a program of science and monitoring linked to a robust adaptive management program that allows it to change course.

At the time of this review, the science and adaptive management component of BDCP was, by the project proponents' own admission, a work in progress with many of the key elements yet to be determined. We briefly review here the available information with the understanding that these elements are likely to change, possibly considerably, before the public draft is released.

Adaptive Management Program

The plan documents recognize that BDCP is compelled to adhere to an array of standards for adaptive management of the program (summarized in Chapter 3 of BDCP). This includes requirements of USFWS and NMFS five-point policy on adaptive management (65 Fed. Reg. 35241-35257), NCCPA requirements for monitoring and adaptive management programs (Fish & Game Code § 2820(a)(7) & (8), and the requirements of the Delta Reform Act for science-based adaptive management of all ecosystem and water management programs in the Delta (Water Code § 85308(f)).

The BDCP documents describe the well-known adaptive management cycle involving: *plan*, where management problems are recognized leading up to a plan of action to test management actions, *do*, where plans are implemented, accompanied by monitoring, and *evaluate*, where monitoring information is evaluated to measure effectiveness, and information learned initiates anew the planning portion of the cycle. As described in BDCP, the conceptual approach to adaptive management is closely aligned to the approach codified in the Delta Plan and the draft Delta Science Plan.

Governance and Implementation of Adaptive Management

BDCP envisions that its adaptive management program will be organized and run by its Implementation Office. The office will be run by a Program Manager who will be hired by the Authorized Entity Group (AEG). The AEG will be made up of DWR, Reclamation, and the state and federal water contractors. The Program Manager selects and supervises a Science Manager, who takes on the responsibilities of running the adaptive management programs and coordinating, in unspecified ways, all science and monitoring activities.

The Science Manager will chair and manage an Adaptive Management Team (AMT) made up of a broad array of regulators, regulated entities, and science programs. These include representatives appointed by members of the AEG, the Permit Oversight Group (POG: CDFW, USFWS, NMFS), the Interagency Ecological Program (IEP), Delta Science Program (DSP), and NOAA Southwest Fisheries Science Center. This group will receive input from a Technical Facilitation Subgroup, part of a Stakeholder Council made up of multiple of stakeholder groups, regulated entities, and regulating entities.

The AMT, led by the Science Manager, will have the responsibility for designing, administering and evaluating the BDCP adaptive management program, including the development of performance measures, monitoring and research plans, synthesis of data, solicitation of independent review, and developing proposals to modify biological goals and objectives as well as conservations measures.

The AMT is to operate by consensus only, meaning all members must agree to all actions. Where consensus cannot be reached the matter is elevated to the AEG and POG for resolution. As a matter of course, all changes in conservation measures and biological goals and objectives must be approved by the POG and AEG. The entity responsible for decisionmaking (for example, NMFS regarding changes in biological goals and objectives for salmon) will decide the issue. However, as discussed in Chapter 8, *any member of the AEG or POG may request review of the decision at the highest level of the relevant federal department or state, up to the appropriate department secretary or the Governor of California* (BDCP Chapter 7, Section 7.1.7).

An essential goal of the adaptive management program—seeking consensus for all decisions from all regulated and regulating entities as well as key providers of science—is understandable and, if it could be achieved, laudable. However, for several reasons this is unlikely to be successful.

First, as discussed in Chapter 8, this structure confuses the roles of regulators and regulated entities. It gives exceptional decision power to regulated entities, particularly those with a great financial stake in outcomes (state and federal water contractors). We are skeptical that difficult, perhaps costly decisions could be achieved in an efficient and effective manner since *any* member of the AEG or POG can, in effect, elevate any decision, no matter how trivial, to the highest levels of government. This is likely to have a chilling effect on decisionmaking, making all parties cautious and risk-averse. These traits—caution and fear of taking risks—are antithetical to the principles of adaptive management by which all management decisions are viewed as experimental and inherently risky. The most likely outcome from this approach to governance of adaptive management is that preliminary decisions made during the initial phases of the plan are, through sheer inertia, likely to remain permanent, rendering the concept of adaptive management moot.

Second, the AMT is made up of a mix of regulators, regulated entities, and scientific providers such as IEP and DSP. This places the science providers in the position of being decisionmakers, creating clear conflicts of interest. Most importantly, as discussed below, this eliminates one of the most important aspects of science in support of adaptive management: scientific independence.

Adaptive Capacity

The AMT, with approval from the POG, AEG or higher federal and state authorities, will oversee implementation of the adaptive management program, presumably through the Science Manager. A central issue likely to arise when finalizing BDCP is the adaptive flexibility available. All such programs have a natural tension between wanting to provide assurances—such as how much water will be exported from the Delta—and needing flexibility in amount and timing of exports to test and implement adaptive management programs. The current BDCP documents offer little to no guidance on adaptive capacity. This is likely to play a major role in how adjustments are made in conservation measures and, more importantly, how real-time operations (an element of adaptive management) are implemented. BDCP has sought to defer this decision, both within the document and to its Decision Tree process (discussed below).

Science Program

Science should underpin the discussions and information needed to make and implement adaptive management decisions. The extensive literature on adaptive management cites a strong, well-funded, and well-organized science and monitoring program as essential for adaptive management. The BDCP documents do not provide extensive information about science to support adaptive management, other than a solid commitment to build and support a strong science program and, in the EIR/EIS, a significant funding commitment. As currently described, the science program would be run by the Science Manager under the direction of the Program Manager and the AEG. The role of the science manager would be to fund an array of activities, guide synthesis and analysis, and coordinate with the numerous public and private institutions working on the Delta. Beyond this, there are few specifics.

BDCP's current efforts on science have come in for extensive criticism from several entities, including the National Research Council (2012), the Delta Independent Science Board (Memo to Delta Stewardship Council dated May 20, 2013) and the Public Policy Institute of California (Hanak et al., 2013, Gray et al., 2013). To be fair, the project proponents recognize that the BDCP science program is a work in progress and likely to change before the public draft of the plan is released. However, several significant issues will need to be resolved:

- *Integration*: the National Research Council in its review of Delta science was highly critical of the lack of integration of scientific efforts in the Delta. The NRC and others have pointed out that coordination is less effective than integration. BDCP is a once-in-a-generation opportunity to reorganize science in the Delta to make it more integrated and more effective for addressing the major issues of the day. As structured, BDCP builds a new stand-alone science program that seeks to coordinate with other programs, such as IEP and DSP, rather than to integrate them. This is unlikely to prove successful.

- *Independence*: as noted above, the AMT blurs the distinction among decision-makers, regulated entities, and the providers of science and technical advice. In addition, the BDCP science program is, in effect, run by the regulated entities and lacks independence. This creates the potential for bias in the selection of what science gets funded and what is ultimately made available to the public. Given that most major disputes in the Delta come down to differences of opinion in court about the best available science, demonstrating scientific integrity and transparency should be the highest priority.
- *Oversight*: as currently structured, there is no independent oversight of the BDCP science program. There is a commitment to promoting peer-review of scientific work products and plans. In addition, there is mention of coordinating with the existing DSP and the Delta Independent Science Board. But oversight, which is essential for creating public assurances that the best available science is being utilized in decision-making, is currently absent from the plan.
- *Funding*: science is expensive, and for a program this large and complex, it is likely to be *very* expensive. There are no discussions regarding budget in the BDCP plan documents. However, in the administrative draft EIR/EIS there are substantial commitments to funding a science program. There are categories of funding (monitoring, research, etc.), but little information as to how it would be distributed, organized and administered. Still, this level of commitment is significant and necessary.

To be effective, during revision of the plan documents, BDCP will have to address the considerable weaknesses in science governance, integration with other programs, independence and transparency, oversight and funding. Notably, there is a parallel process underway, led by the DSC, to develop a comprehensive plan for science in the Delta. This “One Delta, One Science” effort is essential for the success of BDCP. It seems to us that BDCP’s science effort should be fully integrated with the Delta Science Plan, if not led by the DSP. However, to date, BDCP has had limited involvement with this planning process.

Decision Tree

Earlier chapters of this review note that most controversial decisions, or decisions with high scientific uncertainty, are proposed to be resolved through adaptive management (i.e., *deferred*). One of the most important decisions will involve initial operations of the dual export facilities approximately ten years after issuance of the HCP/NCCP permit. The operations are to be based on the best available science on how to meet the co-equal goals of ecosystem benefit and water supply, with the goal of meeting the HCP/NCCP conservation standards.

A fundamental tension exists between two competing hypotheses regarding BDCP. The first, controlling hypothesis is that better management of existing export volumes with the dual facility, coupled with significant investments in floodplain, channel margin, and tidal marsh habitat to improve food webs, will improve conditions for covered species sufficiently to meet the HCP/NCCP standards. The second, embedded within the agency red flag comments and "progress reports", is that these steps are insufficient and that lower exports (higher outflow) will be needed to meet these standards. This issue is a paramount concern since it directly affects the economic viability of water supplied from the project.

As part of CM#1, BDCP will use a decision tree to address initial starting operations. As a starting point, BDCP embodies the two competing hypotheses in the LOS and HOS operating criteria, viewing them as brackets on the potential range of operations. The goal of the decision tree is to conduct a series of detailed studies and experiments to develop specific flow criteria, particularly for spring outflow (longfin smelt) and Fall X2 (delta smelt), in the decade before operation of the export facility begins.

The decision tree is the first, and probably most important, element of the BDCP adaptive management program. Much of the success of the adaptive management program will be tied to this element, since the original adaptive management and science infrastructure will presumably be built around addressing the competing hypotheses.

The decision tree approach to addressing starting operations is, in our view, laudable and appropriate. It makes no sense to wait until all uncertainties over this issue are resolved (a course of action proposed by diverse stakeholder groups). Experience says this issue will never be resolved to everyone's satisfaction and will require constant (and contentious) adaptive management. This is a necessary and appropriate step. Regrettably, there is little information given in the BDCP documents about how the decision tree would be implemented, including who would fund it, how it would be structured, how decisions would be made, what science experiments would be conducted, etc. The lack of detail about the decision tree in the BDCP documents raises several key concerns:

- It takes time to develop and implement a large, complex scientific undertaking of the kind envisioned by the decision tree approach. The POD crisis in the mid-2000's and the mobilization of the scientific community to address it is an example of a successful approach. But that still took considerable time and many issues addressed by the POD effort remain unresolved.

- To inform the potential placement and design of habitat restoration efforts to support food webs, new approaches to numerical modeling will be needed that better represent how these habitats function. Finding and funding the technical teams for this kind of work will take time and resources. A particular concern is whether contracting will be run through existing state and federal agencies who are notoriously slow at developing contracts.

- In addition, field experiments will be needed to inform and calibrate these models. This involves identifying locations to conduct experiments, modeling and designing actions, acquiring land or easements, implementing pre-project monitoring programs, implementing actions, monitoring responses, and incorporating results into system models. All of these actions take time and resources, but as is well-known by anyone working on ecosystem restoration in the Delta, the rate-limiting step is inevitably the length of time it takes to secure permits (see recent review in Hanak et al., 2013).
- Because any decision made regarding flow and habitat will have multiple, competing constituencies and regulatory interests, an extensive and often contentious public engagement effort will be needed. The history of the Delta suggests that all such significant decisions are litigated, further slowing this process.

These four concerns, as well as others, make us skeptical that the decision tree is likely to achieve the goal of resolving operations issues within a 10 to 15 year time period. We cannot say with certainty that it will not be successful. A committed, well-funded, well-managed effort on the part of all parties may yield useful conclusions. However, given that this is the less likely outcome, it seems imperative that BDCP negotiate export operations criteria that, in the absence of a successful decision tree process, will be implemented at the start of the project.

Our work in previous chapters has cast doubt on the viability of the controlling hypothesis that underpins BDCP. To this end, we think it prudent to, at minimum, adopt the HOS operating criteria as the starting condition if the decision try fails to identify operating procedures. In addition, if BDCP is truly committed to adaptive management and the use of best available science, it is not appropriate to set artificial boundaries—HOS and LOS—on the decision tree process. It is our view that the decision tree research effort should seek to define best operating procedures rather than being forced to operate within the HOS and LOS range. There is a reasonable chance that the decision tree process may ultimately determine that the HOS flow criteria are not protective enough.

Conclusion

The draft documentation provided by BDCP makes a strong commitment to the principles of adaptive management supported by a robust science program. Given the complexity of BDCP and the great scientific uncertainties underpinning many of the central elements of BDCP, this is absolutely necessary for success. As currently described, the BDCP adaptive management program either lacks sufficient information to be assessed or is unlikely to achieve its overall goals and objectives. This stems from two basic problems:

- The adaptive management program has a confused and conflicting governance structure that, in our view, is likely to inhibit adaptation rather than promote it.
- There is insufficient information, beyond funding levels, to judge how the science program might function and how the knowledge it generates would be converted to action. The current information in the documents indicates that the program lacks integration with existing programs, scientific independence and transparency, and sufficient independent oversight.

We recommend that BDCP seek substantive engagement (beyond "coordination") with the ongoing efforts by the DSC and the Delta Stewardship Council to develop a Delta Science Plan. The goal should be to integrate BDCP science and adaptive management into the broader science infrastructure of the Delta and not to construct a new, stand-alone science organization. Additionally, BDCP needs to revisit how adaptive management decisions are made, reallocating planning and decisionmaking authorities.

The decision tree process that seeks to resolve issues over initial operating criteria and habitat restoration investments is both appropriate and necessary. Unfortunately only limited information is available about this program so we cannot evaluate it. We are confident, however, that it is unlikely to resolve the major issues over the trade-offs between flow and ecosystem investments. For this reason, in the absence of resolution of decision tree process starting operations should be similar to HOS criteria.

Chapter 10: Summary and Recommendations

Introduction

We present a narrow review of aspects of BDCP that relate to conservation of federally listed fishes. We identify both strengths and weaknesses of BDCP's conservation measures in its effort to balance water supply reliability with ecosystem goals and objectives. Due to time and resource limits this review is incomplete. We did not examine all issues associated with aquatic ecosystems. For example, we did not evaluate habitat restoration on the San Joaquin River. Nor did we evaluate conservation issues for all covered fishes, giving limited attention to Sacramento splittail, San Joaquin steelhead, sturgeon and lamprey. Instead, we focused on the conservation measures that affect winter-run and spring-run Chinook salmon, delta smelt, and longfin smelt, because these measures are the most controversial and have greatest impacts on water supply operations. We also focused on a limited subset of the alternatives listed in BDCP documentation: the Early Long Term conditions under a No-Action Alternative (NAA), Low Outflow Scenario (LOS) and High Outlflow Scenario (HOS)[1].

We summarize our findings on the six guiding questions identified in Chapter 1, plus several recommendations sought by the NGOs after we began our work. These are intended to help inform The Nature Conservancy and American Rivers in their engagement efforts with BDCP. Where appropriate, we describe alternative approaches that might be taken for BDCP to more effectively meet its goals. On many issues we have no recommendations.

Question 1: Operations

Do operations of the dual facilities meet the broader goal of taking advantage of wet and above average years for exports while reducing pressure on below average, dry and critically dry years? What substantive changes in operations (and responses, see below) are there both seasonally and interannually?

We analyzed the CALSIM data on export operations under NAA , HOS and LOS for ELT conditions. We note that the modeling of flows under BDCP has three compounding uncertainties: uncertainty over system understanding and future conditions, model uncertainties associated with CALSIM, DSM2 and UnTrim, and behavioral/regulatory uncertainty, where the model cannot fully capture operational flexibility. For this reason, model outputs should be viewed as

---

[1] NAA ELT is the no-project alternative using the 2008, 2009 BiOps with high spring outflow, 2025 climate and sea level conditions. LOS is with-project alternative with low fall and spring outflow, 2025 climate and sea level conditions. HOS is with-project alternative with high spring and fall outflow standards, 2025 climate and sea level conditions.

approximations useful for comparing different scenarios rather than as a predictor of future conditions. This issue influences all of our conclusions.

Based on our review we conclude:

- The array of existing and projected flow regulations significantly constrains operations in BDCP. The assumed operational flexibility associated with new North Delta facility is limited.
- HOS and LOS operations promote greater export during wet periods through increased use of North Delta diversions during the winter and spring. During dry and critical years, there is not much difference in *average* exports compared to NAA. For this reason, BDCP generally fails to meet the broader objective of reducing pressure on the Delta during dry periods.
- In some dry periods regulatory controls on OMR flows and North Delta diversions lead to significant increases in outflow and OMR flows over NAA. These unexpected results are the consequence of stricter flow requirements for HOS and LOS and operations being tied to previous water-year type in the fall and early winter. We are unsure if the project would actually be operated this way under these conditions.
- We evaluated how NAA, HOS and LOS performed during extended droughts. Of the three scenarios, HOS appears to be most protective of both supply and ecosystems by reducing the frequency and duration of dead pool conditions on Sacramento Valley reservoirs and assuring higher spring and fall outflows.

Recommendations: caution must be used in interpreting CALSIM model results for both export and environmental performance of BDCP due to compounding uncertainties. However, modeling results suggest that overall flow conditions are improved over NAA.

Question 2: Impacts of North Delta Facility

Based on operations criteria, does the Plan properly identify ecological impacts likely to occur adjacent to and in the bypass reach downstream of the new North Delta diversion facilities? If there will be direct and indirect harm to listed species by the facilities, does the Plan prescribe sufficient mitigation measures?

We reviewed the Conservation Measures and Effects Analysis of BDCP, including supporting appendices to evaluate conditions upstream of the North Delta facility, as well as near- and far-field effects of the facility itself. Our focus was on winter- and spring-run Chinook salmon, rather than all covered species. Based on this review we conclude:

- The BDCP consultants have appropriately identified the range of impacts on listed salmon likely to be associated with the operations of the North Delta facility. These include near-field effects such as impingement on intake screens and high predation losses at the facility, to far-field effects such as reduced survivorship of juvenile salmon due to higher transit times and redirection into the interior Delta. Using multiple modeling approaches, they have created reasonable estimates of losses due to operation of the facility.

- Mitigation for take associated with the new facility includes restricting diversion flows during initial pulse flows in the river, predator control, non-physical barriers, real-time operations to protect outmigrants, and modification of the Fremont Weir to divert fish onto the Yolo Bypass. With the possible exception of benefits from Fremont Weir modifications the uncertainties over mitigation actions are all high.
- We see high potential value in the Yolo Bypass for mitigating the effects of North Delta diversions on juvenile salmon, particularly in drier conditions. Therefore, existing adaptive management programs on the Bypass must be supported, with accelerated pilot studies, monitoring and ecological modeling, to ensure success of any modifications of the Bypass.
- Mitigation is hampered by the lack of a viable adaptive management plan or real-time management plan in the current BDCP for the North Delta facility. Still, even with these uncertainties, if managed well, fully implemented and functioning as described in the plan, the actions appear to mitigate for losses associated with the North Delta facilities.
- These mitigation efforts alone are unlikely to lead to significant increases in salmon populations, and extinction risk remains high for winter- and spring-run Chinook salmon, particularly during extended drought and warm periods when reservoirs are low. However, reservoir management is not within the scope of BDCP.

Recommendations: given the uncertainties over mitigation for the North Delta facility, we recommend that all mitigation actions be evaluated and completed prior to initiating operations the North Delta facility. Of highest priority is to bolster and complete adaptive management activities in progress on the Yolo Bypass. Additionally, we recommend establishing an adaptive management and real-time management program with the capacity to conduct significant experiments in flow management, predator control, and non-physical barrier implementation *prior* to initiating facility operation. These should be conditions of the HCP/NCCP take permit.

Question 3: In-Delta Conditions

Are changes in operations and points of diversion prescribed in the Plan sufficient to significantly improve in-Delta conditions for covered species? The focus is on listed species, including delta and longfin smelt, steelhead, winter and spring run Chinook, and green sturgeon.

We focused our analysis on in-Delta conditions that may affect delta smelt and longfin smelt. We reviewed the effects analysis and supporting documentation and conducted our own modeling based on CALSIM output. Based on this work we conclude:

- The CALSIM output we used showed conditions that appeared anomalous based on our understanding of how the system would actually be operated. Although we have been assured that these conditions were logical consequences of model design and operation to meet flow requirements, we remain unconvinced that they reflect actual future operations under the hydrologic conditions simulated. We therefore caution that **the conclusions below are contingent upon the actual operations of the system resembling those in the model output.** They are also contingent on the biological models accurately reflecting responses of the species to flow conditions.

- Roughly half of the export from the Delta will go through the North Delta facility. In addition, OMR flow regulations are more restrictive (protective) under HOS and LOS scenarios than NAA. Thus the incidence of positive OMR flows rose from 11% under NAA to 16% under HOS and LOS conditions. HOS and LOS are consistently more protective of smelt than NAA under these modeling assumptions.

- OMR flow regulation under HOS and LOS for October through January is governed by previous water year type. This leads to anomalously high (positive) OMR flows and corresponding outflow during some dry periods, creating apparent benefits for delta smelt. We are uncertain if this would manifest in real operations.

- Entrainment results in fractional population losses of delta smelt that can be calculated from modeled flow conditions. Based on these calculations, we estimate that HOS and LOS reduced fractional population losses by half compared to NAA. If actual operations were similar to the model results, they would lead to significant decreases in entrainment.

- Estimates of relative differences in long-term survival percentages (not predictions) showed a 19-fold increase for HOS and 11-fold increase for LOS over NAA, albeit with large uncertainty. A difference of this magnitude over the last 20 years would have reversed the decline of delta smelt in the 2000s.

- Increases in spring outflow are projected by the models to produce only a very small increase in longfin smelt abundance index under HOS compared to NAA, and a comparable decrease under LOS.

- Increases in fall outflow under HOS are projected to produce a small increase in recruitment by the following summer, and under LOS a modest decrease, but because of high variability in the data used to make these predictions, these values are very uncertain.

Recommendations: we remain uncertain about significant reduction in fractional population losses of delta smelt under the new HOS and LOS operating criteria. We recommend investment in resolving these uncertainties before operations are finalized. If these relationships are supported, then operational rules need to be refined to protect the benefits of these improvements over a broad range of conditions.

Question 4: Benefits of Habitat Restoration

Are covered pelagic fish like longfin smelt and delta smelt likely to benefit from restoration of floodplain and tidal marsh habitat at the scale proposed by the Plan? Given the current state of knowledge, and assuming that all Plan commitments are met, are these efforts likely to result in relaxed X2 and spring outflow standards?

A fundamental hypothesis embedded in the BDCP goals and objectives is that improvements in physical habitat, particularly floodplain and tidal marsh, will improve conditions for covered fishes. We focused our assessment on the relationship between habitat restoration and longfin and delta smelt. Based on this analysis we conclude:

- BDCP correctly identifies food limitation as a significant stressor on delta and longfin smelt, particularly in spring through fall. Increasing food availability in smelt rearing areas would likely lead to increases in population.
- Tidal marshes can be sources or sinks for phytoplankton and zooplankton. Most appear to be sinks, particularly for zooplankton. There is high on-site consumption of productivity within marshes.
- Even under the most highly favorable assumptions, restored marshes would have at best a minor contribution to plankton production in smelt rearing areas.
- Smelt can benefit by having direct access to enhanced productivity. This is likely the case for the subpopulation of smelt that reside in Cache Slough.
- BDCP is too optimistic about benefits of tidal marsh and floodplain restoration for smelt, particularly the extent of food production. These optimistic views are indirectly guiding the LOS outflow criteria. There is no clear connection, however, between the two and investments in marsh restoration are unlikely to lead to reduced demand for outflows.

Recommendations: it is possible but unlikely that marsh restoration will materially improve conditions for smelt, although other ecosystem and species benefits of marsh restoration are much more likely. Only moderate- to large-scale experimental restoration projects are likely to resolve this uncertainty and to help in designing future efforts. BDCP should design and describe a specific program to resolve this issue. Until this uncertainty is resolved flow management will remain the principal tool to mitigate project impacts.

Question 5: Governance

Does the Plan provide achievable, clear and measurable goals and objectives, as well as governance that is transparent and resilient to political and special interest influence?

We analyzed the proposed governance structure of BDCP, including the responsibilities and authorities of new entities such as the Authorized Entity Group (AEG), the Permit Oversight Group (POG), the Adaptive Management Team (AMT), Implementation Office, Program Manager and Program Scientist. Based on this review we conclude the following:

- The governance plan, as structured, blurs the responsibilities between implementation and regulation. It grants AEG final decisionmaking power over actions that should be solely within the authority of the permitting agencies. It also involves the permitting agencies too heavily in implementation of the project.
- As written, the plan grants the AEG veto authority over proposed changes in the program, including any changes in biological goals and objectives or conservation measures.
- The AEG has the power to veto any minor modification, revision or amendment to the Plan that may be necessary to manage listed species.
- The regulatory assurances set forth in the draft Plan severely constrain the fish agencies' ability to respond to inadequacies in biological objectives.
- Given the high uncertainties inherent in BDCP, it is very likely that unforeseen circumstances will require significant changes in biological goals and objectives and conservation actions. Under the 50-year "no surprises" guarantee, the fish agencies assume financial responsibility for many significant changes. This liability could deter needed regulatory changes to BDCP and CVP/SWP operations.
- The procedural hurdles necessary to revoke the incidental take permit of BDCP are so great that revocation is unlikely to occur over the 50-year life of the permit. Indeed, permit revocation and termination of the BDCP would be unprecedented under both state and federal law.

Recommendations: The POG should be granted exclusive regulatory authority to determine whether budgets and workplans are consistent with the permit and to approve revisions to the biological goals and objectives or amendments to the plan. It should have the authority to initiate changes needed to insure protection of the covered species. The POG's functions should be limited to regulatory oversight rather than direct involvement in implementation. There should be a "no surprises" guarantee for construction of the project. Upon completion of the project, there should be renewable "no surprises" guarantees every ten years. These renewals should be based on conditions at the time of renewal and appropriateness of biological goals and objectives. This approach creates an incentive for all parties to adapt to changes in conditions to sustain covered species, rather than simply fulfilling obligations on conservation measures.

Question 6: Science and Adaptive Management

Is there a robust science and adaptive management plan for BDCP? As described, is the proposed "decision tree" likely to resolve major issues regarding Fall X2 and Spring Outflow prior to initial operations?

We reviewed the science and adaptive management plans in both the plan and EIS/EIR documents. Most issues with high uncertainty or controversy in the Plan are relegated to resolution through an adaptive management process. Based on the documentation, we conclude:

- Given the major uncertainties facing BDCP a robust, well-organized and nimble adaptive management plan will be necessary. The current plan adheres to and strongly promotes the principles of adaptive management and science.
- The requirement of unanimous consent for all decisions by the AMT, and veto power of any member of the AEG and POG is a barrier to adaptive management.
- There is a blurring of the responsibilities between regulators and those responsible for implementation of adaptive management that has the potential to create conflicts. There is a conflicting relationship between AMT decisionmaking and the scientific organizations providing support for decisonmaking.
- The plan recognizes the importance of adaptive capacity, meaning flexibility in operations and actions that allow for learning. Yet it does not describe this capacity in a meaningful way.
- There is almost no description of a science program. What is provided lacks evidence for integration with existing programs, transparency, independence from bias and influence, and structured oversight. These are all necessary for success.
- The decision tree process to establish initial operating conditions is appropriate. Done well, it can resolve many issues. However, it is unlikely to resolve the central issue over starting conditions in time to implement them.

- Although difficult decisions are relegated to a future adaptive management program, actually implementing such a program on such a scale will be very difficult and will require careful design. BDCP does not provide information sufficient to determine whether it will be effective. We remain skeptical that it will.

Recommendations: many of the recommendations for changes in governance made previously will go a long way toward improving the adaptive management program, including the separation of regulators from implementation efforts. However, the plan still needs a complete description of how its adaptive management program would function. The AMT, in whatever form it takes, should be advised by a science program, without scientists responsible for decisionmaking. The science program should be integrated with existing Delta science programs, rather than inventing a new parallel program. The best opportunity for integration is the current efforts to establish a Delta Science Plan through the Delta Science Program and Delta Stewardship Council. Given that the decision tree is unlikely to fully reduce uncertainties in time, coupled with our concerns over how the project would be operated rather than modeled, we recommend that default starting operating conditions be negotiated that approximates the HOS scenario, with a goal of identifying and operationalizing attributes of this scenario that are most beneficial to listed fishes.

Table 3.4.1-1. Water Operations Flow Criteria

<table>
<tr><th>Parameter</th><th>Criteria</th></tr>
<tr><td>Old and Middle River/San Joaquin inflow-export ratio</td><td>
October, November: Flows will not be more negative than an average of −2000 cfs during D-1641 San Joaquin River pulse periods, or −5,000 cfs during nonpulse periods.
November, December: Flows will not be more negative than an average of −5,000 cfs and no more negative than an average of −2,000 cfs when the delta smelt action 1 triggers.
January, February: Flows will not be more negative than an average of 0 cfs during wet years, −3,500 cfs during above-normal years, or −4,000 cfs during below-normal to critical years, except −5,000 in January of critical years.
March: Flows will not be more negative than an average of 0 cfs during wet or above-normal years or −3,500 cfs during below-normal to critical years.
April, May: Allowable flows depend on gaged flow measured at Vernalis. If Vernalis flow is below 5,000 cfs, OMR flows will not be more negative than −2,000 cfs. If Vernalis is 5,000 to 6,000 cfs, OMR flows will not be more negative than −1,000 cfs. If Vernalis exceeds 6,000 cfs, OMR flows will be at least 1,000 cfs. If Vernalis exceeds 10,000 cfs, OMR flows will be at least 2,000 cfs. If Vernalis exceeds 15,000 cfs, OMR flows will be at least 3,000 cfs. If Vernalis exceeds 30,000 cfs, OMR flows will be at least 6,000 cfs.
June: Similar to April, but if Vernalis is less than 3,500 cfs, OMR flows will not be more negative than −3,500 cfs. If Vernalis exceeds 3,500 cfs, OMR flows will be at least 0 cfs. If Vernalis exceeds 10,000 cfs, OMR flows will be at least 1,000 cfs. If Vernalis exceeds 15,000 cfs, OMR flows will be at least 2,000 cfs.
July, August, September: No constraints.
</td></tr>
<tr><td>Head of Old River gate operations</td><td>
December, June 16 to September 30: Operable gate will be open.
All other months: Operable gate will be partially or completely closed as needed to support OMR flow criterion and, via real-time operations, to minimize entrainment risk for outmigrant juvenile salmonids and/or manage San Joaquin River water quality.
</td></tr>
<tr><td>Spring outflow</td><td>
March, April, May: As described in Section 3.4.1.4.4, <i>Decision Trees</i>, initial operations will be determined through the use of a decision tree. If at the initiation of dual conveyance, the best available science resulting from structured hypothesis testing developed through a collaborative science program indicates that spring outflow is needed to achieve the longfin smelt abundance objective the following water operations would be implemented within the decision tree. The evaluated starting operations would be to provide a March–May average outflow scaled to the 90% forecast for the water year, with scaling as summarized in the table below.

<p>March–May Average Outflow Criteria for “High Outflow” Outcome of Spring Outflow Decision Tree</p>

</table>

Table 3.4.1-1. Continued

Parameter	Criteria
	70% 13,274 80% 11,382 90% 9,178 • Alternatively, if best available science resulting from structured hypothesis testing developed through a collaborative science program shows that Delta foodweb has improved, and evidence from the collaborative science program shows that longfin smelt abundance is not strictly tied to spring outflow, the alternative operation under the decision tree for spring outflow would be to follow flow constraints established under the Bay-Delta Water Quality Control Plan. • February, June: Flow constraints established under the Bay-Delta Water Quality Control Plan will be followed. • All other months: No constraints.
Fall outflow	• September, October, November: As described in Section 3.4.1.4.4, *Decision Trees*, initial operations will be determined through the use of a decision tree. Within that tree, the evaluated starting operations would be to implement the USFWS (2008) BiOp requirements, and the alternative operation would be to revert to the Bay-Delta Water Quality Control Plan requirements. The alternative operation would be allowed, if the research and monitoring conducted through the collaborative science program show that the position of the low-salinity zone does not need to be located in Suisun Bay and the lower Delta, as required in the BiOp, to achieve the BDCP objectives for Delta smelt habitat and abundance. • All other months: No constraints.
Winter and summer outflow	• Flow constraints established under the Bay-Delta Water Quality Control Plan will be followed.
North Delta bypass flows	• October, November: Flows will exceed 7,000 cfs. • July, August, September: Flows will exceed 5,000 cfs. • December through June: Variable, as shown in **Error! Reference source not found.**.
Export to inflow ratio	The export to inflow (E:I) ratio for CM1 operations is under development. Two options are under consideration, with the primary difference being the location at which inflow from the Sacramento River is measured. Option 1 (assumed in the low-outflow scenario [LOS] and the evaluated starting operations [ESO] scenario): • Combined export rate is defined as the diversion rate of the Banks Pumping Plant and Jones Pumping Plant from the south Delta channels. • Delta inflow is defined as the sum of the Sacramento River flow downstream of the proposed north Delta diversion intakes, Yolo Bypass flow, Mokelumne River flow, Cosumnes River flow, Calaveras River flow, San Joaquin River flow at Vernalis, and other miscellaneous in-Delta flows. Option 2 (assumed in the high-outflow scenario [HOS]): • Combined export rate is defined as the sum of the diversion rate of the Banks Pumping Plant and Jones Pumping Plant from the south Delta channels and the diversion at the proposed north Delta intakes. • Delta inflow is defined as the sum of the Sacramento River flow at Freeport (upstream of the proposed north Delta diversion intakes), Yolo Bypass flow, Mokelumne River flow, Cosumnes River flow, Calaveras River flow, San Joaquin River flow at Vernalis, and other miscellaneous in-Delta flows.

OMR = Old and Middle Rivers

Table 3.4.1-2. Flow Criteria for North Delta Diversion Bypass Flows from December through June

Constant Low-Level Pumping (December–June)

Diversions up to 6% of river flow for flows greater than 5,000 cfs. No more than 300 cfs at any one intake.

Initial Pulse Protection

Low-level pumping maintained through the initial pulse period. For the purpose of monitoring, the initiation of the pulse is defined by the following criteria: (1) Wilkins Slough flow changing by more than 45% over a 5-day period and (2) flow greater than 12,000 cfs. Low-level pumping continues until (1) Wilkins Slough returns to prepulse flows (flow on first day of 5-day increase), (2) flows decrease for 5 consecutive days, or (3) flows are greater than 20,000 cfs for 10 consecutive days. After pulse period has ended, operations will return to the bypass flows identified below under Post-Pulse Operations. These parameters are for modeling purposes. Actual operations will be based on real-time monitoring of fish movement.

If the first flush begins before December 1, May bypass criteria must be initiated following first flush and the second pulse period will have the same protective operation.

Post-Pulse Operations

After initial flush(es), Level I operations apply. After 15 total days of bypass flows above 20,000 cfs, Level II operations apply. After 30 total days of bypass flows above 20,000 cfs, Level III operations apply.

Based on the objectives stated above, it is recommended to implement the following operating criteria:

- Bypass flows sufficient to prevent upstream tidal transport at two points of control: Sacramento River upstream of Sutter Slough and Sacramento River downstream of Georgiana Slough. These points are used to prevent upstream transport toward the proposed intakes and to prevent upstream transport into Georgiana Slough.

Appendix B: Impaired flows into an impaired estuary

The Sacramento River watershed is the main source of inflow to the Delta and is integral to current operations of the SWP and CVP. The construction of a new North Delta facility will not change the reliance on the Sacramento watershed very much. However, in conjunction with limited changes in reservoir operations and modifications to the Yolo Bypass, it will alter the timing of inflows to the Delta.

One of the goals of BDCP and the Delta Plan is to create a more natural flow regime. As noted in Chapter 4, there is little natural about the landscape, and humans are fully integrated into the ecosystem. Still, returning more natural seasonal flow changes will help in managing species whose life history traits are tied to flow cues.

The projected changes in outflow under BDCP are presented in Figure 3.1. These monthly averages are compared to current (not ELT) unimpaired outflow from the Delta, an imperfect measure of outflow under unregulated conditions that can be used for comparison of BDCP scenarios. All alternatives, including the no-project alternatives, do little to alter the significant changes in Delta outflow regime. The winter flood pulse associated with high runoff from mixed rain/snow storms has been greatly reduced in all but wet years. More significantly, the spring snowmelt pulse is attenuated, and largely missing in most of the drier years. Only late summer/early fall baseflow seasons have flows that are equal to or larger than unimpaired conditions.

Since the Sacramento outflow is a dominant signature for estuarine conditions (second to tides), we examined the magnitude of change in inflow from the Sacramento and compared it to unimpaired flow conditions. We used two simple methods to illustrate the magnitude of change overall and relative changes between ELT scenarios. The first involves calculating a monthly impairment index, I, where:

I = (scenario flow)-(unimpaired flow)/(unimpaired flow)

Where I approaches 0, the scenario flow is less impaired, where $I > 0$ scenario flows exceed unimpaired flows and where $I < 0$, scenario flows are less than unimpaired flows. The magnitude of I is a simple way of describing the magnitude of seasonal impairment. These results are summarized in Figure 3.2 for all water year types.

The impairment index is strikingly similar in pattern for all year types, with high negative impairments during the winter and spring and high positive impairments for the summer and early fall. This result is surprising because there are only subtle differences between year classes. The only significant variation between year classes occurs in the late summer/early fall when Fall X2 outflow rules predominate.

This broad similarity in impairment highlights how uniform the hydrology of the Delta has become: an issue raised in Lund et al., 2007 and Hanak et al, 2011 as contributing to the regime change in Delta ecosystems. It also shows how little effect the HOS and LOS scenarios are likely to have on Sacramento inflows to the Delta.

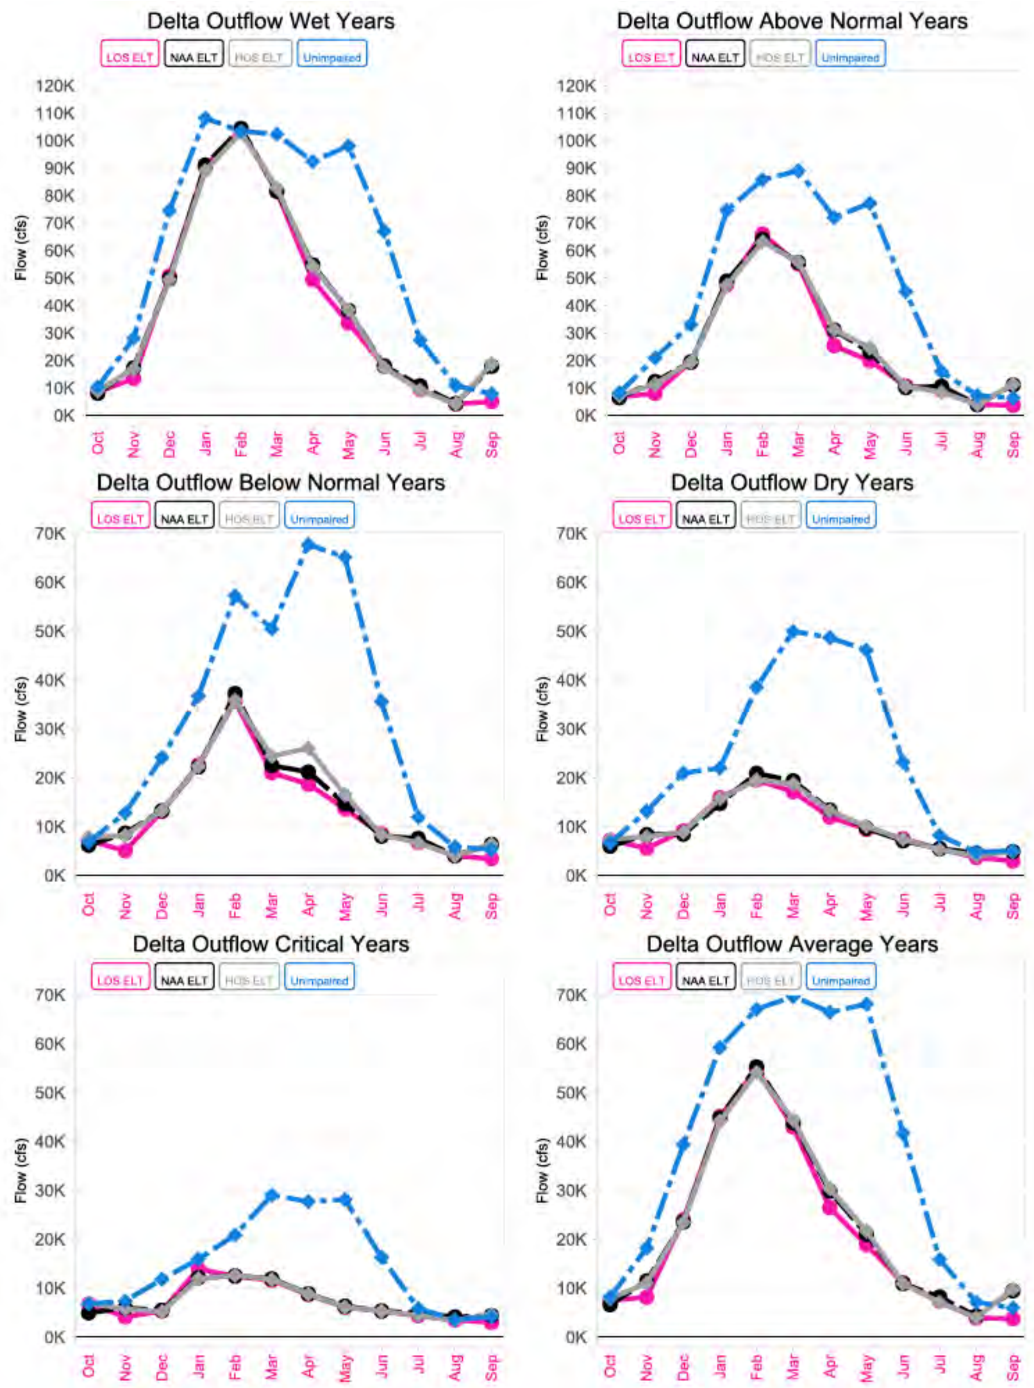

Figure 3.1: Delta outflow under HOS, LOS, and NAA ELT in comparison to unimpaired outflow

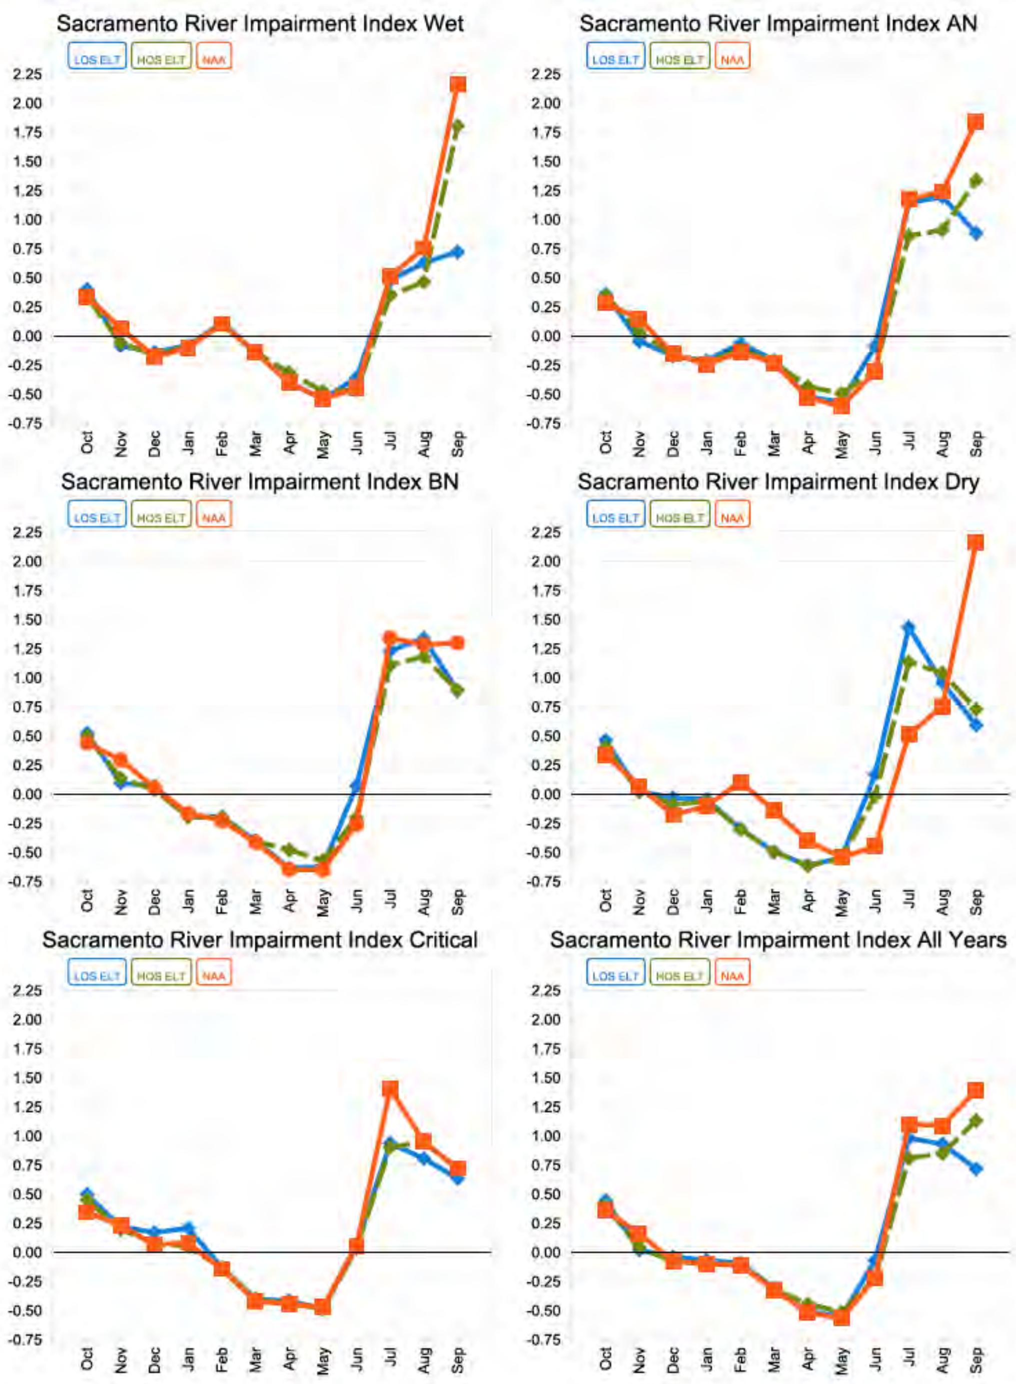

Figure 3.2: Sacramento River impairment index for HOS, LOS and NAA ELT.

A second approach can be used to characterize total impairment of individual year types. In this, we have plotted unimpaired vs. impaired flow for each scenario and each year type, and fitted a line and calculated r^2. The deviation of the slope of the line from 1 (impaired = unimpaired) illustrates the overall magnitude of impairment, while r^2 is a measure of variation in relative impairment. These results are shown in Figures 3.3-3.5.

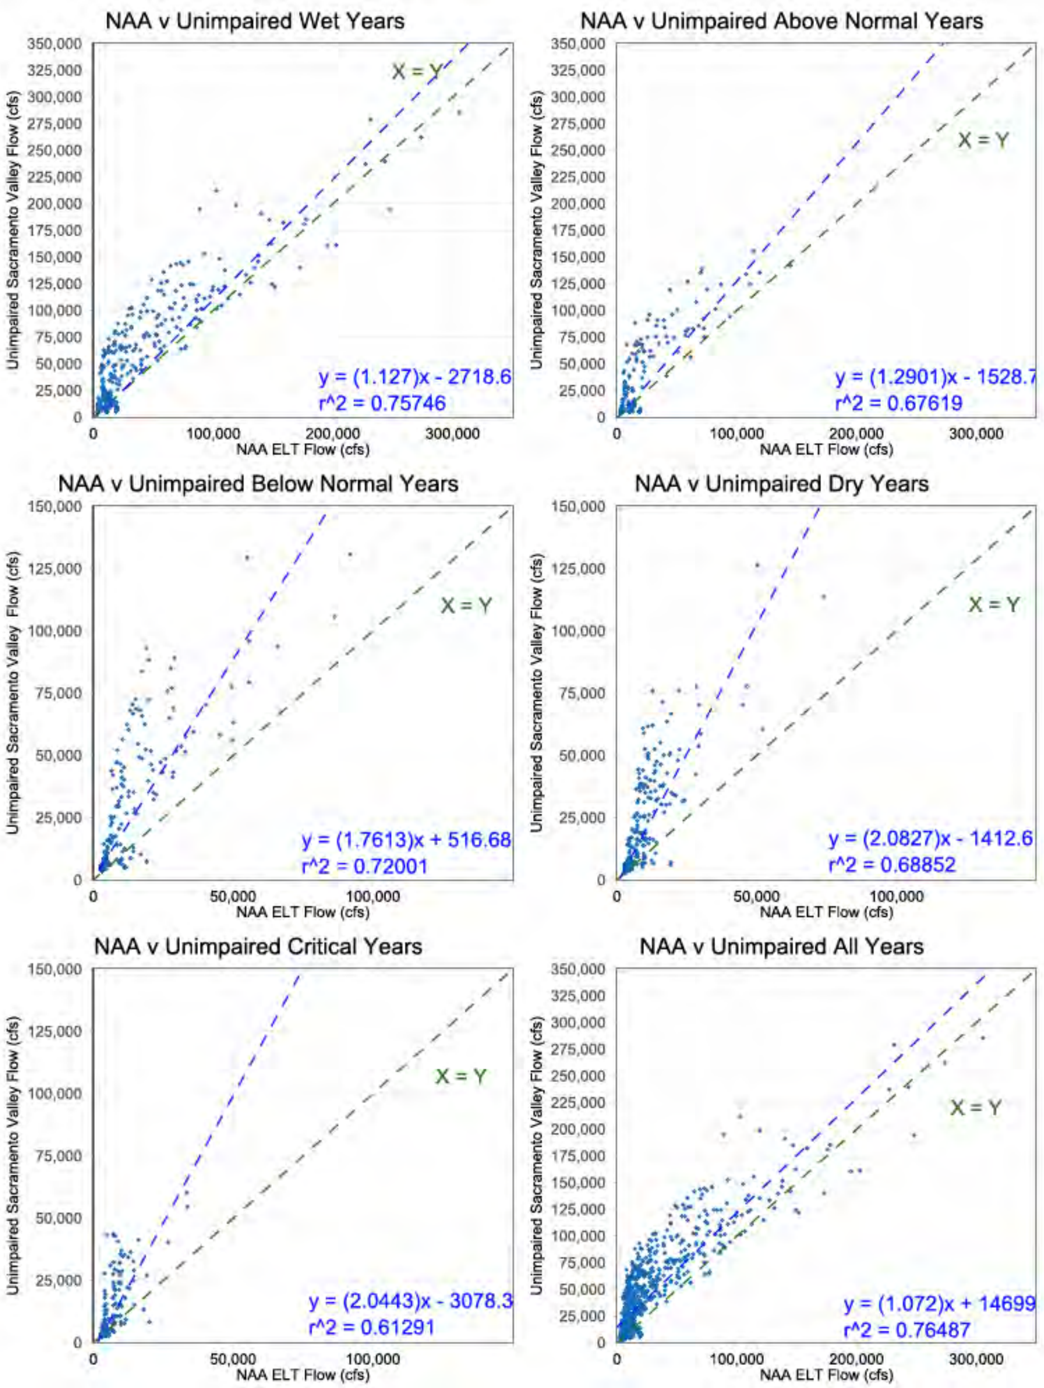

Figure 3.3. Scatterplot of NAA alternative Delta outflows vs. estimated unimpaired flows for ELT conditions. Higher slope and lower r² provide a relative measure of impairment.

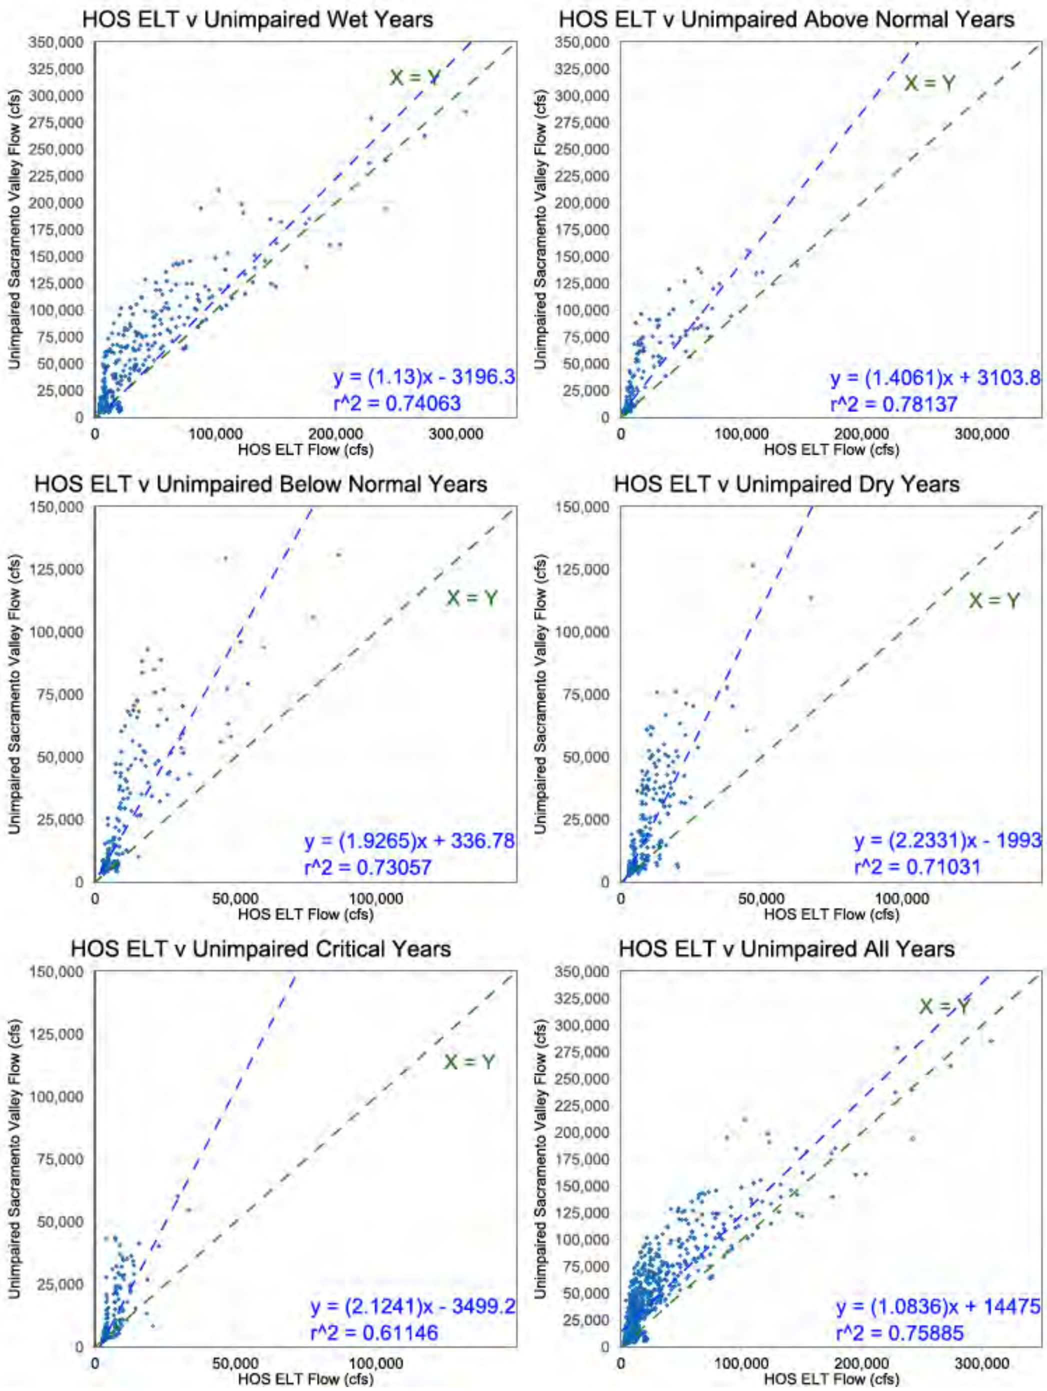

Figure 3.4: Scatterplot of HOS alternative Delta outflows vs. estimated unimpaired flows for ELT conditions. Higher slope and lower r² provide a relative measure of impairment.

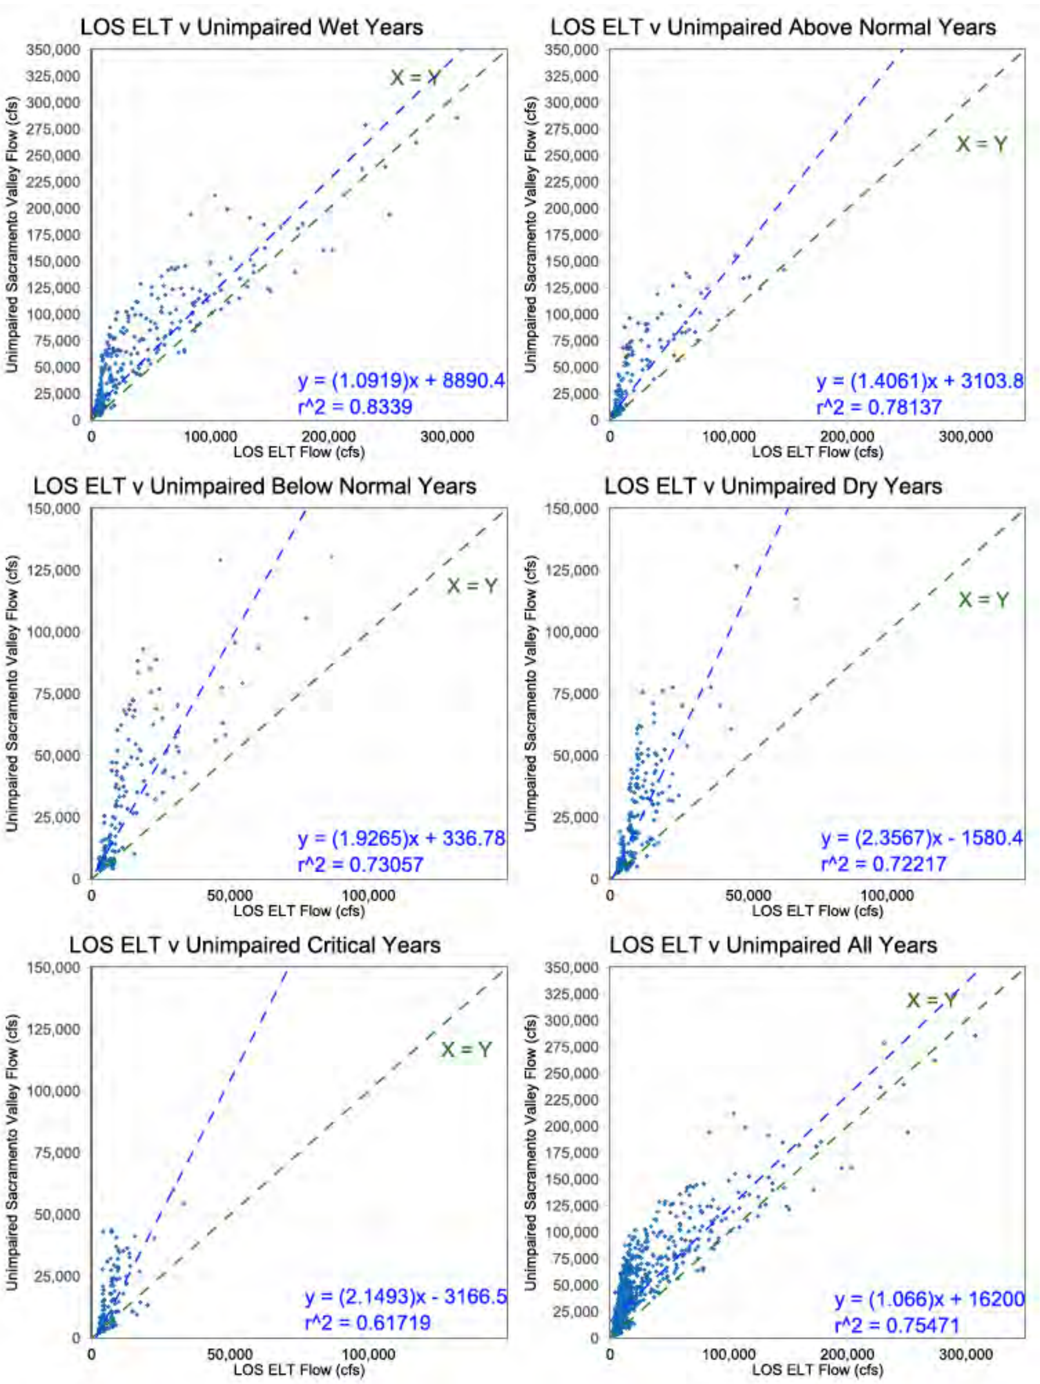

Figure 3.5. Scatterplot of HOS alternative Delta outflows vs. estimated unimpaired flows for ELT conditions. Higher slope and lower r^2 provide a relative measure of impairment.

The results of impairment scatterplots shows that in general, the magnitude of impairment, as measured by slope, and the magnitude of variation from unimpaired flow, as measured by r^2, are least in wet years and maximum in drier years. This reflects the dominance of water use and operations on Delta hydrology during dry years when the capacity for water alteration is greatest. In addition, there appears to be no substantive difference between the scatterplots of the different scenarios.

Conclusion

Examination of two closely related flow regimes, Delta outflow and Sacramento inflows, show that there is little difference in NAA, HOS, and LOS conditions. All represent high levels of impairment, in comparison to unimpaired flows, and the new North Delta facility and changes in export timing and magnitude have little impact on overall flow regime.

Appendix C: Effects of changes in flow conditions on entrainment losses of delta smelt

This Appendix describes the methods and results of analyses of flows in the South Delta and their potential effects on delta smelt. The general procedure was to determine a relationship between survival or recruitment during some life stages of delta smelt, and calculate the expected response based on conditions modeled using CALSIM and using historical data. CALSIM results were available for 1922-2003 for three BDCP scenarios: NAA, HOS and LOS. Historical data were used for inflow, export flow, and outflow during 1955-2003, and Old and Middle River flows from 1980 to 2003.

The calculations were based on results of Kimmerer (2008) as amended for adult delta smelt by Kimmerer (2011). Miller (2011) pointed out some potential biases in that analysis. Young delta smelt may be more abundant in the northern Delta than previously believed, which would mean that the proportional losses calculated by Kimmerer (2008) were too high (Miller 2011); however, this potential bias was not considered amenable to quantitative analysis with the available data (Kimmerer 2011). Nevertheless, the estimates of entrainment losses and reductions in losses herein may actually be somewhat overestimated.

The principal assumptions for this analysis are stated in Chapter 6. For the analyses of export losses we used a resampling method to account for uncertainty in the underlying statistical relationships between flow and entrainment. The error distributions from these models were sampled 1000 times to arrive at uncertainty estimates. The same 1000 samples were used for each year and scenario. This allowed us to include variability due to model uncertainty, and to allow direct comparisons among scenarios. The calculation was repeated for each year to provide the variability due to the hydrological conditions modeled under each scenario. Confidence limits were estimated as quantiles of the resulting set of simulated values for each parameter.

Losses of adult delta smelt

Losses as a proportion of the population of adult delta smelt had been estimated from salvage density, catches in the Spring Kodiak and Fall Midwater Trawl surveys, and flows in the south Delta (Kimmerer 2008, 2011). We related these estimates to total southward flow in Old and Middle Rivers:

$$Q_{sd} = mean_{Dec-Mar}\begin{pmatrix} 0, Q_{OM} \geq 0 \\ -Q_{OM}, Q_{OM} < 0 \end{pmatrix} \qquad (1)$$

where Q_{SD} is mean flow in the South Delta during December-March, and Q_{OM} is monthly mean or modeled flow in Old and Middle Rivers.

Estimated annual proportional losses P_L were related to Q_{SD} by linear regression for each year during which data were available (water years 1995-2006),

$$P_L \sim \max(0, a + bQ_{SD}) \tag{2}$$

where a=-0.03 and b= 0.0082 ± 0.0034 are regression coefficients. P_L was calculated using a revised estimate of the scaling factor Θ which accounts for uncertainty in the calculation of P_L; Θ has a mean of 22 and standard deviation of 5.2 (Kimmerer 2011).

Because P_L is a mortality we calculated means for a 20-year period by converting these values to survival, calculating geometric means, and converting back to proportions lost:

$$\overline{P_L} = 1 - \frac{1}{N}\prod_N (1 - P_{Li}) \tag{3}$$

where the overbar indicates a mean, N is the total number of years, and P_{Li} is the proportional loss for each year. The 20-year period was somewhat arbitrary but is roughly the timescale for the decline in abundance of delta smelt. To examine differences between pairs of the three scenarios we calculated the arithmetic means of differences for each pair.

There was little difference in mean P_L values between the full time series used in the analysis and the reduced time series that included the historical period (1980-2003). The No-Action Alternative (NAA) had a slightly lower percent annual loss than the historical period. The High and Low-Outflow scenarios (HOS and LOS) had similar values that were slightly below half of that of the NAA, or a net change in loss of about 3%/year.

Losses of juvenile delta smelt

Losses as a proportion of the population of juvenile delta smelt had been estimated from the spatial distribution of fish in the 20mm survey and flows in the south Delta supplemented by particle-tracking results (Kimmerer and Nobriga 2008, Kimmerer 2008). We related these estimates to total inflow to the Delta and export flow, noting that these results may vary depending on the proportion of inflow that is from the San Joaquin River. As with adults, CALSIM output was averaged over March – May for each year and scenario.

Annual proportional loss was calculated from a regression originally derived from particle-tracking data and applied to estimated losses of young smelt:

$$P_L \sim \max(0, a + bQ_{In} + cQ_{Ex} + dQ_{In}Q_{Ex}) \tag{4}$$

where a=-3, b= 0.36 ± 0.17, c= 0.90 ± 0.24, and d= -0.10 ± 0.03 are regression coefficients (Kimmerer 2008).

P_L values were accumulated and plotted as above (see Figures in Chapter 6). The annual means for the NAA were somewhat lower than the historical values, reflecting overall lower export flows than in the historical period. Both of the alternative scenarios resulted in substantial decreases in loss rates from about 14%/year to 3-5 %/year, and the LOS showed about a 2%/year higher loss rate than the HOS.

Appendix D: Evidence for food limitation of the smelt species

Delta smelt larvae consume mainly early life stages of copepods, switching to adult copepods as soon as they are able to catch and ingest them (Nobriga 2002, Hobbs et al. 2006, L. Sullivan, SFSU, pers. comm.). Juvenile delta smelt feed mainly on adult copepods (Moyle et al. 1992, Lott 1998, Nobriga 2002, Hobbs et al. 2006), although they consume other zooplankton such as cladocerans in freshwater. The diets of adults include larger organisms such as mysids and amphipods (Bippus et al. poster 2013; Johnson and Kimmerer 2013 talk).

Evidence in favor of food limitation (numbers in parentheses indicate the steps in the logic chain in Chapter 7)

Both smelt species

1. (1) Following the spread of the overbite clam *Potamocorbula* in 1987, sharp declines occurred in phytoplankton biomass and productivity, diatom production, and abundance of copepods and mysids, which are the principal prey of both species (Alpine and Cloern 1992, Kimmerer et al. 1994, Orsi and Mecum 1996, Kimmerer and Orsi 1996, Kimmerer 2005, Winder and Jassby 2011)
2. (1) At around the same time abundance indices of several fish species declined, notably anchovy, longfin smelt, and striped bass (Kimmerer 2002, 2006, Kimmerer et al. 2009), indicating an overall response of estuarine fish populations to the decline in food abundance. The decline in anchovy abundance in brackish waters (but not in high salinity) was particularly sharp and closely tied in time to the 1987 decline in phytoplankton biomass.

Delta smelt

3. (1) Gut fullness of delta smelt larvae was positively related to copepod density (Nobriga 2002). This suggests that when there is more food the smelt larvae eat more.
4. (1) Feyrer et al. (2003) found that delta smelt guts averaged about 40% full in Suisun Marsh before *Potamocorbula* arrived. This was similar to the gut fullness of most other fish species. It suggests that if there were more food the fish would have eaten more, or that there is some other limit to gut fullness.
5. (1) The functional response of larval delta smelt from laboratory experiments shows that the feeding rate saturates at a prey concentration well above that seen in any zooplankton samples in the smelt habitat during May –July of 1993-2011 (L. Sullivan, SFSU, unpublished; see Figure A7.1).

6. (2) Glycogen was depleted in 30% of fish in summer and 60% of fish in fall of 1999 (Fig. 28C in Bennett 2005) which could be interpreted as evidence of poor nutrition either because of a food shortage or because of some toxic effect; however the frequency of toxic damage was <10% in these fish.
7. (2) Mean lengths declined in either 1989 (Bay Study) or 1993 (FMWT study; Fig. 29 in Bennett 2005). The latter year is when the copepod *Pseudodiaptomus forbesi* shrank back from the LSZ in summer-fall, presumably because of the combined effects of clams and the introduction of other copepods. Bennett (2005, Figure 30) also showed positive relationships between mean length of delta smelt and copepod density (Bennett Fig. 30).
8. (3a) Copepod biomass is correlated with an index of survival from summer to fall (Kimmerer 2008).
9. (3a) Abundance data show evidence for density dependence between summer and fall when the early years are included (Bennett 2005 Fig. 17). A likely cause of density dependence is food limitation, although other mechanisms are also possible.
10. (1-4) Several model analyses show strong effects of food supply on the population rate of increase (Maunder and Deriso 2011, Rose et al. 2013a, b, Kimmerer and Rose, in prep). Note, however, that these models are incomplete and can only show effects based on what is in them.
11. A multivariate autoregressive (MAR) model (Mac Nally et al. 2010) showed weak support for a positive link between calanoid copepod abundance and delta smelt abundance index.

Longfin smelt

12. (1) Longfin smelt prey mainly on mysids after summer (Feyrer et al. 2003). Mysids declined sharply after 1987 (Orsi and Mecum 1996, Winder and Jassby 2011).
13. (Overall) Abundance of longfin smelt declined sharply after the introduction of *Potamocorbula*, when the strong effect of freshwater flow is taken into account (Kimmerer 2002, Kimmerer et al. 2009). Striped bass, which also feed on mysids (Feyrer et al. 2003), also declined at that time.
14. A multivariate autoregressive (MAR) model (Mac Nally et al. 2010) showed weak support for a positive link between calanoid copepod abundance and longfin smelt abundance index.

Evidence that does not support food limitation or is missing

15. The abundance of delta smelt did not change when *Potamocorbula* arrived or 1993, which were the two times of greatest change in calanoid copepod abundance in the low-salinity habitat of delta smelt

16. A changepoint model (Thomson et al. 2010) showed no link between abundance of various zooplankton and abundance indices of either smelt species.
17. Sampling for zooplankton is at too coarse a scale to represent the prey abundance that the smelt perceive, and the spatial distribution of prey cannot be replicated in the laboratory. Therefore it may be misleading to extrapolate functional responses from the laboratory to the field.
18. There is no direct evidence for effects of food on survival, maturity, or fecundity.

Appendix E: Model of plankton subsidy from marsh to estuary

Here we assume that the restored areas will actually produce an excess of phytoplankton or zooplankton over adjacent waters, and ask what additional level of food availability to the smelt would result. This is based on a very simple model and some calculations using data from IEP monitoring, as noted below. These calculations are unpublished except where a citation is given; details of calculations are available on request.

The additional zooplankton biomass available to the open-water areas as a result of production in restored shallow subtidal areas depends on the excess production in the restored areas, the resulting gradient in biomass, the tidal exchange rate between the restored areas and open waters, and the net population growth rate of the zooplankton in the open waters. The benefit of that additional supply to the smelt species depends on the proximity of the restored area to the population centers of the smelt (Fig. 7.2).

A simple model of this subsidy is:

$$F = (B_R - B)V_R X / BV \qquad (1)$$

where F (d^{-1})is the subsidy as a daily proportion of plankton biomass in the receiving water, B is biomass per unit volume, V is volume, B_R and V_R are biomass and volume in the restored area, and X is exchange rate as a daily proportion of the volume of the restored area (d^{-1}). Biomass and volume units cancel out.

It is clear from Equation 1 that the subsidy is maximized when the restored area is large, the zooplankton biomass in the restored area is well above that in the open water, and exchange rate is high. However, there is an the interplay among biomass B_R, volume V_R, and exchange rate X. First, water depth has three competing effects: 1) Phytoplankton growth rate is highest in shallow water where light penetration is high; 2) For a given area of restoration, volume is inversely related to water depth; 3) any bivalve grazing consumes phytoplankton and zooplankton in inverse proportion to depth. Second, as the exchange rate X increases, net population growth rate within the restored area decreases as organisms are removed by the exchange. If there is no exchange there is no subsidy, but at high levels of exchange there is also no subsidy because the zooplankton are being mixed rapidly compared to their internal growth processes (see Figure 7.3). Cloern (2007) showed that the efficiency of conversion of phytoplankton to zooplankton in a linked shallow-deep system was maximized when the tidal exchange rate X was equal to the net population growth rate of the primary consumers.

It is beyond our scope to model explicitly the growth and other processes and consequent biomass levels. However, it is possible to constrain the total phytoplankton and zooplankton biomass within a marsh using available data. During strong blooms nutrients are converted to phytoplankton biomass, but conversion is incomplete because some is lost to other foodweb components such as detritus, bacteria, and zooplankton. Thus, the total amount of dissolved inorganic nitrogen (DIN, comprising nitrate, nitrite, and ammonium) can set an upper limit to total phytoplankton biomass.

We used data from the IEP water quality and zooplankton monitoring programs from 1975-2012. Data used were from May to October to avoid the high variability of winter flows, and to focus on the dry season when the smelt species may be most constrained by food supply. Data were taken from the low-salinity zone, extended to a salinity of 0.5 – 10, about the range of salinity where delta and longfin smelt are abundant in their first summer, and averaged by year and month.

Chlorophyll was converted to phytoplankton C using a carbon:chlorophyll ratio of 50, under the assumption of high light availability. To examine bloom conditions, we used only data for which phytoplankton biomass exceeded 200 mgC/m^3. From these data, we determined the zero-intercept of a linear model of phytoplankton carbon vs. dissolved inorganic nitrogen (DIN), under the assumption that this represented the maximum conversion of DIN to phytoplankton biomass. This corresponded to about 900 mgC/m^3 (about 40% of the sum of phytoplankton C and DIN converted to C using a molar ratio of 6.6:1). We used that value as the upper limit for phytoplankton C in a marsh. Calanoid copepod C for adults and copepodites was estimated to be about 2.5% of actual phytoplankton C, and we assumed that this proportion would apply to the maximum phytoplankton C, or about 23 mgC/m^3. Using the same data the median phytoplankton and calanoid copepod C in the open water during 1994 – 2011 were 73 and 3 mgC/m^3 respectively.

The optimum exchange rate was calculated separately for phytoplankton and for zooplankton. For calculation we assume a mean depth of 2m and an area of 1000 ha (2500 ac) in the restored area. From Lopez et al. (2006) the growth rate of phytoplankton in a shallow area can be modeled as

$$\mu_P = -0.09 + 1.91/H, \qquad (2)$$

where H is water depth. At a water depth of 2m, this evaluates to 0.86 d^{-1}, which we use although a similar model using data from the LSZ in 2006-2007 gave a growth rate that was about 25% lower. We assume that benthic grazing in the restored area is negligible, but cannot neglect grazing by microzooplankton. This can be modeled either as:

$$g = \max(0, 0.93\ \mu_P - 0.3) \qquad (3)$$

based on experimental results from the Low-Salinity Zone in 2006-2007 (York et al. 2011), or

$$g = 0.6\ \mu_P \qquad (4)$$

from a review of microzooplankton grazing estimates, using values for estuaries (Calbet and Landry 2004). These yield growth rates of 0.5 and 0.35 d^{-1} respectively. The latter value is probably more generally representative of a wide range of conditions and for this analysis gives a higher net phytoplankton growth rate.

Using an exchange coefficient X set to be close to the net phytoplankton growth rate less grazing of 0.35 d^{-1} and using the volume of the LSZ of 0.5 km^3 as V in Equation 1, we get:

$$F = (B_R - B)V_R X / BV = (900-73)\ (1000 \times 10^{-2} \times 2 \times 10^{-3})\ 0.35 / (73 \times 0.5)$$

or about 0.16 d^{-1}. This is about half of phytoplankton growth, and about twice the (negative) net of growth less grazing by microzooplankton and clams in the LSZ based on field measurements during 2006-2008, which is now subsidized by mixing from other areas of the estuary. Thus, the extremely ideal conditions proposed above would lead to a substantial subsidy of phytoplankton to the LSZ. However, this assumes nearly perfect tuning of the exchange, ideal growth of the phytoplankton with no benthic grazing within the restored area, and perfect mixing of the discharged phytoplankton into the LSZ, which is unlikely because of its tidal movement in relation to the outlet of any marsh.

For calanoid copepods the equivalent calculation to that above is

$$F = (23 - 3)\ (1000 \times 10^{-2}) \times (2 \times 10^{-3})\ 0.1 / (3 \times 0.5)$$

or about 0.03 d^{-1}. As before, this represents an upper limit of the likely subsidy to LSZ zooplankton. This corresponds to a turnover time of about a month, considerably longer than the population turnover time of the copepods. As with phytoplankton, this is an upper limit of the potential subsidy of copepods, which would be reduced by behavioral resistance to movement such as vertical migration, and by excess predation in the marsh compared to the adjacent open waters. Both of these reductions are likely to be very large.

Zooplankton export from Suisun Marsh

One of the proposed restoration areas is in the northern end of Suisun Marsh. Biomass of calanoid copepods in the southern part of the marsh was about 2× that of the adjacent Grizzly Bay, based on a short-term field study and long-term monitoring data (Kimmerer and Marcal 2004). Biomass in the smaller sloughs to the north is apparently higher although nothing has been published on that (J. Durand, UC Davis, pers. comm.).

We used output from the UnTRIM hydrodynamic model (MacWilliams et al. in prep., Kimmerer et al. in press) and the FISH-PTM particle tracking model (Kimmerer et al. in prep.) to examine the residence time of particles within Suisun Marsh during the dry season. The hydrodynamic model simulates the entire estuary including marsh channels and bathymetry, but is not specifically set up to replicate flows in the marsh and therefore the results should be considered preliminary. For the entire network of channels it should give acceptable results, but to model the smaller sloughs would require a finer grid for that area.

The PTM was run for 45 days in a dry period in the historical data set (starting 1 July 1994) to examine the influence of vertical movement on retention in the estuary. The model was started with particles released throughout the northern estuary in a pattern similar to the distribution of the copepod *Eurytemora affinis*, the most abundant LSZ resident zooplankton species before *Potamocorbula* was introduced. Over 9000 particles were released for each run at approximately the same number per unit volume throughout the marsh. Residence time was estimated as the rate of decline of the log of total particles remaining in the marsh.

For neutrally-buoyant (i.e., passive) particles, the residence time of the marsh was about 28 days, and particles continuously left the marsh during the 45-day run. Particles that either sank or migrated tidally (down on the ebb and up on the flood) had a more complex pattern but generally the particles in the northern part of the marsh did not leave the marsh during the 45-day run.

Taking the passive case first and using available bathymetric data for the volumes of the marsh and Suisun Bay, Equation 1 can be reduced to the following:

$$F = (B_R / B - 1) \times V_R / (RT \times V) = (B_R / B - 1) \times 0.07 / (28 \times 0.11)$$

$$= 0.02\ (B_R / B - 1)$$

Based on the existing data cited above for Suisun Marsh, this flux would provide an additional 2%/d of copepods to Suisun Bay if the copepods behaved as passive particles. This is unlikely to produce a noticeable increase in copepod biomass, as their population growth rates are on the order of 10%/d. Any tidal migration or tendency to remain near the bottom (which can be common among zooplankton in shallow, well-lit waters) would greatly reduce or even eliminate the net flux from the marsh to the open waters.

Appendix F: Effects of floodplain inundation

This Appendix explores available data on the response of phytoplankton and zooplankton biomass to flooding of the Yolo Bypass. This is to provide a basis for anticipating effects on the estuarine foodweb from floodplain inundation at lower flows in the Sacramento River.

One assumption underlying BDCP plans for increased inundation of the Yolo Bypass is that it would provide a source of phytoplankton and zooplankton to the open waters of the estuary. If so, the much larger floods that occasionally inundate the Bypass now should produce measurable increases in phytoplankton and zooplankton at monitoring stations in the estuary.

The basis for this analysis was to use the IEP monitoring data to try to detect an influence of inundation of the Bypass on phytoplankton biomass as chlorophyll concentration, and zooplankton biomass calculated from abundance. IEP data were obtained from six stations in the western Delta to eastern Suisun Bay.

Chlorophyll concentration has been determined since 1976 in the zooplankton survey. Abundance of zooplankton has been determined since 1972 by species and gross life stage. We used data on adult and juvenile calanoid copepods, which are common in the diets of delta smelt and other fishes. Abundance data were converted to biomass using carbon mass per individual by species and life stage (see Kimmerer 2006 for details; carbon estimates have been updated).

Neither chlorophyll nor copepod biomass showed any effect of inundation of the Bypass. This lack of response is clear for copepod biomass in Fig. F.1, which shows that under high flows in the Bypass the biomass was generally lower than when flows were lower. The data have been stratified by groups of years separated by the time that the clam *Potamocorbula amurensis* was introduced. During both periods biomass was generally higher when the Bypass was dry than when it was flowing at a low rate ($< 500\ m^3s^{-1}$). Biomass increased slightly in a handful of times when the Bypass was flowing at a higher rate, but even with this increase biomass still did not match that at the lowest flows. The difference in biomass between the pre- and post-clam period is notable at low Bypass flows.

Most of the high flows in the Bypass occurred during winter when zooplankton biomass is at its seasonal low. Inundation of the Bypass later in spring at a lower stage of the Sacramento River than is now necessary might provide conditions for higher productivity, but the lack of response of the current system at lower Bypass flows is not promising.

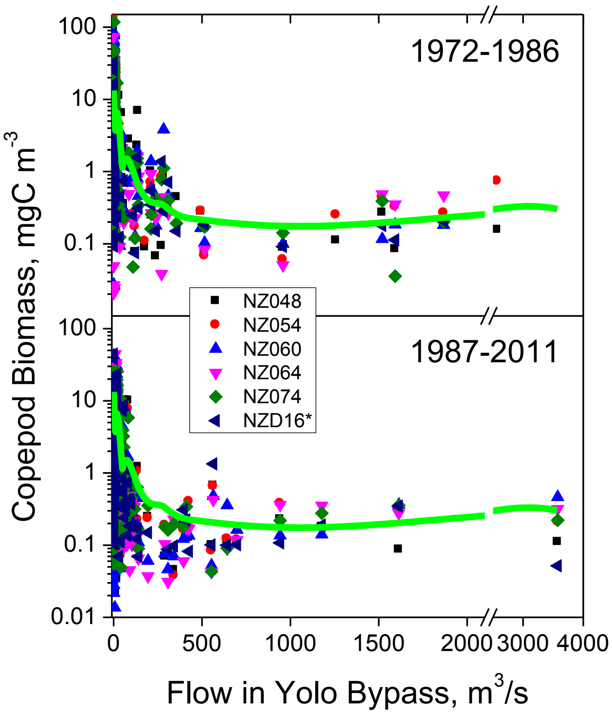

Figure F.1. Copepod biomass as a function of flow in the Yolo Bypass for two time periods. Symbol shapes and colors show the sampling stations from the IEP zooplankton monitoring survey. Green line is from a generalized additive model with a loess (locally-weighted) smoothing function applied to the pre-1987 period and shown in the lower graph for comparison.

Appendix G: Can incidental take permits be issued to water contractors?

Do the federal Endangered Species Act and the California Natural Community Conservation Planning Act allow the U.S. Fish and Wildlife Service, the National Marine Fisheries Service, and the California Department of Fish and Wildlife to issue incidental take permits to the Central Valley Project and State Water Project contractors?

This question is significant, because the draft BDCP provides that the Authorized Entity Group shall be comprised of the Director of the California Department of Water Resources as operator of the SWP, the Regional Director of the U.S. Bureau of Reclamation as operator of the CVP, and one representative each of the CVP and SWP contractors if the contractors are issued permits under the Plan. BDCP 7-8. If we correctly understand the premise of this question, it is that only the owners and operators of the two projects—the U.S. Bureau of Reclamation and the California Department of Water Resources—are eligible to hold the incidental take permit that would govern construction and operation of the facilities authorized by the BDCP.

Although there is no definitive answer to this question, we conclude that the CVP and SWP contractors may receive incidental take permits. We base this conclusion on four factors: (1) There is nothing in either the federal Endangered Species Act or the California Natural Community Conservation Planning Act that prohibits the fish and wildlife agencies from issuing incidental take permits to entities such as the CVP and SWP contractors who receive water service from (and therefore are beneficiaries of) the permitted project operators. (2) The text of both statutes allows for the grant of incidental take permits to persons or entities other than the owners and direct operators of the projects governed by an HCP and NCCP. (3) There is precedent for the inclusion of both government entities and private landowners and resource users within a single HCP/NCCP. (4) There are good reasons both for the CVP and SWP contractors to seek the protections of an incidental take permit and for the fish and wildlife agencies to include the contractors within the management structure of the BDCP. It is therefore likely that the courts would defer to the agencies' decision to issue incidental take permits to the contractors.

The incidental take permitting and HCP provisions of section 10 of the federal ESA authorize the taking of individual members of a listed species that otherwise would be prohibited by section 9(a)(1)(B) of the Act. 16 U.S.C. § 1538(a)(1)(B). The take prohibition of section 9 applies to "any person subject to the jurisdiction of the United States." *Id.* § 1538(a)(1). The statute defines "person" as meaning

> an individual, corporation, partnership, trust, association, or any other private entity; or any officer, employee, agent, department, or instrumentality of the Federal Government, of any State, municipality, or political subdivision of a State, or of any foreign government; any State, municipality, or political subdivision of a State; or any other entity subject to the jurisdiction of the United States. [*Id.* § 1532(13).]

This definition expressly includes the CVP and SWP contractors, which are comprised primarily of instrumentalities of the state (and, in the case of the CVP, includes some individuals). The statute thus extends eligibility for (limited and conditional) exemption from the take prohibition of section 9 to the project contractors, and it contains no exclusion from this eligibility based on the fact that the contractors do not themselves own or operate the project.

The California Natural Community Conservation Planning Act addresses this question even more directly. In its articulation of the purposes of the statute, the Legislature stated:

> Natural community conservation planning is a cooperative process that often involves local, state, and federal agencies and the public, including landowners within the plan area. The process should encourage the active participation and support of landowners and others in the conservation and stewardship of natural resources in the plan area during plan development using appropriate measures, including incentives. [California Fish & Game Code § 2801(j).]

The Act also declares that "Any person, or any local, state, or federal agency, independently, or in cooperation with other persons, may undertake natural community conservation planning." *Id.* § 2809.

Indeed, the fish and wildlife agencies approved this type of multiparty, multijurisdictional, cooperative approach in the Orange County HCP/NCCP for the protection of the coastal gnatcatcher, other target species, and their habitat. The cooperating and individually permitted entities include the County of Orange, the cities of Anaheim, Costa Mesa, Newport Beach, Irvine, Laguna Beach, Orange, and San Juan Capistrano, as well as other participating public and private landowners and water users, such as Southern California Edison, the Metropolitan Water District, Irvine Ranch Water District, the Irvine Company, UC Irvine, the California Department of Parks and Recreation, and transportation corridor agencies. COUNTY OF ORANGE, FINAL NATURAL COMMUNITY CONSERVATION PLAN AND HABITAT CONSERVATION PLAN, CENTRAL AND COASTAL SUBREGION (1996), document available at http://www.naturereserveoc.org/documents.htm. Although this situation does not precisely mirror the relationship between the CVP and SWP and their contractors, it does serve as precedent for creation of an HCP/NCCP that includes both land and resource management agencies and public/private land and resource users as incidental take permit holders.

Finally, it makes sense for the CVP and SWP contractors to seek the protections of the incidental take permits governing operation of the facilities authorized by the BDCP, as it is their uses of project water that would potentially violate the federal and state take prohibitions. The contractors thus would benefit both from the security provided by the incidental take permits and from participation in the decisions that would shape implementation and compliance with the terms and conditions limiting coordinated CVP/SWP operations set forth in the BDCP. Concomitantly, it is in the fish and wildlife agencies' interest to have the contractors participate as permittees so that disputes between the contractors and USBR and DWR as project operators may be resolved within the forum of the Authorized Entity Group, rather than outside the purview and procedures of the BDCP. Under these circumstances, we believe that it is likely that the courts would defer to the fish and wildlife agencies' reasonable interpretation of the statutes as authorizing the grant of incidental take permits to the CVP and SWP contractors. *See Chevron U.S.A. v. Natural Resources Defense Council,* 467 U. S. 837 (1984); *American Coatings Ass'n. v. South Coast Air Quality Dist.*, 54 Cal.4th 446 (2012).

Foreword

In 2009, California lawmakers passed historic legislation that marked an important step toward improving the state's water supply reliability and restoring the Sacramento-San Joaquin Delta ecosystem. A critical challenge to achieving the goals of the legislative package is providing more effective management of groundwater resources at a time when California's reliance on its groundwater basins is growing due to a variety of short- and long-term factors.

The Association of California Water Agencies (ACWA) developed this Framework to describe current groundwater management efforts and identify proactive steps to advance sustainable groundwater management as part of the state's overall water management portfolio. ACWA believes the challenge of providing sustainable groundwater management must be met by local and regional agencies and not by centralized state regulation. Locally controlled groundwater management is effective because it is best able to respond to the particular circumstances of, and significant differences in, groundwater basins throughout the state. Local expertise and direct reliance on the resource ensures immediate response to problems and trends, and provides the strongest basis for collaborative regional approaches.

But as this Framework emphasizes, the job is far from done. While there are numerous case studies in successful management, efforts must be expanded in many parts of the state to achieve sustainable outcomes.

ACWA members are not daunted by the challenge. The actions and policy recommendations outlined in this document reflect the on-the-ground experience of experts involved in managing groundwater in every region of California and in a variety of geographic and hydrologic settings. Implementing these actions will help empower local agencies to strengthen their management efforts and contribute to the state's overall need for sustainable groundwater management, today and into the future.

To be successful, sustainable groundwater management must be accomplished in the context of a comprehensive solution that includes conveyance improvements in the Delta, investments in additional surface storage and groundwater storage to meet the co-equal goals, and massive investments in local water resources development.

ACWA members are prepared to step up to the challenge of providing sustainable groundwater management. We stand ready to work with policy makers and water managers to carry out actions and initiatives to promote more effective local groundwater management as part of a comprehensive solution.

Overview

Groundwater has long been an integral part of California's water supply. Today, it has an even more critical role to play as the state grapples with significant water supply challenges.

California's water management system is arguably among the most complex and innovative in the world. Massive amounts of water are captured, stored and delivered through a combination of man-made and natural features to serve urban, agricultural and environmental needs.

Groundwater was widespread and abundant at the beginning of the 20th century. Its extensive availability contributed to large-scale agricultural and urban growth, which in turn steadily increased demand for and dependence on the resource. Effective management quickly became critical to protecting the future availability and quality of California's groundwater supplies. While many strategies have been implemented over the years to address groundwater management challenges, some are falling short today and require modernization.

Though California does not have a formal state-administered system of regulating and permitting groundwater use, it does have a long history of managing groundwater resources through locally controlled programs developed and refined over the past century.

Many of these programs have been very effective in addressing the state's most difficult groundwater management problems over the years. However, the array of challenges on the horizon will demand even more of local agencies and require a greater commitment to ensuring that local decisions and management contribute to statewide water policy goals.

The current state of California's groundwater should not be considered in isolation since it is largely reflective of broader water management concerns in the state. It has become increasingly clear in recent years that California's aging water supply and management infrastructure can no longer reliably meet the economic and environmental needs of the state. This is readily apparent in the Sacramento-San Joaquin Delta and elsewhere where challenges associated with population growth, drought, climate change, unmanaged groundwater overdraft and environmental concerns await resolution. The growing uncertainty of surface water supplies due to these and other factors has triggered greater reliance on groundwater as a principal or supplemental supply for urban, agricultural and environmental uses (e.g. wildlife refuges). It has also focused attention on groundwater basins as a potential storage solution.

The shift toward greater reliance on groundwater has magnified long-term risks to the quality and quantity of water available from California's groundwater basins. While Californians have relied on groundwater resources to varying degrees over the years, ACWA strongly believes today's growing dependence – intensified by both cyclical and long-term factors – will continue to stress California's groundwater basins unless proactive steps are taken at the local and regional level.

The California Legislature took an important step toward addressing the state's water challenges with passage of comprehensive water legislation in 2009. In addition to an $11.14 billion water bond now targeted for the November 2012 ballot and policy bills addressing Delta governance, water conservation, and water diversion and use, the package included new requirements for groundwater elevation monitoring to help track seasonal and long-term trends in groundwater basins.

ACWA developed this Framework to complement that legislation and advance the dialog on sustainable groundwater management. Produced by a task force of local groundwater managers from throughout the state, the Framework has four main purposes:

1. To define "sustainability" in terms that promote effective groundwater basin management;
2. To describe the current state of groundwater management in California, including an increasing number of successful local and regional management and conjunctive use programs, to provide an accurate and comprehensive foundation on which the public, policy makers and other stakeholders may make informed decisions;
3. To articulate groundwater management practices to address current and future challenges in California groundwater management; and
4. To identify specific policy development needs and recommend ways to enhance accountability, transparency, and the efficacy of sustainable groundwater management in California and its appropriate integration as a critical part of California's overall water management planning portfolio.

As evidenced by effective local and regional programs highlighted in this Framework, (see map, page 22), existing mechanisms for managing groundwater basins are providing an excellent foundation for sustainable management now and into the future. These examples, along with many other programs throughout the state, have generated impressive results and should be utilized as models for other agencies to help achieve the goal of sustainable groundwater management in California.

Locally controlled groundwater management is effective because local and regional entities are the most knowledgeable about their local basins and tend to be the first to notice changes or problems. They are also best suited to address issues unique to their region, including the implementation of proactive plans and actions to meet current and future groundwater needs.

Groundwater management plans developed under AB 3030, SB 1938 and the Integrated Regional Water Management Planning Act offer prime opportunities to enhance effective management and incorporate strategies that can help address the potential consequences of a large-scale shift to groundwater, whether cyclical or permanent. Doing so will also improve coordination and collaboration with state agencies as elevation data is collected pursuant to the new requirements of SBX7 6, enacted as part of the 2009 comprehensive legislative water package.

ACWA believes the state Legislature should encourage and support local management policies that appropriately reflect California's geographic and hydrologic diversity rather than institute a state-administered centralized control structure for regulating or permitting the use of groundwater. Statewide permitting and regulation would undermine the effectiveness of existing and planned local investments and would be counterproductive because it would not account for the significant differences in California groundwater basins throughout the state.

The Legislature should focus instead on incentivizing the development and implementation of the best practices outlined in this Framework. Recommendations for doing so are outlined beginning on page 29.

Ultimately, for sustainable groundwater management to succeed, California must invest in improvements to its water storage and conveyance infrastructure to optimize both surface and groundwater supplies. Such investments are critical if conjunctive use and groundwater banking are to realize their full potential as effective strategies to meet California's future demands, both economic and environmental. These investments must complement an ongoing commitment to expanded water use efficiency and water reuse.

ACWA believes that with the actions and policy modifications recommended in this Framework, local agencies can provide sustainable groundwater management, to the benefit of California, without the addition of new layers of state bureaucracy or regulation.

In addition to this Framework, ACWA has adopted Groundwater Management Policy Principles to provide further guidance and recommendations for sustainable management of the state's groundwater resources. The principles can be found on page 32. The Framework and the principles together provide a solid foundation for achieving groundwater management goals in California, and an effective basis for collaboration among the water and environmental communities, agriculture, business and labor leaders, and state and local governments.

Defining Sustainability

Sustainability has emerged as an important principle in natural resources management in recent years. ACWA has adopted policy principles that identify environmental and economic sustainability as co-equal priorities for water management in California.

In the context of groundwater, ACWA defines sustainability as actively managing the resource at the local level in a way that satisfies the needs of both the environment and the economy while ensuring the continued health of the basin. Given the importance of groundwater to California's water supply, sustainable management of the state's groundwater resources is essential to ensuring a reliable water supply and a healthy environment – both today and for generations of Californians to come.

The United States Geological Survey characterizes groundwater sustainability as the "development and use of groundwater in a manner that can be maintained for an indefinite time without causing unacceptable environmental, economic, or social consequences."[1]

Inherent in that definition as applied is the long-term protection and maintenance of both groundwater quantity and quality. As evidenced by effective local and regional programs throughout the state, managing groundwater basins to achieve sustainability has many benefits, including:

- More reliable surface and groundwater resources
- Increased opportunities for conjunctive use and recharge projects
- Environmental health / stability
- Drought mitigation
- Water quality improvements
- More effective land use planning and management
- Reduced energy costs associated with pumping

On the other hand, the lack of effective groundwater management contributes no such benefits and has led to the further decline of groundwater resources in certain areas of California. Unacceptable consequences include depletion of existing groundwater supplies, land subsidence, water quality degradation and environmental damage.

Groundwater Management Today

In California, groundwater management generally refers to a locally developed and controlled program that integrates groundwater protection, recharge, extraction and monitoring to achieve the long-term sustainability of the resource. Since groundwater basins vary greatly around the state, local control and supervision allow for the most effective and careful management of the resource. One size does not fit all when it comes to groundwater management.

California is known for its diverse ecosystems, topography and geology and for its highly variable water resources. With more than 38 million people and a land area of 100 million acres, California is the most populous state and the third-largest geographically in the country. It is also the most productive agricultural state, producing over half the fruits, nuts and vegetables in the nation.

In 2000, an average water year, California cities and suburbs used about 8.9 million acre-feet (MAF) of water. California agriculture irrigated 9.6 million acres of cropland (includes multi-cropping) using roughly 34 MAF of applied water. Dedicated environmental uses of water, including in-stream flows, wild and scenic flows, required Delta outflow, and managed wetlands, exceeded 39 MAF.[2]

In an average year (based on 1998-2005 data), groundwater resources supply about 35 percent of California's urban, agricultural and managed wetlands water demands (about 15 million acre-feet per year).[3] In dry years, this percentage increases to 40 percent or higher statewide and as high as 60 percent or more in some regions. Nearly half of California's drinking water supply comes from groundwater.

In addition to contributing essential water supplies, the state's groundwater basins provide significant water storage capacity. This storage capability is important in and of itself, but when used in conjunction with surface water storage it can go a long way toward meeting local and regional needs for greater flexibility, increased water supply reliability and improved water quality. This potential is limited, however, by current regulatory and infrastructure constraints on groundwater recharge and extractions. Optimizing large-scale conjunctive use programs will require investments in both surface and groundwater storage.

APPLIED WATER VS. CONSUMPTIVE USE

According to the California Department of Water Resources, applied water is the amount of water from any source needed to meet the demand for beneficial use by the user. It includes consumptive use, reuse, and outflows. Consumptive use is a quantity of applied water that is not available for immediate or economical reuse. It includes water that evaporates, transpires, or is incorporated into products, plant tissue, or animal tissue. Consumptively used water is removed from available supplies without return to a water resource system (uses such as manufacturing, agriculture, landscaping, food preparation, and in the case of Colorado River water, water that is not returned to the river.)*

*DWR California Water Plan Update 2005 http://www.waterplan.water.ca.gov/docs/cwpu2005/vol2/v2glossary.pdf

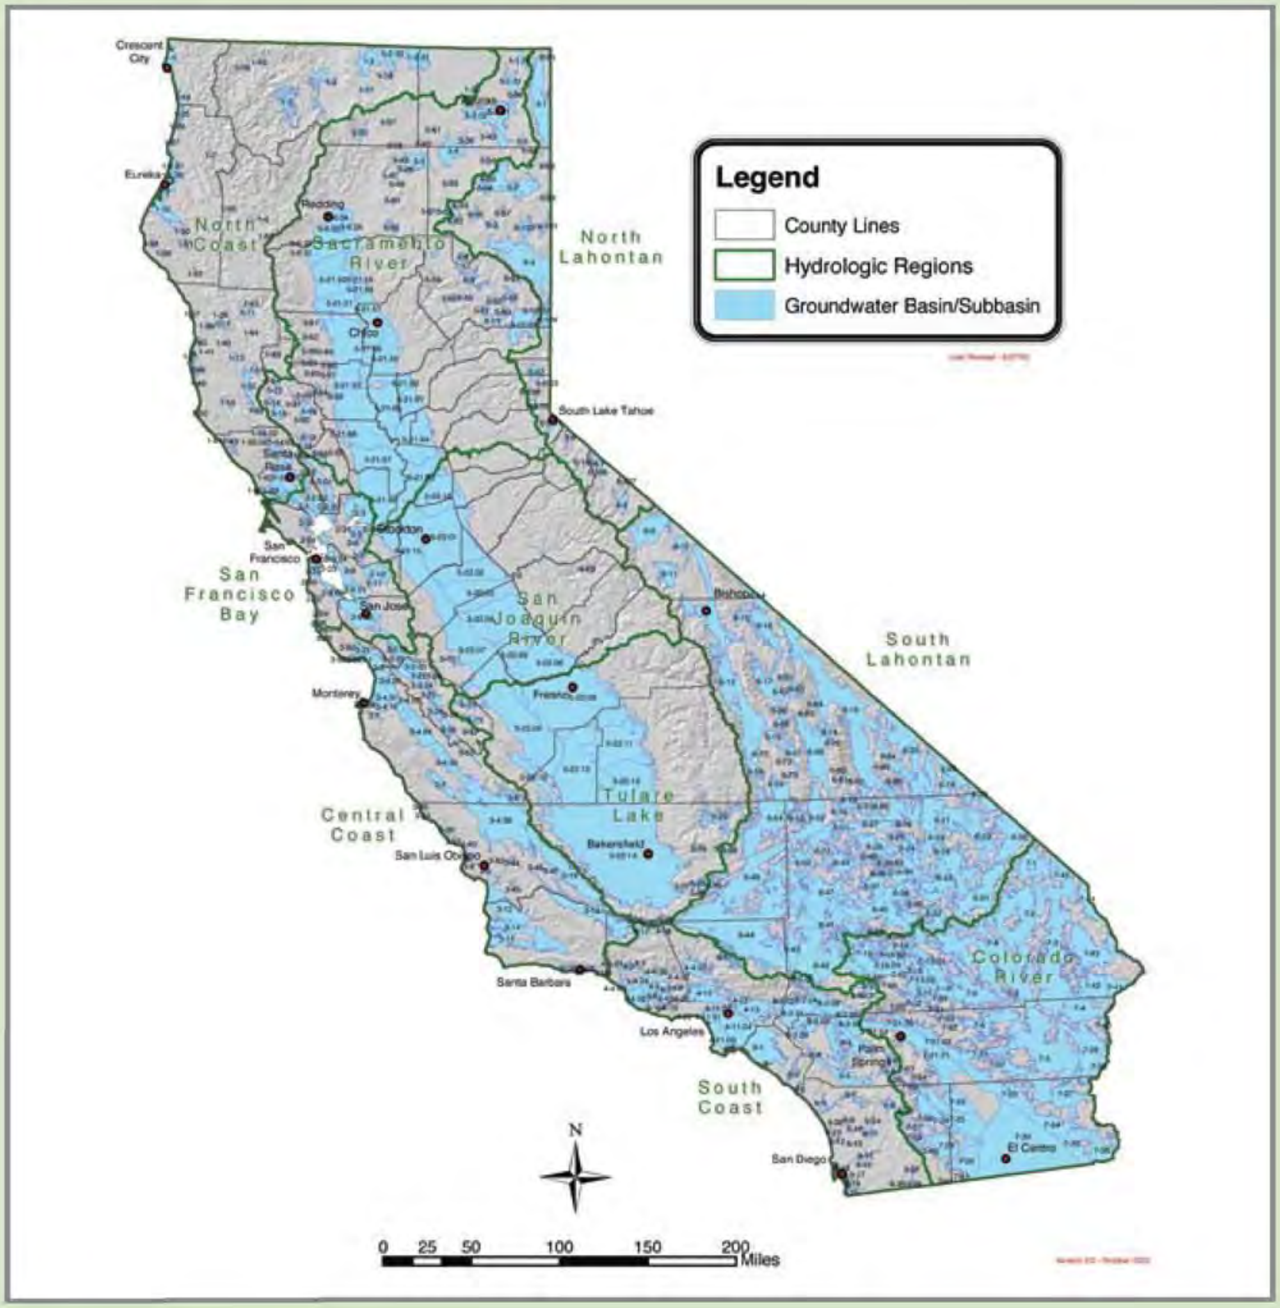
WHERE DOES GROUNDWATER COME FROM?

Much of the water from snowmelt and rain that flows into surface water formations (e.g. creeks, streams, rivers, ponds) percolates into the ground and becomes groundwater. Groundwater can be thousands of years old, but most of the groundwater typically used in California today is extracted a few years to a few decades after its original percolation.

Groundwater is found in two main types of geologic settings in California. The vast majority of groundwater in the state is stored in alluvial basins, which are composed of sediments such as gravel, sand, silt or clay and cover nearly 40 percent of the geographic area of the state. Alluvial basins account for all 515 basins and sub-basins identified in DWR's Bulletin 118. (http://www.water.ca.gov/pubs/groundwater/bulletin_118)

However, groundwater is also stored and extracted from fractured bedrock or sandstone. About 20 percent of the state's municipal supply wells are located in this type of formation, with prime examples found in the Sierra Nevada and the Coast Ranges.

Groundwater Basins in California



Water Supply Infrastructure: Key to Meeting Needs

Precipitation in California varies widely—from place to place, from season to season, and from year to year. Wet years can bring the threat of floods, while dry years can reduce available water supplies and require the temporary draw-down of stored water. This unpredictable hydrology affects not only the amount of surface water available in a given year but also the amount of groundwater available for extraction and use.

The state's water storage and delivery infrastructure was designed to address that unpredictability, protecting communities from floods and capturing winter precipitation and spring snowmelt for strategic delivery in the drier summer and fall months. The system also contributes to effective groundwater management by providing surface water to augment local supply sources and alleviate pressure on groundwater basins.

California's two largest water delivery systems are the State Water Project (SWP) and the federal Central Valley Project (CVP). The SWP, operated by the California Department of Water Resources, delivers water to 25 million Californians and 755,000 acres of irrigated farmland. The CVP, operated by the United States Bureau of Reclamation, provides water for more than 3 million acres of farmland and drinking water to nearly 2 million consumers.

All told, California has nearly 200 surface storage reservoirs with a capacity of 10,000 acre-feet or more, for a combined storage capacity of more than 41 MAF. In addition, there are many other reservoirs smaller than 10,000 acre-feet that are used to manage water for a wide range of uses.

Given the state's highly variable hydrology, surface and groundwater storage facilities are critical to supplying cities, farms, businesses and the environment with adequate water year-round. They are particularly effective when used in concert with each other to make maximum use of water when it's available and store it for use in dry times.

Conjunctive Use: A Critical Part of Sustainable Management

Conjunctive use or management refers to the coordinated and planned use of both surface water and groundwater resources to maximize the availability and reliability of water supplies in a region to meet various management objectives. Since surface water and groundwater resources can differ significantly in their availability, quality, cost and other characteristics, managing both resources together, rather than in isolation from each other, allows water managers to use the advantages of each for maximum benefit.

WHAT IS GROUNDWATER BANKING?

Groundwater banking is a water management tool designed to increase water supply reliability. By using dewatered aquifer space to store water during wet years (when there is abundant rainfall and surplus water available), water can be pumped and used during dry years (when there is little rainfall and no surplus water).

Groundwater banking is accomplished two ways: through in-lieu and direct recharge. In-lieu recharge is storing water by utilizing surface water "in-lieu" of pumping groundwater, thereby storing an equal amount in the groundwater basin. Direct recharge is storing water by allowing it to percolate directly to storage in the groundwater basin.*

CONJUNCTIVE MANAGEMENT OF LOCAL AND IMPORTED WATER SUPPLIES: THE KEY TO A SUSTAINABLE SILICON VALLEY

Graphic courtesy of Santa Clara Valley Water District

The Santa Clara Valley Water District has a long record of conjunctive water management. Established in the late 1920s to address groundwater overdraft and subsidence, the district constructed seven dams by 1935 to impound surface water for recharge into percolation facilities. As the graphic illustrates, the post-war boom brought increased demands for water and the return of unsustainable declines in groundwater elevation. Surface reservoir capacity was quadrupled by constructing four additional reservoirs in the 1950s. In 1965, the district began importing surface water from the State Water Project. Groundwater levels began to recover and the rate of subsidence slowed significantly. The rise of Silicon Valley brought increased demands again, and the district added Central Valley Project deliveries to its supply portfolio in the late 1980s. By the mid-1990s groundwater elevations had returned to levels seen at the turn of the 20th century.

Conjunctive use has been practiced for decades in California. In general, conjunctive use programs take advantage of available groundwater storage capacity to “bank” or store surface water through natural and / or artificial recharge for later extraction and use. In many areas, there is tremendous potential to enhance local supplies even further by utilizing storm flows and recycled water with appropriate safeguards to augment groundwater recharge.

Well-planned conjunctive use programs not only enhance local and regional water supply reliability, but can also provide other benefits such as enhanced flood management, improved environmental water management, reduced reliance on the Delta to meet future water supply needs, and water quality improvements.

Conjunctive use projects require investments in surface storage, conveyance systems, recharge and extraction facilities, and management of groundwater basins. Conveyance systems may include lined and / or unlined canals, pipelines, and streams. Recharge options include direct spreading and infiltration in artificial ponds, injection via wells, and induced natural recharge in natural systems. In the strategy known as in-lieu recharge, surface water can be provided to users who normally use groundwater to allow supplies to stay in groundwater basins.

Groundwater may be extracted later for direct use, for pumping back to conveyance systems, or for surface water exchange.

KEY WATER PROJECTS IN CALIFORNIA

<<<

WHAT ARE SOME OF THE SOURCES FOR CONJUNCTIVE USE PROJECTS?

Imported water – Water that is transferred across hydrologic region boundaries from one agency to another. Many parts of the state receive imported water from the State Water Project and Central Valley Project.

Local surface water – Direct deliveries of water from stream flows, as well as water supplies from local storage facilities.

Recycled water – Municipal, industrial, or agricultural wastewater that is treated to produce water that can be reused.

Reclaimed water – Treated water where the inflow water supply is polluted, contaminated, or otherwise tainted.

Desalinated water – Water that has been treated to remove salt for beneficial use. Source water can be brackish (low salinity) or seawater.

Stormwater (runoff) – Water that collects during a precipitation event and may carry pollutants to water courses, causing degradation.*

*For more information, please see Bulletin 160 Water Plan Update 2009 Glossary (http://www.waterplan.water.ca.gov/docs/cwpu2009/0310final/v4c01ag_cwp2009.pdf)

The Current Regulatory Landscape

California is often criticized for being one of the only Western states without a formal state-administered system of regulating and permitting groundwater use. But while it is true there is no *centralized* system to regulate the use of groundwater, California has developed and refined an effective system of locally controlled groundwater management over the past century.

As noted by the California Legislative Analyst's Office[4], the current system has been successful in addressing the state's most difficult groundwater management problems over the years. The growing list of challenges on the horizon, however, will demand more of local agencies and require a greater commitment to ensuring that local decisions and management contribute to achieving statewide water policy goals.

To that end, ACWA is confident that, with certain modifications recommended in this Framework, local agencies can provide sustainable groundwater management for the benefit of California without the addition of new layers of state bureaucracy or regulation.

Basic Legal Principles Set Foundation

As a general rule, landowners in California are entitled to pump and use a reasonable amount of groundwater from a basin underlying their land. Under the doctrine known as "correlative rights," landowners overlying a common source of groundwater are limited to using a reasonable share, typically based on the amount of overlying land owned by each and the physical condition of the basin. When there is insufficient water to meet the demands of overlying landowners, those users are expected to reduce their demands correlatively to bring their groundwater extractions within the safe yield of the basin and prevent overdraft.

Entities other than overlying users, such as cities, may be entitled to "appropriate" water from the basin for use as a municipal supply when water surplus to the needs of overlying users is available. Unless otherwise prescribed, appropriators must curtail their use when there is no surplus.

As the above paragraphs suggest, the interrelated concepts of "safe yield," "surplus" and "overdraft" are central elements in the legal landscape addressing California groundwater. As defined by the California Supreme Court in the landmark *Los Angeles v. San Fernando* case in 1975, "safe yield" refers to "the maximum quantity of water which can be withdrawn annually from a groundwater supply under a given set of conditions without causing an undesirable result." The phrase "undesirable result" is understood to refer to "a gradual lowering of the groundwater levels resulting eventually in depletion of the supply." "Surplus" refers to "the amount of water in a groundwater basin in excess of safe yield." *City of Los Angeles v. City of San Fernando* (1975) 14 Cal.3d at 278.

The *San Fernando* court also clarified that an overdraft occurs only when extractions exceed safe yield plus "temporary surplus," the latter term defined as the amount of water that can be pumped from a basin to provide storage space for surface water that would otherwise be lost during wet years if it could not be stored in the basin. *Id.* at 279.

Recognizing Interplay Between Surface Water and Groundwater

Though surface water and groundwater are often interconnected from a hydrologic perspective, they are generally managed and regulated through separate legal regimes in California. The Legislative Analyst's Office and others have called for California's groundwater law to be "modernized" to better reflect the well-established physical connection between groundwater and surface water in many areas.

That recommendation fails to consider, however, that California has a long and reasonably well-developed history of successfully integrating the use of surface water and groundwater, despite the existence of two different legal regimes. Though this "dual system" may not always appear neat and orderly, case law is sufficiently well-developed to suggest that California courts are fully aware of the interplay between surface water and groundwater in specific instances and have crafted legal doctrines to address those hydrologic realities.

A LOOK AT LEGAL CASES OVER THE YEARS

Under California law, water is characterized as being surface water or groundwater. Groundwater is further classified as either a subterranean stream or as percolating groundwater. Surface water and groundwater classified as a subterranean stream are subject to the permitting authority of the State Water Resources Control Board, while groundwater classified as percolating groundwater is not subject to that authority.

In areas where there is a hydrologic connection between groundwater and surface water resources, a number of early cases established the legal rules for interconnected surface water and groundwater systems. These rules form the foundation of groundwater management today.

Potential Interference by Groundwater Pumpers with Surface Water Rights

Case Information	Result
City of Los Angeles v. Hunter (1909) 156 Cal. 603, 607; *McClintock v. Hudson* (1903) 141 Cal. 275, 278; *Los Angeles v. Pomeroy* (1899) 124 Cal. 597, 624.	Found that a user of percolating groundwater may diminish flows in a surface stream only if the groundwater is put to reasonable use on lands overlying the groundwater basin.
Hudson v. Dailey (1909) 156 Cal. 617, 624-627.	Virtually ignores the distinction between riparian rights to surface water and correlative rights to groundwater in finding a right to extract groundwater for use on overlying lands despite impacts on downstream riparians and downgradient overlying pumpers.
Barton Land & Water Co. v. Crafton Water Co. (1915) 171 Cal. 89, 94-95.	Owner of lands overlying a subterranean stream cannot extract water from that stream so as to have an adverse impact on surface water diverters.

Potential Interference by Surface Water Diverters with Groundwater Rights

Case Information	Result
Miller v. Bay Cities Water Co. (1910) 157 Cal. 256, 276-279 (overruled on other grounds in *City of Lodi v. East Bay Municipal District* (1936) 7 Cal.2d 316, 338-339).	California Supreme Court decision that articulated a broad standard protecting the owner of percolating groundwater from surface appropriations of water on non-riparian lands
United States v. Fallbrook Pub. Util. Dist. (S.D. Cal. 1958) 165 F.Supp. 806, 847 (citing *McClintock*, 141 Cal. at 281; *Hudson*, 156 Cal. at 628).	Federal district court decision that found riparian and overlying rights are treated as extracting water from one common source and so have joint rights to reasonable shares of the resource.

Challenges to Sustainable Groundwater Management

To advance sustainable groundwater management, it is essential to understand the growing list of challenges related to California's groundwater basins.

Addressing these challenges will require comprehensive efforts by local agencies individually and within regional partnerships to develop and implement sustainable groundwater management practices. This brief overview describes a number of factors confounding the management of California's groundwater resources.

Declining Sacramento-San Joaquin Delta

The Sacramento-San Joaquin Delta is the hub of California's two main water delivery systems – the State Water Project and the federal Central Valley Project. Court-ordered restrictions to protect species have significantly reduced deliveries from these projects in recent years. This reduction in surface water supplies has hampered conjunctive use projects in some parts of the state and highlighted the need for more sustainable groundwater management as urban, agricultural and environmental users have turned to local groundwater resources as a substitute for increasingly unreliable SWP and CVP deliveries.

Periodic, Inevitable Droughts

The southwestern United States, including California, is prone to periodic droughts. Most recently, three consecutive dry years from 2006-2009 resulted in some of the driest conditions in decades and reduced water storage in key reservoirs to record lows. Regulatory restrictions on SWP and CVP deliveries magnified the impacts of this natural drought.

Prolonged drought has multiple effects on groundwater resources and management. The lack of available surface water can place additional demands on groundwater basins. Less surface water also means less water available for groundwater recharge. If groundwater levels drop as a result of increased demand or reduced recharge, there are additional energy costs to pump groundwater and greater potential for overdraft conditions. Further, the strategic value of conjunctive use projects that rely on surface water reliability can be undermined.

Changing Climate

Climate change will exacerbate the existing water management challenges facing California, including those affecting groundwater resources. Possible consequences include more frequent drought periods, reduced snowpack in the Sierra Nevada, increased flooding intensity as well as impacts to the operation of the state's surface storage facilities.[5] Higher temperatures, particularly in inland areas, could lead to increased demands on water supplies for urban, agricultural and environmental uses.

Changes in rainfall patterns could also result in faster local runoff and reduced natural groundwater recharge. Collectively, these impacts could result in less reliable water supplies and an overall increase in the demand for groundwater supplies.

---

[5] ACWA Policy Principles on Climate Change. March 2010.

"HIGHER HIGHS, LOWER LOWS"

Based upon historical data and modeling, DWR projects that the Sierra snowpack will decline by 25 percent to 40 percent from its historic average by 2050. Climate change is also anticipated to bring warmer storms that result in less snowfall at lower elevations, reducing the total snowpack.* These storm events will, however, increase peak flows and affect the length of the recharge and recovery cycle of reservoirs that is critical to effective conjunctive use projects.

* California Department of Water Resources. *Managing an Uncertain Future: Climate Change Adaptation Strategies for California's Water.* October 2008.

Unmanaged Overdraft and Subsidence

Overdraft is defined as the condition of a groundwater basin when the amount of water withdrawn by pumping over the long term exceeds the amount of water that recharges the basin, either through natural or artificial methods. A basin in overdraft tends to not fully recover, even in wet years. While the occasional extraction of groundwater in amounts greater than annual recharge can be part of an effective groundwater management plan, unmanaged or excessive extractions can result in land subsidence, water quality degradation, and environmental impacts.

Protracted Drought on the Colorado River

The Colorado River is a key source of water for seven states and Mexico, providing water for some 30 million people to drink and meet household needs, irrigate crops and urban landscapes, operate businesses and replenish groundwater basins. California's annual allocation is 4.4 MAF for irrigation and domestic uses. The Colorado River Basin is in the midst of a multi-year drought that has reduced reservoir storage to record-low levels. These conditions are affecting the reliability of Colorado River supplies for conjunctive use projects and other beneficial uses throughout Southern California. Climate change is expected to further diminish the reliability of deliveries to California.

Aging System and Maintenance Backlog

California has not made significant investments in its backbone water storage and delivery systems, the SWP and CVP, in more than 40 years. In addition, several key components of the projects as originally planned were never built. Constructed when the state's population was just 18 million, the projects are struggling to meet the needs of 38 million Californians today. They also lack the flexibility to meet 21st century demands for both ecosystem health and water supply reliability. These aging facilities also suffer from a backlog of maintenance and repair needs arising from budget and contracting constraints.

Further complicating the effective maintenance of the state's water infrastructure is the growing number of issues related to an aging workforce. It is becoming increasingly difficult to secure professionals for policy and technical positions (such as engineers and water treatment operators), particularly those with extensive experience in California's water industry. As those individuals with expertise begin to retire en masse or find employment elsewhere, effective operation of the state's complex water infrastructure will further erode.

As a result of the increasing physical and workforce limitations, contractual and historic water delivery expectations are not being met and the existing facilities have neither the capacity nor flexibility to adapt to the approaching challenges presented by climate change. The deterioration of the delivery capabilities and reliability of this surface water infrastructure has resulted in, and will continue to contribute to, reductions in the amount of supply available for effective recharge and increasing demands for already-stressed groundwater resources.

At the local and regional level, efforts to maintain and upgrade facilities can be constrained by factors such as Propositions 218, which limits the ability of local agencies to raise rates and fees for a variety of projects and purposes. In addition, the practice of restricting bond funds solely for new construction and not for retrofitting and major maintenance needs can undermine past investments by allowing the foundation upon which they rely to crumble.

Groundwater Quality Degradation

Groundwater quality degradation has become a significant challenge for agencies that manage groundwater. Though groundwater quality can be affected by many factors, some of the most significant threats include chemical contaminants, both naturally occurring and man-made, salinity (including seawater intrusion), landfills and other hazardous waste sites. When groundwater quality is compromised, it may become unsafe for consumption or other uses and it can, without remediation, render the basin unfit for conjunctive use and artificial recharge projects.

Efforts to remediate groundwater contamination can be complicated by a number of issues. Under current law, local agencies that wish to initiate a remediation effort can face numerous disincentives that can hinder or even prevent a proactive approach. Difficulties related to liability, water quality standards, anti-degradation versus non-degradation concerns, assignment of costs and other factors are impediments to clean-up efforts.

Limited Data Collection, Interpretation and Use

In many areas, the lack of a comprehensive approach to systematically managing data on California's groundwater resources is a considerable challenge to sustainable groundwater development. Due to inadequate funding, a comprehensive assessment of groundwater level trends in California's groundwater basins has not been conducted since 1980. While some data is collected through ongoing efforts such as the Groundwater Level and Quality Monitoring Program (DWR), the Groundwater Ambient Monitoring and Assessment (GAMA) Program (administered by the U.S. Geological Survey under contract to the State Water Resources Control Board), and the U.S. Geological Survey Groundwater Information Program, these initiatives are weakened by their limited geographic scope. DWR and the

HOW DOES LAND SUBSIDENCE OCCUR?

Land subsidence is the gradual settling or sudden sinking of the Earth's surface due to changes that take place underground. This movement of earth can be the result of many factors, including groundwater extraction. In some types of groundwater basins, water that is pumped to the surface is drawn from spaces between sand and gravel. In addition, layers of clay can contain large amounts of water, and water pressure in the surrounding aquifer keeps the clay particles slightly apart from each other. When the water pressure in such a basin drops due to extensive pumping, the clay particles are pushed together by the weight of the overlying sediments, which is no longer in equilibrium with the (now lower) water pressure. As clay particles are pressed together for lack of water pressure, water drains out of the clay and the clay layers become compressed (thinner).

The effect of thinner clay layers is seen as a lowering of the land surface – sometimes as much as 20 or 30 feet over the course of a few decades. The lowering of land surface elevation from this process is permanent. Effective groundwater management utilizes the storage capabilities of groundwater basins while preventing significant subsidence from occurring. More information can be found at http://www.water.ca.gov/groundwater/well_info_and_other/land_subsidence.cfm, http://geochange.er.usgs.gov/sw/changes/anthropogenic/subside/.

SWRCB do not adequately coordinate their statewide monitoring efforts. This lack of comprehensive data management will continue to hinder the ability of local and regional agencies to optimize the use of California's groundwater resources.

Small System Vulnerability

Small community water systems, including many that serve disadvantaged populations, can face unique management challenges not shared by their larger counterparts. Such systems that are dependent on groundwater and / or private wells are especially vulnerable to drought and the effects of climate change because they are typically located in isolated areas with few opportunities for interconnections with other systems, water transfers, or emergency relief. This can also make it more challenging to develop successful conjunctive use programs or implement costly water quality treatment technologies.

Fragmented Regulations

California has a multifaceted and complex regulatory structure. Numerous agencies have jurisdiction over various aspects of groundwater recharge and banking projects, particularly those involving underground storage supplements (USS) and aquifer storage and recovery (ASR). Regulations governing these projects tend to be fragmented, duplicative or unnecessarily complicated. Often-conflicting regulatory requirements affecting the same basin or water supply can also slow or even stall progress on critical projects.

Mounting Environmental Requirements

In addition to a complicated regulatory landscape, local water agencies must adhere to an array of environmental statutes as they plan, develop and operate projects. The California Environmental Quality Act (CEQA), for example, adds numerous layers and requirements that can be a hurdle to moving projects forward. Depending on how they are implemented, the state and federal Endangered Species Acts can also affect development and operation of projects, sometimes at great cost to water supplies. Loss of surface water supplies as a result of environmental regulations can result in greater short-term reliance on groundwater, often with long-term ramifications.

Land Use Decisions and Population Growth

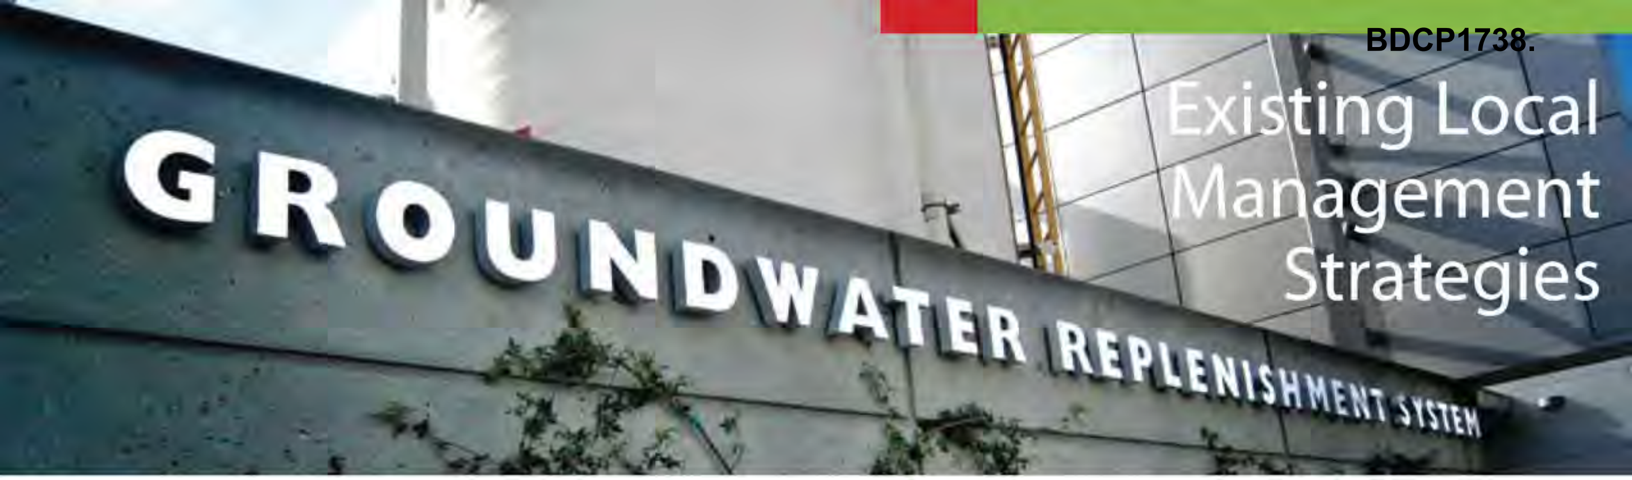
Population growth and commercial development continue to put pressure on resources throughout California. As competition increases for a limited amount of developable land, the need to retain adequate groundwater recharge capability is often overlooked in decisions affecting land use. Activities such as paving and development change the absorption capacity of land, thereby reducing opportunities for natural recharge. In some watershed areas, forestry practices affect in-stream recharge by contributing to siltation, which blocks the absorption capability of creek and river bottoms.

Land use policies and regulations that fail to consider and protect natural and artificial recharge and extraction capabilities create long-term challenges for successful sustainable groundwater management, including permanent reductions in permeable acreage, water quality degradation and land subsidence. Such policies can also exacerbate problems associated with management of stormwater runoff.

CONJUNCTIVE USE OPERATIONS AND "OVERDRAFT"

An increasingly common practice in California is to operate a groundwater basin in conjunction with available surface water supplies on a local or regional level. The practice involves exercising the basin, a process that causes the groundwater level to go up and down with wet and dry annual and periodic cycles. During the wet season and during wetter years, surface water is relied on more and the groundwater basin is recharged with surplus surface water, from local and / or imported sources, resulting in groundwater level increases. Such recharge occurs through direct means via spreading basins or in-lieu via surface deliveries that otherwise offset groundwater pumping. During dry years, when less surface water is available, groundwater is relied on more, drawing the groundwater levels down.

In the event of a periodic drought lasting several years, when less surface water is available and groundwater is used more extensively to meet demands, groundwater level trends can sometimes decline quite dramatically without any notable recovery for a longer period of time. The groundwater level trend in a conjunctively managed basin over a period of several years during a drought may appear as long-term overdraft; however, some would refer to this as "managed overdraft" as the downward trend will be offset by recovery cycles in wetter periods utilizing the direct or in-lieu groundwater recharge methods.



Existing Local Management Strategies

California relies on a variety of mechanisms to promote the local control and management of groundwater resources. Since the earliest efforts to manage California's groundwater, the effectiveness and complexity of these strategies has continued to evolve with changing urban and environmental needs and conditions.

As previously noted, every groundwater basin in California presents unique physical and hydrogeological characteristics. In addition, each basin has unique beneficial uses dependent upon water quality, water rights, number and breadth of stakeholders, institutional type and complexity, and other features.[6]

Locally-controlled groundwater management is effective because local and regional entities are the most knowledgeable about their local basins and tend to be the first to notice changes or problems. They are also best suited to address issues unique to their region, including the implementation of proactive plans and actions to meet current and future groundwater needs.

Since local stakeholders and management agencies receive the direct benefits of sustainable management, they are more inclined to support investments in local infrastructure and water quality projects, which in turn leads to more consistent implementation of improvements. Local agencies are also in the best position to identify and assess the consequences of over-reliance on groundwater resources and to evaluate options for improved management. While a certain degree of coordination with the state is important, particularly with regard to data management and funding, one-size-fits-all mandates and uniform statewide protocols tend to be counterproductive because they do not recognize the significant differences in California groundwater basins.

Basic Management Mechanisms

As noted in the Department of Water Resources' California Groundwater Bulletin 118[7], there are three basic mechanisms available for managing groundwater resources in California. These mechanisms include: 1) management by local agencies under authority granted by state statute; 2) coordinated agreements and ordinances; and 3) court adjudications.

Local and regional agencies employ a variety of successful management strategies under these mechanisms, reflecting the diversity of the state's groundwater basins and the diverse beneficial uses of water from those basins. Examples can be found on pages 22 and 23. Financial support and incentives at the state and local levels have also contributed to the success of local and regional groundwater management plans. State policy makers can play a key role in promoting these efforts by providing consistent support and assistance through legislation and funding. Propositions 204, 13, 50 and 84 are examples of this constructive support.

Local Management under Authority Granted by State Statute

Many local water agencies are authorized by statute to institute and conduct some form of groundwater management. Agencies formed under the Water Replenishment District Act and the Water Conservation District Act, for example, are authorized to carry out groundwater replenishment programs and assess fees to pay for groundwater management programs.

FINANCIAL SUPPORT FOR LOCAL GROUNDWATER MANAGEMENT

The California Legislature and voters have approved several propositions that included funding for groundwater quality remediation or local and regional management. The following are the most recent and largest allocations:

The Safe, Clean, Reliable Water Supply Act of 1996 (Proposition 204)

This measure authorized the state to sell $995 million in general obligation bonds for the purposes of restoration and improvement of the Bay-Delta; wastewater treatment, water supply and conservation; and local flood control and prevention. Funds were included in Proposition 204 for a water conservation and groundwater recharge loan program ($30 million) and local water supply development and environmental mitigation ($25 million).

The Safe Drinking Water, Clean Water, Watershed Protection and Flood Protection Act of 2000 (Proposition 13)

Proposition 13 was a $1.97 billion general obligation bond with $230 million earmarked for groundwater programs. The act authorized $200 million for grants for feasibility studies, project design, and construction of conjunctive use facilities (Water Code, § 79170 et seq.) and $30 million in loans for local agency acquisition and construction of groundwater recharge facilities and feasibility study grants for projects potentially eligible for the loan program (Water Code, § 79161 et seq.).

Water Security, Clean Drinking Water, Coastal and Beach Protection Act of 2002 (Proposition 50)

California voters approved the Water Security, Clean Drinking Water, Coastal and Beach Protection Act of 2002 (Proposition 50; Water Code, § 79500 et seq.), which provided for more than $3.4 billion in funding, subject to appropriation by the Legislature, for a number of land protection, water quality and water management activities. Proposition 50 provided $500 million for integrated regional water management, water management projects that will protect communities from drought, protect and improve water quality, and reduce dependence on imported water supplies.

The Safe Drinking Water, Water Quality and Supply, Flood Control, River and Coastal Protection Bond Act of 2006 (Proposition 84)

Proposition 84 authorized $5.488 billion in general obligation bonds to fund safe drinking water, water quality and supply, flood control, waterway and natural resource protection, water pollution and contamination control, state and local park improvements, public access to natural resources, and water conservation efforts. Within Proposition 84 is $60 million for projects that prevent or reduce groundwater contamination, and $1 billion for integrated regional water management (IRWM) planning and implementation.

*Note: The 2009 legislative package included an $11.14 billion water bond (set for the November 2012 ballot) with additional funding for groundwater activities. See page 28 for more on the package.

Currently, 13 local agencies throughout California have specific authority under special legislation to limit or regulate groundwater extraction.

AB 3030 Plans

The Groundwater Management Planning Act, commonly known as AB 3030, greatly expanded the number of local agencies with authority and responsibility over groundwater resources. The act, which became effective in January 1993, was aimed at encouraging more effective local management as an alternative to establishing a state-administered groundwater management structure. AB 3030 was developed by ACWA and its Groundwater Committee, partially in response to the U.S. Environmental Protection Agency's Comprehensive State Ground Water Protection Program (CSGWPP), which promoted comprehensive groundwater quality management on the state level with EPA providing proposed oversight and coordinated funding.

After the passage of AB 3030, many water agencies developed voluntary "3030" plans and significantly increased their involvement in groundwater management. As of 2003, more than 200 agencies have adopted an AB 3030 groundwater management plan.[8] This legislation was a big step forward in formalizing and supporting the local management of groundwater in California. Some plans prepared under its provisions, however, have suffered from little or no implementation, while others have focused primarily on limiting exports of groundwater to other regions, rather than incorporating all elements of a comprehensive management program.

---

[8] California Department of Water Resources. *California's Groundwater, Bulletin 118 - Update 2003: Ch. 2.* (http://www.water.ca.gov/pubs/groundwater/bulletin_118/california%27s_groundwater__bulletin_118_-_update_2003_/bulletin118-chapter2.pdf)

SB 1938 Groundwater Management Programs

In 2002, the Legislature passed SB 1938. This statute provides additional direction and technical guidance to local agencies for developing groundwater management plans and requires the inclusion of basin management objectives relative to groundwater quantity and quality, subsidence and monitoring programs. SB 1938 also requires agencies to have a groundwater management plan that meets certain requirements in order to be eligible for any state grant or loan programs for groundwater projects.

Building upon the positive elements of AB 3030, SB 1938's passage strengthened the effectiveness of groundwater management plans in California. Many agencies have supplemented their existing plans by incorporating the bill's new provisions or are developing entirely new SB 1938 plans to not only sustain the resource but also to ensure eligibility for state grants or loans.

AB 3030 and SB 1938 plans have provided the basis for action and progress. Under the Local Groundwater Assistance Program (AB 303), DWR awarded nearly $28 million in grants between 2000 and 2005 to local agencies to conduct 128 projects involving groundwater management plans or related activities.[9]

DWR also distributed $205 million in funds from Proposition 13 to groundwater recharge and storage feasibility studies, pilot projects and construction projects between 2000 and 2004, with the total value of those efforts (when combined with leveraged local dollars) totaling over $1 billion. Primary benefits from these activities were enhanced groundwater management and improved water supply reliability, but there have been other benefits as well, including improved drinking water quality, groundwater protection, reduced wastewater discharges, dedicated environmental water and improved habitat / wetlands restoration. It is estimated that these projects provide an additional 300,000 acre-feet per year to local California water supplies.[10]

More recent water bond measures have also included funding to support local groundwater management programs. When distributed, that funding will assist local management entities to ensure further progress in the implementation of their plans.

Groundwater management plans developed under AB 3030 and SB 1938 are among the most effective and widely used management techniques in California. As noted, more than 200 plans have been implemented throughout the state. Entities implementing this type of management are also best prepared to work with state agencies as elevation data is collected pursuant to the new requirements of SBX7 6, enacted as part of the 2009 comprehensive legislative package on water. The comprehensive structure of AB 3030 and SB 1938 plans provides a vehicle to simultaneously provide effective management now and into the future while remaining focused on local hydrologic and economic conditions.

Integrated Regional Water Management Plans (IRWMPs)

Proposition 50's passage in 2002 provided additional grants and matching funding for local projects consistent with the new integrated regional water management plan (IRWMP) initiative. IRWMPs require various local entities to

COMMON CHARACTERISTICS OF SUCCESSFUL GROUNDWATER MANAGEMENT

Elinor Ostrom, who recently won the Nobel Prize in Economics for her work on local governments' management of natural resources, identified a number of characteristics shared by successful efforts to manage groundwater resources. These characteristics include: (i) clearly defined boundaries, both in area and in participants; (ii) rules that are tailored to the local circumstances; (iii) local governance; (iv) active monitoring for compliance with adopted rules; (v) graduated sanctions for violations of those rules; (vi) conflict resolution mechanism within the institution; and (vii) support for local institutions by external governments.*

Case Studies in Effective Local Groundwater Mar

Glenn County Groundwater Management Plan
Structure: Groundwater Ordinance

Utilizing a mission and goals statement and a memorandum of understanding (MOU) among local stakeholders, the Glenn County Board of Supervisors adopted a groundwater ordinance in 2000. The ordinance builds on earlier work by a water advisory committee and identifies basin management objectives in key areas to help overcome challenges associated with defining safe yield and overdraft in the Sacramento Valley. Instead of a "one-size-fits-all" approach, the ordinance calls for management objectives to be set for minimum groundwater levels, minimum water quality and maximum subsidence for each of 17 sub-areas in the basin. The creation of the advisory committee, adoption of the ordinance and the subsequent adoption of a Four County MOU in 2006 have led to increased coordination and improved water resources understanding at the county and regional level. An Integrated Regional Water Management Planning process is also under way. (www.glenncountywater.org/management_plan.aspx)

Sonoma Valley Groundwater Management Program
Structure: AB 3030 / SB 1938 Plan

With a primary goal of sustaining groundwater resources for future generations, the Sonoma Valley Groundwater Management Program centers on an SB 1938-compliant plan adopted in 2007. The program includes four main management strategies: conservation, recycled water use to offset groundwater pumping, use of stormwater to recharge groundwater, and banking of winter Russian River water to recharge the basin. Cooperative efforts have helped to bring stakeholders together, while information gathered from the expansion of a voluntary groundwater-level monitoring program has led to increased understanding of the basin hydrogeology, improved public awareness, and better planning. Initiation of a groundwater banking feasibility study, a flood control / groundwater recharge study, and development of a guidebook for homeowners to better manage stormwater are expected to yield broader benefits such as reducing localized groundwater depressions and minimizing or eliminating seawater intrusion. (www.scwa.ca.gov)

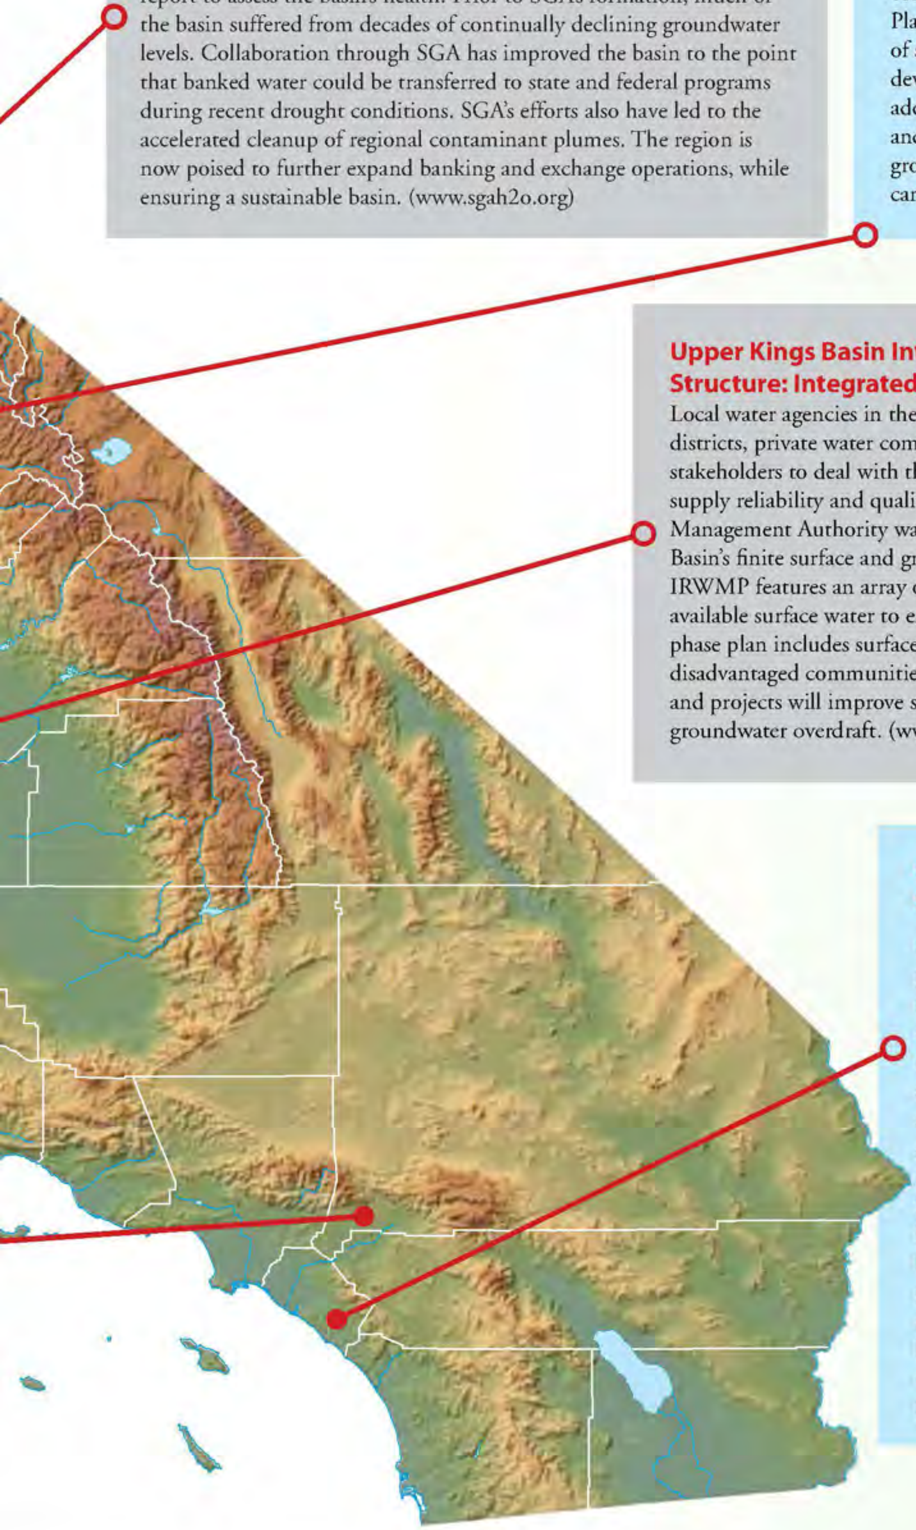
Soquel-Aptos Area Groundwater Management Plan
Structure: AB 3030 / SB 1938 Plan

Soquel Creek Water District, Central Water District, the City of Santa Cruz Water Department and the County of Santa Cruz are working cooperatively to manage resources and prevent seawater intrusion. The program centers on activities to limit water demand, maintain groundwater extractions within sustainable quantities, and closely monitor changes in all or part of four groundwater basins. Efforts include aggressive conservation, conjunctive use, and development of a seawater desalination project that will provide water for in-lieu recharge. Cooperative groundwater management has slowed the decline of coastal water levels by collectively reducing demand and reducing pumping toward sustainable levels. Opportunities for interagency projects are identified through regular communications and a collaborative approach. Projects that could not have been undertaken by any one agency are being jointly funded through cost-sharing agreements and / or Integrated Regional Water Management grant funding. (www.soquelcreekwater.org/content/groundwater-management-plan)

Chino Basin Watermaster
Structure: Adjudicated Basin

The Chino Basin Watermaster manages the Chino groundwater basin under a 1978 court judgment. Through its Optimum Basin Management Program (OBMP), the watermaster monitors production, recharge, groundwater levels, water quality and subsidence. The watermaster also carries out stormwater and supplemental water recharge activities that have increased recharge capacity by 140,000 acre-feet per year to date. Other initiatives include local and regional conjunctive use programs totaling 500,000 acre-feet, salt and nutrient management, operation of groundwater desalting facilities that produce 29,000 acre-feet of drinking water per year (soon to be expanded to 37,000 acre-feet), and 60,000 acre-feet of recycled water reuse. The OBMP has enhanced the sustainable yield of the basin, improved water supply reliability as well as water quality, reduced subsidence, and expanded the direct use and recharge of recycled water. It has also reduced demand for imported water from the State Water Project and the Colorado River. (www.cbwm.org)

agement in California



Sacramento Groundwater Authority
Structure: Joint Powers Authority

SGA draws its authority from a 1998 agreement between the cities of Sacramento, Citrus Heights, Folsom, and the County of Sacramento to utilize their common police powers to protect the basin. Through its SB1938-compliant groundwater management plan and a comprehensive update completed in 2008, SGA has developed a dedicated monitoring well network, a regional groundwater model, a comprehensive groundwater database, and a biennial basin management report to assess the basin's health. Prior to SGA's formation, much of the basin suffered from decades of continually declining groundwater levels. Collaboration through SGA has improved the basin to the point that banked water could be transferred to state and federal programs during recent drought conditions. SGA's efforts also have led to the accelerated cleanup of regional contaminant plumes. The region is now poised to further expand banking and exchange operations, while ensuring a sustainable basin. (www.sgah2o.org)

Zone 7 Water Agency
Structure: AB 3030 Plan

Zone 7 Water Agency has actively managed the Livermore Valley Groundwater Basin for more than 40 years for municipal water supply. It began importing State Water Project water into the watershed in 1962 to reduce groundwater extractions that had left the basin in overdraft. Soon after, the district began artificially recharging the basin by using local "losing" streams to convey and percolate imported water. It continues to manage the basin conjunctively through a comprehensive Groundwater Management Plan that incorporates salinity management to offset the addition of salts from imported and recycled water. Plans are being developed to augment the district's artificial recharge capacity by adding nine aggregate quarry pits that will be used as water storage and aquifer recharge basins. Through its efforts, Zone 7 has curbed groundwater pumping and replenished basin aquifers to levels that can be managed sustainably. (www.zone7water.com)

Upper Kings Basin Integrated Regional Water Management Authority
Structure: Integrated Regional Water Management Plan

Local water agencies in the Kings Groundwater Basin have created a coalition of water districts, private water companies, cities, counties, environmental interests, and other stakeholders to deal with the most pressing local water issues—groundwater depletion, supply reliability and quality. The Upper Kings Basin Integrated Regional Water Management Authority was formed in 2009 to create a sustainable supply of the Kings Basin's finite surface and groundwater resources through balanced regional planning. The IRWMP features an array of projects, including groundwater banking facilities to capture available surface water to enhance local groundwater levels and water quality. A second-phase plan includes surface water exchanges and a groundwater treatment plant to serve disadvantaged communities currently using water of lesser quality. Regional planning and projects will improve supply reliability in dry years and mitigate the Kings Basin's groundwater overdraft. (www.krcd.org/water/ukbirwma)

Orange County Water District
Structure: Special District Act

OCWD was the first agency in California to adopt a groundwater management plan. Originally adopted in 1989, the plan was updated most recently in 2009. In addition to operating one of the most advanced groundwater recharge and monitoring systems in the nation, OCWD manages the largest constructed wetlands in Southern California to naturally filter and clean Santa Ana River flows before entering the recharge area. The district has an active groundwater conjunctive use storage agreement with Metropolitan Water District of Southern California and has constructed the largest planned indirect potable reuse project in the world, the Groundwater Replenishment System, which provides 72,000 acre-feet per year of highly purified water for an expanded seawater barrier and recharge to the aquifer. Successful management of the basin has helped reduce the region's reliance on imported water from Northern California and the Colorado River. (www.ocwd.com) work collaboratively within a region to develop common water resources management goals and objectives through a transparent process including public involvement. These standards include a list of water management strategies and objectives, including surface and groundwater management, water quality protection and improvement, recycled water and desalination (where appropriate).

The intent of the IRWMP program is to encourage integrated regional strategies for management of water resources and to provide funding, through competitive grants, for projects that protect communities from drought and other extreme weather events, ensure sustainable water uses and environmental stewardship, protect and improve water quality, and improve local water security by reducing dependence on imported water.

Similar to the AB 3030 and SB 1938 processes, local and regional stakeholders have collaborated to develop common water resources management goals and objectives. Multiple plans have emerged since 2002, bolstered by over $1 billion in funding from Propositions 50, 84 and 1E for those agencies with groundwater management plans and / or an urban water management plan. It is anticipated the comprehensive approach outlined through the IRWMP process will continue to play a vital role in sustaining California's overall water supply, particularly if the considerable financial support for the program is maintained in the future.

Coordinated Agreements and Ordinances

Some agencies have entered into coordinated agreements over the years in which multiple water purveyors commit to participate in mutually beneficial management activities, including the analysis of a jointly used basin and the development of joint capital projects and joint operational policies. Enforcement of the agreement and the collection of any fees or levies may be jointly shared among the parties.

In addition, groundwater ordinances have been adopted by some cities and counties. These ordinances may include controls intended to limit or prohibit exports of groundwater to protect the area's groundwater basins. The more general intent is to better coordinate management of water supply and land development. Local governments implementing this type of groundwater management utilize their police power, land use authority and general plan provisions to regulate the use of groundwater in their jurisdiction. These governmental entities are often faced with unique, internal management issues, such as planning department goals that must be coordinated with water or public works department goals and objectives. These ordinances have been most successful when coordinated with an AB 3030 / SB 1938 groundwater management plan.

Other voluntary management strategies are less common, but they can also be successful when implemented proactively and in cooperation with other local and regional stakeholders. Coordinated agreements such as the Sacramento Area Water Forum (including the Sacramento Groundwater Authority) have produced positive results in some regions.

Adjudication

Adjudication is a management method for groundwater basins that have typically exhibited a condition of sustained overdraft for a period of at least five consecutive years. Adjudication is the product of a judicial process involving parties in a groundwater basin to determine the nature and quantity of each producer's share of the basin's safe yield. The process includes the appointment of a watermaster to oversee the court judgment that specifies how much each of the parties to the decision can extract from the basin. There are 22 settled court adjudications of groundwater basins in California, mostly in Southern California.[11] The first basin-wide adjudication of groundwater rights in California was in the Raymond Basin in Los Angeles County in 1949 (*Pasadena v. Alhambra*)[12]and the majority of adjudications were initiated or completed prior to the passage of AB 3030 in 1992.

Adjudicated groundwater basins in California can help to provide certainty by defining and quantifying specific rights for individual producers in the basin. However, application of this strategy indicates significant challenges exist in the affected basin, and parties entering into adjudication should understand the process is time consuming, expensive and complex for the involved parties.

Advancing Sustainable Groundwater Management

It is increasingly clear that California's reliance on groundwater is growing. Local groundwater management plans must reflect that reality and incorporate strategies that consider the potential consequences of a large-scale shift to groundwater, whether cyclical or permanent.

The components of AB 3030 and SB 1938, along with the Integrated Regional Water Management Plan approach, provide an excellent foundation for this type of management and their use should be encouraged and incentivized. Engaging stakeholders in the process is a key way to promote broad participation in the development of such plans. As experience shows, cooperation and participation by a wide spectrum of stakeholders — including surface water users — can be extremely beneficial to the development and implementation of sustainable groundwater management programs.

The ideal groundwater management plan addresses the resource on a local level, provides for operational flexibility, and satisfies the needs of both the environment and the economy while ensuring the continued health of the basin.

The following management objectives reflect best practices that will maximize the effectiveness and sustainability of local groundwater management plans.

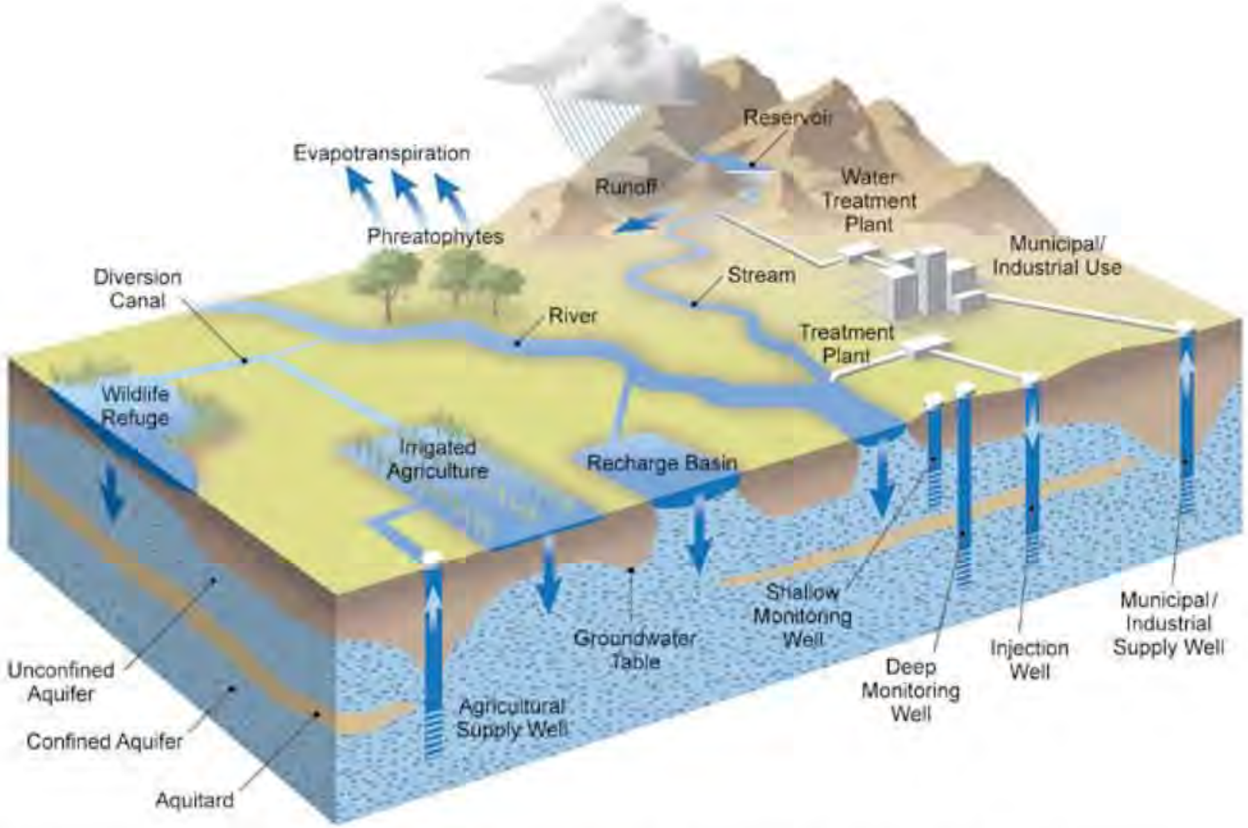
Optimize conjunctive management of surface and groundwater resources. California must invest in surface storage and conveyance improvements as part of a comprehensive plan to restore the Delta ecosystem, ensure a reliable statewide water supply and help recover, improve and sustain the state's economy. Because surface water and groundwater resources are most effective when used in concert with each other, significant investments in surface water storage and conveyance facilities are critical to the success of conjunctive use projects and sustainable groundwater management throughout California.

One of the most effective methods to do this is to ensure that grant programs and regulatory policies reflect the critical link between local and regional groundwater management programs and investments in new storage and conveyance infrastructure. This link is integral to maximizing California's overall water management flexibility.

Groundwater management agencies must also prepare for the effects of future surface water shortages and develop strategies to augment natural and artificial recharge. These strategies should include the increased use of alternative water sources such as stormwater, recycled and desalinated water, as well as additional conservation / water use efficiency efforts, to expand the portfolio of options for groundwater recharge.

Integrate conservation and water use efficiency. Many of the challenges facing groundwater management agencies are driven by the general availability of water for beneficial uses. A continued and intensified commitment to conservation and water use efficiency is critical to addressing these issues. In the context of California water management, water use efficiency means "using water more efficiently to reduce water demand for a given set of beneficial uses."

As with groundwater management efforts, water conservation and water use efficiency programs will only be successful if local water agencies are responsible for their design and implementation. Local water agencies are accountable to their customers for making locally cost-effective decisions that will provide reliable water supplies while balancing other factors, consistent with applicable regulatory requirements. Water conservation and water use efficiency programs are indispensable tools in any agency's portfolio as it develops a sustainable water management plan.



Conceptual model of a typical water management system. Courtesy of the Department of Water Resources.

Undertake comprehensive data collection and analysis. While large amounts of groundwater information are currently being collected and used by multiple local, regional, state and federal agencies and organizations, there are data gaps that can prevent the optimal beneficial use of a groundwater basin. These gaps may also affect relationships among agencies and limit opportunities for regional efforts to sustainably manage a basin's resources. Filling data gaps, ensuring adequate and sustained local groundwater monitoring and making periodic evaluations of the data are the most effective ways to gauge the long-term management risks to groundwater basins (both from a quality and quantity perspective) resulting from increased reliance on groundwater resources. Such fundamental data gathering and assessment are prerequisites to successful, sustainable groundwater management.

Sustainable groundwater management has the best chance of being achieved and maintained if a proper and frequent assessment of the state's groundwater resources is completed, including groundwater level trends, average quantities of groundwater available, and unused storage capacity. Efforts should also focus on groundwater quality data, the effects of current and future contamination and management options for better protecting basins over the long term. This assessment of the groundwater basins' level trends, availability, capacity and quality should be completed and reported by DWR and the appropriate federal agencies (e.g. USGS, NASA), working cooperatively with local groundwater management agencies and optimizing local agency data, evaluations and reports. ACWA was encouraged by the inclusion of a provision requiring such a document in the SBX7 6 legislation and has been working with DWR to develop appropriate, effective and efficient protocols for engaging with local groundwater management agencies.

Most of the groundwater served in California is well managed by local agencies utilizing the appropriate scale of monitoring, data evaluation and reporting through a well-designed groundwater management program. Those areas without, but in need of, active groundwater management programs should be identified, and local agencies should be engaged to implement strategies to move toward sustainability. However, at this time there is limited large-scale groundwater data and information available to systematically assess and accurately describe the status of groundwater basins throughout the state. In addition to developing such information, it is important that representative groundwater level and quality information already collected be made transparent and accessible to interested stakeholders, including adjacent local groundwater managers.

Local and regional entities should share appropriate information and collaborate with other pertinent agencies and the state in developing and implementing sustainable groundwater management programs. Additional efforts may be required to engage individual landowners on a case-by-case basis because sustainable local management of groundwater resources requires accountability, stewardship and transparency by all users. This data collection and transparency of information will not only provide a means for communication and education about the resource, but ultimately will help provide protection to all groundwater users, ensuring a high quality, reliable water supply in each basin. Appropriate local monitoring, measurement and reporting of groundwater basin activity are the only ways to assess whether groundwater basin objectives are being achieved.

Consider the implications of land use decisions. Land use policies that maximize conjunctive use projects and minimize subsidence and groundwater contamination often conflict with common practices of agricultural and urban development throughout California. The constant pressure of residential and commercial development can result in the loss of critical acreage that could be utilized to recharge groundwater basins or ensure storage for areas with unreliable surface supplies. Ironically, areas developed in a way that prevents adequate recharge have the potential to suffer subsidence and a loss of the infrastructure built over the basin. IRWMPs can be an important tool in minimizing such impacts, but it is necessary to collaborate with the developer community to ensure effective communication and reduce potential conflict.

Local agencies should be proactive in identifying and including in a sustainable groundwater management plan the most appropriate areas to serve as dedicated recharge or conjunctive use locations. In addition, land use practices to protect indirect recharge should be promoted to land use jurisdictions for their consideration and implementation, through ordinance where necessary. One example of an indirect approach to conjunctive use is promoting low-impact development (LID), a strategy increasingly used to improve the effectiveness of groundwater recharge and extraction options by minimizing the loss of recharge areas and requiring certain construction practices that increase or maintain the absorption capability of lands overlying groundwater basins. Such efforts, when developed and implemented in coordination with other actions such as enhanced water use efficiency and / or water recycling, present an important opportunity for coordination with local governments and collaboration with stakeholders.

Make public communication and education a priority. Many local and regional groundwater management agencies continue to improve and implement plans that effectively maintain or enhance the health of their basins and provide the foundation for future sustainable management activities. Efforts to educate the public (including policy makers, other local agencies and regulators) about groundwater and successful management approaches can be significantly improved and should be a higher priority for agencies already implementing or working to craft a sustainable groundwater management plan. Information should be made available in a variety of formats and regular workshops should be designed to appeal to all audiences.

WHAT IS LOW-IMPACT DEVELOPMENT?

Low-impact development (LID) is a sustainable practice that benefits water supply and contributes to water quality protection. Unlike traditional stormwater management, which collects and conveys stormwater runoff through storm drains, pipes, or other conveyances to a centralized stormwater facility, LID takes a different approach by using site design and stormwater management to maintain the site's pre-development runoff rates and volumes. The goal of LID is to mimic a site's predevelopment hydrology by using design techniques that infiltrate, filter, store, evaporate, and detain runoff close to the source of rainfall.*

* State Water Resources Control Board. *Low Impact Development – Sustainable Storm Water Management*. 2011. (http://www.swrcb.ca.gov/water_issues/programs/low_impact_development/index.shtml)

THE 2009 LEGISLATIVE WATER PACKAGE

The comprehensive water package enacted in November 2009 marked a new era for California water. At its core, the new law formalized the co-equal goals of water supply reliability and ecosystem health as state water management policy. The package includes four policy bills and an $11.14 billion water bond measure now targeted to go before California voters on the November 2012 ballot. The policy bills address the Delta ecosystem and its governance, statewide conservation policies applicable to urban, industrial and agricultural water suppliers, development of updated in-stream flow criteria, and groundwater elevation monitoring requirements in every basin and sub-basin in California.

While all of the bills include policies or actions that will directly or indirectly impact groundwater resources, the groundwater monitoring bill, SBX7 6, requires the most of groundwater managers and users. This legislation requires groundwater elevation monitoring for all basins and sub-basins by January 1, 2012 to demonstrate seasonal and long-term elevation trends in groundwater basins. The monitoring provisions are designed to help better manage the resource during both normal water years and drought conditions.

Under the legislation, a local agency or other eligible organization in each basin or sub-basin interested in assuming responsibility for monitoring and reporting groundwater elevations for its respective area was to notify DWR by January 1, 2011. If no entity volunteers for a particular area, DWR will assume the responsibility for monitoring and the affected county and entities will become ineligible for state grants or loans.

This legislation supports local groundwater management by appropriately looking to local and regional agencies as the authorities for monitoring groundwater elevations. ACWA has been an active partner with DWR as the monitoring program protocols have been developed. The state's commitment to supporting the local management approach will help ensure effective implementation.

In addition to the groundwater provisions in SBX7 6, accomplishing the goals included in the Delta package will be a critical part of securing a healthy Delta ecosystem and improvements in water supply reliability for the entire state. It will allow for a more reliable surface supply for users who may otherwise shift to groundwater to satisfy part or all of their water needs.

Implementing activities to reach conservation targets outlined in SBX7 7 will also be important as local agencies seek to reduce long-term stress on groundwater resources, particularly during periods when access to surface water supplies is reduced or eliminated.

While this historic package of water legislation includes much that will contribute to improved water management in California, it alone will not lead to sustainable groundwater management. Though it reflects recognition that the state is facing a multi-faceted water crisis and provides policy and financial support for many projects, much work remains to be done to ensure groundwater resources can be sustained through active management on a local or regional scale.

Recommendations

Throughout this Framework ACWA has described key elements of groundwater management and the growing number of challenges facing local water managers today. Examples of successful, locally coordinated approaches to groundwater management have been provided to highlight best practices that may enhance the effectiveness of management plans. Plans such as these should be developed and expanded at the local or regional level, understanding that sometimes there is a need to engage beyond an individual agency's jurisdictional boundaries.

ACWA firmly believes the state Legislature should encourage and support local management policies that appropriately reflect California's geographic and hydrologic diversity rather than institute a state-administered centralized control structure for regulating or permitting the use of groundwater. Statewide permitting and regulation would undermine the effectiveness of existing and planned local investments and would be counterproductive. The Legislature should focus instead on incentivizing the development and implementation of the best practices outlined in this Framework.

In addition, ACWA stands ready to collaborate in the development of appropriate regulatory and policy-related actions and initiatives that will further promote more effective and comprehensive local groundwater management. To that end, we make the following management and policy recommendations to help ensure the sustainability of California's groundwater resources.

ACWA Groundwater Framework Recommendations

Local Agency Level

1. Excluding small or undeveloped basins, groundwater basins in California that are identified in DWR Bulletin 118 should be operated by local agencies and / or stakeholders consistent with a locally developed groundwater management plan that achieves sustainability with the level of management appropriate for the basin. Groundwater management agencies within any basin where extractions are a significant percentage of the groundwater budget should develop formal groundwater management plans with stated policies and practices. The development of these plans should be open and transparent to allow public engagement in the process and should specifically address all factors related to groundwater management including, but not limited to, conjunctive use where appropriate.

2. Consistent with their respective groundwater management plans and state law, groundwater management agencies should be encouraged to collect and disseminate comprehensive groundwater information to demonstrate short- and long-term sustainability of the basin. Agencies should actively provide that information to DWR and make it accessible to the public.

3. Agencies that do not have an SB 1938 groundwater management plan (or functional equivalent), where applicable, should be ineligible for water-related state grants and loans. Financial support and incentives should be made available to agencies that lack sufficient resources but are committed to developing a groundwater management plan.

State and Regional Agencies

1. DWR should improve the functionality of existing online access portals such as IWRIS and the Water Data Library for groundwater information that utilizes the data collected from local agencies to provide improved public access. Representative information should also be transparent and accessible statewide through other avenues, including the California Water Plan (Bulletin 160) and any updates to Bulletin 118.
2. Where an SB 1938 groundwater management plan (or the functional equivalent) exists, state agencies should develop procedures, where applicable, to issue necessary permits for groundwater projects within 60 days of the certification of the CEQA document by the lead agency. This is especially critical for groundwater replenishment projects.
3. A multi-agency team led by DWR should be created and charged with developing an approach to both coordinate review and facilitate implementation of new local and regional groundwater recharge, groundwater banking and conjunctive use projects. Interagency coordinated review and facilitation of groundwater projects is required to ensure that these sustainable resource management opportunities are implemented efficiently once approved by a local agency as part of its groundwater management plan.
4. The Natural Resources Agency and Cal/EPA should work together to develop incentives for local agencies to implement small-scale groundwater replenishment projects, consistent with the applicable local groundwater management plan.
5. Regional Water Quality Control Boards should encourage and facilitate the process for capable local agencies responsible for groundwater management to proactively remediate contaminated groundwater basins when the local agency determines such remediation will contribute to more sustainable groundwater management.
6. The California Department of Public Health should develop draft criteria for SB 918 (2010), which directs the California Department of Public Health to develop criteria for using recycled water to supplement water storage, no later than December 31, 2011.
7. California agencies must develop a new methodology for encouraging, promoting and supporting infrastructure investments, particularly those that would improve water supply reliability at the local level and those that can work in conjunction with the state's backbone water delivery systems.

Legislative / Legal

1. The state of California should designate the use of surface water for groundwater recharge as a "beneficial use." The designation should apply even when there is no plan for future extraction of the water, as long as it is consistent with an SB 1938 groundwater management plan (or the functional equivalent).
2. California law should be clarified to state that once surface water is recharged as part of a conjunctive use project consistent with an SB 1938 groundwater management plan (or the functional equivalent), such water becomes "groundwater" outside the scope of State Water Resources Control Board jurisdiction.
3. The state of California should provide appropriate protection from liability for any agency responsible for groundwater management that undertakes the cleanup of a contaminated groundwater basin in order to use that basin, including as part of a conjunctive use program.
4. Voting requirements should be reduced to 55 percent for approval of local funding initiatives targeted at investments in new or existing water management infrastructure.
5. California anti-degradation policy, as it is currently interpreted with respect to groundwater recharge projects, should allow local agencies to optimize their groundwater resources, providing that maximum benefit to the public is maintained. Any changes should be made in coordination with groundwater management plans, recognizing the variety of different circumstances throughout the state.
6. County general plans should be required to incorporate land use elements that contribute to and promote effective implementation of an SB 1938 groundwater management plan (or the functional equivalent), as determined in consultation with local agencies responsible for groundwater management.

7. The state of California should ensure that "in-lieu" recharge is protected as part of a conjunctive use program. Put otherwise, a conjunctive use project need not require the direct recharge of surface water or the actual extraction of groundwater if near-term demands can be shifted from one source to the other, thereby accomplishing the goal of the conjunctive use project in both wet and dry years.

Collaborative Actions

1. In order to implement large-scale conjunctive use projects in the Central Valley and elsewhere, the Legislature and federal government should invest in surface water storage and improved Delta conveyance, provide financial support for local and regional infrastructure projects, and modify operations and regulatory policies to optimize conjunctive use opportunities.
2. The state, working with appropriate local entities, should address groundwater-related drinking water quality issues in small or disadvantaged communities by providing technical assistance to identify the best approach to protecting public health.
3. In implementing applicable state laws and developing ordinances, local governments should carefully consider the implications of policies and regulations that affect land use in the areas that overlie basins and advocate projects in collaboration with the developer community that maximize opportunities for recharge and conjunctive use.
4. Sustainable groundwater management may be improved through the use of quantitative groundwater models; state and federal agencies should provide financial support to assist local agencies in constructing such models where appropriate.
5. Protecting groundwater quality should be considered as important as the development of sustainable groundwater supplies. Using the best available science, regulatory and policy efforts to identify long-term solutions for the remediation of contamination issues should be supported on a local, regional and statewide scale, such as the salt and nutrient management plans identified in the State Water Resources Control Board Recycled Water Policy.

BDCP1738.

ACWA Policy Principles on Groundwater Management

"Groundwater – Invisible No More"

Groundwater is an invaluable resource for California and a critical asset in the state's comprehensive water management portfolio. Groundwater management should be implemented throughout California, and should be done so consistent with the following policy principles adopted by ACWA's Board of Directors.

1. Groundwater resources are best managed by local jurisdictions to effectively and efficiently manage water quality and supplies for beneficial uses. ACWA encourages and supports regional groundwater management strategies such as Integrated Regional Water Management Plans (IRWMP) and other regional partnerships.
2. Local management of groundwater resources requires accountability, stewardship and transparency; and appropriate local monitoring, measurement and reporting of groundwater basin activity to assure groundwater basin objectives are being achieved.
3. ACWA opposes state interference with existing legal rights to groundwater and believes that a state-administered water rights system for groundwater would undermine effective groundwater management and local investments.
4. California's groundwater resources are unique and diverse in physical characteristics, beneficial uses, water rights, legal and institutional governance and management structures, stakeholders and other features. One-size-fits-all state mandates are ineffective and counterproductive.
5. ACWA supports expansion of conjunctive management of surface water and groundwater supplies that contributes to the protection, reliability and sustainability of local, regional and statewide water supplies for water users and the environment. Such an expansion requires increased groundwater and surface storage, the re-operation of surface reservoirs as appropriate, and improved Delta conveyance.
6. Groundwater quality management is integral to optimizing California's groundwater resources. It must be science-based and include improved data management, basin assessments, monitoring, reporting, protection and, where appropriate, remediation.
7. ACWA supports the use of potable, desalinated, recycled and storm waters for groundwater recharge, with appropriate water quality safeguards that protect beneficial uses.
8. Land use policies and regulations that identify, preserve and protect natural and artificial recharge and extraction capabilities are essential for sustainable groundwater management. Land use policies must consider and analyze impacts and potential impacts to groundwater quality.
9. ACWA supports statewide and regional regulatory consistency that acknowledges the diversity of groundwater resources to facilitate the achievement of local and statewide groundwater storage and basin utilization goals.
10. Groundwater management strategies must anticipate and adapt to the effects of climate change.
11. Optimal groundwater management throughout California will require significant federal, state, regional, local and private investment in infrastructure and related facilities. ACWA further supports increased funding for groundwater research, monitoring, and other management programs.
12. ACWA encourages other statewide associations, regional entities and groundwater-related organizations to educate and advocate for expanded and more effective groundwater management throughout California, and will help coordinate such activities.

ACWA is a statewide non-profit association whose 450 public agency members are responsible for about 90% of the water deliveries in California.

MISSION.

ACWA's mission is to assist its members in promoting the development, management and reasonable beneficial use of good quality water at the lowest practical cost in an environmentally balanced manner.

GROUNDWATER AND SURFACE WATER IN SOUTHERN CALIFORNIA

A GUIDE TO CONJUNCTIVE USE

Association of Ground Water Agencies

Table of Contents

Background

The Association of Ground Water Agencies, or AGWA, was formed in 1994 by a group of eight groundwater basin management agencies. In 1995, it was incorporated in Southern California as a nonprofit Public Benefit Corporation.

Mission Statement

The mission of the Association of Ground Water Agencies is to promote interagency solutions that enhance the quality and management of groundwater resources.

AGWA's purpose is to create a forum for the discussion of groundwater issues for management of our groundwater basin resources, and to take action in connection with these. AGWA's primary objectives are to:

- promote enhanced management of groundwater basins
- improve the reliability of existing groundwater supplies
- assure the protection and enhancement of groundwater quality

Members and Affiliates

Membership in AGWA consists of Members and Affiliates. Membership as of July 1999 is listed below.

Members

Calleguas Municipal Water District
Chino Basin Watermaster
Eastern Municipal Water District
Kern County Water Agency
Main San Gabriel Basin Watermaster
Mojave Water Agency
Orange County Water District
Raymond Basin Management Board
San Bernardino Valley Water Conservation District
Six Basins Watermaster
Tehachapi-Cummings County Water District
Upper Los Angeles River Area Watermaster
Water Replenishment District of Southern California
Western Municipal Water District

Affiliates

GROUNDWATER AND SURFACE WATER IN SOUTHERN CALIFORNIA

A GUIDE TO CONJUNCTIVE USE

Published by the Association of Ground Water Agencies

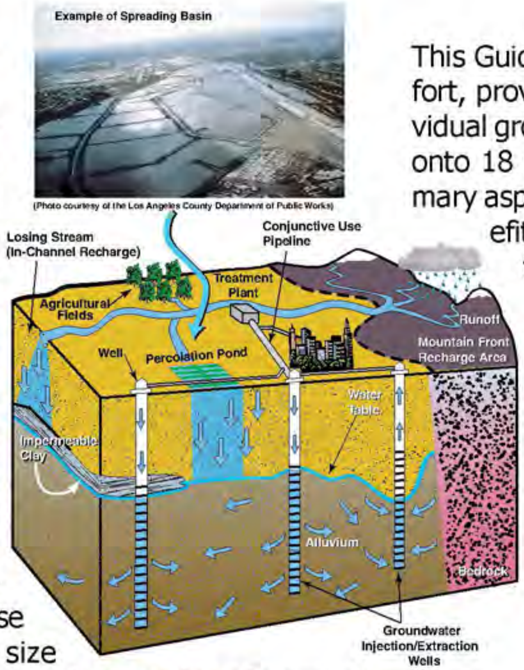
Executive Summary

Groundwater (underground water) is a critical component of California's water supply. The semi-arid climate of California has prompted the development of our groundwater resource to supplement our surface water supply. Some critical facts about groundwater include:

- The amount of underground water stored in California is far greater than that stored in the state's surface water reservoirs, although only a portion of these groundwater resources can be practically and economically extracted for use.
- Groundwater serves as our only supply in those areas of the state isolated from surface water connections.
- In an average year, groundwater meets about 30 percent of California's urban and agricultural water need. In drought years, when surface supplies are reduced, groundwater supports an even larger percentage of use.
- As the state-wide population continues its growth toward a projected 47.5 million people by 2020, the demand for water will continue to increase and further development of our groundwater resources will help meet this demand.
- Meeting this demand will require significant improvements and innovations in how we optimize our existing water supplies. One of these ways is the storage of excess water during wet years beneath the ground for use during dry years. **This coordinated management of surface water and groundwater is called conjunctive use.**

The Association of Ground Water Agencies (AGWA), representing major groundwater basin management agencies throughout Southern California, formed in 1994 to promote interagency solutions that enhance the effective management of groundwater resources, especially conjunctive use. Focusing on 18 major Southern California groundwater basin groupings, this AGWA publication represents the most comprehensive evaluation to date of the potential to significantly improve the coordinated use of surface water and groundwater to meet California's water needs. Based on a survey of groundwater basin managers, this document describes areas where conjunctive use is (or may be) a viable groundwater basin management option, and will serve as a useful educational tool for teachers, legislators, elected officials, lay people, and technicians.

Prepared for AGWA Association of Ground Water Agencies by MONTGOMERY WATSON and Water Education Foundation



By no means a new concept, conjunctive use was first used in California during the Spanish mission era. Ongoing since the 1940s and shown in the photo on the next page, the spreading of surface water in Los Angeles County provides critical recharge of the underlying groundwater basins. Conjunctive use programs vary in size and type, depending on the specifics of a groundwater basin. The following figure depicts some of these storage and retrieval methods. Through the preparation of this guide, **AGWA has documented that over 21.5 million acre-feet of additional groundwater storage is available in Southern California groundwater basins, enough to fill Diamond Valley Lake, our largest surface water reservoir, 26 times.** One acre-foot of water is approximately 326,000 gallons, enough water to cover a football field to a depth of one foot. This stored water could be used during times of drought or natural disaster when surface water supplies are not available. This storage would reduce some of the need for the construction of large dams and reservoirs, which are expensive and often viewed as environmentally unfriendly.

To evaluate this storage potential, AGWA surveyed each of the groundwater basin managers to obtain data used in this study. Montgomery Watson assisted AGWA in the analysis of data and presentation of survey results. The Water Education Foundation prepared the overview of conjunctive use. In analyzing each basin, this Guide includes information on basin location, basin management (governance), available storage, present operational safe yield, and basin sediments (geology).

This Guide represents the culmination of that effort, providing overviews for each of the 85 individual groundwater basins evaluated and grouped onto 18 maps. The Guide also explores five primary aspects of conjunctive use: 1) need, 2) benefits, 3) methods, 4) governance, and 5) potential problems.

In summary:

- Conjunctive use is a well-proven method to increase our ability to meet California's increasing water demand.
- Conjunctive use improves water supply reliability.
- The need for environmentally controversial surface water reservoirs may be reduced by conjunctive use programs.
- Assuming resolution of institutional, water quality, and other issues, over 21.5 million acre-feet of additional water can be stored and used in Southern California groundwater basins.

Summary of Long-Term Storage Potential of the Basins Included in This Guide.

Basin Groupings	Potential Storage for Use in Dry Years* (Acre-Feet)
Kern County Basin	8,000,000
Tehachapi/Cummings Basin	Not Available as of July 2000
Ventura County Basins	500,000
San Fernando Valley Basins	150,000
Raymond Basin	144,000
San Gabriel Basin	400,000
Los Angeles Coastal Plain Basins	1,089,000
Orange County Coastal Plain Basin	300,000
Six Basins	30,000
Upper Santa Ana River Basins	1,854,000
Bunker Hill Basin	0
San Jacinto Watershed Basins	1,284,000
Upper Santa Margarita River Basins	200,000
San Diego County Basins	270,700
Mojave River Basins	1,790,100
Hayfield Basin	500,000
Cadiz Valley Basin	1,000,000
Coachella Valley Basin	4,000,000
TOTAL	**21,511,800**

* Data provided by groundwater basin managers

Association of Ground Water Agencies

A Guide to Conjunctive Use in Southern California

What is Conjunctive Use?

Conjunctive use is the coordinated management of surface water and groundwater supplies to increase the yield of both. The conjunctive use concept is intended to increase total supplies and enhance water supply reliability.

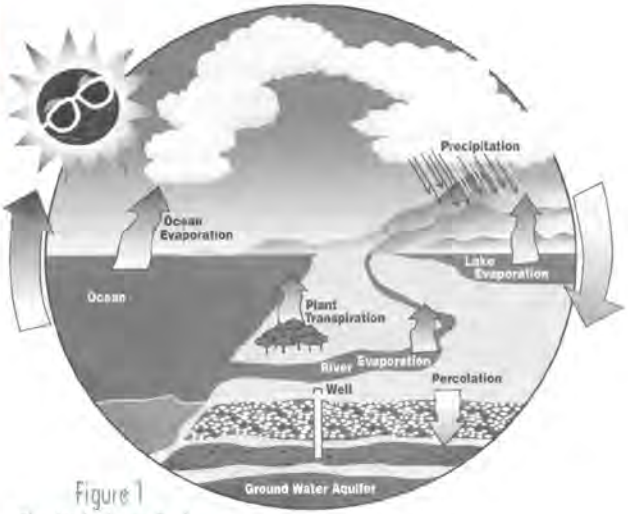


Figure 1
The Hydrologic Cycle
(courtesy of
Water Education Foundation)

Why Conjunctive Use?

Water is essential to life in California. It fuels industries, grows crops, provides habitats for thousands of plant and animal species, and allows over 33 million Californians a cool, refreshing drink.

In nature and without our intervention, water is continuously recycled. Water evaporates from oceans, lakes, streams and rivers, condenses into clouds, and returns to earth as precipitation, most commonly, in the form of rain and snow. From there, rain and melted snow flow back into lakes, rivers and oceans, replenishing these surface supplies and continuing the hydrologic cycle (Figure 1). Though much of California's water comes from these surface supplies, water from the surface also percolates into the ground creating California's largely unseen water supply: groundwater.

In California, on average, 15 million acre-feet (one acre-foot of water is approximately 326,000 gallons, enough water to cover a football field to a depth of one foot or supply one to two families for a year) of groundwater (underground water) are extracted from wells each year. With more than half of all Californians relying on groundwater for at least a portion of their water supply, groundwater supplies approximately 25-30 percent of California's water needs. The state's population is expected to reach 47.5 million by 2020 and approximately one-half (7 million people) of this growth is anticipated to occur in Southern California (Figure 2). With this growth will come an increased reliance on groundwater.

Benefits of Conjunctive Use

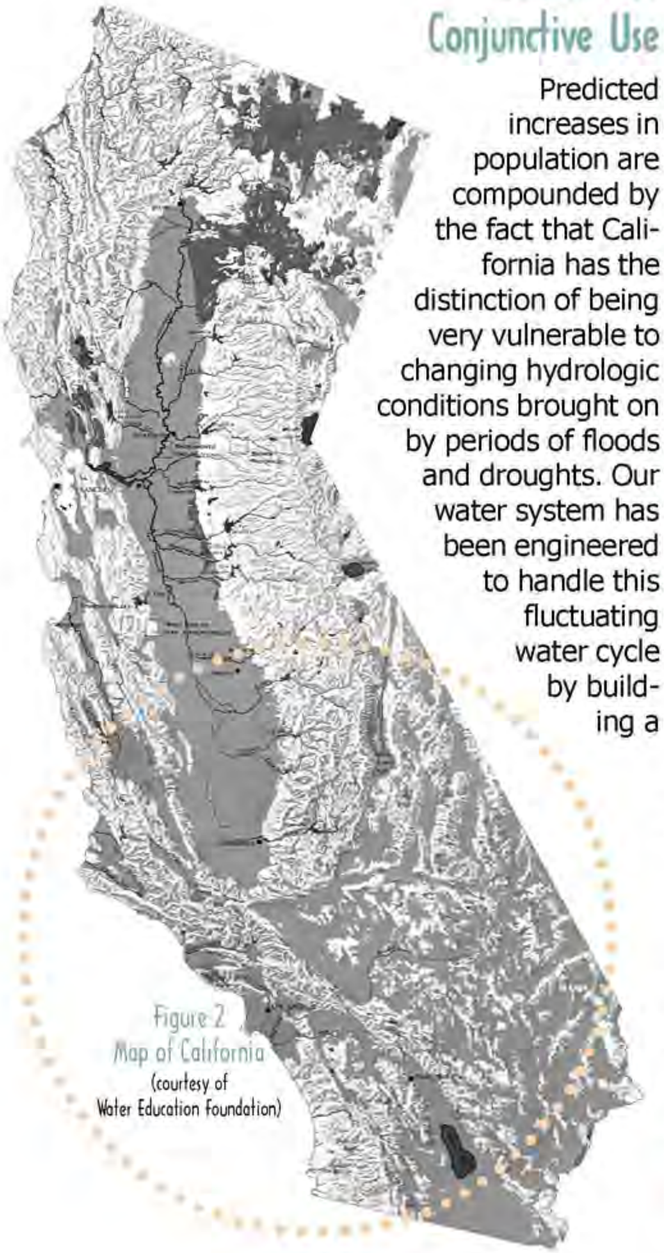

Figure 2
Map of California
(courtesy of
Water Education Foundation)

Predicted increases in population are compounded by the fact that California has the distinction of being very vulnerable to changing hydrologic conditions brought on by periods of floods and droughts. Our water system has been engineered to handle this fluctuating water cycle by building a series of large, above-ground reservoirs to hold water when it is needed. Despite the integral role that above-ground reservoirs can have in conjunctive use, they are expensive to build and are viewed by some as environmentally damaging. Thus, greater use of storage capacity in aquifers via conjunctive use has become an increasingly popular alternative for water storage, thereby improving California's water supply.

As defined previously, conjunctive use is the coordinated management of surface water and groundwater supplies to increase the yield of both. It is intended to increase total supplies and enhance water supply reliability–in essence to rely more on surface water supplies during wet or normal years and groundwater in dry years. This process can be enhanced by storing excess water supplies underground during wet years for use during the dry year–a form of drought proofing. Figures 3 and 4 illustrate the concept of conjunctive use and methods commonly used to introduce and remove groundwater from the subsurface.

Currently, during droughts, the state turns to aquifers as if they were savings accounts — relying on groundwater for as much as 60 percent of a year's supply to keep farm fields in production and urban areas supplied with water. In addition, Southern California receives a large part of its water from the Sacramento-San Joaquin Delta near San Francisco, Owens Valley east of the Sierra, and the Colorado River– all of which are subject to changing conditions from wet years to droughts.

The potential for conjunctive use projects is phenomenal given that aquifers in the state hold 850 million acre-feet of water, nearly 20 times the amount of water that can be stored behind all of California's dams. However, some of this amount may not be usable because of salt water intrusion, subsidence, poor quality, or high pumping costs. If California were flat, the volume of its groundwater would be enough to flood the entire state eight feet deep! In addition to a more assured supply of water during dry years, conjunctive use also can reduce pumping costs for water users because of the decreased lift. With more water in the aquifer, water is closer to the surface and therefore requires less energy (and money) to pump it out. Conjunctive use also can maximize water use more efficiently than groundwater and surface water projects operated separately – allowing for greater conservation.

Other advantages of conjunctive use include the ability to use and expand upon existing facilities, thus allowing for easier integration and a staged development approach; a smaller drainage system; fewer costs from canal lining; reduced evapotranspiration losses; reduced danger from dam failure; and improved timing of water distribution. Other possible advantages and possible disadvantages are listed in Table 1. Actual advantages and disadvantages will vary by project.

Methods of Conjunctive Use

Conjunctive use can be applied in several ways. One method uses artificial recharge by placing the water directly into the aquifers through percolation and/or injection. Percolation occurs naturally as part of the hydrologic cycle but can be enhanced by creating spreading basins atop aquifers. Water also can be put into an aquifer using wells and pumps to inject water.

Example of Spreading Basin

(Photo courtesy of the Los Angeles County Department of Public Works)

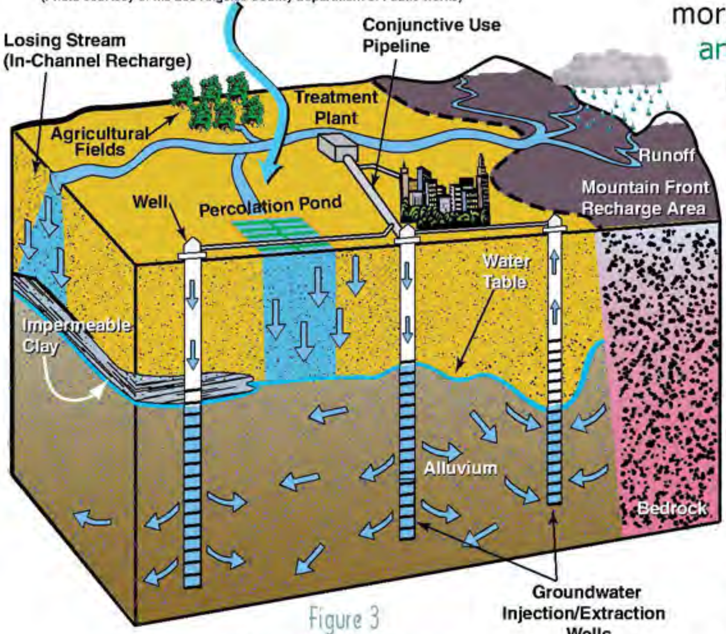

Figure 3
Conjunctive Use Program
Wet or Normal Year Operation

Another method, in-lieu recharge, works on the idea of reducing the amount of water pumped from the aquifer. That is, those who would normally rely on groundwater wells to meet their water needs instead use excess surface water supplies when available. This allows groundwater supplies to be replenished indirectly.

Rules Governing Conjunctive Use

In groundwater basins where overdraft occurs, groundwater users may work with the court to adjudicate a groundwater basin. Adjudication allows specific water rights to water users and compels the cooperation of pumpers. In other words, in adjudicated basins, the amount of groundwater that may be pumped annually by users is limited. This limit is generally based on the concept of "safe yield"—the amount of water that can be pumped each year without causing a continual reduction of water in storage (overdraft). The safe yield is dependent upon the average amount of water that can be stored in and used from the groundwater reservoir over a period of normal water supply under a given set of conditions. The safe yield of the basin, in some cases, can be substantially augmented by engineering controls. For example, more water can be made available through artificial recharge by spreading or injection wells, or by lowering groundwater levels to reduce evapotranspiration, to capture rejected recharge, or to capture surface water from streams. Safe yield augmented by such engineering controls is referred to as "operational yield" in this guide.

Of the 18 groundwater basins adjudicated in California, 17 lie in Southern California, primarily due to development pressures and an absence of adequate natural surface water supplies.

Another tool which helps manage groundwater use is AB 3030 (California Water Code Sections 10750-10756). Passed in 1992 by the State Legislature and placed into effect on January 1, 1999, this measure is intended

Table 1

POSSIBLE ADVANTAGES AND DISADVANTAGES OF USING AQUIFERS FOR STORING WATER UNDERGROUND*

Possible Advantages	Possible Disadvantages
Water quality improvement	Less hydroelectric power through avoidance of dam construction
Water supply reliability	Greater power consumption to extract groundwater
Greater water conservation	Increase in salt loading
Decreased dependence on imported supply during dry years and emergencies	More involved project operation
Less additional surface storage required	More difficult cost allocation
Fewer drainage system improvements	Over-pumping may cause land subsidence
Greater flood control	Liquefaction from shallow groundwater levels
Ready integration with existing development	May require active control of salt water intrusion
Storage programs can be phased	May cause contaminant movement
Low evaporative losses	Increased groundwater monitoring
Improvement of power load and pumping plant use factors	Increased need for diversion and/or conveyance of surface water during wet years
Less threat from dam failure	
Better timing of water distribution	

*** NOTE: Specific possible advantages and disadvantages will vary from project to project and should be evaluated on a case-by-case basis.**

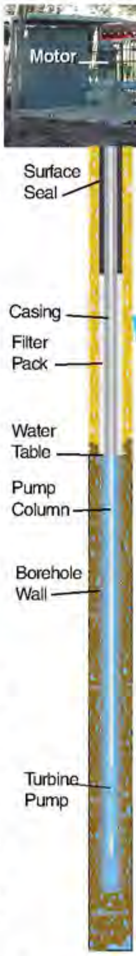
to provide local water agencies with the ability to tailor groundwater management plans to meet problems in their area (subsidence, salt water intrusion, contamination). The law does not allow local districts to impose binding water rights on pumpers but does, after a general election, allow them to impose fees on pumping. Additionally, in the 1994 case of *Baldwin v. County of Tehama*, it was determined that state law does not preclude cities and counties from regulating groundwater.

Problems Facing Conjunctive Use

Conjunctive use projects should be actively managed to avoid problems such as overdraft and pollution.

According to the California Department of Water Resources, in an average year, Californians use approximately 1.3 million acre-feet more groundwater than is either naturally or artificially

Example of Groundwater Injection/Extraction Well



recharged. This groundwater overdraft can create problems including subsidence and salt water intrusion. Additionally, increasing basin yield may necessitate large fluctuations in water levels, which can contribute to these problems.

Subsidence may occur when too much groundwater is pumped and the subsurface sediments are drained. Once drained, these sediments can compact under the weight of the overlying soil, creating depressions and fissures at the ground surface.

Salt water intrusion also can result from lowering of water levels in an aquifer. For example, drawing large volumes of groundwater out of an aquifer can cause groundwater levels to be lower than sea level. When this occurs in a coastal location, seawater has a higher elevation than groundwater, thereby enabling seawater to flow from a higher elevation to a lower elevation into the aquifers and toward the areas where the groundwater was removed. Once salt water infiltrates a groundwater basin, water quality can be seriously degraded. Since the 1950s and 1960s, water agencies have combated this problem by injecting surface water into the ground or by recharging water in spreading basins. By doing so, a hydraulic barrier is created between the freshwater aquifer and the intruding salt water.

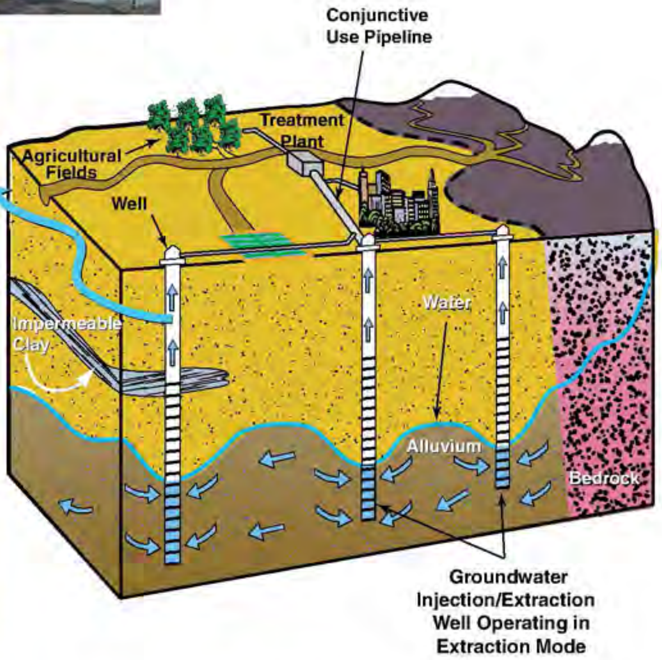


Figure 4
Conjunctive Use Program
Dry Year Operation

Pollution from both naturally occurring and manmade contaminants also can cause problems for groundwater users. Radon and arsenic, both natural byproducts of decaying rocks, occur in various areas throughout California. Contaminants from urban and agricultural centers can result from leaking gasoline tanks, sewers, landfills, industrial waste discharges, fertilizers, pesticides, and failed septic systems. In Southern California, fuels and solvents – the byproduct of military bases and private industries that support defense efforts – have been found in several groundwater basins including the San Gabriel and San Fernando Valleys. These sites are being cleaned up under the supervision of local, state and federal agencies. High concentrations of nitrates and total dissolved solids resulting from agricultural activities also pose serious threats to groundwater quality.

Increased monitoring, detection and advanced treatment techniques are helping to curb these threats to groundwater.

Additional problems facing conjunctive use projects may include less new hydroelectric power production due to fewer new dams; decreased well pumping efficiency; more complex project operations and consequently, more difficult cost allocations; and the reliance on artificial recharge to keep the project operating.

Conjunctive Use Potential In Southern California

In preparation of this document, AGWA surveyed and collected information from 25 management agencies for approximately 85 individual groundwater basins in Southern California. The managers were asked to provide the following information for each basin:

- Conjunctive Use
- Replenishment Activities
- Overview of Groundwater Basin
- Water Supply and Demand
- Type of Aquifers Within Basin
- Basin Size
- Basin Storage Capacity

This information is presented on 18 maps showing individual basins or basin groupings. Figure 5 is an index map showing the relative locations of the 18 basin groupings featured in the guide. The configuration and location of basins shown on Figure 5 were taken from "California's Groundwater," published by the Department of Water Resources as Bulletin Number 118, in 1975. The numbering system shown on Figure 5 is arbitrarily assigned for this guide and generally progresses from north to south and west to east. The individual basin maps are provided on the following pages. Basin boundaries and descriptive information have been provided by the basin managers unless otherwise noted. A contact list of basin managers is included at the end of this report.

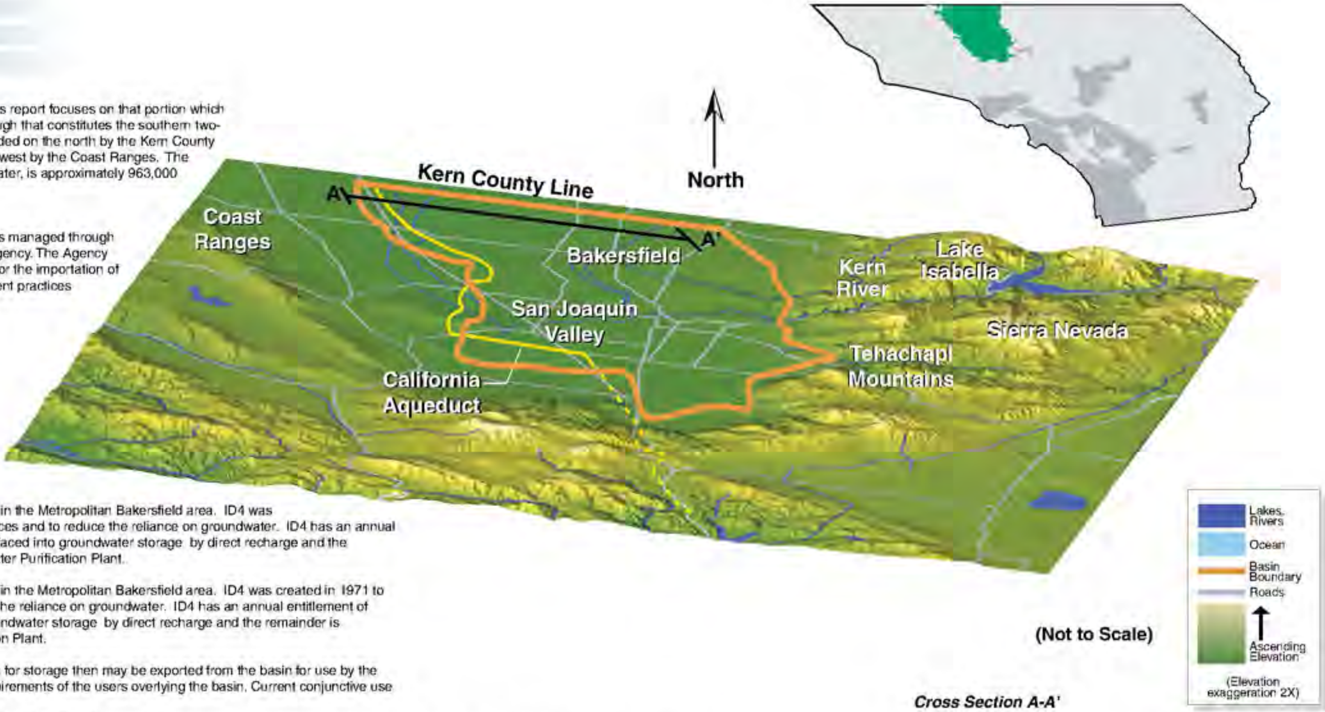
Figure 5
Index Map Showing the Relative Location of Basin Groupings Featured in the Guide

1. Kern County Basin



Location
The Kern County Groundwater Basins are made up of many differing geologic and climatic areas. This report focuses on that portion which occupies the southern San Joaquin Valley, which is a broad alluvial, northwest-trending structural trough that constitutes the southern two-thirds of the Central Valley. The Basin is located within the Tulare Lake hydrologic region and is bounded on the north by the Kern County line, on the east by the Sierra Nevada foothills, on the south by the Tehachapi Mountains, and on the west by the Coast Ranges. The principal watershed is drained by the Kern River. Surface area of the Basin overlying usable groundwater, is approximately 963,000 acres (1,505 square miles).

Basin Management
The Central Valley portion of the Kern County Groundwater Basin is an un-adjudicated Basin, which is managed through cooperative programs of individual Water Districts, the County of Kern, and the Kern County Water Agency. The Agency serves as a local contracting entity for the State Water Project (SWP). One of the primary purposes for the importation of SWP water into Kern County is to improve groundwater conditions within the Basin. Water management practices exercised by the Agency, the County, the City of Bakersfield and other Districts include the following:

- Groundwater recharge for overdraft correction and banking
- Importation to meet annual water requirements, and for conjunctive use and banking
- Replenishment
- Determination of groundwater storage
- Administration of water well ordinance
- Coordination with land use planning
- Controlling saline water intrusion
- Identification and management of recharge areas
- Groundwater quality and level monitoring
- Administration of groundwater quality and level databases

The Agency also administers Improvement District No. 4 (ID4), a successful conjunctive use program in the Metropolitan Bakersfield area. ID4 was created in 1971 to provide a supplemental surface water supply to augment local groundwater resources and to reduce the reliance on groundwater. ID4 has an annual entitlement of approximately 83,000 acre-feet from the SWP, approximately 60% to 70% of which is placed into groundwater storage by direct recharge and the remainder is delivered for urban use in-lieu of pumping groundwater through the Henry C. Garnett Water Purification Plant.

The Agency also administers Improvement District No. 4 (ID4), a successful conjunctive use program in the Metropolitan Bakersfield area. ID4 was created in 1971 to provide a supplemental surface water supply to augment local groundwater resources and to reduce the reliance on groundwater. ID4 has an annual entitlement of approximately 83,000 acre-feet from the SWP, approximately 60% to 70% of which is placed into groundwater storage by direct recharge and the remainder is delivered for urban use in-lieu of pumping groundwater through the Henry C. Garnett Water Purification Plant.

Groundwater banking programs differ from conjunctive use in that water may be imported to the basin for storage then may be exported from the basin for use by the entity banking the water. Conjunctive use programs typically are designed to help meet the water requirements of the users overlying the basin. Current conjunctive use and banking programs include the following programs for overlying users and bankers:

Banking Programs

NAME	STORAGE (MAF)	ANNUAL YIELD (AF/Y)
Kern Water Bank Authority Banking Project	1	287,000
Agency Pioneer Recharge and Recovery Project	.4	98,000
Joint Agency and Berrenda Mesa Water District Banking Project	.2	46,000
Arvin-Edison Water Storage District/ MWD Banking Project	.25	40,000
City of Bakersfield - 2800 Acre Spreading Grounds	.8	46,000
Semitropic Water Storage District Banking Project with Metropolitan Water District Water, Alameda County Water Agency, Santa Clara Water District District, Vidler Water Company, Zone 7 Water Agency	1	223,000
Buena Vista Water Storage District and West Kern Water District Recharge and Recovery Projects	.25	45,000

Overlying Use Programs

NAME	DEWATERED STORAGE (MAF)	ANNUAL WATER REQUIREMENTS (AF/Y)
Arvin-Edison WSD	2.9	337,000
Buena Vista WSD	0.3	134,000
Cawelo WD	0.6	142,000
Delano-Earlimart ID	0.1	32,000
Henry Miller	.05	60,000
ID#4	.3	119,000
Kern Delta WD	0.7	412,000
North Kern WSD	0.9	212,000

Semitropic WSD	2.2	544,000
Shafter Wasco ID	.4	116,000
Southern San Joaquin MUD	0.4	181,000
Wheeler Ridge - Maricopa Water Storage District	2.0	346,000
Kern-Tulare and Rag Gulch Water Districts	0.5	58,700

Available Storage
De-watered storage space is estimated to be about 12 million AF. Storage space used for current Banking Projects is about 4 million AF. Remaining de-watered space available for additional banking and overdraft correction is estimated to be 8 million AF.

Present Operational Safe Yield
The natural recharge of the Basin is about 180,000 AF/Y.
The increase in operational yield for overlying users due to importation and conjunctive use is about 2 million AF/Y.

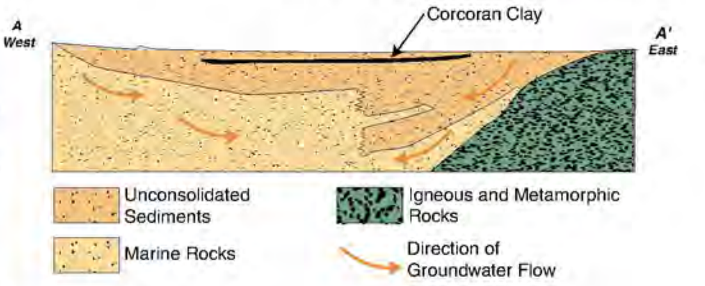
The maximum dry year recovery capacity of the Banking Projects is currently about 785,000 AF/Y provided enough water can be imported and placed into storage for recovery. The future increase in dry year recovery capacity is about 284,000 AF/Y provided increases in delta diversions or other surface supplies are made available.

Basin Sediments
Sediments that comprise the Basin are unconsolidated deposits of Tertiary and Quaternary age. These deposits include alluvium, lacustrine, deltaic, and flood-basin deposits consisting of sand and gravel with thin lenses of silt and clay, as well as the Tulare and Kern River Formations. In northeastern Kern County, some water production is derived from the Santa Margarita and Olcese Formations. Unconsolidated sediments overlie the igneous and metamorphic basement complex of the Sierra Nevada to the east and marine rocks of the Coast Ranges to the west.

In the eastern third of the Basin, groundwater occurs primarily under unconfined and semi-confined conditions. In the north - central portion of the Basin the Corcoran Clay is present at depths from 300 to 650 feet. Below the Corcoran Clay, groundwater is confined.

The major sources of natural recharge are infiltration of rainfall on the valley floor and percolation of runoff from the Kern River and adjacent mountains. The Basin also receives imported water from the SWP and Federal CVP and return flow from applied water.

Cross Section A-A'



(From USGS, 1965, Professional Paper 1401-C)

Conjunctive Use Potential
The results of AGWA's survey indicate existing conjunctive use programs have increased the basin operational yield by 2,000,000 AFY. Additionally, the survey indicated the potential to store up to 8,000,000 AF of water for use in dry years and a potential increase in basin operational yield of 284,000 AFY.

2. Tehachapi/Cummings Basin

Location
The Tehachapi/Cummings Groundwater Basin is located between the southern end of the Sierra Nevada and the northeastern side of the Tehachapi Mountains. The Tehachapi/Cummings Groundwater Basin includes the Tehachapi Basin, Cummings Basin, and Brite Basin. Brite Basin is generally located between the Cummings and Tehachapi Basins but is not shown on the map because it lacks distinct boundries. The basin is bounded on all sides by crystalline bedrock. The surface areas of the basins are as follows:

- Tehachapi Basin, 99 square miles (63,500 acres)
- Cummings Basin, 38 square miles (24,600 acres)
- Brite Basin, 12 square miles (7,900 acres)

Basin Management
The basin is adjudicated and is managed by the Tehachapi-Cummings Water District (Watermaster).

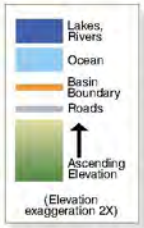
Available Storage
Not available as of July 2000.

Present Operational Safe Yield
The present operational safe yield of Tehachapi Basin is 5,500 acre-feet per year (AFY) and 4,090 AFY for Cummings Basin, and 500 AFY for Brite Basin (not shown on map), yielding a combined total operational safe yield of 10,090 AFY.

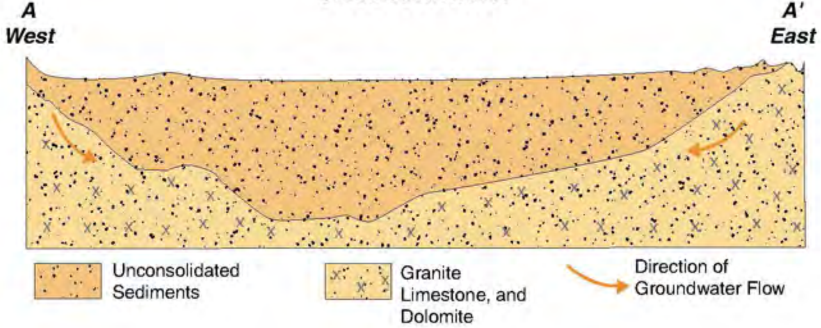
Basin Sediments
Basin sediments consist of unconsolidated deposits underlain by marine rocks.

Conjunctive Use Potential
The Tehachapi-Cummings Water District is currently conducting studies to determine the conjunctive use potential of the basin.

(Not to Scale)



Cross Section A-A'



3. Ventura County Basins

Locations
The groundwater basins of Ventura County are located beneath the Oxnard Coastal Plain and in the surrounding river valleys. The four largest valleys consist of the Santa Clara River Valley, Pleasant Valley, Arroyo Santa Rosa Valley, and Las Posas Valley. In total, there are 32 groundwater basins in Ventura County. Of these 32 basins, the 14 basins having total storage capacities in excess of 50,000 acre-feet (AF) each are listed and shown on this basin map.

Basin Management
The groundwater basins are generally not managed by a particular agency with the following noted exceptions:

Basin	*Management Structure*
Oxnard Coastal Plain and Forebay	State Legislation and Ordinances
Fillmore Basin	AB-3030 Plan and United Water Conservation District
Santa Paula Basin	United Water Conservation District
Piru Basin	United Water Conservation District
Arroyo Santa Rosa Basin	State Legislation and Ordinances
North Las Posas Basin	State Legislation and Ordinances

The Calleguas Municipal Water District (CMWD) and the Metropolitan Water District of Southern California (MWD), are currently developing a conjunctive use program in the North Las Posas Basin. The program calls for MWD to finance up to 30 injection and pumping wells in the basin. MWD will have the right to store up to 210,000 AF of water in the basin. During times of need, MWD will decrease its surface water deliveries to CMWD and replace that water with stored water extracted from the North Las Posas Basin.

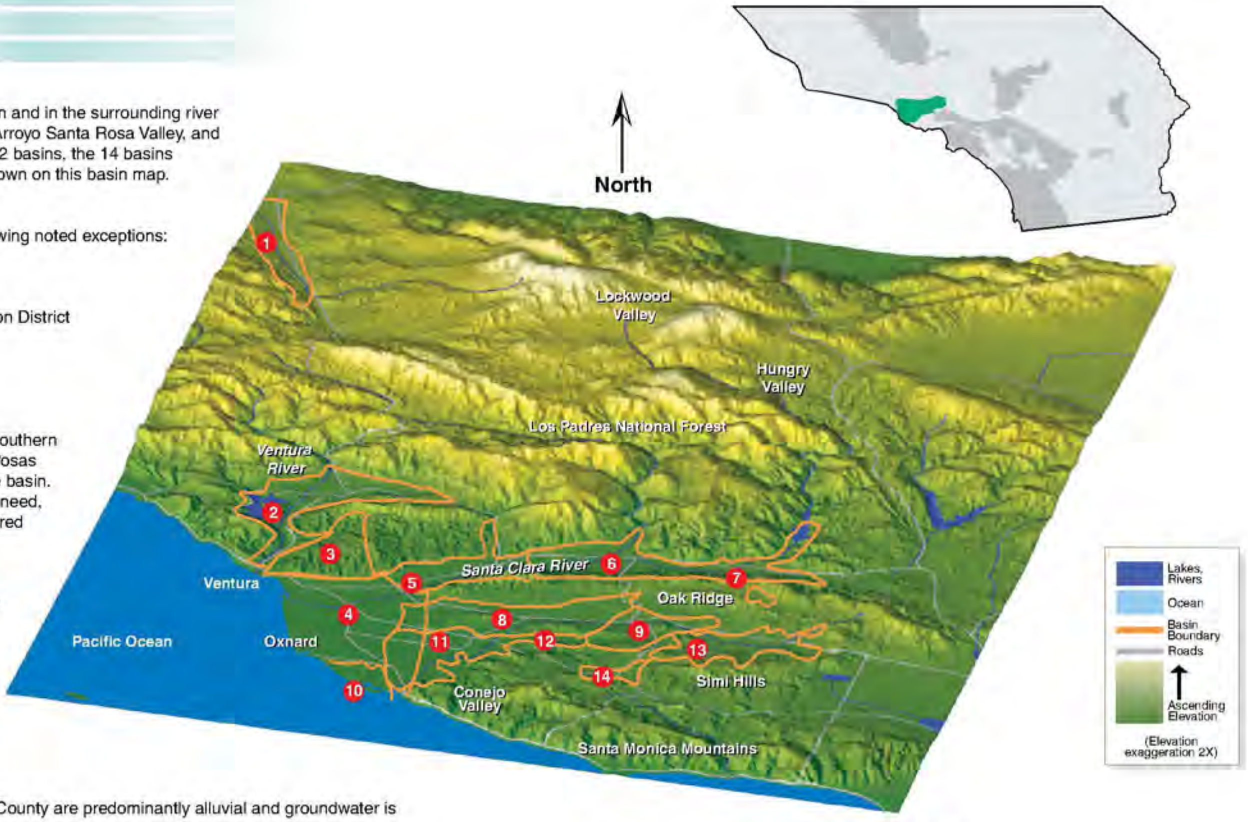
Available Storage
The freshwater storage capacity of all Ventura County groundwater basins is 32,000,000 AF. Approximately 27,400,000 AF are currently in storage with 500,000 AF of available storage potential.

Present Operational Safe Yield
The present operational safe yield of the Basins of Ventura County is 176,538 acre-feet per year (AFY). Future operational yield is anticipated to increase by 87,600 AFY.

Basin Sediments
Sediments that comprise the groundwater basins underlying the river valleys of Ventura County are predominantly alluvial and groundwater is typically unconfined.

Sediments that comprise the larger groundwater basins of Ventura County are predominantly alluvial. Groundwater in these basins is both confined and unconfined. Several smaller basins in this area are comprised of sedimentary rocks, limited volcanics, and sandstone or siltstone. These smaller basins have limited storage potential.

Conjunctive Use Potential
The results of AGWA's survey indicate the potential to store up to 500,000 AF of water for use in dry years and a potential increase in basin operational yield of 87,600 AFY.



(Not to Scale)

4. San Fernando Valley Basins

Location

The groundwater basins of the San Fernando Valley, located within the Upper Los Angeles River Area (ULARA) watershed, consist of the following:

- Sylmar Basin
- Verdugo Basin
- San Fernando Basin

The surface area of the ULARA watershed is approximately 514 square miles or 327,000 acres.

Basin Management

The groundwater basins are adjudicated under the auspices of the ULARA Watermaster. The basins were adjudicated on January 29, 1979 under the case referred to as the San Fernando Judgement.

Available Storage

The fresh water storage capacity of the San Fernando basins ranges from 0 to 550,000 acre-feet (AF). The actual amount of water in storage is determined by the ULARA Watermaster. Annual natural recharge and artificial recharge is approximately 44,000 and 61,000 acre-feet per year (AFY), respectively.

Present Operational Safe Yield

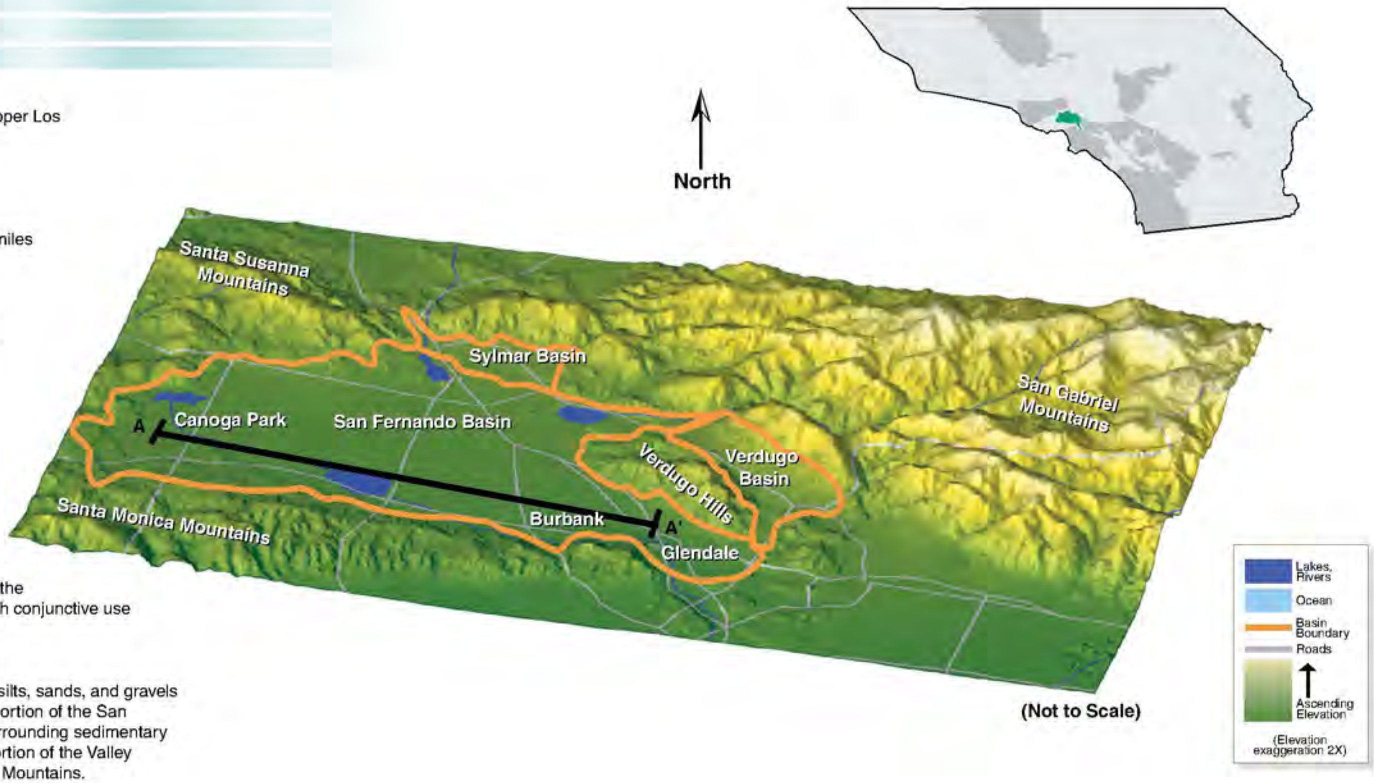
The present operational safe yield of the San Fernando Valley basins is approximately 105,000 AFY, providing approximately 15-20% of the water supply for the cities of Burbank, Glendale, and Los Angeles. Through conjunctive use programs, these cities have stored approximately 356,000 AF.

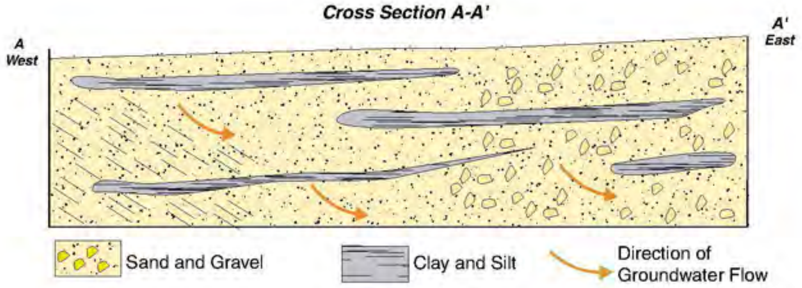
Basin Sediments

The alluvial sediments in the San Fernando Valley are a mixture of clays, silts, sands, and gravels that extend to a depth of at least 1,000 feet in some areas. The western portion of the San Fernando Valley is composed of fine-grained material derived from the surrounding sedimentary rocks in the Santa Susanna and Santa Monica Mountains. The eastern portion of the Valley consists of coarse sand and gravel deposits derived from the San Gabriel Mountains.

Conjunctive Use Potential

The results of AGWA's survey indicate existing conjunctive use programs have increased the basin operational yield by 43,700 AFY. Additionally, the survey indicated the potential to store up to 150,000 AF of water for use in dry years and a potential increase in basin operational yield of 27,300 AFY.





Cross Section A-A'

5. Raymond Basin

Location

The Raymond Groundwater Basin is located in the central portion of Los Angeles County. The basin is bounded on the north by the San Gabriel Mountains, on the south and east by the Raymond fault and adjacent San Gabriel Valley, and on the west by the San Rafael Hills and the Verdugo Basin. The entire basin lies within the watershed of the Los Angeles River. Principal streams include the Arroyo Seco, Eaton Wash, and Santa Anita Wash. The surface area of the Basin is 40 square miles or 25,600 acres.

Significant faults in the Basin include the following:

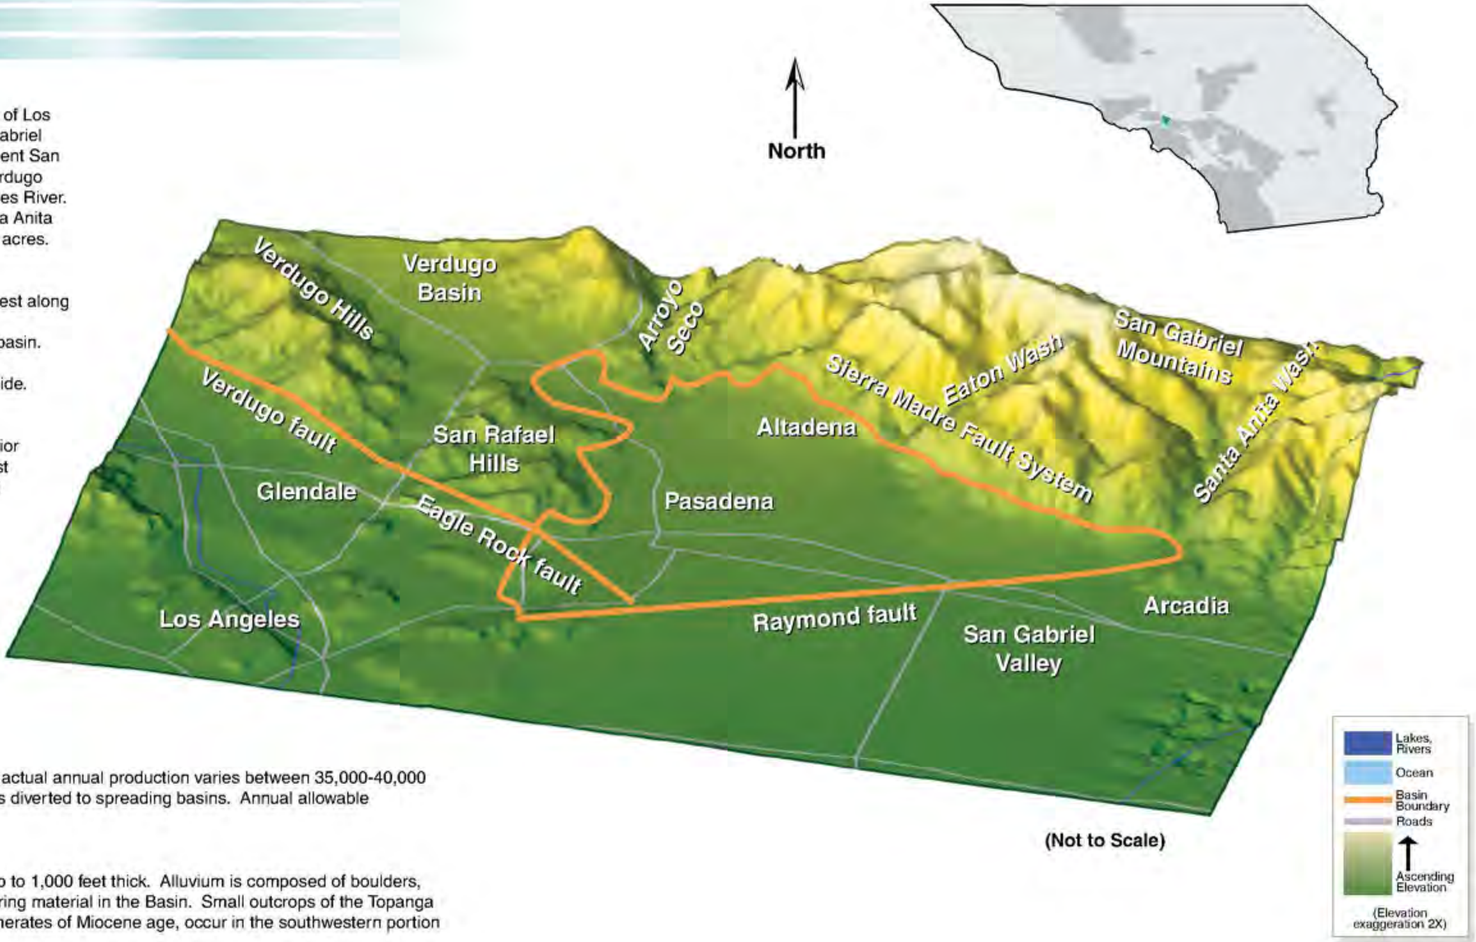
- Sierra Madre Fault System that trends southeast to northwest along the base of the San Gabriel Mountains.
- Raymond fault, which forms the southern boundary of the basin.
- Eagle Rock fault in the southwestern part of the basin.
- Eaton Wash fault, which occurs intrabasin on the eastern side.

Basin Management

The Raymond Basin was adjudicated in 1944, following the Superior Court Judgment Pasadena v. Alhambra, et al. This marked the first groundwater adjudication in the State of California. The Raymond Basin Management Board governs the basin.

Available Storage

The fresh water storage capacity of the basin is a minimum of 250,000 acre-feet (AF). As of June 30, 1999, approximately 56,000 AF of water was stored in the Basin by various parties and approximately 194,000 AF of unused storage was available. Raymond Basin recently began implementation of a conjunctive use program with Metropolitan Water District to store 75,000 AF of water for use during dry years.



Present Operational Safe Yield

The present operational safe yield of the Basin is 30,622 AFY, but actual annual production varies between 35,000-40,000 AFY depending upon the amount of local storm runoff water that is diverted to spreading basins. Annual allowable extractions vary between 35,000-43,000 AFY.

Basin Sediments

Raymond Basin is underlain by unconsolidated alluvial deposits up to 1,000 feet thick. Alluvium is composed of boulders, gravel, sand, silt, and clay, and constitutes the principal water-bearing material in the Basin. Small outcrops of the Topanga Formation, which consists of consolidated sandstone and conglomerates of Miocene age, occur in the southwestern portion of the Basin.

Conjunctive Use Potential

The results of AGWA's survey indicate the potential to store an additional 144,000 AF of water for use in dry years.

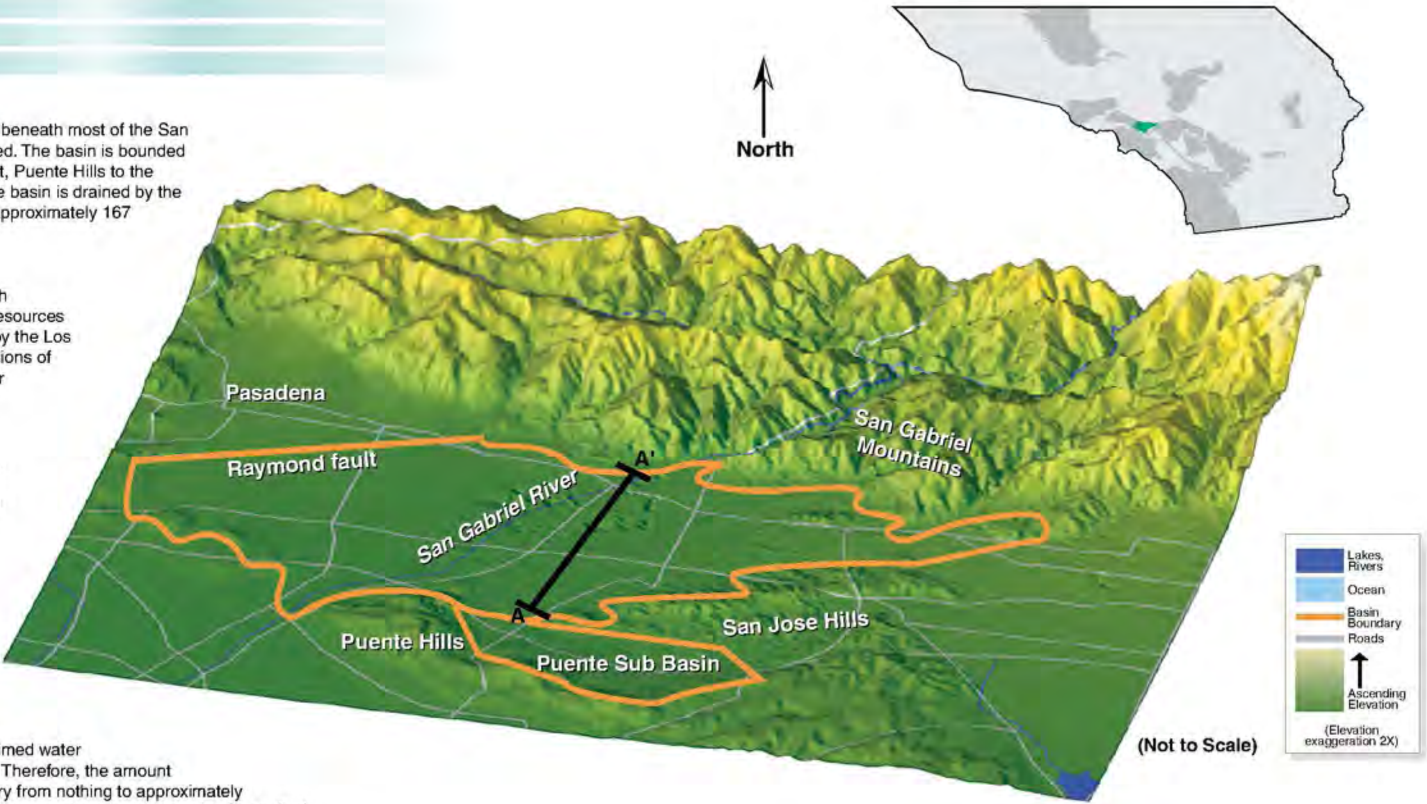
6. Main San Gabriel Basin

Location
The Main San Gabriel Basin underlies eastern Los Angeles County, beneath most of the San Gabriel Valley and a portion of the upper San Gabriel River watershed. The basin is bounded by the San Gabriel Mountains to the north, San Jose Hills to the east, Puente Hills to the south, and by a series of hills and the Raymond fault to the west. The basin is drained by the San Gabriel River and Rio Hondo. The surface area of the Basin is approximately 167 square miles or 106,880 acres.

Basin Management
The Main San Gabriel Basin Watermaster is the agency charged with administering adjudicated water rights and managing groundwater resources within the basin. The Watermaster, a nine-person board appointed by the Los Angeles County Superior Court, administers and enforces the provisions of the Judgement that established water rights and the responsibility for efficient management of the quantity and quality of the basin's groundwater.

The Puente Subbasin is located in the southeast portion of the map, and is hydraulically connected to the basin, with no barriers to groundwater movement. However, the Puente Subbasin is not within the legal jurisdiction of the Watermaster, and is thus considered a separate entity for management purposes.

Available Storage
The freshwater storage capacity of the basin is estimated to be about 8.6 million acre-feet (AF). Of this amount, approximately 400,000 acre-feet is usable for water supply. Historically, the maximum utilization of basin storage has been 900,000 AF; however, the storage available for imported and reclaimed water is dependent upon the water surface elevation at the Baldwin Park Key Well. When the water surface elevation exceeds 250 feet, neither imported nor reclaimed water can be placed in storage, except in the eastern portion of the basin. Therefore, the amount of storage generally available for imported or reclaimed water will vary from nothing to approximately 400,000 AF. To date, 170,000 AF has already been committed to various producers and agencies for cyclical storage.



(Not to Scale)

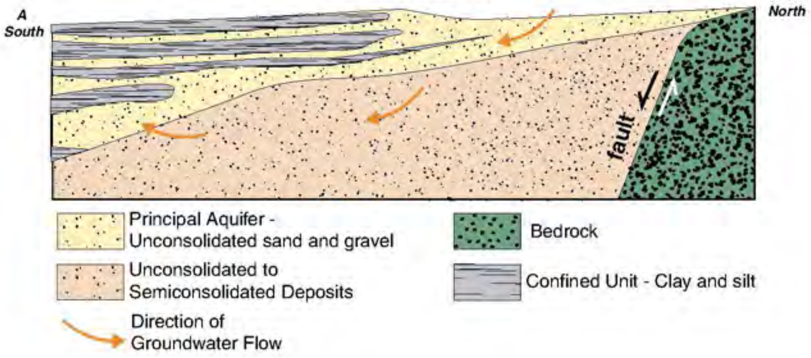
Present Operational Safe Yield
The operational safe yield of the basin is determined annually by the Watermaster and has ranged from a low of 140,000 AF to a high of 230,000 AFY averaging almost 200,000 AFY since 1973-74. The operational safe yield for fiscal year 2000-01 is 220,000 AFY.

Basin Sediments
The principal water-bearing formations of the basin are unconsolidated and semi-consolidated sediments that range from fine-grained sands to coarse gravel.

The major sources of groundwater recharge are infiltration of rainfall on the valley floor and percolation of runoff in unlined storm channels and off-channel spreading grounds. The basin also receives imported water and return flow from applied water.

Conjunctive Use Potential
The results of AGWA's survey indicate existing conjunctive use programs have increased the basin operational yield by 76,000 AFY. Additionally, the survey indicated the potential to store up to 400,000 AF of water for use in dry years and a potential increase in basin operational yield of 187,000 AFY.

Cross Section A-A'



7. Los Angeles Coastal Plain Basins

Location

The Los Angeles Coastal Plain is underlain by a structural basin formed by folding of the consolidated sedimentary, igneous, and metamorphic rocks that underlie the basin at great depths. Although the subsurface structure of the coastal plain is complex, two major northwest-trending troughs, which are separated for most of their length by the Newport-Inglewood Fault Zone (uplift), contain the sediments that compose the aquifer system. These sediments are as thick as 30,000 feet in some areas.

The Los Angeles Coastal Plain is bordered by the Santa Monica Mountains to the north, the Palos Verdes Hills and Pacific Ocean to the west, the Puente, Elysian, Repetto, and Merced Hills to the northeast, and the Los Angeles/Orange County line to the east and southeast. Primarily the Los Angeles and San Gabriel River systems drain the Coastal Plain.

The Coastal Plain is divided into four groundwater basins:

- The **Central Basin** extends over most of the coastal plain, east and northeast of the Newport-Inglewood Uplift. The basin occupies approximately 278 square miles (177,920 acres) and contains unconfined and confined alluvial aquifers (further subdivided into the Montebello Forebay, Los Angeles Forebay, Whittier Area, and Central Basin Pressure Area).

- The **West Coast Basin** extends southwesterly from the Newport-Inglewood Uplift to Santa Monica Bay, to the drainage divide on the Palos Verdes Hills, and to San Pedro Bay. The basin occupies approximately 172 square miles (110,080 acres) and contains mostly confined alluvial aquifers.

- The **Santa Monica Basin** is bounded by the Santa Monica Mountains to the northwest, the Hollywood Basin to the northeast and east, the West Coast Basin to the south, and Santa Monica Bay to the west (further subdivided into the Coastal, Charnock, and Crestal sub-basins). The basin occupies approximately 46 square miles (29,440 acres) and contains mostly confined alluvial aquifers.

- The **Hollywood Basin**, which is approximately 16 square miles (10,240 acres) in size, is an east-west syncline that lies between two branches of the Hollywood fault. The basin is bounded by the Newport-Inglewood Uplift on the west, the Elysian Hills on the east, the La Brea High to the south, and the Santa Monica Mountains to the north. The aquifers are both confined and unconfined.

Basin Management

The Central and West Coast Basins are both adjudicated. The California Department of Water Resources is the court-appointed Watermaster and the Water Replenishment District of Southern California has assumed the role of groundwater basin manager.

The Santa Monica and Hollywood Basins are neither adjudicated nor formally managed.

Total Stored Water	**Present Operational Safe Yield**	**Available Storage**
Central Basin - 13,800,000 AF	Central Basin - 217,367 AFY[1]	Central Basin - 789,000 AF
West Coast Basin - 6,500,000 AF	West Coast Basin - 64,468 AFY[1]	West Coast Basin - 300,000 AF
Santa Monica Basin - 1,100,000 AF	Santa Monica Basin - 100 AFY[2]	Santa Monica Basin - not available
Hollywood Basin - 200,000 AF	Hollywood Basin - 4,400 AFY[2]	Hollywood Basin - not available

Basin Sediments

Deposition in the Los Angeles Coastal Plain has been largely influenced by sea-level fluctuations combined with alluvial sedimentation related to ancestral river systems that traversed the Coastal Plain. Water-bearing sediments are primarily of Pleistocene age and 11 aquifers have been named:

- Semi-perched
- Gaspur
- Artesia
- Exposition
- Gage
- Gardena
- Hollydale
- Jefferson
- Lynwood
- Silverado
- Sunnyside

Groundwater also occurs in the Pliocene Pico Formation, but generally at insufficient quantities and quality to supply production wells.

Each aquifer consists of a distinct layer of water-yielding sand and gravel usually separated from other sand and gravel beds by clay and silt confining units. In many places, however, the water-yielding sediments of the different aquifer may be in direct hydraulic contact with each other, or the intervening confining units contain sufficient sand and gravel to allow water to pass between adjacent aquifers.

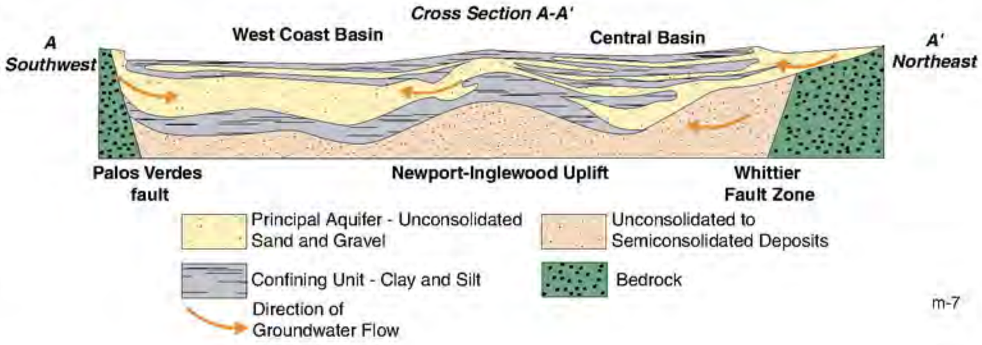
A layer of clay and silty clay of marine and continental origin, which is at or near the land surface over most of the coastal plain, is a competent confining unit where it does not contain large amounts of sand and gravel. This confining unit ranges from less than 1 foot to about 180 feet in thickness. In the Los Angeles and Montebello Forebays, the confining unit is not present, and groundwater is under unconfined, or water table, conditions.

Freshwater is contained within deposits that range in age from Holocene to late Pliocene. The main freshwater body extends from depths of less than 100 to about 4,000 feet. At greater depths, the water is saline and unpotable. The freshwater body is thickest near the axis of the troughs where water-yielding sediments reach their greatest thickness, and thinnest where these sediments overlie anticlines or become thin at the margins of the aquifer system.

The Montebello and Los Angeles Forebays are areas of groundwater recharge, whereby deep aquifers are hydraulically connected to the ground surface and further characterized by the absence of the Bellflower aquiclude (a thick silt/clay layer). The Pressure Area is typified by the presence of the Bellflower aquiclude near the ground surface, thereby preventing groundwater recharge.

Conjunctive Use Potential

The results of AGWA's survey indicate existing conjunctive use programs have increased the basin operational yield by 54,000 AFY. Additionally, the survey indicated the potential to store up to 1,089,000 AF of water for use in dry years and a potential increase in basin operational yield of 54,300 AFY.



---

[1] Adjudicated amount

[2] DWR Bulletin 104-B, 1962 "Safe Yield Determinations", Table 27

8. Orange County Coastal Plain Basin

Location
The Orange County groundwater basin underlies the Orange County Coastal Plain, beneath the broad lowlands known as the Tustin and Downey Plains. The basin is bounded by the Los Angeles County Line, Coyote Hills, and Chino Hills to the north, the Pacific Ocean and Newport-Inglewood Uplift to the west, the Santa Ana Mountains to the east, and non-water bearing formations that occupy the southern half of Orange County to the south. The surface area of the basin is approximately 350 square miles or 224,000 acres.

Basin Management
The basin is managed by the Orange County Water District (OCWD) and is not adjudicated.

OCWD was created in 1933 by California State legislation to manage and protect the vast groundwater basin under north central Orange County. Since that time, OCWD has tripled the yield of the basin through a tradition of innovation that includes expansion and improvements to recharge facilities, employment of well head and other treatment technologies, water research, conservation and reclamation projects. OCWD's Water Factory 21, which remains a model for water reclamation around the world, provides millions of gallons of water each day to create a fresh water barrier against seawater intrusion and to replenish the basin. OCWD's Green Acres irrigation and industrial water project frees up thousands of acre-feet of potable water each year.

OCWD supplies reliable, high-quality groundwater to more than 23 cities and water agencies serving 2 million residents. The basin is recharged primarily from the Santa Ana River and to a lesser extent from imported water purchased from the Metropolitan Water District of Southern California. OCWD monitors the groundwater extracted each year to ensure that the basin is not overdrawn and carries out an assessment program to pay for operating expenses and the cost of imported replenishment water.

OCWD has one of the most sophisticated groundwater protection programs in the world using an array of monitoring wells. The wells provide input to a three-layer groundwater model of the basin that is used for basin management.

Available Storage
The freshwater storage capacity of the basin is 1,000,000 AF and there are 300,000 AF of available storage.

Present Operational Safe Yield
The present operational safe yield of the basin is 350,000 AFY and this is expected to increase in the future by 130,000 AF.

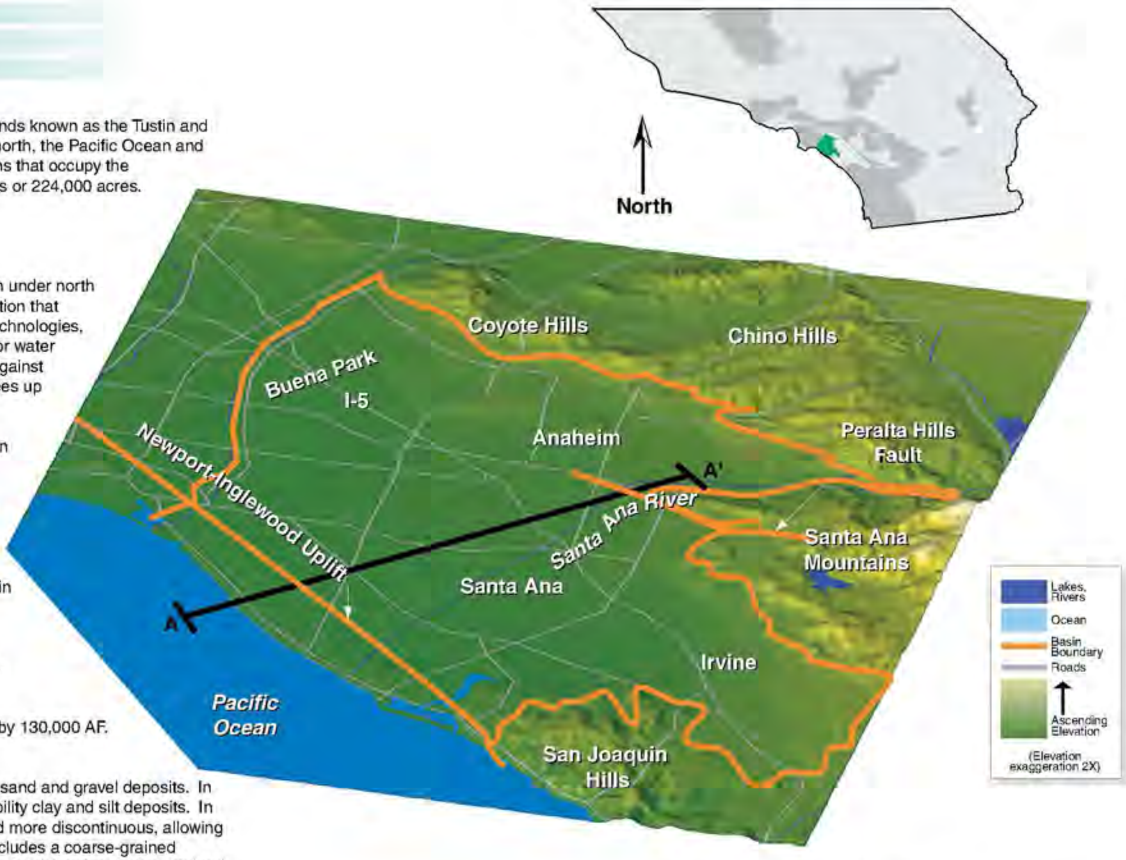
Basin Sediments
The aquifers comprising the basin extend over 2,000 feet deep and form a complex series of interconnected sand and gravel deposits. In the coastal and central portions of the basin, these deposits are more separated by extensive lower permeability clay and silt deposits. In the inland area of the basin, generally northeast of Interstate 5, the clay and silt deposits become thinner and more discontinuous, allowing groundwater to flow more easily between shallow and deeper aquifers. The northeast portion of the basin includes a coarse-grained unconfined forebay area. Moving toward the coast, the basin becomes confined with finer-grained sediments overlying the coarser-grained aquifer.

The basin is divided into two hydrologic components, the forebay and pressure areas. The forebay/pressure boundary generally delineates the area where surface water nor shallow groundwater can/cannot move downward in significant quantities. The boundary represents a transition zone where low-permeability clay and silt deposits increasingly occur in near-surface sediments southwest of the boundary.

The forebay refers to the area of intake or recharge, where the majority of recharge to the basin occurs primarily by direct percolation of Santa Ana River water. The forebay area, underlying most of the cities of Anaheim, Fullerton, and Villa Park, and portions of the cities of Orange and Yorba Linda, is characterized by highly permeable sands and gravel with few clay and silt deposits.

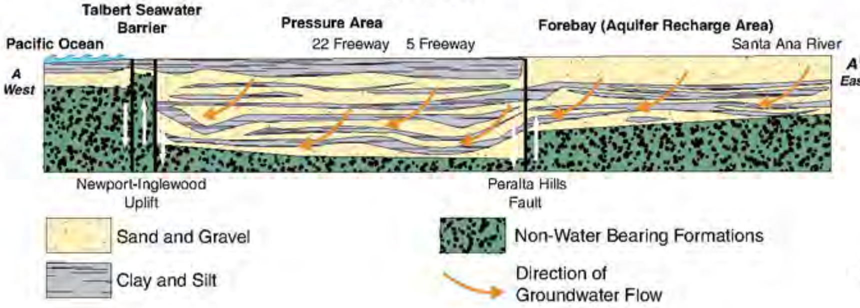
The pressure area is defined as the area in the basin where surface water and near surface groundwater are prevented from percolating in large quantities into the producible aquifers by clay and silt layers at shallow depths. Most of the central and coastal portions of the basin fall within the pressure area.

Conjunctive Use Potential
The results of AGWA's survey indicate existing conjunctive use programs have increased the basin operational yield by 150,000 AFY. Additionally, the survey indicated the potential to store up to 300,000 AF of water for use in dry years and a potential increase in basin operational yield of 130,000 AFY.



(Not to Scale)

Cross Section A-A'



9. Six Basins

Location
Six Basins is comprised of the following groundwater basins:

- San Antonio Canyon Basin
- Live Oak Basin
- Upper Claremont Heights Basin
- Lower Claremont Heights Basin
- Pomona Basin
- Ganesha Basin

Six Basins underlie the cities of Claremont, La Verne, and Pomona in northeastern Los Angeles County and northwestern San Bernardino County.

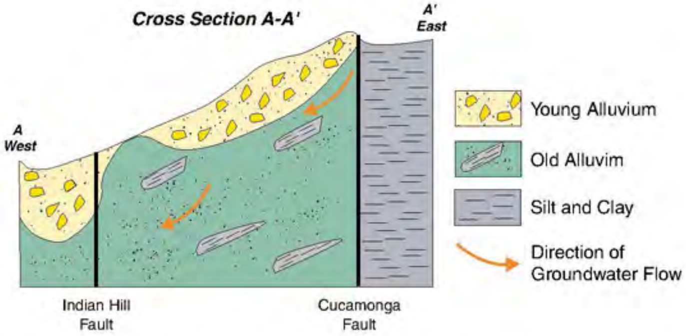
Basin Management
The Six Basins Watermaster was formed by a stipulated agreement, the final Judgement becoming effective January 1999. The judgement establishes groundwater rights and provides a structure for the operation and management of the Six Basins.

Available Storage
The available freshwater storage capacity of the aquifer is 30,000 acre-feet (AF).

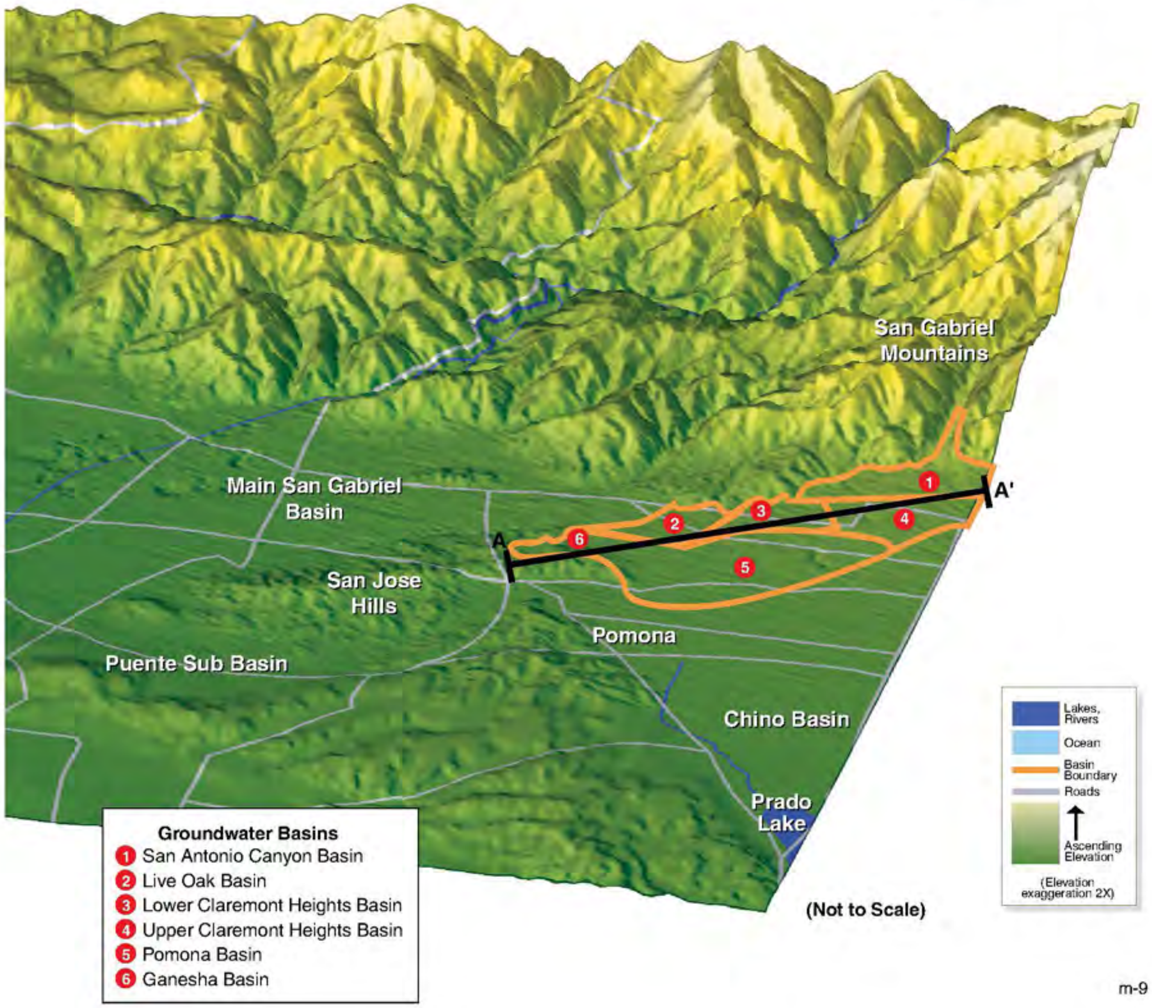
Present Operational Safe Yield
The present operational safe yield of Six Basins is 24,000 acre-feet per year (AFY).

Basin Materials
Aquifer materials consist primarily of sand and gravel deposited as alluvial fans. Silt and clay deposits increase with distance away from the San Gabriel Mountains. Basin depth generally increases with distance away from the San Gabriel Mountains, but is complicated by faulting.

Cross Section A-A'



Conjunctive Use Potential
The results of AGWA's survey indicate the potential to store up to 30,000 AF of water for use in dry years and a potential increase in basin operational yield of 30,000 AFY.



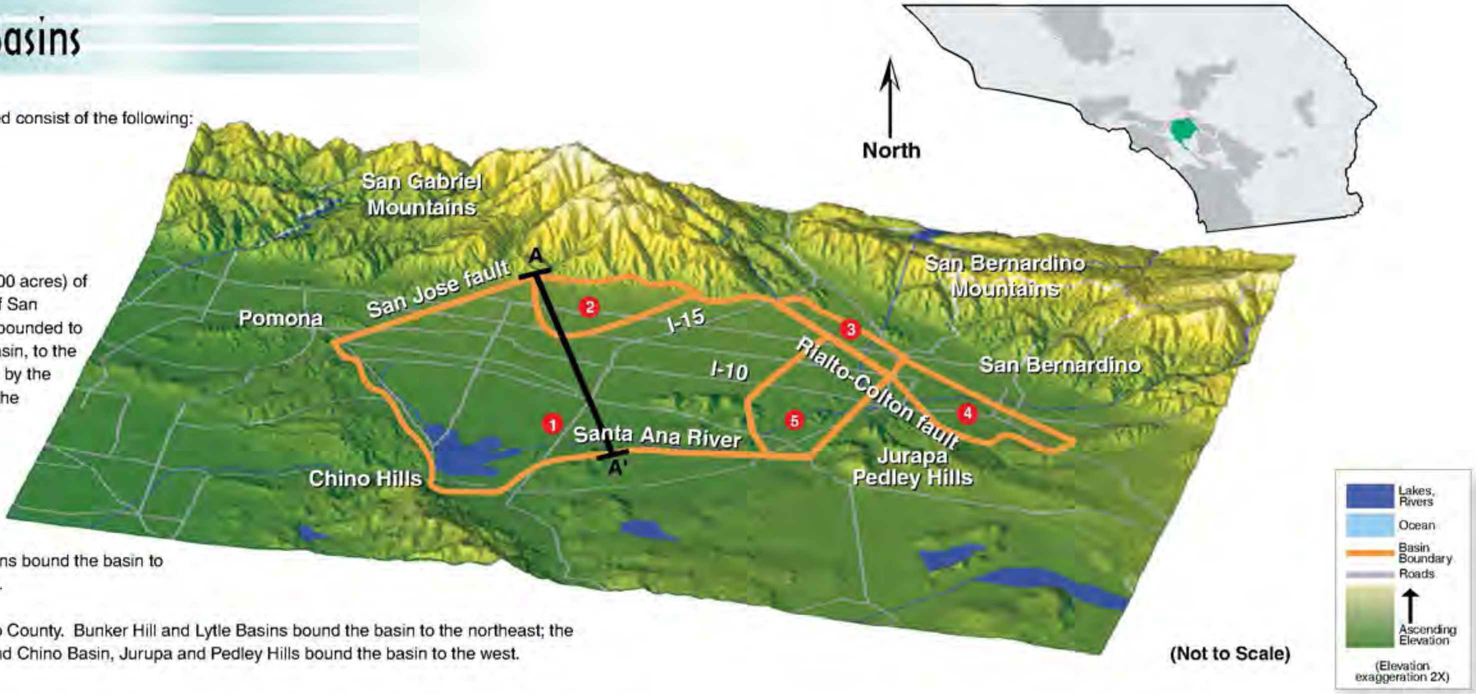
(Not to Scale)

10. Upper Santa Ana River Basins

Location

The groundwater basins of the upper Santa Ana River watershed consist of the following:

- Chino Basin
- Cucamonga Basin
- Rialto Basin
- Colton Basin
- Riverside Basin



Chino Basin consists of approximately 235 square miles (154,400 acres) of the Upper Santa Ana River Watershed and underlies portions of San Bernardino, Los Angeles and Riverside Counties. The basin is bounded to the north by the San Gabriel Mountains and the Cucamonga Basin, to the south by the La Sierra area and the Temescal Basin, to the east by the Colton and Rialto basins, Jurupa Hills, and Pedley Hills, and to the west by the Chino Hills, Puente Hills, and the Pomona and Claremont basins.

Cucamonga Basin comprises approximately 22 square miles (14,000 acres) and is located at the base of the San Gabriel Mountains near the communities of Upland, Rancho Cucamonga, Etiwanda, and Fontana. The San Gabriel Mountains bound the basin to the north. The Red Hill fault bounds the basin on all other sides.

Rialto and Colton Basins are located in western San Bernardino County. Bunker Hill and Lytle Basins bound the basin to the northeast; the San Bernardino Mountains bound the basin to the northwest; and Chino Basin, Jurupa and Pedley Hills bound the basin to the west.

Basin Management

Chino Basin is an adjudicated basin managed by the Chino Basin Watermaster (Watermaster). The Watermaster was established under a judgement entered in the Superior Court of the State of California for the County of San Bernardino, entitled "Chino Basin Municipal Water District vs. City of Chino et al". The Basin has been operated as described in the 1978 judgement.

Cucamonga Basin was adjudicated in 1958 and is jointly managed by the Cucamonga County Water District and San Antonio Water Company. The Rialto and Colton Basins were adjudicated in 1961.

Available Storage

The unused storage capacity in Chino and Riverside-Colton Basins is 1,000,000 acre-feet (AF) and 98,000 AF, respectively. Cucamonga Basin has no unused storage capacity.

Present Operational Safe Yield

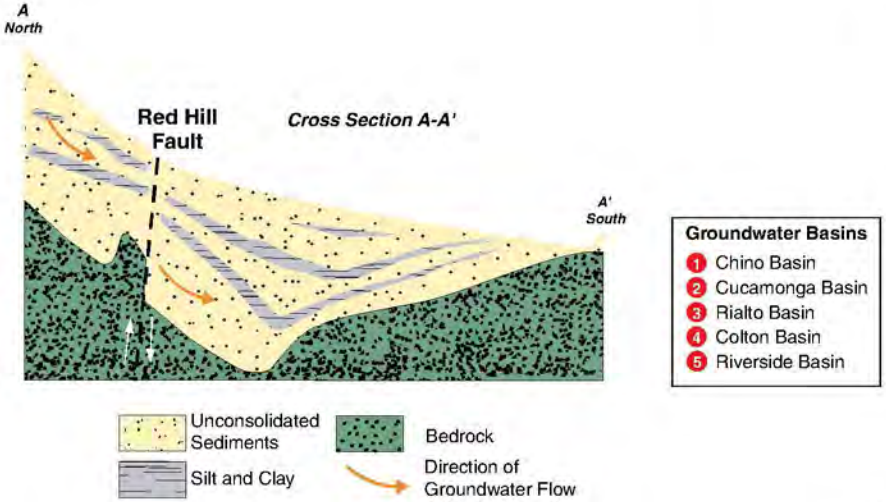
The present operational safe yield of Chino Basin is 145,000 acre-feet per year (AFY), and that of Cucamonga and Riverside-Colton Basins is about 14,000 to 22,000 and 9,000 AFY, respectively.

Basin Materials

Sediments in Chino Basin are alluvial in origin and derived from the surrounding San Bernardino and San Gabriel Mountains. Sediments are coarser in the northern part of the basin and the aquifer is unconfined. From north to south, the aquifer becomes finer-grained and semi-confined. Alluvial sediments also dominate in Cucamonga Basin, Rialto, and Colton Basins.

Conjunctive Use Potential

The results of AGWA's survey indicate existing conjunctive use programs have increased the basin operational yield by 43,000 AFY. Additionally, the survey indicated the potential to store up to 1,854,000 AF of water for use in dry years and a potential increase in basin operational yield of 47,000 AFY.



11. Bunker Hill Basin

Location

The Bunker Hill Groundwater Basin is located in San Bernardino County, and is partially overlain by the City of San Bernardino. The basin is bounded on the northeast by the San Andreas fault, on the southwest by the San Jacinto fault, on the southeast by the Crafton Hills fault, and on the northwest by the San Bernardino Mountains.

Basin Management

The basin is adjudicated. The San Bernardino Valley Municipal District (SBVWCD) Watermaster manages the basin.

Available Storage

The fresh water storage capacity of the basin is estimated at 1,432,000 AF. Currently, the basin is essentially full.

Present Operational Safe Yield

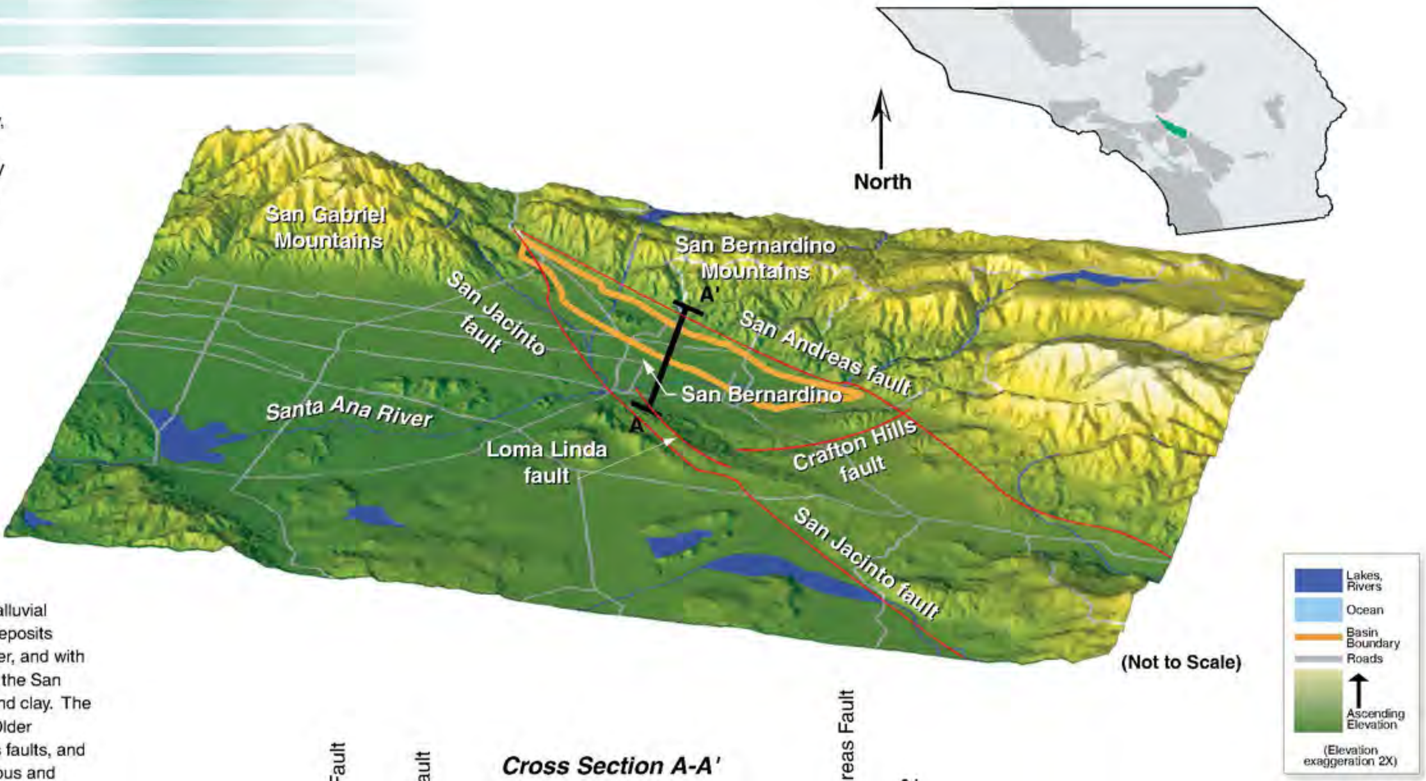
The present operational safe yield of the basin is 224,300 AFY.

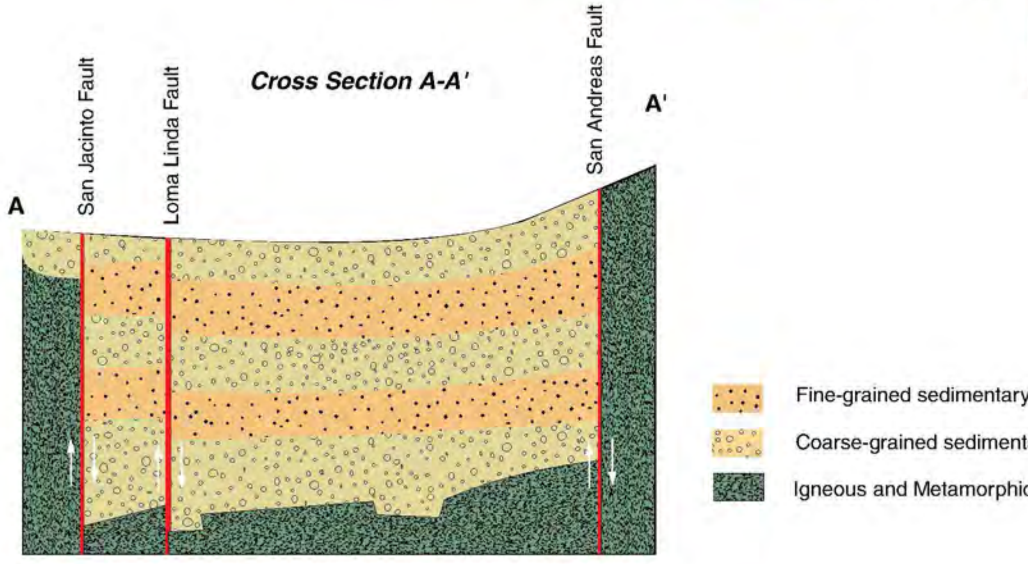
Basin Sediments

The basin is a sediment-filled structural trough between the San Andreas and San Jacinto faults in the upper part of the Santa Ana River Watershed near the base of the San Bernardino Mountains. Sediments generally consist of unconsolidated alluvial fan deposits derived from the surrounding mountains and hills. These deposits interfinger with river-channel deposits, primarily from the Santa Ana River, and with freshwater marsh deposits associated with groundwater discharge near the San Jacinto fault. Younger alluvium consists of boulders, gravel, sand, silt, and clay. The depth to the base of the younger alluvium ranges from 70 to 110 feet. Older alluvium consists of gravel, sand, silt, and clay, is fractured by numerous faults, and constitutes the principal aquifer of the area. A bedrock complex of igneous and metamorphic rocks underlies valley fill sediment.

Conjunctive Use Potential

The results of AGWA's survey indicate existing conjunctive use programs have increased the basin operational yield by 6,000 AFY. The basin is full so there is currently no storage space available for dry year storage.





12. San Jacinto Watershed Basins

Location
The basins of the San Jacinto Watershed are located in western Riverside County and consist of the following subbasins:

- Lakeview
- Perris North and South
- Winchester
- San Jacinto - Lower Pressure
- Menifee
- East Valley or East San Jacinto Groundwater Basin Area
- San Jacinto - Canyon
- San Jacinto - Intake and Upper Pressure
- Hemet

Basin Management
The Lakeview, Perris North, Perris South, Winchester, San Jacinto Lower Pressure, and Menifee subbasins are managed under the West San Jacinto Groundwater Management Plan (AB3030) adopted in June 1995. The Eastern Municipal Water District (EMWD) is the basin manager under the Plan. The basins are not adjudicated.

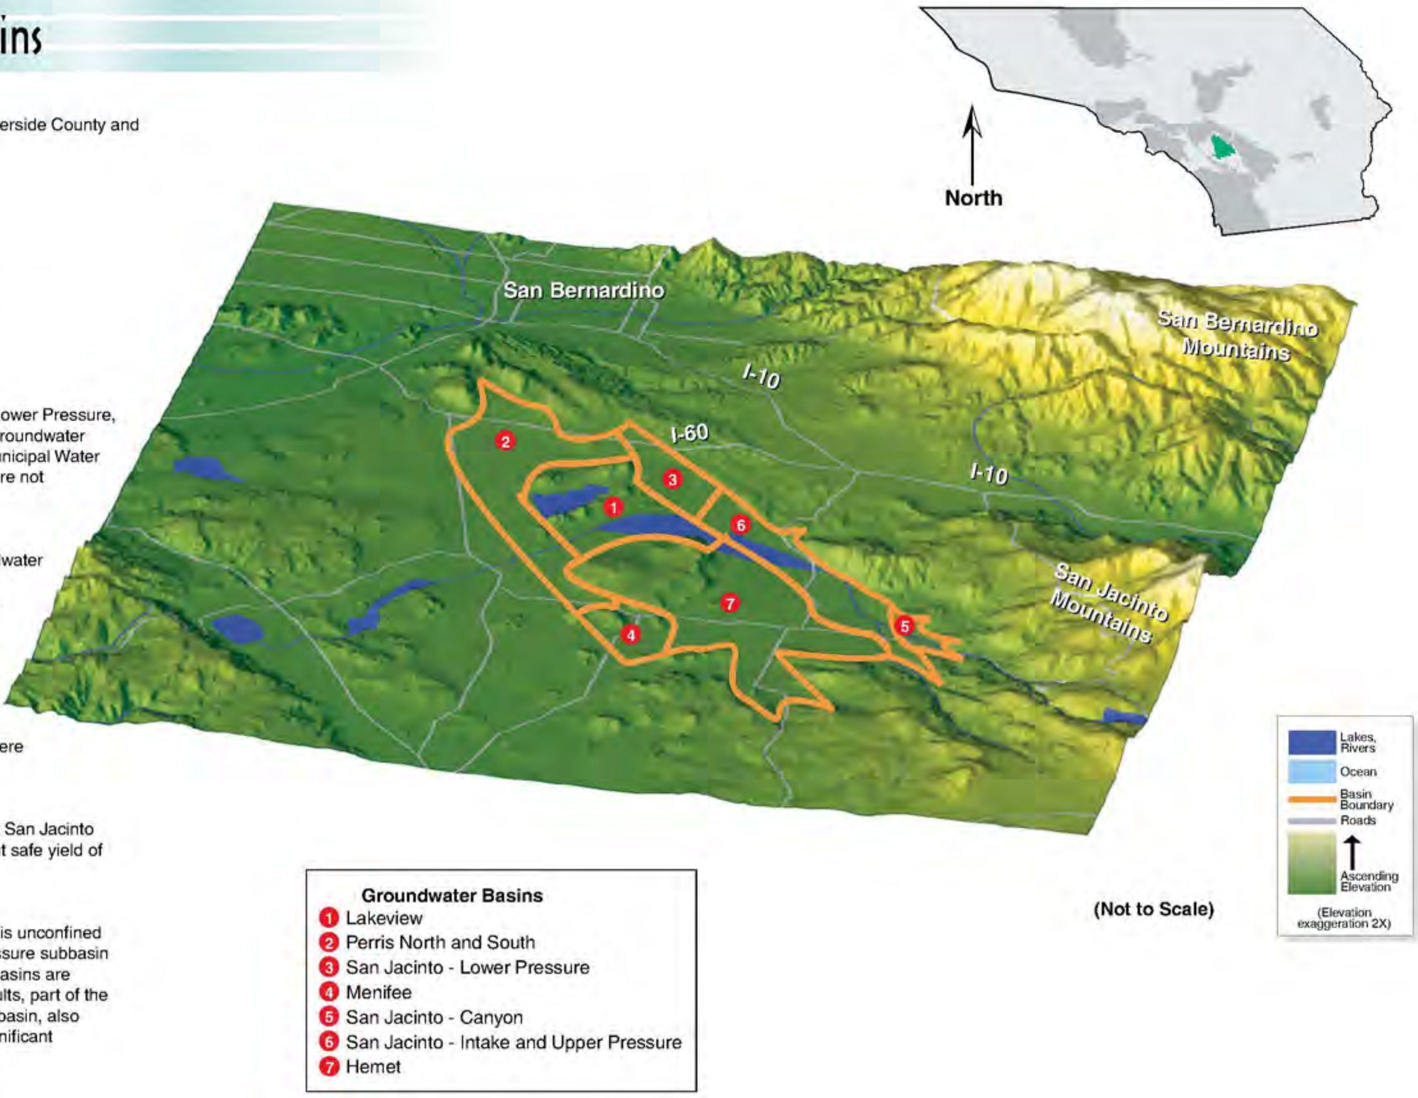
The San Jacinto Canyon, Intake and Upper Pressure, and Hemet subbasins are known as the East Valley or East San Jacinto Groundwater Basin Area. EMWD, local agencies/cities, and private groundwater producers are working to develop a groundwater management plan. The basins are not adjudicated.

Available Storage
The freshwater storage capacity of the basins of the West San Jacinto Groundwater Management Plan Area is 5,254,500 AF, and there are 726,000 AF of available storage. The freshwater storage of the basins of the East Valley Area is 5,080,000 AF and there are 558,000 AF of available storage.

Present Operational Safe Yield
The present operational safe yield of the nine subbasins in the West San Jacinto Groundwater Management Plan Area is 22,000 AFY and the present safe yield of the three subbasins in the East Valley Area is 60,000 AFY.

Basin Sediments
The groundwater aquifers consist of alluvial deposits. Groundwater is unconfined with the exception of the groundwater in the San Jacinto Lower Pressure subbasin which is a confined aquifer. The San Jacinto Upper and Lower subbasins are defined by the graben formed by the Casa Loma and Claremont Faults, part of the San Jacinto Fault Zone. The fault zone, in the northeast part of the basin, also contains the Park Hill, Bautista, and other named faults, and is a significant feature in the Basin.

Conjunctive Use Potential
The results of AGWA's survey indicate existing conjunctive use programs have increased the basin operational yield by 3,000 AFY. Additionally, the survey indicated the potential to store up to 1,284,000 AF of water for use in dry years and a potential increase in basin operational yield of 10,000 AFY.



Groundwater Basins
1. Lakeview
2. Perris North and South
3. San Jacinto - Lower Pressure
4. Menifee
5. San Jacinto - Canyon
6. San Jacinto - Intake and Upper Pressure
7. Hemet

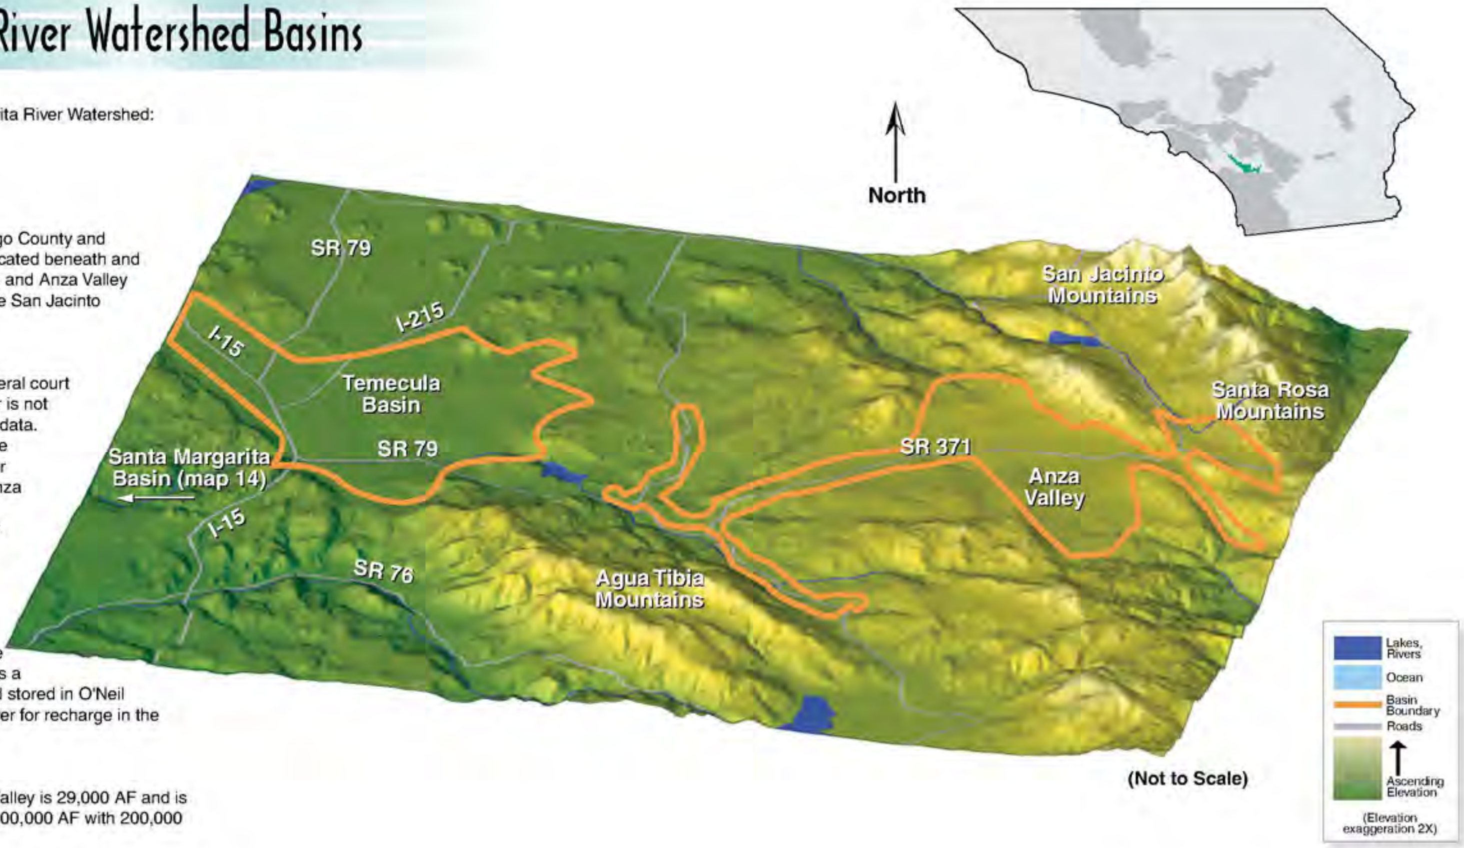
13. Upper Santa Margarita River Watershed Basins

Location
There are three major groundwater basins of the Santa Margarita River Watershed:

- Santa Margarita Basin (location shown on map 14 due to its location in San Diego County)
- Temecula Basin
- Anza Valley

The Santa Margarita Basin is located in northwestern San Diego County and underlies Camp Pendleton (See map 14). Temecula Basin is located beneath and around the City of Temecula, in south-central Riverside County, and Anza Valley is located to the east along Highway 371 and to the south of the San Jacinto Mountains and to the west of the Santa Rosa Mountains.

Basin Management
The Santa Margarita River Watershed is adjudicated under federal court jurisdiction. The Santa Margarita River Watershed Watermaster is not charged with basin management but does collect and manage data. The Santa Margarita Basin is managed by Camp Pendleton; the Temecula Basin is largely managed by Rancho California Water District and to a lesser extent by Murietta Water District; and Anza Valley is not managed. Currently, the watershed has three ongoing conjunctive use projects, two of which are operated by Rancho California Water District and one by Camp Pendleton. Rancho California Water District imports water for recharge into spreading basins and extracts the water using wells. The District also owns Vail Lake on Temecula Creek. During wet years, water is impounded behind Vail Lake and later released, recharged in spreading basins and the creek bottom, and extracted by wells. Camp Pendleton operates a seasonal conjunctive use project whereby water is diverted and stored in O'Neil Lake during the wet months and later released back into the river for recharge in the fall.



Available Storage
The freshwater storage capacity of the Santa Margarita River Valley is 29,000 AF and is currently full. The storage capacity of the Temecula Basin is 2,000,000 AF with 200,000 AF of available storage.

Present Operational Safe Yield
The present operational safe yields of the Santa Margarita Basin, Temecula Basin, and Anza Valley are 5,600 AFY, 37,700 AFY and 12,000 AFY respectively.

Basin Sediments
Groundwater generally occurs in three aquifer zones:

- Younger to older alluvium (Top Zone)
- Pauba Aquifer (Middle Zone)
- Temecula Arkose (Bottom Zone)

All three zones are present in the Temecula Basin, whereas younger alluvium dominates the Santa Margarita Basin and both older and younger alluvium comprise the Anza Valley.

Conjunctive Use Potential
The results of AGWA's survey indicate existing conjunctive use programs have increased the basin operational yield by 10,000 AFY. Additionally, the survey indicated the potential to store up to 200,000 AF of water for use in dry years and a potential increase in basin operational yield of 10,000 AFY.

14. San Diego County Basins

Location
San Diego County overlies numerous groundwater basins. Seven of the basins, each with a total storage capacity greater than 10,000 AF, are listed below and shown on the map.

- Santa Margarita River Basin
- Warner Basin
- San Pasqual Basin
- Santa Maria Basin
- Santee/El Monte Basin
- Mission Valley Basin
- San Diego Formation Aquifer
- San Luis Rey River Basin

Basin Management
Water rights court decisions have been rendered within the Santa Margarita Basin, upper San Luis Rey River, lower Tijuana River Valley, and the San Diego River watersheds. Other watersheds in the county remain non-adjudicated; however, a number of agencies have long-standing surface water rights.

Available Storage
The combined fresh water storage capacity within the alluvial aquifers is estimated to exceed 700,000 acre-feet (AF). In addition to the shallow alluvial aquifers, a deeper aquifer exists in the southwest corner of the county, termed the San Diego Formation Aquifer. The San Diego Formation aquifer has been estimated to have a storage capacity in excess of 960,000 AF. Though active management of both groundwater pumping and groundwater quality, storage in these basins can be utilized for conjunctive use.

Present Operational Safe Yield
The present operational safe yield of these basins is approximately 60,000 AF.

Basin Sediments
The principal aquifer materials are alluvium, semi-consolidated sediment, and to a lesser degree, consolidated sediment, residuum, and fractured crystalline rock. Unconsolidated deposits of alluvium and residuum are typically found near the surface in major river and stream valleys.

Conjunctive Use Potential
The results of AGWA's survey indicate the potential to store up to 270,700 AF of water for use in dry years and a potential increase in basin operational yield of 41,500 AFY.

Groundwater Basins

1. Santa Margarita River Basin
2. Warner Basin
3. San Pasqual Basin
4. Santa Maria Basin
5. Santee/El Monte Basin
6. Mission Valley Basin
7. San Diego Formation Aquifer
8. San Dieguito River Basin
9. Lower Tijuana River Valley Basin
10. Sweetwater River
11. San Luis Rey River Basin

15. Mojave River Basins

Location
The Mojave Basin, traversed by the Mojave River, extends from the north side of the San Bernardino Mountains to the north and east through the cities of Victorville and Barstow. The basin is comprised of the following subbasins:

- Alto
- Centro
- Baja
- Este

Basin Management
The Mojave Water Agency (MWA) oversees groundwater production and recharge within the basin. The basin is adjudicated, with the goals of balancing pumped groundwater with imported water and natural recharge, in addition to returning groundwater levels to those of the 1930s. Although MWA does not currently restrict groundwater pumping, well owners must pay an assessment for groundwater pumped in excess of an annual allowance determined by MWA. Alternatively, a well owner may acquire unused pumping allowances from well owners located in the same groundwater subbasin. Ultimately, the assessment value will be equal to the cost of delivery and replacement of groundwater pumped in excess of the well owner's allowance.

Two pipelines bring imported surface water to the Mojave Basin. MWA currently oversees the operation of four groundwater recharge facilities that draw water from these pipelines. The recharge facilities and associated theoretical maximum recharge rates are listed below.

In addition to the above recharge facilities, discharges from Lake Silverwood occasionally provide recharge to the west fork of the Mojave River. Historic discharge rates vary from 2,000 to 25,000 AFY.

(Not to Scale)

Available Storage
Water levels in the Mojave Basin have been declining since the 1930s. As a result, the amount of available storage for conjunctive use has increased substantially. Since one of the goals of the basin adjudication is to return groundwater levels to pre-development conditions, the available storage may decrease in the future. Presently, the available storage of the basin is estimated as follows:

Subbasin	Available Storage
Alto	1,041,500 AF
Centro	217,700 AF
Baja	415,000 AF
Este	115,900 AF

Present Operational Safe Yield
The present operational safe yield of the Basin is summarized in the table below:

Subbasin	Present Operational Safe Yield
Alto	69,860 AFY
Centro	33,380 AFY
Baja	20,680 AFY
Este	7,160 AFY

Basin Sediments
The Mojave Basin is comprised of sand, gravel, and occasional clay deposits created by the Mojave River and surrounding streams. Impermeable metamorphic and igneous rocks that comprise the San Bernardino Mountains limit the southern extent of the basin. Intermittent streams generated by winter and summer precipitation supply natural groundwater recharge to this sedimentary basin.

Conjunctive Use Potential
The results of AGWA's survey indicate existing conjunctive use programs have increased the basin operational yield by 46,000 AFY. Additionally, the survey indicated the potential to store up to 1,790,100 AF of water for use in dry years and a potential increase in basin operational yield of 24,000 AFY.

16. Hayfield Basin

Location
The Hayfield Groundwater Basin is located in Riverside County, east of the Coachella Valley, west of Chuckwalla Valley, and south of the Eagle Mountains. Surface area of the basin is approximately 37 square miles (23,900 acres).

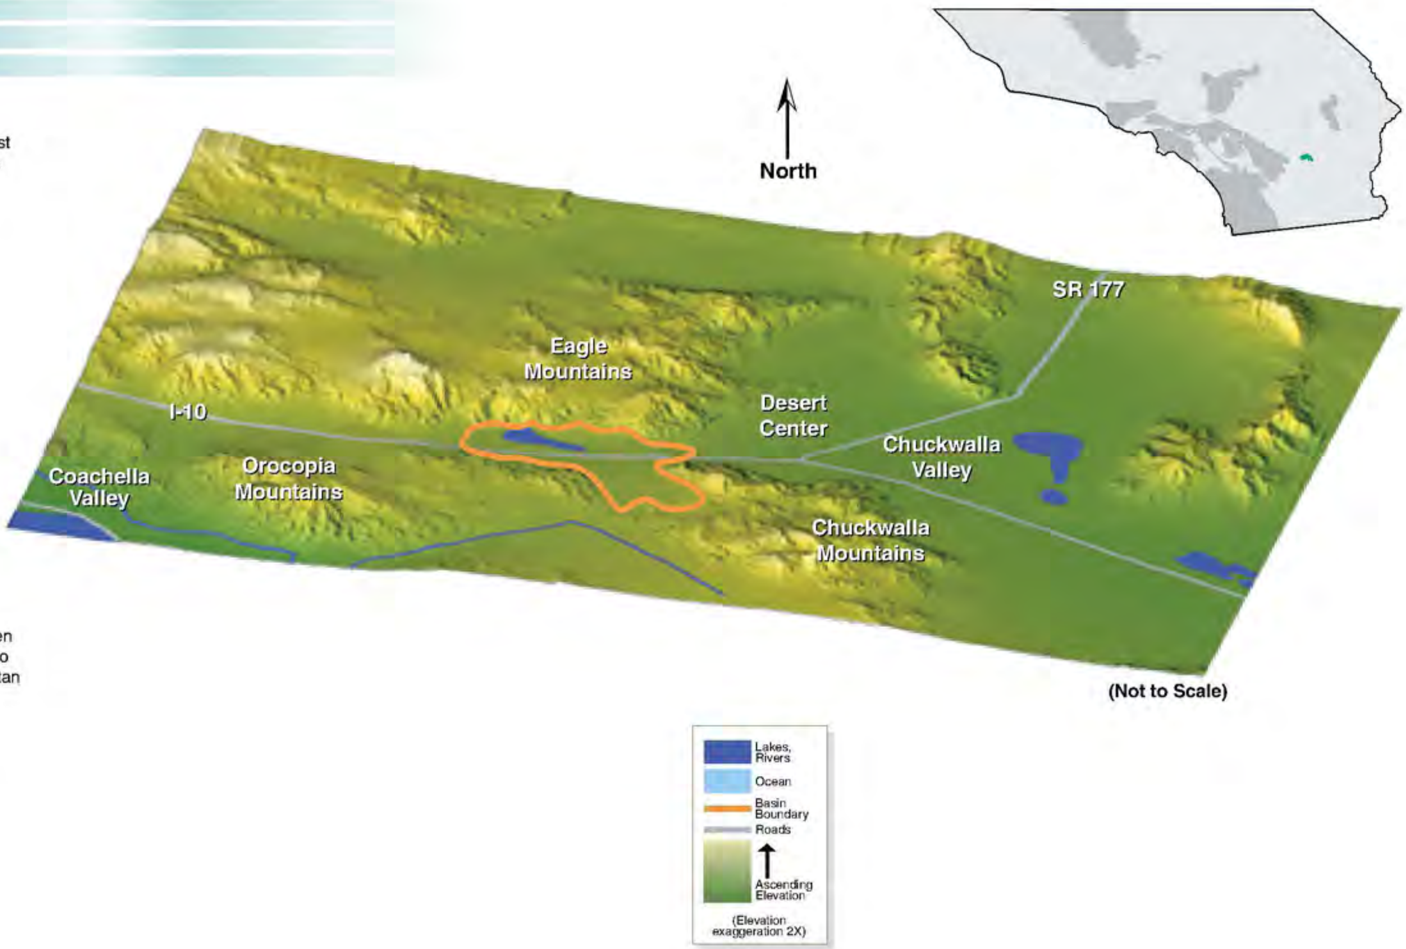
Basin Management
The Basin is neither adjudicated nor formally managed.

Available Storage
The total estimated storage capacity of the basin is 2,800,000 acre-feet (AF), with about 2,000,000 AF of native water in storage.

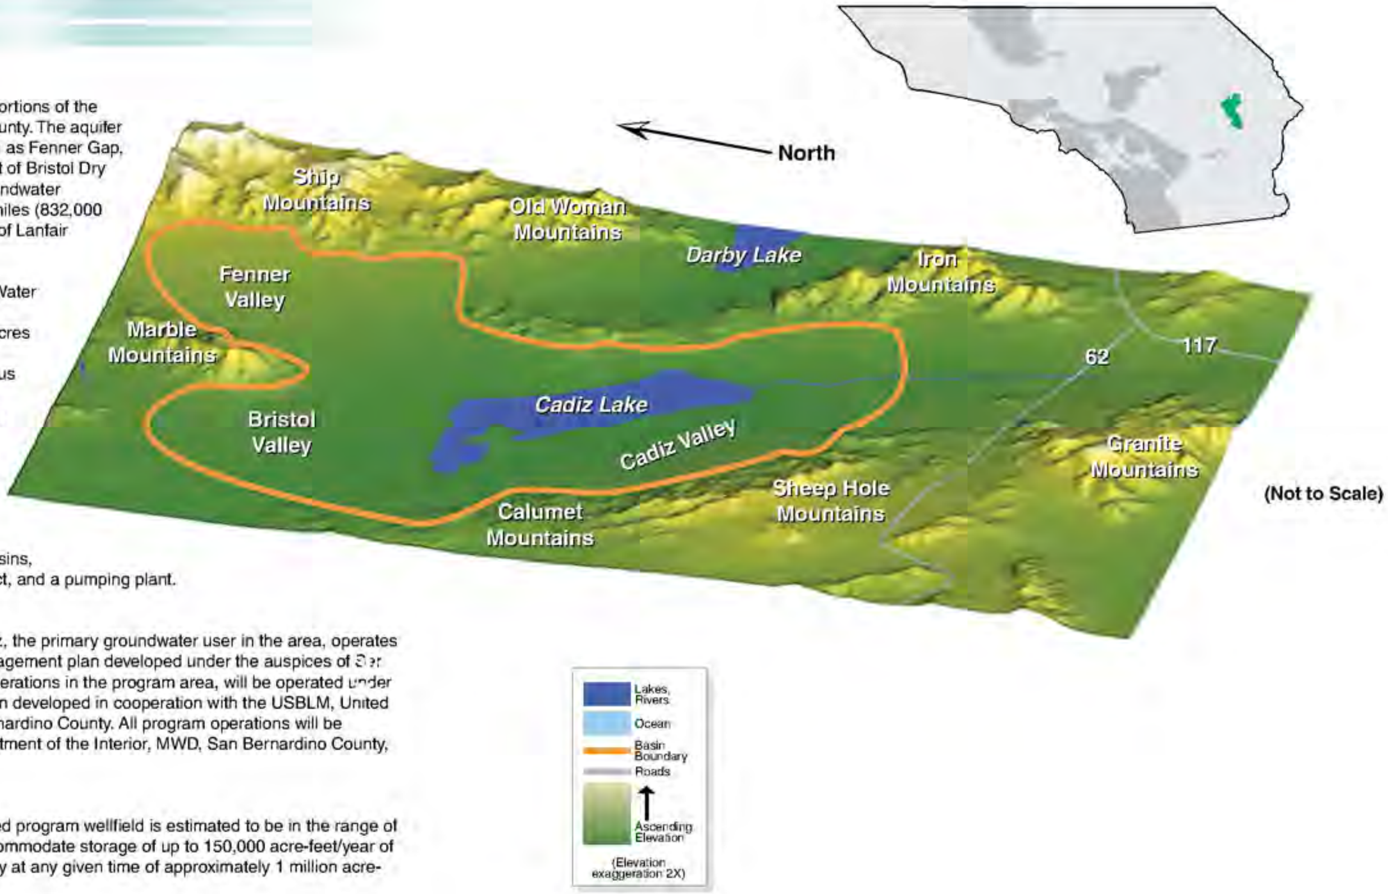
Present Operational Safe Yield
The present operational safe yield is undefined. Future operational yield may be 150,000 acre-feet per year (AFY) in a drought year.

