The Pittsburg Power Plant (PPP) consists of seven natural gas-fired generating units, four of which have been retired. PPP Units 5&6 were built in 1960 and 1961, respectively, and generate a total of 660 gross megawatts (gMW) of power. PPP Unit 7 was built in 1972 and generates 740 gMW. Cooling water for the PPP is withdrawn from Suisun Bay through two adjacent shoreline intake structures. Units 5&6, both once-through cooled units, are each serviced by two variable frequency circulating water pumps (CWP) that withdraw water from the Units 5&6 intake structure. Each pump has a maximum design flow of 115.6 million gallons per day (MGD) (354.7 acre-feet (AF)/day) or 231.1 MGD (709.3 AF/day) per unit. The approach water velocity in front of the bar racks can range from 0.5 to around 0.2 feet per second depending upon how much electric generation is needed and the number of the variable frequency pumps in operation. Unit 7, which is equipped with two mechanical-draft cooling towers and a large cooling water canal, withdraws make-up water through the Units 1-7 intake structure. Unit 7's closed-cycle system uses up to 43.6 MGD (133.9 AF/day) of make-up water.

In addition to the Units 5-7 cooling water intake requirements, the PPP withdraws water from the Units 1-4 intake structure for station water supplies, for intermittent intake screen washing, and for fire suppression purposes. At maximum operation, these additional uses account for approximately 43.6 MGD (133.7 AF/day). The total current design flow for all PPP operations is approximately 549.4 MGD (1,686.2 AF/day).

Contra Costa Power Plant

The Contra Costa Power Plant (CCPP) consists of seven natural gas-fired generating units, five of which have been retired. Units 6&7 were built in 1964 and generate a total of 690 gMW of power. Units 6&7 are equipped with once-through cooling which utilizes water withdrawn from the San Joaquin River. Units 6&7 are each serviced by two variable frequency circulating water pumps (CWP) that each have a maximum design flow of 152,800 gpm, or 220 MGD (675 AF/day). The total design flow for both Unit 6 and Unit 7 is approximately 305,600 gpm, or 440 MGD (1,351 AF/day). The approach water velocity in front of the bar racks can range from 0.6 to around 0.2 feet per second depending upon how much electric generation is needed and the number of the variable frequency pumps in operation.

In addition to the Unit 6 and Unit 7 cooling water intake requirements, the CCPP utilizes water for station water supplies, for intermittent intake screen washing, and for fire suppression purposes. At maximum operation, these additional uses account for approximately 22 MGD (67.5 AF/day). The total current design flow for all CCPP operations is approximately 462 MGD (1,418 AF/day).

Variable Frequency Drive (VFD) Circulating Water Pump Operations

The circulating water pumps at CCPP Units 6&7 and PPP Units 5-6 are mixed flow vertical centrifugal pumps equipped with A-C induction motor drives. The drives have been modified to utilize VFD controls, as well as to operate at full rated speed. The VFD controls provide a means to vary drive speed by varying frequency. For a centrifugal pump, flow is proportional to pump speed. Therefore as frequency and drive/pump speed are reduced, pump flow is also reduced proportionally (i.e., 50 percent pump speed => 50 percent pump flow).

When operating in VFD mode, the circulating water pump speed/flow is typically at its minimum level when the unit is at minimum load. The minimum circulating water pump speed/flow is limited by both the pump and motor design and the system head requirements. For PPP Units 5&6 and CCPP Units 6&7 minimum flow is 50 percent of design and minimum load is ~25–45 MW. As unit load increases, pump speed and flow are increased in accordance with unit conditions. Maximum circulating water speed/flow, 95–100 percent of design, is typically reached at ~90–145 MW for PPP Units 5&6 and CCPP Units 6&7. River water temperature, tide, condenser vacuum, steam flow, etc., all have an effect on circulating water flow requirements.

Current Actual Operational Cooling Water Flows

Actual flow rates at the Delta Plants have steadily decreased in recent years to be consistently substantially below all maximum permitted flow limits. Capacity utilization rates (the ratio between the annual net generation of power and the total net capability of the facility to generate power) at the Plants have steadily declined in recent years, and intake flows have correspondingly decreased (Table 4-2). While the California Independent System Operator (CAISO) requires that the Delta Plants be available at any time during the year, the Delta Plants are primarily used during California's peak energy demand periods, particularly in the crucial summer months.

Table 4-2.Electrical capacity utilization and cooling water flows for CCPP and PPP from 2004 to 2008

Plant/Year	*Capacity Utilization (MWh)/(MW Capacity* hours of generation)*			*Combined Annual Cooling Water Flows (MG/yr)*	*Combined Annual Cooling Water Flows (million AF/yr)*
CCPP	**Unit 6**	**Unit 7**		**Units 6&7**	**Units 6&7**
2004	4.1	21.7		60,926	0.19
2005	1.2	10.1		29,874	0.09
2006	0.8	3.9		15,641	0.05
2007	1.4	3.3		12,879	0.04
2008	1.9	3.4		18,004	0.06
PPP	**Unit 5**	**Unit 6**	**Unit 7**	**Units 5&6**	**Units 5&6**
2004	24.0	20.8	9.5	71,751	0.22
2005	12.5	7.3	1.8	34,710	0.11
2006	7.7	5.3	1.4	25,112	0.08
2007	2.7	2.6	0.8	11,562	0.04
2008	2.3	2.4	0.8	14,859	0.05

In addition to once-through cooling flows, Mirant discharges process wastewater and stormwater (quantity and quality of discharges are subject to permits issued by the State Water Resources Control Board and San Francisco and Central Valley Regional Water Quality Control Boards).

Mirant's operations are constrained by (1) its Clean Water Act National Pollution Discharge Elimination System (NPDES) permits and specifically by Clean Water Act Section 316(b) of the federal Clean Water Act; (2) incidental take permits issued by the National Marine Fisheries Service and U.S. Fish and Wildlife Service pursuant to the Endangered Species Act; (3) a Memorandum of Understanding with the California Department of Fish and Game authorizing incidental take of species listed under the California Endangered Species Act; and (4) regulatory requirements imposed by federal and State energy agencies. These independent regulatory constraints may alter Mirant's covered activities for the purposes of the BDCP in both the short-term and long-term.

Future Operations

The remaining PPP units (Units 5-7, of which Units 5-6 use once-through cooling and Unit 7 uses closed-cycle cooling) are currently contracted through a tolling agreement with PG&E through the end of 2010. Over the course of 2010, Mirant Delta will determine whether the PPP units (1) will be retired, (2) will continue to operate for a certain term in their existing configuration followed by retirement (as at CCPP Units 6-7 discussed below), or (3) will continue to operate for a certain term with retrofits to reduce or eliminate the use of once-through cooling. Mirant Delta anticipates that, under any of these scenarios, capacity utilization at the PPP units will be consistent with the last five years of operations and will remain in the low single digits, with the units being called on to run for reliability purposes primarily in August and September.

The State Water Resources Control Board recently issued its statewide once-through cooling policy which provides for the gradual phase-out of once-through cooled units throughout California and includes a compliance due date of 2017 for the PPP. Independent of ESA/CESA requirements, Mirant Delta's once-through cooled units will be required to comply with this policy.

Mirant Delta entered into a tolling agreement with PG&E in 2009 providing for the continued operation of the remaining CCPP units (Units 6-7) until April 30, 2013, at which time Mirant Delta will permanently retire CCPP Units 6-7, the only remaining once-through cooled units at the CCPP. The CCPP units are called on to operate for reliability purposes, primarily in August and September, and capacity utilization rates have been and are anticipated to continue to be in the low single digits.

4.2.3.1.2 Activity

Mirant Delta, LLC is seeking ESA Section 10 and NCCPA Section 2835 permits for all existing and future operations of the CCPP and PPP not otherwise restricted by BDCP operating criteria.

4.2.3.2 Existing and Future Plant Maintenance, Modification Activities, and Monitoring Activities

4.2.3.2.1 Background

<u>Maintenance Dredging, Equipment Maintenance, Modifications and De-commissioning, and Levee and Flood Control Maintenance</u>

Maintenance and modification activities include those routine and non-routine activities that maintain the capacity and operational features of the existing power generation facilities at the Delta Plants described above. These activities include periodic maintenance dredging in front of and in the plant cooling water intake structures to remove naturally occurring accumulated sediments to ensure that the approach velocity of cooling water entering the intake structure remains relatively uniform across the intake screen and as close to design levels as possible, and to prevent undue damage to the facility from sediment in the cooling water and the related abrasion and wear of power plant equipment, such as condenser tubes and circulating water pumps. Dredging is also sometimes required around the docks and in the discharge outfalls to remove the sediment buildup so that these structures can function and operate as designed. These activities also include recurrent equipment maintenance and modifications (such as shoreline and pier maintenance, maintenance and repair of all improvements, infrastructure, roads, electrical facilities, underground linear facilities, vegetation management, etc.), as well as modifications to existing facilities and infrastructure as needed to ensure continued power generation; levee maintenance (such as placement of riprap for shoreline protection and erosion control) as needed to protect the power generation facilities; and flood control maintenance (such as maintenance of Willow Creek at the PPP) as needed. As existing power generation units are retired, de-commissioning activities may include demolition and/or removal of improvements and fixtures as needed. Regarding de-commissioning activities, simply retiring the units would not involve any construction or demolition activities and therefore would have no physical effects. If and when demolition occurs, most improvements would be located on disturbed uplands within the industrial site footprint and would not impact natural habitats. Shoreline improvements (e.g. cooling water intake structures), would likely be retired in place, however, if these structures are removed, restoration of the associated bankline would be conducted and would be a covered activity.

Aquatic Studies & Covered Species Monitoring

Mirant Delta is conducting, and will recurrently conduct, aquatic and covered species studies and monitoring, specifically involving data collection in the vicinity of the plants, in front of the intake and outfall structures, and within the cooling water system.

4.2.3.2.2 Activity

All maintenance, modification, de-commissioning, and monitoring described in this section that could affect species or modify critical habitat protected under ESA or CESA are covered activities, and the effects of those activities are addressed by the BDCP (see Chapter 3, *Conservation Strategy* and Chapter 5, *Effects Analysis*).

4.2.4 Habitat Restoration, Enhancement, and Management Activities

Habitat restoration, enhancement, and management activities are covered activities under BDCP include all actions that may be undertaken to implement the physical habitat conservation measures described in Chapter 3, *Conservation Strategy*. Types of actions necessary to implement habitat restoration and enhancement conservation measures are anticipated to include, but are not limited to:

- Grading, excavation, and placement of fill material;
- Breaching, modification, or removal of existing levees and construction of new levees;
- Modification, demolition, and removal of existing infrastructure (e.g., buildings, roads, fences, electric transmission and gas lines, irrigation infrastructure);

- Construction of new infrastructure (e.g., buildings, roads, fences, electric transmission and gas lines, irrigation infrastructure);
- Removal of existing vegetation and planting/seeding of vegetation;
- Controlling the establishment of nonnative vegetation to encourage the establishment of target native plant species; and
- Control of nonnative predator and competitor species (e.g., feral cats, rats, and nonnative foxes).

Habitat management actions include all activities undertaken to maintain the intended functions of protected, restored, and enhanced habitats over the term of the BDCP. Habitat management actions are anticipated to include, but are not limited to:

- Minor grading, excavation, and filling to maintain infrastructure and habitat functions (e.g., levee maintenance, grading or placement of fill to eliminate fish stranding locations);
- Maintenance of infrastructure (e.g., buildings, roads, fences, electric transmission and gas lines, irrigation infrastructure, fences);
- Maintaining vegetation and vegetation structure (e.g., grazing, mowing, burning, trimming); and
- Ongoing control of terrestrial and aquatic nonnative plant and wildlife species.

The scope of the physical habitat actions provided for under the BDCP is presented in Table 4-3. The extent of the habitat and natural communities conservation actions set out in this section reflects both an assessment of the long-term conservation needs of individual covered species (i.e., habitat function, quantity, connectivity, and distribution), and an analysis of existing and future constraints that could affect habitat conservation, including land surface subsidence, habitat values, and land use.

A primary conservation goal of the BDCP is to restore 80,000 acres of tidal habitat, riparian habitat, and new floodplain for the benefit of fish, wildlife, and plants and ecosystem processes in the Delta and Suisun Marsh. The BDCP physical habitat conservation program is organized geographically across the northern, eastern, southern and western regions of the Delta. It is also organized by habitat type, and temporally into near-term and a long-term implementation phases. The schedule for protection, enhancement, and restoration of physical habitat is described in Chapter 6, Implementation Plan. Protection, enhancement, and restoration of other natural communities and habitats would be undertaken in both the near-term and long-term implementation periods as described in Chapter 6, Implementation Plan. In the near-term, prior to completion of the tunnel/pipeline facility, the BDCP targets for habitat restoration include 14,000 acres of tidal habitat. Within 15 years, the goal is for tidal habitat restoration to reach 25,000 acres and riparian restoration to reach 400 acres and the addition of 1,000 acres of new seasonally inundated floodplain habitat. By year 40, the BDCP goal is to have established

65,000 acres of tidal habitat, 5,000[7] acres of riparian habitat, and 10,000 acres of new seasonally inundated floodplain.[8]

In the near-term BDCP implementation period, actions to restore tidal habitat and riparian habitats will likely be directed at the Cache Slough, West Delta, Cosumnes/Mokelumne and Suisun Marsh Restoration Opportunity Areas (ROAs) in Conservation Zones 1, 2, 4, 5 and 11 (see Figures 3-1 and 3-2). The initial focus on these locations reflects the anticipated productivity benefits that may be achieved in the near-term prior to changes to the existing through Delta conveyance system. These near-term elements of the habitat program will parallel adjustments in water management and flow regimes that are designed together to realize substantial improvements in aquatic productivity and function for covered species while the structural long-term improvements are constructed. Following commencement of dual water conveyance operations (i.e., the long-term BDCP implementation period), restoration of tidal and riparian habitat would continue in these Conservation Zones and would be expanded significantly into Conservation Zone 7.

Table 4-3. Extent of BDCP Natural Communities and Habitat Types Conserved Over the Term of the BDCP

*[**Note to reviewers:** Acreages provided are subject to change based on results of Effects Analysis and revisions to Conservation Strategy]*

Conserved Natural Community/Habitat Type	***Extent of Natural Community and Habitat Type Conserved***[1]		
	Protected[2]	**Enhanced**	**Restored**
Seasonally Inundated Floodplain	0	Increased frequency and duration of Yolo Bypass flooding[3]	10,000
Freshwater and Brackish Tidal, Subtidal, and Transition Habitats	0	0	65,000
Channel Margin	0	0	20 linear miles[7]
Riparian	0[4]	0	5,000[6]
Grassland	8,000[4]	0	2,000[5]
Nontidal Perennial Emergent Wetland and Nontidal Perennial Aquatic	0[4]	0	400
Alkali Seasonal Wetland Complex	400	0	0
Vernal Pool Complex	300	0	200
Managed Seasonal Wetland	0	TBD	TBD
Agricultural Habitat	16,620-32,640	0	0

[1]All values are in acres unless otherwise noted.
[2]Though not included in the *Enhanced* column, all protected natural communities/habitat types will also be managed to maintain or increase their habitat functions for covered species.
[3]Enhancement of the existing Yolo Bypass floodplain would be provided with operation of a modified Fremont Weir to increase the duration and frequency of seasonally inundated floodplain habitat. The conditions under which this increased inflow would be provided are described in conservation measure *CM2, Yolo Bypass Fisheries Enhancement.*
[4]An undefined additional extent of these natural communities/habitat types are likely to be protected in small patches where they occur within larger patches of other protected natural communities/habitat types (e.g., existing patches of riparian habitat within preserved agricultural lands would be protected).
[5]Some of the restored grassland may be restored within the transitional component of restored tidal habitat and thus the total land base required for grassland restoration may be less than shown.
[6]Riparian habitat restoration will all occur within the restoration lands for seasonally inundated floodplain, channel margin, and freshwater tidal areas.
[7]This could be up to 40 linear miles through the adaptive management process.

[7] Portions of the 5,000 acres of riparian would be included within the 10,000 acres of floodplain and 65,000 acres of tidal habitat.

[8] The 10,000 acre target for new floodplain restoration does not include floodplain habitat enhanced in the Yolo Bypass under a separate conservation measure.

4.2.5 Activities to Reduce Contaminants

Activities to reduce contaminants that could result in incidental take are covered activities under BDCP. A more detailed discussion of these activities is provided in Chapter 3. These activities include the following:

- **Control of Methylmercury Load in BDCP Restoration Sites -** The purpose of this measure is to minimize the methylation of inorganic mercury in BDCP habitat restoration areas caused by BDCP restoration actions. The BDCP Implementation Office will minimize to the extent practicable any increase in mercury methylation associated with habitat restoration conservation measures through the design and implementation of restoration projects. The BDCP Implementation Office will work with DWR and the Central Valley Regional Water Quality Control Board (CVRWQCB) to identify and implement methods for minimizing the methylation of mercury in BDCP restoration areas.

4.2.6 Activities to Reduce Predators and Other Sources of Direct Mortality

Activities to reduce predators and other sources of direct mortality that could result in incidental take are covered activities under BDCP. A more detailed discussion of these activities is provided in Chapter 3. These activities include the following:

- **Reduce Effects of Predators -** Reduce local effects of predators on covered fish species by conducting focused predator control in high predator density locations. The BDCP Implementation Office will reduce the local effects of predators on covered fish species by conducting focused predator control using a variety of methods in locations in the Delta that are known to have high densities of predators ("predator hot spots").
- **Non-physical Barriers -** The purpose of this conservation measure is to improve the survival of outmigrating juvenile salmonids by using non-physical barriers to re-direct them away from channels in which survival is lower. The BDCP Implementation Office will install non-physical barriers at the junction of channels with low survival of outmigrating juvenile salmonids to deter fish from entering these channels.
- **Control Nonnative Submerged and Floating Aquatic Vegetation in BDCP Tidal Habitat Restoration Areas -** The BDCP Implementation Office will control the growth of Brazilian waterweed (*Egeria densa*), water hyacinth (*Eichhornia crassipes*), and other nonnative submerged and floating aquatic vegetation (SAV and FAV) in BDCP tidal habitat restoration areas.

4.2.7 Monitoring and Research Programs

As described in Chapter 3, various types of monitoring activities will be conducted during BDCP implementation including preconstruction surveys, construction monitoring, compliance monitoring, effectiveness monitoring, and system monitoring. In addition, focused research will be undertaken or contracted to develop information necessary to better inform BDCP implementation. Such monitoring and research activities could result in incidental take and these activities are covered activities under BDCP. Though individual instances of take are expected to be minor, there are likely to be many such instances over a long period of time.

4.2.8 Other Conservation Actions

All other conservation actions included in Chapter 3, *Conservation Strategy*, that could result in incidental take, not described above, are covered activities. Although take levels are expected to be low, other conservation actions that could result in take of covered species and therefore require authorization as covered activities are included. Examples of actions include:

- **Dissolved Oxygen -** The purpose of this conservation measure is to maintain dissolved oxygen concentrations above levels that impair covered fish species in the Stockton Deep Water Ship Channel during periods when covered fish species are present. The BDCP Implementation Office will operate and maintain an oxygen aeration facility in the Stockton Deep Water Ship Channel to increase dissolved oxygen concentrations.
- **Conservation Hatcheries** - The purpose of this conservation measure is to establish new and expand existing conservation propagation programs for delta and longfin smelt. The BDCP Implementation Office will support: (1) the development of a delta and longfin smelt conservation hatchery by the USFWS to house a delta smelt refugial population and provide a source of delta and longfin smelt for supplementation or reintroduction, if deemed necessary by Fishery Agencies, and (2) the expansion of the refugial population of delta smelt and establishment of a refugial population of longfin smelt at the University of California, Davis Fish Conservation and Culture Laboratory to serve as a population safeguard in case of a catastrophic event in the wild.

4.2.9 Emergency Actions

The Plan covers emergency activities related to facilities constructed and operated under the BDCP and emergency activities within BDCP habitat conservation lands (including both restored and protected habitats) necessary to prevent and minimize the loss of human life, property, critical infrastructure, and sensitive natural resources. Emergency activities are the immediate response actions that may occur in response to such events as failure of water operations infrastructure, levee failure, fire, toxic or hazardous materials spills, or other natural disasters and accident response. By their nature, these events and the response actions to them cannot be planned for or directed to areas with less sensitive resources.

Emergency actions include, but are not limited to: initial temporary repair of water operations infrastructure; initial repair of structures damaged by flooding associated with levee failure where such repairs cannot be delayed due to the imminent loss of life or property; initial repair, replacement, and/or removal of damaged or failed structures and associated facilities; emergency fire fighting actions; temporary shoring-up of levees; emergency cleanup of spilled hazardous materials and/or waste; evacuation of injured persons or livestock; and use of motorized vehicles for conducting emergency activities.

Once an emergency has been addressed, the BDCP includes planned responses to deal with the aftermath of the emergency. Planned responses following emergency actions that have substantial effects on covered species or natural communities (e.g., vegetation rehabilitation after a major fire) are considered remedial actions to changed circumstances or adaptive management. Section 6.3.2 *Changed Circumstances* describes the required planned responses to levee failures, fires, failure of water operations infrastructure, toxic or hazardous spills, and other such events. Other planned responses may be conducted as part of the adaptive management process (Section 3.7, *Adaptive Management Program*).

4.3 Federal Actions Associated with the BDCP

The activities described in this section have been designated as "federal actions associated with the BDCP." These actions consist of CVP-related activities within the Delta that are authorized, funded, or carried out by Reclamation. These federal actions differ from "covered activities," which encompass those BDCP actions that are the responsibility of non-federal entities. The federal actions associated with the BDCP are subject to the ESA Section 7 consultation process; and as such, Reclamation will consult with USFWS and NMFS regarding the effect of these actions on listed species and designated critical habitat. For the federal actions set out in this section, the BDCP is intended to provide the basis for a biological assessment (BA) to support Section 7 consultations with the federal fish and wildlife agencies. Reclamation's actions that are outside the scope of the BDCP will be addressed as part of a consultation that covers the totality of CVP-related operations.

4.3.1 CVP Operations and Maintenance

This section describes actions by Reclamation related to the operations and maintenance of existing CVP facilities in the Delta that will be addressed in the BDCP.

The CVP's Delta Division[9] facilities within the Plan Area consist of the Delta Cross Channel (DCC); the eastern portion of the Contra Costa Canal, including the Contra Costa Water District's (CCWD) diversion facility at Rock Slough; the Jones Pumping Plant (formerly Tracy Pumping Plant); the Tracy Fish Collection Facility (TFCF); and the northern portion of the Delta Mendota Canal (DMC) (Figures 4-1 and 4-2). These CVP facilities are used to convey water

[9] The Delta Division is one of several CVP divisions covering various geographical areas and facilities of the CVP including the American River, Friant, East Side, Sacramento River, San Felipe, West San Joaquin, and Shasta/Trinity River divisions. The CVP Delta Division includes facilities within the Plan Area (described in this chapter) and facilities outside the Plan Area (not included in this chapter).

from the Sacramento River in the north Delta to the south Delta and to export that water from the Delta into canals and pipelines that carry it to agricultural and municipal and industrial (M&I) contractors to the south and west of the Delta. These facilities are integral components of the CVP and contribute to the functional capacity of the overall system. This section describes these facilities, their operational requirements, and the actions necessary to maintain their viability. The operation and maintenance of these facilities are not only integral to the water supply system, but are also important to the BDCP Conservation Strategy and the protection and conservation of the aquatic ecosystem and covered fish species.

The existing CVP facilities described in this section would be operated under both the BDCP near-term and long-term implementation, but with differing operating criteria following completion of new facilities. The BDCP near- and long-term operational criteria and adaptive operational range are described in Chapter 3, *Conservation Strategy*, and include descriptions of operations of CVP facilities in the Plan Area.

All operations and maintenance of CVP facilities described in this section are federal actions associated with the BDCP and the effects of those actions are addressed by the BDCP Conservation Strategy (see Chapter 3, *Conservation Strategy* and Chapter 5, *Effects Analysis*) and will be covered in the BDCP Section 7 consultation.

4.3.1.1 Delta Cross Channel

4.3.1.1.1 Background

The DCC is a gated diversion channel between the Sacramento River, near Walnut Grove, and Snodgrass Slough (Figure 4-1). Flows into the DCC from the Sacramento River are controlled by two 60-foot by 30-foot radial gates. When the gates are open, water flows from the Sacramento River through the cross channel to Snodgrass Slough and from there to channels of the lower Mokelumne River and into the central Delta. Once in the central Delta, the water is conveyed primarily via Old and Middle rivers to the Jones Pumping Plant by the draw of the pumps. The DCC operation improves water quality in the interior Delta by improving circulation patterns of good quality water from the Sacramento River towards Delta diversion facilities.

Reclamation operates the DCC in the open position to (1) improve the transfer of water from the Sacramento River to the export facilities at the SWP Banks (see description of SWP facilities) and CVP Jones pumping plants; (2) improve water quality in the southern Delta; and (3) reduce salt water intrusion rates in the western Delta. During the late fall, winter, and spring, the gates are often periodically closed to protect out-migrating salmonids from entering the interior Delta where they are subject to higher levels of predation and greater potential for entrainment at the CVP and SWP south Delta export facilities. When flows in the Sacramento River at Sacramento reach 20,000 to 25,000 cfs (on a sustained basis) the gates are closed to reduce potential scouring and flooding that might occur in the channels on the downstream side of the gates.

4.3.1.1.2 Action

See Chapter 3, *Conservation Strategy*, for a description of operations of the DCC gates under the BDCP to provide for protection of salmon in conjunction with water conveyance. Reclamation is seeking ESA Section 7 authorization for all operations and maintenance of the DCC consistent with BDCP operations conservation measures.

4.3.1.2 C.W. Jones Pumping Plant

4.3.1.2.1 Background

The CVP and SWP use the Sacramento River, San Joaquin River, and Delta channels to transport water to pumping plants located in the south Delta (Figures 4-1 and 4-2). The CVP's Jones Pumping Plant, about five miles northwest of Tracy, consists of six available pumps. The Jones Pumping Plant is located at the end of an earth-lined intake channel about 2.5 miles in length. Jones Pumping Plant has a physical capacity of 5,100 cfs and State Water Resources Control Board (Water Board) permitted diversion capacity of 4,600 cfs with maximum pumping rates typically ranging from 4,500 to 4,300 cfs during the peak of the irrigation season and approximately 4,200 cfs during the winter non-irrigation season until construction and full operation of the proposed DMC/California Aqueduct Intertie. The winter-time physical constraints on the Jones Pumping Plant operations are the result of a DMC freeboard constriction near O'Neill Forebay, O'Neill Pumping Plant capacity, and the current water demand in the upper sections of the DMC.

4.3.1.2.2 Action

See Chapter 3, *Conservation Strategy*, for description of south Delta operations of CVP and SWP under the BDCP to provide for protection of covered fish species in conjunction with water conveyance and diversion. Reclamation is seeking ESA Section 7 authorization on all operations and maintenance of the Jones Pumping Facility not otherwise restricted by the BDCP operating criteria.

4.3.1.3 Tracy Fish Collection Facility

4.3.1.3.1 Background

At the head of the intake channel leading to the Jones Pumping Plant, TFCF louver screens intercept fish that are then collected, held, and transported by tanker truck to Delta release sites away from the south Delta facilities. The TFCF uses behavioral barriers consisting of primary and secondary louvers to guide entrained fish into holding tanks. The primary louvers are located in the primary channel just downstream of the trashrack structure. The secondary louvers are located in the secondary channel just downstream of the traveling water screen. The louvers allow water to pass through onto the Jones Pumping Plant but the openings between the slats are tight enough and angled against the flow of water in such a way as to prevent most fish from passing between them and instead enter one of four bypass entrances along the louver arrays. The holding tanks on hauling trucks used to transport salvaged fish to release sites are injected with oxygen and contain an eight parts per thousand salt solution to reduce stress on fish. The CVP uses two release sites, one on the Sacramento River near Horseshoe Bend and the other on the San Joaquin River immediately upstream of the Antioch Bridge.

4.3.1.3.2 Action

See Chapter 5, *Effects Analysis*, for a description of the level of take associated with the operations of the TFCF. Reclamation is seeking ESA Section 7 authorization for all operations and maintenance of the TFCF consistent with the BDCP operating criteria.

4.3.1.4 Contra Costa Water District Diversion Facilities

4.3.1.4.1 Background

Contra Costa Water District (CCWD) diverts water from the Delta for irrigation and municipal and industrial (M&I) uses under CVP contract and under its own water rights. Under its CVP contract, CCWD can divert water at Rock Slough for direct use and divert water at its intake on Old River near State Route 4 (designated CCWD's Old River Intake) and its new intake on Victoria Canal near Middle River (designated CCWD's Middle River Intake) for either direct use or for storage. Under its own State Water Board permit and license, CCWD can divert water for direct use at Mallard Slough, and under its own Los Vaqueros water right permit, CCWD can divert water at its Old River and Middle River intakes for storage in Los Vaqueros Reservoir.

CCWD's water system includes intake facilities at Mallard Slough, Rock Slough, Old River, and Victoria Canal near Middle River (Middle River intake); the Contra Costa Canal and shortcut pipeline; Contra Loma Reservoir; the Martinez Terminal Reservoir; and the Los Vaqueros Reservoir. The Rock Slough intake facilities, the Contra Costa Canal, the shortcut pipeline, the Contra Loma Reservoir, and the Martinez Terminal Reservoir are owned by Reclamation, and operated and maintained by CCWD under contract with Reclamation. Mallard Slough Intake, Old River Intake, Middle River Intake (on Victoria Canal), and Los Vaqueros Reservoir are owned and operated by CCWD.

CCWD's operations are governed by Biological Opinions issued to Reclamation under separate Section 7 consultations (hereafter, "CCWD-specific BOs"). CCWD's operations are included in the project description and modeling for the long-term CVP/SWP operations Biological Assessment, which resulted in the current Biological Opinions on CVP/SWP operations (USFWS 2008; NMFS 2009). CCWD also has California Endangered Species Act take authorization for all its operations under a 2081 permit issued in 2009 by the California Department of Fish and Game.

Reclamation and CCWD are currently planning two projects to modify facilities: addition of a fish screen to the Rock Slough Intake and expansion of the Los Vaqueros Reservoir. For each of these projects, Reclamation, in coordination with CCWD, consulted with the USFWS and NMFS under Section 7, and CCWD, in coordination with Reclamation, has consulted with DFG.[10]

Rock Slough Fish Screen

The Rock Slough Intake is located about four miles southeast of Oakley, where water flows into the earth-lined portion of the Contra Costa Canal. This section of the canal is open to tidal influence and continues for four miles to Pumping Plant 1, which has capacity to pump up to 350 cfs into the concrete-lined portion of the canal. Prior to completion of the Los Vaqueros Project in 1997, this was CCWD's primary diversion point. Consistent with Central Valley Project Improvement Act (CVPIA) and as required by the USFWS Biological Opinion for the Los Vaqueros Project (USFWS 1993), Reclamation, in collaboration with CCWD, is in the process of constructing a fish screen at the Rock Slough intake. This project is covered by a separate ESA Section 7 consultation. With the completion of this project, all of CCWD's Delta intakes will include positive barrier fish screens. CCWD's other intakes (Mallard Slough, Old River and the new Middle River intake on Victoria Canal) are screened.

Los Vaqueros Reservoir Expansion Project

CCWD has certified the environmental documents for an expansion of Los Vaqueros Reservoir from its current 100,000 acre-feet to 160,000 acre-feet. CCWD is in the process of completing permits and final design, and expects to begin construction in 2011, with completion of the expansion in 2012. The expansion will improve CCWD water quality, water supply reliability and emergency storage, and will have the effect of shifting CCWD diversions from drier periods to wetter periods. The expansion will not increase CCWD overall diversions from the Delta or modify any Delta facilities; operation of the expanded reservoir will continue to be governed by existing CCWD-specific biological opinions. The expansion will impact terrestrial habitat and species within the Los Vaqueros watershed, which is outside of the Delta; CCWD and Reclamation are currently consulting with USFWS (under Section 7) to develop a biological opinion covering the terrestrial impacts, mitigation, and adaptive management, separate and independent from the BDCP Section 7 consultation.

4.3.1.4.2 Action

Reclamation would include CCWD's operations described above in the BDCP ESA Section 7 Biological Assessment as part of the existing operations. CCWD is not an ESA Section 10 permit applicant under BDCP, and operation of CCWD facilities will not change under the BDCP. However, all operations and maintenance of CCWD facilities described in this section that could affect species or modify designated critical habitat protected under ESA will be included in the analysis of Delta operations in the BDCP Section 7 Biological Assessment. This will ensure that existing and ongoing operations in the Delta are accurately analyzed in the consultation on the effects of the BDCP and CVP operations. If, as a result of the BDCP ESA Section 7 consultation, any of the criteria for reinitiation of consultation set forth in the CCWD-

[10] For the Los Vaqueros project, consultation has been initiated but not completed.

specific Biological Opinions are triggered, Reclamation and CCWD will reinitiate consultation under ESA Section 7.

4.3.1.5 Central Valley Project Diversions

4.3.1.5.1 Background

The volume of water delivered by the CVP is and will continue to be variable, but in any year will be equal to the amount of water that is hydrologically available and that can be diverted under current contractual rights consistent with the terms and conditions of the BDCP Conservation Strategy and then-existing permits and regulations. Reclamation delivers water transported through facilities in the Delta to senior water rights contractors, long-term CVP water service contractors, refuges and waterfowl areas, and temporary water service contractors south of the Delta. The total volume under contract, including Level 2 refuge supplies, is approximately 3.3 MAF. Additionally, the CVP provides Level 4 refuge water totaling approximately 100,000 AF. In addition, as part of the San Joaquin River Restoration Program implementation, Reclamation anticipates submitting a petition to add a point of diversion to the State Water Board to allow re-diversion of the restoration flows either upstream of or in the Delta. Moreover, in wet hydrologic conditions when CVP storage is not available, Delta is in excess conditions, water is made available under temporary contracts for direct delivery. The volume of water available for conveyance through the Delta is a result of hydrologic conditions, upstream reservoir operations, upstream demands, regulatory constraints on CVP operations, and from transfers of water from upstream water users to south of Delta water users.

4.3.1.5.2 Action

See Chapter 3, *Conservation Strategy*, for description of near-term and long-term operations and adaptive range of CVP and SWP under the BDCP to provide for protection of covered fish species in conjunction with water conveyance and diversion. All CVP diversions described in this section are federal actions associated with the BDCP, and the effects of those actions are addressed by the BDCP (see Chapter 3, *Conservation Strategy* and Chapter 5, *Effects Analysis*) and will be covered in the BDCP Section 7 consultation. Water passing through the Delta associated with water transfers (e.g., Drought Water Bank and Dry Year Water Purchase Programs) is also a covered action. Reclamation is seeking ESA Section 7 authorization for all CVP diversions consistent with the BDCP operating criteria.

4.3.1.6 Associated Maintenance and Monitoring Activities

4.3.1.6.1 Background

Maintenance and replacement means those activities that maintain the capacity and operational features of the existing CVP water diversion and conveyance facilities described above including the DCC, Jones Pumping Plant, TFCF, and Contra Costa Diversion Facilities. Maintenance activities include maintenance of electrical power supply facilities; maintenance as needed to ensure continued operations and replacement of facility or system components when necessary to maintain system capacity and operational capabilities; and upgrades and technological improvements of facilities to maintain system capacity and operational capabilities.

Monitoring activities refers to those actions necessary for monitoring water quality and fisheries as conditioned by water rights permits and biological opinions, those actions undertaken as a result of the CVPIA and agreements, and any additional monitoring under the BDCP as described in Chapter 3, *Conservation Strategy*, for which Reclamation is responsible. These actions include routine daily, annual or other periodic sampling of water quality constituents as well as trawls for various fish species in the Delta (including actions associated with the Interagency Ecological Program). Reclamation currently operates and maintains more than 20 monitoring stations in the Delta which provide near-realtime water quality data. As the BDCP Conservation Strategy is implemented, the nature of, and requirements for, monitoring would be expected to change.

4.3.1.6.2 Action

All CVP maintenance and monitoring described in this section are federal actions associated with the BDCP, and the effects of those actions are addressed by the BDCP (see Chapter 3, *Conservation Strategy* and Chapter 5, *Effects Analysis*) and will be covered in the Section 7 consultation.

4.4 JOINT FEDERAL AND NON-FEDERAL ACTIONS

This section describes activities that will be carried out jointly by DWR and Reclamation. These actions are categorized as covered activities under ESA Section 10 and NCCPA Section 2835 for DWR because of DWR's involvement in these joint actions. The activities identified in this section for federal actions by Reclamation are not "covered activities" for the purposes of the ESA Section 10(a)(1)(b) permit. These federal actions are actions that occur within the Delta which will be coordinated with DWR to support DWR's compliance with the ESA Section 10 permit. Reclamation's activities are subject to ESA Section 7, and Reclamation will consult under ESA Section 7 on those actions. The Section 7 consultation will also include other CVP operations that are not within the Plan Area.

4.4.1 Joint Point of Diversion Operations

4.4.1.1 Background

Under State Water Board Decision 1641 (D-1641) (December 1999; revised March 2002), Reclamation and DWR are authorized to use/exchange diversion capacity between the Projects to enhance the beneficial uses of both Projects. The use of one Project's diversion facility by the other Project is referred to as the Joint Points of Diversion (JPOD). There are a number of requirements in D1641 that restrict JPOD to protect water quality and fishery resources.

In general, JPOD capabilities are used to accomplish four basic CVP-SWP objectives:

- When wintertime excess pumping capacity becomes available during Delta excess conditions and total CVP-SWP San Luis storage is not projected to fill before the spring pulse flow period, the project with the deficit in San Luis storage may elect to use JPOD capabilities.
- When summertime pumping capacity is available at Banks Pumping Plant and CVP reservoir conditions can support additional releases, the CVP may elect to use JPOD capabilities to enhance annual CVP south of Delta water supplies.
- When summertime pumping capacity is available at Banks or Jones Pumping Plant to facilitate water transfers, JPOD may be used to further facilitate the water transfer.
- During certain coordinated CVP-SWP operation scenarios for fishery entrainment management, JPOD may be used to shift CVP-SWP exports to the facility with the least fishery entrainment impact while minimizing export at the facility with the most fishery entrainment impact.

4.4.1.2 Activity/Action

All in-Delta JPOD operations are included as either covered activities or federal actions associated with the BDCP and the effects of those activities/actions are addressed by the BDCP (see Chapter 3, *Conservation Strategy* and Chapter 5, *Effects Analysis*). Those actions associated with Reclamation will receive authorization through the ESA Section 7 consultation process and those actions associated with DWR will be covered under ESA Section 10 permits and Section 2835 permits issued pursuant to the NCCPA.

4.4.2 Operations of New Water Intake and Conveyance Facilities

4.4.2.1 Background

DWR would own and operate the new intake and conveyance facilities and their operations would be covered activities as described in Section 4.2.2, *New Facilities Construction, Operation, and Maintenance*. Reclamation and/or the CVP Contractors would enter into agreements to wheel CVP water through the new facilities and this action by Reclamation would be an associated federal action.

4.4.2.2 Activity/Action

All operations of new intake and conveyance facilities are included as either covered activities or federal actions associated with the BDCP and the effects of those activities/actions are addressed by the BDCP (see Chapter 3, *Conservation Strategy* and Chapter 5, *Effects Analysis*). Those actions associated with Reclamation will receive authorization through the ESA Section 7 consultation process and those actions associated with DWR will be covered under ESA Section 10 permits and Section 2835 permits issued pursuant to the NCCPA.

4.4.3 Transfers

4.4.3.1 Background

State and federal laws enacted governing water use in California promote the use of water transfers to manage water resources, particularly water shortages, provided that certain conditions of transfer are adopted to protect source areas and users. Transfers requiring export from the Delta are conducted at times when pumping and conveyance capacity at the CVP or SWP export facilities is available to move the water. Additionally, operations to accomplish these transfers must be carried out in coordination with CVP and SWP operations, such that the capabilities of the Projects to exercise their own water rights or to meet their legal and regulatory requirements are not diminished or limited in any way.

CVP and SWP contractors have independently acquired water and arranged for its pumping and conveyance through SWP facilities. State Water Code provisions grant other parties access to unused conveyance capacity, although SWP contractors have priority access to capacity not being used by DWR to meet SWP contract amounts.

4.4.3.2 Activity/Action

Delta operations involving water passing through the Delta associated with water transfers are covered activities and federal actions, however, the effects on place of origin and use are not proposed for coverage. The effects of Delta water operations, including transfers, are addressed in Chapter 5, *Effects Analysis*.

4.4.4 Suisun Marsh Facilities Operations and Maintenance

4.4.4.1 Background

The existing Suisun Marsh facilities consist of:

- Suisun Marsh Salinity Control Gates;
- Morrow Island Distribution System;
- Roaring River Distribution System;
- Goodyear Slough Outfall; and
- Various salinity monitoring and compliance stations throughout the Marsh.

Since the early 1970s, the California Legislature, State Water Board, Reclamation, DFG, Suisun Resource Conservation District (SRCD), DWR, and other agencies have engaged in efforts to preserve beneficial uses of Suisun Marsh to mitigate for potential impacts on salinity regimes associated with reduced freshwater flows to the marsh. Initially, salinity standards for Suisun Marsh were set by the State Water Board's Decision 1485 to protect alkali bulrush production, a primary waterfowl plant food. Subsequent standards set under the State Water Board's Decision-1641 reflect the intention of the State Water Board to protect multiple beneficial uses. A contractual agreement between DWR, Reclamation, DFG and SRCD includes provision for measures to mitigate the effects of SWP and CVP operations and other upstream diversions on Suisun Marsh channel water salinity. The Suisun Marsh Preservation Agreement requires DWR and Reclamation to meet specified salinity standards, sets a timeline for implementing the Plan of Protection, and delineates monitoring and mitigation requirements.

The existing operation of the Suisun Marsh Facilities is covered for ESA and CESA compliance under the OCAP biological opinions and the related consistency determination. The Suisun Marsh Facilities will be covered under the BDCP for existing operations criteria and for future criteria discussed below.

The BDCP includes conservation actions that will change land use and water operations in Suisun Marsh over time. These changes in land use and water operations are covered activities and are addressed by the BDCP. See Chapter 3, *Conservation Strategy*, for descriptions of tidal brackish marsh restoration (CM4 *Tidal Habitat Restoration*) and water operations (CM1 *Water Facilities Operation)*. The existing operation and maintenance of the Suisun Marsh Salinity Control Gates and other facilities would not change until BDCP actions require changes in their operation. Operations of the Suisun Marsh Facilities under the existing operational criteria, as well as changes to operation as described in CM1 would be covered by BDCP. Generally, as habitat restoration in Suisun Marsh is conducted with the implementation of BDCP conservation measures, and changes in land uses occur, the operation of the Suisun Marsh Salinity Control Gates will trend towards limiting the operation of the gates and increasing the period during which the gates allow tidal inflows into Montezuma Slough to provide for the conservation of covered fish species in conjunction with all other water operations under BDCP.

4.4.4.2 Activity/Action

The BDCP covers operations of the Salinity Control Gates and other Suisun Marsh facilities under the existing and future operational criteria and future construction and maintenance of tidal habitat in Suisun Marsh identified in CM 1 and CM 4 in Chapter 3, *Conservation Strategy*. These activities/actions are included as covered activities and associated federal actions and the effects of those activities/actions are addressed by the BDCP (see Chapter 3, *Conservation Strategy* and Chapter 5, *Effects Analysis*). Those actions associated with Reclamation will receive authorization through the ESA Section 7 consultation process and those actions associated with DWR will be covered under ESA Section 10 permits and Section 2835 permits issued pursuant to the NCCPA.

CHAPTER 5. OVERVIEW OF THE EFFECTS ANALYSIS

*[**Note to Reviewers:** The Effects Analysis is currently underway and expected to be completed in early 2011 and is an iterative process. This chapter is a summary of an initial draft of the Effects Analysis and has not been read or reviewed by the Steering Committee. It is the consultant's work product and provides their overview of the Effects Analysis: its development and context; a brief description of the methodologies used; the current status of the Effects Analysis; and the summary of preliminary findings presented in the August 19, 2010 Working Draft and the September 9, 2010 draft enhanced habitat analysis for covered fish species. These preliminary findings are subject to modification as the revised analyses are being completed.]*

This draft is a high level summary that captures the consultant's view of where the effects analysis is as of September 9, 2010. It does not include subsequent findings of the technical "theme teams" or other comments that were developed in the weeks preceding this draft.

Notwithstanding any text to the contrary in this chapter, the Effects Analysis is a work in progress and continues to be reviewed by the technical staff of the Steering Committee representatives and will be revised. To date, several issues have been identified that may necessitate changes to the conservation strategy or initial long-term operating criteria. These include (but are not limited to):

- *North Delta intake configuration related to predation concerns (in-river vs on-bank)*
- *Spring-run salmon egg mortality on the Sacramento River in the fall*
- *Reduced Sacramento River flows downstream of the North Delta intakes*
- *Refinement of April-May south Delta operations*
- *Winter-spring X2 and outflow effects on longfin smelt*
- *Summer and fall X2 and delta smelt abiotic habitat*

The Effects Analysis process has begun to evaluate how modifications to some of the conservation measures, including initial long-term operating criteria (see CM1 Note to Reviewers) might address some of these issues in a manner that provides a refined approach to fishery protection while being sensitive to the water supply goals. This will lead to an iteration process involving the Oversight Committee and Steering Committee that will take place for the purpose of describing the final conservation strategy and the initial long-term operating criteria for complete evaluation in the effects analysis. Also, as part of this process, an adaptive range for the operational criteria will be developed.

Further, the theme teams and the Effects Analysis Oversight Team will continue to meet to address and resolve technical comments about the methods used in the analysis, as described in Section 5.3.1. The analysis will be revised once those comments are resolved.

Finally the Steering Committee will further consider whether the results can support a conservation strategy that meets the biological goals and objectives of the BDCP.]

5.1 INTRODUCTION

An effects analysis is the principal analytical component of a habitat conservation plan. It presents conclusions regarding the expected outcomes of the conservation strategy and covered activities. The analysis includes the effects of the proposed project on covered species, including federally and state listed species, and other sensitive species potentially affected by the proposed project. The effects analysis is a systematic, scientific look at the potential impacts of a proposed project on these species and how these species would benefit from conservation actions.

This effects analysis provides a description of the outcomes of the BDCP Conservation Strategy (Chapter 3) and covered activities (Chapter 4). The BDCP is being developed to promote the recovery of endangered, threatened, and sensitive fish and wildlife species and their habitats in the Sacramento-San Joaquin Delta in a way that will also protect and restore water supplies.

As described in Chapter 3, the Delta was once a vast marsh and floodplain intersected by meandering channels and sloughs that provided habitat for a rich diversity of fish, wildlife, and plants. The Delta of today is a system of artificially channeled and dredged waterways constructed into static geometries, initially designed to support farming, and later, limited urban development on Delta islands; to protect against flooding; and to convey water supplies to cities and farms in the Bay Area, San Joaquin Valley and southern California. The physical disturbances within the Delta, the introduction of nonnative species that have disrupted the foodweb, along with multiple other environmental challenges to the ecosystem have contributed to declines in fish, wildlife, and plant species and other organisms. In recent years, these factors have caused a significant drop in the population of key native fish species, which has triggered major reductions in water supply.

Developing the effects analysis is challenging because of the scale of changes to the Delta ecosystem proposed in the BDCP Conservation Strategy. The approach embodied in the conservation strategy reflects a significant departure from the manner in which at-risk Delta fish and wildlife species and their habitats have been managed in the past. The BDCP approach seeks to contribute to the restoration of the health of the ecological systems in the Delta by focusing on ecological functions and processes on a broad landscape scale. Proposed actions would result in fundamental, systemic, long-term physical changes to the Delta, such as substantial alterations to water conveyance infrastructure and water management regimes and extensive restoration of tidal, floodplain, and terrestrial habitats. Addressing such fundamental and large-scale change has necessitated the use of a broad and complex analysis that has derived new analytical tools and an expansion in ways of looking at the Delta system and its species.

The effects analysis is built on and reflects the extensive body of scientific investigation, study, and analysis of the Delta compiled over several decades (see The State of Bay-Delta Science 2008), including the results and findings of numerous studies initiated under the CALFED Bay-Delta Science Program and Ecosystem Restoration Program, the long-term monitoring programs conducted by the Interagency Ecological Program, research and monitoring conducted by state and federal resource agencies, and research contributions of academic investigators. To ensure that the BDCP would be based on the best scientific and commercial data available, the BDCP Steering Committee also undertook a rigorous process to develop new and updated information and to evaluate a wide variety of issues and approaches as it formulated a cohesive, comprehensive Conservation Strategy. This effort included an evaluation in early 2009, conducted by multiple teams of experts, of BDCP conservation options using the CALFED Bay-Delta Ecosystem Restoration Program's Delta Regional Ecosystem Restoration Implementation Plan (DRERIP) evaluation process. Implementation of the DRERIP evaluation process pulled together a large group of scientific experts on various aspects of the Delta ecosystem and its species and the information generated from the process provided some of the most advanced thinking on the effects of conservation actions on key ecological stressors. Results of this DRERIP evaluation were used, as applicable, to add support to various parts of the BDCP effects analysis.

Over 60 species, 14 natural communities, and a broad range of ecological stressors are analyzed in this effects analysis. Some of the species evaluated spend all or most of their lives in the Delta; others spend only portions of their lives navigating their way through various parts of the Delta via the water, land, or air. It is important to consider the effects of the BDCP on each species over the whole of its life span, not just during individual life stages.

The aquatic effects analysis begins with an evaluation of how specific identified stressors could potentially affect the various components of the ecosystem. The results of this analysis are used in the analysis of individual fish species that is described in individual sections that follow and address specific covered fish species. The terrestrial effects analysis begins with an analysis of the effects of BDCP actions on natural communities in the Delta. Similar to the use of the stressors analysis in the analyses of covered fish species, the results of the analysis of natural communities is used in analyzing the effects on specific covered wildlife and plants that follow. Each wildlife and plant species is assessed individually for the effects of BDCP actions and the overall expected outcome for each species is summarized.

The analysis for each evaluation period is based on the physical and biological conditions anticipated to be present with implementation of the BDCP actions at the end of each of the timeframes described in the conservation measures in Chapter 3, *Conservation Strategy*, and the implementation schedule in Chapter 6, *Plan Implementation*. The effects of climate change (e.g., sea level rise, temperature, and hydrology) were evaluated for early and late points in time of BDCP implementation based on climate change scenarios developed by the consultant team, technical staff from the lead agencies, and outside climate change experts (see Appendix K, *Climate Change Evaluation Methods*, for a discussion of this analysis).

The remainder of this section provides descriptions of the effects analysis regulatory scope, spatial scope, actions evaluated, existing biological conditions, temporal scope, and approach to the analysis.

5.1.1 Regulatory Scope

The effects analysis is designed to address the requirements of federal Endangered Species Act (ESA) sections 10 and 7 and California Natural Community Conservation Planning Act (NCCPA). Section 10 of the ESA requires that habitat conservation plans identify the impacts likely to result from the proposed taking of federally listed threatened and endangered species. Section 7 of the ESA requires a biological assessment be prepared that identifies the effects on all federally listed threatened and endangered species likely to be affected by a federal action. Section 7 of the ESA requires the effects analysis to evaluate all direct and indirect effects, including the effects of interrelated and interdependent actions, on federal threatened and endangered species and designated critical habitat[1]. The NCCPA requires that plans provide for the conservation of covered species and natural communities.

The analysis addresses both federal and non-federal actions. Federal actions include all actions by Reclamation, USFWS, and NMFS in the Plan Area and Central Valley Project (CVP) actions upstream of the Delta that are interrelated and interdependent with BDCP actions. Chapter 4, *Covered Activities*, includes descriptions of federal actions in the Plan Area. Federal actions upstream of the Plan Area are described in the BDCP Biological Assessment *[**Note to Reviewers** – the BDCP Biological Assessment is expected to be prepared by Reclamation in 2011 and would include a description of all CVP and Joint CVP/SWP actions that change as a result of BDCP implementation]*. Non-federal actions are all actions of the permit applicants under Section 10 of the ESA permits and Section 2835 of the NCCPA permit in the Plan Area, including changes in SWP operations upstream of the Delta that result from BDCP actions.

This effects analysis may also serve as part of the foundation for state and federal permitting and approvals that will be needed from agencies such as the US Army Corps of Engineers (USACE), US Environmental Protection Agency (EPA), and State Water Resources Control Board (SWRCB) prior to implementing the conservation plan.

5.1.2 Spatial Scope

The analysis addresses the effects of BDCP implementation on covered species, designated critical habitat, and essential fish habitat in the Plan Area[2], upstream Delta tributaries, CVP and State Water Project (SWP) reservoirs, and downstream of the Plan Area. The analysis addresses the effects on NCCP natural communities for the Plan Area and upstream and downstream of the Plan Area if natural communities could be affected by changes in water operations. The Effects Analysis addresses all effects of BDCP implementation on all covered species[3] in the "action

[1] *Effects* of the action refers to the direct and indirect effects of an action on the species or critical habitat, together with the effects of other activities that are interrelated or interdependent with that action, that will be added to the environmental baseline… *Indirect* effects are those that are caused by the proposed action and are later in time, but still are reasonably certain to occur. *Interrelated actions* are those that are part of a larger action and depend on the larger action for their justification. *Interdependent actions* are those that have no independent utility apart from the action under consideration. (50 CFR 402.02)

[2] The Plan Area includes the legal Delta (as defined in California Water Code section 12220) Suisun Marsh, and the Yolo Bypass (see Chapter 1 *Introduction* for description and map location of Plan Area).

[3] The southern resident killer whale is not a BDCP proposed covered species but is evaluated in the Effects Analysis because it is a listed species that is potentially indirectly effected by BDCP actions

area" as defined under ESA regulations[4]. For information on Plan Area boundaries and the distribution of biological resources within the Plan Area and in relevant upstream and downstream locations see Chapter 2, *Existing Ecological Conditions* and Appendix A, *Covered Species Accounts*.

5.1.3 Actions Evaluated

The analysis evaluates the construction of a new water diversion, isolated conveyance and other water-related facilities, operations of current system components, dual operations of current and proposed facilities, power plant operations, physical habitat restoration, protection and enhancement of existing habitats, control of nonnative species, and other actions described in Chapter 3, *Conservation Strategy*, that address ecological stressors on the system and covered species. Assumptions used in this analysis regarding the footprint locations of new conveyance facilities and descriptions of construction-related activities (e.g., construction schedule, construction methods) and maintenance activities and schedules for new facilities have been provided by DWR. Full descriptions of conservation measures evaluated in the Effects Analysis are in Chapter 3, *Conservation Strategy*. Full descriptions of covered activities evaluated in the Effects Analysis are in Chapter 4, *Covered Activities*.

5.1.4 Existing Biological Conditions

The effects analysis evaluates how conservation measures and covered activities result in changes to the existing biological conditions of the covered species and natural communities. Existing biological conditions for natural communities are described in Chapter 2, *Existing Ecological Conditions* and for covered species in Appendix A, *Covered Species Accounts*. The Effects Analysis evaluates the aggregate effect on covered species of the environmental baseline[5] and the implementation of the BDCP.

5.1.5 Temporal Scope

Implementation of the BDCP is divided into two periods: 1) the "Near-Term" implementation period is defined as the period before the North Delta Diversion Facilities become operable (i.e., through-Delta conveyance operations only) and 2) the "Long-Term" implementation period is defined as the period after the North Delta Diversion Facilities become operable (i.e., dual conveyance operations). The effects analysis assesses the outcomes for covered species and natural communities at three timeframes over the term of the BDCP:

[4] *Action area* means all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action. (50 CFR 402.02)

[5] Under ESA regulations, the *environmental baseline* includes the past and present impacts of all Federal, State, or private actions and other human activities in the action area, the anticipated impacts of all proposed Federal projects in the action area that have already undergone formal or early section 7 consultation, and the impact of State or private actions which are contemporaneous with the consultation in process. (50 CFR 402.02)

1. Near-Term (NT) Evaluation Period: Effects from BDCP authorization through approximately 10 years following approval (i.e., conditions during the period prior to completion of construction of a new isolated conveyance facility and dual operations);

   *[**Note to Reviewers**: There are currently no proposed BDCP near-term water operational criteria; therefore, the analysis is based on a continuation of the SWP and CVP operations under existing authorizations. The effects of near term actions were evaluated for all covered wildlife and plant species. For covered fish species, the NT period is not called-out separately in the evaluation of operations (since operations are assumed not to change from EBC), but NT effects on fish are evaluated for facilities construction (i.e., intake structures). While overall habitat restoration effects on covered fish species are included in this document, the more limited effects on fish of NT habitat restoration will be provided in the evaluation currently underway.]*

2. Early Long-Term (ELT) Evaluation Period: Effects from approximately 10 years following BDCP authorization through approximately 15 years following authorization (approximately 5 years after initiation of dual operations); and

3. Late Long-Term (LLT) Evaluation Period: Effects from approximately 15 years following BDCP authorization through 50 years following authorization (the end of the permit terms).

The analysis for each evaluation period is based on the physical and biological conditions anticipated to be present with implementation of the BDCP actions at the end of each of the timeframes as described in the conservation measures in Chapter 3, *Conservation Strategy* and the implementation schedule in Chapter 6, *Plan Implementation*. The effects of climate change (e.g., sea level rise, temperature and hydrology) on conditions within each timeframe were evaluated for the early long-term and late long-term timeframes based on climate change scenarios developed by the consultant team, technical staff from the lead agencies, and outside climate change experts (see Appendix K, *Climate Change Evaluation Methods*).

5.1.6 Approach to the Analysis

The BDCP Effects Analysis utilized a broad range of analytical tools including hydrologic and hydrodynamic models; temperature models; biological models for different life stages of covered fish species; statistical relationships between physical conditions and covered fish species; conceptual models for ecological conditions and individual fish species; and habitat models for fish, wildlife, and plants. Some of these models were created and used for the first time in this analysis. The methods used were developed in collaboration among technical experts from USFWS, NMFS, DFG, Reclamation, and DWR and other experts on specific species addressed and analytical tools used.

The specific location of and details of implementation approaches to most of the BDCP conservation measures are not known and will not be known until BDCP is implemented through an adaptive management process. As such, the level of adverse and beneficial effects on biological resources were evaluated using reasonable assumptions regarding the potential location and implementation approaches that could be applied during BDCP implementation. Major types of assumptions used in the analysis are listed in Section 5.3.1.2.

The analysis was conducted using an ecologically scaled hierarchy. Changes to aquatic ecosystem-level functions (e.g., flow, hydrodynamics, physical habitat restoration, food web dynamics, toxic contaminants, and salinity) that are relevant to multiple fish species were evaluated first. The results of these analyses were then used in the individual covered fish species evaluations along with species-specific evaluation tools. In similar fashion, effects on natural communities (e.g., estimating the extent of effects and effects on ecological processes, gradients, and habitat function) were evaluated and the results were then used in the evaluation of covered wildlife and plant species along with species-specific evaluation tools.

Covered fish species were evaluated using a broad range of available tools and best professional judgment. Fish species were evaluated by specific life stages (e.g., egg/embryo, larvae, juvenile, adult) and then the effects on all life stages were combined to synthesize a summary conclusion of population and species level effects. In many cases, more than one tool or approach was used to assess the effect of an ecological stressor on a fish species, providing a better understanding the full range of potential outcomes and adding greater certainty to conclusions. Where there was uncertainty regarding the use of an analytical tool or approach, the strengths and weaknesses of the tool or approach were described.

Covered wildlife and plant species were evaluated mainly through the use of occurrence data and geographic information system (GIS) based models of potentially suitable habitat developed specifically for the BDCP. GIS was used extensively in spatially identifying the location of existing species habitat and of proposed BDCP actions and in calculating the extent of overlap between them. GIS proximity models were also developed and used to estimate disturbance effects of covered activities on specific wildlife and plant species.

The analysis provides an estimate of effects on:

- covered species, where possible at the individual, population, and species levels, including estimates of take;

  *[**Note to Reviewers**: Estimates of take have not been completed for covered fish species.]*

- designated critical habitat;
- natural communities;
- Essential Fish Habitat (EFH)[6].

Conclusions of the effects analysis are predictions based on current knowledge which has many gaps and uncertainties. As a result, the level of scientific uncertainty is identified throughout the methods, results, and conclusions discussions.

[6] Under the Magnuson-Stevens Act, essential fish habitat for federally managed fish species is defined as "those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity." Chinook salmon are the only BDCP covered species identified for management under this Act.

Climate change is an important factor in predicting the future biological conditions in the Delta ecosystem and for covered species. The evaluation includes modeling of a range of possible climate change outcomes for hydrology, sea level, and water temperature. Climate change projections are included in the analysis as part of the aggregate effect of existing biological conditions and the proposed BDCP on covered species. The analysis includes the evaluation of a future with climate change but without implementation of BDCP to separate the effect of the BDCP on ecological processes and species from the effects of climate change.

For each covered species, the summary conclusions consider the viability factors of abundance, spatial distribution, population growth, and genetic diversity, along with the level of uncertainty, in predicting the expected outcome.

5.2 STATUS OF THE EFFECTS ANALYSIS

The full effects analysis was initiated in early February 2010, after several years of discussions and evaluations culminated in a set of conservation measures and long-term water operations approved for purposes of analysis by the BDCP Steering Committee on January 29, 2010.

Discussions directly related to performance of the effects analysis were informally conducted prior to June 2009 as consultants and federal (NMFS, USFWS, and Reclamation) and state (DWR and DFG) agency staff began to formulate an approach to evaluate effects of the BDCP. The basic approach to performing the effects analysis was developed between June and November 2009. During this time, the consultants worked with federal and state agency staff to discuss an approach to a combined effects analysis that would be used in preparation of the following documents:

- BDCP HCP/NCCP;
- BDCP EIR/EIS biological resources section;
- BDCP biological assessment; and
- USFWS and NMFS biological opinions.

A “mini-effects analysis” for the covered fish species was conducted between November 2009 and January 2010 with the charge of identifying major issues in the proposed conservation strategy being considered at that time and elevating these issues to the BDCP Steering Committee. The mini-effects analysis evaluated the effects of proposed water operations and a set of proposed habitat restoration and other stressors conservation measures identified at Steering Committee meetings during summer and fall 2009. The analysis process was directly overseen by the Effects Analysis Managers, a group of policy-level individuals initially from the five federal and state agencies and PREs, and later joined by NGOs. The mini-effects analysis evaluated the effects of the BDCP only on covered fish species and was divided into three interactive groups: foodweb and water quality, anadromous fish, and pelagic fish. These groups were composed of technical experts that were selected by Effects Analysis Managers from agencies, NGOs, PREs, and consultants. The analysis process consisted primarily of weekly meetings of each group to discuss and document the effects of proposed actions on the covered fish species. Between meetings, group members conducted analyses and wrote results, and presented their findings at the next meeting. The results were documented as a set of tables for each species that were organized by lifestage and stressor.

The results of the mini-effects analysis were discussed at Steering Committee meetings in January 2010. While the mini-effects analysis concluded that the project was mostly beneficial, several areas of scientific disagreement were identified. As a result, the Steering Committee made minor revisions to the proposed conservation strategy.

Early in February 2010, the full effects analysis was initiated to evaluate the revised Conservation Strategy, with the exception of the near-term operational criteria, which were still under development. The full effects analysis includes the evaluation of the BDCP on covered fish, plant, and wildlife species as well as covered natural communities. Methodologies for the analyses were discussed with technical experts from federal and state agencies, NGOs, and PREs through June 2010. Preliminary results of these analyses were presented to Effects Analysis Managers between May and July. Preliminary results of the effects analysis for covered wildlife and plant species and natural communities were also presented at the July 15, 2010 Steering Committee meeting. The Working Draft Effects Analysis was delivered to the Effects Analysis Managers on August 19, 2010.

The five agencies (NMFS, USFWS, Reclamation, DFG, and DWR) reviewed the August 19, 2010 Effects Analysis. The consultants reviewed and are addressing comments that were provided to them in writing; and entered into extensive discussions with the agencies, PREs, and NGOs regarding areas of significant scientific disagreement. In an effort to reach resolution regarding areas of scientific disagreement, a series of “theme team” meetings occurred during September and October 2010.

Two “theme teams” were established, one for anadromous fish and one for pelagic fish species. These “theme team” meetings included technical staff from each of the agencies and the consultant team, and were joined by representatives from the PREs and NGOs. These teams were overseen by an Oversight Committee whose composition included the BDCP Management Team and managers from the each of the five agencies, PREs and NGOs. Each meeting was led by three managers, one from the federal agencies, one from the state agencies, and one from the consultant team. The three managers reported regularly to the Oversight Committee regarding the status of the scientific discussions at the “theme team” meetings.

The charge to the “theme teams” was to air and resolve major issues with the effects analysis. Issues that could not be resolved within the “theme team” process, either because of significant technical disagreement or because the issues required policy-level decisions, were to be elevated to the Oversight Committee for additional discussion and resolution by high level agency managers. In late October, a new process evolved as the Oversight Committee began to discuss possible refinements to the BDCP Conservation Strategy based on the review of the aquatic effects analysis and subsequent “theme team” discussions and efforts. The “theme team” process will continue in the future.

To date, the following six items have been identified as requiring further consideration and evaluation by the Effect Analysis Oversight Committee. These are the first six items identified and others may be identified.

1. **North Delta intake configuration**
   Near-shore, in-river intakes in the north Delta create increased predator habitat. This is predicted to have large predation effects on juvenile salmonids. An onshore intake design will greatly reduce the adverse effects of predation of the design evaluated in the effects analysis. A decision was made at the November 10, 2010 Oversight Committee meeting to analyze an on-bank configuration for the January 31, 2011 Draft Effects Analysis. Refinements to the locations and sizes of intakes are also under consideration.

2. **Increased spring-run salmon egg mortality**
   Approximately 10 percent of the spring-run Chinook salmon population spawns in the Sacramento River. Preliminary modeling results indicate that water temperatures could potentially cause a 10 percent increase in spring-run Chinook salmon egg mortality during wet, below normal, and above normal water year types for the 10 percent of the population that spawns in the Sacramento River.

3. **Reduced Sacramento River flows downstream of the intakes**
   Flows are reduced downstream of the north Delta diversion facilities during spring, summer, and fall in wet, above normal, and below normal water years. This may have an effect on migratory cues of adult anadromous fish species, and possibly increase straying into other adjacent watersheds.

4. **April-May south Delta operations potentially effecting Delta smelt**
   OMR flows in April and May would be modified by the proposed BDCP long-term operations, as compared to the operations described in the existing biological opinions.

5. **Spring X2/outflow effects on longfin smelt**
   The X2 location is higher (more easterly) in winter and spring months, which may negatively affect longfin smelt abundance according to a statistical correlation between X2 location and longfin smelt abundance.

6. **Fall X2 - Changes in hydrodynamics potentially affecting delta smelt**
   If one assumes that the Fall X2 objective is in the baseline and compares that to the proposed project without the objective, the X2 position is higher (more easterly) in fall and summer months in the above normal and wet water years.

The aforementioned issues will be the subject of further analysis after the release of the November 2010 document. Moreover, to ensure that the final effects analysis is sufficiently rigorous, comprehensive and complete, the technical discussions between the state and federal agencies, PREs and NGOs will continue throughout the development of the effects analysis and related documentation. Potential refinements are anticipated to be incorporated into the final BDCP effects analysis for the proposed project, which is expected in early 2011.

5.3 METHODOLOGY

*[**Note to Reviewer:** Comments and questions have been received on the methods used for the effects analysis. The use of specific methods are the subject of ongoing "theme team" and Oversight Committee meetings.]*

This section provides a summary of methods used to conduct the August 19, 2010 Draft Effects Analysis and the September 9, 2010 Draft Enhanced Habitat Analysis for covered fish species. It contains short descriptions of analytical tools, assumptions, and specific analytical approaches. These methods were developed largely in collaboration with technical experts from USFWS, NMFS, DFG, Reclamation, DWR and others. The effects analysis is divided into aquatic and terrestrial analyses with little overlap. Aquatic methods consist of initial physical modeling based on operating criteria agreed to at the January 29, 2010 Steering Committee meeting that fed inputs into biological models and system wide analyses, such as water quality, toxics, and the aquatic foodweb (Figure 5-1). Biological models and system-wide analyses informed species and lifestage evaluations. For terrestrial species, the effects of the BDCP on natural communities were evaluated primarily using GIS analysis with some physical model outputs. GIS, species habitat models, and output from natural community-level analyses were used to evaluate effects on individuals covered wildlife and plant species.

The BDCP was divided into three evaluation periods for the Effects Analysis, near-term, early long-term and late long-term (Section 5.1). The August 19, 2010 Draft Effects Analysis only included evaluations during the early late long-term periods because near-term water operations had not yet been agreed upon.

The proposed project was modeled with predicted future climate change for the early long-term and late long-term periods. As a result, the existing biological conditions to which the proposed project was compared also included climate change predictions for the early long-term and late long-term evaluation periods. To determine the effects of the BDCP on a specific parameter without incorporating the effects of future climate change, the results of that parameter for the existing biological conditions scenario was compared to that of the proposed project during the same evaluation period.

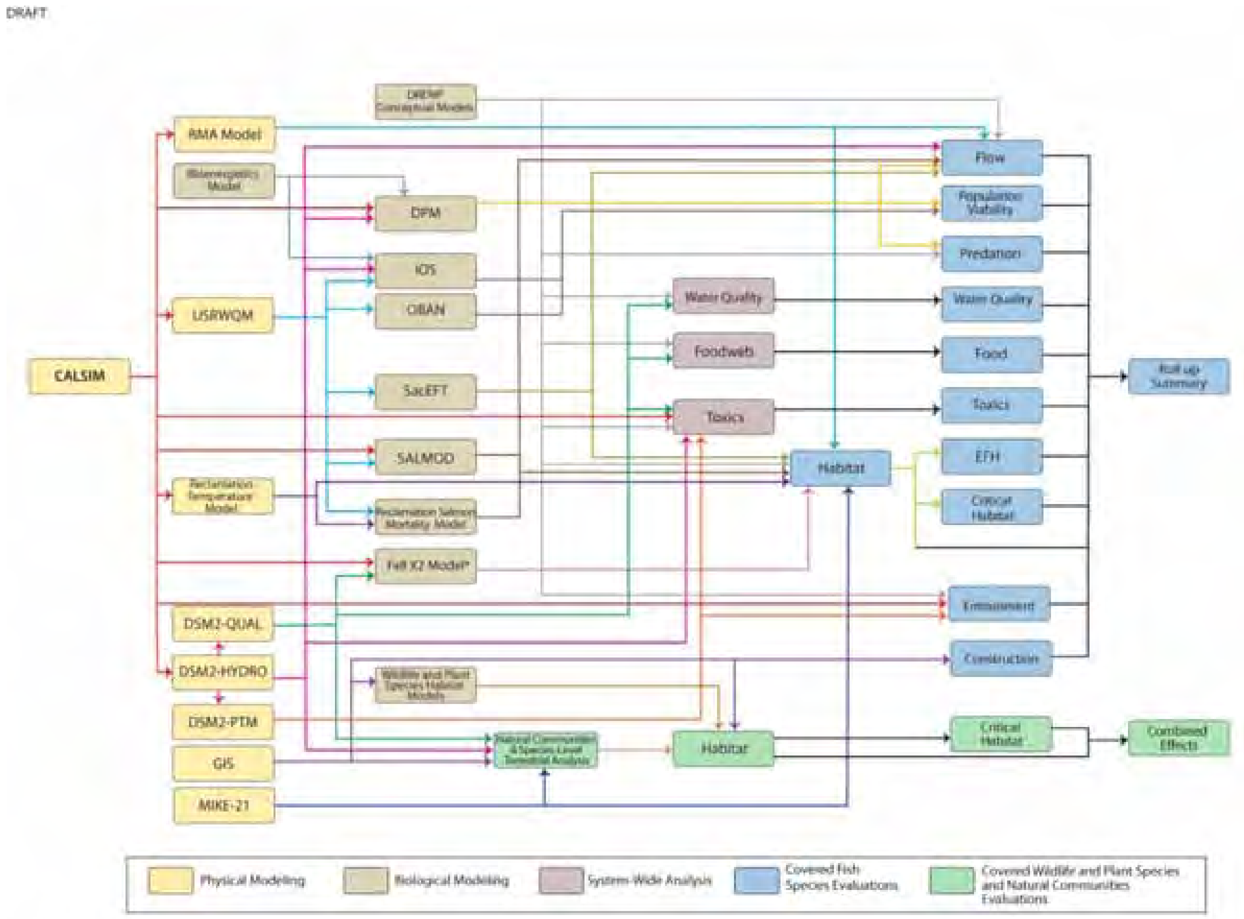

Figure 5-1. Relationships Among Physical and Biological Modeling Tools and System-Wide and Species-Level Evaluations for the BDCP Effects Analysis

5.3.1 Analytical Tools and Assumptions

5.3.1.1 Analytical Tools

Several types of analytical tools were used in performance of the aquatic effects analysis. These analytical tools can be categorized as physical and biological. Figure 5-1 summarized the relationships between the various analytical tools and biological evaluations used in the effects analysis. The following sections briefly describe the models, their outputs and use in the effects analysis.

5.3.1.1.1 CALSIM II

The CALSIM II planning model simulates the operation of the CVP and SWP over a range of hydrologic conditions. CALSIM II produces key outputs that include river flows and diversions, reservoir storage, Delta flows and exports, Delta inflow and outflow, deliveries to project and non-project users, and controls on project operations. Inputs to CALSIM II include water diversion requirements (demands), stream accretions and depletions, rim basin inflows, irrigation efficiency, return flows, non-recoverable losses, groundwater operation, and in-Delta operating criteria. In-Delta operating criteria for intake bypass flows, Sacramento River pulse flows, Delta Cross Channel operations, X2 standards, water quality standards, Yolo Bypass spills, and south Delta exports and flows that were agreed to at the January 29, 2010 Steering Committee were used as model inputs. Sacramento Valley and tributary rim basin hydrologies were developed for CALSIM II using a process designed to adjust the historical sequence of monthly stream flows over an 82-year period (1922 to 2003) to represent a sequence of flows at a future level of development. As can be seen in Figure 5-1, CALSIM II outputs were used as the basis for other physical and biological models and analyses.

5.3.1.1.2 DSM 2

DSM2 is a one-dimensional hydrodynamic and water quality simulation model used to simulate hydrodynamics, water quality, and particle tracking in the Sacramento-San Joaquin Delta (DWR 2002). The DSM2 model has three separate components, or modules: HYDRO, QUAL, and PTM.

DSM-HYDRO simulates velocities and water surface elevations and provides the flow input for QUAL and PTM. DSM2-HYDRO predicts changes in flow rates and depths as a result of the BDCP and climate change. Outputs were used to determine the effects of these hydrodynamic parameters on covered terrestrial and fish species and as inputs to other biological models.

The DSM-QUAL module simulates fate and transport of conservative and non-conservative water quality constituents, including salts, given a flow field simulated by HYDRO. Outputs were used to estimate changes in salinity and their effects on covered species as a result of the BDCP and climate change. Outputs of this model were used in the system-wide analysis of toxics.

An add-on to the DSM-QUAL module, the nutrient model, predicts the effects of changes to hydrology on temperature, dissolved oxygen, nitrogen and phosphorus concentrations (including speciation of each), and algal production. Outputs were used in the system-wide analyses for water quality, the aquatic foodweb, and toxics.

The DSM-PTM module simulates fate and transport of neutrally buoyant particles through space and time. Outputs were used to estimate the effect of hydrodynamic changes on the fate and transport of larval fish and toxics through the Delta.

5.3.1.1.3 RMA Model

The RMA model is a generalized free surface hydrodynamic model that is used to compute two-dimensional depth-averaged velocity and water surface elevation. The model uses CALSIM outputs as well as existing bathymetry and topography as inputs. The RMA model output was used to evaluate the effects tidal habitat restoration on flows throughout the Delta and the subsequent effects on covered species.

5.3.1.1.4 Upper Sacramento River Water Quality Model (USRWQM)

The USRWQM uses the HEC-5Q model to simulate mean daily (using 6-hour meteorology) reservoir and river temperatures at key locations on the Sacramento River. After being temporally downsized to daily average flows, monthly flows from CALSIM II for an 82 year period (WY 1922-2003) are used as input into the USRWQM. Output from the USRWQM was used as an input to a number of biological models for upstream lifestages of salmonids and sturgeon.

5.3.1.1.5 Reclamation Temperature Model

The Reclamation Temperature Model is a reservoir and stream temperature model that simulates monthly reservoir and stream temperatures for evaluating the effects of CVP/SWP project operations on mean monthly water temperatures in the Feather, Stanislaus, Trinity, Sacramento, and American river basins and upstream reservoirs based on hydrologic and climatic input data. The model uses CALSIM II output. The Reclamation Temperature Model was used to predict the effects of operations on water temperatures in the Feather, Stanislaus, Trinity, and American river basins, which were then used as inputs to the Reclamation Salmon Mortality Model and species-specific habitat evaluations.

5.3.1.1.6 MIKE-21

The MIKE-21 flexible mesh model is a two-dimensional hydrodynamic model that predicts changes in water surface elevation, flow, and average velocity in the Yolo Bypass as a result of inundation under CM14 Yolo Bypass Fisheries Enhancements. The model incorporates existing LiDAR and Toe Drain/Tule Canal bathymetry as well as estimated west-side tributary flows. Outputs were used to predict the potential benefits to species that use the Yolo Bypass as habitat when inundated (e.g., splittail, Chinook salmon) and to food production.

5.3.1.1.7 Delta Regional Ecosystem Restoration Implementation Plan (DRERIP)

The DRERIP conceptual models and scientific evaluation process were developed to aid in planning and decision making for potential ecosystem restoration actions in the Delta. Conceptual models contain background biological information on covered species and their stressors. The DRERIP scientific process was used twice for BDCP, once for a coarse-level evaluation of draft conservation measures in late 2008, then for a full evaluation of draft conservation measures in early 2009. Results of these previous evaluations, as well as the conceptual models themselves, were used for qualitative assessments and best professional judgment throughout the effects analysis.

5.3.1.1.8 Striped Bass Bioenergetic Model

A striped bass bioenergetic model was developed to estimate predation by striped bass based on water temperature, striped bass size, and the density and size of prey encountered. Inputs to the model include water temperature, prey density, and striped bass fork lengths taken from historical data for the Delta. This model was used to estimate predation rates of striped bass on covered fish species at the proposed North Delta diversion intakes. Results of the model were also used as inputs to the Delta Passage Model and Interactive Object-Oriented Salmon Simulation (IOS) Model.

5.3.1.1.9 Delta Passage Model

The Delta Passage Model (DPM) simulates migration and mortality of juvenile Chinook salmon entering the Delta from the Sacramento, Mokelumne, and San Joaquin rivers through a simplified Delta channel network similar to that depicted in Perry et al. (2010), and provides quantitative estimates of relative juvenile Chinook salmon survival through the Delta to Chipps Island. The DPM is based on a detailed accounting of migratory pathways and reach-specific mortality as smolts travel through a network of Delta channels. The model uses input from CALSIM II, DSM2-HYDRO, and the bioenergetics model to estimate predation pressure on juvenile salmon. The model was used to predict relative reach-specific survival estimates for winter, spring, and fall-run juvenile Chinook salmon passing through the Delta.

5.3.1.1.10 Interactive Object-Oriented Salmon Simulation (IOS) Model

The IOS model is a spatially explicit winter-run Chinook salmon life cycle model that examines environmental effects of multiple parameters on the abundance, size, and survival of winter-run Chinook salmon through successive life-stages. The IOS model uses simulated upstream daily flow and water temperatures from USRWQM and in-Delta flows from DSM2 as inputs. The model was used to evaluate the effects of multiple aspects of the BDCP on survival of winter-run Chinook salmon and population viability.

5.3.1.1.11 Oncorhynchus Bayesian Analysis (OBAN) Model

The OBAN model is a winter-run Chinook salmon life cycle analytical framework used to predict the effects of multiple actions on winter-run Chinook salmon by incorporating various sources of mortality in all phases of the life history. The model uses simulated upstream daily flow and water temperatures from USRWQM. Complementary to IOS, OBAN was used to predict the effects of multiple BDCP actions on winter-run Chinook salmon survival and population dynamics and population viability.

5.3.1.1.12 Sacramento River Ecological Flows Tool (SacEFT)

The SacEFT model is a database-centered software system for linking flow management actions to changes in the physical habitats for several focal species of concern. The model employs a set of functional relationships to generate habitat-centered performance measures for all races of Chinook salmon, steelhead, and green sturgeon that change in response to flow management scenarios. The model uses daily temperature and flow outputs from the USRWQM. SacEFT was used to predict the effects of flow changes in the Sacramento River on a set of physical (spawning area, juvenile rearing area, redd scour, and redd dewatering) and biological (egg survival, juvenile stranding, and juvenile growth) parameters for all races of Chinook salmon and steelhead. The model also predicted flow-based effects on green sturgeon egg survival.

5.3.1.1.13 SALMOD

SALMOD estimates both anadromous and resident juvenile salmonid production in freshwater, as a result of habitat. Habitat area (quantified as weighted usable area or WUA) is computed from flow versus microhabitat area functions developed empirically or by using Physical Habitat Simulation (PHABSIM) software or a similar physical habitat model. The inputs to the model include CALSIM flows, water temperature from USRWQM, spawning distribution based on aerial surveys, spawning timing depending on salmon race, and the number of spawners provided by the user (e.g., recent average escapement). SALMOD was used to predict the effects of flows in the Sacramento River on habitat quality and quantity and ultimately on juvenile production of all races of Chinook salmon.

5.3.1.1.14 Reclamation Salmon Mortality Model

This model uses temperature exposure mortality criteria resulting from changes in water operations for the three life stages, spawning distribution data, and output from the river temperature models to estimate percentages of egg and fry losses of a given brood of eggs for each run of Chinook salmon. The model uses water temperature output from the USRWQM for the Sacramento River; and the Reclamation Temperature Model for other Trinity, Feather, American, and Stanislaus rivers. The model was used to predict temperature-related proportional losses of eggs and fry for each race of Chinook salmon in the Trinity, Sacramento, Feather, American, and Stanislaus rivers.

5.3.1.1.15 Fall X2 Model

Delta smelt abiotic habitat during fall (September-December) has been calculated as surface area and related to the position of X2 (Feyrer et al. 2007). The use X2 position as an indicator of delta smelt habitat, and the technical basis for this analysis (Feyrer, et. Al. 2007), are the subject of significant scientific debate. The model was used nevertheless in the effects analysis because it was an RPA action identified by the USFWS in the current biological opinion. The statistical relationship was also modified based on BDCP proposed habitat restoration.

5.3.1.1.16 Covered Wildlife and Plant Species Habitat Models

As part of the BDCP analysis, habitat models were developed for each of the covered wildlife and plant species based on vegetation/land cover associations that support each species' habitat type and the spatial requirements (e.g., minimum habitat patch size that can support use by a species, proximity to other habitat areas that is necessary to support species use) of each species. Descriptions of the components of each species habitat model (i.e., the GIS vegetation/land cover types and other assumptions used to define each covered species habitat types) and maps of each species modeled are presented in Appendix A, *Covered Species Account*s.

5.3.1.2 Major Assumptions

The BDCP effects analysis relies on many assumptions regarding how the physical and biological processes of the Plan Area function and support natural communities and covered species; how restored habitats will develop over time; and how the physical and biological processes, natural communities, and covered species will respond to implementation of the conservation measures over time. These assumptions represent a reasonable interpretation of the best available information regarding how the Delta ecosystem functions and the life history requirement of the covered species. These assumptions are continuing to be refined and improved as new information is generated through the BDCP planning process.

Major assumptions used to conduct the effects analysis have been formulated for the following topic areas:

- The schedule for implementing conservation measures (from the implementation schedule presented in draft Chapter 6, *Implementation Plan*);
- Footprint locations and extents for habitat restoration/enhancement and other stressors conservation measures used to calculate effects on existing natural communities and habitat, effects on water quality and hydrodynamic conditions, and to model the extent of future restored tidal habitat;
- Habitat restoration and enhancement designs and the development of restored and enhanced habitat functions;
- Future effects of sea level rise;

- Types of and locations for implementing nonnative predator control actions and the effectiveness of such actions;
- Effectiveness of non-physical fish barrier and methylmercury control actions;
- Extent, frequency, and effectiveness of nonnative aquatic vegetation control actions;
- Location and effects of conveyance facilities construction and maintenance activities;
- Types and effectiveness of Yolo Bypass fisheries enhancement actions;
- Effects of restoration and construction-related noise and visual disturbances on covered wildlife species.

5.3.2 System-Level Analysis Approach to Support Assessments

5.3.2.1 Physical Modeling

To support the effects analysis, physical modeling is required to evaluate changes to conditions affecting resources within the Delta as well as effects to upstream and downstream resources. Hydrologic, operations, hydrodynamics, water quality, and particle tracking analyses are required to provide baseline and comparative information for habitat, fisheries, water supply, and water quality assessments. These analyses are also required to assess changes in the function of the Proposed Project under varying assumptions of future, non-project conditions such as climate change, future demands, and changes in Delta landforms (planned and unplanned).

The BDCP physical modeling can be separated into the following major elements:

1. Climate and Sea Level Change Scenarios;
2. Regional Hydrologic Modeling;
3. Hydrology and Systems Operations Modeling;
4. Yolo Bypass Floodplain Hydraulics;
5. Reservoir and River Temperature Modeling;
6. Delta Hydrodynamics and Water Quality Modeling; and
7. Delta Particle Transport and Fate Modeling.

Climate and sea level change analysis was conducted using a set of climate change scenarios that were spatially downscaled and entered into the regional Variable Infiltration Capacity (VIC) hydrologic model. This macro-scale model translated the effects of future climate conditions on watershed processes ultimately affecting the timing and volume of runoff. Results from this model informed hydrologic and system operations modeling, which was conducted using CALSIM II. As shown in Figure 5-1, CALSIM II formed the base of hydrologic modeling from which multiple hydrologic, hydrodynamic, and biological models and analyses received inputs. Yolo Bypass floodplain hydraulics were predicted using MIKE-21, a two-dimensional modeling for the Yolo Bypass, and CALSIM II output to better understand inundation characteristics under modifications to the Fremont Weir. For upstream out-of-Delta analyses, CALSIM II outputs were entered into the USRWQM, which calculated daily flows and water temperatures in the upper Sacramento River and the Reclamation Temperature Model, which calculates monthly averaged reservoir and river temperatures in multiple upstream rivers and reservoirs. Outputs of USRWQM were used in a number of biological models and analyses to determine the effect of flows and water temperature on anadromous fish species migration and survival. In the Delta, CALSIM II outputs informed Delta hydrodynamics and water quality modeling such as the RMA model, DSM2-HYDRO and DSM2-QUAL. These models were used to predict the effects of the BDCP on to tidal stage, velocity, flows, and salinity in the Delta. CALSIM II outputs also informed Delta particle transport and fate modeling using DSM2-PTM.

5.3.2.2 Food Web

The BDCP is predicted to affect the Bay-Delta foodweb in two primary ways: (1) changes to hydrology and hydrodynamics in Delta channels; and (2) restoration of tidal marsh, riparian, channel margin, and floodplain. To evaluate the effect of hydrology and hydrodynamics, the DSM2-QUAL nutrient model was used to estimate algal production. The effects of habitat restoration on the foodweb was estimated using existing data from within and outside the Delta, and best professional judgment was used to estimate the effects on covered fish species.

5.3.2.3 Toxics

There were six toxicants deemed important to the Delta aquatic community and, therefore, analyzed for the effects analysis: mercury, selenium, pyrethroids, endocrine disrupting compounds, copper, and ammonia/um.

The BDCP is predicted to affect mercury loads and methylmercury production as a result of three actions: (1) water operations, (2) tidal habitat restoration, and (3) enhanced Yolo Bypass inundation. The effects of the BDCP water operations on mercury were evaluated using DSM-QUAL source water fingerprinting outputs. The proportion of water predicted from DSM-QUAL from the Sacramento River and San Joaquin River at two locations in the Delta was multiplied by historical mercury loads calculated for water from each river. To determine the effects of tidal habitat restoration on methylmercury loads, average rates of methylation in wetlands and open water areas from the Delta mercury TMDL were multiplied by the area (in acres) of restored habitat and floodplain to determine estimates of overall production of methylmercury in project areas. To determine the effects of Yolo Bypass inundation on methylmercury loads, the empirical relationship between net methylmercury production in Yolo Bypass and outflow from Foe et al. (2008) was applied to the frequency duration using CALSIM II output and area of inundated land using MIKE-21 output to determine the overall change in net methylmercury production as a result of increased inundation of the Yolo Bypass.

The BDCP is predicted to affect selenium loads by changing the hydrology of the Delta such that the proportion of water entering the Delta from the San Joaquin versus the Sacramento River will be altered. This effect was analyzed using the source water fingerprinting method described for methylmercury.