Basin Sediments
Basin sediments consist of alluvial deposits with interbeds of sand, gravel, silt, and clay. Groundwater is unconfined.

Conjunctive Use Potential
The results of AGWA's survey indicate the potential to store between 500,000 and 800,000 AF of water for use in dry years. A program to utilize this storage potential is currently being planned by Metropolitan Water District of Southern California.



17. Cadiz Valley Basin



Location

The Cadiz Groundwater Storage and Dry-Year Supply Program is located in portions of the Cadiz and Fenner Valleys in the Mojave Desert of eastern San Bernardino County. The aquifer system to be utilized by this conjunctive use program underlies an area known as Fenner Gap, located between the Marble and Ship mountains, approximately ten miles east of Bristol Dry Lake and ten miles north of Cadiz Dry Lake. The watershed that supplies groundwater recharge to the program area covers an area of approximately 1,300 square miles (832,000 acres), and includes the Fenner Valley, Orange Blossom Wash, and a portion of Lanfair Valley.

This conjunctive use program is a cooperative venture between Metropolitan Water District of Southern California (MWD) and Cadiz Inc. (Cadiz) a publicly traded agricultural and water development company. Cadiz owns more than 27,000 acres in the program area and has developed approximately 1,600 acres of citrus orchards, table grape vineyards, and specialty row-crops utilizing the indigenous groundwater. MWD and Cadiz have conducted extensive engineering and hydrological studies in the program area, including an 8-month pilot spreading basin test to measure site-specific infiltration rates. Over the 50-year term of the proposed program, MWD will store water imported from its Colorado River Aqueduct during periods of excess supply. This stored water and indigenous groundwater will be conveyed back to the Colorado River Aqueduct as needed. In cooperation with the United States Bureau of Land Management (USBLM), MWD has completed a Draft EIR/EIS and a supplement to the Draft EIR/EIS. Program facilities will include spreading basins, extraction wells, a 35-mile conveyance pipeline to the Colorado River Aqueduct, and a pumping plant.

Basin Management

The aquifer system in the vicinity of the program area is not adjudicated. Cadiz, the primary groundwater user in the area, operates its agricultural wellfield in compliance with a groundwater monitoring and management plan developed under the auspices of San Bernardino County. The conjunctive use program, and all future agricultural operations in the program area, will be operated under a comprehensive groundwater monitoring and management plan that has been developed in cooperation with the USBLM, United States Geological Society (USGS), National Park Service (NPS) and San Bernardino County. All program operations will be overseen by a Basin Management Group to be represented by the U.S. Department of the Interior, MWD, San Bernardino County, and Cadiz.

Available Storage

The volume of indigenous groundwater in storage in the vicinity of the proposed program wellfield is estimated to be in the range of 3.65 to 6.69 million acre-feet. The conjunctive use program is designed to accommodate storage of up to 150,000 acre-feet/year of water imported from the Colorado River Aqueduct, with a total storage capacity at any given time of approximately 1 million acre-feet.

Present Operational Safe Yield

Estimates of safe yield will be refined as more data become available during operation of the conjunctive use program. Storage and extraction of imported water and transfers of indigenous groundwater will be authorized by the Basin Management Group only to the extent these operations will not adversely impact critical environmental resources in and surrounding the program area.

Basin Sediments

The aquifer system underlying the conjunctive use program area is composed of alluvial sediments of mid- to late-Tertiary and Quaternary age. These sediments are derived from Precambrian basement rock, Paleozoic sediments, and Tertiary volcanic rocks that are exposed in the mountain ranges in and surrounding the watershed. Geophysical surveys indicate that this alluvial fill locally exceeds 3,500 feet in thickness beneath portions of the program area.

Conjunctive Use Potential

The results of AGWA's survey indicate the potential to store up to 1,000,000 AF of water for use in dry years.

18. Coachella Valley Basin

Location
The Coachella Valley is located approximately 107 miles east of Los Angeles. The vast majority of the valley lies within Riverside County. Coachella Valley is bounded on the north by the San Bernardino and Little San Bernardino Mountains, on the east by Mecca Hills, on the south by the Salton Sea and Santa Rosa Mountains, and on the west by the San Jacinto Mountains. The San Andreas, Banning and Mission Creek faults separate the valley into three sub-basins: the Indio, Mission Creek and Desert Hot Springs sub-basins. Each of these faults are effective barriers to groundwater flow. The Whitewater River drains the valley to the Salton Sea, which has no outlet.

Basin Management
The Coachella Valley Stormwater District was formed in 1915 followed by formation of the Coachella Valley Water District (CVWD) in 1918. These districts merged in 1937. In 1918, a contract was awarded to construct spreading facilities northwest of Palm Springs to recharge stormwater from the Whitewater River.

The Coachella Valley is heavily dependent on groundwater and imported water to meet water demands. In response to declining groundwater levels, CVWD signed a contract with the federal government to construct the Coachella Branch of the All-American Canal, which was completed in 1949. Canal water is delivered to farms and golf courses for irrigation.

In 1963, CVWD and Desert Water Agency (DWA) signed contracts with State of California for 61,200 acre-feet per year (AFY) of entitlements to State Water Project (SWP) water. CVWD and DWA exchange their SWP entitlements with the Metropolitan Water District of Southern California (MWD) for Colorado River water. This exchange water is recharged at the Whitewater Spreading Facility located north of Palm Springs. CVWD, DWA and MWD signed an advanced delivery agreement in 1984 that allows Metropolitan to store surplus Colorado River Water in the valley. CVWD and DWA have also purchased unused SWP water when it is available. Since 1973, over 1.7 million acre-feet (AF) imported water has been recharged at the whitewater facility. MWD currently has about 290,000 AF of water stored in the valley.

CVWD and DWA also have active water recycling and water conservation programs. Currently, about 8,000 AFY of recycled water is used for park and golf course irrigation. Water conservation programs focus on public information, school education, and use of water-efficient irrigation systems and landscaping techniques.

CVWD is completing a water management plan to resolve the on-going groundwater overdraft. This plan includes increased water conservation, water recycling, delivery of Colorado River water to additional farms, golf courses and municipal users and groundwater recharge. CVWD has conducted a pilot recharge test program at Dike No. 4 located south of La Quinta. If successful, a facility capable of recharging 30,000 to 60,000 AFY could be constructed at this location. Additional recharge facilities are also being evaluated. Additional imported water is expected to come from SWP entitlement transfers and quantification of California's Colorado River allocation.

The groundwater basin is not adjudicated. However, CVWD and DWA collect replenishment assessments from groundwater producers in the northwestern portion of the Indio sub-basin.

Available Storage
The freshwater storage capacity of the valley is approximately 37 million AF. Of this amount, the Indio sub-basin has a capacity of about 30 million AF. Available storage capacity in the Indo sub-basin is about 4 million AF.

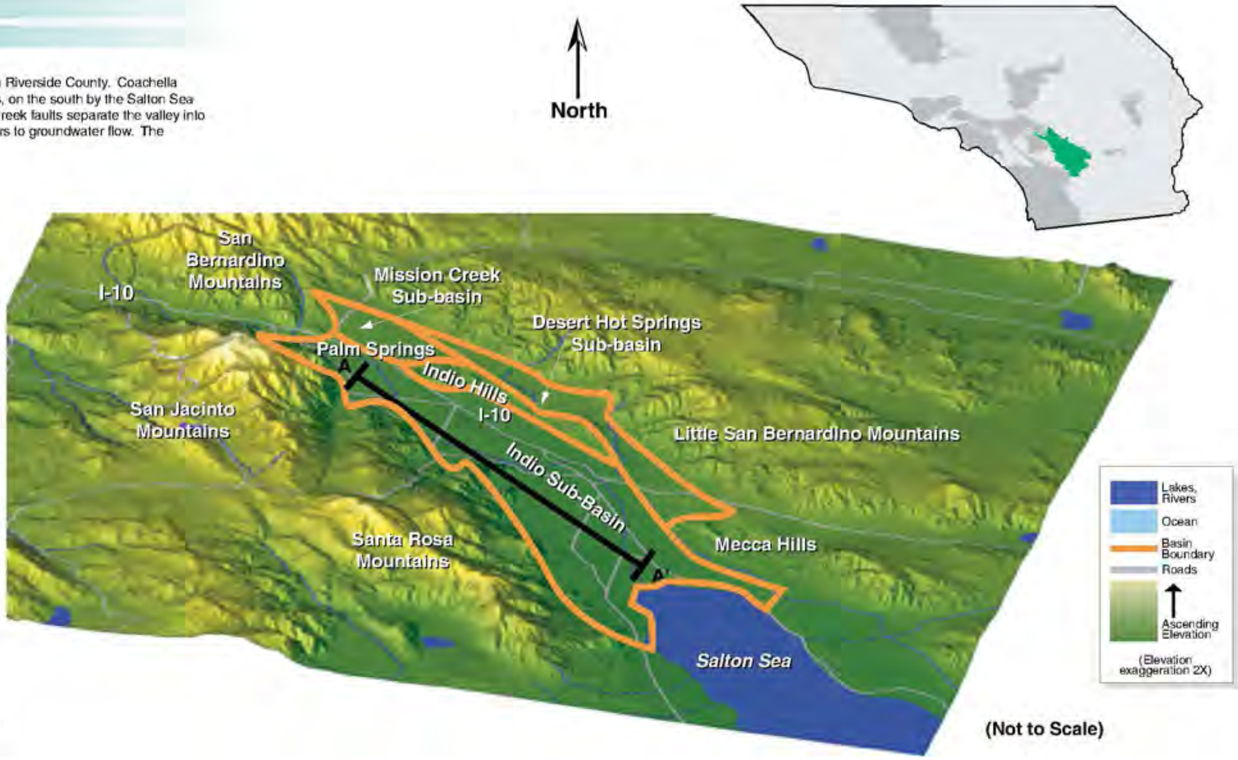
Present Operational Safe Yield
The present operational safe yield of the valley is estimated to be 220-250,000 AFY.

Basin Materials
The conceptual hydrogeological model of the Coachella Valley includes four zones :

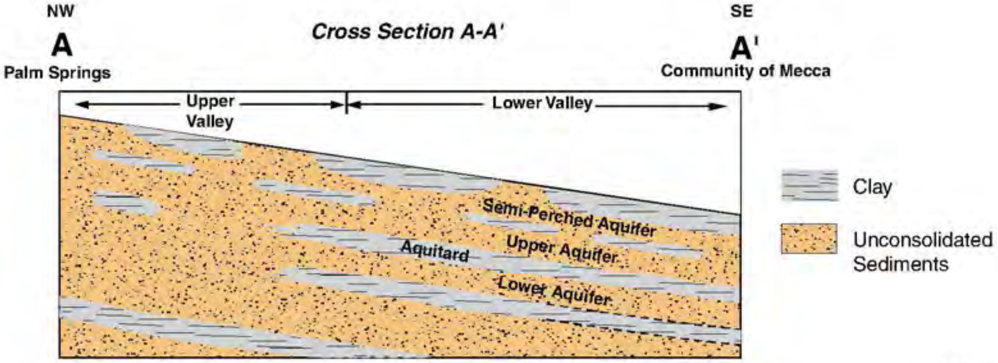
- The Semi-Perched aquifer and intervening retarding layers (correlated with Recent lake deposits and alluvium)
- The Upper aquifer (correlative with Upper Pleistocene Alluvium)
- An aquitard
- The Lower aquifer (correlative with the Pleistocene Ocotillo conglomerate)

South of Indio, all four hydrostratigraphic units are clearly present in the center of the Indio sub-basin. At the margins of the sub-basin, the proportion of clay decreases thereby allowing for continuity between the Upper and Lower aquifers. Because of the thick clay aquitard separating the Upper and Lower aquifers, groundwater recharge is limited to the margins of the Valley. North of Indio, the aquitard is discontinuous or absent throughout much of the sub-basin. Therefore, this area provides greater opportunity for direct groundwater recharge.

Conjunctive Use Potential
The results of AGWA's survey indicate existing conjunctive use programs have increased the basin operational yield by 50,000 AFY. Additionally, the survey indicated the potential to store up to 4,000,000 AF of water for use in dry years and a potential increase in basin operational yield of 80,000 AFY.



(Not to Scale)



Responses to AGWA's Questionnaire

Compiling the survey responses, AGWA has estimated the storage available for conjunctive use in some 85 groundwater basins of Southern California. For the purposes of this guide, conjunctive use potential includes both dry-year or longer-term storage and shorter-term programs such as annual put and take or seasonal storage operations. By using the groundwater aquifer for storage, surplus water available in wet years is used to meet future dry-year demand as shown in Figure 6. Stored water can also be used to increase the basin yield.

Many basins already have conjunctive use programs in place. Existing conjunctive use programs currently provide an estimated 2.5 MAF of water per year as shown on Figure 7.

However, these existing programs represent only a small fraction of the conjunctive use potential identified by the AGWA survey throughout Southern California. Figure 8 illustrates the dry-year storage available by basin, which totals 21.5 million acre-feet (MAF) for all basins combined. The short-term storage, or future increase in operational yield, totals 1.3 MAF per year as shown on Figure 9.

Summary

Over the centuries, people have devised ways to regulate the flows of surface water systems by impounding rivers and streams behind dams to capture and retain water for use in dry periods and releasing controlled amounts in order to accommodate downstream demands. However, substantial amounts of water remain unused, particularly in wet years, due to inherent limitations in these surface water systems. Major improvements in these systems could be achieved by coordinating the use of both surface water and groundwater. This coordination involves diverting and/or conveying water for storage underground

Figure 6

Without Conjunctive Use

With Conjunctive Use

Figure 7

Existing Increase in Basin Yield from Conjunctive Use Programs

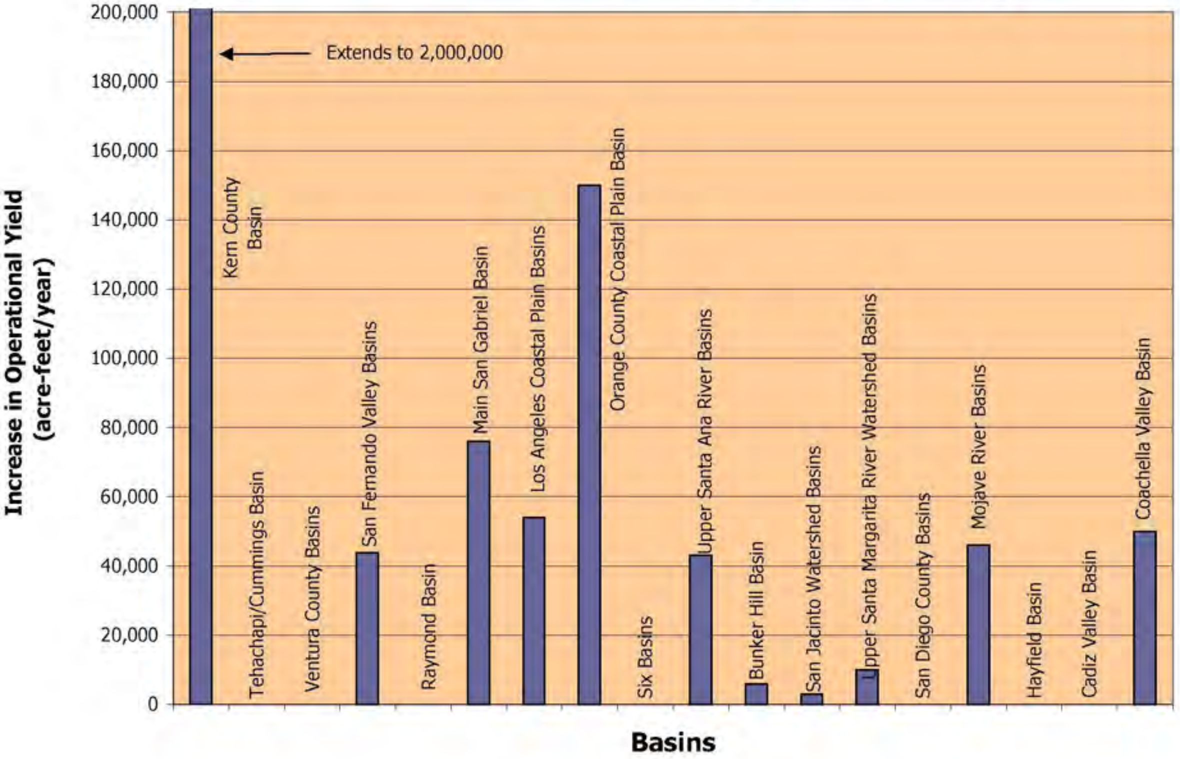

Figure 8

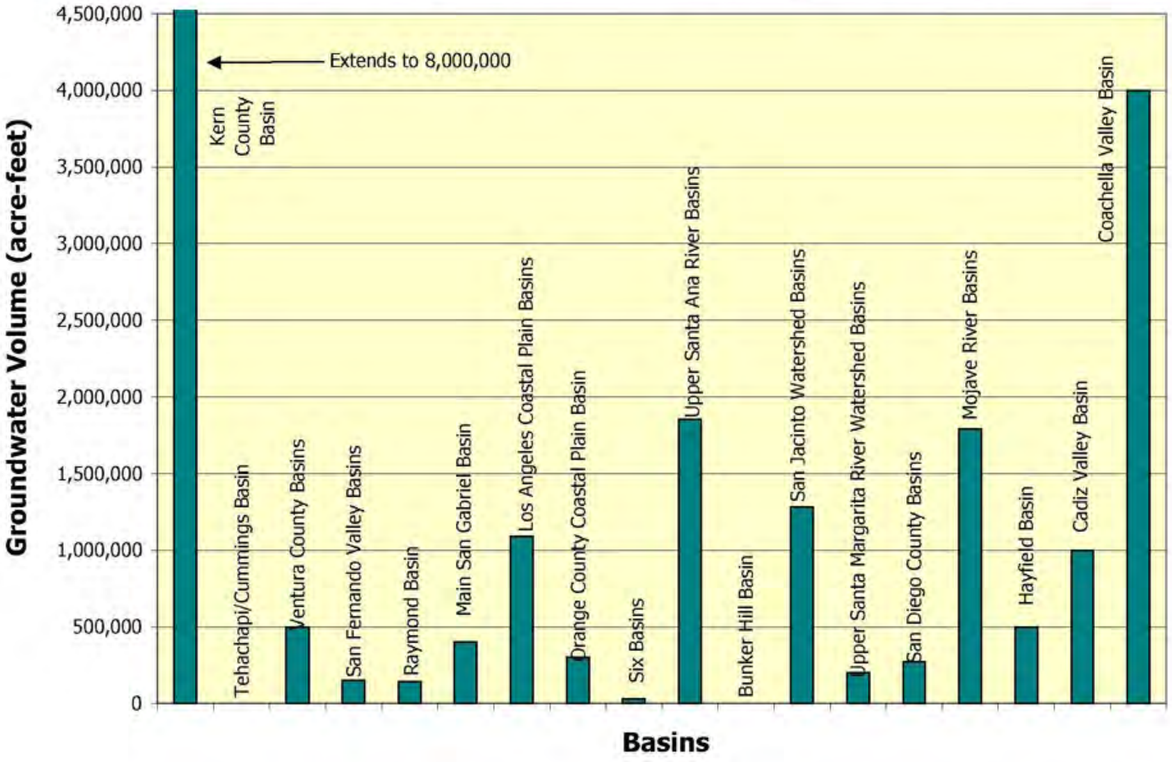
Potential Dry Year or Long Term Groundwater Storage From Conjunctive Use



when surface water is in abundance to provide reliability during drought periods. During droughts, the stored water can be pumped from underground and used to meet present demands. Stored underground water may also be used to meet "peak" demand, so that surface water storage and distribution systems can be built to an average-demand capacity rather than a peak load capacity. Such "conjunctive use" of groundwater and surface or imported supplies improves the overall reliability, efficiency and value of our water system.

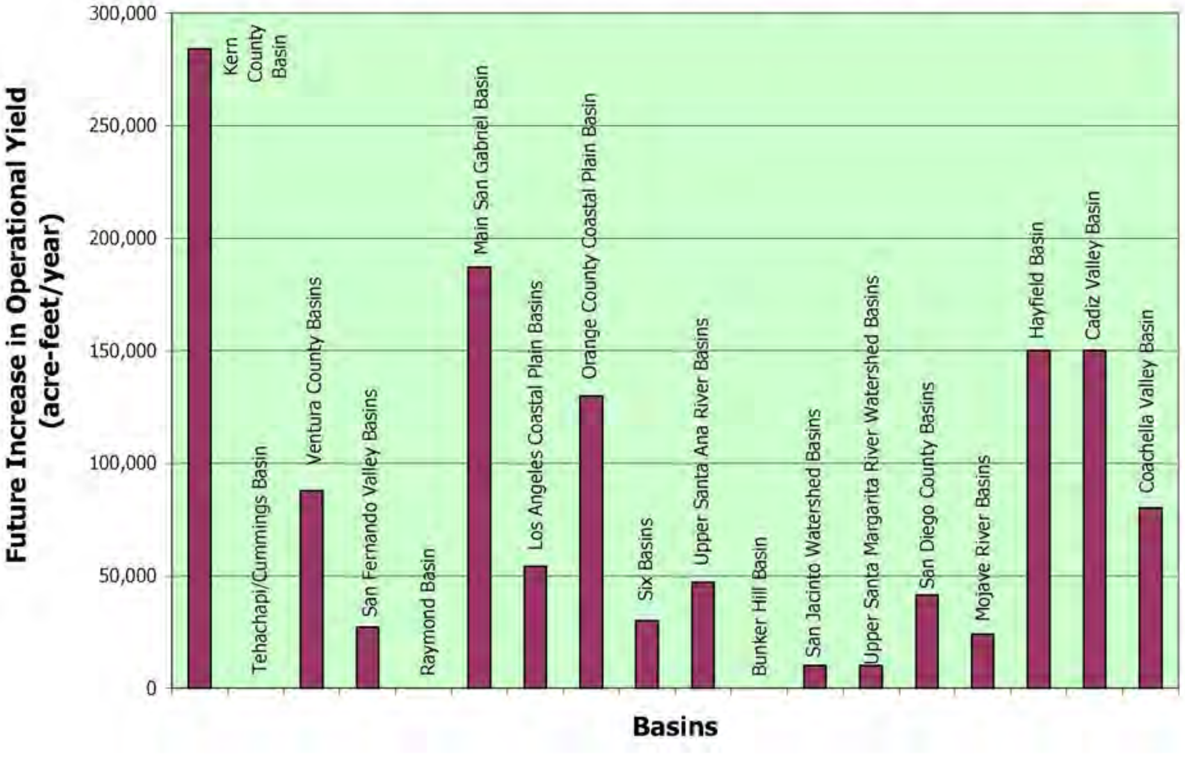
Through the data collected in the preparation of this guide, AGWA has documented the following:

- Conjunctive use is a well-proven method to increase our ability to meet California's increasing water demand.
- Conjunctive use improves water supply reliability.
- The need for additional, environmentally controversial, surface water reservoirs may be reduced by conjunctive use programs.
- Assuming resolution of institutional, water quality, and other issues, over 21.5 million acre-feet of additional water can be stored and used in Southern California groundwater basins.

Conjunctive use is becoming a key part of California's overall water management strategy for allocating an increasingly scarce resource among a steadily growing population. This guide demonstrates that in Southern California basins alone, approximately 21.5 million acre-feet of additional conjunctive use potential is available, enough to fill Diamond Valley Lake, Southern California's largest surface water reservoir, 26 times over. This stored water could be used during times of drought or natural disaster when surface water supplies are reduced or not available.

Figure 9

Potential Annual Operational Yield Increase from Conjunctive Use



Glossary

acre-foot—325,851 gallons, or enough water to cover an acre of land 1 foot deep. An acre-foot can supply the annual needs of between one and two average California households.

artificial recharge— the purposeful addition of surface water to a groundwater basin by human activity such as percolation ponds or injection wells.

aquifer—a geologic formation that stores, transmits, and yields significant quantities of water to wells or springs.

available storage—the current amount of space in a groundwater basin that can be used for water storage.

confined aquifer—an aquifer that is bound above and below by impermeable layers of soil or rock.

conjunctive-use potential— For the purposes of this guide, conjunctive use potential includes both dry-year or longer-term storage and shorter-term programs such as annual put and take or seasonal storage operations.

dry year—a year with below-average precipitation.

evapotranspiration—the combined losses of water through the processes of evaporation and uptake and use by vegetation (transpiration).

extraction— the process of withdrawing groundwater from storage by pumping or other controlled means.

groundwater—water stored underground in pore spaces within rocks and other alluvial materials and in gaps between fractured hard rock.

hydrologic cycle— the natural recycling process powered by the sun that causes water to evaporate into the atmosphere, condense, and return to the earth as precipitation.

impermeable—having a texture that does not permit water to move through quickly.

in-lieu recharge—an indirect method of recharge caused by reducing the amount of water pumped from the aquifer.

operational yield—The augmentation of safe yield by the use of engineering controls (i.e. recharge basins, injection wells) such that more water is made available to meet an increased demand.

overdraft— intentional or inadvertent withdrawal of water from an aquifer in excess of the amount of water that recharges the basin over a period of years.

percolation—the movement of water through small openings within a porous material.

permeability—the capability of soil or rock to transmit water.

recharge—flow to groundwater storage from precipitation, irrigation, spreading basins and other sources of water.

safe yield—the amount of water that can be pumped each year without causing a continual reduction of water in storage (overdraft). The safe yield is dependent upon the average amount of water that can be stored in and used from the groundwater reservoir over a period of normal water supply under a given set of conditions.

saturated zone— the area below the water table in which the soil is completely saturated with groundwater.

seasonal (short-term) storage—For the purposes of this guide, the short term or seasonal storage quantity represents the amount of water that can be put in and taken out of storage on an annual basis.

salt water intrusion—the movement of salty water into fresh water aquifers. When groundwater pumps draw up fresh water from the aquifer, salty water can flow into the aquifer and make it unuseable.

subsidence—lowering or sinking of the land surface due to a number of factors, of which groundwater extraction is one.

surface water—water that remains on the earth's surface in rivers, streams, lakes, reservoirs or oceans.

unsaturated zone—the subsurface zone, usually starting at the land surface and ending at the water table, that includes both water and air in spaces between rocks.

Contact List of Basin Managers

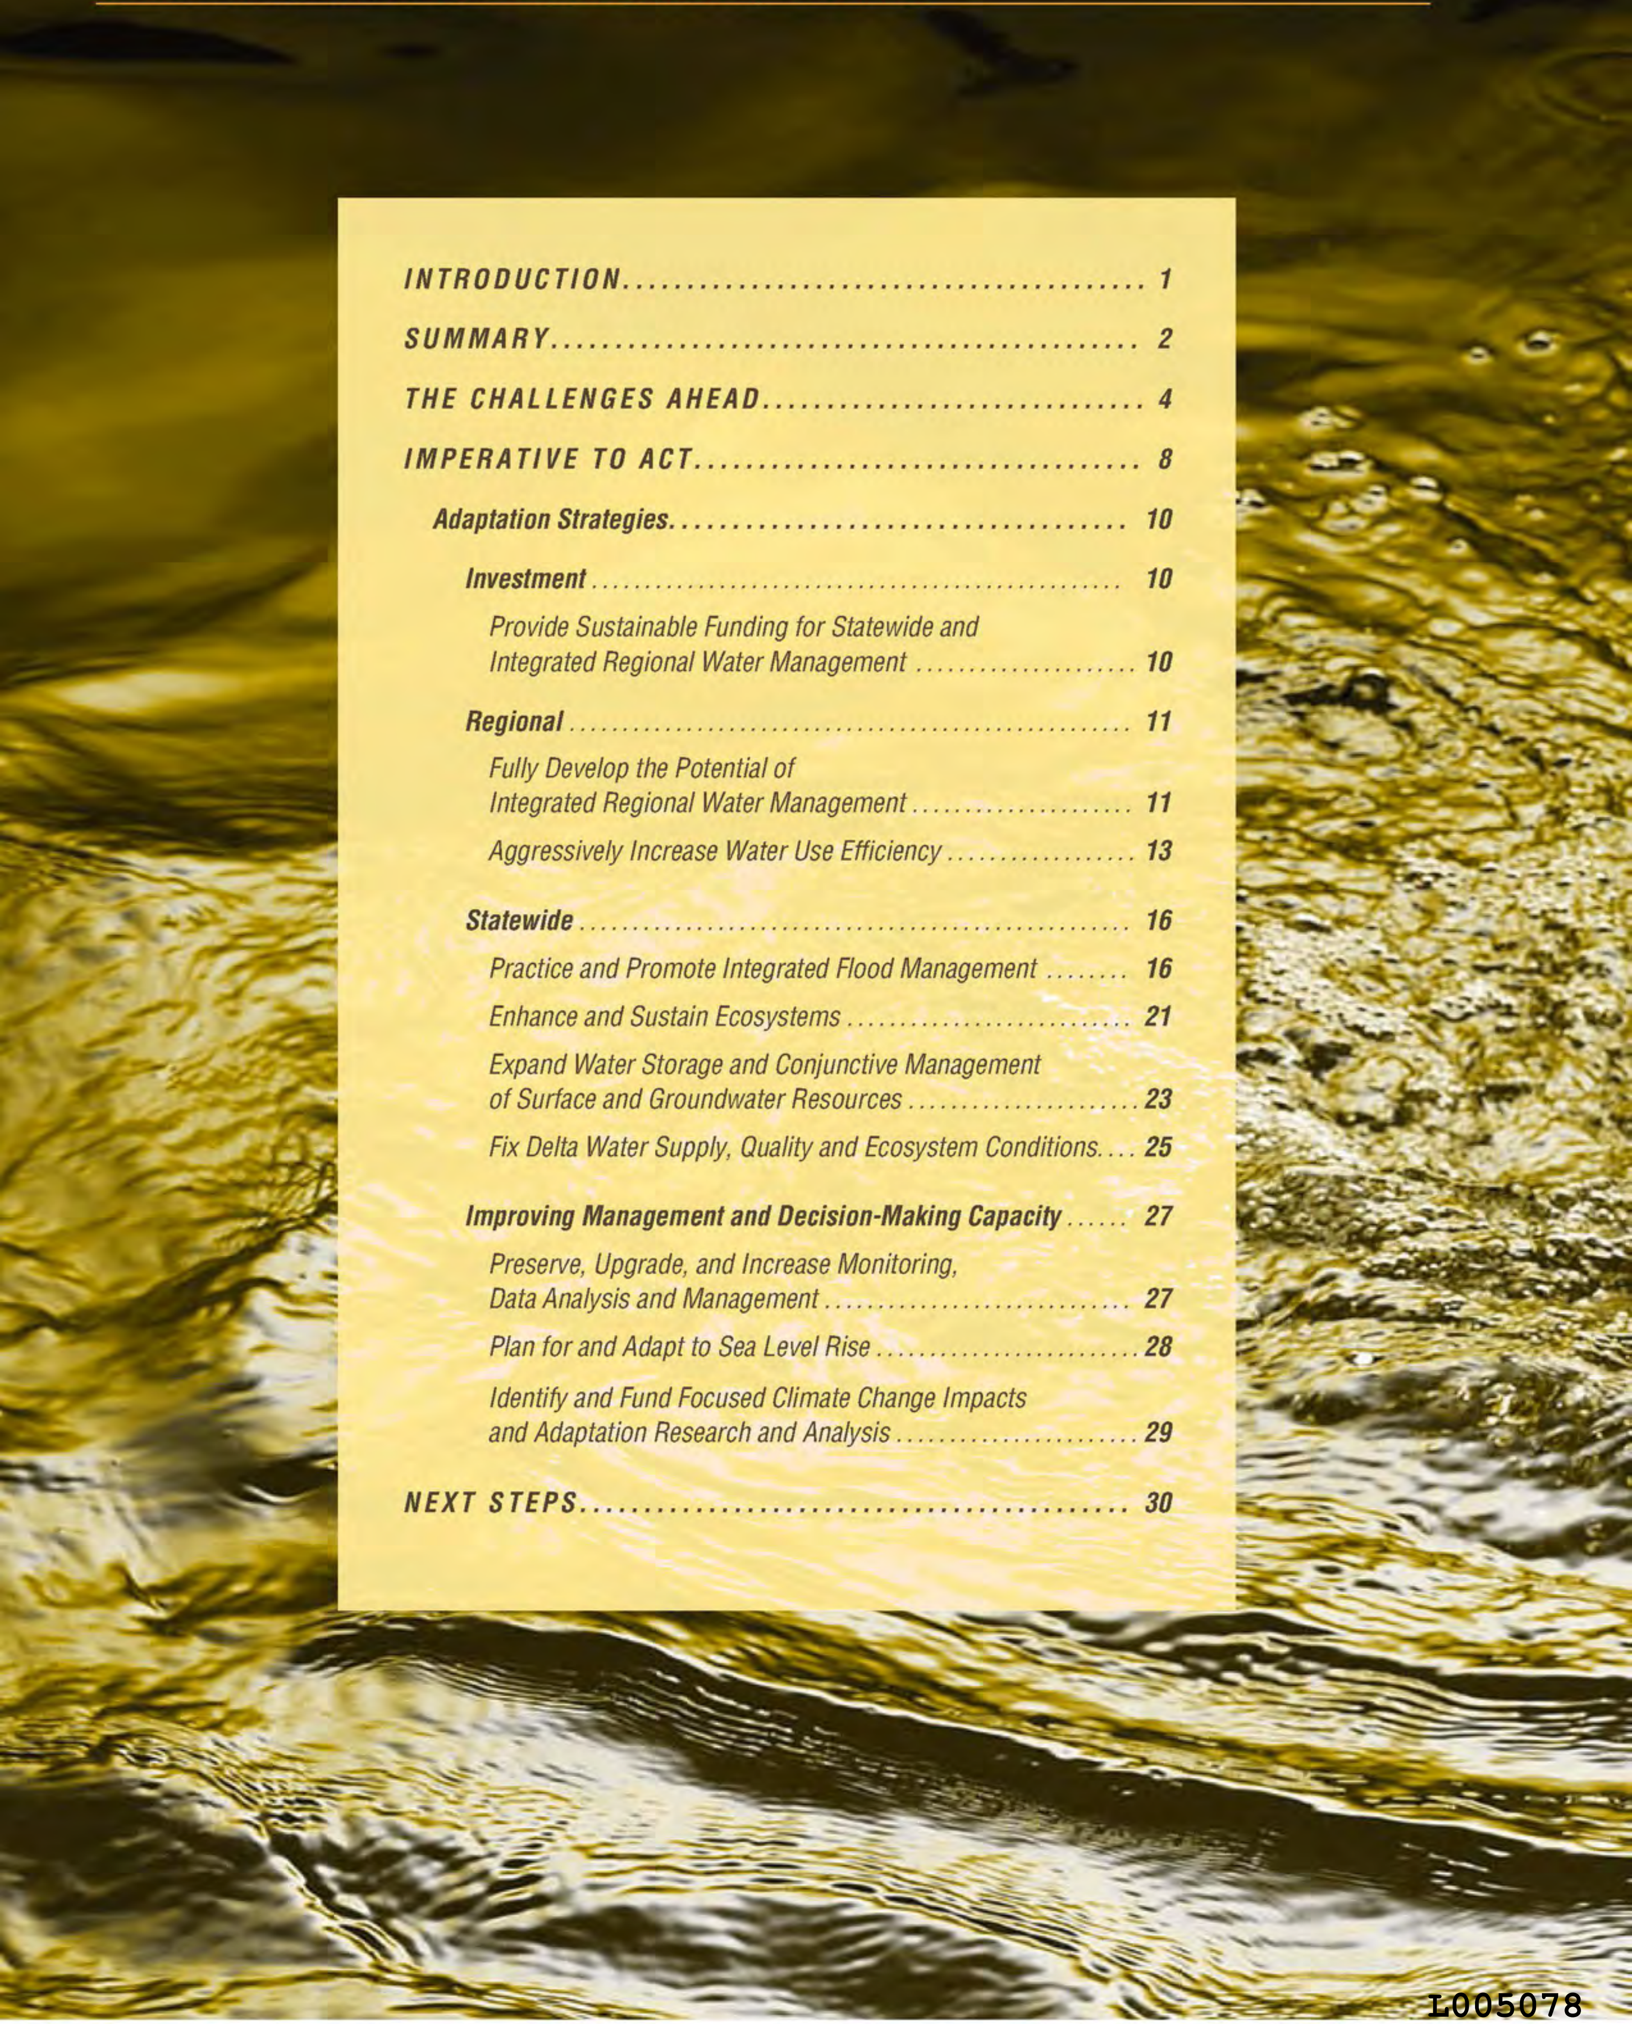
STATE OF CALIFORNIA
THE RESOURCES AGENCY
DEPARTMENT OF WATER RESOURCES
OCTOBER 2008

MANAGING AN UNCERTAIN FUTURE

Climate Change Adaptation Strategies for California's Water



INTRODUCTION

For California water managers, the future is now. Climate change is already having a profound impact on water resources as evidenced by changes in snowpack, river flows and sea levels.

The Department of Water Resources (DWR) will continue to play a leadership role in adapting to these changes. DWR is already engaged in a number of efforts designed to improve California's ability to cope with a changing climate. However, more must be done. This report recommends a series of adaptation strategies for state and local water managers to improve their capacity to handle change. Many of the strategies will also help adapt our water resources to accommodate non-climate demands including a growing population, ecosystem restoration and greater flood protection.

Adapt or perish,
now as ever, is nature's
inexorable imperative.
- H. G. Wells

Several of the recommendations in this report are ready for immediate adoption, while others need additional public deliberation and development. Some can be implemented using existing resources and authority, while the majority will require new resources, sustained financial investment and significant collaborative effort.

Many of California's most important water resource investments remain dependent on bond funding approved by voters. As a result, they are well-funded in some years, but underfunded in most. This history of uneven and irregular investment has delayed progress in areas that have the potential to yield substantial gains over short periods of time.

DWR presents this report as part of the process of updating the California Water Plan, and as part of the California Resources Agency's draft statewide Climate Adaptation Plan. Overall, this report urges a new approach to managing California's water and other natural resources in the face of a changing climate.

Lester A. Snow
Director

SUMMARY

Climate change is already affecting California's water resources. Bold steps must be taken to reduce greenhouse gas emissions. However, even if emissions ended today, the accumulation of existing greenhouse gases will continue to impact climate for years to come. Warmer temperatures, altered patterns of precipitation and runoff, and rising sea levels are increasingly compromising the ability to effectively manage water supplies, floods and other natural resources. Adapting California's water management systems in response to climate change presents one of the most significant challenges of this century.

Chinook salmon

What we know:

- Historic hydrologic patterns can no longer be solely relied upon to forecast the water future;
- Precipitation and runoff patterns are changing, increasing the uncertainty for water supply and quality, flood management, and ecosystem functions;
- Significant and ongoing investments must be made in monitoring, researching, and understanding the connection between a changing climate, water resources and the environment;
- Extreme climatic events will become more frequent, necessitating improvements in flood protection, drought preparedness and emergency response;
- Water and wastewater managers and customers – businesses, institutions, farms, and individuals – can play a key role in water and energy efficiency, the reduction of greenhouse gas emissions, and the stewardship of water and other natural resources;
- Impacts and vulnerability will vary by region, as will the resources available to respond to climate change, necessitating regional solutions to adaptation rather than the proverbial one-size-fits-all approach; and
- An array of adaptive water management strategies, such as those outlined in this White Paper, must be implemented to better address the risk and uncertainty of changing climate patterns.

California's water crisis

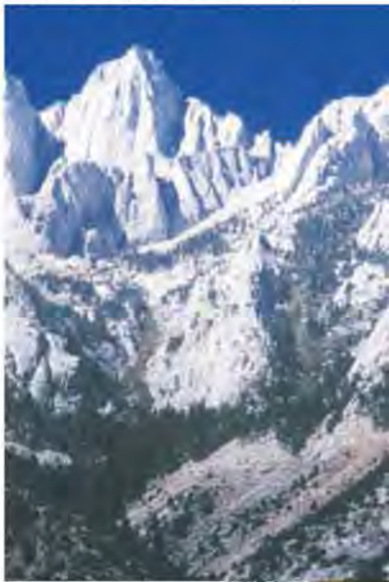
The history of water in California is one of conflict and perseverance. Concerns over the availability, quality and distribution of water are not new, but those concerns are growing. Solutions are becoming more complex as water managers navigate competing interests to reliably provide quality water to farms, businesses, and homes, while managing floods, protecting the environment, and complying with legal and regulatory requirements.

California water management includes an array of complicated issues. For example, the Sacramento-San Joaquin Delta, the hub of the state's water supply and delivery system and a crossroads of other critical infrastructure, faces serious ecosystem problems and substantial seismic risk that threaten water supply reliability and quality. Many groundwater basins suffer from overdraft and pollution. The Colorado River, an important source of water for Southern California, has suffered an historic drought that has helped to highlight the changing hydrology and its impact on water supplies. Throughout California, flood risk grows as levees age and more people live and work in floodplains, and changing climate yields higher flood flows.

What's happened already?

While the exact conditions of future climate change remain uncertain, there is no doubt about the changes that have already happened. Analysis of paleoclimatic data (such as tree-ring reconstructions of streamflow and precipitation) indicates a history of naturally and widely varying hydrologic conditions in California and the west, including a pattern of recurring and extended droughts. The average early spring snowpack in the Sierra Nevada decreased by about 10 percent during the last century, a loss of 1.5 million acre-feet of snowpack storage (one acre-foot of water is enough for one to two familes for one year). During the same period, sea level rose seven inches along California's coast. California's temperature has risen 1° F, mostly at night and during the winter, with higher elevations experiencing the highest increase. A disturbing pattern has also emerged in flood patterns; peak natural flows have increased on many of the state's rivers during the last 50 years. At the other extreme, many Southern California cities have experienced their lowest recorded annual precipitation twice within the past decade. In a span of only two years, Los Angeles experienced both its driest and wettest years on record.

Bottom: *Sacramento River*
Below: *Snowpack on Mt. Whitney*



THE CHALLENGES AHEAD

The trends of the last century – especially the increases in hydrological variability – will likely intensify this century, and abrupt changes in climate could also occur. The Intergovernmental Panel on Climate Change (IPCC) notes that the western United States may be especially vulnerable to water shortages. While the existing system has some capacity to cope with climate variability, extreme weather events resulting in increased droughts and floods will strain that capacity to meet future needs. California has invested in, and now depends upon, a system that relied on historical hydrology as a guide to the future for water supply and flood protection. However, due to climate change, the hydrology of the past is no longer a reliable guide to the future.

Rising temperatures affect California's snowpack levels

Loss of natural snowpack storage

One of the most critical impacts for California water management may be the projected reduction in the Sierra Nevada snowpack – California's largest surface "reservoir." Snowmelt currently provides an annual average of 15 million acre-feet of water, slowly released between April and July each year. Much of the state's water infrastructure was designed to capture the slow spring runoff and deliver it during the drier summer and fall months. Based upon historical data and modeling, DWR projects that the Sierra snowpack will experience a 25 to 40 percent reduction from its historic average by 2050. Climate change is also anticipated to bring warmer storms that result in less snowfall at lower elevations, reducing the total snowpack.

Historical and Future Hydrology

Use of historical hydrologic data has long been the standard of practice for designing and operating water supply and flood protection projects. For example, historical data are used for flood forecasting models such as the National Weather Service's River Forecast System Model and to forecast snowmelt runoff for water supply. This method of forecasting assumes climate "stationarity" – that the climate of the future will be similar to that of the relatively brief period of historical hydrologic record.

Paleoclimatology (which relies upon records from ice sheets, tree rings, sediment, and rocks to determine the past state of Earth's climate system), as well as other research revealing expected impacts of climate change, indicate that our traditional hydrologic approach can no longer be solely relied upon. That is, the hydrologic record cannot be used to predict expected increases in frequency and severity of extreme events such as floods and droughts. Going forward, model calibration or statistical relation development must happen more frequently, new forecast-based tools must be developed, and a standard of practice that explicitly considers climate change must be adopted.

Drought

Warming temperatures, combined with changes in rainfall and runoff patterns will exacerbate the frequency and intensity of droughts. Regions that rely heavily upon surface water (rivers, streams, and lakes) could be particularly affected as runoff becomes more variable, and more demand is placed on groundwater. Combined with urbanization expanding into wildlands, climate change will further stress the state's forests, making them more vulnerable to pests, disease and changes in species composition. Along with drier soils, forests will experience more frequent and intense fires, resulting in subsequent changes in vegetation, and eventually a reduction in the water supply and storage capacity benefits of a healthy forest.

Climate change will also affect water demand. Warmer temperatures will likely increase evapotranspiration rates and extend growing seasons, thereby increasing the amount of water that is needed for the irrigation of many crops, urban landscaping and environmental water needs. Reduced soil moisture and surface flows will disproportionately affect the environment and other water users that rely only on annual rainfall such as non-irrigated agriculture, livestock grazing on non-irrigated rangeland and recreation.

Floods

The amount of snow is critical for water supply and environmental needs, but so is the timing of snowmelt runoff into rivers and streams. Rising snowlines caused by climate change will allow more of the Sierra Nevada watersheds to contribute to peak storm runoff. High frequency flood events (e.g. 10-year floods) in particular will likely increase with a changing climate. Along with reductions in the amount of the snowpack and accelerated snowmelt, scientists project greater storm intensity, resulting in more direct runoff and flooding. Changes in watershed vegetation and soil moisture conditions will likewise change runoff and recharge patterns. As streamflows and velocities change, erosion patterns will also change, altering channel shapes and depths, possibly increasing sedimentation behind dams, and affecting habitat and water quality.
With potential increases in the frequency and intensity of wildland fires due to climate change, there is a potential for more floods following fire, which increase sediment loads and water quality impacts.

The Colorado River

Climate research in the Colorado River basin has shown that natural climate variability alone has resulted in droughts far more severe than those in the basin's measured historical record. Understanding additional impacts of climate change on the Southwest's most important river basin has been a subject of ongoing interest in the academic community. In addition to impacts on runoff, anticipated warming in the arid Southwest is also expected to increase water demands.

For the purposes of federal flood insurance, the Federal Emergency Management Agency (FEMA) has traditionally used the 100-year flood event, which refers to the level of flood flows that has a one-percent chance of being exceeded in any single year. As California's hydrology changes, what is currently considered a 100-year flood may strike more often, leaving many communities at greater risk. Moreover, as peak flows and precipitation change over time, climate change calls into question assumptions of "stationarity" that is used in flood-related statistical analyses like the 100-year flood (see sidebar on page 4). Planners will need to factor a new level of safety into the design, operation, and regulation of flood protection facilities such as dams, floodways, bypasses and levees, as well as the design of local sewers and storm drains.

Water quality

Changes in the timing of river flows and warming atmospheric temperatures may affect water quality and water uses in many different ways. At one extreme, flood peaks may cause more erosion, resulting in turbidity and concentrated pulses of pollutants. This will challenge water treatment plant operations to produce safe drinking water. Flooding can also threaten the integrity of water works infrastructure. At the other extreme, lower summer and fall flows may result in greater concentration of contaminants. These changes in streamflow timing may require new approaches to discharge permitting and non-point source pollution. Warmer water will distress many fish species and could require additional cold water reservoir releases. Higher water temperatures can also accelerate some biological and chemical processes, increasing growth of algae and microorganisms, the depletion of dissolved oxygen, and various impacts to water treatment processes. An increase in the frequency and intensity of wildfires will also affect watersheds, vegetation, runoff and water quality.

Sea level rise

Sea levels are rising, and it is generally accepted that this trend will continue. However, the exact rate of rise is unknown, due to ongoing scientific uncertainty about the melting of ice sheets on western Antarctica and Greenland and the potential for abrupt changes in ocean conditions. Recent peer-reviewed studies estimate a rise of between seven to 55 inches by 2100 along California's coast.

Winter storm in southern Sierra Nevada mountain range

The implications of a seven-inch rise are dramatically different than a rate of rise towards the upper end of the range. However, even a rise at the lower end of this range poses an increased risk of storm surge and flooding for California's coastal residents and infrastructure, including many of the state's wastewater treatment plants. Moreover, sea level rise can contribute to catastrophic levee failures in the Delta, which have great potential to inundate communities, damage infrastructure, and interrupt water supplies throughout the state.

Even without levee failures, Delta water supplies and aquatic habitat will be affected due to saltwater intrusion. An increase in the penetration of seawater into the Delta will further degrade drinking and agricultural water quality and alter ecosystem conditions. More freshwater releases from upstream reservoirs will be required to repel the sea to maintain salinity levels for municipal, industrial and agricultural uses. Alternatively, changes in upstream and in-Delta diversions, exports from the Delta, and improved conveyance through or around the Delta may be needed. Sea level rise may also affect drinking water supplies for coastal communities due to the intrusion of seawater into overdrafted coastal aquifers.

Hydroelectric generation

Climate change will reduce the reliability of California's hydroelectricity operations, which, according to the California Climate Action Registry and the California Air Resources Board, is the state's largest source of greenhouse gas emissions-free energy. Changes in the timing of inflows to reservoirs may exceed generation capacity, forcing water releases over spillways and resulting in lost opportunities to generate hydropower. Higher snow elevations, decreased snowpack, and earlier melting may result in less water available for clean power generation during hot summer months, when energy demand is highest. The impact is compounded overall by anticipated increased energy consumption due to higher temperatures and greater water demands in summer when less water is available. The potential for lengthier droughts may also lower reservoir levels below that which is necessary for power generation.

Thermalito Diversion Dam Powerplant

Dam Safety

Implemented by DWR's Division of Safety of Dams (DSOD), California has one of the most comprehensive dam safety programs in the world.

Preliminary assessments by DSOD of how climate change may potentially impact dam safety reveal that increased safety precautions may be needed to adapt systems to higher winter runoff, frequent fluctuation of water levels, and the potential for additional sediment and debris from drought-related fires. Additionally, climate change will impact the ability of dam operators to estimate extreme flood events.

THE IMPERATIVE TO ACT

As understanding of climate change improves, the challenge for California's water community is to develop and implement strategies that improve resiliency, reduce risk, and increase sustainability for water and flood management systems and the ecosystems upon which they depend.

California water management systems have provided the foundation for the state's economic vitality for more than 100 years, providing water supply, sanitation, electricity, recreation and flood protection.

With the state's water resources already stressed, additional stress from climate change will only intensify the competition for clean, reliable water supplies. While doing its part to reduce greenhouse gas emissions and expand the use of clean energy sources, California's water community must concentrate on adaptation strategies to respond to the anticipated changes. The IPCC's Fourth Assessment Report (2007) states that adaptation "will be necessary to address impacts resulting from the warming which is already unavoidable due to past emissions." As understanding of climate change improves, the challenge for California's water community is to develop and implement strategies that improve resiliency, reduce risk, and increase sustainability for water and flood management systems and the ecosystems upon which they depend.

Governor Schwarzenegger signing the Global Warming Solutions Act (AB 32) in 2006

Mitigation Response

The mitigation response to climate change, or the reduction of greenhouse gas emissions that contribute to our changing climate, has received more international attention to date than adaptation. On a global scale, greenhouse gas emissions must be reduced to slow the effects of warming and climate change. California is leading the nation to enact major greenhouse gas reductions on an ambitious timeline. In 2006, Governor Arnold Schwarzenegger and the California Legislature enacted Assembly Bill (AB) 32 - The Global Warming Solutions Act. The law requires a statewide cap on greenhouse gas emissions, reductions in emissions from major sources, and the development of a mandatory reporting system for these emissions.

While water generates much of the state's electricity, according to the California Energy Commission (CEC), water-related energy use in California also consumes approximately 20 percent of the state's electricity, and 30 percent of the state's non-power plant natural gas (i.e. natural gas not used to produce electricity). The CEC also found that most of the energy intensity of water use in California is in the end uses by the customer (e.g. heating, processing, and pressurizing water). In fact, the CEC states that 75 percent of the electricity and nearly all of the natural gas use related to water in California is associated with the end use of water, mostly for water heating.

The Governor's Climate Action Team is overseeing the implementation of AB 32 including a multi-agency Water-Energy subgroup tasked with the development of greenhouse gas mitigation strategies for energy consumption related to water use.

Fortunately, there are multiple strategies that can help reduce the risks presented by climate change. To be successful, these adaptation strategies must be well-coordinated at the state, regional and local levels in order to maximize their effect. No single project or strategy can adequately address the challenges California faces, and tradeoffs must be explicitly acknowledged and decided upon. That said, planning and investing now in a comprehensive set of actions that informs water managers and provides system diversity and resilience will help prepare California for future climate uncertainty.

ADAPTATION STRATEGIES

The following pages present 10 climate change adaptation strategies for California's water. The strategies fall under four major categories: Investment, Regional, Statewide and Improving Management and Decision-Making Capacity.

...climate change presents an ongoing risk that requires a long-term commitment of funding that is properly matched to anticipated expenditures, beneficiaries and responsible parties.

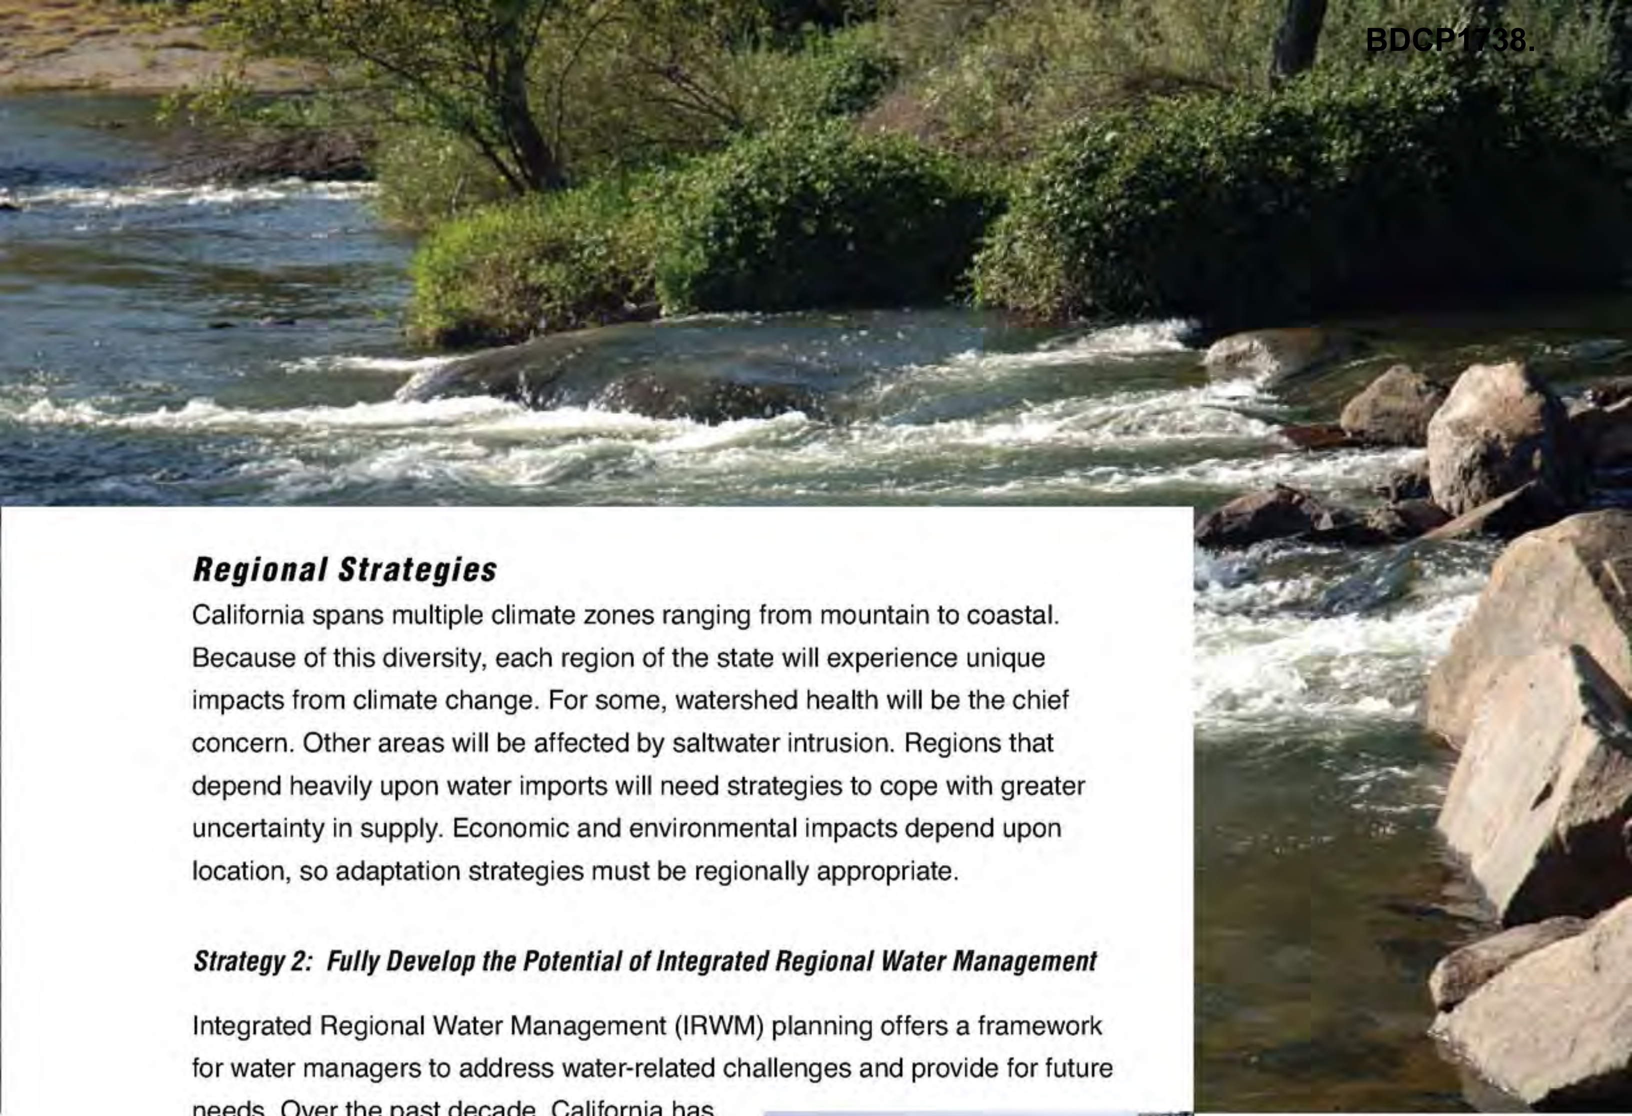
Investment Strategy

Adaptive responses to climate change will not come without a cost. Climate change magnifies the problems that exist with an aging water infrastructure and growing population. While recent bond measures have provided a down payment for improving California's water and flood systems, climate change presents an ongoing risk that requires a long-term commitment of funding that is properly matched to anticipated expenditures, beneficiaries and responsible parties.

Strategy 1: Provide Sustainable Funding for Statewide and Integrated Regional Water Management

- The State Legislature should initiate a formal assessment of state and local financing mechanisms to provide a continuous and stable source of revenue to sustain the programs described herein. Activities in particular need of certainty and continuity in funding include regional water planning, inspection, maintenance, repair, and rehabilitation of flood management facilities, observational networks and water-related climate change adaptation research.

Levee repair site on Sacramento River



San Joaquin River

Regional Strategies

California spans multiple climate zones ranging from mountain to coastal. Because of this diversity, each region of the state will experience unique impacts from climate change. For some, watershed health will be the chief concern. Other areas will be affected by saltwater intrusion. Regions that depend heavily upon water imports will need strategies to cope with greater uncertainty in supply. Economic and environmental impacts depend upon location, so adaptation strategies must be regionally appropriate.

Strategy 2: Fully Develop the Potential of Integrated Regional Water Management

Integrated Regional Water Management (IRWM) planning offers a framework for water managers to address water-related challenges and provide for future needs. Over the past decade, California has improved its understanding of the value of regional planning and made significant steps to implement IRWM. Formally, IRWM is a comprehensive approach for determining the appropriate mix of water demand and supply management options and water quality actions. This approach provides reliable water supplies at lowest reasonable cost and with highest benefits for economic development, environmental quality and other societal objectives. Moreover, if appropriately developed and implemented, IRWM plans—in combination with other regional planning efforts for transportation and land use—can serve as the basis for broader community adaptation plans for climate change.

Suspended irrigation system

The state will encourage—through both financial and technical assistance—IRWM planning and implementation activities that adapt water management to a changing climate.

- By 2011, all IRWM plans should identify strategies that can improve the coordination of local groundwater storage and banking with local surface storage and other water supplies such as recycled municipal water, surface runoff and floodflows, urban runoff and stormwater, imported water, water transfers, and desalinated groundwater and seawater.

- By 2011, all IRWM plans should include specific elements to adapt to a changing climate, including:
    - An assessment of the region's vulnerability to the long-term increased risk and uncertainty associated with climate change.
        - An integrated flood management component.
        - A drought component that assumes, until more accurate information is available, a 20 percent increase in the frequency and duration of future dry conditions.
    - Aggressive conservation and efficiency strategies.
    - Integration with land use policies that:
        - Help restore natural processes in watersheds to increase infiltration, slow runoff, improve water quality and augment the natural storage of water.
        - Encourage low-impact development that reduces water demand, captures and reuses stormwater and urban runoff, and increases water supply reliability.
    - A plan for entities within a region to share water supplies and infrastructure during emergencies such as droughts.

- Large water and wastewater utilities should conduct an assessment of their carbon footprint and consider implementation of strategies described in the draft AB 32 Scoping Plan to reduce greenhouse gas emissions. To take advantage of an existing framework and process for calculating their carbon footprint, these utilities should join the Climate Action Registry.

IRWM is a comprehensive approach for determining the appropriate mix of water demand and supply management options and water quality actions to provide reliable water supplies at lowest reasonable cost and with highest benefits for economic development, environmental quality and other societal objectives.

Strategy 3: Aggressively Increase Water Use Efficiency

Using water efficiently is a foundational action for water management, one that serves to mitigate and adapt to climate change. Water conservation reduces water demand, wastewater discharges, and can reduce energy demand and greenhouse gas emissions. Efficient water use can help communities cope with water shortages that may result from climate change, thus reducing economic and environmental impacts of water shortages. Water use efficiency must be a cornerstone of every water agency's water portfolio.

- As directed by Governor Schwarzenegger, DWR in collaboration with the Water Boards, the California Energy Commission (CEC), the California Public Utilities Commission, the California Department of Public Health, and other agencies, are developing and will implement strategies to achieve a statewide 20 percent reduction in per capita water use by 2020.
  - By 2010, all Urban Water Management Plans must include provisions to fund and implement all economic, feasible, and legal urban best management practices established by the California Urban Water Conservation Council (CUWCC) (see sidebar).

Drought tolerant landscaping in Southern California

Model Water Efficient Landscape Ordinance

The Water Conservation in Landscaping Act of 2006, Assembly Bill 1881, requires DWR to update the existing Model Water Efficient Landscape Ordinance (model ordinance) and adopt the model ordinance by January 1, 2009. Each local agency is required to adopt either the updated model ordinance or its own local landscape ordinance that is at least as effective by January 1, 2010. DWR is developing the updated model ordinance to reflect new technology and advances in landscape water management and to increase outdoor water conservation through improved landscape design, management and maintenance. The ordinance provides guidance to local agencies in developing and adopting landscape ordinances leading to water savings, which will reduce water demand, waste and water-related energy use.

Conservation

Urban Best Management Practices

In 1991, water suppliers and environmental organization members of the CUWCC reached agreement on a series of Best Management Practices (BMPs) that define urban water conservation measures and implementation levels. The BMPs define required actions or goals and are now widely accepted as the minimum level of conservation effort for most water suppliers in California. The BMPs are intended to reduce long-term urban demands from what they would have been without implementation of these practices.
The 14 BMPs include residential ultra-low flush toilet replacement programs, conservation pricing, large landscape conservation, and high efficiency clothes washer rebates.

The CUWCC is currently in the process of revising and updating the BMPs. More information is at **www.cuwcc.org**.

Conservation

Agricultural Efficient Water Management Practices

In 1996, the Agricultural Water Management Council prepared a list of agricultural water best management practices known as "Efficient Water Management Practices" (EWMPs). The EWMPs fall under three major categories: generally applicable, conditionally applicable and other, and include the following:

- preparation and adoption of a water management plan
- pump testing and evaluation
- canal and ditch lining
- implementation of tail-water recovery systems
- use of real-time irrigation scheduling and evapotranspiration data
- beneficial use of recycled water
- optimization of conjunctive use of ground water and surface water supplies
- incentivized pricing

Additional information and the full list of the EWMPs can be found online at **www.agwatercouncil.org**.

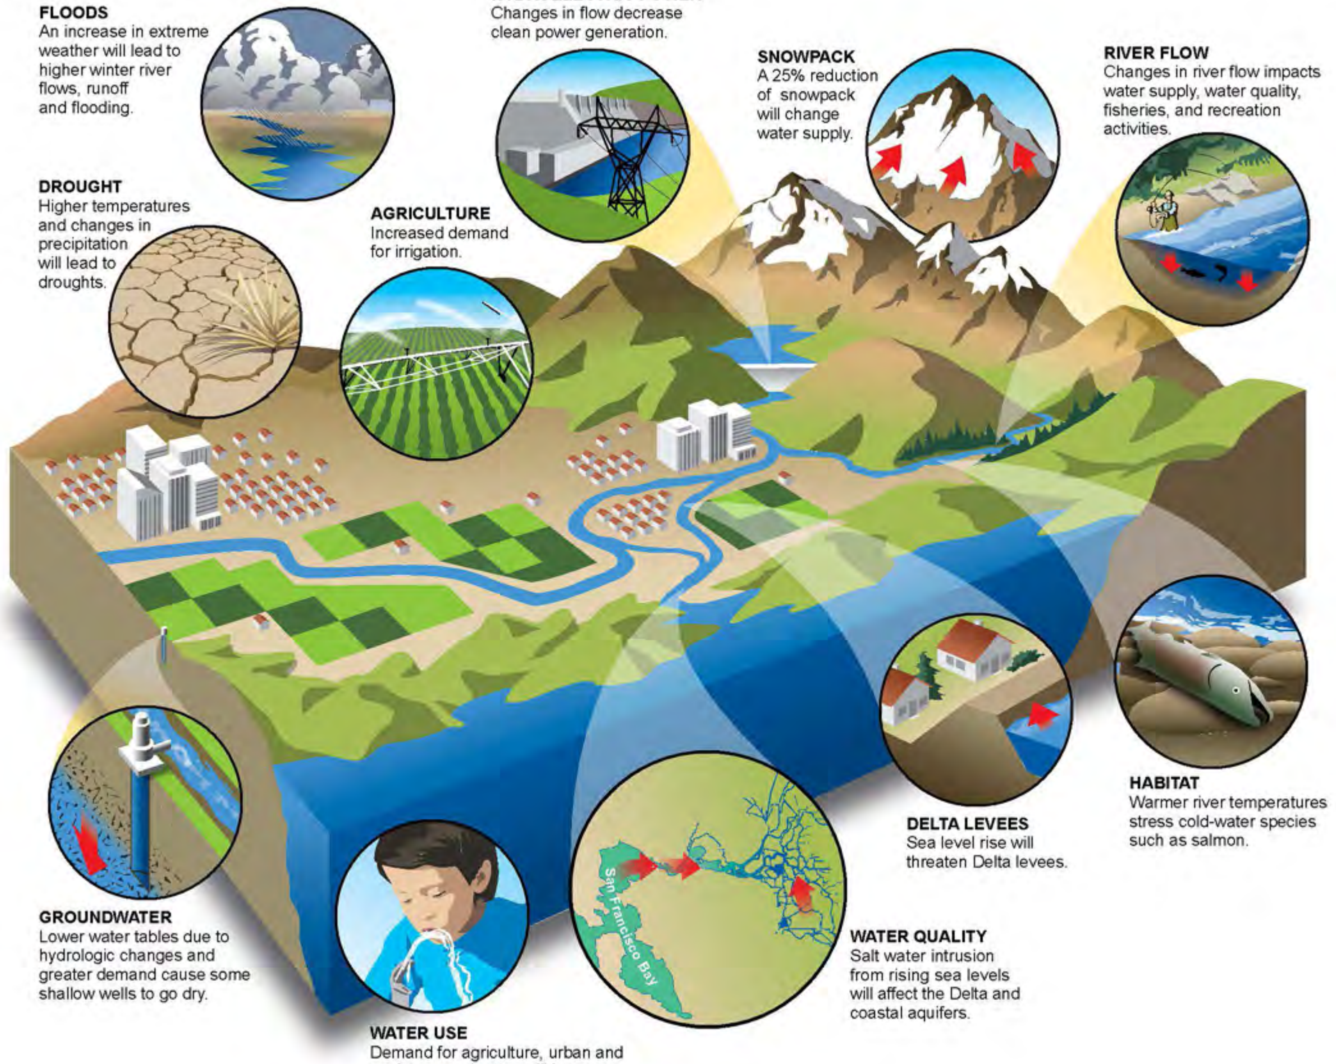
- All local governments are required by statute to adopt the State Model Water Efficient Landscape Ordinance (MWELO) or equivalent (see sidebar). Because the model ordinance only addresses new development, local governments must pursue conservation programs to reduce water use on existing landscapes.
- Notwithstanding other water management objectives, local and regional water use efficiency programs—agricultural, residential, commercial, industrial and institutional—should emphasize those measures that reduce both water and energy consumption.

These agencies, in coordination with the rest of the Water-Energy subgroup of the Governor's Climate Action Team and the CUWCC, will develop urban water use efficiency recommendations for incorporation into the California Water Plan Update 2009.

- Agricultural entities should apply all feasible Efficient Water Management Practices (EWMPs) to reduce water demand and improve the quality of drainage and return flows, and report on implementation in their water management plans.
- Recycled water is a drought-proof water management strategy that may also be an energy efficient option in some regions.
  - In those regions, wastewater and water agencies should collaboratively adopt policies and develop facility plans that promote the use of recycled water for all appropriate, cost-effective uses while protecting public health.
  - In consultation with DWR and the Department of Public Health, the Water Boards should identify opportunities to optimize water recycling consistent with existing permitting authority.

The State Water Resources Control Board (SWRCB) and the California Public Utilities Commission are authorized to impose water conservation measures in permitting and other proceedings to ensure attainment of these conservation efforts. Additionally, the Legislature should authorize and fund new incentive-based programs to promote the widespread and mainstream adoption of aggressive water conservation by urban and agricultural water systems and their users.

How climate change impacts a watershed



FLOODS
An increase in extreme weather will lead to higher winter river flows, runoff and flooding.

HYDROELECTRIC POWER
Changes in flow decrease clean power generation.

SNOWPACK
A 25% reduction of snowpack will change water supply.

RIVER FLOW
Changes in river flow impacts water supply, water quality, fisheries, and recreation activities.

DROUGHT
Higher temperatures and changes in precipitation will lead to droughts.

AGRICULTURE
Increased demand for irrigation.

HABITAT
Warmer river temperatures stress cold-water species such as salmon.

DELTA LEVEES
Sea level rise will threaten Delta levees.

GROUNDWATER
Lower water tables due to hydrologic changes and greater demand cause some shallow wells to go dry.

WATER QUALITY
Salt water intrusion from rising sea levels will affect the Delta and coastal aquifers.

WATER USE
Demand for agriculture, urban and environmental water will increase.

Oroville Dam

Statewide Strategies

California has an unparalleled water infrastructure system that stores and conveys water, manages flood flows, and interconnects many of the state's regions. However, current water resources infrastructure is already strained to meet existing, competing objectives for water supply, flood protection, environmental protection, water quality, hydropower and recreation. In a changing climate, the conflicts between competing interests are even greater as supplies become less reliable. This system of reservoirs, canals, flood bypasses and levees must be modified and managed differently to accommodate the increased variability brought by climate change. As the prediction of climate change impacts will never be perfect, flexibility must be a fundamental tactic, especially regarding water system operations.

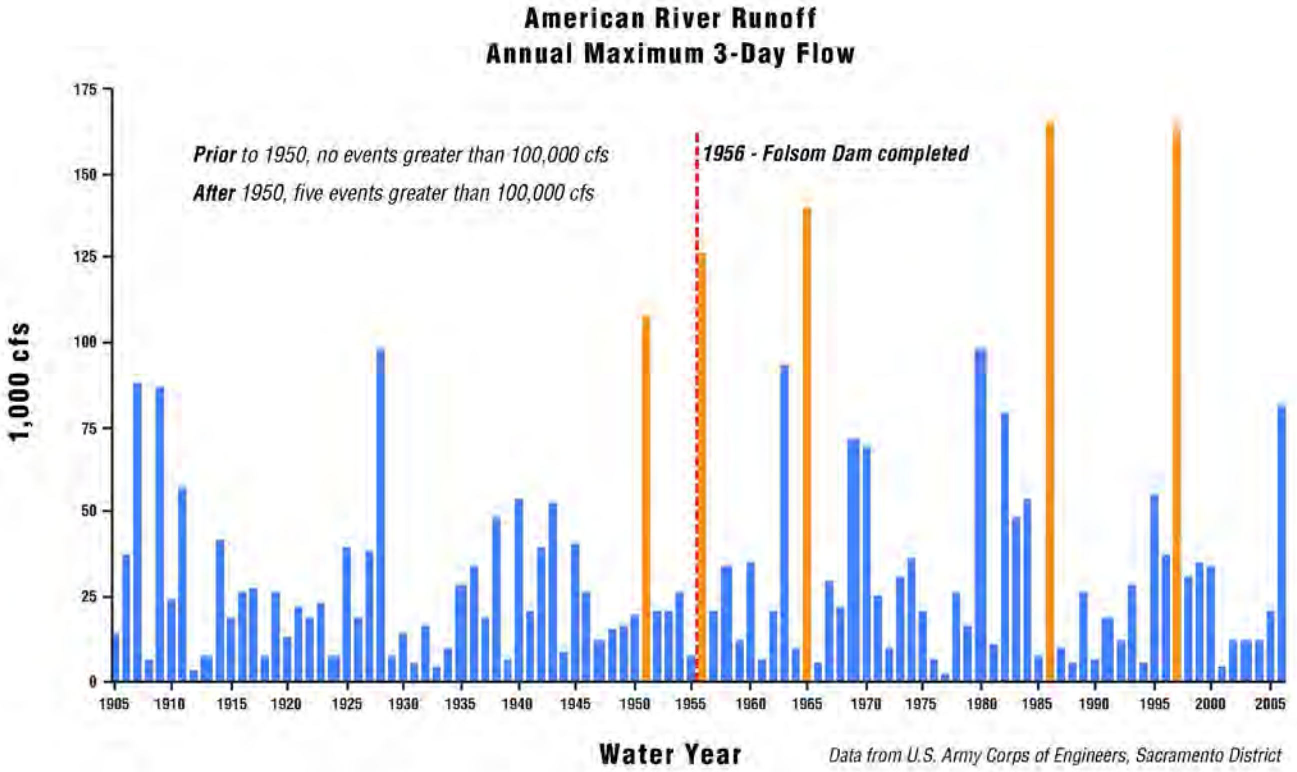
Flood systems throughout the state must be upgraded and managed to accommodate the higher variability of flood flows, to protect public safety, the economy and ecosystems.

Strategy 4: Practice and Promote Integrated Flood Management

Many Californians already face an unacceptable risk of flooding. Catastrophic flooding within the Central Valley could mirror the economic, social and environmental damages caused by Hurricane Katrina in 2005. Millions of people in California's Central Valley live behind or depend upon levees to protect them, with populations in these regions continuing to grow. Climate change will increase the state's flood risk by causing a shift toward more intense winter storms which could produce higher peak flows. Flood systems throughout the state must be upgraded and managed to accommodate the higher variability of flood flows, to protect public safety, the economy and ecosystems.

- Flood management systems must better utilize natural floodplain processes. Thus, flood management should be integrated with watershed management on open space, agricultural, wildlife areas, and other low density lands to lessen flood peaks, reduce sedimentation, temporarily store floodwaters and recharge aquifers, and restore environmental flows.

Liberty Island



Data from U.S. Army Corps of Engineers, Sacramento District

The five highest floods of record on the American River have occurred since 1950.

The improved performance of existing water infrastructure cannot be achieved by any single agency, and will require the explicit cooperation of many agencies. Systemwide operational coordination and cooperation must be streamlined to respond to extreme events that may result from climate change. Successful system reoperation will require that the benefits and tradeoffs of such actions are evident to federal and local partners.

- The state will establish a System Reoperation Task Force comprised of state personnel, federal agency representatives and appropriate stakeholders that will:
  - Quantify the potential costs and benefits and impacts of system reoperation for water supply reliability, flood control, hydropower, water quality, fish passage, cold water management for fisheries and other ecosystem needs;

System Reoperation

California's water resources system includes both physical elements (such as reservoirs, aquifers, rivers, pumping plants, and canals) and non-physical elements (such as operating rules, land use practices, and environmental regulations). The addition or removal of a structural element or a change in a non-structural element often provides opportunities to optimize the operational benefits of other elements of the system.

The key to system reoperation is to integrate and connect individual system elements to illustrate how changes in use of one element can be balanced by changes in the use of other elements.

The largest challenge to system reoperation is that individual system elements are often owned and operated by independent entities.

  - Support the update of U.S. Army Corps of Engineers' operations guidelines for Central Valley reservoirs;
  - Support the update of flood frequency analyses on major rivers and streams;
  - Evaluate the need to amend flow objectives;
  - Expand the study of forecast-based operations for incorporation into reservoir operations;
  - Include watershed level analyses that detail localized costs and benefits; and
  - Identify key institutional obstacles that limit benefits.

- To coordinate California's water supply and flood management operations, state and federal agencies collaboratively established the Joint Operations Center (JOC). To successfully meet the challenges posed by climate change, the JOC capacity must be expanded to improve tools and observations to better support decision-making for individual events and seasonal and interannual operations, including water transfers. The JOC should be enhanced to further improve communications and coordination during emergencies, such as floods and droughts.

- By January 1, 2012, DWR will collaboratively develop a Central Valley Flood Protection Plan that includes actions to improve integrated flood management and considers the expected impacts of climate change. The plan will provide strategies for greater flood protection and environmental resilience, including:
  - Emergency preparedness, response, evacuation and recovery actions;
  - Opportunities and incentives for expanding, or increasing the use of floodway corridors to reduce stress on critical urban levees and provide for habitat, open space, recreation and agricultural land preservation;
  - Options and recommendations to provide at least 200-year level protection for all urban areas within the Sacramento-San Joaquin Valley;

  - Increased use of setback levees, flood easements, zoning, and land acquisitions to provide greater public safety, floodplain storage, habitat and system flexibility;
  - Flood insurance requirements to address residual risk;
  - Extensive, grassroots public outreach and education; and
  - The integration of flood management with all aspects of water resources management and environmental stewardship.

- All at-risk communities should develop, adopt, practice and regularly evaluate formal flood emergency preparedness, response, evacuation and recovery plans.

- Local governments should implement land use policies that decrease flood risk.
  - Local land use agencies should update their General Plans to address increased flood risks posed by climate change. General Plans should consider an appropriate risk tolerance and planning horizon for each locality.
  - Local governments should site new development outside of undeveloped floodplains unless the floodplain has at least a sustainable, 200-year level of flood protection.
  - Local governments should use low-impact development techniques to infiltrate and store runoff.
  - Local governments should include flood-resistant design requirements in local building codes.

Adaptive Capacity and Resilience

Adaptive capacity is the ability of systems, organizations, and individuals to:

- adjust to actual or potential adverse changes and events,
- take advantage of existing and emerging opportunities that support essential functions or relationships, and/or
- cope with adverse consequences, mitigate damages, and recover from system failures.

Resilience is the capacity of a resource or natural system to return to prior conditions after a disturbance.

California Conservation Corps workers strengthen a levee during a high water event

FloodSAFE CALIFORNIA

FloodSAFE California is a multi-faceted, strategic initiative to improve public safety through integrated flood management. Primarily funded by Propositions 1E and 84, the FloodSAFE program is a collaborative statewide effort to accomplish the following five broad goals:

Reduce the Chance of Flooding
Reduce the frequency and size of floods that could damage California communities, homes and property, and critical public infrastructure.

Reduce the Consequences of Flooding
Take actions prior to flooding that will help reduce the adverse consequences of floods when they do occur and allow for quicker recovery after flooding.

Sustain Economic Growth
Provide continuing opportunities for prudent economic development that supports robust regional and statewide economies without creating additional flood risk.

Protect and Enhance Ecosystems
Improve flood management systems in ways that protect, restore, and where possible, enhance ecosystems and other public trust resources.

Promote Sustainability
Take actions that improve compatibility with the natural environment and reduce the expected costs to operate and maintain flood management systems into the future.

Additional information is available at **www.water.ca.gov/floodsafe**.

Setback levee being constructed near Bear River

Strategy 5: Enhance and Sustain Ecosystems

Reliable water supplies and resilient flood protection depend upon ecosystem sustainability. Building adaptive capacity for both public safety and ecosystems requires that water and flood management projects maintain and enhance biological diversity and natural ecosystem processes. Water supply and flood management systems are significantly more sustainable and economical over time when they preserve, enhance and restore ecosystem functions, thereby creating integrated systems that suffer less damage from, and recover more quickly after, severe natural disruptions. By reducing existing, non-climate stressors on the environment, ecosystems will have more capacity to adapt to new stressors and uncertainties brought by climate change.

- Water management systems should protect and reestablish contiguous habitat and migration and movement corridors for plant and animal species related to rivers and riparian or wetland ecosystems. IRWM and regional flood management plans should incorporate corridor connectivity and restoration of native aquatic and terrestrial habitats to support increased biodiversity and resilience for adapting to a changing climate.
- Flood management systems should seek to reestablish natural hydrologic connectivity between rivers and their historic floodplains. Setback levees and bypasses help to retain and slowly release floodwater, facilitate groundwater recharge, provide seasonal aquatic habitat, support corridors of native riparian forests and create shaded riverine and terrestrial habitats. Carbon sequestration within large, vegetated floodplain corridors may also assist the state in meeting greenhouse gas emissions reductions mandated by AB 32.
- The state should work with dam owners and operators, federal resource management agencies, and other stakeholders to evaluate opportunities to introduce or reintroduce anadromous fish to upper watersheds. Reestablishing anadromous fish, such as salmon, upstream of dams may provide flexibility in providing cold water conditions downstream, and thereby help inform system reoperation. Candidate watersheds should have sufficient habitat to support spawning and rearing of self-sustaining populations.

Sheep grazing in the Yolo Bypass, west of Sacramento

- The state should identify and strategically prioritize for protection lands at the boundaries of the San Francisco Bay and Sacramento-San Joaquin Delta that will provide the habitat range for tidal wetlands to adapt to sea level rise. Such lands help maintain estuarine ecosystem functions and create natural land features that act as storm buffers, protecting people and property from flood damages related to sea level rise and storm surges.
- The state should prioritize and expand Delta island subsidence reversal and land accretion projects to create equilibrium between land and estuary elevations along select Delta fringes and islands. Sediment-soil accretion is a cost-effective, natural process that can help sustain the Delta ecosystem and protect Delta communities from inundation.
- The state should consider actions to protect, enhance and restore upper watershed forests and meadow systems that act as natural water and snow storage. This measure not only improves water supply reliability and protects water quality, but also safeguards significant high elevation habitats and migratory corridors.

Left: *Sacramento-San Joaquin Delta, with Mount Diablo in background*

Below: *Los Vaqueros Reservoir*

Strategy 6: Expand Water Storage and Conjunctive Management of Surface and Groundwater Resources

Surface and groundwater resources must be managed conjunctively to meet the challenges posed by climate change. Additional water storage and conveyance improvements are necessary to provide flexibility to facilitate water transfers between regions and to provide better flood management, water quality and system reliability, in response to daily and seasonal variations and uncertainties in water supply and use.

Historically, California has depended upon its groundwater, particularly during droughts. However, many aquifers are contaminated and must be remediated before they can be used as water banks. Groundwater resources will not be immune to climate change; in fact, historic patterns of groundwater recharge may change considerably. Climate change may worsen droughts, so more efficient groundwater basin management will be necessary to avoid additional overdraft, to take advantage of opportunities to store water underground and eliminate existing overdraft.

Better management of surface storage reservoirs can also provide benefits in a changing climate. Among the benefits are capturing higher peak flows, providing cold water releases for fish, repulsing seawater intrusion to protect drinking water quality, generating clean hydroelectricity, and offsetting the loss of snowpack storage with increased water storage.

- California must expand its available water storage including both surface and groundwater storage.
- DWR will incorporate climate change considerations as it works with the U.S. Bureau of Reclamation (Reclamation) and local agencies to complete surface storage feasibility studies and environmental documentation for the Sites Reservoir and Upper San Joaquin River Basin Storage Investigations. DWR will also make climate change recommendations as it works cooperatively with Contra Costa Water District on the Los Vaqueros Reservoir Expansion Investigation, and DWR will advise Reclamation on climate change matters on the Shasta Lake Water Resources Investigation.

Conjunctive Management

Conjunctive management of surface water and groundwater refers to the joint and coordinated management of both resources. Surface water and groundwater resources typically differ significantly in their availability, quality, management needs, and development and use costs. Managing both resources together, rather than in isolation from one another, allows water managers to use the advantages of both resources for maximum benefit.

Groundwater pump

- State, federal, and local agencies should develop conjunctive use management plans that integrate floodplain management, groundwater banking and surface storage. Such plans could help facilitate system reoperation and provide a framework for the development of local projects that are beneficial across regions.

- Local agencies should develop and implement AB 3030 Groundwater Management Plans as a fundamental component of IRWM plans. Local agencies must have such groundwater management plans to:
    - Effectively use aquifers as water banks;
    - Protect and improve water quality;
    - Prevent seawater intrusion of coastal aquifers caused by sea level rise;
    - Monitor withdrawals and levels;
    - Coordinate with other regional planning efforts to identify and pursue opportunities for interregional conjunctive management;
    - Avert otherwise inevitable conflicts in water supply; and
    - Provide for sustainable groundwater use.

Irrigation in California's Central Valley

- Local land use agencies should adopt ordinances that protect the natural functioning of groundwater recharge areas.

Strategy 7: Fix Delta Water Supply, Quality and Ecosystem Conditions

The Sacramento-San Joaquin Delta is a vital water supply for 25 million Californians, a diverse and complex ecosystem, home to many communities and ultimately is a place unique to California. The Delta is not considered sustainable under current management efforts. Warmer temperatures, sea level rise and higher flood flows brought by climate change threaten to further erode the Delta's sustainability. The Delta Vision Task Force published its vision for the Delta in December 2007. In that vision, the Task Force described a future in which the Delta will continue to thrive over the coming generations, despite major challenges including climate change. The Task Force is working on a strategic plan that will outline the recommendations to realize the Task Force's vision.

In addition to the work of Delta Vision, there are three other major public processes also focusing on the Delta: the Bay-Delta Conservation Plan (BDCP), the Delta Risk Management Strategy (DRMS) and the Delta Regional Ecosystem Restoration Implementation Plan (DRERIP) (see next page).

- State agencies and stakeholders should continue to support the work of the Delta Vision Task Force, BDCP, DRMS, and DRERIP, and encourage the incorporation of adaptive responses to climate change for the Delta in all four processes.
- By June 2009, affected state agencies, led by DWR, will initiate a coordinated effort to invest in the Delta ecosystem, water conveyance improvements, flood protection and community sustainability in order to achieve a sustainable Delta.

Canadian Geese in Sacramento-San Joaquin Delta

Delta at sunset

Delta Planning Processes and Climate Change

State government is currently involved in four major planning efforts to evaluate Sacramento-San Joaquin Delta ecosystem and water supply issues and to recommend strategies and actions for their improvement — the Delta Vision, Bay-Delta Conservation Plan (BDCP), Delta Risk Management Strategy (DRMS), and Delta Regional Ecosystem Restoration Implementation Plan (DRERIP). These efforts are complementary but each process has a specific focus. All are considering the impacts of climate change on the Delta as well as a number of response strategies. Together, they should provide a set of adaptive strategies and actions that are comprehensive, consistent and build upon each other to improve the Delta ecosystem and water supply reliability.

The Governor established **Delta Vision** in 2006 to develop a durable vision for sustainable management of the Delta. Over the long term, the Delta Vision process aims to restore and maintain functions and values that are determined to be important to the environmental quality of the Delta and the economic and social well being of the people of the state. In December 2007, the Delta Vision Task Force published its Delta Vision Report comprised of 12 recommendations and in October 2008, submitted their Delta Strategic Plan to the Delta Vision Cabinet Commitee. The Cabinet Commitee will provide specific recommendations to the Governor and Legislature by the end of 2008. More information is available at **www.deltavision.ca.gov**.

The purpose of the **BDCP** is to help recover endangered and sensitive species and their habitats in the Delta in a way that also provides for sufficient and reliable water supplies. The BDCP will (1) identify and implement conservation strategies to improve the overall ecological health of the Delta, (2) identify and implement ecologically friendly ways to move fresh water through and/or around the Delta, (3) address toxic pollutants, invasive species and impairments to water quality, and (4) provide a framework to implement the plan over time. More information is available at **www.resources.ca.gov/bdcp**.

DRMS is evaluating the risks from Delta levee failures and ways to reduce those risks. Preliminary evaluations by DRMS show that the risks from earthquakes and floods are substantial and are expected to increase in the future. In Phase 1, DRMS evaluates the risk and consequences to the Delta and statewide associated with the failure of Delta levees. In Phase 2, DRMS will evaluate strategies and actions to reduce risks and consequences. Additional information is available at **www.drms.water.ca.gov**.

The **DRERIP** is identifying restoration opportunities within the Delta and Suisun Marsh ecological restoration zones. It applies the Ecosystem Restoration Program Conservation Strategy to the Delta, refines existing and develops new Delta restoration actions, and includes a conceptual model, implementation guidance, program tracking, performance evaluation, and adaptive management feedback. Additional information at **www.delta.dfg.ca.gov/erpdeltaplan**.

Improving Management and Decision-Making Capacity

Determining the impacts of climate change on the varying regions of the state requires that data about our environment be collected and analyzed in a consistent and comprehensive way. Analysis of past records, current conditions, and trends can help provide a forecast for weather, climate, supply, and flooding variables. Unfortunately, sensors and gauges that measure this information, both offshore and over land, are currently inadequate. Strategic investment is needed in measurement networks, data analysis and archiving, and forecast tools that can support operational and policy decisions by users. Additionally, funding must be sustained in all of these areas to preserve the unbroken records that are vital to understanding the impacts of climate change.

Strategy 8: Preserve, Upgrade and Increase Monitoring, Data Analysis and Management

Uncertainty in the rate and magnitude of long-term climate change must be reduced. As one example, there are currently large gaps in the hydrologic observational network (e.g. rain and snow gauges) in the areas of California most vulnerable to climate change. Improved data analysis, and interpretation supported by a robust monitoring network can help identify trends, provide for better real-time system management, and evaluate and, if necessary, correct, adaptation strategies.

- For data to be useful in climate monitoring and climate change detection, there must be better and more consistent monitoring of critical variables such as temperature, precipitation, evapotranspiration, wind, snow level, vegetative cover, soil moisture and streamflow. Expanded monitoring is especially needed at high elevations and in wilderness areas to observe and track changes occurring in the rain/snow transition zone, which is critical for projecting future water supply.
- Similarly, improved observations of atmospheric conditions are needed to help define and better understand the mechanisms of the underlying atmospheric processes that lead to California's seasonal and geographic distribution of precipitation. This will help climate modelers to better project future rain and snow patterns on a regional scale.
- Information on water use is currently limited and often unreliable. Accurate measurement of water use can facilitate better water planning and management. By 2009, DWR, the state and regional Water Boards, the Department of Public Health, and the California Bay-Delta Authority will complete a feasibility study for a water use measurement database and reporting system.

Western Governors' Association

In 2006, the Western Governors' Association (WGA) released its report on Water Needs and Strategies for a Sustainable Future, which called for member states to take specified actions to incorporate consideration of climate change into state water management. That document was followed by a 2008 WGA Next Steps report which further detailed recommendations to "change for the better the way states and the federal government carry out their respective responsibilities regarding water management in the West."

For more information about the implementation of the reports' recommendations go to **www.westgov.org**.

Strategy 9: Plan for and Adapt to Sea Level Rise

Of the many impacts of climate change, sea level rise presents the most difficult planning challenge because of the great uncertainty around ice sheet dynamics, and the resulting range of consequences. In addition, sea level rise depends upon regional factors such as land movement (e.g. tectonic uplift) and atmospheric conditions. Much of the Sacramento-San Joaquin Delta consists of islands that are below sea level and protected by levees of varying stability. Rising sea levels increase pressure on fragile levees and pose a threat to water quality. Local and regional investments in coastal water and flood management infrastructure, as well as coastal and bay wetlands, beaches and parks, are also vulnerable to rising seas.

- The state will establish an interim range of sea level rise projections for short-term planning purposes for local, regional and statewide projects and activities.
- The Resources Agency, in coordination with DWR and other state agencies, should convene and support a scientific panel of the National Research Council (NRC) to provide expert guidance regarding long-range sea level rise estimates and their application to specific California planning issues.
- Based upon guidance from the NRC, DWR, in collaboration with other state agencies, will develop long-range sea level rise scenarios and response strategies to be included in the California Water Plan Update 2013.

PIER

In 2003, the California Energy Commission created the California Climate Change Center to implement the Commission's Public Interest Energy Research (PIER) Program long-term climate change research plan. The Center is a virtual research organization with core research at the Scripps Institute and complementary research at other scientific institutions in California.

Of particular interest to the water community are studies from the 2006 and upcoming 2008 Biennial Climate Science Reports required by Executive Order S-3-05, signed by Governor Schwarzenegger on June 1, 2005.

For more information go to **www.climatechange.ca.gov/research**.

Strategy 10: Identify and Fund Focused Climate Change Impacts and Adaptation Research and Analysis

Developing more focused research can help narrow the range of uncertainty in climate change, with a concentration on the vulnerability of water and other natural resources. This research will assist in planning for new projects, management activities and policies.

State Capitol, Sacramento

- In association with research institutions such as the Regional Integrated Sciences and Assessment centers, Lawrence Livermore and Berkeley National Laboratories, and the University of California, state agencies should identify focused research needs to provide guidance on activities to reduce California's vulnerability to climate change. The state should also explore partnerships with the federal government, other western states, and research institutions on climate change adaptation.

- Since some uncertainty will always exist, the state's water supply and flood management agencies need to perform sensitivity analyses of preliminary planning studies, and risk-based analyses for more advanced planning studies. As noted earlier, until better information becomes available, local agencies should plan for droughts 20 percent more severe than historic droughts. For flooding, sensitivity and risk-based analyses should consider an appropriate risk tolerance and planning horizon for each individual situation. Selection of climate change scenarios for these analyses can be guided by recommendations of the Governor's Climate Action Team.

- The state should sponsor science-based, watershed adaptation research pilot projects to address water management and ecosystem needs. Funding for pilot projects should only be granted in those regions that have adopted IRWM plans that meet DWR's plan standards and have broad stakeholder support.

- As part of the California Water Plan Update process, every five years DWR will provide revised estimates of changes to sea level, droughts, and flooding that can be expected over the following 25 years.

NEXT STEPS

CALIFORNIA WATER PLAN UPDATE 2009

California Water Plan Update 2009 builds upon Update 2005; a strategic plan for managing California's water that promotes Integrated Regional Water Management and improved statewide water management systems. The Update 2009 collaborative process has at its center a steering committee of 20 state agencies with jurisdictions over California water issues. The improved interagency coordination provides a robust statewide perspective and the inclusion of state companion plans helps inform an added emphasis on climate change, water quality, and integrated flood management. Update 2009 is specifically advised by a Climate Change Technical Advisory Group composed of scientists and engineers with climate change expertise.

CALIFORNIA CLIMATE ADAPTATION STRATEGY

Building upon the recommendations and strategies set forth in this document, the California Resources Agency is coordinating the development of a statewide, cross-sector Climate Adaptation Strategy (CAS). The CAS will synthesize the most up-to-date information on expected climate change impacts to California, provide preliminary strategies to reduce the state's vulnerability to these impacts and develop plans for short and long-term actions.

For more information please go to **www.climatechange.ca.gov/adaptation**.

ACKNOWLEDGEMENTS

Satellites measure recent rates of groundwater depletion in California's Central Valley

J. S. Famiglietti,[1,2] M. Lo,[1,2] S. L. Ho,[2,3] J. Bethune,[4] K. J. Anderson,[2] T. H. Syed,[2,5] S. C. Swenson,[6] C. R. de Linage,[2] and M. Rodell[7]

Received 8 December 2010; revised 29 December 2010; accepted 4 January 2011; published 5 February 2011.

[1] In highly-productive agricultural areas such as California's Central Valley, where groundwater often supplies the bulk of the water required for irrigation, quantifying rates of groundwater depletion remains a challenge owing to a lack of monitoring infrastructure and the absence of water use reporting requirements. Here we use 78 months (October, 2003–March, 2010) of data from the Gravity Recovery and Climate Experiment satellite mission to estimate water storage changes in California's Sacramento and San Joaquin River Basins. We find that the basins are losing water at a rate of 31.0 ± 2.7 mm yr^{-1} equivalent water height, equal to a volume of 30.9 km^3 for the study period, or nearly the capacity of Lake Mead, the largest reservoir in the United States. We use additional observations and hydrological model information to determine that the majority of these losses are due to groundwater depletion in the Central Valley. Our results show that the Central Valley lost 20.4 ± 3.9 mm yr^{-1} of groundwater during the 78-month period, or 20.3 km^3 in volume. Continued groundwater depletion at this rate may well be unsustainable, with potentially dire consequences for the economic and food security of the United States. **Citation:** Famiglietti, J. 1. Introduction

[2] Nearly 2 billion people rely on groundwater as a primary source of drinking water and for irrigated agriculture [*Alley et al.*, 2002]. However, in many regions of the world, groundwater resources are under stress due to a number of factors, including salinization, contamination and rapid depletion [*Wada et al.*, 2010]. When coupled with the pressures of changing climate and population growth, the stresses on groundwater supplies will only increase in the decades to come.

[3] In spite of its importance to freshwater supply, groundwater resources are often poorly monitored, so that a consistent picture of their availability is difficult and sometimes impossible to construct. Moreover, water withdrawals from pumping wells are often unrestricted and unmonitored, further complicating attempts to estimate rates of groundwater consumption. In short, no comprehensive framework for monitoring the world's groundwater resources currently exists.

[4] Satellite observations of time-variable gravity from the Gravity Recovery and Climate Experiment (GRACE) mission [*Tapley et al.*, 2004] may ultimately provide an important component of such a monitoring framework. Recent studies have clearly demonstrated that GRACE-derived estimates of variations of total water storage, TWS (all of the snow, ice, surface water, soil water and groundwater in region), when combined with auxiliary hydrological datasets, can provide groundwater storage change estimates of sufficient accuracy to benefit water management [*Yeh et al.*, 2006; *Zaitchik et al.*, 2008]. Most recently, the GRACE-based approach has been applied to estimate rates of groundwater depletion in northern India, a vast agricultural region that relies heavily on unmonitored groundwater withdrawals for its irrigation water supply [*Rodell et al.*, 2009; *Tiwari et al.*, 2009].

[5] In this study we use 78 months of GRACE data, from October, 2003 through March, 2010, to examine water storage changes in California's Sacramento and San Joaquin River Basins (~154,000 km^2) (Figure 1), which encompass the Central Valley (~52,000 km^2) and its underlying groundwater aquifer system. The Sacramento Basin and San Joaquin Basin, which includes the internally-draining Tulare Basin, are home to California's major mountain water source, the snowpack of the Sierra Nevada range. The Central Valley is the most productive agricultural region in the U. S., growing more than 250 different crops, or 8 percent of the food produced in the U. S. by value [*Faunt*, 2009]. It accounts for 1/6 of the country's irrigated land and supplies 1/5 of the demand for groundwater in the United States. As the second most pumped aquifer in the U. S. after the High Plains aquifer, the Central Valley offers a compelling example of the importance of groundwater as a resource, as well as the need to manage its use for sustained availability and productivity.

2. Data and Methods

[6] We use 78 months of GRACE gravity coefficients from Release-04 computed at the Center for Space Research at the University of Texas at Austin. The temporal mean was removed to compute gravity anomalies, and each field was

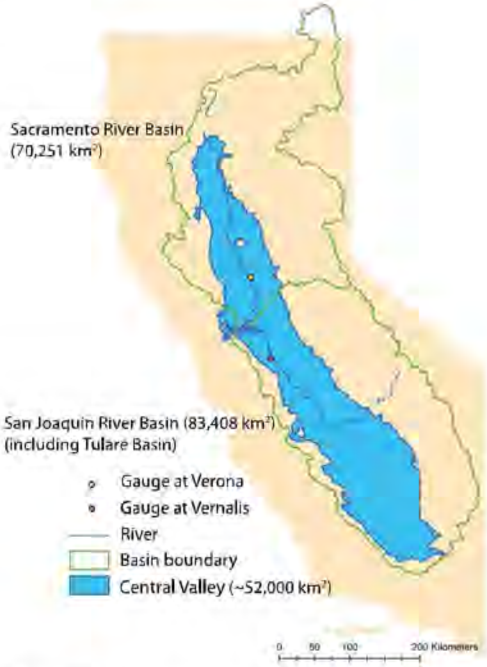

Figure 1. The Sacramento and San Joaquin river basins, including the Tulare basin and the Central Valley in California.

filtered to reduce noise [*Swenson and Wahr*, 2006] and then converted to mass in units of equivalent water height. We then used the method of averaging kernels [*Swenson and Wahr*, 2002] convolved with the GRACE coefficients to estimate the average water storage change for the combined Sacramento and San Joaquin River Basins. In order to restore power of the signal reduced by the truncation of the gravity coefficients (at degree and order 60) and filtering, the original estimate of GRACE TWS was scaled by a factor of 2.35 in order to recover an unbiased mass change estimate for the region [*Velicogna and Wahr*, 2006].

[7] Precipitation (P) data from the PRISM system [*Daly et al.*, 2008], satellite-based evapotranspiration (E) [*Tang et al.*, 2009] and U. S. Geological Survey (USGS) streamflow (Q) measurements at the Verona and Vernalis gauging stations (see Figure 1) were used in a water balance to assess the accuracy of the GRACE data (see Results).

[8] Snow, surface water and soil moisture data were required to isolate the groundwater contribution to TWS changes. Snow water equivalent (SWE) data were obtained from the National Operational Hydrologic Remote Sensing Center, and were determined from a combination of remote, field survey and *in situ* observations assimilated into an operational snow simulation model [http://www.nohrsc.noaa.gov/technology/]. Surface water storage data were compiled for the 20 largest reservoirs in the river basins, which accounted for the bulk of the observed surface water changes, and were obtained from the California Department of Water Resources [http://cdec.water.ca.gov/reservoir.html]. Soil moisture content is largely unmeasured in the United States. Consequently, we estimated soil moisture storage using the average of three different soil moisture simulations [*Rodell et al.*, 2009] for the corresponding time period taken from land surface models [*Ek et al.*, 2003; *Koster and Suarez*, 1992; *Liang et al.*, 1994] included in the NASA Global Land Data Assimilation System [*Rodell et al.*, 2004a].

[9] GRACE TWS monthly errors are 45.3 mm, which is the sum of the leakage error [*Swenson and Wahr*, 2002] and the residual error in the filtered, scaled GRACE data. Since no published error estimates for the monthly surface water and SWE were available, we assumed an error of 15 percent of the mean absolute changes in each, i.e., 4.0 mm for surface water and 7.0 mm for snow. Soil moisture error was estimated as the mean monthly standard deviation of the three model time series, or 11.9 mm. These errors combine to yield a monthly error in our groundwater estimate of 47.5 mm. Uncertainties in the GRACE TWS, SWE, and surface water trends were estimated using a least squares fit, and then propagating errors from the monthly data using the covariance matrix. We find trend errors of 2.7 mm yr^{-1}, 0.4 mm yr^{-1}, and 0.2 mm yr^{-1} for GRACE TWS, SWE, and surface water respectively. Error in the soil moisture trend was computed as the standard deviation of trends from the three models, which is 2.8 mm yr^{-1}. The total error estimate for the groundwater trend, 3.9 mm yr^{-1}, combines these values and assumes that the individual errors are uncorrelated.

3. Results

[10] To assess the accuracy of our GRACE-derived water storage estimate for the combined river basins, we compared its time derivative, dS/dt, to that determined from an independent water balance for the region ($dS/dt = P - E - Q$). Figure 2a shows the monthly-averaged P, E, and Q data. Figure 2b shows that the observed water balance agrees well with the storage changes observed from GRACE, giving confidence that the GRACE data accurately capture the storage changes in the basins and can be used to estimate groundwater storage trends. The blue shading in Figure 2b represents the error in the GRACE dS/dt of 63 mm month^{-1}. The red shading represents the uncertainty in our water balance estimate of dS/dt, calculated after *Rodell et al.*

(b) GRACE dS/dt vs Observed P−ET−Q

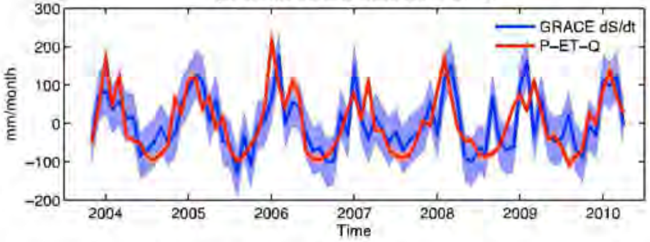

Figure 2. (a) Precipitation (P), evapotranspiration (E), and streamflow (Q) (mm/month) from October 2003–March 2010. (b) Comparison between observed total water storage change (dS/dt) and that from GRACE. Blue shading shows GRACE dS/dt errors. Red shading shows uncertainty in the observed water balance estimate of dS/dt.

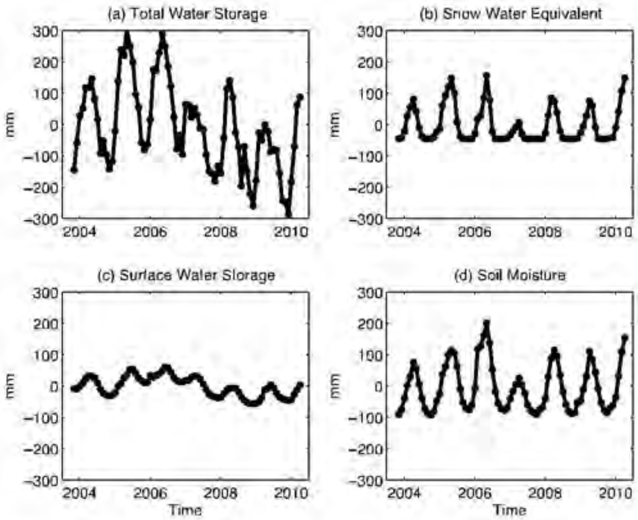

Figure 3. Monthly anomalies of (a) total water storage; (b) snow water equivalent; (c) surface water storage; and (d) soil moisture for the Sacramento and San Joaquin River Basins in mm from October 2003 to March 2010.

[2004a, 2004b] assuming relative errors of 15 percent in P [*Jeton et al.*, 2005] and E [*Tang et al.*, 2009], and 5 percent in Q [*Rodell et al.*, 2004b].

[11] Figure 3a shows the GRACE-based estimate of TWS variations for the combined Sacramento-San Joaquin Basins. The regional drought conditions, which persisted from 2006 through the end of the study, are evident. During the 78-month period beginning in October, 2003, total water storage declined at a rate of 31.0 ± 2.7 mm yr^{-1} equivalent water height, which corresponds to a total volume of 30.9 km^3 for the study period.

[12] In order to isolate groundwater storage variations from the GRACE TWS estimate, water mass variations in snow, surface water and soil moisture were estimated and subtracted from the total. Below-average SWE (Figure 3b) during the winters of 2006/07 through 2008/09 is apparent, consistent with the regional drought conditions, as are above-average conditions before and after that time period. These data show a slight decrease of 1.6 ± 0.4 mm yr^{-1} equivalent water height, which corresponds to 1.5 km^3 of water loss in 78 months. Figure 3c shows that surface water storage has been declining slightly since 2006. Over the length of the study period, surface water storage decreased at a rate of 8.8 ± 0.2 mm yr^{-1}, accounting for 8.7 km^3 of water loss. The loss of soil moisture (Figure 3d) was not significant during the study period. The trends for total water storage, SWE, surface water, soil moisture, and groundwater, along with the corresponding total volume changes for the October, 2003–March, 2010 period, are summarized in Table 1.

[13] Subtracting the snow, surface water and soil moisture components from GRACE TWS for the combined basins yields the groundwater storage variations shown in Figure 4. Over the course of the study period, groundwater storage decreased by 20.4 ± 3.9 mm yr^{-1}, which corresponds to a volume of 20.3 km^3 of water loss, or two-thirds of the total water storage loss in the river basins. We assume in this work that nearly all of the groundwater loss occurs in the Central Valley, and that the other major geological features in the combined basins, that is, the mountain ranges surrounding the Valley, have limited capacity to store groundwater. Based on separate water budget analyses of the Sacramento and San Joaquin basins (not shown) we estimate that over 80 percent of the 20.3 km^3 of groundwater loss occurred in the San Joaquin river basin, including the Tulare basin, which is consistent with a recent USGS report on groundwater availability in the Central Valley [*Faunt*, 2009]. The San Joaquin portion of the Valley has always relied on groundwater more heavily than its Sacramento counterpart because its drier climate results in more limited natural surface water availability.

Table 1. Trends in Water Storage for the Combined Sacramento-San Joaquin River Basins[a]

	Trend (mm yr^{-1})	Volume Lost (km^3)
Total Water Storage	−31.0 ± 2.7	30.9 ± 2.6
Snow Water Equivalent	−1.6 ± 0.4	1.5 ± 0.3
Surface Water Storage	−8.8 ± 0.2	8.7 ± 0.1
Soil Moisture	−0.2 ± 2.8	0.1 ± 2.7
Groundwater Storage	−20.4 ± 3.9	20.3 ± 3.8
Groundwater Storage (2003/10–2006/03)	−1.4 ± 12.7	0.5 ± 4.8
Groundwater Storage (2006/04–2010/03)	−38.9 ± 9.5	23.9 ± 5.8

[a] Trends and volumes are for October, 2003–March, 2010 unless otherwise noted.

[14] Figure 4 also shows a distinct break in the behavior of groundwater storage variations. Prior to the onset of drought conditions in 2006, there was no significant change in groundwater storage. However, beginning with the drought in 2006, a steep decline in groundwater storage of 38.9 ± 9.5 mm yr^{-1} (6.0 km^3 yr^{-1}) occurred between April, 2006 and March, 2010. Our estimate of the current depletion rate is nearly as large as previous model-based estimates of

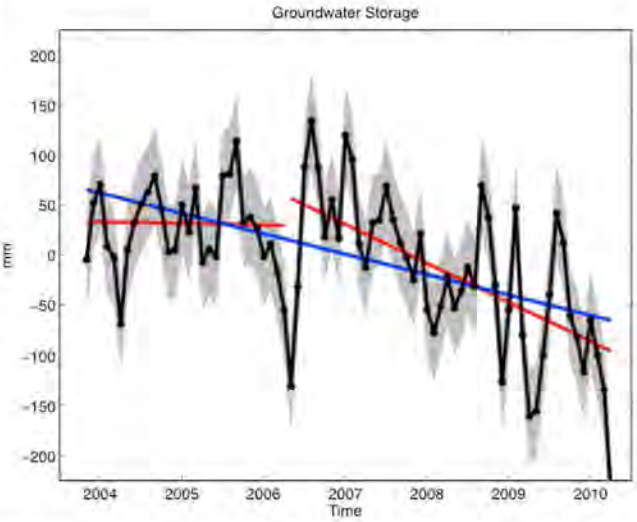

Figure 4. Monthly groundwater storage anomalies for the Sacramento and San Joaquin River Basins in mm, from October 2003 to March 2010. Monthly errors shown by gray shading. The blue line represents the overall trend in groundwater storage changes for the 78-month period. The red lines represent the trends from October 2003 and March 2006 and April 2006 through March 2010.

groundwater losses [*Faunt*, 2009] during the two major droughts of the last 50 years. Reported groundwater losses during those periods were approximately 12.3 km^3 yr^{-1} from 1974–76, and 8.2 km^3 yr^{-1} from 1985–89. Our estimated rate is also slightly larger than the loss of 4.9 km^3 yr^{-1} reported by *Faunt* [2009] for the more recent dry period between 1998 and 2003. Combining the USGS estimates of groundwater depletion between 1998 and 2003 with our GRACE-based estimates for October, 2003 through March, 2010 indicates that nearly 48.5 km^3 of groundwater has been lost from the Central Valley in the 12-year time period.

4. Discussion

[15] The picture that emerges from our GRACE based analysis is in agreement with *Faunt* [2009], and extends aspects of that study from its end date in 2003 to the present. Furthermore, results are consistent with the historical pattern of Central Valley agricultural water use. Facing significant cuts in managed surface water allocations during periods of drought, farmers, in particular those in the drier San Joaquin Valley, are forced to tap heavily into groundwater reserves to attempt to meet their irrigation water demands – this in a region where groundwater dependence is already high. Under these conditions, groundwater use rates exceed replenishment rates, and groundwater storage and the water table drop. Given the naturally low rates of groundwater recharge in the San Joaquin Valley, combined with projections of decreasing snowpack [*Cayan et al.*, 2006] and population growth, continued groundwater depletion at the rates estimated in this study may become the norm in the decades to come, and may well be unsustainable on those time scales.

[16] GRACE-based estimates of groundwater storage changes provide a holistic view of aquifer behavior that may not be otherwise possible, in particular in the developing world. Even in well-instrumented regions, a typical groundwater availability study is a massive undertaking, often several years in the making assembling supporting datasets and implementing numerical groundwater models. While there is no substitute for a dense network of ground-based observations and detailed groundwater model simulations, it is not clear that the major effort required for model-based studies can be sustained as part a routine monitoring program. Satellite gravimetry offers an important complement to both *in situ* observations and modeling studies by enabling independent estimates of groundwater storage changes, and by providing the opportunity to constrain aquifer-scale groundwater model simulations [*Zaitchik et al.*, 2008; *Lo et al.*, 2010].

[17] **Acknowledgments.** This research was funded by grants from NASA's GRACE Science Team, Terrestrial Hydrology and Earth and Space Sciences fellowship program. Claudia Faunt of the U. S. Geological Survey provided critical datasets used in this work. We thank Q. Tang at the University of Washington for providing evapotranspiration data.

UWMP	Urban Water Management Plan

EXECUTIVE SUMMARY

Unusually among western states in the United States, California has no statewide regulation of groundwater allocation or management. Rather, a complicated network of local agencies manages groundwater. The lack of state oversight means that there is little easily accessible information about how these agencies plan for the development and management of groundwater resources. We do know that significant areas of the State suffer from critical conditions of overdraft, where groundwater pumpers withdraw a far greater volume of groundwater than appears to be sustainable. These continually lowering water tables threaten serious economic, social, and environmental harms. Even so, groundwater use is increasing, and is projected to increase at a greater rate in the future.

Over decades, commentators have advocated reforming California's groundwater laws to alleviate problems of groundwater overdraft. Many suggestions derive useful inspiration from the experience of other States, and sometimes other countries. This report takes a different tack. It draws inspiration from how local agencies currently manage groundwater in California. It analyzes a collection of over 50 local groundwater management plans—most sourced directly from the agencies themselves—to find promising and innovative approaches to local groundwater management. These approaches are organized into four key themes: involving stakeholders, collecting good information, adopting a diverse "portfolio" of approaches to groundwater management, and taking steps to ensure that a plan can be implemented in practice.

Contrary to popular expectations, the report uncovers a treasure trove of innovative strategies for groundwater management in California. Among other things, we see agencies using measurable objectives for limiting groundwater drawdown; analyzing suites of management options with transparent decision criteria and simulations; collaborating with neighboring agencies; involving a broad range of agricultural, municipal, environmental, State, and federal stakeholders in their planning decisions; undertaking groundwater metering as well as monitoring; actively controlling pumping to limit groundwater drawdown; and protecting hydrologically connected surface waters and groundwater-dependent ecosystems. These practices may not be common, but they should be. This report is intended, in part, as a resource for local agencies, to enable these practices to become more widespread.

The home-grown innovations uncovered by this report point the way forward for local agencies to better manage groundwater in California, and the way towards an updated and improved State policy structure to encourage them to do so. Strengthening California's legislation for groundwater management planning, informed by current best practice, would provide a path towards better groundwater management and retain the State's historical focus on local agencies driving local change. The local planning actions uncovered by this report are not only innovative, they are also practical, down-to-earth and doable—they are being undertaken by different types of local agencies, with widely varying resources, across the State, right now.

PART ONE: INTRODUCTION

Unusually among western states in the United States, California has no statewide regulation of groundwater allocation or management. And although the State Water Resources Control Board has the legal power to prevent the "unreasonable use" of groundwater in the State and to control pumping by initiating adjudications of groundwater rights (Cal. Water Code §§ 2100-2102), it does not exercise that power (Sandino, 2005, p. 478). Instead, by convention, the state refrains from intervening and leaves these matters to local agencies, of which there are many different "species" established under different state statutes.

Commentators have advocated reforming California's groundwater laws over decades. Their suggestions have ranged from regulating groundwater at the State level (Hanak et al., 2010; Sax, 2003, p. 288; Taylor, 2010), to enforcing and improving prohibitions on wasting water generally (Neuman, 1998), to establishing a groundwater reserve as protection from drought (Langridge, 2009). Many suggestions derive useful inspiration from the experience of other States, and sometimes other countries. But in the short term, wholesale State-level water reform seems a distant prospect.

This report takes a different tack. It draws inspiration from how local agencies currently manage groundwater in California. Based on an analysis of a randomly selected collection of 52 groundwater management plans made by local agencies under Californian law (out of some 130 in total), this report highlights current "best practice" in local groundwater management planning in California. Here, best practice is defined by reference to accepted principles of water resources planning, like collecting adequate information, involving stakeholders, and pursuing multiple goals and strategies.

The innovations presented here are neither common nor representative of groundwater management in California—they are exceptional. Even putting the desirability of longer term reforms aside, these practices chart a path forward for local agencies in California in a way that is innovative, practical, down-to-earth and doable—a path that requires only that Californians look to each other for inspiration.

This report marks the start of a multi-year groundwater research program—part of the Joint Initiative on Water in the West, of the Woods Institute for the Environment and the Bill Lane Center for the American West at Stanford University. As a preliminary step, it does not seek to offer definitive solutions. Rather, it aims to challenge the common view of all groundwater management in California as lawless and backward, by highlighting innovative practice that can help chart a path to reforms which could grow organically from current practice. It also hopes to spur further empirical research on how groundwater management planning activities on paper translate to challenges and successes on the ground, by pointing to selected agencies and areas that show promise.

Part Two of this report sets out key practical and policy rationales for local water agencies to engage in groundwater management, with reference to the effects of overdraft. Part Three describes in more detail what is meant by "groundwater management planning" and presents a vision that defines "best practice" for the purposes of this report. Part Four sets the stage, outlining the roles of groundwater pumpers and local water agencies in managing groundwater in California, and how Californian law and policy provide for groundwater management plans. It suggests that this law and policy is now out of date and in need of reform, when compared to other legal developments in water planning in California. Part Five gives detailed examples of how selected local agencies in California approach groundwater management in an innovative and practical way. Part Six concludes and suggests how the innovations outlined in this report could lead to further policy developments in, and research on, Californian groundwater management.

PART TWO: WHY MANAGE GROUNDWATER?

To appreciate the need to manage groundwater, and the responsibilities that local agencies face in doing so, it is necessary to consider how groundwater is used and the consequences of depletion at the ground level. Californians use groundwater primarily for irrigation (around 75%) and municipal and domestic purposes (around 23%) (Kenny & U.S. Geological Survey, 2009, p. 7). Groundwater use is increasing, and is projected to increase at a greater rate as climate change threatens the reliability of surface water supplies (Cal. Dep't of Water Resources, 2008, p. 5).

Even at current rates of use, in some regions of California, groundwater pumpers withdraw a far greater volume of groundwater than appears to be sustainable. The latest state assessment of critical groundwater overdraft in California dates from 1980. It found that 11 basins suffered from "critical conditions of overdraft", meaning that "continu[ing] present water management practices would probably result in significant adverse overdraft-related environmental, social, or economic impacts"—terms which are defined at the local level (Cal. Dep't of Water Resources, 2003, p. 98).

Economically, water production costs may increase because diminishing groundwater levels mean that more energy is needed to pump water to the surface. It also costs more to treat groundwater that has been affected by quality problems associated with overdraft, such as intruding seawater, saline groundwater, or newly mobilized contaminants (Zekster, et al., 2005, pp. 402-403). At the extreme, impaired quality can render groundwater unusable (Cal. Dep't of Water Resources, 2003, p. 8), and possibly without economic value. Groundwater extraction has caused groundwater levels to decrease by more than 200 feet in some parts of California (U.S. Geological Survey, 2003, p. 3), and ground subsidence affects over half of the San Joaquin Valley (Zekster, et al., 2005, p. 401). This permanently reduces the storage capacity of the aquifer and may damage overlying infrastructure and aggravate seawater intrusion. In some areas, subsidence has resulted in the need for costly flood control infrastructure (Santa Clara Valley Water Dist., 2001, pp. 13, 44).

Intensive groundwater use also represents a powerful potential source of social conflict, although it has certainly provided significant social benefits from economic development (Llamas & Martinez-Santos, 2005). Though there appears to be little sustained work on the social effects of overdraft in California, the economic harms described above naturally have corresponding social effects.

In ecological terms, groundwater depletion may adversely affect connected streams, lakes, wetlands, springs, coastal environments, and the flora and fauna which depend on aquifers directly, or on these connected systems (Alley, et al., 1999, pp. 30-44). The ecological impacts of groundwater overdraft in California include diminished streamflow and lake levels, damaged vegetation, and corresponding effects on fish and migratory birds. Effects are felt at Lake Merced near San Francisco, Redwood Creek in northern California, the Cosumnes River near Sacramento, and the Owens River Valley, to name a few (Zekster, et al., 2005, pp. 398-401).

Groundwater management planning is a key way to prevent and holistically deal with these effects on a vital water supply for farms and cities in California.

PART THREE: GROUNDWATER MANAGEMENT PLANNING

Historically, water resource problems were considered "technical challenges to be resolved through purely technical means" (Feldman, 1991, pp. 72-73). A more modern view of water resources management conceives of a much more comprehensive, planning-based approach to water management. Such an approach involves managing all water sources, involving stakeholders, meeting the basic needs of both human water users and the environment, and managing demand through greater efficiency, public education, and incentives to conserve water—in addition to simply augmenting water supplies (Brooks, et al., 2009; Palaniappan & Gleick, 2009, p. 13). This report adopts this holistic understanding of groundwater management and draws out elements of California's local agency plans that together, build such an approach. Before discussing these local approaches in detail, it is appropriate to consider in greater depth what each element of this holistic vision of groundwater management planning requires.

1. Overview of water resources planning

Water resources planning refers to a process of (Gardner, et al., 2009, p. 273; Gleick, 1998):

- systematically gathering information about a water resource, including its status and its environmental, social and economic values;
- identifying existing rights and interests;
- evaluating present and future water needs;
- setting guidelines for future management;
- regularly reviewing the plan to ensure it can adapt to changing circumstances; and
- publicly reporting on the plan's implementation.

Water planning is particularly important as a way to formally anticipate and deal with variable water availability in arid and semi-arid areas, and as groundwater extraction and resource stress intensify. Although some jurisdictions use water plans as a primary way to control access to groundwater, in California, management plans for groundwater overlay allocation systems founded on common law rights. Groundwater management plans are one type of water management plan among many, including:

- the five-yearly State Water Plan, which sets out goals and objectives (Cal. Water Code § 10004);
- integrated water resources management plans (Cal. Water Code §§ 10530-10550);
- urban water management plans (Cal. Water Code §§ 10610-10656); and
- agricultural water conservation programs (Cal. Water Code §§ 10520-10523).

Whether or not they have legal force, plans are "the basic instrument for ensuring the rational management of the water resources available" (Caponera, 2007, p. 137; Sax, 2003, p. 317).

2. Involving stakeholders

Public participation has been a feature of water planning in the United States for decades, though its implementation has not always been uncontroversial (Wengert, 1971). The two key issues are who to consult, and what role they should play. It is increasingly recognized that in water matters, "everyone is a stakeholder", including disadvantaged groups, individuals, non-government entities, and local groups of all kinds (Global Water Partnership Technical Advisory Comm., 2000, pp. 15-17; Iza & Stein, 2009, p. 86). Stakeholders should make "significant contributions to outcomes", rather than merely "legitimize decisions already made" (Bergkamp, et al., 2009, p. 39; Global Water Partnership Technical Advisory Comm., 2000, pp. 15-17). For example, in the groundwater sphere, stakeholders should be involved in "decid[ing] the specific conditions under which the undesirable consequences [of groundwater depletion] can no longer be tolerated" (Alley, et al., 1999, p. 76). Formal advisory committees of stakeholders assist local water agencies by providing a variety of perspectives, reducing future conflicts, achieving local buy-in, and broadening the discussion beyond purely operational issues (City of San Diego Water Dep't, 2007, pp. 3-18).

3. Collecting information

Pumping groundwater without monitoring extraction or the state of the aquifer has been compared to a business continually withdrawing money from a bank account without any bookkeeping system (U.S. Geological Survey, 2003, p. 4). Indeed, the Californian Legislature itself acknowledges that information about groundwater is required to properly manage the resource (Cal. Water Code § 10750(b)). The most fundamental data for groundwater management relates to groundwater levels, quality, extraction (Taylor & Alley, 2001, p. 1), and the health of dependent ecosystems. When local agencies require well owners to register and meter their wells, and report groundwater extraction, they gain crucial information about the stress on the resource and the wider local impacts of depletion, for example, ground subsidence. When they also collect ecological information—information that may initially seem outside their "mission"—they gain the ability to manage the resource for broader and longer-term sustainability, beyond a narrow focus on short-term water supply goals.

4. Adopting a portfolio approach to groundwater management strategies

A portfolio approach to groundwater management, as presented here, has two key characteristics—it involves multiple goals, and it involves using multiple strategies to pursue each goal. Traditionally, local water agencies in California focus on a narrow portfolio of goals. They focus very strongly on groundwater supply for consumptive purposes, often to the exclusion of other goals, like maintaining or restoring ecosystems, protecting connected surface waters, or ensuring that groundwater use minimizes third-party impacts on society.

Historically, California has also preferred engineering solutions to water problems over other approaches, and to some extent, this remains true, unnecessarily impoverishing California's portfolio of water management strategies (Hanak, et al., 2010, p. 25). Rather than seeking a "silver bullet", water problems are better approached with a portfolio of strategies (Hanak, et al., 2010, p. 34). Although the local context will determine which strategies are likely to be effective, empirical evidence suggests that having a larger and more diverse suite of water management actions is likely to enhance overall effectiveness and robustness; redundancy can encourage greater compliance because different users will respond to different approaches and increase "complementarity", whereby different approaches reinforce each other (Cash, 2006, p. 285).

Water resources literature is filled with different methods of dealing with managing groundwater to control depletion. Given the historical emphasis on engineered, supply-side solutions, this report focuses on how local Californian agencies manage groundwater demand using voluntary and mandatory measures; infrastructure measures are covered to a lesser degree, with an emphasis on the conjunctive management context, as described below.

A mandatory approach to demand management involves limiting extraction to a target level by mandating reductions in existing pumping, limiting the construction of new wells, or requiring conservation measures. Ideally, the target extraction level should avoid irremediable impacts on immediate and downstream freshwater ecosystems and maintain their integrity; consider links with water quality; and include "measures aimed at coping with droughts", such as a drought reserve, given that groundwater is often required as a buffer against drought (Dellapenna, 2004, pp. 89, 90; Flint, 2004, pp. 41, 47; Nevill, 2009, p. 2627). Since mandatory measures often encounter strong opposition from existing and aspiring rights-holders; limits should be set well before extraction approaches those levels (Nevill, 2009, p. 2628).

A voluntary approach to demand management entails using fees, educational measures or water efficiency projects to reduce groundwater pumping. The fee-based approach entails charging private well owners fees for groundwater extraction. In theory, the economic value of water comprises both its market value and its "non-market values to human capital and ecosystem service values" (Lant, 2007, p. 64). In practice, realizing this vision through fees is difficult—it is far easier to leave out or under-account for costs that are difficult to calculate, like the costs of "servicing the regulatory framework, environmental degradation, forced social change, impacts on future generations and this generation in the future" (Connell, 2007, p. 31). One method of introducing fees while reducing resistance and encouraging conservation is to use tiered charges, or allow users to pump a certain volume free of charge (Schiffler, 1998, p. 171).

Infrastructure measures entail either constructing or changing the operation of existing infrastructure. Infrastructure measures include reducing demand for local groundwater by treating and recycling wastewater or importing water from other basins. However, it must be noted that relying heavily on imported surface water may be ecologically damaging to the source area (Langridge, 2009, pp. 317-318). Another infrastructure-related measure is conjunctive management—using surface water and groundwater in a coordinated way, such that surface water is used to recharge groundwater when surface supplies are abundant, and groundwater is used preferentially ("recovered") in times of shortage. This can involve directly replenishing aquifers using spreading basins, injection wells or riverbeds. While this has obvious advantages, recovering groundwater from storage during a severe drought can compromise connected surface water systems and cause all of the problems of severe overdraft discussed above (Langridge, 2009, pp. 317-318). Alternative solutions include changing the spatial or temporal management of pumping to reduce the intensity of local depletion effects (Alley, et al., 1999, pp. 72-73).

This Part has presented a theoretical vision of holistic groundwater management planning. With this vision in mind, Part Four now examines the law and policy of groundwater management planning in California, before Part Five discusses Californian groundwater management planning in practice.

PART FOUR: GROUNDWATER PUMPERS, WATER AGENCIES, AND THE LAW AND POLICY OF GROUNDWATER MANAGEMENT PLANNING IN CALIFORNIA

Before discussing how Californian law provides for groundwater management plans, this report first sets the stage by presenting answers to two vital preliminary questions. What role do groundwater users have in controlling groundwater? And which local water agencies have an interest in managing groundwater?

1. What role do groundwater pumpers have in managing groundwater?

In most areas, well owners can pump groundwater without holding any administrative permit (Sax, 2003, p. 270). The common law doctrine of correlative rights regulates the taking and use of groundwater, unless local arrangements apply. That doctrine limits groundwater pumping to the "safe yield", being the volume of natural and artificial recharge of the aquifer, which is shared by overlying landowners on an "equitable basis" (regardless of their particular uses), and by non-overlying landowners, if there is sufficient water available (Katz v. Walkinshaw, 74 P. 766 (Cal. 1903)).

These common law rules have been heavily criticized as insufficient to properly manage groundwater or control groundwater depletion (Sandino, 2005, p. 479). To limit extraction, they require an individual user to file a lawsuit to settle all the groundwater rights in a basin, a course of action which is expensive and time-consuming (Langridge, 2009), and one which most agencies are very eager to avoid. As a result it is rarely done: adjudications cover only 22 of California's 431 basins (Cal. Dep't of Water Resources, 2003, p. 106; 2009). Without basin adjudications, "users can continue their use unabated", and the system may even encourage overpumping (Krieger & Banks, 1962, pp. 61-62; Sandino, 2005, p. 477). Adjudications are also limited thematically, since they cannot regulate groundwater pumping to protect water quality (Cal. Dep't of Water Resources, 2003, p. 40), nor plan for future changes in supply. Finally, some view resolving water disputes adversarially, rather than collaboratively, as inherently "dysfunctional", a process that "hinders our ability to create win-win outcomes" (Sheer, 2010, pp. 3, 4).

Groundwater management plans can help to address some of the problems with this common law system. In contrast to basin adjudications, groundwater management plans can cover large areas, and can integrate considerations of water quantity and quality, all with an eye to the future. Nonetheless, even with California's system of voluntary groundwater management plans, if local water agencies do not act, groundwater pumpers have complete management control over the resource, with no higher level of cooperation or rational planning.

2. Which local water agencies have an interest in managing groundwater?

California's Water Code provides for an astounding array of over 20 general types of local water agencies, which may be established anywhere in the State (Cal. Dep't of Water Resources, 2003, p.34, Table 32). On the ground, there are around 2300 of these agencies,[2] which may have interests in groundwater. These agencies may supply groundwater to their customers, or supply surface water to customers who also use groundwater, or they may wish to protect the resource because they plan to use it as a source of supply in the future. Such agencies include California water districts, county water

---

[2] This number was arrived at by taking the 20 statutes, which the current State Groundwater Bulletin indicates may have groundwater management powers, and noting the number of agencies which fall into these types, as set out in the California Controller's latest report on special districts (Cal. Dep't of Water Resources, 2003, p. 34; Cal. State Controller, 2010, p. 1061).

districts, irrigation districts, reclamation districts, water conservation districts, water replenishment districts, water storage districts, and waterworks districts.

In addition to these general types of agencies, several State acts target specific geographical areas suffering from local groundwater problems by creating special districts with powers tailored to dealing with these problems. Their powers include controlling in-basin pumping in situations of actual or threatened overdraft, limiting exports, spacing wells to minimize well interference, and imposing groundwater-related charges. Some view these districts as "the state-of-the-art in local groundwater management . . . successful in addressing their groundwater problems, and [] useful models to be considered for use in other parts of the state", while conceding that State-level political will may be insufficient to extend this technique to other overdrafted basins (Sandino, 2005, p. 484). Indeed, sometimes a local water agency is created in the form of a general statutory district (not a special district) to deal with serious groundwater depletion problems, possibly giving force to this view (Turlock Groundwater Basin Assoc., 2008, pp. 33-34). The DWR lacks an oversight function in relation to water management by both local water agencies and also special districts (Cal. Dep't of Water Resources, 2003, p. 33).

As these complicated agency arrangements suggest, a vast range of local agencies has an interest in managing groundwater. This includes many general statutory types of agencies which have varying interests in managing groundwater—as an existing or potential future user, or as a supplier of surface water to customers who also use groundwater. It also includes specially created districts which were established to deal with serious local groundwater problems.

3. How do Californian law and policy provide for groundwater management plans?

In California, statutory arrangements for groundwater management plans overlay the common law allocation system, and allow agencies to manage groundwater more proactively than is possible under common law rules (Hanak, 2003, p. 108; Sandino, 2005, p. 484).

California's Groundwater Management Act (AB 3030) encourages local-level groundwater management in basins with significant water use, which are not adjudicated (Cal. Water Code §§ 10750(a), 10750.2, 10752(b)). It permits a local agency, which includes a special district or a group of agencies, to adopt and implement a groundwater management plan (GWMP) for all or part of the agency's service area (Cal. Water Code §§ 10752(g), 10753(a), 10755.2).

Adopting a GWMP involves formal procedural steps, including making specific resolutions, issuing public notices and conducting public hearings (Cal. Water Code §§ 10753.2-10753.6). If landowners representing more than 50 percent of the assessed value of the land within the local agency protest against the GWMP, the local agency may not adopt it (Cal. Water Code § 10753.6). A GWMP may cover 12 enumerated matters. The quantity-related matters are: mitigating conditions of overdraft, replenishing extracted groundwater, monitoring groundwater, facilitating conjunctive use operations, and constructing and operating groundwater recharge, conservation, water recycling, and extraction projects (Cal. Water Code § 10753.8). An agency "shall adopt rules and regulations to implement and enforce" a GWMP (Cal. Water Code § 10753.9(a)).

When a local agency adopts a GWMP, it gains power to manage groundwater that may go beyond its powers under its establishing legislation. First, it may limit or suspend groundwater extractions, provided it "has determined through study and investigation that groundwater replenishment programs or other alternative sources of water supply have proved insufficient or infeasible to lessen the demand for groundwater" (Cal. Water Code § 10753.9). In this context, it is important to note that pumping limits need not amount to a constitutional taking, since groundwater pumpers are restricted to pumping for a reasonable beneficial use (Allegretti & Co. v. County of Imperial, 42 Cal. Rptr. 3d 122 (Cal. App. 2006)). Second, a local agency may impose charges for groundwater extraction or replenishment on the endorsement of a majority of voters (Cal. Water Code § 10754.3). On the other hand, failing to adopt a GWMP makes a water agency ineligible to receive water grants and loans from the state (Cal. Water Code § 10753.7(b)).

Californian law for GWMPs fills the void of comprehensive management that common law rules create, granting California's complicated web of local water agencies powers to plan and manage local groundwater proactively. But it is now out of date, and does not match up to modern principles of groundwater planning. It emphasizes augmenting supply to the exclusion of managing demand, and does not require local agencies to take any sort of action, even in cases of severe overdraft (Cooley, et al., 2009, p. 11; Hanak, 2003, pp. 107-108). While procedures are set out for amending a GWMP, a local agency is not *required* to review its GWMP, keep it up-to-date, or even implement it. Indeed, agencies have sometimes adopted GWMPs as a strategy to head off state intervention, without a strong intention to implement them (Hanak, 2003, p. 107).

Almost twenty years of groundwater management planning in California (since 1992) have seen policy on the subject mature. Early GWMPs focused on preventing the export of groundwater from local areas rather than on comprehensive management, and did not focus strongly on implementation (Cal. Dep't of Water Resources, 2003, p. 54). The Legislature responded by requiring greater rigor, directing the DWR to develop criteria for evaluating GWMPs, and requiring a local agency to prepare a GWMP that met certain requirements in order to be eligible for public funds for groundwater projects (Cal. Dep't of Water Resources, 2003, p. 54).

There are five broad types of information that local agencies preparing GWMPs either *must* include to meet the funding criteria, or *should* include, according to the DWR (Cal. Dep't of Water Resources, 2003, pp. 54-62):

- **Context**: a description of the area to be managed under the plan, and a map showing the basin, the agency's service area, and surrounding agencies;

- **Public and agency involvement**: a plan to involve other local agencies with overlapping service areas; a description of current or planned actions to coordinate with agencies that have powers over land use and surface zoning; a statement that the public was informed of how they could participate in developing the GWMP; and an advisory committee of interested parties to help develop and implement the plan;

- **Basin management objectives** and links between these objectives and the goals and actions of the plan;

- **Monitoring**: components related to monitoring and managing groundwater levels and quality, subsidence, and changes in surface flow and surface water quality that directly affect groundwater levels or quality, or are caused by pumping; monitoring protocols for the purpose of measuring against the basin management objectives; and a detailed description of the monitoring plan, including elements that relate to the type of monitoring, the type of measures, and the frequency and locations of monitoring;

- **Accountability and review**: a commitment to produce periodic reports that cover implementation of monitoring, management actions, the success or otherwise of management actions in meeting objectives, proposed management actions, and any plan changes; and a commitment to periodically re-evaluate the entire plan.

While DWR's official groundwater bulletin sets out a small number of examples in relation to some of these elements, it provides little guidance on innovative planning approaches or best practice (Cal. Dep't of Water Resources, 2003, pp. 54-62). Nonetheless, GWMPs have reached significant milestones, sometimes the result of truly impressive multi-year collaborations between multiple agencies and scores of stakeholders (N.E. San Joaquin County Groundwater Banking Auth., 2004, p. 4; Sacramento County Water Agency, 2006, p. 1-8; Sonoma County Water Agency, 2007, p. 1-6).

Recognizing that there is currently very little information available on sophisticated groundwater management planning efforts across California, and that water planning principles in California have moved beyond DWR's recommendations of 2003, the next section describes elements of current local GWMPs which capably address broader issues in groundwater management.

Stepping back from GWMPs, water planning practice more generally has become much more sophisticated both inside and outside California since the GWMP provisions were last amended. Rigorous legislative requirements, developed between 2002 and 2009, now apply to urban water management plans (UWMPs). These requirements demonstrate that best practice water planning in California now involves higher expectations than local agencies are asked to meet under the elements that are required or recommended for GWMPs.

Under the UWMP legislation, large water suppliers *must* adopt UWMPs, including for groundwater sources, regardless of whether they are seeking grants from the State (Cal. Water Code §§ 10610-10656). UWMPs must include:

- **Greater analysis of the planning context** through an evaluation of climate-related risks, and by considering environmental, social, and technological factors (Cal. Water Code § 10631(c), (g)(1));
- **More extensive public involvement**, namely involving disadvantaged groups in the planning process (Cal. Water Code § 10642);
- **A focus on managing demand in addition to enhancing supply**, including methods for evaluating the effectiveness of demand management measures, prohibiting wasteful uses during water shortages and imposing penalties for excessive use (Cal. Water Code §§ 10615, 10620(f)); and
- **More rigorous requirements for accountability and review**—requirements to review and update UWMPs every five years and to *implement* the UWMP or become ineligible for water management grants or loans from state water agencies (Cal. Water Code §§ 10621(a), 10631.5, 10640). UWMPs are also required to be much more accessible, transparent, and subject to accountability requirements than GWMPs. UWMPs must be submitted to the DWR, the California State Library, and "any city or county within which the supplier provides water supplies within 30 days after adoption" (Cal. Water Code § 10644(a)). DWR must also submit a report on the status of UWMPs and data on their effectiveness to the Legislature (Cal. Water Code § 10644(b)). None of this is true of GWMP plans.

Water planning law and policy have undoubtedly moved beyond the current requirements and policy recommendations in relation to GWMPs. In response, Part Six suggests reforms, inspired by the vision of groundwater planning presented in Part Three, the newer provisions for UWMPs discussed here, and the innovations in GWMPs now presented in Part Five.

PART FIVE: INNOVATIONS IN GROUNDWATER MANAGEMENT PLANNING IN CALIFORNIA

California's local water agencies have significant powers to plan and manage their local groundwater resources. But they are not subject to any legal mandates to do so, and they may come under significant pressure from local groundwater users to refrain from curbing local use or imposing additional responsibilities (Mendocino City Community Services Dist., 1990 (as amended, 2007), p. 39).

Despite these pressures, some local water agencies in California develop and implement innovative approaches to groundwater management. But few know about them. Not only is there very little academic or policy literature on GWMPs in California, but there is no comprehensive State-wide database of digital GWMPs, and information barriers sometimes prevent even neighboring agencies from finding out about planning activities. GWMPs themselves refer to the "independent character" of local water agencies creating fragmented governance and management, and to the difficulty of sharing control, building trust, and resolving inter-agency differences (GEI Consultants, 2009, p. 60; Kings River Conservation Dist., 2005, p. 5-1; N.E. San Joaquin County Groundwater Banking Auth., 2004, p. 98). Others also recognize that acting independently, local agencies "have found it difficult to wield the political and financial power necessary to mitigate conditions of groundwater overdraft" (N.E. San Joaquin County Groundwater Banking Auth., 2004, p. 20).

Acknowledging these substantial pressures, and the present lack of any widely available analysis of local groundwater management planning efforts, the body of this report describes elements of current local GWMPs that address key issues in groundwater management, and give substance to the theoretical vision of holistic groundwater management planning presented in Part Three. Where possible, examples of different statutory types of entities (for example a county government vs. a water district vs. an irrigation district) or entities in different circumstances (a large vs. a small irrigation district) are given for each issue. As the examples show, elements of best practice planning are found in the actions of small agencies with very limited resources, as well as in large agencies; in the actions of general water districts as well as special districts dedicated to groundwater management; and in the elements of older as well as more recent GWMPs.

While each solution may not be universally feasible or legally possible, it is hoped that local agencies around California will consider the approaches described here in formulating their own groundwater management actions, recognizing that management innovation is not necessarily precluded by scarce resources, or any particular statutory form.

It is important to emphasize that this Part discusses examples of single innovative practices in groundwater planning. It does not evaluate each GWMP as a whole, but rather, suggests that the particular element found in that GWMP, together with other elements suggested here, would constitute innovative practice. This Part also does not suggest that the elements of GWMPs given here are the only examples of these elements, or that they are the best that GWMPs can be; indeed, there are elements of best practice described in the foregoing sections that do not appear in any of the GWMPs reviewed for this report.

This Part largely takes the form of tables which collate elements of agencies' GWMPs, in the following categories:

- **Planning for action**: elements that help to ensure that GWMPs may successfully be implemented, independent of their content;
    - Table 1: Examples of governance structures for implementing GWMPs, listed in increasing levels of formality;

  - Table 2: Determining goals and assessing and reporting performance;

- **Cooperation and stakeholder participation**: elements for meaningfully using stakeholder collaboration to pursue the goals of a GWMP:
  - Table 3: Subjects of collaboration between water agencies in GWMPs;
  - Table 4: Structures for involving stakeholders in GWMPs;
  - Table 5: Avoiding and resolving disputes when formulating and implementing GWMPs;

- **Collecting information about the groundwater context**: ensuring informed planning by collecting information on groundwater and its context:
  - Table 6: Gathering and standardizing information on groundwater status and use;

- **A portfolio approach to groundwater management planning**: embracing multiple goals and multiple strategies for achieving GWMP goals:
  - Table 8: Methods of managing groundwater demand;
  - Table 9: Methods of using different water sources conjunctively;
  - Table 10: Methods of protecting and enhancing recharge and examples of water banking;
  - Table 11: Methods of protecting connected surface waters;
  - Table 12: Methods of restoring ecosystems and minimizing ecological impacts; and
  - Table 13: Methods of considering economic and financial sustainability.

References to groundwater basins and agencies appear in bold.

1. Moving beyond words: Planning for action

As Part Four described, many early GWMPs did not focus strongly on implementation—so much so that the Legislature took action to require them to be more rigorous. Nonetheless, it stopped short of requiring an agency to *implement* its GWMP, as is the case for UWMPs. Regardless of legal requirements, foremost among the desirable characteristics of a GWMP are that it should be able to be implemented, and it should be possible to determine whether it is working with reference to goals.

Choosing an appropriate governance structure is an important part of ensuring that a GWMP can be implemented. Various governance structures are used to implement GWMPs, at varying levels of formality (Table 1). Considerations relevant to deciding on a governance structure include: the powers necessary to implement the plan; how stakeholders will be represented; how other interest groups can participate; how the group will coordinate with basin neighbors; how it will be funded; and whether an independent coordinating group will construct projects, rather than individual members (N.E. San Joaquin County Groundwater Banking Auth., 2004, p. 98).

Table 1: Examples of governance structures for implementing GWMPs, listed in increasing levels of formality

Loose group based on MOUs	The **Stanislaus and Tuolumne Rivers Groundwater Basin Association** is a loosely bound group of entities, organized around a memorandum of understanding which aims to promote coordination of groundwater management planning activities (Stanislaus & Tuolumne Rivers Groundwater Basin Assoc., 2005, App. A). Similarly, a series of MOUs links the **Kaweah Delta Water Conservation**

	District and, as of 2007, each of 16 stakeholder entities (Kaweah Delta Water Conservation Dist., 2006, pp. 50-51; 2008, p. 19).
Non-profit corporation	Local water and land management agencies may become voluntary members of a non-profit corporation, to which they pay dues. This form of group is not a new agency, but operates by consensus for the mutual benefit of its member agencies. The **Water Resources Association of San Benito County** is one such group. Its purposes include to "refine, select, and coordinate implementation of management actions" set out in the GWMP, deal with proposals for water banking and transfers, and communicate with the public (Jones & Stokes Assoc., 1998, p. 67; http://wrasbc.isoars.com/index.html).
Joint powers authority	A joint powers authority (JPA) is formed by two or more public agencies. Such an entity is a separate legal entity which can, for example, issue bonds, employ staff, and construct, operate and maintain facilities. JPAs themselves can prepare, adopt, and implement GWMPs. Examples of such entities, which have adopted and implemented GWMPs, are the **Soquel-Aptos Area Groundwater Management Committee**, the **Chowchilla Water District-Red Top Resource Conservation District** JPA, the **Sacramento Central Groundwater Authority**, and the **Tulare Lake Bed Groundwater Basin** JPA (Angiola Water Dist. et al., 1999, p. 1; Chowchilla Water Dist.-Red Top Resource Conservation Dist. Joint Powers Auth., 1997; Sacramento Cent. Groundwater Auth., 2009, p. 1; Soquel Creek Water Dist. & Cent. Water Dist., 2007, p. 1).

As a result of legislative amendments in 2002, Californian GWMPs are now required to include basin management objectives (BMOs) to identify issues and goals for the plan area. Regardless of the precise nature of groundwater management objectives (see section 5.4 for a discussion of their content), they should have specific criteria that make it possible to determine whether they are being achieved, and they should trigger management actions if they are not achieved (Table 2). Agencies may choose between the many management options available to them by running performance simulations and using decision criteria that are keyed to their BMOs. Agencies can also demonstrate their commitment to implementing a GWMP and increase their accountability by including a plan of prioritized actions with a timeline and reporting structure.

Table 2: Determining goals and assessing and reporting performance

Using measurable objectives	The objectives of the GWMP for **Central Sacramento County** include: • Maintaining the long-term average groundwater extraction rate at or below 273,000 af/yr, a level which was agreed to avoid undue risk "to private and public well owners by dewatering wells, degrading water quality, creating ground subsidence, and adding cost to pumping groundwater from lower elevations". The GWMP provides a full definition of "long-term average" and supporting material on the modeling process used to develop the limit (Sacramento County Water Agency, 2006, pp. 2-29, 3-22). • Maintaining groundwater elevations within all areas of the basin within

specific operating ranges. A five-square-mile grid is used to define and report on this objective (Sacramento County Water Agency, 2006, pp. 3-2 to 3-3).

The **Eastern San Joaquin Groundwater Basin** GWMP envisions setting "basin operations criteria", being "quantitative target groundwater levels and descriptive basin condition levels". The primary uses of these targets would be judging the effectiveness of groundwater recharge and controlling groundwater exports (N.E. San Joaquin County Groundwater Banking Auth., 2004, p. 147).

Using triggers for management action

Each objective of the **Central Sacramento** GWMP has four defined "trigger points", at which the basin governance body will consider taking specified actions, in response to conditions not meeting the objective. These actions include: investigating the cause of the condition, reducing pumping to comply with the objective, and imposing a monetary assessment against well owners who continue to pump at high levels in areas that do not comply with the objective (Sacramento County Water Agency, 2006, p. 4-3).

Similarly, the **Ojai Basin Groundwater Management Agency** plans to establish "action levels" for groundwater elevations and stream flow, at which it will take special action to protect groundwater supplies in the basin. These will be implemented, in part, through ordinances dealing with conservation measures (Ojai Basin Groundwater Mgmt. Agency, 2007, p. 9).

Analyzing management options with decision criteria and simulations

The **San Benito** GWMP applies explicit selection criteria to compare and select management options. Options are favored if they meet multiple objectives, do not adversely affect any objective, are cost-effective, equitable, maintain management flexibility, involve relatively little administrative effort, have few permitting requirements and raise few legal issues, and are likely to win public acceptance (Jones & Stokes Assoc., 1998, pp. 44-45).

Borrego Water District's GWMP transparently evaluates the costs of different combinations of strategies, where each combination would solve the 17,000 af annual overdraft experienced in the region (Borrego Water Dist., 2002, pp. 66-69).

The GWMP for the **Eastern San Joaquin Basin** describes a process of modeling groundwater elevations and groundwater salinity based on a no-action (status quo management) scenario, projected to 2030. The plan considers a wide range of management options related to groundwater quantity, including options relating to surface supply, groundwater recharge and demand reduction. For each option, it compares the cost per acre-foot of water, infrastructure requirements, land requirements, effectiveness, and operation and maintenance requirements (N.E. San Joaquin County Groundwater Banking Auth., 2004, pp. 72-74, 85). However, it does not fully explain the "effectiveness" criterion, nor how this was calculated for each option. Nor does it quantify or model the basin impacts that would result from implementing each option or combinations of options. As a result, the infrastructure-based projects described later in the plan seem disconnected

	from the groundwater management options initially presented. The **Sonoma Valley** GWMP assesses the benefit of different management options by modeling them under a range of different water availability scenarios, taking into account projected changes in demand. The results are presented as quantified changes in groundwater storage and levels to 2030 for each scenario. The plan anticipates, but does not quantify, changes in extraction costs, quality degradation, streamflow, and environmental conditions (Sonoma County Water Agency, 2007, pp. 2-38 to 2-41). Similarly, the GWMP for the **Consolidated Irrigation District** uses an integrated surface and groundwater model to simulate changes in groundwater levels and flow direction (GEI Consultants, 2009, pp. 37-44). The **Sacramento Groundwater Authority** considers how climate change might impact future hydrologic conditions, and how such impacts might affect conjunctive use operations (Sacramento Groundwater Auth., 2008, pp. 55, 65). The **Central Sacramento County** GWMP models different management options and measures impacts in terms of water quality degradation, dewatering of wells, higher pumping costs, and ground subsidence. *See Table 7: Methods of controlling groundwater extraction.*
Formulating an implementation plan	In its implementation plan, **Butte County** sets out an implementation schedule for a series of actions. They are categorized into five GWMP "components" which aim to achieve seven management objectives. The actions range from cooperating with other parties to undertake groundwater monitoring, to sponsoring annual stakeholder meetings, to administering ordinances that relate to the proper construction and permitting of wells, limits on well pump capacity, well spacing, and minimum domestic well depths (Butte County, 2005, pp. 3-1 to 3-22). The **Fox Canyon Groundwater Management Agency**'s GWMP presents an action plan that categorizes and ranks its strategies (most of which are physically carried out by other agencies) more broadly, in 5-year intervals (Fox Canyon Groundwater Mgmt. Agency, et al., 2007, pp. 82-85).
Reporting on implementation	The **San Benito County Water District** provides an electronic, publicly available annual report on groundwater resources. The report includes water management activities, water supply sources, groundwater levels and trends, water demand, revenues, expected future conditions, and recommendations for refining management (Todd Engineers, 2009). The **Santa Clara Valley Water District** produces an electronic, publicly available annual report on groundwater protection and augmentation activities. The report includes information on current and project water requirements, programs to sustain the reliability of water supplies, and financial information (Santa Clara Valley Water Dist., 2009). The District also provides a monthly report on groundwater levels

(http://www.valleywater.org/Services/GroundwaterMonitoring.aspx).

Butte County's GWMP plans the development of quantitative BMOs, supported by a county ordinance (now Ch. 33A, Butte County Code) (Butte County, 2005, pp. 3-13, 13-20). That ordinance requires representatives from each BMO sub-area annually to report groundwater levels, groundwater quality, and subsidence monitoring results to the County water department to be assessed against the BMOs. Under its GWMP, **Butte County** also commits to pursuing funding to develop a web-based BMO Information Center for monitoring and reporting information. The Information Center's interactive maps show monitoring wells for four adjacent counties. Each well can be selected to show current and historical groundwater elevation and quality data (sometimes stretching back decades), color-coded to show compliance or non-compliance with the county's BMOs. *See Figure 1: Basin Management Objective Information Center for Butte, Tehama, Glenn and Colusa Counties – screenshot of map interface and individual well information.* The Information Center also houses annual BMO documents for each BMO sub-area, which explain how BMOs were developed for that year, and include monitoring data (http://www.buttecounty.net/Water%20and%20Resource%20Conservation/BMO.aspx).

2. Cooperation and stakeholder participation

There are numerous barriers to local water agencies cooperating in groundwater management planning, including difficulties in building trust between local water management entities, and difficulties in matching benefits and funding burdens (GEI Consultants, 2009, p. 60). Further barriers prevent local water agencies from cooperating with other agencies, which undertake activities that can affect groundwater management, for example city land-use planning departments. Yet cooperation can save agencies time and money by reducing duplication in management efforts, taking advantage of economies of scale when contracting for similar goods and services, and avoiding inadvertently counterproductive management measures being taken by neighbors that are unaware of each other's actions. The examples given below show the wide range of groundwater management issues on which local water agencies can cooperate.

Table 3: Subjects of collaboration between water agencies in GWMPs

Collaborating to investigate GW resources	In 2001, a group of 15 local water districts in the San Joaquin Valley, including the **Poso Creek Regional Management** group of 7 districts, jointly prepared a report analyzing local groundwater resources to identify favorable areas for groundwater recharge and recovery (Kern-Tulare Water Dist. & Rag Gulch Water Dist., 2006, p. 17).
Collaborating on a strategic data collection plan	After the **Sacramento Groundwater Authority** identified significant inconsistencies between the data collection methods of its 14 member agencies, it initiated a Standard Operating Procedure (SOP) for collecting water level data, provided member agencies with DPH guidelines for the collection of water quality data, and offered training in the use of these standards (Sacramento Groundwater Auth., 2008, pp. 44, App.D). *NB: See also Table 6: Gathering and standardizing information on groundwater status and use.*
Coordinating to control groundwater-intensive development	An ordinance of the **Sierra Valley Groundwater Management District** (SVGMD) (Ordinance 83-01) puts in place arrangements commonly known as "assured water supply" rules. It requires any person who is seeking a land use approval from a local land use agency for a development that will use groundwater within the SVGMD's boundaries, to file documents regarding the water source with the SVGMD. The SVGMD makes a finding as to whether there is sufficient groundwater available, and only then may the local agency approve the development. *NB: In relation to groundwater intensive development, see also Table 8: Methods of managing groundwater demand.*

In addition to local agencies collaborating between themselves, a vast range of stakeholder groups has helped formulate GWMPs in California. Undeniably, broad stakeholder involvement takes time. Some GWMPs that cover large areas report up to 6 years of consensus-building and negotiation with tens of stakeholder groups (Sacramento County Water Agency, 2006, p. 1-4). However, broad stakeholder involvement brings multiple perspectives to help meet multiple objectives, and can help avoid conflicts that have derailed past groundwater management efforts, which were otherwise promising (Thomas, 2001, pp. 15-16, 19). Their involvement also helps to ensure that plans and programs are consistent across agencies, avoiding potential inter-governmental conflict, which can be particularly problematic in the groundwater sphere, when jurisdictional boundaries are blurred and may overlap (Thomas, 2001, pp.

24-25). Table 4 sets out examples of different structures for involving stakeholders in GWMPs.

Table 4: Structures for involving stakeholders in GWMPs

Structures for involving stakeholders	Stakeholders may be involved as part of a formal Stakeholder Group, or on formal committees such as a Technical Committee or Policy Committee formed to advise the GWMP agency, as is the case at the **Borrego Water District** (Borrego Water Dist., 2002, p. 17). Similarly, the **Glenn-Colusa Irrigation District**'s GWMP provides for establishing a Basin Management Committee consisting of stakeholder representatives, which is charged with creating a Technical Advisory Committee to set limits on withdrawals and mitigation measures. The Basin Management Committee considers changes to the GWMP, the rules and regulations required to implement it, and budget issues (Glenn-Colusa Irrigation Dist., 1995, p. 35}.
Involving a broad range of stakeholders	GWMPs have involved a wide range of stakeholders, including: • Other local water supply-oriented entities, including water districts, irrigation districts, city utility departments, water agencies, water conservation districts, public works districts, county water districts, private water companies, surface water masters, etc (Castaic Lake Water Agency, 2003, p. 4; Yuba County Water Agency, 2005, p. 29). • General agricultural and business interests, e.g. farm bureaus, and chambers of commerce (Sacramento County Water Agency, 2006, p. 3-10). • Local residents who pump groundwater, including agricultural users and domestic users, and representatives from water users associations (Butte County, 2005, pp. 3-17, 13-18; HydroMetrics LLC, 2007, p. 8). • Members of the public generally (HydroMetrics LLC, 2007, p. 8). • Local, regional, and state-level environment- and community-oriented entities, e.g. the Sierra Club, The Nature Conservancy, other local environmental non-profits, the League of Women Voters, recreation and parks districts, and community associations (City of San Diego Water Dep't, 2007, App.G; Sacramento County Water Agency, 2006, p. 3-10). • State participants, including staffers of members of the State Senate and Assembly, representatives of the Department of Water Resources, the Department of Fish and Game, Regional Water Quality Control Boards, and nearby State Parks (HydroMetrics LLC, 2007, p. 8; N.E. San Joaquin County Groundwater Banking Auth., 2004, p. 4) • Federal participants, including the Natural Resource Conservation Service, U.S. Geologic Survey, U.S. Army Corps of Engineers (N.E. San Joaquin County Groundwater Banking Auth., 2004, p. 27).

Collaborating widely with agencies and stakeholders with different interest areas can attract numerous benefits, but may also invite disputes. GWMPs can address this proactively by incorporating explicit procedures for resolving disputes locally. Such procedures exist at various levels of formality (Table 5).

Table 5: Avoiding and resolving disputes when formulating and implementing GWMPs

Reaching consensus and avoiding disputes	The planning efforts of the **Northeastern San Joaquin Groundwater Banking Authority** and the **Sacramento Groundwater Authority** (formerly Sacramento North Area Groundwater Management Authority) both benefited from using the California Center for Collaborative Policy as a neutral third-party facilitator. These entities consider that using professional facilitators in the context of complex stakeholder negotiations is a key factor contributing to the success of their efforts (N.E. San Joaquin County Groundwater Banking Auth., 2004, p. 102; Thomas, 2001, p. 48).
Resolving disputes	The **Olympic Valley** and **Soquel Area** GWMPs explicitly nominate a process and a forum for resolving disputes. The body charged with implementing the GWMP hears disputes, receives submissions, holds public hearings, and makes decisions by majority vote, guided by "what action would serve the best interest of the public" (HydroMetrics LLC, 2007, p. 95; Soquel Creek Water Dist. & Cent. Water Dist., 2007, p. 136). The **Kaweah Delta Water Conservation District** uses a formal dispute resolution policy to avoid litigation in relation to groundwater management by encouraging mediation (Kaweah Delta Water Conservation Dist., 2006, App.C). The GWMP for the **Turlock Groundwater Basin** uses meetings of the Turlock Groundwater Basin Association, an association of local water agencies, to resolve issues associated with groundwater management. Meetings are open to the public (Turlock Groundwater Basin Assoc., 2008, pp. 1, 67).

3. Collecting information about groundwater context

Formulating a GWMP often occurs in complex and uncertain hydrological and ecological contexts. Collecting information about the status of groundwater bodies and groundwater use; standardizing data collection; sharing data; and considering the ecological impacts of management options all arise as concerns for GWMPs.

Historically, Californian local water agencies have strongly resisted metering groundwater use. This sentiment is slowly changing. Many special districts and some general districts now apply mandatory or voluntary groundwater metering. There is great variation in the motivations and practice of metering. Some agencies use metering as part of a program of imposing groundwater augmentation charges on users; others simply to improve their knowledge of the groundwater resource. Agencies require metering at different levels of use, and with different arrangements for reporting use.

There is much greater acceptance of the need to monitor groundwater levels, as distinct from use. However, many problems can strike a monitoring system, potentially compromising its comprehensiveness, accuracy, and the length of its record. Such issues appear common around the State. It is worth listing a small selection of these problems, to demonstrate the challenges that GWMPs should be designed to withstand. Economic factors can intervene: budget cuts can result in data gaps and infrequent measurements; older wells with long measurement records can be abandoned when they require expensive maintenance; and production wells may be used without any dedicated monitoring wells, which can risk inaccurate data caused by a non-static water surface (Kings River Conservation Dist., 2005, p. 4-26; Turlock Groundwater Basin Assoc., 2008, p. 55; Yuba County Water Agency, 2005, p. 31). Data may be collected but not compiled into a useful format for many years (Yuba County Water Agency, 2005, p. 31). In some cases, the construction data associated with monitoring wells may be unknown, so that it is not clear which of several aquifers are being monitored (City of Tracy, 2007, p. 27). Sometimes monitoring systems are simply not evaluated for their sufficiency, particularly for assessing whether a GWMP is meeting its objectives, or to model the safe yield, or to model predicted responses to management actions selected for the GWMP.

There is also significant variation across the State in relation to monitoring groundwater quality, which is much less commonly monitored outside of municipal areas (see e.g., Carpinteria Valley Water Dist., 1996, p. 2; Kreinberg, 1994, p. 3-5). This makes it quite difficult to draw links between overdraft and changing water quality, although it is not uncommon for agencies to report such a connection (Indian Wells Valley Cooperative Groundwater Mgmt. Group, 2006, p. 2; Stanislaus & Tuolumne Rivers Groundwater Basin Assoc., 2005, p. 12; Turlock Groundwater Basin Assoc., 2008, p. 41). Using standard data collection and management methodologies or protocols to ensure that the data collected are accurate and consistent is as important as monitoring.

Final, as ecological concerns are becoming more prevalent in GWMPs, the plans should include strategies to collect information to determine how ecological conditions influenced by groundwater management are faring.

Table 6 sets out examples of how agencies gather and standardize data on groundwater and its context.

Table 6: Gathering and standardizing information on groundwater status and use

Monitoring the status of groundwater bodies	The **Sacramento Groundwater Authority** (SGA) and **Western Placer County** GWMPs aim to maintain a "consistent long-term network" of wells to monitor groundwater elevation, each measured at least semi-annually. The wells are selected "to provide uniform geographic coverage" throughout the respective areas, using a grid of polygons, each containing a monitoring well. Non-producing wells with long records of consistently collected data are favored for inclusion in the network (City of Roseville et al., 2007, p. 3-8; Sacramento County Water Agency, 2006, p. 3-11; Sacramento Groundwater Auth., 2008, pp. 38-39). **Butte County**'s Groundwater Conservation Ordinance requires a countywide groundwater monitoring program that involves monitoring groundwater elevations either continuously using water level sensors, or otherwise at least four times per year (Butte County, 2005, p. 3-3), whereas semi-annual readings are much more common throughout the State. **Yuba County** uses its monitoring network "both for the health of the *long-term basin storage* and for *localized-short-term* impacts of pumping", with the latter particularly aimed at the effects of external groundwater transfers (Yuba County Water Agency, 2005, p. 30).
Metering groundwater use	The **Pajaro Valley Water Management Agency** generally requires every groundwater pump that produces 10 af/yr or more to be metered. It reads each flow meter twice per

	year for the purposes of assessing groundwater augmentation charges (Pajaro Valley Water Mgmt. Agency, 1993; 1996). The **Fox Canyon Groundwater Management Agency** requires metering of all wells except those which serve domestic purposes on parcels of land of one acre or less. The owner is responsible for associated expenses and must report groundwater use twice annually. The Agency undertakes random checks of meter reports to ensure they are accurate (Fox Canyon Groundwater Mgmt. Agency, et al., 2007, p. 49). In certain zones of the **Salinas Valley**, the **Monterey County Water Resources Agency** requires wells used for agricultural, urban or industrial purposes to be metered if they have a diameter of three inches or more, with operators required to report their use annually (Monterey County Water Resources Agency, 2006, p. 4-2).
Standardizing data collection and management, and sharing data	The primary purpose of the GWMP for the **Gillibrand Groundwater Basin** is to "present a standard methodology for the collection of data" on groundwater levels, use and quality, which applies to the basin's two largest water users, being a county waterworks district and a private mining company. The methodology covers measurement instruments, the frequency of measurement, quality assurance procedures, data storage, and procedures for reporting data (Geoscience Support Services Inc., 2007). The GWMP demonstrates that private and public entities can work together to standardize data collection and management. The **San Benito** GWMP includes in its list of actions for meeting its objectives, a plan to develop jointly with "all local agencies involved in water-related data collection and management ... a strategic program for data collection and management", aimed at supporting groundwater management decision-making. It should "specify the types of data to be collected and the frequency of measurement; evaluate the accuracy of data collection procedures; outline the structure, format, and units to be used in computerized databases; and indicate procedures to ensure data consistency and transfer among agencies" (Jones & Stokes Assoc., 1998, p. 65). The **Sacramento Groundwater Authority** is also developing a standard Water Accounting Framework for its member agencies. *See Table 10: Methods of protecting and enhancing recharge and examples of* water banking.
Collecting data relevant to the health of groundwater dependent ecosystems	The **Lassen County** GWMP "supports efforts to map and compile information on riparian habitats and phreatophyte vegetation" (Brown & Caldwell, 2007b, p. 3-7). Whereas much groundwater use for consumptive purposes in California depends on deep aquifers, ecosystems associated with wetlands may be connected to shallow aquifers. In such situations, monitoring the state of shallow aquifers is important to assessing ecological impacts. The **Squaw Valley Public Service District**'s GWMP includes monitoring shallow groundwater levels in the Olympic Valley meadow, which are connected to wetlands that have high ecological and aesthetic value (HydroMetrics LLC, 2007, p. 64).

4. A portfolio approach to groundwater management planning

A portfolio approach to groundwater management planning responds to information collected (including information from stakeholders) about the values of a resource, with goals that champion those values and multiple strategies for pursuing those goals. Goals include securing water supplies for consumptive purposes, maintaining or restoring ecosystems, protecting connected surface waters, and ensuring that groundwater use minimizes third-party impacts on society. This section sets out examples of agencies that adopt and pursue each of these goals, and the strategies they use to do so.

4.1 Securing groundwater supply for the long term

Securing groundwater supplies for consumptive purposes is the overriding focus of many GWMPs. The innovative strategies presented here emphasize an extensive range of options, beyond simply building more—or bigger—infrastructure solutions. They include limiting waste or drawdown in different ways, managing water demand using fees and education, using different water sources conjunctively, protecting and enhancing recharge, and water banking.

Table 7 outlines various mandatory measures to limit pumping, either directly, or by controlling developments that use groundwater intensively.

Table 7: Methods of controlling groundwater extraction: limiting waste, groundwater drawdown, or pumping

Defining sustainable yield and an acceptable operating range	The **Central Sacramento County** GWMP uses a "long-term average annual pumping limit" of 273,000 af/yr which stakeholders accepted as a negotiated limit "under which groundwater can be pumped and not exceed average natural recharge over a long-term period of time". Negotiators developed this limit by using groundwater models to quantify basin conditions in terms of four key areas of impact: • water quality degradation; • dewatering of wells; • higher pumping costs; and • ground subsidence, in 10-year increments from 1990 to 2030, comparing the impacts of different pumping levels to baseline pumping levels. The chosen sustainable yield level was found to maximize the yield of the aquifer while minimizing the four key impacts. In addition, the GWMP sets out an "operating range" of groundwater levels that will minimize these impacts for different areas of the basin (Sacramento County Water Agency, 2006, pp. 2-29, 3-23, App.A). However, the projections included in the GWMP do not include uncertainties, and it appears that historical hydrological data was used rather than data which attempts to factor in potential climate change impacts.
Taking action in response to non-compliance with BMOs	**Glenn County**'s GWMP, which itself is an ordinance, sets out a process for taking action in the event that its basin management objective for groundwater levels is breached. Its Technical Advisory Committee reports the details of the non-compliance to its Water Advisory Committee and the public, and recommends a course of action within five days. Negotiation with parties in the area is the preferred way to resolve the non-compliance, but should that fail, "the Water Advisory Committee may recommend a plan to the Board to modify, reduce or terminate groundwater extraction in the

	affected area for the remainder of that irrigation season", first in relation to wells involved in exports, then in relation to all other wells (Glenn County, 2000, [20.03.120], [120.103.130]).
Controlling pumping by using area limits	The **Western Canal Water District** GWMP envisions its Board of Directors annually re-evaluating its basin management objectives, including by considering whether to establish "quantitative limitations on groundwater extractions from particular areas . . . to limit adverse impacts of groundwater extractions on wells within and without the District" (Western Canal Water Dist., 2005, [3.2.3]). The District has adopted rules and regulations to implement and enforce its GWMP (Western Canal Water Dist., 2006); this would presumably be the vehicle for implementing pumping limits.
Controlling pumping by using individual extraction permits	The Groundwater Extraction Permit Ordinance of the **Mendocino City Community Services District** (MCCSD) requires any person who seeks "to extract groundwater for a new development, change in use, expansion of existing use, or to construct or modify a well" to obtain a permit. A permit allows the holder to extract only the quantity of water which is deemed necessary under "water use standards" that form part of the Ordinance. New wells are metered, and the District retains the right to enter the permit holder's premises to collect meter information. Violating the ordinance attracts penalties, including rescission of an extraction permit (Mendocino City Community Services Dist., 1990 (as amended, 2007), p. 21, 2007).
Controlling pumping by prohibiting new wells	**MCCSD**'s GWMP envisions prohibiting any new wells in times of serious water shortage, in addition to other mandatory measures (Mendocino City Community Services Dist., 1990 (as amended, 2007), p. 108). Under **Sutter Extension Water District**'s GWMP, after 1995, landowners who wish to construct new wells "may be required" to request the approval of the District's Board of Directors, which may approve the request with conditions (Sutter Extension Water Dist., 1995, p. 8).
Controlling water waste	The **Pajaro Valley Water Management Agency** has adopted an ordinance prohibiting water waste (Ordinance 92-1). The Ordinance defines water waste and prohibits listed wasteful practices within the boundaries of the Agency. It prohibits wasteful practices in agriculture as well as urban settings, although the former are specified in vague terms (e.g. "unreasonable evaporation loss" and "unreasonable deep percolation loss"). The Ordinance sets out a system of warnings followed by enforcement proceedings heard before a panel, and a penalty structure for first and repeated violations.
Adjudicating groundwater basins	Only one GWMP reviewed for this report—that of the **Borrego Water District**—lists adjudicating the groundwater basin as a management tool, albeit the lowest priority option (Borrego Water Dist., 2002, p. 74).
Limiting the expansion of water-intensive uses	Spurred by the recommendations of a local planning advisory group, **Borrego Water District**'s GWMP includes the following potential strategies to limit the development of water-intensive land uses (Borrego Water Dist., 2002, pp. 57-59): • prohibiting the as-of-right conversion of unused land to agriculture (agriculture would only be allowed to be developed under a permit to be issued after a public

	hearing and environmental review); • designating all unused land as "Desert Estate", which would allow 10 or 20 acre lot subdivisions, but would limit the use of non-native plants to a small portion of the lot; and • requiring future developments that seek a domestic water service from the Borrego Water District to sign over their rights to extract groundwater to the District (a strategy for which there is a precedent in the Borrego Valley).
Rotating/ fallowing cropland	The **Eastern San Joaquin Basin** GWMP very cautiously mentions "voluntary crop rotation", which would compensate farmers for removing cropland from production, as a groundwater management tool (N.E. San Joaquin County Groundwater Banking Auth., 2004, p. 87). The **Borrego Water District** more proactively includes in its GWMP a goal of obtaining funding to acquire agricultural land from willing sellers, and contemplates "paying farmers to not farm". The GWMP suggests that such a program could be funded by a water use fee, and sets out sample costs (Borrego Water Dist., 2002, pp. 60-64, 71-73).

GWMPs commonly include general statements about "raising public awareness" of overdraft and groundwater management or implementing "education measures" about conservation. However, relatively few refer to concrete actions to manage water demand; even fewer are specific to groundwater, or relate to non-municipal contexts. Moreover, no surveyed plan quantifies the effectiveness of such voluntary demand management programs. It is therefore difficult to describe best practice in this area.

Some examples of education measures contemplated by GWMPs include: water utilities participating in local fairs, inserts in water bills detailing water conservation tips, public signs, demonstration gardens for low water use, fact-sheets, water use audits and surveys, school education, rebates on water efficient appliances, water education classes and presentations (Borrego Water Dist., 2002, p. 73; City of San Diego Water Dep't, 2007, App.G-6; HydroMetrics LLC, 2007, p. 86; Mendocino City Community Services Dist., 1990 (as amended, 2007), pp. 111-112; Neuman, 1998; Orange County Water Dist., 2009, p. 1-9; Soquel Creek Water Dist. & Cent. Water Dist., 2007, pp. 59, 113-117, 125-127).

In the agricultural conservation sphere, programs include supporting organizations that carry out field irrigation evaluations and farm water conservation assistance and farm water tours (Kaweah Delta Water Conservation Dist., 2006, p. 16; North Kern Water Storage Dist. & Rosedale Range Improvement Dist., 1993, p. 10; Reclamation Dist. 2068, 2005, p. 3-9). More detailed examples of agricultural water demand reduction programs have been compiled outside of GWMPs (Agricultural Water Mgmt. Council, 2008).

Reducing water demand may, unfortunately, jeopardize the ability of agencies to carry out resource-intensive groundwater management programs by reducing revenue (Orange County Water Dist., 2009, p. 6-14). Ensuring that groundwater management programs are financially sustainable is vital (see section 4.4 of this report).

Fees can be used both to reduce demand and also to sustain other groundwater management actions. Table 8 sets out methods of reducing demand using fees.

Table 8: Methods of managing groundwater demand

Using fees to manage demands on aquifers	Under **Orange County Water District**'s much-celebrated pump-and-pay system, retail groundwater pumpers pay fees (a "replenishment assessment") to OCWD based on their metered usage. Additional fees (a "basin equity assessment") apply above a pre-determined allowable pumping amount, expressed as a ratio of the customer's groundwater pumping to its total water usage (the "basin production percentage", BPP). These fees are used to purchase imported water to replenish groundwater, administer water monitoring, and maintain the replenishment systems. The fees are structured so as to create a disincentive to use groundwater above the BPP (Orange County Water Dist., 2009, pp. 1-5, 5-28, 26-13). Similarly, the **Fox Canyon Groundwater Management Agency** imposes penalties on pumpers who extract more water than is allowed under the Agency's detailed allocation system. Its GWMP proposes using these penalties to purchase water to replace the extracted water (Fox Canyon Groundwater Mgmt. Agency, et al., 2007, p. 80). The **Soquel Creek Water District** uses tiered pricing (also described as increasing block water pricing) in the context of groundwater distribution systems for residential, commercial and agricultural purposes (Soquel Creek Water Dist. & Cent. Water Dist., 2007, p. 59).

Beyond manipulating demand by mandatory, voluntary or fee-based means, agencies may effectively increase their water supplies by using water from different sources in a conjunctive way (Table 9). This can involve introducing altogether new sources of water with different characteristic reliability profiles. For example, desalinated water and recycled water from municipal sources provide a supply that is largely unaffected by climatic conditions. Managing pumping distribution can "smooth" pumping pressure and ensure more uniform drawdown, avoiding deep cones of depression. This technique is also used to help avoid harming groundwater quality, and the flows and quality of connected surface waters.

Table 9: Methods of using different water sources conjunctively

Encourage greater surface water use	Agencies in the **Modesto Sub-Basin** and the **Chowchilla Groundwater Basin** regard annexation as a potential groundwater management tool, through in-lieu recharge—annexation enables areas reliant solely on groundwater to access surface water, thereby reducing pumping pressure (Chowchilla Water Dist.-Red Top Resource Conservation Dist. Joint Powers Auth., 1997, p. 13; Stanislaus & Tuolumne Rivers Groundwater Basin Assoc., 2005, pp. 28-29, 96). The **Soquel Creek Water District** uses incentives to encourage private well owners to cease using well water and connect to water distribution systems (Soquel Creek Water Dist. & Cent. Water Dist., 2007, p. 107).
Managing surface water-groundwater substitutions	The **Western Canal Water District** envisions transferring surface water out of the district, to be replaced by increased groundwater pumping. In such cases, monitoring and metering rules apply to ensure that: (1) the action does not create or exacerbate overdraft; (2) the additional volume pumped does not exceed the volume of surface water transferred; and (3) to mitigate any adverse effects of lower groundwater levels

	on farmers, e.g. by compensating them for additional energy costs (Western Canal Water Dist., 2005, p. 19, 2006, section VI).
Using desalinated seawater or brackish groundwater	Several agencies commit to investigating and pursuing desalinating brackish groundwater as an additional source of supply (City of San Diego Water Dep't, 2007, pp. 1-5, 3-49, 43-50; Monterey County Water Resources Agency, 2006, p. 2-1). **Alameda County Water District**'s Newark Desalination Facility (part of its Aquifer Reclamation Program) has desalinated brackish groundwater caused by past seawater intrusion, since 2003. The Program aims to meet multiple objectives: "1) increase useable basin storage, 2) improve overall water quality, 3) prevent movement of brackish water toward ACWD production wells, and 4) provide (future) supply augmentation" (Alameda County Water Dist., 2010, p. 6; 2001, pp. 4, A1-7, A1-8). Agencies in the **Fox Canyon Groundwater Management Agency**'s area have also seriously considered desalinating brackish groundwater to move pumping away from areas of lowering groundwater levels, increase supply, deal with water quality degradation, and potentially also restore coastal wetlands (Fox Canyon Groundwater Mgmt. Agency, et al., 2007, pp. 54-58). The **Soquel Creek Water District** intends to partner with the **City of Santa Cruz** to construct and operate a seawater desalination plant as a way to reduce pumping demands during dry years and reduce the potential for seawater intrusion (City of Santa Cruz & Soquel Creek Water Dist., 2010; Soquel Creek Water Dist. & Cent. Water Dist., 2007, p. 62).
Managing pumping distribution	**Orange County Water District**'s Temporary Coastal Pumping Transfer Program shifted pumping pressure from the coast to inland areas to minimize seawater intrusion (Orange County Water Dist., 2009, pp. 6-16). Similarly, modeling a shift in pumping pressure in the **Pajaro Valley** was found to "nearly double the basin sustainable yield" by preventing seawater intrusion (Pajaro Valley Water Mgmt. Agency, 2002, p. 3-4). In the inland area of **Indian Wells Valley**, managing the spatial distribution of new wells to minimize adverse effects on groundwater *quality* is a GWMP objective (Indian Wells Valley Cooperative Groundwater Mgmt. Group, 2006, p. 3). Similarly, the GWMP for the **Modesto Sub-Basin** contemplates optimizing well operations to achieve multiple different objectives, including "minimizing pumping costs, maintaining groundwater levels within a specified range . . . avoiding the migration of contaminant plumes", and improving downstream water quality by reducing high groundwater levels in areas of poor groundwater quality (Stanislaus & Tuolumne Rivers Groundwater Basin Assoc., 2005, p. 123). County well permitting requirements that apply within the **Fox Canyon Groundwater Management Agency**'s area shift pumping from a lower aquifer system to an upper aquifer system, to reduce the potential for overdraft and seawater intrusion in the lower system and ensure conjunctive use of both groundwater sources. Another tool considered in the area is shifting pumping to areas which are comparatively easy to recharge (Fox Canyon Groundwater Mgmt. Agency, et al., 2007, pp. 47, 76).

In addition to limiting extraction from a basin, agencies' GWMPs also plan to maximize "deposits" to a basin, by either protecting or enhancing natural recharge, or "banking" water for themselves or third parties, using recharge basins or injection wells (Table 10).

California's groundwater laws—or rather, legal uncertainties—challenge the development of groundwater banking. Legal uncertainties surround who is liable for displacing natural recharge; how to control the actions of third parties who are not party to management agreements, where their actions affect the quality or quantity of stored water; and liability for changes in water quality, to name a few (Foley-Gannon, 2008). One GWMP refers to "the monumental task of overcoming the institutional, political, financial and physical challenges of groundwater banking" (N.E. San Joaquin County Groundwater Banking Auth., 2004, p. 20).

Table 10: Methods of protecting and enhancing recharge and examples of water banking

Protecting existing recharge areas	As an initial step, the **Sonoma Valley** GWMP calls for "studies to identify groundwater recharge areas, to develop approaches to enhance groundwater recharge, and to identify ways to protect recharge areas from being covered by low permeability surfaces" (Sonoma County Water Agency, 2007, p. 3-3). The GWMP for the **Modesto Sub-Basin** takes a slightly more developed approach. It directs its implementing agencies to "[i]dentify areas having high potential for contributing to aquifer recharge and encourage agencies to communicate with land use planning entities to enact measures that will protect these lands from development that would reduce their value as recharge sites". It also includes, as a potential groundwater management tool, "pricing and incentive programs to encourage the continued use of surface water for flood irrigation" in areas with significant recharge potential (Stanislaus & Tuolumne Rivers Groundwater Basin Assoc., 2005, pp. 108, 120). The GWMP of the **Fox Canyon Groundwater Management Agency** considers a strategy of requiring "Low Impact Development" to maximize the infiltration of stormwater in new developments that overlie recharge areas, but does not outline how this might be achieved (Fox Canyon Groundwater Mgmt. Agency, et al., 2007, p. 69). The GWMP for the **Soquel-Aptos area** outlines an objective of participating in land use planning processes and supporting Santa Cruz County to protect and enhance groundwater recharge zones. Specific actions include supporting the County to update its groundwater recharge maps, supporting USGS in its work characterizing recharge areas, and pursuing a formal system for allowing water agencies to review development proposals that could affect primary recharge zones (Soquel Creek Water Dist. & Cent. Water Dist., 2007, pp. 75, 99, 100).
Enhancing recharge	The GWMP for the **Soquel-Aptos area** documents cooperation between Santa Cruz County, the GWMP agencies, and other neighboring water and resource agencies to introduce a recharge enhancement element to projects designed to control erosion and reduce stormwater runoff. The GWMP agencies pledge to "support County efforts to develop a program that will include standards regulating impervious surfaces . . . and provide for water impoundments, protecting and planting

	vegetation, and installing cisterns, dry wells, bioswales and other measures to increase runoff retention and groundwater recharge". They also commit to incorporating such design features in their own construction projects (Soquel Creek Water Dist. & Cent. Water Dist., 2007, pp. 102-103).
Replenish GW for later use	The **Santa Clara Valley Water District** manages extensive recharge facilities, including 90 miles of stream channel and spreader dams, 71 off-stream recharge ponds, and an injection well. Its recharge water sources are imported water and local surface water. The aim of the program is to "sustain groundwater supplies through the effective operation and maintenance of District recharge facilities" (Santa Clara Valley Water Dist., 2001, pp. 16-18). The District releases an annual report on its groundwater augmentation activities, the most recent of which states that 65% of groundwater pumped in the County originates from artificially replenished water (Santa Clara Valley Water Dist., 2010, p. i). The **Kings River Conservation District** GWMP includes the North Fork Group Program as an economical recharge strategy. It involves flooding seasonally fallowed agricultural areas and keeping canals full to increase percolation. It proposes to continue this Program and develop better ways of monitoring and measuring recharge (Kings River Conservation Dist., 2005, pp. 4-10, 14-11, 14-14, 16-14, 16-15).
Water banking for third parties	The **Arvin Edison Water Storage District** is party to a 25-year agreement with the **Metropolitan Water District of Southern California** (MWD), which began in 1997, to bank 250,000 ac-ft of MWD's water below Arvin-Edison. Water is delivered to Arvin-Edison using the Cross Valley Canal, and is returned (since 2003) during drought years, using the California Aqueduct. The program funded $25 million of capital works and reimburses Arvin-Edison for pass-through water banking costs (Arvin-Edison Water Storage Dist., 2003, p. 6). Arvin-Edison's Rules and Regulations specify that where it spreads water, or delivers surface water to landowners in lieu of them pumping, it has the exclusive right to use the groundwater storage to recover the water to supply district landowners or third parties (Arvin-Edison Water Storage Dist., 2006, cl.9). The **Sacramento Groundwater Authority**, which manages the North Area Groundwater Basin in cooperation with its 14 member agencies, is developing a centralized Water Accounting Framework (WAF) to support groundwater banking programs by "setting forth rules for operating a model groundwater bank, and monitoring the basin to ensure its sustainability". The SGA will maintain modeling and management tools needed to assess conjunctive use operations and maintain accounting systems for "deposits" and "withdrawals" (Sacramento Groundwater Auth., 2008, pp. 54-55). The GWMP of the **Northeastern San Joaquin County Groundwater Banking Authority**, which has eleven member agencies, adopts third party water banking and conjunctive use partnerships as a key element of the plan. This involves many individual sites, some then operating and some to be developed, numerous different surface supply sources, and all forms of recharge methods (direct injection, percolation, and in-lieu) (N.E. San Joaquin County Groundwater Banking Auth., 2004). The Authority recently released its Eastern San Joaquin Integrated

	Conjunctive Use Program Draft Environmental Impact Report (http://www.gbawater.org/news_events/public_notices.html).

4.2 Protecting connected surface waters

Californian law generally treats groundwater and surface water separately, though there are some exceptions to this (Hanak, et al., 2010, pp. 54-57). Some local agencies explicitly seek to ensure that groundwater pumping does not cause adverse impacts on surface waters, and implement corresponding measures (Table 11). These measures include studying the interaction between water bodies and reducing the effects of groundwater extraction on surface water.

Table 11: Methods of protecting connected surface waters

Explicitly recognize a goal relating to surface water impacts of groundwater pumping, or vice versa	The **Sonoma Valley GWMP** includes as a Basin Management Objective (**BMO**) to "protect against adverse interactions between groundwater and surface water" in relation to Sonoma Creek, which provides habitat for fish and other wildlife and is a source of supply for agriculture, businesses and residences (Sonoma County Water Agency, 2007, pp. 3-4). The **Olympic Valley GWMP** includes BMOs to "[p]romote viable and healthy riparian and aquatic habitats by avoiding or minimizing future impacts from pumping on stream flows" and to "[s]upport ongoing stream restoration efforts as they relate to groundwater management" (HydroMetrics LLC, 2007, p. 70). The **Western Canal Water District GWMP** aims both to "[m]inimize changes to surface water flows and quality that directly affect groundwater levels or quality" and also to "[m]imimize the effect of groundwater pumping on surface water flows and quality" (Western Canal Water Dist., 2005, [1.2]), although the GWMP does not appear to include any measures directly specifically to these aims.
Study surface water-groundwater interaction	A component of the **Soquel-Aptos area GWMP** is to use stream gauges and shallow groundwater monitoring wells adjacent to and in Soquel Creek to investigate surface water-groundwater interactions (Soquel Creek Water Dist. & Cent. Water Dist., 2007, pp. 77, 83). The **Olympic Valley GWMP** includes as management measures participating in stream/aquifer interaction studies, and annually analyzing baseflow trends, shallow groundwater level trends, and "changes in apparent stream-aquifer interaction" (HydroMetrics LLC, 2007, p. 71). The **Central Sacramento County GWMP** provides for updating and using an integrated groundwater and surface water model (Sacramento County Water Agency, 2006, p. 3-22).
Include measures to reduce pumping impacts on surface waters	The **Soquel-Aptos area GWMP** documents a policy of the Soquel Creek Water Management District to use incentives (such as reduced connection fees) to encourage groundwater users with wells located near Soquel Creek to connect to the District's distribution system. The GWMP includes modifying pumping distribution based on annual analyses of data collected under the District's groundwater and

	surface water data program, if, for example, it discloses evidence of baseflow depletion (Soquel Creek Water Dist. & Cent. Water Dist., 2007, pp. 107-108). The **Olympic Valley GWMP** envisions carrying out its BMOs related to surface water interaction by redistributing pumping to reduce surface water impacts and reducing pumping through conservation (HydroMetrics LLC, 2007, pp. 70-71). It does not explicitly address the potential reduction in runoff from conservation, and any consequences for streamflow.

4.3 Restoring ecosystems and minimizing ecological impacts

Many of the measures described above in relation to securing a long-term groundwater supply and protecting surface waters from the adverse impacts of groundwater pumping also help to protect ecosystems from adverse impacts. For example, conservation measures can reduce total groundwater extraction, limiting groundwater drawdown and therefore helping to maintain connections with wetlands. Conversely, some ecological projects can benefit groundwater storage, for example, stream restoration can result in greater recharge, increasing shallow groundwater levels and thereby increasing shallow groundwater storage (HydroMetrics LLC, 2007, p. 64).

Table 12 presents examples of agencies consciously aiming for and acting on ecological goals in groundwater management planning.

Table 12: Methods of restoring ecosystems and minimizing ecological impacts

Explicitly recognize ecological goals	The **Squaw Valley Public Service District's GWMP** includes as one of three overarching goals, to "protect, promote, and improve the environmental quality of Olympic Valley" (HydroMetrics LLC, 2007, p. 62). The Basin Management Objectives which underlie this goal include to: • "promote viable and healthy riparian and aquatic habitats by avoiding or minimizing future impacts from pumping on stream flows", • "minimize future impacts from pumping on identified wetlands", and • "support ongoing stream restoration efforts as they relate to groundwater management" (HydroMetrics LLC, 2007, pp. 63-64). The **Lassen County GWMP** includes as an objective to "maintain springs, seeps and riparian habitat" (Brown & Caldwell, 2007b, pp. 1-2).
Recognize and quantify environmental water demands	The **Alpine County GWMP** includes, by way of characterizing the aquifer and its context, environmental water demands, which "would include State and Federal wildlife refuges, and publicly or privately managed wetland habitat". However, for reasons that are unclear, these demands are allocated zero acre-feet of water (Brown & Caldwell, 2007a, p. 37). Similarly, the **Central Sacramento County Water Authority GWMP** recognizes "environmental water" as a source of demand, but simply notes that the demand has not been defined for various streams, and does not allocate responsibility for defining

	these demands or attempt to estimate them (Sacramento County Water Agency, 2006, p. 2-47). The **Soquel-Aptos area GWMP** seeks to "avoid alteration of stream flows that would adversely impact the survival of populations of aquatic and riparian organisms". This is defined as maintaining baseflow depletion (caused by pumping aquifers adjacent to identified streams) below current detection levels in order to avoid "significant adverse biological effect" (Soquel Creek Water Dist. & Cent. Water Dist., 2007, p. 76).
Mitigate effects of overdrafted areas on stream flows	The East Sacramento County Replacement Water Supply Project, described in the **Central Sacramento County Water Authority GWMP**, provides for releasing environmental water to the ecologically significant Cosumnes River. Although the Cosumnes River historically flowed year-round, it now has completely dry stretches during summer (primarily due to groundwater pumping), when flows are lost to the aquifer. The Project pre-wets the riverbed so that a smaller volume of late fall and summer flows is lost from the river to the underlying overdrafted aquifer, with adverse effects on riparian habitat (Sacramento County Water Agency, 2006, pp. 2-7, 2-44, 3-18).
Locate & design recharge basins to enhance wildlife habitat	The **Kings River Conservation District's GWMP** describes the 6000-acre Gragnani constructed wetland project, which was designed for habitat purposes. It has the secondary benefit of providing "in lieu recharge" by offering an alternative water supply to former groundwater users. The project was developed by the USDA Natural Resources Conservation Service purchasing conservation easements and recharging the wetlands using flood waters (Kings River Conservation Dist., 2005, pp. 4-2, 4-3). The Farmington groundwater recharge project described in the **Eastern San Joaquin GWMP** uses land leased from farmers at market rates, primarily to reduce saline intrusion and overdraft, and secondarily to provide seasonal habitat for migratory waterfowl. The American Society of Civil Engineers awarded it the Water/Environment Project of the Year in 2003 (N.E. San Joaquin County Groundwater Banking Auth., 2004, pp. 30, 133-137; http://www.farmingtonprogram.org/).
Remove non-native invasive species	The **San Diego City** water department supports programs that map and remove giant reed, tamarisk, and perennial pepperweed, which are local non-native invasive species that impact groundwater quantity, although the GWMP does not quantify what impact this has on water supplies (City of San Diego Water Dep't, 2007, p. 2-44).

4.4 Considering economic and financial sustainability

Economic factors are often the elephant in the groundwater management room. While many GWMPs cite the economically "unfeasible" nature of reducing groundwater usage through methods such as voluntary crop fallowing, no GWMP reviewed for this report quantified such impacts, nor estimated the impacts of *not* controlling groundwater use. Encouragingly, some GWMPs at least recognize the gravity of the latter.

Some agencies also seek to put in place measures to compensate well owners for the adverse economic impacts of decreasing groundwater levels.

Ironically, water shortages, including shortages caused by overdraft, threaten not just water users, but also the financial ability of agencies to undertake groundwater management actions to alleviate shortages. The costs of managing groundwater are likely to increase markedly during droughts, with additional enforcement and public outreach, for example, while the revenue of an agency may decrease as water usage drops. Finding a mechanism for sustainably funding groundwater management, under which customer water usage is decoupled from agency revenue is therefore vitally important (Mendocino City Community Services Dist., 1990 (as amended, 2007), p. 112).

Table 13 presents examples of agencies considering economic and financial sustainability in groundwater management planning.

Table 13: Methods of considering economic and financial sustainability

Considering the economic costs of not controlling groundwater use	The GWMP for the **Merced Groundwater Basin** acknowledges that long-term groundwater level declines due to pumping can increase the cost of pumping water and "restrict economic development" (AMEC Geomatrix Inc, 2008, p. 6). The **Eastern San Joaquin Groundwater Basin** GWMP recognizes that failing to address water management needs will lead to adverse impacts that will result in "business flight, job loss, loss of revenue for public services and general economic decline" (N.E. San Joaquin County Groundwater Banking Auth., 2004, p. 20). However, neither plan attempts to quantify these effects, or assess the long-term economic costs of overdraft against the short-term economic benefits of pumping.
Mitigating the economic costs of overdraft	The **Central Sacramento County** GWMP includes establishing a Central Basin Well Protection Program, including a "well protection trust fund". The fund will compensate owners of wells that have failed due to declining groundwater levels for the cost of deepening or replacing wells. The fund will be financed by fees collected as part of building permits for new construction, or well drilling permits. Only well owners who register their wells are eligible for compensation, so that the system also improves information about groundwater use. The fund came about because the sustainable yield negotiated for the GWMP was expected to result in further declines in groundwater levels, before they stabilized, and "current groundwater users should not have to subsidize future growth in the basin by paying the cost of deepening or replacing existing wells" (Sacramento County Water Agency, 2006, pp. 4-7 to 4-9). The recent economic downturn has resulted in the implementation of the fund being delayed (Sacramento Cent. Groundwater Auth., 2009, p. 22).
Ensuring sustainable funding for groundwater management	The **Mendocino City Community Services District** ensures that its groundwater management activities are sustainable even during droughts, when revenue may drop, by using a surcharge on wastewater and sewer usage fees to fund groundwater management (Mendocino City Community Services Dist., 1990 (as amended, 2007), p. 112).

PART SIX: CONCLUSION AND NEXT STEPS

The stage for California's groundwater management planning is a complicated and crowded one, filled with numerous actors of different types, who face difficult and sometimes critical groundwater depletion problems. Various institutional barriers often prevent these actors from talking to each other and sharing their stories of groundwater management successes and challenges. Since California's groundwater management planning laws do not involve State oversight, information about GWMPs is difficult to collect, and the state of Californian groundwater management has remained in shadow.

First and foremost, this report has shone a spotlight on some of these actors, and demonstrated that elements of their groundwater management planning efforts present promising and innovative approaches to local groundwater management. While their innovations are not necessarily common, they chart a path to better groundwater management that is practical and doable in a wide variety of different agency circumstances. It is hoped that local agencies around California will consider the approaches described here in formulating their own groundwater management actions, recognizing that management innovation is not necessarily precluded by scarce resources, or any particular statutory form.

Having used GWMPs to identify agencies whose water *planning* efforts stand out as exceptional in California, the next step is to determine whether these efforts are resulting in successful *implementation*, on the ground. Further research should ask of agencies questions like:

- Do you actively use your groundwater management plan—is it a "living" document, or a reference for occasional use?
- Which elements of your plan have been implemented?
- Did the process of formulating and implementing the plan lead to changes in how you manage groundwater?
- What are your success stories in formulating and implementing the plan?
- What constraints have you encountered in formulating and implementing the plan?

At a higher level, this report has contrasted California's groundwater management planning laws with those for urban water management plans, and suggested that water planning law has moved far beyond the current requirements and policy in relation to GWMPs. The many examples of innovative groundwater management planning by California agencies also confirm that the aspirations of GWMP law and policy are out of date.

Questions of State regulation of groundwater aside, there is a need to reform California's GWMP laws and policies to include demand management, and require greater analysis of the planning context, greater accountability through stakeholder participation, and the pursuit of multiple goals. Strengthening California's legislation for groundwater management planning provides a path towards better groundwater management, retaining the State's historical focus on local agencies driving local change. Reform that strengthen and update this legislation would build on a familiar base, and, judging from the significant number of plans in California, one with which many local agencies are comfortable. Law and policy should follow California's innovative local groundwater management agencies, and lead its groundwater agencies as a whole, down the path that this report suggests is both desirable, and also possible.

Sacramento, CA 95814

Re: Comments on BDCP First Amendment to the Memorandum of Agreement Regarding Collaboration on the Planning, Preliminary Design And Environmental Compliance for the Delta Habitat Conservation and Conveyance Program in Connection with the Development of the Bay Delta Conservation Plan.

Comments Regarding Improved Transparency and Stakeholder Involvement in the BDCP Process.

Dear Director Glaser:

This office represents the Save the California Delta Alliance ("STCDA"). STCDA is a membership organization headquartered in Discovery Bay, California, and comprised of individuals and organizations interested in preserving and restoring the California Delta. Among others, STCDA represents the interests of recreational boaters who use the California Delta, individual homeowners who own waterfront property in the Delta and obtain their drinking water from the Delta, and businesses that earn their living from Delta-oriented activities, including recreational activities centered on the waters of the Delta. STCDA's primary mission is to improve habitat, support the recovery of listed species, improve water quality, and enhance recreational opportunities in the Delta.

STCDA represents an active and enthusiastic constituency and regularly turns out three to four hundred people at our town hall style meetings held in Discovery Bay.

STCDA would like to thank the United States Bureau of Reclamation ("Reclamation") for the opportunity to comment on the First Amendment to the Memorandum of Understanding ("Amendment") and for the opportunity to comment on ways to improve stakeholder participation in the BDCP process. We believe the invitation to comment is a much needed step in the right direction for a process that has gotten off track.

STCDA is particularly concerned with the dramatic change in the role and status of State Water Project Contractors ("SWP Contractors") and Central Valley Project Contractors ("CVP Contractors"), (collectively "Water Contractors") reflected in the Amendment. Below, we discuss the Water Contractor problem in the context of what we believe are systemic problems with the BDCP process that are manifested in the current Water Contractor controversy.

I. The Process Got Off On The Wrong Foot By Inaccurately Stating What The Major Federal Action Under Contemplation Actually Is.

We believe that one important problem with the BDCP process thus far is the failure to accurately describe and categorize the actions that are being taken within the well-established NEPA regulatory framework. Once actions are accurately described and categorized a better understanding of what is being done and what is and is not appropriate (and lawful) follows.

We believe that the entire process got off on the wrong foot because Reclamation has never accurately stated what the "major federal action" being contemplated is. 42 U.S.C. § 4332(c). The February 13, 2009, Notice of Intent to prepare an Environmental Impact Statement, 74 Fed. Reg. 7257, ("NOI") states that the proposed federal actions are issuance of ESA permits and implementation of one or more components of the BDCP. However, this is incorrect. The major federal action is continued operation of the CVP at increased rates of export through one of three alternative conveyance options ("Peripheral Canal"). Reclamation may recall that in recent litigation against the CVP Contractors it successfully argued that the major federal action at issue in that litigation was not the issuance of biological opinions but rather "planned coordinated operation of the Projects [CVP] that creates the jeopardy found by the BiOp." *Delta Smelt Consolidated Cases*, 686 F. Supp. 2d 1026, 1042 (E.D. Cal. 2009); *see also* U.S. Fish & Wildlife Service, *Habitat Conservation Plans*, *available at http://library.fws.gov/Pubs9/hcp_section10.pdf* (last visited Nov. 14, 2011) (noting that "[t]he purpose of the incidental take permit is to authorize the incidental take of a listed species, not to authorize the activities that result in the take"). Here, it is the continued operation of the CVP and SWP at increased export levels and with a Peripheral Canal that creates the jeopardy to the smelt and other listed species (and the take); the Habitat Conservation Plan ("HCP") and the take permits are incidental to the underlying activity.

The NOI's misstatement of the major federal action[1] has carried through the process and resulted in widespread public perception that the BDCP is "a twelve billion dollar canal dressed up as a habitat plan."

---

[1] We are aware that BDCP prevailed against a similar claim in *Cent. Delta Water Agency v. U.S.F.W.S.,* 653 F. Supp. 2d 1066 (E.D. Cal. 2009). Two observations are in order with regard to *Central Delta Water Agency*: first the court dismissed the action on standing and ripeness grounds. *See id.* at 1083. The court did not reach the merits of whether the NOI was inadequate. Challenge to the project based on an inadequate NOI upon issuance of the Record of Decision is in no way impaired by *Central Delta Water Agency.* Second, and more to the point for BDCP policy guidance going forward, the court and the parties in *Central Delta Water Agency* entirely missed the appropriate claim, which is "informational injury." Had a properly framed complaint bringing an informational injury claim been brought, none of the factors cited by the court would have precluded the standing, ripeness, and finality requirements being satisfied. *See, e.g., Ctr. For Biological Diversity v. Brennan*, 571 F. Supp. 2d 1105, 1118 (N.D. Cal. 2007) (noting that "[i]t is well settled that plaintiffs may suffer injury as a result of a denial of information to which they are statutorily entitled" and "recognizing that a purely informational injury may be sufficient to confer standing") (citation omitted); *see also*

The term “peripheral canal” is the conventional label for transporting water from the north Delta to the Clifton Court Forebay outside of the rivers and sloughs of the Delta. Its use engenders instant public recognition and understanding of what is at stake. And it provokes instant response and controversy. Not using a conventional label when one is available strongly suggests to the reader that the writer is not referring to the object conventionally so labeled. It is misleading, particularly to the general public. *See also Railroaded Salmon,* available at http://vimeo.com/31740676 (last visited November 15, 2011) (noting “outrageous claim that new diversion facility is a conservation measure”); San Jose Mercury News, October 30, 2011, *Federal Delta water pact fails on every count,* available at http://www.mercurynews.com/opinion/ci_19217860 (last visited November 15, 2011) (criticizing BDCP “lack of transparency” and “favoritism toward water-export agencies”).

The habitat plan and conservation measures are actually very much needed and if properly fleshed out and evaluated could provide great benefit to the Delta. We think a robust habitat plan deserves broad public support. It would receive public support more readily if Reclamation were more forthcoming about identifying the Peripheral Canal for what it is, more clearly making a commitment to the HCP with or without a canal attached to it, and clearly stating an enforceable, ironclad, mechanism for ensuring that harmful levels of water export will never occur.

The current Water Contractor problem is another aspect of the mis-designation and lack of clarity in the BDCP process.

II. **The Amendment Dramatically Changes The Role Of The Water Contractors From That Contemplated In All Previous Documents And Understandings By Inappropriately Designating Them As “Responsible Agencies” Under CEQA and “Cooperating Agencies” Under NEPA.**

The Water Contractors are described for the first time in the BDCP process in the Amendment as “responsible agencies.” Amendment, Recital E and Paragraph II(I). The Federal White Paper on the 2011 Bay Delta Conservation Plan MOA (“White Paper”), issued in response to concerns expressed by Congressman Miller, is the first document to describe the Water Contractors as “Cooperating Agencies.” White Paper at 2. The term “Responsible Agency” is a statutorily defined term with a specific role under CEQA. Cal. Pub. Resources Code § 21069; CEQA Guidelines §§ 15096, 15381. The term “Cooperating Agency” is a term defined by the NEPA Implementing Guidelines with a specific role under NEPA. 40 C.F.R. §§ 1501.6 & 1508.5. Elevation to Responsible Agency and Cooperating Agency status gives the Water Contractors the ability to influence the process shielded from public view. *See* 43 C.F.R. § 46.225(d) (requiring Cooperating Agencies to make “a commitment to maintain the confidentiality of documents and deliberations during the period prior to the public release by the bureau of

---

Daniel L. Mandelker, *Nepa Law and Litigation* § 4.17 (informational and procedural injury as injury in fact). Because informational injury was not litigated *Central Delta Water Agency* has no preclusive effect with respect to informational injury claims.

any NEPA documents, including drafts"). It also provides them with much more influence over the process. *See* 40 C.F.R. § 1501.6(a)(2) (Lead Agency must "[u]se the environmental analysis and proposals of cooperating agencies . . . to the maximum extent possible"); 40 C.F.R. § 1501.6(b)(3) (Cooperating Agency may prepare "environmental analysis including portions of the environmental impact statement"); 40 C.F.R. § 1501(b)(4) (Cooperating Agency to provide its own staff to work on preparation of EIS); 43 C.F.R. § 46.230 (Cooperating Agency may analyze data; develop alternatives; evaluate alternatives; estimate effects of implementing alternatives; carry out any other task related to the development of the EIS); 40 C.F.R. § 1506.5(c) (Cooperating Agency may select consultants engaged to prepare EIS).

Elevating the Water Contractors to Cooperating Agency status through a federal white paper that explains and defends the Amendment, when the term Cooperating Agency was nowhere used with respect to the Water Contractors prior to the White Paper, including in the Amendment, is not consistent with NEPA implementing regulations or standard agency practice.

Rather, NEPA implementing regulations contemplate that Cooperating Agencies will be designated through a formal process and will be publicly announced prior to beginning the scoping process, usually in the NOI. *See* 40 C.F.R. § 1501.5 (c) ("lead agencies *shall* determine by letter or memorandum which agency shall be the lead agency and which shall be cooperating agencies") (emphasis added); 40 C.F.R. § 1501.6(b)(2) (requiring that "[e]ach cooperating agency *shall* . . . [p]articipate in the scoping process") (emphasis added); Memorandum for the Heads of Federal Agencies, Subject: Reporting Cooperating Agencies in Implementing the Procedural Requirements of the National Environmental Policy Act (Dec. 23, 2004) (requirement for all federal agencies for "reporting the designation of Federal and non-federal cooperating agencies"); Memorandum for the Heads of Federal Agencies From James Connaughton, Subject: Cooperating Agencies in Implementing the Procedural Requirements of the National Environmental Policy Act (Jan. 30, 2002) (instructing heads of agencies to "identify as early as practicable" Cooperating Agencies); Memorandum For The Heads of Federal Agencies From James L. Connaughton, Subject: Report on Cooperating Agencies in Implementing the Procedural Requirements of the National Environmental Policy Act (May 26, 2005) (noting Lead Agencies are "designating formal cooperating agencies when beginning their NEPA process").

Here Reclamation did in fact comply with the regulations and standard agency practice by formally announcing the Cooperating Agencies in the NOI. However the Cooperating Agencies selected did not include the Water Contractors. Instead Reclamation properly designated The Army Corps of Engineers ("ACOE") and the United States Environmental Protection Agency ("USEPA") as the Cooperating Agencies. NOI, 74 Fed. Reg. at 7257. On the other hand, the NOI designates the Water Contractors as "Potentially Regulated Entities or PREs." NOI, 74 Fed. Reg. at 7258. It is clear that at issuance of the NOI, which is the appropriate time to select Cooperating Agencies, the Water Contractors were <u>not</u> to be designated as Cooperating Agencies because it is not appropriate for a *regulated* entity to serve as a Cooperating Agency.

Rather the federal *regulators*, ACOE and USEPA, were appropriately designated as the Cooperating Agencies[2].

Likewise, if the Water Contractors were to be Responsible Agencies under CEQA, the Notice of Preparation ("NOP") filed by DWR did not follow required procedures for doing so. CEQA Guideline[3] section 15082(a) provides that "the lead agency shall send to the Office of Planning and Research and each responsible and trustee agency a notice of preparation stating that an environmental impact report will be prepared." The distribution list attached to the NOP indicates that it was sent to twenty-two public agencies. The list does not include the Water Contractors. CEQA Guideline § 15096(b)(2) provides in pertinent part that "not longer than 30 days after receiving a Notice of Preparation from the Lead Agency, the Responsible Agency shall send a written reply by certified mail or any other method which provides the agency with a record showing that the notice was received. The reply shall specify the scope and content of the environmental information which would be germane to the Responsible Agency's statutory responsibilities in connection with the proposed project." The reply must also be sent to the State Clearinghouse. The State Clearinghouse website indicates that no reply was received from the Water Contractors. *See* SCH Number: 2008032062. That DWR did not follow required procedures for designating the Water Contractors as Responsible Agencies is not surprising because, like the NOI, the NOP identifies that Water Contractors not as Responsible Agencies but as "Potentially Regulated Entities." NOP at 2. Public accountability is the cornerstone of CEQA. Whatever discussions or understandings the Water Contractors may have had with DWR regarding their roles at the time of preparation of the NOP are irrelevant. CEQA requires a specific *public* process to be followed in designating Responsible Agencies.

The original Memorandum of Agreement Regarding Collaboration on the Planning Preliminary Design and Environmental Compliance for the BDCP ("Original MOU") referred to the Water Contractors as "SWP contractors" and "CVP contractors." Original MOU at 1. Like the NOI and NOP, the Original MOU designates the Water Contractors as "Potentially Regulated Entities." Original MOU, Recital B. Paragraph II(H) of the Original MOU deals with roles under NEPA and CEQA and describes DWR as the "lead agency under CEQA" and Reclamation as "one of the lead agencies under NEPA." Paragraph B(3) identifies the California Department of Fish and Game as a Responsible Agency but <u>does not</u> designated the Water Contractors as Responsible Agencies.

---

[2] For an example of the formalities observed in the Cooperating Agency designation process *see Letter From U.S.E.P.A to U.S.F.W.S.,* Nov. 12, 2008, *available at* http://www.epa.gov/region9/water/watershed/sfbay-delta/pdf/EPA_CooperatingAgencyStatus_BDCP_111208.pdf (formally accepting designation as BDCP Cooperating Agency, outlining EPA's expected role, and identifying areas of EPA expertise that will be applied).

[3] We refer to the Guidelines by their common name. The Guidelines, however, are not suggestions. They are published in the California Code of Regulations at Title 14, Chapter 3. They are "binding on all public agencies in California." Guideline § 1500.

The Agreement Regarding Preparation Of A Joint Environmental Impact Report/Environmental Impact Statement For The Bay Delta Conservation Plan ("Lead Agency Agreement") spells out how tasks will be assigned to the consultant and how the work of the consultant will be directed. Lead Agency Agreement at C(1)(b). It reserves all these tasks to the Lead Agencies. Under the Amendment much of this critical phase of environmental review may well be ceded to the Water Contractors.

Through the White Paper, Reclamation has reached out to calm public concern about the new role of the Water Contractors by explaining that there is really nothing new or different. But that is not consistent with elevation to Cooperating and Responsible Agency status, which the record demonstrates is a new development, and which the relevant statutes and regulations demonstrate is a very different and elevated role.

III. **The Underlying Purposes Of Cooperating/Responsible Agency Status Are Not Served By Designating the Water Contractors as Cooperating/Responsible Agencies.**

The underlying purpose of Responsible Agency designation under CEQA is to ensure that an agency will consider the environmental impacts and develop mitigation measures to the maximum extent practicable before carrying out or approving any portion of a project for which it is responsible. CEQA Guideline § 15096. The underlying purpose of Cooperating Agency designation under NEPA is to help the Lead Agency identify and analyze environmental impacts. 43 C.F.R § 46.230. These purposes are not served, or intended to be served, by designating the Water Contractors as Responsible/Cooperating Agencies. The special expertise to identify impacts and require mitigation measures and the discretionary approval power for the project do not lie with the Water Contractors, but with other agencies (DWR, Reclamation, DFG, NMFS, USFWS, USEPA and several others who are already intimately involved in the project). Further expertise on Delta ecology and impacts will be obtained by engaging the CalFed Delta science team for independent peer review at the appropriate time. The Water Contractors' interest here is to obtain more water for their customers. This is a legitimate and essential purpose, but it is not commensurate with the underlying environmental protection purposes of Responsible and Cooperating Agency status.

We find unpersuasive the argument that because the Water Contractors must participate in decisions about diversion rates and are responsible for developing and implementing the HCP they need to be intimately involved in non-public portions of a coterminous NEPA/CEQA review of that plan as it is being developed. We also believe, as discussed below, that this combined process is contrary to NEPA-implementing regulations.

On the other hand, it is standard practice for project beneficiaries to finance, in part or in whole, the costs of preparing an EIR with explicit guarantees to the public that they will have no control over or participation in the process as a means of assuring the public that there is no undue influence. For example, typically developers applying to build a shopping center or hotel collaborate with planning staff on developing their project, make a payment into a trust account to cover the cost of preparing an EIR, then sit back and wait like everyone else while the EIR is being drafted. Why isn't this well-settled procedure, aimed at maintaining public trust, applicable here?

IV. The Combining of Scoping, Project Development and EIS Preparation "On The Fly" Leads To Outcome-Driven Results Rather Than Objective Analysis, Is Contrary To NEPA Implementing Regulations, And Is Particularly Troublesome If The Water Contractors Are Cooperating/Responsible Agencies.

The melding of scoping, project development, and formal environmental review tends to lead to outcome-driven results rather than an effective development of alternatives and an objective appraisal of the project's impacts. A better process would be to fully develop the Peripheral Canal alternatives and other elements of the project in a public scoping process before beginning the formal EIS/EIR preparation process. At this point the description of the canal alternatives is skeletal and several important alternatives have not yet been considered at all (at least not publicly). The most controversial aspects of the project remain as wholly unsettled controversies. We are aware that a menu of algorithms to determine levels of water export has been included in the latest public draft of the BDCP at section 3.4.2.1. The introduction to that section appears to indicate that adaptive management protocols might be used to determine how the diversion rates stated in section 3.4.2.1 might be modified if conditions require it. The introduction also seems to indicates that "a process has begun" to determine how long term operating criteria will be established. We are unsure if it is this process that will address adaptive management protocols. The introduction also refers the reviewer to the February 11 steering committee agenda and attached handouts for more information. However, the steering committee agenda/handout link on the website appears to be broken.

Although the short time allowed to prepare these comments did not afford us the luxury for a comfortable review of all BDCP documents, from what we have seen so far is appears that operating criteria, adaptive management protocols and triggers, and scoping of alternatives for diversion rates is very preliminary. Section 3.7.3.2 reveals that no "decision body" has yet been formulated to decide when water export levels need to be curtailed. Section 3.7.3.2, as it is currently formulated, could result in an indefinite impasse in any effort to change export rates in response to new information. For thirty years the crux of the Peripheral Canal issue has been how to attach iron clad guarantees that the canal cannot be operated in a way that will harm the Delta. Colloquially put, once the canal is built how will we ever be able to wrest control of the faucet from the Water Contractors? This issue must be resolved through public dialog before any NEPA review begins. Frankly, failure to address this issue up front spells doom for the Peripheral Canal this time around just as it did in 1982.

The BDCP appears to take the approach of using a simplistic algorithm to determine diversion rates. We believe that if a simplistic algorithm is to be used (which, given an algorithm's ability to peg a bright line standard, might well be the best approach), the trigger for allowing diversion to commence should be set at flood stage of the Sacramento River. This would require building additional storage capacity as flood flows may exceed the capacity of the CVP. We discuss this approach in more detail below under the heading "Yolo Bypass Alternative." It would seem at first blush that diverting only peak flows would produce abundant water (if there was capacity to store it) and would have the least potential for environmental harm. It would also set a bright line standard as to when diversion could take place. We would also like to ask how the algorithms published thus far capture a situation in which the preceding several years have been very dry years? Aren't ecological conditions different and in-stream flow more critical after a series of dry years? We did not see this in the materials that we were able to find. We think all of this needs to be addressed in one complete document with adequate time for the public to digest it and offer suggestions before NEPA review can begin. We think that these questions, and the fact that the reader has to scurry around gathering up meeting agendas to understand what the BDCP is about when EIS preparation is but weeks away confirms that the process is unduly rushed.

The combination of scoping with EIS preparation is also not consistent with NEPA implementing regulations. CEQ regulations indicate that if an agency intends to engage in combined scoping and EIS preparation, it should first adopt procedures that will govern such a combined process through notice and comment rulemaking. *See* 40 C.F.R. § 1501.7(b)(3) & § 1507.3. Neither DOI nor Reclamation has adopted the required regulations. We believe that such regulations would provide much needed guidance as to how a condensed scoping/EIS process would work and would provide safeguards that would prevent rushing into the process in a way that truncates public participation when it is needed in the development of alternatives[4].

One of the most contentious of the open questions is what level of water exports are being guaranteed to the Water Contractors. This is related to the failure to properly describe what the major federal action is. *See supra* Section I. The statement of project purpose in the NOI provides that deliveries of "full contract amounts" will be restored to the Water Contractors. However, this would be inconsistent with law because California Water Code section 85021 states that "the policy of the State of California is to reduce reliance on the Delta in meeting California's future water supply needs" and that each water district should develop its own supplies regionally. What is meant by restoring full contract amounts has never been settled and is the subject of heated controversy. *See, e.g., Letter from U.S.E.P.A. to Reclamation, USFWS, and NMFS,* June 10, 2010, *available at http://www.epa.gov/region9/water/watershed/sfbay-delta/pdf/EpaR9CommentsBdcpPurpStmt6-10-2010.pdf* (noting unclear purpose statement because "within the federal family, as well as in the broader debate, there seems to be little agreement on exactly" what is being promised to the Water Contractors).[5] Reclamation has been subject to repeated criticism for lack of transparency for this kind of issue from both the scientific community and the public at large. *See generally CalFed Science Review of the 2-Gates Project.*

---

[4] Where a regulation contemplates notice and comment before adopting a procedure and the regulation is not followed a cause of action stating a claim for procedural injury immediately accrues. *Brennan*, 571 F. Supp. 2d at 1118.

[5] We are aware that the Lead Agencies replied to EPA's concerns by letter dated October 26, 2010.

It is our understanding that the project purpose statement will be revised and that revision will be announced to the public through publication of the draft EIR/EIS. This is particularly inappropriate. The project purpose statement and the effect of Water Code section 85021 are *threshold questions.* They should be addressed through *public* scoping at the very beginning of the process. It is also offensive to the public that issues of central public concern and controversy will be decided behind closed doors through negotiations with the Water Contractors, justified by the fact that the Water Contractors are Responsible/Cooperating Agencies.

V. **The Rushed Process Has Overlooked Important Alternatives And May Amount To Impermissible Segmenting.**

The Yolo Bypass Alternative Has Been Overlooked.

One of the BDCP guiding concepts is the "big gulp, little sip" principle, meaning that water diversion will be greatest at periods of high river flow and minimized when flow is less. We want to suggest that this concept should be applied to the canal alternatives through what we will call the Yolo Bypass Alternative(s)[6]. The Yolo Bypass intake is located upstream of the City of Sacramento and provides flood control for the City of Sacramento. During periods of very high river stage, the river overtops the Freemont Weir and vast quantities of water are diverted from the Sacramento River and down the Yolo Bypass. The limited time available to prepare these comments did not allow for hydrological research and exact figures, but those involved with the BDCP will be well aware that very large quantities of high quality water are diverted in this way. An intake for the Peripheral Canal could be located in some portion of the Yolo Bypass so a portion of these very high stage flows could be diverted and stored for use during the summer months. A variation of the Yolo Bypass Alternative would be to place an intake for the Peripheral Canal upstream of Sacramento on the Sacramento River. This intake would then capture the flood flows (and only the flood flows) and divert them for storage and beneficial use. Perhaps this intake could relieve the Yolo Bypass of its flood control function and the Freemont Weir could be operated solely for conservation values, enhancing the habitat and conservation functions of the Yolo Bypass. We are aware that the current capacity of the CVP is 15,000 cfs and this might present an operational limitation on how much water could be diverted at peak flow. Could some of the flood flow (in excess of 15,000 cfs) be stored underground? Could any of the Delta Islands be converted to storage (perhaps with a conservation and recreation benefit as well)? Could Los Vaqueros Reservoir accommodate some additional storage? What other storage options might be available? Again, we do not endorse any of these measures, but they are important aspects of the Peripheral Canal problem not currently being considered because they are the only canal alternatives thus far broached that would take no water that currently flows through the central and south Delta.

The Yolo Bypass Alternative also presents a tight fit with the purpose of the CVP:

---

[6] This in no way implies that STCDA supports a Peripheral Canal. However, we point out that if a Peripheral Canal is to be analyzed under NEPA, all reasonable and prudent canal configurations should be analyzed.

> [The CVP's purpose is to] improve navigation, regulate the flow of the San Joaquin River and the Sacramento River, *control floods, provide for storage* and for the delivery of the stored waters thereof, for the reclamation of arid and semiarid lands and lands of Indian Reservations, and other beneficial uses, and for the generation and sale of electric energy.

Westlands Water District v. U.S., 337 F.3d 1092, 1095 (9th Cir. 2003) (citing Pub. L. No. 75-392, 50 Stat. 844, 850 (1937) (emphasis added)). In creating the CVP, Congress intended that flood control and providing water for beneficial use were two sides of the same coin: water diverted to control floods would go to beneficial use. Failure to consider the Yolo Bypass Alternative, with its flood control and storage features, and unique attribute of taking no Delta flows, might amount to failure "to consider an important aspect of the problem" and/or a failure to consider "the relevant factors" as specified by Congress. *Motor Vehicle Mfrs. Ass'n v. State Farm Mut. Auto. Ins. Co.,* 463 U.S. 29, 43 (1983). In this same vein, we have not yet seen where BDCP has considered improvements to navigation or even impacts on navigation. STCDA intends to look more closely at the BDCP and to provide substantive comments on the issue of navigation under separate cover.

We believe these examples demonstrate that the formal preparation of the EIS/EIR is not ready to start; that more time and public involvement should be put into identifying alternatives and fleshing out what are now skeletal plans into a complete plan before preparation of the EIR/EIS begins.

Failure To Include The 2-Gates Project And Other Gates Projects May Amount To Impermissible Segmenting.

Reclamation has been considering the 2-Gates Project and other gates projects in the Delta for some time. Recent inquiries were unable to determine what the exact status of these projects is. We understand that Reclamation is trying to validate the smelt-turbidity hypothesis through research currently being conducted by Jon Burau and Bill Bennett. It appears that the gates projects are still under consideration. The gates projects are within the BDCP project area and are intimately related to the water supply purpose of the BDCP as well as being proffered to benefit the smelt and reduce or eliminate the incidental take of smelt by operation of the CVP and SWP. Unless Reclamation has made a decision and will shortly be issuing a ROD on the gates projects adopting the no project alternative, failure to include the gates projects under the BDCP could well be impermissible segmenting of environmental review. The gates projects should be included as part of the BDCP (if they are still under consideration) or as alternatives to the Peripheral Canal. NEPA review of the gates projects should be conducted as a part of BDCP NEPA review. Given the potential for impermissible segmenting if the gates are not considered as part of BDCP review, the entire BDCP EIR/EIS might be found inadequate if the gates are not addressed.

VI. Improving The Stakeholder Process.

We believe that the credibility of the BDCP as a stakeholder driven process (as opposed to the current perception of a water grab by the Water Contractors) can only be restored by reconstituting the steering committee. We understand that the Brown administration has considered and rejected this idea. We believe that recent events portend an abrupt downhill slide for the BDCP in the court of public opinion unless decisive action is taken. We urge the Brown administration to reconsider.

All current members of the steering committee should be invited to stay on. It should be made clear that reconstituting the steering committee does not imply that current members have done anything other than contribute heroic amounts of time and energy in a selfless effort of public service.

A public outreach effort aimed at defining the additional slots on the steering committee should be undertaken. At a minimum, we believe additional slots should include representation of 1) navigation (this would include the interest of Delta marinas); 2) fishing (certain salmon fishing organizations have been among the BDCP's most vocal critics and they should be considered to fill a stakeholder slot); 3) local government; 4) Delta related business (perhaps the Delta Chamber of Commerce); and 5) Discovery Bay.

We include Discovery Bay because of the unique position of Discovery Bay and its extreme vulnerability to impacts of the BDCP. Discovery Bay is a community of waterfront homes built around a series of deep water bays connected to Delta waterways. An engineered water circulation system maintained by Reclamation District 800 moves water from Kellogg Creek to Old River through the bays. Approximately 3500 homes have attached docks fronting the bays. There is approximately two billion dollars worth of investment in direct boating access to the wider Delta from the bays and recreational use of the bays themselves.

First, Discovery Bay represents by far the largest concentration of waterfront homes in the Delta. Virtually all 13,000 residents of Discovery Bay are regular users of the Delta for recreation and many of them derive their livelihood from Delta related businesses. A broad cross section of currently unrepresented Delta interests would be captured by a Discovery Bay slot. Second, all BDCP alternatives are designed to change the hydraulic regime of the rivers and sloughs that feed our bays. What might appear as a minimal impact from the perspective of a coarse grained Delta-wide analysis might well prove catastrophic if examined with a specific focus on the bays of Discovery Bay. Silting of the bays could well result from increases in hydraulic residence time, which is a stated goal of several BDCP elements. Increases in dissolved oxygen are also of significant concern, as are changes in turbidity. Recent years have seen an epidemic of invasive weeds in Discovery Bay. The weeds have just recently been gotten under control. Changes in any or all of the parameters mentioned above could thwart our efforts to control these invasive species, which, if left unchecked, would obliterate the boating and recreational value of our bays.

Upon proper study, mitigation measures might be identified that could ameliorate these impacts. Such measures might include BDCP funding for ongoing weed control, BDCP funding for construction and operation of wing dams or other hydraulic structures at the mouth of each bay that could offset changes in circulation patterns, BDCP funding for implementation and ongoing operation of other yet to be identified measures to offset impacts to water quality. Likely, Discovery Bay mitigations measures could also contribute to enhanced habitat value and recovery of listed species.

VII. Specific Recommendations

Based upon the foregoing, we offer the following specific recommendations;

1) Reconstitute the Steering Committee as discussed above;

2) Reverse the decision to appoint the Water Contractors as Cooperating/Responsible Agencies.

3) Establish a process for the Water Contractors to fund the preparation of the EIR/EIS but with hands off the process itself.

4) Separate scoping, project development, and preparation of the EIR/EIS into distinct sequential phases with a tentative schedule as follows: complete scoping by June 30, 2012; complete project development by Jan 30, 2013; preparation of draft EIR/EIS Jan 30, 2013–June 30, 2013; public comment draft EIR/EIS June. 30, 2013–Nov. 30, 2013; preparation final EIR/EIS Nov. 30, 2013– Feb. 30 2014; public comment final EIR/EIS Feb.30, 2014–May 30, 2014; adopt ROD July 30, 2014.

5) Explicitly identify the most contentious issues and resolve them or develop a menu of resolutions for study through the public scoping process.

6) Reorganize the BDCP plan chapters so the Peripheral Canal is no longer referred to as a conservation measure and has its own chapter titled "Peripheral Canal Alternatives."

7) If the agencies wish to engage in combined scoping and EIS preparation in the future, initiate notice and comment rulemaking to adopt the appropriate procedures.

VII. Invitation To Make Public Presentation At Discovery Bay Town Hall Meeting And Conclusion.

We would like to take this opportunity to extend an invitation to hold a town hall meeting in Discovery Bay some time after the new year. We would envision a presentation of the BDCP by appropriate agency staff followed by a Q & A. Likely many attendees will be adamantly opposed to any Peripheral Canal. But talking to opponents is part of the NEPA process. This also might serve as an opportunity to explain the very real benefits of the HCP. It would also be an important gesture in reaching out to the general public, as opposed to interest group representatives who have dominated the BDCP process to date.

Conclusion

Thank you again for extending the invitation to comment and for considering our view.

Sincerely,

s/Michael Brodsky
Michael A. Brodsky Dated: Nov. 16, 2011

BDCP1738.

RECLAMATION
Managing Water in the West

Madera Irrigation District Water Supply Enhancement Project

Final Environmental Impact Statement

EIS-06-127

U.S. Department of the Interior
Bureau of Reclamation
Mid Pacific Region
South Central California Area Office
Fresno, California

June 2011

Mission Statements

The mission of the Department of the Interior is to protect and provide access to our Nation's natural and cultural heritage and honor our trust responsibilities to Indian Tribes and our commitments to island communities.

The mission of the Bureau of Reclamation is to manage, develop, and protect water and related resources in an environmentally and economically sound manner in the interest of the American public.

BDCP1738.

Madera Irrigation District Water Supply Enhancement Project
Final Environmental Impact Statement
Madera County, California

Lead Agency
Bureau of Reclamation
United States Department of the Interior
Bureau of Reclamation
Mid-Pacific Region
South-Central California Office

Cooperating Agencies
U.S. Fish and Wildlife Service and U.S. Army Corps of Engineers

The United States Department of the Interior, Bureau of Reclamation (Reclamation), prepared this Final Environmental Impact Statement (EIS) for the Madera Irrigation District Water Supply Enhancement Project (MID WSEP). The MID WSEP Proposed Action is to construct a groundwater bank on the property known as Madera Ranch, west of the City of Madera, Madera County, California. The Federal actions include approval from Reclamation for MID to bank a portion of their CVP Friant Division contract water supply outside of its service area in the newly constructed groundwater bank at Madera Ranch and approval to extend the Reclamation-owned 24.2 Canal.

This Final EIS analyzes the potential direct, indirect and cumulative impacts of implementing the MID WSEP Reduced Alternative B (Proposed Action) which would involve banking CVP water outside the MID Service Area using select swales, recharge basins and the alteration of Reclamation-owned facilities.

This Final EIS also analyzes the potential direct, indirect and cumulative impacts of implementing the following alternatives:

- Alternative A - No Action Alternative;
- Alternative B - Banking CVP Water outside of the MID Service Area Using Swales and Alteration of Reclamation-owned Facilities;
- Alternative C - Banking CVP Water outside the MID Service Area without Swales and Alteration of Reclamation-owned Facilities;
- Alternative D - Banking CVP Water outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal (no alteration of Reclamation-owned Facilities).

Executive Summary

Please note that text that has been revised since the Draft Environmental Impact Statement (EIS) is marked with a vertical line in the right margin. Text found to be redundant or unnecessary in the Draft EIS has been removed.

ES-1 Introduction

Madera Irrigation District (MID) approved a Water Supply Enhancement Project (WSEP) located on the property known as Madera Ranch, west of the city of Madera, in Madera County, California in September 2005. This approval was based on their Final Environmental Impact Report (EIR) completed for compliance with the California Environmental Quality Act (CEQA). At that time, there was no federal action that would require compliance with the National Environmental Policy Act (NEPA).

The U.S. Department of the Interior, Bureau of Reclamation (Reclamation) commented on the Draft EIR, stating that once MID proposed a federal action, Reclamation would need to complete and satisfy all NEPA requirements as well as all other legal requirements before approving any federal action. A Draft EIS was initiated in response to MID's request that Reclamation approve the banking of MID Central Valley Project (CVP) water outside MID's service area in the proposed WSEP, and the modification of the 24.2 Canal, a federal facility.

Pursuant to the requirements of NEPA, Reclamation published a Notice of Intent to prepare a Draft EIS and Notice of Public Scoping Meetings in the *Federal Register* on September 28, 2007. Reclamation and MID held Draft EIS scoping meetings at MID's offices in Madera on October 22 and 29, 2007. Before the meetings, public notices were posted at MID's offices and published in the *Madera Tribune* and the *Fresno Bee* announcing the time, date, location, and purpose of the meetings. Each scoping meeting included an overview of the meeting's purpose, the proposed project and alternatives, potentially significant environmental issues, and opportunities for future public involvement.

Reclamation filed a Notice of Availability in the *Federal Register* on July 28, 2009 for the Draft EIS. The Draft EIS underwent public review for 60 days, during which time Reclamation held a public meeting. After comments had been received, Reclamation prepared responses to comments and has included them in this Final EIS. Reclamation upon filing the Notice of Availability for this Final EIS in the *Federal Register* will circulate this Final EIS for at least 30 days before issuing a Record of Decision (ROD).

This Final EIS has been completed for compliance with NEPA by Reclamation as the Federal lead agency. Reclamation has been coordinating with the U.S. Army Corps of Engineers (Corps) and U.S. Fish and Wildlife Service (USFWS) to analyze the potential direct, indirect and cumulative environmental impacts of the Proposed Action.

ES-2 Purpose and Need

Currently, farmers in MID's service area use a combination of groundwater and surface water. During dry years, there is not adequate surface water to meet the water demand and groundwater pumping increases substantially. The amount of groundwater that has been pumped from the aquifer in the vicinity of Madera Ranch has exceeded the amount of water that has recharged the aquifer, resulting in groundwater overdraft. Even in wet years, the groundwater basin is in severe overdraft because groundwater pumping is steadily increasing for agricultural use as well as municipal and industrial (M&I) use. This overdraft has caused the water table to decline and groundwater quality to degrade and has resulted in excess space in the aquifer that could be used to bank surface water.

In the vicinity of Madera Ranch, the water table has declined more than 90 feet over the last 60 years. These conditions have made it increasingly expensive for farmers to pump groundwater. Additionally, in many years, MID has been unable to deliver sufficient surface water to farmers because water is available primarily during the early months of the year when irrigation demand is low, and often water is available only for short periods of time during the growing season.

The purpose of the proposed federal action is to:

- enhance water supply reliability and flexibility by using the excess aquifer space for surface water storage (water banking);
- reduce existing and future aquifer overdraft;
- reduce groundwater pumping costs;
- increase groundwater quality;
- encourage conjunctive use in the region as a means toward regional self-sufficiency.

ES-3 Description of the Project Alternatives

To meet these project purposes, MID proposes to implement the WSEP, by which MID would bank a portion of their CVP water from the San Joaquin and Fresno Rivers and other non-CVP water in the aquifer underlying Madera Ranch. Water would be banked in the aquifer, and 10% of the water would be left behind to reduce overdraft.

This Final EIS analyzes the potential direct, indirect and cumulative impacts of implementing the MID WSEP Reduced Alternative B (Proposed Action) which would involve banking CVP water outside the MID Service Area using select swales, recharge basins and the alteration of Reclamation-owned facilities.

This Final EIS also analyzes the potential direct, indirect and cumulative impacts of implementing the following alternatives:

- Alternative A - No Action Alternative;
- Alternative B - Banking CVP Water outside of the MID Service Area Using Swales and Alteration of Reclamation-owned Facilities;
- Alternative C - Banking CVP Water outside the MID Service Area without Swales and Alteration of Reclamation-owned Facilities;
- Alternative D - Banking CVP Water outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal (no alteration of Reclamation-owned Facilities).

ES-3.1 Alternative A

Under the No Action Alternative, MID would not bank MID CVP water (MID Long-Term Water Service Contract supplies from both the Friant Division and Hidden Unit) on Madera Ranch (Figure 2-1) and Reclamation's delivery canals would not be enlarged. MID may bank non-CVP water on the property, and other limited on-site water banking and recovery facilities may be constructed if MID is able to find participants and funding to support these efforts. MID estimates that under the No Action Alternative, MID only could apply less than 5,000 acre-feet (AF) per year (AF/year) of their own non-CVP water, and recovery operations likewise would be limited if Reclamation-owned facilities were not altered. The number of other participants and amount of water they could bring to the project are uncertain. If the proposed project does not proceed, MID likely would sell the property to other agricultural interests. MID has had numerous offers from prospective buyers, including dairy, orchard, and row crop farmers. The No Action conditions would allow for agricultural activities.

ES-3.2 Alternative B

Alternative B would be completed in two phases. Phase 1 would involve only recharge-related facilities. Phase 2 would involve supplemental recharge facilities and facilities for recovery of banked water. Reclamation would approve a total banking capacity of 250,000 AF of MID CVP water outside the MID service area and issuance of an MP-620 permit (a Reclamation Mid-Pacific Region-specific permit issued for additions or alterations to Reclamation-owned conveyance and distribution facilities) for Lateral 24.2. After alteration of the Reclamation-owned facilities (Lateral 24.2) and certain MID facilities, MID would be able to recharge and recover a maximum of 55,000 AF annually.

Phase 1 activities would involve:

- reconditioning and extending canals to provide at least 200 cubic feet per second (cfs) of conveyance capacity into Madera Ranch;
- constructing approximately 55 acres of recharge basins on current agricultural land to regulate flow, remove sediment, and provide some recharge;
- applying recharge flows to approximately 700 acres of swales; and
- integrating approximately 2,600 acres of Madera Ranch row crops and vineyards into an in-lieu recharge program in which surface water periodically would be served in lieu of groundwater pumping subject to approval by the Madera Ranch Oversight Committee (MROC).

Phase 2 activities for recharge and recovery facilities would involve:

- additional upgrades to existing canals,
- construction of up to 1,000 acres of new on-site recharge basins and canals as required to supplement Phase 1 facilities and achieve 200 cfs of recharge capacity (if required),
- use of up to 15 existing wells for recovery,
- installation of up to 49 new wells and recovery pipelines (in phases over several years) to provide 200 cfs of recovery capacity, and
- installation of up to 12 lift stations on MID canals and one lift station on Gravelly Ford Canal (GF Canal) (in phases over several years) to provide 200 cfs of pump-back capacity into the MID service area.

ES-3.3 Reduced Alternative B

Reduced Alternative B represents a scaled-back version of Alternative B that uses fewer swales in order to minimize effects to vernal pools and limits the number of recharge basins to the number needed for the project to be practicable. It is included in the Final EIS as a revision to Alternative B to allow the public to see how the project has been modified, demonstrate how effects have been reduced, and facilitate the Corps use of this document in their permitting of the project. As with Alternative B, Reduced Alternative B would complete the water bank in two phases. Phase 1 would involve constructing necessary delivery infrastructure improvements (except for the Section 8 canal southwest extension), using select natural swales for recharge (550 acres versus 700 acres as proposed under Alternative B), and installing approximately five soil berms to direct recharge flows. Phase 2 would involve constructing a limited number of recharge basins (323 acres versus up to 1,000 acres under Alternative B) and facilities for recovery of banked water. Reclamation would approve banking of CVP water outside the MID service area and alteration of Reclamation-owned facilities.

ES-3.4 Alternative C

Alternative C is a variation of the Proposed Action that would complete the water bank in two phases and replace natural swale recharge solely with recharge basins. Phase 1 would involve recharge-related facilities only. Phase 2 would involve facilities for recovery of banked water. Reclamation would approve banking of CVP water outside the MID service area and alteration of Reclamation-owned facilities.

Phase 1 activities would involve:

- reconditioning and extending existing canals to provide at least 200 cfs of conveyance capacity into Madera Ranch,
- constructing up to 1,000 acres of new on-site recharge basins and canals as required to achieve 200 cfs of recharge capacity, and
- integrating approximately 2,600 acres of Madera Ranch row crops and vineyards into an in-lieu recharge program in which surface water periodically would be served in lieu of groundwater pumping subject to approval by the MROC.
- Phase 2 recharge and recovery facilities would involve:
- up to 15 existing wells for recovery;

- up to 49 new wells and recovery pipelines (in phases over several years) to provide 200 cfs of recovery capacity; and
- up to 12 lift stations on MID canals and one lift station on GF Canal (in phases over several years, total of 13 lift stations) to provide 200 cfs of pump-back capacity into the MID service area.

ES-3.5 Alternative D

Under Alternative D, MID would enter into an agreement with Gravelly Ford Water District (GFWD) to improve the GF Canal to allow water to be conveyed from the San Joaquin River through the GF Canal to Madera Ranch for banking of water and recovery of water from the ranch back through the canal to the river. The existing GFWD pumping plant would be enlarged; the existing, associated pipeline replaced with a larger-diameter line; the GF Canal re-graded to a flat-bottom (zero slope) configuration to allow two-way flow; a new connection to the river constructed to allow recovery water to reach the river without flowing through the pumps; and appropriate gate structures constructed. On-site improvements allowing water banking and extraction, including a pumping plant and pipeline to allow distribution of water uphill from the GF Canal, would be constructed.

MID would complete Alternative D in two phases. Phase 1 would involve recharge-related facilities only. Phase 2 would involve supplemental recharge facilities and facilities for recovery of banked water. Reclamation would approve the banking of CVP water outside the MID service area as described under Alternative B. No alteration of Reclamation-owned facilities would occur under Alternative D.

Phase 1 activities would involve:

- reconditioning of existing canals to provide at least 200 cfs of conveyance capacity into Madera Ranch;
- construction of approximately 26 acres of recharge basins on current agricultural land to regulate flow, remove sediment, and provide some recharge;
- application by MID of recharge flows to approximately 700 acres of swales; and
- integration of approximately 2,600 acres of Madera Ranch row crops and vineyards into an in-lieu recharge program in which surface water would be periodically served in lieu of groundwater pumping subject to approval by the MROC.
- Phase 2 recharge and recovery facilities would use or include:
- up to 15 existing wells for recovery,
- up to 49 new wells and recovery pipelines (in phases over several years) to provide 200 cfs of recovery capacity, and
- one lift station on GF Canal to provide 200 cfs of pump-back capacity to the San Joaquin River.

ES-4 Overview of Environmental Impacts

The EIS evaluates the direct, indirect, and cumulative environmental changes and/or impacts on the following resources:

- Aesthetics
- Agriculture
- Air Quality
- Biological Resources
- Cultural Resources
- Environmental Justice
- Geology, Soils, Seismicity, and Erosion
- Global Climate
- Growth-Inducing Effects
- Hazards, Public Health, and Safety
- Indian Trust Assets
- Land Use
- Noise
- Public Services and Utilities
- Socioeconomics
- Traffic and Circulation
- Water Resources
- Water Supply
- Wetlands

A comparison of the Alternative impacts is displayed in the following Executive Summary table.

Table ES-1 Executive Summary Impacts and Mitigation Table

Potential Impact	Alternative	Potential Impact Determination	Avoidance/Mitigation Measures
Aesthetics			
AES-1: Temporary Degradation of Visual Character or Quality from Construction-Related Activities	B, Reduced B, C, D	Yes	
AES-2: Degradation of Visual Character or Quality from New Permanent Features	B, C, D	No	
Agriculture			
AG-1: Alteration of Madera Ranch Agricultural Operations	B, Reduced B, C, D	No	
AG-2: Conflict with Williamson Act Contracts	B, Reduced B, C, D	No	
AG-3: Loss of Agricultural Land Designated as Prime Farmland or Farmland of Statewide Importance	B, C, D	Yes	AG-1
AG-4: Conflict with Local Zoning Designations	B, Reduced B, C, D	No	

Air Quality			
AQ-1: Generation of Construction Emissions in Excess of Federal *de minimis* Threshold Levels	B, Reduced B, C, D	Yes	AQ-1, AQ-2
AQ-2: Generation of Operational Emissions in Excess of Federal *de minimis* Threshold Levels	B, Reduced B, C, D	No	
AQ-3: Result in a Cumulatively Considerable Net Increase of Any Criteria Pollutant for which the Region Is in Nonattainment under an Applicable Federal or State Ambient Air Quality Standard (Including Releasing Emissions that Exceed Quantitative Thresholds for Ozone Precursors)	B, Reduced B, C, D	Yes-cumulative	AQ-1, AQ-2
Biological Resources			
BIO-1: Temporary Disturbance of California Annual Grassland and Alkali Grassland during Construction	B, Reduced B, C, D	No	
BIO-2: Permanent Removal of California Annual Grassland and Alkali Grassland Habitats during Construction	B, Reduced B, C, D	Yes	BIO-1
BIO-3: Loss or Disturbance of Iodine Bush Scrub or Sensitive Plant Species Habitat as a Result of Construction	B, Reduced B, C, D	Yes	BIO-2a, BIO-2b
BIO-4: Potential for Construction-Related Mortality of Sensitive Vernal Pool Crustaceans	B, Reduced B, C, D	Yes	BIO-2a, BIO-2b
BIO-5: Potential for Operation- and Maintenance-Related Mortality of Sensitive Vernal Pool Crustaceans	B, Reduced B, C, D	Yes	BIO-2a, BIO-2b
BIO-6: Potential for Construction-Related Mortality of San Joaquin Tiger Beetle	B, Reduced B, C, D	No	
BIO-7: Potential for Operation- and Maintenance-Related Mortality of San Joaquin Tiger Beetle	B, Reduced B, C, D	No	
BIO-8: Potential for Construction-Related Mortality of California Tiger Salamander	B, Reduced B, C, D	Yes	BIO-1, BIO-2a, BIO-2b, BIO-4a, BIO-4b, BIO-4c
BIO-9: Potential for Operation- and Maintenance-Related Mortality of California Tiger Salamander	B, Reduced B, C, D	Yes	BIO-1, BIO-2a, BIO-2b
BIO-10: Potential for Construction- and/or Operation- and Maintenance-Related Mortality of Western Spadefoot Toad	B, Reduced B, C, D	Yes	BIO-2a, BIO-2b
BIO-11: Potential for Construction- and/or Operation- and Maintenance-Related Effects on Blunt-Nosed Leopard Lizard	B, Reduced B, C, D	Yes	BIO-1, BIO-5, BIO-5a, BIO-5b, BIO-5c
BIO-12: Potential for Construction- and/or Operation- and Maintenance-Related Mortality of California Horned Lizard	B, Reduced B, C, D	No	

BIO-13: Potential for Construction- and/or Operation- and Maintenance-Related Mortality of Silvery Legless Lizard	B, Reduced B, C, D	No	
BIO-14: Potential for Operation- and Maintenance-Related Harm and Harassment of Giant Garter Snake	B, Reduced B, C, D	No	
BIO-15: Potential for Construction-Related Disturbance of Nesting Swainson's Hawk and White-Tailed Kite	B, Reduced B, C, D	Yes	BIO-6
BIO-16: Potential Loss of Foraging Area for Greater Sandhill Crane, Golden Eagle, Ferruginous Hawk, Prairie Falcon, Merlin, Mountain Plover, Long-Billed Curlew, and Short-Eared Owl	B, Reduced B, C, D	No	
BIO-17: Potential for Construction-Related Mortality of Western Burrowing Owl	B, Reduced B, C, D	Yes	BIO-1, BIO-7
BIO-18: Potential for Operation-Related Mortality of Western Burrowing Owl	B, Reduced B, C, D	No	
BIO-19: Potential for Construction-Related Harm to Loggerhead Shrike	B, Reduced B, C, D	Yes	BIO-1
BIO-20: Potential for Construction-Related Foraging Habitat Loss for Tricolored Blackbird	B, Reduced B, C, D	No	
BIO-21: Potential for Effects on San Joaquin Kit Fox	B, Reduced B, C, D	Yes	BIO-1, BIO-8
BIO-22: Potential for Effects on Fresno Kangaroo Rat	B, Reduced B, C, D	Yes	BIO-9
BIO-23: Potential for Mortality of San Joaquin Pocket Mouse	B, Reduced B, C, D	No	
BIO 24: Potential Mortality of Sensitive Species during Construction	C, D	Yes	BIO-10
BIO-25: Potential for Entrainment of Anadromous Fish If Restored to the San Joaquin River	D	Yes	BIO-11
BIO-26: Result in a Cumulatively Considerable Loss of Grassland	Cumulative	Yes	BIO-11
BIO-27: Result in a Cumulatively Considerable Loss of Habitat for Endangered Species	Cumulative	Yes	BIO-1
Cultural Resources			
CR-1: Damage to or Destruction of Nine Historic Features on Madera Ranch through Construction of Recharge Basins	B, Reduced B, C, D	No	
CR-2: Physical Modifications of Gravelly Ford Canal (P-20-2402)	B, Reduced B, C, D	No	
CR-3: Physical Modifications of Historic Main No. 1, Main No. 2 and Section 8 Canal	B, Reduced B, C, D	No	
CR-4: Physical Modification of 24.2 Canal	B, Reduced B, C, D	No	
CR-5: Physical Disturbance of Currently Undiscovered Cultural Resources	B, Reduced B, C, D	Yes	CR-1

Environmental Justice			
EJ-1: Disproportionate effects on minority or low-income populations	B, Reduced B, C, D	No disproportionate effects on minority or low-income populations	
Geology, Soils, Seismicity, and Erosion			
GEO-1: Potential Exposure of People or Structures to Substantial Adverse Effects Resulting from Liquefaction	B, Reduced B, C, D	No	
GEO-2: Potential Subsidence Caused by Groundwater Overdraft	B, Reduced B, C, D	No	MROC
GEO-3: Potential Risks to Property Caused by Construction on an Expansive Soil	B, Reduced B, C, D	No	
GEO-4: Potential Loss of a Substantial Amount of Topsoil from Land Grading Operations	B, Reduced B, C, D	No	
GEO-5: Increase in Wind and Water Erosion Rates during and Shortly after Construction	B, Reduced B, C, D	No	
GEO-6: Increase in Long-Term Wind and Water Erosion Rates	B, Reduced B, C, D	Yes	GEO-1
GEO-7: Potential Destruction of a Unique Pedologic Feature	B, Reduced B, C, D	Yes	BIO-1
GEO-8: Potential Soil Salinization from Elevated Groundwater Levels	B, Reduced B, C, D	No	
GEO-9: Potential Destruction of a Sensitive Paleontological Resource	B, Reduced B, C, D	Yes	GEO-2
Global Climate			
CC-1: Increased GHG Emissions during Construction	B, Reduced B	No	AQ-1, AQ-2
CC-1: Increased GHG Emissions during Construction	C, D, Cumulative	Yes	AQ-1, AQ-2
CC-2: Increase in GHG Emissions as a Result of Operation and Maintenance	B, Reduced B, C, D	Yes	AQ-3
CC-3: Secondary Emissions at Power Plants	B, Reduced B, C, D, Cumulative	No	
Growth-Inducing Effects			
GI-1: Inducement of Growth Attributable to Municipal and Industrial Participation in Water Bank	B, Reduced B, C, D	No	

Hazards, Public Health and Safety			
PHS-1: Potential Creation of a Public Hazard from Risk of Drowning	B, Reduced B, C, D, Cumulative	Yes	PHS-1a
PHS-2: Potential Creation of a Public Hazard from Risk of Berm Failure	B, Reduced B, C, D, Cumulative	No	
PHS-3: Potential Creation of a Public Hazard from Risk of Wildland Fire	B, Reduced B, C, D	Yes	PHS-1b, PHS-1b
PHS-4: Potential for Increase in Adult Mosquito Populations	B, Reduced B,C, D	Yes	PHS-2
PHS-5: Potential Exposure or Disturbance of Hazardous Materials or Wastes	B, Reduced B, C, D	No	WQ-1b
Indian Trust Assets			
ITA-1: Indian Trust Assets (ITA) are legal interests in property held in trust by the U.S. for federally-recognized Indian tribes or individual Indians.	B, Reduced B, C, D	No	
Land Use			
LU-1: Conflict with Applicable Land Use Plans, Policies, or Regulations, Including Land Use Designations and Zoning Ordinances	B, Reduced B, C, D	No	
LU-2: Land Use/Operational Conflicts between Existing and Proposed Land Uses	B, Reduced B, C, D	No	
LU-3: Conflict with Recreational Land Uses	B, Reduced B, C, D	No	
Noise			
NOI-1: Exposure of Residences to Noise from Grading and Construction Activities	B, Reduced B, C, D	Yes	NOI-1
NOI-2: Exposure of Residences to Noise from Well Drilling Operations	B, Reduced B, C, D	Yes	NOI-2
NOI-3: Exposure of Residences to Noise from Operation of Engines at Wells	B, Reduced B, C, D	No	
NOI-4: Exposure of Residences to Noise from Operation of Engines at Lift Stations	B, Reduced B, C, D	Yes	NOI-4
Effect NOI-5: Exposure of Residences to Noise from Operation of Engines at Lift Stations	B, Reduced B, C, D	Yes	NOI-4
Public Services and Utilities			
PSU-1: Increased Demand for Utilities	B, Reduced B, C, D	No	
PSU-2: Potential Disruption of Emergency-Response Routes (Moderate)	B, Reduced B, C, D	Yes	PSU-1a, PSU-1b
PSU-3: Temporary Disruption of Irrigation Service as a Result of Construction	B, Reduced B, C, D	No	
Effects related to the disruption of emergency response routes within Madera County	Cumulative	Yes	PSU-2a, PSU-2b
Socioeconomics			
SE-1: Increase in Temporary Construction-Related Employment and Income in the Fresno Metropolitan Statistical Area	B, Reduced B, C, D	Beneficial	

SE-2: Increase in Permanent Employment and Income in the Local Area	B, Reduced B, C, D	Beneficial	
SE-3: Increase in Water Costs Influencing Agricultural Production	B, Reduced B, C, D	No	
SE-4: Reliability of Water Supply on Changes in Employment and Income in the Local Area because of Increased Water Supply Reliability	B, Reduced B, C, D	Beneficial	
Traffic			
TRAF-1: Temporary Construction-Related Increase in Traffic Volumes on Local and Regional Roadways	B, Reduced B, C, D	No	
TRAF-2: Potential Increase in Construction-Related Traffic Volume Delay and Hazard on Local and Regional Roadways	B, Reduced B, C, D	Yes	PSU-1b
TRAF-3: Potential Damage to the Roadway Surface during Construction	B, Reduced B, C, D	Yes	TRAF-1
TRAF-4: Potential Increase in the Demand for Parking Space at the Construction Site(s)	B, Reduced B, C, D	No	
Water Resources			
WQ-1: Degradation of Water Quality Resulting from Construction Runoff	B, Reduced B, C, D	Yes	WQ-1a, WQ-1b
WQ-2: Water Quality Effects from Construction-Related Dewatering	B, Reduced B, C, D	Yes	WQ-2
WQ-3: Potential Effects on Groundwater or Surface Water Quality from Recharge or Recovery Operations	B, Reduced B, C, D, Cumulative	No	MOCP, MROC
WQ-4: Potential Soil Salinization from Elevated Groundwater Levels (also in Section 3.6, *Geology*)	B, Reduced B, C, D	No	
WQ-5: Potential Erosion Attributable to Reversal of Flows in 24.2 Canal and Cottonwood Creek/Main No. 2 Canal	B, Reduced B, C, Cumulative	Yes	MOCP, MROC, WQ-1a, WQ-1b, WQ-2
WQ-6: Potential Erosion Attributable to Reversal of Flows in Gravelly Ford Canal	D, Cumulative	No	MOCP, MROC
Water Supply			
WS-1: Changes in Groundwater Supplies or Overdraft Rates in Madera County	B, Reduced B, C, D	Beneficial	
WS-2: Substantial Effects on Surrounding Groundwater Wells as a Result of Recovery Operations	B, Reduced B, C, D, Cumulative	No	MOCP, MROC
WS-3: Substantially Alter the Existing Drainage Pattern or Contribute to Existing Local or Regional Uncontrolled Flows	B, Reduced B, C, D, Cumulative	No	MOCP, MROC
WS-4: Adverse Effects on the Area of Origin of Water from Amendments to Existing Water Rights	B, Reduced B, C, D	No	
WS-5: Reduced Surface Water Availability in Madera County or the Area of Origin	B, Reduced B, C	No	
WS-6: Water Supply Reliability Improvement in Dry Years	B, Reduced B, C, D	Beneficial	

WS-7: Adverse Effects on the Area of Origin of Water from Amendments to Existing Water Rights	D	No	
WS-8: Reduced Surface Water Availability in Madera County or the Area of Origin	D, Cumulative	No	
Wetlands			
WET-1: Permanent Removal of Vernal Pools and Alkali Rain Pools during Construction, Operation, and Maintenance	B, Reduced B, C, D	Yes	BIO-2a, BIO-2b
WET-2: Other Wetland Effects during Construction, Operation, and Maintenance	B, Reduced B, C, D	No	
WET-3: Cumulative Loss of Wetlands	Cumulative		

MOCP = Monitoring and Operational Constraint Plan (Appendix D)
MROC = Madera Ranch Oversight Committee

Section 1 Introduction

For any proposed major Federal action, Federal agencies must comply with the National Environmental Policy Act (NEPA), including full disclosure of potential direct, indirect and cumulative impacts as well as avoidance, minimization and mitigation measures in response to those impacts. This Final Environmental Impact Statement (EIS) satisfies the requirements for compliance with NEPA. NEPA requires the federal government to use all practical means and measures, consistent with other essential considerations of national policy, to promote a healthy human environment. It establishes policy, sets goals, and provides means for carrying out the policy. NEPA encourages the wise use of natural resources by requiring that environmental factors be considered in federal agency decision-making. NEPA also enables the public, private organizations, state and local agencies, and Native American tribal governments to be involved in and informed about the decision-making process.

This Final EIS has been completed for compliance with NEPA by the Department of Interior, Bureau of Reclamation (Reclamation) as the Federal lead agency for the Madera Irrigation District (MID) Water Supply Enhancement Project (WSEP) in Madera County, California. This Final EIS is an informational document that must be used by Reclamation when considering a decision on the MID WSEP Proposed Action or an alternative. Reclamation's NEPA process involves circulation of the Final EIS for 30 days prior to issuing a Record of Decision (ROD) and taking action. The ROD will describe the decision, the alternatives considered, the environmentally preferable alternative, relevant factors considered in the decision, and mitigation and monitoring requirements.

Reclamation's action relevant to the WSEP is to approve the banking of MID Central Valley Project (CVP) water outside MID's service area in the proposed Madera Ranch WSEP, and the alteration of the 24.2 Canal, a Reclamation-owned facility, as proposed by MID and described in Section 2 of this document. Reclamation owns and operates the CVP, a system of 20 reservoirs and more than 500 miles of major canals and aqueducts. The CVP includes Millerton Lake, contained by the Friant Dam on the San Joaquin River, which provides a portion of MID's water supply.

The Draft EIS for the MID WSEP was distributed for public review and comment on July 24, 2009. This Final EIS includes response to comments received on the Draft EIS in accordance with 40 Code of Federal Regulations (CFR) 1503.4. This Final EIS also discusses an alternative not discussed in the Draft EIS known as the Reduced Alternative B which has been selected as the preferred alternative, also referred to as the Proposed Action. Reduced Alternative B represents a scaled-back version of Alternative B that uses fewer swales in order to minimize effects to vernal pools and limits the number of recharge basins to the number needed for the project to be practicable. It is included in the FEIS as a revision to Alternative B to allow the public to see how the project has been modified, demonstrate how effects have been reduced, and facilitate the Corps use of this document in their permitting of the project.

In accordance with 40 CFR 1501.6, the lead Federal agency shall request that any other Federal agency which has jurisdiction by law be a cooperating agency. In addition, the lead Federal agency will collaborate to the fullest extent possible, with all cooperating agencies concerning issues relating to their jurisdiction and special expertise. To meet this requirement, Reclamation invited and received assistance from the U.S. Fish and Wildlife Service (USFWS) and the U.S. Army Corps of Engineers (Corps) as cooperating agencies. Reclamation provided the Draft EIS to the cooperating agencies for their review and assistance. These agencies will also be provided the Final EIS before its circulation.

1.1 Background

MID encompasses an area of 128,292 acres and delivers water to its service area as part of the Hidden Unit (Fresno River) and Friant Division (San Joaquin River) Long-Term Water Supply contracts with Reclamation. MID operates and maintains a gravity irrigation distribution system of approximately 300 miles of open flow canal systems and 150 miles of pipelines. In addition to the services rendered to the lands within MID, the District conveys agricultural water to the Gravelly Ford Water District (GFWD). MID is also a member of the Madera-Chowchilla Water and Power Authority, which operates and maintains the Madera Canal under an agreement with Reclamation.

The vicinity of Madera Ranch west of the city of Madera, in Madera County, California has long been considered a viable area to operate a water bank because of the aquifer space availability, fast percolation rate, and other characteristics. Other entities have previously explored opportunities to develop a water bank in the area, but for reasons not relevant to this analysis, these proposals were not implemented. These previous efforts, however, presented opportunities from which to learn and were a basis for development of more viable options that ultimately have resulted in MID's current WSEP proposal. MID as the state lead agency approved the WSEP in accordance with the California Environmental Quality Act (CEQA) in September 2005, based on their Final Environmental Impact Report (EIR) (State Clearinghouse #2005031068).

At the time, there was no proposed Federal action. Reclamation commented on the Draft EIR, stating that once MID proposed a Federal action, Reclamation would need to complete and satisfy all NEPA and all other Federal requirements before approving any Federal action.

In November, 2010, MID also adopted its Supplemental EIR to address new information and changed circumstances since the WSEP was approved in 2005. The Supplemental EIR provided updated information on MID's water supply relevant to the San Joaquin River Restoration settlement; updated information and analysis of impacts regarding bank participants, including 10,000 acre-feet (AF) of municipal and industrial (M&I) water users and 10,000 AF of water allocated to environmental users; and updated information and analysis of impacts on biological resources and new mitigation measures to protect biological resources, including special-status species and sensitive natural communities.

The Draft EIS was initiated in response to MID's request that Reclamation approve the banking of MID CVP water outside MID's service area in the proposed WSEP, and the modification of the 24.2 Canal, a federal facility.

The Draft EIS evaluated the potential environmental impacts of the No Action Alternative; Banking CVP Water Outside of the MID Service Area Using Swales and Alteration of Reclamation-owned Facilities; Banking CVP Water Outside the MID Service Area without Swales and Alteration of Reclamation-owned Facilities; and Banking CVP Water Outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal (no alteration of Reclamation-owned Facilities).

MID has been working toward securing federal funds to assist in the cost of purchasing Madera Ranch and construction of the WSEP. In March 2009, Omnibus Public Land Management Act of 2009 (Public Law 11-111; H.R. 146-308) became law. Section 9102 of the law includes the WSEP and thus, has been authorized by the U.S. Congress and is eligible for federal funding. MID is pursuing funding through the appropriations process. MID will continue to pursue additional federal grants.

1.2 Proposed Action

On completion of the Proposed Action MID would bank a portion of their CVP water from the San Joaquin and Fresno Rivers and other non-CVP water in the aquifer underlying Madera Ranch. Water would be banked in the aquifer, and 10% of the water would be left behind to reduce overdraft. The Proposed Action (Reduced Alternative B) would involve two phases. Phase 1 would involve constructing necessary delivery infrastructure improvements (except for the Section 8 canal southwest extension), using select natural swales for recharge (550 acres versus 700 acres as proposed under Alternative B), and installing approximately five soil berms to direct recharge flows. Phase 2 would involve constructing a limited number of recharge basins (323 acres versus up to 1,000 acres under Alternative B) and facilities for recovery of banked water.

Reclamation would approve banking of CVP water outside the MID service area and alteration of Reclamation-owned facilities. Similar to Alternative B, Reduced Alternative B may include funding by Reclamation, under the Omnibus Public Land Management Act of 2009, the Policy and Program Services, Challenge Grant Program: Recovery Act of 2009 Water Marketing and Efficiency Grants, or any other funding source. Regardless of whether this funding is acquired, the project components and associated effects would be the same. A complete description of the Reduced Alternative B can be found in Section 2.

1.3 Purpose and Need

Currently, farmers in MID's service area use a combination of groundwater and surface water. During dry years there is not adequate surface water to meet the water demand and groundwater pumping increases substantially. The amount of groundwater that has been pumped from the aquifer in the vicinity of Madera Ranch has exceeded the amount of water that has recharged the aquifer, resulting in groundwater overdraft. Even in wet years, the groundwater basin is in severe overdraft because groundwater pumping is steadily increasing for agricultural use as well as M&I use. This overdraft has caused the water table to decline and groundwater quality to degrade and has resulted in excess space in the aquifer that could be used to bank surface water.

In the vicinity of Madera Ranch, the water table has declined more than 90 feet over the last 60 years. These conditions have made it increasingly expensive for farmers to pump groundwater. Additionally, in many years, MID has been unable to deliver sufficient surface water to farmers because water is available primarily during the early months of the year when irrigation demand is low, and often water is available only for short periods of time during the growing season.

The purpose of the proposed Federal action is to:

- enhance water supply reliability and flexibility by using the excess aquifer space for surface water storage (water banking);
- reduce existing and future aquifer overdraft;
- reduce groundwater pumping costs;
- increase groundwater quality;
- encourage conjunctive use in the region as a means toward regional self-sufficiency.

1.4 Applicable Regulatory Requirements and Required Coordination

This EIS is intended to fulfill the requirements of NEPA (42 United States Code [U.S.C.] §§ 4321-4370d) and the following statutes:

- Bald and Golden Eagle Protection Act (BGEPA), 16 U.S.C. §§ 668-668d, June 8, 1940, as amended 1959, 1962, 1972, and 1978.
- Clean Air Act (CAA), as amended, 42 U.S.C. §§ 7401-7671p, including 1990 General Conformity Rule;
- Clean Water Act (CWA), 33 U.S.C. §§ 1251-1387;
- Endangered Species Act (ESA), 16 U.S.C. §§ 1531-1544;
- Executive Order (EO) 11988 – Floodplain Management
- EO 11990 – Protection of Wetlands;
- EO 13007 – Indian Sacred Sites
- EO 13112 – Invasive Species; and
- EO 13186 – Migratory Birds
- EO 12898 – Environmental Justice;
- Farmland Protection Policy Act
- Federal Flood Insurance Program
- Memoranda on Farmland Preservation
- Migratory Bird Treaty Act (MBTA), 16 U.S.C. § 703 et seq.;
- National Historic Preservation Act (NHPA), 16 U.S.C.§§ 470-470x-6;

1.5 Public Involvement

- Reclamation published a Notice of Intent to prepare an EIS for the MID WSEP Proposed Action in the *Federal Register* on September 28, 2007.
- Reclamation held scoping meetings on October 22 and October 29, 2007 at MIDs offices. Before the meetings, public notices were posted at MID's offices and published in the *Madera Tribune* and the *Fresno Bee* announcing the time, date, location and purpose of the meetings. Each scoping meeting included an overview of the meeting's purpose, the proposed project and alternatives, potentially significant environmental issues, and opportunities for future public involvement.
- Pursuant to NEPA, the Draft EIS was made available for a 60-day public review period from July 24, 2009 to September 25, 2009. A notice of availability of the Draft EIS was published in the *Federal Register* July 27, 2009.
- To provide the public with opportunities to submit verbal and written comments on the Draft EIS, a public meeting was held during the Draft EIS circulation period at the MID Office, 12152 Road 28¼, Madera, California on August 27, 2009. The public comment period on the Draft EIS closed September 25, 2009. Written comments were received from two federal agencies, three state agencies, and four other entities.
- NEPA requires agencies to respond to comments on the Draft EIS that are received during the public comment period (President's Council on Environmental Quality (CEQ) Regulations for Implementing NEPA Section 1503.4). This document has been prepared pursuant to these requirements. Reclamation has considered all the comments received on the Draft EIS and has incorporated changes to Proposed Action based on comments received. Changes are denoted by a line on the right side of the document.

Details for the public outreach process are described in Section 4.

1.6 Regulatory Requirements

Permits and approvals would be required for the Proposed Action from a number of agencies as summarized in Table 1-1.

Table 1-1 Permits/Approvals Required

Agency	Permit/Approval
U.S. Army Corps of Engineers	Section 404 of the CWA permit
U.S. Fish and Wildlife Service	Section 7 of the ESA consultation
Bureau of Reclamation	MP620 permit (a Reclamation Mid-Pacific Region-specific permit issued for additions or alterations to Reclamation-owned conveyance and distribution facilities)
State Historic Preservation Office	Section 106 of the NHPA review
Regional Water Quality Control Board	Section 401 of the CWA certification; General Permit for Storm Water Discharges Associated with Construction Activity (CWA Section 402)
California Department of Fish and Game	Streambed Alteration Permit

THIS PAGE INTENTIONALLY LEFT BLANK

Section 2 Alternatives

2.1 Introduction

A Reduced Alternative B is included in this section. It is now the Proposed Action and is the result of a coordinated effort with the Corps, U.S. Environmental Protection Agency (EPA), USFWS, California Department of Fish and Game (DFG), MID and Reclamation to reduce overall environmental impacts. This alternative would use fewer swales and fewer basins than Alternative B.

This section provides a summary of the alternative screening process; a description of the Proposed Action, the three action alternatives, and the No Action Alternative. This chapter also provides a comparative evaluation of the potential environmental effects of the alternatives; and identifies the preferable alternative. The five alternatives analyzed in detail in this EIS are:

- Alternative A—No Action;
- Alternative B Banking water Outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities;
- Reduced Alternative B (Proposed Action)—Banking CVP water Outside the MID Service Area Using Select Swales and Alteration of Reclamation-Owned Facilities;
- Alternative C—Banking CVP water Outside the MID Service Area Without Swales and Alteration of Reclamation-Owned Facilities; and
- Alternative D—Banking CVP water outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal (no alteration of Reclamation-Owned Facilities).

2.2 Alternative A – No Action

Under the No Action Alternative, MID would not bank MID CVP water (MID Long-Term Water Service Contract supplies from both the Friant Division and Hidden Unit on Madera Ranch) and Reclamation's delivery canals would not be enlarged (Figure 2-1). The No Action Alternative also excludes any funding by Reclamation, that would be available to the action alternatives, under the Omnibus Public Land Management Act of 2009, the Policy and Program Services, Challenge Grant Program: Recovery Act of 2009 Water Marketing and Efficiency Grants, or any other funding source.

MID may bank non-CVP water via a Warren Act contract with Reclamation on the property, and other limited on-site water banking and recovery facilities may be constructed if MID is able to find participants and funding to support these efforts. MID estimates that under the No Action Alternative, MID could only apply up to 5,000 AF per year (AF/year) of their own non-CVP water, and recovery operations likewise would be limited if Reclamation-owned facilities were not altered. The number of other participants and amount of water they could bring to the project is uncertain. Many participants, even if they bring their own supplies, also would have to obtain Reclamation's approval because banking of CVP water outside CVP contractor's service areas, transfers or exchanges of CVP water would be needed to deliver the water to the property and to recover it. Therefore, without the ability to bank MID CVP water outside MID's service area, the project likely would be infeasible for MID. MID's customers would be subject to continued water supply uncertainty and higher water costs because of a reduced supply and ongoing groundwater overdraft conditions.

If the Proposed Action does not proceed, MID likely would sell the property to other agricultural interests. MID has had numerous offers from prospective buyers, including dairy, orchard, and row crop farmers. The No Action conditions would continue to support agricultural activities. However, the type and extent of the activities are uncertain at this time. Future owners would be subject to compliance with all applicable Federal, State and local laws and regulations and any associated permits and/or approvals.

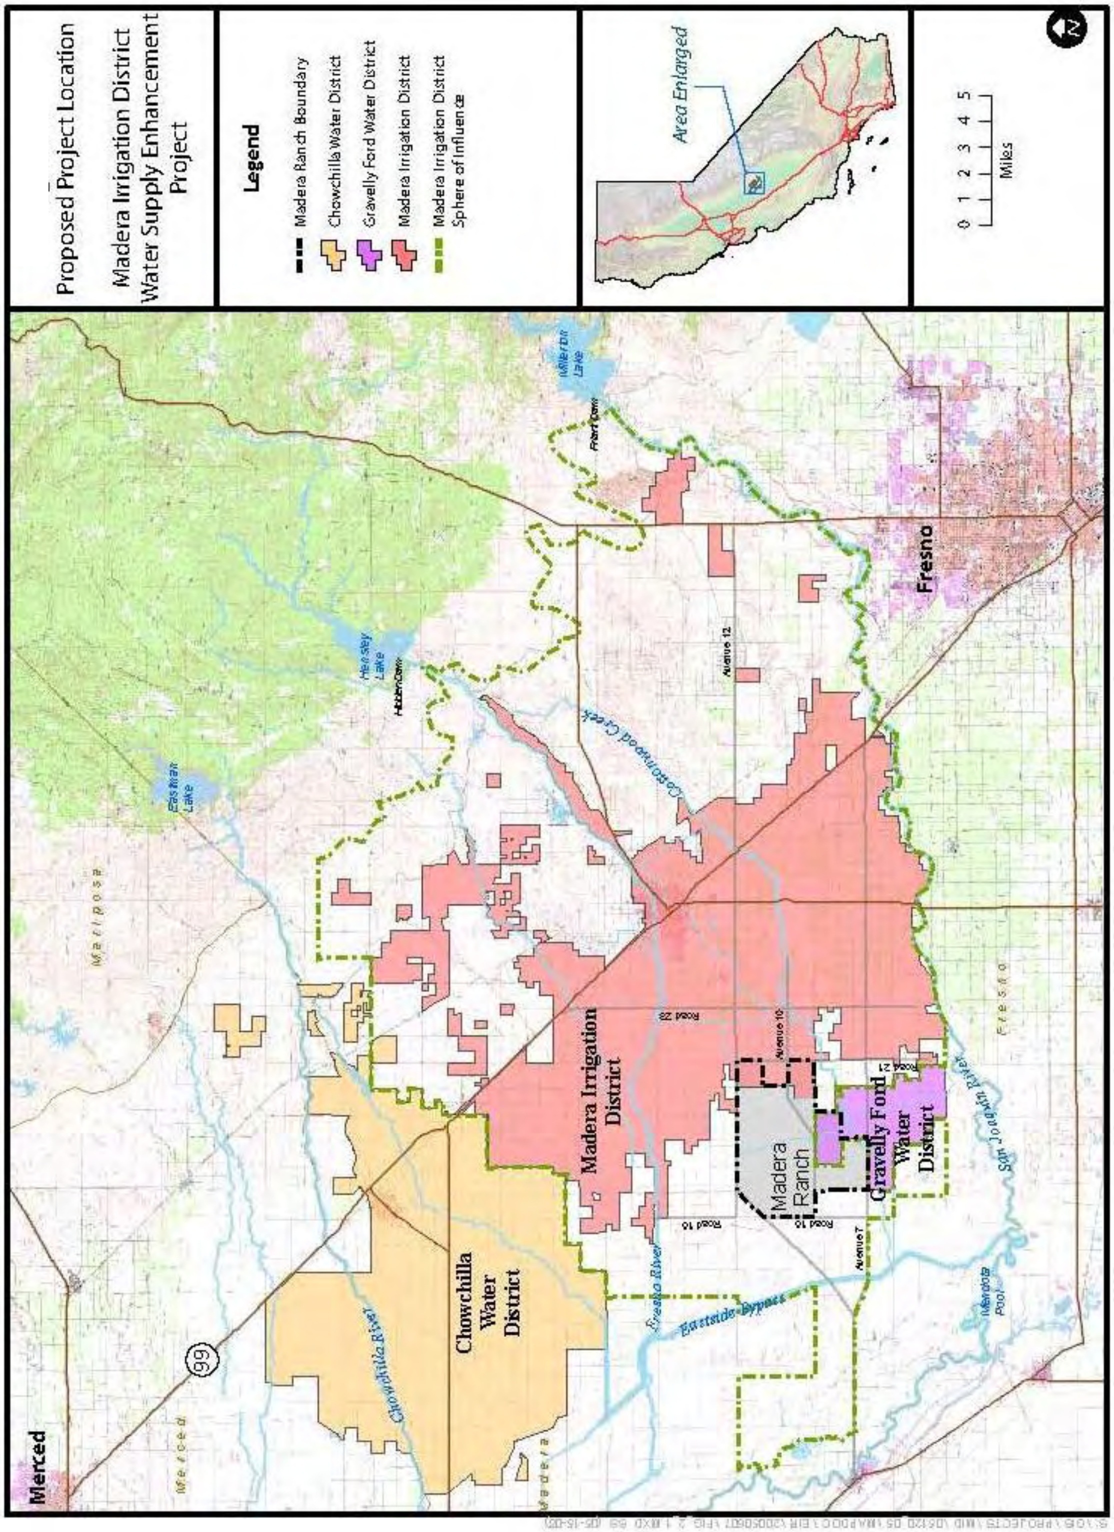

Figure 2-1 Proposed Project Location

2.3 Alternative B – Water Banking Outside MID Service Area Using Swales and Alteration of Reclamation-owned Facilities

Alternative B would be completed in two phases. Phase 1 would involve only recharge-related facilities. Phase 2 would involve supplemental recharge facilities and facilities for recovery of banked water. Reclamation would approve a total banking capacity of up to 250,000 AF of MID CVP water outside the MID service area and issuance of an MP-620 permit (a Reclamation Mid-Pacific Region-specific permit issued for additions or alterations to Reclamation-owned conveyance and distribution facilities) for alterations to Lateral 24.2. After alteration of the Reclamation-owned facilities (Lateral 24.2) and certain MID facilities, MID would be able to recharge and recover a maximum of 55,000 AF annually.

Alternative B also includes funding by Reclamation. MID has been working toward securing federal funds to assist in the cost of purchasing Madera Ranch and construction cost. In January 2009, the U.S. Congress passed the ―Omnibus Public Land Management Act of 2009" (Public Law 11-111; H.R. 146-308). Section 9102 of the Omnibus bill includes the ―Madera Water Supply Enhancement Project, California." Thus, the WSEP has been authorized by the U.S. Congress and is eligible for federal funding in the next budget cycle, in 2011. MID is currently pursuing federal funding through the appropriations process. In addition, MID pursued a grant award through Reclamation's Policy and Program Services, Challenge Grant Program: Recovery Act of 2009 Water Marketing and Efficiency Grants. The grant was not funded. Alternative B components and associated effects would be the same under various funding scenarios.

2.3.1 Phase 1

MID would implement Phase 1 to increase the capacity of existing MID conveyance facilities to deliver water to Madera Ranch facilities. Phase 1 would use primarily natural swales as recharge areas. Phase 1 activities would involve:

- reconditioning and extension of canals to provide at least 200 cubic feet per second (cfs) of conveyance capacity into Madera Ranch;
- construction of approximately 55 acres of recharge basins on current agricultural land to regulate flow, remove sediment, and provide some recharge;
- application of recharge flows to approximately 700 acres of swales; and
- integration of approximately 2,600 acres of Madera Ranch row crops and vineyards into an in-lieu recharge program in which surface water periodically would be served in lieu of groundwater pumping subject to approval by the Madera Ranch Oversight Committee (MROC).

Diversion and Conveyance Facilities

Figure 2-2 depicts the locations of existing canals in the vicinity of Madera Ranch.

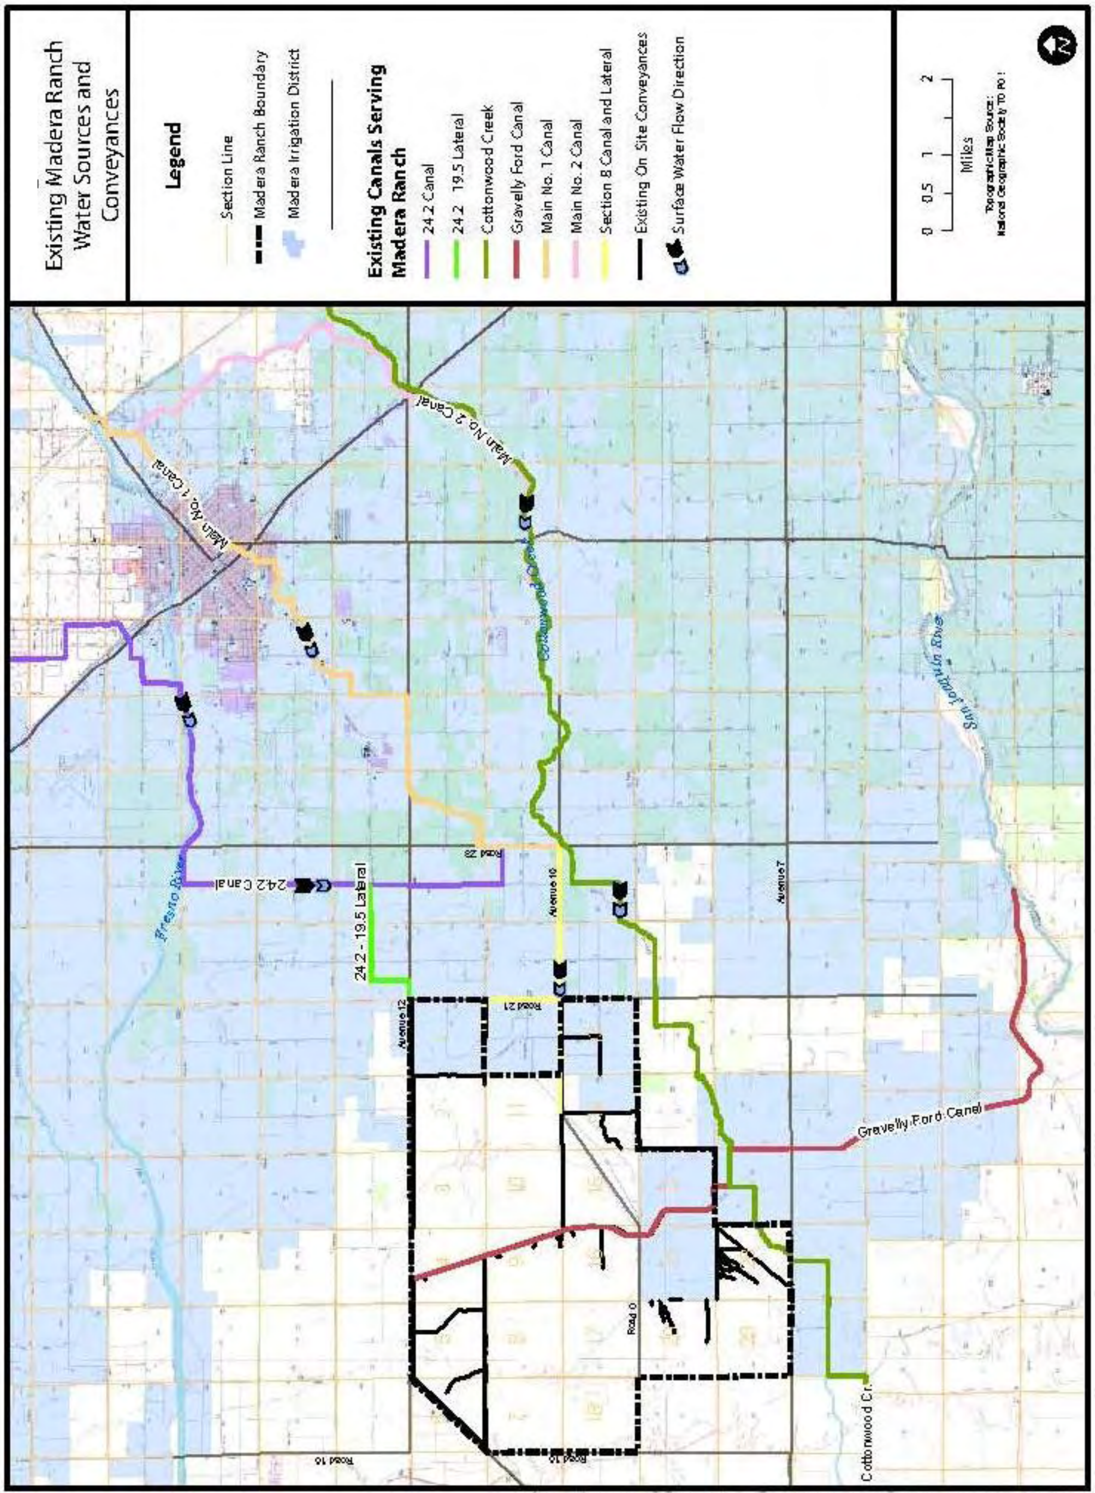

Figure 2-2 Existing Madera Ranch Water Sources and Conveyances

Upgrades to Existing Canals

During Phase 1, MID would upgrade canals to enable gravity delivery of at least 200 cfs into Madera Ranch. Upstream portions of Cottonwood Creek, the 24.2 Canal and the Main No. 1 Canal collectively provide more than 200 cfs of gravity feed conveyance capacity above MID's normal service needs during nonpeak irrigation months, and lesser amounts of capacity during peak irrigation months. However, the portions of these conveyances and the Section 8 Canal within two miles of the ranch are undersized, causing a bottleneck such that the capacity to deliver water to the ranch is less than 100 cfs. Specifically, the confluence of Cottonwood Creek, the Main No. 1 Canal, and the Section 8 Canal, approximately two miles east of the ranch, has a capacity of less than 100 cfs. In addition, the Section 8 Canal running from this confluence into the ranch has a capacity of less than 50 cfs, and the 24.2 Canal, 1.5 miles from the ranch, also has a capacity of less than 50 cfs and does not tie into the Section 8 Canal.

The following sections summarize how these and other conveyances would be upgraded to provide up to 200 cfs delivery capacity to and from Madera Ranch.

Reclamation Conveyance Facilities

MID would extend the Reclamation-owned earthen 24.2 Canal approximately 0.75 mile south to connect with the Section 8 Canal (Figure 2-3). The connector would be a buried pipeline, not an open canal. In addition, approximately 1.75 miles of the southern portion of the existing 24.2 Canal would be widened and deepened to accommodate 100 cfs of flow. In total, the extension pipeline and canal enlargement would involve moving approximately 36,000 cubic yards (cy) of soil. MID would acquire additional easements and fee title for canal expansion.

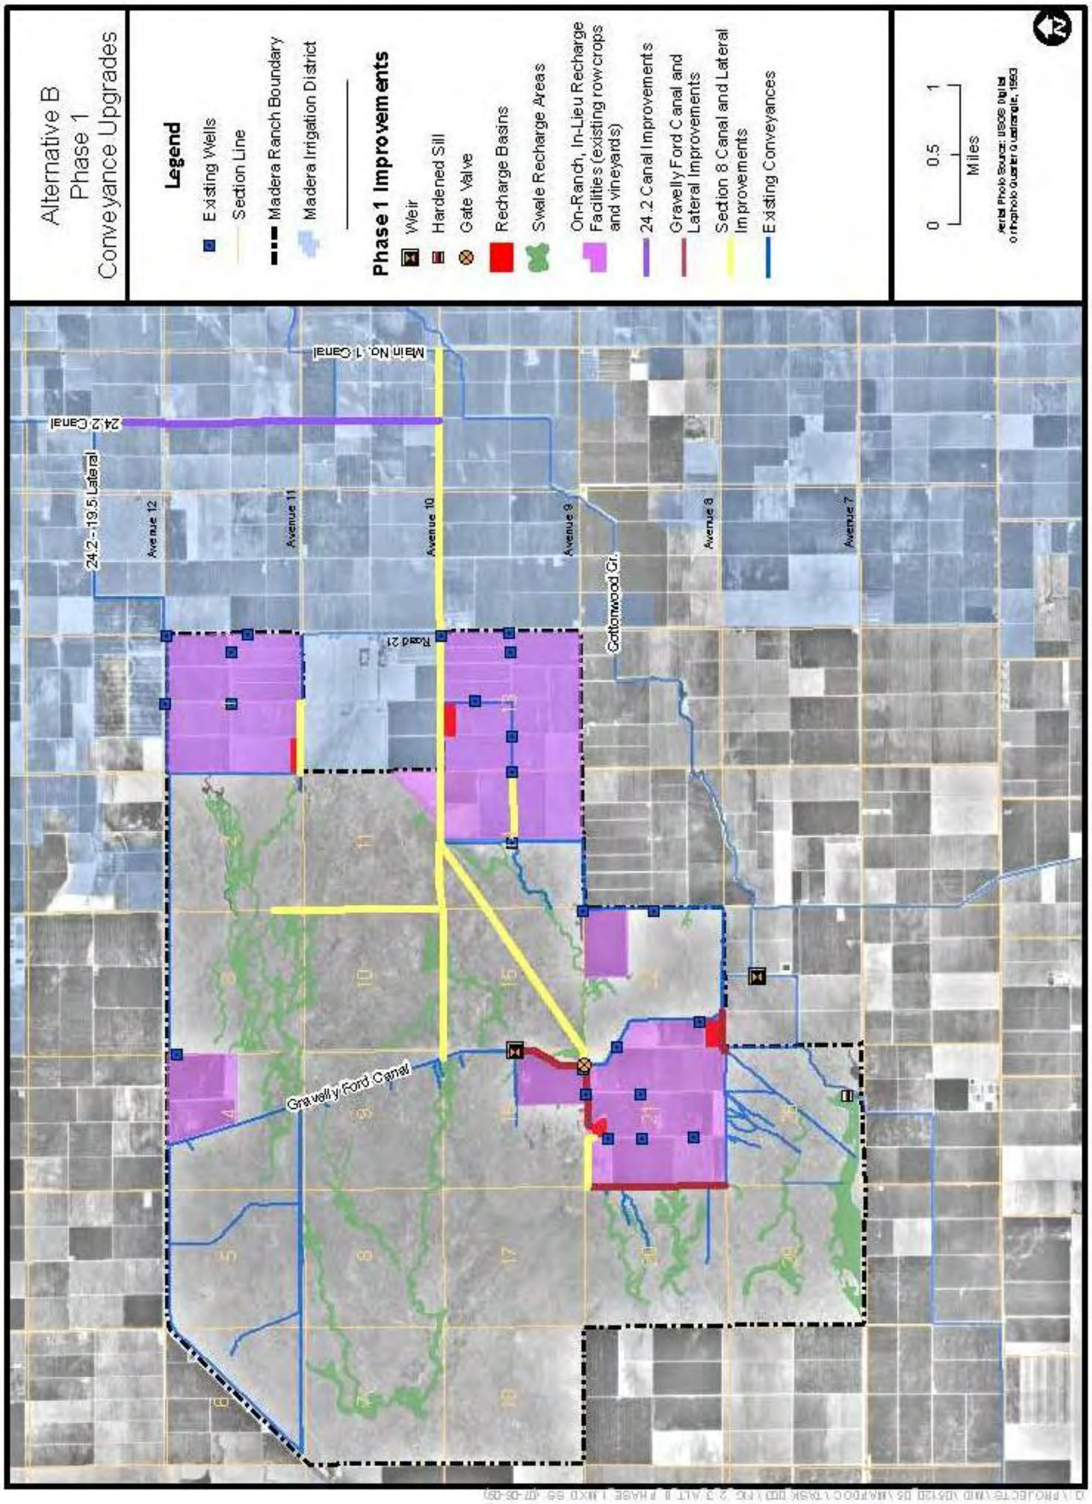

Figure 2-3 Alternative B Phase 1 Conveyance Upgrades

MID Conveyance Facilities

Section 8 Canal, Cottonwood Creek, and Main No. 1 Canal Connection Upgrade The existing connection between the Section 8 Canal (an earthen ditch built in the late 19th century), Cottonwood Creek, and Main No. 1 Canal would be widened and deepened to accommodate 100 cfs of flow. Only the connection would be widened; Cottonwood Creek would not be widened as its capacity is sufficient to meet the needs of the alternative. Work would be performed in an approximately 500-foot-long and 100-foot-wide area, requiring a temporary construction easement of 1.2 acres from neighboring landowners. No new permanent easements would be required.

Section 8 Canal Upgrade An approximately 1.75-mile segment of the earthen Section 8 Canal (from Road 23 to within approximately 0.25 mile of the Madera Ranch boundary at Road 21) would be reconstructed to expand from one-way, 50-cfs capacity to two-way (flat bottomed), 200-cfs capacity (Figure 2-3). The 1.75-mile segment of the canal from 0.25 mile east of the ranch, along the north side of Section 13 and to the western edge of ranch row crop land on the north side of Section 14, would be replaced with an approximately 1.75-mile-long, 84-inch reinforced concrete pipe (RCP), 200-cfs (two-way) pipeline placed within the channel of the existing canal.

During construction, Avenue 10 would be closed temporarily (local traffic only) to allow work on the canal. To expand the canal, an additional 40-foot corridor would be required, for a total of 8.9 acres of easement or fee simple ownership. The last 0.25 mile of the west end of the canal off-ranch would be carried in concrete pipe buried in the existing canal such that additional right-of-way would not be needed. A 40-foot-wide temporary construction easement may be required for this last 0.25 mile off-ranch (resulting in an easement of 1.2 acres). In total, this reconstruction involves moving approximately 76,000 cy of soil.

Section 8 Canal Western Extension A new, approximately 1.55-mile-long, 50 to 60-cfs earthen ditch would be constructed within a paved road in Sections 14 and 15 from the new Section 8 Canal pipeline to the Gravelly Ford Canal (GF Canal). The ditch would be constructed within the existing leveled shoulder (Figure 2-3). In total, this construction involves moving approximately 18,000 cy of soil.

Section 8 Canal Southwestern Extension Sections 14 and 15 are bisected diagonally by a 30- to 40-foot-wide, dirt farm road that was previously a ditch. A new approximately 1.8-mile-long, 20-cfs earthen ditch would be constructed from the new Section 8 Canal pipeline, along the shoulder of this road and to the GF Canal (Figure 2-3).

Section 8 Canal Northern Extension Sections 10 and 11 are divided by a 20- to 40-foot-wide dirt farm road bordered by the remnants of a ditch. A new approximately 1.2-mile-long, 20- to 50-cfs earthen ditch would be constructed along the alignment of the old ditch (Figure 2-3). In total, this construction involves moving approximately 14,000 cy of soil.

Section 8 Canal Section 14 Lateral Extension An existing Section 8 Canal lateral (20 cfs) that flows across Section 13 would be extended approximately 0.5 mile across Section 14 (Figure 2-

3). All work would be performed along the edge of row crop land. In total, this construction involves moving approximately 2,800 cy of soil.

Section 8 Canal Section 1 Lateral Extension An existing Section 8 Canal lateral (20 cfs) that flows east-west along the southern side of Section 1 would be extended approximately 0.5 mile to the southwestern corner of Section 1 (Figure 2-3). All work would be performed along the edge of row crop land.

Gravelly Ford Canal Sedimentation Basin and Flow Regulation Area With GFWD's permission, an approximately 3,000-foot-long segment of the GF Canal on the southeastern side of Section 16 would be equipped with a weir/control structure on the north side to allow use of the channel as a combined recharge area, sedimentation basin, and flow regulation area.

Gravelly Ford Canal Flow Control Weir at Cottonwood Creek With GFWD's permission, a new weir would be installed on the GF Canal approximately 1,000 feet south of Section 22 where the canal intersects and shares a channel with Cottonwood Creek. All work would be performed in the existing artificial channel and on adjacent farm roads.

Gravelly Ford Canal Section 21 Northern Lateral A new approximately 0.45-mile-long, 20- to 50-cfs earthen ditch would be constructed along the northern side of Section 21 from the GF Canal to a Phase 1 recharge basin located on farmland (Figure 2-3).

Gravelly Ford Canal Section 21 Western Lateral A new approximately 1-mile-long north/south canal would be constructed along the western side of Section 21 off of an existing 20- to 50-cfs earthen ditch bordering the southern side of the section. The new canal would be constructed on the shoulder of a dirt farm road bordering row crop land in Section 21 (Figure 2-3).

Gravelly Ford Canal Section 22 Southern Lateral A new approximately 0.28-mile-long, 20- to 50-cfs earthen ditch would be constructed along the southern side of Section 22 from the GF Canal to an existing ditch (Figure 2-3).

Cottonwood Creek Overflow Improvements A hardened sill (compacted or armored material with low potential for erosion) would be constructed on the existing Cottonwood Creek berm to protect the berm and to accommodate flow measurements. Sections 28 and 29 are inundated by Cottonwood Creek uncontrolled flows regularly during wet springs. These uncontrolled flows generally are prevented from flowing onto Avenue 7 by an earthen berm that runs along the southern boundary of Section 28 and north along the western boundary of Section 29.

Reconditioning of Existing Canals and Ditches Reconditioning would involve reconditioning GF Canal (described below), replacement of turnout gates (described below), brush removal, repair of berms that have been worn down over time, reconstruction of segments that have been filled by recent farm operations, and installation of farm road crossings as required.

Gravelly Ford Canal GF Canal is an earth-lined flat-bottom channel that conveys irrigation water from the San Joaquin River to Madera Ranch. Project elements affecting GF Canal include:

- Construction of a new weir structure and lift station (GF Canal sedimentation basin and flow regulation area as described above);
- Grading approximately 2.6 miles of the canal back to original design contour and capacity;
- Installing approximately three to five new turnouts;
- Replacing approximately two to three old turnouts; and
- Installing one flow monitoring station.

Gravelly Ford Canal Reconditioning GF Canal would be reconditioned north of the new weir and lift station to Avenue 12 (2.6 miles). Material that has eroded from the banks and settled in the bottom of the canal would be used to reform the banks of the canal. A grader and scraper would be used in the canal bottom to recontour the canal. Approximately 16,000 cy of dirt would be moved to reshape the existing berms of the canal.

Gravelly Ford Turnouts Approximately two new east berm turnouts would be installed to deliver water into the recharge areas. Three west berm turnouts would be replaced and three new west berm turnouts would be constructed (one to a recharge basin in agricultural lands, one gate structure to a new lateral canal system constructed in uplands, and one to an upland recharge areas). A flow monitoring station would also be installed. Each turnout is approximately 3-feet wide by 6-feet long by 6-feet tall and is/would be buried in the existing banks of the canal. The turnouts are constructed off-site at MID headquarters. Construction of the turnouts would require excavating approximately 32 cy of soil and the addition of 3 cy of fill material to install a gate and compact the soil adjacent to it.

Recharge Facilities

Recharge Basins Phase 1 would involve construction of approximately 55 acres of basins, approximately two basins that are 1,100 feet square, as shown in Figure 2-3 on agricultural land in order to:

- help regulate flows,
- allow settling of sediments before application of water to swales, and
- provide some recharge capacity.

The preliminary locations of four Phase 1 recharge basins are entirely on current agricultural land in Sections 1, 13, 21, and 22. The basins would be designed with 1.5:1 to 2:1 interior side slopes and average depths of four to five feet and surrounded by low earthen dikes created from the dirt excavated from the basin. Construction of the Phase 1 recharge basins could involve the movement of approximately 444,000 cy of soil.

Swale Recharge Areas Alternative B would entail diversion of water into approximately 700 acres of swales. The water would be conveyed to Madera Ranch through the existing and upgraded MID conveyances and to the swales through the existing, rehabilitated, and new ditches described above. At the head of each swale, a manually operated farm turnout (equipped with a gate valve and totalizing flow meter) would be installed to regulate and measure the flow into each swale. Several turnouts currently exist on GF Canal and these would be replaced and several new ones would be added. Flows at each turnout, based on pilot studies, would be no greater than 20 cfs and would average five cfs at the turnout. Maximum overall flows would be around one cfs per acre of application. Locations of the swales anticipated to be used during Phase 1 are depicted on Figure 2-3.

In-Lieu Recharge Facilities Madera Ranch includes 2,666 acres of row crops and vineyards that are irrigated entirely by a system of 23 wells. MID would recondition existing turnouts and install new turnouts under the Alternative B canals, pipelines, and ditches to enable delivery of surface water to these fields in lieu of groundwater pumping (Madera Irrigation District 2008*)*.

These agricultural fields were purchased from MID in July 2008 by Grimmway Enterprises, Inc. Grimmway will continue to manage the property for agricultural uses. However, MID has retained rights to existing and future easements that would allow this Alternative to be implemented.

2.3.2 Phase 2

Phase 2 would expand the areas used to recharge, develop wells and piping to recover the banked water, and install pumps to deliver the recovered water as shown in Figures 2-4 and 2-5.

Phase 2 activities for recharge and recovery facilities would involve:

- additional upgrades to existing canals,
- construction of up to 1,000 acres of new on-site recharge basins and canals as required to supplement Phase 1 facilities and achieve 200 cfs of recharge capacity (if required),
- use of up to 15 existing wells for recovery,
- installation of up to 49 new wells and recovery pipelines (in phases over several years) to provide 200 cfs of recovery capacity, and
- installation of up to 12 lift stations on MID canals and one lift station on GF Canal (in phases over several years) to provide 200 cfs of pump-back capacity into the MID service area.

Upgrades to Existing Canals

Section 8 Canal Southwestern Lateral Upgrade The 20- to 50-cfs, Phase 1 earthen canal running diagonally across Sections 14 and 15 would be partially replaced with an approximately 1.75-mile-long, 72-inch to 84-inch RCP, 135- to 200-cfs (two-way) buried pipeline. The pipeline would extend from the Phase 1 Section 8 Canal upgrade (200-cfs pipeline) to the GF Canal beneath an existing 30- to 40-foot-wide dirt farm road (Figure 2-4).

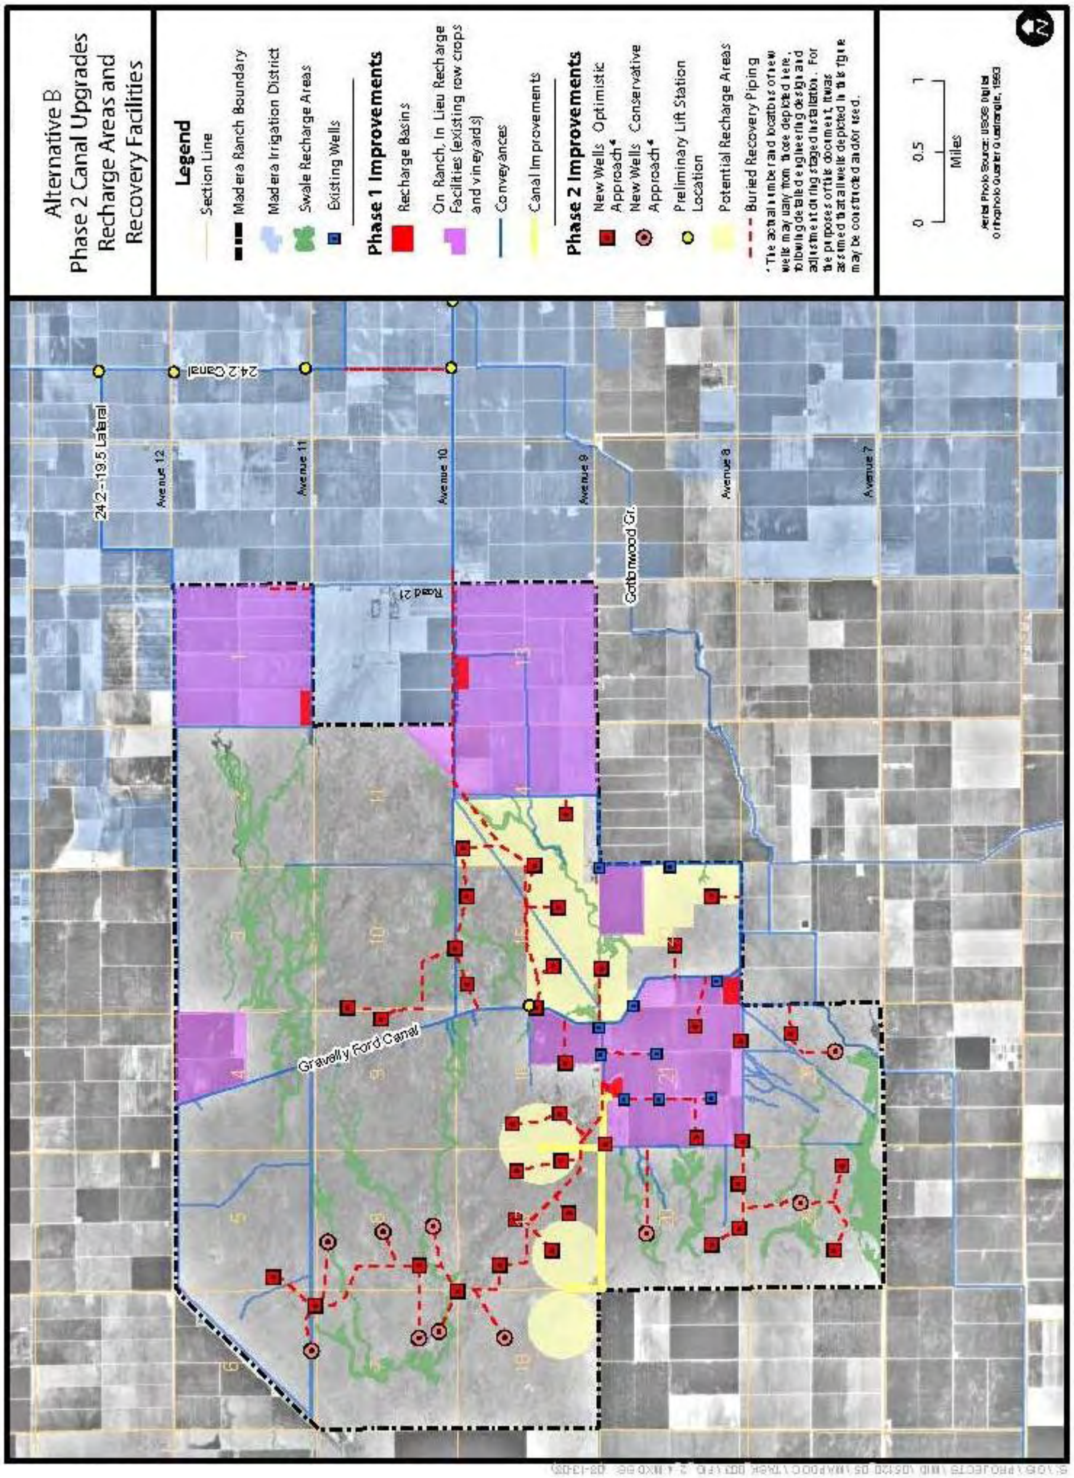

Figure 2-4 Alternative B Phase 2 Canal Upgrades, Recharge Areas, and Recovery Facilities

Gravelly Ford Canal Section 21 Northern Lateral The 0.45-mile-long Phase 1 ditch along the northern side of Section 21 would be replaced with an approximately 2.1-mile-long, 135-cfs, east-west earthen lateral canal along the north side of Sections 21 and 20 with two north-south sub-lateral canals running northward along the east and the west sides of Section 17.

Depending on the recharge basin acreage and construction methods up to 3.2 miles of 20- to 100-cfs earthen ditches would be constructed within the Phase 2 recharge basin area to distribute water into recharge areas.

Recharge Facilities

Depending on the performance of Phase 1 recharge facilities, up to approximately 1,000 acres of recharge basins may be constructed within a 1,300-acre area. Following pre-construction surveys as outlined in the Environmental Commitments, MID would begin construction of the basins. The following steps to construct recharge basins may occur, but would be dependent on final agency permits.

- *Stage 1:* Berming of recharge area boundaries along topographic contours using farm roads wherever possible and farm grading techniques, but no excavation (similar to unleveled rice fields).
- *Stage 2:* Deep ripping of corridors within the bermed areas, interspersed with corridors of undisturbed land.
- *Stage 3:* Excavation of basins varying from four to five feet deep.

The final number of recharge basins constructed and techniques summarized above is uncertain, and the highest estimated acreage is highly unlikely to be required. This EIS evaluates the potential effects associated with up to 1,000 acres of excavated basins. Recharge basins would be clustered in sets of three or four varying in size from 5 to 80 acres, with the first basin constructed in each set serving as both a settling and a recharge basin.

Construction of the recharge basins and internal routing ditches could involve the moving of up to approximately 7.7 million cy of soil. Basins would be designed with 1.5:1 to 2:1 interior side slopes and average depths of four to five feet. Low earthen dikes would be constructed around the recharge basins using excavated materials. Topsoil would be segregated during excavation and respread over the berm and construction disturbance areas to promote reestablishment of vegetation.

Recovery Facilities

Recovery Wells Banked water would be recovered using up to 15 existing wells and approximately 49 new wells, as shown in Figure 2-4. Wells would be placed, whenever possible, at locations that could be accessed by existing farm roads and at least 0.25 mile within the interior of the Madera Ranch boundary. The wells would be connected via a manifold to a buried pipeline, and a canal and lift station system would deliver the water back to MID.

Recovery Pipelines and Electrical Facilities Up to 11.6 miles of 8-inch- to 60-inch-diameter polyvinyl chloride (PVC) to RCP buried recovery pipelines, as shown in Figure 2-4, would run from recovery wells to the GF Canal and the Section 8 Canal for delivery back to farmers. The recovery pipelines would be buried 2–3 feet beneath the ground surface. Electrical lines servicing the electrical well pumps would be placed in the same trenches as the recovery pipelines to minimize disturbance and to ensure that all electrical lines are placed below grade. The recovery pipelines would be constructed during the same stage of project development as the well construction.

Recovery Lift Stations The MID delivery system is currently all gravity feed from east to west. In order to deliver up to 200 cfs from the recovery wells to MID's customers, up to 13 lift stations would be required on the same conveyances used to deliver water into the water bank, as depicted in Figure 2-5.

- *Stage 1:* One lift station would be constructed along the GF Canal to pump water recovered from wells on the west side of Madera Ranch. Four lift stations with capacity stepping downward from approximately 100 cfs to 80 cfs would be constructed on the 24.2 Canal.
- *Stage 2:* Six lift stations with capacity stepping downward from approximately 100 cfs to 80 cfs would be constructed on Cottonwood Creek and Main No. 2 Canal.
- *Stage 3:* After several years of operation, up to two additional lift stations may be added to the upper reaches of the Main No. 2 Canal as dictated by the required additional level of delivery.

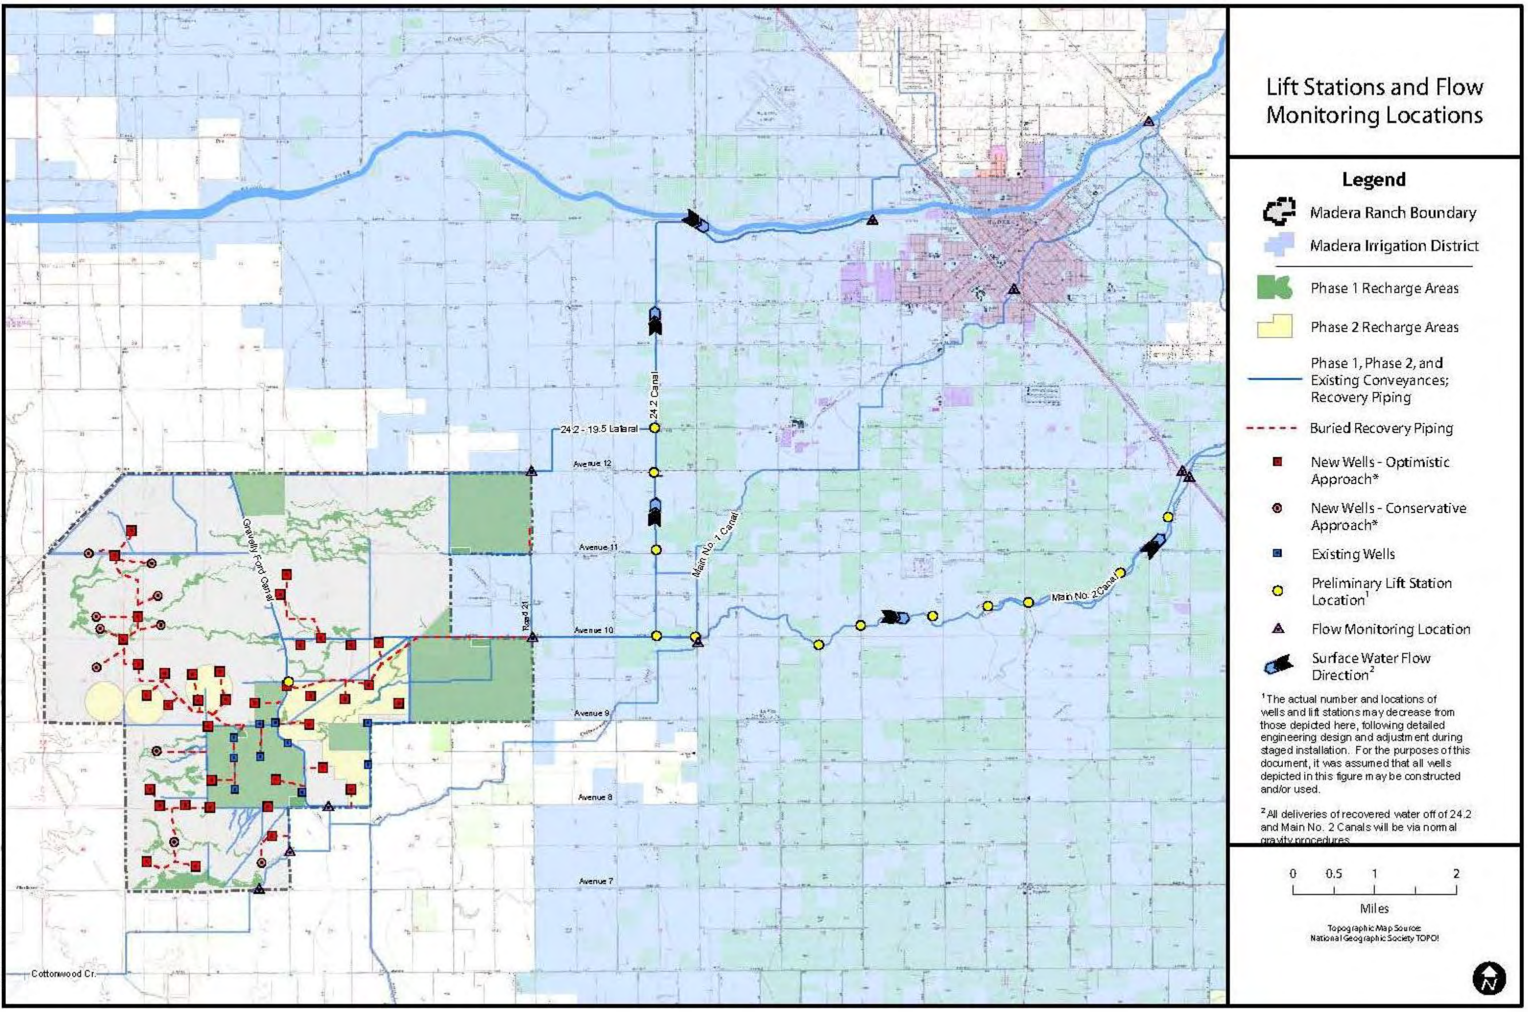

Figure 2-5 Lift Stations and Flow Monitoring Locations

2.3.3 Construction

The following construction activities would be similar for all action alternatives unless specified under a particular alternative.

Conveyance Facilities

Upgrade of Section 8 Canal, Cottonwood Creek, and Main No. 1 Canal Connection   The connection between the Section 8 Canal, Cottonwood Creek, and Main No. 1 Canal would be widened and deepened to accommodate 100 cfs of flow. Upgrading the connection would involve the following steps:

1. Draining the canals.
2. Excavating mud or silt from the bottom of the canals, and storing the wet material on site or transporting it to a storage site.
3. Excavating the canals to a sufficient width and depth to provide adequate capacity.
4. Transporting the excavated material to Madera Ranch for use as fill required by other proposed construction.
5. Installing piping for road crossings.

Water to control fugitive dust emissions would be supplied by a water truck. An excavator and dump truck would be required. Approximately 12 people would be employed during the upgrade of the connection.

Section 8 Canal Upgrade   Phase 1 construction would involve installation of approximately 1.5 miles of 84-inch diameter RCP on Madera Ranch and an additional 0.25 mile of 84-inch RCP immediately east of Madera Ranch, all in the channel of the existing Section 8 Canal. Installation of the pipeline would involve the following steps.

1. Draining the canal.
2. Excavating mud or silt from the bottom of the canal, and storing the wet material on site, or transporting it to a storage site. The material would be used to backfill the excavation, if suitable. The stored mud or silt would not be placed on wetlands.
3. Excavating the canal to a sufficient depth to provide adequate cover over the RCP, and preparing the pipe bed.
4. Transporting the pipe to the site on low-bed trucks. Unloading and stringing the pipe together using a large crane or large forklift.
5. Setting the pipe into the trench with the crane.
6. Placing backfill around the pipe using front loaders and a bulldozer.
7. Compacting the material around the pipe with an excavator-mounted compacting wheel. Compacting material above the pipe with a vibrating sheepsfoot roller.
8. Finishing the grade over the pipe with a motor grader.
9. Crossing in an area with steep banks. Both crossings would also require Section 404 permits from the Corps.

Water to control fugitive dust emissions would be supplied by a water truck. A gang truck and two or more pickup trucks would be required during pipe laying. Approximately 12 people would be employed during the installation of the pipeline. Installation of the 84-inch RCP temporarily would affect an area of approximately 32 acres adjacent to farmland.

Off-Ranch Canal Expansion and Extension Several reaches of the Section 8 Canal (1.75 miles), the 24.2 Canal (1.75 miles), and the Main No. 1 Canal (500 feet) would need to be expanded to increase their capacities to 200 cfs, 100 cfs, and 100 cfs, respectively.

Canal expansion would employ methods, equipment, and labor similar to the conveyance upgrades discussed above (see Upgrade of Section 8 Canal, Cottonwood Creek, and Main No. 1 Canal Connection). Temporary construction activities would affect about 53 acres. Additionally, MID would extend the 24.2 Canal approximately 0.75 mile to the south through a new pipeline to connect with the Section 8 Canal. Canal extension would employ methods, equipment, and labor similar to canal construction and pipeline installation. Temporary construction effects associated with extension of the 24.2 Canal would affect about nine acres.

On-Ranch Canal Extensions Existing on-ranch canals would be extended to deliver water to the recharge areas. Approximately 7.5 miles of canals would be extended on Madera Ranch. Extending the canals would involve the following steps.

1. Excavating the canal using an excavator or a Briscoe ditching machine pulled by a tractor.
2. Placing fill material for the canal embankments. Every effort would be made to balance cut and fill so that no import of material is necessary. Spoil material can be placed in the embankments.
3. Compacting the embankments using a vibrating sheepsfoot roller.
4. Finishing canal and embankment shaping with a diesel-powered, rubber-tired Gradall and motor grader.

Moisture for compaction of embankments would be applied from a water truck. The water truck also would provide dust control. A gang truck and two or more pickup trucks would be required to support canal construction. Approximately 10 people would be employed during canal construction. The area temporarily affected by canal extension would be approximately 81 acres on Madera Ranch.

On-Ranch Canal Reconditioning A diesel-powered, rubber-tired Gradall excavator; a Briscoe ditching machine pulled by tractor; and a diesel-powered, rubber-tired backhoe/front end loader would be used for reconditioning ditches and cutting farm road crossings within Madera Ranch.

Weir Installation Two weirs would be installed on GF Canal. Construction of the weirs would involve the following steps.

1. Clearing and grubbing the site with a motor grader and backhoe.
2. Excavating for the structure with an excavator.
3. Constructing wooden forms for the structure. Installing reinforcing steel bars within the forms.

4. Placing concrete from ready-mix trucks. A concrete pump may be used if necessary. Finishing the concrete surfaces and applying curing compound. Allowing the concrete to cure. Removing the forms and repairing the surface as necessary.
5. Placing backfill around the structure with a front end loader. Compacting the backfill with hand whackers.
6. Finishing the grade with a motor grader.

A pickup truck and a flatbed truck would be required to haul materials during construction. Approximately five people would be employed during construction. The areas temporarily affected by construction would be about 1 acre.

Recharge Facilities

Recharge Swales (Phase 1) Phase 1 recharge swales would remain unaltered and would not be subject to any construction activities.

Construction of Recharge Basins (Phase 2) The following staging may occur, but would be dependent on final agency permits.

- *Stage 1:* Berming of recharge area boundaries along topographic contours and using farm roads wherever possible. These recharge areas would be constructed using graders that follow prestaked topographic contours to raise 1- to 3-foot-high berms around the downslope portions of areas ranging from five acres to 80 acres. Berm material would be obtained from an approximate 50-foot-wide corridor parallel to the interior toe of the berm. Topsoil would be segregated during excavation and respread over the berm and construction disturbance areas to promote reestablishment of vegetation.
- *Stage 2:* Deep ripping of corridors within the bermed areas, interspersed with corridors of undisturbed land. This would be done to ensure deeper percolation is maximized during project operation.
- *Stage 3:* Excavation of basins varying from four to five feet deep. Because of the demonstrated permeability of soils at Madera Ranch, Stage 3 recharge basins are unlikely to be required. However, in the event these basins were used, they would be clustered in sets of three or four varying in size from five acres to 80 acres, with the first basin in each set serving as both a settling and a recharge basin. Basins would be designed with 1.5:1 to 2:1 interior side slopes and average depths of four to five feet. After excavation, each basin would be shallow-ripped or disked by construction equipment in order to break up compaction of the bottom soils in the recharge basin. Low earthen dikes would be constructed around the recharge basins using excavated materials. Topsoil would be segregated during excavation and respread over the berm and construction disturbance areas to promote reestablishment of vegetation. Excess soil removed during excavation would be managed to ensure that top layers are stockpiled, excavated soils would be mounded between basins, and stockpiled topsoil would be placed on top of the soil pile.

It is estimated that Stage 3 recharge basins would be constructed using:

- three to 20 heavy diesel-powered scrapers (40- to 60-yard capacity);
- three to five 500-horsepower (hp) diesel-powered skip loaders;

- 15 to 30 heavy-duty, off-road-type trucks (60-yard capacity);
- three to five large, diesel-powered, crawler-type tractors; and
- three to five diesel-powered motor graders.

The final combination of the acreages and techniques summarized above is uncertain. However, as previously discussed, this EIS evaluates the potential effects associated with 1,000 acres of Stage 3 excavated basins.

Recovery Facilities

Recovery facilities include recovery wells, pipelines, and lift stations.

Construction of Recovery Wells The recovery wells would be constructed by drilling to a depth of approximately 300–320 feet below ground surface. The wells would be gravel-packed between the casings and bore holes to maximize efficiency. Construction techniques would involve drilling, flushing, development, and testing to maximize well efficiency and longevity. The screen opening size, screen length, and screen depth of each well would be determined in the field by a registered geologist.

Drill rigs would use portable steel mud pits rather than excavated pits to reduce effects on surrounding habitat. Drilling water would be trucked in to most drill sites and stored in portable tanks. Two small berms would be used to control accidental spills during drilling operations, as required by Occupational Safety and Health Administration. A small berm would be constructed with a small front loader around the perimeter of the 100-foot-by-100-foot temporary construction area. Another berm would be constructed around all drilling equipment, and the area inside the berms would be lined with tarps to contain accidental spills of fuels, lubricants, and drilling effluent. These berms would be constructed of local materials. After drilling is completed, all equipment and fluids would be disposed of in a lawful manner; the berms would be leveled, and the sites would be restored to near preconstruction condition.

Each new well would be equipped with a line-shaft-driven, deep-well turbine pump typical of agricultural pumps. Each wellhead would be fitted with an electric motor, controls, valves, and individual water meters and would be mounted on a concrete slab, approximately five feet by five feet, to stabilize and seal the well and provide a stable foundation for the motor, controls, and piping. The new pumps could be driven by 25- to 200-hp electric motors. Electricity would be supplied to the wells through underground electrical cable adjacent to the collection pipeline. A transformer, switchgear, and control cabinet would be constructed adjacent to each well on a concrete slab, approximately six feet by 14 feet. Each well would be fenced within an enclosure of approximately 600 square feet to allow most areas of Madera Ranch to continue to be grazed by cattle. Well maintenance is described in the Maintenance section.

Five of the existing wells to be used for recovery are currently powered by diesel engines, and nine of these wells are powered by electric motors. These operations could be changed so that all recovery wells could be powered by electric motors, but the assumption is that existing propane powered pumps could remain and that new pumps could be propane gas–powered. Installation of each well would temporarily affect an area of approximately one acre, and each facility would permanently affect about 0.1 acre.

Installation of Recovery Pipelines The recovery pipelines would be constructed by trenching rectangular ditches wide enough to lay the pipe. Trenching would be performed by backhoes, track hoes, or trenching machines. Soil would be temporarily sidecast within the construction corridor and pushed back into the trench once the pipeline is in place. Backfill would be compacted using a vibrating sheepsfoot roller. Piping would be of manufactured materials, such as PVC or polyethylene, with the exception of steel pipe at the wellheads and RCP for larger diameters approaching 60 inches. Pipeline installation would temporarily disturb about 140 acres.

Construction of Recovery Lift Stations Lift stations would consist of reinforced concrete check structures with pumping equipment to reverse flow. The gates would allow control of flows of surface water to Madera Ranch and would be closed to accommodate reverse flows when recovered water is being pumped back to MID's customers.

Construction of the structures would require excavation of the site, erection of forms, installation of steel reinforcement and embeds, placement of concrete, stripping of forms, concrete patching, placement of backfill around the structure, and compaction of the backfill. Material from the structural excavation would be used for backfill after being conditioned to attain the proper moisture content.

Discharge piping would be installed for connection to the pumps. The pump connection would be aboveground, and the discharge to the canal would be underground for discharge below the water level. A trench would be excavated for the buried portion of the piping. The pumps would require installation of structural steel beams and grating, mounting of the pumps and drivers, and installation of electrical wiring and controls.

Required equipment would include an excavator, a backhoe, a water truck, a pickup truck, vibrating plate compactors, concrete ready-mix trucks, a compressor, a generator, a boom truck or crane, and an electrician's truck. Labor would require, at various times, a superintendent, carpenters, steel workers, laborers, operators, and electricians. The maximum crew probably would not exceed 12 persons.

Lift stations would be constructed in three phases, requiring about 90 to 120 days for each phase. Each lift station would require a work area of about 0.25 acre that would be disturbed during construction. The final area occupied by the structure would be about 2,500 square feet. The total area permanently affected by the lift stations would be less than 1.2 acres.

Staging Areas

MID would use its existing off-ranch facilities for the long-term storage and maintenance of materials and equipment. However, Madera Ranch has a central headquarters area with equipment laydown areas and storage buildings. MID would use these facilities as needed to store equipment and materials that would be used to construct, maintain, and operate this Alternative.

Construction Traffic

The primary transportation corridors to Madera Ranch would be State Route (SR) 99, Avenue 7, and Avenue 12 (Figure 2-1). The majority of the vehicle trips generated by Alternative B most likely would originate in Madera and Fresno, proceeding up SR 99 to either the Avenue 7 or the Avenue 12 exit, then to Road 23, Road 21, and Avenue 10, where traffic would enter Madera Ranch.

2.3.4 Maintenance

Maintenance Corridors

The maintenance corridors would include new roads in the recharge basin area and areas with heavy disturbance, and unimproved routes in grassland areas. The maintenance corridors would be configured to take advantage of existing farm roads, fence lines, farmed areas, and recharge basin areas. Maintenance corridors through undisturbed grassland areas would not be graded or gravel-packed.

Diversion and Conveyance Facilities

Maintenance of the Section 8 Canal, Cottonwood Creek, the 24.2 Canal and Main No. 1 Canal would be consistent with maintenance of most water infrastructure in the San Joaquin Valley. Channels would require cleaning every several years. Each channel would be cleaned using mechanized dredging. The dredged material would be disposed of in a lawful manner. Cleaning would be scheduled during periods when the canal is not in operation. Banks of channels would be kept clear of brush and trees, and small mammal burrows would be filled to minimize erosion of the channel banks.

Maintenance of the on-ranch conveyance ditches and canals also would be consistent with that of most water infrastructure in the San Joaquin Valley. Pumps, gates, and appurtenances would be serviced when they are not operating to keep the system in top condition. The exterior canal slopes would be kept clear of large brush and trees, but grass and small shrubs would be acceptable as long as the root systems do not compromise the interior canal lining. Noxious weeds and brush would be removed to prevent them from becoming established on nearby cropland. Canals and ditches on MID property would be unlined but would be kept clear of vegetation. Mechanical removal and permitted herbicides would be used to control unwanted vegetation. Any evidence of small mammal burrows would be monitored and burrows filled in to reduce the possibility of damage, leakage, and potential collapse of canal banks. Maintenance roads parallel to the canals and ditches would have all-weather surfaces; vegetation would be controlled.

Access to canal bottoms would be by intermittent ramps that would allow mechanical equipment access into the canals for cleaning. Deeper sections of canals would be cleaned using small mechanical equipment such as rubber-tired front-end loaders or ―bobcats.” Materials removed from the canal bottoms would be disposed of by legal means, including spreading on farmland as allowed or on the maintenance areas of the groundwater bank property. Shallow sections of canals or ditches may be cleaned out using Gradall excavators that would work from access roads. The frequency of cleaning operations would be determined by what is necessary to maintain reasonable flow regimes in the canals.

Recharge Facilities

Recharge swales and basins would stand idle during dry years, when water is not available for banking. No maintenance would be performed in swales during these times, but recharge basins may be scarified as described below. During operation of recharge basins, it may be necessary to apply algaecide or other chemicals to keep vegetation in check and to minimize algae growth. Algaecides would not be used within natural swales used for recharge. Basin operation would require infrequent delivery of miscellaneous repair equipment, usually in smaller trucks such as non-semi, three-axle rigs. On average, after five years of actual use, basin bottoms would be scarified to remove the thin layer of low impermeable material that would develop over time. Other maintenance activities would be conducted as necessary.

Recovery Facilities

Recovery Wells Wells, meters, pumps, and appurtenances would be maintained during periods when recovery is not in progress to allow ready startup when a bank participant requests water. The wells are expected to run for up to five operating years before needing maintenance or repair. The well pumps are expected to operate for at least 10 years before requiring maintenance or repair. When a pump needs to be removed, a ―pump rig,” consisting of a truck-mounted boom designed to easily remove deep well pumps, would be brought in and backed up to the wellhead. The well discharge head and pump column, normally in 20-foot lengths, would be removed and ―laid by” the well on wood planking to keep them reasonably clean. The pump would be replaced with a new or refurbished pump by reversing the removal operation. The pump then would be taken to the shop for repair or overhaul. During operation, some fuels and lubricants may be transported to the site. Wells would be reworked on an average 20-year cycle.

Recovery Pipelines Nominal maintenance of recovery pipelines would be required. The anticipated life of recovery pipelines is approximately 50 years; however, in the event of a break in a pipeline or excessive leakage, segments of a pipeline would need to be replaced. Depending on the size and length of the segment to be replaced, the pipeline would be either mechanically or hand-excavated.

Maintenance Roads and Corridors Nominal maintenance on the maintenance roads and corridors would be required. The maintenance roads may require maintenance during wet winters if portions of the roads wash out or become impassable. To minimize effects on grassland habitat, no maintenance of the corridors in grassland areas is proposed.

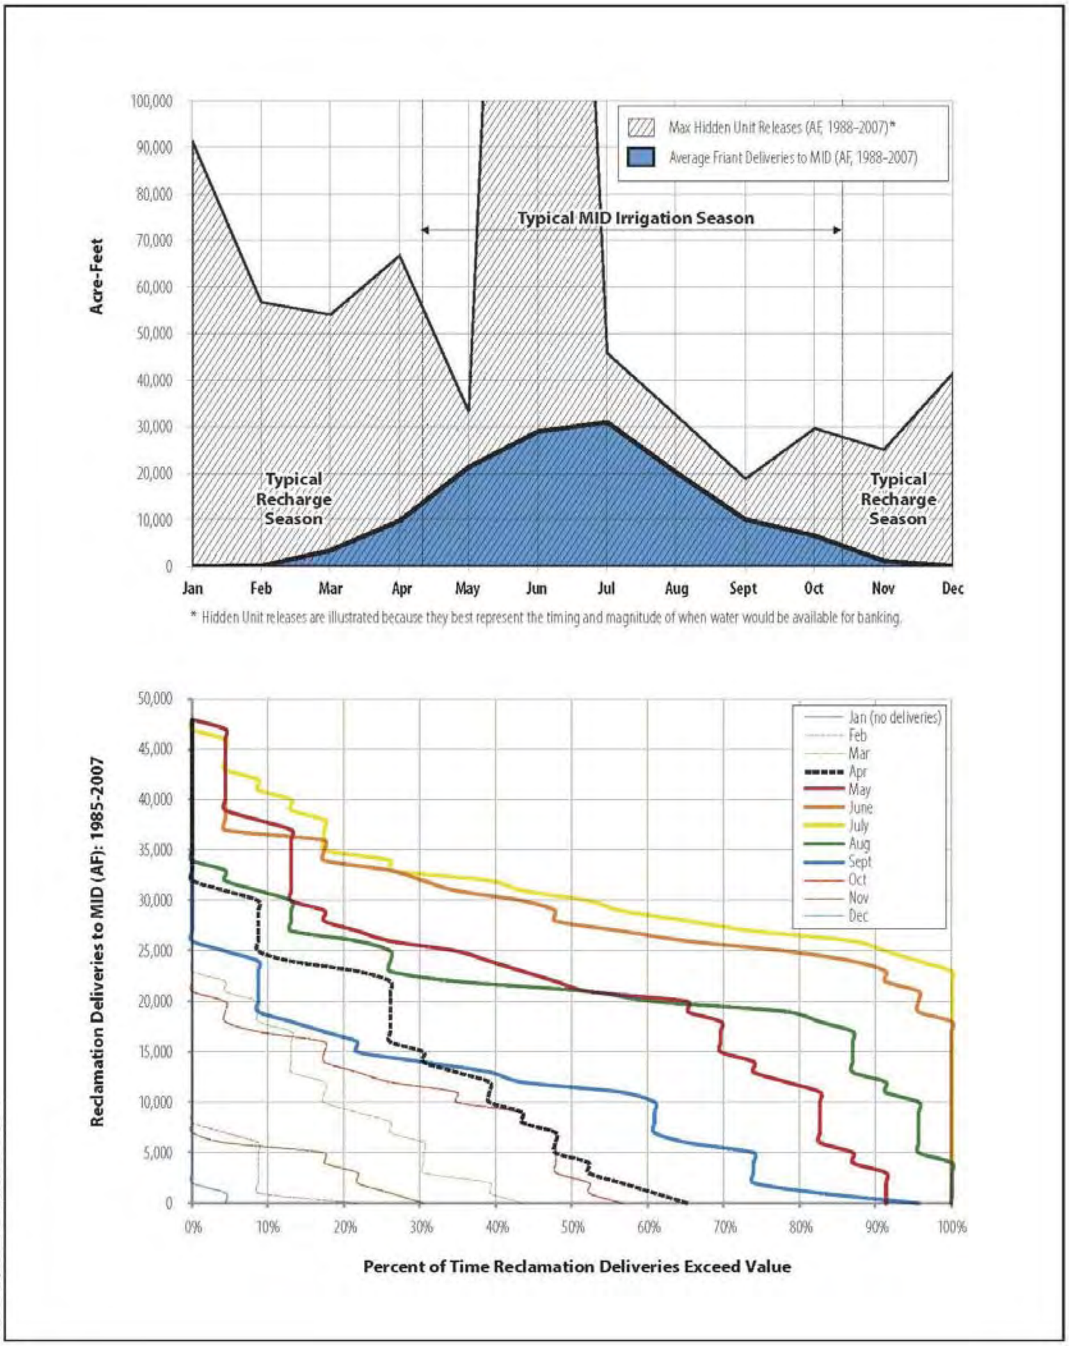
2.3.5 Operations

Madera Ranch operations, including banking, water recovery, and maintenance to support banking and recovery, are described below, including measures to monitor potential effects on neighboring farmers and districts (adjacent stakeholders).

Water Banking

MID would bank a portion of its long-term water supply made available by contracts with Reclamation (Friant Division and Hidden Unit supplies), CVP uncontrolled flows provided under temporary contract and MID's pre-1914 non-CVP water rights supply. It is expected that average annual water available for banking would be approximately 20,000 AF (15,000 AF with river restoration) with wet years providing up to 55,000 AF (see the Water Supply Section for additional information). Water typically would be banked from mid-October through mid-April, depending on water-year type and availability.

Figure 2-6 illustrates the typical recharge season and historic deliveries. The upper part of the figure shows maximum Hidden Unit releases in relation to average Friant Division deliveries to MID, and indicates that off-season deliveries could occur and be used for recharge when water is available. Large amounts of water are unlikely to be banked during the summer because MID's system is being used to convey water to farmers. The lower part of the figure shows that based on historic deliveries, more than 45,000 AF was available less than 5% of the time; in May, for example, approximately 45,000 AF was available 5% of the time, 25,000 AF was available 70% of the time, and 18,000 AF was available 100% of the time. Water supply estimates based on the record from 1985 through 2007 indicate great variability in banking opportunities, ranging from less than 20,000 AF in 61% of years to more than 20,000 AF in 39% of years.



Graphics\Projects\20051 051 20.05 EIS (4-09) Sesh

Figure 2-6 Typical Recharge Season and Historic Deliveries

Water would be delivered into distribution ditches, swales, and recharge basins through the enlarged Section 8 Canal (converting to a pipeline within Madera Ranch), the 24.2-19.5 lateral, the GF Canal, and Cottonwood Creek. Parshall flumes and weirs would be installed in these conveyances to regulate and measure flows.

Upstream recharge basins would be used for sedimentation. Flows through ditches, swales, and basins would be regulated in accordance with monitoring and operating criteria designed to prevent overflows and unacceptably high water table elevations beneath adjoining properties. MID would control upstream, off-site flows to avoid spillage in the same manner that current water operations are conducted. Ditch riders would monitor the flow in each canal, ditch, swale, and recharge basin to ensure proper control of flows and to ensure that programmed water levels in the recharge areas are maintained. Spillage would be minimized through diligent observation of conditions in accordance with MID’s standard operating schedule.

Flows in the swales would be constrained by acreage (approximately 550 acres) and the canal’s capacity to deliver water to the swales. Water depths could range from several inches to several feet depending on the topography of the swales, percolation rates, and the amount of water being applied. Flows in the canals would be constrained by capacity, and recharge for banking in the canals, including GF Canal, would depend on the percolation rates. During water years with limited water available for banking, MID would use canals and selected swales to bank available supplies. The swales would be selected based on readily available canal delivery locations and other management needs. Flows to the recharge basins, should they be needed, would be similarly constrained by seasonal water availability and delivery capacity.

Reclamation worked with MID to determine the maximum area that would be inundated and discussed this approach with the USFWS, Corps, and DFG in February 2010. In general, when doing initial operations, MID would step up the flow into a swale in discrete increments (typically around 2-5 cfs per increment) and once the inundation for that flow has stabilized (typically within one day), MID would mark the wetted extent with global positioning system (GPS). MID would then step up to the next higher flow increment and repeat the process. MID followed this process in a pilot project until they reached the maximum wetted extent. These flow-versus-inundated acreage data pairs allowed MID to build a –rating curve” for a swale. This curve allowed MID to predict very accurately the wetted area given a certain flow. MID would then repeat the construction of the rating curves approximately two to three more times during a recharge season so that MID can observe how the swales perform over time. Because MID is stepping up from low to high flows, MID would be able to observe how each incremental segment of a swale contributes to or detracts from performance.

Monitoring and Operational Constraints Plan

Alternative B would recover no more than 90% of banked water, ensuring that there is a net gain by the aquifer. Recovered water would be delivered to farmers within MID, and potentially for M&I and environmental uses, ensuring that any deep percolation is recharged into the local aquifer system.

Madera Ranch Oversight Committee Adjacent property owners have expressed concern that water levels could rise and flood root zones during recharge events and that pumping costs might increase as the water table declines during recovery events. MID determined that modeled predictions would not provide sufficient security for adjacent stakeholders. Therefore, on April 17, 2006, the MID Board approved formation of the 10-member MROC composed of:

- the five MID board members;
- one elected board member from GFWD, as selected by the GFWD board;

- three independent members, representing the interests of surrounding landowners not within the service areas of MID or GFWD; and
- one County Supervisor.

The MROC would:

- ensure implementation of the Monitoring and Operational Constraints Program (MOCP) for Alternative B;
- protect adjacent landowners from unacceptable impacts by reviewing monitoring results and making recommendations for adjustments to operations if data suggest unacceptable impacts may occur;
- make recommendations for adjustment to the monitoring program as appropriate,
- prepare annual monitoring reports; and
- make available complete raw monitoring data to the Conservation Easement holder, the USFWS, the Corps, the DFG, and Reclamation within two weeks of obtaining the data from the MID. Provide the annual monitoring reports to these same five agencies as well as inform them within two weeks of any votes taken by the MROC, and the outcomes.

The MROC would meet monthly during recharge/recovery periods (usually winter/spring and summer, respectively) and quarterly during other periods when the facility is not in operation.

The MROC would implement the MOCP (Madera Irrigation District 2007) to ensure there are no unacceptable impacts on groundwater levels or quality. The draft MOCP includes the following components:

Water Level Monitoring MID would monitor water levels in on-site and off-site wells and adjust recharge operations to prevent off-site water levels from rising to within 30 feet of the ground surface. In the event that off-site water levels rise to within 30 feet of the ground surface, recharge operations would be halted and not be restarted until approved by the MROC. During recovery operations, MID would monitor water levels with operational adjustment, compensation, or provision of alternate sources of water in the event that water levels drop to unacceptable levels in off-site wells as a consequence of operations.

Water levels would be monitored in a network of wells that would include:

- recovery wells,
- wells near the Madera Ranch boundary, and
- select irrigation wells located at varying distances from Alternative B facilities.

The MROC would determine the numbers and locations of wells to be monitored. All wells installed only for monitoring purposes would be constructed within existing roads or lands already disturbed by other components of this Alternative (e.g., recharge basins).

The MROC would establish protocols to adjust operations and to avoid, minimize, or recommend compensation for adverse effects. Monitoring data collected during recharge and recovery would be interpreted using methods preapproved by the MROC to provide two levels of protection. First, data would be used in real time to adjust operations. Second, if, after adjusting operations, data indicate that off-site water levels would decline or rise (or have declined or risen) an unacceptable amount as a consequence of operations, the MROC would be immediately notified.

MROC would provide monthly raw data to the Corps and USFWS on request.

Water Quality Monitoring This Alternative primarily would convey and recharge water originating from Millerton Lake (Friant Division water) with lesser potential contributions of Fresno River water originating from Hensley Lake. These waters have been conveyed through the MID system and used for irrigation throughout the district for over 50 years. Friant water is recognized as high quality and generally of higher quality than the underlying groundwater.

MID's daily, ongoing operations currently include surveillance of conveyance facilities to ensure that accidental spills of hazardous materials that may occur near its facilities are discovered and addressed to prevent contamination of MID's water. This surveillance would continue and extend to the facilities constructed as part of this Alternative.

In addition to these precautions, MID believes it is important to monitor water quality. Water banked at Madera Ranch must not impair any designated beneficial uses of water or violate the water quality standards and objectives as defined in the Water Quality Control Plan for the Sacramento and San Joaquin River (Central Valley Regional Water Quality Control Board 2007). Therefore, in addition to its ongoing surveillance program, the MOCP water quality monitoring includes:

- sampling and analysis of recovered water leaving Madera Ranch and groundwater flowing away from Madera Ranch for total dissolved solids (TDS) to ensure that levels remain appropriate for irrigation purposes; and
- sampling and analysis of samples from drinking water wells within one mile of the Alternative for fecal coliform, TDS, and select components of TDS as specified by the MROC.

Water Accounting MID already extensively monitors flow throughout its system and those data would be used by this Alternative. Flows would be monitored where water enters Madera Ranch and where water leaves Madera Ranch. In addition, MID would monitor flows to specific recharge areas and from individual recovery wells for operational purposes. Recharge areas include swales, recharge basins, and in-lieu recharge areas.

Precipitation, wind, evaporation, and temperature would be monitored to calculate net precipitation and evaporation effects. Taken together, the data and estimates from all of these systems would be used to estimate evapotranspiration losses (from vegetation, crops, and recharge areas), recharge during conveyance, recharge into the facility, and recovery.

Recoverable Recharge Recharge that occurs during conveyance through the off-ranch MID system is part of normal MID operations and thus would not be considered banked because it is an existing condition that would not be changed by the Alternative. Flow into Madera Ranch and recharge areas would be monitored. Flow into recharge areas, minus estimated evaporation and evapotranspiration, would be considered banked. However, only 90% of the banked water would be considered recoverable, because 10% of the water applied would be retained in the bank to reduce overdraft rates.

Recovery Flow from recovery wells, minus recharge during conveyance to the perimeter of Madera Ranch, would be considered recovered water. Recharge of recovered water during conveyance would be considered returned to the water bank.

Almost all aquifer banking projects experience migration of recharged water away from recovery systems over time. In addition, a portion of early-season recharge water typically becomes inaccessible to recovery systems either through perching above silts/clays or through banking in sediments that drain too slowly to be of practical use to recovery systems. MID has concluded that actual aquifer losses cannot be reasonably predicted in a way that would adequately protect surrounding landowners from —over-extraction.” Therefore MID has committed to operational constraints to leave 10% of the recharged water behind to ensure that the Alternative results in a net reduction in the rate of overdraft and to prevent —over-recovery.”

Subsidence Monitoring Historically, subsidence has occurred to the west of Madera Ranch. However, ground elevation monitoring conducted by the U.S. Geological Survey (USGS) has indicated that no more than one foot of subsidence has occurred on Madera Ranch even though the area of Madera Ranch has been subjected to more than 100 years of intense groundwater pumping from above and below the Corcoran Clay. Therefore, it is unlikely that subsidence would be a factor in operations. Nonetheless, MID envisions that operations would include high accuracy GPS monitoring of multiple locations on Madera Ranch before and during operation of this Alternative. The elevations of on-site markers would be measured annually by MID and compared to distant USGS benchmarks to allow detection of any change in ground elevations. The MROC would monitor subsidence and has the authority to impose operational constraints or mitigation on the WSEP, depending on the level of impact, if any.

Water Recovery Operations

Water would be recovered using existing wells and new wells installed in the vicinity and downgradient of the recharge areas. As noted above, the MOCP would constrain recovery operations to prevent unacceptable impact on surrounding landowners. Recovered water would be pumped into collection piping, through the main pipeline, and into the enlarged Section 8 Canal.

Water would be conveyed via the Section 8 Canal into the MID distribution system through a series of lift stations. All of these deliveries would be made in lieu of normal surface water deliveries from Millerton Lake or Hensley Lake. Therefore, an equal volume of water would be made available in these respective reservoirs for delivery to other parts of the MID service areas, increasing the net supply of available water.

The recovery operations described above depend on farmer irrigation demand. As a consequence, recovery would be constrained to the irrigation season, typically running from mid-

March through mid-October. Peak irrigation demand, when 200 cfs of recovery capacity would be needed, typically occurs from May through August.

Use of the Water Bank Facilities by Other Entities

Under Alternative B, MID could use the entire annual recovery capacity (55,000 AF) of the facilities for its agricultural customers in some years. Based on MID's business plan, MID's capacity would be allocated as follows:

- 20,000 AF/year for MID overall in-district agricultural use;
- 5,000 AF/year for individual MID agricultural users;
- 10,000 AF/year for other Madera County agricultural users;
- 10,000 AF/year for all other Madera County users including industrial, commercial, and residential development; and
- 10,000 AF/year for environmental water obligations.

MID's Friant Division Long-Term contract with Reclamation does not provide for delivery of Millerton water to M&I users. However, there is a need for water storage by other Madera County water users. Other potential users would require separate environmental analysis and approvals, and would rely on their own water entitlements in using the proposed groundwater banking and recovery facilities.

If capacity is available after Madera County needs have been met, MID's banking facilities could be used by regional customers. Potential participants would be required to provide their own water for banking and would take delivery of banked water through exchange. Participant water would be gravity delivered through MID conveyances for recharge through the proposed facilities.

Potential non-MID participation could result in a wide array of agreements, water rights amendments, transfers, or changes to the operation of existing non-MID facilities. However, the specific tenants, potential agreements, and other related actions are not reasonably foreseeable. Therefore, analysis of these potential elements would be remote and speculative. As a result, the environmental analysis presented in this document has been conducted without regard to the specific entities or organizations that may desire to bank water in the proposed facility. Specifically, this environmental document does not evaluate:

- potential amendments to existing water rights, contracts, permits, or licenses that would allow prospective participants to use the facility;
- changes to operations of existing non-MID local, state, or federal facilities that could result from prospective participants seeking to use the facility; or
- individual water transfers or exchanges that could occur as a result of prospective participant use of the facility.

The types of actions would be subject to environmental analyses as separate projects. If any water rights amendments, water transfers, or changes in operation to federal, state, or non-MID local facilities would be required for use of the facility, the potential participant(s) would be the party(ies) responsible for complying with applicable environmental analyses requirements.

Mitigation

MID has developed a Madera Ranch Mitigation, Grazing, and Management Plan that describes future management issues associated with Madera Ranch related to grazing, water, species, vernal pools, and monitoring. A total of approximately 4,500 acres would need to be set-aside for mitigation with this alternative. Figure 2-7 MID's conceptual mitigation areas are from the Madera Ranch Mitigation, Monitoring and Reporting Plan which is provided in Appendix C of the Final EIS.

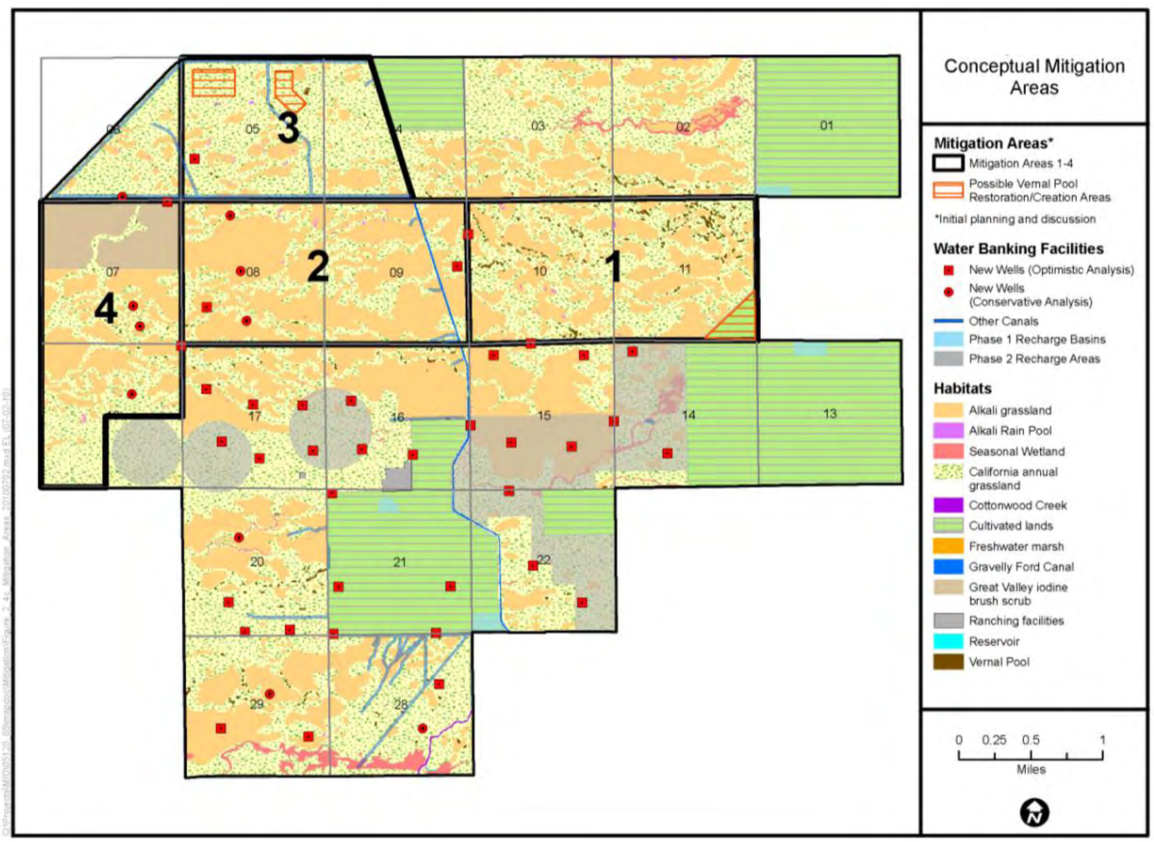


Figure 2-7 Conceptual Mitigation Areas

2.4 Reduced Alternative B – Water Banking Outside the MID Service Area Using Select Swales and Alteration of Reclamation-owned Facilities (Proposed Action)

As described in the introduction, Reduced Alternative B is now the Proposed Action and was developed with additional agency input. Reduced Alternative B represents a scaled-back version of Alternative B that uses fewer swales to minimize effects to vernal pools and limits the number of recharge basins to the minimum for the project to be practicable. Reduced Alternative B also directs recharge activities in the swales on a priority basis to help avoid effects to vernal pools. As with Alternative B it would complete the water bank in two phases. Phase 1 would involve constructing necessary delivery infrastructure improvements (except for the Section 8 canal southwest extension), using select natural swales for recharge (550 acres versus 700 acres as proposed under Alternative B), and installing approximately five soil berms to direct recharge flows. Phase 2 would involve constructing a limited number of recharge basins (323 acres versus up to 1,000 acres under Alternative B) and facilities for recovery of banked water. Reclamation would approve banking of CVP water outside the MID service area and alteration of Reclamation-owned facilities. Similar to Alternative B, Reduced Alternative B may include funding by Reclamation, under the Omnibus Public Land Management Act of 2009, the Policy and Program Services, Challenge Grant Program: Recovery Act of 2009 Water Marketing and Efficiency Grants, or any other funding source. Regardless of whether this funding is acquired, the project components and associated effects would be the same. A description of the Reduced Alternative B, the Proposed Action, follows.

2.4.1 Phase 1 Facilities

MID would implement Phase 1 to increase the capacity of existing MID conveyance facilities to deliver water to Madera Ranch facilities. Phase 1 would use primarily natural swales as recharge areas.

Phase 1 activities would involve:

- reconditioning and extension of canals to provide at least 200 cfs of conveyance capacity into Madera Ranch;
- construction of approximately 55 acres of recharge basins on current agricultural land to regulate flow, remove sediment, and provide some recharge;
- application of recharge flows to approximately 550 acres of swales; and
- integration of approximately 2,600 acres of Madera Ranch row crops and vineyards into an in-lieu recharge program in which surface water periodically would be served in lieu of groundwater pumping subject to approval by the MROC.

Diversion and Conveyance Facilities

Upgrades to Existing Canals Figure 2-2 depicts the locations of existing canals in the vicinity of Madera Ranch. During Phase 1, MID would upgrade canals to enable gravity delivery of at least 200 cfs into Madera Ranch. Upstream portions of Cottonwood Creek, the 24.2 Canal and the Main No. 1 Canal collectively provide more than 200 cfs of gravity feed conveyance capacity above MID’s normal service needs during nonpeak irrigation months, and lesser amounts of capacity during peak irrigation months. However, the portions of these conveyances and the Section 8 Canal within two miles of the ranch are undersized, causing a bottleneck such that the capacity to deliver water to the ranch is less than 100 cfs. Specifically, the confluence of Cottonwood Creek, the Main No. 1 Canal, and the Section 8 Canal, approximately two miles east of the ranch, has a capacity of less than 100 cfs. In addition, the Section 8 Canal running from this confluence into the ranch has a capacity of less than 50 cfs, and the 24.2 Canal, 1.5 miles from the ranch, also has a capacity of less than 50 cfs and does not tie into the Section 8 Canal. The following sections summarize how these and other conveyances would be upgraded to provide up to 200 cfs delivery capacity to and from Madera Ranch.

Reclamation Conveyance Facilities

24.2 Canal Improvements MID would extend the earthen 24.2 Canal approximately 0.75 mile south to connect with the Section 8 Canal (Figure 2-8). The connector would be a buried pipeline, not an open canal. In addition, approximately 1.75 miles of the southern portion of the existing 24.2 Canal would be widened and deepened to accommodate 100 cfs of flow. In total, the extension pipeline and canal enlargement would involve moving approximately 36,000 cy of soil.

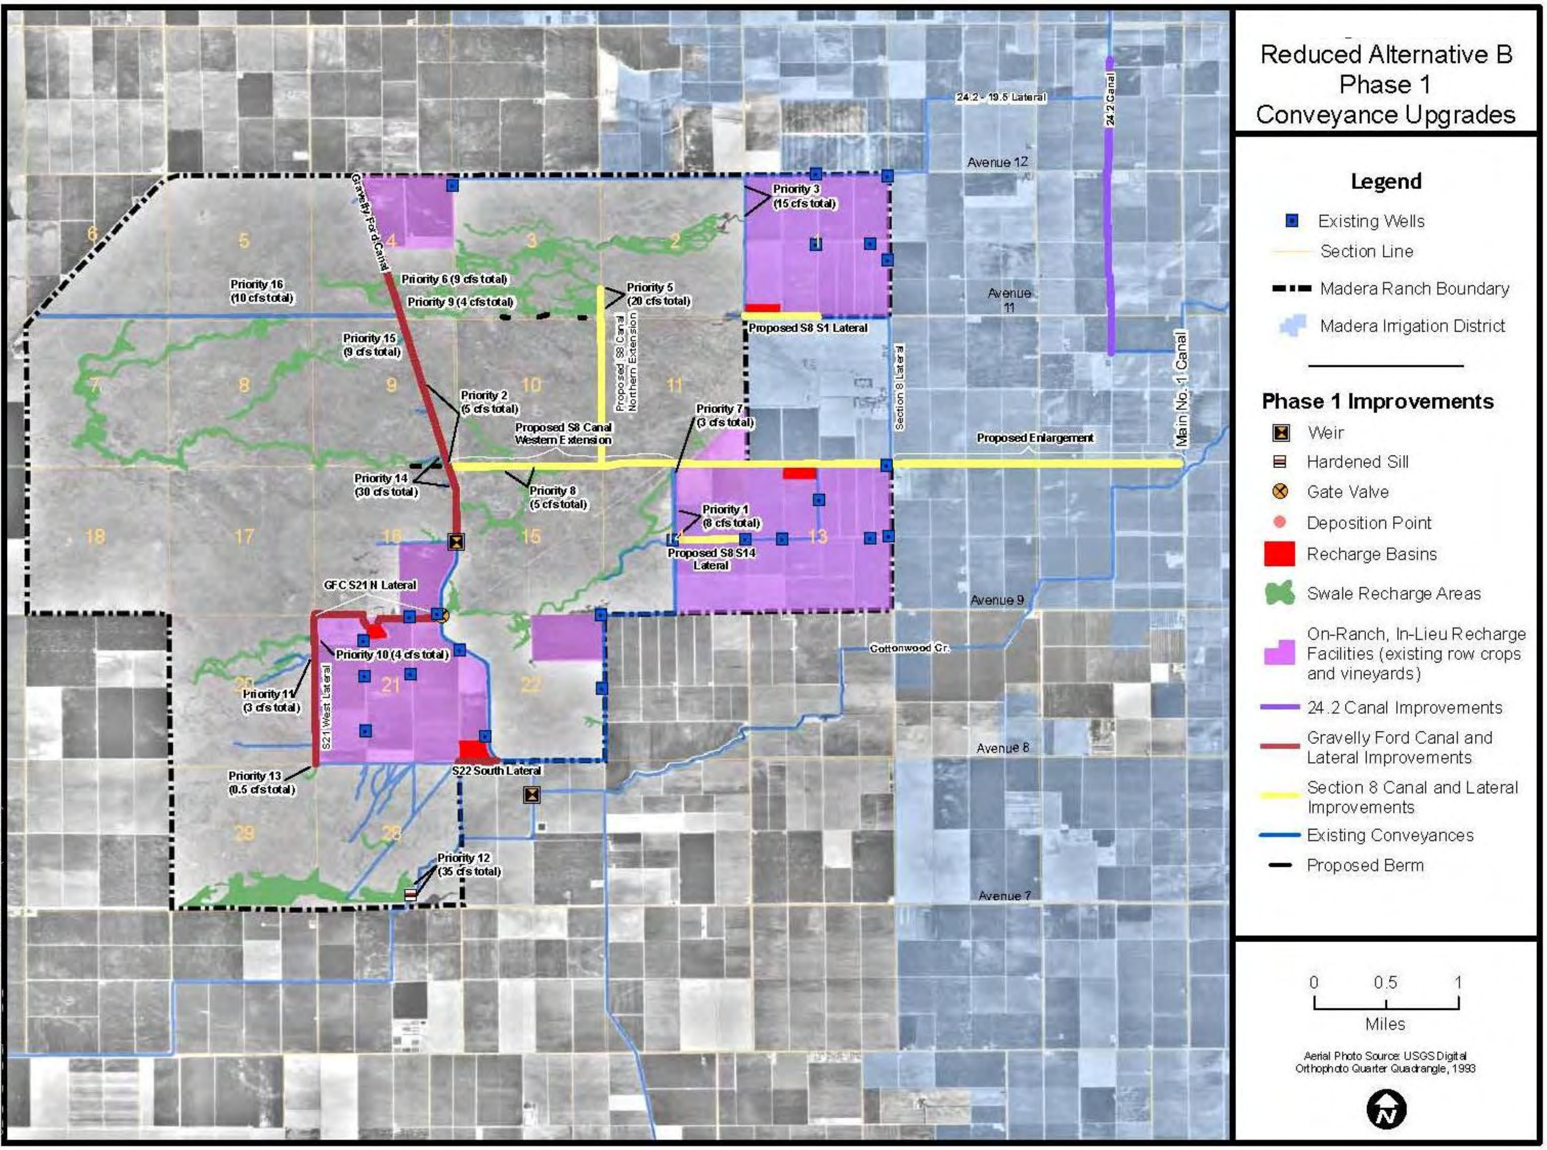

Figure 2-8 Reduced Alternative B Phase 1 Conveyance Upgrades

MID Conveyance Facilities

Section 8 Canal, Cottonwood Creek, and Main No. 1 Canal Connection Upgrade The existing connection between the Section 8 Canal (an earthen ditch built in the late 19th century), Cottonwood Creek, and Main No. 1 Canal would be widened and deepened to accommodate 100 cfs of flow (Figure 2-2 and Figure 2-8). Only the connection would be widened; Cottonwood Creek would not be widened as its capacity is sufficient to meet the needs of the alternative. Work would be performed in an approximately 500-foot-long and 100-foot-wide area, requiring a temporary construction easement of 1.2 acres from neighboring landowners. No new permanent easements would be required.

Section 8 Canal Upgrade An approximately 1.75-mile segment of the earthen Section 8 Canal (from Road 23 to within approximately 0.25 mile of the Madera Ranch boundary at Road 21) would be reconstructed to expand from one-way, 50-cfs capacity to two-way (flat bottomed), 200-cfs capacity (Figure 2-8). The 1.75-mile segment of the canal from 0.25 mile east of the ranch, along the north side of Section 13 and to the western edge of ranch row crop land on the north side of Section 14, would be replaced with an approximately 1.75-mile-long, 84-inch RCP, 200-cfs (two-way) pipeline placed within the channel of the existing canal.

During construction, Avenue 10 would be temporarily closed (local traffic only) to allow work on the canal. To expand the canal, an additional 40-foot corridor would be required, for a total of 8.9 acres of easement or fee simple ownership. The last 0.25 mile of the west end of the canal off-ranch would be carried in concrete pipe buried in the existing canal such that additional right-of-way would not be needed. A 40-foot-wide temporary construction easement may be required for this last 0.25 mile off-ranch (resulting in an easement of 1.2 acres). In total, this reconstruction involves moving approximately 76,000 cy of soil.

Section 8 Canal Western Extension A new, approximately 1.55-mile-long, 50- to 60-cfs earthen ditch would be constructed within a paved road in Sections 14 and 15 from the new Section 8 Canal pipeline to the GF Canal. The ditch would be constructed within the existing leveled shoulder (Figure 2-8). In total, this construction involves moving approximately 18,000 cy of soil.

Section 8 Canal Northern Extension Sections 10 and 11 are divided by a 20- to 40-foot-wide dirt farm road bordered by the remnants of a ditch. A new approximately 1.2-mile-long, 20- to 50-cfs earthen ditch would be constructed along the alignment of the old ditch (Figure 2-8). In total, this construction involves moving approximately 14,000 cy of soil.

Section 8 Canal Section 14 Lateral Extension An existing Section 8 Canal lateral (20 cfs) that flows across Section 13 would be extended approximately 0.5 mile across Section 14 (Figure 2-8). All work would be performed along the edge of row crop land. In total, this construction involves moving approximately 2,800 cy of soil.

Section 8 Canal Section 1 Lateral Extension An existing Section 8 Canal lateral (20 cfs) that flows east-west along the southern side of Section 1 would be extended approximately 0.5 mile to the southwestern corner of Section 1 (Figure 2-8). All work would be performed along the edge of row crop land.

Gravelly Ford Canal Sedimentation Basin and Flow Regulation Area With GFWD's permission, an approximately 3,000-foot-long segment of the GF Canal on the southeastern side of Section 16 would be equipped with a weir/control structure on the north side to allow use of the channel as a combined recharge area, sedimentation basin, and flow regulation area.

Gravelly Ford Canal Flow Control Weir at Cottonwood Creek With GFWD's permission, a new weir would be installed on the GF Canal approximately 1,000 feet south of Section 22 where the canal intersects and shares a channel with Cottonwood Creek. All work would be performed in the existing artificial channel and on adjacent farm roads.

Gravelly Ford Canal Section 21 Northern Lateral A new approximately 0.45-mile-long, 20- to 50-cfs earthen ditch would be constructed along the northern side of Section 21 from the GF Canal to a Phase 1 recharge basin located on farmland (Figure 2-8).

Gravelly Ford Canal Section 21 Western Lateral A new approximately 1-mile-long north/south canal would be constructed along the western side of Section 21 off of an existing 20- to 50-cfs earthen ditch bordering the southern side of the section. The new canal would be constructed on the shoulder of a dirt farm road bordering row crop land in Section 21 (Figure 2-8).

Gravelly Ford Canal Section 22 Southern Lateral A new approximately 0.28-mile-long, 20- to 50-cfs earthen ditch would be constructed along the southern side of Section 22 from the GF Canal to an existing ditch (Figure 2-8).

Cottonwood Creek Overflow Improvements A hardened sill (compacted or armored material with low potential for erosion) would be constructed on the existing Cottonwood Creek berm to protect the berm and to accommodate flow measurements. Sections 28 and 29 are inundated by Cottonwood Creek uncontrolled flows regularly during wet springs. These uncontrolled flows generally are prevented from flowing onto Avenue 7 by an earthen berm that runs along the southern boundary of Section 28 and north along the western boundary of Section 29 (Figure 2-8).

Reconditioning of Existing Canals and Ditches Reconditioning would involve reconditioning GF Canal (described below), replacement of turnout gates (described below), brush removal, repair of berms that have been worn down over time, reconstruction of segments that have been filled by recent farm operations, and installation of farm road crossings as required.

Gravelly Ford Canal Gravelly Ford Canal is an earth-lined flat-bottom channel that conveys irrigation water from the San Joaquin River to Madera Ranch. Project elements affecting Gravelly Ford Canal include:

- Construction of a new weir structure and lift station (GF Canal sedimentation basin and flow regulation area as described above);
- Grading approximately 2.6 miles of the canal back to original design contour and capacity;

- Installing approximately three to five new turnouts;
- Replacing approximately two to three old turnouts; and
- Installing one flow monitoring station.

Gravelly Ford Canal Reconditioning GF Canal would be reconditioned north of the new weir and lift station to Avenue 12 (2.6 miles). Material that has eroded from the banks and settled in the bottom of the canal would be used to reform the banks of the canal. A grader and scraper would be used in the canal bottom to recontour the canal. Approximately 16,000 cy of dirt would be moved to reshape the existing berms of the canal.

Gravelly Ford Turnouts Approximately two new east berm turnouts would be installed to deliver water into the recharge areas. Three west berm turnouts would be replaced and three new west berm turnouts would be constructed (one to a recharge basin in agricultural lands, one gate structure to a new lateral canal system constructed in uplands, and one to upland recharge areas). A flow monitoring station would also be installed. Each turnout is approximately 3-feet wide by 6-feet long by 6-feet tall and is/will be buried in the existing banks of the canal. The turnouts are constructed off-site at MID headquarters. Construction of the turnouts would require excavating approximately 32 cy of soil and the addition of three cy of fill material to install a gate and compact the soil adjacent to it.

Recharge Facilities

Recharge Basins Phase 1 would involve construction of approximately 55 acres of basins, approximately four basins that are 1,100 feet square, as shown in Figure 2-3 on agricultural land in order to:

- help regulate flows,
- allow settling of sediments before application of water to swales, and
- provide some recharge capacity.

The preliminary locations of four Phase 1 recharge basins are entirely on current agricultural land in Sections 1, 13, 21, and 22. The basins would be designed with 1.5:1 to 2:1 interior side slopes and average depths of four to five feet and surrounded by low earthen dikes created from the dirt excavated from the basin. Construction of the Phase 1 recharge basins could involve the movement of approximately 444,000 cy of soil.

Swale Recharge Areas The Proposed Action would entail diversion of water into approximately 550 acres of swales. The water would be conveyed to Madera Ranch through the existing and upgraded MID conveyances and to the swales through the existing, rehabilitated, and new ditches described above. At the head of each swale, a manually operated farm turnout (equipped with a gate valve and totalizing flow meter) would be installed to regulate and measure the flow into each swale. Several turnouts currently exist on GF Canal and these would be replaced and several new ones will be added. Flows at each turnout, based on pilot studies, would be no greater than 20 cfs and would average five cfs at the turnout. Maximum overall flows would be around one cfs per acre of application. Locations of the swales anticipated to be used during Phase 1 are depicted on Figure 2-3.

In-Lieu Recharge Facilities Madera Ranch includes 2,666 acres of row crops and vineyards that are irrigated entirely by a system of 23 wells. MID would recondition existing turnouts and install new turnouts from the Proposed Action canals, pipelines, and ditches to enable delivery of surface water to these fields in lieu of groundwater pumping (Madera Irrigation District 2008).

These agricultural fields were purchased from MID in July 2008 by Grimmway Enterprises, Inc. Grimmway will continue to manage the property for agricultural uses. However, MID has retained rights to existing and future easements that would allow the Proposed Action to be implemented.

2.4.2 Phase 2 Facilities

Phase 2 would expand the areas used to recharge, develop wells and piping to recover the banked water, and install pumps to deliver the recovered water (Figures 2-9 to 2-11).

Phase 2 activities for recharge and recovery facilities would involve:

- additional upgrades to existing canals,
- construction of up to 323 acres of new on-site recharge basins and canals as required to supplement Phase 1 facilities and achieve 200 cfs of recharge capacity (if required),
- use of up to 15 existing wells for recovery,
- installation of up to 49 new wells and recovery pipelines (in phases over several years) to provide 200 cfs of recovery capacity, and
- installation of up to 12 lift stations on MID canals and one lift station on GF Canal (in phases over several years) to provide 200 cfs of pump-back capacity into the MID service area.

Diversion and Conveyance Facilities

Recovery Pipeline An approximately 1.75-mile-long, 72-inch to 84-inch RCP, 135- to 200-cfs (two-way) buried pipeline would be installed under the road that runs diagonally across Sections 14 and 15. The pipeline would extend from the Phase 1 Section 8 Canal upgrade (200-cfs pipeline) to the GF Canal beneath an existing 30- to 40-foot-wide dirt farm road (Figure 2-4).

Gravelly Ford Canal Section 21 Northern Lateral The 0.45-mile-long Phase 1 ditch along the northern side of Section 21 would be replaced with an approximately 2.1-mile-long, 135-cfs, east-west earthen lateral canal along the north side of Sections 21 and 20 with two north-south sub-lateral canals running northward along the east and the west sides of Section 17.

Depending on the recharge basin acreage and construction methods, up to 3.2 miles of 20- to 100-cfs earthen ditches would be constructed within the Phase 2 recharge basin area to distribute water into recharge areas.

Recharge Facilities

Recharge Basins Depending on the performance of Phase 1 recharge facilities, up to 323 acres of recharge basins may be constructed within a 1,300-acre area (Figures 2-10 and 2-11).

Following surveys as outlined in the Environmental Commitments section, MID would begin construction of the basins. The following steps to construct recharge basins may occur.

- *Stage 1:* Berming of recharge area boundaries along topographic contours using farm roads wherever possible and farm grading techniques, but no excavation (similar to unleveled rice fields).
- *Stage 2:* Deep ripping of corridors within the bermed areas, interspersed with corridors of undisturbed land.
- *Stage 3:* Excavation of basins varying from four to five feet deep.

The final number of recharge basins constructed and techniques summarized above is uncertain, and the highest estimated acreage is highly unlikely to be required. This EIS evaluates the potential effects associated with up to 323 acres of excavated basins. Recharge basins would be arranged to minimize species and habitat effects, and a site visit in July 2010 with the resource agencies indicated MID should proceed with basin construction first on the west side of GF Canal (Figure 2-10); MID would maximize the use of this area before constructing basins on the eastern side of the property.

Construction of the recharge basins and internal routing ditches could involve the moving of up to 2.5 million cy of soil. Basins would be designed with 3:1 interior side slopes and average depths of four to five feet. Low earthen dikes would be constructed around the recharge basins using excavated materials. Topsoil would be segregated during excavation and respread over the berm and construction disturbance areas to promote reestablishment of vegetation.

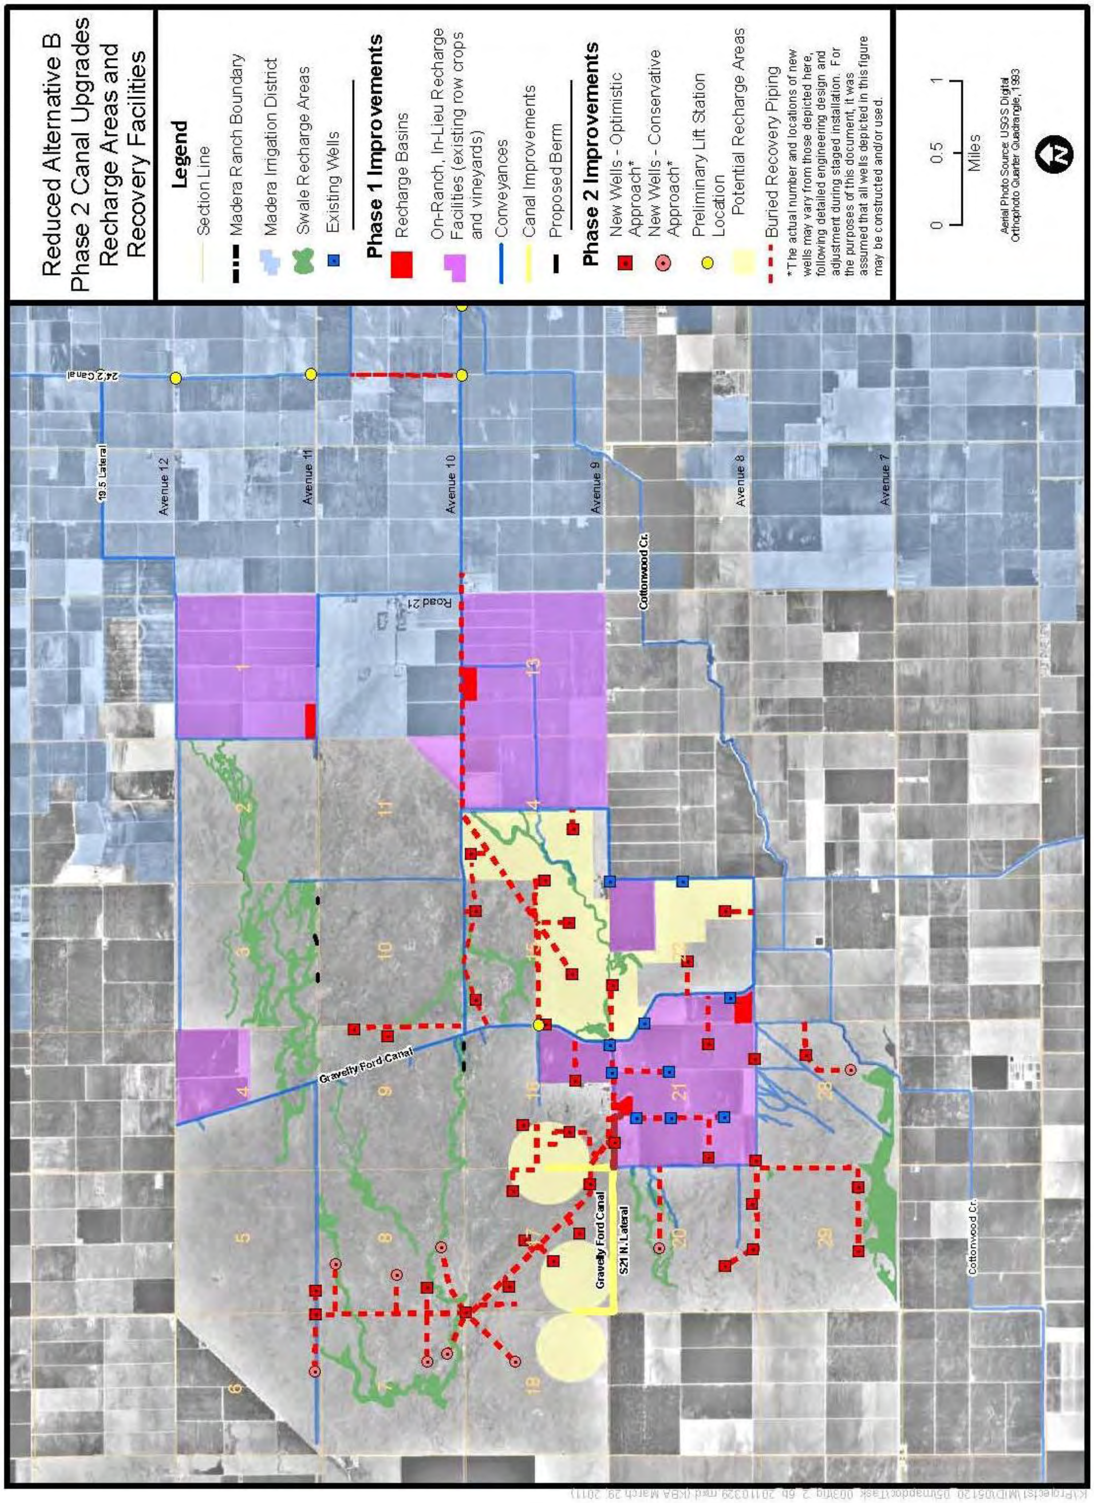

Figure 2-9 Reduced Alternative B Phase 2 Canal Upgrades, Recharge Areas, and Recovery Facilities

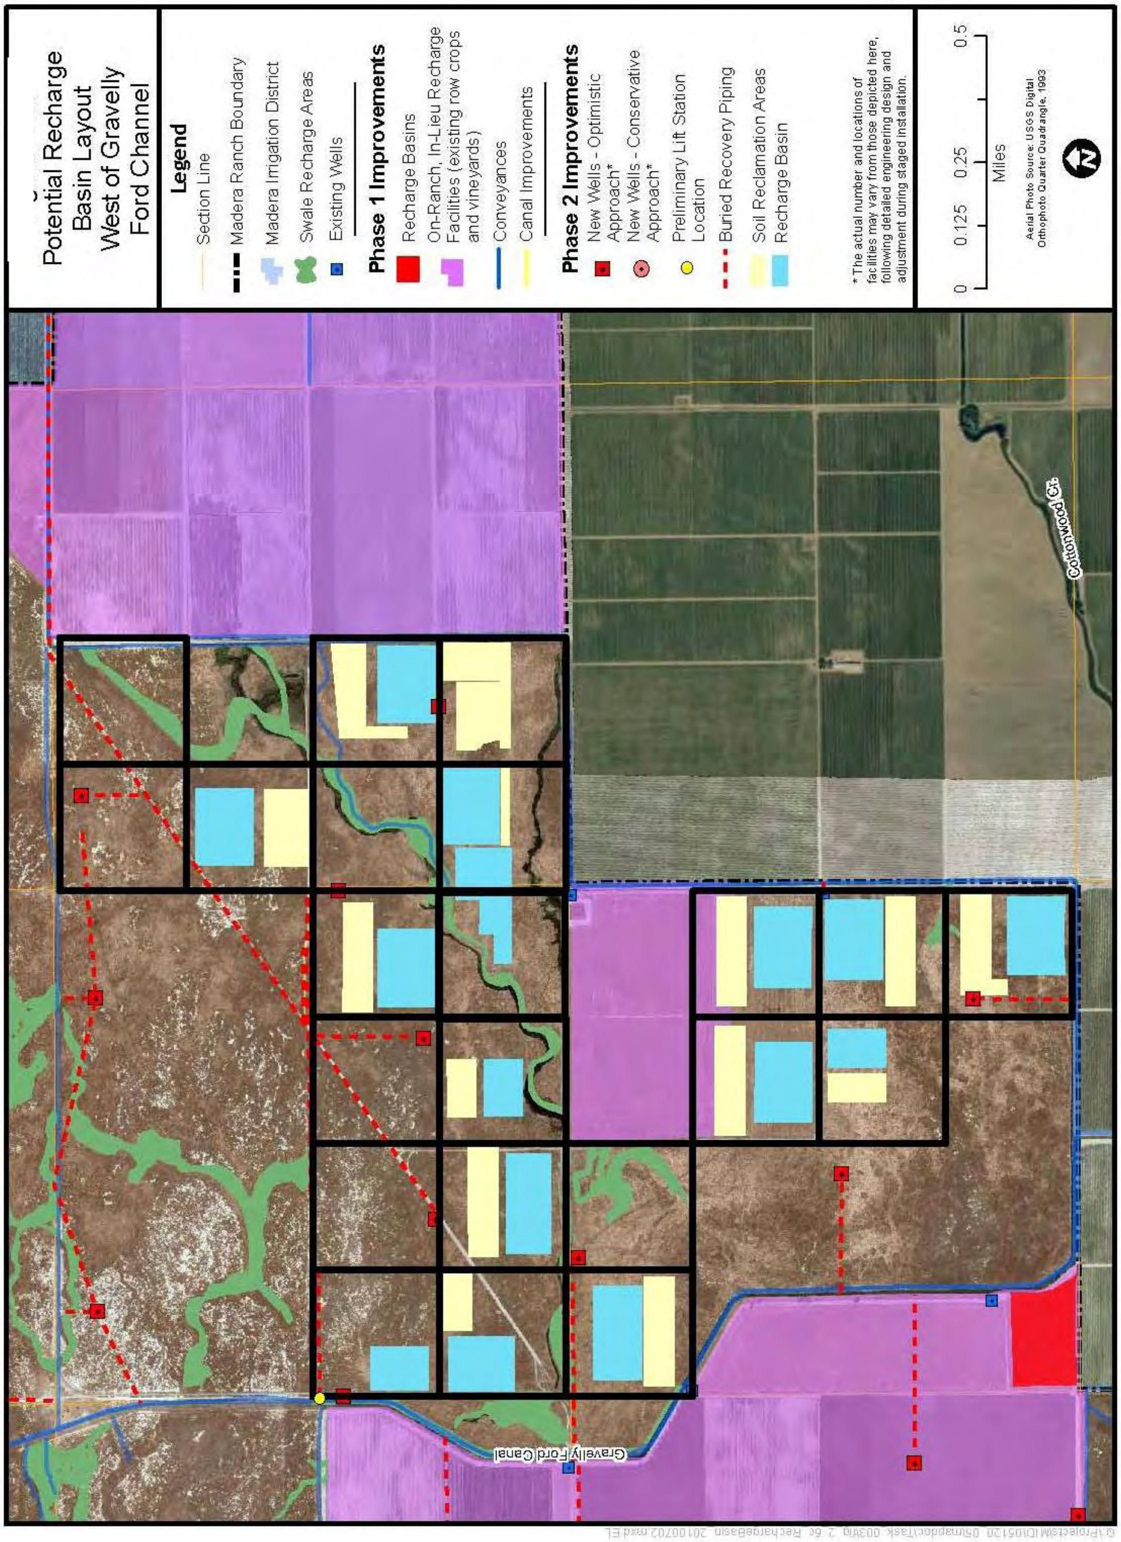

Figure 2-10 Potential Recharge Basin Layout West of Gravelly Ford Canal

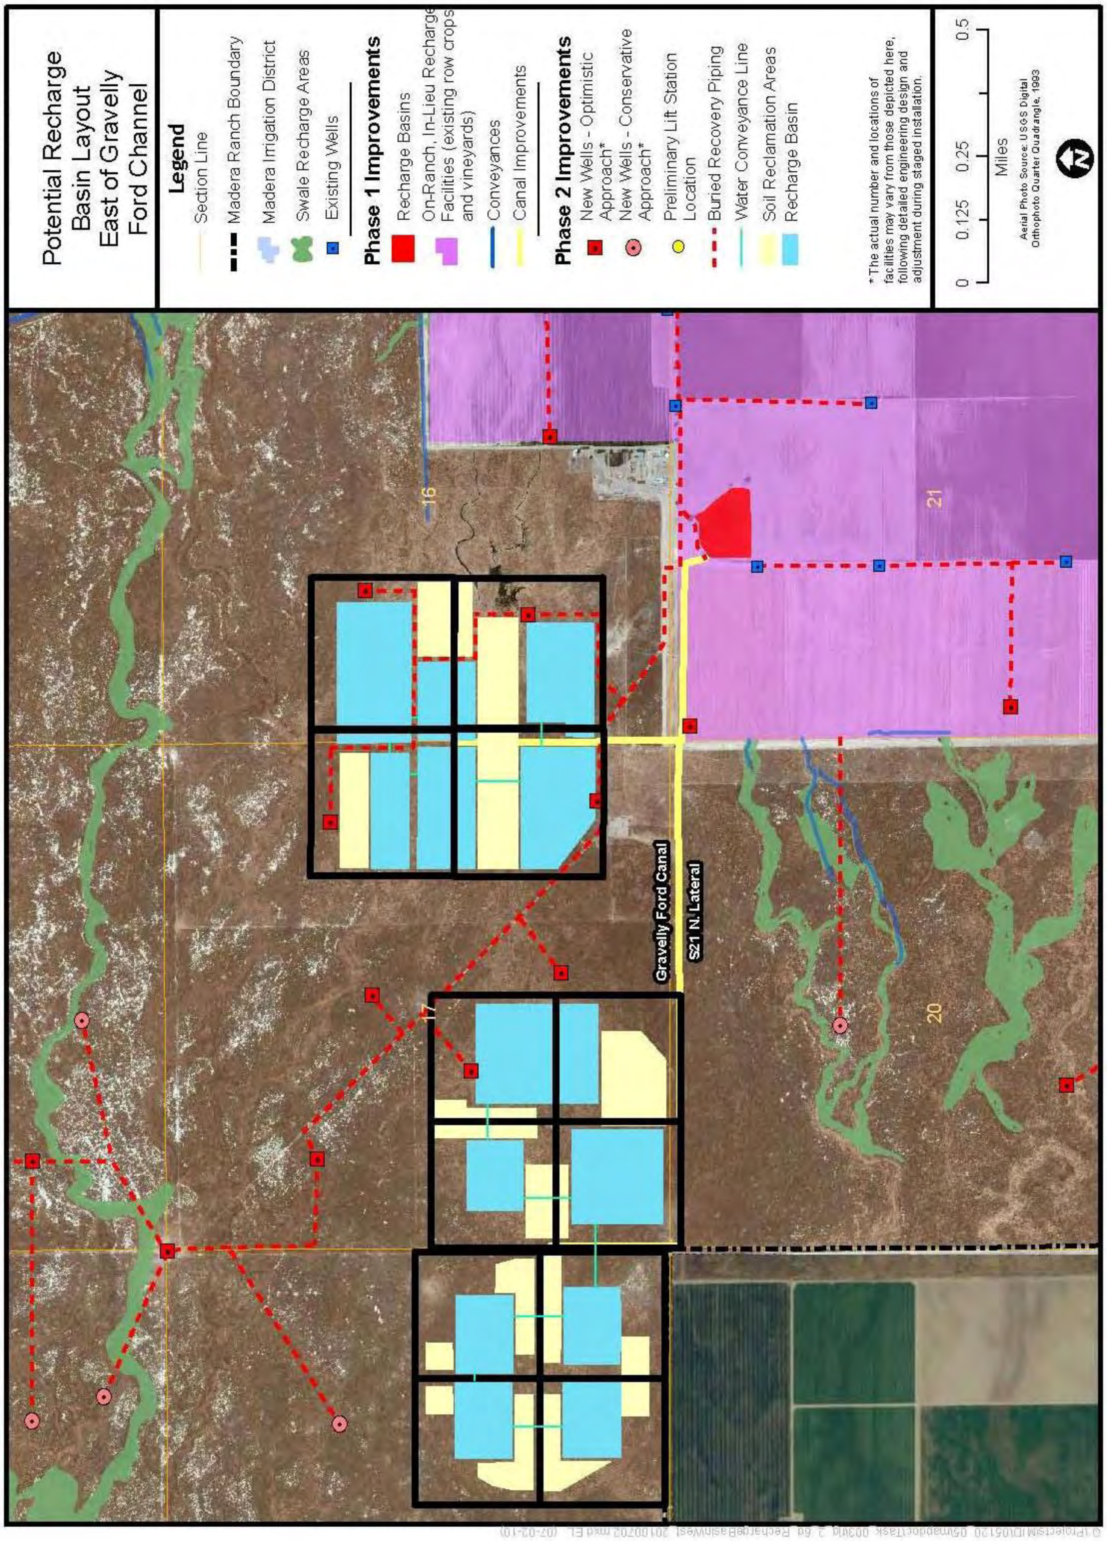

Figure 2-11 Potential Recharge Basin Layout East of Gravelly Ford Canal

Recovery Facilities

These elements are the same as described under Alternative B.

2.4.3 Construction

Conveyance Facilities

These elements are the same as described under Alternative B.

Recharge Facilities

Phase 1 recharge swales would largely remain unaltered and would not be subject to any construction activities. However, to ensure water is directed to desired swale areas up to five micro-berms could be installed. The location of these are illustrated in Figure 2-9. They could be approximately 100 feet long and a maximum of three feet high at the center to provide sufficient freeboard and long-term stability. MID and farmers on Madera Ranch routinely perform this type of earthwork. This project element would be completed in one day using district-owned equipment as follows:

- MID would perform a topographic survey along the fence line to confirm required dimensions;
- MID would temporarily remove fencing as necessary;
- MID would use a front-end loader to haul in the dirt from on-site canal excavation areas, place it, and compact it in approximately 6-inch lifts by driving over the fill material with the rubber tires of the loader; and
- following emplacement and compaction, MID would re-install the fence.

Construction of Recharge Basins (Phase 2) The staging of recharge basin construction proposed would proceed as follows.

- *Stage 1:* Berming of recharge area boundaries along topographic contours and using farm roads wherever possible. These recharge areas would be constructed using graders that follow prestaked topographic contours to raise 1- to 3-foot-high berms around the downslope portions of areas ranging from five acres to 80 acres. Berm material would be obtained from an approximate 50-foot-wide corridor parallel to the interior toe of the berm. Topsoil would be segregated during excavation and respread over the berm and construction disturbance areas to promote reestablishment of vegetation.
- *Stage 2:* Deep ripping of corridors within the bermed areas, interspersed with corridors of undisturbed land. This will be done to ensure deeper percolation is maximized during project operation.
- *Stage 3:* Excavation of basins varying from four to five feet deep. Because of the demonstrated permeability of soils at Madera Ranch, Stage 3 recharge basins are unlikely to be required. However, in the event these basins were used, they would be constructed to minimize species and habitat effects, and possibly clustered in sets of two to four varying in size from five acres to 80 acres, with the first basin in each set serving as both a settling and a recharge basin. Basins would be designed with 1.5:1 to 2:1 interior side slopes and average depths of four to five feet. After excavation, each basin would be shallow-ripped or disked by construction equipment in order to break up compaction of the bottom soils in the recharge basin. Low earthen dikes would be constructed around

the recharge basins using excavated materials. Topsoil would be segregated during excavation and respread over the berm and construction disturbance areas to promote reestablishment of vegetation. Excess soil removed during excavation would be managed to ensure that top layers are stockpiled, excavated soils would be mounded between basins, and stockpiled topsoil would be placed on top of the soil pile.

It is estimated that Stage 3 recharge basins would be constructed using:

- three to 20 heavy diesel-powered scrapers (40- to 60-yard capacity);
- three to five 500- hp diesel-powered skip loaders;
- 15 to 30 heavy-duty, off-road-type trucks (60-yard capacity);
- three to five large, diesel-powered, crawler-type tractors; and
- three to five diesel-powered motor graders.

The final combination of the acreages and techniques summarized above is uncertain. However, as previously discussed, this EIS evaluates the potential effects associated with up to 323 acres of excavated basins.

Recovery Facilities

These elements are the same as described under Alternative B.

Staging Areas

These elements are the same as described under Alternative B.

2.4.4 Maintenance

These elements are the same as described under Alternative B.

2.4.5 Operations

These elements are the same as described under Alternative B.

Mitigation

MID has developed a Madera Ranch Mitigation, Grazing, and Management Plan that describes future management issues associated with Madera Ranch related to grazing, water, species, vernal pools, and monitoring of conservation lands.

MID has proposed mitigation for the potential effects to protected species and their habitats that could result from implementation of the Proposed Action. Three mitigation areas are proposed, the first two areas would include 2,357 acres of land managed to provide affected species habitat. The third mitigation area includes 3,456 acres, approximately 375 acres of which are planned as recharge swales.

These lands would be managed for both recharge and species protection purposes, and would provide relatively natural lands between the swales that can provide habitat for the effected species and connects the compensation areas (Figure 2-12).

Vernal pools created or restored would be inoculated with cysts and seeds from other high quality vernal pools on site in accordance with USFWS-approved methods.

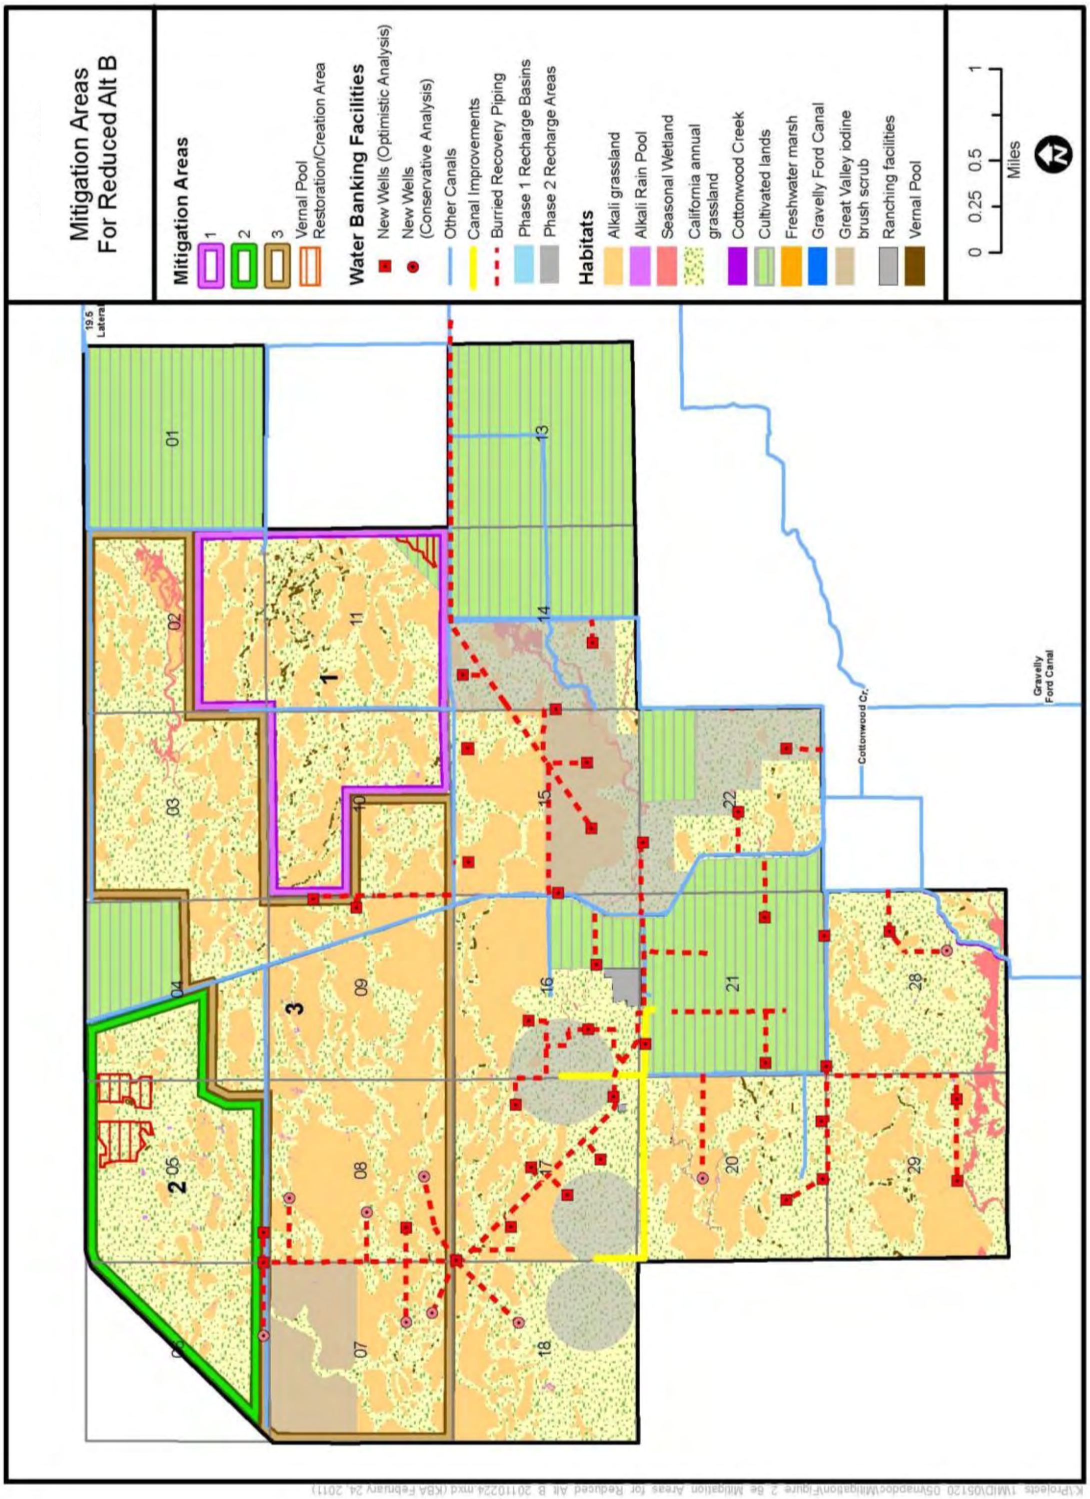

Figure 2-12 Mitigation Areas for Reduced Alternative B

2.5 Alternative C – Water Banking Outside the MID Service Area without Swales, and Alteration of Reclamation-owned Facilities

Alternative C is a variation of Alternative B that would complete the water bank in two phases and replace natural swale recharge solely with recharge basins. Phase 1 would involve recharge-related facilities only. Phase 2 would involve facilities for recovery of banked water. Reclamation would approve banking of CVP water outside the MID service area and alteration of Reclamation-owned facilities. Similar to Alternative B, Alternative C includes funding by Reclamation, under the Omnibus Public Land Management Act of 2009, the Policy and Program Services, Challenge Grant Program: Recovery Act of 2009 Water Marketing and Efficiency Grants, or any other funding source. Regardless of whether this funding is acquired, the project components and associated effects would be the same. A description of Alternative C follows.

2.5.1 Phase 1 Facilities

MID would implement Phase 1 to increase the capacity of existing MID conveyances to deliver water to Madera Ranch facilities. Phase 1 would use engineered basins as recharge areas (Figure 2-13).

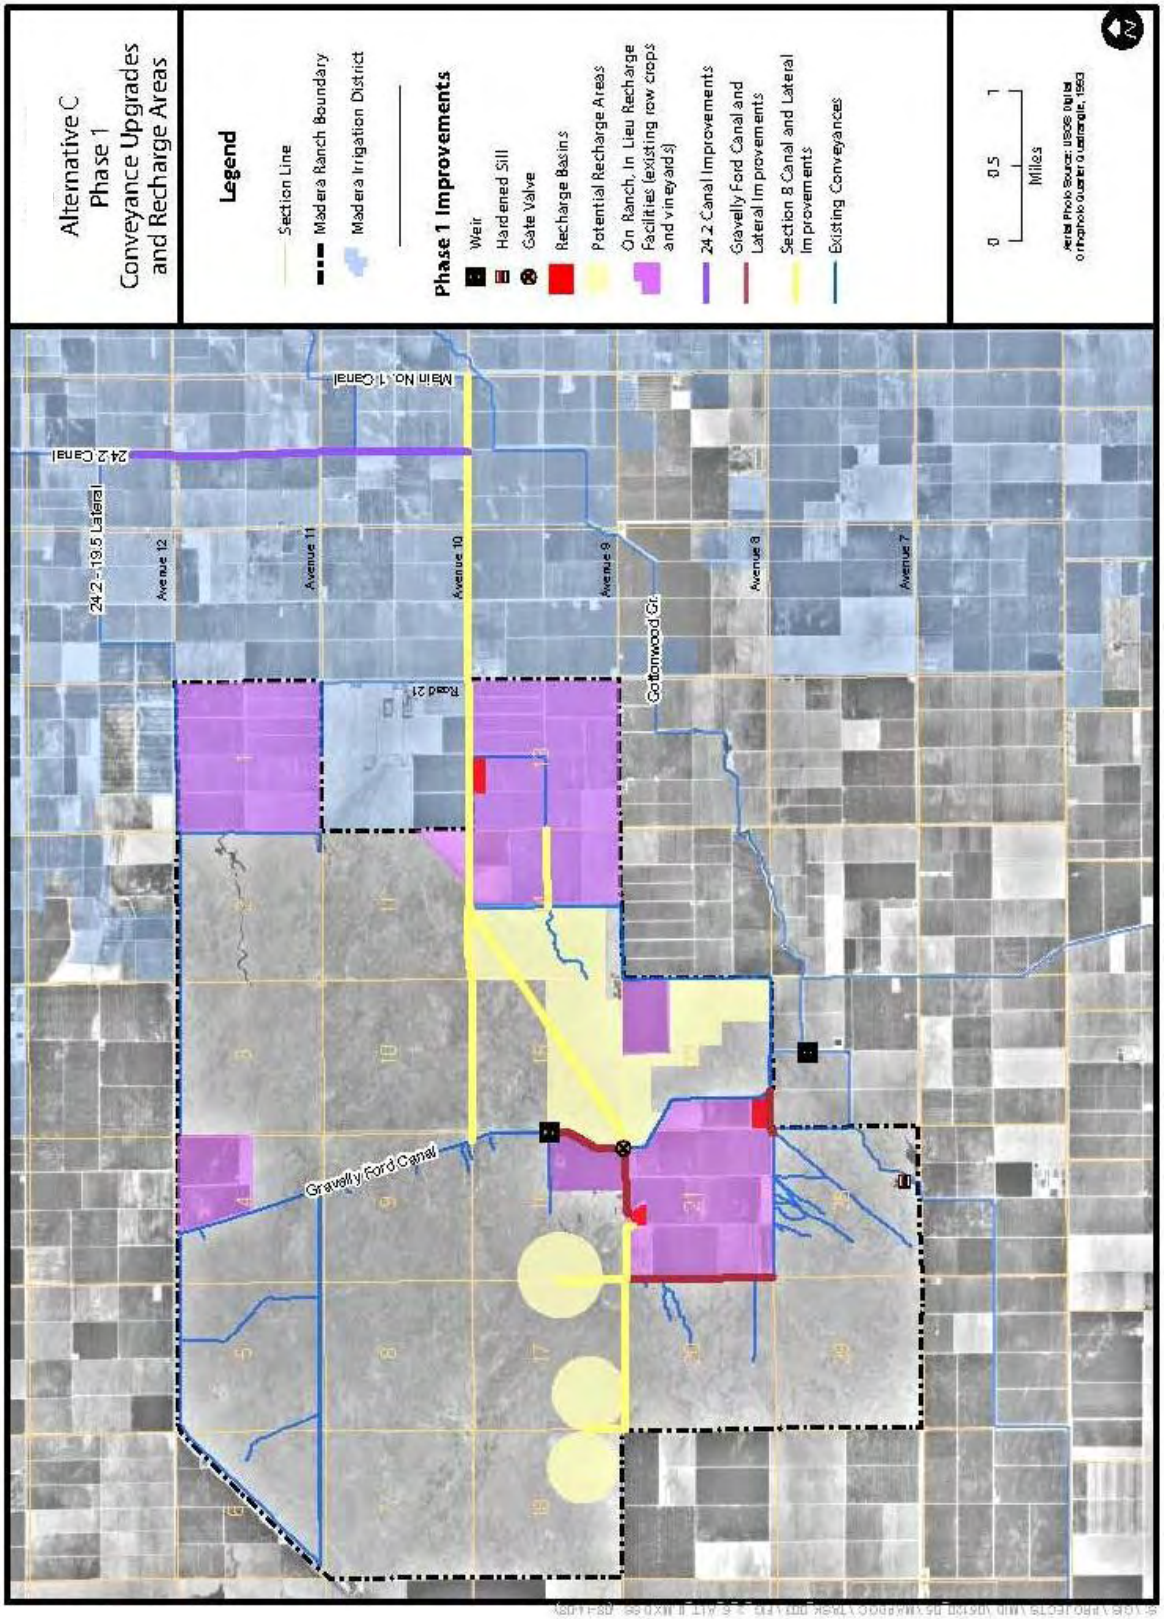

Figure 2-13 Alternative C Phase 1 Conveyance Upgrades and Recharge Areas

Phase 1 activities would involve:

- reconditioning and extension of existing canals to provide at least 200 cfs of conveyance capacity into Madera Ranch;
- construction of up to 1,000 acres of new on-site recharge basins and canals as required to achieve 200 cfs of recharge capacity; and
- integration of approximately 2,600 acres of Madera Ranch row crops and vineyards into an in-lieu recharge program in which surface water periodically would be served in lieu of groundwater pumping subject to approval by the MROC.

Diversion and Conveyance Facilities

Under Alternative C, conveyance facilities would be identical to those proposed under Alternative B, with the exception that neither the Section 8 Canal Northern Extension nor the Section 8 Canal Section 1 Lateral Extension would be required and Phase 2 conveyance upgrades under Alternative B would be constructed during Phase 1 of Alternative C to convey water to the engineered recharge basins.

Recharge Facilities

Recharge Basins Approximately 1,000 acres of recharge basins would be constructed within a 1,300-acre area. Recharge basins would be clustered in sets of three or four, varying in size from five to 80 acres, with the first basin constructed in each set serving as both a settling and a recharge basin.

Construction of the recharge basins and internal routing ditches could involve the movement of up to approximately 7.7 million cy of soil. Basins would be designed with 1.5:1 to 2:1 interior side slopes and average depths of four to five feet. Low earthen dikes would be constructed around the recharge basins using excavated materials. Topsoil would be segregated during excavation and respread over the berm and construction disturbance areas to promote reestablishment of vegetation.

In-Lieu Recharge Facilities As under Alternative B, MID would recondition existing turnouts and install new turnouts as in the Alternative B canals, pipelines, and ditches to enable delivery of surface water to these fields in lieu of groundwater pumping.

2.5.2 Phase 2 Facilities

Phase 2 would develop wells and piping to recover the banked water, and install pumps to deliver the recovered water as shown in Figure 2-14.

Phase 2 recharge and recovery facilities would involve:

- up to 15 existing wells for recovery;
- up to 49 new wells and recovery pipelines (in phases over several years) to provide 200 cfs of recovery capacity; and

- up to 12 lift stations on MID canals and one lift station on GF Canal (in phases over several years, total of 13 lift stations) to provide 200 cfs of pump-back capacity into the MID service area.

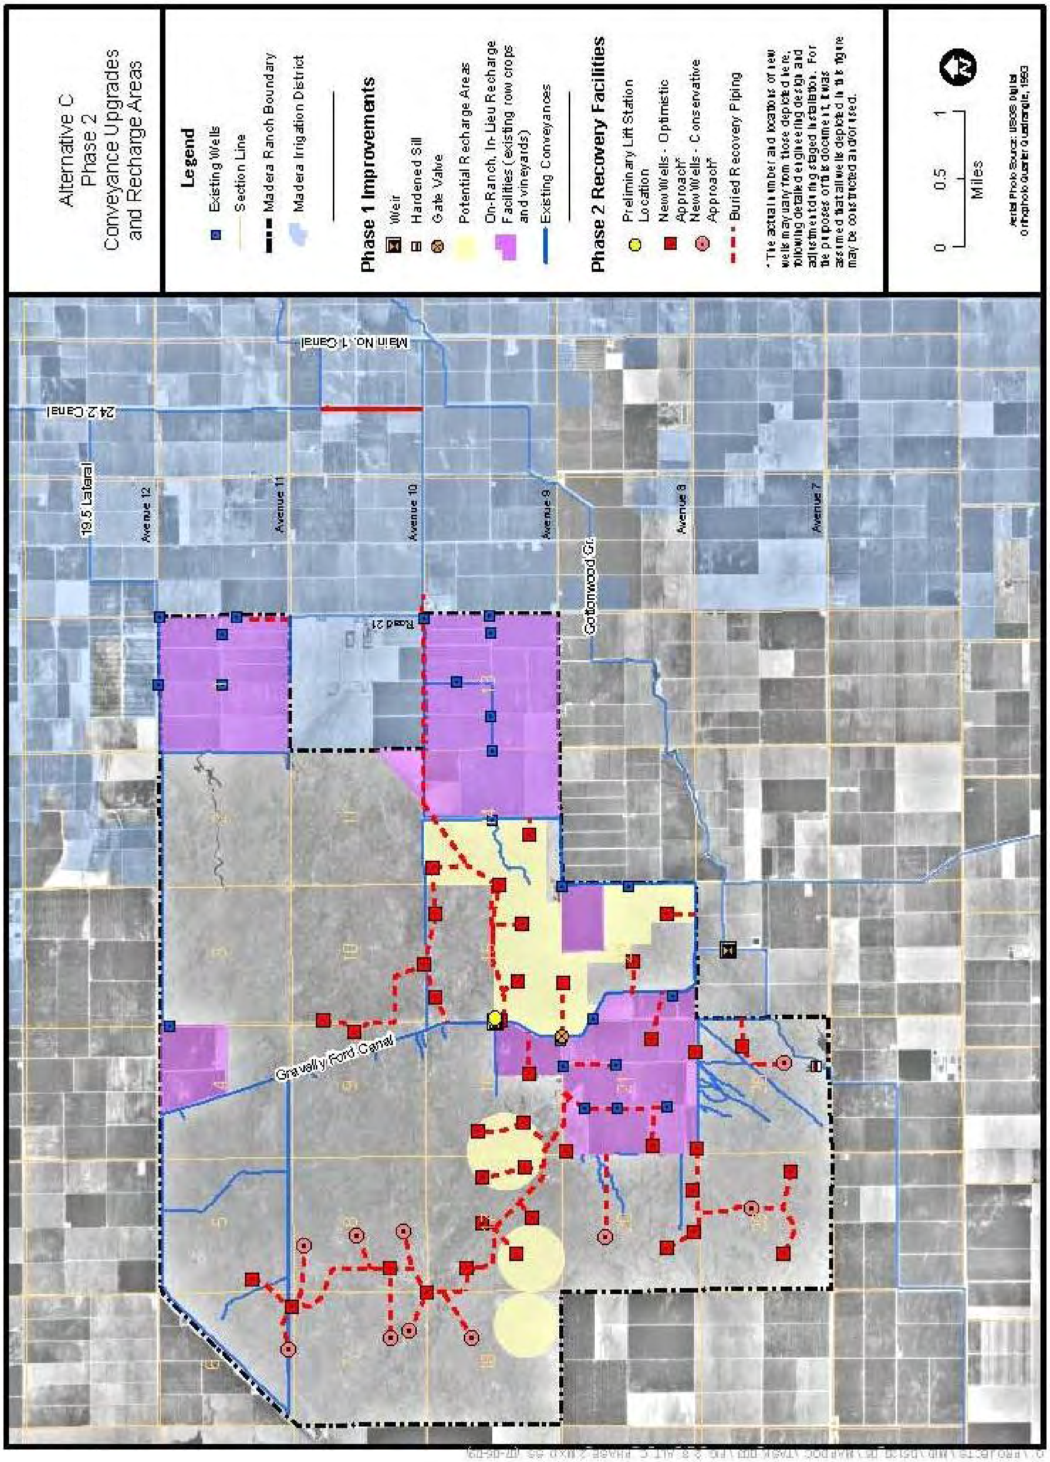

Figure 2-14 Alternative C Phase 2 Conveyance Upgrades and Recharge Areas

Recovery Facilities

Recovery Wells As under Alternative B, banked water would be recovered using up to 15 existing wells and approximately 49 new wells (Figure 2-14).

Recovery Pipelines and Electrical Facilities As under Alternative B, up to 11.6 miles of 8-inch- to 60-inch-diameter PVC to RCP buried recovery pipelines would run from recovery wells to the GF Canal and the Section 8 Canal for delivery back to farmers (Figure 2-14).

2.5.3 Construction

All construction methodologies necessary to construct Alternative C are described in detail under Alternative B – Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities.

Recovery Lift Stations

As under Alternative B, up to 13 lift stations would be required on the same conveyances used to deliver water into the water bank (Figure 2-14).

2.5.4 Maintenance

All maintenance methodologies necessary to operate Alternative C are described in detail under Alternative B – Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities.

Maintenance Corridors

As under Alternative B, the maintenance corridors would include new roads in the recharge basin area and areas with heavy disturbance, and unimproved routes in grassland areas.

2.5.5 Operations

Please refer to the Operations subsection of Alternative B – Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities. Discussion related to swales would not apply to Alternative C, but all other aspects of recharge operations would be identical.

Mitigation

Mitigation anticipated for Alternative C could be approximately 3,500 acres based on effects from facility and recharge basin construction.

2.6 Alternative D – Water Banking Outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal

Under Alternative D, MID would enter into an agreement with GFWD to improve the GF Canal to allow water to be conveyed from the San Joaquin River through the GF Canal to Madera Ranch for banking of water and recovery of water from the ranch back through the canal to the river. The existing GFWD river pumping plant would be upsized; the existing, associated pipeline replaced with a larger-diameter line; the GF Canal regraded to a flat-bottom (zero slope) configuration to allow two-way flow; a new connection to the river constructed to allow recovery water to reach the river without flowing through the pumps; and appropriate gate structures constructed. On-site improvements allowing water banking and extraction, including a pumping plant and pipeline to allow distribution of water uphill from the GF Canal, would be constructed.

MID would complete Alternative D in two phases. Phase 1 would involve recharge-related facilities only. Phase 2 would involve supplemental recharge facilities and facilities for recovery of banked water. Reclamation would approve the banking of CVP water outside the MID service area as described under Alternative B. No alteration of Reclamation-owned facilities would occur under Alternative D. However, similar to Alternative B, Alternative D includes funding by Reclamation, under the Omnibus Public Land Management Act of 2009, the Policy and Program Services, Challenge Grant Program: Recovery Act of 2009 Water Marketing and Efficiency Grants, or any other funding source. Regardless of whether this funding is acquired, the project components and associated effects would be the same.

2.6.1 Phase 1 Facilities

MID would implement Phase 1 to increase the capacity of existing conveyances to deliver water to Madera Ranch.

Phase 1 would use primarily natural swales as recharge areas. Phase 1 activities would involve:

- reconditioning of existing canals to provide at least 200 cfs of conveyance capacity into Madera Ranch;
- construction of approximately 26 acres of recharge basins on current agricultural land to regulate flow, remove sediment, and provide some recharge;
- application by MID of recharge flows to approximately 700 acres of swales; and
- integration of approximately 2,600 acres of Madera Ranch row crops and vineyards into an in-lieu recharge program in which surface water would be periodically served in lieu of groundwater pumping subject to approval by the MROC.

Diversion and Conveyance Facilities

Upgrades to Existing Canals Figure 2-2 depicts the locations of existing canals in the vicinity of Madera Ranch. During Phase 1, MID would upgrade existing canals to enable delivery of at least 200 cfs into Madera Ranch. The following sections summarize how these and other conveyances would be upgraded to provide 200 cfs of delivery capacity to and from Madera Ranch.

Gravelly Ford Canal The configuration of the GF Canal, as shown on record drawings from 1966, indicates that the canal cannot convey 200 cfs, in part because of its highly irregular bottom. To allow a two-way flow of up to 200 cfs, the canal would have to be regraded, and the intake pipeline on the San Joaquin River connecting the pump plant to the open canal segments enlarged to a 72-inch-diameter concrete pipe. A flow meter would be installed in the pipeline. In addition to the canal improvements, an upsized pumping plant and pipeline improvements would be completed. Additional improvements would involve:

- installation of three checkdams,
- reconstruction of culvert crossings and farm road bridges, and

- installation of a Parshall flume at the edge of Madera Ranch to measure recovery volumes.

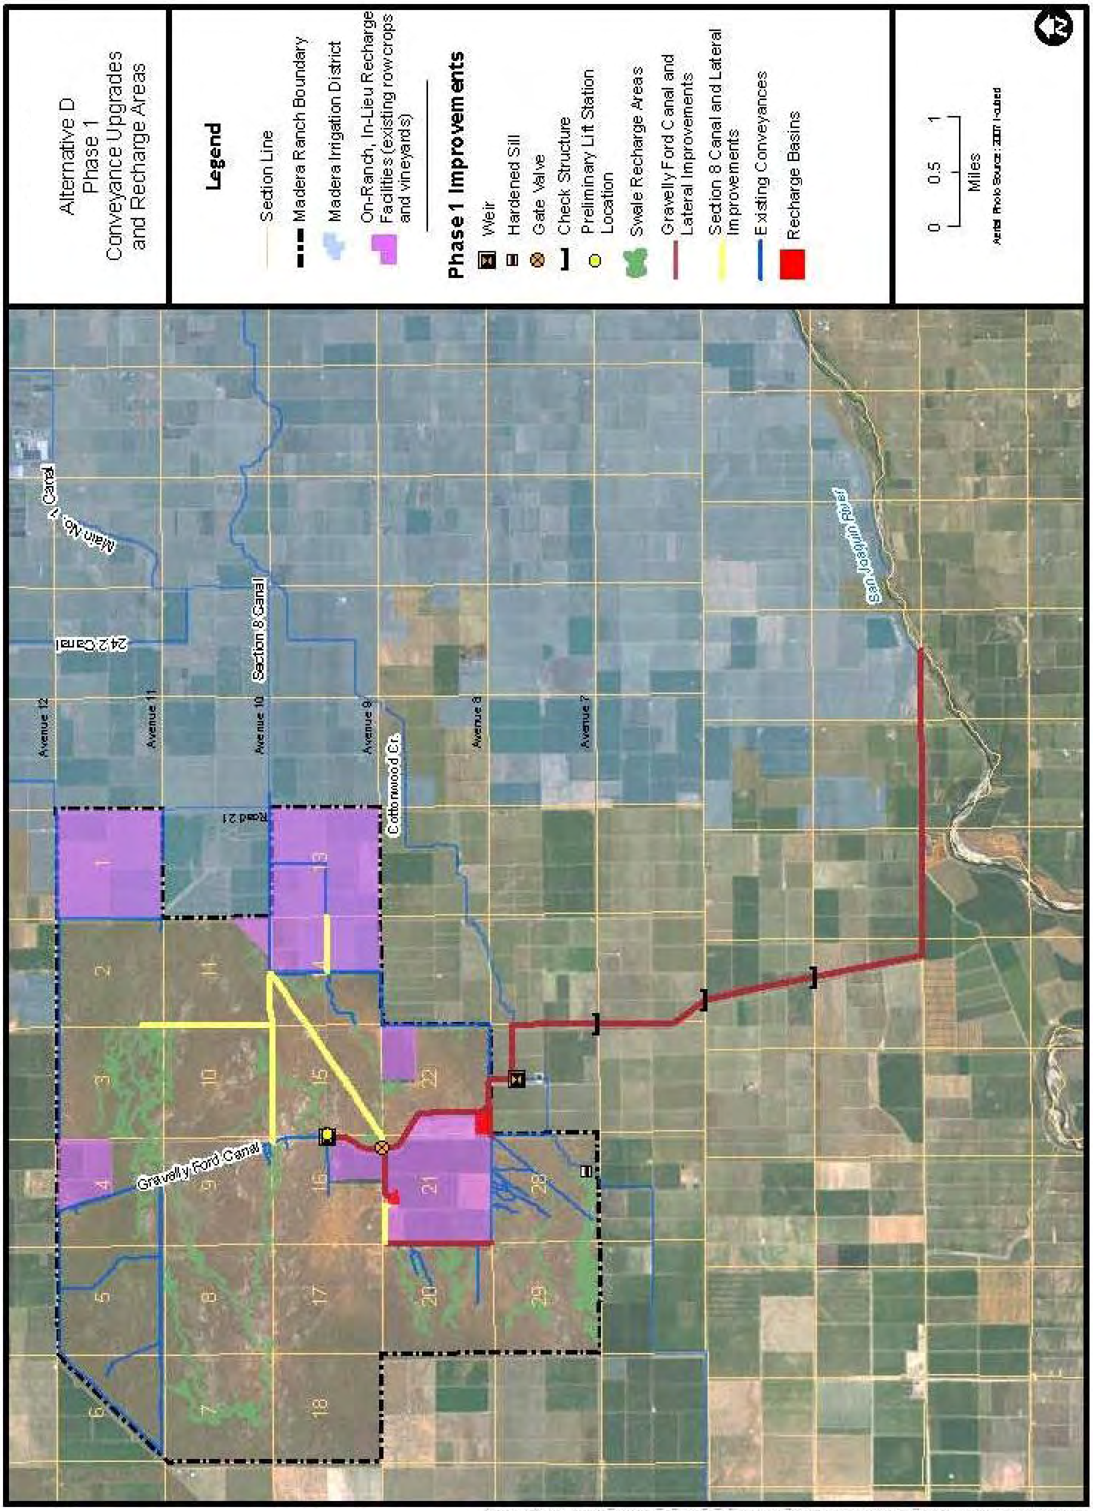

Figure 2-15 Alternative D Phase 1 Conveyance Upgrades and Recharge Areas

Additionally, a 400-hp pumping plant, consisting of two 200-hp pumps, would be required on-ranch to move water from the GF Canal uphill to the east as far as Section 13 so that water could be delivered to swales for recharge and in-lieu fields east of the canal.

Gravelly Ford Canal Sedimentation Basin and Flow Regulation Area With GFWD's permission, an approximately 0.6 mile segment of the GF Canal on the southeastern side of Section 16 would be equipped with a weir/control structure on the north side to allow use of the channel as a combined recharge area, sedimentation basin, and flow regulation area.

Gravelly Ford Canal Flow Control Weir at Cottonwood Creek As under Alternative B, with GFWD's permission, a new weir would be installed on the GF Canal approximately 1,000 feet south of Section 22 where the canal intersects and shares a channel with Cottonwood Creek (Figure 2-15).

Section 8 Canal/Gravelly Ford Canal Connection As under Alternative B, a new, approximately 1.55-mile-long, 20- to 50-cfs, earthen ditch would be constructed adjacent to a paved road in Sections 13, 14 and 15 to the GF Canal from the existing terminus of the Section 8 Canal (Figure 2-15).

Gravelly Ford Canal Section 21 Northern Lateral As under Alternative B, a new approximately 0.45-mile-long, 20- to 50-cfs earthen ditch would be constructed along the northern side of Section 21 from the GF Canal to a Phase 1 recharge basin located on farmland (Figure 2-15).

Gravelly Ford Canal Section 21 Western Lateral As under Alternative B, a new approximately one-mile-long north/south canal would be constructed along the western side of Section 21 off of an existing 20- to 50-cfs earthen ditch bordering the southern side of the section (Figure 2-15).

Gravelly Ford Canal Section 22 Southern Lateral As under Alternative B, a approximately 0.28-mile-long, 20-to 50-cfs earthen ditch would be constructed along the southern side of Section 22 from the GF Canal to an existing ditch (Figure 2-15).

Section 8 Canal Southwestern Extension Sections 14 and 15 are bisected diagonally by a 30- to 40-foot-wide, dirt farm road that was previously a ditch. As under Alternative B, a new approximately 1.8-mile-long, 20-cfs earthen ditch would be constructed from the Section 8 Canal along the shoulder of this road and to the GF Canal. This canal would require at least one pumping plant to deliver water from the GF Canal to the east (Figure 2-15).

Section 8 Canal Northern Extension As under Alternative B, Sections 10 and 11 are divided by a 20- to 40-foot-wide dirt farm road bordered by the remnants of a ditch. A new approximately 1.2-mile-long, 20- to 50-cfs earthen ditch would be constructed along the alignment of the old ditch (Figure 2-15).

Section 8 Canal Section 14 Lateral Extension An existing Section 8 Canal Lateral (20 cfs) that flows across Section 13 would be extended 0.5 mile across Section 14. All work would be performed along the edge of row crop land. This canal would require one pumping plant to deliver water to the east (Figure 2-15).

Reconditioning of Existing Ditches As under Alternative B, reconditioning would involve replacement of turnout gates, brush removal, repair of berms that have been worn down over time, reconstruction of segments that have been filled by recent farm operations, and installation of farm road crossings as required.

Recharge Facilities

Recharge Basins Phase 1 would involve construction of approximately 26 acres of basins, as shown in Figure 2-15, on agricultural land in order to:

- help regulate flows,
- allow settling of sediments prior to application of water to swales, and
- provide some recharge capacity.

The preliminary locations of two Phase 1 recharge basins are entirely on current agricultural land in Sections 21 and 22. The basins would be designed with 1.5:1 to 2:1 interior side slopes and average depths of four to five feet surrounded by low earthen dikes. Construction of the Phase 1 recharge basins could involve the movement of approximately 210,000 cy of soil. Topsoil would be segregated during excavation and respread over the berm and construction disturbance areas to promote reestablishment of vegetation.

Swale Recharge Areas As under Alternative B, water would be diverted into approximately 700 acres of swales. The water would be conveyed to Madera Ranch through the existing and upgraded MID conveyances and GF Canal and to the swales through the existing, rehabilitated, and new ditches described above. Locations of the swales anticipated to be used during Phase 1 are depicted on Figure 2-15.

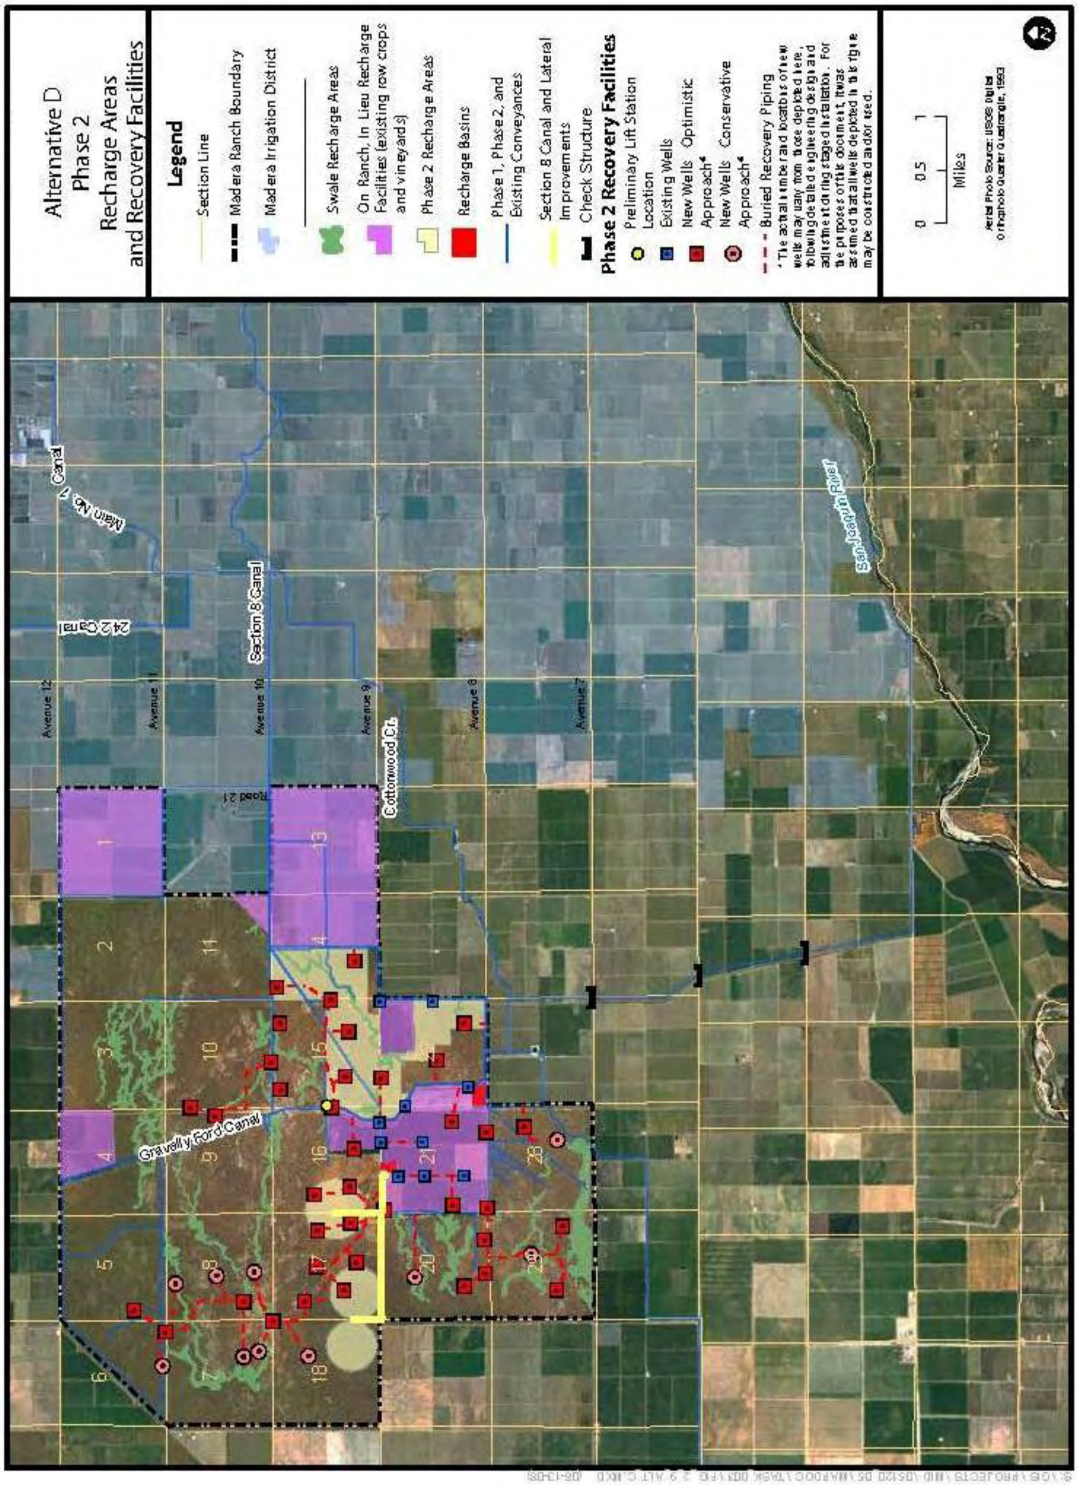
In-Lieu Recharge Facilities As under Alternative B, MID would recondition existing turnouts and install new turnouts from canals, pipelines, and ditches to enable delivery of surface water to these fields in lieu of groundwater pumping.

2.6.2 Phase 2 Facilities

Phase 2 would require the construction of wells and piping to recover the banked water, and installation of pumps to deliver the recovered water as shown in Figure 2-16.

Phase 2 recharge and recovery facilities would use or include:

- up to 15 existing wells for recovery,
- up to 49 new wells and recovery pipelines (in phases over several years) to provide 200 cfs of recovery capacity, and
- one lift station on GF Canal to provide 200 cfs of pump-back capacity to the San Joaquin River.



Aerial Photo Source: USGS Digital Orthophoto Quarter Quadrangle, 1993

Figure 2-16 Alternative D Phase 2 Recharge Areas and Recovery Facilities

Diversion and Conveyance Facilities

Upgrades to Existing Canals As under Alternative B, up to 3.2 miles of 20- to 100-cfs earthen ditches would be constructed within the Phase 2 basin window to distribute water into recharge areas.

Gravelly Ford Canal Section 21 Northern Lateral As under Alternative B, the 0.45-mile-long Phase 1 ditch along the northern side of Section 21 would be replaced with an approximately 2.1-mile-long, 135-cfs east-west earthen lateral canal along the north side of Sections 21 and 20 with two north-south sub-lateral canals running northward along the east and the west sides of Section 17.

Recharge Facilities

Recharge Basins As under Alternative B, depending on the performance of Phase 1 recharge facilities, up to approximately 1,000 acres of recharge basins may be constructed in a 1,300-acre area.

Recovery Facilities

Recovery Wells As under Alternative B, banked water would be recovered using up to 15 existing wells and approximately 49 new wells (see Figure 2-16).

Recovery Pipelines and Electrical Facilities As under Alternative B, up to 11.6 miles of 8-inch- to 60-inch-diameter PVC to RCP buried recovery pipelines would run from recovery wells to the GF Canal (Figure 2-16).

Recovery Lift Station One lift station would be constructed along the GF Canal to pump water recovered from wells back to the San Joaquin River through the canal

2.6.3 Construction

All construction methodologies necessary to construct MID facilities under Alternative D are described in detail under Alternative B – Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities. Construction of facilities on GFWD land and in GF Canal is described below.

Gravelly Ford Canal Improvements

Construction methods necessary for the upgrade of GF Canal are discussed in Alternative B under the subsections Upgrade of Section 8 Canal, Cottonwood Creek, and Main No. 1 Canal Connection, Weir Installation, and Construction of Recovery Lift Stations. The regrading of the off-ranch portions of GF Canal will require the movement of an additional 15,000 cy of soil.

2.6.4 Maintenance

All maintenance activities necessary to operate Alternative D are described in detail under Alternative B – Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities.

Maintenance Corridors

As under Alternative B, the maintenance corridors would include new roads in the recharge basin area and areas with heavy disturbance, and unimproved routes in grassland areas.

2.6.5 Operations

Madera Ranch operations, including banking, water recovery, and maintenance to support banking and recovery, are described below, including measures to monitor potential effects on neighboring farmers and districts (adjacent stakeholders).

Water Banking

Please refer to the Banking subsection of Alternative B – Water Banking outside MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities. Fewer swales, including those in Section 2, would be used under this alternative.

Monitoring and Operational Constraints Plan

Please refer to the Monitoring and Operational Constraints Plan subsection of Alternative B-Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities. The MROC would revise the plan to accommodate additional monitoring in GF Canal if this alternative is selected.

Delivery Protocol

As no Reclamation or MID conveyances to Madera Ranch would be upgraded under this Alternative, MID would not be able to recover banked water for conveyance to MID's users or other bank participants.

In order to implement this Alternative, MID would need to enter into a wheeling agreement with Reclamation using San Joaquin River Restoration water. Under this scenario, in years when water is available for banking, it would be wheeled through the San Joaquin River and then the GF Canal and banked at Madera Ranch. In years when the water is needed by MID, it would be recovered from wells and allowed to flow back through the GF Canal to the San Joaquin River. MID's releases of recovered water to the San Joaquin River would be used as San Joaquin River Restoration flows in exchange for deliveries of San Joaquin River Restoration water from Millerton Lake to Madera Ranch water bank participants.

These deliveries would be made in lieu of normal surface water deliveries from Millerton Lake or Hensley Lake. Therefore, an equal volume of water would be made available to MID from these reservoirs for delivery to other parts of the MID service areas, increasing the net supply of available water.

Water Recovery Operations

Water would be recovered using existing wells and new wells installed in the vicinity and downgradient of the recharge areas. As noted above, recovery operations would be constrained by the MOCP to prevent unacceptable impact on surrounding landowners. Recovered water would be pumped into collection piping and into the GF Canal for delivery to the San Joaquin River. Recovered water would be delivered through exchange agreements as discussed above in the Delivery Protocol subsection of Alternative D.

The recovery operations described above do not depend on farmer irrigation demand but would depend on the schedule of required flows for San Joaquin River restoration, which may not match banking participant needs.

Use of the Water Bank Facilities by Other Entities
Please refer to the Use of the Water Bank Facilities by Other Entities subsection of Alternative B.

Mitigation
MID would revise its mitigation commitments under this alternative. Mitigation anticipated for Alternative D could be less than approximately 4,500 acres depending on the number of acres of recharge basins constructed. MID's conceptual mitigation areas would include a portion of the areas illustrated in Figure 2-12.

2.7 Environmental Commitments

The following environmental commitments would be implemented where applicable, in association with construction activities for the alternatives The environmental commitments section was developed by Reclamation and MID in coordination with the Corps and USFWS. Each commitment would be implemented in accordance with each agency's policies, guidance, and authorities. Additional detail on the environmental commitments is in the Affected Environment and Environmental Consequences section.

Table 2-2 Environmental Commitments

Identifier	Environmental Commitment	Commitment Specifications
Agriculture		
AG-1	Permanently Preserve Farmland by Establishing a Conservation Easement on Agricultural Land	MID will establish conservation easements on agricultural land at an effect-to-mitigation ratio of 2:1 to prevent permanent conversion of the land to urban uses and to increase farm viability. This mitigation will be in kind and used to mitigate the loss of farmland classified as prime farmland or farmland of statewide importance.
Air Quality		
AQ-1	Implement San Joaquin Valley Air Pollution Control District Regulation VIII Control Measures for construction emissions of PM10.	• All disturbed areas, including storage piles, that are not being actively used for construction purposes will be effectively stabilized against dust emissions using water, chemical stabilizer/suppressant, or vegetative ground cover. Chemical stabilizer/suppressants will not be used near waters of the United States. • All on-site unpaved roads and off-site unpaved access roads used during construction will be effectively stabilized against dust emissions using water or chemical stabilizer/suppressant. • All land-clearing, grubbing, scraping, excavating, land-leveling, grading, cut-and-fill, and demolition activities will be effectively controlled against fugitive dust emissions by applying water or presoaking. • All operations will limit or expeditiously remove the accumulation of mud or dirt from adjacent public streets at least once every 24 hours during operations (The use of dry rotary brushes is expressly prohibited except where preceded or accompanied by sufficient wetting to limit visible dust emissions. The use of blower devices is expressly forbidden.). After materials are added to or removed from the surface of outdoor storage piles, the piles will be effectively stabilized against fugitive dust emissions using sufficient water or chemical stabilizer/suppressant.
AQ-2	Reduce Emissions Associated with Idling Equipment	Per California Air Resources Board regulations (Title 13 of the California Code of Regulations, Sections 2480 and 2485), which limit idling of diesel-fueled commercial motor vehicles, MID will require that all diesel engines be shut off when not in use to reduce emissions from idling.
AQ-3	Use Electric Pumps	MID will use as many electric pumps as possible for recovery operations to reduce emissions associated with propane. If propane pumps are needed, MID will use engines with catalytic controls and that meet SJVAPCD best available control technology (BACT) requirement for engines over 50 hp.
Biological Resources		
BIO-1	Establish a Grasslands Conservation Easement	Mitigation for the loss of California annual grassland, alkali grassland, or Great Valley iodine brush scrub would consist of establishing a grasslands conservation easement at Madera Ranch over an area of habitat larger than the area subject to long-term degradation (2 acres conserved: 1 acre affected for swales) or permanent loss (3 acre conserved: 1 acre lost). MID also would implement a Madera Ranch Mitigation, Grazing, and Management Plan to improve existing on-site habitat through grazing management and species monitoring. This measure would compensate completely for the loss of these habitats.
BIO-2a	Preconstruction Surveys/Avoid Effects on Vernal Pools and Alkali Rain Pools	MID will minimize effects on species in this habitat by avoiding these wetlands to the extent practical. A buffer area will be established around suitable habitat for listed crustaceans in the action area, i.e., vernal pools. Buffer areas will be demarcated by installing fencing 250 feet from each occupied pool. A qualified biologist will flag the pools to be fenced, and temporary fences will be installed as the first order of work. Construction barrier fencing will be placed at the edge of the buffer areas. Temporary fences will be furnished, constructed, maintained, and later removed as shown on the construction plans, as specified in the special provisions, and as directed by the project engineer. Temporary fencing will be four feet high, orange, commercial-quality woven polypropylene. No construction activities will be permitted within the buffer zone (including staging or sidecasting of material) other than those activities necessary to erect the fencing. Erosion control measures will be employed adjacent to occupied listed crustacean habitat to prevent soil from eroding or falling into these areas. Natural/ biodegradable erosion control measures (e.g., straw wattles, hay bales) will be used. Plastic monofilament netting (erosion control matting) will not be allowed.
BIO-2b	Create, Restore, and/or Preserve Vernal Pools	MID will create, restore and/or preserve vernal pool habitat at Madera Ranch in an area protected under a conservation easement. Five acres of vernal habitat would be restored and/or preserved for each acre of vernal pool or alkali rain pool habitat lost as a result of activities associated with the Proposed Action (5 acre created: 1 acre lost). MID anticipates that the approximate split of these acreages will be 3:1 preservation and 2:1 creation/restoration. This ultimately will be determined based on wetland locations, soil conditions, and consultation with the Corps; soils, hydrology, vegetation, and species will be monitored. The performance standard for created vernal pools is to ensure the new vernal pools emulate the natural pools at Madera Ranch. Created vernal pools would have similar plant species composition and vegetation cover and invertebrate fauna as the vernal pools that are being removed by activities associated with the Proposed Action. Success of the vernal pool creation would be assessed by comparing the pools with undisturbed natural vernal pools at Madera Ranch. Restored vernal pools will have similar success criteria. This mitigation would compensate for the loss of vernal pool habitat. Restoration is more likely to be successful in areas with degraded habitat and where preservation is the most assured. In addition, MID will comply with Reclamation's wetlands mitigation and enhancement policy, which focuses on protecting, restoring, and enhancing wetlands and ensuring no overall net loss of wetlands. Wetland mitigation creation and restoration sites will be monitored until it is proven successful to the Corps, USFWS, and DFG. Mitigation sites must function for at least three years without human intervention.
BIO-3a	Avoid Effects on Iodine Bush Scrub	MID will locate the well and pipeline to avoid direct effects on iodine bush scrub habitat in the northern portion of Section 7 associated with construction activities. If wells and pipelines need to be constructed in this habitat, MID will conduct botanical surveys and mark plants to be avoided during construction.
BIO-3b	Survey for Sensitive Plants	During Phase 1, two botanists conducted visual surveys for palmate-bracted bird's beak (*Cordylanthus palmatus*) and other sensitive plant species along a 60-foot corridor (30 feet per side) along the proposed pipeline and canal alignments and in the swales east of Gravelly Ford Canal. The surveys were conducted in April and July and reference populations were visited. No listed species were found and sensitive *Atriplex* species were mapped to minimize future effects. The results of the botanical surveys will be used to determine which avoidance, minimization, and environmental commitments will be employed. During Phase 2, additional botanical surveys will be conducted in the area proposed for recharge basin creation. Complete visual surveys will be conducted in a similar manner in all areas proposed for permanent ground disturbance. If palmate-bracted bird's beak is found, the population will be delineated with highly visible flagging tape or plastic fencing and avoided. If other sensitive species are found, MID, DFG and USFWS will coordinate to determine the feasibility of avoiding the population.
BIO-4a	Preconstruction Surveys for California Tiger Salamander	A USFWS-approved biologist will conduct preconstruction surveys for California tiger salamander (*Ambystoma californiense [=A. tigrinum c.]*) in suitable aquatic and upland habitat. Before the start of ground-disturbing activities or vegetation removal, the approved biologist or biological monitor will survey the area to be affected that day for California tiger salamanders. The biologist also will examine any open trenches, which will have ramps or be closed when unattended, for the presence of salamanders. If a salamander is found in the construction area, the approved biologist will remove the animal from the area and release it into a suitable burrow at least 300 feet outside the construction area. The biologist will document the results of surveys on preconstruction survey log sheets, which will be kept on file at MID.
BIO-4b	Restrict Construction Activity in Suitable Aquatic and Upland Habitat for California Tiger Salamander to the Dry Season (April 1–November 1)	To avoid and minimize potential mortality and injury of breeding and dispersing California tiger salamanders, construction will take place only during the dry season (between April 1 and November 1 or before the onset of the rainy season, whichever occurs first) in suitable aquatic and upland habitat for the species. Upland habitat is defined as all habitat within one mile of occupied or suitable aquatic habitat. Specifically, this measure applies to all pipeline construction on Madera Ranch and during work at all delivery canals. This measure does not apply to construction activities in gravel shoulders and heavily disturbed non-habitat areas where construction is confined entirely to areas devoid of upland grassland habitat.
BIO-4c	Fence the Construction Zone and Implement Erosion Control Measures	The construction zone will be fenced in areas where suitable aquatic habitat for California tiger salamander is adjacent to the construction area. The purpose of the fence is to restrict construction equipment to the designated area only. Erosion control measures also will be implemented in these areas to prevent any soil or other materials from entering aquatic habitat. Locations of temporary

Identifier	Environmental Commitment	Commitment Specifications
	in Areas Where Suitable Aquatic Habitat for California Tiger Salamander Is Present	fences and erosion control measures will be shown on the construction plans and will be reviewed by a qualified biologist. Construction barrier fencing will be installed along the edge of the work area as the first order of work. Temporary fences will be furnished, constructed, maintained, and later removed as shown on the plans, as specified in the special provisions, and as directed by the project engineer. No construction activities will be permitted outside the designated construction zone other than those activities necessary to erect the fencing. Erosion control measures will be installed adjacent to suitable aquatic habitat to prevent soil from eroding or falling into these areas. Natural/biodegradable erosion control measures (e.g., straw wattles, hay bales) will be used. Plastic monofilament netting (erosion control matting) will not be allowed because salamanders can be caught in this type of material.
BIO-5	Pre-Activity Surveys for Blunt-Nosed Leopard Lizard	The objective of the blunt-nosed leopard lizard (*Gambelia [=Crotaphytus] sila*) (blunt-nosed leopard lizard) surveys is to avoid take of blunt-nosed leopard lizard during use of the swales for water banking and construction of water delivery canals and other facilities. Specific measures for linear facilities and swales are described below.
Bio-5a	Install exclusion fencing and conduct clearance surveys and construction monitoring for blunt-nosed leopard lizards	*Linear Facilities* Prior to construction of linear facilities in grassland and/or saltbush scrub/Valley sink scrub habitat and adjacent dirt roadways MID, in consultation and coordination with qualified wildlife biologists, shall create exclusion corridors based on habitat suitability and the need to create exclusion zones for burrows, scalds, and wetlands. Construction of linear facilities is restricted to May 1st through August 1st and may commence in areas only after Blunt-Nosed Leopard Lizard (—BNLL”) pre-construction surveys are completed. Pre-activity BNLL surveys were coordinated with the USFWS and CDFG since California's Fish and Game Code does not allow take of this species. Pre-activity surveys shall consist of the following minimum parameters: 1. Surveys for adult BNLL shall be conducted between April 28th and July 1st and shall occur when the air temperature (as measured at 1-2 cm above the ground over a surface most representative of the area being surveyed) is between 25 °C - 35 °C (77 °F – 95 °F). Once the air temperature falls within the optimal range, surveys may begin after sunrise (once sun is high enough to shine directly on the ground surface being surveyed) and must end by 1400 hours or when the maximum air temperature is reached, whichever occurs first. 2. Time of day and air temperature shall be recorded at the start and end of each survey. 3. Surveys will not be conducted on overcast (cloud cover > 90%) or rainy days or when sustained wind velocity exceeds 10 mph (>3 on Beaufort wind scale). 4. Surveys shall be conducted on foot and transects shall be no larger than 10 meters wide, consist of a slow pace, and be conducted on a north-south orientation when possible. 5. Surveys shall be conducted for 12 days over the course of a 30 day period. Surveys shall be conducted for 4 consecutive days, weather permitting with at least one survey session consisting of a 4 consecutive day period. 6. The starting/ending locations of surveys should be modified/alternated to the extent practicable, but resulting in the same area surveyed. This is so that different portions of the site are surveyed at different time/temp periods. 7. Surveyors must be approved by the DFG and USFWS to conduct the BNLL reconnaissance surveys. The survey crew conducting focused BNLL surveys shall consist of no more than 3 Level I surveyors for every Level II surveyor. The names of every surveyor must be recorded for each survey day. 8. All herpetofauna observations shall be recorded/tallied. All BNLL observations shall be recorded with GPS, time of observation, name of observer, sex (if evident), and lifestage (adult, juvenile, hatchling). If BNLL is observed in association with or observed entering a particular burrow, burrow location (via GPS) should be recorded as well. 9. If a BNLL is observed within such areas, consultation with CDFG must immediately occur. However, if BNLL observations are made, BNLL surveys should not be halted; the entire survey should be completed for the entirety of the construction footprint; continuing the surveys is important to maximize detections and to best help inform where the lizards occur and may not occur. Partial surveys cannot be used to inform whether or not avoidance can or will occur. (hereafter 1- 9 collectively referred to as, —BNLL Pre-Construction Survey Parameters”.) A. <u>Installation of Barrier</u> - Within 3 days after BNLL pre-construction surveys are completed, biologists shall oversee the creation an exclusion area by installing a non-gaping non-climbable barrier using a material approved by DFG and the USFWS along 3 sides of the planned linear facility construction perimeter. The barrier installation shall be overseen by biologists who have BNLL experience and who have been approved in advance by USFWS and DFG (hereafter, qualified BNLL biologists). The barrier fencing shall be installed perpendicular to the ground (vertical) and shall be sealed to ensure there are no gaps between segments or under the fencing. An example of possible suitable material can be found at http://www.ertecsystems.com/. Small mammal burrows and burrow complexes shall be excluded from the liner facility construction areas to the maximum extent practicable and a no disturbance buffer zone shall be established and clearly delineated from any burrows / burrow complexes. The day following the installation of the fencing, the qualified BNLL biologists shall walk approximately 10 meter transects along the partially fenced linear facility construction area during the time of day when air temperatures fall within the optimum range for species detection, during the peak BNLL activity season, and as outlined above. If no BNLL are detected, the fourth side of fencing may be installed and MID may begin work within the fenced area. At least two DFG and USFWS approved biologists will be present within the construction area when construction and other activities within the exclusion area are in progress. B. <u>Walking Surveys Throughout Construction</u> - Throughout construction, the biologists shall conduct walking surveys of the construction area, looking for BNLL. All open holes and trenches within habitat will be inspected at the beginning of the day, middle of the day, and end of day for trapped animals. If BNLL are detected at any time and within any area of the basin construction site, biologists will halt all work, open a section of the exclusion fencing, and allow the lizard to leave the area on its own (no chasing, following, etc. can occur). C. <u>Inadvertent Entrapment Prevention</u>-- To prevent inadvertent entrapment of BNLL or any other wildlife during the construction phase of the linear facilities, all excavated, steep-walled holes or trenches more than 2 feet deep shall be covered at the close of each working day by plywood or similar materials or provided with one or more escape ramps (with no greater than a 3:1 slope) constructed of earth fill or wooden planks. Before such holes or trenches are filled, they shall be thoroughly inspected for trapped animals by a qualified biologist. If BNLL are trapped, then it shall be allowed to escape on its own. In addition, all construction pipe, culverts, or similar structures with a diameter of 7.6 centimeters (3 inches) or greater that are stored at the construction site for one or more overnight periods will be thoroughly inspected for BNLL before the pipe is subsequently moved, buried, or capped. If during inspection one of these animals is discovered inside a pipe that section of pipe shall not be moved until the animal has escaped on its own. D. <u>Construction Time</u> - The permitted construction time is from one hour after sunrise to one hour before sunset, and two biological monitors shall also be active at all times when construction or other activities are in progress. The biological monitors shall survey the construction area during construction, scanning the ground for BNLL and routinely checking excavated soils to ensure that BNLL are not present. The biological monitors shall stop work if a lizard is found within the construction area until the lizard has been excluded from the work area. E. <u>Multiple Construction Areas</u> More than one linear facility construction area may be established and under construction at the same time provided the minimum number of biologists and biological monitors are present at each of the sites at all times during construction or other related activities.

Identifier	Environmental Commitment	Commitment Specifications
		F. <u>Notification of Dead or Injured BNLL</u> - If any dead or injured BNLL are observed on or adjacent to the construction site, or along haul roads/travel routes for worker and/or equipment, regardless of assumed cause, DFG and USFWS shall be notified. The initial notification to DFG and USFWS shall include information regarding the location, species, and the number of animals injured or killed. Following initial notification, MID shall send DFG and USFWS a written report within 2 calendar days. The report shall include the date and time of the finding or incident, location of the carcass, and if possible provide a photograph, explanation as to cause of death, and any other pertinent information. G. <u>Fully Protected Species</u> - These measures shall not be required if the species' fully protected status is rescinded and MID obtains incidental take authorization from DFG for this species for this project. *Recharge Basins* MID, in consultation and coordination with qualified wildlife biologists, shall create appropriately sized recharge basin construction areas before construction of recharge basins in grassland and/or saltbush scrub/Valley sink scrub habitat and adjacent dirt roadways within the former center pivot areas of Section 16, 17, and 18 on Madera Ranch. Construction areas shall be prioritized initially by reconnaissance surveys no more than 60 days prior to any basin construction activities or ground disturbance to identify areas with the fewest burrows and least suitable habitat for BNLL. Construction of basins will be restricted to May 1st through August 1st and may commence in areas identified through the above referenced reconnaissance surveys only after BNLL pre-construction surveys are completed by way of the BNLL Pre-Construction Survey Parameters (See paragraph I.A. above). The information gathered from these surveys will be used by DFG to determine which habitat is most likely occupied and to identify appropriate exclusion areas. (Basins shall initially be planned to be sited in the former center pivot areas of Section 16, 17, and 18.) If no BNLL is observed within 3 days after the completion of the BNLL pre-construction survey, biologists shall create an exclusion area by installing non-gaping non-climbable barrier. The installation for such barrier shall comply with the installation guidelines listed above under linear facilities, and must be supervised by a qualified BNLL biologist. (See paragraph I.B above.) Construction of the recharge basins is permitted from one hour after sunrise to one hour before sunset. (See I.E above.) More than one percolation basin construction area may be establish and under construction at the same time provided the minimum number of biologists and biological monitors are present at each of the sites at all times during construction or other related activities. Throughout construction, Biologists shall conduct walking surveys of the construction area to determine whether there is any detection of the BNLL. The survey procedures shall comply with paragraph I.C. listed above. Also during construction, all excavated, steep-walled holes or trenches more than 2 feet deep shall be covered as described under I.D above, to prevent inadvertent entrapment of BNLL or any other wildlife. Finally, if any dead or injured BNLL are observed on or adjacent to the construction site, then MID must notified DFG and USFWS in accordance with the outline procedures listed above under I.G. If the BNLL fully protected status is rescinded and an incidental take permit is granted, then these measures will not be required. *On-Ranch Ground Disturbing Facility Maintenance* MID will have an agency approved biologist review future ground disturbing facility maintenance work locations and sizes to evaluate the potential for effects to BNLL. If the activity is in suitable habitat and could affect burrows, MID will conduct the work during the appropriate seasonal window and implement site-specific exclusion measures such as fencing and additional surveys as prescribed above for linear facilities.
Bio-5b	Conduct blunt-nosed leopard lizard and burrow surveys of swales proposed for inundation	MID will conduct BNLL and burrow surveys of swales prior to inundation in swales. Those portions of swales that have been inundated annually for extended periods prior to Project approval will not be surveyed because potential burrows likely have been inundated and eroded, and BNLL are unlikely to aestivate in these areas. Pre-wetting BNLL surveys will be consistent with the *BNLL Pre-Construction Survey Parameters* listed above under I.A.. The information from these surveys will be used to determine which habitat is most likely occupied and to identify appropriate swale use areas. If no BNLL are found during the surveys, water may be applied throughout that following year. If a BNLL is sighted within the low point of a swale (i.e., the expected inundation area) it will be difficult to determine whether the burrows in the area are being used for nesting or refugia. Therefore, MID will delay using the swale for banking until the active season (April 28 to July 1); then MID will apply water to the swale slowly (i.e., approximately 12 inches per minute) to ensure lizards can escape burrows. These measures shall not be required if the species' fully protected status is rescinded and MID obtains incidental take authorization from DFG for this species for this project.
Bio-5c	Implement other protective measures for blunt-nosed leopard lizard	MID will implement other protective measures for blunt-nosed leopard lizard. MID would create at least three canal crossings along Gravelly Ford Canal and 6 canal crossings along the Section 8 Canal Northern Extension; the width of the crossings will vary from approximately 16 feet along Gravelly Ford Canal to approximately eight feet along the Section 8 Canal Northern Extension. While making Gravelly Ford Canal improvements and installing the Section 8 Canal Northern Extension, MID would excavate slightly below the bottom grade of the canal to install a culvert and provide for a crossing to connect the habitat units. The area would be backfilled, covering the crossing with soil from the canal improvement. A similar concept would be employed for the Section 8 Canal Northern Extension, though the length of the pipe segment would be four to eight feet and because of the flat hydraulic grade one larger pipe may be used. Additionally, on-ranch canal side slopes will be designed to allow BNLL to avoid entrapment.
BIO-6	Preconstruction Surveys and Avoidance Activities for Raptors	Preconstruction surveys would determine whether any sensitive raptors are nesting at Madera Ranch. If a tree is occupied at the time of construction, construction activities will be restricted to areas outside 0.5 mile of the tree. Setbacks will be marked with brightly colored temporary fencing.
BIO-7	Preconstruction Surveys for Western Burrowing Owl	The initial daytime burrow survey will help inform the Western burrowing owl (*Athene cunicularia*) survey. A qualified wildlife biologist will conduct a burrowing owl survey in accordance with DFG guidelines. The survey area will include the construction corridor and a 500-foot buffer. An initial survey will determine whether burrowing owls are present. Three additional surveys will be conducted to determine presence or absence of burrowing owls. In accordance with DFG survey guidelines, these surveys must be conducted on four separate days—two in the early morning and two in the late afternoon/early evening. Non-nesting owls may be passively relocated, also using DFG's guidelines.
BIO-8	Preconstruction Surveys for San Joaquin Kit Fox	Because of historical records and suitable San Joaquin kit fox (*Vulpes macrotis mutica*) habitat on or in the vicinity of Madera Ranch, it is assumed that kit foxes could be present at Madera Ranch. To avoid potential mortality of kit fox, agency approved (by USFWS and DFG) experienced biologists will survey to locate any natal dens, non-natal active dens, and/or potential dens in the Proposed Action area. Visual surveys will be conducted during meandering transects of the 1,000 foot corridor. If an active natal den is found, USFWS and DFG will be notified and MID will delay construction within 1,000 feet of the den until the pups have been weaned or moved to an off-site den, and/or reroute the construction corridor to avoid impacts on the kit foxes. Standard Kit fox provisions will be followed in accordance with USFWS guidelines.

Identifier	Environmental Commitment	Commitment Specifications
		Surveying will include meandering transect surveys for active dens (non-natal) out to 250 feet from the proposed facilities, which will involve simultaneous surveys for potential den sites out to 100 feet. If an active den is found, it will be avoided until the foxes have vacated the den. All potential dens will be flagged. Any potential den immediately in the construction corridor may need additional monitoring. Because construction is expected to proceed quickly—approximately 1,000 feet per day with trenches being open one to two nights—potential dens will not be collapsed. All surveys will be conducted within 30 days of site-specific construction by a qualified biologist. In addition, during construction, USFWS standard kit fox conservation measures such as speed limits, exit ramps, controlling toxic (oil or gas) spills from construction equipment, and covering pipes will be implemented to prevent harm or disturbance to kit foxes using the area. Any open pipes, newly dug pipeline trenches, and canals will be surveyed daily prior to construction to ensure kit foxes are not present.
BIO 9	Conduct Pre-Activity Surveys for Fresno Kangaroo Rat	The objective of the Fresno kangaroo rat (*Dipodomys nitratoides exilis*) surveys is to determine whether the Fresno kangaroo rat is present on the portion of Madera Ranch that could be affected by use of the swales for water banking and construction of water delivery canals. Initial trapping focused on the swales and canals east of GF Canal and determined the species was not present. Subsequent trapping will occur 1-year before use of swales or construction of facilities west of GF Canal. Surveys in swales will be conducted 1 to 2 years before the first wetting of the swale and will be valid for 5 years after the wetting of the swale. If the swale is re-wetted within the 5-year period, it will not need to be surveyed for another 5-year period. No additional survey efforts will be conducted of any swale areas that have been surveyed twice with neither survey resulting in a single trapping of the Fresno kangaroo rat. Kangaroo rat trapping efforts will be conducted by a surveyor holding a recovery permit for the Fresno kangaroo rat (10[a][1][A] permit). Meandering visual transect surveys for kangaroo rat burrow complexes and sign (e.g., tail drags, sand baths, seed caches) will be conducted by two to four biologists over all habitat within and out to 250 feet from the edge of the WSEP footprint, including swales, and within 100 feet of the top of GF Canal. All burrow complexes found will be recorded on a GPS unit, and data on the number of burrows, level of activity, and general suitability for kangaroo rats will be recorded in field notes (burrows suitable for kit fox also will be noted on GPS as part of this effort); information on vegetation type and percent cover also will be recorded. Following completion of the survey, potential trapping-sites will be prioritized based on a combination of the level of kangaroo rat activity (as evidenced by burrow density and/or the presence of other sign, though some areas without obvious sign may also be trapped) and project area coverage. Live trap stations and trap lines then will be established (staked and recorded with a GPS unit) by permitted biologists at the highest priority sites. Traps (Sherman live traps [Model XLKR: 13 inches x 3.5 inches x 3 inches]) will be set near active burrows, dust baths, or tracks, particularly along evident runways. Ten or more traps (or a number determined by the surveyor) will be set in relatively tight clusters (5-foot trap spacing) at high activity areas. Traps also will be set at 10 to 15 meter intervals (two traps per station) along evident movement corridors. Traps will be baited with a mixture of millet seed, crimped oats, wild birdseed, or other suitable seed. Bedding (crumpled unbleached paper towel) will be placed at the inside end of each trap and will not be allowed to contact the tripping mechanism. Paper towels will be replaced each time an animal is captured in the trap. Traps will be opened and baited at sunset and checked 1-2 times/evening as deemed appropriate by the lead biologist. All traps will be closed after they have been checked at dawn. Trapping will be conducted at each trap site for five consecutive nights. Trapping will not be conducted during the week of a full moon, unless the sky is overcast and moonlight is substantially reduced. Trapping will not be conducted in December or January or in periods of cold or inclement weather detrimental to kangaroo rats and as stipulated in the surveyor's recovery permit. Although Fresno kangaroo rats are active year round, their populations generally are lowest at this time. All non-Fresno kangaroo rats captured will be marked with a nontoxic semi-permanent ink marker on the belly to identify the re-trapping of the same animal(s). Trapping will cease with the capture of a Fresno kangaroo rat and MID, the USFWS, and DFG will be notified as soon as possible, if not the same day, then the next workday, or no later than the Monday following the capture should it occur on a Friday or Saturday night. Any measurements obtained to provide evidence that the animal captured is a Fresno kangaroo rat will be achieved with minimal and delicate handling fur and tissue samples will be taken only by a qualified, permitted biologist in accordance with their permit terms. A photo of the animal's hind legs (showing toes and including a ruler) will be taken and the animal will be immediately released; the animal's eyes will be shielded from the flash. The lead biologist will notify MID of the proposed trapping schedule and will inform MID weekly which trapping areas have been completed. Any capture of Fresno kangaroo rat will be reported immediately to MID, the USFWS, DFG, and Reclamation.
BIO-10	Conduct Preconstruction Surveys for Sensitive Species along the Off-Ranch Portion of Gravelly Ford Canal	Proposed off-ranch work areas associated with GF Canal improvements will be evaluated by a USFWS-approved biologist to determine whether habitat suitable to support sensitive species is present. If suitable habitat is discovered, MID will evaluate work locations to determine which species could be present and whether additional surveys may be needed. Depending on the results of this survey, MID also may implement Environmental Commitment BIO-1: Establish a Grasslands Conservation Easement, Environmental Commitment BIO-5: Pre-Activity Surveys for Blunt-Nosed Leopard Lizard, Environmental Commitment BIO-6: Preconstruction Surveys and Avoidance Activities for Raptors, and Environmental Commitment BIO-7: Preconstruction Surveys for Western Burrowing Owl.
BIO-11	Implement Protective Measures for Anadromous Fish	MID would work with Reclamation and the National Marine Fisheries Service (NMFS) to determine appropriate protective measures for migratory fish once they are restored to the San Joaquin River, including seasonal restrictions on diversions or intake screening in the event water is moved to and from Madera Ranch via GF Canal (Alternative D). Inter-agency discussions would occur at least two years in advance of the reintroduction of these species to the San Joaquin River.
Cultural Resources		
CR-1	Stop Construction If Cultural Resources Are Discovered	In the event of any inadvertent cultural resources discovery, human or otherwise, uncovered during construction or other ground-disturbing activities, the construction contractor will immediately stop work in the immediate vicinity and a minimum 100-foot buffer area from the find. The contractor will notify MID immediately and MID will notify Reclamation of the inadvertent discovery. A professionally qualified archaeologist will be sent to evaluate the inadvertent discovery for National Register of Historic Places (NRHP) eligibility. If human remains are discovered during ground-disturbing activities, the party responsible for CEQA will comply with state laws[1] relating to the disposition of human remains pursuant to Public Resources Code (PRC) section 5097. Reclamation may have additional responsibilities under Section 106 of the NHPA and will follow the procedures in 36 CFR Part 800.13.
Geology, Soils, Seismicity and Erosion		
GEO-1	Amend Soils as Required in Topsoiled Areas	Topsoiled areas with insufficient vegetation cover will be amended with gypsum and/or elemental sulfur in combination with high-quality irrigation water to reduce soil salinity, alkalinity, and exchangeable sodium to acceptable levels, such that acceptable vegetation cover is established in such areas within one year after topsoil is applied. All soil sampling and amendment recommendations will be conducted by, or under the supervision of, a certified professional soil scientist.
GEO-2	Stop Work in Event of Fossil Discovery	In the event that a fossil or material that could be a fossil is unexpectedly discovered during excavation operations, work will cease in the immediate vicinity of the find. A qualified paleontologist will be called to the site to evaluate the find and determine the sensitivity of the fossil. If the fossil is determined to be sensitive, the paleontologist will recover it from the site and submit it to an appropriate

---

[1] Madera Ranch does not include federal land, so only state human-remains laws apply.

Identifier	Environmental Commitment	Commitment Specifications
		museum or other repository for curation.
Hazards, Public Health and Safety		
PHS-1a	Implement Necessary Emergency Preparedness Plan(s)	MID will work with the Madera County Department of Public Health and the local fire districts to coordinate the preparation of emergency preparedness plan(s) that may be required by federal, state, and County statutes and regulations.
PHS-1b	Comply with Local Fire District Requirements	MID will consult the local fire districts to ensure that all regulations are complied with during construction.
PHS-2	Implement an Agreement with the Madera County Mosquito and Vector Control District	MID will enter into an agreement with the Madera County Mosquito Abatement & Vector Control District (MCMAVCD) regarding a specific mosquito abatement program. The agreement will allow the MCMAVCD to access Madera Ranch and also will include quantitative abatement thresholds and financial compensation requirements for MCMAVCD activities, if necessary. The MCMAVCD will monitor mosquito larvae production in the recharge basins, drainages, and distribution canals at no cost to MID, given that the amount of monitoring required is not excessive. Larvae populations will be tracked using methods and thresholds approved by the MCMAVCD, and suppression measures will be employed when thresholds are exceeded. Suppression measures may include environmental and biological methods, such as stocking mosquitofish, controlling emergent vegetation, and applying insecticides. Insecticide controls will be used only as a last resort, and use of insecticides over open water will be minimized to the extent feasible, given the mosquito abatement mandate of the MCMAVCD. The insecticides that may be used are only those that are approved for such uses by the U.S. Environmental Protection Agency (EPA). Mosquitofish, if used, will need to be stocked annually by the MCMAVCD. If operations result in an increase in mosquito production such that an extensive monitoring program is needed, MID will hire a professional pest control service and will bear the cost of that service.
Noise		
NOI-1	The construction contractor will employ noise-reducing construction practices so that noise from construction does not exceed County noise-level standards at adjacent residences.	Measures to be implemented would include the following. • Restrict construction to beyond 3,900 feet from residences during nighttime hours (10 p.m. to 7 a.m.). • Provide construction equipment with sound-control devices no less effective than those provided on the original equipment. No equipment will have an unmuffled exhaust. • Implement appropriate additional noise environmental commitments, including (but not limited to) changing the location of stationary construction equipment, shutting off idling equipment, rescheduling construction activity, notifying adjacent residents in advance of construction work, and installing acoustic barriers around stationary construction noise sources.
NOI-2	The construction contractor will employ noise-reducing methods during well drilling operations	The drilling contractor will employ noise-reducing construction practices so that noise from drilling does not exceed County noise-level standards at adjacent residences. Measures to be implemented may include those following. • Restrict well drilling to beyond 2,900 feet from residences during nighttime hours (10 p.m. to 7 a.m.), where feasible. • Use sound attenuation enclosures around noise-generating elements of the drilling operation.
NOI-3	The construction contractor will employ noise-reducing practices so that noise from well operations does not exceed County noise-level standards at adjacent residences.	Measures to be implemented may include: • restricting well installations to beyond 1,250 feet from residences, where feasible; • using electric pumps where well installations are within 1,250 feet of residences; and • using sound attenuation enclosures designed to achieve noise reductions sufficient to comply with County standards for noise-generating elements of the well operation when no other feasible control method is available.
NOI-4	The construction contractor will employ noise-reducing practices so that noise from lift station operations does not exceed County noise-level standards at adjacent residences	Measures to be implemented may include: • restricting lift station installations to beyond 1,600 feet from residences, where feasible; • using electric pumps where lift station installations are within 1,600 feet of residences; or • using sound attenuation enclosures designed to achieve noise reductions sufficient to comply with County standards for noise-generating elements of the lift station operation when no other feasible control method is available.
Public Services		
PSU-1a	Notify Emergency-Response Agencies of Proposed Traffic-Route Changes	Before beginning construction activities, MID or the construction contractor will contact local emergency-response agencies (law enforcement and fire protection) to provide information on the timing and location of any traffic control measures required during construction activities. Emergency-response agencies will be notified of any change to traffic control measures as the construction phases proceed so that emergency-response providers can modify their response routes to ensure that response time would not be affected.
PSU-1b	MID will require the construction contractor to prepare and implement a traffic safety plan (TSP) before the onset of construction activities.	The TSP will address: • appropriate vehicle size and speed, • travel routes, • detour or lane-closure plans, • flag person requirements, • locations of turnouts to be constructed, • coordination with law enforcement and fire control agencies, • coordination with California Department of Transportation (Caltrans) personnel (for work affecting state road rights-of way), • emergency access to ensure public safety, and • traffic and speed-limit signs.
Traffic		

Identifier	Environmental Commitment	Commitment Specifications
TRAF-1	MID will require the construction contractor to prepare and implement a road improvement plan (RIP) before the onset of the construction phase.	The RIP will identify road segments, bridges, and culverts that need to be improved and turnout locations that need to be constructed (as applicable) to accommodate construction activities. The plan also will identify damage that is caused by construction vehicles and that needs to be repaired.
Water Resources		
WQ-1a	Comply with National Pollutant Discharge Elimination System General Construction Permit	To reduce or eliminate construction-related water quality effects, before onset of any construction activities, MID or its contractor will obtain coverage under the National Pollutant Discharge Elimination System (NPDES) General Construction Permit. MID will be responsible to ensure that construction activities comply with the conditions in this permit, which will require development of a stormwater pollution prevention plan (SWPPP), implementation of best management practices (BMPs) identified in the SWPPP, and monitoring to ensure that effects on water quality are minimized. As part of this process, MID will implement multiple erosion and sediment control BMPs in areas with potential to drain to surface water (see Section 3.6, Geology, for a discussion of erosion and sediment control BMPs). These BMPs will be selected to achieve maximum sediment removal and represent the Best Available Technology (BAT) that is economically achievable. BMPs to be implemented as part of this environmental commitment may include, but are not limited to, the following measures. • Temporary erosion control measures (such as silt fences, staked straw bales/wattles, silt/sediment basins and traps, check dams, geofabric, sandbag dikes, and temporary revegetation or other ground cover) would be employed to control erosion from disturbed areas. • Drainage facilities in downstream off-site areas would be protected from sediment using BMPs acceptable to the Regional Water Quality Control Board (RWQCB). MID or its agent will perform routine inspections of the construction area to verify that the BMPs specified in the SWPPP are properly implemented and maintained. MID will notify its contractors immediately if there is a noncompliance issue and will require compliance.
WQ-1b	Implement a Spill Prevention and Control Program	MID or its contractor will develop and implement a spill prevention control and countermeasures program (SPCCP) to minimize the potential for, and effects from, spills of hazardous, toxic, or petroleum substances during construction activities for all contractors. The program will be completed before any construction activities begin. Implementation of this measure will comply with state and federal water quality regulations and minimize the effects of the Proposed Action. MID will review and approve the SPCCP before the onset of construction activities. MID will routinely inspect the construction area to verify that the measures specified in the SPCCP are properly implemented and maintained. MID will notify its contractors immediately if there is a noncompliance issue and will require compliance. The federal reportable spill quantity for petroleum products, as defined in the EPA's CFR (40 CFR 110), is any oil spill that (1) violates applicable water quality standards, (2) causes a film or sheen upon or discoloration of the water surface or adjoining shoreline, or (3) causes a sludge or emulsion to be deposited beneath the surface of the water or on adjoining shorelines. If a spill is reportable, the contractor's superintendent will notify MID, and MID will need to contact the appropriate safety and clean-up crews to ensure the SPCCP is followed. A written description of reportable releases must be submitted to the RWQCB. This submittal must include a description of the release, including the type of material and an estimate of the amount spilled, the date of the release, an explanation of why the spill occurred, and a description of the steps taken to prevent and control future releases. The releases will be documented on a spill report form. If a spill has occurred, MID will coordinate with responsible regulatory agencies to implement measures to control and abate contamination.
WQ-2	Implement Provisions for Dewatering	Before discharging any water from dewatering operations to surface water, MID or its contractors will obtain an NPDES permit and Waste Discharge Requirements (WDRs) from the RWQCB. Depending on the volume and characteristics of the discharge, coverage under the RWQCB's General Construction Permit or General Dewatering Permit is possible. As part of the permit, the permittee would design and implement measures as necessary so that the discharge limits identified in the relevant permit are met. As a performance standard, these measures will be selected to achieve maximum sediment removal and represent the BAT that is economically achievable. Implemented measures may include retention of water from dewatering operations until particulate matter has settled before it is discharged, use of infiltration areas, and other BMPs. Final selection of water quality control measures will be subject to approval by the RWQCB. MID will verify that coverage under the appropriate NPDES permit has been obtained before allowing dewatering activities to begin. MID or its agent will perform routine inspections of the construction area to verify that the water quality control measures are properly implemented and maintained. MID will notify its contractors immediately if there is a noncompliance issue and will require compliance.
Wetlands		
WET-1	Preservation of vernal pools and alkali rain pools.	Implementation of Environmental Commitments BIO-2a: Preconstruction Surveys/Avoid Effects on Vernal and Alkali Rain Pools and BIO-2b: Create, Restore, or Preserve Vernal Pools would minimize the extent of and compensate for adverse effects.
WET-2	Reduction of impacts to Waters of the United States from the discharge of fill	In GF Canal there are seasonal wetlands, including approximately 2 acres of freshwater marsh that would be affected. These effects would be offset by the development of freshwater marsh within GF Canal during operation and formation of seasonal wetlands within the swales during banking.

Biological Opinion Commitments

On April 26, 2011, the USFWS issued a Biological Opinion to Reclamation (File Number 81420-2008-F-0279-1 (Appendix B) to address the impacts of Reduced Alternative B on Federally listed species. The following additional commitments (terms and conditions) are also imposed on Reduced Alternative B from the incidental take statement that was provided with the Biological Opinion.

1. Reclamation shall ensure through conditions in its approval letter or any funding for the proposed project that MID fully implements and adheres to the Environmental Commitments presented in the Biological Assessment and restated here in this Biological Opinion. These Environmental Commitments must be adhered to, regardless of species status under the California ESA.

2. Reclamation shall ensure through conditions in its approval letter for the proposed project the following Terms and Conditions:

    a) Reclamation shall ensure that MID grants and records an appropriate, USFWS-approved Conservation Easement with a USFWS-approved Conservation Easement holder for the mitigation lands described in the Biological Assessment, prior to project implementation.
    b) Reclamation shall ensure that MID incorporates by reference its Mitigation and Management Plan, developed for these mitigation lands, into said Conservation Easement.
    c) Reclamation shall ensure that MID includes language in the Conservation Easement stating that the Mitigation and Management Plan created for this project is a living document, to be viewed and used as an adaptive management plan under the direction and approval of the USFWS, DFG & Corps, with the goal of ensuring optimum habitat conditions for the species of concern.
    d) Reclamation shall ensure that MID has in place prior to project implementation an adequate, USFWS-approved funding mechanism, such as a non-wasting endowment held by a USFWS-approved endowment holder to fund the long-term management activities on their mitigation lands.

3. Reclamation shall ensure through conditions in its approval letter or any funding instrument for the proposed project that MID develops and implements an appropriate USFWS-approved hydrological study or studies, designed to monitor and report on conditions related to changing ecosystem characteristics in and adjacent to the swales used for water banking purposes. Such studies, and the information obtained from them, shall be used to inform Reclamation and MID of the degree and nature of habitat modification from current conditions, and whether take resulting from vegetative changes beyond the perimeter of water applications (i.e., greater than 20 percent) is exceeded. The information gathered from these studies shall be provided to the USFWS and DFG on thirty-day cycles or within thirty days of conclusion of a study cycle.

4. Reclamation shall ensure through conditions in its approval letter or any funding for the proposed project that MID develop a USFWS-approved monitoring and reporting

approach for the inundated swales and adjacent habitat sufficient to determine whether Fresno kangaroo rats and blunt-nosed leopard lizards re-colonize these areas during dry periods.

2.8 Environmentally Preferred Alternative

As described above, Reduced Alternative B, the Proposed Action is the preferred alternative. The No Action Alternative would not satisfy the purpose and need. In addition, groundwater overdraft would continue in Madera County. While Alternatives B, Reduced Alternative B, C, and D would facilitate growth that would not likely occur under the No Action Alternative, the No Action Alternative results in greater adverse effects on both water quality and water supply in Madera Ranch and the surrounding area. Alternative B, if fully built out would result in substantial effects to upland species and wetlands. Alternative C has reduced effects on wetland biological resources, a substantial effect on upland biological resources, and short-term increased effects on air quality. It is considered financially infeasible for MID as the cost outlay for 1,000 acres of recharge basins in Phase 1 of Alternative C does not give time for the bank to be operational prior to construction of basins (which under Alternative B and Reduced Alternative B banking within the swales would provide the financial ability to implement Phase 2). Alternative D reduces impacts on farmland of statewide importance relative to Alternative B, Reduced Alternative B, and C, and results in similar effects on biological resources relative to Alternative B. However, Alternative D includes the complication of having to operate the bank solely through water exchanges with the San Joaquin Settlement Water and could result in increased air quality effects during construction because of extensive additional canal construction along the off-site portions of GF Canal. While feasible, basing the bank on exchanges makes MID dependent on other agencies to receive water. Reliance on other agencies for water is not desirable, and the benefits of the alternative are not enough to compensate for this deficiency. In addition, it should be noted that Alternative D would rely on San Joaquin River restoration operations that have not yet been finalized and that may not come online within the time frame of desired Proposed Action implementation.

Given the elimination of the Section 8 canal southwest extension, reduction in the total number of swales used to minimize effects to wetlands, and identification of fewer basins to be constructed, Reclamation considers Reduced Alternative B to be the environmentally preferable alternative as well as the best overall alternative.

2.9 Alternatives Screening Process

The Draft EIS must present the environmental effects of the Proposed Action and alternatives in comparative form, sharply defining the issues and providing a clear basis for choice by decision-makers and the public (40 CFR 1502.14; Forty Questions No. 1).

The draft EIS must rigorously explore and objectively evaluate a reasonable range of alternatives along with the Proposed Action. Reasonable alternatives are those that feasibly may be carried out based on technical, economic, and environmental factors. Reclamation is not required to evaluate alternatives beyond the reasonable range of alternatives discussed in the environmental document. If alternatives have been eliminated from detailed study, the EIS must briefly discuss the reasons for their elimination (40 CFR 1502.14[a]; Forty Questions No. 1[a]).

The screening of alternatives starts with the statement of purpose and need, as identified in Chapter 1. In addition to the statement of purpose and need, Reclamation developed screening factors, based on cost, logistics, technology, social, environmental, and legal factors, that were considered in alternatives screening.

Typically, the development, evaluation, and selection of alternatives is a process in which Reclamation first lists a broad range of choices and then progressively narrows down the list to meet the purpose and need for action and feasibility factors. However, since the early 1990s the property has been conceived of for use as a groundwater bank, and an array of regional and site-specific alternatives has been considered. This information and past screening of viable approaches to water banking provide important context in the evaluation of alternatives and the reasoning that has led to the currently proposed alternatives. The screening process is described below following Background.

2.9.1 Background

Early project screening was conducted by former property owner Heber Perrett, Reclamation, California Department of Water Resources (DWR), former property owner Azurix Corporation, and MID. These groups explored a variety of alternatives, structural and nonstructural, throughout California. However, almost all of the proposed alternatives did not meet the objectives of a regional conjunctive-use groundwater bank in Madera County with an objective of increasing water supply reliability to MID farmers. Consequentially, these alternatives were not advanced as feasible alternatives because they failed screening as discussed below. Past alternatives considered and eliminated by these groups, including MID, included the following:

Water Conservation

Water conservation–related alternatives have limited potential to increase water supply reliability and reduce groundwater degradation in Madera County given the amount of water demand and size of the current and future overdraft anticipated. Water conservation is a component of all water management plans, but it is only one small component of voluntary and regulatory programs that are needed in Madera County (Madera County 2008).

Surface Water Storage

Surface water storage likely will be needed over the long term to address ongoing water supply and reliability issues throughout California and possibly in Madera County. However, there are few surface water storage options in Madera County that provide MID with necessary capacity to provide increased operational flexibility and groundwater overdraft protection. Furthermore, the surface water storage options are in the foothills, are likely to cost hundreds of millions of dollars, and are many years from obtaining water right entitlements and construction. The primary storage facility under consideration is Temperance Flat. This regional facility is still in the early planning phase and the cost required by MID and MID farmers would be substantially higher for a surface storage facility. Valley floor facilities are not feasible because of the limiting nature of geologic, topographic, and land use conditions in Madera County that eliminate the possibility of surface water storage.

Groundwater Banking in Other Areas

A variety of groundwater banking options in other areas was considered, including groundwater banking north of the Delta; groundwater banking in San Joaquin, Kern, or Fresno County; groundwater banking in other areas outside Madera County; and other groundwater banking sites in Madera County.

These alternatives were eliminated because of lack of existing water rights; lack of storage space in other areas; a substantial increase in water costs because of incurring storage and conveyance costs (see Water Transfers below); lack of contribution to groundwater overdraft protection in Madera County because there would be no recharge to the local aquifer; and significantly higher costs to construct a project on high-value land.

Water Transfers

Water transfers from imported water supplies likely would have to come from other CVP contractors. The CVP as a whole, like the Friant Division, is experiencing water supply reliability problems attributable to drought, water quality, and biological issues. Therefore, basing the project on water transfers would, in essence, be predicating achieving the purpose and need on long-term transfer agreements for another unreliable water supply. Water delivery through the Delta is constrained significantly per the 2008 BO on the Continued Operations of the CVP on CVP and State Water Project (SWP) operations.

In-Lieu Recharge

In-lieu recharge is a component of an overall water management program. Encouraging farmers to use surface supplies in-lieu of pumping groundwater would depend on the water year type and availability of the water supply, including a component of the water supply being available via banking or transfers. As described above, groundwater banking in other areas and water transfers are costly and do not meet the purpose and need. In-lieu recharge has limited potential to increase water supply reliability in Madera County and would increase the cost of conveyance to MID users if using out-of-area water.

MID's Alternatives

Previous screening as described above narrowed the range of alternatives to the use of the Madera Ranch property and potentially other locations in Madera County. However, as detailed below, other potential locations in Madera County were not found to be large enough, or underlain by sufficient banking space, to meet WSEP needs. Therefore, alternatives screening ultimately focused on alternative configurations and layouts for the project-specific facilities to minimize effects on biological resources while still meeting the objectives of the Proposed Action and the engineering design requirements.

The primary objective ~~is~~ to meet the need for additional storage and reliable and affordable water supplies for MID customers.” Accordingly, MID’s 2005 EIR alternatives analysis, which is incorporated by reference, was limited to Madera County. As such, a wide variety of potential water delivery and banking locations was evaluated in or adjacent to MID’s existing service area.

MID, through the 2005 EIR process, determined that only Madera Ranch offered sufficient areas of land with adequate groundwater recharge qualities, proximity to existing water conveyances, and available groundwater banking space to meet its identified objectives. Areas considered to be fatally flawed or impractical were screened out because of effects related to land use conversion, neighboring groundwater users, habitat, geohydrologic resources, and cost (Madera Irrigation District 2005).

MID developed alternatives based on the sources of water to be recharged, the capacities of the groundwater banking facilities, and the configuration of proposed facilities within the boundaries of Madera Ranch. Based on MID’s screening during the 2005 EIR process, two alternatives were carried forward for analysis in the EIR.

Alternative 1 in the 2005 EIR (previously proposed by Azurix) is an ―engineered” alternative that focused on the construction of percolation ponds and a large 12-mile delivery canal. It would require an approximately 3,000-acre area and use of both grassland and agricultural land. It would include a diversion site approximately one mile upstream of Mendota Dam on a portion of the San Joaquin River that receives water from the Bay-Delta. An intake channel and 12-mile-long canal would need to be constructed to convey the diverted water via three lift stations to Madera Ranch. The canal would be lined with concrete between the first pumping plant and Madera Ranch. MID did not select this alternative because of the environmental effects including those associated with using lower-quality water and removing agricultural land from production, and the higher cost associated with constructing the canal.

Alternative 2 in the 2005 EIR (MID’s Proposed Action, or Alternative B) would upgrade existing MID conveyances and add additional recharge areas and new recovery wells on the Madera Ranch property. These facilities would be used to bank San Joaquin River and Fresno River surface water and to recover the banked water when needed. The recovery of water would be limited to 90% of the amount recharged, thereby reducing the rate of overdraft of the underlying aquifer. MID would construct Alternative B in two phases.

A No Action Alternative (Alternative A), consisting of the sale and use of the property for other agricultural uses (e.g., dairies), also was analyzed.

2.9.2 Alternatives Screening

Alternatives that do not meet the purpose and need or cannot be technically implemented can be eliminated from detailed study, but the EIS must contain a description of the screening process used to exclude alternatives from the reasonable range. While Reclamation’s scope is fairly narrowly defined to include improvements to Reclamation’s facilities and banking outside MID’s service area, Reclamation is compelled under NEPA to review all potential alternatives to ensure that no feasible alternatives are capriciously excluded from consideration and analyze a reasonable range of alternatives. Viable alternatives brought forward for consideration in the NEPA process were evaluated using the following criteria.

- The alternative can meet the purpose and need;
- The alternative can be reasonably and technically implemented;
- The cost or environmental impacts would not be prohibitive.

Screening criteria against which all alternatives should be measured should include such items as cost limits, geographical boundaries, and meeting the purpose and need.

The study area for Reclamation was limited to the regional area of Madera County, primarily MID's service area, in order to meet the purpose and need. The range of alternatives for this alternatives analysis was not limited to the Madera Ranch property, as alternatives outside of Madera Ranch still have the potential to meet the purpose and need. The following alternatives were considered.

- Nonstructural alternatives, including water transfers and conservation.
- New recharge basins on Madera Ranch within MID service area.
- New recharge basins on other properties (i.e., not on Madera Ranch) within MID service area.
- A Mendota Pool–supplied project (the Azurix project).
- Injection well recharge.
- Expansion of MID's delivery facilities.
- The Proposed Action with swale recharge only.
- Other users of the bank for storage.
- Reduced recharge basin options.

Each of these alternatives is described below.

Alternatives Considered but Eliminated from Further Consideration

Nonstructural Alternatives, Including Water Transfers and Conservation The groundwater overdraft situation in Madera County is so dire that many techniques and projects will need to be implemented to meet future agricultural and urban water demand (Madera County 2008). Water transfers and conservation are being explored and implemented by various water districts as part of a comprehensive county-wide water management approach. However, the yield from these projects is small compared to MID's needs, these approaches do not result in additional dry-year banking capacity to support a reliable water supply, and these projects contribute only a small amount to reducing groundwater overdraft (Madera County 2008). MID, Madera County, and other local irrigation and water districts will continue to implement transfer and conservation efforts, but this alternative would not meet MID's objectives or Reclamation's purpose and need and would not be reasonable to implement.

New Recharge Basins on Madera Ranch within MID Service Area This alternative would involve the creation of recharge basins on portions of Madera Ranch within MID's service area (Figure 2-1). This alternative was rejected for two key reasons.

1. Soils on Madera Ranch within MID's service area are not appropriate to allow for sufficient recharge and would require an additional 1,000 acres of recharge area on properties along the eastern edge of Madera Ranch (Bookman-Edmonston 2003).
2. Construction of ponds on Madera Ranch in MID's service area would require conversion of 1,600 acres of prime agricultural lands on Madera Ranch and another 1,000 acres of

prime agricultural lands on adjacent properties in MID's service area; this would results in effects that are contrary to MID's mission of providing water to farmers by removing existing agricultural lands from production and would require substantial additional capital expenditures. It does not meet MID's objectives or Reclamation's purpose and need, and cannot be reasonably implemented.

New Basins on Other Properties within MID Service Area This alternative would involve the expansion of MID's existing recharge ponds and/or construction of new recharge ponds on other properties within MID's service area. MID's existing recharge ponds are not large enough to meet the required recharge needs and could not meet the recharge needs even if expanded. The key reason the use of other properties was rejected is that other sites with permeable soils cannot achieve the 55,000 AF/year volume anticipated at Madera Ranch. Madera Ranch is relatively large and is in a key location near the end of MID's service area and conveyance facilities. The Madera Ranch property also has a smaller number of adjacent groundwater users compared to the majority of MID's service area, which reduces the risk of infiltrated water being withdrawn by adjacent users. Use of other sites for recharge also would require conversion of prime agricultural lands, thus resulting in increased agricultural effects. Acquisition necessary to implement this alternative would require substantial additional capital expenditures and be cost-prohibitive for MID under current market conditions.

Mendota Pool Supplied Project The Mendota Pool Supplied Project (the Azurix project) was one of the alternatives analyzed by MID in its 2005 EIR. This alternative would consist of a combination of distribution system improvements and groundwater recharge conducted using engineered recharge basins constructed on the portions of the Madera Ranch property where active cultivation currently exists. The water supply for the alternative would be Bay-Delta CVP water from Mendota Pool. The diversion site would be approximately one mile upstream from Mendota Dam. An intake channel and 12-mile-long canal would need to be constructed to convey the diverted water via three lift stations to the Proposed Action area. The canal would be concrete-lined between the first pumping plant and Madera Ranch. In order to finance the acquisition of land for the new canal and finance construction of the engineered recharge basins, the project would require double the capacity of the Proposed Action and would require non-local participation to facilitate the water transfers necessary to acquire water from Mendota Pool. MID does not hold water rights to water in Mendota Pool and therefore would be required to enter into long-term transfer and exchange agreements with third parties such as the San Joaquin River Exchange Contractors to make water available for banking. In addition, the project would not include conveyances for direct delivery of recovered water into MID. Rather, it would rely on the following chains of exchanges and transfers to enable delivery of banked water back to MID.

- Banked water would be recovered from Madera Ranch and pumped back to Mendota Pool for use by others such as the San Joaquin River Exchange Contractors in lieu of their normal Delta-Mendota Canal deliveries.
- The equivalent volume of water now made available in the Bay-Delta would be conveyed through the California Aqueduct to the southern part of the Central Valley and delivered to a southern Friant Division contractor in lieu of its normal Friant deliveries, making an

equivalent volume of water available in Millerton Reservoir available for delivery to MID farmers.

- As analyzed in MID's 2005 EIR, water quality in Mendota Pool is of substantially lower quality compared to MID's Friant Division and Hidden Unit contract supplies and compared to the existing groundwater quality beneath Madera Ranch. For this reason, the MROC, the committee responsible for monitoring the operations of the WSEP, requires prior approval before any use of Mendota Pool water by a vote of nine consenting, with no dissenters among the 10-person committee. This requirement, as well as concerns regarding water quality and cost of constructing a new 12-mile canal, resulted in MID determining that this alternative does not meet the purpose and need. In addition, for MID to physically receive water from this configuration for its farmers, MID would be required to perform a complex set of exchanges and transfers with SWP and Southern Friant Contractors, resulting in reduced reliability due to uncertainties associated with long-term availability of pumping capacity in the Delta, as well as delivery capacity in other conveyances not controlled by MID and long-term willingness of several third parties to perform exchanges and transfers. This alternative would not meet the screening criteria for Reclamation as the alternative is prohibitively greater in cost and in environmental impacts than the other alternatives, and the alternative cannot be reasonably implemented.

Injection Well Recharge This alternative would achieve recharge directly using injection wells rather than swales and basins as proposed by MID. This alternative does not satisfy MID's purpose and need because of costs and technical and logistical issues. Similarly, Reclamation eliminated this alternative from further analysis because of its technical infeasibility and high costs compared to the cost of other feasible alternatives. Recharge using injection wells would pose the following significant challenges (Schmidt 2009).

- Injection wells typically accept water at lower rates than they can pump. Assuming that the Proposed Action (Alternative B) planned project wells are configured for both injection and recovery, Schmidt (2009) estimated that an additional 60 injection wells would be required to attain a recharge rate of 200 cfs. Injection wells require a higher quality of construction, instrumentation, and control than pumping wells. Taken together, Schmidt (2009) estimated that use of injection wells would increase well field capital costs by at least 50%. This increase in costs does not include the significant additional piping and a regulation reservoir that also would be required.
- Water would require treatment before injection to remove air, suspended particulates, bacteriological constituents, nutrients, organic constituents, and algae that would clog the wells, clog the geologic formation the water is injected into, and degrade groundwater quality. In addition, treatment may create trihalomethanes. Schmidt (2009) estimates that a 130-million gallon per day (MGD) treatment plant would be required, with capital costs ~~in~~ the hundreds of millions of dollars." MID does not have the staffing or equipment to operate a treatment plant and would be required to invest millions of dollars to obtain this functionality. It also should be noted that operation of the treatment system would generate solid wastes requiring disposal.

- A high degree of expertise and operational infrastructure that MID lacks would be required to successfully operate and maintain injection wells over the long term, significantly increasing project operations and maintenance (O&M) costs. Schmidt (2009) estimated that injection wells would increase O&M costs by approximately $2.4 million dollars per year. This O&M estimate does not include O&M costs associated with the treatment plant.
- Surface-based recharge systems can last indefinitely with appropriate maintenance. However, even with treatment systems and the facilities summarized above, the useful life of injection wells would be no more than 30 years, resulting in a need for MID to incur periodic replacement costs.

Taken together, use of injection wells would increase WSEP capital costs by hundreds of millions of dollars, increase O&M costs by millions of dollars per year, provide uncertain performance, and require a complete reinvention of MID’s O&M staffing and equipment resources. Schmidt (2009) reviewed numerous water banking and recharge projects throughout the Central Valley and found that injection wells were not selected for any of the projects for the variety of reasons summarized above.

Expansion of MID’s Delivery Facilities This alternative would involve the expansion of delivery facilities, including widening, deepening, and constructing new canals within MID’s service area to attain storage, recharge, and conveyance goals. This would allow MID to move their water allocation to users more effectively without requiring additional banking. MID could further enlarge the Section 8 Canal and also use Cottonwood Creek, which would contribute a small amount to groundwater recharge. However, the groundwater overdraft situation in Madera County is so dire that canal expansion and extensions would not reduce this problem; many techniques and projects, including conveyance projects, would need to be implemented to meet future agricultural and urban water demand (Madera County 2008). More importantly, this alternative would not meet MID’s needs, as it would not provide sufficient banking to enable provision of water to users in dry years because the recharge amounts would be small. This alternative was not advanced for technical reasons and because it does not meet the overall purpose and need.

The Proposed Action with Swale Recharge Only This alternative would be similar to the Proposed Action, but would rely solely on the swales to put water into the bank. This alternative assumes that engineered recharge basins would not be needed. This alternative could meet the purpose and need. MID has proposed retaining the recharge ponds to ensure the alternative remains technically feasible and acceptable from a regulatory perspective. Extensive pilot testing indicates that the identified swales could provide the required recharge capacity, but the long-term performance is uncertain. Additionally, controversy remains regarding the use of the swales relative to biological impacts because of the uncertainty of these effects on endangered species. Therefore, in order to provide certainty that the project can meet objectives, MID is obligated to contemplate Phase 2 recharge basins as a back-up in the event that the swales cannot provide the required long-term performance. A swale-only alternative provides a reduction in biological effects associated with grassland conversion and a reduction in air quality effects from construction of the ponds. However, as described above, other biological resources could be adversely and unacceptably affected by use of the swales. Because there is still some question regarding its feasibility and because of existing concerns by the USFWS and DFG, it was eliminated according to Reclamation's screening criteria.

Other Users of the Bank for Storage MID's Proposed Action identifies agricultural users with 64% of the bank's annual operational capacity; industrial, commercial, and residential users with 18% of the capacity; and environmental users with 18% of the capacity. Under an Other Users alternative, the percentage of capacity used for urban or environmental purposes could be increased. This would increase the water supply reliability for urban or environmental users provided they could obtain the needed water rights to bank the water. The direct, indirect, and cumulative effects of this alternative would vary depending on which user received the majority allocation. However, this alternative would not achieve MID's objectives of providing its customers with a significant increase of dry year water supply. This alternative would not meet Reclamation's purpose and need for this project.

Reduced Recharge Basin Options After discussions with the Corps, U.S. EPA, USFWS and DFG, MID and Reclamation developed Reduced Alternative B (Proposed Action) that reduced the number of acres of swales used and the number of acres of basins created. In these various options, the number of swales could be reduced and basins could be constructed to make up for the reduction in the number of acres of swales that would be used for exchange. Options ranging from basins only (Alternative C) to use of 700 acres of swales and 200 acres of basins were evaluated. Options with a heavy emphasis on basins (i.e., more than 350 acres of basins) were eliminated by Reclamation and the Corps because of environmental, logistic and cost considerations.

Section 3 Affected Environment and Environmental Consequences

This section describes the existing proposed action area environment and the potential direct, indirect and cumulative impacts to the following resources resulting from the alternatives under consideration.

- Aesthetics
- Agriculture
- Air Quality
- Biological Resources
- Cultural Resources
- Environmental Justice
- Geology, Soils, Seismicity, and Erosion
- Global Climate
- Growth Inducement
- Hazards, Public Health, and Safety
- Indian Trust Assets (ITA)
- Land Use
- Noise
- Public Services and Utilities
- Socioeconomics
- Traffic and Circulation
- Water Resources
- Water Supply
- Wetlands

3.1 Aesthetics

This section describes the potential direct, indirect and cumulative impacts to visual resources in the vicinity of Madera Ranch.

Baseline conditions in the Madera Ranch vicinity were determined by studying photographs, conducting drive-through reconnaissance, conducting research, and discussing the nature of the existing facilities with MID and Madera Ranch staff. The aesthetic effects of the alternatives were determined by assessing the visual resource changes that could result and predicting how viewers would respond to those changes.

Numerous federal agencies and organizations have developed visual assessment methodologies to standardize the quality and accuracy of visual analyses. The approach used for this visual assessment is adapted from the Federal Highway Administration's visual effects assessment system (Federal Highway Administration 1983), which is widely accepted for general visual analysis.

The visual effects assessment process involves identifying:

- relevant policies and concerns for protection of visual resources;
- visual resources (i.e., visual character and quality) of the region, the immediate vicinity of the project, and the project site;
- important viewing locations and the general visibility of the project site using descriptions and photographs;
- viewer groups and their sensitivity; and
- potential effects, mitigation of effects, and other recommendations.

The analysis of effects on aesthetics includes a qualitative assessment of the effects that construction and operation of the alternatives would have on the area's visual character and quality. A survey was conducted of the Madera Ranch site and surrounding roadways to characterize existing conditions and to identify areas sensitive to visual changes. In addition, the County's General Plan (Madera County 1995a, 1996b) was analyzed for policies or direction related to aesthetics and to determine whether there are any designated scenic roadways, vistas, or areas.

Roadways with substantial traffic in the area, specifically Avenue 7, Avenue 12, and Road 21, were considered visually sensitive, as the highest number of viewers would use these routes. Although the area contains scattered rural residential development, no residences were identified as being in direct proximity of any alternatives (i.e., immediately adjacent to the Madera Ranch site and unbuffered by distance or existing agricultural operations).

3.1.1 Affected Environment

The aesthetic value of an area is a measure of its visual character and quality, combined with the viewer response to the area (Federal Highway Administration 1983). The scenic quality component can best be described as the overall impression that an individual viewer retains after driving through, walking through, or flying over an area (U.S. Bureau of Land Management 1980).

Regional Character

Madera Ranch is located in the largely agricultural western portion of Madera County, in the area known as the Valley Floor. It is bordered by Avenue 12 to the north, Avenue 7 to the south, Road 21 to the east, and agricultural lands to the west (Figure 3-1). The regional character of this area is typical of rural agricultural regions. Typical views of the region include:

- agricultural operations, such as tree, row, and field crop production;
- agricultural storage and maintenance areas;
- irrigation canals;
- rural residences;

- agricultural wells; and
- aboveground utility facilities

Vicinity Character

The vicinity of the WSEP is considered the Madera Ranch, which is typical of the region as described above but has a greater percentage of grasslands. Figure 3-1 shows the existing land uses at Madera Ranch and surrounding lands. The majority of the site is covered with grasslands that are used for grazing. Smaller portions of the site are used for agriculture, including vineyards and row crops. A farm headquarters and storage area is located near the center of the site, and two residences are on the east side of the site. Madera Ranch is generally level with little vertical relief. Views of the foreground consist of grasslands and some row crops. To the east, the Sierra Nevada may be visible in the distance, depending on weather conditions.

Sensitive Viewers

The primary viewer groups of Madera Ranch are residents and motorists. A few farmhouses are scattered throughout the vicinity, surrounded by agricultural land. Many of the residents of these farmhouses both live and work in the area; they generally make their living from the land and thus often hold their surroundings in high esteem. They typically are sensitive to visual change because of their familiarity with the view, their investment in the area (if they are homeowners or long-time residents), and their sense of ownership of the view. The view from their homes and yards represents a visual extension of their property, and changes in this view are quickly recognized and can cause the residents to have strong reactions, both positive and negative.

In addition to local residents, people traveling on Avenue 7, Avenue 12, and Road 21 are exposed to Madera Ranch. These individuals are considered to have moderately low sensitivity to changes because they are focused more on driving and are exposed to the site for only a short period of time. However, the roadways are very straight, giving roadway travelers some limited opportunities to take in the scenery around them.

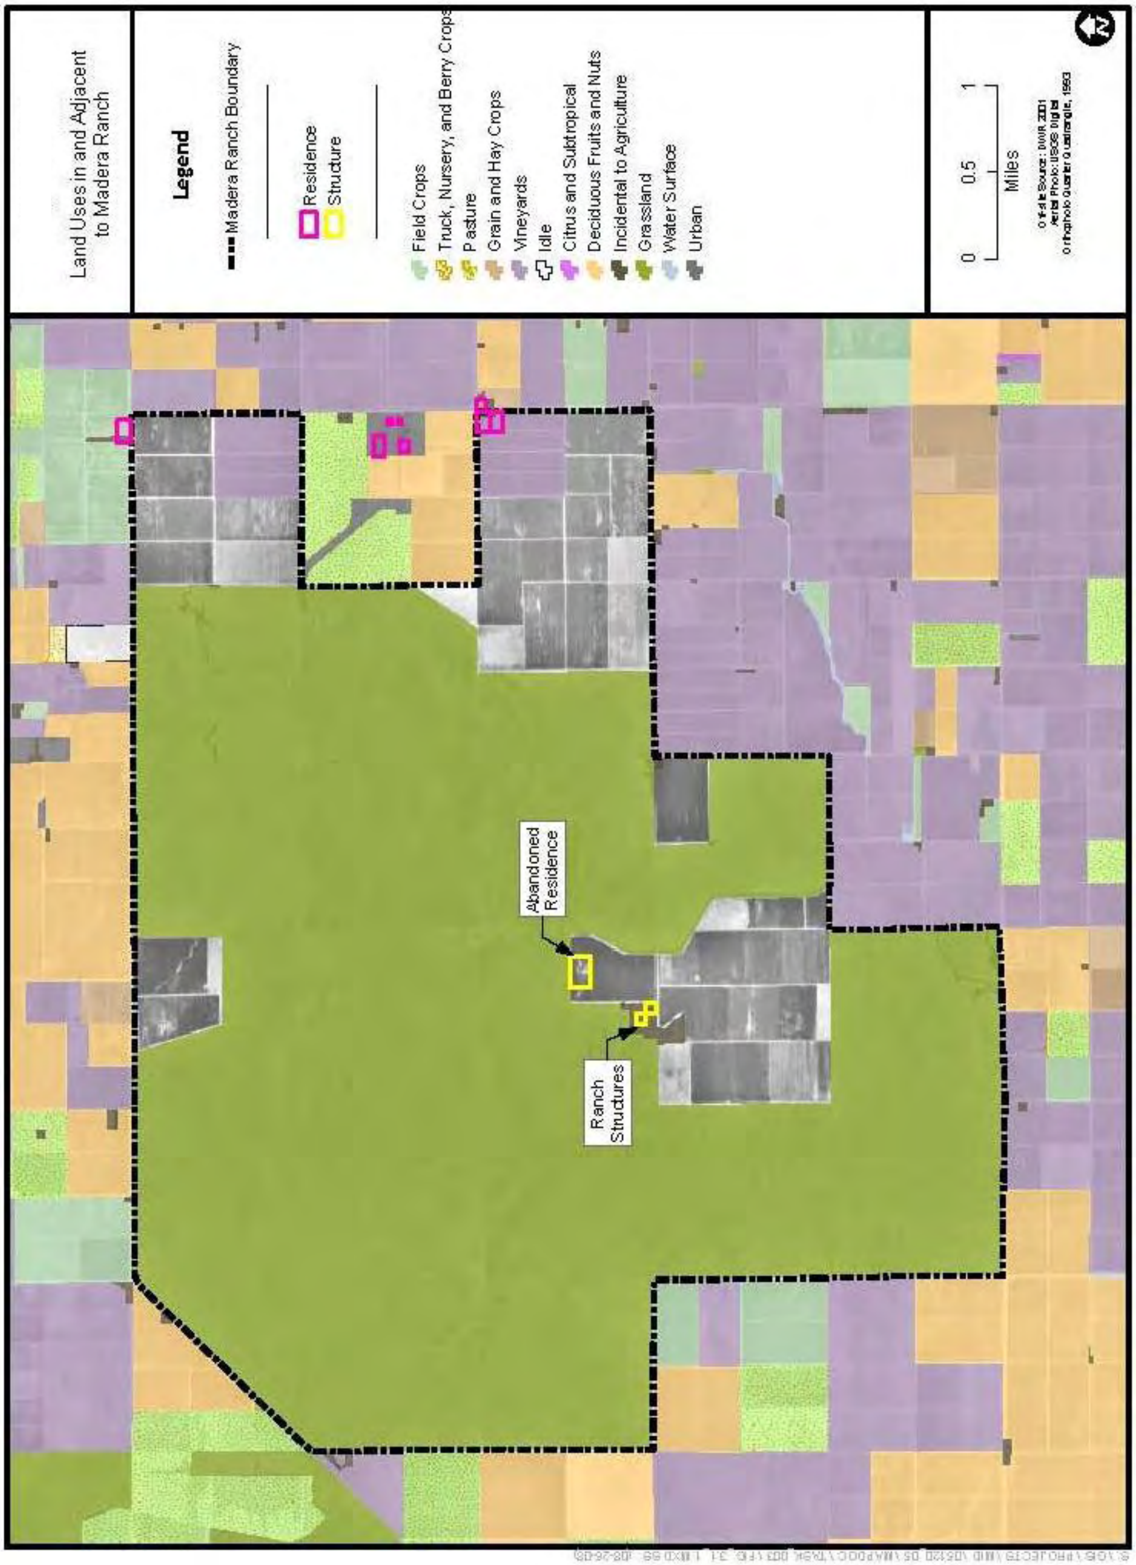


Figure 3-1 Land Uses In and Adjacent to Madera Ranch

3.1.2 Environmental Consequences

Based on a review of the *Madera County General Plan Background Report* (Madera County 1995b) and Caltrans Scenic Highway Program (California Department of Transportation 2008), no designated scenic vistas or highways are visible from or within the vicinity of the alternatives. Thus, none of the alternatives would affect scenic vistas or resources. As no night lighting is proposed, no effects associated with glare could occur.

There are no federally or state-designated scenic roadways or vistas within Madera Ranch site boundaries or its vicinity. In addition, there are no County-designated scenic roadways or vistas, and those that are eligible for such designation are located far beyond the viewshed of Madera Ranch (California Department of Transportation 2008).

Alternative A—No Action

Under the No Action Alternative, Reclamation would not approve the banking of CVP water outside MID's service area, nor would Reclamation issue an MP-620 permit (a Mid-Pacific Region specific permit for modification or alteration of Reclamation-owned facilities) to approve modifications to its distribution system. The future conditions could change to support agricultural activities. Because Madera Ranch would not be visible from population centers or major circulation routes, and because the expected features associated with the future no action conditions would appear very similar to those already present under existing conditions, the No Action Alternative would have no effect on aesthetics.

Alternative B—Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities

Effect AES-1: Temporary Degradation of Visual Character or Quality from Construction-Related Activities Construction of Alternative B action would require the use of heavy equipment and large trucks, which would cause the area to resemble a typical construction site. Construction activities involving grading, trenching, and the storage of construction equipment and materials on Madera Ranch would be visible from Avenue 7, Avenue 12, and Road 21 and adjoining properties. Construction-related activities along Cottonwood Creek, the 24.2 Canal, and Section 8 Canals also would be visible to motorists and rural residents. However, the operation of construction equipment is similar to agricultural activities that already occur in the area, including field-leveling, disking, and harvesting. In addition, construction activities would be only temporary in nature, lasting for six months for each of two construction seasons. As such, there would not be a considerable change in views, and construction-related activities would not result in a substantial adverse effect on visual character or quality.

Effect AES-2: Degradation of Visual Character or Quality from New Permanent Features Alternative B would involve:

- modification and extension of canals and drainage ditches;
- use of natural swales and construction of engineered recharge basins to recharge water; and
- installation of recovery wells, pipelines, and lift stations.

Madera Ranch would not be visible from population centers or major circulation routes. However, it would be visible from nearby residences and Avenue 7, Avenue 12, and Road 21.

Canals and drainage ditches are common visual features in the agricultural areas of Madera County and are visible from Madera Ranch. The proposed new construction and/or modifications to existing canals and drainage ditches would be consistent with the agricultural nature of the area and would be similar to other visual features already occurring in the area.

The recharge basins that would be constructed as part of Alternative B would look similar to drainage ponds that already exist in the area, which blend in visually with the surrounding environment. Environmental oriented viewer groups may find the new facilities constructed in grassland offensive because of the change in visual character due to a change in land use, however, the recharge basins would be located several miles from Avenue 12, are not expected to be visible from this road, and this group composes a minority of those using Avenue 12. Diversion of water to the swales would mimic natural processes, thus blending in with the natural environment. None of the drainages or swales to be used for recharge is visible from surrounding roads or properties. If increased numbers of migratory birds using the site were visible to motorists passing by, some of them might consider the increased migratory bird use to be a beneficial change. Under Alternative B, portions of Sections 28 and 29 periodically would be inundated, and portions of this water would be visible from Avenue 7. However, this condition would be identical to that which has existed at that location for more than 13 years. All of these recharge facilities would appear similar to flooded agricultural fields. Therefore, recharge basins and swales proposed under Alternative B would blend in with existing agricultural features in the area.

New wells, pipelines, lift stations, and utilities also would be constructed as part of Alternative B. The planned pipelines would be buried and follow alignments along existing roadways. The wells, lift stations, and utilities would be similar to features commonly found in western Madera County and the area surrounding Madera Ranch.

Because Madera Ranch would not be visible from population centers or major circulation routes, and because the planned new features would appear very similar to those present under existing conditions, Alternative B would not have an adverse aesthetic effect.

Reduced Alternative B—Water Banking Outside the MID Service Area Using Select Swales and Alteration of Reclamation-Owned Facilities

Reduced Alternative B is similar in scope and design to Alternative B, with the primary exception that a reduced number of natural swales will be used and a reduced number of ponds will be constructed. This would not result in any differences from what was described above for Alternative B relative to temporary degradation of visual character or quality from construction-related activities changes, or degradation of visual character or quality from construction of new permanent features. The effects of Reduced Alternative B would result in nearly identical effects to those that would occur under Alternative B (Effects AES-1 and AES-2), and thus, not considered adverse.

Alternative C—Water Banking Outside the MID Service Area without Swales and Alteration to Reclamation-Owned Facilities

Alternative C is similar in scope and design to Alternative B, with the primary exception that the natural swales that occur on the site would not be used for recharge. Thus, the visual character of the proposed engineered recharge basins would be very similar to the visual identity of the swales in Alternative B, and the effects would be nearly identical (Effects AES-1 and AES-2). As described above for these effects, the area is used for agricultural purposes, and the construction activities and resulting changes in facilities (such as canals and lift stations) would result in similar views from within the ranch and from nearby residences and Avenue 7, Avenue 12, and Road 21 compared to the existing activities and facilities on the Ranch. Pipelines would be buried and would result in no changes in aesthetics. The constructed basins proposed as part of Alternative C would be similar to flooded fields. Thus, there would be no considerable changes in aesthetics during or after construction that would result in any adverse visual effects.

Alternative D—Water Banking Outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal

Alternative D is similar in scope and design to Alternative B, with the exception that water conveyance to the site occurs primarily through GF Canal and not the Section 8 Canal and other local conveyances. Thus, the visual character of the alternative would be similar to Alternative B, and the effects on aesthetics would be nearly identical (Effects AES-1 and AES-2). As described above for these effects, the area is currently used for agricultural purposes, and the construction activities and resulting changes in facilities (such as canals and lift stations) would result in similar views from within the ranch and from nearby residences and Avenue 7, Avenue 12, and Road 21 compared to the existing activities and facilities on the Ranch. Pipelines would be buried and would result in no changes in aesthetics. The constructed basins proposed as part of Alternative D would be similar to flooded fields. More water than usual would be seen in GF Canal, but this would not represent a significant change in the visual character of the area and would not represent an adverse effect. Thus, there would be no considerable changes in aesthetics during or after construction that would result in any substantial adverse visual effects.

Cumulative Effects

Because the Proposed Action and alternatives will not result in adverse effects on visual resources, no cumulative effects are anticipated.

3.2 Agriculture

This section describes the agricultural resources for the areas potentially affected by the proposed alternatives. It discusses the affected environment, relevant regulations and policies, methods of analysis, and possible effects.

3.2.1 Affected Environment

Agricultural lands make up 47% (648,300 acres) of the total Madera County land area. In 2007, the top five crops were grapes, almonds, nuts, and hulls, milk, pistachios; cattle and calves. Nuts, almonds, hulls, grapes, and pistachios (along with many other crop types in the county) represent permanent crops that cannot easily be abandoned or fallowed from year to year. Approximately 86% of the cultivated land in Madera County is in permanent crops.

The majority of the land in the Madera Ranch vicinity is used for grazing with some areas in row crop production. A small portion is planted in vineyards. Table 3-1 summarizes these land uses and lists the corresponding acreages.

Table 3-1 Summary of Current Land Use on Madera Ranch

Land Use	Acres
Vineyards	320
Grain and hay crops	2,424
Annual grassland used for grazing	10,878
Semi-agricultural & incidental to agriculture*	24
Total	13,646

* Ranching facilities and Cottonwood Creek.

Table 3-2 shows land classification acreages on Madera Ranch and in the entire county. Madera Ranch represents approximately 1.8% of the county's total Important Farmland (California Department of Conservation 2006b).

Table 3-2 Acreages of Important Farmland

Important Farmland Category	Madera Ranch	County
Prime Farmland	1,085	97,489
Farmland of Statewide Importance	491	85,135
Unique Farmland	1,017	163,973
Farmland of Local Importance	151	17,415
Grazing Land	10,978	399,499
Total	**13,722**	**765,159**

Note: Acreages reported by various agencies differ slightly from those reported by the Madera County Assessor's Office.

Source: California Department of Conservation 2006b (2004–2006 data).

Agricultural land can be protected under the Williamson Act within designated agricultural preserves[1]. The entire site at Madera Ranch is under Williamson Act contracts. These Williamson Act contracts will remain in effect indefinitely because no notice of nonrenewal or application for cancellation has been submitted (Upton pers. comm.). Portions of the properties outside of Madera Ranch along the Section 8 and 24.2 Canals are also part of the farmland security zone.

---

[1] An *agricultural preserve* is the –area within which a city or county will enter into Williamson Act contracts with landowners. The boundary [of the agricultural preserve] is designated by resolution of the board or city council having jurisdiction. Agricultural preserves must generally be at least 100 acres in size" (California Department of Conservation 2007).

Potential effects of an action on agricultural resources fall into two categories: indirect effects on the ability of farmland to support various levels of crop or livestock production, and the direct removal of land from agricultural use. Direct effects are caused by the action and occur at the same time and place. Indirect effects are caused by the action and are later in time or farther removed in distance but are still reasonably foreseeable. The effects on agricultural resources are assessed based on direct disturbances related to construction and changes in land use resulting from new facilities, and indirect changes related to changes in water supplies for agricultural uses.

The ability of farmland to support various levels of crop or livestock production is referred to as *farmland quality*. The factors that affect farmland quality include the physical and chemical characteristics of a site's soils and the topography, climate, and quality and availability of irrigation water.

Under its Farmland Mapping and Monitoring Program (FMMP), the California Department of Conservation prepares maps of Important Farmlands, as described below (California Department of Conservation 2004, 2006a). Important Farmland maps are prepared periodically for most of the state's agricultural areas based on information from Natural Resources Conservation Services (NRCS) soil survey maps and land inventory and monitoring criteria developed by the NRCS. These criteria generally are expressed as definitions that characterize the land's suitability for agricultural production, physical and chemical characteristics of the soil, and actual land use. Important Farmland maps generally are updated every 2 years.

The Important Farmland mapping system uses eight mapping categories—five categories relating to agricultural lands and three categories associated with nonagricultural lands. The five agricultural mapping categories are summarized below.

- *Prime Farmland* includes lands with the combination of physical and chemical features best able to sustain long-term production of agricultural crops. The land must be supported by a developed irrigation water supply that is dependable and of adequate quality during the growing season. It also must have been used for the production of irrigated crops at some time during the 4 years before the mapping data were collected.
- *Farmland of Statewide Importance* refers to lands with agricultural characteristics, irrigation water supplies, and physical characteristics similar to prime farmland but with minor shortcomings, such as steeper slopes or less ability to hold and store moisture.
- *Unique Farmland* is lands with lesser quality soils used for the production of California's leading agricultural cash crops. These lands usually are irrigated but may be nonirrigated orchards or vineyards as found in some of the state's climatic zones.
- *Farmland of Local Importance* refers to lands of importance to the local agricultural economy, as determined by each county's board of supervisors and a local advisory committee. The county includes in its definition of farmland of local importance those lands that are presently under cultivation for small grain crops but that are not irrigated. The definition also includes lands that are currently in irrigated pasture but have the potential to be cultivated for row/field crop use.

- *Grazing Land* is land on which the existing vegetation is suited to the grazing of livestock.

Figure 3-2 shows the FMMP categories present on Madera Ranch.

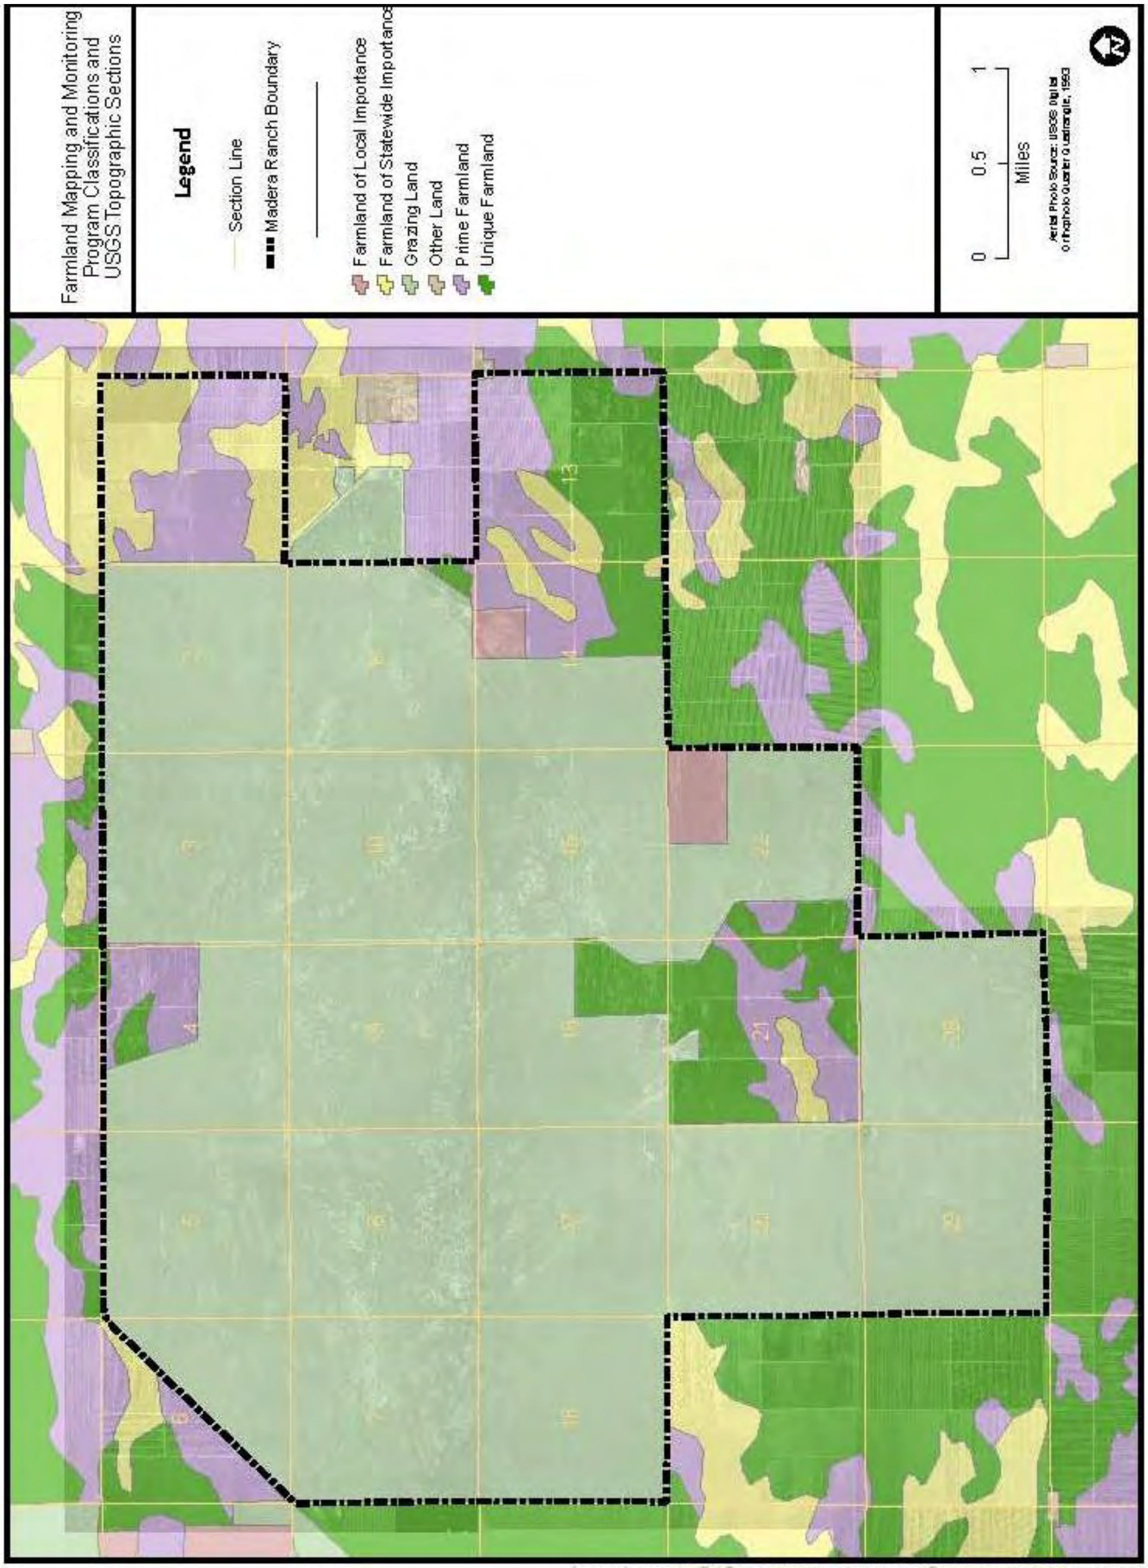

Figure 3-2 Farmland Mapping and Monitoring Classifications and USGS Topographic Classifications

3.2.2 Environmental Consequences

Alternative A—No Action

Under the No Action Alternative, Reclamation would not approve the banking of CVP water outside MID's service area, nor would Reclamation issue an MP-620 permit, a Mid-Pacific Region specific permit for modifications to its distribution system. However, the future conditions would likely change. If MID sells the property to agricultural users, additional property on Madera Ranch would go into agricultural production. Potential conflicts with Williamson Act contracts, loss of agricultural land designated as important farmland, or conflict with local zoning designations would need to be evaluated by MID or the County under CEQA, depending on the discretionary permits needed. Until MID sells the property, it would continue in its current use of grazing.

Alternative B—Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities

Effect AG-1: Alteration of Madera Ranch Agricultural Operations Alternative B would not change the pattern of agricultural operations at the site. Furthermore, MID's water conveyance facilities allow delivery of surface water to the property without any physical changes. Proposed canal expansions would allow an increase in water delivery to the property that would be banked on site for later recovery and use in MID's current service area. It is not expected that the banked water would be recovered for use on Madera Ranch. Rather, the water would be transferred back into MID's service area for use. Thus, there would be no effect on agricultural areas associated with water banking operations at Madera Ranch.

Effect AG-2: Conflict with Williamson Act Contracts According to the Williamson Act (Government Code sec. 51202[e]), a compatible use is any use determined by the county or city administering the agricultural preserve to be compatible with the agricultural, recreational, or open-space use of land within the preserve and subject to contract. The County Planning Department previously has determined that development of a groundwater bank on the Madera Ranch site would not conflict with the AE designation (Merchen pers. comm.). According to the County, the following activities are considered compatible uses: “the erection, construction, or maintenance of a water facility” (Madera County Rules and Procedures for Agricultural Preserves, California Government Code 51238). In addition, as discussed above, the changes resulting from Alternative B would be compatible with existing agricultural land use and zoning designations. Additionally, water banked and recovered at Madera Ranch would be used by MID, which provides water primarily for agricultural uses. One of the project purposes is to improve the reliability of the water supply. It is expected that will help ensure that any Williamson Act properties to which this water is applied can be maintained in their current land use. For these reasons, Alternative B would not conflict with any Williamson Act contracts and would have no effect on Williamson Act compatibility.

Effect AG-3: Loss of Agricultural Land Designated as Prime Farmland or Farmland of Statewide Importance Implementation of the Alternative B would result in the direct loss of approximately 27 acres of prime farmland. Approximately 13 acres of farmland of statewide importance would be lost at Madera Ranch, and an additional 4.6 acres of farmland of statewide importance would be lost as a result of the 24.2 Canal extension (for a total of 17.3 acres). This represents a loss of approximately 2.8% of the prime farmland and farmland of statewide importance at Madera Ranch. However, the majority of the changes associated with Alternative B would occur on land classified by the FMMP as grazing land. Figure 3-3 shows the locations of the facilities that would result in the direct conversion of farmland, and Table 3-3 shows the acreages of farmland that would be converted. Alternative B would not result in conversion of farmland outside Madera Ranch; rather it is likely that the WSEP would support existing prime farmland and farmland of statewide importance because the increased water supply reliability would maintain favorable conditions for farmers to continue farming operations on those lands.

Although the loss of prime farmland and farmland of statewide importance at Madera Ranch is relatively small, and a primary objective of the WSEP is to help preserve agricultural land use through the provision of reliable and affordable water supplies, this effect is considered adverse because it would convert prime farmland or farmland of statewide importance to a nonagricultural land use. Conservation easements on agricultural land would be established (Environmental Commitment AG-1) that would reduce the intensity of this effect.

Effect AG-4: Conflict with Local Zoning Designations Madera Ranch is located within the AE general plan land use designation and is zoned for agricultural use, meaning that the future land use must be compatible with agricultural uses. The County Planning Department previously has determined that development of groundwater storage on the Madera Ranch site would not conflict with the AE designation (Merchen pers. comm.).

In addition, only a small portion of the site, approximately 1,101 acres or 8% of the site, would be used for water banking facilities under Alternative B. Agriculture would continue on Madera Ranch except where recharge basins would be established and permanent, unburied facilities would be located. Land removed from agricultural production would continue to support agricultural practices and be consistent with the Agricultural Exclusive (AE) designation. Grazing would continue on the majority of the ranch along with row crop production. MID does not propose to establish grassland conservation easements on prime farmland, unique farmland, or farmland of statewide importance. However, other areas of the ranch may continue to be used for grazing per grassland conservation easements.

Modification and extension of existing ditches and canals would cause only temporary disruption and would result in changes that also would be consistent with continued agricultural production on the extensive agricultural areas of the site as well as on adjoining properties. Furthermore, implementation of Alternative B would enhance water reliability and flexibility and help to maintain water costs at levels that are affordable to farmers. Because Alternative B would not conflict with local zoning designations, there would be no effect.

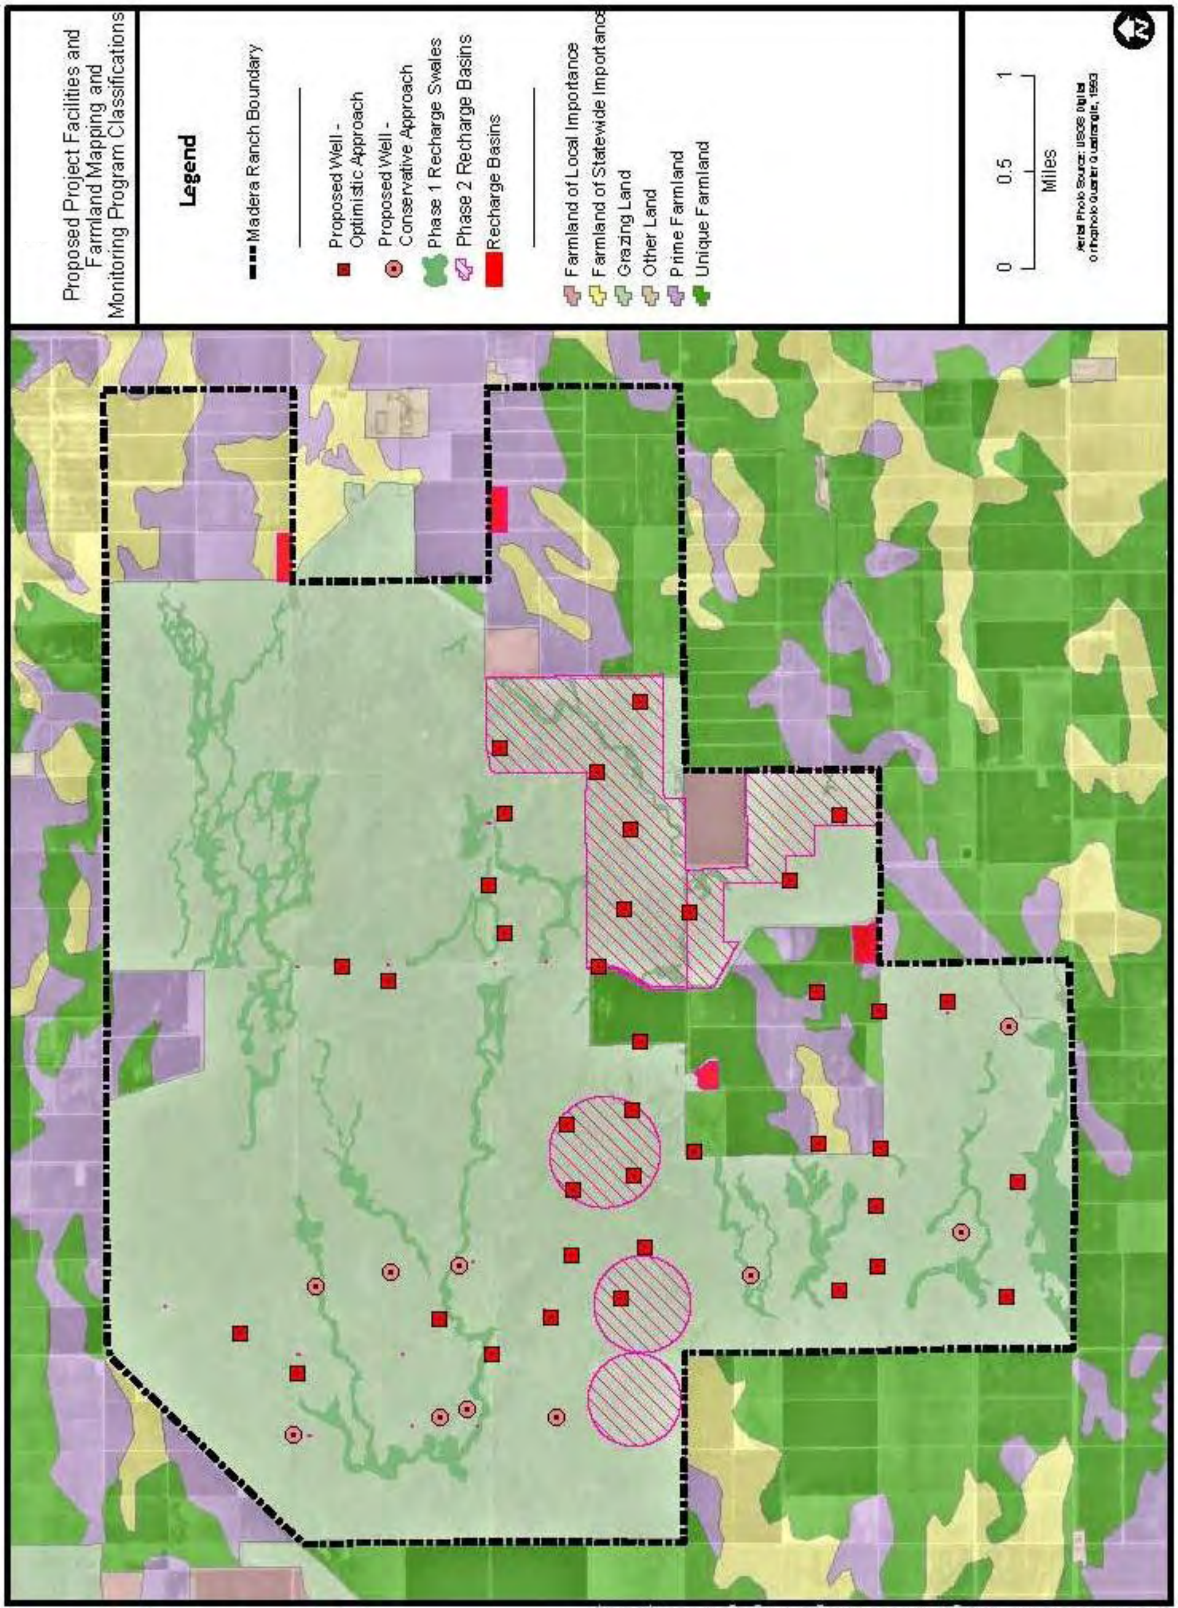

Figure 3-3 Proposed Project Facilities and Farmland and Monitoring Program Classifications

BDCP1738.

Table 3-3 Areas of Farmland Affected by the Proposed Alternatives

Madera Ranch		Alternative B				Reduced Alternative B				Alternative C				Alternative D			
		Phase 1	Phase 2*	Total	Percent	Phase 1	Phase 2*	Total	Percent	Phase 1	Phase 2**	Total	Percent	Phase 1	Phase 2*	Total	Percent

Grazing Land	10,978	18.0	1,020*	1038	9.5	0	501	501	9.6	1,038	n/a	1038	9.5	18.0	1,020*	1038	9.5
Total	**13,722**			**1,101.62**				**564.62**			**1,101.62**				**1,084.32**		

*The potential impacts of Alternative B, Reduced Alternative B and Alternative D, Phase 2 to grazing land represent a maximum value. These impacts, which would be associated with construction of engineered recharge basins, would not occur if the use of natural swales for recharge under Phase 1 meets the proposed objectives.

**Under Alternative B, all recharge facilities are constructed during Phase 1.

Source: California Department of Conservation 2006b (2004–2006 data).

Reduced Alternative B—Water Banking Outside the MID Service Area Using Select Swales and Alteration of Reclamation-Owned Facilities

Reduced Alternative B is similar in scope and design to Alternative B, with the primary exception that a reduced number of natural swales will be used and a reduced number of ponds will be constructed. Reduced Alternative B would also exclude construction of the Section 8 canal southwest extension. Similar to what was described for Alternative B above for Effects AG-1, AG-2, AG-3, and AG-4, Reduced Alternative B would result in conversion of approximately 27 acres of prime farmland and 17 acres of farmland of statewide importance, but would not change agricultural operations on Madera Ranch or elsewhere and would not result in conflicts with Williamson Act contracts or County zoning regulations. Thus, effects on agricultural resources are considered equivalent to those that would occur under Alternative B and are considered adverse only because of conversion of prime farmland or farmland of statewide importance to a nonagricultural land use (as described in Effect AG-3). Conservation easements on agricultural land would be established (Environmental Commitment AG-1) that would reduce the intensity of this effect.

Alternative C—Water Banking outside the MID Service Area without Swales and Alteration of Reclamation-Owned Facilities

Alternative C is similar in scope and design to Alternative B, with the primary exception that the natural swales that occur on the site would not be used for recharge. However, the expected footprint of recharge basins under Alternative C would be identical to Alternative B and would result in similar effects. Similar to what was described for Alternative B above for Effects AG-1, AG-2, AG-3, and AG-4, Alternative C would result in conversion of approximately 27 acres of prime farmland and 17 acres of farmland of statewide importance, but would not change agricultural operations on Madera Ranch or elsewhere and would not result in conflicts with Williamson Act contracts or County zoning regulations. Thus, effects on agricultural resources are considered equivalent to those that would occur under Alternative B and are considered adverse only because of conversion of prime farmland or farmland of statewide importance to a nonagricultural land use (as described in Effect AG-3). Conservation easements on agricultural land would be established (Environmental Commitment AG-1) that would reduce the intensity of this effect.

Alternative D—Water Banking outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal

Alternative D is similar in scope and design to Alternative B, with the exception that water would be conveyed to the site via GF Canal. For this reason, one recharge basin would not be built under Alternative D that was proposed under Alternative B. The expected footprint of recharge basins under Alternative D would be similar to Alternative B and would result in equivalent effects relative to changes in agricultural land use, consistency with zoning and the general plan, and effects on lands included in Williamson Act contracts (Effects AG-1, AG-2, AG-3, and AG-4). However, under Alternative D, the loss of farmland of statewide importance would be less than that described for Alternative B. (Less than 1/10 of an acre under Alternative D compared to approximately 17 acres converted under Alternative B). Thus, effects on agricultural resources are considered similar in scope to those that would occur under Alternative B and are considered adverse only because of conversion of prime farmland or farmland of statewide importance to a nonagricultural land use (as described in Effect AG-3). Conservation easements on agricultural land would be established (Environmental Commitment AG-1) that would reduce the intensity of this effect.

Cumulative Effects

Other projects, combined with the WSEP, have the potential to result in a cumulative effect on agriculture in Madera County. Specifically, development projects could result in permanent conversion of agricultural land to urbanized areas, and reductions in county-wide agricultural production would continue as water becomes more expensive and limited. However, the WSEP's contribution is not considerable. Agriculture would continue on Madera Ranch except where permanent, unburied facilities are located. MID does not propose to establish grassland conservation easements on prime farmland, unique farmland, or farmland of statewide importance. However, other areas of the ranch may continue to be used for grazing per grassland conservation easements. MID is mitigating agricultural conservation easements at a 2:1 ratio to fully compensate for the loss of prime farmland, unique farmland, and farmland of statewide importance associated with all of the alternatives. Furthermore, the alternatives would help maintain the viability of agriculture in Madera County. Thus, it is not anticipated that the alternatives would contribute to cumulative impacts on agriculture.

3.3 Air Quality

This section describes the existing air quality conditions in the areas potentially affected by the Proposed Action and alternatives. It discusses the affected environment, relevant regulations and policies, methods of analysis, possible effects, and mitigation efforts.

3.3.1 Affected Environment

Ambient air quality is affected by the climate, topography, and the type and amount of pollutants emitted. The location of the WSEP, Madera Ranch, is subject to a combination of topographical and climatic factors that result in high potential for regional and local accumulation of pollutants.

Climate and Topography

Madera Ranch is located in the San Joaquin Valley Air Basin (SJVAB). The mountain ranges bordering the air basin near the site (the Coast Ranges to the west and Sierra Nevada to the east) influence wind directions and speeds and atmospheric inversion layers in the San Joaquin Valley. These mountain ranges channel winds through the valley, affecting both the climate and dispersion of air pollutants.

Because of the mountain ranges bordering the air basin, temperature inversions occur frequently in the valley. Inversions occur when the upper air is warmer than the air beneath it, thereby trapping pollutant emissions near the earth's surface and not allowing them to disperse upward. Inversions occur frequently throughout the year in the San Joaquin Valley, although they are more prevalent and of a greater magnitude in the late summer and fall months.

Ambient Air Quality Standards and Existing Air Quality Conditions

The Proposed Action area lies within the SJVAB under the jurisdiction of the San Joaquin Valley Air Pollution Control District (SJVAPCD). The pollutants of greatest concern in the San

Joaquin Valley are carbon monoxide (CO), ozone (O_3), O_3 precursors such as volatile organic compounds (VOC), inhalable particulate matter between 2.5 and 10 microns in diameter (PM_{10}) and particulate matter less than 2.5 microns in diameter ($PM_{2.5}$).

The SJVAB has reached Federal and State attainment status for CO, nitrogen dioxide (NO_2), and sulfur dioxide (SO_2). Federal attainment status has been reached for PM_{10} but is in non-attainment for O_3, $PM_{2.5}$, and VOC. There are no established standards for oxides of nitrogen (NO_x); however, NO_x does contribute to NO_2 standards (San Joaquin Valley Air Pollution Control District 2011).

The Federal CAA, enacted in 1963 and amended several times thereafter establishes the framework for modern air pollution control. The EPA has established National Ambient Air Quality Standards (NAAQS) (Table 3-4) for criteria pollutants. Criteria pollutants include CO, NO_2, SO_2, O_3, PM_{10}, and $PM_{2.5}$, and lead. Most standards have been set to protect public health. For some pollutants, standards have been based on other values (such as protection of crops, protection of materials, or avoidance of nuisance conditions).

Table 3-4 Applicable State and Federal Ambient Air Quality Standards

Pollutant	**Averaging Time**	**California Standards**		**National Standards**	
		Concentration	**Attainment Status**	**Concentration**	**Attainment Status**
O_3	8 Hour	0.070 ppm (137 µg/m^3)	**Nonattainment**	0.075 ppm (147 µg/m^3)	**Nonattainment**
	1 Hour	0.09 ppm (180 µg/m^3)	**Nonattainment**	--	--
CO	8 Hour	9 ppm (10 mg/m^3)	Attainment	9.0 ppm (10 mg/m^3)	Attainment
	1 Hour	20 ppm (23 mg/m^3)	Unclassified	35 ppm (40 mg/m^3)	Unclassified
NO_2	Annual arithmetic mean	0.030 ppm (56 µg/m^3)	Attainment	0.053 ppm (100 µg/m^3)	Attainment
	1 Hour	0.18 ppm (338 µg/m^3)	Attainment	--	--
SO_2	Annual average	--	--	0.03 ppm (80 µg/m^3)	Attainment
	24 Hour	0.04 ppm (105 µg/m^3)	Attainment	0.14 ppm (365 µg/m^3)	Attainment
	1 Hour	0.25 ppm (655 µg/m^3)	Attainment	--	--
PM_{10}	Annual arithmetic mean	20 µg/m^3	**Nonattainment**	--	--
	24 Hour	50 µg/m^3	**Nonattainment**	150 µg/m^3	Attainment
$PM_{2.5}$	Annual Arithmetic mean	12 µg/m^3	**Nonattainment**	15 µg/m^3	**Nonattainment**
	24 Hour	--	--	35 µg/m^3	Attainment
Lead	30 day average	1.5 µg/m^3	Attainment	--	--
	Rolling-3 month average	--	--	0.15 µg/m^3	Unclassified

Source: California Air Resources Board 2011; San Joaquin Valley Air Pollution Control District 2011; 40 CFR 93.153
ppm = parts per million
mg/m^3 = milligram per cubic meter
µg/m^3 = microgram per cubic meter
-- = No standard established

Federal Conformity Requirements

The CAA and amendments require that all federally funded projects come from a plan or program that conforms to the appropriate State Implementation Plan (SIP). Federal actions are subject to either the transportation conformity rule (40 CFR 51[T]), which applies to federal highway or transit projects, or the general conformity rule. Because the Proposed Action is not a federal highway or transit project, it is subject to the General Conformity Rule.

The purpose of the general conformity rule is to ensure that federal projects conform to applicable SIPs so that they do not interfere with strategies employed to attain the NAAQS. The rule applies to federal projects in areas designated as nonattainment areas for any of the six criteria pollutants and in some areas designated as maintenance areas.

Madera Ranch is located in a federal extreme nonattainment area for O_3 and nonattainment area for $PM_{2.5}$. Consequently, to fulfill general conformity requirements, an analysis must be undertaken to identify whether the Proposed Action's total emissions of O_3, and $PM_{2.5}$:

- are below the appropriate *de minimis* levels, and
- are regionally insignificant (total emissions are less than 10% of the area's total emissions inventory for that pollutant).

3.3.2 Environmental Consequences

The Proposed Action would generate construction-related emissions and operational emissions. The approach used to evaluate construction and operational effects is described below.

Construction Effects Assessment Methods

Construction of the Proposed Action would generate pollutant emissions from a variety of emission sources and activities. All phases of project construction – project mobilization, site preparation, site clearing and grubbing, and construction – would generate air emissions. The primary pollutant-generating activities associated with these phases include:

- exhaust emissions from off-road construction vehicles and equipment;
- exhaust emissions from vehicles used to deliver supplies to the project site or to haul materials from the site;
- exhaust emissions from worker commute trips;
- fugitive dust from grading; and
- fugitive dust from equipment operating on exposed earth and from the handling of sand, gravel, aggregate, and associated construction materials.

Construction of the Proposed Action would generate emissions of Reactive Organic Gases (ROG), NO_x, CO, sulfur oxides (SO_x), and PM_{10}. Construction-related emissions also would include fugitive PM_{10} dust from site grading and exhaust emissions resulting from worker commute trips and off-road construction equipment. Emissions from off-road construction equipment are estimated based on the California Air Resources Boards's off-road model (California Air Resources Board 2007). Fugitive dust emission factors are based on research done by the Midwest Research Institute for the South Coast Air Quality Management District (Midwest Research Institute 1996).

Construction equipment for the Proposed Action during Phase 1 would most likely include:

- 18 heavy diesel-powered scrapers (40- to 60-yard capacity);
- five 500- hp diesel-powered skip loaders;
- 30 heavy-duty, off-road-type, diesel-powered, bottom dump trucks (60-yard capacity);
- five large, diesel-powered, crawler-type tractors;
- five diesel-powered motor graders;
- three diesel-powered, large-capacity water tankers;
- three diesel-powered trackhoes;
- four well drill rigs (most likely diesel-powered) and support equipment in the form of semi-trailer trucks;
- five rubber-tired, diesel-powered backhoes; and
- support equipment, such as maintenance rigs.

In addition to the equipment listed above, construction would require up to 3,500 loads of concrete in diesel-powered transit mixers, 50 diesel semi-trailer loads of well casing, 15 diesel semi-trailer loads of pumping equipment, and 20 diesel semi-trailer loads of other equipment.

All but the off-road bottom dumps and drill rigs would be brought in on semi-trailer trucks. Some of the haul rigs would be up to 13-axle rigs to carry the weight of the scrapers. Except for some maintenance rigs, all would be stored on site during the construction period.
Several daily trips would be made to pick up supervising staff, surveyors, and inspectors. In addition, equipment operators would be traveling to and from the site daily. During construction, fuels and lubricants would be transported on a daily basis.

During Phase 2, a similar but lesser amount of heavy equipment would be mobilized and used on the Madera Ranch to construct the additional ponds in Sections 16, 17, and 18.

The grading phase of construction would use the largest amount of heavy-duty construction equipment and would be the primary source of emissions during construction. Under the Proposed Action, the construction site would be mass graded, with a first grading phase of about 540,000 cy and a possible second phase grading of about eight million cy; grading activities would occur over several years. Based on the description of the Proposed Action, the grading activity is estimated to involve four bulldozers, eight rubber-tired scrapers, two graders, and as many as three water trucks used for controlling dust and conveying compaction water. The actual number of water-spreading pieces of equipment would depend on how much compaction water could be directly applied through hoses and pipes. In addition to the emissions associated with operation of construction equipment, worker commute trips would contribute a small amount of emissions.

The information shown in Table 3-5 was used to estimate construction-related emissions during peak construction days.

Table 3-5 Amount and Types of Heavy Equipment to Be Used for Mass Grading during Peak Construction Activities

Equipment Type	Alternatives B, Reduced Alternative B and C	Alternative D
Bulldozers	4	2
Rubber-tiered scrapers	8	6
Motor grader	2	1
Water trucks	3	2

The estimated size and number of engines for wells and lift station pumps used worst-case engine hp requirements to ensure that all potentially adverse effects are disclosed. However, actual or average emissions may be substantially lower.

Alternative A—No Action

Under the No Action Alternative, Reclamation would not approve the banking of CVP water outside MID's service area, nor would Reclamation approve of modifications to its distribution system. The No Action Alternative would have no adverse effects on air quality. However, the future conditions would change to support agricultural activities or water banking activities.

Under the No Action Alternative, the changes to air quality could vary. MID likely would sell the property to agricultural users and additional air quality effects could occur because additional lands would go into agricultural production; however, the amount and type of air quality effects would depend on the future agricultural practices. The SJVAB, which includes Madera County, would continue to be in severe nonattainment for O_3 and for $PM_{2.5}$. The future conditions would be evaluated by MID or the County under CEQA depending on the discretionary permits needed. If MID sells the property to others interested in water banking, the effects would be similar to those described under the Proposed Action. The types of facilities and number of wells may vary depending on the quantity of water proposed to be banked.

Alternative B—Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities

Effect AQ-1: Generation of Construction Emissions in Excess of Federal de Minimis Threshold Levels Grading associated with Alternative B, including balanced cut and fill, would require the movement of approximately 8.8 million cy of soil. Grading would be balanced on site in order to eliminate the need to haul additional fill material to the site or to haul excess material off site. These preliminary grading activities are expected to involve multiple pieces of heavy construction equipment, listed in Table 3-6.

Construction of Alternative B would generate short-term fugitive PM_{10} dust as a result of activities that disturb the soil, such as grading and excavation, and ROG, NO_x, CO, PM_{10}, and $PM_{2.5}$ from exhaust. Estimated annual air pollutant emissions during on-site grading are shown in Table 3-6. Estimates are based on a fugitive dust emission factor developed for construction activities in California. Actual fugitive dust emissions may differ slightly based on variations in soil type, wind, and soil moisture.

Table 3-6 Maximum Yearly Construction Emissions for Alternative B (tons per year)

Emission Source	ROG	NO_x	PM_{10}	$PM_{2.5}$
Alternative B (on-site heavy equipment including fugitive dust and worker trips)				
Phase 1	6.5	28.3	19.7	4.8
Phase 2	3.5	28.4	19.9	4.9
Worker Trips—Fresno	0.6	0.5	0.4	0.1
Worker Trips—Madera	0.1	0.1	0.0	0.0
Worker Trips—Chowchilla/Firebaugh	0.0	0.0	0.0	0.0
Haul Trucks	0.5	7.1	0.3	0.3
Total	**11.2**	**64.4**	**40.3**	**10.1**
Federal *de minimis* Threshold Levels	10	10	100	100
Regionally Significant Threshold (10% threshold)	13,870	23,881.95	10,902.55	10,902.55

Construction activities also would generate fugitive dust and exhaust PM_{10}. Sources of fugitive dust and PM_{10} include:

- excavating soils and sediment,
- loading the excavated material onto trucks,
- tracking dirt onto paved surfaces,
- generating truck exhaust, and
- releasing dust to blow in the wind.

As shown in Table 3-6, Alternative B would result in a net increase in ROG, NO_x, PM_{10}, and $PM_{2.5}$ emissions. The increases ROG and NO_x emissions are in excess of the federal *de minimis* threshold levels. Environmental Commitments AQ 1: Implement SJVAPCD Regulation VIII Control Measures, and AQ-2: Reduce Emissions Associated with Idling Equipment, would reduce these emissions, but not to below federal *de minimis* levels. Consequently, implementation of Alternative B is not found to be a conforming project, and there would be an adverse effect.

Effect AQ-2: Generation of Operational Emissions in Excess of Federal de Minimis Threshold Levels Operation of Alternative B would require pumping at wells and lift stations to deliver water to users. For the purpose of this analysis, MID has conservatively assumed that all new pump locations could be propane-powered. Propane-fueled IC engines that exceed 50 hp would require a permit from the SJVAPCD. These new engines would be subject to SJVAPCD rules and regulations and would have to meet best available control technology (BACT) standards. Alternative B includes an engine specification requiring the purchase and use of IC engines with catalytic controls. In addition, all engines greater than 50 hp would need to meet the emission limitations published in the SJVAPCD BACT clearinghouse. Therefore, the emission estimates for operations that are compared to the threshold are the controlled engine emission estimates. Emissions above this level would not be expected to occur because they would not meet the engine specifications set by MID nor would they comply with the applicable BACT guideline. Because the electric pumps at existing wellhead locations are not expected to contribute any operational emissions, they are not addressed in this analysis, which focuses instead on the potential emissions associated with cycling and operation of the propane-fueled IC (catalytic-controlled) engines.

The engines could be used up to 24 hours per day and up to a total operating time of 2,880 hours per year. The emission estimate uses the worst-case scenario of 102 engines with a combined total of 7,385 hp. As shown in Table 3-7, normal operation of the propane-fueled engines with emission control devices is not expected to generate emissions in excess of the federal *de minimis* thresholds. Thus, given the commitment to use engines with catalytic control and the SJVAPCD BACT requirement for engines over 50 hp, the controlled emissions are less than the threshold. Therefore, the potential effect is not considered adverse.

Table 3-7 Alternative B–Related Emissions from Operations (tons per year)

	VOC	NO_x	PM_{10}
Controlled emissions from IC engines at wells and lifts/stations	3.51	3.51	14.05
Federal *de minimis* Threshold Levels	10	10	100
Regionally Significant Threshold (10% threshold)	13,870	23,881.95	10,902.55

Notes:
Estimate assumes a combined total of 7,385 hp.
Estimate assumes engine operating time of 2,880 hours per year.
Emission factors based on SJVAPCD BACT Guideline 3.3.12 (San Joaquin Valley Air Pollution Control District 2002).

This emission estimate is based on a worst-case scenario of all engines operating on propane fuel and pessimistic assumptions for the maximum number of engines required. In the event that a combination of propane- and electric-powered engines is used or fewer engines are required, the emissions would be reduced.

Reduced Alternative B—Water Banking Outside the MID Service Area Using Select Swales and Alteration of Reclamation-Owned Facilities

Reduced Alternative B is similar in scope and design to Alternative B, with the primary exception that a reduced number of natural swales will be used and a reduced number of basins will be constructed. Reduced Alternative B would also exclude construction of the Section 8 canal southwest extension. However, the construction activities and operational needs under Reduced Alternative B would be similar to Alternative B and would result in equivalent effects on air quality (Effects AQ-1 and AQ-2). Thus, effects on air quality are considered equivalent to those which would occur under Alternative B and are considered adverse for construction activities. Implementation of Environmental Commitment AQ-1: Implement SJVAPCD Regulation VIII Control Measures, and AQ-2: Reduce Emissions Associated with Idling Equipment, would reduce the severity of this effect.

Alternative C—Water Banking outside the MID Service Area without Swales and Alteration of Reclamation-Owned Facilities

Alternative C is similar in scope and design to Alternative B, with the primary exception that the natural swales that occur on the site would not be used for recharge. However, the construction activities and operational needs under Alternative C would be similar to Alternative B and would result in equivalent effects on air quality (Effects AQ-1 and AQ-2). Thus, effects on air quality are considered equivalent to those which would occur under Alternative B and are considered adverse for construction activities. Implementation of Environmental Commitment AQ-1: Implement SJVAPCD Regulation VIII Control Measures, and AQ-2: Reduce Emissions Associated with Idling Equipment, would reduce the severity of this effect.

Alternative D—Water Banking outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal

Alternative D is nearly identical in scope and design to Alternative B, with the exception that water would be conveyed to the site via GF Canal. The off-ranch portions of the GF Canal would require the movement of 15,000 cy of soil, and operation of the following equipment is anticipated, in addition to the equipment in Table 3-3:

- 18 heavy diesel-powered scrapers (40- to 60-yard capacity);
- five 500-hp diesel-powered skip loaders;
- 30 heavy-duty, off-road-type, diesel-powered, bottom dump trucks (60-yard capacity);
- five large, diesel-powered, crawler-type tractors;
- five diesel-powered motor graders;
- two diesel-powered, large-capacity water tankers;
- three diesel-powered trackhoes;
- four well drill rigs (most likely diesel-powered) and support equipment in the form of semi-trailer trucks;
- five rubber-tired, diesel-powered backhoes; and
- support equipment, such as maintenance rigs.

Construction activities associated with Alternative D are shown in Table 3-8.

Table 3-8 Maximum Yearly Construction Emissions for Alternative D (tons per year)

Emission Source	ROG	NO_x	PM_{10}	$PM_{2.5}$
Alternative B (on-site heavy equipment including fugitive dust and worker trips)				
Phase 1	8.4	36.6	20.2	5.2
Phase 2	3.5	28.4	19.9	4.9
Worker Trips—Fresno	0.6	0.5	0.4	0.1
Worker Trips—Madera	0.1	0.1	0.0	0.0
Worker Trips—Chowchilla/Firebaugh	0.0	0.0	0.0	0.0
Haul Trucks	0.5	7.1	0.3	0.3
Total	**13.1**	**72.7**	**40.8**	**10.5**
Federal *de minimis* Threshold Levels	10	10	100	100
Regionally Significant Threshold (10% threshold)	13,870	23,881.95	10,902.55	10,902.55

As shown in Table 3-8, Alternative D would result in a net increase in ROG, NO_x, PM_{10}, and $PM_{2.5}$ emissions. The increase in NO_x emissions is in excess of the federal *de minimis* threshold levels. Implementation of Environmental Commitments AQ 1: Implement SJVAPCD VIII Control Measures, and AQ-2: Reduce Emissions Associated with Idling Equipment, would reduce the intensity of this effect, but not to below federal *de minimis* levels. Consequently, implementation of Alternative D is not found to be a conforming project, and there would be an adverse effect.

Operational needs that effect air quality under Alternative D would be similar to Alternatives C and B and would result in equivalent effects on air quality (Effect AQ-2). Therefore, the potential effect is not considered adverse.

Cumulative Effects

Effect AQ-3: Result in a Cumulative Net Increase of Any Criteria Pollutant for Which the Region Is in Nonattainment under an Applicable Federal or State Ambient Air Quality Standard (Including Releasing Emissions That Exceed Quantitative Thresholds for O_3 Precursors) The Madera Ranch site is located in the SJVAB, where air quality conditions are regulated by SJVAPCD. Although the application of the Guide for Assessing and Mitigating Air Quality Impacts (GAMAQI) control measures to this effect would minimize adverse effects, the SJVAPCD assumes air emissions to be cumulatively adverse if, with Environmental Commitments, there remains any increase in a pollutant for which the SJVAB is classified as a nonattainment area (69 FR 20550). The SJVAB is in nonattainment for O_3 and PM_{10}.

The SJVAPCD has not established threshold criteria for construction emissions. However, because construction would result in emissions of O_3 precursors (ROG and NO_x) and PM_{10}, and could result in the cumulative net increase in these pollutants, effects of construction emissions could be adverse. Because construction would not be long-term, construction of the alternatives would not contribute to the cumulative SJVAB's long-term air pollution problems.

As seen in Table 3-5, operation of the alternatives would not result in an increase in O_3 precursor (NO_x) emissions above the SJVAPCD thresholds of 10 tons per year. Although the GAMAQI states that these emissions would not be considered a cumulative net increase in O_3 precursors, as noted previously, the SJVAPCD assumes air emissions to be cumulatively adverse if, with Environmental Commitments, an alternative results in any increase in a pollutant for which the SJVAB is classified as a nonattainment area. Thus, the effect is considered adverse.

Implementation of control measurements for construction emissions of PM_{10} required by SJVAPCD (Environmental Commitment AQ-1) would reduce emissions of PM_{10} associated with construction. Emissions of PM_{10}, ROG, and NO_x associated with operations would be reduced by the emission-control devices described for the propane-fueled engine. In addition, MID would shut off the diesel engines when not in use (Environmental Commitment AQ-2) to reduce the severity of the effect.

3.4 Biological Resources

This section describes the existing biological resources in the areas potentially affected by the proposed alternatives. It discusses the affected environment, relevant regulations and policies, methods of analysis, and possible effects.

3.4.1 Affected Environment

Madera Ranch is located in southwestern Madera County and encompasses 13,646 acres. The topography slopes gently downward from east to west, ranging in elevation from about 215 feet above mean sea level (feet msl) to about 175 feet msl. The site is gently undulating and traversed by numerous shallow swales that generally run from east to west.

Watersheds and Streams

Madera Ranch lies in the historical floodplain between the Fresno River and San Joaquin River, and the south side of the ranch lies in the active floodplain of Cottonwood Creek. With the exception of Sections 28 and 29, which are inundated with Cottonwood Creek water in wet years, uncontrolled flows are rare because the surrounding areas are protected by upstream reservoirs, levees, and water diversions, and upstream off-site portions of drainages have been filled in by farmer field-leveling. The average annual rainfall at Madera Ranch is approximately 11 inches, most of which falls between October and April (California Irrigation Management Information System Station #145).

The most significant water features on Madera Ranch are Cottonwood Creek and GF Canal. Cottonwood Creek is a channelized, seasonally flowing stream that crosses Madera Ranch at the southwest corner of Section 28. The Cottonwood Creek channel has been deepened and widened by excavation throughout its length on and off the ranch. Natural streamflow occurs only during the wet season, typically from January through March. During this wet season, uncontrolled flows from the creek frequently flow out onto the southern portions of Sections 28 and 29 through a berm system that was installed in the early 1990s. From April through October, MID uses Cottonwood Creek to convey and distribute San Joaquin River and Fresno River water to growers. The creek is typically dry in November and December. MID periodically removes sediment, debris, and vegetation from the creek channel and banks using a variety of heavy equipment that moves up and down the dry creek channel. The mean width of Cottonwood Creek within the ordinary high-water mark is 40 feet.

GF Canal is a 40- to 90-foot-wide, 9- to 16-foot-deep trapezoidal irrigation and uncontrolled flow conveyance canal that bisects Madera Ranch. GFWD uses GF Canal to convey agricultural water to Section 21 and part of Section 22. In the past, during above-normal water years, waters flowed through GF Canal to Avenue 12. There are several turnouts on GF Canal where water historically has been directed to flow into grassland areas in Sections 4, 9 and 16 of Madera Ranch.

Watersheds at Madera Ranch are highly localized, and most rainfall infiltrates rapidly into the ground. Historically, the swales at Madera Ranch likely received uncontrolled flows from Cottonwood Creek and other drainages south of the Fresno River. However, as surrounding lands were brought into agricultural use and leveled, these swales have been isolated from upstream sources of water, with the exception of uncontrolled flows from Cottonwood Creek onto swales in Section 28 and 29.

Plant Communities and Wildlife Habitats

Seven native and one nonnative plant communities were identified on Madera Ranch. The names of the plant communities used in this report are based on the conventions described by Sawyer and Keeler-Wolf (1995) and are used to describe the wildlife habitats. The descriptions of these communities and habitats include a listing of the representative plants and wildlife that typically occur in each area and the regional distribution of the community type in the vicinity of Madera Ranch. Table 3-9 shows the acreage of each of these communities, and Figure 3-4 shows the distribution of each community on Madera Ranch. Table 3-10 lists sensitive plants that occur or may occur at the project site.

Table 3-9 Plant Communities on Madera Ranch

Community	Approximate Size in Acres
California annual grassland	6,462
Alkali grassland	4,044
Vernal pool	22
Great Valley iodine brush scrub	292
Freshwater marsh	2
Alkali rain pool	16
Riparian woodland	2
Cultivated lands	2,745
Pond	2
Other Land-Cover Types:	
Cottonwood Creek (Canal)	4
Gravelly Ford Canal	33
Ranching facilities	22
Total	**13,618**

Table 3-10 Special-Status Plants Occurring or Potentially Occurring at Madera Ranch

Name	Status* Federal/State /CNPS	Distribution	Habitat	Occurrence in Project Area
Palmate-bracted bird's-beak *Cordylanthus palmatus*	E/E/1B	Livermore Valley and scattered locations in the Central Valley from Colusa County to Fresno County	Alkaline grasslands, chenopod scrub; blooms May–October	Unlikely to occur
Succulent owl's-clover *Castilleja campestris* ssp. *succulenta*	T/E/1B	Eastern edge of San Joaquin Valley and adjacent foothills, from Stanislaus County to Fresno County	Vernal pools; blooms April–May	Unlikely to occur (out of range)
San Joaquin Orcutt grass *Orcuttia inaequalis*	T/E/1B	Scattered locations along east edge of the San Joaquin Valley and adjacent foothills, from Stanislaus County to Tulare County	Large, deep vernal pools; blooms May–September	Suitable habitat not present
Hairy Orcutt grass *Orcuttia pilosa*	E/E/1B	Scattered locations along east edge of the Central Valley and adjacent foothills, from Tehama County to Merced County	Large, deep vernal pools; blooms May–August	Suitable habitat not present
Greene's tuctoria *Tuctoria greenei*	E/R/1B	Eastern Central Valley and foothills	Large, deep vernal pools; blooms May–June	Suitable habitat not present
Heartscale *Atriplex cordulata*	–/–/1B	Alameda, Butte, Colusa, Fresno, Glenn, Kern, Madera, Merced, San Joaquin, San Luis Obispo, Solano, Stanislaus, Tulare, and Yolo Counties	Chenopod scrub, meadows and seeps, valley foothill grassland. Blooms April-October.	Could be present and would be impacted.
Lesser saltscale *A. miniscula*	–/–/1B	Butte, Fresno, Kern, Madera, Merced, Stanislaus, and Tulare Counties	Chenopod scrub, Playas, Valley and foothill grassland/alkaline, sandy. Blooms May-October.	Could be present and would be impacted.
Vernal pool smallscale *A. persistens*	–/–/1B	Glen, Madera, Merced, Solano, Stanislaus, and Tulare Counties.	Alkaline vernal pools. Elevation 10-115 meters. Blooms June-October.	Could be present and would be impacted.
Subtle orache *A. subtillis*	–/–/1B	Butte, Fresno, Kings, Kern, Madera, Merced, and Tulare Counties	Valley and foothill grassland. Blooms June-August (October but not common).	Could be present and would be impacted.
Lost Hills crownscale *A. vallicota*	–/–/1B	Fresno, Kings, Kern, Merced, and San Luis Obispo Counties	Chenopod scrub, Valley and foothill grassland, Vernal pools/alkaline. Blooms April-August.	Unlikely to occur (out of range)
Hoover's cryptantha *Cryptantha hooverii*	E/R/1B	Contra Costa , Kern, Madera, and Stanislaus Counties	Inland dunes, Valley and foothill grassland. Blooms April-May.	Could be present and would be impacted.
Recurved larkspur *Delphinium recurvatum*	–/–/1B	Alameda, Butte, Contra Costa, Colusa, Fresno, Glenn, Kings, Kern, Madera, Merced, Monterey, San Joaquin, San Luis Obispo, Solano, and Tulare Counties	Chenopod scrub, cismontane woodland, valley and foothill grassland, alkaline substrates. Blooms March-June.	Could be present and would be impacted.
Sanford's arrowhead *Sagittaria sanfordii*	–/–1B	Butte, Del Norte, El Dorado, Fresno, Merced, Mariposa, Orange, Placer, Sacramento, Shasta, San Joaquin, Tehama, and Ventura Counties	Marshes and swamps (assorted shallow freshwater). Blooms May-October.	Suitable habitat not present

Name	Status* Federal/State /CNPS	Distribution	Habitat	Occurrence in Project Area

* Status explanations:

Federal

– = No status
E = Listed as —endangered” under the federal Endangered Species Act.
T = Listed as —threatened” under the federal Endangered Species Act.

State

– = No status
E = Listed as —endangered” under the California Endangered Species Act.
R = Listed as —rare” under the California Endangered Species Act.

California Native Plant Society

California Native Plant Society (CNPS). 2010. Inventory of Rare and Endangered Plants (online edition, v7-10c). California Native Plant Society. Sacramento, CA. Accessed on Fri, Aug. 27, 2010 from http://www.cnps.org/inventory.

1B = List 1B species: rare, threatened, or endangered in California and elsewhere.

Madera Ranch lies in the San Joaquin Valley subregion of the California Floristic Province (Hickman 1993). The local flora include 198 taxa (species, subspecies, and varieties) in 39 plant families. Nonnative species represent 53 taxa (26.8%), which is on the low end of the range (20–71%) reported for the proportion of nonnatives in other California annual grasslands (Heady 1988).

Although the surrounding land has been converted to agriculture, most of Madera Ranch is open, grazed rangeland. Rangeland vegetation consists primarily of annual grassland. Two grassland plant communities (California annual grassland and alkali grassland) and two wetland plant communities (vernal pool and alkali rain pool) are present in the annual grassland. In addition, Great Valley iodine bush scrub occurs in the northern half of Section 7. Freshwater marsh is present in portions of the channel of the GF Canal. Riparian woodland is present on the margins of a small pond in Section 28. Vineyards, orchards, and cropland are present in cultivated portions of the ranch (Figure 3-4).

California Annual Grassland California annual grassland is open grassland composed of annual grasses and forbs (Sawyer and Keeler-Wolf 1995). Although the dominant grasses are of Mediterranean or Eurasian origin, the annual and perennial herbs are mostly native to the California Floristic Province. At Madera Ranch, California annual grassland occupies sandy loam soils, primarily of the Pachappa soil series.

At Madera Ranch, characteristic species include the following:

- Soft chess (*Bromus hordeaceus*).
- Foxtail barley (*Hordeum murinum* ssp. *leporinum*).
- Rattail fescue (*Vulpia myuros*).
- Common fiddleneck (*Amsinckia menziesii*).
- Popcornflower (*Plagiobothrys canescens*).
- Johnny-tuck (*Triphysaria eriantha*).
- Blue dicks (*Dichelostemma capitata*).
- California goldfields (*Lasthenia californica*).
- Purple owl’s-clover (*Castilleja exerta*).
- Bird’s-eye gilia (*Gilia tricolor* ssp. *diffusa*).

California annual grassland is the most widespread plant community at Madera Ranch, occurring in most uncultivated areas on the ranch, in both uplands and swales.

Within the California annual grassland community, small areas of accumulated wind-blown sand derived from basin soils are characterized by showy annual wildflower species, including baby blue-eyes (*Nemophila menziesii*), California poppy (*Eschscholzia californica*), sun cup (*Camissonia campestris*), and tidy-tips (*Layia platyglossa*).

California annual grasslands have experienced historical agricultural disturbance in several areas of Madera Ranch, including Sections 14, 15, 16, 17, 18, and 22 (Figure 3-4). Grasslands in

Sections 16, 17, and 18 were disturbed more than 10 years ago, and there is little discernable difference between this habitat and areas that have not experienced agricultural production.

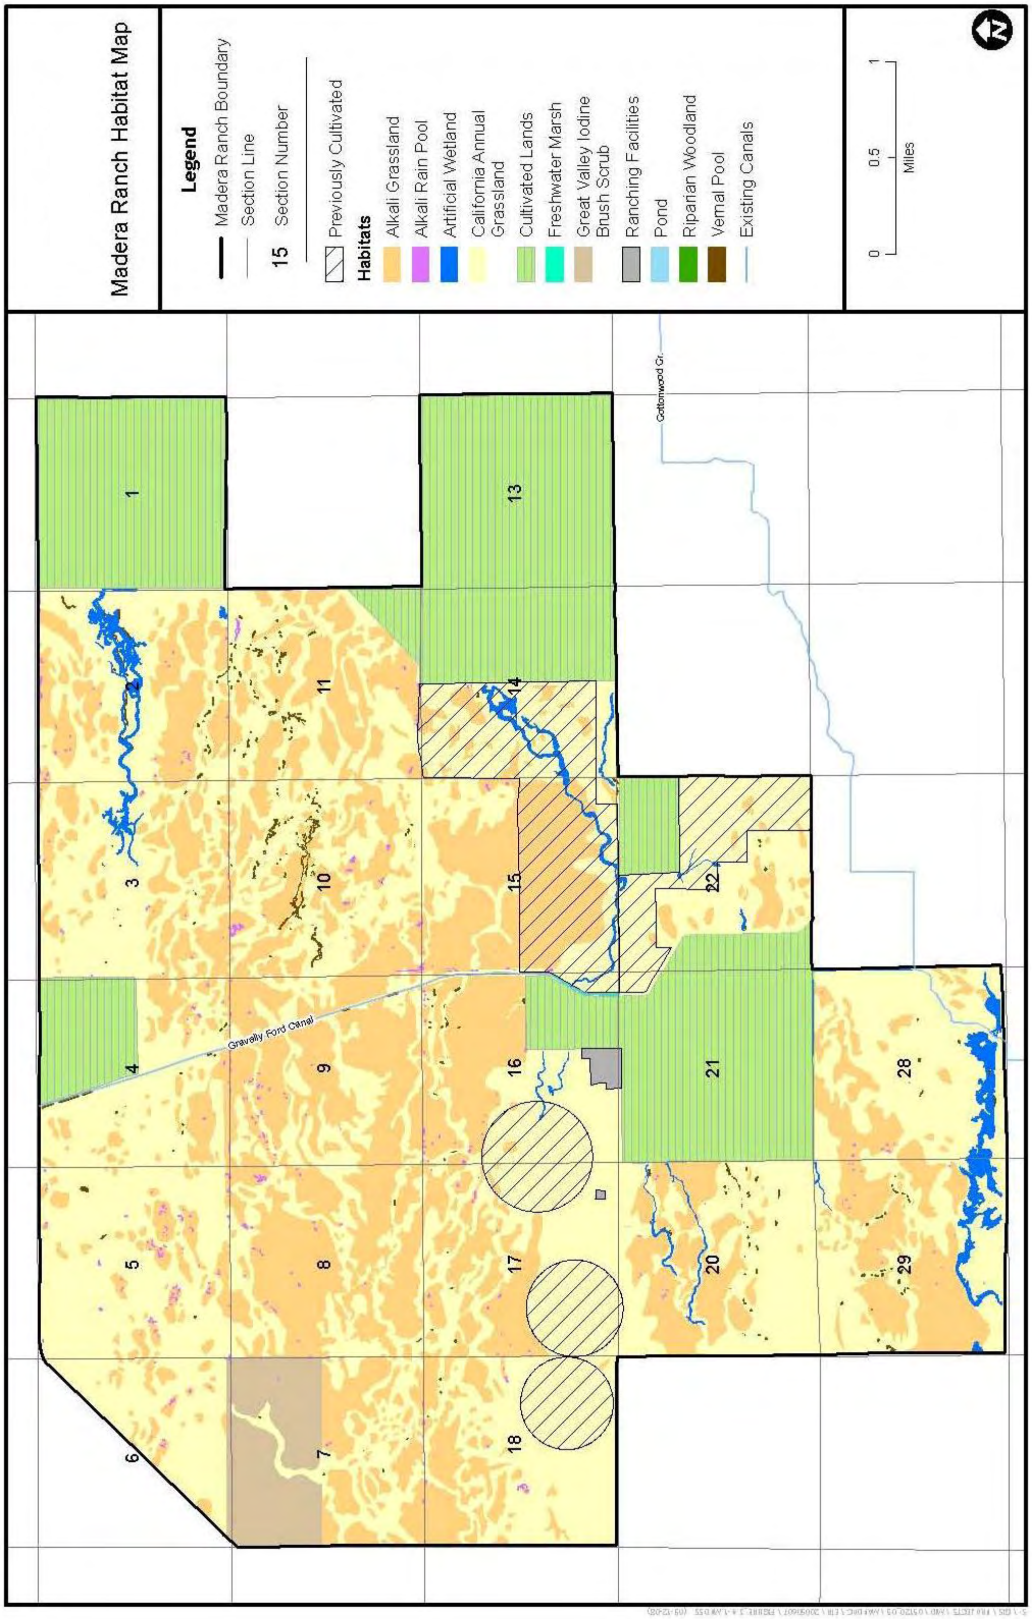

Figure 3-4 Madera Ranch Habitat Map

Grassland in Section 22 was disturbed more recently than 10 years ago, and annual grasses there are similar to undisturbed areas but have not completely recovered. Even though furrows are still present, grassland in Sections 14 and 15 is most similar to undisturbed areas. The similarities found between historically cultivated areas and undisturbed areas suggest that California annual grasslands can recover from relatively severe effects. However, there are some actions such as deep ripping of certain soil types that cannot recover.

Overall vegetative differences including density and composition may persist for many years in areas with new roads or pipelines. This is supported by the one published study based on a Central Valley site (Holmstead and Anderson 1998). In this study, some aspects of regenerating vegetation were documented for sites restored after excavations at oil fields in the southern San Joaquin Valley. On sites restored by replacing stockpiled topsoil and planting seed, vegetation was sparser (i.e., had a lower density and cover of plants) than on undisturbed sites. Sites where stockpiled topsoil was replaced but no seeds were planted had a cover and density of plants lower than the seeded sites and much lower than adjacent undisturbed areas. The species composition of the sites and their long-term recovery were not documented in this study.
On Madera Ranch, portions of the property appear to have recovered from previous disturbance within five years, such as the access roads to the test pond work areas. Also, larger tracts of land have become re-established with annual grasslands, specifically, the western ½ of Section 14, the southern ½ of Section 15, and portions of Section 16, 17, 18 and 22 were cultivated approximately 30 years ago.

Wildlife Many wildlife species use annual grassland for foraging, but these species usually require special habitat features such as burrows, rock outcrops, ponds, or habitats with shrubs or trees for breeding, resting, and escape cover. Mammals commonly found in grassland habitat include desert cottontail (*Sylvilagus audobonii*), black-tailed jackrabbit (*Lepus californicus*), Heermann’s kangaroo rat (*Dipodomys heermanni*), San Joaquin pocket mouse (*Perognathus inornatus*), California ground squirrel (*Spermophilus beecheyi*), American badger (*Taxidea taxus*), and coyote (*Canis latrans*).

Common birds known to breed in annual grasslands include western meadowlark (*Sturnella neglecta*) and California horned lark (*Eremophila alpestris actia*).

Grasslands also provide important foraging habitat for a variety of raptors including:

- red-tailed hawk (*Buteo jamaicensis*),
- northern harrier (*Circus cyaneus*),
- white-tailed kite (*Elanus leucurus*),
- American kestrel (*Falco sparverius*),
- western burrowing owl (*Athene cunicularia hypugea*),
- short-eared owl (*Asio flammeus*),
- prairie falcon (*Falco mexicanus*), and
- turkey vulture (*Cathartes aura*).

Amphibian species that typically breed in ponds and vernal pools in grassland habitat include:

- western spadefoot toad (*Scaphiopus hammondii*),
- western toad (*Bufo boreas*), and
- Pacific treefrog (*Hyla regilla*).

Characteristic reptiles that breed in grasslands include:

- western fence lizard (*Sceloporus occidentalis*),
- side-blotched lizard (*Uta stansburiana*),
- common garter snake (*Thamnophis sirtalis*), and
- gopher snake (*Pituophis melanoleucus*).

Regional Distribution California annual grassland is the typical grassland community of the California Central Valley and adjacent foothills. Although common in foothill areas, California annual grassland is regionally uncommon in the Central Valley as a result of conversion to cropland. Few areas of California annual grassland are left in Madera County west of SR 99. Therefore, California annual grassland at Madera Ranch is a sensitive plant community.

Alkali Grassland The alkali grassland community present at Madera Ranch occurs on strongly saline-alkali soils, generally of the Fresno and El Peco soil series. This plant community is uncommon and has not been characterized in the ecological literature. In addition to the typical grassland species cited above, perennial and halophytic species (species that grow in salty soils) are common. Perennial species present in the alkali grasslands include interior goldenbush (*Isocoma acradenia* var. *bracteosa*), locoweed (*Astragalus* spp.), alkali sacaton (*Sporobolus airoides*), and saltgrass (*Distichlis spicata*). The presence of these perennial species suggests that the vegetation in areas of strongly saline-alkali soils historically was a shrub community dominated by saltbush (*Atriplex* spp.) or iodine bush (*Allenrolfea occidentalis*). Except for the absence of shrubby saltbush species, the floristic composition and cover of annual grasses and forbs in alkali grassland at Madera Ranch is very similar to that of valley saltbush scrub.

Slickspots, also called alkali scalds, are common in the alkali grassland. Slickspots are relatively shallow, sparsely vegetated depressions containing strongly saline-alkali soils (Reid et al. 1993). At Madera Ranch, they are interspersed on nearly level inter-swale landforms where soils are mapped as different stages and/or complexes of the Fresno, El Peco, and Dinuba series. These soil series are strongly to slightly saline-alkali and possess a carbonate-silica cemented hardpan at depths ranging from 20 to 40 inches. The slickspots have a fringe of annual halophytic species, including common spikeweed (*Centromadia pungens*), bush seepweed (*Suaeda moquinii*), alkali peppergrass (*Lepidium dictyotum*), large-flowered sand spurry (*Spergularia macrotheca* var. *leucantha*), and annual saltscale (*Atriplex* spp.) species.

As described above under California annual grassland, some areas of alkali grassland have experienced historical agricultural disturbance. Alkali grassland was not entirely disturbed, or has recovered from these activities, and during botanical surveys it was observed in historical agricultural areas in Sections 14, 15, and 22. Alkali grasslands were much less extensive in former agricultural land in Sections 16, 17, and 18 (Figure 3-4).

Wildlife Many of the wildlife species characteristic of California annual grasslands described above are the same as those species associated with the alkali grasslands. Western burrowing owl, western meadowlark, and California horned lark are the more visible bird species of this area. Badger, coyote, and black-tailed jackrabbit also have been observed in this habitat. Regional Distribution Alkali grasslands are a sensitive plant community restricted to a few occurrences along the central trough of the Central Valley at the lower end of older alluvial fans. These alluvial fans historically received finer-textured, water-transported sediments and water-soluble salts derived from granitic rocks (San Joaquin Valley) or sedimentary and metamorphic rocks (Sacramento Valley). Areas with alkali grasslands have (or historically had) a high water table, and the capillary rise of water to the soil surface and subsequent evaporation deposits salts at or near the soil surface. Alkali grasslands are not well-documented, although areas with soils suitable for the support of alkali grasslands occur from Glenn County to Kern County. However, many of these areas of alkali soils have been converted to cropland, with scattered remnants present primarily in the National Wildlife Refuge System. In Madera County, alkali grasslands occur west of SR 99 in the area between the Fresno River and the San Joaquin River where natural vegetation is present.

Vernal Pools Vernal pools are seasonal wetlands that form in depressions, generally in annual grassland habitat. Water collects in the pool basins during winter rainfall, and extended ponding is maintained by a subsurface layer that is very slowly permeable.

At Madera Ranch, vernal pools occur in swales, primarily on soils mapped under the Pachappa series. Although a claypan or hardpan is absent, wetland hydrology is maintained by the very slow permeability of the soil surface horizons caused by the high salinity. Holland (1978) reports that vernal pools are uncommon on the soil series group that includes the Pachappa series because of the absence of a restrictive layer. Because vernal pools are so uncommon on this soil type, neither Holland (1986) nor Sawyer and Keeler-Wolf (1995) include this type of vernal pool in their plant community descriptions. Vernal pool fairy shrimp (*Branchinecta lynchi*) are present in the vernal pools at Madera Ranch.

The vernal pools at Madera Ranch are floristically similar to northern claypan vernal pools (Holland 1986; Sawyer and Keeler-Wolf 1995). They are often dominated by Mediterranean barley (*Hordeum marinum* ssp. *gussoneanum*), which is often seen in vernal pools of relatively brief ponding. Typical vernal pool endemics present in the pools include coyote thistle (*Eryngium vaseyi* var. *vallicola*), Fremont's goldfields (*Lasthenia fremontii*), California water-starwort (*Callitriche marginata*), bracted popcornflower (*Plagiobothrys bracteatus*), Pacific foxtail (*Alopecurus saccatus*), American pillwort (*Pilularia americana*), and vernal pool smallscale (*Atriplex persistens*).

Most of the vernal pools on Madera Ranch are connected by swales. The swales are shallow drainages that convey surface runoff during and immediately after storms. Swales may be an important route for dispersal of aquatic organisms between vernal pools. Because the swales at

Madera Ranch lack a duripan and the vegetation does not differ substantially from the adjacent grasslands, the swales are not distinguished as separate features on Figure 3-4.

Wildlife Vernal pools and swales provide important breeding habitat during the wet season for various wildlife species, including California tiger salamander (*Ambystoma californiense*), western spadefoot toad, and vernal pool fairy shrimp. During the wet season, dabbling ducks may use the pools, and Brewer's blackbirds (*Euphagus cyanocephalus*), common snipe (*Gallinago gallinago*), long-billed dowitcher (*Limnodromus scolopaceus*), least sandpiper (*Calidris minutilla*), and American pipits (*Anthus reubescens*) may graze and glean from pool shorelines. American avocets (*Recurvirostra americana*), California horned larks, and western meadowlarks nest in the swales and adjacent grasslands. Mourning doves (*Zenaida macroura*) and lesser nighthawks (*Chordeiles acutipennis*) may nest in the dry vernal pool beds.