The BDCP is expected to result in regional changes in pyrethroid concentrations as a result of changes in hydrodynamics. While the BDCP is not a source of increased pyrethroid loading, it may affect dilution flows both positively and negatively by changing circulation patterns. The BDCP may also reduce pyrethroid loading when land is retired from more intensive land uses and restored. The effects of water operations on pyrethroids entering Delta waterways and exposure to fish were analyzed in three ways. First, changes in loads of upstream pyrethroid sources into the Delta were estimated by calculating median application rates of multiple pesticides from Department of Pesticide Regulation (DPR) databases for each county within the Sacramento and San Joaquin River watersheds and using the source water fingerprinting techniques described for methylmercury to predict how much water from each watershed would enter the Delta. Second, effects of water operations on changes to pyrethroid concentrations from waste water treatment plants (WWTPs) were estimated using existing concentrations of pyrethroids from Weston and Lydy (2010). These concentrations, in combination with discharge estimates from WWTPs outside the Delta, as well as the Stockton and Sacramento WWTPs, were used to compare estimated annual loads of pyrethroids entering Delta waterways with and without the BDCP. Third, residence time calculations from DSM2-PTM at multiple locations within the Delta were used to predict the effect of water operations on the exposure time of an organism to pyrethroids within the Delta. The effect of changes in land use resulting primarily from BDCP habitat restoration was analyzed by using DFG land use maps to determine acreages of specific crop types on hypothetical habitat restoration sites, calculating average application rates of pyrethroids on each crop type from the DPR database, and calculating total application rate. Using the assumption that 0.11 percent of the pyrethroid application loads onto fields enters the Sacramento and San Joaquin waterways as runoff (Werner and Oram 2008), the total reduction in loads was calculated.

The analysis of the effects of the BDCP on changes to endocrine disrupting compound loads was combined with the analysis of pyrethroids because the best available data on EDC loads to the Delta consist of information on pyrethroid applications for agricultural and commercial use and in wastewater treatment plant effluent.

While the BDCP is not a source of increased copper loading, it is expected to affect copper loads as a result of four actions: water operations, nonnative aquatic vegetation control under CM9, tidal habitat restoration in the Cache Slough ROA and enhanced floodplain inundation in the Yolo Bypass, and changed land use. The effect of water operations were predicted using existing copper concentrations and the source water fingerprinting methods described for methylmercury. The effect of nonnative aquatic vegetation control on copper concentrations in Delta waterways was addressed using existing application rates used by the Department of Boating and Waterways for their existing nonnative plant removal programs and the acreage of anticipated removal under the BDCP. Due to a paucity of information, a qualitative assessment was conducted to determine the effect of restoration in Cache Slough and the Yolo Bypass, two locations with large copper deposits. The effect of changes in land use on copper pesticide use was analyzed identically to the analysis of pyrethroid pesticides.

The effect of the BDCP on ammonia/ammonium loads was estimated using the DSM2-QUAL nutrient model. The analysis did not assume future changes to ammonia/ammonium loading based on existing trends from WWTPs.

5.3.2.4 Water Quality

The effect of the BDCP on water temperature, dissolved oxygen concentration, turbidity, and salinity in the Delta and Suisun Marsh/Bay were estimated. Effects of the BDCP on Delta-wide water temperature and dissolved oxygen concentration were estimated using the DSM2-QUAL nutrient model. Additional analyses were conducted to determine the effects at smaller spatial scales. Effects on turbidity were assessed using the RMA turbidity model. Predicted changes in salinity were estimated using the DSM2-QUAL model.

5.3.3 Fish Species Assessment Methods

This section briefly describes the methods for used for each of the analyses of covered fish species. These analyses are for upstream spawning and rearing habitat (including flow and water temperature), in-Delta habitat, migration flows, entrainment, in-Delta toxics and water quality, predation, food availability, hatcheries, harvest, and construction.

5.3.3.1 Upstream Spawning and Rearing Habitat

Upstream spawning and rearing habitat was evaluated only for anadromous species: salmonids, sturgeon, and lamprey. A number of analytical tools were available to analyze multiple parameters depending on the species and the parameter. For example, the Reclamation Salmon Mortality Model and SacEFT were both used to determine the effects of flows on redd dewatering risk and other factors on Chinook salmon and steelhead eggs; SacEFT was used to determine the effect of flows on temperature related mortality of green sturgeon eggs; available literature in combination with water temperature outputs from USRWQM and the Reclamation Temperature Model were used to estimate the incidence of lethal temperatures for lamprey eggs and ammocoetes. Other upstream variables evaluated include spawning weighted usable area, redd dewatering, redd scour, juvenile stranding, and rearing weighted usable area, primarily through the use of SacEFT, SALMOD, and the Reclamation Salmon Mortality Model for salmonids. Temperature and flow-related effects for larval and adult salmonids and sturgeon were further evaluated using outputs from USRWQM, CALSIM, and the Reclamation Temperature Model in combination with known or assumed thermal tolerances for each species. Flow-related effects (redd dewatering) for lamprey were analyzed using CALSIM II and USRQWM model outputs.

5.3.3.2 In-Delta Habitat

In-Delta habitat was analyzed for all lifestages of delta smelt, longfin smelt, and splittail and the juvenile and adult phases of anadromous species using hypothetical restoration locations developed by RMA to assist in the flow analyses. The evaluation of the effects of tidal habitat, floodplain, channel margin, and riparian habitat restoration on covered fish species was mostly qualitative; used DRERIP conceptual models; and focused on changes in physical habitat restoration, food production, alternative migration pathways, juvenile growth rates, predation, stranding, water quality, and toxics.

The frequency, duration, and areal extent to which the Yolo Bypass will flood as a result of the BDCP was analyzed using daily flow data from CALSIM II coupled with flooded area data from two-dimensional hydrodynamic modeling using MIKE-21. These results were used to assess benefits of Yolo Bypass inundation to splittail spawning and juvenile rearing as well as juvenile salmonid rearing.

The fall X2 regression model was used to estimate how BDCP water operations and habitat restoration might affect the surface area of open water in the western Delta and Suisun Bay with suitable salinity and turbidity for use by delta smelt. The use of this model and interpretation of its results related to delta smelt habitat has been heavily debated by technical experts; no consensus on the direction of the effects analysis has yet been reached.

5.3.3.3 Food Availability

Food availability is expected to change as a result of the BDCP through two primary mechanisms: changes water operations and habitat restoration. The evaluation of the effects of BDCP water operations on food availability was conducted primarily using the DSM2-QUAL nutrient model. This model provides algal production estimates based on nutrient levels, light availability, and water temperature. The effects of habitat restoration on food availability were conducted using best professional judgment based on existing data within and outside the Delta. The combined effect of changes to food availability to each covered fish species foraging in the Delta was conducted using best professional judgment.

5.3.3.4 Flow

The BDCP may affect both downstream transport flows and upstream migration cues to anadromous fish species. The evaluation of downstream transport flows in the upper rivers and tributaries on salmonids, sturgeon, and lamprey used CALSIM outputs to determine flow rates in multiple upstream rivers as well as multiple channels within the Delta during periods of migration for each species. The Delta passage model, which uses known relationships between flows in the Delta and juvenile salmon survival, was used to evaluate transport flows for salmonids. The analysis of transport flows for delta and longfin smelt used daily and monthly flow data from areas of known presence within the Delta and Suisun Bay during periods of migration for each species.

The evaluation of changes to upstream migration cues on salmonids, sturgeon, and lamprey compared DSM2-QUAL source water fingerprinting data between existing biological conditions and under the proposed project to determine changes in flow splits at the confluence of the Sacramento and San Joaquin rivers during periods of migration through the Delta for each species. The evaluation also compared CALSIM II monthly flow data or USRWQM daily flow data at the confluence of larger rivers to determine changes in the amount of water coming from tributaries during periods of migration for each species. The effect of the BDCP on barriers to migration, including the Stockton Deep Water Ship Channel, Sacramento Deep Water Ship Channel, and the Yolo Bypass, were also evaluated by examining model outputs and using best professional judgment.

The effects analysis also evaluated the change in Delta outflow/X2 in December through May as an indicator of longfin smelt abundance in the DFG Fall Midwater Trawl (Kimmerer et al. 2009). This evaluation of flow effects on longfin smelt abundance will be revised for the January 31, 2011 draft to include the consensus among various BDCP Oversight Committee technical staff that other factors, such as food availability also drive longfin smelt abundance.

5.3.3.5 Entrainment

This analysis included an evaluation of BDCP effects on four sources of entrainment: SWP/CVP south Delta facilities, proposed north Delta facilities, agricultural diversions, and power plant intakes. The evaluation of entrainment at south Delta facilities varied by species and, for some species, by lifestage. The analysis of salmonids, sturgeon, splittail, and lamprey began with calculating historical expanded salvage loss and export rates. The loss density of each species or race was calculated by dividing salvage by export rate. This density was then applied to predicted future monthly export rates from CALSIM II output. Entrainment of delta smelt larvae and longfin smelt larvae and younger juveniles was assessed using particle tracking with a number of starting positions based on historical trawl data and hydrologic conditions based on DSM2-PTM scenarios. Entrainment of juvenile and adult delta smelt and older juvenile and adult longfin smelt used the loss density method that were normalized by annual fall midwater trawl indices for each species. A number of modifications will be made to these methods for the January 31, 2011 draft Effects Analysis. In addition, other methods will be used for the evaluation of some species or lifestages.

The evaluation of the north Delta facilities examined existing design features of screens, flow and sweeping velocities, and size and shape of fish to qualitatively assess effects.

The evaluation of the removal of agricultural diversions due to habitat restoration and construction used best professional judgment to assess effects to covered fish species.

The evaluation of entrainment risk on Mirant’s Pittsburg and Contra Costa power plants was qualitative and utilized recent regulations to phase out completely Mirant’s once-through cooling systems by 2017.

5.3.3.6 In-Delta Toxics and Water Quality

Best professional judgment was applied to the results of the system-level analyses to estimate the effects of the BDCP on toxics loads and water quality parameters in the Delta to qualitatively evaluate the effects of these changed loads on covered fish species health and survival.

5.3.3.7 Predation

There are two primary ways the BDCP is expected to change predation risk: installation of north Delta intakes, and CM15 *Predator control*. To evaluate the effects of the north Delta intakes for salmonids, a striped bass bioenergetics model was developed that estimates predation rates. Densities and total numbers of predators were estimated using existing density data; the zone of influence (the area in which flows are altered and predators live) was estimated using best professional judgment. Bioenergetics model outputs on predation rates were used by the DPM and IOS to evaluate population level effects to salmonids. The effects of north Delta intakes on other species were assessed by calculating estimated losses of individuals to predation. There was much discussion about the assumptions and methods used for this analysis during the "theme team" meetings. These issues are being resolved for the January 31, 2011 draft Effects Analysis.

The effects of CM15 Predator Control on covered fish species were mostly evaluated qualitatively. As with the evaluation of the north Delta intakes, the assumptions used for this evaluation have been reconsidered and will be revised for the January 31, 2011 draft.

5.3.3.8 Hatcheries

There are two hatchery-related conservation measures in the BDCP: CM17 *Hatchery and Genetic Management Plans* that proposes to assist DFG and USFWS in completing and implementing hatchery and genetic management plans; and CM19 *Conservation Hatcheries* that proposes to provide funding and support to conservation hatcheries for delta smelt and longfin smelt. Both conservation measures were analyzed using best professional judgment.

5.3.3.9 Harvest

Best professional judgment was used to evaluate the effect of CM18 *Illegal Harvest* on Chinook salmon, steelhead, sturgeon, and splittail.

5.3.3.10 Construction

Existing information on the techniques to be used for the construction and maintenance of the five north Delta intakes was obtained. A set of best management practices (e.g., work windows, protection from oil spills, use of sediment screens) was assumed based on other in-Delta construction projects. Best professional judgment was used to evaluate the effects of these practices on covered fish species.

5.3.4 Killer Whale Analysis Methods

The analysis of the effects of the BDCP on southern resident killer whale was not included in the August 19, 2010 draft Effects Analysis. This analysis will be completed for the January 2011 draft and will be based primarily on the results of the Chinook salmon evaluation because Chinook salmon are a preferred prey item of the southern resident killer whale. Fecundity and survival of the distinct population segment appear to be correlated with abundance of Chinook salmon in inland Pacific Northwest waters (Ward et al 2009, Ford et al. 2009). Methods to be used will be consistent with the NMFS Biological Opinion on the CVP and SWP (NMFS 2009).

5.3.5 Natural Community Assessment Methods

Information and analytical tools used to conduct the effects analysis on the natural communities, including ecological processes, ecological gradients, native species habitat functions supported by each of the natural communities as well as the extent of natural communities in the Plan Area, included:

- Draft Chapter 2, *Existing Ecological Conditions*, including the BDCP GIS vegetation and natural community data base;
- Descriptions of the BDCP conservation measures in Draft Chapter 3, *Conservation Strategy*;
- The conservation implementation schedule in BDCP Chapter 6, *Implementation Plan*;
- DHCCP draft conveyance facility construction schedules;
- Applicable DRERIP models;
- Assumptions regarding development of restored and enhanced habitats (see Section 5.3.1.2, *Major Assumptions*);
- Descriptions of relevant avoidance and minimization measures in Draft Chapter 3, *Conservation Strategy*;
- Results of relevant modeling (e.g., modeled changes in salinity gradients);
- GIS data layers of conveyance facility footprints; and
- BDCP hypothetical footprints of restored and enhanced tidal, seasonally inundated floodplain, channel margin, and riparian habitats.

The analysis was based on an assessment of the effects mechanisms associated with each of the covered activities that could result in an adverse or beneficial effect on the natural communities. Changes in the permanent, temporary, and periodic inundation effects on the extent of each natural community were determined using GIS by intersecting (i.e., overlaying) the footprint effect area of each of the covered activities with the GIS natural community data base layer. The combined effects of constructing conveyance facilities and restoring habitats were qualitatively evaluated to assess effects on habitat connectivity and movement of native wildlife species. The process for calculating the extent of footprint, noise, and visual effects of implementing water conveyance facility construction and habitat restoration actions on each of the natural communities is illustrated in Figure 5-2.

Effects of covered activities on aquatic ecological processes and gradients were evaluated based on results of hydrodynamic and water quality modeling and the assumptions regarding the evolution of enhanced and restored tidal, channel margin, riparian, vernal pool, seasonally inundated floodplain, and grassland habitats.

Draft

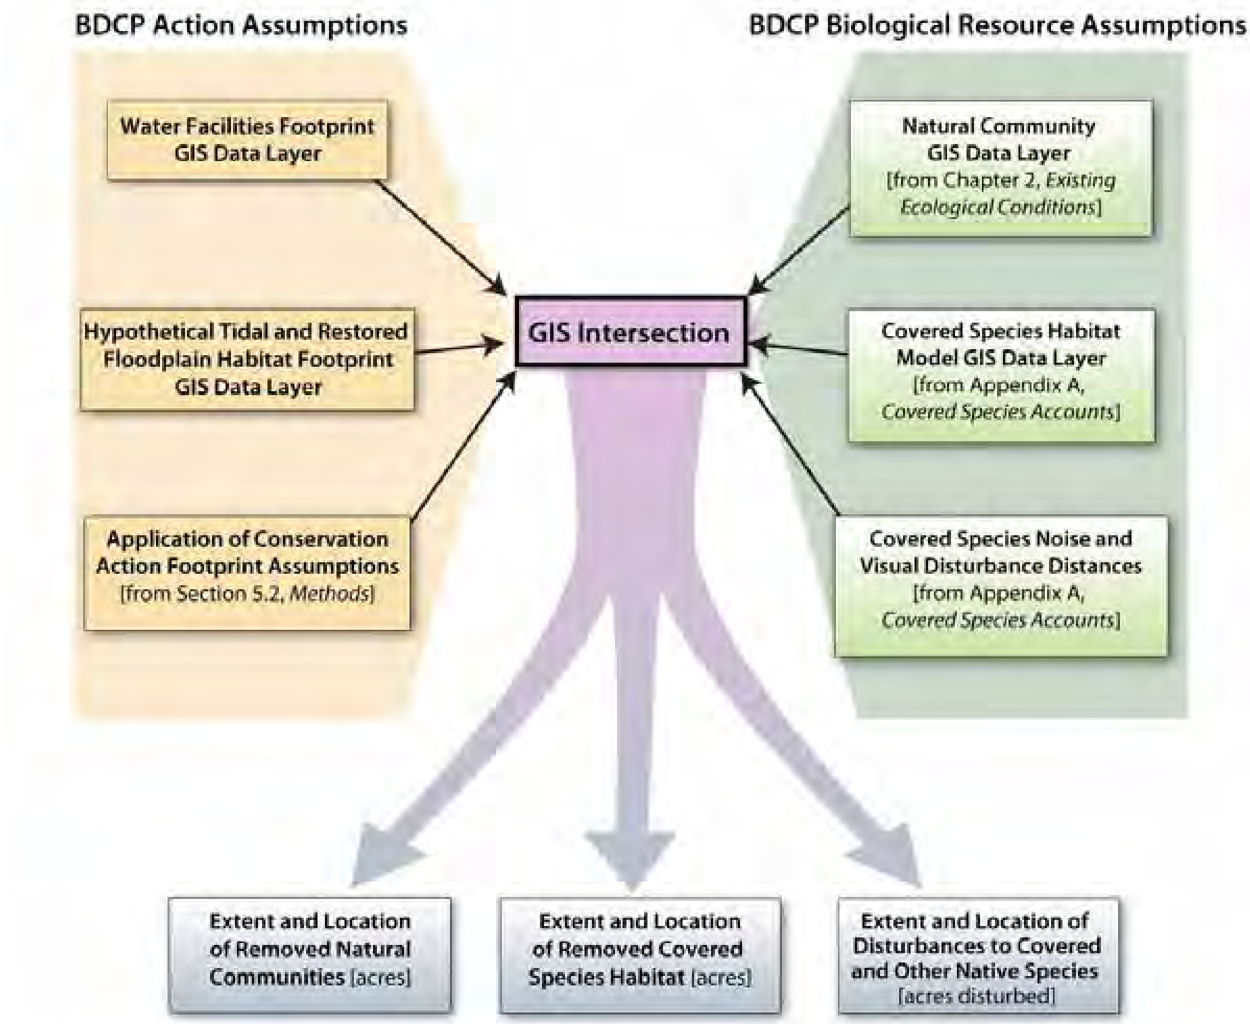

Figure 5-2. Process for Calculating Extent of BDCP Covered Activity and Conservation Action Footprint Effects on Natural Communities and Covered Species Habitats

5.3.6 Covered Wildlife and Plant Species Assessment Methods

Information and analytical tools used to conduct the effects analysis on covered wildlife and plant species included:

- The BDCP covered wildlife and plant species habitat models (Appendix A, *Covered Species Accounts*);
- Species information in BDCP Appendix A, *Covered Species Accounts*;
- Applicable DRERIP models;
- Descriptions of the BDCP conservation measures in Draft Chapter 3, *Conservation Strategy*;
- The conservation implementation schedule in Draft Chapter 6, *Implementation Plan*;
- DHCCP draft conveyance facility construction schedules;
- Draft Chapter 2, *Existing Ecological Conditions*;
- Assumptions regarding development of restored and enhanced habitats (see Section 5.3.1.2, *Major Assumptions*);
- Application of relevant avoidance and minimization measures in Draft Chapter 3, *Conservation Strategy*;
- Results of relevant modeling (e.g., modeled changes in salinity gradients);
- GIS data layers of conveyance facility footprints; and
- BDCP hypothetical footprints of restored and enhanced tidal, seasonally inundated floodplain, channel margin, and riparian habitats.

The analysis was based on an assessment of the effects mechanisms associated with each of the covered activities that could result in an adverse or beneficial effect on each of the covered wildlife and plant species. Changes in the permanent, temporary and periodic inundation effects of on the extent of each species' habitat types were determined using GIS by intersecting the footprint effect area of each covered activities with each species' habitat model data base layers. The process for calculating the extent of footprint and noise and visual effects of implementing water conveyance facility construction and habitat restoration actions on covered species and their habitats is illustrated in Figure 5-2. Effects of changes in salinity and hydrodynamic conditions were evaluated based on results of hydrodynamic and water quality modeling and the assumptions regarding the evolution of enhanced and restored tidal, channel margin, riparian, vernal pool, seasonally inundated floodplain, and grassland habitats.

5.4 Summary of Results

*[**Note to Reviewers:** This section presents draft Section 5.4,* Summary of Results*, section of Chapter 5,* Effects Analysis*, for the November 18, 2010 BDCP document.*

Section 5.4.1 summarizes the results of the effects analysis results of covered fish species from the August 19, 2010 draft for fish species and the subsequent September 9, 2010 draft enhanced habitat analysis. This section is sub-divided into a description of results for each covered fish species or groups of similar fish species. Where applicable, summaries of the effects on population viability, designated critical habitat, and essential fish habitat are included.

Sections 5.4.2 and 5.4.3 summarize the effects analysis results for the natural communities and covered wildlife and plant species. These two sections consist of the revised "summary of effects" sections from the August 19, 2010 draft for the natural communities and species for only the late long-term outcomes with full BDCP implementation. Tables presenting the extent of impacts on and the level of conservation provided for each of the natural communities and covered wildlife and plant species habitats at the late long-term evaluation point are provided at the end of this draft.]

This section summarizes the results of the August 19, 2010 draft of the BDCP effects analysis and the September 9, 2010 draft enhanced habitat analysis for covered fish species. Owing to the complexity and comprehensiveness of this effects analysis, there have been over 1,400 pages of results and over 1,900 pages of accompanying appendices generated to date. Therefore, the results section presented here is a very condensed summary of the full analysis. The August 19 draft effects analysis did not include a southern resident killer whale effects analysis or estimated levels of take and overall syntheses and conclusions for covered fish species and, therefore, are not included in this section.

5.4.1 Covered Fish Species

5.4.1.1 Delta Smelt

5.4.1.1.1 BDCP Effects on Stressors

The results of the effects analysis indicate that implementation of the BDCP conservation strategy will result in a number of major changes that will reduce the impacts of stressors on the delta smelt population and improve habitat conditions for larval, juvenile, and adult rearing. Some adverse effects were also noted. These major findings include:

Expansion of habitat through physical restoration. Habitat restoration under the BDCP will increase subtidal habitat extent in Suisun Marsh and West Delta ROAs by 11,000 acres in the LLT. Approximately 21,000 acres of subtidal habitat will be added in the other ROAs in the LLT, including 7,400 acres in the Cache Slough area, which is used extensively by delta smelt.

Approximately 11,000 acres will be created in the South Delta ROA, which is not used extensively by delta smelt currently, but was historically. Expansion of suitable delta smelt habitat to the south Delta offers the opportunity to re-establish range expansion for delta smelt, geographic diversity within the Delta population, and the potential to re-establish another independent spawning population of delta smelt that would be consistent with Population Viability Assessment (PVA) and recovery criteria for threatened and endangered fish populations. This restored habitat would provide additional spawning and rearing habitat for delta smelt if these new habitat areas were to contain suitable hydraulics and water quality, and was not extensively colonized by submerged aquatic vegetation or introduced predators. As discussed above, the BDCP monitoring, research, and adaptive management programs will address this uncertainty and provide for continual improvement in implementation design over time to ensure that newly restored habitat contains suitable features for delta smelt. Specific measures are included in the BDCP to control submerged aquatic vegetation and nonnative predators. In total, the extent of subtidal habitat in the Delta will increase by approximately 35 percent over existing subtidal habitat in the Delta and Suisun Marsh and Bay.

Increased food production. It has been postulated that food is a limiting factor for delta smelt (Feyrer et al. 2007, Baxter et al. 2008, Glibert 2010, Miller unpubl. data). Changes in operations and habitat restoration under the BDCP will increase hydraulic residence time in some areas of the Delta, which has the potential to increase food production in those areas. In other areas, residence time will decrease, which has the potential to reduce food production. The types of primary producers found in the Delta water column are determined in part by the nutrient composition of the water (Glibert 2010). The net near term effect of hydraulic changes is therefore uncertain.

Habitat restoration has substantial potential to enhance food production within and adjacent to restoration sites because of the substantial increase in intertidal and subtidal habitat in the ELT and LLT. Delta smelt are expected to receive the greatest benefits from the creation of additional habitat in the Cache Slough area. This area currently has favorable food web productivity (Lehman 2010) and has supported a relatively large delta smelt population in recent years. Although shallow intertidal habitat is not expected to be used by delta smelt for rearing, primary production in these areas is expected to be high in the future. Adjacent subtidal areas will also produce food, as well as provide delta smelt habitat as described above. The high food production from intertidal marsh areas may be carried from these areas into adjacent subtidal habitats that provide suitable habitat for delta smelt, increasing production there, which would increase growth rates, and presumably benefit the delta smelt population. There are two schools of thought regarding the amount of production expected to be exported from intertidal marsh: some experts believe that export of primary production could be moderate to high whereas other experts believe that exports would be low and sporadic.

An unknown fraction of this increased production could be consumed by the introduced overbite and Asian clams. Colonization of expanded habitat areas by the Asian clam *Corbula*, or future colonization of these habitats by nonnative clams and mussels in the future, could reduce the benefits of production in restored habitats. However, the BDCP Implementation Office will learn from monitoring and research much more about successful and unsuccessful habitat restoration design features to minimize effects of nonnative clams during the 50 year term of the BDCP and will, therefore, adaptively manage restoration design to minimize these effects.

Changes in Fall X2. In comparison with the RPAs in the existing delta smelt biological opinion, BDCP will modify the location of X2 position during fall in below normal, above normal and wet water years. However, this RPA has not yet been implemented due to lack of suitable hydrological circumstances. Moreover, it was not accepted by Reclamation and is under contention in litigation, the outcome of which cannot be predicted here. Thus it is not currently an existing condition for purposes of comparison to BDCP. In order to be conservative, however, analysis has been conducted to evaluate the change in fall X2 location that would occur under BDCP relative to the fall X2 RPA.

Under the BDCP, X2 position will move upstream in the fall months of below normal, above normal and wet years relative to its location assuming “existing biological conditions (EBC)” in the existing RPA. In fall, this would occur in the wettest 60 percent of years, although it would not be different from the EBC under the driest 40 percent of conditions. Higher X2 position will reduce the surface area of open water with salinity and turbidity levels that some consider suitable habitat for delta smelt (see e.g., Feyrer et al., 2007) by 30-40 percent, assuming the current Delta configuration. These changes are similar for the ELT and the LLT. When habitat restoration by the BDCP is included in the evaluation of effects on X2 position (based on LLT projections), the BDCP is projected to result in approximately 25 percent more habitat in the western Delta and Suisun Marsh/Bay than the EBC under the driest 50 percent of years and 20-40 percent less habitat under wetter years.

There is an ongoing discussion regarding whether or not fall X2 position is an appropriate indicator of delta smelt habitat and whether it is useful in predicting population responses. This issue has been identified as one of the remaining issues that require further evaluation and discussion amongst the scientific community. Further analysis will be completed on this issue over the next few months.

Reduced losses of adult delta smelt at south Delta SWP/CVP facilities. While entrainment in the existing project facilities has not been shown to have a population level effect, project related improvements will benefit the species. Dual export facility operations will reduce adult delta smelt losses at the south Delta export facilities by approximately 50 percent from existing conditions. This effect is especially pronounced during the earlier months of the migration season, which will protect older, larger fish that are presumed to spawn earlier and provide a disproportionately greater percentage of successful recruits in any given year. Adult losses will likely increase in April, but this effect is outweighed by reduced losses during December through March. The reduction in adult delta smelt losses is comparable between the ELT and LLT implementation periods.

Reduced losses of juvenile delta smelt in south Delta SWP/CVP facilities. While neither entrainment in the existing project facilities, nor project related changes in hydrodynamics, has ever been shown to have a population level effect; project related improvements in these areas will benefit the species. Dual export facility operations will reduce juvenile delta smelt losses at the south Delta export facilities by approximately 15 percent in the ELT and 26 percent in the LLT relative to corresponding existing biological conditions (EBC) conditions at the SWP facilities. Little difference in loss was identified between the BDCP and the EBC at the CVP facilities for juvenile delta smelt. This effect will provide a benefit for delta smelt, as well, but not as great as that achieved through reductions of adult losses. Losses were slightly reduced for larval delta smelt, based on PTM results, but this difference was quite small (less than 3 percent in many cases) and, given the high variability in the results, is not concluded to be different from that under EBC.

Negligible entrainment risk at north Delta intakes. As a result of the state-of-the-art design characteristics (i.e., 0.2 ft/sec approach velocity, screen mesh size, screen cleaning, etc.), and the northern location of the proposed intake structures relative to the geographic distribution of delta smelt, the risk of entrainment or impingement of all life stages of delta smelt at the north Delta intakes is negligible.

Entrainment in non-project diversions will be marginally reduced. The removal of non-project diversion due to changing land use in the Delta as a result of BDCP conservation measures (e.g., conversion of agricultural land use to restored natural habitat) will provide a marginal benefit to reducing entrainment risk for delta smelt.

Entrainment in Mirant power plants will be greatly reduced. The expected transition to exclusive closed cycle water use at Mirant's Contra Costa and Pittsburg power plants by 2017 is predicted to substantially reduce and avoid entrainment and impingement of delta smelt.[

Changes in toxicant levels. Toxicants (e.g., pyrethroids, copper, ammonia) have been identified as a potential stressor to delta smelt (Sommer et al. 2007, Baxter et al. 2008, Werner 2010). Much of the research on the effects of toxicants to delta smelt is preliminary. Under the BDCP, toxicant concentrations will decrease in the west Delta as a result of minor decreases in loading from upstream sources, changes in hydrodynamics, and in-Delta land use changes. Results for central Delta are more mixed. Because the bulk of the delta smelt population occurs in the northern Delta and confluence, the net effect of the project with regard to toxicants is beneficial.

Removal of submerged aquatic vegetation (SAV). SAV removal is an important secondary action to habitat restoration. SAV has the potential to make habitat unsuitable for delta smelt by encroaching on areas used by smelt for spawning and rearing, providing habitat for introduced predators, and reducing turbidity both within SAV beds and in nearby areas. Without SAV removal, some portion of the intertidal and subtidal restored habitat will be colonized by SAV and become unsuitable for delta smelt. This action would be beneficial to delta smelt by keeping newly created habitat available for smelt.

Predator removal. Localized removal of predators (e.g., striped bass, largemouth bass, smallmouth bass) is expected to provide only negligible benefits to delta smelt. Currently, there are few studies evaluating the effect of predation on delta smelt. After further study, more information regarding the importance of predation on the delta smelt population will be known, and effective predator management programs can be developed.

Establishment of a conservation hatchery. Establishing viable refuge populations of delta smelt in a conservation hatchery will provide insurance against the potential extinction of the wild populations and is an important consideration, given the low numbers of wild delta smelt. It also will provide a stock of fish that could be used to assess the effects of various stressors on the species without impacting wild stocks. There would be more risk and uncertainty associated with increasing the scale of the facility to enhance the natural population. Long-term benefits would outweigh these risks if program managers develop and maintain populations whose genetic diversity and fitness are comparable to those of wild populations.

5.4.1.1.2 BDCP Effects on Delta Smelt Designated Critical Habitat

The U.S. Fish and Wildlife Service has identified the important physical and biological features, or primary constituent elements (PCEs), essential for the conservation of delta smelt as: "…physical habitat, water, river flow, and salinity concentrations required to maintain delta smelt habitat for spawning, larval and juvenile transport, rearing, and adult migration" (59 FR 65256). Results of the effects analysis led to the following conclusions regarding the effects of BDCP actions on designated critical habitat for delta smelt spawning, larval and juvenile transport, rearing and adult migration.

Effects on Physical Habitat. The BDCP will result in increased spawning habitat availability through habitat restoration and the removal of nonnative aquatic vegetation. With respect to habitat restoration, it is unknown whether restored areas will provide suitable spawning substrate, although there is evidence from recent BREACH III sampling suggesting that delta smelt spawn in or near Liberty Island (P. Hrodey, pers. comm.). However, the projected increases in intertidal and subtidal habitat are expected to result in substantial increases in the availability of suitable rearing habitat. In addition to increasing spawning and rearing habitat area, increased local food production and export to adjacent pelagic habitats may occur where the frequency and duration of inundation would be increased relative to existing biological conditions as a result of habitat restoration (Jassby and Cloern 2000, Kneib et al. 2008, Opperman 2008).

There is uncertainty associated with the projected benefits of habitat restoration (based on delta smelt use of restored areas, proximity to population sources for native vs. exotic plants and animals, etc.). The biological benefits of expanded aquatic habitat will depend, in part, on the location of the habitat feature with respect to the geographic distribution of the species and their lifestages, compatibility of physical habitat features with species- and life-stage specific habitat requirements and preferences, the specifics of the habitat design, physical processes, and configuration that would serve to reduce and avoid colonization by nonnative filter-feeding macroinvertebrates and predatory fish. As discussed above, the design and implementation of the BDCP conservation measures include specific design characteristics (e.g., habitat diversity and complexity, water depths and velocities, hydraulic flushing and residence times, wind and wave induced turbidity, etc.) that work in concert with phased implementation of habitat restoration, coupled with integrated monitoring and evaluation, to assess habitat performance, improve performance of the habitat restoration projects, and reduce uncertainty. Through careful phased implementation of habitat features developed in accordance with physical and biological design characteristics, the net effect is expected to be an increase in suitable physical habitat for delta smelt.

Effects on Water. The BDCP would have little effect on water temperature relative to the effects of climate change. Water temperatures will increase in the future primarily as a result of climate change, and are not expected to be intensified as a result of the BDCP. In fact, during small periods during summer months, tidal marsh restoration is predicted to reduce water temperature in and near marshes, which would offset some of the increases due to climate change. The projected reductions in contaminant concentrations in the vicinity of the confluence will decrease delta smelt contaminant exposure. These changes will range from relatively minor (in the NT and ELT) to substantial (in the LLT). Finally, increases in turbidity associated with floodplain, channel margin, subtidal and intertidal habitat enhancement and restoration in particular, will provide a benefit to delta smelt critical habitat. These benefits will accrue during spawning, larval and juvenile transport, rearing, as well as adult migration.

Effects on River Flows. Transport flows for larval delta smelt would decrease under the proposed project during the late winter and spring in the tidal reaches of the lower Sacramento River downstream of the north Delta diversions. The greatest flow reductions are expected in wet, above normal, and below normal hydrologic conditions. These transport flows are likely to be unimportant if temperatures are suitable and food supply is sufficient to provide adequate nourishment (Nobriga pers. comm.) further upstream in the lower Sacramento River, as will likely be the case in wetter periods. The project will have little effect on transport flows in drier years. Consequently, changes in transport flows are expected to have little to no effect on larval delta smelt critical habitat. Investigation of the potential effects of changes in Sacramento River flows on delta smelt is continuing.

River flow rates and hydrologic conditions within the Delta may have some effect on the potential for larval and juvenile delta smelt to be entrained at water diversion facilities. With BDCP implementation, entrainment losses of delta smelt at the north and south Delta export facilities combined are projected to decrease for larval, juvenile, and adult delta smelt. The reduction in entrainment risk for delta smelt reflects the combined effects of increased exports from the north Delta intakes which would be located near the upstream boundary of the delta smelt geographic distribution as well as reductions in south Delta diversions and an associated reduction in reverse flows in Old and Middle Rivers and other south and central Delta channels. Although there will be a minor adverse effect with regard to larval transport flows within the tidal reach of the Sacramento River downstream of the north Delta diversions, the improvements in Delta hydrologic conditions, including both reduction in Old and Middle River reverse flows as well as improvements in the net downstream flow of water through the Delta and associated improvements in aquatic habitat and production of food organisms within tidal habitats and Delta channels, is expected to be such that no net adverse effect on critical habitat will result. The net effect will be a benefit to the species.

Effects on Salinity (X2 Position). There is significant scientific disagreement regarding the biological importance of X2 in the fall and summer. This issue has been identified as requiring further research, analysis, and discussion amongst the scientific community. Further analysis will be undertaken.

To the extent that X2 is an indicator of delta smelt distribution, it is expected that the proposed habitat projects will increase the availability of physical habitat. Under the various distribution scenarios based on the potential future locations of X2, delta smelt will benefit from the newly restored physical habitat in the Cache Slough complex, western Delta and/or Suisun Marsh.

5.4.1.1.3 BDCP Effects on Delta Smelt Population Viability

This section addresses the population viability of delta smelt, although a formal population viability analysis has not been developed. The analysis is based on the results of the effects analysis and focuses on how the BDCP will affect the following criteria (based on those described for salmonids):

- Population abundance (population size) as reflected in the numbers of adult delta smelt returning the Delta to spawn;
- Population growth rates (productivity) as reflected in survival rates for each life stage and increasing population abundance trends (positive cohort replacement);
- Population spatial structure (habitat and population distribution) as reflected in the geographic distribution of suitable habitat, habitat heterogeneity and complexity; and
- Diversity (variation in behavioral and genetic traits) as reflected in diversity and complexity of habitat types, variation in life history timing, and access to suitable upstream spawning and rearing habitat and migration pathways.

Additional considerations include reducing and avoiding threats and stressors on the delta smelt population associated with actions such as changes in instream flows, water diversion effects, increased vulnerability to predation, and other factors.

Results of the BDCP effects analysis indicate that the BDCP conservation strategy and actions are consistent with the principles of delta smelt recovery planning and will address many of the stressors for delta smelt as identified in the Recovery Plan for the Sacramento/San Joaquin Delta

Native Fishes (USFWS 1996). The BDCP conservation actions are expected to result in the following outcomes related to delta smelt population viability:

Protection and expansion of habitat will increase abundance, growth rate, spatial structure, and diversity. The BDCP will contribute to increased abundance of delta smelt through protection and enhancement of suitable habitat conditions in existing areas utilized by delta smelt and through habitat restoration actions that increase the amount of suitable habitat available to smelt and, potentially increase smelt geographic distribution. In the south Delta, which smelt used historically but do so only occasionally now, conditions will be improved through decreased entrainment, increased residence time, and increased San Joaquin River flow at Verona. Increased residence time and reduced entrainment losses of phytoplankton, zooplankton, and nutrients from the central and southern Delta are projected to result in increased phytoplankton and zooplankton densities in the Delta and contribute to increased turbidity, which will increase habitat value for delta smelt. These beneficial effects could be reduced by increased water temperature resulting from climate change, but this effect may be offset by the effects of BDCP habitat restoration actions. Overall, these factors are expected to increase larval and juvenile growth and survival, contributing to increased adult abundance. These increases in habitat and abundance will contribute to increased diversity within the delta smelt population, increasing the resilience of the population to extinction risk and the ability to adapt to a changing environment.

Increased habitat will enhance food availability. The expanded floodplain, tidal wetland, and channel margin habitat restoration implemented as part of BDCP will provide an increase in intertidal habitat of approximately 14,360 acres and an increase in subtidal habitat of 31,320 acres over existing habitat. These habitats will be maintained by natural processes and will offer a wide range of residence times, water depths, water velocities, tidal mixing, and habitat conditions. These expanded habitats will substantially contribute to improved juvenile rearing by contributing to food production and availability. The expanded area and diversity of juvenile delta smelt rearing habitat and adult spawning habitat resulting from the BDCP will provide a broader range of habitats within the Delta for delta smelt and increased population abundance. These increases in habitat and abundance will likely contribute to increased diversity within the delta smelt population, increasing the resilience of the population to extinction risk and the ability to adapt to a changing environment.

Reduction in SWP/CVP losses will increase survival. While entrainment in the existing project facilities has ever been shown to have a population level effect, the BDCP will substantially reduce entrainment of juvenile and adult delta smelt at south Delta facilities by approximately one fourth and one half, respectively. This effect will increase survival of spawners and increase recruitment of juveniles to the adult lifestage.

5.4.1.1.4 Overall Conclusions for Delta Smelt

The following overall conclusions were made based on the results of the effects analysis for delta smelt.

Contribution to Recovery. *[**Note to Reviewers:** The Steering Committee has not completed discussion on the sufficiency of the BDCP to contribute to recovery of covered species]* As a comprehensive package of conservation measures, BDCP will contribute to the survival and recovery of the delta smelt population through cumulative reduction in stressors and improvements in habitat that together contribute to increase population abundance. The BDCP conservation strategy and actions are consistent with the principles of delta smelt recovery planning and will address many the stressors of delta smelt as identified in the Recovery Plan for the Sacramento/San Joaquin Delta Native Fishes (USFWS 1996). Habitat conditions and water operations resulting from implementation of BDCP conservation measures will allow for increased individual growth and survival, and consequently, increased delta smelt population abundance within the Delta. There are no actions proposed as part of BDCP that are inconsistent or incompatible with long-term delta smelt recovery plan implementation.

Net Beneficial Effects on Designated Critical Habitat. The BDCP implementation is expected to improve critical habitat for delta smelt. The PCEs for delta smelt critical habitat include physical habitat, water quality and food availability, to support delta smelt spawning, larval and juvenile transport, rearing habitat, and adult migration. It will result in a substantial increase in available habitat area, although the utility of this habitat cannot be fully known from existing information. This increase in habitat extends beyond the rearing space that delta smelt occupy and incorporates areas that are likely to experience increased food production. BDCP habitat restoration will likely increase turbidity, which would increase feeding success for delta smelt and assist in the avoidance of predators. The proposed project will reduce the concentration of toxic compounds in the areas most used by delta smelt, although changes in concentration are variable.

Need for Adaptive Management. Due to a limitation of available analytical tools, the magnitude of the effects of BDCP actions on delta smelt could not be quantified. There are a number of uncertainties described in the analyses of the effects of the project on delta smelt. Many of these uncertainties result from substantial scientific uncertainties regarding the factors affecting current trends in species abundance, basic life history requirements, and how the Delta may respond to large-scale changes in its habitat area and hydrology. To address this uncertainty, the BDCP includes an extensive monitoring program to evaluate the effectiveness of BDCP actions, a research program to expand the knowledge base, and an adaptive management program that provides the flexibility to adjust water operations criteria for certain parameters within specified adaptive ranges (see CM1 *Water Facilities and Operations* in Chapter 3, *Conservation Strategy*). The habitat restoration program will be adaptively managed as habitat is restored in phases over time. This phasing of restoration will provide an opportunity to learn which restoration strategies work and which do not, and to employ that knowledge to subsequent project planning to maximize their success. Because these monitoring, research and adaptive management programs are integral components of the project, there is the opportunity and flexibility to adaptively change the conservation measures, within prescribed bounds, reduce uncertainty, and improve outcomes.

5.4.1.2 Longfin Smelt

5.4.1.2.1 BDCP Effects on Stressors

The results of the effects analysis indicate that implementation of the BDCP conservation strategy will result in a number of major changes that will reduce the impacts of stressors on the longfin smelt population and improve habitat conditions for larval, juvenile, and adult rearing, although some adverse effects were also noted. These major findings include:

Expansion of habitat through physical restoration. Habitat restoration under the BDCP will increase subtidal habitat extent in Suisun Marsh and West Delta ROAs by 11,000 acres in the LLT , which are used extensively by longfin smelt. Approximately 11,000 acres will be created in the South Delta ROA, which is not used extensively by longfin smelt currently, but was historically. These restored subtidal areas may provide additional spawning and rearing habitat for longfin smelt if these areas are constructed to have appropriate hydraulics and water quality, and are not extensively colonized by SAV or introduced predators (BDCP includes specific measures to control SAV and predators). In total, the extent of subtidal habitat in the Delta will increase by approximately 35 percent over existing subtidal habitat in the Delta and Suisun Marsh and Bay.

Increased food production. It has been postulated that food is a limiting factor for longfin smelt (Baxter et al. 2008). Changes in operations and habitat restoration under the BDCP will increase hydraulic residence time in some areas of the Delta, which has the potential to increase food production in those areas. The types of primary producers found in the Delta water column are determined, in part, by the nutrient composition of the water (Glibert 2010). The net near term effect of hydraulic changes is therefore uncertain.

Habitat restoration has substantial potential to enhance food production within and adjacent to restoration sites because of the substantial increase in intertidal and subtidal habitat in the ELT and LLT. Although shallow intertidal habitat is not expected to be used by longfin smelt for rearing, primary production in these areas is expected to be high in the future. Adjacent subtidal areas will also produce food, as well as provide longfin smelt habitat as described above. The high food production from intertidal marsh areas may be carried from these areas into adjacent subtidal habitats that provide suitable habitat for longfin smelt, increasing production there, which would increase growth rates, and presumably benefit the longfin smelt population. There are two schools of thought regarding the amount of production expected to be exported from intertidal marsh: some experts believe that export of primary production could be moderate to high whereas other experts believe that exports would be low and sporadic.

An unknown fraction of this increased production could be consumed by the introduced overbite and Asian clams. Colonization of expanded habitat areas by the Asian clam *Corbula*, or future colonization of these habitats by nonnative clams and mussels in the future, could reduce the benefits of production in restored habitats. This potential effect could be off-set by concentrating early habitat actions in areas like Suisun Marsh, which have not been colonized by *Corbula* and where brackish conditions are inhospitable to freshwater SAV such as *Egeria*. The BDCP Implementation Office will learn from monitoring and research much more about successful and unsuccessful habitat restoration design features to minimize effects of nonnative clams during the 50 year term of the BDCP and will, therefore, adaptively manage restoration design to minimize these effects.

Reduced losses of longfin smelt at south Delta SWP/CVP facilities. Dual export facility operations under the BDCP will reduce adult longfin smelt losses by approximately 60 percent at both south Delta export facilities relative to existing biological conditions during both the ELT and LLT. While adult entrainment in the south Delta project facilities has been negligible in all but a few very dry years, the further reduction in proportional entrainment under the BDCP will benefit the species. Dual operations will likely increase juvenile longfin smelt losses in the ELT by approximately 20 percent at the south Delta SWP facility and 4-7 percent at the CVP facility. In the LLT, no difference was detected in juvenile longfin smelt losses between the BDCP and EBC at either facility. Dual operations will likely result in negligible reductions (less than 2 percent in many cases) in larval entrainment under the BDCP relative to the EBC. Based on the relative magnitude of differences in predicted losses under the BDCP and the EBC for each of these lifestages, and the relative importance of each lifestage to the overall population, reductions in adult losses are expected to outweigh increases in entrainment projected for juveniles, resulting in a net benefit to longfin smelt.

Negligible entrainment risk at north Delta intakes. As a result of the state-of-the-art design characteristics (i.e., 0.2 ft/sec approach velocity, screen mesh size, screen cleaning, etc.), and the northern location of the proposed intake structures relative to the geographic distribution of longfin smelt, the risk of entrainment or impingement of all life stages of longfin smelt at the north Delta intakes is negligible.

Entrainment in non-project diversions will be marginally reduced. The removal of non-project diversion due to changing land use in the Delta as a result of BDCP conservation measures (e.g., conversion of agricultural land use to restored natural habitat) will provide a marginal benefit to reducing entrainment risk for longfin smelt.

Entrainment in Mirant power plants will be greatly reduced. The expected transition to exclusive closed cycle water use at Mirant's Contra Costa and Pittsburg power plants by 2017 is predicted to substantially reduce and avoid entrainment and impingement of longfin smelt.

Changes in Delta hydrodynamics. There is significant disagreement regarding the biological importance of the location of X2. While the y-intercept of the statistical relationship between

Delta outflow and longfin smelt abundance reported by Kimmerer (2002) and Rosenfield and Baxter (2007) has decreased in recent years, the relationship is still present (Sommer et al. 2007, Rosenfield and Baxter 2007). At the same time, the response of longfin smelt abundance to levels of flow has dramatically declined, with the same magnitude of flows expected to produce less and less smelt over time.

Documented decreases in abundance between Age 1 and Age 2 fish (Rosenfeld and Baxter 2009) also suggest that a population bottleneck occurs after the recruitment from larvae to juvenile, suggesting that potential reductions in larval abundance based on reduced transport flows occurring prior to this bottleneck may not have significant population level effects.

Due to the scientific uncertainty regarding how to interpret any potential changes in the location of X2, this issue has been identified as requiring further research, analysis, and discussion amongst the scientific community. Further analysis will be undertaken.

Changes in toxicant levels. Toxicants (e.g., pyrethroids, copper, ammonia) have been identified as a potential stressor to longfin smelt (Sommer et al. 2007, Baxter et al. 2008, Werner 2010). Although studies focusing on the effects of toxics on longfin smelt have not yet been conducted, research on delta smelt should provide an indication of the magnitude of the impact on longfin smelt. Much of this research, however, is preliminary. Under the BDCP, toxicant concentrations will decrease in the west Delta as a result of minor decreases in loading from upstream sources, changes in hydrodynamics, and in-Delta land use changes. Results for the central Delta are more mixed. Because the bulk of the longfin smelt population occurs in the northern Delta and confluence, the net effect of the project with regard to toxicants is beneficial.

Removal of submerged aquatic vegetation (SAV). SAV removal is an important secondary action to habitat restoration. SAV has the potential to make habitat unsuitable for longfin smelt by encroaching on areas used by smelt for spawning and rearing, providing habitat for introduced predators, and reducing turbidity both within beds and in nearby areas. Without SAV removal, some portion of the intertidal and subtidal restored habitat will be colonized by SAV and become unsuitable for longfin smelt. This action would be beneficial to longfin smelt by keeping newly created habitat available for smelt.

Predator removal. Localized removal of predators (e.g., striped bass, largemouth bass, smallmouth bass) is expected to provide only negligible benefits to longfin smelt. Currently, there are few studies evaluating the effect of predation on longfin smelt. After further study, more information regarding the importance of predation on the longfin smelt population will be known, and effective predator management programs can be developed.

Establishment of a conservation hatchery. Establishing a viable refugial population of longfin smelt in a conservation hatchery will provide insurance against the potential extinction of the wild population and is an important consideration, given the low numbers of wild longfin smelt. It also will provide a stock of fish that could be used to assess the effects of various stressors on the species without impacting the wild stock. There would be more risks and uncertainty associated with increasing the scale of the facility to enhance the natural population. Long-term benefits would outweigh these risks if program managers develop and maintain populations whose genetic diversity and fitness are comparable to those of wild populations.

5.4.1.2.2 BDCP Effects on Longfin Smelt Population Viability

This section addresses the population viability of longfin smelt, although a formal population viability analysis has not been developed. The analysis is based on the results of the effects analysis and focuses on how the BDCP will affect the following criteria (based on those described for salmonids):

- Population abundance (population size) as reflected in the numbers of adult longfin smelt returning to the Delta to spawn;
- Population growth rates (productivity) as reflected in survival rates for each life stage and increasing population abundance trends (positive cohort replacement);
- Population spatial structure (habitat and population distribution) as reflected in the geographic distribution of suitable habitat, habitat heterogeneity and complexity; and
- Diversity (variation in behavioral and genetic traits) as reflected in diversity and complexity of habitat types, variation in life history timing, and access to suitable upstream spawning and rearing habitat and migration pathways.

Additional considerations include reducing and avoiding threats and stressors on the longfin smelt population associated with actions such as changes in instream flows, water diversion effects, increased vulnerability to predation, and other factors.

Results of the BDCP effects analysis show that the BDCP conservation strategy and actions are consistent with the principles of longfin smelt recovery planning and will address many of the stressors for longfin smelt as identified in the Recovery Plan for the Sacramento/San Joaquin Delta Native Fishes (USFWS 1996). The BDCP conservation actions are expected to result in the following outcomes related to longfin smelt population viability:

Protection and expansion of habitat will increase abundance, growth rate, spatial structure, and diversity. The BDCP will contribute to increased abundance of longfin smelt through protection and enhancement of suitable habitat conditions such as food availability and turbidity within upstream spawning and juvenile rearing habitats, as well as contribute to an increased smelt geographic distribution of adult spawning and juvenile rearing habitat within the Delta. Increased access to, and extent of suitable rearing habitat, as well as increased food resources, from habitat restoration will contribute to increased juvenile growth and survival, thereby contributing to increased adult abundance.

Long-term implementation of BDCP conservation measures will reduce the adverse effects of a number of current stressors and improve longfin smelt survival that will result in improved population growth rates (a greater probability of maintaining positive cohort replacement) over a wide range of hydrologic and environmental conditions that occur within the Central Valley.

Increased habitat will enhance food availability. The expanded floodplain, tidal wetland, and channel margin habitat restoration implemented as part of the BDCP will provide an increase in intertidal habitat of approximately 14,360 acres and an increase in subtidal habitat of 31,320 acres over existing habitat. These habitats will be maintained by natural processes and will offer a wide range of residence times, water depths, water velocities, tidal mixing, and habitat conditions. These expanded habitats will contribute to improved juvenile rearing by contributing to food production and availability. The expanded area and diversity of juvenile rearing habitat and adult spawning habitat resulting from the BDCP will provide a broader range of habitats within the Delta for longfin smelt which is expected to contribute to increased population abundance. These increases in habitat and abundance will likely contribute to increased diversity within the longfin smelt population, increasing the resilience of the population to extinction risk and the ability to adapt to a changing environment.

Reduction in SWP/CVP losses will increase survival. Adult entrainment in the south Delta project facilities has been negligible in all but a few very dry years. Nevertheless, as the BDCP would further reduce proportional entrainment, the species will benefit. The BDCP will reduce losses of adult longfin smelt at south Delta facilities by approximately 60 percent. This effect will contribute to an increased production of eggs and greater larval abundance. Losses of juvenile longfin smelt will be higher by approximately 15 to 26 percent, although this increase is outweighed by reduced losses to adults, due to differences in magnitude, and the relative importance of adults compared to juveniles to the population (an adult has already survived to the age of reproduction, whereas a juvenile has not).

5.4.1.2.3 Overall Conclusions for Longfin Smelt

The following overall conclusions were made based on the results of the effects analysis for longfin smelt.

Contribution to Recovery. *[**Note to Reviewers:** The Steering Committee has not completed discussion on the sufficiency of the BDCP to contribute to recovery of covered species]* As a comprehensive package of conservation measures, BDCP will contribute to the survival and recovery of the longfin smelt population through cumulative reduction in stressors and improvements in habitat that together contribute to increase population abundance. The BDCP conservation strategy and actions are consistent with the principles of longfin smelt recovery planning and will address many the stressors of longfin smelt as identified in the Recovery Plan for the Sacramento/San Joaquin Delta Native Fishes (USFWS 1996). Habitat conditions and water operations resulting from implementation of BDCP conservation measures will allow for increased individual growth and survival, and consequently, increased longfin smelt population abundance within the Delta. There are no actions proposed as part of BDCP that are inconsistent or incompatible with long-term longfin smelt recovery plan implementation.

Need for Adaptive Management. Due to a limitation of available analytical tools, the magnitude of the effects of BDCP actions on longfin smelt could not be quantified. There are a number of uncertainties described in the analyses of the effects of the project on longfin smelt. Many of these uncertainties result from substantial scientific uncertainties regarding the factors affecting current trends in species abundance, basic life history requirements, and how the Delta may respond to large-scale changes in its habitat area and hydrology. To address this uncertainty, the BDCP includes an extensive monitoring program to evaluate the effectiveness of BDCP actions, a research program to expand the knowledge base, and an adaptive management program that provides the flexibility to adjust water operations criteria for certain parameters within specified adaptive ranges (see CM1 *Water Facilities and Operations* in Chapter 3, *Conservation Strategy*). The habitat restoration program will be adaptively managed as habitat is restored in phases over time. This phasing of restoration will provide an opportunity to learn which restoration strategies work and which do not, and to employ that knowledge to subsequent project planning to maximize their success. Because these monitoring, research and adaptive management programs are integral components of the project, there is the opportunity and flexibility to adaptively change the conservation measures, within prescribed bounds, reduce uncertainty, and potentially improve outcomes.

5.4.1.3 Salmonids

5.4.1.3.1 BDCP Effects on Stressors

The results of the effects analysis indicate that implementation of the BDCP conservation strategy will result in a number of major changes that will reduce the impacts of stressors on the Chinook salmon and Central Valley steelhead populations and improve habitat conditions for juvenile rearing and migration within the Delta, and adult upstream migration to natal spawning areas, although some adverse effects were also noted. These major findings include:

Greater access to habitats used by juvenile salmonids. BDCP conservation measures will result in substantially increased access to expanded seasonal floodplain, tidal wetland, and channel margin habitat, geographically distributed throughout the Delta. This restoration will benefit juvenile salmon and steelhead produced in the Sacramento River Basin, east side tributaries, and the San Joaquin River Basin. Intertidal habitat could be expanded by approximately 6,040 acres in the near-term with an additional 7,250 acres in subtidal habitat. During the early long-term intertidal habitat could be expanded by 10,990 acres and subtidal habitat could be expanded by 9,350 areas. During the late long-term intertidal habitat could be expanded by 14,360 acres and subtidal habitat could be expanded by 31,320 acres. The Yolo Bypass floodplain rearing habitat would be enhanced by increased frequency and duration of flood flows. Up to 10,000 acres of new floodplain habitat would be restored across the Delta, mostly in the south Delta along the San Joaquin, Old, and Middle Rivers.

Among the salmonids winter-run and fall-run Chinook salmon are expected to receive the greatest benefit from expanded juvenile rearing habitat within the Delta. Both of these species have fry that rear within the Delta for several months before migrating into the ocean. During the juvenile rearing and emigration period (late winter and spring months) these juveniles would benefit from increased access to seasonally inundated floodplain habitat as well as shallow-water, low-velocity juvenile rearing habitat located throughout the various regions of the Delta. Late fall-run and spring-run Chinook salmon and steelhead primarily rear in upstream riverine habitats and typically their juveniles do not spend a prolonged period rearing within the Delta. The older juveniles and smolt stages of these and other salmonids would, however, gain benefits from increased availability of channel margin habitat and food production in tidally inundated wetland habitat during their emigration from the Sacramento and San Joaquin River systems. The increased access to suitable habitat for foraging and rearing, and the increased availability of prey, are expected to contribute directly to increased growth, juvenile health, and survival.

Habitat benefits for Sacramento River salmonids. Major expansion in access to floodplain habitat (Yolo Bypass), tidal habitat (Cache Slough complex, Suisun Marsh, West Delta ROAs), and channel margin habitat (e.g., along the mainstem Sacramento River and Sutter and Steamboat sloughs) will occur in the northern and western Delta, and will serve to benefit juvenile steelhead, spring-run, winter-run, fall-run, and late fall-run Chinook salmon produced in the Sacramento River Basin. Intertidal habitat could be expanded by approximately 2,950 acres in Cache Slough in the near-term with an additional 1,210 acres in subtidal habitat. During the early long-term intertidal habitat in Cache Slough could be expanded by 5,750 acres and subtidal habitat could be expanded by 2,320 areas. During the late long-term intertidal habitat could be expanded by 6,710 acres from existing conditions and subtidal habitat could be expanded by 7,400 acres. Additional substantial tidal and subtidal habitat expansion in the western Delta and Suisun Marsh, and channel margin habitat enhancement on the Sacramento River (at least 5 miles) and on Sutter and Steamboat sloughs, would also be available on the migration pathway for juvenile steelhead, winter-run, spring-run, fall-run, and late fall-run Chinook salmon.

Rearing habitat function for Sacramento River Basin salmonids of the existing floodplain in the Yolo Bypass will be enhanced through an increase in the frequency and duration of inundation with an approximately a 2- to -3 fold increase in frequency of short duration flood events (>30 days), as much as a 2- to 6-fold increase in frequency of intermediate duration flood events (between 30-45 days), and as much as a 3- to 9-fold increase in frequency of long duration flood events (>45 days). Extended rearing opportunities within the floodplain habitat have been shown to result in increased growth and survival of juvenile Chinook salmon (Sommer et al. 2001). Results of bioenergetic modeling suggested that feeding success was greater on the floodplain than in the Sacramento River (Sommer et al. 2001). Survival rates of marked salmon were found to be overall greater for those fish rearing in the floodplain, likely due to increased feeding success, increased prey availability, increased seasonal water temperatures, and availability of shallow-water low-velocity rearing habitat, although there was variation in the data showing equal or reduced survival in some years. The factors that contributed to increased and decreased juvenile survival and growth within the Yolo Bypass are continuing to be analyzed.

The benefits of rearing on seasonally inundated floodplain habitat within the Yolo Bypass would be available for all salmonids produced in the Sacramento River watershed with the exception of those from the lower American River. Rearing by juvenile winter-run, spring-run, fall-/late fall-run Chinook and steelhead within the floodplain and the interconnected Cache Slough tidal complex also offers the opportunity for greater life history diversity, such as extended fry rearing, and a wider range of ocean entry times that reduce the risk of adverse population-level effects in response to poor seasonal habitat conditions. Expanding opportunities for life history diversity for salmonids and other Central Valley fish is consistent with conservation principles and recovery planning.

Habitat Benefits for Eastside Tributary salmonids. Intertidal habitat will be expanded in the lower regions of the Mokelumne and Cosumnes rivers by approximately 850 acres in the near-term and subtidal habitat will be expanded by 1,970 acres. These expanded intertidal and subtidal habitats will then continue to function during the ELT and LLT to benefit east side steelhead and fall-run Chinook salmon, as well as other aquatic species. Mokelumne and Cosumnes river basin salmonids will also benefit from habitat expansion in the western Delta and Suisun Marsh and channel margin enhancements along distributaries of the Mokelumne and Cosumnes rivers.

Habitat benefits for San Joaquin River salmonids. Expansion of intertidal and subtidal habitat in the south Delta along the migratory pathway for juvenile steelhead and Chinook salmon produced in the San Joaquin River basin will occur in the LLT. Approximately 1,850 acres of intertidal and 10,950 acres of subtidal habitat will be restored in the LLT. Restoration floodplain habitat along the San Joaquin, Old, and Middle rivers will periodically (in years of flood events) provide rearing habitat for San Joaquin River salmonids. San Joaquin River salmonids will also benefit from habitat expansion in the western Delta and Suisun Marsh and channel margin enhancements along the mainstem and distributaries of the San Joaquin River.

BDCP creates alternative migratory routes. Juvenile Sacramento River basin salmonid survival will improve as a result of expanded access to seasonal floodplain within the Yolo Bypass, which will provide opportunities for juvenile Chinook salmon and steelhead to access alternative migration pathways that will circumvent the new north Delta intake structures as well as the existing Delta Cross Channel and Georgiana Slough. This is expected to lead to improved survival of Sacramento River basin juveniles.

BDCP creates conditions of enhanced food production, with potential to offset survival risk from stranding, predation, and water quality. Expanded access to seasonal floodplain, tidal wetland, and improved channel margin habitat will provide shallow water, low-velocity, habitat areas with increased food production. Expanded access to suitable habitat is expected to benefit juvenile salmon and steelhead rearing through access to alternative migration pathways, access to improved juvenile rearing habitat, and access to increased food production, all of which are collectively expected to result in increased juvenile growth rates and survival.

The magnitude of these benefits on the population abundance of Chinook salmon and steelhead from BDCP expanded habitat has not been quantified. The potential to improve juvenile salmonid rearing, and reduce risks associated with stranding, predation and exposure to potential toxics and adverse water quality conditions is unknown relative to existing biological conditions. Rigorous monitoring, adaptive management, and expanded habitat design serve to reduce uncertainty and the risk of adverse effects resulting from habitat expansion.

Potential benefits to all Central Valley salmonid populations. Distributing expanded access to suitable habitat for juvenile salmonid rearing throughout the Delta would offer potential net biological benefits to all populations of Central Valley salmonids.

Potential but unquantified benefits from habitat modifications along levees. Currently, habitat conditions within the Delta are characterized by large areas of riprap stabilized channel margin with little shallow water or low velocity habitat for fry and juvenile rearing. Expanded access to habitat areas characterized by shallow-water, low velocities, increased hydraulic residence time, and increased food availability, as well as providing a wider geographic distribution of diverse and complex habitats within the Delta, is consistent with salmonid conservation principles and increases opportunities for a broader range of life history expression including extended fry and juvenile rearing within the Delta.

Expanding life history diversity through expanded diverse habitat conditions is thought to improve rearing and growth, increase survival, and increase the range of life histories. This increased range of life histories includes varying juvenile rearing strategies and an expanded range of ocean entry dates that serve to reduce the risk of adverse habitat conditions on a single area of the species range (e.g., upstream habitat, or ocean conditions), which then contribute to reduced population-level declines in survival and abundance. The benefits of increased access to expanded habitat for fry and juvenile rearing on the population dynamics, resiliency, and robustness of Central Valley salmonids exposed to a wide range of environmental conditions, however, has not been quantified.

Reduced losses of salmonids at SWP/CVP facilities. While entrainment in the south Delta project facilities has never been found to have a population level effect, the project is expected to provide some benefits through reduced entrainment. Dual export facility operations would result in a reduction in juvenile steelhead losses, including pre-screen losses, at the south Delta export facilities by 40-60 percent relative to existing conditions. Dual export facility operations will reduce juvenile winter-run Chinook salmon losses at the south Delta export facilities by 50-60 percent relative to existing conditions. Dual export facility operations will result in small changes (a reduction of 1 percent to an increase of 12 percent) in juvenile spring-run salmon entrainment and salvage losses at the south Delta export facilities relative to existing conditions**.** The estimated reduction in fall-run Chinook salmon losses is 3-15 percent.

Negligible entrainment risk at north Delta intakes. As a result of the state-of-the-art design characteristics (i.e., 0.2 ft/sec approach velocity, screen mesh size, screen cleaning, etc.), the risk of entrainment or impingement of juvenile Sacramento River Basin salmonids at the north Delta intakes is negligible.

Entrainment in non-project diversions will be marginally reduced. The removal of non-project diversions due to changing land use in the Delta as a result of BDCP conservation measures (e.g., conversion of agricultural land use to restored natural habitat) will provide a marginal benefit to reducing entrainment risk for juvenile steelhead and salmon.

Entrainment in Mirant power plants will be greatly reduced. The expected transition to exclusive closed cycle water use at Mirant's Contra Costa and Pittsburg power plants by 2017 is predicted to substantially reduce and avoid entrainment and impingement of juvenile steelhead and Chinook salmon.

Increased predation resulting from north Delta in-river intakes. The use of five in-river intake structures located in the north Delta would create conditions that attract predatory fish such as striped bass, and thus increase the risk of Sacramento River juvenile steelhead and salmon to predation losses. No increase in predation risk is expected for salmonids produced in east side tributaries or San Joaquin River basin. Actions that could reduce the predation risk include reconfiguration of the intakes to an on-bank design that reduces predator habitat, although additional analyses must be conducted to verify this conclusion, and implementation of an aggressive and sustained local and regional predator removal and control program under CM6 *Predator Control*.

Improved survival of juvenile steelhead and salmon is expected from re-operation of the Delta Cross Channel (DCC) gates and installation of non-physical barriers. Closure of the DCC gates and installation and operation of non-physical barriers at key locations such as the confluence between Georgiana Slough and the Sacramento River and at the head of Old River will serve to improve survival of juvenile Sacramento River and San Joaquin River runs of steelhead and salmon migrating downstream in the rivers and through the Delta. DCC gate closure in the fall may also improve attraction flows, and thus improve olfactory cues, for upstream migrating adult Sacramento River Basin salmonids and reduce inter-basin straying. It should be noted that the effectiveness of non-physical barriers and their interaction with predators is based on limited testing; thus outcomes for salmonids remain uncertain.

Reduced reverse flow conditions. BDCP dual facility operations will result in substantial improvements in Old and Middle River (OMR) reverse flows within the south and central Delta and a net improvement in downstream flows through the Delta, particularly from the San Joaquin, Mokelumne, and Consumes river systems. These improvements in Delta hydrodynamics are expected to result in improvements in habitat conditions for juvenile steelhead and salmon rearing and survival during emigration.

No adverse upstream impacts of BDCP operations measures on steelhead, winter-run, fall-run, and late fall-run salmon. No major adverse effects were detected on upstream habitat conditions (e.g., reservoir storage, instream flows, and water temperatures during egg incubation) for steelhead, winter-run, fall-run, and late fall-run Chinook salmon in the Sacramento, Feather, and American rivers. Small positive and negative changes were detected in the Sacramento and

Feather rivers, such as reduced summer and fall flows in the Sacramento River relative to existing conditions. None of these changes would be expected to have a substantial effect on salmonid life history (i.e., migration, spawning, and juvenile rearing). No changes in habitat (i.e., instream flows and seasonal water temperatures) were detected in other rivers including the Trinity, San Joaquin, and Stanislaus or Clear Creek. BDCP operations would have no effect on habitat in non-CVP/SWP rivers including the Mokelumne, Consumes, Tuolumne, and Merced rivers, or Deer, Mill, Butte, Battle, and other tributary creeks.

Uncertainty regarding potential egg mortality for Sacramento River spring-run salmon. Results of egg mortality estimates for spring-run Chinook salmon on the Sacramento River downstream of Keswick Dam showed an increase in egg mortality of approximately 5 percent during early long term and 10 percent during late long term under BDCP operations in wet, above normal, and below normal water years relative to existing conditions. Refinement in reservoir operations and coldwater pool management may reduce this effect, but potential operational changes have not been evaluated using the hydrologic and water temperature simulation models. Spring-run Chinook salmon primarily inhabit tributaries to the Sacramento River, such as Clear Creek, Butte Creek, Mill Creek, Deer Creek, and others. Therefore, the effects of increased egg mortality on the Sacramento River would potentially adversely affect only a small proportion of the spring-run Chinook salmon spawning in the Sacramento River Basin. Results of the effects analysis detected no BDCP-related adverse effects to upstream habitat conditions (e.g., instream flows, water temperatures during egg incubation) for spring-run Chinook salmon in the Trinity River, Clear Creek, or Feather River low flow channel. BDCP operations will have no effect on instream flows, temperatures, or other habitat conditions affecting spring-run Chinook salmon spawning or egg incubation in other Sacramento River tributaries such as Mill, Butte, Deer, or Battle Creeks.

Spring-run Chinook salmon are sensitive to drought and climate change. Spring-run Chinook salmon egg mortality in the mainstem Sacramento River is extremely sensitive to effects of dry and critically dry hydrologic conditions and future climate change. Increased egg mortality under these conditions reflects natural seasonal and inter-annual variation in rivers flows, coldwater storage, and temperature effects on incubating eggs that were independent of BDCP operations.

Due to the scientific uncertainty regarding the nature and magnitude of this effect, particularly after mitigation, this issue has been identified as requiring additional analysis. Further review will be undertaken.

Uncertain effects related to operation of north Delta intake. Sacramento River flows downstream of the north Delta intakes will be reduced under BDCP operations relative to existing conditions. Flows will be reduced less during the winter than during the other seasons. Flows will be reduced most in the wetter years. The effects of flow reduction within the lower reach of the Sacramento River on the attraction and olfactory cues for upstream migrating adult salmonids and survival of downstream migrating juvenile salmonids are uncertain. Flows in the lower Sacramento River are influenced by tidal hydrodynamics, which also affect adult salmonid attraction and juvenile migration. Increased flows in drier years offer a benefit of increased attraction and olfactory cues that will contribute to reduced adult straying among watersheds.

Interannual and long-term hydrologic changes occur with or without BDCP operations. The greatest changes in habitat conditions result from natural variation in inter-annual hydrology (e.g., between wet and dry years) and future climate changes. These major effects on habitat were largely independent of differences between existing conditions and BDCP operations. Spring-run Chinook salmon were found to have the greatest risk among the salmonids of high egg mortality resulting from exposure to elevated water temperatures, particularly in critically dry water years, because of the effects of projected climate change independently, whether from existing conditions or conditions with BDCP implementation;

Net benefits of other stressor conservation measures. Collectively, other stressor conservation measures provide additional benefits to salmonids relative to existing conditions. Benefits of conservation actions such as removing structures that create habitat for and attract predators, reducing illegal harvest, and implementing hatchery and genetic management plans, although small, contribute to the cumulative biological benefits to salmonids of BDCP.

5.4.1.3.2 BDCP Effects on Salmonid Designated Critical Habitat

Critical habitat for salmonids was designated in 2005 for Sacramento River winter-run Chinook salmon, Central Valley spring-run Chinook salmon, and the distinct population segment of Central Valley steelhead (70FR170: 52488-52627). Habitat for these species is further characterized in the Federal Register Final Rule for each listed species (steelhead: 70 FR 52488; winter-run Chinook: 58 FR 33212; Spring-run Chinook: 70 FR 52488). The effects analysis for salmonids addressed how changes in SWP and CVP water operations and other BDCP conservation actions would affect, beneficially or adversely, the primary constituent elements (PCEs) of steelhead and Chinook salmon critical habitat.[7] The PCEs used in the effects analysis were:

- Freshwater spawning sites (i.e., providing suitable water temperatures and instream flows for successful spawning in the upstream reaches of the tributary rivers);
- Freshwater rearing sites (i.e., providing suitable water quality for juvenile rearing, instream flows to support physical habitat, connectivity with floodplains, tidal habitat, channel margin habitat, and other juvenile rearing areas, and providing suitable food resources for juvenile rearing);
- Freshwater migration corridors (i.e., reducing and avoiding passage barriers and impediments, providing suitable water quality and instream flows to support access and

[7] Other important habitats for salmonids include nearshore and offshore marine coastal habitats, which will not be affected by BDCP conservation actions.

connectivity for migration within the tributary rivers, seasonally inundated floodplains and tidal habitats, and migration pathways through the Delta);

- Estuarine areas (i.e., providing unobstructed migration and rearing opportunities, suitable water quality with salinity conditions that support juvenile and adult physiological transitions between freshwater and saltwater, and providing food resources to support juvenile growth and survival).

The effects analysis examined, through hydrologic and water quality simulation modeling, predicted changes in habitat conditions that would potentially affect the quality and availability of suitable habitat for each of the freshwater lifestages of Chinook salmon and steelhead.

Effects on Freshwater Spawning Sites. Although minor adverse and beneficial changes in habitat conditions (instream flow, water temperature, and the risk of redd dewatering) were detected for salmonid spawning and egg incubation in some locations, these changes will not have a substantive effect on habitat conditions for steelhead or winter-run Chinook salmon. Based on results of the egg mortality analysis for spring-run Chinook salmon in the mainstem Sacramento River, additional analyses are underway to assess the significance of increased egg mortality on spring-run salmon population dynamics, recognizing that only a small fraction of the population spawns in the Sacramento River, and potential refinements to Shasta Reservoir operations to reduce adverse effects. For a majority of the Central Valley rivers there was no effect of the BDCP on habitat conditions for spawning relative to the EBC. The greatest observed changes in habitat quality or availability are in response to interannual variation in Central Valley hydrologic conditions (e.g., wet years and dry years) and in response to long-term changes in Central Valley climate. Therefore, the BDCP would not affect critical habitat or the success of steelhead and Chinook salmon spawning within Central Valley rivers.

Effects on Freshwater Rearing Sites. Although minor adverse and beneficial changes in habitat conditions (flow and water temperature) were detected for salmonid rearing in some locations, these changes will not have a substantive effect on habitat conditions for Chinook salmon or steelhead. For a majority of the Central Valley rivers, there was no effect of the BDCP on habitat conditions for juvenile rearing relative to the EBC. The greatest observed changes in habitat quality or availability are in response to interannual variation in Central Valley hydrologic conditions (e.g., wet years and dry years) and in response to long-term changes in Central Valley climate.

Restoration of additional floodplain, tidal, and channel margin habitat that is geographically distributed throughout the Delta will provide substantial benefits to all Central Valley salmonids. The predicted magnitude of these benefits to increased juvenile growth and survival, and the contribution of these conservation measures to increased adult salmonid abundance have not been quantified, although positive trends towards recovery are anticipated based on salmonid recovery plans. Floodplain enhancement actions designed to increase the frequency and duration of access for juvenile Sacramento River basin Chinook salmon and steelhead to seasonally inundated floodplain habitat in Yolo Bypass will be a significant environmental benefit of

BDCP. Similarly, the BDCP will substantially increase the availability of, and access to, shallow water, low velocity tidal and channel margin habitat that is geographically distributed along the Sacramento River and within the eastern and southern Delta and Suisun Marsh, which will increase rearing habitat for juvenile Chinook salmon and steelhead from all Central Valley rivers relative to existing conditions. The increased tidal and seasonal floodplain habitat proposed under BDCP will contribute to improved ecological functions related to increased food production and availability of prey for juvenile salmon and steelhead. Uncertainty in expanded habitat performance and ecological functions will be addressed through a rigorous monitoring, research, and adaptive management programs.

Overall, BDCP will not adversely modify habitat conditions for freshwater rearing in upstream habitats within rivers tributary to the Delta. Instead, BDCP conservation actions will improve habitat access, quality, and availability for juvenile Chinook salmon and steelhead rearing within the lower reaches of the Sacramento and San Joaquin rivers and within the Delta and Suisun Marsh. Implementation of BDCP conservation measures will contribute to a substantial increase in suitable habitat for juvenile Chinook salmon and steelhead rearing.

Effects on Freshwater Migration Corridors. The BDCP conservation strategy includes measures specifically designed to improve migratory corridors and reduce the effects of obstructions that impede salmonid passage under existing conditions. Proposed actions include increasing fish passage opportunities for juvenile salmon and steelhead migration into the seasonally inundated Yolo Bypass floodplain, improving passage at the Fremont Weir, using non-physical barriers to guide downstream migrating salmon and steelhead, improving dissolved oxygen concentrations in the lower San Joaquin River, and modifying operation of the Suisun Marsh Salinity Control Structure to improve fish passage. Operations under BDCP will also improve hydrologic conditions as reflected by an increase in positive flows in Old and Middle Rivers, as well as maintenance of instream flows within the tributaries to the Delta. These conditions are intended to improve the survival of juvenile Chinook salmon and steelhead migrating downstream through the Delta, in part by reducing their vulnerability to entrainment losses at the existing south Delta water export facilities. Implementation of additional floodplain and tidal habitat has been identified as being beneficial for all Central Valley salmonids. There is a high degree of uncertainty, however, in the quantification of the magnitude of net benefits to the salmonid populations, although positive trends towards recovery are anticipated based on salmonid recovery plans. Reductions in instream flow in the lower reaches of the Sacramento River have the potential to reduce olfactory cues and attraction flows for upstream migrating adult Chinook salmon and steelhead, and river flows for downstream migrating juveniles in the reach downstream of Walnut Grove. Upstream of the north Delta intakes, river flows are similar between the BDCP and existing conditions. In the downstream estuarine region of the Delta, tidal flows are dominant. No information is available to quantitatively assess the potential effects of local flow reductions on migration and survival of Chinook salmon or steelhead.

Construction of five north Delta intake structures would modify local hydrodynamic conditions as well as obstruct a portion of the river channel by the footprint of each intake structure. These effects of the north Delta intakes would occur whether or not the intake is actually diverting water. Although these physical structures and their effects on local instream flow patterns and turbulence would adversely affect critical and essential habitat for salmonids in the lower reaches of the Sacramento River, these effects are expected to be localized and relatively small in comparison to the large areas of subtidal and intertidal aquatic habitat that would be restored and available for salmonid foraging, rearing, and migration.

Overall, the BDCP will not adversely affect habitat conditions for Chinook salmon or steelhead in migration corridors within the tributaries of the Delta and would improve passage conditions for salmonids migrating through the Delta. BDCP conservation actions will reduce obstructions to salmon and steelhead passage within the lower reaches of the Sacramento and San Joaquin rivers and within the Delta and Suisun Marsh. Implementation of BDCP conservation measures is expected to contribute to an increase in habitat conditions for juvenile Chinook salmon and steelhead migration.

Effects on Estuarine Areas. The BDCP conservation strategy will contribute to a substantial increase in access to suitable juvenile salmonid rearing habitat within the estuarine regions of the Delta through channel margin habitat enhancements in the western Delta, as well as substantial increases in aquatic habitat within Suisun Marsh adjacent to Suisun Bay (approximately 24,570 acres in the LLT). The increased access of shallow water, lower velocity juvenile rearing habitat within the estuarine region of the Delta will contribute to an increase in ecological functions of aquatic habitat including increased habitat diversity and complexity, foraging habitat and food resources for migrating juvenile Chinook salmon and steelhead. Implementation of additional tidal habitat will be beneficial to salmonids. Although positive trends towards recovery are anticipated based on salmonid recovery plans, there is a high degree of uncertainty in the magnitude of net population level benefits to the salmonid populations.

Operations under BDCP will also improve hydrologic conditions as reflected by an increase in positive flows in Old and Middle rivers and maintenance of instream flows within the rivers tributary to the Delta. These conditions will improve the survival of juvenile Chinook salmon and steelhead migrating downstream through the Delta and improve estuarine rearing habitat conditions. These improvements will benefit juvenile salmon and steelhead by providing a potential for increased growth, which should contribute to increased survival. Improvements in central Delta habitat and hydrodynamics will provide the greatest benefits for salmon and steelhead produced in the Mokelumne, Cosumnes, and San Joaquin river basins.

Operations under BDCP during the late winter and spring months when juvenile salmon and steelhead are migrating downstream through the estuarine region of the Delta provide outflow and salinity conditions that are comparable to those under existing conditions.

Overall, the BDCP will not adversely affect habitat conditions for Chinook salmon and steelhead within the estuarine region of the Delta. BDCP conservation actions will reduce obstructions to salmon and steelhead passage within Suisun Marsh. The BDCP will contribute to an increase in habitat for juvenile Chinook salmon and steelhead migration within the estuarine region of the Delta.

5.4.1.3.3 BDCP Effects on Essential Fish Habitat for Pacific Salmon

The Bay-Delta system has been identified as Essential Fish Habitat (EFH) under the Magnuson-Stevens Act for several groups of fish species including Pacific salmon, Coastal Pelagic Species, and West Coast Groundfish. EFH includes those waters and substrate necessary for fish production needed to support a long-term sustainable fishery and contributions to a healthy ecosystem. The BDCP effects analysis included an assessment of EFH for Pacific salmon which includes winter-run, spring-run, fall-run, and late fall-run Chinook salmon from all Central Valley river systems.

The BDCP conservation measures and operations will result in localized temporary effects on EFH. These effects would be reduced through implementation of BMPs during construction and other actions. The BDCP actions would result in small changes in local habitat conditions in some areas of the upstream rivers and Delta, but would also result in improvements in aquatic habitat conditions through changes in local hydrodynamics such as reductions in Old and Middle River reverse flows and significant expansion of aquatic habitat within a variety of regions distributed throughout the Delta and within Suisun Marsh. Operations will not result in substantial or detectable changes in habitat conditions for EFH species inhabiting regions of the Bay-Delta downstream of Suisun Bay. Based on these factors, it was concluded that implementation of BDCP will not result in adverse effects to EFH that would impact Chinook salmon at a population level. Instead, many of the proposed conservation actions will contribute to enhanced EFH conditions within the Delta.

5.4.1.3.4 BDCP Effects on Salmonid Population Viability

The long-term recovery of Central Valley Chinook salmon and steelhead is measured by four fundamental viable salmonid population (VSP) criteria as described in the NMFS (2009) draft Central Valley salmonid recovery plan and Lindley et al. (2007):

- Population abundance (population size) as reflected in the numbers of adult Chinook salmon and steelhead returning to Central Valley rivers to spawn;
- Population growth rates (productivity) as reflected in survival rates for each life stage and increasing population abundance trends (positive cohort replacement);
- Population spatial structure (habitat and population distribution) as reflected in the geographic distribution of suitable habitat, habitat heterogeneity and complexity, abundance of juvenile smolts produced in different watersheds, and dispersal of distinct population segments among watersheds; and
- Diversity (variation in behavioral and genetic traits) as reflected in diversity and complexity of habitat types, reduced percentage of hatchery produced Chinook salmon

and steelhead, variation in life history and run timing, and access to suitable upstream spawning and rearing habitat and migration pathways.

Additional considerations include reducing and avoiding threats and stressors on the populations associated with actions such as changes in instream flows, water diversion effects, increased vulnerability to predation, and other factors.

Results of the BDCP effects analysis indicate that changes predicted to occur as a direct result of implementation of the conservation strategy are consistent with the principles of recovery planning for Central Valley salmonids. The BDCP conservation actions will contribute to recovery for salmonids because they will result in the following:

Restoration of habitat will increase abundance, growth rate, spatial structure, and diversity. The BDCP will contribute to increased abundance of Central Valley Chinook salmon and steelhead through protection and enhancement of suitable habitat conditions such as instream flows and water temperatures within the upstream spawning and juvenile rearing habitats, as well as contribute to increased geographically distributed and complex juvenile rearing habitat within the Delta. Increased access to expanded seasonal floodplain, tidal wetlands, and improved channel margin habitat will contribute to increased juvenile growth and survival, thereby improving survival and contributing to increased adult abundance. Long term implementation of BDCP conservation measures will reduce the adverse effects of a number of current stressors and improve juvenile and adult Chinook salmon and steelhead survival that will result in improved population growth rates (a greater probability of maintaining positive cohort replacement) over a wide range of hydrologic and environmental conditions that occur within the Central Valley.

Salmonid independent populations. Conservation measures included as part of BDCP would not result in the expansion of winter-run or spring-run Chinook salmon or Central Valley steelhead populations into additional upstream habitats or result in the formation of additional independent spawning populations. Habitat conditions and water operations within the Sacramento River and Delta, however, would be complementary to the formation of additional winter-run or spring-run Chinook salmon or steelhead populations within the Central Valley if that should occur in the future.

Reduction in SWP/CVP losses will increase survival. While entrainment in the south Delta SWP and CVP project facilities has never been determined to have a population level effect, reduced entrainment would provide some increases in survival thereby benefiting the species. Reduction in south Delta SWP and CVP exports through dual facility operations would contribute to: (1) increased juvenile winter-run and fall-run Chinook salmon and steelhead survival through a reduction in losses resulting from reductions in south Delta SWP and CVP export operations; (2) increased juvenile rearing habitat and survival, particularly for juvenile Chinook salmon and steelhead produced in the San Joaquin, Mokelumne, and Consumes river watersheds as a result of reductions in Old and Middle river reverse flows and associated increases in net downstream flows through the Delta; and (3) reduced risk of indirect mortality for juvenile salmonids migrating through the Delta and improvements in net downstream flows through the Delta channels. Actions such as expanded closure times of the Delta Cross Channel gates and installation and operation of non-physical barriers at key locations (Georgiana Slough, head of Old River) will further contribute to increased juvenile survival, improved attraction, and reduced straying for adult Chinook salmon and steelhead returning to the San Joaquin River system and east side tributaries.

5.4.1.3.5 Overall Conclusions for Chinook Salmon and Steelhead

The following overall conclusions were made based on the results of the effects analysis for Chinook salmon and steelhead.

Net Beneficial Effects on San Joaquin River Salmonids. Steelhead, fall-run Chinook, and future re-introduced spring-run Chinook salmon runs in the San Joaquin River Basin would benefit from BDCP implementation by a reduction in south Delta exports and the associated reduced risk of entrainment at the export facilities, reduction in the magnitude of Old and Middle rivers reverse flows and improvement in the net downstream flow of water from the San Joaquin River through the Delta. Reduction in potential indirect effects on the survival of juvenile salmonids. Expansion of aquatic habitat in the south Delta in the LLT and habitat expansion in the west Delta and Suisun Marsh in the ELT and LLT will provide opportunities for juvenile salmonids emigrating from the San Joaquin River system to rear and contribute to increased juvenile growth rates and survival. BDCP would have no effect on instream flows, water temperatures, or other habitat conditions within the mainstem San Joaquin River or its tributaries relative to existing biological conditions. Increased flow from the San Joaquin River passing through the Delta will improve adult salmonid attraction and olfactory cues and contribute to improved survival of emigrating juveniles. Application of a non-physical barrier at the head of Old River and the effects of reductions in other stressors would contribute to the cumulative benefits of BDCP conservation measures on the growth, survival, and abundance of San Joaquin River salmonids.

Net Beneficial Effects on Mokelumne and Cosumnes River Salmonids. Steelhead and fall-run Chinook runs in the Mokelumne and Cosumnes rivers would benefit under BDCP by a reduction in south Delta exports and the associated risk of entrainment at the export facilities, reduction in the magnitude of Old and Middle River reverse flows and improvement in the net downstream flow of water from the Mokelumne and Cosumnes rivers through the Delta. Expansion of aquatic habitat in the lower reaches of the Mokelumne and Cosumnes rivers and habitat expansion in the west Delta and Suisun Marsh would provide opportunities for juvenile salmonids emigrating from the Mokelumne and Cosumnes rivers to rear and contribute to increased juvenile growth rates and survival. BDCP would have no effect on instream flows, water temperatures, or other habitat conditions within either the Mokelumne or Cosumnes rivers relative to existing biological conditions. Closure of the Delta Cross Channel gates during the fall would potentially improve attraction to the Mokelumne and Cosumnes rivers and reduce straying to other Central Valley rivers. The effects of reductions in other stressors would contribute to the cumulative benefits of BDCP conservation measures on the growth, survival, and abundance of steelhead and fall-run Chinook salmon produced in the two rivers.