Regional Distribution Northern claypan vernal pools are a sensitive plant community present at scattered locations throughout the Central Valley, generally occurring on the alluvial fan terraces along both margins of the valley but also occurring in the central trough. The distribution of northern claypan vernal pools is similar to that of alkali grasslands described above. The presence of vernal pools in Madera County west of SR 99 previously had not been documented (California Natural Diversity Database 2004), although additional vernal pools could occur on other lands where soils and vegetation are similar to those at Madera Ranch. Vernal pools have been documented in Madera County east of SR 99, but these are a different type of habitat classified as northern hardpan vernal pools.

Alkali Rain Pools Alkali rain pools are a rare type of vernal pool that has not been described in the ecological literature and appears to have been little studied. Jones & Stokes previously identified this habitat in Tulare County (Jones & Stokes Associates 1998). Alkali rain pools form in slickspots that pond water for long duration. Alkali rain pools are unvegetated except for a fringe of annual halophytic species, including bush seepweed, alkali peppergrass, dwarf popcornflower (*Plagiobothrys humistratus*), California alkali grass (*Puccinellia simplex*), large-flowered sand spurry, and annual saltscale species.

Alkali rain pools differ from other vernal pools in their vegetation, soils, and hydrology. Alkali rain pool vegetation is sparse and concentrated on the pool margins and along soil cracks. In contrast, vegetation in other vernal pools typically covers the entire pool bottom. Moreover, alkali rain pools lack plant species characteristic of vernal pools. Instead, vegetation in alkali rain pools is composed of mostly annual, halophytic/alkali-tolerant species.

Wildlife When wet, alkali rain pools on Madera Ranch provide habitat for crustaceans and other invertebrates, such as Lindahl's fairy shrimp (*Branchinecta lindahli*). Alkali fairy shrimp (*Branchinecta mackini*) and Lindahl's fairy shrimp are present in the alkali rain pools, indicating that the pH ranges from 6.9 to 9.6 (Jones & Stokes 2000). The longhorn fairy shrimp (*Branchinecta longiantenna*), a potential inhabitant of alkali rain pools, was not observed at Madera Ranch. San Joaquin tiger beetle (*Cicindela tranquebarica* ssp. undescribed) is present around the moist margins of the alkali rain pools and other slickspots. Brewer's blackbirds and a variety of shorebirds, including killdeer (*Charadrius vociferus*), common snipe (*Gallinago gallinago*), long-billed dowitcher (*Limnodromus scolopaceus*), and least sandpiper (*Calidris* *minutilla*), forage for insects along the shores of the rain pools. In the dry season, this habitat is used by many of the same species associated with the alkali grasslands and dry vernal pool beds.

Regional Distribution Alkali rain pools form a sensitive plant community that has been documented only at the Carrizo Plains, Madera Ranch, one site in Tulare County, and Semitropic Water Bank in Kern County. However, alkali rain pools are expected to occur at other locations where strongly saline/alkali soils are found. These soils occur primarily in the central trough of the Central Valley at the lower end of older alluvial fans, as described above for alkali grasslands. In Madera County, alkali rain pools are known only at Madera Ranch, although they could occur on other parcels in western Madera County where soils and vegetation are similar to those at Madera Ranch.

Great Valley Iodine Bush Scrub Great Valley iodine bush scrub is an open or dense scrub community dominated by iodine bush. In typical Great Valley iodine bush scrub, cover of annual grasses and forbs is generally low, being inhibited by a high water table and soils that are highly saline or alkali (Holland 1986). At Madera Ranch, other perennial species associated with this community include interior goldenbush, locoweed, rusty molly (*Kochia californica*), alkali sacaton, and saltgrass. The herbaceous understory of Great Valley iodine bush scrub is similar to that of alkali grassland, with a high cover of grass and forb species except where slickspots are present. On Madera Ranch, cover of annual grasses and forbs is high, consistent with the fact that the water table is no longer close to the surface (Water Resources Section).

Wildlife Wildlife species associated with this habitat include many of the same species found in the annual grassland habitat.

Regional Distribution Great Valley iodine bush scrub is a sensitive plant community reported from about 30 scattered locations in the Central Valley, ranging from Contra Costa County to Kern County (California Natural Diversity Database 2008). Most of the occurrences are found in the basins along the trough of the Central Valley, where the water table historically was high. At Madera Ranch, this plant community is present in the northern half of Section 7 (Figure 3-4). Great Valley iodine bush scrub has also been reported along Avenue 12, on property adjacent to Madera Ranch.

Freshwater Marsh Freshwater marsh is a wetland habitat dominated by emergent perennials, typically tules (*Schoenoplectus* spp.) or cattails (*Typha* spp.). Freshwater marsh occurs in the southeastern corner of Section 16 within the channel of the GF Canal (Figure 3-4). Dominant species include common bulrush (*Schoenoplectus acutus*), narrow-leaved cattail (*Typha angustifolia*), broad-leaved cattail (*T. latifolia*), and yellow cress (*Rorippa palustris*).

Wildlife Representative wildlife species favoring this habitat include the Pacific treefrog, common garter snake (*Thamnophis sirtalis*), red-winged blackbird (*Agelaius phoeniceus*), mallard (*Anas platyrhynchos*), great egret (*Ardea alba*), and great blue heron (*Ardea herodias*).

Regional Distribution Freshwater marsh is found throughout the Central Valley. Historically, freshwater marsh was extensive in the Delta and in the flood basins associated with the major river systems. Currently, the main occurrences are along sloughs associated with the larger river systems (Sacramento, San Joaquin, and others) or at wildlife refuges and duck clubs (California Natural Diversity Database 2008). Small pockets of freshwater marsh occur in many areas where standing water is present for all or much of the year, including both natural and human-made features such as irrigation and drainage canals and stock ponds. Freshwater marsh is a sensitive plant community because of state and federal policies and regulations mandating no net loss of wetlands.

Riparian Woodland Riparian woodland is an open-canopied, tree-dominated habitat occurring along streams, adjacent to lakes and ponds, or on alluvial fans or floodplains where a high water table is present. The woody canopy is generally dominated by cottonwood (*Populus* spp.) or willow (*Salix* spp.) trees. The understory may be shrubby (willows, blackberry [*Rubus* spp.], wild rose [*Rosa* spp.], buttonwillow [*Cephalanthus occidentalis* var. *californicus*]) or composed primarily of herbaceous species, such as mugwort (*Artemisia douglasiana*).

At Madera Ranch, a stand of riparian woodland is present around the margins of the small pond in the southeastern corner of Section 28 (Figure 3-4). Cottonwood and willow trees also occur along the GF Canal on the western side of Section 22.

Wildlife Riparian woodland habitat provides foraging and breeding habitat for many wildlife species. Swainson's hawk (*Buteo swainsoni*), American kestrel (*Falco sparverius*), great horned owl (*Bubo virginianus*) and mourning dove use the larger cottonwoods in this habitat for roosting and perching between foraging trips. Downy woodpecker (*Picoides pubescens*) and house finches (*Carpodacus mexicanus*) also nest in the trees.

Regional Distribution Riparian woodland occurs at scattered locations throughout the Central Valley, primarily along rivers and streams. Isolated patches of habitat occur around farm ponds or along drainage canals. In Madera County, riparian woodland occurs along the San Joaquin, Fresno, and Chowchilla Rivers. Riparian woodland is a sensitive plant community at Madera Ranch because it is locally and regionally uncommon.

Cultivated Lands Madera Ranch includes approximately 2,700 acres of land currently in agricultural production and approximately 1,500 acres of land that previously have been cultivated (Figure 3-4). Lands currently in agricultural production are planted with cotton and vineyards and lack native vegetation. Lands that have not been cultivated recently have reverted to California annual grassland and support wildlife associated with undisturbed grassland.

Other Habitats Two other habitat types found at Madera Ranch are described below. These habitats are a small pond and bird-nesting habitat. Bird-nesting habitat is located within previously described habitats and communities.

Pond A two-acre pond is located in the southeastern corner of Section 28 (Figure 3-4). The hydrology of this wetland is artificially maintained. The pond is connected to Cottonwood Creek via a culvert that was constructed in the 1990s. GFWD occasionally diverts water from Cottonwood Creek into the pond, and inflow is controlled by a gate valve. If the water level in the pond is high enough, a portion of the water stored in the pond can be returned to Cottonwood Creek when needed.

The pond is vegetated by vernal pool species and ruderal wetland species characteristic of disturbed seasonal wetlands such as stock ponds or detention basins. The species present include bracted popcornflower, purslane speedwell (*Veronica peregrina*), dock (*Rumex* spp.), weedy cudweed (*Gnaphalium luteo-album*), hyssop loosestrife (*Lythrum hyssopifolium*), and yellow cress (*Rorippa* spp.). A stand of riparian woodland dominated by Fremont cottonwood (*Populus fremontii* ssp. *fremontii*) and black willow (*Salix gooddingii*) is present around the margins. Barn swallows (*Hirundo rustica*), several species of bats (*Myotis* spp.), and common nighthawks (*Chordeiles minor*) forage over the pond, and raccoons (*Procyon lotor*), striped skunks (*Mephitis mephitis*), and deer mice (*Peromyscus maniculatus*) likely find food and water along the edges of the basin.

Ponds are a common habitat in the Central Valley. No sensitive plants are present in the pond at Madera Ranch.

Bird Nesting Habitat There are four distinct nesting habitats on Madera Ranch: grassland habitats, tree habitats, tule/shrub habitats, and agricultural land. Grassland nesting habitat is the most abundant on site. The diversity in soil types, frequency of burrows, and grassland cover provide several ecological niches for nesting. Key grassland nesting species on site include:

- killdeer,
- western burrowing owl,
- western meadowlark,
- California horned lark, and
- savannah sparrow (*Passerculus sandwichensis*).

Tree nesting habitat is more limited on Madera Ranch, but there are approximately two dozen trees that provide suitable nesting habitat. Most of these trees are near ranching facilities; several are along GF Canal; and another cluster of nesting trees is in the riparian woodland in Section 28.

Tule/shrub nesting habitats also are limited on Madera Ranch. Tule nesting habitat is located along GF Canal in the southeast corner of Section 16. Shrub nesting habitats are found along GF Canal and other agricultural drainage ditches (Figure 3-4). Tule/shrub nesting species on site include song sparrow (*Melospiza melodia*) and red-winged blackbird (*Agelaius phoeniceus*).

Agricultural land also can provide nesting habitat depending on the crop type and cropping patterns. Agricultural land in alfalfa production, including land in Sections 1, 4, 13, 14, 16, 21 and 22, could provide foraging habitat for tricolored blackbirds (*Agelaius tricolor*).

Threatened and Endangered Plants

Five plants listed by USFWS as threatened or endangered under the Federal ESA, or species that are candidates for possible future listing as threatened or endangered under ESA, are known to occur in the vicinity of Madera Ranch: palmate-bracted bird’s-beak (*Cordylanthus palmatus*), succulent owl’s-clover, San Joaquin Orcutt grass, hairy Orcutt grass, and Greene’s tuctoria. None of these species was located on Madera Ranch during the botanical surveys.

Palmate-Bracted Bird's-Beak Palmate-bracted bird's-beak is a federally and state-listed endangered species that was collected along Firebaugh-Madera Road in 1937 (California Natural Diversity Database [CNDDB] 2008). Sections 6 and 7 are adjacent to the location of this occurrence. Palmate-bracted bird's-beak grows in chenopod scrub and alkali meadows in association with iodine bush, common glasswort (*Salicornia subterminalis*), bush seepweed, western borax-weed, saltgrass, alkali heath, common spikeweed, and low barley (California Natural Diversity Database 2008). This habitat occurs in the northern half of Section 7. Consultant biologists surveyed the northern half of Section 7 and detected no palmate-bracted bird's-beak. However, there remains a possibility that palmate-bracted bird's beak is present in the seed bank and in other alkali grassland areas (Cypher pers. comm.).

Succulent Owl's-Clover Succulent owl's-clover (*Castilleja campestris* ssp. *succulenta*) is federally listed as threatened and state-listed as endangered. It occurs in northern hardpan vernal pools in association with coyote thistle (*Eryngium castrense*), stipitate popcornflower (*Plagiobothrys stipitatus*), white-headed navarretia (*Navarretia leucocephala*), Fremont's goldfields, tricolor monkeyflower (*Mimulus tricolor*), woolly marbles, and downingia (*Downingia* spp.) (California Natural Diversity Database 2008). Madera Ranch is outside the known range for succulent owl's-clover, and northern hardpan vernal pools, which are habitat for the species, do not occur on Madera Ranch. Therefore, succulent owl's-clover is presumed to be absent from the site.

Orcutt Grasses Three Orcutt grasses (San Joaquin Orcutt grass [*Orcuttia inaequalis*], hairy Orcutt grass [*Orcuttia pilosa*], and Greene's tuctoria [*Tuctoria greenei*]) are present in the Madera Ranch vicinity. San Joaquin Orcutt grass is federally listed as threatened and state-listed as endangered. Hairy Orcutt grass is both federally and state-listed as endangered. Greene's tuctoria is federally listed as endangered and state-listed as rare. All three species occur in large, deep northern hardpan vernal pools (California Natural Diversity Database 2008). Madera Ranch is outside of the known range for these three species, and northern hardpan vernal pools, which are habitat for the species, do not occur on Madera Ranch. Therefore, most Orcutt grasses are presumed to be absent from the site. However, there remains a possibility that Greene's tuctoria is present (Cypher pers. comm.).

Threatened, Endangered, and Other Sensitive Wildlife

Table 3-11 lists the federally listed wildlife species that occur, or potentially could occur, at Madera Ranch. The listing status, distribution, habitat requirements, and estimated probability of occurrence at Madera Ranch are also presented. There is no designated critical habitat on Madera Ranch.

Table 3-11 Special-Status Wildlife Species Occurring or Potentially Occurring at the Project Site

Species Name	Status* Fed/State	California Distribution	Habitat Requirements	Occurrence on Madera Ranch
Invertebrates				
Vernal pool fairy shrimp *Branchinecta lynchi*	T/–	Central Valley, interior North and South Coast Ranges; from Tehama County to Santa Barbara County; isolated populations also in Riverside County	Vernal pools; also found in sandstone rock outcrop pools	Documented in vernal pools on Madera Ranch
Vernal pool tadpole shrimp *Lepidurus packardi*	E/–	Shasta County to Merced County	Vernal pools and ephemeral stock ponds	Not recorded from Madera County. Not found during surveys
Conservancy fairy shrimp *Branchinecta conservatio*	E/–	Disjunct occurrences in Solano, Merced, Tehama, Butte, and Glenn Counties	Large, deep vernal pools in annual grasslands	Not recorded from Madera County. Not found during surveys
Longhorn fairy shrimp *Branchinecta longiantenna*	E/–	Eastern margin of South Coast Ranges from Contra Costa County to San Luis Obispo County and in Merced County	Small, clear to moderately turbid, clay- or grass-bottomed pools in sandstone rock outcrops	Not recorded from Madera County. Not found during surveys
Mid-valley fairy shrimp *Branchinecta mesovalliensis*	–/–	Sacramento, Solano, Contra Costa, San Joaquin, Madera, Merced, and Fresno Counties	Shallow vernal pools; vernal swales; and various artificial ephemeral wetland habitats, including roadside puddles, scrapes, and ditches	Not found during surveys
Insects				
San Joaquin tiger beetle *Cicindela tranquebarica* ssp.	–/–	San Joaquin Valley and Carrizo Plain	Alkali and clay flats, sand dunes, sand bars, beeches, and sandy soils	Documented on Madera Ranch
Amphibians				
Western spadefoot *Scaphiopus hammondii*	–/SSC	Sierra Nevada foothills, Central Valley, Coast Ranges, coastal counties in southern California	Shallow streams with riffles and seasonal wetlands, such as vernal pools in annual grasslands and oak woodlands	Widespread occurrence in Madera County. Documented on Madera Ranch during surveys
California tiger salamander *Ambystoma californiense* (=*A. tigrinum* c.)	T/-	Central Valley, including Sierra Nevada foothills below approximately 1,000 feet, and coastal regions; from Butte County south to Santa Barbara County	Small ponds, lakes, or vernal pools in grasslands and oak woodlands for larvae; rodent burrows, rock crevices, or fallen logs for cover for adults and for summer dormancy	Widespread occurrence in Madera County. Not found during surveys but suitable habitat occurs on Madera Ranch
Reptiles				
Blunt-nosed leopard lizard *Gambelia* (=*Crotaphytus*) *sila*	E/E, FP	San Joaquin Valley from Stanislaus County through Kern County and along eastern edges of San Luis Obispo and San Benito Counties	Open habitats with scattered low bushes on alkali flats, and low foothills, canyon floors, plains, washes, and arroyos; substrates may range from sandy or gravelly soils to hardpan	Historically documented on-site in Sections 5 and 29; suitable habitats present in slickspots and other open habitats on Madera Ranch; transect surveys conducted in May 2009 confirmed that this species is present

Species Name	Status* Fed/State	California Distribution	Habitat Requirements	Occurrence on Madera Ranch
Giant garter snake *Thamnophis gigas*	T/T	Central Valley from Fresno north to Gridley/Sutter Buttes area; has been extirpated from areas south of Fresno	Sloughs, canals, and other small waterways where there is a prey base of small fish and amphibians; requires grassy banks and emergent vegetation for basking and areas of high ground protected from flooding during winter	Documented at Mendota Pool; but not found during surveys on Madera Ranch. Unlikely to occur there because of limited and marginal habitat and lack of connectivity to populations outside Madera Ranch
California horned lizard *Phrynosoma coronatum frontale*	–/SSC	Sacramento Valley, including foothills, south to southern California; Coast Ranges south of Sonoma County; below 4,000 feet in northern California	Grasslands, brushlands, woodlands, and open coniferous forests with sandy or loose soil; requires abundant ant colonies for foraging	Widespread occurrence in Madera County. Suitable habitat on Madera Ranch, but none observed during wildlife surveys
Silvery legless lizard *Anniella pulchra pulchra*	–/SSC	Along Coast, Transverse, and Peninsular Ranges from Contra Costa County to San Diego County, with spotty occurrences in San Joaquin Valley	Habitats with loose soil for burrowing or thick duff or leaf litter (often forages in leaf litter at plant bases); may be found on beaches, sandy washes, and in woodland, chaparral, and riparian areas	Possible occurrence. Documented in San Joaquin Valley. Is a subterranean species. Suitable habitat exists on Madera Ranch
Birds				
Swainson's hawk *Buteo swainsoni*	–/T	Lower Sacramento and San Joaquin Valleys, Klamath Basin, and Butte Valley; highest nesting densities occur near Davis and Woodland, Yolo County	Nests in oaks or cottonwoods or near riparian habitats; forages in grasslands, irrigated pastures, and grainfields	Nesting pairs documented in the center of the property; high potential to use Madera Ranch for foraging
Mountain plover *Charadrius montanus*	PT/SSC	Does not breed in California; in winter, found in Central Valley south of Yuba County, along the coast in parts of San Luis Obispo, Santa Barbara, Ventura, and San Diego Counties and in parts of Imperial, Riverside, Kern, and Los Angeles Counties	Open plains or rolling hills with short grasses or very sparse vegetation; nearby bodies of water are not needed; may occupy newly plowed or sprouting grainfields	Documented in nearby areas of San Joaquin Valley; may occur seasonally on Madera Ranch but not known to breed there
White-tailed kite *Elanus leucurus*	–/FP	Yearlong resident in coastal and valley lowlands, closely associated with agricultural areas	Inhabits herbaceous and open spaces of most habitats in cismontane California	Documented in and probably nests on Madera Ranch
Ferruginous hawk *Buteo regalis*	–/SSC	Does not nest in California; winter visitor along the coast from Sonoma County to San Diego County, eastward to Sierra Nevada foothills and southeastern deserts, Inyo-White Mountains, plains east of Cascade Range, and Siskiyou County	Open terrain on plains and in foothills where ground squirrels and other prey are available	Documented on Madera Ranch. Seasonal occurrence during migration only. Good foraging habitat on Madera Ranch, but does not breed there

Species Name	Status* Fed/State	California Distribution	Habitat Requirements	Occurrence on Madera Ranch
Long-billed curlew *Numenius americanus*	–/SSC	Nests in northeastern California in Modoc, Siskiyou, and Lassen Counties; winters along the coast and in interior valleys west of Sierra Nevada	Nests in high-elevation grasslands adjacent to lakes or marshes; during migration and in winter, frequents coastal beaches, mudflats, interior grasslands, and agricultural fields	Documented on Madera Ranch; winter foraging flocks. Does not breed on Madera Ranch
Western burrowing owl *Athene cunicularia*	–/SSC	Lowlands throughout California, including Central Valley, northeastern plateau, southeastern deserts, and coastal areas; rare along South Coast	Level, open, dry, heavily-grazed or low-stature grassland or desert vegetation with available burrows	Nesting pairs documented throughout upland habitats on Madera Ranch. Extensive foraging habitat on Madera Ranch
Loggerhead shrike *Lanius ludovicianus*	C/SSC	Resident and winter visitor in lowlands and foothills throughout California; rare on coastal slope north to Mendocino County, occurring only in winter	Open habitats with scattered shrubs, trees, posts, fences, utility lines, or other perches	Documented on and likely breeds on Madera Ranch
Tricolored blackbird *Aglaius tricolor*	–/SSC	Permanent resident in Central Valley from Butte County to Kern County; breeds at scattered coastal locations from Marin County south to San Diego County and at scattered locations in Lake, Sonoma, and Solano Counties; rare nester in Siskiyou, Modoc, and Lassen Counties	Nests in dense colonies in emergent marsh vegetation, such as tules and cattails, or upland sites with blackberries, nettles, thistles, and grainfields; habitat must be large enough to support 50 pairs; probably requires water at or near nesting colony	Documented on Madera Ranch; high-quality foraging habitat throughout uplands. Nomadic breeder, so occurrence on Madera Ranch is probably irregular
Golden eagle *Aquila chrysaetoss*	–/FP	Nests in Siskiyou, Modoc, Trinity, Shasta, Lassen, Plumas, Butte, Tehama, Lake, and Mendocino Counties and in Lake Tahoe Basin; reintroduced into central coast; winter range includes the rest of California, except southeastern deserts, very high altitudes in Sierra Nevada, and east of Sierra Nevada south of Mono County	In western North American, inhabits mountain forests and open grasslands. Breeds from Alaska east across northern Canada south to Mexico, Canadian prairie provinces, and Labrador.	Documented in foraging on grasslands
Bald eagle *Haliaeetus leucocephalus*	D/E, FP	Nests in Siskiyou, Modoc, Trinity, Shasta, Lassen, Plumas, Butte, Tehama, Lake, and Mendocino Counties and in Lake Tahoe Basin; reintroduced into central coast; winter range includes the rest of California, except southeastern deserts, very high altitudes in Sierra Nevada, and east of Sierra Nevada south of Mono County	In western North America, nests and roosts in coniferous forests within 1 mile of a lake, reservoir, stream, or the ocean	Documented in Madera County; lack of habitat on Madera Ranch; could potentially forage for waterfowl using artificial pond and proposed recharge basins

Species Name	Status* Fed/State	California Distribution	Habitat Requirements	Occurrence on Madera Ranch
American peregrine falcon *Falco peregrinus anatum*	-E/ FP	Permanent resident along North and South Coast Ranges; may summer in Cascade and Klamath Ranges and through Sierra Nevada to Madera County; winters in Central Valley south through Transverse and Peninsular Ranges and plains east of Cascade Range	Nests and roosts on protected ledges of high cliffs, usually adjacent to lakes, rivers, or marshes that support large prey populations	Documented in Madera County. May occur incidentally on Madera Ranch while foraging
Mammals				
San Joaquin pocket mouse *Perognathus inornatus*	–/–	Eastern side of San Joaquin Valley	Grasslands and oak savannas with friable soils	Documented on Madera Ranch and in Madera County near project site
Fresno kangaroo rat *Dipodomys nitratoides exilis*	E/E	Fresno and Madera Counties y only	Found in alkali-sink habitats at elevations from 200 to 300 feet	Historic records of occurrence adjacent to Madera Ranch. Potential burrows for this species present throughout upland habitats on Madera Ranch, although extensive surveys revealed no Fresno kangaroo rats. No extant populations of this species are known
San Joaquin kit fox *Vulpes macrotis mutica*	E/T	Principally occurs in San Joaquin Valley and adjacent open foothills to the west; recent records show this species present in 17 counties, extending from Kern County north to Contra Costa County	Saltbush scrub, grasslands, oak, savannas, and freshwater scrub	Documented in Madera County near Madera Ranch; suitable burrow sites were present in every section, but no positive evidence of occurrence obtained during wildlife surveys
Nelson's antelope ground squirrel *Ammospermophilus nelsoni*	–/T	Western side of San Joaquin Valley from southern Merced County south to Kern and Tulare Counties; also found on Carrizo Plain in San Luis Obispo County and Cuyama Valley in San Luis Obispo and Santa Barbara Counties	Arid grasslands from 200 to 1,200 feet in elevation, with loamy soils and moderate shrub cover of Atriplex and other shrub species	Madera Ranch is within subspecies' historical range, but no documented occurrences. None observed during extensive wildlife surveys on Madera Ranch. Not likely to occur there

Species Name	Status* Fed/State	California Distribution	Habitat Requirements	Occurrence on Madera Ranch

*Species status definitions

Federal

E = listed as endangered under the federal ESA.
T = listed as threatened under ESA.
PT = proposed for federal listing as threatened under ESA.
PD = federally proposed for delisting.
– = no listing.

State

E = listed as endangered under the California Endangered Species Act (CESA).
T = listed as threatened under CESA.
FP = fully protected under the California Fish and Game Code.
SSC = species of special concern in California.
– = no listing.

Sources: California Natural Diversity Database 2004 and Jones and Stokes file data.

The two federally listed species documented as occurring on Madera Ranch during the biological surveys are vernal pool fairy shrimp and blunt-nosed leopard lizard. Surveys in 2009 resulted in blunt-nosed leopard lizard sightings in sections 3, 10, 14, and 15.

San Joaquin kit foxes have been documented previously near Madera Ranch, but none were seen on the property during the surveys conducted for this study. The grassland habitats of Madera Ranch provide suitable habitat for Fresno kangaroo rats, and records from CNDDB and university museum collections show this area to be within the historical distributional range of this species. However, the field transect and trapping surveys conducted for this study did not document the presence of Fresno kangaroo rats at Madera Ranch. It should be noted that a property-wide trapping survey was conducted for the Fresno kangaroo rat in 2000, but a more intensive trapping survey was conducted in 2009 only for that portion of Madera Ranch lying east of the GF Canal.

Additionally, none of the following species was documented during surveys conducted to date, although limited suitable habitat is present for them at Madera Ranch:

- vernal pool tadpole shrimp (*Lepidurus packardi*),
- Conservancy fairy shrimp (*Branchinecta conservatio*),
- mid-valley fairy shrimp (*Branchinecta mesovallensis*),
- California tiger salamander, (*Ambystoma californiense* [=*A. tigrinum* c.])
- California horned lizard (*Phrynosoma coronatum frontale*),
- silvery legless lizard (*Anniella pulchra pulchra*), and
- American peregrine falcon (*Falco peregrinus*)

Invertebrates
Vernal Pool Fairy Shrimp The vernal pool fairy shrimp is listed as threatened under ESA. Vernal pool fairy shrimp were documented in several pools on Madera Ranch during reconnaissance surveys. Vernal pool and alkali rain pool habitat on Madera Ranch is potentially suitable for this species. Wetland areas with greater disturbance, like those in GF Canal and near the property boundary in Section 28, are less likely to support this species because of agricultural contamination (Figure 3-4).

Vernal Pool Tadpole Shrimp The vernal pool tadpole shrimp is listed as threatened under ESA. Vernal pool and alkali rain pools are the most suitable habitat for this species on Madera Ranch, but no tadpole shrimp have been documented.

Conservancy Fairy Shrimp The Conservancy fairy shrimp is a federally listed endangered species. In contrast to the habitat requirements of vernal pool fairy shrimp and vernal pool tadpole shrimp, vernal pool and alkali rain pool habitat on Madera Ranch is least suitable for Conservancy fairy shrimp because the species normally inhabits large, turbid pools called playa pools (Eriksen and Belk 1999; Vollmar 2002), and there are few of these large, turbid pools on the Madera Ranch site. No Conservancy fairy shrimp have been documented in the Madera Ranch area. However, there remains a possibility that this species is present on the property (Owens pers. comm.). Recently, small pools at the Sandy Mush Conservation Bank in Merced

County have been found to have Conservancy fairy shrimp, therefore the species is assumed to potentially be present in any of the vernal and alkali rain pools on Madera Ranch.

Mid-Valley Fairy Shrimp The mid-valley fairy shrimp is not listed under ESA. The USFWS recently reviewed a petition to list this species and determined that listing is not warranted at this time. Its habitat requirements are similar to those of vernal pool fairy shrimp and vernal pool tadpole shrimp, but the species has not been documented at Madera Ranch.

San Joaquin Tiger Beetle The San Joaquin tiger beetle is not a federally or state-listed species but is considered sufficiently rare by the scientific community to qualify for such listing. Most habitats on Madera Ranch are suitable for this species, although alkali scalds and vernal pools are most suitable because these habitat types provide foraging opportunities (Figure 3-4). Several live individuals, one dead individual, and other signs of beetle activity were documented at Madera Ranch.

Amphibians

Western Spadefoot Toad The western spadefoot toad is designated as a species of special concern by DFG. Western spadefoot toad tadpoles were observed in GF Canal in 2000, in Sections 4 and 9. Vernal and alkali rain pools are potential breeding and estivation habitat for this species. Wetlands near the property boundary in Section 28 are less likely to support this species because of their connectivity to other sources of water that support mosquitofish (*Gambusia affinis*) and bullfrogs (*Rana catesbeiana*) (Figure 3-4).

California Tiger Salamander The California tiger salamander is federally listed as threatened. Vernal and alkali rain pools are potential breeding habitat for this species, and upland areas within approximately 1 mile of a wetland are potential nonbreeding areas. Madera Ranch has suitable habitat for this species and is within its historical distribution range, but no evidence of California tiger salamanders was found during reconnaissance surveys conducted for amphibians while surveying for vernal pool crustaceans.

California Red-Legged Frog The California red-legged frog is federally listed as threatened. The California red-legged frog was likely never common on the valley floor, and subsequent habitat destruction and modification, as well as many years of pesticide use, appear to have extirpated the species from this portion of its former range. No habitat in the potentially affected area was considered suitable for this species.

Reptiles

Blunt-Nosed Leopard Lizard The blunt-nosed leopard lizard is listed as endangered under California Endangered Species Act (CESA) and ESA and as a fully protected species under the California Fish and Game Code. Historical records indicate the presence of blunt-nosed leopard lizard in the vicinity of Madera Ranch and on Madera Ranch in 1987. The approximately 4,044 acres of alkali grassland habitat and high kangaroo rat burrow density make much of Madera Ranch suitable for blunt-nosed leopard lizard (Table 3-9 and Figure 3-4). Transect surveys conducted in May 2009 confirmed that this species is present.

Giant Garter Snake The giant garter snake is listed as threatened under CESA and ESA. The giant garter snake has been documented at Mendota Pool (California Natural Diversity Database 2004), but no records of this species have been documented on Madera Ranch. Although limited marginal habitat for this species exists along the GF Canal in Section 16, it is not viably connected with any areas of documented occurrences in the vicinity (Figure 3-4). The giant garter snake was not located during surveys and is not likely to occur in this area. Similarly, because of significant regional population declines, no extant records within Madera County, the prolonged periods of dryness, seasonal fluctuation of water, and lack of consistent prey base, giant garter snake is unlikely to be within the canals of Mendota Wildlife Management Area (MWMA).

California Horned Lizard The California horned lizard is a California species of special concern. The Madera Ranch area is in the historical range of the California horned lizard, and the property contains suitable habitat, although none was observed during extensive transect surveys.

Silvery Legless Lizard The silvery legless lizard is listed as a California species of special concern. Madera Ranch is within the historical range of the silvery legless lizard and includes suitable habitat. Silvery legless lizards live primarily in the soil and would not have been readily detected during the field surveys conducted during summer 2000.

Birds

Swainson's Hawk The Swainson's hawk is listed as threatened under CESA. Nesting sites and potential breeding Swainson's hawk pairs have been documented on Madera Ranch near ranch headquarters in Section 16. All habitats on Madera Ranch provide suitable foraging habitat from March through September when the species may be present. There is limited nesting habitat because of the relatively few trees on site (Figure 3-4), but the site has definitely been used by a limited number of Swainson's hawks.

White-Tailed Kite The white-tailed kite is designated as a fully protected species under the Fish and Game Code. The white-tailed kite nests in all 14 ecological zones throughout its range in California. Madera Ranch is located in one of these zones, and pairs of kites have been sighted on the property and could be present year-round. It could breed in the Fremont cottonwoods in Section 28 or other mature trees around the ranch. Annual and alkali grasslands provide suitable foraging habitat for this species (Figure 3-4).

Ferruginous Hawk The ferruginous hawk is designated as a state species of special concern by DFG. Ferruginous hawks were documented at Madera Ranch during the October, November, and December 2000 and January 2001 surveys. It is a migratory visitor to this area and does not breed there. Annual and alkali grasslands provide suitable foraging habitat for this species (Figure 3-4).

Long-Billed Curlew The long-billed curlew is designated as a bird of conservation concern by USFWS and a species of special concern by DFG. A wintering population of approximately 200 long-billed curlews has been documented from October to March on Madera Ranch. Annual and alkali grasslands provide suitable habitat for foraging or rest during wintering migration (Figure 3-4), but the long-billed curlew is not expected to nest at Madera Ranch.

Western Burrowing Owl The western burrowing owl is designated as a species of special concern by DFG and is covered under the MBTA. Numerous burrowing owls were observed and documented at Madera Ranch during transect surveys. Annual and alkali grasslands provide suitable foraging and nesting habitat for this species (Figure 3-4).

Loggerhead Shrike The loggerhead shrike is a federal bird of conservation concern and a state species of special concern. Loggerhead shrikes have been documented throughout the Madera Ranch area. Annual and alkali grasslands provide suitable foraging habitat, and some nesting habitat exists along GF Canal and cultivated portions of the property (Figure 3-4).

Tricolored Blackbird The tricolored blackbird is designated as a state species of special concern by DFG. It is also designated as a migratory nongame bird of management concern by USFWS. The Madera Ranch area is in the historical range of the tricolored blackbird, and the ranch contains suitable habitat. Several hundred tricolored blackbirds were documented foraging between the agricultural land and grassland in Section 16. There is very little wetland breeding habitat, although other habitat (such as blackberry thickets) may be used for breeding; however, there is ample foraging habitat in the alfalfa fields to support a large breeding colony of thousands of pairs (Figure 3-4). This species tends to be nomadic in its breeding, selecting different locations different years depending on suitability and availability of the habitat.

Golden Eagle The golden eagle is a fully protected species by DFG and is federally protected under the BGEPA. Golden eagles have been detected periodically foraging on Madera Ranch.

Bald Eagle The bald eagle is federally protected under the BGEPA, is endangered under CESA, and is a fully protected species under the California Fish and Game Code. Bald eagles could periodically forage on Madera Ranch, but regionally have primarily been found foraging and nesting around Millerton Lake.

American Peregrine Falcon The American peregrine falcon has been removed from the ESA Threatened and Endangered list however it is designated as a fully protected species, pursuant to the Fish and Game code [FGC §3511 (b)(1)] under CESA. No American peregrine falcons were observed on Madera Ranch during the October, November, and December 2000 and January 2001 wintering bird surveys. All habitats on Madera Ranch, particularly the annual and alkali grasslands (Figure 3-4), provide suitable foraging habitat for this species. This species is not likely to breed on Madera Ranch.

Mammals

San Joaquin Pocket Mouse The San Joaquin pocket mouse is not a federally or state-listed species but is considered sufficiently rare by the scientific community to qualify for such listing. Annual and alkali grasslands provide suitable habitat for this species, and San Joaquin pocket mice were captured throughout Madera Ranch during small mammal trapping (Figure 3-4).

Fresno Kangaroo Rat The Fresno kangaroo rat was state-listed as endangered on October 20, 1980, and federally listed as endangered on January 30, 1985. Madera Ranch has suitable grassland habitat for Fresno kangaroo rats, but none have been identified on Madera Ranch, despite two live trapping surveys conducted in suitable habitat on Madera Ranch. The first survey was a property-wide survey conducted in 2000, and the other was conducted only east of GF Canal in 2009. Much of the habitat on Madera Ranch is homogeneous, likely a result of the long history of cattle grazing, making the property less suitable for the Fresno kangaroo rat. The most recent surveys show that the species is not currently present east of GF Canal. Currently, no extant populations or individuals are known to exist anywhere.

San Joaquin Kit Fox The San Joaquin kit fox was listed as endangered by the USFWS in 1967 and by the state in 1971. San Joaquin kit foxes have been previously documented in Madera County near Madera Ranch (T12S R14E) (California Natural Diversity Database 2004), but none on Madera Ranch during transect, spotlighting, or camera/bait station surveys. Numerous burrow dens potentially suitable for kit fox were observed in every section of Madera Ranch during the surveys, but none of them contained direct evidence of kit fox occupancy (e.g., scat, fur, natal pups, etc.).

Documentation of Biological Resources at Madera Ranch

Biologists documented biological resources at Madera Ranch through a phased series of surveys, beginning with reconnaissance-level surveys and concluding with focused and intensive surveys. To prepare for this survey effort, biologists:

- identified applicable state, federal, and local regulations governing protection of biological resources at Madera Ranch, including off-site canals;
- conducted computer searches of the CNDDB (California Natural Diversity Database 2008) and the California Native Plant Society's Electronic Inventory (California Native Plant Society 2007) to obtain information on the presence of threatened and endangered plant and wildlife species and sensitive communities at or in the vicinity of Madera Ranch and off-site canals;
- consulted the USFWS, DFG, and local experts to obtain additional information on the status of threatened and endangered species in the Madera Ranch vicinity, and off-site canals;
- obtained and reviewed applicable scientific literature and environmental reports germane to describing and evaluating the status of biological resources on Madera Ranch and off-site canals; and
- reviewed the USGS topographic map (Bonita Ranch 7.5-minute quadrangle) and soil survey map for Madera County (Stromberg 1951). Madera Ranch is in T12S, R16E, and includes Sections 1, 2, 3, 4, 5, 7, 8, 9, 10, 11, 13, 14, 15, 16, 17, 18, 20, 21, 22, 28, and 29 and the southeast half of Section 6. Because much of the natural resource setting references these Public Land Survey System section numbers, Figure 3-4 provides a graphical illustration of the location of each section throughout the property.

Field Surveys Field surveys were designed to lay the foundation for determining the presence and abundance of threatened and endangered species. The specific goals of these surveys were to:

- document the actual and potential occurrence and distribution of threatened and endangered plants and animals on Madera Ranch,
- evaluate Madera Ranch in terms of its overall habitat quality and potential to support threatened and endangered species, and
- provide a summary and conclusions for biological constraints to be considered in an alternatives analysis and for effect analysis.

During February–April 2000, Consultant biologists conducted reconnaissance-level surveys at Madera Ranch (Jones & Stokes 2000). Additional detailed surveys were conducted during June – November 2000 and in April 2001. In May 2009 biological consultants initiated additional surveys for wildlife. Consultant biologists conducted detailed surveys of facility corridors for plants in April 2009. Wetland delineations also were conducted in 2000 and 2005 to map and characterize wetlands occurring in the project area, with an update in 2009. As discussed in more detail below, these surveys included:

- reconnaissance-level surveys to characterize habitats present in the project area,
- delineation of wetlands and identification of vernal swales that contribute to the wetlands and vernal pools,
- focused plant surveys to identify areas that likely contain threatened and endangered plants on portions of Madera Ranch where these plants have not yet been identified,
- detailed-transect wildlife surveys to identify and evaluate habitat conditions and document the actual and potential occurrence of sensitive species throughout Madera Ranch, and
- focused surveys for Fresno kangaroo rat and San Joaquin kit fox.

Results of the botanical and wildlife surveys are summarized in Existing Conditions below. Details of the survey results have been documented previously (Jones &Stokes 2000, 2008). The spring 2009 surveys were documented in summer 2009.

Botanical Surveys Plant surveys included reconnaissance visits to the site, aerial photo interpretation, field surveys for threatened and endangered plants, and delineation of wetlands. The entire Madera Ranch property was assessed with reconnaissance-level surveys and photo interpretation.

Botanists performed reconnaissance-level surveys of the entire Madera Ranch property – other than cultivated areas (Sections 1, 13, 21, the eastern half of Section 14, the northeastern quarter of Sections 4 and 22, the southeastern quarter of Section 16, and the western edge of Section 22) – in February and March 2000. The purpose of the surveys was to become familiar with Madera Ranch and plant communities and to determine the appropriate survey protocols for the sensitive species surveys. Sections 15, 16, 17, 20, 21, 22, 28, and 29 were surveyed following the guidelines for assessing effects of proposed developments on rare and endangered plants and plant communities (California Department of Fish and Game 2000a). Early-blooming-season floristic surveys were performed during the week of April 3–7, 2000. In addition to conducting the floristic inventory, the survey team characterized the plant communities present and mapped the wetlands. Surveys for summer-blooming species were conducted on June 5 and 6, 2000, focusing on habitat for the summer-blooming species identified during the April surveys. On June 27, 2000, the northern half of Section 7 was surveyed for palmate-bracted bird's-beak. The northern half of Section 7 was the only potential habitat area identified for this endangered species. Reference locations were not visited.

Biologists completed additional fieldwork during 2005 focused on two issues: (1) additional wetland delineation surveys conducted in response to comments from the Corps and (2) reconnaissance-level habitat evaluations of proposed facilities locations outside of Madera Ranch. The wetland delineation work was intended to ground-truth the results of aerial interpretation work conducted previously and to provide additional data points for evaluating wetlands across the entire Madera Ranch site. Reconnaissance-level habitat evaluations were conducted for facilities that would be constructed along the Main No. 2 Canal, Cottonwood Creek, 24.2 Canal, and Section 8 Canal. These locations are beyond the boundaries of Madera Ranch and had not been surveyed previously.

Biologists conducted detailed walking transect surveys on April 14 and 15, 2009, with two botanists walking 30 feet apart throughout the Phase 1 facility corridors. These spring surveys did not reveal any federally or state-listed plant species. Additional late season surveys were conducted in July 2009 and those surveys also didn't result in any observations of listed plants.

Wildlife Surveys Wildlife surveys included:

- six reconnaissance visits to the site;
- more than 320 miles of walking transect surveys looking for blunt-nosed leopard lizards (*Gambelia sila*), San Joaquin kit fox burrows, kangaroo rat (*Dipodomys* spp.) burrows, burrowing owl (*Athene cunicularia hypugea*) burrows, and other sensitive species;
- 10 nights of spotlighting for kit fox;
- 45 camera/bait stations and 442 camera nights of surveys for kit fox;
- 11,120 trap nights for kangaroo rats;
- fairy shrimp sampling; and
- surveys for wintering birds.

Figure 3-5 includes an overview of the phased project facilities in relation to habitat types within the Proposed Action area.

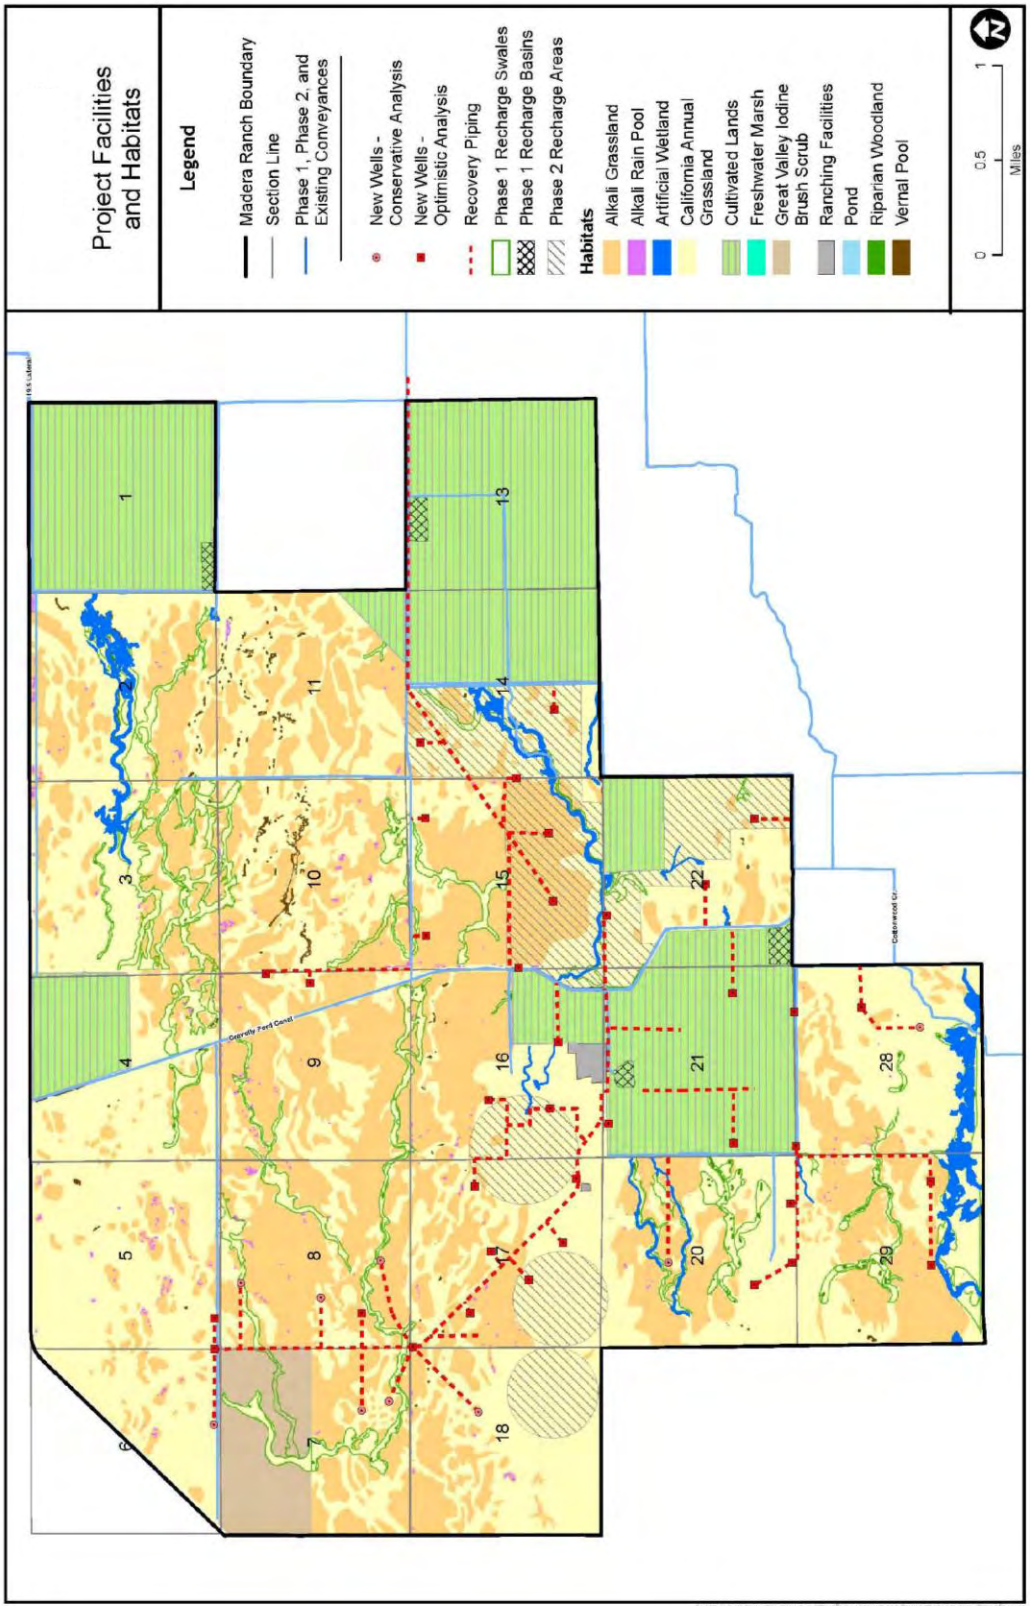

Figure 3-5 Project Facilities and Habitat within Proposed Action Area

A summary of Proposed Action habitat effects within Madera Ranch by project alternatives is included in Table 3-12.

Table 3-12 Effects of Proposed Action Alternatives on Madera Ranch Habitat

Habitat	Effect (acres[a])			
	Flooding Swales	Temporary Construction Effects	Permanent Construction Effects[b]	No Anticipated Effect
Alternative B				
California annual grassland	660	178	790	4,850
Alkali grassland	30	100	230	3,698

Total	**645.9**	**349.14**	**1085.2**	**11,536**

[a] Temporary effects include the effects associated with extraction facilities.

[b] Permanent effects include up to 40 acres of facilities in Phase 1. The total reflects conservative assumptions that all Phase 2 recharge bases would be constructed under the Alternative. Phase 2 recharge bases would only be constructed as required to augment Phase 1 recharge facilities. Acreages associated with construction of the Phase 2 recharge basins are apportioned across habitat types within a 1,300-acre area.

A summary of Proposed Action project elements located within water bodies and upland habitats are included in Table 3-13.

Table 3-13 Project Elements within and near Water Bodies and Uplands

Project Elements	U.S. Water Subject to CWA 404	Approximate Length/ Surface Area/Cut/Fill
Proposed Water Body Components		
Section 8 Canal, Cottonwood Creek, and Main No. 1 Canal Connection Upgrade (Section 8 Canal/Cottonwood Creek Connection)	Yes	250 lf cut
Gravelly Ford Canal Sedimentation Basin and Flow Regulation Area (Weir #1)	Yes	500 sf
Gravelly Ford Canal Flow Control Weir at Cottonwood Creek (Weir #2)	Yes	500 sf
Cottonwood Creek overflow improvements (rock slope protection)	Yes	350 lf
Reconditioning of existing canals and ditches (canal maintenance)	Yes	Excavation to previous shape
Reconditioning of existing canals and ditches (canal maintenance)	Yes	75 sf each
Planned Water Body Components		
Cottonwood Creek Lift Stations	Yes	500 sf each
Gravelly Ford Canal Section 21 Northern/Western Laterals	Yes	100 sf
Gravelly Ford Canal Section 22 Southern Lateral	Yes	100 sf
Other Components within and near Water Bodies		
24.2 Canal improvements	Yes	36,000 cy excavation; (1.75 mile expanded and 0.75 mile new)
Section 8 Canal upgrades/extensions	Yes	76,000 cy excavation; (1.75 mile expanded, 1.75 mile existing to pipe, and multiple new extensions)
Use of swales for recharge(1) (2)	No	No cut or fill. <6 acres vernal pool/alkali rain pool from use of swales (Alternative B) and <2 acres for Reduced Alternative B
55 acres of recharge basins in agricultural lands	No	55 acres
Recharge basins in grasslands	No	Varies
Recovery wells	No	<0.1 acre/well
Recovery pipelines and electrical facilities (3)	No	<1.5 ac vernal pool/alkali rain pools from corridors

Notes:
1 Vernal pools are located in swales and are subject to review under ESA Section 7 and CWA Section 404.
2 Swales not used for recharge under Alternative C. See Table 3-12 for vernal pool/alkali rain pool effects under each Alternative.
3 Alternatives B, Reduced Alternative B, C, and D are the same for recovery facilities because the layout does not change.
CWA = Clean Water Act; lf = linear feet; sf = square feet; cy = cubic yards.

The Proposed Action could result in both direct and indirect effects. Activities that could result in direct effects on sensitive habitats and sensitive species include:

- flooding swales on a seasonal basis;
- excavating areas to construct recharge basins and distribution canals/ditches;
- disposing of soil from excavation activities;
- drilling recovery wells and building pump plants;
- trenching to install the distribution and collection pipelines;

- blading of existing access roads (annually) and pesticide use;
- during operation of recharge basins, applying algicide or other chemicals if necessary to keep vegetation in check and minimize algae growth;
- compacting soils by traffic on and adjacent to construction access corridors and staging areas and by vehicle use of maintenance roads;
- potentially spilling toxic substances from vehicles during construction and operations and maintenance;
- creating noise during construction and maintenance; and
- disturbing bird nests.

The Proposed Action also may cause indirect effects. Indirect effects occur later in time or are farther removed in distance but must be predictable and reasonably certain to occur in order to be assessed. Potential mechanisms of indirect effects on sensitive habitats and sensitive species include:

- changes in hydrology, such as altered patterns of runoff or changes to the surface water retention pattern and capacity and elevation of the perched water table;
- erosion and sedimentation that result from grading and other activities that remove vegetation;
- water quality effects from contaminants such as road runoff or pesticides; and
- introduction of invasive nonnative species, including mosquitofish and bullfrog.

The activities described above can result in both permanent and temporary effects. Effects were characterized as permanent if they would result in the conversion of habitat to nonhabitat for the life of the Proposed Action. The extent of permanent and temporary effects on habitats at Madera Ranch was estimated by overlaying the outline of proposed recharge basins, canals/ditches, extraction wells, pipelines, and maintenance roads (proposed footprint) on the map of habitats. The footprint for the buried pipelines, maintenance roads, and canals/ditches is estimated to be a linear corridor 10 feet wide. The proposed footprint for the extraction wells is estimated to be 0.1 acre each.

Regularly traveled maintenance roads could remain all or partially unvegetated for the life of the Proposed Action as a result of disturbance and soil compaction. During construction activities, individual plants could be uprooted, buried, or crushed.

3.4.2 Environmental Consequences

Alternative A—No Action

Under the No Action Alternative, Reclamation would not approve the banking of CVP water outside MID's service area, nor would Reclamation issue an MP-620 permit, a Mid-Pacific Region-specific permit for modifications to its distribution system. Reclamation's action would have no adverse effects on biological resources. The future conditions would continue to support agricultural activities; the type and extent of the activities is uncertain at this time. Future owners would be subject to comply with CESA and ESA and the effects may be evaluated by the County under CEQA if discretionary permits are needed.

Alternative B—Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities

Effect BIO-1: Temporary Disturbance of California Annual Grassland and Alkali Grassland during Construction Construction activities (e.g., traffic, laydown, work areas) could remove approximately 178 acres of California annual grassland and 100 acres of alkali grassland (Table 3-12 and Figure 3-5). California annual grassland and alkali grassland are resilient plant communities, as demonstrated in Sections 14, 15, 16, 17, 18, and 22 at Madera Ranch, where they have recovered from previous cultivation (Figure 3-5). Effect BIO-1 is not expected to cause long-term degradation and therefore would not be considered adverse.

Effect BIO-2: Permanent Removal of California Annual Grassland and Alkali Grassland Habitats during Construction Construction of the proposed recharge basins, canals/ditches, extraction wells, pipelines, and maintenance roads could permanently remove up to approximately 790 acres of California annual grassland and up to approximately 230 acres of alkali grassland habitats (Table 3-12 and Figure 3-5). Effect BIO-2 would be an adverse effect because it would substantially reduce the amount of this locally uncommon habitat. Environmental Commitment BIO-1: Establish a Grasslands Conservation Easement would compensate for this loss of habitat.

Effect BIO-3: Loss or Disturbance of Iodine Bush Scrub or Sensitive Plant Species Habitat as a Result of Construction Iodine bush scrub habitat on Madera Ranch is limited to the northern half of Section 7 (Figure 3-5). Up to one well and a pipeline to deliver recovered groundwater back into MID's distribution system would be constructed in the northwest corner of the project area. Thus, activities associated with Effect BIO-3 could result in the loss or temporary disturbance of iodine bush scrub in Section 7. The effect would be considered adverse. Similarly, although previous botanical surveys indicated that state- and federally listed plants are not present, if there is a localized effect, it could be substantial to regional populations of iodine bush scrub. Therefore, Environmental Commitment BIO-3a: Avoid Effects on Iodine Brush Scrub and Environmental Commitment BIO-3b: Survey for Sensitive Plants are proposed.

Effect BIO-4: Potential for Construction-Related Mortality of Sensitive Vernal Pool Crustaceans Excavating, grading, trenching, soil movement, soil compaction, and removal of vernal pools, alkali rain pools, or artificial wetlands could result in direct adverse effects on vernal pool crustaceans (Impacts on wetlands are described in the Wetlands section). Trenching and soil movement could result in indirect adverse effects by altering suitable habitat, such as changing the hydrology of or increasing sedimentation in the pools (Table 3-12).

Vernal pool fairy shrimp, listed as threatened under the ESA, was identified in several pools during surveys at Madera Ranch. No other vernal pool crustaceans were found during those surveys, although suitable habitat may be present. Construction activities would avoid most of the naturally occurring vernal pools. Vernal pools previously were mapped in GF Canal, but these have been inundated for the past several years and are unlikely to function as vernal pools.

Effect BIO-4 could have an adverse effect on vernal pool fairy shrimp and substantially reduce the local distribution of sensitive biological resources occurring at Madera Ranch. This effect is considered adverse and would be minimized and compensated for with the implementation of Environmental Commitment BIO-2a: Preconstruction Surveys/Avoid Effects on Vernal Pools and Alkali Rain Pools and Environmental Commitment BIO-2b: Create, Restore, or Preserve Vernal Pools.

Effect BIO-5: Potential for Operation- and Maintenance-Related Mortality of Sensitive Vernal Pool Crustaceans Operation and maintenance of MID facilities could result in direct effects on vernal pool crustaceans. Flooding swales on a seasonal basis could result in degradation of vernal pool habitat for vernal pools within the swales and major adverse effects on vernal pool crustaceans in these areas. Temporary rapid expansion of the existing pools from uncontrolled flows could move extant crustaceans and their eggs to peripheral areas where they could be subject to increased mortality from desiccation and/or predation during subsequent rapid pool-size decrease as the waters percolate into the subsurface. Other operational effects are also possible.

As described in the Public Health and Safety Section, if the swales pond water and mosquitoes become an issue with the Madera County Mosquito and Vector Control District (MCMAVCD), the abatement district may use mosquitofish to control mosquitoes. These fish also could prey on vernal pool species, should they survive prolonged inundation. However, the overall need for mosquitofish is expected to be low because water levels would fluctuate rapidly as water flows through the swales and generally would not persist after flows cease.

Furthermore, if swales are wet or moist year-round, they could become a dispersal corridor for bullfrogs. Bullfrogs could prey on vernal pool species. However, swales are not expected to be wet year-round and periodic drying of the swales would inhibit the establishment of bullfrogs in the interior of the property. Maintenance of new permanent facilities will take place more than 250 feet from existing vernal pools, but adverse effects potentially could occur.

Effect BIO-5 is adverse because it could affect fairy shrimp occurring at Madera Ranch. This effect would be minimized and compensated for with the implementation of Environmental Commitment BIO-2a: Preconstruction Surveys/Avoid Effects on Vernal Pools and Alkali Rain Pools and Environmental Commitment BIO-2b: Create, Restore, or Preserve Vernal Pools.

Effect BIO-6: Potential for Construction-Related Mortality of San Joaquin Tiger Beetle Construction activities and modification of annual grassland and alkali grassland, slickspots in particular, could have an adverse effect on the San Joaquin tiger beetle. The San Joaquin tiger beetle is not a federally or state-listed species but is sufficiently rare to be of concern. Most habitats on Madera Ranch are suitable for this species, although alkali scalds and vernal pools are most suitable because these habitat types provide foraging opportunities.

Some individual beetles could be killed from direct effects during construction activities and indirect effects caused by habitat modification. Excavating, grading, trenching, soil movement, soil compaction, and vehicle traffic in the Madera Ranch vicinity could result in direct effects on the species. Adults and larval beetles could be trapped inside their burrows during grading or trenching, crushed on the ground by construction-related vehicles, or disturbed to the point that they abandon their foraging areas. Construction activities near occupied habitats also could result in indirect effects. Trenching and soil movement could result in indirect effects such as altering the hydrology and soil microenvironment, making it unsuitable for egg deposition or larva habitation. Construction of the recharge basins could remove up to approximately 230 acres of alkali grassland containing slickspot habitat (Table 3-12).

Potential habitat for San Joaquin tiger beetle is widely distributed, and construction would disturb less than 10% of its potential habitat on Madera Ranch. Therefore, Effect BIO-6 is considered adverse, but it does not represent a substantial reduction in the local or regional distribution of San Joaquin tiger beetles.

Effect BIO-7: Potential for Operation- and Maintenance-Related Mortality of San Joaquin Tiger Beetle The San Joaquin tiger beetle could be affected by operations and maintenance of MID facilities. Operating and maintaining the recharge basins and extraction facilities and maintaining the banks of the conveyance canals could have direct adverse effects on this species if they use these areas. Adults and larval beetles could die from contact with herbicides, be trapped inside their burrows during disking or filling of burrows, be crushed by vehicles, or be disturbed by these activities to the point that they abandon their foraging areas. Flooding swales on a seasonal basis also could cause mortality of tiger beetles and larvae.

Potential habitat for San Joaquin tiger beetle is widely distributed, and operations would disturb less than 10% of its potential habitat on Madera Ranch. Therefore, Effect BIO-7 is not considered adverse because it does not represent a substantial reduction in the local or regional distribution of San Joaquin tiger beetles.

Effect BIO-8: Potential for Construction-Related Mortality of California Tiger Salamander Construction and modification, including direct and indirect effects on naturally occurring vernal pools, alkali rain pools, wetlands in GF Canal, annual grassland, and alkali grassland could have major adverse effects on California tiger salamander if this species is present on Madera Ranch (Impacts on wetlands are described in a separate section on Wetlands).

The California tiger salamander is federally listed as threatened and is a candidate for listing under CESA. Vernal and alkali rain pools are potential breeding habitat for this species, and upland areas within 1.25 miles of a wetland are potential nonbreeding habitat. Madera Ranch has suitable habitat for this species, and it is within the historical distribution range, but no evidence of California tiger salamanders was found during reconnaissance surveys conducted for amphibians while surveying for vernal pool crustaceans.

Excavating, grading, trenching, soil movement, soil compaction, and removing vernal pools and adjacent nonbreeding habitat could result in direct effects on this species. Tiger salamanders could be trapped inside their estivation or shelter burrows, crushed by construction vehicles, or displaced to adjacent areas where they could be subject to increased exposure, food shortages, and predation. Grading, trenching, and soil movement could alter the hydrology of the habitat and compact available animal burrows suitable for shelter and estivation, causing additional indirect adverse effects on the species.

If tiger salamanders are present, Effect BIO-8 would have an adverse effect on a species that is listed as threatened under the ESA and is a candidate for listing under CESA and could substantially reduce the local distribution of sensitive biological resources occurring at Madera Ranch. This effect would be minimized and compensated for with the implementation of Environmental Commitments BIO-1: Establish a Grasslands Conservation Easement; BIO-2a: Preconstruction Surveys/Avoid Effects on Vernal Pools and Alkali Rain Pools; BIO-2b: Create, Restore, or Preserve Vernal Pools; BIO-4a: Preconstruction Surveys for California Tiger Salamander; BIO-4b: Restrict Construction Activity in Suitable Aquatic and Upland Habitat for California Tiger Salamander to the Dry Season (April 1–November 1); and BIO-4c: Fence the Construction Zone and Implement Erosion Control Measures in Areas Where Suitable Aquatic Habitat for California Tiger Salamander Is Present.

Effect BIO-9: Potential for Operation- and Maintenance-Related Mortality of California Tiger Salamander Operation and maintenance of MID facilities could result in direct effects on California tiger salamander if this species is found to occur in vernal pools that would be near these activities. Flooding natural swales on a seasonal basis could result in beneficial or adverse effects on this species. Expanded pool size and duration could benefit breeding tiger salamanders by increasing the area and time available for breeding. However, rapid pulsing of water input and percolation loss following the initiation of breeding could result in the movement of adults, larvae, and eggs to areas beyond the traditional boundaries of the vernal pool and result in increased loss from desiccation and/or predation. Other operational effects are also possible. As described in the Public Health and Safety Section, if the swales pond water and mosquitoes become an issue with the MCMAVCD, the abatement district may use mosquitofish to control mosquitoes. These fish could also prey on California tiger salamander larvae. However, the overall need for mosquitofish is expected to be low because water levels would fluctuate rapidly as water flows through the swales and generally would not persist after flows cease. Furthermore, if swales are wet or moist year-round, they could become a dispersal corridor for bullfrogs. Bullfrogs could prey on California tiger salamander. However, swales are not expected to be wet year-round, and periodic drying of the swales would inhibit the establishment of bullfrogs in the interior of the property.

If California tiger salamanders are present, an adverse effect could occur on a species that is listed as threatened under the ESA and could substantially reduce the local distribution of sensitive biological resources occurring at Madera Ranch. This effect would be minimized and compensated for with the implementation of Environmental Commitment BIO-1: Establish a Grasslands Conservation Easement; Environmental Commitment BIO-2a: Preconstruction Surveys/Avoid Effects on Vernal Pools and Alkali Rain Pools; and Environmental Commitment BIO-2b: Create, Restore, or Preserve Vernal Pools.

Effect BIO-10: Potential for Construction- and/or Operation- and Maintenance-Related Mortality of Western Spadefoot Toad Construction and operations/maintenance activities potentially could result in direct or indirect loss of western spadefoot toads currently known to occupy vernal pools on Madera Ranch. The western spadefoot toad is designated as a species of special concern by DFG.

Western spadefoot toad tadpoles were observed in GF Canal in 2000 (Figure 3-4). Vernal and alkali rain pools are potential breeding and estivation habitat for this species. Other operational effects as describe above related to mosquitofish and bullfrogs also possibly could occur.

Although western spadefoot toads are widely distributed throughout California, suitable habitat at Madera Ranch is limited to vernal pools and alkali rain pools. Therefore, Effect BIO-10 is potentially moderately adverse because it could substantially reduce the local distribution of western spadefoot toads. This effect would be minimized and compensated for with the implementation of Environmental Commitment BIO-2a: Preconstruction Surveys/Avoid Effects on Vernal Pools and Alkali Rain Pools and Environmental Commitment BIO-2b: Create, Restore, or Preserve Vernal Pools.

Effect BIO-11: Potential for Construction- and/or Operation- and Maintenance-Related Effects on Blunt-Nosed Leopard Lizard Construction activities and modification of annual grassland and alkali grassland habitat could have an adverse effect on blunt-nosed leopard lizard habitat. The blunt-nosed leopard lizard is listed as endangered under CESA and ESA and as a fully protected species under the California Fish and Game Code. Historical records indicate the presence of blunt-nosed leopard lizard in the vicinity of Madera Ranch and on Madera Ranch, and a few individuals were recently confirmed on site. The approximately 4,044 acres of alkali grassland habitat and high kangaroo rat burrow density make much of Madera Ranch suitable for blunt-nosed leopard lizard (Figure 3-5).

Construction activities, including excavating, grading, trenching, soil movement, and noise and disturbance from vehicle traffic, could result in harm to and harassment of the species. Operational activities, including banking water in the swales, also could result in harm to and harassment of this species. Direct mortality is not authorized under California Fish and Game Code. Therefore, Effect BIO-11 is considered an adverse effect because direct mortality of this species must be avoided to comply with state law and because any effect could be a substantial adverse effect on the species or a substantial reduction in the local or regional distribution of blunt-nosed leopard lizard.

In the event Phase 2 is constructed, up to 230 acres of alkali grassland habitat and 790 acres of annual grassland could be permanently affected. The extent of this effect on the species depends on the presence and abundance of the species in the construction area and the species' ability to persist in the area post-construction. If the species is present, the effects could be substantial. However, initial surveys indicate densities are likely to be low and these areas have previously been cultivated. To offset these potential habitat effects, MID would establish a conservation easement equivalent to the size of the disturbance area.

To minimize and mitigate the potential effect of Alternative B, MID would implement Environmental Commitments BIO-1: Establish a Grasslands Conservation Easement and BIO-5: Pre-Activity Surveys for Blunt-Nosed Leopard Lizard.

Effect BIO-12: Potential for Construction- and/or Operation- and Maintenance-Related Mortality of California Horned Lizard Construction and modifying grassland and alkali grassland habitat could have an adverse effect on the California horned lizard, which is listed as a California species of special concern.

Constructing facilities could result in converting existing grassland habitat suitable for the species. Direct mortality could result from excavating, grading, trenching, and soil movement. Individuals could be trapped inside burrows during construction; crushed by construction vehicles; or displaced to adjacent areas where they could be subject to increased exposure, food shortages, and predation. Flooding swales on a seasonal basis also could result in loss of some individuals. The level of loss from all activities associated with Alternative B, however, is anticipated to be low, if loss occurs at all, because no California horned lizards were observed during transect surveys.

Potential habitat for California horned lizards is widely distributed in California, specifically in Madera County and on Madera Ranch. Therefore, Effect BIO-12 is not considered adverse because it does not represent a substantial reduction in the local or regional distribution of California horned lizards.

Effect BIO-13: Potential for Construction- and/or Operation- and Maintenance-Related Mortality of Silvery Legless Lizard Construction and modifying grassland and alkali grassland habitat could have an adverse effect on the silvery legless lizard, which is considered sufficiently rare and/or vulnerable by the scientific community to be of concern. Constructing facilities could result in converting existing grassland habitat suitable for the species. Direct mortality could result from excavating, grading, trenching, and soil movement. Individuals could be trapped inside burrows during construction; crushed by construction vehicles; or displaced to adjacent areas where they could be subject to increased exposure, food shortages, and predation. Flooding swales on a seasonal basis also could result in the loss of some individuals. The level of loss from all activities associated with Alternative B, however, is anticipated to be low, if loss occurs at all.

Effect BIO-13 would not be considered adverse because it would not substantially reduce the local or regional distribution of this species.

Effect BIO-14: Potential for Operation- and Maintenance-Related Harm and Harassment of Giant Garter Snake Alternative B would have no effect on this species on Madera Ranch because aquatic habitat does not pond for a sufficient duration to support a prey base for this species. Focused surveys for this species by Dr. Sean Barry confirmed that the habitat was unsuitable and the species was not present. Similarly, canals within the MWMA are also unsuitable for giant garter snake because of extended periods of dryness, seasonal fluctuation of water, and lack of consistent prey base. Long-term habitat conditions on Madera Ranch are not expected to improve for giant garter snake because of the seasonal nature of MID's operations. If DFG uses the bank to store water for management activities at MWMA, the activities would only be those that are in the current management plan, which is in compliance with Federal ESA and CESA. Therefore, project operations and maintenance would have no effect on this species.

Effect BIO-15: Potential for Construction-Related Disturbance of Nesting Swainson's Hawk and White-Tailed Kite Construction of facilities has the potential to directly affect nesting Swainson's hawk and white-tailed kite. The Swainson's hawk is designated federal bird of conservation concern and the white-tailed kite is a fully protected species under the California Fish and Game Code. Both species have been documented on Madera Ranch. Suitable foraging habitat is present throughout the area, but nesting habitat is limited because few trees are present. Noise associated with excavating, grading, trenching, and drilling at the Madera Ranch site could result in displacement of adult birds from active nests, resulting in the loss of eggs or nestlings. Conversion of cultivated lands to recharge basins also could result in loss of potential foraging habitat for these species – particularly Swainson's hawk – requiring individuals to fly farther to obtain food. The energy costs required to obtain food could affect annual productivity of nesting pairs in the area.

Alternative B is not expected to have direct effects on individuals of these species. The indirect effect of conversion of cultivated lands is minor because approximately 60 acres of farmland would be converted to nonagricultural use and the surrounding areas are dominated by agricultural lands. The potential indirect effect of construction-related noise on active nests (Effect BIO-15) would be adverse because it could substantially reduce the local distribution of sensitive biological resources. This effect would be minimized with the implementation of Environmental Commitment BIO-6: Preconstruction Surveys and Avoidance Activities for Raptors.

Effect BIO-16: Potential Loss of Foraging Area for Greater Sandhill Crane, Golden Eagle, Ferruginous Hawk, Prairie Falcon, Merlin, Mountain Plover, Long-Billed Curlew, and Short-Eared Owl Construction and modification of annual grassland and alkali grassland could result in loss of potential foraging habitat for these species (Table 3-11). Greater sandhill crane is state listed as threatened. Golden eagle, ferruginous hawk, prairie falcon, merlin, mountain plover, long-billed curlew, and short-eared owl are species of concern for the USFWS or DFG. The golden eagle also is a fully protected species under the California Fish and Game Code and the BGEPA. These species use Madera Ranch during the nonbreeding season for foraging and resting; none of these species is likely to use the area for breeding.

Construction of the facilities could result in the use and conversion of approximately 5–10% of the grassland habitat at Madera Ranch that could be used for resting and foraging (Table 3-11). However, these species are highly mobile and forage in a variety of sites throughout the Central Valley, and no direct mortality is anticipated from the indirect effect of losing available prey as a result of this habitat conversion, and no breeding habitat would be lost. Therefore, Effect BIO-16 is not considered adverse because it would not substantially reduce the local or regional distribution of these species.

Effect BIO-17: Potential for Construction-Related Mortality of Western Burrowing Owl Western burrowing owl could be crushed during grading and soil movement activities proposed. The Western Burrowing Owl is designated as a federal species of special concern by USFWS. The Western Burrowing Owl has been documented on Madera Ranch. Western Burrowing Owls nest in burrows, with annual and alkali grasslands providing suitable foraging and nesting habitat.

Excavating, grading, trenching, soil movement, and soil compaction at the Madera Ranch site could result in direct effects on burrowing owls. Individuals could be trapped inside their burrows during grading or trenching, crushed on the ground by construction-related vehicles, or disturbed to the point that they abandon their burrows. Burrowing owls displaced to adjacent areas ultimately may die as a result of starvation, exposure, or predation. Construction activities near occupied habitats also could result in indirect effects. Construction of the recharge basins could remove vegetation and habitat for various prey species. A decline in forage species availability could be an indirect effect on the burrowing owls.

The potential effect of construction on this species could be adverse because it could have a substantial local adverse effect on a sensitive species and substantially reduce the local distribution of sensitive biological resources. This effect would be minimized with the implementation of Environmental Commitment BIO-1: Establish a Grasslands Conservation Easement and BIO-7: Preconstruction Surveys for Western Burrowing Owl.

Effect BIO-18: Potential for Operation-Related Mortality of Western Burrowing Owl
Western burrowing owls, their eggs, and their fledglings nest in burrows. Flooding swales on a seasonal basis would not be expected to adversely affect the active nests of these species because flooding typically would begin well before the start of the breeding season (mid-March) and end before the peak of the breeding season (mid-April). Western Burrowing Owls also prefer nest locations that are not at the low-point of swales to minimize predation and dry to increase nest success. The owls on site are also habituated to ranch vehicles and farm equipment traveling around the site, and most facilities would need to be accessed in the summer, post-breeding season. Some loss of burrowing owl habitat would occur. However, lost burrows would be replaced.

Effect BIO-19: Potential for Construction-Related Harm to Loggerhead Shrike The Loggerhead shrike is a federal bird of conservation concern. Loggerhead shrikes have been documented throughout the Madera Ranch area. Annual and alkali grasslands provide suitable foraging habitat, but nesting habitat is limited to portions of GF Canal and cultivated portions of the property (Figure 3-4).

Construction activities and modification of grassland and alkali grassland habitat could have an adverse effect on loggerhead shrikes, and Alternative B would result in the loss of approximately 5–10% of their foraging habitat (Table 3-12).

Noise associated with excavating, grading, trenching, and vehicle traffic at the Madera Ranch site could result in displacement of loggerhead shrikes from active nests, resulting in the loss of eggs or nestlings. Individual, nonbreeding birds also may respond to the disturbance of construction activities by leaving the area.

The potential loss of foraging habitat and indirect effect of construction-related noise on active nests would be adverse because it could substantially reduce the local distribution of sensitive biological resources. This effect would be minimized and compensated for with the implementation of Environmental Commitment BIO-1: Establish a Grasslands Conservation Easement.

Effect BIO-20: Potential for Construction-Related Foraging Habitat Loss for Tricolored Blackbird Converting agricultural land could have an adverse effect on Tricolored Blackbirds. The Tricolored Blackbird is designated as a state species of special concern by DFG and as a species of federal special concern by USFWS. Madera Ranch area is in the historical range of the tricolored blackbird, and Madera Ranch contains suitable habitat. Tricolored blackbirds occur infrequently on Madera Ranch, foraging on the grasslands and agricultural lands. No mortality is anticipated from direct or indirect effects of the construction activities associated with Alternative B. Crop production would continue on agricultural lands still under the ownership of MID. Effect BIO-20 would not be considered adverse because of the nomadic nature of breeding in this species and the availability of other crop breeding areas at or near Madera Ranch.

Effect BIO-21: Potential for Effects on San Joaquin Kit Fox Vehicle traffic, excavating, grading, trenching, soil movement, and soil compaction could result in direct effects on this species, if present. San Joaquin kit foxes, if present, potentially could be trapped inside their den burrows, crushed by construction vehicles, or displaced to adjacent areas where they could be subject to increased exposure, food shortages, and predation. Additionally, noise and ground vibration from intermittent well operation may mask important natural sounds used by kit foxes to detect prey and avoid predators.

Operational effects, including vegetation changes resulting from seasonal inundation of swales, also have the potential to affect this species. These operational effects are unlikely to adversely affect the kit fox because of their mobility and home range size. Foraging is unlikely to be affected because prey populations are expected to be the same post-project. Other types of vehicle traffic, soil movement, and compaction effects associated with maintenance may occur intermittently, in small areas where repairs are needed. These effects may occur along the same corridor in which the facility was initially installed. Overall, because of the abundance of the grasslands and the species' habitat requirements, these effects are unlikely to adversely affect the potential for San Joaquin kit fox to persist on Madera Ranch, should they be present.

In the event Phase 2 is constructed, up to 230 acres of alkali grassland habitat and 790 acres of annual grassland could be permanently affected. The extent of this effect on the species depends on the presence and abundance of the species in the construction area and the species' ability to persist in the area post-construction. If the species is present, the localized direct effects could be substantial if the species is not avoided. However, initial surveys indicate densities are likely to be low and these areas have previously been cultivated.

This effect is considered potentially moderate and would be minimized with the implementation of Environmental Commitments BIO-1: Establish a Grasslands Conservation Easement and BIO-8: Preconstruction Surveys for San Joaquin Kit Fox.

Effect BIO-22: Potential for Effects on Fresno Kangaroo Rat Excavating, grading, trenching, soil movement, soil compaction, and removing grassland habitat could adversely affect the Fresno kangaroo rat, if present. Habitat losses in Phase 1 include approximately 280 acres of temporary effects and 40 acres of permanent effects. Individuals could be trapped inside their burrows, crushed by construction vehicles, or displaced to adjacent areas where they could be subject to increased exposure, food shortages, and predation. Trenches left open during the night could trap Fresno kangaroo rats that might be active within the construction area. Operational effects also have the potential to result in effects on this species. Use of the swales could result in a new mosaic of habitats, including new plant species. The overall implications of this change in habitat conditions, and thereby the Fresno kangaroo rat, are difficult to predict. The plant species composition is likely to change because the wetter conditions may favor the growth of wetland species or upland species that are less drought-tolerant. This process has been observed on Madera Ranch, as swales with irrigation runoff discharged into them have experienced an increase in nonnative weedy plants. In Section 7, Great Valley iodine bush scrub habitat (10 acres) could benefit from a rising water table. Approximately 710 acres of annual grasslands, some with friable soils, are in the swales. Foraging is unlikely to be affected because seed production is expected to be similar following implementation of Alternative B. Dispersal is unlikely to be affected because the swales historically have flooded, and because these areas still would be usable for most of the year for the species life history requirement (including movement, food storage, and sand-bathing). Overall, because of the abundance of the grasslands and the species habitat requirements, localized vegetation changes are unlikely to adversely affect the Fresno kangaroo rat populations on Madera Ranch, should they be present.

While the potential for Fresno kangaroo rat to be present is small based on previous surveys, acoustic degradation of habitat attributable to noise and ground vibration from well operation potentially could disturb them in the vicinity of the pumps. Pump noise also may mask sounds of approaching predators, thereby increasing the potential of predation for this species. However, very little is known about nature of these potential impacts, nor the adaptive capacity of kangaroo rats to accommodate to such noise. However, kangaroo rats are especially sensitive to low-frequency sounds. Work on the desert kangaroo rat and other dune vertebrates have shown that off-road vehicle sound levels have a serious impact on hearing acuity (Brattstrom and Bondello 1983 cited in Goldingay et al. 1997). The pumps would operate intermittently and only during periods of water extraction. To some degree, the operation of construction equipment could cause these same effects.

In the event Phase 2 is constructed, up to 230 acres of alkali grassland habitat and 790 acres of annual grassland could be permanently affected. The extent of this effect on the species depends on the presence and abundance of the species in the construction area and the species' ability to persist in the area post-construction. If the species is present, the localized direct effects could be substantial if the species is not avoided. Despite possible low densities, Effect BIO-22 is considered adverse because, if Fresno kangaroo rat is present, it could substantially reduce the local or regional distribution of this species. This effect would be minimized with the implementation of Environmental Commitment BIO-1: Establish a Grasslands Conservation Easement and Environmental Commitment BIO-9: Conduct Pre-Activity Surveys for Fresno Kangaroo Rat.

Effect BIO-23: Potential for Mortality of San Joaquin Pocket Mouse Construction and modifying annual grassland and alkali grassland could have an adverse effect on San Joaquin pocket mouse. Annual and alkali grasslands provide suitable habitat for this species, and San Joaquin pocket mice were captured throughout Madera Ranch during small mammal trapping. Excavating, grading, trenching, soil movement, soil compaction, and vehicle traffic at the Madera Ranch site could result in direct effects on pocket mice. Individuals could be trapped inside their burrows during grading or trenching, crushed on the ground by construction-related vehicles, or disturbed to the point that they abandon their burrows. Construction of recharge basins could modify and remove forage vegetation and habitat for burrows. Flooding swales on a seasonal basis also could displace individuals from their burrows, making them vulnerable to exposure and predation. The San Joaquin pocket mouse is known to enter torpor (a dormancy period) during colder weather. If flooding occurred during these colder time periods (such as early spring), individuals could be at risk of drowning in their burrows.

However, because there are successful breeding individuals on Madera Ranch and because suitable habitat will continue to be abundant on site, localized effects are not expected to inhibit future breeding success. Therefore, Effect BIO-23 is not adverse because it would not substantially reduce in the local or regional distribution of these species.

Reduced Alternative B—Water Banking Outside the MID Service Area Using Select Swales and Alteration of Reclamation-Owned Facilities

Reduced Alternative B is similar in scope and design to Alternative B, with the primary exception that a reduced number of natural swales will be used in order to minimize effects to vernal pools, and a reduced number of ponds will be constructed. As with Alternative B it would complete the water bank in two phases. Phase 1 would involve constructing necessary delivery infrastructure improvements (except for the Section 8 canal southwest extension), using select natural swales for recharge (550 acres versus 700 acres as proposed under Alternative B), and installing approximately five soil berms to direct recharge flows. Phase 2 would involve constructing a limited number of recharge basins (323 acres versus up to 1,000 acres under Alternative B) and facilities for recovery of banked water.

Reduced Alternative B would result in nearly identical effects on biological resources as those identified under Alternative B, with the exception of the following effects:

- Effect BIO-4: Potential for Construction-Related Mortality of Sensitive Vernal Pool Crustaceans
- Effect BIO-5: Potential for Operation- and Maintenance-Related Mortality of Sensitive Vernal Pool Crustaceans
- Effect BIO-6: Potential for Construction-Related Mortality of San Joaquin Tiger Beetle
- Effect BIO-9: Potential for Operation- and Maintenance-Related Mortality of California Tiger Salamander
- Effect BIO-10: Potential for Construction- and/or Operation- and Maintenance-Related Mortality of Western Spadefoot Toad

The reduced footprint of recharge basins and number of swales proposed under Reduced Alternative B would reduce the potential for Effects BIO-4, BIO-5, BIO-6, BIO-9 and BIO-10.

The Environmental Commitments identified for Alternative B associated with effects on biological resources would be appropriate and applicable under Reduced Alternative B.

Alternative C—Water Banking outside the MID Service Area without Swales and Alteration of Reclamation-Owned Facilities

Alternative C is similar in scope and design to Alternative B, with the exception that recharge is achieved using engineered recharge basins in lieu of the natural swales that occur on the site. Thus, engineered basins would be built in Phase 1 instead of using the swales in Phase 1 under Alternative B. However, the expected footprint of recharge basins under Alternative B would be identical to the maximum build-out of Phase 2 of Alternative B and would result in nearly identical effects on biological resources (Effects BIO-1, BIO-2, BIO-4, BIO-6 through BIO-10, BIO-12 through BIO-21, and BIO-23).

Effect BIO-3: Loss or Disturbance of Iodine Brush Scrub or Sensitive Plant Species Habitat and Effect BIO-5: Potential for Operation- and Maintenance-Related Mortality of Sensitive Vernal Pool Crustaceans are lower under this alternative because the swales are not used for recharge and fewer vernal pools and alkali rain pools, including plant species habitat (habitat for Greene's tuctoria), would be inundated from banking activities.

In contrast, Effect BIO-11: Potential for Construction- and Operation- and Maintenance-Related Effects on Blunt-Nosed Leopard Lizard; Effect BIO-21: Potential Effects on San Joaquin Kit Fox; and Effect BIO-22: Potential for Effects on Fresno kangaroo Rat would be higher, as grassland habitat would be guaranteed to be permanently affected by the creation of permanent recharge basins (under Alternative B the overall need and quantity of ponds likely will be lower than the maximum 1,000 acres possible). The Environmental Commitments identified for Alternative B associated with these effects would be appropriate and applicable under Alternative C.

Alternative D—Water Banking outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal

Alternative D is similar in scope and design to Alternative B, with the exception that water would be conveyed to the site via GF Canal. For this reason, one recharge basin would not be built under Alternative D that was proposed under Alternative B. The majority of the swales proposed under Alternative C would also be used (less approximately 100 acres), and the expected footprint of recharge basins under Phase 2 of Alternative D would be nearly identical to Phase 2 of Alternative B. Alternative D would result in nearly identical effects on biological resources as Alternative B, including Effects BIO-1 through BIO-23. The Environmental Commitments associated with these effects are still appropriate and applicable. Off-site improvements on GF Canal would occur in agricultural lands along the existing GF Canal. However, two additional effects were identified for this alternative (Effects BIO-24 and BIO-25 described below).

Effect BIO 24: Potential Mortality of Sensitive Species during Construction The off-ranch GF Canal alignment has not been surveyed for sensitive wildlife species. However, aerial photos and DWR land-cover review indicate that the majority of the alignment of the canal, more than 95%, is located in intensive agricultural lands and is unsuitable for many sensitive species.

However, construction of the checkdams, culvert crossings, and other facilities has the potential to adversely affect local individual species should suitable habitat be present. The potential effect of construction on sensitive species could be adverse because it could have a substantial local effect on a sensitive species and substantially reduce the local distribution of sensitive biological resources should they be present. This effect would be minimized with the implementation of Environmental Commitment BIO-10: Conduct Preconstruction Surveys for Sensitive Species along the Off-Ranch Portion of Gravelly Ford Canal.

Effect BIO-25: Potential for Entrainment of Anadromous Fish If Restored to the San Joaquin River When the San Joaquin River Restoration Program (SJRRP) proceeds and anadromous fish are restored to the San Joaquin River, Alternative D potentially could result in the entrainment of salmon and steelhead trout into the GF Canal. While these species currently are not present because of downstream barriers and the lack of suitable habitat, future restoration efforts contemplate the reintroduction of these species to the San Joaquin River. The potential effect of operation on anadromous species could be adverse because it could interfere substantially with the movement of any migratory fish. This effect would be minimized with the implementation of Environmental Commitment BIO-11: Implement Protective Measures for Anadromous Fish.

Cumulative Effects

Effect BIO-26: Result in a Cumulative Loss of Grassland Alternative D could potentially result in the loss or conversion of up to 700 acres of annual and alkali grassland habitat in recharge swales and up to 1,000 acres in recharge basins, which could contribute to the historical cumulative habitat loss. Substantial areas of Madera County have been converted to other uses, including agriculture and urban development, and this trend is expected to continue.

Environmental Commitment BIO-1: Establish a Grasslands Conservation Easement would help reduce this effect; MID's proposed grasslands conservation easement at Madera Ranch would preserve in perpetuity an area of habitat equivalent in size to the area subject to long-term degradation or permanent displacement (1:1 ratio of acres conserved to acres lost). To compensate for the potential incremental cumulative effect of Alternative B, the preservation ratio will be increased to 1.2:1. This compensation would contribute to reduction of the projected future cumulative loss of this habitat type in western Madera County.

Effect BIO-27: Result in a Cumulative Loss of Habitat for Endangered Species Given the likely low density of most federally listed species on the property, the conservation measures proposed as part of Alternative B, the continued operation of the majority of the property in open space, and the mitigation lands that would be provided, vernal pool fairy shrimp, California tiger salamander, San Joaquin kit fox, blunt-nosed leopard lizard, and Fresno kangaroo rat are not anticipated to be irreparably harmed by the approval of Alternative B. However, there remains an adverse cumulative effect on these species because of the overall loss of their habitats throughout the Central Valley.

As both Alternatives C and D are similar in scope and effect to Alternative B, it is anticipated that Alternative C or D also would contribute to cumulative impacts on biological resources. Alternative B would contribute to cumulative impacts on grassland and biological resources dependent on grassland. The cumulative effects on grasslands are expected to be higher under Alternative C or D than under Alternative B because fewer ponds likely would be constructed, though the cumulative effects on vernal pools are expected to be lower because the swales would not be used for banking. Reduced Alternative B would have less cumulative impacts than Alternative B. The use of GF Canal under Alternative D is expected to result in a cumulative benefit to migratory fish because of increasing water supply reliability and storage and developing a water bank that facilitates instream flows.

3.5 Cultural Resources

The Proposed Project is considered a federal undertaking because Reclamation will be involved in project permitting. As a federal undertaking, the endeavor is subject to the provisions of Section 106 of the NHPA. The Section 106 process is a consultation process that involves the State Historic Preservation Office (SHPO) throughout; the process also calls for including Native American Tribes and interested members of the public, as appropriate, throughout the process.

Criteria for Determining Significance of a Resource

Section 106 requires federal agencies to consider the effects of their actions on properties that may be eligible for listing or are listed in the National Register of Historic Places (NRHP). To determine whether an undertaking could affect NRHP eligible properties, cultural resources (including archeological, historical, and architectural properties) must be inventoried and evaluated for the NRHP. To qualify for listing in the NRHP, a property must be at least 50 years old or, if fewer than 50 years old, be of exceptional historic significance. It must represent a significant theme or pattern in history, architecture, archaeology, engineering, or culture at the local, state, or national level. The criteria for evaluating the eligibility of cultural resources for listing in the NRHP are found in 36 CFR Part 60.4. A property must meet at least one of the following criteria:

1. is associated with events that have made a significant contribution to the broad patterns of our history; or
2. is associated with the lives of persons significant in our past; or
3. embodies the distinctive characteristics of a type, period or method of construction, or represents the work of a master, or possesses high artistic value, or represents a significant and distinguishable entity whose components may lack individual distinction; or
4. has yielded, or may be likely to yield, information important in prehistory or history.

In addition to meeting the significance criteria, potentially historic properties must possess integrity to be considered eligible for listing in the NRHP. Integrity refers to a property’s ability to convey its historic significance. Integrity is a quality that applies to historic resources in seven specific ways: location, design, setting, materials, workmanship, feeling, and association. A resource must possess two, and usually more, of these kinds of integrity, depending on the context and the reasons the property is significant.

3.5.1 Affected Environment

As a result of prefield research, historical research, the 2000 survey, 2002 survey, 2005 survey, and the 2009 survey, 16 cultural resources were identified within the Area of Potential Effect (APE) and evaluated for NRHP significance. These cultural resources are presented in Table 3-14. A detailed description and significance evaluation of these resources previously have been documented (Jones & Stokes 2002) and more recently have been documented (ICF Jones & Stokes 2009). None of these cultural resources appears to meet the significance criteria for NRHP listing. Reclamation requested SHPO concurrence on a finding of no historic properties affected. SHPO agreed with Reclamation's findings on August 31, 2009, and concurrence was received August 31, 2009 (Appendix E). However, since that time, a number of additional activities have been proposed which require expanding the APE. These activities include the proposed widening of the Section 8 Canal by 5 feet to accommodate additional water capacity; the addition of the southwest corner of Section 11 and the northern portion of Section 4 and 5 as a vernal pool areas; the proposed construction site of the Cottonwood Creek weir in Section 28; and the proposed construction site of the Gravelly Ford and Cottonwood Creek weir near Avenue 7 in Section 27. These areas and activities were not included in the original SHPO consultation package. Additional site surveys of this area were conducted on March 7-8, 2011 and no previously unknown cultural resources were identified. An updated memorandum (Appendix F) was prepared by consulting archaeologists.

Table 3-14 Cultural Resource Sites Identified at Madera Ranch

Primary Number or Trinomial	Temporary Site Number	Description
P-20-2402	JSA-Cultural-2	GF Canal
P-20-2385	JSA-Cultural-6	Road 17 segment
P-20-2386	JSA-Cultural-7	Historic road
P-20-2400	JSA-Cultural-8	Levee and associated ditches
P-20-2389	N/A	Concrete Footings
P-20-2390	JSA-Cultural-21	Historic road
CA-Mad-2309-H	JSA-Cultural-22	Water pumping location and access road
P-20-2393	JSA-Cultural-A-1	Irrigation ditch
P-20-2394	JSA-Cultural-B-1	Levee and associated ditches
CA-Mad-2310-H	JSA-Cultural-B-2	Water pumping location
P-20-2398	JSA-Cultural-B-6	Concrete ditch
P-20-2399	JSA-Cultural-B-7	Dry pond
P-20-2389	JSA-Cultural-B-18	Concrete footings
Main No. 1 Canal		Irrigation canal
Main No. 2 Canal		Irrigation canal
Section 8 Canal		Irrigation canal
24.2 Canal		Irrigation canal

A concise summary of regional prehistoric, ethnographic, and historic backgrounds is presented below. A detailed discussion of the regional setting for cultural resources previously has been documented in *Draft Cultural Resources Inventory* and Evaluation Report for the Proposed Madera Water Bank, Madera County, California (Jones & Stokes 2002) and in *Cultural Resources Inventory and Evaluation for the Madera Irrigation District Water Supply Enhancement Project, Madera County, California* (ICF Jones & Stokes 2009).

Prehistory

The Madera Ranch vicinity lies in the San Joaquin Valley cultural region (Moratto 1984). This region comprises the following four complexes, which describe specific cultural traits within a given time period:

- the Positas Complex,
- the Pacheco Complex,
- the Gonzaga Complex, and
- the Panoche Complex.

The Positas Complex (3300–2600 BC) is characterized by small, shaped mortars; short, cylindrical pestles; millingstones; perforated flat cobbles; and spire-lopped *Olivella* beads.

The Pacheco Complex (2600 BC–AD 300) comprises two phases: A and B. Phase B (2600–1600 BC) is characterized by foliated bifaces; rectangular *Haliotis* ornaments; and thick, rectangular *Olivella* beads. Phase A (1600 BC–AD 300) is represented by more varied types of shell beads. *Olivella* beads of spire-ground, modified saddle, saucer, and split-drilled types are present, as are *Haliotis* disc beads and ornaments. Other artifacts characteristic of this phase include perforated canine teeth; bone awls, whistles, and grass saws; large-stemmed and side-notched points; and an abundance of millingstones, mortars, and pestles (Moratto 1984; Olsen and Payen 1969).

The Gonzaga Complex (AD 300–1000) is characterized by burials in which the bodies of the deceased are either extended or flexed. This complex also is characterized by bowl mortars and shaped pestles; squared- and tapered-stem projectile points; few bone awls and grass saws; and a shell industry composed of distinctive *Haliotis* ornaments and rectangular, split-punched, and oval *Olivella* beads.

The Panoche Complex (AD 1500–European contact) is characterized by the presence of few millingstones and varied mortars and pestles; small side-notched arrow points; clamshell disc beads; *Haliotis* epidermis disc beads; *Olivella* lipped, side-ground, and rough disc beads; and bone awls, whistles, saws, and tubes. Flexed burials and primary and secondary cremations are found (Moratto 1984; Olsen and Payen 1969).

Ethnography

The Madera Ranch vicinity lies within the traditional homelands of the Northern Valley Yokuts (specifically the Huechi and Hoyima Yokuts), whose territory extended southward from just north of the Calaveras River to the bend of the San Joaquin River near Fresno. The foothills of the Diablo Range probably marked the western boundary of Northern Valley Yokuts territory, while the eastern boundary is at the lower foothills of the Sierra Nevada. The Northern Valley Yokuts made their livelihood through fishing and hunting and gathering various plant foods, especially acorns. Most principal settlements sat perched on top of low mounds, on or near the banks of large watercourses. The elevated positions helped to keep the inhabitants, their houses, and their possessions above the waters of the spring floods. A strong tendency toward residence in permanent villages, fostered by the abundant riverine resources, was evident; the same sites were occupied for generations (Kroeber 1925; Wallace 1978).

Historical Content

This historical context focuses on the development of irrigation in the Madera area because the three newly identified cultural resources (Main No. 2 Canal, 24.2 Canal, and Section 8 Canal) are associated with this theme. It should be noted that this section is derived from several sources. In some instances, these sources are not consistent with one another.

The development of large-scale irrigation literally changed the face of California by allowing the development of large-scale agriculture, residential and industrial power, and substantial new recreation areas. The Spanish and Mexicans had practiced irrigation on a limited scale by diverting water from streams to mission orchards, gardens, and pueblos via open ditches. The development of large farms in the post-gold rush era and a series of devastating droughts in the 1860s, however, provided the impetus for the construction of more extensive irrigation projects (Hart 1978:205).

In the late 1880s, the portion of present-day Madera County between the Chowchilla and San Joaquin Rivers and the lower Sierra foothills and Chowchilla Canal was one of the last large areas of the San Joaquin Valley with ready water sources at hand; yet it had relatively little land under irrigation. Following in the wake of the Wright Act, the Madera Irrigation District (not related to the present MID) was established in 1888, comprising 280,000 acres. Owners of large areas of land on the lower San Joaquin River, such as Miller & Lux, however, objected to the formation of the district and the proposed use of San Joaquin waters. Opposition to the newly formed district was bolstered by owners of large landholdings who were content with the methods of farming then in use in the region. The Madera Irrigation District found itself in a losing legal battle, with the prospect of extended litigation. The organizers of the district dissolved the entity in 1896 (Adams 1929:199; Barnes 1963:7; Harding 1960:100; Rodner 1948:6).

The Madera Canal and Irrigation Company (MC&IC) was a contemporary of the first Madera Irrigation District. The MC&IC used the Fresno River as its sole water supply and sold water rights to the MC&IC, formed in 1888, to —acquire, hold and dispose of water and water rights" (Barnes 1963:2). Flow from the Fresno River was supplemented by up to 100 cfs from the North Fork of the San Joaquin River, Big Creek, and Chilcoot Ditch. The MC&IC had rights to only 200 cfs from the Fresno River, which did not allow for adequate service to the canal company's customers. In addition, the organization suffered from a lack of available funding and insufficient maintenance and operation of the system (Adams 1929:200).

The conditions outlined above led to an interest in a larger irrigation project. An irrigation bureau was formed, and the manager of the MC&IC, R. L. Hargrove, filed a preliminary engineering report proposing to divert 3,000 cfs from the San Joaquin River and store some several hundred thousand-acre feet of water at the site of present Friant Dam. Subsequent investigations were conducted, and a plan was drawn up for a 350,000-acre irrigation district. The current MID was formed in 1920 and was immediately subjected to litigation from Miller & Lux, who opposed diversion of water from the San Joaquin River by MID. As a result of legal conflicts, the San Joaquin River Water Storage District was organized to include both Miller & Lux and MID land and to institute a suitable compromise to the interests of the former two groups. Agreement was never reached, however, and the storage district was dissolved in 1929 (Adams 1929; Madera Irrigation District 1981:3–6; Miller 1993).

Meanwhile, the state had conceived the State Water Plan and planned to construct Friant Dam and Reservoir. Anticipating state assistance with the development of a water supply for the district, MID purchased the Friant site. The water project was turned over to Reclamation, however, and MID waited until 1939 before being granted a water supply from Friant Dam, which was built in 1944 (Madera Irrigation District 1981:6). MID began supplying water to its customers in 1949, when the distribution system in the central part of the district was purchased from the MC&IC. The rest of MID distribution system was built in 1955 and 1959 by Reclamation. It is the last open-ditch irrigation system built by Reclamation in California (Madera Irrigation District 1981:6).

The building of the area's irrigation systems spurred development of the region's rich agricultural industry from the 1870s to the present. The growth of Madera County, in turn, is tied to the region's agricultural development. People began settling in Madera County to establish farming colonies. In time, several self-sufficient communities emerged, prompting the development of infrastructure and small industries. In present-day Madera County, logging, mainly of sugar pine, developed concurrently with other industries, such as copper and granite mining. Grapes, raisins, figs, cotton, alfalfa, fruit, cattle, and seed and field crops are historically important crops and remain significant today (Clough 1968; Madera County 2007).

Historical Research

Historical research identified two broad contexts within which to evaluate cultural resources identified in the Madera Ranch vicinity: ranching/agricultural pursuits and irrigation. Cultural resources related to ranching/agricultural pursuits are evaluated within a historic framework of the development of ranching in Madera County and the resources' association with the Pope and Talbot families. Research on irrigation identified historic canals built by Miller & Lux to irrigate range and agricultural lands; these resources are evaluated within the framework of Miller & Lux's role in the irrigation of the San Joaquin Valley. Later irrigation efforts that culminated in the formation of MID are an important subset of the irrigation theme.

Evaluation of cultural resources identified as a result of the present investigation indicates that the alternatives considered in this analysis would not affect historic, archaeological, architectural, or traditional cultural properties that appear to be eligible for inclusion NRHP because there are no such properties within the project area. However, the alternatives do have the potential to affect as-yet-unidentified cultural resources, such as buried archaeological sites. Effects could result from the physical disturbance of unidentified cultural resources during construction or construction-related activities.

The following discussion of cultural resources is based on a review of existing information regarding the prehistoric, ethnographic, and historical context of the Madera Ranch vicinity. Additional information was requested from the Native American Heritage Commission (NAHC) and from Native American individuals with knowledge of local resources of concern to Native Americans. Archaeologists conducted a preliminary field visit, consulted historic maps, and conducted a mixed-strategy survey of the vicinity to identify cultural resources. Additionally, historical research was carried out at statewide repositories in Sacramento and local repositories in the Madera vicinity to evaluate cultural resources identified in the field.

Prefield Research

A records search was conducted at the Southern San Joaquin Valley Information Center (SSJVIC) at California State University, Bakersfield, on April 7, 2000, and records search updates were requested on February 24 and March 7, 2005. Specific records reviewed at the SSJVIC included those from surveys previously conducted and sites previously recorded in and within a 0.5-mile radius of the Madera Ranch vicinity. The NRHP (including updates through January 2000 and March 7, 2005), the California Inventory of Historic Resources (California Department of Parks and Recreation 1976), California Historical Landmarks (California Department of Parks and Recreation 1996), and the California Register of Historical Resources (CRHR) also were reviewed.

The records searches indicate that one cultural resource study had been conducted in the project area of potential effect (APE) (Jones & Stokes 2002), and seven cultural resource investigations have been conducted within a 0.5-mile radius of Madera Ranch (Baloian and Flint 2002; Cannon 1986; Hudlow 2000; Nissley et al. 1975; Price 2001; Ptomey 1990; Riddell 1975). Consulting archaeologists (2002) recorded a total of 13 historic-era cultural resources in and adjacent to the present APE, on Madera Ranch. In addition to these resources, one prehistoric archaeological site (CA-Mad-300) and historic Cottonwood Creek Bridge (P-20-2323) have been recorded within a 0.49 mile radius of the APE (Feldman 2001; Hudlow 2000; Peak and Gerry 1975). CA-Mad-300 consists of three oval depressions and –several” round depressions thought to be prehistoric structural remnants. The site is located 1.24 miles south of Madera Ranch above a filled-in slough (Peak and Gerry 1975).

Historical Research

Historical research was conducted at the following repositories in Sacramento:

- library at California State University, Sacramento;
- California History Room of the California State Library;
- library of the California Department of Conservation, California Geological Survey;
- California State Archives; and
- Bureau of Land Management (BLM) cadastral survey records.

Research also was conducted at the following repositories in the Madera vicinity:

- the County library, Madera;
- the County Recorder’s and Assessor’s offices, Madera;
- MID, Madera;
- GFWD, Madera; and
- Columbia Canal Company, Firebaugh.

The results of this research are presented in the Historical Context section of the cultural resources inventory and evaluation report (Jones & Stokes 2002) and were used to evaluate the cultural resources identified in the field.

Native American Consultation

On April 4, 2000, March 3 and 7, 2005, and again on February 12, 2009, consultants requested that NAHC staff members in Sacramento conduct a search of the sacred lands file for cultural resources. NAHC personnel reported that no cultural resources listed in the sacred lands file are present in the Madera Ranch vicinity. They also provided the consultants with a list of interested Native American individuals and organizations that may have knowledge of cultural resources in the vicinity. The consultants contacted each Native American contact by letter and telephone. To date, this consultation has not yielded information regarding cultural resources in the vicinity.

Field Visit and Map Research

On May 30, 2000, two consulting archaeologists conducted a driving survey of the Madera Ranch vicinity to become familiar with current land use and access issues on the property and to identify areas sensitive for cultural resources. The information gathered during the field visit was used to design the cultural resources survey strategy and to identify potential effects on cultural resources.

During the field visit, the archaeologists mapped current land uses, topography, vegetation, and cultural resource locations on topographic maps of the area. The information obtained was cross-checked with aerial photographs of the vicinity. Historic maps were obtained from BLM survey records and the California Geological Survey Library, both in Sacramento. Potential cultural resource locations as indicated on historic maps were cross-checked with field notes and aerial photographs, resulting in the identification of eight cultural resources in the vicinity.

Field Survey The APE was systematically surveyed to identify cultural resources. In 2000, consulting archaeologists conducted an intensive pedestrian survey of 650 acres of the Madera Ranch property. The area was surveyed by walking transects spaced 100 feet between surveyors. In March 2005, the consulting archaeologists returned to the Madera Ranch vicinity to visit locations beyond the boundaries of Madera Ranch where construction would occur (i.e., along the Main No. 2, Section 8, and 24.2 Canals).

In March 2009, consulting archaeologists conducted further surveys of approximately 1,319 acres of the Madera Ranch property and 10 locations beyond the boundaries of Madera Ranch where construction would occur (i.e., adjacent to Cottonwood Creek and 24.2 Canal). These surveys included intensive pedestrian surveys and subsurface trenching of six areas identified as sensitive for buried cultural resources. The pedestrian survey was conducted by walking transects spaced 100 feet between surveyors. The subsurface trenching consisted of six 15-foot trenches with an average depth of 7 feet at six areas on Madera Ranch where paleosols were identified as a result of past geotechnical studies.

3.5.2 Environmental Consequences

As documented previously, cultural resources CA-Mad-2309-H, P-20-2385, P-20-2386, P-20-2389, P-20-2390, P-20-2393, P-20-2394, P-20-2398, P-20-2400, P-20-2402, , CA-Mad-2310-H, P-20-2399, the Main No. 1 Canal, the Main No. 2 Canal, the 24.2 Canal, and the Section 8 Canal, were evaluated previously under the NRHP's significance criteria. None of these resources were found to be eligible under the NRHP's significance criteria (Jones & Stokes 2002; ICF Jones & Stokes 2009) and SHPO concurred with these determinations on August 31, 2009 (Appendix E).

Alternative A—No Action

Under the No Action Alternative there would be no impacts to cultural resources. However, it is expected that under this alternative, conditions would change to support agricultural activities.

Alternative B—Water Banking Outside the MID Service Area and Alteration of Reclamation-Owned Facilities

Effect CR-1: Damage to or Destruction of Nine Historic Features on Madera Ranch through Construction of Recharge Basins Alternative B would result in damage to or destruction of nine historic features (CA-Mad-2309-H, P-20-2386, P-20-2389, P-20-2390, P-20-2393, P-20-2394, P-20-2398, and P-20-2400) on Madera Ranch as a result of the excavation of recharge basins. Brief resource descriptions are presented in Table 3-14. Consulting archaeologists (2002:26–29; 2007:46, 48–50, 52; ICF Jones & Stokes 2009:53-68) evaluated these nine resources for eligibility for listing in the NRHP and recommended all as ineligible for NRHP listing. Modification of these resources would not be considered an adverse effect on cultural resources.

Effect CR-2: Physical Modifications to Gravelly Ford Canal (P-20-2402) Alternative B would result in physical modifications to the GF Canal (P-20-2402) for use in the proposed water-collection system. Modifications would consist of grading the canal bottom and side slopes, as well as construction of three to five permanent canal crossings. Consulting archaeologists (2002:26; 2007:44) evaluated P-20-2402 for eligibility for inclusion in the NRHP and recommended the canal as ineligible. Modification of this resource would be considered no impact to cultural resources.

Effect CR-3: Physical Modifications to Historic Main No. 1, Main No. 2, and Section 8 Canal Alternative B would result in physical modifications to the Main No. 1, Main No. 2, and Section 8 Canals. Modifications include the installation of lift gates and other ancillary features and canal widening.

The Main No. 1, Main No. 2, and Section 8 Canals are components in the MC&IC system, which MID purchased for distributing water in 1949 (Madera Irrigation District 1981:6). The addition of the MC&IC canal system gave MID access to Fresno River and San Joaquin River water, increasing its service capabilities (Barnes 1963:3). The MC&IC portion of MID irrigation system is associated with the early development of irrigation in the Madera region, which promoted the cultivation of new and diverse crops. The period of significance for the Main No. 2 and the Section 8 Canals is therefore 1870–1920, the former date marking the approximate construction of the MC&IC system and the latter marking the inception of MID.

Because of the system's association with early irrigation and agricultural development, the Main No. 1, Main No. 2, and Section 8 Canals appear to meet NRHP Criterion A at the local level of significance. Main No. 1, Main No. 2 and Section 8 Canals do not, however, retain integrity of workmanship and design because MC&IC and MID have modified the canals through regular maintenance and redesign since 1920. These modifications resulted in water conveyance structures that do not resemble their historic antecedents but look like modern ditches and canals. As modern canals, the Main No. 1, Main No. 2, and Section 8 Canals do not physically convey their historical significance. Therefore, the Main No. 1, Main No. 2 and Section 8 Canals do not appear to be historic properties. Modification of these canals would not be considered an impact on cultural resources.

Effect CR-4: Physical Modification of 24.2 Canal Reclamation, under contract with MID, built 24.2 Canal in 1955 as a component of MID's distribution system (Madera Irrigation District 1981). Although certainly important in MID's service operations, construction of the system is not a historically important event. The 24.2 Canal is not associated with historically consequential persons and is not associated with the work of a renowned engineer. For these reasons, the 24.2 Canal does not appear to meet the significance criteria of the NRHP and would not qualify as a historic property. Modification of the 24.2 Canal would be considered no impact on a cultural resource.

Effect CR-5: Physical Disturbance of Currently Undiscovered Cultural Resources The present analysis is based on record searches and a review of prehistoric, ethnographic, and historic literature pertaining to the Madera Ranch vicinity; consultation with Native Americans; historical research; and a pedestrian survey of the vicinity (Jones & Stokes 2002, 2007, 2011). Despite the comprehensiveness of the cultural resources inventory, construction may unearth or reveal additional cultural resources that have not been recorded previously and may not have been visible during surveys conducted to date (Jones & Stokes 2007:39–42, 55). The physical disturbance of undiscovered cultural resources could result in an impact. Implementation of Environmental Commitment CR-1 to stop construction if cultural resources are discovered would reduce the intensity of the effect.

Reduced Alternative B—Water Banking Outside the MID Service Area Using Select Swales and Alteration of Reclamation-Owned Facilities

Reduced Alternative B is similar in scope and design to Alternative B, with the primary exception that a reduced number of natural swales will be used and a reduced number of ponds will be constructed. Reduced Alternative B would also exclude construction of the Section 8 canal southwest extension. This would not result in any differences from what was described above for Alternative B relative to effects to cultural resources. The effects of Reduced Alternative B would result in nearly identical effects to those that would occur under Alternative B (Effects CR-1, CR-2, CR-3, CR-4 and CR-5), and thus, would be considered no impact to cultural resources.

Alternative C—Water Banking Outside the MID Service Area without Swales and Alteration of Reclamation-Owned Facilities

Alternative C is similar in scope and design to Alternative B, with the primary exception that the natural swales that occur on the site would not be used for recharge. However, the expected footprint of recharge basins under Alternative C would be nearly identical to Phase 2 of Alternative B and would result in equivalent effects on cultural resources (Effects CR-1, CR-2, CR-3, CR-4, and CR-5). None of the cultural resources identified are eligible for inclusion in the NRHP. Thus, under NEPA, there is no impact to cultural resources. If cultural resources are discovered during construction (as described in Effect CR-5), it could result in an impact to cultural resources under NEPA. Implementation of Environmental Commitment CR-1 to stop construction if cultural resources are discovered would reduce the intensity of this effect.

Alternative D—Water Banking Outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal

Alternative D is similar in scope and design to Alternative B, with the exception that water would be conveyed to the site via GF Canal. For this reason, one recharge basin would not be built under Alternative D that was proposed under Alternative B. However, the expected footprint of recharge basins under Alternative D would be nearly identical to Alternative B and would result in equivalent effects on cultural resources (Effects CR-1, CR-2, CR-3, CR-4, and CR-5). None of the cultural resources identified would be recommended for eligibility. Thus, there would be no impact to cultural resources unless cultural resources are discovered during construction (as described in Effect CR-5). Implementation of Environmental Commitment CR-1 to stop construction if cultural resources are discovered would reduce the intensity of this effect.

Cumulative Effects

Alternative B could result in the physical disturbance of undiscovered cultural resources. MID would halt construction if artifacts are discovered and require evaluation by a professionally qualified archaeologist. This would minimize effects on cultural resources and therefore would not result in a significant regional cumulative effects on cultural resources in Madera County.

As Reduced Alternative B and Alternatives C and D are equivalent to Alternative B in scope and effect, it is not anticipated these alternatives would contribute to cumulative impacts on cultural resources.

3.6 Environmental Justice

This section presents the environmental background necessary to analyze compliance with EO 12898 and provides background information on the ethnic and income characteristics of the study area.

On February 11, 1994, President Clinton issued EO 12898, Federal Actions to Address Environmental Justice in Minority and Low-Income Populations. The purpose of the order is to avoid the disproportionate placement of any adverse environmental, economic, social, or health effects from federal actions and policies on minority and low-income populations.

3.6.1 Affected Environment

To comply with Executive Order 12898, the most current U.S. Census Bureau demographic data available (http://quickfacts.census.gov/qfd/states/06/0645022.html) were analyzed at a geographic scale commensurate with the area of potential effect. The WSEP would be implemented west of the city of Madera in unincorporated Madera County. Consequently, the environmental justice assessment focused on an examination of the overall Madera County statistics and not the city of Madera (Table 3-15). Income and ethnicity variables for Madera County were analyzed to determine whether the county has a relatively high population of low-income or minority residents.

Table 3-15 Population and Percent Ethnicity Data for Madera County

Area	Total 2009 Population	White	African American	Native American	Asian	Hispanic
Madera County	148,632	87.6%	4.6%	3.3%	2.1%	51.7%
City of Madera	54,959	48.1%	3.9%	2.8%	1.4%	67.8%

Notes: All ethnicity data population data (city and county) are for 2009 U.S. Census State and County QuickFacts.

Population and Demographics

The total population of Madera County in 2000 was 148,632, a 20.7% increase between April 1, 2000 and July 1, 2009. Madera County is considered ethnically diverse; minority populations account for an estimated 38% of the county's total population.

Median household income for Madera County is $36,286. Persons in poverty were estimated at 21% of Madera County population for the 2000 census year (Table 3-16).

Table 3-16 Income Data for Madera County

Area	Median 2008 Household Income	Percent above Poverty Level	Percent below Poverty Level
Madera County	$46,000	79	21

Notes: Income data are from 2009 U.S. Census State and County QuickFacts.

3.6.2 Environmental Consequences

After the alternatives were selected, the environmental effects of the WSEP were reviewed and evaluated to determine whether they could result in disproportionate effects on minority or low-income populations. Implementation of the Proposed Action would be for a largely rural and undeveloped area of Madera County. According to a review of census data for 2009, both Madera County and the Madera Ranch area are considered similarly ethnically diverse. Minority populations account for an estimated 61.7% of Madera County's total population.

Although minority and/or low-income populations may be located in the vicinity of the Madera Ranch site, census data indicate that the overall percentage of minority and low-income populations located in the vicinity of Madera Ranch is fairly similar to that of the overall Madera County population. Consequently, the Madera Ranch area is not considered to be composed of a disproportionately high level of minority or low-income populations.

As described elsewhere in this chapter, environmental effects considered include traffic, land use, air quality, noise, public safety, and hazardous materials. None of the environmental effects identified for either the Proposed Action or any of the alternatives would affect a specific population group. Consequently, implementation of the Proposed Action would not disproportionately affect a specific ethnic or income group.

3.7 Geology, Soils, Seismicity, and Erosion

This section describes the geologic, seismic and soil conditions in the proposed action area. This section also includes the paleontological conditions in the Proposed Action area.

3.7.1 Affected Environment

In some instances, the affected area is extended to include land located outside the site (in the Madera Ranch vicinity) that could be affected by potential changes in the groundwater table resulting from the Proposed Action or alternatives.

Geology

The Madera Ranch site is located on the level and nearly level alluvial landforms that occupy the east-central flank of the San Joaquin Valley, a large northwest-trending structural trough filled with a thick layer of alluvial sediments (Bailey 1966). The regional geologic map compiled by Jennings and Strand (1958) indicates that the site is underlain by basin and alluvial fan deposits, which consist of gravels, sands, silts, and clays deposited by rivers and streams during the last 10,000 years. The basin and alluvial fan deposits are of similar age.

The basin deposits consist of instream, natural levee, and floodplain deposits that have been salinized in areas by groundwater. These salinized basin deposits serve as the primary parent material of the moderately and strongly saline-alkali soils that dominate the affected area. The alluvial fan deposits compose portions of the east-west–trending San Joaquin River, Fresno River, and Cottonwood Creek alluvial fans, which coalesce in the Madera area.

Land subsidence is the lowering of the land-surface elevation from changes that take place underground. Common causes of land subsidence from human activity are pumping water, oil, and gas from underground reservoirs; collapse of underground mines; drainage of organic soils; and initial wetting of dry soils.

Overdrafting of aquifers is the major cause of subsidence in the southwestern United States. In many aquifers, groundwater is pumped from pore spaces between grains of sand and gravel. If an aquifer has beds of clay or silt within or next to it, the lowered water pressure in the sand and gravel causes slow drainage of water from the clay and silt beds. The reduced water pressure is a loss of support for the clay and silt beds. Because these beds are compressible, they compact (become thinner), and the effects are seen as a lowering of the land surface. The lowering of land surface elevation from this process is permanent. For example, if lowered groundwater levels caused land subsidence, recharging the aquifer until groundwater returned to the original levels would not result in an appreciable recovery of the land-surface elevation.

In the San Joaquin Valley, most subsidence is correlated with reduced water pressure in confined aquifers. Subsidence from 1926 to 1973 occurred in significant amounts southwest of Madera County, with subsidence of 28 feet approximately 15 miles southwest of Madera Ranch and eight miles southwest of Mendota. During this period no subsidence was experienced at Madera Ranch (Bookman-Edmonston 2003). The County has indicated there has been some recent subsidence in the western portion of the county above the Corcoran Clay resulting from groundwater overdraft, but the amount was not described (Madera County 2008).

Soils

Soils in Madera County were surveyed by the NRCS during the 1950s (Stromberg et al. 1962). When the survey was conducted, much of the land in western Madera County was uncultivated and undisturbed so native soils were extensive in the vicinity of Madera Ranch. Since that time, many of the native soils in western Madera County have been physically and/or chemically altered from their natural condition by agricultural practices, such as subsoiling (ripping), saline-alkali soil reclamation, leveling, ditch construction, and groundwater pumping (which can lower the water table). Consequently, the descriptions of soils in these areas provided by the NRCS only describe the overall soil composition as there may be localized alterations.

Although all of the soils in these areas formed from alluvium derived primarily from granitic rock, the soil map units delineated by Stromberg et al. (1962) can be grouped into one of two general categories based on the relative age of the granitic rock alluvium from which they formed and the type of geomorphic surfaces on which they occur:

- soils formed from recent alluvial fan and floodplain deposits and
- soils formed from older alluvial fan and basin deposits.

The soils that make up each of these groups typically exhibit a common range of characteristics. For example, soils formed from older alluvial fan and basin deposits are more developed, exhibit substantial textural variation with depth, and typically are excessively saline and alkaline. In contrast, soils formed from recent floodplain and alluvial fan deposits typically are less developed, exhibit relatively little textural variation with depth, and are less affected by excess salinity and alkalinity. In general, the swales proposed for recharge as part of Alternative B Phase 1 are underlain by the relatively recent alluvial fan and floodplain deposits, which have lower salt content. The swales are mapped mostly as Pachappa series soils (described below).

Soils on older alluvial fan and basin deposits include those of the Fresno, El Peco, Traver, Dinuba, Chino, Borden, and Calhi series. They occupy the greatest proportion of total land area in Madera Ranch and support most of the alkali grasslands, slickspots, and alkali rain pools that exist on the uncultivated portions of the site. With the exception of the fine-textured and moderately fine-textured subsoil horizons (i.e., layers) that occur in some of these soils, they are typically coarse-textured and moderately coarse-textured throughout and are at least slightly saline-alkali.

Most of the older alluvial fan and basin soils on Madera Ranch also contain a lime-silica–cemented hardpan or a weakly cemented silty substratum at depths ranging from five to 36 inches below the ground surface. In their natural condition, these soils are slowly to moderately permeable, are moderately well- to somewhat poorly drained, and typically have relatively low organic matter content and low to moderate native fertility.

Soils of the Fresno and El Peco Series The moderately coarse-textured soils of the Fresno and El Peco series occupy the greatest proportion of land at Madera Ranch. The soils of both series occur on level and nearly level surfaces that, in their natural condition, frequently exhibit low, hummocky (mound-intermound) microrelief. They typically consist of sandy loams, fine sandy loams, silt loams, and loams to depths of more than 60 inches and contain a discontinuous, five-to six-inch-thick lime-silica–cemented hardpan at depths ranging from five to 36 inches below the ground surface.

Most of the Fresno and El Peco soils at the site are moderately to strongly saline-alkali. Because of the high content of exchangeable sodium and the water-restrictive duripans, these soils are very slowly permeable and somewhat poorly drained. Most of the slickspots and alkali rain pools that exist on the uncultivated portions of the site occur on moderately to strongly saline-alkali soils of the Fresno and El Peco series (not all mapped areas of these series support slickspots or alkali rain pools).

Soils of the Traver, Dinuba, Chino, and Borden Series The coarse-textured soils of the Traver series and the moderately coarse-textured soils of the Dinuba series are found in association with soils of the El Peco series on the southern half of the Madera Ranch site.

Soils of the Traver and Dinuba series are similar to the soils of the Fresno and El Peco series in that they typically consist of slightly to strongly saline-alkali sandy loams and fine sandy loams that exist on level and nearly level surfaces that frequently exhibit a low, hummocky microtopography. However, they typically do not contain a lime-silica–cemented hardpan, although soils of the Dinuba series are sometimes underlain by a weakly cemented layer of stratified silts and fine sands at depths ranging from 26 to 36 inches below the ground surface. Soils of the Dinuba and Traver series are slowly to moderately permeable. Because they lack a true duripan, they have better internal drainage than the soils of the Fresno and El Peco series.

Soils of the Chino series occur in nearly level, swale-like positions throughout Madera Ranch. They are similar to soils of the Traver series but consist of slightly finer textures and have poorer internal drainage.

Soils of the Borden series occur on nearly level surfaces near the northeast part of Madera Ranch. They differ from the soils of the Traver, Dinuba, and Chino series mainly in that they typically have a moderately clay-enriched subsoil horizon and are not as strongly affected by excess salinity and alkalinity. Soils of the Borden series have moderately slow permeability and are well-drained.

Soils of the Calhi Series Soils of the Calhi series occur in small areas throughout Madera Ranch. They formed from granitic alluvium that was reworked by wind, are slightly to moderately saline-alkali, and typically consist of loamy fine sands throughout. They generally occur on undulating ridges and small mounds within larger areas of Fresno, El Peco, and Dinuba soils. Because of their uniform, sandy texture and lack of subsurface restrictive layers, they have moderate permeability and good internal drainage.

Soils on recent alluvial fan and floodplain deposits include those of the Pachappa, Greenfield, Cajon, Wunjey, Tujunga, and Visalia series. They are less developed, less extensive, and show less morphologic variation with depth than the older basin and alluvial fan soils described above. These soils typically occur on level and nearly level surfaces and in long, swale-like positions that are often subject to continued alluvial deposition. They lack the fine-textured subsoil horizons and duripans found in the basin soils; with few exceptions, they are coarsely textured throughout and consist of loamy sands, sandy loams, and fine sandy loams to depths of more than 60 inches.

Most of the recent alluvial fan and floodplain soils are not as severely affected by excess salinity and alkalinity as the soils formed from older alluvial fan and basin soils. They typically have moderate to rapid permeability, are moderately well to somewhat excessively drained, and are characterized by low organic matter content and low native fertility.

Soils of the Pachappa and Greenfield Series The coarse- and moderately coarse-textured soils of the Pachappa and Greenfield series formed from the oldest of the recent alluvial fan and floodplain deposits that exist at Madera Ranch. Soils of the Pachappa series occupy relatively large areas throughout the site, while soils of the Greenfield series are much less extensive. The soils of both series typically are located on nearly level surfaces in narrow, swale-like positions that are not usually subject to continued alluvial deposition; they generally consist of fine sandy loams and sandy loams with the slightly finer-textured subsoil horizons.

Soils of the Pachappa and Greenfield series are, at most, slightly affected by excess salinity and alkalinity near the surface, but they become moderately to strongly saline-alkali with depth. The soils of both series typically are moderately rapidly permeable and well-drained, but they support many of the vernal pools that occur at the site.

Soils of the Cajon, Grangeville, Wunjey, Tujunga, and Visalia Series The coarse-textured soils of the Cajon, Grangeville, Wunjey, Tujunga, and Visalia series formed from the youngest of the recent alluvial fan and floodplain deposits at Madera Ranch. The soils of these series typically are located on nearly level surfaces and in narrow, swale-like depressions that can be subject to continued alluvial deposition; they generally show little textural variation with depth and consist of sandy loams, loamy sands, and sands that are moderately rapidly permeable and moderately well- to somewhat excessively drained. The soils of the Cajon, Grangeville, Wunjey, and Visalia series are slightly to strongly saline-alkali; soils of the Tujunga series typically are nonsaline and nonalkali throughout.

Subsurface Soils Extensive data have been collected on the subsurface geology of the property (Bookman-Edmonston 2003). These findings include:

- an average of 260 feet of sediments are deposited above the Corcoran clay beneath Madera Ranch;
- since the Pleistocene, the migration of rivers has produced a network of thick overlapping bands of sandy channel deposits trending from east-northeast to west-southwest;
- five major stratigraphic units were identified above the Corcoran clay;
- the Corcoran clay is discontinuous under the eastern and southeastern portion of the property and is continuous under the western portion of the property;
- approximately 13% of the aquifer material is clayey, 28% is silty, and 59% is sandy;
- the most extensive clayey zones occur at depths of about 70 to 100 feet; and
- there are no identified fault zones under the project site.

Saline-Alkali (Salt-Affected) Soils As discussed above, most of the soils at Madera Ranch, especially those formed from older alluvial fan and basin deposits, are classified as saline-alkali. The properties of and classification system for these soils are discussed in detail below.

Properties and Classification The term saline-alkali is somewhat ill-defined, but, in general, it is applied to soils that contain sufficient salinity, alkalinity, and/or exchangeable sodium to interfere with the growth of most agricultural crops. Stromberg et al. (1962) assigned the saline-alkali soils in Madera County to three categories based on soluble salt content (salinity) and the effect of alkalinity on plant growth (Table 3-17).

Table 3-17 Categories of Saline-Alkali Soils in Madera County

Category	Soluble Salt Content[a]	Effect of Alkalinity on Plant Growth[b]
Normal	< 0.2	No significant
Slightly saline-alkali	0.2–0.5	Slight
Moderately saline-alkali	0.5–1.0	Moderate
Strongly saline-alkali	> 1.0	Strong

Source: Stromberg et al. 1962.

Notes: [a] A measure of soil salinity; percentage on dry-weight basis.

[b] A qualitative measure of soil alkalinity.

According to this system, soils classified as strongly saline-alkali are more likely to have a substantial effect on plant growth than soils classified as moderately or slightly saline-alkali. Although Stromberg et al. (1962) did not state explicitly what part of the soil profile the above categories refer to, soil profile descriptions provided in the Madera area soil survey suggest that they refer to conditions in the topsoil layers, which are the layers in which most plant roots are found. This interpretation is consistent with the fact that many soils classified as slightly saline-alkali by Stromberg et al. (1962) have slightly alkaline topsoils but moderately to strongly alkaline subsoils.

The classification system presented in Table 3-17 is no longer used by the NRCS for the purpose of classifying salt-affected soils. It has been replaced by a new system that was developed by workers at the U.S. Salinity Laboratory (Table 3-18). Most of the saline-alkali soils at Madera Ranch probably would be classified as saline-sodic or sodic under the new system, although it is difficult to determine for certain because of the paucity of available chemical data for soils in Madera County.

Table 3-18 Current Classification Scheme for Salt-Affected Soils

Category	Electrical Conductivity of Saturated Soil Extract[a] (deciSiemens per meter)	Soil pH[b]	Exchangeable Sodium[c]
Normal	< 4.0	< 8.5	< 15
Saline	> 4.0	< 8.5	< 15
Sodic	< 4.0	> 8.5	> 15
Saline-sodic	> 4.0	< 8.5	> 15

Notes: [a] A measure of soil salinity.

[b] A function of soil alkalinity.

[c] Percentage on a dry-weight basis.

The terms *soil salinity*, *soil alkalinity*, and *exchangeable sodium* are defined below, as are the detrimental effects that each of these soil parameters can have on soil properties and plant growth when present in excessive quantities.

- *Soil salinity*: The amount of soluble salts (e.g., sodium chloride) present in a soil. The main effects of high soil salinity are stunted plant growth and poor seed germination. The mechanisms responsible for these effects are primarily osmotic: soluble salts have a strong affinity for water, so when they are present in high concentrations, they make it difficult for plants to extract water from the soil. Specific salt ions, such as sodium (Na^+), can have toxic effects on some plant species and can induce nutrient imbalances if present in sufficient quantities.
- *Soil alkalinity*: The degree or intensity of alkalinity in a soil. Alkalinity can be measured directly by summing the concentrations of bicarbonate and carbonate in a soil solution, or it can be calculated from soil pH. Soils with appreciable alkalinity typically have pH values greater than 7.0. The main effect of high soil alkalinity is to increase soil pH and reduce the availability of essential plant nutrients. Alkalinity induces precipitation reactions that remove nutrients, such as iron and calcium, from the soil solution, making them unavailable to plants.
- *Exchangeable sodium*: The fraction of a soil's cation exchange capacity that is occupied by sodium ions. Exchangeable sodium is a direct function of a soil's soluble salt content and usually is determined by measuring the ionic concentration of sodium in a saturated soil extract. The main effect of high levels of exchangeable sodium is on the physical properties of the soil, which in turn affect plant growth. When soil salinity is low, exchangeable sodium disperses soil clays and destroys the soil structure, interfering with the ability of plant roots to obtain necessary air and water. Because exchangeable sodium reduces soil permeability and infiltration rates, it can increase runoff and erosion. High levels of exchangeable sodium also can induce nutrient deficiencies by displacing other essential plant nutrients from the soil's exchange complex. When soil salinity is high, the detrimental effects of exchangeable sodium are generally less evident because high concentrations of soluble salts help keep soil clays flocculated (i.e., clustered in aggregates or flocks).

Sources of Soluble Salts in Madera Ranch Soils The chemical composition of soluble salts commonly found in soils can be traced to many sources. Some of the most common and significant sources include mineral weathering reactions, groundwater, and human-caused inputs such as fertilizer and irrigation water.

The excess quantities of soluble salts found in Madera Ranch soils are derived primarily from mineral weathering reactions, shallow groundwater, and surface floodwaters temporarily retained in the soil pore space by restrictive subsoil horizons, such as the lime-silica–cemented hardpans that occur in soils of the Fresno and El Peco series (Stromberg et al. 1962). Largely because of the San Joaquin Valley's semiarid climate, soluble salts from these sources have accumulated gradually over time, resulting in the saline soil conditions that exist in much of western Madera County. The fact that many of the saline soils at Madera Ranch are alkaline and contain excess exchangeable sodium (i.e., are saline-alkali) suggests that sodium bicarbonate constitutes a significant proportion of the accumulated salts.

Saline-Alkali Soil Reclamation To improve the suitability of saline-alkali soils for agricultural crop production, the soils typically must be treated with chemical amendments, such as gypsum and elemental sulfur, and large volumes of high-quality irrigation water. This practice is commonly referred to as soil reclamation. Gypsum is applied to displace exchangeable sodium from the soil, and the elemental sulfur is used to neutralize excess soil alkalinity. Gypsum- and sulfur-amended soils are subsequently flood irrigated to flush excess salts and displaced sodium ions from the root zone. The reclamation process typically is repeated until soil drainage and aeration improve and soil salinity and pH reach acceptable levels.

The proposed pond areas that would be affected by the alternatives were dry land farmed agriculture intermittently in the 1930s through 1970s. Crops that have been grown in these sections include row and forage crops, such as sugar beets, alfalfa, barley, and wheat, all of which have good to moderate salt tolerance. Agricultural lands were reclaimed (i.e., treated with gypsum and/or sulfur) in the past (Roughton pers. comm. [1]). The rest of Madera Ranch is grazed and probably has not been subject to reclamation efforts.

Slickspots and Alkali Rain Pools Slickspots, also referred to as panspots, alkali scalds, and small playas, are commonly occurring features in the uncultivated and marginally disturbed portions of Madera Ranch. They are located primarily on nearly level surfaces underlain by the moderately to strongly saline-alkali soils of the Fresno, El Peco, Traver, and Dinuba series. Although they vary considerably in size and form, the slickspots on Madera Ranch typically consist of relatively shallow, oval, and irregularly shaped depressions that range in size from a few square feet to more than 0.5 acre.

The slickspots that pond water for significant duration during the wet season are classified as alkali rain pools, a specific type of seasonal wetland (see Biological Resources Section). The slickspots on Madera Ranch are largely devoid of vegetation but are rimmed with salt- and alkali-tolerant plant species.

The soil survey of the Madera area indicates that the pre-1962 distribution of slickspots in the county was fairly extensive (Stromberg et al. 1962). Like the slickspots on Madera Ranch, they were located primarily in uncultivated areas underlain by moderately and strongly saline-alkali soils of the Fresno, El Peco, Dinuba, and Traver series, primarily in the westernmost portions of Madera County. Many of these areas since have been cultivated for agriculture, resulting in a significant reduction in the number and distribution of slickspots in the county.

Although no exhaustive statewide surveys have been conducted, the consensus is that slickspots in California form primarily on sodic soil landscapes in the Sacramento and San Joaquin Valleys and in smaller, nearby valleys, such as the Carrizo Plain (Reid et al. 1993, Arroues pers. comm.). Because many, if not most, of these landscapes also have been cultivated for agriculture, it is reasonable to assume that the statewide distribution of slickspots also has been reduced significantly. A review of historical aerial photographs contained in soil surveys of counties in the San Joaquin and Sacramento Valleys generally supports this conclusion; it indicates that a significant proportion of the remaining uncultivated sodic soil landscapes that contain slickspots are located in wildlife refuges and natural areas that have been protected for their species diversity and habitat value.

Seismicity

Well-defined, active earthquake faults are almost nonexistent on the alluvial plains of the San Joaquin Valley. Most known faults that exist in the San Joaquin Valley show no evidence of displacement during the last 1.6 million years (i.e., precede the Quaternary period and therefore are considered inactive) and are concealed by overlying sediments. Known faults in the immediate vicinity of Madera Ranch are of this type and include two unnamed fault traces located approximately two miles southwest of Madera Ranch (Jennings 1994). These fault traces do not present a hazard of ground surface rupture for the WSEP. No known active faults cross the Madera Ranch site (Hart and Bryant 1997). All known active faults in the San Joaquin Valley and surrounding mountain ranges are located more than 20 miles from the site.

Seismic ground-shaking has been identified as the primary seismic hazard in Madera County (Madera County 1995a). In the western portion of the county, unconsolidated alluvial sediments, which amplify the destructive energy of seismic waves to a greater degree than hard bedrock, are the main geologic substrate and potential risk. Only low levels of ground shaking would be expected to occur in the eastern and central portions of the San Joaquin Valley during the maximum probable earthquake on the San Andreas fault (located approximately 60 miles west of the proposed site) (Madera County 1995a). While seismic ground-shaking is identified as the primary seismic hazard in Madera County, the hazard is relatively low compared to other regions of California that are located closer to active fault systems.

The findings of the California Division of Mines and Geology probabilistic seismic hazard assessment are generally consistent with those of the *Five County Seismic Safety Element* prepared by the Tulare County Council of Governments for the counties of Fresno, Kings, Tulare, Madera, and Mariposa in 1974 (Tulare County Council of Governments 1974). The five-county hazard assessment indicated that only relatively low levels of ground-shaking would be expected to occur in the eastern and central portions of the San Joaquin Valley during the maximum probable earthquake on the San Andreas fault (magnitude 8–8.5 on the Richter scale) (Madera County 1995a). Thus, although seismic ground-shaking is the most significant type of seismic hazard in the Madera area, both of the above seismic hazard assessments indicate that the hazard is relatively low compared to other regions of California that are located closer to active fault systems.

Water and Wind Erosion Hazards Water and wind erosion are processes by which individual soil particles are detached and transported from one location to another by rain and the shear forces of wind and overland water flows. The most direct and detrimental effects of water and wind erosion are the loss of nonrenewable topsoil resources, the degradation of soil quality, and the degradation of air and receiving-water quality.

The poorly structured, fine sandy loam surface soils that occupy most of Madera Ranch have high erodibility. However, the prevailing slope gradient on the site is extremely low (typically 0–1%). Therefore, the rate of runoff is slow and the hazard of water erosion, even under disturbed conditions, is slight to nonexistent (Stromberg et al. 1962).

As with water erosion, the susceptibility of a given soil to wind erosion depends largely on inherent soil properties, such as organic matter content, coarse-fragment (e.g., gravel) content, aggregate stability, calcium carbonate content, and, most importantly, soil texture.

The NRCS established wind erodibility groups. All the soils on proposed action site belong moderately susceptible to highly susceptible wind erodibility groups.

Paleontological Resources

A number of geologic units in the project area have some potential to contain paleontological resources. These include the Modesto Formation, Riverbank Formation and Turlock Lake Formation. The Turlock Lake Formation is overlain by the Riverbank Formation which is overlain by the Modesto Formation. The following discussion provides additional information on these formations, which are considered particularly sensitive on a regional basis. Other units are also locally sensitive.

Quaternary alluvial and fluvial strata flooring the Central Valley record erosional dissection of the Sierran and Coast Ranges uplifts. Fossil remains of vertebrates are common in Pleistocene units throughout California, and Pleistocene alluvial units in particular can contain diverse vertebrate fauna representing various evolutionarily important taxa. Sloths, horses, camels, mammoths, and bison have been collected from middle to late Pleistocene sediments in many areas throughout central California (Jefferson 1991, Dundas et al. 1996, Hilton et al. 2000). Vertebrate mammalian fossils have proved helpful in determining the relative age of alluvial fan sedimentary deposits (Louderback 1951, Savage 1951, Albright 2000). Mammalian inhabitants of the Pleistocene alluvial fan and floodplain included mammoths, horses, mastodons, camels, ground sloths, and pronghorns. The Pleistocene epoch, known as the –great ice age,” began approximately 1,800,000 years ago.

Diverse vertebrate fauna, dominated by large herbivorous mammals, were discovered in May 1993 at the Madera County Landfill in alluvial fan, fan channel, and marsh/lacustrine (sedimentary lake deposits) sediments representing the upper unit of the Turlock Lake Formation. A late Irvingtonian age is indicated for the fauna. The fossil-bearing stratum normally is magnetized and is inferred to have an upper bound on the age of the fauna at 780,000 BC. The site location in Fairmead, California, where these fauna were discovered is approximately 16 miles from the project site. Because the geologic units that exist at the fossil discovery site in Fairmead are also present at the subject project site, the potential for similar paleontological resources to be present is high (Dundas et al. 1996).

The Modesto Formation, which is Late Holocene/Early Pleistocene in age, is present in the immediate vicinity of the project area. The formation is composed of alluvium derived from the interior of the Sierra Nevada upper fans and terraces as well as fine-grained stratified alluvium of flood basins and lower fans. Also present is the Turlock Lake formation, which is late Pleistocene in age and is composed of undifferentiated alluvium. Turlock Lake is the older of these formations and the Modesto Formation is the younger.

The Modesto Formation can be divided into an upper and lower member (i.e., distinct upper and lower levels), both of which occur in the project area. The lower member of the Modesto is composed of consolidated, slightly weathered, well-sorted silt and fine sand, locally containing gravels. Age estimates for the lower member range from 42,000 to 73,000 years BP. The upper member of the Modesto Formation is composed of unconsolidated, unweathered gravel, sand, silt, and clay. These deposits form alluvial terraces that are topographically higher than those of the lower member. Age estimates for the upper member range from 12,000 to 26,000 years BP (Dundas 1996).

A unit that is not present locally and surficially at Madera Ranch, but is known to have been deposited between the Modesto and Turlock Lake Formations, is the Riverbank Formation, which consists of approximately 10 to 13 feet of massive clayey sand. All three formations serve as ideal preservation environments for paleontological resources. The Modesto Formation and Upper Riverbank Formation are considered to be Rancholabrean, and the Lower Riverbank Formation and Turlock Lake Formation are considered to be Irvingtonian.

Surveys of Late Cenozoic land mammal fossils in northern California have been provided by Hay (1927), Stirton (1939), Savage (1951), Lundelius et al. (1983), and Jefferson (1991a, 1991b). On the basis of his survey of vertebrate fauna from the nonmarine Late Cenozoic deposits of the San Francisco Bay region, Savage (1951) concluded that two major divisions of Pleistocene-age fossils could be recognized: the Irvingtonian (older Pleistocene fauna) and the Rancholabrean (younger Pleistocene and Holocene fauna). These two divisions of Quaternary Cenozoic vertebrate fossils are widely recognized today in the field of paleontology. The age of the more recent Pleistocene, Rancholabrean fauna was based on the presence of bison and on the presence of many mammalian species that are inhabitants of the same area today. In addition to bison, large land mammals identified as part of the Rancholabrean fauna include mammoths, mastodons, camels, horses, and ground sloths (Dundas 1996).

Remains of land mammals have been found at a number of localities in alluvial deposits of the Modesto Formation or the Riverbank Formation. These units are Pleistocene in age, and remains discovered in these units would be considered fossils. Thus action-related activities may have an effect on paleontological resources if conducted on these units and resources are present. No paleontological resources have been discovered in the course of dozens of soil test-pits conducted for the project, but there remains a potential for them to be present.

3.7.2 Environmental Consequences

Alternative A—No Action

Under the No Action Alternative, there would be no adverse effects on geologic resources. However, the future conditions would change to support agricultural activities. Potential effects would be evaluated by the County under CEQA, depending on the discretionary permits needed.

Alternative B—Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities

Effect GEO-1: Potential Exposure of People or Structures to Substantial Adverse Effects Resulting from Liquefaction Based on existing conditions, the potential for liquefaction to occur in Madera County is low. Implementation of Alternative B would raise the groundwater table to depths as shallow as 30 feet below the ground surface in places under and near Madera Ranch; however, it would not increase the potential for liquefaction because soils and sediments on and in the vicinity of Madera Ranch generally are not susceptible to liquefaction. Additionally, there would be few structures constructed as part of this alternative, and it is not expected that the risk to people or structures would change. As such, there would be no effect.

Effect GEO-2: Potential Subsidence Caused by Groundwater Overdraft The potential for subsidence on Madera Ranch is low to moderate depending on subsurface geological effects influenced by the location of application of banked water and the location and depth of recovery of banked water. Banking of water would be located in areas with the greatest percolation capacity, including the swales that have historically supported natural percolation. Recovery of banked water would be from a depth above the confined aquifer and would not directly affect the confined aquifer. However, operations would indirectly affect recharge to the confined aquifer and directly affect the seepage stress across the Corcoran clay underlying Madera Ranch. In the east of the site, the Corcoran clay is thin and the area tends to respond as a single unconfined aquifer, making subsidence in this area unlikely. On the western portion of the site, the Corcoran clay is thicker and project operations could have an effect on head differences above and below the Corcoran clay (Bookman-Edmonston 2003). No substantial increases in subsidence are expected to occur because pumping would be above the Corcoran clay, MID would leave 10% of the banked water in the aquifer, and the MROC would monitor the effects on ground surface elevations and would restrict project operations if subsidence is observed. As such, there would be no adverse effect.

Effect GEO-3: Potential Risks to Property Caused by Construction on an Expansive Soil Most of the soils and sediments on which facilities would be constructed are coarse- and moderately coarse-textured and would not be classified as expansive according to Table 18-1-B of the Uniform Building Code. However, some portions of the area in which facilities would be constructed are in areas with expansive soils. All of the facilities would be engineered and designed according to the Uniform Building Code in order to prevent any structural damage from soil expansion and contraction. There would be no effect.

Effect GEO-4: Potential Loss of a Substantial Amount of Topsoil from Land Grading Operations Topsoil materials would be stripped from all areas to be graded, temporarily stockpiled, and reapplied as a top-dressing once final grade is attained. There would be no effect.

Effect GEO-5: Increase in Wind and Water Erosion Rates during and Shortly after Construction The extensive land- and soil-stockpiling activities could cause a temporary increase in wind and water erosion rates. Such increased rates would occur during and shortly after construction. The potential for land-grading and soil-stockpiling activities to have such an effect on erosion rates would be greatest in a groundwater recharge basin, where the volume of soil disturbed and changes to existing slope gradients would be the most extensive.

An increase in wind erosion rates could result in the loss or redistribution of soil material and could have an adverse effect on air quality. However, the consequences of increased water erosion rates during and shortly after construction would vary considerably with the location.

To control water and wind erosion during construction, MID will prepare a Storm Water Pollution Prevention Plan (SWPPP) in compliance with the requirements of the National Pollutant Discharge Elimination System (NPDES) General Construction Permit, and the Central Valley Regional Water Quality Control Board (RWQCB) would administer the SWPPP (Environmental Commitment WQ-1a). The SWPPP would prescribe temporary Best Management Practices (BMPs) to control accelerated wind and water erosion during and shortly after construction and permanent BMPs to control erosion and sedimentation once construction is complete. The County would require that MID prepare an erosion-control plan and obtain a grading permit before initiating construction of facilities. This effect is not considered adverse.

Effect GEO-6: Increase in Long-Term Wind and Water Erosion Rates Extensive land-grading activities that would be undertaken during construction temporarily would increase the hazard of erosion at the Madera Ranch site by increasing slope gradients and exposing highly erodible soils to erosion by wind and water. The potential for an action alternative to have such an effect would be greatest in the groundwater recharge window, where the volume of soil disturbed and changes to existing slope gradients would be the most significant.

Once construction is complete, all graded surfaces, including the soil disposal areas located between the groundwater recharge basins, would be revegetated by re-applying stockpiled topsoil using methods to be described in the SWPPP.

The SWPPP may specify that topsoil will be stripped from the footprint of the recharge basins during initial grading operations, temporarily stockpiled, and reapplied to the surfaces of the soil disposal piles once final grade is established. The strippings, which would contain the rhizomes and seeds of native and naturalized grasses and forbs, would serve as the main seedbank for revegetation. Topsoiling is intended to establish native and naturalized vegetation to control potential wind and water erosion. The vegetation should be sufficient to stabilize the soil disposal piles and maintain erosion rates at or near preconstruction levels once construction is complete. However, many of the topsoils that exist in the footprint of the Phase 2 groundwater recharge basins are at least slightly saline-alkali.

Although many of the soils in these areas have been partially reclaimed for agricultural purposes (Roughton pers. comm.[1]), most probably still contain excess salinity, alkalinity, and exchangeable sodium, which can limit soil infiltration capacity and permeability and interfere with normal plant growth and seed germination. Repeated handling of weakly structured topsoil materials during grading operations would degrade the soil structure, which would exacerbate the adverse effect of excess exchangeable sodium on soil infiltration capacity. Therefore, the chemical and physical properties of the topsoil materials that would be applied to the surfaces of the soil disposal piles for revegetation purposes could cause significant runoff and interfere with the establishment and survival of vegetation. As a result, wind and water erosion rates could increase above preconstruction levels.

The degree to which soil salinity, alkalinity, and exchangeable Na+ would retard vegetation establishment in topsoiled areas is unknown because of the variability in depth of excavation, distribution of salts throughout the soil profile, and other factors. As an example, the vegetation at a pilot infiltration pond that was constructed in 2000 fully established in a reasonable amount of time, although the area was mapped as strongly saline-alkali, the applied soil was not segregated, and disturbed areas were not seeded.

However, if vegetation does not sufficiently establish (i.e., minimum of 70% vegetative cover one year after application) in topsoiled areas, substantial accelerated erosion could occur. This effect could be adverse, unless measures were implemented to promote vegetation growth.

Implementing of Environmental Commitment GEO-1, Amend Soils as Required in Topsoiled Areas, in the event of insufficient vegetation establishment would reduce the intensity of this effect.

Effect GEO-7: Potential Destruction of a Unique Pedologic Feature Research indicates that soil slickspots are a unique pedologic feature that occurs on sodic soil landscapes throughout the United States. In California, they once occurred primarily on alluvial landforms in the San Joaquin and Sacramento Valleys. However, because of the extensive agricultural development that has occurred in these areas, the abundance and distribution of slickspots in California have been reduced significantly. Consequently, slickspots have become somewhat rare.

Some of the groundwater recharge basins and other elements of Alternative B are proposed in areas supporting generally undisturbed soil slickspot terrain. Permanent effects on such terrain could extend over more than 300 acres. Grading and excavation to form the recharge basins and other elements could permanently destroy the slickspots. This effect is considered adverse because it could result in the loss of unique, nonrenewable pedologic features.

Implementing Environmental Commitment BIO-1, Establish a Grasslands Conservation Easement, would reduce the extent and intensity of this effect because the easement at Madera Ranch would incorporate an area larger than the area subject to long-term degradation: (2 acres conserved: 1 acre affected for swales) or permanent loss (3 acre conserved: 1 acre lost).

Effect GEO-8: Potential Soil Salinization from Elevated Groundwater Levels Alternative B could raise existing groundwater elevations (and salinity) significantly. In certain areas on and near the Madera Ranch site, an elevated water table could result in the salinization of the root zones of economically important, deep-rooted fruit and nut crops that occur in the vicinity of the site and could thereby adversely affect their growth.

Simply defined, *salinization by groundwater* is a process by which excess soluble salts are concentrated in the soil (root zone) during the evapotranspiration (ET) of saline groundwater. The mechanisms involved in this process vary, depending on the location of the water table relative to the root zone.

When groundwater is shallow enough to occupy all or a portion of the root zone, ET occurs directly from the water table. Salts dissolved in the groundwater are left behind in the process and accumulate in the root zone, where they can have various adverse effects on soil properties and plant growth.

When the water table is beneath the lower boundary of the root zone, the process of salinization by groundwater is somewhat more complex. In such a situation, plant roots cannot access the groundwater directly, and evaporation of groundwater at the soil surface can be negligible. However, groundwater and dissolved salts can move upward into the root zone in response to the water potential gradient (i.e., the potential for water to move upward) that exists between the surface of the water table and overlying soil materials. Once in the root zone, the groundwater can evaporate at the soil surface and be transpired by vegetation. In this case, soluble salts in the groundwater are left behind and accumulate in the root zone, as described above. Because the capillary forces that arise as a result of the interaction between water and soil are a major driving force in this upward movement of groundwater, the process frequently is referred to as *capillary flow* or *capillary rise*, and soil salinization resulting from capillary flow frequently is referred to as *capillary salinization*.

The upward, capillary flow of groundwater can be extensive (several yards), but the rate of flow generally decreases with increasing height above the water table. Because the rate of salt movement is in proportion to the rate of water movement, it also decreases with increasing height above the water table. The distance at which the rate of capillary flow becomes too small for any significant upward movement of salt is defined as the *critical capillary height* (H_c) (Smedema and Rycroft 1983). The critical capillary height is primarily a function of soil texture, with fine-textured soils generally having greater values than coarse-textured soils. Because the upward movement of salt is the product of the capillary flow rate and the salt content, H_c also increases with the salt content of the groundwater. Characteristic values of H_c for some common soil textures are as follows:

- sand, 19.6-29.5 inches;
- loamy sand and sandy loam, 39.3-59.0 inches;
- loam, clay loam, and clay, 39.3-59.0 inches; and
- fine sandy loam and silt loam, 39.3- 78.7.

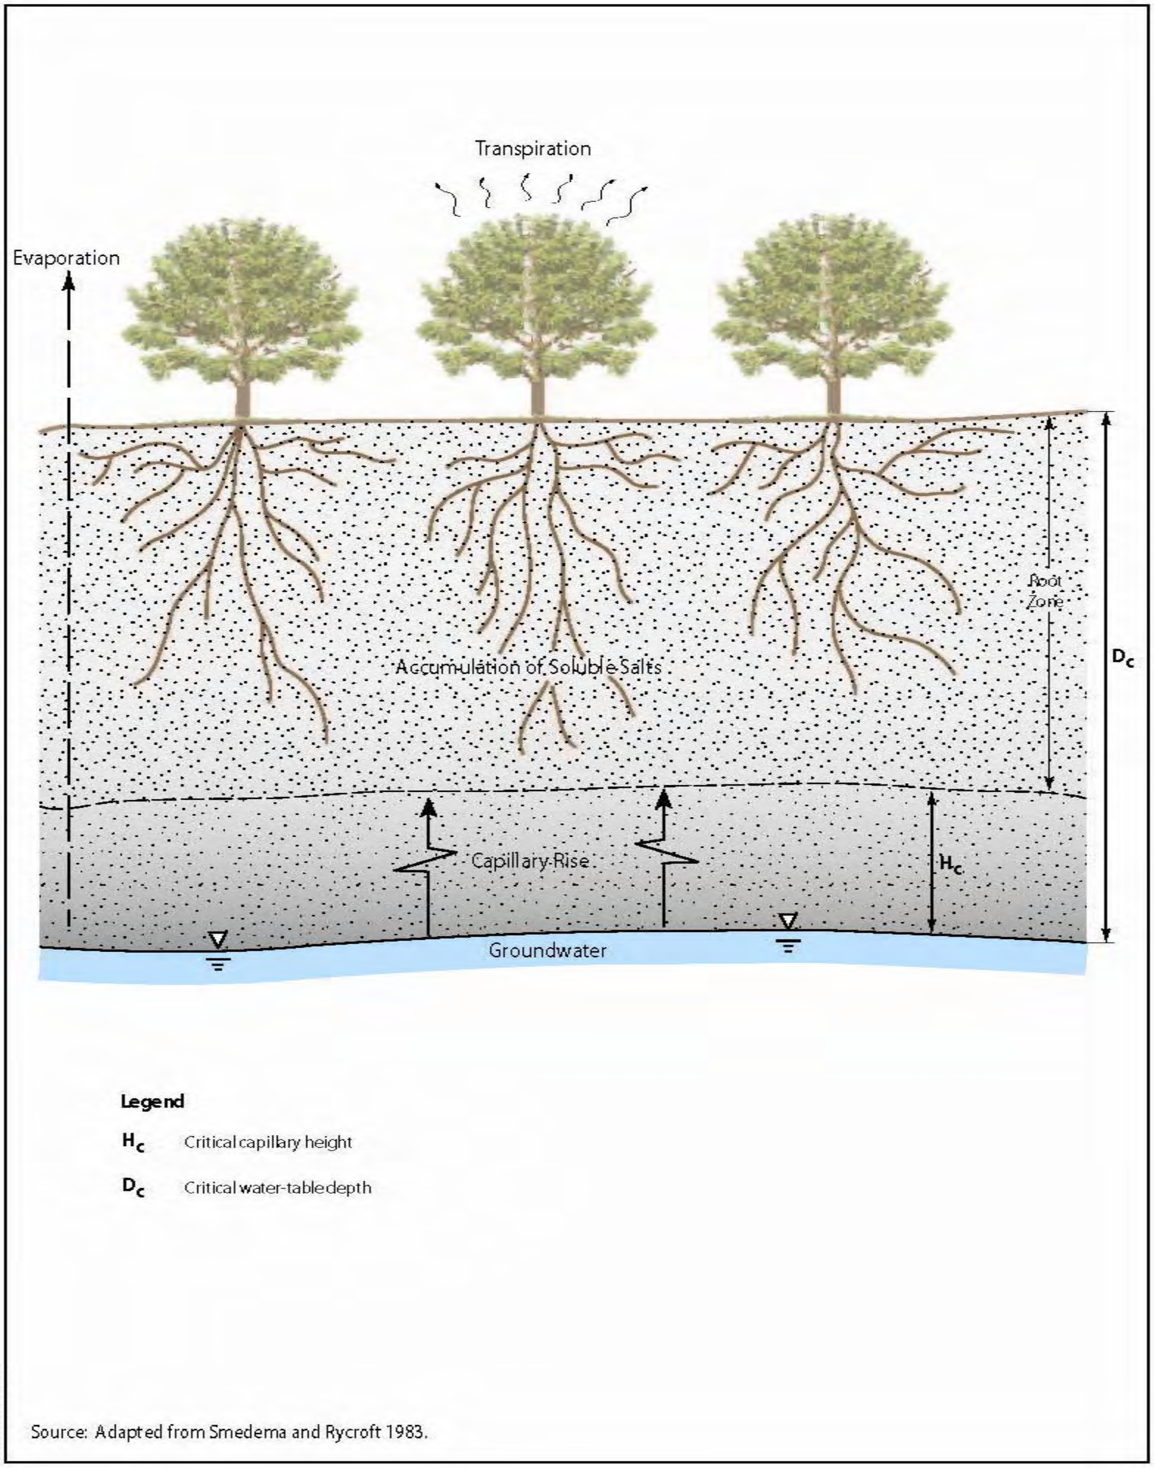
If the water table falls below a certain elevation, known as the *critical water-table depth* (D_c) (Figure 3-6), the capillary zone (H_c) will not extend into the root zone, and capillary salinization will not occur. If the water table is located above the critical water-table depth, capillary salinization is possible (Figure 3-6). Regardless of the depth of the water table or the value of Hc, there will be little capillary salinization of the root zone if the salinity of the groundwater remains less than 1,000 milligrams per liter (mg/l) (i.e., Electrical Conductivity less than 1.5 deciSiemens/meter) (Smedema and Rycroft 1983).

A soil scientist determined the potential for water tables affected by Alternative B to salinize the soil (root zone) in Madera Ranch. To do so, the soil scientist calculated D_c based on a worst-case estimate for the value of H_c and a reasonable estimate of the maximum rooting depth for three common, deep-rooting fruit and nut crops grown at Madera Ranch: almonds, grapes, and pistachios.

Almond-tree roots have been found as deep as 25 feet in Madera County (Holtz pers. comm.); however, University of California Extension farm advisors indicate that a reasonable estimate of the maximum rooting depth of almonds, grapes, and pistachios in a relatively uniform soil with no restrictive layers (i.e., slowly permeable soil horizons) is approximately eight–10 feet (Ferguson pers. comm., Freeman pers. comm.). Assuming that the value of H_c at Madera Ranch is at most 6.5 feet, the value of D_c would be approximately 14–17 feet below the ground surface. Because Alternative B would be operated and constrained so that affected water tables would not reach elevations higher than 30 feet below the ground surface at the Madera Ranch site boundary (i.e., would not extend above D_c), groundwater would not cause salinization of the root zones of important, deep-rooting agricultural crops surrounding Madera Ranch. Therefore, there would be no effect.

Effect GEO-9: Potential Destruction of a Sensitive Paleontological Resource Sensitive paleontological resources (e.g., fossils, trackways) have been reported in various sediments in the San Joaquin Valley, particularly in the relatively older (and usually deeper) geologic formations. Because the near-surface sediments underlying the site are geologically young and because the depth of excavation would be fairly shallow, there is a relatively low probability that excavation activities would disturb buried fossils. Nevertheless, because the possibility exists for a sensitive fossil to be discovered, the potential exists for Alternative B to destroy a sensitive paleontological resource, resulting in an adverse effect.

Implementing Environmental Commitment GEO-2, Stop Work in Event of Fossil Discovery, would minimize the intensity of the effect.



Source: Adapted from Smedema and Rycroft 1983.

Figure 3-6 Capillary Salinization of the Root Zone by Groundwater

Reduced Alternative B—Water Banking Outside the MID Service Area Using Select Swales and Alteration of Reclamation-Owned Facilities

Reduced Alternative B is similar in scope and design to Alternative B, with the primary exception that a reduced number of natural swales will be used (550 acres versus 700 acres as proposed under Alternative B) and a reduced number of basins will be constructed (323 acres versus up to 1,000 acres under Alternative B). Reduced Alternative B would also exclude construction of the Section 8 canal southwest extension. Because Reduced Alternative B would use fewer swales and limit the number of recharge basins, the potential for erosion by wind and water due to extensive land-grading activities and potential for destruction of a sensitive paleontological resource or unique Pedologic Feature (Effects GEO-6, GEO-7, and GEO-9) would be reduced. Under Reduced Alternative B, effects on geologic resources (Effects GEO-1, GEO-2, GEO-3, GEO-4, GEO-5, GEO-6, GEO-7, GEO-8, and GEO-9) would be considered minor, except for the loss of soil slickspot terrain (Effect GEO-7) and the potential loss of paleontological resources discovered during construction (Effect GEO-9), which are considered adverse. Implementation of Environmental Commitments BIO-1 and GEO-2, respectively, would reduce the intensity and minimize the extent of these effects. The effect of implementing Reduced Alternative B on local groundwater conditions has been determined to be beneficial.

Alternative C—Water Banking outside the MID Service Area without Swales and Alteration of Reclamation-Owned Facilities

Alternative C is similar in scope and design to Alternative B, with the primary exception that the natural swales that occur on the site would not be used for recharge. Thus, engineered basins could change slightly the pattern of groundwater recharge at the site. The expected footprint of recharge basins under Alternative C would be similar to Phase 2 of Alternative B and would result in equivalent effects on geologic resources during construction and operation (Effects GEO-1, GEO-2, GEO-3, GEO-4, GEO-5, GEO-6, GEO-7, GEO-8, and GEO-9). Effects on geologic resources would be considered minor, except for the loss of soil slickspot terrain (Effect GEO-7) and the potential loss of paleontological resources discovered during construction (Effect GEO-9), which are considered adverse. Implementation of Environmental Commitments BIO-1 and GEO-2, respectively, would reduce the intensity and minimize the extent of these effects. The effect of implementing Alternative C on local groundwater conditions has been determined to be beneficial.

Alternative D—Water Banking outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal

Alternative D is similar in scope and design to Alternative B, with the exception that water would be conveyed to the site via GF Canal. For this reason, one recharge basin would not be built under Alternative D that was proposed under Alternative B. However, the expected footprint of recharge basins under Alternative D would be nearly identical to that under Alternative B and would result in equivalent effects on geologic resources during construction and operation (Effects GEO-1, GEO-2, GEO-3, GEO-4, GEO-5, GEO-6, GEO-7, GEO-8, and GEO-9). Effects on geologic resources would not be considered adverse, excluding the loss of soil slickspot terrain (Effect GEO-7) and the potential loss of paleontological resources discovered during construction (Effect GEO-9), which are considered adverse. Implementation of Environmental Commitments BIO-1 and GEO-2, respectively, would reduce the intensity and minimize the extent of these effects. The effect of Alternative D on local groundwater conditions has been determined to be beneficial.

Cumulative Effects

None of the effects described above has the potential to result in an adverse contribution to the regional cumulative effects on geologic resources in Madera County, with one potential exception. The abundance and distribution of slickspots in California have been reduced significantly; thus, losses at Madera Ranch could result in an adverse cumulative effect on this pedologic resource. Environmental Commitment BIO-1 is anticipated to protect this resource at Madera Ranch and thus not contribute to regional cumulative effects.

As Reduced Alternative B and Alternatives C and D are equivalent in scope and overall effect to Alternative B, it is anticipated that these alternatives would not contribute to cumulative effects on geologic resources.

3.8 Global Climate

Climate change refers to significant change in measures of climate (e.g., temperature, precipitation, or wind) lasting for decades or longer. Many environmental changes can contribute to climate change [changes in sun's intensity, changes in ocean circulation, deforestation, urbanization, burning fossil fuels, etc.] (Environmental Protection Agency 2010a)

Gases that trap heat in the atmosphere are often called greenhouse gases (GHG). Some GHG, such as carbon dioxide (CO_2), occur naturally and are emitted to the atmosphere through natural processes and human activities. Other GHG (e.g., fluorinated gases) are created and emitted solely through human activities. The principal GHG that enter the atmosphere because of human activities are: CO_2, methane (CH_4), nitrous oxide (N_2O), and fluorinated gasses (Environmental Protection Agency 2010a).

During the past century humans have substantially added to the amount of GHG in the atmosphere by burning fossil fuels such as coal, natural gas, oil and gasoline to power our cars, factories, utilities and appliances. The added gases, primarily CO_2 and CH_4, are enhancing the natural greenhouse effect, and likely contributing to an increase in global average temperature and related climate changes. At present, there are uncertainties associated with the science of climate change (Environmental Protection Agency 2010b).

The most notable regulation related to GHG emissions in the Proposed Action area is the California Global Warming Solutions Act of 2006, widely known as Assembly Bill 32, which requires the California Air Resources Control Board (CARB) to develop and enforce regulations for the reporting and verification of statewide GHG emissions. The CARB is directed to set a GHG emission limit, based on 1990 levels, to be achieved by 2020. The bill sets a timeline for adopting a scoping plan for achieving GHG reductions in a technologically and economically feasible manner.

3.8.1 Affected Environment

More than 20 million Californians rely on the SWP and CVP. Increases in air temperature may lead to changes in precipitation patterns, runoff timing and volume, sea level rise, and changes in the amount of irrigation water needed due to modified evapotranspiration rates. These changes may lead to impacts to California's water resources and project operations.

The Proposed Action is located in the SJVAB, which is within the jurisdiction of the SJVAPCD. The SJVAPCD has not adopted programs addressing global climate change. However, at its August 21, 2008, meeting, the governing board of the SJVAPCD took action authorizing the Air Pollution Control Officer to begin development of a Climate Change Action Plan, which would include development of guidance for considering GHG in the CEQA process; development of a carbon exchange bank for voluntary GHG reductions in the SJVAB; development of voluntary emission reduction agreements to mitigate GHG increases associated with new projects; and encouragement of the development of climate protection measures that reduce GHG emissions as well as toxic and criteria pollutants and opposition to measures that result in significant increases in toxic or criteria pollutant emissions in already affected areas.

3.8.2 Environmental Consequences

The Proposed Action's incremental increases in GHG emissions associated with off-road construction equipment would contribute to regional increases in GHG emissions and associated climate change effects. Operational effects resulting from pumping at wells and lift stations to deliver water to users also would produce GHG emissions through the combustion of propane if propane pumps are used. The assessment of climate change impacts considers each of these potential sources.

Construction Effects Assessment Methods

Construction emissions were calculated based on the type and magnitude of development that would occur during the construction period. Proposed Action–related factors used to evaluate construction climate change impacts include:

- *CO_2, CH_4, and N_2O Emissions from Construction Equipment:* Type, number of pieces, and usage for each type of construction equipment; estimated fuel usage and type of fuel (diesel, gasoline) for each type of equipment; and emission factors for each type of fuel.
- *CO_2, CH_4, and N_2O Emissions from Delivery and Haul Trucks:* Type, capacity, number of trips, haul distance, and Emfac2007 emission factors from URBEMIS 2007.
- *CO_2, CH_4, and N_2O Emissions from Grading, Excavation, and Hauling Equipment:* Type and number of pieces of equipment to be used, projected haul routes associated with soil movement, and fuel emission factors.
- *CO_2, CH_4, and N_2O Emissions from Other Mobile Sources:* Mobile source emissions associated with haul truck activities and worker commute trips were evaluated based on information provided by the project applicant.

The URBEMIS 2007 model (version 9.2.4) was used to calculate CO_2 emissions associated with construction. URBEMIS 2007 accounts for CO_2 emissions resulting from fuel use by construction equipment and worker commutes.

URBEMIS does not quantify CH_4 and N_2O emissions, although these two pollutants are emitted from construction equipment. CH_4 and N_2O emissions associated with construction emissions from off-road equipment were determined by scaling the construction CO_2 emissions predicted by URBEMIS by the ratio of CH_4/CO_2 and N_2O/CO_2 emissions expected per gallon of diesel fuel according to the California Climate Action Registry diesel fuel emission estimates (The Climate Registry 2008).

Because GHG have long atmospheric lifetimes, total GHG emissions were summed for the length of the construction period.

Operational Effects Assessment Methods

Operation emissions for the action alternatives would include both indirect mobile-source emissions and direct stationary source emissions. Emissions from mobile sources associated with operation of the alternatives would be generated by workers commuting, but because the alternatives would employ only a few workers, the emissions associated with commute trips would be negligible.

If propane engines are used, direct emissions from stationary sources would result from their operation to drive pumps installed at wells and lift stations. The primary operational emissions associated with the Proposed Action are expected to include CO_2, CH_4, and N_2O emitted as IC engine exhaust. Operational emissions of GHG were estimated using calculations based on emission factors from The Climate Registry (The Climate Registry 2008).

MID provided information on the estimated size and number of engines for wells and lift station pumps. Worst-case engine hp requirements were used to estimate emissions for the purposes of this analysis to ensure that all potentially adverse effects are disclosed. However, actual or average emissions likely will be substantially lower than the worst-case emissions scenario.

Alternative A—No Action

Under the No Action Alternative, changes in the GHG emissions. However, the future conditions would likely change to support agricultural activities or water banking activities. Thus, additional climate change effects could occur based on future land use; the amount and type of climate change effects would depend on future practices.

Alternative B—Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities

Effect CC-1: Increased GHG Emissions during Construction Increases in GHG in the atmosphere may result in climate changes. California relies on snowpack for summer streamflows to provide energy, municipal water, watershed health, and irrigation. A potential rise in sea levels could threaten California's coastal communities. Reduced snowpack, changes in the timing of streamflows, extreme or unusual weather events, rising sea levels, increased occurrences of vector-borne diseases, and effects on crop health could significantly affect the environment in Madera County. Construction of the Proposed Action would result in the direct emissions of GHG through the use of petroleum fuels and indirect emissions through the use of electrical power.

Section 2, ―Alternatives," presents measures that would be implemented as part of the Proposed Action to reduce dust (Environmental Commitment AQ-1) and vehicle exhaust emissions (Environmental Commitment AQ-2), and some of these measures also would help reduce GHG emissions.

The Proposed Action's incremental increases in GHG emissions associated with off-road construction equipment would contribute to regional increases in GHG emissions and associated climate change effects. This analysis presents the quantity of GHGs that would be emitted with implementation of the Proposed Action in the context of the total GHG emissions in California. The GHG mass calculations were performed using The Climate Registry's emissions factors for diesel fuel for construction equipment and were converted into units of carbon dioxide equivalents (CO_2e) using the IPCC's Second Assessment Report global warming potential values. Table 3-19 provides a summary of the estimated indirect and direct GHG emissions from construction.

Table 3-19 Maximum Construction Emissions for the Proposed Action (metric tons)

Emission Source	CO_2	CH_4	N_2O	CO_2e
On-site heavy equipment, including fugitive dust and worker trips				
Phase 1	4,884.6	0.3	0.1	4,929.3
Phase 2 (grading)	3,683.9	0.2	0.1	3,717.6
Worker Trips—Fresno	390.2	0.0	0.0	393.8
Worker Trips—Madera	38.0	0.0	0.0	38.3
Worker Trips—Chowchilla/Firebaugh	18.7	0.0	0.0	18.9
Haul Trucks	875.9	0.1	0.0	883.9
Total	**9,891.4**	**0.6**	**0.3**	**9,981.8**

The total estimated CO_2e emissions during construction would be approximately 9,982 metric tons. This is approximately 0.002% of the CO_2e emissions for California in 2004 (California Air Resources Board 2007). These emissions would not continue past the Proposed Action completion date. As such, this would not result in a substantial change in GHG emissions, and there would be no adverse effect.

Effect CC-2: Increase in GHG Emissions as a Result of Operation and Maintenance

Operation of the Proposed Action would require pumping at wells and lift stations to deliver water to users. For the purpose of this analysis, MID conservatively has assumed that all new pumps could be propane-powered. Use of electric pumps in place of propane pumps would reduce GHG emissions from operations. Propane-fueled IC engines that exceed 50 hp would require a permit from the SJVAPCD. Because the electric pumps at existing wellhead locations are not expected to contribute any operational emissions as a result of this action, they are not addressed in this analysis, which focuses instead on the worst-case scenario, the potential emissions associated with cycling and operation of the propane-fueled IC (catalytic-controlled) engines.

The engines could be used up to 24 hours per day and up to a total operating time of 2,880 hours per year. The emission estimate uses the worst-case scenario of 102 engines with a combined total of 7,385 hp. It was assumed that the pumps would consume 8,500 British thermal units per horsepower-hour (btu/hp-hr) (Israelson 1962). Table 3-20 provides a summary of the estimated direct GHG emissions from operation.

Table 3-20 Alternative B–Related Emissions from Operations (tons per year)

	CO_2	CH_4	N_2O	CO_2e
Controlled emissions from IC engines at wells and lifts/stations	11,402.1	0.02	0.07	11,425.4

Notes:
Estimate assumes a combined total of 7,385 hp.
Estimate assumes engine operating time of 2,880 hours per year.
Propane fuel consumption estimated at 8,500 btu/hp-hr (Israelson 1962). Emission factors for propane based on The Climate Registry General Reporting Protocol (The Climate Registry 2008).

This emission estimate is based on a worst-case scenario of all engines operating on propane fuel and pessimistic assumptions for the maximum number of engines required. In the event that a combination of propane- and electric-powered engines is used or fewer engines are required, the emissions would be reduced.

The annual estimated operational increase in CO_2e emissions under the Proposed Action would be approximately 11,425 metric tons. This is approximately 0.002% of the projected CO_2e emissions for California in 2004 (California Air Resources Board 2007).

The Proposed Action's contribution to global climate change is small compared to the total California emissions, but operation of propane-powered pumps over the life of the WSEP could result in an adverse effect. Implementation of Environmental Commitments AQ-3: Use Electric Pumps would reduce the severity of this effect.

Effect CC-3: Secondary Emissions at Power Plants Electricity and natural gas usage by the pumps and any additional facilities to be constructed or improved as a result of the Proposed Action is expected to be minimal. Use of electricity instead of propane for the pumps is expected to decrease GHG emissions from pumping activities. Maintenance activities of existing facilities, including facility upkeep and operation, would not change as a result of the Proposed Action. Additionally, the maintenance associated with new facilities such as ponds would not result in noticeable changes in emissions. Table 3-21 summarizes electricity-related GHG emissions associated with project operations. These emissions would not be considered an adverse effect.

Table 3-21 Electricity-Related GHG Emissions Operations, Alternatives B–D (metric tons per year)

	Total Electricity Usage (kWh/year)	CO_2 Emissions	CH_4 Emissions	N_2O Emissions	CO_2e Emissions
kWh Off peak	1,738,613	385.76	0.0238	0.0064	388.2
kWh Partial peak	1,096,082	243.20	0.0150	0.0040	244.8
kWh On peak	944,898	209.65	0.0129	0.0035	211.0
kWh Off peak	180,986	40.16	0.0025	0.0007	40.4
kWh Partial peak	180,986	40.16	0.0025	0.0007	40.4
Total	**4,141,565**	**919**	**0**	**0**	**925**

Reduced Alternative B—Water Banking Outside the MID Service Area Using Select Swales and Alteration of Reclamation-Owned Facilities

Reduced Alternative B is similar in scope and design to Alternative B, with the primary exception that a reduced number of natural swales would be used and a reduced number of basins would be constructed. Reduced Alternative B would also exclude construction of the Section 8 canal southwest extension. The construction activities and operational needs under Reduced Alternative B would be similar to Alternative B and would result in similar effects on climate change. Consequently, GHG emissions would be similar to those described under Alternative B.

Alternative C—Water Banking outside the MID Service Area without Swales and Alteration of Reclamation-Owned Facilities

Alternative C is similar in scope and design to Alternative B, with the primary exception that the natural swales that occur on the site would not be used for recharge, and ponds would be constructed instead. The construction activities and operational needs under Alternative C would be similar to Alternative B and would result in similar effects on climate change. Consequently, GHG emissions would be similar to those described under Alternative B because recharge ponds would be constructed under this alternative.

Effect CC-1: Increased GHG Emissions during Construction Construction activities under Alternative C would be similar to those under Alternative B. The total estimated CO_2e emissions during construction are estimated to be approximately 9,982 metric tons (Table 3-19). Consequently, the effect on climate change from construction activities is considered similar to the effect under Alternative B. These emissions would be considered an adverse effect. Implementation of Environmental Commitments AQ-1, AQ-2, and AQ-3 would reduce the intensity of this effect.

Effect CC-2: Increase in GHG Emissions as a Result of Operation and Maintenance Operational activities under Alternative C would be similar to those under Alternative B. The annual estimated operational increase in CO2e emissions under Alternative C would therefore be approximately 11,425 metric tons (Table 3-20). Consequently, the effect on climate change from operational activities is considered equivalent to that under Alternative B. These emissions would be considered an adverse effect. Implementation of Environmental Commitment AQ3: Use Electric Pumps would reduce the intensity of this effect.

Effect CC-3: Secondary Emissions at Power Plants Electricity and natural gas usage required by the pumps and any additional facilities to be constructed or improved as a result of Alternative C is expected to be minimal. Use of electricity instead of propane for the pumps is expected to decrease GHG emissions from pumping activities. Maintenance activities, including facility upkeep and operation, do not change as a result of this alternative. Table 3-21 summarizes electricity-related GHG emissions associated with project operations. These emissions would not be considered an adverse effect.

Alternative D—Water Banking outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal

Alternative D would result in an increase in GHG during construction due to additional grading and reshaping of the off-site portions of GF Canal. These effects would be larger than the reduction in air quality effects associated with fewer Section 8 canal improvements and elimination of the 24.2 lateral improvements.

Effect CC-1: Increased GHG Emissions during Construction Construction activities under Alternative D are summarized in Table 3-22.

Table 3-22 Alternative D–Related Emissions from Construction (metric tons)

Emission Source	CO_2	CH_4	N_2O	CO_2e
On-site heavy equipment, including fugitive dust and worker trips				
Phase 1	6,240.9	0.4	0.2	6,297.9
Phase 2 (grading)	3,683.9	0.2	0.1	3,717.6
Worker Trips—Fresno	390.2	0.0	0.0	393.8
Worker Trips—Madera	38.0	0.0	0.0	38.3
Worker Trips—Chowchilla/Firebaugh	18.7	0.0	0.0	18.9
Haul Trucks	875.9	0.1	0.0	883.9
Total	**11,247.6**	**0.6**	**0.3**	**11,350.4**

The total estimated CO_2e emissions during construction therefore are estimated to be approximately 11,350 metric tons. Consequently, the effect on climate change from construction activities is considered equivalent to that which would occur under Alternative B. These emissions would be considered an adverse effect. Implementation of Environmental Commitments AQ-1 and AQ-2 would reduce the intensity of this effect.

Effect CC-2: Increase in GHG Emissions as a Result of Operation and Maintenance Operational activities under Alternative D would be similar to those under Alternative B. The annual estimated operational increase in CO_2e emissions under Alternative D therefore would be approximately 11,425 metric tons. Consequently, the effect on climate change from operational activities is considered equivalent to that under Alternative B. These emissions would be considered an adverse effect. Implementation of Environmental Commitments AQ-1, AQ-2, and AQ-3 would reduce the intensity of this effect.

Effect CC-3: Secondary Emissions at Power Plants Electricity and natural gas usage required by the pumps and any additional facilities to be constructed or improved as a result of Alternative D is expected to be minimal. Use of electricity instead of propane for the pumps is expected to decrease GHG emissions from pumping activities. Maintenance activities, including facility upkeep and operation, do not change as a result of implementing this alternative. Table 3-21 summarizes electricity-related GHG emissions associated with project operations. These emissions would not be considered an adverse effect.

Cumulative Effects

Climate change is a global problem, and GHG are global pollutants. As such, impacts of the Proposed Action and its alternatives on climate change (Effects CC-1 to CC-3) have been evaluated from a cumulative perspective. Although emissions resulting from the Proposed Action and its alternatives may not be significant on a project level, the combination of emissions from many sources results in substantial effects on climate change. Consequently, emissions generated from the Proposed Action and its alternatives are considered to have adverse effects on climate change as discussed above.

Table 3-23 provides a summary of the estimated GHG emissions from construction and operation of the Proposed Action. These emissions were calculated for construction and operational activities under Alternatives B and C, as Alternatives B and C are nearly identical in scope and design. Thus, the construction activities and operational needs under Alternatives B and C would be similar.

Table 3-23 Alternative B/C–Related Emissions from Construction and Operations (tons per year)

	CO_2	**CH_4**	**N_2O**	**CO_2e**
Construction	9,401.0	0.3	0.4	9,525.7
Operation	11,402.1	0.02	0.07	11,425.4
Total	**20,803.1**	**0.32**	**0.47**	**20,951.1**

Reduced Alternative B would result in less construction activity and less emissions than Alternative B. In addition, Table 3-24 summarizes GHG emissions from construction and operation of the Proposed Action under Alternative D.

Table 3-24 Alternative D–Related Emissions from Construction and Operations (tons per year)

	CO_2	CH_4	N_2O	CO_2e
Construction	8,395.3	0.5	0.2	8,472.1
Operation	11,402.1	0.02	0.07	11,425.4
Total	**19,797.4**	**0.5**	**0.3**	**19,897.5**

The total estimated CO_2e emissions during construction and operation of the Proposed Action would be approximately 19,898 metric tons. This is approximately 0.004% of the CO_2e emissions for California in 2004 (California Air Resources Board 2007). Construction emissions would not continue past the Proposed Action completion date of 2010, and Environmental Commitments AQ-1 and AQ-2 would reduce the intensity of these effects. Operational emissions are a result of using propane pumps. Environmental Commitment AQ-3 would reduce the intensity of this effect. As such, the Proposed Action would not make a considerable contribution to climate change effects.

3.9 Growth-inducing Effects

Under authority of NEPA, CEQ Regulations require EISs to consider the potential indirect impacts of a proposed action. The indirect effects of an action are those that occur later in time or farther away in distance, but are still reasonably foreseeable, and “may include growth inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate” (40 CFR 1508.8[b]). Specifically, this evaluation of potential growth-inducing impacts addresses whether the project would directly or indirectly: foster economic, population, or housing growth; remove obstacles to growth; increase population growth that would tax community service facilities; or encourage or facilitate other activities that cause significant environmental effects.

Madera County's General Plan and California Department of Finance data sets were consulted for information related to current and future land use, population statistics, and planned growth rates for Madera County. In addition, both the GFWD and MID have developed groundwater management plans to evaluate the availability of groundwater resources to support current and future demands. The City of Madera has finalized its urban water management plan prepared pursuant to state law that documents how the available water supply would accommodate planned growth. Additionally, both the County and the City of Madera were consulted to determine whether projects approved and in process would be facilitated through the availability of M&I banking capacity at Madera Ranch.

The *California Water Plan* (California Department of Water Resources 2005), the *Critical Water Shortage Contingency Plan* (California Department of Water Resources 2000a), *Preparing for California's Next Drought*, *DWR Drought Report* (California Department of Water Resources 2000b), and *Integrated Regional Water Management Plan* (Madera County 2008) were consulted for data on statewide and local water needs, growth, and current and anticipated water shortages.

MID's budget for allocating banking capacity to local M&I users under the Proposed Action and alternatives is up to 10,000 AF/year, while MID could recover up to 45,000 AF/year for its agricultural users. It is important to note that the WSEP is intended to help offset dry or below normal water years, and water recovery for M&I uses is not expected to happen in wet or above normal years. It is reasonable to assume that there would be a net banking in wet years and a net recovery in dry years. As water year types vary, it is not expected that the WSEP would provide firm, or consistent, water supplies to those using the bank. Rather, the WSEP would provide greater water supply reliability in dry or below normal water year types. It would not increase the total amount of water supply available to any users.

Water supply by itself does not drive growth. Development at the local level is guided by many considerations, among them the availability of the water supply. Cities and counties regulate land uses by adopting general plans, zoning, and measures for the control of local growth. However, economic forces largely govern the rate and location of growth.

At the same time, economic and population growth depend on adequate water supplies. A wide range of wholesale and retail institutions plan for and manage water supply to meet current and future demands. It is conceivable that water banked at Madera Ranch could be used to improve water supply reliability or expand water supplies to users in the San Joaquin Valley and Southern California. However, MID's business plan only allows for the use of 10,000 AF/year in support of M&I projects and only within Madera County.

3.9.1 Affected Environment

California is a rapidly growing state with a 2009 population of 37 million people (U.S. Census Bureau-Last Revised: Thursday, 04-Nov-2010). The population is expected to rise to nearly 50 million by 2025 (California Department of Finance 2007).

Locally, the population of Madera County is estimated to have increased from 123,109 in 1991 to 148,632 in 2009 (U.S. Census Bureau-Last Revised: Thursday, 04-Nov-2010). The population of Madera County is estimated to increase to 212,874 by 2020 (California Department of Finance 2007).

Water use in Madera County in 2006 was 1.2 million AF, with approximately 97% (1.17 million AF) applied for agricultural purposes. Within the valley floor area of Madera County, groundwater accounted for approximately 75% of the total agricultural water use. Additionally, all urban and rural water is supplied by groundwater sources. The total county water demand is expected to be about 1.3 million AF/year by 2030, an increase of about 100,000 AF of water, most of which is attributed to growing urban and rural demand. Current overdraft is approximately 100,000 AF and is expected to rise to 155,000 AF if no action is taken in the county (Madera County 2008).

Development has proceeded in Madera County despite the existing overdraft condition. To date, the presence or absence of available groundwater has not been an obstacle to growth. With the preparation of the *Integrated Regional Water Management Plan* the County may revisit its development approval conditions and is looking seriously at a variety of options to resolve the overdraft problem. One option that may be considered is the use of Madera Ranch.

Current and Planned Development

Several residential and commercial developments are currently approved or in a discretionary permit process with the County. These projects have existing water supply rights that could utilize the water bank M&I allocation (Table 3-25). Within Madera County, there is already 7,455 AF/year of existing water supply for planned development that could potentially be banked under the M&I allocation of the alternatives. An additional 12,000 AF/year of existing water supply that could potentially utilize the bank for future development projects has also been identified. Thus, 19,455 AF/year of existing, known water supply identified for use in future land use development have been identified within Madera County. This represents almost double the amount of M&I shares (with one share equaling one AF of water) available at Madera Ranch under the proposed action and alternatives.

Additionally, many potential development projects are also identified in the *Integrated Regional Water Management Plan*; these are more speculative and water supplies for these potential projects have not yet been identified. The source of water for these projects would likely need to be groundwater or out-of-county sources. All of these projects would proceed only after County approvals and after obtaining a firm water supply, which is in no way dependent on the WSEP.

Table 3-25 Known Proposed Future Development in Madera County, Water Supply, and Potential Participants

Development	Total Project Acreage	Residential Units	Commercial/ Industrial Acreage	Status	Total af/ year (if known)	Water Supply Secured Elsewhere	Water Supply Source	Back up Dry Year Storage Needed	Potential Water Bank Participant	Potential Banked at Madera Ranch (af)
Gateway Village	2,392	6,455	185.6	Approved	6,374	Yes	Surface Water Groundwater	Yes	Yes	2,170
North Fork Village—North	2,238	2,522	82.3	Final EIR Pending	1,355	Yes	Unknown	Possibly	Unknown	1,355
Gunner Ranch West	1,135	3,014	209	Plan Pending	–	?	Unknown	Unknown	Unknown	
North Fork Village—Central Green	793	1,646	n/a	Supplemental EIR Pending	–	?	Unknown	Unknown	Unlikely	
Tesoro Viejo	1,574	4,600	n/a	Draft EIR Pending	4,810	Yes	Surface Water & Reclaimed	Possibly	Yes	3,930
Jim Cobb	350	350	60	Application Pending	–	?	Unknown	Unknown	Unlikely	
Dunmore Homes	368	2,064	n/a	Application Pending	–	?	Unknown	Unknown	Unknown	
City of Madera—Existing Homes	n/a	n/a	n/a	Existing Homes	–	?	Groundwater	Unknown	Yes	2,000
City of Madera—New Growth	500–1,000	300–400	50	Various Applications	–		Unknown	Unknown	Yes	1,000
Developer A	1,000–1,500	600	Unknown	Various Applications	1,000–1,200	Yes	Transfers	Yes	Yes	1,000
Developer B	500–1,000	500–1,000	Unknown	Application Pending	500–1,000	Yes	Transfers	Yes	Yes	1,000
Developer C	3,000	7,000	Unknown	Application Pending	7,000	Yes	Transfers	Yes	Yes	7,000
Total										**19,455**

Notes: Developers A–C are not named because final agreements have not been signed.

3.9.2 Environmental Consequences

The effect of MID water banking at Madera Ranch would be to increase the reliability and certainty of water supplies for current users with existing water rights or entitlements. The Proposed Action and alternatives do not include an application to appropriate water, would not involve water transfers, and would not create new water supplies that could be dedicated to urban development. The Proposed Action and alternatives are not anticipated to result in additional employment or demand for residential development within Madera County and therefore would not induce growth through increased economic activity.

Effect GI-1: Inducement of Growth due to Municipal and Industrial Participation in Water Bank

Between the currently identified planned projects and the current overdraft situation, the full 10,000 AF/year of non-MID M&I banking capacity is very likely, if not certain, to be fully utilized. Only participants with an existing water supply would be allowed to participate in the Bank. The banking of this water would not change the overall amount of water available to these M&I users, but does improve the reliability of the supply since the banking capacity provided by the WSEP helps M&I users manage their supplies. This firm supply would be applied to the planned growth regardless of implementation of the WSEP. The WSEP would therefore not cause growth, but removes an obstacle to growth because the increased reliability could make development easier or more attractive.

This growth could result in the conversion of agricultural and other open land to urban. It would be extremely speculative to identify specific areas where growth could occur or the indirect effects on specific community service facilities. The impacts of this growth, if any, would be (and in some cases have been) analyzed either in general plan EIRs for the local jurisdictions or in project-level CEQA compliance documents.

3.10 Hazards, Public Health, and Safety

This section describes the existing environmental setting for analyzing hazards and public health issues potentially affected by the proposed alternatives. The issues include hazardous materials, mosquitoes, drowning, and wildland fire.

3.10.1 Affected Environment

Historical and current agricultural, commercial, and industrial activities associated with the Madera Ranch site and adjoining area have been associated with hazardous materials usage, storage, and disposal. An environmental site assessment was conducted for the area, including Madera Ranch and a greater study area with a radius of five miles. In addition, a limited phase-2 site assessment was completed (TRC 1999, 2002).

Soil Contamination

There are no residences within one mile of known soil contamination and no schools in the vicinity of Madera Ranch. A site assessment was conducted in September 1999 and again in July 2002. This assessment included reconnaissance of Madera Ranch, review of regulatory databases, interviews of property owners and regulatory agency personnel, and limited sampling of groundwater (TRC 1999, 2002). The initial environmental site assessment found no evidence of on-site contamination. However, some past and present on-site fuel storage may have resulted in soil contamination in the immediate area of the storage sites.

Records of three on-site underground storage tanks (UST) were found. The records disclosed that the UST had been removed under the oversight of County Environmental Health Department officials. For all three UST removals, closure letters were issued indicating that no further action was required. The only contamination found through observations during UST removal and limited soil sampling was trace amounts of toluene at one of the UST sites (TRC 1999).

Several of the irrigation wells in Sections 1 and 13 of the Madera Ranch property have been fitted with diesel motors and supporting aboveground storage tanks (AST). These 1,500-gallon diesel AST do not have secondary containment but recently have been equipped with drip collection pans. The soil in the region of the motor and AST pads was stained (TRC 1999). Although stained soil was observed at these AST locations, significant contamination as a result of AST operation is not likely.

Mosquito-Borne Diseases

In addition to being a nuisance, mosquitoes can act as disease-carrying vectors. All species of mosquitoes require standing water to complete their growth cycle. Mosquitoes reproduce year-round, but reproduction is substantially diminished during the cool winter season, roughly October through April, and mosquito suppression activities in Madera County typically begin in March (Dillahunti pers. comm.). Water quality also affects mosquito reproduction. Generally, poor-quality water (water with limited circulation, high temperature, and high organic content) produces greater numbers of mosquitoes than high-quality water (water with high circulation, low temperature, and low organic content) (Collins and Resh 1989). In addition, irrigation and flooding practices may influence the level of mosquito production associated with a water body. Typically, water bodies with water levels that slowly increase or recede produce greater numbers of mosquitoes than water bodies with water levels that are stable or that rapidly fluctuate (Collins and Resh 1989).

Mosquito Species of Concern In Madera County, two species of mosquito are primary targets for suppression (Dillahunti pers. comm.). These two species, *Culex pipiens* and *C. tarsalis*, are potential vectors of encephalitis and West Nile virus. Other species of mosquitoes exist in Madera County that can cause a substantial nuisance in surrounding communities, but the *Culex* mosquito is the vector species of primary concern.

Although the West Nile virus can be transmitted by a number of mosquito species, *Culex* is the most common carrier. This disease is thought to be a seasonal epidemic that flares up in the summer and fall. West Nile virus is spread when mosquitoes that feed on infected birds bite humans and other animals (U.S. Department of Health and Human Services 2005).

The encephalitis mosquito (*C. tarsalis*) breeds in almost any freshwater pond. Birds appear to be the primary blood-meal hosts of this species, but the insect also will feed on domestic animals and humans (Bohart and Washino 1978). This species is the primary carrier in California of western equine encephalitis, St. Louis encephalitis, and California encephalitis and is considered a significant disease vector of concern in the state.

The house mosquito (*C. pipiens*) usually breeds in waters with a high organic material content (Bohart and Washino 1978). This species often is identified by its characteristic buzzing near its host's ear. Although the primary blood-meal host is birds, the house mosquito also can seek out humans. The house mosquito can be a vector of St. Louis encephalitis.

Mosquito Concerns at Madera Ranch Potential mosquito habitat exists on the Madera Ranch site. Natural water features, including swales and vernal pools, are potential mosquito breeding sites. In addition, agricultural ditches and canals and irrigated cropland are potential mosquito breeding sites. Orchards and vineyards surrounding the Madera Ranch site have been identified as breeding areas (Dillahunti pers. comm.).

3.10.2 Environmental Consequences

Hazardous Materials

Effects related to hazardous materials include the mixing of known contaminated soil or groundwater with imported water. Reconnaissance of the site, review of regulatory databases, and interviews of property owners and regulatory agency personnel contained in the initial site assessment (TRC 1999, 2002) form the basis for understanding potential hazardous materials effects. Limited confirmatory sampling, including sampling of agricultural groundwater wells and agricultural soils, was conducted to identify existing and potential groundwater concerns with regard to the mobilization and transport of agricultural nonpoint-source pesticides. California Department of Pesticide Regulation's existing database of groundwater management zones, which was developed using a statistical approach to determine areas of groundwater vulnerability, was reviewed to identify potential areas of pesticide mobilization concerns.

Health Hazards

The creation, removal, and/or management of habitat types, including irrigated agriculture, could increase or decrease the amount of potential breeding habitat for mosquitoes. Management and design of recharge facilities could substantially affect mosquitoes' breeding success. Breeding conditions and abatement requirements were evaluated based on mosquito ecology and control literature, communication with MCMAVCD staff, and the design and operational management specifications of each alternative.

Safety Hazards

Potential physical safety hazards, including drowning and wildland fire, were reviewed based on various risk factors, such as proximity to human populations, ease of public access, and public rights-of way. Potential physical hazards from dam failure were evaluated quantitatively by comparing recharge basin design to the DWR's Division of Safety of Dams (DSOD) criteria.

Alternative A—No Action

Under the No Action Alternative, there would be no adverse effects on public health and safety. However, the future conditions would change to support agricultural activities. Potential effects would be evaluated by the County under CEQA depending on the discretionary permits needed.

Alternative B—Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities

Alternative B would involve the use of hazardous materials during construction and operations (e.g., fuels, lubricants, paints, coatings, pesticides). Also, the water that would be banked in the swales and/or recharge basins could support mosquitoes. Mosquito breeding success could be substantially affected by management and design of the swales or recharge basins. Alternative B could increase or decrease the amount of potential breeding habitat for mosquitoes.

Effect PHS-1: Potential Creation of a Public Hazard from Risk of Drowning Several canals would be enlarged or extended as a result of Alternative B. Maintenance ramps would provide egress at several locations along the canals, most likely near points of Madera County road crossings. Reasonable measures to prevent trespass also have been included in the design of facilities. Safety precautions, such as fencing around the entire Madera Ranch property, warning signs, and setbacks, will be taken. MID will implement Environmental Commitment PHS-1a, Implement Necessary Emergency Preparedness Plan(s), to minimize the potential for this effect. Therefore, the potential hazard of drowning represented by Effect PHS-1 is not considered adverse.

Effect PHS-2: Potential Creation of a Public Hazard from Risk of Berm Failure Recharge basins would be constructed on up to 1,000 acres under Alternative B, although individual basin cells would be on the order of five–80 acres each. These basins would be excavated, and some spoils would be used to form low berms to achieve an effective depth of up to five feet to prevent wind-induced waves from overtopping the berms. Berm heights would vary, depending on topography, but would not exceed five feet.

The DWR's DSOD has developed criteria delineating its jurisdiction over impounded surface water bodies. Because the berms would not exceed a height of five feet, they would be below the DSOD jurisdictional height limit of six feet. The nearest residence is approximately 0.75 mile away, uphill of the recharge basin locations and outside the fenced ranch perimeter. Given the topography of the area between the recharge basins and residences, water escaping in the event of berm failure would pool on land between Madera Ranch and the residence. Thus, there would be no effect.

Effect PHS-3: Potential Creation of a Public Hazard from Risk of Wildland Fire Madera Ranch is covered primarily by annual grassland. During summer months, this dry grassland could pose a fire hazard. Although dense population centers, such as the city of Madera, are physically separated from Madera Ranch by surrounding agriculture, there are several residences near the Madera Ranch site. Existing roads on Madera Ranch would be bladed on a regular basis and could act as firebreaks. The potential fire hazard to the public as a result of accidental ignition of grassland is low, and once constructed Alternative B would not result in changes in this hazard. However, a minor increase in wildfire risks could occur during construction as a result of using construction equipment in the vicinity of dry grassland. Environmental Commitments PHS-1a and PHS-1b would reduce the intensity of this hazard.

Effect PHS-4: Potential Increase in Adult Mosquito Populations Under Alternative B, water would be diverted into 700 acres of swales. Up to 1,000 acres of recharge basins also could be flooded to about three to five feet deep and would have berms with 1:1.5 to 1:2 vertical-to-horizontal slopes. Recharge basins and canals would be managed to control and eliminate emergent vegetation.

During the mosquito-breeding period of March–October, recharge basins and swales used to perform recharge generally would not contain standing water. During nonoperational periods, recharge basins and swales are expected to be fully drained approximately eight months of any given year. The size of each recharge basin cell would be about five to 80 acres, which is enough area to generate wave action from winds, which would suppress development of mosquito larvae. Waves can disrupt the ability of mosquito larvae to penetrate the surface of water and take flight, thus effectively suppressing the population.

Water in the swale areas would range in depth from several inches to four feet, and water flowing through the swales also would discourage development of mosquito larvae. During pilot testing of recharge on the property, MID observed that water percolates quickly. Typically, no standing water remained more than 24 hours after flow to the swales and basins had ceased. Thus, MID expects that mosquito production would be inhibited because during application, water levels would fluctuate rapidly as water flows through the swales and generally would not persist after flows cease. Additionally, only during a few months in spring would the timing for application of the water and the breeding season overlap.

Emergent vegetation is a critical element of mosquito breeding habitat because the vegetation is used as a structure to hold eggs and/or cover larvae. Emergent vegetation would be eliminated from the recharge basins whenever possible to further reduce the likelihood of mosquito production. However, vegetation would not be removed from the swales.

New and enlarged MID conveyances under Alternative B would convey water through the irrigation season according to the currently used schedules but would contain water more frequently because of the conveyance of water to and from the water bank. Months of operation would vary, although the conveyances would carry water primarily during the summer and fall under extraction operations and during the winter under recharge operations. Although mats of algae or other vegetation could develop in the conveyances, providing suitable habitat for mosquito production, algae growth (and control measures) would be the same as under current conditions.

It is conceivable that a net increase in mosquito production, and resulting increased public health risks, could occur; therefore, Effect PHS-4 is potentially adverse. The Environmental Commitment PHS-2 to Implement an Agreement with the MCMAVCD would reduce the intensity of adverse effects.

Effect PHS-5: Potential Exposure or Disturbance of Hazardous Materials or Wastes An initial environmental site assessment at Madera Ranch, including site reconnaissance, database review, and interviews, was conducted in September 1999 and again in July 2002. The site assessment did not identify substantial soil or groundwater contamination on or in the vicinity of

Madera Ranch related to past or present storage, handling, or disposal of hazardous materials and wastes. The initial site assessment also did not identify any significant regional groundwater contamination plume or significant Resource Conservation and Recovery Act-permitted storage facilities within a five-mile radius of the Madera Ranch site.

Although there are no substantial hazardous materials concerns in the Madera Ranch site and vicinity, surface soil contamination associated with AST in Sections 1 and 13 was identified during the site reconnaissance. This type of contamination is commonly found at similar diesel-powered pump engines, and as described above, it was determined that the contamination is limited to the immediate area of the AST. However, Sections 1 and 13 are currently used to grow grain and hay crops and would continue to be used for that purpose as part Alternative B. No recharge basins are proposed for construction in Section 1 or 13, and there are no swales in these sections that could be used for recharge. The only change proposed as part of Alternative B would be that MID would deliver surface water, when available, in lieu of pumping groundwater to irrigate the fields.

During construction and operation, the use of fuels and lubricants for construction equipment and propane pumps has the potential to accidentally release hazardous materials into the environment. To reduce this adverse effect, Environmental Commitment WQ-1b: Implement a Spill Prevention and Control Program would be implemented. Therefore, exposure or disturbance of hazardous materials or waste is not anticipated and there is no effect.

Reduced Alternative B—Water Banking Outside the MID Service Area Using Select Swales and Alteration of Reclamation-Owned Facilities

Reduced Alternative B is similar in scope and design to Alternative B, with the primary exception that a reduced number of natural swales would be used (550 acres versus 700 acres as proposed under Alternative B) and a reduced number of basins would be constructed (323 acres versus up to 1,000 acres under Alternative B). Reduced Alternative B would also exclude construction of the Section 8 canal southwest extension. Thus, there would be no substantive differences in public health and safety effects between Alternative B and Reduced Alternative B. Reduced Alternative B would result in equivalent effects related to an increase in drowning risks at new canals and ditches, berm failure, wildland fires during construction, mosquito production at the recharge basins, and release or disturbance of hazardous materials (Effects PHS-1, PHS-2, PHS-3, PHS-4, and PHS-5). Adverse effects resulting from fire risk (Effect PHS-3) would be mitigated as described under Alternative B (Environmental Commitment PHS-1a and 1b). Although Reduced Alternative B would use fewer swales and limits the number of recharge basins, it still provides similar open-water habitats and would result in similar potential effects regarding mosquito breeding (Effect PHS-4) that would be minimized as described under Alternative B (Environmental Commitment PHS-2).

Alternative C—Water Banking Outside the MID Service Area without Swales and Alteration of Reclamation-Owned Facilities

Alternative C is similar in scope and design to Alternative B, with the primary exception that the natural swales that occur on the site would not be used for recharge. Thus, there would be no substantive differences in public health and safety effects between Alternatives B and C. Alternative C would result in equivalent effects related to an increase in drowning risks at new canals and ditches, berm failure, wildland fires during construction, mosquito production at the recharge basins, and release or disturbance of hazardous materials (Effects PHS-1, PHS-2, PHS-3, PHS-4, and PHS-5). Adverse effects resulting from fire risk (Effect PHS-3) would be mitigated as described under Alternative B (Environmental Commitment PHS-1a and 1b). Alternative C provides similar open-water habitats and would result in similar potential effects regarding mosquito breeding (Effect PHS-4) that would be minimized as described under Alternative B (Environmental Commitment PHS-2).

Alternative D—Water Banking Outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal

Alternative D is similar in scope and design to Alternative B, with the exception that water would be conveyed to the site via GF Canal. For this reason, one recharge basin would not be built under Alternative D that was proposed under Alternative B and lift station would be built in different locations than proposed under Alternative B. Thus, there would be no substantive differences in public health and safety effects between Alternatives B and D. Alternative D would result in equivalent effects (Effects PHS-1, PHS-2, PHS-3, PHS-4, and PHS-5). Adverse effects resulting from fire risk still would be present (Effect PHS-3) and would be minimized as described under Alternative B (Environmental Commitment PHS-1a and 1b). Alternative D provides similar open-water habitats as described under Alternative B and would result in equivalent potential effects regarding mosquito breeding (Effect PHS-4) and would be mitigated as described under Alternative B (Environmental Commitment PHS-2).

Cumulative Effects

Effects related to fire and increased mosquito production could have cumulative impacts in Madera County. Development of emergency preparedness plans (Measure PHS-1a) and compliance with local fire district requirements (Measure PHS-1a) would negate any cumulative fire risk. Likewise, completion of an implementation agreement with the MCMAVCD (Measure PHS-2) would eliminate the risk of any potential contribution to regional increases in adult mosquitoes.

As Reduced Alternative B and Alternatives C and D are identical to Alternative B in scope and effect, it is not anticipated that these alternatives would not contribute to cumulative effects on public health and safety as well.

3.11 Indian Trust Assets

ITA are legal interests in property held in trust by the United States for federally recognized Indian tribes or individual Indians. An Indian trust has three components: (1) the trustee, (2) the beneficiary, and (3) the trust asset. ITA can include land, minerals, federally reserved hunting and fishing rights, federally reserved water rights, and instream flows associated with trust land. Beneficiaries of the Indian trust relationship are federally recognized Indian tribes with trust land; the United States is the trustee. By definition, ITA cannot be sold, leased, or otherwise encumbered without approval of the United States. The characterization and application of the United States trust relationship have been defined by case law that interprets Congressional acts, executive orders, and historical treaty provisions.

Consistent with President William J. Clinton's 1994 memorandum, Government-to-Government Relations with Native American Tribal Governments, Reclamation assesses the effect of its programs on tribal trust resources and federally recognized tribal governments. Reclamation is tasked to actively engage federally recognized tribal governments and consult with such tribes on a government-to-government level (59 FR 1994) when its actions affect ITA.

The U.S. Department of the Interior Departmental Manual Part 512.2 ascribes the responsibility for ensuring protection of ITA to the heads of federal bureaus and offices (U.S. Department of the Interior 1995). Part 512, Chapter 2, of the Departmental Manual states that it is the policy of the DOI to recognize and fulfill its legal obligations to identify, protect, and conserve the trust resources of federally recognized Indian tribes and tribal members. All Federal bureaus are responsible for, among other things, identifying any effect of their plans, projects, programs or activities on ITA; ensuring that potential effects are explicitly addressed in planning, decision, and operational documents; and consulting with recognized tribes who may be affected by the WSEP.

Consistent with this, Reclamation's Indian trust policy states that Reclamation will carry out its activities in a manner that protects ITA and avoids adverse effects when possible, or provides appropriate mitigation or compensation when it is not. To carry out this policy, Reclamation incorporated procedures into its NEPA compliance procedures to require evaluation of the potential effects of its proposed actions on trust assets (Bureau of Reclamation 1993). Reclamation is responsible for assessing whether the alternatives have the potential to affect ITA. Reclamation will comply with procedures contained in Departmental Manual Part 512.2, guidelines, which protect ITA.

3.11.1 Affected Environment

The nearest ITA to the WSEP is the Table Mountain Rancheria which is located approximately 28 miles east-northeast of the Proposed Action area.

3.11.2 Environmental Consequences

No tribes possess legal property interests held in trust by the United States in the area affected by any of the alternatives. Thus, none of the alternatives would affect ITA.

3.12 Land Use

This section describes the existing and planned land uses for the areas potentially affected by the proposed alternatives.

The affected environment was determined by analyzing various documents, examining aerial photographs of the site, and holding discussions with MID and County Planning Department staff. Future planned uses for the vicinity were identified by examination of the County General Plan and County zoning maps. The determination of effects was made by comparing the existing and planned environmental setting for land use with how each resource would be affected by implementation of the alternatives.

The sources of information used in this section include:

- Madera County General Plan Background Report (Madera County 1995a),
- Madera County General Plan Policy Document (Madera County 1995b), and
- Madera County General Plan Land Use Diagram (Madera County 1995c).

3.12.1 Affected Environment

Madera Ranch is located in western Madera County, several miles from the city of Madera and the unincorporated community of Firebaugh. The site is situated in a rural agricultural area under the jurisdiction of the County. No other established communities are located in the vicinity of Madera Ranch.

As shown in Figure 3-7, most of Madera Ranch consists of grasslands, with smaller portions of the site in agricultural production. Agricultural land uses include a mix of field crops, hay and grain crops, and a small portion in vineyard production. In addition to agricultural land uses, Madera Ranch contains numerous on-site access roads, irrigation wells, various related utilities, canals, drainage ditches, and a shop/storage area.

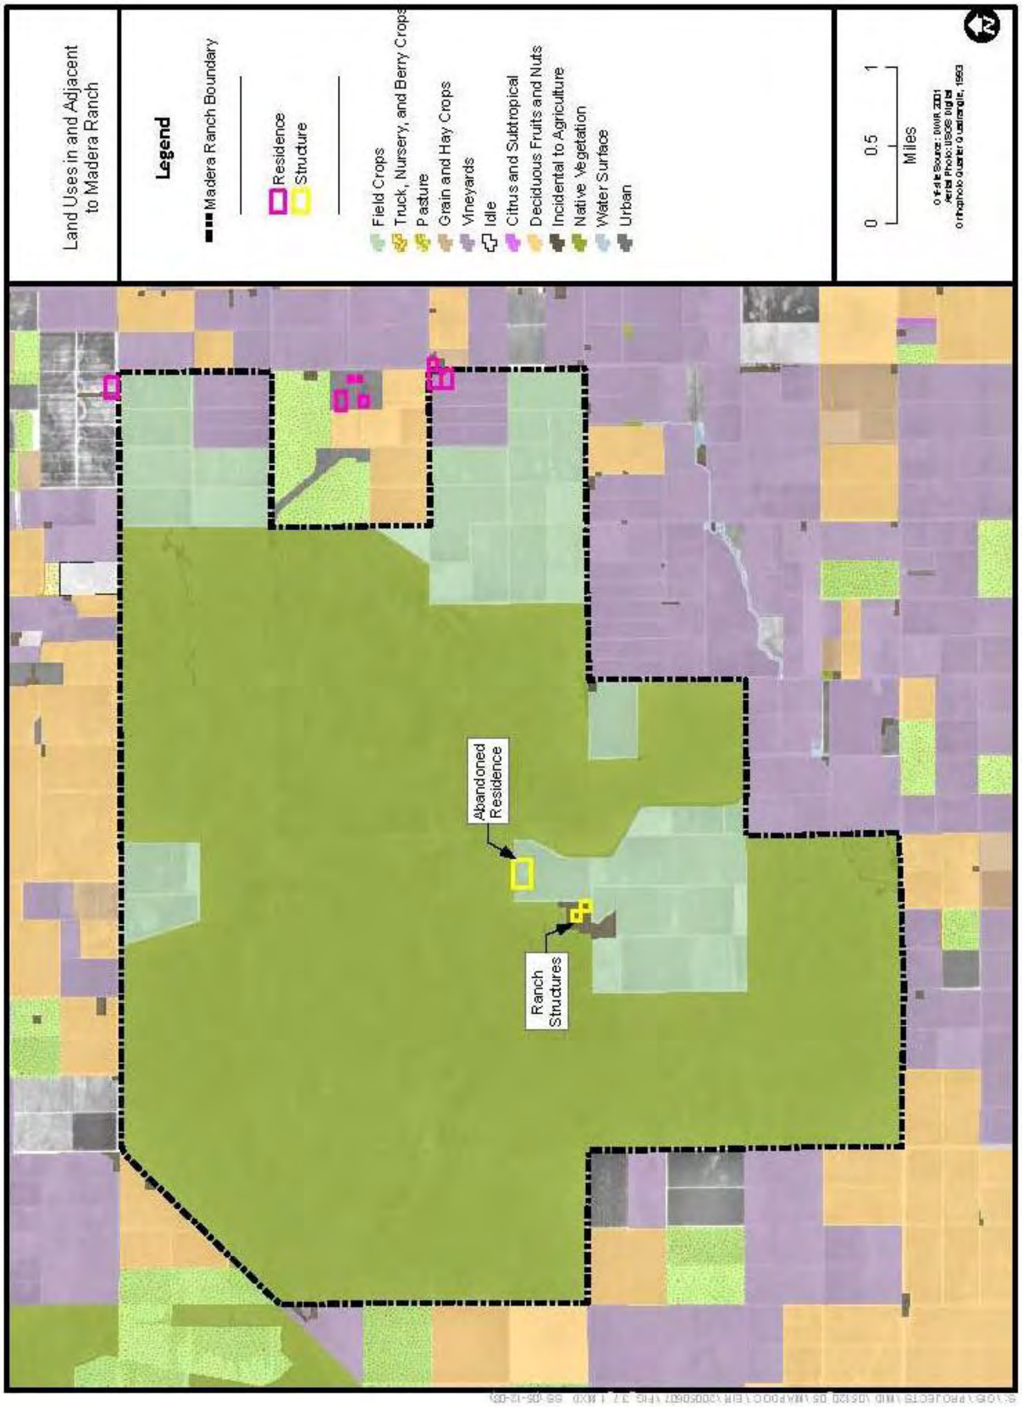


Figure 3-7 Land Uses in and Adjacent to Madera Ranch

3.12.2 Environmental Consequences

Alternative A—No Action

Under the No Action Alternative there would be no adverse effects on land use. However, the future conditions could change to support agricultural activities. Potential effects would be evaluated by the County under CEQA depending on the discretionary permits needed.

Alternative B—Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities

Madera Ranch is located in western Madera County and is generally bounded by Avenue 7, Avenue 12, and Road 21. The site is located several miles from the city of Madera and the unincorporated community of Firebaugh. No other established communities are in the vicinity of Madera Ranch. Because the proposed water bank is located at a distance from both of these communities and would retain traffic flow along Avenue 7, Avenue 12, and Road 21, it would not physically divide an established community.

There is no habitat conservation plan that applies to the Madera Ranch site; therefore, there would be no effects associated with potential conflict with an applicable habitat conservation plan.

Effect LU-1: Conflict with Applicable Land Use Plans, Policies, or Regulations, Including Land Use Designations and Zoning Ordinances Madera Ranch is designated by the General Plan land use diagram as AE (agricultural exclusive). The site also is zoned for agricultural rural exclusive (40-acre minimum). For the effect to be minor, future proposed land uses must be compatible with current agricultural land use designations. The County Planning Department previously determined that development of a groundwater bank on the Madera Ranch site would not conflict with the AE designation (Merchen pers. comm.). In addition, grazing and agricultural land use would continue on most of the ranch, along with some row crop production. While some of the modifications would directly remove a small portion of farmland from production, these modifications would be consistent with continued agricultural production because they would enhance agricultural production by providing improved water storage and supply for agricultural irrigation. Because Alternative B would not conflict with applicable land use plans, policies, or regulations, Effect LU-1 would have no effect.

Effect LU-2: Land Use/Operational Conflicts between Existing and Proposed Land Uses As discussed under Effect LU-1, modifications to the Madera Ranch site would be compatible with agricultural land uses at Madera Ranch. Construction activities might disrupt agricultural operations at Madera Ranch, but these disruptions would be only temporary and would not result in permanent conflict with agricultural land uses. In addition, the resulting changes would not fragment agricultural land or result in modifications that would indirectly preclude agricultural land uses. As mentioned above, the proposed facilities (recharge basins, canals, and ditches) would be similar to existing structures that do not conflict with agricultural uses, but rather facilitate agricultural production by providing improved water supply and storage for agricultural irrigation. Effect LU-2 is not considered adverse because implementation of Alternative B would not conflict with existing or proposed land uses.

Effect LU-3: Conflict with Recreational Land Uses No recreational areas are located in or near the Madera Ranch site nor would Alternative B affect recreational activities. The purpose of Alternative B is to enhance water supply services, and it would not affect recreation or increase the need for recreational services. Alternative B would not conflict with recreational land uses. Effect LU-3 would result in no effect.

Reduced Alternative B—Water Banking Outside the MID Service Area Using Select Swales and Alteration of Reclamation-Owned Facilities

Reduced Alternative B is similar in scope and design to Alternative B, with the primary exception that a reduced number of natural swales would be used and a reduced number of ponds would be constructed. This would not result in any differences from what was described above for Alternative B relative to land use effects. Reduced Alternative B would not conflict with applicable land use plans, policies, or regulations; recreational land uses; or existing or proposed land uses (Effects LU-1, LU-2 and LU-3). Similar to Alternative B, under Reduced Alternative B, Effects LU-1 and LU-3 would result in no effect, and Effect LU-2 is not considered adverse.

Alternative C—Water Banking Outside the MID Service Area without Swales and Alteration of Reclamation-Owned Facilities

Alternative C is similar in scope and design to Alternative B, with the primary exception that the natural swales that occur on the site would not be used for recharge. Thus, there would be no differences in land use between Alternatives B and C. Alternative C would result in equivalent effects on land use (Effects LU-1, LU-2, and LU-3) and would not conflict with applicable land use plans, policies, or regulations; or recreation or other land uses. Identified effects on land use related to minor disruptions of agriculture are not considered adverse (Effect LU-2).

Alternative D—Water Banking Outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal

Alternative D is similar in scope and design to Alternative B, with the exception that recharge is achieved using engineered recharge basins in lieu of the natural swales that occur on the site, and water would be delivered to and from the site using the GF Canal. Thus, there would be no differences in land use between Alternatives B and D. Alternative D would result in equivalent effects on land use (Effects LU-1, LU-2, and LU-3) and would not conflict with applicable land use plans, policies, or regulations; or recreation or other land uses. Identified effects on land use related to minor disruptions of agriculture during construction are not considered adverse (Effect LU-2).

Cumulative Effects

The alternatives would not result in conflicts with existing or proposed land uses in the Madera Ranch area. As such, Alternative B would not result in a considerable contribution to cumulative effects. As Reduced Alternative B and Alternatives C and D are equivalent in scope and overall effect as Alternative B, these alternatives would not result in cumulative effects on land use.

3.13 Noise

This section describes potential temporary and permanent increases to noise levels resulting from the construction and operation of the WSEP.

Potential sources of noise associated with the WSEP are:

- activities associated with construction of the canals and the recharge basins,
- drilling of the recovery wells,

- operation of the well pumps, and
- operation of the engines at the lift stations.

Sound levels produced by these various sources are based on data from standard references, previous studies, and equipment manufacturers' data. Projected sound levels from these sources then are estimated using a point-source attenuation model. With this model, noise from the source is assumed to attenuate at a rate of 6 decibels for each doubling of distance. To determine potential noise effects, the distances needed for noise to attenuate to County noise-level standards of 45 dBA (nighttime) and 50 dBA (daytime) are assessed for each source.

A brief discussion of common noise terminology and descriptors used in this section follows.

- *Sound:* A vibratory disturbance created by a vibrating object that, when transmitted by pressure waves through a medium such as air, can be detected by a receiving mechanism like human ears or a microphone.
- *Noise:* Sound that is loud, unpleasant, unexpected, or otherwise undesirable.
- *Decibel (dB):* A measure of sound or vibration amplitude on a logarithmic scale that indicates the squared ratio of sound pressure or vibration velocity root-mean-squared amplitude to a reference sound pressure or vibration amplitude. For sound, the reference pressure is 20 micropascals.
- *A-weighted decibel (dBA):* An overall frequency-weighted sound level in decibels that approximates the frequency response of the human ear.

In general, human sound perception is such that a change in sound level of 3 dB is just noticeable, a change of 5 dB is clearly noticeable, and a change of 10 dB is perceived as a doubling or halving of the sound level (Cowan 1994).

Sources of information for this section are field measurements conducted by Project Consultants, regulatory information from the County of Madera, and sound level data provided by U.S. Electrical Motors.

3.13.1 Affected Environment

The Madera Ranch site is composed of agricultural and grazing land, with scattered residences. Sources of noise in the area include distant traffic, wildlife, agricultural activities, groundwater pumps, and irrigation district lift stations. A field investigation was conducted to quantify existing background noise conditions and noise from groundwater pumping operations on Madera Ranch. The investigation was conducted on November 6, 2000, between 7:30 a.m. and noon using a sound-level meter that was checked for proper calibration before and after each measurement session. Temperature, wind speed, and humidity were sampled manually throughout the day. There were minimal clouds and in the morning, wind conditions were generally calm (speeds less than 2 miles per hour [mph]). As the day progressed, wind speeds increased to the range of 8 to 13 mph.

Ambient sound levels of 35–51 dBA were measured throughout the day. The quietest ambient sound level (35 dBA) was measured in the early morning when wind speeds were lowest; this sound level was generated primarily by noise from distant traffic and natural sources (e.g., birds). As wind speeds increased, it became clear that the effects of the wind were governing the ambient sound level and increasing background sound levels.

Sound level measurements were taken in the vicinity of two groundwater pumps driven by diesel engines and in the vicinity of four groundwater pumps driven by electric motors. At a distance of 50 feet, the diesel engines produced sound levels of 81–86 dBA. At a distance of 25 feet, three of the electric pumps produced sound levels of 57–58 dBA, and the fourth electric pump produced a sound level of 68 dBA. The fourth pump was producing a high-frequency squeal, indicating that it may not have been operating properly. Diesel engines are probably louder than electric engines (Breault et al. 2009), which explains why they had a higher sound level at a further distance than the electric engines.

Sensitive receptors in the area of the proposed recharge and recovery wells include residences that are approximately 1,320 feet from the location of the nearest proposed new well. There are also sensitive residential receptors along the two canals where new lift stations would be located. The closest sensitive receptor to a noise source is a residence located approximately 300 feet from a proposed lift station on Main No.2 Canal.

3.13.2 Environmental Consequences

Alternative A—No Action

Under the No Action Alternative there would be no adverse effects on noise. However, the future conditions could change to support agricultural activities. Potential effects would be evaluated by the County under CEQA depending on the discretionary permits needed.

Alternative B—Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities

Effect NOI-1: Exposure of Residences to Noise from Grading and Construction Activities

Construction of the canals and grading to develop the recharge basins under Alternative B would involve the use of heavy construction equipment. Table 3-26 summarizes typical noise levels produced by heavy equipment.

Table 3-26 Typical Noise Levels Produced by Heavy Equipment

Equipment	Typical Noise Level (dBA) 50 Feet from Source
Backhoe	80
Dozer	85
Grader	85
Scraper	89
Truck	88

Source: Federal Transit Administration 1995.

For this assessment, it is assumed that one backhoe and two graders could be operating in a local area concurrently and that they could operate at any time during the day or night. The combined sound from these sources is 89 dBA at 50 feet. The distances needed for a source of this sound level to attenuate to County noise-level standards are:

- 3,900 feet for 45 dBA (nighttime standard) and

- 2,600 feet for 50 dBA (daytime standard).

Residences near the southeastern end of Madera Ranch are located within 2,600 feet of the proposed recharge facilities. This effect is, therefore, considered adverse because noise levels would exceed County standards at these residences. Implementation of Environmental Commitment NOI-1to Employ Noise-Reducing Construction Practices would minimize the intensity and timing of the effect.

Effect NOI-2: Exposure of Residences to Noise from Well-Drilling Operations At each well site, well drilling would involve initial drilling 24 hours a day for several days, then intermittent drilling during daytime hours for several days. The specific types of drilling units to be used are not known. Experience from previous studies indicates that a source level of 85 dBA at 50 feet is a reasonably conservative assumption for well drilling operations. The distances needed for a source of this sound level to attenuate to County noise-level standards are:

- 2,900 feet for 45 dBA (nighttime standard) and
- 2,000 feet for 50 dBA (daytime standard).

Although all wells would be located at least 0.25 mile (1,320 feet) from the nearest residences, this analysis indicates that noise from drilling could exceed County noise standards at these residences. This effect therefore is considered adverse. Implementation of Environmental Commitment NOI-2to Employ Noise-Reducing Methods during Well-Drilling Operations would minimize the intensity and timing of the effect.

Effect NOI-3: Exposure of Residences to Noise from Operation of Engines at Wells A single pump with an engine rating of up to 100 hp would be used at each wellhead. The pumps could be either electric or propane-fueled. Data provided by U.S. Electrical Motors for a 100-hp electric motor running under no load (Roughton pers. comm.) indicate that the motor would produce a sound level of 56 dBA at 50 feet. To approximate the sound level produced under load, 3 dB were added to the no-load condition for a resulting source level of 59 dBA at 50 feet. The distances needed for a source of this level to attenuate to County noise-level standards are:

- 250 feet for 45 dBA (nighttime standard) and
- 140 feet for 50 dBA (daytime standard).

The sound level of a similarly sized pump operated by a propane-fueled reciprocating engine was calculated using the equations for reciprocating engines from Noise Control for Buildings, Manufacturing Plants, Equipment and Products (Hoover and Keith 1996). Based on these calculations, a 100-hp propane-fueled engine would produce a sound level of 75 dBA at 50 feet. This sound level represents a reasonable worst-case scenario at the well locations.

The distances needed for a source of this level to attenuate to County noise-level standards are:

- 1,250 feet for 45 dBA (nighttime standard) and
- 800 feet for 50 dBA (daytime standard).

All wells would be located at least 0.25 mile (1,320 feet) apart and would be located at least 0.25 mile (1,320 feet) from the nearest property line. Accordingly, no meaningful cumulative effects of simultaneous pump operation noise are anticipated. As such, the analysis is based on the noise from a single pump. This analysis indicates that noise from propane-fueled well pumps with the maximum horsepower rating is not likely to exceed County nighttime noise standards at the nearest residences. Therefore no adverse effect from operation of engines at wells is anticipated.

Effect NOI-4: Exposure of Residences to Noise from Operation of Engines at Lift Stations
Two propane-fueled pumps totaling 200 hp could be used at each of the lift stations located along the Main No. 2 Canal under Alternative B. Noise from engines typically increases at a rate of 3 dB for each doubling of horsepower (Hoover and Keith 1996). Using the sound data for the 100-hp pump described above, the noise level from the two pumps is estimated to be 78 dBA (75 dBA + 3 dB) at 50 feet. The distances needed for a source of this sound level to attenuate to County noise-level standards are:

- 1,600 feet for 45 dBA (nighttime standard) and
- 1,000 feet for 50 dBA (daytime standard).

The lift stations along Main No. 2 Canal potentially would be located as close as 300 feet to the nearest residence (Dorrance pers. comm.). This analysis indicates that there is potential for noise from the lift stations under the maximum horsepower scenario to exceed County noise standards at residences. This effect therefore is considered adverse. Implementation of Environmental Commitment NOI-4 to Employ Noise-Reducing Methods during Lift Station Operations would result in avoidance of the effect or minimization to below County standards.

Reduced Alternative B—Water Banking Outside the MID Service Area Using Select Swales and Alteration of Reclamation-Owned Facilities

Reduced Alternative B is similar in scope and design to Alternative B, with the primary exception that a reduced number of natural swales would be used and a reduced number of ponds would be constructed. Reduced Alternative B would also exclude construction of the Section 8 canal southwest extension. However, the expected footprint of facilities, including noise-producing pumps for recovery wells and lift stations, and associated construction, under Reduced Alternative B would be similar to Alternative B and would result in equivalent effects related to construction (grading and drilling) and operation (recovery and lift station pumps) noise near residences (Effects NOI-1, NOI-2, NOI-3, and NOI-4). Thus, noise effects are considered equivalent to those that would occur under Alternative B and are considered adverse. Implementation of Environmental Commitments NOI-1, NOI-2, NOI-3, and NOI-4 would reduce the intensity of these effects.

Alternative C—Water Banking Outside the MID Service Area without Swales and Alteration of Reclamation-Owned Facilities

Alternative C is similar in scope and design to Alternative B, with the primary exception that the natural swales that occur on the site would not be used for recharge. However, the expected footprint of facilities, including noise-producing pumps for recovery wells and lift stations, and associated construction, under Alternative C would be similar to Alternative B and would result in equivalent effects related to construction (grading and drilling) and operation (recovery and lift station pumps) noise near residences (Effects NOI-1, NOI-2, NOI-3, and NOI-4). Thus, noise effects are considered equivalent to those that would occur under Alternative B and are considered adverse. Implementation of Environmental Commitments NOI-1, NOI-2, NOI-3, and NOI-4 would reduce the intensity of these effects.

Alternative D—Water Banking Outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal

Alternative D is similar in scope and design to Alternative B, with the exception that water would be conveyed to the site via GF Canal. For this reason, one recharge basin would not be built under Alternative D that was proposed under Alternative B and lift stations would be built in locations different from those proposed under Alternative B. Thus, Alternative D would result in unique potential adverse effects related to lift stations (Effect NOI-5, described below). All other anticipated construction and operation effects under Alternative D would be similar to Alternative B and would result in similar effects related to construction (grading and drilling) and operation (recovery pumps) noise near residences (Effects NOI-1, NOI-2, and NOI-3). Thus, noise effects are considered equivalent to those that would occur under Alternative B for Effects NOI-1, NOI-2, and NOI-3and are considered adverse. Implementation of Environmental Commitments NOI-1, NOI-2, and NOI-3, respectively, would reduce the intensity of these effects.

Effect NOI-5: Exposure of Residences to Noise from Operation of Engines at Lift Stations

One propane-fueled pump totaling 200 hp could be used on the proposed lift station located on the GF Canal. Noise from engines typically increases at a rate of 3 dB for each doubling of horsepower (Hoover and Keith 1996). Using the sound data for the 100-hp pump described above, the noise level from the pump is estimated to be 78 dBA (75 dBA + 3 dB) at 50 feet. The distances needed for a source of this sound level to attenuate to County noise-level standards are:

- 1,600 feet for 45 dBA (nighttime standard) and
- 1,000 feet for 50 dBA (daytime standard).

As the final location of this station is not known, the lift station potentially could be located within 1,000 feet of a residence. This analysis indicates that there is potential for noise from the lift stations under the maximum horsepower scenario to exceed County noise standards at residences. This effect therefore is considered adverse. Implementation of Environmental Commitment NOI-4 (as discussed above under Effect NOI-4) would result in avoidance of the effect or minimization to below County standards.

Cumulative Effects

None of the effects described for each alternative above have the potential to result in an adverse cumulative contribution to local noise. No other construction is proposed during the anticipated construction period that would contribute to cumulative noise increases during construction. Operational noise from pumps could contribute to a cumulative local increase in noise effects. However, proposed mitigation (Environmental Commitments NOI-3 and NOI-4) is anticipated to reduce this effect at Madera Ranch during operations and thus not contribute to local cumulative effects. No additional mitigation is proposed.

As Alternative C is equivalent in scope and overall effect to Alternative B, it is anticipated that Alternative C would not contribute to cumulative noise effects. Alternative D could result in additional effects related to the propane-fueled pump, but this effect would be reduced by implementing Environmental Commitment NOI-4. As such, none of the alternatives is expected to contribute to cumulative effects.

3.14 Public Services and Utilities

This section describes the existing public services and utilities in the areas potentially affected by the Proposed Action and alternatives. The analysis addresses effects of each alternative on fire protection, police protection, wastewater (sewage), water service, and electricity.

Schools are not discussed because Madera Ranch is not located in the vicinity of a school and the alternatives would not cause any increase in schoolchildren or result in effects on school facilities. Solid waste is not discussed because construction and operation of the alternatives would not increase development that would require the disposal of solid waste.

3.14.1 Affected Environment

Information in this section is primarily from the Madera County General Plan Policy Document (1995b).

The Madera Ranch site is in the service areas of the following utility providers:

- The Pacific Gas and Electric Company (PG&E) (electricity);
- AT&T (telephone);
- County Fire Department, contracted to the California Department of Forestry (firefighting); and
- Madera County Sheriff's Department (law enforcement).

MID delivers water to Sections 1, 13 ½, and 14 of Madera Ranch, but Madera Ranch is not served by community drinking water, wastewater, or stormwater services, and there are no schools in the vicinity of Madera Ranch; therefore, these services and facilities are not discussed in this section.

Local

Local power and communication utility lines cross the Madera Ranch site. These lines serve development on the site, including the shop area and well facilities. An electrical substation is located immediately north of the site across Avenue 12. The County Fire Department and the California Department of Forestry provide fire protection to the site, and the County Sheriff's Department provides law enforcement services to the site. MID and GFWD provide irrigation water to farmers in the area, generally between March and October. Only part of Madera Ranch is located in MID or GFWD boundaries.

3.14.2 Environmental Consequences

Alternative A—No Action

Under the No Action Alternative there would be no adverse effects on public services and utilities. However, future conditions would change to support agricultural activities. Potential effects would be evaluated by the County under CEQA, depending on the discretionary permits needed.

Alternative B—Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities

Effect PSU-1: Increased Demand for Utilities Alternative B would involve the installation of up to 49 new 75–100-hp groundwater wells and up to 20 lift station pumps, which would increase demand for electricity for the site. Electricity either would be provided by PG&E in accordance with PG&E and the California Public Utility Commission regulations or would be purchased directly from the power grid. A connection would be made to existing electric lines along either Avenue 7 or Avenue 9. To provide the necessary service, a new utility substation would be constructed on Madera Ranch. All costs associated with constructing and maintaining required facilities would be borne by MID. Because PG&E could provide service to the water banking facility along existing utility lines and MID would provide substation facilities, this action would not result in an adverse effect.

Effect PSU-2: Potential Disruption of Emergency-Response Routes As described in the Traffic and Circulation Section, all the local roadways are currently operating at acceptable Levels of Service. The construction-related activities would not substantially increase the number of daily and peak-hour vehicles currently traveling along these roadways and would not contribute to exceedance of traffic thresholds recommended by the Institute of Transportation Engineers. However, the increase in slow-moving traffic during construction in the vicinity of Madera Ranch could reduce emergency response times on the affected roads. Because of this potential increase in emergency response times, Effect PSU-2 is considered adverse. Implementation of Environmental Commitments PSU-1a and PSU 1b would minimize adverse effects associated with Alternative B.

Effect PSU-3: Temporary Disruption of Irrigation Service as a Result of Construction Several canals that currently provide irrigation water would be reconditioned or extended. These canals would need to be dry during construction and, therefore, would not be able to convey irrigation water during these times. To minimize the disruptions to irrigators using these canals, MID would ensure that construction on these facilities is limited to winter, when the canals are not required to deliver irrigation water. As such, Effect PSU-3 is not considered adverse.

Reduced Alternative B—Water Banking Outside the MID Service Area Using Select Swales and Alteration of Reclamation-Owned Facilities

Reduced Alternative B is similar in scope and design to Alternative B, with the primary exception that a reduced number of natural swales would be used and a reduced number of ponds would be constructed. Reduced Alternative B would also exclude construction of the Section 8 canal southwest extension. Thus, there would be no substantive differences in potential effects on public services and utilities between Alternative B and Reduced Alternative B. Reduced Alternative B would result in equivalent effects on electricity use, emergency services, and irrigation services (Effects PSU-1, PSU-2, and PSU-3). Adverse effects resulting from the potential disruption of emergency service routes during construction would be mitigated as described under Alternative B (Environmental Commitment PSU-1a and 1b).

Alternative C—Water Banking Outside the MID Service Area without Swales and Alteration of Reclamation-Owned Facilities

Alternative C is similar in scope and design to Alternative B, with the primary exception that the natural swales that occur on the site would not be used for recharge. Thus, there would be no substantive differences in potential effects on public services and utilities between Alternatives A and B. Alternative C would result in equivalent effects on electricity use, emergency services, and irrigation services (Effects PSU-1, PSU-2, and PSU-3). Adverse effects resulting from the potential disruption of emergency service routes during construction would be mitigated as described under Alternative B (Environmental Commitment PSU-1a and 1b).

Alternative D—Water Banking Outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal

Alternative D is similar in scope and design to Alternative B, with the exception that water would be conveyed to the site via GF Canal. For this reason, one recharge basin would not be built under Alternative D that was proposed under Alternative B and lift stations would be built in locations different from those proposed under Alternative B. However, there would be no substantive differences in potential effects on electricity use, emergency services, or irrigation services between Alternatives B and D. Alternative D would result in equivalent effects (Effects PSU-1, PSU-2, and PSU-3). Adverse effects resulting from the potential disruption of emergency service routes during construction would be mitigated as described under Alternative B (Environmental Commitment PSU-1a and 1b).

Cumulative Effects

Effects related to the disruption of emergency response routes could have cumulative impacts in Madera County. Development of a traffic safety plan (Measure PSU-2b) and notifying emergency service providers of traffic route changes (Measure PSU-2a) would negate any potential for cumulative effects. As Alternatives C and D are identical in scope and effect to Alternative B, it is not anticipated that Alternatives C and D would contribute to cumulative effects on public services.

3.15 Socioeconomics

This section presents the environmental background necessary to analyze the socioeconomic effects of the proposed alternatives. Specific topics include current employment, income, and demographic information for Madera County. Existing levels of agricultural production and income also are described.

Implementation of the alternatives could affect the socioeconomic characteristics of the study area by:

- temporarily increasing construction-related employment opportunities in the area, and

- increasing or decreasing the amounts of agriculture-related employment and income in Madera County.

This analysis assumes that enough construction workers to staff the activities reside within a reasonable commute distance from the site and that these workers already have housing; therefore, the effect of the alternatives on the local housing supply is expected to be minimal. Consequently, no setting or background information related to housing supply and housing availability is provided in the following section.

This socioeconomic analysis assesses the potential effects resulting from implementation of the alternatives, which would generate temporary employment related to construction and permanent employment related to operations. Effects on employment were evaluated for the Fresno metropolitan statistical area (MSA). Activities occurring at or near the site could trigger effects on employment and income if there is an insufficient local workforce. However, the site is within a reasonable commute distance from the cities that make up the Fresno MSA, which contains an adequate construction workforce.

The following assumptions were used to assess socioeconomic effects under each of the alternatives.

- Estimates of construction-related employment were provided by MID (Roughton pers. comm.). Implementation of the alternatives would generate about 101 temporary construction-related employment positions over the period of construction, and 1–2 permanent operations staff positions.
- Enough construction workers reside within a reasonable commute distance from the Madera Ranch site and presumably already have housing. Therefore, effects on population and housing are expected to be minimal and are not assessed further.
- Construction of the alternatives is not expected to take place within an existing residential area; therefore, implementation is not anticipated to result in the displacement of any existing residences or community facilities.

The socioeconomic effects associated with the alternatives would be focused on the effects on employment and income resulting from a small, temporary increase in regional employment during construction, and estimates about how farmers might respond to changes in water costs and reliability.

3.15.1 Affected Environment

The alternatives are proposed for Madera Ranch, which is located in southwestern Madera County. The Madera Ranch site and Madera County as a whole are characterized as highly rural areas with low population levels. However, the site is within a reasonable commute distance from the cities that comprise the Fresno MSA (e.g., Madera, the greater Fresno metropolitan area). This section includes background or regional employment and income information for the Fresno MSA, as defined by the California Employment Development Department. This MSA includes both Fresno and Madera Counties and occupies a geographic area described by the U.S. Bureau of Economic Analysis as possessing extensive economic interactions and linkages. Activities occurring at or near the site could trigger socioeconomic effects.

Methods and Terminology

Information for the socioeconomic analysis was obtained from the California Department of Finance, the U.S. Bureau of Economic Analysis, and the U.S. Census Bureau. In addition, Madera County's general plan documents (Madera County 1995a, 1995b), the County Economic Development Commission, and the California Water Plan Update (California Department of Water Resources 2005) were consulted for information related to current and future land use, population statistics, and planned growth rates for Madera County and the state. In addition, both the GFWD and MID have developed groundwater management plans to evaluate the availability of groundwater resources to support current and future demands. Information on existing agricultural uses and agricultural productivity was obtained from the County Agricultural Commissioner's Office.

Employment and Income

Overall, the labor market of the Fresno MSA is dominated by agriculture and agriculture-related services and industries. In addition to employment resulting from the direct production of a variety of both field and orchard crops, agriculture contributes indirectly to other MSA jobs in manufacturing (e.g., grain, nut, and fruit processing) and wholesale trade (e.g., farm and food processing machinery, and farm supplies).

The California Employment Development Department reports that 432,000 were in the labor force within the Fresno Metropolitan Service in March 2011. Of that amount, 353,100 were employed and 79,600 were unemployed for an unemployment rate of 18.4-percent.

Residents of the Fresno MSA generate a relatively large demand for retail products and services. Combined employment in the retail trade and professional services industries accounts for 49% (169,600) of the total number of jobs in the MSA (Table 3-27).

Table 3-27 Selected Employment Characteristics for the Fresno Metropolitan Statistical Area

Industry	Number of Full-Time and Part-Time Jobs
Total Labor Force	315,500
Farm (including production and services)	36,300
Non-farm	279,200
Mining and Construction	11,000
Manufacturing	25,000
Transportation, Public Utilities and Trade (including wholesale and retail)	54,200
Professional Services	26,400
Leisure and Hospitality	26,600
Government	68,600
Other	9,900

Source: California Employment Development Department 2011.

The traditional reliance of Madera County and the overall MSA on agricultural production and food processing as main sources of employment has resulted in substantial seasonal fluctuations in the unemployment rate. This, combined with a small industrial base, perpetuates consistently high unemployment rates.

Population and Demographics

The total population in Madera County in 2000 was 123,109; of this total, 68,775 residents (56%) lived in the unincorporated portions of the county (Table 3-28). For 2000, Madera County's ethnic composition ranged from 62% white to 1% Asian/Pacific Islander. The County is considered ethnically diverse; minority populations account for an estimated 38% of Madera County's total population.

Table 3-28 Population and Percent Ethnicity Data[*] for Madera County

Area	Total 2000 Population	White	African American	Native American	Asian/Pacific Islander	Hispanic
Madera County	148,632	87.6%	4.6%	3.3%	2.4%	51.7%
City of Madera	61,416	48%	2.7%	0.5%	0.1%	76.7%
City of Chowchilla	11,127	64%	10%	3%	1%	28%
Unincorporated Area	68,775	NA	NA	NA	NA	NA

Notes:
NA=Not applicable
*All ethnicity data population data (e.g., city and county) are from 2000 sources: California Department of Finance 2000a.

Median household income for Madera County is $36,286. Persons in poverty were estimated at 21% of the county population for the 2000 census year (Table 3-29).

Table 3-29 Income Data for Madera County

Area	Median Household Income	Percent above Poverty Level	Percent below Poverty Level
Madera County	$36,286	79	21

Relationship between Water Costs and Crop Production

About 86% of the cultivated lands in Madera County are permanent crops such as orchards or vineyards that are cultivated for many seasons without the need to replant each season. As such, these crops are established for long-term production and fallowing or abandonment from year to year is difficult. Permanent crop farmers tend to ensure these crops receive water in dry years so as not to compromise the ability of the crop to produce over the long term.

For those crops that are not permanent, farmers may choose to fallow land and wait until conditions are better for planting or change crop types to better balance the water costs and market values of the crop. However, permanent crops are difficult to change or fallow, and therefore, changes in water costs generally do not have an effect on permanent crop production or type.

Although the overall permanent crop production may not change in years when water costs are higher, the regional economy could be affected by farmers cutting other costs, such as employment and investment in equipment.

3.15.2 Environmental Consequences

Alternative A—No Action

Under the No Action Alternative there would be no adverse effects on socioeconomics. However, the future conditions at Madera Ranch would change to support agricultural activities.

Potential effects would be evaluated by the County under CEQA, depending on the discretionary permits needed. Regardless of changes at Madera Ranch, the No Action Alternative would result in a decreased water supply reliability in the MID service area, which could adversely affect farming economies in the region by increasing water costs. With reduced supplies, farmers are likely to have to pay more for water and modify other operational costs, by measures such as reducing workforce. This would have an adverse effect on the regional economy.

Alternative B—Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities

Effect SE-1: Increase in Temporary Construction-Related Employment and Income in the Fresno Metropolitan Statistical Area Under Alternative B, approximately 100 seasonal workers would be employed annually for a period of 12 months. This work force would be required only for construction and not indefinitely. Generally, direct effects on employment would result from expenditures on the design, engineering, and construction of facilities. This spending also would result in direct effects on local businesses that provide goods and services to the engineering and construction firms. Construction positions most likely would be filled by residents of the local area, including residents of the greater Fresno MSA. Because implementing Alternative B would increase construction-related employment opportunities and income for local workers, Effect SE-1 is considered beneficial.

Effect SE-2: Increase in Permanent Employment and Income in the Local Area Attributable to Operation of the Water Supply Enhancement Project An estimated one to two jobs would be created by Alternative B to handle operation and maintenance responsibilities when the facilities are completed. The new jobs would generate minor direct effects on local businesses that provide goods and services needed to support operation of the water bank. The employment and income effects of Effect SE-2 are considered beneficial.

Effect SE-3: Effects on the Agricultural Economy Attributable to an Increase in Water Costs The costs associated with implementation of Alternative B would be paid by those who choose to use the bank by purchasing banking space. Water rates for non-participants would stay within the current range during all year types. In dry years, when farmers may want to recover banked water, additional water rates would apply to those who opt to participate in the bank by purchasing banking space to supplement their supplies. These water rates would be slightly less than projected costs of non-MID water, such as that obtained by transfers or spot market purchases of water.

Therefore, water costs would rise only in dry years and only related to the banked water. Because water costs are not expected to increase beyond the reasonable range of historical costs as a result of Alternative B, and because there would not be a change in crop production for the majority of crops as many of the crops in Madera County are permanent, there would be no adverse effect on agricultural economies related to increased water costs. Additionally, farmers could benefit in dry years by securing supplies at rates less than transfer costs or other options, such as spot market transfers.

Effect SE-4: Changes in Employment and Income in the Local Area because of Increased Water Supply Reliability Alternative B has the potential to have two differing effects on employment and income, one beneficial and one negative. The actual effect would depend on farmers' responses to changes in water costs and water reliability from year to year and the effect that has on their long-term planning for farming operations. The beneficial effect is related to improving the reliability of the surface water supplies for MID contractors, which would result in greater certainty in regard to maintaining the current agricultural lands. This certainty has the potential to result in increased employment and associated incomes because farmers are more likely to hire and retain workers and invest in equipment for long-term use. This increase in employment and income is beneficial.

However, in response to increased costs, some farmers may choose to reduce their workforce or not invest in equipment. These choices depend on crop type, existing workforce, and existing cultivated land. This could have a negative impact on the regional economy if these types of choices are made by many farmers over several years. As described above under SE-3, water costs are not expected to rise beyond the normal range of costs. The increased reliability has the potential to offset some of these costs. As such, it is not expected that there would be a substantial change, and this effect is not considered adverse.

Reduced Alternative B—Water Banking Outside the MID Service Area Using Select Swales and Alteration of Reclamation-Owned Facilities

Reduced Alternative B is similar in scope and design to Alternative B, with the primary exception that a reduced number of natural swales would be used and a reduced number of ponds would be constructed. Reduced Alternative B would also exclude construction of the Section 8 canal southwest extension. Thus, there would be no substantive differences in potential effects on public services and utilities between Alternative B and Reduced Alternative B. Increased water costs are not expected to have an effect on the environment (SE-3). Reduced Alternative B would result in equivalent effects (Effects SE-1 and SE-2) on temporary and permanent employment. Similar to Alternative B, Reduced Alternative B has the potential to result in beneficial socioeconomic effects (SE-4).

Alternative C—Water Banking outside the MID Service Area without Swales and Alteration of Reclamation-Owned Facilities

Alternative C is similar in scope and design to Alternative C, with the primary exception that the natural swales that occur on the site would not be used for recharge. Thus, there would be no substantive differences in potential effects on public services and utilities between Alternatives B and C. Increased water costs are not expected to have an effect on the environment (SE-3). Alternative C would result in equivalent effects (Effects SE-1 and SE-2) on temporary and permanent employment. Alternative C would result in beneficial socioeconomic effects (SE-4).

Alternative D—Water Banking outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal

Alternative D is similar in scope and design to Alternative B, with the exception that recharge is achieved using engineered recharge basins in lieu of the natural swales that occur on the site and some differences in the types of conveyance facility improvements. Thus, there would be no substantive differences in potential effects on public services and utilities between Alternatives B and D. Alternative D would result in equivalent effects (Effects SE-1 and SE-2) on temporary and permanent employment. Increased water costs are not expected to have an effect on the environment (SE-3). Alternative D would result in beneficial socioeconomic effects (SE-4).

Cumulative Effects

As none of the alternatives would result in adverse effects on socioeconomics, there would be no cumulative effects.

3.16 Traffic and Circulation

This section describes the existing traffic and circulation conditions in the areas potentially affected by the proposed alternatives. It discusses the affected environment, relevant regulations and policies, methods of analysis, and possible effects.

3.16.1 Affected Environment

Roadway Levels of Service Level of service (LOS) measures the quality of service provided by a roadway. LOS criteria established by the Transportation Research Board are shown in Table 3-30. These criteria use a letter rating to describe the peak-period driving conditions for a particular facility. The roadway traffic conditions become progressively worse from A to F.

Table 3-30 Roadway Level of Service Definitions

Level of Service Rating	Definition
A	Free flow; insignificant delays
B	Stable operations; minimal delays
C	Stable operations; acceptable delays
D	Approaching unstable; queues develop rapidly but no excessive delays
E	Unstable flow; significant delays
F	Forced flow; low operating speeds

Source: Transportation Research Board 1994.

LOS criteria for highways are established by Caltrans and take into account numerous variables, including annual average daily traffic, roadway capacity, grade, and environment (urban versus rural). According to Caltrans policy and the County's criteria, LOS D is acceptable for planning purposes, and LOS E and F are unacceptable. As shown in Table 3-31, all the roadways potentially affected by the alternatives are currently operating at LOS D or better; therefore, all the roadways are operating at acceptable levels.

Table 3-31 Roadway Characteristics near Madera Ranch

Roadway	Responsibility	Functional Classification	Average (vehicles per day)	Peak Hour (vehicles per day)	LOS
SR 99[a]	Caltrans	4-lane freeway	62,000–63,000	5,600–6,200	D
Avenue 7[b]	Madera County	2-lane local road	3,256	326	C
Avenue 10[c]	Madera County	2-lane local road	2,440	244	B/C
Avenue 12 [b]	Madera County	2-lane local road	2,419	242	A/B
Road 16[b]	Madera County	2-lane local road	371	37	A
Road 21[b]	Madera County	2-lane local road	Unavailable	Unavailable	A

Roadway	Responsibility	Functional Classification	Average (vehicles per day)	Peak Hour (vehicles per day)	LOS

Notes:
[a] Source: California Department of Transportation 2007.
[b] Source: Madera County Transportation Commission 2007. Traffic counts for Avenue 7 are from 2004, Avenue 12 from 2007, and Road 16 from 2005. Counts have never been conducted for Road 21.
[c] Source: Stone pers. comm. and Levine pers. comm. Based on the most recent available data from 1998.

Madera County is in a major transportation corridor between northern and southern California; SR 99 is the primary route for north/south travel. The county's economy is based on farming, agricultural processing, and manufacturing. Because most of the county's products are shipped to outside locations, interstate and intrastate transportation are vital.

Roadways As shown in Figure 3-8, Madera Ranch is regionally served by SR 99, which is generally a four-lane divided roadway (oriented north/south), and locally served by Avenues 7, 10, and 12 and Roads 16 and 21, which are all two-lane roadways maintained by the County. SR 99 is under the jurisdiction of Caltrans. Roadways and roadway segments potentially affected by the WSEP are:

- SR 99 from Madera to Fresno,
- Avenue 7 from Firebaugh to SR 99,
- Avenue 14 to Avenue 23 to Avenue 10,
- Avenue 10 from Road 23 to Road 21 (the Madera Ranch site),
- Avenue 12 from Road 16 to SR 99,
- Road 16 from Chowchilla to Avenue 12, and
- Road 21 from Avenue 12 to Avenue 7.

Information about the most current traffic volumes, roadway classifications, and LOS is provided in Table 3-31. Avenues 7 and 12 are considered major truck routes (Stone pers. comm.). Although estimates of truck traffic on local roadways serving the Madera Ranch site are currently unavailable, it is estimated that the percentage of trucks or other slower moving vehicles (e.g., farm vehicles) is higher than average because of local agriculture.

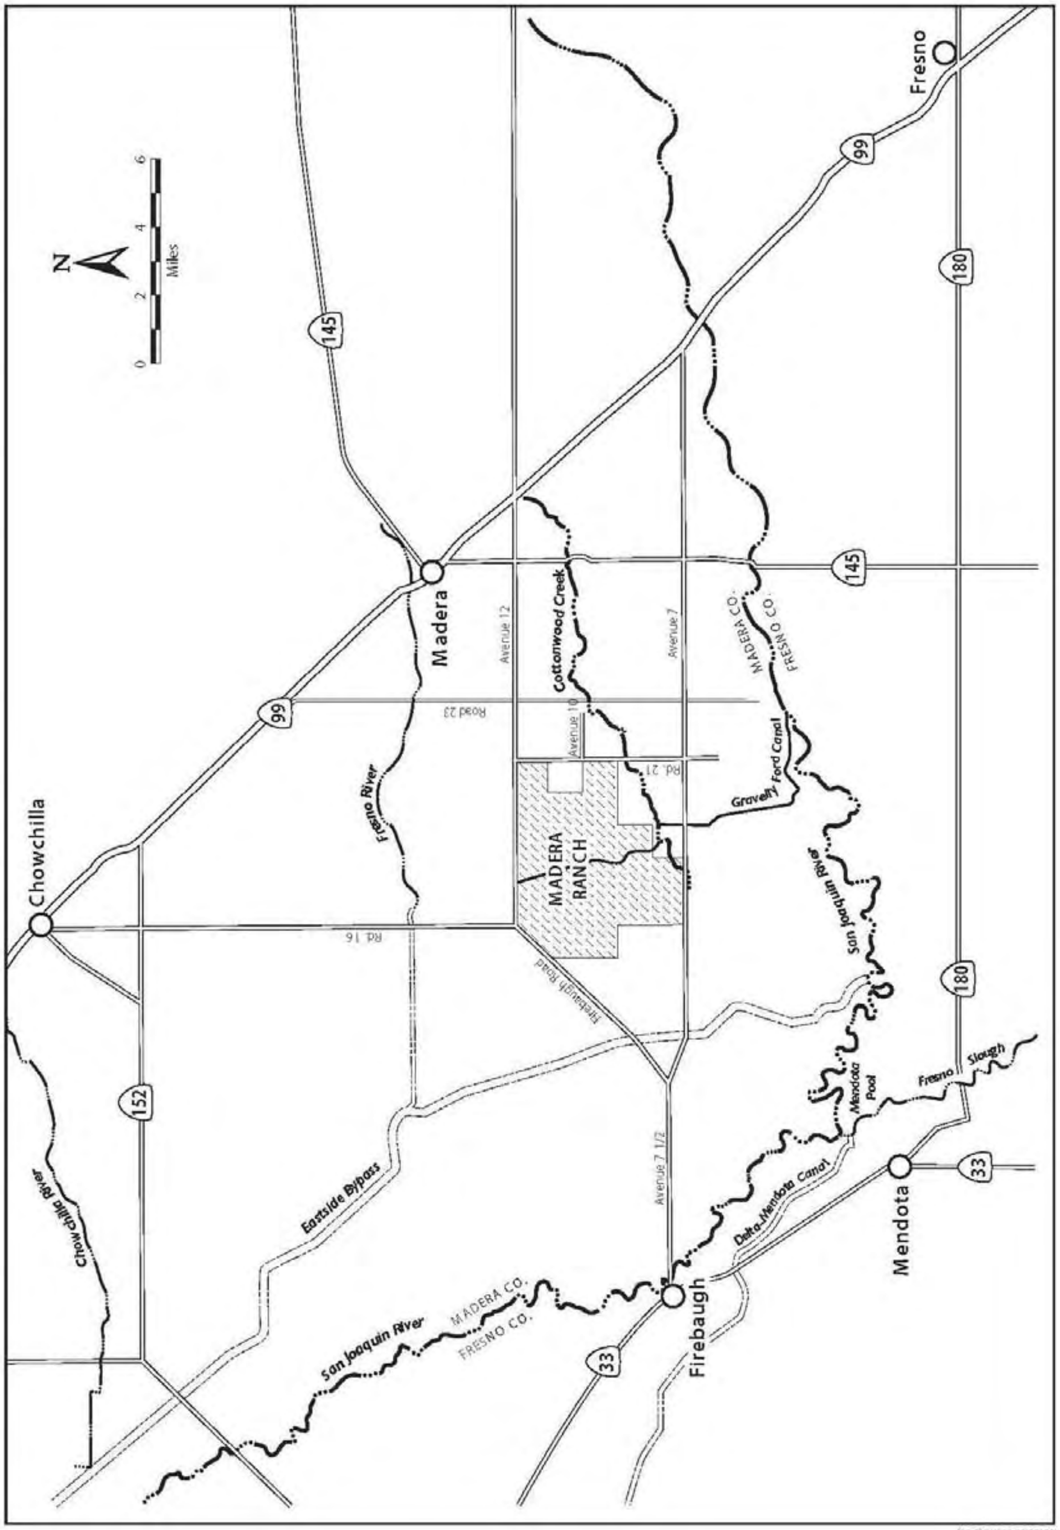

Figure 3-8 Regional and Local Roadway Network near Madera Ranch

3.16.2 Environmental Consequences

Traffic counts from 1998 through 2007 are used to provide traffic data for roadways in the vicinity of Madera Ranch. Consequently, 1998–2007 traffic data are used to characterize the baseline traffic condition for this transportation and circulation analysis. Traffic and circulation effects would be limited to construction, and each of the alternatives involves a similar construction effort. As such, it is assumed that each of them generates the same vehicle trips.

Vehicle Access and Parking

Madera Ranch is located in the largely agricultural western portion of Madera County, approximately five miles southwest of the city of Madera and 10 miles northwest of Fresno. The Madera Ranch site would be accessed locally from Avenues 7 and 12. Avenue 10 would provide direct access to the site.

Trip Distribution

As shown in Table 3-34, the traffic analysis assumes that construction workers under the alternatives would come from the Fresno MSA. The analysis assumes origination of the construction workforce would be:

- 70% from Fresno,
- 20% from Madera,
- 5% from Chowchilla, and
- 5% from Firebaugh.

The analysis assumes that 100% of the total number of heavy-truck trips would be generated from the greater Fresno metropolitan area.

Trip Generation

To assess the magnitude and directional variation of vehicle trips associated with construction of the alternatives, vehicle-trip generation was analyzed using an estimate of the required construction-related workforce. Assuming a worst-case scenario, construction of the alternatives could require up to 60 construction workers. Implementation of the Proposed Action could generate up to 3,600 heavy-truck (e.g., concrete, equipment) trips during construction of the recharge basins. Table 3-32 provides an estimate of the total number of construction-related vehicle trips that would be generated, including the peak and average daily vehicle trips.

The traffic and circulation analysis also assumes a worst-case scenario in which each of the 60 workers would drive a separate vehicle to Madera Ranch, making two trips per day, or one round-trip from home to the site and back. Under this scenario, construction of the alternatives would result in an average of approximately 176 vehicle trips per day and about 68 total vehicle trips per day during the peak morning and afternoon traffic periods (Table 3-32) during the period of construction (approximately 365 days).

In addition, it is estimated that construction-related activities would include the use of several types of equipment, including backhoes, scrapers, water trucks, pickup trucks, and front loaders. It is assumed that equipment would be stored on site while in use and would not result in a substantial increase in the overall daily trip generation.

O&M–related activities would require only occasional inspection visits; therefore, operations and maintenance–related traffic would be negligible and is not expected to affect the operating conditions of existing roadways. Consequently, operations-related traffic is not addressed further in this analysis.

Table 3-32 Anticipated Construction Vehicle Trip Generation and Workforce Distribution

Vehicle Origin City	Percent Distribution of Local Workforce	Daily Workforce	Daily Vehicle Trips	Daily Peak-Hour Vehicle Trips
Fresno				
Construction Workers	70.	42	84	42
Heavy Trucks	100.	28	56	8
Total		70	140	50
Madera	20	12	24	12
Chowchilla	5	3	6	3
Firebaugh	5	3	6	3
Total	**100**	**88**	**176**	**68**

Alternative A—No Action

Under the No Action Alternative there would be no adverse effects on traffic. However, the future conditions would change to support agricultural activities. Some increase in traffic in the region could occur as a result of development. Potential effects would be evaluated by the County under CEQA, depending on the discretionary permits needed.

Alternative B—Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities

Effect TRAF-1: Temporary Construction-Related Increase in Traffic Volumes on Local and Regional Roadways Construction of Alternative B temporarily would increase the traffic volumes on SR 99; Avenues 7, 10, and 12; and Roads 16 and 21. It is assumed that the route preferred by construction workers and truck drivers traveling from the Fresno metropolitan area would be north along SR 99 to Avenue 7, west to Road 21, north to Avenue 10, and west to the Madera Ranch site. Workers originating from Madera most likely would travel south along SR 99 to Avenue 12, west to Road 21, south to Avenue 10, and west to the site.

From Chowchilla, workers most likely would travel south along Road 16 to Avenue 12, east to Road 21, south to Avenue 10, and west to the Madera Ranch site. Workers originating from Firebaugh most likely would travel east along Avenue 7 to Road 21, north to Avenue 10, and west to the site.

Using the above-mentioned travel pattern assumptions, Figure 3-9 identifies the preferred travel routes for both daily and peak-hour traffic volumes. Table 3-33 also provides estimates of the increase in traffic on local and regional roadways that would be anticipated to result from the construction workforce commuting to and from the construction site. As the anticipated construction activities are similar in scope, the anticipated construction workforce is assumed to be identical, regardless of alternative.

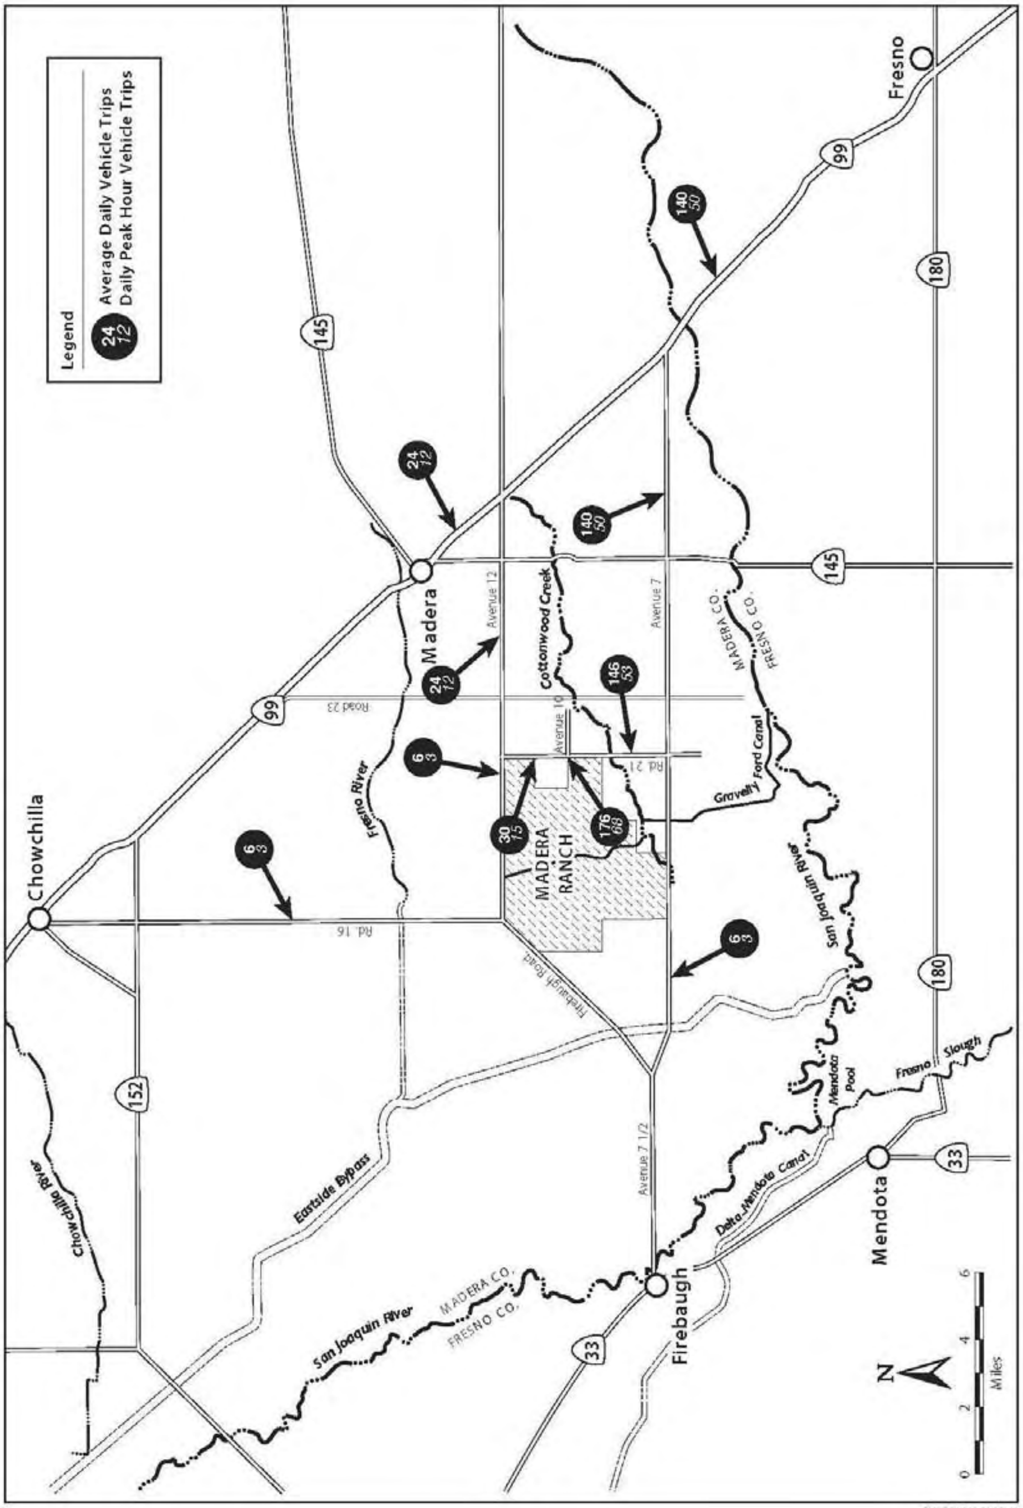

Figure 3-9 Project-related Trip Distribution – Construction Period

As described above, all the roadways are currently operating at an acceptable LOS. Because construction-related activities would not substantially increase the number of daily and peak-hour vehicles traveling along these roadways and would not contribute to exceedance of traffic thresholds recommended by the Institute of Transportation Engineers, Effect TRAF-1 is not considered adverse.

Table 3-33 Increase in Construction-Related Traffic on Regional and Local Roadways

Roadway Segment	Existing Average Daily Trips	Existing LOS	Daily Trips (Percent Increase)	Existing Peak-Hour Trips	Peak-Hour Trips (Percent Increase)
State Route 99	52,000	D	164 (0.3)	4,700	62 (1)
Avenue 7	3,300	B/C	146 (4)	330	53 (16)
Avenue 10	2,440	B/C	176 (7)	244	68 (28)
Avenue 12	2,270–8,520	B/C	30 (0.4–1)	227-852	15 (2–7)
Road 16	580	B/C	6 (1)	58	3 (5)
Road 21	NA	B/C	176 (NA)	NA	68 (NA)

NA = not available.
LOS = level of service.

Effect TRAF-2: Potential Increase in Construction-Related Traffic Volume Delay and Hazard on Local and Regional Roadways Construction-related activities would involve the daily use of heavy trucks, which could increase safety hazards on local roadways. Although construction-related activities would take place for only a short time, these activities would result in greater-than-normal truck traffic along local roadways. As additional heavy trucks travel to and from the Madera Ranch site, there could be conflicts between drivers of slow-moving vehicles (including farm equipment) and drivers of other vehicles on local roadways; therefore, Effect TRAF-2 is considered adverse. Implementation of Environmental Commitment PSU-1b, Implement a Traffic Safety Plan, would minimize the intensity of this effect.

Effect TRAF-3: Potential Damage to the Roadway Surface during Construction The increased volume and frequency of vehicle traffic along local and regional roadways during the construction period would not result in a substantial deterioration of the roadway surface. However, heavy trucks and construction equipment accessing the site could affect the structure or maintenance needs of specific turnout or access points from local roadways. Currently, both the County and Caltrans implement programs that provide for the maintenance of safe and reliable roadways. Effect TRAF-3 is considered adverse. Implementation of Environmental Commitment TRAF-1, Implement a Road Improvement Plan, would minimize the timing and intensity of this effect.

Effect TRAF-4: Potential Increase in the Demand for Parking Space at the Construction Site(s) Implementation of Alternative B would increase the demand for parking spaces for construction employees and would require the development of an equipment staging area at the Madera Ranch site. However, as described more fully in the Alternatives Section, adequate parking and equipment staging areas would be included as part of Alternative B. Because construction-related parking and equipment storage needs would be addressed in the design of the alternative, Effect TRAF-4 is not considered adverse.

Reduced Alternative B—Water Banking Outside the MID Service Area Using Select Swales and Alteration of Reclamation-Owned Facilities

Reduced Alternative B is similar in scope and design to Alternative B, with the primary exception that a reduced number of natural swales would be used and a reduced number of ponds would be constructed. Reduced Alternative B would also exclude construction of the Section 8 canal southwest extension. This would not result in changes to the overall construction and/or operational traffic patterns or levels anticipated under Alternative B and would result in equivalent effects (Effects TRAF-1, TRAF-2, TRAF-3, and TRAF-4). Thus, traffic effects are considered similar to those that would occur under Alternative B and are considered adverse. Implementation of Environmental Commitments PSU-1b and TRAF-1 would reduce the intensity of these effects.

Alternative C—Water Banking outside the MID Service Area without Swales and Alteration of Reclamation-Owned Facilities

Alternative C is similar in scope and design to Alternative B, with the primary exception that the natural swales that occur on the site would not be used for recharge. Thus, engineered basins would be built earlier in the design cycle than under Alternative B. This would not result in changes to the overall construction and/or operational traffic patterns or levels anticipated under Alternative B and would result in equivalent effects (Effects TRAF-1, TRAF-2, TRAF-3, and TRAF-4). Thus, traffic effects are considered similar to those that would occur under Alternative B and are considered adverse. Implementation of Environmental Commitments PSU-1b and TRAF-1 would reduce the intensity of these effects.

Alternative D—Water Banking outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal

Alternative D is nearly identical in scope and design to Alternative B, with the exception that water would be conveyed to the site via GF Canal. For this reason, one recharge basin would not be built under Alternative D that was proposed under Alternative B and lift stations would be built in locations different from those proposed under Alternative B. This would not result in changes to the overall construction and/or operational traffic patterns or levels anticipated under Alternative B and would result in equivalent effects (Effects TRAF-1, TRAF-2, TRAF-3, and TRAF-4). Thus, traffic effects are considered similar to those that would occur under Alternative B and are considered adverse. Implementation of Environmental Commitments PSU-1b and TRAF-1 would reduce the intensity of these effects.

Cumulative Effects

Temporary construction (Effect TRAF-1, TRAF-2 and TRAF-3) and parking effects (Effect TRAF-4) would not contribute to any cumulative effect as construction traffic is only temporary in duration and the project would provide sufficient parking for the activity under all of the alternatives.

As both Alternatives C and D are equivalent in scope and overall effect to Alternative B, it is anticipated that neither Alternative C nor D would contribute to cumulative traffic effects.

3.17 Water Resources

This section examines the potential effects of the proposed alternatives on water quality, as influenced by surface water hydrology and flooding, groundwater hydrology, surface water quality, and groundwater quality.

3.17.1 Affected Environment

This section provides an overview of water quality conditions in surface water and groundwater resources of the affected environment. The affected environment consists of water resources that exist within or flow through the study area, an area that includes Madera Ranch; the immediate surrounding area; the underlying groundwater aquifer; and surface drainage features such as GF Canal, Cottonwood Creek, the Fresno River, and the San Joaquin River. This section also discusses potential environmental effects on water quality associated with the alternatives and their conformance with the applicable federal, state, and local regulations.

MID and previous property owners collected a large amount of data for evaluating the existing physical and chemical conditions in surface water and groundwater resources in the area. These data include hydrologic and geophysical properties of soils, deeper geologic features, and groundwater aquifers. All of these data were evaluated for this analysis.

Climate

The San Joaquin Valley is surrounded by the Coast Ranges to the west, by the San Emigdio and Tehachapi Mountains to the south, by the Sierra Nevada to the east, and by the Delta and Sacramento Valley to the north. The climate of the valley floor is arid to semi-arid with dry, hot summers and mild winters. Summer temperatures may be higher than 100 degrees Fahrenheit (°F) for extended periods; winter temperatures are only occasionally below freezing (32°F). The average annual rainfall at Madera Ranch is approximately 11 inches, most of which falls between October and March. The winter snowpack, which accumulates above 5,000 feet elevation, primarily in the Sierra Nevada, supplies the vast majority of water in the basin. The west-side streams contribute little to water totals in the valley because the Coast Ranges are too low to accumulate a snowpack, and their eastern slopes are subject to a rain shadow phenomenon, producing only seasonal runoff.

Surface Water

The San Joaquin River is the major surface water feature south and west of the area (Figure 2-1). The total San Joaquin River basin drains 7,395 square miles, of which 4,320 square miles are in the Sierra Nevada and 2,273 square miles are in the San Joaquin Valley (Kratzer et al. 2002). According to USGS flow records from 1951 to 1995, 66% of the average San Joaquin River flow comes from three major east-side river basins: the Merced River (15%), the Tuolumne River (30%), and the Stanislaus River (21%) (Kratzer et al. 2002). The remaining flow in the San Joaquin River comes from the Bear Creek Basin, which includes Mud and Salt Sloughs, and small ephemeral creeks that drain from the west, including Orestimba Creek, Del Puerto Creek, and various drainage canals.

The other two major rivers in the action area are the Fresno River and the Chowchilla River. The Fresno River drains a watershed of approximately 237 square miles above Hidden Dam and

Hensley Lake. Historically, the Fresno River has had ephemeral flows consisting of large winter uncontrolled flows and no summer flows. The Chowchilla River forms the northern boundary of the Madera area and drains approximately 236 square miles above Buchanan Dam. The Chowchilla River, like the Fresno River, has ephemeral flows consisting of large winter uncontrolled flows and no summer flows. Minor drainages in the vicinity of Madera Ranch include Cottonwood Creek and its tributaries (Figures 2-1 and 2-2). These minor drainages convey water from the Madera Canal to local canals, and all of their flows are diverted for use. Madera Canal is 36 miles long and extends northwest from Friant Dam to Ash Slough and diverts water to MID. The canal crosses the Fresno River 3 miles downstream of Hidden Dam. West of the area is the Eastside Bypass, which conveys uncontrolled flows from the San Joaquin River and from miscellaneous drainages to northwestern Madera County.

Cottonwood Creek is an ephemeral stream in which MID and GFWD maintain flow recorders. The creek is fed by runoff within a rural basin that lies generally between the Sierra foothills and SR 99 and SR 49. Data from 1954 through 2003 indicate that natural flows occur only during the rainy season, typically beginning in mid-January and ending in late March, with the highest flows in February. In wet years, the creek frequently overflows its banks at the intersection of Road 23 and Avenue 10 (two miles east of the ranch) and on the south side of the ranch. Federal Emergency Management Agency (FEMA)-designated floodplains at Madera Ranch include the southeast half of Sections 13, 22, and 28. All of these floodplains are associated with Cottonwood Creek, which crosses Madera Ranch in Section 28 only. During the irrigation season (typically beginning in late March and running through September) MID uses the creek as an extension of the Main No. 2 Canal. Creek flows during this time are Millerton Lake and Hidden Lake waters being delivered to farmers by MID. Without these deliveries, the creek would be dry during this time throughout Madera Ranch and its vicinity.

Surface Water Quality Surface waters from the San Joaquin River, Fresno River, and Cottonwood Creek have been used to irrigate land around and on Madera Ranch for more than 100 years. In general, these waters are known for their high quality for agricultural use.

The average specific conductance for the San Joaquin River is 45 microSiemens per centimeter (µS/cm) which refers to the electrical conductivity of water (approximately 28 mg/L TDS; Table 3-34), which indicates a much lower TDS than the groundwater beneath Madera Ranch, which averages 466 µS/cm (approximately 291 mg/L TDS). Friant and Hensley Lake water delivered to Madera ranch in 2005–2007 had a TDS ranging from 28 to 100 mg/L, whereas groundwater quality beneath the ranch during this same period ranged from 180 to 660 mg/L TDS (MID groundwater monitoring report summary October 29, 2007). The 2001 Annual Water Quality Report for Hensley Lake (Chan 2002) states that nutrient alkalinity and chemical oxygen demand data show that excessive nutrients are not present. The average specific conductance for the Fresno River below Hensley Lake is 116 µS/cm (approximately 72.5 mg/L TDS; Table 3-35), also lower than the groundwater at Madera Ranch. Tables 3-34 and 3-35 present water quality data for the San Joaquin River and Fresno River, respectively, and are representative of the source water for the Proposed Action. The source water for the WSEP would dilute concentrations of minerals and other constituents in the native groundwater, and, as a consequence, recovered water would be of generally better quality than the native groundwater.

Table 3-34 Summary of Water Quality Data: San Joaquin River below Friant Dam, 1958–1988

	Count[a]	Maximum	Minimum	Average[b]	Criteria
Flow (cfs)	91	7,090	25	411	Not listed
pH (standard units)	123	8.2	6.5	7.1	<6.5 or >8.5[c]

Section 303(d) of the CWA establishes the total maximum daily load (TMDL) process to assist in guiding the application of state water quality standards. Under this section, states must identify streams whose water quality is impaired (affected by the presence of pollutants or contaminants) and establish the TMDL or the maximum quantity of a particular constituent that a water body can assimilate without experiencing adverse effect (U.S. Environmental Protection Agency 2007). The Fresno River, Cottonwood Creek, and upper San Joaquin River are not included on the 303(d) list. The 303(d) list does include reaches of the San Joaquin River, but all of the listed river reaches are downstream of the Madera Canal diversion and are not pertinent to this action.

EPA's STORET database (Storage and Retrieval of U.S. Waterways and Parametric Data) was searched for surface water quality information for Cottonwood Creek, but no data were available (STORET 2007). Because of the operations summarized above, the quality of Cottonwood Creek water is likely similar to that of all other MID conveyances during the irrigation season. During the rainy season (and based on the surrounding rural land uses), water quality is suspected to be similar to typical small rural streams, which are primarily dependent on mineral composition of the soils and associated parent materials within a watershed, hydrologic characteristics, and sources of contaminants in the watershed.

Groundwater

Madera Ranch is located in the Madera subbasin of the San Joaquin Valley Groundwater Basin. The total surface area of the subbasin is 394,000 acres or 614 square miles (California Department of Water Resources 2004). The Madera subbasin aquifer system consists of unconsolidated continental deposits, including older Tertiary and Quaternary age deposits overlain by a younger Quaternary deposit (California Department of Water Resources 2004). Groundwater recharge in the Madera subbasin occurs from river and stream seepage, deep percolation of irrigation water, canal seepage, and intentional recharge (California Department of Water Resources 2004). Groundwater flow is generally southwestward in the eastern portion of the subbasin, and to the northwest in the western portion (California Department of Water Resources 2004). However, groundwater flow directions vary on a local basis as a result of intense agricultural, municipal, and industrial groundwater pumping that also has caused overdraft in a variety of locations, including Madera Ranch. See the section on Water Supply, for additional information about groundwater hydrology.

Groundwater Quality Groundwater in the vicinity of Madera Ranch is used primarily for agricultural supply, although domestic wells serve rural residents. The section on Geology, describes the geologic and hydrogeologic characteristics of the local groundwater aquifer system, which is composed of an unconfined layer above the Corcoran Clay layer (E-clay) and a confined layer located beneath the Corcoran Clay layer.

Groundwater quality differences between the confined and unconfined aquifers are difficult to distinguish from production well samples because the majority of wells are perforated both above and below the Corcoran Clay, providing a mix of waters from both aquifers. In addition, the clay is thin to absent in some areas. Consequently, the majority of well sample data represent an average of water quality from within the confined and unconfined aquifers. However, it is known that the base of fresh water in the confined aquifer beneath the E-clay layer occurs about 1,000 feet below ground surface. The underlying saline groundwater originated from prehistoric periods when the Central Valley was a marine environment inundated by salt water (California Department of Water Resources 1975).

In general, groundwater quality in the eastern San Joaquin Valley is excellent with the dominant cation and anion being sodium and bicarbonate, respectively. The confined aquifer tends to have larger proportions of calcium. At the western edge of Madera County near the San Joaquin River, sodium and chloride are more prevalent. Nitrate is the most prevalent constituent that exceeds drinking water maximum contaminant levels (MCL) in the eastern San Joaquin groundwater basin (U.S. Geological Survey 2001). Agricultural practices are known to be the major cause of this nitrate contamination, with the MCL of 10 PPM of nitrogen being exceeded in about 40% of shallow wells. Concentrations of trace metals and other toxic inorganic constituents such as selenium, arsenic, and boron are generally low. The USGS frequently has detected pesticides in groundwater samples from the eastern San Joaquin Valley. However, only five pesticides were found in more than 10% of the samples, including atrazine, desethylatrazine, simazine, 1,2-dibromo-3-chloropropane (DBCP), and diuron (U.S. Geological Survey 2001). Concentrations of pesticides were generally low (less than 0.1 parts per billion [PPB]) and less than drinking water MCL. The widely used soil fumigant DBCP violated its MCL (0.2 PPB) in about 20% of domestic wells and 40% of agricultural wells located in vineyard production areas. Because this regional data showed elevated nitrate and DBCP, sampling of groundwater was conducted at Madera Ranch to determine whether this was an issue of concern.

Groundwater samples were collected from wells on the Madera Ranch site during 1999–2001 (TRC 1999, 2002) and 2005–2007 and were tested for organic and inorganic constituents. The locations of these wells are shown on Figure 3-10. Seven wells were tested for organic constituents. No organic constituents were detected, except for 1,2,3-Trichloropropane, which was detected in two wells located in Section 1 (RW-2 and RW-4) but was not detected in a third well located in Section 1 (RW-1) or in a downgradient well located in Section 4 (RW-21) (Table 3-36). There are no state and federal drinking water standards for this fumigant, but EPA Region IX has listed a health advisory – a drinking water equivalent level of approximately 0.02 micrograms per liter (µg/L). Contacts with the Madera County Agricultural Commission indicate that agricultural chemicals have been used on site, but based on a review of material safety data sheets, 1,2,3-Trichloropropane was not identified as an ingredient in the agricultural chemicals applied on site historically (TRC 2002). Based on the available data, the extent of effects on groundwater may be limited to the vicinity of these two wells.

Table 3-36 Summary of Groundwater Analysis Results for 1,2,3-Trichloropropane on Madera Ranch (μg/l)

3.17.2 Environmental Consequences

Alternative A—No Action

Under the No Action Alternative there would be no adverse effects to water quality. However, the future conditions would change to support agricultural activities. The type and extent of water quality effects from agricultural activities would vary based on the type of activities conducted; these effects would be evaluated by the County under CEQA, depending on the discretionary permits needed.

Alternative B—Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities

Effect WQ-1: Degradation of Water Quality Resulting from Construction Runoff
Construction of the recharge ponds, upgrades of canals, and installation of the recovery wells and recovery system would require grading and excavation along with disturbances of soils and vegetation under Alternative B. Although construction would be intermittent, stormwater runoff could cause soil erosion of disturbed sites and transport other construction-related contaminants (e.g., fuels, oil, concrete, paint) to nearby receiving waters and thereby impair water quality and aquatic organisms and their habitats. The extent of the effect depends on soil erosion potential, type of construction practice, extent of disturbed area, timing of precipitation events, and proximity to drainage channels.

This effect is considered adverse. Environmental Commitments WQ-1a and WQ-1b would minimize the extent and intensity of effects.

Effect WQ-2: Water Quality Effects from Construction-Related Dewatering Discharge of water from construction-related dewatering during lift station construction and enlarging of the Section 8 Canal could result in the release of contaminants to surface water or groundwater. Primary construction-related contaminants that may reach groundwater would include sediment, oil and grease, and construction-related hazardous materials.

This effect would be considered adverse if the quality of water in the canal or underlying groundwater exceeded established standards as a result of construction activities. Implementation of Environmental Commitment WQ-2 would ensure that this potential effect does not occur.

Effect WQ-3: Potential Effects on Groundwater or Surface Water Quality from Recharge or Recovery Operations Recharge operations may increase the potential for water quality degradation as a result of dispersion of contaminants from uncontrolled flows or a spill upstream of MID's diversion points. If contaminants were to enter the aquifer and concentrate to a degree that violates water quality standards, a major effect would result. As described below, MID would continue surveillance operations of MID conveyances to ensure that contaminants from uncontrolled flows or spills upstream do not enter the recharge facilities.

Alternative B temporarily may increase TDS in the groundwater beneath the ranch as a result of short-term leaching of salts during recharge. TDS in the native groundwater beneath the Madera Ranch ranges from about 180 to 660 mg/L (as shown in Table 3-37). Recharge water allocated from the San Joaquin River and Fresno River would contain approximately 28 to 100 mg/L TDS (Tables 3-34 and 3-35). MID had three percolation studies performed and found that leaching of salts from the soil profile would be largely complete during the initial three- to four-month recharge season. They further concluded that the increase in TDS would be short-term, temporary, and localized. After the initial flushing of salts has occurred, TDS concentrations would begin to decline as the low TDS recharge water mixes with the higher TDS groundwater. Over the long term, it is expected that TDS concentrations in groundwater would drop below current levels. An additional factor reducing the potential effect of leaching salts is that the swale recharge areas were chosen specifically because they overlie the highest-permeability soils with the lowest salt concentrations in the Madera Ranch area. Taken together, over the long term, the recovered water is expected to be more reflective of the source water quality, which has lower TDS concentrations than the native groundwater. There would be no adverse effect on groundwater quality over the long term.

The MROC, as described Section 2, would be responsible for development and implementation of the MOCP, which includes:

- monitoring recovery operations to ensure that 10% of the banked water is left behind to help abate the overdraft;
- monitoring TDS in recovered water leaving Madera Ranch and in groundwater flowing away from Madera Ranch to ensure that water quality remains suitable for irrigation purposes;
- monitoring drinking water wells within one mile of Madera Ranch for fecal coliform, TDS, and select components of TDS as specified by the Oversight Committee;
- monitoring water levels in perimeter wells during recharge operations and shutting down recharge operations if off-site water levels rise to within 30 feet of the ground surface;
- monitoring water levels in off-site wells during recovery operations and adjusting operations, providing compensation, or providing an alternate source of water in the event that water levels drop to unacceptable levels in off-site wells as a consequence of operations; and
- ongoing surveillance of MID conveyances to ensure that if accidental spills of hazardous materials occur, they do not enter the recharge facilities.

Implementation of the MOCP would ensure that effects associated with spills or leached salts are avoided or minimized. This effect is not considered adverse.

Effect WQ-4: Potential Soil Salinization from Elevated Groundwater Levels (also in Geology section) Because Alternative B will be operated and constrained so that water tables affected would not reach elevations higher than 30 feet below the ground surface at the Madera Ranch site boundary, groundwater would not cause salinization of the root zones of important, deep-rooted agricultural crops surrounding the site. Therefore, there would be no effect.

Effect WQ-5: Potential Erosion Attributable to Reversal of Flows in 24.2 Canal and Cottonwood Creek/Main No. 2 Canal In Phase 2, MID is proposing to construct lift stations on 24.2 Canal and Cottonwood Creek/Main No. 2 Canal to provide as much as 100 cfs of pump-back delivery capacity. Recovered water would be pumped back up the 24.2 Canal between Avenue 10 and the Fresno River. Recovered water would be pumped back up Cottonwood Creek/Main No. 2 Canal between Road 23 and SR 99.

During existing MID operations, Cottonwood Creek commonly carries 300 cfs, and no adverse scouring or bank erosion has been noted (Howard pers. comm.). Because only as much as 100 cfs is expected with Alternative B and velocities would likely be one foot per second or less, no adverse scouring or bank erosion is expected. This effect is not considered adverse.

Reduced Alternative B—Water Banking Outside the MID Service Area Using Select Swales and Alteration of Reclamation-Owned Facilities

Reduced Alternative B is similar in scope and design to Alternative B, with the primary exception that a reduced number of natural swales would be used (550 acres versus 700 acres as proposed under Alternative B) and a reduced number of recharge basins would be constructed (323 acres versus up to 1,000 acres under Alternative B). Reduced Alternative B would also exclude construction of the Section 8 canal southwest extension. Although Reduced Alternative B would use fewer swales and limits the number of recharge basins, thereby reducing effects associated with degradation of water quality resulting from construction runoff and from recharge or recovery operations (Effects WQ-1 and WQ-3), it would not result in changes to the quality of water sources or the overall patterns of water banking anticipated under Alternative B. With the implementation of the MOCP, Reduced Alternative B would result in similar effects (Effects WQ-1, WQ-2, WQ-3, WQ-4, and WQ-5), from construction and operation of the WSEP. Thus, water quality effects would be similar to those that would occur under Alternative B, and Effects WQ-1 and WQ-2 are considered adverse. Implementation of Environmental Commitments WQ-1a, WQ-1b, and WQ-2 would reduce the intensity of these effects.

Alternative C—Water Banking outside the MID Service Area without Swales and Alteration of Reclamation-Owned Facilities

Alternative C is similar in scope and design to Alternative B, with the primary exception that the natural swales that occur on the site would not be used for recharge. Thus, engineered basins would be built earlier in the design cycle than under Alternative B. This would not result in changes to water sources or the overall patterns of water banking anticipated under Alternative B and, with the implementation of the MOCP, would result in similar effects (Effects WQ-1, WQ-2, WQ-3, WQ-4, and WQ-5) resulting from construction and operation of the WSEP. Thus, water quality effects are considered equivalent to those that would occur under Alternative B, and Effects WQ-1 and WQ-2 are considered adverse. Implementation of Environmental Commitments WQ-1a, WQ-1b, and WQ-2 would reduce the intensity of these effects.

Alternative D—Water Banking outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal

Alternative D is similar in scope and design to Alternative B, with the exception that water would be conveyed to the site via GF Canal. For this reason, one recharge basin would not be built under Alternative D that was proposed under Alternative B. This would not result in changes to quality of the water sources or the overall patterns of water banking anticipated under Alternative B and, with the implementation of the MOCP, would result in similar effects (Effects WQ-1, WQ-2, WQ-3, and WQ-4). Use of GF Canal for conveyance does alter the pattern of dispersal of water into the bank but is not anticipated to alter the water quality characteristics of the bank. Effects resulting from reversal of flows (Effect WQ-5) still could occur but would occur on GF Canal (Effect WQ-6).

Thus, overall water quality effects are considered equivalent to those that would occur under Alternative B and are considered adverse. Implementation of Environmental Commitments WQ-1a, WQ-1b, and WQ-2 would reduce the intensity of these effects.

Effect WQ-6: Potential Erosion Attributable to Reversal of Flows in Gravelly Ford Canal
In Phase 2, MID is proposing to construct a lift station on GF Canal to provide as much as 200 cfs of pump-back delivery capacity. Recovered water would be pumped back up GF Canal to the San Joaquin River.

During existing GFWD operations, GF Canal always carries less than 200 cfs, and no adverse scouring or bank erosion has been noted (Dorrance pers. comm.). Under Alternative D, improvements to the GF Canal would be engineered to accommodate as much as 200 cfs with velocities of up to one foot per second, which is the highest flow that would occur under this alternative. Thus, no substantial scouring or bank erosion is expected. This effect is not considered adverse.

Cumulative Effects

Construction-related effects (WQ-1 and WQ-2) would have no regional water quality cumulative effect because environmental commitments included as part of Alternative B would be implemented to avoid impacts on water quality. Adverse water quality effects related to operations could have cumulative impacts within Madera County (Effects WQ-3, WQ-5, and WQ-6). Implementation of the MOCP (Madera Irrigation District 2007) and the ongoing activities of the MROC would ensure that local water quality effects are avoided and minimized. No additional activities are known to exist that would affect water quality in local canals and in the groundwater in and around Madera Ranch. Thus, no potential cumulative effects are anticipated for any of the alternatives (Alternatives B, C, and D).

3.18 Water Supply

The policies and regulations that govern Reclamation and the Corps must be taken into account in the analysis of the alternatives and in assessing potential effects on local or regional sources of surface water supply. MID's proposed operations would be subject to the conditions of MID's existing contracts with Reclamation and of MID's water rights.

The analysis of surface water resources and supply is based on a comparison of the range of historical diversions by MID to what is expected with the Proposed Action and alternatives. The analysis of groundwater resources and supply is based on an assessment of current groundwater basin conditions and expected conditions with the Proposed Action and alternatives.

3.18.1 Affected Environment

Sources of water for the Proposed Action and alternatives include MID's long-term water supply contracts with Reclamation (Friant Division supplies and Hidden Unit supplies), CVP non-storable uncontrolled flows delivered under temporary contract, and MID's pre-1914 water rights.

Friant Division Supplies

MID has a CVP water supply contract with Reclamation for delivery from the Friant Division of 85,000 AF/year of Class 1 water and 186,000 AF/year of Class 2 water, both for irrigation purposes (long-term renewal contract 175r-2891-D; December 29, 2010). Class 1 water is

–firm” supply, and Class 2 water is less reliable water that is dependent on seasonal runoff accumulating behind Friant Dam. Class 2 water may be available after all Class 1 obligations have been met. MID’s yield from all the water supply contracts averaged 167,342 AF/year during the period from 1985 to 2007. The long-term agricultural water supply contracts that supply water to the Madera area are summarized in Table 3-38.

Table 3-38 CVP Water Supply Contracts in Madera Area (AF/year)

Contractor	CVP Source	Class 1 Supply	Class 2 Supply	Other CVP Supplies
MID	Friant Division	85,000	186,000	
	Hidden Unit (from Hensley Lake on the Fresno River)			40,357 (average 1985–2007)
GFWD	Friant Division	–	14,000	
CWD	Friant Division	55,000	160,000	
	Buchanan Unit (from Eastman Lake on the Chowchilla River)		–	24,000
Madera County	Friant Division	200	–	

Notes:
GFWD = Gravelly Ford Water District.
CWD = Chowchilla Water District.
CVP = Central Valley Project.
– = no contract.

Water available from behind Friant Dam is diverted into the Madera Canal (for MID and CWD), the San Joaquin River (for GFWD), and the Friant-Kern Canal (for the remaining Friant contractors) (Figure 2-1). MID receives water from the Madera Canal through diversions into the district at the Lateral 6.2, Hildreth Creek (sporadically), the Fresno River (Lateral 18.8 with downstream diversion into the Main Canal), Dry Creek–Lateral 24.2, Berenda Creek, and at Lateral 32.2. Water for GFWD and several other users is released down the San Joaquin River for diversion at various points above Gravelly Ford.

However, the SJRRP, as described previously, would result in roughly a 25% decrease of water available from the Friant Division. The effects of this water supply reduction on MID water supply are described further under Historical and Proposed Diversions.

Hidden Unit Supplies

MID also has a contract with Reclamation that makes available for delivery to MID –the entire quantity of Project Water from Hidden Unit for irrigation purposes” (Long-Term Renewal Contract 14-06-200-4020A-E; December 29, 2010). The Hidden Unit includes CVP water stored or flowing through Hensley Lake on the Fresno River. The yield from the Hidden Unit has averaged 52,952 AF/year since 1992 (Dorrance pers. comm.). The Corps, which operates Hidden Dam/Hensley Lake, releases water down the Fresno River from Hensley Lake for diversion by MID into its Main Canal. The river typically is dry downstream of the MID diversion, although when flood control parameters have been exceeded, excess flows are released past the MID diversion. In some years, flows in excess of MID needs extend to the Eastside Bypass for short periods. MID also uses the Fresno River channel to convey Friant water from the Madera Canal to the Main Canal diversion.

Other Supplies

MID has pre-1914 water rights that average 7,938 AF/year from Big Creek and 7,719 AF/year from Soquel Creek (Dorrance pers. comm.). Water from Soquel Creek is regulated in Bass Lake and then flows into Millerton Lake and is diverted into the Madera Canal. Water from Big Creek is diverted through Hensley Lake.

Friant Section 215 water, which occasionally is available to MID, is CVP water that Reclamation determines is available at Friant Dam as the result of an unusually large water supply not otherwise storable for CVP purposes, or infrequent and otherwise-uncontrolled flows of short duration. MID must enter into a temporary contract with Reclamation, not to exceed 1 year, to obtain Friant Section 215 water.

Historical and Proposed Diversions

MID diverts an average of 167,342 AF/year (1985–2007) of surface water from the sources discussed above. Of that amount, an average of 102,756 AF/year (1985–2007) of surface water is delivered to district farmers. The remaining surface water, averaging 64,586 AF/year (1985–2007), has been recharged (with a small amount lost to evapotranspiration) through MID conveyances at eight existing percolation facilities, or incidentally recharged as a result of spills Table 3-39 provides details regarding historical availability of water for the bank with and without the estimated impact of the SJRRP on water supply. The presented data are based on continuous, daily, weekly, and monthly flow measurements by MID and Reclamation at various points of diversion and readings from more than 800 farm turnouts. This table includes estimated diversions of MID entitlements toward the SJRRP. Detailed notes on assumptions and calculations follow the table.

NA = not applicable.

[1] MID performs water accounting on a calendar year basis.

[2] Year Type: W = Wet year type. AN = Above normal year type. BN = Below normal year type. D = Dry year type. C = Critical year type

[3] Diversions include transfers-in and MID Entitlements: Friant Class I, Friant Class II, Friant 215, Hidden Unit, Big Creek, North Fork Willow, and carryover of MID entitlements in Millerton Reservoir. It does not include: natural waters and other non-MID flows in creeks used in the MID distribution system; City of Madera run-off entering the MID distribution system; or Fresno River flows that were not diverted into the MID distribution system.

[4] As measured by MID.

[5] As measured by MID at Airport Pit, Burgess Pond, Allende Pond, Russell Pond, Dirt/Beeman Pit, Hospital Pond, and Pistoresi Pond. Deliveries to these locations were not formally measured by MID prior to 1993 but were generally minor for the period 1985-1992. MID also periodically sends water to Lake Madera, which is located adjacent to the Fresno River upstream of the MC&I intake. Consequently, these flows are not tracked in this spreadsheet and are excluded from Water that Would Have Been Available to the Project.

[6] Required Carriage Water includes normal operational conveyance recharge, evaporation, evapotranspiration, and water that flows out of the MID's distribution

Calendar Year[1]	Year Type[2]	MID Diversions[3]	Surface Water Delivered To MID Customers[4]	Water Sent to Existing Recharge Basins[5]	Required Carriage Water[6]	Water that would have been available for the Proposed Action[7]	Water that would have been available for the Proposed Action with River Restoration[8]

system back into the Fresno River and San Joaquin River. Normal conveyance recharge, evaporation, and evapotranspiration were calculated using 2004 as a benchmark year in which uncontrolled recharge was minimal and by back-calculating the amount of recharge per day that MID ran water in its system. This factor was then applied to other years adjusting for the actual number of days that MID ran water during those years.

[7] Water that Would Have Been Available to the Project represents MID entitlement water that was diverted, but not delivered to MID customers or to existing recharge basins or used as carriage water. Values in this column have been capped at 55,000 acre-feet because that is the annual recharge capacity of the Project. In years with transfers-in, the deductions for deliveries, recharge, and carriage water were adjusted downward using the ratio:
Diversions of MID Entitlements/(Diversions of MID Entitlements + Transfers-in).

[8] San Joaquin River restoration impact on available water was estimated by using the Steiner (September 2005) estimated reduction in MID Class 1 and 2 allocations for 1985–2004 and the averages for the year types of 2005–2007 as detailed in the Kondolf hydrographs used in the Stipulation of Settlement (September 2006). First, the Steiner reduction was reduced by the amount of Class 1 and 2 allocations that were not called by MID in that year because other cheaper water was available (e.g., 215 and uncontrolled flows). Under a River Restoration scenario MID would have called this water. Second, the total MID diversions for that year were reduced by the adjusted Steiner reduction. Third, the diverted water was allocated in the following order to stay consistent with the philosophy that MID will not reduce other uses and recharge as a consequence of the Proposed Action:

- First: Water required for conveyance recharge and ET (carriage water),
- Second: MID Farmer Deliveries
- Third: Water sent to existing recharge basins
- Fourth: Spill back to SJ and Fresno Rivers
- Fifth: Water Bank

The MID service area includes approximately 129,000 acres (more than 200 square miles) and approximately 417 miles of open-flow gravity conveyances, of which 192 miles are unlined and 225 miles are clay-lined (MID AB3030 Groundwater Management Plan prepared by Boyle Engineering 1999). The system does not include any telemetry or Supervisory Control and Data Acquisition systems to provide real-time adjustment of flows in response to changing conditions. Ditch tenders adjust flows in response to farmer demand by adding or removing boards from weir structures that are usually miles from locations where flow adjustment is required—resulting in significant lag times and inaccuracy. Historically, water that was not accounted for as delivered to farmers or sent to existing recharge basins or carriage water was attributable to:

- unauthorized diversions of MID's water for agricultural use;
- irregular, uncontrolled spills at a variety of locations that changed from month to month and year to year, depending on operational circumstances throughout the 200–square mile service area; and
- extended evaporative and seepage losses (above those indicated in the column titled Required Carriage Water) from conveyances that were filled to capacity and continued to hold water above immediate irrigation needs.
- The extensive conveyance system has been used as a form of temporary banking to accommodate uncontrolled flows and to allow greater flexibility in MID's deliveries.

In response to these conditions, MID's operations have become more efficient. Ditch tenders are required to be more responsive to farmers' demands and to curtail lag time and inaccuracies. In addition, MID has become more vigilant in preventing unauthorized diversions of its water supplies. Thus, MID is not proposing to increase the amount of water it diverts, reduce deliveries to farmers, or reduce deliveries to existing recharge basins, on average, and would be consistent with the SJRRP.

Table 3-39 details the historical availability of MID water that could have been banked, and conservatively excludes all water that returns to the Fresno and San Joaquin Rivers from diversions of MID's entitlements. This exclusion is conservative because non-MID water also is diverted by others into MID's conveyance system, such as uncontrolled flows and city of Madera runoff. Use of the conveyance system to control uncontrolled flows and runoff is likely to continue and is under the control of other agencies. MID has not included in Table 3-39 such flows as being available for the WSEP because it has no control over such operations. Further, it should be noted that MID uses an approximately 12-mile reach of the Fresno River to convey water from the Madera Canal and Hensley Lake to the main intake (MC&IC intake) of the MID distribution system. All losses and non-MID uses of water along this reach of the Fresno River have been excluded from the WSEP availability calculation.

Historically, there would have been water available for recharge in each of the last 22 years, with an average availability of 20,367 AF/year. Over the last 22 years, available water exceeded the proposed banking capacity of the WSEP.

However, the implementation of the SJRRP would result in a decrease in the supplies available to MID from the Friant Division. As such, the water that would be available for use by the

WSEP is less than what it would have been historically. The impact of the SJRRP on available water was estimated by using the Steiner (September 2005) estimated reduction in MID Class 1 and 2 allocations for 1985–2004 and the averages for the year types of 2005–2007 as detailed in the Kondolf hydrographs used in the Stipulation of Settlement (MID September 2006). Under the SJRRP, MID water would have been available for recharge in only 11 of the last 22 years (50% of the time), with an average availability of 15,398 AF/year. Thus, the majority of water that historically would have been available to the project (more than 75% over the period 1985–2007) would still be available after implementation of the San Joaquin River restoration settlement agreement. Other than this decrease in MID's entitlement to Friant Division supply, the SJRRP has no effect on the WSEP. State and federal agencies currently are evaluating the effects of the SJRRP in a program-level EIS/EIR.

Groundwater Hydrology

The WSEP is located in the Madera subbasin of the San Joaquin Valley groundwater basin. The total surface area of the subbasin is 394,000 acres or 614 square miles (California Department of Water Resources 2004). Surface water in the northern portion of the San Joaquin Valley, including MID's service area, is drained toward the Delta by the San Joaquin River and its tributaries. Surface water in the southern portion of the valley is drained internally by the Kings, Kaweah, Tule, and Kern Rivers, which flow into the Tulare drainage basin. Under natural conditions, these surface water flow patterns historically were mimicked by groundwater flows. Those conditions no longer prevail because of more than 100 years of intense groundwater pumping. The Madera subbasin (DWR Number 22.06) is bounded on the north by the Chowchilla subbasin (DWR Number 22.05), on the south by the Kings subbasin (DWR Number 22.08, separated by the San Joaquin River), on the west by the Delta-Mendota subbasin (DWR Number 22.07, separated by the San Joaquin River), and on the east by the crystalline bedrock of the Sierra Nevada foothills.

The Madera subbasin groundwater aquifer system consists of unconsolidated continental deposits, including older Tertiary and Quaternary age materials overlain by younger Quaternary deposits. Groundwater in the Madera subbasin is recharged by natural river and stream seepage, deep percolation of irrigation water, canal seepage, and intentional recharge. Groundwater flow is generally to the southwest in the eastern portion of the subbasin and to the northwest in the western portion. Locally, however, groundwater flow directions vary significantly because of the intense agricultural, municipal, and industrial groundwater pumping, which also has caused overdraft in a variety of locations, including the vicinity of Madera Ranch (Madera Irrigation District 1999; California Department of Water Resources 2004; Schmidt pers. comm.). The amount of groundwater pumping within the Madera subbasin varies from year to year, depending on the availability of MID surface water, precipitation, and temperature. In critically dry years, groundwater pumping can more than double over the amount of pumping during wet years.

As detailed in MID's AB3030 Groundwater Management Plan and in DWR's *Bulletin 118* (California Department of Water Resources 2004), the Madera subbasin has been subjected to severe long-term groundwater overdraft. A variety of overdraft estimates has been compiled for various portions of the basin. At the request of MID, Ken Schmidt and Associates compiled the results of these various efforts to estimate overdraft for the entire basin. Based on the compiled prior work and independent calculations, Schmidt estimated an average groundwater overdraft of

100,000 AF/year as of 2000 (Schmidt pers. comm.). The recent draft Integrated Regional Water Management Plan substantiated these findings and indicated overdraft could be as much as 200,000 AF/year by 2030 (Madera County 2008).

As depicted in Figure 3-11, groundwater levels in the Madera subbasin have declined an average of 67 feet since 1945 and 30 feet since 1980 (California Department of Water Resources 2005). Although there have been some years of slight recovery, the overall trend is downward. Similar groundwater level declines have occurred in the vicinity of Madera Ranch. Since 1943, groundwater levels beneath Madera Ranch and the surrounding area have declined at least 90 feet, and the trend remains downward.

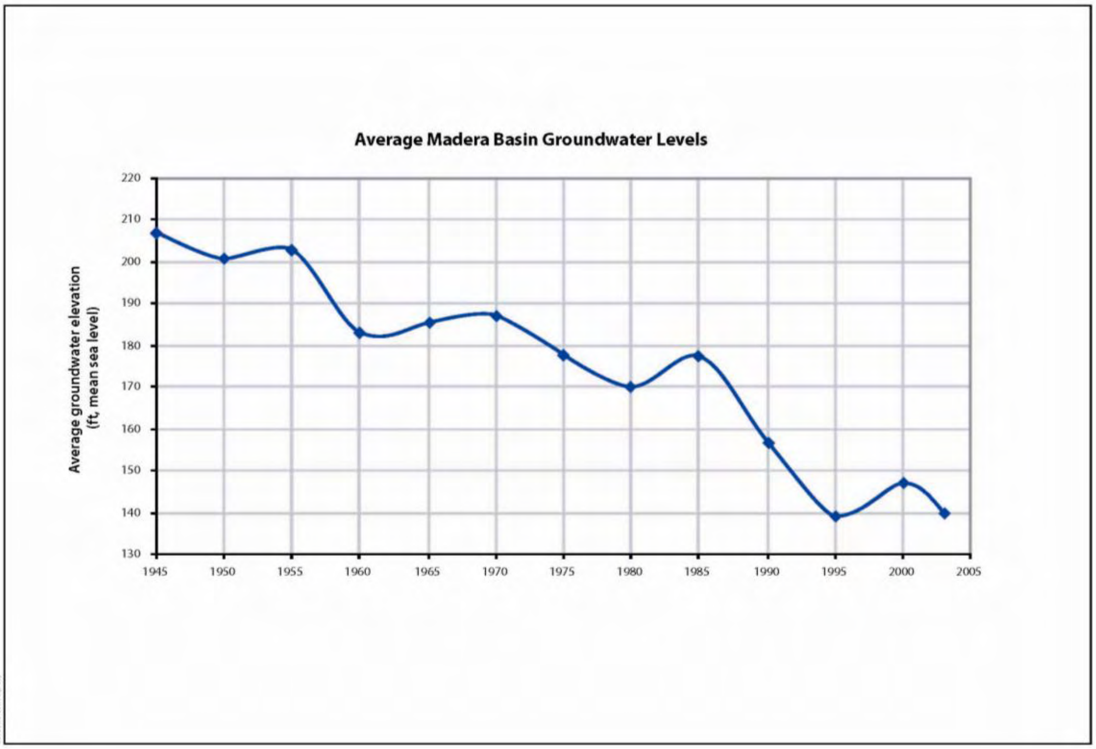

Figure 3-11 Historical Trends in Average Groundwater Levels in the Madera Subbasin

The available banking capacity in the dewatered aquifer beneath the Madera Ranch area (above the current water table) has been estimated to range from 286,720 to 573,440 AF, with 400,000 AF most commonly estimated (CALFED Bay-Delta Program 2000; Bureau of Reclamation 1998).

3.18.2 Environmental Consequences

The WSEP's design capacity is based on facilities to divert and convey as much as 200 cfs of water from either Friant Division or Hidden Unit operations to Madera Ranch for recharge. Recovered water would flow by gravity or be pumped to MID. Each of the alternatives, including the Proposed Action, specifies an annual recharge capacity of 55,000 AF/year. These specifications have been established for design purposes. The operating conditions and the ability to bank water would be determined primarily by:

- availability of wheeling capacity in the Madera Canal and MID conveyances,
- percolation rate and total area available to recharge the water,
- ability of the groundwater basin to bank and transmit water,
- hydrologic conditions that would influence the volume and timing of diversions of water for banking from the Friant Division or Hidden Unit operations,
- farmer irrigation demand in the pump-back area, and
- San Joaquin River restoration.

The effects of the alternatives on water supply and management are related primarily to the amount of water that would be diverted to local users. MID is not proposing to increase the amount of water it diverts; rather, the alternatives include banking a portion of the water that historically has been diverted.

Alternative A—No Action

Under the No Action Alternative, Reclamation would not approve the banking of CVP water outside MID's service area, nor would Reclamation issue an MP-620 permit, a Mid-Pacific Region-specific permit to approve modifications to its distribution system. Reclamation's No Action Alternative would have no adverse effects on water supply. However, the future conditions could change to support agricultural activities. The type and extent of water supply effects from agricultural activities would vary based on the type of activities conducted; in general increased agricultural operations would be expected to contribute to the groundwater overdraft situation in the County. These effects would be evaluated by MID or the County under CEQA depending on the discretionary permits needed.

Alternative B—Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities

Effect WS-1: Changes in Groundwater Supplies or Overdraft Rates in Madera County

MID proposes to limit water recovery to 90% of the water that is recharged at Madera Ranch under the Proposed Action. This limitation would ensure that the Proposed Action does not deplete groundwater supplies in Madera County but rather contributes to the reduction of the rate of groundwater overdraft over time. Compared to the current overdraft conditions, the Proposed Action would have only a slight benefit. However, over the life of the project, the reduction in the rate of overdraft would be a beneficial effect.

Effect WS-2: Substantial Effects on Surrounding Groundwater Wells as a Result of Recovery Operations Under Alternative B, approximately 40 new wells would be used to recover banked water. While the well field has been designed to draw from the mound of banked surface water, it is possible that this pumping could cause the water levels in surrounding wells to decline below levels that would occur absent Alternative B. As described in Chapter 2, the MROC will monitor water levels in perimeter wells and impose operational constraints to avoid or minimize effects. The MROC is responsible for implementation of the MOCP. The plan would include the following basic activities.

- Monitor recovery operations to ensure that 10% of the banked water is left behind to help alleviate overdraft.

- Monitor TDS in recovered water leaving Madera Ranch and in groundwater flowing away from Madera Ranch to ensure that water quality remains appropriate for irrigation purposes.
- Monitor drinking water wells within one mile of Alternative B for fecal coliform, TDS, and select components of TDS, as specified by the MROC.
- Monitor water levels in perimeter wells during recharge operations and shut down recharge operations in the event that off-site water levels rise to within 30 feet of the ground surface.
- Monitor water levels in off-site wells during recovery operations and adjust operations, provide compensation, or provide an alternate source of water in the event that water levels drop to unacceptable levels in off-site wells as a consequence of operations.
- Perform ongoing surveillance of MID conveyances to ensure that, if accidental spills of hazardous materials occur, these spills do not enter the recharge facilities.

Implementation of the MOCP would ensure that effects are avoided or minimized. This effect is not considered adverse.

Effect WS-3: Substantially Alter the Existing Drainage Pattern or Contribute to Existing Local or Regional Uncontrolled Flows Madera Ranch and the surrounding landscape are fairly level. Standard measures for erosion control and management of the stormwater runoff would be included in the construction plans for Alternative B, and, therefore, this alternative would not substantially alter any existing drainage pattern.

One thousand acres of recharge basins would be constructed within an area as large as 1,300 acres, although individual basin cells would be on the order of five–80 acres each. These basins would be excavated and some spoils would be used to form low berms to achieve an effective depth of approximately five feet to prevent wind-induced waves from overtopping the berms. Berm heights would vary, depending on topography, but would not exceed five feet.

DWR’s DSOD has developed criteria delineating its jurisdiction over impounded surface water bodies. Dams that meet jurisdictional coverage must meet specific safety and integrity requirements based on the risk associated with their potential failure. Water would be impounded in shallow excavations, and most of the berms would be lower than five feet and below the DSOD jurisdictional height limit of six feet. The nearest residence is approximately 0.75 mile away from the recharge basin window and outside the fenced ranch perimeter. Given the area between the recharge basins and residences, water escaping in the event of berm failure would pool on land between the Madera Ranch site and the residence. This effect is not considered adverse.

Effect WS-4: Adverse Effects on the Area of Origin of Water from Amendments to Existing Water Rights MID is not proposing to amend its existing water rights and is not proposing to buy water as part of Alternative B. Water exchanges between MID and other potential users would require additional analysis, but generally would include only water that historically was diverted for agricultural use or that previously has been exchanged between parties in a similar manner.

MID does intend to sell banking space to local M&I users. Banking capacity also could be reserved and used to help implement the SJRRP. MID would allocate 10,000 AF each for M&I and environmental water users in Madera County. M&I users are broadly evaluated in the section on Growth Inducing Effects. All potential users would require separate environmental approvals and would rely on their own water entitlements in using the proposed groundwater banking and recovery facilities. These exchanges would not reduce the availability of water in the area of origin. There is no effect.

Effect WS-5: Reduced Surface Water Availability in Madera County or the Area of Origin Alternative B does not involve diversion of water directly from the San Joaquin River or Fresno River to the water bank. Friant Division and Hidden Unit water would be diverted from the Millerton Lake and Hensley Lake, respectively, as MID has done historically, and then delivered to Madera Ranch. The quantities of water diverted would be within the range of historical diversions. There would be no direct influence on the San Joaquin River or Fresno River water availability or streamflows.

Nothing in Alternative B would allow MID or its participants to divert or transfer water out of the area of origin, and would not deprive those with legal rights or entitlements to the San Joaquin River or Fresno River from obtaining water supplies currently available. Alternative B does not include, nor seek changes to, water rights, in terms of type, place, or point of use, for water that originates in the San Joaquin River or Fresno River.

There are no known adverse water supply effects that would be associated with the proposed diversion of Class 1, Class 2, or Section 215 water because:

- this water is available as part of permitted operations of the Friant Division,
- reductions in diversions resulting from the SJRRP would not prohibit the bank from meeting MID or Reclamation’s purpose and need,
- operations are already conditioned under the existing Biological Opinion, and
- current facilities would be used.

Because these waters would be used within existing local service areas, Alternative B would not reduce local water supplies. In fact, it provides a net benefit in available water supplies to Madera County. Water reductions resulting from the SJRRP would reduce the average availability of water by roughly 25%. However, this reduction would not significantly inhibit MID’s ability to meet the water needs of the project because the SJRRP would not result in a reduction of water available in wet years (Table 3-39).

Thus, there would be no substantial adverse reduction in surface water availability in Madera County or the San Joaquin area of origin.

Effect WS-6: Water Supply Reliability Improvement in Dry Years Under Alternative B, up to 55,000 AF of banked water would be available in dry years. The actual amount available would depend on the amount of water banked in previous years. This would be an improvement in water supply reliability during dry years because the banked water would be used to offset supply reductions in dry years, thereby making supply more dependable in all year types. This would be a beneficial effect.

Reduced Alternative B—Water Banking Outside the MID Service Area Using Select Swales and Alteration of Reclamation-Owned Facilities

Reduced Alternative B is similar in scope and design to Alternative B, with the primary exception that a reduced number of natural swales would be used and a reduced number of ponds would be constructed. This would not result in any differences from what was described above for Alternative B relative to changes to existing water rights or the overall method of water banking and, with the implementation of the MOCP, would result in nearly identical effects (Effects WS-1, WS-2, WS-3, WS-4, WS-5, and WS-6). Thus, water supply effects are considered identical to those that would occur under Alternative B and not considered adverse. Similar to Alternative B, groundwater overdraft reduction would be beneficial.

Alternative C—Water Banking outside the MID Service Area without Swales and Alteration of Reclamation-Owned Facilities

Alternative C is similar in scope and design to Alternative B, with the primary exception that the natural swales that occur on the site would not be used for recharge. This would not result in any differences from what was described above for Alternative B relative to changes to existing water rights or the overall method of water banking and, with the implementation of the MOCP, would result in nearly identical effects (Effects WS-1, WS-2, WS-3, WS-4, WS-5, and WS-6). Thus, water supply effects are considered identical to those that would occur under Alternative B and not considered adverse. Similar to Alternative B, groundwater overdraft reduction would be beneficial.

Alternative D—Water Banking outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal

Alternative D is similar in scope and design to Alternative B, with the exception that water would be conveyed to the site via GF Canal. This could result in substantial effects on existing water rights (Effect WS-7) or regional surface water availability (Effect WS-8) that does not occur under either Alternative B or Alternative C (Effects WS-4 and WS-5).

Alternative D still would result in beneficial effects on local groundwater supply (Effect WS-1) nearly identical to those that occur under Alternative B and would not adversely affect local groundwater wells and existing drainage patterns (Effects WS-2, WS-3, respectively).

Effect WS-7: Adverse Effects on the Area of Origin of Water from Amendments to Existing Water Rights MID is not proposing to amend its existing water rights and is not proposing to buy water as part of Alternative D. However, significant water exchanges would need to occur in order to facilitate the use of GF Canal as the primary conveyance route for water coming into and out of the bank. As water would not be able to be pumped back into MID's service area, MID would release water into the San Joaquin River in exchange for other water releases from the Friant Dam. Reclamation is the only feasible partner for such exchanges that would allow MID to bank its existing water right at Madera Ranch and then exchange that water for releases of SJRRP water into MID's service area.

MID does intend to sell banking capacity to local M&I users. Additional banking capacity also could be reserved and used to help implement the SJRRP in addition to water exchanges that would facilitate the functionality of Alternative D. Under Alternative B, MID would allocate 10,000 AF each for M&I and environmental water users in Madera County. M&I users are broadly evaluated in the Section on Growth Inducing Effects. All potential users would require separate environmental approvals and would rely on their own water entitlements in using the proposed groundwater banking and recovery facilities. None of the proposed exchanges would reduce the availability of water in the area of origin. There is no effect.

Effect WS-8: Reduced Surface Water Availability in Madera County or the Area of Origin
Alternative D would involve the diversion of water during wet years directly from the San Joaquin River to the water bank via GF Canal, and could therefore alter the flows in the river and by diverting water at the beginning of Reach 2. However, this diversion would be compliant with the flow requirements set forth under the Settlement, which has been developed to protect downstream beneficial uses. As shown in Table 3-39, MID would be able to bank available water during most wet years. During dry years, water would not be available to the bank, as it would be needed for restoration flows, and no diversions via GF Canal would occur.

Under Alternative D, MID could bank water during wet years without adversely affecting restoration flows. During dry years, MID would not bank and could make releases to the San Joaquin River for restoration flows in exchange for the delivery of restoration flows to MID users. The flow release schedule for the SJRRP calls for the release of 116,662 AF during critical low years, representing the smallest release under the Settlement. During the eight critical dry years during 1984–2007, MID surface water deliveries averaged 67,122 AF (with total diversions averaging 100,732 AF) and a maximum surface water delivery of 97,570 AF in 2007. Thus, settlement releases could be exchanged with MID deliveries, even in critical dry years. This trend holds true for deliveries under all water type conditions, and thus MID could exchange flows with the SJRRP releases without adverse effects on San Joaquin River flows. These exchanges would, in years that exchanges occur, allow Reclamation to achieve its flow objectives in Reach 2, but Reclamation still would be required to make releases to support five-cfs flows in Reach 1 (from Friant Dam to GF Canal). This would not represent an adverse effect on flows in the San Joaquin River as it would have no effect on the benchmarks necessary to meet the goals of the San Joaquin River Settlement. No loss of surface water is expected.

Additionally, nothing in Alternative D would allow MID or its participants to divert or transfer water out of the area of origin, and Alternative B would not deprive those with legal rights or entitlements to the San Joaquin River or Fresno River from obtaining water supplies currently available. Alternative D does not include, nor seek changes to, water rights in terms of type, place, or point of use, for water that originates in the San Joaquin River or Fresno River.

No known adverse water supply effects would be associated with the proposed diversion of Class 1, Class 2, or Section 215 water because additional supplies are not being requested and SJRRP would not diminish the effectiveness of the WSEP because:

- both MID's CVP supplies and the SJRRP water are available as part of permitted operations of the Friant Division,
- overall reductions in contract water and deliveries resulting from San Joaquin River restoration would not prohibit the bank from meeting MID or Reclamation's purpose and need,
- operations are already conditioned under the existing Biological Opinion(s) governing CVP operations, and
- current facilities would be used, and in several areas resized, to allow more operational flexibility.

Because these waters would be used within existing local service areas, Alternative D would not reduce local water supplies. It is anticipated that Alternative D would result in a net benefit in available water supplies to Madera County. Water reductions resulting from the SJRRP would reduce the average availability of water by roughly 15%. However, this reduction would not significantly reduce the water available for banking in the WSEP to the extent that the project would lose feasibility. San Joaquin River restoration would result in no reduction of water available in wet years (Table 3-39).

There would be no reduction in surface water availability in Madera County or the San Joaquin area of origin as a result of Alternative D. There is no effect.

Cumulative Effects

Adverse water supply effects related to operations could have cumulative impacts in Madera County (Effects WS-2, WS-3, and WS-8). Under all action alternatives, Effect WS-2 could cumulatively contribute to impacts on surrounding groundwater wells. However, implementation of the MOCP (Madera Irrigation District 2007) and the ongoing activities of the MROC should ensure that local groundwater supply effects are avoided and minimized. Additionally, the project does not contribute to the ongoing cumulative effect of groundwater overdraft but rather provides a benefit by limiting the amount of water recovered so that 10% of the water banked is left in the aquifer.

3.19 Wetlands

This section describes the existing wetland resources in the areas potentially affected by the proposed alternatives. It discusses the affected environment, relevant regulations and policies, methods of analysis, and possible effects.

The approach used to analyze effects of the Proposed Action on wetlands is to:

- conduct extensive surveys to document wetland resources on Madera Ranch;
- identify effect mechanisms to analyze effects of the alternatives; and
- determine the extent and duration of effects.

The wetland terminology used in this section is slightly different than the terminology used in the Biological Resources section. For example, freshwater marsh and ponds are treated as habitat types in the biological resources section because they have different wildlife habitat functions than other vegetation types. Under this section freshwater marsh, ponds, and swales that have water applied to them regularly are seasonal wetlands. Vegetation in these areas will fluctuate back and forth between grassland and wetland depending on the amount of water and area applied.

3.19.1 Affected Environment

MID consultants delineated waters of the United States at Madera Ranch by a combination of field surveys and aerial photograph interpretation. The initial wetland delineation was started in early 2000, with updates in late 2000, 2004, 2005, and 2009.

Wetlands were identified using the routine onsite determination procedure from the Corps wetlands delineation manual (Environmental Laboratory 1987). The 1987 manual provides technical guidelines and methods for determining the boundaries of jurisdictional wetlands based on three parameters: hydrophytic vegetation, hydric soils, and wetland hydrology. The wetland indicator of plant species was taken from the national list of plant species that occur in wetlands (Reed 1988). Although the study area was larger than five acres, the routine determination procedure was used instead of the comprehensive determination procedure because the areas of potential wetlands were small and widely scattered across the site. Sampling along regular transects would not have been an effective or efficient means for determining wetland boundaries.

Wetland delineators made hydrological observations on wetlands present at Madera Ranch during reconnaissance surveys on December 9, 1999; February 3, 2000; and March 10, 2000. Wetland hydrology was not observed directly for all wetlands at Madera Ranch. Instead, selected representative areas with evident wetland hydrology were noted, mapped, and marked as reference locations for later surveys. Photographs of wetland areas were taken during the March 10 site visit.

Wetland delineators revisited the study area on March 20, 21, and 22, 2000. Sample points were established at 14 representative locations throughout the study area. At each sample point, the dominant plant species within six feet of the sample point were recorded. A shallow soil pit (less than 18 inches deep) was excavated by hand at each sample point to compare soil characteristics with the mapped unit and to determine whether soils exhibited redoximorphic features. Data from each sample point were recorded on standard data forms.

From April 3 through April 7, 2000, biologists conducted vegetation surveys of the study area. Surveys were performed by walking line transects across each section at approximately 150-foot intervals and recording plant species and plant communities present. During this survey, the delineation study area was inspected, and all wetlands present were identified and mapped using the vegetation and hydrology indicators determined from the representative sample points.

Wetlands at Madera Ranch are seasonal and, as such, are a type of problem area (Environmental Laboratory 1987). At Madera Ranch, wetland hydrology is evident only during the rainy season (mid-October to mid-April). Because no rain fell between March 8 and April 13, wetland hydrology was not evident in most wetlands during the late March and April surveys. Corps guidelines for problem areas recommend that, when a wetland indicator is absent because of a normal seasonal variation in environmental conditions, a wetland delineator may determine the parameters of their survey based on personal ecological knowledge of the range of an area's normal environmental conditions. Wetland delineators inferred the presence of wetland hydrology during their late March and early April surveys by comparing each area they surveyed with the reference areas observed to have wetland hydrology during the February 3 and March 10 surveys.

The potential extent of Corps jurisdiction along Cottonwood Creek was determined by visual estimation of the ordinary high water mark (OHWM), defined as ―the line on the shore established by the fluctuations of water and indicated by physical characteristics such as a clear, natural line impressed on the bank, shelving, changes in the character of soil, destruction of terrestrial vegetation, the presence of litter and debris, or other appropriate means that consider the characteristics of the surrounding areas" (33 CFR 328.3[e]).

Natural Resources Conservation Service/U.S. Army Corps of Engineers

Site Verification Visit in 2000 On June 27, 2000, the NRCS and Corps visited the site with the lead wetland delineator to verify the wetland delineation and stream mapping. It was determined that the delineation of Sections 15, 16, 17, 20, 21, 22, 28, and 29 was accurate and certified the delineation. For the purposes of the project that was contemplated at that time (a water bank), it was agreed upon that the remaining areas of the ranch could be delineated by photo interpretation for the purposes of planning and the Section 404 permit process.

Photo Interpretation in 2000 Wetlands in Sections 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 13, 14, and 18 were delineated by aerial photography interpretation in 2000. Aerial photographs of the entire Madera Ranch were taken on March 15, 2000, by Aerial Photomapping Services of Clovis, California. Aerial photographs provided for the delineation were unrectified black and white prints (1 inch = 800 feet).

The photo signatures of potential wetlands in these sections were compared with the photo signatures of wetlands identified in the field survey study area. Standing water was visible in deeply ponding wetlands. Other wetlands produced characteristic photo signatures. Slickspots possess a high albedo and are readily apparent. Alkali rain pools were indicated by a darker signature corresponding to an area of saturated soil. Shallow vernal pools were indicated by sharply defined darker areas within the lighter grassland matrix, typically occurring within swales.

Site Verification Visit in 2004 On August 26, 2004, NRCS visited the site with the lead wetland delineator to verify the photo-interpreted portions of the project site. NRCS determined that additional data collection was needed before the delineation could be certified (Nielson pers. comm.). The Corps concurred with this assessment and also requested that additional data be collected (Norton pers. comm.). In response, additional field studies were undertaken in 2005 to collect data from the portions of Madera Ranch not field surveyed in 2000.

Field Surveys in 2005 In 2005, the delineation study area was expanded to include the sections evaluated in 2000 by aerial photography. Areas with apparent wetland photo signatures were field verified to confirm that wetland indicators were present. Data were collected from all sections of Madera Ranch and offsite locations where other activities would occur.

Wetland delineators made hydrological observations on wetlands in the northern sections of Madera Ranch during reconnaissance surveys on March 3, 4, 9, 10, and 11, 2005. Areas with wetland hydrology were noted and mapped as reference locations for later surveys. Wetland delineators revisited the study area on April 4, 5, 6, 14, and 15, 2005, to collect data from 85 additional sample points, primarily in the northern sections of Madera Ranch. Data collection methods were the same as in 2000.

Observations were also made at Cottonwood Creek, the West Lateral canal, the 24.2 Canal, the Section 8 Canal, and the Main #2 Canal on March 11, April 14, and July 12, 2005. Each canal was visually inspected to document the general characteristics and to evaluate it for potential Corps jurisdiction.

Photo Interpretation in 2008 During 2006, MID advanced a test project to determine the feasibility of using swales for groundwater recharge; this included letting agricultural tail-water spill into the swale in Section 14 and 15. This effort concluded use of the swales was feasible and preferable to pond construction because of cost. MID continued the effort in 2007. Also, between 2005 and 2008, several agricultural tenants changed as did the crop types being grown on the property. The new tenants also let agricultural water spill into swales in several locations on the property. Cottonwood Creek was allowed to spill into the bottom of Section 28 and 29 as it had historically, and the northern reach of GF Canal was also used during this period of time. Therefore, to update the delineation to reflect current site conditions, Consultants used one-half meter resolution imagery from Aerials Express (August 2006) and one meter resolution imagery from the National Agricultural Imagery Program (June 2005) to map artificial wetlands, Cottonwood Creek, GF Canal, and other interpretable canals. One-half meter imagery was used for most of the property and one-meter imagery was used for Sections 6, 7, 18, and the western 1/8th of Sections 5, 8, 17, 20, and 29. The features were digitized at a scales ranging from 1:2,000 (for half-meter photos) to 1:4,500 (for one-meter photos). The alkali rain pools and vernal pools appeared to be shifted with the new aerial photographs because they were previously digitized using un-rectified aerial photographs. Therefore, the pool locations were adjusted, using a GIS software rubber sheeting process, to overlay the registered 2005 and 2006 aerial photographs.

Site Verification Visit in 2009 On February 3, 2009, The Corps visited the site with Consultant staff to further assess Cottonwood Creek, GF Canal, and swales. As a result of this site visit, the Corps requested several additional revisions to the delineation.

Results and Discussion

The area of wetlands delineated at Madera Ranch include seasonal wetlands, GF Canal, Cottonwood Creek and many small, isolated vernal pools and alkali rain pools (including those previously delineated but affected by agricultural activities). Project elements within water bodies and uplands are summarized in Table 3-13 (located in the Biological Resources section). A discussion of the delineation results and a description of the wetlands and other waters are presented below.

Field Verification of 2000 Aerial Photography Interpretation Interpretation of aerial photography overestimated both the extent of alkali rain pools and the extent of vernal pools. The slightly darker photo signature apparent in some slick spots was found to be saturated soils, where the wet portions of the pools were in clear contrast with the lighter dry portions. However, a dark photo signature was also found to be present in some slick spots that do not pond, presumably because of a difference in soil chemistry from slickspots with light photo signatures.

Extensive areas with darker photo signatures in swales in Sections 10 and 11 were interpreted in 2000 as indicating the presence of large wetland areas. However, large areas of wetlands were not observed in these sections during the subsequent surveys. The darker signatures indicate both small vernal pools and wetter areas of annual grassland, areas that do not pond for a sufficiently long period to have wetland hydrology but that do have more vigorous plant growth than the adjacent, drier grassland.

General Hydrologic Observations Precipitation data for the 1999–2000 rainfall year was obtained from the California Irrigation Management Information System (CIMIS) station in Madera (MADERA.A, CIMIS station #145). Precipitation during the 1999–2000 rainfall year (July 1 to June 30) was near average (10.4 inches) as of May 18, 2000. However, the rainfall season was compressed within a short timeframe. Rainfall was less than 15% of average until mid-January. Most of the season's precipitation fell between mid-January and the first week of March.

During surveys on February 3, 2000, and March 10, 2000, ponding was observed in isolated wetlands. By February 3, rainfall was at 32.9% of normal. At that time, only the deeper wetlands were ponded. By March 10, rainfall was 85.1% of average and all areas subsequently delineated as wetlands were ponded.

Precipitation data for the 2004–2005 rainfall year is an average of the data from the MADERA.A and MADERA.T (Touchstone station #32) CIMIS stations. The amount and pattern of rainfall in 2004–2005 was substantially different than in 1999–2000. Precipitation during the 2004–2005 rainfall year was well above average, with 153% of normal rainfall as of May 31, 2005. By March 3, 2005, rainfall was 113% of normal. In addition, rainfall events were spread relatively evenly across the rainfall year, with weekly rainfall totals exceeding 0.7 inches in 10 weeks between late October and early May.

Precipitation was below average in 2005 at 8.52 inches, above average in 2006 at 11.4 inches, and below average in 2007 at 5.29 inches.

Changing Site Conditions

Recent application of agricultural tail-water to several locations throughout the property and a wet year during 2006 has resulted in some changed conditions on the property. The overall number of vernal pools on the property appears to have been reduced by inundation, and some have been recategorized from earlier mapping efforts. In general, the inundated vernal pools appear to be at low spots within existing swales and conveyances. Mapping in 2001 indicated the presence of vernal pools in GF Canal and at the southern portion of the property in Sections 28 and 29, and these areas have been recategorized because of their human influence and artificial hydrology. A November 2007 site visit confirmed that the swales in Section 2, 3, 14, and 15 continued to be used for agricultural tail-water.

Wetlands

Vernal Pools The area of vernal pools delineated in the field study area is 21.22 acres. Vernal pools occur in swales, primarily on soils mapped under the Pachappa series. A duripan is absent and wetland hydrology is maintained by the very slow permeability of the soil surface horizons. Holland (1978) reports that vernal pools are uncommon in the soil series group that includes the Pachappa series because there is no restrictive layer. Because vernal pools are so uncommon on this soil type, neither Holland (1986) nor Sawyer and Keeler-Wolf (1995) include this type of vernal pool in their plant community descriptions. Invertebrate biologists found vernal pool fairy shrimp, *Branchinecta lynchi*, in the vernal pools during surveys in 2000–2001, which indicates that the pH is between 6.8 and 7.6 (Jones & Stokes file information). Vernal pools at Madera Ranch meet all three wetland parameters: hydrophytic vegetation, hydric soils, and wetland hydrology.

Vegetation The pools on Madera Ranch are often dominated by Mediterranean barley, which is usually seen in vernal pools that pond for a relatively short time. Typical vernal pool endemics present in the pools include coyote thistle, Fremont's goldfields, California water-starwort, bracted popcorn flower, mousetails, Pacific foxtail, and American pillwort. The dominant plant species are usually or almost always found in wetlands. Therefore, vernal pool vegetation meets the criterion for hydrophytic vegetation.

Vernal Pool Soils Vernal pools in the study area exist primarily within shallow depressions located on nearly level to gently sloping swale-like landforms. Soils in these swale-like landforms are mapped primarily as various phases of the Pachappa series. Soils in vernal pools located within Pachappa soil map units typically had finer subsoil textures, yellower matrix hues, and lower matrix chromas than are characteristic for soils of the Pachappa series. Additionally, most of the vernal pool soils in these map units exhibited redoximorphic features that consisted of a few faint to moderately prominent iron concentrations and depletions in the surface A horizon and/or immediately above a fine-textured (i.e., sandy clay loam) subsoil horizon. Vernal pool soils located within Pachappa soil map units with low chroma matrix colors and/or redoximorphic iron concentrations and/or depletions within 14 inches of the soil surface meet the hydric soils criterion.

Vernal pool soils located within Cajon loamy sand with low chroma matrix colors within 10 inches of the soil surface meet the hydric soils criterion.

Hydrology Vernal pools at Madera Ranch are inundated for several weeks during the growing season and, therefore, have wetland hydrology. Wetland hydrology of Madera Ranch vernal pools clearly differs from the hydrology of typical vernal pools. Vernal pools generally are found on soils that have a subsoil restrictive layer – either a duripan, claypan, or both (Holland 1978). The restrictive layer creates a perched water table near the soil surface that regulates water levels in the pools (Hanes et al. 1990). Water lost to evaporation and transpiration is replaced by subsurface flow from the adjacent uplands.

At Madera Ranch, the vernal pool soils do not have an identifiable restrictive layer above which a perched water table is present. Ponding appears to be attributable to very low permeability at the soil surface or in the upper soil horizons. The vernal pools with longer ponding duration appear to have the most clay present in the soil, with a clay Bt horizon. The duration of ponding depends primarily on the amount and timing of rainfall. Unlike typical vernal pools, the duration of ponding in vernal pools at Madera Ranch is not affected by the total amount of rainfall during the rainy season because there is no restrictive layer in the lower soil horizons to prevent the excess water from percolating deep into the ground. Observations of ponding depth and duration in vernal pools in 2005 were essentially the same as those in 2000, despite the greater amount of precipitation and more regular rainfall pattern in 2005.

Some of the vernal pools adjacent to the agricultural areas have had their hydrology altered by irrigation runoff.

Wetland Assessment Vernal pools at Madera Ranch meet all three wetland parameters: hydrophytic vegetation, hydric soils, and wetland hydrology.

Alkali Rain Pools The area of alkali rain pools delineated in the field study area is 16.33 acres. Alkali rain pools have not been described in the ecological literature and appear to have been little studied. Consultants previously identified this habitat in Tulare County (Jones & Stokes Associates 1998). Alkali rain pools form in slickspots that pond water for a long time. Invertebrate biologists found Lindahl's fairy shrimp in the alkali rain pools during surveys in 2000–2001, which indicates that the pH ranges from 6.9 to 8.6 (Jones & Stokes file information). Alkali rain pools at Madera Ranch meet all three wetland parameters: hydrophytic vegetation, hydric soils, and wetland hydrology.

Vegetation Alkali rain pools have different vegetation, soils, and hydrology than vernal pools (soils and hydrology are discussed below). Alkali rain pool vegetation is sparse, concentrated on the pool margins and along soil cracks. In contrast, vegetation in vernal pools typically covers the entire pool bottom. Alkali rain pools lack plant species characteristic of vernal pools, such as those found in vernal pools at Madera Ranch. Instead, vegetation of alkali rain pools is composed of halophytic/alkali tolerant, mostly annual species. Dominant species include seepweed, alkali peppergrass, dwarf popcorn flower, California alkali grass, large-flowered sand spurry, and annual *Atriplex* species.

The dominant plant species are usually or almost always found in wetlands. Therefore, the alkali rain pool vegetation meets the hydrophytic vegetation criterion. Because of the low vegetation cover, an alkali rain pool might be classified not as a wetland, but as other water, similar to a mud flat or playa lake. However, alkali rain pools are small and a component of a grassland ecosystem. The overall landscape is terrestrial and vegetated, not aquatic and unvegetated, as in mud flats and playa lakes.

Soils Alkali rain pools form in slickspots, which are relatively shallow, sparsely vegetated depressions containing strongly saline-alkali soils (Reid et al. 1993). In the study area, they are interspersed on nearly level interswale landforms where soils are mapped as different phases and/or complexes of the Fresno, El Peco, and Dinuba series, all of which are strongly to slightly saline alkali and possess a carbonate silica cemented hardpan at depths ranging from 20 to 40 inches.

Soils in alkali rain pools generally lacked hydric soil indicators such as low chroma matrix colors and other redoximorphic features but often showed evidence of inundation, such as sediment deposits and mudcurls. The lack of hydric soil indicators in slickspots inundated for significant periods of time (i.e., alkali rain pools) may be partially the result of their high soluble salt content, which results in low plant density and low microbiological activity within the pool boundaries. Despite the lack of hydric soil indicators, the slickspot soils are classified on the Madera County Hydric Soils List as hydric because they meet Criterion 3 (i.e., they are ponded for a long duration or a very long duration during the growing season) of the list.

Hydrology Alkali rain pools at Madera Ranch are inundated for several weeks during the growing season and, therefore, have wetland hydrology. Wetland hydrology of alkali vernal pools also differs from that of typical vernal pools. Although the Fresno and El Peco species soils have a duripan, no perched water table was observed above it. Therefore, all ponding occurs at the soil surface, similar to vernal pools on Madera Ranch.

Several factors appear to be responsible for ponding. Slickspots that pond water have a compact surface crust with a platy structure, and the pores are largely vesicular; both of these factors reduce permeability (Reid et al. 1993). In addition, slickspots have been observed to possess higher clay content than the adjacent soil (Reid et al. 1993). High sodium levels may cause clay particles (that would otherwise be aggregated) in the upper part of the A horizon to deflocculate, causing soil pores to become ―plugged”. This reduces permeability to the point that water ponds on the soil surface.

In contrast, nonponding slickspots at Madera Ranch lacked a compact surface crust. The reason for this difference is unclear; perhaps nonponding slickspots have lower levels of clay. Alkali rain pools were often found along fence lines or roads, suggesting that soil compaction by cattle or vehicles may have a role in creating the surface crust.

The presence of shrimp exoskeletons, although not a standard wetland hydrology indicator when the delineation field work was performed, was a useful indicator of wetland hydrology for differentiating between alkali rain pools and nonponding slickspots. Free-swimming crustaceans, including seed shrimp (*Ostracoda*) and fairy shrimp (*Branchinecta* sp.), were observed in all vernal pools and alkali rain pools during the February 3 and March 10, 2000, surveys, and during the March 2005 surveys. Free-swimming crustaceans need two or more weeks of ponding to complete their life cycles. The presence of crustacean exoskeletons in dried pool basins indicates that inundation was present for two weeks or longer, sufficient time for these shrimp to live and reproduce.

Wetland Assessment Alkali rain pools at Madera Ranch meet all three wetland parameters: hydrophytic vegetation, hydric soils, and wetland hydrology.

Seasonal Wetlands The delineation indicates there could be approximately 153 acres of seasonal wetlands on site. This number has varied over time and will continue to vary based on the amount and duration of application of additional water via agricultural tail-water or banking. Seasonal wetlands are observable from aerial photos in Sections 2, 3, 14, 15, 16, 20, 22, 28 and 29. These areas primarily have this classification because they have the hydrology component of wetlands. In many instances wetland soils are not present and there is limited wetland vegetation. Their primary function is grassland, except when they are wetted. Wetlands in the northern swales in Section 2 were classified as seasonal wetlands rather than vernal pools because they do not provide the functions and values of vernal pool habitat. Wetland hydrology of the northern swales is artificial and results from irrigation runoff or pumping of water into the swales for stock watering. During the wetlands reconnaissance of Madera Ranch and the botanical survey conducted in 2000, Consultants observed ponded areas at several locations along the northern swale and subsequently mapped these areas as vernal pools. In 2005, during the wetland delineation work to ground-truth areas delineated in 2000 by photointerpretation, only the easternmost portion of the northern swale exhibited ponding and that most of the swale did not appear to have been inundated recently. Vegetation in the swale consisted of upland grasses and forbs, and the soils did not exhibit hydric soil indicators. During subsequent site visits, Project consultants again observed input of irrigation water and dominance by weedy wetland species, including smartweed (*Polygonum* sp.). Because the water source is not rainfall based and plant species normally associated with vernal pools were absent, these wetlands are best classified as seasonal wetlands.

Wetlands west of Cottonwood Creek at the south end of Section 28 were characterized as vernal pools during the original wetland delineation in 2000. Although the wetlands were not dominated by vernal pool endemics, they were in shallow depressions. One of the dominant wetland species was water chickweed (*Montia fontana*), a wetlands generalist; other vernal pool endemics were not found. Although Project consultants observed drift lines in the swale adjacent to the pools, they were unaware that the swales received periodic inflows from Cottonwood Creek. In 2005, Project consultants observed that the area of inundation was much greater and of longer duration than had been observed in 2000, and perennial wetland vegetation, including rushes (*Juncus* spp.) had become established. Aerial photographs from 2006 indicate a continuation of this trend. The source of the wetland hydrology was overflow from Cottonwood Creek, the bank of which had been breached to redirect flood flows into the swale at the south end of Sections 28 and 29. In a 2009 site visit the west berm of the creek had been reconstructed, though MID indicates this area will continue to flood during high flow events. Because the hydrology is not rainfall based and vernal pool endemics were absent, these wetlands are best classified as seasonal wetlands.

The small pond located in the southeastern corner of Section 28 was also classified as a seasonal wetland. The basin is vegetated by vernal pool species and ruderal wetland species characteristic of disturbed seasonal wetlands, such as stock ponds or detention basins. A stand of riparian woodland is present around the margins. The pond was inundated during the April 2000 surveys. Based on the presence of hydrophytic vegetation and wetland hydrology, a wetland is present in the basin. However, this is an artificially maintained wetland.

The pond is connected to Cottonwood Creek via a culvert, and inflow is controlled by a gate valve. Therefore, the wetland hydrology is artificially maintained. If the inflows were discontinued, there is no reason to expect that wetland hydrology would continue. Other deeply excavated areas on Madera Ranch (e.g., Sections 16, 18, and the northern section of GF Canal) do not pond and do not exhibit wetland hydrology.

A second small pond is present along the eastern edge of Section 2. This pond was unvegetated at the time of the surveys in 2000. The wetland hydrology is artificially maintained by pumping water into the pond.

Other Waters

Other waters were delineated only on the Madera Ranch property. However, other waters in the vicinity of Madera Ranch were evaluated for their jurisdictional status.

Cottonwood Creek Cottonwood Creek is a natural stream that has been channelized along portions of its length. The channel has been deepened and widened by excavation. It is used to convey irrigation water from the Main No. 2 Canal and also conveys flood water during storm events. Cottonwood Creek becomes channelized approximately 2.75 miles east of Madera Ranch, near Road 22. Cottonwood Creek crosses Madera Ranch at the southwest corner of Section 28. The extent of Cottonwood Creek on Madera Ranch was delineated on the basis of its OHWM. The mean width of Cottonwood Creek within the OHWM on Madera Ranch is approximately 40 feet.

Cottonwood Creek continues west to just before the Eastside Bypass (approximately 7 miles west of Madera Ranch), where it turns north, paralleling the Bypass in a 15- to 20-foot-wide channel that is separated from the bypass by a levee. The channel showed evidence of having standing water, but no evidence of scour. Hydrophytes are present, at least in places, in the channel. It eventually flows into the Fresno River at Latitude 36.97695 degrees north, Longitude 120.366670 degree west.

Although historically it may have been a tributary of a water of the United States, Cottonwood Creek (an ephemeral flowing water body) does not currently appear to have a hydrological connection to the Fresno River under normal circumstances. As noted above, the creek has been channelized and realigned, conveying mainly irrigation water and, at times during the rainy season, runoff from surrounding areas and ditches. Such flooding and high flows, however, are rare in Cottonwood Creek, as indicated by the lack of channel scour, because of storage in local reservoirs such as Bass Lake, Millerton Lake, and Hensley Lake. Only in response to very extreme rainfall events does water flow the 15.5 miles from Madera Ranch to Cottonwood Creek's connection to the Fresno River. According to the Maintenance Supervisor for the Lower San Joaquin Levee District, Cottonwood Creek might connect to the Fresno River once every 10 years (Batey pers. comm.).

Canals

Gravelly Ford Canal GF Canal is a flat-bottom earth-lined channel that conveys irrigation water from the San Joaquin River to Madera Ranch. GF Canal and Cottonwood Creek share a quarter-mile reach of channel in the northeast quarter of Section 27. Flow into the northern reach of GF Canal is via a flow control structure on Cottonwood Creek. Flow is one-way; water conveyed via GF Canal is directed onto crops. The portion of the channel north of the ranch road along the boundary between Sections 16 and 21 was thought to have been abandoned during earlier versions of the delineation, but has conveyed flows in recent years. Freshwater marsh is present in the portion of the channel immediately north of the ranch road. Other portions of the canal north of the ranch road are vegetated by annual grassland and seasonal wetlands.

24.2 Canal The 24.2 Canal is an earth-lined channel that conveys irrigation water to areas east of Madera Ranch. Flow is one-way; water conveyed via the 24.2 Canal is directed onto crops or into the Main No. 1 Canal, which flows into the Main No. 8 Canal. The canal terminates in agricultural land.

Section 8 Canal The Section 8 Canal is an earth-lined channel that conveys irrigation water from the Main No. 1 Canal and Main No. 2 Canal (via Cottonwood Creek) to the east side of Madera Ranch. Flow is one-way; water conveyed via the Section 8 Canal is directed onto crops, and any surplus runoff is directed into swales, where it percolates into the ground. The canal terminates in agricultural land.

24.2–19.5 West Lateral Canal The 24.2–19.5 West Lateral Canal is an earth-lined channel that conveys irrigation water from the 24.2 Canal to the northeast corner of Madera Ranch. Flow is one-way; water conveyed via the 24.2–19.5 West Lateral Canal is directed onto crops, and any surplus runoff is directed into swales, where it percolates into the ground. The canal terminates in agricultural land.

Main No. 2 Canal The Main No. 2 Canal originates at the Madera Main Canal. It connects and terminates with Cottonwood Creek east of Road 25.

Uplands

Two grassland plant communities are present: California annual grassland and alkali grassland. Alkali grassland, which occurs on strongly saline-alkali soils, is discussed below. Slickspots are scattered within the grasslands. Few slickspots occur within California annual grassland; most occur within alkali grassland and are discussed in the ―Alkali Grassland" section.

California Annual Grassland Vegetation California annual grassland is the typical grassland community of the California Central Valley and adjacent foothills, composed of non-native annual grasses and forbs (Sawyer and Keeler-Wolf 1995). California annual grassland is the most widespread plant community at Madera Ranch, occurring in most uncultivated areas on the ranch, in both uplands and swales.

The dominant species in California annual grassland usually are not found in wetlands. Therefore, California annual grassland does not meet the hydrophytic vegetation criterion.

Soils California annual grassland occurs on Pachappa-Grangeville soils and on the slightly saline-alkali Fresno-El Peco soils. In the study area, soil samples in California annual grassland were generally restricted to the swales. The soils in the swales differed from soils of the Pachappa series in that they often possessed fine textured (i.e., sandy clay loam) subsoil horizons. The moderately sandy clay loam subsoil horizons were also found in vernal pools but at shallower depths than those in the grasslands. Soils in California annual grassland were not classified as hydric because they typically lacked the low chroma matrix colors and other redoximorphic features observed in the vernal pool soils.

Hydrology On March 10, 2000, and in March 2005, when wetlands on Madera Ranch were observed to be inundated, no inundation or soil saturation was observed in California annual grassland. No other wetland hydrology indicators were observed.

Wetland Assessment California annual grassland at Madera Ranch lacks all three wetland parameters: hydrophytic vegetation, hydric soils, and wetland hydrology.

Alkali Grassland Vegetation On Madera Ranch, alkali grassland is intermediate between typical California annual grassland and Valley sink scrub or Valley saltbush scrub (Holland 1986) communities. In Valley sink scrub, iodine bush (*Allenrolfea occidentalis*) is the dominant perennial shrub, and cover of annual grasses and forbs is generally low. At Madera Ranch, Valley saltbush scrub occurs only in the northern half of Section 7, outside the study area. In addition to the typical grassland species cited above, perennial and halophytic species are common. Perennial species present in the alkali grasslands include interior goldenbush, locoweed, alkali sacaton, and saltgrass. Slickspots are common and have a fringe of annual halophytic species, as described above for alkali rain pools.

In alkali grasslands that occur on clay soils, such as in the northern San Joaquin Valley, the vegetation is dominated by halophytic species that usually are found in wetlands (Jones & Stokes Associates 1990). At Madera Ranch, however, alkali grassland is dominated by species that are usually not found in wetlands. Hydrophytic or halophytic species are present but constitute a small percentage of the composition and cover. Therefore, alkali grassland on Madera Ranch does not meet the criterion for hydrophytic vegetation.

Soils Soils in alkali grassland are mapped as Fresno, El Peco, or Dinuba series and are moderately to strongly saline-alkali. Characteristics of soil samples taken in alkali grassland match those reported for those soils in the soil survey report. These soils were not classified as hydric because they lacked hydric soil indicators and were not classified as hydric on the Madera County Hydric Soils List.

Soils examined at sample points located within slickspots typically had finer textures and shallower hardpans than are characteristic for soils of the Fresno, El Peco, or Dinuba series. Soils in slickspots generally lacked hydric soil indicators such as low chroma matrix colors and other redoximorphic features. Slickspot soils were not classified as hydric because they lacked hydric soil indicators and were not classified as hydric on the Madera County Hydric Soils List.

Hydrology On March 10, 2000, and March 2005, when wetlands on Madera Ranch were observed to be inundated, no inundation or soil saturation was observed in alkali grassland or in slickspots. No other wetland hydrology indicators were observed.

Wetland Assessment Alkali grassland at Madera Ranch lacks all three wetland parameters: hydrophytic vegetation, hydric soils, and wetland hydrology. The slickspots were fringed by hydrophytic vegetation but lacked hydric soils and wetland hydrology.

Cultivated Lands

Cultivated lands at Madera Ranch include: all of Sections 1, 13, and 21; the northeast quarter of Section 4; the east half of Section 14; the southeastern quarter of Section 16; the northeastern quarter of Section 22; and, the portion of Section 22 west of the GF Canal. These cultivated areas are planted in alfalfa or corn and lack native vegetation except along the margins of roadsides and fence lines. Soils in the cultivated areas have been modified by cultivation and mostly were not examined in detail. Historically, the soils in the cultivated areas were mapped primarily as Fresno, El Peco, and Pachappa series. The cultivated areas appear to have been leveled at some time prior to this survey. On March 10, 2000, and in March 2005, when wetlands on Madera Ranch were observed to be inundated, no inundation or soil saturation was observed on cultivated lands.

Any wetlands that were present in the cultivated areas were converted to cropland before the passage of the Farm Security Act in 1985. Section 21 has been cultivated longer than any other section on Madera Ranch; it has been farmed since the mid-1960s. Section 22 was tilled and dryland cropped intermittently from the late 1960s until the early 1980s. Sections 16 and 17 contained center pivots for irrigated pasture and crops in the mid-1970s (Loquaci pers. comm.). The south half of Section 15 and a portion of Section 17 were also cultivated for between 10 and 15 years, starting around 1970, but are no longer cultivated. Therefore, any wetlands formerly present in the cultivated areas would be prior converted wetlands. No farmed wetlands are present in the cultivated areas.

3.19.2 Environmental Consequences

The Proposed Action could affect up to approximately 2,100 acres of Madera Ranch. Of this amount, approximately 130 acres currently are cultivated. MID would deliver surface water to approximately 700 acres of swales on a seasonal basis and would construct canals, ditches, and pipelines to convey the water to and from its facilities on Madera Ranch. MID would drill wells, install pump heads, and construct lift stations on the 24.2 Canal and the Main No. 2 Canal to deliver recovered water back into MID's system. As needed, MID would construct as much as approximately 1,000 acres of engineered recharge basins to supplement the recharge capacity of the swales (Figure 3-5). Effects on seasonal wetlands of the Alternative B, Reduced Alternative B, and Alternative C are similar as approximately 150 acres of swales mapped as seasonal wetland would continue to be inundated. Alternative D includes the inundation of approximately 45 acres of seasonal wetlands because fewer swales would be used to bank water. Inundation of an additional 400 acres (Reduced Alternative B) and 550 acres (Alternative B and Alternative C) of swale areas would result in the greatest effect to vernal pools and alkali rain pools under Alternative B (5.9 acres) and Alternative D (5.9 acres), followed by Reduced Alternative B (1.7 acres), and Alternative C (0 acres). For all alternatives, temporary construction would affect approximately one acre of alkali rain pools and less than 0.5 acre of vernal pools, and permanent construction would affect up to approximately two acres of alkali rain pools and no vernal pools.

Project elements within water bodies and uplands are summarized in Table 3-40.

Table 3-40 Project Elements within and near Water Bodies

Project Elements	U.S. Water Subject to CWA 404	Approximate Length/ Surface Area/Cut/Fill
Proposed Water Body Components		
Section 8 Canal, Cottonwood Creek, and Main No. 1 Canal Connection Upgrade (Section 8 Canal/Cottonwood Creek Connection)	Yes	250 lf cut
Gravelly Ford Canal Sedimentation Basin and Flow Regulation Area (Weir #1)	Yes	500 sf
Gravelly Ford Canal Flow Control Weir at Cottonwood Creek (Weir #2)	Yes	500 sf
Cottonwood Creek overflow improvements (rock slope protection)	Yes	350 lf
Reconditioning of existing canals and ditches (canal maintenance)	Yes	Excavation to previous shape
Reconditioning of existing canals and ditches (canal maintenance)	Yes	75 sf each
Cottonwood Creek Lift Stations	Yes	500 sf each
Gravelly Ford Canal Section 21 Northern/Western Laterals	Yes	100 sf
Gravelly Ford Canal Section 22 Southern Lateral	Yes	100 sf
Canal turnouts (seven new turnouts, two turnout replacements)	Yes	75 sf (0.04 ac) each
Wildlife crossings for Gravelly Ford Canal (three crossings)	Yes	1,018 sf (88 cy) each
Other Components within and near Water Bodies		
24.2 Canal improvements	No	36,000 cy excavation; (1.75 mile expanded and 0.75 mile new)
Section 8 Canal upgrades/extensions	No	76,000 cy excavation; (1.75 mile expanded, 1.75 mile existing to pipe, and multiple new extensions)
Use of swales for recharge[1] [2]	No	No cut or fill. <6 acres vernal pool/alkali rain pool from use of swales (Alternative B) and <2 acres for Reduced Alternative B
55 acres of recharge basins in agricultural lands	No	55 acres
Recharge basins in grasslands	No	Varies
Recovery wells	No	<0.1 acre/well
Recovery pipelines and electrical facilities [3]	No	<1.5 ac vernal pool/alkali rain pools from corridors

Notes: CWA = Clean Water Act; lf = linear feet; sf = square feet; cy = cubic yards.
[1] Vernal pools are located in swales and are subject to review under ESA Section 7.
[2] Swales not used for recharge under Alternative C. See Table 3-12 for vernal pool/alkali rain pool effects under each Alternative.
[3] Alternatives B, Reduced Alternative B, C, and D are the same for recovery facilities because the layout does not change.

The Proposed Action also may cause indirect effects. Indirect effects occur later in time or are farther removed in distance but must be predictable and reasonably certain to occur in order to be assessed. Potential mechanisms of indirect effects on wetlands include:

- changes in hydrology, such as altered patterns of runoff or changes to the surface water retention pattern and capacity and elevation of the perched water table;
- erosion and sedimentation that result from grading and other activities that remove vegetation; and
- water quality effects from contaminants such as road runoff or pesticides.

The activities described above can result in both permanent and temporary effects. Effects were characterized as permanent if they would result in the conversion of wetlands for the life of the Proposed Action. The extent of permanent and temporary effects on wetlands at Madera Ranch was estimated by overlaying the outline of proposed recharge basins, canals/ditches, extraction wells, pipelines, and maintenance roads (proposed footprint) on the map of wetlands. The footprint for the buried pipelines, maintenance roads, and canals/ditches is estimated to be a linear corridor 10 feet wide. The proposed footprint for the extraction wells is estimated to be 0.1 acre each.

Alternative A—No Action

Under the No Action Alternative there would be no adverse effects on wetlands. However, the total extent of seasonal wetlands could decrease depending on how the water is managed on Madera Ranch and if MID continues to bank its pre-1914 water. The future conditions would continue to support agricultural activities; the type and extent of the activities is uncertain at this time. Future owners would be subject to comply with CESA and ESA and the effects may be evaluated by the County under CEQA if discretionary permits are needed.

Alternative B—Water Banking outside the MID Service Area Using Swales and Alteration of Reclamation-Owned Facilities

Effect WET-1: Permanent Removal of Vernal Pools and Alkali Rain Pools during Construction, Operation, and Maintenance Construction of the proposed recharge basins, canals/ditches, extraction wells, pipelines, and maintenance roads would occur more than 250 feet from vernal pools and alkali rain pools. However, a possibility remains that these wetlands could experience both direct (construction of permanent facilities, compaction of soils) and indirect (changes to nearby hydrogeology or introduction of sediment) disturbances. In several instances, vernal pools are located within the swales proposed for operation. Flooding swales on a seasonal basis could result in degradation of vernal pool habitat for vernal pools within the swales. This effect is considered to be adverse. Implementation of Environmental Commitments BIO-2a: Preconstruction Surveys/Avoid Effects on Vernal and Alkali Rain Pools and BIO-2b: Create, Restore, or Preserve Vernal Pools would minimize the extent of and compensate for adverse effects associated with Alternative B.

Effect WET-2: Other Wetland Effects during Construction, Operation, and Maintenance
Implementation of the Proposed Action would result in minor amounts of fill of waters of the United States subject to Corps jurisdiction under the CWA during installation of the weirs along Cottonwood Creek and improvements to GF Canal. Additionally, excavation is expected to occur where the Section 8 Canal connects with Cottonwood Creek. No construction-related impacts on wetlands are expected in the swales or constructed basin. The total amount of fill is still being evaluated by the Corps based on the project description, preliminary engineering designs, and relationship of project elements to waters of the United States and is expected to be

less than five acres. No substantial effects are expected to occur during construction along Cottonwood Creek because there are limited wetlands in this area. In GF Canal there are seasonal wetlands, including approximately two acres of freshwater marsh that would be affected. These effects would be offset by the development of freshwater marsh within GF Canal during operation and formation of seasonal wetlands within the swales during banking. Direct or indirect effects could occur on vernal pools and alkali rain pools, as described above in Effect WET-1.

Operational effects associated with the banking of water in the swales likely would increase the acreage of seasonal wetlands that occur on Madera Ranch. This acreage will fluctuate based on the water year type and length of time water is banked in the swales. This increase in seasonal wetlands is expected to result in greater wetland functions and values on site that could benefit waterfowl. No maintenance is proposed within the swales, and therefore no adverse operational effects are expected to occur in the swales. Maintenance of the canals periodically may result in the removal of wetland features that grow during operational periods. No substantial operational effects are expected to occur because no maintenance is proposed in the swales, limited wetland resources are expected to develop within the canals, and wetlands within in the canals would retain their previous functions after maintenance. As such, construction and operational effects on wetlands are not adverse.

Reduced Alternative B—Water Banking Outside the MID Service Area Using Select Swales and Alteration of Reclamation-Owned Facilities

Reduced Alternative B is similar in scope and design to Alternative B, with the primary exception that a reduced number of natural swales would be used in order to minimize effects to vernal pools, and a reduced number of ponds would be constructed. Reduced Alternative B also directs recharge activities in the swales on a priority basis to help avoid effects to vernal pools. As with Alternative B it would complete the water bank in two phases. Phase 1 would involve constructing necessary delivery infrastructure improvements (except for the Section 8 canal southwest extension), using select natural swales for recharge (550 acres versus 700 acres as proposed under Alternative B), and installing approximately five soil berms to direct recharge flows (the berms would be placed to avoid fill of wetlands). Phase 2 would involve constructing a limited number of recharge basins (323 acres versus up to 1,000 acres under Alternative B) and facilities for recovery of banked water. The reduced footprint of recharge basins and number of swales proposed under Reduced Alternative B would reduce the temporary and permanent construction effects on wetlands discussed under Alternative B (Effects WET-1 and WET-2). Environmental Commitments BIO-2a and BIO-2b would reduce the adverse Effect WET-1.

Alternative C—Water Banking Outside the MID Service Area without Swales and Alteration to Reclamation-Owned Facilities

Alternative C is similar in scope and design to Alternative B, with the exception that recharge is achieved using engineered recharge basins in lieu of the natural swales that occur on the site. Thus, engineered basins would be built in Phase 1 instead of using the swales in Phase 1 under Alternative B. The total amount of seasonal wetlands would decrease under this alternative because water would no longer be applied to any swales. This is not considered an adverse effect because these areas primarily function as grassland. The expected footprint of recharge basins under Alternative B would be identical to the maximum build-out of Phase 2 of

Alternative B and would result in nearly identical temporary and permanent construction effects on wetlands (Effects WET-1 and WET-2) and Environmental Commitments BIO-2a and BIO-2b would reduce the adverse Effect WET-1.

Alternative D—Water Banking Outside the MID Service Area with Banking and Recovery via Gravelly Ford Canal

Alternative D is similar in scope and design to Alternative B, with the exception that water would be conveyed to the site via GF Canal. For this reason, one recharge basin would not be built under Alternative D that was proposed under Alternative B. The majority of the swales proposed under Alternative C would also be used (less approximately 100 acres), and the expected footprint of recharge basins under Phase 2 of Alternative D would be nearly identical to Phase 2 of Alternative B. Alternative D would result in nearly identical temporary and permanent construction effects on wetlands as Alternative B (Effects WET-1 and WET-2). However, the extent of wetlands that could be affected could be greater under Alternative D because of the increased disturbance to GF Canal. However, as described under Effect WET-2, this effect is not adverse. The Environmental Commitments associated with Effect WET-1 are still appropriate and applicable.

Cumulative Effects

Effect WET-3: Cumulative Loss of Wetlands The WSEP would result in a minor conversion of wetlands (no more than five acres for any of the alternatives). At the same time, the use of swales for alternatives B and D have the potential to increase wetlands on Madera Ranch depending on the specific operations. Other projects, such as development and projects proposed in the County, have the potential to also convert wetlands, while banking efforts could result in increased wetlands. Overall, wetland loss in the region and throughout California is substantial, but regulatory programs and other efforts generally ensure no net loss of wetlands. Each of the alternatives includes commitments to offset wetlands loss attributable to the project, and therefore, there would be no cumulative effect.

Section 4 Consultation and Coordination

4.1 Coordination with other Agencies

Both the Corps and USFWS are cooperating agencies and provided comments to Reclamation at various stages in the EIS process. The Corps verified the preliminary wetland delineation provided by MID on November 13, 2009, and MID sought permits for reshaping existing drainage ditches and adding structures in artificial canals. Reclamation submitted a biological assessment to the USFWS for the WESP in April 2008, which analyzed Alternative B. The USFWS has provided two insufficiency memos requesting additional information on the project and Reclamation has responded to these memos. The USFWS's comments related primarily to avoiding and minimizing effects on federally listed species that may use the swales and associated habitat on Madera Ranch. On May 13, 2009, Reclamation responded to USFWS's request. From May 2009 to July 2010, Reclamation, MID representatives, USFWS, Corps, DFG and EPA met to modify the project description in order to meet the Least Environmentally Damaging Practicable Alternative, pursuant to section 404 of the CWA. In January of 2011, Reclamation provided a revised biological assessment to the USFWS, which analyzed Reduced Alternative B.

4.2 Public Outreach Process

This section describes the scoping and public outreach process that was followed for the MID WSEP Draft EIS. The public outreach efforts were conducted in accordance with NEPA to determine the focus and content of this EIS, and to solicit and consider the views of federal, state, and local agencies, and the general public regarding the scope and content of the environmental analyses contained in the MID WSEP Draft EIS. These efforts are described here.

4.2.1 Notice of Intent

Pursuant to the requirements of NEPA, Reclamation published a Notice of Intent to prepare a Draft EIS and Notice of Public Scoping Meetings in the *Federal Register* on September 28, 2007. The Notice of Intent was circulated to the public, local, state, and federal agencies, and other interested parties to solicit comments on the MID WSEP Proposed Action.

4.2.2 Scoping Process

NEPA requires a formal scoping process for the preparation of an EIS (40 CFR 1501.7). The main objective of the scoping process is to provide the public and potentially affected resource agencies with information on the alternatives and to solicit public input regarding the issues and concerns that should be evaluated in the environmental documentation. The scoping process is generally intended to provide Reclamation with information regarding the range of actions, alternatives, resource issues, and mitigation measures that are to be analyzed in depth in the EIS and to eliminate from detailed study those issues found not to be significant.

The scoping process for the MID WSEP Proposed Action was conducted to elicit comments from public agencies, other interested organizations and the public on the scope of the potential environmental effects and issues to be addressed in the Draft EIS. Reclamation and MID held EIS scoping meetings at MID's offices in Madera on October 22 and 29, 2007. Before the meetings, public notices were posted at MID's offices and published in the *Madera Tribune* and the *Fresno Bee* announcing the time, date, location, and purpose of the meetings. Each scoping meeting included an overview of the meeting's purpose, the Proposed Action and alternatives, potentially significant environmental issues, and opportunities for future public involvement. Attendees were given the opportunity to provide both oral and written comments. Only one verbal comment was made and a summary of that comment is included in Appendix A.

4.3 Draft EIS Availability

Pursuant to NEPA, the Draft EIS was made available for a 60-day public review period from July 24, 2009 to September 25, 2009. A notice of availability of the Draft EIS was published in the *Federal Register* July 27, 2009. The purpose of the notice was to inform interested parties of the availability of the Draft EIS for public review and comment. Reclamation also issued a press release on its website to notify persons about the public meeting and sent written notice to all agencies and individuals on the MID WSEP Draft EIS mailing list.

Copies of the Draft EIS were made available for public review at Reclamation, Denver Office Library; Natural Resources Library, U.S. Department of the Interior; Reclamation, Mid-Pacific Regional Office Library; the South-Central California Area Office of Reclamation, Fresno, California; Madera Library, Madera, California; Chowchilla Library, Chowchilla, California; Madera Ranchos Library, Madera, California; Fresno County Public Library, Fresno, California; and Clovis Regional Library, Clovis, California.

In addition, an electronic copy was made available on the Reclamation web site at: http://www.usbr.gov/mp/nepa/nepa_projdetails.cfm?Project_ID=3128

The public comment period on the Draft EIS closed September 25, 2009. Written comments were received from two federal agencies, three state agencies, and four other entities and are included in Appendix A. Comments (verbal and written) pertained to the following topics (Appendix A):

- potential impacts on water quality,
- potential impacts on water supply,
- potential water rights issues,
- potential impacts on biological resources, and
- socioeconomic concerns related to economic impacts on farmers.

NEPA requires agencies to respond to comments on the Draft EIS that are received during the public comment period (President's CEQ Regulations for Implementing NEPA Section 1503.4). This document has been prepared pursuant to these requirements. Reclamation has considered all the verbal and written comments received on the Draft EIS and has determined the Draft EIS requires some changes to the Proposed Action. Responses to comments are also included in Appendix A.

The public agencies that provided comments on the Draft EIS include:

- United States EPA
- RWQCB, Central Valley Region
- DFG
- Corps
- California Farm Bureau Federation

Reclamation will provide copies of the Final EIS to these agencies.

4.4 Regulatory Environment

The Proposed Action must comply with the following Federal Regulations:

4.4.1 Clean Air Act

The federal CAA was enacted to protect and enhance the nation's air quality in order to promote public health and welfare and the productive capacity of the nation's population (42 U.S.C. 85). The CAA requires an evaluation of any federal action to determine its potential impact on air quality in the project region.

Federal Conformity Requirements

The CAA Amendments of 1990 require that all federally funded projects are consistent with the plan or program that conforms to the appropriate SIP. Federal actions are subject to either the transportation conformity rule (40 CFR 51[T]), which applies to federal highway or transit projects, or the general conformity rule.

The purpose of the general conformity rule is to ensure that federal projects conform to applicable SIPs so that they do not interfere with strategies employed to attain the NAAQS. As described in the Air Quality section, each of the alternatives would conform to the applicable SIP. Table 2.2 describes the environmental commitments to implement the SJVAPCD Regulation VIII Control Measures for construction emissions of PM_{10}, to reduce emissions associated with idling equipment and for the use of electric pumps.

4.4.2 Federal Endangered Species Act

Section 7 of the ESA requires federal agencies, in consultation with the Secretary of the Interior and/or Commerce, to ensure that their actions do not jeopardize the continued existence of endangered or threatened species, or result in the destruction or adverse modification of the critical habitat of these species. In addition, Section 9 of ESA prohibits removing, digging up, cutting, and maliciously damaging or destroying federally listed plants on sites under federal jurisdiction or doing so on nonfederal land in violation of any state law or regulation. Moreover, under Section 7 of ESA, federal agencies are prohibited from jeopardizing the continued existence of any federally listed species as a result of taking an action. Thus, the Section 7 process protects federally listed plants from the adverse effects of federal actions.

As described previously, Reclamation submitted a revised biological assessment as part of the formal consultation process with the USFWS. The USFWS issued a Final Biological Opinion on April 26, 2011 (Appendix B). Table 2.2 and Section 2 describe the environmental commitments required for compliance to the Biological Opinion.

4.4.3 Fish and Wildlife Coordination Act

The Fish and Wildlife Coordination Act (FWCA) requires that public and private entities consult with fish and wildlife agencies (federal and state) on specific water development projects that could affect fish and wildlife resources. The amendments enacted in 1946 require consultation with the USFWS and State fish and wildlife agencies ―whenever the waters of any stream or other body of water are proposed or authorized to be impounded, diverted, the channel deepened, or the stream or other body of water otherwise controlled or modified for any purpose whatever, including navigation and drainage, by any department or agency of the United States, or by any public or private agency under Federal permit or license". Consultation is to be undertaken for the purpose of ―preventing the loss of and damage to wildlife resources". CEQ regulations, §1502.25 (a) requires that ―…. agencies shall prepare draft environmental impact statements concurrently with and integrated with environmental impact analyses and related surveys and studies required by the Fish and Wildlife Coordination Act (16 U.S.C. 661 et seq.), the National Historic Preservation Act of 1966 (16 U.S.C. 470 et seq.), the Endangered Species Act of 1973 (16 U.S.C. 1531 et seq.), and other environmental review laws and executive orders."

As required by both FWCA and NEPA, Reclamation initiated early involvement with both USFWS and CDFG to obtain their recommendations on fish and wildlife resources, giving those recommendations equal consideration with respect to the project purpose and need. The Final EIS describes action-related effects to wildlife resources and identifies alternative means and measures necessary to enhance or mitigate impacts to wildlife resources. Because FWS was a cooperating agency, Reclamation consulted with CDFG, and all recommendations for wildlife enhancement were fully considered by Reclamation, this EIS provides Reclamations compliance with the FWCA.

4.4.4 Migratory Bird Treaty Act

The MBTA (16 U.S.C. 703 et seq.) implements various treaties and conventions among the United States, Canada, Japan, Mexico, and the former Soviet Union for the protection of migratory birds. Unless permitted by regulations, the MBTA makes it unlawful to pursue, hunt, take, capture, or kill; attempt to take, capture or kill; possess, offer to or sell, barter, purchase, deliver, or cause to be shipped, exported, imported, transported, carried or received any migratory bird, part, nest, egg or product, manufactured or not. Subject to limitations of the MBTA, the Secretary of the Interior may adopt regulations determining the extent to which these activities may be allowed, having regard for temperature zones, distribution, abundance, economic value, breeding habits, and migratory flight patterns. Preconstruction surveys and avoidance measures for western burrowing owls and other raptors would ensure compliance with the MBTA (Table 2-2).

Executive Order 13186—MTBA Responsibilities of Federal Agencies

EO 13186 directs federal agencies to take certain actions to further implement the MBTA. Each federal agency taking actions that have, or are likely to have, a measurable negative effect on migratory bird populations was directed to develop and implement, within two years of the order date (January 10, 2001), a Memorandum of Understanding (MOU) with the USFWS to promote the conservation of migratory bird populations. Reclamation has not signed an MOU with the USFWS regarding migratory birds. After a review of EO 13186, it was determined that, at that time, no MOU was appropriate. Nevertheless, the order states that notwithstanding the requirement to finalize an MOU within two years, each federal agency is encouraged to immediately begin implementing the conservation measures set forth in the order, as appropriate and practical. The preservation of grassland under conservation easement would aid in conserving potentially affected western burrowing owls and raptors (Table 2-2).

4.4.5 Bald and Golden Eagle Protection Act

The BGEPA prohibits the taking or possession of and commerce in bald and golden eagles, with limited exceptions. BGEPA makes it unlawful for any person to take, possess, sell, purchase, barter, offer to sell or purchase or barter, transport, export, or import at any time or in any manner a bald or golden eagle, alive or dead; or any part, nest, or egg of these eagles; or violate any permit or regulations issued under BGEPA. ―Take" includes pursue, shoot, shoot at, poison, wound, kill, capture, trap, collect, molest, or disturb. Transport includes convey or carry by any means and also deliver or receive for conveyance. The golden eagle is known to forage on Madera Ranch but does not nest there. As a result, there is no risk of take of golden eagles as defined under the BGEPA. Bald eagles are unlikely to use Madera Ranch, but if they do, they would only forage on the site and would therefore not be impacted (Table 2-2).

4.4.6 National Historic Preservation Act

Section 106 of the NHPA (15 U.S.C. 470 *et seq*.) requires that federal agencies evaluate the effects of federal undertakings on historical, archeological, and cultural resources and provide opportunities for the Advisory Council on Historic Preservation to comment on the proposed undertaking. The first step in the process is to identify cultural resources eligible for inclusion in the NRHP that are located in or near the project area. The second step is to identify the possible effects of the proposed federal actions. The lead agency must examine whether there are feasible alternatives that would avoid such effects. If an effect cannot reasonably be avoided, measures must be taken to minimize or mitigate potential adverse effects. The physical disturbance of undiscovered cultural resources could occur during construction; however, implementation of Environmental Commitment CR-1 (Table 2.2) to stop construction if cultural resources are discovered would reduce the intensity of the effect. As described in the Cultural Resource section, there would be no impacts to cultural resources.

Reclamation requested SHPO concurrence on a finding of no historic properties affected. SHPO agreed with Reclamation's findings on August 31, 2009, and concurrence was received August 31, 2009 (Appendix E). However, since that time, a number of additional activities have been proposed which require expanding the APE as described in the Cultural Resources section.

These areas and activities were not included in the original SHPO consultation package. Additional site surveys of this area were conducted on March 7-8, 2011 and no previously unknown cultural resources were identified. An updated memorandum (Appendix F) was prepared by consulting archaeologists.

4.4.7 Clean Water Act

Federal water quality regulations are established primarily in the CWA and administered by the EPA. These regulations are subsequently implemented primarily by the State Water Resources Control Board, Corps and other state agencies as deemed appropriate.

Several sections of the CWA pertain to regulating effects on waters of the United States. Section 101 specifies the objectives of CWA implemented largely through Title III (Standards and Enforcement) and Section 301 (Prohibitions). The discharge of dredged or fill material into waters of the United States is subject to permitting specified under Title IV (Permits and Licenses) of CWA and specifically under Section 404 of the act (Discharges of Dredge or Fill Material). Section 401 (Certification) specifies additional requirements for permit review, particularly at the state level.

Section 401

Under CWA Section 401, applicants for a federal license or permit to conduct activities that may result in the discharge of a pollutant into waters of the United States must obtain certification from the state in which the discharge would originate or, if appropriate, from the interstate water pollution control agency with jurisdiction over affected waters at the point where the discharge would originate. Therefore, all projects that have a federal component and may affect state water quality (including projects that require federal agency approval [such as issuance of a Section 404 permit]) must also comply with CWA Section 401. In California, the authority to grant water quality certification has been delegated to the State Water Resources Control Board, and applications for water quality certification under CWA Section 401 are typically processed by the RWQCB with local jurisdiction. Water quality certification requires evaluation of potential impacts in light of water quality standards and CWA Section 404 criteria governing discharge of dredged and fill materials into waters of the United States. MID coordinated with the Corps facilitated by Reclamation to determine if waters of the United States would be affected. A permit for compliance to Section 401 of the CWA certification; General Permit for Storm Water Discharges Associated with Construction Activity (CWA Section 402) is required.

Section 402—National Pollutant Discharge Elimination System Program

The 1972 amendments to the federal Water Pollution Control Act established the NPDES permit program to regulate discharges of pollutants from point sources (Section 402). The 1987 amendments to CWA created a new section of CWA devoted to stormwater permitting. The EPA has granted the state primacy in administering and enforcing the provisions of the CWA and the NPDES permit program. The NPDES permit program is the primary federal program that regulates point-source and nonpoint-source discharges to waters of the United States. The State Water Resources Control Board issues both general and individual permits for certain activities. A NPDES General Permit for storm water discharges associated with construction activity is required under Section 402.

Section 404

Section 404 of the CWA regulates the discharge of dredged or fill material into waters of the United States. Under Section 404, the Corps is responsible for issuing permits authorizing the placement of dredged or fill materials into jurisdictional water of the United States. MID coordinated with the Corps to ensure that effects on waters are minimized. A Section 404 Permit for discharges associated with construction activity is required.

4.4.8 Federal Flood Insurance Program

Congress passed the National Flood Insurance Act of 1968 and the Flood Disaster Protection Act of 1973. The intent of these acts was to reduce the need for large, publicly funded flood control structures and disaster relief by restricting development on floodplains.

FEMA administers the National Flood Insurance Program to provide subsidized flood insurance to communities that comply with FEMA regulations limiting development in floodplains. FEMA issues flood insurance rate maps for communities participating in the National Flood Insurance Program. These maps delineate flood hazard zones in the community. The WSEP does not include any development that would increase risk to people or property as a result of uncontrolled flows.

4.4.9 Executive Order 11988 – Floodplain Management

EO 11988 (May 24, 1977) requires federal agencies to prepare floodplain assessments for proposed actions located in or affecting floodplains. If an agency proposes to conduct an action in a floodplain, it must consider alternatives to avoid adverse effects and incompatible development in the floodplain. If the only practical alternative involves siting in a floodplain, the agency must minimize potential harm to or in the floodplain and explain why the action is proposed in the floodplain. The WSEP would be located within a floodplain, but would not affect the capacity of the floodplain or increase risk to people or property.

4.4.10 Executive Order 11990 – Protection of Wetlands

EO 11990 (May 24, 1977) requires federal agencies to prepare wetland assessments for proposed actions located in or affecting wetlands. Agencies must avoid undertaking new construction in wetlands unless no practical alternative is available and the Proposed Action includes all practical measures to minimize harm to wetlands. MID coordinated with the Corps to ensure that effects on wetlands are minimized. Table 2.2 describes the environmental commitments required for compliance to EO 11990.

4.4.11 Executive Order 12898 – Environmental Justice

EO 12898 (February 11, 1994) requires federal agencies to identify and address adverse human health or environmental effects of federal programs, policies, and activities that could be disproportionately high on minority and low-income populations. Federal agencies must ensure that federal programs or activities do not directly or indirectly result in discrimination on the basis of race, color, or national origin. Federal agencies must provide opportunities for input into the NEPA process by affected communities and must evaluate the potentially significant and adverse environmental effects of proposed actions on minority and low-income communities during environmental document preparation. Even if a proposed federal project would not result in adverse effects on minority and low-income populations, the environmental document must describe how EO 12898 was addressed during the NEPA process. As described in the Environmental Justice section, there would be no disproportionately high adverse impacts on minority and low-income populations.

4.4.12 Executive Order 13007 – Indian Sacred Sites and April 29, 1994, Executive Memorandum

EO 13007 (May 24, 1996) requires federal agencies with land management responsibilities to accommodate access to and ceremonial use of Indian sacred sites by Indian religious practitioners and avoid adversely affecting the physical integrity of such sacred sites. Where appropriate, agencies are to maintain the confidentiality of sacred sites. Among other things, federal agencies must provide reasonable notice of proposed actions or land management policies that may restrict future access to or ceremonial use of, or adversely affect the physical integrity of, sacred sites. The agencies must comply with the April 29, 1994, Executive Memorandum, *Government-to-Government Relations with Native American Tribal Governments*. No sacred sites are known to exist on or near facilities or other aspects of the project that would be affected by the WSEP.

4.4.13 Farmland Protection Policy Act and Memorandum on Farmland Preservation

Two policies require federal agencies to include assessments of the potential effects of a proposed project on prime and unique farmland. These policies are the Farmland Protection Policy Act and the Memoranda on Farmland Preservation, dated August 30, 1976, and August 11, 1980, respectively, from the CEQ. Under requirements set forth in these policies, federal agencies must determine these effects before taking any action that could result in converting designated prime or unique farmland for nonagricultural purposes. If implementing a project would adversely affect farmland preservation, the agencies must consider alternative actions to lessen those effects. Federal agencies also must ensure that their programs, to the extent practicable, are compatible with state, local, and private programs to protect farmland. The NRCS is the federal agency responsible for ensuring that these laws and policies are followed.

MID has consulted with the NRCS and has evaluated potential impacts to agricultural land using the land evaluation and site assessment process. The rating assigned by the NRCS for the loss of prime farmland identifies this loss as adverse. Environmental commitments to establish conservation easements on agricultural land are included to reduce the intensity of this effect (Table 2.2).

4.4.14 Service Area under Madera Irrigation District's Contracts

MID needs Reclamation approval for banking of CVP water in lands outside MID's service area. MID is coordinating with Reclamation in preparing this EIS and would obtain Reclamation approval through the ROD before implementing the Proposed Action.

Groundwater recharge programs are provided for under MID's contracts with Reclamation, as long as they are consistent with applicable state and federal law and are described in MID's Water Conservation Plan. MID has included the proposed WSEP in its 2005 update to its Water Conservation Plan. Under the Proposed Action, MID proposes to bank diversions that remain available following deliveries to farmers and deliveries to existing recharge basins (in a manner comparable to past operations) and after accounting for normal conveyance losses. For the Proposed Action, there would not need to be any water right amendments or applications. MID could only bank the water that they are already able to divert and use

Exchanges of CVP Water under Madera Irrigation District's Contracts

MID's contracts with Reclamation require prior written approval from Reclamation before an exchange can be implemented. The water banking space provided by the Proposed Action could facilitate a range of water exchanges among MID, GFWD, Chowchilla Water District, and potentially other water users in Madera County. For exchanges to proceed, additional environmental analysis would be necessary to ensure the direct, indirect, and cumulative effects of the exchange are addressed. Several examples of potential exchanges follow. GFWD has a Class 2 entitlement that could be delivered to Madera Ranch for recharge and water banking. As much as 90% of the banked water (minus conveyance losses) then could be delivered directly back to GFWD through existing conveyance facilities (e.g., GF Canal and Cottonwood Creek) or through an exchange. Similarly, Chowchilla Water District, which has both Class 1 and Class 2 water entitlements, could exchange water with MID farmers in lieu of their normal deliveries from Millerton Lake, thereby making an equal volume of water available in Millerton Lake for delivery to Chowchilla Water District through the San Joaquin River in the same fashion as used currently.

MID or other exchange participants would coordinate with Reclamation regarding any exchanges and would obtain Reclamation approval prior to implementation.

4.4.15 State Water Resources Control Board

Under the California Water Code, the State Water Resources Control Board is responsible for allocating surface water rights and permitting diversion and use of water throughout the state. The two most common types of surface water rights in California are riparian and appropriative. Through its Division of Water Rights, the State Water Resources Control Board issues permits to divert water for new appropriations or to change existing appropriative water rights.

The Proposed Action would not involve water obtained through riparian rights and would not impair any existing or known riparian rights to water in the San Joaquin River, Fresno River, or other rivers and streams.

The Proposed Action would enable banking of water for MID, a holder of both CVP contract entitlements and appropriative water rights. No water right amendments or applications are necessitated by the Proposed Action. Persons or entities that participate in and make use of the Proposed Action would not affect other appropriative water rights.

4.4.16 Madera County General Plan

The Madera County General Plan Policy Document (Madera County 1995b) contains agricultural water supply policies (General Plan 3.C.12) that state that the County would work with local irrigation districts to preserve local water rights. The County and MID oppose public and private sales of water rights to users outside Madera County. Specifically, the County's goal is to protect and enhance the natural qualities of streams, creeks, and groundwater (Goal 5.C). The general plan specifically states that the County shall protect and preserve areas with prime percolation capabilities (Goal 5.C.1).

4.4.17 Madera Irrigation District AB3030f Groundwater Management Plan

MID approved its AB3030 Groundwater Management Plan in May 1999. Some of the primary goals of the plan include:

- ensuring long-term availability of high-quality groundwater,
- maintaining local control of groundwater resources within MID, and
- prohibiting the net export of groundwater from MID and use of groundwater to replace surface water removed from MID as a result of a transfer.

The Proposed Action conforms to the mission statement and meets the primary goals listed above. The Proposed Action would ensure the long-term availability of high-quality groundwater, would maintain local control, and would avoid the net export of groundwater or surface water.

4.4.18 Madera County Integrated Regional Water Management Plan

The Integrated Regional Water Management Plan (Madera County 2008) contains detailed recommendations for long-term water quality protection and water supply planning in Madera County.

Section 5 Preparers and Reviewers

Bureau of Reclamation
Mid Pacific Region
South Central California Area Office
Fresno, California

July 2011

Introduction

Madera Irrigation District (MID) approved a Water Supply Enhancement Project (WSEP) located on the property known as Madera Ranch, west of the city of Madera, in Madera County, California in September 2005. MID adopted a Notice of Determination based on the Madera Irrigation District Water Supply Enhancement Project Final Environmental Impact Report (EIR) in compliance with the California Environmental Quality Act.

In 2006, MID approached The U.S. Department of the Interior, Bureau of Reclamation (Reclamation) to request the use of Central Valley Project (CVP) contract water outside of MID's current service area, modification of CVP facilities and federal funding for the WSEP. MID has been working toward securing federal funds to assist in the cost of purchasing Madera Ranch, as well as certain pre-construction, and construction activities associated with the WSEP.

In March 2009, the "Omnibus Public Land Management Act of 2009" (Public Law 111-11; H.R. 146-308) became law. Section 9102 of P.L. 111-11 includes authorization for the Secretary of the Interior to enter into a cooperative agreement through Reclamation with MID for the support of the final design and construction of the WSEP. Among other things, the cooperative agreement will address costs associated with the planning, design, permitting, and construction of the WSEP. Section 9102 limits the federal cost share to 25% of the total cost of the project or $22.5 million, whichever is less. Though federal funding is authorized none has yet to be appropriated.

Reclamation, as lead federal agency, prepared an Environmental Impact Statement (EIS 06-127) to analyze the impacts of approving the banking of MID CVP water outside MID's service area in the proposed WSEP, the modification of Reclamation's 24.2 Canal, and any potential federal funding to assist in the cost of the project. The U.S. Army Corps of Engineers (USACE) and the U.S. Fish and Wildlife Service (USFWS) were cooperating agencies during preparation of the EIS.

The Draft EIS was made available for public review for 60 days ending September 25, 2009, during which time Reclamation held a public meeting. Reclamation prepared responses to comments received during the public review and those responses were included in the Final EIS noticed in the Federal Register on June 8, 2011.

This Record of Decision (ROD) documents Reclamation's decision to approve Reduced Alternative B which includes the banking of MID CVP water outside MID's service area in the proposed WSEP, modification of Reclamation's 24.2 canal and potential federal funding. This ROD was prepared in accordance with the National Environmental Policy Act [NEPA] (42 USC 4321 et seq.) and the Council on Environmental Quality's NEPA implementing regulations (40 CFR 1500-1508). The decision made herein is based on the information and analysis contained within the Final EIS for the *Madera Irrigation District Water Supply Enhancement Project*. Reclamation has considered all comments received on the Proposed Action in developing this ROD.

Background

Currently, farmers in MID's service area use a combination of groundwater and surface water. During dry years there is not adequate surface water to meet the water demand and groundwater pumping increases substantially. The amount of groundwater pumped from the aquifer in the vicinity of Madera Ranch exceeds the amount of water recharged to the aquifer, resulting in groundwater overdraft. Even in wet years, the groundwater basin is in severe overdraft because groundwater pumping is steadily increasing for agricultural, municipal, and industrial use. This overdraft has caused the water table to decline resulting in degraded water quality and excess space in the aquifer that could be used to bank surface water.

The purpose of the proposed project is to:

- enhance water supply reliability and flexibility by using the excess aquifer space for surface water storage (water banking);
- reduce existing and future aquifer overdraft;
- reduce groundwater pumping costs;
- increase groundwater quality;
- encourage conjunctive use in the region as a means toward regional self-sufficiency.

The purpose of the proposed Federal action is to analyze the impacts of banking MID CVP water outside MID's service area, modifying of Reclamation's 24.2 Canal and potentially providing federal funding to assist in the cost of the project.

Decision

Reduced Alternative B, identified in Section 1.2 of the Final EIS as the Preferred Alternative, has been chosen as the best overall alternative as it meets a portion of MID's current and future water storage needs; utilizes space underground for surface water storage; reduces aquifer overdraft; encourages conjunctive use as a means toward regional self-sufficiency; and is the environmentally preferable alternative.

Reduced Alternative B directs recharge activities in fewer swales than Alternative B on a priority basis to help avoid effects to vernal pools , and limits the number of recharge basins to the minimum needed to meet the purpose of the action. Reduced Alternative B also incorporates other best management practices and mitigation measures as described in Section 2.7 of the Final EIS. These measures are required to implement the preferred alternative.

Reduced Alternative B will complete the water bank in two phases. Phase 1 will involve constructing necessary delivery infrastructure improvements, selectively using 550 acres of natural swales for recharge, and installing approximately five soil berms to direct recharge flows. Phase 2 will involve constructing 323 acres of recharge basins and facilities for recovery of banked water. Reclamation would approve banking of CVP water outside the MID service area and alteration of Reclamation's 24.2 canal.

Alternatives Considered in the Final EIS

Four Action Alternatives and a No Action Alternative were considered in the Final EIS. Each alternative other than the No Action Alternative met the purpose and need of the action however they varied in design features, cost and potential environmental impacts. The following is a brief description of project alternatives; specific details were published in the Final EIS.

Alternative A

For Alternative A, the No Action Alternative, MID would not bank MID CVP water (MID Long-Term Water Service Contract supplies from both the Friant Division and Hidden Unit) on Madera Ranch and Reclamation's delivery canals would not be altered. MID could bank non-CVP water on the property, and other limited on-site water banking and recovery facilities may be constructed if MID is able to find participants and funding to support these efforts.

MID estimates they would be able to apply less than 5,000 acre-feet (AF) per year of their own non-CVP water. Recovery operations likewise would be limited if Reclamation-owned facilities were not altered. This Alternative would not satisfy the purpose and need, and groundwater overdraft would continue in Madera County.

Alternative B

For Alternative B, Reclamation would approve a total banking capacity of 250,000 AF of MID CVP water outside the MID service area and the issuance of an MP-620 permit (a Reclamation Mid-Pacific Region permit issued for additions or alterations to Reclamation facilities) for modification to Reclamation's 24.2 canal and potential federal funding. After modification of the 24.2 canal and certain MID facilities, MID would be able to recharge and recover a maximum of 55,000 AF annually.

Alternative B will complete the water bank in two phases. Phase 1 will involve constructing necessary delivery infrastructure improvements using 700 acres of select natural swales for recharge, and will install approximately five soil berms to direct recharge flows. Phase 2 will involve constructing 1000 acres of recharge basins and facilities for recovery of banked water.

Alternative B met the purpose and need of the action, however, this Alternative could result in adverse effects to upland species and wetlands and as such resulted in the development of Reduced Alternative B.

Reduced Alternative B

Reduced Alternative B has a smaller footprint than Alternative B. As with Alternative B, this alternative will complete the water bank in two phases. Phase 1 will involve constructing necessary delivery infrastructure improvements using select natural swales for recharge (550 acres versus 700 acres as proposed under Alternative B), and will install approximately five soil berms to direct recharge flows. As with Alternative B, Reduced Alternative B will require issuance of a MP-620 permit for modification to Reclamation's 24.2 canal. Phase 2 will involve constructing a limited number of recharge basins (323 acres versus up to 1,000 acres under

Alternative B) and facilities for recovery of banked water. Reclamation will approve banking of CVP water outside the MID service area, alteration of the canal and potential federal funding.

Alternative C

Alternative C is a variation of Reduced Alternative B that would replace natural swale recharge solely with recharge basins. Phase 1 would involve recharge-related facilities only. Phase 2 would involve facilities for recovery of banked water. Reclamation would approve banking of CVP water outside the MID service area and alteration of Reclamation-owned facilities and potential federal funding.

This Alternative was considered financially infeasible for MID due to the construction costs for 1,000 acres of recharge basins during Phase 1.

Alternative D

For Alternative D, MID would enter into an agreement with Gravelly Ford Water District (GFWD) to improve the Gravelly Ford (GF) Canal to allow water to be conveyed from the San Joaquin River through the GF Canal. The water would be banked at Madera Ranch for later recovery and delivery through the canal back to the San Joaquin River. The existing GFWD pumping plant would be enlarged; the existing, associated pipeline replaced with a larger-diameter line; the GF Canal re-graded to a flat-bottom configuration to allow two-way flow; a new connection to the river constructed to allow recovery water to reach the river without flowing through the pumps; and appropriate gate structures constructed. On-site improvements allowing water banking and extraction, including a pumping plant and pipeline to allow distribution of water uphill from the GF Canal, would be constructed.

Phase 1 would involve recharge-related facilities only. Phase 2 would involve supplemental recharge facilities and facilities for recovery of banked water. Reclamation would approve banking of CVP water outside the MID service area and potential federal funding but no alteration of Reclamation-owned facilities would occur.

Alternative D was eliminated from consideration because it would require that the bank operate solely through water exchanges along the San Joaquin River which would have made MID dependent on other agencies to receive water. In addition, this Alternative would rely on San Joaquin River restoration operations that have not yet been finalized and that may not occur within the desired implementation time frame.

Basis of Decision, Issues Evaluated, and Factors Considered

Reclamation evaluated the potential direct, indirect and cumulative effects of the proposed alternatives. Resources evaluated include: aesthetics, agriculture, air quality, biological resources, cultural resources, environmental justice, geology, soils, seismicity and erosion, global climate change, growth inducing effects, hazards, public health and safety, land use, noise, public services and utilities, socioeconomics, traffic and circulation, water resources, water supply and wetlands.

In addition, Reclamation's evaluation determined that none of the alternatives would affect Indian Trust Assets (ITA) as the nearest ITA to the WSEP is the Table Mountain Rancheria which is located approximately 28 miles east-northeast of the Action area. No tribes possess legal property interests held in trust by the United States in the area affected by any of the alternatives.

Public and public agency comments were considered by Reclamation and addressed in the Final EIS. Concerns included potential impacts on water quality, water supply, water rights issues, impacts on biological resources, determination of the least environmentally damaging practicable alternative (LEDPA), Fish and Wildlife Coordination Act compliance, impacts to wetlands, mitigation and monitoring, habitat loss, and socioeconomic concerns related to economic impacts on farmers.

Environmentally Preferable Alternative

The President's Council on Environmental Quality Regulations Section 1505.2(b) states that where an EIS has been prepared, the Record of Decision shall "Identify all alternatives considered by the agency in reaching its decision, specifying the alternative or alternatives which were considered to be environmentally preferable".

Given the elimination of the Section 8 Canal Southwest Extension, reduction in the total number of swales used to minimize effects to wetlands, and identification of fewer basins to be constructed, Reclamation considers Reduced Alternative B the environmentally preferable alternative. In addition, it will have less adverse effects on both water quality and water supply in Madera Ranch and the surrounding area than Alternative A, the No Action Alternative; has less adverse effects to upland species and wetlands than Alternative B; is more financially feasible than Alternative C; and would not have to rely on San Joaquin River restoration operations as anticipated in Alternative D.

Implementing the Decision and Environmental Commitments

Reclamation will serve as project lead for the implementation of laws to protect water quality, natural resources and cultural resources including but not limited to the:

- National Environmental Policy Act;
- Clean Water Act;
- Clean Air Act;
- Endangered Species Act;
- National Historic Preservation Act;

- Archaeological Resources Protection Act;
- Native American Graves Protection and Repatriation Act.

Environmental Commitments

The following table describes the environmental commitments developed through a cooperative process involving Reclamation, USACE, USFWS, CDFG and MID. Each commitment will be implemented in accordance with the policies, guidance, and authorities of the agency having jurisdiction. Additional details on the environmental commitments are included in the Final EIS. The Final EIS also includes the Madera Ranch Mitigation, Grazing and Management Plan and the Monitoring and Operational Constraint Plan as appendices.

It should be noted that one of the planned locations (Section 5) for vernal pool creation discussed in the Final EIS is no longer suitable due to the July 2011 observation of blunt nosed leopard lizards (fully protected under the California Fish and Game Code). Additional environmental analysis and documentation would be required if the vernal pools are located outside of the area previously analyzed for potential impacts.

Identifier	Environmental Commitment	Commitment Specifications
Agriculture		
AG-1	Permanently Preserve Farmland by Establishing a Conservation Easement on Agricultural Land	MID will establish conservation easements on agricultural land at an effect-to-mitigation ratio of 2:1 to prevent permanent conversion of the land to urban uses and to increase farm viability. This mitigation will be in kind and used to mitigate the loss of farmland classified as prime farmland or farmland of statewide importance.
Air Quality		
AQ-1	Implement San Joaquin Valley Air Pollution Control District Regulation VIII Control Measures for construction emissions of PM10.	• All disturbed areas, including storage piles, that are not being actively used for construction purposes will be effectively stabilized against dust emissions using water, chemical stabilizer/suppressant, or vegetative ground cover. Chemical stabilizer/suppressants will not be used near waters of the United States. • All on-site unpaved roads and off-site unpaved access roads used during construction will be effectively stabilized against dust emissions using water or chemical stabilizer/suppressant. • All land-clearing, grubbing, scraping, excavating, land-leveling, grading, cut-and-fill, and demolition activities will be effectively controlled against fugitive dust emissions by applying water or presoaking. • All operations will limit or expeditiously remove the accumulation of mud or dirt from adjacent public streets at least once every 24 hours during operations (The use of dry rotary brushes is expressly prohibited except where preceded or accompanied by sufficient wetting to limit visible dust emissions. The use of blower devices is expressly forbidden.). After materials are added to or removed from the surface of outdoor storage piles, the piles will be effectively stabilized against fugitive dust emissions using sufficient water or chemical stabilizer/suppressant.
AQ-2	Reduce Emissions Associated with Idling Equipment	Per California Air Resources Board regulations (Title 13 of the California Code of Regulations, Sections 2480 and 2485), which limit idling of diesel-fueled commercial motor vehicles, MID will require that all diesel engines be shut off when not in use to reduce emissions from idling.
AQ-3	Use Electric Pumps	MID will use as many electric pumps as possible for recovery operations to reduce emissions associated with propane. If propane pumps are needed, MID will use engines with catalytic controls and that meet SJVAPCD best available control technology (BACT) requirement for engines over 50 hp.
Biological Resources		
BIO-1	Establish a Grasslands Conservation Easement	Mitigation for the loss of California annual grassland, alkali grassland, or Great Valley iodine brush scrub would consist of establishing a grasslands conservation easement at Madera Ranch over an area of habitat larger than the area subject to long-term degradation (2 acres conserved: 1 acre affected for swales) or permanent loss (3 acre conserved: 1 acre lost). MID also would implement a Madera Ranch Mitigation, Grazing, and Management Plan to improve existing on-site habitat through grazing management and species monitoring. This measure would compensate completely for the loss of these habitats.
BIO-2a	Preconstruction Surveys/Avoid Effects on Vernal Pools and Alkali Rain Pools	MID will minimize effects on species in this habitat by avoiding these wetlands to the extent practical. A buffer area will be established around suitable habitat for listed crustaceans in the action area, i.e., vernal pools. Buffer areas will be demarcated by installing fencing 250 feet from each occupied pool. A qualified biologist will flag the pools to be fenced, and temporary fences will be installed as the first order of work. Construction barrier fencing will be placed at the edge of the buffer areas. Temporary fences will be furnished, constructed, maintained, and later removed as shown on the construction plans, as specified in the special provisions, and as directed by the project engineer. Temporary fencing will be four feet high, orange, commercial-quality woven polypropylene. No construction activities will be permitted within the buffer zone (including staging or sidecasting of material) other than those activities necessary to erect the fencing. Erosion control measures will be employed adjacent to occupied listed crustacean habitat to prevent soil from eroding or falling into these areas. Natural/ biodegradable erosion control measures (e.g., straw wattles, hay bales) will be used. Plastic monofilament netting (erosion control matting) will not be allowed.
BIO-2b	Create, Restore, and/or Preserve Vernal Pools	MID will create, restore and/or preserve vernal pool habitat at Madera Ranch in an area protected under a conservation easement. Five acres of vernal habitat would be restored and/or preserved for each acre of vernal pool or alkali rain pool habitat lost as a result of activities associated with the Proposed Action (5 acre created: 1 acre lost). MID anticipates that the approximate split of these acreages will be 3:1 preservation and 2:1 creation/restoration. This ultimately will be determined based on wetland locations, soil conditions, and consultation with the Corps; soils, hydrology, vegetation, and species will be monitored. The performance standard for created vernal pools is to ensure the new vernal pools emulate the natural pools at Madera Ranch. Created vernal pools would have similar plant species composition and vegetation cover and invertebrate fauna as the vernal pools that are being removed by activities associated with the Proposed Action. Success of the vernal pool creation would be assessed by comparing the pools with undisturbed natural vernal pools at Madera Ranch. Restored vernal pools will have similar success criteria. This mitigation would compensate for the loss of vernal pool habitat. Restoration is more likely to be successful in areas with degraded habitat and where preservation is the most assured. In addition, MID will comply with Reclamation's wetlands mitigation and enhancement policy, which focuses on protecting, restoring, and enhancing wetlands and ensuring no overall net loss of wetlands. Wetland mitigation creation and restoration sites will be monitored until it is proven successful to the Corps, USFWS, and DFG. Mitigation sites must function for at least three years without human intervention.
BIO-3a	Avoid Effects on Iodine Bush Scrub	MID will locate the well and pipeline to avoid direct effects on iodine bush scrub habitat in the northern portion of Section 7 associated with construction activities. If wells and pipelines need to be constructed in this habitat, MID will conduct botanical surveys and mark plants to be avoided during construction.
BIO-3b	Survey for Sensitive Plants	During Phase 1, two botanists conducted visual surveys for palmate-bracted bird's beak (*Cordylanthus palmatus*) and other sensitive plant species along a 60-foot corridor (30 feet per side) along the proposed pipeline and canal alignments and in the swales east of Gravelly Ford Canal. The surveys were conducted in April and July and reference populations were visited. No listed species were found and sensitive *Atriplex* species were mapped to minimize future effects. The results of the botanical surveys will be used to determine which avoidance, minimization, and environmental commitments will be employed. During Phase 2, additional botanical surveys will be conducted in the area proposed for recharge basin creation. Complete visual surveys will be conducted in a similar manner in all areas proposed for permanent ground disturbance. If palmate-bracted bird's beak is found, the population will be delineated with highly visible flagging tape or plastic fencing and avoided. If other sensitive species are found, MID, DFG and USFWS will coordinate to determine the feasibility of avoiding the population.
BIO-4a	Preconstruction Surveys for California Tiger Salamander	A USFWS-approved biologist will conduct preconstruction surveys for California tiger salamander (*Ambystoma californiense [=A. tigrinum c.]*) in suitable aquatic and upland habitat. Before the start of ground-disturbing activities or vegetation removal, the approved biologist or biological monitor will survey the area to be affected that day for California tiger salamanders. The biologist also will examine any open trenches, which will have ramps or be closed when unattended, for the presence of salamanders. If a salamander is found in the construction area, the approved biologist will remove the animal from the area and release it into a suitable burrow at least 300 feet outside the construction area. The biologist will document the results of surveys on preconstruction survey log sheets, which will be kept on file at MID.
BIO-4b	Restrict Construction Activity in Suitable Aquatic and Upland Habitat for California Tiger Salamander to the Dry Season (April 1–November 1)	To avoid and minimize potential mortality and injury of breeding and dispersing California tiger salamanders, construction will take place only during the dry season (between April 1 and November 1 or before the onset of the rainy season, whichever occurs first) in suitable aquatic and upland habitat for the species. Upland habitat is defined as all habitat within one mile of occupied or suitable aquatic habitat. Specifically, this measure applies to all pipeline construction on Madera Ranch and during work at all delivery canals. This measure does not apply to construction activities in gravel shoulders and heavily disturbed non-habitat areas where construction is confined entirely to areas devoid of upland grassland habitat.
BIO-4c	Fence the Construction Zone and Implement Erosion Control Measures in Areas Where Suitable Aquatic Habitat for California Tiger Salamander Is Present	The construction zone will be fenced in areas where suitable aquatic habitat for California tiger salamander is adjacent to the construction area. The purpose of the fence is to restrict construction equipment to the designated area only. Erosion control measures also will be implemented in these areas to prevent any soil or other materials from entering aquatic habitat. Locations of temporary fences and erosion control measures will be shown on the construction plans and will be reviewed by a qualified biologist. Construction barrier fencing will be installed along the edge of the work area as the first order of work. Temporary fences will be furnished, constructed, maintained, and later removed as shown on the plans, as specified in the special provisions, and as directed by the project engineer. No construction activities will be permitted outside the designated construction zone other than those activities necessary to erect the fencing. Erosion control measures will be installed

Identifier	Environmental Commitment	Commitment Specifications
		adjacent to suitable aquatic habitat to prevent soil from eroding or falling into these areas. Natural/biodegradable erosion control measures (e.g., straw wattles, hay bales) will be used. Plastic monofilament netting (erosion control matting) will not be allowed because salamanders can be caught in this type of material.
BIO-5	Pre-Activity Surveys for Blunt-Nosed Leopard Lizard	The objective of the blunt-nosed leopard lizard (*Gambelia [=Crotaphytus] sila*) (blunt-nosed leopard lizard) surveys is to avoid take of blunt-nosed leopard lizard during use of the swales for water banking and construction of water delivery canals and other facilities. Specific measures for linear facilities and swales are described below.
Bio-5a	Install exclusion fencing and conduct clearance surveys and construction monitoring for blunt-nosed leopard lizards	Prior to construction of linear facilities in grassland and/or saltbush scrub/Valley sink scrub habitat and adjacent dirt roadways MID, in consultation and coordination with qualified wildlife biologists, shall create exclusion corridors based on habitat suitability and the need to create exclusion zones for burrows, scalds, and wetlands. Construction of linear facilities is restricted to May 1st through August 1st and may commence in areas only after Blunt-Nosed Leopard Lizard ("BNLL") pre-construction surveys are completed. Pre-activity BNLL surveys were coordinated with the USFWS and CDFG since California's Fish and Game Code does not allow take of this species. Pre-activity surveys shall consist of the following minimum parameters: • Surveys for adult BNLL shall be conducted between April 28th and July 1st and shall occur when the air temperature (as measured at 1-2 cm above the ground over a surface most representative of the area being surveyed) is between 25 °C - 35 °C (77 °F – 95 °F). Once the air temperature falls within the optimal range, surveys may begin after sunrise (once sun is high enough to shine directly on the ground surface being surveyed) and must end by 1400 hours or when the maximum air temperature is reached, whichever occurs first. • Time of day and air temperature shall be recorded at the start and end of each survey. • Surveys will not be conducted on overcast (cloud cover > 90%) or rainy days or when sustained wind velocity exceeds 10 mph (>3 on Beaufort wind scale). • Surveys shall be conducted on foot and transects shall be no larger than 10 meters wide, consist of a slow pace, and be conducted on a north-south orientation when possible. • Surveys shall be conducted for 12 days over the course of a 30 day period. Surveys shall be conducted for 4 consecutive days, weather permitting with at least one survey session consisting of a 4 consecutive day period. • The starting/ending locations of surveys should be modified/alternated to the extent practicable, but resulting in the same area surveyed. This is so that different portions of the site are surveyed at different time/temp periods. • Surveyors must be approved by the DFG and USFWS to conduct the BNLL reconnaissance surveys. The survey crew conducting focused BNLL surveys shall consist of no more than 3 Level I surveyors for every Level II surveyor. The names of every surveyor must be recorded for each survey day. • All herpetofauna observations shall be recorded/tallied. All BNLL observations shall be recorded with GPS, time of observation, name of observer, sex (if evident), and lifestage (adult, juvenile, hatchling). If BNLL is observed in association with or observed entering a particular burrow, burrow location (via GPS) should be recorded as well. • If a BNLL is observed within such areas, consultation with CDFG must immediately occur. However, if BNLL observations are made, BNLL surveys should not be halted; the entire survey should be completed for the entirety of the construction footprint; continuing the surveys is important to maximize detections and to best help inform where the lizards occur and may not occur. Partial surveys cannot be used to inform whether or not avoidance can or will occur. • (hereafter 1- 9 collectively referred to as, "BNLL Pre-Construction Survey Parameters".) Installation of Barrier - Within 3 days after BNLL pre-construction surveys are completed, biologists shall oversee the creation an exclusion area by installing a non-gaping non-climbable barrier using a material approved by DFG and the USFWS along 3 sides of the planned linear facility construction perimeter. The barrier installation shall be overseen by biologists who have BNLL experience and who have been approved in advance by USFWS and DFG (hereafter, qualified BNLL biologists). The barrier fencing shall be installed perpendicular to the ground (vertical) and shall be sealed to ensure there are no gaps between segments or under the fencing. An example of possible suitable material can be found at http://www.ertecsystems.com/. Small mammal burrows and burrow complexes shall be excluded from the liner facility construction areas to the maximum extent practicable and a no disturbance buffer zone shall be established and clearly delineated from any burrows / burrow complexes. The day following the installation of the fencing, the qualified BNLL biologists shall walk approximately 10 meter transects along the partially fenced linear facility construction area during the time of day when air temperatures fall within the optimum range for species detection, during the peak BNLL activity season, and as outlined above. If no BNLL are detected, the fourth side of fencing may be installed and MID may begin work within the fenced area. At least two DFG and USFWS approved biologists will be present within the construction area when construction and other activities within the exclusion area are in progress. Walking Surveys Throughout Construction - Throughout construction, the biologists shall conduct walking surveys of the construction area, looking for BNLL. All open holes and trenches within habitat will be inspected at the beginning of the day, middle of the day, and end of day for trapped animals. If BNLL are detected at any time and within any area of the basin construction site, biologists will halt all work, open a section of the exclusion fencing, and allow the lizard to leave the area on its own (no chasing, following, etc. can occur). Inadvertent Entrapment Prevention-- To prevent inadvertent entrapment of BNLL or any other wildlife during the construction phase of the linear facilities, all excavated, steep-walled holes or trenches more than 2 feet deep shall be covered at the close of each working day by plywood or similar materials or provided with one or more escape ramps (with no greater than a 3:1 slope) constructed of earth fill or wooden planks. Before such holes or trenches are filled, they shall be thoroughly inspected for trapped animals by a qualified biologist. If BNLL are trapped, then it shall be allowed to escape on its own. In addition, all construction pipe, culverts, or similar structures with a diameter of 7.6 centimeters (3 inches) or greater that are stored at the construction site for one or more overnight periods will be thoroughly inspected for BNLL before the pipe is subsequently moved, buried, or capped. If during inspection one of these animals is discovered inside a pipe that section of pipe shall not be moved until the animal has escaped on its own. Construction Time - The permitted construction time is from one hour after sunrise to one hour before sunset, and two biological monitors shall also be active at all times when construction or other activities are in progress. The biological monitors shall survey the construction area during construction, scanning the ground for BNLL and routinely checking excavated soils to ensure that BNLL are not present. The biological monitors shall stop work if a lizard is found within the construction area until the lizard has been excluded from the work area. Multiple Construction Areas More than one linear facility construction area may be established and under construction at the same time provided the minimum number of biologists and biological monitors are present at each of the sites at all times during construction or other related activities. Notification of Dead or Injured BNLL - If any dead or injured BNLL are observed on or adjacent to the construction site, or along haul roads/travel routes for worker and/or equipment, regardless of assumed cause, DFG and USFWS shall be notified. The initial notification to DFG and USFWS shall include information regarding the location, species, and the number of animals injured or killed. Following initial notification, MID shall send DFG and USFWS a written report within 2 calendar days. The report shall include the date and time of the finding or incident, location of the carcass, and if possible provide a photograph, explanation as to cause of death, and any other pertinent information. Fully Protected Species - These measures shall not be required if the species' fully protected status is rescinded and MID obtains incidental take authorization from DFG for this species for this project.

Identifier	Environmental Commitment	Commitment Specifications
		Recharge Basins MID, in consultation and coordination with qualified wildlife biologists, shall create appropriately sized recharge basin construction areas before construction of recharge basins in grassland and/or saltbush scrub/Valley sink scrub habitat and adjacent dirt roadways within the former center pivot areas of Section 16, 17, and 18 on Madera Ranch. Construction areas shall be prioritized initially by reconnaissance surveys no more than 60 days prior to any basin construction activities or ground disturbance to identify areas with the fewest burrows and least suitable habitat for BNLL. Construction of basins will be restricted to May 1st through August 1st and may commence in areas identified through the above referenced reconnaissance surveys only after BNLL pre-construction surveys are completed by way of the BNLL Pre-Construction Survey Parameters (See paragraph I.A. above). The information gathered from these surveys will be used by DFG to determine which habitat is most likely occupied and to identify appropriate exclusion areas. (Basins shall initially be planned to be sited in the former center pivot areas of Section 16, 17, and 18.) If no BNLL is observed within 3 days after the completion of the BNLL pre-construction survey, biologists shall create an exclusion area by installing non-gaping non-climbable barrier. The installation for such barrier shall comply with the installation guidelines listed above under linear facilities, and must be supervised by a qualified BNLL biologist. (See paragraph I.B above.) Construction of the recharge basins is permitted from one hour after sunrise to one hour before sunset. (See I.E above.) More than one percolation basin construction area may be establish and under construction at the same time provided the minimum number of biologists and biological monitors are present at each of the sites at all times during construction or other related activities. Throughout construction, Biologists shall conduct walking surveys of the construction area to determine whether there is any detection of the BNLL. The survey procedures shall comply with paragraph I.C. listed above. Also during construction, all excavated, steep-walled holes or trenches more than 2 feet deep shall be covered as described under I.D above, to prevent inadvertent entrapment of BNLL or any other wildlife. Finally, if any dead or injured BNLL are observed on or adjacent to the construction site, then MID must notified DFG and USFWS in accordance with the outline procedures listed above under I.G. If the BNLL fully protected status is rescinded and an incidental take permit is granted, then these measures will not be required. *On-Ranch Ground Disturbing Facility Maintenance* MID will have an agency approved biologist review future ground disturbing facility maintenance work locations and sizes to evaluate the potential for effects to BNLL. If the activity is in suitable habitat and could affect burrows, MID will conduct the work during the appropriate seasonal window and implement site-specific exclusion measures such as fencing and additional surveys as prescribed above for linear facilities.
Bio-5b	Conduct blunt-nosed leopard lizard and burrow surveys of swales proposed for inundation	MID will conduct BNLL and burrow surveys of swales prior to inundation in swales. Those portions of swales that have been inundated annually for extended periods prior to Project approval will not be surveyed because potential burrows likely have been inundated and eroded, and BNLL are unlikely to aestivate in these areas. Pre-wetting BNLL surveys will be consistent with the *BNLL Pre-Construction Survey Parameters* listed above under I.A.. The information from these surveys will be used to determine which habitat is most likely occupied and to identify appropriate swale use areas. If no BNLL are found during the surveys, water may be applied throughout that following year. If a BNLL is sighted within the low point of a swale (i.e., the expected inundation area) it will be difficult to determine whether the burrows in the area are being used for nesting or refugia. Therefore, MID will delay using the swale for banking until the active season (April 28 to July 1); then MID will apply water to the swale slowly (i.e., approximately 12 inches per minute) to ensure lizards can escape burrows. These measures shall not be required if the species' fully protected status is rescinded and MID obtains incidental take authorization from DFG for this species for this project.
Bio-5c	Implement other protective measures for blunt-nosed leopard lizard	MID will implement other protective measures for blunt-nosed leopard lizard. MID would create at least three canal crossings along Gravelly Ford Canal and 6 canal crossings along the Section 8 Canal Northern Extension; the width of the crossings will vary from approximately 16 feet along Gravelly Ford Canal to approximately eight feet along the Section 8 Canal Northern Extension. While making Gravelly Ford Canal improvements and installing the Section 8 Canal Northern Extension, MID would excavate slightly below the bottom grade of the canal to install a culvert and provide for a crossing to connect the habitat units. The area would be backfilled, covering the crossing with soil from the canal improvement. A similar concept would be employed for the Section 8 Canal Northern Extension, though the length of the pipe segment would be four to eight feet and because of the flat hydraulic grade one larger pipe may be used. Additionally, on-ranch canal side slopes will be designed to allow BNLL to avoid entrapment.
BIO-6	Preconstruction Surveys and Avoidance Activities for Raptors	Preconstruction surveys would determine whether any sensitive raptors are nesting at Madera Ranch. If a tree is occupied at the time of construction, construction activities will be restricted to areas outside 0.5 mile of the tree. Setbacks will be marked with brightly colored temporary fencing.
BIO-7	Preconstruction Surveys for Western Burrowing Owl	The initial daytime burrow survey will help inform the Western burrowing owl (*Athene cunicularia*) survey. A qualified wildlife biologist will conduct a burrowing owl survey in accordance with DFG guidelines. The survey area will include the construction corridor and a 500-foot buffer. An initial survey will determine whether burrowing owls are present. Three additional surveys will be conducted to determine presence or absence of burrowing owls. In accordance with DFG survey guidelines, these surveys must be conducted on four separate days—two in the early morning and two in the late afternoon/early evening. Non-nesting owls may be passively relocated, also using DFG's guidelines.
BIO-8	Preconstruction Surveys for San Joaquin Kit Fox	Because of historical records and suitable San Joaquin kit fox (*Vulpes macrotis mutica*) habitat on or in the vicinity of Madera Ranch, it is assumed that kit foxes could be present at Madera Ranch. To avoid potential mortality of kit fox, agency approved (by USFWS and DFG) experienced biologists will survey to locate any natal dens, non-natal active dens, and/or potential dens in the Proposed Action area. Visual surveys will be conducted during meandering transects of the 1,000 foot corridor. If an active natal den is found, USFWS and DFG will be notified and MID will delay construction within 1,000 feet of the den until the pups have been weaned or moved to an off-site den, and/or reroute the construction corridor to avoid impacts on the kit foxes. Standard Kit fox provisions will be followed in accordance with. U.S. Fish and Wildlife Service Standardized Recommendations for Protection of the Endangered San Joaquin Kit Fox Prior to or During Ground Disturbance. Surveying will include meandering transect surveys for active dens (non-natal) out to 250 feet from the proposed facilities, which will involve simultaneous surveys for potential den sites out to 100 feet. If an active den is found, it will be avoided until the foxes have vacated the den. All potential dens will be flagged. Any potential den immediately in the construction corridor may need additional monitoring. Because construction is expected to proceed quickly—approximately 1,000 feet per day with trenches being open one to two nights—potential dens will not be collapsed. All surveys will be conducted within 30 days of site-specific construction by a qualified biologist. In addition, during construction, USFWS standard kit fox conservation measures such as speed limits, exit ramps, controlling toxic (oil or gas) spills from construction equipment, and covering pipes will be implemented to prevent harm or disturbance to kit foxes using the area. Any open pipes, newly dug pipeline trenches, and canals will be surveyed daily prior to construction to ensure kit foxes are not present.
BIO 9	Conduct Pre-Activity Surveys for Fresno Kangaroo Rat	The objective of the Fresno kangaroo rat (*Dipodomys nitratoides exilis*) surveys is to determine whether the Fresno kangaroo rat is present on the portion of Madera Ranch that could be affected by use of the swales for water banking and construction of water delivery canals. Initial trapping focused on the swales and canals east of GF Canal and determined the species was not present. Subsequent trapping will occur 1-year before use of swales or construction of facilities west of GF Canal. Surveys in swales will be conducted 1 to 2 years before the first wetting of the swale and will be valid for 5 years after the wetting of the swale. If the swale is re-wetted within the 5-year period, it will not need to be surveyed for another 5-year period. No additional survey efforts will be conducted of any swale

Identifier	Environmental Commitment	Commitment Specifications
		areas that have been surveyed twice with neither survey resulting in a single trapping of the Fresno kangaroo rat. Kangaroo rat trapping efforts will be conducted by a surveyor holding a recovery permit for the Fresno kangaroo rat (10[a][1][A] permit). Meandering visual transect surveys for kangaroo rat burrow complexes and sign (e.g., tail drags, sand baths, seed caches) will be conducted by two to four biologists over all habitat within and out to 250 feet from the edge of the WSEP footprint, including swales, and within 100 feet of the top of GF Canal. All burrow complexes found will be recorded on a GPS unit, and data on the number of burrows, level of activity, and general suitability for kangaroo rats will be recorded in field notes (burrows suitable for kit fox also will be noted on GPS as part of this effort); information on vegetation type and percent cover also will be recorded. Following completion of the survey, potential trapping-sites will be prioritized based on a combination of the level of kangaroo rat activity (as evidenced by burrow density and/or the presence of other sign, though some areas without obvious sign may also be trapped) and project area coverage. Live trap stations and trap lines then will be established (staked and recorded with a GPS unit) by permitted biologists at the highest priority sites. Traps (Sherman live traps [Model XLKR: 13 inches x 3.5 inches x 3 inches]) will be set near active burrows, dust baths, or tracks, particularly along evident runways. Ten or more traps (or a number determined by the surveyor) will be set in relatively tight clusters (5-foot trap spacing) at high activity areas. Traps also will be set at 10 to 15 meter intervals (two traps per station) along evident movement corridors. Traps will be baited with a mixture of millet seed, crimped oats, wild birdseed, or other suitable seed. Bedding (crumpled unbleached paper towel) will be placed at the inside end of each trap and will not be allowed to contact the tripping mechanism. Paper towels will be replaced each time an animal is captured in the trap. Traps will be opened and baited at sunset and checked 1-2 times/evening as deemed appropriate by the lead biologist. All traps will be closed after they have been checked at dawn. Trapping will be conducted at each trap site for five consecutive nights. Trapping will not be conducted during the week of a full moon, unless the sky is overcast and moonlight is substantially reduced. Trapping will not be conducted in December or January or in periods of cold or inclement weather detrimental to kangaroo rats and as stipulated in the surveyor's recovery permit. Although Fresno kangaroo rats are active year round, their populations generally are lowest at this time. All non-Fresno kangaroo rats captured will be marked with a nontoxic semi-permanent ink marker on the belly to identify the re-trapping of the same animal(s). Trapping will cease with the capture of a Fresno kangaroo rat and MID, the USFWS, and DFG will be notified as soon as possible, if not the same day, then the next workday, or no later than the Monday following the capture should it occur on a Friday or Saturday night. Any measurements obtained to provide evidence that the animal captured is a Fresno kangaroo rat will be achieved with minimal and delicate handling fur and tissue samples will be taken only by a qualified, permitted biologist in accordance with their permit terms. A photo of the animal's hind legs (showing toes and including a ruler) will be taken and the animal will be immediately released; the animal's eyes will be shielded from the flash. The lead biologist will notify MID of the proposed trapping schedule and will inform MID weekly which trapping areas have been completed. Any capture of Fresno kangaroo rat will be reported immediately to MID, the USFWS, DFG, and Reclamation.
BIO-10	Conduct Preconstruction Surveys for Sensitive Species along the Off-Ranch Portion of Gravelly Ford Canal	Proposed off-ranch work areas associated with GF Canal improvements will be evaluated by a USFWS-approved biologist to determine whether habitat suitable to support sensitive species is present. If suitable habitat is discovered, MID will evaluate work locations to determine which species could be present and whether additional surveys may be needed. Depending on the results of this survey, MID also may implement Environmental Commitment BIO-1: Establish a Grasslands Conservation Easement, Environmental Commitment BIO-5: Pre-Activity Surveys for Blunt-Nosed Leopard Lizard, Environmental Commitment BIO-6: Preconstruction Surveys and Avoidance Activities for Raptors, and Environmental Commitment BIO-7: Preconstruction Surveys for Western Burrowing Owl.
BIO-11	Implement Protective Measures for Anadromous Fish	MID would work with Reclamation and the National Marine Fisheries Service (NMFS) to determine appropriate protective measures for migratory fish once they are restored to the San Joaquin River, including seasonal restrictions on diversions or intake screening in the event water is moved to and from Madera Ranch via GF Canal (Alternative D). Inter-agency discussions would occur at least two years in advance of the reintroduction of these species to the San Joaquin River.

Biological Opinion Commitments

On April 26, 2011, the USFWS issued a Biological Opinion to Reclamation (File Number 81420-2008-F-0279-1) to address the impacts of Reduced Alternative B on Federally listed species. The Biological Opinion was included in the Final EIS as Appendix B. The following additional commitments (terms and conditions) are also imposed on Reduced Alternative B from the incidental take statement that was provided with the Biological Opinion.

Reasonable and Prudent Measures		Terms and Conditions
The Service believes the following reasonable and prudent measures are necessary and appropriate to minimize the effects of the proposed Madera Irrigation District Water Supply Enhancement Project on the San Joaquin kit fox, blunt-nosed leopard lizard, Fresno kangaroo rat, vernal pool fairy shrimp, vernal pool tadpole shrimp, Conservancy fairy shrimp, and California tiger salamander.		In order to be exempt from the prohibitions of section 9 of the Act, Reclamation must comply with the following terms and conditions, which implement the reasonable and prudent measures. These terms and conditions are non-discretionary.
1.	All Environmental Commitments as described in the Biological Assessment, and as restated here in the *Description of the Proposed Action* of this Biological Opinion, must be fully implemented and adhered to.	To implement Reasonable and Prudent Measure #1, Reclamation shall ensure through conditions in its approval letter or any funding for the proposed project that Madera Irrigation District fully implements and adheres to the Environmental Commitments presented in the Biological Assessment and restated here in this Biological Opinion. These Environmental Commitments must be adhered to, regardless of species status under the California Endangered Species Act.
2.	Land that is to be set aside as habitat compensation and managed for the primary purpose of benefitting those listed species impacted by the proposed project must be protected in perpetuity, and with the intent to provide optimum conditions for those species.	To implement Reasonable and Prudent Measure #2, Reclamation shall ensure through conditions in its approval letter for the proposed project the following Terms and Conditions: a) Reclamation shall ensure that Madera Irrigation District grants and records an appropriate, Service-approved Conservation Easement with a Service-approved Conservation Easement holder for the mitigation lands described in the Biological Assessment, prior to project implementation. b) Reclamation shall ensure that Madera Irrigation District incorporates by reference its Mitigation and Management Plan, developed for these mitigation lands, into said Conservation Easement. c) Reclamation shall ensure that Madera Irrigation District includes language in the Conservation Easement stating that the Mitigation and Management Plan created for this project is a living document, to be viewed and used as an adaptive management plan under the direction and approval of the Service, CDFG & Corps, with the goal of ensuring optimum habitat conditions for the species of concern. d) Reclamation shall ensure that Madera Irrigation District has in place prior to project implementation an adequate, Service-approved funding mechanism, such as a non-wasting endowment held by a Service-approved endowment holder to fund the long-term management activities on their mitigation lands.
3.	To ensure that the expected changes to ecological conditions resulting from swale inundation do not result in take of Fresno kangaroo rats and blunt-nosed leopard lizards beyond what is anticipated in this biological opinion, hydrological conditions must be maintained such that there is no more than a 20 percent increase in acreage of vegetative changes beyond the perimeter of water applications (footprint of swales and seasonal wetlands).	To implement Reasonable and Prudent Measure #3, Reclamation shall ensure through conditions in its approval letter or any funding instrument for the proposed project that MID develops and implements an appropriate Service-approved hydrological study or studies, designed to monitor and report on conditions related to changing ecosystem characteristics in and adjacent to the swales used for water banking purposes. Such studies, and the information obtained from them, shall be used to inform Reclamation and MID of the degree and nature of habitat modification from current conditions, and whether take resulting from vegetative changes beyond the perimeter of water applications (i.e., greater than 20 percent) is exceeded. The information gathered from these studies shall be provided to the Service and CDFG on thirty-day cycles or within thirty days of conclusion of a study cycle.
4.	The periodicity of swale inundation over the duration of this project must be monitored and adjusted, if necessary, to ensure that the time interval between swale flooding events does not result in a biological "sink" for Fresno kangaroo rats and blunt-nosed leopard lizards, whereby individuals of these species that may re-colonize burrows in or immediately adjacent to swales during dry periods are then taken by subsequent flooding. These adjustments could include repeated and/or more frequent wetting if the water supply is available, varying the priority/rotation of wetted swales, scaling back swale operations consistent with overall banking operational objectives, or other measures agreed to by MID, Reclamation, the Service, and CDFG.	To implement Reasonable and Prudent Measure #4, Reclamation shall ensure through conditions in its approval letter or any funding for the proposed project that Madera Irrigation District develop a Service-approved monitoring and reporting approach for the inundated swales and adjacent habitat sufficient to determine whether Fresno kangaroo rats and blunt-nosed leopard lizards re-colonize these areas during dry periods.

Identifier	Environmental Commitment	Commitment Specifications
Cultural Resources		
CR-1	Stop Construction If Cultural Resources Are Discovered	In the event of any inadvertent cultural resources discovery, human or otherwise, uncovered during construction or other ground-disturbing activities, the construction contractor will immediately stop work in the immediate vicinity and a minimum 100-foot buffer area from the find. The contractor will notify MID immediately and MID will notify Reclamation of the inadvertent discovery. A professionally qualified archaeologist will be sent to evaluate the inadvertent discovery for National Register of Historic Places (NRHP) eligibility. If human remains are discovered during ground-disturbing activities, the party responsible for CEQA will comply with state laws[1] relating to the disposition of human remains pursuant to Public Resources Code (PRC) section 5097. Reclamation may have additional responsibilities under Section 106 of the NHPA and will follow the procedures in 36 CFR Part 800.13.
Geology, Soils, Seismicity and Erosion		
GEO-1	Amend Soils as Required in Topsoiled Areas	Topsoiled areas with insufficient vegetation cover will be amended with gypsum and/or elemental sulfur in combination with high-quality irrigation water to reduce soil salinity, alkalinity, and exchangeable sodium to acceptable levels, such that acceptable vegetation cover is established in such areas within one year after topsoil is applied. All soil sampling and amendment recommendations will be conducted by, or under the supervision of, a certified professional soil scientist.
GEO-2	Stop Work in Event of Fossil Discovery	In the event that a fossil or material that could be a fossil is unexpectedly discovered during excavation operations, work will cease in the immediate vicinity of the find. A qualified paleontologist will be called to the site to evaluate the find and determine the sensitivity of the fossil. If the fossil is determined to be sensitive, the paleontologist will recover it from the site and submit it to an appropriate museum or other repository for curation.
Hazards, Public Health and Safety		
PHS-1a	Implement Necessary Emergency Preparedness Plan(s)	MID will work with the Madera County Department of Public Health and the local fire districts to coordinate the preparation of emergency preparedness plan(s) that may be required by federal, state, and County statutes and regulations.
PHS-1b	Comply with Local Fire District Requirements	MID will consult the local fire districts to ensure that all regulations are complied with during construction.
PHS-2	Implement an Agreement with the Madera County Mosquito and Vector Control District	MID will enter into an agreement with the Madera County Mosquito Abatement & Vector Control District (MCMAVCD) regarding a specific mosquito abatement program. The agreement will allow the MCMAVCD to access Madera Ranch and also will include quantitative abatement thresholds and financial compensation requirements for MCMAVCD activities, if necessary. The MCMAVCD will monitor mosquito larvae production in the recharge basins, drainages, and distribution canals at no cost to MID, given that the amount of monitoring required is not excessive. Larvae populations will be tracked using methods and thresholds approved by the MCMAVCD, and suppression measures will be employed when thresholds are exceeded. Suppression measures may include environmental and biological methods, such as stocking mosquitofish, controlling emergent vegetation, and applying insecticides. Insecticide controls will be used only as a last resort, and use of insecticides over open water will be minimized to the extent feasible, given the mosquito abatement mandate of the MCMAVCD. The insecticides that may be used are only those that are approved for such uses by the U.S. Environmental Protection Agency (EPA). Mosquitofish, if used, will need to be stocked annually by the MCMAVCD. If operations result in an increase in mosquito production such that an extensive monitoring program is needed, MID will hire a professional pest control service and will bear the cost of that service.
Noise		
NOI-1	The construction contractor will employ noise-reducing construction practices so that noise from construction does not exceed County noise-level standards at adjacent residences.	Measures to be implemented would include the following. • Restrict construction to beyond 3,900 feet from residences during nighttime hours (10 p.m. to 7 a.m.). • Provide construction equipment with sound-control devices no less effective than those provided on the original equipment. No equipment will have an unmuffled exhaust. • Implement appropriate additional noise environmental commitments, including (but not limited to) changing the location of stationary construction equipment, shutting off idling equipment, rescheduling construction activity, notifying adjacent residents in advance of construction work, and installing acoustic barriers around stationary construction noise sources.
NOI-2	The construction contractor will employ noise-reducing methods during well drilling operations	The drilling contractor will employ noise-reducing construction practices so that noise from drilling does not exceed County noise-level standards at adjacent residences. Measures to be implemented may include those following. • Restrict well drilling to beyond 2,900 feet from residences during nighttime hours (10 p.m. to 7 a.m.), where feasible. • Use sound attenuation enclosures around noise-generating elements of the drilling operation.
NOI-3	The construction contractor will employ noise-reducing practices so that noise from well operations does not exceed County noise-level standards at adjacent residences.	Measures to be implemented may include: • restricting well installations to beyond 1,250 feet from residences, where feasible; • using electric pumps where well installations are within 1,250 feet of residences; and • using sound attenuation enclosures designed to achieve noise reductions sufficient to comply with County standards for noise-generating elements of the well operation when no other feasible control method is available.
NOI-4	The construction contractor will employ noise-reducing practices so that noise from lift station operations does not exceed County noise-level standards at adjacent residences	Measures to be implemented may include: • restricting lift station installations to beyond 1,600 feet from residences, where feasible; • using electric pumps where lift station installations are within 1,600 feet of residences; or • using sound attenuation enclosures designed to achieve noise reductions sufficient to comply with County standards for noise-generating elements of the lift station operation when no other feasible control method is available.

---

[1] Madera Ranch does not include federal land, so only state human-remains laws apply.

Identifier	Environmental Commitment	Commitment Specifications
Public Services		
PSU-1a	Notify Emergency-Response Agencies of Proposed Traffic-Route Changes	Before beginning construction activities, MID or the construction contractor will contact local emergency-response agencies (law enforcement and fire protection) to provide information on the timing and location of any traffic control measures required during construction activities. Emergency-response agencies will be notified of any change to traffic control measures as the construction phases proceed so that emergency-response providers can modify their response routes to ensure that response time would not be affected.
PSU-1b	MID will require the construction contractor to prepare and implement a traffic safety plan (TSP) before the onset of construction activities.	The TSP will address: • appropriate vehicle size and speed, • travel routes, • detour or lane-closure plans, • flag person requirements, • locations of turnouts to be constructed, • coordination with law enforcement and fire control agencies, • coordination with California Department of Transportation (Caltrans) personnel (for work affecting state road rights-of way), • emergency access to ensure public safety, and • traffic and speed-limit signs.
Traffic		
TRAF-1	MID will require the construction contractor to prepare and implement a road improvement plan (RIP) before the onset of the construction phase.	The RIP will identify road segments, bridges, and culverts that need to be improved and turnout locations that need to be constructed (as applicable) to accommodate construction activities. The plan also will identify damage that is caused by construction vehicles and that needs to be repaired.
Water Resources		
WQ-1a	Comply with National Pollutant Discharge Elimination System General Construction Permit	To reduce or eliminate construction-related water quality effects, before onset of any construction activities, MID or its contractor will obtain coverage under the National Pollutant Discharge Elimination System (NPDES) General Construction Permit. MID will be responsible to ensure that construction activities comply with the conditions in this permit, which will require development of a stormwater pollution prevention plan (SWPPP), implementation of best management practices (BMPs) identified in the SWPPP, and monitoring to ensure that effects on water quality are minimized. As part of this process, MID will implement multiple erosion and sediment control BMPs in areas with potential to drain to surface water (see Section 3.6, Geology, for a discussion of erosion and sediment control BMPs). These BMPs will be selected to achieve maximum sediment removal and represent the Best Available Technology (BAT) that is economically achievable. BMPs to be implemented as part of this environmental commitment may include, but are not limited to, the following measures. • Temporary erosion control measures (such as silt fences, staked straw bales/wattles, silt/sediment basins and traps, check dams, geofabric, sandbag dikes, and temporary revegetation or other ground cover) would be employed to control erosion from disturbed areas. • Drainage facilities in downstream off-site areas would be protected from sediment using BMPs acceptable to the Regional Water Quality Control Board (RWQCB). MID or its agent will perform routine inspections of the construction area to verify that the BMPs specified in the SWPPP are properly implemented and maintained. MID will notify its contractors immediately if there is a noncompliance issue and will require compliance.
WQ-1b	Implement a Spill Prevention and Control Program	MID or its contractor will develop and implement a spill prevention control and countermeasures program (SPCCP) to minimize the potential for, and effects from, spills of hazardous, toxic, or petroleum substances during construction activities for all contractors. The program will be completed before any construction activities begin. Implementation of this measure will comply with state and federal water quality regulations and minimize the effects of the Proposed Action. MID will review and approve the SPCCP before the onset of construction activities. MID will routinely inspect the construction area to verify that the measures specified in the SPCCP are properly implemented and maintained. MID will notify its contractors immediately if there is a noncompliance issue and will require compliance. The federal reportable spill quantity for petroleum products, as defined in the EPA's CFR (40 CFR 110), is any oil spill that (1) violates applicable water quality standards, (2) causes a film or sheen upon or discoloration of the water surface or adjoining shoreline, or (3) causes a sludge or emulsion to be deposited beneath the surface of the water or on adjoining shorelines. If a spill is reportable, the contractor's superintendent will notify MID, and MID will need to contact the appropriate safety and clean-up crews to ensure the SPCCP is followed. A written description of reportable releases must be submitted to the RWQCB. This submittal must include a description of the release, including the type of material and an estimate of the amount spilled, the date of the release, an explanation of why the spill occurred, and a description of the steps taken to prevent and control future releases. The releases will be documented on a spill report form. If a spill has occurred, MID will coordinate with responsible regulatory agencies to implement measures to control and abate contamination.
WQ-2	Implement Provisions for Dewatering	Before discharging any water from dewatering operations to surface water, MID or its contractors will obtain an NPDES permit and Waste Discharge Requirements (WDRs) from the RWQCB. Depending on the volume and characteristics of the discharge, coverage under the RWQCB's General Construction Permit or General Dewatering Permit is possible. As part of the permit, the permittee would design and implement measures as necessary so that the discharge limits identified in the relevant permit are met. As a performance standard, these measures will be selected to achieve maximum sediment removal and represent the BAT that is economically achievable. Implemented measures may include retention of water from dewatering operations until particulate matter has settled before it is discharged, use of infiltration areas, and other BMPs. Final selection of water quality control measures will be subject to approval by the RWQCB. MID will verify that coverage under the appropriate NPDES permit has been obtained before allowing dewatering activities to begin. MID or its agent will perform routine inspections of the construction area to verify that the water quality control measures are properly implemented and maintained. MID will notify its contractors immediately if there is a noncompliance issue and will require compliance.
Wetlands		
WET-1	Preservation of vernal pools and alkali rain pools.	Implementation of Environmental Commitments BIO-2a: Preconstruction Surveys/Avoid Effects on Vernal and Alkali Rain Pools and BIO-2b: Create, Restore, or Preserve Vernal Pools would minimize the extent of and compensate for adverse effects.
WET-2	Reduction of impacts to Waters of the United States from the discharge of fill	In GF Canal there are seasonal wetlands, including approximately 2 acres of freshwater marsh that would be affected. These effects would be offset by the development of freshwater marsh within GF Canal during operation and formation of seasonal wetlands within the swales during banking.

Comments on the Final Environmental Impact Statement

Reclamation's Notice of Availability of the Final EIS was published June 8, 2011 and the U.S. Environmental Protection Agency's Notice of Availability was published June 17, 2011. Copies of the FEIS were distributed to those who requested a copy. A press release was issued June 9, 2011 and the Final EIS was made available on Reclamation's website:

http://www.usbr.gov/mp/nepa/nepa_projdetails.cfm?Project_ID=3128

One comment letter on the Final EIS was received from the Environmental Protection Agency during the 30-day waiting period. The issue raised and Reclamation's responses follow:

Nature of Comment: The Environmental Protection Agency recommended that the additional discretionary conservation recommendations identified in the Biological Opinion to Reclamation (File Number 81420-2008-F-0279-1) dated April 26, 2011 issued by USFWS be considered for inclusion in the Environmental Commitments.

Agency Response: As stated in the April 26, 2011 Biological Opinion: "Section 7(a)(1) of the Act directs Federal agencies to utilize their authorities to further the purposes of the Act by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations are discretionary agency activities to implement recovery actions, to help implement recovery plans, to develop information, or otherwise further the purposes of the Act". As such, Reclamation in cooperation with MID will continue to seek funding opportunities to implement the discretionary conservation recommendations described in the Biological Opinion.

Northern Sacramento Valley Conjunctive Water Management Program

A Collaborative Planning Effort Co-Sponsored by
Glenn Colusa Irrigation District and the Natural Heritage Institute

Funded by the Bureau of Reclamation and
California Department of Water Resources

Final Report Public Briefing

4/12/2012

Introductory Perspectives

- Motivating Factors
- Regional Responses
- The Role of Groundwater

Motivating Factors: External Pressures

- Is Region Sustainable?
  - Environmental, Economic, Social
- The Delta
  - SWRCB Water Quality Control Plan Update (Flow Report stated Sac River 75% unimpaired flow to the Delta November-June)
  - Delta Species (smelt) dominate; Longfin Smelt Listing
  - Delta Stewardship Council
  - Bay Delta Conservation Plan
- System Re-operation:
  - SB x2-1 directs DWR to investigate climate change and conjunctive operations (see http://wwwdwr.water.ca.gov/system_reop/)
- Groundwater
  - State interest in groundwater regulation
  - Latest National Research Council recommended more regulation of groundwater
  - Scott Valley/Siskiyou County Groundwater Pumping Lawsuit

Regional Reponses

- Define Desired Regional Outcome
  - Sustainability of water, environment, economy
- Understand risks and pressures to region
  - Delta Flow Report, Export needs, Delta Plan
- Develop Regional Response and Solutions
  - IRWM, Stakeholder processes, Others?
- Develop Projects/Policies/Positions
- Understand outcomes of Solutions and weigh to Original Risk, Adaptive Management
- Response – Implement Solutions or Plan B?

The Role of Groundwater

- Sacramento Valley water demands have been satisfied for decades through conjunctive *use*
- Regional sustainability depends on conjunctive *management* in some form
- Groundwater investigations will happen, like surface water, how will regional interest and collaboration happen?

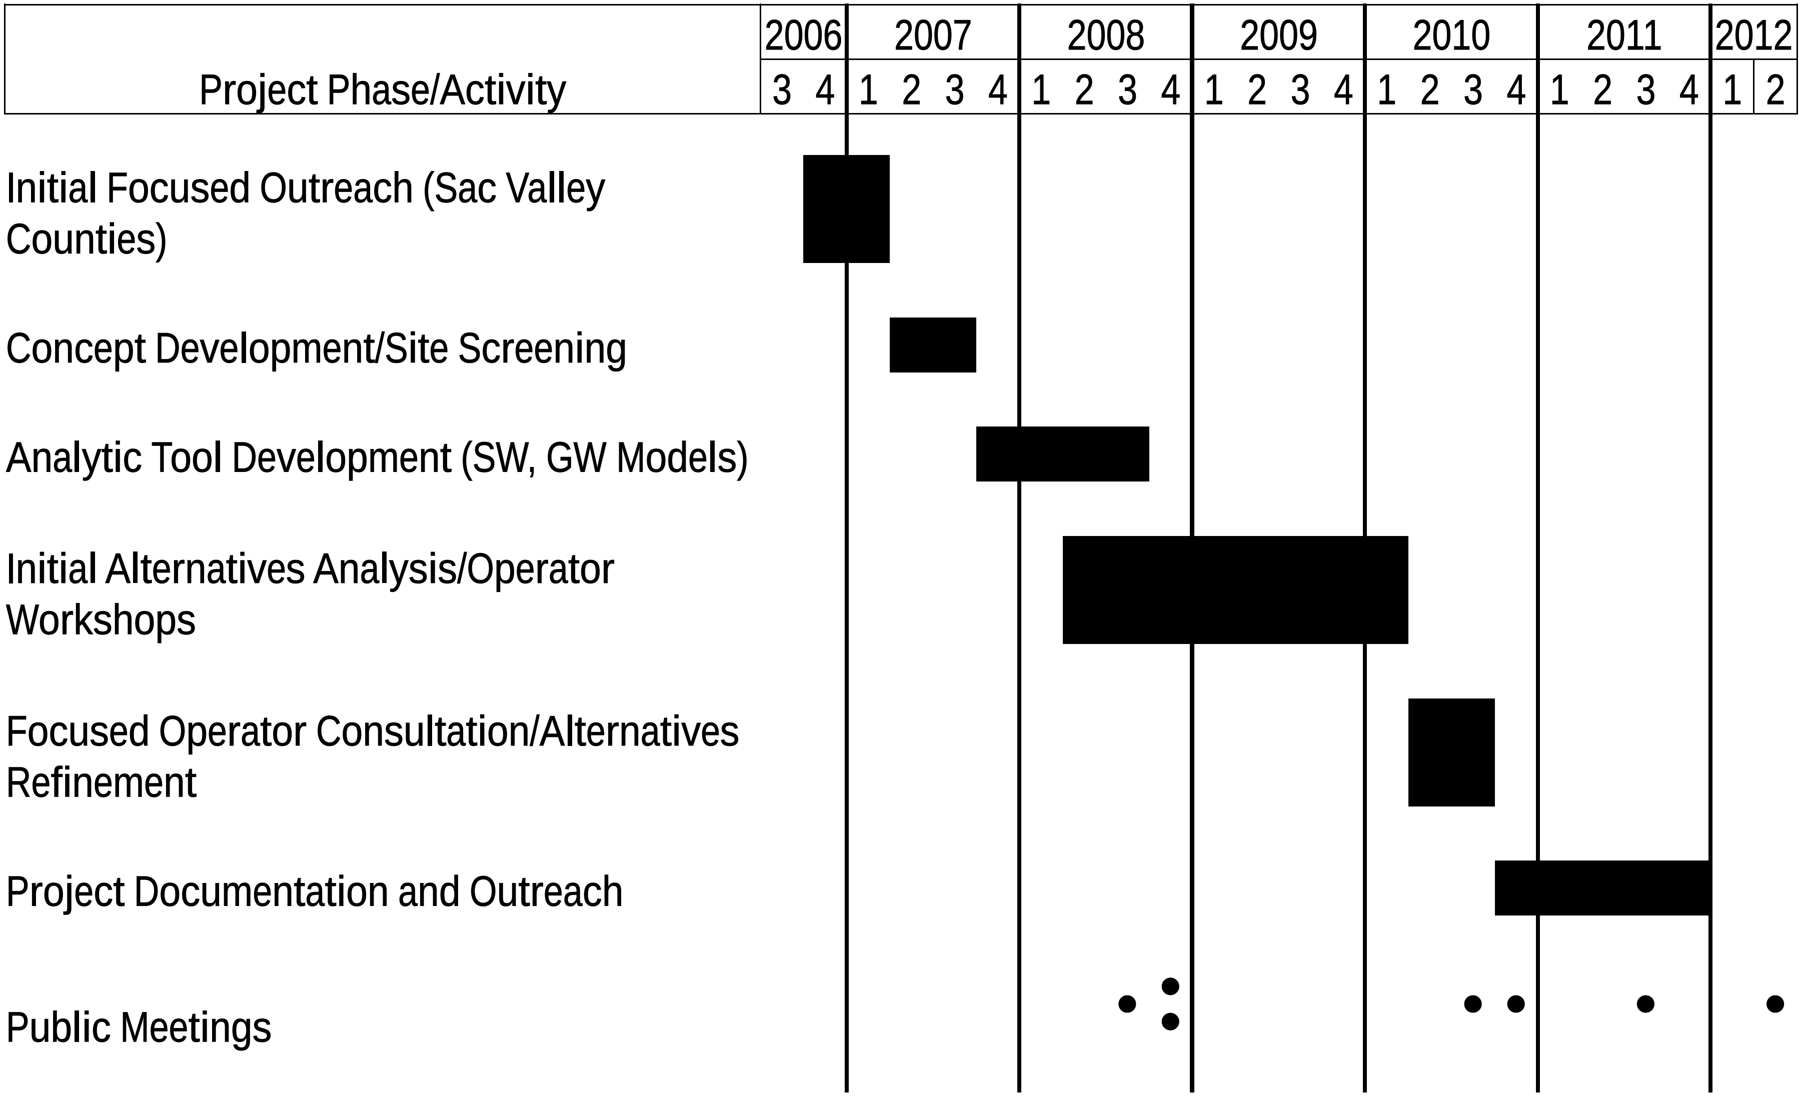
Briefing Topics

- High-Level Overview
- Core Conjunctive Management Concept
- Project Objectives and Principles
- Technical Approach and Analytic Tools
- Project Benefits
- Project Impacts
- Project Economics
- Conclusions and Recommendations

Overview:
Sponsors and Funding

- Jointly sponsored by Glenn-Colusa Irrigation District and the Natural Heritage Institute
- Funded by State and Federal grants:
  - Dept. of Water Resources: $500,000
  - Bureau of Reclamation: $700,000

Overview: Project Timeline



Project Phase/Activity

Initial Focused Outreach (Sac Valley Counties)

Concept Development/Site Screening

Analytic Tool Development (SW, GW Models)

Initial Alternatives Analysis/Operator Workshops

Focused Operator Consultation/Alternatives Refinement

Project Documentation and Outreach

Public Meetings

Overview: What Was Studied?

- Can additional water supplies be generated for use within the Sacramento Valley through the conjunctive management of existing surface water reservoirs and groundwater aquifers?
  - Lake Shasta and Lake Oroville
  - Intermediate aquifer and deep aquifer
  - Water used for environmental enhancement in the Sac and Feather Rivers and for agricultural water supply

Overview: What Was Learned?

- Traditional groundwater banking…storing surplus surface water underground and extracting it when needed…is not workable in the Sacramento Valley
  - Available aquifer storage capacity is inadequate
- Re-operation of existing storage reservoirs to draw them down further going into the refill season can generate additional water supplies
  - Evacuated reservoir space captures surplus stream flow
  - Reservoir “payback” is needed infrequently, when surplus stream flow is inadequate

Overview: What Was Learned?

- Reservoir “payback” by not making reservoir releases that would otherwise be made and pumping groundwater instead is feasible
  - Groundwater pumping required very infrequently
- Reservoir payback by temporarily idling crops to reduce reservoir demands is not efficient or cost-effective
  - Timing issues/idling cannot be turned on/off

Overview: Benefits to Groundwater

	Groundwater Pumping Capacity (thousand acre-feet)			
Scenario	Project	New Yield to Ag	Groundwater Pumped	**Net Gain to Groundwater**
1,3,4	CVP	1,148	246	**902**
1,3,4	SWP	820	246	**574**
2	CVP	1,804	738	**1,066**
2	SWP	1,886	574	**1,312**

Overview: What Was Learned?

- Impacts to existing groundwater users and streams is negligible
  - Payback pumping appreciable but required very infrequently
- As evaluated, the conjunctive management alternatives evaluated are not economically feasible
  - Benefits based solely on “in-Valley” value of water
  - No monetary value attached to the environmental benefits

Overview: Conclusions

- Further investigation is warranted but depends on regional interest and collaboration
  - Potential component of Integrated Regional Water Management Plans?
- Certain technical refinements recommended if further investigation undertaken, including climate change sensitivity

Core Concept:
Re-operate Existing Reservoirs

- Draw reservoirs down further going into the winter refill season
  - Produce additional water supply by capturing surplus surface flows
  - Increases risk that reservoirs will not refill
- When they do not refill, recover reservoirs by substituting alternative supplies or reducing water demands
  - Referred to as “reservoir payback”

Reservoir Payback Mechanisms

- Extract groundwater “banked” in prior years (not feasible)
- Reduce reservoir releases that would otherwise be made from reservoirs
  - Substitute with pumped groundwater
  - Temporary crop idling (on a voluntary, compensated basis)

Project Objectives

- Enhance ecosystem functions in the Sacramento and Feather Rivers by making additional reservoir releases for specific purposes
- Improve local (in-Valley) water supply reliability, particularly during times of scarcity
  - Reduce reliance on groundwater pumping
  - Reduce water shortages/lost production

Enhance Ecosystem Functions

- Geomorphic processes: sediment transport, bed mobilization and scour, etc.
- Floodplain inundation: provide habitat for rearing of juvenile salmon
- Spring pulse flows: enhance rearing and out-migration of juvenile salmon
- Riparian habitat

Specific flow rates, timing and durations developed for each objective, along with dynamic prioritization

Improve In-Valley Water Supply

- Historical unmet agricultural surface water demands <u>used as surrogates</u> for additional in-Valley water needs
  - Central Valley Project (CVP) water supply contractors along Tehama-Colusa Canal
  - Feather River water rights holders subject to shortages in dry years
  - Minimize crop idling and groundwater pumping

Additional water supplies could be used for any purpose.

Project Principles

- Honor all existing CVP and SWP obligations and operational requirements
- Achieve net environmental benefits recognizing potential for tradeoffs
- Hold existing groundwater users harmless by avoiding, minimizing, mitigating impacts
- Try to generate net positive economic benefits

Technical Approach and Analytic Tools

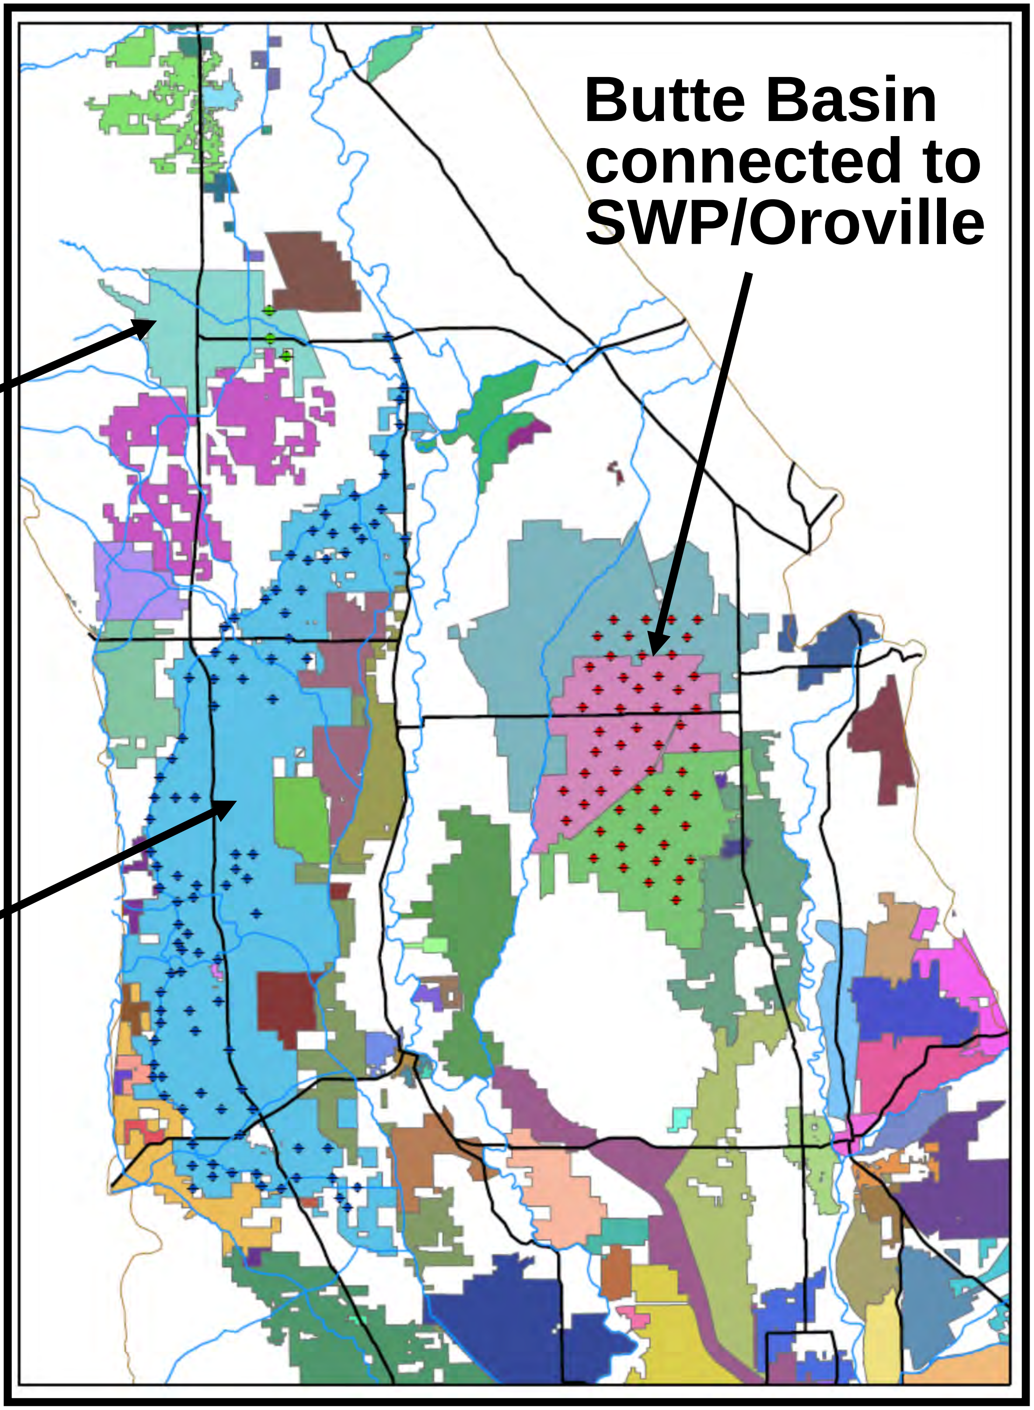
- Site screening and selection
- Groundwater and surface water models
- Project scenarios

Initial Site Screening

Attractive Site Features

- Groundwater conditions
  - Available aquifer storage space
  - Viable recharge mechanism
  - Productive groundwater wells
  - Suitable GW quality
- Surface water conditions
  - Reliable surface water supplies
  - Connection to CVP, SWP or other reservoirs that could be re-operated
  - Dual SW and GW use option
- Impacts/mitigation
  - Isolation from important surface streams
  - Isolation from existing groundwater production wells
  - Ability to mitigate or compensate impacts that cannot be avoided

Nine Sites Evaluated; Three Promising Sites Identified



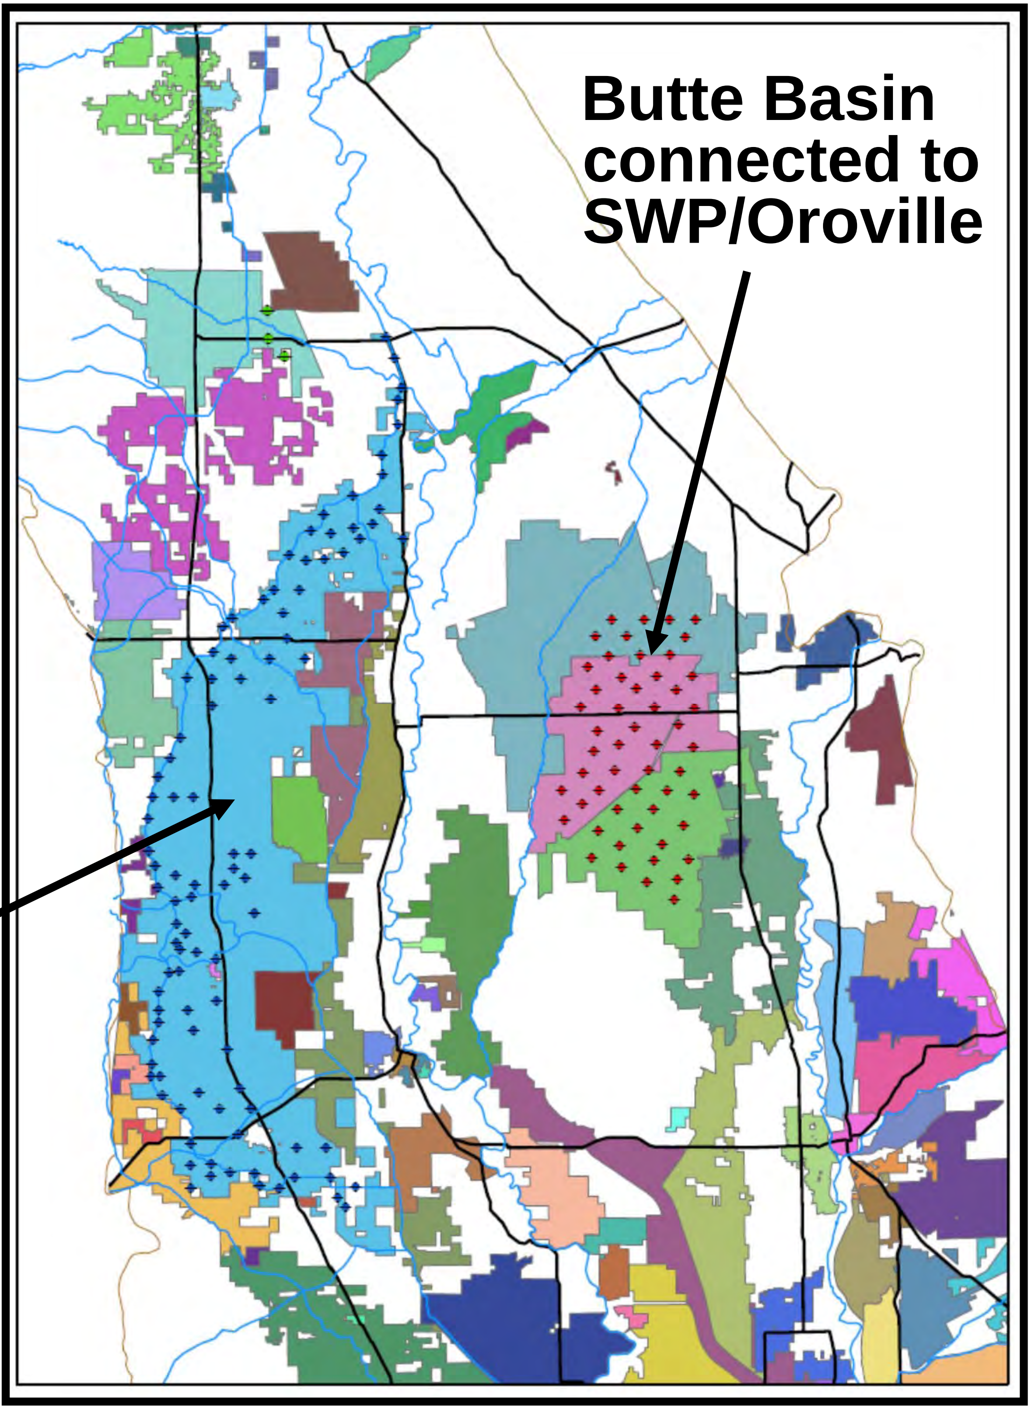
Orland Unit connected to Stony Creek Reservoirs

Glenn-Colusa ID connected to CVP/Shasta

Butte Basin connected to SWP/Oroville

4/12/2012

Two Sites Selected for Modeling



Butte Basin connected to SWP/Oroville

Glenn-Colusa ID connected to CVP/Shasta

4/12/2012

Modeling Requirements

- Honor existing CVP and SWP operations
- Account for stream-aquifer interaction and impacts to existing pumpers
- Fast and flexible model operation
  - Test many configurations and scenarios
  - "Gaming" with Project Operators

Conclusion: Use separate but coordinated SW and GW models.

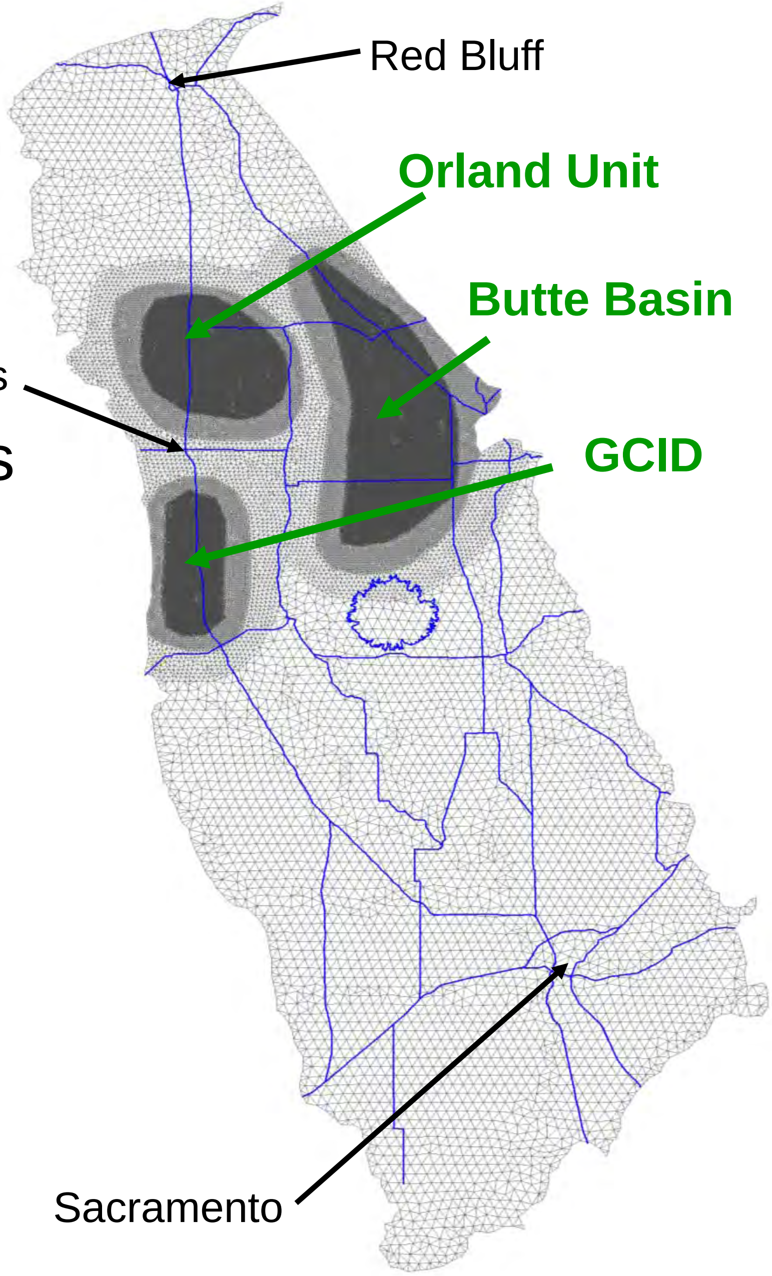
Surface Water Model

- Spreadsheet-based model designed for incremental analysis of CALSIM II outputs
  - Honor existing CVP and SWP operations
- Based on 1922 through 2003 hydrology
  - Climate variability not evaluated at this stage of study
- Simulations “driven” by additional target deliveries
  - Ecosystem flow targets in Sacramento and Feather Rivers
  - Unmet Sacramento Valley agricultural demands
- Uses generalized SW-GW interaction functions derived from GW model

Groundwater Model

- Regional scale with high spatial detail
  - 5,950 square miles
  - 88,922 surface nodes
  - 7 vertical layers
- Aquifer properties based on analysis of more than 1,000 production well records
- Calibration
  - Static calibration for year 2000
  - Water levels from 257 monitoring wells
- 1982 - 2003 hydrology

(Model has been developed further since being used for this project)



Parameters Defining Project Scenarios

- Maximum reservoir “payback” capacity
  - Maximum volume of groundwater pumping to be called on, as needed, to repay reservoirs when they don’t refill with surplus runoff
  - Defines the scale of the conjunctive operation
- Groundwater pumping period
  - “Summer” (May through August)
  - “Fall” (September through November)
  - “Summer and Fall” (May through November)
  - Influences the intensity of pumping and nature of impacts

Project Scenarios Evaluated

Scenario	Groundwater Pumping Capacity (thousand acre-feet)			Pumping Season
	GCID (CVP)	Butte Basin (SWP)	Total	
1	100	50	150	summer
2	200	100	300	summer
3	100	50	150	fall
4	100	50	150	summer & fall

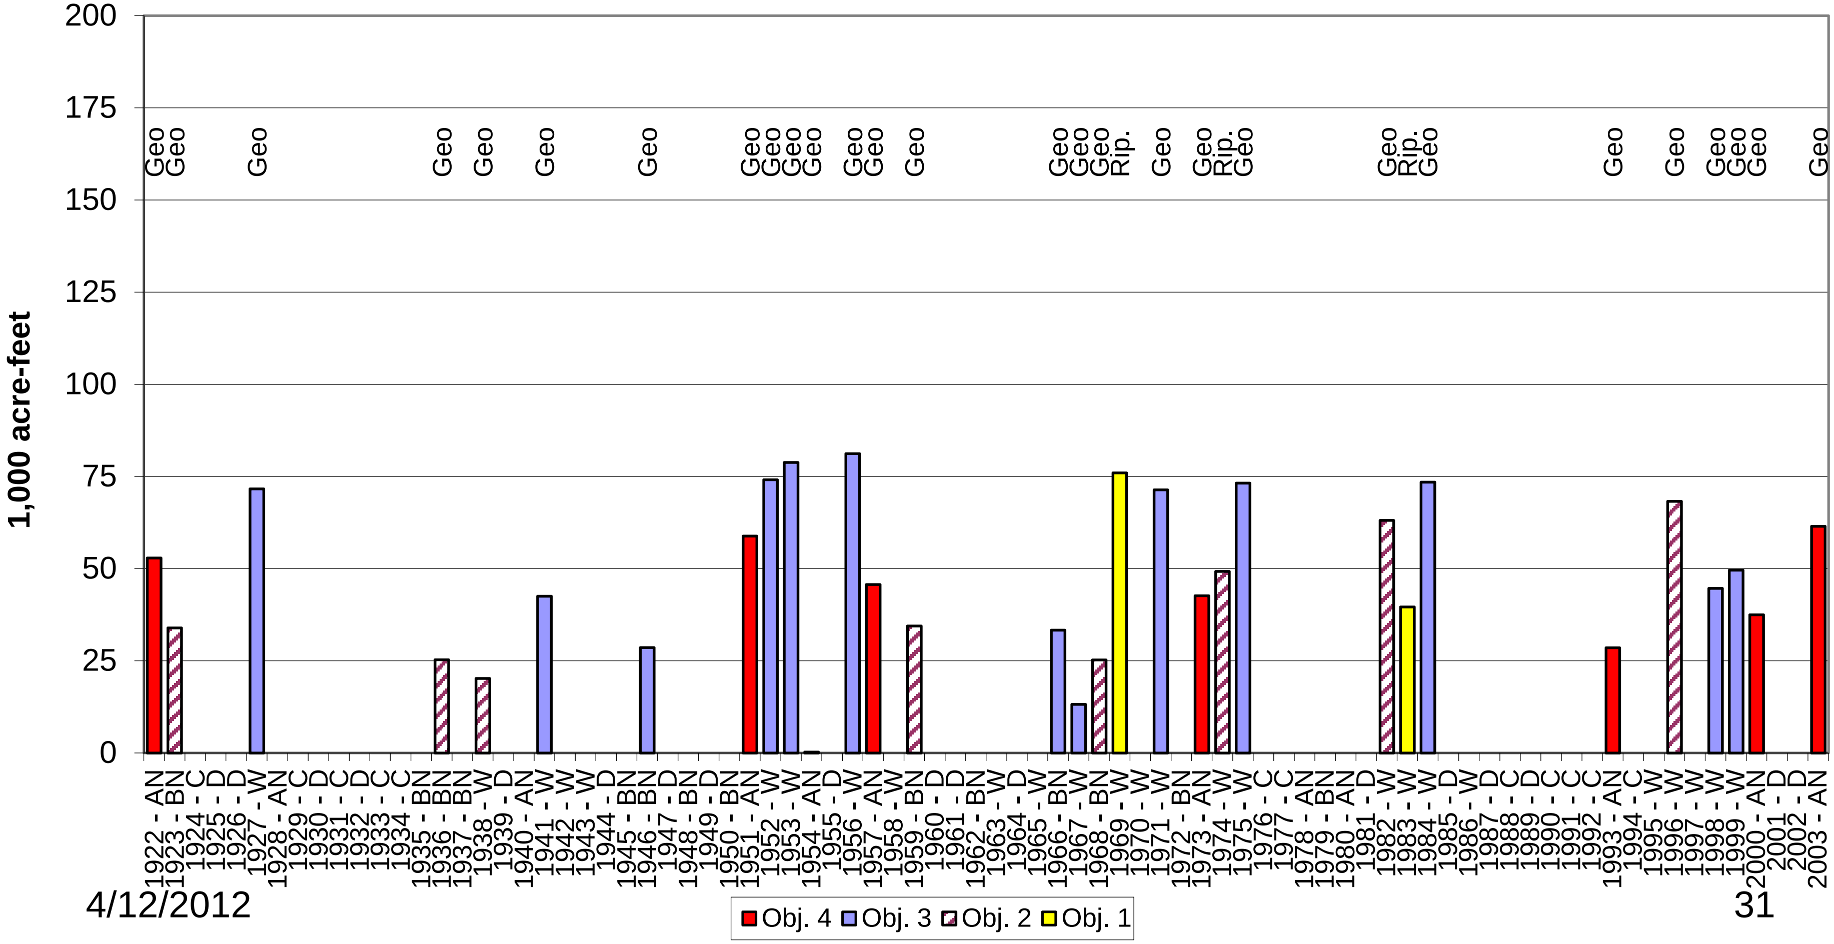
All scenarios modeled with an existing (shallow) and new (deep) well field to reveal range of potential impacts to streams and existing pumpers.

Results for Butte Basin—Scenario 2 (100 TAF Project Pumping Capacity)

- Environmental flow releases
- Agricultural deliveries
- Reservoir refill from surplus surface water and from groundwater pumping
- Oroville storage

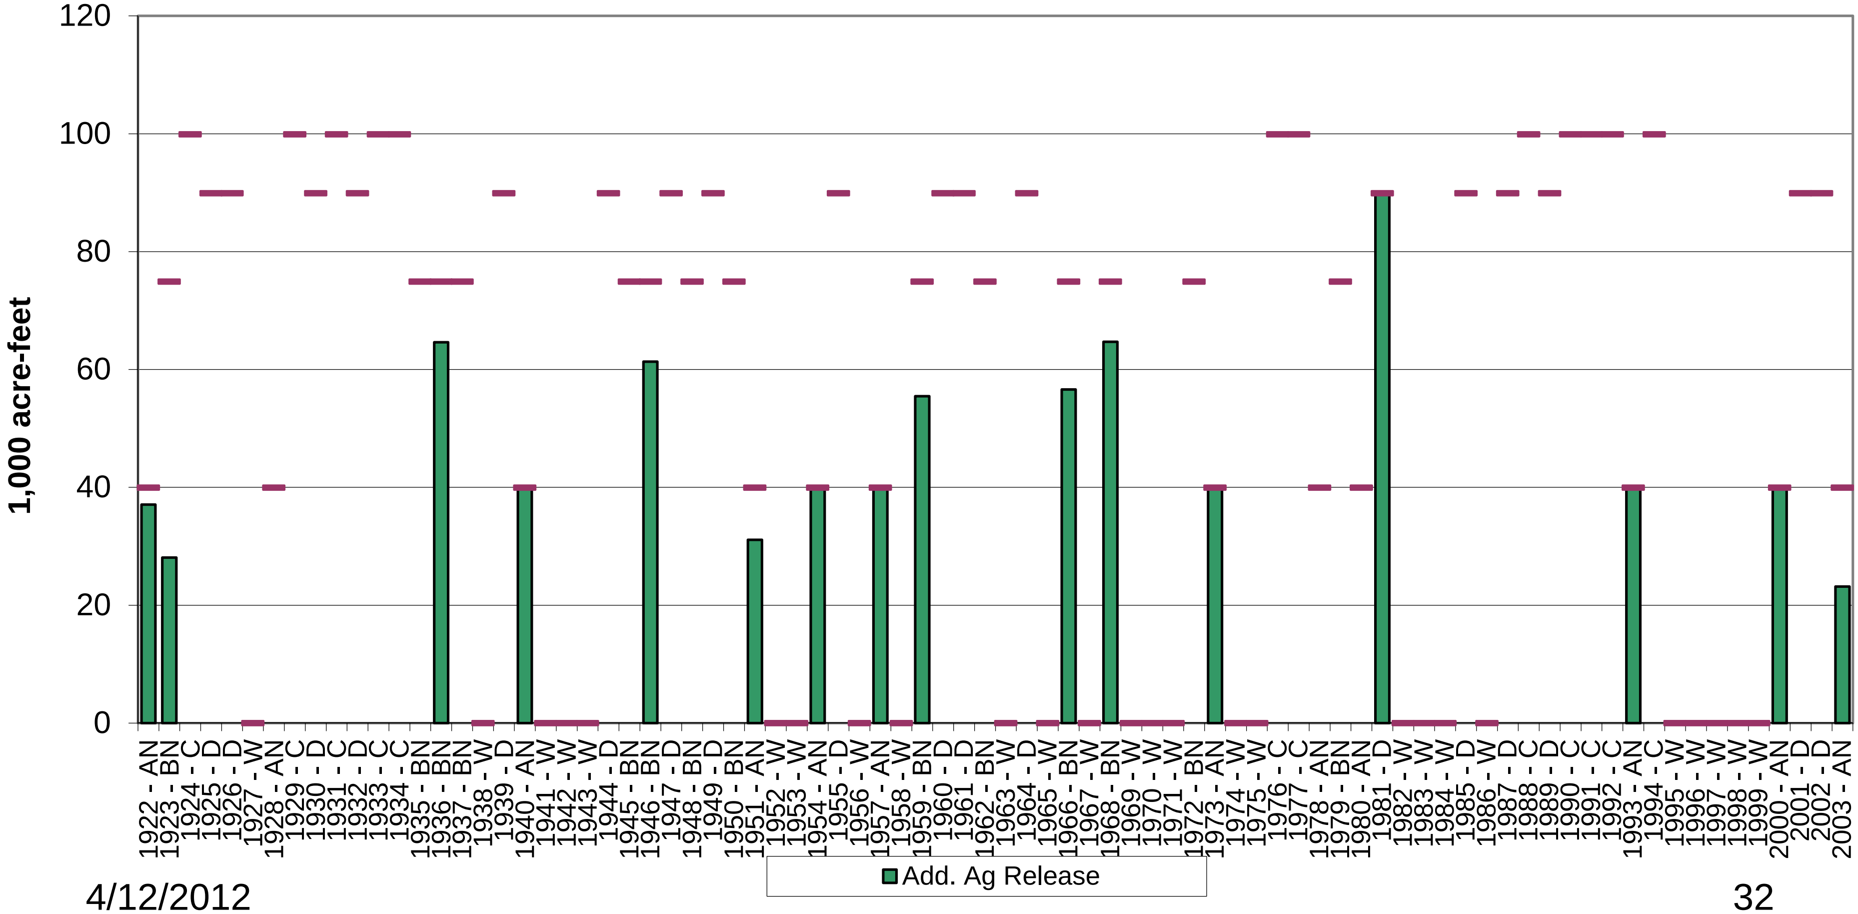
Results for Butte Basin—Scenario 2 (100 TAF Project Pumping Capacity)

Environmental Flow Releases

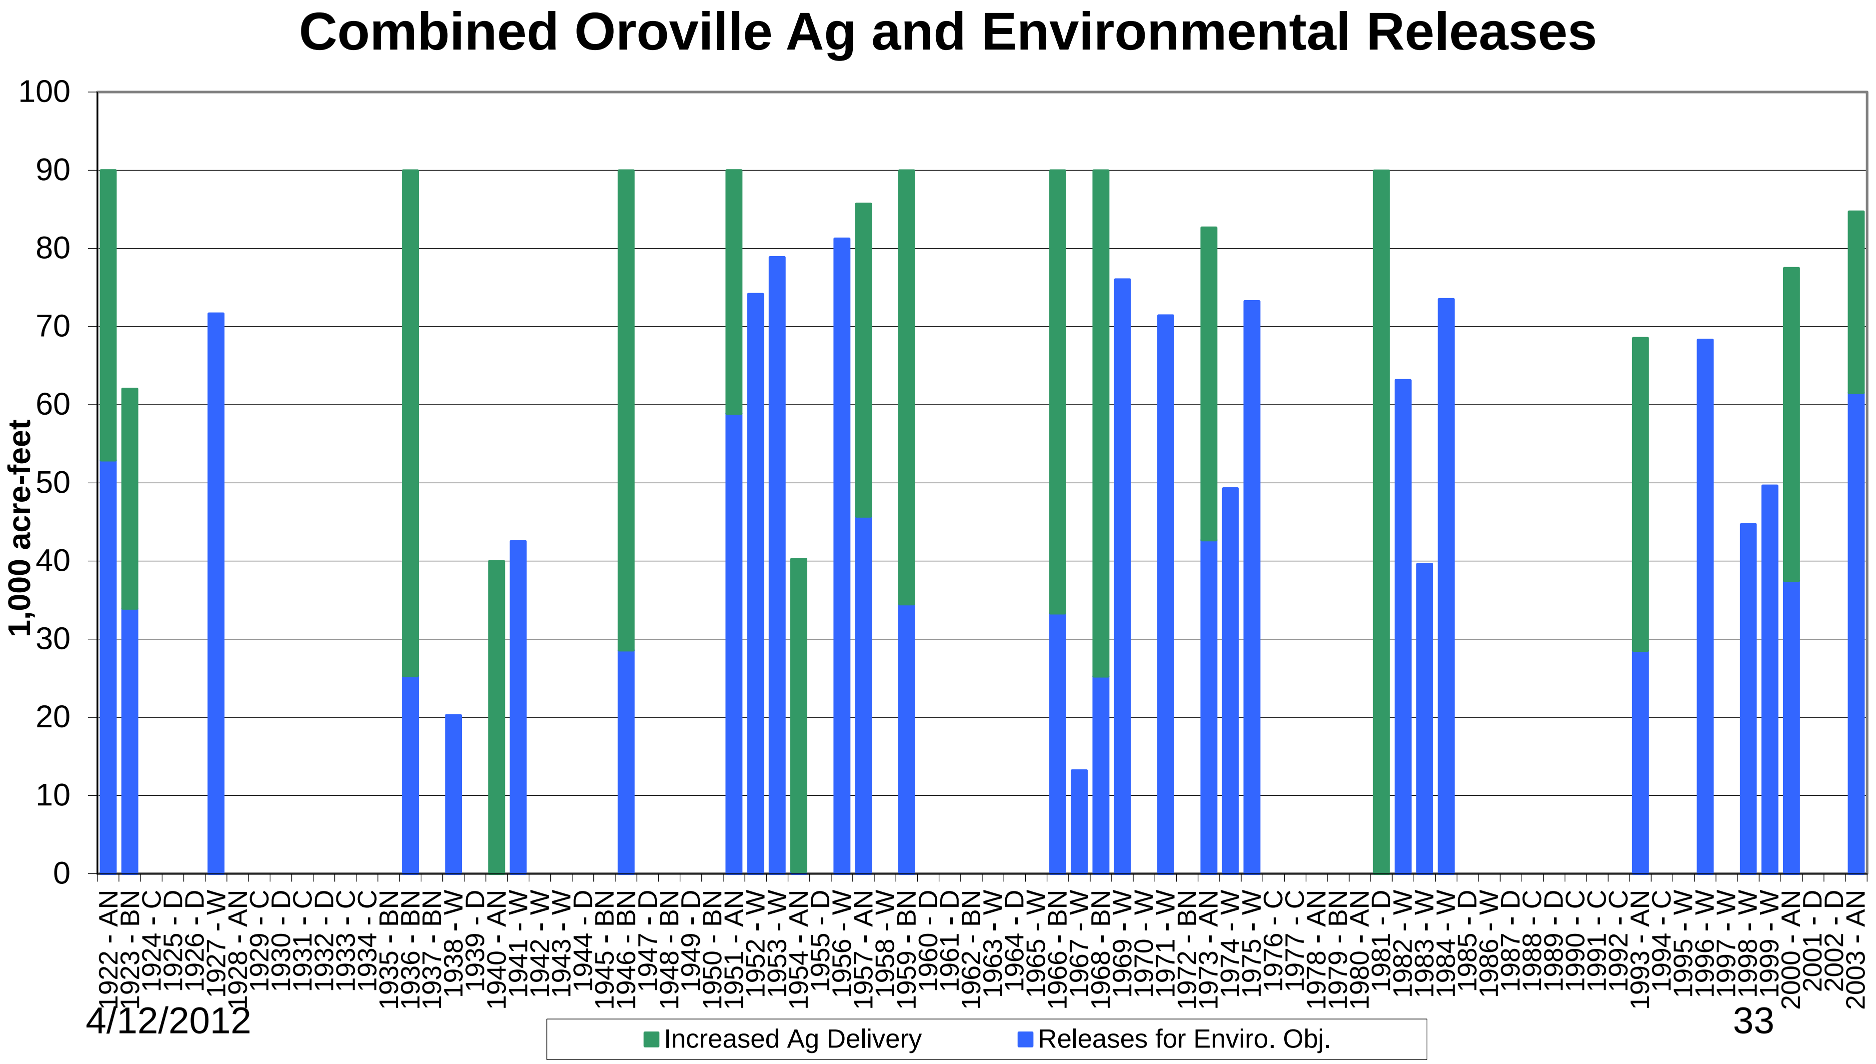


Results for Butte Basin—Scenario 2 (100 TAF Project Pumping Capacity)

Feather River Unmet Ag Demand and Additional Delivery

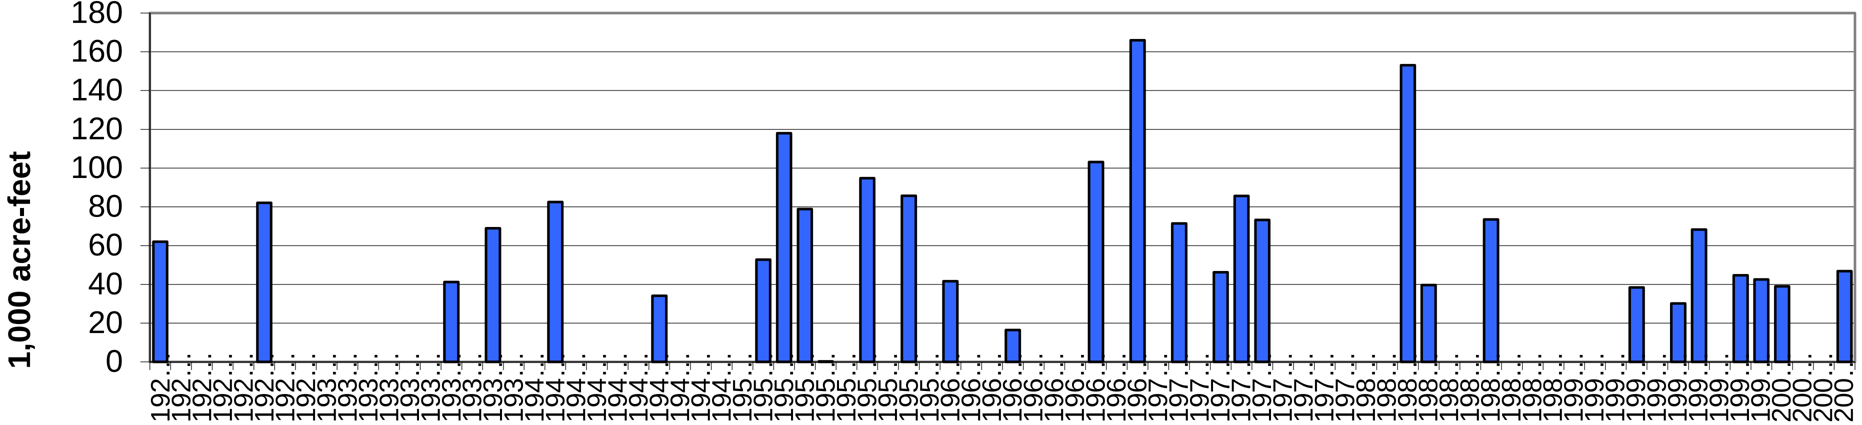


Results for Butte Basin—Scenario 2 (100 TAF Project Pumping Capacity)

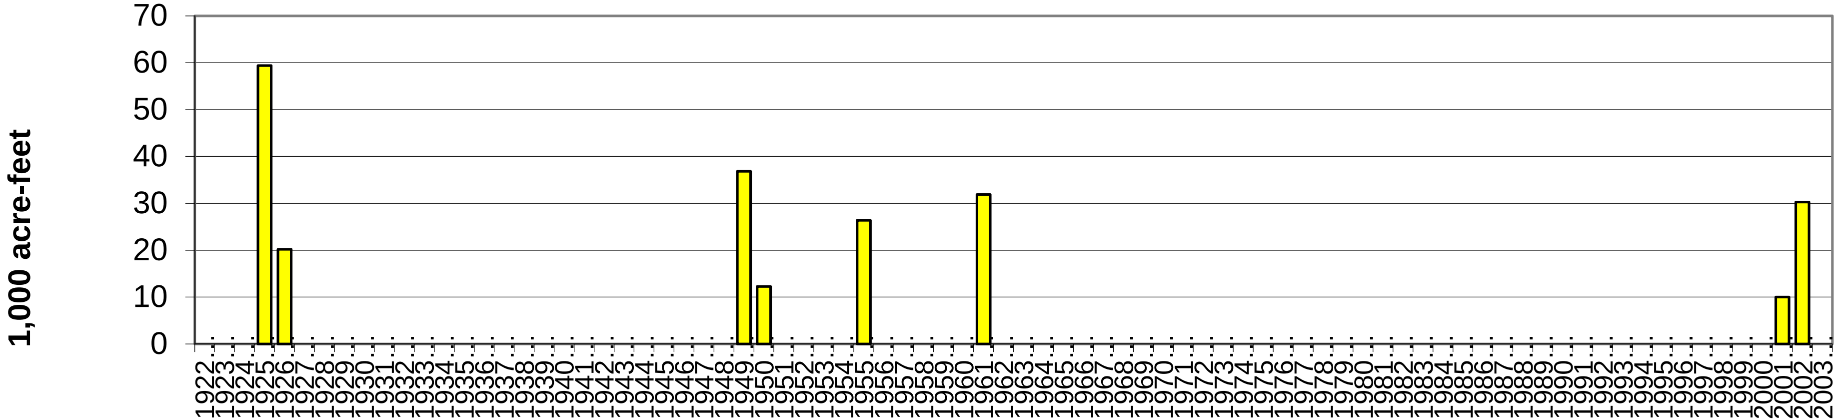


Results for Butte Basin—Scenario 2 (100 TAF Project Pumping Capacity)

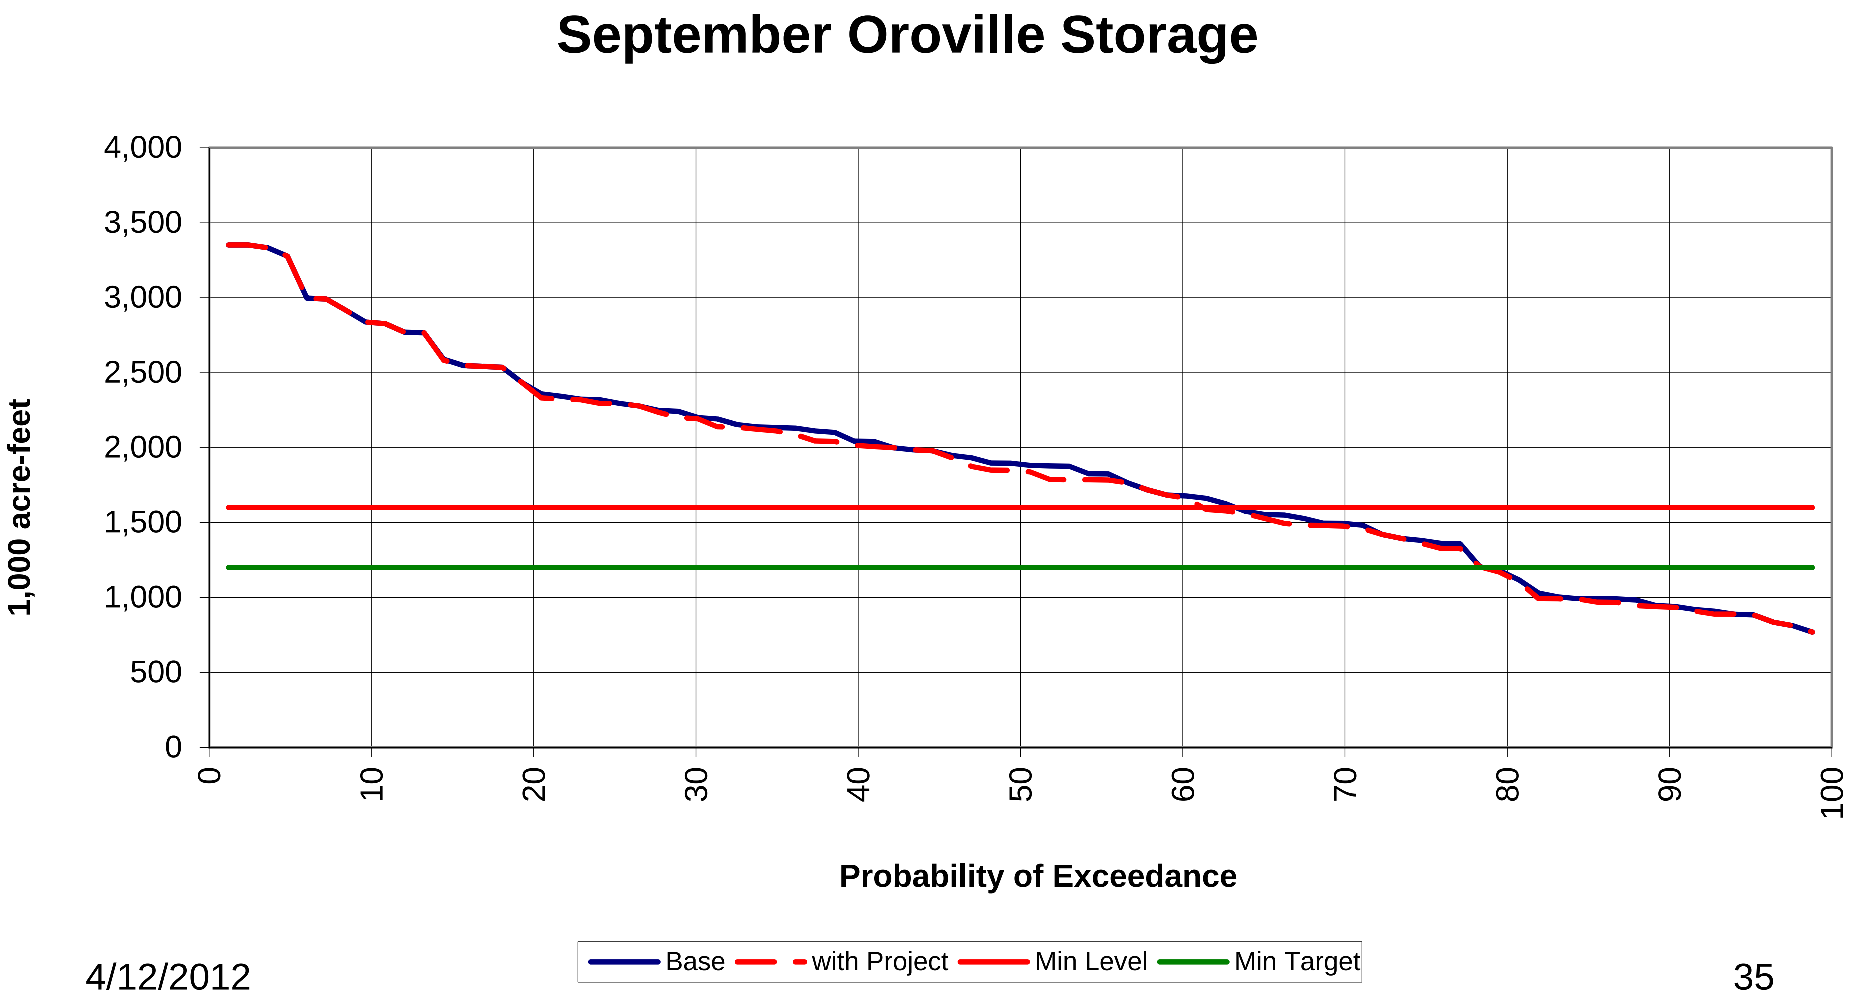
Oroville Refill from Surplus Inflow



Butte Basin Project Pumping



Results for Butte Basin—Scenario 2 (100 TAF Project Pumping Capacity)



Summary of Model Results
Project Benefits

Scenario(s)	Project/System	Payback Pumping Capacity (TAF)	Environmental Benefits			Agricultural Benefits		
			Number of Years	Avg in Yrs of Occurrence (TAF)	Avg Over All Yrs (TAF)	No. Yrs.	Avg in Yrs of Occurrence (TAF)	Avg Over All Yrs (TAF)
1, 3 and 4	GCID/CVP Lake Shasta-Sac R	100	23	46	13	24	46	14
1, 3 and 4	Butte Basin/SWP Lake Oroville-Feather R	50	28	21	7	30	27	10
2	GCID/CVP Lake Shasta-Sac R	200	40	96	47	24	75	22
2	Butte Basin/SWP Lake Oroville-Feather R	100	44	43	23	30	52	20

Summary of Model Results
Reservoir Refill

Scenario(s)	Project/System	Payback Pumping Capacity (TAF)	Surplus Surface Water Number of Years	Surplus Surface Water Avg in Yrs of Occurrence (TAF)	Surplus Surface Water Avg Over All Yrs (TAF)	Project Groundwater Pumping No. Yrs. 2	Butte Basin/SWP Lake Oroville-Feather R	100	43	72	36	8	75	7	100

Project Impacts Due to Additional Groundwater Pumping

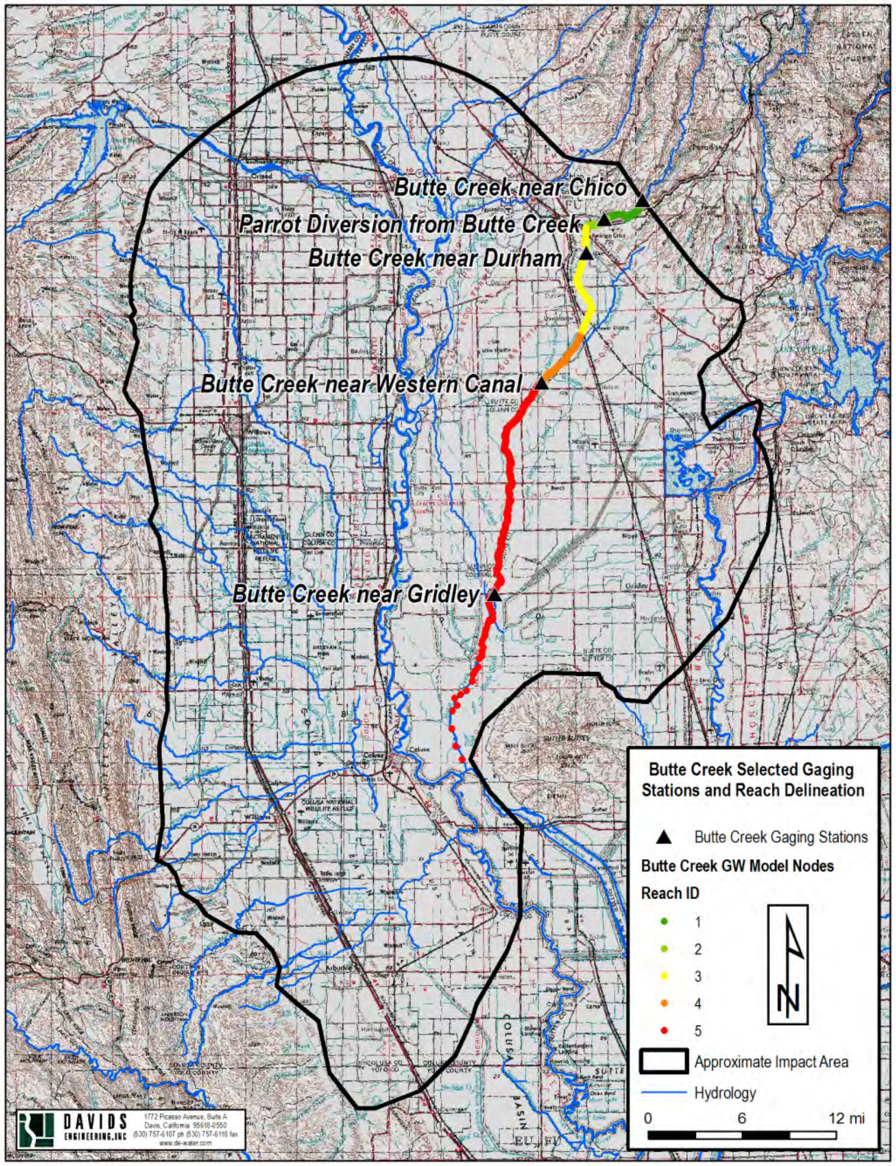
- Stream flow reduction
  - Butte Creek in affected area
  - Other critical streams not in affected areas
  - Ephemeral streams not analyzed
- Groundwater levels and existing wells
  - Well yield impacts
  - Incremental pumping costs (due to additional lift)

Peak Monthly Effects on Streamflow from Payback Pumping

	Scenario 1		Scenario 2		Scenario 3		Scenario 4	
Stream	**Existing (cfs)**	**New (cfs)**	**Existing (cfs)**	**New (cfs)**	**Existing (cfs)**	**New (cfs)**	**Existing (cfs)**	**New (cfs)**
All Streams[a]	54	53	111	105	80	90	64	65
Butte Creek	13	12	72	69	50	48	39	33
Sacramento River – GCID to Wilkins Slough	42	37	32	28	16	18	16	15
Feather River	3	3	6	6	4	4	4	4
Little Chico Creek	3	3	6	5	4	3	4	3
Salt River	1	5	5	8	2	5	2	5
Stone Coral Creek	6	9	11	15	7	10	6	9
Stony Creek	4	5	7	7	4	6	4	4

Butte Creek Streamflow Reduction

- Develop baseline flow from available gauging stations
- Synthesize “with-project” flows based on cumulative reductions in streamflow from changes in stream leakance from GW model



4/12/2012

Butte Creek Impacts

- No impact in upper reaches (primary spawning and holding areas)
- Greatest flow reduction in Jan. – Mar.
  - During times of highest discharge
- Greatest % reduction in summer/early fall
  - Spring-run have already migrated
  - Steelhead just beginning to enter stream
- Rarely drops below in-stream standards
  - June during early '90s drought
- Tradeoffs between Butte Creek impacts and main stem benefits
- Potential to Reoperate with PGE and increase releases from into Butte Creek, exchange reoperated flows from Oroville to PGE Projects

Interference Drawdown Due to Project Pumping

	Interference Drawdown (ft)				
Pumping Scenario	Min	Max	Mean	Median	Std. Dev.
300 TAF Summer Pumping, New Well Field	0.0	13.6	0.5	0.3	0.7
300 TAF Summer Pumping, Existing Well Field	0.0	8.3	0.4	0.2	0.6
150 TAF Summer Pumping, New Well Field	0.0	6.2	0.3	0.2	0.4
150 TAF Summer Pumping, Existing Well Field	0.0	5.4	0.3	0.2	0.4
150 TAF Fall Pumping, New Well Field	0.0	7.0	0.4	0.2	0.4
150 TAF Fall Pumping, Existing Well Field	0.0	6.1	0.4	0.2	0.5
150 TAF Summer & Fall Pumping, New Well Field	0.0	5.9	0.4	0.2	0.4
150 TAF Summer & Fall Pumping, Existing Well Field	0.0	5.0	0.4	0.2	0.5

Conclusions

- Traditional groundwater banking…storing surplus surface water underground and extracting it when needed…is not workable in the Sacramento Valley
  - Available aquifer storage capacity is inadequate
- Re-operation of existing storage reservoirs to draw them down further going into the refill season can generate additional water supplies
  - Evacuated reservoir space captures surplus streamflow
  - Reservoir “payback” is needed infrequently, when surplus streamflow is inadequate

Conclusions, (cont.)

- Reservoir “payback” by not making reservoir releases that would otherwise be made and pumping groundwater instead is feasible
  - Groundwater pumping required very infrequently
- Reservoir payback by temporarily idling crops to reduce reservoir demands is not efficient
  - Timing issues/idling cannot be turned on/off

Conclusions, (cont.)

- Impacts to existing groundwater users and streams appear to be manageable
  - Payback pumping appreciable but required very infrequently
- As evaluated, the conjunctive management alternatives evaluated are not economically feasible
  - Benefits based solely on “in-Valley” value of water
  - No monetary value attached to the environmental benefits

Conclusions, (cont.)

- Further investigation may be warranted but depends on regional interest and collaboration
  - Potential component of Integrated Regional Water Management Plans?

Recommended Further Study

- Reconcile tradeoffs among environmental water uses in reservoir operations
- Refine reservoir operation rules
- Refine payback strategies and costs
- Develop system-wide accounting conventions
- Update models
- Evaluate effects of climate change/variability

Executive Summary

The Sacramento-San Joaquin River Delta is the grand confluence of California's waters, the place where the state's largest rivers merge in a web of channels—and in a maze of controversy. The Delta is a zone where the wants of a modern society come into collision with each other and with the stubborn limitations of a natural system. In 2009, seeking an end to decades of conflict over water, the Legislature established the Delta Stewardship Council with a mandate to resolve long-standing issues. The first step toward that resolution is the document you have before you, the Delta Plan.

Though more than 50 miles inland from the Golden Gate, Delta waters rise and fall with ocean tides. The Delta is in fact the upstream, mostly freshwater portion of the San Francisco Estuary, the largest estuarine system on the West Coast of the Americas, and one of California's prime natural assets. It is a major stop on the Pacific Flyway and the portal through which important fish species, including anadromous Chinook salmon, pass on their way to and from their spawning grounds in the interior.

The system of waters in which the Delta is so central has changed dramatically since California became a state. Rivers have been dammed and aqueducts built. Natural flows and fluxes have been disrupted to support cities and make the Central Valley the fruit basket and salad bowl of the nation. Approximately half of the water that historically flowed into and through the Delta is now diverted for human use, never reaching the sea. Much of this diversion occurs at points upstream, before the rivers come down to the Delta; but the last and largest draws take place in the Delta itself. On the southeast edge of the region, near Byron, two sets of mighty pumps extract water for shipment as far south as San Diego. Two-thirds of California's people and 4.5 million acres of farmland receive some part of their water from the Delta.

The Delta landscape we know is itself the result of a great transformation, from a primeval wetland complex to an archipelago of diked islands, where soils that once grew vast thickets of tules now yield bountiful corn, alfalfa, tomatoes, and many other crops. The Delta is home to about 12,000 people on farms and in small historic communities, and to about half a million in the larger cities that are

pressing into the region from the fringe. More millions come to it for boating, fishing, hunting, bird watching, even windsurfing on its 700 miles of channels. Steeped in history, combining notes of the American heartland and of Holland, the Delta looks and feels like no other place in California. This is a land that people love.

It is not doing so well.

The very shape of the modern Delta is in danger. Farming of peat-rich ground like this always leads to oxidation, the literal vanishing of soil, and thus to subsidence. Many Delta islands now lie 15 feet or more below sea level and depend on aging dikes to prevent the water in adjacent channels from pouring in. Higher river flows in winter or spring, predicted results of climate change, will add to the pressure, and a great earthquake, sooner or later, will shake the region like a paint can on a mixer. Encroaching urbanization, meanwhile, puts more people and property on dangerous ground.

After years of slow decline, the condition of the Delta's watery ecosystem, as measured especially by the population of wild salmon and other native fishes, has gone critical. The list of causes begins, but does not end, with all those water withdrawals, a kind of tax that leaves the system in a condition of chronic drought. The specific, peculiar manner in which the last large gulps of water are withdrawn adds to the ecological cost. The continual introduction of alien aquatic species from around the world is altering the web of life, often at the expense of native and other valued species. Pollution from the vast and busy watershed does its share of harm.

Today, all those who depend on or value the Delta are, in a word, afraid. Delta residents face the possibility of floods from the east when the rivers flow strongly and of salinity intrusion from the west if they flow too feebly. Fishermen, both commercial and recreational, fret about the future of salmon and other species. Water suppliers that receive water from the Delta find those supplies insecure, subject to interruption by weather vagaries, levee failures, or pumping restrictions imposed in the desperate attempt to stem the decline of fish.

>
> ***It is not doing so well.***

The Coequal Goals, the Delta Stewardship Council, and the Delta Plan

Since the middle 1980s, California has been looking for ways to secure the natural and human values of the Delta while maintaining its place in the state's water plumbing. These efforts have generally started in hope and ended in impasse. In recent years environmentalists turned to the courts, using the blunt tool of the federal Endangered Species Act to force curtailment of water exports at certain times. In reaction, water suppliers south of the Delta have complained of "regulatory drought."

In 2009 the Legislature made its latest, most determined bid to find solutions, passing the Delta Reform Act and associated bills. First and foremost, it declared that State policy toward the Delta must henceforth serve two "coequal goals":

- Providing a more reliable water supply for California, and
- Protecting, restoring, and enhancing the Delta ecosystem.

These goals, the Legislature added, must be met in a manner that:

- Protects and enhances the unique cultural, recreational, natural resource, and agricultural values of the Delta as an evolving place.

By affirming the equal status of ecosystem health and water supply reliability, the Legislature changed the terms of the conversation. It changed them further with the following pronouncement: "The policy of the state of California is to reduce reliance on the Delta in meeting California's future water supply needs." Here was recognition that, for the sake of the water system and the Delta both, a partial weaning of the one from the other is required.

The Delta Stewardship Council is the body entrusted with giving practical meaning to these directives. Publication of this Delta Plan completes its first assignment. The product of eight drafts, almost 100 public meetings, and nearly 10,000 comments, the Delta Plan pulls together in one place the steps that need to be taken to meet the coequal goals—measures that, in one way or another, could affect almost everyone in California. The Plan is to be revised every 5 years, or sooner as circumstances change.

The Delta Plan contains 87 provisions, some broad and some narrowly technical, some novel, some commonsensically familiar. What, in essence, does the Plan propose be done differently? At the risk of oversimplification, we can say that it asks California and Californians to do six large things:

- In order to improve and secure our water supply, while taking pressure off the Delta, we must use water more efficiently in cities and on farms, and develop alternative, usually local, sources.
- We must also get much better at capturing and storing the surplus water that nature provides in the wettest years, building reserves that can be drawn on in dry ones.
- To revitalize the Delta ecosystem, we must provide adequate seaward flows in Delta channels, on a schedule more closely mirroring historical rhythms: what the Plan calls natural, functional flows.
- We must also bring back generous wetlands and riparian zones in the Delta for the benefit of fish and birds.
- To preserve the Delta as a place, we must restrict new urban development to those peripheral areas already definitely earmarked for such growth, while supporting farming and recreation in the Delta's core.
- And we must floodproof the Delta, as far as feasible, mainly by improving levees and by providing more overflow zones where swollen rivers can spread without doing harm.

What about today's headline issue concerning the Delta—the proposed construction of tunnels to improve the way water destined for export southwards reaches the pump intakes near Byron? This initiative is part of what is called the Bay Delta Conservation Plan (BDCP). The BDCP is a different and more narrowly focused undertaking than the Delta Plan, into which, if certain conditions are met, it will be fused (see section, A Better System: Delta Conveyance).

The Delta Plan is *California's* plan for the Delta, prepared in consultation with, and to be carried out by, all agencies in the field: the State Water Resources Control Board, ultimate arbiter of water rights and water quality; the California Department of Water Resources, the state's water planner and also operator of the great State Water Project; the California Department of Fish and Wildlife, responsible for the welfare of the living system of the Delta; the Delta Protection Commission, which oversees land use and development on low-lying Delta islands; and many more agencies, State and local. Add to the list federal players like the Bureau of Reclamation, which runs the Central Valley Project; the U.S. Fish and Wildlife Service; the National Marine Fisheries Service; and the U.S. Army Corps of Engineers. Their cooperation has been promised, and it is vital.

The working parts of the Plan are 73 *Recommendations* and 14 *Policies*. *Recommendations* call attention to tasks being done or to be done by others. *Policies* are legal requirements that anyone undertaking a significant project in the Delta must meet. See the sidebar, From Plan to Reality, for more on the mechanics of realizing the Plan and pages ES-15 to ES-35 for a survey of all 87 provisions.

Where Is the Money?

The Legislature sees "adequate and secure funding" as a need "inherent in the coequal goals." In order to know what this entails, we need to form a clearer picture of the costs of the work now proposed for the Delta or on its behalf and how those costs might be met. This first edition of the Delta Plan proposes research toward that clarity.

FROM PLAN TO REALITY

The Legislature instructed the Delta Stewardship Council to "direct efforts across state agencies." This "direction" has three distinct aspects.

First of all, the Council is to **coordinate**. It will chair a high-powered committee dedicated to implementing the Plan. The heads of key State and local agencies will be at that table, together with federal representatives. This body will meet for the first time in fall 2013. Agency staffs will work with that of the Council daily.

Second, the Council is to **keep track of progress**. Using specific performance metrics contained in the Plan, and guided by the Delta Science Program (see sidebar, Science at the Center), it will monitor what is actually being done toward Plan goals, and what changes of course may be indicated. The results will be widely publicized.

Third, in certain key areas, the Council can be called upon to **block damaging actions**. The Plan provisions that can trigger this authority are called Policies. To avoid premature encroachment on the work of other agencies, the Legislature devised an indirect path leading to Council intervention.

Actions subject to these Policies are called "covered actions," but the Council itself cannot declare an action to be covered. It is the proposing agency that makes this determination. Legal standards apply, however, and if an action is questionably deemed not to be covered, the Council or any other party can take the agency to court.

Once an action is determined to be covered, the proposing agency must make sure it is in line with the Policies of the Delta Plan, filing a Certification of Consistency with contents specified in Delta Plan **Governance Policy 1**. If the agency says the action is consistent but another party or citizen thinks it is not, the opponent can then appeal to the Delta Stewardship Council. A Council member or the Council's Executive Officer may initiate the appeal.

SCIENCE AT THE CENTER

The Delta Reform Act mandates that the Delta Plan be based on the best available scientific knowledge of our day. It must, moreover, be open to change as knowledge changes—and as paper proposals meet the test of reality. The results of every action are to be closely tracked, so that corrections can be made in a timely way—a process, much discussed but not sufficiently practiced, known as adaptive management.

To be more than a buzzword, adaptive management must bring two things to bear: new information, and a readiness to let new information disrupt old plans. Both, in the past, have been in scant supply.

Though Delta knowledge has expanded hugely in recent years, it is often a challenge to pull that data together and draw conclusions from it. Studies are done by different agencies for specific purposes and in narrow contexts; findings can be hard to integrate. The Delta Science Program, a function of the Council, will seek to overcome these gaps, linking the whole community of scientists at work. Guided by a top-flight Delta Independent Science Board, it will prepare, by December 31, 2013, a companion to the Delta Plan called the Delta Science Plan (**Governance Recommendation 1**).

The Delta Science Plan will propose a collaborative structure for doing science in the Delta. It will suggest ways of improving communication, resolving conflicting results, and accommodating uncertainty. It will offer priorities: how to apportion attention between immediate practical questions, on the one hand, and research aimed at increasing long-term understanding, on the other. It will sketch a more integrated approach to monitoring, so that results from different settings can be compared, and consider how computer modeling of the intricate Delta system might be improved.

Once a year, the Council will bring scientists together to assess what has been learned and what changes in ongoing plans and projects the new knowledge may suggest. Another conference? Yes, but with a difference: These findings will feed directly into ongoing refinement of the Delta Plan.

First step is an inventory: How much is now actually being spent, by all the agencies involved, that can be chalked up to furthering the coequal goals? Second comes an assessment of costs: How much will it take to carry out the projects and programs described in the Delta Plan, and what might the sources of support be for each one? The third step must be a comparison of resources and needs, and a reckoning of gaps: What key elements lack probable funding, and what might be done to fill these holes? (**Funding Principles Recommendations 1 through 3**.)

Providing a More Reliable Water Supply for California...

The Delta's contribution to the overall statewide water supply is smaller than many people think. The proportion drawn directly from the Delta, mostly through the pumps near Byron, is only about 8 percent of the total. The bulk of California's water comes from more local sources, and always has.

Nevertheless, the Delta supply is important to many regions. Southern California imports about 25 percent of its water via the Byron pumps. The Tulare Lake Basin, the southern end of the Great Central Valley, gets 27 percent of its water by that route. Even the San Francisco Bay Area takes 16 percent of its supply from Delta pumps. On a more local scale, several water suppliers rely entirely on the Delta, and others have become dependent on this one overtaxed source to a risky degree.

In addition to water pulled directly from the Delta, a great deal is drawn from the Delta's tributary streams before they come down to sea level. San Francisco Bay Area cities reach far inland to tap the Tuolumne and Mokelumne Rivers in the Sierra Nevada, taking 27 percent of their water needs from these sources. Parts of the Central Valley tributary to the Delta get all of their water from that watershed by definition, as do the people and farms of the Delta itself. (See also sidebar, The Problem with Numbers.)

> ***California water planning is full of good intentions. If the laws and policies that are now on the books were consistently carried out, the state's water system—including that part that is tied to the Delta—would work much better.***

The Delta Plan addresses water supply on three scales: California-wide, on the Delta watershed level, and in the areas that receive water from the Delta pumps. (See Figure ES-1, The Delta Watershed and Areas Receiving Delta Water.)

California water planning is full of good intentions. If the laws and policies that are now on the books were consistently carried out, the state's water system—including that part that is tied to the Delta—would work much better. The Delta Plan calls on *all* water suppliers to obey the many laws and guidelines that exist, and on the State's regulatory agencies to insist on compliance (**Water Resources Recommendation 1**).

THE PROBLEM WITH NUMBERS

In talking of California water, we put trust in numbers: flows, usages, capacities, trends. But some seemingly solid and much-quoted figures are little more than guesses. By and large, we do not truly know how much water we are using or how much we are saving through conservation efforts. We know less than we should about Delta inflows and outflows. We know little about groundwater except that water tables in too many places are dropping. What information is available is often packaged in inscrutable ways. The Delta Plan asks all the agencies and water suppliers involved to provide or demand better information, and to communicate it better (**Water Resources Policy 2, WR Recommendations 16 through 19**).

Whatever the outcome of some current debates, California's next large increment of water supply will not come from major new engineering but from water conservation, recycling, local stormwater capture, and reasonable use of aquifers (see section, A Better System: Storing Floods to Ride Out Droughts). These measures can yield an amount of water larger than the total that is drawn from the Delta today. State agencies in charge of water matters should systematically promote these practices, and *all* State agencies should model them in their own water usage. (**Water Resources Recommendations 6, 8, and 14.**)

Zooming in a bit from the statewide picture, the Delta Plan calls for all water users linked to the Delta—whether they take water from it directly, or tap the watershed—to reduce their draws. The State Water Resources Control Board should give special scrutiny to water use applications that could boost demand on the watershed. Urban and agricultural water suppliers are already required to write water management plans; these now should include "water supply reliability elements," discussing, among other things, how to deal with the cascading effects if Delta pumping were halted for as long as 3 years. (**Water Resources Recommendations 3, 4, 5, and 7.**)

The Delta Watershed and Areas Receiving Delta Water

Figure ES-1

The Plan speaks most directly to those suppliers that serve water within the Delta or pump water out of the region—including the State Water Project, the Central Valley Project, and by extension the many agricultural and urban water purveyors that are the customers of these giants. Any organization that receives water from the projects must do its share to reduce reliance on the Delta, setting specific reduction targets and actually putting measures in place.

The State Water Project is called on to write the corresponding provisions into contracts with its clients when these agreements are renewed or revised (**Water Resources Policies 1 and 2, WR Recommendation 2**).

A Better System: Storing Floods to Ride Out Droughts (and Give the Delta a Break)

The measures so far mentioned will take pressure off the Delta while actually increasing California's developed water supply. The further key to both goals is to harvest and store the water that is available from Central Valley rivers in the wettest years, at the least environmental cost. The need is heightened by the fact of climate change, which stands to make rainy years all the wetter, and droughts all the more severe.

There are few opportunities left in California to build large new dams (or to raise the height of old dams), and the options that exist are dauntingly expensive. The California Department of Water Resources and the Bureau of Reclamation have been studying the possibilities. The Delta Plan urges the agencies to wrap up these studies, so that the State can decide the fate of these proposals once and for all (**Water Resources Recommendations 13 and 14**).

Much more water storage space exists right under our feet: in groundwater basins, or aquifers.

California began its history with a vast supply of water stored naturally in underground gravel fields and free for the taking via wells. In parts of the state, including most of the southern Central Valley, this endowment has been squandered, and groundwater levels have dropped, sometimes by hundreds of feet. One of the rationales for sending water south from the Delta has been to recharge aquifers, but not enough recharging has occurred. And the State's last comprehensive assessment of its groundwater situation was published in 1980—a third of a century ago.

The Delta Plan calls for a rededication to the conservative idea of using aquifers like bank accounts: to be filled up in wet times, in order that they may be drawn from in dry. It calls on the State to do the indispensable groundwater update, on local suppliers to write plans for sustainable groundwater management, and on the State Water Resources Control Board to stand ready to intervene in seriously overdrafted areas, if good local plans are not forthcoming, leading perhaps to the court procedure called groundwater adjudication. (**Water Resources Recommendations 9, 10, 11, and 14**.)

> ***The Delta Plan calls for a rededication to the conservative idea of using aquifers like bank accounts: to be filled up in wet times, in order that they may be drawn from in dry.***

There is another tool for making the supply stretch further: the sale or trade of water between suppliers, especially in times of shortage. Existing rules governing such transfers are found cumbersome by some and insufficiently protective of water rights and the environment by others. The State Water Resources Control Board should reformulate the guidelines by mid-2016 (**Water Resources Recommendations 14 and 15**).

A Better System: Delta Conveyance

As noted, many of the state's water suppliers take their water from rivers at points upstream of the Delta. The two biggest, however—the State Water Project and the Central Valley Project—are different. Though most of the water they transport has its origin to the north, in the Sacramento River, their withdrawal points are deep in the Delta and well to the south, on the channel called Old River. Unlike most other water withdrawals, these affect the region not only by removing water but also by distorting flows.

The pumps at Byron have so much power that they essentially give the Delta a second mouth. In many channels, water runs backward at times, toward the pump intakes, not toward the sea. This situation is bad for salmon, Delta smelt, and other sensitive and legally protected species. Under the Bay Delta Conservation Plan, the Department of Water Resources and the federal Bureau of Reclamation are planning a kind of arterial bypass, segregating the water meant for the pumps at a new northern intake on the Sacramento River. The water corralled at this point would be sent to the pumps via a pair of tunnels. This arrangement is intended to alleviate the backward flows that harm fish; in conjunction with major habitat improvements and other measures, it is supposed to bring endangered species far enough back from the brink to satisfy protective laws. Many Delta residents and environmentalists, though, fear that the new system will simply allow more water to be shipped south, doing, on balance, more harm than good.

The Delta Stewardship Council is not the author of the BDCP. Its role for now is to advise and to urge timely completion (**Water Resources Recommendation 12**). Later on, though, the Council may have a decisive say. Once the proposal is complete, the Department of Fish and Wildlife must declare that it meets the standards of the Delta Reform Act, and this declaration can in turn be appealed to the Council. If the Council does not concur, certain aspects of the BDCP will lose access to State funding. If all hurdles have been cleared, on the other hand, the BDCP will take its place as a component of the Delta Plan.

...and Protecting, Restoring, and Enhancing the Delta Ecosystem...

The effort to improve the fortunes of the Delta ecosystem has two components that are vital: guaranteeing adequate flows from the rivers feeding into and through Delta channels, and creating new wetlands and other habitats in partial replacement for what has been lost. Three other components are merely very important: combating harmful exotic species, improving the management of salmon hatcheries, and protecting and improving water quality.

Toward "Natural Functional Flows"

Humans have not only reduced the total quantity of runoff through the Delta toward the ocean but also have changed its timing, decreasing the historical torrents of spring and increasing the formerly feeble flows of autumn. In a natural system that evolved with wide variation, this shift toward a steady state is itself a source of harm.

Humans have not only reduced the total quantity of runoff through the Delta toward the ocean but also have changed its timing, decreasing the historical torrents of spring and increasing the formerly feeble flows of autumn.

The minimum seaward flows to be maintained in Delta channels are set by the State Water Resources Control Board, according to season and year type (wet, above normal, below normal, dry, or critical). These required flows help fish; they also prevent saltwater intrusion. As a not-incidental side effect, the rules limit the amount of water that can be exported through the pumps.

The Water Board is now preparing to revise this flow regime, last updated in 2006. As a later step, the Water Board is to issue comparable flow standards for the major tributary rivers of the Delta. The Delta Plan recommends deadlines for these processes (mid-2014 and mid-2018). The adopted regulations will become elements of the Plan. The Delta Stewardship Council can be called upon to review any project that could affect Delta flows in the light of adopted flow criteria (**Ecosystem Restoration Policy 1, ER Recommendation 1**).

Habitat Restoration

In its primeval state, the Delta was no uniform sea of reeds but a vast mesh of habitats including tule marsh threaded with rivers and sloughs, perched lakes filled by floods and very high tides, natural levees with big trees on them, and seasonal overflow basins behind the levees. Most of this mosaic has disappeared, converted to fifty large and many small leveed islands. Evidence of what was remains in agricultural soils of uncommon quality (and fragility).

The old scene will never return, but careful habitat restoration projects can help to reverse the region's ecological decline. Biologists have spent years locating the likeliest areas for such revival. The Delta Plan incorporates the latest thinking, essentially the Conservation Strategy drafted in 2011 by the Department of Fish and Wildlife (formerly the Department of Fish and Game).

Since the heart of the Delta is now well below sea level, due to subsidence, the suitable restoration sites are mostly found near Delta margins, where the soil surface is still high enough to permit marsh plants and riparian vegetation to take root. The Plan outlines six such zones: the Yolo Bypass, the floodplain west of Sacramento into which the Sacramento River spills in wet years; the Cache Slough Complex, where the Bypass rejoins the body of the Delta; a nexus in the eastern Delta, where the Mokelumne River and the Cosumnes River add their strands to the Delta's web; a zone in the southern Delta along the San Joaquin River; a collection of small tracts at the western apex of the Delta, where it narrows to meet Suisun Bay; and finally the Suisun Marsh, fringing that bay to the north. This fresh-to-brackish water marsh, the largest wetland in California, is mostly managed by hunting clubs for seasonal waterfowl ponds, but sizeable areas should be restored to full tidal action. The existing plan for Suisun Marsh, written by the San Francisco Bay Conservation and Development Commission, is 36 years old and does not take into account, for example, probable sea level rise.

The Delta Plan calls for the habitat restorations in the Conservation Strategy to be carried out by the Department of Fish and Wildlife and by the Delta Conservancy, a body established for such purposes in 2009; and it calls for a plan update for Suisun Marsh. The Delta Stewardship Council can be appealed to, if necessary, to block development or any other intrusion that might interfere with a restoration site. (**Ecosystem Restoration Policies 2 and 3, ER Recommendations 2, 3, and 5**.)

Much of the remaining good habitat in the Delta is found in strips along the water side of levees, and the Delta Plan looks to protect and widen these green margins. When levees are rebuilt or altered, the possibility of shifting them farther away from the water should always be explored. The growth of trees along the waterline should be encouraged. However, authority over many levees lies with the U.S. Army Corps of Engineers, and the Corps requires removal of trees and shrubs, on the theory that root systems have a weakening effect. (The matter is debated.) Given the value of tall vegetation for habitat, the Delta Plan asks the Corps to exempt Delta levees from this rule, where appropriate. (**Ecosystem Restoration Policy 4 and ER Recommendation 4**.)

Exotic Species

One of the less-visible forces to buffet the Delta ecosystem is the proliferation of nonnative aquatic species—fish, crustaceans, plants, and even the microscopic floating animals of zooplankton. Some were introduced deliberately; others arrived by random routes including the discharge of bilgewater from oceangoing ships and the dumping of goldfish bowls.

New arrivals keep appearing. Some of these intruders affect the system little, but other species, notably certain aquatic plants and filter-feeding clams, transform the web of life profoundly. The Delta Plan prohibits actions that could bring in new exotics or improve conditions for exotics that are here, and endorses the measures the Department of Fish and Wildlife is already planning to take against them. (**Ecosystem Restoration Policy 5, ER Recommendation 7**.)

Among the exotics are game species introduced in the nineteenth century and well-loved by fishermen: striped, largemouth, and smallmouth bass. It has become apparent that these voracious game fish are helping to deplete salmon, Delta smelt, and other species in trouble. The Delta Plan asks the Department of Fish and Wildlife to change angling rules to permit heavier fishing and somewhat suppress the bass population (**Ecosystem Restoration Recommendation 6**).

Management of Hatchery Fish

When dams on many rivers cut off spawning grounds for salmon and steelhead trout, hatcheries were built to compensate. Now there is worry that hatchery-raised salmon, less genetically diverse than their wild cousins, may mix with and reduce the fitness of the wild strains. Various solutions are proposed, including capturing wild fish to add their eggs to hatchery stock. The Delta Plan asks the Department of Fish and Wildlife and the U.S. Fish and Wildlife Service to put these ideas and recommendations into effect (**Ecosystem Restoration Recommendations 8 and 9**).

Water Quality

Pollution from the watershed is bad for the Delta ecosystem and for water users. The Delta Plan urges the responsible agencies—the State Water Resources Control Board, the Central Valley Regional Water Quality Control Board, and the San Francisco Bay Regional Water Quality Control Board—to protect "beneficial uses" of water in the Delta and Suisun Bay. Various ongoing projects of planning, rulemaking, and construction should be brought to conclusion. All agencies should look at water quality when weighing actions covered under the Delta Plan. Special attention should be paid to pollution that might degrade habitat restoration sites. (**Water Quality Recommendations 1 through 12**.)

...In a Way that Protects and Enhances the Values of the Delta as an Evolving Place

Because of its role in greater systems—the San Francisco Estuary, the state water plumbing—the Delta is a subject of statewide debate. The conversation can seem to take place over the heads of the people who actually live in the region; and it can seem to overlook the lasting values of the place that is: its thriving agriculture, the beauty of its countryside, its cultural heritage, and its recreational bounty. The Delta Plan strives to redress this balance without promising what is probably impossible: the retention of the landscape exactly as it is today.

Honorific labels do not protect valuable assets, but they can help us recognize them. The Delta Plan asks that the Delta be declared a National Heritage Area by Congress and that Highway 160, its north-south artery, be designated a National Scenic Byway by the U.S. Department of Transportation (**Delta-as-Place Recommendations 1 and 2**).

Many Delta people fear that their concerns will be brushed aside as new water facilities and habitat restorations get under way. While deference cannot be guaranteed, the Delta Plan calls on the agencies to respect local plans in siting such projects, to minimize conflict when possible, and to buy land from willing sellers when they can (**Delta-as-Place Policy 2, DP Recommendation 4**).

The distinctive Delta landscape has been much altered by urban encroachment, often entailing higher flood risk. The Delta Protection Commission, created in 1992 and strengthened by the Delta Reform Act of 2009, oversees development in the core area called the Primary Zone: Local decisions affecting this zone can be appealed to the Commission and overturned by it. However, this authority does not extend to the peripheral Secondary Zone, where the development pressure is strongest. The Delta Plan tightens control further, steering new development to the 26,000 acres in the Peripheral Zone that are already earmarked for urbanization in local plans. Small housing developments that may occur outside these limits must meet high flood control standards (**Delta-as-Place Policy 1, Risk Reduction Policy 2**). (See Figure ES-2, Delta Communities.)

A little more bustle might actually benefit 11 historic small towns or settlements within the Delta, known as the legacy communities. Most are spaced along the Sacramento River: Freeport, Clarksburg, Hood, Courtland, Locke, Walnut Grove, Ryde, Isleton, and Rio Vista. Knightsen and Bethel Island are near the lower channel of the San Joaquin River. Planners at all levels should respect the character, and promote the vitality, of these places (**Delta-as-Place Recommendation 3**).

The Delta Protection Commission has written an Economic Sustainability Plan containing numerous ideas for the support of the region's farm economy, parks and recreation, and roads and infrastructure. The Delta Plan adapts many of these as **Delta-as-Place Recommendations 5 through 19**.

Flood Risk Reduction

In its primeval state, most of the Delta was wetland and slightly above sea level. Since levees created the modern islands and cultivation began, soils have subsided deeply. Many Delta tracts are strikingly below the level of the water in adjacent channels; rising sea level will make the differential worse. While the occasional levee break is part of Delta lore, multiple failures could bring disaster to the Delta landscape, economy, and ecosystem.

The Delta Plan urges all agencies in the Delta to plan for emergencies and to join forces in a regional response consortium, as proposed by the Delta Multi-Hazard Coordination Task Force. Every responsible party, public and private, should allocate money for flood prevention and reaction. Utilities should plan to minimize interruptions of service. The Department of Water Resources should expand its stockpiles of stone and earth for the use of all when breaches require rapid plugging. Higher levels of private flood insurance should be required, and the State should gain immunity from lawsuits related to flooding beyond its power to prevent. (**Risk Reduction Recommendations 1, 9, and 10**.)

> ***It is estimated that only about half the Delta's acreage is adequately protected. There is not enough money for all the desirable improvements, nor is there a mechanism for sharing costs among all who benefit.***

Delta Communities

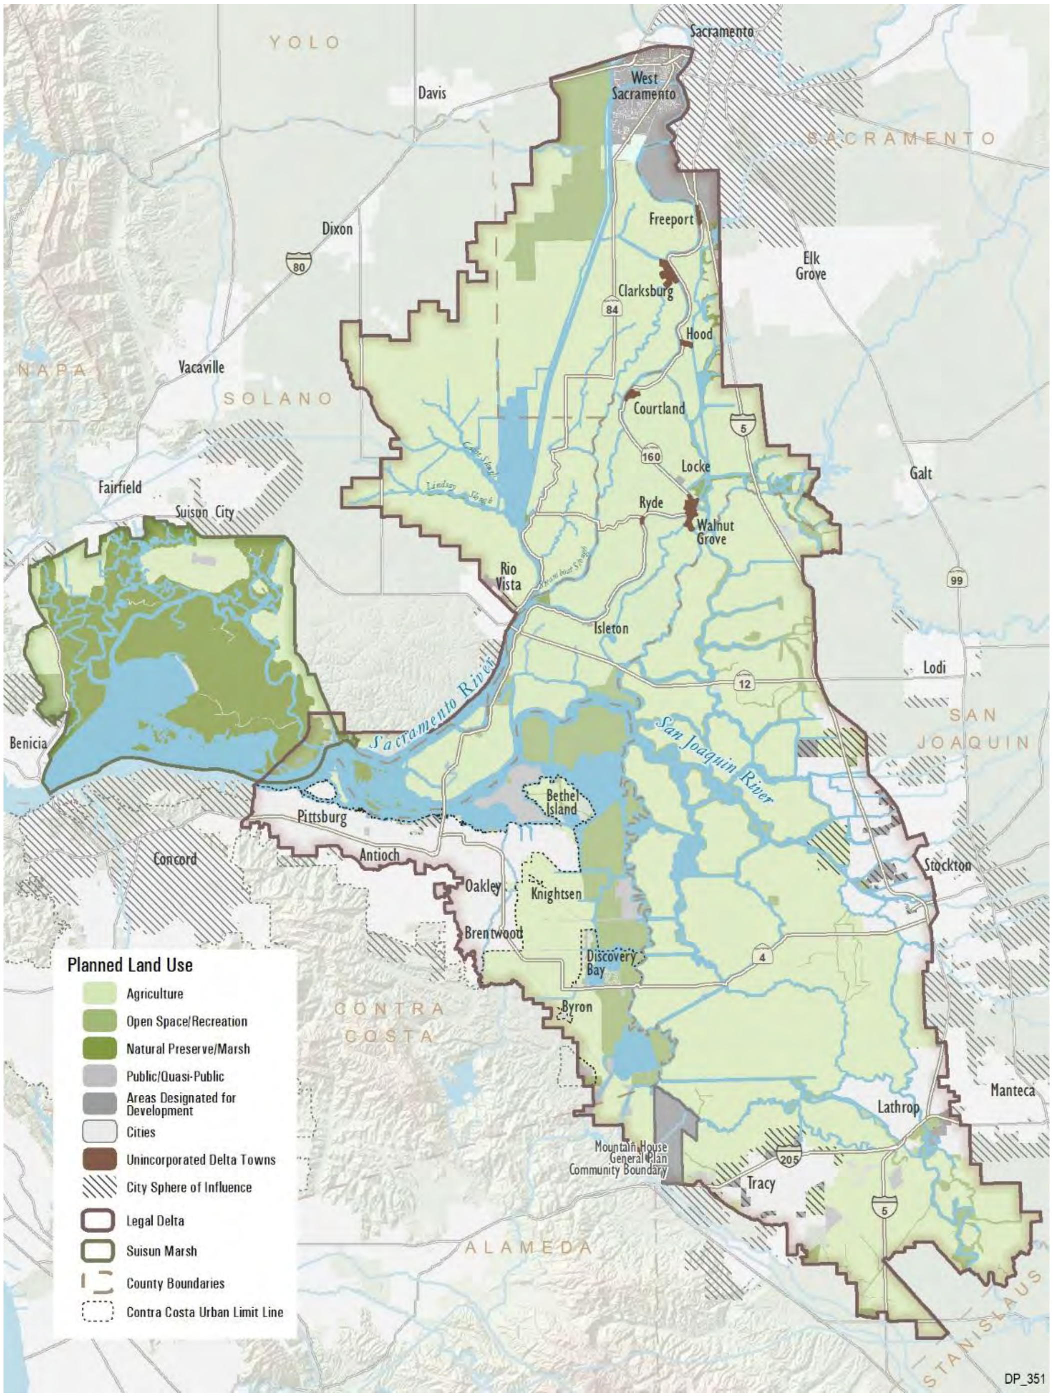

Figure ES-2 *Sources: City of Benicia 2003, Contra Costa County 2008, Contra Costa County 2010, City of Fairfield 2008, City of Lathrop 2012, City of Manteca 2012, Mountain House Community Services District 2008, City of Rio Vista 2001, SACOG 2009, City of Sacramento 2008, Sacramento County 2011, Sacramento County 2012, Sacramento County 2013, San Joaquin County 2008a, San Joaquin County 2008b, Solano County 2008a, Solano County 2008b, City of Stockton 2011a, City of Stockton 2011b, City of Suisun City 2011, City of Tracy 2011a, City of Tracy 2011b, City of West Sacramento 2010, Yolo County 2010a, Yolo County 2010b.*

There are more than 1,000 miles of Delta levees. The State is directly responsible for about one-third of the system; nearly 70 local Reclamation Districts are in charge of the rest. It is estimated that only about half the Delta's acreage is adequately protected. There is not enough money for all the desirable improvements, nor is there a mechanism for sharing costs among all who benefit. The Delta Plan calls on the Legislature to establish a locally based Delta Flood Risk Management Assessment District to raise money for combined defenses. Public and private utilities, too, should invest in defense of their facilities and lines. (**Risk Reduction Recommendations 2 and 3**.)

The State contributes massively to levee costs throughout the Delta, but on a not very systematic basis. The Legislature directed the Delta Stewardship Council to set priorities for these investments. **Risk Reduction Policy 1** offers broad principles. Urban areas come first; special attention must be paid to levees guarding roads and energy facilities. The channels through which water flows toward export pumps require protection, as does the pipeline that brings Sierra water across the Delta for the East Bay Municipal Utility District. Levees on the western islands, whose failure could bring salinity deep into the Delta, are also of high concern.

A more detailed study is to follow. Building on work being done by the Department of Water Resources, the Council will assess, island by island, the state of levees, the degree of subsidence, the extent and value of assets to be protected, and the cost of long-term defense. The result, due at the end of 2014, will be a tiered priority list for the expenditure of State levee funds (**Risk Reduction Recommendation 4**).

To take pressure off the levee system, floodwaters need room to move and to spread without causing harm (and often to the benefit of plants, birds, and fish). Two such safety valves already exist at the Yolo Bypass and the Cosumnes-Mokelumne floodplain; a third such zone is proposed for the lower San Joaquin River at Paradise Cut. The Delta Plan urges expansion of the flood relief system, and requires that present or potential overflow areas be kept free of encroachments. Levee setbacks are also encouraged. (**Risk Reduction Policies 3 and 4, RR Recommendations 5 through 8**.)

Given time, land subsidence can actually be reversed. Experimental plots show that soils can be deepened by growing tules in shallowly flooded fields, at a rate of a little over an inch a year. The tule plots also fix a lot of atmospheric carbon and thus do their bit toward slowing climate change. The Delta Plan encourages expansion of this work (**Delta-as-Place Recommendation 7**).

Finding the Way Through

When the first Spanish explorers took their boats into the Sacramento-San Joaquin River Delta, they were feeling their way. They could see the channel they were in, as far as the next bend or junction of sloughs. They had a general idea of where they were going. Between the near and the far, though, were mysteries. Which waterways connected to others, which petered out in the marshes? Where was the real way through?

Tangible marks of progress may at first be as subtle as shifting shoreline features seen from a Delta boat.

This first edition of the Delta Plan is a little like such an exploration. A short reach of channel is visible; another stretch can be assessed from local information. After that, the route is a matter of educated guesswork.

The Delta Plan can be fairly specific about steps to be taken in the next 5 years. The Delta Science Plan is already under way. The in-depth study of levees will begin by fall 2013. The Interagency Implementation Committee will meet by the end of the year. Just around the next bend, the State Water Resources Control Board will adopt its momentous new flow rules; a final decision on Delta conveyance (the Bay Delta Conservation Plan) looms beyond that.

It will not have escaped the reader how many of these measures seem rather abstract, involving studies, rule-making, the gathering of information, the refining of procedures, the testing of powers—not so much doing as planning, and even planning how to plan. This is simply the phase we are in. Tangible marks of progress may at first be as subtle as shifting shoreline features seen from a Delta boat. Here, though, are some markers to look for. We will be doing well if, in a few years' time:

- Many urban and rural water suppliers that draw on the Delta have taken real steps to reduce that reliance, with measured, reported results.
- Flows in Delta channels, controlled under new State Water Resources Control Board rules, are looking a good deal more like the historical ones.
- Several new habitat restoration projects in the Delta have moved from the planning to the construction stage.
- Subsidence reversal planting has expanded from the small pilot projects seen today.
- Measurably less acreage of Delta waters is dominated by nonnative water plants.
- Stocks of endangered fish are showing a rebound.
- Key levees have been strengthened, especially in the environs of Stockton and Sacramento.
- No further rural farmland has been lost to urbanization.

The next edition of the Delta Plan, due in 2018 or sooner, will be a little longer on specifics and a little shorter on question marks. A few more miles of the channel ahead will have come into view. New uncertainties, no doubt, will have replaced old. The captains will continue to disagree. But, just as it was in the old days, the route through the Delta will be the one way forward.

Beyond all local debates and confusions, the destination is clear. We want a Delta landscape that remains essentially itself while adapting gradually and gracefully to a future marked by climate change and sea level rise. We want a Delta ecosystem that works markedly better than today's, reflected partly in a resurgence of native fish. And we want an end to the endless wrangling about Delta flows and plumbing—a truce that can only be achieved if the entire California water system undergoes a measure of reform.

> ***In solving the "Delta problem," we will not only be doing right by a treasured land- and waterscape. We will be putting the entire state of California on a sounder development path.***

Driven by cost, environmental concern, and sheer practicality, the water world is already shifting away from reliance on distant dams and aqueducts and toward trust in conservation, local sources, and better use of groundwater storage. This change is reflected in the fact, startling to many, that California's total water consumption has not climbed in recent years; in fact, despite our increasing population, use has slightly dropped. The Delta Plan gives a push to trends already under way.

In solving the "Delta problem," we will not only be doing right by a treasured land- and waterscape. We will be putting the entire state of California on a sounder development path.

Delta Plan Policies and Recommendations

The Delta Plan contains a set of regulatory policies that will be enforced by the Delta Stewardship Council's appellate authority and oversight. The Delta Plan also contains priority recommendations, which are nonregulatory but call out actions essential to achieving the coequal goals.

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE
Chapter 2		
G P1 (23 CCR section 5002)	Detailed Findings to Establish Consistency with the Delta Plan	*(a) This policy specifies what must be addressed in a certification of consistency filed by a State or local public agency with regard to a covered action. This policy only applies after a "proposed action" has been determined by a State or local public agency to be a covered action because it is covered by one or more of the regulatory policies contained in Article 3. Inconsistency with this policy may be the basis for an appeal.* *(b) Certifications of consistency must include detailed findings that address each of the following requirements:* *(1) Covered actions, in order to be consistent with the Delta Plan, must be consistent with this regulatory policy and with each of the regulatory policies contained in Article 3 implicated by the covered action. The Delta Stewardship Council acknowledges that in some cases, based upon the nature of the covered action, full consistency with all relevant regulatory policies may not be feasible. In those cases, the agency that files the certification of consistency may nevertheless determine that the covered action is consistent with the Delta Plan because, on whole, that action is consistent with the coequal goals. That determination must include a clear identification of areas where consistency with relevant regulatory policies is not feasible, an explanation of the reasons why it is not feasible, and an explanation of how the covered action nevertheless, on whole, is consistent with the coequal goals. That determination is subject to review by the Delta Stewardship Council on appeal;* *(2) Covered actions not exempt from CEQA must include applicable feasible mitigation measures identified in the Delta Plan's Program EIR (unless the measure(s) are within the exclusive jurisdiction of an agency other than the agency that files the certification of consistency), or substitute mitigation measures that the agency that files the certification of consistency finds are equally or more effective;* *(3) As relevant to the purpose and nature of the project, all covered actions must document use of best available science;* *(4) Ecosystem restoration and water management covered actions must include adequate provisions, appropriate to the scope of the covered action, to assure continued implementation of adaptive management. This requirement shall be satisfied through both of the following:* *(A) An adaptive management plan that describes the approach to be taken consistent with the adaptive management framework in Appendix 1B, and* *(B) Documentation of access to adequate resources and delineated authority by the entity responsible for the implementation of the proposed adaptive management process.*

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE
		(c) A conservation measure proposed to be implemented pursuant to a natural community conservation plan or a habitat conservation plan that was: *(1) Developed by a local government in the Delta; and* *(2) Approved and permitted by the California Department of Fish and Wildlife prior to May 16, 2013* *is deemed to be consistent with sections 5005 through 5009 of this Chapter if the certification of consistency filed with regard to the conservation measure includes a statement confirming the nature of the conservation measure from the California Department of Fish and Wildlife.*
G R1	Development of a Delta Science Plan	*The Delta Stewardship Council's Delta Science Program should develop a Delta Science Plan by December 31, 2013. The Delta Science Program should work with the Interagency Ecological Program, Bay Delta Conservation Plan, California Department of Fish and Wildlife, and other agencies to develop the Delta Science Plan. To ensure that best science is used to develop the Delta Science Plan, the Delta Independent Science Board should review the draft Delta Science Plan.* *The Delta Science Plan should address the following:* ▪ *A collaborative institutional and organizational structure for conducting science in the Delta* ▪ *Data management, synthesis, scientific exchange, and communication strategies to support adaptive management and improve the accessibility of information* ▪ *Strategies for addressing uncertainty and conflicting scientific information* ▪ *The prioritization of research and balancing of the short-term immediate science needs with science that enhances comprehensive understanding of the Delta system over the long term* ▪ *Identification of existing and future needs for refining and developing numerical and simulation models along with enhancing existing Delta conceptual models (e.g., the Interagency Ecological Program (IEP) Pelagic Organism Decline (POD) and the Delta Regional Ecosystem Restoration Implementation Plan (DRERIP) models)* ▪ *An integrated approach for monitoring that incorporates existing and future monitoring efforts* ▪ *An assessment of financial needs and funding sources to support science*
Chapter 3		
WR P1 (23 CCR section 5003)	Reduce Reliance on the Delta through Improved Regional Water Self-Reliance	*(a) Water shall not be exported from, transferred through, or used in the Delta if all of the following apply:* *(1) One or more water suppliers that would receive water as a result of the export, transfer, or use have failed to adequately contribute to reduced reliance on the Delta and improved regional self-reliance consistent with all of the requirements listed in paragraph (1) of subsection (c);* *(2) That failure has significantly caused the need for the export, transfer, or use; and* *(3) The export, transfer, or use would have a significant adverse environmental impact in the Delta.*

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE
		(b) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers a proposed action to export water from, transfer water through, or use water in the Delta, but does not cover any such action unless one or more water suppliers would receive water as a result of the proposed action. *(c) (1) Water suppliers that have done all of the following are contributing to reduced reliance on the Delta and improved regional self-reliance and are therefore consistent with this policy:* *(A) Completed a current Urban or Agricultural Water Management Plan (Plan) which has been reviewed by the California Department of Water Resources for compliance with the applicable requirements of Water Code Division 6, Parts 2.55, 2.6, and 2.8;* *(B) Identified, evaluated, and commenced implementation, consistent with the implementation schedule set forth in the Plan, of all programs and projects included in the Plan that are locally cost effective and technically feasible which reduce reliance on the Delta; and* *(C) Included in the Plan, commencing in 2015, the expected outcome for measurable reduction in Delta reliance and improvement in regional self-reliance. The expected outcome for measurable reduction in Delta reliance and improvement in regional self-reliance shall be reported in the Plan as the reduction in the amount of water used, or in the percentage of water used, from the Delta watershed. For the purposes of reporting, water efficiency is considered a new source of water supply, consistent with Water Code section 1011(a).* *(2) Programs and projects that reduce reliance could include, but are not limited to, improvements in water use efficiency, water recycling, stormwater capture and use, advanced water technologies, conjunctive use projects, local and regional water supply and storage projects, and improved regional coordination of local and regional water supply efforts.*
WR R1	Implement Water Efficiency and Water Management Planning Laws	*All water suppliers should fully implement applicable water efficiency and water management laws, including urban water management plans (Water Code section 10610 et seq.); the 20 percent reduction in statewide urban per capita water usage by 2020 (Water Code section 10608 et seq.); agricultural water management plans (Water Code section 10608 et seq. and 10800 et seq.); and other applicable water laws, regulations, or rules.*
WR R2	Require SWP Contractors to Implement Water Efficiency and Water Management Laws	*The California Department of Water Resources should include a provision in all State Water Project contracts, contract amendments, contract renewals, and water transfer agreements that requires the implementation of all State water efficiency and water management laws, goals, and regulations, including compliance with Water Code section 85021.*
WR R3	Compliance with Reasonable and Beneficial Use	*The State Water Resources Control Board should evaluate all applications and petitions for a new water right or a new or changed point of diversion, place of use, or purpose of use that would result in new or increased long-term average use of water from the Delta watershed for consistency with the constitutional principle of reasonable and beneficial use. The State Water Resources Control Board should conduct its evaluation consistent with Water Code sections 85021, 85023, 85031, and other provisions of California law. An applicant or*

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE
		petitioner should submit to the State Water Resources Control Board sufficient information to support findings of consistency, including, as applicable, its urban water management plan, agricultural water management plan, and environmental documents prepared pursuant to the California Environmental Quality Act.
WR R4	Expanded Water Supply Reliability Element	*Water suppliers that receive water from the Delta watershed should include an expanded water supply reliability element, starting in 2015, as part of the update of an urban water management plan, agricultural water management plan, integrated water management plan, or other plan that provides equivalent information about the supplier's planned investments in water conservation and water supply development. The expanded water supply reliability element should detail how water suppliers are reducing reliance on the Delta and improving regional self-reliance consistent with Water Code section 85201 through investments in local and regional programs and projects, and should document the expected outcome for a measurable reduction in reliance on the Delta and improvement in regional self-reliance. At a minimum, these plans should include a plan for possible interruption of water supplies for up to 36 months due to catastrophic events impacting the Delta, evaluation of the regional water balance, a climate change vulnerability assessment, and an evaluation of the extent to which the supplier's rate structure promotes and sustains efficient water use.*
WR R5	Develop Water Supply Reliability Element Guidelines	*The California Department of Water Resources, in consultation with the Delta Stewardship Council, the State Water Resources Control Board, and others, should develop and approve, by December 31, 2014, guidelines for the preparation of a water supply reliability element so that water suppliers can begin implementation of WR R4 by 2015.*
WR R6	Update Water Efficiency Goals	*The California Department of Water Resources and the State Water Resources Control Board should establish an advisory group with other State agencies and stakeholders to identify and implement measures to reduce impediments to achievement of statewide water conservation, recycled water, and stormwater goals by 2014. This group should evaluate and recommend updated goals for additional water efficiency and water resource development by 2018. Issues such as water distribution system leakage should be addressed. Evaluation should include an assessment of how regions are achieving their proportional share of these goals.*
WR R7	Revise State Grant and Loan Priorities	*The California Department of Water Resources, the State Water Resources Control Board, the California Department of Public Health, and other agencies, in consultation with the Delta Stewardship Council, should revise State grant and loan ranking criteria by December 31, 2013, to be consistent with Water Code section 85021 and to provide a priority for water suppliers that includes an expanded water supply reliability element in their adopted urban water management plans, agricultural water management plans, and/or integrated regional water management plans.*
WR R8	Demonstrate State Leadership	*All State agencies should take a leadership role in designing new and retrofitted State-owned and -leased facilities, including buildings and California Department of Transportation facilities, to increase water efficiency, use recycled water, and incorporate stormwater runoff capture and low-impact development strategies.*

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE
WR R9	Update Bulletin 118, California's Groundwater Plan	*The California Department of Water Resources, in consultation with the Bureau of Reclamation, U.S. Geological Survey, the State Water Resources Control Board, and other agencies and stakeholders should update Bulletin 118 information using field data, California Statewide Groundwater Elevation Monitoring (CASGEM), groundwater agency reports, satellite imagery, and other best available science by December 31, 2014, so that this information can be included in the next California Water Plan Update and be available for inclusion in 2015 urban water management plans and agricultural water management plans. The Bulletin 118 update should include a systematic evaluation of major groundwater basins to determine sustainable yield and overdraft status; a projection of California's groundwater resources in 20 years if current groundwater management trends remain unchanged; anticipated impacts of climate change on surface water and groundwater resources; and recommendations for State, federal, and local actions to improve groundwater management. In addition, the Bulletin 118 update should identify groundwater basins that are in a critical condition of overdraft.*
WR R10	Implement Groundwater Management Plans in Areas that Receive Water from the Delta Watershed	*Water suppliers that receive water from the Delta watershed and that obtain a significant percentage of their long-term average water supplies from groundwater sources should develop and implement sustainable groundwater management plans that are consistent with both the required and recommended components of local groundwater management plans identified by the California Department of Water Resources Bulletin 118 (Update 2003) by December 31, 2014.*
WR R11	Recover and Manage Critically Overdrafted Groundwater Basins	*Local and regional agencies in groundwater basins that have been identified by the California Department of Water Resources as being in a critical condition of overdraft should develop and implement a sustainable groundwater management plan, consistent with both the required and recommended components of local groundwater management plans identified by the California Department of Water Resources Bulletin 118 (Update 2003), by December 31, 2014. If local or regional agencies fail to develop and implement these plans, the State Water Resources Control Board should take action to determine if the continued overuse of a groundwater basin constitutes a violation of the State's Constitution Article X, Section 2, prohibition on unreasonable use of water and whether a groundwater adjudication is necessary to prevent the destruction of or irreparable injury to the quality of the groundwater, consistent with Water Code sections 2100 and 2101.*
WR R12	Complete Bay Delta Conservation Plan	*The relevant federal, State, and local agencies should complete the Bay Delta Conservation Plan, consistent with the provisions of the Delta Reform Act, and receive required incidental take permits by December 31, 2014.*
WR R13	Complete Surface Water Storage Studies	*The California Department of Water Resources should complete surface water storage investigations of proposed off-stream surface storage projects by December 31, 2012, including an evaluation of potential additional benefits of integrating operations of new storage with proposed Delta conveyance improvements, and recommend the critical projects that need to be implemented to expand the state's surface storage.*
WR R14	Identify Near-term Opportunities for Storage, Use, and Water Transfer Projects	*The California Department of Water Resources, in coordination with the California Water Commission, Bureau of Reclamation, State Water Resources Control Board, California Department of Public Health, the Delta Stewardship Council, and other agencies and stakeholders, should conduct a survey to identify projects throughout California that could be implemented within the next 5 to 10 years to expand existing surface and groundwater storage facilities, create new storage, improve operation of existing Delta conveyance*

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE
		facilities, and enhance opportunities for conjunctive use programs and water transfers in furtherance of the coequal goals. The California Water Commission should hold hearings and provide recommendations to the California Department of Water Resources on priority projects and funding.
WR R15	Improve Water Transfer Procedures	*The California Department of Water Resources and the State Water Resources Control Board should work with stakeholders to identify and recommend measures to reduce procedural and administrative impediments to water transfers and protect water rights and environmental resources by December 31, 2016. These recommendations should include measures to address potential issues with recurring transfers of up to 1 year in duration and improved public notification for proposed water transfers.*
WR P2 (23 CCR section 5004)	Transparency in Water Contracting	*(a) The contracting process for water from the State Water Project and/or the Central Valley Project must be done in a publicly transparent manner consistent with applicable policies of the California Department of Water Resources and the Bureau of Reclamation referenced below.* *(b) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers the following:* *(1) With regard to water from the State Water Project, a proposed action to enter into or amend a water supply or water transfer contract subject to California Department of Water Resources Guidelines 03-09 and/or 03-10 (each dated July 3, 2003), which are attached as Appendix 2A; and* *(2) With regard to water from the Central Valley Project, a proposed action to enter into or amend a water supply or water transfer contract subject to section 226 of P.L. 97-293, as amended or section 3405(a)(2)(B) of the Central Valley Project Improvement Act, Title XXXIV of Public Law 102-575, as amended, which are attached as Appendix 2B, and Rules and Regulations promulgated by the Secretary of the Interior to implement these laws.*
WR R16	Supplemental Water Use Reporting	*The State Water Resources Control Board should require water rights holders submitting supplemental statements of water diversion and use or progress reports under their permits or licenses to report on the development and implementation of all water efficiency and water supply projects and on their net (consumptive) use.*
WR R17	Integrated Statewide System for Water Use Reporting	*The California Department of Water Resources, in coordination with the State Water Resources Control Board, California Department of Public Health, California Public Utilities Commission, California Energy Commission, Bureau of Reclamation, California Urban Water Conservation Council, and other stakeholders, should develop a coordinated statewide system for water use reporting. This system should incorporate recommendations for inclusion of data needed to better manage California's water resources. The system should be designed to simplify reporting; reduce the number of required reports where possible; be made available to the public online; and be integrated with the reporting requirements for the urban water management plans, agricultural water management plans, and integrated regional water management plans. Water suppliers that export water from, transfer water through, or use water in the Delta watershed should be full participants in the data base.*

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE
WR R18	California Water Plan	*The California Department of Water Resources, in consultation with the State Water Resources Control Board, and other agencies and stakeholders, should evaluate and include in the next and all future California Water Plan updates information needed to track water supply reliability performance measures identified in the Delta Plan, including an assessment of water efficiency and new water supply development, regional water balances, improvements in regional self-reliance, reduced regional reliance on the Delta, and reliability of Delta exports, and an overall assessment of progress in achieving the coequal goals.*
WR R19	Financial Needs Assessment	*As part of the California Water Plan Update, the California Department of Water Resources should prepare an assessment of the state's water infrastructure. This should include the costs of rehabilitating/replacing existing infrastructure, an assessment of the costs of new infrastructure, and an assessment of needed resources for monitoring and adaptive management for these projects. The California Department of Water Resources should also consider a survey of agencies that may be planning small-scale projects (such as storage or conveyance) that improve water supply reliability.*
Chapter 4		
ER P1 (23 CCR section 5005)	Delta Flow Objectives	*(a) The State Water Resources Control Board's Bay Delta Water Quality Control Plan flow objectives shall be used to determine consistency with the Delta Plan. If and when the flow objectives are revised by the State Water Resources Control Board, the revised flow objectives shall be used to determine consistency with the Delta Plan.* *(b) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, the policy set forth in subsection (a) covers a proposed action that could significantly affect flow in the Delta.*
ER R1	Update Delta Flow Objectives	*Development, implementation, and enforcement of new and updated flow objectives for the Delta and high-priority tributaries are key to the achievement of the coequal goals. The State Water Resources Control Board should update the Bay Delta Water Quality Control Plan objectives as follows:* *(a) By June 2, 2014, adopt and implement updated flow objectives for the Delta that are necessary to achieve the coequal goals.* *(b) By June 2, 2018, adopt, and as soon as reasonably possible, implement flow objectives for high-priority tributaries in the Delta watershed that are necessary to achieve the coequal goals.*[1] *Flow objectives could be implemented through several mechanisms including negotiation and settlement, Federal Energy Regulatory Commission relicensing, or adjudicative proceeding.*[2] *Prior to the establishment of revised flow objectives identified above, the existing Bay Delta Water Quality Control Plan objectives shall be used to determine consistency with the Delta Plan. After the flow objectives are revised, the revised objectives shall be used to determine consistency with the Delta Plan.*

---

[1] SWRCB staff should work with the Council and DFW to determine priority streams. As an illustrative example, priority streams could include the Merced River, Tuolumne River, Stanislaus River, Lower San Joaquin River, Deer Creek (tributary to Sacramento River), Lower Butte Creek, Mill Creek (tributary to Sacramento River), Cosumnes River, and American River. Implementation through hearings is expected to take longer than the deadline shown here.

[2] Implementation through adjudicative proceedings or FERC relicensing is expected to take longer than the deadline shown here.

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE
ER P2 (23 CCR section 5006)	Restore Habitats at Appropriate Elevations	*(a) Habitat restoration must be carried out consistent with Appendix 3, which is Section II of the Draft Conservation Strategy for Restoration of the Sacramento-San Joaquin Delta Ecological Management Zone and the Sacramento and San Joaquin Valley Regions (California Department of Fish and Wildlife 2011). The elevation map attached as Appendix 4 should be used as a guide for determining appropriate habitat restoration actions based on an area's elevation. If a proposed habitat restoration action is not consistent with Appendix 4, the proposal shall provide rationale for the deviation based on best available science.* *(b) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers a proposed action that includes habitat restoration.*
ER P3 (23 CCR section 5007)	Protect Opportunities to Restore Habitat	*(a) Within the priority habitat restoration areas depicted in Appendix 5, significant adverse impacts to the opportunity to restore habitat as described in section 5006, must be avoided or mitigated.* *(b) Impacts referenced in subsection (a) will be deemed to be avoided or mitigated if the project is designed and implemented so that it will not preclude or otherwise interfere with the ability to restore habitat as described in section 5006.* *(c) Impacts referenced in subsection (a) shall be mitigated to a point where the impacts have no significant effect on the opportunity to restore habitat as described in section 5006. Mitigation shall be determined, in consultation with the California Department of Fish and Wildlife, considering the size of the area impacted by the covered action and the type and value of habitat that could be restored on that area, taking into account existing and proposed restoration plans, landscape attributes, the elevation map shown in Appendix 4, and other relevant information about habitat restoration opportunities of the area.* *(d) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers proposed actions in the priority habitat restoration areas depicted in Appendix 5. It does not cover proposed actions outside those areas.*
ER P4 (23 CCR section 5008)	Expand Floodplains and Riparian Habitats in Levee Projects	*(a) Levee projects must evaluate and where feasible incorporate alternatives, including the use of setback levees, to increase floodplains and riparian habitats. Evaluation of setback levees in the Delta shall be required only in the following areas (shown in Appendix 8): (1) The Sacramento River between Freeport and Walnut Grove, the San Joaquin River from the Delta boundary to Mossdale, Paradise Cut, Steamboat Slough, Sutter Slough; and the North and South Forks of the Mokelumne River, and (2) Urban levee improvement projects in the cities of West Sacramento and Sacramento.* *(b) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers a proposed action to construct new levees or substantially rehabilitate or reconstruct existing levees.*
ER R2	Prioritize and Implement Projects that Restore Delta Habitat	*Bay Delta Conservation Plan implementers, California Department of Fish and Wildlife, California Department of Water Resources, and the Delta Conservancy should prioritize and implement habitat restoration projects in the areas shown on Figure 4-8. Habitat restoration projects should ensure connections between areas being restored and existing habitat areas and other elements of the landscape needed for the full life cycle of the species that will benefit from the restoration project.*

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE
		Where possible, restoration projects should also emphasize the potential for improving water quality. Restoration project proponents should consult the California Department of Public Health's Best Management Practices for Mosquito Control in California*.* ▪ ***Yolo Bypass.*** *Enhance the ability of the Yolo Bypass to flood more frequently to provide more opportunities for migrating fish, especially Chinook salmon, to use this system as a migration corridor that is rich in cover and food.* ▪ ***Cache Slough Complex.*** *Create broad nontidal, freshwater, emergent-plant-dominated wetlands that grade into tidal freshwater wetlands, and shallow subtidal and deep open-water habitats. Also, return a significant portion of the region to uplands with vernal pools and grasslands.* ▪ ***Cosumnes River–Mokelumne River confluence.*** *Allow these unregulated and minimally regulated rivers to flood over their banks during winter and spring frequently and regularly to create seasonal floodplains and riparian habitats that grade into tidal marsh and shallow subtidal habitats.* ▪ ***Lower San Joaquin River floodplain.*** *Reconnect the floodplain and restore more natural flows to stimulate food webs that support native species. Integrate habitat restoration with flood management actions, when feasible.* ▪ ***Suisun Marsh.*** *Restore significant portions of Suisun Marsh to brackish marsh with land-water interactions to support productive, complex food webs to which native species are adapted and to provide space to adapt to rising sea level action. Use information from adaptive management processes during the Suisun Marsh Habitat Management, Preservation, and Restoration Plan's implementation to guide future habitat restoration projects and to inform future tidal marsh management.* ▪ ***Western Delta/Eastern Contra Costa County.*** *Restore tidal marsh and channel margin habitat at Dutch Slough and western islands to support food webs and provide habitat for native species.*
ER R3	Complete and Implement Delta Conservancy Strategic Plan	*As part of its Strategic Plan and subsequent Implementation Plan or annual work plans, the Delta Conservancy should:* ▪ *Develop and adopt criteria for prioritization and integration of large-scale ecosystem restoration in the Delta and Suisun Marsh, with sustainability and use of best available science as foundational principles.* ▪ *Develop and adopt processes for ownership and long-term operations and management of land in the Delta and Suisun Marsh acquired for conservation or restoration.* ▪ *Develop and adopt a formal mutual agreement with the California Department of Water Resources, California Department of Fish and Wildlife, federal interests, and other State and local agencies on implementation of ecosystem restoration in the Delta and Suisun Marsh.* ▪ *Develop, in conjunction with the Wildlife Conservation Board, the California Department of Water Resources, California Department of Fish and Wildlife, Bay Delta Conservation Plan implementers, and other State and local agencies, a plan and protocol for acquiring the land necessary to achieve ecosystem restoration consistent with the coequal goals and the Ecosystem Restoration Program Conservation Strategy.*

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE
		- *Lead an effort, working with State and federal fish agencies, to investigate how to better use habitat credit agreements to provide credit for each of these steps: (1) acquisition for future restoration; (2) preservation, management, and enhancement of existing habitat; (3) restoration of habitat; and (4) monitoring and evaluation of habitat restoration projects.* - *Work with the California Department of Fish and Wildlife and the U.S. Fish and Wildlife Service to develop rules for voluntary safe harbor agreements with property owners in the Delta whose actions contribute to the recovery of listed threatened or endangered species.*
ER R4	Exempt Delta Levees from the U.S. Army Corps of Engineers' Vegetation Policy	*Considering the ecosystem value of remaining riparian and shaded riverine aquatic habitat along Delta levees, the U.S. Army Corps of Engineers should agree with the California Department of Fish and Wildlife and the California Department of Water Resources on a variance that exempts Delta levees from the U.S. Army Corps of Engineers' levee vegetation policy where appropriate.*
ER R5	Update the Suisun Marsh Protection Plan	*The San Francisco Bay Conservation and Development Commission should update the Suisun Marsh Protection Plan and relevant components of the Suisun Marsh Local Protection Program to adapt to sea level rise and ensure consistency with the Suisun Marsh Preservation Act, the Delta Reform Act, and the Delta Plan.*
ER P5 (23 CCR section 5009)	Avoid Introductions of and Habitat Improvements for Invasive Nonnative Species	*(a) The potential for new introductions of or improved habitat conditions for nonnative invasive species, striped bass, or bass must be fully considered and avoided or mitigated in a way that appropriately protects the ecosystem.* *(b) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers a proposed action that has the reasonable probability of introducing or improving habitat conditions for nonnative invasive species.*
ER R6	Regulate Angling for Nonnative Sport Fish to Protect Native Fish	*The California Department of Fish and Wildlife should develop, for consideration by the Fish and Game Commission, proposals for new or revised fishing regulations designed to increase populations of listed fish species through reduced predation by introduced sport fish. The proposals should be based on sound science that demonstrates these management actions are likely to achieve their intended outcome and include the development of performance measures and a monitoring plan to support adaptive management.*
ER R7	Prioritize and Implement Actions to Control Nonnative Invasive Species	*The California Department of Fish and Wildlife and other appropriate agencies should prioritize and fully implement the list of "Stage 2 Actions for Nonnative Invasive Species" and accompanying text shown in Appendix J taken from the* Conservation Strategy for Restoration of the Sacramento–San Joaquin Delta Ecological Management Zone and the Sacramento and San Joaquin Valley Regions *(DFG 2011). Implementation of the Stage 2 actions should include the development of performance measures and monitoring plans to support adaptive management.*
ER R8	Manage Hatcheries to Reduce Genetic Risk	*As required by the National Marine Fisheries Service, all hatcheries providing listed fish for release into the wild should continue to develop and implement scientifically sound Hatchery and Genetic Management Plans (HGMPs) to reduce risks to those species. The California Department of Fish and Wildlife should provide annual updates to the Delta Stewardship Council on the status of HGMPs within its jurisdiction.*

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE
ER R9	Implement Marking and Tagging Program	*By December 2014, the California Department of Fish and Wildlife, in cooperation with the U.S. Fish and Wildlife Service and the National Marine Fisheries Service, should revise and begin implementing its program for marking and tagging hatchery salmon and steelhead to improve management of hatchery and wild stocks based on recommendations of the California Hatchery Scientific Review Group, which considered mass marking, reducing hatchery programs, and mark selective fisheries in developing its recommendations.*
Chapter 5		
DP R1	Designate the Delta as a National Heritage Area	*The Delta Protection Commission should complete its application for designation of the Delta and Suisun Marsh as a National Heritage Area, and the federal government should complete the process in a timely manner.*
DP R2	Designate State Route 160 as a National Scenic Byway	*The California Department of Transportation should seek designation of State Route 160 as a National Scenic Byway, and prepare and implement a scenic byway plan for it.*
DP P1 (23 CCR section 5010)	Locate New Urban Development Wisely	*(a) New residential, commercial, and industrial development must be limited to the following areas, as shown in Appendix 6 and Appendix 7:* *(1) Areas that city or county general plans as of May 16, 2013, designate for residential, commercial, and industrial development in cities or their spheres of influence;* *(2) Areas within Contra Costa County's 2006 voter-approved urban limit line, except no new residential, commercial, and industrial development may occur on Bethel Island unless it is consistent with the Contra Costa County general plan effective as of May 16, 2013;* *(3) Areas within the Mountain House General Plan Community Boundary in San Joaquin County; or* *(4) The unincorporated Delta towns of Clarksburg, Courtland, Hood, Locke, Ryde, and Walnut Grove.* *(b) Notwithstanding subsection (a), new residential, commercial, and industrial development is permitted outside the areas described in subsection (a) if it is consistent with the land uses designated in county general plans as of May 16, 2013, and is otherwise consistent with this Chapter.* *(c) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers proposed actions that involve new residential, commercial, and industrial development that is not located within the areas described in subsection (a). In addition, this policy covers any such action on Bethel Island that is inconsistent with the Contra Costa County general plan effective as of May 16, 2013. This policy does not cover commercial recreational visitor-serving uses or facilities for processing of local crops or that provide essential services to local farms, which are otherwise consistent with this Chapter.* *(d) This policy is not intended in any way to alter the concurrent authority of the Delta Protection Commission to separately regulate development in the Delta's Primary Zone.*

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE
DP P2 (23 CCR section 5011)	Respect Local Land Use When Siting Water or Flood Facilities or Restoring Habitats	(a) *Water management facilities, ecosystem restoration, and flood management infrastructure must be sited to avoid or reduce conflicts with existing uses or those uses described or depicted in city and county general plans for their jurisdictions or spheres of influence when feasible, considering comments from local agencies and the Delta Protection Commission. Plans for ecosystem restoration must consider sites on existing public lands, when feasible and consistent with a project's purpose, before privately owned sites are purchased. Measures to mitigate conflicts with adjacent uses may include, but are not limited to, buffers to prevent adverse effects on adjacent farmland.* (b) *For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers proposed actions that involve the siting of water management facilities, ecosystem restoration, and flood management infrastructure.*
DP R3	Plan for the Vitality and Preservation of Legacy Communities	*Local governments, in cooperation with the Delta Protection Commission and Delta Conservancy, should prepare plans for each community that emphasize its distinctive character, encourage historic preservation, identify opportunities to encourage tourism, serve surrounding lands, or develop other appropriate uses, and reduce flood risks.*
DP R4	Buy Rights of Way from Willing Sellers When Feasible	*Agencies acquiring land for water management facilities, ecosystem restoration, and flood management infrastructure should purchase from willing sellers, when feasible, including consideration of whether lands suitable for proposed projects are available at fair prices.*
DP R5	Provide Adequate Infrastructure	*The California Department of Transportation, local agencies, and utilities should plan infrastructure, such as roads and highways, to meet needs of development consistent with sustainable community strategies, local plans, the Delta Protection Commission's* Land Use and Resource Management Plan for the Primary Zone of the Delta, *and the Delta Plan.*
DP R6	Plan for State Highways	*The Delta Stewardship Council, as part of the prioritization of State levee investments called for in Water Code section 85306, should consult with the California Department of Transportation as provided in Water Code section 85307(c) to consider the effects of flood hazards and sea level rise on State highways in the Delta.*
DP R7	Subsidence Reduction and Reversal	*The following actions should be considered by the appropriate State agencies to address subsidence reversal:* ▪ *State agencies should not renew or enter into agricultural leases on Delta or Suisun Marsh islands if the actions of the lessee promote or contribute to subsidence on the leased land, unless the lessee participates in subsidence reversal or reduction programs.* ▪ *State agencies currently conducting subsidence reversal projects in the Delta on State-owned lands should investigate options for scaling up these projects if they have been deemed successful. The California Department of Water Resources should develop a plan, including funding needs, for increasing the extent of their subsidence reversal and carbon sequestration projects to 5,000 acres by January 1, 2017.* ▪ *The Delta Stewardship Council, in conjunction with the California Air Resources Board (CARB) and the Delta Conservancy, should investigate the opportunity for the development of a carbon market whereby Delta farmers could receive credit for carbon sequestration by reducing subsidence and growing native marsh and wetland plants. This investigation should include the potential for developing offset protocols applicable to these types of plants for subsequent adoption by the CARB.*

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE
DP R8	Promote Value-added Crop Processing	*Local governments and economic development organizations, in cooperation with the Delta Protection Commission and the Delta Conservancy, should encourage value-added processing of Delta crops in appropriate locations.*
DP R9	Encourage Agritourism	*Local governments and economic development organizations, in cooperation with the Delta Protection Commission and the Delta Conservancy, should support growth in agritourism, particularly in and around legacy communities. Local plans should support agritourism where appropriate.*
DP R10	Encourage Wildlife-friendly Farming	*The California Department of Fish and Wildlife, the Delta Conservancy, and other ecosystem restoration agencies should encourage habitat enhancement and wildlife-friendly farming systems on agricultural lands to benefit both the environment and agriculture.*
DP R11	Provide New and Protect Existing Recreation Opportunities	*Water management and ecosystem restoration agencies should provide recreation opportunities, including visitor-serving business opportunities, at new facilities and habitat areas whenever feasible; and existing recreation facilities should be protected, using California State Parks'* Recreation Proposal for the Sacramento-San Joaquin Delta and Suisun Marsh *and Delta Protection Commission's* Economic Sustainability Plan for the Sacramento-San Joaquin Delta *as guides.*
DP R12	Encourage Partnerships to Support Recreation and Tourism	*The Delta Protection Commission and Delta Conservancy should encourage partnerships between other State and local agencies, and local landowners and business people to expand recreation, including boating, promote tourism, and minimize adverse impacts to nonrecreational landowners.*
DP R13	Expand State Recreation Areas	*California State Parks should add or improve recreation facilities in the Delta in cooperation with other agencies. As funds become available, it should fully reopen Brannan Island State Recreation Area, complete the park at Delta Meadows-Locke Boarding House, and consider adding new State parks at Barker Slough, Elkhorn Basin, the Wright-Elmwood Tract, and south Delta.*
DP R14	Enhance Nature-based Recreation	*The California Department of Fish and Wildlife, in cooperation with other public agencies, should collaborate with nonprofits, private landowners, and business partners to expand wildlife viewing, angling, and hunting opportunities.*
DP R15	Promote Boating Safety	*The California Department of Boating and Waterways should coordinate with the U.S. Coast Guard and State and local agencies on an updated marine patrol strategy for the region.*
DP R16	Encourage Recreation on Public Lands	*Public agencies owning land should increase opportunities, where feasible, for bank fishing, hunting, levee-top trails, and environmental education.*
DP R17	Enhance Opportunities for Visitor-serving Businesses	*Cities, counties, and other local and State agencies should work together to protect and enhance visitor-serving businesses by planning for recreation uses and facilities in the Delta, providing infrastructure to support recreation and tourism, and identifying settings for private visitor-serving development and services.*
DP R18	Support the Ports of Stockton and West Sacramento	*The ports of Stockton and West Sacramento should encourage maintenance and carefully designed and sited development of port facilities.*

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE
DP R19	Plan for Delta Energy Facilities	*The California Energy Commission and California Public Utilities Commission should cooperate with the Delta Stewardship Council as described in Water Code section 85307(d) to identify actions that should be incorporated in the Delta Plan by 2017 to address the needs of Delta energy development, storage, and distribution.*
Chapter 6		
WQ R1	Protect Beneficial Uses	*Water quality in the Delta should be maintained at a level that supports, enhances, and protects beneficial uses identified in the applicable State Water Resources Control Board or regional water quality control board water quality control plans.*
WQ R2	Identify Covered Action Impacts	*Covered actions should identify any significant impacts to water quality.*
WQ R3	Special Water Quality Protections for the Delta	*The State Water Resources Control Board or regional water quality control board should evaluate and, if appropriate, propose special water quality protections for priority habitat restoration areas identified in recommendation ER R2 or other areas of the Delta where new or increased discharges of pollutants could adversely impact beneficial uses.*
WQ R4	Complete Central Valley Drinking Water Policy	*The Central Valley Regional Water Quality Control Board should complete the Central Valley Drinking Water Policy by July 2013.*
WQ R5	Complete North Bay Aqueduct Alternative Intake Project	*The California Department of Water Resources should complete the North Bay Aqueduct Alternate Intake Project Environmental Impact Report by December 31, 2012, and begin construction as soon as possible thereafter.*
WQ R6	Protect Groundwater Beneficial Uses	*The State Water Resources Control Board should complete development of a Strategic Workplan for protection of groundwater beneficial uses, including groundwater use for drinking water, by December 31, 2012.*
WQ R7	Participation in CV-SALTS	*The State Water Resources Control Board and Central Valley Regional Water Quality Control Board should consider requiring participation by all relevant water users that are supplied water from the Delta or the Delta watershed or discharge wastewater to the Delta or the Delta watershed to participate in the Central Valley Salinity Alternatives for Long-Term Sustainability Program.*
WQ R8	Completion of Regulatory Processes, Research, and Monitoring for Water Quality Improvement	*The State Water Resources Control Board and the San Francisco Bay and Central Valley Regional Water Quality Control Boards are currently engaged in regulatory processes, research, and monitoring essential to improving water quality in the Delta. In order to achieve the coequal goals, it is essential that these ongoing efforts be completed and, if possible, accelerated, and that the Legislature and Governor devote sufficient funding to make this possible. The Delta Stewardship Council specifically recommends that:* ▪ *The State Water Resources Control Board should complete development of the proposed policy for nutrients for inland surface waters of the State of California by January 1, 2014.* ▪ *The State Water Resources Control Board and the San Francisco Bay and Central Valley Regional Water Quality Control Boards should prepare and begin implementation of a study plan for the development of objectives for nutrients in the Delta and Suisun Marsh by January 1, 2014. Studies needed for development of Delta and Suisun Marsh nutrient objectives should be completed by January 1, 2016. The water boards should*

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE
		adopt and begin implementation of nutrient objectives, either narrative or numeric, where appropriate, for the Delta and Suisun Marsh by January 1, 2018. ▪ *The State Water Resources Control Board and the Central Valley Regional Water Quality Control Board should complete the Central Valley Pesticide Total Maximum Daily Load and Basin Plan Amendment for diazinon and chlorpyrifos by January 1, 2013.* ▪ *The State Water Resources Control Board and the Central Valley Regional Water Quality Control Board should prioritize and accelerate the completion of the Central Valley Pesticide Total Maximum Daily Load and Basin Plan Amendment for pyrethroids by January 1, 2016.* ▪ *The State Water Resources Control Board and the San Francisco Bay and Central Valley Regional Water Quality Control Boards have completed Total Maximum Daily Load and Basin Plan Amendments for methylmercury, and efforts to support their implementation should be coordinated. Parties identified as responsible for current methylmercury loads or proponents of projects that may increase methylmercury loading in the Delta or Suisun Marsh should participate in control studies or implement site-specific study plans that evaluate practices to minimize methylmercury discharges. The Central Valley Regional Water Quality Control Board should review these control studies by December 31, 2018, and determine control measures for implementation starting in 2020.*
WQ R9	Implement Delta Regional Monitoring Program	*The State Water Resources Control Board and Regional Water Quality Control Boards should work collaboratively with the California Department of Water Resources, California Department of Fish and Wildlife, and other agencies and entities that monitor water quality in the Delta to develop and implement a Delta Regional Monitoring Program that will be responsible for coordinating monitoring efforts so Delta conditions can be efficiently assessed and reported on a regular basis.*
WQ R10	Evaluate Wastewater Recycling, Reuse, or Treatment	*The Central Valley Regional Water Quality Control Board, consistent with existing water quality control plan policies and water rights law, should require responsible entities that discharge wastewater treatment plant effluent or urban runoff to Delta waters to evaluate whether all or a portion of the discharge can be recycled, otherwise used, or treated in order to reduce contaminant loads to the Delta by January 1, 2014.*
WQ R11	Manage Dissolved Oxygen in Stockton Ship Channel	*The State Water Resources Control Board and the Central Valley Regional Water Quality Control Board should complete Phase 2 of the Total Maximum Daily Load and Basin Plan Amendment for dissolved oxygen in the Stockton Deep Water Ship Channel by January 1, 2015.*
WQ R12	Manage Dissolved Oxygen in Suisun Marsh	*The State Water Resources Control Board and the San Francisco Bay Regional Water Quality Control Board should complete the Total Maximum Daily Load and Basin Plan Amendment for dissolved oxygen in Suisun Marsh wetlands by January 1, 2014.*

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE
Chapter 7		
RR R1	Implement Emergency Preparedness and Response	*The following actions should be taken by January 1, 2014, to promote effective emergency preparedness and response in the Delta:* ▪ *Responsible local, State, and federal agencies with emergency response authority should consider and implement the recommendations of the Sacramento-San Joaquin Delta Multi-Hazard Coordination Task Force (Water Code section 12994.5). Such actions should support the development of a regional response system for the Delta.* ▪ *In consultation with local agencies, the California Department of Water Resources should expand its emergency stockpiles to make them regional in nature and usable by a larger number of agencies in accordance with California Department of Water Resources' plans and procedures. The California Department of Water Resources, as a part of this plan, should evaluate the potential of creating stored material sites by "over-reinforcing" west Delta levees.* ▪ *Local levee-maintaining agencies should consider developing their own emergency action plans, and stockpiling rock and flood-fighting materials.* ▪ *State and local agencies and regulated utilities that own and/or operate infrastructure in the Delta should prepare coordinated emergency response plans to protect the infrastructure from long-term outages resulting from failures of the Delta levees. The emergency procedures should consider methods that also would protect Delta land use and ecosystem.*
RR R2	Finance Local Flood Management Activities	*The Legislature should create a Delta Flood Risk Management Assessment District with fee assessment authority (including over State infrastructure) to provide adequate flood control protection and emergency response for the regional benefit of all beneficiaries, including landowners, infrastructure owners, and other entities that benefit from the maintenance and improvement of Delta levees, such as water users who rely on the levees to protect water quality.* *This district should be authorized to:* ▪ *Identify and assess all beneficiaries of Delta flood protection facilities.* ▪ *Develop, fund, and implement a regional plan of flood management for both project and nonproject levees of the Delta, including the maintenance and improvement of levees, in cooperation with the existing reclamation districts, cities, counties, and owners of infrastructure and other interests protected by the levees.* ▪ *Require local levee-maintaining agencies to conduct annual levee inspections per the California Department of Water Resources subventions program guidelines, and update levee improvement plans every 5 years.* ▪ *Participate in the collection of data and information necessary for the prioritization of State investments in Delta levees consistent with RR P1.* ▪ *Notify residents and landowners of flood risk, personal safety information, and available systems for obtaining emergency information before and during a disaster on an annual basis.* ▪ *Potentially implement the recommendations of the Sacramento-San Joaquin Delta Multi-Hazard Coordination Task Force (Water Code section 12994.5) in conjunction with local, State, and federal agencies, and maintain the resulting regional response system*

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE
		and components and procedures on behalf of SEMS jurisdictions (reclamation district, city, county, and State) that would jointly implement the regional system in response to a disaster event. ▪ *Identify and assess critical water supply corridor levee operations, maintenance, and improvements.*
RR R3	Fund Actions to Protect Infrastructure from Flooding and Other Natural Disasters	▪ *The California Public Utilities Commission should immediately commence formal hearings to impose a reasonable fee for flood and disaster prevention on regulated privately owned utilities with facilities located in the Delta. Publicly owned utilities should also be encouraged to develop similar fees. The California Public Utilities Commission, in consultation with the Delta Stewardship Council, the California Department of Water Resources, and the Delta Protection Commission, should allocate these funds among State and local emergency response and flood protection entities in the Delta. If a new regional flood management agency is established by law, a portion of the local share would be allocated to that agency.* ▪ *The California Public Utilities Commission should direct all regulated public utilities in their jurisdiction to immediately take steps to protect their facilities in the Delta from the consequences of a catastrophic failure of levees in the Delta, to minimize the impact on the State's economy.* ▪ *The Governor, by Executive Order, should direct State agencies with projects or infrastructure in the Delta to set aside a reasonable amount of funding to pay for flood protection and disaster prevention. The local share of these funds should be allocated as described above.*
RR P1 (23 CCR section 5012)	Prioritization of State Investments in Delta Levees and Risk Reduction	*(a) Prior to the completion and adoption of the updated priorities developed pursuant to Water Code section 85306, the interim priorities listed below shall, where applicable and to the extent permitted by law, guide discretionary State investments in Delta flood risk management. Key priorities for interim funding include emergency preparedness, response, and recovery as described in paragraph (1), as well as Delta levees funding as described in paragraph (2).* *(1) Delta Emergency Preparedness, Response, and Recovery: Develop and implement appropriate emergency preparedness, response, and recovery strategies, including those developed by the Delta Multi-Hazard Task Force pursuant to Water Code section 12994.5.* *(2) Delta Levees Funding: The priorities shown in the following table are meant to guide budget and funding allocation strategies for levee improvements. The goals for funding priorities are all important, and it is expected that over time, the California Department of Water Resources must balance achievement of those goals. Except on islands planned for ecosystem restoration, improvement of nonproject Delta levees to the Hazard Mitigation Plan (HMP) standard may be funded without justification of the benefits. Improvements to a standard above HMP, such as that set by the U.S. Army Corps of Engineers under Public Law 84-99, may be funded as befits the benefits to be provided, consistent with the California Department of Water Resources' current practices and any future adopted investment strategy.*

<table>
<tr><th>POLICY OR RECOMMENDATION NUMBER</th><th>SHORT TITLE</th><th>POLICY/RECOMMENDATION LANGUAGE</th></tr>
<tr><td></td><td></td><td>

Priorities for State Investment in Delta Integrated Flood Management

Categories of Benefit Analysis

<table>
<tr><th>Goals</th><th>Localized Flood Protection</th><th>Levee Network</th><th>Ecosystem Conservation</th></tr>
<tr><td>1</td><td>Protect existing urban and adjacent urbanizing areas by providing 200-year flood protection.</td><td>Protect water quality and water supply conveyance in the Delta, especially levees that protect freshwater aqueducts and the primary channels that carry fresh water through the Delta.</td><td>Protect existing and provide for a net increase in channel-margin habitat.</td></tr>
<tr><td>2</td><td>Protect small communities and critical infrastructure of statewide importance (located outside of urban areas).</td><td>Protect floodwater conveyance in and through the Delta to a level consistent with the State Plan of Flood Control for project levees.</td><td>Protect existing and provide for net enhancement of floodplain habitat.</td></tr>
<tr><td>3</td><td>Protect agriculture and local working landscapes.</td><td>Protect cultural, historic, aesthetic, and recreational resources (Delta as Place).</td><td>Protect existing and provide for net enhancement of wetlands.</td></tr>
</table>

(b) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers a proposed action that involves discretionary State investments in Delta flood risk management, including levee operations, maintenance, and improvements. Nothing in this policy establishes or otherwise changes existing levee standards.