Net Beneficial Effects on Sacramento River Salmonids. Steelhead, winter-run, spring-run, fall-run and late fall-run Chinook runs in the Sacramento River Basin would benefit from BDCP implementation by a reduction in south Delta exports and the associated risk of entrainment at the export facilities. Diversions from the north Delta would make use of state-of-the-art positive barrier fish screens designed and operated to avoid entrainment and impingement of juvenile salmonids. An increased risk of predation associated with the north Delta intake structures was identified in the effects analysis, but can be substantially reduced by intake re-design in combination with predator management. Reduction in the magnitude of Old and Middle rivers reverse flows and improvement in Delta habitat available for juvenile salmonid rearing will provide an improvement in hydrologic conditions affecting habitat and survival of juvenile salmonids in the central and south Delta. Reduction in reverse flows and reductions in south Delta exports results in a reduction in potential indirect effects on the survival of juvenile salmonids. Expansion of aquatic habitat in the north Delta through substantial increases in the frequency and duration of access to expanded seasonal floodplain rearing habitat within the Yolo Bypass, that is interconnected to substantially increased tidal habitat within the Cache Slough complex, will increase juvenile growth and survival, contribute to increased habitat diversity and complexity, and provide opportunities for expanded diversity of life history characteristics. In combination, these changes would result in greater juvenile survival and increased adult salmonid abundance. Habitat expansion in the west Delta and Suisun Marsh would provide opportunities for juvenile salmonids emigrating from the Sacramento River and its tributaries to rear and contribute to increased juvenile growth rates and survival. BDCP would have no effect on instream flows, water temperatures, or other habitat conditions in many of the Sacramento River tributaries. Relatively small beneficial and adverse changes in upstream habitat within the mainstem Sacramento River and Feather River were identified. Refinements in Shasta Reservoir operations may help reduce a projected increase in spring-run Chinook salmon egg mortality in wetter years in the mainstem Sacramento River. Reduced flows in the lower reach of the Sacramento River downstream of the north Delta intakes in wetter years may affect adult salmonid attraction and juvenile survival, however, the potential for adverse effects within the tidal reach of the river are uncertain. Installation of a non-physical barrier at Georgiana Slough and the effects of reductions in other stressors would contribute to the cumulative benefits of BDCP conservation measures on the growth, survival, and abundance of Sacramento River salmonids.

Contribution to Recovery. [**Note to Reviewers:** The Steering Committee has not completed discussion on the sufficiency of the BDCP to contribute to recovery of covered species] BDCP conservation measures are consistent with and complementary to salmonid recovery within the Central Valley as identified in the NMFS draft recovery plan (NMFS 2009). BDCP conservation measures would not result in the establishment of new independent salmonid populations within the Central Valley. Habitat conditions and water operations within the Sacramento River and Delta would, however, be complementary to the formation of additional winter-run or spring-run Chinook salmon or steelhead populations within the Central Valley if that should occur in the future. There are no actions proposed as part of BDCP that are inconsistent or incompatible with long-term salmonid recovery plan implementation.

Net Beneficial Effects on Designated Critical Habitat. BDCP conservation actions would contribute substantially to improved habitat availability and diversity that would benefit juvenile salmonids and reduce stressors that currently adversely affect Chinook salmon and steelhead growth, survival, and population abundance. Substantial reductions in Old and Middle River reverse flows and expanded intertidal, subtidal, and seasonal floodplain habitat represent major contributions toward improved critical habitat for winter-run and spring-run Chinook salmon and steelhead within the Delta. These improvements in critical habitat conditions for listed salmonids would contribute to increased juvenile growth and survival, greater life history and habitat diversity, and are expected to result in increased adult salmonid abundance. Effects of BDCP operations on critical habitat upstream of the Delta has been evaluated and results show relatively small adverse and beneficial effects on habitat conditions for spawning and juvenile rearing on the mainstem Sacramento River and Feather River, but no incremental changes in habitat conditions on other Central Valley river systems. The magnitude of beneficial effects associated with changes in water operations, expanded aquatic habitat, improved hydrologic conditions within the Delta, and reduction in other stressors have not been quantified. Uncertainties regarding the ecological functions and net biological response of salmonids to expanded diverse habitats geographically distributed in various regions of the Delta, and changes in water operations and hydrologic conditions within the rivers and Delta will be addressed through the BDCP monitoring, research, and adaptive management programs.

Net Beneficial Effects on Essential Fish Habitat. Based on results of the effects analysis it was concluded that implementation of BDCP conservation measures and operations would result in localized temporary effects on EFH. These effects would be reduced through implementation of BMPs during facilities construction and other actions. The BDCP actions would result in small changes in local habitat conditions in some areas of the upstream rivers and Delta but would also result in substantial improvements in aquatic habitat conditions through changes in local hydrodynamics such as reductions in Old and Middle River reverse flows and significant expansion of aquatic habitat within a variety of regions distributed throughout the Delta and within Suisun Marsh as a result of BDCP habitat restoration actions. Operations would not be expected to result in substantial or detectable changes in habitat conditions for EFH species inhabiting regions downstream of Suisun Bay. Based on these factors, it was concluded that implementation of BDCP would not result in adverse effects to EFH that would impact species at a population level and that many of the proposed conservation actions would contribute to enhanced EFH conditions within the Delta.

Need for Adaptive Management. As a comprehensive package of conservation measures, BDCP will contribute to the survival and recovery of Central Valley Chinook salmon and steelhead populations through cumulative reduction in stressors and improvements in habitat that together contribute to increase population abundance. The magnitude of the effects of BDCP actions on Chinook salmon and steelhead recovery, however, has not been quantified. There remain areas of uncertainty regarding the effectiveness of various individual conservation actions that will be addressed as part of BDCP implementation through the BDCP monitoring, research, and adaptive management programs.

5.4.1.4 Sacramento Splittail

5.4.1.4.1 BDCP Effects on Stressors

Based on results of the effects analysis, the BDCP will produce a number of major changes within the Delta that will reduce the impacts of ecological stressors on the Sacramento splittail population and improve habitat conditions for adult reproduction and larval and juvenile rearing. These major effects analysis findings include:

Increased Yolo Bypass inundation creates more spawning and rearing habitat. Limited availability of spawning habitat and rearing habitat for the larval and early juvenile life stages is a primary stressor on the splittail population, especially in dry years when floodplains are not inundated. Implementation of CM2, *Yolo Bypass Fishery Enhancement*, will increase the frequency and duration of Yolo Bypass inundation, resulting in substantial increases in spawning and rearing habitat availability. The increased duration of flooding events will reduce the risk of stranding. Rates of predation on splittail larvae will not be affected by CM2. Increases in habitat surface area are predicted to be especially large (on a percentage basis) in dry years, when Sacramento River flow is low. Predicted habitat increases are somewhat larger with the combined effects of the proposed project and climate change in the ELT and LLT. There is some uncertainty regarding the level of flow from the Bypass that is sufficient to trigger spawning migration by the splittail adults, although the BDCP includes monitoring, research, and adaptive management to identify refinements in operations to further increase spawning habitat availability.

Restored inundated floodplain habitat in other parts of the Delta would increase habitat availability. Restoration of 10,000 acres of new seasonally inundated floodplain under the BDCP will provide substantial new splittail rearing and spawning habitat in different areas of the Delta in the LLT. Increases in the ELT will be 1,000 acres. Benefits to splittail will occur only with flood events which will be more frequent in wet years, when inundated floodplain habitat is currently most available. The main benefit of this conservation action will be to increase habitat diversity, as discussed below.

Enhance channel margin habitat expected to benefit emigrating young of the year (YOY). Currently, channel margin habitat conditions within the Delta are characterized by large areas of riprap stabilized channel margin with little shallow water or low velocity habitat for fry and juvenile rearing. Under the proposed project expansion of access to habitat areas characterized by shallow-water, low-velocities, increased hydraulic residence time, and increased food availability will enhance growth and survival of YOY juvenile splittail during their downstream migrations. Availability of rearing habitat for juveniles during their downstream migration is an important stressor, but less so than the availability of inundated floodplain habitat. Enhancement of channel margin habitat under the proposed project will increase rearing habitat availability and geographic distribution. Channel margin habitat may be used for spawning in dry years, when spawning habitat is limited, but the degree to which splittail spawn in channel margin habitats in the Delta, and conditions required for successful egg/embryo and larval development, are not well known.

Restored tidal habitat would provide additional rearing and foraging habitat. Restoration of tidal and subtidal habitats under the proposed project will substantially increase the availability of rearing and foraging habitat for splittail. Availability of rearing habitat for juveniles following completion of their downstream migration is an important stressor, but less so than availability of inundated floodplain habitat. Restoration in the Cache Slough and Suisun Marsh ROAs will be especially beneficial. The Cache Slough area receives most of the YOY splittail emigrating from the Yolo Bypass, resulting in heavy use, whereas Suisun Marsh is the most important rearing habitat destination for juvenile splittail. The benefits of the restored tidal habitats will increase progressively from the NT to the ELT and to the LLT, as areas of restored habitat increase. These benefits could be substantially reduced, however, if nonnative vegetation and predatory fish colonize newly restored habitats. Conservation measures to control SAV and nonnative predators and the BDCP adaptive management program will be aimed at maintaining high habitat function by addressing these stressors. Tidal habitat may be used for spawning in dry years, when spawning habitat is limited, but the degree to which splittail spawn in tidal habitats in the Delta and the conditions required for successful egg/embryo and larval development are not well understood.

Increased Yolo Bypass inundation and channel margin and tidal habitat restoration would result in greater local food production and increased export of production to other areas of the Delta. The increases in Yolo Bypass inundated floodplain habitat and other habitat improvement measures will result in greater food web resources for splittail larvae and juveniles rearing on the floodplain and adults preparing to spawn and for rearing juveniles and foraging adults in channel margin and tidal habitats. More food for splittail will contribute to higher growth rates, survival, and fecundity of splittail. Export of food web resources produced on the floodplain and other restored habitats is expected, which would benefit splittail in other areas, but the degree to which food is exported is uncertain.

Habitat restoration over a wide geographic range will have several potential benefits. Restoration of tidal, floodplain, and channel margin habitats under the proposed project will increase the geographic distribution of spawning and rearing habitat for splittail, which will: 1) increase the range of available habitat conditions, thereby improving the likelihood of providing suitable conditions for spawning, eggs/embryo development, larval and juvenile rearing, and adult foraging; and 2) buffer against unforeseen future adverse environmental effects (including catastrophic events).

Uncertain effects on exposure to methylmercury. Enhanced frequency and duration of flooding of the Yolo Bypass has the potential to increase exposure of splittail to methylmercury because: 1) the Yolo Bypass experiences high levels of methylmercury loading, particularly from

Cache Creek, 2) splittail use of the Yolo Bypass would increase, and 3) the inundation regime on the Bypass will be altered, increasing the rate of mercury methylation. These effects, however, may be mitigated by dilution and advection effects of increased Sacramento River inflows. The thresholds of toxicity of methylmercury concentrations are unknown. The BDCP conservation measure to control methylmercury, implemented with adaptive management, is expected to reduce methylmercury loading. Splittail in Delta habitats are expected to receive increased exposure to methylmercury because habitat restoration activities increase methylmercury production. Splittail are expected to be especially at risk in the Cache Slough ROA because methylmercury concentrations in this area are already high. The BDCP will have a low, but relatively uncertain, negative outcome with regard to methylmercury exposure.

Uncertain effects on exposure to pyrethroids. Pyrethroid concentrations in the Delta will decrease under the proposed project during most of the April to July period of juvenile emigration. Residence time also affects exposure to pyrethroids. Residence time, as determined by flow, will increase in some areas of the Delta and decrease in other areas, depending on hydrologic conditions, with no net effect on splittail expected. Habitat restoration under the BDCP will result in reduced pyrethroid loading because agricultural land will be taken out of production. On balance, the BDCP will provide a low, but uncertain, benefit with respect to splittail exposure to pyrethroids.

Increased exposure to selenium. The BDCP will result in increased exposure of splittail to toxic levels of selenium. The adult life stage is the most important with regard to selenium because of its relatively long duration and a diet including overbite clams, which contain high concentrations of selenium. Selenium bioaccumulates with age, although eggs and embryos, which receive high levels of selenium in maternal transfer, are the most susceptible to selenium toxicity. The BDCP will result in increased exposure of adults to selenium because it is predicted to cause increased selenium concentrations in the west Delta during the summer and fall. The west Delta is the primary foraging habitat of adult splittail and summer and fall are the principal seasons for grazing by the overbite clam. The effects will be similar in the ELT and LLT relative to EBC, independent of projected climate change. These increases will likely result in increased reproductive failure in splittail, but the magnitude of the effect is uncertain, particularly at the population level.

Reduced losses at south Delta SWP/CVP facilities. While it has never been determined that entrainment has a population level effect, reductions in entrainment will increase survival and benefit the species. Dual export facility operations under the proposed project will result in a reduction in juvenile and adult splittail losses at the south Delta export facilities relative to EBC**.** Juvenile splittail are at risk of losses primarily during May through July, as they migrate to downstream rearing habitats, whereas adult splittail are at risk of loss primarily between December and March, during their upstream spawning migration. The BDCP will result in a substantial reduction in losses of both life stages because exports at the south Delta export facilities, which currently entrain large numbers of splittail, will be reduced, while entrainment of splittail at the new screened north Delta intakes will be negligible. In both the ELT and LLT, the reductions in entrainment of juveniles are predicted to exceed 65 percent at both the CVP and SWP south Delta facilities relative to EBC. For scenarios that take into account projected climate change conditions, the reductions are 75 percent or greater. For adults, the reductions in entrainment at both the CVP and SWP facilities, for all the analysis scenarios, will be between 60 and 66 percent relative to EBC. The benefits of these reductions are limited because past studies have found no evidence that entrainment of splittail significantly affects population abundance. The removal of non-project diversions due to changing land use in the Delta as a result of the BDCP will provide a marginal benefit to reducing entrainment risk for larval and juvenile splittail.

Effects of BDCP on predation uncertain. Many BDCP conservation actions have the potential to affect predation on splittail, including habitat restoration, changes in lower Sacramento River flow, and north Delta intake structures. Habitat restoration will result in increased numbers of predators and increased numbers of splittail. If predation rates do not change significantly, the net effect will be an increase in the total population of splittail. Diversions of Sacramento River flow at the new north Delta intakes will result in reduced flow rates downstream. Studies on juvenile salmon indicate that flow reductions reduce rates of downstream migration, which increases time of exposure to predators. During May and June, the peak months of juvenile splittail emigration, BDCP operations will reduce average flows by 2 to 3 percent in drier years and 35 to 42 percent in wetter years. When climate change is included, average flows will be negligibly reduced in drier years and reduced by approximately 25 percent in wetter years. The flow reductions will result in little change on predation on juvenile splittail in drier years, but could result in a substantial increase in predation in wetter years. The north Delta intakes will provide new habitat for piscivorous fish such as striped bass, resulting in increased predation on the emigrating juveniles. The increases could be substantial for both the ELT and LLT, exceeding numbers currently entrained at the south Delta facilities. This conclusion is highly uncertain because the actual predation rates by striped bass and other Delta piscivores on splittail are unknown. The BDCP conservation measures to control nonnative predators and removal of SAV will result in minor reductions in predation in the Delta. Overall, the BDCP will have moderately negative but uncertain effects with respect to predation on splittail in both the ELT and LLT.

Entrainment in Mirant power plants will be greatly reduced. The expected transition to exclusive closed cycle water use at Mirant's Contra Costa and Pittsburg power plants by 2017 will substantially reduce and avoid entrainment and impingement of juvenile splittail.

5.4.1.4.2 Overall Conclusions for Splittail

The following overall conclusions were made based on the results of the effects analysis for Sacramento splittail.

Contribution to Increased Reproduction. Overall, the BDCP will contribute to increased reproduction of Sacramento splittail. The most important component of the BDCP for splittail is the increase in seasonally inundated floodplain habitat, including expected increases in food web resources. Several studies have concluded that the Sacramento splittail population is largely limited by the availability of floodplain habitat. Splittail year classes are nearly always high in wet years, when large areas of floodplain are inundated, and low in dry years. The BDCP Yolo Bypass floodplain enhancement will substantially increase the acreage of inundated floodplain, particularly in dry years. Restoration of new floodplain under BDCP will provide additional seasonally inundated floodplain habitat, primarily in wet years, and will increase the geographic distribution and diversity of the available habitat for splittail. Restoration of tidal, subtidal, and channel margin habitats under the proposed project will provide additional spawning habitat in all water year types.

Need for Adaptive Management. Results of the effects analysis indicate that the BDCP will reduce adverse effects of major stressors and is consistent with, supportive of, and complementary to recovery planning for splittail (USFWS 1996). Uncertainties remain, however, regarding the magnitude of population-level effects on the dynamics and recovery of the population. The BDCP includes adaptive management based on extensive monitoring and research that will be used to address areas of uncertainty and to refine the conservation measures to improve the overall net environmental benefits of the program, in combination with other recovery actions, in contributing to the long-term recovery of splittail. The adaptive ranges for a number of water operations parameters allow for adjustments such that, if initial operations do not support the outcomes expected for splittail, there is the opportunity and flexibility to adaptively change operations and potentially improve biological outcomes.

5.4.1.5 Sturgeon

5.4.1.5.1 BDCP Effects on Stressors

Results of the effects analysis indicate that the BDCP conservation strategy will result in a number of major changes within the Delta that will reduce the impacts of stressors on green and white sturgeon populations and improve habitat conditions for juvenile sturgeon rearing and adult and juvenile sturgeon migration. These major effects analysis findings for stressors on sturgeon are described below.

Greater access to rearing habitats potentially used by juvenile sturgeon. BDCP conservation measures will result in substantially increased access to expanded subtidal, tidal wetland and channel margin habitat, geographically located throughout the Delta, which will potentially benefit juvenile sturgeon that utilize the Sacramento River and the San Joaquin River basins, Suisun Marsh and Bay, and the Delta. As noted for salmonids, intertidal habitat will be expanded by approximately 7,900 acres in the NT with an additional 7,300 acres in subtidal habitat. During the ELT, intertidal habitat will be expanded to 13,000 acres and subtidal habitat will be expanded by 9,400 areas. During the LLT intertidal habitat will be expanded by 16,400 acres and subtidal habitat will be expanded by 32,300 acres.

Habitat benefits for sturgeon. Major expansion in access to tidal habitat and channel margin habitat will result from the proposed project in the northern Delta (Yolo Bypass and Cache Slough complex) as well as channel margin habitat along the mainstem Sacramento River, Sutter and Steamboat sloughs, and western Delta, and tidal habitat expansion within Suisun Marsh that would serve to benefit juvenile sturgeon produced in the Delta. As noted for salmonids, intertidal habitat will be expanded by approximately 3,000 acres in Cache Slough in the NT with an additional 1,200 acres in subtidal habitat. During the ELT, intertidal habitat in Cache Slough will be expanded to 5,900 acres and subtidal habitat will be expanded by 2,300 areas. During the LLT intertidal habitat will be expanded by 6,900 acres from existing conditions and subtidal habitat will be expanded by 7,400 acres. Additional habitat expansion in the western Delta, five miles of channel margin habitat enhancement on the Sacramento River, and substantial increases in habitat in the western Delta and Suisun Marsh will also be made available by the proposed project on the migration pathway for juvenile sturgeon.

Expansion of intertidal and subtidal habitat in the south Delta along the migratory pathway for juvenile white sturgeon produced in the San Joaquin River basin will result from the proposed project in the LLT. San Joaquin River white sturgeon will also benefit from subtidal and tidal habitat expansion in the western Delta and Suisun Marsh.

Creation of alternative migratory routes and access to more habitat. Juvenile Sacramento River basin sturgeon survival may improve as a result of the potential use of expanded access to seasonal floodplain within the Yolo Bypass, which would provide opportunities for juvenile sturgeon to access alternative migration pathways that would circumvent the north Delta intake structures, the Delta Cross Channel, and Georgiana Slough;

BDCP implementation will create conditions of enhanced food production, with potential to offset survival risk from stranding, predation, and water-quality. Expanded access to tidal wetland and improved channel margin habitat will provide shallow water, low-velocity habitat areas with increased food production. Expanded access to suitable habitat will benefit juvenile sturgeon rearing through access to alternative migration pathways, access to improved juvenile rearing habitat, and access to increased food production that collectively are expected to result in increased juvenile growth rates and survival.

The magnitude of these benefits on the population abundance of sturgeon from BDCP expanded habitat is uncertain. The potential to improve juvenile sturgeon rearing; and risks associated with predation and exposure to potential toxics and adverse water quality conditions is unknown relative to existing biological conditions. Rigorous monitoring, adaptive management, and continual improvements to habitat restoration design will serve to reduce uncertainty and the risk of adverse effects resulting from habitat expansion.

Potential, but unquantified, benefits from habitat modifications along levees. Currently, habitat conditions within the Delta are characterized by large areas of riprap stabilized channel margin with little shallow water or low velocity habitat for juvenile sturgeon rearing. Expanded access under the proposed project to habitat areas characterized by shallow-water, low-velocities, increased hydraulic residence time, and increased food availability, as well as the provision of a wider geographic distribution of diverse and complex habitats within the Delta is consistent with sturgeon conservation, and increases the opportunities for a broader range of life history expression including extended juvenile rearing within the Delta. Expanding opportunities for a wide range of life histories is consistent with sturgeon conservation and recovery principles.

Improved survival of juvenile sturgeon from re-operation of the Delta Cross Channel (DCC) gates. Expanded closure of the DCC gates and installation and operation of non-physical barriers at key locations such as the confluence between Georgiana Slough and the Sacramento River and at the head of Old River will improve survival of juvenile sturgeon migrating downstream in the rivers and through the Delta. Extended DCC gate closure may also improve attraction flows and thus improve olfactory cues for upstream migrating adult sturgeon and reduce inter-basin straying.

Reduced reverse flow conditions. BDCP dual facility operations will result in substantial improvements in Old and Middle River (OMR) reverse flows within the south and central Delta and a net improvement in downstream flows through the Delta, particularly from the San Joaquin River system. These improvements in Delta hydrodynamics will result in substantial improvements in habitat conditions for juvenile sturgeon rearing and survival in these habitats.

Reduced losses of sturgeon in SWP/CVP facilities. While it has never been determined that entrainment has a population level effect, reductions in entrainment will increase survival and benefit the species. Dual export facility operations will result in a reduction in juvenile sturgeon entrainment and salvage losses at the south Delta export facilities by 30-60 percent for white sturgeon and 25-70 percent for green sturgeon relative to existing conditions;

Negligible entrainment risk at north Delta intakes. As a result of the state-of-the-art design characteristics (i.e., 0.2 ft/sec approach velocity, screen mesh size, screen cleaning, etc.), and the demersal behavior of post-larval sturgeon, the risk of entrainment of age-0 sturgeon at the north Delta intakes will be negligible, but is currently not quantifiable.

Entrainment in non-project diversions will be marginally reduced. The removal of non-project diversions due to changing land use in the Delta as a result of the BDCP will provide a marginal benefit to reducing entrainment risk for age-0 sturgeon.

Entrainment in Mirant power plants will be reduced. The expected transition to exclusive closed cycle water use at Mirant's Contra Costa and Pittsburg power plants by 2017 will substantially reduce and avoid entrainment and impingement of juvenile sturgeon.

No adverse upstream impacts on sturgeon. No major adverse effects were detected in the effects analysis on upstream habitat conditions (e.g., reservoir storage, instream flows, and water temperatures during egg incubation) for sturgeon in the Sacramento or San Joaquin rivers. Small positive and negative changes were detected in the Sacramento and Feather rivers, such as reduced summer and fall flows in the Sacramento River relative to existing conditions. None of these changes will have a substantial effect on sturgeon life history (i.e., migration, spawning, and juvenile rearing). No significant changes in upstream habitat (i.e., instream flows and seasonal water temperatures) were detected in the San Joaquin and Stanislaus rivers. BDCP operations will have no effect on habitat in rivers not controlled by the CVP or SWP operations.

No increase in egg mortality for Sacramento River or San Joaquin River sturgeon. Results of the SacEFT model for green sturgeon on the Sacramento River indicate an adverse effect on temperature conditions for sturgeon as a result of climate change, but with no apparent effect attributable to the proposed project. Results of the effects analysis detected no BDCP-related adverse effects to upstream habitat conditions (e.g., instream flows, water temperatures during egg incubation) for sturgeon in the Sacramento or San Joaquin rivers.

Late summer flow decreases in the Feather River. Within the Feather River, small decreases in July flows under the proposed project, most significant in below normal and dry years in the upper river, may adversely affect green sturgeon egg/embryo; however the adverse affects may be offset by the larger increases in April-June flows under the proposed project, relative to EBC. However, large decreases in late summer flows (Aug-Sept) related to BDCP water operations may adversely affect the downstream migration of green sturgeon larvae.

Uncertain Effect of Decrease in Sacramento River flows on adult cue detection. Adult green sturgeon attraction flows from November-July will decrease in the Sacramento River downstream at Rio Vista under proposed project operations. The large decreases in flows at Rio Vista in November were affected not only by north Delta diversions, and the operations of upstream dams, as indicated by the reduced mean monthly flows at Keswick and Verona, but the requirements for cold water pool storage necessary to support upstream salmonid spawning habitat. A good portion of the November-July attraction flow period (December–April) occurs during periods of greatest Sacramento River flows at this portion of the river. Proposed north Delta operations are designed to divert additional waters during the highest flows, to maintain flows during drier periods of the year for threatened and endangered salmonids. However, in the absence of data investigating minimum flow requirements for adult green sturgeon attraction and migratory cues, the certainty at which flow reductions will result in reduced cue detection is low.

Uncertain effects related to operation of north Delta intake. Sacramento River flows downstream of the north Delta intakes will be reduced under BDCP operations relative to existing conditions. Flows will be reduced less during the winter than during other seasons. Flows will be reduced most in wet, above normal, and below normal water years; flows are projected to increase under BDCP operations in dry and critical years. The effects of flow reduction within the lower reach of the Sacramento River, on the attraction and olfactory cues for upstream migrating adult sturgeon and survival of downstream migrating juvenile sturgeon are uncertain.

Interannual and long-term hydrologic changes occur with or without BDCP operations. The greatest changes in habitat conditions result from natural variation in interannual hydrology (e.g., between wet and dry years) and the effects on hydrology from future climate change. These major effects on habitat were largely independent of differences between existing conditions and BDCP operations. Sturgeon are sensitive to the risk of exposure to elevated water temperatures and decreased flow in the Feather River, potentially decreasing habitat suitability, particularly in drier water years under both existing conditions and proposed BDCP operations.

Net benefits of other stressor reduction measures. Collectively, other stressor conservation measures provide additional benefits to sturgeon relative to existing conditions. Benefits of conservation actions such as removing unscreened water diversions and structures that attract predators, although incrementally small, contribute to the cumulative biological benefits of BDCP. Conservation measures with the greatest benefit to sturgeon include the revised operations of Fremont Weir, the installation of 1-3 sturgeon ramps facilitating upstream migration and eliminating the stress of the bottleneck, and the increased game enforcement to significantly reduce the poaching of sturgeon that occurs in the Delta. BDCP will, through the installation of an aeration facility in the Stockton Deep Water Ship Channel (SDWSC), effectively raising dissolved oxygen in much of the channel above levels that cause stress in adult sturgeon. The outcome of this conservation measures will be to reduce the upstream passage impediment of adult sturgeon in the vicinity of the SDWSC and facilitate the migration to suitable upstream spawning habitats in the San Joaquin basin. These other stressors measures, in combination with habitat restoration, will provide the greatest benefit to sturgeon from the proposed project.

5.4.1.5.2 BDCP Effects on Green Sturgeon Designated Critical Habitat

Critical habitat for green sturgeon was designated in 2009 (74 FR 52300). The effects analysis for green sturgeon addressed how the BDCP would beneficially or adversely affect the primary constituent elements (PCEs) of green sturgeon critical habitat. PCEs in the upstream reaches not affected by BDCP actions and, therefore, not addressed in the effects analysis include substrate type or size and water depth. The green sturgeon PCEs addressed in the effects analysis were:

- Freshwater spawning sites (i.e., providing suitable water temperatures, and instream flows for successful spawning in the upstream reaches of the Sacramento River and tributaries);
- Freshwater rearing sites (i.e., providing suitable water quality for juvenile rearing, instream flows for downstream migration, sediment quality, tidal habitat and other juvenile rearing areas, and the effect of suitable quantity of food resources for juvenile growth and rearing);
- Freshwater migration corridors (i.e., the allowance for safe and timely passage by reducing and avoiding passage barriers and impediments for both juveniles and adults, providing suitable water quality and instream flows to support access and connectivity for migration, both within tidal habitats and through the Delta);

- Estuarine areas (i.e., providing safe and timely passage via unobstructed migration and rearing opportunities, suitable water quality with salinity conditions that support juvenile and adult physiological transitions between freshwater and saltwater, sediment quality, and providing food resources to support juvenile, subadult, and adult growth, survival, and facilitate the access to upstream spawning habitats).

The effects analysis included a number of analytical approaches, including modeling analyses (i.e. hydrologic and water quality), to predict changes in habitat physical and biological conditions that would potentially affect the quality and availability of suitable habitat influenced by proposed BDCP actions.

Effects on Freshwater Spawning Sites. Although minor adverse and beneficial changes in habitat conditions (instream flow, water temperature) were detected for upstream green sturgeon spawning and egg incubation in some locations, these changes will not have a substantive effect on habitat conditions for green sturgeon. The greatest change was noticeable in the reduction of late summer flows in the Feather River. However, as flows are greater in late spring/early summer, it is unknown if these changes will have a substantive effect on habitat conditions in the Feather River. Within the Sacramento and Feather rivers there was little or no cumulative adverse effect of the BDCP on habitat conditions for spawning relative to the EBC. The greatest observed changes in habitat quality or availability are in response to interannual variation in Central Valley hydrologic conditions (e.g., wet years and dry years) and in response to long-term changes in Central Valley climate. Therefore, the proposed project would not affect critical habitat or the success of green sturgeon spawning within the Sacramento or Feather rivers.

Effects on Freshwater Rearing Sites. Minor adverse and beneficial changes in habitat conditions (flow and water temperature) were detected for sturgeon rearing. In general, within the Sacramento and Feather rivers, there was no effect of the proposed project on habitat conditions for juvenile rearing relative to the EBC. The greatest observed changes in habitat quality or availability are in response to interannual variation in Central Valley hydrologic conditions (e.g., wet years and dry years) and in response to long-term changes in Central Valley climate.

Restoration of additional floodplain, tidal, and channel margin habitat that is geographically distributed throughout the Delta will provide substantial benefits to green sturgeon, with the greatest potential coming through benefits to the foodweb. The predicted magnitude of these benefits to increased juvenile growth and survival, and the contribution of these conservation measures to increased adult sturgeon abundance have not been quantified. Floodplain enhancement actions designed to increase the frequency and duration of seasonally inundated floodplain habitat in Yolo Bypass will be a significant environmental benefit of BDCP. Similarly, BDCP implementation will substantially improve ecological functions and increase the availability of, and access to, intertidal and subtidal habitat that is geographically distributed along the Sacramento River and within the eastern and southern Delta and Suisun Marsh, that will increase rearing habitat and food production for juvenile, subadult, and adult sturgeon, relative to existing conditions. Uncertainty in expanded habitat performance and ecological functions will be addressed through a rigorous BDCP monitoring, research, and adaptive management programs.

Overall, the proposed project will not adversely modify habitat conditions for freshwater rearing in upstream habitats within rivers tributary to the Delta. Instead, BDCP conservation actions will improve habitat access, quality, and availability for juvenile green sturgeon in the lower reaches of the Sacramento and Feather rivers and within the Delta and Suisun Marsh. Implementation of BDCP conservation measures will contribute to a substantial increase in suitable habitat for juvenile and subadult rearing.

Effects on Freshwater Migration Corridors. The BDCP conservation strategy includes measures specifically designed to improve migratory corridors and reduce the effects of obstructions that impede both juvenile and adult sturgeon passage under existing conditions. Proposed actions include improving passage at the Fremont Weir through the installation of sturgeon ramps, notching the weir, increasing game enforcement to reduce the poaching of adult sturgeon, increasing closure of the Delta Cross Channel gates to improve migration and upstream cue detection. Operations under BDCP will also improve hydrologic conditions as reflected by an increase in positive flows in Old and Middle rivers, as well as maintenance of instream flows within the tributaries to the Delta. These conditions are intended to improve the survival of juvenile sturgeon migrating downstream through the Delta, in part by reducing their vulnerability to entrainment losses at the existing south Delta water export facilities. Restoration of additional floodplain and tidal habitat would be beneficial for sturgeon. There is a high degree of uncertainty, however, in the quantification of the magnitude of net benefits to sturgeon populations. Reductions in instream flow in the lower reaches of the Sacramento River have the potential to reduce olfactory cues and attraction flows for upstream migrating adult sturgeon, and river flows for downstream migrating juveniles. Upstream of the north Delta intakes, river flows are similar between the proposed project and existing conditions. In the vicinity of Rio Vista, flows would be reduced during the period for upstream cue detection. The effect of this reduction on population dynamics is currently unknown. In the downstream estuarine region of the Delta, tidal flows are dominant. No information is available to quantitatively assess the potential effects of local flow reductions on migration and survival of green sturgeon.

Overall, the BDCP will not adversely modify habitat conditions for green sturgeon migration corridors within the tributaries of the Delta and would improve passage conditions for green sturgeon migrating through the Delta. BDCP conservation actions will reduce obstruction to juvenile and adult sturgeon passage within the lower reaches of the Sacramento River and throughout the Delta and Suisun Marsh. Implementation of BDCP conservation measures is expected to contribute to an increase in habitat conditions for juvenile and adult sturgeon migration.

Effects on Estuarine Areas. The BDCP conservation strategy will contribute to a substantial increase in access to suitable juvenile and subadult green sturgeon rearing habitat within the estuarine regions of the Delta through channel margin habitat enhancements in the western Delta, as well as substantial increases in aquatic habitat within Suisun Marsh adjacent to Suisun Bay (approximately 24,570 acres in the LLT). The increased access of intertidal and shallow subtidal rearing habitat within the estuarine region of the Delta will contribute to an increase in ecological functions of aquatic habitat including increased habitat diversity and complexity, foraging habitat and food resources for juvenile green sturgeon. Restoration of additional tidal habitat will be beneficial to green sturgeon. Although positive trends towards recovery are anticipated, there is a high degree of uncertainty in the magnitude of net population level benefits to green sturgeon.

Water operations under the proposed project will improve hydrologic conditions as reflected by an increase in positive flows in Old and Middle rivers and maintenance of instream flows within the rivers tributary to the Delta. These conditions will improve the survival of juvenile sturgeon migrating downstream through the Delta and improve estuarine rearing habitat conditions. These improvements will benefit juvenile green sturgeon by providing a potential for increased growth conditions, which should contribute to increased survival. Improvements in central Delta habitat and hydrodynamics will provide the greatest benefits for green sturgeon rearing in estuarine habitats.

Overall, the BDCP will not adversely modify habitat essential for green sturgeon within the estuarine region of the Delta. The BDCP will contribute to an increase in habitat for juvenile and subadult green sturgeon migration within the estuarine region of the Delta.

5.4.1.5.3 Overall Conclusions for Sturgeon

The following overall conclusions were made based on the results of the effects analysis for green and white sturgeon.

Contribution to Recovery. *[**Note to Reviewers:** The Steering Committee has not completed discussion on the sufficiency of the BDCP to contribute to recovery of covered species]* BDCP conservation measures are consistent with and complementary to sturgeon recovery within the Central Valley. In addition to habitat benefits provided by BDCP conservation measures, additional measures to reduce poaching and facilitate upstream migration will increase the protection and survival of reproducing members of the populations. There are no actions proposed as part of BDCP that are inconsistent or incompatible with long-term sturgeon recovery;

Net Beneficial Effects on Designated Critical Habitat. BDCP conservation actions would contribute substantially to improved habitat availability and diversity that would benefit green sturgeon by reducing stressors that currently affect growth, survival, migration, and population abundance. These improvements in critical habitat conditions for green sturgeon would contribute to increased juvenile growth and survival, greater life history and habitat diversity, and are expected to result in increased green sturgeon abundance. Effects of BDCP operations on critical habitat upstream of the Delta has been evaluated and results show relatively small adverse and beneficial effects on habitat conditions for spawning and juvenile rearing on the mainstem Sacramento River and Feather River. The magnitude of beneficial effects associated with changes in water operations, expanded aquatic habitat, improved hydrologic conditions in the Delta, and reduction in other stressors such as poaching and migration barriers have not been quantified. Uncertainties regarding the ecological functions and net biological response of green sturgeon to expanded diverse habitats geographically distributed in various regions of the Delta, and changes in water operations and hydrologic conditions within the rivers and Delta, will be addressed through the monitoring, research, and adaptive management programs. Therefore, the construction and operation of the proposed project, including adaptive management actions, would not be expected to adversely modify green sturgeon critical habitat.

Need for Adaptive Management. As a comprehensive package of conservation measures, BDCP will contribute to the survival and recovery of white and green sturgeon through cumulative reduction in stressors and improvements in habitat, that together contribute to increased population abundance. The magnitude of the effects of BDCP actions on green sturgeon recovery, however, has not been quantified. There remain areas of uncertainty regarding the effectiveness of various individual conservation actions that will be addressed as part of BDCP implementation through the BDCP monitoring, research, and adaptive management programs.

5.4.1.6 Lamprey

5.4.1.6.1 BDCP Effects on Stressors

Based on results of the effects analysis, implementation of the BDCP conservation strategy will result in a number of changes that will reduce the impacts of stressors on Pacific and river lamprey. Some adverse effects were also noted. These effects analysis findings include:

No major effects on downstream migration flows in most rivers. There are no measurable predicted effects of BDCP on downstream macropthalmia migration of changes in flows in the Sacramento, San Joaquin, or Stanislaus rivers. Flow effects on downstream macropthalmia migration during December through May in the Feather River will improve by 5 to 25 percent as a result of the proposed project. There is a 3-15 percent predicted reduction in flows in the Sacramento River in the Delta. Climate change will generally increase flows during January through March and decreases flows during May. There is moderate certainty regarding these conclusions because they are based entirely upon model output.

Within the Delta, upstream migration conditions will greatly improve in the San Joaquin River but decline slightly in the Sacramento River. As a result of changes in diversion points and dual operations under the proposed project, there will be large benefits to San Joaquin River attraction flows for both Pacific lamprey (mean increases during December through May of 36-146 percent) and river lamprey (mean increases during September through November of 374-733 percent) under the proposed project. In addition, passage impediments such as the Stockton Deep Water Ship Channel low dissolved oxygen barrier will be reduced significantly as a result of the proposed project. There will be small reductions in attraction flows for Pacific lamprey adults in the Sacramento River (predicted 4-12 percent reduction in mean in-Delta attraction flows) and moderate reductions for river lamprey in the Sacramento River (predicted 11-17 percent in mean in-Delta attraction flows). Climate change is predicted to have variable effects on Sacramento River contributions and marginal benefits in the San Joaquin River to lamprey attraction flows. There is low certainty in these conclusions because of limited understanding of the use of upstream migration cues by lamprey.

Upstream of the Delta, there are small benefits or no changes in predicted adult Pacific lamprey attraction flows and highly variable, but predominantly adverse predicted effects on river lamprey attraction flows. There will be no effects of the proposed project on Pacific lamprey adult attraction flows during December through May in the Sacramento, San Joaquin, or Stanislaus rivers. There will be small benefits to Pacific lamprey in the Feather and American rivers due to changes in upstream reservoir operations. For river lamprey, there will be highly variable, but predominantly reduced, adult attraction flows during September through November upstream of the Delta in the Sacramento, Feather, Trinity, and American rivers. There will be no effects in the Stanislaus or San Joaquin rivers to river lamprey. There are minimal and inconsistent effects of climate change on these upstream flows during January through June (Pacific) and September through November (river). There is low certainty in these conclusions due to limited understanding of the use of upstream migration cues by Pacific and river lamprey.

No major effects on upstream water temperatures. Upstream water temperatures during egg, embryo, and ammocoete occurrence for both Pacific and river lamprey will not change in a measurable or consistent way as a result of the proposed project. Climate change is predicted to moderately increase water temperature and this effect far outweighs effects of the proposed project. There is moderate certainty regarding these conclusions because multiple models were used to derive temperature outputs.

No major effects on redd dewatering incidence in most rivers. Predicted changes in redd dewatering incidence for both Pacific and river lamprey will be small and inconsistent among all evaluated locations except for the Feather River. The incidence of redd dewatering in the Feather River will increase moderately in both the ELT and LLT. Climate change has small and variable effects on redd dewatering. However, due to the lack of instream models available for lamprey redds, there is low certainty that the metric used in this analysis (50 percent reduction month-over-month instream flows) represents actual redd dewatering, although they are likely correlated.

Entrainment in SWP and CVP intakes will be moderately reduced. While it has never been determined that entrainment has a population level effect, small reductions in entrainment will increase survival and benefit the species. Entrainment and impingement of both Pacific and river lamprey at the north Delta diversions will be minimal because of the size and swimming ability of macropthalmia at the time of passage past the intakes compared to the slot size of screens and approach velocity. In the south Delta, entrainment will decline by approximately 40-50 percent due to reduced diversions and the change in seasonal timing of diversions in the south Delta. Climate change effects will be small relative to the reductions by the BDCP and inconsistent among months and between SWP and CVP facilities. The certainty regarding these results is limited due to high temporal variability in salvage numbers.

Entrainment in non-project diversions will be marginally reduced. The removal of non-project diversions due to changing land use in the Delta as a result of the implementation of BDCP habitat restoration will provide a marginal benefit to both Pacific and river lamprey macropthalmia. Climate change is not expected to affect these results. There is relatively low certainty in these results due to the lack of rigorous sampling of agricultural diversions to date.

Entrainment in Mirant power plants will be greatly reduced. The transition to exclusive closed cycle water use at Mirant's Contra Costa and Pittsburg power plants by 2017 will greatly reduce entrainment of both Pacific and river lamprey macropthalmia. Climate change is not expected to affect these results. Because the effect of entrainment at power plants under existing biological conditions is not well understood, the magnitude of this benefit is uncertain.

Upstream predation will not change; Delta predation will increase. Changes to potential upstream predator abundance and consumption rates of both Pacific and river lamprey eggs, embryos, and ammocoetes as measured by water temperature will not change due to the proposed project because temperatures would increase only 1-2 °F. However, there are slightly greater predicted temperature increases (1-4 °F) due to climate change. There is low certainty of these conclusions due to lack of understanding of predation pressure on Pacific and river lamprey and lack of direct analysis on predator abundance and consumption rates.

Predation rates of both Pacific and river lamprey macropthalmia at the north Delta diversion intake will increase from background predation rates. Some of this increase will be offset by predator reduction actions under the proposed project at the intake facilities and other predator hotspots in the Delta, although these actions are predicted to provide short-term, small scale benefits. Climate change may increase predation rates because predators will need to consume more to keep up with their increased temperature-dependent metabolism. There is low certainty regarding these results due to a lack of understanding of predation rates of lamprey fish predators that would be attracted to the north Delta intakes.

5.4.1.6.2 Overall Conclusions for Lamprey

The following overall conclusions were made based on the results of the effects analysis for Pacific and river lamprey.

Contribution to Reduction in Stressors. Overall, the BDCP will contribute to the net reduction in adverse stressors on both Pacific and river lamprey. Positive upstream effects on flow and water temperatures at some locations and during some months will outweigh adverse effects, even though most of the upstream effects are small. The reduction in attraction flows in the Sacramento River below the new intakes will be partially offset by improved Yolo Bypass flows and large improvements in the San Joaquin River. Predation effects on lamprey at the north Delta intakes will be greater than the reduction in entrainment effects in the south Delta. The collective benefits of additional BDCP actions, including predator control, non-project entrainment reductions, and power plant entrainment reductions will add to the benefits to lamprey populations.

Need for Adaptive Management. The results of the effects analysis indicate that the proposed water project operations would avoid and minimize adverse effects on lamprey and, in combination with other conservation measures, contribute to recovery of the two lamprey species. There are many uncertainties regarding the magnitude of population-level effects of the BDCP on the dynamics and recovery of the species. The BDCP includes adaptive management based on extensive monitoring and research that will be used to address areas of uncertainty and to refine the conservation measures to improve the overall net environmental benefits of the program, in combination with other recovery actions, in contributing to the long-term recovery of lamprey. The adaptive ranges for a number of water operations parameters allow for adjustments such that, if initial operations do not support the outcomes expected for lamprey, there is the opportunity and flexibility to adaptively change operations and potentially improve biological outcomes.

*[**Note to Reviewers:** the following are the draft natural communities and covered wildlife and plant species sections of Chapter 5, Effects Analysis, for the November 18, 2010 BDCP document. These sections consist of revised "summary of effects" sections from the August 19, 2010 draft for the natural communities and species for only the late long-term outcomes with full BDCP implementation. The text has been modified to indicate whether or not restoration/ protection of natural communities and habitats will keep pace with the expected rate of impacts. The results include the "population-level" effects section for each of the covered species and the assessment of effects on critical habitat for applicable species. The "estimated level of take" sections from that document are not included. Tables presenting the extent of impacts on and the level conservation provided for each of the natural communities and covered wildlife and plant species habitats at the late long-term evaluation point are provided at the end of this draft.]*

5.4.2 Natural Communities

The following summarizes the overall effects of implementing the BDCP actions on each of the natural communities. The extent of each natural community that would be permanently and temporarily removed and periodically affected by BDCP at the late long-term evaluation point is presented in Table 5-1. The table also indicates the total extent of each natural community that will be present in the Plan Area following full implementation of the BDCP. The extent of the contribution to conservation of each natural community following full BDCP implementation through implementation is presented in Table 5-2. The complete effects analysis will describe the combined effects of implementing all BDCP actions for each of the natural communities at the near-term, early long-term, and late long-term evaluation periods.

The complete effects analysis will present the permanent, temporary, and periodic effects on each natural community for each of the evaluation periods for the entire Plan Area and each of the 11 Plan Area Conservation Zones (see Figure 3-1) and will describe the combined effects of implementing all BDCP actions for each of the natural communities at the near-term, early long-term, and late long-term evaluation periods. The mechanisms associated with each of the BDCP actions that can result in a permanent or temporary direct or indirect effect, or periodic effect on each of the natural communities will also be described and evaluated in the full effects analysis.

5.4.2.1 Tidal Perennial Aquatic Natural Community

The implementation of all BDCP actions would result in overall benefits for the tidal perennial aquatic community, including the restoration and ongoing management of subtidal aquatic habitats and a return to more-natural channel water salinity in habitats restored in Suisun Marsh. Based on RMA modeling of hypothetical tidal habitat restorations (see Appendix N.3), approximately 25,000 to 32,000 acres of tidal perennial aquatic natural community would be restored, resulting in a 29 to 37 percent increase in subtidal aquatic habitat in the Plan Area (see Table 5-1). The export of nutrients and food restored tidal marsh plains, floodplain, and channel margin habitats would improve the habitat functions of the tidal perennial aquatic community for covered fish species and other aquatic species. Improvements in the habitat function of the tidal perennial aquatic community for covered fish species and other aquatic species would result from BDCP actions specifically designed for or incidentally resulting in the reduction of stressors such as nonnative predators, nonnative invasive plant species, and agricultural pesticides and herbicides. BDCP actions are estimated to remove 46 acres of the tidal perennial aquatic community, amounting to less than 2 percent of the extent of BDCP restored tidal perennial aquatic community (Table 5-2). There are no temporal losses of the community because the extent that would be removed by the covered activities at each evaluation point is exceeded by the extent of tidal perennial aquatic community that would be restored.

5.4.2.2 Tidal Mudflat

The implementation of the BDCP would result in overall benefits for the tidal mudflat community through the restoration of at least 20 linear miles of tidal mudflat edge as a component of the 65,000 acres of BDCP restored tidal and channel margin habitats. This increase in the extent of tidal mudflat is expected to provide foraging habitat for shorebirds, wading birds, and other native wildlife species as well as substrates suitable for the establishment of covered and other tidal mudflat plant species. Implementation of the covered activities is expected to affect an indeterminable extent of tidal mudflat through construction of new intake facilities and restoration of tidal, floodplain, and channel margin habitats. Restoration of tidal, floodplain, and channel margin habitats, however, are expected to result in an overall increase in the extent of tidal mudflat. Changes in water operations may also affect the long-term distribution of tidal mudflat if those changes alter the current patterns of erosion and deposition in tidal channels. No temporal losses of tidal mudflats are expected because the extent that would be removed by the covered activities at each evaluation point is expected to be exceeded by the extent of tidal mudflat that would be restored.

5.4.2.3 Tidal Brackish Emergent Wetland

Implementation of the BDCP would result in overall benefits for the tidal brackish emergent wetland community, including the restoration and ongoing management of tidal brackish emergent wetlands and a return to more-natural channel water salinity. Based on RMA modeling of hypothetical tidal habitat restorations (see Appendix N.3), between 3,600 and 4,800 acres of tidal brackish emergent wetland community would be restored in Suisun Marsh (Conservation Zone 11), resulting in a 37 to 51 percent increase in the tidal brackish emergent wetland community in the Plan Area (see Table 5-1). There are no temporal losses of the community because the extent of tidal brackish emergent wetland that would be removed by the covered activities at each evaluation point is exceeded by the extent of tidal brackish emergent wetland that would be restored. Restoration and subsequent management of this community to maintain its ecological functions is expected to benefit aquatic food web processes in support of the covered and other native fish species and covered and other native wildlife and plant species dependent on Suisun Marsh tidal habitats.

5.4.2.4 Tidal Freshwater Emergent Wetland Natural Community

The implementation of the BDCP would result in overall benefits for the tidal freshwater emergent wetland community through restoration and ongoing management of the community. Based on RMA modeling of hypothetical marsh restorations, between 13,200 to 21,600 acres of tidal freshwater emergent wetland community would be restored in the Cache Slough Complex, the South Delta, the Cosumnes/Mokelumne, and the West Delta ROAs (Conservation Zones 1, 2, and 4-7), more than doubling the total extent of tidal freshwater emergent wetland community in the Plan Area (Table 5-1). The restored areas of tidal freshwater emergent wetland community are expected to support higher habitat functions for associated-covered and other native wildlife species because they are expected to be much larger than the existing tidal freshwater emergent wetlands that primarily occur in small and isolated patches. There are no temporal losses of the community because the extent of tidal brackish emergent wetland that would be removed by the covered activities at each evaluation point is exceeded by the extent of tidal brackish emergent wetland that would be restored. Restoration and subsequent management of this community to maintain its ecological functions is expected to benefit aquatic food web processes in support of the covered and other native fish species and covered and other native wildlife and plant species associated with tidal habitats of the Delta.

5.4.2.5 Valley/Foothill Riparian Natural Community

Implementation of the BDCP would result in overall benefits for the valley/foothill riparian natural community through restoration and ongoing management of 5,000 acres of riparian communities. BDCP actions are expected to permanently and temporarily remove and periodically inundate 1,114 acres, 165 acres, and 589 acres of riparian habitats, respectively (Table 5-1). Following implementation of riparian restoration actions, there would be a 22 percent increase in the total extent of riparian habitats in the Plan Area and an 80 percent increase in the amount of protected riparian habitat in the Plan Area (Tables 5-1 and 5-2). Restored riparian natural community is expected to support higher habitat functions for associated covered and other native wildlife species because restoration would occur in large patches within floodplains and along channel margins compared with the small, narrow, isolated patches of existing riparian habitat in the Plan Area. Restored sites would also provide more structural and species diversity than most existing patches with an increase in ecological function. There is a temporal loss of riparian habitat because most of the affected riparian vegetation is removed in the near-term implementation period, while large quantities of riparian habitat will not be restored until the early and late long-term implementation periods (Figure 5-3).

Each mapped polygon of riparian vegetation that would be removed by BDCP actions were categorized as supporting low, moderate, or high habitat functions for the riparian-associated and other native wildlife based on the following criteria:

- Type of vegetation (woodland, scrub, or herbaceous),
- Extent and structural qualities of riparian vegetation (dense multistoried vegetation versus a few trees with no understory) within the polygon,
- Hydrology and connectivity (along an active natural stream, man-made canal, irrigation ditch, or isolated patch with no riparian function), and
- Polygon size.

Based on this assessment, Figure 5-3 illustrates the extent of affected riparian vegetation that support low, moderate, and high wildlife habitat values, and Figure 5-4 depicts the size distribution of affected riparian vegetation polygons as an indicator of habitat patch size.

Effects of this temporal loss of riparian communities on associated covered and other native wildlife species is expected to be minimal because most of the affected community is comprised of small patches of riparian scrub and herbaceous vegetation that are fragmented and distributed across the agricultural landscape of the Plan Area. Consequently, much of the affected valley/foothill riparian natural community supports relatively low-functioning habitat for associated covered species and other native species and is not expected to result in a measurable change in the abundance or distribution of these species in the Plan Area. Restoration and subsequent management of this community are expected to benefit covered species habitat and food web processes and result in an increase in ecological function as large stands of new valley foothill riparian community develop within natural landscape and hydrological positions. Figure 5-3 illustrates the expected development of restored riparian habitat functions over time for the riparian-associated covered wildlife species.

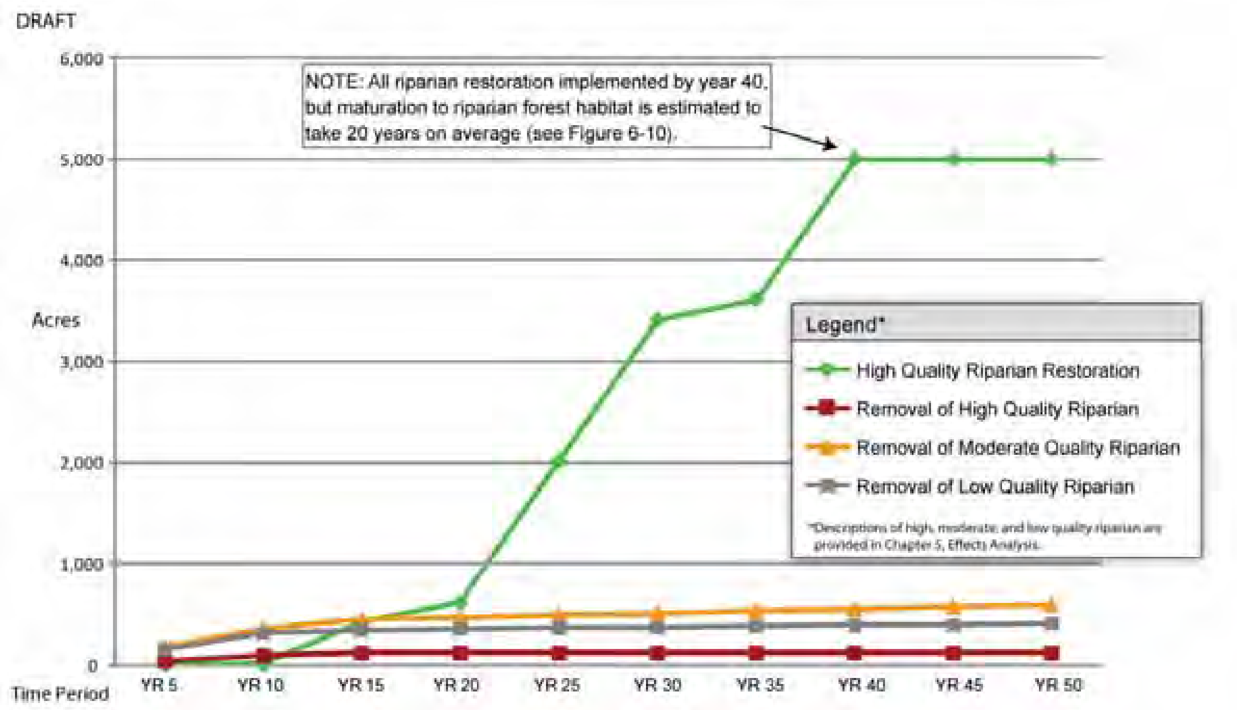

Figure 5-3. Cumulative Riparian Habit Restoration versus Cumulative Permanent Removal

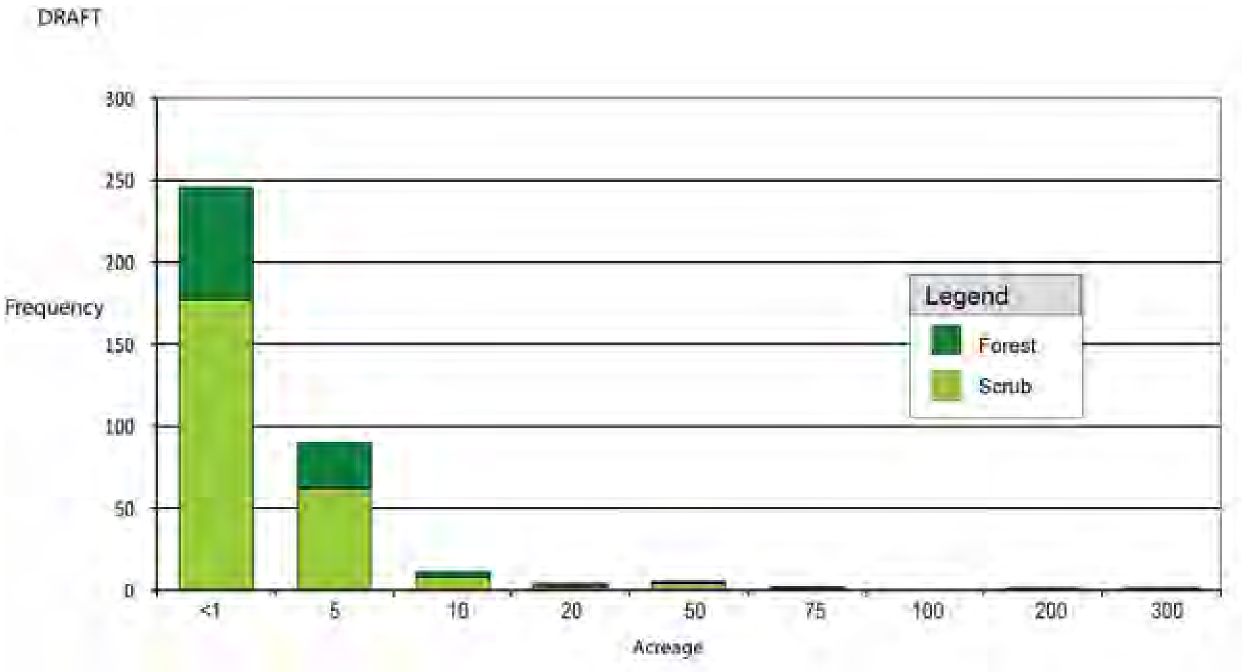

Figure 5-4. Size Distribution of Affected Riparian Forest and Scrub Polygons

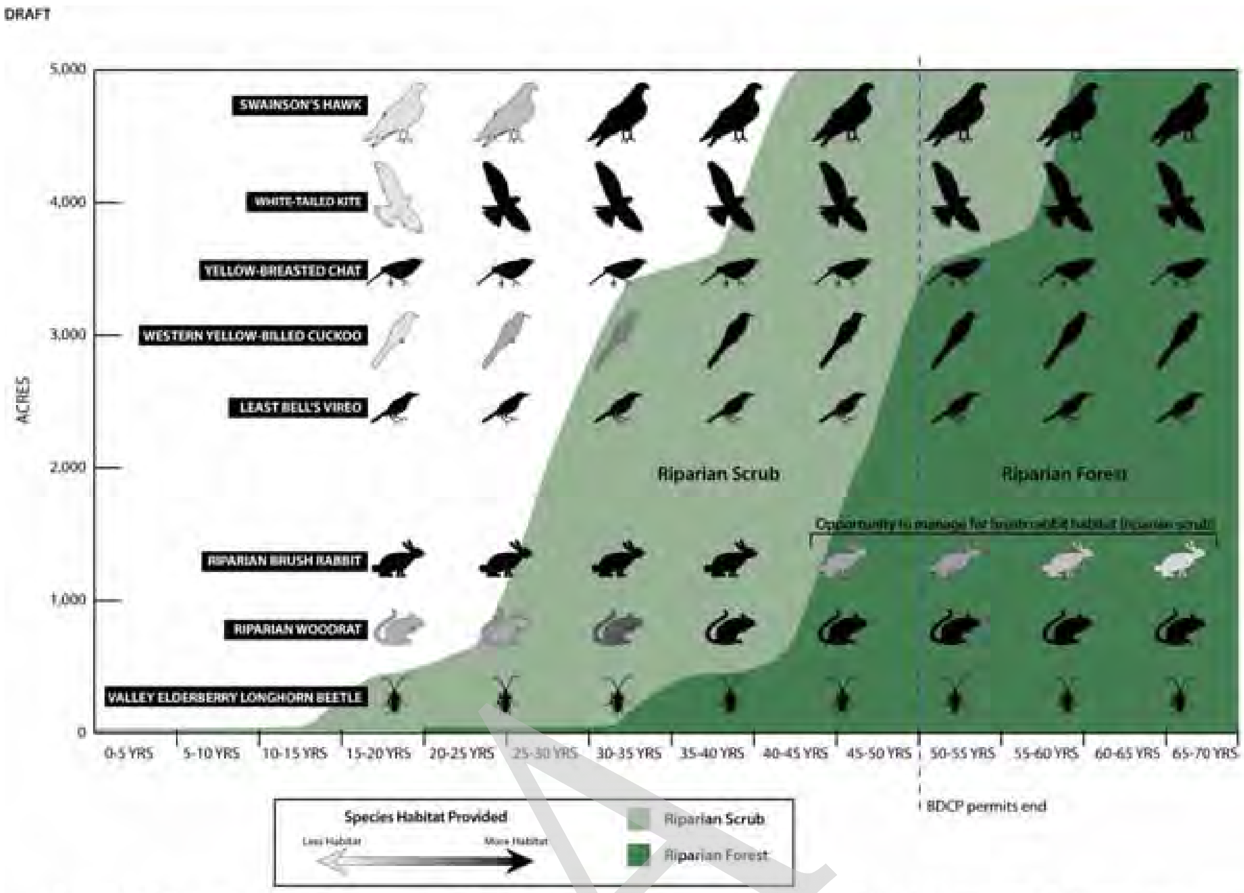

Figure 5-5. Maturation and Succession of Restored Riparian Forest and Scrub and Use by Covered Wildlife Species

5.4.2.6 Grassland Natural Community

The implementation of the BDCP would result in overall benefits for the grassland community through protection and enhancement of existing and restoration of 10,000 acres of grassland habitats. These conservation actions would increase the amount of grassland with protected status in the Plan Area from a current 14,984 acres, or 24 percent, to approximately 23, 955 acres, a 60 percent increase in the extent of protected habitat area (Table 5-2). BDCP actions are expected to permanently, temporarily, and periodically remove 2,831 acres, 437 acres, and 2,111 acres of grassland, respectively (Table 5-1). Sufficient grassland habitat, however, will be protected, enhanced, and restored at each of the evaluation points to address any temporal loss of habitat functions and to contribute to the conservation of grassland-associated covered and other native species.

The 1,854 acres of grassland removed as a result of tidal and associated riparian habitat restoration are subsided, historically supporting tidal habitats rather than grassland (Table 5-1). Furthermore, most of the grassland to be removed consists of naturalized communities of exotic species on lands that were drained for agriculture and on levees; these communities typically support low ecological functions for covered species and other native species. With restoration of 2,000 acres of grassland, there would be a net loss of 823 acres of grassland from the Plan Area (Table 5-1). In contrast to most of the removed grasslands, the grasslands to be protected, enhanced, and restored would be in landscape positions at which grasslands occurred historically. Existing unprotected grassland would be protected in large patch sizes connected to existing large areas of grassland that would serve as gene dispersal and migration corridors as well as transitional habitat areas to maximize the ecological functions of the grasslands for covered and other native wildlife and plant species. The overall habitat quality of protected, enhanced, and restored grassland is expected to be greater than the grasslands adversely affected by the BDCP.

5.4.2.7 Alkali Seasonal Wetland Complex

The implementation of the BDCP would result in overall benefits for the alkali seasonal wetland complex community through protection and enhancement of 400 acres of existing alkali seasonal wetland complex. Priority for protection under the BDCP is given to alkali seasonal wetlands that support occurrences of covered plant species, thus contributing to their conservation (e.g., heartscale, brittlescale, and Carquinez goldenbush). These conservation actions would increase the extent of protected alkali seasonal wetland complex in the Plan Area to 87 percent, representing a 12 percent increase in the extent protected. BDCP actions could permanently remove up to 136 acres and increase the extent of alkali seasonal wetland complex periodically inundated in the Yolo Bypass by 825 acres (Table 5-1). Sufficient alkali seasonal wetland complex, however, will be protected and enhanced at each of the evaluation points to address any temporal loss of habitat functions and to contribute to the conservation of alkali seasonal wetland complex -associated covered and other native species.

Existing unprotected alkali seasonal wetland complex would be protected in conjunction with protected and restored grassland and vernal pool complex to establish large mosaics of these interdependent communities that are connected to existing large areas of grassland. These large patches of protected communities would serve as gene dispersal and migration corridors as well as transitional habitat areas to maximize the ecological functions of protected the alkali seasonal wetland complex for covered and other native species. Consequently, the overall habitat quality of the protected and enhanced alkali seasonal wetland complex is expected to be greater than the affected alkali seasonal wetland complex.

5.4.2.8 Vernal Pool Complex

The implementation of the BDCP would result in overall benefits for the grassland community through protection and enhancement of existing and restoration of 500 acres of vernal pool complex. Priority for protection under the BDCP is given to vernal pool complex that support occurrences of covered plant species, thus contributing to their conservation (e.g., San Joaquin spearscale, dwarf downingia, and delta button celery). These conservation actions would increase the extent of protected vernal pool complex to 69 percent, representing an 11 percent increase in the extent of protected vernal pool complex in the Plan Area (Table 5-2). BDCP actions could permanently remove up to 88 acres of vernal pool complex as a result of restoring tidal habitats (Table 5-1). Sufficient vernal pool complex, however, will be protected and enhanced at each of the evaluation points to address any temporal loss of habitat functions and to contribute to the conservation of vernal pool complex-associated covered and other native species.

Existing unprotected vernal pool complex would be protected and restored in conjunction with protected and restored grassland and the alkali seasonal wetland complex to establish large mosaics of these interdependent communities that are connected to existing large areas of grassland. These large patches of protected communities would serve as gene dispersal and migration corridors as well as transitional habitat areas to maximize the ecological functions of protected and restored vernal pool complex for covered and other native species. Consequently, the overall habitat quality of the protected, enhanced, and restored vernal pool complex is expected to be greater than the affected vernal pool complex.

5.4.2.9 Other Natural Seasonal Wetlands

Implementation of BDCP actions would permanently remove 1 acre of other natural seasonal wetlands, representing less than 1 percent of the existing extent of this community in the Plan Area, and would increase inundation frequency of 2 acres on restored floodplains (see Table 5-1). Protection, enhancement, and management of other natural seasonal wetlands that are present on agricultural lands acquired in fee-title would prevent removal or degradation of other natural seasonal wetlands that function as habitat for covered species resulting from future changes in land use. Enhancement and management of protected wetlands would increase their function as habitat for associated covered plant and other native species.

5.4.2.10 Nontidal Freshwater Perennial Emergent Wetland

Implementation of the BDCP would result in an overall benefit for the nontidal freshwater permanent emergent wetland community through restoration of 400 acres of high functioning nontidal freshwater marsh, of which the nontidal freshwater permanent emergent wetland community will be a component. If at least 200 acres comprises nontidal freshwater permanent emergent wetland, there would be a net increase of 108 acres (approximately 10 percent) of nontidal freshwater permanent emergent wetland in the Plan Area (Table 5-1) and a 37 percent increase in the amount of protected nontidal freshwater permanent emergent wetland in the Plan Area (Table 5-2). The 400 acres of nontidal freshwater marsh will be restored in the near-term implementation period, thus minimizing any temporal loss of habitat functions associated with implementation of BDCP actions on the community. Restored nontidal freshwater marsh would be designed primarily to benefit giant garter snake and other wetland species in Conservation Zones 2 and 4. Restored nontidal freshwater marsh is expected to support higher habitat functions for associated covered and other native species because restoration would occur in relatively large patches compared with the small, isolated patches that currently exist in the Plan Area.

Restoration of 400 acres of nontidal marsh is expected to increase the extent of high value emergent marsh habitat for giant garter snake, western pond turtle, and other native wildlife species (e.g., wintering and resident waterfowl). In addition to restoration and enhancement of habitats that support native wildlife species associated with the nontidal freshwater permanent emergent wetland community, existing emergent marsh habitats present on BDCP-protected lands would be managed to maintain and, where appropriate, increase their habitat functions in support of covered and other native wildlife species (e.g., modifying agricultural conveyance maintenance practices to minimize effects on associated wildlife).

5.4.2.11 Nontidal Perennial Aquatic Natural Community

Implementation of the BDCP would result in an overall benefit for the nontidal perennial aquatic natural community through restoration of 400 acres of high functioning nontidal freshwater marsh, of which the nontidal perennial aquatic natural community will be a component. If at least 200 acres of the restored marsh is comprised of nontidal perennial aquatic habitat, there would be a loss of 45 acres (0.9 percent) of nontidal perennial aquatic natural community in the Plan Area (Table 5-1) and a 12 percent increase in the amount of protected nontidal perennial aquatic community in the Plan Area (Table 5-2). The majority of removed nontidal perennial aquatic community is associated with agricultural ditches and drains and support limited ecological function. Restored nontidal freshwater marsh would be designed primarily to benefit giant garter snake and other wetland species in Conservation Zones 2 and 4. While non-tidal freshwater marsh would be protected on BDCP lands, directed restoration and management of 400 acres would occur primarily to benefit giant garter snake and other wetland species in Conservation Zones 2 and 4. Restored nontidal freshwater marsh is expected to support higher habitat functions for associated covered and other native species because restoration would occur in relatively large patches compared with the small, isolated patches that currently exist in the Plan Area. Restoration of 400 acres of nontidal marsh is expected to increase the extent of high value open water habitat for giant garter snake, western pond turtle, and other native wildlife species (e.g., wintering and resident waterfowl). In addition to restoration and enhancement of habitats that support native wildlife species associated with the nontidal perennial aquatic community, existing open water habitats present on BDCP-protected lands would be managed to maintain and, where appropriate, increase their habitat functions in support of covered and other native wildlife species (e.g., modifying agricultural conveyance maintenance practices to minimize effects on associated wildlife).

5.4.2.12 Inland Dune Scrub Natural Community

Implementation of the BDCP would result in overall beneficial effects on the inland dune scrub community. No BDCP actions would affect inland dune scrub natural community. The BDCP would result in an overall benefit to the ecological function of the inland dune scrub community in the Plan Area though financially supporting the USFWS' existing restoration, long-term management, and enhancement of the community.

5.4.2.13 Managed Wetlands

The implementation of BDCP actions are expected to remove 12,196 acres of managed wetlands, primarily from Suisun Marsh as a result of restoration of tidal habitats (see Appendix N.3, *RMA Description of Hypothetical Restoration Design and Effects).* The habitat functions provided by these managed wetlands for associated covered wildlife species are also supported by natural communities (e.g., tidal and grassland habitats) and agricultural habitats that will be protected, enhanced, and restored under the BDCP. Based on the assessment of effects on these covered wildlife species (see Section 5.5.3, *Covered Wildlife and Plant Species*), protection, enhancement, and restoration of these replacement habitats are expected to result overall benefits for covered wildlife species that use managed wetlands. Managed wetlands are typically managed to provide habitat for wintering waterfowl and migrant shorebirds. As described for covered wildlife species, protection, enhancement, and restoration of natural communities and agricultural habitats also provide waterfowl and shorebird habitats. Based on an evaluation of the effects of BDCP actions on the waterfowl and shorebird habitat functions provided by affected managed wetlands and other natural communities, implementation of BDCP habitat conservation measures are expected to replace or provide greater habitat functions for these species than the affected waterfowl and shorebird habitats (see Appendix N.6, *Waterfowl and Shorebirds Effects Analysis*). Consequently, although BDCP actions will result in a reduction in the extent of managed wetlands within the Plan Area, the habitat functions for covered and other native wildlife species that use managed wetlands are expected to be maintained or increased beyond current conditions.

5.4.2.14 Agricultural Land

Implementation of the BDCP would result in an overall benefit to the ecological function of agricultural lands as habitat for associated covered species through protection and enhancement of 16,620 to 32,640 acres of high value cover types and associated habitats (e.g., adjacent riparian or other woodlands, roadside tree rows, hedge rows, wetlands, etc.) that occur within the agricultural matrix. While there will be an approximate 8 percent net reduction in the extent of agricultural lands in the Plan Area resulting primarily from the restoration of tidal communities, the BDCP would increase the amount of agricultural land under protected status from 11 percent to between 15 and 18 percent (Table 5-2). A sufficient extent agricultural land providing habitat values for covered and other wildlife species, however, will be protected and enhanced at each of the evaluation points to address any temporal loss of habitat functions and to contribute to the conservation of agricultural land-associated covered and other native species.

Agricultural land protection could occur in all Conservation Zones; however, conservation efforts would be directed geographically in order to meet the objectives for individual covered species, including greater sandhill crane, Swainson's hawk, and giant garter snake. BDCP-managed agricultural lands are expected to support higher habitat functions for associated covered species by farming crop types that provide high habitat values for covered and other native wildlife species and, where possible, enhancing patches of native habitat within the agricultural landscape. Because the value of agricultural lands is highly variable and fluid, protected acres were calculated based on an analysis of habitat/cover type value and a conversion to habitat units. Of the 503,799 acres of agricultural land within the Plan Area, approximately 155,000 acres (31 percent) is considered moderate to high value for covered species. Thus, the management of BDCP-protected lands as high value agricultural habitat can successfully offset the overall reduction in the extent of agricultural lands across the landscape and meet the habitat objectives for each agricultural-associated covered species. In addition, the restoration of tidal and nontidal marshes, riparian forests and scrub, and grasslands with the agricultural matrix would enhance the overall ecological value of the adjacent agricultural lands.

5.4.3 Covered Wildlife and Plant Species

The following summarizes the overall effects of implementing the BDCP actions on each of the covered wildlife and plant species. The extent of each covered wildlife and plant species' habitat that would be permanently and temporarily removed and periodically affected by BDCP at the late long-term evaluation point are presented in Table 5-3. The table also indicates the total extent of each species' habitat types that will be present in the Plan Area following full implementation of the BDCP. The extent of habitat benefits provided through implementation of conservation measures to protect and enhance existing habitats and restore new habitat areas for each of the covered wildlife and plant species following full BDCP implementation are presented in Table 5-4.

The complete effects analysis will present the permanent, temporary, and periodic effects on each species for each of the evaluation periods for the entire Plan Area and each of the 11 Plan Area Conservation Zones (Figure 3-1) and will describe the combined effects of implementing all BDCP actions for each of the covered wildlife and plant species at the near-term, early long-term, and late long-term evaluation periods. The mechanisms associated with each of the BDCP actions that can result in a permanent or temporary direct or indirect effect or periodic effect on each of covered wildlife and plant species will also be described and evaluated in the full effects analysis.

5.4.3.1 San Joaquin Kit Fox

Implementation of all BDCP actions will result in an overall benefit to San Joaquin kit fox within the Plan Area and adjacent areas though a directed process of protecting the highest functioning grassland supporting kit fox breeding habitat both intrinsically and in association with other habitat types and habitat corridors and managing protected grasslands to maximize their ecological functions. The BDCP will protect and enhance 1,000 acres kit fox grassland breeding and foraging habitat in Conservation Zone 8 and protect and increase connectivity of its limited Plan Area habitats with extensive kit fox habitat areas outside of the Plan Area. Protected habitat will be managed to enhance rodent prey availability for the kit fox. Following implementation, 31 percent of kit fox breeding habitat within the Plan Area will be protected, increasing the total area of protected breeding habitat by 144 percent (Table 5-4). In addition, any portion of the 2,000 acres of BDCP restored grassland that is located in Conservation Zone 8 would also be expected to benefit the kit fox.

All protection of kit fox habitat would be provided in and all adverse effects on San Joaquin kit fox habitat would be incurred in the near-term evaluation period. Permanent adverse effects on San Joaquin kit fox from implementing BDCP actions include the loss of 163 acres of grassland breeding and 663 acres of adjacent agricultural movement habitat (Table 5-3). Temporary adverse effects include the temporary removal of 161 acres of grassland and 481 acres of adjacent agricultural land, which are expected to be restored following the completion of water conveyance construction (Table 5-3). In contrast to the removed grassland habitats, the grasslands to be protected and enhanced occur in areas of historical natural grassland vegetation.

5.4.3.1.1 Population-Level Effects on San Joaquin Kit Fox

BDCP actions are not expected to have an adverse or beneficial population-level effect on San Joaquin kit fox in the near-term, early long-term, or late long-term evaluation points because species abundance within the Plan Area is considered to be low based on recent data and modeled habitat and because removed habitat is typically low value. There are very few recent records of San Joaquin kit fox from anywhere within its northern range of Alameda and Contra Costa counties. Modeled kit fox habitat to be removed by BDCP actions is low value, highly disturbed, and fragmented from intact grasslands to the west, and occurs on the extreme edge of the species range. Effects associated with implementation of BDCP actions therefore are not expected to adversely affect the regional San Joaquin kit fox population.

5.4.3.2 Riparian Woodrat

Implementation of all BDCP actions will result in an overall potential benefit to riparian woodrat within the Plan Area through protection and restoration of its habitat. The BDCP will restore 5,000 acres of riparian habitat, approximately 4,000 of which will be in Conservation Zone 7. A substantial portion of this is expected to provide high value riparian habitat for the riparian woodrat without implementing site-specific enhancement actions. However, because the extent of high value habitat cannot be quantified, BDCP will also directly restore 300 acres to meet the ecological and habitat requirements of the riparian woodrat in Conservation Zone 7 or 8. Restoration of 300 acres of riparian habitat will increase the extent of available habitat for the riparian woodrat in the Plan Area by 18 percent and increase the number of protected areas by 306 percent (Table 5-3 and 5-4). The actual increase in available and protected acres is expected to be substantially higher due to the overall extent of riparian restoration.

The species is not known to occur in the Plan Area and thus is not expected to be affected by BDCP actions unless the species were to establish in the Plan Area over the term of the BDCP. BDCP actions that affect riparian woodrat modeled habitat consist only of floodplain restoration and protection and management of natural communities. BDCP actions are projected to permanently remove 25 acres, temporarily remove 14 acres, and periodically inundate 98 acres of modeled woodrat habitat, respectively. The majority of these acres would not be affected until the late-long term and would be addressed by ongoing riparian habitat restoration.

5.4.3.2.1 Population-Level Effects on Riparian Woodrat

BDCP actions will not have an adverse population-level effect on riparian woodrat because it is not currently present in the Plan Area and will not be affected by BDCP actions unless the riparian woodrat were to establish in the Plan Area before full BDCP implementation. Implementation of actions to restore 5,000 acres of riparian habitat, 300 of which will be restored specifically to meet the habitat requirements of the riparian woodrat is expected to provide a population-level benefit by providing habitat to accommodate the expansion of existing populations near the Plan Area, increase its distribution and abundance, and reduce the risk for its extinction.

5.4.3.3 Salt Marsh Harvest Mouse

Implementation of all BDCP actions will result in an overall benefit to salt marsh harvest mouse within the Plan Area through restoration and enhancement of its habitat. Based on the RMA hypothetical tidal habitat restorations (see Appendix N3, *RMA Description of Hypothetical Restoration Design and Effects*), 3,600 to 4,800 acres of tidal brackish wetlands supporting salt marsh harvest mouse habitat will be restored in Suisun Marsh (Conservation Zone 11; Table 5-3). BDCP actions are expected to adversely affect salt marsh harvest mouse habitat through the permanent removal of 2,487 acres of modeled wetland habitat and 674 acres of modeled upland habitat (Table 5-3). However, this effect will be gradual and phased over time as restoration is occurring. Tidal wetlands will be restored in large patches supporting a natural gradient extending from subtidal to upland zones which is expected to increase the extent of high value tidal marsh that supported the salt marsh harvest mouse's historical tidal habitat and help achieve the draft Tidal Marsh Ecosystems Recovery Plan (USFWS 2010) salt marsh harvest mouse objectives. The enhancement and restoration of 350-700 acres of upland habitat adjacent to restored marshes are expected to provide high functioning flood refuge habitat for the mouse. Based on the hypothetical tidal marsh restorations, (see Appendix N3, *RMA Description of Hypothetical Restoration Design and Effects*), after full implementation of the BDCP there will be a 10 to 21 percent increase in the extent of salt marsh harvest mouse habitat in the Plan Area. The extent of existing protected salt marsh harvest mouse tidal wetland habitat is expected to increase to 13 to 25 percent (Table 5-4).

5.4.3.3.1 Population-Level Effects on Salt Marsh Harvest Mouse

Salt marsh harvest mouse are restricted to natural saline and brackish wetlands along the northern borders of San Pablo and Suisun Bays and BDCP conservation measures are expected to have a beneficial effect on the overall population of salt marsh harvest mouse by increasing the extent of tidal brackish wetlands that support high function salt marsh harvest mouse habitat. Restoration and subsequent management of this habitat is expected to provide the basis for increasing the abundance of salt marsh harvest mouse such that the Suisun Marsh portion of its population is maintained and increased.

5.4.3.4 Riparian Brush Rabbit

Implementation of all BDCP actions will result in an overall potential benefit to riparian brush rabbit within the Plan Area through protection and restoration of its habitat. The BDCP will restore 5,000 acres of riparian habitat, approximately 4,000 of which will be in Conservation Zone 7. A substantial portion of this is expected to provide high value riparian habitat for the riparian brush rabbit without implementing site-specific enhancement actions. However, because the extent of high value habitat cannot be quantified, BDCP will also directly restore 300 acres to meet the ecological and habitat requirements of the riparian brush rabbit in Conservation Zone 7. Restoration of 300 acres of riparian habitat will increase the extent of available habitat for the riparian brush rabbit in the Plan Area by 8 percent and increase the number of protected acres by 215 percent (Table 5-4). The actual increase in available and protected acres is expected to be substantially higher due to the overall extent of riparian restoration.

BDCP actions that affect riparian brush rabbit modeled habitat consist of water conveyance construction, floodplain restoration, and protection and management of natural communities. None of the affected habitat areas are currently known to be occupied by riparian brush rabbit. BDCP actions are projected to permanently remove 62 acres, temporarily remove 19 acres, and periodically inundate 264 acres of modeled brush rabbit habitat, respectively (Table 5-4). The majority of these acres would not be affected until the late-long term and would be offset by ongoing riparian restoration.

5.4.3.4.1 Population-Level Effects on Riparian Brush Rabbit

BDCP actions will not have an adverse population level effect on riparian brush rabbit because affected areas are not currently occupied by brush rabbit populations. BDCP actions may benefit the riparian brush rabbit by providing potential habitat for future population expansion in the early long-term and late long-term implementation periods. Restoration of 5,000 acres of riparian habitat, 300 acres of which will be restored specifically to meet the habitat requirements of the riparian brush rabbit habitat is expected to provide a population-level benefit by providing habitat to accommodate the expansion of existing populations in the Plan Area, increase its distribution and abundance, and reduce the risk for its extinction.

5.4.3.5 Townsend's Big-eared Bat

Implementation of BDCP actions will result in an overall benefit to Townsend's big-eared bat within the Plan Area through protection and restoration of its foraging and roosting habitats. BDCP actions will restore 5,000 acres of riparian roosting and primary foraging habitat, 2,600 acres of grassland, vernal pool complex, and nontidal marsh foraging habitat, up to 65,000 acres of tidal wetland foraging habitat, and protect 8,000 acres of grassland and up to 32,640 acres of agricultural foraging habitat. Restoration actions will increase the extent of primary foraging and roosting habitat for the Townsend's big-eared bat by 69 percent and increase the overall number of protected acres of foraging and roosting habitat by 258 percent (Table 5-4). Restored foraging habitats replace primarily agricultural lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be higher in restored wetlands and uplands on which application of pesticides will be reduced relative to affected agricultural habitats.

All BDCP actions will affect Townsend's big-eared bat modeled habitat; however, BDCP actions are expected to increase the habitat value of the majority of affected acres. BDCP actions are expected to permanently convert 860 acres of primary foraging habitat, nearly all of it due to tidal habitat restoration, to other types of foraging habitat. They are also expected to remove 268 acres of roosting and primary foraging habitat and convert 60,051 acres of secondary foraging habitat (primarily agricultural land) in the Plan Area to other foraging habitat types (Table 5-3). The majority of affected acres will convert agricultural land to natural communities with higher potential foraging and roosting value, such as riparian, tidal and non-tidal wetlands, and periodically inundated lands. Temporary effects on the Townsend's big-eared bat are comparatively small, affecting only 76 acres of primary foraging habitat, 86 acres of roosting and primary foraging habitat, and 4,592 acres of secondary foraging habitat (Table 5-3). BDCP actions are expected to periodically convert 291 acres of modeled primary foraging habitat, 301 acres of modeled roosting/primary foraging habitat, and 30,619 acres of modeled secondary foraging habitat to seasonally inundated foraging habitat. Similar to permanent habitat impacts, most temporary and periodic impacts convert existing habitat to higher value habitat and enhance the foraging and roosting functions of BDCP lands for Townsend's big-eared bat.

5.4.3.5.1 Population-Level Effects on Townsend's Big-Eared Bat

BDCP actions will not have an adverse population-level effect on Townsend's big-eared bat because the species is not known to roost and is otherwise uncommon in the Plan Area and because most BDCP actions will enhance habitat function and value for this species. While there will be a temporal loss of primary riparian roosting and foraging habitat (Section 5.4.2.5, *Valley/Foothill Riparian*), the availability of this habitat in the Plan Area likely exceeds the current habitat need based on the lack of documented occurrences of this species in the Plan Area and surrounding lands. The protection, restoration, and enhancement of 5,000 acres of Townsend's big-eared bat roosting and primary foraging habitat by the late-long term period along with the conversion of agricultural lands to higher value foraging habitat is expected to sustain any Townsend's big-eared bat population, were it to establish in the Plan Area.

5.4.3.6 Suisun Shrew

Implementation of all BDCP actions will result in an overall benefit to Suisun shrew within the Plan Area resulting from a net increase in the extent and contiguity of high value historical Suisun shrew tidal habitat. Based on the RMA hypothetical tidal habitat restorations (see Appendix N.3, *RMA Description of Hypothetical Restoration Design and Effects*), 3,600 to 4,800 acres of tidal brackish wetlands supporting Suisun shrew habitat will be restored in Suisun Marsh (Conservation Zone 11; Table 5-3). BDCP actions are expected to adversely affect Suisun shrew habitat through the permanent removal of 6,237 acres of modeled habitat, consisting primarily of managed wetlands (Table 5-3); however, this effect will be gradual and phased over time as restoration is occurring. Tidal wetlands will be restored in large patches supporting a natural gradient extending from subtidal to upland zones which is expected to increase the extent of high value tidal marsh that supported the Suisun shrew's historical tidal habitat and help achieve the draft Tidal Marsh Ecosystems Recovery Plan (USFWS 2010) Suisun shrew objectives. Based on the hypothetical tidal marsh restorations, (see Appendix N.3, *RMA Description of Hypothetical Restoration Design and Effects*), after full implementation of the BDCP there will be a 5 to 9 percent reduction in the extent of Suisun shrew habitat in the Plan Area (Table 5-3), comprised primarily of low value Suisun shrew managed wetland habitat. Because restored tidal wetland habitats are expected to support higher functions as habitat for the Suisun shrew than the affected nontidal wetlands, the overall outcome for Suisun shrew will be beneficial, providing conditions favorable for increasing the distribution and abundance of Suisun shrew within the Plan Area.

5.4.3.6.1 Population-Level Effects on Suisun Shrew

Since Suisun shrew are restricted to natural tidal wetlands along the northern borders of San Pablo and Suisun Bays and BDCP conservation measures are expected to have a beneficial effect on the overall population of Suisun shrew by increasing the extent of tidal brackish emergent wetlands that support high function Suisun shrew habitat. Restoration and subsequent management of this habitat are expected to provide the basis for increasing the abundance of Suisun shrew such that the Suisun Marsh portion of its population is maintained and increased.

5.4.3.7 Tricolored Blackbird

Implementation of all BDCP actions will result in an overall benefit to tricolored blackbird within the Plan Area through restoration and protection of its foraging and nesting habitats. Habitat restoration actions will result in restoration/creation of 17,900 to 26,800 acres of tricolored blackbird nesting habitat (based on the RMA hypothetical tidal habitat restorations presented in Appendix N3, *RMA Description of Hypothetical Restoration Design and Effects*), and after full implementation of the BDCP, 8,700 acres of non-agriculture foraging habitat and 16,620 to 32,640 acres of agriculture foraging habitat will be protected and enhanced for tricolored blackbird and other covered species. As a result of BDCP restoration actions, the total amount of tricolored blackbird nesting habitat within the Plan Area will increase 57 to 94 percent from current conditions (Table 5-4). While the extent of modeled foraging habitat will be reduced by 6 percent (non-agricultural) and 9 percent (agricultural), tricolored blackbirds may also use the restored tidal and nontidal wetland habitats for foraging, a function that was not included in the model formulation (Table 5-3). As a result, implementation of all BDCP actions is expected to result in an overall beneficial effect on tricolored blackbird as BDCP implementation will increase the extent of protected nesting and agricultural and non-agricultural foraging habitats in the Plan Area that will no longer be subject to loss that could result from future changes in land use by 101 to 163 percent, 12 percent, and 43 to 91 percent, respectively, from current conditions (Table 5-4). In addition, restoration of large and contiguous protected patches of nesting habitat is expected to increase the likelihood for increasing the number and distribution of nesting colonies and the abundance of tricolored blackbirds in the Plan Area.