</td></tr>
<tr><td>RR R4</td><td>Actions for the Prioritization of State Investments in Delta Levees</td><td>

The Delta Stewardship Council, in consultation with the California Department of Water Resources, the Central Valley Flood Protection Board, the Delta Protection Commission, local agencies, and the California Water Commission, should develop funding priorities for State investments in Delta levees by January 1, 2015. These priorities shall be consistent with the provisions of the Delta Reform Act in promoting effective, prioritized strategic State investments in levee operations, maintenance, and improvements in the Delta for both levees that are a part of the State Plan of Flood Control and nonproject levees. Upon completion, these priorities shall be considered for incorporation into the Delta Plan.

The priorities should identify guiding principles, constraints, recommended cost share allocations, and strategic considerations to guide Delta flood risk reduction investments,

</td></tr>
</table>

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE

		supported by, at a minimum, the following actions to be conducted by the California Department of Water Resources, consistent with available funding:
		■ *An assessment of existing Delta levee conditions. This should include the development of a Delta levee conditions map based on sound data inputs, including, but not limited to:*
		  ■ *Geometric levee assessment*
		  ■ *Flow and updated stage-frequency analysis*
		■ *An island-by-island economics-based risk analysis. This analysis should consider, but not be limited to, values related to protecting:*
		  ■ *Island residents/life safety*
		  ■ *Property*
		  ■ *Value of Delta islands' economic output, including agriculture*
		  ■ *State water supply*
		  ■ *Critical local, State, federal, and private infrastructure, including aqueducts, state highways, electricity transmission lines, gas/petroleum pipelines, gas fields, railroads, and deep water shipping channels*
		  ■ *Delta water quality*
		  ■ *Existing ecosystem values and ecosystem restoration opportunities*
		  ■ *Recreation*
		  ■ *Systemwide integrity*
		■ *An ongoing assessment of Delta levee conditions. This should include a process for updating Delta levee assessment information on a routine basis.*
		This methodology should provide the basis for the prioritization of State investments in Delta levees. It should include, but not be limited to, the public reporting of the following items:
		■ *Tiered ranking of Delta islands, based on economics-based risk analysis values*
		■ *Delta levee conditions status report, including a levee conditions map*
		■ *Inventory of Delta infrastructure assets*

RR P2 (23 CCR section 5013)	Require Flood Protection for Residential Development in Rural Areas	*(a) New residential development of five or more parcels shall be protected through flood-proofing to a level 12 inches above the 100-year base flood elevation, plus sufficient additional elevation to protect against a 55-inch rise in sea level at the Golden Gate, unless the development is located within:* *(1) Areas that city or county general plans, as of May 16, 2013, designate for development in cities or their spheres of influence;* *(2) Areas within Contra Costa County's 2006 voter-approved urban limit line, except Bethel Island;* *(3) Areas within the Mountain House General Plan Community Boundary in San Joaquin County; or* *(4) The unincorporated Delta towns of Clarksburg, Courtland, Hood, Locke, Ryde, and Walnut Grove, as shown in Appendix 7.* *(b) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers a proposed action that involves new residential development of five or more parcels that is not located within the areas described in subsection (a).*

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE
RR P3 (23 CCR section 5014)	Protect Floodways	*(a) No encroachment shall be allowed or constructed in a floodway, unless it can be demonstrated by appropriate analysis that the encroachment will not unduly impede the free flow of water in the floodway or jeopardize public safety.* *(b) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers a proposed action that would encroach in a floodway that is not either a designated floodway or regulated stream.*
RR P4 (23 CCR section 5015)	Floodplain Protection	*(a) No encroachment shall be allowed or constructed in any of the following floodplains unless it can be demonstrated by appropriate analysis that the encroachment will not have a significant adverse impact on floodplain values and functions:* *(1) The Yolo Bypass within the Delta;* *(2) The Cosumnes River-Mokelumne River Confluence, as defined by the North Delta Flood Control and Ecosystem Restoration Project (McCormack-Williamson), or as modified in the future by the California Department of Water Resources or the U.S. Army Corps of Engineers (California Department of Water Resources 2010); and* *(3) The Lower San Joaquin River Floodplain Bypass area, located on the Lower San Joaquin River upstream of Stockton immediately southwest of Paradise Cut on lands both upstream and downstream of the Interstate 5 crossing. This area is described in the Lower San Joaquin River Floodplain Bypass Proposal, submitted to the California Department of Water Resources by the partnership of the South Delta Water Agency, the River Islands Development Company, Reclamation District 2062, San Joaquin Resource Conservation District, American Rivers, the American Lands Conservancy, and the Natural Resources Defense Council, March 2011. This area may be modified in the future through the completion of this project.* *(b) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers a proposed action that would encroach in any of the floodplain areas described in subsection (a).* *(c) This policy is not intended to exempt any activities in any of the areas described in subsection (a) from applicable regulations and requirements of the Central Valley Flood Protection Board.*
RR R5	Fund and Implement San Joaquin River Flood Bypass	*The Legislature should fund the California Department of Water Resources and the Central Valley Flood Protection Board to evaluate and implement a bypass and floodway on the San Joaquin River near Paradise Cut that would reduce flood stage on the mainstem San Joaquin River adjacent to the urban and urbanizing communities of Stockton, Lathrop, and Manteca in accordance with Water Code section 9613(c).*
RR R6	Continue Delta Dredging Studies	*The current efforts to maintain navigable waters in the Sacramento River Deep Water Ship Channel and Stockton Deep Water Ship Channel, led by the U.S. Army Corps of Engineers and described in the Delta Dredged Sediment Long-Term Management Strategy (USACE 2007, Appendix K), should be continued in a manner that supports the Delta Plan and the coequal goals. Appropriate dredging throughout other areas in the Delta for maintenance purposes, or that would increase flood conveyance and provide potential material for levee maintenance or subsidence reversal should be implemented in a manner that supports the Delta Plan and coequal goals. Coordinated use of dredged material in levee improvement, subsidence reversal, or wetland restoration is encouraged.*

POLICY OR RECOMMENDATION NUMBER	SHORT TITLE	POLICY/RECOMMENDATION LANGUAGE
RR R7	Designate Additional Floodways	*The Central Valley Flood Protection Board should evaluate whether additional areas both within and upstream of the Delta should be designated as floodways. These efforts should consider the anticipated effects of climate change in its evaluation of these areas.*
RR R8	Develop Setback Levee Criteria	*The California Department of Water Resources, in conjunction with the Central Valley Flood Protection Board, the California Department of Fish and Wildlife, and the Delta Conservancy, should develop criteria to define locations for future setback levees in the Delta and Delta watershed.*
RR R9	Require Flood Insurance	*The Legislature should require an adequate level of flood insurance for residences, businesses, and industries in floodprone areas.*
RR R10	Limit State Liability	*The Legislature should consider statutory and/or constitutional changes that would address the State's potential flood liability, including giving State agencies the same level of immunity with regard to flood liability as federal agencies have under federal law.*
Chapter 8		
FP R1	Conduct Current Spending Inventory	*An inventory of current State and federal spending on programs and projects that do or may achieve the coequal goals will be conducted. Data sources to be used include the CALFED cross-cut budget, State bond balance reports, and the annual State budget, among others. Consideration will be given to selecting an independent agency (which could include a non governmental organization) to conduct the inventory.*
FP R2	Develop Delta Plan Cost Assessment	*Costs will be assigned to the projects and programs proposed in the Delta Plan (Chapters 2 through 7) and sources of funding will be identified.*
FP R3	Identify Funding Gaps	*Current State and federal funding gaps will be identified that are determined to hinder progress toward meeting the coequal goals.*

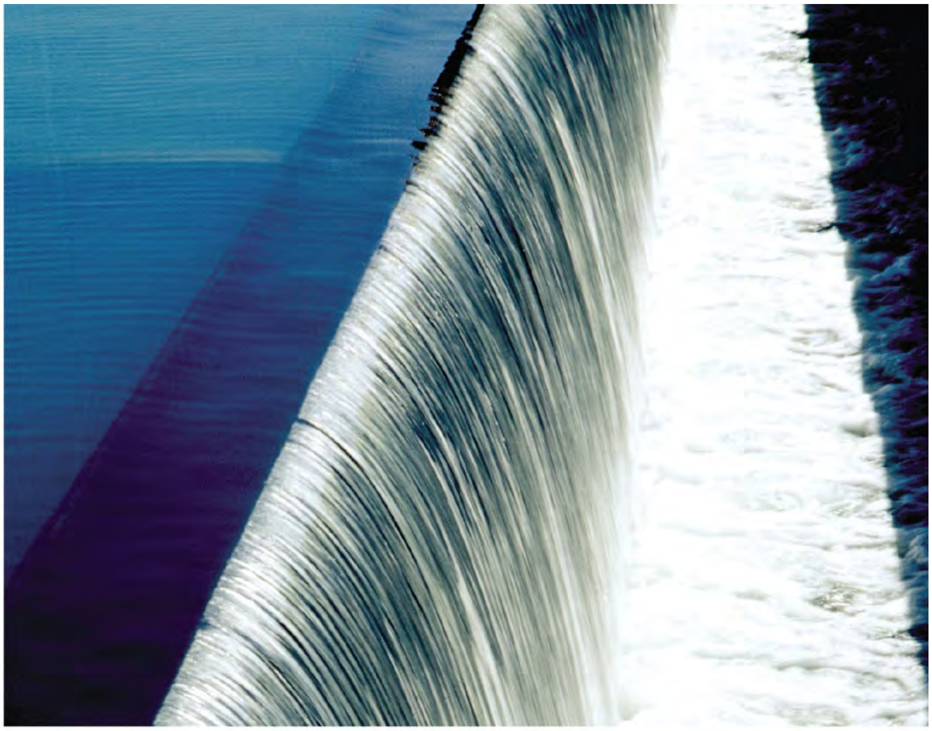
CHAPTER 1

Introduction



ABOUT THIS CHAPTER

This chapter offers historical and current contextual information about the uses and conflicts that besiege the Sacramento-San Joaquin Delta (Delta). The reader will come to understand how and why the West Coast's largest estuary has evolved from a huge tidal marsh to the maze of islands and channels it is today – shaped over more than a century and a half by the effects of hydraulic mining, flood control, agricultural and urban development, and its placement as the "hub" of California's major water systems.

The chapter then delves into the realities of decades of stand-offs among the key interests in the Delta and resulting years of relative inaction, leading finally to the bipartisan movement that created the Sacramento-San Joaquin Delta Reform Act of 2009 (Delta Reform Act or Act) and its mandate to develop a long-term sustainable management plan for the Delta. The chapter concludes with an overarching explanation of how this Delta Plan (or Plan) will bring about a fundamental and positive sustainability and reformation of this immense natural resource.

CHAPTER 1

Introduction

Throughout the past 160 years, the delta formed by California's two largest rivers, the Sacramento and the San Joaquin, has been a gateway to many of the state's collective hopes and dreams. Once the pathway to the Gold Country, it is today a critical component of the state's water supply infrastructure, a source of sustenance for farmers and fishermen, and home to half a million people and a vast array of fish, birds, and wildlife.

The Sacramento-San Joaquin Delta and Suisun Marsh are referred to throughout this Plan collectively as "the Delta," unless otherwise specified (see Figure 1-1).[1] Once a great marsh, the Delta now is a network of channels and sunken "islands" that cover—together with Suisun Marsh—about 1,300 square miles. Laid over those islands and channels is the infrastructure of a twenty-first century economy: water supply conduits; major arteries of the state's electrical grid; natural gas fields, storage facilities, and pipelines; highways and railways; and shipping channels, all surrounded by an increasingly urban landscape. Water from the vast Delta watershed, spanning over 45,000 square miles (30 million acres), fuels both local economies and those in export areas hundreds of miles away (see Figure 1-2).

Today the Delta is many things to many people, and is universally regarded in "crisis" because people have not yet been able to find balance in the tradeoffs among competing demands for the Delta's resources. Tradeoffs and integration define the Delta dilemma: water conveyance facilities that built strong urban and agricultural economies threaten ecosystem health. Water that is beneficial for fish is alive with plankton and organic material, but sources of drinking water are best in as pure a form as possible. The pollutants of upstream urban and agricultural uses cause problems for downstream fish and water diverters alike. The same ocean-going ships that opened the Central Valley to world trade also introduced nonnative species that alter the Delta ecosystem. High water flows that historically improved habitat and a diverse food web come with the threat of lost homes, flooded farmland, and disaster for Delta residents and the California economy.

Conceived decades ago, a series of water projects has engineered the Delta estuary over time to perform as a water conveyance system, moving water stored upstream to users throughout the state who hold State of California (State) or federal water contracts. This system relies on dredged channels, which at times run counter to natural flow directions as the result of export pumping that occurs in the south Delta. For a number of years, and currently at the publishing time of this Plan, State and federal agencies are exploring options to reconfigure the manner in which the Delta is used to convey water in a way that lessens ecosystem impacts and improves water supply reliability. At this time, the Delta Plan does not make recommendations regarding Delta conveyance (see Appendix A).

As a result of imperfect tradeoffs, key species are endangered or threatened, the amount of water that can be exported from the Delta is determined not just by the state's variable precipitation and storage but also by court order to protect endangered species, and geologists and engineers continue to worry that the Delta itself is one of the greatest flood risks in the West.

---

[1] The Sacramento-San Joaquin Delta is defined in Water Code section 12220, and Suisun Marsh means the area defined in Public Resources Code section 29101 and protected by Division 19 (commencing with section 29000).

The evolution of the Delta has come in fits and starts, driven by individual initiative, governmental incentive, and crisis. John Hart, writing for *Bay-Nature*, puts it this way:

> *The History of the modern Delta belies the image of the region as a static landscape. Reclamation was a battle with many setbacks, almost given up for lost in the 1870s. In the 1880s the 'crisis' was the clogging of channels by hydraulic mining debris. In the 1920s, salinity was on the march. A brief calm at midcentury gave way to the ever-spiraling tension over water exports and ecosystem decline. The Delta seems always to have been in crisis, under intensive study, and at the intersection of hostile interests.*

Governmental institutions have reacted to each crisis predictably, often treating individual problems rather than taking a systemwide approach. Over the years, dozens of agencies, task forces, and working groups have been created in a series of sometimes overlapping efforts to find the right combination of leadership and collaboration—incentives and regulation—to provide clean, reliable water; protect our environment; and reduce the risk of flooding.

After decades of conflict and unsuccessful efforts to comprehensively address the many problems and challenges of the Delta, the California Legislature (or Legislature), water agencies, and environmental groups throughout the state united in an unprecedented manner in 2009 to pass a series of water-related measures, including the Delta Reform Act.

The Delta Reform Act created the Delta Stewardship Council (Council) with a primary responsibility to develop and implement a legally enforceable, long-term management plan for the Delta. The Legislature required the Delta Plan to advance the coequal goals of protecting and enhancing the Delta ecosystem and providing for a more reliable water supply for California, and to do so in a manner that protects and enhances the Delta as an evolving place.

This Delta Plan is intended to be a foundational document that prioritizes actions and strategies in support of key objectives such as the State's requirement to reduce reliance on the Delta to meet future water supply needs. It also restricts actions that may cause harm; serves as a guidebook for all plans, projects, and programs that affect the Delta; and calls for further investigation and focused study of specific issues.

Successful implementation of the Delta Plan depends not only on the Council, but also on coordinated actions by other government agencies—federal, State, and local—and by the stakeholders to whom these agencies are responsible. To be effective, decision making in a dynamic context such as the Delta must be flexible and have the capacity to change policies and practices in response to what is learned over time. Through this Delta Plan, the Council details an interagency structure for decision making that fosters communication among scientists; local, State, and federal decision makers; and stakeholders. Future Plan iterations will build on successes as well as lessons learned in order to achieve the coequal goals.

The Delta and California's Water Supply

The story of California's annual water supply is one of great variability in amount, timing, and distribution, and of the human desire to impose certainty and order. Rain and snow fall mostly in the northern and eastern portions of the state, but most Californians live along the coast and in the south. Most of the state's precipitation occurs in only 5 to 15 days, and that rain and snowfall result in an annual supply that is ample in average years, too little in dry ones, and too much in wet years (see Figure 1-3).

The Sacramento-San Joaquin Delta and Suisun Marsh

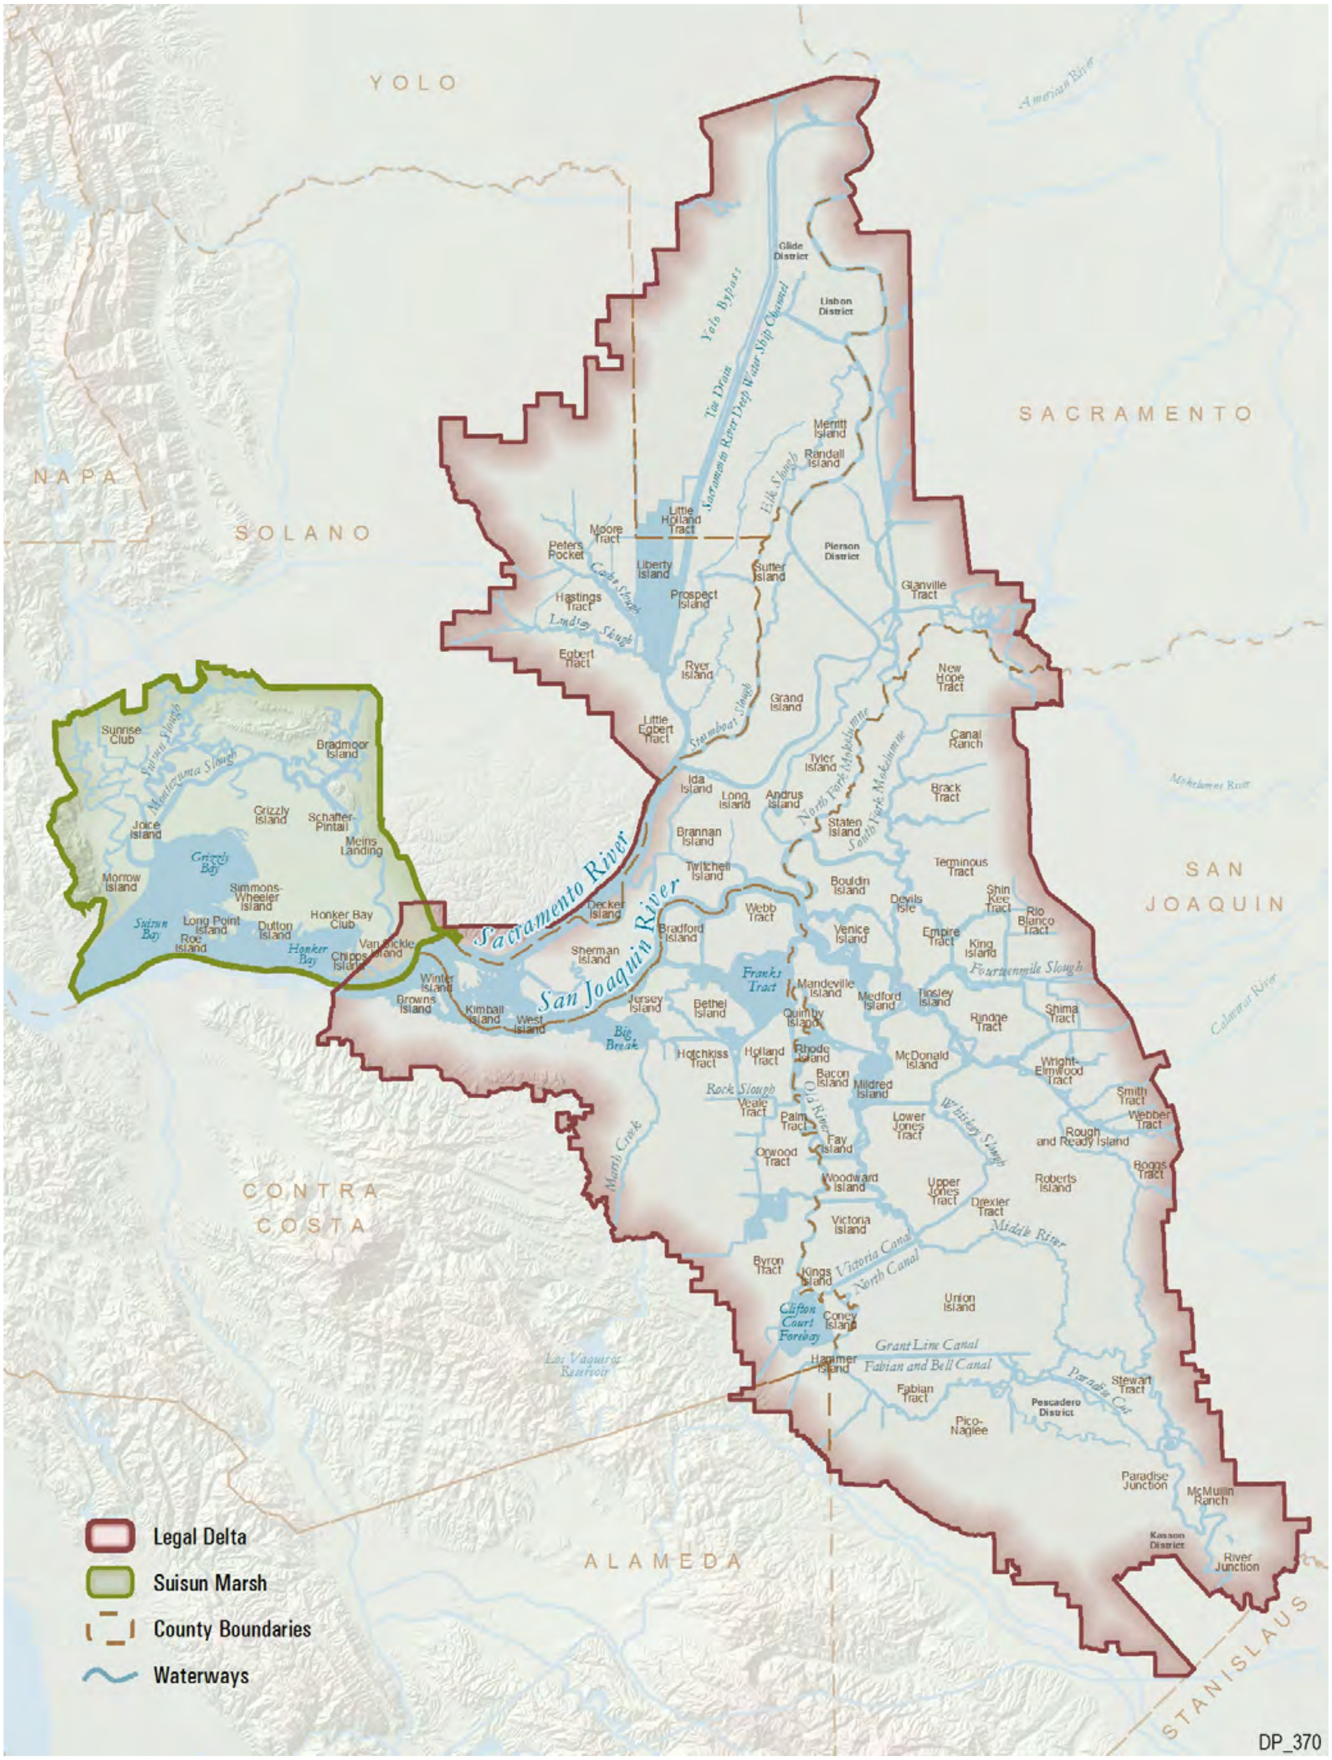


Figure 1-1 *Source: DWR 2011a*

The Delta Watershed and Areas Receiving Delta Water

Figure 1-2

To meet water demand, Californians over the past 160 years have built a vast array of reservoirs, canals, pipelines, and tunnels, all in an effort to capture water when it was available, store it for when it was not, and to move it to the people when and where they wanted it.

As residents in both Northern and Southern California feared they would outgrow their local supplies, they turned to the vast Delta watershed for relief. The river systems flowing into the Delta drain about 40 percent of the land in California and carry about half of the state's total annual runoff.

And so, at the turn of the twentieth century, San Francisco tapped the Tuolumne River, diverting water through an aqueduct that bypasses the San Joaquin River and Delta. Shortly thereafter, Oakland and the eastern San Francisco Bay Area tapped the Mokelumne River, diverting water through a pipeline across the Delta. Later, construction of the federal Central Valley Project (CVP) and the State Water Project (SWP) resulted in additional diversions directly from the Delta for the Bay Area, Central Valley, and Southern California.

California's Variable Precipitation

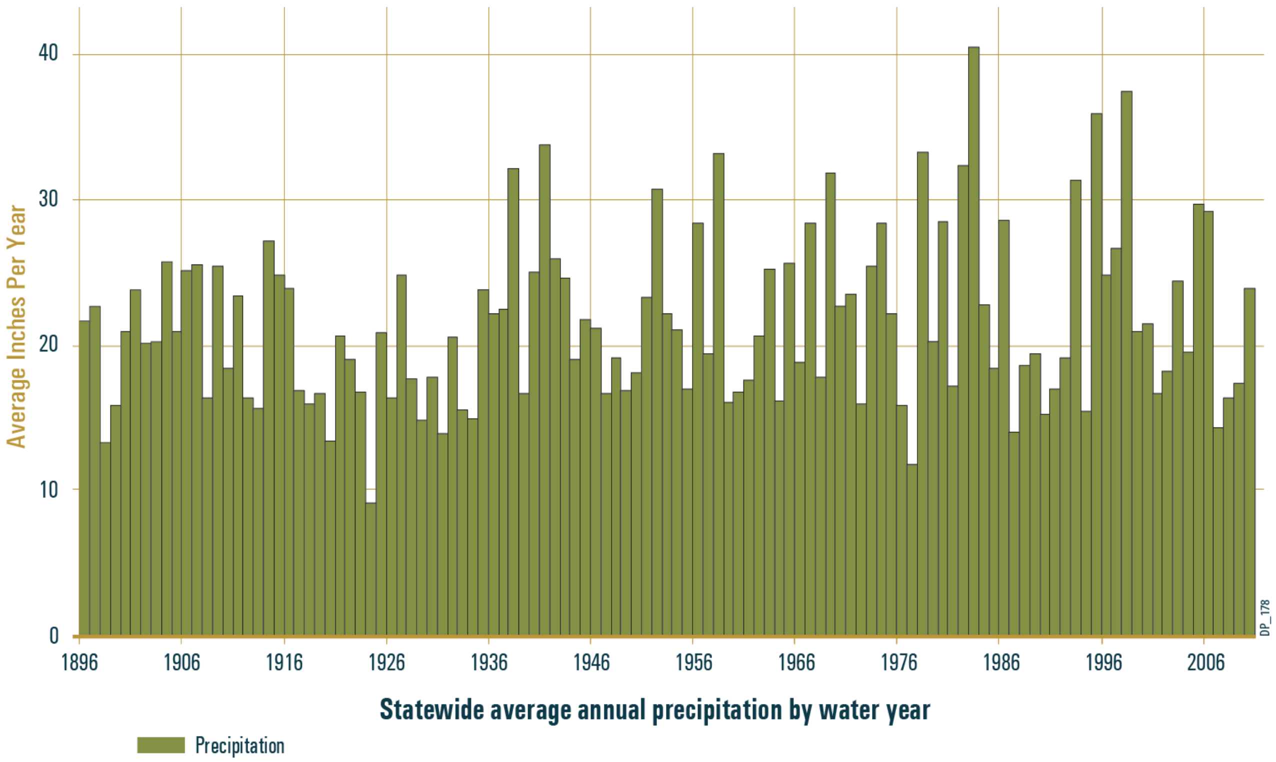

Figure 1-3 The unpredictability of the state's rainfall and its history of multiyear droughts make the management of water to reliably meet environmental and human uses extremely challenging. Yearly precipitation was calculated from the average of 95 stations located across California. Data were collected by Jim Goodridge, former State climatologist.

Source: Western Regional Climate Center 2011

Today, some two-thirds of the state's population (approximately 27 million people) depend on water from the Delta watershed for some portion of their water supply, as do more than 3 million acres of irrigated farmland that grow crops for in-state, national, and international distribution. That said, water exported through the Delta represents approximately 8 percent of the state's annual average water supply. Local and regional water resources, including surface diversions, groundwater, local and out-of-state imports, and water reuse, meet the remaining 84 percent.

Who uses all that water, how it is used, how much returns to the rivers and streams for downstream users, and in what quality, is less than certain on a statewide basis. Data for actual water use and water quality suffer from significant gaps, which may affect the ability of California's water managers to make timely and better-informed decisions. Since 1914, the State Water Resources Control Board (SWRCB) has issued permits to post-1914 appropriative-right water diverters in the Delta, but actual annual diversion amounts are not thoroughly measured or reported. Owners and operators of nearly one-third of irrigated lands in the Delta watershed do not participate in programs to meet water quality standards, and their compliance with State law is unclear.

Although groundwater and surface water are often interconnected, the SWRCB has limited authority to regulate groundwater. Groundwater is sustainably managed in some areas of the state through either adjudication or special districts, but other areas suffer from unsustainable overdraft and require improved management efforts. Attempts to correct this overdraft often put more pressure on water supplies from the Delta, demonstrating once again the interconnectedness of California's water systems.

The Delta and Its Ecosystem

Although much of the debate over the Delta has centered on events in the last 50 years, the roots of its problems run much deeper. A Delta that for millennia had been a land and waterscape of dynamic floodplain and tidal marshland, rich in flora and fauna, was changed forever by passage of the federal Swamp Land Act of 1850 and similar State legislation in 1861, which provided incentives for the "reclamation" of "nuisance" swampland to reduce threats of vector-borne disease and to gain productive land for farming. Within the Delta, seasonally and tidally flooded land impeding agricultural development led to land reclamation and channelization, and subsequent habitat loss. More than a century ago, with little or no engineering analyses and limited construction tools, Delta residents began to build an intricate levee system to channel water and dry out land, which converted hundreds of thousands of acres of seasonally and tidally flooded wetlands into fertile agricultural fields. As a result of continued land use change and urbanization, 95 percent of the historical tidal marsh in the Delta has been lost. Further detail regarding the historical Delta landscape is provided in Chapter 4.

Hydraulic gold mining, which reached its peak in the 1860s, sent tons of mercury-laden debris down toward the Delta, clogging channels and streams, and leading to devastating floods. Corrective actions—dredging and new levee construction—resulted in the loss of 90 percent of the Central Valley's riparian habitat (Katibah 1984). This massive-scale destruction has had lasting consequences for ecosystem health and, in turn, declining ecosystem health has had direct consequences for water supply operations.

The Hetch Hetchy and Mokelumne aqueducts diverted water (as they do currently) before it reached the Delta, and water use upstream increased considerably during the mid- and late 1900s. Construction of the CVP and SWP in the 1940s and 1960s, respectively, introduced new pressures on the Delta. Indeed, it is unusual to use an estuary—normally where fresh and salt water mix according to variable tidal and tributary flows—as a conveyance system for large amounts of fresh water to meet seasonal user demands.

The resulting configuration today causes river channels at times to run backward; and some fish, lacking clear migration corridors and/or migration cues, end up in dead-end channels or, worse yet, “salvaged” at the export pumps. Conflict between these competing uses was soon apparent and continues to plague water policy today.

Fish species have changed over time in response to changing habitat and flows, and from introductions both planned and accidental. Among the first introductions, in 1879, were two eastern game fish—striped bass and American shad. Today, striped bass, which are voracious predators, both support a major sport fishery and are blamed by some for the decline of smelt and salmon. Among the accidental tourists who came to stay are Asian clams, voracious eaters who can deplete the water of nutrients for native species. Of the more than 50 species of fish in the Delta today, more than half, including the most successful, are nonnative.

In addition, growing agricultural production in the Central Valley has resulted in increased runoff of pesticides and fertilizer flowing to the Delta. Runoff and wastewater discharges from increasing upstream urbanization have altered Delta water quality and, thus, its ecosystem. Increased commercial and recreational boat traffic in the Delta, as well as other causes, have introduced many nonnative species that have altered the Delta ecosystem.

The Delta as a Unique and Evolving Place

The Delta is a unique place distinguished by geography, legacy communities, a rural and agricultural setting, vibrant natural resources, and a mix of economic activities. Much has changed over the past 160 years; and although some may desire to maintain a static picture of the Delta as it is today, the past, as well as emerging science, predict constant change.

Once a marshland that was the drain of the vast Central Valley watershed, the Delta changed dramatically following the discovery of gold on the American River in 1848. Suddenly, large numbers of prospectors and service providers were beating a pathway through the Delta to the foothills and, at the peak of the rush, more than 300 steamboats plied the waters between San Francisco and Sacramento. Twenty-one years later, completion of the transcontinental railroad in 1869 freed a huge workforce, many of whom found alternative work dredging Delta channels and building levees.

Communities developed to support river traffic to and from the gold country, and later to transport agricultural products from the newly productive farmland reclaimed from the Delta marshes. The advent of the automobile resulted in a flurry of ferry construction and bridge building in the 1920s; by the 1930s, cars and trucks were replacing steamships for transportation and commercial shipping. The Stockton Deepwater Ship Channel was completed in 1933, opening a direct connection from the San Joaquin Valley to the world, and 30 years later, the Sacramento Deepwater Ship Channel did the same for the Sacramento Valley. Not coincidentally, these channels also opened the Delta to a host of exotic invasive species that hitched rides on the bottoms and in the ballast of oceangoing freighters.

Central Valley Chinook salmon have long been a critically important part of California’s fishing industry, passing through the Delta on their way from and to spawning grounds in upstream rivers and streams. Between 1900 and 1950, the fall run numbered more than a million fish returning annually to the Sacramento and San Joaquin river systems. Drought and changing Delta and ocean conditions, however, reduced those numbers to only 66,000 in 2008, resulting in a closure of the salmon fisheries off California and restrictions that lingered into 2010, devastating fishing economies (DFG 2009).

Dredging opened many of the Delta channels for sport fishing, recreational boating, and commercial enterprise. Today there are more than 100 marinas and waterside resorts, RV parks, grocery stores, and dockside restaurants; and house boating remains popular. The Delta is dotted with numerous public parks and fishing sites as well.

The Delta now is a major producer of corn, alfalfa, pasture, and tomatoes; and wine grapes are growing in prominence. Residents and visitors alike celebrate the Delta's agricultural heritage with the Asparagus Festival in Stockton and the Courtland Pear Fair.

Today, although still largely rural, the Delta is crisscrossed by interstate electric transmission lines, natural gas pipelines, and interstate roads and railroads; and it faces increasing pressure—at least on its periphery—for additional housing development. Those elements, combined with the increasing certainty of sea level rise and changing climate patterns, mean continual change for the Delta.

The Delta Problem

In California, sustainable management of the Delta is an exceedingly complex topic fraught with longstanding conflicts and challenges. The Delta and Suisun Marsh ecosystem is the largest estuary on the West Coast and a critical stopping point on the Pacific flyway. The estuary extends westward to the Golden Gate and southward to San Jose. Delta water also flushes southern San Francisco Bay. It is also the hub of the state's major water supply systems. But the Delta today is failing to balance the tradeoffs inherent in these functions, as well as to provide a place to live, work, and play for residents and visitors alike.

Today the Delta is relied upon for many services and, as a result, is not meeting the demands of farmers and urban water users who want assurances of supply and, in some cases, more water. Nor does the Delta adequately serve the needs of fish and wildlife—some threatened or endangered species' numbers remain perilously low. And the Delta itself remains inherently floodprone.

Fish Declines. In late 2004, scientists noted that several fish species in the upper San Francisco estuary (delta smelt, young striped bass, longfin smelt, and threadfin shad) had remained unusually low since 2001. Although the numbers had historically fluctuated, this steep and lasting dropoff signaled an ecological crisis. Scientists acknowledged many causes such as invasive and predatory species, upstream agricultural and urban runoff, and diminished Delta habitat. The export pumps of the SWP and CVP were culpable as well, and restrictions ensued.

Water Exports Cut. These regulatory and court-ordered restrictions on State and federal pumping, in combination with the 2007–2009 drought, significantly reduced exported water deliveries to SWP and CVP contractors. As a result, some San Joaquin Valley farmers pumped groundwater from already overtapped aquifers, fallowed fields, and, in some cases, plowed under permanent crops. The national economic recession, combined with reduced water deliveries, hit the San Joaquin Valley hard. Although the plight of farmers captured much media attention, the salmon fishery was shut down in 2008 and was restricted in 2009–2010, causing economic hardship for the commercial and recreational fishing industries. Urban water managers in the Bay Area and Southern California drew down storage and increased conservation efforts until the rains and snows of 2011 saved the day.

DELTA BY THE NUMBERS

- The 45,600-square-mile Delta watershed provides all or a portion of surface water or groundwater supplies to more than 27 million California residents.
- Approximately 8 percent of the state's water supply is exported from the Delta (DWR 2009).
- The Delta and Suisun Marsh support more than 55 fish species and more than 750 plant and wildlife species. Of these, approximately 100 wildlife species, 140 plant species, and 13 taxonomic units of fish are considered special-status species and are afforded some form of legal or regulatory protection (CNDDB 2010, USFWS 2010, CNPS 2010).
- The Delta and Suisun Marsh are home to more than one-half million residents living in dozens of communities, including portions of 12 incorporated cities such as Stockton and Sacramento, and support more than 146,000 jobs (DPC 2010).
- Approximately 57 percent of the Delta and Suisun Marsh—more than 480,000 acres of agricultural land—currently supports a highly productive agricultural industry that is valued at hundreds of millions of dollars annually (DWR 2007a, DWR 2007b, DOC 2008, DPC 2010).
- The Delta and Suisun Marsh levees and lands support interstate and state highways and railroad tracks that support intrastate and interstate traffic, more than 500 miles of major electrical transmission lines, 60 substations, and more than 400 miles of major natural gas pipelines that provide energy throughout Northern California, as well as critical pipelines that carry transportation fuels to airports and other fuel depots throughout the San Francisco Bay Area and Sacramento (DPC 2010, DWR 2009).
- The Delta and Suisun Marsh have more than 1,335 miles of levees that protect more than 800,000 acres of land and play a role in the water supplies conveyed through the Delta.
- The Delta experiences more than 12 million visitor days annually from recreational boaters (DPC 2012).* Fishing, hunting, birdwatching, and camping draw even more visitors to the area.

* The *Sacramento–San Joaquin Delta Boating Needs Assessment* (2000-2020) estimated 6.4 million annual boating-related visitor days and 2.13 million boating trips to the Delta in 2000 (DBW 2002).

DP-318

Lawsuits. Over the years, improved understanding about water quality needs and environmental protection in the Delta launched an era of complex regulation that today governs SWP and CVP water supply operations. Litigation over a host of issues related to the CVP and SWP has created a recent spate of water management actions guided by courtroom decisions. Incomplete understanding about how water project operations, pollution, invasive species, and other factors affect native Delta fish species has resulted in a regulatory scheme affecting water supplies that is characterized by uncertainty. Changing rules to curtail pumping and increase Delta outflow have compounded water supply uncertainty for agencies that use water conveyed through the Delta, particularly in drier years when ecosystem conflicts are most pronounced. Some of those agencies have contributed to the uncertainty by becoming increasingly reliant on Delta exports that were intended to be supplemental supplies, but in some cases are now relied upon as core water supplies.

Flood Threats. Adding to the complexity of these problems is the increasing volatility of Delta water supplies as a consequence of climate change, including more rain and less snow, earlier snowmelt, and higher winter and lower spring-summer runoff patterns. The potential for catastrophic levee failure in the Delta and the risk to residents and infrastructure alike posed by floods, sea level rise, earthquakes, and land subsidence is real, growing, and has outpaced the State's ability to manage and fund risk-reduction measures.

Pursuit of Balance. Finding the right balance of these competing needs and demands on the Delta has bedeviled California policy makers for decades. The media and the political system tend to focus on water supply shortages, droughts, flood risk, and the decline of fisheries. Although notable and consequential, these events are all symptoms of a greater resource problem. Not unlike other policy areas, when it comes to natural resource issues, California has long attempted to manage symptoms rather than treat core problems.

Governance and the Delta Reform Act of 2009

California has a history of addressing each problem with yet another project and/or program, each generally left to find its own way among all others already set in motion or completed. Today, more than 200 federal, State, regional, and local agencies have responsibility for some aspect of the Delta. As each agency focuses on its specific mission, cooperation, collaboration, and cohesiveness have at times been elusive.

Although the seeds were sown in governmental decisions throughout the early twentieth century, California's water "wars" came to a head during the years 1987 through 1992, when a 6-year drought in California slowed water deliveries, water quality deteriorated, and two fish species unique to the Delta—the delta smelt and winter-run Chinook salmon—were pushed to the brink of extinction. During these 6 drought years, average runoff to the state's two largest rivers dipped dramatically: 44 percent into the Sacramento River and 53 percent into the San Joaquin.

State and federal officials tried, often in conflict with each other, to deal with issues of water quality, protection of Delta fisheries, and water impacts on the state's urban and agricultural water users. In the early 1990s, endangered species listings by federal fish agencies imposed export restrictions on water users. SWRCB efforts to address aquatic resource degradation under State water laws ground to a halt after the governor complained about excessive federal interference under both the Endangered Species Act and the Clean Water Act. In 1991, the U.S. Environmental Protection Agency (USEPA) formally disapproved the SWRCB water quality control plan; and in 1992, Congress passed the Central Valley Project Improvement Act (CVPIA), which reallocated a significant portion of federal (CVP) water supplies to environmental purposes. Virtually every action taken by a State or federal agency during this period ended up in court.

Amid this chaos of competing interests and regulations, the cornerstone for future cooperation was laid when three long-time adversarial interests—environmentalists, agriculture, and urban water users—agreed to work together to find common ground. Four federal agencies—the USEPA, Bureau of Reclamation, National Marine Fisheries Service, and U.S. Fish and Wildlife Service—began collaboration on Delta issues and became known as "Club Fed." After being on the losing side of a 5-year-long State-federal tug of war over water quality standards, the State and federal administrations negotiated updated water quality standards and, in 1995, created the CALFED Bay-Delta Program.

After 5 years of negotiations and planning, the CALFED agencies completed an ambitious 30-year plan and record of decision heavily dependent on goodwill, generous State and federal funding, and Delta conditions remaining generally as they had in the immediate past. Instead, goodwill and funding evaporated in the face of fiscal crisis, scientists learned more about looming effects of climate change and emerging stressors on the Delta, and competing interests turned back to the courts to force one viewpoint or the other.

While CALFED attempted to bring a holistic focus, it was criticized for not having authority to hold individual agencies and projects accountable for interrelationships and progress and—toward the end of its first 7 years (Stage 1, 2000 through 2008)—for not being focused enough on the Delta. And yet the inescapable truth remains: actions that affect the Delta's ecosystem and its ability to provide a reliable amount of water for export are inextricably linked. The Delta Vision Task Force, created by then-Governor Arnold Schwarzenegger in 2006 to point the path forward from CALFED, reinforced the need for integration and linkage in both its 2008 *Vision for the Delta* and its *Strategic Plan*.

IS MORE GOVERNANCE REFORM NEEDED?

Senate Bill X7 1 (SBX7 1), which included the Delta Reform Act, enacted the most significant governance reform related to water and the Delta since the mid-twentieth century. Two new bodies were formed, the Sacramento-San Joaquin Delta Conservancy and the Council; the Delta Protection Commission was reorganized; and a new Delta Watermaster position was created at the SWRCB. However, some argue that governance change should not stop there.

In recent years, two nonpartisan and independent entities have proposed new water and Delta governance models, with the State's Little Hoover Commission (LHC) releasing reports in 2005 and 2010, and the Public Policy Institute of California (PPIC) releasing reports in 2007 and 2011.* Their conclusions are summarized here.

Little Hoover Commission: LHC is an independent state oversight agency established in 1962. It has a mission to identify and spur government reform in various policy areas, and has confronted the topic of water governance multiple times. In August 2010, LHC proposed dramatic restructuring of Delta and water governance in its report *Managing for Change: Modernizing California's Water Governance* (www.lhc.ca.gov).

Public Policy Institute of California: Established in 1994, the mission of PPIC is to inform and improve public policy in California through independent, objective, nonpartisan research. In 2011, PPIC released *Managing California's Water: From Conflict to Resolution* (Hanak et al. 2011), which focused more on thematic reforms building on current practices such as increasing urban water conservation and streamlining water transfers (www.ppic.org).

Although PPIC and LHC would remake water governance differently, both proposals have considerable thematic overlap:

- California lacks a system to adequately incorporate the needs of public trust resources with water supply management and planning.
- California lacks a centralized leadership structure to set statewide policy goals and manage inevitable conflicts.
- The institutional separation of water rights planning, administration, and enforcement responsibilities from water supply management complicates policy making.
- Insufficient incentives exist to promote regional cooperation and local consistency with State policy directions.
- There is concern that the demands of California Department of Water Resources' role in managing the SWP conflicts with its overall statewide water planning responsibilities.

This Delta Plan recommends governance reform related to regional Delta participation in flood management activities. As part of its role in coordinating overall efforts in the Delta, the Council will hold hearings and recommend additional governance reform to the Legislature.

** LHC 2005, LHC 2010, Lund et al. 2007, Hanak et al. 2011*

DP-180

The recommendations from the Delta Vision Task Force, along with general understanding and support from a wide variety of competing interest groups, allowed the Legislature, in 2009, to craft a package of bills that would, for the first time, begin to define those linkages in law and require accountability for implementation. In addition to the Delta Reform Act, the package included measures that set ambitious water conservation policy (20 percent reduction in statewide urban per capita water use by 2020), ensure better groundwater monitoring, and provide for increased enforcement to prevent illegal water diversions. It also included a bond measure that would help fund implementation of various parts of the package, and local and regional water supply and ecosystem projects.

The fifth bill in the package was Senate Bill X7 1 (SBX7 1), which included the Delta Reform Act. With its passage, California embarked upon a new era in Delta governance with creation of the Council, and established as overarching State policy coequal goals of a more reliable water supply for California and protecting, restoring, and enhancing the Delta ecosystem. Through its hybrid approach—both regulatory and collaborative—the Council now has the task of facilitating coordination across a broad range of entities to achieve the State's water policy objectives.

The Delta Reform Act includes an important caveat: while past Delta efforts focused almost exclusively on water supply reliability or ecosystem protection, the Delta Reform Act requires that the coequal goals be achieved in a manner that protects and enhances the unique cultural, recreational, natural resource, and agricultural values of the Delta as an evolving place.

In addition, the Delta Reform Act recognized the need to change the way the Delta is viewed, asking not what can be taken, but instead what can be given back. Thus, the Legislature established that the policy of the State is to reduce reliance on the Delta in meeting future water supply needs through a statewide strategy of investing in improved regional supplies, conservation, and water use efficiency. The Delta Reform Act specifies that each region depending on water from the Delta watershed shall improve its regional self-reliance for water through investment in water use efficiency, water recycling, advanced water technologies, local and regional water supply projects, and improved regional coordination of local and regional water supply efforts.

Finally, in a distinct departure from CALFED and the status quo of disparate agencies struggling to tackle complex modern resource problems, the Council was established with the authority and responsibility to develop a legally enforceable Delta Plan, and to coordinate and collaborate across the myriad governmental agencies that have responsibility for some aspect of the Delta. The Council also was charged with ensuring that actions by State and local agencies in the Delta are consistent with the Delta Plan, and adequately incorporate the best available science and adaptive management principles.

The Delta Plan

The foundation of the Delta Reform Act is the adoption of the coequal goals and direction to the Council to develop an enforceable Delta Plan to further those goals. Figure 1-4 shows the primary area covered by the Delta Plan, including features and uses referred to in policies and recommendations. Accordingly, the Council presents a Delta Plan that is practical, foundational, integrated, and adaptive:

- **Practical:** The Delta Plan builds on years of planning efforts and incorporates actions, recommendations, and strategies developed by other entities—governmental and nongovernmental—that have already invested countless hours on Delta issues and have specialized expertise.
- **Foundational:** The Delta Plan addresses intertwined challenges and establishes foundational actions for Delta management throughout this century. It lays the groundwork for near-term actions for improvement and focuses on the immediate avoidance of further harm or increased risk to the Delta. The Delta Plan shines a spotlight on urgently needed Delta habitat projects and the significant potential for local and regional water supply development. Similarly, the Delta Plan seeks to immediately halt practices known to be detrimental to the sustainability of the Delta's many functions and services.
- **Integrated:** The Delta Plan establishes an open and accountable governance mechanism for coordinating actions across agency jurisdictions and statutory objectives.

The Delta Plan

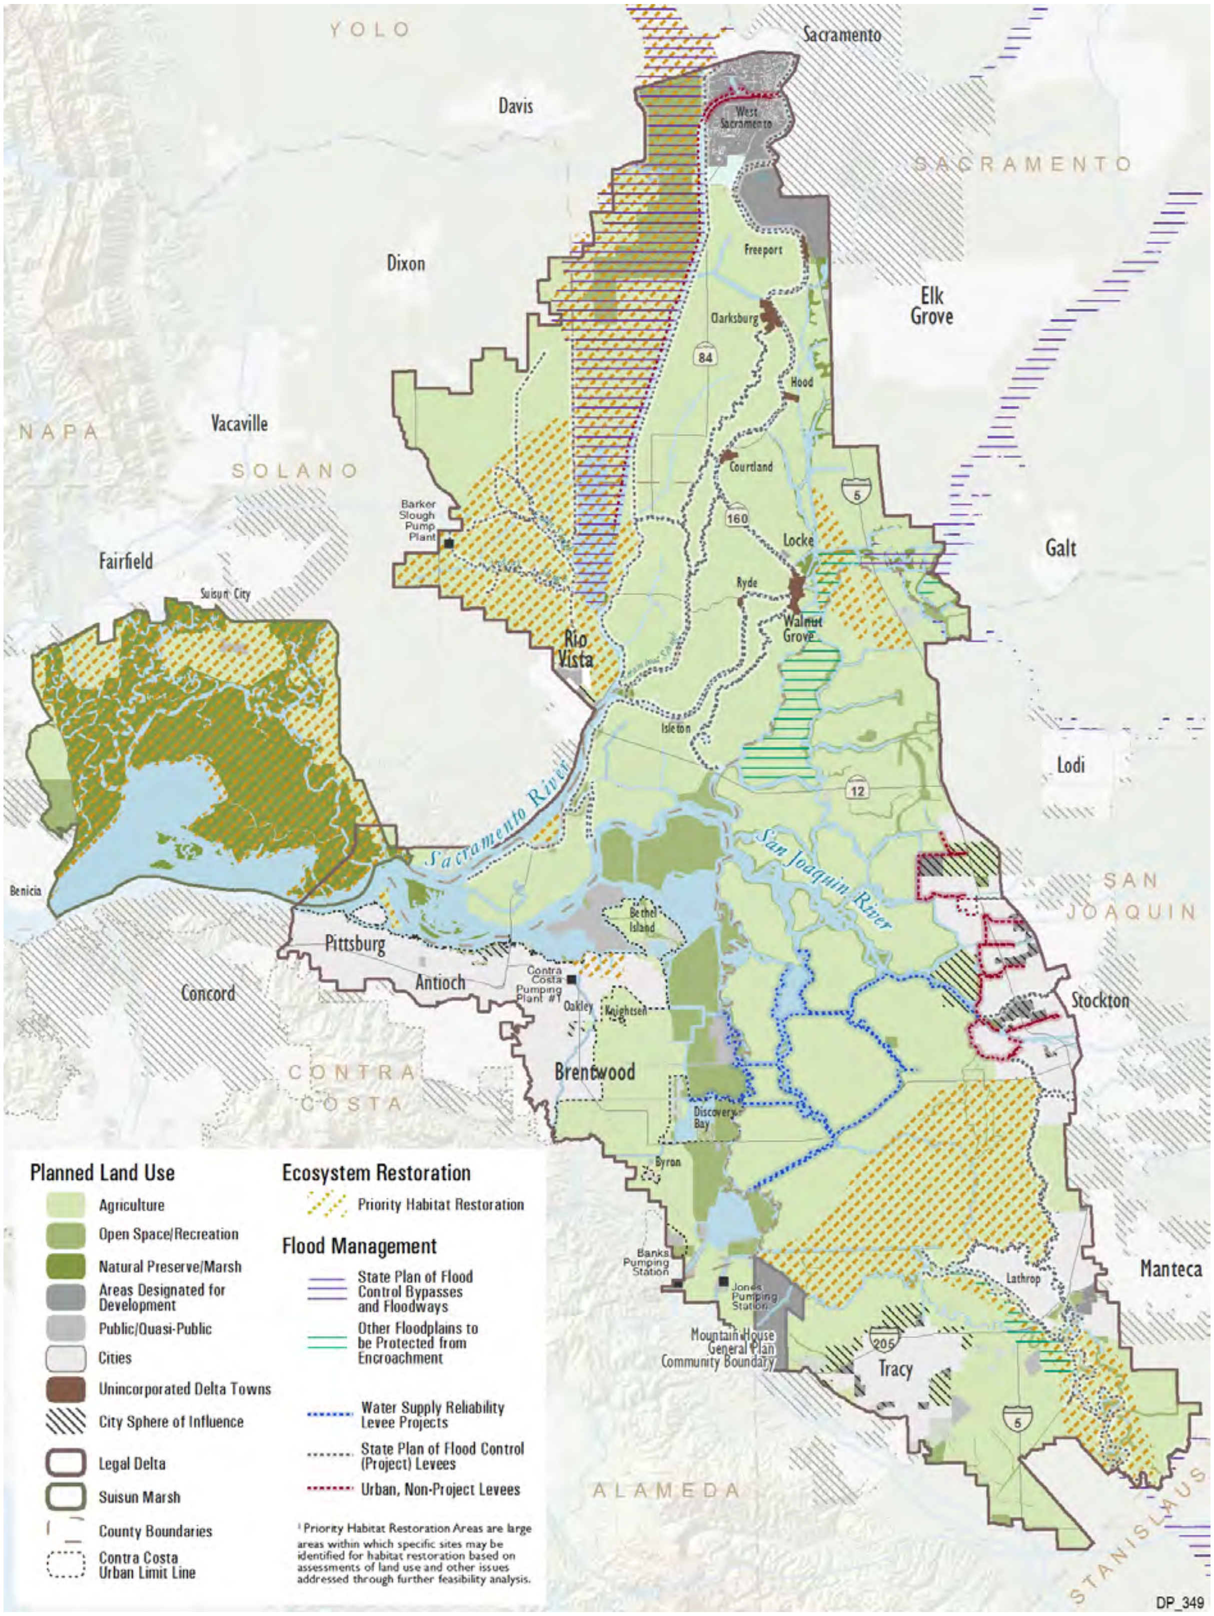

Figure 1-4 The map shows land uses designated by city and county general plans. Within cities' spheres of influences (SOIs), the map shows land use designations proposed in city general plans, where available. In cases where cities have not proposed land uses within their SOIs, the map shows land uses designated by county general plans.

Sources: City of Benicia 2003, Contra Costa County 2008, Contra Costa County 2010, DWR 2011b, DWR 2011c, DWR 2011d, City of Fairfield 2008, Jones & Stokes 2007, City of Lathrop 2012, City of Manteca 2012, Mountain House Community Services District 2008, City of Rio Vista 2001, SACOG 2009, City of Sacramento 2008, Sacramento County 2011, Sacramento County 2013, Sacramento County 2013, San Joaquin County 2008a, San Joaquin County 2008b, Solano County 2008a, Solano County 2008b, South Delta Levee Protection and Channel Maintenance Authority 2011, City of Stockton 2011a, City of Stockton 2011b, City of Suisun City 2011, City of Tracy 2011, City of Stockton 2011b, City of West Sacramento 2010, Yolo County 2010a, Yolo County 2010b.

- **Adaptable:** The Delta Plan sets direction through policies and recommendations and can incorporate other plans and new information as it becomes available. Informed by science and consistent monitoring, portions of the Delta Plan that do not adequately meet or make progress toward stated goals over time will be refined or revised. The Delta Plan will be updated at least every 5 years, and likely sooner, given the major changes facing the Delta under the Bay Delta Conservation Plan (BDCP) and the Council's commitment to Delta levee prioritization.

It is inevitable that the Delta Plan will generate controversy. This Delta Plan integrates existing State and federal laws and policies and ongoing programs, and is informed by the best available science to chart a course to further the coequal goals. The Council is one of many agencies with an interest in the Delta, and it was not granted unlimited authority over actions related to water supply and the environment. Specific and targeted authority and actions, however, were included by the Delta Reform Act; these form the basis for the Delta Plan's enforceable policies and nonenforceable recommendations.

The Delta Plan's policies and recommendations are based on the following imperatives:

- **Act now.** We have been studying the problems of California's water supply and the declining Delta ecosystem for decades. While all parties agree the *status quo* is not acceptable, failure to take action only prolongs a worsening *status quo*. Near-term actions must move forward while the long-term conveyance, storage, and ecosystem solutions are being decided over the next 5, 10, and 15 years. Waiting is NOT an option. We must continue to invest in the Delta ecosystem and in the improvement of California's water supplies and water use efficiency.
- **Success depends on integrated approaches and awareness of tradeoffs.** Tradeoffs are inherent in managing a supply for multiple benefits. Water exports out of the Delta can harm the ecosystem unless carefully managed. Protecting the Delta as a place means focusing development in urban areas to reduce effects on agricultural land, and risk to people, property, and state interests. Multiple stressors affect the ecosystem in ways that are not yet fully understood and which may be impossible to completely control. The most effective actions will depend upon the coordinated actions of multiple actors.
- **Improve water supply reliability.** Fundamentally, water supply reliability means that California must better match its demands for and use of water to the available supply. Everyone in California must conserve water and must increase their efforts to do so. New surface and groundwater storage is necessary to manage the timing of water for people and for fish. Done right, additional storage can make efficient water management possible and better allow for water use that is wildlife friendly. Improved Delta conveyance, including successful completion of the BDCP, is essential; and it should be done as soon as possible.
- **Commit to Delta ecosystem restoration.** We must preserve land in the Delta for future habitat restoration, and we must immediately begin restoration efforts on long-studied priority areas. In the Delta, the conflict between the way we move water and the health of native species must be resolved. A successfully permitted BDCP is key to that, including water quality objectives updated by the SWRCB for beneficial uses including the Delta's ecosystem. Without adequate water flow (the right mix of timing and amount), we cannot expect fisheries to recover, no matter how well we deal with the range of other stressors.
- **Preserve Delta as a place.** The Delta serves many demands, but we must preserve and protect a unique sense of place distinguished by geography, legacy communities, a rural and agricultural setting, vibrant natural resources, and a mix of economic and recreational activities.

What the Delta Plan Will Achieve

The Delta Plan seeks to further the coequal goals and their inherent objectives in the face of dramatically changing conditions. The Delta of 2100 likely will be very different from the Delta of today (see Table 1-1 for examples of anticipated changes). Some of the changes will be intentional or predictable, and others will be unintended and surprising. Changes are likely or expected to result from population growth, climate change and sea level rise, land subsidence, and earthquakes—most beyond human ability or willingness to control. Human-made changes in land use and water use are also expected to continue.

All of this will involve tradeoffs between competing—in some cases, mutually exclusive—values, goals, and objectives. The Delta Plan seeks to ensure that these decisions are made in a timely and open manner, and based on best available information and science as a predictor of the future. The law requires that the Delta Plan be updated every 5 years, and each update is intended to build on an evolving base of knowledge, directing near- and mid-term actions, and preserving and protecting longer-term opportunities as yet unknown.

Summary of Anticipated Changes Affecting the Delta by 2050 and 2100

TABLE 1-1

Anticipated Change	Change Predicted by 2050	Change Predicted by 2100
Population of California[a]	Increase from 37.2 million in 2010 to 51 million	Continued increase in population
San Francisco Bay/East Bay Area earthquake affecting Delta by 2032[b]	63% probability of at least one magnitude 6.7 or greater earthquake	
Probability of island flooding from high water, relative to 2005 conditions[c]	In range of 200% increase (medium risk scenario)	In range of 450% increase (medium risk scenario)
Increased weather variability, including longer-term droughts[d]	Models and analyses of tree rings and other evidence back to the year 800 suggest greater variability and long periods of drought, especially for the Colorado River Basin, a current source of some water to California.	
Sea level rise, relative to 2000[e]	14 inches	55 to 65 inches
Snow pack, relative to 1956–2000 average of 15 MAF[f]	Reduction of 25% (4.5 MAF) to 40% (6 MAF)	Continued reduction expected

MAF: million acre-feet

The Delta Plan lays out 14 regulatory policies and 73 recommendations that start the process of addressing the current and predicted ecological, flood management, water quality, and water supply reliability challenges. As required by statute, the Delta Plan adopts a science-based adaptive management strategy to manage decision making in the face of uncertainty (Water Code section 85308(f)). All of these changes—some foreseeable, some not—will create a dynamic context in which the Delta Plan must adapt.

Over the life of the Delta Plan, the coequal goals of providing a more reliable water supply for California and restoring the Delta ecosystem are the foundation of all State water management policies. No water rights decisions or water contracts that directly or indirectly impact the Delta are made without consideration of the coequal goals. Over time, balanced application of the Public Trust Doctrine and the California Constitution, Article 10, Section 2 (requirements for beneficial use, reasonable water use, and no waste), have produced optimized water use, including high levels of water use efficiency and protection of public trust resources throughout the state. California has a comprehensive, fully integrated system for tracking and evaluating actual water use and water quality for both surface water and groundwater supplies.

The Delta Plan seeks first to arrest declining water reliability and environmental conditions related to the Delta ecosystem, and ultimately to improve them. It seeks to achieve a more resilient ecosystem that can absorb and adapt to current and future effects of multiple stressors. Additionally, it seeks to reduce flood risk, improve water quality, increase recreation opportunities in the Delta, and protect Delta legacy communities. Generally speaking, these are long-term goals to reduce and reverse increasing long-term environmental impacts caused by inaction. The vision of the Delta in 2100 will be realized through a series of near-term and longer-term actions informed by performance measures and overall adaptive management.

By 2100:

- **California's water supply** will be considerably more efficient, local and regional projects will be online to increase supplies and meet the demands of a growing population, and storage will have increased to meet the challenge of climate change and the needs of water transfer systems. Regions reliant on receiving some portion of their water from the Delta watershed will have reduced their reliance and improved regional self-reliance through increased conservation and diversification of their local and regional sources of supply. Delta conveyance will be managed in an adaptive manner that successfully balances ecosystem restoration and protection with more reliable water deliveries. Water quality in the Delta will support a healthy ecosystem and the multiple beneficial uses of water, including municipal supply and recreational uses such as fishing and swimming.
- **The Delta and Suisun Marsh ecosystem** will have the capacity to provide the environmental and societal benefits the public demands (viable populations of desired species, wild habitats for recreation and solace, land for agriculture, and the conveyance of reliable and high-quality fresh water). Large areas of the Delta will be restored in support of a healthy estuary. A diverse mosaic of interconnected habitats will be re-established in the Delta and its watershed. Migratory corridors for fish, birds, and terrestrial wildlife will be largely protected and restored. Actions have been taken to ensure that sufficient freshwater flows following a more natural, functional hydrograph are now dedicated to support a healthy ecosystem. Actions have reduced the impacts caused by stressors such as invasive species, poor water quality, loss of habitat, and urban development, resulting in improved conditions for native species of fish, birds, and wildlife that depend on the Delta and its watershed.

BDCP1738.

- **The Delta itself** will be a safe, nationally recognized and vibrant place, with well-defined cities and towns, a strong agricultural sector, and a well-deserved reputation as a recreational destination. Despite an increase in sea levels and altered runoff patterns, risks will be reduced, and residents and agencies will be prepared to respond when floods threaten. In 2100, the Delta will retain its rural heritage and be a place where agricultural, recreational, and environmental uses are uniquely integrated and continue to contribute in important ways to the regional economy.

Timeline for Implementing Priority Actions of the Delta Plan

Figure 1-5 contains a timeline for implementing the priority actions contained in the Delta Plan. The timeline emphasizes near-term and intermediate-term actions. In some instances, precedent or complementary actions need to be undertaken by other agencies or entities to ensure success of the Delta Plan.

Priority Action Timeline

TIMELINE

CHAPTER 1: Priority Actions

	ACTION (REFERENCE #)	LEAD AGENCY(IES)	NEAR TERM 2012–2017	INTERMEDIATE TERM 2017–2025	ACTION DEPENDS ON
POLICIES	**Reduce reliance on the Delta through improved regional water self-reliance** (WR P1)	Council, DWR, SWRCB	●	●	State, local water agency cooperation and compliance
	Delta flow objectives (ER P1)	SWRCB	●	●	SWRCB completes on time
	Prioritization of State investments in Delta levees and risk reduction (RR P1)	Council, DWR	●	●	Council completion; legislative adoption and implementation
RECOMMENDATIONS	**Update Delta flow objectives** (ER R1)	SWRCB	●	●	SWRCB completes on time
	Prioritize and implement projects that restore Delta habitat (ER R2)	DFW, DWR, Delta Conservancy	●	●	Funding, multiagency cooperation
	Designate the Delta as a National Heritage Area (DP R1)	DPC	●		Federal action, Congress
	Finance local flood management activities (RR R2)	DPC	●	●	
	Actions for the prioritization of State investments in Delta levees (RR R4)	Council, DWR	●		Council completion; legislative adoption and implementation
	Complete Bay Delta Conservation Plan (WR R12)	DWR, Council incorporates	●	●	State, federal agency action
	Complete surface water storage studies (WR R13)	DWR	●	●	
	Completion of regulatory processes, research, and monitoring for water quality improvements (WQ R8)	SWRCB, RWQCBs	●		
	Development of a Delta Science Plan (G R1)	Council	●	●	
OTHER	Complete Delta Finance Plan	Council	●		Ongoing funding
	Initiate Delta Plan Interagency Implementation Committee	Council	●	●	Agency cooperation
	Evaluate and update Delta Plan	Council	●		Ongoing funding

Agency Key:

Council: Delta Stewardship Council
Delta Conservancy: Sacramento-San Joaquin Delta Conservancy
DFW: California Department of Fish and Wildlife
DPC: Delta Protection Commission
DWR: California Department of Water Resources
RWQCB: Regional Water Quality Control Board
SWRCB: State Water Resources Control Board

Figure 1-5

Organization of the Delta Plan

The Delta Plan is organized around the coequal goals and specific subgoals, strategies, actions, and measures set forth in the Delta Reform Act. The following chapters describe in detail the problems, expected outcomes, and performance measures associated with the various policies and recommendations:

- Chapter 2, The Delta Plan
- Chapter 3, A More Reliable Water Supply for California
- Chapter 4, Protect, Restore, and Enhance the Delta Ecosystem
- Chapter 5, Protect and Enhance the Unique Cultural, Recreational, Natural Resource, and Agricultural Values of the California Delta as an Evolving Place
- Chapter 6, Improve Water Quality to Protect Human Health and the Environment
- Chapter 7, Reduce Risk to People, Property, and State Interests in the Delta

In addition, Chapter 8, Funding Principles to Support the Coequal Goals, provides history and background for water project and program financing by discussing various funding schemes and by providing some current data on water-related expenditures in California. It also outlines guiding principles for developing stable financing for Delta Plan implementation and describes urgently needed near-term funding requirements for certain critical activities.

CHAPTER 2

The Delta Plan

ABOUT THIS CHAPTER

This chapter discusses the purpose and role of the Delta Stewardship Council (Council) in the context of Sacramento-San Joaquin Delta (Delta) governance. It also describes the Council's approach to developing, implementing, and updating the Delta Plan, all within the framework of adaptive management. It describes why best available science and adaptive management are particularly important tools in the Delta, and proposes the development of a new Delta Science Plan to aid in the coordination and focus of science efforts across agencies. For State of California (State) or local agencies that propose a plan, program, or project occurring in whole or in part in the Delta, this chapter contains a description of the regulatory application of the Delta Plan. For instance:

- What is a covered action?
- Certifications of consistency
- Covered action consistency appeals

The chapter includes one policy and one recommendation.

RELEVANT LEGISLATION

The Sacramento-San Joaquin Delta Reform Act of 2009 established the Delta Stewardship Council to achieve more effective governance while providing for the sustainable management of the Delta ecosystem and a more reliable water supply, using an adaptive management framework, as reflected in the Water Code sections below.

> *85001 (c) By enacting this division, it is the intent of the Legislature to provide for the sustainable management of the Sacramento-San Joaquin Delta ecosystem, to provide for a more reliable water supply for the state, to protect and enhance the quality of water supply from the Delta, and to establish a governance structure that will direct efforts across state agencies to develop a legally enforceable Delta Plan.*
>
> *85020 (h) Establish a new governance structure with the authority, responsibility, accountability, scientific support, and adequate and secure funding to achieve these objectives.*
>
> *85022 (a) It is the intent of the Legislature that state and local land use actions identified as "covered actions" pursuant to Section 85057.5 be consistent with the Delta Plan. This section's findings, policies, and goals apply to Delta land use planning and development.*
>
> *85052 "Adaptive management" means a framework and flexible decision making process for ongoing knowledge acquisition, monitoring, and evaluation leading to continuous improvement in management planning and implementation of a project to achieve specified objectives.*
>
> *85204 The council shall establish and oversee a committee of agencies responsible for implementing the Delta Plan. Each agency shall coordinate its actions pursuant to the Delta Plan with the council and the other relevant agencies.*
>
> *85211 The Delta Plan shall include performance measurements that will enable the council to track progress in meeting the objectives of the Delta Plan. The performance measurements shall include, but need not be limited to, quantitative or otherwise measurable assessments of the status and trends in all of the following:*
>
> > *(a) The health of the Delta's estuary and wetland ecosystem for supporting viable populations of aquatic and terrestrial species, habitats, and processes, including viable populations of Delta fisheries and other aquatic organisms.*
> >
> > *(b) The reliability of California water supply imported from the Sacramento River or the San Joaquin River watershed.*
>
> *85225.5 To assist state and local public agencies in preparing the required certification, the council shall develop procedures for early consultation with the council on the proposed covered action.*
>
> *85225.10 (a) Any person who claims that a proposed covered action is inconsistent with the Delta Plan and, as a result of that inconsistency, the action will have a significant adverse impact on the achievement of one or both of the coequal goals or implementation of government-sponsored flood control programs to reduce risks to people and property in the Delta, may file an appeal with regard to a certification of consistency submitted to the council.*
>
> > *(b) The appeal shall clearly and specifically set forth the basis for the claim, including specific factual allegations, that the covered action is inconsistent with the Delta Plan. The council may request from the appellant additional information necessary to clarify, amplify, correct, or otherwise supplement the information submitted with the appeal, within a reasonable period.*
> >
> > *(c) The council, or by delegation the executive officer, may dismiss the appeal for failure of the appellant to provide information requested by the council within the period provided, if the information requested is in the possession or under the control of the appellant.*
>
> *85300(c) The council shall review the Delta Plan at least once every five years and may revise it as the council deems appropriate. The council may request any state agency with responsibilities in the Delta to make*

recommendations with respect to revision of the Delta Plan.

(d) (1) The council shall develop the Delta Plan consistent with all of the following:

(A) The federal Coastal Zone Management Act of 1972 (16 U.S.C. Sec.1451 et seq.), or an equivalent compliance mechanism.

(B) Section 8 of the federal Reclamation Act of 1902.

(C) The federal Clean Water Act (33 U.S.C. Sec. 1251 et seq.).

(2) If the council adopts a Delta Plan pursuant to the federal Coastal Zone Management Act of 1972 (16 U.S.C. Sec. 1451 et seq.), the council shall submit the Delta Plan for approval to the United States Secretary of Commerce pursuant to that act, or to any other federal official assigned responsibility for the Delta pursuant to a federal statute enacted after January 1, 2010.

85300(a) The Delta Plan shall include subgoals and strategies to assist in guiding state and local agency actions related to the Delta.

85302(e) The following subgoals and strategies for restoring a healthy ecosystem shall be included in the Delta Plan:

(1) Restore large areas of interconnected habitats within the Delta and its watershed by 2100.

(2) Establish migratory corridors for fish, birds, and other animals along selected Delta river channels.

(3) Promote self-sustaining, diverse populations of native and valued species by reducing the risk of take and harm from invasive species.

(4) Restore Delta flows and channels to support a healthy estuary and other ecosystems.

(5) Improve water quality to meet drinking water, agriculture, and ecosystem long-term goals.

(6) Restore habitat necessary to avoid a net loss of migratory bird habitat and, where feasible, increase migratory bird habitat to promote viable populations of migratory birds.

85300(a) The Delta Plan may also identify specific actions that state or local agencies may take to implement the subgoals and strategies.

85302(a) Implementation of the Delta Plan shall further the restoration of the Delta ecosystem and a reliable water supply.

85302(b) The Delta Plan may include recommended ecosystem projects outside the Delta that will contribute to achievement of the coequal goals.

85302(c) The Delta Plan shall include measures that promote all of the following characteristics of a healthy Delta ecosystem:

(1) Viable populations of native resident and migratory species.

(2) Functional corridors for migratory species.

(3) Diverse and biologically appropriate habitats and ecosystem processes.

(4) Reduced threats and stresses on the Delta ecosystem.

(5) Conditions conducive to meeting or exceeding the goals in existing species recovery plans and state and federal goals with respect to doubling salmon populations.

85302(d) The Delta Plan shall include measures to promote a more reliable water supply that address all of the following:

(1) Meeting the needs for reasonable and beneficial uses of water.

(2) Sustaining the economic vitality of the state.

(3) Improving water quality to protect human health and the environment.

85302(h) The Delta Plan shall include recommendations regarding state agency management of lands in the Delta.

85303 The Delta Plan shall promote statewide water conservation, water use efficiency, and sustainable use of water.

85304 The Delta Plan shall promote options for new and improved infrastructure relating to the water conveyance in the Delta, storage systems, and for the operation of both to achieve the coequal goals.

85305(a) The Delta Plan shall attempt to reduce risks to people, property, and state interests in the Delta by promoting effective emergency preparedness, appropriate land uses, and strategic levee investments.

85305(b) The council may incorporate into the Delta Plan the emergency preparedness and response strategies for the Delta developed by the California Emergency Management Agency pursuant to Section 12994.5.

85306 The council, in consultation with the Central Valley Flood Protection Board, shall recommend in the Delta Plan priorities for state investments in levee operation, maintenance, and improvements in the Delta, including both levees that are a part of the State Plan of Flood Control and nonproject levees.

85307(a) The Delta Plan may identify actions to be taken outside of the Delta, if those actions are determined to significantly reduce flood risks in the Delta.

85307(b) The Delta Plan may include local plans of flood protection.

85307(c) The council, in consultation with the Department of Transportation, may address in the Delta Plan the effects of climate change and sea level rise on the three state highways that cross the Delta.

85307(d) The council, in consultation with the State Energy Resources Conservation and Development Commission and the Public Utilities Commission, may incorporate into the Delta Plan additional actions to address the needs of Delta energy development, energy storage, and energy distribution.

85308 The Delta Plan shall meet all of the following requirements:

> *(a) Be based on the best available scientific information and the independent science advice provided by the Delta Independent Science Board.*
>
> *(b) Include quantified or otherwise measurable targets associated with achieving the objectives of the Delta Plan.*
>
> *(c) Where appropriate, utilize monitoring, data collection, and analysis of actions sufficient to determine progress toward meeting the quantified targets.*
>
> *(d) Describe the methods by which the council shall measure progress toward achieving the coequal goals.*
>
> *(e) Where appropriate, recommend integration of scientific and monitoring results into ongoing Delta water management.*
>
> *(f) Include a science-based, transparent, and formal adaptive management strategy for ongoing ecosystem restoration and water management decisions.*

This page intentionally left blank.

CHAPTER 2

The Delta Plan

No single entity in California has the sole responsibility or authority for managing water supply and the Delta ecosystem. Instead, authority, expertise, and resources are spread out among a cadre of federal, State, and local agencies, with no single government agency empowered to provide leadership or a long-term vision. This is why governance reform enacted by the Delta Reform Act is fundamentally different from past approaches to managing the Delta. The milestone legislation created the Council, and gave it the direction and authority to serve two primary governance roles: (1) set a comprehensive, legally enforceable direction for how the State manages important water and environmental resources in the Delta through the adoption of a Delta Plan, and (2) ensure coherent and integrated implementation of that direction through coordination and oversight of State and local agencies proposing to fund, carry out, and approve Delta-related activities.

Recommended in significant part by the Delta Vision Task Force effort in 2008, this new approach is different from governance attempts over the past several decades that have tried, but largely failed, to provide effective and stable leadership. The *Delta Vision Strategic Plan* referred to some 200 agencies that play some role in managing the Delta's varied resources (Delta Vision 2008). One of the major goals articulated in that strategic plan was the establishment of a new governance structure with sufficient authority, responsibility, accountability, science support, and secure funding to achieve the coequal goals of providing a more reliable water supply for California and protecting, restoring, and enhancing the Delta ecosystem. The creation of the independent Council was a significant step toward implementing this goal. The Council is made up of seven members who provide a broad, statewide perspective and diverse expertise, and is advised by a 10-member board of nationally and internationally renowned scientists, the Delta Independent Science Board (ISB). The Delta Reform Act instructs the Council to "direct efforts across state agencies," but considerable challenges lie ahead in coordinating and supporting the multitude of agencies to achieve the goals of the Delta Plan.

The first major task for the newly created Council is the development of this Delta Plan. The Delta Reform Act requires the Council to develop and adopt a legally enforceable, long-term management plan for the Delta that uses best available science and is built upon the principles of adaptive management. The Delta Reform Act also established the Delta Science Program within the Council to provide the best possible unbiased scientific information to inform water and environmental decision making in the Delta. Because California's Delta is linked to so many statewide issues, described in Chapter 1, the Delta Plan's scope and purview encompasses statewide water use, flood management, and the Delta watershed, but with a specific focus on the legal Delta and Suisun Marsh. The Delta Plan contains a set of regulatory policies that will be enforced by the Council's appellate authority and oversight, described in this chapter. These regulatory policies and supporting documents are contained in Appendix B. The Delta Plan also contains priority recommendations, which are nonregulatory but call out actions essential to achieving the coequal goals. The Council has chosen to apply its regulatory authority in a targeted manner, and does so in an effort to ensure that all significant activities occurring in whole or in part in the Delta become better aligned over time with State policy priorities, including—and especially—the achievement of the coequal goals. The process for demonstrating compliance with Delta Plan policies is described in detail in this chapter.

In developing the first Delta Plan, the Council sought extensive public, stakeholder, and government agency input and, based on that input, developed the foundational set of policies and recommendations detailed in the following chapters to guide actions over the first few years of Plan implementation. Every stage of implementing the Delta Plan will necessitate leadership by the Council and ongoing coordination across a broad range of agencies, nongovernmental entities, and stakeholders.

The Delta Stewardship Council

As described in Chapter 1, the Delta of today is the result of centuries of natural and human-made actions and reactions. Government historically has worked to treat individual problems rather than adopt a systemwide approach. Dozens of agencies, task forces, and working groups have struggled to find the right combination of policy, science, and structure to address what are now California's fundamental goals for managing the Delta, the coequal goals.

The mission of the Council is to further the achievement of the coequal goals. To do so, the Council was charged with the development of a legally enforceable, long-term management plan for the Delta. To accomplish this, the Council will apply a common-sense approach based on a strong scientific foundation in an adaptive management framework to protect and restore the Delta ecosystem; improve the quality and reliability of California's water supplies; reduce risk to people, property, and State interests; and protect and enhance the Delta as an evolving place.

The Council's most important and challenging role is the facilitation, coordination, and integration of a range of actions and policies in support of the coequal goals. Implementation will occur through the Council's leadership of a formal Interagency Implementation Committee, ongoing informal staff-to-staff agency coordination, development of science to support the Delta Plan, and use of the Council's various authorities to ensure progress and accountability in how the Delta is managed. See Table 2-1 for a reference list of agencies with responsibilities in the Delta or related to the management of the Delta.

In addition to its role in setting State policy for the Delta in the Delta Plan, and in facilitating and coordinating agencies to achieve policy objectives, the Council was granted specific regulatory and appellate authority over certain actions that take place in whole or in part in the Delta. To do this, the Delta Plan contains a set of regulatory policies with which State and local agencies are required to comply. The Delta Reform Act specifically established a certification process for compliance with the Delta Plan. This means that State and local agencies that propose to carry out, approve, or fund a qualifying action in whole or in part in the Delta, called a "covered action," must certify that this covered action is consistent with the Delta Plan and must file a certificate of consistency with the Council that includes detailed findings. This process is described in the section "Covered Actions and Delta Plan Consistency" later in this chapter.

Agencies with Responsibilities in the Delta

TABLE 2-1

State	
Delta Stewardship Council	Established in 2009 by the Delta Reform Act to further the achievement of the coequal goals through the development and implementation of a legally enforceable Delta Plan.
California Department of Fish and Wildlife	Provides fish and wildlife protection and management, including management of wildlife areas and ecological reserves, public access, conservation planning, permitting, and implementation of the Ecosystem Restoration Program.
California Department of Water Resources	Owns and operates the State Water Project (which stores water upstream and conveys water through the Delta), has emergency response and flood planning responsibilities, holds water quality/supply contracts with Delta water agencies, and coordinates overall statewide water planning.
Delta Protection Commission	Prepares a comprehensive long-term resource management plan for land uses within the approximate 500,000-acre Primary Zone. Local government plans must be consistent.
Sacramento-San Joaquin Delta Conservancy	A primary State agency to implement ecosystem restoration in the Delta and also to assist/protect the region's agricultural, cultural, economic, and historical value.
State Water Resources Control Board	Required to develop in 2010 nonregulatory flow criteria for the Delta ecosystem necessary to protect public trust uses to inform planning proceedings for the Delta Plan and Bay Delta Conservation Plan (BDCP). Responsible for developing and implementing the Bay-Delta Water Quality Control Plan to establish water quality objectives, including flow objectives, to ensure reasonable protection of beneficial uses in the Bay-Delta. Responsible for establishing, implementing, and enforcing water right requirements to ensure the proper allocation and efficient use of water in and out of the Delta, including the role of the Delta Watermaster and implementation of the Bay-Delta Water Quality Control Plan. With regional boards, responsible for developing and implementing other water quality standards and control plans consistent with State and federal laws to reasonably protect aquatic beneficial uses.
California Emergency Management Agency	Plans, prepares emergency response, and coordinates the activities of all State agencies in connection to an emergency in the Delta; provides resources if local agencies are overwhelmed.
Central Valley Flood Protection Board	Plans flood control along the Sacramento and San Joaquin rivers and their tributaries in cooperation with the U.S. Army Corps of Engineers.
Office of the Delta Watermaster	Created in 2009 to oversee day-to-day administration of water rights, enforcement activities, and reports on water right activities regarding diversions in the Delta.
California Natural Resources Agency	Coordinates with a group of local water agencies, environmental and conservation organizations, State and federal agencies, and other interest groups developing the BDCP, a conservation strategy to be compliant with the Endangered Species Act (ESA) and Natural Community Conservation Planning Act, to be implemented over the next 50 years.
Other State agencies	Have various roles or responsibilities in the Delta relevant to the agency's concern (for example, California Department of Food and Agriculture, California Department of Transportation, California State Parks, California Department of Boating and Waterways, State Lands Commission, California Environmental Management Agency, and others).

Agencies with Responsibilities in the Delta

TABLE 2-1

Federal	
Bureau of Reclamation	Owns and operates the Central Valley Project, which, among other activities, pumps water through and out of the Delta.
U.S. Fish and Wildlife Service	Develops plans for the conservation and recovery of fish and wildlife resources, and addresses the variable needs of fish and wildlife pursuant to the ESA.
U.S. Army Corps of Engineers	Involved with both federal and nonfederal partners in assessing channel navigation, ecosystem, and flood risk management projects in the Delta. Works cooperatively with its nonfederal partners regarding the regulation, maintenance, and improvement of project levees in the Delta.
National Marine Fisheries Service	Develops plans for the conservation and recovery of salmonids in the Delta pursuant to the ESA.
U.S. Environmental Protection Agency	Responsible for protection and restoration of water quality in the Delta, pursuant to the Clean Water Act, which regulates the discharge of pollutants into waterways and sets standards for water quality. Oversees implementation of Clean Water Act programs and policies delegated to the State.
Other federal agencies	Various roles or responsibilities in the Delta relevant to the agency's concern (for example, U.S. Department of Agriculture, Natural Resources Conservation Service, and others).
Local	
Hundreds of local reclamation districts, resource conservation districts, water districts, city and county governments, and other special districts.	

DP-177

To be effective, governance to support science and implement adaptive management for a changing Delta must be flexible and have the capacity to change policies and practices in response to what is learned over time. An adaptive management approach as detailed in this chapter will ensure that the Delta Plan is updated as often as necessary to incorporate new information or modify policies and recommendations to ensure achievement of the coequal goals. The following section discusses the particular importance of science and adaptive management as they relate to the Delta.

Science and Adaptive Management in the Delta

The Delta Reform Act requires that the Delta Plan be based on and implemented using the best available science, and requires the use of science-based, transparent, and formal adaptive management strategies for ongoing ecosystem restoration and water management decisions. This section describes the importance of science, especially as it relates to the Delta, describes how the Delta Plan itself uses an adaptive management plan, and proposes the development of a Delta Science Plan as a companion to the Delta Plan.

The State of Bay-Delta Science report concluded that most of the decision making in the Delta was occurring on the basis of a false understanding that the Delta was a static system, and that "the Delta of the future would be much the same as the Delta of today" (Healey et al. 2008). Science indicates that significant changes are expected in the Delta over the coming decades, including climate change and the potential for earthquakes and flooding, as described in Chapter 1. In addition, current planning processes for habitat restoration, changes to water conveyance in the Delta, urban expansion, and other human drivers could reshape the Delta as we know it today.

The State of Bay-Delta Science urged a new perspective for decision making in the Delta (Healey et al. 2008). Decision making should be based on best available science, should account for risk and uncertainty, should acknowledge the dynamic nature of ecosystems, and should be responsive and adaptive to future change. The Delta Reform Act, enacted 1 year after that report, requires a strong science foundation for Council decisions. This includes the ongoing provision of scientific expertise to support the Council and other agencies through the Delta Science Program and Delta ISB. The Delta Science Program's mission is to provide the best possible scientific information for water and environmental decisions in the Bay-Delta system. The Delta ISB provides oversight of the scientific research, monitoring, and assessment programs that support adaptive management of the Delta to ensure that the application of the best science is used in Delta programs. The Delta ISB reviewed early drafts of this Delta Plan to ensure that the best science was used in the Delta Plan.

Why is it important that the Delta Plan emphasize science? First, science provides the basis of nearly all current understanding of the Delta's status (Healey et al. 2008, Lund et al. 2010). Second, new perspectives on science and policy in the Delta instill urgency for addressing the health of Delta ecosystems and the need for a more reliable water supply. Third, the interaction of multiple stressors to the ecosystem must be understood if they are to inform effective policy decisions.

Science and adaptive management are not simply academic exercises; they are tools that provide managers and decision makers an approach for using public funds more effectively, and increase the likelihood of success for a given project. Science by itself does not make or prioritize management decisions; it only informs actions and proposals. "Using the best science is only part of what is needed to resolve the competing interests…" that clamor over the Delta (NRC 2012).

The next sections describe what the Council means when it comes to best available science and adaptive management in the context of the coequal goals.

Best Available Science

Not all science is created equal nor deserves equal weight in decision making. Best available science provides the knowledge base for making sound decisions and is foundational for adaptive management. Best available science provides understanding for defining problems, developing conceptual models, identifying potential management actions, monitoring ecological and physical responses, and analyzing responses relative to the actions taken. Adaptive management both uses best available science and contributes to the creation of the best available science.

Best available science is specific to the decision being made and the time frame available for making that decision. There is no expectation of delaying decisions to wait for improved scientific understanding. Action may be taken on the basis of incomplete science if the information used is the best available at the time.

Best available science is developed through a process that meets the criteria of (1) relevance, (2) inclusiveness, (3) objectivity, (4) transparency and openness, (5) timeliness, and (6) peer review (NRC 2004). Best available science is consistent with the scientific process (Sullivan et al. 2006). Ultimately, best available science requires scientists using the best information and data to assist management and policy decisions. The processes and information used should be clearly documented and effectively communicated to foster improved understanding and decision making.

Under the Delta Plan, covered actions are required to demonstrate the use of best available science in their decision making (see policy G P1 in this chapter). Guidelines and criteria for identifying or developing best available science are provided in Appendix C.

SCIENCE IN THE DELTA – ADVANCES IN UNDERSTANDING

The following is a partial list of scientific advances that have changed understanding of the Delta and California's water supply over the last decade.

Effects of Climate Change on People and the Environment

- Increased frequency of (1) extreme water heights that cause floods, (2) water temperatures lethal to salmon and delta smelt, and (3) flooding in the Yolo Bypass, which will be much more common by the latter half of this century (Cloern et al. 2011).
- Trends in snowfall versus rainfall precipitation in the western United States show that temperatures have warmed during winter and early spring storms; and, consequently, the fraction of precipitation that falls as snow has declined while the fraction that falls as rain has increased. This shift from snowfall to rainfall will reduce natural water storage and is likely to increase risks of winter and spring flooding (Knowles et al. 2006).
- By mid-century, the Colorado River Reservoir System will not be able to meet all of the demands placed on it, including water supply for Southern California and the inland southwest, because reservoir levels will be reduced by over one-third and releases reduced by as much as 17 percent. Reductions in precipitation for the Colorado River Basin will threaten the ability to meet mandated water allocations (Barnett et al. 2004).

Water Supply Reliability

- The rate of groundwater depletion in the Central Valley was quantified using satellite imaging; approximately 2.5 million acre-feet per year of groundwater was lost during the period from October 2003 to March 2010 (Famiglietti et al. 2011).
- Precipitation and streamflow are proportionally more variable from year to year in California than in any other part of the United States (Dettinger et al. 2011).

Ecosystem Restoration

- Several open-water (pelagic) fish species have undergone steep declines known as the Pelagic Organism Decline (POD) (Sommer et al. 2007). The Interagency Ecological Program investigation of these declines led to new insights about the effects of multiple stressors on these species and the Delta ecosystem (summarized in Baxter et al. 2010). Improved knowledge about the POD also led to regulatory changes for water exports and pollutant discharges.
- In 86 percent of approximately 3,000 assessed streams across the United States, streamflow magnitudes (especially flow maxima and minima) were altered. In comparison to other evaluated stressors, streamflow alterations were found to have the greatest significance for explaining ecological impairment (Carlisle et al. 2011).
- Altered flow regimes by human activities influence the ecological impact of drought anomalies and increase the susceptibility of ecosystems to biological invasion. Extreme climatic events act together with environmental disturbances to enable the establishment of invasive species (Winder et al. 2011).
- Ratios of nutrients in Delta waters have been hypothesized to be a primary driver in the composition of aquatic food webs in the Bay-Delta (Glibert et al. 2011).

Water Quality

- Ammonium concentrations may be having a significant impact on phytoplankton composition and open-water food webs because of suppression of diatom blooms in the Bay-Delta (Dugdale et al. 2007).
- Pyrethroid pesticides largely derived from urban and suburban runoff are regularly found at levels that are toxic to aquatic invertebrates (Weston et al. 2005, Weston and Lydy 2010).

Risk Reduction

- With permanently flooded conditions and managed water depths, short-term sediment accretion rates as high as 7 to 9 centimeters per year can be obtained to help reverse subsidence on Delta islands (Miller et al. 2008).
- Atmospheric rivers (narrow corridors of concentrated moisture in the atmosphere) contribute 33 to 50 percent of the total average amount of rainfall for California and have been the source of many floods along the West Coast of the United States. California's water resources and floods come from the same storms to an extent, which makes integrated flood and water resources management all the more important (Dettinger et al. 2011).

DP-168

Adaptive Management

Adaptive management is defined in the Delta Reform Act as:

> *a framework and flexible decision making process for ongoing knowledge acquisition, monitoring, and evaluation leading to continuous improvements in management planning and implementation of a project to achieve specified objectives (Water Code section 85052).*

Adaptive management is useful in that it provides flexibility and feedback to manage natural resources in the face of often considerable uncertainty. This approach requires careful science-based planning followed by measurement to determine whether a given action actually achieves intended goals.

If goals are not achieved, informed adjustments can be made. This is especially important in the context of the Delta because, in some instances, competing and uncertain explanations arise, and decision making cannot be delayed until causes are better understood (Healey et al. 2008). The Council has adopted a three-phase adaptive management framework for the purposes of developing, implementing, and updating the Delta Plan, described later in this chapter, and also for use by ecosystem restoration and water management covered actions, as set forth in G P1 with additional detail in Appendix C.

A Delta Science Plan

Multiple frameworks for science in the Delta have been proposed, but a comprehensive science plan that specifies how scientific research, monitoring, analysis, and data management will be coordinated among entities has yet to be developed. Currently, science efforts in the Delta are performed by multiple entities with varying missions and mandates, and without an overarching plan. The National Research Council (NRC) found that "only a synthetic, integrated, analytical approach to understanding the effects of suites of environmental factors (stressors) on the ecosystem and its components is likely to provide important insights that can lead to enhancement of the Delta and its species" (NRC 2012). Therefore, a comprehensive science plan for the Delta is needed to organize and integrate ongoing scientific research, monitoring, and learning about the Delta as it changes over time.

A Delta Science Plan will guide efficient use of resources for balancing investments in addressing short-term science needs and those that build understanding over the long run. This plan will address effective governance for science in the Delta, strategies for addressing uncertainty and conflicting scientific information, the prioritization of research, near-term science needs, financial needs to support science, and more. Such a plan is essential to support the adaptive management of ecosystem restoration and water management decisions in the Delta.

Additional detail regarding the proposed Delta Science Plan is provided in recommendation G R1 in this chapter.

The Delta Plan

The Delta Reform Act established the Council and directed it to develop an overarching, long-term management plan for the Delta. Figure 2-1 shows the roles assigned to the Council under the Act. The Act specifically requires that this plan for the Delta include a science-based, formal adaptive management strategy for ongoing ecosystem restoration and water management decisions.

This section presents a three-phase adaptive management framework (Plan, Do, and Evaluate and Respond), describes specific considerations that went into the development of the Delta Plan, and provides the overarching framework for how the Council (in collaboration with others) will implement and continuously amend the Delta Plan to achieve the coequal goals.

Council Roles and the Delta Plan

Council Roles and the Delta Plan

COORDINATE
- Develop, implement, and update Delta Plan
- Establish and oversee Interagency Implementation Committee

ENSURE CONSISTENCY
- Determine consistency of covered actions upon appeal
- Advise local and regional agencies on consistency with Delta Plan

INFORM

Adaptive management of the Delta Plan: Develop and use best available science and information to inform decision making in the Delta

COMMENT

Review and comment on environmental impact reports and other Delta-related programs and projects

ENSURE ACCOUNTABILITY
- Hold hearings
- Request reports
- Track performance measures

BDCP OVERSIGHT
- Serve as responsible agency on EIR
- Independent appellate role

Figure 2-1

The Council’s Three-phase Adaptive Management Framework

Several existing frameworks for adaptive management provide the basis for the Delta Plan’s own adaptive management approach.[1] Although there are differences among various frameworks, they generally consist of three broad phases: Plan, Do, and Evaluate and Respond. Throughout all three phases of the adaptive management process, decisions are made by managers, policy makers, and/or technical experts. In developing an adaptive management plan, the best available science should be used to inform all phases of the adaptive management process.

In addition to requiring adaptive management for certain proposed covered actions, the Council, in coordination with others, will use adaptive management to develop, implement, and update the Delta Plan. The Council will rely in large part on the Delta Science Program to determine the relevance, value, and reliability of the best available science and to organize that information for its use in the Council’s decisions. The Council has the final responsibility for determining the best available science used in support of its actions, including when a choice among competing interpretations of available science must be made.

The three phases of the Council’s adaptive management framework (Plan, Do, and Evaluate and Respond) are shown on Figure 2-2, and are further broken down into nine steps, which are described in detail in Appendix C.

The Delta Stewardship Council’s Three-phase Adaptive Management Framework

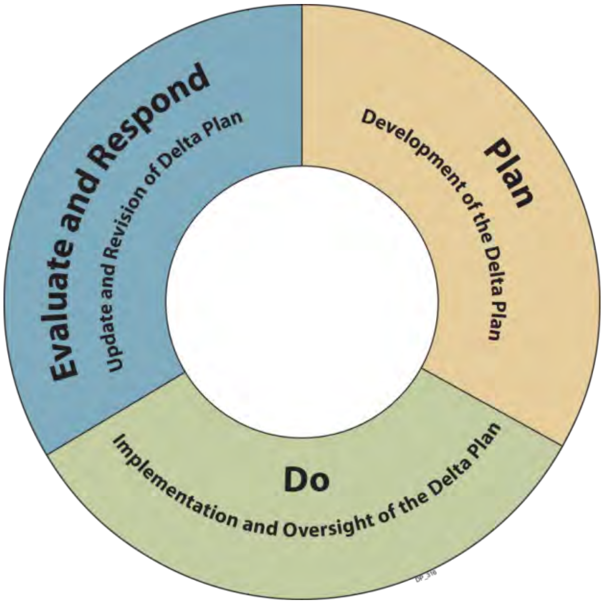

Figure 2-2

[1] Christensen et al. 1996, Stanford and Poole 1996, CALFED Bay-Delta Program 2000, Habron 2003, Abal et al. 2005, Healey et al. 2008, Kaplan and Norton 2008, Bay Delta Conservation Plan Independent Science Advisors on Adaptive Management 2009, Williams et al. 2009.

Plan: Development of the Delta Plan

The first phase of adaptive management is "Plan." The Plan phase requires clear definition of the problem, establishment of objectives, how to achieve those objectives, and actions for implementation. Performance measures are included to evaluate whether the actions are successfully meeting their intended objectives. As described in Chapter 1, the Council was established in response to an ongoing crisis in the Delta. Water supply reliability and the health of the Delta ecosystem are both at risk, and the status quo—including the patchwork governance of State, local, and federal agencies—is not making acceptable progress toward reversing disturbing trends in a balanced and sustainable manner.

The Delta Plan is intended to be foundational and adaptive. It is foundational in that the Council has built on previous efforts, including CALFED, the Delta Vision, the California Water Plan, planning efforts of the State Water Resources Control Board (SWRCB), the Delta Protection Commission (DPC), and others. The framework established in this Delta Plan is intended to advance the coequal goals of water supply reliability and ecosystem health, and to employ adaptive management to improve the Plan over time.

This Delta Plan officially supersedes and replaces the Interim Delta Plan adopted by the Council on August 27, 2010.

Structure of the Delta Plan

The Delta Plan contains five core policy chapters (Chapters 3 through 7) and a chapter on Funding Principles to Support the Coequal Goals (Chapter 8). The narrative sections of each policy chapter provide subject matter context and rationale for the selection and implementation of core strategies. These core strategies are then broken down into actions: the policies and recommendations. The policies in the Delta Plan are regulatory in nature, and compliance is required for those who propose covered actions. In each policy chapter, the Policies and Recommendations section is followed by a section identifying both science needs and key issues for future evaluation by the Council.

Finally, each policy chapter concludes with a set of performance measures. The Delta Reform Act requires that the Delta Plan include performance measures to evaluate whether it is achieving its objectives over time. Information learned from performance measures will be an important part of how the Council determines when and how to update the Delta Plan as part of the Evaluate and Respond phase of the adaptive management process. See the sidebar, Performance Measures in the Delta Plan, later in this chapter.

Considerations in the Development of the Delta Plan

The Delta Reform Act set forth certain requirements and guidance for the development of the Delta Plan. The Act required the development of several State agency plans to inform the Delta Plan planning process and set forth statutory guidelines for the consideration or inclusion of certain plans, some of which were not yet completed at the date of Delta Plan publication and will be considered in future plan updates.

- **Delta Reform Act objectives.** The Act lists numerous objectives and, in some sections, provides detailed guidance for what the Delta Plan shall include (see Table 2-2).
- **State agency proposals.** Specific agencies are named in the Delta Reform Act as being responsible for submitting reports or recommendations to the Council for consideration for inclusion in the Delta Plan. The DPC, California State Parks, and the California Department of Food and Agriculture (CDFA) all submitted proposals that were considered in the development of this Delta Plan.
- **Consistency with federal law.** The Delta Reform Act requires that the Delta Plan be developed consistent with the federal Clean Water Act, Section 8 of the federal Reclamation Act of 1902, and the federal Coastal Zone Management Act of 1972 (CZMA), or an equivalent compliance mechanism. See sidebar, Federal Participation in Implementing the Delta Plan, for more information.

Delta Plan Requirements by Water Code Section

TABLE 2-2

Water Code Section	Requirement
85211	The Delta Plan shall include performance measurements that will enable the council to track progress in meeting the objectives of the Delta Plan. The performance measurements shall include, but need not be limited to, quantitative or otherwise measurable assessments of the status and trends in all of the following:
85211(a)	– The health of the Delta's estuary and wetland ecosystem for supporting viable populations of aquatic and terrestrial species, habitats, and processes, including viable populations of Delta fisheries and other aquatic organisms.
85211(b)	– The reliability of California water supply imported from the Sacramento River or the San Joaquin River watershed.
85300(a)	The Delta Plan shall include subgoals and strategies to assist in guiding state and local agency actions related to the Delta.
85302(e)	The following subgoals and strategies for restoring a healthy ecosystem shall be included in the Delta Plan:
85302(e)(1)	– Restore large areas of interconnected habitats within the Delta and its watershed by 2100.
85302(e)(2)	– Establish migratory corridors for fish, birds, and other animals along selected Delta river channels.
85302(e)(3)	– Promote self-sustaining, diverse populations of native and valued species by reducing the risk of take and harm from invasive species.
85302(e)(4)	– Restore Delta flows and channels to support a healthy estuary and other ecosystems.
85302(e)(5)	– Improve water quality to meet drinking water, agriculture, and ecosystem long-term goals.
85302(e)(6)	– Restore habitat necessary to avoid a net loss of migratory bird habitat and, where feasible, increase migratory bird habitat to promote viable populations of migratory birds.
85300(a)	The Delta Plan may also identify specific actions that state or local agencies may take to implement the subgoals and strategies.
85302(a)	Implementation of the Delta Plan shall further the restoration of the Delta ecosystem and a reliable water supply.
85302(b)	The Delta Plan may include recommended ecosystem projects outside the Delta that will contribute to achievement of the coequal goals.
85302(c)	The Delta Plan shall include measures that promote all of the following characteristics of a healthy Delta ecosystem:
85302(c)(1)	– Viable populations of native resident and migratory species.
85302(c)(2)	– Functional corridors for migratory species.
85302(c)(3)	– Diverse and biologically appropriate habitats and ecosystem processes.
85302(c)(4)	– Reduced threats and stresses on the Delta ecosystem.
85302(c)(5)	– Conditions conducive to meeting or exceeding the goals in existing species recovery plans and state and federal goals with respect to doubling salmon populations.
85302(d)	The Delta Plan shall include measures to promote a more reliable water supply that address all of the following:
85302(d)(1)	– Meeting the needs for reasonable and beneficial uses of water.
85302(d)(2)	– Sustaining the economic vitality of the state.
85302(d)(3)	– Improving water quality to protect human health and the environment.
85302(h)	The Delta Plan shall include recommendations regarding state agency management of lands in the Delta.

Delta Plan Requirements by Water Code Section

TABLE 2-2

Water Code Section	Requirement
85303	The Delta Plan shall promote statewide water conservation, water use efficiency, and sustainable use of water.
85304	The Delta Plan shall promote options for new and improved infrastructure relating to the water conveyance in the Delta, storage systems, and for the operation of both to achieve the coequal goals.
85305(a)	The Delta Plan shall attempt to reduce risks to people, property, and state interests in the Delta by promoting effective emergency preparedness, appropriate land uses, and strategic levee investments.
85305(b)	The council may incorporate into the Delta Plan the emergency preparedness and response strategies for the Delta developed by the California Emergency Management Agency pursuant to Section 12994.5.
85306	The council, in consultation with the Central Valley Flood Protection Board, shall recommend in the Delta Plan priorities for state investments in levee operation, maintenance, and improvements in the Delta, including both levees that are a part of the State Plan of Flood Control and nonproject levees.
85307(a)	The Delta Plan may identify actions to be taken outside of the Delta, if those actions are determined to significantly reduce flood risks in the Delta.
85307(b)	The Delta Plan may include local plans of flood protection.
85307(c)	The council, in consultation with the Department of Transportation, may address in the Delta Plan the effects of climate change and sea level rise on the three state highways that cross the Delta.
85307(d)	The council, in consultation with the State Energy Resources Conservation and Development Commission and the Public Utilities Commission, may incorporate into the Delta Plan additional actions to address the needs of Delta energy development, energy storage, and energy distribution.
85308	The Delta Plan shall meet all of the following requirements:
85308(a)	– Be based on the best available scientific information and the independent science advice provided by the Delta Independent Science Board.
85308(b)	– Include quantified or otherwise measurable targets associated with achieving the objectives of the Delta Plan.
85308(c)	– Where appropriate, utilize monitoring, data collection, and analysis of actions sufficient to determine progress toward meeting the quantified targets.
85308(d)	– Describe the methods by which the council shall measure progress toward achieving the coequal goals.
85308(e)	– Where appropriate, recommend integration of scientific and monitoring results into ongoing Delta water management.
85308(f)	– Include a science-based, transparent, and formal adaptive management strategy for ongoing ecosystem restoration and water management decisions.

- **Incorporation of the Bay Delta Conservation Plan into the Delta Plan.** The Bay Delta Conservation Plan (BDCP) is a major project considering large-scale improvements in water conveyance and large-scale ecosystem restoration in the Delta. When completed, it must be incorporated into the Delta Plan if it meets certain statutory requirements. Completion of the BDCP process and the number of projects now under consideration in that process would have large impacts on the Delta and would affect the coequal goals. (More detailed discussions of the BDCP are provided in Chapters 3 and 4.) The Delta Reform Act describes a separate, explicit process for incorporating the BDCP into the Delta Plan (Water Code section 85320), and the

Council has adopted administrative procedures governing appeals to the Council related to BDCP incorporation (see Appendix D). If the BDCP is incorporated into the Delta Plan, it becomes part of the Delta Plan and, therefore, part of the basis for future consistency determinations.

- **Incorporation of other plans into the Delta Plan.** The Council may incorporate other plans or programs in whole or in part into the Delta Plan to the extent that they promote the coequal goals.

Do: Implementation and Oversight of the Delta Plan

The second phase of adaptive management is "Do." The "doing," or implementation, of the Delta Plan will occur over time (through 2100) through the coordinated efforts of many State, local, and federal agencies, in cooperation with nongovernmental organizations and private parties, and Council oversight and exercise of appellate authorities.

Federal participation in implementing the Delta Plan and the coequal goals is described in detail in the sidebar, Federal Participation in Implementing the Delta Plan.

The Council is responsible for overseeing the Delta Plan's implementation. Given the numerous government agencies that frequently have conflicting or overlapping jurisdictional and programmatic interest in Delta matters (see Table 2-1), there is a compelling need for the Council to fulfill the role as integrator of Delta policy and coordinator of actions. This integration and coordination will occur through convening a formal Interagency Implementation Committee, providing ongoing informal staff-to-staff agency coordination, providing comments and advice from the Council to other agencies on proposed or ongoing plans and programs, holding public hearings, developing science to support the Delta Plan, and using the Council's appellate authority over consistency of significant actions in the Delta with the Delta Plan.

Delta Plan Interagency Implementation Committee

Perhaps the most significant tool the Council will have for implementing the Delta Plan and ensuring accountability is a formal method for active agency coordination. The Delta Reform Act directs the Council to establish and oversee a committee of agencies responsible for implementing the Delta Plan. Notably, the law states that "each agency shall coordinate its actions pursuant to the Delta Plan with the Council and other relevant agencies" (Water Code section 85204). Governance challenges have long plagued management of the Delta and California's ability to achieve stated objectives for water supply and the Delta ecosystem. Ambiguous and sometimes conflicting authorities and responsibilities among agencies thwart real progress (NRC 2012).

The Council, therefore, will coordinate implementation of the Delta Plan through the establishment and leadership of an Interagency Implementation Committee to do the following:

- Monitor progress of priority actions and agency activities to implement the Delta Plan;
- Report regularly on implementation plans and actions;
- Identify opportunities for integration and leveraging of funding;
- Identify funding needs and support development of a finance plan to implement the Delta Plan;
- Assist in the ongoing development and tracking of Delta Plan performance measures;
- Coordinate regulatory actions on significant projects to implement the Delta Plan, as appropriate; and
- Discuss common issues and resolve interagency conflicts.

The Interagency Implementation Committee, which shall convene at least twice each year and more often as needed, will be overseen by the Council and will be organized around the implementation of the Delta Plan. The Interagency Implementation Committee will include federal, local, and State agency representatives as dictated by the specific matter or subject area in the Delta Plan. At a minimum, the Interagency Implementation Committee will consist of the Council's Executive Officer, the Delta Science Program lead

FEDERAL PARTICIPATION IN IMPLEMENTING THE DELTA PLAN

The Delta Reform Act recognizes the federal government's critical role in achieving the coequal goals through the Delta Plan's comprehensive, Delta-wide planning and implementation effort. This effort goes beyond federal participation in the more narrowly focused BDCP. This recognition builds upon the history of federal-State cooperative governance efforts in the Delta made necessary by the multitude of federal and State agencies working on interconnected, cross-jurisdictional issues in and related to the Delta, including water project operations, water quality regulation, levee maintenance, habitat restoration, and endangered species regulation.

Federal Law Now Incorporates the Coequal Goals

The federal Energy and Water Development Appropriations Act of 2012 (Title II of the Consolidated Appropriations Act of 2012 (PL 112-074)) contains, in pertinent part, the following:

> *The Federal policy for addressing California's water supply and environmental issues related to the Bay-Delta shall be consistent with State law, including the coequal goals of providing a more reliable water supply for the State of California and protecting, restoring, and enhancing the Delta ecosystem…Nothing herein modifies existing requirements of Federal law. (Section 205)*

The Council's staff will work with federal agency representatives to explore opportunities for federal participation in Delta Plan implementation efforts to help those agencies comply with this new Congressional policy directive.

The current regulatory provisions of the Delta Plan, including the consistency review and appeals process, apply to only covered actions of State and local agencies. However, once the Delta Plan is adopted, the Delta Reform Act requires the Council to pursue a compliance mechanism that requires consistency of federal actions. The Delta Reform Act identifies the CZMA, or "an equivalent compliance mechanism," as the preferred means to accomplish this objective. Under the CZMA, states are authorized to review certain activities of federal agencies, including activities directly conducted by federal agencies and activities permitted or licensed by these agencies, for consistency with a state's federally approved coastal management program. This review authority applies to any activity that affects any land or water use or natural resource of the state coastal zone.

In this regard, the Council staff has met, and will continue to meet, with federal agency representatives to identify the appropriate process to submit the Delta Plan to the Secretary of Commerce for approval under the CZMA (and with representatives of the California Coastal Commission and the San Francisco Bay Conservation and Development Commission, which administer California's coastal management program).

DP-181

scientist, and executive officers or directors from the California Department of Water Resources (DWR); California Department of Fish and Wildlife (DFW); SWRCB and regional water quality control boards; the San Francisco Bay Conservation and Development Commission; the California Water Commission; the Sacramento-San Joaquin Delta Conservancy; the DPC; the Delta Watermaster; the CDFA; the Natural Resources Agency; the Business, Transportation and Housing Agency; and the California Environmental Protection Agency. Federal agencies such as National Oceanic and Atmospheric Administration Fisheries, U.S. Fish and Wildlife Service, Bureau of Reclamation, Natural Resources Conservation Service, U.S. Geological Survey, U.S. Army Corps of Engineers, U.S. Environmental Protection Agency, and others, as appropriate, will be invited to participate and provide status reports on various projects and programs related to Delta Plan implementation.

The meetings of the Interagency Implementation Committee will be open to the public, and the agenda will be noticed in advance. The committee will create ad hoc workgroups as appropriate to facilitate focus on specific issues. Stakeholder representatives will be encouraged to participate in the various workgroups. The work of both the formal Interagency Implementation Committee and the workgroups may be supplemented with meetings or hearings conducted by the Council.

The Delta Protection Commission's Role in Delta Plan Implementation

The Delta Protection Act states that the DPC is the appropriate agency to identify and provide recommendations to the Council on methods of preserving the Delta as an evolving place. The DPC developed and submitted a set of recommendations to the Council, many of which were incorporated in this Delta Plan (DPC 2012). The Delta Protection Act outlines a process for the DPC to review and provide comments and recommendations to the Council on any significant project or proposed project within the scope of the Delta Plan that may affect the unique values of the Delta (Public Resources Code section 29773(a)). The Council's adopted procedures include a process whereby the Council will notify the DPC of covered action appeals.

Other Delta Plan Implementation Actions

In addition to convening the Interagency Implementation Committee and carrying out the other responsibilities assigned to it by the Delta Reform Act, the Delta Plan assigns other tasks that will further refine the Delta Plan to the Council. These tasks are described in the following recommendations: G R1 (Chapter 2), WR R5 (Chapter 3), WR R15 (Chapter 3), DP R7 (Chapter 5), DP R19 (Chapter 5), RR R4 (Chapter 7), and FP R1 through R3 (Chapter 8).

Additional Council Authorities in Implementing the Delta Plan

The Delta Reform Act enumerated a range of specific authorities for the Council related to the implementation of the Delta Plan (as shown on Figure 2-1). A full list of authorities can be found in Water Code section 85210 and in various sections of the Delta Reform Act. In implementing the Delta Plan, the Council has the authority to:

- **Comment on environmental impact reports.** The Council has a role in commenting on any State agency environmental impact reports (EIRs) as appropriate to the mission of the Council.
- **Comment on policies related to the coequal goals and implementation of the Delta Plan.** As appropriate, the Council may comment formally on any proposed policies or regulations that will impact the achievement of the coequal goals and the implementation of the Delta Plan.
- **Advise local governments.** The Council has a role in advising local and regional planning agencies regarding the consistency of their planning documents with the Delta Plan. As described in Chapter 5, the Council will review sustainable community strategies and regional transportation plans to prevent conflicts with the Delta Plan and to coordinate metropolitan development with actions in the Delta.
- **Request reports from State, federal, and local agencies.** The Council has the authority to request reports from agencies on issues related to the implementation of the Delta Plan.
- **Hold hearings.** The Council has the authority to hold hearings in all parts of the state and to subpoena witnesses.
- **Develop, coordinate, and promote the use of science through the Delta Science Program.** The Council has a role in providing the best available unbiased scientific information to inform water and environmental decision making in the Delta by funding research, synthesizing and communicating scientific information to policy makers and decision makers, promoting independent peer review, and coordinating with Delta agencies to promote science-based adaptive management.
- **Make consistency determinations upon appeal.** The Legislature intended that State and local actions that would have a significant impact on the coequal goals or a government-sponsored flood control program be consistent with the Delta Plan. The Council has the authority to implement the Delta Plan in part through the enforcement of consistency of covered actions with the Delta Plan upon appeal. The Delta Reform Act also gave the Council a specific appellate role with respect to the BDCP and its future incorporation into the Delta Plan. The Council's appellate roles, the definition of a covered action, and the consistency determination process and appeals process are described in detail in the Covered Actions and Delta Plan Consistency section later in this chapter.

Monitoring Progress toward Achieving the Coequal Goals

The Council will use existing monitoring efforts (such as the efforts of the Interagency Ecological Program, California Water Quality Monitoring Council, and California Statewide Groundwater Elevation Monitoring) and new monitoring efforts to inform progress toward achieving the performance measures in the Delta Plan. The Council will monitor the progress of programs and projects toward achieving the administrative, output, and outcome performance measures in the current Delta Plan and those developed in the future. Working with others, in particular the Interagency Implementation Committee, the Council will use coordinated information about relevant status and trends and progress toward meeting the coequal goals to inform revisions to the Delta Plan. The Council's monitoring activities will be reported on the Council website.

Evaluate and Respond: Updating and Amending the Delta Plan

The third phase of Delta Plan adaptive management is "Evaluate and Respond." According to the Delta Reform Act, the Council must review the Delta Plan at least once every 5 years and can revise it as the Council deems appropriate. This authority is consistent with the Council's obligation to base the Delta Plan on the best available scientific information and to use an adaptive management approach in updating the Plan as new information becomes available.

When updating the Delta Plan, the Council will consider information from other adaptive management activities in the Delta; evaluation of Delta Plan policies and recommendations; performance measures; other completed plans related to the Delta; and coordination, hearings, and oversight. The Council will rely in large part on the Delta Science Program for determining the relevance, value, and reliability of the best available science, and organizing that information for its use in the Council's decisions. The Council has the final responsibility for determining the best available science used in support of its actions, including when a choice among competing interpretations of available science must be made.

Reporting on Delta Plan Performance Measures

This Delta Plan contains preliminary performance measures developed to monitor performance of Delta Plan policies and recommendations. (See sidebar, Performance Measures in the Delta Plan, for more detailed information.) Upon adoption of the Delta Plan, staff will take the lead, working with scientific, agency, and stakeholder experts to continue to refine the Delta Plan's performance measures. Delta Plan performance measures will be periodically reviewed by independent expert review panels and will be sent to the Delta ISB for further review and comment. The resulting updated performance measures will be developed no later than December 31, 2014, for consideration by the Council for incorporation into the Delta Plan. The Council will issue periodic public reports on the status of performance measures.

Data collection related to the Delta and water management in California is already occurring, although more is needed. The Council, through the Interagency Implementation Committee and working with stakeholders, will report regularly on Delta Plan performance measures and the Delta Plan's progress in advancing the coequal goals. These reports will be made available to the public.

PERFORMANCE MEASURES IN THE DELTA PLAN

The performance measures included in this Delta Plan are primarily administrative measures focused on implementation of near-term actions (generally, actions contained within policies and recommendations of the Delta Plan) that support the coequal goals. This initial set of performance measures will be expanded and refined after adoption of the Delta Plan and will be considered for inclusion in subsequent updates of the Delta Plan.

Delta Plan performance measures have been placed into three general classes:

- Administrative performance measures describe decisions made by policy makers and managers to finalize plans or approve resources (funds, personnel, projects) for implementation of a program or group of related programs.
- Output (also known as "driver") performance measures evaluate the factors that may be influencing outcomes and include on-the-ground implementation of management actions, such as acres of habitat restored or acre-feet of water released, as well as natural phenomena outside of management control (such as a flood, earthquake, or ocean conditions).
- Outcome performance measures evaluate responses to management actions or natural outputs.

Administrative performance measures are included in Appendix E. Output and outcome performance measures, where appropriate, are included at the end of individual chapters.

Development of informative and meaningful performance measures is a challenging task that will continue after the adoption of the Delta Plan. Performance measures need to be designed to capture important trends and to address whether specific actions are producing expected results. Efforts to develop performance measures in complex and large-scale systems like the Delta are commonly multiyear endeavors. The Council will improve all performance measures, but will focus on outcome measures through a multiyear effort, using successful approaches for developing performance measures employed by similar efforts elsewhere (such as the Kissimmee River Restoration, The State of San Francisco Bay, and Healthy Waterways Southeast Queensland, Australia) as positive examples (see Appendix C for more information).

DP-301

Communication and the Delta Plan

Keeping the public and decision makers informed as future Delta Plan changes are proposed and considered is a vital step. The Council is committed to open communication of current understanding gained through the evaluation of performance measures, monitoring, science, and adaptive management. This communication will be continuous as the Council receives and produces information that will be used to adapt its strategy toward meeting the coequal goals and updating the Delta Plan.

The Council's website and meetings will remain the central hub for communicating information about progress toward meeting the coequal goals and the objectives of the Delta Plan. Information learned from the analysis, synthesis, and evaluation of how well the policies and recommendations in the Delta Plan are meeting their intended goals will be gathered and communicated through a number of media and forums that may include:

- The Council's meetings and workshops, website, social media, and newsletter
- Staff reports on the status and trends of the Delta Plan performance measures
- Reports, presentations, and correspondence presented to the Council
- Interagency Implementation Committee meetings and products
- The Delta Science Program website, *Science News*; the online journal, *San Francisco Estuary & Watershed Science*; brown bag seminars; and Biennial Bay-Delta Science Conference
- Delta ISB meetings and products

Covered Actions and Delta Plan Consistency

The Delta Reform Act directs the Council to develop a legally enforceable long-term management plan for the Delta (this Delta Plan) and includes a mechanism for enforcement of Delta Plan policies over State and local actions identified as covered actions (Water Code sections 85001(c) and 85022). The Council has taken a hybrid approach to developing the Delta Plan by including both regulatory policies and nonregulatory recommendations. This section presents a discussion of the process and general requirements for certifying consistency with the Delta Plan through compliance with its regulatory policies, and includes examples of covered actions and exemptions.

Delta Plan regulatory policies are not intended and shall not be construed as authorizing the Council or any entity acting pursuant to this section to exercise their power in a manner that will take or damage private property for public use without the payment of just compensation. These policies are not intended to affect the rights of any owner of property under the Constitution of the State of California or the United States. None of the Delta Plan policies increases the State's flood liability.

Covered Actions Must Comply with Delta Plan Policies

The Delta Reform Act requires State and local actions that fit the legal definition of a covered action to be consistent with the policies included in the Delta Plan. The mechanism for determining consistency is the filing of a certification of consistency. Not all actions that occur in whole or in part in the Delta are covered actions. Only certain activities qualify as covered actions, and the Delta Reform Act establishes specific criteria and exclusions, discussed in this chapter. Furthermore:

- The State or local agency that carries out, approves, or funds a proposed action determines whether that proposed plan, program, or project is a covered action (subject to judicial review of whether the determination was reasonable and consistent with the law).
- The State or local agency that carries out, approves, or funds a covered action ("proponents") needs to certify consistency with the policies included in the Delta Plan.
- In the case of all other actions (those that do not meet the criteria of being a covered action or are otherwise explicitly excluded), the Delta Plan's policies, where applicable, are recommendations.

What Is a Covered Action?

For a State or local agency to determine whether its proposed plans, programs, or projects are covered actions under the Delta Plan and, therefore, subject to the regulatory provisions in the plan, it must start with the Delta Reform Act, which defines a covered action as (Water Code section 85057.5(a)):

> *…a plan, program, or project as defined pursuant to Section 21065 of the Public Resources Code that meets all of the following conditions:*
>
> 1. *Will occur, in whole or in part, within the boundaries of the Delta or Suisun Marsh;*
> 2. *Will be carried out, approved, or funded by the state or a local public agency;*
> 3. *Is covered by one or more provisions of the Delta Plan;*
> 4. *Will have a significant impact on the achievement of one or both of the coequal goals or the implementation of government-sponsored flood control programs to reduce risks to people, property, and state interests in the Delta.*

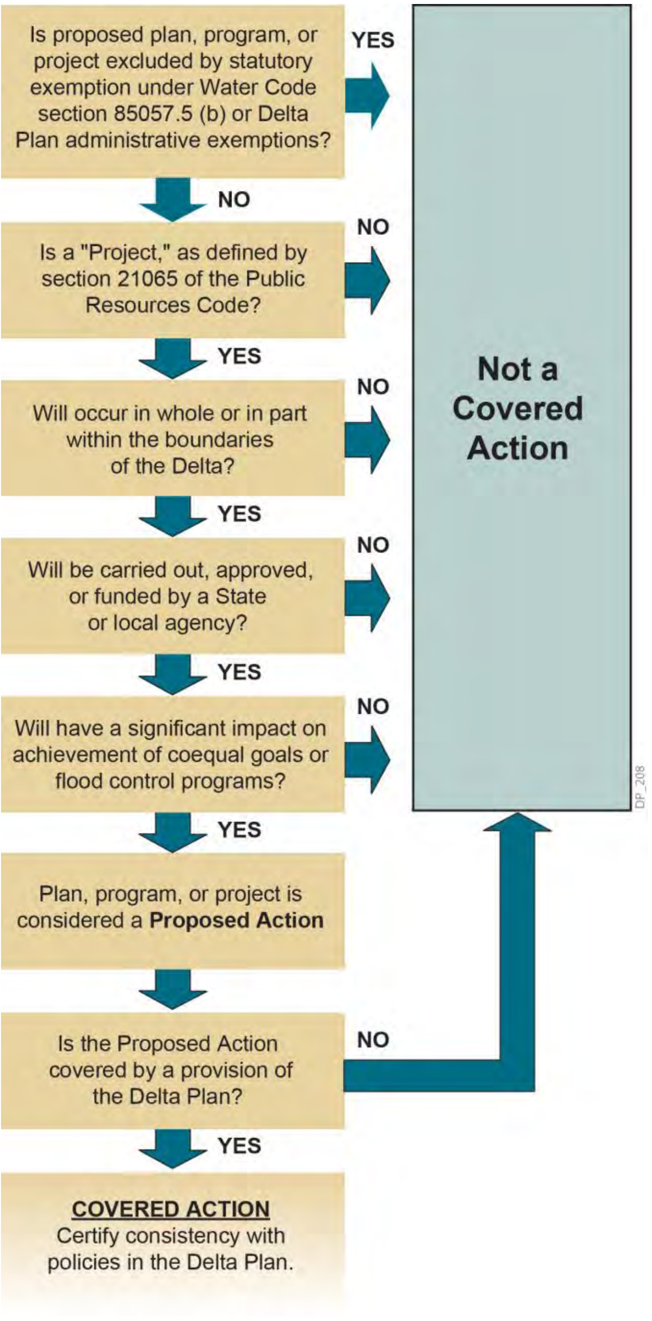
Figure 2-3 shows the steps to follow for identifying whether a proposed plan, project, or program is a covered action.

Screening Criteria for Covered Actions

As used in this Delta Plan, the statutory criteria for covered actions under the Delta Plan are collectively referred to as "screening criteria." Before using the screening criteria, a project proponent should first determine whether its proposed plan, program, or project is exempt from covered action status under either the Council's administrative exemptions or the Delta Reform Act's statutory exemptions, discussed below. Early consultation with Council staff is encouraged and can assist in this determination.

1. **Is a "Project," as defined by section 21065 of the Public Resources Code.** A proponent's first step in determining whether a plan, program, or project is a covered action is to identify whether it meets the definition of a project as defined in Public Resources Code section 21065. That particular provision is the section of the California Environmental Quality Act (CEQA) that defines the term "project" for purposes of potential review under CEQA.[2] If the plan, program, or project does indeed meet the definition of a project under CEQA, the next step in determining a covered action is to review the four additional screening criteria in the definition of covered action, *all* of which must be met by a proposed plan, program, or project for it to qualify as a covered action (see sidebar, What Does CEQA Consider a "Project"?).

2. **Will occur in whole, or in part, within the boundaries of the Delta or Suisun Marsh.** To qualify as a covered action, a project must include one or more activities that take place at least partly within the Delta or Suisun Marsh. This means, for example, that the diversion and use of water in the Delta watershed that is entirely upstream of the statutory Delta or Suisun Marsh would not satisfy this criterion. By contrast, this criterion *would* be met if water intended for use upstream were transferred through the statutory Delta or Suisun Marsh (pursuant, for example, to a water transfer longer than 1 year in duration).



Decision Tree for State and Local Agencies on Possible Covered Actions

Figure 2-3

---

[2] It is important to note that CEQA's various statutory and categorical exemptions—which are considered only after the threshold determination of a CEQA "project" is made—are not similarly incorporated by cross-reference in the definition of covered action. Therefore, the Delta Plan must expressly incorporate a CEQA exemption for it to apply to the Delta Plan.

3. **Will be carried out, approved, or funded by the State or a local public agency.** If these screening criteria are met, it is recommended that the “significant impact” criteria be analyzed next.

4. **Will have a significant impact on the achievement of one or both of the coequal goals or the implementation of a government-sponsored flood control program to reduce risks to people, property, and State interests in the Delta.** In addition, a proposed project must have a “significant impact” as defined under Water Code section 85057.5(a)(4) to qualify as a covered action. For this purpose, significant impact means a substantial positive or negative impact on the achievement of one or both of the coequal goals or the implementation of a government-sponsored flood control program to reduce risks to people, property, and State interests in the Delta, that is directly or indirectly caused by a project on its own or when the project’s incremental effect is considered together with the impacts of other closely related past, present, or reasonably foreseeable future projects. The coequal goals and government-sponsored flood control programs are further defined in Chapters 3, 4, and 7.

The following categories of projects will not have a significant impact for this purpose:

- “Ministerial” projects exempted from CEQA, pursuant to Public Resources Code section 21080(b)(1);
- “Emergency” projects exempted from CEQA, pursuant to Public Resources Code section 21080(b)(2) through (4);
- Temporary water transfers of up to 1 year in duration. This provision shall remain in effect only through December 31, 2016, and as of January 1, 2017, is repealed, unless the Council acts to extend the provision prior to that date. The Council contemplates that any extension would be based upon DWR and the SWRCB’s participation with stakeholders to identify and implement transfer measures, as recommended in WR R15;
- Other projects exempted from CEQA, unless there are unusual circumstances indicating a reasonable possibility that the project will have a significant impact under Water Code section 85057.5(a)(4). Examples of unusual circumstances could arise in connection with, among other things:
    - Local government general plan amendments for the purpose of achieving consistency with the DPC’s Land Use and Resource Management Plan; and
    - Small-scale habitat restoration projects, as referred to in CEQA Guidelines, section 15333 of Title 14 of the California Administrative Code, proposed in important restoration areas, but which are inconsistent with the Delta Plan’s policy related to appropriate habitat restoration for a given land elevation.

WHAT DOES CEQA CONSIDER A “PROJECT”?

Public Resources Code section 21065 (which is incorporated by reference in the Delta Reform Act) defines the term “project” in the following manner:

> *21065. “Project” means an activity which may cause either a direct physical change in the environment, or a reasonably foreseeable indirect physical change in the environment, and which is any of the following:*
>
> *(a) An activity directly undertaken by any public agency.*
>
> *(b) An activity undertaken by a person which is supported, in whole or in part, through contracts, grants, subsidies, loans, or other forms of assistance from one or more public agencies.*
>
> *(c) An activity that involves the issuance to a person of a lease, permit, license, certificate, or other entitlement for use by one or more public agencies.*

DP-182

The Council will consider, as part of its ongoing adaptive management of the Delta Plan, whether these exemptions remain appropriate and/or whether the Delta Plan should be amended to include other types of projects.

If the above four screening criteria are met, then for purposes of the Delta Plan, the plan, program, or project is referred to as a "proposed action." Although a proposed action meets the first four screening criteria, the action has not yet been reviewed by the State or local agency to determine whether it meets the fifth screening criterion: is the proposed action covered by one or more Delta Plan policies? If the proposed action is covered by at least one Delta Plan regulatory policy, then the proposed action is a "covered action." If the proposed action is not covered by any Delta Plan regulatory policy, it is not a covered action.

5. **Is covered by one or more provisions of the Delta Plan.** This means that the proposed action must be covered by one or more regulatory policies contained in Chapters 3 through 7 of the Delta Plan. Each of those regulatory policies specifies the types of proposed actions that they cover. If the proposed action is covered by one or more provisions of the Delta Plan—the final criteria—the proposed action is, therefore, a covered action.

Statutory Exemptions

Certain actions are statutorily excluded from the definition of covered action and are exempt from the Council's regulatory authority (Water Code section 85057.5(b)). A complete list is included in Appendix F. These exemptions include:

- A regulatory action of a State agency (such as the adoption of a water quality control plan by the SWRCB, or the issuance of a California Endangered Species Act take permit by DFW)
- Routine maintenance and operation of the State Water Project or the Central Valley Project
- Routine maintenance and operation of any facility located, in whole or in part, in the Delta, that is owned or operated by a local public agency (such as routine maintenance of levees by a reclamation district)

Although a regulatory action by another State agency is not a covered action, the underlying action regulated by that agency can be a covered action (provided it otherwise meets the definition). The Council has concurrent jurisdiction over covered actions when that action is also regulated by another State agency. For example, the issuance of a California Endangered Species Act take permit by DFW is a regulatory action of a State agency and, therefore, is not a covered action. However, the underlying action requiring the take permit could be a covered action, and, if it is, it must be consistent with the Delta Plan's policies. Therefore, even when a covered action is regulated by another agency (or agencies), the covered action still must be consistent with the Delta Plan. In the situation where a covered action is governed by multiple agencies and laws, the action must comply with all relevant legal requirements.

Who Determines Whether a Proposed Plan, Program, or Project Is a Covered Action?

A State or local agency that proposes to carry out, approve, or fund a plan, program, or project is the entity that must determine whether that plan, program, or project is a covered action. That determination must be reasonable, made in good faith, and consistent with the Delta Reform Act and relevant provisions of this Plan. If requested, Council staff will meet with an agency's staff during early consultation to review consistency with the Delta Plan and to offer advice as to whether the proposed plan, program, or project appears to be a covered action, provided that the ultimate determination in this regard must be made by the agency. If an agency determines that a proposed plan, program, or project is not a covered action, that determination is not subject to Council regulatory review, but is subject to judicial review as to whether it was reasonable, made in good faith, and is consistent with the Delta Reform Act and relevant provisions of this Plan.

Mitigation of Significant Adverse Impacts on the Environment

Public Resources Code section 21081.6 requires a public agency to adopt a mitigation monitoring or reporting program (MMRP) to ensure compliance with the mitigation measures adopted by the agency at the time of project approval. The MMRP is a working implementation document to ensure that mitigation measures are implemented. The MMRP for the *Delta Plan Program Environmental Impact Report* (PEIR) ensures compliance with the Delta Plan mitigation measures. The Delta Plan MMRP lists the mitigation measures incorporated into the Delta Plan, when they need to be implemented, who is responsible for implementing them, and who reports on compliance. As specified in policy G P1 of the Delta Plan, any covered action that is not exempt must include either the mitigation measures identified in the Delta Plan's PEIR, if applicable and feasible; substitute mitigation measures that the proposing agency finds to be equally or more effective than those identified in the Delta Plan PEIR; or an explanation of why such mitigation is not feasible. Monitoring and/or reporting on implementation of the adopted Delta Plan mitigation measures will be accomplished through the certification of consistency process as part of the certification forms. The MMRP can be found on the DSC's website at http://deltacouncil.ca.gov/.

Certifications of Consistency

Once a State or local agency has determined that their plan, program, or project is a covered action under the Delta Plan, they are required to submit a written certification to the Council, with detailed findings, demonstrating that the covered action is consistent with the Delta Plan (Water Code section 85225 et seq.). Furthermore:

- The first policy in the Delta Plan, G P1, describes requirements to be included in the certification of consistency for all covered actions and is included in this chapter.
- The certification of consistency must be submitted to the Council prior to initiating implementation of the covered action.
- The certification of consistency should not be submitted to the Council until the covered action has been fully described and the impacts associated with the covered action have been identified; this coincides with the completion of the CEQA process.
- Should the covered action project change substantially, the agency will be required to submit a new certification of consistency to the Council.

The Council has developed a discretionary checklist that agencies may use to facilitate the process, as well as certification forms and related materials, available on the Council website.

Bay Delta Conservation Plan Covered Activity Consistency Certification

The Delta Reform Act describes a specific process for the potential incorporation of BDCP into the Delta Plan. If BDCP is incorporated, an agency proposing a qualifying "covered activity" under BDCP that also meets the statutory definition of a covered action must file a short form certification of consistency with findings indicating only that the covered action is consistent with the BDCP. Consistency for these purposes shall be presumed if the certification filed by the agency includes a statement to that effect from DFW.

Covered Action Consistency Appeals

In contrast to how many other governmental plans are implemented, the Council does *not* exercise direct review and approval authority over covered actions to determine their consistency with the regulatory policies in the Delta Plan. Instead, State or local agencies self-certify Delta Plan consistency, and the Council serves as an appellate body for those determinations.

Any person, including any member of the Council or its Executive Officer, who claims that a covered action is inconsistent with the Delta Plan and, as a result of that inconsistency, will have a significant adverse impact on the achievement of one or both of the coequal goals or implementation of government-sponsored flood control program, may file an appeal with regard to a certification of consistency submitted to Council.

The Council has appellate authority to determine the consistency of covered actions with the Delta Plan if they are challenged. The Council is required to apply the standard of substantial evidence when reviewing covered action appeals. State or local agencies are required to submit detailed findings upon filing their consistency determination, described previously. These findings and the record will provide the basis for the Council's decision making.

Per statute, an appeal must be filed within 30 days; if a valid appeal is filed, the Council is responsible for subsequent evaluation and determination—as provided in statute and the Council's Administrative Procedures Governing Appeals—of whether the covered action is consistent with the Delta Plan's policies. More than one policy in the Delta Plan may apply to a covered action. If no person appeals the certification of consistency, the State or local public agency may proceed to implement the covered action.

In the event of an appeal of a covered action, the Council may consult with the DPC consistent with Public Resources Code section 29773.

Upon receiving an appeal, the Council has 60 days to hear the appeal and an additional 60 days to make its decision and issue specific written findings. If the covered action is found to be inconsistent, the project may not proceed until it is revised so that it is consistent with the Delta Plan.

The appeals process is described in statute and further defined in the appeals procedures adopted by the Council; it is attached for reference purposes as Appendix D.

POLICIES AND RECOMMENDATIONS

State and local agencies approve many important plans, programs, and projects annually that are in or otherwise affect the Delta. Interagency coordination is often limited and, despite the Delta's special status, there are no overarching guidelines or coordinated best management practices to ensure that all significant actions use best available science or adaptive management in particular. The Delta Reform Act, in describing a process for coordinating actions under the Delta Plan, requires that State or local government actions are consistent with the Delta Plan and supported by detailed findings. Policy G P1 describes compliance requirements for covered actions that are to be included in the project proponent's written findings.

Problem Statement

Independent and disparate actions by individual agencies can lead to conflict and reduce successful achievement of the coequal goals. Lack of uniform use of best available science and adaptive management for water supply and ecosystem projects can lead to unintended consequences, reduced likelihood of project success, and increased likelihood of adverse environmental impacts. In addition, management actions can be delayed when uncertainty exists, while adaptive management allows for flexible decision making despite uncertainty.

In some cases, project proponents do not carefully plan for the resources and costs of monitoring and tracking, and full adaptive management does not occur. Failure of significant Delta-related actions to comply with existing law can thwart the successful achievement of the coequal goals.

Policies

The appendices referred to in the policy language below are included in Appendix B of the Delta Plan.

G P1. Detailed Findings to Establish Consistency with the Delta Plan

(a) This policy specifies what must be addressed in a certification of consistency filed by a State or local public agency with regard to a covered action. This policy only applies after a "proposed action" has been determined by a State or local public agency to be a covered action because it is covered by one or more of the policies contained in Article 3. Inconsistency with this policy may be the basis for an appeal.

(b) Certifications of consistency must include detailed findings that address each of the following requirements:

(1) Covered actions, in order to be consistent with the Delta Plan, must be consistent with this regulatory policy and with each of the regulatory policies contained in Article 3 implicated by the covered action. The Delta Stewardship Council acknowledges that in some cases, based upon the nature of the covered action, full consistency with all relevant regulatory policies may not be feasible. In those cases, the agency that files the certification of consistency may nevertheless determine that the covered action is consistent with the Delta Plan because, on whole, that action is consistent with the coequal goals. That determination must include a clear identification of areas where consistency with relevant regulatory policies is not feasible, an explanation of the reasons why it is not feasible, and an explanation of how the covered action nevertheless, on whole, is consistent with the coequal goals. That determination is subject to review by the Delta Stewardship Council on appeal;

(2) Covered actions not exempt from CEQA must include applicable feasible mitigation measures identified in the Delta Plan's Program EIR (unless the measure(s) are within the exclusive jurisdiction of an agency other than the agency that files the certification of consistency), or substitute mitigation measures that the agency that files the certification of consistency finds are equally or more effective;

(3) As relevant to the purpose and nature of the project, all covered actions must document use of best available science;

(4) Ecosystem restoration and water management covered actions must include adequate provisions, appropriate to the scope of the covered action, to assure continued implementation of adaptive management. This requirement shall be satisfied through both of the following:

(A) An adaptive management plan that describes the approach to be taken consistent with the adaptive management framework in Appendix 1B, and

(B) Documentation of access to adequate resources and delineated authority by the entity responsible for the implementation of the proposed adaptive management process.

(c) A conservation measure proposed to be implemented pursuant to a natural community conservation plan or a habitat conservation plan that was:

(1) Developed by a local government in the Delta; and

(2) Approved and permitted by the California Department of Fish and Wildlife prior to May 16, 2013

is deemed to be consistent with sections 5005 through 5009 of this Chapter if the certification of consistency filed with regard to the conservation measure includes a statement confirming the nature of the conservation measure from the California Department of Fish and Wildlife.

Problem Statement

Currently, science efforts related to the Delta are performed by multiple entities with multiple agendas and without an overarching plan for coordinating data management and information sharing among entities. Increasingly, resource management decisions are made in the courtroom as conflicting science thwarts decision making and delays action. Multiple frameworks for science in the Delta have been proposed, but a comprehensive science plan that organizes and integrates ongoing scientific research, monitoring, analysis, and data management among entities has yet to be fully formulated.

Recommendations

G R1. Development of a Delta Science Plan

The Delta Stewardship Council's Delta Science Program should develop a Delta Science Plan by December 31, 2013. The Delta Science Program should work with the Interagency Ecological Program, Bay Delta Conservation Plan, California Department of Fish and Wildlife, and other agencies to develop the Delta Science Plan. To ensure that best science is used to develop the Delta Science Plan, the Delta Independent Science Board should review the draft Delta Science Plan.

The Delta Science Plan should address the following:

- *A collaborative institutional and organizational structure for conducting science in the Delta*
- *Data management, synthesis, scientific exchange, and communication strategies to support adaptive management and improve the accessibility of information*
- *Strategies for addressing uncertainty and conflicting scientific information*
- *Prioritization of research and balancing of the short-term immediate science needs with science that enhances comprehensive understanding of the Delta system over the long term*
- *Identification of existing and future needs for refining and developing numerical and simulation models along with enhancing existing Delta conceptual models (e.g., the Interagency Ecological Program (IEP) Pelagic Organism Decline (POD) and the Delta Regional Ecosystem Restoration Implementation Plan (DRERIP) models)*
- *An integrated approach for monitoring that incorporates existing and future monitoring efforts*
- *An assessment of financial needs and funding sources to support science*

Timeline for Implementing Policies and Recommendations

Figure 2-4 lays out a timeline for implementing the policies and recommendations described in the previous section. The timeline emphasizes near-term and intermediate-term actions.

CHAPTER 3

A More Reliable Water Supply for California

ABOUT THIS CHAPTER

This chapter provides an overview of California's water supply, where it comes from, and how it is used. It also describes California's water policy foundations, including federal, State of California (State), and local policies, laws, and programs, and the need for continued improvements in local water planning, management, and information. It explains the special role of the Sacramento-San Joaquin Delta (Delta) in California's water, including its history, conflicts and challenges, and necessary investments and changes to achieve flexibility, improve resiliency, and increase water supply reliability.

As a starting point for this Delta Plan, four core water strategies must be implemented throughout the state to achieve the coequal goal of providing a more reliable water supply for California:

- Increase water conservation and expand local and regional supplies
- Improve groundwater management
- Improve conveyance and expand storage
- Improve water management information

These core strategies form the basis of the 2 policies and 19 recommendations found at the end of the chapter.

RELEVANT LEGISLATION

The Sacramento-San Joaquin Delta Reform Act of 2009 declares State policy for California's water resources and the Delta (Water Code section 85054):

> *"Coequal goals" means the two goals of providing a more reliable water supply for California and protecting, restoring, and enhancing the Delta ecosystem. The coequal goals shall be achieved in a manner that protects and enhances the unique cultural, recreational, natural resource, and agricultural values of the Delta as an evolving place.*

The Legislature declares the following objectives inherent in the coequal goals for management of the Delta (Water Code section 85020):

> *(a) Manage the Delta's water and environmental resources and the water resources of the State over the long term.*
>
> *(d) Promote statewide water conservation, water use efficiency, and sustainable water use.*
>
> *(f) Improve the water conveyance system and expand statewide water storage.*

The Legislature declared that:

> *85004(b) Providing a more reliable water supply for the state involves implementation of water use efficiency and conservation projects, wastewater reclamation projects, desalination, and new and improved infrastructure, including water storage and Delta conveyance facilities.*

Reduced reliance on the Delta for water supplies is established as State policy, along with an associated mandate for regional self-reliance (Water Code section 85021):

> *The policy of the State of California is to reduce reliance on the Delta in meeting California's future water supply needs through a statewide strategy of investing in improved regional supplies, conservation, and water use efficiency. Each region that depends on water from the Delta watershed shall improve its regional self-reliance for water through investment in water use efficiency, water recycling, advanced water technologies, local and regional water supply projects, and improved regional coordination of local and regional water supply efforts.*

Water Code sections 85302, 85303, 85304, and 85211 provide direction on measures that must be included in the Delta Plan to meet the statewide water supply policy goals and objectives, and ultimately the coequal goal of increased water supply reliability:

> *85302(d) The Delta Plan shall include measures to promote a more reliable water supply that address all of the following:*
>
> > *(1) Meeting the needs for reasonable and beneficial uses of water.*
> >
> > *(2) Sustaining the economic vitality of the State.*
> >
> > *(3) Improving water quality to protect human health and the environment.*
>
> *85303 The Delta Plan shall promote statewide water conservation, water use efficiency, and sustainable use of water.*
>
> *85304 The Delta Plan shall promote options for new and improved infrastructure relating to the water conveyance in the Delta, storage systems, and for the operation of both to achieve the coequal goals.*
>
> *85211 The Delta Plan shall include performance measurements that will enable the council to track progress in meeting the objectives of the Delta Plan. The performance measurements shall include, but need not be limited to, quantitative or otherwise measurable assessments of the status and trends...*
>
> > *(b) The reliability of California water supply imported from the Sacramento River or the San Joaquin River watershed.*

The longstanding constitutional principle of reasonable use and the Public Trust Doctrine form the foundation of California's water management policy, and are particularly applicable to the Delta watershed and to the others areas that use Delta water as the basis for resolving water conflicts (Water Code section 85023). The constitutional principle is defined in Section 2 of Article X of the California Constitution as:

> *The right to water or to the use or flow of water in or from any natural stream or water course in this State is and shall be limited to such water as shall be reasonably required for the beneficial use to be served, and such right does not and shall not extend to the waste or unreasonable use or unreasonable method of use or unreasonable method of diversion of water.*

Water Code sections 85031 and 85032 provide clarification that existing water rights, procedures, or laws are not affected:

> *85031(a) This division does not diminish, impair, or otherwise affect in any manner whatsoever any area of origin, watershed of origin, county of origin, or any other water rights protections, including, but not limited to, rights to water appropriated prior to December 19, 1914, provided under the law. This division does not limit or otherwise affect the application of Article 1.7 (commencing with Section 1215) of Chapter 1 of Part 2 of Division 2, Sections 10505, 10505.5, 11128, 11460, 11461, 11462, and 11463, and Sections 12200 to 12220, inclusive.*
>
> > *(b) For the purposes of this division, an area that utilizes water that has been diverted and conveyed from the Sacramento River hydrologic region, for use outside the Sacramento River hydrologic region or the Delta, shall not be deemed to be immediately adjacent thereto or capable of being conveniently supplied with water therefrom by virtue or on account of the diversion and conveyance of that water through facilities that may be constructed for that purpose after January 1, 2010.*
> >
> > *(c) Nothing in this division supersedes, limits, or otherwise modifies the applicability of Chapter 10 (commencing with Section 1700) of Part 2 of Division 2, including petitions related to any new conveyance constructed or operated in accordance with Chapter 2 (commencing with Section 85320) of Part 4 of Division 35.*
> >
> > *(d) Unless otherwise expressly provided, nothing in this division supersedes, reduces, or otherwise affects existing legal protections, both procedural and substantive, relating to the state board's regulation of diversion and use of water, including, but not limited to, water right priorities, the protection provided to municipal interests by Sections 106 and 106.5, and changes in water rights. Nothing in this division expands or otherwise alters the board's existing authority to regulate the diversion and use of water or the courts' existing concurrent jurisdiction over California water rights.*
>
> *85032 This division does not affect any of the following:*
>
> > *(a) The Natural Community Conservation Planning Act (Chapter 10 (commencing with Section 2800) of Division 3 of the Fish and Game Code).*
> >
> > *(b) The California Endangered Species Act (Chapter 1.5 (commencing with Section 2050) of Division 3 of the Fish and Game Code).*
> >
> > *(c) The Fish and Game Code.*
> >
> > *(d) The Porter-Cologne Water Quality Control Act (Division 7 (commencing with Section 13000).*
> >
> > *(e) Chapter 8 (commencing with Section 12930) of Part 6 of Division 6.*
> >
> > *(f) The California Environmental Quality Act (Division 13 (commencing with Section 21000) of the Public Resources Code).*
> >
> > *(g) Section 1702.*
> >
> > *(h) The application of the public trust doctrine.*
> >
> > *(i) Any water right.*
> >
> > *(j) The liability of the state for flood protection in the Delta or its watershed.*

CHAPTER 3

A More Reliable Water Supply for California

In California, the conflicts over water are legendary. The connotations of wealth and power associated with control over water were captured in dramatic fashion in the 1974 film *Chinatown*. A decade later, Marc Reisner's bestselling nonfiction book, *Cadillac Desert*, described vast, arid California land tracts turned to lush, productive fields through the modern magic of water diversion and irrigation. California is known for many things: the urban, cultural giant that is Los Angeles; the great Central Valley, breadbasket to the world; cutting-edge technological advances hailing from Silicon Valley; and the fertile human-made islands of the Delta. The thread that ties these places together is a supply of fresh water from the Sacramento-San Joaquin watershed. Similarly, dozens of fish species—some of them threatened by extinction—and a diverse palette of flora and fauna also depend on this water. As described in Chapter 1, at the heart of California's water troubles are scarcity of supply and competing uses—in particular, conflict with the water needs of the ecosystem. This dynamic of conflict characterizes the essential debate over management of the Delta.

Building on the foundations of California water policy, the Delta Reform Act established the goal of providing "a more reliable water supply for California." This is coequal with the goal of "protecting, restoring, and enhancing the Delta ecosystem." Both must be accomplished while protecting and enhancing the unique values of the Delta as an evolving place. (See sidebar, What Does It Mean to Achieve the Goal of Providing a More Reliable Water Supply for California?)

The Delta Reform Act recognizes that the "Delta watershed and California's water infrastructure are in crisis and existing Delta policies are not sustainable" (Water Code section 85001(a)). The economies of major regions of the state are reliant upon the ability to use water within the Delta watershed or on water imported from the Delta watershed. Yet, the long-term impacts of these diversions, on the Delta and its watershed, in combination with many other factors, are causing native fisheries to decline. In recent years, the populations of salmon and several other fish species have reached their lowest numbers in recorded history, and many of California's salmon runs are now listed as endangered by the State or federal government. The courts have responded by imposing constraints, particularly in dry years, on water diversions through the Delta. As a result, water deliveries—particularly those that come from the State Water Project (SWP) and the federal Central Valley Project (CVP)—have become increasingly unpredictable.

The Delta Reform Act mandates many strategies that the Delta Plan must address to improve water supply reliability for California:[1]

- Promote, implement, and invest in water efficiency and conservation
- Implement and invest in wastewater reclamation and water recycling
- Increase and invest in desalination and advanced water treatment technologies
- Promote and implement options for improved water conveyance

---

[1] See Water Code sections 85004(b), 85020(d) and (f), 85021, 85023, 85302(d), 85303, and 85304.

- Expand and invest in storage
- Improve water quality to protect human health and the environment
- Invest in local and regional water supply projects and coordination
- Prohibit waste and unreasonable use, consistent with Article X, Section 2 of the California Constitution, and protect public trust resources consistent with the Public Trust Doctrine

California's precipitation is extremely variable, and both droughts and floods are not uncommon, even occurring in back-to-back years. Therefore, the State must adapt its water infrastructure and operations in the Delta to make better use of the greater volumes of water that are and, in the future, will continue to be available during wet years, and to take less water during dry years when conflicts with the Delta ecosystem and in-Delta water quality are at their greatest. Concurrently, the development and careful management of local water resources hold tremendous potential for improving water reliability and must be a priority for California.

Management of any natural resource is a continual balancing act. Establishment of the coequal goals provides policy priorities when it comes to managing water, but continuing disputes are inevitable. Given that water in California is scarce, actions that occur in one corner of the state can have ripple effects hundreds of miles away. Levee failures in the Delta may interrupt water supplies to industry in San Diego. Conversely, the way Southern California regions manage their water may affect California's water-dependent ecosystems. The management of a salinity regime to benefit the environment has implications for in-Delta water users. Upstream water use can affect the quality and quantity of water for all downstream users—urban, agricultural, or environmental. Decades-old decisions to drain swamps, build intrastate water projects, and mine gold have left legacy imprints on California's water and ecosystem management.

Although exports from the Delta account for only a fraction of California's water supplies, the Delta is of widespread importance given its geographic location and influential role in ecosystem dynamics. Those who live in the Delta watershed are concerned about how management actions in the Delta may affect them; those who live in the Delta are keenly aware of others' interest in their backyard; and those who rely fully or partially on Delta exports, in some cases located hundreds of miles from the Delta itself, fear the impacts of reduced water supply reliability on their local economies and standard of living.

The broad influence of the Delta is precisely why the Delta crisis cannot be resolved by taking actions in the Delta alone. The Delta Reform Act establishes a new policy for California of reducing "reliance on the Delta in meeting California's future water supply needs" (Water Code section 85021). Reduced reliance is to be achieved through a statewide strategy of investing in improved local and regional supplies, conservation, and water use efficiency so that "each region that depends on water from the Delta watershed shall improve its regional self-reliance." The State's water planning document, the *California Water Plan – Update 2009*, estimates that California could reduce water demand and increase water supply in the range of 5 to 10 million acre-feet (MAF) by 2030 just through the implementation of existing strategies and technology (DWR 2009). This amount of water is more than enough to meet the projected water demands of California's growing population through 2050. An integrated approach that includes increased water efficiency, local and regional diversification of water supplies, reduced reliance on water from the Delta, improved regional self-reliance, and concurrent improvements to storage and Delta infrastructure will build the resiliency and reliability of California's water supply.

WHAT DOES IT MEAN TO ACHIEVE THE GOAL OF PROVIDING A MORE RELIABLE WATER SUPPLY FOR CALIFORNIA?

Achieving the coequal goal of providing a more reliable water supply for California means better matching the state's demands for reasonable and beneficial uses of water to the available water supply.

- This will be done by promoting, improving, investing in, and implementing projects and programs that improve the resiliency of the state's water systems, increase water efficiency and conservation, increase water recycling and use of advanced water technologies, improve groundwater management, expand storage, and improve Delta conveyance and operations. The evaluation of progress toward improving reliability will take into account the inherent variability in water demands and supplies across California.

Regions that use water from the Delta watershed will reduce their reliance on this water for reasonable and beneficial uses, and improve regional self-reliance, consistent with existing water rights and the State's area of origin statutes and Reasonable Use and Public Trust Doctrines.

- This will be done by improving, investing in, and implementing local projects and programs that increase water conservation and efficiency, increase water recycling and use of advanced water technologies, expand storage, improve groundwater management, and enhance regional coordination of local and regional water supply development efforts.

Water exported from the Delta will more closely match water supplies available to be exported, based on water year type and consistent with the coequal goal of protecting, restoring, and enhancing the Delta ecosystem.

- This will be done by improving conveyance in the Delta and expanding groundwater and surface storage both north and south of the Delta to optimize diversions in wet years when more water is available and conflicts with the ecosystem less likely, and limit diversions in dry years when conflicts with the ecosystem are more likely. Delta water that is stored in wet years will be available for water users during dry years, when the limited amount of available water must remain in the Delta, making water deliveries more predictable and reliable. In addition, these improvements will decrease the vulnerability of Delta water supplies to disruption by natural disasters, such as earthquakes, floods, and levee failures.

DP-142

Accordingly, the Delta Stewardship Council (Council) envisions a future in which California has achieved the coequal goal of improved water supply reliability. In the future:

- California's water resources will be better managed, consistent with the State's Reasonable Use and Public Trust Doctrines.
- Improved efficiency and a greater diversity of sources will make more water available to meet the state's demands.
- Groundwater resources will be sustainably managed, and critical overdraft in groundwater basins will have been eliminated.
- Water suppliers in regions that use water from the Delta watershed will have reduced their reliance on this water and improved their regional self-reliance. California will be better prepared to meet the challenges of climate change and catastrophic events that may affect future water deliveries.

In the future, water exports from the Delta will more closely match water supplies available to be exported, consistent with California's variable hydrology and the coequal goal of protecting, restoring, and enhancing the Delta ecosystem. Conveyance facilities in the Delta will be improved, and additional groundwater and surface storage, both north and south of the Delta, will help optimize diversions in wet years when more water is available and conflicts with the ecosystem are less likely, and limit diversions in dry years when conflicts with the ecosystem are more likely. These patterns of Delta exports will be consistent with more natural flow patterns in the Delta, which will aid native species and reduce regulatory uncertainty. At the same time, deliveries of Delta water will be more predictable due to use of storage to deliver wet-year water that is exported and stored for future use. Flexibility of export operations will be enhanced through implementation of local and regional water efficiency, improved conveyance to reduce conflicts with the ecosystem, and water supply projects that reduce pressure on the Delta and reliance on these deliveries.

California's Water Supply Picture

California's water supply picture makes it unlike any other state in the nation. Geography, hydrology, circumstance, and governance have shaped the political landscape of California water in a manner that has both intrigued and frustrated people for decades. Engineering alterations have enabled urban metropolises to thrive—and sprawl—and expansive agricultural regions with global influence to flourish with supplemental water, imported in some cases from hundreds of miles away and across county and even state boundaries. A complex and sometimes conflicting system of laws and policies means that in dry years, frequent in California, a given water district might have surplus supplies with which to grow lettuce or alfalfa, while a district next door battles drought conditions and the associated economic and environmental impacts. A growing awareness of how past water management practices have led to current environmental conflicts and overall competition for water supplies, combined with the knowledge that past climate patterns are not necessarily indicative of the next century's hydrograph, are shaping how California plans for its water future (see Figure 3-1).

This section provides an overview of where California's water comes from and how it is used, the state's vast water supply infrastructure system, and the implications of climate change on California's water supplies.

Sources of California's Water Supply

Variability and uncertainty are the dominant characteristics of California's water resources. Precipitation is the primary source of California's water supply. However, this precipitation varies greatly from year to year, as well as by season and where it falls geographically in the state, which makes management of the state's water resources complex and challenging. Groundwater, which is often connected to surface supplies, contributes to a significant portion of California's water use, on average supplying 8 MAF (20 percent) of California's urban and agricultural uses; but in some areas, this figure is considerably higher and can be as much as 60 to 80 percent of a region's water supply (DWR 2009). Groundwater, and implications for its overuse, is discussed in greater detail later in this chapter.

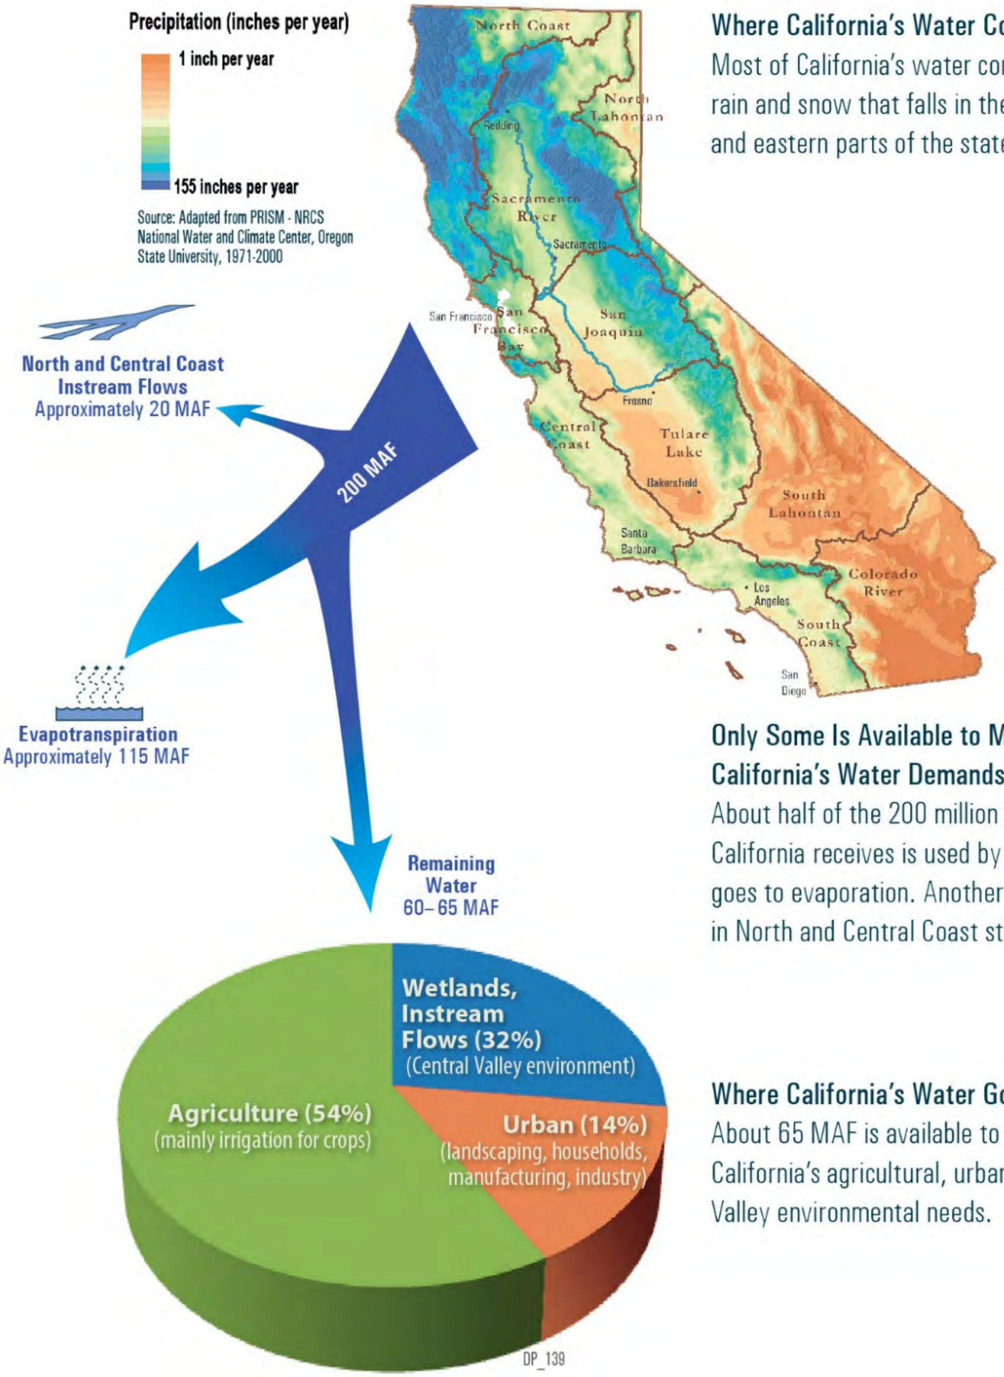
The total amount of precipitation in an average year provides California with about 200 MAF of surface water falling as either rain or snow (DWR 2009).[2] The actual volume of water the state receives each year varies dramatically depending on whether the year is dry or wet. California may receive less than 100 MAF of water during a dry year and more than 300 MAF in a wet year (Western Regional Climate Center 2011a).

The term "average water year" in California is useful for explanatory purposes, but can be misleading as a measurement for planning. In fact, California experiences the most unpredictable pattern of precipitation in the nation, with the bulk of its annual water falling within just 5 to 15 days (Dettinger et al. 2011). This means that in years when fewer storms pass over California, the state faces the problem of too little water; conversely, a few extra storms may result in flooding. For example, between 2005 and 2008, Los Angeles experienced both its driest and wettest years on record (California Natural Resources Agency 2008). The historical record shows that California has frequently experienced long multiyear droughts, as well as extremely wet years that coincide with substantial flooding and consequent risk to people and property (Hanak et al. 2011).

---

[2] Includes up to 10 MAF of precipitation that occurs in Oregon, Mexico, and the Colorado River and is imported into California.

How California's Water Is Used



Where California's Water Comes From

Most of California's water comes from rain and snow that falls in the northern and eastern parts of the state.

Only Some Is Available to Meet California's Water Demands

About half of the 200 million acre-feet (MAF) California receives is used by vegetation or goes to evaporation. Another 20 MAF stays in North and Central Coast streams.

Where California's Water Goes

About 65 MAF is available to meet California's agricultural, urban, and Central Valley environmental needs.

Figure 3-1 *Sources: Adapted from DWR 2009, USGS 2010*

Most of California's precipitation occurs between November and April, yet most of the state's agricultural and urban water demand is in the hot, dry months of summer and early fall, creating a management challenge. In addition, most of the precipitation falls in the mountains in the middle to northern half of the state, far from major population and agricultural centers. In some years, the far north of the state can receive 100 inches or more of precipitation while the southernmost regions receive only a few inches (Western Regional Climate Center 2011b). These basic characteristics of precipitation in California—seasonal timing and geography—and their fundamental disconnect with where and when Californians demand water provide the basic explanation for why water in California is such a complicated and controversial matter.

How California's Water Is Used

The amount of water available to meet agricultural, urban, and ecosystem water demands starts with the state's annual precipitation. On average, about half of this water evaporates; is used by surface vegetation for transpiration; or flows to deep subsurface areas, saline sinks, or the ocean (DWR 2009). The rest of this water—known as "dedicated water"[3]—is used to supply urban municipal and industrial uses, agricultural irrigation, water for ecosystem protection and restoration, and for storage in surface and groundwater reservoirs (DWR 2009).

Patterns of how and when water is used in the state vary with the type of water year. In fact, although best available estimates are included in this Delta Plan, state water managers often work with limited or incomplete information related to water use. The California Department of Water Resources (DWR) uses five water year–type classifications for planning and management purposes: wet, above normal, below normal, dry, and critically dry. In wet years, due to plentiful local rainfall, agricultural and urban landscape irrigation water demands are generally lower. Water demands are usually highest in years of reduced rainfall and because local supplies are low (DWR 2009). Ironically, agricultural and urban water demands may be lower during critically dry years because of short-term water use reduction actions, such as rationing or cropland fallowing to cope with water shortages.

In an average water year, this dedicated water totals approximately 80 to 85 MAF.[4] Again, the fluctuations between wet and dry years can be extreme, with wet years providing more than 95 MAF and critically dry years producing less than 65 MAF of available supply (LAO 2008, DWR 2009, USGS 2010).

However, not all of the 80 to 85 MAF is available to meet water demands within the Central Valley, Bay Area, and Southern California. In the late 1970s, the California Legislature secured State and federal protection of California's North Coast rivers and, in doing so, precluded major diversions from these rivers, including parts of the Trinity, Scott, Salmon, Eel, and Klamath rivers. Water from these rivers is now largely mandated to the environment by law, with the exception of diversions from the Trinity River to the Sacramento River for CVP supplies that are limited by federal law (Hanak et al. 2011). As a result, in an average year, approximately 20 MAF (out of the available supply of 80 to 85 MAF) are reserved for Wild and Scenic Rivers and other instream flow requirements in the North Coast and San Francisco Bay regions and some Central Coast and South Coast areas. Most of this water falls outside the Delta watershed. Although original State water plans and State and federal water contracts envisioned its capture and conveyance, permanent legal protections now prohibit it. (See the CVP and SWP Water Delivery Challenges section.)

---

[3] DWR uses the terms "dedicated" and "developed" interchangeably in their publications. DWR identifies California's average annual dedicated water supply as 85 MAF.

[4] All statewide average water use values were calculated using information in Volume 5 DWR Water Plan 2009 (including average values for years 1998 through 2005) and results from CALSIM II model runs prepared for DWR State Water Project Reliability Studies (DWR 2010b, DWR 2011c).

This means that the remaining water supply (of 60 to 65 MAF in an average year) goes to meet agricultural and urban demands and Central Valley environmental needs.[5,6] In an average year, irrigated agriculture uses approximately 34 MAF (54 percent) of this water, urban areas use about 9 MAF (14 percent), and 20 MAF (32 percent) is mandated to meet instream flow requirements, including State Water Resources Control Board (SWRCB) Delta water quality requirements and Central Valley wildlife refuge commitments (DWR 2009).

Accounting for how much water each sector actually uses is complicated because water may be reused several times for different purposes or it may be taken from surface or groundwater storage held from previous years.[7] The lack of consistent and accurate estimates of statewide water use is a significant challenge that has important implications for improved water management in California.

Future population and economic growth is expected to result in increased water demand. Today, California's water supply supports a population of 36.5 million people, an economy of $1.9 trillion, and diverse natural resources (LAO 2011). The largest economic sectors in the state are trade, transportation, and financial services, with agricultural services contributing about $38 billion (2 percent). Projections by the California Department of Finance in 2010 forecast that the population may grow to 60 million people by 2050, but the rate of growth is slowing and could be much lower.[8] As more development occurs, water use will continue to shift away from agricultural toward urban uses (DWR 2005, DWR 2009, LAO 2008, Hanak et al. 2011). At the same time, increasing water needs for ecosystem protection will likely exacerbate conflicts with agricultural and urban water demands.

California's Water Supply Infrastructure

To provide more reliable water supplies despite the state's hydrologic variability and diverse geography, and also to manage floods during wet years, State, federal, and local agencies have built a vast, interconnected infrastructure system throughout California (see Figure 3-2). The Delta, because of its geographic location and role in conveying water supplies, is often described as the "linchpin" of California's water infrastructure. Rivers and dredged channels act as conveyance canals, and pumping plants provide the momentum to move stored water to areas south. California's overall system includes a range of surface reservoirs, aqueducts, pumping plants, operable gates, groundwater wells, and water treatment facilities constructed over the last hundred plus years.

---

[5] Data are from 2000, which DWR categorized as an "average" rainfall year for the state.

[6] The "remaining water" of approximately 60 to 65 MAF, (62.4 MAF for purposes of percentage calculations) is referred to throughout this chapter as "total water use," unless otherwise specified. Total water use includes urban, agricultural, and Central Valley environmental uses such as instream flow requirements and non-CVP-managed wetlands.

[7] For example, water that is dedicated to instream flows often becomes available for downstream diversion to agricultural and urban uses. Some portion of the water that is used for agricultural irrigation or drinking water is returned to the ecosystem through agricultural tailwater releases, infiltration of irrigation water into groundwater, and discharges from sewage treatment plants. The State does not have a system for documenting these multiple uses.

[8] Growth projections by the California Department of Finance are regularly revised and over the past 2 decades reflect a trend toward slower expected growth for the state. Between 1993 and 2004, the California Department of Finance's population projections for 2040 declined by 12 million people, from 62 million to 50 million.

Moving and Storing California's Water

Figure 3-2

Large State, federal, and local dams and canal systems play an important role in storing and conveying water throughout California to meet a variety of urban and agricultural water demands.

Source: Adapted from DWR 2009

On average, local and regional water supplies account for 52 MAF (84 percent) of the state's total water use. Of the 52 MAF, about 44 MAF (84 percent) of the water supply comes from local surface water storage and deliveries, and includes sources such as the Santa Ana, Los Angeles, and Ventura river watersheds in Southern California; local diversions from the Sacramento and San Joaquin rivers; and stream drainages in the central coastal areas. In addition, groundwater supplies about 8 MAF (13 percent) of the state's total water use in average years (20 percent of urban and agricultural water use), and during droughts, can provide up to 60 percent or more for specific regions (DWR 2009). A small but rapidly growing percentage of local water comes from recycled water and water reuse projects.

Supplemental water supplies are conveyed from wetter regions of California, primarily through diversions of runoff from the great Sierra Nevada mountain range and some water from the Trinity River in the north state. In most regions, these imported water supplies augment local and regional sources, especially in dry years and dry seasons. On average, approximately 10.1 MAF (16 percent) of the state's total water use comes through a combination of major conveyance and storage facilities from water sources within California and from other states, with the SWP and CVP making up the majority of these imports (5.1 MAF, about 8 percent), and Hetch Hetchy (0.2 MAF), Mokelumne (0.3 MAF), and the Los Angeles Aqueduct (0.2 MAF) comprising the remaining in-state imports. A significant portion of the state's water supplies are imported from outside California, primarily from the Colorado River (4.3 MAF) through the Colorado River Aqueduct, which serves agricultural and urban demand in Southern California.

The network of infrastructure to store and convey water in California is impressive by modern standards and compared to other states. The state's single largest "reservoir" is the Sierra Nevada snowpack, which holds approximately 15 MAF per year on average (DWR 2009). However, for comparison, local, State, and federal agencies in California have constructed more than 1,200 major reservoirs with a combined storage capacity of 43 MAF, about half the average annual runoff for the entire state (Hanak et al. 2011, DWR 2011a).

Most of California's largest surface storage reservoirs are owned and operated by the federal government and total approximately 17 MAF of storage capacity. The largest federal facility, part of the CVP, is Shasta Lake, which holds 4.5 MAF. The State's single largest storage facility and keystone feature of the SWP, Lake Oroville Dam on the Feather River, has a capacity of 3.5 MAF (LAO 2008). Operating with other reservoirs as a system, these multibenefit facilities reduce the potential for floods at the same time that they make water available for seasonal water agricultural and urban demand, particularly in the summer and fall. They also generate clean electricity. Although these storage facilities provide many benefits, they have also significantly altered the natural ecology of these rivers. Dams and their associated facilities can present barriers to migrating fish and reduce or eliminate downstream gravel and sediment replenishment to the detriment of native species such as salmon. Moreover, reservoir operations have significantly modified the amount and timing of instream flows, as well as water temperature, further contributing to the decline of the state's native fish and ecological resources.

Looking to the future, fewer high-yielding surface storage sites are available in the state now because most of these areas have already been developed (NRC 2012). However, there are significant opportunities throughout California to expand groundwater storage and to reoperate surface storage in conjunction with groundwater storage (also known as conjunctive management or groundwater banking) and other programs to maximize the water supply and environmental benefits of these systems.

Climate Change Complicates Management of California's Water

With climate change, the state's water supply will become even more erratic. Weather patterns are expected to become more extreme with long, multiyear droughts becoming more frequent as well as extremely wet years. Since 1906, California has seen "dry or critically dry" years one-third of the time. This trend is increasing (California Data Exchange Center 2011).

By 2050, temperature increases of 1 to 3 degrees Celsius are expected to cause more winter precipitation to fall as rain, as opposed to snow, and to reduce the Sierra Nevada snowpack (the source of much of California's runoff) by 25 to 40 percent (DWR 2010d). Runoff patterns will shift, leading to greater cool-season runoff and decreased warm-season runoff (Reclamation 2011a). The pattern of spring runoff is also expected to change, with a more rapid spring snowmelt leading to a shorter, more intense spring period of river flow and freshwater discharge accompanied by higher flooding risks (Knowles and Cayan 2004, Knowles et al. 2006, Null et al. 2010, Willis et al. 2011). Because the Delta watershed provides a portion of the water supply for approximately 27 million Californians and irrigates millions of acres of farmland, rising sea levels leading to increased salinity intrusion, along with changes in the form of precipitation and timing of snowmelt, will profoundly alter the way water is managed in California.

Specifically, an anticipated shift in runoff patterns will present a management challenge to existing reservoir operations, with large runoff events increasingly putting pressure on reservoirs managed for multiple benefits, including flood control. Reduced natural water storage in the form of snowpack will diminish statewide carryover storage capacity, making the state increasingly vulnerable during prolonged dry periods and negatively affecting water supply reliability. Sea level rise, as much as 55 inches by 2100 (OPC 2011), will result in high salinity levels in the Delta interior, which will impair water quality for agricultural and municipal uses, and change habitat for fish species. Maintaining freshwater conditions in the Delta could require unanticipated releases of water from storage, which will reduce available water supplies for fish. Rising seas also will dramatically increase the risk of catastrophic interruption of water exports as a result of levee failure and flood events, particularly in the interior Delta where substantial subsidence has already occurred. Warmer temperatures throughout the state will cause higher evaporation rates, particularly during the hot summer and early fall months, contributing to reduced streamflows, drier soils, reduced groundwater infiltration, higher losses of water from surface reservoirs, increased urban and agricultural demand for irrigation water, and more water needed for ecosystem protection (California Natural Resources Agency 2008).

The precise local impacts of climate change on regional water resources remain less certain. Many communities in the state already experience water shortages during droughts (California Environmental Protection Agency 2006, LAO 2009). Improved modeling, especially downscaling of global climate change information to regional and local levels, will help communities to evaluate the extent of their vulnerability and to develop water management strategies that will increase the resilience of their water supply systems (USEPA and DWR 2011).

Foundations of Water Policy in California

Over the past 160 years, the California water rights system has evolved into a complex mix of public and private rights and contractual obligations that were intended to create more certainty about how water is to be allocated among urban, agricultural, and environmental uses during droughts, catastrophic interruptions in water supplies, and other times of scarcity. (See sidebar, California's Complex Water Rights System.) Yet some of these rights and obligations conflict, and now, in many years, there is insufficient water in California to support them all.

California's legal system recognizes limitations on water rights based on the longstanding doctrines of Reasonable Use and Public Trust (NRC 2012). The Delta Reform Act reiterates that the principles of reasonable use and public trust "shall be the foundation of state water management policy" and that they are "particularly important and applicable to the Delta" (Water Code section 85023). The coequal goals of improving water supply reliability for the state and restoring the Delta cannot be achieved by actions in the Delta alone. Every region in California, along with the cities and farms that receive Delta water, will need to improve their management of the state's scarce water resources.

This section discusses the legal foundations for California water policy, explains the state's system of water rights, and describes new water policies and priorities, including reduced reliance on the Delta and improved regional self-reliance, established by the Delta Reform Act.

Reasonable Use and the Public Trust Doctrines

The Reasonable and Beneficial Use and Public Trust Doctrines, in combination with existing water rights and the State's area of origin statutes, have long been the legal and policy foundation for water management in California. The State's Reasonable and Beneficial Use Doctrine specifically limits all water rights and water use in California to "such water as shall be reasonably required for the beneficial use to be served, and such right does not and shall not extend to the waste or unreasonable use or unreasonable method of use or unreasonable method of diversion of water" (California Constitution, Article X, Section 2).

The SWRCB is the primary agency responsible for ensuring that water is not wasted and that the reasonable use standard is not violated. However, DWR also shares with them the duty to "take all appropriate proceedings and actions…to prevent waste, unreasonable use, unreasonable method of use, or unreasonable method of diversion in this state" (Water Code section 275). The SWRCB also is responsible for determining whether any water remains available in a stream or watershed for appropriation and whether the water is being fully used for "beneficial uses," consistent with State law that identifies the types of water uses that are permitted.[9] The State can review and modify existing water rights as well as consider approval of new permits and water rights to

reflect new conditions, including California statutes that require efficient water use and improved water management.

The Public Trust Doctrine provides the State with additional authority to reconsider past water allocation decisions in light of new information and changing water demands and social values, and to modify or revoke previously granted water rights if warranted. In a 1983 landmark legal decision, the California Supreme Court unanimously affirmed that the state's navigable lakes and streams are resources that are held in trust for the public and are to be protected for navigation, commerce, fishing, recreational, ecological, and other public values. The State "has an affirmative duty to take the public trust into account in the planning and allocation of water resources and to protect public trust uses whenever feasible" (*National Audubon Society v. Superior Court*, 33 Cal. 3d 419, 658 P.2d 709, 189 Cal. Rptr. 346, 1983 Cal.). This has significant implications for governance of water resources. In fact, both the Public Policy Institute of California and Appeals Court Associate Justice Ron Robie recently called for the establishment of a public trust advocate at the SWRCB to ensure that the State's duty to protect California's public trust resources is being performed adequately (Robie 2012, Hanak et al. 2011).

---

[9] Beneficial uses recognized in California include domestic, fire protection, fish and wildlife, industrial, irrigation, municipal, power production, recreation, and other uses (SWRCB 2010).

CALIFORNIA'S COMPLEX WATER RIGHTS SYSTEM

Whatever the type of water right that is held by an individual, business, or public agency, no one "owns" the water they use in California (Littleworth and Garner 2007). All water within the state is held in trust for the benefit of all the people of California (Water Code sections 102, 1201). Water rights holders have the right to "take and use water, but they do not own the water and cannot waste it" (*Central and West Basin Water Replenishment District v. Southern California Water Co.* (2003) 109 Cal. App. 4th 891, 905).

Riparian Rights – Landowners who own property that abuts a natural water course are entitled to make reasonable use of water on or flowing past their property. The water must be from a natural flow (not released stored water). Water cannot be stored under a riparian right and may only be used on property that is within the drainage of the water's source. If there is not enough water in a watershed to satisfy both riparian and appropriative rights, then riparian rights must be fulfilled first. In times of shortage, riparian right holders allocate the reduced water supply by sharing the shortage among the riparian users.

Appropriative Rights – An appropriative right is typically used when the prospective water user intends to use water on nonriparian land or the water user needs to store water for later use. Pre-1914, these rights were asserted in a manner similar to the filing of a mining claim; a water user filed a public notice of his or her intent to divert water and then diverted the water for a legally recognized beneficial use such as mining, irrigation, or drinking water. In times of shortage, appropriative right holders allocate the reduced water supply among themselves under a first in time, first in right priority system. Generally, water received through appropriative rights is more predictable than riparian rights, but appropriative rights can be lost through nonuse (because beneficial use is the basis for receiving the right), and shortages are allocated based on seniority (NRC 2012). California law recognizes water conservation as a "reasonable beneficial use" so that water efficiency improvements cannot be used as a reason to reduce appropriative rights held by a water user (Water Code section 1011(a)).

CVP and SWP Contractors – The Bureau of Reclamation and DWR hold appropriative water rights for the operation of the CVP and SWP, respectively. In many instances, these project rights are junior in priority to the rights held by water users in the Delta and within the Delta watershed. This means that during droughts and other periods of water shortages, the ability of the SWP and CVP to divert water from the Delta is limited by riparian owners and by more senior appropriative water rights.

Area of Origin Laws – Several statutes provide protections to areas within the Delta and the Delta watershed where the rivers originate (Littleworth and Garner 2007). Also known as "watershed protection" statutes, these laws provide the opportunity for water users in these areas to obtain water rights with a more senior priority than the SWP and CVP contractors so that local demands might be met before water becomes available for export.

Reasonable Use and Public Trust Doctrines – The SWRCB has the authority to review and modify existing water rights as well as approve new rights. This is an important principle because it enables the State to consider what is "reasonable" based on modern societal values, the need to protect other water users, protect the environment, and prevent the waste and unreasonable use of water. This authority derives in part, from the Public Trust Doctrine, under which the State has an ongoing duty to protect the navigable waters of the state for environmental protection, fishing, navigation, and commerce; and from the Reasonable Use Doctrine of the California Constitution, a provision mandating the reasonable and beneficial use of all waters in the state (Article X, Section 2).

DP-338

California's Water Rights System and Use Reporting

California's water rights system is of great legal significance. However, our water rights system does not and cannot guarantee a supply of water that exceeds what nature provides. Nor does any individual, business, industry, or agricultural enterprise "own" the water they use.

The amount of water used in California's stream systems is not fully known because water users under pre-1914 and riparian water rights have not been required, until recently, to submit annual reports accounting for their diversions. In 2009, the State adopted statewide water diversions reporting requirements (Water Code section 5100 et seq.); and in 2010, the SWRCB adopted regulations requiring online reporting of water use by all water rights holders, including all surface and groundwater users. In addition, there is limited information available to the State on consumptive use or the number of times that water is used within a stream system.

Discussed previously, the SWRCB has the authority to determine when a river or stream has been "over-appropriated," in other words, whether the amount of water available in a stream is less than the demands placed on that water. A right to use water represents potential diversions and uses. Actual water use in many rivers and streams is frequently far less than the total volume of asserted water rights. The difference between water rights and water received can be explained by restrictions or conditions in the permits/licenses, operation restrictions on the storage and transport facilities themselves, physical and economic limitations, non-consumptive uses such as hydroelectric power generation, and the use and reuse of water.

Understanding and reconciling the human demands for water to the supply available, while providing enough water to ensure desired and legally protected environmental and water quality goals, is a difficult process. This process is nonetheless essential to achievement of the coequal goals.

The Coequal Goals and Reducing Reliance on the Delta

In 2009, California further defined its water policy priorities as they relate to the Delta, including express recognition that the Delta crisis cannot be resolved by taking action in the Delta alone. Given the interconnected nature of the Delta with the water use patterns of large parts of Northern, Central, and Southern California, the new coequal goals of statewide water supply reliability and an improved, protected, and restored Delta ecosystem will fundamentally reshape California water management over the course of this century. Achieving these coequal goals is expected to be done, in significant part, through compliance with the Delta Reform Act's various mandates and goals relating to statewide water conservation, efficiency, and sustainable use, including the State's new policy to reduce reliance on the Delta and related mandate to improve regional self-reliance.

In particular, the Delta Reform Act mandates many statewide strategies that the Delta Plan must address to achieve the coequal goals, including water efficiency and conservation; wastewater reclamation and recycling; desalination and advanced water treatment technologies; improved water conveyance, surface, and groundwater storage; improved water quality; and implementation of local and regional water supply projects (Water Code sections 85004(b), 85020(d) and (f), 85021, 85023, 85303, and 85304). These measures help achieve the requirements of Water Code section 85021, which declares that the State's policy is "to reduce reliance on the delta in meeting California's future water supply needs through a statewide strategy of investing in improved regional supplies, conservation, and water use efficiency." That section also mandates that "[e]ach region that depends on water from the delta watershed shall improve its regional self-reliance for water through investment in water use efficiency, water recycling, advanced water technologies, local and regional water supply projects, and improved regional coordination of local and regional water supply efforts."

Consequently, to achieve the statewide water supply mandates and the coequal goal of statewide water supply reliability, regions located outside the Delta also must take actions outside the Delta to increase water efficiency and develop sustainable local and regional sources of water, which will contribute to improved water supply reliability.

Individual actions by water suppliers throughout the state will be vital to success in this regard. The implementation of programs and projects that result in a significant reduction in the amount of water used, or in the percentage of water used, from the Delta watershed (evaluated at the local, regional, and statewide levels) will be the foundational measures for assessing the State's progress in achieving these policies. The baseline for this evaluation will be existing water use and supplies, as documented in the most recently adopted urban and agricultural water management plans. (See Appendix G, Achieving Reduced Reliance on the Delta and Improved Regional Self-Reliance.)

It is important to recognize that reliance on water from the Delta and the Delta watershed varies throughout California, from region to region, and supplier to supplier. (See sidebar, Reliance on the Delta Varies by Region.) Some water suppliers have greater access to alternative water supplies or have a greater ability to implement a diverse range of water efficiency and water supply projects. Others, particularly in the upper watershed, may have a narrower range of options.

The key is that every supplier is doing its part and is taking appropriate action to contribute to the achievement of the coequal goals, including the State's policy of reduced reliance and associated mandate to improve regional self-reliance.

The Delta's Role in California's Water Supply

The Delta is the terminus for California's largest watershed, which encompasses the western slopes of the Sierra Nevada, the eastern slopes of the coastal range, and the valleys that lie between these ranges. Water in the Delta watershed starts as precipitation in the Sacramento River and San Joaquin River watersheds and, unless diverted or otherwise used, flushes San Francisco Bay and flows out to the ocean under the Golden Gate Bridge. Once again, this estuarine delta where California's two largest rivers meet is at the geographic and political center of water in California.

The CVP and the SWP rely on the Delta's artificial network of channels to convey water stored in upstream reservoirs to regions south of the Delta including the Bay Area, San Joaquin Valley, Tulare Lake Basin, Central Coast, and Southern California. (See sidebar, Reliance on the Delta Varies by Region, and Figure 3-3.)

Because of the Delta's central location, the water demands of many Californians are connected in some way to the Delta. Water diverted from the Delta watershed provides some portion of water supply for more than 27 million of the state's residents and approximately 3 million irrigated acres of farmland (DWR 2007a, DWR 2009, DWR 2011c, Reclamation 2011b). This water plays a critical role in helping to sustain a major portion of the state's $1.9 trillion economy.

This section provides an overview of water use and water infrastructure in the Delta watershed, followed by a description of water project operations in the Delta and the challenges and conflicts associated with these. The section concludes with a discussion of the importance of improving the flexibility of project operations, through improved conveyance, storage, and water management, in achieving the coequal goals.

Use of Water from the Delta Watershed

About half the state's runoff flows through the Delta watershed. Since the 1849 Gold Rush, communities throughout California have planned and constructed facilities to tap into this water to support economic development.

Many diversions in the Delta watershed occur in the upper watershed. On average, approximately 31 percent of the flow from the Delta watershed is diverted before it ever reaches the Delta (DWR 2011c). See Figure 4-5 in Chapter 4. These diversions are done through an extensive network of locally constructed dams, canals, and diversion structures that have been built over the past 160 years on nearly every stream and drainage within the Delta watershed (California Natural Resources Agency 2010). Some of the water diverted from Delta tributaries is returned to the tributaries through wastewater effluent and agricultural return flows, albeit at a degraded quality.

Water from these diversions sustains the economies of the residents, businesses, and growers who live in the areas where the water comes from—the "area of origin"—as well as the economies in the export areas. Some of these historical diversions occur through two large aqueduct and reservoir systems that were constructed early in the twentieth century to serve the growing water demands of San Francisco and East Bay Area communities. These facilities divert water before it reaches the Delta and convey it directly to reservoirs, treatment facilities, or customers in the Bay Area region. The Hetch Hetchy reservoir system on the Tuolumne River, and the Pardee and Camanche reservoirs system on the Mokelumne River account on average for approximately 0.5 MAF, or about 1.6 percent of the flow from the Delta watershed, of annual water deliveries from the Delta's upper watershed (DWR 2009).

RELIANCE ON THE DELTA VARIES BY REGION

Water exported from the Delta supplies about 8 percent of the state's total water use, and local and regional water supplies provide over 84 percent on average. However, reliance on water from the Delta watershed varies throughout California from region to region, supplier to supplier, and user to user.

For example, in the Sacramento and San Joaquin river watersheds, including water uses on the valley floor, foothills, mountain communities, and the Delta, the vast majority of the water supply comes from local sources: the rivers and reservoirs that flow into the Delta or from local groundwater resources that are replenished from runoff within the Delta watershed. Most of this water is used for irrigated agriculture, although increasing amounts are being shifted to drinking water and other municipal uses by the cities and towns that are growing in these regions. High-growth areas surrounding the Delta, including Fairfield, Sacramento, Stockton, and Tracy, are increasing urban water use and decreasing agricultural water use as the communities are developed.

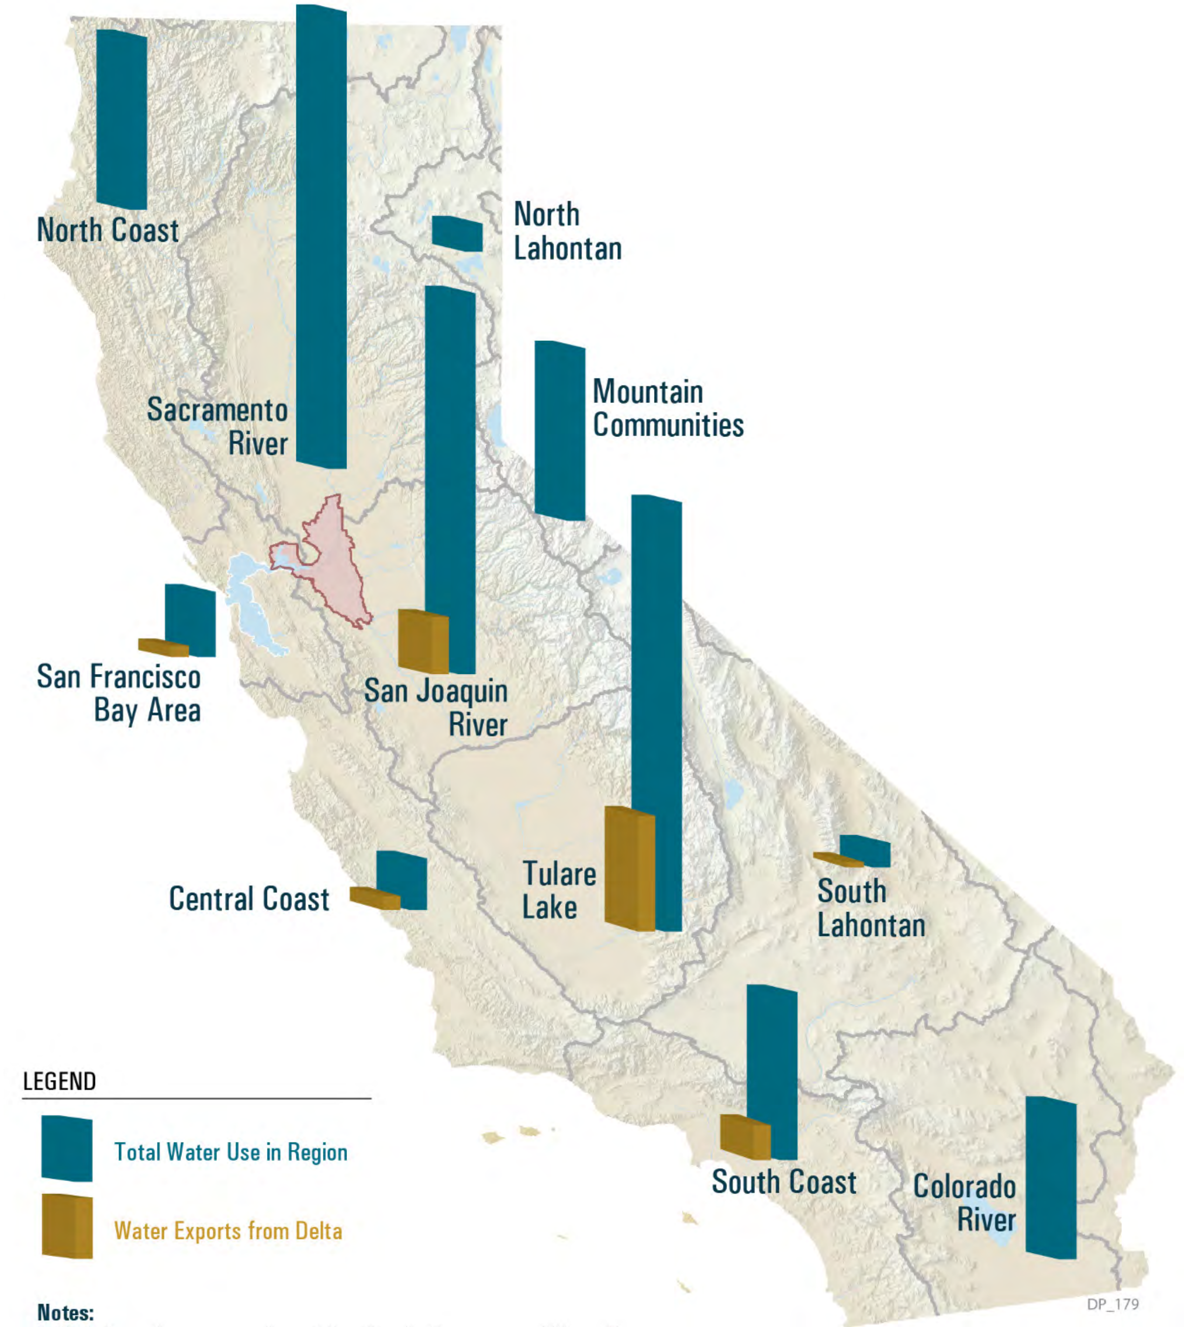
Other regions, including the Tulare Lake region of the Central Valley, the San Francisco Bay Area, the South Coast, and the Central Coast, receive some portion of their water supply from diversions from the Delta's eastern tributaries or from water that is pumped from the Delta to supplement their limited local surface water and groundwater supplies. These exports vary by region and, for specific water users, the significance of these exports varies dramatically. For example:

- **Tulare Lake:** This region relies upon exports delivered through the Central Valley Project (CVP) and State Water Project (SWP) for 27 percent of its regional water supply, and most of this water use is for irrigated agriculture (on average 96 percent of CVP water deliveries and 89 percent of SWP deliveries). Kern County Water Agency, a water wholesaler, has the largest SWP import contract in the Tulare Lake Basin at nearly 1 million acre-feet (MAF) (DWR 2009).
- **San Francisco Bay Area:** This region's predominant water supply is from local sources (57 percent from surface and groundwater alone). However, diversions from the Delta's tributary streams provide up to 27 percent of this region's water, and CVP and SWP exports account for another 16 percent (DWR 2009). The reliance of the region's individual water suppliers on water from the Delta varies dramatically; the Marin Municipal Water District uses none (MMWD 2010), and the Zone 7 Water Agency in Alameda County receives as much as 82 percent of its water from SWP exports (Zone 7 2010).
- **Southern California:** This region is home to 50 percent of the state's population (with most in densely urbanized areas), and 80 percent of its water use is for drinking water, municipal, and industrial uses. SWP exports from the Delta account for roughly 25 percent of the region's water supplies, and local sources (groundwater, surface water, and increasingly recycled water) comprise another 50 percent, and imported water from the Colorado River about 25 percent (DWR 2009). Within the Metropolitan Water District of Southern California, the largest wholesaler in Southern California, the dependence of its member agencies on SWP imports can vary dramatically. Some agencies have few alternative water sources, while others have sufficient local supplies and are now planning to reduce their future reliance on imported water or to roll off the system completely (WBMWD 2010, City of Santa Monica 2012).

With increasing uncertainty over the reliability of Delta water exports, many communities have developed plans and projects to increase and diversify local water supplies and to increase water efficiency. Even with improvements in Delta operations that provide more reliable Delta water exports, regions will need to implement additional local and regional water management strategies to reliably meet their future water demands.

DP-339

Local Water Sources Meet Most of California's Water Needs



Notes:
1. Hydrological regions are those defined by the Department of Water Resources
2. Delta water exports include contract amounts to maintain wetlands

Sources: DWR 2009, Reclamation 2011b, DWR 2011c

Figure 3-3 The vast majority of California's water comes from local sources. Exports from the Delta comprise 8 percent of California's water use. Yet, the Delta supply is important to many regions south of the Delta.

Within the Delta, growers and residents historically have relied on water from the Delta. In-Delta water use has remained relatively constant over the past 100 years (DWR 2007a) and averages about 4 percent (0.9 MAF) of inflows into the Delta. Most of this water is used for agricultural irrigation, and small and large communities throughout the Delta.

The CVP and SWP export systems became operational in the late 1940s after much of the local Delta development had occurred. Exports from the Delta now range from approximately 3 MAF in dry years to around 6.5 MAF in wet years (DWR 2009, Reclamation 2011b, Reclamation 2011c). In total, the SWP and CVP facilities export on average approximately 5.1 MAF per year from the Delta. These water diversions account for 24 percent of the inflows into the Delta (see Figures 3-4a and 3-4b).

Joint Federal and State Delta Operations

The federal CVP and California SWP were born out of long-range planning documents developed from the 1870s through the 1920s, including the 1919 Marshall Plan completed by U.S. Geological Survey and the 1930 Division of Water Resources Bulletin No. 25, "Report to the Legislature of 1931 on State Water Plan." These planning investigations developed and evaluated alternatives to provide:

- Fresh water to industries in Contra Costa and Alameda counties along Suisun and San Pablo bays
- Irrigation water to portions of the San Joaquin Valley that have substantial and increasing groundwater overdraft conditions, especially in the Tulare Lake region
- Supplemental water for Southern California urban development totaling 2 million acres in San Diego, Orange, and Ventura counties and the San Gabriel and San Bernardino valleys with water from Owens Valley, Mono Basin, and Colorado River

The California Legislature approved this plan in 1941 as the first State Water Plan (now the current California Water Plan), which included a description of facilities that would eventually be constructed as part of the CVP and SWP. Although design and construction of storage and conveyance facilities was done separately for CVP and SWP, both are operated in a coordinated manner for Delta operations.

Central Valley Project

Congress appropriated $20 million in Emergency Relief Appropriation Funds and authorized construction of the CVP by the U.S. Army Corps of Engineers (USACE) as part of the Rivers and Harbors Act of 1935. When the Rivers and Harbors Act was reauthorized in 1937, the construction and operation of the CVP was instead assigned to the Bureau of Reclamation (Reclamation).

Construction of the CVP by the federal government began in 1937. The first water was sold from the CVP to the City of Antioch from the initial reaches of the Contra Costa Canal in 1940, to support shoreline industries.

By the late 1940s, it had become apparent that California's rapid urban, agricultural, and industrial growth would quickly increase demands for water and power to levels that exceeded the initial CVP system capacity. In response, Congress authorized additional federal reservoirs and conveyance facilities over the next few decades, including Folsom Dam along the American River, Tehama-Colusa Canal along the west side of the Sacramento Valley, Trinity River Dam to provide additional water from the Trinity River into the Sacramento River for CVP operations, and New Melones Dam on the Stanislaus River. In 1960, the San Luis Unit, in the western San Joaquin Valley, was authorized by Congress to be constructed under a contract between the federal government and the State.

Where Delta Water Comes From and Goes

Data presented as a long-term average. Information based on DWR CALSIM II modeling, which includes projected conditions to protect fisheries.

Delta-Suisun in-Delta use includes water to the Contra Costa Canal and to the Mokelumne and Hetch Hetchy aqueducts.

Figure 3-4a

Over the past century, the combination of regional diversions from within the Delta watershed and water diverted directly from the Delta has transformed the Bay-Delta ecosystem, reducing historical outflows by an average of 50 percent.

Sources: LAO 2008, Reclamation 2011b, DWR 2011c

Delta Water Flows in Wet and Dry Years

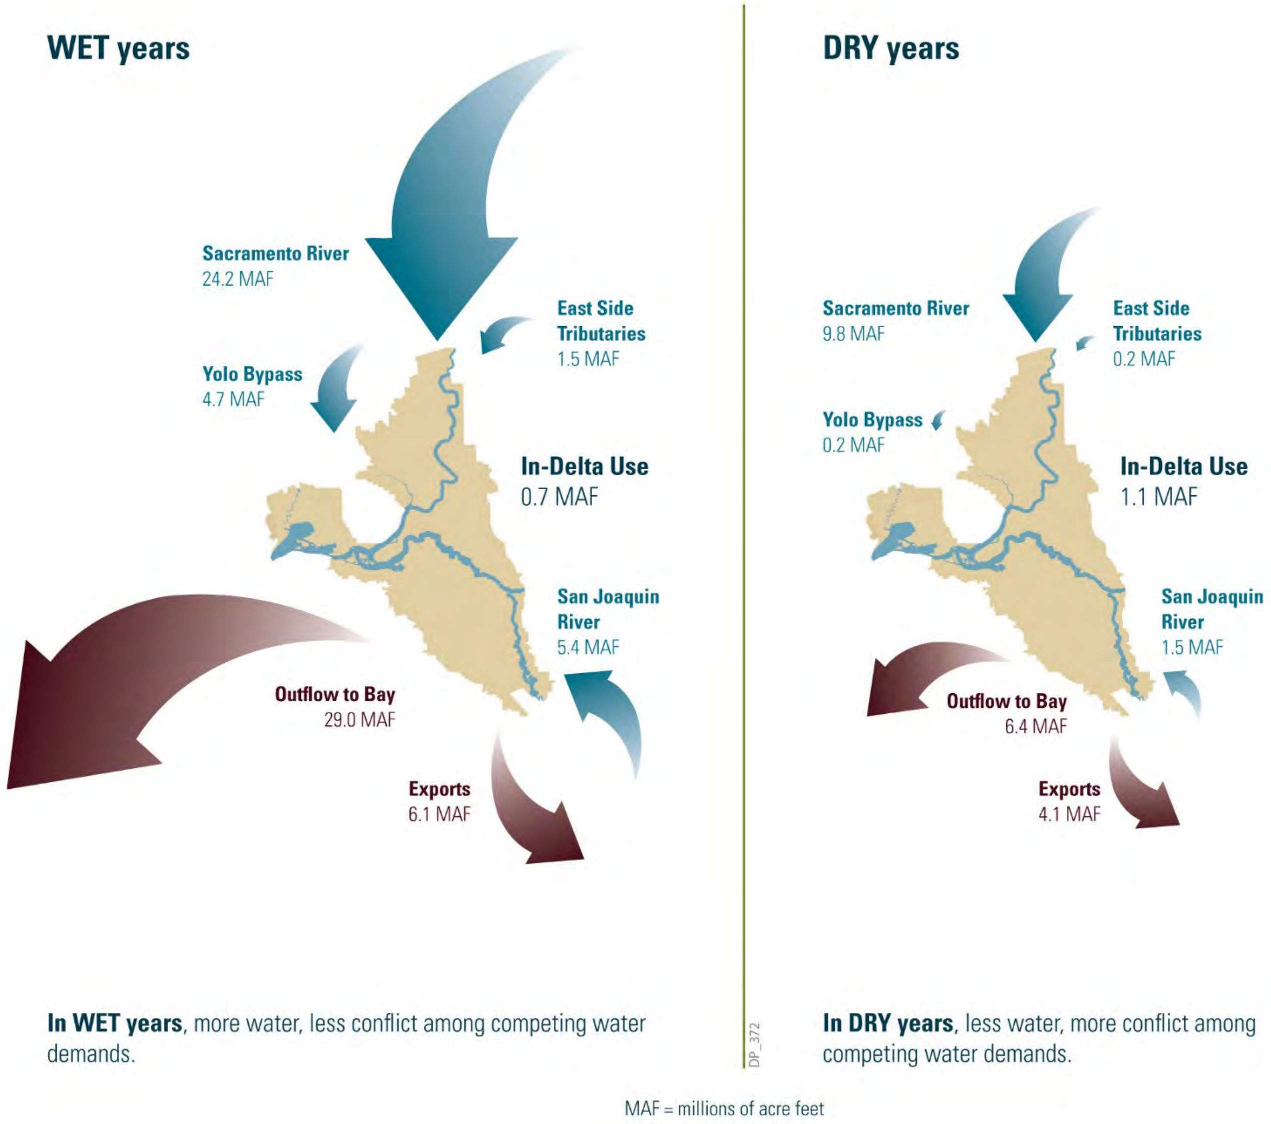


Figure 3-4b *Sources: LAO 2008, Reclamation 2011b, DWR 2011c*

The CVP is the largest surface water storage and delivery system in California, with a geographic scope covering 35 of the state's 58 counties. The project includes 20 reservoirs with a combined storage capacity of approximately 11 MAF, 8 power plants and 2 pumping-generating plants, 2 pumping plants, and approximately 500 miles of major canals and aqueducts. The CVP provides water through water service contracts and water rights agreements for a total of about 9.6 MAF per year (including water service contractors that use water from the Stanislaus River and San Joaquin River).

State Water Project

In 1947, the State began an investigation to consider the next phases of the State Water Plan to meet the state's anticipated supplemental water demands through development of the SWP and to control salinity intrusion in the Delta. In 1953, the State adopted the Abshire-Kelly Salinity Control Barrier Act to evaluate placement of a saltwater barrier near Suisun Bay to protect Delta water users and allow transfer of fresh water from the Sacramento Valley to the San Joaquin Valley. This plan was not implemented primarily due to costs and technical considerations, but alternatives continue to be evaluated today.

In 1957, Bulletin No. 3 was published, which described the need for SWP facilities to convey water from the Sacramento Valley to water-short areas of California. The report identified an urgency to expand statewide water facilities because of projected population growth and to support a balanced economy; major industrial growth; 6,875,000 acres of irrigated agriculture, or approximately 25 percent of all agricultural acreage in the United States; and flood control in Northern California. The study identified that there was a "seasonal deficiency" of 2,675,000 acre-feet of water in 1950 that had been met with groundwater pumping primarily from overdrafted aquifers. In 1960, California voters authorized the Burns-Porter Act to construct the initial projects of the SWP, including Oroville Dam and Lake Oroville on the Feather River, San Luis Dam and Reservoir to be jointly constructed and operated with Reclamation, the North and South Bay aqueducts, and the 444-mile California Aqueduct. Notably, DWR continues to project a 1- to 2-MAF deficit in average annual groundwater pumping from overdrafted aquifers (DWR 2009). A more detailed discussion of groundwater is provided later in this chapter.

Delta Operations

Prior to the 1960s, the CVP and SWP operated in the Delta unrestrained by environmental regulations. However, beginning in the 1970s, with the passage of environmental laws, including the federal Clean Water Act, Endangered Species Act, Central Valley Project Improvement Act, Porter-Cologne Water Quality Control Act, California Endangered Species Act, Wild and Scenic legislation, and many others, protection of the ecosystem became an explicit legal obligation for the SWP and CVP in addition to delivery of fresh water for agricultural and urban use.

In the modern context, CVP and SWP facilities operate according to a complex web of permits, licenses, and, in some cases, court orders that impose explicit conditions on how, when, and how much water can be exported from the Delta. Some of the entities that regulate water project operations in and upstream of the Delta include:

- The SWRCB and regional boards require the SWP and CVP to meet specific water quality criteria that result in operational standards within the Delta and the Delta watershed. The SWRCB also sets instream flow standards.
- USACE sets operational "rule curves" for reservoirs that provide flood protection upstream of the Delta. The Central Valley Flood Protection Board regulates encroachments on designated floodplains and floodways. (See Chapter 7.)
- The presence of threatened and endangered species in California's waterways and landscapes requires the California Department of Fish and Wildlife (DFW), U.S. Fish and Wildlife Service, and National Marine Fisheries Service to regulate water project operations in the Delta. Federal biological opinions that govern agency regulatory activities have been the subject of extensive recent litigation by water agencies and other interested parties.

To comply with these regulations and to optimize system efficiencies, DWR (for the SWP) and Reclamation (for the CVP) jointly coordinate their pumping operations in the Delta under the 1986 Coordinated Operating Agreement (COA). One of the benefits of the COA is that it resulted in improved reliability of deliveries for the SWP (DWR 2008). They also jointly manage portions of the water delivery facilities in the Central Valley. There are times when the CVP may use SWP export capacity or that the SWP may need to use CVP export capacity. This close coordination has resulted in flexible operation of the Delta facilities to improve reliability of Delta water deliveries as well as to reduce system vulnerability to disruption.

Additional operational changes are on the horizon for the CVP and SWP. The SWRCB has initiated a phased process to review and amend—or to adopt new—water quality and flow objectives for the Delta by 2014. Phase 1 of that review is focused on southern Delta water quality and San Joaquin River flows. Phase 2 is focused on other changes that may be needed to the remainder of the Bay-Delta Water Quality Plan to protect fish and wildlife beneficial uses. See Chapter 4 for more information on flow in the Delta and the relationship to ecosystem health, and Chapter 6 for more information on the Council's recommendations on the SWRCB process to update the Bay-Delta Water Quality Plan. Furthermore, conveyance alternatives under consideration by the Bay Delta Conservation Plan (BDCP) could mean large-scale changes to Delta infrastructure and operations.

Challenges and Conflicts in the Delta

Over time, the Delta has been transformed, mostly by human hands, to serve many purposes. As mentioned, the SWP and CVP were originally engineered to reliably deliver water to water service contractors and water rights holders without commensurate consideration for impacts on native species. The Delta is the only saltwater estuary in the world that is used as a conveyance system to deliver fresh water for export. This creates substantial water supply and ecosystem conflicts.

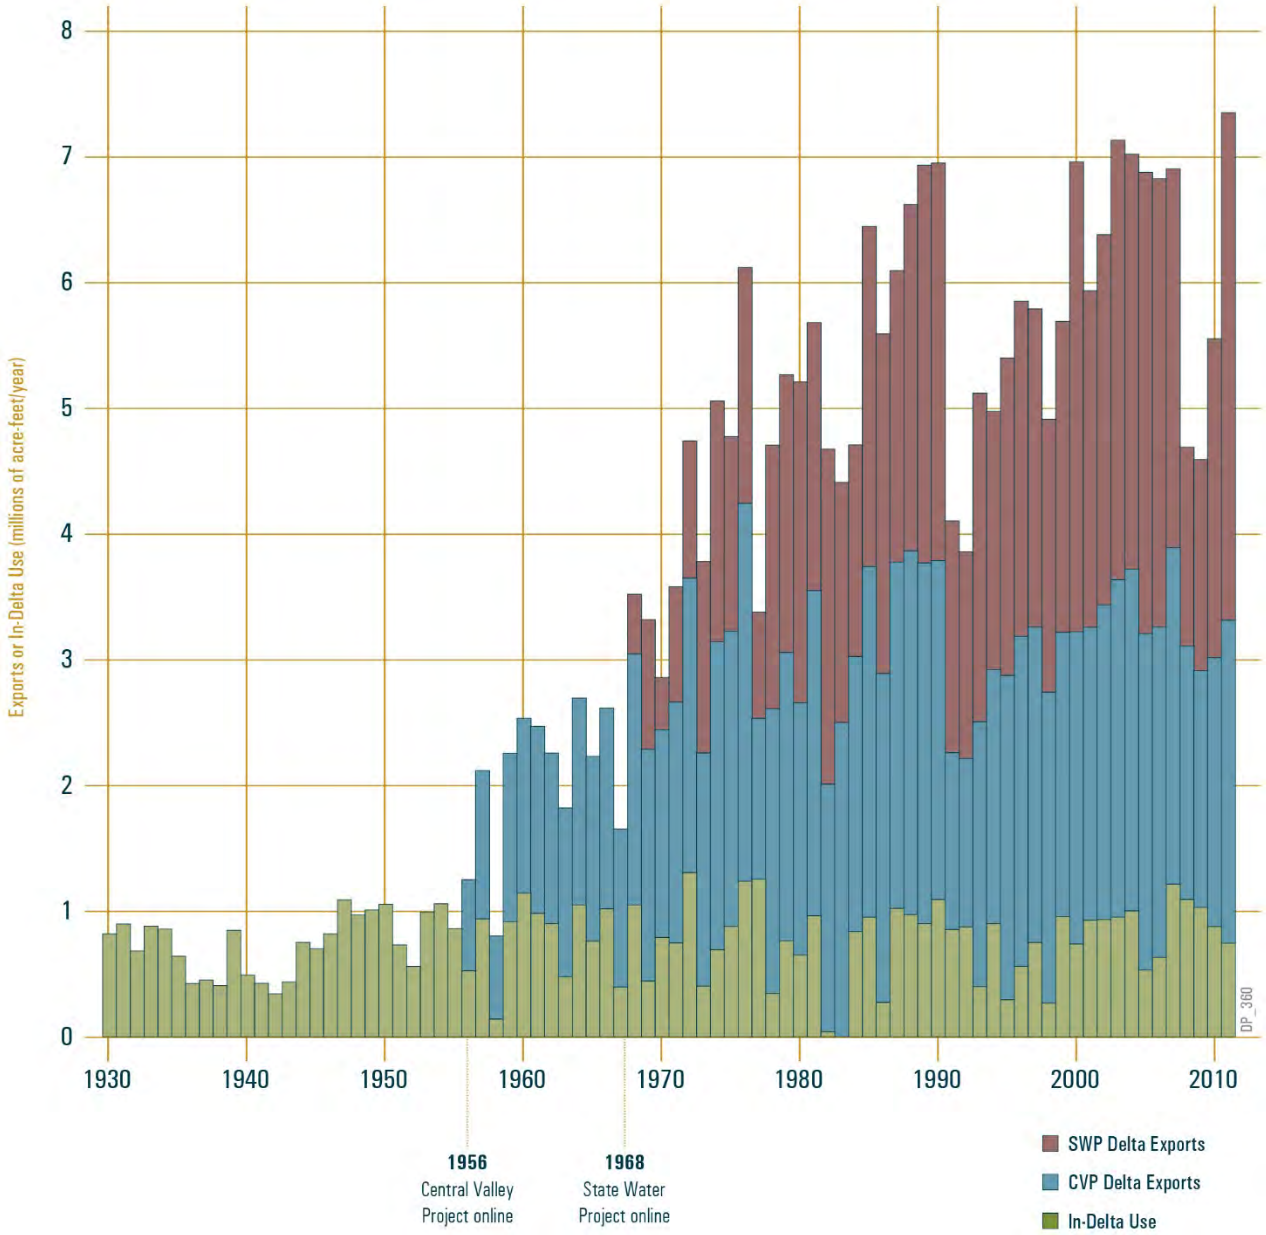
Legal changes in recent decades, combined with growing societal awareness and scientific understanding of water project operations on ecosystem health, had major implications for water operations in the Delta. The collision of changing societal values, growing demands for water deliveries from the Delta, and declining health of the Delta ecosystem have resulted in numerous complex and often bitter legal challenges that have increasingly shifted critical Delta water management decisions to the courts.

CVP and SWP Water Delivery Challenges

Overall, exports from the Delta have been rising over the past 4 decades (see Figure 3-5). Historically, the SWP and CVP have pumped more water from the Delta during dry years than wet years; but over time, exports have increased in all water year types, except in critically dry years. The SWP and CVP have each reached record exports in the past 10 years. In part, this is because recent increases in surface and groundwater storage south of the Delta have enabled more water to be taken during wet years. Increased south-of-Delta storage has also led to more agricultural-to-urban water transfers, which help improve the flexibility of operations in the Delta.

Yet, many factors threaten the ability of State and federal water managers to continue pumping water through the two projects at current export levels. Subsidence of the agricultural lands on the Delta islands, rising sea level, and earthquakes threaten the physical integrity of the Delta ecosystem and the levees that protect the export water quality. The location of the two pumping stations (one each for the CVP and SWP) in the south Delta is a problem for fisheries. Described previously, most of the water enters the Delta from the north through the Sacramento River. Pumping stations for the CVP and SWP are located in the south Delta and, when operating, frequently cause a net "flow reversal" in the central and south Delta channels. (See Chapter 4 for more details.) This reverse flow affects fish movement, including migration through the Delta, and often results in species that are free-floating or have weak swimming capability being drawn into the pumping facilities where they can be entrained (Grimaldo et al. 2009). Water quality is an issue too. A portion of the water flowing into the Delta is specifically allocated to Delta outflow to help repel salinity intrusion from the San Francisco Bay and to maintain low-salinity water near the western edge of the Delta. This means that water that might otherwise be used for exports must be released from upstream reservoirs to help control salinity (NRC 2012).

Historical Exports and In-Delta Use



1956
Central Valley
Project online

1968
State Water
Project online

Figure 3-5 Overall exports from the Delta have been rising over the past 4 decades, while in-Delta uses have remained fairly constant. Exports by the CVP and SWP have reached record levels in the past 10 years.

Conflicts over water use are further complicated by original SWP and CVP contracts that assumed greater water export quantities than consistently can be delivered. Since 1990, the CVP has fulfilled 100 percent of its contract water allocations only three times, and the SWP has delivered 100 percent of its contract amounts only twice (Reclamation 2011c, DWR 2010b). The CVP's ability to meet maximum contracted amounts, particularly during dry years, has diminished since the addition of new municipal and industrial contractors who have priority over agricultural water deliveries.[10] Also, the 1992 passage of the Central Valley Project Improvement Act dedicated up to 800,000 acre-feet of CVP exports for wildlife refuges and environmental needs (Public Law 102-575, section 3406(b)(2)). The original SWP contract amounts were based on assumptions that additional major new dams and conveyance facilities would be constructed at a later date, which did not occur. As a result, even though the SWP had contracted to supply 4.2 MAF, average SWP exports between 1996 and 2006 were just 2.9 MAF (DWR 2008).

The reality is that the State and federal systems have never been able to reliably deliver the full contract amounts. Now, additional court-ordered and regulatory restrictions on State and federal pumping of export water, in combination with the 2007 through 2009 drought, further reduced the reliability of Delta water exports to SWP and CVP contractors. According to DWR, SWP deliveries are now expected to average 60 percent of maximum contract amounts in future years, down from 66 to 69 percent estimated in 2005 (DWR 2010b).

The process for allocating water shortages within the State and federal projects also impacts the extent to which various contractors experience different levels of Delta water supply reliability. Within the SWP, shortages are uniformly distributed across all water contractors. Within the CVP, municipal and industrial water users have a higher priority than agricultural water users. As a result, in dry years, CVP water rights contractors, such as the Sacramento River Settlement Contractors, may receive 100 percent of their water allocations while non-water rights contractors, including Westlands Water District, may receive as little as 10 percent.

North-to-south water transfers across the Delta can be an important tool for improving water supply reliability. However, transfers require the use of SWP or CVP facilities and, as such, are subject to the regulatory constraints on Delta exports. Because Delta pumping windows of opportunity are shorter and generally filled by contract deliveries, excess capacity for water transfers is increasingly hard to come by.

Although lesser known, an increasing challenge to Delta export reliability relates to the operations and maintenance of the large, complex facilities that make up the SWP. The SWP has experienced a significant and growing decline in operational reliability that has directly impacted DWR's ability to store and move water, produce electricity, and export water from the Delta when the appropriate hydrological conditions present themselves (DWR 2010b). These challenges include maintaining SWP delivery capabilities under continued manpower resource limitations, aging infrastructure, and constraints in providing competitive employee compensation despite adequate SWP funding. Further resource challenges are attributed to complex and cumbersome State contracting processes and State hiring freezes.

Improving Delta Water Supply Reliability through Investments in System Flexibility

Because California's annual precipitation is remarkably variable, the past expectation that each year—wet or dry—should yield the same quantity of water exported from the Delta watershed is unrealistic and can be an obstacle to necessary improvements in water supply reliability.

---

[10] Additional municipal and industrial water contracts were implemented in the late 1980s for the CVP San Felipe Unit and in the last 10 years for the CVP American River Division.

The greatest conflicts between the water needs of people and fish within the Delta occur during dry years. That is when the least amount of water is flowing into the Delta and, historically, when exports have been a much larger percentage of Delta inflows than in wet years (see Figure 3-6). On average, exports have diverted about 17 percent of Delta inflows in wet years and about 36 percent during dry years (DWR 2011c). In past years, exports have exceeded 60 percent of Delta inflows in some dry months, but recent regulatory decisions now constrain such operations.

The recovery of the Delta ecosystem and listed species will help reduce regulatory restrictions on Delta exports and increase the long-term stability and predictability of rules governing Delta pumping.

More natural flow patterns in the Delta can be compatible with improving the reliability of water deliveries from the Delta. More water can be taken in wet years when more water is available, less water will be taken in dry years when it is needed for in-Delta water quality and environmental protections, and operations can be improved to increase seasonal flexibility to avoid impacts on Delta species and habitat. Many local water management actions that help reduce reliance on the Delta and improve regional self-reliance are also essential to improving overall flexibility of Delta operations and improving reliability of water supplies during periods when pumping is constrained.

Upstream, downstream, and in-Delta improvements can all add to export system flexibility, producing both water supply and ecosystem benefits. Storage capacity, however, is a current limitation to this scenario, and will worsen under anticipated climate change conditions. Were sufficient storage available, flows that exceed water needed to meet environmental and other requirements could be captured and stored. This stored water could then be released later in the year or carried over into subsequent years.

Fish predation and mortality at the export pumps could be reduced if the diversion points of the State and federal water projects in the Delta were moved or modified. Risks to a reliable source of fresh water conveyed through the Delta could be reduced through conveyance alternatives that could provide multiple diversion locations in the Delta (as those being analyzed in the BDCP process) and through strategic levee investments.

It is important to note that storage can increase the benefits of conveyance improvements, and conveyance improvements may be limited without the benefit of added storage. Improved operational flexibility, consistent with ecosystem restoration, can result in more reliable water supplies for all beneficial uses from year to year and, when managed for multiple benefits, can also ensure adequate flows to meet public trust needs, including the protection of the Delta ecosystem.

The Role of Storage in Increased Flexibility

Statewide water storage capacity, both above and below ground, is currently inadequate, especially south of the Delta, to facilitate export of water at times of surplus when the impacts on the Delta's ecosystem are reduced and the only impediment is lack of available storage capacity (DWR 2009). For example, in 2010, the SWP and CVP pump operations were slowed even though water was available to be pumped at a time when it would not have conflicted with endangered species or other water quality requirements. The SWP and CVP could not convey the surplus water through the Delta at that time because storage capacity south of the Delta was full.

Historical Delta Inflow and Delta Exports

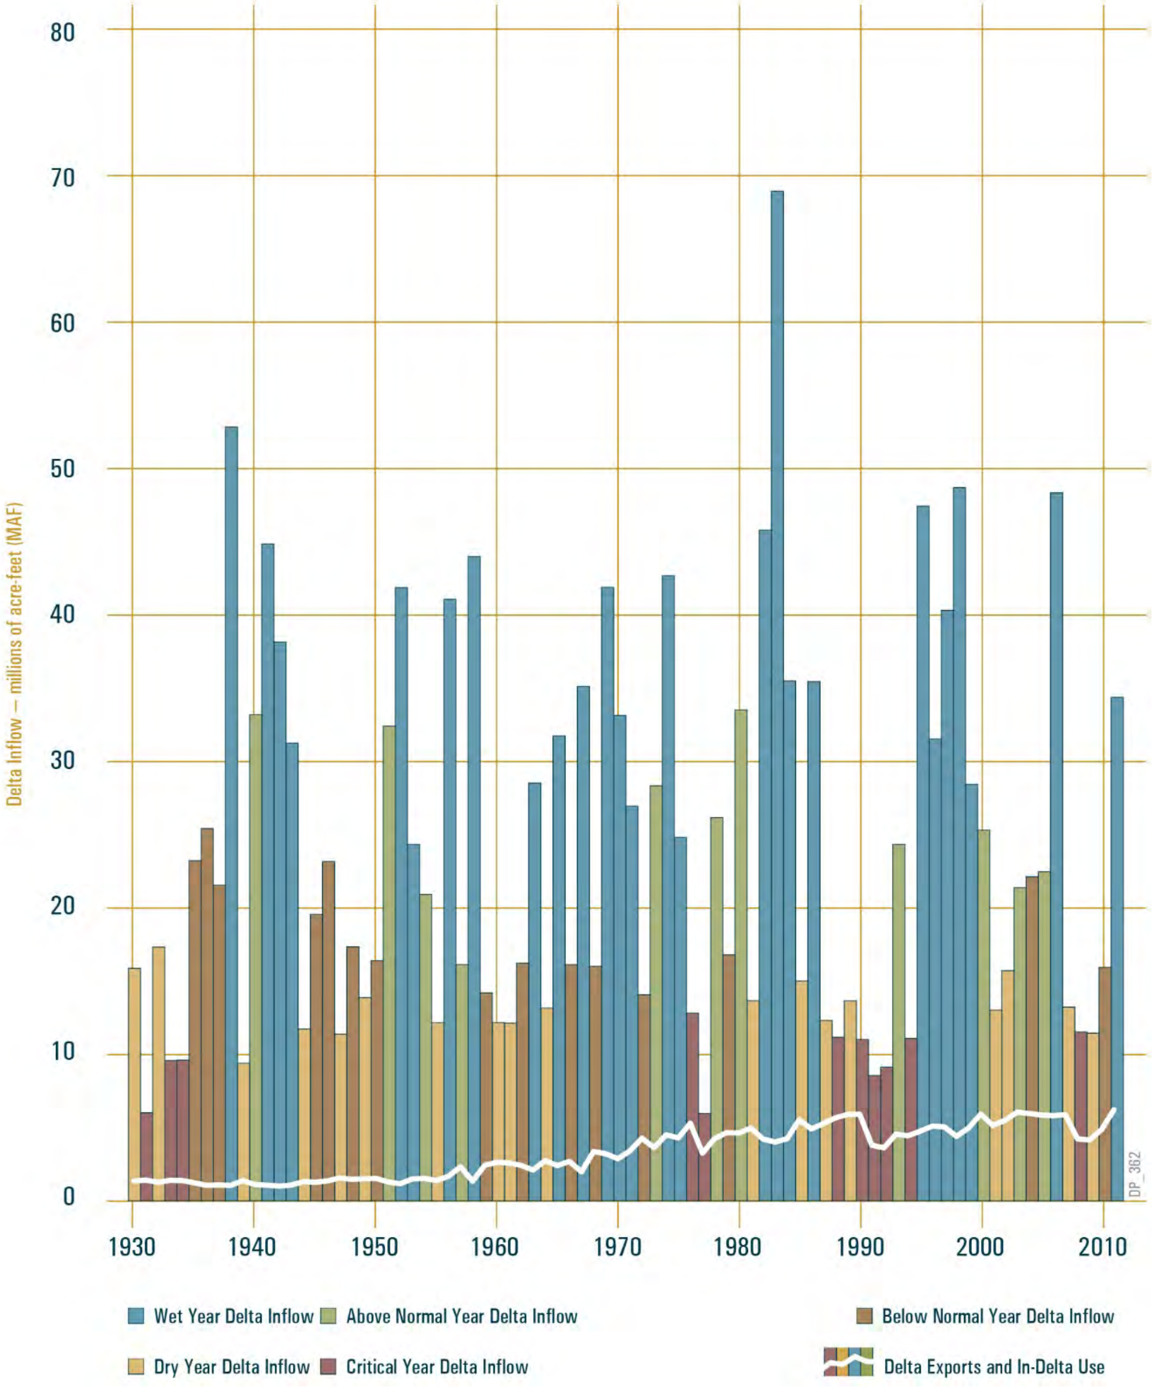


Figure 3-6

In many years, water flowing into the Delta greatly exceeds the amount of water that is exported from or used in the Delta. However, in dry years, total exports and in-Delta use have averaged as much as 36 percent of inflows.

Source: DWR 2012a

Applying Adaptive Management To Water Management Decisions

An adaptive management approach for water management decisions should be taken to plan for and assess the water supply outcomes of conveyance and storage improvement actions. The following is a hypothetical example of how the Council's three-phase and nine-step adaptive management framework (see Appendix C) could be applied to a water management decision.

		Adaptive Management Step	Hypothetical Water Supply Reliability Improvement Project
Plan	1	Define/redefine the problem	Current storage and conveyance configuration is not adequate for providing a more reliable water supply to south-of-Delta users under modern operating rules.
	2	Establish goals and objectives	**Goal:** Improve water supply reliability for south-of-Delta water users. **Objective:** Optimize storage for south-of-Delta water users in wet years so that interruptions in deliveries are reduced and the amount of water delivered during wet years can be increased consistent with environmental regulations in the Delta.
	3	Model linkages between objectives and proposed action(s)	There are inadequate options for south-of Delta water users to optimize storage in wet years, leading to vulnerability to interruptions and reduced capacity to divert water when it is available. The San Luis Reservoir is the only CVP water source for San Luis Unit, Cross-Valley Contractors, and San Felipe Division (SFD) water users. SFD serves water to Santa Clara and San Benito counties. As the San Luis Reservoir is drawn down during the summer and into the late fall (when predictable water supplies are needed most), a dense layer of algae develops near the surface. As the water level lowers, this algae gets captured by SFD intakes. The algae degrade water quality and make water more difficult to treat. As a result, SFD deliveries can be interrupted when the reservoir falls below 300,000 acre-feet. It is hypothesized that improving the San Luis Reservoir low-point intake would increase the predictability of water deliveries and make more water available to south-of-Delta water users during dry years. Alternatives to improving the low-point intake could include expanding the Pacheco Reservoir to provide storage for SFD water users. As a result of taking one or a combination of these actions, progress would be made toward improving water supply reliability for south-of-Delta water users by (1) reducing potential for interruptions, (2) diverting more water during wet years, and (3) making this water available during dry years when water from the Delta may not be available.
	4	Select action(s) (research, pilot, or full-scale) and develop performance measures	**Selected Action:** Conduct feasibility analyses and modeling to determine which option would enable the highest increase in the reliability of water conveyance for south-of-Delta users in compliance with environmental requirements. **Performance Measures:** ▪ Administrative – Complete feasibility analyses and modeling. ▪ Output – Select and implement an improvement project (e.g., improve the low-point intake at San Luis Reservoir only). ▪ Outcome – Progress toward improving water supply reliability by (1) reducing potential for interruptions, (2) diverting more water during wet years, and (3) making this water available during dry years when water from the Delta may not be available.
Do	5	Design and implement action(s)	Design and implement the feasibility analyses and modeling.
	6	Design and implement monitoring plan	Design and implement the monitoring plan, including baseline monitoring, and measurement of (1) reduced interruptions of SFD deliveries when the reservoir falls below 300,000 acre-feet, (2) the amount of increased delivery of water during wet years, and (3) the amount of increased water deliveries from the reservoir during dry years to offset reduced Delta diversions.
Evaluate and Respond	7	Analyze, synthesize, and evaluate	Analyze, synthesize, and evaluate the feasibility analyses and model outputs, and make recommendations for selecting a project or adjusting the conceptual model.
	8	Communicate current understanding	Provide project manager(s) and decision makers with synthesized information learned. For example, present information on the extent to which interruptions would be reduced, the value of the reduced interruptions, and the benefits of a specific operation scheme as part of a cost-benefit analysis.
	9	Adapt	The DWR, Reclamation, and SFD contractors decide on a pilot- or full-scale improvement project.

DP-332

In the past decade, the State has spent tens of millions of dollars on integrated studies to evaluate how large surface storage and conveyance may be improved. DWR is now completing surface storage investigations that were initiated under CALFED more than 10 years ago (DWR 2010a). The three proposed new major surface storage reservoirs that are being evaluated are the North-of-the-Delta Offstream Storage (Sites Reservoir), Los Vaqueros Reservoir Expansion, and Upper San Joaquin River Basin Storage investigation (Temperance Flat Reservoir). DWR expects to make its decision on recommended projects by 2014.

In the meantime, smaller facility improvements, particularly for storage, are being implemented. Since 1995, more than 1.2 MAF of additional surface storage has been constructed at the regional level, including the Diamond Valley, Seven Oaks, and Olivenhain reservoirs in Southern California, and the Los Vaqueros Reservoir in Contra Costa County.[11] The sidebar, Applying Adaptive Management to Water Management Decisions, provides a hypothetical example of an approach to providing more reliable water supplies.

A legacy of both overdraft and water quality contamination has compromised groundwater storage in many regions of the state; however, important improvements are being made through expanded regional groundwater storage north and south of the Delta. Notably, an assessment of groundwater storage in 2000 identified more than 21 MAF of potential groundwater storage in Southern California and the southern portion of the San Joaquin groundwater basin (AGWA 2000). A more detailed discussion of groundwater management in California is included later in this chapter.

Significant opportunities are available to improve the operation of existing storage and conveyance facilities, build small-scale storage projects, or enhance opportunities for groundwater conjunctive management and water transfers in the next 5 to 10 years that are consistent with the coequal goals. DWR is leading a System Reoperation Task Force with Reclamation; USACE; and other State, federal, and local agencies to study and assess opportunities for reoperating existing reservoir and conveyance facilities to improve flood protection and capture of available water runoff, particularly in the context of climate change. Reservoir reoperation is also addressed in Chapter 7.

Many local storage and conjunctive management projects were identified through competitive State and federal grant funding application processes in the past decade. Most of these projects could not be funded because of limited funding and restrictions in some of the grant provisions. Later in this chapter, the New Water for California section provides further detail on the range of options and describes necessary steps that regions should take to improve regional self-reliance and reduce reliance on the Delta.

The Role of Conveyance in Increased Flexibility

Conveyance improvements can enhance the operational flexibility of the Delta system to divert and move water at times and from locations that are less harmful to fisheries, or to reliably transport environmental water supplies to specific locations at times when it can benefit fish and water quality (California Natural Resources Agency 2010). Existing configurations of Delta water conveyance and associated conveyance facilities do not provide adequate long-term reliability to meet current and projected water demands for SWP and CVP water exports from the Delta watershed (DWR 2009).

---

[11] Contra Costa Water District will complete a 160,000-acre-foot expansion of Los Vaqueros Reservoir in 2012. The feasibility of an additional 275,000-acre-foot expansion is still under consideration by State and federal agencies.

Conveyance improvements and associated ecosystem restoration actions are being evaluated as part of the multiagency BDCP effort. (See sidebar, Bay Delta Conservation Plan and Water Supply Reliability.) Once decisions are made regarding whether to build and, if so, in what manner to build conveyance improvements, construction of these facilities will likely take at least a decade or more and will not provide near-term reliability improvements. This means that Delta operations and deliveries of export supplies will continue to be constrained by existing infrastructure for at least the next 15 years.

During this time, steps must be taken to implement local water management programs and projects, described later in this chapter. Additionally, the State needs to address the continuing vulnerability of the Delta levee system and make improvements to protect the existing in-Delta conveyance system from catastrophic failure. (See Chapter 7 for a discussion of the benefits and vulnerabilities of Delta levees.) In particular, immediate improvements to the Delta levee system are critical because of the current instability and interdependence of the levees—the failure of one can affect the entire system (NRC 2012).

BAY DELTA CONSERVATION PLAN AND WATER SUPPLY RELIABILITY

The BDCP is a Habitat Conservation Plan (HCP) and Natural Community Conservation Plan (NCCP) that "proposes major physical changes to the Delta, including new diversion and conveyance facilities and their operational criteria, extensive new aquatic habitat, and other measures to help reverse the Delta's ecological decline and secure water supplies from the Delta for human use" (BDCP 2012c).

The BDCP is planned to be implemented over a 50-year timeframe using an adaptive management and monitoring program to adapt as conditions change and new information emerges. The parties seeking one of several permits pursuant to the BDCP include DWR, Reclamation, Metropolitan Water District of Southern California, Kern County Water Agency, Santa Clara Valley Water District, Zone 7 Water Agency, Westlands Water District, and the State and Federal Water Contractors Agency (BDCP 2012a). The goal of these parties, with the exception of Reclamation, is to formulate a plan that could ultimately be approved by the U.S. Fish and Wildlife Service and the National Marine Fisheries Service as an HCP under the provisions of Endangered Species Act section 10(a)(1)(B) and as an NCCP by DFW under Fish and Game Code section 2800 et seq. and/or the California Endangered Species Act section 2050 et seq. Reclamation intends to use information developed as part of the BDCP process to help inform its Endangered Species Act Section 7 consultation on the coordinated long-term operation of the CVP and SWP with the U.S. Fish and Wildlife Service and the National Marine Fisheries Service. If the BDCP is successfully completed, and DFW determines that the BDCP meets the requirements in Water Code section 85320, it must be incorporated into the Delta Plan. That determination by DFW may be appealed to the Council (Water Code section 85320 (e)).

The BDCP is being developed to contribute to improving water supply reliability by modifying Delta conveyance facilities to create a more natural flow pattern in the Delta and allow for water exports when hydrologic conditions result in the availability of sufficient water, consistent with the requirements of State and federal law and the terms and conditions of SWP and CVP water delivery contracts, and other existing applicable agreements.

The BDCP process is considering a range of options for conveying water through or around the Delta:

- **Through-Delta Conveyance:** Continue to divert water in the southern Delta at existing or modified intakes/diversions for SWP and CVP operations.
- **Isolated Conveyance:** Divert water from the Sacramento River at new intakes/diversions and convey the water to the existing SWP and CVP pumping plants through a pipeline/tunnel.
- **Dual Conveyance:** Combine through-Delta conveyance and isolated conveyance to allow operational flexibility.

The BDCP process is ongoing. As of this publication, the public draft of the BDCP and the related environmental impact report/environmental impact statement are planned for release by late 2012, with final documents expected to be released in mid-2013 (BDCP 2012b). The Council is a Responsible Agency for California Environmental Quality Act purposes.

New Water for California

The fact that water is a scarce resource does not mean that California is "running out of water" (NRC 2012). It does mean that California will need to develop plans, and implement programs and projects that can adapt to a highly variable and uncertain water future. The primary source of new water supplies for California in the future will come from local and regional sources.

This section discusses local water supply opportunities, the importance of local and regional water management planning, and the need for improved groundwater management and water data so that the state can better match its water demands to the available supplies.

California's Wealth of Water Opportunities

California has many new and underused water resources that can be developed to improve regional self-reliance. In 2009, DWR estimated that the state could further reduce water demand and increase water supplies in the range of 5 to 10 MAF by 2030 through the use of existing strategies and technologies (see Figure 3-7).[12] If the state developed only half this water (about 5 MAF) through water efficiency and new local supplies, it would be sufficient to support the addition of almost 30 million residents, more than the population growth that is expected to occur by 2050.[13]

Nearly all these potential supplies will come from a combination of improved conservation and water use efficiency in the urban and agricultural sectors, local groundwater and surface storage, conjunctive management, recycled water, drinking water treatment, groundwater remediation, and desalination. DWR has identified 27 "resource management strategies" that water suppliers should consider when expanding their water management programs throughout the diverse regions of the state (DWR 2009). Resource managers can combine these strategies into a response package, crafting them to provide multiple water resource benefits, diversify their water portfolio, and become more regionally self-reliant.

Often, the new local and regional water supplies have the additional advantage of being available even during extreme drought conditions, making them some of the most reliable sources of water for urban and agricultural uses. In particular, recycled water and the treatment and reuse of poor-quality groundwater are two of the most resilient water supplies under conditions of drought and climate change. The treatment of poor-quality groundwater also can significantly improve drinking water supplies, especially for rural and economically disadvantaged communities that have limited alternatives to secure clean water. In 2012, the California Legislature enacted Assembly Bill (AB) 685, declaring the established State policy that "every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes" (Water Code section 106.3 (a)). For more about drinking water quality, see Chapter 6.

For some local water resources, California has adopted specific targets, including:

- **Urban water conservation.** The State's goal is to achieve a reduction in statewide per capita urban water use of 20 percent, from a 2005 baseline of an estimated

---

[12] The range of 5 to 10 MAF is a conservative estimate and is consistent with recent studies that assess California's potential for increased water savings and water supplies. DWR provides a cautionary note that the water supply benefits summarized in the California Water Plan are not intended to be additive, recognizing the same resource management strategies may complement or compete with one another for funding, system capacity, or other elements that are necessary for implementation. In addition, unlike the 2005 version, DWR did not include in the 2009 California Water Plan an estimate for water supply benefits from improved conveyance. Instead, DWR states that the main benefits of conveyance improvements are increased water supply reliability, water quality protection, and operational flexibility (DWR 2009).

[13] Under California law, water conservation is considered a source of supply (Water Code section 1011(a)). A 2008 report from the Los Angeles Economic Development Corporation found that "using water more efficiently reduces demand, which has the same effect as adding water to the system." For Southern California, the report concludes that "urban water conservation could have an impact equivalent to adding more than 1 MAF of water to the regional supply (about 25 percent of current annual use)" (LAEDC 2008).

198 gallons per capita daily (GPCD) to 166 GPCD (DWR 2012b). This represents a potential annual water savings of approximately 1.8 MAF per year that will be accomplished by 2020. This is consistent with DWR's 2009 estimate that 2.1 MAF can be conserved in roughly the same period through increased use of water-efficient appliances, reduced water use for landscaping, and tiered rate structures, such as increasing block rates or budget-based rate structures.

- **Recycled water.** The State's goal is to increase the use of recycled water over 2002 levels by at least 1 MAF per year by 2020, and by at least 2 MAF per year by 2030 (DWR et al. 2010). DWR's 2009 estimate indicates that as much as 2.25 MAF could be recovered, about half of the amount of wastewater that is treated and released to flow to the ocean.
- **Stormwater runoff.** The State's goal is to increase capture and reuse of stormwater by at least 500,000 acre-feet per year by 2020, and at least 1 MAF per year by 2030 (DWR et al. 2010). The 2008 Scoping Plan for California's Global Warming Solutions Act of 2006 (AB 32) finds that up to 333,000 acre-feet of stormwater could be captured on an annual average for reuse in Southern California alone (CARB 2008).

California's Wealth of New Water Supplies

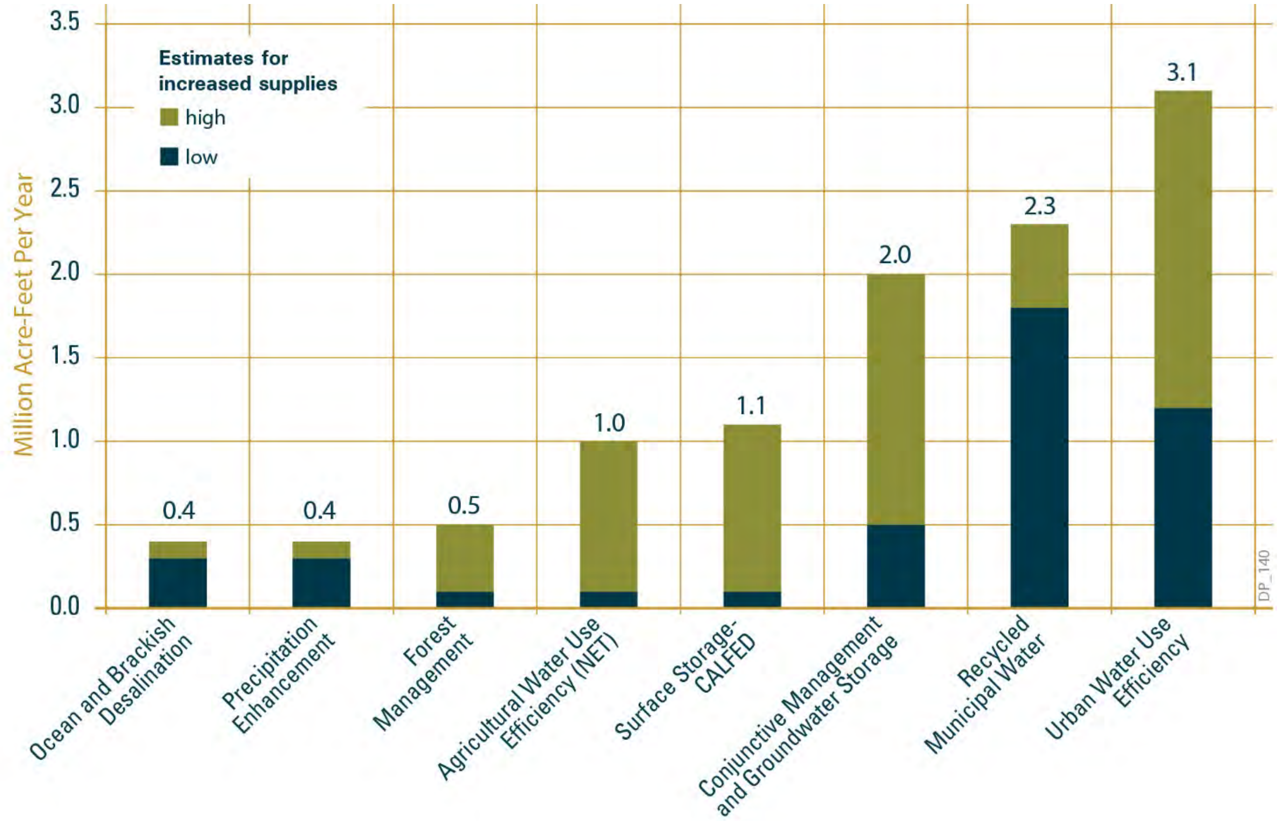

Figure 3-7 DWR estimates that California could further reduce its water demands and increase water supplies by 5 to 10 MAF per year over the next 30 years through the use of existing technologies.

Source: DWR 2009

The Importance of Local Water Management Planning

Over the past few decades, the State has built on successful local water management planning and, when possible, has provided funding for local districts to develop and implement water management plans. These plans are of benefit to all regions, not just those who rely on the Delta or Delta watershed.

These programs and projects increase the reliability of water supplies by increasing water efficiency and diversify the portfolio of water sources for urban and agricultural water suppliers that are more resilient under conditions of drought, emergency shortage, and climate change. Water developed through these activities can help reduce conflicts among urban, agricultural, and environmental uses, and can contribute to the ability of regions in California to reduce their reliance on water from the Delta watershed.[14]

The responsibility for implementing most of these water management strategies and achieving State objectives lies with over 600 local water agencies, including several privately owned and operated companies, plus wastewater districts, community service districts, and other special districts. The sheer number of local agencies engaged in water management makes it difficult to monitor and account for the significant new amounts of water supplies and increased water efficiency that is being implemented. Later in this chapter, the Informed Decision Making Requires Information section details this challenge and associated water management implications.

Since the mid-1980s, California has enacted progressively more stringent water conservation, efficiency, and water planning requirements for urban and agricultural water suppliers (see Appendix H). Beginning in 1983, wholesale and retail municipal water suppliers (those with at least 3,000 connections or delivering at least 3,000 acre-feet per year) have been required by the Urban Water Management Planning Act to prepare 20-year urban water management plans to guide investments in future water reliability. This law has been strengthened through several revisions to include specific water conservation goals (such as the 20 percent reduction in urban per capita water usage by 2020 adopted in 2009), compliance with demand management measures including adoption of rate structures that promote water conservation (AB 1420 in 2007), landscape conservation requirements (AB 1881 in 2006), and required installation of water meters (AB 2572 in 2004).

Existing law requires that urban water suppliers include a water supply reliability element and water shortage provisions in their urban water management plans, recognizing that suppliers need to prepare for extended droughts, the effects of climate change, and potential catastrophic interruption of deliveries caused by earthquakes or other events. Water suppliers must evaluate whether their water sources may be available at a consistent level of use and describe their plans for supplementing or replacing these sources, to the extent practicable with alternatives or water demand management measures (Water Code section 10631(c)(2)). Water suppliers must also describe the tools and options that will be used to maximize resources and minimize the need to

---

[14] As used in the Delta Plan, "regions" refer to the 10 hydrologic areas identified by DWR that correspond to the state's major water drainage basins, and included the two regional overlays for the Mountain Counties area and the Delta. The use of these regions as planning boundaries allows consistent tracking of their natural water runoff and accounting of surface and groundwater supplies.

import water from other regions (Water Code section 10620(f)).

Agricultural water suppliers (those that provide water to 25,000 or more irrigated acres, or 10,000 irrigated acres and who receive State funding to implement the plan provisions) have a requirement similar to urban suppliers and must prepare agricultural water management plans. The Agricultural Water Management Planning Act was adopted in 2009 (Senate Bill X7 7 [SBX7 7]). Requirements include reporting on farm gate water deliveries, adoption of rate structures that promote water conservation, and identification and implementation of locally cost-effective and technically feasible water efficiency measures.

Since 2000, the State has also promoted voluntary integrated regional water management plans (IRWMPs), recognizing that collaboration among multiple agencies, especially within watersheds, provides opportunities for better water management decisions and coordinated infrastructure investments. Significant bond funding has been made available to support implementation of projects identified through these IRWMPs. A 2006 report on the investments made for IRWMP projects identified over 1.2 MAF of water benefits in combined water supply and demand reductions that have been achieved through the expenditure of $1 billion in State bond funds in local and regional projects (DWR 2009). An additional $1 billion or more of local dollars were leveraged because of this State investment. Applicants for IRWMP funding must now demonstrate how their plans help reduce their region's dependence on water imported from outside their region (DWR 2010c).

As climate change begins to affect California's water supplies, the U.S. Environmental Protection Agency (Region 9) and DWR are encouraging water managers to plan for these impacts and to take steps to adapt to them. IRWMPs, and the agricultural and urban water management plans provide an excellent framework for addressing water-related climate change impacts (USEPA and DWR 2011). Because each region is unique, there is no single "correct" planning approach. Key concepts include risk assessment, such as the potential for interruption of water supplies for up to 36 months due to catastrophic events impacting the Delta, including earthquakes or floods. For example, DWR identified the potential for some portion of Delta deliveries to be interrupted for up to 36 months if a catastrophic earthquake occurred (DWR 2010b). Although this would have a primary impact on water suppliers that rely on water from the Delta, it might also affect upstream water suppliers that may be called upon to release more water into the Delta during the crisis.

Another useful tool is the regional water balance. According to DWR, the purpose of a regional water balance is to provide an accounting of all water that enters and leaves a specific hydrologic region, how it is used, and how it is exchanged between regions. A regional water balance can be used to compare how water supplies and uses in a region can vary between wet and critically dry hydrologic conditions, and how each region's water balance compares with other regions and with the state's overall water balance. This is important to all water planning activities and provides a basis for evaluating unsustainable water management practices and making appropriate improvements (DWR 2009).

Implementing a Path to Success in Local Water Management

Many agricultural and urban water suppliers are taking commendable action to improve water conservation and efficiency, and to expand their local and regional water supplies. (See sidebar, Regional Success Stories.) However, others are not.

For example, despite longstanding State laws that require preparation and implementation of urban water management plans, many water suppliers still regard these plans as voluntary because the only consequence of not completing them has been ineligibility to receive State grant and loan funding

REGIONAL SUCCESS STORIES

Significant improvements in water management are being implemented throughout California, especially in regions that rely upon water from the Delta and the Delta watershed. The 2010 urban water management plan updates and voluntary IRWMP grant applications filed in 2010 provide insight into what individual water agencies and regional planning efforts are doing to improve water efficiency and develop additional local water supplies. Examples of successful strategies to reduce reliance on the Delta and improve regional self-reliance follow.

In Southern California:

- **West Basin Municipal Water District.** Increased water efficiency and diversification of the district's water supplies between 2010 and 2035 will enable West Basin Municipal Water District to reduce its potable water demand despite expected future population growth. The total volume of imported water usage is projected to decline by 40,000 acre-feet over this period, and conservation, recycled water, and ocean desalination will expand the district's water resources by over 60,000 acre-feet (RMC Water and Environment 2011).
- **City of Los Angeles.** Today the City of Los Angeles uses less water than it did 30 years ago, despite population growth of more than 1 million residents. In 2011, per capita water usage was 123 gallons daily—the lowest in Los Angeles in more than 40 years and the lowest among any United States city with a population over 1 million (LADWP 2012). Through regional watershed planning efforts, the city is bringing together local and county public works departments, planning agencies, local and regional water supplies, and citizen groups to develop integrated multibenefit projects. In 2004, the city overwhelmingly approved Proposition O, which authorized $500 million in local bonds to fund water efficiency, stormwater capture, water treatment, recycled water, flood protection, open space, recreation, and other projects.

In the central San Joaquin Valley and Tulare Lake regions:

- **Poso Creek Regional Water Management Group.** The IRWMP focuses on more effective coordination of each participating irrigation district's water assets, recognizing that competition for the three sources of water that meet the region's demands (local supplies/Kern River, CVP, and SWP) is increasing. Proposed improvements include 400 acres of spreading ponds and additional conveyance (canals, pipelines, and pumping plants) between the Friant-Kern Canal and California Aqueduct and among irrigation districts, which will enable the region to take advantage of wet-year (unscheduled) water diversions from the Delta and reduce diversions in dry years (Semitropic Water Storage District 2011).

In the Delta:

- **East Contra Costa County.** Located entirely within the statutory Delta, all the water suppliers that participate in this IRWMP rely upon the Delta for more than 80 percent of average-year water demands, with three water suppliers receiving 100 percent. The IRWMP priorities for reducing reliance on the Delta include expanded use of recycled water, installation of water meters, increased water conservation, and new wellhead treatment for groundwater supplies (Contra Costa Water District 2011).

In the Bay Area:

- **City and County of San Francisco.** Increased water efficiency has resulted in general decline in total consumption and per capita water use since the mid-1970s to record low levels in the state despite growth in the county's population. Recognition of the vulnerability of the city's Hetch Hetchy Reservoir and aqueduct system to earthquakes and other emergencies, San Francisco is working to diversify its local water supplies, including increased conservation, new local groundwater wells, expansion of recycled water, use of gray water, rainwater harvesting, and participation in the Bay Area Regional Desalination Project with Contra Costa Water District, East Bay Municipal Utility District, Santa Clara Valley Water District, and Zone 7 Water Agency (San Francisco Public Utilities Commission 2011).

In the Delta upper watershed:

- **American River Basin.** The IRWMP features reduced reliance on water in the Delta's American River tributaries through expanded conjunctive use operations, development of recycled water, and increased water conservation. More water will be diverted during wetter periods and made available as groundwater in drier periods, which will help increase regional water supply reliability while improving flow and temperature conditions that benefit salmon and steelhead fisheries in the lower American River (Regional Water Authority 2011).

DP-348

to implement water projects. In the 2005 round of urban water management plan submittals, this incentive increased the number of plans submitted over previous years; however, only 75 percent of agencies that should submit plans actually did as of December 31, 2006, and more than 50 percent of these failed to include required conservation or drought contingency plans (DWR 2006). In the 2010 round of urban water management plan submittals, 66 percent of the agencies required to submit plans actually did by the August 2011 deadline. One year later, this percentage had increased to 85 percent, but no assessment for completeness has been performed (DWR 2012b).

Widespread compliance with existing water management laws alone would achieve great progress in improving water supply reliability for California. Compliance with all State water efficiency and management statutes and policies, at a minimum, should be the starting point for assessing a water supplier's reasonable use of California's water. In particular, water suppliers that do not engage in efficient use of water, particularly where the implementation of proven measures and technologies are economically justifiable, locally cost effective, and do not harm other water users, should be held accountable for wasting water. The SWRCB should be encouraged to use its authority to prevent waste and unreasonable use by seeking enforcement of these requirements. The potential for this type of action was anticipated in the Water Conservation Act of 2009 (SBX7 7), which explicitly recognized that the failure of urban water suppliers to reduce urban per capita water demand consistent with the State's 20 percent by 2020 conservation targets can be used after January 2021 to establish a violation of the law for the purposes of State administrative or judicial proceedings (Water Code section 10608.8(a)(2)).

Importantly, for those who prepare them, urban water management plans and integrated regional water management plans appear to be working. As a result of these efforts and increased irrigation efficiency, the amount of water needed to meet future urban and agricultural demands has changed. Since 1980, the total volume of water used in the urban and agricultural sectors has declined. Urban areas that have implemented the strongest water conservation programs show the greatest improvements in water efficiency and the largest reductions in water use (see Figure 3-8).

Groundwater Overdraft Is an Impediment to the Coequal Goals

Groundwater is a major source of water supply for nearly every region in California and a vital component of the state's water storage system, particularly during droughts (DWR 2009). More than 40 percent of Californians rely on groundwater for part of their water supply, and many small- to moderate-sized towns and cities are entirely dependent on groundwater for their drinking water systems (DWR 2003a). The state's most significant groundwater use occurs in regions that also rely on water from the Delta watershed, including the San Joaquin Valley, Tulare Lake, Sacramento Valley, Central Coast, and South Coast (see Figures 3-9 and 3-10). The Tulare Lake region alone accounts for more than one-third of the state's total groundwater pumping (DWR 2009). Because of historical groundwater overdraft and resulting land subsidence experienced in these regions, water users switched to using surface water from the CVP and SWP when the water projects were completed in the late 1960s. However, groundwater pumping and overdraft continued to become more severe as water demands continued to exceed available supplies. Recent satellite imaging revealed that the Central Valley lost approximately 25 MAF of stored groundwater during the period of October 2003 to March 2010 (Famiglietti et al. 2011).

As a result of use continually exceeding recharge, many of California's groundwater basins are in overdraft, and groundwater levels are declining over the long term (Faunt 2009). In some areas, overdraft can lead to a permanent loss of groundwater storage. According to DWR, a groundwater basin is in a state of "critical overdraft" when continuation of present water management practices would result in significant adverse overdraft-related environmental, social, or economic impacts. DWR estimates statewide average overdraft of about 1 to 2 MAF per year (DWR 2009). Groundwater use is also increasing, and is expected to grow at a faster rate in future decades as climate change reduces the reliability of surface water deliveries and increases the potential for extended droughts (DWR 2009). Without more efficient management, the state's groundwater resources will be significantly impacted, and in severe overdraft conditions, the aquifer's capacity to store groundwater may be irretrievably lost (DWR 2003a). Improved management is also needed to take advantage of opportunities to store water underground, particularly to aid flexibility when done in coordination with improved operations in the Delta.

California has established laws, regulations, and programs to protect the quality of its groundwater resources. Despite the major importance of this water supply to California, however, the quantity of groundwater used by agencies or individuals is largely unregulated at the State level. Except for Texas, California is the only state where use of its groundwater resources is managed at the local rather than State level. The lack of State oversight means that limited and often incomplete information is available to the public about how California's groundwater basins are being managed. So little is known, that in 2003, DWR was unable to revise the designation of critically overdrafted basins in its update on California's groundwater (DWR 2003a). Lacking current information and having limited resources to complete additional investigations, DWR simply republished the list of 11 basins identified in 1980.

Trends in California's Water Use

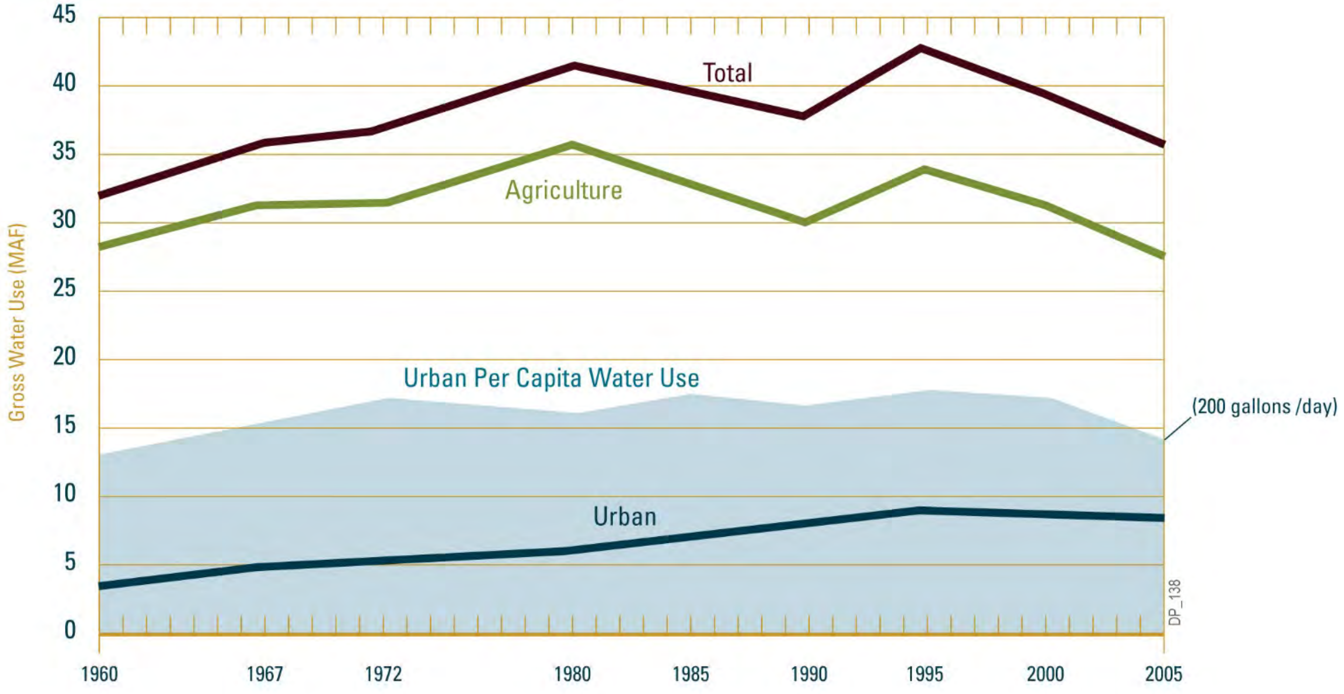

Figure 3-8

California's water use is declining, primarily due to increased water efficiency in both agricultural and urban areas. The City of Los Angeles, like many other cities, reports that it is using the same amount of water as it did over 30 years ago, even though its population has grown by more than 1 million people.

Sources: Hanak et al. 2011; adapted from DWR 2009

Critically Overdrafted Groundwater Basins

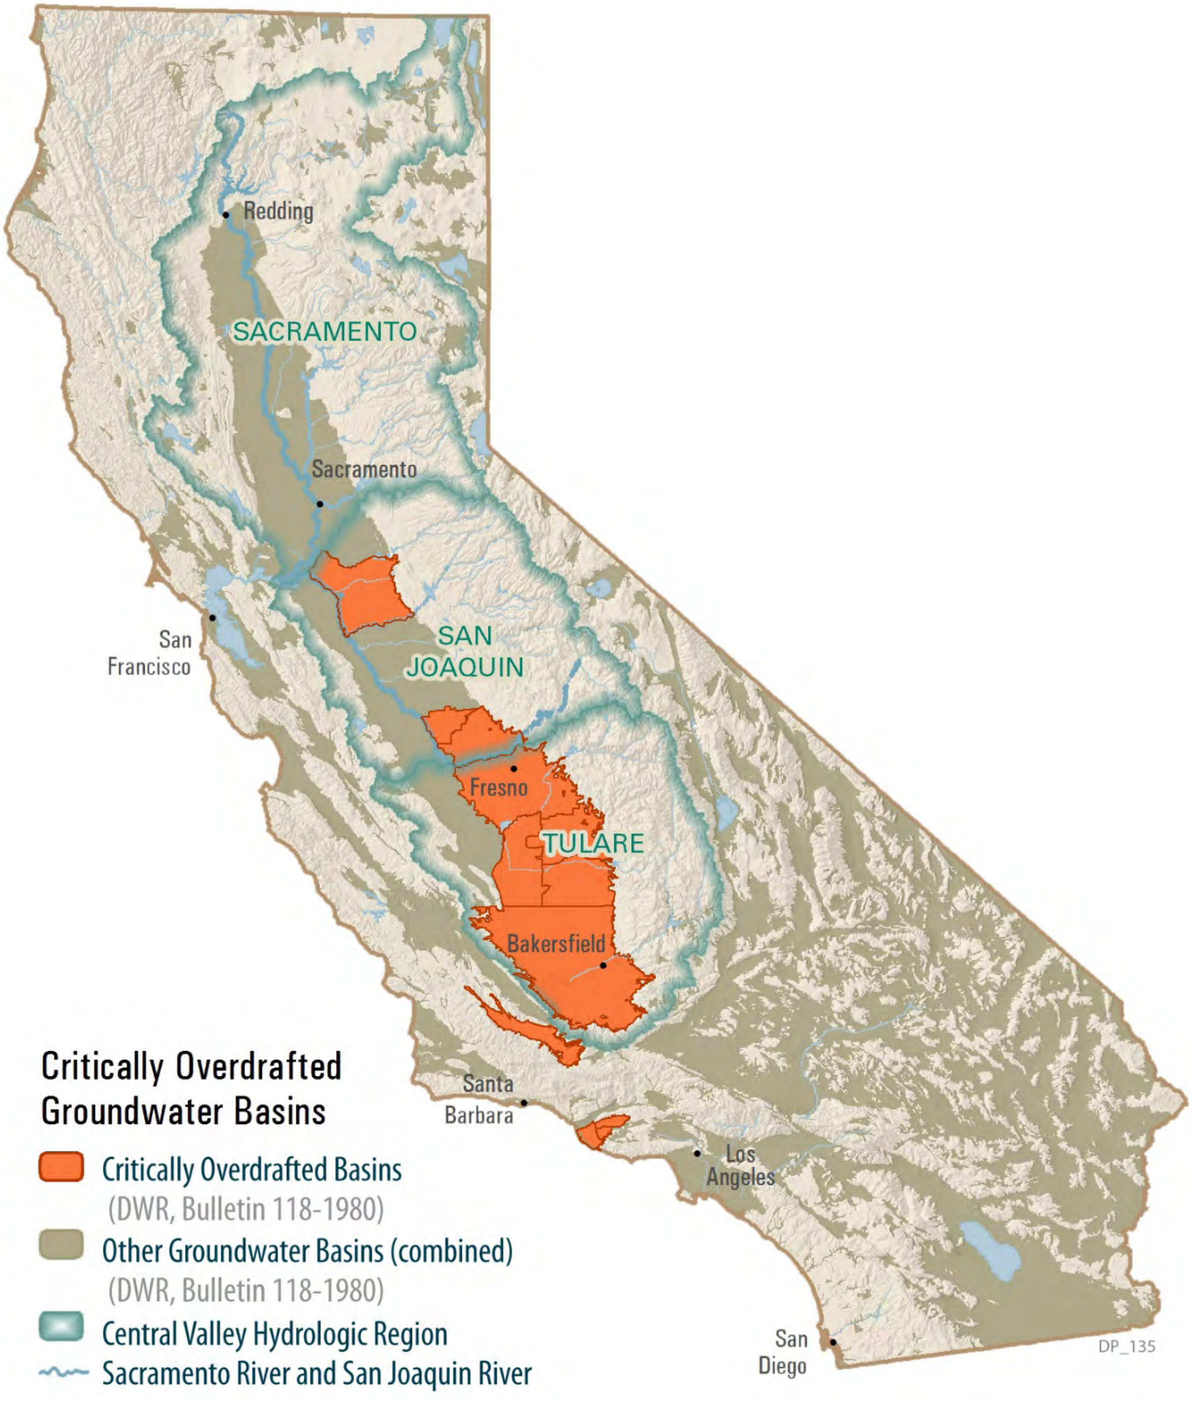

Figure 3-9

Groundwater overdraft is a critical water supply problem, especially in the Central Valley. More than 40 percent of Californians rely on groundwater for some portion of their supply, and many small- and moderate-sized communities are entirely dependent on groundwater for drinking water.

Sources: DWR 2003a; DWR 2009

San Joaquin Groundwater Pumping Is Unsustainable

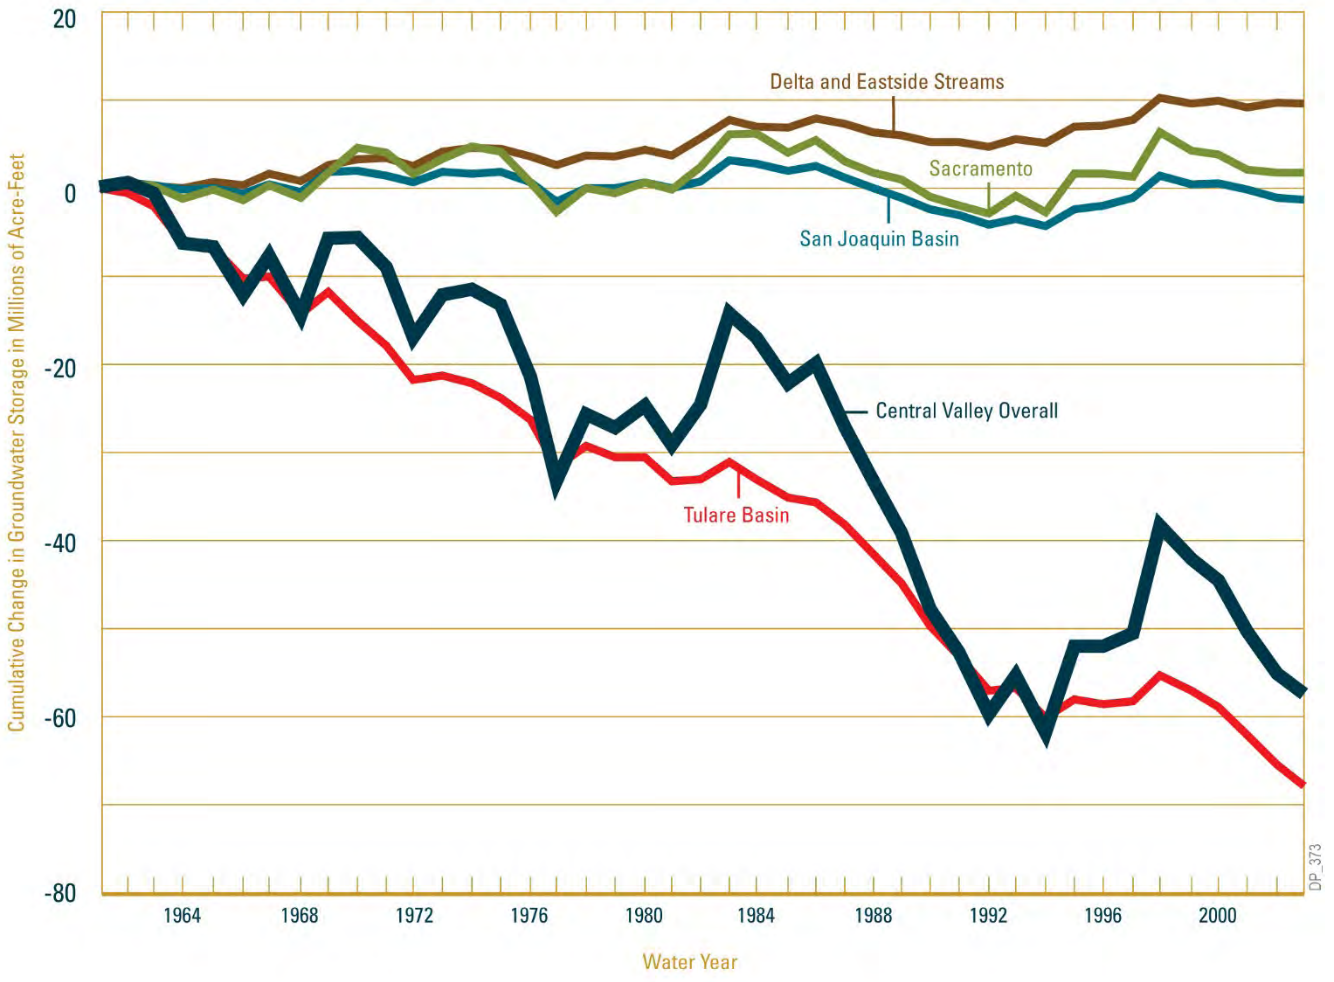

Figure 3-10

Estimated cumulative annual changes in groundwater storage in the Tulare Lake Basin due to over-pumping are more than 60 MAF since 1960. Serious land subsidence and loss of groundwater storage capacity impacts more than half of this region.

Source: Faunt 2009

Some regions appear to be making significant progress in developing sustainable groundwater management programs through regional water balances and voluntary groundwater management plans (known as AB 3030 plans), local ordinances, and court adjudications (Nelson 2011).[15] In 2009, the State created a mandatory statewide program for local reporting of groundwater elevation data, the California Statewide Groundwater Elevation Monitoring Program. This program will collect reported groundwater elevations and make the data available online.

Informed Decision Making Requires Information

One of the greatest challenges to California water management is the lack of consistent, comprehensive, and accurate estimates of actual water use by the type of use (agricultural, urban, and environmental) and by hydrologic region. The water use that is reported to the State is a combination of measured uses and estimated use that are not measured, with limited verification of actual water use. This means that California does not have a clear understanding of its water demands, the amount of water available to meet those demands, how water is being managed, and how that management can be improved to achieve the coequal goals for the Delta.

Key concerns include:

- Not all water uses are required to be monitored and measured. Many water rights were issued decades ago when water measurement was not required. Until reforms were approved by the California Legislature in 2009, water rights holders were not required to provide detailed information on water diversions and use. As a result, total diversion amounts are currently unknown and may be over-allocated in some locations or during dry periods (SWRCB 2008, SWRCB 2011, NRC 2012). Similarly, many groundwater withdrawals are not monitored or reported.
- Not all water users report data even when they are required to do so. A 2009 report prepared for the Legislature by the SWRCB on the development of a coordinated measurement database indicated that historically, about 67 percent of water permit and license holders actually report their water use information, and fewer than 35 percent of other water right claimants who are required to report actually do so (SWRCB 2009).
- SWP contractors are not required by DWR to provide data similar to that collected by Reclamation for CVP contractors. Reclamation has established best management practices for water efficiency, consistent with the federal Reclamation Reform Act and the Central Valley Project Improvement Act, and performs a "Water Needs Assessment" for each federal contractor with input from that contractor. Reclamation also requires contractors to submit an annual report that includes a full water balance (production from all sources, system losses, and changes in storage and water), and implement an effective water conservation and efficiency program based on the contractor's approved water conservation plan (Reclamation 2011b).
- SWP contract amendments in the past have not always been developed and approved in a transparent manner, and have resulted in litigation over implications for the management of the state's water supplies. In 2003, as part of a legal settlement, DWR adopted policies for how future contracts and contract amendments would be reviewed and adopted through an open and transparent process (DWR 2003b). Consistent application of this policy is important (see Appendix B).
- More detailed information on changes in groundwater levels, rates of groundwater extraction, and the location

---

[15] The State encourages additional voluntary development of locally controlled groundwater monitoring programs and related management plans through AB 3030 (1992), AB 303 (2000), AB 599 (2001), and SB 1938 (2002); through the IRWMP Program (through funding provided by Propositions 13, 50, and 84); and by limiting availability of State funding for water infrastructure to those agencies that have adequate groundwater management plans in place. The State also provides technical assistance to help local agencies more efficiently and sustainably manage groundwater resources, and has identified 14 required and recommended components for groundwater plans. Prior to 2002, there were no required elements for groundwater plans.

of basins with severe and chronic overdraft is needed as a baseline for the State's water resource management efforts. Basic groundwater management data (estimates of safe yield, monitoring of changes in storage in the aquifers and water quality conditions, and identification of replenishment sources and connections with surface water supplies) need to be quantified for many areas, but especially in those regions that rely upon water from the Delta watershed (DWR 2003a). The State's goal should be to sustainably maintain and maximize long-term reliability of these groundwater supplies, with a focus on preventing significant degradation of groundwater quality (DWR 2003a, ACWA 2011).

Recent legislation has resulted in significant improvements to the State's water monitoring and reporting requirements. However, time and resources will be necessary to assess the results from these improvements, which will also serve to inform future Delta Plan updates. For example, recently enacted provisions are now being implemented for:

- Groundwater monitoring (Water Code section 10920 et seq.)
- In-Delta and statewide water diversion reporting (Water Code section 5100 et seq.)
- In-Delta enforcement investigations under the authority of the Delta Watermaster (Water Code section 85230)
- Compliance with the State's goal of achieving a 20 percent reduction in statewide urban per capita water use by 2020 (Water Code section 10608 et seq.)
- Improved reporting on agricultural water use efficiency measures (Water Code section 10608 et seq. and 10800 et seq.)

In late 2010, the SWRCB also adopted regulations requiring online reporting of water use by all water rights holders, including appropriative, riparian, and pre-1914 surface water users, and groundwater users. Since 2008, DWR, SWRCB, and the California Department of Public Health have been working to develop a coordinated database to track the urban and agricultural water use data that are provided to each agency. This tool is central to the development of a statewide integrated system for streamlined data collection and analysis that will support improved water management in California.

POLICIES AND RECOMMENDATIONS

Policies and recommendations for providing a more reliable water supply for California are based on four core strategies:

- Increase water conservation and expand local and regional supplies
- Improve groundwater management
- Improve conveyance and expand storage
- Improve water management information

Increase Water Conservation and Expand Local and Regional Supplies

Approximately 84 percent of California's water supplies come from local and regional sources, including surface runoff, groundwater, recycled water, and water made available through advanced treatment. Improved management of these resources, including water conservation and efficiency, is central to the state's ability to better match its demands to the amount of supply that is available. Over the next 30 years, the *California Water Plan Update 2009* estimates that, with the use of existing technology, the state can reduce its demands and increase its water supplies in the range of 5 to 10 MAF. This is more than enough water to meet California's projected water demands beyond 2050 and to sustain its economic vitality.

The State's constitutional principle of reasonable use and the Public Trust Doctrine form the legal foundation for California's water management policies. Importantly, along with the coequal goals, the Delta Reform Act also established a new policy for California of reducing reliance on the Delta and improving regional self-reliance in meeting California's future water supply needs. The Delta Reform Act mandates many strategies that the Delta Plan must address to improve water supply reliability for California including water efficiency and conservation, wastewater reclamation and recycling, desalination and advanced water treatment technologies, improved water conveyance, surface and groundwater storage, improved water quality, and implementation of local and regional water supply projects and coordination (see Water Code sections 85004(b), 85020(d) and (f), 85201, 85023, 85303, and 85304).

An assessment of future water supply reliability is now required in urban water management and agricultural water management plans, as well as in voluntary regional water planning documents known as IRWMPs. In areas that rely upon water from the Delta watershed, water suppliers will need to identify, evaluate, and implement locally cost-effective and technologically feasible measures that reduce their reliance on the Delta and improve regional self-reliance.

Problem Statement

The lack of participation by some water suppliers throughout California to implement laws, programs, and projects that improve water efficiency, expand local and regional water supplies, and reduce reliance on the Delta and the Delta watershed contributes to higher water demands, less water supply to meet these demands, greater pressure on the Delta ecosystem for its water, and more vulnerability to the impacts of climate change and catastrophic events. Given the Delta Reform Act mandates to improve water supply reliability for California, reduce reliance on the Delta, and improve regional self-reliance, at a minimum, all water suppliers should demonstrate full compliance with State water efficiency and management laws, goals, and regulations to demonstrate reasonable and beneficial use of the state's water resources. California's success in achieving the policy of reduced reliance on the Delta and improving regional self-reliance will be demonstrated through a significant reduction in the amount of water used or in the percentage of water used from the Delta watershed. See Appendix G for additional information regarding how to achieve reduced reliance on the Delta and improved regional self-reliance.

Policies

WR P1. Reduce Reliance on the Delta through Improved Regional Water Self-Reliance

(a) Water shall not be exported from, transferred through, or used in the Delta if all of the following apply:

(1) One or more water suppliers that would receive water as a result of the export, transfer, or use have failed to adequately

contribute to reduced reliance on the Delta and improved regional self-reliance consistent with all of the requirements listed in paragraph (1) of subsection (c);

(2) That failure has significantly caused the need for the export, transfer, or use; and

(3) The export, transfer, or use would have a significant adverse environmental impact in the Delta.

(b) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers a proposed action to export water from, transfer water through, or use water in the Delta, but does not cover any such action unless one or more water suppliers would receive water as a result of the proposed action.

(c) (1) Water suppliers that have done all of the following are contributing to reduced reliance on the Delta and improved regional self-reliance and are therefore consistent with this policy:

(A) Completed a current Urban or Agricultural Water Management Plan (Plan) which has been reviewed by the California Department of Water Resources for compliance with the applicable requirements of Water Code Division 6, Parts 2.55, 2.6, and 2.8;

(B) Identified, evaluated, and commenced implementation, consistent with the implementation schedule set forth in the Plan, of all programs and projects included in the Plan that are locally cost effective and technically feasible which reduce reliance on the Delta; and

(C) Included in the Plan, commencing in 2015, the expected outcome for measurable reduction in Delta reliance and improvement in regional self-reliance. The expected outcome for measurable reduction in Delta reliance and improvement in regional self-reliance shall be reported in the Plan as the reduction in the amount of water used, or in the percentage of water used, from the Delta watershed. For the purposes of reporting, water efficiency is considered a new source of water supply, consistent with Water Code section 1011(a).

(2) Programs and projects that reduce reliance could include, but are not limited to, improvements in water use efficiency, water recycling, stormwater capture and use, advanced water technologies, conjunctive use projects, local and regional water supply and storage projects, and improved regional coordination of local and regional water supply efforts.

23 CCR Section 5003

NOTE: Authority cited: Section 85210(i), Water Code.

Reference: Sections 10608, 10610.2, 10610.4, 10801, 10802, 85001(c), 85004(b), 85020(a), 85020(d), 85020(h), 85021, 85022(d)(1), 85022(d)(5), 85023, 85054, 85300, 85302(d), 85303, and 85304, Water Code.

Recommendations

WR R1. Implement Water Efficiency and Water Management Planning Laws

All water suppliers should fully implement applicable water efficiency and water management laws, including urban water management plans (Water Code section 10610 et seq.); the 20 percent reduction in statewide urban per capita water usage by 2020 (Water Code section 10608 et seq.); agricultural water management plans (Water Code section 10608 et seq. and 10800 et seq.); and other applicable water laws, regulations, or rules.

WR R2. Require SWP Contractors to Implement Water Efficiency and Water Management Laws

The California Department of Water Resources should include a provision in all State Water Project contracts, contract amendments, contract renewals, and water transfer agreements that requires the implementation of all State water efficiency and water management laws, goals, and regulations, including compliance with Water Code section 85021.

WR R3. Compliance with Reasonable and Beneficial Use

The State Water Resources Control Board should evaluate all applications and petitions for a new water right or a new or changed point of diversion, place of use, or purpose of use that would result in new or increased long-term average use of water from the Delta watershed for consistency with the constitutional principle of reasonable and beneficial use. The State Water Resources Control Board should conduct its evaluation consistent with Water Code sections 85021, 85023, 85031, and other provisions of California law. An applicant or petitioner should submit to the State Water Resources Control Board sufficient information to support findings of consistency, including, as applicable, its urban water management plan, agricultural water management plan, and environmental documents prepared pursuant to the California Environmental Quality Act.

WR R4. Expanded Water Supply Reliability Element

Water suppliers that receive water from the Delta watershed should include an expanded water supply reliability element, starting in 2015, as part of the update of an urban water management plan, agricultural water management plan, integrated water management plan, or other plan that provides equivalent information about the supplier's planned investments in water conservation and water supply development. The expanded water supply reliability element should detail how water suppliers are reducing reliance on the Delta and improving regional self-reliance consistent with Water Code section 85201 through investments in local and regional programs and projects, and should document the expected outcome for a measurable reduction in reliance on the Delta and improvement in regional self-reliance. At a minimum, these plans should include a plan for possible interruption of water supplies for up to 36 months due to catastrophic events impacting the Delta, evaluation of the regional water balance, a climate change vulnerability assessment, and an evaluation of the extent to which the supplier's rate structure promotes and sustains efficient water use.

WR R5. Develop Water Supply Reliability Element Guidelines

The California Department of Water Resources, in consultation with the Delta Stewardship Council, the State Water Resources Control Board, and others, should develop and approve, by December 31, 2014, guidelines for the preparation of a water supply reliability element so that water suppliers can begin implementation of WR R4 by 2015.

WR R6. Update Water Efficiency Goals

The California Department of Water Resources and the State Water Resources Control Board should establish an advisory group with other State agencies and stakeholders to identify and implement measures to reduce impediments to achievement of statewide water conservation, recycled water, and stormwater goals by 2014. This group should evaluate and recommend updated goals for additional water efficiency and water resource development by 2018. Issues such as water distribution system leakage should be addressed. Evaluation should include an assessment of how regions are achieving their proportional share of these goals.

WR R7. Revise State Grant and Loan Priorities

The California Department of Water Resources, the State Water Resources Control Board, the California Department of Public Health, and other agencies, in consultation with the Delta Stewardship Council, should revise State grant and loan ranking criteria by December 31, 2013, to be consistent with Water Code section 85021 and to provide a priority for water suppliers that includes an expanded water supply reliability element in their adopted urban water management plans, agricultural water management plans, and/or integrated regional water management plans.

WR R8. Demonstrate State Leadership

All State agencies should take a leadership role in designing new and retrofitted State-owned and -leased facilities, including buildings and California Department of Transportation facilities, to increase water efficiency, use recycled water, and incorporate stormwater runoff capture and low-impact development strategies.

Improve Groundwater Management

Groundwater is the source, on average, of 20 percent of California's urban and agricultural water supplies. The state's most significant groundwater use occurs in regions that also rely upon water from the Delta watershed. In many of these groundwater basins, more water is pumped than is recharged, and groundwater levels are declining over the long term. The ***California Water Plan Update 2009*** estimates that the state, on average, overdrafts its groundwater basins by about 1 to 2 MAF per year and that the level of unsustainable groundwater pumping is increasing.

Problem Statement

The continued existence of major California groundwater basins in a chronic condition of overdraft combined with key regions of the state that depend on water from the Delta watershed and have poor groundwater practices, including unsustainable groundwater pumping, water quality contamination, irreversible loss of groundwater storage, and no groundwater plan for addressing these problems, is a major impediment to the achievement of the coequal goals.

Policies

No policies with regulatory effect are included in this section.

Recommendations

WR R9. Update Bulletin 118, California's Groundwater Plan

The California Department of Water Resources, in consultation with the Bureau of Reclamation, U.S. Geological Survey, the State Water Resources Control Board, and other agencies and stakeholders, should update Bulletin 118 information using field data, California Statewide Groundwater Elevation Monitoring (CASGEM), groundwater agency reports, satellite imagery, and other best available science by December 31, 2014, so that this information can be included in the next California Water Plan Update and be available for inclusion in 2015 urban water management plans and agricultural water management plans. The Bulletin 118 update should include a systematic evaluation of major groundwater basins to determine sustainable yield and overdraft status; a projection of California's groundwater resources in 20 years if current groundwater management trends remain unchanged; anticipated impacts of climate change on surface water and groundwater resources; and recommendations for State, federal, and local actions to improve groundwater management. In addition, the Bulletin 118 update should identify groundwater basins that are in a critical condition of overdraft.

WR R10. Implement Groundwater Management Plans in Areas that Receive Water from the Delta Watershed

Water suppliers that receive water from the Delta watershed and that obtain a significant percentage of their long-term average water supplies from groundwater sources should develop and implement sustainable groundwater management plans that are consistent with both the required and recommended components of local groundwater management plans identified by the California Department of Water Resources Bulletin 118 (Update 2003) by December 31, 2014.

WR R11. Recover and Manage Critically Overdrafted Groundwater Basins

Local and regional agencies in groundwater basins that have been identified by the California Department of Water Resources as being in a critical condition of overdraft should develop and implement a sustainable groundwater management plan, consistent with both the required and recommended components of local groundwater management plans identified by the California Department of Water Resources Bulletin 118 (Update 2003), by December 31, 2014. If local or regional agencies fail to develop and implement these plans, the State Water Resources Control Board should take action to determine if the continued overuse of a groundwater basin constitutes a violation of the State's Constitution Article X, Section 2, prohibition on unreasonable use of water and whether a groundwater adjudication is necessary to prevent the destruction of or irreparable injury to the quality of the groundwater, consistent with Water Code sections 2100 and 2101.

Improve Conveyance and Expand Storage

The greatest conflicts between the water needs of people and fish within the Delta occur during dry years. That is when the least amount of water is flowing into the Delta and, historically, when exports have been a much larger percentage of Delta inflows compared with wet years. The timing and pattern of Delta diversions must be shifted so that more water can be exported during wet years, when there is significantly more water available for diversion, and less is taken in dry years, when the water is needed for in-Delta water quality and ecosystem protections.

The ability to export larger amounts of water from the Delta during wet years will require improved conveyance to increase operational flexibility as well as more storage both north and south of the Delta so that this water can be captured, stored, and ultimately delivered to meet the water needs of both people and fish. With these improvements, Delta operations and, importantly, Delta export deliveries will become more predictable.

As an interim step toward increasing California's water supply reliability, the State should identify, prioritize, and implement smaller and more incremental operational, conveyance, and storage improvements (such as expanding existing facilities or constructing new ones) that can be accomplished quickly, preferably within the next 5 to 10 years.

Problem Statement

The state's interconnected network of surface and groundwater storage is insufficient in volume, conveyance capacity, and flexibility to achieve the coequal goals. The completion of the BDCP and the implementation of major new surface and groundwater storage facilities are needed but may take many years to implement, which will require more near-term actions to improve Delta operations and reduce the state's vulnerability to potential disruptions in water exports from the Delta due to floods and earthquakes or the need for additional regulatory protections for the environment.

Policies

No policies with regulatory effect are included in this section. See Appendix A, The Delta Stewardship Council's Role Regarding Conveyance.

Recommendations

WR R12. Complete Bay Delta Conservation Plan

The relevant federal, State, and local agencies should complete the Bay Delta Conservation Plan, consistent with the provisions of the Delta Reform Act, and receive required incidental take permits by December 31, 2014.

WR R13. Complete Surface Water Storage Studies

The California Department of Water Resources should complete surface water storage investigations of proposed off-stream surface storage projects by December 31, 2012, including an evaluation of potential additional benefits of integrating operations of new storage with proposed Delta conveyance improvements, and recommend the critical projects that need to be implemented to expand the state's surface storage.

WR R14. Identify Near-term Opportunities for Storage, Use, and Water Transfer Projects

The California Department of Water Resources, in coordination with the California Water Commission, Bureau of Reclamation, State Water Resources Control Board, California Department of Public Health, the Delta Stewardship Council, and other agencies and stakeholders, should conduct a survey to identify projects throughout California that could be implemented within the next 5 to 10 years to expand existing surface and groundwater storage facilities, create new storage, improve operation of existing Delta conveyance facilities, and enhance opportunities for conjunctive use programs and water transfers in furtherance of the coequal goals. The California Water Commission should hold hearings and provide recommendations to the California Department of Water Resources on priority projects and funding.

WR R15. Improve Water Transfer Procedures

The California Department of Water Resources and the State Water Resources Control Board should work with stakeholders to identify and recommend measures to reduce procedural and administrative impediments to water transfers and protect water rights and environmental resources by December 31, 2016. These recommendations should include measures to address potential issues with recurring transfers of up to 1 year in duration and improved public notification for proposed water transfers.

Improved Water Management Information

One of the greatest challenges to improved management of California's water supplies is the lack of consistent, comprehensive, and accurate estimates of actual water use in the state, both by sector of use (agricultural, urban, and environmental) and by regions within the state. The sheer number of water management agencies in California is a key logistical factor. Current data reported to various State agencies is a combination of measured uses and estimated uses, with limited verification of actual water use. This means that California does not have a clear understanding of its water demands, the amount of water available to meet those demands, how water is being managed, and how that management can be improved to achieve the coequal goals.

Problem Statement

Accurate, timely, consistent, and transparent information on the management of California water supplies and beneficial uses is an important tool used in the achievement of the coequal goals. The State needs sufficient information to assess the current reliability of its water supplies or to meaningfully measure progress toward achievement of more reliable water supplies for California.

Policies

The appendices referred to in the policy language below are included in Appendix B of the Delta Plan.

WR P2. Transparency in Water Contracting

(a) The contracting process for water from the State Water Project and/or the Central Valley Project must be done in a publicly transparent manner consistent with applicable policies of the California Department of Water Resources and the Bureau of Reclamation referenced below.

(b) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers the following:

  (1) With regard to water from the State Water Project, a proposed action to enter into or amend a water supply

or water transfer contract subject to California Department of Water Resources Guidelines 03-09 and/or 03-10 (each dated July 3, 2003), which are attached as Appendix 2A; and

(2) With regard to water from the Central Valley Project, a proposed action to enter into or amend a water supply or water transfer contract subject to section 226 of P.L. 97-293, as amended or section 3405(a)(2)(B) of the Central Valley Project Improvement Act, Title XXXIV of Public Law 102-575, as amended, which are attached as Appendix 2B, and Rules and Regulations promulgated by the Secretary of the Interior to implement these laws.

23 CCR Section 5004
NOTE: Authority cited: Section 85210(i), Water Code.
Reference: Sections 85020, 85021, 85300, and 85302, Water Code.

Recommendations

WR R16. Supplemental Water Use Reporting

The State Water Resources Control Board should require water rights holders submitting supplemental statements of water diversion and use or progress reports under their permits or licenses to report on the development and implementation of all water efficiency and water supply projects and on their net (consumptive) use.

WR R17. Integrated Statewide System for Water Use Reporting

The California Department of Water Resources, in coordination with the State Water Resources Control Board, California Department of Public Health, California Public Utilities Commission, California Energy Commission, Bureau of Reclamation, California Urban Water Conservation Council, and other stakeholders, should develop a coordinated statewide system for water use reporting. This system should incorporate recommendations for inclusion of data needed to better manage California's water resources. The system should be designed to simplify reporting; reduce the number of required reports where possible; be made available to the public online; and be integrated with the reporting requirements for the urban water management plans, agricultural water management plans, and integrated regional water management plans. Water suppliers that export water from, transfer water through, or use water in the Delta watershed should be full participants in the database.

WR R18. California Water Plan

The California Department of Water Resources, in consultation with the State Water Resources Control Board and other agencies and stakeholders, should evaluate and include in the next and all future California Water Plan updates information needed to track water supply reliability performance measures identified in the Delta Plan, including an assessment of water efficiency and new water supply development, regional water balances, improvements in regional self-reliance, reduced regional reliance on the Delta, and reliability of Delta exports, and an overall assessment of progress in achieving the coequal goals.

WR R19. Financial Needs Assessment

As part of the California Water Plan Update, the California Department of Water Resources should prepare an assessment of the state's water infrastructure. This should include the costs of rehabilitating/replacing existing infrastructure, an assessment of the costs of new infrastructure, and an assessment of needed resources for monitoring and adaptive management for these projects. The California Department of Water Resources should also consider a survey of agencies that may be planning small-scale projects (such as storage or conveyance) that improve water supply reliability.

Timeline for Implementing Policies and Recommendations

Figure 3-11 lays out a timeline for implementing the policies and recommendations described in the previous section. The timeline emphasizes near-term and intermediate-term actions.

Timeline for Implementing Policies and Recommendations

Council: Delta Stewardship Council
DPH: California Department of Public Health
DWR: California Department of Water Resources
RWQCB: Regional Water Quality Control Board(s)
SWRCB: State Water Resources Control Board
Water suppliers: refers to both urban and agricultural water suppliers

Figure 3-11

Science and Information Needs

An improved understanding of the state's hydrologic systems, patterns of water use, and effects of climate change, especially within the Delta watershed and areas that receive water from the Delta, is essential to improving the management of California's water supplies to achieve the coequal goals. Key areas of needed research include:

- Improved projections for and measurement of surface water flows (amounts, timing, quality) and how they may be impacted by environmental regulations, changing land uses, and climate change
- Improved water supply and demand forecasting models that incorporate vulnerability to extreme events (droughts, floods, earthquakes) and account for the impacts of climate change
- Improved methods for downscaling climate change models (including dynamic downscaling) and improved models for water scenario planning that incorporates these data
- Improved information on effective watershed management actions to restore and enhance capacity of rural and urban landscapes to process stormwater for water quality and water supply benefits
- Improved models for assessing the interaction between water management scenarios in the Delta and ecosystem function, including implications of revised instream flow requirements on inflows to the Delta and revised wet year/dry year export scenarios
- Improved information on changing water use patterns in response to urban and agricultural water efficiency measures, including water pricing, and implications for future water demands
- Improved characterization of groundwater basins and subbasins, and improved estimates of groundwater supplies (amounts, quality)
- Improved models of aquifer and surface-groundwater relationships, which include the effects of climate change on evaporation, runoff, groundwater recharge, subsurface interactions, and the implications of these effects for safe yield and implementation of conjunctive use and water transfer programs

Issues for Future Evaluation and Coordination

Additional areas of interest and concern related to water supply and the Delta may deserve consideration in the development of future Delta Plan updates, including:

- **Delta water delivery predictability.** A Delta Delivery Predictability Index should be developed that depicts, by hydrologic year types, the estimated streamflows entering the Delta and suggested levels of water exports that would be consistent with in-Delta and ecosystem protections. As part of the index, a system for tracking the use of stored Delta water also should be developed. The index will lead to a better understanding of how water exported and stored during wet years would be available to urban and agricultural users during dry years to offset reduced exports. This information is key to better understanding how investments in new storage and improved conveyance contribute to improved reliability of California's water supplies.
- **Performance measures for reduced reliance on the Delta.** The Delta Plan identifies two core measures for assessing progress in reducing reliance on the Delta: (1) a significant reduction in the amount of water used from the Delta watershed, or (2) a significant reduction in the percentage of water used from the Delta watershed. The Council will collaborate with DWR, SWRCB, and stakeholders to develop a standardized method or methods by which progress to reduce reliance on the Delta and improve regional self-reliance should be reported (1) in the urban and agricultural water management plans; (2) in IRWMPs; and (3) in the California Water Plan. Potential additional measures should be identified and evaluated that will benefit the amount of water, quality of water, and timing of flows in and

through the Delta, and contribute to reduced reliance on the Delta and improving regional self-reliance consistent with Water Code section 85021.

- **Evaluation of urban and agricultural water management plans.** The Council will work with DWR and the State Legislature to identify resources and secure authority, if necessary, to conduct further evaluation of water management information contained in urban and agricultural water management plans. The goal of these actions is to improve knowledge about water management in California and, specifically, to facilitate the aggregation and evaluation of water management data over time to gauge success toward reducing reliance on the Delta, increasing regional self-reliance, and achieving the coequal goals.
- **Integrated water resource management.** The value of integrated regional water management planning is widely recognized, but information on how to implement effective integrated water management projects is not well understood. The number of conjunctive management programs that combine green urban design, flood control, stormwater infiltration, water conservation, recycled water, and groundwater elements are increasing. Information about the successful integration of water management infrastructure needs to be shared and consideration given as to how to effectively promote implementation of these integrated strategies.
- **Agricultural and urban water efficiency.** Improved demand management through urban and agricultural water conservation and efficiency is the fastest and least expensive strategy for making more water available to the Delta through inflows and reducing the pressure to export more water from the Delta. Additional best management practices should be identified and promoted, including evaluation of new water conservation-based rate structures and how they contribute to water savings while maintaining more stable revenue for water suppliers.
- **Delta Watermaster.** The Delta Watermaster is in the process of completing an assessment of potential illegal water diversions within the Delta. This assessment should be expanded to evaluate illegal water diversions throughout the Delta watershed.
- **Reoperation of upstream reservoirs.** DWR is working with USACE and other agencies to develop a coordinated proposal for the reoperation of reservoirs above the Delta to address the impacts of climate change on flood protection and water supply operations. This proposal should include consideration of improved watershed management actions that will also help attenuate flood flows as well as improve ecosystem functions and water supply availability.

Performance Measures

Development of informative and meaningful performance measures is a challenging task that will continue after adoption of the Delta Plan. Performance measures need to be designed to capture important trends and to address whether specific actions are producing expected results. Efforts to develop and track performance measures in complex and large-scale systems like the Delta are commonly multiple-year endeavors. The recommended output and outcome performance measures listed below are provided as examples and subject to refinement as time and resources allow. Final administrative performance measures are listed in Appendix E and will be tracked as soon as the Delta Plan is completed.

Output Performance Measures

- Water suppliers that receive water from the Delta watershed have documented the expected outcome for a measureable reduction in reliance on the Delta and improvement in regional self-reliance. (WR R1, WR R4)
- Progress made in achieving existing water conservation and water supply performance goals, and setting expanded future goals for local, regional, and statewide

water conservation, water use efficiency, and water supply development. (WR R6)

- Information in updated Bulletin 118 is included in the next (2013) California Water Plan Update and in the 2015 urban water management plans and agricultural water management plans. (WR R9)

Outcome Performance Measures

- Progress toward increasing local and regional water supplies, measured by the amount of additional supplies made available (reported in 5-year increments from 2000). (WR P1)
- Progress toward meeting California's conservation goal of achieving a 10 percent reduction in statewide urban per capita water usage by 2015 and a 20 percent reduction by 2020. (WR R1)
- Progress toward improved reliability of Delta water exports and reductions in the vulnerability of Delta exports to disruption. (WR R12, ER P1, RR P1)
- Progress toward increasing the predictability of water deliveries from the Delta in a variety of water year types. (WR R12, WR R14)
- Progress toward achieving California's goal for the increased use of stormwater runoff of at least 500,000 acre-feet per year by 2020 and by at least 1 MAF per year by 2030. (WR R6)

CHAPTER 4

Protect, Restore, and Enhance the Delta Ecosystem

ABOUT THIS CHAPTER

This chapter describes the Sacramento-San Joaquin Delta (Delta) ecosystem and the factors that affect and too often degrade it. It proposes policies and recommendations for restoring the Delta ecosystem organized into five core strategies to achieve the coequal goals of the Delta Reform Act:

- Create more natural functional flows
- Restore habitat
- Improve water quality to protect the ecosystem
- Prevent introduction of and manage nonnative species impacts
- Improve hatcheries and harvest management

These core strategies form the basis of the five policies and nine recommendations found at the end of the chapter.

RELEVANT LEGISLATION

The coequal goals for the Delta (Water Code section 85054) are relevant to ecosystem restoration:

> *"Coequal goals" means the two goals of providing a more reliable water supply for California and protecting, restoring, and enhancing the Delta ecosystem. The coequal goals shall be achieved in a manner that protects and enhances the unique cultural, recreational, natural resource, and agricultural values of the Delta as an evolving place.*

Eight objectives in Water Code section 85020 are inherent in the coequal goals. Section 85020(a), (c), and (e) are relevant to this chapter:

> *85020 The policy of the State of California is to achieve the following objectives that the Legislature declares are inherent in the coequal goals for management of the Delta:*
>
> > *(a) Manage the Delta's water and environmental resources and the water resources of the state over the long term.*
> >
> > *(c) Restore the Delta ecosystem, including its fisheries and wildlife, as the heart of a healthy estuary and wetland ecosystem.*
> >
> > *(e) Improve water quality to protect human health and the environment consistent with achieving water quality objectives in the Delta.*

The coequal goals and inherent objectives seek broad protection of the Delta. Achievement of these broad goals and objectives requires implementation of specific strategies. Water Code sections 85022 and 85302 provide direction on the implementation of specific measures to promote the coequal goals and inherent objectives related to the Delta ecosystem restoration.

> *85022(d)(5) Develop new or improved aquatic and terrestrial habitat and protect existing habitats to advance the goal of restoring and enhancing the Delta ecosystem.*
>
> > *(6) Improve water quality to protect human health and the environment consistent with achieving water quality objectives in the Delta.*
>
> *85302(c) The Delta Plan shall include measures that promote all of the following characteristics of a healthy Delta ecosystem.*
>
> > *(1) Viable populations of native resident and migratory species.*
> >
> > *(2) Functional corridors for migratory species.*
> >
> > *(3) Diverse and biologically appropriate habitats and ecosystem processes.*
> >
> > *(4) Reduced threats and stresses on the Delta ecosystem.*
> >
> > *(5) Conditions conducive to meeting or exceeding the goals in existing species recovery plans and state and federal goals with respect to doubling salmon populations.*
>
> *85302(d) The Delta Plan shall include measures to promote a more reliable water supply that address all of the following:*
>
> > *(1) Meeting the needs for reasonable and beneficial uses of water.*
> >
> > *(3) Improving water quality to protect human health and the environment.*
>
> *85302(e) The following subgoals and strategies for restoring a healthy ecosystem shall be included in the Delta Plan.*
>
> > *(1) Restore large areas of interconnected habitats within the Delta and its watershed by 2100.*
> >
> > *(2) Establish migratory corridors for fish, birds, and other animals along selected Delta river channels.*
> >
> > *(3) Promote self-sustaining, diverse populations of native and valued species by reducing the risk of take and harm from invasive species.*
> >
> > *(4) Restore Delta flows and channels to support a healthy estuary and other ecosystems.*
> >
> > *(5) Improve water quality to meet drinking water, agriculture, and ecosystem long-term goals.*
> >
> > *(6) Restore habitat necessary to avoid a net loss of migratory bird habitat and, where feasible, increase migratory bird habitat to promote viable populations of migratory birds.*

This page intentionally left blank.

CHAPTER 4

Protect, Restore, and Enhance the Delta Ecosystem

In the Delta Reform Act, the goal of protecting, restoring, and enhancing the Delta ecosystem is coequal to the goal of providing a more reliable water supply for California. Both must be accomplished while protecting and enhancing the unique cultural, recreational, natural resource, and agricultural values of the Delta as an evolving place.

Some past land and water uses have put these goals in conflict. For example, reliable water supplies have been associated with artificially stabilized flows and a complex human-made system of infrastructure that includes dams, levees, and channelized rivers and sloughs. Yet healthy rivers and estuaries, and the native species that live in them depend on naturally variable water flows and a dynamic landscape. Many native species also depend on wetlands that have been drained for farming and other human uses.

Despite these conflicts, the Delta Stewardship Council (Council) must work to achieve the goal of protecting, restoring, and enhancing the Delta ecosystem. Inherent in that goal is the objective to "restore the Delta ecosystem, including its fisheries and wildlife, as the heart of a healthy estuary and wetland ecosystem" (Water Code section 85020(c)). (See sidebar, What Does It Mean to Achieve the Goal of Protecting, Restoring, and Enhancing the Delta Ecosystem?)

The Council envisions a future in which the Delta ecosystem has the following characteristics:

- Native species, including algae and other plants, invertebrates, fish, birds, and other wildlife, are self-sustaining and persistent.
- The tidal channels and bays in the Delta and Suisun Marsh connect with freshwater creeks, upland grasslands, and woodlands.
- The Sacramento and San Joaquin rivers and other Delta tributaries include reaches where streams are free to meander and connect seasonally to functional floodplains.
- Habitats for resident and rearing migratory fish, birds, and upland wildlife are connected by migratory corridors, including areas with high-quality cover and feeding opportunities.
- More natural variations in water flows and conditions make aquatic habitats, tidal marshes, and floodplains more dynamic, encourage survival of native species, and resist invasions by weeds and animal pests.
- The ecosystem is resilient enough to absorb and adapt to current and future effects of multiple stressors without significant declines in ecosystem services.
- The Delta will provide more reliable water supplies, in part because survival of its wildlife, fish, and plants do not require extraordinary regulatory protection.
- Californians recognize and celebrate the Delta's unique natural resource values through wildlife observation, angling, waterfowl hunting, and other outdoor recreation.

This future Delta will differ from the Delta that greeted the first Californians and will probably be different from the current ecosystem. Not every species or natural area now found in the Delta may persist through the changes ahead, including climate change, but Californians' use and management of the Delta will be directed and coordinated to sustain conditions that make species' survival more likely while maintaining the many other benefits provided by the Delta ecosystem.

WHAT DOES IT MEAN TO ACHIEVE THE GOAL OF PROTECTING, RESTORING, AND ENHANCING THE DELTA ECOSYSTEM?

Achieving the coequal goal of ecosystem protection, restoration, and enhancement means successfully establishing a resilient, functioning estuary and surrounding terrestrial landscape capable of supporting viable populations of native resident and migratory species with diverse and biologically appropriate habitats, functional corridors, and ecosystem processes.

For this purpose, the term "restoration" is defined in Water Code section 85066 as follows:

> *"the application of ecological principles to restore a degraded or fragmented ecosystem and return it to a condition in which its biological and structural components achieve a close approximation of its natural potential, taking into consideration the physical changes that have occurred in the past and the future impact of climate change and sea level rise."*

Restoration actions may include restoring interconnected habitats within the Delta and its watershed, restoring more natural Delta flows, or improving ecosystem water quality.

"Protection" means preventing harm to the ecosystem, which could include preventing the conversion of existing habitat, the degradation of water quality, irretrievable conversion of lands suitable for restoration, or the spread of invasive nonnative species.

"Enhancement" means improving existing desirable habitat and natural processes. Enhancement might include flooding the Yolo Bypass more often to support native species, or to expand or better connect existing habitat areas. Enhancement includes many fish and wildlife management practices, such as managing wetlands for waterfowl production or shorebird habitat, installing fish screens to reduce entrainment of fish at water diversions, or removing barriers that block migration of fish to upstream spawning habitats.

DP-306

A Restored Delta Ecosystem Is Key to a Reliable Water Supply

Delta water supplies can be more reliable only when the Delta ecosystem is restored. The water projects that rely on the Delta were developed without contemporary understanding of the Delta's ecology or anticipation of the value that Californians now place on a healthy environment. As the effects of the projects on the Delta ecosystem became apparent, a series of adjustments in their operation has been put in place. Each adjustment affected the water diversions, altering volume and timing to reduce damage, but without fully mitigating harm to the Delta ecosystem. The perilous condition of salmon, delta smelt, and other species remains a key limit on project operations. Only as these populations recover will water project operations become more flexible and reliable.

To restore the Delta ecosystem, Californians will need to use water management facilities in new ways. Reservoirs will need to hold and release water for ecosystem purposes as well as for water users. Storage and the development of alternative supplies will be needed to help reduce reliance on the Delta and improve regional self-reliance. Multipurpose bypasses and levees will need to provide habitat while also controlling flooding. Channels and water controls will need to be able to deliver water for habitats as well as for farms and cities. Modern water diversions will need to protect fish while providing reliable water supplies. For these reasons, restoring the Delta ecosystem will require new investment in water facilities and alternative supplies, not just regulation of water project operations or restoration of habitats for fish and wildlife. Other actions undertaken to protect the ecosystem can also benefit water users; for example, vigilance in preventing invasive species introduction can avoid future costs to manage mussel infestations in pipelines or other water structures. Tradeoffs may be necessary as we better match demands to the supply available, consistent with ecosystem protection, and match our expectations about the ecosystem to the changing climate.

A restored Delta ecosystem is also important to the Delta's future as an attractive place to live, work, and recreate. Water flows are important not just to water exporters, fish, and aquatic environments, but also to the Delta's municipal, industrial, and agricultural waters users, who will need consideration as system changes are planned and implemented. Restoration actions will require careful design so they are attuned to local needs: locating habitats to minimize conflicts with existing and planned uses; working with farmers by promoting wildlife-friendly farming; providing buffers between wildlife areas and farms; working with landowners regarding how to manage restored wildlife populations on or near their lands; and improving opportunities for outdoor recreation, including boating, angling, and hunting, that are enjoyed by residents and also attract visitors. Integrating habitat improvements when levees are rebuilt or flood channels are improved can draw new sources of funds to strengthen the Delta flood control system. In essence, a systems approach that recognizes tradeoffs and the value of balance will be necessary for California to achieve the coequal goals.

The Delta Ecosystem, Past and Present

In the Delta, the Central Valley's great rivers—the Sacramento from the north and San Joaquin from the south—join the Cosumnes, Mokelumne, and Calaveras here in a vast and complex estuary influenced by tides and river currents (see Figure 4-1).

Before the early 1800s, the rivers flowed through approximately 400,000 acres of tidal wetlands and other aquatic habitats that connected with several hundred thousand acres of nontidal wetlands and riparian forest. Flows of the Delta's rivers and tidal channels varied by season and year-to-year, sometimes pouring from the Sierra in great floods whose fresh waters overflowed wetlands and floodplains, and at other times declining as droughts shriveled rivers and brackish tidewaters pushed inland. To the west, the rivers joined to discharge through marsh-fringed Suisun Bay to the Carquinez Straight, San Francisco Bay, and the Pacific Ocean.

The Delta's historical landscape also varied from north to south (see Figure 4-2). In the north Delta, flood basins occurred where the Sacramento River intertwined with tidal channels. A vast area of freshwater wetlands dominated by tules transitioned into tidal wetlands. Shallow perennial ponds and lakes, broad riparian forests along natural levees, and seasonal wetlands at the upland edge were also common. The central Delta was characterized by large, tidal islands that flooded during spring tides (or more frequently) intersected by networks of branching tidal channels. Channel banks were low and covered by the willows, grasses, sedges, shrubs, and ferns that also grew in island interiors. The south Delta contained a complex network of channels formed predominantly by riverine processes. The floodplain comprised emergent wetlands, perennial and seasonal ponds, willow thickets, and seasonal wetlands. Driftwood and other woody debris filled some channels, likely from riparian forest along the San Joaquin River's natural levees.

Historical records show a rich and complex Delta with habitats supporting diverse and abundant native plants and animals (Grossinger et al. 2010, Whipple et al. 2010, Whipple 2011). Some fish, including smelt, schooled in the open waters of the western Delta's bays and channels, moving east when brackish water intruded from San Francisco Bay. Other resident wildlife and plants also prospered: rails in tidal and tule marshes, giant garter snakes in freshwater wetlands and ponds, and riparian brush rabbits and wood rats in willow thickets and riparian forests. Each fall, salmon and steelhead, drawn by the swelling Sacramento and San Joaquin rivers, migrated inland from the ocean and navigated upstream to spawning areas in their tributaries. As river flows receded, their young, emerging from these tributaries' spawning gravel, would return downstream and shelter in driftwood-lined eddies or undercut riverbanks and feed in Delta sloughs, marshes, and floodplains before returning to the sea. Waterfowl, cranes, and shorebirds migrated through the Delta along a north-south route that stretched from the Arctic to Mexico or beyond. Songbirds followed a similar path through riparian woodlands that connected from the Sacramento Valley through the Delta to the San Joaquin Valley.

To immigrants arriving in the nineteenth century, the Delta and Central Valley appeared a wild and dangerous place that had to be "reclaimed" to support the agricultural way of life they had inherited from their ancestors. The rapid transformation of the historical Delta over 160 years involved many changes. Over 1,000 miles of levees were constructed to drain wetlands and protect islands from damaging floods. Channels were cut between sloughs or through islands to ease navigation and encourage drainage without regard to effects on the estuary. Forests were cut and land leveled for farming (Hanak et al. 2011). This transformation produced the rich agricultural economy and rural culture of the Delta described in Chapter 5. But it came at a cost: loss of the original estuarine ecosystem and its species, and native people.

Comparison of Historical (early 1800s) and Modern Delta Waterways

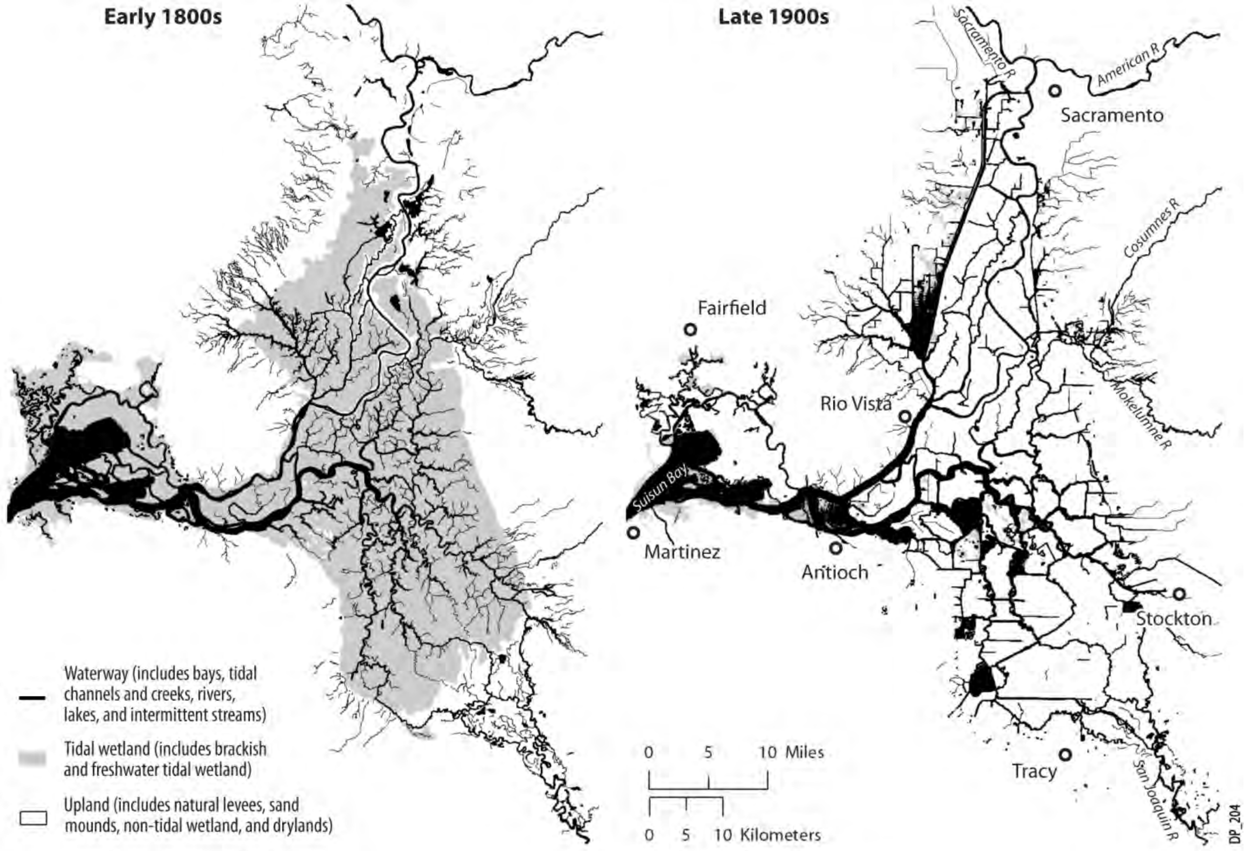

Figure 4-1 The map at left shows the complexity of early 1800s Delta hydrography (black) within tidal wetland (gray). The modern hydrography at right shows major differences such as channel widening, meander cuts, cross levees, and loss of within-island channel networks and tidal wetland.

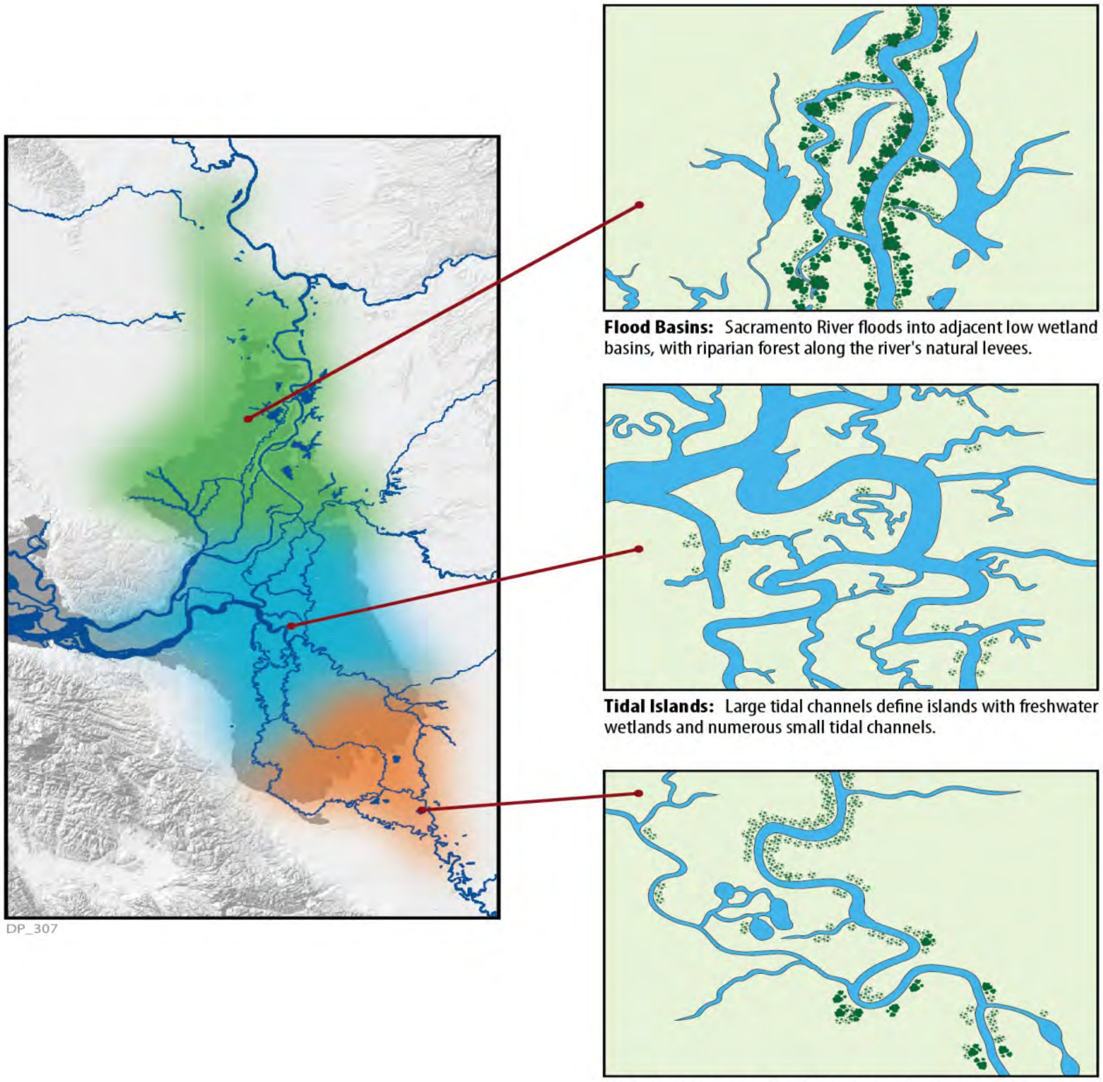
Source: San Francisco Estuary Institute 2012

Primary Landscapes in the Historical Delta



Flood Basins: Sacramento River floods into adjacent low wetland basins, with riparian forest along the river's natural levees.

Tidal Islands: Large tidal channels define islands with freshwater wetlands and numerous small tidal channels.

Distributary Rivers: San Joaquin River branches merge into tidal wetlands within a floodplain with a wide mix of habitats.

Figure 4-2

The historical Delta can be divided into three primary landscapes: flood basins in the north Delta, tidal islands in the central Delta, and distributary rivers (rivers with multiple branches flowing away from main channels) in the south Delta. Transitions between these landscapes occurred gradually, across broad areas. Though these landscapes held many habitat types in common, characteristics and spatial patterns varied greatly—these large-scale patterns are what helped define the landscapes, which in turn provided different functions for native species. Understanding these major landscape types is a valuable framework for evaluating current and future restoration strategies in the Delta, providing a baseline between the current landscapes and the long-established historical patterns.

Source: Whipple 2011

Nearly all the rivers historically flowing to the Delta were dammed, creating Shasta, Folsom, Millerton, and Oroville lakes and other impoundments described in Chapter 3. These dams, together with levees constructed to prevent flooding, blocked access to spawning areas and other habitats critical to salmon, splittail, and other fish. The once pronounced seasonal and year-to-year variability of river flows has given way to more stable, artificially regulated conditions. The formerly complex Delta sloughs have been replaced by a simplified grid of straightened channels, cuts, and often rock-lined rivers fixed in space and time, and used for water conveyance and shipping. Pumps to divert water for irrigation or municipal use south or west of the Delta further disrupted the estuary (see Figure 4-3).

Ecosystem restoration cannot restore the historical Delta. Its alteration is too complete to reverse and could not occur without damage to other beneficial uses of its water and land. The Delta Reform Act recognizes these limitations and defines restoration as a "...close approximation of its natural potential..." (Water Code section 85066).

Ecosystem Stressors

Many factors stress the Delta's ecosystem (Baxter et al. 2010). Stressors are actions or factors, whether caused by humans or nature, that negatively affect the ecosystem processes and functions. Stressors include altered flows, habitat loss, entrainment in Delta diversions, degraded water quality, harmful nonnative species, migration barriers, and impacts from hatcheries. Reducing one stressor, or even several stressors, is unlikely to solve all environmental problems in the Delta (Delta ISB 2011, see Appendix I). Many restoration projects fail because multiple stressors have been insufficiently considered (Palmer et al. 2005). Because of uncertainty over cause and effect, ecosystem restoration must address as many stressors as possible through adaptive management, as described in Chapter 2 and Appendix C.

Organizing stressors into categories, such as those developed by the Delta Independent Science Board (ISB), helps resource managers to think about, assess, and manage them. (See sidebar, Stressor Categories to Help with Management Options.) Ecosystem stressors and their effects can be categorized by what causes them (sources of stress) or by what can be done about them. The Delta Plan's ecosystem restoration strategies address the following current stressors:

- Delta flows
- Habitat
- Ecosystem water quality
- Nonnative species
- Hatcheries and harvest management

STRESSOR CATEGORIES TO HELP WITH MANAGEMENT OPTIONS

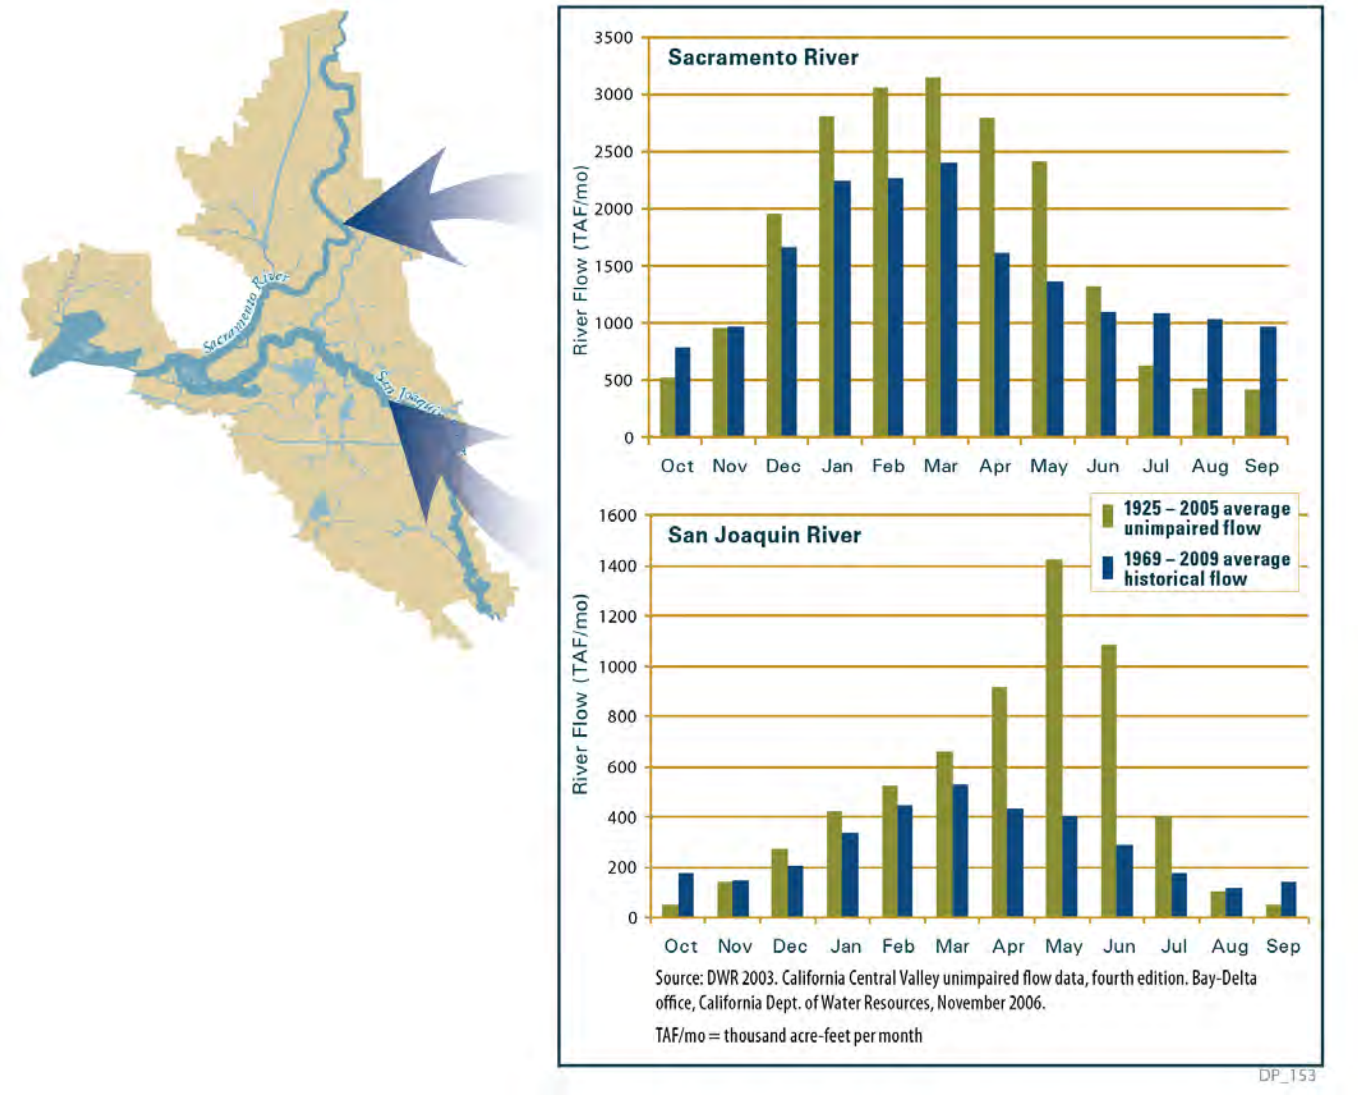
The Delta ISB developed categories that put Delta stressors into broad context to help assess management options (for example, what can be done about them) (Delta ISB 2011). Management options are stressor reduction, elimination, or mitigation. When this is not possible, adaptation to stressors must be promoted. The Delta ISB has proposed the following categories:

- **Current stressors** result from ongoing human activities that at least in some cases can be eliminated (for example, fish entrainment at water diversions and pollution from point sources).
- **Legacy stressors** result from past actions that cannot be undone, but their impact can sometimes be reduced or mitigated (for example, mercury pollution from historical gold mining and past introductions of nonnative species).
- **Globally determined stressors** result from large-scale human activities or natural processes that cannot be eliminated or mitigated within the purview of the Delta Plan and require larger-scale planning and adaptation (for example, global climate change and human population growth).
- **Anticipated future stressors** require preparation (for example, future land subsidence, urban expansion, and new invasions by nonnative species).

These categories have some overlap; for example, a globally determined stressor such as sea level rise also can be an anticipated future stressor.

DP-317

Changes in Historical Flows Challenge Delta Ecology



Source: DWR 2003. California Central Valley unimpaired flow data, fourth edition. Bay-Delta office, California Dept. of Water Resources, November 2006.

TAF/mo = thousand acre-feet per month

Figure 4-3

Habitat for native species has been shaped in the past by natural cycles of river flows.* Since the 1960s, our water system, with its upstream reservoirs, diversions, and other management facilities, has changed these patterns in two ways. First, seasonal flows are much less variable and encourage nonnative fish and vegetation, which can crowd out native species that thrive in a more varied environment. Second, peak flows now come at lower magnitudes and occur earlier on the San Joaquin; this shift affects water temperatures, salinity, and access to habitat, causing stress on native species.

** Natural flow is runoff that would have occurred had the landscape and waterways remained unaltered. Our best estimate of natural Delta inflow is "unimpaired flow," the flow that would be expected if reservoirs were removed but the contemporary watershed and valley land uses remained. However, natural and unimpaired Delta inflow are not the same, and the difference between them could be substantial at times.*

Climate Change

Climate change will cause major stresses on the Delta ecosystem. Rising sea level could inundate freshwater marshes and other freshwater aquatic habitats, potentially with brackish water, reducing habitat for native plants, fish, and wildlife. In addition to rising sea level, the amount of ideal low-salinity habitat for native fish such as the delta smelt will be affected by changes in runoff timing and intensity, which will also affect erosion and sedimentation patterns, again altering fish habitat. Increased water temperature will negatively affect smelt, salmon, and other coldwater-dependent fish, and will likely increase the range of invasive species (Healey et al. 2008, Villamanga and Murphy 2010). In terrestrial habitats, warming could create soil moisture deficits, change plant community composition, and even disrupt timing between pollinators and plants (California Natural Resource Agency 2009). Overall climate change will exacerbate current challenges to the protection and restoration of Delta ecosystems.

Ecosystem Restoration

Restoration of the Delta ecosystem does not mean a return to predevelopment conditions with only its native plants and animals. That is beyond human ability. Instead, restoration seeks to return areas to a close approximation of their natural potential, including re-establishing natural habitat and ecosystem functions, as feasible, within the context of the current configuration of the Delta, the current biological communities, and the permanent modifications to Delta land forms and hydrology. Successful ecosystem restoration rehabilitates key elements—the living and nonliving features such as soils, elevation, waterways, species, populations, and habitats—and the structure and processes that connect them. This section summarizes the principles of and considerations for ecosystem restoration in the Delta.

Much work has been done to develop ecological principles specific to the Delta. (See sidebar, Delta Ecological Principles.) Restoration projects that adhere to these principles are more likely to achieve their goals and objectives.

The Delta Reform Act's definition of restoration recognizes that the ecosystem will be dynamic, changing in response to restoration actions and future climate change (Healey et al. 2008, Delta ISB 2011). The desired future condition is an evolving ecosystem that supports communities of both native and nonnative species, and continues to provide value such as clean water, flood storage, or recreational fishing. A dynamic, restored Delta ecosystem can be a natural complement to the Delta as an "evolving place" described in Chapter 5.

To increase the likelihood of ecosystem restoration success, plans and actions must incorporate the principles of adaptive management (see Chapter 2 and Appendix C for a detailed discussion). This begins with a clear, practical vision of what will be achieved for the ecosystem, together with human need for water supply reliability and flood risk reduction. Additional examples are provided in the sidebar, Current Delta Ecosystem Restoration Efforts.

DELTA ECOLOGICAL PRINCIPLES

The following are ecological principles for the Delta adapted from those developed for the Delta Vision Blue Ribbon Task Force by former CALFED Lead Scientist Michael Healey (2007a, 2007b) and for the Bay Delta Conservation Plan (BDCP) Steering Committee by the BDCP Independent Science Advisors (2007).

Principle 1: Humans are part of the Delta ecosystem. Human activities over the past 160 years have produced a Delta ecosystem that is different from the historical ecosystem, and will remain so even as human-induced stressors are modified.

Management implications: Strategic management of human activities, and uses of the landscape and water in the Delta will be integral to the successful protection, restoration, and enhancement of the Delta ecosystem.

Principle 2: The Delta ecosystem is part of larger ecosystems. The Delta ecosystem affects and is affected by surrounding ecosystems. High year-to-year variability in precipitation and river flows are, in part, caused by climate patterns that span the entire Pacific Ocean. In addition, many animals that use the Delta do so for only part of their life cycles, spending other parts upstream in the rivers, in the ocean, or as far as away as South America and northern Canada.

Management implication: Management of the Delta cannot occur independently of structures and events upstream and in the ocean, in regional and state economies, or in the wider governance context.

Principle 3: The Delta ecosystem is a mosaic of smaller terrestrial and aquatic ecosystems. These ecosystems interact in important ways (for example, exchange of material, energy, and species). This landscape mosaic determines overall performance of the ecosystem. The size, shape, arrangement, and connections within the mosaic are critical to the way the Delta functions.

Management implication: Management plans and decisions need to be informed by a landscape perspective that recognizes interrelationships among patterns of land and water use, patch size, location and connectivity, and species success. The landscape perspective needs to be developed at several physical and temporal scales.

Principle 4: The Delta ecosystem is naturally dynamic. This includes disturbances and extreme events such as very wet and very dry years. Changes in one part of the Delta may have far-reaching effects in space and time.

Management implication: The Delta cannot be managed as a homogenous or static system.

Principle 5: Native Delta species are adapted to a naturally dynamic Delta ecosystem. The natural Delta is dynamic and variable, and the organisms living there are adapted to that variability.

Management implication: In order to successfully protect, restore, and enhance the Delta, management needs to include actions that mimic, to some extent, the historical natural variability.

Principle 6: Each native Delta species has particular tolerances for habitat variables such as temperature, dissolved oxygen, salinity, turbidity, and toxic substances. Species distributions may shift if conditions change and exceed these tolerances. Increase of air and water temperature by even 2 degrees may make the Delta uninhabitable for some local species and also make it potentially inhabitable for species from warmer regions.

Management implication: Loss of some species from the ecosystem may be inevitable. For local species, refugia may have to be located in cooler regions if extinction is to be prevented. Additional actions may be necessary to alleviate a potential increase in nonnative invasive species.

DP-308

CURRENT DELTA ECOSYSTEM RESTORATION EFFORTS

Several significant ecosystem restoration planning and implementation efforts are worth noting:

- The draft Ecosystem Restoration Program (ERP) Conservation Strategy was released by the California Department of Fish and Wildlife (DFW) in 2011 (DFG 2011) to update the CALFED ERP plans from 2000. DFW collaborates with its federal fish agency partners, the U.S. Fish and Wildlife Service and National Marine Fisheries Service, to implement the ERP, including providing grants for Delta and Suisun Marsh restoration research and implementation.
- DFW and the California Department of Water Resources (DWR) are continuing to implement and plan for ecosystem restoration projects begun under the CALFED Bay-Delta Program located in Suisun Marsh, at Dutch Slough, at Cache Slough, in the Yolo Bypass, and at the Cosumnes Preserve's North Delta project.
- The *Suisun Marsh Habitat Management, Preservation, and Restoration Plan* is a comprehensive approach to restoring 5,000 to 7,000 acres of tidal wetlands and maintaining managed wetlands and their functions consistent with the CALFED program, the Suisun Marsh Preservation Agreement, applicable species recovery plans, and other interagency goals.
- The Bay Delta Conservation Plan (BDCP) is an overarching approach to large-scale ecosystem restoration now in the planning process (see sidebar, Bay Delta Conservation Plan and Delta Ecosystem Restoration).
- Several Habitat Conservation Plans (HCP) and Natural Community Conservation Plans (NCCP) for parts of the Delta are in place or under development in the Delta. These plans' purpose is to minimize and mitigate the impact of authorized incidental take of the endangered or rare species and their habitats. Completed HCPs and NCCPs in the Delta include the San Joaquin HCP and East Contra Costa County HCP/NCCP. The BDCP, Yolo County HCP/NCCP, South Sacramento HCP, and Solano Multispecies HCP are under development.
- The State Water Resources Control Board (SWRCB) is updating its Bay-Delta Water Quality Control Plan (Bay-Delta Plan). The first phase focuses on objectives to protect water quality for south Delta agriculture and San Joaquin River flow objectives to protect fish and wildlife. The second phase focuses on other changes to its Bay-Delta Plan to protect fish and wildlife, including Delta outflow objectives, Sacramento River flow objectives, export/inflow objectives, Delta Cross Channel Gate closure objectives, Suisun Marsh objectives, potential new reverse flow objectives for Old and Middle rivers, potential new floodplain habitat flow objectives, potential changes to the monitoring and special studies program, other potential changes to the program of implementation, and issues identified through the BDCP process. As part of the SWRCB's review of its Bay-Delta Plan, it will consider information developed as part of its 2010 staff technical report *Development of Flow Criteria for the Sacramento–San Joaquin Delta Ecosystem* (SWRCB 2010) along with information about other factors, such as coldwater pool requirements and other water uses.
- In 2009, the Legislature established the Sacramento–San Joaquin Delta Conservancy (Delta Conservancy) as a primary State agency to implement ecosystem restoration in the Delta, along with supporting efforts that advance environmental protection and the economic well-being of Delta residents. The Delta Conservancy adopted a strategic plan to guide its planning and implementation efforts in March 2012.
- DWR's Delta Levees Special Flood Control Projects program provides funding to local agencies in the Delta for habitat projects linked to flood management improvements. Similarly, DWR's *2012 Central Valley Flood Protection Plan* proposes new or enhanced flood bypasses, levee setbacks, and fish passage improvements that provide both flood risk reduction and habitat. This effort is discussed in more detail in Chapter 7.

DP-303

Delta Flows

The Delta is the upstream portion of the San Francisco Estuary, where ecosystems dominated by the Central Valley's rivers transition to the more ocean-influenced ecosystem of the downstream portions of the estuary. Water flow is a "master variable," driving the ecological health of rivers and their ability to support valued environmental services (Poff et al. 1997, Postel and Richter 2003). In estuaries, the interaction of river flows and ocean tides produces a salinity gradient from fresh water to brackish and salty water. River flows and ocean tides also deposit and erode sediment to shape the estuarine landscape and its habitats. Estuarine species are adapted to the complex natural flow, salinity, and sediment dynamics in their native estuaries.

Delta flows can be divided into three categories: (1) river and floodplain flows, (2) in-Delta net channel flows, and (3) net Delta outflows (SWRCB 2010). Each category has different ecological effects. (See sidebar, Flow Is More than Just Volume.)

BAY DELTA CONSERVATION PLAN AND DELTA ECOSYSTEM RESTORATION

The parties seeking permits pursuant to the Bay Delta Conservation Plan (BDCP) are attempting to formulate a 50-year plan that, if successful, would ultimately contribute to the recovery of priority species, restoration of a more naturally functioning Delta ecosystem, and establishment of a secure and reliable water supply from the Delta for human use.

As discussed in the Chapter 3 sidebar, BDCP and Water Supply Reliability, the BDCP is a planning process intended to result in the issuance of permits from the California Department of Fish and Wildlife (DFW) under the Natural Community Conservation Planning Act and from the U.S. Fish and Wildlife Service and the National Marine Fisheries Service pursuant to Section 10 of the federal Endangered Species Act (ESA). In addition, the Bureau of Reclamation will use the information developed from this process to obtain incidental take authorization through an ESA Section 7 process. The BDCP proposes to contribute to the restoration of the health of the Delta's ecological systems by contributing to a more natural flow pattern than existing conditions within the Delta and by implementing a comprehensive restoration program.

As currently proposed, the BDCP takes an approach to supporting landscape-level processes by creating a reserve system consisting of a mosaic of natural communities that would be adaptable to changing conditions (including sea level rise) to sustain populations of covered species and maintain or increase native biodiversity (BDCP 2012). The proposal considers protection of at least 31,000 acres of existing natural communities, and restoration or creation of at least 72,809 acres of natural communities, including at least 65,000 acres of tidally influenced natural communities. In addition, the BDCP is intended to improve the Delta ecosystem by taking actions such as:

- Protecting and improving habitat linkages to promote the movement of native species
- Accommodating future sea level rise by providing transitional areas that allow future upslope establishment of tidal wetlands
- Allowing natural flooding to promote the regeneration of vegetation and related ecosystem processes
- Connecting rivers and their floodplains to recharge groundwater, provide fish spawning and rearing habitat, and increase food supply
- Managing the distribution and abundance of nonnative predators to reduce predation on native special-status species

Examples of elements of the BDCP strategy to support natural communities include:

- Controlling invasive nonnative plant species
- Restoring or creating 5,000 acres of riparian forest
- Restoring corridors of riparian vegetation along 20 miles of channel margin
- Restoring 2,000 acres of grassland
- Protecting at least 20,000 acres of cultivated land to support suitable habitat for native species

The BDCP also plans to propose comprehensive programs for monitoring, research, and adaptive management.

If the process is successful and DFW approves the BDCP as a natural community conservation plan pursuant to Chapter 10 (commencing with Section 2800) of Division 3 of the Fish and Game Code, and determines that the BDCP meets the requirements of this section, and the BDCP has been approved as a habitat conservation plan pursuant to the federal ESA (16 United States Code section 1531 et seq.), the Council shall incorporate the BDCP into the Delta Plan (Water Code section 85320(e)). The Council has a potential appellate role regarding the inclusion of the BDCP in the Delta Plan.

As of this publication, the final public draft of the BDCP and the related environmental impact report/environment impact statement are expected to be released in late 2013. The Council is a Responsible Agency for California Environmental Quality Act purposes.

DP-311

1. **River and floodplain flows.** The Sacramento and San Joaquin rivers and their tributaries provide fresh water into the Delta. Along the margins of the Delta, these rivers seasonally inundate floodplains. Inundated floodplains stimulate the food web by enhancing plant growth, triggering aquatic invertebrate production, exporting food that becomes available to animals downstream, and providing spawning and rearing habitat on the floodplain for fish such as salmon and splittail. In recent decades, floodplains like the Yolo Bypass are flooded primarily by very high flows that flood the Yolo Basin about one year in three. Floodplain restoration could re-establish topographic connections that flood the bypass more often and at lower flows.

2. **In-Delta net channel flows.** Delta flows are primarily driven by tides affected by the moon's cycles, river inflows, in-Delta agricultural diversions, and water exports through the Central Valley Project (CVP) and the State Water Project (SWP). Averaging these influences in any Delta channel over about 1 day gives the "net flow." Locations near the CVP and SWP export pumps, such as parts of Old River and Middle River in the south Delta, experience net "reverse" flows when export pumping by the water projects exceeds these channels' normal downstream flows. The average flow in these channels actually runs backward at times, which affects the Delta's aquatic ecosystems both directly and indirectly (see Figure 4-4). Reverse flow in the southern Delta is associated with increased entrainment of some fish species (Grimaldo et al. 2009) and disruption of migration cues for migratory fish (see the Migratory Corridors for Native Species section for more detail). Reverse and otherwise altered flows caused by upstream reservoir operations, the constraints of artificially connected Delta channels, plus water exports affect Delta habitat largely through effects on water residence time, water temperature, and the transport of sediment, nutrients, organic matter, and salinity (Monsen et al. 2007). These reverse flows could, in turn, affect the behavior of migrating fish, and habitat suitability for resident and migratory fish and other species. Finally, aquatic organisms often get drawn (entrained) into water pumping facilities, as described later in this chapter.

3. **Net Delta outflows.** Net Delta outflow is the sum of all inflows to, and diversions from, the Delta. It is the flow out of the Delta that would occur in the absence of tides (Oltmann 1988). During dry periods, outflow is a low percentage of the instantaneous tidal flow in the western Delta. Nevertheless, over periods longer than 2 weeks, Delta outflow transports river-derived organic matter to Suisun Bay (Jassby and Cloern 2000) and controls the location of the salinity gradient (Jassby et al. 1995). Delta outflow objectives are based on the monthly average location of the low-salinity zone in the western Delta. Outflow variability is recognized as a key factor promoting diverse native fish communities (Moyle and Mount 2007, Moyle et al. 2010).

FLOW IS MORE THAN JUST VOLUME

Flow is not simply the volume of water, but also the direction of flow, the timing of flow, the frequency of specific flow conditions, the duration of various flows, and the rate of change in flows.

Bunn and Arthington (2002) present four key principles underlying the links between hydrology and aquatic biodiversity and the impacts of altered flow regimes: (1) flow determines physical habitat, (2) aquatic species have evolved life history strategies based on natural flow regimes, (3) upstream-downstream and lateral connectivity are essential to organism viability, and (4) invasion and success of nonnative species is facilitated by flow alterations. Altered flow regimes have been shown to be a major source of degradation to aquatic ecosystems worldwide (Petts 2009).

DP-169

Flow Direction in South Delta

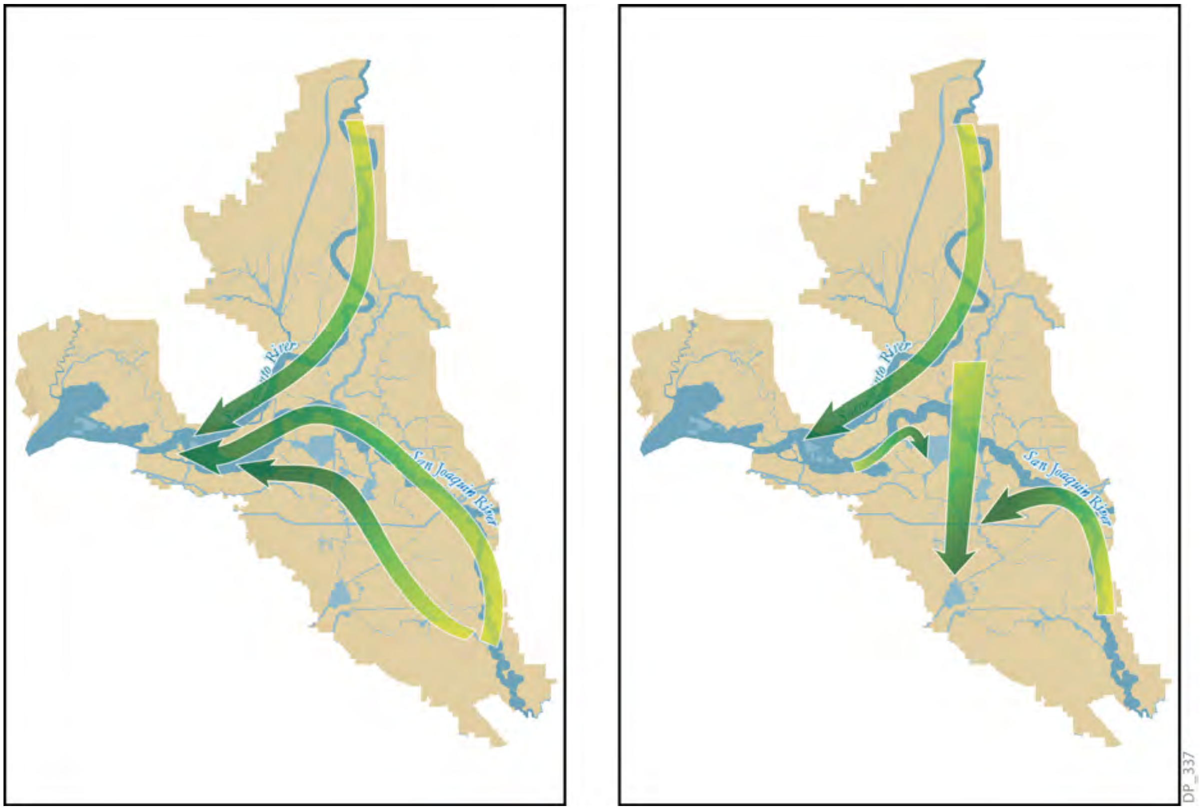


Figure 4-4 The left panel depicts the tidally averaged flow direction in the absence of export pumping. The right panel depicts reversal of tidally averaged flows that occurs during times of high exports (pumping) and low inflows to the Delta.

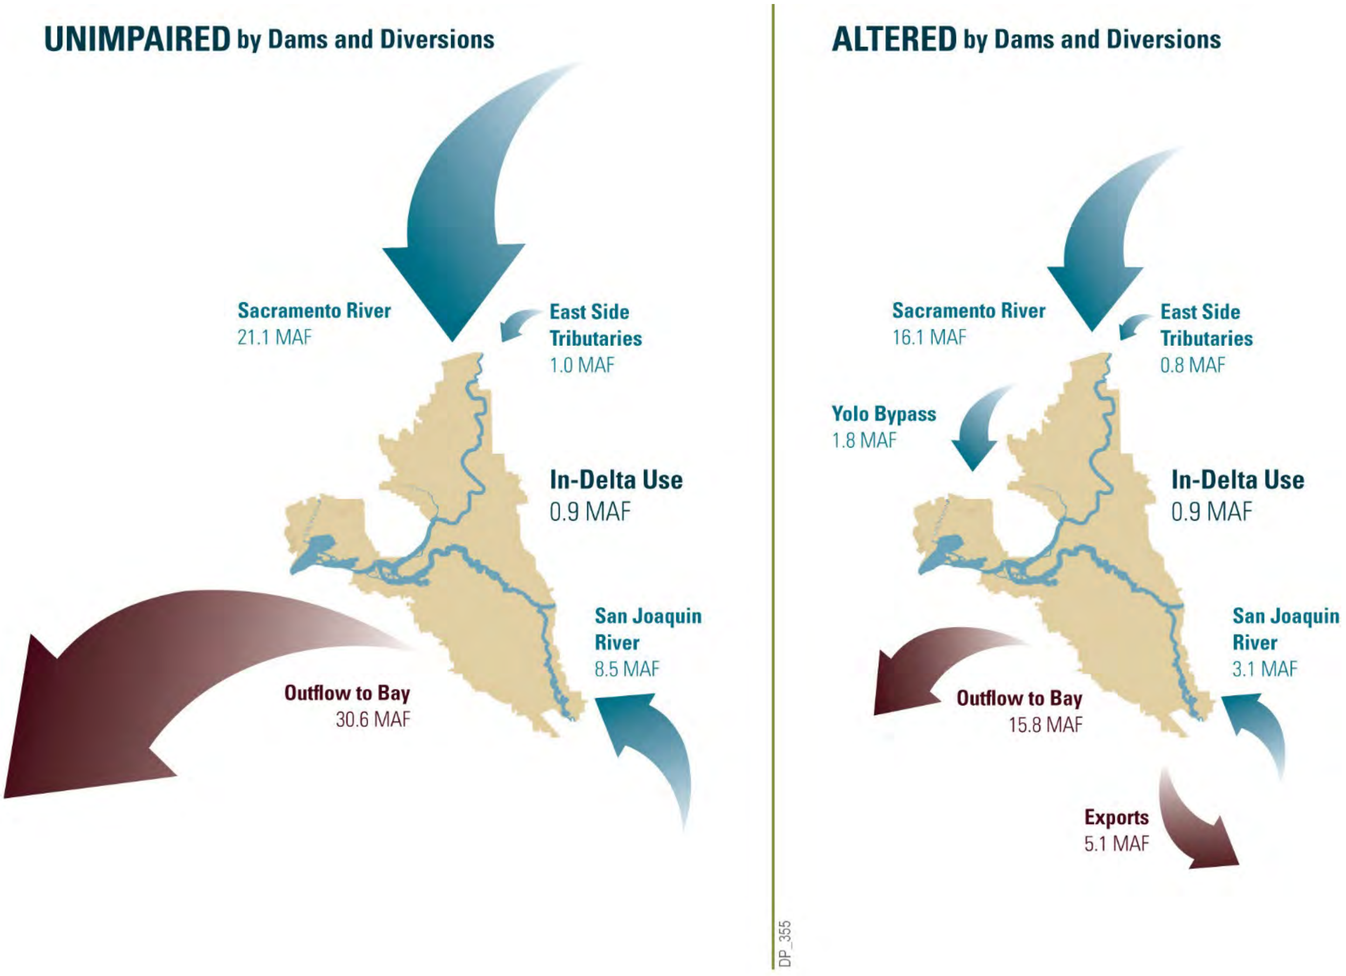
Present-day Delta flows are very different from historical, natural flows. Water flows have been altered by water supply and flood control infrastructure, including dams on the Sacramento and San Joaquin rivers and their tributaries; levees along these rivers and the Delta's channels; and draining of floodplains, wetlands, and groundwater basins (see Figure 4-5). Flows sometimes have not reflected the Fish and Game Code section 5937 requirement that dam owners should allow sufficient water at all times to pass through a fishway, or in the absence of a fishway, to pass over, around, or through the dam, to keep in good condition any fish that may have been planted or that exist below the dam (DFG 2012). Flows are now closely managed by releases from reservoirs to supply water for agricultural and urban uses, control salinity, and reduce floods. In the Delta, flows have also been rerouted through artificial channels. Flow management and modified Delta channel geometry have altered the salinity and sediment regimes in the Delta (Enright and Culberson 2010, Wright and Schoellhamer 2004), managing salinity for human uses rather than for fish and wildlife. Low winter-spring flows disrupt turbidity and salinity cues for migrating fish (Grimaldo et al. 2009), reduce access to spawning and rearing habits in tributaries and floodplains (Sommer et al. 1997, Feyrer 2004, Feyrer et al. 2007), and limit success for young fish trying to follow natural migration patterns (Feyrer and Healy 2003). Current flow management regulations provide some protection for ecological functions and native species, but the current Delta flow regime is generally harmful to many native aquatic species while encouraging nonnative aquatic species (SWRCB 2010).

Effects of Dams and Diversions on Delta Inflows and Outflows



Data presented as a long-term average. Information based on DWR CALSIM II modeling, which includes projected conditions to protect fisheries.

Delta-Suisun in-Delta use includes water to the Contra Costa Canal and to the Mokelumne and Hetch Hetchy aqueducts.

MAF = millions of acre-feet

Figure 4-5

Water flows more closely approximating the timing, frequency, duration, volume, and rate of change of flow produced naturally by a region's climate are best for native aquatic communities (Poff et al. 1997, Bunn and Arthington 2002, Carlisle et al. 2010). Flow is a major environmental input that shapes ecological processes, habitat, and biotic composition in riverine and estuarine ecosystems such as the Delta. Returning to a more naturally variable hydrograph is a key component of ecosystem restoration because the hydrograph works hand-in-hand with habitat restoration to produce diverse and interconnected food webs, refuge options, spawning habitat, and regional food supplies (Carlisle et al. 2010). Flows should provide species benefits and water supply reliability in the context of current hydrological conditions and degraded habitat. In some cases, flows to benefit the ecosystem will deviate from historical "natural" flows, because the channel geometry, land-water connectivity, and infrastructure limits our ability to mimic historical conditions. Flows will also need to be modified as habitat areas are restored. The Delta Plan, therefore, calls for "more natural functional flows" in the Delta as an important aspect of ecosystem restoration. (See sidebar, More Natural Functional Flow, for a description.)

Flow-related stressors can be reduced or mitigated through improved flow management and concurrent reduction of other stressors. Improved flow management comes from better use of current or improved water infrastructure. The challenge in managing flows is to both restore the Delta ecosystem and improve water supply reliability. Flow-related stressors are likely to increase as population grows and the climate changes. Preparation for these changes must start now.

The State Water Resource Control Board's (SWRCB's) Bay-Delta Water Quality Control Plan (Bay-Delta Plan) identifies water quality objectives to protect beneficial uses of the Bay and Delta, and an implementation program including control of salinity (caused by saltwater intrusion, municipal discharges, and agricultural drainage) through water projects operations. This is a contentious issue of public policy, and the Delta Reform Act directed the SWRCB to develop its new flow criteria using the best available science (Water Code section 85086).

The SWRCB is updating the 2006 Bay-Delta Plan with these steps: (1) review and update water quality objectives, including flow objectives, and the program of implementation in the 2006 Bay-Delta Plan, and (2) make any needed changes to water rights and water quality regulation consistent with the program of implementation. Updating the water quality objectives for the Delta, including an update of flow objectives, is important to protect the Delta ecosystem and the reliability of the Delta's water supplies. The sooner these objectives are set, the earlier the ecosystem can be protected and restored, the greater the possibility that a successful Bay Delta Conservation Plan (BDCP) will be approved, the earlier a more reliable water supply can be improved, and, therefore, the earlier the coequal goals can be achieved. That is why the Delta Plan calls upon the SWRCB to complete its work by specified deadlines. A more detailed explanation of the SWRCB's development of water quality objectives, including flow objectives, is included in Chapter 6.

Entrainment Is One Effect of Altered Flows

Entrainment occurs when fish and other aquatic life are drawn into a water diversion intake and are unable to escape. In the Delta, entrainment occurs primarily at the CVP facilities (Tracy Fish Facility and the nearby Delta-Mendota Canal) and the SWP facilities (including Clifton Court Forebay and the Skinner Fish Facility), as well as other smaller Delta intakes.

Much of the time, net channel flows in most of the south Delta are toward the pumps. This increases the probability that small, weak-swimming young smelt or salmon will be entrained. Depending on the type and size of the fish, the closer a fish is to the pumps, the more likely it is to be entrained. Greater reverse flows caused by pumping in the south Delta increase the numbers of fish entrained.

Some of the entrained fish are "salvaged," meaning they are caught in facilities at the pumps and then trucked and released to an area beyond the pumps' influence. The salvage process decreases the mortality of entrained fish (including salmon). Unfortunately, however, many fish, including delta smelt, are not able to survive the collection, handling, transport, and release.

MORE NATURAL FUNCTIONAL FLOW

What is natural Delta flow? Natural Delta flow is the historical (before 1849) pattern of watershed flows that eventually arrived in the Delta. Historical Delta flows resulted from rainfall in the watershed and the pattern of water storage and release from mountain snowpack, forest and valley soil and vegetation, and the natural topography of creeks, rivers, natural levees, and valley floodplains. These landscape patterns have been modified since 1849, and will largely not be returned to their former state.

Why is natural flow important? Native species are adapted (by natural selection) to the seasonal, interannual, and spatial variability of the historical flow pattern and the functions that come with it. Flows interact with land to create physical habitats and connections where species find food, refuge, and reproduction space. Through a variety of mechanisms, native species can survive, grow, and reproduce better when flows occur in more natural historical patterns.

What does natural flow look like? There were no measurements of natural Delta flow before the watershed was modified by gold mining, agriculture, and water storage. In general, natural flows rise in concert with precipitation patterns and fall slowly as the natural water storage capacity of the watershed is released. Natural flows are not simply water volumes but also include the seasonal timing, magnitude, frequency, duration, and rate-of-change in flows. It is often asserted that "unimpaired Delta inflow" is a good approximation of natural flow. For the Delta, unimpaired flow is the inflow that would be expected if reservoirs were removed but contemporary watershed and valley land uses remained. Unimpaired Delta inflow may overestimate the magnitude of natural Delta inflow and abridge the timing of seasonal peaks.

Will more natural flow work to meet ecosystem goals? Not by itself. Natural flows exist only in the context of natural landscape patterns. The pattern of historical natural flow reflected seasonal and interannual interaction with the historical landscape. For example, historical high flows in winter and spring were intercepted and stored by natural floodplains and then released slowly to the Delta through the summer. Much of the ecosystem functional value of natural flows occurs in these seasonal land and water interactions.

We do not have natural landscapes, so now what? Until large-scale restoration is in place, we can meet ecosystem goals in the interim by using the best available scientific understanding of the *functions* that flows provide to native species. For example, winter-run salmon historically survived low summer flows by finding cold-spring creeks in the watershed for spawning. These creeks are now blocked by dams, but cold water can be released from reservoirs to improve spawning habitat farther down. Another example is using Delta outflow to position the low salinity zone ("X2") in Suisun Bay at key times of the year when the salinity, refuge, and food resources there can benefit native fish. More natural flow is therefore understood to emphasize more natural *functions* rather than the shape of the hydrograph. More natural functional flows could include diverting more flow in wet years and less flow in dry years, as described in Chapter 3. With landscape restoration over time, managing water for functional natural flows should be adaptively managed as ecosystem conditions change. The Delta Plan call for "more natural functional flow" suggests that we can adaptively manage the *functions* that flows provide to the life history needs of native species. Therefore, managing for more natural functional flows protects, restores, and enhances the Delta ecosystem.

DP-347

Alteration of water flows also leads to losses of fish from predation. High rates of predation occur at the pumps, and the sloughs and channels near the pumps. Small fish drawn into this part of the Delta have a very low chance of survival. Juvenile salmon drawn into the central Delta through the Delta Cross Channel or Georgiana Slough also have a lower chance of survival than fish staying in the Sacramento River's mainstem. Whether the effects of flow on fish are direct through entrainment or indirect through increased mortality caused by altered flows and predation, the results are the same: fish lost as a result of Delta diversions.

Because of all these factors, managing flows within the Delta is a difficult but important tool for protecting fish. For example, the SWRCB requires reductions in diversions and increases in San Joaquin River inflows during springtime to increase the survival of outmigrating juvenile salmon. The biological opinions for salmon and smelt include measures to reduce entrainment and indirect loss of fish due to altered flows caused by the SWP and CVP diversions. These actions include restrictions on reverse flows in the Old River and Middle River channels in the south Delta and requirements for closing the Delta Cross Channel gates.

Entrainment does not just occur at the Delta pumps. It also can occur at other diversions upstream from the Delta. Larger diversions upstream and in the Delta are screened, but many smaller diversions are not. In-Delta unscreened diversions do not currently appear to entrain substantial numbers of salmon or smelt.

Habitat

Appropriate habitat is required for any organism to survive and reproduce (Hall et al. 1997). Because no two species have exactly the same requirements, habitats are species-specific components of ecosystems.

Expanding habitats for native species is an essential part of restoring the Delta's ecosystem. Recent biological opinions controlling long-term operations of the CVP and SWP require restoration of at least 8,000 acres of intertidal and associated subtidal habitats in the Delta, including Suisun Marsh (USFWS 2008). They also require restoration of 17,000 to 20,000 acres of floodplain rearing habitat for salmon in the Yolo Bypass and lower Sacramento River, including side channels and re-created floodplain terrace areas (NMFS 2009). Some of the tidal marsh acreage may also fulfill requirements for restored floodplains, depending on its location.

Habitat restoration, like water flow, is not just about quantity (or extent), but also about quality, connectivity, and diversity. Land cover types, such as open-water and riparian vegetation, vary greatly and are only one element of habitat (Lindenmayer et al. 2008); an organism's habitat is much more than just land cover. For example, the area of the Delta covered by open water has not changed substantially during the last few decades, but several open-water fish have declined steeply (Sommer et al. 2007, Baxter et al. 2010). This suggests that some of the Delta's open waters have become inhospitable to these certain fish species. The functional habitat available to these open-water fish has shrunk even though the area covered by open water has remained fairly stable. This means that simply changing land cover (for example, increasing riparian habitat) does not automatically increase target species. Other stressors such as poor water quality, predation, or entrainment may make these areas unsuitable.

Habitat loss and fragmentation resulting from human land use causes species loss worldwide (Foley et al. 2005). In estuaries and coastal areas, habitat destruction, coupled with exploitation such as overfishing, are the leading causes of species declines and extinctions (Lotze et al. 2006). Habitat restoration can help recover native species, particularly when other stressors such as altered flows, degraded water quality, or predation by introduced species are also reduced (Carlisle et al. 2010, Lotze et al. 2006).

Taking a large view of an ecosystem, habitats are species-specific "patches" in spatially varied landscapes. The survival and success of organisms is closely associated with the total amount of usable habitat, as well as with habitat patch sizes, shapes, and arrangements (Hannon and Schmiegelow 2002). Habitats that are too small, fragmented, or isolated may not provide long-term support for specific organisms. In general, more, larger, and better-connected patches of a specific habitat create the conditions for persistence or recovery of the species associated with that habitat (Lindenmayer et al. 2008). (See sidebar, Landscape Ecology: A Fundamental Tool for Restoration Planning.)

Much of the original habitat for the Delta's native fish, wildlife, and plants has been urbanized or converted to agriculture over the past 160 years (Healey et al. 2008, Moyle et al. 2010, Baxter et al. 2010). This habitat loss is one of the largest legacy stressors to the Delta ecosystem. The current Delta ecosystem continues to be productive, but its habitat types and conditions support a much different mix of species than the historical Delta. Many of the thriving species are nonnative, such as largemouth bass and the Brazilian water weed *Egeria densa*. Some consider a few nonnative species, such as bass prized by anglers, to be desirable. But too many nonnative plants and animals can upset an ecosystem's balance, creating conditions unsuitable for native aquatic and terrestrial species (Sommer et al. 2007, Healey et al. 2008, Baxter et al. 2010). This conflict and the inadequate habitat for native species that reside in and migrate through the Delta is an important current ecosystem stressor that must be addressed.

LANDSCAPE ECOLOGY: A FUNDAMENTAL TOOL FOR RESTORATION PLANNING

Landscape ecology examines the influence of spatial patterns on ecological processes (Wiens 2002) and considers the ways that species use the landscape for finding food and refuge, and for adapting to change (Simenstad et al. 2000, Lindenmayer et al. 2008). The mosaic of landscape features—or "patches"—and the connections between patches affect species' locations, food and cover, the energy required to obtain those resources, and, ultimately, survival. The landscape perspective considers connections and exchanges between uplands; riversides and wetland edges; and the sloughs, channels, and bays that make up estuarine aquatic habitats. The food webs of these adjacent systems exchange organisms and energy that, in turn, can increase the productivity of each (Cloern 2007). Native estuarine species—terrestrial, semiaquatic, and aquatic—are adapted to the rhythms of the landscape's mosaic of connected habitats and its dynamic processes.

From a landscape perspective, "form begets function." Therefore, correct spatial structure and patterns are prerequisites for restoring and maintaining desired ecosystem processes and functions, and for providing appropriate habitat for native species. In the long term, restoring spatial patterns at ecologically appropriate scales can promote the "self-repair" of ecosystem processes and functions (Teal et al. 2009) and increase resilience to stressors. Consequently, this approach could reduce the operating and maintenance costs of restoration in an era of limited resources. Planning for ecosystem restoration should always consider appropriately large spatial scales (regional or larger), but restoration actions can proceed at smaller scales to optimize the benefits that can be achieved with the often limited opportunities and resources available for restoration (Hermoso et al. 2012).

Additionally, landscape ecology considers people's role in shaping landscape patterns and processes (Turner 1989). Restored landscapes often have agricultural and urban neighbors. Each land use affects the other because they are connected by air, land, and water. Yet humans often want conflicting things (nature areas nearby with abundant wildlife, but also with convenient recreation facilities, no mosquitoes, and no impacts on adjoining farms). A functioning ecosystem depends on many things, including understanding and dealing with its relationship to human activities. The current regulatory and political framework for restoration projects often puts short-term benefits, such as low acquisition cost or immediacy of land availability, before long-term benefits of connectivity and appropriateness of scale. Landscape ecology provides a set of tools for assessing and prioritizing limited restoration opportunities. For example, using the principles of landscape ecology, decisions about land acquisitions for restoration must address how small parcels that become available for restoration might be connected and combined to maximize ecological benefits over the long term.

DP-313

The Importance of Land Elevation in Habitat Restoration

Opportunities for habitat restoration in the Delta are constrained first and foremost by the elevation of land, which determines the potential of an area to be restored. As described in Chapter 5, much of the Delta has subsided too deeply to restore its original ecological functions (see Figure 4-6).

Deeply subsided Delta lands can provide terrestrial and wetland habitat for native species only at great cost and with intensive management. They offer few opportunities to recover native ecosystem forms and functions. However, deeply subsided islands could include seasonal wetlands for waterfowl and wildlife-friendly agriculture. Actions that promote carbon sequestration, subsidence reversal, and improved migratory bird habitat are especially valuable.

The most promising restoration opportunities are found in the less-subsided flood basins, river corridors, and brackish tidal marshes on the Delta's perimeter, leading the Council to recommended six priority habitat restoration areas:

- **Yolo Bypass, from the Fremont Weir south toward the Delta.** Winter and spring flooding of the Yolo Bypass provides substantial benefits for spawning and rearing of Sacramento splittail and rearing of salmon (Sommer et al. 2001, Moyle et al. 2007). Projects in the planning stage include fish passage improvements and various approaches, such as notching the Fremont Weir to increase the frequency and duration of inundation during times of the year critical for spawning and rearing of native fish. Restoration of the Yolo Bypass can create conditions that promote enhanced growth and survival of juvenile spring- and winter-run salmon, among other species, and can benefit other migrating salmon.

Habitat Types Based on Elevation, Shown with Developed Areas in the Delta and Suisun Marsh

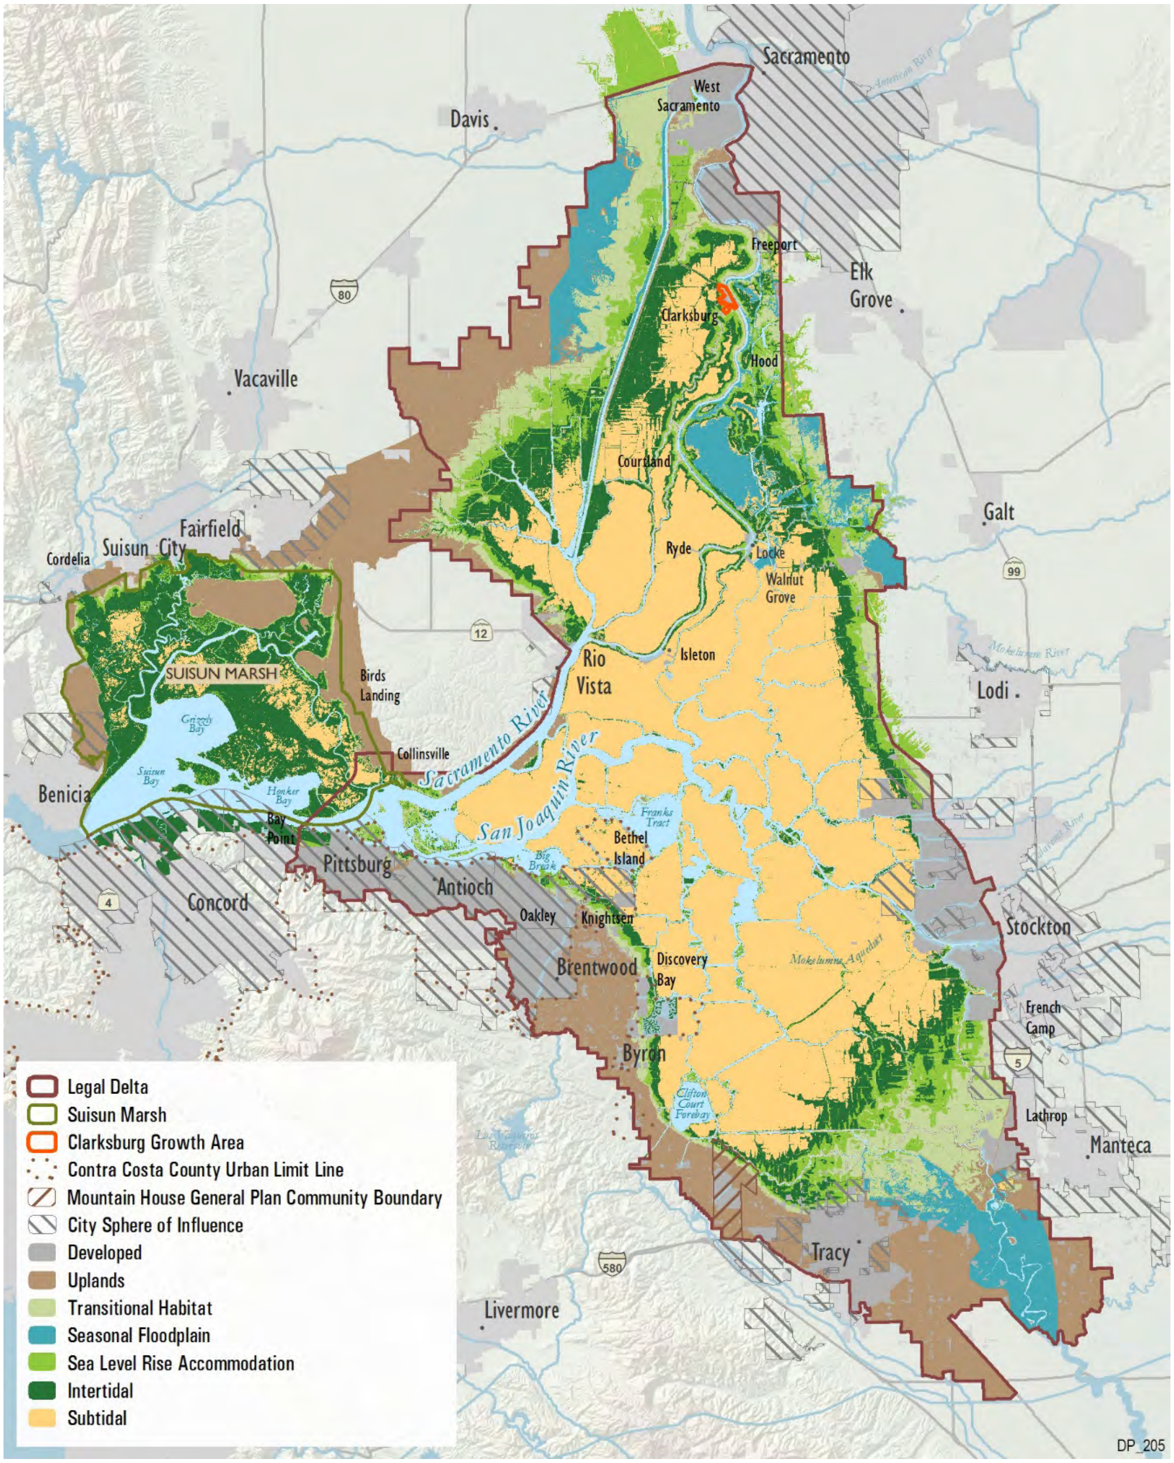


Figure 4-6

Source: Adapted from DFG 2011

- **Cache Slough Complex, southwest of the Yolo Bypass.** The flood basins entering the Cache Slough Complex are at the interface between river and tidally influenced portions of the Delta. A restoration project in this area is Liberty Island, which is being allowed to passively restore to marsh after floods breached the island's levees in 1997. Projects in the planning stage include California Department of Water Resource's (DWR's) Prospect Island restoration project. Habitat restoration at Cache Slough can create conditions that help recover delta smelt and that benefit migrating salmon. See the sidebar, Applying Adaptive Management to Ecosystem Restoration, for a hypothetical example implementing principles of adaptive management in projects such as these.
- **Cosumnes River–Mokelumne River confluence.** An existing restoration project is the Cosumnes River Preserve floodplain. Projects in the planning stage include DWR's North Delta Flood Control and Ecosystem Restoration Project on McCormack-Williamson Tract. Restoration here can benefit migrating salmon and contribute to the Delta's food webs.
- **Lower San Joaquin River floodplain between Stockton and Manteca.** Historically, the south Delta and its connection to the lower San Joaquin River contained a complex network of channels with low natural berms, large woody debris, willows, and other shrubs with upland areas supporting open oak woodlands. Projects in the planning stage include the Lower San Joaquin Flood Bypass proposed by the South Delta Levee Protection and Channel Maintenance Authority and its partners. Restoration to a mix of tidal marsh, riparian habitats, and wildlife-friendly agriculture could create conditions to recover riparian brush rabbits and Swainson's hawks, benefit migrating salmon, and serve to reduce the risks from flooding for urban areas.
- **Suisun Marsh.** This is the largest wetland area on the West Coast of the contiguous United States. Suisun Marsh is mostly managed for waterfowl, with levees that disconnect its wetlands from the estuary. An ongoing restoration project is DWR's Blacklock Restoration Project. Projects in the planning stage include California Department of Fish and Wildlife's (DFW's) Hill Slough Restoration Project. Restoration of tidal marsh and associated habitats here can create conditions that contribute to food webs in Suisun and Honker bays, and aid the recovery of longfin smelt and spring- and winter-run salmon.

  Unique local benefited species would also include Suisun song sparrows, saltmarsh harvest mice, and plants such as soft bird's-beak and Suisun thistle. Enhanced management of wetlands can reduce impacts on water quality while still maintaining or improving habitat for waterfowl of other wildlife.
- **Western Delta/Eastern Contra Costa County.** Some islands and tracts at appropriate elevations may be desirable sites for restoration of tidal marsh and channel margins to support food webs and provide habitat for native species. Decker Island is a recent restoration project in this area, and restoration at Dutch Slough is planned. Additional restoration of other islands or tracts may be considered in the BDCP or in local Natural Community Conservation Plans/Habitat Conservation Plans.

These six regions have been highly altered by more than a century of human use and exposure to multiple stressors. Returning a portion of these altered regions to habitat for native species requires a careful assessment of opportunities and challenges. Recommendations provided later in this chapter include actions to prevent or mitigate adverse impacts on opportunities for habitat restoration in these priority restoration areas.

Applying Adaptive Management To Ecosystem Restoration

An adaptive management approach to ecosystem restoration should be used to plan for and assess the ecological outcomes of the restoration action. The following is a hypothetical example of how the Council's three-phase and nine-step adaptive management frame-work (see Appendix C) could be applied to an ecosystem restoration project in the Cache Slough Complex.

Adaptive Management Step			Hypothetical Cache Slough Ecosystem Restoration Project
Plan	1	Define/redefine the problem	The Cache Slough Complex includes high biodiversity; however, ecological processes and habitat that benefit native species in the Cache Slough Complex are degraded.
	2	Establish goals, objectives, and performance measures	**Goal:** Re-establish natural ecological processes and habitats to benefit native species in the Cache Slough Complex. **Objective:** Re-establish the hydrologic, geomorphic, and ecological processes necessary for the long-term sustainability of native habitats, and the plant and animal communities that depend upon them. Improve floodplain connectivity and aquatic habitat quality for native estuarine species, including delta smelt, longfin smelt, Sacramento splittail, and Chinook salmon, by offering a suite of natural habitats and improving the food web fish require.
	3	Model linkages between objectives and proposed action(s)	The Cache Slough Complex provides high potential for restoration success because of its physical and biological attributes (such as tidal range, elevation, high amounts of suspended sediment, abundant zooplankton, and observed use by delta smelt). It is hypothesized that improved vernal pool and grassland habitats along with broad nontidal, freshwater, emergent-plant-dominated wetlands that grade into tidal freshwater wetland, shallow subtidal, and deep open-water habitat will increase the amount and quality of food for native species in the estuary. It is hypothesized that restoring tidal channel, wetland, and upland networks will improve conditions for native fishes. It is hypothesized that increases in the quality and quantity of food for native species will lead to increases in native species populations in the estuary. Native species expected to benefit from this restoration include delta smelt, juvenile Chinook salmon, Sacramento splittail, and longfin smelt.
	4	Select action(s) (research, pilot, or full-scale) and develop performance measures	Pilot-scale restoration project in the Cache Slough Complex: restore a subset of the processes supporting the creation of tidal channel, wetland, and upland networks to support native fishes. Performance measures: ▪ Administrative – Properties are identified for the pilot study. Funding sources and budgets for the project and monitoring are in place. Properties are acquired. Restoration planning and design is completed. Environmental compliance permits are obtained. Restoration contractors are selected. ▪ Output – Pilot-scale Delta habitat restoration project is implemented. Progress toward restoring diverse and interconnected habitats for native resident and migratory species in the Cache Slough Complex. ▪ Outcome – Progress toward achieving viable populations of native resident and migratory species. Trends in native Delta species are upward over the next decade.
Do	5	Design and implement action(s)	Design and implement the pilot-study restoration project.
	6	Design and implement monitoring plan	Design and implement the monitoring plan, including baseline monitoring of food abundance for pelagic organisms. Monitor the extent and quality of targeted habitats, connectivity of habitats, and abundance and diversity of species.
Evaluate and Respond	7	Analyze, synthesize, and evaluate	Analyze, synthesize, and evaluate the status and trends of changes in habitats, connectivity of habitats, abundance, and species health and diversity.
	8	Communicate current understanding	Provide project manager(s) and decision makers with annual reports of synthesized information learned. For example, provide a score card of the status and trends of species abundance and diversity, habitat connectivity, and so on.
	9	Adapt	The managers and implementers of the restoration project reconsider their understanding of the problem statement and conceptual model, and decide whether or not to expand from a pilot-study project to a larger-scale restoration effort.

DP-332

Migratory Corridors for Native Species

Habitat restoration often targets resident species that use the restored habitat year-round. Successful restoration, however, must also consider species that only periodically use particular habitat patches and corridors. The historical Delta provided migration corridors and rearing habitat for many migratory bird and fish species, including the threatened greater sandhill crane, many species of ducks and geese, salmon, sturgeon, and the introduced striped bass.

In the past, the Delta was a migration route and also an important nursery area for young salmon (or "smolts"). Much of the Delta today presents real risks to migrating salmon; it is no longer a suitable nursery for salmon smolts (Williams 2006). Some Delta channels do provide a greater chance of fish survival than others. For example, salmon leaving the Sacramento River and entering the interior Delta through the Delta Cross Channel have significantly lower survival than fish that stay in the river (Newman 2008), demonstrating that the central Delta has become a gauntlet of risk instead of a viable migratory corridor.

Entrainment at the CVP and SWP southern Delta pumps and increased predation kill salmon smolts. Toxic contaminants and periods of low dissolved oxygen can be harmful. Important factors for route selection and survival of salmon smolts on their way to the ocean include differences in flows through different channels, feeding opportunities, growth rates, and vulnerability to predation (Perry et al. 2009).

On their way back from the ocean to spawn, adult salmon must navigate a maze of Delta waterways where water from many different sources is mixed in artificially connected channels, and where rivers sometimes flow backward (reverse net flows in Old and Middle rivers; see the Delta Flows section) (Monsen et al. 2007). A unique problem is presented by the San Joaquin River, whose polluted and reduced flows are often drawn to the SWP and CVP pumps as a result of reverse flows. During these times, almost no water from the San Joaquin River reaches the confluence with the Sacramento River. Instead, water from the Sacramento River and its tributaries fills most of the Delta, obscuring and confusing the chemical and flow cues that salmon and other migratory fish depend on to find their destinations.

In addition to altered water flow and chemical disruption, migratory fish encounter dams, reservoirs, and other physical barriers that hinder their historical migration. The most formidable barriers are upstream on the Sacramento and San Joaquin rivers and their tributaries, especially the many large and small dams associated with reservoirs, including Shasta, Folsom, and Millerton lakes and Lake Oroville. In the Central Valley, less than one-fifth of the historical spawning habitat is still accessible to Chinook salmon and steelhead (Reynolds et al. 1993, Yoshiyama et al. 1996).

Physical barriers in the Delta help maintain water supplies for agriculture but interrupt fish migration; structures with ledges and drops, such as bridge pilings, boat docks, narrow channels with riprapped edges, or the intakes of the SWP and CVP pumps, create attractive spots for predatory fish to feed on migrating species. The Delta Cross Channel is an example. Sometimes, a barrier can have positive effects. Federal, State, and local officials have recently tested novel bio-acoustic fish fences (BAFFs) at Old River and Georgiana Slough that use light, sound, and air bubbles to steer migrating fish into channels that are thought to provide better habitat and a greater chance of survival.

Some high-quality migratory fish rearing and migration habitat remains at the margins of the Delta, if not in its core. The Yolo Bypass and Cosumnes River floodplains provide good migratory and rearing habitat for salmon, and important habitat for other native fish, birds, and bats. DFW manages the Vic Fazio Yolo Wildlife Area, a 16,000-acre public-private restoration project in the Yolo Bypass, to promote waterfowl and other bird populations. The 46,000-acre Cosumnes River Preserve is jointly owned and operated by The Nature Conservancy, Ducks Unlimited, the Bureau of Land

Management, DFW, DWR, Sacramento County, and private owners to create, enhance, and protect a variety of habitats. These are good illustrations of ecosystem and flood risk reduction projects working together. Wildlife-friendly agriculture also occurs in these floodplain preserve areas and their surroundings. During winter and early spring floods, these floodplains provide plentiful food for migrating salmon and native fish such as splittail, prickly sculpin, and Sacramento sucker (Sommer et al. 2001, Crain et al. 2004). Salmon migrating through these floodplains grow faster and have greater survival. (See sidebar, Better Habitat Equals Greater Growth.) Native fish do particularly well when flows through these floodplains follow more natural patterns. Early February through April, strong flood flows with cool water temperatures benefit many young native fish. Nonnative fish benefit more from later and lower flows with higher temperatures. Floodplain restoration should thus focus on early flooding followed by careful draining. This provides important migration and nursery habitat for native species while keeping nonnative species, including predators, at bay.

BETTER HABITAT EQUALS GREATER GROWTH

This comparison illustrates faster growth in floodplain habitat compared to river habitat. Salmon on the left were reared within Cosumnes River channel habitat, and the salmon on the right were reared within Cosumnes River floodplain habitat. All salmon shown are the same age.

DP-162

Actions above and below the Delta also complement actions in the Delta to restore migratory corridors for fish and wildlife. The Bureau of Reclamation, U.S. Fish and Wildlife Service, and DFW have modified Shasta Dam to release colder water for salmon and trout, removed barriers to fish migration such as the Red Bluff Diversion Dam, screened water diversions to reduce entrainment, restored riparian habitats at the Sacramento River National Wildlife Refuge (NWR) and San Joaquin River NWR, and improved habitats in Sacramento and San Joaquin river tributaries where salmon spawn. Efforts to restore flows in the San Joaquin River also can rebuild these migratory corridors.

For example, on Battle Creek, actions to remove multiple dams and fish ladders are being implemented through the Battle Creek Salmon and Steelhead Restoration Project. The primary objective of the restoration project is to restore the ecological processes that would allow the recovery of steelhead and Chinook salmon populations in Battle Creek while minimizing the loss of clean and renewable hydroelectric power through modifications to the hydroelectric project. This project is among the largest coldwater anadromous fish restoration efforts in North America and will restore approximately 42 miles of habitat in Battle Creek and an additional 6 miles of habitat in its tributaries. It will also help restore critically imperiled winter- and spring-run Chinook salmon and Central Valley steelhead. Additional restoration actions are planned for other Sacramento River tributaries including Clear Creek, Deer Creek, and Mill Creek.

On the mainstem of the San Joaquin River between Friant Dam and its confluence with the Merced River, the San Joaquin Settlement Agreement will increase flows, expand channel capacity, and remove barriers to migration to restore spring-run Chinook salmon runs. This long-term action is expected to occur in stages over 20 years. On the Tuolumne River, the largest tributary of the San Joaquin River, the Central Valley Project Improvement Act (CVPIA)

Restoration Plan actions focus on restoring spawning, rearing, and floodplain habitat. The Bobcat Flat Restoration Project includes excavation of 48,500 cubic yards of gravel and coarse material that will be used to restore 1.6 miles of fall-run Chinook salmon and Central Valley steelhead spawning and rearing habitat. Similar habitat restoration projects have been implemented or are planned on other tributaries of the San Joaquin River and the Delta, including the Merced, Stanislaus, Calaveras, and Mokelumne rivers. However, 16 years after the creation of the CVPIA restoration fund, a panel of independent scientists issued a report on the CVPIA Fisheries Program (Reclamation and USFWS 2008) concluding that more could be done to effectively address the most serious impediments to survival and recovery of salmonids.

Wetlands bordering San Pablo Bay downstream of the Delta are home to a host of native and nonnative fish, waterfowl, shorebirds, other wildlife, and endangered plants and important stopping points on the Pacific Flyway. Uncommon species found in and around San Pablo Bay wetlands include longfin smelt, delta smelt, salt marsh harvest mouse, California clapper rail, San Pablo song sparrow, and black rail. All Central Valley anadromous fish migrate through the bay and depend on its open water and marshes for some critical part of their life cycle. The bay and its adjacent marshes are also important nursery grounds for many marine, estuarine, and anadromous fish. More than 40,000 acres of diked baylands and wetlands bordering the San Pablo Bay have been protected and are being restored.

In the Sacramento and San Joaquin valleys, actions to protect, restore, and enhance wetlands carried out by the Central Valley Joint Venture have significantly increased wildlife habitat resources for migratory waterfowl, shorebirds, waterbirds, and riparian songbirds in accordance with conservation actions identified in the Joint Venture's Implementation Plan. The Joint Venture establishes population objectives for these migratory birds then determines the appropriate amount of food, habitat, and water supply necessary to meet the objectives. Wetland restoration becomes a priority when habitat and forage needs for population objectives are not being met.

Successful recovery of native species requires effective habitat restoration. In addition to restoring physical habitat and corridors for movement, reducing other stressors is important too. Together, they help in achieving the coequal goal of a healthier Delta ecosystem.

Riparian and Shaded Riverine Aquatic Habitat

Fish and birds migrating through the Delta need abundant floodplains and appropriate water flows; but they also need streamside trees and shrubs that shade and cool the rivers; undercut riverbanks where smolts and other small fish rest and hide; and trees that drop insects and leaves that contribute to the food web and provide cover, food, and nest sites for songbirds and other wildlife. Unfortunately, along most of the Sacramento and San Joaquin rivers, levees are near the water's edge, not set back from rivers, leaving little room for these habitat features, which often are provided only by trees growing immediately adjacent to or even on the levees themselves.

Because of the importance of these streamsides, water supply or flood risk policies and projects that affect the Delta's rivers and other channels should consider the impact on remaining riparian and shaded riverine habitat. Setting back levees can create additional area for habitat and increased capacity for flood flows. Setting back levees, however, can be expensive and difficult. At the same time, there is considerable controversy over the current policy of the U.S. Army Corps of Engineers (USACE) to require removal of trees and most shrubs from levees under their jurisdiction. A technical manual issued by the Federal Emergency Management Agency (FEMA) for earthen dams has been relied upon heavily to support this vegetation removal policy (FEMA 2005). There is little riverine habitat left. If implemented as proposed, the USACE's order would destroy much of what remains. The Delta Plan calls for the

USACE to reconsider and change its policy in order to protect riverine habitat.

Safe Harbor Agreements

Voluntary safe harbor agreements between wildlife agencies and landowners can contribute to the recovery of species protected by the State or federal Endangered Species Acts. These agreements assure the landowners that the presence of endangered species on their property will not result in restrictions on other activities undertaken on their land. Facilitating and creating standard rules for these agreements with Delta landowners may encourage more landowners to participate in conservation programs.

Suisun Marsh and the Bay Conservation and Development Commission

The Suisun Marsh is one of the Delta Plan's priority habitat restoration areas. It is one of the largest contiguous estuarine wetlands in North America; an important nursery for fish; a wintering and nesting area for waterfowl and waterbirds; and an essential habitat for plants, fish, and wildlife, including several scarce and sensitive species. Suisun Marsh offers unique restoration opportunities because of its position in the Delta ecosystem and the diversity of physical processes it hosts. Suisun Marsh harbors a greater percentage of native fish than the remainder of the Delta, in part because its brackish water limits nonnative species. Additionally, the marsh has many diverse tidal sloughs that provide options for food and refuge (Moyle et al., 2010).

Unlike the deeply subsided Delta, much of the Suisun Marsh is still at elevations suitable for restoration of intertidal habitat, including tidal marsh and shallow water habitat. This area provides the brackish portion of the estuary with the potential to support productive and complex food webs, and with space to adapt to sea level rise. State and local land use policies should reflect the unique role that Suisun Marsh can play.

The San Francisco Bay Conservation and Development Commission (BCDC) is responsible for protecting San Francisco Bay and its shoreline, including Suisun Marsh, through the San Francisco Bay Plan, as described in Chapter 5. It is developing regional strategies to address the impacts of sea level rise and climate change on the Bay. BCDC provides special protection of the Suisun Marsh under the Suisun Marsh Preservation Act through the Suisun Marsh Protection Plan (SMPP). BCDC recently amended the San Francisco Bay Plan to address climate change and sea level rise. The climate change policy, among other things, incorporates sea level rise projection ranges consistent with those developed by the California Ocean Protection Council (2011) and calls for development of a long-term regional strategy to address sea level rise and storm activity. The SMPP and the Suisun Marsh Local Protection Program should also be amended to address climate change and rising sea level.

Ecosystem Water Quality

Chapter 6 deals with water quality issues and contains many recommendations for action. Impaired water quality makes it much harder to restore a healthy Delta ecosystem. Recommendations in Chapter 6 regarding salinity and environmental water quality cover key linkages between ecosystem restoration and water quality.

Consistently good water quality is crucial for successful restoration of aquatic habitats, sustenance of native plants and animals, and other beneficial uses of Delta water. Salinity should be more consistent, with a naturally variable estuarine hydrograph with high-quality river inflows. Nutrient composition and concentrations should not cause excessive growth of nuisance aquatic plants or blooms of harmful algae, and should support diverse and productive aquatic food webs. Dissolved oxygen levels, water temperatures, turbidity, and other attributes should meet the needs of native species. At all times the Delta should be free of substances that exceed toxic concentrations. Discharge of treated wastewater, urban runoff, or agricultural return flows should not adversely affect the Delta.

Chapter 6 focuses on four key areas where the best available science shows the need to protect and improve water quality to achieve the coequal goals (see Chapter 6 for a complete discussion):

- Requiring Delta-specific water quality protection
- Protecting beneficial uses by managing salinity
- Improving drinking water quality
- Improving environmental water quality

Nonnative Species

Among the world's estuaries, the Delta and San Francisco Bay are among the most invaded by nonnative species (Cohen and Carlton 1998). Some nonnative species have been in the Delta for more than a century and seem to be a permanent feature of the Delta ecosystem. Because it is nearly impossible to eradicate nonnative species once they are established, many can be considered legacy stressors that can be managed but not eliminated.

However, the introduction of any new nonnative species has consequences, particularly for native species. Nonnatives can take over habitat space, compete for food and nutrients, alter food webs, modify the physical habitat structure, or prey upon native species (DFG 2011). In wetlands and riparian areas, nonnative vegetation often crowds out native plants and reduces diversity used by resident and migrating birds and other animals (PRBO CalPIF 2008). The result is that nonnative plants, invertebrates, and fish may replace native species, and that change on their native counterparts is often combined with the other stressors such as altered flow, impaired habitat, and poor water quality.

Significant nonnative species in the Delta include (DFG 2008):

- **Overbite clam.** The overbite clam, a bottom-dwelling filter feeder, entered the Delta in the late 1980s and adapted well to its brackish areas. Overbite clams contribute to the reduction of algae and some invertebrates in the Delta, especially in Suisun Bay (Kimmerer 2006), causing loss at the base of the food web, which contributes to the decline of delta smelt and other open-water fish (Sommer et al. 2007).
- **Asian clam.** The Asian clam was first found in the Delta in 1946 (USGS 2001). This clam does not tolerate saline water, but is abundant in freshwater parts of the Delta and in the mainstems of the Sacramento and San Joaquin rivers. Ecologically, this species can alter channel bottoms and competes with native freshwater mussels for food and space (Claudi and Leach 2000). Overbite and Asian clams cannot be effectively controlled, according to many experts (Healey et al. 2008), but they may be managed by manipulating environmental conditions such as flow or salinity to seasonally control their distribution.
- **Zooplankton.** Surveys of Delta waters reveal that introduced zooplankton, probably discharged in ocean ship ballast water in the San Francisco Bay and Delta, have almost completely replaced the original native zooplankton (Winder and Jassby 2011). The success of nonnative zooplankton species was accompanied by an overall decline in zooplankton biomass and size that suggests a decrease in their nutritional value for fish (Winder and Jassby 2011).
- **Nonnative invasive aquatic plants.** The floating water hyacinth, imported as a landscaping plant, proliferated in the Delta in the early 1980s. The Brazilian waterweed was introduced in the 1960s, probably from home aquariums, but did not reach nuisance levels until after the 1987-1992 drought (Jassby and Cloern 2000). These and other nonnative aquatic weeds in the Delta, including water pennywort, Eurasian water milfoil, and parrot feather, pose serious problems to native plants and animals, and hinder boating. The weeds flourish in a wide area where they act as powerful "ecosystem engineers" (Jones et al. 1994, Breitburg et al. 2010) through alteration of habitats, sometimes creating dense mats or thickets that displace native plants, reduce the food web

productivity, reduce turbidity, and interfere with water conveyance and flood control facilities. These invasive plants benefit nonnative predatory fish like largemouth bass. Areas of dense, submerged aquatic vegetation (SAV) may reduce the abundance of native fish larvae and adults (Grimaldo et al. 2004, Nobriga et al. 2005, Brown and Michniuk 2007). Restoration of aquatic habitats must be designed and managed to reduce nonnative SAV if conservation goals are to be met (Nobriga and Feyrer 2007).

- **Bass and sunfish.** Several species of nonnative fish have been introduced in the Delta. Largemouth and smallmouth bass, sunfish including bluegills and warmouth, crappies, and other fish in the centrarchid family are the best examples. They prey on salmon smolts, smelt, and other native fish. The increase in SAV, especially in and around "flooded islands" in the central Delta, enhances bass and bluegill populations (Brown and Michniuk 2007) and possibly populations of other nonnative predators (Grimaldo et al. 2009). Centrarchids harm native fish through predation and competition (Nobriga and Feyrer 2007, Brown and Michniuk 2007). The distribution of centrarchids may be modified by managing conditions such as water velocity, nutrients, salinity, and turbidity to reduce SAV.

The invasion of nonnative species is in the category of globally determined stressors because these species' arrival in the Delta is the result of large-scale natural processes and human activities that are beyond the purview of the Delta Plan. Nonnative species have persisted because they found favorable environments in which to live. Native species are adapted to the varied, complex floodplains, marshes, and other habitats of the historical Delta, with its tidal currents and river flows that constantly change physical, chemical, and biological conditions. In contrast, the stabilized flow pattern, altered habitats, and impaired water quality of the modern Delta often favor nonnative species. Reducing the impacts of nonnative species in the Delta will require addressing flow alterations, pollution (especially nutrients), and physical habitat characteristics.

Future invasions by zebra and quagga mussels are likely and will require considerable preparation, followed by interagency coordination and action. These mussels are an example of an "anticipated stressor" under the Delta ISB's classification of stressor types. Neither has been observed in the Delta yet, but they have proven to be highly invasive when conditions are right. They pose threats comparable to threats from the overbite and Asian clams. They can colonize hard and soft surfaces, often in large densities (greater than 2,800 individuals per square foot) that impede the flow of water through canals and pipes. These mussels also remove particulates in the water, unnaturally enhancing water clarity.

Once introduced, nonnative species are difficult and expensive to control, and often impossible to eradicate. The California Department of Boating and Waterways supports programs to control Brazilian waterweed and water hyacinths where they hinder boating, but only where conditions create the worst nuisances. The best way to prevent new infestations is to avoid the introduction of new species. Improvements in managing ballast water by shipping companies have been instituted recently, but likely more needs to be done.

There is no agreement about the value—or lack of value—of nonnative species. Opinions vary depending on the species and the interest of Delta users. Striped bass are nonnative but prized for their sport and economic value. Introduced to the Delta in the nineteenth century, they prey on native open-water fish such as delta smelt, longfin smelt, and juvenile salmon and steelhead. Striped bass are at the center of an ongoing debate about whether fishing regulations for introduced species should conserve the fish or should be less restrictive to reduce their abundance (DFG 2011).

The draft Ecosystem Restoration Program (ERP) Conservation Strategy acknowledges that many nonnative species will likely remain in the Delta, and emphasizes prevention and adaptation strategies such as public education, preventing establishment of additional nonnative species, and reducing the impacts of established nonnative species. DFW issued its *California Aquatic Invasive Species Management Plan* in 2008, which aims to coordinate the various State efforts to minimize harmful ecological, economic, and human health impacts from aquatic invasive species (DFG 2008).

Hatcheries and Harvest Management

In the Delta, people have harvested fish and shellfish for millennia. Today, fishing, crabbing, crawdadding, and clamming are important recreation activities. Central Valley salmon—most raised in hatcheries—migrate through the Delta and support an economically and culturally important coastal fishery. In the Delta and its tributary rivers, recreational fishing for salmon, sturgeon, striped bass, largemouth bass, shad, and other fish attracts anglers from throughout California and the world. Fishing in the Delta is a centerpiece of the unique cultural, recreational, and natural heritage that makes the Delta a special place (see Chapter 5).

The use of hatcheries to breed fish and regulations to limit overfishing have long been important tools for aquatic resource management. But they carry their own risk. Hatcheries can allow interbreeding, weakening the genetic fitness of a fish species (Israel et al. 2011). Harvest of hatchery-enhanced fish stocks can pose additional risks to native species. Overfishing itself reduces genetic diversity. Fishing regulations generally protect fish from overharvest, but regulations can also help or hurt other fish species. For example, DFW recently proposed changes to striped bass sport fishing regulations to allow greater harvest of striped bass in the hopes of reducing bass predation on native fish, especially salmon. These changes were rejected by the Fish and Game Commission, but it is likely other regulations will be recommended, particularly as the emphasis on saving native fish from nonnative invasives continues. Future proposals should be based on an improved understanding of anglers' behavior as well as a better understanding of the likely response in populations of striped bass and other predators. Harvest regulations and management practices must consider broader effects on nontarget species, including other predators, and the ecosystem.

Striped bass, for example, are not the only animals that prey on salmon. Predators are natural parts of any ecosystem, and predation is a basic ecosystem process. Fish predators in the Delta include many water birds, mammals, and fish such as native pikeminnows and introduced largemouth bass, smallmouth bass, striped bass, catfish, and other species. Nonnative fish consume salmon and other species of concern in the Delta and its tributaries (Lindley and Mohr 2003). Acoustic tagging studies in the San Joaquin River and southern Delta suggest significant predation on hatchery-reared salmon smolts. Survival of tagged salmon smolts released in the lower San Joaquin River was estimated to be only 5 percent in 2010, with much of the loss attributed to predation (San Joaquin River Group Authority 2010). However, despite the evidence of locally high predation, the overall contribution of predation to the decline of salmon, steelhead, and smelt populations is not clear, and the effect of predator controls will remain uncertain without additional study.

Hatchery Management

Another important tool for harvest management is raising fish in hatcheries, later to be released into natural waterways.

In California, hatcheries are particularly important to compensate for dams that block migration routes for salmon and steelhead (see previous Ecosystem Restoration section). The first salmon hatchery in the state was on the McCloud River. Today, California hosts two federal and twenty-one State hatcheries for salmon, steelhead, or trout. In recent years, "conservation hatcheries" for various threatened and endangered species were considered to prevent extinction of a species while restoration and stressor reduction activities are under way.

Hatcheries are important tools, but they involve genetic and ecological risks:

- **Genetic risks.** Human intervention in the rearing of wild animals has the potential to cause genetic change in fish such as salmon (Israel et al. 2011). These changes can impact fish diversity and the health of fish populations. Inbreeding in a fish hatchery can occur when a limited stock is used at the hatchery. Inbreeding can affect the survival, growth, and reproduction of fish. Ironically, conditions in the hatchery may favor fish that best survive in hatchery, not natural, environments. When released, hatchery-produced fish mix with naturally spawned fish, resulting in a lower survival rate once fish are released into rivers and streams. Finally, loss of genetic diversity is a documented effect of overfishing (Holmes 2011), which some have suggested is encouraged by the use of hatchery fish.

- **Ecological risks.** Wild and hatchery fish of the same species often compete in nature. For example, wild and hatchery-reared Chinook salmon share the same habitat and diet. Hatchery-released salmon are larger than wild salmon, resulting in possible predation on wild salmon of the same age. Hatchery production of salmon masks the decline of wild salmon, contributes to the genetic dilution and loss of wild salmon, and increases competition for limited freshwater and ocean resources on which wild salmon depend (McGinnis 1994). Throughout the world, overfishing has led to collapsing fish stocks and food web disruptions (Pauly et al. 1998). Hatchery and harvest effects often also interact. Harvest of salmon from waters where both hatchery and wild fish occur has put wild salmon and steelhead at risk (Lackey 2003). Wild salmon mortalities occur even with controlled fishing regulations. A portion of all fish released after being hooked and caught do not survive. Capture methods such as use of barbless hooks and use of landing nets can help reduce mortality of released fish.

Hatcheries and harvest are not the root problem of species declines in the Delta and Central Valley (DFG and NMFS 2001). Despite considerable fishing pressure in the first part of the twentieth century, striped bass, salmon, and steelhead remained abundant in California. Large declines followed the construction of dams on almost all Central Valley rivers, which greatly reduced access to spawning and rearing habitat. Once fish populations are low and habitat is damaged, their harvest can be an especially important control factor. Hatcheries were intended to substitute for lost spawning and rearing habitat, but nature cannot be so easily mimicked. Artificial propagation can provide abundant fish for restocking, but it cannot replace the abundance, productivity, life history diversity, and broad distribution of viable populations. Successful hatchery propagation will work best if it goes hand in hand with habitat restoration. Ultimately, fish produced in hatcheries must thrive and naturally reproduce once they have left the hatchery (Israel et al. 2011). Accordingly, close attention needs to be paid to genetic management to reduce genetic risks.

Hatchery and harvest regulations, and management practices related to those regulations must be based on the best available science and follow adaptive management protocols for monitoring and evaluating the results. Evaluations of hatchery fish impacts would be aided by better hatchery fish-marking techniques and more extensive marking.

POLICIES AND RECOMMENDATIONS

Policies and recommendations for restoring the Delta ecosystem include the following core strategies to reduce the impact of ecosystem stressors:

- Create more natural functional Delta flows
- Restore habitat
- Improve water quality to protect the ecosystem
- Prevent introduction of and manage nonnative species impacts
- Improve hatcheries and harvest management

Success of Delta ecosystem restoration depends on considering and addressing all stressor categories as well as completing and implementing the BDCP described in Chapter 3. Because reducing or eliminating some stressors, especially the globally determined and legacy stressors, will be difficult, adaptation to unmitigable stressors is also imperative.

Create More Natural Functional Flows

Water flow in the Delta is critically important because flow affects the reliability of water supplies and the health of the Delta ecosystem. The best available science demonstrates that flow management is essential to restoration of the Delta ecosystem. Several important ecosystem stressors, including entrainment, are linked to altered water flows. Greater reverse flows in the south Delta increase the numbers of fish entrained.

Problem Statement

Altered flows in the Sacramento and San Joaquin rivers and their tributaries change flows within and out of the Delta, and affect salinity and sediment in the Delta. Fish and other aquatic species native to the Delta are adapted to natural flow, salinity, and sediment regimes. Current flow, salinity, and sediment regimes harm native aquatic species and encourage nonnative species. The best available science suggests that currently required flow objectives within and out of the Delta are insufficient to protect the Delta ecosystem (SWRCB 2010). Additionally, uncertainty regarding future flow objectives for the Delta impairs the reliability of water supplies that depend on the Delta or its watershed. The predictability of water exports cannot be improved, and the BDCP cannot be implemented without timely SWRCB action to update flow objectives.

Policy

ER P1. Delta Flow Objectives

(a) *The State Water Resources Control Board's Bay Delta Water Quality Control Plan flow objectives shall be used to determine consistency with the Delta Plan. If and when the flow objectives are revised by the State Water Resources Control Board, the revised flow objectives shall be used to determine consistency with the Delta Plan.*

(b) *For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, the policy set forth in subsection (a) covers a proposed action that could significantly affect flow in the Delta.*

23 CCR Section 5005
NOTE: Authority cited: Section 85210(i), Water Code.
Reference: Sections 85020, 85054, 85086, 85087, 85300, and 85302, Water Code.

Recommendations

ER R1. Update Delta Flow Objectives

Development, implementation, and enforcement of new and updated flow objectives for the Delta and high-priority tributaries are key to the achievement of the coequal goals. The State Water Resources Control Board should update the Bay Delta Water Quality Control Plan objectives as follows:

(a) *By June 2, 2014, adopt and implement updated flow objectives for the Delta that are necessary to achieve the coequal goals.*

(b) *By June 2, 2018, adopt, and as soon as reasonably possible, implement flow objectives for high-priority tributaries in the Delta watershed that are necessary to achieve the coequal goals.* [1]

---

[1] SWRCB staff should work with the Council and DFW to determine priority streams. As an illustrative example, priority streams could include the Merced River, Tuolumne River, Stanislaus River, Lower San Joaquin River, Deer Creek (tributary

Flow objectives could be implemented through several mechanisms including negotiation and settlement, Federal Energy Regulatory Commission relicensing, or adjudicative proceeding. [2]

Prior to the establishment of revised flow objectives identified above, the existing Bay Delta Water Quality Control Plan objectives shall be used to determine consistency with the Delta Plan. After the flow objectives are revised, the revised objectives shall be used to determine consistency with the Delta Plan.

Restore Habitat

Loss of habitat is one of the largest stressors to the Delta ecosystem. The Delta Plan adopts the approach of the multiagency ERP Conservation Strategy (DFG 2011), which includes a map and accompanying text identifying appropriate habitat restoration types within the Delta and Suisun Marsh based on land elevation, included in the Delta Plan within Appendix B. Delta Plan Figure 4-6 is based on the ERP Conservation Strategy map. Policy ER P3 requires habitat restoration actions to use this figure and accompanying text (see Appendix B for additional information). For example, restoring tidal marsh habitat would generally not be appropriate outside the areas labeled “intertidal” on Figure 4-6 unless they connect other tidal marshes into large habitat areas or can recover elevation over time by natural processes.

An integrated, adaptive approach to restoring habitat must address several issues. Each problem statement below highlights one of these issues, followed by specific policies and recommendations intended to address it.

Problem Statement

Features of the Delta landscape, particularly the condition of its waterways, the elevation of its land, and other environmental conditions, have changed dramatically over the past 160 years. Damage to the habitats that support native species in the Delta has led to declines in native animal and plant populations, affecting both resident and migratory species.

Policies

The appendices referred to in the policy language below are included in Appendix B of the Delta Plan.

ER P2. Restore Habitats at Appropriate Elevations

(a) *Habitat restoration must be carried out consistent with Appendix 3, which is Section II of the* Draft Conservation Strategy for Restoration of the Sacramento-San Joaquin Delta Ecological Management Zone and the Sacramento and San Joaquin Valley Regions *(California Department of Fish and Wildlife 2011). The elevation map attached as Appendix 4 should be used as a guide for determining appropriate habitat restoration actions based on an area’s elevation. If a proposed habitat restoration action is not consistent with Appendix 4, the proposal shall provide rationale for the deviation based on best available science.*

(b) *For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers a proposed action that includes habitat restoration.*

23 CCR Section 5006
NOTE: Authority cited: Section 85210(i), Water Code.
Reference: Sections 85020, 85022, 85054, 85300, and 85302, Water Code.

ER P3. Protect Opportunities to Restore Habitat

(a) *Within the priority habitat restoration areas depicted in Appendix 5, significant adverse impacts to the opportunity to restore habitat as described in section 5006, must be avoided or mitigated.*

(b) *Impacts referenced in subsection (a) will be deemed to be avoided or mitigated if the project is designed and implemented so that it will not preclude or otherwise interfere with the ability to restore habitat as described in section 5006.*

(c) *Impacts referenced in subsection (a) shall be mitigated to a point where the impacts have no significant effect on the opportunity to restore habitat as described in section 5006. Mitigation shall be determined, in consultation with the California Department of Fish and Wildlife, considering the size of the area impacted by the covered action and the type and value of habitat that could be restored on that area, taking into account existing and proposed restoration plans, landscape attributes, the elevation map shown in Appendix 4, and other relevant information about habitat restoration opportunities of the area.*

(d) *For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers proposed actions in the priority habitat restoration areas depicted in Appendix 5. It does not cover proposed actions outside those areas.*

---

to Sacramento River), Lower Butte Creek, Mill Creek (tributary to Sacramento River), Cosumnes River, and American River. Implementation through hearings is expected to take longer than the deadline shown here.

[2] Implementation through adjudicative proceedings or FERC relicensing is expected to take longer than the deadline shown here.

23 CCR Section 5007
NOTE: Authority cited: Section 85210(i), Water Code.
Reference: Sections 85020, 85022, 85054, 85300, 85302, and 85305, Water Code.

Figure 4-7 provides examples of ways a project can implement ER P3.

ER P4. Expand Floodplains and Riparian Habitats in Levee Projects

(a) *Levee projects must evaluate and where feasible incorporate alternatives, including the use of setback levees, to increase floodplains and riparian habitats. Evaluation of setback levees in the Delta shall be required only in the following areas (shown in Appendix 8): (1) The Sacramento River between Freeport and Walnut Grove, the San Joaquin River from the Delta boundary to Mossdale, Paradise Cut, Steamboat Slough, Sutter Slough; and the North and South Forks of the Mokelumne River, and (2) Urban levee improvement projects in the cities of West Sacramento and Sacramento.*

(b) *For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers a proposed action to construct new levees or substantially rehabilitate or reconstruct existing levees.*

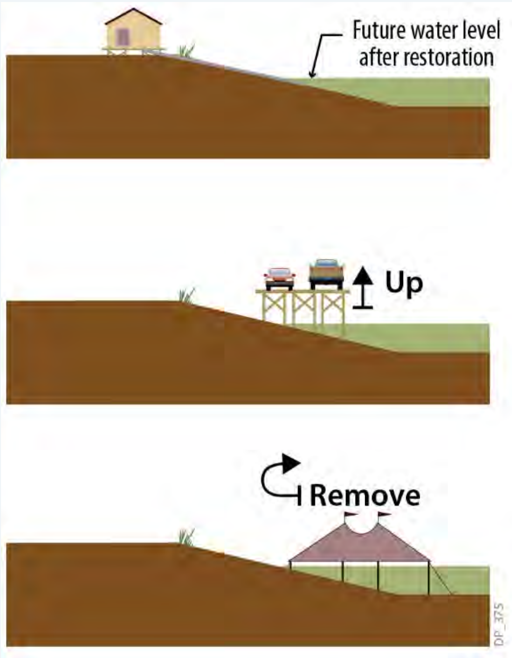
23 CCR Section 5008
NOTE: Authority cited: Section 85210(i), Water Code.
Reference: Sections 85020, 85022, 85054, 85300, 85302, and 85305, Water Code.

Recommendations

ER R2. Prioritize and Implement Projects that Restore Delta Habitat

Bay Delta Conservation Plan implementers, California Department of Fish and Wildlife, California Department of Water Resources, and the Delta Conservancy should prioritize and implement habitat restoration projects in the areas shown on Figure 4-8. Habitat restoration projects should ensure connections between areas being restored and existing habitat areas and other elements of the landscape needed for the full life cycle of the species that will benefit from the restoration project. Where possible, restoration projects should also emphasize the potential for improving water quality. Restoration project proponents should consult the California Department of Public Health's Best Management Practices for Mosquito Control in California.

How Projects Can Comply with ER P3



Locate structures at the edge of a habitat restoration area, rather than in the middle, to improve opportunities for restoring habitat connectivity.

Elevate structures so that water can flow underneath to allow for restoration of aquatic habitat dependent on tides or periodic flooding.

Allow temporary uses and require the removal of structures and cleanup afterward to protect opportunities for habitat restoration.

Figure 4-7

ER P3 requires projects located in the priority habitat restoration areas (shown on Figure 4-8) to protect opportunities to restore habitat. This figure shows conceptual examples of how to implement this policy.

Recommended Areas for Prioritization and Implementation of Habitat Restoration Projects

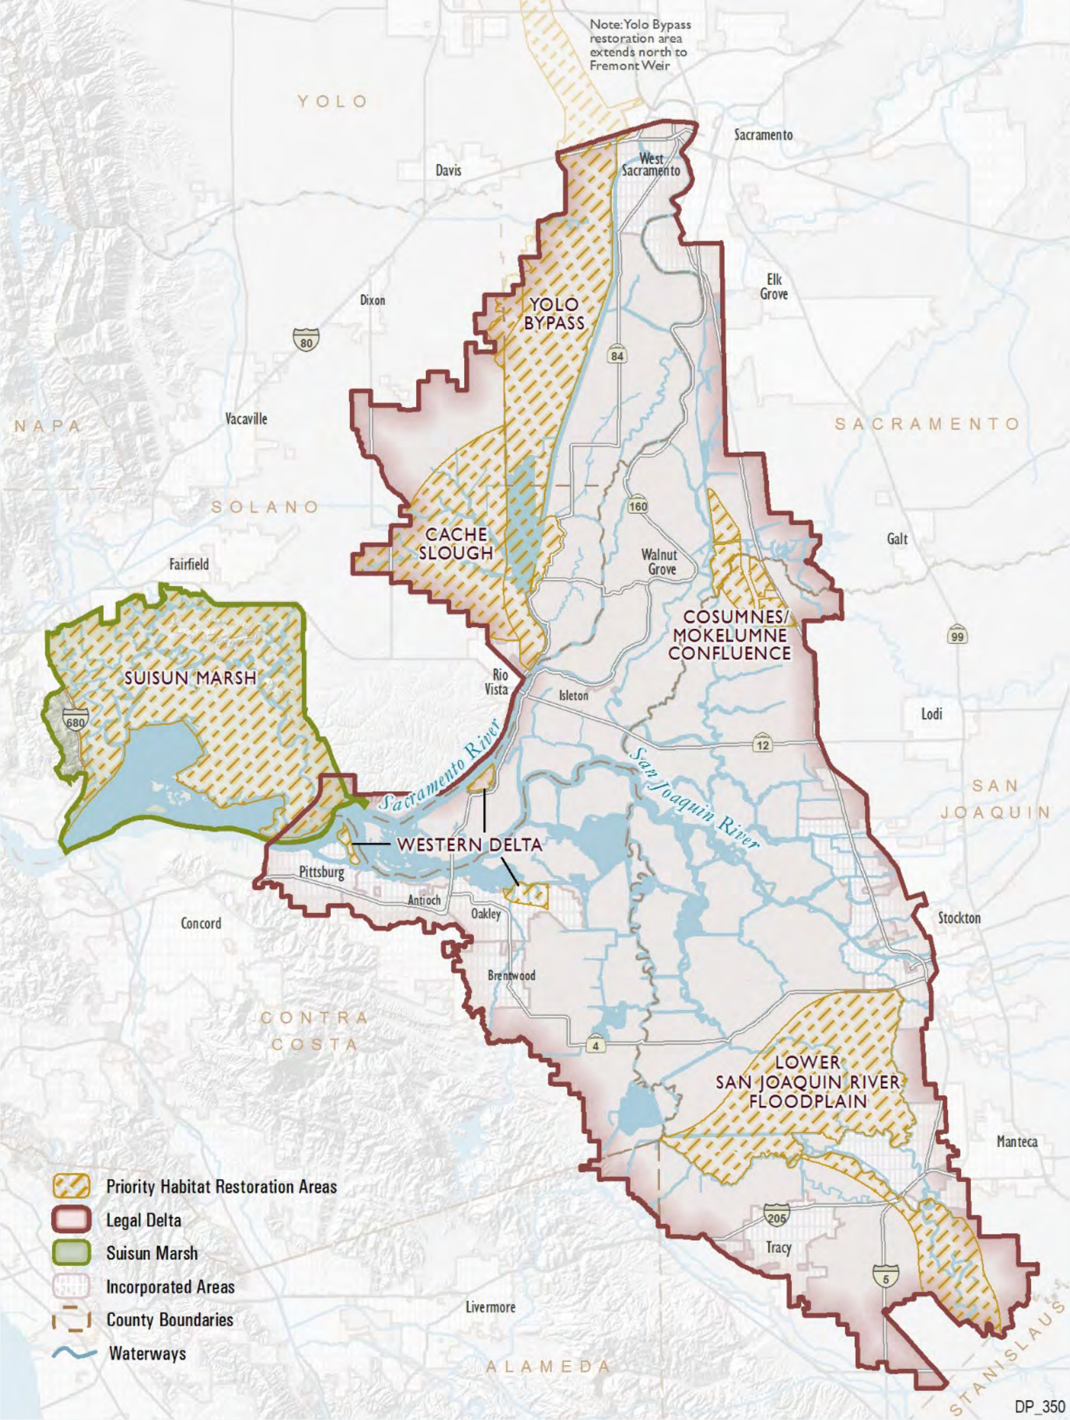


Figure 4-8

Priority habitat restoration areas are large areas within which specific sites may be identified for habitat restoration based on assessments of land use and other issues addressed through further feasibility analysis.

Source: DFG 2011

- ***Yolo Bypass.*** *Enhance the ability of the Yolo Bypass to flood more frequently to provide more opportunities for migrating fish, especially Chinook salmon, to use this system as a migration corridor that is rich in cover and food.*
- ***Cache Slough Complex.*** *Create broad nontidal, freshwater, emergent-plant-dominated wetlands that grade into tidal fresh-water wetlands, and shallow subtidal and deep open-water habitats. Also, return a significant portion of the region to uplands with vernal pools and grasslands.*
- ***Cosumnes River–Mokelumne River confluence.*** *Allow these unregulated and minimally regulated rivers to flood over their banks during winter and spring frequently and regularly to create seasonal floodplains and riparian habitats that grade into tidal marsh and shallow subtidal habitats.*
- ***Lower San Joaquin River floodplain.*** *Reconnect the floodplain and restore more natural flows to stimulate food webs that support native species. Integrate habitat restoration with flood management actions, when feasible.*
- ***Suisun Marsh.*** *Restore significant portions of Suisun Marsh to brackish marsh with land-water interactions to support productive, complex food webs to which native species are adapted and to provide space to adapt to rising sea level action. Use information from adaptive management processes during the* Suisun Marsh Habitat Management, Preservation, and Restoration Plan's *implementation to guide future habitat restoration projects and to inform future tidal marsh management.*
- ***Western Delta/Eastern Contra Costa County.*** *Restore tidal marsh and channel margin habitat at Dutch Slough and western islands to support food webs and provide habitat for native species.*

ER R3. Complete and Implement Delta Conservancy Strategic Plan

As part of its Strategic Plan and subsequent Implementation Plan or annual work plans, the Delta Conservancy should:

- *Develop and adopt criteria for prioritization and integration of large-scale ecosystem restoration in the Delta and Suisun Marsh, with sustainability and use of best available science as foundational principles.*
- *Develop and adopt processes for ownership and long-term operations and management of land in the Delta and Suisun Marsh acquired for conservation or restoration.*
- *Develop and adopt a formal mutual agreement with the California Department of Water Resources, California Department of Fish and Wildlife, federal interests, and other State and local agencies on implementation of ecosystem restoration in the Delta and Suisun Marsh.*
- *Develop, in conjunction with the Wildlife Conservation Board, the California Department of Water Resources, California Department of Fish and Wildlife, Bay Delta Conservation Plan implementers, and other State and local agencies, a plan and protocol for acquiring the land necessary to achieve ecosystem restoration consistent with the coequal goals and the Ecosystem Restoration Program Conservation Strategy.*
- *Lead an effort, working with State and federal fish agencies, to investigate how to better use habitat credit agreements to provide credit for each of these steps: (1) acquisition for future restoration; (2) preservation, management, and enhancement of existing habitat; (3) restoration of habitat; and (4) monitoring and evaluation of habitat restoration projects.*
- *Work with the California Department of Fish and Wildlife and the U.S. Fish and Wildlife Service to develop rules for voluntary safe harbor agreements with property owners in the Delta whose actions contribute to the recovery of listed threatened or endangered species.*

Problem Statement

Current USACE policy requires removal of vegetation from Delta levees, which would reduce already sparse riparian and shaded aquatic habitat along the channels.

Policies

No policies with regulatory effect are included in this section.

Recommendation

ER R4. Exempt Delta Levees from the U.S. Army Corps of Engineers' Vegetation Policy

Considering the ecosystem value of remaining riparian and shaded riverine aquatic habitat along Delta levees, the U.S. Army Corps of Engineers should agree with the California Department of Fish and Wildlife and the California Department of Water Resources on a variance that exempts Delta levees from the U.S. Army Corps of Engineers' levee vegetation policy where appropriate.

Problem Statement

The SMPP and the Local Protection Program components of the SMPP do not yet include climate change provisions. Without these amendments, it is unclear if and how Suisun Marsh will be managed to adapt to rising sea level.

Policies

No policies with regulatory effect are included in this section.

Recommendation

ER R5. Update the Suisun Marsh Protection Plan

The San Francisco Bay Conservation and Development Commission should update the Suisun Marsh Protection Plan *and relevant components of the Suisun Marsh Local Protection Program to adapt to sea level rise and ensure consistency with the Suisun Marsh Preservation Act, the Delta Reform Act, and the Delta Plan.*

Improve Water Quality to Protect the Ecosystem

Chapter 6 includes recommendations about salinity and ecosystem water quality. These recommendations support the protection of water quality for all beneficial uses of water and encourage the identification of water quality impacts of proposed actions. The recommendations also address acceleration of certain total maximum daily loads, low dissolved oxygen, implementation of a Delta Regional Monitoring Program, treatment of wastewater effluent and urban runoff, and Regional Water Quality Control Board engagement in Suisun Marsh.

Problem Statement

The Delta ecosystem is impaired by pollutants from municipal, industrial, agricultural, and other discharges and legacy pollutants flowing into the Delta and its tributaries, including pollutants that bioaccumulate and biomagnify in the food web.

Policies

No policies with regulatory effect are included in this section.

Recommendations

Recommendations for improving ecosystem water quality are included in Chapter 6.

Prevent Introduction of and Manage Nonnative Species Impacts

Problem Statement

Nonnative species are a major obstacle to successful restoration of the Delta ecosystem because they affect the survival, health, and distribution of native Delta wildlife and plants. There is little chance of eradicating most established nonnative species, but management can reduce the abundance of some. The resilience of native species is reduced by ongoing introductions of nonnative species and management actions that enhance conditions for nonnative species.

Policy

ER P5. Avoid Introductions of and Habitat Improvements for Invasive Nonnative Species

(a) The potential for new introductions of or improved habitat conditions for nonnative invasive species, striped bass, or bass must be fully considered and avoided or mitigated in a way that appropriately protects the ecosystem.

(b) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers a proposed action that has the reasonable probability of introducing or improving habitat conditions for nonnative invasive species.

23 CCR Section 5009
NOTE: Authority cited: Section 85210(i), Water Code.
Reference: Sections 85020, 85054, 85300, and 85302, Water Code.

Recommendations

ER R6. Regulate Angling for Nonnative Sport Fish to Protect Native Fish

The California Department of Fish and Wildlife should develop, for consideration by the Fish and Game Commission, proposals for new or revised fishing regulations designed to increase populations of listed fish species through reduced predation by introduced sport fish. The proposals should be based on sound science that demonstrates these *management actions are likely to achieve their intended outcome and include the development of performance measures and a monitoring plan to support adaptive management.*

ER R7. Prioritize and Implement Actions to Control Nonnative Invasive Species

The California Department of Fish and Wildlife and other appropriate agencies should prioritize and fully implement the list of "Stage 2 Actions for Nonnative Invasive Species" and accompanying text shown in Appendix J taken from the Conservation Strategy for Restoration of the Sacramento–San Joaquin Delta Ecological Management Zone and the Sacramento and San Joaquin Valley Regions *(DFG 2011). Implementation of the Stage 2 actions should include the development of performance measures and monitoring plans to support adaptive management.*

Improve Hatcheries and Harvest Management

Problem Statement

Hatcheries and harvest regulation are important tools in fisheries management, but they also pose genetic and ecological risks to native species and the Delta ecosystem. These practices need to employ adaptive management strategies to predict and evaluate outcomes, and minimize risks.

Policies

No policies with regulatory effect are included in this section.

Recommendations

ER R8. Manage Hatcheries to Reduce Genetic Risk

As required by the National Marine Fisheries Service, all hatcheries providing listed fish for release into the wild should continue to develop and implement scientifically sound Hatchery and Genetic Management Plans (HGMPs) to reduce risks to those species. The California Department of Fish and Wildlife should provide annual updates to the Delta Stewardship Council on the status of HGMPs within its jurisdiction.

ER R9. Implement Marking and Tagging Program

By December 2014, the California Department of Fish and Wildlife, in cooperation with the U.S. Fish and Wildlife Service and the National Marine Fisheries Service, should revise and begin implementing its program for marking and tagging hatchery salmon and steelhead to improve management of hatchery and wild stocks based on recommendations of the California Hatchery Scientific Review Group, which considered mass marking, reducing hatchery programs, and mark selective fisheries in developing its recommendations.

Timeline for Implementing Policies and Recommendations

Figure 4-9 lays out a timeline for implementing the policies and recommendations described in the previous section. The timeline emphasizes near-term and intermediate-term actions.

Timeline for Implementing Policies and Recommendations

TIMELINE CHAPTER 4: Ecosystem Implementation

	ACTION (REFERENCE #)	LEAD AGENCY(IES)	NEAR TERM 2012–2017	INTERMEDIATE TERM 2017–2025
POLICIES	Delta flow objectives (ER P1)	SWRCB	●	●

Figure 4-9

Issues for Future Evaluation and Coordination

Additional areas of interest and concern related to the Delta ecosystem may deserve consideration in the development of future Delta Plan updates:

- **Landscape-scale conceptual models.** The Delta Science Program will collaborate with other agencies, academic institutions, and stakeholders to develop landscape-scale conceptual models for the six priority restoration areas identified in ER R2.
- **Workshops to address stressor impacts.** The Delta Science Program, in collaboration with other agencies, academic institutions, and stakeholders, will hold workshops to develop additional recommendations to the Council for measures to reduce stressor impacts on the Delta ecosystem that would support and be consistent with the coequal goals. Recommended measures could be adopted as policies or recommendations by the Council into an amended Delta Plan.
- **Above-the-Delta migration corridors.** The Council will consult with fish and wildlife agencies and others as they complete or update plans to restore habitats for migratory species, such as anadromous fish or songbirds in the Sacramento and San Joaquin valleys above the Delta.

Science and Information Needs

The Delta ecosystem is not static; therefore, additional information is needed for decision making and adaptive management. Specifically, the following information is needed in the following areas:

- Landscape-scale conceptual models for Delta ecosystem restoration.
- Assessment of how flows benefit or harm native wildlife and plants.
- Effects of changing habitat quality and quantity on Delta fish and invertebrates. Examples might include (1) threadfin shad in the south and central Delta, (2) comparison of shallow shoal habitat and deep channel habitat to food resources of young striped bass, and (3) relationship between water turbidity and native fish migration, survival, growth, and/or reproduction.
- Hatchery, harvest, and/or predation impacts on natural fish populations.
- Tools to assess native fish response to restored habitats.
- Entrainment effects on fish populations.
- Tools to assess potential impacts of climate change and sea level rise to viability of species in intertidal habitats.

Performance Measures

Development of informative and meaningful performance measures is a challenging task that will continue after the adoption of the Delta Plan. Performance measures need to be designed to capture important trends and to address whether specific actions are producing expected results. Efforts to develop and track performance measures in complex and large-scale systems like the Delta are commonly multiyear endeavors. The recommended output and outcome performance measures listed below are provided as examples and subject to refinement as time and resources allow. Final administrative performance measures are listed in Appendix E and will be tracked as soon as the Delta Plan is completed.

The Delta Reform Act specifies some performance measures for large-scale ecosystem restoration within the Delta. Ecosystem performance measures should address progress in achieving the objectives set forth in Water Code sections 85302(c) and 85302(e).

Note that performance measures for ecosystem water quality are provided in Chapter 6.

Output Performance Measures

- The SWRCB adopts Delta flow objectives by June 2, 2014. (ER R1)
- The SWRCB adopts flow objectives for the major tributaries by 2018 (or soon as reasonably possible). (ER R1)
- Pilot-scale Delta habitat restoration projects are developed and initiated in the priority areas described in ER R2 by 2015. These projects include tidal brackish and freshwater marsh as well as floodplain restoration, and have clear adaptive management plans aimed at improving outcomes and providing lessons for the development of large-scale restoration projects. Metrics: acres restored by habitat type, and lessons learned. (ER R2)
- Progress, measured in acres of restored or enhanced habitat, is being made toward the biological opinions' targets of restoring 8,000 acres of tidal marsh and 17,000 to 20,000 acres of floodplain rearing habitat. (ER R2)
- The DFW and other appropriate agencies fully implement the list of "Stage 2 Actions for Nonnative Invasive Species." (ER R7)

Outcome Performance Measures

- Progress toward restoring in-Delta flows to more natural functional flow patterns to support a healthy estuary. Metrics: results from hydrological monitoring and hydrodynamic modeling. (ER R1)
- Progress toward decreasing annual trends in both the number of new and existing aquatic and terrestrial nonnative species, and the abundance and distribution of existing aquatic and terrestrial nonnative species in the Delta over the next decade. These trends will be derived from long-term animal and plant monitoring surveys conducted by the Interagency Ecological Program agencies, the California Department of Boating and Waterways, the U.S. Department of Agriculture, the San Francisco Estuary Institute, and others. (ER P5)
- Progress toward the documented occurrence and use of protected and restored habitats and migratory corridors by native resident and migratory Delta species. Trends in occurrence, use, and performance of native species in protected and restored habitats and corridors will be upward over the next decade. These trends will be derived from animal and plant monitoring surveys that are conducted as part of adaptive management strategies for the protection and restoration of these areas. (ER R2)
- Progress toward achieving the State and federal "doubling goal" for wild Central Valley salmonids relative to 1995 levels. Trends will be derived from long-term salmonid monitoring surveys conducted by the National Marine Fisheries Service, U.S. Fish and Wildlife Service, and others. (ER R2)

CHAPTER 5

Protect and Enhance the Unique Cultural, Recreational, Natural Resource, and Agricultural Values of the California Delta as an Evolving Place

ABOUT THIS CHAPTER

This chapter describes the unique values that distinguish the Sacramento-San Joaquin Delta (Delta) and make it a special region. It also outlines the Delta Stewardship Council's (Council) five core strategies for protecting and enhancing these values:

- Designate the Delta as a special place worthy of national and state attention
- Plan to protect the Delta's lands and communities
- Maintain Delta agriculture as a primary land use, a food source, a key economic sector, and a way of life
- Encourage recreation and tourism that allow visitors to enjoy and appreciate the Delta, and that contribute to its economy
- Sustain a vital Delta economy that includes a mix of agriculture, tourism, recreation, commercial and other industries, and vital components of state and regional infrastructure

The 2 policies and 19 recommendations to carry out these strategies are found at the end of the chapter. Protecting the Delta as a place also depends on the strategies to reduce flood and other risks to the Delta that are described in Chapter 7.

RELEVANT LEGISLATION

The Sacramento-San Joaquin Delta Reform Act of 2009 declared State policy for the resources and values of the Delta (Water Code section 85054):

> *"Coequal goals" means the two goals of providing a more reliable water supply for California and protecting, restoring, and enhancing the Delta ecosystem. The coequal goals shall be achieved in a manner that protects and enhances the unique cultural, recreational, natural resource, and agricultural values of the Delta as an evolving place.*

The Legislature declares the following objectives inherent in the coequal goals for management of the Delta (Water Code section 85020):

> *(a) Manage the Delta's water and environmental resources and the water resources of the state over the long term.*
>
> *(b) Protect and enhance the unique cultural, recreational, and agricultural values of the California Delta as an evolving place.*

Water Code section 85302(h) provides direction on the implementation of measures to promote the coequal goals and inherent objectives:

> *(h) The Delta Plan shall include recommendations regarding state agency management of lands in the Delta.*

The Delta Reform Act states (Water Code section 85022 (d)):

> *(d) The fundamental goals for managing land use in the Delta are to do all of the following:*
>
> > *(1) Protect, maintain, enhance, and, where feasible, restore the overall quality of the Delta environment and its natural and artificial resources.*
> >
> > *(2) Ensure the utilization and conservation of Delta resources, taking into account the social and economic needs of the people of the state.*
> >
> > *(3) Maximize public access to Delta resources and maximize public recreational opportunities in the Delta consistent with sound resources conservation principles and constitutionally protected rights of private property owners.*
> >
> > *(4) Encourage state and local initiatives and cooperation in preparing procedures to implement coordinated planning and development for mutually beneficial uses, including educational uses, in the Delta.*
> >
> > *(5) Develop new or improved aquatic and terrestrial habitat and protect existing habitats to advance the goal of restoring and enhancing the Delta ecosystem.*
> >
> > *(6) Improve water quality to protect human health and the environment consistent with achieving water quality objectives in the Delta.*

Public Resources Code section 29703.5 describes the Delta Protection Commission's role in providing recommendations to the Delta Stewardship Council:

> *(a) The Delta Protection Commission created pursuant to Section 29735 provides an existing forum for Delta residents to engage in decisions regarding actions to recognize and enhance the unique cultural, recreational, and agricultural resources of the Delta. As such, the commission is the appropriate agency to identify and provide recommendations to the Delta Stewardship Council on methods of preserving the Delta as an evolving place as the Delta Stewardship Council develops and implements the Delta Plan.*
>
> *(b) There is a need for the five Delta counties to establish and implement a resources management plan for the Delta and for the Delta Stewardship Council to consider that plan and recommendations of the commission in the adoption of the Delta Plan.*

This page intentionally left blank.

CHAPTER 5

Protect and Enhance the Unique Cultural, Recreational, Natural Resource, and Agricultural Values of the California Delta as an Evolving Place

The Delta Reform Act provides that the coequal goals of providing a more reliable water supply and protecting, enhancing, and restoring the Delta ecosystem shall be achieved in a manner that protects the unique cultural, natural, recreational, resource, and agricultural values of the Delta as an evolving place. Achieving this objective begins with recognizing the values that make the Delta a distinctive and special place:

- The Delta's geography of low-lying islands and tracts, many below the water level and shaped by sloughs, shipping channels, and rivers; tidal influences; levees; and other water controls is unique among California landscapes.
- The Delta retains a rural heritage, characterized by farms and small towns linked by navigable waterways and winding country roads.
- The Delta's agricultural economy is vital to the region and contributes to California's important agricultural economy.
- The Delta is a region where maritime ports, commercial agriculture, and expanding cities coexist with a unique native ecosystem that is home to many species of wildlife and fish.
- The Delta is a place of multicultural tradition, legacy communities, and family farms.
- The Delta provides opportunities for recreation and tourism because of its unique geography, mix of activities, and rich natural resources.

The Delta's uniqueness, however, does not exempt it from change. Increasing pressures of growing populations, shifting commodity markets, climate changes, and rising sea level will require new ways of adaptation for this region. Some changes are driven by the Delta's location at the center of California's water systems and are required to meet statewide goals of restoring the Delta's ecosystem and improving water supply reliability. Other changes may be caused by floods, earthquakes, or other events that threaten the Delta's levees and islands. Some changes can be managed by policies that shape how the Delta's traditions are honored and its history preserved; guide new development; enhance recreation and tourism; and encourage agriculture, business expansion, and economic development.

Protecting the Delta as an evolving place means accepting that change will not stop, but that the fundamental characteristics and values that contribute to the Delta's special qualities and that distinguish it from other places can be preserved and enhanced while accommodating these changes (Delta Vision Blue Ribbon Task Force 2008). It does not mean that the Delta should be a fortress, a preserve, or a museum.

The Council envisions a future where the Delta's unique qualities are recognized and honored. Agriculture will continue to thrive on the Delta's rural lands; and its cities, ports, and rural villages will be desirable places to live, work, and do business. Visitors to the region will enjoy recreation on and in its waterways, marshes, resorts, parks, and historic legacy communities. The Delta's land uses and development will be resilient, protecting the rural character of the area, reducing risks to people and property, adjusting to changing conditions, and promoting the ability to recover readily from distress. The Delta's economic vitality will provide resources to respond to change and to support the families and businesses that make the Delta home. The vision of the Delta as an evolving place also acknowledges the role of Delta residents in shaping the future of the region through active and effective participation in Delta planning and management.

Creating a Common Vision of the Delta as a Place

The Delta Reform Act recognizes not only the uniqueness of the region, but also that it is managed and influenced by many State of California (State), federal, and local agencies, often with differing views about the Delta and with overlapping and sometimes conflicting jurisdictions. Through the Delta Plan, the Council intends to foster a common vision for the future of the Delta as a place and to promote more effective coordination among these agencies. (See sidebar, Looking at the Delta.)

Fashioning this common vision has begun by drawing much of the information and many of the strategies of this chapter from these agencies' reports and recommendations, including the following documents:

- The *Proposal to Protect, Enhance, and Sustain the Unique Cultural, Historical, Recreational, Agricultural, and Economic Values of the Sacramento-San Joaquin Delta as an Evolving Place* developed by the Delta Protection Commission (DPC) (DPC 2012a)
- The DPC's *Economic Sustainability Plan for the Sacramento-San Joaquin Delta* (ESP) (DPC 2012b)
- The *Recreation Proposal for the Sacramento-San Joaquin Delta and Suisun Marsh* (Recreation Proposal) developed by California State Parks (California State Parks 2011)
- The Sacramento-San Joaquin Delta Conservancy's (Delta Conservancy) *Strategic Plan*

The Public Resources Code (section 29703.5(a)) names the DPC as "the appropriate agency to identify and provide recommendations to the Council on methods of preserving the Delta as an evolving place." The DPC is an agency created in 1992 by the Delta Protection Act to plan for and guide natural resource conservation and enhancement in the legal Delta while sustaining agriculture and meeting increased recreational demand.

LOOKING AT THE DELTA

The Delta presents itself from three vantages that display alternative aspects of its character.

From the water, the Delta is a thicket of sloughs, rock-lined channels, and open waterways where the land lies unseen behind tall levees and riparian vegetation. This is a Delta of recreational boating and oceangoing freighters, piers and lift bridges, diversions and water control structures, fish and diving ducks, resorts and marinas.

Another view of the Delta is a predominantly rural, agricultural landscape dotted with historic villages and where waterways are hidden on the other side of the levee, to be glimpsed only from bridges and levee-top roads. This is a Delta of vineyards, orchards, farm fields, ditches, and waterfowl hunting clubs; of historic farmsteads and one-of-a-kind shops and restaurants; and of farm machinery and bicyclists.

A third view of the Delta looks out from its metropolitan areas: Stockton, Manteca, Lathrop, Tracy, Contra Costa County's shoreline suburbs, Suisun City, Fairfield, Sacramento, and West Sacramento. This is a Delta of downtowns, neighborhoods, and new suburbs; cooling summer breezes and clammy winter fog; waterfront parks and a catch of striped bass in the freezer; and ports, warehouses, offices, and other job sites.

DP-188

As provided in Water Code section 85301, the DPC developed the *Proposal to Protect, Enhance, and Sustain the Unique Cultural, Historical, Recreational, Agricultural, and Economic Values of the Sacramento-San Joaquin Delta as an Evolving Place* (DPC 2012a). This proposal was submitted to the Council for incorporation into the Delta Plan. The proposal includes a plan to recognize the Delta as a place of special significance by applying for a federal designation of the Delta as a National Heritage Area (NHA). The NHA designation is granted by the U.S. Congress to places where natural, cultural, historic, and recreational resources combine to form a distinctive landscape and tell a nationally important story about the country and its experience.

The DPC also recommends strategies to support increased investment in agriculture, recreation, tourism, and other resilient land uses in the Delta. These strategies are derived from the ESP (DPC 2012b). Established in 2009, the Delta Conservancy is responsible for implementing ecosystem restoration projects protecting and preserving agriculture and working landscapes; increasing recreation and tourism opportunities; promoting legacy communities and economic vitality; and protecting, conserving, and restoring the region's physical, agricultural, cultural, historical, and living resources (Public Resources Code section 32322). Careful coordination between the DPC and Delta Conservancy can maximize the impact of both agencies' economic development activities.

Protecting the Delta as an Evolving Place Is Inherent in the Coequal Goals

Protecting the Delta as an evolving place is inherent in the coequal goals of providing a more reliable water supply for California and protecting, restoring, and enhancing the Delta ecosystem. This is partly because attaining these two goals will necessitate a growing awareness among Californians of the Delta and its values, including its agriculture, recreation, natural resources, and unique culture. It is also because Delta residents benefit from the levees that help convey fresh water through the Delta; enjoy the wildlife, fish, and recreation that the Delta ecosystem produces; and work for its water management agencies and facilities. Changes required to provide a more reliable water supply or restore the ecosystem will influence the kind of place the Delta becomes, especially if structures to improve conveyance or areas of restored habitat significantly alter the Delta's familiar farming landscape. At the same time, the needs to protect the Delta's land uses and people will shape and constrain decisions about water supplies and ecosystem restoration, including allocation of water supplies, flow and salinity objectives, levee priorities, and how impacts to communities and land uses are mitigated.

Water for agricultural, municipal, and industrial uses is a key to the Delta as a place. Delta communities are the most dependent of all Californians on Delta water supplies, which support its residents, businesses, and farms. They, like other Californians, can often do more to use water more efficiently and to develop alternative supplies through recycling, conjunctive use of groundwater, or participation in regional water supply projects. Because the communities and economy of the Delta require water of reliable quality as well as amount, updates to the Bay-Delta Water Quality Control Plan have special influence on the region. The Delta is also influenced by other Central Valley water quality plans because they protect the quality of water for Delta consumers, farmers, and recreationists and the costs Delta residents and businesses pay to meet clean water standards.

A healthy ecosystem is also important to the Delta's communities. Residents find joy and relaxation in outdoor recreation and the connection with nature that the Delta ecosystem provides. Visitors drawn to its scenery, waterways, fish, and wildlife support tourism businesses. Protecting the ecosystem maintains these benefits and restoring it can expand them, especially when it can be accomplished in ways that enhance the Delta's working landscape. Coordinating restoration with planning for flood control can help control costs for levee improvement and management, draw on multiple sources of funds for multipurpose flood control investments, and provide alternate uses for areas that cannot be protected cost effectively. Restoring marshes, riverbanks, and riparian areas will alter how some land is used, but the impacts of these changes on the Delta's unique values can be managed through cooperation, careful design to lessen or avoid adverse effects, or reasonable mitigation of unavoidable impacts.

The Delta as a Place

The California Delta is a unique place distinguished by its geography, legacy communities, a rural and agricultural setting, vibrant natural resources, and a mix of economic activities. This section describes the features that make the Delta unique. Its 839,640 acres of land, sometimes centered on a wide river but laced with a network of narrow channels and sloughs, stretch to the horizon, bounded only by the levees that were built to drain the Delta's marshes and floodprone riversides. The Legislature has found that the Delta's uniqueness is particularly characterized by its hundreds of miles of meandering waterways and the many islands adjacent to them, and has described the Delta's highly productive agriculture, recreational assets, fisheries, and wildlife as invaluable resources (Water Code section 12981(b)). These natural assets, including the ecosystem and water resources as described in Chapters 3, 4, and 6, are among the Delta's important values.

The Delta is composed of three areas recognized in California law. The Primary Zone is the largest and includes 490,050 acres at the heart of the Delta (Public Resources Code section 29728). It is primarily rural farmland, but also includes several small towns established in the nineteenth and twentieth centuries. The Secondary Zone includes 247,320 acres surrounding the Primary Zone (Public Resources Code section 29731). It also includes farmland, but is increasingly dominated by the region's cities and suburbs. Suisun Marsh lies northwest of the Primary Zone, encompassing 106,570 acres (Public Resources Code section 29101) primarily of managed wetland. The Suisun Marsh overlaps the boundary of the Delta by about 4,300 acres (see Figure 5-1).

The Legislature has declared that the Delta is a natural resource of statewide, national, and international significance, and that the cities, towns, and settlements within the Delta are of significant historical, cultural, and economic value (Public Resources Code sections 29701 and 29708). However, not all Delta users, visitors, or residents recognize or appreciate the Delta's values. In a recent survey, 78 percent of Californians said they had not heard of or did not know about the Delta (Probolsky Research 2012). A survey in 2007 found that nearly half of Stockton residents had only a vague idea—or none at all—that they lived in or near the Delta (*Stockton Record* 2012).

This lack of a clearly recognized, widely communicated identity for the Delta is described as the lack of a "brand." Delivering a coordinated message about the Delta and its resources is difficult because responsibilities for the Delta are divided among so many agencies. Many visitors and even some residents of Delta cities and suburbs are unfamiliar with the region beyond their travel route or community, or know it only in name from news media reports about conflicts over its water and natural resources. To some, the Delta's flat agricultural landscape is dull and monotonous, and its resources are "out of sight and out of mind." Access into the Delta by first-time visitors can be difficult because of its winding roads and lack of amenities that signify a special region; simplify wayfinding; educate travelers about an area's history, culture, and natural resources; or encourage public access and recreation.

Delta Primary and Secondary Zones and Suisun Marsh

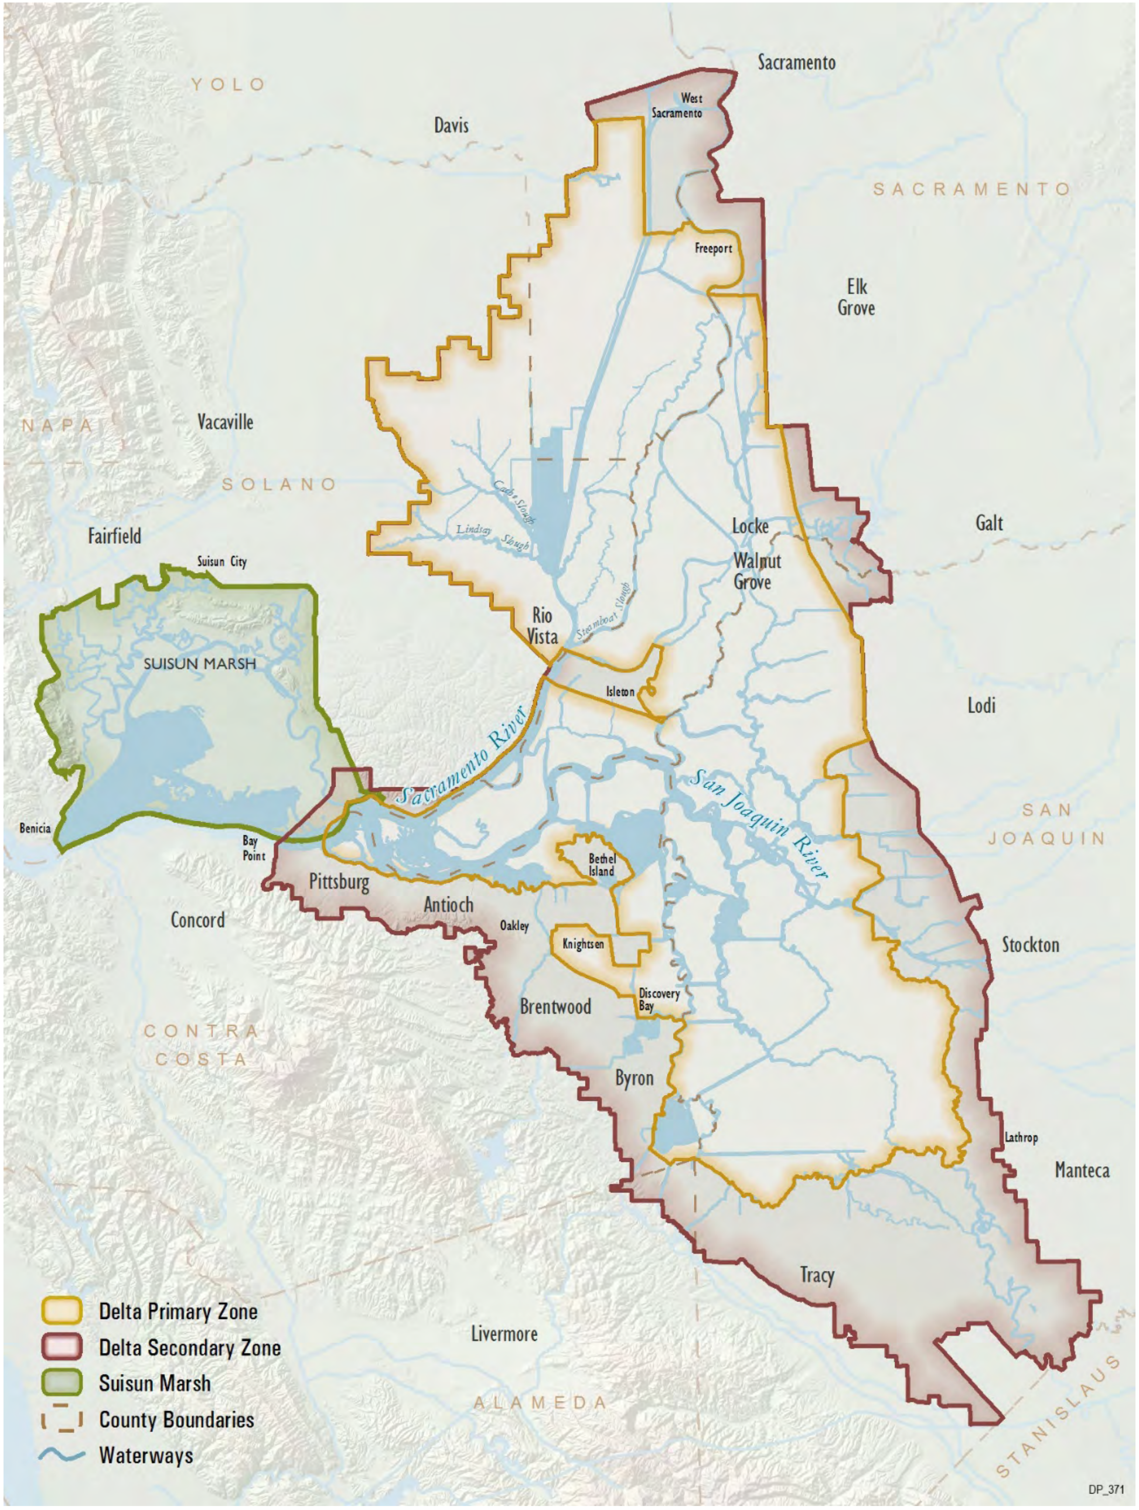

Figure 5-1

The Delta's People

About 570,000 people reside in the Delta, according to the 2010 Census. Ninety-eight percent of them live in the Delta's Secondary Zone, with the remainder in the Primary Zone. Prior to the recent recession, the population of the Delta's Secondary Zone had been growing rapidly, increasing almost 56 percent since the 1990 Census, a rate twice as fast as the state as a whole. Much of that increase occurred in new communities in previously unincorporated county areas, such as Discovery Bay; rapidly growing towns and communities such as Brentwood and Oakley on State Route 4; and cities such as Sacramento, West Sacramento, Stockton, and Lathrop. The age and household composition of the Delta's population is similar to California as a whole, but with slightly younger and larger families. About half the Delta's population is between the ages of 21 and 54, and about 29 percent are younger than 18 years old (DPC 2012b).

In contrast, the population of the Primary Zone has been essentially unchanged over those 20 years. The Primary Zone is also composed primarily of older people without children, living in smaller households.

Today, most Delta residents describe themselves as white or Hispanic, with the next largest groups being Asian, other races, and African-American or black. About one-third describe themselves as Hispanic. This diverse population reflects the many United States regions and foreign lands from which settlers emigrated to the Delta, including Mexico, China, Japan, Portugal, the Philippines, and other countries. These origins are reflected in communities and neighborhoods like Locke, an early twentieth century town built primarily by Chinese farmworkers. Cultural events honor many ethnic traditions in the Delta, including Chinese and Cambodian New Years, Portuguese festas, Greek holidays, Indian Diwali celebrations, Filipino fiestas, Cinco de Mayo events, and Juneteenth commemorations. Other festivals feature Delta agriculture, such as the Courtland Pear Fair and the Stockton Asparagus Festival (California State Parks 2011).

The Delta's Communities

The region's urban communities include the cities of Sacramento, West Sacramento, Stockton, Lathrop, Manteca, Tracy, Oakley, Brentwood, Antioch, Pittsburg, Benicia, Fairfield, Suisun City, Rio Vista, and Isleton, and the unincorporated communities of Freeport, Mountain House, Byron, Discovery Bay, Bethel Island, and Knightsen. They are located entirely or partially in the Delta's Secondary Zone or in the secondary management area of Suisun Marsh. Unincorporated communities in the Primary Zone include Clarksburg, Courtland, Hood, Locke, Walnut Grove, and Ryde. Appendix B includes maps of these unincorporated communities.

The general plans of Delta cities and counties describe where development of these communities may occur. These plans or actions by the local area formation commissions describe "spheres of influence" (SOIs) for each jurisdiction and often identify an urban limit line beyond which intense development cannot occur without amendment of the plan. About 26,000 acres of the Delta within these SOIs are expected to undergo urbanization (DPC 2012b) (see Figure 5-2). To encourage the location of new development within these SOIs rather than in rural areas, Chapter 7 policies exempt development in these areas from policies to increase flood protection standards. The Delta Plan includes no policies or recommendations to control land use or density in these communities.

Among the Delta's unincorporated communities, Bethel Island warrants a special note because of its flood risks, the development planned there, and its lack of public services. Its developed area occupies part of the 3,500-acre island, most of which is planned for rural agricultural or visitor-serving commercial uses. About 2,100 people reside on the island in about 1,300 residences concentrated on the island's south central shoreline, four mobile home parks, or 13 commercial marinas. Approximately 15 miles of levees surround the island, which is below sea level, limiting the drainage of floodwaters in the event of a levee breach.

A single road, Bethel Island Road, links the island to the mainland at the city of Oakley, complicating emergency response or evacuation in the event of flooding. Although the entire island is included in the urban limit line that Contra County's voters approved in 2006, development on the island clusters around Delta Coves, a 495-unit water-oriented residential development that was permitted in 1973, but that still remains unfinished, in part because of the bankruptcy of its developer. Other development includes mobile home parks and retail areas. Rural uses include single-family homes along the island's shoreline, marinas, resorts, a golf course, rural residential uses, and farmland. Contra Costa County's General Plan seeks to preserve and enhance the rural quality of Bethel Island and still allow for planned residential and commercial growth related to water-oriented recreation. The general plan notes that development other than a single home on existing parcels must await resolution of several issues, including improvement of the community's public services, levees, and emergency evacuation routes. Because of its flood risks and its rural character, Bethel Island is not excluded from the Delta Plan policy limiting new urban development. Restrictions on development on Bethel Island are consistent with the Contra Costa County General Plan.

As described in Chapter 2, covered actions subject to the Delta Reform Act do not include plans, programs, or projects within the Delta's Secondary Zone that a metropolitan planning agency has determined are consistent with a sustainable communities strategy adopted under California planning law. These sustainable communities strategies will, in part, accomplish the following:

- Identify the general location of uses, residential densities, and building intensities within the region.
- Identify areas within the region over their 20-plus-year planning period sufficient to house the population of the region.
- Identify areas within the region sufficient to house an 8-year projection of the regional housing need for the region.
- Identify a transportation network to serve the transportation needs of the region.
- Gather and consider information regarding resource areas and farmland in the region.
- Set forth a forecast development pattern, which, when integrated with the transportation network and other transportation measures and policies, will reduce greenhouse gas emissions from automobiles and light trucks. The sustainable community strategy development pattern will need to be based upon "current planning assumptions" that include the information in local general plans and SOI boundaries.

As provided in Water Code section 85212, the Council will cooperate with local and regional planning agencies to provide timely advice about sustainable community strategies and other local and regional plans for consistency with the Delta Plan. This will include reviewing their consistency with the ecosystem restoration needs of the Delta and whether these plans set aside sufficient lands for natural resource protection to meet the Delta's ecosystem needs. Through this coordination, decisions about locating and planning new urban development in the Secondary Zone can be coordinated to meet local communities' housing and other needs, as Water Code section 85022(d)(4) provides, while protecting and enhancing the Delta as an evolving place.

Delta Communities

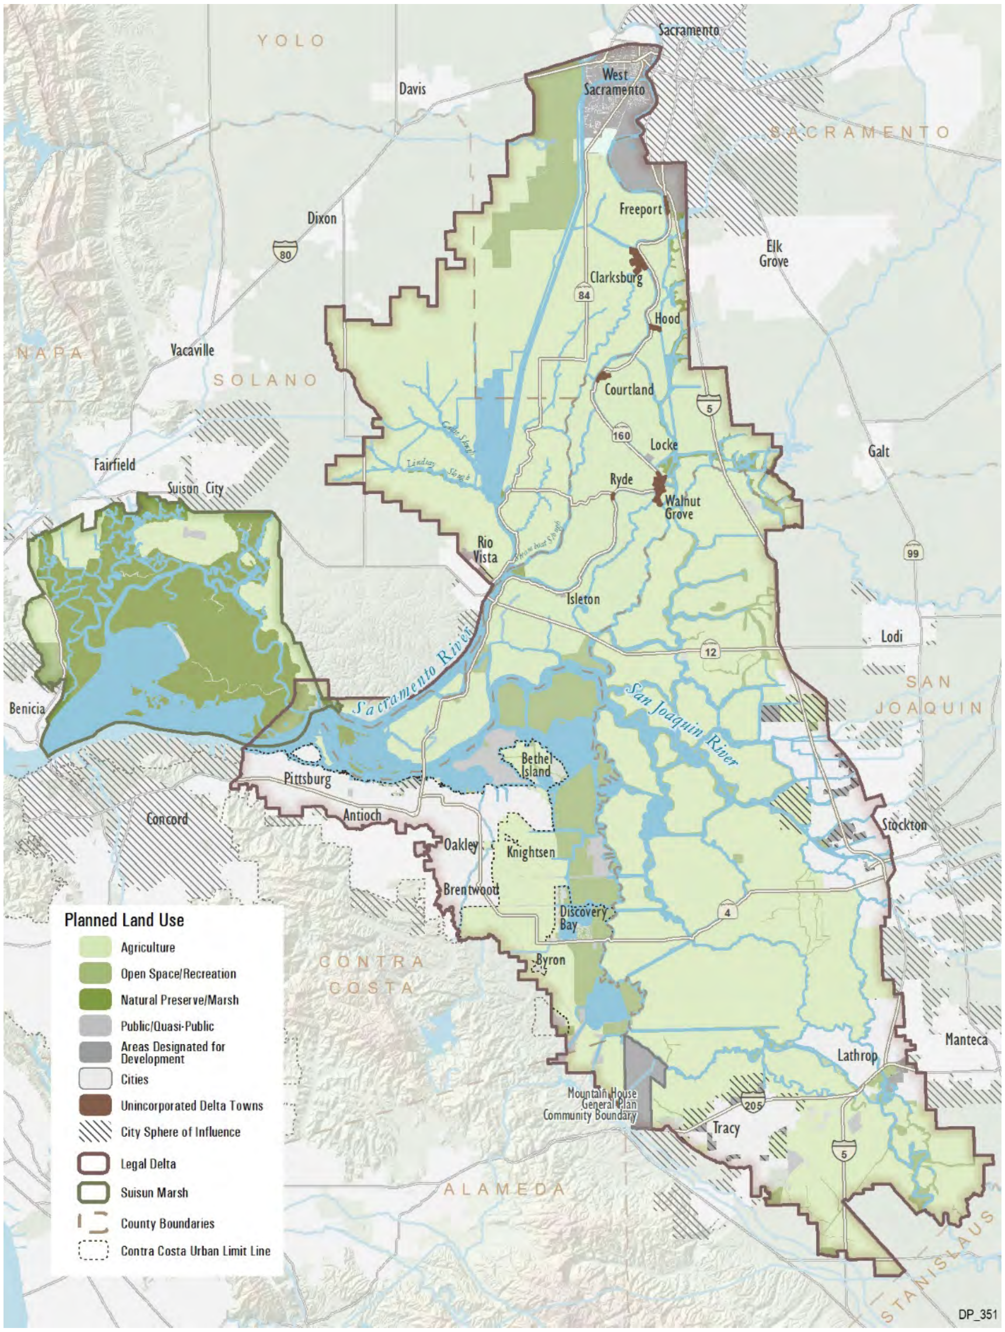

Figure 5-2 The map shows land uses designated by city and county general plans. Within cities' SOIs, the map shows land use designations proposed in city general plans, where available. In cases where cities have not proposed land uses within their SOIs, the map shows land uses designated by county general plans.

The Delta's Legacy Communities

Bethel Island, Clarksburg, Courtland, Freeport, Hood, Isleton, Knightsen, Rio Vista, Ryde, Locke, and Walnut Grove are the Delta's legacy communities (Public Resources Code section 32301(f)). They are the residential, commercial, processing, and retail centers of the Delta, and resonate with its history and culture. Each community has its own character. Bethel Island is a recreation destination. Clarksburg and Courtland are centers for wine and pear production. Freeport and Hood were transportation centers, with river landings and rail spurs to move goods. Locke and Walnut Grove had large Asian populations who worked at packing sheds and surrounding local farms. Ryde is known for its landmark hotel, and Isleton is known for festivals and visitor-serving businesses. Rio Vista is the largest community, and Knightsen is a small community known for several nearby horse ranches. All legacy communities except Freeport, Isleton, and Bethel Island are in the Primary Zone. Rio Vista is partly in the Primary Zone and partly outside the Delta. The DPC ESP highlights the rich cultural histories of these distinctive communities and notes the importance of enhancing their legacy themes and creating better awareness of them. It highlights planning to strengthen these communities by building on the agricultural uses that surround them. It also recommends enhancing the Delta's recreation and tourism opportunities by improving these towns' lodging, entertainment, and retail options; encouraging agritourism; restoring historic buildings; and promoting context-sensitive infill development, including housing for the Delta's workforce.

Flood risks in these communities are higher than in the Delta's cities, as noted in Chapter 7, and they are too small to be capable of financing major levee improvements without significant assistance. According to the ESP, opportunities for residential or visitor-serving recreation developments in these communities may be impaired if flood risks are too high or development regulations are unpredictable or too burdensome. Although improvements to these communities' historic structures are exempt from Federal Emergency Management Agency (FEMA) floodproofing standards (FEMA 2008), flood risks, floodproofing standards for new development, and flood insurance costs can be barriers to business investment or development.

THE LEGACY OF THE DELTA'S NATIVE CALIFORNIA INDIANS

People have occupied the Delta for thousands of years. Early people gathered wild plants, including seeds, roots, greens, mushrooms, and nuts; hunted for rabbits, waterfowl, tule elk, or antelope; and speared or netted salmon, sturgeon, and other fish. Acorn processing allowed populations to grow. Permanent villages of 100 or more residents were established on sand mounds along major waterways, at the margins of tule marshes, and on the shores of Suisun Bay. Sandy uplands on Delta islands held smaller settlements. Boats of tule reeds were used to travel Delta waterways. Trade with neighbors brought obsidian and other tool stones, shell or bone ornaments, charm stones, and other goods from the coast and Sierra.

Four main groups resided in the Delta: Nisenan on the north, Miwok on the east, Yokuts in the south Delta and Contra Costa shoreline, and Patwin around Suisun Marsh and Putah Creek. Their presence is still acknowledged in place names (for example, Yolo, Suisun, and Mokelumne) and in artifacts such as stone pestles and bedrock mortars for grinding seeds and nuts; twined basketry of rushes and other plants; ancient habitations demarked by charcoal, shells, or other refuse; and cemeteries where loved ones were carefully buried, sometimes with ochre, beads, and other objects, or cremated. Today their descendants sustain a contemporary native California Indian community in the Delta.

DP-189

Climate Change

Historical, cultural, and economic resources of the Delta are subject to the impacts of climate change. An increase in sea level of up to 55 inches is projected to occur by 2100. Along with increased flood risk associated with rising sea levels and changes in runoff timing and intensity, levees, highways, and other infrastructure that support the Delta's communities and economy will be threatened. In addition, land use planning is complicated by the prospect of rising sea levels and increased flooding that may accompany climate change. Rising water levels and more severe flooding will increase hazards to land uses and developments, and confound efforts to identify safe locations for new homes and businesses.

Impacts on agriculture, such as decreasing revenues, are also likely if Delta water supplies increase in salinity (Lund et al. 2007) and water demand increases. Impacts on agriculture from warming temperatures could reduce yields and increase vulnerability to weeds and pests (California Resources Agency 2008), as well as increase soil subsidence rates through increased rates of organic matter oxidation. In addition, Delta recreation and tourism could be affected by changes in Delta fisheries.

Land Use Planning in the Delta and Suisun Marsh

The land uses in the Delta are the result of myriad decisions made by residents, businesses, investors, and others since its settlement. These decisions are shaped today by local and State agencies that are responsible for planning or regulating land use or development. Primary authority for land use planning rests with the Delta's twelve cities and five counties, which are required to adopt comprehensive long-range general plans to guide development. In addition, the Legislature has authorized three State agencies to oversee land use planning by local governments or directly regulate land use actions in the Delta and the Suisun Marsh: the Council, the DPC, and the San Francisco Bay Conservation and Development Commission (BCDC). The Council and the DPC have concurrent jurisdiction in the Delta's Primary Zone, while the Council and BCDC have concurrent jurisdiction in the Suisun Marsh. The DPC and BCDC must ensure that local land use planning is consistent with their own laws and plans, and must also certify that any covered actions that they carry out or approve, such as updating their plans, are consistent with the Delta Plan (see Table 5-1).

The Council's Role

The Legislature has declared that existing developed uses and future developments that are carefully planned and developed consistent with Delta Reform Act policies are essential to Californians' economic and social well-being, especially those who live or work in the Delta. The Delta Reform Act includes six goals for managing land use (Water Code section 85022(d)):

> (1) *Protect, maintain, enhance, and, where feasible, restore the overall quality of the Delta environment and its natural and artificial resources.*
>
> (2) *Ensure the utilization and conservation of Delta resources, taking into account the social and economic needs of the people of the state.*

State Agencies with Land Use Jurisdiction in the Delta

TABLE 5-1

State Agency	Law	Plan
Delta Stewardship Council	Sacramento-San Joaquin Delta Reform Act of 2009	Delta Plan
Delta Protection Council	Delta Protection Act of 1992	Delta Land Use and Resource Management Plan for the Primary Zone of the Delta
San Francisco Bay Conservation and Development Commission	McAteer-Petris Act of 1965, Suisun Marsh Preservation Act of 1977	San Francisco Bay Plan, Suisun Marsh Protection Plan

> *(3) Maximize public access to Delta resources and maximize public recreational opportunities in the Delta consistent with sound resources conservation principles and constitutionally protected rights of private property owners.*
>
> *(4) Encourage state and local initiatives and cooperation in preparing procedures to implement coordinated planning and development for mutually beneficial uses, including educational uses, in the Delta.*
>
> *(5) Develop new or improved aquatic and terrestrial habitat and protect existing habitats to advance the goal of restoring and enhancing the Delta ecosystem.*
>
> *(6) Improve water quality to protect human health and the environment consistent with achieving water quality objectives in the Delta.*

Goals 2, 3, and 4 are addressed in this chapter.

In addition, Water Code section 85305(a) provides, in part:

> *The Delta Plan shall attempt to reduce risks to people, property, and state interests in the Delta by promoting…appropriate land uses.*

Water Code section 85022(a) directs "state and local land use actions identified as covered actions pursuant to section 85057.5 be consistent with the Delta Plan" and that the section's "findings, policies, and goals apply to Delta land use planning and development." Thus, the Council's role in reviewing land use actions is to consider the full range of State interests in the Delta, including the economic and social well-being of Californians, environmental protection, use and conservation of resources, public access and recreation, habitat restoration and enhancement, water quality, and flood protection.

The DPC's Role

The DPC *Land Use and Resource Management Plan for the Primary Zone of the Delta* (2010) guides land uses in the Primary Zone. Local government general plans must be consistent with the DPC's land use and resource management plan. Local government land use actions may be appealed to the DPC for review of consistency with the land use and resource management plan. Chapter 2 describes the special role that the Delta Reform Act gives to the DPC to review and comment on significant projects or programs, such as ecosystem restoration or flood control projects, under consideration by the Council. The referral of projects to DPC for its review and comment and the membership of the DPC chair on the Council assure that the Delta communities will have a voice concerning actions' effects on existing and planned uses of the Delta.

The DPC's management plan states these goals for land use in the Primary Zone (DPC 2010):

> *Protect the unique character and qualities of the Primary Zone by preserving the cultural heritage, strong agricultural/economic base, unique recreational resources, and biological diversity of the Primary Zone. Direct new non-agriculturally oriented non-farmworker residential development within the existing unincorporated towns (Walnut Grove, Clarksburg, Courtland, Hood, Locke, and Ryde).*
>
> *Encourage a critical mass of farms, agriculturally-related businesses and supporting infrastructure to ensure the economic vitality of agriculture within the Delta.*

DPC's management plan also acknowledges the importance of balancing urban development with the protection of agriculture and other rural lands (DPC 2010):

> *The periphery of the Delta is undergoing rapid urbanization associated with substantial population growth. Current and future population growth increases the demand for developable land, particularly in areas near the Bay area, Stockton, and Sacramento. This demand results in the conversion of open space, primarily agricultural land, to residential and commercial uses. Increasing concern exists regarding the potential for urbanization and projects in the Secondary Zone to impact the Primary Zone.*

Thus, the DPC's role in land use review is primarily to protect agricultural land, recreational uses, and biological diversity in the Delta's Primary Zone from urban development, direct most residential development within existing towns, and ensure the economic vitality of Delta agriculture.

BCDC's Role

The BCDC was established by the McAteer-Petris Act in 1965. The agency prepared the *San Francisco Bay Plan* to guide the conservation of the Bay's natural resources and development of its shoreline. In 1977, BCDC's authority was expanded to protect wildlife use and retain biological diversity of the Suisun Marsh under the Suisun Marsh Preservation Act. With respect to land use, the Suisun Marsh Preservation Act (Public Resources Code section 29003(e) and (f)) calls for:

- Development and implementation of plans and policies to protect the marsh from degradation by excessive human use
- Definition and establishment of a buffer area consisting of upland areas that have high wildlife values themselves and also contribute to the integrity and continued wildlife use of the wetlands within the marsh

BCDC's *Suisun Marsh Protection Plan* (SMPP) guides land use and development in the Marsh (BCDC 1976). The SMPP designates an 89,000-acre primary management area of waterways, including Suisun, Honker, and Grizzly bays, tidal marshes, and managed wetlands; and a buffer zone of upland grasslands and agricultural land composing a 22,500-acre secondary management area. Both the Bay Plan and the SMPP apply to Suisun Marsh, and the SMPP controls if there is a conflict. BCDC also is the federally designated State coastal management agency for the San Francisco Bay segment of the California coastal zone. The federal Coastal Zone Management Act (CZMA) empowers BCDC to ensure that federal projects and activities are consistent with BCDC's laws and policies. A marsh development permit from BCDC is required to place fill, dredge, construct a structure, substantially change land use, subdivide property, or grade land in the wetlands and waterways of the Suisun Marsh.

BCDC retains planning and permitting authority in the primary management area of the Marsh, but shares authority in the secondary management area with local government agencies and special districts. The Suisun Marsh Preservation Act authorizes BCDC to delegate authority to issue marsh development permits to local agencies and special districts with jurisdiction in the marsh after BCDC has certified that their components of the Suisun Marsh Local Protection Program (LPP) are consistent with the Suisun Marsh Preservation Act and the SMPP. BCDC first certified all the components of the LPP in the early 1980s. LPP components can be amended only after BCDC holds a public hearing and votes for recertification. Permits granted by local governments for projects in the secondary management area under the authority of their LPP component may be appealed to BCDC.

Thus, BCDC's role in the Suisun Marsh is to protect the unique natural resources of the Suisun Marsh from the potential adverse effects of development by directly regulating land use in the primary management area of the marsh and working with local government to regulate land use in the secondary management area.

Other Agency Jurisdictions

Land use and development in the Delta are also affected by other State and federal agencies. The State Lands Commission has jurisdiction over hundreds of miles of waterways in the Delta, and issues leases for in-stream structures and uses. The Central Valley Flood Protection Board issues permits to encroach in floodways and State flood management facilities. The State and regional water quality control boards control discharges from development to public waters. The California Department of Fish and Wildlife (DFW) regulates projects that affect waterways or habitats of State-listed endangered or rare species.

Among federal agencies, FEMA has a significant effect in the region by establishing floodproofing standards for new development in communities that participate in its National Flood Insurance Program. The U.S. Army Corps of Engineers oversees the filling of public waters and wetlands. The U.S. Fish and Wildlife Service and the National Marine Fisheries Service regulate development that affects essential fish habitat or federally listed endangered or rare species. Some Delta landowners see these complex rules as a barrier to the development and use of private land. As described in Chapter 2, the Delta Plan Interagency Implementation Committee will improve coordination among regulatory agencies to ease some of these barriers.

Minimizing Land Use Conflicts

Poorly sited or designed development can also encourage additional people to place their lives and property at risk as well as restrict ecosystem restoration opportunities (see Chapter 4 and Chapter 7). Many uses are already in hazardous locations. For example, about 116,000 residential structures are located in the 100-year floodplain of the Delta, mostly near Sacramento, West Sacramento, and Stockton. Almost 8,000 residences are below mean higher high water (DWR 2008). Land use planning is complicated by the prospect of rising sea levels and increased flooding that may accompany climate changes. Some necessary water facilities, ecosystem restoration projects, or flood management facilities may need to be located on farmlands or in other locations that are inconsistent with local land use plans. State and federal agency projects are not required to secure approvals from local governments or the DPC, but nevertheless should avoid conflicts with existing and planned land uses when feasible. These projects can alter scenic views, make noise, create conflicts with adjoining land uses, generate traffic, or disrupt transportation routes if not planned carefully. Fully considering local resident views and local government positions can minimize misunderstandings, reduce avoidable conflicts, and build trust and cooperation.

The Delta's Economy

This section provides an overview of the primary sectors that make up the Delta economy. The Delta's economy is primarily urban and service oriented. The Delta is a diverse, growing, and economically integrated region that in many respects is outperforming the state as a whole. Transportation, warehousing, and utilities are important sectors. Construction, housing, and real estate are also important, but have declined with the recent recession. Retail, education, health care, and accommodations are the top employment sectors. The Primary Zone is less diverse, and depends on agriculture and, to a lesser extent, recreation and tourism. Stockton, Sacramento, and other nearby urban areas provide employment for professionals who commute from the Primary Zone, and less-skilled workers commute into the Primary Zone to jobs in agriculture and food processing.

Agriculture and the Delta's Economy

The total value of Delta crops was approximately $702 million in 2009. Truck and vineyard crops account for 54 percent of crop revenues on 18 percent of acreage. The top five Delta crops in terms of value were (1) processing tomatoes, (2) wine grapes, (3) corn, (4) alfalfa, and

(5) asparagus. The highest per-acre values in the Delta come from truck crops mainly situated in the southern Delta and deciduous crops principally located in the northern Delta. Table 5-2 summarizes top crops by gross value and acreage.

Top Five Crops in the Delta

TABLE 5-2

Position (2009)	By Gross Value	By Acres Grown
1	Tomatoes	Corn
2	Wine Grapes	Alfalfa
3	Corn	Tomatoes
4	Alfalfa	Wheat
5	Asparagus	Wine Grapes

Source: DPC 2012b

When related value-added manufacturing such as wineries, canneries, and dairy products are included, the total economic impact of Delta agriculture is 13,179 jobs, $1.059 billion in value added, and nearly $2.647 billion in economic output in the five Delta counties. Including value-added manufacturing, the statewide impact of Delta agriculture is 25,125 jobs, $2.135 billion in value added, and $5.372 billion in economic output (DPC 2012b).

See the Agriculture in the Delta section for a more detailed description of agriculture and its contribution to the Delta's way of life and economy.

The Delta's Recreation and Tourism Economy

Recreation and tourism are important contributors to the Delta's economy. DPC's ESP estimates that Delta recreation and tourism support 3,000 jobs with $100 million in wages in the Delta counties; $312 million in direct expenditures in the Delta by anglers, hunters, boaters, picnickers, campers, hikers, bicyclists, visitors driving for pleasure, and others who recreate in parks, wildlife areas, trails, or roadways; and a total of $175 million in value added to the regional economy. Statewide, Delta recreation and tourism support 5,200 jobs and contribute $348 million in value added.

Despite these significant contributions, the Delta's recreation and tourism economy has been relatively flat since the 1990s. The recreation and tourism sectors suffer from limited recognition and understanding of the Delta, and the lack of an overall marketing strategy for the region. Brannan Island State Recreation Area, the best improved State park, is scheduled to close due to budget constraints. Many other public lands lack facilities for visitors. Motor boat registrations have declined in the region. Participation in fishing and hunting has declined also. Private-sector recreation and tourism businesses are stagnant, with employment unchanged over 2 decades and little investment in new facilities. Inadequate levees leave key visitor attractions, including the legacy communities, at risk, as described in Chapter 7. Flood risks, flood insurance, and difficulties in designing attractive but floodproof visitor facilities hinder new investment in recreation and tourism businesses.

Other Contributors to the Delta Economy

The Delta's infrastructure not only supports its residents and businesses, but also includes facilities that transport people and products through the Delta from the Sierra on the east to the Bay Area on the west, or from the Sacramento Valley on the north to the San Joaquin Valley on the south. The Delta's economy benefits from the surface transportation, utilities, and other infrastructure that crisscross the Delta to serve local needs, provide access to regional urban markets, and, in turn, link the Delta's economy to national and global markets.

The Delta's most recognizable infrastructure components are its levees, which are described in Chapter 7. Key transportation corridors include Interstates 80, 5, and 205; State Routes 4, 12, and 160; and railroads operated by Union Pacific, Burlington Northern Santa Fe, Amtrak, and the Altamont Commuter Express. County roads are important for transporting crops to market and for local circulation.

The ports at Stockton and West Sacramento are served by deep water shipping channels that the U.S. Army Corps of Engineers maintains along the San Joaquin and Sacramento rivers, and the Sacramento Deep Water Ship Channel. These ports connect to San Francisco Bay and ultimately to the Pacific Ocean, providing a valuable asset to Delta communities. Rice and other crops grown in the Central Valley and other products are exported across their docks, and fertilizer and other bulk commodities are imported. The Maritime Highway Corridor is a recent initiative to expand maritime traffic between the Delta ports and the Port of Oakland, in part to reduce truck travel and its air quality impacts. Areas for water-dependent industries are located in Collinsville, Rio Vista, Pittsburg, and Antioch, where they benefit from the Delta's abundant and high-quality water.

Other infrastructure in the Delta includes water, drainage, and wastewater treatment facilities. Stockton and Sacramento draw drinking water at least partly from the Delta and discharge wastewater there. The Delta is the site of forebays, pumps, and water control structures of the Central Valley Project and State Water Project, as described in Chapter 3. Aqueducts and other facilities serving the East Bay Municipal Utility District, the Contra Costa Water District, and other areas are located in the Delta. Natural gas wells in the Delta fuel power plants and other energy uses. Wind turbines and other renewable power sources also are located in the Delta. Electric transmission lines and fuel pipelines cross the Delta to carry energy to energy users. Communications towers support broadcasting and telecommunications. These facilities need to be planned carefully to avoid conflicts with water supply, ecosystem restoration, or flood management facilities, and existing and planned land uses.

Delta Investment Fund

In 2009, the Legislature established a Delta Investment Fund in the State Treasury (Public Resources Code section 29778.5). DPC's ESP recommends forming a regional agency to manage the fund, and to implement and facilitate economic development efforts, either through expansion of the DPC's authority or creation of a joint powers authority composed of local governments.

Agriculture in the Delta

Agriculture is among the qualities that define the Delta as a place. This section provides additional detail about the role of agriculture and discusses issues such as subsidence and water quality that must be considered in policy making. The Delta's initial reclamation created farmland, and ongoing maintenance of its levees and water controls allows for continued farming in the region. Agriculture dominates the Delta landscape, as shown on Figure 5-3, and provides the setting for Delta residents' communities, homes, and job sites. Agriculture benefits from the Delta's productive soils, special climate, and abundant water. Delta farms provide a local source of nutritious food and forage for nearby dairies. Farming, food processing, and related industries contribute significantly to the economy, particularly in the Delta's Primary Zone, where they predominate economic output, employment, and value-added activities. Characteristic local crops, such as pears, asparagus, and dried beans, are celebrated at annual festivals and county fairs.

Agriculture in the Delta depends on high-quality farmland. Prime farmlands with the best soils comprise about 400,600 acres, close to 85 percent of all farmland in the Delta. Another 101,760 acres are unique farmland, farmland of statewide or local importance, or farmland of potential local importance (DOC 2009). Because of the fertile peat soils and the moderating marine influence, Delta agriculture's per-acre yields are almost 50 percent higher than the state's average (Trott 2007). As described in Chapters 3 and 4, reliable, abundant fresh water is also an essential contributor to Delta agriculture.

Agricultural Land Use in the Delta

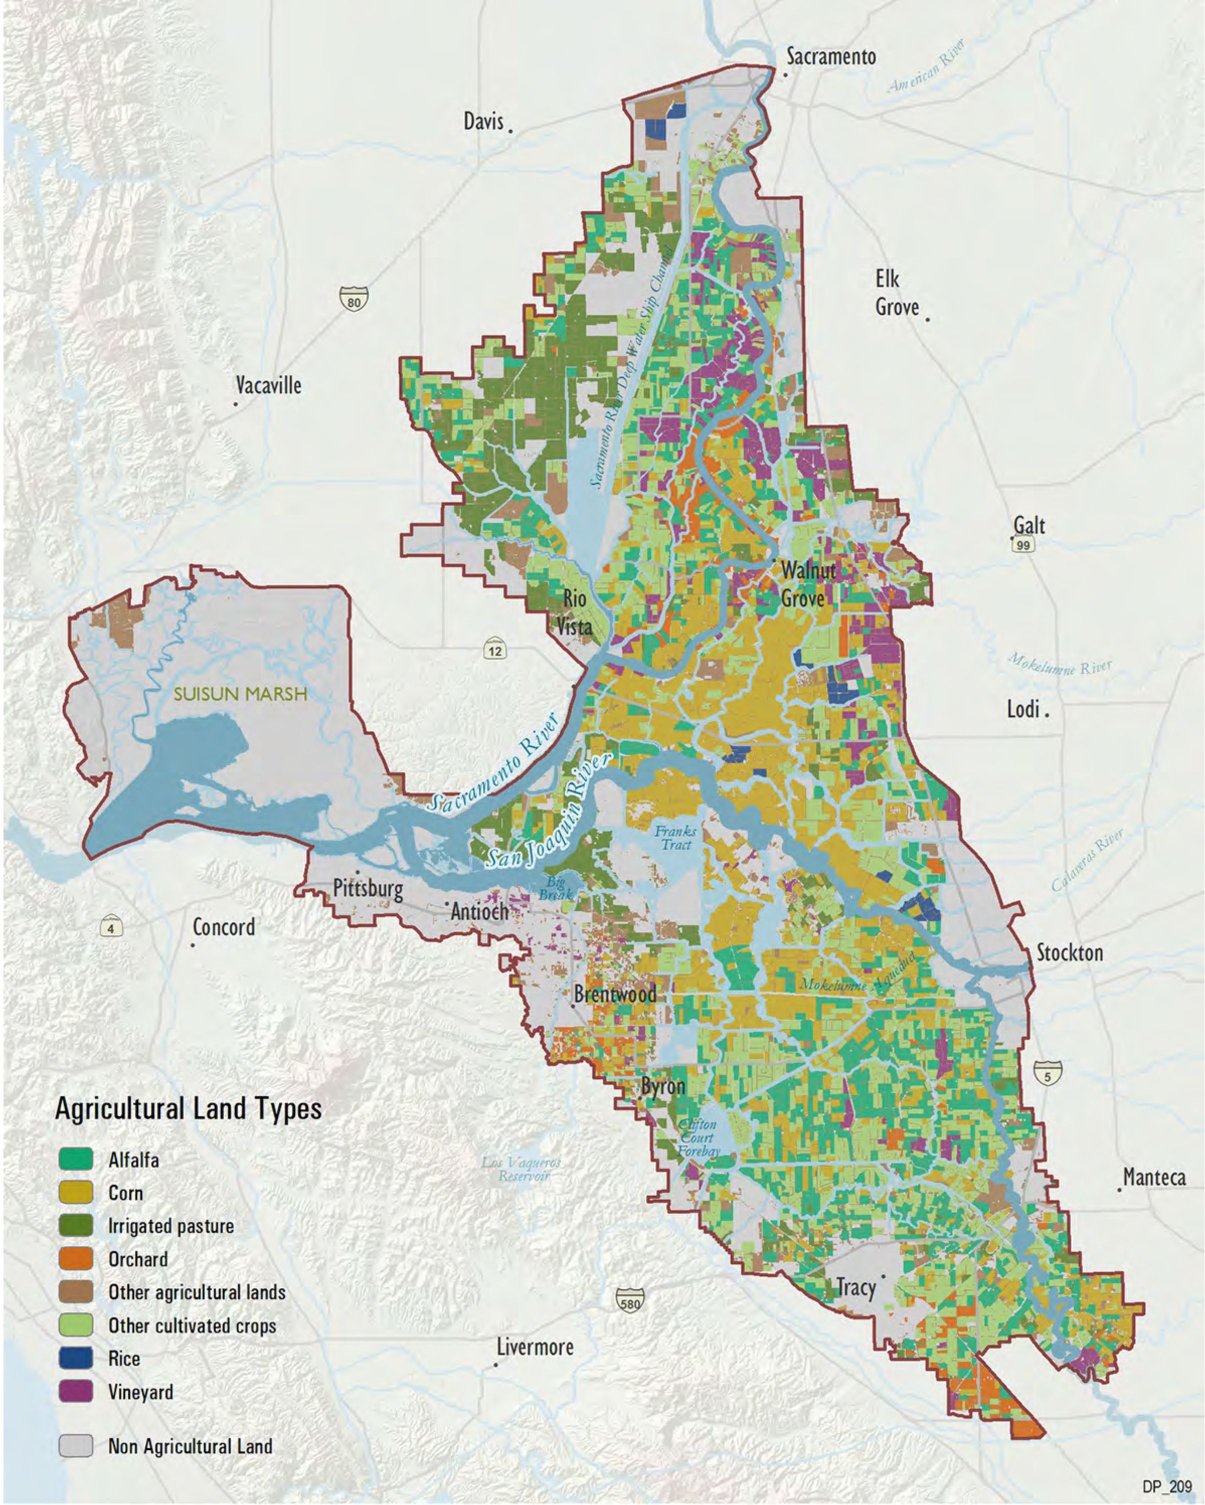

Figure 5-3 *Source: DOC 2008*

Field crops and pasture cover most of the Delta agricultural acreage. In 2010, about one-fourth of farmland in the Delta was corn, much of which is harvested as silage and used in the dairy industry. Alfalfa, the second most widely planted crop, covered about 20 percent of the Delta's farmland. Together, these croplands comprise about 10 percent of the irrigated acreage supporting California's dairy industry. Barley, wheat, and oats were planted on about 69,000 acres. About 41,000 acres of irrigated pasture are used by livestock. Truck crops, including processing tomatoes, asparagus, cucumbers, potatoes, pumpkins, and melons, covered nearly 52,500 acres. Almost 31,000 acres support vineyards. Orchards of pears, almonds, walnuts, and cherries grow on about 17,000 acres (DPC 2012b).

The DPC ESP forecasts that high-value crops, including truck, deciduous, and vineyard crops, are likely to increase in coming decades, potentially increasing farm incomes and economic output. Lower value crops, including field and grain crops, are likely to decline. Some traditional Delta crops are losing markets due to changing consumer preferences and competition from other regions. For example, the Bartlett pear market peaked around World War I, when 50 percent of all Bartletts were produced in California, mainly in the Delta. Until 1930, the Delta was also the world's asparagus capital, producing 90 percent of the globe's production (DPC 2011). Today, a mere 7,200 acres of asparagus fields remain. But growth of wine grapes and other crops, and expansion of local crop processing, particularly winemaking, could enhance agriculture's contribution to the Delta's economy (DPC 2012b). Urban development, ecosystem restoration, or flood control facilities that take farmland out of production could hasten the decline of agriculture.

Value is added to Delta crops when they are processed for ease of use or shipment. Examples include food and beverage manufacturing, such as the tomato canneries or sugar processors that were prominent twentieth century Delta businesses. Today's opportunities include winemaking or emerging sectors such as olive pressing. Special local markets that serve consumers in the Delta counties or Bay Area, such as farm-to-school programs or community-supported agriculture, also may provide new markets for some Delta crops. Facilities that improve the region's capacity to aggregate and distribute its crops to these local markets may enhance Delta agriculture (SACOG 2011). Consistent interpretation and application of regulations about food processing and distribution could help local producers and distributors establish facilities (Sumner and Rosen-Molina 2011).

Protecting Productive Farmlands

Although agriculture is the principal land use in the Delta, the total area of agricultural lands (including fallow lands) in the combined Delta and Suisun Marsh area has declined from about 549,420 acres in 1984[1] to 460,450 acres in 2008, and the percentage of agricultural land has decreased from about 65 percent of this combined area in 1984 to about 55 percent in 2008 (DOC 1984, DOC 1988, DOC 1990, DOC 2008). An additional 28,000 acres of farmland may be lost in the near future under current local government general plans. The Delta Plan acknowledges this loss since it focuses growth within existing city boundaries. However, any further loss of farms to urban development is unacceptable. The continued viability of agriculture in the Delta will require the protection of sufficient farmland and fresh water to support commercially viable operations and provide ways for agriculture to coexist with habitat restoration. Policies DP P1 and DP P2 acknowledge the importance of protecting these lands. The DPC and local governments play key roles in the protection of these lands.

The loss of some farmland to urbanization, habitat, and flooding is inevitable, the DPC ESP concludes; but continued shifts to higher-valued crops and value-added activities, as well as planning restoration in appropriate locations, may help compensate if land loss is not too great. As described in Chapter 4, elevations, locations, and other factors are key

---

[1] Data for Sacramento and San Joaquin counties were not available in the 1984 DOC report; thus, data for these counties were taken from the 1988 and 1990 reports, respectively.

determinants of the optimal sites for ecosystem restoration. When these restoration areas include farmlands, achieving the coequal goals of restoring the Delta ecosystem and improving water supply reliability may make some loss of productive agricultural lands unavoidable. Some conveyance alternatives could take farmland out of production, too. Improving flood control facilities may also unavoidably affect some farmland.

Subsidence

The reclamation of Delta islands and their cultivation for agriculture initiated a process of land subsidence, mostly due to oxidation of peat soils, but also from wind erosion. Drainage and cultivation dried the saturated peat, reducing its volume by approximately 50 percent. Early cultivation practices also included burning, which further reduced the volume of the soil and altered its structure. Over time, long-term oxidation reduced about 2.6 to 3.3 billion cubic yards of these peaty soils to small particles and gases. As a result, much of the central Delta today is below sea level, with some islands 12 to 15 feet below sea level. Many islands now more closely resemble bowls surrounded by water, with high sides defined by levees and deep, hollowed-out bases. Although subsidence has slowed in some areas, other regions of the Delta continue to lose soil to oxidation and wind erosion at a rate of 5 to 15 tons/acre/year. It is projected that some areas of the Delta could subside an additional 2 to 4 feet by 2050 (Deverel and Leighton 2010), resulting in the loss of up to 350 to 500 million cubic yards of soil at a rate of 5 to 15 tons/acre/year (see Figure 5-4).

Land subsidence impairs Delta agriculture, not only because of soil loss, but also by increasing the difficulty of maintaining drainage systems and levees. As described in Chapter 7, subsidence makes levees less stable and increases flood risks. The costs to recover a flooded island could be great. Some suggest that many islands would cost more to reclaim after flooding than the value of the land for agriculture. In 1998, 4,200 acres of farmland were lost when Liberty Island flooded and was not reclaimed (Reclamation District 2093 2009). Other once-farmed islands that were not reclaimed after flooding include Big Break, Franks Tract, and Mildred Island (Suddeth et al. 2010).

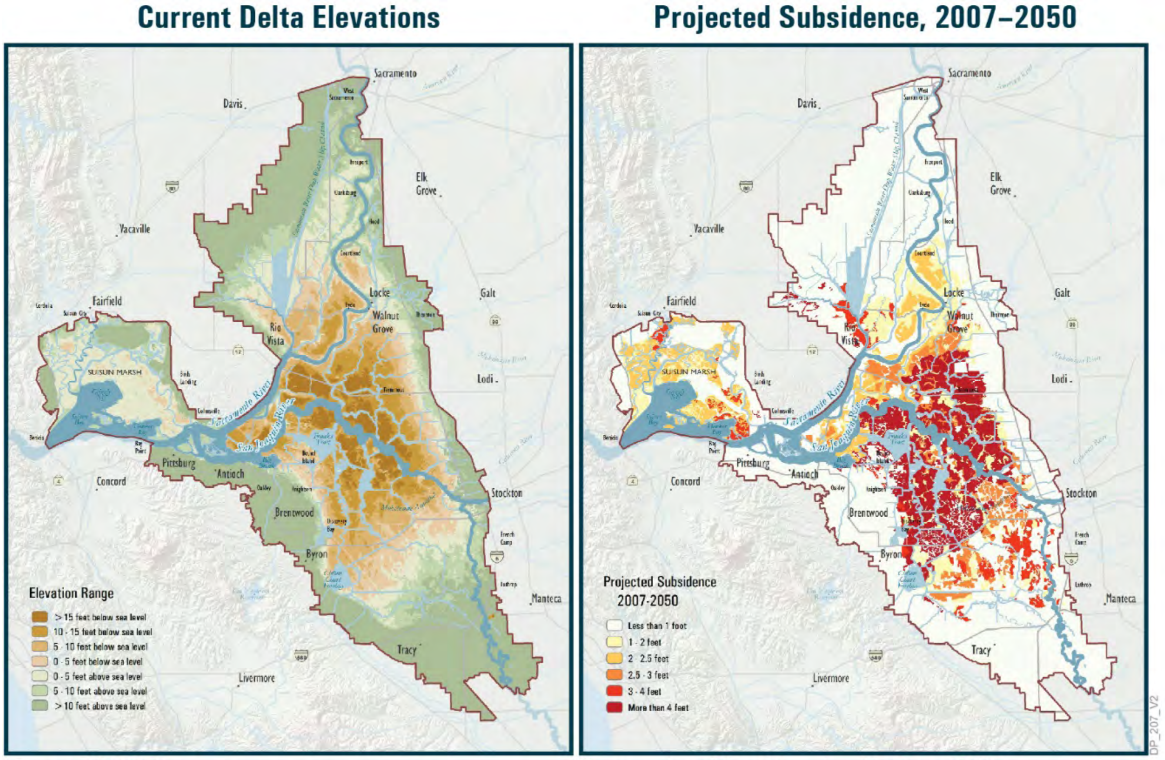
Oxidation of peat soils also liberates vast quantities of carbon dioxide (CO_2), contributing to global warming (Armentano 1980). Oxidation of the Delta's agricultural soils emits about 4.4 to 5.3 million tons of CO_2 annually (Delta Conservancy 2012). For comparison, a typical 500-megawatt coal-fired power plant emits 3 million tons of CO_2 per year.

The potential to retire croplands on deeply subsided islands and manage them to rebuild peat and sequester carbon is sometimes pondered as an alternative to continued farming (Armentano 1980). State and federal agency investigations of alternative land management practices show that soils can be rebuilt, reversing subsidence and sequestering carbon, with some appropriately managed activities, such as tule farming (Miller 2008). Recent actions by the California Air Resources Board, under the California Global Warming Solutions Act of 2006 (Health and Safety Code section 38500 et seq.), provide for the development of a carbon market program, whereby certain activities may be considered acceptable for providing offset credits. Although this program is still in its initial stages, future opportunities may exist for Delta farmers to gain offset credits for growing plants that promote subsidence reversal and sequester carbon.

Agriculture and Water Quality

The DPC's ESP provides scenarios for how potential declines in water quality that could accompany some water conveyance, ecosystem restoration, or water quality actions could affect Delta agriculture. The potential for the agricultural economy to grow in the Delta will depend, in part, on the protection of the Delta's abundant fresh water and the policy response. Chapter 6 contains a detailed discussion of water quality and the Council's strategies for water quality.

Subsidence in the Delta



Source: DWR 2009

Source: adapted from Deverel and Leighton 2010

Figure 5-4 Oxidation of peat soils through natural processes and human activities has caused the land elevation in the Delta to drop. Much of the central Delta is now at or below sea level. Future subsidence has been projected in these areas. As subsidence progresses, levees must be continually maintained, strengthened, and periodically raised to support increasing hydraulic stress.

Wildlife-friendly Agriculture

Agriculture has the potential to coexist with and even enhance restoration of the Delta ecosystem despite the conversion of some farmland to habitat. Techniques that integrate management of agriculture and wildlife habitat, often called "wildlife-friendly agriculture," include crop rotations that include soil-building crops or fallowing; integrated pest management to reduce pesticides; cover crops; the strategic use of permanent crops, such as pasture, to reduce soil disturbance and oxidation; and conservation tillage for field and row crops (Trott 2007). Some native species have adapted to using agricultural lands as habitat in place of tidal marshes, grasslands, and seasonal wetlands. Rice and other flood-irrigated crops support a range of wildlife, especially waterfowl, shorebirds, wading birds, and giant garter snakes. Swainson's hawk, other raptors, and coyote feed on small mammals and ground-nesting birds that inhabit alfalfa fields and other irrigated pastures. Waste grain also provides food for species such as ring-necked pheasant and greater sandhill crane (Trott 2007).

To support Delta agriculture and species recovery, farmers in the Delta are encouraged to implement management practices to maximize habitat values. Some U.S. Department of Agriculture (USDA) programs provide financial incentives for landowners to manage natural areas on their properties, including the Wildlife Habitat Incentives Program, the Environmental Quality Incentives Program, and the Conservation Reserve Program. The DFW, U.S. Fish and Wildlife Service, and Delta Conservancy also can assist landowners who want to enhance wildlife habitat.

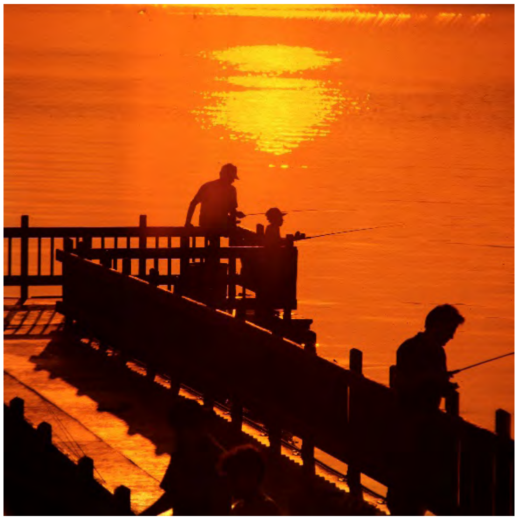
As described in Chapter 4, safe harbor agreements can assure these landowners that the presence of an endangered species on their property will not result in restrictions on activities on their land. Facilitating and creating standard rules for these agreements with Delta landowners may encourage more landowners to participate in conservation programs. Restoring wildlife and fish through wildlife-friendly agriculture can help achieve ecosystem restoration objectives while reducing the loss of farmland to habitat restoration.

Agritourism

Agritourism is another opportunity to add further value to the Delta economy from agricultural activities. Defined as recreational, educational, and other visits to working farms, agritourism is a small but fast-growing source of income for farms in the region and a growing segment of the Delta economy. In the Delta, agritourism destinations may include wineries, on-farm duck clubs, farm stands, and other places. Agritourism was estimated by USDA to generate $4 million in income for farms in the five Delta counties in 2007 (DPC 2012b). For farmers who choose to participate, agritourism can provide additional income, an opportunity to sell farm products directly to consumers, or alternative uses for unproductive lands or buildings. The Discover the Delta Foundation's Delta Discovery Center combines several agritourism functions, including a produce stand, wine sales, and interpretive features that teach people about the Delta's importance (Sumner and Rosen-Molina 2011).

Recreation and Tourism in the Delta

This section provides an overview of recreation and tourism in the Delta. DPC estimates that about 12 million activity days of recreation occur in the Delta annually (DPC 2012b). Recreational users originate from both within and outside the Delta. Visitors value the wide expanses of open land, interlaced waterways, historic towns, and the lifestyle offered by the Delta. The region's mix of land and water offers diverse recreation experiences and facilities, including fishing, boating, birdwatching, other nature activities, hunting, enjoying restaurants, campgrounds, picnic areas, and historic towns and buildings. Recreation also benefits from the Delta's open, agricultural landscape, with its scenic vineyards, orchards, and farmsteads. These are often backed by views of Mt. Diablo or the Montezuma Hills on the horizon, which provide a setting for outdoor photography, a scenic bike ride, or a drive along the Delta's roads. Special events draw visitors to taste local produce and wine, and learn about this unique place. These recreation opportunities are described in more detail in the DPC's ESP and in the Recreation Proposal that California State Parks submitted to the Council and DPC pursuant to Water Code section 85301(c)(1). Figure 5-5 shows the locations of State parks and other protected lands in the Delta. Figure 5-6 shows the variety and distribution of some of these opportunities in the Delta.



State Parks and Other Protected Lands

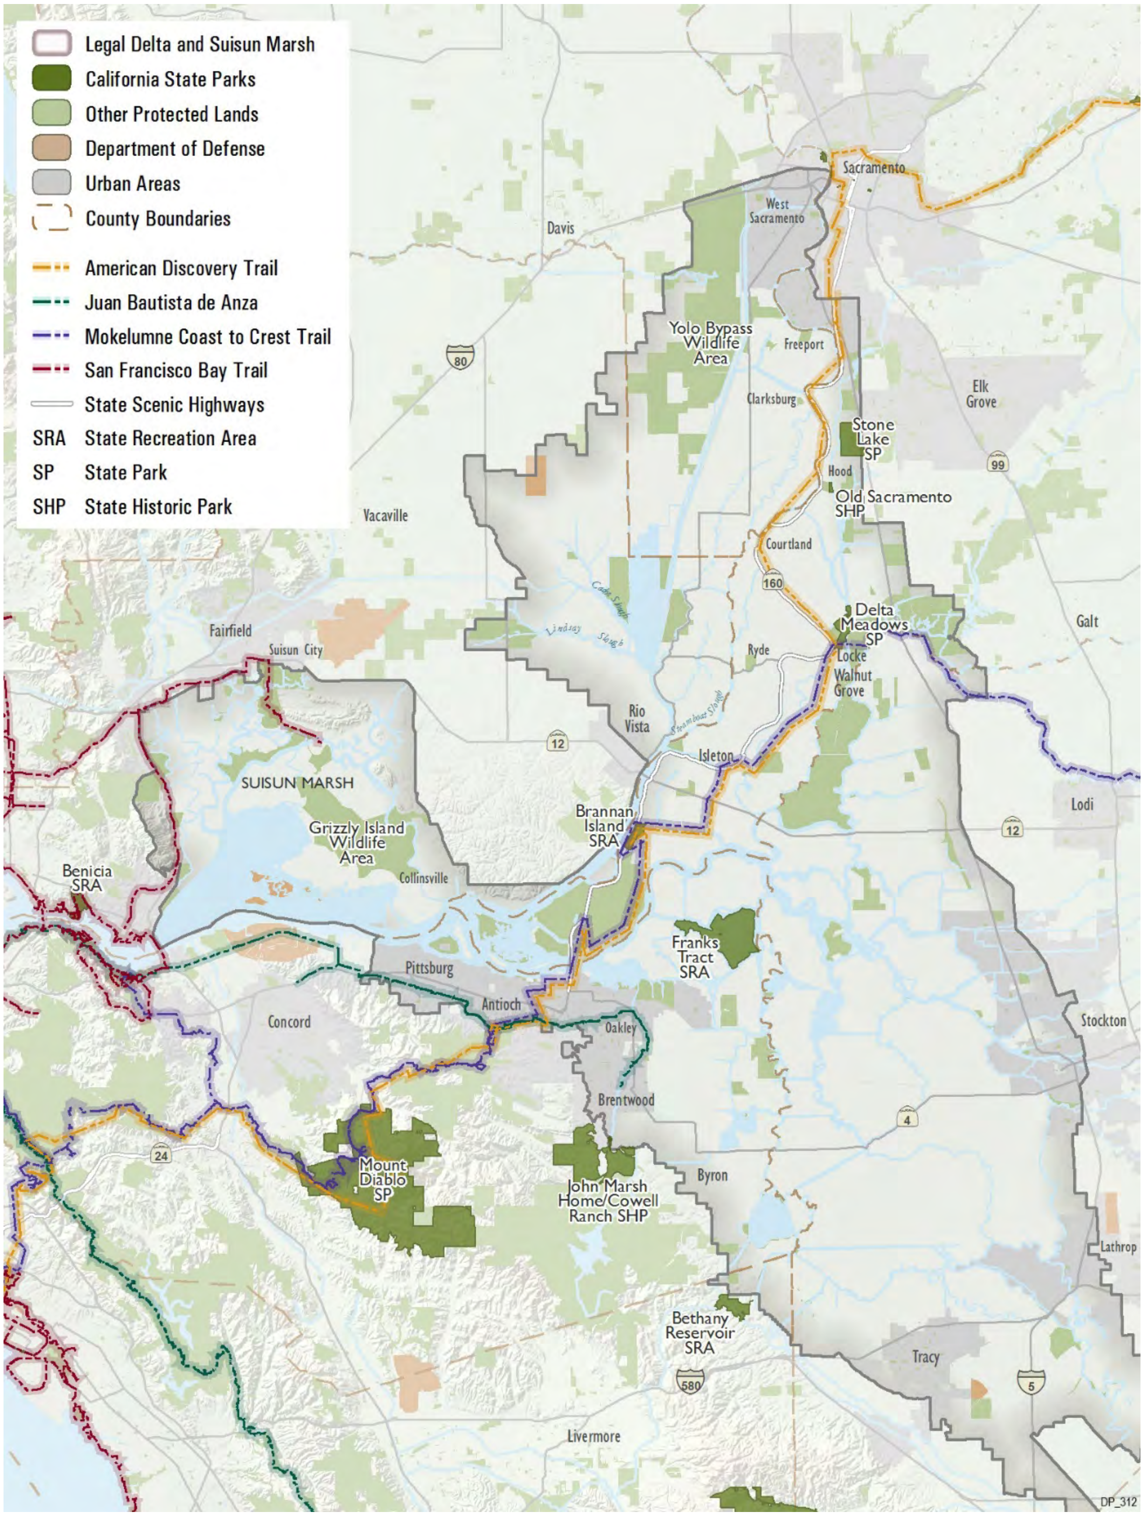


Figure 5-5 *Source: California State Parks 2011*

Major Delta Resources and Recreation

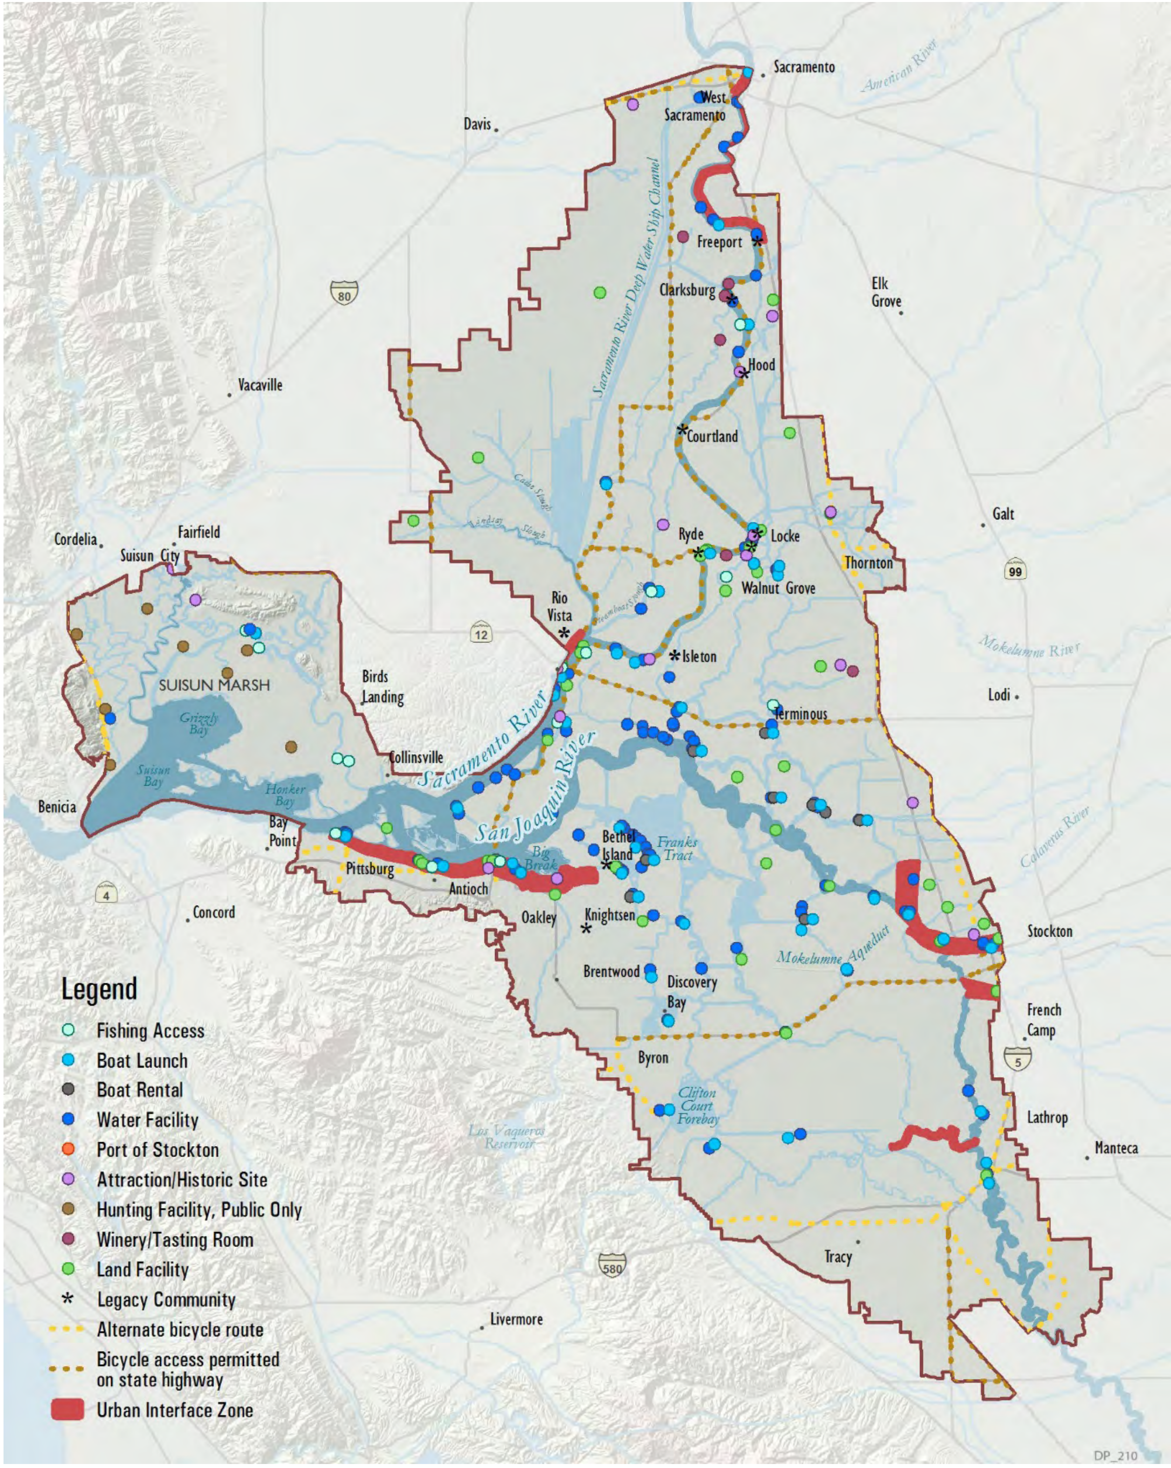

Figure 5-6

Sources: California Chambers and Visitors Bureau 2010, California Resources Agency 2007, DPC 2006, Discover the Delta Foundation 2010, California Department of Fish and Game 2009

The DPC ESP and the California State Parks Recreation Proposal both foresee opportunities to increase recreation and tourism in the Delta as the population of surrounding areas grows, especially with improved branding and marketing. Both reports emphasize improvements of "gateways" to the region on the Delta's urban edges and "base camps," focal points for visitors inside the Delta at destinations such as resorts, legacy communities, and parks. They also recommend diversifying dispersed outdoor recreation "adventures" at points of interest and activity areas for boaters, nature area visitors, and others. Ecosystem restoration, as described in Chapter 4, can enhance opportunities for nature-based recreation and boating, especially by nonmotorized boats, according to both reports.

The California State Parks Recreation Proposal recommends enhancing State parks and other State agencies' properties and programs to create a network of recreation areas in the Delta, and encourages improvement of public access along the shorelines of growing Delta communities, consistent with Water Code section 85022(d)(3). It recommends that recreation improvements be provided in new water management and habitat restoration projects unless they are inconsistent with the project purposes, in conformance with Water Code sections 11910–11915.5, or public safety. DPC's ESP also recommends that recreation facilities be included in ecosystem restoration projects when feasible. Additionally, the ESP emphasizes growing the tourism and recreation economy through private, visitor-serving businesses, and collaboration and partnerships between public- and private-sector recreation providers.

Future prospects for Delta recreation and tourism will be strongly influenced by decisions about the Delta ecosystem, water quality, levee improvements, and governance, including land use and environmental standards. The Bay Delta Conservation Plan (BDCP), Delta water quality plans, levee investments, and other decisions yet to be made can all significantly affect recreation and tourism.

Boating

Navigable waterways in the Delta and Suisun Marsh are available for public access and provide many recreational opportunities. Boating activities total more than 6.4 million visitor days annually, composed of 2.13 million annual boat trips with a projected growth to 8 million visitor days by 2020, according to the Department of Boating and Waterways. Almost 100 marinas, with more than 11,000 boat slips, and almost 60 launch ramp lanes support boating in the Delta and Suisun Marsh (DBW 2002). Popular activities include powerboating on the Sacramento and San Joaquin rivers, paddling sloughs and channels in canoes and kayaks, and sailing on the open water of Suisun and Honker bays. About 116,000 boats are registered in the five Delta counties, creating a large pool of potential recreationists (California State Parks 2011).

Public Recreation Lands

Public lands comprise about 10 percent of the Delta. State and local parks, State or national wildlife areas and refuges, ecological preserves, and other public lands provide important sites for relaxing outdoors, a family picnic, camping, and other outdoor recreation in the Delta. California State Parks owns three properties in the Delta: Brannan Island State Recreation Area and properties at Locke Boarding House-Delta Meadows and Stone Lakes. The DFW and the State Lands Commission also manage important State-owned recreation areas. The largest State ownerships are the California Department of Water Resources (DWR) lands on Sherman and Twitchell islands, which are available seasonally for hunting.

Table 5-3 summarizes the agency responsibilities, recreation-related opportunities, and examples of recreation facilities in the Delta managed by the State. City and county parks, including those of the East Bay Regional Park District, also provide important public recreation areas. These public lands are increasingly important for Delta recreation because privately owned riverbanks and levees, which comprise most of the Delta's shoreline, are increasingly posted to prevent trespass, reducing access to rivers and sloughs for bank fishing, nature observation, and outdoor relaxation.

State Agencies with Responsibility for Recreation in the Delta

TABLE 5-3

State Agency Name and Role	Recreation-related Facilities and Opportunities	Delta and Suisun Marsh Examples
California State Parks offers high-quality outdoor recreation and educational opportunities, protects natural and cultural resources, awards grants for local parks, and oversees the California Recreational Trails System.	Day-use picnic areas, campgrounds, marinas, trails, excursion railroads, interpretive services, heritage resource protection, restrooms	Brannan Island State Recreation Area, Old Sacramento State Historic Park, American Discovery Trail
California Department of Fish and Wildlife manages hunting and fishing; operates public lands for wildlife conservation, hunting, fishing, environmental education, and nature study; and encourages private conservation.	Ecological reserves, wildlife areas, boat launches, nature-based recreation and events, fish hatcheries	Woodbridge Ecological Reserve, Grizzly Island Wildlife Area, Clarksburg boat launch
California Department of Boating and Waterways provides public recreational boating facilities on public lands, marine patrol law enforcement, boating safety and clean and green education, and controls of aquatic invasive species.	Public boat launching facilities, public visitor docks, boat-in day use and overnight facilities, vessel pumpout facilities, floating restrooms, floating campsites	Antioch Marina, Brannan Island State Recreation Area, Sherman Island, Belden's Landing, Bethany Reservoir, and Rio Vista boat launch facilities
California Department of Transportation operates state highways, historic bridges, and ferries, and designates state scenic highways.	Scenic highways, ferries, historic bridges	State Highway 160, J-Mack Ferry, Steamboat Slough Bridge
California Department of Water Resources manages California's water resources, including State Water Project reservoirs, dams, land, and waterways available for recreation use.	Reservoirs, water conveyance infrastructure (canals, diversion sites, waterway flows), flood control projects, habitat management sites and facilities	Bethany Reservoir, Sacramento River flows, Fremont Weir, Suisun Marsh salinity control structure, Dutch Slough habitat restoration project
State Lands Commission has jurisdiction over hundreds of miles of waterways in the Delta and issues leases for instream recreation infrastructure.	Navigable waterways, submerged lands, dock and pier leases	Threemile Slough, Walnut Grove Public Dock

State Agencies with Responsibility for Recreation in the Delta

TABLE 5-3

State Agency Name and Role	Recreation-related Facilities and Opportunities	Delta and Suisun Marsh Examples
Sacramento-San Joaquin Delta Conservancy will implement ecosystem restoration, advance environmental protection, and support economic sustainability, including tourism and recreation.	Projects that enhance natural resources, cultural resources, or economic sustainability in a manner complementary to increased recreation, tourism, and environmental education	The Delta Plan, Bay Delta Conservation Plan, Economic Sustainability Plan, and Delta Conservancy Strategic Plan will guide projects
State Coastal Conservancy makes grants to purchase, protect, restore, and enhance coastal resources, including San Francisco Bay and Suisun Marsh, and to provide access to the shore.	Shoreline accessways, trails, habitat protection and restoration areas, farmland and open space protection	Rush Ranch protection, San Francisco Bay Area water trail, Marsh Creek stream restoration and trail
Delta Protection Commission adaptively manages the Delta's Primary Zone, including, but not limited to, agriculture, wildlife habitat, and recreation activities.	Heritage resource recognition and enhancement, agritourism program, regional trails	National Heritage Area feasibility study, Great California Delta Trail, Economic Sustainability Plan

Nature-based Recreation

Many recreation opportunities depend on the region's wildlife and fish, which support angling, nature observation, and hunting. Anglers pursue native fish, such as salmon and sturgeon, and introduced species such as striped bass, largemouth bass, and catfish. Some of the most visited public wildlife areas include the Yolo Bypass Wildlife Area, Lower Sherman Island, Calhoun and Acker Island, Stone Lakes National Wildlife Refuge, Cosumnes River Preserve, Solano County Land Trust's Jepson Prairie and Rush Ranch, and Suisun Marsh's wildlife management areas, including Grizzly Island and Joice Island. Hunting waterfowl is especially important in Suisun Marsh, most of which is managed by private duck clubs. Careful management of wildlife and fish is important to maintaining nature-based recreation, which can benefit from the restoration of fisheries and expansion of wildlife habitat.

Heritage Tourism

The Delta's legacy communities and other historic sites, from house museums to twentieth century industrial sites and weather-beaten marine facilities, attract history buffs and heritage tourists. Museums, nature centers, and interpretive programs draw visitors who want to learn about the Delta's natural and cultural resources. The region's productive farms and wineries, and its diverse ethnic heritage are attractions for food and wine tourism, and for community festivals and other special events. (Agritourism is discussed earlier in the Agriculture in the Delta section.)

Linking these areas and providing access to them are the Delta's waterways and roads. State Route 160 has a special role and provides visitors from metropolitan Sacramento and Contra Costa County with access to the Sacramento River, legacy communities, and the Delta's State parks. Its attractive rural landscape is reflected in its designation as a state scenic highway. California State Parks' Recreation Proposal recommends that the California Department of Transportation seek national scenic byway status for this route and prepare a scenic byway plan that would identify opportunities to improve signage, interpretation, and amenities for access, recreation, and nonautomobile circulation. A national scenic byway is a road recognized by the U.S. Department of Transportation for its archaeological, cultural, historic, natural, recreational, and/or scenic qualities. The program preserves and protects the nation's scenic but often less-traveled roads, and promotes tourism and economic development. Funding for byway-related projects is granted annually by the Federal Highway Administration. State Routes 4 and 12 are also important for recreational travel.

The American Discovery Trail, Mokelumne Coast-To-Crest Trail, and Great Delta Trail (Public Resources Code section 5852 et seq.) are State trails that can provide recreational access for bicyclists, hikers, and others. DPC's ESP and California State Parks' Recreation Proposal also recommend a system of water trails to guide boaters through the Delta's channels.

POLICIES AND RECOMMENDATIONS

The policies and recommendations presented in this section address the unique values that distinguish the Delta and make it a special region, and outline the Council's five core strategies for protecting and enhancing these values as follows:

- Designate the Delta as a special place worthy of national and state attention
- Plan to protect the Delta's lands and communities
- Maintain Delta agriculture as a primary land use, a food source, a key economic sector, and a way of life
- Encourage recreation and tourism that allow visitors to enjoy and appreciate the Delta and that contribute to its economy
- Sustain a vital Delta economy that includes a mix of agriculture, tourism, recreation, commercial and other industries, and vital components of state and regional infrastructure

Protecting the Delta also depends on the strategies to reduce flood and other risks, as detailed in Chapter 7.

Designate the Delta as a Special Place

Designating the Delta as a special place can build public recognition of the Delta and its unique resources. The DPC proposes to seek the Delta's designation as an NHA to recognize and promote "Delta-as-a-Place" and to cultivate appreciation and understanding of the Delta. The DPC recommends that the NHA include the legal Delta and Suisun Marsh, as well as adjoining areas in Rio Vista and the Carquinez Strait.

The proposed NHA's vision is "a regional network of partner sites, with interpretive/educational components, that will be linked where possible and serve as the primary attractions, on existing public properties or on private properties with the voluntary consent and involvement of the landowners." The NHA's goals are to "brand the Delta as a region of national significance to educate the public about 'Delta-as-a-Place,' and build more support for preserving, protecting, and enhancing the Delta." Other goals relate to economic development, public access, historic preservation, interpretation, and more.

Although State Route 160 is already recognized as a state scenic highway, national scenic byway status under the U.S. Department of Transportation and a scenic byway plan would provide opportunities to improve signage, interpretation, and amenities for access, recreation, and nonautomobile circulation. The byway program would qualify the route for special funding from the Federal Highway Administration.

Problem Statement

Because the Delta is different, it is sometimes unappreciated and misunderstood. Without a clear message about the Delta and its importance, the region and its resources can suffer from inattention or misuse. If the Delta's unique cultural, recreational, and agricultural values are not recognized, they are unlikely to be protected and enhanced.

Policies

No policies with regulatory effect are included in this section.

Recommendations

DP R1. Designate the Delta as a National Heritage Area

The Delta Protection Commission should complete its application for designation of the Delta and Suisun Marsh as a National Heritage Area, and the federal government should complete the process in a timely manner.

DP R2. Designate State Route 160 as a National Scenic Byway

The California Department of Transportation should seek designation of State Route 160 as a National Scenic Byway, and prepare and implement a scenic byway plan for it.

Plan to Protect the Delta's Lands and Communities

Protecting the Delta's lands and communities involves a multipronged policy approach. In the coming years and decades, the Delta will face increasing pressures from a growing population, changes in commodity markets, and changes in climate and sea level that will require flexibility and adaptation.

Some changes will be driven by the Delta's role in California's water systems, and they will be required to meet statewide goals of restoring the Delta's ecosystem and improving water supply reliability. These and other changes will shape how the Delta's communities and history are preserved, guide new development, affect recreation and tourism, and influence agriculture, business expansion, and economic development.

The policies and recommendations below reflect the Council's approach to fostering land uses and development that are resilient to these changes, reduce risks to people and property, adjust to changing conditions, and recover readily from distress. Protecting the Delta also depends on sustaining its economic vitality and maintaining the region as a desirable place to live, do business, and visit.

The maps that the following policies and recommendations reference are based on the best information available to the Council, but they may not precisely match either the built environment or local government land use plans. Where uncertainty exists with respect to the boundaries of areas referenced in these policies, the following rules should be considered in making determinations:

- The areas depicted should be assumed to generally follow parcel lines or other major landmarks, such as a road or highway, or river and stream.
- Local government general plans, including their land use diagrams, in effect at the time of the Delta Plan's adoption, may be consulted.

Problem Statement

Poorly sited or designed projects can detract from the values that contribute to the Delta's distinctive character, including its primarily rural, agricultural landscape; conflict with established uses, including farming and tourism; reduce opportunities for ecosystem restoration; or increase flood risks. By limiting significant new development to areas currently designated for development in cities, their SOIs, and unincorporated towns, the Council intends to foster a land use pattern that enhances the Delta's unique sense of place by protecting agriculture and the open, rural landscape while reducing risks to people and property. Outside the urban areas and towns mentioned above, in areas designated as agriculture, open space, recreation, natural preserve or marsh, or public/quasi-public, minor projects that are consistent with local land use designations, such as farmworker housing in areas designated as agriculture, are also appropriate. Similar limitations are already in place in the Primary Zone of the Delta, where the Delta Protection Act requires that new development must be consistent with the DPC's Land Use and Resource Management Plan. Additional protections for the Secondary Zone are needed. Diligent local *implementation of State law regarding flood protection in urban, urbanizing, and rural lands, and the National Flood Insurance Program will provide complementary flood protection benefits. New residential subdivisions, if any, in rural areas will also need to include adequate flood protection, as described in RR P2.*

Therefore, outside the urban areas and towns mentioned above, in areas that are designated as agriculture, open space, recreation, natural preserve or marsh, or public/quasi-public, the Council intends to enable counties to move forward with approval of minor projects that are consistent with these designations, such as farmworker housing in areas designated as agriculture. However, any proposals to site new residential development in rural areas will need to include adequate flood protection, as described in RR P2.

Careful planning for development in legacy communities is needed to protect their unique character and overcome barriers to investment. The Delta's urban areas will also continue to need sites for housing, employment, and businesses, supported by adequate roads and other infrastructure. Water management facilities, ecosystem restoration actions, and flood control projects will need to be accommodated in the Delta, too. Avoiding condemnation of property for water management, ecosystem restoration, and flood management facilities, when feasible, can promote better relations with Delta residents and local governments.

Policies

The appendices referred to in the policy language below are included in Appendix B of the Delta Plan.

DP P1. Locate New Urban Development Wisely

(a) New residential, commercial, and industrial development must be limited to the following areas, as shown in Appendix 6 and Appendix 7:

(1) Areas that city or county general plans as of May 16, 2013, designate for residential, commercial, and industrial development in cities or their spheres of influence;

(2) Areas within Contra Costa County's 2006 voter-approved urban limit line, except no new residential, commercial, and industrial development may occur on Bethel Island unless it is consistent with the Contra Costa County general plan effective as of May 16, 2013;

(3) Areas within the Mountain House General Plan Community Boundary in San Joaquin County; or

(4) The unincorporated Delta towns of Clarksburg, Courtland, Hood, Locke, Ryde, and Walnut Grove.

(b) Notwithstanding subsection (a), new residential, commercial, and industrial development is permitted outside the areas described in subsection (a) if it is consistent with the land uses designated in county general plans as of May 16, 2013, and is otherwise consistent with this Chapter.

(c) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers proposed actions that involve new residential, commercial, and industrial development that is not located within the areas described in subsection (a). In addition, this policy covers any such action on Bethel Island that is inconsistent with the Contra Costa County general plan effective as of May 16, 2013. This policy does not cover commercial recreational visitor-serving uses or facilities for processing of local crops or that provide essential services to local farms, which are otherwise consistent with this Chapter.

(d) This policy is not intended in any way to alter the concurrent authority of the Delta Protection Commission to separately regulate development in the Delta's Primary Zone.

23 CCR Section 5010
NOTE: Authority cited: Section 85210(i), Water Code.
Reference: Sections 85020, 85022, 85300, 85302, and 85305, Water Code.

DP P2. Respect Local Land Use When Siting Water or Flood Facilities or Restoring Habitats

(a) Water management facilities, ecosystem restoration, and flood management infrastructure must be sited to avoid or reduce conflicts with existing uses or those uses described or depicted in city and county general plans for their jurisdictions or spheres of influence when feasible, considering comments from local agencies and the Delta Protection Commission. Plans for ecosystem restoration must consider sites on existing public lands, when feasible and consistent with a project's purpose, before privately owned sites are purchased. Measures to mitigate conflicts with adjacent uses may include, but are not limited to, buffers to prevent adverse effects on adjacent farmland.

(b) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers proposed actions that involve the siting of water management facilities, ecosystem restoration, and flood management infrastructure.

23 CCR Section 5011
NOTE: Authority cited: Section 85210(i), Water Code.
Reference: Sections 85020, 85022, 85054, 85300, and 85305, Water Code.

Recommendations

DP R3. Plan for the Vitality and Preservation of Legacy Communities

Local governments, in cooperation with the Delta Protection Commission and Delta Conservancy, should prepare plans for each community that emphasize its distinctive character, encourage historic preservation, identify opportunities to encourage tourism, serve surrounding lands, or develop other appropriate uses, and reduce flood risks.

DP R4. Buy Rights of Way from Willing Sellers When Feasible

Agencies acquiring land for water management facilities, ecosystem restoration, and flood management infrastructure should purchase from willing sellers, when feasible, including consideration of whether lands suitable for proposed projects are available at fair prices.

DP R5. Provide Adequate Infrastructure

The California Department of Transportation, local agencies, and utilities should plan infrastructure, such as roads and highways, to meet needs of development consistent with sustainable community strategies, local plans, the Delta Protection Commission's Land Use and Resource Management Plan for the Primary Zone of the Delta, *and the Delta Plan.*

DP R6. Plan for State Highways

The Delta Stewardship Council, as part of the prioritization of State levee investments called for in Water Code section 85306, should consult with the California Department of Transportation as provided in Water Code section 85307(c) to consider the effects of flood hazards and sea level rise on State highways in the Delta.

DP R7. Subsidence Reduction and Reversal

The following actions should be considered by the appropriate State agencies to address subsidence reversal:

- *State agencies should not renew or enter into agricultural leases on Delta or Suisun Marsh islands if the actions of the lessee promote or contribute to subsidence on the leased land, unless the lessee participates in subsidence reversal or reduction programs.*
- *State agencies currently conducting subsidence reversal projects in the Delta on State-owned lands should investigate options for scaling up these projects if they have been deemed successful. The California Department of Water Resources should develop a plan, including funding needs, for increasing the extent of their subsidence reversal and carbon sequestration projects to 5,000 acres by January 1, 2017.*
- *The Delta Stewardship Council, in conjunction with the California Air Resources Board (CARB) and the Delta Conservancy, should investigate the opportunity for the development of a carbon market whereby Delta farmers could receive credit for carbon sequestration by reducing subsidence and growing native marsh and wetland plants. This investigation should include the potential for developing offset protocols applicable to these types of plants for subsequent adoption by the CARB.*

Maintain Delta Agriculture

Agriculture is the principal land use in the Delta; however, in recent decades, the total area of agricultural lands has declined, as has the overall percentage of lands in agricultural use. The continued viability of agriculture in the Delta will require the protection of sufficient farmland and fresh water to support commercially viable operations and provide ways for agriculture to coexist with habitat restoration. Policies DP P1 and DP P2 acknowledge the importance of protecting these lands. Farming in the Delta will have to respond to changing conditions and new challenges in the coming years. Among these challenges are shifting commodity markets and consumer demand, changes in climate and water supplies, and subsidence of reclaimed agricultural lands. To support both Delta agriculture and species recovery, farmers in the Delta are encouraged to implement "wildlife-friendly" management practices to maximize habitat values. Restoring wildlife and fish through wildlife-friendly agriculture can help achieve ecosystem restoration objectives while reducing the loss of farmland to habitat restoration. Agritourism is a small but fast-growing source of income for farms in the region. It is another opportunity to add further value to the Delta economy from agricultural activities.

Problem Statement

Agriculture in some parts of the Delta is threatened by urbanization, subsidence, and changing markets due to increased competition from other countries and regions, and shifting consumer preferences. The impacts from water conveyance facilities, ecosystem restoration, changing water quality, and flood management plans are yet to be determined, but rapid and significant changes could disrupt agriculture. Farmers are concerned that regulations and other barriers to conducting business and using their land also threaten the continued viability of agriculture.

Policies

No policies with regulatory effect are included in this section.

Recommendations

DP R8. Promote Value-added Crop Processing

Local governments and economic development organizations, in cooperation with the Delta Protection Commission and the Delta Conservancy, should encourage value-added processing of Delta crops in appropriate locations.

DP R9. Encourage Agritourism

Local governments and economic development organizations, in cooperation with the Delta Protection Commission and the Delta Conservancy, should support growth in agritourism, particularly in and around legacy communities. Local plans should support agritourism where appropriate.

DP R10. Encourage Wildlife-friendly Farming

The California Department of Fish and Wildlife, the Delta Conservancy, and other ecosystem restoration agencies should encourage habitat enhancement and wildlife-friendly farming systems on agricultural lands to benefit both the environment and agriculture.

Encourage Recreation and Tourism

The Delta region offers diverse recreation experiences and facilities such as fishing, boating, birdwatching, other nature activities, hunting, campgrounds, parks and picnic areas, and historic towns and buildings. DPC and California State Parks foresee opportunities to improve and increase recreation and tourism in the Delta. Both agencies recommend improvements of “gateways” to the region on the Delta’s urban edges and “base camps” inside the Delta at destinations such as resorts, legacy communities, or parks that are focal points for visitors. Building on the reports of the DPC and California State Parks, the Council recommends protecting and improving existing recreation opportunities while seeking ways of providing new, and better coordinated, opportunities. Ecosystem restoration, as described in Chapter 4, can also enhance opportunities for nature-based recreation and boating. Future prospects for recreation and tourism will be influenced by decisions about the Delta ecosystem, water quality, levee improvements, and governance, including land use and environmental standards. The BDCP, Delta water quality plans, levee investments, and other decisions yet to be made can all significantly affect recreation and tourism.

Problem Statement

Recreation opportunities abound, but many have not been fully developed due to inadequate visitor information, aging and inadequate facilities, and restricted access to public lands. Limited cooperation in marketing, planning, and public-private partnerships between public recreation providers, other government land managers, businesses, and others hinders recreation and tourism, and impedes expansion of visitor-serving businesses.

Policies

No policies with regulatory effect are included in this section.

Recommendations

DP R11. Provide New and Protect Existing Recreation Opportunities

Water management and ecosystem restoration agencies should provide recreation opportunities, including visitor-serving business opportunities, at new facilities and habitat areas whenever feasible; and existing recreation facilities should be protected, using California State Parks’ Recreation Proposal for the Sacramento-San Joaquin Delta and Suisun Marsh *and Delta Protection Commission’s* Economic Sustainability Plan for the Sacramento-San Joaquin Delta *as guides.*

DP R12. Encourage Partnerships to Support Recreation and Tourism

The Delta Protection Commission and Delta Conservancy should encourage partnerships between other State and local agencies, and local landowners and business people to expand recreation, including boating, promote tourism, and minimize adverse impacts to nonrecreational landowners.

DP R13. Expand State Recreation Areas

California State Parks should add or improve recreation facilities in the Delta in cooperation with other agencies. As funds become available, it should fully reopen Brannan Island State Recreation Area, complete the park at Delta Meadows-Locke Boarding House, and consider adding new State parks at Barker Slough, Elkhorn Basin, the Wright-Elmwood Tract, and south Delta.

DP R14. Enhance Nature-based Recreation

The California Department of Fish and Wildlife, in cooperation with other public agencies, should collaborate with nonprofits, private landowners, and business partners to expand wildlife viewing, angling, and hunting opportunities.

DP R15. Promote Boating Safety

The California Department of Boating and Waterways should coordinate with the U.S. Coast Guard and State and local agencies on an updated marine patrol strategy for the region.

DP R16. Encourage Recreation on Public Lands

Public agencies owning land should increase opportunities, where feasible, for bank fishing, hunting, levee-top trails, and environmental education.

DP R17. Enhance Opportunities for Visitor-serving Businesses

Cities, counties, and other local and State agencies should work together to protect and enhance visitor-serving businesses by planning for recreation uses and facilities in the Delta, providing infrastructure to support recreation and tourism, and identifying settings for private visitor-serving development and services.

Sustain a Vital Delta Economy

Many of the policies and recommendations in this chapter deal with aspects of the Delta's economy such as maintaining agriculture and encouraging recreation and tourism. The Delta's economy also benefits from the surface transportation, utilities, and other infrastructure that crisscross the Delta to serve local needs and link the Delta to regional, national, and global markets. Facilities such as natural gas wells, wind turbines, other renewable power sources, electric transmission lines, and fuel pipelines need to be planned carefully to avoid conflicts with water supply, ecosystem restoration, or flood management facilities and existing and planned land uses. The ports at Stockton and West Sacramento are valuable assets to Delta communities and the state. Areas for water-dependent industries are located in Collinsville, Rio Vista, Pittsburg, and Antioch.

Problem Statement

Other economic opportunities in the Delta, including port and energy uses, could suffer if unplanned development, flooding, or other land uses interfere with them.

Policies

No policies with regulatory effect are included in this section.

Recommendations

DP R18. Support the Ports of Stockton and West Sacramento

The ports of Stockton and West Sacramento should encourage maintenance and carefully designed and sited development of port facilities.

DP R19. Plan for Delta Energy Facilities

The California Energy Commission and California Public Utilities Commission should cooperate with the Delta Stewardship Council as described in Water Code section 85307(d) to identify actions that should be incorporated in the Delta Plan by 2017 to address the needs of Delta energy development, storage, and distribution.

Timeline for Implementing Policies and Recommendations

Figure 5-7 lays out a timeline for implementing the policies and recommendations described in the previous sections. The timeline emphasizes near-term and intermediate-term actions.

Timeline for Implementing Policies and Recommendations

TIMELINE

CHAPTER 5: Delta as an Evolving Place

	ACTION (REFERENCE #)	LEAD AGENCY(IES)	NEAR TERM 2012–2017	INTERMEDIATE TERM 2017–2025
POLICIES	Locate new urban development wisely (DP P1)	Local governments	●	●
	Respect local land use when siting water or flood facilities or restoring habitats (DP P2)	Local governments and State agencies	●	●
RECOMMENDATIONS	Designate the Delta as a National Heritage Area (DP R1)	DPC	●	
	Designate State Route 160 as a National Scenic Byway (DP R2)	Caltrans	●	
	Plan for the vitality and preservation of legacy communities (DP R3)	Local governments, DPC, Delta Conservancy	●	
	Buy rights of way from willing sellers when feasible (DP R4)	Local, State, and federal agencies	●	●
	Provide adequate infrastructure (DP R5)	Caltrans, local agencies, and utility providers	●	●
	Plan for State highways (DP R6)	Council, Caltrans	●	
	Subsidence reduction and reversal (DP R7)	State agencies	●	
	Promote value-added crop processing (DP R8)	Local governments and economic development organizations	●	●
	Encourage agritourism (DP R9)	Local governments and economic development organizations	●	●
	Encourage wildlife-friendly farming (DP R10)	DFW, Delta Conservancy	●	●
	Provide new and protect existing recreation opportunities (DP R11)	Water management and ecosystem restoration agencies	●	●
	Encourage partnerships to support recreation and tourism (DP R12)	DPC, Delta Conservancy	●	●
	Expand State Recreation Areas (DP R13)	Parks	●	●
	Enhance nature-based recreation (DP R14)	DFW	●	●
	Promote boating safety (DP R15)	Boating and Waterways	●	
	Encourage recreation on public lands (DP R16)	DWR, DFW, Delta Conservancy, Parks	●	
	Enhance opportunities for visitor-serving businesses (DP R17)	Local governments and State agencies	●	●
	Support the Ports of Stockton and West Sacramento (DP R18)	Ports of Stockton and West Sacramento	●	●
	Plan for Delta energy facilities (DP R19)	California Energy Commission and PUC	●	

DP_344

Agency Key:

Boating and Waterways: California Department of Boating and Waterways
Delta Conservancy: Sacramento-San Joaquin Delta Conservancy
Caltrans: California Department of Transportation
Council: Delta Stewardship Council
DFW: California Department of Fish and Wildlife
DPC: Delta Protection Commission
DWR: California Department of Water Resources
Parks: California State Parks
PUC: California Public Utilities Commission

Figure 5-7

Science and Information Needs

Better information about recreation and tourism in the Delta and additional research into best practices for managing farmlands in the Delta can contribute to efforts to protect the Delta's unique values. These needs include the following:

- Surveys of Delta recreation at regular intervals, such as every 5 years, to inform marketing and planning for recreation and tourism
- Assessments of opportunities to control or reverse subsidence of farmland
- Analysis of land and water use by agriculture, including land ownership (resident vs. absentee; age of owner; size of holding, etc.), cropping patterns, soil types, and other factors to identify the Delta's agricultural regions, their competitive advantages, threats and opportunities
- Analysis of farm labor housing needs.

Issues for Future Evaluation and Coordination

Many Delta agencies and residents are concerned that the region's economy may suffer if agriculture or other uses decline significantly due to habitat restoration or water conveyance projects, especially the BDCP described in Chapter 3, or changes in State priorities for levee investment resulting from the studies recommended in Chapter 7. DPC's ESP forecasts adverse economic impacts from farmland loss based on a scenario of how these decisions may affect the region. Its Proposal to Protect the Delta as a Place recommends that the Delta Investment Fund support protection of the Delta economy, and be administered by the DPC and guided by an investment committee appointed by the DPC's commissioners (DPC 2012a). The Delta Conservancy will also play a role in some economic development efforts, as provided in Public Resources Code section 32322(b).

Because BDCP and new levee investment priorities are not yet complete, the magnitude of any impacts to farmland, other uses, or the Delta's economy cannot reasonably be forecast. If significant adverse impacts to the Delta economy do result from farmland losses or other impacts due to habitat restoration, water conveyance, or revised levee investment priorities, then measures to compensate for these losses may warrant consideration. This consideration should include creation of a regional agency to implement and facilitate economic development efforts, guided by the DPC's ESP. The agency's responsibilities could include the following:

- Branding and marketing the Delta
- Coordinating with counties and cities to encourage planning and infrastructure development that is aligned with economic sustainability strategies
- Providing regulatory assistance to reduce impediments to priority activities, including visitor-serving developments, dredging, levee construction, and ecosystem restoration, to reduce impediments and lower costs of these activities
- Encouraging value-added processing of Delta crops, agritourism, visitor-serving commercial businesses, and preservation of the historic buildings in legacy communities
- Recommending and overseeing expenditures from the Delta Investment Fund

Performance Measures

Development of informative and meaningful performance measures is a challenging task that will continue after the adoption of the Delta Plan. Performance measures need to be designed to capture important trends and to address whether specific actions are producing expected results. Efforts to develop and track performance measures in complex and large-scale systems like the Delta are commonly multiyear endeavors. The recommended output and outcome performance measures listed below are provided as examples and subject to refinement as time and resources allow. Final administrative performance measures are listed in Appendix E and will be tracked as soon as the Delta Plan is completed.

Recommended performance measures for protection and enhancement of the unique cultural, recreational, natural resources, and agricultural values of the Delta as an evolving place are described below.

Output Performance Measures

- Congress designates the Delta and Suisun Marsh as an NHA by January 1, 2014. (DP R1)
- Water management, ecosystem restoration, and flood management projects minimize conflicts with adjoining uses by including adequate mitigation measures to avoid adverse effects. (DP P2)
- Recreation facilities are included in new ecosystem restoration projects. (DP R9)
- The DWR and others increase the extent of their subsidence reversal and carbon sequestration projects to 5,000 acres by January 1, 2017. (DP R7)

Outcome Performance Measures

- No further rural farmland in the Delta is lost to urban development. (DP P1)
- Progress toward protecting the Delta legacy communities, as indicated by renovation of historic structures, floodproofing, and other reductions in flood hazards, and maintenance or growth of small businesses and population. (DP R3)
- Increasing tonnage of cargo and the number of jobs at the ports of Stockton and West Sacramento. (DP R18)

CHAPTER 6

Improve Water Quality to Protect Human Health and the Environment

ABOUT THIS CHAPTER

This chapter discusses the trade-offs and conflicts inherent in managing water quality for multiple objectives. It recommends strategies to make balanced improvements primarily through the prioritization of projects and programs. It also provides support to related information in Chapters 3, 4, and 5.

Other State of California (State) agencies have broad authority to protect and regulate water quality. This chapter sets forth priority Sacramento-San Joaquin Delta (Delta)-specific recommendations for those agencies and focuses on four core strategies where best available science shows the need for improved water quality to achieve the coequal goals:

- Require Delta-specific water quality protection
- Protect beneficial uses by managing salinity
- Improve drinking water quality
- Improve environmental water quality

These core strategies form the basis of the 12 recommendations found at the end of this chapter. These major aspects are critical to protecting human health and improving the environment. Salinity is discussed in a separate section because of its importance as a defining characteristic of the estuary and its implications to ecosystem health, its linkage to water project operations, and its historical importance in the Delta.

RELEVANT LEGISLATION

The protection and improvement of water quality is inherent to meeting the coequal goals of the State. Water quality plays a critical role in the achievement of a more reliable water supply and protection, restoration, and enhancement of the Delta ecosystem. Water quality also contributes to the values of the Delta as an evolving place. The Sacramento-San Joaquin Delta Reform Act of 2009 calls for improving water quality as follows:

> *85020 The policy of the State of California is to achieve the following objectives that the Legislature declares are inherent in the coequal goals for management of the Delta:...(e) Improve water quality to protect human health and the environment consistent with achieving water quality objectives in the Delta.*

85022(d) The fundamental goals for managing land use in the Delta are to do all of the following: ... (6) Improve water quality to protect human health and the environment consistent with achieving water quality objectives in the Delta.

85302(d) The Delta Plan shall include measures to promote a more reliable water supply that address all of the following: ... (3) Improving water quality to protect human health and the environment.

85302(e) The following subgoals and strategies for restoring a healthy ecosystem shall be included in the Delta Plan... (5) Improve water quality to meet drinking water, agriculture, and ecosystem long-term goals.

This page intentionally left blank.

CHAPTER 6

Improve Water Quality to Protect Human Health and the Environment

The Delta Reform Act acknowledges water quality as an important element of a reliable water supply and directs the Delta Stewardship Council (Council) to improve water quality to protect human health and the environment. In general, water quality is an abstract concept unless it is discussed relative to protection of the beneficial uses of that water. The Delta Reform Act highlights drinking water, agriculture, and ecosystem goals as important beneficial uses for the purpose of the Delta Plan. The Council's role with respect to water quality is to ensure that the policies and recommendations in the Delta Plan balance the protection of myriad—and sometimes competing—beneficial uses of water.

In California, the entities primarily responsible for managing water quality in the state are the nine regional water quality control boards (RWQCBs) and the State Water Resources Control Board (SWRCB). The RWQCBs are responsible for water quality planning, permitting and enforcement, and financial assistance, when funds are available. The SWRCB is responsible for statewide plans, permits, and policies, and serves as a review body for RWQCB decisions. The SWRCB also has the important and challenging task of administering the State's complex water rights system of permits and licenses. As part of these duties, the SWRCB sets water quality objectives for major waterways, including the tributaries of the Delta, as described in Chapter 4. The Central Valley RWQCB is the regional board with primary jurisdiction in the Delta and Delta watershed.

Water quality in the Delta is influenced by many factors. Seasonal rainfall, snow runoff, and reservoir releases flow in from several rivers and streams, primarily the Sacramento and the San Joaquin rivers. During very high flows, some of this water flows across floodplains before it enters the Delta. Tides can bring saline waters into the Delta from the San Francisco Bay. There are also discharges from cities, industries, and agricultural lands. As all of these flows enter the Delta, they bring with them a variety of contaminants. Additionally, water is diverted from the Delta, either for use within the Delta or for use in Central and Southern California and other service areas. The timing and physical qualities of these flows into and out of the Delta affect the water quality needed to support the beneficial uses of Delta waters.

In achieving the coequal goals, the Council envisions a Delta where improved water quality supports a healthy ecosystem and the multiple beneficial uses of water, including municipal supply and recreational uses such as fishing and swimming. To support a more resilient and healthy Delta ecosystem, salinity patterns should be consistent with more natural flow patterns with inflows of high-quality water. Nutrient concentrations should support diverse and productive aquatic food webs, and should not cause excessive growth of nuisance aquatic plants or blooms of harmful algae. Physical attributes of the aquatic environment, such as dissolved oxygen (DO) concentrations, temperature ranges, and turbidity levels, should support the needs of native species. At all times, the Delta should be free of harmful concentrations of toxic substances. Discharges of treated wastewater, urban runoff, or agricultural return flows should be regulated so that they do not have a negative effect on the Delta. High water quality is imperative to the coequal goals and crucial for protecting the beneficial uses of Delta water, successful restoration of aquatic habitats, and sustenance of native plants and animals.

Beneficial uses of Delta waters involve trade-offs that are important to recognize and address when establishing water quality goals. These trade-offs emerge in cases where acceptable or even ideal water quality for one use may have unintended or adverse effects on another use. For example, variable salinity levels are beneficial for many native species in the Delta, but can be problematic for agricultural or municipal uses. Bromide salts, one component of salinity, can result in cancer-causing disinfection byproducts with some water treatment methodologies. Similarly, organic carbon in drinking water sources can contribute to harmful disinfection byproduct formation (Leenheer and Croue 2003). However, for ecosystem purposes, organic carbon is beneficial and is increased by wetland creation. Also, wetland creation can result in increased methylation of mercury, resulting in bioaccumulation of mercury in fish species, a threat to human health when these fish are consumed. Water quality is strongly connected to water supply, as reservoir releases to control salinity can reduce the availability of fresh water at times of the year when it is needed most. These and other issues affecting water quality policy are discussed in this chapter.

Beneficial Uses of Water in and from the Delta

A goal of the Delta Plan is to maintain water quality at a level that supports and enhances designated beneficial uses. Table 6-1 lists the beneficial uses for water in the Delta as specified in the SWRCB's 2006 *Water Quality Control Plan for the San Francisco Bay/Sacramento–San Joaquin Delta Estuary* (Bay-Delta Plan).

The most important part of any water quality discussion is identifying the existing and potential uses of the water in question. These uses drive the level of water quality that must be attained, and what requirements and limitations must be placed on dischargers and diverters of that water to protect those uses. Specific discharge limitations are based on adopted science-based objectives necessary to protect associated beneficial uses. These limitations are then included in discharge permits.

Factors Influencing Water Quality in the Delta

This section provides an overview of factors that influence water quality in the Delta and existing water quality regulations. Water quality in the Delta is influenced by factors such as:

- Freshwater inflows and outflows
- In-Delta land use
- Dredging
- The Delta levee system
- Tides
- Point source inputs of pollutants
- Nonpoint source inputs of pollutants
- In-Delta water use
- Export diversions and operations

Delta Water Beneficial Uses

TABLE 6-1

Beneficial Use	Description
Municipal and Domestic Supply	Uses of water for community, military, or individual water supply systems including, but not limited to, drinking water supply.
Industrial Service Supply	Uses of water for industrial activities that do not depend primarily on water quality including, but not limited to, mining cooling water supply, hydraulic conveyance, gravel washing, fire protection, and oil well repressurization.
Industrial Process Supply	Uses of water for industrial activities that depend primarily on water quality.
Agricultural Supply	Uses of water for farming, horticulture, or ranching including, but not limited to, irrigation, stock watering, or support of vegetation for range grazing.
Groundwater Recharge	Uses of water for natural or artificial recharge of groundwater for purposes of future extraction, maintenance of water quality, or halting of saltwater intrusion into freshwater aquifers.
Navigation	Uses of water for shipping, travel, or other transportation by private, military, or commercial vessels.
Water Contact Recreation	Uses of water for recreational activities involving body contact with water, where ingestion of water is reasonably possible. These include, but are not limited to, swimming, wading, water skiing, skin and scuba diving, surfing, white-water activities, fishing, or use of natural hot springs.
Non-contact Water Recreation	Uses of water for recreational activities involving proximity to water, but not normally involving body contact with water, where ingestion is reasonably possible. These include, but are not limited to, picnicking, sunbathing, hiking, beachcombing, camping, boating, tide pool and marine life study, hunting, sightseeing, or aesthetic enjoyment in conjunction with the above activities.
Shellfish Harvesting	Uses of water that support habitats suitable for the collection of filter-feeding shellfish (e.g., clams, oysters, and mussels) for human consumption, commercial, or sports purposes.
Commercial and Sport Fishing	Uses of water for commercial or recreational collection of fish, shellfish, or other organisms including, but not limited to, uses involving organisms intended for human consumption or bait purposes.
Warm Freshwater Habitat	Uses of water that support warmwater ecosystems including, but not limited to, preservation of aquatic habitats, vegetation, fish, or wildlife, including invertebrates.
Cold Freshwater Habitat	Uses of water that support coldwater ecosystems including, but not limited to, preservation or enhancements of aquatic habitats, vegetation, fish, or wildlife, including invertebrates.
Migration of Aquatic Organisms	Uses of water that support habitats necessary for migration or other temporary activities by aquatic organisms, such as anadromous fish.
Spawning, Reproduction, and/or Early Development	Uses of water that support high-quality aquatic habitats suitable for reproduction and early development of fish.
Estuarine Habitat	Uses of water that support estuarine ecosystems including, but not limited to, preservation or enhancement of estuarine habitats, vegetation, fish, shellfish, or wildlife (e.g., estuarine mammals, waterfowl, shorebirds).
Wildlife Habitat	Uses of water that support estuarine ecosystems including, but not limited to, preservation and enhancement of terrestrial habitats, vegetation, wildlife (e.g., mammals, birds, reptiles, amphibians, invertebrates), or wildlife water and food sources.
Rare, Threatened, or Endangered Species	Uses of water that support habitats necessary, at least in part, for the survival and successful maintenance of plant or animal species established under State or federal law as being rare, threatened, or endangered.

Source: SWRCB 2006

Generally, water quality is better in the northern Delta than in the central and southern Delta because higher-quality Sacramento River inflows are greater than inflows from the San Joaquin River, and the proportion of agricultural water use and drainage in the San Joaquin Valley is greater than in the Sacramento Valley. The SWRCB has listed Delta waterways (various streams, rivers, and sloughs in the Delta), the Carquinez Strait, and San Francisco Bay as having impaired water quality pursuant to the federal Clean Water Act (CWA) section 303(d) list[1] (SWRCB 2010). Pollutants of concern include insecticides, herbicides, mercury, selenium, nutrients, and legacy organic pollutants such as dichlorodiphenyltrichloroethane (DDT) and polychlorinated biphenyls (PCBs). Additional water quality issues in the Delta include temperature, salinity, turbidity, low DO, bromide, dissolved organic carbon, pathogens, and harmful algal blooms (HABs). Amounts of these constituents that are too high (or in some cases too low) can impair the ability of these waters to support beneficial uses, such as municipal water supply, recreational use, agricultural water supply, and habitat that supports healthy fish and wildlife populations. See Chapter 4 for additional discussion on how these water quality stressors can affect the Delta and its ecosystem.

Protecting Water Quality Is a Balancing Act

Water quality is central to the State's goals for the Delta – restoring the Delta ecosystem and providing for a more reliable water supply, while protecting and enhancing the Delta as a unique and evolving place. Conditions that affect water quality must be managed and balanced in a way that allows these goals to be met simultaneously. When one use is protected, steps must be taken to minimize impacts on other uses. The following examples of this interconnectedness illustrate the difficulty of the challenge at hand.

Water supply for agricultural, municipal, and industrial use requires control of chemical constituents such as salinity, and certain pollutants that could pose a threat to human health. Efforts to protect, enhance, and restore the Delta ecosystem, however, require the management of volume and timing of flows to provide beneficially variable salinity for certain species and sufficient fresh water for others. This management regime must also consider management of nutrients and suspended solids to ensure a viable food chain within the Delta.

Protecting the communities within the Delta and their water use involves many of these same salinity and pollutant controls that are important for any water supply, but water quality in the Delta must also support recreational uses such as swimming, fishing, and boating. Cumulative discharges of pollutants from Delta communities and from recreational craft can affect in-Delta uses. Sea level rise caused by climate change will affect in-Delta water use and the manner in which flows are managed to meet water quality demands. Levee construction and placement is important to guard against flooding that could threaten in-Delta and exported water supplies. In addition, levee construction can either disrupt ecosystem processes or help provide important habitat benefits, depending on the project's location and individual attributes.

Climate Change

Impacts on water quality from climate change are difficult to predict. However, a recent analysis by the U.S. Geological Survey (USGS) suggests that climate change poses a significant threat to water quality (Cloern et al. 2011). Increases in sea level would increase salinity intrusion into the Delta, threatening water quality for agricultural and municipal uses. Increased air and water temperatures would result in increased runoff amounts in winter, with less in spring and summer. Warmer water can directly affect the life cycle of many fish species and stimulate growth of nuisance aquatic plants or blooms of harmful algae, which can lead to

---

[1] The "303(d) list" is the list of impaired and threatened waters (stream/river segments, lakes) that states have identified as not meeting water quality standards and other requirements. Under section 303(d), the law requires that states establish priority rankings for waters on the list and develop total maximum daily loads (TMDLs) for these waters.

decreases in DO and increases in organic carbon. Increased runoff in the winter could result in more erosion and greater pulses of pollutants.

Existing Water Quality Regulations

Many different agencies have a role in the regulation of water quality in the Delta. The SWRCB and the RWQCBs have primary responsibility over discharges affecting beneficial uses of water in California with the oversight of the U.S. Environmental Protection Agency (USEPA). Drinking water supply is regulated by the California Department of Public Health, also with oversight by USEPA. Additionally, the California Department of Pesticide Regulation regulates the sale and use of pesticides, which affect water quality. (See sidebar, A Water Quality Success Story.)

A WATER QUALITY SUCCESS STORY

Widespread use of the organophosphorus pesticide diazinon in the Central Valley and episodes of aquatic toxicity caused the Central Valley RWQCB to add the Sacramento and Feather rivers to its list of impaired water bodies in 1994. A total maximum daily load for diazinon was adopted in 2003. Stakeholders also took action to implement a diazinon control strategy, and the USEPA and California Department of Pesticide Regulation took steps to restrict approved uses of diazinon. Grants from the USEPA, the former CALFED Bay-Delta Program, and other agencies provided funding support for control program implementation and research throughout the Central Valley region, including the San Joaquin River.

These water quality control efforts have helped to reduce levels of diazinon to the point that violations of water quality standards in the Sacramento and San Joaquin rivers are rare. Although pesticide pollution is still a problem in parts of some Central Valley streams and rivers, the experience with diazinon shows that programs to address these and other water quality problems can be effective (USEPA 2010).

DP-185

The RWQCBs develop water quality control plans (known as Basin Plans) that establish water quality standards and implementation plans for achieving standards for all surface water and groundwater in their respective regions. Water quality standards include identification of beneficial uses, numeric and narrative water quality objectives to protect those uses, and water quality control policies. The RWQCBs issue discharge permits and requirements that specify the amounts of pollutants that may be discharged based on these objectives. Although these permits are intended to ensure protection of these beneficial uses, some water bodies continue to exceed standards, and beneficial uses are not being protected. These impaired water bodies are identified and listed pursuant to federal CWA section 303(d).

Placement of a water body on the CWA 303(d) list initiates a process to develop a pollution limit, or total maximum daily load (TMDL), to address each pollutant causing the impairment. A TMDL defines how much of a pollutant a water body can tolerate and still meet water quality standards. The TMDL must account for all sources of a pollutant, including point sources and nonpoint sources (discharges from wastewater treatment facilities; runoff from urban areas, agricultural inputs, and streets or highways; “toxic hot spots”; and aerial deposition). In addition to accounting for past and current activities, TMDLs may also consider projected future population growth that could increase pollutant levels. The TMDL identifies allocations for point sources and for nonpoint sources, and includes a margin of safety to account for uncertainty. An implementation plan is developed that specifies a set of actions that must be carried out to ensure that the TMDL results in achievement of water quality standards. TMDLs are usually implemented through amendments to the appropriate Basin Plan, which, in turn, will result in changes to discharge permits as they are reissued. Once a TMDL is approved, it may be some time before the necessary studies are completed to set and apportion specific discharge limitations among all dischargers and potential dischargers.

The 2008-2010 Integrated Report (SWRCB 2010), which includes the 303(d) list, prioritizes TMDLs to be developed for each water body-pollutant combination on the CWA section 303(d) list, and establishes schedules for completion of the TMDLs. Approved TMDLs and TMDLs under development are listed in Table 6-2.

On February 10, 2011, the USEPA issued an Advanced Notice of Proposed Rulemaking (USEPA 2011) as part of an effort to assess the effectiveness of current water quality programs designed to protect aquatic species in the San Francisco Bay and the Delta (referred to here as the Bay-Delta). The document identified key water quality issues affecting Bay-Delta aquatic resources and summarized current research for each of these issues, including total ammonia, selenium, pesticides, emerging contaminants, and other parameters affecting estuarine habitat and the migratory corridors of anadromous fish. The notice was intended to solicit public comment on possible USEPA actions to address water quality conditions affecting the Bay-Delta. USEPA may make changes to programs in the Bay-Delta through a formal rulemaking process as a result of further evaluation and consideration of public comment. These changes could affect federal water quality programs administered by the State.

Water quality in the Delta is also regulated by the San Francisco Bay Conservation and Development Commission (BCDC), which has jurisdiction on all tidal areas of the Bay, including Suisun Bay and Suisun Marsh. BCDC policies regarding water quality are intended to prevent the release of pollution into Bay waters to the greatest extent feasible. The BCDC makes decisions regarding water quality impacts based on evaluation by and the advice of the San Francisco Bay RWQCB. The BCDC reviews State and federal actions, permits, projects, licenses, and grants affecting the Bay, including Suisun Marsh, pursuant to the federal Coastal Zone Management Act.

In the Delta and the Suisun Marsh, the Bay-Delta Plan establishes water quality objectives for which implementation is achieved through assigning responsibilities to water right holders and water users (SWRCB 2006). (See sidebar, Water Board Regulation and the Bay-Delta Plan.) This is because the parameters to be controlled are significantly affected by flows and diversions; these responsibilities were established in Water Rights Decision 1641 in 1999. The Bay-Delta Plan also provides protection for beneficial uses that require control of salinity and operations of the various water projects in the Delta, including the State Water Project (SWP) and Central Valley Project (CVP) (SWRCB 2006).

TMDLs Approved and under Development in the Central Valley, Delta, and Suisun Bay

TABLE 6-2

Water Bodies	Pollutants	Status
American River	Mercury	Under Development
Cache Creek, Bear Creek, Harley Gulch	Mercury	Approved
Central Valley	Organochlorine Pesticides	Under Development
Central Valley	Pesticides	Under Development
Clear Lake	Mercury	Approved
Clear Lake	Nutrients	Approved
Grasslands	Selenium	Approved
North San Francisco Bay (includes Suisun Bay)	Selenium	Under Development
Sacramento and Feather Rivers	Diazinon	Approved
Sacramento County Urban Creeks	Diazinon and Chlorpyrifos	Approved
Sacramento-San Joaquin River Delta	Diazinon and Chlorpyrifos	Approved
Sacramento-San Joaquin River Delta	Mercury	Approved
Salt Slough	Selenium	Approved
San Francisco Bay (includes Suisun Bay)	Mercury	Approved
San Francisco Bay (includes Suisun Bay)	PCBs	Approved
San Francisco Bay Area Urban Creeks	Diazinon/Pesticide Toxicity	Approved
San Joaquin River	Salt and Boron	Approved
San Joaquin River	Diazinon and Chlorpyrifos	Approved
San Joaquin River	Selenium	Approved
Stockton Deep Water Ship Channel (Phase 1)	Dissolved Oxygen	Approved
Stockton Deep Water Ship Channel (Phase 2)	Dissolved Oxygen	Under Development
Stockton Urban Sloughs	Dissolved Oxygen	Under Development
Stockton Urban Water Bodies	Pathogens	Approved
Suisun Marsh	Dissolved Oxygen	Under Development
Suisun Marsh	Mercury	Under Development
Upper Sacramento River	Cadmium, Copper, and Zinc	Approved

The SWRCB and RWQCBs are the regulatory agencies with statutory authority to adopt water quality control plans, including regulating waters for which water quality standards are required by the federal CWA (Water Code sections 13170 and 13240). The Council recognizes the SWRCB's role and authority in regulating water quality, and supports and encourages the timely development and enforcement of programs (for example, water quality objectives and waste discharge requirements (WDRs), TMDLs, and National Pollutant Discharge Elimination System [NPDES] permits) to reduce pollutant loads that are causing water quality impairments in the Delta. The Council also supports and encourages the completion of the elements of the SWRCB's 2010 *Update to Strategic Plan 2008-2012* (June 2010) and the *Strategic Workplan for Activities in the San Francisco Bay/Sacramento–San Joaquin River Delta Estuary* (July 2008) prepared by the SWRCB, Central Valley RWQCB, and San Francisco Bay RWQCB.

WATER BOARD REGULATION AND THE BAY-DELTA PLAN

Water Quality Criteria, Objectives, and Standards. The SWRCB and RWQCBs have primary responsibility for the regulation of discharges and control of pollutants that affect California's surface and groundwater resources.

The water boards do this by using scientific studies and information to first determine the water quality *criteria* that are needed for specific beneficial uses of that water. Examples of beneficial uses include drinking water use, agricultural use, recreation, and others listed in the Bay-Delta Plan. The water quality criteria are then used to develop water quality objectives.

Water quality *objectives* account for additional information such as economic impacts, effects on other uses, available technology, and similar factors. Water quality objectives are considered equivalent to water quality *standards* required by the USEPA. The RWQCBs adopt water quality control plans that contain these objectives; they identify specific beneficial uses of each water body covered by that plan and specific water quality objectives to protect those uses. These plans are then used to issue general or site-specific discharge permits with specific pollutant discharge limitations.

Section 303(d) of the federal CWA requires that California create a listing of impaired water bodies that are not meeting water quality standards. Water bodies on this 303(d) list require development of a TMDL, which establishes a limitation on the amount of pollution that water body can be exposed to without adversely affecting its beneficial uses. This TMDL allocates proportions of the total limitation among dischargers to the impaired surface water. TMDLs typically result in changes to water quality control plans, so that existing and future permits contain pollutant limits or other provisions necessary to ensure that the water quality standards are met.

Flow Objectives. The SWRCB is responsible for administering and overseeing the right to take and use water in California. Where storage, transport, diversion, and use of water threaten to adversely affect water quality and beneficial uses, the SWRCB may adopt plans that set objectives for water quality and flow where necessary to protect beneficial uses. As a special kind of water quality objective, *flow objectives* are developed on the basis of scientifically developed information and account for other factors, such as economic impacts, physical constraints, and effects on other uses such as water supply and agricultural use.

The Bay-Delta Plan. In the case of the Delta, the SWRCB has adopted the Bay-Delta Plan. This plan contains water quality objectives, including flow objectives. The Delta Reform Act required that certain flow criteria be developed, which the SWRCB completed in 2010.

In early 2012, the SWRCB officially launched the comprehensive review of the Bay-Delta Plan. The water quality control planning phase of this review will include review of potential modifications to current objectives included in the Bay-Delta Plan, the potential establishment of new objectives, and modifications to the program of implementation for those objectives. It will also include potential changes to the monitoring and special studies program included in the Bay-Delta Plan. The water quality control planning process will not include amendments to water rights and other measures to implement a revised Bay-Delta Plan. A separate environmental impact report will be prepared for these actions. In addition, a separate substitute environmental document is being prepared to address updates to the water quality objectives for the protection of southern Delta agricultural beneficial uses, San Joaquin River flow objectives for the protection of fish and wildlife beneficial uses, and the program of implementation for those objectives.

DP-186

Salinity in the Delta

The Delta is an estuary, and like any estuary, fresh water from rivers and tributaries flows downstream where it mixes with salt water. The location, extent, and dynamics of the freshwater-saltwater interface are important drivers of many estuarine (ecological) processes and important considerations in water management for human uses. The geographic extent of water of the correct salinity is important to many estuarine species as it is an important characteristic of their habitat. Crops vary in their tolerance of salt content in water used for irrigation, and salinity can reduce yields of sensitive crops at relatively low levels. Salt in municipal water supplies increases corrosion of pipes and appliances, can affect taste, and can contribute to the formation of disinfection byproducts that are harmful to human health. The management-intensive regulation of salinity in the Delta for multiple benefits is another example of the highly altered system the Delta has become. This section provides a summary of the history of Delta salinity problems and the effects of salinity on agricultural, municipal, and industrial water use.

History and Causes of Delta Salinity Problems

The location of the freshwater-saltwater interface in the estuary shifts with the seasons and the tides and from year to year depending on the amount of precipitation, water diversions, and Delta outflow (Kimmerer 2004; Malamud-Roam et al. 2007; Stahle et al. 2011). The location, extent, and dynamics of this freshwater-saltwater gradient have changed over the past 150 years because of landscape modification, water management and flood management infrastructure such as dams and conveyance facilities, channel dredging, and climate change.

Figure 6-1 is a representation of salinity over a range of concentrations relevant to suitability for water supply. It shows the salinity gradient in the western Delta under high and low outflow conditions. Changes in seasonal inflow to the Delta caused by upstream diversions, storage of water behind the State and federal water project dams, and operation of the State and federal Delta pumps have generally shifted the salinity gradient upstream and have changed seasonal and interannual salinity patterns. Even with these measurable shifts in salinity caused by diversion, storage, and conveyance of water, a primary driver of seasonal and annual salinity variability in the western Delta and Suisun Marsh continues to be the amount of precipitation in the watershed (Enright and Culberson 2010).

The examination of tree rings throughout the mountains of California provides a good indicator of precipitation over the last 650 years, but tree rings alone cannot accurately reproduce the details of Delta salinity over this period (Stahle et al. 2011). However, strong evidence indicates that the western Delta was a freshwater ecosystem for 2,500 years before human modification in the nineteenth and twentieth centuries (Malamud-Roam and Ingram 2004). Channel dredging, significant reductions in tidal marsh area, and levee construction have changed Delta salinity by increasing the strength of tides in the Delta, increasing connections between channels, and reducing the moderating effects of wetlands and floodplains on outflow. Consequently, simply allowing more variability in Delta outflow will not produce the same salinity patterns that existed before development.

Although sea water is the primary source of salinity in the western Delta and Suisun Marsh, it is not the only source. Agricultural drainage is another significant source of salinity, particularly in the San Joaquin Valley. Municipal and industrial discharges also can locally increase salinity, although such salinity increases are generally small compared to increases from brackish water inputs. All surface waters and groundwaters contain some amount of salt, and this salt is concentrated with use through evaporation and transpiration of water by plants (Central Valley Drinking Water Policy Workgroup 2007). The remaining water in drainage, agricultural return flows, or percolated groundwater has a higher salt concentration than the supply water. This normal increase in salinity with water use is exacerbated in some parts

Salinity in the Delta Varies by Inflow Volumes

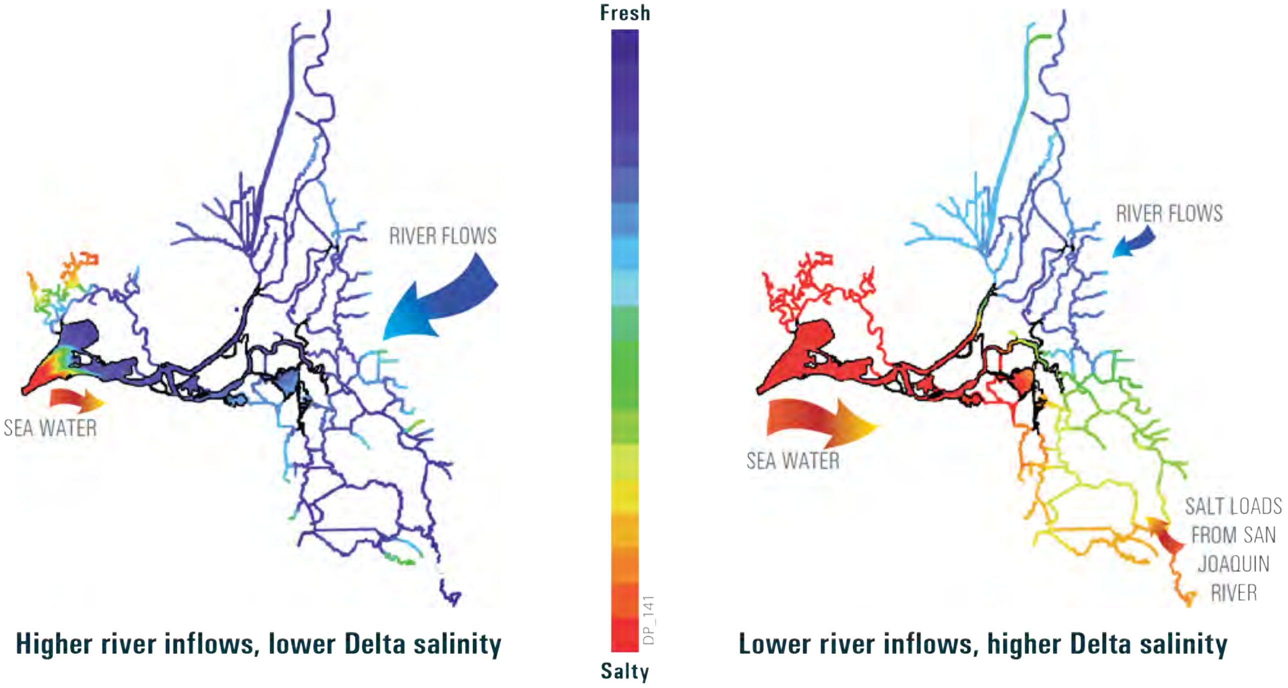

Figure 6-1

Delta salinity varies with inflow and outflow. Very high flows (left) push fresh water well into Suisun Bay and produce low-salinity conditions throughout the Delta. During very low flow periods (right), sea water can be seen pushing into the interior Delta from Suisun Bay with high salinity also entering from the San Joaquin River in the southeastern Delta.

Source: Central Valley Drinking Water Policy Workgroup 2007; images created by Resource Management Associates

of the San Joaquin Valley by naturally occurring salts in soils and a Delta water supply that already includes salt. Some of the salt load in the San Joaquin Valley accumulates in groundwater, affecting a variety of uses. Another manifestation of the salt problem is elevated salinity in the San Joaquin River at the point where it enters the Delta; this level is much higher than in the Sacramento River and marginally meets applicable water quality standards for much of the year. At times, salinity from sea water mixing into the western Delta and salinity from the San Joaquin River creates a Delta with a “freshwater corridor” leading from the Sacramento River to the State and federal water export pumps in the south Delta.

Salinity in the Delta Ecosystem

The role of water quality characteristics in ecosystem function, including salinity, temperature, turbidity, and DO, is discussed in detail in Chapter 4. Salinity is a defining characteristic of habitat for estuarine organisms and perhaps the most important water quality characteristic affecting municipal, industrial, and agricultural water use. However, salinity patterns that benefit native species are sometimes in conflict with human uses of water.

The salinity tolerances and preferences of fish vary by species. Delta smelt spawn in fresh water, but juveniles and adults generally show a preference for salinity in the range of 0.5 to 5 parts per thousand (ppt). Adult longfin smelt tolerate a much wider range of salinity and thrive in salinities greater than 5 ppt. Splittail do well in a wide range of salinities from fresh water up to 18 ppt (Moyle 2002). Largemouth bass and bluegill, introduced species, prefer fresh water and are rarely found at salinities greater than 1 to 2 ppt. The location, extent, and dynamics of the freshwater-saltwater interface in the Bay-Delta is an important factor in the distribution and abundance of many fish, invertebrate, and plant species, and is largely determined by the amount of fresh water flowing from the Delta west into Suisun Bay.