Implementation of BDCP actions is expected to result in the permanent removal of approximately 4,104 acres of modeled nesting habitat, 5,878 acres of non-agriculture foraging habitat, and 24,781 acres of agriculture foraging habitat (Table 5-3). Approximately 35 acres of nesting habitat, 471 acres of non-agriculture foraging habitat, and 1,959 acres of agriculture foraging habitat will be temporarily removed. An additional 303 acres of nesting habitat, 5,414 acres of non-agriculture foraging habitat, and 6,599 acres of agriculture foraging habitat will be periodically affected by BDCP actions.

5.4.3.7.1 Population-Level Effects on Tricolored Blackbird

BDCP actions will not have an adverse population level effect on the tricolored blackbird because protection, restoration, and enhancement of a large extent of tricolored blackbird habitat within the Plan Area is expected to increase the stability of tricolored blackbird populations within and adjacent to the Plan Area and provide for the potential future growth of the local and regional populations.

5.4.3.8 Suisun Song Sparrow

Implementation of all BDCP actions will result in an overall benefit to Suisun song sparrow within the Plan Area through restoration of its habitat. Based on the RMA hypothetical tidal habitat restorations (see Appendix N.3, *RMA Description of Hypothetical Restoration Design* *and Effects*), 3,600 to 4,800 acres of tidal brackish wetlands supporting Suisun song sparrow habitat will be restored in Suisun Marsh (Conservation Zone 11; Table 5-2). BDCP actions are expected to adversely affect Suisun song sparrow through the permanent removal of 5,272 acres of modeled habitat, consisting primarily of managed wetlands (see Table 5-3). However, this effect will be gradual and phased over time as restoration is occurring. Tidal wetlands will be restored in large patches supporting a natural gradient extending from subtidal to upland zones which is expected to increase the extent of high value tidal marsh that supported the sparrow's historical tidal habitat and help achieve the draft Tidal Marsh Ecosystems Recovery Plan (USFWS 2010) Suisun song sparrow objectives.

Based on the hypothetical tidal marsh restorations, (see Appendix N3, *RMA Description of Hypothetical Restoration Design and Effects*), after full implementation of the BDCP there will be a 2-6 percent reduction in the extent of Suisun song sparrow habitat in the Plan Area (Table 5-3), comprised primarily of low value Suisun song sparrow managed wetland habitat. Because tidal habitat restoration in Conservation Zone 11 will affect primarily managed wetland habitats, many of which are protected through conservation easements, the extent of existing protected Suisun song sparrow habitat is expected to decrease by up to 6 percent (Table 5-4). Because restored tidal wetland habitats are expected to support higher functions as habitat for the Suisun song sparrow than the affected nontidal wetlands, the overall outcome for Suisun song sparrow will be beneficial, providing conditions favorable for increasing the distribution and abundance of Suisun song sparrow within the Plan Area.

5.4.3.8.1 Population-Level Effects on Suisun Song Sparrow

BDCP actions will not have an adverse population-level effect on Suisun song sparrow in the near-term, early long-term, or late-long term evaluation points because affected habitat in Suisun Marsh will be sequenced with habitat restoration activities to minimize adverse effects on habitat that could affect that population. Because the entire population of Suisun song sparrow is found within the Plan Area, BDCP tidal habitat restoration actions are expected to be beneficial for the entire Suisun song sparrow population by replacing marginal managed wetland habitat with high quality tidal habitat, and thus creating the potential for extending the species abundance and distribution.

5.4.3.9 Yellow-breasted Chat

Implementation of all BDCP actions is expected to result in an overall benefit to yellow-breasted chat within the Plan Area through restoration of 5,000 acres of its riparian habitat of which at least 2,000 acres is expected to support vireo habitat. BDCP actions are expected to result in the permanent and temporary removal of up to 1,049 acres and 129 acres of modeled yellow-breasted chat habitat, respectively (Table 5-3), primarily due to tidal marsh restoration actions, although the affected habitat is not known to be occupied. Restoration of 5,000 acres of riparian habitat is expected to increase the extent of yellow-breasted chat habitat in the Plan Area by 4,087 acres, or 28 percent, and the extent of chat habitat under protected status within the Plan Area is expected to increase by about 85 percent (Tables 5-3 and 5-4). Most of this restored valley/foothill riparian will be in large patches associated with restored floodplain and tidal habitats. The restoration of such a large area of riparian forest and scrub increases the potential for increasing the abundance and distribution of nesting yellow-breasted chat in the Plan Area and is expected to improve the function of the Plan Area as a migration corridor. As described in Section 5.4.2.5, *Valley/Foothill Riparian*, there is a temporal loss of riparian habitat in the near-term evaluation period because most of the affected riparian vegetation is removed in the near-term implementation period, while large quantities of riparian habitat will not be restored until the early and late long-term implementation periods (Figures 5-3 and 5-5). Effects on yellow-breasted chat of this temporal loss of riparian vegetation is expected to be minimal because much of the riparian habitat in the Plan Area is not known to be currently occupied by the species and most of the affected community is comprised of small patches of riparian scrub and herbaceous vegetation that are fragmented and distributed across the agricultural landscape of the Plan Area (Figure 5-4) and thus are likely to provide no or low value habitat for the chat.

In summary, the yellow-breasted chat is not an established breeder within the Plan Area and seems to use the area as an infrequent migrant. Consequently, BDCP actions are unlikely to adversely affect the species. The overall effect of implementing BDCP actions on yellow-breasted chat is expected to be beneficial as a result of increasing the extent of riparian forest and scrub that supports high-functioning yellow-breasted chat habitat. Restoration and subsequent management of this habitat will provide the basis for increasing the abundance of yellow-breasted chat such that its population is maintained and increased.

5.4.3.9.1 Population-Level Effects on Yellow-breasted Chat

Because yellow-breasted chat is not known to be established in the Plan Area, BDCP actions are not expected to have any adverse population-level effect on yellow-breasted chat populations. BDCP riparian habitat restoration actions are expected to be beneficial for yellow-breasted chat by creating the potential for extending the species occupied range and providing habitat that, if yellow-breasted chat becomes established as a breeding species, could provide a source population for establishment of other historically occupied Central Valley habitats.

5.4.3.10 Least Bell's Vireo

Implementation of all BDCP actions is expected to result in an overall benefit to yellow-breasted chat within the Plan Area through restoration of 5,000 acres of riparian vegetation of which at least 2,000 acres is expected to support vireo habitat. Implementation of BDCP actions is expected to result in the permanent and temporary removal of up to 1,049 acres and 129 acres, respectively of modeled least Bell's vireo habitat (Table 5-3), primarily due to tidal marsh restoration actions. Although least Bell's vireo were observed in the Plan Area in spring 2010, it is not known to currently occupy habitat within the Plan Area, therefore effects are evaluated based on the potential removal or restoration of modeled habitat and some potential for future occupation. Restoration of at least 2,000 acres of riparian forest and scrub that is expected to support least Bell's vireo habitat will increase the extent of potential least Bell's vireo habitat in the Plan Area by approximately 1,092 acres, or 7 percent, and the extent of vireo habitat under protected status within the Plan Area is expected to increase to more than 25 percent (Tables 5-3 and 5-4). Most of this restored valley/foothill riparian will be in large patches associated with restored floodplain and tidal habitats. The restoration of such a large area of riparian forest and scrub increases the potential for restoring formally occupied habitat by establishing the least Bell's vireo as a breeding species within the Plan Area. As described in Section 5.4.2.5, *Valley/Foothill Riparian*, there is a temporal loss of riparian habitat in the near-term evaluation period because most of the affected riparian vegetation is removed in the near-term implementation period, while large quantities of riparian habitat will not be restored until the early and late long-term implementation periods (Figures 5-3 and 5-5). This temporal loss is expected to have no or minimal effects on least Bell's vireo because it is not currently known to occupy the Plan Area.

In summary, the least Bell's vireo is not an established breeder within the Plan Area, and BDCP actions are unlikely to adversely affect the species. The overall effect of implementing BDCP actions on least Bell's vireo is expected to be beneficial as a result of increasing the extent of riparian forest and scrub that supports higher-functioning least Bell's vireo habitat. Restoration and subsequent management of this habitat will to provide the basis for increasing the range of least Bell's vireo by establishing it as a breeding species in the Plan Area.

5.4.3.10.1 Population-Level Effects on Least Bell's Vireo

Because least Bell's vireo is not known to be established in the Plan Area, BDCP actions are not expected to have an adverse population-level effect on least Bell's vireo populations. Overall, BDCP riparian habitat restoration actions are expected to be beneficial for least Bell's vireo by creating the potential for extending the species occupied range northward. By restoring at least 2,000 acres of riparian forest and scrub habitat, BDCP will provide habitat that, if least Bell's vireo becomes established as a breeding species, could support a source population for establishment of other historically occupied Central Valley habitats.

5.4.3.11 Western Burrowing Owl

Implementation of BDCP actions are expected to result in an overall benefit to the burrowing owl in the Plan Area through restoration, protection, and management of its habitat. The BDCP will restore 2,000 acres and protect 8,000 acres of high value grassland habitat within Conservation Zones 1, 8, and 11; and of the 12,000 to 28,000 acres of non-rice agricultural lands that will be protected, 3,000 acres will target moderate and high value (pastureland and grassland) burrowing owl habitats, for a total of 13,000 acres of high and moderate value burrowing owl habitat restored and/or protected in the Plan Area. Through these actions, protection of high and moderate value habitats for burrowing owl will increase by 31 percent and at least 18 percent, representing a total of 45 percent and 40 percent of protected modeled high and moderate value habitat in the Plan Area, respectively (Table 5-4).

BDCP actions are expected to adversely affect burrowing owl through the permanent removal or conversion of 3,569 acres of modeled high value habitat and 4,260 acres of moderate-value habitat. The largest extent of habitat conversion, 21,631 acres, is low value (agricultural land) habitat (Table 5-3). An additional 410 acres of high value habitat and 46 acres of moderate value habitat will be removed temporarily and 2,923 acres of high value habitat and 1,651 acres of moderate value habitat will be periodically affected. Similarly, the largest extent of temporary and periodic habitat effects is low value habitat, 1,970 and 10,265 acres, respectively (Table 5-3). While the extent of modeled high value and moderate value burrowing owl habitat will be reduced in the Plan Area by 2 percent and 8 percent, respectively, BDCP restoration, protection, and enhancement actions, particularly the increase in protection of high and moderate value habitat in the Plan Area is expected to provide for the protection and future expansion of the burrowing owl population (Table 5-3).

5.4.3.11.1 Population-Level Effects on Burrowing owl

BDCP actions will not have an adverse population-level effect on burrowing owl in the Plan Area. The Plan Area represents only a small fraction of the known distribution of burrowing owls in California. The protection, restoration, and enhancement of 13,900 acres of burrowing owl high and moderate-value habitat associated with BDCP action is expected to at least sustain burrowing owl numbers within and adjacent to the Plan Area and increase the permanent protection of high quality habitat for the species.

5.4.3.12 Western Yellow-Billed Cuckoo

Implementation of all BDCP actions is expected to result in an overall benefit to western yellow-billed cuckoo within the Plan Area through restoration of restoration of 5,000 acres of riparian vegetation of which at least 1,000 acres is expected to support cuckoo habitat. BDCP actions are expected to result in the permanent and temporary removal of up to 574 acres and 228 acres of modeled yellow-billed cuckoo breeding and migratory habitat, respectively (Table 5-3), primarily due to tidal marsh restoration actions. The western yellow-billed cuckoo is not known to currently occupy habitat within the Plan Area, therefore effects are evaluated based on the potential removal or restoration of modeled habitat and some potential for future occupation. Restoration of at least 1,000 acres of riparian forest is expected to increase the extent of western yellow-billed cuckoo breeding habitat in the Plan Area by at least 426 acres. A large proportion of the remaining 4,000 acres of the 5,000 acres of riparian forest and scrub to be restored under the BDCP is expected to develop as breeding or migratory western yellow-billed cuckoo.

Most of this restored valley/foothill riparian will be in large patches, as opposed to the primarily smaller isolated patches of affected habitat, associated with restored floodplain and tidal habitats. The restoration of such a large area of riparian forest and scrub increases the potential for restoring formally occupied habitat by establishing western yellow-billed cuckoo as a breeding species within the Plan Area. As described in Section 5.5.2.5, *Valley/Foothill Riparian*, there is a temporal loss of riparian habitat in the near-term evaluation period because most of the affected riparian vegetation is removed in the near-term implementation period, while large quantities of riparian habitat will not be restored until the early and late long-term implementation periods

(Figures 5-3 and 5-5). This temporal loss is expected to have no or minimal effects on western yellow-billed cuckoo because it is not currently known to occupy the Plan Area.

In summary, the yellow-billed cuckoo is not an established breeding species within the Plan Area and seems to use the area as an infrequent migrant. BDCP actions are unlikely to adversely affect the species. The overall effect of implementing BDCP actions on western yellow-billed cuckoo will be beneficial as a result of increasing the extent of riparian forest that supports high-functioning western yellow-billed cuckoo habitat. Restoration and subsequent management of this habitat are expected to provide the basis for increasing the range of western yellow-billed cuckoo by increasing the potential for establishing it as a breeding species in the Plan Area.

5.4.3.12.1 Population-Level Effects on Yellow-billed Cuckoo

Because western yellow-billed cuckoo is not known to be established in the Plan Area, BDCP actions are not expected to have any adverse population-level effect on western yellow-billed cuckoo. BDCP riparian habitat restoration actions are expected to be beneficial for western yellow-billed cuckoo by creating the potential for extending the species occupied range and providing habitat that, if western yellow-billed cuckoo becomes established as a breeding species, could provide a source population for establishment of other historically occupied Central Valley habitats.

5.4.3.13 California Least Tern

Implementation of the BDCP will result in overall beneficial effects on California least tern through restoration of an estimated 10,000 to 20,000 acres of its tidal aquatic foraging habitat, increasing its foraging habitat area by 11 to 23 percent. Implementation of BDCP actions will avoid direct disturbance of California least tern nesting colonies and, compared to the extent of restored habitat, will remove a relatively small about of its tidal aquatic foraging habitat (Table 5-3). Restoration of more than of tidal perennial aquatic will result in enhanced habitat function for California least tern by its proximity to restored and existing aquatic and upland habitats in a natural elevation gradient. The overall outcome for California least tern is beneficial due to restoration of foraging habitat.

5.4.3.13.1 Population-Level Effects on California Least Tern

BDCP actions are not expected to have any adverse effect on California least tern in the Plan Area and, therefore, are not expected to have an adverse population-level effect on California least tern. Only a small fraction of the total California least tern population uses the Plan Area and the Plan Area is not identified as a priority area for conservation action in recovery documents associated with the California least tern. Although BDCP actions are expected to increase the extent of shallow subtidal aquatic California least tern foraging habitat and, potentially increase aquatic food production, the response of the tern to these habitat improvements may be minimal because they do not address major known stressors on the species.

5.4.3.14 Greater Sandhill Crane

Implementation of all BDCP actions will result in an overall benefit to greater sandhill crane within the Plan Area through protection and management of high value foraging habitat and restoration of two roost sites Habitat restoration actions will result in restoration/creation of 320 acres of greater sandhill crane roosting habitat, and habitat protection actions will protect at least 4,800 acres of high value greater sandhill crane agricultural foraging habitat in Conservation Zones 4, 5, or 6. In addition, the restoration of 7,100 acres of tidal freshwater wetlands in Conservation Zones 4 and 7 will provide additional roosting and foraging habitat for cranes. BDCP conservation measures will increase the extent of protected agricultural foraging habitats in the primary use area by at least 4 percent from current conditions (Table 5-4), and protected lands will no longer be subject to loss that could result from future changes in land use. In addition, creation and maintenance of two crane roost sites will help improve the distribution of cranes in the primary use area and ensure the long-term availability of this required and limited habitat, without which cranes could not inhabit the Plan Area.

BDCP actions will permanently remove 6,739 acres of modeled greater sandhill crane foraging habitat and temporarily remove 1,318 acres of modeled crane foraging habitat in the Plan Area (Table 5-3) calculated to total 3,971 habitat units. While there will be a net reduction in the extent of modeled winter foraging habitat in the Plan Area of approximately 4 percent (Table 5-3), management of protected agricultural foraging habitat will focus on providing high value crane foraging habitat and will be maintained such that a minimum of 3,971 habitat units are available on conservation lands each year.

5.4.3.14.1 Population-Level Effects on Greater Sandhill Crane

BDCP actions will not have an adverse population-level effect on greater sandhill crane. Protection, restoration, and enhancement of 5,120 acres of greater sandhill crane foraging and roosting habitat is expected to increase the stability of traditional greater sandhill crane wintering use within and adjacent to the Plan Area and provide for the potential future growth of the local wintering population.

5.4.3.15 California Black Rail

Implementation of all BDCP actions will result in an overall benefit to California black rail within the Plan Area through restoration of its tidal habitats. Based on the RMA hypothetical tidal habitat restorations (see Appendix N.3, *RMA Description of Hypothetical Restoration Design and Effects*), 17,500 to 26,400 acres of tidal brackish and freshwater wetlands supporting California black rail habitat will be restored (Table 5-2). BDCP actions are expected to adversely affect California black rail habitat through the permanent and temporary removal of 5,949 acres and 4 acres of modeled habitat, respectively, consisting primarily of managed wetlands (Table 5-3). Tidal wetlands will be restored in large patches supporting a natural gradient extending from subtidal to upland zones which is expected to increase the extent of high value tidal marsh that supported the rail's historical tidal habitat and help achieve the draft Tidal Marsh Ecosystems Recovery Plan (USFWS 2010) California black rail objectives.

Based on the hypothetical tidal marsh restorations, (see Appendix N.3, *RMA Description of Hypothetical Restoration Design and Effects*), after full implementation of the BDCP there will be a 34 to 61 percent increase in the extent of California black rail habitat in the Plan Area (Table 5-3). The extent of existing protected California black rail tidal wetland habitat is expected to increase to 50 to 86 percent (Table 5-4).

5.4.3.15.1 Population-Level Effects on California Black Rail

BDCP actions are not expected to have an adverse population-level effect on California black rail in the near-term, early long-term, or late-long term because affected habitat in the Delta support very low densities of rail and removal of higher value habitats Suisun Marsh will be sequenced with habitat restoration activities to minimize adverse effects on habitat that could affect that population. Since a significant portion of the entire California black rail population resides in Suisun Marsh, BDCP tidal habitat restoration actions are expected to be beneficial for California black rail by creating the potential for extending the species distribution and abundance in the Delta and its abundance in Suisun Marsh.

5.4.3.16 California Clapper Rail

Implementation of all BDCP actions will result in an overall benefit to California clapper rail within the Plan Area through restoration of its brackish tidal habitats. Based on the RMA hypothetical tidal habitat restorations (see Appendix N.3, *RMA Description of Hypothetical Restoration Design and Effects*), 3,600 to 4,800 acres of tidal brackish wetlands supporting California clapper rail will be restored in Suisun Marsh (Conservation Zone 11; Table 5-3). BDCP actions are expected to adversely affect California clapper rail habitat through the permanent removal of 327 acres of its modeled habitat in Suisun Marsh as a result of tidal habitat restoration actions (Table 5-3). However, this effect will be gradual and phased over time as restoration is occurring. Tidal wetlands will be restored in large patches supporting a natural gradient extending from subtidal to upland zones which is expected to increase the extent of high value tidal marsh that supported the rail's historical tidal habitat and help achieve the draft Tidal Marsh Ecosystems Recovery Plan (USFWS 2010) California clapper rail objectives. Based on the hypothetical tidal marsh restorations, (see Appendix N.3, *RMA Description of Hypothetical Restoration Design and Effects*), after full implementation of the BDCP there will be a 42 to 57 percent increase in the extent of salt marsh harvest mouse habitat in the Plan Area. The extent of existing protected salt marsh harvest mouse tidal wetland habitat is expected to increase to 67 to 89 percent (Table 5-4).

5.4.3.16.1 Population-Level Effects on California Clapper Rail

BDCP actions are not expected to have an adverse population-level effect on California clapper rail in the near-term, early long-term, or late-long term evaluation points because affected habitat in Suisun Marsh will be sequenced with habitat restoration activities to minimize adverse effects on habitat that could affect that population. Because the entire California clapper rail population is restricted to the San Francisco Estuary, BDCP tidal habitat restoration actions are expected to be beneficial for California clapper rail by creating the potential for extending its abundance and distribution in Suisun Marsh, which comprises a sizeable portion of its range and overall population.

5.4.3.17 Swainson's Hawk

Implementation of BDCP actions will result in an overall benefit to Swainson's hawk within the Plan Area through restoration of its nesting and protection and management of its foraging habitats. BDCP protection and enhancement of 20,020 to 36,040 acres of Swainson's hawk foraging habitat to provide a minimum of 17,758 habitat units will increase the extent and quality of Swainson's hawk foraging habitat under protected status within the Plan Area (Table 5-4). Restoration of at least 4,000 acres of riparian habitat is expected to increase the extent of Swainson's hawk nesting habitat in the Plan Area by 3,294 acres (32 percent) and the extent of nesting habitat under protected status within the Plan Area is expected to be increased by 108 percent (Tables 5-3 and 5-4).

BDCP actions are expected to adversely affect Swainson's hawk through the temporary and permanent removal of 40,678 acres (17,758 habitat units) of modeled Swainson's hawk foraging and 844 acres of nesting habitat (Table 5-2). Following full BDCP implementation, the extent of Swainson's hawk nesting habitat acres will increase by 32 percent and the extent of foraging habitat acres will decrease by approximately 9 percent (Table 5-3). However, the overall effect of implementing BDCP actions on Swainson's hawk is expected to be beneficial as a result of protecting a large proportion of its foraging habitat in the Plan Area from loss or degradation that could be associated with future changes in land use, providing consistently high value Swainson's hawk foraging habitat on BDCP lands, restoration of 4,000 acres of nesting habitat that is expected to provide future nesting habitat within the Plan Area, and through enhancement of protected habitats to increase their functions as Swainson's hawk foraging and nesting habitat over the term of the BDCP.

5.4.3.17.1 Population-Level Effects on Swainson's Hawk

BDCP actions will not have an adverse population-level effect on Swainson's hawk. Through the protection, restoration, and enhancement of 24,020 to 40,040 acres of Swainson's hawk foraging and nesting habitat, BDCP is expected to sustain the current range and abundance of Swainson's hawk within the Plan Area and provide for potential increases in Swainson's hawk abundance and distribution within and adjacent to the Plan Area.

5.4.3.18 White-tailed Kite

Implementation of BDCP actions will result in an overall benefit to the white-tailed kite within the Plan Area through restoration of its nesting and protection and management of its foraging habitat. BDCP protection and enhancement of 24,620 to 46,040 acres of white-tailed kite foraging habitat to provide a minimum of 21,693 habitat units will increase the extent and quality of white-tailed kite foraging habitat under protected status within the Plan Area by 12-33 percent (Table 5-4). Restoration of at least 4,000 acres of riparian habitat is expected to increase the extent of white-tailed kite nesting habitat in the Plan Area by 3,132 acres, or 23 percent, and the extent of nesting habitat under protected status within the Plan Area is expected to be increased by 76 percent (Tables 5-3 and 5-4).

BDCP actions are expected to adversely affect white-tailed kite through the temporary and permanent removal of 47,563 acres (21,693 habitat units) of modeled white-tailed kite foraging habitat and 1,013 acres of nesting habitat (Table 5-3). Following full BDCP implementation, the extent of white-tailed kite nesting habitat will increase by 23 percent and the extent of foraging habitat acres will decrease by approximately 9 percent (Table 5-3). However, the overall effect of implementing BDCP actions on white-tailed kite is expected to be beneficial as a result of protecting a large proportion of its foraging habitat in the Plan Area from loss or degradation that could be associated with future changes in land use, providing consistently high value white-tailed kite foraging habitat on BDCP lands, restoration of 4,000 acres of nesting habitat that is expected to provide future nesting habitat within the Plan Area, and through enhancement of protected habitats to increase their functions as white-tailed kite foraging and nesting habitat over the term of the BDCP.

5.4.3.18.1 Population-Level Effects on White-tailed Kite

BDCP actions will not have an adverse population-level effect on white-tailed kite. Through the protection, restoration, and enhancement of 26,020 to 44,040 acres of white-tailed kite foraging and nesting habitat, BDCP is expected to sustain the current range and abundance of white-tailed kites within the Plan Area and provide for potential increases in white-tailed kite abundance and distribution within and adjacent to the Plan Area.

5.4.3.19 Giant Garter Snake

Implementation of all BDCP actions will result in an overall benefit to giant garter snake within the Plan Area through implementation of giant garter snake habitat protection, restoration, and enhancement actions. Following full implementation of the BDCP, at least 6,900 acres of aquatic habitat and 7,100 acres of upland habitat will be protected and enhanced for giant garter snake. An additional 13,690 to 22,040 of potential aquatic breeding habitat will be restored through restoration of tidal and nontidal freshwater habitats. There will be a 66 to 108 percent increase in the extent of giant garter snake aquatic breeding, foraging, and movement habitat in the Plan Area (Table 5-3). The extent of existing protected giant garter snake aquatic habitat present in the Plan Area is expected to increase by 354 to 500 percent and the extent of protected giant garter snake upland habitat by 13 percent (Table 5-4).

BDCP actions are expected to adversely affect giant garter snake through permanent removal of 565 acres of modeled aquatic and 13,713 acres of modeled associated upland habitat; temporary removal of 52 acres of aquatic habitat and 941 acres of upland habitat resulting mainly from water conveyance construction; and periodic inundation of 4,932 acres of aquatic and 5,534 acres of upland habitat resulting primarily from periodic seasonal inundation of the Yolo Bypass (Table 5-3). The overall result of BDCP implementation for giant garter snake will be beneficial through expansion and enhancement of habitats associated with core habitat areas within existing populations areas, providing protected habitat corridors to facilitate movement, and by providing conditions that are favorable, relative to the existing condition of primarily cultivated lands, for maintaining, expanding, and increasing the distribution and abundance of giant garter snake within the Plan Area.

5.4.3.19.1 Population-Level Effects on Giant Garter Snake

BDCP actions will not have an adverse population-level effect on giant garter snake because most affected habitat in the Delta are not believed to be occupied by or support very low densities of giant garter snake. Protection and restoration of giant garter snake habitat may have beneficial population-level effects on giant garter snake by maintaining and improving habitats occupied by the two known subpopulations in the Plan Area and by creating the potential for extending the species distribution and abundance within the Plan Area.

5.4.3.20 Western Pond Turtle

Implementation of all BDCP actions will result in an overall benefit to western pond turtle within the Plan Area through implementation of western pond turtle habitat protection, restoration, and enhancement actions. Full implementation of BDCP habitat actions will restore 27,900 to 46,800 acres of pond turtle aquatic habitat and 5,000 acres of upland nesting and overwintering habitat, and will protect and enhance 4,000 acres of dispersal habitat and at least 5,230 acres of upland nesting and overwintering habitat. The extent of existing protected pond turtle aquatic habitat present in the Plan Area is expected to increase by 76 to 138 percent (Table 5-4) and the extent of protected upland nesting and overwintering habitat by more than 42 percent (Table 5-4).

BDCP actions are expected to permanently and temporarily remove or affect 6,013 acres (8 percent), nearly all of it due to tidal habitat restoration in Suisun Marsh (Conservation Zone 11; Table 5-2), and 84 acres of aquatic habitat, respectively. Tidal habitat restoration is expected to change existing water quality conditions at Suisun Marsh rather than lead to direct loss of aquatic habitat. Changes in salinity and restoration of tidal flow where currently habitat consists of calm waters of managed freshwater ponds and wetlands could have an adverse effect on the western pond turtle.

BDCP actions are also expected to permanently and temporarily remove 51,630 acres and 4,680 acres of dispersal and upland nesting and overwintering habitat in the Plan Area (Table 5-3). Fremont Weir operations and inundation of restored floodplains are expected to periodically affect western pond turtle 20,912 acres of dispersal habitat and 4,163 acres of upland nesting and overwintering habitat (Table 5-3).

Overall, BDCP implementation will increase the extent and distribution of high value aquatic and upland nesting and overwintering habitat for western pond turtle in the Plan Area. While the extent of dispersal habitat is expected to be reduced by approximately 9 percent, this habitat is abundant in the Plan Area (comprised primarily of agricultural lands), not believe to be a factor limiting the turtle, and will be replaced with higher value habitats for western pond turtle.

5.4.3.20.1 Population-Level Effects on Western Pond Turtle

BDCP actions are not expected to have an adverse or beneficial population-level effect on western pond turtle, although enhancement and restoration of its habitats in the Delta are expected to increase its abundance within the Plan Area. A projected rise in salinity and current velocities in Suisun Marsh could adversely affect the western pond turtle population at that location. The restoration of large amounts of subtidal aquatic habitat in other parts of the Plan Area has the potential to increase western pond turtle population numbers. On the terrestrial side, the protection, restoration, and enhancement of upland nesting and overwintering habitat is expected to be beneficial to the species..

5.4.3.21 California Red-legged Frog

Implementation of all BDCP actions will result in an overall benefit to California red-legged frog within the Plan Area through protection and management of at least 1,000 acres its grassland and intermittent stream breeding habitats. The BDCP will protect and enhance these habitats in Conservation Zone 8 and protect and increase connectivity of its limited Plan Area habitats with more extensive California red-legged frog habitat areas outside of the Plan Area. Following implementation, 32 percent of California red-legged frog upland habitat and 6 percent of its breeding within the Plan Area will be protected, increasing the total area of protected breeding habitat and upland habitat by 81 percent and 144 percent, respectively (Table 5-4). In addition, any portion of the 2,000 acres of BDCP restored grassland that is located in Conservation Zone 8 would also be expected to benefit the California red-legged frog.

All protection of frog habitat would be provided in and all adverse effects on California red-legged frog habitat would be incurred in the near-term evaluation period. BDCP actions are expected to adversely affect California red-legged frog through permanent removal of 168 acres of California red-legged frog modeled grassland cover and dispersal and 663 acres of modeled agricultural dispersal habitat. An additional 161 acres of modeled grassland cover and 481 acres of modeled agricultural dispersal habitat will be temporarily removed and restored to their previous habitat condition following the completion of construction activities (Table 5-3).

In contrast to the removed grasslands, the grasslands to be protected, enhanced, and restored occur in areas of historical natural grassland vegetation, much of which is within the range of the California red-legged frog.

5.4.3.21.1 Population-Level Effects on California Red-legged Frog

BDCP actions are not expected to have an adverse or beneficial population-level effect on California red-legged frog because there are few occurrences within the Plan Area and only one site with potential to be affected by proposed project activities. In addition, the relatively small about of modeled grassland habitat that would be removed by the proposed project is on the extreme edge of the species range and based on past and current surveys results is unlikely to be occupied. Although 1,000 acres of high value California red-legged frog habitat will be protected and enhanced under BDCP that is located to maintain connectivity with occupied habitat areas adjacent to the Plan Area, because the Plan Area is located at the margin of the species range, BDCP implementation is not expected to have a measurable beneficial population-level effect on California red-legged frog.

5.4.3.21.2 Effects on Critical Habitat

Designated critical habitat for the California red-legged frog overlaps with the Plan Area along the western edge of Conservation Zone 11. Critical Habitat Unit Sol-1 extends along the west side of Interstate 680 (I-680). Approximately 2,460 acres of Sol-1 occurs within the Plan Area boundary. This area is not expected to be affected by any BDCP actions. All tidal restoration within the Suisun Marsh will occur east of I-680 where the land is currently primarily marshland and managed wetlands. The landscape west of I-680 is primarily higher elevation upland grasslands that will not be directly or indirectly affected through changes in hydrology as a result of restoration activities. Therefore, BDCP actions will not affect critical habitat for the California red-legged frog in Conservation Zone 11.

A small amount of designated critical habitat for the California red-legged frog is also present along the western edge of Conservation Zone 8. Critical Habitat Unit CCS-2 extends along the eastern edge of the grassland foothills of Eastern Contra County, approximately 862 acres of which occur within the Plan Area. This area is not expected to be adversely affected by any BDCP actions. All water conveyance construction activities will occur west of the critical habitat boundary with the exception of the proposed 230kV transmission line that extends down the California Aqueduct canal southwest of CCF, but still outside of the critical habitat boundary. Conservation actions to protect and enhance grassland habitat for covered species, including California red-legged frog, in Conservation Zone 8 could include acquisition and enhancement of designated critical habitat for the California red-legged frog, California tiger salamander, and San Joaquin kit fox. Any habitat enhancement actions for these species in designated critical habitat are expected to enhance and not diminish the value of any affected designated critical habitat for conservation of California red-legged frog.

5.4.3.22 Western Spadefoot Toad

Implementation of all BDCP actions will result in an overall benefit on western spadefoot toad within the Plan Area through protection, enhancement, and restoration of its habitat. BDCP conservation measures will restore 200 acres high value vernal pool complex supporting high value western spadefoot toad breeding habitat and protect and enhance 300 acres of existing breeding and 8,400 acres of upland habitat. These protected habitat areas will be located such that they will maintain and enhance connectivity with more extensive patches of suitable habitat adjacent to the Plan Area. BDCP actions are expected to permanently remove of 48 acres of its modeled breeding habitat and permanently and temporarily remove 464 acres and 169 acres of its modeled upland habitat, respectively (Table 5-3). The extent of western spadefoot toad habitat restored and protected at the near-term and early long-term evaluation points exceeds the extent that will be removed by BDCP actions at those evaluation points. Following full implementation of the BDCP, there will be an increase in 158 acres of western spadefoot toad breeding habitat, representing a 2 percent increase in the Plan Area (Table 5-3), and an increase in the extent of existing protected breeding and upland habitat of 12 percent and 173 percent, respectively (Table 5-4).

5.4.3.22.1 Population-Level Effects on Western Spadefoot Toad

There are no records of western spadefoot toad within the Plan Area. Because of the small amount of modeled habitat affected and the overall increase in breeding and protected upland habitats, BDCP actions will not have an adverse effect on western spadefoot toad populations and may have a beneficial effect by providing additional opportunities for colonization and protecting habitat corridors between protected aquatic habitats.

5.4.3.23 California Tiger Salamander

Implementation of all BDCP actions will result in an overall benefit on California tiger salamander within the Plan Area through protection, enhancement, and restoration of its habitat. BDCP conservation measures will restore 200 acres high value vernal pool complex supporting high value California tiger salamander breeding habitat and protect and enhance 300 acres of existing breeding and 8,400 acres of upland habitat. These protected habitat areas will be located such that they will maintain and enhance connectivity with more extensive patches of suitable habitat adjacent to the Plan Area. BDCP actions are expected to permanently remove42 acres of its modeled breeding habitat and permanently and temporarily remove 464 acres and 169 acres of its modeled upland habitat, respectively (Table 5-3). The extent of California tiger salamander habitat restored and protected at the near-term and early long-term evaluation points exceeds the extent that will be removed by BDCP actions at those evaluation points. Following full implementation of the BDCP, there will be an increase in 158 acres of California tiger salamander breeding habitat, representing a 2 percent increase in the Plan Area (Table 5-3), and an increase in the extent of existing protected breeding and upland habitat of 12 percent and 173 percent, respectively (Table 5-4).

5.4.3.23.1 Population-Level Effects on California Tiger Salamander

BDCP actions are not expected to have an adverse or beneficial population-level effect on California tiger salamander because, while several important California tiger salamander populations occur in the vicinity of the Plan Area, only a few records from Conservation Zone 8 confirm their presence within the Plan Area. In addition, habitat restoration actions will remove 42 acres, or less than 1 percent, of its vernal pool complex breeding habitat, which is most limiting for the species. Although 8,900 acres of high value California tiger salamander breeding and upland habitat will be protected, enhanced, and restored under BDCP that is located to maintain connectivity with potentially occupied habitat areas adjacent to the Plan Area, because the Plan Area is located at the margin of the species range, BDCP implementation is not expected to have a measurable beneficial population-level effect on California tiger salamander.

5.4.3.23.2 Effects on Critical Habitat

Designated critical habitat for California tiger salamander is present in the Plan Area along the western edge of Conservation Zone 1. Critical Habitat Unit 2 extends along the west side of State Route 113 (SR 113) from the short east-west portion of SR-113 south of Hay Road on the north to Creed Road on the south. Approximately 1,781 acres of Unit 2 occur within the Plan Area. While this area occurs within the Cache Slough Complex, it is not expected to be affected by BDCP tidal habitat restoration actions. As modeled in the hypothetical tidal habitat restorations (see Appendix E21), tidal habitat will be restored approximately 2 miles east of SR-113 with some restoration occurring along the Barker and Lindsey Slough channels west to approximately SR-113, and a small amount (0.4 acre) occurring along the Lindsey Slough Channel west of SR-113 into Unit 2. While the actual restoration area my vary from the hypothetical restoration area, because of the existing hydrological transition to a vernal pool grassland west of SR-113, there is little potential for tidal marsh restoration occurring in this area with the possible exception of the Lindsey and Barker Slough channels. Further, because the intent is to protect and enhance vernal pool grassland in the area west of SR-113, conversion of this area to tidal habitats is expected to be avoided. Conservation actions to protect and enhance grassland and vernal pool complex habitat for covered species, including California tiger salamander, in Conservation Zone 1 could include acquisition and enhancement of designated critical habitat for the California tiger salamander, covered vernal pool shrimp species, and vernal pool plant species. Any habitat enhancement actions for these species in designated critical habitat are expected to enhance and not diminish the value of any affected designated critical habitat for conservation of California tiger salamander.

5.4.3.24 Lange's Metalmark Butterfly

Implementation of the BDCP will result in overall beneficial effects on Lange's metalmark butterfly. BDCP actions will have no adverse effect Lange's metalmark butterfly or its habitat and will result in an overall benefit to the ecological function of its habitat at the Antioch Dunes NWR and at other suitable locations, if present, in the Plan Area where Lange's metalmark habitat may be protected and enhanced or restored. Habitat enhancement and butterfly propagation programs are expected to maintain and potentially increase the abundance of Lange's metalmark butterfly.

5.4.3.24.1 Population-Level Effects on Lange's Metalmark Butterfly

BDCP support of USFWS restoration and enhancement actions at the Antioch Dunes NWR will have beneficial population-level effects on Lange's metalmark butterfly. BDCP support will help restore inland dune scrub habitat and augment existing populations of Lange's metalmark butterfly through a program of captive breeding and release into areas of inland dune scrub plant habitat. Lange's metalmark butterfly is a subspecies of a widely distributed species and is likely endemic to the Plan Area. Thus, beneficial effects of BDCP actions could affect the range-wide status of Lange's metalmark butterfly.

5.4.3.25 Valley Elderberry Longhorn Beetle

Implementation of all BDCP actions is expected to result in an overall benefit to valley elderberry longhorn beetle within the Plan Area through restoration 5,000 acres of its riparian habitat supporting its elderberry host plant. Restoration of riparian habitats would increase the distribution and extent of elderberry shrubs and the beetle's potential distribution and abundance in the Plan Area. BDCP actions are expected to adversely affect valley elderberry longhorn beetle through permanent removal of 1,722 acres and temporary removal of 352 acres of its modeled habitat (Table 5-3), primarily due to tidal habitat restoration, although the affected habitat is not known to be occupied. Periodic effects (through inundation) of an additional 1,286 acres of habitat are associated with floodplain restoration and enhancement actions (Table 5-3), which are expected to have no or minimal adverse effects on the beetle. Full implementation of the BDCP will result in an increase of 3,898 acres, or 23 percent, in the extent of riparian habitat in the Plan Area, much of which will support the host plant for valley elderberry longhorn beetle; and a 42 percent increase in the extent of existing protected habitat in the Plan Area (Table 5-4).

As described in Section 5.4.2.5, *Valley/Foothill Riparian*, there is a temporal loss of riparian habitat in the near-term evaluation period because most of the affected riparian vegetation is removed in the near-term implementation period, while large quantities of riparian habitat will not be restored until the early and late long-term implementation periods (Figures 5-3 and 5-5). Effects on valley elderberry longhorn beetle of this temporal loss of riparian vegetation is expected to be minimal because much of the riparian habitat in the Plan Area is not known to be currently occupied by the species and most of the affected community is comprised of small patches of riparian scrub and herbaceous vegetation that are fragmented and distributed across the agricultural landscape of the Plan Area (Figure 5-4) and thus are likely to provide no or low value habitat for the beetle.

5.4.3.25.1 Population-Level Effects on Valley Elderberry Longhorn Beetle

BDCP actions will not have an adverse population-level effect on valley elderberry longhorn beetle because BDCP actions will affect less that 5 percent of its modeled habitat, much of which is likely not occupied, and BDCP restoration actions will increase its habitat by 23 percent commensurate or in advance of when habitat will be affected. Increasing the distribution of its habitat and its extent by 23 percent is expected to provide the basis for increasing the abundance and distribution of valley elderberry longhorn beetle in the Plan Area. Depending on where riparian habitats are restored, increasing the extent of riparian habitat is also expected to increase connectivity of its habitat with habitat areas adjacent to the Plan Area, which will help maintain or improve the regional status of the species' population.

5.4.3.26 Vernal Pool Shrimp Species (Vernal Pool Tadpole Shrimp, Conservancy Fairy Shrimp, Longhorn Fairy Shrimp, Vernal Pool Fairy Shrimp, Mid Valley Fairy Shrimp, and California Linderiella)

Implementation of all BDCP actions will result in an overall benefit to the vernal pool shrimp species through the restoration of 200 acres of vernal pool complex and the protection and enhancement of 300 acres of existing vernal pool complex. The restored and protected habitat areas will be located such that they will maintain and enhance connectivity with more extensive patches of vernal pool complex and grassland habitat areas adjacent to the Plan Area. The restoration and protection of vernal pool shrimp habitat is expected to provide conditions favorable for maintaining and increasing the distribution and abundance of the vernal pool shrimp species and their habitats. The implementation of BDCP actions to restore tidal habitat will result in the permanent loss of 42 acres of vernal pool complex (see in Conservation Zones 1 and 11(see Table 5-4). Additionally, 5 acres of the degraded vernal pool complex vegetation type will be lost but that vegetation type is ephemeral habitat that is primarily a byproduct of agricultural land management actions and therefore is not considered to be the removal of vernal pool shrimp species habitat. The extent of vernal pool shrimp species habitat restored and protected at the near-term and early long-term evaluation points exceeds the extent that will be removed by BDCP actions at those evaluation points.

With the full implementation of the BDCP, in the Plan Area there will be an increase in 158 acres of vernal pool shrimp species habitat through restoration, representing a 2 percent increase, and the extent of protected existing habitat will increase by 300 acres or 11 percent (Table 5-4).

5.4.3.26.1 Population-Level Effects on Vernal Pool Shrimp Species

BDCP actions will not have either an adverse or a beneficial population-level effect on vernal pool shrimp species. Although habitat restoration will increase the extent of their vernal pool complex habitat by 2 percent within the Plan Area and will enhance 300 acres of existing habitat, the Plan Area is located at the margin of the distribution of vernal pool shrimp species habitat within the Central Valley and thus, beneficial and adverse effects of BDCP actions are unlikely to affect the status of vernal pool shrimp species populations beyond the Plan Area.

5.4.3.26.2 Effects on Critical Habitat

Designated critical habitat for vernal pool tadpole shrimp, Conservancy fairy shrimp, and vernal pool fairy shrimp is located in the Plan Area along the northern margin of Suisun Marsh in

Conservation Zone 11. The Critical Habitat includes vernal pool tadpole shrimp Unit 11D, Conservancy fairy shrimp Unit 3, and vernal pool fairy shrimp Unit 16A.

Critical Habitat\PCEs for all three species are:

1) Topographic features characterized by mounds and swales, and depressions within a matrix of surrounding uplands that result in complexes of continuously, or intermittently, flowing surface water in the swales connecting the pools described in PCE (2), providing for dispersal and promoting hydroperiods of adequate length in the pools.

2) Depressional features including isolated vernal pools with underlying restrictive soil layers that become inundated during winter rains and that continuously hold water for a minimum time period (41 days for vernal pool tadpole shrimp, 19 days for Conservancy fairy shrimp, 18 days for vernal pool fairy shrimp) in all but the driest years; thereby providing adequate water for incubation, maturation, and reproduction. As these features are inundated on a seasonal basis, they do not promote the development of obligate wetland vegetation habitats typical of permanently flooded emergent wetlands.

3) Sources of food, expected to be detritus occurring in the pools, contributed by overland flow from the pools' watershed, or the results of biological processes within the pools themselves, such as single-celled bacteria, algae, and dead organic matter, to provide for feeding.

4) Structure within the pools described in PCE (2), consisting of organic and inorganic materials, such as living and dead plants from plant species adapted to seasonally inundated environments, rocks, and other inorganic debris that may be washed, blown, or otherwise transported into the pools, that provide shelter.

The only BDCP action that could affect these Critical Habitat Units is restoration of tidal habitat by restoring tidal action to areas that historically were tidal and the resulting reduced tidal prism resulting from those restoration actions (see Appendix E21). PCE 1 does not exist within those areas of designated critical habitat that could be affected because no vernal pool features are present below the historic tide level; PCE 2 does not exist within those areas of designated critical habitat that could be affected because the tidal area is inundated twice a day by tides and not seasonally during winter rains; PCE 3 does not exist within those areas of designated critical habitat that could be affected because these are tidal areas and not vernal pools; and PCE 4 does not exist within those areas of designated critical habitat that could be affected because these areas are tidal areas and not vernal pools. Consequently, tidal habitat restoration actions will have no effect on any of the four PCEs and thus will not diminish the value of any affected designated critical habitat for conservation of vernal pool tadpole shrimp, Conservancy fairy shrimp, and vernal pool fairy shrimp.

5.4.3.27 Vernal Pool Plant Species (Alkali Milk-Vetch, San Joaquin Spearscale, Boggs Lake Hedge-Hyssop, Heckard's Peppergrass, Dwarf Downingia, and Legenere)

Implementation of all BDCP actions will result in an overall benefit to the vernal pool plant species through the restoration of 200 acres vernal pool complex and the protection and enhancement of 300 acres of existing vernal pool complex. The restored and protected habitat areas will be located such that they will maintain and enhance connectivity with more extensive patches of vernal pool complex and grassland habitat areas adjacent to the Plan Area. The restoration and protection of the vernal pool plant species and their habitat is expected to provide conditions favorable for maintaining and increasing the distribution and abundance of vernal pool plant species and their habitats within the Plan Area. The implementation of BDCP actions to restore tidal habitat will result in the permanent loss of 88 acres of vernal pool complex (Conservation Zones 1 and 11 (see Table 5-3). Additionally, 5 acres of affected degraded vernal pool complex vegetation type will be lost but that vegetation type is ephemeral habitat that is primarily a byproduct of agricultural land management actions and therefore is not considered to be the removal of vernal pool plant species habitat. The extent of vernal pool plant species habitat restored and protected at the near-term and early long-term evaluation points exceeds the extent that will be removed by BDCP actions at those evaluation points.

With the full implementation of the BDCP, in the Plan Area there will be an increase of 112 acres of vernal pool plant species habitat through restoration, representing a 2 percent increase, and the extent of protected existing habitat will increase by 300 acres or 11 percent (Table 5-4).

5.4.3.27.1 Population-Level Effects on Vernal Pool Plant Species

BDCP actions will not have either an adverse or a beneficial population-level effect on vernal pool plant species. Although habitat restoration will increase the extent of their vernal pool complex habitat by 2 percent within the Plan Area and will enhance 300 acres of existing habitat, the Plan Area is located at the margin of the distribution of their vernal pool habitats within the Central Valley and thus, the beneficial and adverse effects of BDCP actions are unlikely to affect the status of vernal pool plant species populations beyond the Plan Area.

5.4.3.28 Heartscale and Brittlescale

Implementation of all BDCP actions will result in an overall benefit to heartscale and brittlescale through the protection and enhancement of 150 acres of existing habitat and the protection of at least 3 occurrences of each species. The protected habitat areas will be located such that they will maintain and enhance connectivity with more extensive patches of habitat areas adjacent to the Plan Area. The protection of heartscale and brittlescale, three additional occurrences, and their habitat is expected to provide conditions favorable for maintaining and increasing the distribution and abundance of heartscale and brittlescale and their habitat within the Plan Area. The implementation of BDCP actions to restore tidal habitat will result in the permanent loss of

10 acres of heartscale and brittlescale habitat (Conservation Zones 1, 8, and/or 11) (Table 5-3). The extent of heartscale and brittlescale habitat restored and protected at the near-term and early long-term evaluation points exceeds the extent that will be removed by BDCP actions at those evaluation points.

With the full implementation of the BDCP, there will be a 115 percent increase in the extent of existing protected habitat and 3 additional occurrences of each species will be protected (Table 5-4).

5.4.3.28.1 Population-Level Effects on Heartscale and Brittlescale

BDCP actions will not have an adverse or beneficial population-level effect on either heartscale or brittlescale. Although BDCP actions will protect and enhance 150 acres of heartscale or brittlescale habitat and protect 3 occurrences of each species, the Plan Area is located at the margin of the species distribution within the Central Valley and thus the effects of BDCP actions are unlikely to affect the range-wide status of heartscale and brittlescale populations beyond the Plan Area.

5.4.3.29 Slough Thistle

Implementation of all BDCP actions will result in an overall benefit to slough thistle through the restoration of at least 1,000 acres of seasonally inundated floodplain habitat. The restoration of seasonally inundated floodplain habitat is expected to provide conditions favorable for maintaining and increasing the distribution and abundance of slough thistle within the Plan Area. The implementation of BDCP actions to restore tidal habitat will result in the permanent loss of 5 acres of slough thistle modeled habitat, the temporary removal of 6 acres of habitat, the periodic inundation of 6 acres of habitat, and the indirect disturbance of 25 acres of habitat (Table 5-3). The extent of slough thistle habitat restored and protected at the near-term and early long-term evaluation points exceeds the extent that will be removed by BDCP actions at those evaluation points.

With the full implementation of the BDCP, in the Plan Area there will be an increase in the extent of seasonally inundated flood plain habitat that will support patches of slough thistle habitat within the Plan Area of at least 1,000 acres and there will be an increase in the extent of existing protected habitat of over 532 percent (Table 5-4).

5.4.3.29.1 Population-Level Effects on Slough Thistle

BDCP actions will not have either an adverse or a beneficial population-level effect on slough thistle. Although BDCP actions will restore 1,000 acres of slough thistle habitat that will create the potential for increase the abundance and distribution of the species in the Plan Area, the Plan Area is located much further north than slough thistle's population center which exists in the areas of former lake beds in the southern San Joaquin Valley.

5.4.3.30 Suisun Thistle and Soft Bird's-beak

Implementation of all BDCP actions will result in an overall benefit to slough thistle through the restoration of between 3,600 and 4,800 acres of tidal brackish marsh habitat (based on the RMA hypothetical tidal habitat restorations described in Appendix N.3, *RMA Description of Hypothetical Restoration Design and Effects*) which will contain areas of suitable habitat for these species and the protection of at least 3 occurrences of each species. The restoration of tidal brackish marsh habitat is expected to provide conditions favorable for maintaining and increasing the distribution and abundance of Suisun thistle and soft bird's-beak within the Plan Area. The implementation of BDCP actions to restore tidal habitat will result in the permanent loss of 636 acres of Suisun thistle and soft bird's-beak habitat (Table 5-3). The extent of Suisun thistle and soft bird's-beak habitat restored at the near-term and early long-term evaluation points exceeds the extent that will be removed by BDCP actions at those evaluation points.

With the full implementation of the BDCP, in the Plan Area the extent of protected tidal brackish marsh that could support areas of Suisun thistle and soft bird's-beak habitat within the Plan Area will be increased between 347 and 485 percent and 3 additional occurrences of each species will be protected (Table 5-4).

5.4.3.30.1 Population-Level Effects on Suisun Thistle and Soft Bird's-beak

BDCP actions will have beneficial population-level effects on Suisun thistle and soft bird's-beak. BDCP actions will restore between 3,600 and 4,800 acres of tidal brackish wetland habitat and protect 3 occurrences of each species. Suisun thistle is endemic to the Plan Area and Suisun Marsh represents a large portion of soft bird's-beak overall population. Thus, beneficial effects of BDCP actions could affect the range-wide status of Suisun thistle and soft bird's-beak populations.

5.4.3.30.2 Effects on Critical Habitat

Designated critical habitat for the Suisun thistle and soft bird's-beak is located in the Plan Area exclusively in tidal areas of Suisun Marsh. Suisun thistle Unit 1 and soft bird's-beak Unit 2 are located at Hill Slough Marsh, Suisun thistle Unit 2 is located at Petonia Slough Marsh, Suisun thistle Unit 3 and soft bird's-beak Unit 4 are located at Rush Ranch/Grizzly Island Wildlife Area.

Critical Habitat PCEs for *Cirsium hydrophilum* var. *hydrophilum* are:

1) Persistent emergent, intertidal, estuarine wetland at or above the mean high-water line (as extended directly across any intersecting channels);

2) Open channels that periodically contain moving water with ocean-derived salts in excess of 0.5 percent; and

3) Gaps in surrounding vegetation to allow for seed germination and growth.

Critical Habitat PCEs for *Cordylanthus mollis* ssp. *mollis* are:

1) Persistent emergent, intertidal, estuarine wetland at or above the mean high-water line (as extended directly across any intersecting channels);
2) Rarity or absence of plants that naturally die in late spring (winter annuals); and
3) Partially open spring canopy cover (approximately 790 nanomoles per square meter per second [$nMol/m^2/s$]) at ground level, with many small openings to facilitate seedling germination.

As modeled in the hypothetical tidal habitat restorations (see Appendix N.3, *RMA Description of Hypothetical Restoration Design and Effects*), tidal habitat restoration actions under full implementation of the BDCP will alter the tidal prism and will result in the compression of the tidal range by approximately 1 foot biased towards a lower elevation of mean lower low water. The result will be the loss of an undeterminable amount of designated critical habitat due to a lowered mean high-water line (PCE1 for both species).

The potential for effects on designated critical habitat will be minimized through design of tidal habitat restoration projects and temporal and spatial staging of when and where restoration projects are implemented. Implementation of the tidal habitat restoration projects are expected to restore patches of Suisun thistle and soft bird's-beak habitat and to contribute to the achieving the objectives of the Draft Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (USFWS 2010). Consequently, any adverse effects of habitat restoration on designated critical habitat are not expected to appreciably diminish the value of critical habitat for species conservation.

5.4.3.31 Delta Button Celery

Implementation of all BDCP actions will result in an overall benefit to Delta button celery through the protection of at least 100 acres of alkali habitat and the restoration of at least 1,000 acres of seasonally inundated floodplain habitat that will support areas of Delta button celery habitat. The restoration and protection of Delta button celery habitat is expected to provide conditions favorable for maintaining and increasing the distribution and abundance of Delta button celery and its habitat within the Plan Area. The implementation of BDCP actions to restore tidal habitat will result in the permanent loss of 25 acres of Delta button celery habitat, the temporary removal of 8 acres of habitat, the periodic inundation of 18 acres of habitat (Table 5-3). The extent of Delta button celery habitat restored and protected at the near-term and early long-term evaluation points exceeds the extent that will be removed by BDCP actions at those evaluation points.

With the full implementation of the BDCP, there will be a 407 percent increase in the extent of existing protected habitat (Table 5-4).

5.4.3.31.1 Population-Level Effects on Delta Button Celery

BDCP actions will not have either an adverse or a beneficial population-level effect on Delta button celery. Although BDCP actions will protect at least 100 acres of existing habitat and restore at least 1,000 acres of Delta button celery habitat that will create the potential for increasing the abundance and distribution of the species in the Plan Area, the Plan Area is located at the northern edge of its range and thus will be unlikely to have a population-level effect on the species' abundance and distribution.

5.4.3.32 Inland Dune Scrub Plant Species (Contra Costa Wallflower, Antioch Dunes Primrose)

Implementation of the BDCP will result in overall beneficial effects on Contra Costa wallflower and Antioch Dunes primrose. BDCP actions will have no adverse effect on Contra Costa wallflower and Antioch Dunes primrose or their habitat. BDCP support for USFWS habitat enhancement and propagation programs are expected to maintain and potentially increase the abundance of Contra Costa wallflower and Antioch Dunes primrose.

5.4.3.32.1 Population-Level Effects on Inland Dune Scrub Plant Species

BDCP support of USFWS restoration and enhancement actions at the Antioch Dunes NWR will have beneficial population-level effects on Contra Costa wallflower and Antioch Dunes primrose. BDCP support will help restore inland dune scrub habitat and augment existing populations throughout-planting of nursery grown stock into areas of inland dune scrub plant habitat. Both Contra Costa wallflower and Antioch Dunes evening primrose are subspecies that are endemic to the Plan Area. Thus, beneficial effects of BDCP actions could affect the range-wide status of Contra Costa wallflower and Antioch Dunes evening primrose.

5.4.3.32.2 Effects on Critical Habitat

Designated critical habitat for Contra Costa wallflower and Antioch Dunes primrose is located in the Plan Area on the Antioch Dunes NWR refuge and slightly into the San Joaquin River. It is designated as "an area of land, water, and airspace (exclusive of those existing man-made structures or settlements which are not necessary to the survival or recovery of the species) in Contra Costa County." Inland dune scrub actions supported by the BDCP will be implemented by the USFWS and will have no adverse effect on the designated critical habitat. Any habitat enhancement actions for these species in designated critical habitat are expected to enhance and not diminish the value of any affected designated critical habitat for conservation of Contra Costa wallflower and Antioch Dunes primrose. Proposed changes in water operations will periodically alter the salinity or temperature of the water but will not affect the sediment supply to the due so will have no adverse effect on the designated critical habitat.

5.4.3.33 Carquinez Goldenbush

Implementation of all BDCP actions will result in an overall benefit to Carquinez goldenbush through the protection and enhancement of 300 acres of existing habitat and the protection of at least 3 occurrences. The protected habitat areas will be located such that they will maintain and enhance connectivity with more extensive patches of habitat areas adjacent to the Plan Area. The protection of Carquinez goldenbush, its occurrences, and its habitat is expected to provide conditions favorable for maintaining and increasing the distribution and abundance of Carquinez goldenbush and its habitats within the Plan Area. The implementation of BDCP actions to restore tidal habitat will result in the permanent loss of 42 acres of Carquinez goldenbush habitat and temporarily disturb 17 acres of Carquinez goldenbush habitat (Table 5-3). The extent of Carquinez goldenbush habitat restored and protected at the near-term and early long-term evaluation points exceeds the extent that will be removed by BDCP actions at those evaluation points.

With the full implementation of the BDCP, there will be a 76 percent increase in the extent of existing protected habitat and 3 additional occurrences of Carquinez goldenbush will be protected (Table 5-4).

5.4.3.33.1 Population-Level Effects on Carquinez Goldenbush

BDCP actions will have a beneficial population-level effect on Carquinez goldenbush. The species' range is limited to Solano County, a large portion of which is located in the Plan Area. Implementation of the BDCP will increase the extent of protected and managed Carquinez goldenbush habitat from 38 percent to 70 percent within the Plan Area and protect all remaining known occurrences in the Plan Area.

5.4.3.34 Delta Tule Pea and Suisun Marsh Aster

Implementation of all BDCP actions will result in an overall benefit to Delta tule pea and Suisun Marsh aster through the restoration of between 16,970 to 26,470 acres of tidal marsh habitat (based on the RMA hypothetical tidal habitat restorations described in Appendix N.3, *RMA Description of Hypothetical Restoration Design and Effects*) which will contain areas of suitable habitat for these species. The restoration of Delta tule pea and Suisun Marsh aster habitat is expected to provide conditions favorable for maintaining and increasing the distribution and abundance of Delta tule pea and Suisun Marsh aster and their habitat within the Plan Area. The implementation of BDCP actions to restore tidal habitat will result in the permanent loss of 1,137 acres, the temporary disturbance of 1 acre, and the periodic inundation of 10 acres of Delta tule pea and Suisun Marsh aster habitat (Table 5-3). The extent of Delta tule pea and Suisun Marsh aster habitat restored and protected at the near-term and early long-term evaluation points exceeds the extent that will be removed by BDCP actions at those evaluation points.

With the full implementation of the BDCP, there will be an increase in the extent of tidal habitat with areas of Delta tule pea and Suisun Marsh aster habitat within the Plan Area by 16,970 to

26,470 acres and there will be an increase in the extent of existing protected tidal habitat with areas of Delta tule pea and Suisun Marsh aster habitat of between 430 and 687 percent (Table 5-4).

5.4.3.34.1 Population-Level Effects on Delta Tule Pea and Suisun Marsh Aster

BDCP actions will have beneficial population-level effects on Delta tule pea and Suisun Marsh aster. BDCP actions will restore 16,970 to 26,470 acres of tidal wetland habitat. Delta tule pea and Suisun Marsh aster are nearly endemic to the Plan Area. Thus, beneficial effects of BDCP actions could beneficially affect the range-wide status of Delta tule pea and Suisun Marsh aster.

5.4.3.35 Delta Mudwort and Mason's Lilaeopsis

Implementation of all BDCP actions will result in an overall benefit to Delta mudwort and Mason's lilaeopsis through the restoration of between 16,980 to 26,560 acres of tidal marsh habitat (based on the RMA hypothetical tidal habitat restorations described in Appendix N3, *RMA Description of Hypothetical Restoration Design and Effects*) which will contain areas of suitable habitat for these species. The restoration of Delta mudwort and Mason's lilaeopsis habitat is expected to provide conditions favorable for maintaining and increasing the distribution and abundance of Delta mudwort and Mason's lilaeopsis and their habitat within the Plan Area. The implementation of BDCP actions to restore tidal habitat will result in the permanent loss of 146 acres, the temporary disturbance of 9 acres, and the periodic inundation of 205 acres of Delta mudwort and Mason's lilaeopsis habitat (Table 5-3). The extent of Delta mudwort and Mason's lilaeopsis habitat restored and protected at the near-term and early long-term evaluation points exceeds the extent that will be removed by BDCP actions at those evaluation points.

With the full implementation of the BDCP, there will be an increase in the extent of tidal habitat with areas of Delta mudwort and Mason's lilaeopsis habitat within the Plan Area by 16,980 to 26,560 acres and there will be an increase in the extent of existing protected tidal habitat with areas of Delta mudwort and Mason's lilaeopsis habitat of between 984 and 1,542 percent (Table 5-4).

5.4.3.35.1 Population-Level Effects on Delta Mudwort and Mason's Lilaeopsis

BDCP actions will have beneficial population-level effects on Delta mudwort and Mason's lilaeopsis. BDCP actions will restore 16,980 to 26,560 acres of tidal wetland habitat that will contain areas of delta mudwort and Mason's lilaeopsis habitat. Delta mudwort and Mason's lilaeopsis are nearly endemic to the Plan Area. Thus, beneficial effects of BDCP actions could affect the range-wide status of Delta mudwort and Mason's lilaeopsis.

5.4.3.36 Side-flowering Skullcap

Implementation of all BDCP actions will result in an overall benefit to side-flowering skullcap through the restoration of 5,000 acres of valley/foothill riparian community and between 13,900 and 21,600 acres of tidal freshwater emergent wetland community (based on the RMA hypothetical tidal habitat restorations described in Appendix N.3, *RMA Description of Hypothetical Restoration Design and Effects*). The restoration of the two communities is expected to provide conditions favorable for maintaining and increasing the distribution and abundance of side-flowering skullcap and its habitat within the Plan Area. The implementation of BDCP actions to restore tidal habitat will result in the permanent loss of 37 acres, temporarily disturb 3 acres, and periodically inundate 41 acres of side-flowering skullcap habitat (Table 5-3). The extent of side-flowering skullcap habitat restored and protected at the near-term and early long-term evaluation points exceeds the extent that will be removed by BDCP actions at those evaluation points.

Because of its unique habitat, decaying stumps and pilings, with the full implementation of the BDCP there will be an indeterminable increase in the extent of existing protected habitat of side-flowering skullcap.

5.4.3.36.1 Population-Level Effects on Side-flowering Skullcap

BDCP actions will have beneficial population-level effects on side-flowering skullcap. BDCP actions will restore 5,000 acres of valley/foothill riparian community and between 13,900 and 21,600 acres of tidal freshwater emergent wetland community containing patches of side-flowering skullcap habitat. Within California, side-flowering skullcap is endemic to the Plan Area while it is widely distributed across the United States and Canada. Thus, beneficial effects of BDCP actions will not affect the range-wide status of side-flowering skullcap.

5.4.3.37 Caper-fruited Tropidocarpum

Implementation of all BDCP actions will result in an overall benefit for caper-fruited tropidocarpum within the Plan Area by protecting and enhancing at least 100 acres of its modeled habitat to provide conditions favorable for reestablishing caper-fruited tropidocarpum in the Plan Area. Any occurrences that establish on protected BDCP lands will be managed to maintain and increase the extent of occupied habitat and the abundance of caper-fruited tropidocarpum plants. Adverse effects on caper-fruited tropidocarpum from implementing BDCP includes the temporary removal of 34 acres caper-fruited tropidocarpum habitat through deposits of spoils generated during conveyance construction activities (Table 5-3). Full implementation of BDCP will result in protection of 9 percent of caper-fruited tropidocarpum within the Plan Area, and increase of 476 percent in the extent of protected habitat (Table 5-4).

5.4.3.37.1 Population-Level Effects on Caper-fruited Tropidocarpum

BDCP actions are expected to have no adverse population-level effect on caper-fruited tropidocarpum and could have a beneficial population-level effect if one or more occurrences of this species, which is believed to be extirpated from the Plan Area, become established. BDCP direct effects on caper-fruited tropidocarpum are limited to 34 acres of modeled caper-fruited tropidocarpum habitat which will be temporarily removed through deposits of spoils generated during conveyance construction activities. This will result in no or very little effect on the species' total distribution.

Table 5-1. Summary of Impacts on the Extent of Natural Communities with Full BDCP Implementation (i.e., conditions at the late long-term evaluation point)

Natural Community	**A**	**B**	***Temporarily Removed (acres)*** [2]	***Periodically Removed (acres)*** [3]	**C**	**D=(A-B)+C**	**[(D-A)/A]-1*100**

[1]Permanent impacts represent those associated with construction of forebays, Intake facilities, permanent access roads, shaft locations, muck areas, levee setback footprints, riparian restoration areas, nontidal marsh restoration and conservation hatcheries facilities.
[2]Features in this category include the following conveyance features: Barge Unloading Facility, Control Structure Work Area, Intake Road Work Area, Intake Work Area, Pipeline, Pipeline Work Area, Road Work, Borrow and Spoils sites, Area, Safe Haven Work Area, Temporary Access Road Work Area, Tunnel Work Area.
[3]Periodic impacts represent those associated with the periodic flooding of the Yolo Bypass and floodplain setbacks along the San Joaquin River.
[4]Tidal Perennial Aquatic impacts related to the intake right of ways have been removed as it is assumed that these would not pose an impact to this natural community. Tidal restoration impacts were assessed based on areas expected to become desiccated based on RMA modeling results.
[5]As modeled in the hypothetical tidal habitat restorations, see Appendix Z [RMA tech #4 & SAIC memo]).
[6]Tidal mudflat features were not mapped within the BDCP vegetation layer, however will be evaluated in linear miles of tidal marsh/shallow subtidal aquatic interface.
[7]Impacts assessed for tidal marsh restoration reflect those incurred to tidal brackish emergent wetland habitat components expected to be desiccated based on RMA modeling results.
[8]Actual sum of 400 acres may be distributed differently between non-tidal perennial aquatic and non-tidal permanent freshwater emergent wetland communities.
[9]Does not include removal of agricultural lands to restore 2,000 acres of grassland and 200 acres of vernal pools. These effects will be included in the next version of this table.

Table 5-2. Summary of Conservation Provided for Natural Communities with Full BDCP Implementation (i.e., conditions at the late long-term evaluation point)

[1]Includes both non-tidal freshwater permanent emergent wetland and non-tidal perennial aquatic and does not include patches of these communities that are present on BDCP lands acquired for other purposes and that would be incidentally protected under BDCP

[2]Based on RMA modeling of hypothetical tidal habitat restoration footprints.

[3]The extent of existing tidal mudflat cannot be delineated based on available information.

[4]The extent of total tidal mudflat that will develop as a component of 65,000 acres of tidal habitat restoration could not be reasonably predicted with the models developed. BDCP biological objectives, however, require establishment of at least 20 linear miles of tidal mudflat substrate.

[5]Actual sum of 400 acres may be distributed differently between non-tidal perennial aquatic and non-tidal permanent freshwater emergent wetland communities

[6]The mix of alfalfa, irrigated pasture, and other cultivated crops annually maintained under the BDCP will vary among years over the term of the BDCP depending on market drivers on growers with conservation easements.

[7]Does not include acquisition of any additional lands associated with restoration of 65,000 acres of tidal habitat that may be required to provide transitional upland and sea level rise accommodation space.

[1]Permanent impacts represent those associated with construction of forebays, Intake facilities, permanent access roads, shaft locations, muck areas, levee setback footprints, riparian restoration areas, nontidal marsh restoration and conservation hatcheries facilities

[2]Tidal perennial aquatic impacts related to the intake right of ways have been removed as it is assumed that these would not pose an impact to this natural community. Tidal restoration impacts were assessed based on areas expected to become desiccated based on RMA modeling results.

[3]As modeled in the hypothetical tidal habitat restorations, see Appendix N3 (RMA Description of Hypothetical Restoration Design and Effects).4Impacts assessed for tidal marsh restoration reflect those incurred to habitat that are expected to experience inundation and desiccation.

[1]Permanent impacts represent those associated with construction of forebays, Intake facilities, permanent access roads, shaft locations, muck areas, levee setback footprints, riparian restoration areas, nontidal marsh restoration and conservation hatcheries facilities

[2]Tidal Perennial Aquatic impacts related to the intake right of ways have been removed as it is assumed that these would not pose an impact to this natural community. Tidal restoration impacts were assessed based on areas expected to become desiccated based on RMA modeling results.

[3]Impacts assessed for tidal marsh restoration reflect those incurred to tidal brackish emergent wetland habitat components expected to be desiccated based on RMA modeling results.

[4]Does not include removal of agricultural lands to restore 2,000 acres of grassland and 200 acres of vernal pools. These effects will be included in the next version of this table.

[5]Features in this category include the following conveyance features: Barge Unloading Facility, Control Structure Work Area, Intake Road Work Area, Intake Work Area, Pipeline, Pipeline Work Area, Road Work, Borrow and Spoils sites, Area, Safe Haven Work Area, Temporary Access Road Work Area, Tunnel Work Area

[6]Periodic impacts represent those associated with the periodic flooding of the Yolo Bypass and floodplain setbacks along the San Joaquin River.

[7]Impacts assessed for tidal marsh restoration reflect those incurred to habitat that are expected to experience inundation and desiccation.

[8]Does not include patches of these habitat types that are present on BDCP lands acquired for other purposes and that would be incidentally protected under BDCP.

[9]As modeled in the hypothetical tidal habitat restorations, see Appendix Z [RMA tech #4 & SAIC memo]).

[10]The mix of alfalfa, irrigated pasture, and other cultivated crops annually maintained under the BDCP will vary among years over the term of the BDCP depending on market drivers on growers with conservation easements.

CHAPTER 6 PLAN IMPLEMENTATION

[***Note to Reviewers****: This is a revised version of BDCP Chapter 6, Implementation Plan. The last draft of Chapter 6 was presented to the Steering Committee at the September 9, 2010 meeting. Revisions have been made throughout the text to address comments received, to clarify concepts, and to bring the document up to date with the progress on various components of the BDCP in 2010. The BDCP Steering Committee members have submitted comments to various drafts of this chapter during development, which may or may not have been incorporated into this November 18, 2010 draft. While the text of this chapter is subject to change and revision as the BDCP planning process progresses, the chapter has been drafted and formatted to appear as it may in a completed draft HCP/NCCP. Although the chapter includes declarative statements (e.g., the Implementation Office will…), it is nonetheless a "working draft" that will undergo further modification based on input from the BDCP Steering Committee, state and federal agencies, and the public*.]

To effectively achieve the overall goals of ecosystem restoration and water supply reliability, the Bay Delta Conservation Plan (BDCP) sets out a Conservation Strategy that will be implemented over the long-term. This chapter identifies the key issues that are related to plan implementation and describes the approaches that will be used to address those issues. The chapter, for instance, establishes a schedule for the implementation of the BDCP conservation measures, which will guide the timing and sequencing of measures to enhance opportunities to advance the biological goals and objectives. It further describes requirements for short-term and long-range planning, annual workplans and budgets, monitoring, compliance reporting, and scientific review to ensure transparency in decision-making and to promote refinements to approaches to BDCPimplementation.

The chapter further describes the regulatory assurances under the federal Endangered Species Act (ESA) and the Natural Community Conservation Planning Act (NCCPA) that are expected to be provided to the Authorized Entities. It also describes the commitment of the Implementation Office and the Authorized Entities to respond to foreseeable changes in circumstances that may adversely affect Covered Species and habitats, and identifies a process by which changes that are not foreseeable can be addressed. The chapter identifies the circumstances under which regulatory authorizations may be suspended or revoked. This chapter, in combination with Chapter 3 *Conservation Strategy*, Chapter 7 *Implementation Structure*, and Chapter 8 *Implementation Costs and Funding Sources*, provides the full description of actions, commitments, and approaches to ensure effective implementation of the BDCP.

6.1 PLAN IMPLEMENTATION SCHEDULE

The implementation of the BDCP conservation measures will be guided by a schedule that has been developed to maximize the effectiveness of the Conservation Strategy (Figure 6-1). The BDCP implementation schedule establishes an approximate timeframe and sequence for the initiation of the actions associated with each of the conservation measures. The cumulative habitat outcomes of implementing BDCP conservation measures under this implementation schedule are depicted in Figure 6-2. Implementation of these actions will begin in Year 0, the year in which regulatory authorizations are issued by the state and federal fish and wildlife agencies pursuant to the BDCP. The implementation schedule will inform the Implementation Office as it establishes priorities and develops annual workplans and budgets. This implementation schedule has served as the basis for estimating funding needs over the term of BDCP implementation (see Chapter 8, *Implementation Costs and Funding Sources*). It has also been used in the effects analysis to assess the anticipated timing of biological impacts and benefits to covered species and natural communities associated with the implementation of the BDCP (see Chapter 5, *Effects Analysis*).

[7]Phased implementation occurs in conjunction with tidal habitat restoration schedule.
[8]Implementation occurs at tidal habitat restoration sites 3 years following restoration.

Legend

- Near-term operations
- Long-term operations
- Conservation measure becomes functional (for habitat restorations, initial function may be low, with increasing function over time)
- Interagency coordination, feasibility evaluations, site acquisition, planning, environmental compliance, and construction

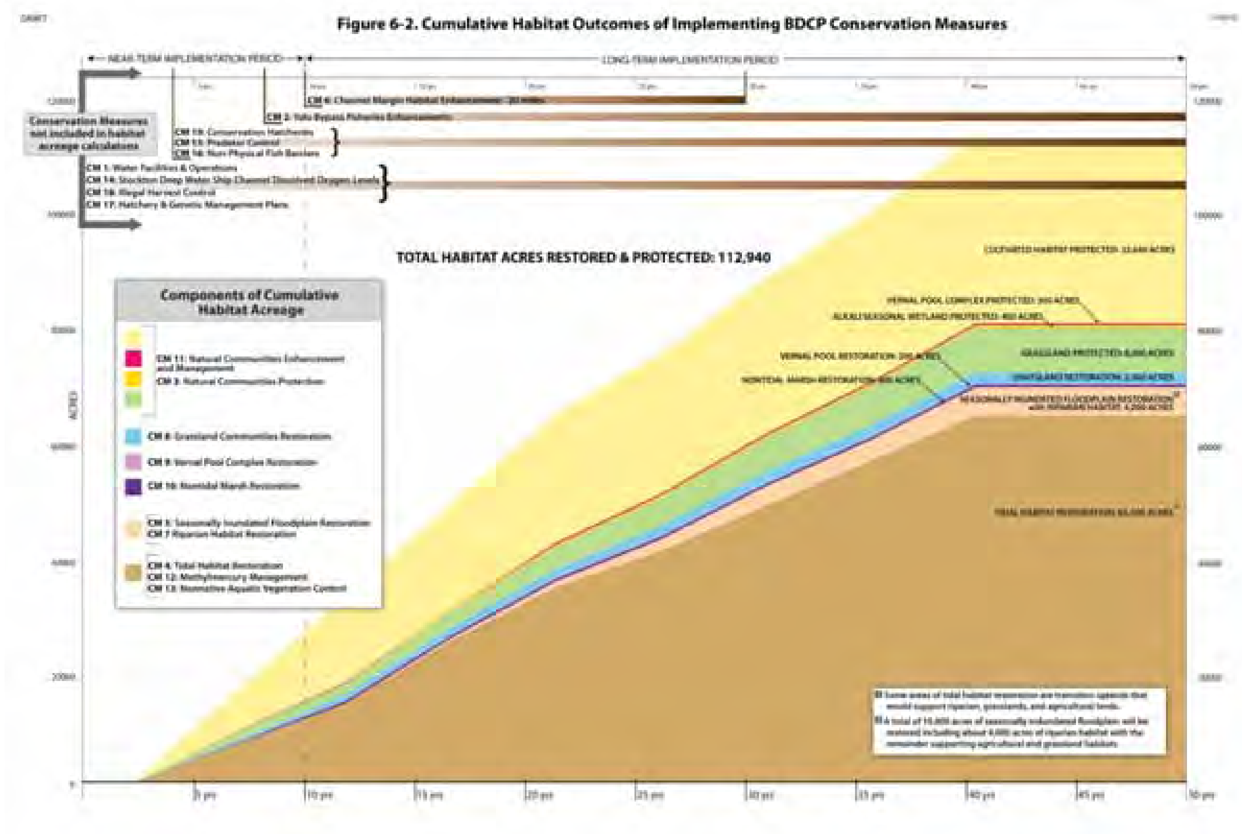

Figure 6-2. Cumulative Habitat Outcomes of Implementing BDCP Conservation Measures

The implementation schedule represents a reasonable estimate of the temporal sequence for implementation of the various interdependent conservation actions over the term of the BDCP based on the best available information. The BDCP is a large and complex plan and, to ensure successful implementation, the Implementation Office will need to retain a degree of flexibility to address new information that is developed over the term of BDCP that may require adjustments in the implementation schedule to better ensure that the biological goals and objectives are achieved. Consequently, the actual timing of implementation of some conservation actions may vary from the implementation schedule described below. Substantial variances in the implementation schedule may need to be addressed through the adaptive management process described in Section 3.7, *Adaptive Management Program*.

The BDCP implementation schedule was informed by information, data, and analysis used to develop the Conservation Strategy, including:

- The near-term, early long-term, and late long-term restoration targets established for tidal, seasonally inundated floodplain, and channel margin habitats (Section 3.4, *Conservation Measures*) and the extent of habitat restoration effects on natural communities and covered species habitats (Chapter 5, *Effects Analysis*);
- Vernal pool complex and grassland restoration targets (Section 3.4, *Conservation Measures*) and the extent of habitat restoration effects on natural communities and covered species habitats (Chapter 5, *Effects Analysis*);
- Vernal pool complex, alkali seasonal wetland complex, grassland, and agricultural habitat protection/preservation targets (Section 3.4, *Conservation Measures*); and
- The pipeline/tunnel construction schedule and the extent of construction effects on natural communities and covered species habitats (Chapter 5, *Effects Analysis*).

The estimated timeframes for implementation of each of the conservation measures were determined based on evaluations of similar type actions that have been completed and on input from individuals experienced with similar types of projects.

6.1.1 Ecosystem-Level Conservation Measures

Ecosystem-level conservation measures include actions that affect large areas of the Delta and large-scale ecosystem processes, including flow, hydrodynamics, water quality, and large areas of terrestrial, floodplain, and aquatic habitat.

6.1.1.1 Conservation Measure CM1: Water Facilities and Operation

6.1.1.1.1 Near-Term Water Operations

The implementation schedule assumes that near-term water operations of the State Water Project (SWP) and Central Valley Project (CVP) will be implemented in year 0 and continue until long-term water operations are implemented (Figure 6-1). Operation of the modified Fremont Weir is assumed to commence in year 7 following completion of construction necessary to install an operable gate on Fremont Weir (Section 6.1.1.2, *Yolo Bypass Fishery Enhancement*). Changes in operation of the Suisun Marsh Salinity Control Gate require changes to existing agreements that are assumed to become effective in early long-term implementation period.

6.1.1.1.2 Construction of North Delta Diversion and Conveyance Facilities

The implementation schedule is based on an assumption that construction of the new north Delta diversion and conveyance facilities and related actions will require up to 10 years to complete (Figure 6-1). Scheduled activities that would be implemented during this period include acquisition of lands, preparation and submittal of regulatory permit applications, preparation and letting of construction-related contracts, and facilities construction. This construction time assumption is based on rough estimates provided by DHCCP engineers.

<u>Long-Term Water Operations</u>

Implementation of the long-term water operations conservation measures is dependent on completion of construction of the north Delta diversion and conveyance facilities, assumed to be 10 years. Long-term operations would then continue over the remaining 50-year term of the BDCP. The schedule is based on the assumption that construction of the north Delta diversion and conveyance facilities will be completed in year 10 and that long-term water operations will commence in year 11 (Figure 6-1).

6.1.1.2 Conservation Measure CM2: Yolo Bypass Fisheries Enhancements

The implementation schedule for the Yolo bypass fisheries enhancements assumes that modifications to the Fremont Weir and any attendant modifications necessary to the configuration of the Yolo Bypass to allow for operation of the weir will be completed in year 6 following BDCP approvals. Implementation activities assumed to occur and to be completed by year 6 include completion of project planning, environmental compliance documentation, permitting, engineering design, acquisition of flood easements and land (if necessary), modification of the Fremont Weir, and construction of Bypass modifications that may be necessary to direct and contain bypass flows resulting from operation of the modified weir. Planning, permitting, and construction of improvements to the Fremont Weir fish passage structures are assumed to be completed by the end of year 4 and the modified passage structures to be operational in year 5.

The implementation schedule assumes that modifications to the Lisbon Weir, lower Putah Creek channel, and any other modifications of the bypass to improve fish passage will be completed by year 6. Initial grading, excavation, and filling that may be required to reduce the potential for fish stranding is also expected to be completed by year 6, although localized actions to further reduce fish stranding are expected to occur in subsequent years under the Adaptive Management Program based on results of fish stranding monitoring. Implementation activities assumed to occur and to be completed by year 6 include completion of any additional regulatory compliance processes, acquisition of land or easements necessary to implement the Bypass modifications, and construction-related activities.

6.1.1.3 Conservation Measure CM3: Natural Communities Protection

The implementation schedule for actions to preserve natural communities assumes that acquisition, protection/preservation, enhancement, and management of existing vernal pool complex, alkali seasonal wetland complex, grassland habitat and agricultural habitats will be implemented approximately concurrent with or in advance of the commensurate adverse effects of BDCP implementation on these natural communities and the covered species habitats they support. The schedule assumes that, except for protection actions implemented in the second year following BDCP authorization, a 2 year period will be necessary to identify and bring under protection (e.g., through conservation easement, fee title acquisition, or other means) existing natural communities. Based on the expected timing of adverse impacts on natural communities and covered species habitat resulting from construction activities early in BDCP implementation, the schedule is based on the assumption that planning for the first increment of protection of existing alkali seasonal wetland complex, grassland, and agricultural habitat will be initiated prior to BDCP authorization.

In addition to the protection of existing natural communities and covered species habitat, natural communities and covered species habitat that will be restored under Conservation Measures CM4-CM10 will be included within the BDCP preserve system. The implementation schedule for habitat restoration actions is described in Section 6.1.2, *Natural Community-Level Conservation Measures*.

The schedule for protection of natural communities and covered species habitat includes time for activities by the Implementation Office to identify specific parcels of land that are available for acquisition that have the physical and biological characteristics that make the lands suitable for achieving habitat protection targets.

Figures 6-3 through 6-6 show the timing of effects of BDCP actions on existing vernal pool complex, alkali seasonal wetland complex, grassland, and agricultural habitats in relation to when these habitat protection/preservation actions are implemented. The implementation schedule assumes that monitoring and management of protected/preserved habitats will occur over the remainder of the term of the BDCP following completion of each restoration increment as described in Conservation Measure CM11: Natural Communities Enhancement and Management.

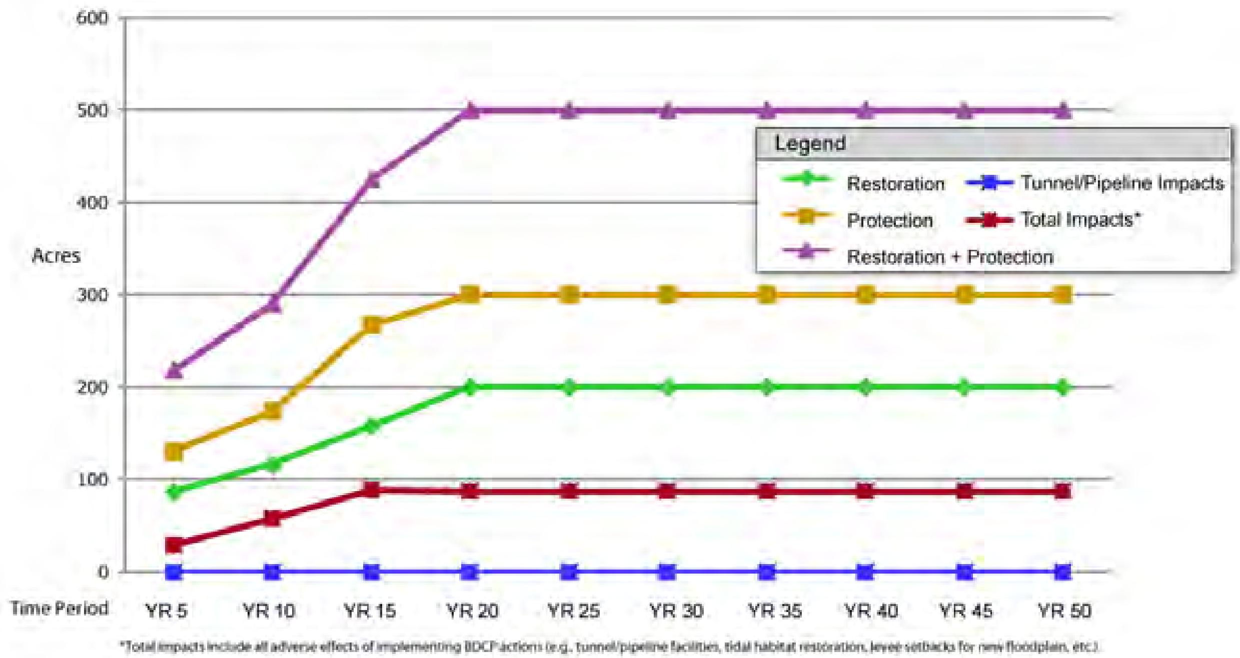

Figure 6-3. Vernal Pool Habitat Restoration and Protection versus Permanent Impacts

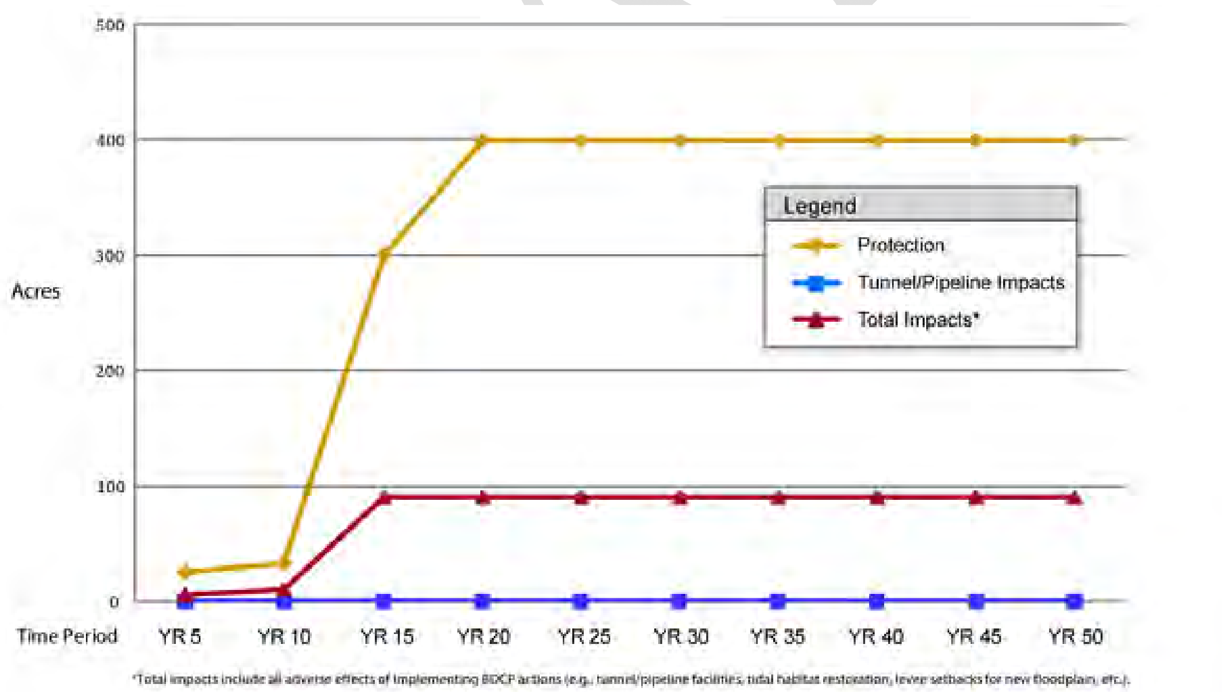

Figure 6-4. Alkali Seasonal Wetland Habitat Protection versus Permanent Impacts

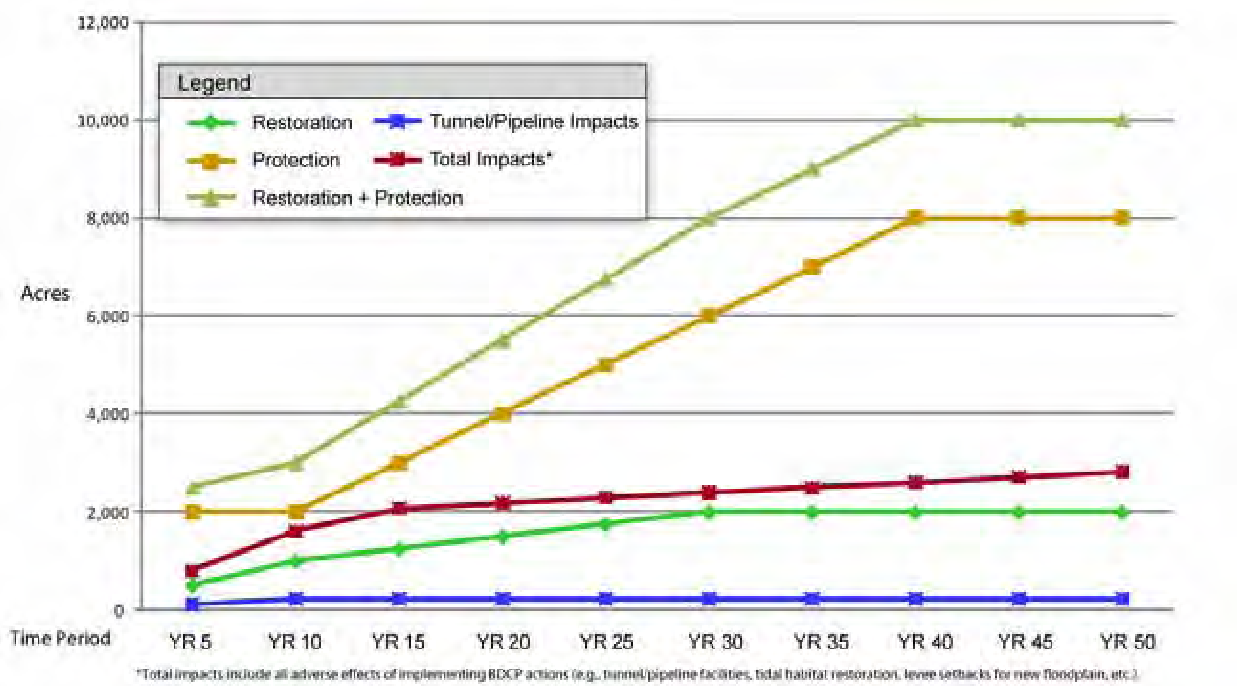

Figure 6-5. Grassland Habitat Restoration and Protection versus Permanent Impacts

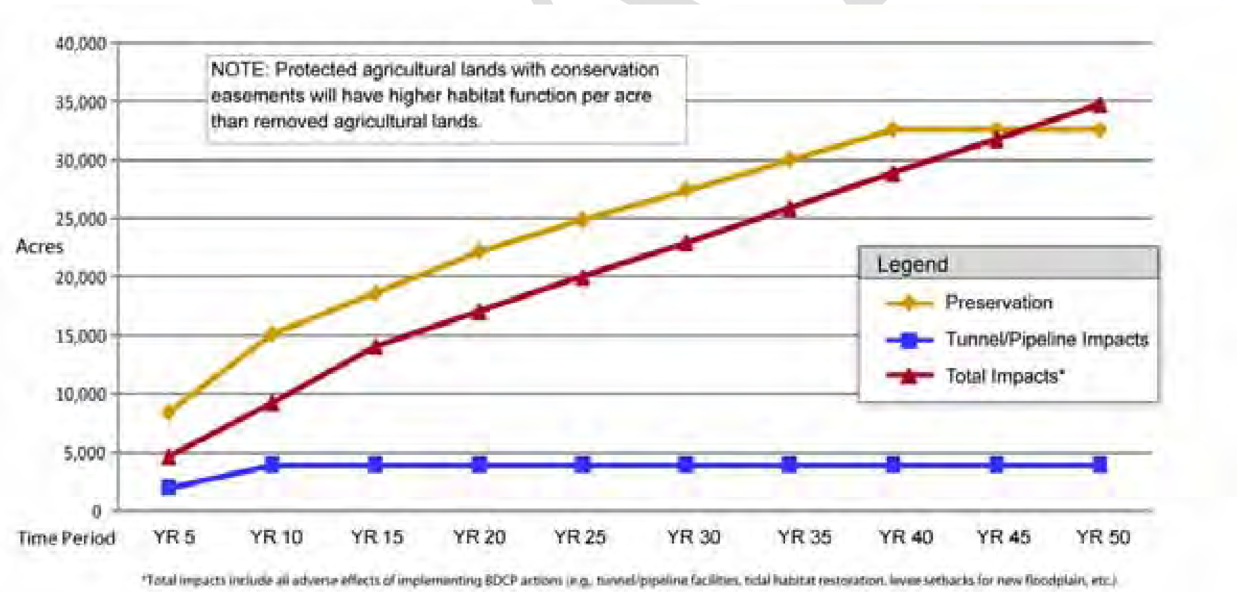

Figure 6-6. Cropland Preservation versus Permanent Impacts

6.1.2 Natural Community-Level Conservation Measures

Natural community conservation measures address actions to restore tidal, riparian, seasonally inundated floodplain, vernal pool complex, and grassland habitat; enhance channel margin habitat; and enhance and manage BDCP preserve lands. The schedule for implementing each habitat restoration action is comprised of the following elements:

- Habitat enhancement and restoration site acquisition;
- Enhancement and restoration planning and design;
- Regulatory compliance; and
- Habitat restoration and enhancement implementation activities.

These elements are generally expected to be implemented concurrently and are aggregated in the implementation schedule (Figure 6-1).

Habitat enhancement and restoration site acquisition. These actions include the identification and acquisition of specific parcels of available land that have the physical and biological characteristics sufficient to advance habitat protection, enhancement, and restoration objectives. Site acquisitions for actions that involve modifications to levees (e.g., setting back levees to restore seasonally inundated floodplain habitat) include obtaining concurrence of the responsible agencies to initiate planning studies.

Enhancement and restoration planning and design. This implementation element includes all activities related to:

- Development of conceptual habitat enhancement and restoration designs, including coordinating development of conceptual restoration designs with stakeholders (e.g., local, state, and federal agencies and potentially affected landowners);
- Development of detailed habitat enhancement and restoration designs and cost estimates;
- Development of bid specifications and drawings; and
- Preparation of habitat enhancement and restoration contracts and contractor selection

Regulatory compliance. This implementation element includes the preparation and submittal of documents and applications associated with compliance with and acquisition of the permits associated with applicable laws and regulations, including:

- Additional project-level review under the California Environmental Quality Act (CEQA), and National Environmental Policy Act (NEPA);
- Sections 401 and 404 of the federal Clean Water Act (CWA), including Nationwide Permit 27, Stream and Wetland Activities;

- California Water Code Sections 1000 et seq. (water rights);
- Water Code Sections 13000 et seq. (water quality);
- Sections 10 (33 USC 403) and 14 (33 USC 408) of the Rivers & Harbors Act of 1899;
- Section 1602 of the California Fish and Game Code (Streambed and Lakebed Alteration Agreements);
- Section 106 of the National Historic Preservation Act; and
- Encroachment permits for work on levees from the Central Valley Flood Protection Board and reclamation districts.

Habitat restoration and enhancement implementation activities. This implementation element includes all activities related to completing habitat restoration actions including:

- Contractor mobilization;
- Site preparation, including grading, excavation, and placement of fill;
- Construction/installation of water management, utility and other operational infrastructure;
- Demolition of or refurbishment of existing infrastructure;
- Construction of dikes, levees, and roads; and
- Planting vegetation.

6.1.2.1 CM4: Tidal Habitat Restoration

The implementation schedule for tidal habitat restoration actions is based on the assumption that site acquisition, planning, and regulatory compliance related activities are initiated prior to BDCP authorization for first 7,000 acres of tidal habitat to be restored in the near-term implementation period. These initial restoration actions could, therefore, be constructed immediately following BDCP authorization. These initial restoration actions are expected to require less time to acquire and permit because they are assumed to be implemented on sites that will be readily available to the Implementation Office (e.g., state and federal owned lands). The schedules for implementation of subsequent tidal habitat restoration actions are based on the assumption that 5 years are required for all the elements of restoration. It is anticipated that most or all of tidal habitat restored during the near-term implementation period will be restored in the Cache Slough Complex, Suisun Marsh, and West Delta areas.

Figure 6-7 shows the timing of adverse effects of construction activities on existing tidal habitats in relation to when tidal habitat restoration actions are implemented. The implementation schedule assumes that monitoring and management of restored tidal habitats will occur over the remainder of the term of the BDCP following completion of each restoration increment as described in Conservation Measure CM11: Natural Communities Enhancement and Management.

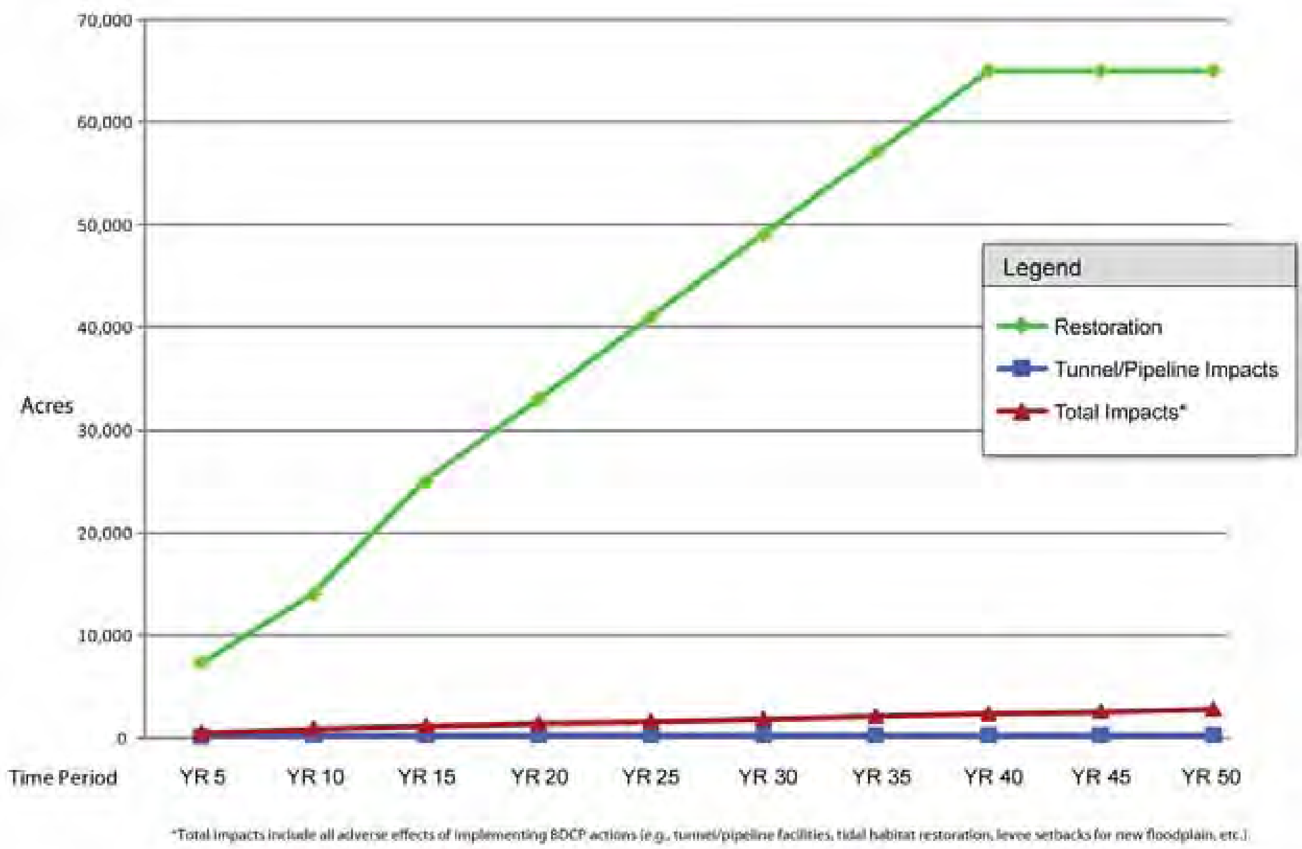

Figure 6-7. Tidal Habitat Restoration versus Permanent Impacts

The tidal habitat restoration conservation measure provides for the restoration of varying amounts of subtidal aquatic, tidal mudflat, and tidal marsh habitat over time, depending on location and restoration design within the Plan Area. Figure 6-8 presents reasonable representations of how restored tidal habitat may develop over time within 1,000 acre conceptual restoration sites at Suisun Marsh, the Cache Slough Complex, and the south Delta. The habitat functions supported for covered species will also change over time as marsh vegetation composition, structure, and density and tidal channels evolve over time.

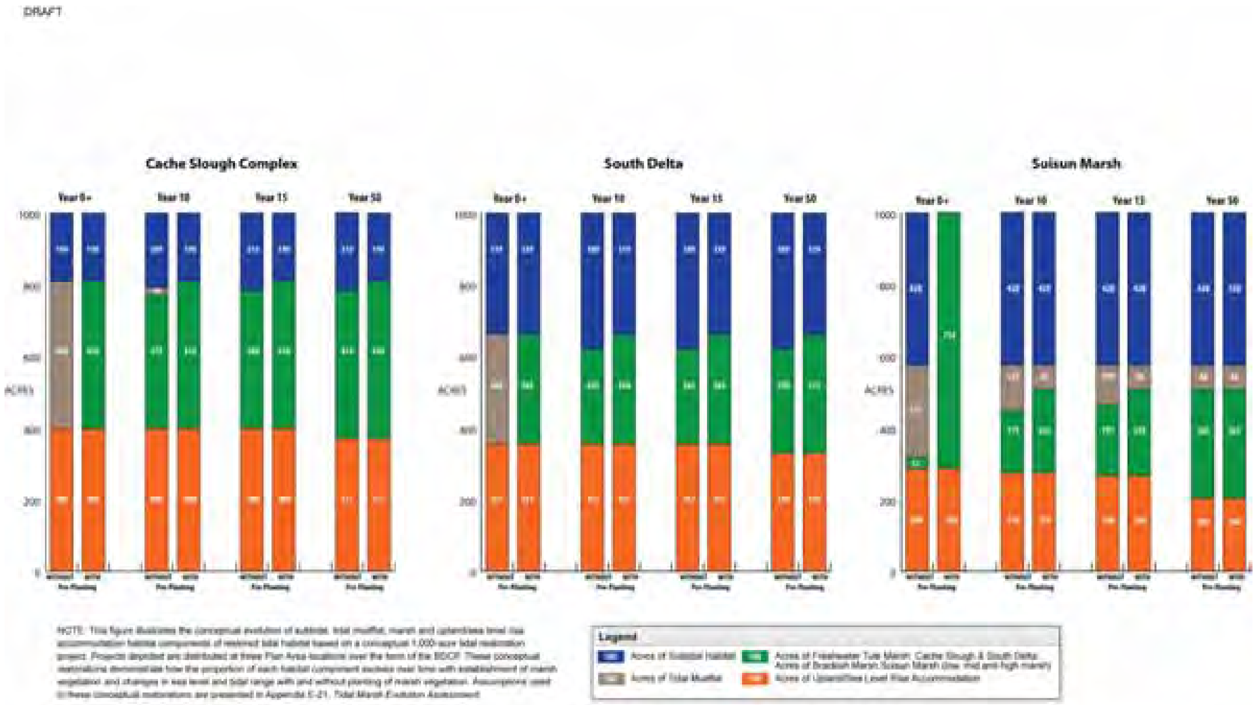

Figure 6-8. Conceptual Evaluation of Restored Tidal Habitat with and without Pre-Planting of Marsh Vegetation at Three BDCP Locations

6.1.2.2 Conservation Measure CM5: Seasonally Inundated Floodplain Restoration

Restoration of seasonally inundated floodplain habitat will require extensive levee setbacks to reconnect historical floodplain with Delta channels. The implementation schedule assumes that at least 1,000 acres of floodplain will be restored by year 15 and that restoration of the remaining 9,000 acres of floodplain restoration will be completed in increments of 3,000 acres by years 25, 30, and 40, respectively. Each floodplain restoration increment will, on average, require five years to identify potential floodplain restoration sites, coordinate planning with the U.S. Army Corps of Engineers (USACE), California Department of Water Resources (DWR) and other flood control agencies and Reclamation Districts, and conduct feasibilities studies prior to implementation. Following approval of floodplain restoration plans, an additional 5 years are assumed to be required to acquire restoration lands, obtain any outstanding regulatory approvals and permits, develop bid specifications and drawings, construct the new levees and floodplain, and breach existing levees.

The implementation schedule assumes that monitoring and management of restored seasonally inundated floodplains will occur over the remainder of the term of the BDCP following completion of each restoration increment as described in CM11: Natural Communities Enhancement and Management.

6.1.2.3 Conservation Measure CM6: Channel Margin Habitat Enhancement

The implementation schedule for enhancing channel margin habitat assumes that channel margin enhancements will be completed in increments of 5 miles of channel (achieved at multiple sites for a total of 5 miles of channel margin length) by years 10, 20, 25, and 30, respectively. Each channel margin habitat enhancement increment will, on average, require 5 years to identify potential channel margin enhancement sites, coordinate planning with USACE, DWR, and other flood control agencies and Reclamation Districts, and conduct feasibilities studies prior to implementation. Following approval of enhancement plans, an additional five years are assumed to be required to obtain any outstanding regulatory approvals and permits and develop bid specifications and drawings and implement channel margin enhancements.

The implementation schedule assumes that monitoring and management of enhanced channel margin habitats will occur over the remainder of the term of the BDCP following completion of each restoration increment as described in Conservation Measure CM11: Natural Communities Enhancement and Management.

6.1.2.4 Conservation Measure CM7: Riparian Habitat Restoration

Restoration of riparian habitat will be a component of tidal habitat restoration, seasonally inundated floodplain restoration, and channel margin habitat enhancement projects; therefore, the schedule for planning, site acquisition, environmental compliance, and implementation of riparian restoration actions is the same as the implementation schedule for those tidal, floodplain, and channel margin habitat restoration actions. The amount of riparian habitat restored varies greatly among the three restoration types. The preponderance of the 5,000 acres of riparian habitat to be restored will be performed in conjunction with seasonally inundated floodplain restoration and tidal habitat restoration in the south Delta in the early long-term and late long-term evaluation periods.

Figure 6-9 shows the timing of adverse effects of construction activities on existing riparian habitats in relation to when riparian restoration actions would be implemented. There is a temporal loss of habitat function as a result of the time lag between when riparian habitats are affected and when riparian habitat is restored and become functional as habitat for associated covered species (Figure 6-9).

The implementation schedule assumes that monitoring and management of restored riparian habitat will occur over the remainder of the term of the BDCP following completion of each restoration increment as described in Conservation Measure CM11: Natural Communities Enhancement and Management. Figure 6-10 illustrates how restored riparian habitats are expected to evolve from riparian scrub to riparian forest and to develop habitat functions that support covered species over time. A description of methods used to identify riparian habitat maturation rates is provided in Appendix N.2, *Riparian Habitat Succession*.

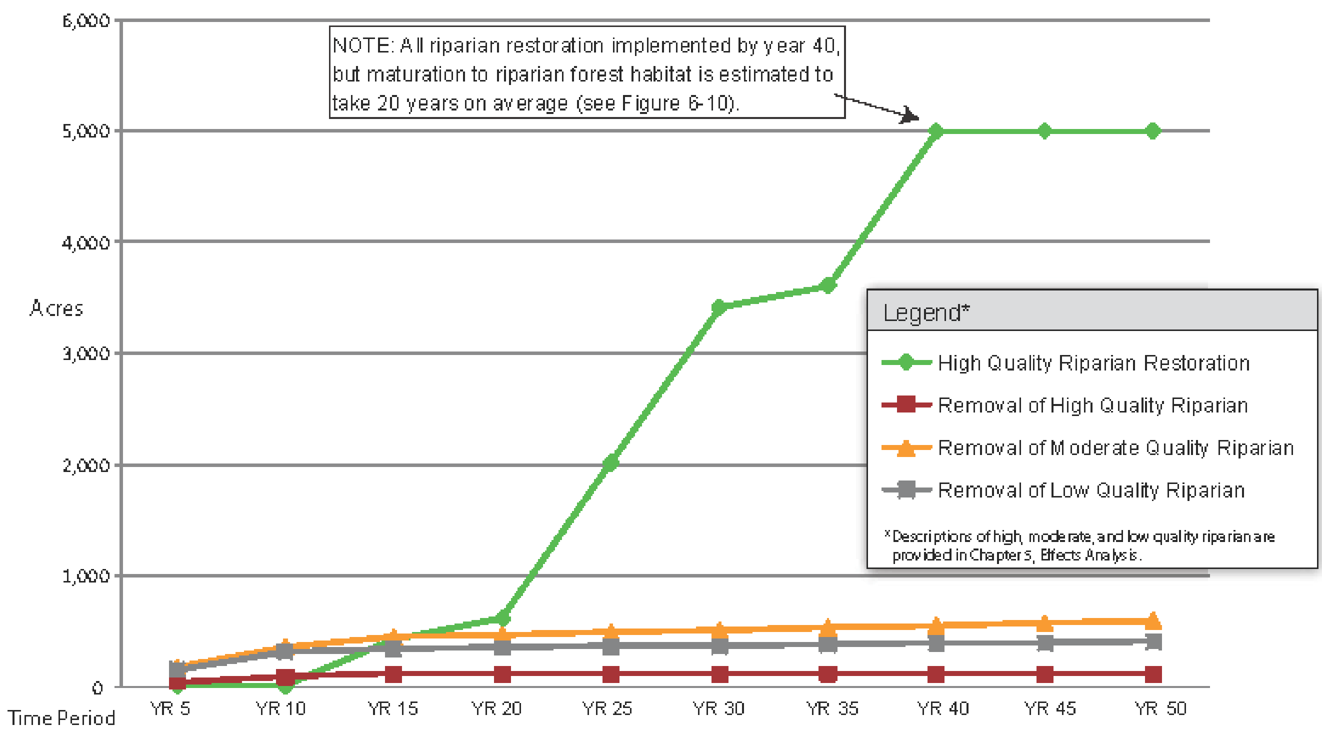

Figure 6-9. Cumulative Riparian Habitat Restoration versus Cumulative Permanent Removal

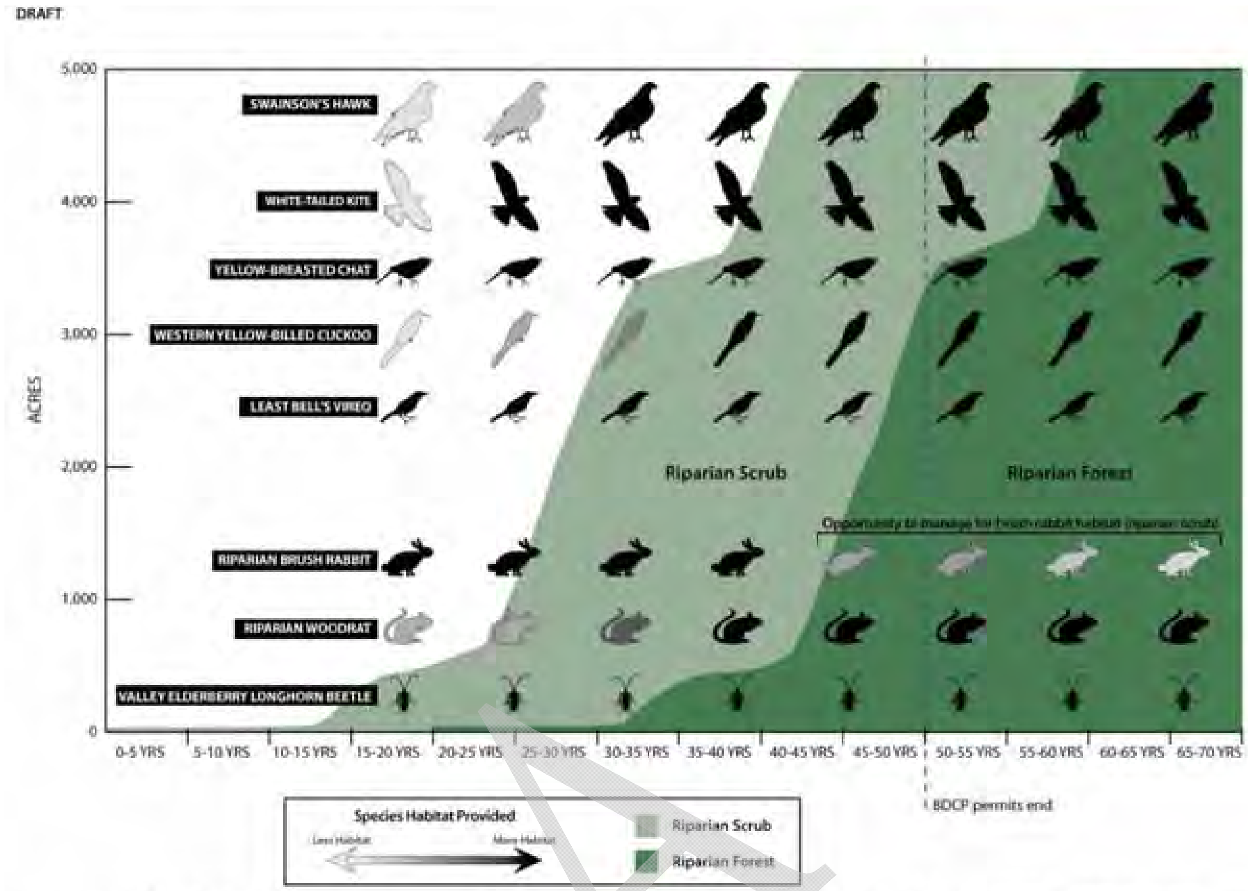

Figure 6-10. Maturation and Succession of Restored Riparian Forest and Scrub and Use by Covered Wildlife Species

6.1.2.5 Conservation Measure CM8: Grassland Communities Restoration

The implementation schedule assumes that all grassland habitat restoration actions will be implemented between years 3 and 30. A total of 1,000 acres of grassland will be restored in the near-term implementation period, 250 acres in the early long-term implementation period, and 750 acres in the late long-term implementation period. The implementation schedule assumes that site acquisition, planning, and regulatory compliance related activities for the first 250 acres of grassland restoration to be completed in year 3 is initiated in the first year following BDCP authorization and requires a total of 2 years to complete those implementation elements. All subsequent restoration increments also require a 2 year period to complete site acquisition, planning, and regulatory compliance prior to implementing restoration actions.

Figure 6-5 shows the timing of adverse effects of BDCP activities on existing grassland habitats in relation to when grassland restoration actions are implemented. The implementation schedule assumes that monitoring and management of restored grassland habitat will occur over the remainder of the term of the BDCP following completion of each restoration increment as described in Conservation Measure CM11: Natural Communities Enhancement and Management.

6.1.2.6 Conservation Measure CM9: Vernal Pool Complex Restoration

The implementation schedule assumes that all vernal pool complex habitat restoration actions will be implemented between years 2 and 15. A total of 116 acres of vernal pool complex will be restored in the near-term implementation period, 42 acres in the early long-term implementation period, and 42 acres in the late long-term implementation period. The implementation schedule assumes that site acquisition, planning, and regulatory compliance related activities for the first 58 acres of vernal pool complex restoration to be completed in year 2 is initiated before BDCP authorization and requires a total of 3 years to complete those implementation elements. All subsequent restoration increments also require a 3 year period to complete site acquisition, planning, and regulatory compliance prior to implementing restoration actions.

Figure 6-3 shows the timing of adverse effects of BDCP activities on existing vernal pool complex habitats in relation to when vernal pool complex restoration actions are implemented. The implementation schedule assumes that monitoring and management of restored vernal pool complex will occur over the remainder of the term of the BDCP following completion of each restoration increment as described in Conservation Measure CM11: Natural Communities Enhancement and Management.

6.1.2.7 Conservation Measure CM10: Nontidal Marsh Restoration

The implementation schedule assumes that all nontidal freshwater marsh restoration actions will be completed by year 9 in the near-term implementation period. The restored nontidal freshwater marsh will be designed specifically to support giant garter snake habitat and would be completed in the near-term implementation period to provide benefits for this endangered species as early as practicable. The implementation schedule assumes that site acquisition, planning, and regulatory compliance related activities for each 100 acres of restoration requires 2 years to complete with the restoration actions being completed in the third year.

The implementation schedule assumes that monitoring and management of restored nontidal freshwater marsh will occur over the remainder of the term of the BDCP following completion of each restoration increment as described in Conservation Measure CM11: Natural Communities Enhancement and Management.

6.1.2.8 Conservation Measure CM11: Natural Communities Enhancement and Management

This conservation measure applies to all BDCP protected and restored habitats and is implemented at the time each parcel of land is acquired for the BDCP conservation lands system. Within two years of acquisition of conservation land parcels, the Implementation Office will conduct surveys to collect the information necessary to assess the ecological condition and function of conserved species habitats and supporting ecosystem processes (note that such surveys would be in addition to due-diligence biological and physical surveys conducted prior to site acquisitions, see Chapter 3, *Conservation Strategy*). Based on results of the assessment, the Implementation Office will develop management plans. These management plans may be prepared for specific parcels or for multiple preserved parcels within a specified geographic area that describe habitat enhancement and management actions necessary to achieve the biological objectives established for the preserve lands addressed by each plan. Subsequent habitat enhancement and management actions will be implemented in accordance with the preserve-specific habitat enhancement and management schedule for each plan.

6.1.2.9 Conservation Measure CM12: Methylmercury Management

This conservation measure provides for specific tidal habitat restoration design elements to reduce the potential for methylation of mercury and/or its bioavailability in tidal habitats. Consequently, this conservation measure is implemented as part of the tidal habitat restoration design schedule indicated in Figure 6-1.

6.1.2.10 Conservation Measure CM13: Nonnative Aquatic Vegetation Control

This conservation measure provides for control of nonnative aquatic vegetation in subtidal habitats restored as a component of BDCP tidal habitat restoration actions. The implementation schedule assumes that nonnative aquatic vegetation control actions will be required at each tidal habitat restoration site 3 years following the restoration. Because current nonnative aquatic vegetation control methods are dependent on the use of herbicides, the implementation schedule assumes 3 years to complete planning and environmental compliance for the first tidal habitat restoration to be completed in year 2. Thereafter, the schedule assumes that planning and environmental compliance processes will be streamlined, requiring no more than 2 years to complete, and run concurrent with planning and compliance elements conducted for each of the subsequent tidal habitat restoration actions.

6.1.3 Species-Level Other Stressors Conservation Measures

6.1.3.1 Conservation Measure CM14: Stockton Deep Water Ship Channel Dissolved Oxygen Levels

The implementation schedule assumes the current Stockton Deep Water Ship Channel dissolved oxygen diffuser demonstration project will be implemented immediately following BDCP authorization (i.e., continued operation). The implementation schedule assumes the dissolved oxygen diffuser technology will need to be modified to provide substantial biological benefits for the covered fish species. The implementation schedule also assumes completion of a demonstration study by at the end of year 1 that will provide guidance on how to modify the diffusers. Additional planning, coordination, environmental compliance, and construction is assumed to require an additional 2 years and, assuming modifications are necessary, the modified dissolved oxygen diffusion facilities becoming operational in Year 4 with operations continuing over the term of the BDCP.

6.1.3.2 Conservation Measure CM15: Predator Control

The implementation schedule assumes that predator control actions to remove artificial structures and abandoned boats from Delta channels will require 2 years of planning and environmental compliance, with actions being implemented in year 3. Authorizations to implement actions to remove nonnative predatory fish from specific locations are assumed to be completed in the first year following BDCP authorization and implemented in year 3. Following the first year of their implementation, predator control actions are assumed to be implemented annually over the term of BDCP.

6.1.3.3 Conservation Measure CM16: Non-Physical Fish Barriers

The existing non-physical fish barrier serving as a pilot project at the Head of Old River is assumed to continue to be operated immediately following BDCP implementation. Planning and compliance activities for placing barriers at the Delta Cross Channel and Georgiana Slough are assumed to be initiated in the year following BDCP approval, requiring 2 years to complete, followed by construction and operation in the third year. The schedule assumes that up to four additional barriers may be constructed at operated if studies indicate substantial benefits for the covered fish species. The implementation schedule assumes 2 years of studies will be conducted following BDCP authorization and, assuming the studies indicate the placement of barriers will be beneficial, that 2 years will be required for planning and compliance and 1 year for construction as described above for the initial barriers.

6.1.3.4 Conservation Measure CM17: Hatchery and Genetic Management Plans

The implementation schedule assumes that preparation of each of the 12 hatchery and genetic management plans is initiated in the year following BDCP authorization and are all completed at the end of the third year of implementation. Because preparation of some plans will have been initiated before BDCP authorization, some of the plans may be completed earlier. The schedule subsequently assumes each plan will be updated every 5 years, requiring 1 year to complete each update. Staff support for implementing and updating plans is assumed to be implemented the year that the initial hatchery and genetic management plans are completed.

6.1.3.5 Conservation Measure CM18: Illegal Harvest

The implementation schedule assumes that planning and coordination with DFG and the existing Delta-Bay Enhanced Enforcement Program (DBEEP) necessary to expand DBEEP staffing will immediately following BDCP authorization such that the conservation measure is implemented by the end of year 2. The funding for enhanced staffing support is assumed to be maintained over the term of the BDCP.

6.1.3.6 Conservation Measure CM19: Conservation Hatcheries

The implementation schedule assumes that site acquisition, planning, and environmental compliance necessary for construction of the new the California Department of Fish and Game (DFG) conservation hatchery facility will require 3 years following BDCP authorization; an additional 2 years would be necessary for construction; and the facility would become operational in year 6. Planning and environmental compliance necessary for the expansion of the UC Davis conservation hatchery are assumed to be initiated before BDCP authorization such that the facility expansion is completed by the end of the second year of BDCP implementation, becoming operational in the year 3 of implementation. Both the USFWS and the University of California at Davis facilities are assumed to be operated over the term of the BDCP once they have become operational.

6.2 Compliance and Progress Reporting

The BDCP Implementation Office will prepare, on a regular basis, planning documents and implementation reports to demonstrate compliance with the BDCP and its associated authorizations and to facilitate interagency coordination, scientific exchange, and public outreach. Under ESA, habitat conservation plans are required to establish monitoring programs to assess the effects of plan implementation on covered species.[1] In addition, the USFWS/ National Marine Fisheries Service (NMFS) Five-Point Policy[2] recommends that such plans provide for annual reporting on matters related to compliance with permit terms and conditions. Similarly, the NCCPA requires that implementation agreements include "provisions for periodic reporting to wildlife agencies and the public for purposes of information and evaluation of plan progress."[3] The Implementation Office will, over the term of the BDCP, submit various reports and plans to the fish and wildlife agencies that serve the following purposes:

- Provide the necessary data and information to demonstrate that the BDCP is being properly implemented;
- Identify the effect of BDCP implementation on covered species and on the effectiveness of the Conservation Strategy at advancing the BDCP biological goals and objectives;
- Document actions taken under the adaptive management program (e.g., process, decisions, changes, results, corrective actions);
- Disclose issues and challenges concerning BDCP implementation, and identify potential modifications or amendments to the BDCP that would increase the likelihood of success;
- Describe schedule and cost related to the implementation of actions over one-year and five-year timeframes.

Throughout the course of BDCP implementation, the Implementation Office will prepare and submit to the fish and wildlife agencies the following documents, as described in this chapter:

- Annual Workplan and Budget;
- Annual Water Operations Strategy;
- Annual Progress Report;
- Annual Water Operations Report;
- Five-Year Comprehensive Review; and
- Five-Year Implementation Plan.

The Implementation Office will work in partnership with DWR, Reclamation, USFWS, NMFS, DFG, the BDCP Stakeholder Committee, the Delta Stewardship Council, and the Delta Science Program in the development of these planning and reporting documents. The totality of these documents will enable the range of interested public and private stakeholders, and the general public, to assess on an ongoing basis the progress and performance of the BDCP toward meeting the biological goals and objectives of the BDCP and make informed recommendations to the Implementation Office regarding matters relating to plan implementation. To accommodate

[1] 50 C.F.R. § 17.22(b)(3) and 50 C.F.R. § 222.307(b)(5)
[2] Five-Point Policy for HCPs, 65 FR 106, June 1, 2000
[3] California Fish & Game Code § 2820(b)(7)

access to this information, these reports will be available to the public and posted on the BDCP website.

6.2.1 Annual Workplan and Budget

On an annual basis[4], the Implementation Office will prepare a workplan and budget for the upcoming implementation year. The workplan will identify planned actions for the implementation of conservation measures and the monitoring, research, and adaptive management programs. The budget will set out the anticipated expenditures and identify the sources of funding for those expenditures. A final Annual Workplan and Budget will be completed no later than one month prior to the beginning of the implementation year. A draft of the Annual Workplan and Budget will be provided to BDCP Implementation Board and the BDCP Stakeholder Committee for review no later than one month prior to the due date for the final plan.

At a minimum, the Annual Workplan and Budget will contain the following information:

- A description of the planned actions (including anticipated adaptive management changes) to implement conservation measures (for water operations conservation measures, see Section 6.2.2 *Annual Water Operations Strategy*) and the entities that will carry out the actions;
- A description of the planned monitoring actions and the entities that will implement those actions;
- A description of the anticipated research studies to be undertaken, and the entities that will conduct the studies;
- A budget reflecting the costs of implementing the planned actions, including a line item for each specific action; and
- A description of the sources of funding to support the budget.

6.2.2 Annual Water Operations Strategy

The Implementation Office will work closely with CVP and SWP operation managers to ensure the proper implementation of operations conservation measures. DWR and Reclamation will retain their authority and obligation to determine overall water project operations consistent with their various permit terms and conditions and other applicable requirements. DWR and Reclamation will conduct Delta operations in close coordination with DFG, USFWS, and NMFS and in accordance with permitted operating criteria, and consistent with the following planning processes.

[4] The Implementation Office will decide how the planning year will be bounded (e.g., calendar year, federal fiscal year, state fiscal year; or water year).

No later than December 15 each year, DWR, Reclamation, DFG, FWS, and NMFS will develop a Water Operations Strategy, including provisions for seasonal variations, that identifies:

- Operations priorities for both fishery and water supply for the coming year;
- Expected operations or "most likely" criteria that will guide operations within the real-time operations ranges established in the water operations conservation measures; and
- Monitoring, data collection, research, and adaptive management experiments associated with that water year's water operations.

The BDCP Science Manager will use prior years' Annual Water Operations Reports to inform development of the Annual Water Operations Strategy. The Science Manager will seek independent science input on an initial draft of the Annual Water Operations Strategy to be submitted for review to an independent science panel in an open, public forum. The independent science panel will review the draft plan and provide a comprehensive written review of the draft plan.

The Annual Water Operations Strategy will include the first of three Seasonal Operations Strategies**.** No later than December 31, March 31, and July 31 of each year, DFG, USFWS, and NMFS will seasonally evaluate then current hydrologic and fishery information and will update the expected operating criteria within the real-time operations range, as necessary. Based on this information, DWR and Reclamation will prepare Seasonal Operations Strategies that update their operating forecasts and expected water supply projections. The Seasonal Operations Strategies documents will be completed no later than January 15, April 15, and August 15.

6.2.3 Annual Progress Report

At the end of each implementation year[5], the Implementation Office will prepare an Annual Progress Report. These reports will provide a summary of the activities carried out during the previous implementation years. The Annual Report, for instance, will include a description and accounting of land acquisitions and habitat restoration activities, and an update on the status of the monitoring and research programs, including a discussion of the synthesis and use of data and information and the identification of important trends. Annual reports will be completed within three months of the close of the reporting year, which will provide sufficient time to compile data and complete analyses.

The annual reports will include the following elements:

1. Documentation of the implementation of habitat conservation measures (i.e., protection/ enhancement/ creation/ restoration) in relationship to the implementation schedule set out in Section 6.1, *Plan Implementation Schedule*, including:

[5] The Implementation Office will decide how the implementation year will be bounded (e.g., calendar year, federal fiscal year, state fiscal year; or water year).

   a) A summary of the completed or in-progress habitat conservation actions, including information related to type, extent, and location of restored, enhanced, and existing protected habitats and natural communities. This summary will identify the habitat lands acquired and the restoration and enhancements actions undertaken over the year, and a description of the covered species that are expected to benefit from each action. The report will document, on an annual and cumulative basis, the habitat conservation actions that have been carried out.

   b) A summary of all land management activities undertaken on BDCP conservation lands, including a description of the management issues facing the Implementation Office at each preserve unit.

   c) Identification of habitat protection, restoration, or enhancement actions that have not been implemented in accordance the implementation schedule (i.e., actions that are either behind or ahead of the implementation schedule) and an explanation for the deviation from the schedule.

2. A summary of the water operations conservation measures implemented during the prior year (a detailed description of water operations will be included in the Annual Water Operations Report [Section 6.2.4]), including:

   a) Documentation of compliance with the water operation criteria in effect during the reporting period.

   b) Documentation and rationale for any deviations from the water operation criteria in effect during the reporting period.

   c) Documentation of “real time” operational decisions.

   d) Documentation of Fremont Weir operations, including:

      i) Periods of operation.

      ii) Flow volume by operation period.

      iii) Documentation and rationale for any deviations from the Fremont Weir operation ranges in effect during the reporting period.

3. A description of the status of natural communities and covered species and their habitats, including:

   a) An assessment of nature and extent of the impacts of covered activities on covered natural communities and covered species. The report will also contain:

      i) The entity that carried out the covered activity.

      ii) The location of habitat permanently or temporarily disturbed.

      iii) A description of the covered activity that disturbed natural communities and covered species habitats.

b) A description of the type, extent, and location of measures implemented to avoid and minimize the potential impacts of Covered Activities on covered species during the reporting period.

c) A summary of the overall level of impacts in the current year and a summation of impacts of all prior years of BDCP Covered Activities on covered natural communities and covered species habitats and a description of how implementation of conservation measures is roughly proportional in time and extent to the impacts on covered species and their habitat.

d) The status of the BDCP conservation lands system assembly with respect to authorized take/habitat loss, and an assessment of the progress toward all acquisition goals, including those related to land-cover types, landscape linkages, covered plant populations, and wetland protection. This assessment will include evaluation of compliance with the reserve design and assembly principles as described in Chapter 3, *Conservation Strategy*.

4. An evaluation of the results of monitoring and research activities, including:

a) A description of the ecosystem/landscape-level, natural-community level and species level monitoring activities (as described in Section 3.6, *Monitoring and Research Program* or in monitoring plans subsequently developed during implementation) undertaken during the reporting period and a summary of monitoring results with appropriate assessment of population trends and status of covered species.

b) A description of all BDCP directed research conducted during the reporting period, a summary of research results to date.

5. A description of adaptive management activities, including:

a) A description of the adaptive management decisions made during the reporting period, including how existing information was used to guide these decisions and the rationale for the action.

b) A description of the use of independent scientists or other experts in the adaptive management decision making processes.

c) A description of adopted and recommended changes to the operating conservation program based on interpretation of monitoring results and research findings.

6. A financial report describing funds provided to the Implementation Office by source; annual and cumulative expenditures by cost category; deviations in expenditures from the annual budget; and other relevant information as appropriate.

7. A description of actions implemented or pending to respond to changed circumstances, including:

a) A description of the changed circumstance and its effects on covered species and natural communities.

b) A description of the actions taken to address the changed circumstance and the effectiveness of those actions, including the outcomes of actions to address changed circumstances from earlier years.

8. A summary of any administrative changes, minor modifications, or major amendments to the Plan proposed or approved during the reporting period.

6.2.4 Annual Water Operations Report

No later than November 15 of each year, DWR and Reclamation, with participation from DFG, USFWS and NMFS, will prepare a Water Operations Report on the prior water year's (October 1 to September 30) operational effects on covered species. The report will include:

- A summary of the prior year's operations, including a comparison of the actual operations with planned operations;
- A discussion of new data collected and information from new scientific research;
- Evaluation of the effectiveness of actions for covered fish species and ecological processes, including the responses to real-time operational changes;
- Description of the extent to which water supply projections in the prior year's Annual and Seasonal Operations Strategies were met, and if not, identification factors affecting the ability to meet projections;
- Consideration of whether any protective actions should be altered in light of new information, an inability to meet fishery protection or water supply reliability targets.

The Science Manager will seek independent science input on the draft of the Water Operations Report.

6.2.5 Five Year Comprehensive Review

The implementation of the BDCP will be subject to a comprehensive review every five years throughout the term of the Plan. As part of this review, the Implementation Office will prepare a report, which will be known as the Five-Year Comprehensive Review, that memorializes the findings of this review.

The objectives of the Five-Year Comprehensive Review are as follows:

- To provide an overview of the status of BDCP implementation, including implementation of conservation measures and the progress made toward meeting biological goals and objectives;
- To assess covered species trends and habitat conditions associated with BDCP implementation relative to overall trends and conditions for covered species and natural

communities based on all relevant information (i.e., not limited to BDCP data and reports);

- To evaluate the relevance of the various monitoring actions and research projects to the implementation of conservation measures; and
- To evaluate changes that have been made in the implementation of the BDCP and set out potential modifications that may be advisable in the future based on new information and lessons learned.

The primary purpose of the Five-Year Comprehensive Review is to provide a periodic, program-level assessment of the progress made under the BDCP toward achieving the biological goals and objectives. As such, the Review will be focused on identifying and evaluating broad ecological trends within the Delta, including covered species abundance, variability, distribution, and population growth rate; ecological processes and stressors such as hydrodynamics, foodwebs, and contaminants; natural community distribution, function, and diversity; habitat restoration extent and functionality; and other relevant measures.

In contrast to the annual reports, the Five-Year Comprehensive Reviews will require significant analysis and synthesis of data collected over time, utilizing data and information compiled from various sources. Five-Year Comprehensive Reviews will include critical evaluations of the assumptions and model outputs upon which the BDCP has been based and of the efficacy of the conservation measures in light of monitoring data and the analysis and synthesis of information through the adaptive management process.

The Five-Year Comprehensive Review will also include an evaluation of the BDCP monitoring program, assessing such issues as the program's capacity to adequately measure the BDCP's progress toward achieving biological goals and objectives. The Review will discuss the lessons that have been learned during the course of implementation and reach conclusions regarding how best to approach monitoring into the future. The Review will also afford an opportunity to evaluate the BDCP biological goals and objectives and assess their continued relevance in light of new information that has become available.

The Five-Year Comprehensive Review will be developed in close coordination with the Interagency Ecological Program (IEP), Delta Science Program, and Independent Science Board. The Implementation Office will work with the IEP Lead Scientist and Science Manager for the Delta Science Program to consolidate data and information from a range of sources. The Review may be scheduled to coincide with the Delta Science Conference to capitalize on the gathering of the community of scientists engaged in Delta issues.

The Implementation Office will post the Five-Year Comprehensive Review on the BDCP website and include a summary of the Review to assist stakeholders and the public in their review of the report.

6.2.6 Five Year Implementation Plan

Based on the Five-Year Comprehensive Review, the Implementation Office will prepare a Five-Year Implementation Plan that covers the upcoming five years. In contrast to the Annual Workplan and Budget, the Five-Year Implementation Plan will focus more broadly on potential future conservation actions and adaptive management changes, other potential modifications to the BDCP, and on the significance of ecological trends. At a minimum, the Five-Year Implementation Plan will contain the following information:

- Description of adaptive management changes to BDCP implementation of conservation measures, monitoring, research, and program administration;
- Modifications, if necessary, to biological goals and objectives;
- Identification of any changes to the BDCP that may require amendments to the permits or other authorizations;
- Summary of the planned actions and schedule to implement conservation measures;
- Description of the long-term and system-wide monitoring actions and anticipated research studies; and
- Summary budget projection reflecting the costs of implementing the planned actions.

In years when Five-Year Plans are prepared, the Annual Workplan and Budget may be included within or prepared separately from the Five-Year Plan.

6.3 Regulatory Assurances and Changed Circumstances and Unforeseen Circumstances

6.3.1 Regulatory Assurances

ESA regulations and provisions of the NCCPA each provide for regulatory and economic assurances to parties covered by approved habitat conservation plans (HCPs) and/or Natural Community Conservation Plans (NCCPs) concerning their financial obligations under a plan. Specifically, these assurances are intended to provide a degree of certainty regarding the overall costs associated with species mitigation and other conservation measures, and add durability and reliability to agreements reached between permittees and the fish and wildlife agencies. That is, if unforeseen circumstances occur that adversely affect species covered by an HCP or NCCP, the fish and wildlife agencies will not require additional land, water, or financial compensation or impose additional restrictions on the use of land, water, or other natural resources.

The assurances provided under the ESA and the NCCPA do not limit or constrain USFWS, NMFS, or DFG, or any other public agency, from taking additional actions to protect or conserve species covered by an NCCP and/or HCP. The state and federal agencies may use the variety of tools at their disposal and take actions to reduce the effects of other stressors to ensure that the needs of species affected by unforeseen events are adequately addressed.

6.3.1.1 Regulatory Assurances under the ESA - The No Surprises Rule

Under the No Surprises Rule,[6] once an incidental take permit has been issued pursuant to an HCP, and its terms and conditions are being fully implemented, the federal government will not require additional conservation or mitigation measures, including land, water (including quantity and timing of delivery), money, or restrictions on the use of those resources.[7] If the status of a species addressed under an HCP unexpectedly declines, the primary obligation for undertaking additional conservation measures rests with the federal government, other government agencies, or other non-federal landowners who have not yet developed HCPs. As explained by the federal fish and wildlife agencies:

> *"Once an HCP permit has been issued and its terms and conditions are being fully complied with, the permittee may remain secure regarding the agreed upon cost of conservation and mitigation. If the status of a species addressed under an HCP unexpectedly worsens because of unforeseen circumstances, the primary obligation for implementing additional conservation measures would be the responsibility of the Federal government, other government agencies, and other non-Federal landowners who have not yet developed an HCP."*[8]

However, the federal fish and wildlife agencies may, in the event of unforeseen circumstances, require additional measures provided they are limited to modifications within conserved habitat areas or to the conservation plan's operating conservation program for the affected species, and that these measures do not involve additional financial commitments or resource restrictions without the consent of the permittee. These assurances are provided to all HCP permittees that properly implement their plans. The No Surprise Rule, however, does not apply to Reclamation, which will use the BDCP as the basis for a biological assessment (BA) to support the issuance of take authorizations from USFWS and NMFS pursuant to Section 7 of the ESA for its actions in the Delta.

The assurances provided by the No Surprises rule, however, are not absolute and are tempered by other regulatory provisions of the ESA. The "Permit Revocation" rule moderates the scope of the No Surprises rule, providing that in instances where a species covered by an HCP is threatened with extinction, assurances may be nullified and USFWS may revoke the HCP permit.[9] The federal fish and wildlife agencies may exercise this authority even if a permittee is

[6] 63 Fed. Reg. 8859 (Feb. 23, 1998).
[7] *Id*. at 8868. The No Surprises rule was promulgated jointly by the Department of the Interior (Service) and the Department of Commerce (National Marine Fisheries Service).
[8] *Id.* at 8867.
[9] 50 C.F.R. § 17.22(b)(8).

in compliance with the terms and conditions of the permit, provided the permitted activity would appreciably reduce the likelihood of the survival and recovery of the species in the wild.[10]

*[**Note to Reviewers:** Additional text will be added regarding the application of the No Surprises rule to the various BDCP authorized entities]*

6.3.1.2 Regulatory Assurances under the NCCPA

Under the NCCPA, DFG provides assurances to permittees commensurate with the long-term conservation assurances and associated implementation measures that will be implemented under the plan.[11] In its determination of the level and term of the assurances to be afforded a permittee, DFG takes into account the conditions specific to the plan, including such factors as: the level and quality of information regarding covered species and natural communities, the sufficiency and use of the best available scientific information in the analysis of impacts on these resources, reliability of mitigation strategies, and appropriateness of monitoring techniques, including the use of centralized information to evaluate the effectiveness of the plan; the adequacy of funding assurances; the range of foreseeable circumstances that are addressed by the plan; and the size and duration of the plan.[12]

The assurances provided to the entities receiving permits under the NCCPA will, at a minimum, ensure that if there are unforeseen circumstances, no additional financial obligations or restrictions on the use of resources will be required of the permittees without their consent. Specifically, the NCCPA directs that, "[i]f there are unforeseen circumstances, additional land, water, or financial compensation or additional restrictions on the use of land, water, or other natural resources shall not be required without the consent of plan participants for a period of time specified in the implementation agreement, unless [DFG] determines that the plan is not being implemented consistent with the substantive terms of the implementation agreement."[13] However, like the provision in the ESA regulations, the NCCPA requires that DFG suspend or revoke a permit, in whole or in part, if the continued take of a covered species would jeopardize its continued existence.

6.3.2 Changed Circumstances

Ecological conditions in the Delta are likely to change as a result of future events and circumstances that may occur during the course of the implementation of the BDCP. The BDCP identifies changes in circumstances that are reasonably foreseeable and that could adversely affect species and natural communities covered by the plan, consistent with the "changed circumstances" provisions of ESA regulations and in the NCCPA.[14] To ensure successful

[10] 69 Fed. Reg. 71723, 71727 (December 10, 2004).

[11] Fish and Game Code section 2820 (f) states "*The department may provide assurances for plan participants commensurate with long-term conservation assurances and associated implementation measures pursuant to the approved plan.*"

[12] DFG bases its determination of the level of assurances on multiple factors. See Fish and Game Code section 2820(f).

[13] Fish and Game Code § 2820(f)(2).

[14] USFWS and NMFS regulations define changed circumstances as "changes in circumstances affecting a species or geographic area covered by a conservation plan that can reasonably be anticipated by plan developers and the [USFWS and NMFS] and that can be planned for…" (50

implementation of the BDCP conservation strategy, the plan further sets out measures designed to respond to these anticipated future changes.

The changed circumstances provisions of the BDCP are intended to address reasonably foreseeable events, both inside and outside of the Delta, that may impede or prevent the BDCP from achieving the biological benefit expected to result from the implementation of the conservation measures in the Plan Area. The BDCP identifies a broad range of potential changed circumstances, including events or conditions that may limit the biological benefits of the conservation measures, such as new invasive species and significant releases of pollutants, or the substantial degradation of habitat functions, from flooding or climate change.

Responses to the changed circumstances provided for in the BDCP will largely be developed and implemented as part of the adaptive management program.[15] For certain specified changed circumstances, measures beyond the scope of the adaptive management program have been developed, as described in this section. The responsive measures set out in the plan reflect approaches that are both practicable and roughly proportional to the impacts of covered activities on covered species and habitat.

Changed circumstances provisions are not intended to remedy events or conditions that are beyond the control of the permittees. Rather, these provisions are intended to protect the plan's operating conservation program in the face of such events. Thus, for example, in the event of changes in water temperatures in the Delta, the BDCP would not provide for actions to moderate such temperature changes. The BDCP, however, would require that the Implementation Office implement responsive actions or contingency plans that provide for a recalibration of habitat restoration strategies or other actions within the context of the defined range of the adaptive management program. Similarly, an occurrence of a major flood event that results in substantial loss of tidal marsh habitat restored under the BDCP would trigger actions under the adaptive management program to restore functions of tidal marsh habitat for covered species.

To address the potential for changed circumstances, the BDCP sets out funding commitments for responsive measures that may be implemented as part of the adaptive management program (Section 3.7, *Adaptive Management*). The BDCP also identifies contingency funding to implement measures to address those changed circumstances not contemplated in the adaptive management program, as described in Chapter 8, *Implementation Costs and Funding Sources*. In the event that changed circumstances occur, the Implementation Office will implement the responsive measures identified in this chapter. However, the BDCP sets out the range of financial commitments of the participating entities, which includes limitations on funding to remediate changed circumstances. As such, responsive measures for changed circumstances will be implemented within the levels of funding set out in the BDCP for these purposes and no

C.F.R. §17.3; 50 C.F.R §222.102). The NCCP Act defines changed circumstances as "…reasonably foreseeable circumstances that could affect a covered species or geographic area covered by the plan." (Fish and Game Code §2805(c)).

[15] See generally, U.S. Fish and Wildlife Service and National Marine Fisheries Service Habitat Conservation Planning Handbook, page 3-28 (November 1996).

additional funding will be required from permittees. [***Note to Reviewers****: The levels of funding for responsive measures have not yet been determined.*]

In the event of such changed circumstances, the BDCP Implementation Office would implement the responsive measures described in this chapter. The following describes the process for identifying the occurrence of changed circumstances, the changed circumstances that would be addressed by the BDCP, and the measures that would be implemented in response to such occurrences.

6.3.2.1 Process to Identify Changed Circumstances

The occurrence of a changed circumstance will generally become apparent to the Implementation Office through information gained from system-wide or effectiveness monitoring, scientific study, or by notification received from another party (e.g., contamination of a terrestrial area reported by a county health agency). Upon an indication that a changed circumstance has occurred, or is likely to occur, the Implementation Office will take immediate steps to investigate and confirm the occurrence of such an event. If a changed circumstance appears to have occurred, the Implementation Office will contact the appropriate fish and wildlife agencies to confirm the changed circumstance. The Implementation Office will notify the BDCP Authorized Entities, relevant Supporting Entities, and the Implementation Committee of the changed circumstance.

For changed circumstances that are anticipated in the BDCP, the Program Manager, in conjunction with the fish and wildlife agencies, will develop thresholds and triggers as appropriate that will be used to signal the onset of change circumstances. After establishing an occurrence of a changed circumstance identified in this chapter, the Implementation Office will determine specific responsive actions that are consistent with the responses described in Section 6.3.2.2, *Changed Circumstances Addressed by the BDCP*, for the particular changed circumstance and develop a schedule for implementation. The Implementation Office will, to the extent necessary, coordinate with the fish and wildlife agencies in the implementation of these responses. For those actions that are to be implemented through the adaptive management program, the decision-making process described in Section 3.7, *Adaptive Management*, will be used. For other responsive actions, the Implementation Office will implement the identified measures after conferring with the relevant fish and wildlife agencies. After implementing responsive actions, the Implementation Office will monitor the effectiveness of the measures and report the associated results and findings.

6.3.2.2 Changed Circumstances Addressed by the BDCP

[***Note to Reviewers:*** *The Steering Committee has initiated discussions of the changed circumstances described in this section and have identified several changed circumstances and topic areas for further discussion, including issues on availability of land, levee failures, failure of water operations facilities, and conflicts with other regulations that might affect water operations.]*

1. Availability of Land Necessary for the Implementation of Habitat Conservation Measures

Nature of the Changed Circumstance

The BDCP Conservation Strategy assumes that sufficient land will be available within the Plan Area to implement the habitat conservation measures set out in the BDCP. In the event that land suitable for these purposes is not available, these changed circumstances will be addressed as set out in this section. A shortfall in available land necessary to implement habitat conservation measures will be deemed to have occurred if land with suitable site conditions and characteristics (e.g., topography, soils, hydrology, proximity to occupied covered species habitats) and in appropriate locations within the Plan Area cannot be reasonably and practicably obtained.

Planned Response

During the course of BDCP implementation, the Implementation Office may determine that land suitable for meeting one or more of the habitat restoration and protection targets are not reasonably and practicably available within the Plan Area. In such instances, the Implementation Office, through the adaptive management process and after consultation with the fish and wildlife agencies, will take all reasonable and practicable steps to: (a) undertake habitat restoration or protection of habitat in areas outside of the BDCP designated Conservation Zone(s), including tidal ROAs, but within the Plan Area, at locations that would benefit the affected covered species, (b) restore or protect habitat in suitable locations outside of the Plan Area, in coordination with local governments, to benefit the associated covered species, or (c) identify and implement alternative conservation measures that would provide equivalent or greater benefits to the affected covered species.

2. Levee Failures

Nature of Changed Circumstance

During the course of BDCP implementation, it is expected that levee failures will occur within the Plan Area, and that such failures may affect benefits to covered species provided by the BDCP. To address such circumstances, the BDCP identifies a range of actions that will be carried out by the Implementation Office to respond to such events. To guide responses to such events, levee failures will be considered a changed circumstance under the BDCP if the failure: (a) diminishes significantly the function of BDCP restored and protected natural communities as habitat for covered species, as jointly determined by the Implementation Office and the fish and wildlife agencies, (b) precludes implementation of habitat conservation measures, and/or (c) impedes the implementation of water operations conservation measures.

Planned Responses

The following sets out several foreseeable scenarios involving the failure of levees that may adversely affect ecological benefits provided by the BDCP, and describes the response that would be provided for under the BDCP.

Failure of levees constructed as part of a BDCP activity result in substantial reduction of the level of benefits to covered species produced by BDCP restored tidal habitat. To reduce the potential for failure of a BDCP levee, BDCP levees will be designed to appropriate standards. However, notwithstanding the integrity of constructed levees, the BDCP Implementation Office may encounter circumstances in which levees constructed pursuant to a BDCP activity subsequently fail. In such an event, the Implementation Office will be responsible for undertaking actions to restore the functions of habitat degraded or lost as a result of the failure. If such restoration of habitat functions is not practicable, the Implementation Office will, through the adaptive management process, restore habitat of comparable biological value elsewhere in the Plan Area or at other locations to replace lost or degraded habitat functions to the extent practicable, as provided for under Changed Circumstance No. 1. The affected habitat may also be replaced at the location of the levee failure site if the breach results in newly created habitat of sufficient value to replace the lost habitat and the new habitat area is or can be made available to the Implementation Office for protection. The Implementation Office will coordinate with appropriate local agencies in developing and implementing the response to the levee failure.

Failure of levees not constructed as part of a BDCP activity reduce the benefits to covered species produced by BDCP tidal habitat restoration and water operations conservation measures. The BDCP Implementation Office is not responsible for repair of failed non-BDCP levees. Following failure of a non-BDCP levee that affects restored BDCP tidal habitat areas, the Implementation Office will determine the extent of effects on the habitat functions for covered species that are supported by the restored habitat. If the intended habitat functions of the restored tidal habitat for covered species are found to be substantially degraded, the BDCP Implementation Office will, to the extent reasonable and practicable, identify and undertake actions through the adaptive management process to adjust implementation of Conservation Measure *CM10: Nontidal Marsh Restoration* to restore or compensate for the degraded or lost habitat. If the failure of a non-BDCP levee affects the implementation of BDCP water operations conservation measures, the Implementation Office will invoke the adaptive management process to determine, in coordination with DWR and Reclamation and the fish and wildlife agencies, appropriate adjustments to water operations or other conservation measures, on a temporary basis and within the established adaptive range of water operations and other conservation measures. Once the circumstances affecting the implementation of the water operations conservation measures have been addressed, the SWP and CVP will resume operations under the parameters that were in place prior to the levee failure.

Failures of levees unrelated to BDCP activities that are not repaired by the responsible flood control entity and inhibit the implementation of water operations conservation measures or reduce the covered species and ecosystem benefits that would be provided by the conservation measure. The BDCP Implementation Office is not responsible for repair of failed non-BDCP levees. Following a determination that a failed non-BDCP levee will not be repaired, the Implementation Office will determine the extent of effects on the aquatic habitat functions for covered species that are supported by the affected water operations. If the intended ecological functions for covered species supported by the water operations are found to be substantially degraded, the BDCP Implementation Office and/or DWR and Reclamation will, through the adaptive management process and subject to the specific circumstances of the event, implement one or more of the following actions to obtain the intended benefits of water operations conservation measures precluded by levee failures: (a) adjust water operations within the permitted adaptive range of water operations to restore benefits to covered species and habitat provided by the measures, to the extent practicable or (b) identify and implement, within the context of the adaptive management program, alternative conservation measures (e.g., additional restoration of physical covered fish species habitats, increase in magnitude of other stressors conservation measures) that will provide similar types and levels of covered species benefits intended by the affected conservation measures. No additional response beyond that contained within the adaptive management program and permit assurances will be required.

Failure of multiple Delta levees substantially alter aquatic conditions such that conservation measures cannot be implemented and/or the covered species habitat benefits provided by conservation measures are substantially reduced as a result of altered aquatic ecosystem conditions or changes in the behavior or distribution of covered fish species. A widespread or catastrophic change in ecological conditions within the Plan Area due to multiple levee failures would be of such magnitude so as to render most responses through the BDCP infeasible. As such, in the event of this changed circumstance, no specific responses would be required under the BDCP; the Implementation Office and DWR and Reclamation, however, will identify and undertake actions to the extent reasonable and practicable within the parameters of the BDCP adaptive management program that would help to moderate the ecological effects of multiple levee failures. Such adaptive management responses would be limited to identifying alternative locations for habitat restoration actions, adjusting water operations within the adaptive management operations range, and adjusting implementation of other stressors conservation measures to more effectively provide benefits for covered fish species under the altered hydrodynamic conditions. The types and extent of potential adjustments in implementation may change over time as Delta conditions evolve towards a new equilibrium.

3. Failure of water operations infrastructure

Nature of Changed Circumstance

For the purpose of this provision, a failure of water operations infrastructure located within the Plan Area will be deemed to have occurred if a malfunction or breakdown of water operations conveyance facilities, including intake and fish screen facilities, pumping facilities, and other appurtenant facilities, and the failure precludes or substantially inhibits the ability to manage water operations within the water operations parameters in effect at the time of the infrastructure failure. Failure of the pipelines, tunnels or canal that comprises the principal conveyance facility are not reasonably foreseeable as a changed circumstance due to the nature of their planned construction.

Planned Response

The water operations infrastructure of the CVP and the SWP are routinely and diligently maintained to greatly reduce the potential for failure. In the unlikely event of such a failure of infrastructure within the Plan Area, the Implementation Office would request that DWR and/or Reclamation repair the affected facilities or make adjustments or modifications to other facilities to restore full operational capacity necessary to implement BDCP conservation measures, as soon as reasonable and practicable, and temporarily adjust water operations within the adaptive range of water operations if such action is deemed necessary to minimize adverse effects on covered species to the extent practicable. Upon completion of facility repairs or alternative modifications to other infrastructure, operations would return to pre-existing levels, parameters and water supply. If the infrastructure failure does not permit operations within the adaptive management range the Implementation Office will operate under the emergency procedures described in Chapter 4, *Covered Activities*.

4. Fire

Nature of Changed Circumstance

Fire is defined as any fire not prescribed by the Implementation Office on BDCP protected lands that removes a sufficient extent of vegetation such that the intended habitat functions of the protected land for covered species is substantially degraded, as jointly determined by the Implementation Office and fish and wildlife agencies.

Fire may substantially degrade the intended habitat functions of natural communities and covered species habitats protected and/or restored under the BDCP. However, the non-aquatic lands within the Plan Area are primarily characterized by intensively managed agriculture, which generally does not provide the conditions for uncontrolled or extensive fire events. Moreover, within the Plan Area, the extensive network of waterways serves as barriers to the rapid spread of fire. While fire is typically a natural component of grassland communities, which represent approximately 8 percent of the Plan Area, most natural communities in the Plan Area, including valley/foothill riparian, wetlands, and agriculture, are typically not prone to fire.

Planned Response

To minimize the risk of fire, the Implementation Office will identify BDCP protected lands that pose a high risk of fire (e.g., grasslands situated near roadways) and carry out a number of preventative measures on those lands. The Implementation Office will ensure that fuel breaks are established and maintained around such lands and that post-fire monitoring plans are developed.

In the event of a fire, the Implementation Office will assess the proportion of the protected habitat area that has burned and its likely effects on habitat use by covered species, will make an initial determination of whether or not a changed circumstance exists, and will notify the fish and wildlife agencies of the fire event. If a changed circumstance is determined to exist, the Implementation Office will implement the appropriate post-fire monitoring plan for a two-year period following the fire. If over the course of the monitoring period it is determined that vegetation is not recovering sufficiently in the burned area to reestablish the original functions of the affected habitat, the Implementation Office will develop and implement through the adaptive management program to the extent practicable a habitat restoration plan to enhance recovery of the affected habitat area. Elements of habitat restoration plans may include provisions for planting and caring for native vegetation and controlling the establishment of invasive plant species.

5. Conflicts related to state or federal environmental laws or regulation

Nature of the Changed Circumstance

In the course of implementing the BDCP, the Implementation Office will seek to obtain various state and federal permits and authorizations necessary to carry out certain conservation actions. The Implementation Office may discover that, in some instances, the implementation of a conservation measure may conflict with the requirements of a state and/or federal law or regulation. The apparent conflict could necessitate changes to the conservation measure or an elimination of the measure altogether.

Planned Response

In the event that it is determined that the implementation of a conservation measure would likely conflict with a state or federal environmental law or regulation, the Implementation Office will pursue one or more of the following actions through the adaptive management process: (a) modify implementation of the conservation measures to ensure compliance with all applicable state and/or federal laws or regulations; (b) identify and implement alternative conservation measures that provide equivalent ecological benefits for the affected covered species. In the alternative, the Implementation Office may also sufficiently reconcile the apparent regulatory conflict in conjunction with the relevant state and/or federal agency and proceed with the implementation of the conservation measure(s).

6. New Species Listings

Nature of the Changed Circumstance

The USFWS, NMFS, or DFG may list additional species as threatened or endangered under the ESA or CESA[16] that occur in the Plan Area that are not BDCP Covered Species. In the event that a fish and wildlife agency lists a species not covered by the BDCP, the provisions of this changed circumstance will be automatically triggered.

Planned Response

Upon a new listing of a species under state or federal endangered species laws, the Implementation Office will undertake the following measures:

[16] A species designated by the State as a "candidate" for listing also receives regulatory protection during the pendency of the candidacy. As such, the provisions set out in this changed circumstance will apply to State-designated candidate species.

- Evaluate the potential impacts of covered activities on the newly-listed species and conduct an assessment of the presence of suitable habitat in areas of potential effect.
- Implement measures to avoid impacts to the newly listed species until such time as the BDCP has been amended to include the newly listed species as a covered species.

In the event that a species not covered by the BDCP becomes listed as threatened or endangered or designated as a candidate species, or is proposed or petitioned for listing, the Implementation Office, on behalf of the Authorized Entities, may request that the appropriate fish and wildlife agency add the species to the relevant take authorizations issued pursuant to the BDCP. In determining whether to seek take coverage for the species, the Implementation Office will consider, among other things, whether the species is present in the Plan Area, if the covered activities could result in the take of the species, and if the existing conservation measures benefit the species and avoid and minimize effects of covered activities on the species. If such take coverage is sought, the BDCP and its authorizations will be amended. Alternatively, the Implementation Office, on behalf of the Authorized Entities could seek new and separate take authorizations. The procedures for Plan modifications and amendments are described in Section 6.4 *Permit Duration and Renewal, Plan Amendments, Permit Suspension and Revocation*.

7. Invasive Species

Nature of Changed Circumstance

A changed circumstance that involves the introduction of an invasive species will be considered to have occurred if the Implementation Office and the fish and wildlife agencies jointly determine that such a species is present and has been established within the Plan Area and that the presence of the invasive species will substantially diminish the benefits to covered species provided by the BDCP conservation measures.

Planned Response

As described in Section 3.6, *Monitoring and Research Plan*, the Implementation Office will take steps to detect, through the monitoring program and through collaboration with other responsible entities, the establishment of new invasive species in the Plan Area. If a new invasive species is discovered, the Implementation Office in coordination with the fish and wildlife agencies will conduct an assessment to determine the possible threats of the invasive species to covered species and the Delta ecosystem. Based on results of the assessment, the Implementation Office will, within the parameters of the adaptive management program, identify and implement, to the extent reasonable and practicable, measures to reduce and/or control the adverse effects of new nonnative species on the functions provided by the conservation measures under the Plan (e.g., control of nonnative plant species in restored tidal marsh that affect food web functions). If methods to adequately reduce and/or control adverse effects of the nonnative species on the functions of restored physical habitats are not available or practicable, the Implementation Office will identify reasonable and practicable alternate design, implementation, and management approaches to future habitat restoration actions within the parameters of the adaptive management program to avoid or minimize potential adverse effects of the invasive species on covered species. If methods are not reasonably and practicably available to reduce and/or control adverse effects of invasive species on water operations, physical habitat, and other conservation measures, the BDCP Implementation Office, within defined adaptive management ranges, will identify and implement alternative conservation measures that provide equivalent or greater benefits to covered species and their habitats to the extent reasonable and practicable.

8. Toxic or Hazardous Spills

Nature of Changed Circumstance

Toxic or hazardous spills will be considered a changed circumstance if the spills of chemicals into Delta waterways or BDCP restored and protected habitats could substantially and adversely affect habitat restored and/or protected through the BDCP, as jointly determined by the Implementation Office and the Fish and Wildlife Agencies.

Planned Responses

The Implementation Office will respond to toxic or hazardous spill events that occur in habitat areas that have been protected, enhanced, or restored through BDCP actions. To minimize the potential effects of a toxic or hazardous spill, the BDCP Implementation Office will develop a toxic and hazardous spill response plan in coordination with responsible regulatory entities (e.g., local, state and federal specialized response teams) to guide its initial responses on detection of a spill event.

For a spill event that is caused by a BDCP action, the BDCP Implementation Office will coordinate its response with DFG's Office for Oil Spill Prevention, the Regional Water Quality Control Board, and other state or federal regulatory entities as appropriate to the nature of the spill event to curtail the immediate spread and minimize the effects of the spill. The Implementation Office will also identify and undertake management measures sufficient to remediate the effects of the toxic substance on covered species and affected habitats (i.e., removal or isolation of the material) and restore the ecological functions of the degraded habitat. If the affected habitat areas cannot be practicably and effectively restored, the Implementation Office, through the adaptive management process, will identify and implement measures to contain the ecological effects of the spill and either compensate for the loss of habitat functions at other locations or implement alternative conservation measures (e.g., expanded or additional contaminant reduction measures) that provide equivalent or greater ecological benefits to the affected covered species.

The BDCP Implementation Office is not responsible for the effects of a spill event that is not the result of a BDCP action. If the spill event is not caused by a BDCP action, the BDCP Implementation Office, would coordinate with responsible regulatory agencies and the party(ies) responsible for the spill event to identity the measures that will need to be funded and/or undertaken by the responsible party(ies) to adequately remediate the effects of the spill and restore the ecological functions of the affected habitat.

9. Climate Change

Nature of Changed Circumstance

The BDCP conservation measures were developed to address the range of predicted effects of climate change on sea level and watershed hydrology over the term of the BDCP using the best scientific information available. Consequently, changes in sea level and watershed hydrology that are of greater magnitude or significance than was assumed during the development of the BDCP conservation strategy are considered a changed circumstance.

Planned Response

In the event changes in sea level and watershed hydrology exceed those used to develop the BDCP conservation strategy, no response is required under the BDCP. The BDCP Implementation Office in coordination with the fish and wildlife agencies, however, may identify and adjust implementation of habitat conservation measures through the parameters of the adaptive management program to the extent such adjustments could be effective at moderating the ecological effects of these hydrological changes. Such adaptive management responses may include expanding the range of environmental gradients to provide for shifting species distributions and habitats. Measures beyond those contemplated by the adaptive management program for habitat conservation measures would likely be impracticable and ineffective given the magnitude and pervasiveness of such changes within Plan Area and, as such, are not provided for under the BDCP.

10. Water Temperature Changes

Nature of Changed Circumstance

Changed circumstances related to water temperature changes are defined as those changes in water temperatures within the Plan Area that exceed the tolerance level for one or more covered fish species, such that one or more of the following conditions occur: (a) a covered fish species no longer inhabits BDCP restored habitats; (b) a covered fish species is no longer present in the Plan Area; (c) a covered fish species no longer accrues benefits from BDCP water operations, habitat restoration, or other stressors conservation measures; and/or (d) a covered fish species' population demonstrates a sustained downward trend in abundance.

Planned Response

Significant changes in water temperature within the Plan Area would likely have widespread, catastrophic impacts on ecological conditions within the Plan Area. As such, the effects of water temperature changes would be of such magnitude as to render any response through the BDCP infeasible and no response to changes in water temperature is required under the BDCP. The BDCP Implementation Office in coordination with the fish and wildlife agencies, however, may identify and implement habitat restoration conservation actions within the parameters of the adaptive management program to the extent such actions could be reasonably and practicably effective at moderating the ecological effects of changed water temperatures. For instance, such adaptive management responses may include identifying alternative locations for implementing habitat restoration actions within the Plan Area such that they create areas of cool water refugia or encourage more rapid passage of covered fish species through areas supporting unsuitable water temperatures for covered fish species.

11. Changes in Ocean Conditions

Nature of Changed Circumstance

Changed circumstances that involve changes in ocean conditions are defined as changes in ocean habitat conditions (e.g., water temperature, upwelling) and ecosystem processes (e.g., food web productivity) that support covered anadromous fish species to a degree that biological goals and objectives cannot be achieved for covered anadromous fish species within the Plan Area. For example, changed ocean conditions could result in lower survival of Chinook salmon in the ocean, resulting in fewer adults returning to spawn upstream of the Delta, which could result in population declines.

Planned Response

Adverse effects on covered anadromous fish species and their habitats resulting from changed ocean conditions could not be reasonably or practicably addressed by the BDCP. Actions to remedy those effects would be well-beyond the capacity of the Implementation Office or the Authorized Entities and no response is required under the BDCP.

12. Long-Term Changes in Precipitation and Temperature

Nature of Changed Circumstance

Long-term changes in precipitation and temperature will be considered a changed circumstance in the event that such changes in the timing and amount of rainfall and ambient air temperature in the Plan Area as a result of climate change are of a magnitude sufficient, as jointly determined by the Implementation Office and Fish and Wildlife Agencies, to diminish the benefit to covered species provided by natural communities restored and protected pursuant to the BDCP conservation measures.

Planned Response

Changes in precipitation and temperature patterns in the Plan Area may affect vegetation composition and structure of BDCP protected, enhanced, and restored habitat areas. In the event of this changed circumstance, the BDCP Implementation Office will identify and implement reasonable and practicable actions within the parameters of the adaptive management program to the extent such actions would help to moderate the ecological effects of changes in precipitation and temperature. Such adaptive management responses may include expanding the range of environmental gradients to provide for shifting species distributions and habitats. Measures beyond those contemplated by the adaptive management program would likely be impracticable and ineffective given the magnitude and pervasiveness of such changes within Plan Area and, as such, are not provided for under the BDCP.

6.3.3 Unforeseen Circumstances

The USFWS and NMFS define unforeseen circumstances as those changes in circumstances that affect a species or geographic area covered by an HCP that could not reasonably have been anticipated by the plan participants during the development of the conservation plan, and that result in a substantial and adverse change in the status of a covered species.[17] Under ESA regulations, if unforeseen circumstances arise during the life of the BDCP, USFWS and/or NMFS may not require the commitment of additional land or financial compensation, or additional restrictions on the use of land, water, or other natural resources other than those agreed to in the Plan, unless the BDCP authorized entities consent.

Within these constraints, USFWS and/or NMFS may require additional measures, but only if: (1) the agencies prove an unforeseen circumstance exists; (2) such measures are limited to modifications of the BDCP's operating conservation program for the affected species; (3) the original terms of the Plan are maintained to the maximum extent practicable; and (4) the overall cost of implementing the BDCP is not increased by the modification. USFWS and/or NMFS bear the burden of demonstrating that unforeseen circumstances exist. A finding of unforeseen circumstances must be clearly documented, based upon the best available scientific and commercial information and made considering certain specific factors.[18] If such a finding is made and additional measures are required, the BDCP authorized entities will work with USFWS and/or NMFS to appropriately redirect resources to address the unforeseen circumstances.

Similarly, unforeseen circumstances are defined in the NCCPA as changes affecting one or more species, habitat, natural community, or the geographic area covered by a conservation plan that could not reasonably have been anticipated at the time of plan development, and that result in a substantial adverse change in the status of one or more covered species.[19] The NCCPA further provides that, in the event of unforeseen circumstances, DFG shall not require additional land, water, or financial compensation or additional restrictions on the use of land, water, or other natural resources without the consent of the plan participants for a period of time specified in the Implementation Agreement. However, such assurances are not applicable in those circumstances in which DFG determines that the plan is not being implemented consistent with the substantive terms of the Implementation Agreement. [20]

[17] 50 C.F.R. §17.3; 50 C.F.R. §222.102

[18] These factors include the following: (1) Size of the current range of the affected species; (2) Percentage of range adversely affected by the conservation plan; (3) Percentage of range conserved by the conservation plan; (4) Ecological significance of that portion of the range affected by the conservation plan; (5) Level of knowledge about the affected species and the degree of specificity of the species' conservation program under the conservation plan; and (6) Whether failure to adopt additional conservation measures would appreciably reduce the likelihood of survival and recovery of the affected species in the wild. 50 C.F.R. §17.22(b)(5)(iii)(C); 50 C.F.R. §222.307(g)(3)(iii).

[19] Fish and Game Code §2805(k)

[20] Fish and Game Code §2820(f)(2)

6.3.4 Applicability of Other Federal Endangered Species Act Issues to the BDCP

6.3.4.1 Future Recovery Plans

Recovery plans under the ESA delineate actions necessary to recover and protect federally listed species. However, these plans are not intended to establish obligations of permittees to undertake specific tasks.

The plan participants, USFWS, and NMFS acknowledge that ESA recovery plans will have no effect on the implementation of the BDCP, except to the extent that they may contribute information to the Adaptive Management Program. Any recovery plan applicable to any Covered Species within the Plan Area that is developed after the approval of the BDCP will:

- Not require any additional water, land, or financial compensation be provided by the Authorized Entities;
- Be finalized only after the USFWS or NMFS has conferred with and requested input from the Implementation Office on the preparation of the recovery plan; and
- In no way diminish the take authorizations provided pursuant to the BDCP, the IA, and the companion biological assessment.

6.3.4.2 Future Section 7 Consultations

The USFWS and NMFS will evaluate the direct, indirect and cumulative effects of the Covered Activities in its internal biological opinion that will be issued in connection with the BDCP and issuance of the Section 10(a) permits and the biological opinion that will be issued to Reclamation. Accordingly, in any consultation under Section 7 that occurs after the approval of the BDCP, the USFWS and NMFS will ensure that any biological opinion issued in connection with the proposed project that is the subject of the consultation is consistent with the BDCP biological opinions. The proposed project must be consistent with the terms and conditions of the BDCP and the IA. Any reasonable and prudent measures included under the terms and conditions of a biological opinion issued subsequent to the approval of the BDCP with regard to the Covered Species and Covered Activities will, to the maximum extent appropriate, be consistent with the measures of the BDCP and the IA. Neither the USFWS nor NMFS will impose measures in excess of those that have been or will be required by the Authorized Entities pursuant to the BDCP, the IA, or the companion biological assessment.

6.4 Permit Duration and Renewal, Plan Amendments, Permit Suspension and Revocation

6.4.1 Permit Duration and Extension

The Plan Participants are seeking take authorizations from the state and federal fish and wildlife agencies with terms of 50 years. The term of the take authorizations issued under the BDCP would begin from the date of their issuance. Prior to their expiration, the authorized entities may apply to the fish and wildlife agencies to renew their take permits. The Permittees will initiate the permit renewal process prior to the expiration of the initial 50-year period and with ample time to allow for the review and processing of the permit renewal.

The proposed 50-year term is necessary to achieve the overall BDCP goals of water supply reliability and ecosystem restoration. Many of the key elements of the BDCP, including the development of substantial new water conveyance infrastructure, restoration of tidal and estuarine habitats, restoration of seasonal floodplain habitat, and establishment and maturation of riparian forest habitat will require substantial commitments of funding and an extended period of time to fully implement. The duration of the permits must be sufficient to justify such expenditures of funds, allow for proper sequencing and effective implementation of the actions contemplated by the Plan, and afford regulatory stability with respect to the operation of the primary water delivery systems for the state of California. A permit term of 50 years provides a practicable time frame in which to carry out the activities that will be authorized under the Plan, including adaptive management strategies, and maximize the benefits of these activities to species and their habitats.

6.4.2 BDCP Administrative Actions That Do Not Require Modification or Amendment

The administration and implementation of the BDCP will require frequent and ongoing interpretation of the provisions of the Plan. Actions taken on the basis of these interpretations that do not substantively change the purpose or intent of the plan provisions will not require modification or amendment of the BDCP or its associated authorizations. Such actions related to the ordinary administration and implementation of the BDCP may include, but are not limited to, the following:

- Clerical corrections to typographical, grammatical, and similar editing errors that do not change the intended meaning; or to maps or other exhibits to address insignificant errors.
- Adaptive management changes to conservation measures, including actions to avoid, minimize, and mitigate impacts, or modifications to habitat management strategies developed through and consistent with the Adaptive Management Program described in Chapter 3.

- Variations in the day-to-day management of reserve system lands, such as adjusting irrigation schedules for created or restored habitat on the basis of observed water needs of planted vegetation;
- Adaptations to the design of directed studies;
- Adjustments to monitoring protocols to incorporate new protocols approved by the Fish and Wildlife Agencies;
- Administration of the Implementation Office;
- Changes in the membership of BDCP advisory committees.

6.4.3 Minor Modifications or Revisions

As part of the process of plan implementation, the Implementation Office will likely need to make minor changes ("Minor Modifications or Revisions") to the BDCP from time to time to respond appropriately to new information, scientific understanding, technological advances, and other such circumstances. Minor Modifications or Revisions will in many instances be technical in nature and will not involve changes that would adversely affect covered species, the level of take, or the obligations of Authorized Entities. The process for implementing Minor Modifications or Revisions is set forth in Section 6.4.3.1 below.

Minor Modifications or Revisions may include, but are not limited to, the following circumstances:

- Minor corrections to land ownership descriptions;
- Changes to survey, monitoring, reporting and/or management protocols that do not adversely affect Covered Species or habitat functions and values;
- Transfers of targeted acreages between ROA consistent with criteria set out in Chapter 3, *Conservation Strategy*;
- Transfers of targeted habitat acreages among BDCP Conservation Zones provided such change does not preclude meeting preserve assembly requirements, significantly increase the cost of the BDCP management or preclude achieving Covered Species and natural community goals and objectives; and
- Extensions of earth moving or ground disturbance outside the rights-of-way limits analyzed in the BDCP for covered activities involving infrastructure development or habitat restoration.
- Updates/corrections to the vegetation or other resource maps and/or species occurrence data.
- Other proposed changes to the Plan that the permitting agencies have determined to be insubstantial and appropriate for implementation as a Minor Amendment

6.4.3.1 Procedures for Minor Modifications or Revisions

The Implementation Office, the Authorized Entities, or the fish and wildlife agencies may propose Minor Modifications or Revisions by providing written notice to the Implementation Office, Authorized Entities, and fish and wildlife agencies. Such notice will include a description of the proposed Minor Modifications or Revisions, an explanation of the reason for the proposed Minor Modifications or Revisions, an analysis of its environmental effects including any impacts to Covered Species, and an explanation of why the effects of the proposed Minor Modifications or Revisions would not:

1. Significantly differ from, and would be biologically equivalent to, the effects described in the BDCP, as originally adopted;
2. Conflict with the terms and conditions of the BDCP, as originally adopted; and
3. Significantly impair implementation of the BDCP Conservation Strategy.

The fish and wildlife agencies and/or the Authorized Entities may submit comments on the proposed Minor Modification or Revision in writing within sixty (60) days of receipt of notice. If any Authorized Entity disagrees with the proposed Minor Modification or Revision for any reason, the Minor Modification or Revision will not be incorporated in the BDCP. If the fish and wildlife agencies do not concur that the proposed Minor Modification or Revision meets the requirements for a Minor Modification or Revision, the proposal must be approved according to the Amendment process. Any Authorized Entity or fish and wildlife agency may institute the informal meet and confer process set forth in the BDCP Implementing Agreement to resolve disagreements concerning a proposed Minor Modifications or Revisions.

If the Authorized Entities are in agreement regarding the proposed Minor Modification or Revision, and the fish and wildlife agencies concur that the requirements for a Minor Modification or Revision have been met and the modification or revision should be incorporated in the Plan, the BDCP will be modified accordingly. If any fish and wildlife agency fails to respond within the 60-day period to the written notice, the agency will be deemed to have approved the proposed Minor Modification or Revision.

6.4.4 Formal Amendment

Under some circumstances, it may be necessary to substantially amend the BDCP. Any proposed changes to the BDCP that do not qualify for treatment under Sections 6.4.2 or 6.4.3 will require Formal Amendment. Formal Amendment to the BDCP will also require corresponding amendment to the Authorizations/Permits, in accordance with applicable laws and regulations regarding permit amendments. The BDCP Implementation Office will be responsible for submitting any proposed Amendments to the fish and wildlife agencies.

Amendments to the BDCP will likely occur infrequently. The process for making Formal Amendments is set forth in Section 6.4.4.1 below. Formal Amendments include, but are not limited to, the following:

- Substantive changes to the boundary of the Plan Area, other than those associated with the acquisition of terrestrial habitat within the surrounding Delta counties, as described in Section 1.4.1, *Geographic Scope of the Plan Area*;
- Additions of species to the Covered Species list;
- Substantial changes in implementation schedules that would have significant adverse effects on the Covered Species;
- Changes in water operations conservation measures or covered water operations that are outside of the ranges established in the Plan for water operations.

6.4.4.1 Process for Formal Amendment

Formal Amendments will involve the same process that was required for the original approval of the BDCP. In most cases, an Amendment will require public review and comment, CEQA/NEPA compliance, and intra-Service Section 7 consultation. Amendments will be subject to review and approval by the Implementation Office and the Permittees. The Fish and Wildlife Agencies will use reasonable efforts to process proposed Amendments within one hundred eighty (180) days.

6.4.5 Suspension of the Federal Permits

Under certain circumstances defined by federal regulation, USFWS or NMFS may suspend, in whole or in part, the regulatory authorizations they issue under the BDCP. However, except where USFWS or NMFS determines that emergency action is necessary to avoid irreparable harm to a Covered Species, it will not suspend an authorization without first (1) attempting to resolve the issue through the informal dispute resolution process set forth in the BDCP Implementing Agreement, and (2) identifying the facts or action/inaction which may warrant the suspension and providing the Implementation Office a reasonable opportunity to implement appropriate responsive actions. Any decision to suspend one or both federal permits must be in writing and must be signed by the Secretary of the Interior and/or the Secretary of Commerce, as the case may be.

6.4.5.1 Reinstatement of Suspended Federal Permit

If USFWS or NMFS suspends a federal permit, as soon as possible but no later than 10 days after the suspension, it will meet and confer with the Implementation Office and Permittees to discuss how the permits can be reinstated. At the conclusion of the meeting, USFWS/NMFS will identify reasonable, specific actions needed to address the suspension. Upon performance or completion of the actions, USFWS and/or NMFS will immediately reinstate the federal permit.

It is the expectation of the BDCP participants that the federal fish and wildlife agencies and the permit holders will strive to reinstate the Federal Permit as soon as possible.

6.4.5.2 Revocation of the Federal Permits

Unless immediate revocation is necessary to avoid the likelihood of jeopardy to a listed species, USFWS and NMFS will not revoke the Federal Permits unless the Authorized Entities fail to fulfill their obligations under the BDCP, and only after (1) completing the informal dispute resolution process described in the BDCP Implementing Agreement, and (2) identifying the actions/inactions that may warrant the revocation and giving the Implementation Office a reasonable opportunity to implement appropriate responsive actions. USFWS and NMFS will revoke or terminate a Federal Permit to avoid the likelihood of jeopardy to a listed species only in accordance with the Federal Permit Revocation Rule as described below. Any decision to revoke one or both Federal Permits must be in writing and must be signed by the Secretary of the Interior and/or the Secretary of Commerce, as the case may be.

6.4.5.3 The Federal Permit Revocation Rule

The No Surprises rule, as promulgated in 1998, did not address circumstances in which a species covered by a permitted HCP experienced significant decline and the continuation of an activity covered by the HCP would contribute to the likelihood of jeopardy to the species. To address such circumstances, the USFWS issued a regulation in 2004, known as the "Permit Revocation Rule," that allows the FWS to nullify regulatory assurances granted under the No Surprises rule and revoke the Section 10 permit only in specified instances, including where continuation of a permitted activity would jeopardize the continued existence of a species covered by an HCP and the impact of the permitted activity on the species has not been remedied in a timely manner.[21]

In the event that such unforeseen circumstances were to arise under the BDCP, the USFWS and/or NMFS would work with the BDCP Implementation Office and the Authorized Entities to obviate the need for such a revocation. The federal Fish and Wildlife Agencies would engage in the following process prior to taking any steps to revoke the BDCP permits:

1. The BDCP Implementation Office and the Fish and Wildlife Agencies would determine, through the adaptive management process, whether changes can be made to the BDCP's operating conservation program to remedy the situation.
2. The USFWS and/or NMFS would determine whether the Fish and Wildlife Agencies or other state and federal agencies can undertake actions that would remedy the situation. It is recognized that the fish and wildlife agencies have available a wide array of authorities and resources that can be used to provide additional protection for the species, as do other state and federal agencies.

[21] 69 Fed. Reg. 71723, December 10, 2004

3. The Implementation Office and the Fish and Wildlife Agencies will determine whether there are additional voluntary conservation actions that the Implementation Office could undertake to remedy the situation.

The USFWS and/or NMFS would only begin the revocation process if no solutions are found and it is determined that the continuation of a BDCP covered activity would appreciably reduce the likelihood of survival and recovery for one or more covered species and that no remedy can be found and implemented. The USFWS and/or NMFS would follow the administrative procedures set out in the BDCP IA and the regulations implementing the Permit Revocation Rule (50 C.F.R. §§ 13.28 & 13.29).

6.4.6 Suspension or Revocation of the State Permit

The NCCPA requires that the implementation agreement include specific terms and conditions that, if violated, result in suspension or revocation of the Section *2835* take permit. Such terms and conditions must include suspension or revocation of the permit if the plan participants fail to provide adequate funding to implement the plan; do not maintain proportionality between impacts on habitats or covered species and conservation measures; adopt or approve changes to the plan that are not consistent with the objectives and requirements of the approved plan without concurrence of the wildlife agencies; or allow the level of take to exceed the permit limits.[22] The DFG must also suspend or revoke a Section 2835 take permit if continued take would result in jeopardy to a species.[23]

If the Authorized Entities violate the terms and conditions of the state permits, or if necessary to avoid jeopardizing the continued existed of a listed species, DFG may suspend or revoke the permits in whole or in part. However, unless immediate revocation is necessary to avoid the likelihood of jeopardy to a listed species or to address rough proportionality (see below), DFG will not suspend or revoke the state permits without first (1) attempting to resolve any disagreements regarding the implementation or interpretation of the BDCP or this Agreement in accordance with the informal dispute resolution process provided in the BDCP Implementing Agreement, and (2) notifying the Implementation Office and permittees of the action/inaction that may warrant the suspension or revocation and providing the Implementation Office and permittees with a reasonable opportunity to take appropriate responsive action. Any decision to suspend or revoke one or both state permits must be in writing and must be signed by the Director of DFG.

6.4.6.1 Failure to Maintain Rough Proportionality

The NCCPA requires revocation of a Section 2835 take permit, in whole or in part, if the plan participants do not maintain rough proportionality between impacts on habitats or covered

[22] Fish and Game Code § 2820(b)(3).
[23] California Fish & Game Code section 2823.

species and conservation measures and do not, within 45 days, remedy such condition or develop a plan with the DFG to provide a remedy.[24]

Rough proportionality will be maintained by implementing the conservation measures substantially in accordance with the agreed upon Plan Implementation Schedule. If DFG determines, after conferring with USFWS, NMFS and the Implementation Office, that rough proportionality is not being maintained, the Implementation Office, permittees, and DFG will meet and confer and, within 45 days of DFG's determination, agree on adjustments to the Implementation Schedule to expeditiously regain rough proportionality. Adjustments to the Implementation Schedule may include any of a variety of commitments or adjustments to BDCP implementation designed to regain rough proportionality, including advancing and/or accelerating plans to acquire, restore, or enhance lands of the appropriate land cover type. The Implementation Office will implement all actions set forth in the agreed upon adjusted Implementation Schedule. As an alternative to the agreement, the Implementation Office may regain rough proportionality within forty-five (45) days by implementing the actions according to the existing Implementation Schedule.

6.4.6.2 State Permit Suspension and Revocation Steps

In the event that such circumstances for permit revocation or suspension were to arise under the BDCP, the DFG would work with the BDCP Implementation Office and the permittees to obviate the need for permit revocation or suspension. The DFG would engage in the following process prior to taking any steps to revoke the BDCP permits:

1. In the event of a failure to maintain rough proportionality, the BDCP Implementation Office will work with DFG to remedy the situation though schedule adjustments as described in Section 6.4.6.1 above and in accordance with the Implementation Agreement. Note that the BDCP monitoring program is designed to identify such issues and that the Implementation Office must report such issues in annual reports.
2. For other situations that could result in permit revocation or suspension or if rough proportionality cannot be regained through schedule adjustments, the BDCP Implementation Office, Permittees, and the DFG would determine, through the adaptive management process, whether other changes can be made to the BDCP's operating conservation program to remedy the situation.
3. The DFG would determine whether the DFG or the federal fish and wildlife agencies or other state and federal agencies can undertake actions that would remedy the situation. It is recognized that the fish and wildlife agencies have available a wide array of authorities and resources that can be used to provide additional protection for the species, as do other state and federal agencies.

[24] Fish and Game Code §-2820(c).

4. The Implementation Office and DFG will determine whether there are additional voluntary conservation actions that the Implementation Office could undertake to remedy the situation.

The DFG would only begin the revocation or suspension process if no solutions are found and it is determined that the continuation of a BDCP covered activity would result in jeopardy to a species or violate any of the terms and conditions for permit revocation or suspension identified in the IA.

CHAPTER 7. IMPLEMENTATION STRUCTURE

CHAPTER 7. IMPLEMENTATION STRUCTURE

[***Note to Reviewers:*** *This draft of Chapter 7, Implementation Structure, includes revisions to the November 4, 2010 draft provided to the Steering Committee. Prior drafts of this chapter have been reviewed by the Steering Committee on the following dates: October 22, 2009, October 20, 2010, November 4, 2010. The consultant and certain committee members revised the November 4, 2010 draft in response to comments made by the Steering Committee at the November 4, 2010 meeting; these revisions have not been reviewed by the Steering Committee, to date. The chapter reflects input from a wide range of agencies and stakeholders over several years of development. Although certain issues will require further discussion, this draft reflects a general agreement on both the overall approach and many of the specific details related to an implementation structure for the BDCP. While the text of this chapter is subject to change and revision as the BDCP planning process progresses, the chapter has been drafted and formatted to appear as it may in a completed draft HCP/NCCP. Although the chapter includes declarative statements (e.g., the Implementation Office will…), it is nonetheless a "working draft" that will undergo further modification based on input from the BDCP Steering Committee, state and federal agencies, and the public.*]

This chapter describes the institutional structure and organizational arrangements that will be established to govern and implement the BDCP, and sets out the roles, functions, authorities, and responsibilities of the various entities that will participate in plan implementation. The implementation structure is designed to ensure that sufficient institutional expertise, capacity, resources, and focus are brought to bear to accomplish the goals and objectives of the BDCP.

The BDCP implementation structure will help ensure effective and efficient plan implementation and ongoing compliance with the terms and conditions of the plan and its associated regulatory authorizations. This implementation approach will also facilitate the clear delineation of roles and responsibilities among the range of public and private entities participating in the process and help define the nature of their engagement. This approach further reflects the commitment to maintain and encourage ongoing collaboration among the range of public and private parties with interest in the Delta, and to facilitate adaptive and responsive plan implementation, guided by new information and scientific understanding.[1]

The approaches to plan governance set out in this chapter have been designed solely to facilitate the implementation of BDCP actions. If over the course of plan implementation matters arise that are outside the scope of the BDCP, any proposed actions related to those new matters may be implemented through the BDCP only upon appropriate modifications and/or amendments to the Plan.

[1]The BDCP implementing agreement includes additional detail regarding the roles and responsibilities of the authorized entities, the Implementation Office, and the fish and wildlife agencies regarding the implementation of the Plan.

The BDCP implementation structure will be organized around a Program Manager who will direct a new "BDCP Implementation Office" (IO), and have responsibility for plan implementation and oversight (Figure 7-1). The BDCP Program Manager will coordinate implementation actions with the authorized entities (i.e., all entities receiving permits or other authorizations under ESA, NCCPA, and/or CESA), the State and federal contractors, the fish and wildlife agencies, and a range of stakeholders and other interests. The State and federal fish and wildlife agencies will maintain the roles described in this chapter to assure that such implementation is consistent with regulatory authorizations issued pursuant to the BDCP. In addition, a "BDCP Implementation Board" will be established to assist with BDCP implementation, and will consist of representatives of the Department of Water Resources (DWR) and the U.S. Bureau of Reclamation (Reclamation), the State and Federal Contractor Water Authority (SFCWA), the State and federal fish and wildlife agencies, and certain other entities as described later in this chapter. Additionally, a "BDCP Stakeholder Committee" will be created to serve as a forum in which other public agencies, non-governmental organizations, interested parties, and the public may offer recommendations regarding BDCP implementation. The Implementation Office will also coordinate with the Delta Stewardship Council, Delta Science Program, Sacramento-San Joaquin Delta Conservancy (Delta Conservancy), and Delta Protection Commission to ensure appropriate engagement and collaboration on matters of common interest. This approach to plan implementation is expected to ensure the timely, efficient, and proper implementation of the commitments reflected in the BDCP.

[***Note to Reviewers*****:** *Additional text will be added to clarify the role of Mirant LLC in the implementation of the BDCP*.]

7.1 Roles and Responsibilities of Entities Involved in BDCP Implementation

The BDCP Program Manager will be selected to oversee and manage the implementation of the BDCP, and to ensure that implementation proceeds in compliance with the Plan, the Implementing Agreement, and the associated regulatory authorizations. The Program Manager will manage the Implementation Office (IO). Various other parties will be integral to the process of shaping decisions and effectuating actions set out in the BDCP. This section describes the roles and responsibilities of the Program Manager, the IO, and of the various other participants in the implementation process.

7.1.1 The BDCP Program Manager and Implementation Office

7.1.1.1 Program Manager: Selection and Designation of Staff

A single BDCP Program Manager will be responsible for BDCP implementation and will direct and oversee the IO. The *"major authorized entities"* will each designate a lead representative from their respective agencies to assist the Program Manager with plan implementation. The Program Manager may fulfill the staffing needs of the IO by drawing from existing personnel at

DWR, Reclamation, SFCWA, and other sources, as appropriate. Staff of the IO, many of whom will be assigned to the IO by DWR, Reclamation, or other entities, will act under the direction of the Program Manager. The engagement of personnel from DWR, Reclamation, and other entities in the IO, however, will not affect or modify the existing authorities of federal, state, and local agencies or non-governmental organizations that pertain to personnel matters

The *major authorized entities* (including DWR and Reclamation) for the BDCP will solicit candidates for the Program Manager position, and will provide their recommendations to the Implementation Board for acceptance. A definition of "*major authorized entities*" is provided in Section 7.1.2 *Authorized Entities*. The *major authorized entities* will, by consensus, select the Program Manager after taking into account the views of other Implementation Board members, and after consulting with the federal and State fish and wildlife agencies. The general qualifications of the Program Manager will have:

- A minimum 10 years experience in the field of natural resources management;
- Familiarity with complex natural resources issues, including water resources issues;
- Experience with State and federal regulatory processes that affect water and other natural resources that fall within the scope of the BDCP;
- Experience with multi-stakeholder processes;
- Experience with the administration or management of large-scale programs or projects; and
- Excellent communication skills.

The specific roles and responsibilities of the Program Manager are described in further detail in Section 7.2, *Implementation Office Administration*, Section 7.3, *Implementation of the Conservation Strategy*, and Section 7.4, *Regulatory Compliance Related to BDCP Implementation*, and Section 7.5, *Public Outreach*.

7.1.1.2 Science Manager: Selection and Function

The Program Manager will select a Science Manager to assist in the implementation of the BDCP and to ensure that such implementation decisions are guided by the best available scientific information. The Program Manager will consult with the Implementation Board in the selection of the Science Manager. The Science Manager will report to the Program Manager. Specifically, the responsibilities of the Science Manager include:

- Assist in the administration and implementation of the adaptive management program;
- Oversee the implementation of the BDCP monitoring and research program, with the assistance of the IEP;
- Oversee the implementation of the BDCP adaptive management program;

- Engage in regular communication and coordination with the Delta Science Program and coordinate with the Independent Science Board as well as other outside scientists to gather independent scientific information and solicit input and review, as needed;
- Support the Program Manager in the preparation of reports and other technical documents; and
- Assist in building sufficient scientific capacity and resources within the IO.

Matters relating to the conduct of scientific reviews and the solicitation of independent scientific advice to assist in the implementation of the BDCP will be conducted by the Science Manager in a manner that ensures their independence and scientific integrity.

Minimum requirements for the Science Manager will be:

- Educational and professional background in relevant scientific discipline,
- At least 10 years experience in the management of large programs,
- Experience managing or senior involvement in large scale research or monitoring programs, and
- Knowledge of issue related to the Delta.

7.1.1.3 Implementation Office: Establishment, Organization, and Functions

The BDCP IO, under the direction of the Program Manager (Section 7.1.1.1), will implement, coordinate, oversee, and report on all aspects of plan implementation. (Figure 7-1). The Program Manager will use the IO staff to assure that the BDCP conservation measures, including those related to protection and restoration of habitat; reduction of ecological stressors; management of conserved habitat; and operation of the water projects, including the development of infrastructure (in its oversight role to ensure plan compliance), are properly implemented throughout the life of the Plan. The Program Manager will use the IO staff to oversee and effectuate the adaptive management program; monitoring, data collection, and scientific research efforts; annual and five-year work plans, budget, and report preparation; and the public outreach process. To ensure that the commitments reflected in the BDCP are carried out in a timely and efficient manner, the Program Manager, through the IO, will institute processes and procedures to adequately address planning, budgeting, sequencing, and scheduling needs related to plan implementation.

The IO may enlist other entities to carry out actions associated with conservation measures or other implementation tasks on behalf of the IO (see "Supporting Entities," below). Notwithstanding the assignment of such responsibilities to other entities to implement projects or actions, the IO will be responsible for ensuring that the work is performed in a manner that complies with the terms and conditions of the BDCP and its associated regulatory authorizations and are properly and fully implemented. As part of that responsibility, the IO will engage and monitor those entities that become involved in aspects of plan implementation. The Program Manager will oversee and coordinate the management of contracts with these other entities to assist in the implementation of the BDCP. Those entities, and the roles and responsibilities they are likely to assume, are generally identified in this chapter and depicted in the organizational framework in Figure 7-1.

The IO will function with a significant level of independence and autonomy from its member entities. The staff of the IO will work closely with these agencies on a range of matters, particularly with respect to actions that affect water operations.

The IO will not be involved in the development or operation of SWP and/or CVP facilities; instead, it will monitor water operations to assemble the information necessary to evaluate and report on compliance with the terms and conditions of the Plan and the authorizations/permits. The BDCP sets out the parameters within which DWR and the Reclamation will carry out CVP and SWP operations and infrastructure development. DWR and Reclamation may chose to operate the projects and develop new infrastructure using their current organizational capacity or by contract with other entities.

The IO will budget for and oversee and coordinate management of the funds and other resources needed to carry out its responsibilities for plan implementation. The authorized entities will dedicate, hold, and release funds and resources necessary for plan implementation, and will not comingle these funds with other funds or resources of the agencies. The authorized entities will be responsible for all appropriated funds and other funds entrusted to them.

The IO will assume responsibility for the implementation of a broad range of actions, including:

- Oversight and coordination of administration of program funding and resources;
- Preparation of annual budgets and work plans;
- Establishment of procedures to implement plan actions;
- Oversight of and engagement in the implementation of conservation measures;
- Management of the monitoring and research and adaptive management programs;
- Implementation of public outreach program; and
- Fulfillment of compliance monitoring and reporting requirements.

The Program Manager will also have responsibility for coordinating with the Delta-wide governance entities (Section 7.2.7. *Coordination with the Delta Stewardship Council, the Delta Science Program, and the Delta Conservancy*) and managers of upstream operations.

The specific roles and responsibilities of the IO are described in further detail in sections 7.2 *Implementation Office Administration*, 7.3 *Implementation of the Conservation Strategy*, and 7.4 *Regulatory Compliance Related to BDCP Implementation*, and 7.5 *Public Outreach*.

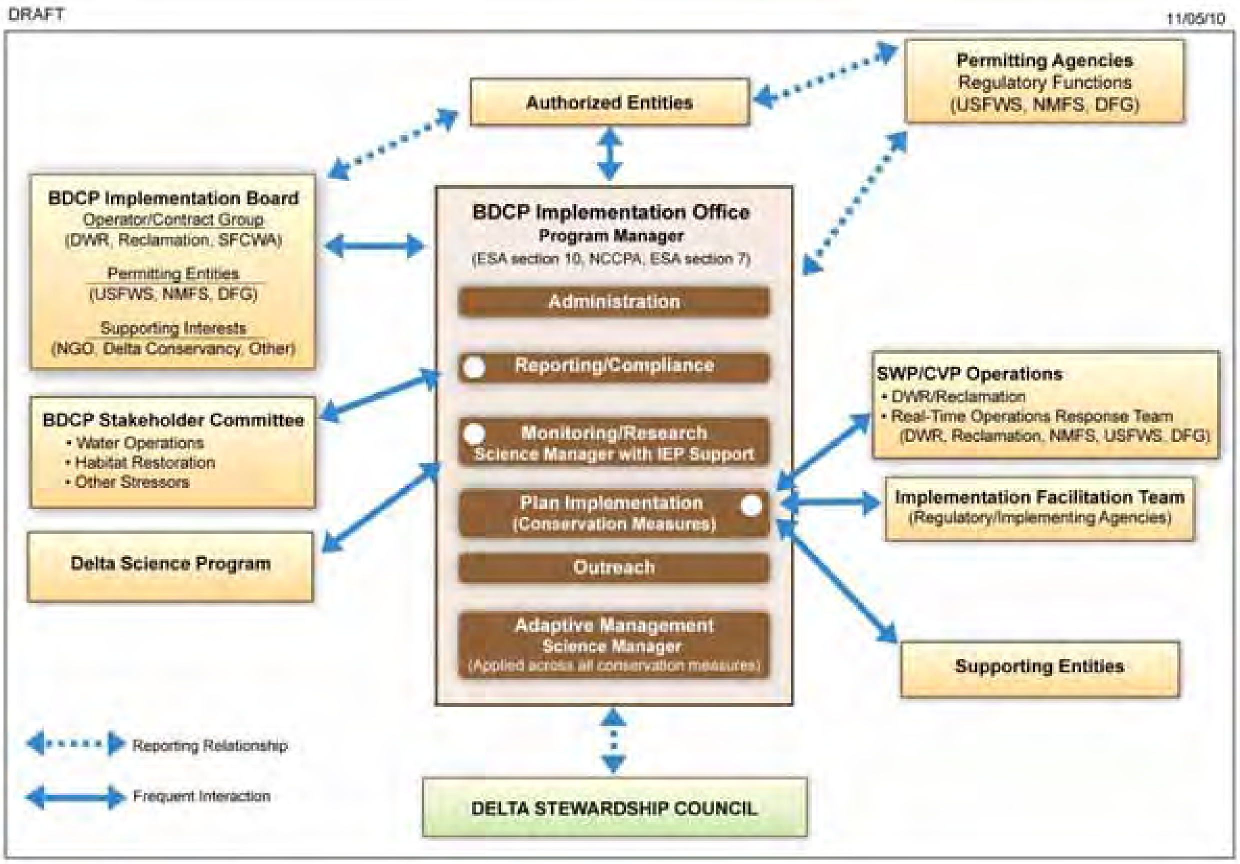

Figure 7-1. BDCP Implementation Structure

7.1.1.4 Assignment of Responsibilities

To effectively implement the BDCP, the Program Manager will be assigned certain responsibilities by DWR and/or Reclamation. DWR and/or Reclamation will provide the Program Manager with sufficient capacity and capability to effectively implement the BDCP and will explicitly define the scope of responsibilities assigned to the Program Manager.

7.1.1.5 No Delegation of Authority

The assignment of responsibility to the Program Manger will not alter or modify existing authorities, mandates, and obligations of the participating State and federal agencies. No general delegation of authority by DWR and/or Reclamation to the Program Manager or one of their employees assigned to the IO will occur, although specific delegation may occur in the event that it is considered by the delegating agency to be beneficial to the efficient operation of the IO. Any such delegation will be conferred, in writing, by the appropriate delegating agency to the appropriate individual within the IO, and will be reviewed by that agency from time to time.

7.1.2 Authorized Entities

[***Note to Reviewer:*** *At this time, a final list of authorized entities under the BDCP has not been developed (i.e., all entities receiving permits or other authorizations under the ESA and the NCCPA). DWR, Reclamation, and Mirant will be authorized entities. In addition, the SFCWA may also be an authorized entity, but this issue is still under consideration. The term "major authorized entities" is used in this chapter, but has not yet been defined. DWR and Reclamation will be included in this category. The SFWCA may be a major authorized entity, but this decision is still under consideration.*]

The BDCP provides the basis for the issuance of regulatory authorizations, under the federal Endangered Species Act (ESA), the California Natural Community Conservation Planning Act (NCCPA) (and potentially the California Endangered Species Act [CESA]), for the incidental take of listed fish and wildlife species that result from Delta water operations and other covered activities (Chapter 4, *Covered Activities).* The entities that receive incidental take authorizations for activities covered under the BDCP are referred to collectively as the "*authorized entities*." Incidental take authorizations will be sought by federal and non-federal entities under the following authorities:

- non-federal entities will seek regulatory coverage pursuant to ESA section 10(a)(1)(B), NCCPA section 2835, and potentially CESA section 2081 or 2080.1 (if applicable), and
- federal agencies will seek regulatory coverage under ESA section 7(a)(2) for federally-listed species.

Each authorized entity will retain full responsibility for proper implementation of the BDCP and compliance with the terms and conditions of the associated regulatory authorizations, regardless of whether another entity is tasked with responsibility for carrying out a required action.

However, the authorized entities and the Program Manager may enter into agreements individually, amongst themselves, or with other entities to designate responsibility for carrying out certain actions under the plan.

The following entities are "authorized entities" for the purpose of the BDCP and its regulatory authorizations. Descriptions of the activities that will be covered under the regulatory authorizations issued to the authorized entities are set out in Chapter 4, *Covered Activities*. The activities identified or described in this document for Federal actions by Reclamation are not "covered activities" for the purposes of the ESA Section 10(a)(1)(b) permit. Reclamation's activities are subject to ESA Section 7 and Reclamation is seeking authorization under ESA section 7 for their actions.

7.1.2.1 California Department of Water Resources

The State of California owns, and DWR manages and operates, the State Water Project's (SWP) existing Delta facilities, including the Clifton Court Forebay and the Banks Pumping Plant. Pursuant to the BDCP, DWR seeks State and federal regulatory authorizations to continue to operate such facilities. The State of California, through DWR, will construct, own, and operate any new diversion and conveyance facilities described in this plan.

7.1.2.2 United States Bureau of Reclamation

The United States owns, and Reclamation operates, the Central Valley Project's (CVP) existing Delta facilities, including the Jones Pumping Plant and the Delta Cross Channel. Consistent with the BDCP, Reclamation seeks federal regulatory authorizations through section 7 consultation for incidental take of listed species from project operations in and upstream of the Delta. Reclamation will likely enter into an agreement with DWR to wheel CVP water through a new conveyance facility.

7.1.2.3 Mirant Corporation

Mirant owns and operates the Pittsburg and Contra Costa Power Plants located in Pittsburg and Antioch. Mirant seeks regulatory permits under ESA section 10 and Fish and Game Code section 2835 for incidental take of listed species from operation of those plants.

7.1.2.4 Major Authorized Entities

DWR and Reclamation will be considered "*major authorized entities*." As *major authorized entities*, DWR and Reclamation will assume a number of specified responsibilities under the

Plan, such as selecting the Program Manager. Mirant[2] will be an authorized entity, but will not be a *major authorized entity*.

7.1.3 Implementation Board

A BDCP Implementation Board will be established to help guide the IO in the implementation of the Plan. Specifically, the Board will provide input to the IO on the proposed Annual Work Plan and Budget, including the anticipated IO actions associated with the adaptive management program and the proposed habitat acquisition and restoration targets. The Board's review of the work plan and budget will focus primarily on the programmatic aspects of the proposed actions. The involvement of the Board in plan implementation is not intended to constrain the Program Manager in day-to-day decision making.

7.1.3.1 Membership

The Implementation Board will consist of approximately 10 members, including DWR, Reclamation, the SFCWA, the State and federal fish and wildlife agencies, and certain other entities (including an NGO and the Delta Conservancy) that will have a significant role in supporting the implementation of the Plan. [***Note to Reviewers:*** *The specific NGO representative, as well as other supporting board members, and the process for future selection of those representatives will be reflected in a later draft of this chapter.*]

7.1.3.2 Function

The Program Manager will organize, convene, and provide support for the Implementation Board and its proceedings.[3] The Implementation Board will receive information from the Program Manager and other sources on the implementation of the BDCP generally, and will have the opportunity to review the proposed Annual Work Plan and Budget, including the targeted acquisitions of land and water interests and the major aspects of anticipated adaptive management actions.

The primary function of the Implementation Board will be to review and concur with the Annual Work Plan and Budget as proposed by the Program Manager. The content of the Annual Work Plan and Budget and the timing of preparation and submission of the document to the Implementation Board are described in Section 6.2 *Compliance and Progress Reporting*. The Annual Work Plan and Budget will be deemed to be "final" once (i) accepted by the Board or (ii) objections to the work plan and budget are resolved through the final decisional authorities (see *Dispute Resolution*, below). The Board will be convened by the Program Manager periodically through the year, as needed, to review issues that arise in the implementation of the annual plan.

---

[2] Mirant will be responsible for all of their own operations separate from the operations of the SWP, CVP, and any other entities involved in BDCP implementation. Mirant will be responsible for implementing BDCP actions specifically identified for them in the BDCP. Mirant may become a member of the Stakeholder Committee.

[3] If the Program Manager position is vacant, then DWR and Reclamation will serve this role.

The Program Manager may request that the Board reconvene to consider proposed amendments to the Annual Work Plan and Budget.

The Implementation Board will consider such matters as:

- Candidates for the Program Manager position;
- Annual work plans and budgets; and
- Adaptive management changes.

The Implementation Board will hold a minimum of two meetings per year. The Implementation Board meetings will be public as provided by applicable law.

7.1.3.3 Dispute Resolution

With respect to those matters that are considered by the Implementation Board, it is expected that reasonable efforts will be made to provide input to the Program Manager that reflects acceptance by the members. A board member, however, will have the right to object to any proposal of the Program Manager concerning the annual work plans, budgets, the acquisition of land and water interests, and the major elements of the adaptive management program. Any objections will be made solely on the basis that the proposal (i) will not adequately contribute to achievement of the goals and objectives of the BDCP or (ii) is inconsistent with the requirements of the Plan and/or the permits/authorizations.

The board member may elevate the matter to the regional director(s) of the relevant federal agency, to the director(s) of the relevant state agency, or to other appropriate authorities, as determined by the locus of responsibility for the action (see examples below). A simplified process for considering and responding to such objections in an orderly and timely manner will be established, including a process to elevate appropriate matters for decision to the responsible official, be it a federal or State cabinet-level official or their designee, or another corresponding authority for other locus of responsibility entities, such as a Delta Conservancy, the SFWCA, or a State or federal water contractor. As required by existing law, final responsibility for plan implementation and permit compliance will remain with the holders of those permits and authorizations. The objection procedures and dispute resolution process may not be used to delay the completion and/or implementation of the Annual Work Plan and Budget.

Examples of locus of responsibility:

- DWR would be responsible for actions that affect facilities or operations of the SWP;
- Reclamation would be responsible for actions that affect facilities or operations of the CVP;
- SFCWA would be responsible for actions that would result in changes to costs of conservation measures for which they have provided funding;

- Delta Conservancy would be responsible for projects charged to the Delta Conservancy through future specific State legislation or bond requirements.

*[**Note to Reviewers**: Implementation Board dispute resolution procedures will be developed for the Plan in a later version of this chapter and/or the Implementing Agreement.]*

7.1.4 DWR and Reclamation: Operation of the SWP and CVP

Implementation of the conservation measures related to water facilities and water operations, as described in Chapter 3 *Conservation Strategy*, will be the responsibility of DWR and Reclamation or entities with whom they may contract. DWR and Reclamation will retain their authority to operate the SWP and the CVP within the parameters of the BDCP and other applicable laws and regulations.

The federal and state operators of the CVP and the SWP will prepare coordinated operation strategies for the federal and state Projects, including the Annual Water Operations Strategy as described in as described in Section 6.2, *Compliance and Progress Reporting*. The IO will incorporate the Annual Water Operations Strategy into the BDCP Annual Work Plan and Budget (as described in Section 6.2, *Compliance and Progress Reporting*).

Decisions related to "real time" water operations will be the responsibility of the Real Time Response Team, as described in Section 7.3.2, *Implementation of Water Operations Conservation Measures*.

7.1.5 Permitting Agencies: Fish and Wildlife Agencies

On the basis of the BDCP, the State and federal fish and wildlife agencies (USFWS, NMFS, and DFG) will issue regulatory authorizations to the authorized entities pursuant to the federal ESA and the NCCPA. Consistent with their authorities under these laws, the fish and wildlife agencies will retain responsibility for enforcing the terms and conditions of the permits and regulatory authorizations. The fish and wildlife agencies retain full responsibility to: (i) determine whether implementation of the BDCP is proceeding in compliance with the terms and conditions of the regulatory authorizations, (ii) enforce the terms and conditions of the regulatory authorizations,, and (iii) modify, suspend, or revoke regulatory authorizations, consistent with the terms and conditions of the Plan, the Implementing Agreement, and applicable State and/or federal law.

These agencies will also provide input on a range of implementation actions that will be carried out by the IO. The IO will work closely with these agencies to ensure ongoing compliance with the permits and authorizations.

7.1.5.1 California Department of Fish and Game

DFG is the agency of the State of California authorized to act as trustee for the state's wildlife. DFG administers and enforces CESA, the NCCPA and other provisions of the Fish and Game Code. DFG is authorized to enter into agreements with federal and local governments and other entities for the conservation of species and habitats, to authorize take under CESA and the NCCPA, and to provide statutory assurances under NCCPA. On an ongoing basis, DFG will consult with the IO and the *major authorized entities* on various aspects of plan implementation, including participation in real-time operations decisions, the adaptive management process, and the monitoring and science programs. DFG will also maintain responsibility for plan enforcement, consistent with the NCCPA and other authorities. DFG owns and manages land within the Plan Area, and may, at the request of the IO, enter into agreements whereby it operates and maintains certain habitat areas that are developed through BDCP habitat preservation and restoration actions. DFG is jointly responsible for implementation of the Ecosystem Restoration Program, which was established to advance ecosystem restoration projects in the San Francisco Bay Delta and its tributaries.

7.1.5.2 National Marine Fisheries Service

NMFS is an agency of the United States Department of Commerce authorized by Congress to administer and enforce the ESA with respect to marine mammals and certain fish species (including anadromous fish); to enter into agreements with states, local governments, and other entities to conserve federally threatened, endangered, and other species of concern; to authorize incidental take under ESA; and to provide regulatory assurances in accordance with 50 C.F.R. section 222.307(g). On an ongoing basis, NMFS will consult with the IO and the *major authorized entities* on BDCP implementation, including participation in the real-time operation and adaptive management processes and the monitoring and science programs. NMFS will also maintain responsibility, jointly with USFWS, for plan enforcement consistent with the ESA and other authorities. NMFS is jointly responsible for implementation of the Ecosystem Restoration Program, which was established to advance ecosystem restoration projects in the San Francisco Bay Delta and its tributaries.

7.1.5.3 United States Fish and Wildlife Service

The USFWS is an agency of the United States Department of the Interior authorized by Congress to administer and enforce the ESA with respect to terrestrial wildlife, certain fish species, insects and plants, to enter into agreements with states, local governments, and other entities to conserve threatened, endangered, and other species of concern, to authorize incidental take under ESA, and to provide regulatory assurances in accordance with 50 CFR section 17.22(b)(5) and section 17.32(b)(5). On an ongoing basis, USFWS will consult with the IO and the *major authorized entities* on various aspects of plan implementation, including participation in real-time operations decisions, the adaptive management process, and the monitoring and science programs. USFWS will also maintain responsibility, jointly with NMFS, for plan enforcement consistent with the ESA and other authorities. USFWS may also, at the request of the IO, enter into agreements whereby it operates and maintains certain habitat areas that are developed through BDCP habitat preservation and restoration actions. USFWS is jointly responsible for implementation of the Ecosystem Restoration Program, which was established to advance ecosystem restoration projects in the San Francisco Bay Delta and its tributaries

7.1.6 Other Regulatory Agencies

The BDCP has been developed as a conservation plan pursuant to the ESA and the NCCPA. To implement the BDCP, certain conservation actions will need to conform to the requirements of various other State and federal laws and regulations not specifically addressed by the Plan. Prior to the implementation of many of the conservation actions set out in the BDCP, regulatory authorizations and approvals will need to be obtained from State and federal agencies under applicable laws. To facilitate compliance with these laws and regulations, the IO will work closely with the appropriate regulatory agencies to plan in advance of future permitting needs and establish processes to expedite such authorizations.

In addition, certain Important Related Actions (IRAs) have been identified that fall within the jurisdictional responsibility of other State and/or federal regulatory agencies. The USFWS, NMFS, DFG, and the IO will work with these regulatory agencies to encourage the implementation of the IRAs. To the extent appropriate, the IO will seek to integrate IRAs into the BDCP Conservation Strategy. [***Note to Reviewers:*** *The approach to Other Stressor Conservation Measures indentified as IRAs is currently under evaluation and changes to this text will be made as the approach is formulated in Chapter 3 Conservation Strategy*.]

It is expected that the actions set out in the BDCP are likely to involve some or all of the following statutes: California Water Code sections 1000 *et seq*. (water rights), Water Code sections 13000 *et seq*. (water quality), California Fish and Game Code sections 1600 and 5900 *et seq*. (channel modification, fish screens), Clean Water Act section 401 (water quality) and section 404 (placement of dredge and fill), Rivers and Harbors Act section 408 (work on levees), Rivers and Harbors Act section 10 (navigation), the Migratory Bird Treaty Act (migratory birds), and the Federal Energy Regulatory Act implemented by the Federal Energy Regulatory Commission.

7.1.7 Implementation Facilitation Team

An “Implementation Facilitation Team” will be established and directed by the Program Manager. The Facilitation Team will include the State and federal fish and wildlife agencies and, as appropriate, Supporting Entities and other State and federal regulatory agencies and other entities involved in the implementation of the BDCP. The Facilitation Team will work closely with the IO and supporting entities to facilitate the process of regulatory compliance under various authorities. The purpose of the Facilitation Team is to ensure regular communication and coordination between the IO, Supporting Entities, and those agencies that have regulatory responsibility for actions that will be implemented under the BDCP. The Facilitation Team will work to address issues that may arise with respect to these regulatory processes, including those related to technical and logistical matters, and will help facilitate the efficient and timely implementation of conservation measures. The role of this team will be limited to technical issues; it will not engage in matters related to the program oversight or management.

7.1.8 Supporting Entities

The Program Manager may assign specific implementation tasks to other entities, referred to as "Supporting Entities," that have the authority, resources, and expertise to successfully and timely complete the task. Where specific tasks are so assigned, the Program Manager will ensure that that tasks and associated responsibilities are carried out properly and in coordination with other BDCP actions. Supporting entities may include, among others:

- DWR.
- Reclamation.
- SFCWA or individual SWP and CVP contractors. It is anticipated that the SFCWA will be substantially involved in the implementation of the BDCP, and will likely assume responsibility for implementing a number of BDCP actions.
- The Delta Conservancy. The Delta Conservancy has been designated by statute as a primary State agency to implement ecosystem restoration in the Delta.
- Sponsors of regional conservation planning programs, including those engaged in NCCP and/or HCP development or implementation, or of other similar conservation programs, that overlap or are adjacent to the Plan Area.
- State and federal regulatory agencies, including USFWS, NMFS, and DFG. In addition to acting in their regulatory roles, these entities may act as supporting entities.
- Other public agencies and private entities that have authority, capacity, or expertise to implement actions described in the conservation strategy in a cost-effective, reliable, and timely manner.

The Program Manager will oversee each supporting entity's performance of its responsibility for carrying out a specific task. Decisions by the Program Manager to engage another entity in the implementation of specific plan elements or actions will be accomplished by written contract and will be based on the entity's jurisdictional authority, level of expertise, and its capacity to carry out the element or action in a timely and successful manner. The Program Manager may terminate a supporting entity's role in plan implementation in the event that the supporting entity does not perform a task adequately.

The take authorizations that will be issued pursuant to the BDCP will provide regulatory coverage under the ESA and the NCCPA for all activities covered by the Plan. As such, no additional take authorizations will be required to implement these activities, regardless of whether the action is carried out by the IO or a Supporting Entity.

7.1.9 BDCP Stakeholder Committee

A BDCP Stakeholder Committee will be established by the Program Manager to provide a forum through which interested public and private entities will consider and discuss matters related to Plan implementation.

7.1.9.1 Membership

The Stakeholder Committee will comprise a broader membership than the Implementation Board and consist of a range of entities and organizations with an interest in BDCP-related issues or engaged in BDCP matters.

Members of the Committee will at a minimum include but not be limited to:

- Members of the BDCP Steering Committee, serving as of the authorization date of the BDCP;
- Representative of the SFCWA
- Representatives of Delta counties and other local Delta government agencies; and,
- Other stakeholders whose assistance will increase the likelihood of the success of plan implementation.

7.1.9.2 Function

The Program Manager will convene and facilitate the Stakeholder Committee periodically to exchange information and provide input to the Program Manager concerning the current significant issues at hand. Stakeholders will have opportunity to inquire about implementation matters, be apprised by the Program Manager of issues of interest, and make recommendations concerning pending decisions. Stakeholder Committee meetings will be open to the public. At least two Stakeholder Committee meetings will be held each year.

For the benefit of the Stakeholder Committee members and the general public, the Program Manager will provide information and briefings regarding plan implementation. In addition, to further facilitate access to information and promote transparency in decision-making, the IO will maintain a public, on-line data base of key documents and information, such as annual implementation reports, work plans, and budgets (Section 6.2, *Compliance and Progress Reporting*).

The Stakeholder Committee will develop its own internal organization and process by committee consensus to best coordinate with the various aspects of BDCP implementation. The Stakeholder Committee process will complement, but not substitute for, ongoing collaboration and communication between stakeholders and the IO, authorized entities, the Implementation Board, and the fish and wildlife agencies. The IO will organize, help convene, and provide support for the Stakeholder Committee and its proceedings.

7.1.10 The General Public

The BDCP implementation process will provide for ongoing and frequent engagement and participation of the public. Other entities that have interests in the conservation of Delta resources, may participate in BDCP implementation through the public outreach process coordinated by the IO (Section 7.5 *Public Outreach*) or through the BDCP Stakeholder Committee, if eligible for membership. Stakeholder Committee meetings will be open to the public and specific times made available for public comment.

7.2 Implementation Office Administration

The Program Manager direct, oversee, and select staff for the IO. The IO, which will not be a legal entity authorized to enter into contracts directly or hold property in its own name, but will instead administer the implementation of the BDCP under the existing authorities of the authorized entities. By relying on the legal authorities of the authorized entities, the IO will be equipped with the resources and capacity necessary to carry out BDCP implementation tasks for which it will be responsible. This structure also contemplates that DWR and the Reclamation will maintain their historic roles as owners and operators of the SWP and CVP, but provides flexibility for changing those roles if so directed by Congress, the California Legislature, or through administrative processes.

Proper implementation of the Plan will require a skilled and expert team consisting of administrators, policy-makers, scientists, engineers, data analysts, and regulatory specialists, capable of working together in a cohesive and unified manner. In addition, effective implementation will necessitate adequate financing of and support for the IO. The BDCP includes funding assurances (Chapter 8 *Implementation Cost and Funding*) that the IO will have such capacity to carry out the responsibilities described in this chapter.

The Program Manager may assign specific implementation tasks to other entities that have the authority, resources, and expertise to successfully complete the task in a timely manner. These other entities can, at the discretion of the Program Manager, include an authorized entity, a regulatory agency, a supporting entity, or any combination thereof. Where specific tasks are so assigned, the Program Manager will ensure that that tasks and associated responsibilities are carried out properly and in coordination with other BDCP actions. The entity selected will be responsible, subject to oversight by the Program Manager, for entering into the necessary contracts and acquiring title to interests in real and personal property, acquiring permits, and taking all other steps needed to complete the implementation task.

The IO's primary functions and responsibilities are described in the following subsections.

7.2.1 Establishing Administrative Capacity

The Program Manager will manage the IO. The Program Manager will enter into an employment relationship with one of the *major authorized entities*. However, the Program Manager will be responsive to all of the *major authorized entities*.

The Program Manager will arrange for and equip the IO office space, hire a staff of sufficient size, and enter into contracts (through the authorities of DWR, Reclamation, and/or other *major authorized entities*) to build capacity to become fully functional and operational.

The Program Manager, with the consent of and pursuant to agreements with any affected agencies, may enlist current employees of the Implementation Board's member agencies, as well as employees of other State, federal, or local agencies, who possess the expertise and experience necessary to carry out the tasks associated with BDCP implementation. The specific staffing needs of the IO will be determined by the Program Manager. All IO staff, including staff from entities that are members of the Implementation Board will work at the direction of the Program Manager.

7.2.2 Preparing Budgets and Managing Expenditures

The Program Manager will develop, propose, and administer budgets for general program administration for acceptance by the Implementation Board pursuant to the dispute resolution process (Section 7.1.3.3 *Dispute Resolution*). The Program Manager will establish systems and processes to centralize oversight of implementation budgets and related expenditures. The Program Manager will also generally oversee budgets and expenditures related to implementation actions carried out by authorized or supporting entities.

7.2.3 Contracting for Services

The IO, through the appropriate entity, may contract for services as necessary to implement the BDCP, including for professional services related to:

- Acquisition and protection of habitat;
- Habitat restoration and management;
- Monitoring and scientific research;
- Legal and regulatory matters;
- Environmental and technical services;
- Engineering and construction (e.g., conservation facilities, water facilities, levees);
- Funding and grant agreements pertaining to state and federal programs and executing sub-grants to third-parties to conduct specific actions; and
- Operations and maintenance.

The Program Manager shall administer such contracts.

7.2.4 Securing, Holding, and Managing Funds to Support Implementation Actions

The IO will coordinate the expenditure of funds from State, federal, and other sources that have been dedicated to the implementation of the BDCP. At least one State and one federal agency member of the Implementation Board will serve as the fiscal agents, consistent with existing agency authorities, for the expenditure of funds by the IO, from both public and private sources, to support implementation actions. The IO will not be authorized to manage the expenditure of funds related to design, construction, operation and maintenance of water diversion and conveyance facilities which are or will be elements of the SWP or CVP.

7.2.5 Coordinating with the Authorized Entities and Supporting Entities

The Program Manager will convene meetings and facilitate communication with the authorized entities and supporting entities. The Program Manager will maintain frequent contact with these entities and provide regular updates concerning implementation matters, including progress in meeting BDCP timetables, dissemination of information, and maintenance and availability of BDCP records and reports.

7.2.6 Coordinating with Regulatory Agencies – Facilitation Team

The USFWS, NMFS, DFG, and other regulatory agencies will coordinate and collaborate through the Facilitation Team with the IO on matters potentially affecting compliance with the terms and conditions of the BDCP and its regulatory authorizations. The Program Manager will coordinate and lead Facilitation Team meetings.

7.2.7 Coordinating with the Delta Stewardship Council, Delta Science Program, and Delta Conservancy

The Program Manager will facilitate and monitor the effective and efficient incorporation of the BDCP into the Delta Stewardship Council's Delta Plan (Delta Plan).[4] The Program Manager will report, at least annually, to the Delta Stewardship Council on the progress of BDCP implementation, including the status of monitoring programs and adaptive management, as required by Water Code section 85320(f). The IO will also respond to questions or concerns raised by the Delta Stewardship Council regarding the implementation of the BDCP.

The IO, lead by the Science Manager, will coordinate with the Delta Science Program and, as necessary, the Delta Independent Science Board, [5] regarding scientific assistance in the

[4] Water Code § 85320.

[5] Water Code § 85280

formulation and implementation of monitoring activities and research efforts to support the BDCP adaptive management process.

The IO will coordinate with the Delta Conservancy concerning implementation of ecosystem restoration projects carried out pursuant to the BDCP Conservation Strategy and other programs being carried out by the Delta Conservancy.

7.2.8 Coordinating with Local Governments, Delta Protection Commission, and Other Public Agencies

The Program Manager will serve as the main point of contact for local, State, and federal agencies interested or engaged in BDCP implementation issues. The Program Manager will prepare, publish, and distribute general information about the BDCP to those agencies and serve as representative of the BDCP in public meetings convened by cities, counties, and other public agencies with jurisdiction within the Delta. The Program Manager will encourage local government participation on the BDCP Stakeholder Committee.

Where regional conservation plans overlap with or adjoin the Plan Area, the IO will collaborate and coordinate with the sponsors of those regional conservation plans on the acquisition and management of habitat lands to be preserved and/or restored within areas common to both plans. The Program Manager will, as appropriate, enlist sponsors of those regional conservation plans and local governments to serve as BDCP supporting entities to assist in the acquisition and/or management of conservation lands. Where mutually beneficial, the IO will encourage joint acquisitions of land with local government plan sponsors to realize economies-of-scale and to secure large, contiguous blocks of habitat. The IO will explore opportunities to fund early conservation actions (i.e., habitat acquisition and/or restoration) that may benefit both the BDCP and other regional conservation plans.

7.2.9 Coordinating with Flood Control Agencies

In the design and implementation of conservation actions that could affect flood control capabilities, the IO will coordinate with agencies responsible for flood control in the Plan Area, including USACE, DWR, Central Valley Flood Protection Board, and local flood control agencies.

7.2.10 Protecting and Defending Against Legal Challenges

The IO, in coordination with the Implementation Board, supporting entities, fish and wildlife agencies, and other appropriate public agencies, will help direct efforts to defend against legal challenges to the BDCP or its associated State and federal authorizations. As necessary, the IO may also provide funding for legal counsel to address the range of legal issues associated with implementation, including: defense against litigation related to the BDCP, liability associated with land acquisition and related matters, disputes arising out of contractual agreements, and general, routine in-house legal matters.

7.2.11 Overseeing Plan Amendments

In the event that an amendment to the BDCP and its authorizations is necessary, the IO will compile information and prepare documentation necessary to support such an amendment and will seek to obtain approvals from the applicable fish and wildlife agencies.

7.2.12 Implementing Mitigation Measures Identified in BDCP-related Environmental Documentation under NEPA and CEQA

Subject to the approval of the NEPA and CEQA lead agency(ies) conducting the environmental review under NEPA and/or CEQA and the Program Manager, the IO will implement the mitigation measures identified in the final environmental documents on behalf of the lead agency(ies). Such mitigation measures must be associated with either the EIS/EIR prepared for the BDCP or environmental documents necessary for the implementation of an action set out in the BDCP.

7.2.13 Undertaking Other Responsibilities

The IO will institute a program to monitor compliance with the BDCP and the BDCP EIR/EIS (as per agreements with NEPA/CEQA lead agencies) and provide the fish and wildlife agencies, on a mutually-agreed upon time-frame, with reports on the results of the monitoring program (Section 6.2 *Compliance and Progress Reporting* and Section 7.3, *Implementation of the Conservation Strategy*). The IO will also obtain other regulatory authorizations and permits necessary to implement BDCP conservation actions (Section 7.4, *Regulatory Compliance Related to BDCP Implementation*) and will engage in public outreach and education (Section 7.5, *Public Outreach*)

7.3 Implementation of the Conservation Strategy

The Program Manager will be responsible for planning, overseeing, and conducting actions set out in the BDCP Conservation Strategy (Chapter 3, *Conservation Strategy* and Chapter 6, *Plan Implementation*). The Program Manager will be afforded sufficient flexibility to use supporting entities and the fish and wildlife agencies to undertake certain actions that will enhance the overall effectiveness of the Conservation Strategy and yield greater efficiencies in plan implementation. The following sets out the tasks and responsibilities of the IO regarding the implementation of the Conservation Strategy.

7.3.1 Implementation of the Habitat Protection and Restoration Conservation Measures

The IO will take actions directly or through the supporting entities to implement conservation measures related to the protection of existing habitat and the enhancement and restoration of habitat within the identified restoration opportunity areas (ROAs) and conservation zones, as well as within other areas in the Plan Area, as described in Chapter 3, *Conservation Strategy*. These measures will primarily involve actions to acquire lands, restore or improve habitat conditions, and manage and maintain conservation lands. The IO will work with, and may contract with the Delta Conservancy or the supporting entities to carry out the conservation measures associated with habitat protection and restoration.

Acquisition and/or Lease of Property Interests. Pursuant to the authorities of DWR, Reclamation, and/or other *major authorized entities*, the IO may acquire interests in real property to facilitate the implementation of a habitat protection and/or restoration conservation measure. Similarly, under the direction of the IO, other entities that have been selected to implement such conservation measures may also acquire interests in real property, as described in Chapter 3 *Conservation Strategy*. The tasks related to the acquisition of fee interest and/or conservation easements, for the purpose of habitat protection, restoration, and creation, will include, among other things:

- Routine "due diligence" review of real property;
- Biological "due diligence" to assess habitat/restoration values;
- Appraisal of property, including oversight of the appraisal process;
- Negotiation and execution of the transaction; and
- Receipt of title or easement to lands.
- Select appropriate mechanism or instrument to ensure the protection of conservation lands.

The selected entity will also acquire or lease lands or facilities, or, with the consent of the Program Manager, contract with the Delta Conservancy or other appropriate entities to do so, for the purpose of conducting scientific research and monitoring, housing administrative offices and equipment, and undertaking other activities as necessary to administer and implement the measure.

Management of Land. The IO will oversee the management and maintenance of lands acquired for conservation, as described in Chapter 3 *Conservation Strategy*, and will select entities that will be responsible for carrying out such management and maintenance. Tasks associated with land management will generally include:

- Habitat management;
- Invasive species control;
- Security patrol;
- Liaison with neighboring landowners;
- Mosquito abatement;

- Management of vegetation on flood control facilities to maintain flood flow capacity;
- Species and habitat monitoring;
- Public access management;
- Research activities;
- Educational services; and
- Agricultural lease management.

Maintenance of Facilities and Improvements. The IO will oversee the maintenance of all related facilities and improvements, such as buildings, fences, levees, roads, as described in Chapter 3, *Conservation Strategy* and necessary for support and protection conservation lands

Funding of Activities of Other Entities. The IO may provide funding to other entities (such as local governments engaged in regional conservation planning processes), subject to appropriate conditions and oversight, to implement habitat and species conservation efforts, both inside and outside the Plan Area, that help advance the biological goals and objectives of the BDCP, as described in Chapter 3, *Conservation Strategy*.

7.3.2 Implementation of Water Operations Conservation Measures

7.3.2.1 Operations of Water Facilities

Implementation of water facilities and water operations conservation measures as described in Chapter 3 *Conservation Strategy* will be the responsibility of DWR and Reclamation, or entities with whom they may contract, consistent with their existing responsibilities and authorities.

7.3.2.2 Real Time Operations Response Team

To enhance the effectiveness of the water operations conservation measures, a "Real Time Operations Response Team" (Response Team) will be established. The Response Team will consist of representatives from DFG, USFWS, NMFS, DWR, and the Reclamation.

7.3.2.2.1 Role of the Real Time Operations Response Team

The Response Team will be assigned the responsibility to make real-time operational recommendations based on covered fish species needs, within the boundaries established by the BDCP CM1 *Water Facilities and Operations* (Chapter 3, *Conservation Strategy*), other applicable regulatory constraints, and the Annual Water Operations Strategy (Section 6.2, *Compliance and Progress Reporting*). The fish and wildlife agencies will make a determination that the proposed real time operational actions are consistent with the biological needs of the covered fish species, within the boundaries established by the BDCP CM1 *Water Facilities and Operations* (Chapter 3, *Conservation Strategy*), other applicable regulatory constraints, and the

Annual Water Operations Strategy (Section 6.2, *Compliance and Progress Reporting*). DWR and Reclamation will implement the real time action.

The Response Team will make recommendations in real time (e.g., hourly/daily/weekly) regarding operations of the SWP and the CVP Delta facilities to achieve the purposes specified above.

Real-time water operations actions will be designed to increase fish benefits while recognizing the importance of meeting the water supply target in the Annual Water Operations Strategy as revised in the Seasonal Operations Strategies as well as to meet other operational requirements. The Response Team's recommendations will take into account upstream reservoir operations and other SWP and CVP operational requirements as well as the allocation, amount, and timing of water delivered, including surplus water that may be available, to the CVP or SWP customers within any water year. [***Note to Reviewers****: Standard for allowable impact on water supply and the real time operation decision making process are under review and development.*]

Notwithstanding the role of the Response Team, the Authorized Entities will retain ultimate legal responsibility for water operations conservation measures and compliance with the Plan and the regulatory authorizations. Similarly, the fish and wildlife agencies will retain legal authority to oversee, enforce, modify, or revoke such authorizations, as described in Chapter 6, *Plan Implementation*, under applicable laws and regulations.

7.3.2.2.2 Coordination between the Program Manager and the Response Team

The Program Manager will coordinate with the Response Team and retain responsibility for overseeing, monitoring, and reporting on the implementation of the water operation conservation measures. The Program Manager will also establish processes to ensure that recommendations made by the Response Team regarding the implementation of water operations conservations measures are transparent and understandable. Water operations will be described each year in a water operations report. Review and reporting requirements on water operations are described in Section 6.2, *Compliance and Progress Reporting*.

7.3.2.2.3 Responsibility of the Response Team to Balance Conservation and Water Supply Goals

The Response Team will be required to take into account the effect of its operational recommendations on water supply. While the Response Team's primary role will be to enhance the effectiveness of the water operations conservation measures, it will make real time recommendations in a manner that considers water supply and timing of delivery from that which would have occurred without variations from the expected operations set forth in the Annual Water Operations Strategy. [***Note to Reviewers****: Standard for allowable impact on water supply is under development.*]

7.3.2.2.4 Informational Resources Available to Support Decisions of the Response Team

In making real-time recommendations regarding the implementation of operations-related conservation measures, the Response Team will utilize data, information, and analysis generated from fisheries and operational technical groups and, where appropriate, outside scientific experts. Specifically, the Response Team will take into account real-time data derived from work conducted by the following groups (or their successors or equivalents, if any), including current fish surveys, flow and temperature information, and determinations regarding salvage or loss at the project facilities; and information about public health, safety, and water supply reliability:[6]

- **The Sacramento River Temperature Task Group (SRTTG):** The SRTTG is a multiagency group formed pursuant to SWRCB Water Rights Orders 90-5 and 91-1, and the NMFS biological opinion, to assist with improving and stabilizing Chinook populations in the Sacramento River. Annually, Reclamation develops temperature operation plans for the Shasta and Trinity divisions of the CVP. Reclamation considers impacts on winter-run and other ESUs of Chinook salmon, and associated project operations. The SRTTG meets initially in the spring to discuss biological, hydrologic, and operational information, objectives, and alternative operations plans for temperature control. Once the SRTTG has recommended an operation plan for temperature control, Reclamation then submits a report to the SWRCB, generally on or before June 1st each year. After implementation of the operation plan, the SRTTG may perform additional studies and commonly holds monthly meetings, as needed through the summer and into fall, to develop revisions based on updated biological data, reservoir temperature profiles and operations data. Updated plans may be needed for summer operations protecting winter-run, or in fall for fall-run spawning season. If there are any changes in the plan, Reclamation submits a supplemental report to SWRCB and to NMFS for review and concurrence.
- **Smelt Working Group (SWG):** The SWG evaluates biological and technical issues regarding delta smelt and develops recommendations for consideration by the USFWS. Since the longfin smelt became a state candidate species in 2008, the Working Group has also developed for DFG recommendations to minimize adverse effects to longfin smelt. USFWS chairs the group which consists of representatives from USFWS, DFG, DWR, EPA, and Reclamation. The SWG compiles and interprets the latest near real-time information regarding state- and federally-listed smelt, such as stages of development, distribution, and salvage. If they agree that a protection action is warranted, the SWG submits their recommendations in writing to USFWS and DFG. The Delta Smelt Risk Assessment Matrix (DSRAM) outlines the conditions when the Working Group will

[6] Additional working groups have been created and governed by SWRCB orders and NMFS and USFWS biological opinions. These work groups are listed here for informational purposes and are not necessary to the implementation of the BDCP

convene to evaluate the necessity of protective actions and provide FWS with a recommendation. This generally occurs weekly during the months of January through June, when smelt salvage at CVP and SWP has occurred historically. However, the SWG may meet at any time at the request of USFWS. Further, with the State listing of longfin smelt, the group will also convene based on longfin salvage history at the request of DFG.

- **Delta Operations for Salmon and Sturgeon (DOSS) Group:** NMFS chairs this working group, which consists of biologists, hydrologists and other staff with relevant expertise from Reclamation, DWR, DFG, and USFWS and may include USGS, EPA, and Regional Water Quality Control Board participation. The DOSS provides recommendations for real-time management measures to reduce adverse effects to salmonids and green sturgeon by coordinating Delta Cross Channel (DCC) gate operations, fishery protection closures, water releases, and/or export reductions. Inputs such as fish life stage and size development, current hydrologic events, fish indicators (such as catch indices), salvage at the export facilities, and current and projected Delta water quality conditions are some of the factors used to make recommendations. The DOSS will coordinate with the SWG and other technical teams to maximize benefits to all listed species.
- **American River Group (ARG):** In 1996, Reclamation established a working group for the Lower American River, known as ARG. Although open to the public, the ARG meetings generally include representatives from several agencies and organizations with on-going concerns and interests regarding management of the Lower American River. The formal members of the group are Reclamation, USFWS, NMFS, and DFG. The ARG convenes monthly or more frequently if needed, with the purpose of providing fishery updates and reports for Reclamation and NMFS to help manage Folsom Reservoir for fish resources in the Lower American River.
- **San Joaquin River Technical Committee** (SJRTC): The SJRTC meets to plan and implement the Vernalis Adaptive Management Plan (VAMP) each year, and oversees two subgroups: Biology and Hydrology. These two subgroups are charged with certain responsibilities, and must also coordinate their activities within the San Joaquin River Agreement (SJRA) Technical Committee. VAMP was officially initiated in 2000 as a 12-year experimental/management program under the SJRA and SWRCB Decision-1641.

7.3.2.3 Annual Reporting and Planning for Water Operations

Planning and reporting requirements for the IO, DWR, Reclamation, and the Response Team are set out in Section 6.2, *Compliance and Progress Reporting*.

7.3.3 Implementation of All Other Conservation Measures

The Program Manager, through the IO, will be responsible for the implementation of the other conservation measures described in Chapter 3, *Conservation Strategy*. The IO may undertake conservation actions directly or arrange for funding to support actions carried out by supporting entities, as described in chapter 3 *Conservation Strategy*. The funds provided to supporting entities will likely be for the purpose of implementing conservation measures that address the adverse effects of other stressors, such as toxic contaminants, nonnative predatory species, low dissolved oxygen zones, and entrainment unrelated to covered activities.

7.3.4 Management of Biological Monitoring, Scientific Research, and Reporting Programs

The Science Manager will be responsible for the overall management and oversight of the BDCP biological monitoring and research program, including the implementation of monitoring-related activities, as described in Chapter 3 *Conservation Strategy* (Section 3.6 *Monitoring and Research Program*).

The Science Manager will identify technical staffing needs and requirements necessary to adequately implement the biological monitoring program. The Science Manager will utilize the Interagency Ecological Program (IEP) to assist in the monitoring program. The Science Manager will oversee the development and implementation of the monitoring program and related scientific activities, with the assistance of the IEP agencies and in coordination with the Delta Science Program. The Science Manager will establish the framework for the monitoring program (*e.g.*, scope, methodologies, and protocols), in coordination with IEP and the fish and wildlife agencies, Delta Science Program, and supporting entities, The Science Manager, in collaboration with these entities, will develop and implement a process for compiling, evaluating, and synthesizing the results of monitoring activities, and will maintain databases and the results of data analysis, obtained through the monitoring program and expand on that currently developed by IEP.

The Science Manager will also manage the BDCP research program, as described in Chapter 3 *Conservation Strategy* (Section 3.6 *Monitoring and Research Program*), in coordination with the IEP agencies and the Delta Science Program. The research program will include establishing research goals and priorities and administering a process to select and coordinate researchers who will be involved in the program. The Science Manager will be responsible for the compilation and synthesis of the results of studies and analysis undertaken by other entities and organizations that are of interest and assistance to BDCP implementation. The Science Manager will also coordinate BDCP funding for research by other entities and organizations, as described in Section 3.6 *Monitoring and Research Program*.

The Program Manager will look to the Delta Science Program and Independent Science Board for science support and review. As appropriate, the Science Manager will seek and obtain input and advice from independent scientists through the Delta Science Program. Matters relating to the conduct of scientific reviews, and the acquisition of independent scientific advice to assist in the implementation of the BDCP, shall be conducted in a manner that ensures their independence and scientific integrity. The Science Manager will work with the Chief Scientist for the Delta

Science Program and IEP Lead Scientist in making sure BDCP science activities, reporting, and reviews are coordinated with other science activities being conducted in the Delta.

The Program Manager will track plan implementation actions and comply with the reporting requirements of the Plan, as described in Section 6.2 *Compliance and Progress Reporting*. Reports prepared by the IO will include, among other things, the results of monitoring and research, an assessment of overall plan performance, and an accounting of the distribution and expenditures of funding by the various entities engaged in plan implementation activities. See Section 6.2 *Compliance and Progress Reporting* for specifics on reporting requirements.

The Program Manager may contract with one or more of the authorized entities, supporting entities, or consultants when appropriate to ensure completion of required monitoring, data analysis, and scientific research.

7.3.5 Management of the Adaptive Management Program

The Science Manager will manage the BDCP adaptive management program, as described in Chapter 3 *Conservation Strategy* (Section 3.7 *Adaptive Management Program*). The Science Manager will establish and chair an Adaptive Management Team to assemble, synthesize, and analyze the results of BDCP monitoring efforts and integrate the results of new and relevant scientific research and studies conducted by other parties, including the Delta Science Program. Based on this information, the Science Manager will facilitate and coordinate discussion and consideration of adaptive management issues among the various participating entities, including the Implementation Board, the fish and wildlife agencies, and the Stakeholder Committee as part of the process of making decisions based on the adaptive management program.

The decision-making process for adaptive management changes, including the roles and responsibilities of the various entities in the BDCP implementation structure, is described in Section 3.7 *Adaptive Management Program*

7.3.6 Implementation of Measures in Response to Changed Circumstances

The Program Manager, through the IO, will be responsible for recognizing and responding to those changed circumstances identified in the plan, and for implementing those responses set out in the BDCP to address those changed circumstances, as described in Section 6.3 *Regulatory Assurances and Changed Circumstances and Unforeseen Circumstances*. The Program Manager will establish a process to ensure timely engagement of the Implementation Board, authorized entities, fish and wildlife agencies, and the Stakeholder Committee in the identification and response to such changed circumstances.

[***Note to Reviewers:*** *This process for ensuring timely engagement of these entities will be included in a future draft of the Plan*]

7.4 Regulatory Compliance Related to BDCP Implementation

The Program Manager, through the IO, will be responsible for ensuring that the BDCP is properly implemented, including ongoing compliance with the elements of the Plan and the terms and conditions of the associated regulatory authorizations. The IO will also identify, seek, and obtain from State and federal agencies any other regulatory permits or authorizations that are necessary to effectuate Plan implementation.

7.4.1 Maintaining Permits/Authorizations and Obtaining Amendments

The Program Manager will establish a process to ensure compliance with all permits and authorizations related to BDCP implementation. If amendments or modifications to any of these permits or authorizations become necessary, the Program Manager and the authorized entities will work with the applicable agency to develop the necessary documentation and obtain the amendment.

7.4.2 Obtaining Additional Regulatory Authorizations

[***Note to Reviewers:*** *Certain specific regulatory authorizations (e.g. water rights) will need to be completed prior to implementation of the BDCP. Other regulatory authorizations will be acquired as necessary during BDCP implementation. This section describes those authorizations that happen during BDCP implementation*.]

The Program Manager will identify and seek regulatory authorizations necessary to implement BDCP actions. The EIR/EIS for the BDCP will provide sufficient environmental review and analysis of the proposed adoption of the Plan by DWR, CVP-related actions undertaken by Reclamation, and of the proposed issuance of take authorizations by the State and federal fish and wildlife agencies pursuant to the Plan, and may provide sufficient environmental review to support other anticipated federal and State regulatory authorizations. However, additional NEPA and CEQA review, as well as compliance with other environmental laws, will be necessary for a number of BDCP-related actions.

The IO will oversee the likely need of supporting entities to obtain permits or authorizations, or conduct environmental review, under the following State and federal laws, regulations, or processes prior to the implementation of certain conservations measures:

- Sections 404 and 401 of the Clean Water Act;
- Sections 10 (33 USC 403) and 14 (33 USC 408) of the Rivers & Harbors Act of 1899;
- Section 1602 of the California Fish and Game Code (Streambed and Lakebed Alteration Agreements);

- Section 106 of the National Historic Preservation Act;
- Encroachment permits from the Central Valley Flood Protection Board and reclamation districts to conduct work on levees;
- Federal Energy Regulatory Act compliance through the Federal Energy Regulatory Commission; and
- The National Environmental Policy Act and the California Environmental Quality Act, as necessary for certain project-related actions.

This list is not intended to be comprehensive and the Program Manager would be responsible for compliance with any additional regulations necessary for Plan implementation.

7.5 PUBLIC OUTREACH

The Program Manager, through the IO, will implement a public outreach and education program to promote public awareness and provide opportunities for public input on matters concerning plan implementation. General objectives of the outreach program will be to:

- Promote public awareness of and understanding about the plan's purpose, specific conservation measures and their implementation;
- Provide streamlined and timely access to information;
- Provide contact with decision-makers; and
- Maintain a transparent process for understanding, clarifying and addressing public input and comments.

Particular emphasis will be placed on outreach efforts focused on the following stakeholders: Delta residents, including landowners, farmers, and business owners; environmental community; agricultural community; boaters; commercial fishing interests; recreational anglers; local governments; reclamation districts; irrigation districts; public utilities; public and private landowners adjacent to BDCP conservation areas; and Native American tribes.

The public outreach and education program will include, at a minimum:

Informational Material. The preparation and distribution of general information materials such as reports, quarterly electronic newsletters, and issue-specific fact sheets in timely manner so as to facilitate public understanding and meaningful public input.

Interactive Website. Development and maintenance of an interactive website that provides real-time access to information, updates regarding implementation activities, and expanded opportunities for public engagement and input. Visual elements such as maps and webcasts will be used to further aid information sharing and public understanding.

Speakers Bureau. Presentation of BDCP implementation information to various groups and at public meetings that occur throughout the state, as well as targeted audiences including Delta communities, Tribes, and specific statewide stakeholder interests.

Annual Public Workshops. Commitment to annual public workshops and others as needed to provide timely opportunities for public dialogue, input and comment regarding a wide range of implementation issues.

Environmental Justice. An environmental justice outreach program will be integrated into overall outreach activities described above to provide minority and low-income communities with access to information about the plan's implementation and opportunities for input. Outreach techniques include dedicated multilingual web page, availability of translation services at public workshops and community presentations, and outreach to ethnic media outlets.

CHAPTER 8. IMPLEMENTATION COSTS AND FUNDING SOURCES

[Note to Reviewers: *This chapter will ultimately address both estimated BDCP implementation costs and sources of funding that will be relied upon to cover these costs. This draft provides descriptions of the assumptions used to develop cost estimates associated with the implementation of the BDCP conservation measures, program administration, and other Plan related actions. Cost estimates presented in this chapter are preliminary. Cost estimates are dependent on the consultant's assumptions about how individual actions will be designed and constructed and could change significantly as these assumptions are reviewed and revised by the BDCP Steering Committee and the project applicants. Readers should note that cost estimates include budget contingencies of twenty to fifty percent due to uncertainty regarding the elements of each proposed action. The cost estimates set out in this chapter will also be adjusted as conservation measures are added, deleted, or modified and when more detailed cost information becomes available. Costs for some parts of the Conservation Strategy (e.g., the monitoring and research program) have not been estimated at this time as there is need for additional specific cost information or additional information or refinement to the actions. Section 8.11, Funding Sources and Assurances, will not be prepared until the total cost estimate has been completed, and hence funding needs can be ascertained and a funding plan developed.*

No agreement has been reached on the apportionment of funding of the various components of this plan beyond the state and federal contractors' commitment to funding the new conveyance and related mitigation costs. Substantial public and other sources of funding are expected to contribute to the cost of implementing the other elements of the Plan.

The BDCP Steering Committee members have submitted comments to various drafts of this chapter during development, which may or may not have been incorporated into this November 18, 2010 draft. While the text of this chapter is subject to change and revision as the BDCP planning process progresses, the chapter has been drafted and formatted to appear as it may in a completed draft HCP/NCCP. Although the chapter includes declarative statements (e.g., the Implementation Office will…), it is nonetheless a "working draft" that will undergo further modification based on input from the BDCP Steering Committee, state and federal agencies, and the public.]

8.1 INTRODUCTION

This chapter outlines estimates of the costs associated with implementation of the Bay Delta Conservation Plan (BDCP) over the proposed 50-year term of the Plan, including the costs related to each of its primary components. The Endangered Species Act (ESA) requires that habitat conservation plans specify "the funding that will be available to implement" conservation actions that minimize and mitigate impacts on covered species.[1] The Natural Community Conservation Planning Act (NCCPA) requires that natural community conservation plans

[1] U.S.C. section 1539(a)(2)(A)

contain "provisions that ensure adequate funding to carry out the conservation actions indentified in the Plan."[2] Based on the estimated costs for BDCP implementation, this chapter identifies the sources of funding that will be relied upon for plan implementation and the mechanisms that will be utilized to secure such funds, and describes the basis for the assurances provided by the Plan Participants that adequate funding will be available to support the implementation of the Plan.

*[**Note to Reviewers**: "Sources and assurances of funding" will be described in a subsequent draft of this chapter.]*

8.1.1 Scope and Purpose of the Cost Analysis

The BDCP identifies a range of actions that will be implemented over the term of the Plan to meet the biological goals and objectives described in the Conservation Strategy and to comply with the requirements of the federal ESA and the NCCPA. Among those actions are measures to avoid, minimize, and mitigate the effects of activities covered by the BDCP on species and natural communities addressed by the Plan and to provide for the conservation of those species. In addition, the BDCP establishes commitments of the Plan Participants to carry out an adaptive management and monitoring program for the species covered by the Plan and to take identified steps to respond to changed circumstances. The BDCP also establishes specific obligations of the Plan Participants regarding Plan implementation.

The cost analysis conducted for the BDCP quantifies both the overall cost of the BDCP and the cost of specific plan components. These estimates were used to establish the funding requirements for plan implementation over the course of a 50-year term and to guide decisions regarding the allocation of funding responsibilities among the Plan Participants.

Specifically, the analysis addresses costs related to the following components of the BDCP:

- **Conservation Measures**
    - **Water Facilities Construction and Operations.** This category covers those conservation measures related to water facilities and water operations. The costs associated with these measures include the development of new water conveyance and other water management facilities that will be located both within and around the Delta. This category also includes actions associated with the operations of both existing and new facilities. These actions were described in Chapter 3, *Conservation Strategy*.
    - **Physical Habitat Restoration and Protection.** This category includes conservation measures associated with the preservation, restoration, and protection of habitat. Specifically, the cost analysis considered actions related to the restoration of 65,000 acres of tidal wetland and associated estuarine habitat, 5,000 acres of riparian habitat, 2,000 acres of grassland, 400 acres of nontidal wetlands and associated aquatic habitat, 200 acres of vernal pool complex, up to 5,000 acres of managed wetlands,

[2] Cal. Fish and Game Code section 2820(a)(10)

and 10,000 acres of floodplain habitat; the enhancement of 20 linear miles of channel margin habitat; and the protection of existing 8,000 acres of grassland, 400 acres of nontidal wetlands, 300 acres of vernal pool complex, 400 acres of seasonal alkali wetland complex, up to 2,000 acres of managed wetlands, and up to 32,640 acres of agricultural land. The analysis also covers costs related to the mitigation of impacts to terrestrial habitat that are expected to occur as a result of certain covered activities. These measures are described in Chapter 3, *Conservation Strategy*.

- **Other Stressors.** This category covers conservation measures designed to reduce the direct and indirect adverse effects of various stressors on ecological functions, covered species, and natural communities. Such stressors include toxic contaminants and other factors affecting water quality, nonnative species, harvest, hatcheries, diversions unrelated to the State Water Project (SWP) or the Central Valley Project (CVP), predators, and migration barriers and other impediments to movement. The range of conservation measures that address other stressors are described in Chapter 3, *Conservation Strategy*.

- **Monitoring and Adaptive Management**. This category includes the start-up and on-going costs of the monitoring, research, and adaptive management programs, including expenses related to research and data collection, management, and analysis. The BDCP monitoring and adaptive management programs are described in Chapter 3, *Conservation Strategy*.
- **Changed Circumstances.** This category covers the cost of implementing measures to respond to changed circumstances. Those measures are set forth in Chapter 6, *Implementation Plan*.
- **Program Administration**. This category consists of expenditures necessary to administer the BDCP. It includes the start-up cost of establishing the BDCP Implementation Office and the ongoing costs of administration, including expenses associated with personnel, offices and other facilities, equipment, vehicles, contracted services, and other overhead and related expenses. A description of the approach to the administration of the BDCP is described in Chapter 7, *Implementation Structure*.

The cost analysis includes sections describing how funding needs were estimated for each plan component, including the assumptions and data used to determine the level and timing of funding needed over the course of plan implementation. Many of the cost estimates are based on conceptual and engineering designs for water facilities and habitat restoration projects available at the time of plan formulation.

This chapter also identifies the sources of funding to implement the BDCP and sets out assurances that adequate funding will be available to perform the terms and conditions of the Plan, consistent with the ESA and the NCCPA. Both the ESA and the NCCPA require that conservation plans include provisions that ensure adequate funding to carry out identified conservation actions. The nature of the BDCP assurances of funding for each of the primary components of the Plan, including actions associated with conservation measures, adaptive management and monitoring, and plan administration, is described in this chapter.

8.1.2 Organization of Chapter

The remainder of this chapter is organized as follows:

- Section 8.2 describes common assumptions used to estimate BDCP implementation costs.
- Sections 8.3 to 8.7 describe the methods, data, and specific assumptions used to estimate implementation costs related to conservation measures, monitoring, research, adaptive management, plan administration, and mitigation.
- Section 8.8 provides the costs of mitigation measures identified in the BDCP EIR/EIS.
- Section 8.9 summarizes the overall implementation costs for the Plan.
- Section 8.10 provides an analysis of net costs of BDCP implementation.
- Section 8.11 identifies the sources of funding for the BDCP and describes how such funding will be assured by the Plan participants.

Appendix J, *Implementation Costs Supporting Materials* provides additional detail on the data and assumptions used to estimate costs presented in this chapter.

8.2 COMMON ASSUMPTIONS FOR COST ESTIMATION

Certain common assumptions were applied to all cost estimates developed for the BDCP. These common assumptions are described in the following subsections.

8.2.1 Cost Periods

Cost estimates are described within 5-year periods, commencing with the first year in which regulatory authorizations have been issued by the fish and wildlife agencies, and concluding at the expiration of the permit's term. The cost estimation assumes that the initial 5-year period covers 2012 to 2016 and the final 5-year period covers 2057 to 2061. Every cost estimate has a temporal dimension, reflecting when those costs are expected to be incurred over the term of the BDCP. The timing of Plan implementation costs are based on the schedule of implementation presented in Chapter 6.

8.2.2 Cost Ranges

Low and high cost estimates are presented for the habitat and other stressor conservation measures. In most cases the low and high estimates reflect different assumptions in project design and/or unit costs. In cases where this was not possible, the low is assumed to be 10 percent less than the estimated cost and the high is assumed to be 10 percent more than the estimated cost.

8.2.3 Cost Contingency

The American Association of Cost Engineers define contingency as a specific provision for unforeseeable elements of cost within the defined project scope. Cost uncertainties may result from incomplete design, unforeseen and unpredictable conditions, or uncertainties within the defined project scope. The amount of contingency will depend on the status of design, procurement, and construction; and the complexity and uncertainties of the component parts of the project. For planning studies, standard contingencies typically range from 20 and 30 percent, but may be as high as 50 percent for experimental or special conditions. Cost estimates developed for major plan elements, such as water facilities, tidal habitat creation, and Yolo Bypass improvements, include various contingencies as specific cost line items. In those cases where cost contingency has not been explicitly factored into a cost estimate, a 20 percent contingency is added.

8.2.4 Financial Assumptions

In cases where present values were calculated or capital costs were amortized, a nominal discount rate of 4.375 percent and a long-term inflation rate of 2.1 percent are assumed. The discount rate was selected to match the fiscal year (FY) 2010 rate that the U.S. Army Corps of Engineers (USACE) and the U.S. Bureau of Reclamation (USBR) are required to use for developing and evaluating proposed plans for water project plan formulation and evaluation.[3] The long-term inflation rate is based on the spread between nominal and inflation-indexed 30-year Treasury notes, as published in Appendix C of Office of Management and Budget (OMB) Circular No. A-94 (revised January 2008).

Costs are reported in constant 2010 dollars.[4] Historical costs have been converted to 2010 dollars using various price indices, including consumer price indices published by the Bureau of Labor Statistics and civil works construction cost indices published by the USACE.

8.2.5 Delta Real Estate Values

Interests in land for the purpose of physical habitat restoration actions, resource protection, and water facilities development may be obtained through the acquisition of fee title or through easement. Estimated costs of acquiring land in fee or by easement to facilitate physical habitat restoration within ROAs in the Delta are based on the per acre land values shown in Table 8-1. Estimated costs of acquiring Delta land in fee or by easement for terrestrial land conservation and water facilities construction are based on the per acre land values shown in Table 8-2. Average land values within the ROAs are expected to be lower than for the broader Delta due to differences in land use and quality.

---

[3] The published rate of 4.0 percent (rounded) does not include any adjustment that may be needed to show the maximum rate of change of ¼ of one percent per year. The FY 2009 rate was 4.625 percent, hence the adjusted FY 2010 rate cannot be less than 4.375 percent.

[4] This means the costs presented in this chapter have been adjusted to reflect 2010 price levels and dollar purchasing power. Adjusting costs for inflation in this way allows for a more accurate comparison of costs over time.

<u>ROA Land Values:</u> Existing agricultural and native vegetation land uses in each ROA were grouped into the following categories:[5] (1) field and pasture crop production, which includes pasture, hay, grain, and other field crops; (2) vegetable crop production; (3) orchard; (4) vineyard; and (5) native vegetation. Land value data published by the California Chapter of the American Society of Farm Managers and Rural Appraisers (CSFMRA 2009) was used to estimate typical land values for agricultural land uses in each ROA. Values for Cache Slough, Suisun Marsh, and Yolo Bypass ROAs were based on data for field crop land (Class II/III), vegetable crop land (Class I/II), pear orchard, vineyards, and rangeland in CSFMRA Region I, South Sutter, Western Placer, Solano and Yolo Counties. Values for Cosumnes/Mokelumne, South Delta, and West Delta ROAs were based on data for Delta cropland, cherry orchard, vineyards, and rangeland in CSFMRA Region III, San Joaquin County. For each agricultural land use, the likely ROA value was set to the average of the low and mid CSFMRA valuation. Values for native vegetation land uses were based on parcel-level county assessment data.[6] The land values shown in Table 8-1 are an acreage-weighted average value based on the mix of land uses in each ROA.

Table 8-1. ROA Land Value Assumptions

ROA	*Avg. Fee Title Value [1] ($/Acre)*
Cache Slough	$4,100
Cos./Mokelumne/East Delta	$5,600
South Delta	$5,500
Suisun Marsh	$3,600
West Delta	$3,200
Yolo Bypass	$4,200

[1] Avg. fee value is the acreage-weighted average value based on the hypothetical tidal habitat restoration footprints used to cost Conservation Measure 4 (CM4), except in the case of Yolo Bypass, where it is the acreage-weighted average value for the entire bypass.

<u>Broader Delta Land Values:</u> A similar procedure was used to estimate typical land values for agricultural and native vegetation land uses for the broader Delta. In the case of Delta land uses outside of the ROAs, the expected value was set to the mid-point CSFMRA value to reflect the greater extent of higher quality agricultural land that may be acquired by BDCP. Table 8-2 shows the land values for specific land use categories used to estimate the cost of land acquisition for terrestrial conservation measures and water facilities. Note that by itself Table 8-2 does not indicate the expected cost of land acquisition for terrestrial conservation measures or water facilities. For a given conservation measure, the expected cost of land acquisition depends

[5] California Department of Water Resources (DWR) land use survey data at the Detailed Analysis Unit (DAU) level were used to classify existing ROA land uses. The DWR Land and Water Use Program collects land use data and develops water use estimates used in statewide water planning. It accomplishes this by conducting surveys of agricultural, urban and environmental land uses, and developing annual estimates of land uses on a regional basis. Since 1986, DWR has compiled land use survey data into georeferenced digital maps. The smallest level of resolution for these maps is the DAU, the smallest study area used by DWR, generally defined by hydrologic features or boundaries or organized water service agencies. In the major agricultural areas, a DAU typically includes 100,000 to 300,000 acres.

[6] Parcels with assessments made between 2000 and 2009 and having at least two-thirds of their land uses classified as native vegetation were used to estimate the average value of land classified as native vegetation in the ROAs. Assessed values were adjusted using USDA's California land value index for non-irrigated farmland to reflect changes in rural land values since the time of the assessment.

upon the mix of existing land uses on the acreage that will be acquired. Those costs are presented later in this chapter.

Table 8-2. Broader Delta Land Value Assumptions

County	*$/Per Acre*					
	Native Veg.	**Field Crop**	**Truck Crop**	**Orchard**	**Vineyard**	**Rangeland**
Contra Costa	$1,500	$5,900	$5,900	$17,800	$16,800	$5,100
Sacramento	$1,500	$7,000	$8,400	$9,200	$20,400	$3,100
San Joaquin	$1,500	$5,900	$5,900	$17,800	$16,800	$5,100
Solano	$1,500	$7,000	$8,400	$9,200	$20,400	$3,100
Yolo	$1,500	$7,000	$8,400	$9,200	$20,400	$3,100

Easement Costs: Easement values in the Delta vary widely, depending on type of easement and restrictions placed on land use. Expressed as a percent of fee title value, surface easement costs may range between 10 and 90 percent while subsurface easements may range between 30 and 50 percent (Davis, per. comm.). For cost estimation, it was assumed surface easements would average 60 percent of fee title value and subsurface easements would average 40 percent of the fee title value.

8.2.6 Transaction Costs Associated with the Acquisition of Interests in Land

Purchases of interests in land, either through fee title or through easements, for the purpose of carrying out habitat restoration actions, ensuring the protection of resources, and undertaking construction of water facilities, are assumed to involve transactional costs in addition to the price paid for that property interest. These transaction costs are likely to consist of: (1) the cost of conducting due diligence, and (2) the cost of undertaking pre-acquisition boundary and habitat surveys. The common assumptions used for computing due diligence and pre-acquisition survey costs are set forth in Table 8-3 and Table 8-4, respectively. Transactional costs are based on the average parcel size and boundary length computed for each BDCP Conservation Zone (CZ), Restoration Opportunity Area (ROA), floodplain region, and water facility right-of-way.[7]

Table 8-3. Land Acquisition Due Diligence Cost Assumptions

Due Diligence Multiplier [1]	1.25
Appraisal Cost ($/Parcel)	$5,300
Preliminary Title Report ($/Parcel)	$530
Phase 1 Site Assessment ($/Parcel)	$6,900
Legal Description ($/Parcel)	$4,300
Boundary Survey ($/Linear Foot of Boundary)	$0.48
Monumentation ($/Linear Foot of Boundary)	$0.37

[1]Applied to the number of acquired parcels to account for the number of parcels considered for purchase but ultimately not purchased.

[7] Transaction costs assumptions based on real estate due diligence and survey costs in *Final East Contra Costa County Habitat Conservation Plan and Natural Community Conservation Plan*. Direct and indirect costs for staff and legal assistance supporting BDCP land acquisition are included as part of the BDCP Implementation Office cost estimate.

Table 8-4. Pre-Acquisition Survey Cost Assumptions

Survey Multiplier [1]	1.25
Land Cover Type Survey (hrs/100 acres)	12
Covered Species Habitat Survey (hrs/100 acres)	16
Covered Plant Habitat Survey (hrs/100 acres)	32
Covered Wildlife Survey (hrs/100 acres)	28
Contractor Cost ($/hr)	$130

[1]Applied to the number of acquired acres to account for the number of acres surveyed for purchase but ultimately not purchased.

8.2.7 Employee Salary Costs and Benefits Multiplier

Plan administration costs include salary costs (Section 8.4, *Plan Administration*). The BDCP Implementation Office will build a staff to oversee or carry out the actions outlined in the BDCP (Chapter 7, *Implementation Structure*). The salary cost estimates associated with these personnel needs are based on proposed FY 2008-09 salary scales for reference positions within various departments of the California Natural Resources Agency, as reported by the California Department of Finance.[8] While federal employees may also be involved in the BDCP Implementation Office, differences between federal and state salaries are expected to be small and inconsequential with respect to overall BDCP administrative costs.

The cost analysis includes a benefits multiplier to account for certain assumed benefits, such as paid leave, health, retirement and other employee benefits, that would be provided to employees of the BDCP Implementation Office. A benefits multiplier of 1.35 was applied to all staff salary costs associated with the BDCP Implementation Office, except in cases where the estimated staffing cost accounted for employee benefits.[9]

8.3 COST ESTIMATE FOR CONSERVATION MEASURES

This section describes the data, methods, and assumptions used to estimate the cost of implementing the BDCP conservation measures. Different costing approaches were used for different conservation measures, depending on the conceptual and engineering design and cost information available at the time of Plan formulation. The approach taken for each conservation measure and the sources of data and other information used for the analysis are described in the following subsections.

8.3.1 CM1: Water Facilities and Operation

*[**Note to Reviewers**: In the main text, the mid-point construction cost estimate is presented for the all pipeline/tunnel conveyance facility option. Because a preferred project has not been selected at this time, the preliminary cost estimate for the eastern alignment option for the conveyance facility is also presented at the end of this section. For the pipeline/tunnel alignment,*

[8] www.dof.ca.gov/budget/historical/2008-09/salaries_and_wages/index.htm

[9] The multiplier is based on average benefits paid by state and local governments as a percent of total employee compensation in 2009, as reported by the U.S. Bureau of Labor Statistics.

the mid-point estimate is the average of the Delta Habitat Conservation and Conveyance Program (DHCCP) PTO Rev. 1 September 2010 construction cost estimate and the 5RMK Independent February 2010 construction cost estimate (escalated using same percentage as DHCCP Rev. 1). Costs are in 2010 dollars. Water facility mitigation costs for non-biological resources, other than property tax revenue replacement, are still being developed and are not included in this draft of chapter 8.]

Cost estimates are presented for the following components of water facilities construction and operation:

- Design, project management, construction management;
- Intake and conveyance construction costs;
- Construction cost contingency;
- Land acquisition;
- Annual operation, maintenance, power, and capital replacement; and
- Local Property Tax and Assessment Revenue Replacement.

Facility features are summarized in Table 8-5. . The mid-point cost estimates for design, project management, construction, contingency and land acquisition are shown in Table 8-6. Operation, maintenance, power, and capital replacement costs are summarized in Table 8-7.

8.3.1.1 Design, Project Management, and Construction Management Costs

Design, project management and construction management costs are assumed to be 18 percent of construction cost. This percentage was derived from comparing historical data from previous programs.

8.3.1.2 Direct Construction Costs

Direct construction costs are based on the Conceptual Engineering Report – All Tunnel Option (now called the Pipeline/Tunnel Option), dated March 2010 as modified by Addendum in August 2010.

The Association for the Advancement of Cost Estimating (AACE International) classifies cost estimates using guidelines identified in Recommended Practice No. 17R-97. Cost estimates are generally classified using several characteristics, the most significant being level of project definition, end usage and methodology.

- **Project Definition (Primary Characteristic) -** These reports are generally considered to be at an approximately 10 percent design level. The cost estimates would therefore fall into the Class 4 or Class 3 Estimate Class.

- **End Usage (Secondary Characteristic) –** These cost estimates are expected to be used for Feasibility or Budget purposes, which would also fall into the Class 4 or Class 3 categories.
- **Methodology –** These estimates were created using a mix of Stochastic and Deterministic methods (primarily Stochastic), which indicates a Class 3 category.

The construction cost estimates developed for the Plan are considered to be in the Class 3 Estimate Class and should have an expected accuracy range of +50 percent / -25 percent.

The estimates are based on a combination of stochastic and deterministic cost estimation methodologies, but primarily stochastic.

Stochastic methodology is defined in this case as involving the probability that an activity will result in a specific cost. This involved researching similar activities from previous projects and reconciling them to the current situation (quantity, year performed, site and market conditions, etc.). These costs were then sorted and a representative unit price selected. This was done without a bottoms-up review of labor, equipment, and materials, etc. The process resulted in a database of "unit prices" that were then applied to activities in the current estimate.

Deterministic methodology is defined in this case to mean a more bottoms-up approach to estimating the cost of an activity. An activity is broken down into its component parts and each part is assigned a set of resources (labor, equipment, materials, etc.) and a production rate (x cubic yards of soil excavated per hour) and the cost is determined.

The construction cost estimates were created using a combination of unit prices developed for similar work in various locations around the United States; historical unit prices compiled over time by the DHCCP estimating staff members; average unit prices recorded by the State of California Department of Transportation in the Contract Cost Data guide; budgetary vendor pricing; and bottoms-up estimates developed specifically for portions of work by the DHCCP estimators. Unit prices were converted to 2010 dollars using United States Bureau of Reclamation (USBR) cost index charts or other methods.

For all activities that required bottoms-up (or deterministic) methods of estimation – e.g., labor, equipment and materials - resource costs were identified as follows:

- **Labor –** General prevailing wage determinations made by the Director of Industrial Relations for Northern California and Sacramento, San Joaquin, Yolo, Solano and Contra Costa counties. Employer cost as well as overhead was calculated and special shift arrangements were factored for overtime.
- **Equipment –** Project rates were developed using USACE, Region VII "Construction Equipment and Operating Expense Schedule," the State of California Department of Transportation "Labor Surcharge and Equipment Rental Rates," and quotes from Northern California equipment rental companies.

- **Materials –** Material quotes were received from various Northern California material vendors. Pumping plant equipment quotes from major national and international suppliers (pumps, valves, etc.) were used**.**

Contingencies were added to the various facility construction costs. In the case of all tunneling work, a contingency of 35 percent was added. For all other work, a contingency of 25 percent was added.

At this stage of project planning, certain assumptions were necessarily made in the creation of the estimate:

- It was assumed that land would be acquired which would be sufficient to "borrow" soil from to construct each facility (canal and forebay embankments, pumping plant pads, etc). These borrow sites will be within a 5-mile haul (one way, using off-highway equipment).
- All excess or unsuitable soil will be deposited (spoiled) within a 1-mile haul from the facility (one-way, using off-highway equipment).
- It is assumed that the soil can be dewatered effectively.
- Installation of sheet pile cofferdams is planned to occur during the allowable windows, however once cofferdams are in place, work within the cofferdam will be allowed to occur year round.
- Tunneling work may continue 24/7; all other work is expected to be performed on five-day, ten-hour shift basis with two shifts per day.
- For the Isolated Conveyance Facility (ICF) East Option, it is assumed that certain sloughs can be completely diverted to allow for complete box culvert siphon construction.

Construction Cost Decomposition: the cost estimate for each conveyance option was decomposed into a logical division of work such as river intake structures, pumping plants, conveyance pipelines, canals, culvert siphons, tunnels, bridges, utilities, forebays, controls and communications, and power supply and grid connections. Major project components were further decomposed into subcomponents which were distinguishable. Decomposition continued until a discreet activity could be identified and either "unit prices" or a detailed estimate could be applied. The following is an example of this decomposition for pumping plants:

- Intake Pumping Plants
- Intermediate Pumping Plant
    - Mobilization/Site Prep/Temporary Facilities
    - Clearing and Grubbing
    - Pumping Plant Excavation and Backfill

- o Approach from Forebay
  - Excavation and Export
  - Excavation and Stockpile
  - Place Stockpiled Material as Backfill
  - Construct Concrete Approach
  - Rebar for Concrete Approach

Activity costs were then summarized at the facility level and all facility costs were summarized for a total alternative cost estimate.

Table 8-5. Summary of Intake and Conveyance Facility Features

Item	*Quantities*			
Intake Capacity	15,000 CFS			
Intake Pumping Plants	5 @ 3,000 CFS each			
Intermediate Pumping Plant Capacity	15,000 CFS			
Gravity Bypass Capacity	Up to 7,000 CFS			
Installed Power Demand	210 MW

Table 8-6. Water Conveyance Capital Cost

Capital Cost Items	***Mid-Point Cost Estimate[1] (in millions)***
PM/CM/Final Design and Construction	**$9,602.1**
Contingency	$2,932.2
Total Cost of Conveyance Facility, including Contingency	**$12,534.3**
Land Acquisition	**$130.4**
Contingency	$26.1
Total Cost of Land Acquisition, including Contingency	**$156.5**
Total Capital Costs	**$12,690.8**

[1]Mid-point construction cost estimate is the average of the DHCCP PTO Rev. 1 September 2010 construction cost estimate and the 5RMK Independent February 2010 construction cost estimate (escalated using same percentage as DHCCP Rev. 1). Estimated land acquisition costs based DHCCP Revision 7b Engineering GIS data (8/6/2010).

Table 8-7. Water Conveyance Annual Operations Cost

Annual Operations Cost Items [1]	***Mid-Point Cost Estimate [2] (in millions)***
SWP Power	$14.3/Yr
CVP Project Power	$3.5/Yr
Operations & Maintenance	$18.9/Yr
Capital Replacement	$45.9/Yr
Property Tax Revenue Replacement[3]	$1.9/Yr

[1]Annual SWP Power, CVP Project Power, and Operations & Maintenance costs assumed to commence by the 11th year of the permit period. Annual Capital Replacement costs assumed to commence by the 21st year of the permit period.
[2] Mid-point annual operations cost estimate is the average of the low and high DHCCP PTO Rev. 1 September 2010 operations cost estimate.
[3]While state agencies such as DWR are statutorily prohibited from making payments in lieu of taxes, recently passed legislation requires payment in lieu of taxes for land used in mitigation of new Delta conveyance facilities. The land acquisition cost estimate includes a provision for payments in lieu of taxes, but does not assign those costs to any specific party.

8.3.1.3 Land Acquisition Costs

Data from DWR land use surveys for Delta counties were combined with hypothetical facility, staging, and borrow site footprints to estimate facility land acquisition and easement requirements.[10] Land acquisition costs were estimated using the per acre fee title, surface easement, and subsurface easement cost assumptions presented in Section 8.2. Transaction costs are approximately 10 percent of fee title value and a 20 percent contingency was added to account for market uncertainties.

8.3.1.4 Facility Operation Costs

Estimated power requirements were based on simulated operations of each of the five intakes and the intermediate pumping plant using output from CALSIM II at 15 minute intervals from

[10] Acreage amounts are reflective of the DHCCP Revision 7b Engineering GIS data (8/6/2010).

October 1974 through September 1991 for a total of 17 years of hydrologic record. Diversion flows were dynamically simulated using operating rules in DSM2. Results were used to characterize typical diversion volumes during wet, normal, and dry year hydrologic conditions. Power requirements for pumping were estimated as a function of the pumping flow rate, total dynamic head, and combined efficiency of the pumps and motors. Pumping power requirements were then increased by 15 percent to account for all other project power uses (e.g. Heating, Ventilating, and Air Conditioning [HVAC], general operations and maintenance, lighting, etc.).

Annual power costs are based on a combination of Western Area Power Administration (WAPA) unit energy costs, estimates of bulk power purchased in northern California, and an estimate of CVP Project Power, with CVP Project Power supplying power for 40 percent of pumped water. The 15-minute model outputs were used to estimate on-peak and off-peak power purchases for typical diversion volumes in wet, normal, and dry year hydrologic conditions. The resulting costs for each hydrologic year were averaged to produce the average annual power cost shown in Table 8-7.[11]

General operations and maintenance (O&M) costs were based on estimated staffing requirements for facility operations and maintenance of the proposed conveyance facilities. Unit staffing costs were based on salary and wage rates, including benefits and overhead, for existing SWP operations.

In addition to general O&M and power costs, annual operating costs include contributions to a reliability and replacement fund to cover costs of major repairs and replacement of major capital equipment (e.g. pumps, motors, high voltage switchgear) over the permit period. For purposes of cost estimating, it is assumed that between $43 and $48 million is contributed to the fund annually starting in the 21st year of the permit period.

8.3.1.5 Property Tax and Assessment Revenue Replacement

New Delta conveyance facilities are required under the California Water Code to offset impacts to property tax or assessments levied by local governments or special districts.[12] Publicly available parcel-level local tax assessment data were combined with the proposed footprint of the conveyance facility to estimate potential impacts on local tax revenues. The average cost of property tax and assessment revenue replacement over the 50-year permit period for private lands acquired for conveyance was estimated to range between $1.5 and $2.3 million per year. While state agencies such as DWR are statutorily prohibited from making payments in lieu of taxes, recently passed legislation requires payment in lieu of taxes for land used in mitigation of new Delta conveyance facilities. The land acquisition cost estimate includes a provision for payments in lieu of taxes, but does not assign those costs to any specific party.

[11] Hydrologic year classifications are established by California Department of Water Resources and are primarily based on annual precipitation and unimpaired flow in the Sacramento River watershed.
[12] California Water Code Section 85088 (2009 Nov SB 1).

[Eastern Alignment Surface Canal Conveyance Option Cost Estimate]

*[**Note to Reviewers**: Because a preferred project has not been selected the preliminary cost estimate for the eastern alignment conveyance facility is presented in the following tables. Estimated construction costs from DHCCP PTO Rev. 1 September 2010 construction cost estimate, including cost of on-bank intake structures. Estimated land acquisition costs are based DHCCP Revision 7b Engineering GIS data (8/6/2010).]*

Table 8-A. Summary of Features for the East Canal Conveyance Option

Item	***East Canal Conveyance***
Intakes with Pumping Plants	*5@3,000 CFS*
Conveyance Pipeline	*5.9 miles (twin 16' diameter)*
Intermediate Pumping Plant	*15,000 CFS*
Intake Capacity	*15,000 CFS*
Canals	*40 miles*
Tunnels	*4 each (2.1 miles)*
Box Culvert Siphons	*8 each*
Forebay Total Acreage	*630 acres*
Bridges	*18 bridges*
Utilities	*150 conflicts*
Gravity Bypass	*none*
Installed Power Demand	*95 MW*
Surge Towers	*none*

Assumptions made for estimating East Canal Conveyance costs and schedule include:

- *All import borrow will be available at an average 5-mile haul using off-highway equipment.*
- *All excess dirt can be spoiled at an average 1-mile haul using off-highway equipment.*
- *No import borrow royalty payment is included.*
- *No allowance for upgrading the existing roadways and/or bridges to accommodate the required number of highway truck trips is included.*
- *The soil can be dewatered effectively.*
- *Certain sloughs can be completely diverted to allow for complete box culvert siphon construction.*
- *For construction of the North Delta Intake facility, once sheet pile cofferdams are in place, work can continue year-round in water.*
- *Work would proceed on a ten-hour day, six-days per week schedule with potentially two shifts per day. All required permits would be in place prior to start of construction.*
- *Real estate acquisition would not delay the construction schedule.*

Table 8-B. East Canal Capital Cost

Capital Cost Items	Cost Estimate [1] *(in millions)*
PM/CM/Final Design and Construction	**$6,334.2**
Contingency	$1,680.6
Total Cost of Conveyance Facility, including Contingency	**$8,014.8**
Land Acquisition	**$344.5**
Contingency	$68.9
Total Cost of Land Acquisition, including Contingency	**$413.4**
Total Capital Costs	**$8,428.2**

[1]DHCCP PTO Rev. 1 September 2010 construction cost estimate. Includes cost for on-bank intakes. Estimated land acquisition costs based DHCCP Revision 7b Engineering GIS data (8/6/2010).

Table 8-C. East Canal Annual Operations Cost

Annual Operations Cost Items [1]	*Cost Estimate [2] (in millions)*
Project Power	$33.6/Yr
Operations & Maintenance	$17.9/Yr
Capital Replacement	$45.9/Yr
Property Tax Revenue Replacement[3]	$2.2/Yr

[1]Annual SWP Power, CVP Project Power, and Operations & Maintenance costs assumed to commence by the 11th year of the permit period. Annual Capital Replacement costs assumed to commence by the 21st year of the permit period.
[2]DHCCP December 2009 operations cost estimate, updated to 2010 dollars.
[3]While state agencies such as DWR are statutorily prohibited from making payments in lieu of taxes, recently passed legislation requires payment in lieu of taxes for land used in mitigation of new Delta conveyance facilities. The land acquisition cost estimate includes a provision for payments in lieu of taxes, but does not assign those costs to any specific party.

8.3.2 CM2: Yolo Bypass Fisheries Enhancements

This conservation measure provides for the implementation of physical modifications within the Yolo bypass to enhance floodplain habitat for spawning and rearing splittail and rearing habitat of juvenile Sacramento River salmonids, as described in Chapter 3, *Conservation Strategy*. The measure includes development of a Yolo Bypass Fishery Enhancement Plan (YBFEP) to determine the best approaches for achieving biological objectives. The key features of the major facilities identified in the conservation measure were used for cost estimating purposes and are summarized below.

1. **Fremont Weir Fish Ladder Replacement**. The existing Fremont Weir Denil fish ladder will be removed and replaced with new salmonid passage facilities. Specific design criteria of the ladder have not yet been determined. This facility will incorporate monitoring technologies to allow for collection of information to evaluate its efficacy at passing adult fishes.

2. **Experimental Sturgeon Ramps**. One or more experimental ramps will be constructed at the Fremont Weir to allow for the effective passage of adult sturgeon and lamprey. Specific design criteria of ramps have not yet been determined. This facility will incorporate monitoring technologies to allow for collection of information to evaluate its efficacy at passing adult fishes.

3. **Deep Fish Passage Gates and Channel**. To enhance adult fish passage through the Fremont Weir, as part of modifications to the Fremont Weir (see action #8, below), a deep fish passage notch will be cut through a much smaller section of the Fremont Weir to an elevation of 11.5 feet (NAVD88). This notch will be fitted with operable "fish passage gates" that will allow controlled flow into the Yolo Bypass. A "fish passage channel" will be excavated to convey water from the Sacramento River to the new fish passage gates, and from the fish passage gates to the Tule Canal.

4. **Stilling Basin Modification**. Modifications will be made to the existing Fremont Weir stilling basin to ensure that the basin drains sufficiently into the deep fish passage channel.

5. **Sacramento Weir Improvements**. Modifications will be made to reduce leakage at the Sacramento Weir and therefore reduce attraction of fish from the Yolo Bypass to the weir. For comparative analysis purposes, YBFEP will review the benefits and necessity of constructing fish passage facilities at the Sacramento Weir to reduce juvenile fish stranding and improve upstream adult fish passage. This action may require excavation of a channel to convey water from the Sacramento River to the Sacramento Weir and from the Sacramento Weir to the Toe Drain, construction of new gates at a portion of the weir, and minor modifications to the stilling basin of the weir to ensure proper basin drainage. Specific design criteria of ramps would need to be determined. The low cost estimate assumes Sacramento Weir improvements are not needed, while the high cost estimate assumes they are.

6. **Tule Canal/Toe Drain and Lisbon Weir Improvements**. The YBFEP will include physical modifications to passage impediments, including road crossings and agricultural impoundments in the Tule Canal/Toe Drain to improve fish passage and survival. The cost estimate assumes the replacement of three existing structures at the northern end of the Tule Canal with bridges or other structures to allow adult fish passage. Lisbon Weir will be redesigned to improve fish passage while maintaining or improving water capture efficiency for irrigation.

7. **Lower Putah Creek Improvements**. The cost estimate assumes a realignment of Lower Putah Creek to improve upstream and downstream passage of Chinook salmon and steelhead in Putah Creek and floodplain habitat restoration to provide benefits for multiple species on existing public lands.

8. **Fremont Weir Modification**. The cost estimate includes engineering designs to physically modify the Fremont Weir to manage the timing, frequency, and duration of inundation of the Yolo Bypass with Sacramento River flows. It was assumed a section of the Fremont Weir will be lowered to 17.5 feet (NAVD88) and fitted with operable gates that will allow for controlled flow into the Yolo Bypass when the Sacramento River stage at the weir exceeds 17.5 feet. New flood channels would be excavated to connect the Sacramento River to the new gate structure and to connect the new gate structure to the Yolo Bypass.

9. **Yolo Bypass Modification**. Grading, removal of existing berms, levees, and water control structures, construction of berms or levees, re-working of agricultural delivery channels, and earthwork or construction of structures to reduce Tule Canal/Toe Drain channel capacities will be conducted to the extent necessary to improve the distribution (e.g., wetted area) and hydrodynamic characteristics (e.g., residence times, flow ramping, and recession) of water moving through the Yolo Bypass. The YBFEP will include modifications that will allow water to inundate in certain areas of the bypass to maximize biological benefits and keep water away from other areas to reduce stranding of covered fish species in isolated ponds, minimize impacts to terrestrial covered species, including giant garter snake, and accommodate other existing land uses (e.g., wildlife, public, and agricultural use areas). If necessary, lands will be acquired, in fee-title and through conservation or flood easements.

10. **Westside Option**. The YBFEP will include a feasibility study and evaluation of a gated channel to provide flows into Yolo Bypass along the west side. Potential flow sources are the Sacramento River, Colusa Basin Drain or Sacramento River flows through Knights Landing Ridge Cut, or augmentation of other western tributaries. Some modification of the existing configuration of the discontinuous channels along the western edge of the Yolo Bypass may also be required. If effective at meeting biological objectives, this option could be included in the implementation of the conservation measure. The low cost estimate assumes a gated channel is not constructed. The high cost estimate assumes it is constructed.

8.3.2.1 Yolo Bypass Improvement Options

The preferred design of Yolo Bypass improvements has not been determined. For purposes of cost estimation, two alternative design options were considered. These are as follows:

- **Option 1:** *Fremont Weir and All Fish Passage Improvements*. This option includes extensive improvements to Fremont Weir, as well as improvements to Lisbon Weir, Tule Canal/Toe Drain, Lower Putah Creek, Los Rios Creek, Yolo Bypass Modification, and some improvements to Sacramento Weir (to reduce stranding juvenile fish). It may optionally include a Westside Option. The high cost estimate for this option includes an allowance for a Westside Option, while the low estimate does not.
- **Option 2:** *Sacramento Weir and Lisbon Weir, Los Rios, and Putah Fish Passage Improvements*. This option includes extensive improvements to Sacramento Weir, as well as improvements to Lisbon Weir, Tule Canal/Toe Drain, Lower Putah Creek, Los Rios Creek, and Yolo Bypass Modification, and some improvements to Fremont Weir fish passage structures to prevent stranding juvenile fish. It does not include a Westside Option.

8.3.2.2 Estimated Construction Costs

[**Note to Reviewers:** *Yolo Bypass improvement options and costs are being reviewed and may be revised by DHCCP-Engineering. It also should be noted that it may be possible to cost-share* *improvements for Fremont and Sacramento Weir with State flood agencies, which would result in a lower overall cost for this conservation measure than estimated below.]*

The estimated construction costs for the two options are summarized in Table 8-8. Construction costs are based on the *Yolo Bypass Construction Cost Estimate*, dated September 14, 2010, prepared by DHCCP-Engineering. The construction cost estimates developed for the Plan are considered to be in the Class 4 Estimate Class and should have an expected accuracy range of +120 percent / -60 percent. Costs were estimated using the same cost estimation methodology used to estimate costs for Conservation Measure 1, *Water Facilities and Operations*. Low and high cost estimates for each option are presented. Costs for Option 1 are used in the BDCP cost summaries presented in Section 8.9 because this option provides a more conservative basis for Plan cost estimation.

Table 8-8. Yolo Bypass Improvement Options Construction Costs

Construction Element		***Low Cost Estimate (in millions)***	
Fac #	Description	Option 1	Option 2
1-4,8	Fremont Weir Fish Facilities	$141.4	$9.0
1-4,8	Other Civil/Site Work near Fremont Weir	$12.0	$0.0
1-4, 6, 8	Other Civil/Site Work for Fremont Weir	$20.0	$0.0
5	Sacramento Weir	$47.6	$192.7
6	Lisbon Weir	$23.3	$23.3
6	Los Rios Check Structure	$16.8	$16.8

7	Putah Creek Realignment	$16.7	$16.7
10	Westside Option	$58.3	$0.0
	Total Direct Cost	$435.3	$275.3
	Planning, Preliminary Engineering & Permitting at 8%	$168.6	$22.0
	Contingency at 50%	$41.4	$137.7
	Subtotal	$687.8	$435.0
	PM/CM/Final Design at 18%	$168.6	$74.3
	Total Construction Cost, including Contingency	$805.3	$509.4

8.3.2.3 Estimated Costs for Flowage and Levee Easements

Flowage easement costs are expected to depend on the incremental changes in flood frequency and duration in the bypass. Bypass acreage was categorized as minimally, moderately, or significantly impacted by incremental flows caused by the weir and other modifications to the bypass. Flowage easements on minimally impacted acreage were assumed to cost 12.5 percent of fee value. Flowage easements on moderately impacted acreage were assumed to cost 25 percent of fee value. Flowage easements on significantly impacted acreage were assumed to cost 37.5 percent of fee value. The fee values for Yolo Bypass described in Section 8.2 were used to calculate easement costs.

The low cost estimate assumed new flowage easements would be required for 21,500 acres within the eastern part of the bypass.[13] It assumed one-third of this acreage would be minimally impacted, one-third moderately impacted, and one-third significantly impacted.

The high cost estimate assumed western tributary flows would cause land within the central and western part of the bypass to also be affected. The high cost estimate assumed new flowage easements would be required for up to 48,000 acres.[14] It assumed 42.5 percent of this acreage would be minimally impacted, 42.5 percent moderately impacted, and 15 percent significantly impacted.[15]

A lump sum allowance of $5 million for levee easements to offset land encroachments for levee widening and other levee modifications to address potential scour and underseepage was also added to the estimate.

Estimated costs for flowage and levee easements are summarized in Table 8-9.

Table 8-9. Yolo Bypass Flowage and Levee Easement Costs

Cost Items	*Low Estimate (in millions)*	*High Estimate (in millions)*
Flowage Easements		
Affected Acreage	21,500	48,000
Easement Cost	**$25.1**	**$48.0**
Contingency at 20%	$5.0	$9.6
Easement Cost, including Contingency	**$30.1**	**$57.6**
Allowance for Levee Easements	**$5.0**	**$5.0**
Total Easement Cost	**$35.1**	**$62.6**

[13] This is based on the estimated extent of flooded acreage given a flow of 6000 cfs over Fremont Weir, per Table 2 of *Technical Study #2: Evaluation of North Delta Migration Corridors: Yolo Bypass*, Updated April 2009.

[14] The estimated extent of flooded acreage under very high Fremont Weir flows, per Table 3 of *Technical Study #2: Evaluation of North Delta Migration Corridors: Yolo Bypass*, Updated April 2009, is used as a proxy of the amount of potentially impacted acreage.

[15] Percentages were calculated by assuming the same distribution of impacted acreage within the eastern part of the bypass as the low cost estimate, and that half the additional 26,500 acres impacted within the central and western parts of the bypass would be minimally impacted, and half would be moderately impacted.

8.3.3 CM3: Natural Communities Protection

This conservation measure provides for the establishment of a preserve system to protect and enhance areas of existing natural communities and covered species habitat, protect and maintain occurrences of selected plant species with very limited distributions, provide sites suitable for restoration of natural communities and covered species habitat, and provide habitat connectivity among the various BDCP conservation land units in the preserve system. Costs were estimated for land acquisition, habitat creation, and nonnative weed control during the plant establishment period.

Land acquisition costs are based on the Terrestrial Habitat Restoration Land Base Requirements (SAIC, 2010). The assumed schedule of land acquisition is shown in Table 8-10. Assumptions for land acquisition and habitat construction cost by type of terrestrial habitat are as follows:

- *Vernal Pool Complex Terrain* – Land acquisition costs are based on acquiring fee-title interest in 300 acres of rangeland in the Conservation Zones listed in Table 8-10. Land costs are based on the land value assumptions presented in Section 8.2 and include allowances for transaction costs and contingency. Vernal pool habitat construction costs are based on costs for comparable restoration projects occurring in and around the Delta (Gause, per. comm.). Costs for vernal pool creation were estimated to range between $25,000 and $40,000 per acre of pool built. Vernal pools were assumed to occupy 45 acres, or 15 percent, of the 300 acre vernal pool complex. The other 255 acres were assumed to be supporting grassland habitat. Costs for grassland habitat restoration were estimated to range between $1,000 to $1,400 per acre. Ten to 20 percent of complex acreage is expected to require weed management each year during the establishment period. Weed management costs were estimated to range between $150 and $500 per treated acre, depending on type of management protocol.
- *Alkali Seasonal Wetland Complex* – Costs are based on acquiring fee-title interest in 400 acres of rangeland in the Conservation Zones listed in Table 8-10 to preserve existing alkali seasonal wetland complex. Land costs are based on the land value assumptions presented in Section 8.2 and include allowances for transaction costs and contingency.
- *Grassland* – Land acquisition costs are based on acquiring fee-title interest in 8,000 acres of rangeland in the Conservation Zones listed in Table 8-10. Land costs are based on the land value assumptions presented in Section 8.2 and include allowances for transaction costs and contingency. Costs for grassland habitat restoration were estimated to range between $1,000 to $1,400 per acre (Gause, per. comm.). It was assumed weed management would be required during the habitat establishment period at a cost of $200 to $400 per acre, depending on type of management protocol (Gause, per. comm.).
- *Cultivated (ag) Habitat* – Costs are based on acquiring fee-title interest in approximately 9,800 acres and securing conservation easements on an additional 22,800 acres of agricultural lands in the Conservation Zones listed in Table 8-10. Fee-title and easement

costs are based on the land value assumptions presented in Section 8.2 and include allowances for transaction costs and contingency.

Estimated costs to preserve natural communities are summarized in Table 8-11.

8.3.3.1 Property Tax and Assessment Revenue Replacement

Foregone property tax and assessments levied by local governments or special districts on private lands converted to terrestrial habitat will be offset by the BDCP. The annual cost of these offsets was estimated to range between three-quarters and one percent of the estimated market value of the converted private acreage.[16] The average cost of property tax and assessment revenue replacement over the 50-year permit period for private lands converted for the preservation of natural communities was estimated to range between $0.6 and $0.8 million per year. While state agencies such as DWR are statutorily prohibited from making payments in lieu of taxes, recently passed legislation requires payment in lieu of taxes for land used in mitigation of new Delta conveyance facilities. The land acquisition cost estimate includes a provision for payments in lieu of taxes, but does not assign those costs to any specific party.

8.3.4 CM4: Tidal Habitat Restoration

Tidal habitat restoration cost estimates are based on the extent and location of hypothetical tidal habitat restoration footprints for the near-term (Plan Year 10), early long-term (Plan Year 15), and late long-term (Plan Year 40) time periods. Table 8-12 shows the amount to tidal restoration that was assumed to have occurred by the end of each plan phase.[17] Chapter 5, *Effects Analysis*, provides a description of how the hypothetical habitat restoration designs were developed. This section presents the estimated costs for tidal habitat land acquisition, county tax revenue replacement, and habitat construction.

[16] Property tax and assessment burdens on parcels within the conveyance facility footprint were calculated to determine the average tax and assessment burden as a percent of estimated market value. Annual burden rates varied by county, but generally ranged between 0.75 and 1.0 percent of estimated market value, which is used to estimate forgone tax and assessment revenue for land converted to tidal and terrestrial habitat.
[17] The acreage foot prints were derived from RMA modeling conducted for the BDCP effects analysis.

Table 8-12. Tidal Habitat Restoration Acreage

Plan Phase	*Acres*	*Cumulative Acres*
Near-Term (Plan Year 10)	14,000	14,000
Early Long-Term (Plan Year 15)	11,000	25,000
Late Long-Term (Plan Year 40)	40,000	65,000

8.3.4.1 Tidal Habitat Restoration Land Acquisition Costs

Spatial data from DWR land use surveys, county parcel maps, and the tidal habitat footprints were combined to determine the number of parcels and amount of acreage by land use classification that would need to be acquired in each ROA.[18] Costs for land acquisition were calculated by multiplying this acreage by the average ROA land values listed in Table 8-1. Estimated transaction costs and contingency were then added to the estimate. Land acquisition costs for tidal habitat are summarized in Table 8-13.

Table 8-13. Tidal Habitat Land Acquisition Costs

ROA	*Estimated Cost (in millions)*
Cache Slough	$106.6
Cosumnes/Mokelumne	$21.9
South Delta	$151.2
Suisun Marsh	$31.9
West Delta	$10.4
Subtotal Land Acquisition	**$322.1**
Contingency at 20%	*$64.4*
Land Acquisition, including contingency	**$386.5**

8.3.4.2 Property Tax and Assessment Revenue Replacement

Foregone property tax and assessments levied by local governments or special districts on private lands converted to tidal habitat will be offset by the BDCP. The annual cost of these offsets was estimated to range between three-quarters and one percent of the estimated market value of the converted private acreage.[19] The average cost of property tax and assessment revenue replacement over the 50-year permit period for private lands converted to tidal habitat was estimated to range between $1.3 and $1.8 million per year. While state agencies such as DWR are statutorily prohibited from making payments in lieu of taxes, recently passed legislation requires payment in lieu of taxes for land used in mitigation of new Delta conveyance facilities. The land acquisition cost estimate includes a provision for payments in lieu of taxes, but does not assign those costs to any specific party.

[18] Parcels were counted only if at least 10 percent of their acreage was included in the footprint in order to avoid counting parcels just touching the footprint or having very little acreage in it.

[19] Property tax and assessment burdens on parcels within the conveyance facility footprint were calculated to determine the average tax and assessment burden as a percent of estimated market value. Annual burden rates varied by county, but generally ranged between 0.75 and 1.0 percent of estimated market value, which is used to estimate forgone tax and assessment revenue for land converted to tidal and terrestrial habitat.

8.3.4.3 Tidal Habitat Construction Cost Estimates

Tidal habitat restoration will involve a broad range of construction activities, as described in Chapter 3, *Conservation Strategy*. Mass grading and construction of temporary and permanent flood-protection levees will account for most of the construction cost. Low and high construction cost estimates were developed, which differ in terms of the extent of mass grading necessary. Two scenarios were assessed because the extent to which surface grading will be used to adjust the mix of intertidal (mainly marsh plain) and subtidal (mainly estuarine aquatic) habitat has not been determined. The estimated intertidal and subtidal habitat acreages for the low and high cost scenarios are summarized in Table 8-14. Acreages in the table are based on the hypothetical tidal habitat footprint and phasing assumptions used for the effects analysis, with minor modifications in the West Delta ROA.[20]

Table 8-14. Tidal Habitat Restoration Area Estimates by Scenario

	Habitat Area (acres)			
	Tidal Marsh	**Subtidal**	**Other**	**Total**
Low Cost Estimate	14,500	33,000	17,500	65,000
High Cost Estimate	29,000	26,500	9,500	65,000

The acreage footprints are derived from hydrodynamic modeling for a July 2002 base period. Tidal habitat is defined as the area between mean lower low water (MLLW) and mean higher high water (MHHW). Subtidal habitat is defined as the area below MLLW. Other habitat includes areas which are currently within intertidal elevations, but would be above high tides, based on the modeling predictions, once restoration is complete. The tidal ranges and associated acreages shown in the table do not account for long-term forecasts of sea level rise.

Large areas within the ROAs have subsided to a degree that natural sedimentation processes alone will not increase intertidal elevations to levels necessary to support the establishment of vegetation. To establish suitable elevations for intertidal marsh restoration, fill will need to be placed (mechanically or hydraulically) in subsided areas or biomass accumulation (also referred to as subsidence reversal) will need to occur prior to levee breaching. Because the extent to which grading will be needed to achieve the desired mix of intertidal and subtidal habitat has not been determined, cost estimates were developed for two conceptual mass grading scenarios. For each scenario, fill settlement has been taken into account in the volume calculations as a function of fill height and approximate depth of underlying peat soils.

The low cost grading scenario assumes 4.9 million cubic yards (MCY) of fill placement would be used to raise grades to suitable intertidal marsh elevations in parts of the West Delta ROA. The high cost grading scenario assumes an additional 13.7 MCY of grading and fill placement would be used to expand the intertidal area in the West Delta, Cache Slough, South Delta, and Cosumnes-Mokelumne ROAs.

Cost estimates were based on the following mass grading assumptions for each ROA.[21]

[20] Due to substantial fill and grading requirements in the West Delta ROA under the original hypothetical footprint, the footprint assumed for the cost analysis was reconfigured slightly to avoid tidal habitat construction in the most subsided parts of the ROA.

[21] It should be noted that alternative methods for converting subtidal habitat to intertidal marsh, such as bioaccumulation (subsidence reversal) and more extensive dredged material fill placement, have not been included in the cost estimates. Bioaccumulation involves planting and

Suisun Marsh: The cost estimate assumed no mass grading would be required. Suisun Marsh has a relatively high potential for estuarine deposition to raise elevations from subtidal to intertidal compared to the Delta ROAs. In addition, because of the regional geomorphic setting of Suisun Marsh, the tide signal is not expected to be as compressed as modeled in the long term, resulting in a relatively high extent of intertidal habitat area created without fill placement.

West Delta: The low cost scenario assumed restoration areas on subsided West Delta islands would be filled with hydraulically-placed dredged material to create a mix of approximately 20 percent intertidal and 80 percent subtidal habitat in all except the most deeply subsided areas (deeper than approximately 9 feet below mean low low-water (MLLW). The high cost scenario assumed these same restoration areas would be filled to create 100 percent intertidal habitat, again with the exception of the most deeply subsided areas. Both cost scenarios assumed the Dutch Slough site mass grading would consist of land-based fill placement (from local borrow and the Ironhouse Sanitary parcel), per the current DWR restoration plan (PWA 2006). Both scenarios assumed existing artificial fill above intertidal elevations would be removed at no cost to the project. West Delta fill costs were based on estimated costs of placing dredged material and the planning-level cost estimate for Dutch Slough.

Cache Slough, South Delta, and Cosumnes-Mokelumne: For these ROAs, the low cost scenario assumed no mass grading is required. The high cost scenario assumed some land-based cut and fill. To estimate the volume of fill required, it was assumed that lands with elevations up to one foot above mean high high-water (MHHW) would be lowered to the MHHW elevation. The cut material would then be placed in shallow subtidal areas to raise them up to the MLLW elevation. Additionally, mass grading costs for the Cache Slough ROA are based on the assumption that earthmoving would be phased over several decades, requiring interim stockpiling of fill material on one or more parcels. Cut and fill areas were broadly categorized based on anticipated haul distances, and the need for interim stockpiling. Unit costs for grading and fill were based on grading and fill costs for a sample of regional tidal marsh restoration projects.

Flood protection levees would be necessary to protect adjacent developed and other lands that have not been protected for tidal habitat restoration. Levee cost estimates were based on a total of 44 miles of permanent levees along the upland edges of the ROAs, 32 miles of permanent levees on subsided areas in the interiors of the ROAs, and 50 miles of temporary levees that would need to be breached or removed as restoration progresses. Estimated levee heights and unit volumes for each type of levee, by ROA, are shown in Table 8-15.

---

controlled flooding of marsh vegetation (e.g., tules, cattails) to allow for the accumulation of organic material over time to increase surface elevations. Allowing bioaccumulation to occur over a period of 20-30 years prior to breaching could increase grades by approximately three feet relative to the tides, assuming an accretion rate of one foot every six years. Bioaccumulation is most applicable to late long term restoration actions because of the time needed to increase surface elevations. To use this approach, the rate of land acquisition set out in the BDCP would need to be accelerated to provide sufficient opportunities for bioaccumulation to occur.

Table 8-15. Estimated Levee Heights and Unit Volumes by ROA

ROA	FEMA Base Flood Elevation (ft NAVD)	Temporary Levees		Permanent Levee (subsided areas)		Permanent Levee (upland edge)	
		Total Height* (ft)	Unit Volume (cy/lf)	Total Height* (ft)	Unit Volume (cy/lf)	Total Height* (ft)	Unit Volume (cy/lf)
Cache Slough	17.0	19.8	62.4			12.1	26.3
Suisun Marsh	10.0	10.8	21.4	9.3	16.7	-	-
Cosumnes-Mokelumne	20.0	-	-	22.5	79.0	-	-
West Delta	9.0	-	-	18.0-26.0	53-105	-	-
South Delta	14.0			20.2	64.9	10.7	21.2

* Total levee height includes allowance for settlement, future sea level rise, and freeboard.

The typical levee height for permanent levees was calculated as the difference between the Federal Emergency Management Agency (FEMA) 100-year flood elevation and a typical ground elevation, plus an allowance for settlement, freeboard and future sea level rise. Typical ground elevation was estimated by ROA and by levee type. Settlement was estimated for each levee type within an ROA as a function of levee height and approximate depth of underlying peat soils. A crest width of 16 feet was assumed for all levees, with average side slopes of 5:1 and 2:1 (horizontal:vertical) on the outboard and inboard sides, respectively.

Unit costs were derived from per cubic yard costs based on similar constructed projects. Unit costs ranging from $5 to $30 per cubic yard, depending on anticipated soil strength and distance of fill material source, were applied. It was assumed that the fill necessary for levee construction would be obtained from sources within the ROA. For island levees, it was assumed that material would be imported from offsite locations by barge and conveyor system.

A unit cost of $3,600 per acre was applied to the acreages shown in Table 8-14 to account for restoration elements other than mass grading and flood protection levees. This unit cost is based on costs for typical, large-scale tidal marsh restorations that have been completed (or are in final stages of design) in the San Francisco Bay: Napa Salt Ponds, South Bay Salt Ponds (multiple sites), Eden Landing Ecological Reserve, Bahia Wetlands, Petaluma Marsh, Cooley Landing, Outer Bair Island and Blacklock Marsh (Suisun Bay). Projects located in San Francisco Bay were used as analogues because of the lack of large-scale tidal habitat restoration projects within the Delta to serve as reference sites.

There are several challenges and limitations associated with estimating construction costs for the tidal habitat restoration. Consequently, estimates of construction costs and of the expected outcomes regarding the extent of habitat acreages created may ultimately be low or high. The uncertainties potentially affecting cost estimates are largely related to the following factors:

- Few, if any, examples of large-scale, planned tidal habitat restoration projects exist in the Delta to serve as reference sites.
- Flexible restoration footprints within the ROAs.
- Flexible sequencing of restoration projects.

- Future determinations regarding desired mix of intertidal marsh and subtidal habitat and therefore relative emphasis on using mass grading and fill to expand intertidal areas.
- Future evaluation of site specific features (e.g., utilities), conditions (e.g., weak soils, degraded levees), and adjacent land uses that may require additional design effort and construction costs.
- Future assessment of actual (versus modeled) changes to tide range over time due to phased restoration actions, geomorphic evolution, and sea level rise.

Each restoration site will have its own unique characteristics, causing actual construction costs to differ from the estimates set out in this chapter. Factors that may affect actual costs include: relocation of existing utilities, improvements necessary for site access, and accommodation for a phased approach to construction. The precise cost of restoration projects will not be known until site-specific designs are completed. A 35 percent contingency was applied to estimated construction costs to account for these unknowns.

Low and high construction cost estimates for tidal habitat restoration are summarized in Table 8-16.

Table 8-16. Total Construction Costs for Tidal Habitat Restoration

Construction Costs	*Low Estimate (in millions)*	*High Estimate (in millions)*
Restoration Costs	$232.2	$235.7
Mass Grading Costs	$36.0	$234.5
Long-term Levee Costs	$307.7	$307.7

Vegetation Establishment at 3%	$33.1	$41.3
Subtotal Related Costs	**$330.9**	**$412.9**
Total Tidal Habitat Construction Costs	**$1,433.7**	**$1,788.4**

8.3.5 CM5: Seasonally Inundated Floodplain Restoration

*[**Note to Reviewers**: At this point in time, cost estimates are presented for two floodplain restoration cost sharing options in order to support deliberations on selection of a preferred option. Once the selection of a preferred option has been made, Chapter 8 will be revised to present the cost estimate for just that option.]*

This conservation measure provides for the creation of 10,000 acres of seasonally inundated floodplain habitat along the San Joaquin River downstream of Vernalis and along Old and/or Middle rivers. The locations identified in this analysis were used solely to estimate costs. The

BDCP floodplain restoration conservation measures provide flexibility for restoration actions to occur along any major channel in the north, east, and south Delta. For cost estimation, it was assumed that floodplain habitat will be created by setting back existing levees, approximately 1,000 feet on each side of a channel. For areas along the San Joaquin River between Vernalis and French Camp Slough, it was assumed that 7,000 acres of floodplain habitat will be created through the relocation of approximately 29 miles of existing levees. It was assumed an additional 3,000 acres of floodplain habitat will be created along Old and/or Middle rivers by moving approximately 12 miles of existing levees.

The assumed schedule of setback levee construction and floodplain habitat creation over the term of the BDCP is shown in Table 8-17.

Table 8-17. Miles of Setback Levees and Acres of Created Floodplain Habitat

Miles of Setback Levees	***Cost Period***									
	1-5	**6-10**	**11-15**	**16-20**	**21-25**	**26-30**	**31-35**	**36-40**	**41-45**	**46-50**

Old/Middle R.	-	0.4	0.9	2.2	2.2	2.2	2.2	2.2		
Total Miles	-	1.3	2.9	7.4	7.4	7.4	7.4	7.4	-	-
Running Total	***-***	***1.3***	***4.2***	***11.6***	***19.0***	***26.4***	***33.8***	***41.3***	***41.3***	***41.3***
Acres of Floodplain	-	300	700	1800	1800	1800	1800	1800	-	-
Running Total	**-**	**300**	**1,000**	**2,800**	**4,600**	**6,400**	**8,200**	**10,000**	**10,000**	**10,000**

Setback levees for both project and non-project levees[22] were assumed to be constructed to the PL84-99 (Delta Specific) Standard. Levees along the San Joaquin River were assumed to already meet this standard, while levees along Old and Middle rivers were assumed to be non-project levees that do not meet this standard. The average levee height was assumed to be 20 feet, with a 5:1 interior slope, a 2:1 exterior slope, and a 16-foot wide crest. It was also assumed a graded, sloping bench to provide opportunities for both passive and active establishment of riparian vegetation will be added to the water-side of the levee.

Floodplain development costs were grouped as follows: (1) land acquisition costs for floodplain habitat and setback levee footprint; (2) planning, design, engineering, and permitting costs; (3) construction management costs; (4) construction costs; and (5) contingency costs.

8.3.5.1 Floodplain Habitat Land Acquisition

Land requirements for floodplain development are summarized in Table 8-18. Floodplain development is expected to involve land acquisition through fee title and easements. Land for graded benches and other habitat features on the water-side of the setback levees are expected to require fee-title acquisition. This accounts for approximately 80 percent of the acreage listed in

[22] Project levees are part of the Sacramento Flood Control Project, which was completed by USACE in 1960. Non-project levees are not part of a federal flood control project. Non-project levees are maintained by local districts with financial assistance from the state.

Table 8-18. It is assumed the remaining 20 percent can be secured through easements. Land acquisition costs are summarized in Table 8-19.

Table 8-18. Flood Plain Habitat Land Requirements

Flood Plain Land Acquisition	***Plan Year***									
	1-5	**6-10**	**11-15**	**16-20**	**21-25**	**26-30**	**31-35**	**36-40**	**41-45**	**46-50**

Table 8-19. Flood Plain Land Acquisition Costs

Cost Items	***Low Estimate (in millions)***	***High Estimate (in millions)***
Land Acquisition		
Fee Title Purchases	$58.1	$71.0
Easements	$9.5	$11.6
Subtotal Land Acquisition	**$67.6**	**$82.6**
Contingency at 20%	*$13.5*	*$16.5*
Land Costs, including Contingency	**$81.1**	**$99.1**

8.3.5.2 Property Tax and Assessment Revenue Replacement

Foregone property tax and assessments levied by local governments or special districts on private lands converted to floodplain habitat will be offset by the BDCP. The annual cost of these offsets was estimated to range between three-quarters and one percent of the estimated market value of the converted private acreage. The average cost of property tax and assessment revenue replacement over the 50-year permit period for private lands converted to floodplain habitat was estimated to range between $0.2 and $0.3 million per year. While state agencies such as DWR are statutorily prohibited from making payments in lieu of taxes, recently passed legislation requires payment in lieu of taxes for land used in mitigation of new Delta conveyance facilities. The land acquisition cost estimate includes a provision for payments in lieu of taxes, but does not assign those costs to any specific party.

8.3.5.3 Setback Levee Construction Costs

Levee construction cost estimates for setback levees were taken from levee cost studies done for Delta Visions (Betchart, 2008). Cost estimates were updated to 2010 dollars using USACE's Civil Works Construction Cost Index for levees and floodwalls. It was assumed upgrading existing levees to the PL84-99 (Delta-specific) standard will cost from $1.5 to $2.1 million per mile. It was assumed setting back levees will cost $2.3 million per mile, while creating the water-side benches for habitat development will cost between $1.2 million and $2.3 million per mile.[23] Based on these estimates, the construction costs to set back levees and create water-side benches for habitat were assumed to be $4.5 million per mile for project levees and $6.8 million per mile for non-project levees. The cost estimate assumed fill will be obtained locally. If fill needs to be imported, costs per mile will increase. The cost estimate includes allowances for mobilization (10 percent), surveys, design, construction management and administration (30 percent), and contingency (10 percent). Low and high costs for levee construction are summarized in Table 8-20.[24]

8.3.5.4 Low and High Cost Share Estimates

*[**Note to Reviewers:** cost estimates are presented for two floodplain restoration cost sharing options in order to support deliberations on selection of a preferred option. Once the selection of a preferred option has been made, Chapter 8 will be revised to present the cost estimate for just that option.]*

Some costs of floodplain development are expected to be funded by state flood management programs. The BDCP cost summaries in Section 8.9 assume that state flood management programs will cover a portion of the setback levee costs. The low cost estimate assumes BDCP will pay for half the incremental levee setback costs, all the habitat development costs, and half the land acquisition costs, while state flood programs will pay for half the setback and land acquisition costs plus upgrading non-project levees to the P.L.84-99 (Delta-specific) standard. The high cost estimate assumes BDCP will pay for all incremental levee setback cost, all habitat development costs, and all land acquisition costs, while state flood programs will pay for upgrading non-project levees to the P.L.84-99 (Delta-specific) standard. These assumptions result in a 50 to 75 percent BDCP cost share. BDCP costs are summarized in Table 8-21.

Table 8-20. Estimated Cost of Setback Levee Construction

Construction Costs	*Low Estimate (in millions)*	*High Estimate (in millions)*
Planning/Design/Permitting	$85.3	$104.3
Direct Construction	$284.3	$347.5
Construction Contingency at 10%	*$28.4*	$34.8
Construction Costs, including Contingency	**$398.0**	**$486.6**

Table 8-21. Low and High Cost Sharing Estimates for Floodplain Habitat

BDCP Cost Share	*Low Estimate (in millions)*	*High Estimate (in millions)*
Land Acquisition and Construction	$239.6	$439.3

[23] The cost ranges cited here are in 2010 dollars. The cost estimates reported in Betchart (2008) were developed by the Delta Risk Management Strategy (DRMS)/URS Levee Optimization workgroup. The estimates are based on a basic estimating system using assumed material quantities and unit prices and are considered to be first-order planning level estimates. Actual costs for constructing levee setbacks would be subject to substantial variation based on local conditions, availability of fill material, and changes in other construction assumptions.

[24] Low and high estimate are +/- 10 percent of the estimated costs for levee construction.

8.3.6 CM6: Channel Margin Habitat Enhancement

This conservation measure provides for the enhancement of 20 linear miles of channel margin habitat in the Delta.[25] For the cost analysis, it was assumed that channel margin habitat enhancement will entail creating low benches that support emergent vegetation and higher elevation benches that support riparian vegetation along existing levees. Large woody material (e.g., tree trunks and stumps) may be anchored into constructed low benches or in existing riprapped levees to provide similar habitat functions.

Channel margin enhancement cost estimates are based on conceptual design cross sections and budget-level cost estimates for 95 USACE bank stabilization project sites (approximately 76,000 linear feet) along the Sacramento River and its tributaries (USACE, 2009). Only bank stabilization projects that included channel margin habitat enhancements for species that are covered under the BDCP were considered for the BDCP cost analysis.

Line item cost estimates for each project were obtained from USACE. Cost items included expenditures for: (1) soil cover, (2) in-stream woody material, (3) fascines, (4) landscape materials, and (5) wetlands construction. Across the 95 projects, the cost of channel margin enhancements averaged $538 per linear foot. This estimate includes the cost of planning, engineering and design (at 12 percent of construction cost), construction management (at 8 percent of construction cost), and contingency (at 20 percent of construction cost). USACE assumed channel margin enhancement projects would not require land purchases or easements, though in some cases construction was assumed to require land-side access to target sites. The BDCP cost estimate adopted the same assumptions.

Estimated costs of channel margin enhancements are presented in Table 8-22.[26]

Table 8-22. Estimated Costs of Channel Margin Improvements by Cost Period

Construction Costs	***Low Estimate (in millions)***	***High Estimate (in millions)***
Planning/Design/Permitting	$4.5	$5.5
Direct Construction	$40.2	$49.1
Construction Contingency at 20%	*$8.9*	$10.9
Construction Costs, including Contingency	**$53.6**	**$65.5**

8.3.7 CM7: Riparian Habitat Restoration

This conservation measure provides for the establishment of 5,000 acres of riparian forest and scrub within areas of restored tidal marsh, floodplain, and channel margin. Establishment of riparian habitat will rely on both natural recruitment and active planting. Nonnative vegetation in riparian restoration areas will be controlled during the first three years of native riparian

[25] This could increase to up to 40 linear miles if adaptive management results in the deobligation of funds from other conservation measures.

[26] Low and high estimate are +/- 10 percent of the estimated costs for channel margin enhancement.

establishment. Assumptions used to estimate the costs of this conservation measure are as follows.

Natural Recruitment in Tidal Marsh Restoration Areas: Natural recruitment of riparian forest and scrub was assumed to occur above the tidal range from MHHW to MHHW +2.5 feet at sites that support suitable soils. Natural recruitment was assumed to take place in up to 20 percent of areas with generally suitable soils, and in up to 40 percent of areas with more fluvial disturbance (e.g., portions of the Cosumnes-Mokelumne ROA), where there is more potential for fluvial inundation and scour to refresh soil surfaces.

Active Planting in Tidal Marsh Restoration Areas: Active planting of riparian forest and scrub was assumed to occur in areas adjacent to naturally recruited vegetation in order to increase riparian patch size and enhance riparian habitat quality. It was assumed that active planting acreage would equal 30 percent of natural recruitment acreage in each ROA. A plant density of 170 plants per acre was assumed, which is consistent with an "over-planting" approach designed to rapidly establish native riparian species and reduce the need for replanting. A 70 percent survivorship rate was assumed over the three-year establishment period. Active planting was estimated at $4,000 per acre, including management, field preparation, irrigation installation, and planting costs. The unit cost assumption is based on riparian establishment costs for comparable projects in the Central Valley. A 20 percent cost contingency was added to the estimate.

Management of Riparian Vegetation in Tidal Marsh Restoration Areas: Control of nonnative vegetation during the three-year establishment period will be required. Control of nonnative vegetation will take place in both natural recruitment and active planting areas. It was assumed that control will occur on 100 percent of active planting areas and 50 percent of natural recruitment areas. Annual control cost in areas of active planting was estimated at $1,300 per acre. The unit cost assumption is based on nonnative vegetation control costs for comparable projects in the Central Valley. Control of nonnative vegetation in natural recruitment areas was assumed to cost 40 percent more than in active planting areas to account for more varied and difficult nonnative control conditions. A 20 percent cost contingency was added to the estimate.

Active Planting in Floodplain and Channel Margin Restoration Areas: The amount of active planting acreage in floodplain and channel margin restoration areas was based on the difference between targeted riparian acreage and estimated tidal marsh riparian acreage for the near-term, early long-term, and late long-term periods of the BDCP. Establishment of riparian habitat within restored floodplain was assumed to occur primarily in the South Delta ROA along the San Joaquin, Old, and Middle Rivers. Natural recruitment in floodplain areas and along channel margins was not assumed to contribute to riparian target acreage because of the likelihood native species composition and density would not result in quality riparian habitat.[27] Active planting

---

[27] Some funds for active planting in floodplain and channel margin restoration areas could be shifted to other conservation measures if subsequent monitoring shows that natural recruitment in these areas creates good riparian habitat.

cost assumptions in floodplain and channel margin restoration areas are the same as for tidal marsh restoration areas.

Management of Riparian Vegetation in Floodplain and Channel Margin Restoration Areas: Nonnative vegetation control costs per acre during the three-year establishment period in floodplain and channel margin restoration areas were assumed to be the same as for tidal marsh restoration areas.

Estimated riparian establishment costs over the term of the BDCP are summarized in Table 8-23.[28]

Table 8-23. Estimated Costs of Riparian Habitat Restoration

Plant Establishment	*Low Estimate (in millions)*	*High Estimate (in millions)*
Active Planting	$12.1	$14.8
Nonnative Control during Establishment	$15.7	$19.2
Subtotal Riparian Establishment	**$27.8**	**$34.0**
Contingency at 20%	*$5.6*	$6.8
Riparian Establishment Cost, including Contingency	**$33.4**	**$40.8**

8.3.8 CM8: Grassland Communities Resotration

This conservation measure provides for the restoration of 2,000 acres of grassland habitat within Conservation Zones 1, 8, and/or 11 (Figure 3.6). Costs were estimated for land acquisition, habitat creation, and on-going weed management during the establishment period.

8.3.8.1 Grassland Communities Land Acquisition Cost

Spatial data from DWR land use surveys and county parcel maps were combined to estimate the expected number of parcels and amount of acreage by land use classification in each Conservation Zone that would need to be acquired, per the acquisition schedule shown in Table 8-24. Costs for land acquisition were calculated by multiplying the acreage in each land use category by the land values listed in Table 8-2. Estimated transaction costs and contingency were then added to the estimate. Land acquisition costs for tidal habitat are summarized in Table 8-25.

Table 8-24. Land Acquisition Schedule for Grassland Habitat

Land Acquisition by CZ	**Acres Acquired by Period**										*Total Acres*
	1-5	**6-10**	**11-15**	**16-20**	**21-25**	**26-30**	**31-35**	**36-40**	**41-45**	**46-50**	
1	250	250	125	125	125	125					1,000
8		250									250

Total	**500**	**500**	**250**	**250**	**250**	**250**					**2,000**

[28] Low and high cost estimates are +/- 10 percent of the riparian establishment cost estimate.

Table 8-25. Grassland Communities Land Acquisition Cost

Cost Items	Cost Estimate *(in millions)*
Land Acquisition	
Fee Title Purchases	$6.9
Subtotal Land Acquisition	**$6.9**
Contingency at 20%	*$1.4*
Land Costs, including Contingency	**$8.3**

8.3.8.2 Property Tax and Assessment Revenue Replacement

Foregone property tax and assessments levied by local governments or special districts on private lands converted to grassland habitat will be offset by the BDCP. The annual cost of these offsets was estimated to range between three-quarters and one percent of the estimated market value of the converted private acreage. The average cost of property tax and assessment revenue replacement over the 50-year permit period for private lands converted to grassland habitat was estimated to range between $0.04 and $0.05 million per year. While state agencies such as DWR are statutorily prohibited from making payments in lieu of taxes, recently passed legislation requires payment in lieu of taxes for land used in mitigation of new Delta conveyance facilities. The land acquisition cost estimate includes a provision for payments in lieu of taxes, but does not assign those costs to any specific party.

8.3.8.3 Grassland Habitat Establishment Costs

Grassland habitat construction costs were based on costs for comparable restoration projects occurring in and around the Delta (Gause, per. comm.). Grassland restoration was estimated to cost $1,000 to $1,400 per acre for grading, disking, and seeding, and seed stock. Annual cost of weed management over the establishment period is expected to range between $200 and $400 per acre.[29] Grassland habitat establishment costs are summarized in Table 8-26.

Table 8-26. Estimated Costs to Restore Grassland Habitat Restoration

Plant Establishment	***Low Estimate (in millions)***	***High Estimate (in millions)***
Active Planting	$2.0	$2.9
Weed Control during Establishment	$1.6	$3.3
Subtotal Grassland Establishment	**$3.6**	**$6.2**
Contingency at 20%	*$0.7*	$1.2
Grassland Establishment Cost, including Contingency	**$4.3**	**$7.4**

8.3.9 CM9: Vernal Pool Complex Restoration

This conservation measure provides for the restoration of 200 acres of vernal pool complex habitat within Conservation Zones 1, 8, and/or 11 (Figure 3.6). Costs were estimated for land

[29] Herbicide choice and type of weeds can greatly affect price. If the sites can be pre-treated for weeds prior to planting using a combination of cultural and chemical control methods the costs for future weed control may be reduced by half.

acquisition, habitat creation, and on-going weed management during the establishment period for the vernal pool complex terrain.

8.3.9.1 Vernal Pool Complex Land Acquisition Cost

Spatial data from DWR land use surveys and county parcel maps were combined to estimate the expected number of parcels and amount of acreage by land use classification in each Conservation Zone that would need to be acquired, per the acquisition schedule shown in Table 8-27. Costs for land acquisition were calculated by multiplying the acreage in each land use category by the land values listed in Table 8-2. Estimated transaction costs and contingency were then added to the estimate. Land acquisition costs for 200 acres of vernal pool complex are summarized in Table 8-28.

Table 8-27. Land Acquisition Schedule for Vernal Pool Complex

Land Acquisition by CZ	**Acres Acquired by Period**										*Total Acres*
	1-5	**6-10**	**11-15**	**16-20**	**21-25**	**26-30**	**31-35**	**36-40**	**41-45**	**46-50**	
1	40		22								62
8	27			22							49

Total	**87**	**29**	**42**	**42**	**0**	**0**	**0**	**0**	**0**	**0**	**200**

Table 8-28. Vernal Pool Complex Land Acquisition Cost

Cost Items	*Cost Estimate (in millions)*
Land Acquisition	
Fee Title Purchases	$0.7
Subtotal Land Acquisition	**$0.7**
Contingency at 20%	*$0.1*
Land Costs, including Contingency	**$0.8**

8.3.9.2 Property Tax and Assessment Revenue Replacement

Foregone property tax and assessments levied by local governments or special districts on private lands converted to vernal pool habitat will be offset by the BDCP. The annual cost of these offsets was estimated to range between three-quarters and one percent of the estimated market value of the converted private acreage. The average cost of property tax and assessment revenue replacement over the 50-year permit period for private lands converted to vernal pool complex was estimated to range between $4 and $5 thousand per year. While state agencies such as DWR are statutorily prohibited from making payments in lieu of taxes, recently passed legislation requires payment in lieu of taxes for land used in mitigation of new Delta conveyance facilities. The land acquisition cost estimate includes a provision for payments in lieu of taxes, but does not assign those costs to any specific party.

8.3.9.3 Vernal Pool Complex Establishment Cost

Vernal pool habitat construction costs are based on costs for comparable restoration projects occurring in and around the Delta (Gause, per. comm.). Costs for vernal pool creation were estimated to range between $25,000 and $40,000 per acre of pool built. Vernal pools were assumed to occupy 30 acres, or 15 percent, of the 200 acre vernal pool complex. The other 170 acres were assumed to be supporting grassland habitat. Costs for grassland habitat restoration were estimated to range between $1,000 to $1,400 per acre. Ten to 20 percent of complex acreage is expected to require weed management each year during the establishment period. Weed management costs were estimated to range between $150 and $500 per treated acre, depending on type of management protocol. Vernal pool complex establishment costs are summarized in Table 8-29.

Table 8-29. Estimated Vernal Pool Complex Establishment Cost

Vernal Pool Establishment Costs	Low Estimate *(in millions)*	High Estimate *(in millions)*
Vernal Pool Construction	$0.8	$1.2
Grassland Establishment	$0.2	$0.2
Weed Control during Establishment	$0.0	$0.1
Subtotal Vernal Pool Establishment	**$1.0**	**$1.5**
Contingency at 20%	*$0.2*	$0.3
Vernal Pool Complex Cost, including Contingency	**$1.2**	**$1.8**

8.3.10 CM10: Nontidal Marsh Restoration

This conservation measure provides for the restoration of 400 acres of nontidal freshwater marsh within Conservation Zones 2 and 4 (Figure 3-1). Restored habitat will be distributed in patches of at least 25 acres and associated with occupied giant garter snake habitat within the proposed 1,000-acre giant garter snake preserves designed to enhance the Caldoni Marsh/White Slough and the Yolo Basin/Willow Slough giant garter snake populations. Costs were estimated for land acquisition, habitat creation, and a backup water supply.

8.3.10.1 Nontidal Freshwater Marsh Land Acquisition Cost

For purposes of cost estimation, it was assumed 200 acres of agricultural land within Conservation Zone 4 would be acquired by year 5 of the Plan and an additional 200 acres of agricultural land within Conservation Zone 2 would be acquired by year 10 of the Plan. Spatial data from DWR land use surveys and county parcel maps were combined to estimate the expected number of parcels and amount of acreage by land use classification in each Conservation Zone that would need to be acquired. Costs for land acquisition were calculated by multiplying the acreage in each land use category by the appropriate land values listed in Table 8-2. Estimated transaction costs and contingency were then added to the estimate. Land acquisition costs for 400 acres of nontidal freshwater marsh are summarized in Table 8-30.

Table 8-30. Nontidal Freshwater Marsh Land Acquisition Cost

Cost Items	Cost Estimate *(in millions)*
Land Acquisition	
Fee Title Purchases	$4.4
Subtotal Land Acquisition	**$4.4**
Contingency at 20%	*$0.9*
Land Costs, including Contingency	**$5.3**

8.3.10.2 Property Tax and Assessment Revenue Replacement

Foregone property tax and assessments levied by local governments or special districts on private lands converted to nontidal freshwater marsh will be offset by the BDCP. The annual cost of these offsets was estimated to range between three-quarters and one percent of the estimated market value of the converted private acreage. The average cost of property tax and assessment revenue replacement over the 50-year permit period for private lands converted to vernal pool complex was estimated to range between $0.04 and $0.05 million per year. While state agencies such as DWR are statutorily prohibited from making payments in lieu of taxes, recently passed legislation requires payment in lieu of taxes for land used in mitigation of new Delta conveyance facilities. The land acquisition cost estimate includes a provision for payments in lieu of taxes, but does not assign those costs to any specific party.

8.3.10.3 Nontidal Freshwater Marsh Establishment Cost

Estimated costs for nontidal freshwater marsh habitat establishment are based on costs for comparable restoration projects occurring in and around the Delta (Gause, per. comm.). Construction of nontidal freshwater marsh habitat, including permitting, project management, monitoring, grading, seeding, and other planting was estimated to cost between $4,600 and $8,100 per acre. This assumes two-thirds of the acreage is converted to aquatic habitat and one-third to upland habitat. The cost estimate also includes allowances for two wells for backup water supply. Well costs were estimated to range between $125,000 and $150,000 per well. Estimated costs for nontidal freshwater marsh establishment are summarized in Table 8-31.

Table 8-31. Nontidal Freshwater Marsh Establishment Cost

Nontidal Freshwater Marsh Establishment Costs	Low Estimate *(in millions)*	High Estimate *(in millions)*
Marsh Construction	$1.8	$3.3
Wells	$0.3	$0.3
Subtotal Freshwater Marsh Establishment	**$2.1**	**$3.6**
Contingency at 20%	*$0.4*	*$0.7*
Freshwater Marsh Cost, including Contingency	**$2.5**	**$4.3**

8.3.11 CM11: Natural Communities Enhancement and Management

*[**Note to Reviewers**: Preserve land management costs are preliminary and subject to revision.]*

This conservation measure provides for the development and implementation of management plans for all conservation lands. This management will provide for the maintenance of the habitat functions of protected existing habitat and restored habitats described in CM3, CM4, CM5, CM6, CM7, CM8, CM9, CM10, and CM11.

Management Costs During Permit Period: Habitat management costs for BDCP conservation lands were based on operating budgets for western U.S. National Wildlife Refuges (NWR) managed by the U.S. Fish and Wildlife Service (USFWS) (USFWS 2007). Data on operating budgets and acreage under management were used to estimate unit costs for habitat management. Estimation details are provided in Appendix J, *Implementation Costs Supporting Materials*.

Habitat acreage was assumed to come under management in the period following the one in which existing habitat was acquired or new habitat restored. Tidal marsh, floodplain, and terrestrial/nontidal wetlands acreage were treated as separate management units and separate unit cost assumptions were applied to these acreages. Unit costs shown in the table are averages across all habitat types.

Non-Wasting Endowment Funding Costs: A non-wasting endowment is expected to be established to pay for the costs of land management following the 50-year permit period. The endowment would be funded over the 50-year permit period. Interest from the fund would be used to pay for on-going land management costs following the end of the permit. This would require contributions of approximately $2 million per year (in 2010 dollars), resulting in a fund balance of approximately $182 million (in 2010 dollars) by the end of the permit period.

Annual costs for land management and endowment funding are summarized in Table 8-32.[30]

Table 8-32. Annual Cost of Preserve Management and Endowment Funding

Preserve Management and Endowment Costs	***Low Estimate*** *(in millions)*	***High Estimate*** *(in millions)*
Preserve Management [1]	$3.1/Yr	$3.8/Yr
Contingency at 20%	$0.6/Yr	$0.8/Yr
Subtotal Preserve Management	**$3.7/Yr**	**$4.6/Yr**
Endowment Funding	*$2.0/Yr*	$2.0/Yr
Total Preserve Management, including Contingency and Endowment	**$5.7/Yr**	**$6.6/Yr**

[1]Annual cost for fully established preserve system.

8.3.12 CM12: Methylmercury Management

BDCP actions to minimize the potential for bioaccumulation of mercury that could occur in areas of restoration actions (CM12) include (1) site characterization of mercury prior to acquisition, (2) restoration design modification to address unacceptable concentrations of mercury in substrate,

[30] Low and high estimated costs are +/- 10 percent of the estimated costs for land management and endowment funding. Note that Table 8-32 is representing the annual management cost once the preserve system is fully established. Annual management costs will increase to this level over the permit period as land is added to the preserve system.

(3) long-term monitoring and (4) adaptive management. This cost estimate addresses actions (1) and (2); costs associated with actions (3) and (4) are included in costs for specific habitat measures (e.g., tidal habitat restoration, CM4). The mercury sampling results described in this section will inform site selection and habitat restoration design for tidal and floodplain habitat (CM 4 and 5, respectively). Costs associated with modified site selection and habitat design fall within the contingencies for those two conservation measures, and therefore are not shown here. Costs for ongoing monitoring of mercury methylation within BDCP habitat are subsumed within the cost estimate for Monitoring, Research, and Adaptive Management. This section describes the assumptions used to estimate the incremental costs associated with soil sampling that will be used to identify mercury hot spots within the restoration opportunity areas.

Pre-Acquisition Site Characterization: Pre-acquisition surveys for mercury, grain size and total organic content would be conducted for proposed tidal habitat areas (CM4; 65,000 acres) and floodplain restoration (CM5; 10,000 acres). The 4,000 acres of West Delta tidal restoration acreage can be eliminated from pre-acquisition surveys because these areas will be extensively filled to attain the targeted elevations, resulting in a total of 71,000 acres to be surveyed. For costing purposes the lower end of a range of sample densities from regional surveys (Heim et al., 2010) is used, 1 sample per 300 acres. Consideration is given to the fact that some sites may require an increased sample density, reflected in a high-end cost estimate that assumes one-quarter of the total restoration acreage would be sampled at a density of 1 sample per 50 acres. Survey costs are based on an estimate of $200,000 for a two-week survey to collect, analyze and provide report of results for 175 samples.

Project Design Surveys: More detailed mercury surveys may be required for designing specific restoration plans. Approximate acreages that may require project design surveys are based on the low-end and high-end scenarios described for tidal habitat restoration, CM4, in Section 8.4.4. For a low end cost estimate, project design surveys for mercury would be conducted for approximately 46,100 acres of restoration area at 1 sample per 300 acres. For the high end cost estimate, sampling density would be increased to 1 sample per 50 acres and would include collection and analysis of composite samples representing the 0 to 12-inch depth interval and on a more limited basis the12-inch to 14 or 16-inch depth interval.

Low and high cost estimates for methylmercury site characterization and project design surveys are summarized in Table 8-33.

Table 8-33. Methylmercury Site Characterization and Project Design Surveys

Methylmercury Survey Cost	*Low Estimate (in millions)*	*High Estimate (in millions)*
Site Characterization Surveys	$0.3	$0.8
Project Design Surveys	$0.3	$1.5
Subtotal Methylmercury Survey Cost[1]	**$0.5**	**$2.3**
Contingency at 20%	*$0.1*	$0.5
Methylmercury Survey Cost, including Contingency	**$0.6**	**$2.8**

[1] Subtotal may not reflect sum of survey costs due to rounding.

8.3.13 CM13: Nonnative Aquatic Vegetation Control

This conservation measure provides for the control of Brazilian waterweed (*Egeria densa*), water hyacinth (*Eichhornia crassipes*), and other nonnative submerged and floating aquatic vegetation (SAV and FAV) in BDCP tidal habitat restoration areas. To implement this conservation measure, the BDCP will apply existing methods used by the California Department of Boating and Waterways' (DBW) *Egeria densa* and Water Hyacinth Control Programs, such as applying herbicides as specific as possible to these species, conducting mechanical removal, and/or using other methods of removal as dictated by site-specific conditions and intended outcome/goal. Application of herbicides or other means to control SAV/FAV will be timed to eliminate or minimize potential negative effects of SAV/FAV removal on covered species.

Nonnative vegetation control costs can vary greatly in the Delta, depending on location, plant density, time of year, method of eradication, and need for environmental monitoring. In recent years, environmental monitoring and regulatory compliance costs have comprised approximately 40 percent of total eradication costs, adding substantially to costs of eradication per acre (DBW 2006). Between 2003 and 2005, DBW's aquatic vegetation removal program costs averaged about $2,500 per acre (2010 dollars). Budgetary estimates contained in the 2006 addendum to DBW's *Egeria densa* EIR suggest per acre costs as high as $4,500 per acre (DBW 2006). However, this higher cost was based on high regulatory compliance costs. Because regulatory costs for BDCP vegetation control are not expected to be this high, the cost estimate for this conservation measure is based on the average cost of $2,500 per acre (2010 dollars) reported by DBW for the period 2003 to 2005.

The amount of acreage that will require treatment annually is expected to vary. The low cost estimate assumes, on average, 5 percent of tidal habitat acreage would be treated each year.[31] The high cost estimate assumes, on average, 10 percent of tidal habitat acreage would be treated each year. Average annual treatment costs are summarized in Table 8-34.[32]

Table 8-34. BDCP Aquatic Vegetation Removal Cost

Aquatic Vegetation Removal Cost	***Low Estimate*** *(in millions)*	***High Estimate*** *(in millions)*
Average Acres Treated	1,679/Yr	3,358/Yr
Average Annual Cost	$4.3/Yr	$8.6/Yr
Subtotal Aquatic Vegetation Removal Cost	**$4.3/Yr**	**$8.6/Yr**
Contingency at 20%	*$0.9/Yr*	$1.7/Yr
Aquatic Vegetation Removal, including Contingency	**$5.2/Yr**	**$10.3/Yr**

[31] Treated acreage is calculated as a percentage of the total tidal marsh footprint, including upland acreage. Therefore, the amount of treated tidal and subtidal acreage, as a percentage of total restored tidal and subtidal acreage, would be much higher than the percentages listed above.

[32] Note that annual removal costs will increase over the permit period with the addition of more tidal marsh habitat. Table 8-34 shows the average annual cost over the 50-year permit period.

8.3.14 CM14: Stockton Deep Water Ship Channel Dissolved Oxygen Levels

This conservation measure, which will occur within the Stockton Deep Water Ship Channel, is designed to maintain dissolved oxygen concentrations at levels that will not adversely affect covered fish species during periods when these fish are present in the channel. The BDCP Implementation Office will operate and maintain an oxygen aeration facility in the channel to increase dissolved oxygen concentrations between Turner Cut and Stockton to meet total maximum daily load (TMDL) objectives established by the Central Valley Regional Water Quality Control Board (above 6.0 mg/L from September 1 through November 30 and above 5.0 mg/L [milligrams per liter] at all times). The existing aeration facility will be modified as necessary and, if necessary, additional aerators and associated infrastructure will be added to optimize oxygen delivery to the river, contingent upon results of an ongoing demonstration project conducted by DWR. Operating costs at DWR's existing demonstration facility vary depending on the flows through the ship channel. During dry years, the facility may operate for up to 100 days per year, while in wet years no operations may be required. Depending on flow conditions, annual operating costs range from $10,000 to $300,000 per year. For the purpose of cost estimation, an average annual operating cost of $150,000 has been assumed. Given expected flows through the ship channel, this provides a conservative estimate of likely operating cost (McLaughlin, pers. comm.).[33]

The existing aeration facility was build in 2007 and cost $3.5 million. It is expected to have a 15 year useful life (McLaughlin, pers. comm.).

Low and high estimated costs over the term of the BDCP are shown in Table 8-35 and Table 8-36.[34]

Table 8-35. SDWSC Dissolved Oxygen Diffuser Capital Cost

Diffuser Capital Costs	**Low Estimate** *(in millions)*	**High Estimate** *(in millions)*
Facility Capital Replacement [1]	$9.6	$11.8
Subtotal Diffuser Facility Capital Cost	**$9.6**	**$11.8**
Contingency at 20%	*$1.9*	$2.4
Diffuser Facility Capital Costs, including Contingency	**$11.5**	**$14.2**

[1]Assumes diffuser facility replacement between the 11th and 15th, 26th and 30th, and41st and 50th years of the permit period.

[33] The operating cost estimate prepared by DWR assumed the facility would operate on average 50 days per year. However, recent changes to the City of Stockton's Regional Wastewater Treatment Facility have resulted in improved water quality in the ship channel. If ship channel water quality improves further as a result of San Joaquin River restoration or Delta improvements, average operating days may dip below the level assumed for the cost analysis.

[34] Low and high estimates are +/- 10 percent of the diffuser cost estimate.

Table 8-36. SDWSC Dissolved Oxygen Diffuser Operation Cost

Diffuser Operation Costs	*Low Estimate (in millions)*	*High Estimate (in millions)*
Avg. Annual Diffuser Operation Cost	$0.14/Yr	$0.17/Yr
Subtotal Diffuser Operation Cost	**$0.14/Yr**	**$0.17/Yr**
Contingency at 20%	*$0.03/Yr*	$0.03/Yr
Diffuser Operation Costs, including Contingency	**$0.17/Yr**	**$0.20/Yr**

8.3.15 CM15: Predator Control

This conservation measure addresses the local effects of nonnative predators on covered fish species by supporting focused predator control in high predator density locations. The BDCP will conduct focused predator control using a variety of methods in locations in the Delta that are known to have high densities of predators (“predator hot spots”). Locations of hot spots in which focused predator control will occur and assumptions used to estimate predator control costs for these sites are listed in Table 8-37.

Table 8-37. Focused Predator Control Locations in Delta

Delta Nonnative Predator Hot Spot	*Assumptions for Cost Estimate*
1. Old structures in or hanging over Delta waterways, such as pier pilings or other artificial structures, that are no longer functional or have been abandoned but affect flow fields and provide shade	Up to 20 structures removed per year
2. Vessels that were abandoned throughout the Delta	Up to 10 vessels removed per year
3. New intake structures of the North Delta Diversions	Daily predator harvest using large purse seine nets at 5 locations from October through May.
4. The deep hole just downstream of the Head of Old River in the San Joaquin River	Daily predator harvest using large purse seine nets at 1 location from October through May.
5. Specific locations in Georgiana Slough, as identified by fishery agencies	Daily predator harvest using large purse seine nets at 3 locations from October through May.
6. Specific locations in Sutter and Steamboat sloughs, as identified by fishery agencies	Daily predator harvest using large purse seine nets at 4 locations from October through May.
7. Release sites of salvaged fish from CVP/SWP facilities	Weekly predator harvest using large purse seine nets at 4 locations from October through May.

8.3.15.1 Structure Removal Cost Assumptions

An average cost of $7,800 per structure was assumed. Average structure removal costs are based on costs to remove 30 feet of docking with piles spaced at 10 foot intervals. Dock demolition and disposal was assumed to cost $100 per foot. Pile removal was assumed to cost $800 per pile. Dock and pile removal costs are based on cost information provided by the Contra Costa County Sheriff Department (Powell, pers. comm.) It was assumed that up to 20 structures per year will be removed.

8.3.15.2 Vessel Removal Cost Assumptions

Vessel removal costs are based on the average cost per vessel for removal of 408 vessels in 2002-03 and 2003-04 by the Department of Boating and Waterways (DBW 2005). The average cost of removal was approximately $3,050 per vessel (in 2010 dollars). It was assumed that up to 10 vessels would be removed per year.

8.3.15.3 Focused Predator Control Cost Assumptions

Predator control using large purse seine nets was assumed to occur daily at 13 locations and weekly at 4 locations in the Delta (Table 8-37) between October and May. A predator control event was assumed to require three boat passes over a hot spot, requiring on average 1.5 hours, plus 0.5 hours for travel between sites. It was estimated that 3.4 full-time-equivalent boat crews would be required to operate 241 days per year.

Boat crews were assumed to consist of two mates and a California Department of Fish and Game (DFG) fish habitat specialist. Labor rates were based on FY 2008-09 salary scales for reference positions within the DFG, as reported by the California Department of Finance (CDFA 2009). Labor rates were increased by a factor of 1.35 to account for benefits. A cost contingency of 20 percent was added to calculated labor costs.

Boats used for predator control were assumed to cost $40,000 and have a 10-year useful life.[35] An annual operating cost, covering fuel, maintenance, repairs, and other incidental costs of $48,200 per boat was estimated.[36] A cost contingency of 20 percent was added to calculated boat purchase and operating costs.

Average annual costs for nonnative predatory control are summarized in Table 8-38.[37]

Table 8-38. Focused Nonnative Predator Control Cost

Nonnative Predator Control Cost Items	***Low Estimate*** *(in millions)*	***High Estimate*** *(in millions)*
Hot Spot Predator Removal	$0.55/Yr	$0.68/Yr
Abandoned Vessel Removal	$0.03/Yr	$0.03/Yr
Abandoned Structure Removal	$0.14/Yr	$0.17/Yr
Subtotal Nonnative Predator Control Cost	**$0.72/Yr**	**$0.88/Yr**
Contingency at 20%	*$0.14/Yr*	$0.18/Yr
Nonnative Predator Control Cost, including Contingency	**$0.86/Yr**	**$1.06/Yr**

[35] Boat cost assumption based on a sample of prices for new 20-25 foot center console fishing boats.

[36] Operating costs are based on sample of hourly vessel operating costs for DFG 20-25 foot boats used for IEP surveys. Costs include fuel, maintenance, repairs, and haul out. Operating costs calculated with DFG Vessel Op Costs spreadsheet model (VesselOpCosts2009.xls).

[37] Low and high estimates are +/- 10 percent of the estimated costs for nonnative predator control.

8.3.16 CM16: Non-Physical Fish Barriers

This conservation measure provides funding for the installation and operation of non-physical barriers at the heads of various Delta channels to redirect outmigrating juvenile salmonids. Potential locations for non-physical barriers are described in Chapter 3, *Conservation Strategy*, and include the Head of Old River, the Delta Cross Channel, Georgiana Slough, Turner Cut, Columbia Cut, the Delta Mendota Canal intake, and the Clifton Court Forebay (CFF).

A pilot project was carried out at the Head of Old River, using 14 sections of bubble generators, each 8 meters long. This project used leased equipment and consultant operators. For the spring season of 2009, equipment and operating costs totaled $1.3 million dollars (Holderman, pers. comm.). DWR expects the experience gained through this pilot program will allow a 10 percent reduction in future operating costs. Operating costs were reduced by 10 percent, resulting in an estimated annual cost of $1.2 million per location, to which a 20 percent contingency was added. Non-physical barriers are expected to be operated at seven Delta locations during outmigration periods. Low and high estimated costs to construct and operate the seven barriers over the term of the BDCP are summarized in Table 8-39.[38]

Table 8-39. Estimated Non-Physical Barriers Program Cost (Millions of 2010 dollars)

Non-Physical Fish Barrier Cost	***Low Estimate*** *(in millions)*	***High Estimate*** *(in millions)*
No. of Barrier Locations	7	7
Equipment Lease and Operation	$7.5/Yr	$9.1/Yr
Subtotal Non-Physical Barrier Cost	**$7.5/Yr**	**$9.1/Yr**
Contingency at 20%	*$1.5/Yr*	$1.8/Yr
Non-Physical Barrier Cost, including Contingency	**$9.0/Yr**	**$10.9/Yr**

8.3.17 CM17: Hatchery and Genetic Management Plans

This conservation measure provides for the accelerated development and implementation of Hatchery and Genetic Management Plans (HGMPs) for state Chinook salmon and steelhead hatcheries located in California's Central Valley. Several coordinating actions with DFG and National Marine Fisheries Services (NMFS) associated with this conservation measure will be undertaken by the BDCP Implementation Office. The costs associated with these efforts will primarily be staff-related and were included in the estimated costs for BDCP Program Administration presented later in this chapter.

In addition to these coordinating actions, the BDCP Implementation Office will provide funding for: (1) the development of the HGMPs, (2) a new DFG HGMP staff position, and (3) additional staff at Central Valley hatcheries needed for HGMP implementation and updating. The costs estimated for each action are as follows.

[38] Low and high estimates are +/- 10 percent of the estimated costs for non-physical barriers.

8.3.17.1 HGMP Development and Updating

The cost analysis assumed 12 HGMPs would be updated every five years.[39] Recent genetic management plans developed by DWR for the Feather River Hatchery have cost $125,000 on average, with approximately 90 percent of this being consultant time, and 10 percent DWR staff time (Kindopp pers. comm.). The estimated cost for all 12 plans is estimated to be $1.5 million every five years.

8.3.17.2 DFG HGMP Coordinator Staff Position

An HGMP Coordinator will be hired to coordinate the development, updating, and implementation of the HGMPS among the state hatcheries. It was assumed the salary for this position would be equivalent to that for a Supervising Biologist with DFG's Fisheries Division. DFG estimated overhead and operating costs for the position at $20,000 per year (Shaffer pers. comm.). Total estimated cost to fund the position, including employee benefits and overhead, is $128,000 per year.

8.3.17.3 Central Valley Hatcheries Staff Positions and Operations

It was assumed that each hatchery would need to hire a biologist to oversee the implementation of the individual management plans. DFG estimated the cost of the position at $92,000 per year, including benefits (Shaffer pers. comm.). It was assumed four biologists would be needed for the state hatcheries and two for the federal hatcheries. DFG estimated overhead and operating costs for each position at $20,000 per year (Shaffer pers. comm.). Each hatchery was assumed to undertake genetic testing of ten salmonids stocks every three years. The cost analysis assumed each test would require 50 samples at a cost of $200 per sample. It was also assumed each hatchery would need to seasonally hire technicians to collect and record population data during salmon runs at a cost of $40,000 per year (Lee pers. comm.).

Average annual costs over the permit period are summarized in Table 8-40.[40]

Table 8-40. Estimated HGMP Development and Implementation Support Cost

HGMP Development & Implementation	***Low Estimate*** *(in millions)*	***High Estimate*** *(in millions)*
HGMP Development & Updates	$0.3/Yr	$0.3/Yr
DFG HGMP Coordinator	$0.1/Yr	$0.1/Yr
Hatcheries Staff & Operations	$0.7/Yr	$0.8/Yr
Subtotal HGMP Cost	**$1.1/Yr**	**$1.2/Yr**
Contingency at 20%	*$0.2/Yr*	$0.3/Yr
HGMP Cost, including Contingency	**$1.3/Yr**	**$1.6/Yr**

[39] Appendix J, *Implementation Costs Supporting Materials* provides the list of Central Valley hatcheries for which it is assumed HGMPs will be developed.

[40] Low and high estimates are +/- 10 percent of the estimated costs for HGMP development.

8.3.18 CM18: Illegal Harvest

This conservation measure provides for the funding of actions designed to reduce incidence of illegal harvest of covered fish species. Over the course of the BDCP, funding will be provided to support 17 field wardens and five supervisory staff that will be assigned to the Delta-Bay Enhanced Enforcement Program (DBEEP). Funding will be used to cover the following expenses: (1) salaries, wages, and benefits, (2) operating expenses, (3) minor equipment, (4) major equipment, and (5) overhead. Cost estimates for each category of expense are based on information provided by DFG.

8.3.18.1 Salaries, Wages, and Benefits

Estimated annual staffing costs are based on the DFG positions and salaries shown in Table 8-41, and the employee benefit assumptions described in Section 8.2.

Table 8-41. DFG Game Warden and Support Staff Wage and Salary Assumptions

Position	*Annual FTE Salary**	*FTE Positions*	*Resources Agency Reference Position*
Fish & Game Warden	$61,000	17	Fish and Game Warden, DFG Law Enforcement Div.
Patrol Lieutenant - Supervisor	$75,000	1.0	Fish and Game Patrol Lieutenant – Supervisor, DFG Law Enforcement Div.
Associate Governmental Program Analyst	$62,000	1.0	Associate Governmental Program Analyst, DFG Law Enforcement Div.
Staff Services Analyst-General	$50,000	2.0	Staff Services Analyst-General, DFG Law Enforcement Div.
Secretary	$39,000	1.0	Secretary, DFG Law Enforcement Div.

*Salary estimates based on proposed salaries for 2008-09 for corresponding positions within the Resources Agency, as reported by the California Department of Finance (www.dof.ca.gov/budget/historical/2008-09/salaries_and_wages/index.htm).
* FTE = full-time equivalent
Annual salary amounts shown in this table were multiplied by 1.35 to account for paid leave, health, retirement and other benefits.

8.3.18.2 Operating Expenses

Operating expenses have been estimated by DFG to be approximately $1.3 million annually. Operating costs include allowances for facilities, vehicles, travel, training, general office expenses, and employee overtime (Naslund pers. comm.).

8.3.18.3 Minor and Major Equipment

Costs for minor equipment were estimated by DFG to be approximately $410,000. Minor equipment is expected to be replaced every five years. Costs for major equipment were estimated by DFG to be approximately $892,000. Major equipment is expected to be replaced every ten years. Boat costs were estimated by DFG to cost $1.15 million. Boats are expected to be replaced every 15 years.

8.3.18.4 Overhead

An overhead multiplier of 0.23 was applied to labor, operating, and equipment costs to account for associated overhead costs DFG expects to incur to support the additional staff and equipment assigned to the DBEEP program.

Average annual costs to reduce illegal harvest are summarized in Table 8-42.[41]

Table 8-42. Estimated Illegal Harvest Reduction Costs by Cost Period

Illegal Harvest Reduction	***Low Estimate*** *(in millions)*	***High Estimate*** *(in millions)*
Salaries & Benefits	$1.6/Yr	$2.0/Yr
Operating Expenses, including equipment	$1.5/Yr	$1.8/Yr
Overhead	$0.7/Yr	$0.9/Yr
Subtotal Illegal Harvest Reduction Cost	**$3.8/Yr**	**$4.7/Yr**
Contingency at 20%	*$0.8/Yr*	$0.9/Yr
HGMP Cost, including Contingency	**$4.6/Yr**	**$5.6/Yr**

8.3.19 CM19: Conservation Hatcheries

This conservation measure provides for the support of existing and establishment of new conservation propagation programs for delta and longfin smelt. The conservation measure includes the following: (1) the development of a USFWS delta and longfin smelt conservation hatchery to house a delta smelt refugial population and provide a source of delta and longfin smelt for supplementation or reintroduction, if deemed necessary by fishery agencies, and (2) the expansion of the refugial population of delta smelt and establishment of a refugial population of longfin smelt at the University of California, Davis Fish Conservation and Culture Laboratory to serve as a population safeguard in case of a catastrophic event in the wild.

8.3.19.1 USFWS Delta and Longfin Smelt Conservation Hatchery

The proposed USFWS hatchery is described in Chapter 3, *Conservation Strategy*. Estimated construction costs for the facility, as developed by USFWS, are $19.4 million (Clarke pers. comm.). Annual operating costs, also developed by USFWS, are $1.5 - $2.0 million (Clarke pers. comm.). It was assumed the facility will be constructed by the end of the fifth year of the BDCP and that an annual operating cost of $1.75 million will be incurred starting in the sixth year of the BDCP.

8.3.19.2 Expansion of Delta and Longfin Smelt Refugial Population

The current fish facility at the University of California, Davis will be expanded to support delta and longfin smelt refugial populations in the near term. U.C. Davis has estimated facility expansion will cost $5 million. It is also estimated that annual operating costs will be $2 million. Operating costs are expected to decrease to approximately $800,000 in the eighth year, once the

[41] Low and high cost estimates are +/- 10 percent of the estimated costs for staff, equipment, and overhead.

USFWS hatchery is in full operation (Lindberg pers. comm.). It is further assumed that expansion will be completed within the first two years of plan implementation and that annual operating costs will accrue starting the third year of plan implementation.

Construction and operation costs for conservation hatcheries are shown in Table 8-43 and Table 8-44, respectively.[42]

Table 8-43. Smelt Propagation Facilities Construction Costs

Smelt Propagation Facilities Costs	***Low Estimate*** *(in millions)*	***High Estimate*** *(in millions)*
FWS Smelt Hatchery Construction	$17.8	$21.8
UC Davis Smelt Refugium Expansion	$4.6	$5.6
Subtotal Smelt Facilities Construction Costs	**$22.4**	**$27.4**
Contingency at 20%	*$4.5*	$5.5
Smelt Facilities Construction Costs, including Contingency	**$26.9**	**$32.9**

Table 8-44. Smelt Propagation Facilities Operation Costs

Smelt Facilities Operation Costs *1/*	***Low Estimate*** *(in millions)*	***High Estimate*** *(in millions)*
FWS Smelt Hatchery Construction	$1.8/Yr	$2.2/Yr
UC Davis Smelt Refugium Expansion	$0.9/Yr	$1.1/Yr
Subtotal Smelt Facilities Operation Costs	**$2.7/Yr**	**$3.3/Yr**
Contingency at 20%	*$0.5/Yr*	$0.7/Yr
Smelt Facilities Operation Costs, including Contingency	**$3.2/Yr**	**$4.0Yr**

1/ Average annual over 50-year permit period.

8.4 PLAN ADMINISTRATION COST ESTIMATE

***[Note to Reviewers:** The composition of the BDCP Implementation Office is still under development and the staff and related costs presented in this section are likely to change as the BDCP Implementation Office is better defined. The assumption that the BDCP Implementation Office is an independent entity is adopted only for the purpose of cost estimation. The specific structure of the BDCP Implementation Office and its relationship to existing state and federal agencies will be determined and described in Chapter 7 of the Plan.]*

The costs associated with the administration of the BDCP reflect all of the expenditures that will be reasonably necessary for the BDCP Implementation Office to effectively oversee the implementation of the BDCP throughout the term of the Plan. Program administration costs include expenditures related to employees, facilities, equipment, vehicles, and associated overhead necessary to support the BDCP Implementation Office. Associated overhead costs include employee benefits, insurance, legal and financial assistance, and travel. For the purpose of the cost analysis, the BDCP Implementation Office is assumed to be an independent entity

[42] Low and high estimates are +/- 10 percent the estimated costs for conservation hatchery construction and operating cost.

located in Sacramento, California. This assumption provides a conservative basis from which to estimate program administration costs. Administrative costs that may be incurred by entities other than the BDCP Implementation Office (e.g., supporting entities – see Chapter 7, *Implementation Structure*) are not included in the program administration cost estimate.

8.4.1.1 Staff and Related Costs

The BDCP Implementation Office employee costs are based on a staffing plan developed for BDCP and the salary and benefit assumptions described in Section 8.2 (see Appendix J, *Implementation Costs Supporting Materials* for details). Staffing costs include allowances for benefits, travel, and training. Staffing levels assumed for the cost estimate vary over the permit period, from a low 41 full-time equivalent (FTE) positions in the first five years of Plan implementation to a maximum of 57 FTE positions by the 21st year of Plan implementation.

8.4.1.2 Office Space and Related Costs

Office space and related costs include the office rental costs, utilities, general office equipment, employee-assigned office equipment, geographic information system (GIS) hardware and software, and public outreach materials. Cost assumptions for each of these items are as follows:

Office Space and Utilities: An office space requirement of 250 square feet per FTE was assumed. Unfurnished office space was estimated to cost $2.50 per square foot per month, including utilities.[43]

General Office Equipment: General office equipment includes copy machines, telephone systems, printers, fax machines, and specialized equipment such as digital cameras, trunked radio systems, and publications and subscriptions. It also includes common area office furniture. Annual costs were estimated by amortizing the purchase cost of each type of equipment or furniture over its useful life.[44] Some items were assumed to include annual service contract costs (see Appendix J, *Implementation Costs Supporting Materials* for details).

Employee-Assigned Office Equipment: Employee-assigned office equipment includes cubicle office furniture, computers, cell phones, and office supplies. Annual costs were estimated by multiplying the number of FTE staff positions by the amortized cost of equipment. Some items were assumed to include annual service contract costs. See Appendix J, *Implementation Costs Supporting Materials* for specific employee-assigned equipment cost assumptions.

GIS Hardware and Software: This category includes a dedicated GIS/database server, tablet personal computer, plotter, global positioning system (GPS) unit, GIS software, and related computer software. Annual costs are based on the estimated purchase cost for each item amortized over its useful life. Some items were assumed to include annual service contract

[43] The rental rate assumption is approximately 125 percent of current office rental rates if downtown Sacramento. The 25 percent premium is added to account for the currently depressed commercial real estate market in Sacramento.

[44] This is equivalent to assuming general office equipment and furniture is leased by the BDCP Implementation Office.

costs. See Appendix J, *Implementation Costs Supporting Materials* for specific GIS equipment cost assumptions.

Public Outreach Costs: This category includes an annual allowance for printed material, public meetings and focus groups, including costs for design, layout, printing, postage, web services, and facilities rental. Annual public outreach costs were assumed to vary over the term of the BDCP. See Appendix J, *Implementation Costs Supporting Materials* for specific public outreach cost assumptions.

8.4.1.3 Vehicle and Related Costs

Vehicle costs include the costs for owned and rented vehicles and as well as allowances for fuel, maintenance, and insurance. Owned vehicle annual costs were based on the vehicle's estimated purchase cost amortized over its useful life plus an annual allowance for fuel, maintenance, and insurance. Annual costs for rented vehicles were based on a daily rental rate multiplied by the number of rental days per year per 1,000 acres of habitat under management. See Appendix J, *Implementation Costs Supporting Materials* for the specific vehicle quantity and cost assumptions.

8.4.1.4 Legal, Accounting, and Insurance Costs

Insurance requirements for the BDCP Implementation Office were assumed to include directors and officers insurance, general liability insurance, and professional liability insurance. Liability insurance was assumed to total $30,000 per year, or $150,000 every five years.[45] The BDCP Implementation Office was assumed to require outside legal and accounting assistance throughout the term of the BDCP.[46] Outside legal costs were calculated by multiplying an hourly rate by annual hours of assistance. The amount of outside legal assistance needed by the Implementing Office was assumed to vary over the term of the BDCP. Accounting assistance costs were based on an annual lump sum allowance for auditing and other financial services. See Appendix J, *Implementation Costs Supporting Materials* for specific legal and accounting assistance cost assumptions.

8.4.1.5 Summary of Program Administration Costs

Annual average program administration costs are summarized in Table 8-45. The allocation of program administration costs to specific program functions is shown in Table 8-46.[47]

---

[45]Vehicle and employee health/disability/workers compensation insurance costs are calculated separately from liability insurance costs. Vehicle insurance costs are included in the vehicle cost estimate, while employee insurance costs are captured by the benefits multiplier applied to wage and salary costs.

[46] These services would be in addition to legal counsel and budget analyst positions within the Implementing Office. See Appendix J, *Implementation Costs Supporting Materials for details.*

[47] Implementation of conservation measures addressing other stressors will be paid for by the contributors to that stressor or by public dollars. However, the SWP and CVP will provide funding for a program that is projected to be about $1 million per year to pay for staff in the BDCP Implementation Office to advocate and pursue research to continue evaluation of other stressors and engage the regulatory agencies to take actions based upon improved scientific understanding to reduce the affects of these stressors on the health of at risk fish species in the Delta.

Table 8-45. Estimated BDCP Implementation Office Costs

Implementation Office Costs 1/	***Low Estimate*** *(in millions)*	***High Estimate*** *(in millions)*
Salary & Benefits	$3.9/Yr	$4.8/Yr
Office, Furniture, Computers	$0.5/Yr	$0.6/Yr
Vehicles	$0.2/Yr	$0.3/Yr
Legal, Accounting, Insurance	$0.5/Yr	$0.6/Yr
Total Implementation Office Costs	**$5.2/Yr**	**$6.4/Yr**

1/ Average annual over 50-year permit period.

Table 8-46. Functional Allocation of BDCP Implementation Office Costs

Implementation Office Cost Allocation	***Low Estimate*** *(in millions)*	***High Estimate*** *(in millions)*
Program Administration	$1.9/Yr	$2.3/Yr
Restoration	$1.8/Yr	$2.2/Yr
Other Stressors Program	$0.9/Yr	$1.1/Yr
Monitoring & Research	$0.7/Yr	$0.8/Yr
Total Implementing Office Cost (Mil/Year)	**$5.2/Yr**	**$6.4/Yr**

8.5 Monitoring/Research and Avoidance and Minimization Measures Cost Estimate

*[**Note to Reviewers:** Monitoring/research and avoidance and minimization measure cost estimates are under development and not included in this draft of Chapter 8. These costs have been roughly estimated to range between $60 and $90 million/year, inclusive of on-going IEP expenditures of roughly $30 million/year.]*

8.6 Adaptive Management Program Cost Estimate

Costs for adaptive management are included in the contingencies of each conservation measure's cost estimate, and therefore are not estimated separately.

8.7 Changed Circumstances Cost Estimate

The changed circumstances provisions of the BDCP are intended to address reasonably foreseeable events that may impede or prevent the BDCP from achieving its biological goals and objectives within the Plan Area. Section 6.3.2, *Changed Circumstances*, of the BDCP identifies a broad range of potential changed circumstances. As noted in Section 6.3.2, responses to changed circumstances will largely be developed and implemented as part of the adaptive management program. In some cases the expected costs associated with responses to changed circumstances are accounted for directly or implicitly through contingencies in the estimated costs of conservation measures. However, responses to certain changed circumstances are expected to result in additional implementation costs, if such responses become necessary. This section describes these costs and how they were estimated.

For purposes of cost estimation, the changed circumstances described in Section 6.3.2 of the BDCP were divided into three categories:

1. Changed circumstances for which responses beyond those contemplated by the adaptive management program would likely be impracticable and ineffective;

2. Changed circumstances for which response costs are accounted for directly or implicitly in the estimated costs of conservation measures, including adaptive management; and

3. Changed circumstances for which responses are expected to result in additional implementation costs.

Changed circumstances for which responses beyond those contemplated by the adaptive management program would likely be impracticable and ineffective. This category includes changed circumstance related to climate, water temperature, ocean conditions, and long-term temperature and precipitation patterns. Responses to significant changes in any of these circumstances, beyond the basic responses dictated by the adaptive management program, are not expected to be practicable or effective, and, as such, are not provided for under the BDCP.

Changed circumstances for which response costs are accounted for directly or implicitly in the estimated costs of conservation measures. This category includes changed circumstances related to water operations infrastructure, conflicts with state or federal environmental regulation, new species listings, invasive species, and toxic or hazardous spills.

- *Water Operations Infrastructure*: A changed circumstance in water operations infrastructure is defined as a malfunction or breakdown of water operations conveyance facilities which precludes or substantially inhibits the ability to manage water operations within the water operations parameters in effect at the time of the infrastructure failure. The planned response to this changed circumstance is to work with DWR and/or Reclamation to make repairs to the affected facilities and restore operations to normal as quickly as possible. The expected costs of minor and major repair and replacement of water operations infrastructure are accounted for directly in the operating cost estimate for Conservation Measure 1, *Water Facilities and Operation*. Costs for minor repairs and maintenance are included in annual costs for O&M, while costs for repairs to and/or replacement of major components of water operations infrastructure are included in the annual reliability and replacement fund, which over the 50-year permit period, provides for roughly $2 billion for these purposes.

- *Conflicts with state or federal environmental regulation*: Responses to conflicts with State or federal environmental regulation include modifying conservation measures to ensure compliance and/or implementing alternative conservation measures that provide equivalent ecological benefits. The cost contingencies, which range from 20 to 50 percent, included in the conservation measure cost estimates are deemed sufficient to accommodate changes in design or implementation required to ensure compliance with applicable state and federal environmental regulations. If compliance necessitates implementation of alternative conservation measures, it is expected that costs would be comparable to the costs of the measures being replaced.

- *New species listing*: In the event that a fish or wildlife agency lists a species not covered by the BDCP, the BDCP Implementation Office will evaluate potential impacts of covered activities on the species and conduct an assessment of suitable habitat in areas of potential effect. It will also implement measures to avoid impacts to the newly listed specified until such time as the BDCP has been amended to include the newly listed species as a covered species. Any incremental costs of these activities are expected to fall within the cost contingencies applied to the conservation measure cost estimates including adaptive management. It is anticipated that the natural communities protected and restored in the Plan Area under the BDCP will include suitable habitat for most if not all newly listed species having a presence in the Plan Area and therefore no additional land acquisition costs would be incurred.
- *Introduction of new invasive species*: Responses to new invasive species will be determined through the adaptive management process and may include measures to reduce or control the adverse effect of new nonnative species and/or implementation of alternative conservation measures that provide equivalent levels of benefit to applicable covered species. The cost contingencies, which range from 20 to 50 percent, included in the conservation measure cost estimates are deemed sufficient to accommodate changes in design or implementation required to control adverse effects of new nonnative species. If presence of new nonnative species necessitates implementation of alternative conservation measures, it is expected that costs would be comparable to the costs of the measures being replaced.
- *Toxic of hazardous spills*: Cost liability is assumed to rest with the party responsible for the spill event. Thus spill events that are not attributable to BDCP actions would not result in additional BDCP cost. Construction activity is considered to be the most likely source of a spill event caused by a BDCP action. In such situations, construction contingencies and bonding/insurance requirements of contractors are expected to cover any costs of spill remediation.

Changed circumstances for which responses are expected to result in additional implementation costs. This category includes changed circumstances related to failure of BDCP constructed levees and damage to BDCP protected lands caused by non-prescribed fire.

- *Failure of BDCP constructed levees*: Both tidal habitat restoration and floodplain development involve modification of existing and/or construction of new levees. Notwithstanding the integrity of constructed levees, the BDCP Implementation Office may encounter circumstances in which these levees subsequently fail. In such an event, the BDCP Implementation Office may be responsible for undertaking actions to restore the functions of habitat degraded or lost as a result of failure. For cost estimating purposes, the response is assumed to include a contribution to repair of the damaged levee and restoration or replacement of damaged habitat. Because of differences in geographic location, land use, and levee design, expected costs of levee failure were estimated separately for levees connected to tidal habitat restoration and floodplain development.[48]

Levees constructed for tidal habitat restoration: A probabilistic model of levee failure was used to estimate the likelihood of a levee failure in each permit year. Failure due to both flood and seismic events was considered. Risk of failure due to flood events was estimated by converting a 1:100 year level of flood protection into an expected rate of failure per mile of constructed levee. Seismic failure rates per mile were assumed to be similar to those for existing levees within the relevant ROA, as estimated by the Delta Risk Management Strategy Phase 1 report.[49] The flood and seismic failure rates per mile were added together to get the composite rate of failure per mile. The composite rate was then multiplied by the number of miles of BDCP constructed levees in each permit year to get the probability of a levee failure for each permit year. A low and high estimate of levee repair cost was used to calculate the expected cost of levee repair in each permit year. The high estimate assumes repair costs for tidal habitat levees would be similar to the average cost of repair for a significant levee failure, as reported by Suddeth, Mount, and Lund (2010).[50] The low estimate set repair costs at half the average cost, on the assumption that it may not be necessary to repair every breach or reclaim all flooded land in tidal habitat zones. It was also assumed that a failed tidal habitat levee would, on average, require reconstruction of 10 percent of the affected tidal habitat at a cost of $6,000 per acre.[51] Expected costs over the 50-year permit period are summarized in Table 8-46 and work out to approximately 10 to 15 percent of the tidal habitat construction cost for Conservation Measure 4, *Tidal Habitat Restoration*.

Levees constructed for floodplain development: A probabilistic model of levee failure similar to the one developed for tidal habitat was used to estimate the probability of floodplain levee failure in each permit year. The average cost of repair for a significant levee failure, as reported by Suddeth, Mount, and Lund (2010). Additionally, it was assumed that damages to land and assets protected by a breached floodplain levee would equal 10 percent of the flooded island's or tract's land and asset value. The two costs were multiplied by the probability of failure for each permit year to estimate the expected cost of floodplain levee failure of the 50-year permit period. This cost was then allocated between the BDCP and state/federal flood agencies according to the cost share percentages used to calculate the low and high cost estimates for Conservation Measure 5 (CM 5), *Seasonally Inundated Floodplain Restoration*.

Damage to BDCP protected lands caused by non-prescribed fire: Most natural communities in the Plan Area, including valley/foothill riparian, wetlands, and agriculture, are typically not prone to fire. The non-aquatic lands within the Plan Area are primarily characterized by intensively managed agriculture, which generally does not provide the conditions for

[48] The detailed calculations are presented in Appendix J, *Implementation Costs Supporting Materials*.

[49] Seismic levee failure probabilities for Delta islands and tracts within each ROA were taken from Table 13-3 of the Final Delta Risk Management Strategy Phase 1 Report. These island failure probabilities were converted to seismic failure rates per mile of levee using data on island levee miles reported in Table 13-1 of the Final Delta Risk Management Strategy Phase 1 Report. The average of these probabilities was used to estimate the seismic risk per mile of BDCP constructed levees in each ROA.

[50] They estimate the average cost of repair, which includes costs of mobilization, breach stabilization, breach closure, and island pump-out, averages $25 million, based on data compiled by the Delta Risk Management Strategy, DWR, and interviews with various Delta engineers.

[51] The per acre cost is derived from the tidal habitat construction cost estimate developed for conservation measure 4 and includes the habitat restoration costs other than land acquisition, levee construction, and major grading.

uncontrolled or extensive fire events. Non-prescribed fire on restored riparian acreage is more likely to go unchecked and may result in significant impairment of habitat function. If it is determined through monitoring that burned riparian vegetation is not recovering at a sufficient rate through natural processes, active reestablishment may be required. These costs are not expected to exceed 5 percent of the initial cost of riparian habitat establishment estimated for Conservation Measure 7, *Riparian Habitat Restoration*.

Average annual incremental costs for changed circumstances are summarized in Table 8-47.

Table 8-47. Incremental Costs of Changed Circumstances

Changed Circumstances Costs [1]	***Low Estimate*** *(in millions)*	***High Estimate*** *(in millions)*
Failure of Constructed Levees for Tidal Habitat	$2.0/Yr	$3.3/Yr
Failure of Constructed Levees for Floodplain Habitat	$0.8/Yr	$1.2/Yr
Restoration of Habitat damaged by Fire	$0.1/Yr	$0.1/Yr
Incremental Costs of Changed Circumstances	**$2.9/Yr**	**$4.6/Yr**

8.8 Mitigation Measures Cost Estimate

*[**Note to Reviewers:** This section will present costs for mitigation measures, which are still underdevelopment. Per Steering Committee request, it will present NEPA/CEQA mitigation costs for non-biological resources to the extent that such costs are developed through the EIR/EIS process.]*

8.9 Summary of Program Costs

BDCP capital outlays over the 50-year permit period are summarized in Table 8-48 for the low and high cost estimates. Capital outlays are shown in five-year increments. Approximately 90 percent of capital outlays are expected to occur within the first 15 years of Plan implementation. Approximately 80 percent of capital outlays are for water conveyance and 20 percent are for habitat conservation measures. Figure 8-1 depicts capital outlays graphically over the 50-year permit period for the midpoint of the low and high cost estimates.

BDCP operating outlays over the 50-year permit period are summarized in Table 8-49 for the low and high cost estimates. Operating outlays are shown in five-year increments. Operating outlays for habitat and other stressor conservation measures are spread fairly evenly over the 50-year permit period. Operating outlays for water conveyance step up significantly starting in the eleventh year of Plan implementation, as the conveyance facility becomes fully operational, and again in the 21^{st} year when contributions to the capital replacement fund are assumed to begin. Approximately 57 percent of operating outlays are for water conveyance, 7 percent are for habitat conservation measures, 27 percent are for other stressor measures, and 9 percent are for program oversight. *[**Note to Reviewers**: share of operating costs for other stressor measures and program oversight will increase once costs for CM 12 and monitoring, research, and avoidance & minimization measures are included in the cost estimate.]* Figure 8-2 depicts operating outlays graphically over the 50-year permit period for the midpoint of the low and high cost estimates.

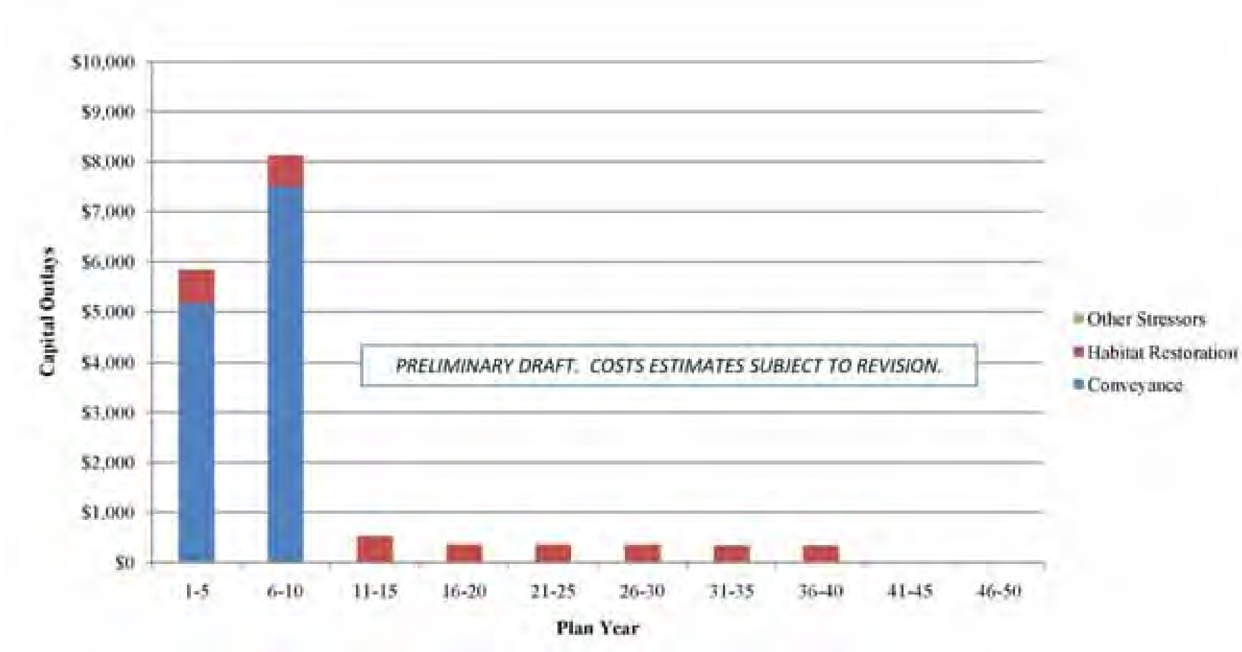

Figure 8-1. BDCP Capital Outlays in Five-Year Increments – Midpoint Cost Estimate (Millions of 2010 Dollars)

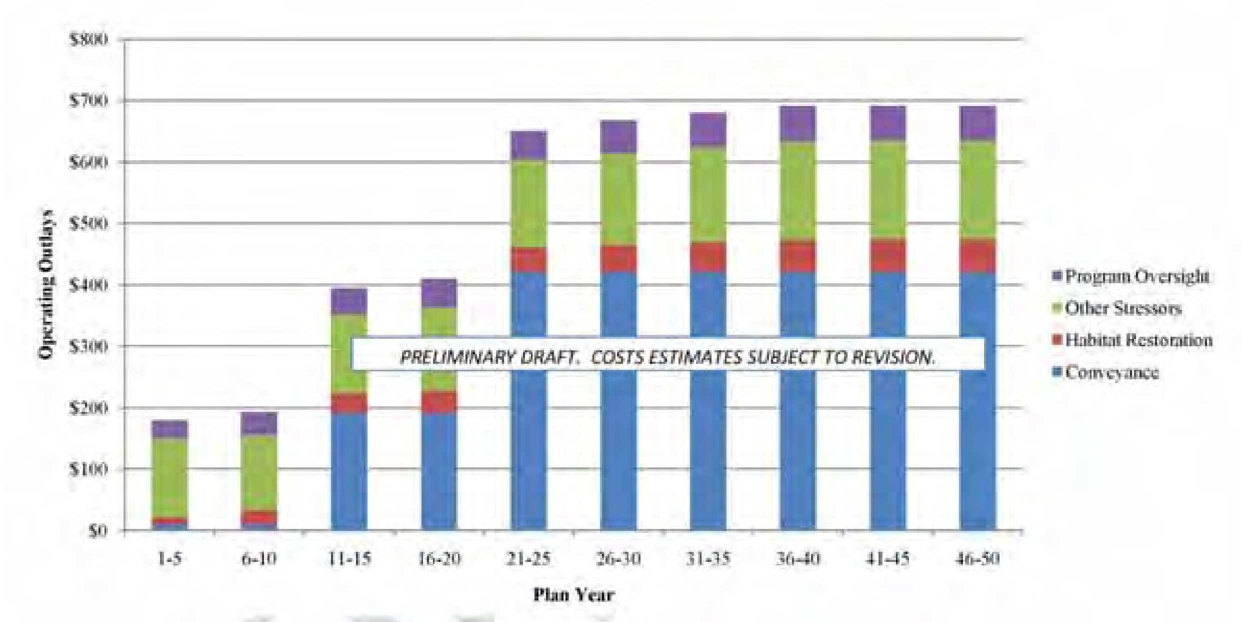

Figure 8-2. BDCP Operating Outlays in Five-Year Increments – Midpoint Cost Estimate (Millions of 2010 Dollars)

Note: Subtotal for Program Oversight does not include costs for Monitoring, Research, and Avoidance & Minimization Measures

8.10 NET BDCP COSTS

[Note to Reviewers: *This section will compare total to net costs of BDCP implementation. Total costs are the sum of costs for all plan components expected to be incurred over the 50-year planning period. Net costs recognize that some of these costs might be incurred even if the Plan were not put into operation. This will be the last step in the cost analysis and cannot be completed until the analyses of total costs for all conservation measures and related activities are completed.]*

8.11 FUNDING SOURCES AND ASSURANCES

[Note to Reviewers: *Funding Sources and Assurances are not included with this draft. This section will be completed following completion of the cost analysis and the development of the funding plan. It should be emphasized that the PREs have not committed to pay for any BDCP costs beyond the conveyance component, and substantial public and other sources of funding are expected to contribute to the cost of implementing the elements of the Plan.]*

CHAPTER 9. ALTERNATIVES TO TAKE

Table of Contents

9.1 Introduction.. 9-1
9.1.1 Regulatory Standard and Evaluation Criteria 9-1

CHAPTER 9. ALTERNATIVES TO TAKE

[**Note to Reviewers:** *This is a first partial draft of Chapter 9 provided to the Steering Committee for review. As of November 18, 2010, it consists of regulatory standard and evaluation criteria. The evaluation of Alternatives to Take will appear in the next version of this chapter. The Effects Analysis of the BDCP proposed project (Chapter 5) will inform both the development and evaluation of these Alternatives to Take. As such, this section of the chapter will be completed once sufficient information is available from the Effects Analysis to ensure consistency among the BDCP chapters. A brief introduction to this Section 9.3 is provided.*]

9.1 INTRODUCTION

During the development of the BDCP, the Steering Committee identified and considered a broad range of alternate approaches to achieving the planning goals and conservation objectives for the Plan. Among the approaches considered were those that would potentially result in less incidental take of species, including species listed as threatened and endangered under the federal Endangered Species Act (ESA), than would be expected to occur under the proposed actions of the BDCP. This chapter describes the alternatives considered during the development of the BDCP that potentially could further reduce levels of take of federally-listed species covered by the Plan and sets out the reasons such alternates were not incorporated in the proposed project.

9.1.1 Regulatory Standard and Evaluation Criteria

The ESA requires that section 10 permit applicants specify in habitat conservation plans what alternative actions to the taking of federally-listed threatened and endangered species were considered and the reasons why those alternatives are not proposed to be used.[1] The USFWS/NMFS HCP Handbook (USFWS/NMFS 1996) provides guidance to applicants regarding the approach that should be followed with regard to the analysis of alternatives. Specifically, the Handbook identifies two types of alternatives that are typically considered in HCPs: 1) alternatives that would result in take levels below those anticipated for the proposed project, and 2) alternatives that would cause no incidental take, thereby eliminating the need for an incidental take permit. Since the evaluation of alternatives to take is a requirement solely of the ESA, and no similar analysis is required under the NCCPA, the following evaluation is focused on take associated with federally-listed species.[2]

[1] 50 CFR 17.22(b)(1)(iii)(C)

[2] The following description and analysis of Alternatives to Take have been developed solely for the purpose of meeting the requirements of Section 10 of the ESA. As part of the NEPA/CEQA processes, a separate set of project alternatives will be identified and evaluated. The analysis of Alternatives to Take serves a specific regulatory purpose, which is separate and apart from the analysis of project alternatives under NEPA and CEQA. The EIS/EIR for the BDCP will identify a reasonable range of alternatives to the project proposed by the BDCP and evaluate a broad array of potential environmental effects of these alternatives in relation to the likely impacts of the proposed project.

The alternatives to take set out in this chapter were evaluated at two levels: first, various alternative approaches to key components of the BDCP Conservation Strategy and to the activities covered by the Plan were identified and evaluated individually for their potential to reduce take. Second, these approaches to the key components and activities were assembled in different combinations to create full alternatives to take that could be compared to the proposed Conservation Strategy.[3] The alternative approaches to each component, as well as the full alternatives to take, were evaluated under the following three criteria:

1. Level of incidental take expected to result and conservation benefits likely to accrue to listed covered species;
2. Consistency with the BDCP overall goals and objectives of ecosystem restoration and water supply reliability; and
3. Practicability in light of cost, logistics and technology.

The evaluation sets out the reasons that each of the component variations and alternatives to take were not adopted in the BDCP Conservation Strategy.

[3] The activities that are proposed for regulatory coverage under the BDCP ("Covered Activities") are generally reflected in the BDCP Conservation Strategy. Consequently, the alternative approaches to the BDCP Conservation Strategy incorporate alternative approaches to the Covered Activities that could potentially reduce take of listed covered species.

CHAPTER 10. INTEGRATION OF INDEPENDENT SCIENCE IN BDCP DEVELOPMENT

CHAPTER 10. INTEGRATION OF INDEPENDENT SCIENCE IN BDCP DEVELOPMENT

[***Note to Reviewers****: Draft text of Chapter 10, Integration of Independent Science in BDCP Development, was provided to the Steering Committee on October 7, 2010. This text is draft and subject to change as the BDCP planning process, including the independent science process, continues. The BDCP Steering Committee members have submitted comments to the October 7, 2010 draft of this chapter, which may or may not have been incorporated into this November 18, 2010 draft. While the text of this chapter is subject to change and revision as the BDCP planning process progresses, the chapter has been drafted and formatted to appear as it may in a completed draft HCP/NCCP. Although the chapter includes declarative statements (e.g., the Implementation Office will…), it is nonetheless a "working draft" that will undergo further modification based on input from the BDCP Steering Committee, state and federal agencies, and the public*.]

10.1 BACKGROUND AND REGULATORY REQUIREMENTS

The BDCP is built upon and reflects the extensive body of scientific investigation, study, and analysis of the Delta compiled over several decades,[1] including the results and findings of numerous studies initiated under the CALFED Bay-Delta Science Program and Ecosystem Restoration Program, the long-term monitoring programs conducted by the Interagency Ecological Program (IEP), research and monitoring conducted by state and federal resource agencies, and research contributions of academic investigators.

In addition, the BDCP Steering Committee considered several other recent reports on the Delta, including reports of the Governor's Delta Vision Blue Ribbon Task Force (January and October 2008), recent reports from the Public Policy Institute of California (Public Policy Institute of California 2007, 2008), and Delta flow criteria recommended by the State Water Resources Control Board and California Environmental Protection Agency (SWRCB and CalEPA 2010) Many elements of the BDCP conservation strategy parallel the recommendations of these other reports.

In the Five-Point Policy for HCPs, USFWS and NMFS encourage the use of independent science to help inform the development of HCPs.[2] The NCCPA requires the planning process to include opportunity for independent scientific input to assist with the development of the plan. This independent scientific input would:

A. Recommend scientifically-sound conservation strategies for species and natural communities proposed to be covered by the plan.

[1] See *The State of Bay-Delta Science* (2008).
[2] 65 Fed. Reg. 35242 (June 1, 2000).

B. Recommend a set of reserve design principles that addresses the needs of species, landscapes, ecosystems, and ecological processes in the planning area proposed to be addressed by the plan.

C. Recommend management principles and conservation goals that can be used in developing a framework for the monitoring and adaptive management component of the plan.

D. Identify data gaps and uncertainties so that risk factors can be evaluated.[3]

Recognizing the need for and value of independent science input, the Steering Committee took a number of steps to engage independent scientists at several stages of the BDCP planning process. Engagement of independent scientists was managed through a neutral facilitation team established specifically for this purpose, as described in more detail below. Advice and recommendations from independent scientists were captured in Independent Science Advisor reports prepared by the advisors and provided to the Steering Committee. All advice provided by independent scientists was given serious consideration by the Steering Committee in the development of the BDCP. The following sections provide more details on the independent science advisory process, recommendations provided, and how these recommendations were incorporated into the BDCP. Examples of recommendations that were not incorporated into the BDCP and rationale for those decisions are provided in this chapter.

10.2 INDEPENDENT SCIENCE ADVISORY PROCESS

To ensure that the BDCP would be based on the best scientific and commercial data available, the Steering Committee sought input and advice from independent scientists on key elements of the Plan. Early in the planning process, the Steering Committee retained the services of an independent Science Facilitation team, consisting of staff from the Conservation Biology Institute and The Essex Partnership, to facilitate independent science panels consistent with the Five Point Policy and the Guidance for the NCCP Independent Science Advisory Process established in 2002 by the California Department of Fish and Game (DFG).[4] The BDCP Steering Committee also established a "Science Liaisons" group consisting of members of the Steering Committee to work with the Science Facilitators to ensure an appropriate level of independent scientific input into the development of the BDCP. The Science Liaisons and the Science Facilitators worked together to identify potential areas of scientific expertise needed to support plan development and to identify issues and questions for the science advisors to address. Basic planning guidelines to select and engage independent scientists were developed (see Appendix G, *Independent Science Advisors Reports*). These planning guidelines were further refined in 2008 when the Science Liaisons and the Science Facilitators developed a process designed to accommodate different levels or tiers of review based on the scope of the input sought. This tiered approach is outlined in Appendix G, *Independent Science Advisors Reports*.

[3] Fish & Game Code § 2810(b)(5).

[4] DFG. 2002. *Guidance for the NCCP Independent Science Advisory Process* at http://www.dfg.ca.gov/habcon/nccp/publications.html

Consistent with the requirements of the NCCPA and the policy directives of the Five-Point Policy,[5] the BDCP Steering Committee directed the facilitators to convene independent scientists at several key stages of the BDCP planning process, enlisting well-recognized experts in ecological and biological sciences to produce recommendations on a range of relevant topics, including approaches to conservation planning for aquatic and terrestrial species in the Delta and developing adaptive management and monitoring programs.[6] Five different groups of independent science advisors were convened during the development of the BDCP.

Each of the independent science efforts are summarized in Section 10.3, *Independent Science Review Teams*, including a brief summary of major findings and information regarding how recommendations were incorporated into the overall planning process. Reports prepared by independent science advisors to the BDCP are provided in Appendix G, *Independent Science Advisors Reports.*

The Steering Committee also engaged a group of over 50 scientists in 2009 to review each of the draft conservation measures in development at that time using a scientific evaluation process developed for the Delta Regional Ecosystem Restoration Implementation Plan (DRERIP). The process for this DRERIP Evaluation is described in Section 10.4 *DRERIP Evaluation Process* and the results of the evaluation are provided in Appendix F, *DRERIP Evaluation Results*.

10.3 INDEPENDENT SCIENCE REVIEWS

10.3.1 Initial BDCP Independent Science Advisors

The first group of Independent Science Advisors gathered in September 2007 to provide guidance on the approach to planning for the conservation of aquatic species and ecosystem processes in the Delta. Specifically, the group advised the Steering Committee on the following elements of the BDCP:

- The application of conservation planning principles within the Plan Area;
- Geographic and temporal scope of the BDCP;
- Addressing facets of Delta ecosystem dynamics;
- Analytical methods used in BDCP formulation, methods of analysis; and
- Adaptive management and monitoring considerations.

Relative to conservation planning, the Advisors offered the following principles:

A. Changes in the estuarine ecosystem may be irreversible.

[5] 65 Fed. Reg. 35242.

B. Future states of the Delta ecosystem depend on both foreseeable changes (e.g., climate change and associated sea-level rise) and unforeseen or rare events (e.g., the consequences of new species invasions).

C. The Delta is part of a larger river-estuarine system that is affected by both rivers and tides. The Delta is also influenced by long-distance connections, extending from the headwaters of the Sacramento and San Joaquin rivers into the Pacific Ocean.

D. The Delta is characterized by substantial spatial and temporal variability, including disturbances and extreme events that are fundamental characteristics of ecosystem dynamics. The Delta cannot be managed as a homogeneous system.

E. Species that use the Delta have evolved life history strategies in response to variable environmental processes. Species have limited ability to adapt to rapid changes caused by human activities.

F. Achieving desired ecosystem outcomes will require more than manipulation of Delta flow patterns alone.

G. Habitat should be defined from the perspective of a given species and is not synonymous with vegetation type, land (water) cover type, or land (water) use type.

H. Changes in water quality have important direct and indirect effects throughout the estuarine ecosystem.

I. Land use is a key determinant of the spatial distribution and temporal dynamics of flow and contaminants which, in turn, can affect habitat quality.

J. Changes in one part of the Delta may have far-reaching effects in space and time.

K. Prevention of undesirable ecological responses is more effective than attempting to reverse undesirable responses after they have occurred.

L. Adaptive management is essential to successful conservation.

M. Conservation measures to benefit one species may have negative effects on other species.

N. Data sources, analyses, and models should be documented and transparent so they can be understood and repeated.

O. Ecosystem responses, especially to changes in system configuration, can be predicted using a combination of statistical and process models. Statistical models document status, trends, and relationships between responses and environmental variables, whereas process-based models are useful in understanding system responses and for forecasting responses to new conditions.

P. There are many sources of uncertainty in understanding a complex system and predicting its responses to interventions and change.

A number of the above principles were used to develop and refine the overall BDCP Conservation Strategy as well as individual conservation measures and the evaluation of those measures. For example, Principles D and E lead to the development of specific BDCP ecosystem goals and objectives that recognize the importance of environmental gradients and the need to provide for a highly variable system. Principles F, and J, lead to efforts to focus on regional strategies that acknowledge particular characteristics and tidal regimes as well as a focus on developing conservation measures that promote broader geographical range diversity for key species. Similarly, Principles N and O were embraced and lead to the development of specific modeling tools designed to predict the outcomes of given actions and combinations of actions as evaluated in the Effects Analysis (Chapter 5, *Effects Analysis*).

In addition to general conservation principles, the first group of Independent Science Advisors also provided a number of more specific recommendations regarding the plan scope, ecosystem dynamics, analytical methods, and adaptive management and monitoring. With regard to the scope of the plan, additional advice was sought regarding geographic scope and additional species were added to the covered species list, as recommended by the Advisors.

Sensitivity analyses were also conducted, as recommended by the Advisors to examine the effect on conservation outcomes of anticipated changes in environmental gradients expected to arise from sea-level rise, subsidence, climate-change induced alteration in the timing of runoff, human activities, and other processes over the time frame of Plan implementation. With regard to ecosystem dynamics, the BDCP was specifically designed to consider relationships between environmental conditions and the covered species in a life cycle context, and to anticipate how changes in environmental conditions, including those associated with covered activities and climate change, may propagate through populations of covered species, as suggested by the Advisors. For example, bypass flow requirements associated with the proposed new north Delta Diversions were carefully designed to minimize or avoid adverse effects on outmigrating juvenile Chinook salmon. Similarly, proposed tidal habitat restoration areas were selected and designed to include a sufficient spatial extent of appropriate elevations to provide for environmental gradients and accommodate sea-level rise.

With regard to analytical methods, the Advisors recommended several specific approaches to hydrodynamic modeling, including the use of models that accurately reproduce tidal flows in the system for analysis of Delta transport and dispersion, and the use of data that span as broad a range of hydrologic and operational conditions as possible. Several detailed two and three-dimensional models were used to analyze the effects of potential conservation actions, particularly with regard to issues of transport, dispersion, residence time, and sea level rise.

With regard to adaptive management and monitoring, the Advisors recommended that the Steering Committee convene a group of science advisors to work with the planning team to develop an appropriate adaptive management and monitoring strategy to support implementation of the BDCP. The Steering Committee convened such a group in 2009, as described in section 10.3.3 below.

A few of the recommendations were not implemented because they were not deemed practicable at this time or other alternate tools were available to address the underlying issue intended by the recommendation. For example, recommendations related to the development of new planning tools (e.g., hydrodynamic, ecosystem, and species models) were not deemed practicable because they could not be developed to a usable form within the timeframe Plan development. Development of these planning tools, however, could be conducted during Plan implementation to inform development and implementation of specific actions in fulfillment of the conservation measures. The BDCP adaptive management program (Section 3.7, Adaptive Management Program) calls for the development and use of such models.

10.3.2 Independent Science Advisors for Non-Aquatic Resources

A second group of Science Advisors convened in September 2008 to consider approaches to planning for the conservation of non-aquatic resources in the Plan Area. The group provided recommendations to the Steering Committee on various issues, including:

- Non-aquatic species to be considered for regulatory coverage under the BDCP;
- Terrestrial natural communities that should be addressed under the BDCP;
- Landscape-level approaches to conservation planning for non-aquatic resources;
- Additional sources of information to be developed to support the non-aquatic resource elements of the BDCP; and
- Conservation strategies that may be considered to address terrestrial and non-tidal wetland communities and dependent wildlife and plant species.

The Advisors offered specific advice on the species selection process, including consideration of listing status, occurrence within the planning area, potential to be affected by Plan actions, and sufficiency of information. The advisors also offered suggestions regarding potential covered species additions and deletions, as well as suggestions regarding potential planning species. The Advisors also offered specific suggestions regarding proposed conservation measures and design considerations regarding the refinement of the conservation strategy for non-aquatic resources. General principles suggested in considering the selection, design, and implementation of conservation measures included:

- Plan conservation measures hierarchically, working from ecosystem to community to species-level considerations. Do not plan conservation measures for specific covered species or communities in isolation, without considering their relationships with other species and communities in the broader ecosystem.
- Design reserve or management areas to achieve mosaics of community types within areas large enough to support the most area-dependent covered (or planning) species and desired ecological services, and to accommodate future shifts due to climate change (e.g., sea-level rise, changing runoff patterns, shifting climate "envelopes").

- Strive for representation of all community types in habitat mosaics well distributed across the Delta, but considering site-specific conditions. Where possible, maintain or create "soft edges" or natural transitions along environmental gradients, as opposed to abrupt transitions or "hard edges" between community types.
- Bigger is better for habitat conservation and restoration sites, but do not ignore small areas that support rare communities or species. For example, small areas of seasonal wetlands, inland dunes, or alkali flats support disproportionate numbers of imperiled species.
- Seek to preserve and enhance natural heterogeneity in elevation, water depth, flooding frequency, nutrient conditions, vegetation types, and adjacency of different habitat types within and among the conserved, restored, or maintained habitat mosaics.
- Enhance and preserve habitat connectivity where possible to maximize potential for natural range shifts, population expansions, escape from disturbance events (fires, floods), and maintenance of ecological processes, and to avoid isolating small populations of those species having limited dispersal abilities.
- Strive to create self-sustaining systems, but recognize that some communities and species may need active or perpetual management. For example, some invasive, nonnative species may require prolonged control efforts to sustain covered species or communities that they adversely affect.

Suggestions regarding covered species and design principles were used to refine the covered species list for the Plan and in refining the proposed conservation measures. The species recommended for coverage by the Advisors were evaluated and added to the BDCP covered species list if they were likely to become listed over the term of the BDCP. Recommended additions to the covered species list that were not included because they did not meet the selection criteria are expected, however, to benefit from implementation of the ecosystem-level and natural community-level conservation measures in the Plan. As specifically suggested by the Advisors, BDCP goals and objectives, as well as the BDCP conservation measures are structured to work from ecosystem to community to species-level considerations. Very few of the conservation measures are oriented toward a specific covered species, and only when proposed landscape or community level actions are not sufficient to address a specific species need. Similarly, all proposed habitat restoration actions in the Plan are designed to preserve and enhance natural heterogeneity in elevation, water depth, flooding frequency, nutrient conditions, vegetation types, and adjacency of different habitat types, as recommended by the Advisors.

10.3.3 Independent Science Advisors on Adaptive Management

[***Note to Reviewers***: *This section describes the scientific advisory process used in development of the BDCP adaptive management plan. As indicated in the note to reviewers at the beginning of the chapter, it is written as though this process is complete. Certain components of the* *adaptive management plan have been drafted, but the adaptive management plan is still in development.*]

The third group of Science Advisors met in December 2008 and provided input on approaches to the development of an adaptive management plan and decision making process for the BDCP, informed by data and information generated by monitoring and research efforts. This group built upon guidance on adaptive management that was provided in the first of the independent science workshops, offering more specific advice based on progress that had since been made in the development of the BDCP.

The Advisors offered eight principles for adaptive management as follows:

1. The scope and degree of reversibility of each proposed action (i.e., conservation measure) determines the form of adaptive management that can be applied (e.g.,"active" or experimental adaptive management versus "passive" adaptive management).
2. The knowledge base about the ecosystem is key to decisions about what to do and what to monitor, and includes all relevant information, not just that derived from monitoring and analysis within the context of BDCP.
3. Program goals should relate directly to the problems being addressed and provide the intent behind the conservation measures; objectives should correspond to measurable, predicted outcomes.
4. Models should be used to formalize the knowledge base, develop expectations of future conditions and conservation outcomes that can be tested by monitoring and analysis, assess the likelihood of various outcomes, and identify tradeoffs among conservation measures.
5. Monitoring should be targeted at specific mechanisms thought to underlie the conservation measures, and must be integrated with an explicitly funded program for assessing the resulting data.
6. Prioritization and sequencing of conservation measures should be assessed at multiple steps in the adaptive management cycle.
7. Specifically targeted institutional arrangements are required to establish effective feedback mechanisms to inform decisions about whether to retain, modify, or replace conservation measures.
8. A dedicated, highly skilled agent (person, team, office) is essential to assimilate knowledge from monitoring and technical studies and make recommendations to senior decision makers regarding programmatic changes.

A number of the principles above have been incorporated into the proposed BDCP Adaptive Management Program, including plans for an explicitly funded monitoring and assessment program, a research program, and clear institutional arrangements to establish feedback mechanisms to support decision making.

10.3.4 Independent Science Input on Logic Chain Approach

[***Note to Reviewers****: The logic chain development and review is currently in process. The results of this process will be used to inform various components of the BDCP as appropriate, including identification and development of biological goals and objectives for covered species and metrics for use in the monitoring and adaptive management programs.*]

The Delta Science Program provided assistance in assembling a fourth group of independent science advisors in February-March 2010 and a fifth group in July-August 2010 to evaluate and provide recommendations on the logic chain planning structure. The logic chain has been proposed as a framework to link recovery goals for covered fish species with BDCP goals, objectives, conservation measures, monitoring, and adaptive management. Two science reports on the Logic Chain were prepared.

In the first report, dated March 19, 2010 (Appendix G, *Independent Science Advisors Reports*), the group of science advisors initially assessed the value of the logic chain as a tool, its internal consistency, and next steps for input of information into the logic chain. The group stated that the logic chain was a useful tool for clearly articulating and linking goals, objectives, actions, and outcomes, but recommended an alternate approach to:

- Clarify the links in the chain and reduce areas of ambiguity;
- Distinguish between order-of-magnitude approximations of goals and objectives that are acceptable in early planning and the more detailed descriptions developed later;
- Frame projected outcomes as testable hypotheses linked to specific conservation measures;
- Use metrics to evaluate the success of outcomes that clearly link to biological functions and consider the judicious use of surrogate metrics;
- Consider constraints to implementation of conservation measures;
- Consider the potential impacts of system dynamics, variation, and change over time; and
- Provide more detail to the adaptive management framework.

As next steps, the group recommended developing logic chains for a few species initially; leaving recovery goal development to responsible regulatory agencies; focusing on development of the BDCP biological goals and objectives; and convening a workshop to develop monitoring metrics. In response to this recommendation, the Steering Committee convened a Logic Chain Group that developed example logic chains for two fish species. These two examples, and the lessons learned from their development formed the basis for a second independent logic chain review.

In the second report, dated August 23, 2010 (Appendix G, *Independent Science Advisors Reports*), the group assessed the two populated logic chains to evaluate internal logic, measurability, and linkages, and consistency in approach. The group also recommended alternative strategies and metrics for goals and objectives and alternative ways to frame goals and objectives to be more practicable and provided advice on constructing an integrated monitoring program linked to the logic chains. Recommendations of this science group included:

- Simplify the logic chain structure to reduce the number of objective statements and to focus on BDCP objectives;
- Identify stressors that are outside of BDCP management;
- Focus BDCP objectives on measures of individual and population-level performance, such as habitat-specific estimates of growth and survivorship, quantitative estimates of abundance, and quantitative measures of movement and/or distribution;
- Take care in populating the compliance and performance monitoring actions and consider three monitoring levels separately, the global goal, the "covered activity" level, and compliance; and
- Link implementation of conservation measures, through monitoring and evaluation, to the adaptive management program.

In Response to the recommendations from the second logic chain review, the Steering Committee directed staff to complete logic chains for all of the BDCP covered fish species in accordance with the guidance provided by the review panel. Draft logic chains were completed in October 2010 and a technical workshop was organized, as recommended by the review panel, to review and refine the drafts.

10.3.5 DRERIP Evaluation Process

The BDCP Steering Committee undertook a rigorous process to incorporate new and updated information and to evaluate a wide variety of issues and approaches as it formulated a cohesive, comprehensive BDCP conservation strategy. This effort included an evaluation conducted early in 2009 by multiple teams of experts of draft BDCP conservation measures in development at that time, using the CALFED Bay-Delta Ecosystem Restoration Program's (ERP) Delta Region Ecosystem Restoration Implementation Plan (DRERIP) Scientific Evaluation Process.

In October 2008, the Steering Committee developed early drafts of BDCP conservation measures related to water operations, habitat restoration, and other stressors. The DRERIP evaluation process was used to evaluate these draft conservation measures. The DRERIP process was specifically developed to aid in planning and decision making regarding potential ecosystem restoration projects in the Delta. The process entails engaging teams of experts to work through a structured, step-by-step examination of the scientific efficacy of proposed restoration actions by analyzing both potential positive and negative outcomes which might result from a given action.

To conduct the DRERIP evaluations, the Steering Committee engaged 52 technical experts assembled into five teams to address related groupings of conservation measures. The DRERIP Technical Team meetings were limited to specific technical experts trained in the DRERIP evaluation process. The teams conducted DRERIP evaluations, from January-April 2009, on 32 draft conservation measures that could be evaluated using the process. The evaluations were conducted using a series of peer-reviewed DRERIP ecosystem and species conceptual models developed specifically for the Delta and additional relevant sources of information (e.g., published literature, recently collected data). The conceptual models describe the current scientific understanding regarding how the Delta ecosystem works and were designed to serve as a foundation for the evaluation process.

A description of the BDCP DRERIP evaluations and evaluation results is presented in Appendix F, *DRERIP Evaluation Results*. Results include an assessment of the likely magnitude of the ecological outcomes and the certainty of those outcomes that could be associated with implementing each evaluated conservation measure. However, because the DRERIP process was designed to evaluate restoration actions independently, it does not provide for a direct assessment of the combined magnitude and certainty of positive and negative ecological outcomes that would be associated with the contemporaneous implementation of multiple conservation measures under BDCP. To address this need, the Steering Committee established the Synthesis Team comprised of Steering Committee member representatives and technical experts that participated in the DRERIP evaluations to conduct an assessment of the likely synergistic ecological effects of concurrent implementation of multiple conservation measures based on the evaluation results for individual conservation measures. The Synthesis Team conducted their evaluation during March-April 2009 and provided recommendations to the Steering Committee for refining conservation measures, sequencing implementation of conservation measures, and adjusting DRERIP results for individual conservation measures based on their synergistic effects with implementation of other conservation measures.

DRERIP evaluation results were also used to inform development of the effectiveness monitoring for conservation measures (see Section 3.6, *Monitoring and Research Program*). DRERIP evaluation results include assessments and sources of uncertainty surrounding the magnitude of ecological outcomes that could be expected with the implementation of each conservation measure. Based on these assessments, effectiveness monitoring was developed to collect the information necessary to address these sources of uncertainty and to inform the need for future adjustments to conservation measures to improve their performance over time through the BDCP adaptive management decision making process (Section 3.7, *Adaptive Management Program*).

CHAPTER 11 LIST OF PREPARERS

[***Note to Reviewers:*** *The list of preparers provided in this first draft of Chapter 11 is partial and will require input from the various organizations and individuals involved in developing the BDCP to identify all appropriate names and affiliations to be included in this chapter.]*

This Chapter provides names of organizations and individuals involved in the development of the BDCP.

11.1 BDCP Steering Committee Members and Alternates

[*Note to Reviewers*: *This section identifies past and present members and alternates on the Steering Committee as of November 18, 2010. Any changes to Steering Committee membership will be reflected in future versions of this chapter. The listing of the names of Steering Committee member entities and individual members and alternates in this chapter only indicates their participation in the BDCP develop process and is not intended to imply any agreement with the materials in this working draft of the BDCP]*

11.1.1 California Natural Resources Agency

Karen Scarborough, committee chair

11.1.2 California Department of Water Resources (Authorized Entity)

Mark Cowin, member

Lester Snow, past member

Jerry Johns, alternate

11.1.3 U.S. Bureau of Reclamation (Authorized Entity)

Don Glaser, member

John Davis, past member

Federico Barajas, alternate

Frank Michny, past alternate

Ann Lubas-Williams, past alternate

Susan Fry, past alternate

11.1.4 Kern County Water Agency (Potential Regulated Entity [PRE])

Brent Walthall, member

Larry Rodriguez, alternate

Tom Clark, past alternate

11.1.5 Metropolitan Water District of Southern California (PRE)

Roger Patterson, member

Randall Neudeck, alternate

11.1.6 San Luis & Delta-Mendota Water Authority (PRE)

Dan Nelson, member

Ara Azhderian, alternate

11.1.7 Santa Clara Valley Water District (PRE)

Jim Fiedler, member

Walt Wadlow, past member

Greg Zlotnick, past member

Cindy Kao, alternate

Tracy Ligon, past alternate

11.1.8 Westlands Water District (PRE)

Tom Birmingham, member

Jason Peltier, alternate

11.1.9 Zone 7 Water Agency (PRE)

Jill Duerig, member

Dale Myers, past member

Karla Nemeth, past member

Kurt Arends, alternate

Karla Nemeth, past alternate

Dale Myers, past alternate

11.1.10 Mirant Delta, LLC (Authorized Entity)

John Chillemi, member

Peter Landreth, alternate

Ron Kino, past alternate

11.1.11 State Water Resources Control Board (*ex officio*)

Les Grober, member

Tom Howard, past member

11.1.12 U.S. Army Corps of Engineers (*ex officio*)

Paul Robershotte, member

11.1.13 American Rivers

Richard Roos-Collins, member

John Cain, alternate

Steve Rothert, past alternate

11.1.14 Defenders of Wildlife

Kim Delfino, member

11.1.15 Environmental Defense Fund

Ann Hayden, member

Michael Bean, past member

Spreck Rosekrans, alternate

Ann Hayden, past alternate

11.1.16 Natural Heritage Institute

Greg Thomas, member

Carson Cox, alternate

John Cain, past alternate

Gerald Meral, past alternate

11.1.17 The Nature Conservancy

Campbell Ingram, member

Anthony Saracino, past member

Campbell Ingram, past alternate

11.1.18 The Bay Institute

Gary Bobker, member

11.1.19 California Farm Bureau Federation

Kenny Watkins, member

11.1.20 Contra Costa Water District

Greg Gartrell, member

11.1.21 Friant Water Authority

Ron Jacobsma, member

Steve Ottemoeller, alternate

11.1.22 North Delta Water Agency

Melinda Terry, member

11.1.23 California Department of Fish and Game (*ex officio*)

John McCamman, member

Don Koch, past member

Carl Wilcox, alternate

John McCamman, past alternate

11.1.24 U.S. Fish and Wildlife Service (*ex officio*)

Ren Lohoefener, member

Steve Thompson, past member

Dan Castleberry, alternate

John Engbring, past alternate

11.1.25 National Marine Fisheries Service (*ex officio*)

Michael Tucker, member

Russ Strach, past member

Maria Rea, past member

Ted Myers, past alternate

Michael Tucker, past alternate

11.1.26 Delta Stewardship Council (*ex officio*)

Joe Grindstaff, member

Keith Coolidge, alternate

11.1.27 California Bay Delta Authority (past *ex officio* member agency)

Joe Grindstaff, past member

Leo Winternitz, past alternate

11.2 MANAGEMENT TEAM

Karen Scarborough (Chair) – California Natural Resources Agency

Jerry Johns – Department of Water Resources

Laura King Moon – State Water Contractors

Karla Nemeth – California Natural Resources Agency

Ron Milligan – Federal Partners (USFWS, NMFS, Reclamation)

Chuck Gardner – Delta Habitat Conservation and Conveyance Program

Susan Ramos – California Department of Water Resources

Marc Ebbin – Ebbin Moser + Skaggs

Paul Cylinder – SAIC

Chadi Groom – SAIC

11.3 SCIENCE APPLICATIONS INTERNATIONAL CORPORATION (SAIC) CONSULTANT TEAM

11.3.1 SAIC

Consultant Team Management

Paul Cylinder, PhD, Consultant Team Leader

Richard Wilder, PhD, Lead Aquatic Resources

Pete Rawlings, Lead Natural Communities and Terrestrial Resources

Christopher McColl, Lead Data Management and GIS

Monica Hood, Lead Covered Activities

Vanessa Emerzian, Project Coordination

Chadi Groome, Program Management

Technical Staff

Jean-Luc Cartron, PhD, Wildlife Ecology

Joel Degner, PE, Data Analysis and GIS

Catherine Fitzgerald, Graphic Arts

Juan Pablo Galvan, Terrestrial Ecology

John Gerlach, PhD, Lead Botany and Vegetation

Catrina Gomez, Terrestrial Ecology

Sharon Goodhart, Project Control

Daniel Heilprin, Fisheries Ecologist

Christopher Hunt, Fisheries Ecology

Andrew Knaack, Project Control

Stephan Kohlmann, PhD, Terrestrial Ecology

Thomas Mulroy, PhD, Botany

Trevor Pattison, Terrestrial Ecology

Ellen Rager, Document Production Manager

Monica Stillman, Restoration Ecology

Bernice Tennenbaum, Wildlife Biology and Marine Mammals

Gregory Wadsworth, Document Production

Laurel Widman, Graphic Arts

Holly Wilson, Project and Meeting Coordination

11.3.2 Canyon Creek Consulting

Jay Brueggeman, marine mammals

11.3.3 CBEC

Chris Bowles, PhD, Hydrology and Hydrodynamics

Chris Campbell, Hydrology and Hydrodynamics

Christopher Hammersmark, PE, Hydrology and Hydrodynamics

John Stofieth, Hydrology and Hydrodynamics

11.3.4 CH2M HILL

Armin Munévar, P.E, Lead Hydrology and Hydrodynamics

Rajat Chakraborti PhD, Hydrology and Hydrodynamics

Chandra Chilmakuri, PhD, PE, Hydrology and Hydrodynamics

Jagjit Kaur, PhD, Hydrology and Hydrodynamics

Chakradhar Goud Malakpet, Hydrology and Hydrodynamics

Sirisha Nemani, Hydrology and Hydrodynamics

Jessica Prince Hydrology and Hydrodynamics

Marcelo Reginato, PE, Hydrology and Hydrodynamics

Ashraf Shaqadan, PhD Hydrology and Hydrodynamics

Paula Silva - Hydrology and Hydrodynamics

Derya Sumer, PhD, PE, Hydrology and Hydrodynamics

Lee Traynham, Hydrology and Hydrodynamics

Kyle Winslow, PhD, PE Hydrology and Hydrodynamics

11.3.5 Conservation Biology Institute

Wayne Spencer – Independent Science Input Facilitation

11.3.6 Cramer Fish Sciences

Paul Bergman, Fisheries Ecology

Brad Cavallo, Fisheries Ecology

Steve Cramer, Fisheries Ecology

Ayesha Grey, PhD, Fisheries Ecology

Jenny Melgo, Fisheries Ecology

11.3.7 Economic Insights

Wendy Illingworth, Economics

11.3.8 ENTRIX

Michael Aceituno, Fisheries Ecology

Jean Baldridge, Fisheries Ecology

Patrick Coulston, Fisheries Ecology

Emily Floyd, PhD, Fisheries Ecology

Rebecca Isquith, Fisheries Ecology

Amy Mai, Fisheries Ecology

Ramona Swenson, PhD, Fisheries Ecology

Thomas Taylor, Fisheries Ecology

Lawrence Wise, Fisheries Ecology

11.3.9 ESA PWA

Matthew Brennan, PE, Restoration Ecology

Rachel Cancienne, Restoration Ecology

Stephen Crooks, PhD, Restoration Ecology

Eric Ginney, Restoration Ecology

Amy Houle, Restoration Ecology

Michelle Orr, PE, Restoration Ecology

Justin Vandever, Restoration Ecology

Covered Species Accounts

APPENDIX A1. CENTRAL VALLEY STEELHEAD (*ONCORHYNCHUS MYKISS*)

A1.1 LEGAL STATUS

The Central Valley steelhead Evolutionarily Significant Unit (ESU) was listed as a threatened species under the Federal Endangered Species Act (ESA) on March 19, 1998, and includes all naturally spawned populations of steelhead in the Sacramento and San Joaquin rivers and their tributaries, including the Bay-Delta (63 FR 13347). Steelhead from San Francisco and San Pablo Bays and their tributaries are excluded from this listing but are included in the Central California Coast DPS, which is also listed as threatened under the ESA. On June 14, 2004, the National Marine Fisheries Service (NMFS) proposed that all West Coast steelhead be reclassified from ESUs to Distinct Population Segments (DPS) and proposed to retain Central Valley steelhead as threatened (69 FR 33102). On January 5, 2006, after reviewing the best available scientific and commercial information, NMFS issued its final decision to retain the status of Central Valley steelhead as a threatened DPS (71 FR 834). This decision included the Coleman National Fish Hatchery and Feather River Hatchery steelhead populations. These populations were previously included in the ESU but were not deemed essential for conservation and thus not part of the listed steelhead population.

Central Valley steelhead are not listed under the California Endangered Species Act but are designated as a California Species of Special Concern.

A1.2 SPECIES DISTRIBUTION AND STATUS

Information on the status and geographic distribution of Central Valley steelhead is extremely limited (The Nature Conservancy et al. 2008). Adult steelhead typically migrate upstream and spawn during the winter months when river flows are high and water clarity is low. Unlike Chinook salmon, adult steelhead do not necessarily die after spawning and can return to coastal waters. Juvenile steelhead cannot be differentiated from resident rainbow trout based on visual characteristics. In addition, steelhead frequently inhabit streams and rivers that are difficult to access and survey. As a result of these and other factors, information on the trends in steelhead abundance within the Central Valley has primarily been limited to observations at fish ladders and weirs (e.g., Red Bluff Diversion Dam [RBDD] when the gates were closed, Woodbridge Irrigation District dam and fish ladders on the Mokelumne River, etc.) and returns to Central Valley fish hatcheries. Juvenile steelhead are collected incidentally in various fishery surveys (e.g., Mossdale and Chipps Island trawls). However, as a result of their relatively large size and good swimming performance, juvenile steelhead are able to avoid capture in most fishery surveys. Therefore, information on the distribution, abundance, habitat use, and behavior of steelhead within the Plan Area is very limited.

A1.2.1 Range and Status

Central Valley steelhead were widely distributed historically throughout the Sacramento and San Joaquin rivers (see Figure A-1a) (Busby et al. 1996, McEwan 2001). Steelhead inhabited waterways from the upper Sacramento and Pit River river systems (now inaccessable due to Shasta and Keswick Dams) south to the Kings River and possibly the Kern River systems, and in both east- and west-side Sacramento River tributaries (Yoshiyama et al. 1996). Lindley et al. (2006) estimated that there were historically at least 81 independent Central Valley steelhead populations distributed primarily throughout the eastern tributaries of the Sacramento and San Joaquin rivers.

The geographic distribution of spawning and juvenile rearing habitat for Central Valley steelhead has been greatly reduced by the construction of dams (McEwan and Jackson 1996, McEwan 2001). Presently, impassable dams block access to 80 percent of historically available habitat, and all spawning habitat for approximately 38 percent of historic populations (Lindley et al. 2006). Existing wild steelhead stocks in the Central Valley inhabit the upper Sacramento River and its tributaries, including Antelope, Deer, and Mill creeks and the Yuba River. Populations may exist in Big Chico and Butte creeks, and a few wild steelhead are produced in the American and Feather rivers (McEwan and Jackson 1996).

Historical Central Valley steelhead run sizes are difficult to estimate given the paucity of data, but may have approached one to two million adults annually (McEwan 2001). By the early 1960s, steelhead run size had declined to approximately 40,000 adults (McEwan 2001). Over the past 30 years, naturally-spawned steelhead populations in the upper Sacramento River have declined substantially (see Figure A-1b). Until recently, Central Valley steelhead were thought to be extirpated from the San Joaquin River system. However, recent monitoring has detected small self-sustaining populations of steelhead in the Stanislaus, Mokelumne, and Calaveras rivers, and other streams previously thought to be devoid of steelhead (McEwan 2001). Incidental catches and observations of steelhead juveniles also have occurred on the Tuolumne and Merced rivers during fall-run Chinook salmon monitoring activities, indicating that steelhead are widespread throughout accessible streams and rivers in the Central Valley (Good et al. 2005). Some of these fish, however, may have been resident rainbow trout, which are the same species but are not anadromous.

A1.2.2 Distribution and Status in the Plan Area

The entire population of the Central Valley steelhead DPS must pass through the Plan Area as adults migrating upstream to spawning areas and juveniles emigrating downstream to rearing areas and the ocean. Furthermore, juvenile steelhead likely use the Delta as well as Suisun Marsh and the Yolo Bypass for rearing. Adult Central Valley steelhead migrating into the San Joaquin River and its tributaries use the central, southern, and eastern edge of the Delta, whereas adults entering the Sacramento River system to spawn use the northern, western, and central Delta as a migration pathway

DRAFT

Figure A-1a. Central Valley Steelhead Inland Range in California

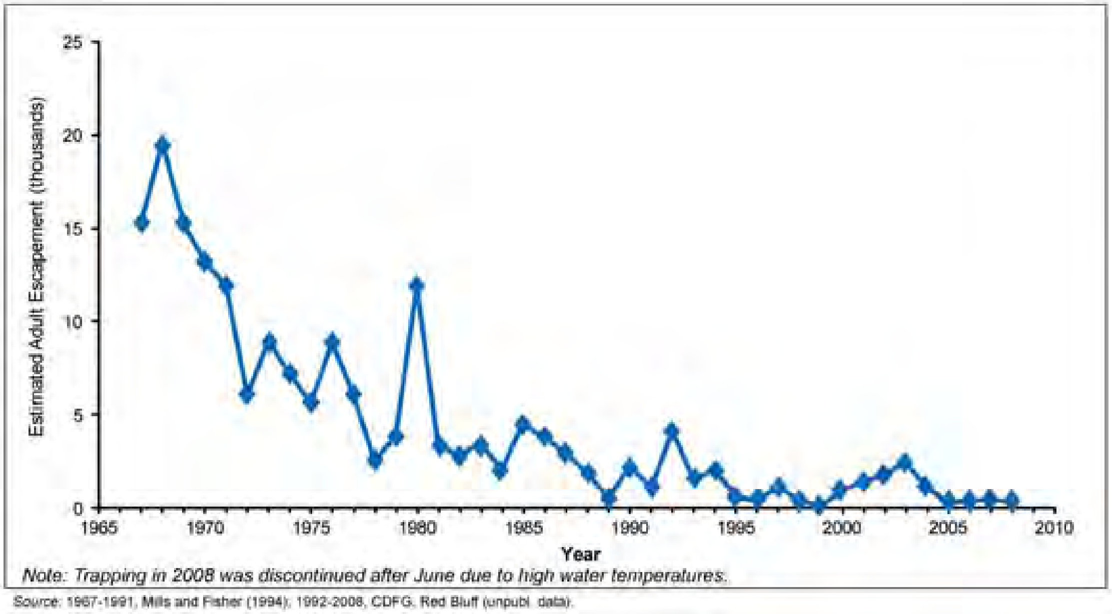

Figure A-1b. Estimated Historical Spawner Escapement of Wild Central Valley Steelhead in the Upper Sacramento River Upstream of the Red Bluff Diversion Dam (1967-2008)

A1.3 HABITAT REQUIREMENTS AND SPECIAL CONSIDERATIONS

Critical habitat for the Central Valley steelhead DPS was designated by NMFS on September 2, 2005 (70 FR 52488) with an effective date of January 2, 2006 and includes 2,308 miles of stream habitat in the Central Valley and an additional 254 square miles of estuarine habitat in the San Francisco-San Pablo-Suisun Bay complex (see Figure A-1c). Critical habitat for Central Valley steelhead includes stream reaches such as those of the Sacramento, Feather, and Yuba rivers; Deer, Mill, Battle, and Antelope creeks in the Sacramento River basin; the San Joaquin River and its tributaries; and the Delta. Critical habitat includes stream channels in the designated stream reaches and the lateral extent as defined by the ordinary high-water line. In areas where the ordinary high-water line has not been defined, the lateral extent of critical habitat is defined by the bankful elevation (defined as the level at which water begins to leave the channel and move into the floodplain; it is reached at a discharge that generally has a recurrence interval of 1 to 2 years on the annual flood series) (70 FR 52488). Critical habitat for Central Valley steelhead is defined as specific areas that contain the Primary Constituent Elements (PCEs) and physical habitat elements or biological features essential to the conservation of a species for which its designated or proposed critical habitat is based on" (USFWS 2004). The following are the habitat types used as PCEs for Central Valley steelhead.

DRAFT

Figure A-1c. Central Valley Steelhead Critical Inland Habitat in California

A1.3.1 Spawning Habitat

Freshwater spawning sites are those with water quantity and quality conditions and substrate supporting spawning, egg incubation, and larval development. Spawning habitat for Central Valley steelhead primarily occurs in mid to upper elevation reaches or immediately downstream of dams located throughout the Central Valley, which contain suitable environmental conditions (e.g., seasonal water temperatures, substrate, dissolved oxygen, etc.) for spawning and egg incubation. Spawning habitat has a high conservation value as its function directly affects the spawning success and reproductive potential of steelhead.

A1.3.2 Freshwater Rearing Habitat

Freshwater steelhead rearing sites are those with suitable instream flows, water quantity (e.g., water temperatures) and floodplain connectivity to form and maintain physical habitat conditions that support juvenile growth and mobility, provide forage species and include cover such as shade, submerged and overhanging large wood, log jams, beaver dams, aquatic vegetation, large rocks and boulders, side channels, and undercut banks. Spawning areas and migratory corridors may also function as rearing habitat for juveniles, which feed and grow before and during their outmigration. Rearing habitat quality is strongly affected by habitat complexity, food supply, and the presence of predators. Some of these more complex and productive habitats with floodplain connectivity are still present in the Central Valley (e.g., the lower Cosumnes River, Sacramento River reaches with set-back levees [i.e., primarily located upstream of the City of Colusa]). The channeled, leveed, and riprapped river reaches and sloughs common in the lower Sacramento and San Joaquin rivers and throughout the Delta, however, typically have low habitat complexity, low abundance of food organisms, and offer little protection from predation by fish and birds. Freshwater rearing habitat has a high conservation value because juvenile steelhead are dependent on the function of this habitat for successful survival and recruitment to the adult population.

A1.3.3 Freshwater Migration Corridors

Optimal freshwater steelhead migration corridors (including river channels, channels through the Delta, and the Bay-Delta estuary) support mobility, survival, and food supply for juveniles and adults. Migration corridors should be free from obstructions (passage barriers and impediments to migration), provide favorable water quantity (instream flows) and quality conditions (seasonal water temperatures), and contain natural cover such as submerged and overhanging large wood, aquatic vegetation, large rocks and boulders, side channels, and undercut banks. Migratory corridors are typically downstream of the spawning area and include the lower Sacramento and San Joaquin rivers, the Delta, and the San Francisco Bay complex extending to coastal marine waters. These corridors allow the upstream passage of adults and the downstream emigration of juvenile steelhead. Migratory corridor conditions are strongly affected by the presence of passage barriers, which can include dams, unscreened or poorly screened diversions, and degraded water quality. For freshwater migration corridors to function properly, they must provide adequate passage, provide suitable migration cues, reduce false attraction, avoid areas where vulnerability to predation is increased, and avoid impediments and delays in both upstream and downstream migration. For this reason, freshwater migration corridors are considered to have a high conservation value.

A1.3.4 Estuarine Areas

Estuarine migration and juvenile rearing habitats should be free of obstructions (i.e., dams and other barriers) and provide suitable water quality, water quantity, and salinity conditions to support juvenile and adult physiological transitions between fresh and salt water. Natural cover, such as submerged and overhanging large wood, aquatic vegetation, and side channels, provide juvenile and adult foraging. Estuarine areas contain a high conservation value as they function to support juvenile steelhead growth, smolting, avoidance of predators, and provide a transition to the ocean environment.

A1.3.5 Ocean Habitats

Although ocean habitats have not been designated as critical habitat for Central Valley steelhead, biologically productive coastal waters are an important habitat component. Juvenile steelhead rear within coastal marine waters for a period of approximately one to three years before returning to the Central Valley rivers as adults to spawn. During their marine residence, steelhead forage on krill and other marine organisms. Offshore marine areas with water quality conditions and food, including squid, crustaceans, and fish (fish become a larger component in the steelhead diet later in life [Moyle 2002]), to support growth and maturation are important habitat elements. These features are essential for conservation because, without them, juveniles cannot forage and grow to adulthood.

Results of oceanographic studies have shown the variation in ocean productivity off the West Coast within and among years. Changes in ocean currents and upwelling have been identified as significant factors affecting nutrient availability, phytoplankton and zooplankton production in near-shore surface waters. Although the effects of ocean conditions on steelhead growth and survival have not been investigated, recent observations since 2007 have shown a significant decline in the abundance of adult Chinook salmon and coho salmon returning to California rivers and streams. This decline has been hypothesized to be the result of declines in ocean productivity and associated high mortality rates during the period when these fish were rearing in near-shore coastal waters (MacFarlane et al. 2008). The importance of changes in ocean conditions on growth, survival, and population abundance of Central Valley steelhead, although potentially similar to that of Chinook salmon, is largely unknown.

A1.4 LIFE HISTORY

Steelhead can be divided into two life history types based on their state of sexual maturity at the time of river entry and the duration of their spawning migration: stream-maturing and ocean-maturing. Stream-maturing steelhead enter freshwater in a sexually immature condition and require several months to mature prior to spawning, whereas ocean-maturing steelhead enter freshwater with well-developed gonads and spawn shortly after river entry. These two life history types are more commonly referred to by their season of freshwater entry (i.e., summer [stream-maturing] and winter [ocean-maturing] steelhead). Only winter steelhead currently are present in Central Valley rivers and streams (McEwan and Jackson 1996). There are, however, indications that summer steelhead were present in the Sacramento River system prior to the commencement of large-scale dam construction in the 1940s (Interagency Ecological Program (IEP) Steelhead Project Work Team 1999, McEwan 2001). At present, summer steelhead are found only in North Coast drainages, mostly in tributaries of the Eel, Klamath, and Trinity river systems (McEwan and Jackson 1996).

There is high polymorphism among steelhead/rainbow trout populations with respect to a continuum from anadromy to permanent freshwater residency (Behnke 1992 as cited in McEwan 2001). Furthermore, there is plasticity in an individual from a specific life history form to assume a different life history strategy if conditions necessitate it (McEwan 2001). For example, if environmental conditions, such as water temperature and flow, allow for year-round residence in freshwater, an individual may choose not to emigrate to the ocean. This polymorphic life history structure provides the flexibility for steelhead to remain persistent within highly variable conditions, particularly near the edges of their range (McEwan 2001).

Central Valley steelhead generally leave the ocean and migrate upstream from August through April (Busby et al. 1996), and spawn from December through April. Peak spawning typically occurs from January though March in small streams and tributaries where cool, well-oxygenated water is available year-round (see Table A-1a; Hallock et al. 1961, McEwan and Jackson 1996). Timing of upstream migration is correlated with higher flow events such as freshets and associated lower water temperatures and increased turbidity. Before the occurrence of large-scale changes to the hydrology of the Delta system, the peak period of adult immigration appears to have been during fall months with a smaller component of immigrants in the winter (as reviewed in McEwan 2001). Unlike Pacific salmon, steelhead are iteroparous, or capable of spawning more than once before death (Busby et al. 1996). It is, however, rare for steelhead to spawn more than twice before dying; most individuals that do spawn more than twice are females (Busby et al. 1996). Iteroparity is more common among southern steelhead populations than northern populations (Busby et al. 1996). Although one-time spawners are the great majority, Shapolov and Taft (1954) reported that repeat spawners are relatively numerous (17.2 percent) in California streams.

After reaching a suitable spawning area, the female steelhead selects a site with good intergravel flow, digs a redd, and deposits eggs while an attendant male fertilizes them. Eggs in the redd are covered with gravel dislodged just upstream by similar redd building actions. The length of time it takes for eggs to hatch varies in response to water temperature. Hatching of steelhead eggs in hatcheries takes about 30 days at 51 °F (10.6 °C). Fry generally emerge from the gravel four to six weeks after hatching, but factors such as redd depth, gravel size, siltation, and water temperature can speed or retard the time to emergence (Shapovalov and Taft 1954, as cited in

Cramer and Associates, Inc. 2000 and 2001; [12]Schaffter 1980

McEwan and Jackson 1996). Newly emerged fry move to shallow, protected areas with lower water velocities associated with the stream margin, and soon establish feeding locations within the juvenile rearing habitat (Shapovalov and Taft 1954, as cited in McEwan and Jackson 1996).

Steelhead rearing during the summer takes place primarily in higher velocity areas in pools, although young-of-the-year also are abundant in glides and riffles. Productive steelhead habitat is characterized by habitat complexity, primarily in the form of large and small woody debris. Cover is an important habitat component for juvenile steelhead both as velocity refugia and as a means of avoiding predation (Meehan and Bjornn 1991, as cited in McEwan and Jackson 1996).

Juvenile steelhead emigrate episodically from natal streams during fall, winter, and spring high flows. Emigrating Central Valley steelhead use the lower reaches of the Sacramento and San Joaquin rivers and the Delta for rearing and as a migration corridor to the ocean. Juvenile Central Valley steelhead feed mostly on drifting aquatic organisms and terrestrial insects and will also take active bottom invertebrates (Moyle 2002).

Some juvenile steelhead may use tidal marsh areas, non-tidal freshwater marshes, and other shallow water areas in the Delta and estuary as rearing areas for short periods prior to their emigration to the ocean. Hallock et al. (1961) found that juvenile steelhead in the Sacramento River basin migrate downstream during most months of the year, but the peak emigration period occurred in the spring, with a much smaller peak in the fall. Nobriga and Cadrett (2003) verified these temporal findings based on analysis of captures in USFWS salmon monitoring conducted near Chipps Island. Diversity and richness of habitat and food sources in the estuary allow juveniles to attain a larger size before entry into the ocean, thereby increasing their chances for survival in the marine environment.

Central Valley steelhead spend from several months to 3 years (with a maximum of 6 years) in the Pacific Ocean before returning to freshwater. The age composition of the steelhead population in the Pacific Ocean is dominated by 1-year (61.9 percent) and 2-year (31.4 percent) fish (Burgner et al. 1992). Ocean migration and distribution of Central Valley steelhead stocks is unknown.

Steelhead experience most of their marine phase mortality soon after they enter the Pacific Ocean (Pearcy 1992). Ocean mortality is poorly understood, however, because few studies have been conducted to evaluate the importance of various factors including predation mortality, changes in ocean currents, water temperatures, and coastal upwelling, on steelhead survival. Possible causes of ocean mortality include predation, competition, starvation, osmotic stress, unauthorized high seas driftnet fisheries, disease, advective losses and other poor environmental conditions (Wooster 1983, Cooper and Johnson 1992, Pearcy 1992). Competition between steelhead and other species for limited food resources in the Pacific Ocean may be a contributing factor to declines in steelhead populations, particularly during years of low productivity (Cooper and Johnson 1992).

Ocean and climate conditions such as sea surface temperatures, air temperatures, strength of upwelling, El Niño events, salinity, ocean currents, wind speed, and primary and secondary productivity affect all facets of the physical, biological, and chemical processes in the marine environment. Some of the conditions associated with El Niño events include warmer water temperatures, weak upwelling, low primary productivity (which leads to decreased zooplankton biomass), decreased southward transport of subarctic water, and increased sea levels (Pearcy 1992). For juvenile steelhead, warmer water and weak upwelling are possibly the most important of the ocean conditions associated with El Niño. Because of the weakened upwelling during an El Niño year, juvenile California steelhead must migrate more actively offshore through possibly stressful warm waters with numerous inshore predators. Strong upwelling is probably beneficial because of the greater transport of smolts offshore, beyond major concentrations of inshore predators (Pearcy 1992). Investigations are currently underway to examine decadal oscillations in coastal marine environmental conditions and the associated biological changes that may affect the survival, growth, and recruitment of steelhead to the adult population.

A1.5 Threats and Stressors

The following have been identified as important threats and stressors to Central Valley steelhead (without priority).

Reduced staging and spawning habitat. Adult steelhead historically migrated upstream into higher gradient reaches of rivers and tributaries where water temperatures were cooler, turbidity was lower, and gravel substrate size was suitable for spawning and egg incubation (McEwan 2001). Steelhead are known to migrate upstream into higher gradient and elevation reaches of the rivers and streams than fall-run Chinook salmon, which predominantly spawn at lower elevations within the valley floor. The majority of historical adult staging/holding and spawning habitat for Central Valley steelhead is no longer accessible to upstream migrating steelhead or has been eliminated or degraded by man-made structures (e.g., dams and weirs) associated with water storage and conveyance, diversions, flood control, municipal, industrial, agricultural, and hydropower purposes (see Figure A-1a) (McEwan and Jackson 1996, McEwan 2001, USBR 2004, Lindley et al. 2006, NMFS 2007). Due to construction of these impediments and barriers to upstream passage, steelhead are currently limited in their geographic distribution within the Central Valley to lower elevation habitats.

Steelhead in the Central Valley migrate upstream into the mainstem Sacramento River and major tributaries (e.g., American, Feather rivers; Clear, Battle creeks and others), and are also known to occur within tributaries to the San Joaquin River (e.g., Mokelumne, Cosumnes, Stanislaus, Merced, Tuolumne rivers), where they spawn and rear. Steelhead do not currently spawn in the mainstem San Joaquin River. The majority of current steelhead spawning habitat exists upstream of the RBDD on the Sacramento River and its tributaries. Although the overall effect of operations of the RBDD on the Central Valley steelhead populations is not well understood, concerns have been expressed regarding the effect of gate operations on upstream and downstream migration by steelhead. Additional concerns include the potential for increased vulnerability of juvenile steelhead to predation by Sacramento pikeminnow, striped bass, and other predators that pass through the RBDD gates or fish ladder.

Reduced flows from dams and upstream water diversions can lower attraction cues for adult spawners, causing straying and delays in spawning or the inability to spawn (California Department of Water Resources [DWR] 2005). Adult steelhead migration delays can reduce fecundity and egg viability and increase susceptibility to disease and harvest.

Reduced rearing and out-migration habitat. Juvenile steelhead prefer to utilize natural stream banks, floodplains, marshes, and shallow water habitats for rearing during out-migration. Modification of natural flow regimes from upstream reservoir operations has resulted in dampening of the hydrograph in most Central Valley rivers, reducing the extent and duration of inundation of floodplains and other flow-dependent habitat used by migrating juvenile steelhead (DWR 2005, 70 FR 52488). Changes in river hydrology that have impacted floodplain inundation may have impacted areas thought to provide significant growth benefits to rearing fish (Sommer et al. 2001). Reductions in flow rates have also resulted in increased water temperature and residence time, and reductions in dissolved oxygen levels in localized areas of the Delta (e.g., Stockton Deep Water Ship Channel) which impact the quality of rearing and migration habitat. Reduced dissolved oxygen levels in the lower San Joaquin River during late summer and early fall have been identified as a barrier and/or impediment to migration for some salmonids (Regional Water Resources Control Board 2003), including Central Valley steelhead (Jassby and Van Nieuwenhuyse 2005). .Much of the Delta has been leveed, channelized, and fortified with riprap for flood protection, reducing and degrading the quality and availability of natural habitat for use by steelhead during migration (McEwan 2001). Furthermore, impacts to the quality, quantity, and availability of suitable habitat is likely to reduce fitness and increase susceptibility to entrainment, disease, exposure to contaminants, and predation.

Predation by non-native species. In general, the effect of non-native predation on the Central Valley steelhead distinct population segment (DPS) is unknown. However, non-native predation is likely an important threat to Central Valley steelhead in areas with high densities of non-native fish (e.g., small and large mouth bass, striped bass, and catfish) are thought to prey on out-migrating juvenile steelhead. Predation risk may covary with increased temperatures. Metabolic rates of non-native, predatory fish increase with increasing water temperatures based on bioenergetic studies (