The interface between fresh water and salt water is a critical region of the estuary for many native fish and other organisms. Although there is no broadly accepted definition, the low salinity zone (LSZ) of the estuary is generally considered to be the region with salinity ranging from fresh water up to about 5 ppt, about one-seventh the salinity of sea water. The part of the salinity gradient centered on 2 ppt is considered to be of particular importance because it is hypothesized to be an area where suspended particulate matter and organisms accumulate. The location in the Bay-Delta where the tidally averaged salinity at 1 meter from the bottom is 2 ppt is known as X2 (measured as distance in kilometers from the Golden Gate Bridge) and serves as a water quality objective to regulate Delta outflow. The endangered Delta smelt show a preference for the LSZ. Their distribution during most of the year is centered near X2 (Nobriga et al. 2008). The position of X2 is also correlated with the abundance of several estuarine fish and invertebrates such as the bay shrimp and longfin smelt. That is, higher outflows (X2 located closer to the Golden Gate Bridge) are correlated with greater abundance of longfin smelt and bay shrimp (Kimmerer 2004). However, the processes linking greater Delta outflow with the abundance of estuarine species in the Bay-Delta system are not clearly understood, and continue to be studied and debated.

One proposed mechanism for the benefits of X2 as a regulatory marker for Delta smelt and other pelagic species is its relationship to the extent of low-salinity habitat. Lower values of X2 place it in the vicinity of Grizzly and Suisun bays, which results in a much larger area of low-salinity habitat than when X2 is located upstream of the confluence of the Sacramento and San Joaquin rivers. One of the potential negative effects of climate change will be a reduction in the availability of suitable low-salinity habitat for Delta smelt. The combined effects of sea level rise and changes in other aspects of estuarine habitat caused by climate change and increased water diversions are likely to pose a significant threat to the future survival of Delta smelt (Feyrer et al. 2011). Additional information on the relationship between flows in the Delta, the low-salinity zone, and implications for ecosystem health is included in Chapter 4.

Effects of Salinity on Agricultural Water Use

As noted in Chapter 5, agricultural use of water in the Delta is a significant factor in the health of the Delta's regional economy. The effect of salinity on agricultural water use varies by crop, soil type, and other factors (Hoffman 2010). The existing water quality objective, designed to protect the most sensitive crops, is set by the SWRCB at 700 microsiemens per centimeter (μS/cm) during the irrigation season and 1,000 μS/cm for the remainder of the year in southern Delta channels. At 700 μS/cm, water is relatively fresh, approximately equivalent to a salinity of 0.37 ppt (about 1 percent). The SWRCB is reviewing this objective based on the most recent information about the impacts of salinity on typical Delta crops. Salts from upstream and in-Delta agricultural drainage and from seawater intrusion from the Bay can affect agricultural water use in the Delta. Poor flow circulation in some parts of the Delta resulting from water diversions and historical channelization can exacerbate salinity problems.

Water quality to protect agricultural water use in the southern Delta is controlled through a combination of San Joaquin River inflow, export pumping, and Delta outflow changes. When salinity threatens to exceed water quality objectives for the San Joaquin River near Vernalis, additional high-quality water is released from New Melones Reservoir.

The effect of these releases is tempered by the installation and operation of flow barriers in the southern Delta to benefit agriculture. Salinity from seawater intrusion is reduced through a combination of reservoir releases, gate closures, and export pumping changes that, when necessary, control Delta outflow. Any significant changes to the way that water moves into or through the Delta, such as sea level rise, changed conveyance, changed inflow, or changed outflow, will change salinity patterns in the Delta.

Water quality at the SWP and CVP export pumps in the southern Delta, while usually meeting all applicable standards for municipal and agricultural use, is significantly higher in salinity than Sacramento River inflow to the Delta. Allowing salinity to vary in a way that might benefit native species could affect agricultural and municipal uses of Delta water.

Effects of Salinity on Municipal and Industrial Water Uses

Salinity contamination of municipal water supplies, as described in the following section on drinking water quality, can make water unpalatable, contributes to the formation of harmful disinfection byproducts, and increases corrosion of pipes and equipment. The existing objectives for protection of municipal and industrial beneficial uses in the southern Delta, expressed as limits on concentration of chloride, were developed to protect former industrial uses, but have been retained because they also protect drinking water quality. Secondary standards (standards that apply to aesthetic properties) for drinking water supplies also apply to water exported from the Delta by the CVP and SWP.

Under the current salinity regulations and operations practices for Delta water, municipal and industrial water supplies generally meet all salinity objectives. However, sea level rise, Delta levee failures, and increasing salt from upstream all threaten Delta municipal and industrial water supplies. Removing salts from water supplies is technically possible, although difficult and expensive; and disposing of the concentrated salt waste stream remains a key challenge.

Increased salinity further affects the reliability of municipal and industrial water supplies by reducing opportunities for water reuse and recycling (Healey et al. 2008), in turn potentially increasing reliance on imported surface water. Moving Delta intakes upstream, away from the influence of seawater intrusion and San Joaquin River inflow, could substantially reduce these water supply threats and is the subject of analysis under the current Bay Delta Conservation Plan process.

The salinity regime in the Delta is driven by natural flows, water management, and human land and water uses in the Delta and its watershed. Achieving the coequal goals will require updated comprehensive flow objectives and water quality control programs for salinity that balance ecosystem and water supply needs. The SWRCB must pay significant attention to the examination and resolution of these water quality issues in its development of new Delta flow requirements and as new plans for Delta conveyance are developed.

Drinking Water Quality

Water moving through the Delta contributes some part of the drinking water supplies for more than 25 million Californians. It is also used extensively for body-contact recreation such as swimming and water skiing. At the current locations where Delta water is diverted for municipal use, the water sometimes contains relatively high concentrations of bromide, organic carbon, nutrients, and dissolved solids (salinity). These drinking water constituents of concern are not directly harmful in drinking water, but they lead to formation of harmful chemicals during drinking water treatment, or contribute to taste, odor, or other municipal water supply problems. Sources of these drinking water constituents of concern include natural processes, such as tidal mixing of sea water into the Delta, and the flux of water and organic matter from wetlands, as well as urban runoff, agricultural runoff, and municipal wastewater discharge. Pathogenic (infectious) protozoa, bacteria, and viruses are also present in Delta waters and are a disease risk for both drinking water and body-contact recreation.

The future of water quality is a major concern for municipalities using Delta water. Current water quality regulations and policies for surface waters do not directly apply to many of the drinking water quality constituents of concern. Sea level rise, levee failure, salinity variability, agricultural water use, and increased urban runoff due to population growth in the watershed all pose a threat to drinking water quality. Clear policies regarding the protection of water quality relevant to the drinking water quality constituents of concern are needed to prevent such degradation. The Central Valley RWQCB is developing a drinking water policy that is, in part, intended to prevent the degradation of high-quality drinking water sources (Central Valley RWQCB 2010).

Disinfection Byproducts

Treatment of public water supplies is necessary to prevent disease caused by pathogenic organisms. However, bromide and organic carbon in municipal water supplies contribute to the formation of harmful disinfection byproducts when water is treated for domestic use (Healey et al. 2008, AWWA 2011). (See sidebar, Disinfection Byproducts.) The disinfection byproducts of primary concern in tap water, such as trihalomethanes (THMs), haloacetic acids, and bromates, are carcinogens subject to stringent public health standards. Treatment of water from the Delta is particularly challenging because it can contain elevated levels of both bromide and organic carbon (DWR 2007). Changes to drinking water treatment processes to reduce the amounts of disinfection byproducts in tap water are technologically challenging and can significantly increase the cost of drinking water treatment (Chen et al. 2010).

Organic carbon (total or dissolved) is an aggregate measure of the amount of a wide variety of organic compounds in water. In fresh water, these compounds typically come largely from decaying plant material. Along with bromide, elevated concentrations of organic carbon contribute to formation of disinfection byproducts. The amount of disinfection byproduct varies with the type and source of organic carbon, but total organic carbon concentration is nearly always correlated with disinfection byproduct formation. Large-scale restoration of wetlands could increase the amount of disinfection byproducts formed in Delta

DISINFECTION BYPRODUCTS

Disinfection byproducts are formed when disinfectants used in water treatment plants react with bromide and/or natural organic matter (decaying vegetation) present in the source water. Different disinfectants produce different types or amounts of disinfection byproducts. Disinfection byproducts identified in drinking water include THMs, haloacetic acids, and bromates. The USEPA has established regulations for these contaminants and set the maximum contaminant levels (MCLs) to prevent health effects (40 *Code of Federal Regulations* Part 141).

Trihalomethanes (THM) are a group of four chemicals formed along with other disinfection byproducts when chlorine or other disinfectants used to control microbial contaminants in drinking water react with naturally occurring organic and inorganic matter in water. The THMs are chloroform, bromodichloromethane, dibromochloromethane, and bromoform. THM violations are the primary difficulty for drinking water systems that use water from the Delta, especially the smaller systems. Some people who drink water containing total THMs in excess of the MCL over many years could experience liver, kidney, or central nervous system problems and increased risk of cancer.

Haloacetic acids are a group of chemicals formed along with other disinfection byproducts when chlorine or other disinfectants used to control microbial contaminants in drinking water react with naturally occurring organic and inorganic matter in water. Haloacetic acids include monochloroacetic acid, dichloroacetic acid, trichloroacetic acid, monobromoacetic acid, and dibromoacetic acid. Some people who drink water containing haloacetic acids in excess of the MCL over many years may have an increased risk of cancer.

Bromate is a chemical formed when ozone used to disinfect drinking water reacts with bromide in source water. Bromate formation is a problem for drinking water systems that use ozone as the primary disinfectant. Bromate violations are uncommon, but are a concern during low-flow years when seawater intrusion causes bromide concentrations in Delta water to increase. Some people who drink water containing bromate in excess of the MCL over many years may have an increased risk of cancer.

DP-187

water used for municipal supplies due to an increased amount of total organic carbon and the greater disinfection byproduct formation potential of wetland-derived organic carbon (Kraus et al. 2008).

Salinity

Salinity, frequently measured as electrical conductivity or total dissolved solids, has several significant effects on the use of water for domestic uses. Salts make water unpalatable at relatively low concentrations, with 500 parts per million total dissolved solids set as the recommended maximum level in the California secondary drinking water standards (California Code of Regulations, Title 22, section 64449). Salinity also increases the cost of treatment and costs to the consumer due to corrosion and other factors (Howitt et al. 2009). One common component of sea water, bromide, is a disinfection byproduct precursor that forms THMs and haloacetic acids with chlorine or chloramine disinfection, and forms bromate with ozone disinfection.

Pathogens

Pathogenic organisms and pathogen indicators are found in most surface waters. Two common protozoan pathogens that cause gastroenteritis, *Giardia lamblia* and *Cryptosporidium parvum*, have been found in Delta waters (at generally low levels) with respect to drinking water sources or body-contact recreation (Tetra Tech 2007). Source waters that exceed drinking water regulatory thresholds for *Cryptosporidium* trigger additional pathogen removal requirements (USEPA 2004). Although available data do not demonstrate that such conditions currently exist at Delta municipal water supply intakes, future plans that move or create new water intakes could result in increased treatment costs. Pathogen indicators such as fecal coliforms or *E. coli* are frequently at levels of concern in urban stormwater runoff. Several urban creeks and Delta water bodies that receive urban runoff are listed as impaired due to the presence of these indicator bacteria.

Nutrients

In the Delta, drinking water supplies with excessive levels of nutrients are primarily of concern because they, along with other factors such as residence time and temperature, can stimulate algae growth in the Delta and in reservoirs (Tetra Tech 2006a, Izaguirre and Taylor 2007). Algal blooms in storage reservoirs can disrupt treatment processes, and cause taste and odor problems. Taste and odor complaints associated with Delta water supplies have been attributed to algae growth in reservoirs or in the Delta itself (DWR 2007).

Drinking Water Intakes

The quality of Delta water with respect to drinking water use varies considerably both geographically and over time. Average organic carbon and bromide concentrations are very low in the Sacramento River where it enters the Delta. San Joaquin River water is moderately high in bromide, salinity, and nutrients, and moderately high in organic carbon. Intakes in the west Delta can be strongly influenced by the estuarine salinity gradient. An intake for the City of Antioch is frequently out of use because of salinity intrusions. The North Bay Aqueduct intake on Barker Slough in the northwest Delta is strongly affected by the local watershed and has the highest average organic carbon concentrations of any Delta municipal water supply intake (Tetra Tech 2006b). In addition to the drinking water quality problems at the current North Bay Aqueduct intake location, the intake may also have a negative effect on the ecosystem because it is located in an area that is otherwise high-quality habitat for listed native fish species.

Groundwater Quality Concerns

The drinking water supply from groundwater for many communities in the Delta and areas served by water exported from the Delta is contaminated by nitrates and other pollutants, particularly in the San Joaquin Valley. Survey findings show that a high financial burden is borne by low-income households when it comes to nitrate-contaminated water

(Pacific Institute 2011). The high cost of accessing water from alternative sources, coupled with the low earnings of these households, often makes safe drinking water in these communities unaffordable (Pacific Institute 2011). Small community and private water systems throughout the Central Valley and in the Delta rely on groundwater as their primary source of drinking water. They are affected by groundwater contamination to a greater degree than larger public water systems because many are in areas that are vulnerable to contamination (SWRCB 2011). Their wells are often shallower than larger community systems, and they have limited resources to treat or respond to contaminated groundwater problems. The California Legislature explicitly recognized these issues when, in 2012, it enacted Assembly Bill 685, declaring the established State policy that "every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes" (Water Code section 106.3(a)). More information on groundwater and how it relates to the Delta can be found in Chapter 3.

Environmental Water Quality

The Delta ecosystem is affected by a variety of pollutants discharged into Delta and tributary waters. Pollutants of concern affecting Delta biological species and ecosystem processes include nutrients, pesticides, mercury, selenium, and other persistent bioaccumulative toxic substances. Newly identified pollutants of potential concern (often referred to as emerging contaminants) also need to be investigated.

Nutrients

Nutrients, and their potential benefits and problems, have become an increasingly important component in the discussion of water quality issues in the Delta. The role of nutrients and nutrient loading for the Delta and Suisun Marsh is a subject of debate. Plant nutrients of concern in water are primarily nitrogen and phosphorus compounds including ammonia, ammonium, nitrite, nitrate, and phosphate. Excessive amounts (over fertilization) or altered proportions of these nutrients in streams, rivers, lakes, estuaries, or the coastal ocean can have detrimental effects on ecosystems. Die-offs of algae that deplete oxygen and cause fish kills are a well-known example, but even less obvious effects of nutrients can have important impacts on aquatic ecosystems. Changes in the types of algae that form the base of the aquatic food web, including growth of toxic algae, have been linked to excessive amounts or altered ratios of plant nutrients. Recent and current research is reconsidering the role of nutrients for aquatic ecosystems of the Delta, as follows:

- **Ammonium.** Ammonium in Delta waters has been shown to affect ecosystem water quality. Dugdale et al. (2007) has determined that ammonium concentrations may be having a significant impact on phytoplankton composition and open-water food webs because of suppression of diatom blooms in the Bay-Delta. Ammonium concentrations in Suisun Bay and the Delta have been increasing, primarily due to point source discharge loading from wastewater treatment facilities. It is not known, however, how much this inhibition extends to freshwater algae in the Delta.
- **Nutrient ratios.** Ratios of nutrients in Delta waters are thought to be a primary driver in the composition of aquatic food webs in the Bay-Delta (Glibert et al. 2011). The effect of ammonium on food webs in the Delta remains an open question, and much active research and healthy scientific debate continue.

- **Harmful algal blooms.** HABs create a toxic environment for aquatic organisms and the organisms that eat them. The emergence of HABs over the past decade threatens environmental water quality. The shift toward greater abundance of cyanobacteria in the Delta includes known HABs such as *Microcystis aeruginosa*. *Microcystis aeruginosa* has become a common bloom-forming component of the phytoplankton of the Delta during the warm summer and early fall months (Lehman et al. 2005, 2008). Interactions between nutrients and HABs in the Delta warrant additional study and are currently being investigated.
- **Nonnative aquatic plants.** Nutrients affect the productivity of aquatic macrophytes (plants visible to the naked eye) and the structure of the aquatic plant community (Wetzel 2001). Two nonnative aquatic plants, Brazilian waterweed and water hyacinth, have become particularly problematic in the Delta. Scientific studies have documented the distribution and spread of these invasive aquatic plants in the Delta (Underwood et al. 2006, Hestir et al. 2008, Khanna et al. 2011, Santos et al. 2011). The role of nutrient enrichment in the spread and productivity of these nonnative aquatic plants is unknown. Further research is required on the potential links between invasive aquatic plants in the Delta and nutrient inputs.

The effects of increased nutrient inputs also need to be considered in light of anticipated changes in the Delta with regard to lowered turbidity and warming temperatures. Figure 6-2 shows increasing nutrients in the Delta over time. As discussed in the following section, nutrients have been implicated in DO depletion in Delta channels due to the stimulation of plant growth with subsequent death and decay, and the microbial conversion of total ammonia to nitrate through the process of nitrification.

Dissolved Oxygen

DO in water is essential to the survival of most fish and many other aquatic organisms. Depletion of DO in a water body because of decaying organic matter is a classic water quality problem that can result in clear signs of pollution, including fish kills and foul odors. Low DO concentrations also can have less obvious effects. DO events occur regularly in the channels of Suisun Marsh and the Stockton Deep Water Ship Channel (SDWSC) and sporadically elsewhere in the Delta, with several waterways listed as impaired by the RWQCB.

One of the most significant water quality issues affecting the Delta in recent decades has been low DO episodes (DO concentrations less than regulatory objectives) in the SDWSC reach of the San Joaquin River in the Delta, which were thought to act as a barrier to salmon migration (Central Valley RWQCB 2005). Until the last few years, low DO events were a regular occurrence in this part of the Delta primarily during the summer and fall months.

The SDWSC DO problem has existed since at least the 1960s. The Central Valley RWQCB added this segment of the Delta to its list of impaired water bodies in 1998, and adopted a TMDL in 2005 that follows a phased approach requiring studies and initial actions followed by reconsideration of TMDL requirements in 2012. Extensive studies have identified several contributing factors, including inputs of algae from upstream (probably related to nutrient loads), discharges of total ammonia from the Stockton Regional Wastewater Control Facility (RWCF), increased channel depth due to dredging, and reduced net flows (Central Valley RWQCB 2005). See sidebar, Applying Adaptive Management in Water Quality Decisions, for more information about an adaptive management approach to DO in the SDWSC.

The improved wastewater treatment processes at the RWCF were fully operational starting in 2006. This, along with other discharge reductions upstream, appears to have greatly reduced the frequency and severity of low DO episodes in the SDWSC. The California Department of Water Resources (DWR) aeration facility also has been shown to be an effective remedy for the occasional DO depletion problem that might occur under current conditions. The actions taken to

Nutrients Create Delta Water Problems

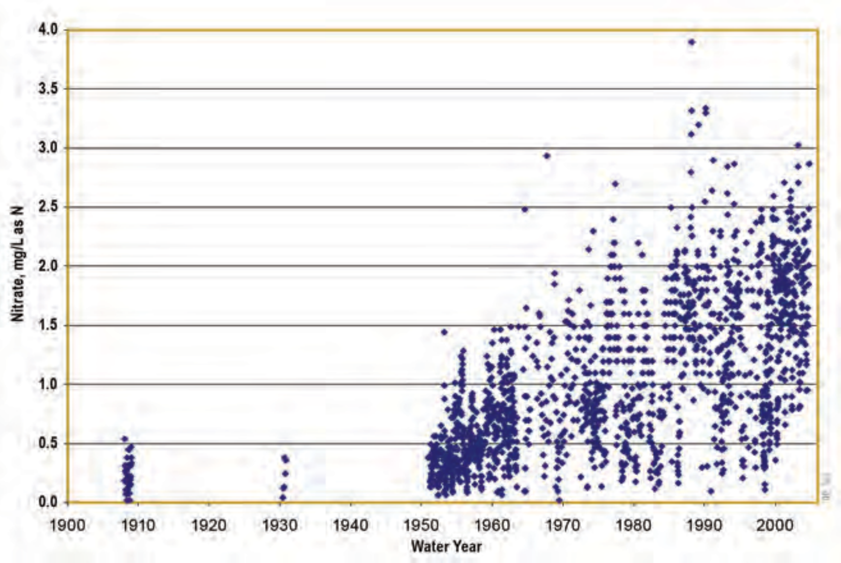

Figure 6-2

Nitrate concentrations at the point where the San Joaquin River enters the Delta dating back to 1908 show how much this important plant nutrient has increased. High nutrient concentrations are linked to a variety of problems including DO depletion, growth of nuisance aquatic plants, and taste and odor problems in drinking water.

Source: Adapted by the Delta Stewardship Council with data provided by USGS

comply with the current TMDL, along with improved flows and load reductions in the San Joaquin River watershed, appear to have provided a solution to this longstanding water quality problem. If continued, the actions taken to comply with the SDWSC TMDL should be sufficient to prevent future DO depletion problems.

The DO depletion problems in Suisun Marsh are caused by seasonal operations of ponds and wetlands managed for waterfowl hunting. For most of the year, duck club ponds are drained and occasionally flooded to promote the growth of plants that are the favored food of water fowl. When these ponds are flooded for hunting in the late summer and fall, the decay of accumulated plant matter followed by tidal exchanges of water with adjoining channels can cause severe DO depletion. Some of these low DO events have caused documented fish kills. The San Francisco Bay RWQCB has started the TMDL process to address DO depletion in Suisun Marsh.

The best pathways to address other Delta low DO problems will vary with local conditions and causes, but likely will be a combination of reduced loadings of oxygen-demanding substances and changes to flow conditions, under the framework of adaptive management. As TMDLs are developed to address low DO concentrations in the Delta, actions needed to improve DO conditions will be implemented through SWRCB and RWQCB programs, including NPDES permits, stormwater NPDES permits, WDRs, waivers of WDRs, and water rights. Low DO conditions in the Delta need to be addressed to prevent these conditions from increasing in extent and severity.

Applying Adaptive Management in Water Quality Decisions

An adaptive management approach to water quality control decisions should be taken to plan for and assess their outcomes. The following is an example of how the Council's three-stage, nine-step adaptive management framework (see Appendix C) was used for water quality decision making in the TMDL process to improve DO concentrations in the SDWSC.

Adaptive Management Step			Improving DO Concentrations in the SDWSC
Plan	1	Define/redefine the problem	Low concentrations of DO in the SDWSC periodically exceeded the Central Valley Basin Plan water quality objectives for DO for many years. Low DO acted as a barrier to migrating salmon.
	2	Establish goals, objectives, and performance measures	**Goal:** Meet the water quality objectives for DO in the SDWSC. **Objectives:** Maintain minimum DO concentrations of 5 milligrams per liter (mg/L) at all times and 6 mg/L September through November.
	3	Model linkages between objectives and proposed action(s)	Hydrodynamic and water quality models informed the development of a Physical and Chemical Processes Conceptual Model and a Biological and Ecological Effects Conceptual Model. The models identified at least four primary factors or processes influencing oxygen concentrations: (1) San Joaquin River flow through the SDWSC, (2) SDWSC volume, (3) algae and oxygen-demanding substances from the San Joaquin River upstream of the SDWSC, and (4) oxygen-demanding substances, including ammonia discharged from the RWCF. http://www.sjrdotmdl.org/concept_model/index.htm
	4	Select action(s) (research, pilot, or full-scale) and develop performance measures	**Selected Actions:** (1) Conduct studies to identify causes for the low DO levels and assign responsibility to correct the problem; (2) reduce RWCF ammonia discharges to the San Joaquin River; and (3) construct a Demonstration Dissolved Oxygen Aeration Facility (Aeration Facility). **Performance Measures:** ▪ Administrative – Implement Phase 1 TMDL actions. ▪ Output – Implement studies; select wastewater treatment improvements to reduce ammonia discharges including engineered wetlands and nitrifying bio-towers; develop pilot-scale aeration project. ▪ Outcome – DO concentrations are maintained at or above the water quality objectives for DO. Aquatic life, including resident and migratory fish, is not affected by low DO conditions.
Do	5	Design and implement action(s)	**Selected Actions:** (1) Conduct ongoing studies to improve the conceptual models; (2) add engineered wetlands and two nitrifying bio-towers to the RWCF; and (3) design, build, and operate the Aeration Facility at Rough and Ready Island to determine its applicability for increasing DO concentrations in the SDWSC.
	6	Design and implement monitoring plan	Collect baseline DO data prior to aerator operations. Conduct ongoing studies to test the understanding of linkages in the conceptual models. Conduct compliance monitoring at the RWCF as required by the permit. Conduct performance monitoring of the Aeration Facility to measure achievement of the target (increased DO concentrations in the SDWSC).
Evaluate and Respond	7	Analyze, synthesize, and evaluate	Technical Working Group will assess the study results and aeration pilot-study results.
	8	Communicate current understanding	Technical reports, study results, and web-based conceptual models were developed and maintained on a website. Pilot Report Aeration System and staff presentation to the Central Valley RWQCB (February 3, 2011).
	9	Adapt	Development of a revised control program (Phase 2 TMDL) including identification of additional or modified actions. Development of an aeration agreement with long-term funding for operation and maintenance of the Aeration Facility, including possible future modifications. Development of a system-level (long-term) monitoring plan for the Aeration Facility. Periodic review of control program actions and aerator operations.

Pesticides

Pesticides include insecticides, herbicides, fungicides, and various other substances used to control pests. In the Bay-Delta region, the primary pesticides of concern include the organophosphorus pesticides (for example, diazinon and chlorpyrifos), pyrethroid insecticides, and the legacy organochlorine pesticides (for example, DDT, chlordane, and dieldrin). These substances are known to have adverse impacts on aquatic organisms or, in some cases (as with the organochlorine pesticides), birds and mammals.

The Sacramento, San Joaquin, and Feather rivers; the Delta; and numerous agriculturally dominated streams in the Central Valley are either listed as impaired or are covered under an existing TMDL for pesticides (Central Valley RWQCB 1998, 2006). Delta waterways were placed on the CWA section 303(d) list for diazinon and chlorpyrifos due to aquatic toxicity (SWRCB 2010).

Smaller agriculturally dominated waterways and urban creeks are particularly vulnerable to toxicity from pesticides. Although agriculture is considered the primary source of pesticide impairment in the Central Valley and Delta, urban sources are also locally important (Kuivila and Hladik 2008). Some of the highest pesticide concentrations have been observed in residential area creeks and waters receiving urban runoff (Weston et al. 2005). Pyrethroid insecticides, which are common replacements for the organophosphorus pesticides, have been implicated as the principal pesticides causing toxicity in surface water samples collected from throughout California (Hunt et al. 2010).

Aquatic invertebrates in the water column are the organisms most affected by chlorpyrifos and diazinon exposure (Giddings et al. 2000); however, pyrethroids—because of their high potential to stick to organic matter—also can affect sediment-dwelling organisms (Werner and Oram 2008, Weston et al. 2004). Pyrethroid pesticides from multiple runoff sources have been found at levels toxic to aquatic invertebrates (Weston et al. 2005, Weston 2010).

Contaminants cannot be eliminated as a possible contributor to the declines in open-water fish populations in the Delta (known as pelagic organism decline [POD]). Johnson et al. (2010) reported that insufficient data are available to determine whether contaminants played an important role in the POD. Research on the role of contaminants in the POD continues with efforts under way to better define the presence of contaminants in the environment, the effects of contaminant mixtures, sublethal effects of contaminants on the POD species, and the effects of contaminants on prey organisms (Baxter et al. 2010). Synergistic effects of pesticide mixtures have been demonstrated for other species including juvenile salmon (Laetz et al. 2009).

Mercury

The Delta and many Delta tributaries are included in the SWRCB's section 303(d) list of impaired water bodies due to mercury contamination (Central Valley RWQCB 2009). Historical mercury mining in California's Coast Ranges and mercury use associated with gold mining in the Sierra Nevada over a century ago have left an environmental legacy of pervasive mercury contamination in many Northern California watersheds (Alpers and Hunerlach 2000). The current regulatory approach for mercury includes the mercury TMDL adopted by the San Francisco Bay RWQCB in 2006 and the Delta methylmercury TMDL adopted by the Central Valley RWQCB in 2010. Unfortunately, however, mercury is likely to persist in California's environment for many years to come.

Mercury is transformed into methylmercury by bacteria in the environment. Methylmercury, initially present at very low concentrations, enters the aquatic food web and can accumulate to levels of concern in long-lived fish at the top of the aquatic food chain, such as striped bass and largemouth bass. Methylmercury has been found in some types of Delta fish at concentrations that may be harmful to human health. The State has issued health advisories for fish consumption due to mercury contamination for a number of water bodies in the Delta and its watersheds. Mercury contamination of fish is of particular concern for people who are frequent consumers of Delta fish (Shilling 2009).

There is general concern that increased concentrations of methylmercury in water, sediment, and plants and animals might result from restoration of wetland and floodplain habitats in the Delta and, thus, must be carefully planned and monitored to minimize the production of methylmercury. For instance, the restoration of wetlands, particularly in areas where the abundance of mercury in soils or sediments is elevated, could accelerate the production of methylmercury and increase the contamination of aquatic plants and animals (Naimo et al. 2000, Wiener and Shields 2000). Additionally, flooding of wetlands or uplands, or fluctuating water levels during tidal cycles could stimulate methylmercury production and transport, thereby increasing concentrations of methylmercury in water and in plants and animals (Hecky et al. 1991, Hall et al. 1998, Paterson et al. 1998, Bodaly and Fudge 1999). Increased methylmercury production is a significant concern for planned wetland and floodplain ecosystem restoration projects, and should be monitored.

Further study is needed to determine the dominant processes affecting methylmercury concentrations in food webs in the Delta. The CALFED Ecosystem Restoration Program developed a framework (Mercury Strategy) for monitoring, research, risk communication, and adaptive management to address mercury problems in the Bay-Delta system (Wiener et al. 2003). The approach taken by the Central Valley RWQCB in its Delta Mercury Control Program, adopted April 22, 2010, is consistent with the Mercury Strategy (Central Valley RWQCB 2010).

Selenium

Selenium, a naturally occurring element, is an essential nutrient at low concentrations for humans and other organisms. However, higher concentrations can be toxic to fish and wildlife. Once selenium enters the aquatic environment, it has a high potential to bioaccumulate in zooplankton and benthic (bottom-dwelling) invertebrates and, subsequently, to biomagnify in the food web as it reaches top-level predators such as fish, birds, and mammals (Skorupa and Ohlendorf 1991, Fan et al. 2002, Hamilton 2004, Stewart et al. 2004, Paveglio and Kilbride 2007).

The major source of selenium loading to San Francisco Bay is the San Joaquin River, which receives selenium-laden agricultural drainage waters from the western San Joaquin Valley (Luoma and Presser 2000). Other sources of selenium loading include oil refineries, municipal and industrial wastewater, urban and nonurban runoff, atmospheric deposition, and erosion and sediment transport from within the north San Francisco Bay. Improved wastewater treatment at petroleum refineries discharging into San Francisco Bay has reduced the amount of selenium discharged, but these facilities are still the most significant point source of this pollutant (San Francisco Bay RWQCB 2011b).

Recent monitoring results indicate that selenium water column concentrations in the north San Francisco Bay are much lower than the current 5-parts per billion objective for chronic exposure (San Francisco Bay RWQCB 2011b). However, levels of selenium in aquatic organisms and fish show that the current regulatory criteria may not be sufficient. Despite progress to reduce selenium in the Bay-Delta system, levels in the food chain are still of concern. Selenium has been identified as a possible contributing factor to the observed decline of white sturgeon, Sacramento splittail, starry flounder, and diving ducks such as surf scoters. The focus of regulatory efforts at the State and national level is shifting from water-column concentrations to the concentration of selenium in the tissues of affected organisms (San Francisco Bay RWQCB 2011b).

Historically, portions of the San Joaquin River downstream of Grasslands, Salt Slough, and Mud Slough contained elevated levels of selenium from agricultural drainage (Saiki et al. 1993). The discharge of selenium from this area also has been significantly reduced from historical levels under a control program administered by Central Valley RWQCB, with plans for further reductions through 2019 (Reclamation 2009).

Contaminants of Emerging Concern

The term "contaminants of emerging concern" refers to a broad class of largely unregulated compounds for which there is concern that adverse effects might occur at environmentally significant concentrations. Examples of manufactured chemicals frequently found in water bodies and organisms include flame retardants, pesticides, human and veterinary pharmaceuticals, and ingredients in personal care products (Kolpin et al. 2002, Daughton 2004, Hoenicke et al. 2007).

Contaminants of emerging concern include many manufactured chemicals. These manufactured chemicals have the potential to alter water quality because of their widespread use, pathways to the environment, and potency. The primary sources for most contaminants of emerging concern include effluent from wastewater treatment plants, agricultural fields, and stormwater runoff. Many chemicals identified as contaminants of emerging concern have not been tested for their potential toxic effects on aquatic life. Most emerging pollutant maximum concentrations in the environment are well below established lethal concentration values for even the most sensitive aquatic species. Sublethal and chronic low-level exposures are of primary concern (Oros 2003, Brander et al. 2009, Ostrach 2009).

Regulatory and chemical monitoring programs should adapt to the quickly changing mix of contaminants of emerging concern identified through current studies and the peer-reviewed scientific literature (best available science). Effective management of contaminants of emerging concern in the Delta will require responsible agencies to perform appropriate scanning-level activities to prioritize a specific list of pollutants of highest concern and to develop or require work plans for special studies, and to conduct or require monitoring in accordance with the work plans. To this end, in 2011, the SWRCB established a Science Advisory Panel to address contaminants of emerging concern in aquatic ecosystems. The panel completed a report in April 2012 that included several recommendations for how the SWRCB should monitor and assess potential impacts of contaminants of emerging concern (Anderson et al. 2012).

POLICIES AND RECOMMENDATIONS

Policies and recommendations to address the water quality issues discussed in the preceding sections are based on the following strategies:

- Require Delta-specific water quality protection
- Protect beneficial uses by managing salinity
- Improve drinking water quality
- Improve environmental water quality

These major aspects of water quality are critical to achieving the coequal goals. The approach described here includes augmenting or accelerating existing programs where it is feasible to address an existing or anticipated water quality problem. The SWRCB and RWQCBs have broad authority to protect and regulate water quality; therefore, this chapter sets forth priority Delta-specific recommendations and does not contain regulatory policies at this time.

Require Delta-specific Water Quality Protection

Water flow, water quality, water supply, and habitat conditions in the Delta are distinctly different from other parts of the watershed and from San Francisco Bay downstream. The Delta is the most valuable estuary and wetland ecosystem on the West Coast of North and South America (Water Code section 85002), and is the primary habitat for a number of special-status species. Many communities in and around the Delta draw their drinking water directly from Delta waterways. Delta waterways also receive urban stormwater, treated wastewater, agricultural drainage, and drainage from managed wetlands. Studies have shown that such discharges can have significant impacts on water quality. These impacts are often more severe near the point of discharge. Stormwater, wastewater, and agricultural drainage discharges into the Delta should be managed so that they do not pose a significant risk to the beneficial uses of water in the Delta.

Problem Statement

Water quality management approaches developed for general application statewide or in other regions may not be sufficient for the unique and dynamic conditions of the Delta, its biological resources, and critical water supply services. Water supplies and habitats for special-status species require proactive and anticipatory measures for water quality protection consistent with their importance in achieving the coequal goals.

Policies

No policies with regulatory effect are included in this section.

Recommendations

WQ R1. Protect Beneficial Uses

Water quality in the Delta should be maintained at a level that supports, enhances, and protects beneficial uses identified in the applicable State Water Resources Control Board or regional water quality control board water quality control plans.

WQ R2. Identify Covered Action Impacts

Covered actions should identify any significant impacts to water quality.

WQ R3. Special Water Quality Protections for the Delta

The State Water Resources Control Board or regional water quality control board should evaluate and, if appropriate, propose special water quality protections for priority habitat restoration areas identified in recommendation ER R2 or other areas of the Delta where new or increased discharges of pollutants could adversely impact beneficial uses.

Protect Beneficial Uses by Managing Salinity

Beneficial uses within the Delta include drinking water, agriculture, and ecosystem protection. Salinity potentially affects these uses, but to varying degrees. The primary sources of salinity in the Delta are from tidal seawater intrusion from the Pacific Ocean through the San Francisco Bay, and to a lesser extent from agricultural and other discharges in the Central Valley. Historically, natural flows through the Delta regulated salinity in a way that favored the Delta ecosystem. Today, salinity in the Delta is dominated by the effects of upstream water diversions and use of the Delta to convey flows to Central and Southern California. The SWRCB is responsible for ensuring protection of beneficial uses through regulation of pollutant discharges, and regulation of water diversions and flows under their water rights authority.

Problem Statement

Salinity affects Delta agricultural, municipal, and environmental beneficial uses, but in different ways. Salinity and flow conditions in the Delta are affecting ecosystem, agricultural, and municipal uses. The timing and distribution of salinity is primarily affected by flow, which is largely determined by water management in the Delta and its watersheds as determined by applicable flow objectives. Delta conditions have changed since the current Delta flow objectives were adopted, and new scientific information about salinity, flow, and their effects on beneficial uses is available.

Policies

ER P1 in Chapter 4 on the SWRCB's Delta Flow Objectives addresses this issue.

Recommendations

ER R1 in Chapter 4 on the SWRCB's Update of Delta Flow Objectives addresses this issue.

Improve Drinking Water Quality

Millions of Californians entirely or partially rely on the Delta as a drinking water supply, and the future quality of that water supply is uncertain. Contamination of groundwater supplies places greater demand on surface waters that are tributary to the Delta for urban and agricultural users. Current water quality regulations and policies for surface waters do not apply directly to many of the drinking water quality constituents of concern. Sea level rise, levee failure, salinity variability, agricultural water use, and increased urban runoff from population growth in the watershed all pose a threat to drinking water quality. To prevent such degradation, we need clear policies regarding the protection of water quality relevant to the drinking water quality constituents of concern. The Central Valley RWQCB's anticipated drinking water policy is intended, in part, to prevent the degradation of high-quality drinking water sources (Central Valley RWQCB 2010).

In 2006, the SWRCB, the Central Valley RWQCB, and stakeholders began a joint effort to address salinity and nitrate problems in California's Central Valley and adopt long-term solutions that will lead to enhanced water quality and economic sustainability. Central Valley Salinity Alternatives for Long-Term Sustainability (CV-SALTS) is a collaborative basin planning effort aimed at developing and implementing a comprehensive salinity and nitrate management program.

Problem Statement

Delta drinking water supplies are degraded by inputs from sea water, regional soils, and sediments; from agricultural, urban, and industrial sources from the watershed; and from in-Delta sources.

Policies

No policies with regulatory effect are included in this section.

Recommendations

WQ R4. Complete Central Valley Drinking Water Policy

The Central Valley Regional Water Quality Control Board should complete the Central Valley Drinking Water Policy by July 2013.

WQ R5. Complete North Bay Aqueduct Alternative Intake Project

The California Department of Water Resources should complete the North Bay Aqueduct Alternate Intake Project Environmental Impact Report by December 31, 2012, and begin construction as soon as possible thereafter.

WQ R6. Protect Groundwater Beneficial Uses

The State Water Resources Control Board should complete development of a Strategic Workplan for protection of groundwater beneficial uses, including groundwater use for drinking water, by December 31, 2012.

WQ R7. Participation in CV-SALTS

The State Water Resources Control Board and Central Valley Regional Water Quality Control Board should consider requiring participation by all relevant water users that are supplied water from the Delta or the Delta watershed or discharge wastewater to the Delta or the Delta watershed to participate in the Central Valley Salinity Alternatives for Long-Term Sustainability Program.

Improve Environmental Water Quality

A variety of pollutants are discharged into Delta and tributary waters. These pollutants affect Delta biological species and ecosystem processes. Pollutants of concern include nutrients, pesticides, mercury, selenium, and other persistent bioaccumulative toxic substances. Newly identified pollutants of potential concern (emerging contaminants) also need to be investigated.

Problem Statement

Pollutants contained in municipal, industrial, agricultural, other nonpoint source discharges, and legacy sources flowing into the Delta and its tributary waterways, including pollutants that bioaccumulate and biomagnify in the food web, impair the Delta ecosystem. Evidence from water quality and ecosystem monitoring continues to show that significant water pollution problems persist in the Bay-Delta system and the Central Valley. Insufficient funding and support could lead to slowing or even erminating the SWRCB and the San Francisco Bay and Central Valley RWQCBs' engagements in regulatory processes, research, and monitoring that are essential to improving water quality in the Delta.

Policies

No policies with regulatory effect are included in this section.

Recommendations

WQ R8. Completion of Regulatory Processes, Research, and Monitoring for Water Quality Improvement

The State Water Resources Control Board and the San Francisco Bay and Central Valley Regional Water Quality Control Boards are currently engaged in regulatory processes, research, and monitoring essential to improving water quality in the Delta. In order to achieve the coequal goals, it is essential that these ongoing efforts be completed and, if possible, accelerated, and that the Legislature and Governor devote sufficient funding to make this possible. The Delta Stewardship Council specifically recommends that:

- *The State Water Resources Control Board should complete development of the proposed policy for nutrients for inland surface waters of the State of California by January 1, 2014.*
- *The State Water Resources Control Board and the San Francisco Bay and Central Valley Regional Water Quality Control Boards should prepare and begin implementation of a study plan for the development of objectives for nutrients in the Delta and Suisun Marsh by January 1, 2014. Studies needed for development of Delta and Suisun Marsh nutrient objectives should be completed by January 1, 2016. The water boards should adopt and begin implementation of nutrient objectives, either narrative or numeric, where appropriate, for the Delta and Suisun Marsh by January 1, 2018.*
- *The State Water Resources Control Board and the Central Valley Regional Water Quality Control Board should complete the Central Valley Pesticide Total Maximum Daily Load and Basin Plan Amendment for diazinon and chlorpyrifos by January 1, 2013.*
- *The State Water Resources Control Board and the Central Valley Regional Water Quality Control Board should prioritize and accelerate the completion of the Central Valley Pesticide Total Maximum Daily Load and Basin Plan Amendment for pyrethroids by January 1, 2016.*
- *The State Water Resources Control Board and the San Francisco Bay and Central Valley Regional Water Quality Control Boards have completed Total Maximum Daily Load and Basin Plan Amendments for methylmercury, and efforts to support their implementation should be coordinated. Parties identified as responsible for current methylmercury loads or proponents of projects that may increase*

methylmercury loading in the Delta or Suisun Marsh should participate in control studies or implement site-specific study plans that evaluate practices to minimize methylmercury discharges. The Central Valley Regional Water Quality Control Board should review these control studies by December 31, 2018 and determine control measures for implementation starting in 2020.

WQ R9. Implement Delta Regional Monitoring Program

The State Water Resources Control Board and Regional Water Quality Control Boards should work collaboratively with the California Department of Water Resources, California Department of Fish and Wildlife, and other agencies and entities that monitor water quality in the Delta to develop and implement a Delta Regional Monitoring Program that will be responsible for coordinating monitoring efforts so Delta conditions can be efficiently assessed and reported on a regular basis.

WQ R10. Evaluate Wastewater Recycling, Reuse, or Treatment

The Central Valley Regional Water Quality Control Board, consistent with existing water quality control plan policies and water rights law, should require responsible entities that discharge wastewater treatment plant effluent or urban runoff to Delta waters to evaluate whether all or a portion of the discharge can be recycled, otherwise used, or treated in order to reduce contaminant loads to the Delta by January 1, 2014.

WQ R11. Manage Dissolved Oxygen in Stockton Ship Channel

The State Water Resources Control Board and the Central Valley Regional Water Quality Control Board should complete Phase 2 of the Total Maximum Daily Load and Basin Plan Amendment for dissolved oxygen in the Stockton Deep Water Ship Channel by January 1, 2015.

WQ R12. Manage Dissolved Oxygen in Suisun Marsh

The State Water Resources Control Board and the San Francisco Bay Regional Water Quality Control Board should complete the Total Maximum Daily Load and Basin Plan Amendment for dissolved oxygen in Suisun Marsh wetlands by January 1, 2014.

Timeline for Implementing Policies and Recommendations

Figure 6-3 lays out a timeline for implementing the policies and recommendations described in the previous section. The timeline emphasizes near-term and intermediate-term actions.

Timeline for Implementing Policies and Recommendations

TIMELINE

CHAPTER 6: Improve Water Quality

	ACTION (REFERENCE #)	LEAD AGENCY(IES)	NEAR TERM 2012–2017	INTERMEDIATE TERM 2017–2025
RECOMMENDATIONS	Protect beneficial uses (WQ R1)	Varies	●	●
	Identify covered action impacts (WQ R2)	Varies	●	●
	Special water quality protections for the Delta (WQ R3)	SWRCB, RWQCB	●	
	Complete Central Valley drinking water policy (WQ R4)	Central Valley RWQCB	●	
	Complete North Bay Aqueduct Alternative Intake Project (WQ R5)	DWR	●	
	Protect groundwater beneficial uses (WQ R6)	SWRCB	●	
	Participation in CV-SALTS* (WQ R7)	SWRCB and Central Valley RWQCB	●	
	Completion of regulatory processes, research, and monitoring for water quality improvements (WQ R8)	SWRCB, San Francisco Bay and Central Valley RWQCBs	●	
	Implement Delta regional monitoring program (WQ R9)	SWRCB and RWQCBs	●	
	Evaluate wastewater recycling, reuse, or treatment (WQ R10)	Central Valley RWQCB	●	
	Manage dissolved oxygen in Stockton Ship Channel (WQ R11)	SWRCB and Central Valley RWQCB	●	
	Manage dissolved oxygen in Suisun Marsh (WQ R12)	SWRCB and San Francisco Bay RWQCB	●

*CV-SALTS: Central Valley Salinity Alternatives for Long-Term Sustainability Program

Agency Key: DWR: California Department of Water Resources RWQCB: Regional Water Quality Control Board(s) SWRCB: State Water Resources Control Board

Figure 6-3

Science and Information Needs

Successful management of water quality depends on a well-designed, comprehensive, and consistent system of water quality monitoring. Current Delta water quality monitoring is fragmented among several different agencies and programs. The Central Valley RWQCB has initiated an effort to develop a Delta Regional Monitoring Program that will consolidate and coordinate most of the current monitoring. Developing a coordinated and thorough regional monitoring program is essential to performance measurement and adaptive management in the Delta.

As identified above, a number of outstanding science questions need to be resolved with respect to water quality. Additional study is needed on the following:

- The effects of salinity on introduced and native plant and animal species
- Trends in concentrations of drinking water constituents of concern
- The effects of nutrients on the Delta ecosystem and municipal water supplies
    - The importance of phytoplankton bloom suppression from ammonium
    - The role of nutrient loading on HABs in the Delta
    - Possible linkages between nonnative aquatic plants and nutrient inputs
- Controlling DO depletion
- The effects of the simultaneous presence of multiple pesticides, even at low levels, on species of concern
- The processes contributing to mercury and selenium compounds in food webs and their effects on the ecosystem
- The impacts of pharmaceutical compounds, personal care products, and other emerging contaminants on the ecosystem
- The combined effects of multiple contaminants and water quality conditions on the ecosystem
- Sources and impacts of pathogens on drinking water sources and recreation in the Delta
- An analysis and evaluation of existing water quality models in the Delta
- Fate and transport of water quality contaminants in the Delta

Issues for Future Evaluation and Coordination

Additional areas of interest and concern related to water quality and the Delta may deserve consideration in the development of future Delta Plan updates, including the following:

- **Small and disadvantaged communities:** Ensuring a safe drinking water supply can have a disproportionate cost for small and disadvantaged communities. Delta communities that are small and disadvantaged include Bethel Island, Courtland, Freeport, Hood, Isleton, Locke, and Walnut Grove. There are also small and disadvantaged communities in areas served by water exported from the Delta that are disproportionately impacted by nitrate and other groundwater pollutants. Available options to correct unsafe drinking water conditions include shared services and facilities; consolidation of several small systems into a single, larger system; centralized treatment; interim point-of-use treatment or use of bottled water; replacement of a contaminated source with an uncontaminated source; and, in the case of chemical contamination, blending of contaminated sources with uncontaminated sources. Consideration also must be given to the new State policy that "every human being has the right to safe, clean, affordable and accessible water adequate for human consumption, cooking, and sanitary purposes" (Water Code section 106.3(a)). Availability and prioritization of funding, restructuring of regulatory requirements, and provision of technical assistance may all be part of the solution, but involve the authority of various agencies including the California Department of Public Health, SWRCB, DWR, U.S. Department of Agriculture, and local cities and counties. An integrated effort including the input and involvement of the regulatory and affected agencies will be needed to properly address these issues and to refine effective recommendations.

- **Coordinated and prioritized water quality monitoring and modeling:** Various water quality monitoring and modeling efforts are ongoing, but are not coordinated among affected agencies. Agencies involved in these efforts include the SWRCB, RWQCBs, DWR, the Interagency Ecological Program, California Department of Fish and Wildlife, and now, the Council. Collective discussion and evaluation by these and other entities will be needed in order to make recommendations regarding the need for and prioritization of water quality modeling in the Delta.
- **Contaminants of emerging concern:** The SWRCB and RWQCBs should continue ongoing efforts to address contaminants of emerging concern. This work should include development of a work plan for conducting or requiring special studies of pollutants, including emerging contaminants and causes of toxicity in Delta waters and sediments.
- **Water quality objectives for selenium:** The identified sources of selenium as a contaminant and its potential to bioaccumulate and biomagnify in the environment are ongoing concerns. The SWRCB and San Francisco Bay and Central Valley RWQCBs should continue efforts to revise water quality objectives for selenium.

Performance Measures

Development of informative and meaningful performance measures is a challenging task that will continue after the adoption of the Delta Plan. Performance measures need to be designed to capture important trends and to address whether specific actions are producing expected results. Efforts to develop and track performance measures in complex and large-scale systems like the Delta are commonly multiyear endeavors. The recommended output and outcome performance measures listed below are provided as examples, and subject to refinement as time and resources allow. Final administrative performance measures are listed in Appendix E and will be tracked as soon as the Delta Plan is completed.

Output Performance Measures

- DWR begins constructing the North Bay Aqueduct Alternate Intake Project as soon as possible after the environmental impact report is completed. (WQ R5)
- Progress toward reducing concentrations of inorganic nutrients (ammonium, nitrate, and phosphate) in Delta waters over the next decade. (WQ R8)
- TMDLs for critical pesticides (for example, diazinon, chlorpyrifos, and pyrethroids) in the waters and sediments of the Delta are met by 2020. (WQ R8)
- A Delta regional water quality monitoring program is implemented within the first 5 years of the Delta Plan. (WQ R9)

Outcome Performance Measures

- Water quality in the Delta meets objectives established in the applicable water quality control plan. (WQ R1)
- Trends in measureable toxicity from pesticides and other pollutants in Delta waters will be downward over the next decade. (WQ R8)
- Progress toward consistently meeting applicable DO standards in the Delta by 2020. (WQ R8, WQ R11, and WQ R12)
- HABs will lessen in severity and spatial coverage in the Delta over the next decade. (WQ R3 and WQ R8)
- The spatial distribution and productivity of nuisance nonnative aquatic plants will decline over the next decade. (WQ R3 and WQ R8)

CHAPTER 7

Reduce Risk to People, Property, and State Interests in the Delta

ABOUT THIS CHAPTER

This chapter provides an overview of flood risk in the Sacramento-San Joaquin Delta (Delta), current flood management efforts, and the most pertinent agencies and regulations. It details the Delta Stewardship Council's (Council) core strategies to reduce risk to people, property, and State interests in the Delta. These core strategies form the basis of the four policies and ten recommendations found at the end of the chapter:

- Improve emergency preparedness and response
- Finance and implement flood management activities
- Prioritize flood management investment
- Improve residential flood protection
- Protect and expand floodways, floodplains, and bypasses
- Integrate Delta levees and ecosystem function
- Limit liability

Reducing flood risks in the Delta also relies on locating urban development in the cities where levees are stronger (as proposed in Chapter 5) and retaining rural lands for agriculture, so that development in the most floodprone areas is minimized.

RELEVANT LEGISLATION

Water Code sections 85305, 85306, 85307, and 85309 require the Delta Plan to include or otherwise consider specific components to attempt to reduce risk.

> *85305(a) The Delta Plan shall attempt to reduce risks to people, property, and state interests in the Delta by promoting effective emergency preparedness, appropriate land uses, and strategic levee investments.*
>
> > *(b) The council may incorporate into the Delta Plan the emergency preparedness and response strategies for the Delta developed by the California Emergency Management Agency pursuant to Section 12994.5.*
>
> *85306 The council, in consultation with the Central Valley Flood Protection Board, shall recommend in the Delta Plan priorities for state investments in levee operation, maintenance, and improvements in the Delta, including both levees that are a part of the State Plan of Flood Control and nonproject levees.*
>
> *85307(a) The Delta Plan may identify actions to be taken outside of the Delta, if those actions are determined to significantly reduce flood risks in the Delta.*
>
> > *(b) The Delta Plan may include local plans of flood protection.*
> >
> > *(c) The council, in consultation with the Department of Transportation, may address in the Delta Plan the effects of climate change and sea level rise on the three state highways that cross the Delta.*
> >
> > *(d) The council, in consultation with the State Energy Resources Conservation and Development Commission and the Public Utilities Commission, may incorporate into the Delta Plan additional actions to address the needs of Delta energy development, energy storage, and energy transmission and distribution.*
>
> *85309 The department, in consultation with the United States Army Corps of Engineers and the Central Valley Flood Protection Board, shall consider a proposal to coordinate flood and water supply operations of the State Water Project and the federal Central Valley Project, and submit the proposal to the council for considerations for incorporation into the Delta Plan. In drafting the proposal, the department shall consider all related actions set forth in the Strategic Plan.*

CHAPTER 7

Reduce Risk to People, Property, and State Interests in the Delta

Reducing flood risks to people, property, and State interests is critical to achieving the Delta Reform Act's coequal goals and protecting the Delta as a place. The Legislature has found that the Delta is "inherently floodprone," and that further improvements and continuing maintenance of the levee system will not resolve all flood risks (Public Resources Code section 29704). Living with risk, whether from floods, earthquakes, fires, coastal storms, or other hazards, is often part of life in California. The Delta's hazards, however, are exceptional because they affect so many State interests, including the reliability of its water supplies, the health of the Delta's ecosystem, and the qualities that make the Delta an attractive place to live, work, and recreate.

To reduce these risks to people, property, and State interests in the Delta, the Delta Reform Act requires that the Delta Plan promote effective emergency response and emergency preparedness, and promote appropriate land use (Water Code section 85305). The Delta Reform Act also directs the Council, in consultation with the Central Valley Flood Protection Board (CVFPB), to recommend priorities for State investments in levee operation, maintenance, and improvements in the Delta, including both levees that are a part of the State Plan of Flood Control and nonproject levees (Water Code section 85306).

The Council envisions a future in which risks of flooding in the Delta are reduced, despite an increase in sea levels and altered runoff patterns. The Council sees a future where Delta residents, local governments, and businesses are better prepared to respond when floods threaten. The Council envisions a future where bypasses are expanded; channels are improved; and strong, well-maintained levees protect local communities—but also protect State interests in a more reliable water supply for California, and a protected and restored Delta ecosystem. These improvements will include new or expanded floodways and bypasses, maintaining and improving levees, and floodproofing new development. The Council envisions that rural areas and the Delta's legacy communities will also be protected from flood risks by careful land use planning that discourages urban development in flood-threatened areas. The Council envisions that local agencies will be better financed and protected through a locally controlled emergency response and flood protection district, with fee assessment authority. State funds for desired projects will be focused at State interests in the Delta, but some of that activity will protect local interests as well. Eliminating flood risks will be impossible, but prudent planning, reasonable land development, and improved flood management will significantly reduce risk, and serve the coequal goals of a more reliable water supply, and a protected and restored Delta ecosystem.

Delta Hazards Threaten Both Coequal Goals and the Delta as a Place

The risks that flooding, earthquakes, and other hazards pose to the Delta imperil California's water supplies and the health of the Delta ecosystem. The channels that convey water through the Delta to users in the Bay Area, San Joaquin Valley, or Southern California, and the islands that prevent saltwater intrusion into Delta water supplies depend upon levees for their preservation. Should the levees that protect these channels fail, the impacts on water supplies could be felt statewide. Improving these Delta levees is an investment in water supply reliability. Another way to reduce these risks is for areas that use Delta water to develop plans for possible interruption of these supplies in a catastrophic event, as recommended in Chapter 3. Integrating water supply and flood control efforts is also important to optimize the management of the multipurpose reservoirs that store water for the Central Valley Project (CVP), State Water Project (SWP), and other water users. For example, a potential benefit of wide flood bypasses leading to the Delta may be greater flexibility in these reservoir operations, creating new opportunities to manage water supplies or generate hydroelectric power.

The Delta levees also affect the health of the ecosystem. Many birds, such as waterfowl or sandhill cranes, thrive in areas that depend on levees for their management. In some locations, careful removal or breaching of levees may create new habitats that benefit fish and wildlife and the ecosystem. Setting levees back deliberately, when feasible, can create both more capacity for flood flows and more habitat for fish and wildlife. But unplanned levee failures often create weed-infested depths that harbor nonnative species rather than refuges for smelt, salmon, or other preferred species. Changes in the area protected by levees also alter water circulation through the Delta, changing the benefit of flows released to protect its ecosystem.

The Delta's residents, farms, and businesses also depend on its levees. They shape the Delta landscape, protecting its farms and communities from destruction. The levee system is the foundation on which the entire Delta economy is built, the Delta Protection Commission's (DPC's) *Economic Sustainability Plan* reports (DPC 2012). Delta residents built the levee system over generations, and they are keenly interested in its maintenance and improvement. (See sidebar, Delta Disaster Recalled, for an example of the consequences of levee failure.)

DELTA DISASTER RECALLED

On a moonlit Wednesday night in June 1972, the San Joaquin River flowed slowly after one of the driest winters on record. It gnawed at the Andrus Island levee 6 miles south of Isleton between Bruno's Yacht Harbor and Spindrift Resort, opening a small hole that grew rapidly. By the time sheriff's deputies arrived on scene shortly after 1 a.m., the river had carved a 100-foot break. By 3 a.m., water covered Highway 12. Shortly after sunrise, the breach had grown to 300 feet, and volunteers were hard at work on a 1.5-mile-long bow levee to protect Isleton.

The battle to save Isleton continued throughout the day, but a rising tide and waves created by 30- to 45-mile-per-hour Delta winds hampered efforts. Within a few hours, officials ordered the evacuation of 1,400 Isleton residents and an additional 1,500 residents of Andrus and Brannan islands. At 9:45 p.m. Thursday, the bow levee breached, and a wall of water rushed into the low-lying residential area of Isleton. Although the city's business district was spared, almost all of Andrus Island and portions of Brannan Island were flooded, in some places up to 20 feet deep.

Then-Governor Ronald Reagan declared the islands a disaster area and asked President Richard Nixon to do the same. Over the next 6 months, the levee was repaired, the 12,000-acre lake that had been Brannan and Andrus Islands was drained, and life began returning to normal. A full year after the levee break, however, more than one-third of the residents had neither moved back into their homes nor begun to rebuild.

Officials estimated that damages were $21.8 million, slightly more than half of that from crop loss and saltwater damage to farmland. The cost for levee repairs was put at $800,000, and $500,000 went to pump the 20 square miles of flooded land dry. More than $1.5 million in federal disaster relief was made available. No definitive cause was ever determined for the levee breach, and a subsequent court case absolved the State of liability (DWR 1973, Sacramento River Delta Historical Society 1996).

DP-361

Flood Risk in the Delta

The Delta is an inherently floodprone area. This section provides an overview of the causes and risks of floods in the Delta. The Sacramento and San Joaquin rivers collectively drain approximately 42,500 square miles of land. Before the Delta was modified by levees and other human structures, these rivers' natural flows overflowed the Delta's low-lying islands and floodplains for long periods each spring.

The biggest floods occurred when warm Pacific storms swept in from the west and southwest, picking up moisture over the ocean and causing torrential rains when intercepted by the mountains surrounding the Central Valley. The risks of flooding were increased when large amounts of sediment were discharged to Central Valley rivers during the Gold Rush, choking their channels and raising their beds above their natural levels and surrounding lands.

Today, flooding of the Delta's complex labyrinth of islands and waterways is prevented by its levees. This system of flood control is supplemented by the flood facilities of the Sacramento River and San Joaquin River flood control projects and multipurpose reservoirs such as Shasta, Folsom, and Millerton lakes and Lake Oroville on the Sacramento and San Joaquin rivers and their tributaries, which hold back floodwater and provide water supplies and other benefits described in Chapter 3.

Many Delta levees were initially constructed more than a century ago using primitive materials and equipment. History has shown that structural failures of the levee system occur as a result of extraordinary events, imperfect knowledge, and imperfect materials. Delta levees face potential threats such as large runoff events, extreme high tides, wind-generated waves, earthquakes, subsidence, and sea level rise. Individually, each of these threats is enough to cause serious concern; together, they represent the potential for catastrophic disruption of the Delta and its economic and ecological services.

A mass or even partial failure of the levee system would have real life-and-death impacts and property losses that could total billions of dollars. Delta flooding could interrupt the conveyance of water through the Delta for the SWP, the CVP, in-Delta users, the Contra Costa Water District, the cities of Antioch and Stockton, and others who depend on the Delta for reliable water supplies (see Chapter 3 for a discussion of water supply reliability). Levee failures could also damage key features of the Delta ecosystem, including managed wetlands in Suisun Marsh and habitats of wintering greater sandhill cranes at Staten Island and nearby tracts. Unplanned levee failure could also degrade water quality in the Delta, because tidewaters would flood into the bowl created by subsidence of Delta islands. These failures would draw saltwater from San Francisco Bay and pollute Delta water with flood debris, farm chemicals, and other pollutants.

Levee failures also could flood homes, farms, and businesses, including historic structures in the legacy communities, and interrupt recreation and tourism. As noted in Chapter 5, about 116,000 residential structures are located in the 100-year floodplain of the Delta, mostly near Sacramento, West Sacramento, and Stockton. Also, 8,000 residences are below mean higher high water (DWR 2008b). Serious consequences also could result from flood-related damage to critical infrastructure in the Delta, including radio, cellular telephone, and television transmission towers; electrical transmission lines, including Pacific Gas and Electric Company, Sacramento Municipal Utility District, and Western Area Power Administration lines; natural gas pipelines serving local gas fields and regional transmission systems; petroleum pipelines; three state highways; and three interstate highways (DWR 2011a).

In simplistic terms, the concept of flood risk can be described as the likelihood of a flood event occurring and the consequences of that event. To many, flood risk simply means the chance a storm event will overwhelm the flood control system to some extent. Figure 7-1 illustrates the variables, namely the probability of flooding and the financial consequences. However, there are many other causes of flood risk, and the consequences can be far more complicated than the immediate damage to property.

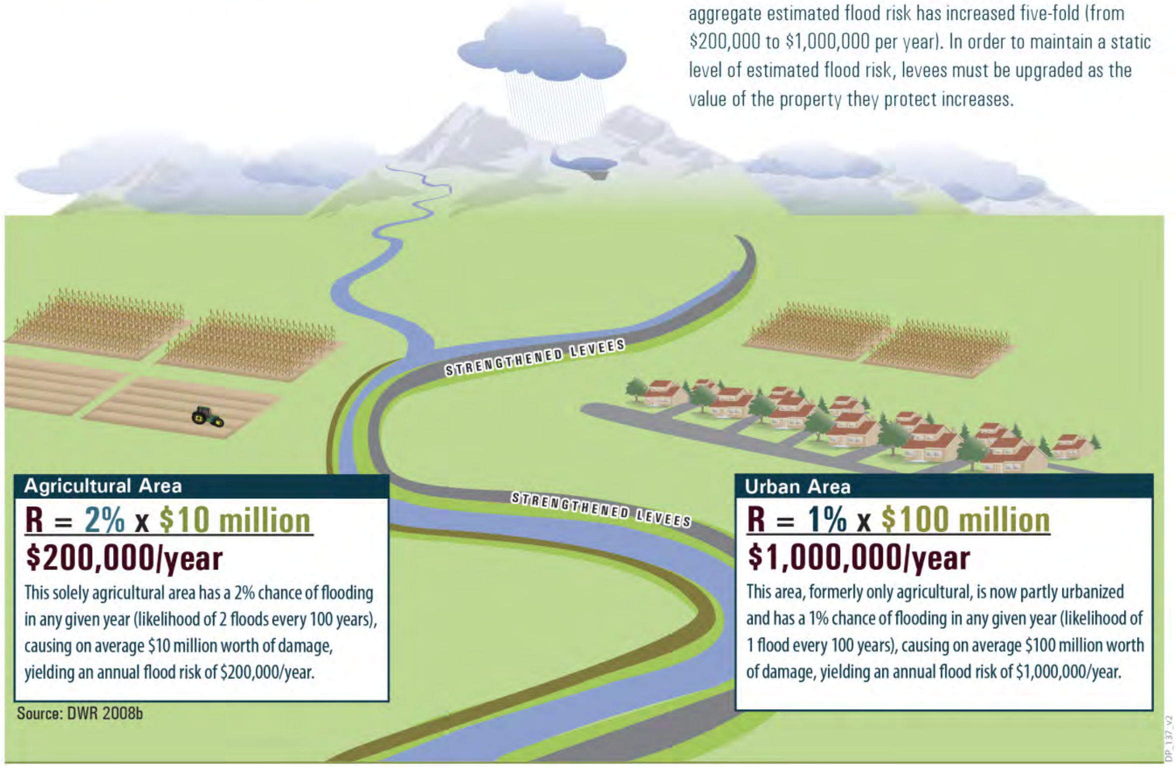
Understanding Delta Flood Risk

Flood risk reflects both the probability of flooding and the consequences that would result from flooding. Flood risk can be calculated as:

R = % x $

Annual Flood Risk = Probability of Flooding X Financial Consequence

The scenario to the right of the river depicts how increasing the value of property, primarily through urbanization, will increase the flood risk in the area. Even though the levees in the urbanizing area have been upgraded to reduce the annual probability of flooding to 1% (or 1 flood every 100 years), by increasing the value of property behind these levees, the aggregate estimated flood risk has increased five-fold (from $200,000 to $1,000,000 per year). In order to maintain a static level of estimated flood risk, levees must be upgraded as the value of the property they protect increases.



Agricultural Area

R = 2% x $10 million

$200,000/year

This solely agricultural area has a 2% chance of flooding in any given year (likelihood of 2 floods every 100 years), causing on average $10 million worth of damage, yielding an annual flood risk of $200,000/year.

Urban Area

R = 1% x $100 million

$1,000,000/year

This area, formerly only agricultural, is now partly urbanized and has a 1% chance of flooding in any given year (likelihood of 1 flood every 100 years), causing on average $100 million worth of damage, yielding an annual flood risk of $1,000,000/year.

Source: DWR 2008b

Figure 7-1

The best defense against these risks is first to better understand the Delta's flood hazards, and then manage and control those risks to the extent possible through public awareness; adequate emergency management planning; structural and nonstructural improvements, including enforcement of existing flood management regulations; and repairs, rehabilitation, and improvement of levees (including setback levees) and flood channels. Improving our understanding of risks through further evaluation and analysis of the flood control system and the assets it protects is essential to developing a rational, prioritized approach to flood management and public investment.

Floods

Flooding during winter storms that results in high water surface elevations and high winds has been a common cause of levee failures in the Delta. For example, the Sacramento River at Rio Vista may flow in excess of 300,000 cubic feet per second (cfs) during winter and early spring floods, 30 times typical late-summer flows of 10,000 cfs. Peak discharges place high stress on Delta levees and can create flood conditions, especially when coupled with high tides.

The likelihood of levee failures caused by high water is substantial, based on the historical performance of these levees over the last century. During the last century, there have been more than 140 levee failures and island inundations, most of which occurred during flood seasons (DWR 2005). High water in the Delta can overtop levees, as well as increase the hydrostatic pressure on levees and their foundations, causing instability and increasing the risk of failure due to through-levee and/or under-levee seepage. Most levee failures in the Delta have occurred during winter storms and related high-water conditions, often in conjunction with high tides and strong winds.

Earthquakes

The Delta's levees are also at risk from the active seismic zones west of the Delta, including the San Andreas and Hayward faults. Less active faults underlie the Delta. A strong earthquake could damage Delta levees because of the potential for liquefaction of levee embankments and foundations. Saturated levees composed of dredged materials in other parts of the country and the world have performed poorly during moderate to strong earthquake shaking (DWR 2009; Delta Stewardship Council Staff 2010a). If a levee failed during high flows or if a flood were to occur soon after an earthquake, the protected area could be inundated.

The risks of earthquakes causing levee breaches and island inundations in the Delta have long been recognized. A California Department of Water Resources (DWR) report begins:

> *There is a long history of levee failures in the Delta that have resulted in extensive economic damage, but no failures of Delta levees are known to be directly attributable to earthquakes. Even so, two factors indicate a possible bleak picture for the future of many Delta levees. First, no serious causative quakes have occurred on the nearby major faults since the San Francisco earthquake of 1906. Second, the Delta levees of today are vastly different than those in the 1906 Delta, which had limited size and extent. (DWR 1980)*

The DWR Delta Risk Management Strategy Phase 1 study evaluated the performance of Delta levees under various seismic threat scenarios, and analyzed potential consequences for water supply, water quality, ecosystem values, and public health and safety. The study concluded that a major earthquake of magnitude 6.7 or greater in the vicinity of the Delta Region has a 62 percent probability of occurring sometime between 2003 and 2032 (DWR 2009). Figure 7-2 illustrates a potential flood scenario in which a 6.5-magnitude earthquake causes a 20-island failure. Although the probabilistic nature of earthquake prediction makes it difficult to quantify the timing and magnitude of seismic threats, it is important to address the threats posed by earthquakes to the Delta levee system because of the potential adverse effects of such events.

High Tides and Sunny-day Risks

Even without an earthquake or flood, Delta levees can fail during high tides or even on sunny days. Generally, these failures may be the result of a combination of high tide, and pre-existing internal levee and foundation weaknesses caused by burrowing animals, internal erosion of the levee and foundation through time, and human interventions such as dredging or excavation at the toe of the levee (DWR 2008b). Examples of sunny-day failures include the Brannon Andrus Tract in 1972 and Upper Jones Tract in 2004. It is estimated that, based on current conditions, a sunny-day failure would occur once every 9 years on average (DWR and DFG 2008).

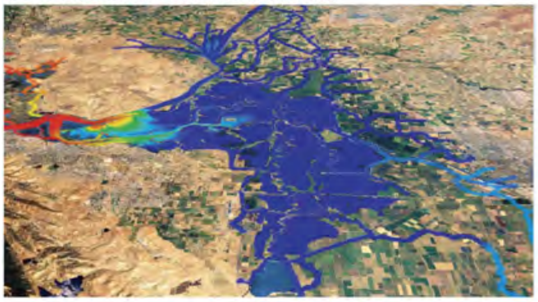
Other hazards that affect the performance of Delta levees include encroachments, penetrations, and burrowing animals. Encroachments such as structures or farming practices on or close to the levee; penetrations of the levee, such as culverts or pipelines; and burrows created by rodents, especially beavers, muskrats, and squirrels, can weaken the structural integrity of levees. Because of unregulated historical construction, levees also contain many hidden hazards. Active programs of inspection, oversight, and maintenance are essential to minimize these hazards.

Simulation of Delta Salinity after a 20-island Failure Caused by a Magnitude 6.5 Earthquake

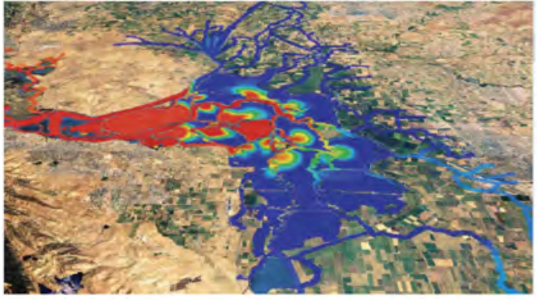
Electrical Conductivity (μmhos/cm)

400 5000

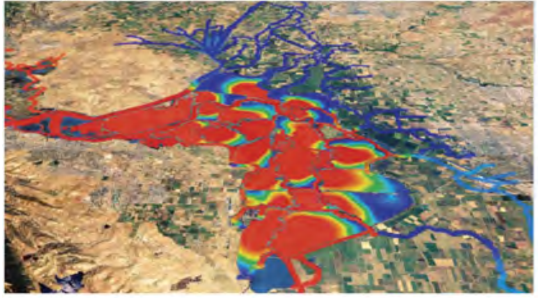
0–6 hours: Islands flood with fresh water



12–24 hours: Salt water intruding into Delta



1–7 days: Salt water throughout Delta



30 days: A saline estuary

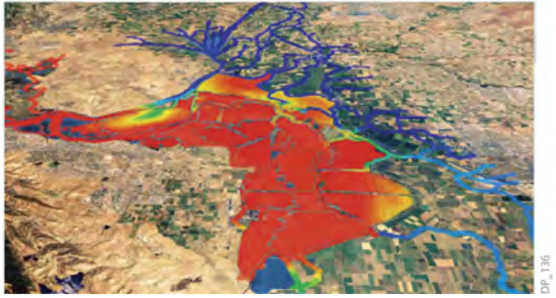


Figure 7-2 *Source: MWD 2010*

Land Subsidence

Because of the land subsidence described in Chapter 5, much of the central Delta is below sea level. Some islands are 12 to 15 feet below sea level, requiring levees 20 to 25 feet in height that act as dikes, holding back water continually rather than only during seasonal floods or extreme tides. As subsidence progresses, accommodation space increases, and levees must be continually maintained, strengthened, and periodically raised to support the increasing hydraulic stresses (Miller 2008, Mount and Twiss 2005). The hydraulic stress also can drive seepage through and under levees, and place levee foundations under more stress. The thinning of the peat soil layer also causes shallow or artesian groundwater conditions. More seepage onto islands will increase the drainage costs associated with additional pumping and decrease levee stability (Deverel and Leighton 2010).

Climate Change and Flood Risk

Climate change has major implications for the Delta, and especially for flood risk management. It is estimated that by the year 2100, sea levels may rise 31 to 69 inches (California Climate Action Team 2010, California Ocean Protection Council 2011), putting additional stress on levees and increasing their risk of failure. Projected changes in the timing and intensity of runoff may increase peak storm runoff and high-frequency flood events (DWR 2008c). Such floods could interrupt water conveyance through the Delta for those who depend on the Delta for water.

Additionally, scientific understanding of large-scale precipitation events is growing, as demonstrated by the ARkStorm scenarios being investigated by the U.S. Geological Survey, which indicate that massive storms and subsequent flooding have occurred and are likely to occur again (USGS 2011). Failure of significant parts of the Delta's flood management system may be unavoidable.

Planning for Flood Management

This section summarizes the current state of flood management planning for the Delta. To reduce the risk of flooding, Delta landowners, local governments, and State and federal agencies have planned and built an extensive levee system in the Delta, and significant flood control works upstream of the Delta. Other government flood control programs plan for emergency response in the event of floods, or help manage flood risks through land use planning, building standards, and flood insurance. The Delta Reform Act refers to these government-sponsored flood control programs in its provisions regarding covered actions (Water Code section 85057.5(a)(4)). The sidebar, What Is a Government-sponsored Flood Control Program?, highlights those programs referenced in statute; and proposed actions in the Delta that will have a significant impact on the implementation of one of these programs may be considered covered actions. Chapter 2 provides details about covered actions.

There are more than 1,000 miles of project and nonproject levees in the Delta and Suisun Marsh. Differences in how levees are classified can influence reports about their length and condition. Approximately 65 percent of the levees in the Delta and all levees in the Suisun Marsh are owned or maintained by local agencies or private owners and are not part of the flood control projects on the Sacramento or San Joaquin rivers. Most of these nonproject levees are maintained by local reclamation districts created and funded by landowners, initially for the purpose of draining ("reclaiming") Delta islands and tracts. The reclamation districts continue to maintain levees and other water control facilities today. These nonproject levees are defined in Water Code section 12980(e).

Many facilities throughout the Delta also drain rainfall runoff from land into Delta channels. Local cities and districts own and maintain urban storm drains in developed areas. Stockton, Sacramento, West Sacramento, Lathrop, Manteca, and Tracy are Delta cities with storm drainage facilities.

WHAT IS A GOVERNMENT-SPONSORED FLOOD CONTROL PROGRAM?

Any State or federal strategy, project, approval, funding, or other effort that is intended to reduce the likelihood and/or consequence of flooding of real property and/or improvements, including risks to people, property, and State interests in the Delta, that is carried out pursuant to applicable law, including, but not limited to, the following code:

- State Water Resources Law of 1945, Water Code section 12570 et seq.
- Sacramento-San Joaquin River Flood Control Projects (Flood Control Act of 1941, Public Law 77–228)
- Local Plans of Flood Protection (Water Code section 8201)
- Central Valley Flood Protection Plan (Water Code section 9600 et seq.)
- Subventions Program, Special Projects Program (Water Code section 12300 et seq.)
- Way Bill 1973 – Subventions Program, Special Projects Program (Water Code section 12980 et seq.)
- Central Valley Flood Protection Board Authority (California Code of Regulations, Title 23, Division 1)
- National Flood Insurance Program (National Flood Insurance Act of 1968, 42 United States Code 4001 et seq., Public Law 90-448)

DP-183

Most Delta islands have a network of agricultural drains and pumps to pump runoff into the Delta channels. Some Delta channels have been dredged to increase their capacity to carry floodwater and to obtain material for levee construction and maintenance.

The flood control projects on the Sacramento and San Joaquin rivers include approximately one-third of the Delta's levees. Known as "project levees," they begin on the left bank of the Sacramento River at Sherman Island, and line most of the riverbanks, as well as the Sacramento River Deep Water Ship Channel and some connecting waterways, north to Sacramento and beyond. The Delta Cross Channel's control gates are an important feature of this levee system, closing during high flows to keep the Sacramento River's floodwaters out of the central Delta. The flood control project also includes the Yolo Bypass, the broad, managed floodplain in Yolo County west of West Sacramento. The wide bypass, which is confined by project levees, draws floodwater through weirs above Sacramento to lower flood heights on the Sacramento River and its tributaries, discharging back to the Delta above Rio Vista. The Yolo Bypass floods about once every 3 years, between December and February. On the San Joaquin River, project levees line the riverbanks from Old River to Stockton. Figure 7-3 shows the locations of project and nonproject levees in the Delta.

Recent evaluations show that some of the flood control project facilities on the Sacramento and San Joaquin rivers are not adequate. Because the system was intended partly to flush Gold Rush-era sediment from rivers and channels, the project levees were often built close to the riverbanks, and are prone to erosion. Many of the system's channels have inadequate capacity to carry the flows for which they were designed, and many levees do not meet contemporary design standards (DWR 2011c).

The CVFPB, as part of its responsibility to oversee the flood control projects on the Sacramento and San Joaquin rivers, has adopted regulations to control encroachments on the project and some of the streams that flow into it. It also regulates encroachments within designated floodways, which are the channels of a river or other watercourse and the adjacent land areas that convey floodwaters (California Code of Regulations [CCR], Title 23, Division 1, Chapter 1, Article 2, Section 4). In the Delta, designated floodways include the Cosumnes River's floodplain and the confluence of the San Joaquin River and the Stanislaus River upstream from Paradise Cut.

Some levees are neither project levees nor nonproject levees. These "unattributed levees" include hundreds of miles of levees in Suisun Marsh and the Delta, and are not part of any State-financed flood control program. They also include some that are unmaintained along the perimeter of permanently flooded islands and no longer serve flood control or drainage purposes.

Multipurpose reservoirs in the Sacramento and San Joaquin river watersheds that play a role in California's water supply also serve critically important roles in managing floods that affect the Delta. The CVP's Shasta, Folsom, and Millerton lakes and New Melones Reservoir; the SWP's Lake Oroville; and other reservoirs are operated in accordance with flood control rules established by U.S. Army Corps of Engineers (USACE), reserving space to capture flood flows that can be released downstream gradually so that channels are not overwhelmed.

Many studies and planning efforts addressing flood management and emergency preparedness, response, and mitigation are under way, and will be considered by the Council for ongoing Delta flood risk management. These studies, efforts, and programs include the following:

- ***Central Valley Flood Protection Plan* (CVFPP).** This strategic plan for improving the flood control projects on the Sacramento and San Joaquin rivers recommends approaches for reducing flood risk and improving the flood control project, including expansion of the Yolo Bypass and construction of a new San Joaquin River Bypass at Paradise Cut (DWR 2011c) (see sidebar, Central Valley Flood Protection Plan).
- **DWR's FloodSAFE Initiative.** In 2006, DWR launched FloodSAFE California—a multifaceted initiative to improve public safety through integrated flood management.
- **DWR's Delta Levees Program.** This program encompasses both the Delta Levees Maintenance Subventions and Delta Levees Special Flood Control Projects programs, which provide State cost-share funding for Delta levee maintenance and upgrades.
- ***Sacramento-San Joaquin Delta Multi-Hazard Coordination Task Force Report.*** This report responds to Senate Bill (SB) 27 (Water Code section 12994.5), which called for the task force to make recommendations to the Governor about Delta multi-hazard emergency response and recovery issues.

- **USACE Delta Islands and Levees Feasibility Study, Long-Term Management Strategy for Dredging and Dredge Material Placement, Periodic Inspection Program, and Levee Safety Portfolio Risk Management System.** USACE has multiple programs addressing Delta-related flood management issues, including levee safety, levee integrity, and the beneficial reuse of dredged material.
- **CVP and SWP Reoperation Studies.** DWR's Forecast-coordinated Operations Program and Systems Reoperation Program address reservoir operational criteria, as noted in Chapter 3.

The Council will consider the findings of these studies and may incorporate them into future Delta Plan updates. The CVFPP and FloodSAFE include many concepts relevant to flood protection in the Delta. At the federal level, the National Committee on Levee Safety (2009) submitted a report to Congress that outlined the critical components of a National Levee Safety Program, and a high-level timeframe and steps for its creation. It is up to Congress to act on these recommendations, which will be monitored by the Council as they relate to the Delta Plan.

The CVFPB, DWR, and USACE each play unique and critical roles in Delta flood risk management. Because of this, the Council's role in facilitation, coordination, and integration of various agencies and other parties is of particular importance. Frequent, ongoing collaboration with other State, federal, and local agencies to improve communication and coordination is essential to meeting the Delta Plan's flood management objectives.

The Delta's Levees

The levees within the legal Delta protect approximately 740,000 acres of land. They define the Delta's physical characteristics; influence the reliability of its water supplies and its ecosystem health; and are critical to the Delta's residents, farms, businesses, cities, and legacy communities. Because many Delta levees protect land below sea level, they hold back water all day, year-round, rather than only during floods, and so are called "the hardest working levees" in America.

CENTRAL VALLEY FLOOD PROTECTION PLAN

The Central Valley Flood Protection Act of 2008 directed DWR to prepare the CVFPP. The CVFPP is a flood management planning effort that addresses flood risks and ecosystem restoration opportunities in an integrated manner. It specifically proposes a systemwide approach to flood management for the areas currently protected by facilities of the State Plan of Flood Control (SPFC). The CVFPP was adopted by the CVFPB in June 2012. It is expected that the CVFPP will be updated every 5 years thereafter.

The CVFPP proposes a systemwide approach to address the following issues:

- Physical improvements in the Sacramento and San Joaquin river basins
- Urban flood protection
- Small community flood protection
- Rural/Agricultural area flood protection
- System improvements
- Non-SPFC levees
- Ecosystem restoration opportunities
- Climate change considerations

The geographic scope of the CVFPP includes the portions of the Delta covered by the SPFC, including about 65 miles of urban, nonproject levees at Stockton; approximately two-thirds of Delta levees are not addressed in the CVFPP.

The effects of systemwide improvements directed by the CVFPP and the potential of redirected impacts to areas within the Delta will be monitored by the Council to ensure alignment with the coequal goals and the Delta Reform Act. Additionally, the Council may, at its discretion, incorporate those portions of the CVFPP into the Delta Plan to the extent that those portions promote the coequal goals (Water Code section 85350).

The 2012 CVFPP is only a descriptive document, highlighting a planning perspective at a reconnaissance level. Follow-on feasibility studies and project-specific development activities will be conducted over the next several years. The Council will continue to monitor and provide input to those activities to ensure that Delta flood risk issues are considered. Flood system improvement actions undertaken upstream of the Delta are of particular concern if not coupled with in-Delta actions that reduce overall systemwide flood risk.

Existing Levee Standards and Guidance

It is more important than ever that the Delta's levees are designed, constructed, and maintained to provide a level of flood risk reduction commensurate with the coequal goals and protection of the Delta's unique values as a place. Over the last few decades, State and federal agencies have developed guidelines and standards for levees. These standards establish minimum criteria for levee design and maintenance. The standards include (1) the level of flood protection California has prescribed for the Central Valley's urban areas, (2) whether sufficient protection is provided by the levees to exempt development financed with federally backed mortgages from requirements to obtain flood insurance, and (3) whether property and infrastructure protected by the levees (including the levees themselves) are eligible for assistance in the event of a catastrophic emergency, including aid from USACE to rehabilitate levees damaged in an emergency or for disaster assistance from the Federal Emergency Management Agency (FEMA).

Four levee standards and guidance applicable to the Delta are discussed below (and shown on Figure 7-4); they are ordered from highest to lowest level of flood protection:

- **DWR 200-year Urban Levee Protection (DWR - 200 Year):** This standard goes beyond criteria for levee height and geometric design to include requirements for freeboard, slope stability, seepage/underseepage, erosion, settlement, and seismic stability (DWR 2011b). It protects against a flood that has a 0.5 percent chance of being equaled or exceeded in any given year (a 200-year level of flood protection). This urban levee standard is the only levee standard that specifically links land uses to levee criteria. State law requires that by 2025, floodprone urban areas with over 10,000 residents must meet this 200-year flood protection standard (Government Code section 65865.5(a)(3)). Compliance likely will be achieved by upgrading levees to meet the 200-year design standard, under development by DWR. Sacramento, West Sacramento, and Stockton are planning levee improvements to attain this level of protection.

  Very few levees in the Delta meet this standard because most Delta levees do not protect urban areas. Under existing law, rural levees are not required to meet this standard.

- **FEMA 100-year (Base Flood) Protection (FEMA – 100 Year):** This "insurance" standard, often called the "1 percent annual chance flood" level of protection, provides criteria that levees must meet to protect against the flooding that is the basis for FEMA's flood insurance rate maps (44 Code of Federal Regulations 65.10). It is often used with established USACE criteria to prescribe requirements for levee freeboard, slope stability, seepage/underseepage, erosion, and settlement. The standard generally does not address seismic stability. In communities where levees provide this level of flood protection, new developments are not required to meet federal floodproofing standards and can obtain federally guaranteed mortgages without purchasing flood insurance.

  Few Delta levees outside of cities meet this standard, and many urban levees need improvement to meet it.

- **Public Law 84-99 (PL 84-99):** The PL 84-99 standard is a minimum requirement established by USACE for levees that participate in its Rehabilitation and Inspection Program (33 United States Code 701n) (69 Stat. 186). Twenty-five Delta reclamation districts, protecting about 31 percent of the legal Delta's land behind about 516 miles of levees, are at or above this standard, according to a recent report to the Council by DWR (DWR 2012). Delta islands or tracts that meet this standard are eligible for USACE funding for levee rehabilitation, island restoration after flooding, and emergency assistance, provided that the reclamation district is accepted into the USACE's program and passes a rigorous initial inspection and periodic follow-up inspections. Eligibility for PL 84-99 was formerly based primarily on levee geometry with minimum freeboard and maximum steepness of slopes. USACE's periodic

DWR - 200 year (DWR Urban Levee Design Criteria 2011)

Figure 7-4

Source: Adapted from Delta Vision Blue Ribbon Task Force 2008 and DWR 2011b inspection program incorporates other elements into eligibility, including presence of structure encroachments, vegetation, rodent control programs, and more. The standard for levee geometry implies a minimum levee height and a slope stability factor of safety, but is not associated with a level of protection (such as a 100-year flood) and does not address seismic stability. In 1987, USACE developed a Delta-specific standard based on the Delta's particular organic soils and levee foundation conditions. The CALFED Record of Decision set a goal of improving Delta levees to the PL 84-99 standard, as does the DPC Economic Sustainability Plan, but funding has been inadequate to attain this objective.

- **FEMA Hazard Mitigation Plan (HMP) Guidance:** FEMA, DWR, the California Office of Emergency Services (now the California Emergency Management Agency [Cal EMA]), and the Delta levee-maintaining agencies negotiated the HMP guidance to reduce the likelihood of repetitive flood damage to Delta levees and islands, so that FEMA disaster assistance would not be requested repetitively for the same islands after minor floods. Fifty-three of the Delta's reclamation districts, protecting over 47 percent of the legal Delta's acreage, fall below this standard, which 139 miles of Delta levees do not meet (DWR 2012). Local communities that do not meet the HMP guidance are not eligible for FEMA disaster reimbursement for flood fights or assistance if levees fail or islands flood. If even a portion of the levee around an island or tract does not meet the HMP guidance, assistance from FEMA to recover from levee damage is unavailable. Fifteen districts comply with this guidance, but are below the PL 84-99 standard. FEMA and Cal EMA have a memorandum of understanding, updated in 2010, that sets forth the requirements for FEMA public assistance funding for emergency flood fighting, emergency repair, permanent restoration, and/or replacement of eligible damaged nonproject levees within Delta reclamation districts (Cal EMA and FEMA 2010). The guidance is based on geometric criteria for the levees. The HMP guidance, negotiated between 1983 and 1987, was intended as an interim guidance, but has not been adjusted using subsequent or projected flood elevations.

No State standards currently address design criteria for flood protection of the state highways and interstate highways that traverse the Delta. Federal standards require that interstate highways must be protected from 50-year flood events to qualify for Federal Highway Administration funds (23 Code of Federal Regulations 650.115). Because most roads in the Delta were constructed before these standards were developed, they do not meet the standards. For example, sections of State Route 12 are 10 feet or more below sea level. A flood on the islands this highway traverses could interrupt transportation and trade, and put motorists at risk.

Levees and Ecosystem Function

Historically, most discussion of levees has emphasized reducing flood risks to life and property. However, habitat and ecosystem values and functions can provide multiple benefits, and must be considered in flood management planning and actions. For example, the CVFPP includes a conservation framework and strategy that outline how environmental elements can be integrated into flood management activities and provide an environmental guide for flood project planning. Setting levees back from the riverbank can expand flood conveyance capacity and reduce flood risk while providing ecosystem restoration and recreational opportunities (USACE 2002). Setback levees also allow opportunities for construction of an improved levee foundation and section using modern design and construction practices, thereby reducing risk of failure.

Much discussion has occurred on how to more effectively accommodate ecosystem function with the current levee system, highlighting the following issues (Healey and Mount 2007):

- Current levees tend to be narrow, with steep waterside slopes that provide little upland habitat value.

- Setback levees may provide habitat value and increased levee integrity.
- Levees can be used to promote specific habitat types (such as waterfowl habitat) by ensuring that some areas of freshwater marsh are sustained.
- Where lands are not heavily subsided, levees can allow for multiple land uses including habitat management and wildlife-friendly agriculture.
- Allowing levees to fail on deeply subsided islands would not generate any obvious ecological benefits.
- Subsidence reversal on deeply subsided islands would rely on levees to appropriately manage water levels during tule growth.

As management efforts in the Delta proceed, it will be important to consider ecosystem functions and their interactions with the levee system, as discussed in Chapter 4. An example where these interactions are already being debated is the USACE's current policy requiring removal of vegetation from levees. Scientific support for and against this policy is mixed. Concerns with maintaining woody vegetation on levees include difficulties with inspection and flood fighting, potential for root holes, and trees toppling from erosion. Other evidence, however, suggests that woody shrubs and small trees on levees enhance levee structural integrity while providing environmental benefits. A study on a channel levee along the Sacramento River concluded that roots reinforced the levee soil and increased shear resistance by providing increased stability against slope failures (Shields and Gray 1992). In either case, the widespread removal of vegetation from Delta levees could have significant adverse environmental impacts that are not well understood.

Floodplains and Channels

Floodplains and channels that provide the capacity to carry and store flood flows are critical for managing flood risks, and for overall Delta water management and ecosystem integrity. The CVFPB and FEMA both play roles in designating floodways and floodplains to accommodate flood flows.

The CVFPB regulates encroachment in floodplains by designating floodways in the Sacramento River and San Joaquin River drainages, including the Delta (Water Code section 8609). A "designated floodway" is the channel of the stream and that portion of the adjoining floodplain, as shown on Figure 7-5, reasonably required to provide for the passage of a specified flood. It may also be the floodway between existing levees as determined by the CVFPB.

The CVFPB regulates encroachments within designated floodways and regulated streams through its permitting authority. The encroachment permit process applies to all projects, existing and proposed (including habitat restoration projects), within State/federal flood control project levees, designated floodways, bypasses, and regulated streams (CCR, Title 23, Division 1). The CVFPB should be consulted prior to the consideration of any projects that may be in a designated floodway in the Delta. Appendix L includes a map of the CVFPB's jurisdictional areas in the Delta.

Additionally, under the National Flood Insurance Program, FEMA maps floodplains that have a 1 percent chance of flooding in any year (a 100-year flood). FEMA works with participating communities to regulate development within these floodplains according to federal regulations. No new construction, substantial improvements, or other development (including fill) may be permitted within specified flood zones on the community's Flood Insurance Rate Map unless it is demonstrated that the cumulative effect of the proposed development, when combined with all other existing and anticipated development, will not increase the water surface elevation of the base flood more than 1 foot at any point within the community.

In some flood channels and bypasses, dredging may have benefits because it increases channel capacity and also provides material that can be used for levee maintenance and other flood risk management activities. Because some

Conceptual Diagrams of Floodways

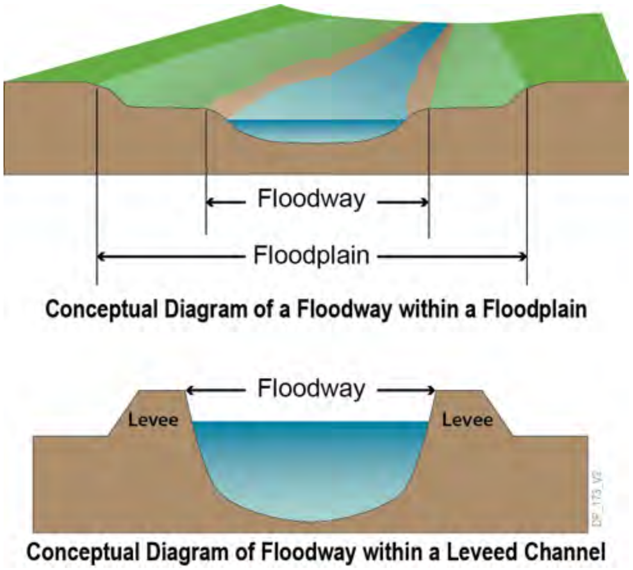

Figure 7-5 The floodway is the channel of the stream and that portion of the adjoining floodplain reasonably required to provide for the passage of a specified flood; it is also the floodway between existing levees as determined by the CVFPB or the Legislature.

Source: FEMA 2006

portions of the Delta are within a tidal pool and other areas are riverine, the efficacy of dredging must be addressed on a site-specific basis and cannot simply be considered useful on a Delta-wide basis.

The benefits and impacts of dredging Delta channels are being investigated by a consortium of federal and State agencies, including U.S. Environmental Protection Agency, USACE, DWR, and the Regional Water Quality Control Boards, under the Delta Dredged Sediment Long-Term Management Strategy (LTMS) Program. The LTMS is designed to improve operational efficiency and coordination of the collective and individual agency decision-making responsibilities resulting in approved dredging and dredged material management actions in the Delta. Approved dredging and dredged material management actions will take place in a manner that protects and enhances Delta water quality, identifies appropriate opportunities for the beneficial reuse of Delta sediments for levee rehabilitation and ecosystem restoration, and establishes safe disposal for materials that cannot be reused (USACE 2007).

Investment in Reducing Risk

Because the Delta's levees protect residents; agricultural land; water supplies; and energy, communications, and transportation facilities, the State has invested considerable funding in Delta levees over several decades through various legislative actions. Legislation sponsored by Senator Howard Way in 1973 established the Delta Levees Maintenance Subventions Program, SB 34 (1988) established the Delta Levees Special Flood Control Projects Program, and Assembly Bill 360 (1996) extended these two programs and initiated a requirement for net habitat enhancement. Bond measures passed since the late 1990s have provided sizeable but one-time funding for levee maintenance, repair, and improvements. Propositions 84 and 1E provided substantial public financing toward most of the recent Delta levee projects. An estimated $700 million of State taxpayer money has been spent by DWR on Delta levee maintenance and improvements since the Delta levee funding programs began in the 1970s. This includes $274 million of bond funds that are encumbered for future Delta levee projects. Funding to improve levees that protect urban and urbanizing areas within the Delta is currently provided by the State via the Early Implementation Program managed by DWR.

The Delta's project levees are authorized as part of the federal flood control project and so are eligible for federal funding (as well as the maintenance subventions mentioned below). The CVFPB serves as the nonfederal partner to USACE for the Delta's project levees.

State investments for nonproject levees in the legal Delta are distributed according to guidelines and criteria of the Delta Levees Maintenance Subventions Program or Delta Levees Special Flood Control Projects Program. These two programs provide State matching funds for maintaining and improving Delta levees. Local agencies in the legal Delta receive partial reimbursement for levee maintenance and rehabilitation from the State when funding is available. Currently, the State contributes up to 75 percent of qualifying costs for maintenance of many Delta levees. Local levee-maintaining agencies provide local cost-share matches, and both local and State efforts contribute to Delta flood risk reduction by maintaining continuous efforts to preserve Delta levees. It is often difficult for local agencies to raise funds for the local cost share of State and federal assistance programs. Funding assistance provided by the Delta Levees Maintenance Subventions Program is governed by guidelines developed by DWR and adopted by the CVFPB. State funds are not available for levee maintenance or improvement in most of Suisun Marsh.

Although the State has contributed the majority of costs for maintaining and improving Delta nonproject levees for many years, the concept of shared responsibility with local landowners is key to the long-term success of the Delta levee system. Neither the State nor the federal government is legally obligated to pay the full cost of Delta flood protection projects. The continued participation and financial support of local reclamation districts is essential. As noted in the Delta Reform Act's Section 85003(b), "Delta property ownership developed pursuant to the federal Swamp Land Act of 1850, and state legislation enacted in 1861, and as a result of the construction of levees to keep previously seasonal wetlands dry throughout the year. That property ownership, and the exercise of associated rights, continue to depend on the landowners' maintenance of those nonproject levees and do not include any right to state funding of levee maintenance or repair."

Prioritizing State Investment in Levees

The Delta Reform Act requires that State investments in Delta levees be prioritized to reduce risks to people, property, and State interests in the Delta (Water Code sections 85305(a) and 85306). Prioritizing investment is necessary to ensure that limited public funds are expended responsibly for improvements critical to State interests, rather than simply applying one objective to all Delta levees regardless of priority. These priorities, in combination with the Delta Reform Act directive that State agencies act consistently with the Delta Plan, will ensure that State spending on Delta levees reflects these priorities in the future. The Delta Reform Act provides that activities of the Council in determining priorities for State levee investments in Delta levees do not increase the State's liability for flood protection in the Delta or its watershed (Water Code section 85032(j)).

This Delta Plan outlines a process to prioritize State investments in levee operation, maintenance, and improvements in the Delta. It is also important to prioritize interim actions while longer-term guidelines are being established. Interim actions taken should consider and, where feasible, incorporate habitat and ecosystem values and enhancement in their development and implementation. This will allow for a more coordinated, effective approach to reducing Delta flood risk and prioritizing both immediate and long-term State investments. This approach will also take into account future actions that may be proposed through other planning efforts such as the CVFPP and Bay Delta Conservation Plan.

To effectively prioritize State investments in levees, a framework is needed to adequately assess Delta flood risk. This framework should include the following steps:

- Assess existing Delta levee conditions. Initially, a sufficient understanding of the current status of Delta levees is needed to establish baseline conditions against which future risk reduction efforts can be gauged. Because Delta levee conditions change, it is critical to conduct periodic assessments so that maintenance and improvement actions can be directed rationally. Assessment methods should be used that provide sufficient information to portray a reasonable snapshot of conditions.
- Develop an economics-based risk analysis for each Delta tract and island. This analysis must address several critical parameters, including life safety, private property, impacts on State water supply, critical infrastructure,

Delta water quality, ecosystem values, and systemwide integrity. Accepted risk analysis methods should be used, such as those developed by USACE (1996, 2006). This analysis could include "expected annual damage" assessments as a metric for analyzing flood risk. This approach, which integrates the likelihood and consequences of flooding, provides values that are useful for comparing flood risk at various locations and for ranking alternative levee projects.

- Conduct ongoing Delta flood risk analyses in an open manner for the public. Baseline and subsequent analytical efforts should always be conducted in manner open to scrutiny, with results being readily available for decision makers, interested parties, and the general public. Flood risk analyses will need to take into account future actions that may be proposed through other planning efforts such as the CVFPP and Bay Delta Conservation Plan.
- Develop an updated understanding of Delta hydrology. An updated understanding of water surface elevations in the Delta is critical for levee design purposes and should be addressed.

The approach must be based on sound scientific and engineering principles, and incorporate appropriate economic and hydrologic data.

As these long-term priorities for State investments in levee operation, maintenance, and improvements are developed, State funds for Delta levee projects should focus on the interim priorities set forth in RR P1, including the following actions:

- Provide a 200-year level of flood protection for existing urban and adjacent urbanizing areas (Water Code section 9600 et seq.).
- Improve the levees that protect aqueducts crossing the Delta and the freshwater pathway to Clifton Court Forebay, as depicted on Figure 7-6, to improve the reliability of these water supplies.
- Improve other Delta levees not specifically planned for ecosystem restoration to the FEMA HMP guidance level to ensure that the Delta's reclamation districts are eligible for public funding for emergency flood fighting, emergency repair, permanent restoration, and/or replacement of eligible damaged nonproject levees.
- Continue to fund and implement the Delta Levees Maintenance Subventions Program to maintain Delta levees.

In addition, the Delta Plan proposes creating a regional agency to assist with the planning, implementation, and financing of Delta flood risk reduction activities (see RR R2). Local levee-maintaining agencies have managed the financing and ongoing maintenance, rehabilitation, and repair of Delta levees, and have improved the levels of levee integrity, reducing overall Delta flood risk. Although the State has provided financial assistance over several decades, these programs have been funded primarily through State general obligation bonds, which face an uncertain future. The unencumbered bond funds that remain available for Delta levee projects total only $123 million.

An alternative funding mechanism could provide a more stable, long-term approach to funding in which local participation by all beneficiaries of flood risk management is more broadly incorporated. A regional flood risk management district with fee assessment authority could address a variety of Delta flood risk-related activities, including levee maintenance and improvements; regional flood management planning; flood facilities inspections; data collection; risk notification; and emergency preparedness planning, response, and mitigation. A regional flood risk management district could complement reclamation district activities. Because two ballot measures, Propositions 218 (1996) and 26 (2010) (discussed in Chapter 8), have raised the approval thresholds for new fees and taxes, the proposed regional assessment district will need to be broadly supported.

Delta Flood Management Facilities

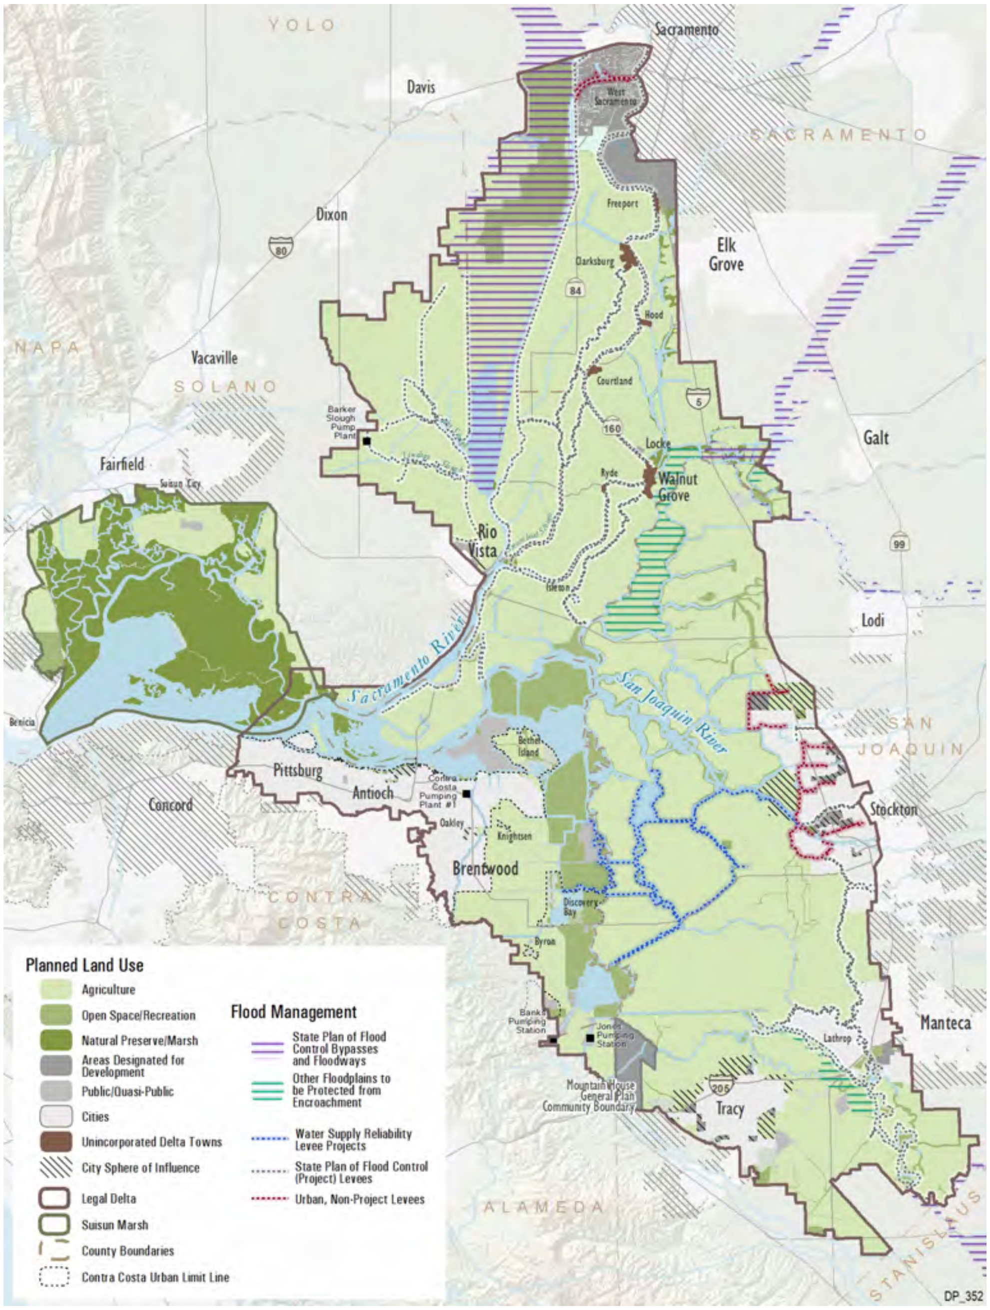

Figure 7-6

The map shows land uses designated by city and county general plans. Within cities' spheres of influences, the map shows land use designations proposed in city general plans, where available. In cases where cities have not proposed land uses within their spheres of influence, the map shows land uses designated by county general plans.

Planning for Floodplain Land Use

The most important step in reducing risk to people in the Delta is to stop putting more people at risk behind levees that do not meet minimum modern standards for flood protection. Actions that increase the demand for higher public spending on flood risk reduction and exacerbate flood risk (for example, urbanizing floodprone areas) should be discouraged.

The DPC *Land Use and Resource Management Plan for the Primary Zone of the Delta* also includes important policies to limit development in floodprone areas of the Primary Zone:

> *Local governments shall carefully and prudently carry out their responsibilities to regulate new construction within flood hazard areas to protect public health, safety, and welfare. These responsibilities shall be carried out consistent with applicable regulations concerning the Delta, as well as the statutory language contained in the Delta Protection Act of 1992. Increased flood protection shall not result in residential designations or densities beyond those allowed under zoning and general plan designations in place on January 1, 1992, for lands in the Primary Zone. (DPC 2010)*

As noted in Chapter 5, the legacy community of Bethel Island warrants a special note because of its flood hazards. About 2,100 people reside on the island in about 1,300 residences concentrated on the south central shoreline and four mobile home parks. The island, which is below sea level, is surrounded by approximately 15 miles of levees, limiting the drainage of floodwaters in the event of a levee breach. A single road, Bethel Island Road, links the island to the mainland at the city of Oakley, complicating emergency response or evacuation in the event of flooding. Because developments on Bethel Island are proposed to be served by the Bethel Island Municipal Improvement District or other adjacent public services, the entire island is within the urban limit line adopted by Contra Costa voters in 2006. The high flood risks on the island and the restricted evacuation opportunities, however, indicate the island has greater hazards to lives and property than the Delta's other areas designated for development. For this reason, it is not excluded from the Delta Plan policy prohibiting new subdivisions unless adequate flood protection is provided. This is consistent with provisions of the Contra Costa County General Plan, which require that development other than a single home on existing parcels await resolution of several issues, including improvement of the community's public services, levees, and emergency evacuation routes.

As described in Chapter 5, urban residential, commercial, and industrial uses should be located in cities, other urban areas, and their spheres of influence, where strong levees can be provided, rather than in rural lands protected only by nonproject levees. Outside of these urban and urbanizing areas and the legacy communities, the Delta Plan prohibits major subdivisions of five or more parcels where 200-year flood protection is not available. Recognizing legacy community needs for incidental growth to maintain their unique cultural values, development within community boundaries should continue consistent with existing general plans, and federal and local flood protection laws. Appendix B provides maps of Delta community boundaries. Maintaining most of the Delta in rural, agricultural land use, as described in Chapter 5, complements policies that reduce the number of properties and the population exposed to high flood risks.

Finally, the participation of Delta counties and cities in the National Flood Insurance Program brings with it a requirement that all residential, commercial, agricultural, and industrial buildings comply with FEMA floodproofing standards, including elevating structure ground floors above the 100-year flood elevation. Examples of floodproofing are shown on Figure 7-7.

Examples of Floodproofing

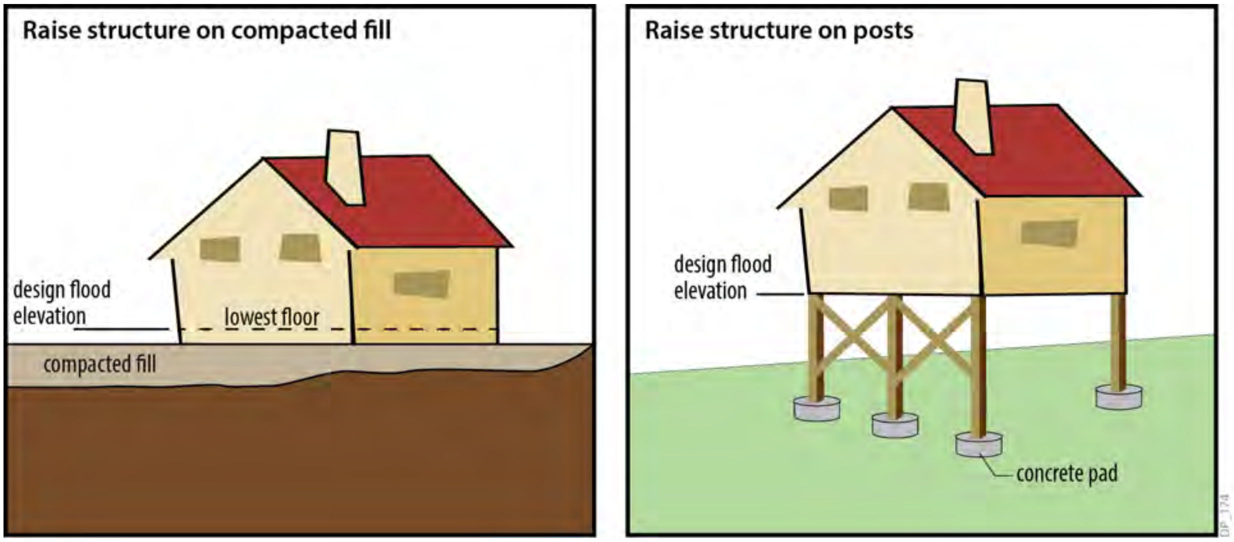

Figure 7-7

Floodproofing in accordance with the National Flood Insurance Program can be achieved through several methods. The illustration on the left shows an example of floodproofing by constructing the lowest floor within a structure above the design flood elevation. The illustration on the right shows floodproofing by raising the bottom of the structure above the design flood elevation.

Emergency Preparedness and Response

Even with the best-engineered levees, channels, and floodways, a residual risk from flooding will always remain; flood risk can never be eliminated. Although investment in flood protection infrastructure can considerably reduce the likelihood of a catastrophic levee failure, failures are inevitable and will require well-coordinated and carefully developed emergency response efforts. To reduce response time and optimize effectiveness of response efforts, such plans need to leverage the unique capabilities of each agency with a mission in the Delta. This section provides an overview of the agencies and planning involved in emergency preparedness and response in the Delta.

Responsibilities for preparing for, declaring, and responding to flood emergencies are distributed among local, State, and federal agencies. Federal agencies with authority include USACE and FEMA. In California, State and local responsibilities fall to county offices of emergency services, local reclamation districts, Cal EMA, and DWR. In a Delta flood emergency, the response efforts by local and State emergency management professionals are guided by California's Standardized Emergency Management System (SEMS). SEMS was established by Government Code section 8607(a), and provides for effective management of multiagency and multijurisdictional emergencies in California, including flood emergencies. This system consists of five organizational levels, which are activated as necessary: (1) field response, (2) local government, (3) operational area, (4) regional, and (5) State. These levels are activated stepwise as the events warrant additional response and resources, meaning that each level of emergency responder contacts the next level above them should they deem the emergency beyond their capabilities to control. Federal resources are called upon if State resources are exhausted or additional assistance is needed. SEMS incorporates the functions and principles of the Incident Command System, the Master Mutual Aid Agreement, existing mutual aid systems, the operational area concept, and multiagency or interagency coordination. A detailed discussion of SEMS can be found in Cal EMA SEMS Guidelines (Cal EMA 2009). Local governments must use SEMS to be eligible for funding of their response-related personnel costs under State disaster assistance programs.

At the State level, Cal EMA's *California Emergency Plan* is the current guiding plan for all State emergencies. The California Emergency Plan incorporates and complies with the principles and requirements found in federal and State laws, regulations, and guidelines. Cal EMA typically defers to DWR for emergency management during floods. DWR emergency flood management actions are guided by its 2007 *Interim Flood Emergency Operations Plan*. DWR is in the process of developing its Delta Flood Emergency Preparedness Response and Recovery Program (EPRRP), which will be the overall guiding flood emergency management program for DWR activities for project and nonproject levees in the Delta. The Delta Flood EPRRP consists of three components: (1) the plan for flood emergency preparedness, response, and recovery actions in the Delta; (2) multiagency plan coordination, which coordinates DWR's plan with the plans of other Delta flood response agencies; and (3) response facilities implementation, which includes the development of flood emergency response facilities in the Delta.

At the federal level, USACE has a standing All-Hazards Emergency Response Plan and standing contracts for emergency response work in the Delta region, and is ready to assist the State, as requested through PL 84-99. These existing plans and procedures are considered in DWR's flood emergency operations plans and are a critical part of the Delta Flood EPRRP Plan. FEMA is responsible for coordinating the response of several federal agencies to a large natural disaster that overwhelms the resources of State and local authorities. The primary duty of FEMA is to ensure services to disaster victims through operational planning and integrated preparedness measures.

Following a flood disaster, various federal programs can provide disaster assistance. USACE has specific criteria concerning eligibility for assistance under PL 84-99. FEMA's HMP criteria must be met to be eligible for its assistance (Delta Stewardship Council Staff 2010b).

To further address emergency preparedness and response issues in the Delta, the Legislature passed SB 27 (Water Code section 12994.5) to develop and implement multi-hazard preparedness and response strategies for the Delta. This legislation required the Office of Emergency Services (now Cal EMA) to establish the Sacramento-San Joaquin Delta Multi-Hazard Coordination Task Force. Led by Cal EMA, the task force consisted of representatives from the DPC, DWR, and representatives of the five Delta counties. The task force was directed to do the following:

- Make recommendations to the Secretary of Cal EMA relating to the creation of an interagency unified command system organizational framework, in accordance with the guidelines of the National Incident Management System and SEMS.
- Coordinate the development of a draft emergency preparedness and response strategy for the Delta region for submission to the Secretary of Cal EMA. Where possible, the strategy shall use existing interagency plans and planning processes of the involved jurisdictions and agencies that are members of the DPC.
- Develop and conduct all-hazard emergency response exercises and training in the Delta that are designed to test or facilitate implementation of regional coordination protocols.

The recommendations being prepared by the task force will likely play an important role in planning efforts for the Delta, and will be considered in the Delta Plan. When this Delta Plan was written, the task force recommendations had been approved by the Secretary of Cal EMA and forwarded to the Governor.

San Joaquin County has developed flood contingency maps and urban evacuation maps as part of its coordinated flood emergency planning efforts. These maps and plans could be used as an example by other Delta counties, and State and federal agencies to prepare a Delta-wide emergency response plan.

Liability Concerns

USACE and other federal agencies are generally afforded some immunity from liability for damages from flood events under the concept of sovereign immunity and provisions of the Flood Control Act of 1928 (33 United States Code section 702c). Congress provided immunity to federal agencies for some but not all tort damages. However, this immunity does not apply to nonfederal agencies.

As the risks of levee failure and corresponding damage increase, California's courts have generally exposed public agencies, and the State specifically, to significant financial liability for flood damages (DWR 2005). The most notable recent court decision on flood liability was the California Court of Appeal decision in *Paterno v. State of California* (2003) (113 Cal. App. 4th 998). The court found the State was liable for damages caused by the failure of a project levee on the Yuba River that the State did not design, build, or even directly maintain. This decision makes it possible that the State will ultimately be held responsible for the structural integrity of much of the federal flood control system in the Delta and Central Valley. The *Paterno v. State of California* decision will ultimately cost State taxpayers approximately $464 million in awarded damages.

In *Arreola v. County of Monterey* (2002) (99 Cal. App. 4th 722), the court held local agencies and the California Department of Transportation (Caltrans) liable for 1995 flood damages to property owners that resulted from a failure to properly maintain levees of the Pajaro River project.

The California *Draft FloodSAFE Strategic Plan* states, "Local communities are responsible for land use decisions, but generally have not been found liable for failure of the flood protection system. Continued local actions to approve development within floodplains may increase flood risk, even if levees and other flood protection improvements are made. This creates liability issues which the State is concerned about. Legislation passed in 2007 addresses the need to connect land use planning with diligent and factual consideration of flood risks for areas of proposed development" (DWR 2008a).

In 2007, the Legislature amended the Water Code to address local community liability for approving development in floodprone areas. It provides that "a city or county may be required to contribute its fair and reasonable share of the property damage caused by a flood to the extent that the city or county has increased the state's exposure to liability for property damage by unreasonably approving new development in a previously undeveloped area that is protected by a state flood control project" (Water Code sections 8307(a) and (b)).

Ultimately, however, it is important to note that the State does not own, operate, control, or maintain nonproject levees, and does not have authority to do so. The Delta levee subventions program grants financial assistance to local reclamation districts for their levees. The State conducts evaluations to make sure subventions program funds have been spent appropriately, but not to ensure the quality of the work or the stability or structural integrity of nonproject levees. Rather, the nonproject levees are the sole responsibility of the reclamation districts, and the State is not liable for damages caused by their failure.

POLICIES AND RECOMMENDATIONS

These policies and recommendations are based on the Council's core strategies for reducing flood risks in the Delta, which are:

- Improve emergency preparedness and response
- Finance and implement flood management activities
- Prioritize flood management investment
- Improve residential flood protection
- Protect and expand floodways, floodplains, and bypasses
- Integrate Delta levees and ecosystem function
- Limit liability

Reducing flood risks also relies on locating urban development in the Delta's cities where levees are stronger, as discussed in Chapter 5, and retaining rural lands for agriculture, so that development in the most floodprone areas is minimized.

Improve Emergency Preparedness and Response

To effectively and reliably reduce risks to people, property, and State interests in the Delta, a multifaceted strategy of coordinated emergency preparedness, appropriate land use planning, and prioritized investment in flood protection infrastructure is necessary (Water Code sections 85305(a) and 85306). Federal, State, and local governments—and Californians—must be prepared for a variety of emergency situations.

The recommendations prepared by the Sacramento-San Joaquin Delta Multi-Hazard Coordination Task Force will likely play an important role in planning efforts for the Delta, and will be considered by the Council for incorporation in future updates of the Delta Plan.

Problem Statement

Levee failures and flooding can and will place human life and property in danger, and can have potentially significant implications for the State's water supply and infrastructure, and the health of the Delta ecosystem. Appropriate emergency preparedness and response planning and implementation activities need to be initiated.

Policies

No policies with regulatory effect are included in this section.

Recommendations

RR R1. Implement Emergency Preparedness and Response

The following actions should be taken by January 1, 2014, to promote effective emergency preparedness and response in the Delta:

- *Responsible local, State, and federal agencies with emergency response authority should consider and implement the recommendations of the Sacramento-San Joaquin Delta Multi-Hazard Coordination Task Force (Water Code section 12994.5). Such actions should support the development of a regional response system for the Delta.*
- *In consultation with local agencies, the California Department of Water Resources should expand its emergency stockpiles to make them regional in nature and usable by a larger number of agencies in accordance with California Department of Water Resources' plans and procedures. The California Department of Water Resources, as a part of this plan, should evaluate the potential of creating stored material sites by "over-reinforcing" west Delta levees.*
- *Local levee-maintaining agencies should consider developing their own emergency action plans, and stockpiling rock and flood-fighting materials.*
- *State and local agencies, and regulated utilities that own and/or operate infrastructure in the Delta should prepare coordinated emergency response plans to protect the infrastructure from long-term outages resulting from failures of the Delta levees. The emergency procedures should consider methods that also would protect Delta land use and ecosystem.*

Finance and Implement Local Flood Management Activities

The responsibility for securing funding for Delta levee maintenance, repairs, and improvements lies with the numerous local levee-maintaining agencies (primarily reclamation districts). Funding is generated through property assessments of local landowners and also is provided by the State under programs administered by DWR (the Delta Levees Special Flood Control Projects and Delta Levees Maintenance Subventions programs). These programs provide State matching funds for addressing Delta flood risk; however, many other entities that benefit from flood risk management are not assessed, nor do they contribute to maintenance and upkeep of Delta levees, including owners of regional infrastructure that crosses the Delta. The duty of providing for Delta flood risk management should be borne by all entities benefitting from these actions, and an equitable methodology of defining and apportioning assessments should be developed and implemented.

Local levee-maintaining agencies have managed the financing and ongoing maintenance, rehabilitation, and repair of Delta levees, and have improved the levels of levee integrity, reducing overall Delta flood risk. Although financial assistance has been provided by the State over several decades, these programs have most recently been funded exclusively through State general obligation bond financing, which faces an uncertain future. The development of an alternative funding mechanism and authority would provide for a more stable, long-term funding approach in which local participation by all beneficiaries of flood risk management is more broadly incorporated. Propositions 218 (1996) and 26 (2010) raised the approval thresholds for new fees and taxes; these thresholds may make it more difficult for a proposed regional assessment district to gain revenue authority.

The establishment of a regional flood risk management district with fee assessment authority could address a variety of Delta flood risk-related activities, including levee maintenance and improvements; regional flood management planning; flood facilities inspections; data collection; risk notification; and emergency preparedness planning, response, and mitigation. Establishing a more centralized and responsive entity could provide a mechanism for addressing issues at the individual district level and for the Delta region overall for the long term.

Problem Statement

No mechanism exists for ensuring that costs of levee maintenance are borne by all beneficiaries. Current financing of levee operations and maintenance is not well coordinated, and future funding sources are uncertain. Financing of local levee operations, maintenance, emergency preparedness and response, and related data collection and reporting efforts would benefit from greater coordination and integration.

Policies

No policies with regulatory effect are included in this section.

Recommendations

RR R2. Finance Local Flood Management Activities

The Legislature should create a Delta Flood Risk Management Assessment District with fee assessment authority (including over State infrastructure) to provide adequate flood control protection and emergency response for the regional benefit of all beneficiaries, including landowners, infrastructure owners, and other entities that benefit from the maintenance and improvement of Delta levees, such as water users who rely on the levees to protect water quality.

This district should be authorized to:

- *Identify and assess all beneficiaries of Delta flood protection facilities.*
- *Develop, fund, and implement a regional plan of flood management for both project and nonproject levees of the Delta, including the maintenance and improvement of levees, in cooperation with the existing reclamation districts, cities, counties, and owners of infrastructure and other interests protected by the levees.*
- *Require local levee-maintaining agencies to conduct annual levee inspections per the California Department of Water Resources subventions program guidelines, and update levee improvement plans every 5 years.*
- *Participate in the collection of data and information necessary for the prioritization of State investments in Delta levees consistent with RR P1.*
- *Notify residents and landowners of flood risk, personal safety information, and available systems for obtaining emergency information before and during a disaster on an annual basis.*
- *Potentially implement the recommendations of the Sacramento-San Joaquin Delta Multi-Hazard Coordination Task Force (Water Code section 12994.5) in conjunction with local, State, and federal agencies, and maintain the resulting regional response system and components and procedures on behalf of SEMS jurisdictions (reclamation district, city, county, and State) that would jointly implement the regional system in response to a disaster event.*
- *Identify and assess critical water supply corridor levee operations, maintenance, and improvements.*

RR R3. Fund Actions to Protect Infrastructure from Flooding and Other Natural Disasters

- *The California Public Utilities Commission should immediately commence formal hearings to impose a reasonable fee for flood and disaster prevention on regulated privately owned utilities with facilities located in the Delta. Publicly owned utilities should also be encouraged to develop similar fees. The California Public Utilities Commission, in consultation with the Delta Stewardship Council, the California Department of Water Resources, and the Delta Protection Commission, should allocate these funds among State and local emergency response and flood protection entities in the Delta. If a new regional flood management agency is established by law, a portion of the local share would be allocated to that agency.*
- *The California Public Utilities Commission should direct all regulated public utilities in their jurisdiction to immediately take steps to protect their facilities in the Delta from the consequences of a catastrophic failure of levees in the Delta, to minimize the impact on the State's economy.*
- *The Governor, by Executive Order, should direct State agencies with projects or infrastructure in the Delta to set aside a reasonable amount of funding to pay for flood protection and disaster prevention. The local share of these funds should be allocated as described above.*

Prioritize Flood Management Investment

A method is needed for prioritizing State funds for use in operating, maintaining, and improving Delta levees with a systemwide approach. Although the State has expended millions of dollars since the early 1970s on Delta levees, almost half of the Delta's acreage is not protected by levees that meet the HMP guidance today. Efforts by landowners, reclamation districts, and other parties using local resources to perform levee upgrades, beyond the standards that may be funded by the State, are encouraged and would be consistent with the goal of reducing Delta flood risk. The Delta Reform Act provides that activities of the Council in determining priorities for State investments in Delta levees do not increase the State's liability for flood protection in the Delta or its watershed.

Problem Statement

The Delta Reform Act (Water Code section 85306) requires the Delta Plan to recommend priorities for State investments in Delta levees, including project and nonproject levees. Currently, no comprehensive method exists to prioritize State investments in Delta levee operations, maintenance, and improvement projects. Without a prioritization methodology, the apportionment of public resources into levees may not occur in a manner that reflects a broader, long-term approach.

Policies

RR P1. Prioritization of State Investments in Delta Levees and Risk Reduction

(a) Prior to the completion and adoption of the updated priorities developed pursuant to Water Code section 85306, the interim priorities listed below shall, where applicable and to the extent permitted by law, guide discretionary State investments in Delta flood risk management. Key priorities for interim funding include emergency preparedness, response, and recovery as described in paragraph (1), as well as Delta levees funding as described in paragraph (2).

(1) Delta Emergency Preparedness, Response, and Recovery: Develop and implement appropriate emergency preparedness, response, and recovery strategies, including those developed by the Delta Multi-Hazard Task Force pursuant to Water Code section 12994.5.

(2) Delta Levees Funding: The priorities shown in the following table are meant to guide budget and funding allocation strategies for levee improvements. The goals for funding priorities are all important, and it is expected that over time, the California Department of Water Resources must balance achievement of those goals. Except on islands planned for ecosystem restoration, improvement of nonproject Delta levees to the Hazard Mitigation Plan (HMP) standard may be funded without justification of the benefits. Improvements to a standard above HMP, such as that set by the U.S. Army Corps of Engineers under Public Law 84-99, may be funded as befits the benefits to be provided, consistent with the California Department of Water Resources' current practices and any future adopted investment strategy.

Priorities for State Investment in Delta Integrated Flood Management Categories of Benefit Analysis

Goals	Localized Flood Protection	Levee Network	Ecosystem Conservation
1	Protect existing urban and adjacent urbanizing areas by providing 200-year flood protection.	Protect water quality and water supply conveyance in the Delta, especially levees that protect freshwater aqueducts and the primary channels that carry fresh water through the Delta.	Protect existing and provide for a net increase in channel-margin habitat.
2	Protect small communities and critical infrastructure of statewide importance (located outside of urban areas).	Protect floodwater conveyance in and through the Delta to a level consistent with the State Plan of Flood Control for project levees.	Protect existing and provide for net enhancement of floodplain habitat.
3	Protect agriculture and local working landscapes.	Protect cultural, historic, aesthetic, and recreational resources (Delta as Place).	Protect existing and provide for net enhancement of wetlands.

(b) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers a proposed action that involves discretionary State investments in Delta flood risk management, including levee operations, maintenance, and improvements. Nothing in this policy establishes or otherwise changes existing levee standards.

23 CCR Section 5012
NOTE: Authority cited: Section 85210(i), Water Code.
Reference: Sections 85020, 85300, 85305, and 85306, Water Code.

Recommendations

RR R4. Actions for the Prioritization of State Investments in Delta Levees

The Delta Stewardship Council, in consultation with the California Department of Water Resources, the Central Valley Flood Protection Board, the Delta Protection Commission, local agencies, and the California Water Commission, should develop funding priorities for State investments in Delta levees by January 1, 2015. These priorities shall be consistent with the provisions of the Delta Reform Act in promoting effective, prioritized strategic State investments in levee operations, maintenance, and improvements in the Delta for both levees that are a part of the State Plan of Flood Control and nonproject levees. Upon completion, these priorities shall be considered for incorporation into the Delta Plan.

The priorities should identify guiding principles, constraints, recommended cost share allocations, and strategic considerations to guide Delta flood risk reduction investments, supported by, at a minimum, the following actions to be conducted by the California Department of Water Resources, consistent with available funding:

- *An assessment of existing Delta levee conditions. This should include the development of a Delta levee conditions map based on sound data inputs, including, but not limited to:*
    - *Geometric levee assessment*
    - *Flow and updated stage-frequency analysis*
- *An island-by-island economics-based risk analysis. This analysis should consider, but not be limited to, values related to protecting:*
    - *Island residents/life safety*
    - *Property*
    - *Value of Delta islands' economic output, including agriculture*
    - *State water supply*
    - *Critical local, State, federal, and private infrastructure, including aqueducts, state highways, electricity transmission lines, gas/petroleum pipelines, gas fields, railroads, and deep water shipping channels*
    - *Delta water quality*
    - *Existing ecosystem values and ecosystem restoration opportunities*
    - *Recreation*
    - *Systemwide integrity*
- *An ongoing assessment of Delta levee conditions. This should include a process for updating Delta levee assessment information on a routine basis.*

This methodology should provide the basis for the prioritization of State investments in Delta levees. It should include, but not be limited to, the public reporting of the following items:

- *Tiered ranking of Delta islands, based on economics-based risk analysis values*
- *Delta levee conditions status report, including a levee conditions map*
- *Inventory of Delta infrastructure assets*

Improve Residential Flood Protection

To reduce the risk to lives, property, and State interests in the Delta, additional standards are needed to address new residential development. Sea level rise, subsidence, and new residential development combine to potentially put many more lives at risk. The policies in this section are designed to reduce risk while preserving the Delta's unique character and agricultural way of life. These policies should be construed as those required to provide the minimum level of flood protection, and should not be viewed as encouraging development in floodprone Delta areas. Flood insurance, and awareness of local emergency preparedness and response policies is strongly encouraged for all who live in floodprone areas of the Delta.

Consistent with existing law, urban development in the Primary Zone should remain prohibited. Urban development in the Secondary Zone should be confined to existing urban spheres of influence where the 200-year design standard will be fully implemented by 2025. The 2007 flood risk management legislation (SB 5) contained provisions affecting city and county responsibilities relating to local planning requirements, such as general plans, development agreements, zoning ordinances, tentative maps, and other actions (Government Code sections 65865.5, 65962, and 66474.5). Future land use decisions should not permit or encourage construction of significant numbers of new residences in the nonurban Delta. For the legacy communities in the Delta, structures developed in these areas are required to meet the legal standard of a 100-year minimum level of flood protection. However, developing and maintaining adequate flood protection remains difficult.

Problem Statement

Continued residential development without adequate flood protection increases risk to lives, property, and State interests in the Delta. Flood risks are expected to grow in light of anticipated climate change effects related to peak flows and sea level rise.

Policies

The appendices referred to in the policy language below are included in Appendix B of the Delta Plan.

RR P2. Require Flood Protection for Residential Development in Rural Areas

(a) New residential development of five or more parcels shall be protected through floodproofing to a level 12 inches above the 100-year base flood elevation, plus sufficient additional elevation to protect against a 55-inch rise in sea level at the Golden Gate, unless the development is located within:

(1) Areas that city or county general plans, as of May 16, 2013, designate for development in cities or their spheres of influence;

(2) Areas within Contra Costa County's 2006 voter-approved urban limit line, except Bethel Island;

(3) Areas within the Mountain House General Plan Community Boundary in San Joaquin County; or

(4) The unincorporated Delta towns of Clarksburg, Courtland, Hood, Locke, Ryde, and Walnut Grove, as shown in Appendix 7.

(b) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers a proposed action that involves new residential development of five or more parcels that is not located within the areas described in subsection (a).

23 CCR Section 5013
NOTE: Authority cited: Section 85210(i), Water Code.
Reference: Sections 85020, 85300, 85305, and 85306, Water Code.

Protect and Expand Floodways, Floodplains, and Bypasses

Local land use policies guiding development in floodways are not consistent across Delta counties. Floodways have not been established for many of the channels in the Delta by FEMA or by the CVFPB. In light of these inconsistencies, the Delta Plan addresses these issues and highlights the need for the protection of floodplains and floodways consistent with improved flood protection. Over the next 100 years, Delta floodways may expand and deepen because of sea level rise and changing precipitation patterns. Development in existing or potential future designated floodplain or bypass locations in the Delta or upstream of the Delta can permanently eliminate the availability of these areas for future floodplain usage. It is important to identify floodplain areas now for immediate protection and eventual integration into the flood protection system.

Problem Statement

The carrying capacity of the existing flood control system is diminished by encroachments into floodways, critical floodplains, and existing floodplain or bypass locations in the Delta. Local land use policies guiding development in floodways are not consistent across Delta counties. The existing system is already at suboptimal capacity. Expected changes in sea level rise and runoff patterns due to climate change are expected to exacerbate the problem.

Policies

RR P3. Protect Floodways

(a) No encroachment shall be allowed or constructed in a floodway, unless it can be demonstrated by appropriate analysis that the encroachment will not unduly impede the free flow of water in the floodway or jeopardize public safety.

(b) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers a proposed action that would encroach in a floodway that is not either a designated floodway or regulated stream.

23 CCR Section 5014
NOTE: Authority cited: Section 85210(i), Water Code.
Reference: Sections 85020, 85300, 85302, and 85305, Water Code.

RR P4. Floodplain Protection

(a) No encroachment shall be allowed or constructed in any of the following floodplains unless it can be demonstrated by appropriate analysis that the encroachment will not have a significant adverse impact on floodplain values and functions:

(1) The Yolo Bypass within the Delta;

(2) The Cosumnes River-Mokelumne River Confluence, as defined by the North Delta Flood Control and Ecosystem Restoration Project (McCormack-Williamson), or as modified in the future by the California Department of Water Resources or the U.S. Army Corps of Engineers (California Department of Water Resources 2010); and

(3) The Lower San Joaquin River Floodplain Bypass area, located on the Lower San Joaquin River upstream of Stockton immediately southwest of Paradise Cut on lands both upstream and downstream of the Interstate 5 crossing. This area is described in the Lower San Joaquin River Floodplain Bypass Proposal, submitted to the California Department of Water Resources by the partnership of the South Delta Water Agency, the River Islands Development Company, Reclamation District 2062, San Joaquin Resource Conservation District, American Rivers, the American Lands Conservancy, and the Natural Resources Defense Council, March 2011. This area may be modified in the future through the completion of this project.

(b) For purposes of Water Code section 85057.5(a)(3) and section 5001(j)(1)(E) of this Chapter, this policy covers a proposed action that would encroach in any of the floodplain areas described in subsection (a).

(c) This policy is not intended to exempt any activities in any of the areas described in subsection (a) from applicable regulations and requirements of the Central Valley Flood Protection Board.

23 CCR Section 5015
NOTE: Authority cited: Section 85210(i), Water Code.
Reference: Sections 85020, 85300, 85302, and 85305, Water Code.

Recommendations

RR R5. Fund and Implement San Joaquin River Flood Bypass

The Legislature should fund the California Department of Water Resources and the Central Valley Flood Protection Board to evaluate and implement a bypass and floodway on the San Joaquin River near Paradise Cut that would reduce flood stage on the mainstem San Joaquin River adjacent to the urban and urbanizing communities of Stockton, Lathrop, and Manteca in accordance with Water Code section 9613(c).

RR R6. Continue Delta Dredging Studies

The current efforts to maintain navigable waters in the Sacramento River Deep Water Ship Channel and Stockton Deep Water Ship Channel, led by the U.S. Army Corps of Engineers and described in the Delta Dredged Sediment Long-Term Management Strategy (USACE 2007, Appendix K), should be continued in a manner that supports the Delta Plan and the coequal goals. Appropriate dredging throughout other areas in the Delta for maintenance purposes, or that would increase flood conveyance and provide potential material for levee maintenance or subsidence reversal should be implemented in a manner that supports the Delta Plan and coequal goals. Coordinated use of dredged material in levee improvement, subsidence reversal, or wetland restoration is encouraged.

RR R7. Designate Additional Floodways

The Central Valley Flood Protection Board should evaluate whether additional areas both within and upstream of the Delta should be designated as floodways. These efforts should consider the anticipated effects of climate change in its evaluation of these areas.

Integrate Delta Levees and Ecosystem Function

Setback levees can provide additional levee system stability, more complex land-water interface structure, and shaded riverine aquatic habitat that benefit ecosystem function in appropriate settings. They can also provide flood control benefits in those areas of the Delta not subject to strong tidal influences where channel capacity improvements can actually increase flood-carrying capacity. Not all locations are amenable or useful for setback levee placement. Each site should be investigated for its potential to provide ecological benefits consistent with levee integrity.

Problem Statement

Criteria for the development and implementation of setback levees in the Delta have not yet been developed by relevant agencies. These criteria are needed to provide appropriate guidance when considering setback levee siting and design. Currently, agencies have no consistent method for determining the appropriateness of setback levee incorporation as they relate to habitat enhancement and flood control benefit.

Policies

No policies with regulatory effect are included in this section.

Recommendations

RR R8. Develop Setback Levee Criteria

The California Department of Water Resources, in conjunction with the Central Valley Flood Protection Board, the California Department of Fish and Game, and the Delta Conservancy, should develop criteria to define locations for future setback levees in the Delta and Delta watershed.

Limit State Liability

The Delta Reform Act requires that the Delta Plan attempt to reduce risks to people, property, and State interests in the Delta by, among other things, recommending priorities for State investments in levee operation, maintenance, and improvements in the Delta, including project and nonproject levees (Water Code sections 85305, 85306, and 85307). The law expressly states that these provisions do not affect the liability of the State for flood protection in the Delta or its watershed (Water Code section 85032(j)). Consequently, no action taken by a State agency as required or recommended by, or otherwise in furtherance of, this Delta Plan shall affect State flood protection liability in the Delta or its watershed. Therefore, the Legislature should consider requiring an adequate level of flood insurance for residences, businesses, and industries in floodprone areas.

Problem Statement

As the risks of levee failure and corresponding damage increase, California courts have generally exposed public agencies and the State, specifically, to significant financial liability for flood damages. DWR's 2005 white paper recommends one way that the State should reduce its liability is to require houses and businesses to have flood insurance (DWR 2005).

Policies

No policies with regulatory effect are included in this section.

Recommendations

RR R9. Require Flood Insurance

The Legislature should require an adequate level of flood insurance for residences, businesses, and industries in floodprone areas.

RR R10. Limit State Liability

The Legislature should consider statutory and/or constitutional changes that would address the State's potential flood liability, including giving State agencies the same level of immunity with regard to flood liability as federal agencies have under federal law.

Timeline for Implementing Policies and Recommendations

Figure 7-8 lays out a timeline for implementing the policies and recommendations described in the previous section. The timeline emphasizes near-term and intermediate-term actions.

Timeline for Implementing Policies and Recommendations

TIMELINE **CHAPTER 7: Risk Reduction**

	ACTION (REFERENCE #)	LEAD AGENCY(IES)	NEAR TERM 2012–2017	INTERMEDIATE TERM 2017–2025
POLICIES	Prioritization of State investments in Delta levees and risk reduction (RR P1)	Council, DWR, CVFPB	●	
	Require flood protection for residential development in rural areas (RR P2)	Local agencies	●	●
	Protect floodways (RR P3)	CVFPB	●	●
	Floodplain protection (RR P4)	CVFPB	●	●
RECOMMENDATIONS	Implement emergency preparedness and response (RR R1)	Local, State, and federal agencies	●	
	Finance local flood management activities (RR R2)	Legislature, DPC	●	
	Fund actions to protect infrastructure from flooding and other natural disasters (RR R3)	PUC	●	
	Actions for the prioritization of State investments in Delta levees (RR R4)	Council, DWR, CVFPB	●	
	Fund and implement San Joaquin River Flood Bypass (RR R5)	Legislature, DWR, CVFPB	●	
	Continue Delta dredging studies (RR R6)	USACE	●	●
	Designate additional floodways (RR R7)	CVFPB	●	
	Develop setback levee criteria (RR R8)	DWR	●	
	Require flood insurance (RR R9)	Legislature	●	
	Limit State liability (RR R10)	Legislature	●

Agency Key:

Council: Delta Stewardship Council
CVFPB: Central Valley Flood Protection Board
DPC: Delta Protection Commission
DWR: California Department of Water Resources
PUC: California Public Utilities Commission
USACE: U.S. Army Corps of Engineers

Figure 7-8

Issues for Future Evaluation and Coordination

The following list of issues should be considered in future updates of the Delta Plan. These and other issues will need to be considered as additional information and materials become available. The various activities called for in this Delta Plan, as well as issues that arise from other planning efforts, such as the Central Valley Flood Protection Plan, will be considered. Additional areas of interest and concern related to flood risk in the Delta may deserve consideration in the development of future Delta Plan updates, including:

- **Reoperation of Upstream Reservoirs and Peak Flow Attenuation:** Reservoir operations upstream of the Delta can have substantial impacts on flood flows through the Delta; therefore, operation procedures among government agencies should be well coordinated and, where possible, focused more on flexibility to prevent flooding in the Delta. Water Code section 85309 directs DWR to develop a proposal to coordinate flood and water supply operations with appropriate State and federal agencies, and this shall be considered by the Council for future inclusion in the Delta Plan.
- **Utility Corridor Consolidation:** An attempt to consolidate infrastructure into "utility corridors" as facilities are added and upgraded over time should be further investigated to determine whether this can allow for better management of flood risk consequences to these critical assets.
- **State Highways and Sea Level Rise:** The Council will consult with Caltrans regarding the potential effects of climate change and sea level rise on the three state highways that cross the Delta (Water Code section 85307 (c)).

Science and Information Needs

The Delta system and its influencing factors are not static; therefore, research is needed to better understand dynamic issues such as climate change, seismicity, sea level rise, subsidence, and other areas. Continuing investigations into the science, engineering, and economic aspects of the Delta are critical to adaptively managing for expected and unexpected changes, and can provide decision makers and stakeholders with key information for future planning and decision making. Specifically, additional information will be needed in the following areas:

- The interaction between Delta levees and ecosystem function
- Sea level rise: impacts on, and incorporation into, flood risk reduction standards
- Climate change: effects of altered hydrology on levee system integrity
- Effects of seismicity on levee integrity
- Updated flood stage-probability functions
- Potential for subsidence reversal and carbon sequestration from growing native marsh plants
- Understanding the impacts on Delta flood management from upstream flood management infrastructure operations, including reservoir operations
- Technologies for assessing levee integrity

Efforts to address these needs and others that arise during Delta Plan implementation should be undertaken in a systematic fashion so that information developed and lessons learned can be incorporated into future Delta Plan updates.

Performance Measures

Development of informative and meaningful performance measures is a challenging task that will continue after the adoption of the Delta Plan. Performance measures need to be designed to capture important trends and to address whether specific actions are producing expected results. Efforts to develop and track performance measures in complex and large-scale systems like the Delta are commonly multiyear endeavors. The recommended output and outcome performance measures listed below are provided as examples and subject to refinement as time and resources allow. Final administrative performance measures are listed in Appendix E and will be tracked as soon as the Delta Plan is completed.

Output Performance Measures

- New residential development takes into account sea level rise in flood protection planning and development. (RR P2)
- Delta land acreage and the number of reclamation districts with levees below HMP are reduced. (RR P1)
- Freshwater aqueducts passing through the Delta and the primary freshwater channel pathways through the Delta are protected by levees that provide adequate protection against floods and other risks of failure. (RR P1)
- Responsible local, State, and federal agencies with emergency response authority implement the recommendations of the Sacramento-San Joaquin Delta Multi-Hazard Coordination Task Force (Water Code section 12994.5). (RR R1)
- DWR and the CVFPB construct a bypass and floodway on the San Joaquin River near Paradise Cut. (RR R5)

Outcome Performance Measures

- No lives are lost in the Delta as a result of flood emergencies, and economic damages associated with Delta flood emergencies decrease. (RR R1)
- Emergency response and recovery costs are eligible for FEMA reimbursement. (RR P1)
- Water deliveries to East Bay Municipal Utilities District, Contra Costa Water District, the CVP, and the SWP are not interrupted by floods or earthquakes. (RR P1)

CHAPTER 8

Funding Principles to Support the Coequal Goals

ABOUT THIS CHAPTER

This chapter provides background information on federal, State of California (State), and local spending for water supply, water quality, flood management, and Delta ecosystem purposes. It proposes the development of a comprehensive finance plan to implement the Delta Plan. It also sets forth guiding principles for the development of a finance plan and proposes near-term funding for support of the Delta Protection Commission, Sacramento-San Joaquin Delta Conservancy, and the Delta Stewardship Council (Council).

A 5-year budget is included in Appendix M. And, as described in Chapter 2, successful implementation of the Delta Plan will depend upon many independent agency authorities and actions under the coordination and leadership of the Council.

CHAPTER 8

Funding Principles to Support the Coequal Goals

In establishing the coequal goals, the Delta Reform Act affirmatively reset spending priorities for the Delta ecosystem and water management. Inherent in the coequal goals is a new governance structure (primarily the Council), which the Legislature intended to have the "authority, responsibility, accountability, scientific support, and adequate *and secure funding to achieve these objectives*." The Council was directed to develop a long-term, legally enforceable management plan for the Delta, and in implementing the Delta Plan, to "direct actions across State agencies," in part through the establishment of an Interagency Implementation Committee. Additionally, as addressed in the preceding Delta Plan chapters, the Delta Reform Act set forth a number of policy objectives and other requirements for how the Delta Plan must be developed and what it must contain, ranging from broad guidance on types of projects the Plan should promote, to specific performance measures for evaluating progress on ecosystem restoration. Accordingly, the Council set forth several priority recommendations and regulatory policies, which together make up this Delta Plan.

The Delta Reform Act does not require the development of a financing plan for the implementation of the Delta Plan; however, given the current economic climate, recent uneven funding for water and ecosystem investment, and the critical nature of what is at stake should the coequal goals fail to be achieved, the Council affirmed the need for a financing plan and is committed to its development.

As the Public Policy Institute of California succinctly stated in its 2011 report on water management in California, "Although money alone is not sufficient for successful water management, it is necessary" (Public Policy Institute of California 2011). In introducing any discussion on financing, particularly in the public sector, it is necessary to acknowledge the political and economic context. America is currently suffering a severe recession, and California's economy has fared even worse. The State has experienced a multiyear budget crisis in which annual spending exceeds available revenue. As a result, financing infrastructure and new programs has become immensely challenging for State and local governments.

Today's economic conditions may limit the ability to adequately finance a full range of water and ecosystem improvements necessary to achieve the coequal goals in the near term. However, the planning timeframe for the Delta Plan runs to the year 2100, and decisions on long-term, sustainable financing for water, ecosystem, and flood protection cannot be delayed much longer without grave and expensive consequences. A long planning horizon allows near-term foundational steps to be taken now toward improving the situation and for implementing agencies to stage actions, policies, and projects over time consistent with an adaptive management structure based on science. Additionally, some activities to implement the Delta Plan are currently funded or can be undertaken with no additional cost, and many of the actions called for in the Delta Plan are certain to result in significant long-term cost savings.

Because of the complex nature of the policy issues and of certain funding and finance methods, a comprehensive and supportable Delta Plan finance plan will take time to develop. Thorough research is needed to identify entities that may be assessed user or stressor fees, determine appropriate levels for these fees, establish tiered fee structures, calculate the public benefits, and work through the legal implications of any financing strategy, including the practical effects of Propositions 218 and 26 on State and local financing mechanisms.

Background

Since the CALFED Bay-Delta Program was instituted in 1995 to restore ecological health and improve water management in the Delta, significant expenditures have been made in the Delta. An estimated $400 million has been spent annually, on average, by federal, State, and local water users.

Traditionally, the State has financed water infrastructure with general obligation bonds. These bonds were approved by the voters, and repayment is guaranteed by the State's general taxing power. With respect to State Water Project (SWP) debt, however, even though repayment was secured by taxes, general obligation bonds were paid back primarily by the water contractors. Since 2000, California voters have authorized $19.4 billion in water-related general obligation bonds spread over six separate bonds (LAO 2008). Several of these bonds authorize expenditures for a multitude of purposes, including assorted water projects, parkland acquisition, habitat restoration, and local assistance grants. One benefit of financing water projects with general obligation bonds is that any expenditure made for a public purpose is repaid by taxpayers, the primary beneficiaries. Currently, remaining fund balances for active bond accounts total approximately $2.2 billion out of the authorized total of $19.4 billion, only a portion of which is for Delta-related spending.

Table 8-1 summarizes the current balances for general obligation bonds by individual bond act related to water, ecosystem restoration, and flood protection. It is important to note that these remaining balances are not fungible; that is, statute generally dictates the specific types of projects or programs on which funds can be spent.

Currently scheduled for the November 2014 ballot, the Safe, Clean, and Reliable Drinking Water Supply Act of 2012 would authorize, upon voter approval, the issue and sale of $11.14 billion in general obligation bonds for financing drought relief projects, water supply reliability projects, Delta sustainability projects, water system improvements, watershed and conservation protection programs, groundwater protection and water quality projects, and water recycling projects. Key Delta projects include $2.25 billion for protection of water supplies from catastrophic levee failure, drinking water quality improvements, levee and flood control facilities improvements, lost property tax replacement, ecosystem restoration, and contaminants reduction.

General Obligation Bonds – California (as of January 2013)

TABLE 8-1

Bond Act (Year)	Authorized ($ Thousands)	Committed ($ Thousands)	Balance ($ Thousands)
Proposition 12 (2000)	2,024,486	6,189	18,456
Proposition 13 (2000)	2,103,000	1,823,874	279,126
Proposition 40 (2002)	2,471,600	16,556	26,536
Proposition 50 (2002)	3,382,630	0	0
Proposition 1E (2006)	4,090,000	4,024,354	65,646
Proposition 84 (2006)	5,388,000	5,080,840	307,160
Total	**$19,378,411**	**$17,221,349**	**$2,157,062**

Although general obligation bonds have been an important part of how California has funded water and ecosystem projects in the past, because of the uncertainty regarding voter approval of future bonds, a more sustainable and long-term financing approach for water, ecosystem, flood protection, and related projects is needed. As new revenue sources are developed, the use of revenue bonds may become more prevalent. For example, the SWP routinely sells and redeems revenue bonds to pay the costs of planning and construction, bond interest, and project operating expenses, as do many local agencies.

Federal-level expenditures in California in recent years have declined as grant programs for wastewater treatment in the late 1970s and 1980s expired, and flood control spending was reduced. It is likely that large federal budget deficits for the foreseeable future will preclude any increases in federal funds for California water projects.

Although State-level expenditures for water-related programs and projects in recent years have been almost entirely funded with general obligation bonds, this contrasts somewhat with the financing methods available to local agencies. Although many of these agencies have at times issued general obligation bonds and revenue bonds, it is more common for them to establish stable income streams by charging dedicated fees to ratepayers to pay the costs of infrastructure projects including water treatment and wastewater systems.

The ability of local agencies to fund flood control and stormwater projects, however, is specifically governed by the provisions of Proposition 218, approved by California voters in 1996. Under Proposition 218, direct voter approval by a majority of property owners or a two-thirds vote of the general public is required to raise funds for these purposes. Results of local Proposition 218 elections in recent years have been mixed, with some agencies gaining voter approval and others falling short of funding needed for local projects. For example, Sacramento voters successfully approved new assessments for flood control projects in 2007, but 1 year later, voters in Orinda (East Bay Area) and Burlingame (Bay Area) failed to approve new assessments for the same purpose (Public Policy Institute of California 2011).

A companion measure, Proposition 26, approved by voters in 2010, effectively raised voting requirements for most State and local regulatory fees from a simple majority to a two-thirds majority. Regulatory fees with a broad public purpose are considered taxes and are subject to a two-thirds vote of the Legislature. Local agencies are also required to seek a two-thirds vote of the general public.

The best available information shows that total annual federal, State, and local spending on water and wastewater treatment in California is approximately $24 billion (see Table 8-2). Operations, maintenance, and capital expenditures for water infrastructure consume significant economic resources in California. This total likely includes some overlap, but the expenditures are significant. Other sources cite higher expenditures for some of these categories. During development of the finance plan, this table will be updated to reflect the most recent data.

Bay Delta Conservation Plan

Described in various sections of this Delta Plan, the Bay Delta Conservation Plan (BDCP) is a massive water and ecosystem public works planning process under way in the Delta. The Council supports the completion of the BDCP according to the provisions set forth in the Delta Reform Act. The scope or type of any water facility improvements, related Delta ecosystem mitigation, and other habitat improvements to be included is very preliminary at this time. The BDCP's ongoing planning costs are currently funded by State and federal water contractors. Currently available information from the BDCP indicates that, once it is completed, the first 5 years of implementation will require between $5.7 and $5.9 billion total for capital outlay, of which approximately $5.2 billion is for water conveyance. Additionally, the BDCP estimates that $3.6 billion total plus $46 million annually will be required for Delta ecosystem

Annual Budgets/Expenditures in California for Selected Agencies

TABLE 8-2

Agency	Budget/Expenditures Operating ($ Millions)	 Capital ($ Millions)	Source
Local cities, counties, and special districts water	10,100	2,000	California State Controller 2011a, 2011b, 2011c
Local cities, counties, and special districts wastewater	5,400	1,100	California State Controller 2011a, 2011b, 2011c
Local cities, counties, and special districts flood control	1,000	300	California State Controller 2011a, 2011b, 2011c

restoration (BDCP Steering Committee 2010). The BDCP will include a funding plan that will address estimated implementation costs and sources of funding that will be relied upon to cover these costs. The sidebar, Bay Delta Conservation Plan Costs and Existing Funding Sources, provides additional background information about the BDCP.

Overview of Current State and Federal Delta-related Expenditures

The CALFED Bay-Delta Program was incorporated into the Council in 2010. However, some program elements endure because bond funds are dedicated by law for CALFED purposes. Additionally, the CALFED program is still referenced in federal statutes. For these reasons, an annual cross-cut budget showing State and federal expenditures for active CALFED programs and projects is developed each January.

Because the cross-cut budget includes State and federal expenditure details on all the CALFED programs, those data can be summarized to show expenditures for program elements displayed in the budget. The results are shown in Table 8-3.

Annual State and Federal Expenditures in California by Program Element (2012–2013)

TABLE 8-3

Program Element	California	Federal	Total
Governance	$21,145,596	$20,490,000	$41,635,596
Water Supply Reliability	$161,523,833	$18,774,000	$180,297,833
Ecosystem Restoration	$64,119,524	$92,275,000	$156,394,524
Water Quality	$6,368,631	$5,000,000	$11,368,631
Risk Reduction/Levee Integrity	$8,949,231	$45,560,000	$54,509,231
Total	**$262,106,815**	**$182,099,000**	**$444,205,815**

BAY DELTA CONSERVATION PLAN COSTS AND EXISTING FUNDING SOURCES

Potential future funding sources for the BDCP will likely compete with funding required for implementation of some elements of the Delta Plan, and for the plans and projects of State, federal, and local agencies. The Council does not consider any funding source to be solely available for the BDCP, or for any other program or plan. They are solely considered to be options at this stage.

Based on current information from the BDCP, the approximate costs of a facility and related ecosystem improvements needed for State and federal approval are approximately $15.8 to $16.7 billion in capital costs and an additional $4.9 to $5.6 billion in operating costs over the 50-year permit period. These costs are divided among the BDCP's four primary functions—water conveyance, habitat restoration, management of other stressors, and program oversight—as shown in the table below. The Council notes that preliminary cost estimates are just that: preliminary. Going forward, refined estimates will be required to complete this planning process.

Options for BDCP Funding

The BDCP is premised on the pledge of participating State and federal water contractors to pay the full cost of any new Delta export facility and the associated Delta ecosystem mitigation required to meet the requirements imposed on the BDCP by federal and State laws. Habitat and ecosystem restoration activities, beyond mitigation requirements, are considered to provide a general benefit to the State and should be funded accordingly.

Prior to completion of the BDCP and a full understanding of the Delta ecosystem improvements related to the BDCP, it is impossible to project the detailed funding options that might be necessary. However, it is highly likely that user fees, revenue bonds, and sources other than the State General Fund will be the primary sources of funding.

Summary of BDCP Costs and Existing Funding Sources ($ millions)

	Bay Delta Conservation Plan[a]		
Program Function	**Capital Costs**	**Operating Costs**	**Total**
Water Conveyance[b]	$12,691	$2,936	$15,627
Habitat Restoration[c]	$3,108–$4,009	$346–$437	$3,454–$4,446
Other Stressors[c]	$12–$15	$1,213–$1,679	$1,225–$1,694
Program Oversight[c]		$404–$548	$404–$548
Total	$15,811–$16,715	$4,899–$5,600	$20,710–$22,315

[a] Over 50-year permit period [b] Midpoint cost estimate [c] Range of low-high estimate given

DP-171

A Delta Finance Plan

The Council proposes to initiate development of a finance plan following adoption of the Delta Plan. This process will require the active participation of the Interagency Implementation Committee described in Chapter 2. Financing and funding mechanisms to be considered in developing the finance plan are included in Appendix N.

Guiding Principles

A finance plan to fund the Delta Plan should follow these principles:

- The finance plan should first consider currently available funds that can legally support expenditures for Delta-related projects. Spending priorities should be established that address near-term funding requirements as contained in this Delta Plan.
- Implementation of the Delta Plan will undoubtedly require an array of funding sources, including new funding sources and new statutory authority. Broad-based financing and diversity in funding sources will enhance revenue stability. Likewise, State and federal funds for activities that implement the Delta Plan must be reserved for public benefits not otherwise required for project mitigation or required by law for other purposes. Appendix N describes potential funding sources.
- The Delta Plan recommends many projects that have multiple benefits; this increases opportunities to blend fund sources and builds on the tradition of past investments in multipurpose water projects with diversified fund sources.
- A clear and analytically based methodology for assessing public benefits should be evaluated and implemented.
- Targeted finance plans should be developed for major Delta Plan plans and projects (ecosystem restoration, flood risk reduction, regional water supply investments, science, administration, and water conveyance). Beneficiaries and stressors should be identified in each of these areas, and user fees should be developed to match these stressors and beneficiaries with planned investments in each of these areas.
- Economic and financial analyses should be done as early as possible during the planning of large capital projects. This will assist agencies in the design of cost-effective projects and will help ensure that the projects are actually completed and implemented. Financial analyses should account for all of the costs of a project, both direct and indirect, including acquisition, planning, capital and interest, mitigation, science and monitoring, and operations and maintenance.

User Fees

- User fees, including beneficiary fees and stressor fees, are essential and should be established to support the coequal goals and the implementation of the Delta Plan.
- The "beneficiaries pay" principle is a common financing approach for water projects. The challenge is to determine the beneficiaries and design a cost-allocation method scaled to the benefit.
- A companion principle to "beneficiaries pay" is "stressors pay." Human activity that causes negative operational or environmental impacts should be assessed a fee, or otherwise charged, to repair the damage. An example of the stressors pay approach might be a surcharge on pesticides that are found to negatively impact the Delta ecosystem. Capital construction projects, whether for water reliability purposes or Delta ecosystem improvements, should be undertaken simultaneously with the development of beneficiary and user fees. Delay in establishing beneficiaries/stressors fee structures will inevitably delay any needed capital improvement projects. The development of information related to financing (such as the identification of beneficiaries and stressors, and detailed financing scenarios) should be undertaken simultaneously with the development of major capital decisions so that it can inform planning efforts.

- The finance plan should include mechanisms to ensure that user fees are legally dedicated to their intended purpose. Given State and federal budget constraints, statutory protections must be enacted to assure users that their assessments will not be diverted to other purposes.
- The finance plan should include opportunities to generate revenue when planning projects, where possible, to ensure long-term financing stability.
- To the extent possible, user fees should be based on the amount of water used or, for stressors, the volume of contaminants discharged. Tiered fee structures also should be explored where applicable.
- Long-term, stable funding approaches, such as the Delta Flood Risk Management Assessment District recommended in Chapter 7 or other beneficiary user fees, should be established to support the Delta Levees Maintenance Subventions Program, Delta Levees Special Flood Control Projects Program, and implementation of the Central Valley Flood Protection Plan.

Near-term and Annual Funding Requirements

The following items describe activities that must be addressed and funded as soon as possible. They describe the urgent need to immediately address the steps needed to achieve the coequal goals, begin implementation of the Delta Plan, and establish annual funding for key Delta agencies:

- **Urgent expenditures for water supply reliability and ecosystem protection.** Immediate steps should be taken to protect the existing Delta water export system from flood risks and carry out ecosystem improvements being implemented pursuant to existing mitigation commitments of the SWP and the Central Valley Project. Those immediate needs are discussed in the various chapters of the Delta Plan.
- **Create a regional Delta Flood Risk Management Assessment District.** The Legislature should create a regional district with the authority to assess fees on Delta levee beneficiaries, including landowners, infrastructure owners, and other entities, to fund flood control protection, including levee maintenance and improvement, and emergency response, as recommended in Chapter 7.
- **Fund a strong Delta Science Program.** Funding is needed for continued operation of the Independent Science Board, development of the proposed Delta Science Plan, the State's share of the Interagency Ecological Program, and other activities that support a strong science foundation for Delta Plan implementation. Funding for the Interagency Ecological Program should continue from participating agencies.
- **Fund urban and agricultural water management plans.**
- **Continue the existing operational duties imposed by the Delta Reform Act.** The Act created the Council (which includes the Delta Science Program and Independent Science Board) and the Sacramento-San Joaquin Delta Conservancy, and modified the duties of the Delta Protection Commission. Future estimated annual operating costs for these agencies are provided in Appendix M.
- **Fees for services.** The Legislature should grant authority to the Council to assess fees to cover the costs of providing specified services related to covered actions, specifically early consultations and reviewing appeals of consistency certifications.

POLICIES AND RECOMMENDATIONS

Administrative performance measures for the following recommendations can be found in Appendix E.

FP R1 Conduct Current Spending Inventory

An inventory of current State and federal spending on programs and projects that do or may achieve the coequal goals will be conducted. Data sources to be used include the CALFED cross-cut budget, State bond balance reports, and the annual State budget, among others. Consideration will be given to selecting an independent agency (which could include a nongovernmental organization) to conduct the inventory.

FP R2 Develop Delta Plan Cost Assessment

Costs will be assigned to the projects and programs proposed in the Delta Plan (Chapters 2 through 7), and sources of funding will be identified.

FP R3 Identify Funding Gaps

Current State and federal funding gaps will be identified that are determined to hinder progress toward meeting the coequal goals.

Timeline for Implementing Recommendations

Figure 8-1 lays out a timeline for implementing the recommendations described in the previous section.

Timeline for Implementing Recommendations

TIMELINE **CHAPTER 8: Funding Principles to Support the Coequal Goals**

	ACTION (REFERENCE #)	LEAD AGENCY	NEAR TERM 2012–2017	INTERMEDIATE TERM 2017–2025
RECOMMENDATIONS	Conduct current spending inventory (FP R1)	Council	●	
	Develop Delta Plan cost assessment (FP R2)	Council	●	
	Identify funding gaps (FP R3)	Council	●

Glossary

The first section of this glossary provides definitions that appear in 23 California Code of Regulations section 5001. The second section provides definitions and explanations of key terms, acronyms, and abbreviations used in the Delta Plan.

Definitions in 23 California Code of Regulations Section 5001

As used in this division, the terms listed below shall have the meanings noted:

(a) *"Adaptive management" means a framework and flexible decision-making process for ongoing knowledge acquisition, monitoring, and evaluation leading to continuous improvement in management planning and implementation of a project to achieve specified objectives.*

(b) *"Agricultural water management plan" means a plan prepared, adopted, and updated by an agricultural water supplier pursuant to the Agricultural Water Management Planning Act, Water Code section 10800 et seq.*

(c) *"Agricultural water supplier" under the Water Code refers to both agricultural retail water suppliers and agricultural wholesale water suppliers, but not the California Department of Water Resources or the United States Bureau of Reclamation, and includes both of the following:*

> (1) *A water supplier, either publicly or privately owned, providing water to 10,000 or more irrigated acres, excluding recycled water; and*
>
> (2) *A water supplier or contractor for water, regardless of the basis of the water right, that distributes or sells water for ultimate resale to customers.*

(d) *"Base Flood" means the flood that has a 1-percent probability of being equaled or exceeded in any given year (also referred to as the 100-year flood).*

(e) *"Base Flood Elevation" (BFE) means the water surface elevation associated with the base flood.*

(f) *"Best available science" means the best scientific information and data for informing management and policy decisions. Best available science shall be consistent with the guidelines and criteria found in Appendix 1A.*

(g) *"Central Valley Flood Protection Board" or "Board" means the Central Valley Flood Protection Board (formerly The Reclamation Board) of the Resources Agency of the State of California as provided in Water Code section 8521.*

(h) *"Coequal goals" means the two goals of providing a more reliable water supply for California and protecting, restoring, and enhancing the Delta ecosystem. The coequal goals shall be achieved in a manner that protects and enhances the unique cultural, recreational, natural resource, and agricultural values of the Delta as an evolving place. In addition, "achievement" for the purpose of determining whether a plan, program, or project meets the definition of a ''covered action'' under section 5001(j) is further defined as follows:*

> (1) *"Achieving the coequal goal of providing a more reliable water supply for California" means all of the following:*
>
> > (A) *Better matching the state's demands for reasonable and beneficial uses of water to the available water supply. This will be done by promoting, improving, investing in, and implementing projects and programs that improve the resiliency of the state's water systems, increase water efficiency and conservation, increase water recycling and use of advanced water technologies, improve groundwater management, expand storage, and improve Delta conveyance and operations. The evaluation of progress toward improving reliability will take into account the inherent variability in water demands and supplies across California;*

(B) Regions that use water from the Delta watershed will reduce their reliance on this water for reasonable and beneficial uses, and improve regional self-reliance, consistent with existing water rights and the State's area-of-origin statutes and Reasonable Use and Public Trust Doctrines. This will be done by improving, investing in, and implementing local and regional projects and programs that increase water conservation and efficiency, increase water recycling and use of advanced water technologies, expand storage, improve groundwater management, and enhance regional coordination of local and regional water supply development efforts; and

(C) Water exported from the Delta will more closely match water supplies available to be exported, based on water year type and consistent with the coequal goal of protecting, restoring, and enhancing the Delta ecosystem. This will be done by improving conveyance in the Delta and expanding groundwater and surface storage both north and south of the Delta to optimize diversions in wet years when more water is available and conflicts with the ecosystem are less likely, and limit diversions in dry years when conflicts with the ecosystem are more likely. Delta water that is stored in wet years will be available for water users during dry years, when the limited amount of available water must remain in the Delta, making water deliveries more predictable and reliable. In addition, these improvements will decrease the vulnerability of Delta water supplies to disruption by natural disasters, such as, earthquakes, floods, and levee failures.

(2) "Achieving the coequal goal of protecting, restoring, and enhancing the Delta ecosystem" means successfully establishing a resilient, functioning estuary and surrounding terrestrial landscape capable of supporting viable populations of native resident and migratory species with diverse and biologically appropriate habitats, functional corridors, and ecosystem processes.

(3) "Achieving the coequal goals in a manner that protects and enhances the unique cultural, recreational, natural resource, and agricultural values of the Delta as an evolving place" means accepting that change, including change associated with achieving the coequal goals, will not cease, but that the fundamental characteristics and values that contribute to the Delta's special qualities and that distinguish it from other places can be preserved and enhanced while accommodating these changes. In this regard, the following are core strategies for protecting and enhancing the unique values that distinguish the Delta and make it a special region:

(A) Designate the Delta as a special place worthy of national and state attention;

(B) Plan to protect the Delta's lands and communities;

(C) Maintain Delta agriculture as a primary land use, a food source, a key economic sector, and a way of life;

(D) Encourage recreation and tourism that allow visitors to enjoy and appreciate the Delta and that contribute to its economy;

(E) Sustain a vital Delta economy that includes a mix of agriculture, tourism, recreation, related industries and business, and vital components of state and regional infrastructure; and

(F) Reduce flood and other risks to people, property, and other interests in the Delta.

(i) "Commercial recreational visitor-serving uses" means a land use designation that describes visitor-serving uses, accommodations, restaurants, and shops, that respect the rural character and natural environmental setting. These uses also include campgrounds and commercial recreational facilities.

(j)(1) "Covered action" means a plan, program, or project that meets all of the following criteria (which are collectively referred to as covered action screening criteria):

(A) Is a "project," as defined pursuant to section 21065 of the Public Resources Code;

(B) Will occur, in whole or in part, within the boundaries of the Delta or Suisun Marsh;

(C) Will be carried out, approved, or funded by the State or a local public agency;

(D) Will have a significant impact on achievement of one or both of the coequal goals or the implementation of government-sponsored flood control programs to reduce risks to people, property, and State interests in the Delta; and

(E) Is covered by one or more provisions of the Delta Plan, which for these purposes, means one or more of the regulatory policies contained in Article 3.

(2) "Covered action" does not include any plan, program, or project that is exempted pursuant to Water Code section 85057.5(b).

(3) A State or local public agency that proposes to carry out, approve, or fund a plan, program, or project that may be subject to this Chapter must determine whether that proposed plan, program, or project is a covered action. That determination, which is subject to judicial review, must be reasonable, made in good faith, and consistent with the Delta Reform Act and this Chapter.

(4) Nothing in the application of the definition of a "covered action" shall be interpreted to authorize the abrogation of any vested right whether created by statute or by common law.

(k) "Delta" means the Sacramento-San Joaquin Delta as defined in section 12220 of the Water Code and the Suisun Marsh, as defined in section 29101 of the Public Resources Code.

(l) "Delta Plan" means the comprehensive, long-term management plan for the Delta to further the achievement of the coequal goals, as adopted by the Delta Stewardship Council in accordance with the Sacramento-San Joaquin Delta Reform Act of 2009.

(m) "Designated Floodway" means those floodways, as defined in California Code of Regulations, Title 23, section 4(i), under the jurisdiction of the Central Valley Flood Protection Board.

(n) "Encroachment" means any obstruction or physical intrusion by construction of works or devices, planting or removal of vegetation, or by any means for any purpose, into or otherwise affecting a floodway or floodplain.

(o) "Enhancement" or "enhancing," for purposes of section 5001(h)(2), means improving existing desirable habitat and natural processes. Enhancement may include, by way of example, flooding the Yolo Bypass more often to support native species or to expand or better connect existing habitat areas. Enhancement includes many fish and wildlife management practices, such as managing wetlands for waterfowl production or shorebird habitat, installing fish screens to reduce entrainment of fish at water diversions, or removing barriers that block migration of fish to upstream spawning habitats.

(p) "Feasible" means capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, legal, social, and technological factors.

(q) "Floodplain" means any land area susceptible to being inundated by flood waters from any source.

(r) "Floodplain values and functions" has the same meaning as set forth in 33 Code of Federal Regulations section 320.4(l)(1).

(s) "Floodproofing" means any combination of structural and nonstructural additions, changes, or adjustments appropriate for residential structures, which reduce or eliminate risk of flood damage to real estate, improved real property, or structures with their contents.

(t) "Floodway" means the portion of the floodplain that is effective in carrying flow (that is, the channel of a river or other watercourse and the adjacent land areas that convey flood waters).

(u) "Government-sponsored flood control program to reduce risks to people, property, and State interests in the Delta" means any State or federal strategy, project, approval, funding, or other effort that is intended to reduce the likelihood and/or consequences of flooding of real property and/or improvements, including risks to people, property, and State interests in the Delta, that is carried out pursuant to applicable law, including, but not limited to the following:

(1) State Water Resources Law of 1945, Water Code section 12570 et seq.;

(2) Sacramento-San Joaquin River Flood Control Projects (Flood Control Act of 1941, P.L. 77-228);

(3) Local Plans of Flood Protection prepared pursuant to the Local Flood Protection Planning Act (Water Code section 8200 et seq.), that are consistent with the Central Valley Flood Protection Plan pursuant to Water Code section 9612;

(4) Central Valley Flood Protection Plan (Water Code section 9600 et seq.);

(5) Subventions Program, Special Projects Program (Water Code section 12300 et seq.);

(6) Way Bill 1973-Subventions Program, Special Projects Program (Water Code section 12980 et seq.);

(7) Central Valley Flood Protection Board Authority (California Code of Regulations, Title 23, Division 1); and

(8) National Flood Insurance Program (National Flood Insurance Act of 1968, 42 U.S.C. 4001 et seq., P.L. 90-448).

(v) "Nonnative invasive species," for purposes of section 5009, means species that establish and reproduce rapidly outside of their native range and may threaten the diversity or abundance of native species through competition for resources, predation, parasitism, hybridization with native populations, introduction of pathogens, or physical or chemical alteration of the invaded habitat.

(w) "Nonproject levee" means a local levee owned or maintained by a local agency or private owner that is not a project facility under the State Water Resources Law of 1945, Chapter 1 (commencing with Water Code section 12570) and Chapter 2 (commencing with section 12639 of Part 6 of the Water Code).

(x) "Project levee" means a federal flood control levee that is a project facility under the State Water Resources Law of 1945, Chapter 1 (commencing with Water Code section 12570) and Chapter 2 (commencing with section 12639 of Part 6 of the Water Code).

(y) "Proposed action" means a plan, program, or project that meets the covered action screening criteria listed in section 5001(j)(1)(A) through (D). Proposed action is also a "covered action," and therefore subject to compliance with the regulatory policies contained in Articles 2 and 3—if the proposed action meets the covered action screening criterion listed in section 5001(j)(1)(E).

(z) "Protection" or "protecting," for purposes of section 5001(h)(2), means preventing harm to the ecosystem, which could include preventing the conversion of existing habitat, the degradation of water quality, irretrievable conversion of lands suitable for restoration, or the spread of invasive nonnative species.

(aa) "Regulated stream" means those streams identified in Table 8.1 of California Code of Regulations, Title 23, section 112, under the jurisdiction of the Board.

(bb) "Restoration" or "restoring," for purposes of section 5001(h)(2), has the same meaning as in Water Code section 85066. Restoration actions may include restoring interconnected habitats within the Delta and its watershed, restoring more natural Delta flows, or improving ecosystem water quality.

(cc) "Setback levee" means a new levee constructed behind an existing levee which allows for removal of a portion of the existing levee and creation of additional floodplain connected to the stream. In the Delta, a "setback levee" may not necessarily result in removal of the existing levee.

(dd) "Significant impact" for the purpose of determining whether a project meets the definition of a "covered action" under section 5001(j)(1)(D) means a substantial positive or negative impact on the achievement of one or both of the coequal goals or the implementation of a government-sponsored flood control program to reduce risks to people, property, and State interests in the Delta, that is directly or indirectly caused by a project on its own or when the project's incremental effect is considered together with the impacts of other closely related past, present, or reasonably foreseeable future projects. The following categories of projects will not have a significant impact for this purpose:

(1) "Ministerial" projects exempted from CEQA, pursuant to Public Resources Code section 21080(b)(1);

(2) "Emergency" projects exempted from CEQA, pursuant to Public Resources Code section 21080(b)(2) through (4);

(3) Temporary water transfers of up to one year in duration. This provision shall remain in effect only through December 31, 2016, and as of January 1, 2017, is repealed, unless the Council acts to extend the provision prior to that date. The Council contemplates that any extension would be based upon the California Department of Water Resources' and the State Water Resources Control Board's participation with stakeholders to recommend measures to reduce procedural and administrative impediments to water transfers and protect water rights and environmental resources by December 31, 2016. These recommendations should include measures to address potential issues with recurring transfers of up to 1 year in duration and improved public notification for proposed water transfers;

(4) Other projects exempted from CEQA, unless there are unusual circumstances indicating a reasonable possibility that the project will have a significant impact under Water Code section 85057.5(a)(4), as further defined by this section. Examples of unusual circumstances could arise in connection with, among other things:

(A) Local government general plan amendments for the purpose of achieving consistency with the Delta Protection Commission's Land Use and Resource Management Plan; and,

(B) Small-scale habitat restoration projects, as referred to in CEQA Guidelines, section 15333 of Title 14 of the California Code of Regulations, proposed in important restoration areas, but which are inconsistent with the Delta Plan's policy related to appropriate habitat restoration for a given land elevation (section 5006 of this Chapter).

(ee) "Urban area" means a developed area in which there are 10,000 residents or more.

(ff) "Urbanizing area" means a developed area or an area outside of a developed area that is planned or anticipated to have 10,000 residents or more within the next 10 years.

(gg) "Urban water management plan" means a plan prepared, adopted, and updated by an urban water supplier pursuant to the Urban Water Management Planning Act, Water Code section 10610 et seq.

(hh) "Urban water supplier" refers to both "urban retail water suppliers" and "urban wholesale water suppliers":

(1) "Urban retail water supplier" means a water supplier, either publicly or privately owned, that directly provides potable municipal water to more than 3,000 end users or that supplies more than 3,000 acre-feet of potable water annually at retail for municipal purposes.

(2) "Urban wholesale water supplier" means a water supplier, either publicly or privately owned, that provides more than 3,000 acre-feet of potable water annually at wholesale for municipal purposes.

(ii) "Water supplier" refers to both "urban water suppliers" and "agricultural water suppliers," but for purposes of section 5003, does not include agricultural water suppliers during the time that they may be exempted by section 10853 of the Water Code from the requirements of Parts 2.55 and 2.8 of Division 6 of the Water Code.

23 CCR Section 5001
NOTE: Authority cited: Section 85210(i), Water Code.
Reference: Sections 85057.5, 85059, 85058, 85066, 85020, 85054, 85052, 85302(g), 85308, 85300, 10608.12, and 10853, Water Code.

Key Terms, Acronyms, and Abbreviations Used in the Delta Plan

Term	Definition
100-year flood	A flood event having a 1-in-100 chance of being equaled or exceeded in any given year.
200-year flood	A flood event having a 1-in-200 chance of being equaled or exceeded in any given year.
AB	Assembly Bill
acre-foot	The volume of water that would cover 1 acre of land to a depth of 1 foot; equal to 43,560 cubic feet or 325,851 gallons.
accommodation space	The space in the Delta that lies below sea level and is filled with neither sediment nor water.
Act	See Sacramento-San Joaquin Delta Reform Act of 2009
ACWA	Association of California Water Agencies
administrative procedure	Procedures adopted by the Delta Stewardship Council (Council), in accordance with Water Code section 85225.30, that govern how the Council considers appeals with respect to the following: (1) Adequacy of certifications of consistency with the Delta Plan submitted to the Council by a State or local agency pursuant to Water Code section 85225.10, and (2) Determinations by the California Department of Fish and Wildlife that the Bay Delta Conservation Plan has met the requirements of Water Code section 85320 for inclusion in the Delta Plan.
advanced treatment	Any treatment of sewage that goes beyond the secondary or biological water treatment stage and includes the removal of nutrients, including phosphorus, nitrogen, and a high percentage of suspended solids.
Aeration Facility	Demonstration Dissolved Oxygen Aeration Facility
agricultural water use	Water used for farming, horticulture, or ranching including irrigation, stock watering, or support of vegetation for range grazing. This includes water used for irrigation and nonirrigation purposes. Irrigation water use includes the artificial application of water on land to promote the growth of crops and pasture, or to maintain vegetative growth in recreational lands, parks, and golf courses. Nonirrigation water use includes water used for livestock, which includes water for stock watering, feedlots, and dairy operations, and fish farming and other farm requirements.
agricultural water use efficiency	Defined by California Department of Water Resources as the ratio of applied water to the amount of water required to sustain agricultural productivity. Efficiency is increased through the application of less water to achieve the same beneficial productivity or by achieving more productivity while applying the same amount of water.
AGWA	Association of Groundwater Agencies
anadromous fish	Fish that are born in fresh water, migrate to the ocean to mature, and then return to fresh water to spawn.

Term	Definition
anticipated future stressors	Stressors that require preparation and planning for mitigation in advance of their onset (for example, future land subsidence, urban expansion, and new invasions by nonnative species).
artesian water	A groundwater aquifer under positive pressure. In some cases, the hydrostatic equilibrium elevation of the groundwater is higher than the elevation of the surrounding ground surface. When an artesian aquifer is penetrated by a well, the water level will rise above the top of the aquifer, and even flow out of the ground.
AWWA	American Water Works Association
BAFF	bio-acoustic fish fence
base camp	A park, resort, or town that provides services (for example, park rangers, interpretation, and boat rentals) and facilities (for example, parking, restrooms, picnic sites, boat ramps, and campgrounds). The mix of facilities is determined by adjacent recreation opportunities and nearby public and private facilities.
basin plan	A water quality control plan for a specific basin or region in California. It includes a comprehensive program of actions designed to preserve, enhance, and restore water quality in that basin. The basin plan is the master water quality control planning document for the regional boards. It describes beneficial uses of surface water and groundwater, and establishes water quality objectives to protect those uses.
Bay Plan	San Francisco Bay Plan
Bay-Delta Plan	Bay-Delta Water Quality Control Plan
BCDC	San Francisco Bay Conservation and Development Commission
BDCP	Bay Delta Conservation Plan
beneficial uses	Uses of the waters of the state that include domestic, municipal, agricultural, and industrial supply; power generation; recreation; aesthetic enjoyment; navigation; and preservation and enhancement of fish, wildlife, and other aquatic resources or preserves.
beneficiaries	Entities that benefit from using the resources of the Delta, including water supply, conveyance, and recreation.
benthic	The collection of organisms living on or in sea, lake, or river bottoms.
best management practices (BMPs)	Methods or techniques found to be the most effective and practical means of achieving an objective, such as water conservations. BMPs include, but are not limited to, structural and nonstructural controls, and operation and maintenance procedures. Examples of water conservation BMPs include tiered rate structures and water-efficient plumbing and irrigation systems.
bioaccumulation	The process by which a chemical is taken up by an aquatic organism, both from direct exposure to water and through the consumption of food containing the chemical.
biological opinion	A document stating the opinion of the U.S. Fish and Wildlife Service or the National Marine Fisheries Service as to whether or not federal action is likely to jeopardize the continued existence of a threatened or endangered species, or result in the destruction or adverse modification of critical habitat.

Term	Definition
biomagnify, biomagnification	The sequence of processes in an ecosystem by which higher concentrations of a particular chemical, a pesticide for example, are reached in organisms higher up the food chain, generally through a series of prey-predator relationships.
BMP	See best management practices
bypass	An area of land or a large, constructed structure designed to convey excess floodwaters from a river or stream in order to reduce the risk of flooding on the natural river or stream near a city or other population center.
Cal EMA	California Emergency Management Agency
Caltrans	California Department of Transportation
CARB	California Air Resources Board
carbon sequestration	The process of removing carbon from the atmosphere and storing it. Trees and plants, for example, absorb carbon dioxide, release the oxygen, and store the carbon in their biomass. The stored biomass may eventually turn to peat, other soil-borne organic matter, and fossil fuels such as coal or petroleum that will continue to store the carbon until the fuels are burned.
CASGEM	California Statewide Groundwater Elevation Monitoring Program
CCR	*California Code of Regulations*
CDFA	California Department of Food and Agriculture
centrarchids	Small, carnivorous, freshwater, spiny-finned fishes of North America usually having a laterally compressed body and metallic luster (for example, largemouth bass, smallmouth bass, spotted bass, bluegill, warmouth, redear sunfish, green sunfish, white crappie, and black crappie).
certification of consistency	The written certification to the Delta Stewardship Council, with detailed findings, that a covered action is consistent with the Delta Plan. Certifications of consistency are submitted to the Delta Stewardship Council by the State or local agency that is proposing to carry out, fund, or approve a covered action under the California Environmental Quality Act (Water Code section 85225 et seq.).
CEQA	California Environmental Quality Act
cfs	cubic feet per second
channelization	(1) Natural or intentional straightening and deepening of streams through dredging or construction of levees. (2) A marsh-drainage tactic that can disturb fish and wildlife habitats, aggravate flooding, and decrease the capacity to absorb pollution without suffering damage.
climate change	Any significant change in measures of climate (such as temperature, precipitation, or wind) lasting for an extended period (decades or longer). Climate change may result from (1) natural factors, including changes in the sun's intensity or changes in the Earth's orbit around the sun, (2) natural processes within the climate system (such as changes in ocean circulation), or (3) human activities that change the composition of the atmosphere (for example, through burning fossil fuels) and land surfaces (for example, deforestation, reforestation, urbanization, and desertification).

Term	Definition
CNDDB	California Natural Diversity Database
CNPS	California Native Plant Society
CNRA	California Natural Resources Agency
CO_2	carbon dioxide
COA	Coordinated Operating Agreement
conceptual model	An explicit description of mental models, knowledge, and hypotheses about the structure and function of a system or process.
conjunctive management	The coordinated and planned management of both surface water and groundwater resources to maximize efficient water use. Water is stored in groundwater basins for future use by intentionally recharging the basin during years of above-average surface water supply. Surface water and groundwater resources typically differ significantly in their availability, quality, management requirements, and development and use costs. Managing both resources together, rather than in isolation from one another, allows water managers to use the advantages of both resources for maximum benefit.
conveyance	The movement of water from one place to another. Conveyance infrastructure includes natural watercourses as well as canals, pipelines, and control structures including weirs. Examples of natural watercourses include streams, rivers, and groundwater aquifers. Conveyance facilities range in size from small, local, end-user distribution systems to large systems that deliver water to or drain areas covering multiple hydrologic regions. Conveyance facilities require associated infrastructure including pumping plants, power supply, diversion structures, fish ladders, and fish screens.
Council	Delta Stewardship Council
critical habitat	Specific areas, both occupied and unoccupied, that are essential to the conservation of a listed species and that may require special management considerations or protection (as defined in Section 3 of the federal Endangered Species Act).
current stressors	Stressors that result from ongoing human activities that can, in some cases, be eliminated (for example, fish entrainment at water diversions).
CVFPB	Central Valley Flood Protection Board
CVFPP	Central Valley Flood Protection Plan
CVP	Central Valley Project
CVPIA	Central Valley Project Improvement Act
CV-SALTS	Central Valley Salinity Alternatives for Long-Term Sustainability Program
CWA	Clean Water Act
CZMA	Coastal Zone Management Act of 1972
DBW	California Department of Boating and Waterways
DDT	dichlorodiphenyltrichloroethane

Term	Definition
dedicated (or developed) water	Defined by California Department of Water Resources (DWR) as water distributed among urban and agricultural uses, used for protecting and restoring the environment, or storage in surface water and groundwater reservoirs. In any year, some of the dedicated supply includes water that is used multiple times (reuse) and water that is held in storage from previous years. DWR identifies California's average annual dedicated water supply as 85 million acre-feet. *See also: total water use.*
Delta	Sacramento-San Joaquin Delta
Delta Conservancy	Sacramento–San Joaquin Delta Conservancy
Delta Ecological Management Zone	The Delta conservation strategy adopted by the Department of Fish and Wildlife as the *Ecosystem Restoration Program Conservation Strategy for Restoration of the Sacramento-San Joaquin Delta Ecological Management Zone and the Sacramento and San Joaquin Valley Regions.*
Delta exports	Describes, in general terms, any water diverted from the Delta for use outside the Delta, including water pumped by the State Water Project and Central Valley Project pumping plants, Contra Costa Water District, and other agencies. The term must be precisely defined when applied to specific studies or analyses.
Delta Flood Risk Management Assessment District	As proposed in the Delta Plan, an assessment district authorized to set fees on State and local infrastructure to generate funds for levee maintenance and surveys; adequate flood control protection; and emergency response for the benefit of landowners, infrastructure owners, and other entities that benefit from the maintenance and improvement of Delta levees, including water users who rely on the levees to protect water quality.
Delta Independent Science Board (Delta ISB)	Established by the Sacramento-San Joaquin Delta Reform Act of 2009, the Delta ISB is a standing board of nationally and internationally prominent scientists with appropriate expertise to evaluate the broad range of scientific programs that support adaptive management of the Delta. The Delta ISB will provide oversight of the scientific research, and monitoring and assessment programs that support adaptive management of the Delta through periodic reviews of each of those programs. The overall objective of Delta ISB oversight is to help make the science underlying Bay-Delta programs, the application of that science, and the technical aspects of those programs the best they can be (Water Code section 85280 et seq.).
Delta ISB	See Delta Independent Science Board
Delta Levee Special Flood Control Projects	A California Department of Water Resources program, authorized in Water Code sections 12300 through 12314, that provides financial assistance to local levee-maintaining agencies for rehabilitating levees in the Delta.
Delta Multi-Hazard Coordination Task Force	A task force established to address emergency preparedness and response issues in the Delta by enabling the development and implementation of multi-hazard preparedness and response strategies for the Delta. Led by the California Emergency Management Agency (Cal EMA), the task force consisted of representatives from the Delta Protection Commission, California Department of Water Resources, and representatives of the five Delta counties. The passage of Senate Bill 27 in 2008 required Cal EMA, formerly the Office of Emergency Services, to establish the task force.

Term	Definition
Delta Primary Zone	The Sacramento-San Joaquin River Delta land and water area of primary State concern and statewide significance that does not encompass either the urban limit line or sphere of influence line of any local government general plan or study existing as of January 1, 1992. The precise boundary lines of the Primary Zone include the land and water areas as shown on the map titled "Delta Protection Zones" on file with the California State Lands Commission. Where the boundary between the Primary Zone and Secondary Zone is a river, stream, channel, or waterway, the boundary line is the middle of that river, stream, channel, or waterway. The Primary Zone consists of approximately 500,000 acres (Public Resources Code section 29728).
Delta Reform Act	See Sacramento-San Joaquin Delta Reform Act of 2009
Delta Secondary Zone	All the Delta land and water area within the boundaries of the Delta not included within the Primary Zone, subject to the land use authority of local government, and that includes the land and water areas as shown on the map titled "Delta Protection Zones" on file with the State Lands Commission. The Secondary Zone consists of approximately 238,000 acres (Public Resources Code section 29731).
Delta Vision	Delta Vision Blue Ribbon Task Force
Delta watershed	The watershed of the Sacramento River Hydrologic Region and the San Joaquin River Hydrologic Region as described in the California Water Plan Update 2005, Bulletin 160-05 (Water Code section 85060).
demand management measures	Water conservation measures, programs, and incentives that prevent the waste of water and promote the reasonable use and reuse of available supplies.
desalination	A water treatment process for the removal of salt from water for beneficial use. Source water can be brackish (low salinity) or sea water.
DFG	California Department of Fish and Game
DFW	California Department of Fish and Wildlife (formerly the California Department of Fish and Game)
diversion	A process which, having return flow and consumptive use elements, turns water from a given path. Removal of water from its natural channel for human use. Use of part of a streamflow as a water supply. Channel constructed across the slope for the purpose of intercepting surface runoff, changing the accustomed course of all or part of a stream. A structural conveyance (or ditch) constructed across a slope to intercept runoff flowing down a hillside and divert it to some convenient discharge point.
DO	dissolved oxygen
DOC	California Department of Conservation
DPC	Delta Protection Commission
DPH	California Department of Public Health
DRERIP	Delta Regional Ecosystem Restoration Implementation Plan
drinking water quality	Drinking water quality standards are adopted by the California Department of Public Health (DPH) Drinking Water Program pursuant to the California Safe Drinking Water Act. The standards apply to public drinking water systems and to water delivered to customers, and are enforceable by DPH and local health departments.

Term	Definition
drought	Hydrologic conditions during a defined period, greater than 1 dry year, when precipitation and runoff are much less than average.
DWR	California Department of Water Resources
DWR 200 Year	DWR 200-year Urban Levee Protection
EAD	See expected annual damage
ecosystem	A biotic community and its physical environment, considered as an integrated unit. Implied within this definition is the concept of a structural and functional whole unified through life processes. An ecosystem may be characterized as a viable unit of community and interactive habitat. Ecosystems are hierarchical and can be viewed as nested sets of open systems in which physical, chemical, and biological processes form interactive subsystems. Some ecosystems are microscopic, and the largest comprises the biosphere. Ecosystem restoration can be directed at different-sized ecosystems within the nested set, and many encompass multiple states, more localized watersheds, or a smaller complex of aquatic habitat.
ecosystem enhancement	The improvement of existing desirable habitat and natural processes. Enhancement might include flooding the Yolo Bypass more often, at times, to support native species, or expand or better connect existing habitat areas. Enhancement also includes many fish and wildlife management practices, including managing wetlands for waterfowl production or shorebird habitat, installing fish screens to reduce entrainment of fish at water diversions, or removing barriers that block migration of fish to upstream spawning habitats.
ecosystem protection	Preventing harm to an ecosystem, which could include preventing the conversion of existing habitat, the degradation of water quality, irretrievable conversion of lands suitable for restoration, or the spread of invasive nonnative species.
ecosystem restoration	The application of ecological principles to restore a degraded or fragmented ecosystem and return it to a condition in which its biological and structural components achieve a close approximation of its natural potential, taking into consideration the physical changes that have occurred in the past and the future impact of climate change and sea level rise (Water Code section 85066).
Ecosystem Restoration Program Conservation Strategy	Describes the Ecosystem Restoration Program (ERP) priorities and actions for Stage 2 of the CALFED Bay-Delta Program (summarized in Appendix B). It identifies biologically promising ecosystem restoration opportunities in the Sacramento-San Joaquin Delta Ecological Management Zone and the Sacramento Valley and San Joaquin Valley regions, and it provides the rationale for restoration actions specific to each of these regions. It further provides the conceptual framework and process to guide the refinement, evaluation, prioritization, implementation, monitoring, and review of ERP actions.
ecosystem water quality	The Delta ecosystem is affected by a variety of pollutants discharged into Delta and tributary waters. Pollutants of concern affecting Delta biological species and ecosystem processes include nutrients, pesticides, mercury, selenium, and other persistent bioaccumulative toxic substances. Newly identified pollutants of potential concern (often referred to as emerging contaminants) also should be investigated.
EIR	environmental impact report

Term	Definition
endangered species	As defined by the California Endangered Species Act, an endangered species is a native species or subspecies of a bird, mammal, fish, amphibian, reptile, or plant that is in serious danger of becoming extinct throughout all, or a significant portion, of its range due to one or more causes, including loss of habitat, change in habitat, overexploitation, predation, competition, or disease. Any species determined by the Fish and Game Commission as endangered on or before January 1, 1985, is an endangered species (Fish and Game Code section 2062).
entrainment	Defined by the National Marine Fisheries Service as "the incidental trapping of any life stage of fish within waterways or structures that carry water being diverted for anthropogenic use."
environmental water	Minimum flow levels of a specific quality that are needed in order to assure the continued viability of fish and wildlife resources for a particular water body. This water is used to maintain and enhance the beneficial uses related to the preservation and enhancement of fish, wildlife, and other aquatic resources or preserves as specified in the Porter-Cologne Water Quality Control Act.
environmental water use	Water dedicated to instream environmental needs.
EPRRP	Emergency Preparedness Response and Recovery Program
ERP	Ecosystem Restoration Program
ESA	Endangered Species Act
ESP	The Delta Protection Commission's *Economic Sustainability Plan for the Sacramento-San Joaquin Delta*
estuary	A place where fresh and salt water mix, such as a bay, salt marsh, or where a river enters an ocean.
expanded water supply reliability element	Additional information water suppliers should include in their water supply reliability element, starting in 2015, as part of the update of any urban water management plan, agricultural water management plan, integrated water management plan, or other plan that provides equivalent information on the supplier's planned investments in water conservation and water supply development. This expanded water supply reliability element must detail how water suppliers are improving regional self-reliance and reducing reliance on the Delta through investments in local and regional programs and projects, and must document actual and projected reductions in reliance on Delta exports. At a minimum, the water reliability element must include the following: (1) A plan for possible interruption of Delta water supply due to catastrophic events. (2) A plan for implementation of anticipated investments in water conservation, water efficiency, and water supply development. (3) Evaluation of regional water balance. (4) Conservation-oriented water rate structure.
expected annual damage (EAD)	A metric for analyzing flood risk that integrates the likelihood and consequences of flooding. Generally defined as the average annual flood damages (in dollars) weighted by the probability that a flood will occur in any given year. The U.S. Army Corps of Engineers describes EAD mathematically in *Manual No. 1110-2-1619, Risk-Based Analysis for Flood Damage Reduction Studies*, August 1, 1996.
FEMA	Federal Emergency Management Agency
FEMA 100 Year	FEMA 100-year (Base Flood) Protection

Term	Definition
flood risk	The likelihood and consequence of inundation by floodwaters. Consequences may include direct or indirect economic costs, loss of life, environmental impacts, or other specified measures of flood effect. Flood risk is a function of (1) loading, which is the frequency and magnitude of flood discharge or stage; (2) limits to exposure to the loading due to flood defense measures; and (3) consequence. Therefore, flood management actions may reduce risk by changing loading, exposure, or consequence. For clarity, flood risk is commonly quantified within an identified area for a specified climate condition, land use condition, and with a flood management system (existing or planned) in place.
flow criteria	The development of specific criteria by the State Water Resources Control Board for flows for the Delta ecosystem, including the volume, quality, and timing of water necessary for the Delta ecosystem under different conditions (Water Code section 85086(c)(1)).
flow objectives	Where protection of beneficial uses requires specific flow volumes at certain times, regional water quality control boards may establish flow objectives in water quality control plans. They differ from typical water quality objectives in that they are implemented by the State Water Resources Control Board through modifications and limitations of existing or future water rights to make sure these flows are met.
flow regime	The regulation of ecological processes in river ecosystems: the magnitude, frequency, duration, timing, and rate of change of hydrologic conditions (Poff and Ward 1989, Richter et al. 1996, Walker 1995). These components can be used to characterize the entire range of flows and specific hydrologic phenomena, including floods or low flows, that are critical to the integrity of river ecosystems. Furthermore, by defining flow regimes in these terms, the ecological consequences of particular human activities that modify one or more components of the flow regime can be considered explicitly.
flow requirements	The amount of water required for instream use by agreement, water rights permit, or State/federal law.
freeboard	The height of the physical top of a levee or floodwall above the median design water surface elevation.
gateway	A community, landmark, or signage on the edge of the Delta or Suisun Marsh that serves as a gateway providing information to visitors about recreation opportunities available in the area and equipping them with supplies.
general obligation bond	A bond issued by the State where the principal and interest is paid out of the General Fund. This is different than a revenue bond, where the principal and interest is paid out of a specific dedicated revenue source.
globally determined stressors	Stressors that result from large-scale human activities or natural processes that cannot be eliminated or mitigated within a limited purview and require larger-scale planning and adaptation (such as global climate change and human population growth).
GPCD	gallons per capita daily
groundwater basin	An alluvial aquifer or a stacked series of alluvial aquifers with reasonably well-defined boundaries in a lateral direction and having a definable bottom.
groundwater management plan	A comprehensive written document developed for the purpose of groundwater management and adopted by an agency having appropriate legal or statutory authority.

Term	Definition
groundwater overdraft	The condition of a groundwater basin in which the amount of water withdrawn by pumping exceeds the amount of water that recharges the basin over a period of years during which water supply conditions approximate average conditions.
groundwater remediation	The extraction of contaminated groundwater from an aquifer followed by treatment and (1) replacement in the aquifer or (2) use for agricultural or municipal purposes.
groundwater storage	Defined three ways depending on the context: (1) the quantity of water beneath the land surface that fills the pore spaces of the alluvium, soil, or rock formation; (2) the volume of usable physical space available to store water in the pore spaces of the alluvium, soil, or rock formation beneath the land surface; or (3) the act of storing water in the pore spaces of the alluvium, soil, or rock formation beneath the land surface.
HAB	harmful algal bloom
habitat	The location and the living and nonliving surroundings where a particular plant or animal lives. Habitat includes the presence of a group of particular environmental conditions surrounding an organism including air, water, soil, mineral elements, moisture, temperature, and topography.
Habitat Conservation Plan (HCP)	A plan prepared under the Endangered Species Act by nonfederal parties in order to obtain permits for incidental taking of threatened and endangered species. The HCP describes ways to maintain, enhance, and protect a given habitat type needed to protect species. The plan usually includes measures to minimize impacts, and might include provisions for permanently protecting land, restoring habitat, and relocating plants or animals to another area.
habitat restoration	The manipulation of the physical, chemical, or biological characteristics of a site with the goal of returning the majority of natural functions to the lost or degraded native habitat.
Hazard Mitigation Plan (HMP)	Refers to levee guidance negotiated between various federal, State, and local agencies to assist in reducing the likelihood of repetitive flood damage to Delta levees and islands. This guidance provides geometric levee design criteria that, if maintained, make a Delta levee-maintaining agency eligible for federal disaster assistance funds in the event of a flood emergency.
HCP	See Habitat Conservation Plan
HGMP	Hatchery and Genetic Management Plans
HMP	See Hazard Mitigation Plan
hydraulic mining	The use of high-pressure jets of water to dislodge rock material or move sediment.
hydrodynamics	The description of the change in flow or motion of a liquid.
hydrologic region	A geographical division of the state based on local hydrologic basins. The California Department of Water Resources divides California into 10 hydrologic regions, corresponding to the state’s major water drainage basins: North Coast, San Francisco Bay, Central Coast, South Coast, Sacramento River, San Joaquin River, Tulare Lake, North Lahontan, South Lahontan, and Colorado River.
IEP	Interagency Ecological Program
incidental take permit	A permit issued by federal fisheries agencies that authorizes take of listed species incidental to otherwise lawful projects.

Term	Definition
instream flow	The use of water within its natural watercourse as specified in a contract, a water rights permit, a court order, a Federal Energy Regulatory Commission license, or other documentation. Instream flows support natural ecosystems, create habitat for plants and animals, and may provide additional benefits including recreation. *See also: flow requirements*.
integrated regional water management	A collaborative effort to manage all aspects of water resources in a specified region. Integrated regional water management crosses jurisdictional, watershed, and political boundaries; involves multiple agencies, stakeholders, individuals, and groups; and attempts to address the issues and differing perspectives of all entities involved through mutually beneficial solutions.
integrated regional water management plan (IRWMP)	At a minimum, an integrated regional water management plan describes the major water-related objectives and conflicts within a region; considers a broad variety of water management strategies; identifies an appropriate mix of water demand and supply management alternatives; provides water quality protections and environmental stewardship actions to provide a long-term, reliable, and high-quality water supply; protects the environment; and identifies disadvantaged communities in the region taking into account the water-related requirements of those communities.
invasive species	An alien species whose introduction does or is likely to cause economic or environmental harm or harm to human health (Executive Order 13112, 1999).
land reclamation	The process to recover land through channelization and levee construction of what was previously marsh land.
IRWMP	See integrated regional water management plan.
LADWP	Los Angeles Department of Water and Power
LAEDC	Los Angeles Economic Development Corporation
LAO	California Legislative Analyst's Office
legacy community	A rural community registered as a Historic District by either a State or federal entity. Delta legacy communities include Bethel Island, Clarksburg, Courtland, Freeport, Hood, Isleton, Knightsen, Rio Vista, Ryde, Locke, and Walnut Grove (Public Resources Code section 32301(f)).
legacy stressors	Stressors that result from past actions that cannot be undone, but whose impact can sometimes be reduced or mitigated (for example, mercury pollution from historical gold mining).
Legislature	California Legislature
levee-maintaining agencies	Local special districts, typically reclamation districts, that are public agencies formed for the purpose of levee maintenance and improvement, among other duties, and are funded by local assessments.
levee standards	Standards designed to either establish minimum criteria that would make levees and the properties protected eligible for Federal Emergency Management Agency (FEMA) grants or U.S. Army Corps of Engineers (USACE) rehabilitation funds both in case of catastrophic emergency, or set minimum criteria that would allow development behind the levees. The four main applicable levee standards and guidance for the Delta are (1) FEMA Hazard Mitigation Plan Guidance, (2) USACE Public Law 84-99, (3) FEMA 100-year (Base Flood) Protection, and (4) DWR 200-year Urban Levee Protection.
LHC	Little Hoover Commission

Term	Definition
low salinity zone (LSZ)	Generally, the region in an estuary with salinity ranging from fresh water up to about 5 parts per thousand (ppt), about one-seventh the salinity of sea water. The part of the salinity gradient centered on 2 ppt is considered to be of particular importance because it is hypothesized to be an area where suspended particulate matter and organisms accumulate. The location in the Bay-Delta where the tidally averaged salinity at 1 meter from the bottom is 2 ppt is known as X2 (measured as distance in kilometers from the Golden Gate Bridge) and serves as a water quality objective regulating Delta outflow.
LPP	Suisun Marsh Local Protection Program
LSZ	See low salinity zone
LTMS	Delta Dredged Sediment Long-Term Management Strategy
µS/cm	microsiemens per centimeter
MAF	million acre-feet
managed wetland	Perched wetlands that receive human-induced seasonal flooding for marshland development.
MCL	maximum contaminant level
mg/L	milligram(s) per liter
MWD	Metropolitan Water District of Southern California
NAS	National Academy of Sciences
National Heritage Area (NHA)	Places designated by the United States Congress where natural, cultural, historic, and recreational resources combine to form a cohesive, nationally distinctive landscape arising from patterns of human activity shaped by geography. These areas tell important stories about the nation and are representative of the national experience through both the physical features that remain and the traditions that have evolved within them.
National Pollutant Discharge Elimination System (NPDES)	A permitting program required for all point sources discharging pollutants into waters of the United States. The purpose of the NPDES program is to protect human health and the environment (Clean Water Act of 1977, 33 United States Code section 1311).
Natural Community Conservation Plan (NCCP)	A conservation plan created to meet the requirements of the Natural Community Conservation Planning Act, which identifies and provides for the regional or areawide protection of plants, animals, and their habitats, while allowing compatible and appropriate economic activity. The primary objective of the NCCP program is to conserve natural communities at the ecosystem level while accommodating compatible land use (Fish and Game Code section 2800 et seq.).
NCCP	See Natural Community Conservation Plan
new water	Defined in part by California Department of Water Resources as water that is legally and empirically available for a beneficial use. New water can be developed through many strategies such as capturing surplus water, desalinating ocean water, and improving water efficiency.
NHA	See National Heritage Area
NMFS	National Marine Fisheries Service

Term	Definition
nonpoint source pollution	Diffused sources that do not have a single point of origin or are not introduced into a receiving stream from a specific outlet. The pollutants are generally carried off the land by stormwater runoff. Common categories of nonpoint sources are agriculture, forestry, mining, construction, land disposal, and salt intrusion.
NPDES	See National Pollutant Discharge Elimination System
NRC	National Research Council
NWR	National Wildlife Refuge
OP	organophosphorus
OPC	California Ocean Protection Council
Paterno v. State of California	In *Paterno v. State of California*, the appellate court found the State liable for flood-related damages caused by the failure of a Yuba River levee incorporated into the State system of flood control, even though the State did not design, build, or even directly maintain it (*Paterno v. State* [2003] 113 Cal. App.4th 998 [6 Cal.Rptr.3d 854]).
PCB	polychlorinated biphenyl
peak flow	Maximum instantaneous flow in a specified period.
pelagic fish	A fish species that spends most of its life swimming in the water column with little contact with or dependency on the bottom. Adult spawning usually occurs in open water, often near the surface.
pelagic organism decline (POD)	A steep decline leading to near-record low populations of four pelagic species in the San Francisco Estuary—delta smelt, young striped bass, longfin smelt, and threadfin shad—widely recognized as a serious issue by 2004.
performance measures	A quantitative or qualitative tool to assess progress toward an outcome or goal. The Delta Plan must include performance measurements that will enable the Delta Stewardship Council to track progress in meeting the objectives of the Plan. Performance measurements must include, but need not be limited to, quantitative or otherwise measurable assessments of the status and trends in all of the following: (1) The health of the Delta estuary and wetland ecosystem for supporting viable populations of aquatic and terrestrial species, habitats, and processes including viable populations of Delta fisheries and other aquatic organisms. (2) The reliability of California water supply imported from the Sacramento River or the San Joaquin River watershed.
PL 84-99	See Public Law 84-99
Plan	Delta Plan
POD	See pelagic organism decline

Term	Definition
point source	Any discernible, confined, and discrete conveyance including, but not limited to, any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, landfill leachate collection system, vessel, or other floating craft from which pollutants are or may be discharged. This term does not include return flows from irrigation agriculture or agricultural stormwater runoff (40 *Code of Federal Regulations* 122.2).
pollutant	Defined as "dredged spoil, solid waste, incinerator residue, filter backwash, sewage, garbage, sewage sludge, munitions, chemical wastes, biological materials, radioactive materials, heat, wrecked or discarded equipment, rock, sand, cellar dirt and industrial, municipal, and agricultural waste discharged into water" (Clean Water Act of 1977, 33 United States Code section 1362(6)).
pollution	Defined as the human-made or human-induced alteration of the chemical, physical, biological, and radiological integrity of water (Clean Water Act section 502(19); 33 United States Code section 1362(19)). Pollution is also defined in California law as an alternation of the quality of the waters of the state by waste to a degree that unreasonably affects either the waters for beneficial uses or the facilities that serve these beneficial uses (Water Code section 13050(k)(1)).
ppb	parts per billion
PPIC	Public Policy Institute of California
ppm	parts per million
ppt	parts per thousand
PRBO CalPIF	Point Reyes Bird Observatory California Partners in Flight
Public Law 84-99 (PL 84-99)	A federal levee standard developed by the U.S. Army Corps of Engineers (USACE). Meeting this standard allows the Delta island or tract to be eligible for USACE funding for levee rehabilitation, island restoration after levee failures, and island inundation, provided that the reclamation district applies for and is accepted into the USACE's Rehabilitation and Inspection Program.
Public Trust Doctrine	This doctrine protects the right of the public to use State sovereign lands and waters for commerce, navigation, hunting, fishing, bathing, swimming, boating, and general recreational purposes, and also protects trust lands and waters in their natural state, so that they may serve as ecological units for scientific study, as open space, and as environments that provide food and habitat for birds and marine life, and which favorably affect the scenery and climate of the area. There is also a separate branch of the Public Trust Doctrine that protects the fishery resources in all State waters, including those in nonnavigable waterways, as public trust resources in and of themselves.

Term	Definition
Reasonable and Beneficial Use Doctrine	This doctrine states that a water right does not include the right to waste water and mandates that the water resources of the state be put to beneficial use. "It is hereby declared that because of the conditions prevailing in this State the general welfare requires that the water resources of the State be put to beneficial use to the fullest extent of which they are capable, and that the waste or unreasonable use or unreasonable method of use of water be prevented, and that the conservation of such waters is to be exercised with a view to the reasonable and beneficial use thereof in the interest of the people and for the public welfare. The right to water or to the use or flow of water in or from any natural stream or water course in this State is and shall be limited to such water as shall be reasonably required for the beneficial use to be served, and such right does not and shall not extend to the waste or unreasonable use or unreasonable method of use or unreasonable method of diversion of water. Riparian rights in a stream or water course attach to, but to no more than so much of the flow thereof as may be required or used consistently with this section, for the purposes for which such lands are, or may be made adaptable, in view of such reasonable and beneficial uses; provided, however, that nothing herein contained shall be construed as depriving any riparian owner of the reasonable use of water of the stream to which the owner's land is riparian under reasonable methods of diversion and use, or as depriving any appropriator of water to which the appropriator is lawfully entitled. This section shall be self-executing, and the Legislature may also enact laws in the furtherance of the policy in this section contained" (California Constitution Article X section 2).
reasonable and prudent alternative	The regulations implementing Section 7 of the Endangered Species Act define reasonable and prudent alternatives as alternative actions, identified during formal consultation, that (1) can be implemented in a manner consistent with the intended purpose of the action, (2) can be implemented consistent with the scope of the action agency's legal authority, (3) are economically and technologically feasible, and (4) would, according to the National Marine Fisheries Service, avoid the likelihood of jeopardizing the continued existence of listed species and avert the destruction or adverse modification of critical habitat (Endangered Species Act of 1973, 16 United States Code section 1536).
Reclamation	Bureau of Reclamation
Recreation Proposal	*Recreation Proposal for the Sacramento-San Joaquin Delta and Suisun Marsh*
regional self-reliance	The degree to which a region implements water management options so that it can provide for all of its needs for water from within its own borders.
regional water supplies	Water supplies that are found or developed within a region to be used within its own borders.
reservoir reoperation	Changes to existing operations and management procedures for existing reservoirs and conveyance facilities to increase water-related benefits from these facilities.
resource management strategy	A project, program, or policy that helps federal, State, or local agencies manage water and related resources. Resource management strategies in the California Water Plan are grouped by intended outcomes: reduce water demand, improve operational efficiency and transfers, increase water supply, improve water quality, practice resource stewardship, and improve flood management. Although most of the resource management strategies have multiple potential benefits, any individual site-specific project or program within a resource management strategy may contribute only one, or a few, of the benefits.
riparian area	The land adjacent to a natural watercourse such as a river or a stream. Riparian areas support vegetation that provides important wildlife habitat and important fish habitat when shading the watercourse bank.

Term	Definition
RWCF	Stockton Regional Wastewater Control Facility
RWQCB	Regional Water Quality Control Board
SACOG	Sacramento Area Council of Governments
Sacramento-San Joaquin Delta Reform Act of 2009 (Delta Reform Act or Act)	Included in Senate Bill X71, established a new governance approach for the Sacramento-San Joaquin Delta that is focused on achieving the coequal goals and is fundamentally different from past approaches. The Delta Reform Act created the Delta Stewardship Council and gave it the direction and authority to serve two primary governance roles: (1) set a comprehensive, legally enforceable direction for how the State manages important water and environmental resources in the Delta through the adoption of a Delta Plan, and (2) ensure coherent and integrated implementation of that direction through coordination and oversight of State and local agencies proposing to fund, carry out, and approve Delta-related activities.
Safe Harbor Agreement	A voluntary agreement made between wildlife agencies and landowners in order to recover a listed species.
SAV	submerged aquatic vegetation
SB	Senate Bill
SBX7 1	Senate Bill X7 1
SBX7 7	Senate Bill X7 7
SDWSC	Stockton Deep Water Ship Channel
sea level rise	A change in average global sea level caused by a change in ocean volume. Often discussed in relation to climate change.
seepage	Percolation of water through the soil from unlined canals, ditches, laterals, watercourses, or water storage facilities.
SEMS	See Standardized Emergency Management System
sensitive species	Species not yet officially listed but undergoing status review for listing on the U.S. Fish and Wildlife Service's official threatened and endangered list; species whose populations are small and widely dispersed or restricted to a few localities; and species whose numbers are declining so rapidly that official listing may be necessary.
SFD	San Felipe Division
SHP	State Historic Park
SMPP	BCDC's *Suisun Marsh Protection Plan*
SOI	sphere of influence

Term	Definition
special-status species	Any species that is listed, or proposed for listing, as threatened or endangered by the U.S. Fish and Wildlife Service or National Marine Fisheries Service under the provisions of the Endangered Species Act; any species designated by the U.S. Fish and Wildlife Service as a "listed," "candidate," "sensitive," or "species of concern"; and any species listed by the State in a category implying potential danger of extinction.
SP	State Park
SPFC	State Plan of Flood Control
SRA	State Recreation Area
Standardized Emergency Management System (SEMS)	Established throughout California to manage and coordinate any emergency response involving more than one agency or jurisdiction. It is the cornerstone of the emergency response system and the fundamental structure for the response phase of emergency management. SEMS is authorized under the California Emergency Services Act for managing multiagency and multijurisdictional responses to emergencies in California.
State	State of California
stormwater capture system	A facility operated by a public agency and designed to capture and retain stormwater flowing upon the public right-of-way, or through a public stormwater management system or a public stormwater drainage system, for subsequent use.
stressors (ecosystem)	Actions or factors, whether human or natural, that cause negative impacts on desirable ecosystem elements, processes, and functions. *See also: globally determined stressor, legacy stressors, current stressors, and anticipated future stressors.*
stressor fees	A companion principle to user fee, stressor fees are paid by persons who have been identified as stressing Delta natural systems. The fees fund regulatory and restoration programs.
subsidence	Sinking of the land surface due to a number of factors, including groundwater extraction, agricultural activities, or oil or gas extraction. In the Delta, land subsidence is mainly caused by oxidation of peat soils, but also from wind erosion. Drainage and cultivation dries the saturated peat, reducing its volume by approximately 50 percent.
subsidence reversal	The exposure of bare peat soils to air causes oxidation and decomposition, which results in subsidence, or a loss of soil elevation, on Delta islands. Flooding these lands and managing them as wetlands reduces exposure to oxygen, resulting in less decomposition of organic matter, which stabilizes land elevations. Wetland vegetation cycles lead to biomass accumulation, which sequesters carbon and helps stop and reverse subsidence. As subsidence is reversed, land elevations increase and accommodation space (the space in the Delta that lies below sea level and is filled with neither sediment nor water) on individual islands is reduced. A reduction in accommodation space decreases the potential for water quality impacts from salinity intrusion in the event of one or more levee breaks on deeply subsided Delta islands.

Term	Definition
subventions	Payments made by the State in the form of matching funds for the purpose of maintaining and improving Delta levees. The Delta Levees Maintenance Subventions Program is a cost share program providing technical and financial assistance to local levee-maintaining agencies in the Sacramento–San Joaquin Delta for the maintenance and rehabilitation of nonproject and eligible project levees. The subventions program is authorized by Water Code sections 12980 through 12995 and is managed by the California Department of Water Resources.
surface storage	Reservoirs used to collect and hold water for future release and use.
surface water	Water naturally open to the atmosphere including rivers, lakes, reservoirs, ponds, streams, impoundments, seas, and estuaries.
sustainable communities strategy	Regional transportation agencies are required to develop a sustainable communities strategy. The strategy is intended to demonstrate how the region will meet its greenhouse gas reduction target through integrated land use, housing, and transportation planning.
SWP	State Water Project
SWRCB	State Water Resources Control Board
threatened species	As defined by the California Endangered Species Act, a threatened species is a native species or subspecies of a bird, mammal, fish, amphibian, reptile, or plant that, although not presently threatened with extinction, is likely to become an endangered species in the foreseeable future in the absence of the special protection and management efforts required by the act. Any animal determined to be rare on or before January 1, 1985, is a threatened species (Fish and Game Code section 2067).
THM	trihalomethanes
tiered fee structures	Refers to a block-type fee structure where the unit price of a quantified benefit or impact, such as the amount of water used or the volume of contaminants discharged, increases with each additional block of benefit or impact.
TMDL	See total maximum daily load
total maximum daily load (TMDL)	A calculation of the maximum amount of a pollutant that a water body can receive and still safely meet water quality standards.
total water use	In the Delta Plan, refers to 60 to 65 million acre-feet of water in California that goes to urban, agricultural, and Central Valley environmental water uses such as instream flow requirements and non-CVP managed wetlands.
tributary	A river or stream that flows into a larger river or stream. Usually, a number of smaller tributaries merge to form a river.
unimpaired flow	The natural water production of a river basin, unaltered by upstream diversions, storage, or by export or import of water to or from other watersheds.
urbanization	The expansion of residential, commercial, and industrial development into rural areas or areas that may have previously been used for agricultural or ecosystem habitat.
urban water use	The use of potable and nonpotable water for urban purposes including, but not limited to, residential, commercial, industrial, recreation, energy production, military, and institutional purposes.

Term	Definition
urban water use efficiency	Water management measures that are implemented in residential, commercial, industrial, and institutional settings that reduce water and per capita water use and result in the most effective use of water to prevent its waste, unreasonable use, or unreasonable method of use.
USACE	U.S. Army Corps of Engineers
USDA	U.S. Department of Agriculture
USEPA	U.S. Environmental Protection Agency
user fees	Fees proposed to fund programs identified in the Delta Plan that are paid by the users or beneficiaries of those programs. Fees may be volume-based or impact-based.
USFWS	U.S. Fish and Wildlife Service
USGS	U.S. Geological Survey
UWMP	See urban water management plan
vector-borne disease	Disease that results from an infection transmitted to humans and other animals by blood-feeding anthropods, including mosquitoes, ticks, and fleas. Examples of vector-borne diseases include Dengue fever, viral encephalitis, Lyme disease, and malaria.
waste discharge requirement (WDR)	An order adopted by a regional water board that regulates and permits specified discharges of waste to surface water and discharges of waste to land.
water balance	An analysis of the total developed/dedicated supplies, uses, and operational characteristics of water in a region. The analysis is intended to determine if actual water use equals supply.
water demand	An economic principle that describes consumer desire and willingness to pay a price for a specific amount of water. Holding all other factors constant, the price of a good or service increases as its demand increases and vice versa.
water export	The amount of water that a hydrologic region transfers to another hydrologic region. *See also: Delta exports.*
water import	The amount of water brought in from another hydrologic region or regions.
water quality criteria	Numeric limitations or levels (for example, concentrations) or narrative statements established to protect uses of a water body under the authority of the Clean Water Act. This term has two separate meanings: (1) Water quality criteria promulgated by the U.S. Environmental Protection Agency under Clean Water Act section 303(c) are enforceable components of water quality standards. (2) Recommended water quality criteria published under Clean Water Act section 304(a) are advisory and may be used by states and tribes to develop their own water quality standards or to implement narrative criteria in water quality standards.
water quality objectives	Numeric limitations or levels (concentrations or narrative statements) that are established for the reasonable protection of the beneficial uses of a water body. Determination of what is reasonable may include factors that are not required in federal development of a water quality criterion. Water quality objectives are included in water quality control plans adopted by regional water boards.

Term	Definition
water quality standards	Pursuant to the federal Clean Water Act, water quality standards are provisions of State or federal law that define the water quality goals of a water body, or portion thereof, by establishing (a) designated uses of water to be protected, and (b) water quality criteria to protect those uses. Water quality standards are enforceable in the bodies of water for which they have been promulgated.
water recycling	(1) The treatment of wastewater to remove solids and certain impurities to meet a beneficial use or a controlled use that would not otherwise occur, thus supplanting or augmenting a potable, or potentially potable, supply. (2) The treatment of municipal, industrial, or agricultural wastewater for reuse.
watershed	The land area that drains into a stream. The watershed for a major river may encompass a number of smaller watersheds.
water shortage contingency element	The Urban Water Management Planning Act requires water suppliers to include a water supply reliability and water shortage contingency element in urban water management plans, recognizing that suppliers need to prepare for extended droughts or the potential catastrophic interruption of water deliveries due to earthquakes or other events.
water supply reliability	See sidebar in Chapter 3, "What Does It Mean to Achieve the Goal of Providing a More Reliable Water Supply for California?"
water supply reliability element	Required components of urban water management plans (Water Code section 10631(c)), agricultural water management plans (Water Code section 10826 (b)(7)), and integrated regional water management plans (Water Code section 10540(c)(1)).
water transfer	A temporary or long-term change in the point of diversion, place of use, or purpose of use due to a transfer or exchange of water or water rights. Many transfers, including transfers among contractors of the State Water Project or Central Valley Project, do not fit this definition. A more general definition of a water transfer is a voluntary change in the way water is normally distributed among water users in response to water scarcity. Compared to water exchanges, which are typically water delivered by one water user to another water user, the receiving water user will return the water at a specified time or when the conditions of the agreement are met (Water Code section 1735).
water year	A compilation of hydrologic records collected over a 12-month period.
water year-type classifications	California Department of Water Resources uses five water year-type classifications for planning and water management purposes: wet, above normal, below normal, dry, and critically dry.
WDR	See waste discharge requirement
Wild and Scenic River	A State- and federal-designated river system that includes 17 California rivers and their many forks and tributaries. Approximately 1,900 miles of river are designated wild, scenic, or recreational under the National Wild and Scenic Rivers Act (1968) and the California Wild and Scenic Rivers Act of 1972.
X2	The location in the Bay-Delta where the tidally averaged salinity is 2 parts per thousand.

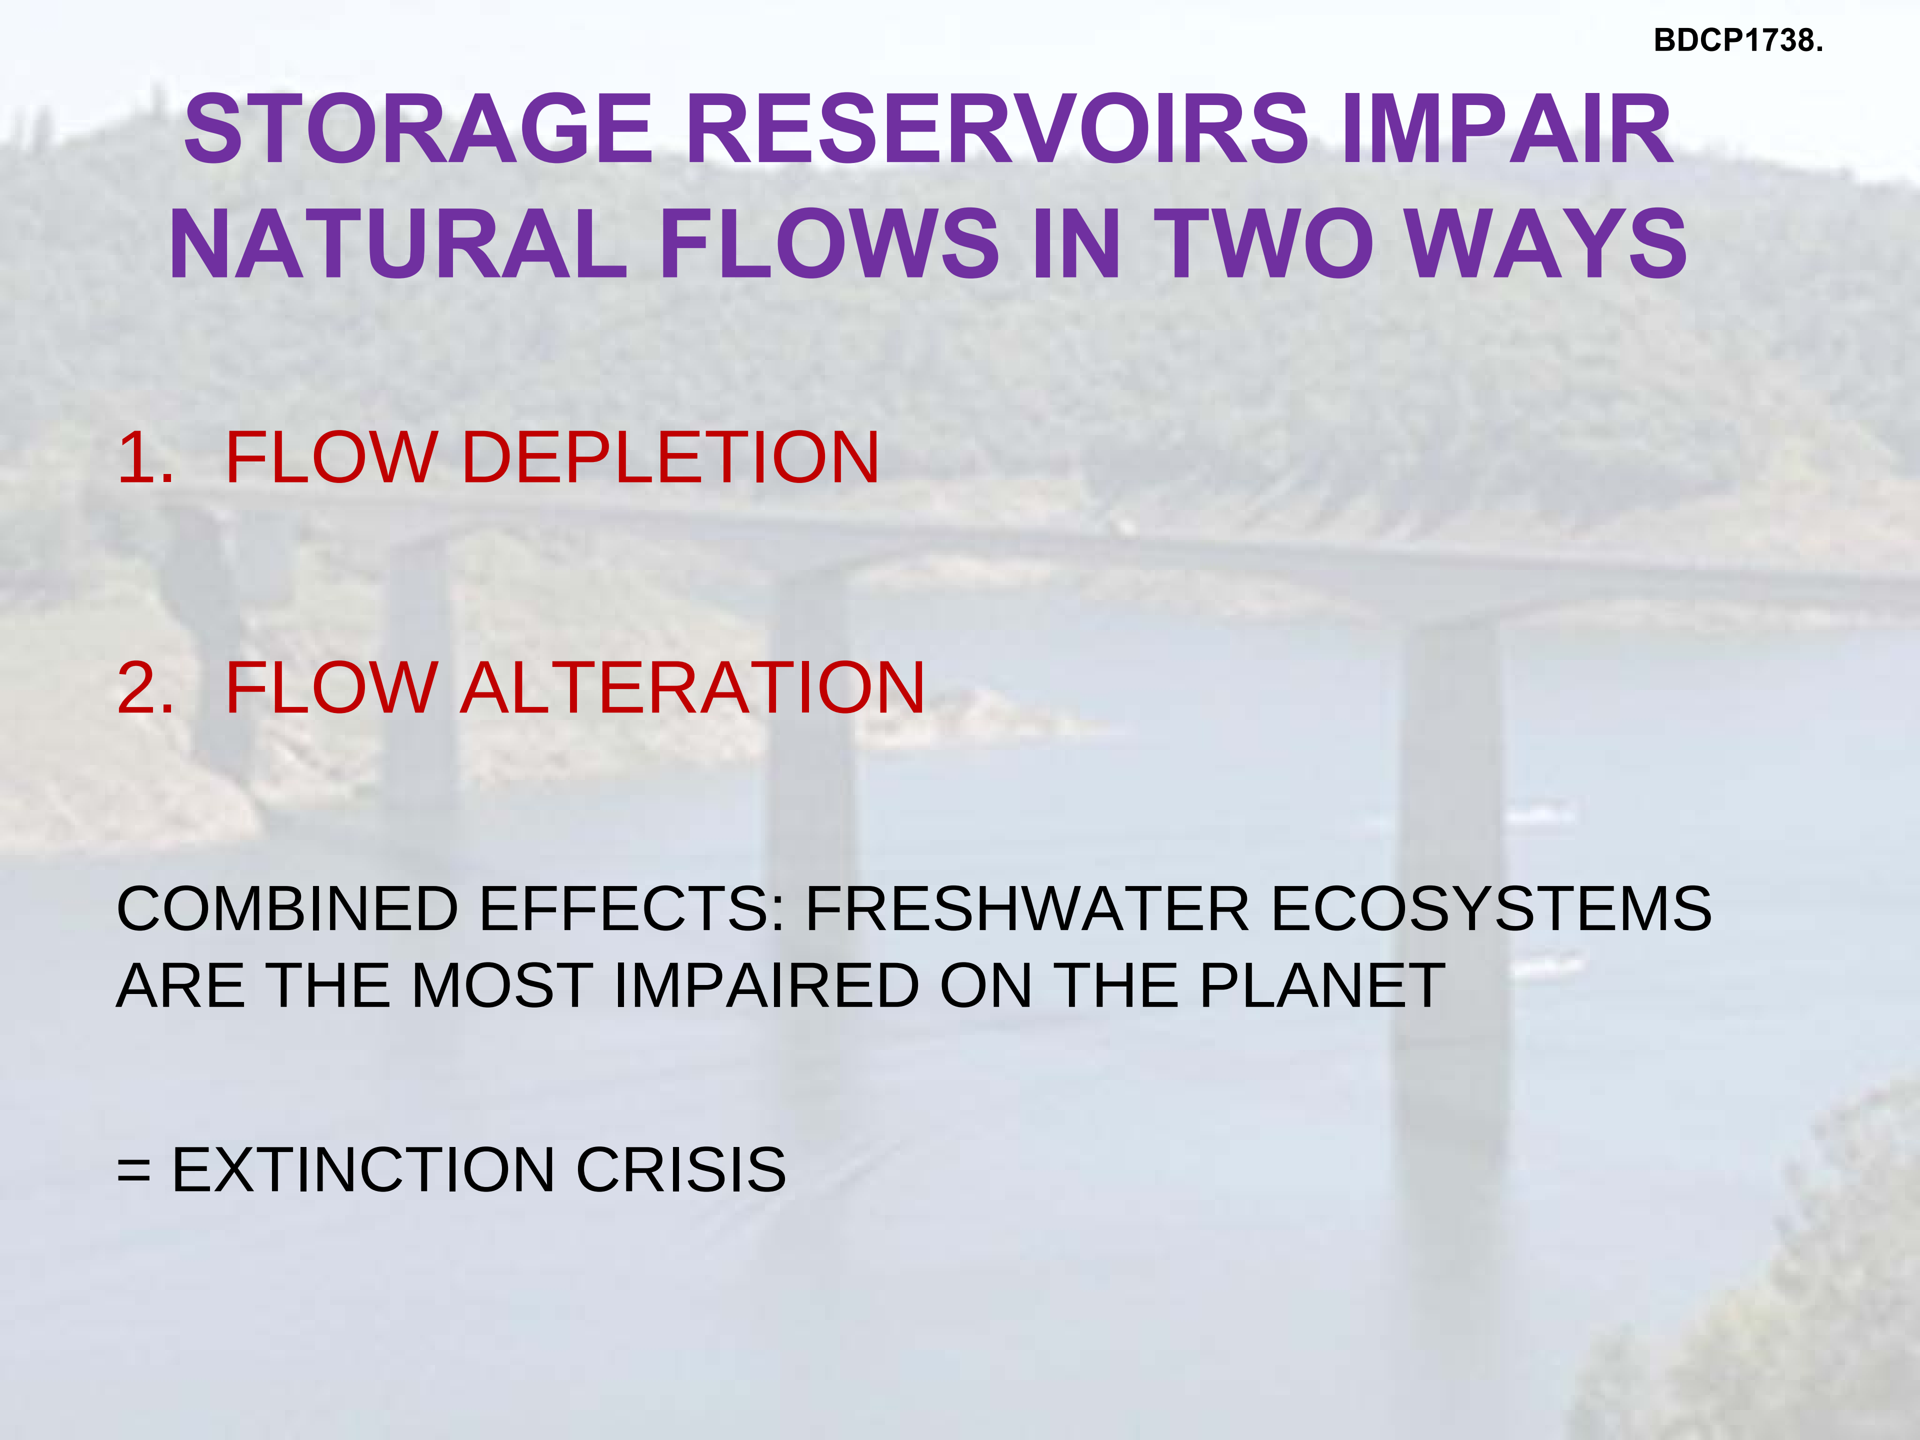
GENERATING ECOSYSTEM RESTORATION FLOWS THROUGH STORAGE AUGMENTATION

RESERVOIR REOPERATION WITH GROUNDWATER BACKSTOPPING

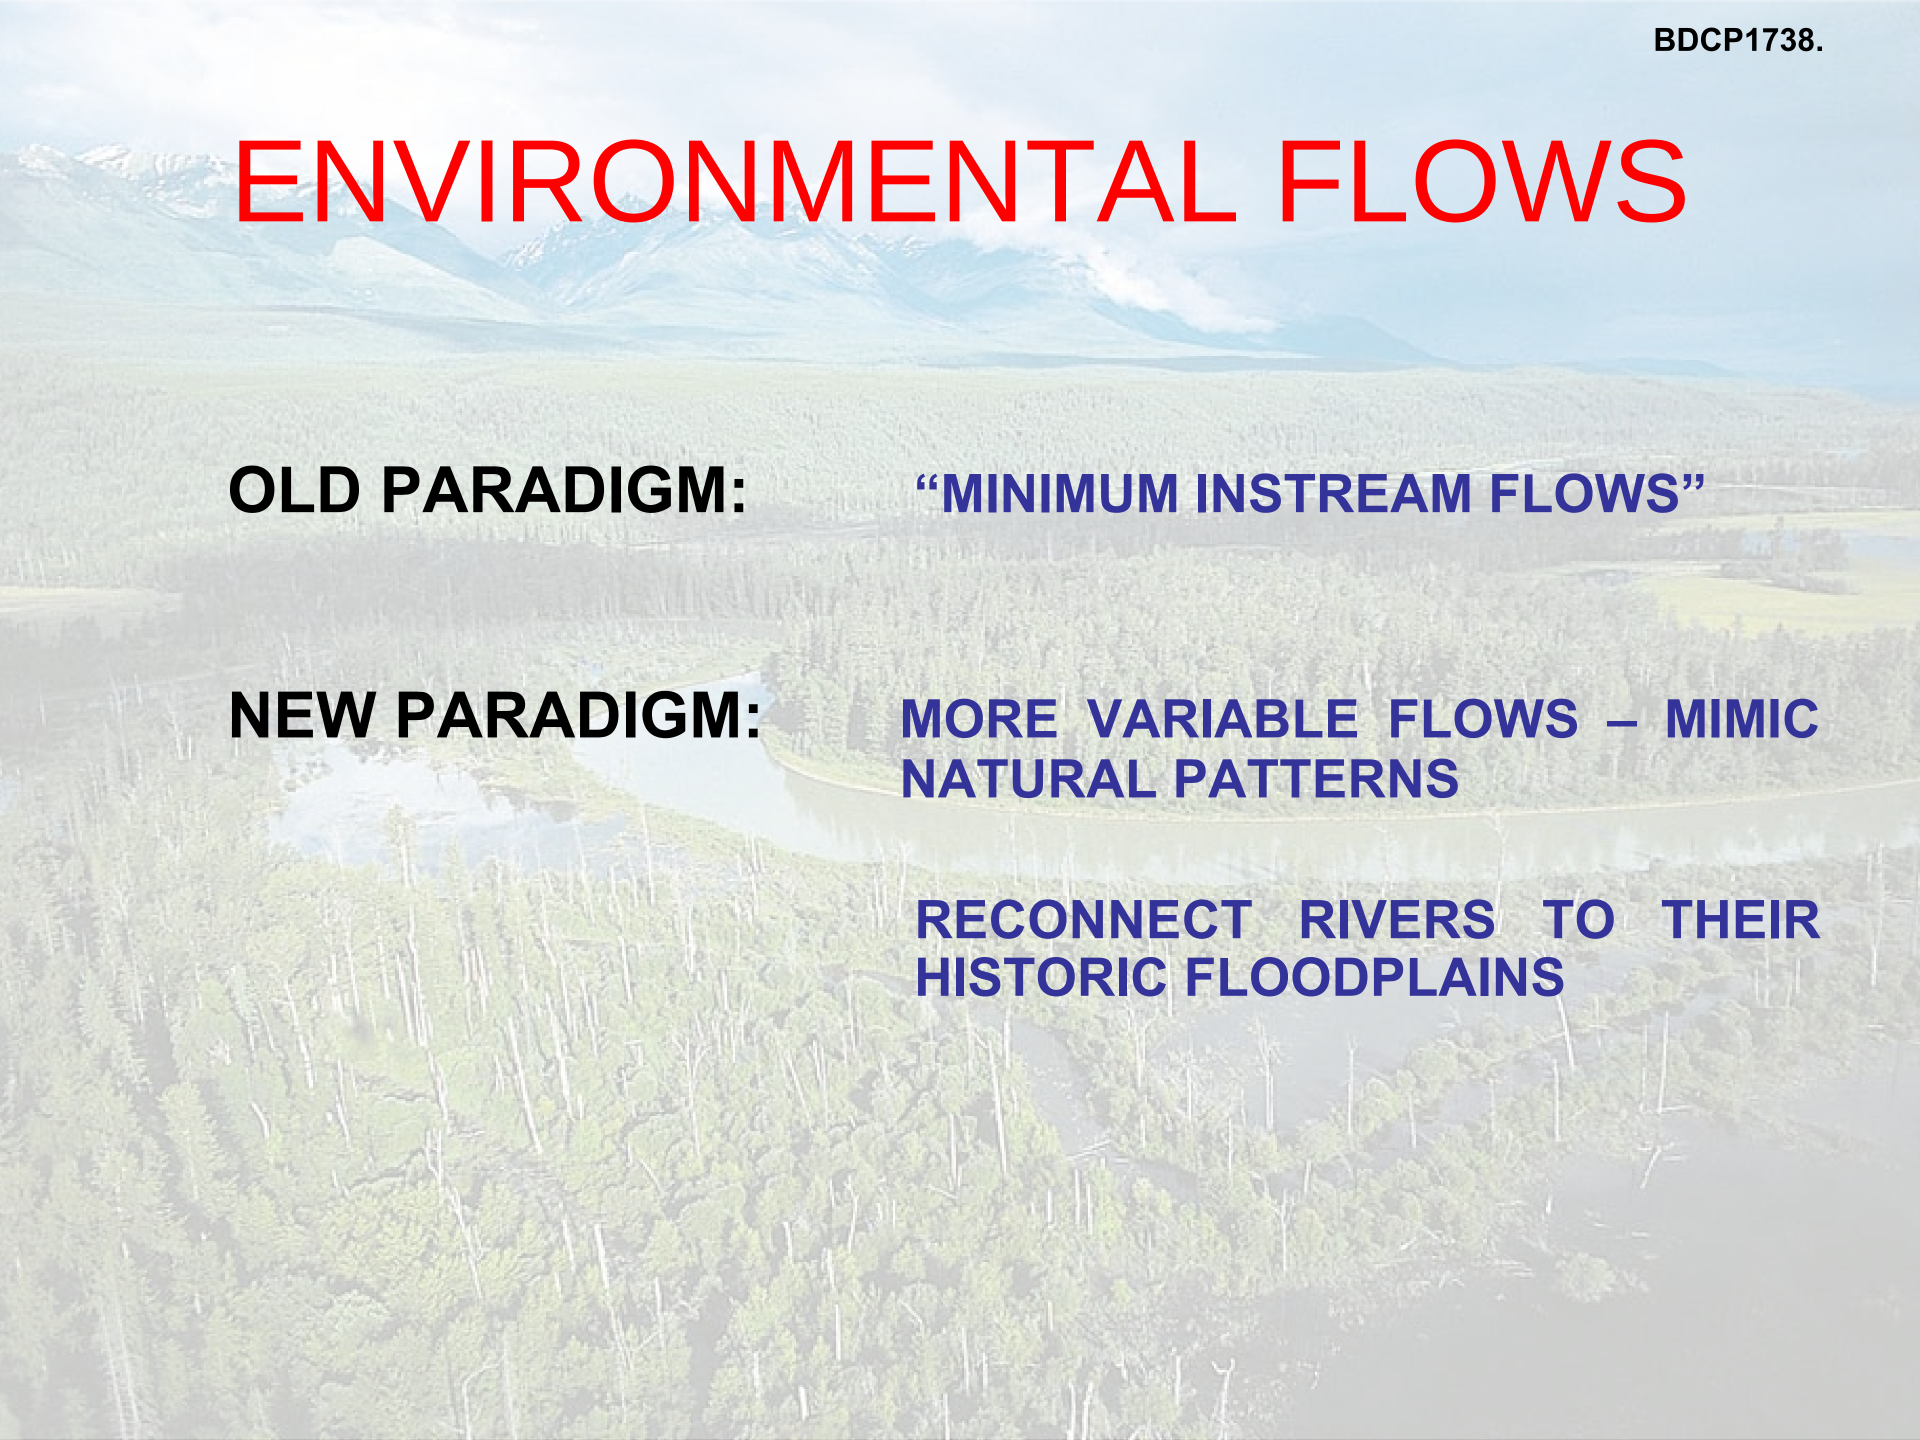


STORAGE RESERVOIRS IMPAIR NATURAL FLOWS IN TWO WAYS

1. FLOW DEPLETION
2. FLOW ALTERATION

COMBINED EFFECTS: FRESHWATER ECOSYSTEMS ARE THE MOST IMPAIRED ON THE PLANET

= EXTINCTION CRISIS



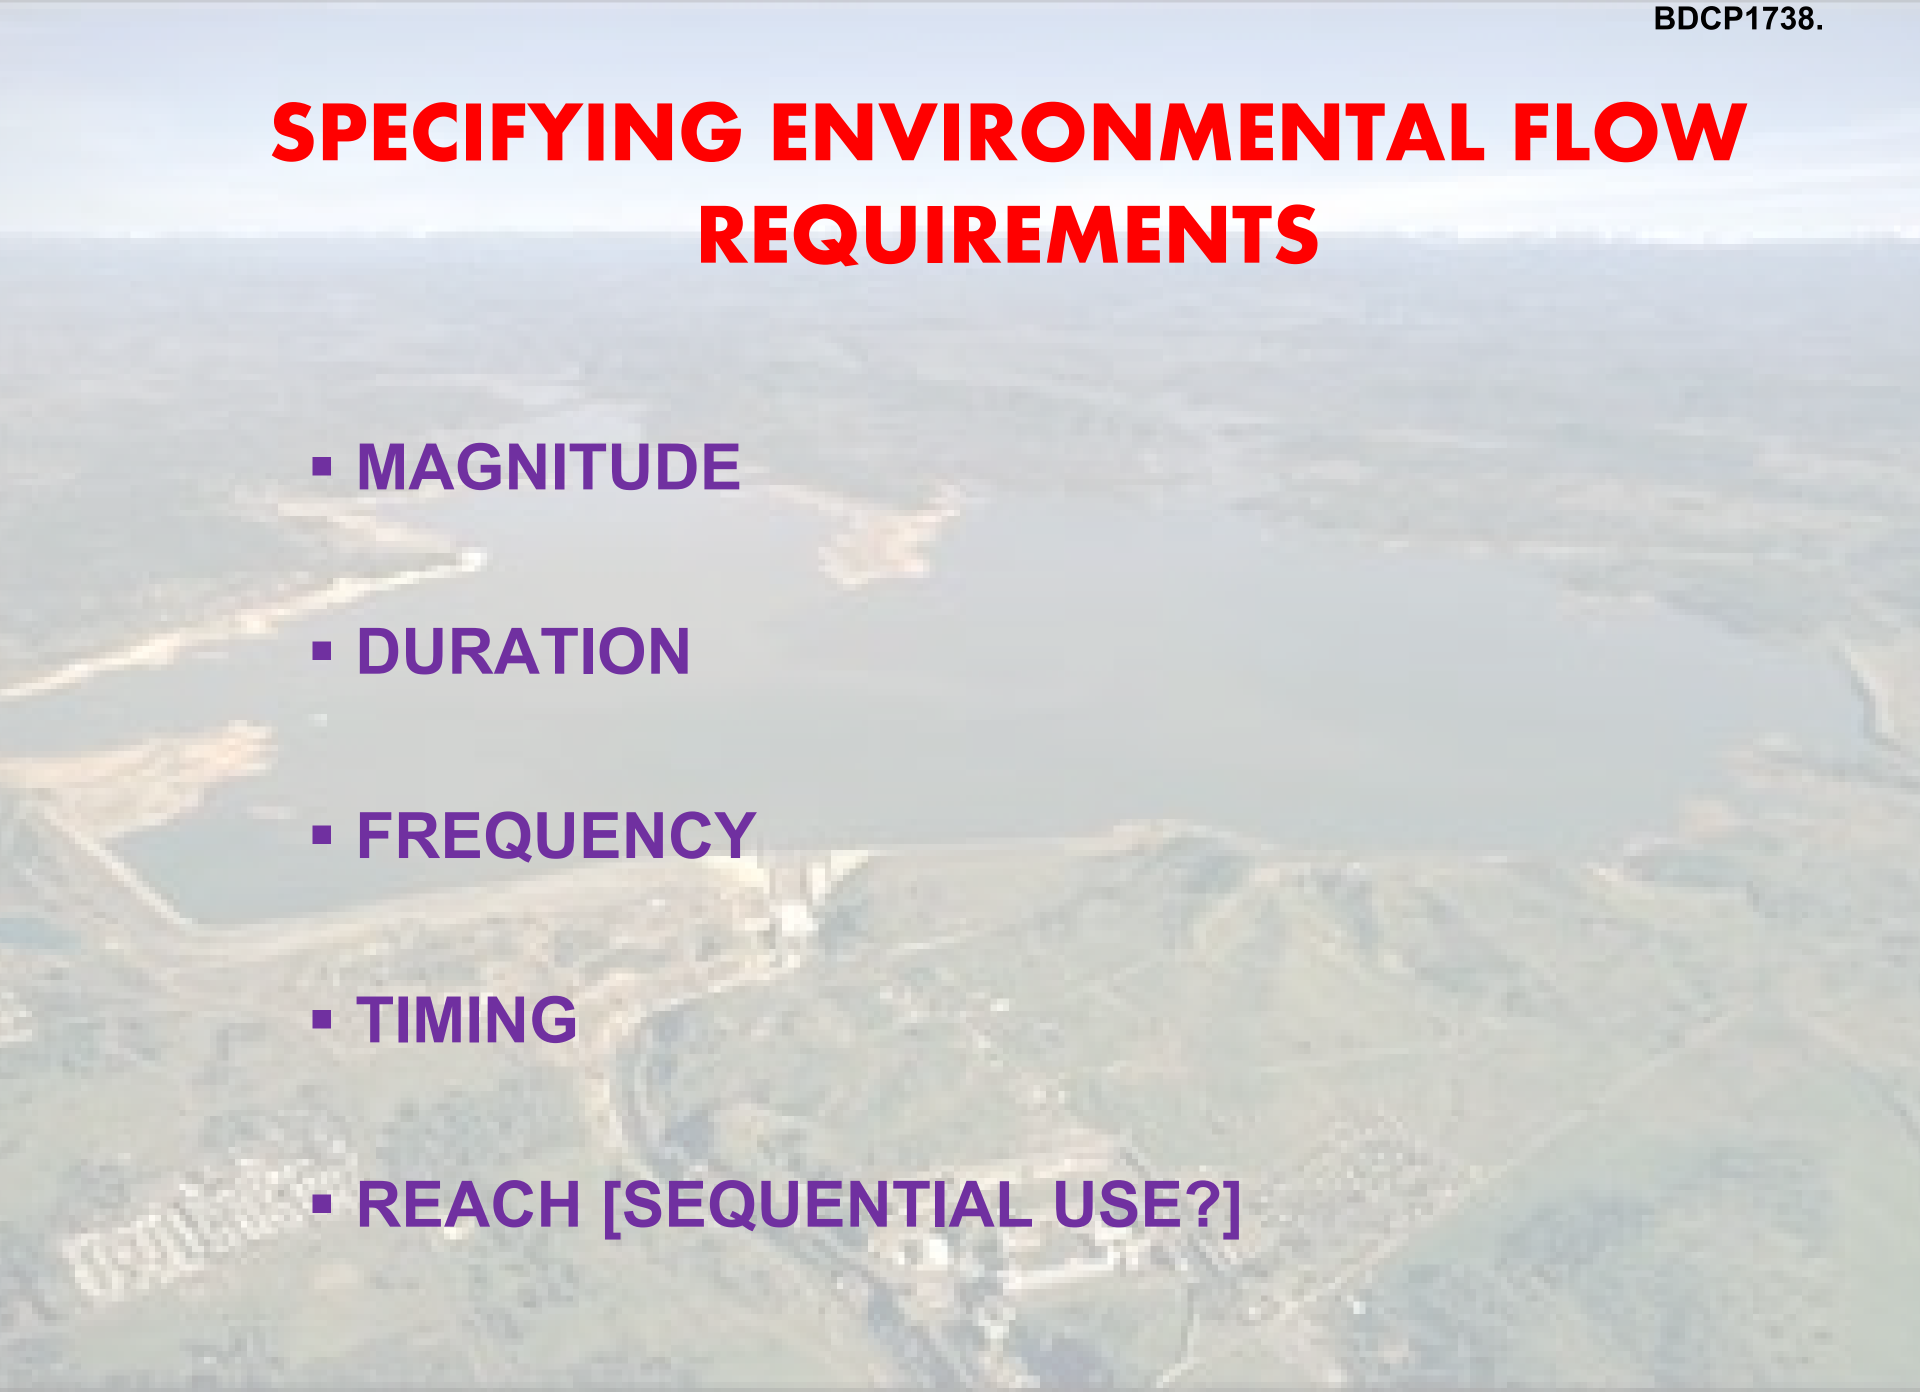
ENVIRONMENTAL FLOWS

OLD PARADIGM: “MINIMUM INSTREAM FLOWS”

NEW PARADIGM: MORE VARIABLE FLOWS – MIMIC NATURAL PATTERNS

RECONNECT RIVERS TO THEIR HISTORIC FLOODPLAINS

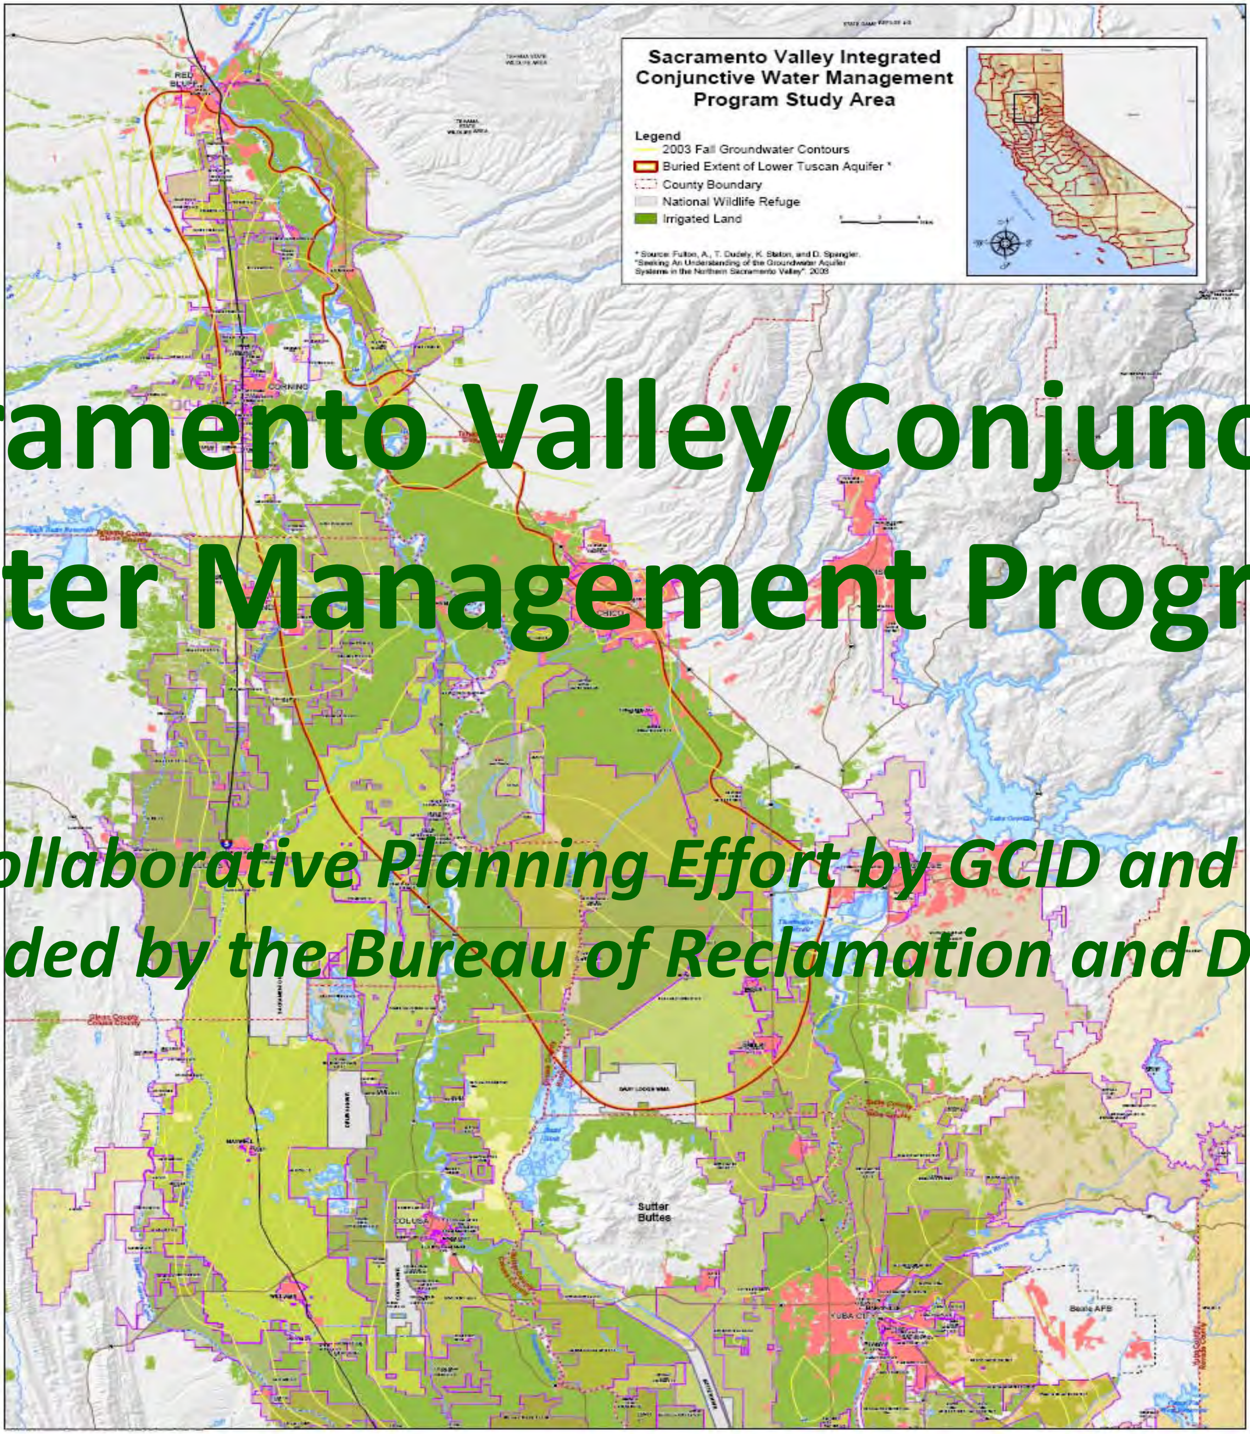
SPECIFYING ENVIRONMENTAL FLOW REQUIREMENTS



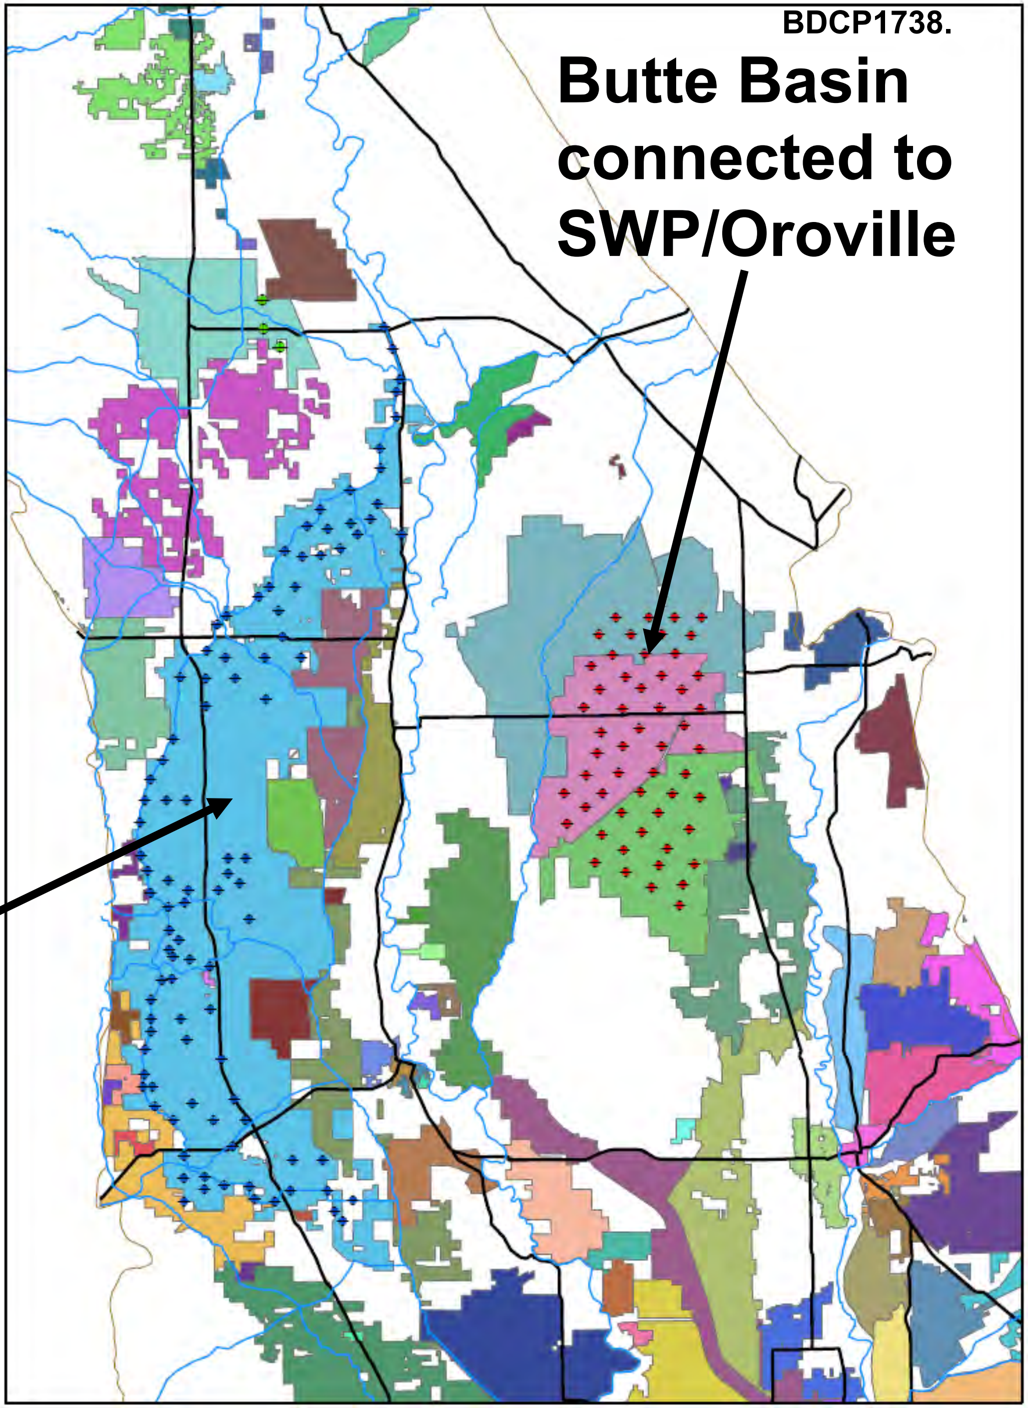
- MAGNITUDE
- DURATION
- FREQUENCY
- TIMING
- REACH [SEQUENTIAL USE?]

Sacramento Valley Conjunctive Water Management Program

A Collaborative Planning Effort by GCID and NHI
Funded by the Bureau of Reclamation and DWR



Two Promising Sites Identified

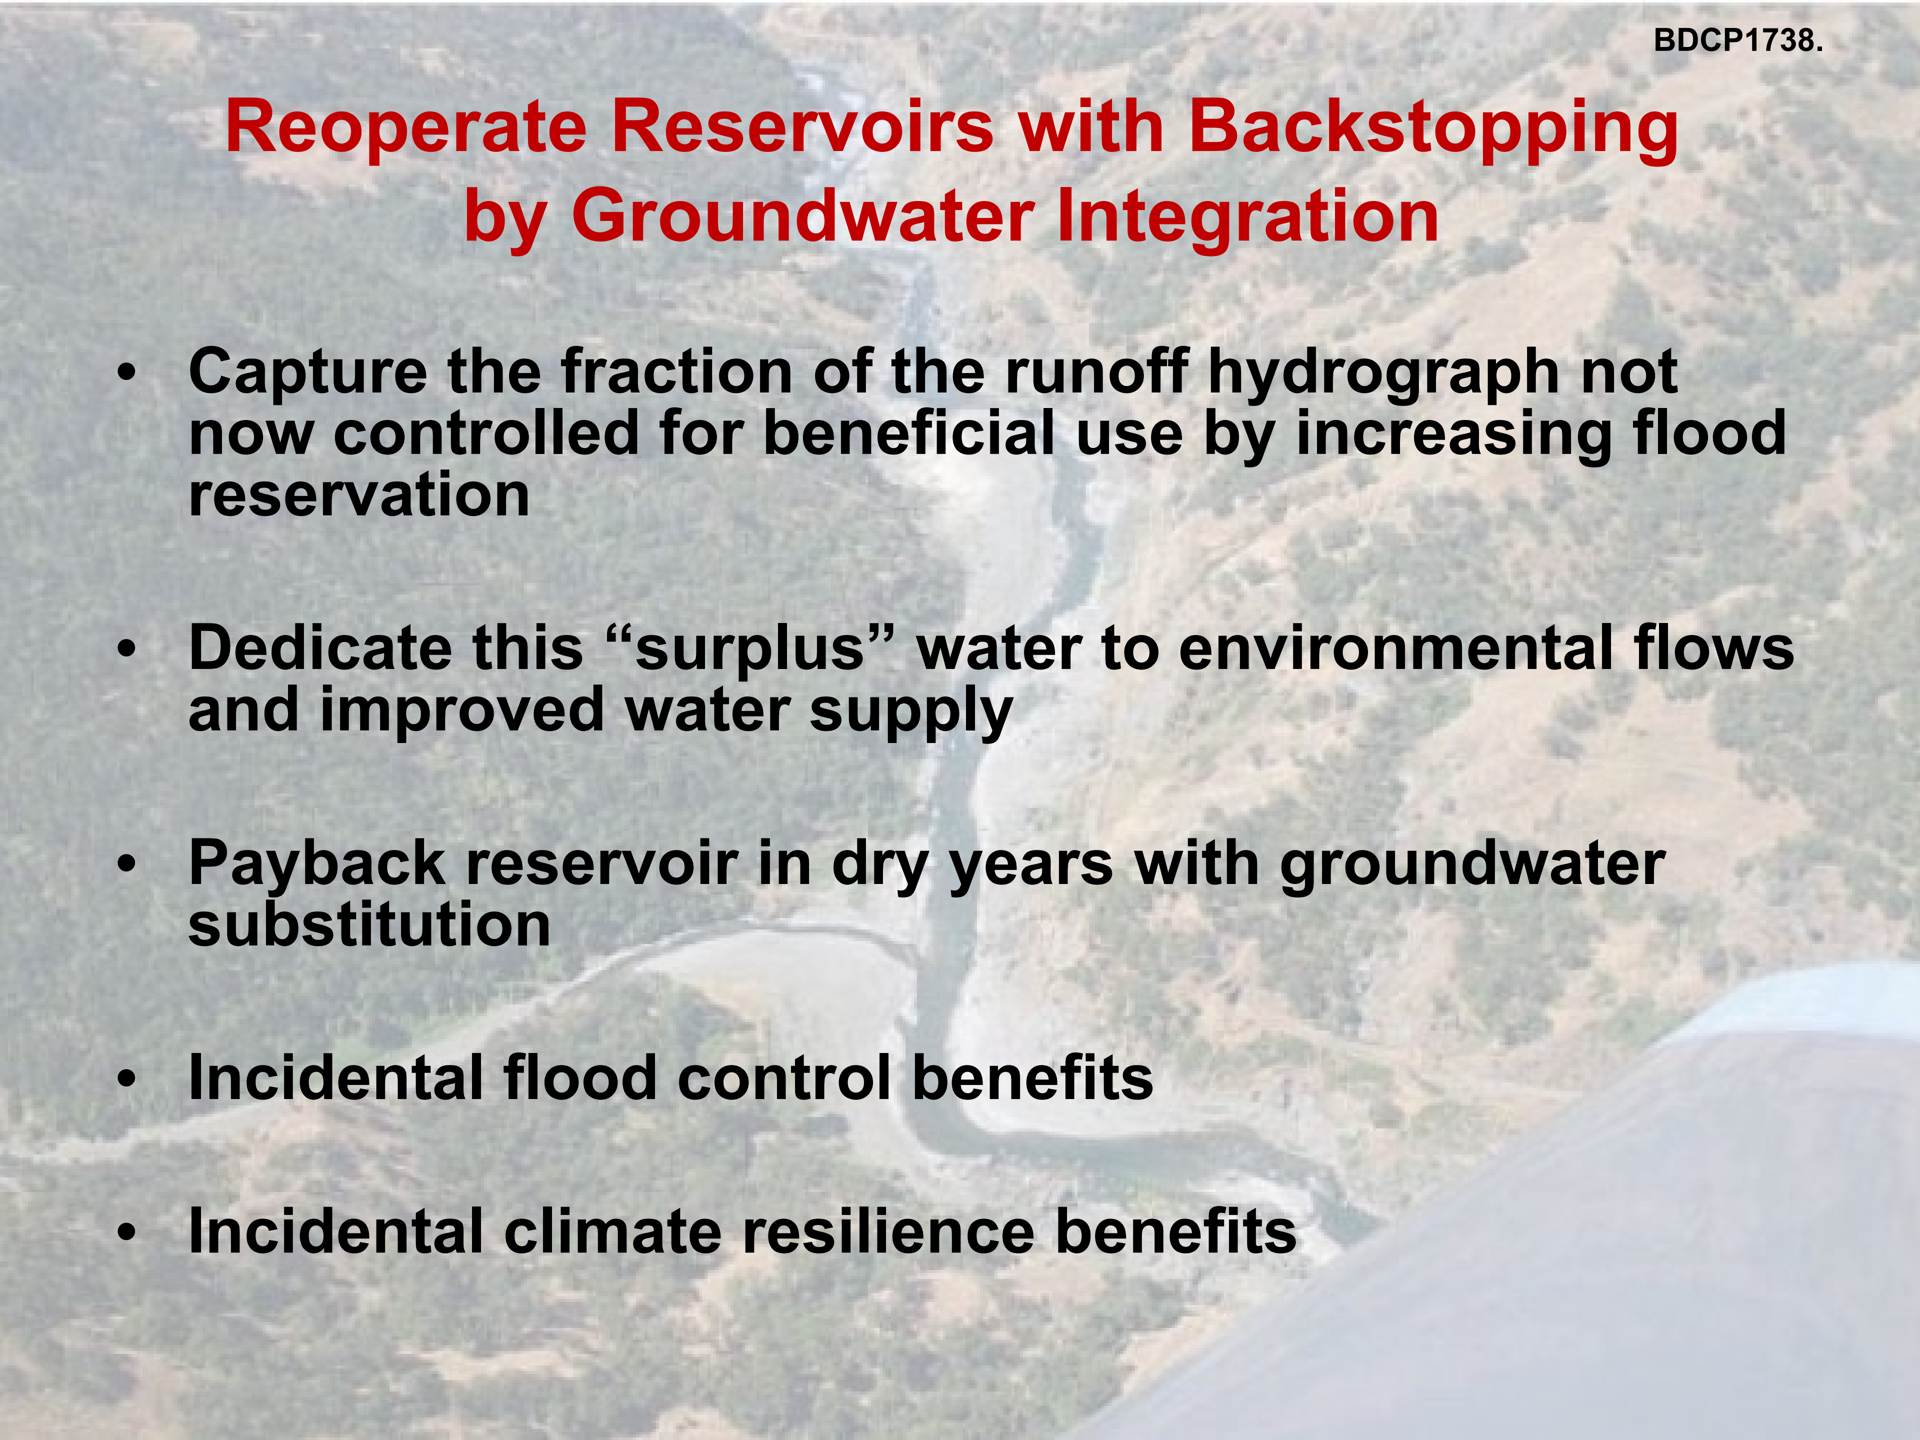


Butte Basin connected to SWP/Oroville

Glenn-Colusa ID connected to CVP/Shasta

Environmental Flow Objectives

- Geomorphic
  - Single day large event
  - February or March
- Riparian establishment
  - Five day large flow with 60 day recession
  - April start
- Flood plain inundation
  - Single day large event with 45 day recession
  - Between February and April
- Spring pulse flow
  - Simulate more natural spring runoff period



Reoperate Reservoirs with Backstopping by Groundwater Integration

- Capture the fraction of the runoff hydrograph not now controlled for beneficial use by increasing flood reservation
- Dedicate this “surplus” water to environmental flows and improved water supply
- Payback reservoir in dry years with groundwater substitution
- Incidental flood control benefits
- Incidental climate resilience benefits

Modes of Groundwater Banking

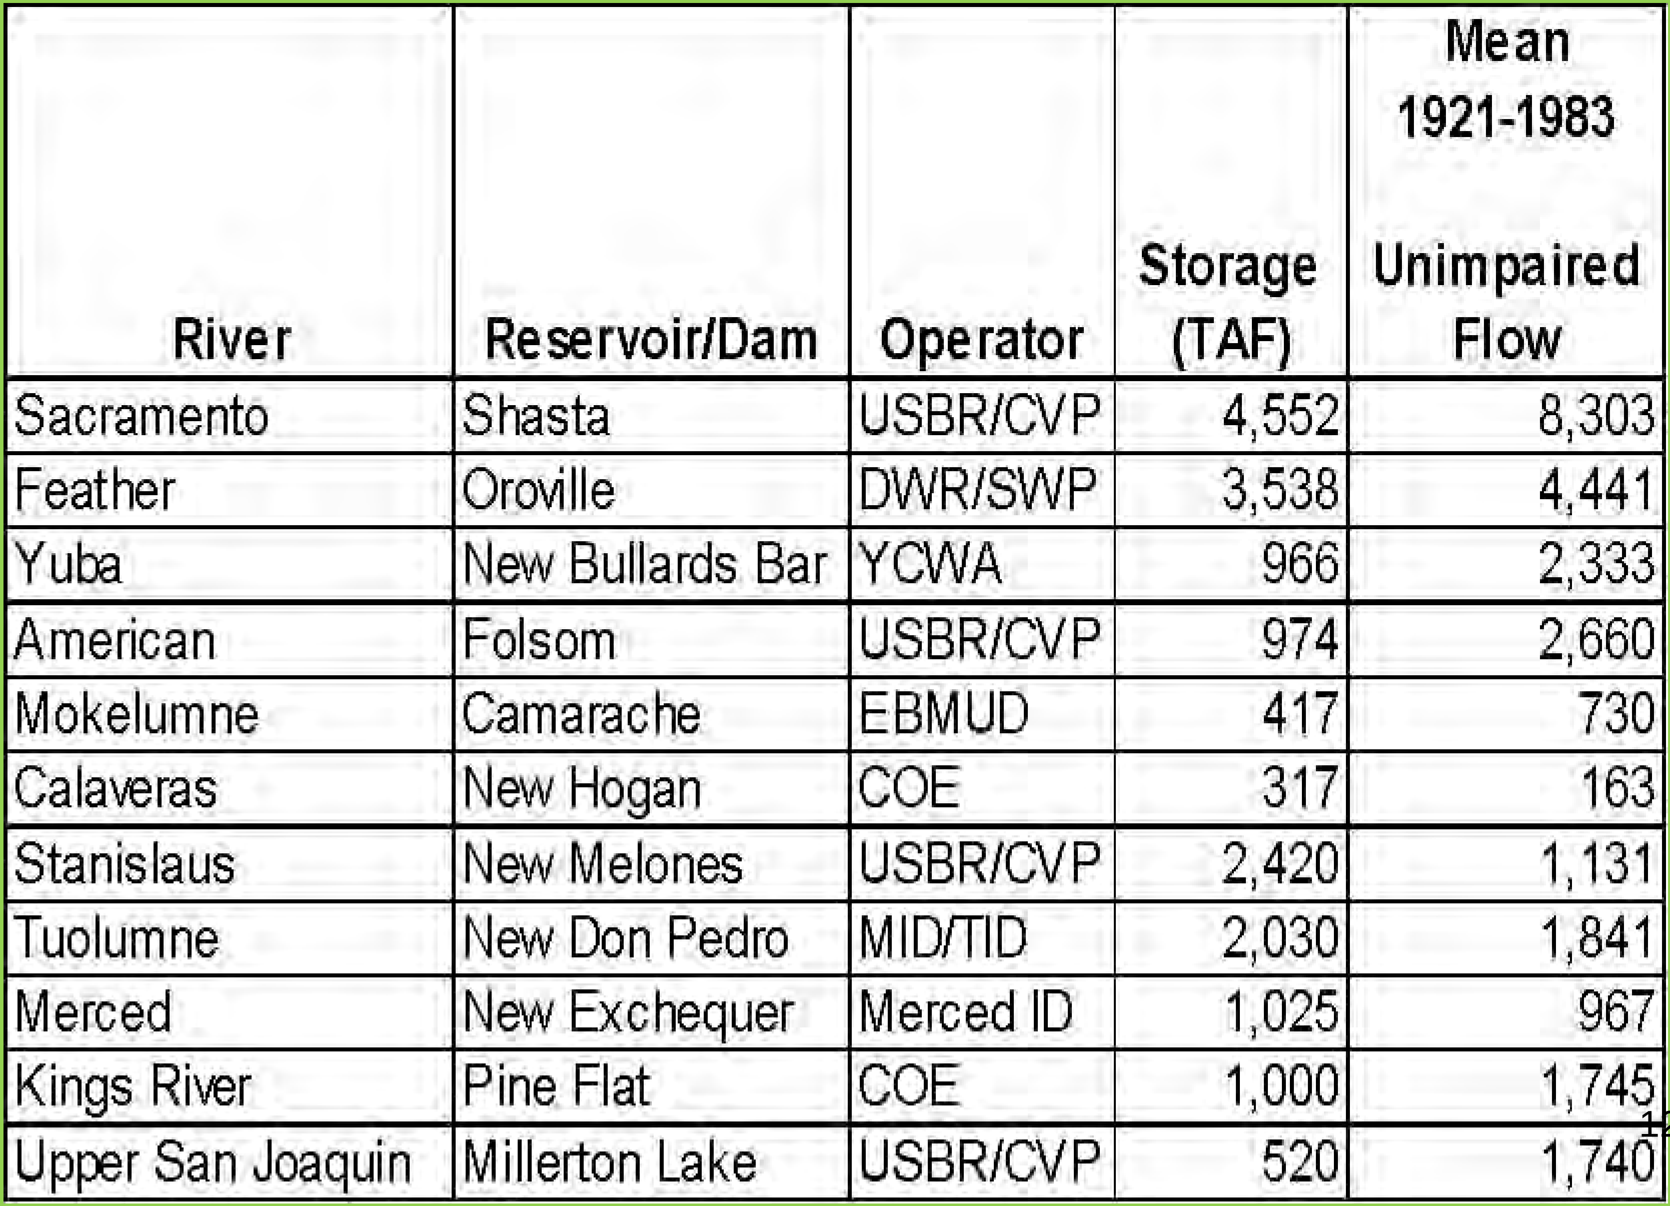
Reservoirs, Ownership, and Capacity



River	Reservoir/Dam	Operator	Storage (TAF)	Mean 1921-1983 Unimpaired Flow
Sacramento	Shasta	USBR/CVP	4,552	8,303
Feather	Oroville	DWR/SWP	3,538	4,441
Yuba	New Bullards Bar	YCWA	966	2,333
American	Folsom	USBR/CVP	974	2,660
Mokelumne	Camarache	EBMUD	417	730
Calaveras	New Hogan	COE	317	163
Stanislaus	New Melones	USBR/CVP	2,420	1,131
Tuolumne	New Don Pedro	MID/TID	2,030	1,841
Merced	New Exchequer	Merced ID	1,025	967
Kings River	Pine Flat	COE	1,000	1,745
Upper San Joaquin	Millerton Lake	USBR/CVP	520	1,740

Average Annual Yield Estimates for Eleven Regulated Tributaries of the Central Valley

River	Conjunctive Use Re-Operation (TAF)
Sacramento	196.8
Feather	126.9
Yuba	144.5
American	80.4
Mokelumne	69.4
Calaveras	25.4
Stanislaus	65
Tuolumne	77.9
Merced	108.1
Upper San Joaquin	100
Pine Flat Reservoir	108
TOTAL	1102.4

Factors Taken Into Account

- Pre-existing rights & entitlements
- Prescribed environmental flows
- Temperature regulation

Factors NOT Taken Into Account

- Delta transfer constraints

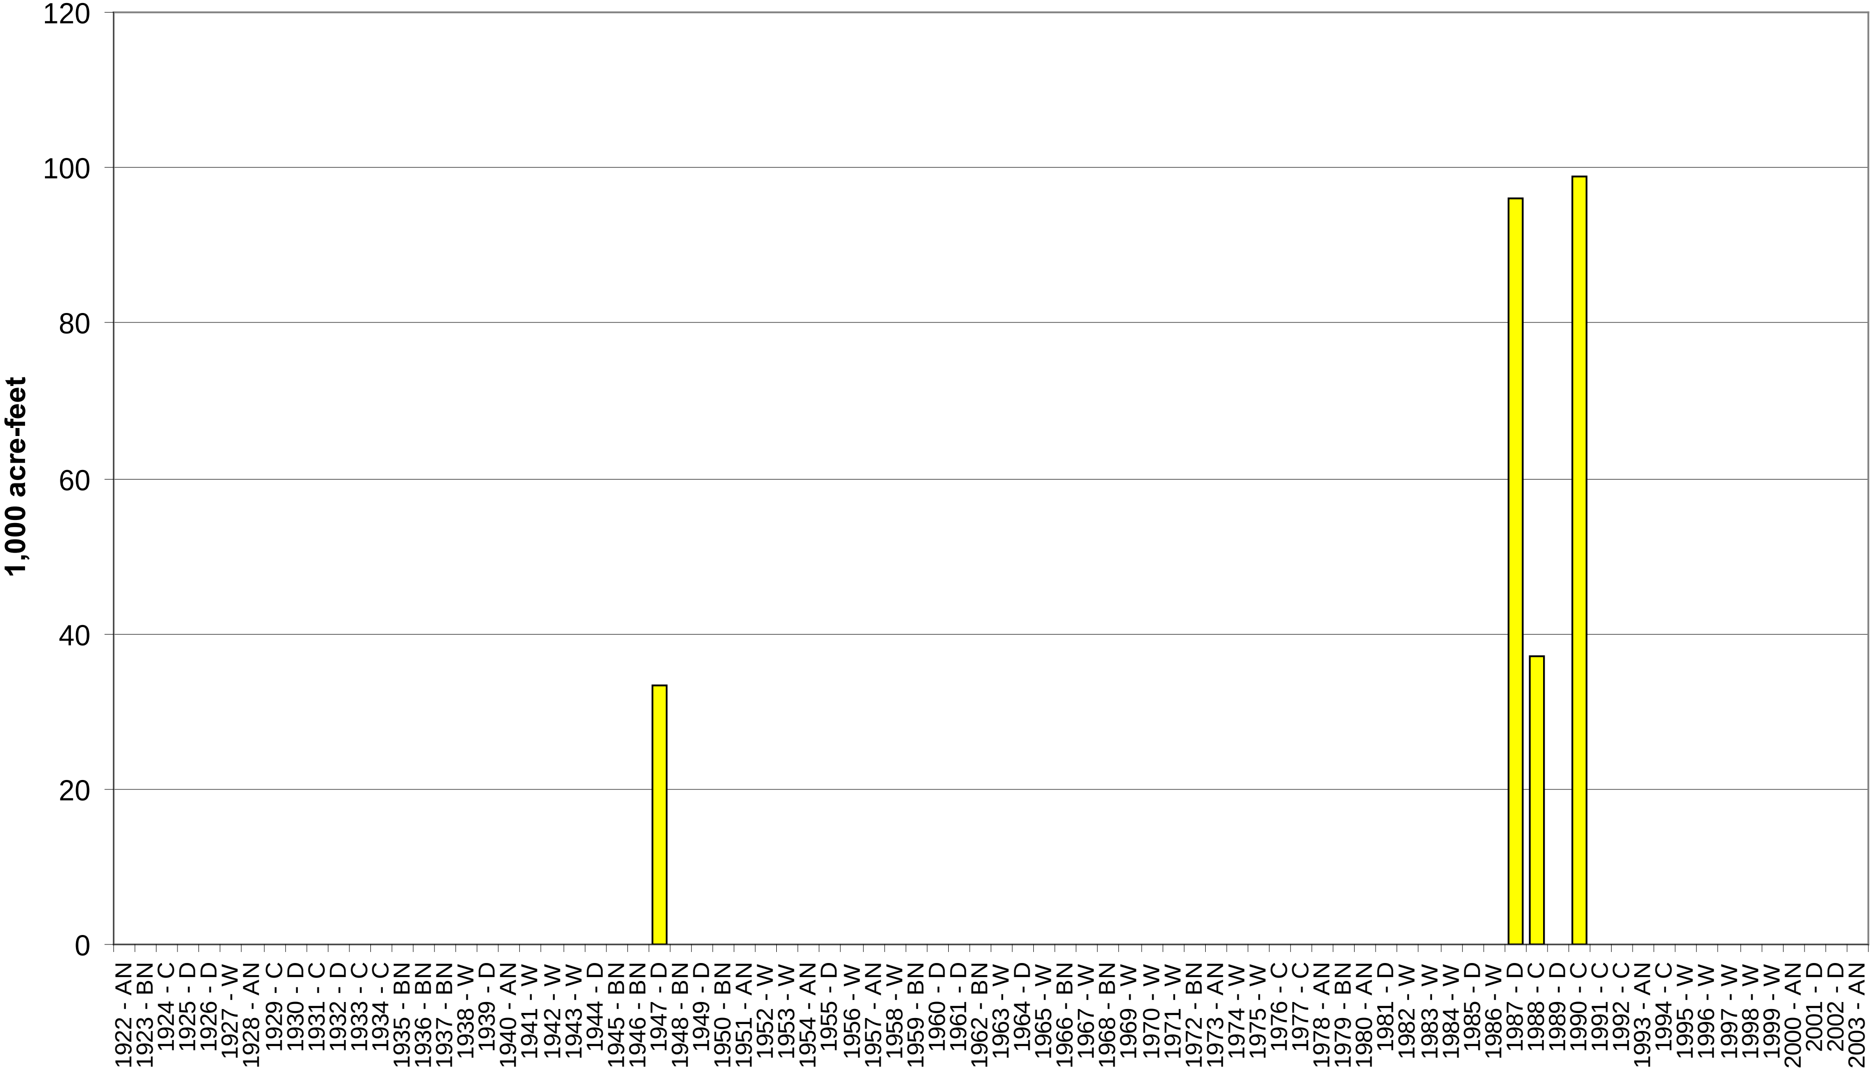
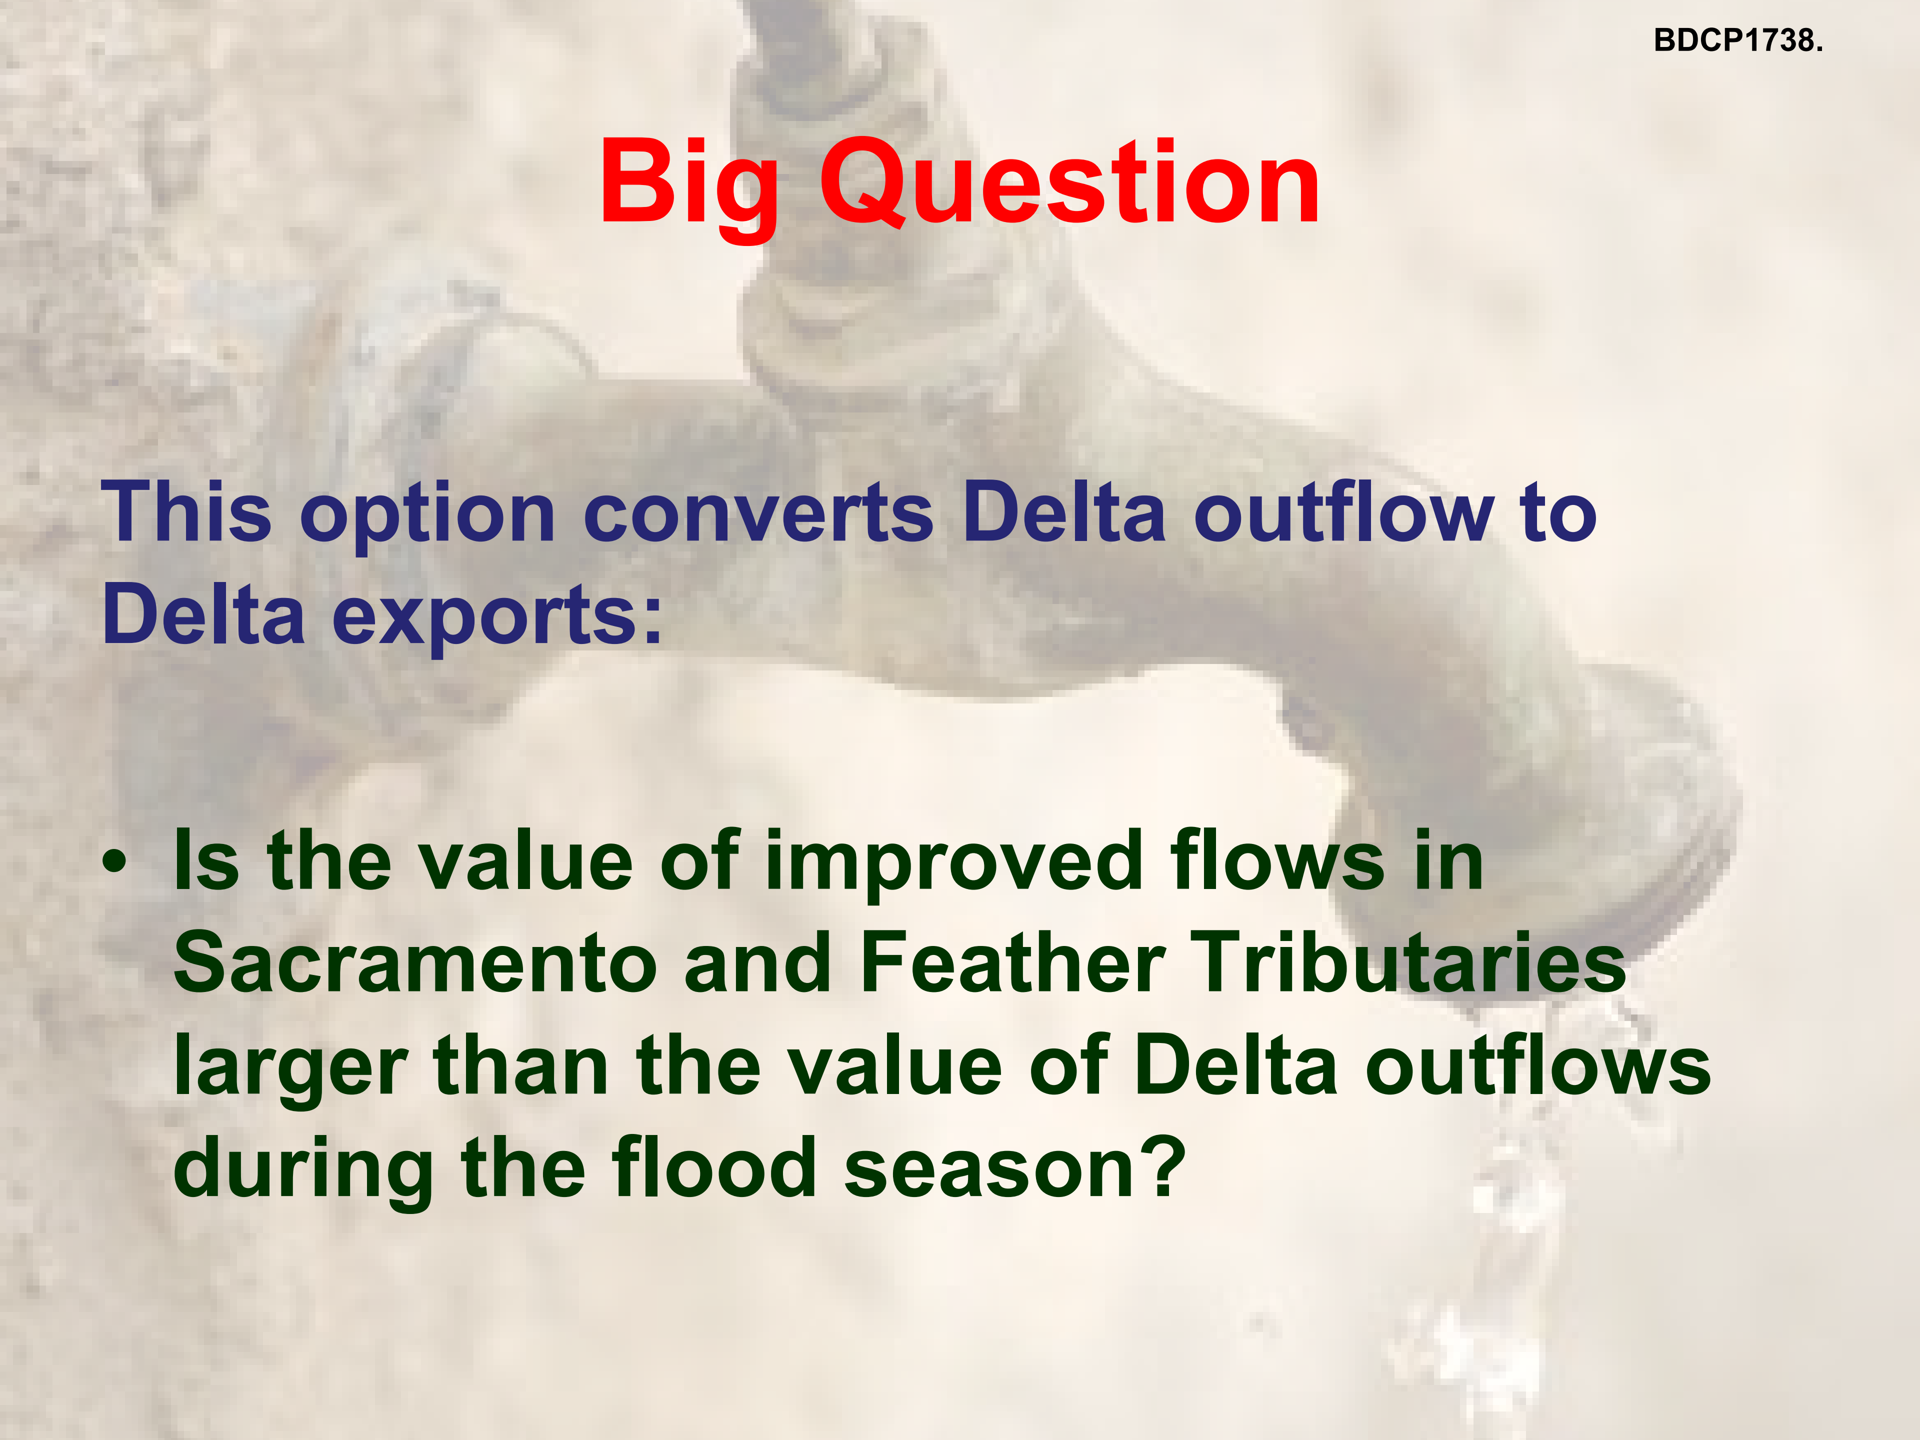
Refill from Groundwater Pumping



Why South of Delta GW Banking is Promising

- Avoid impacts on Sac Valley GW Users
- Extract and use banked water at times of greatest need and economic value
- No increase in Sac Valley exports
- Avoid operational losses for IDC by-pass flows by “riding on the back” of PRE exports

Big Question



This option converts Delta outflow to Delta exports:

- Is the value of improved flows in Sacramento and Feather Tributaries larger than the value of Delta outflows during the flood season?

Fish don't just need water-- they need a river!
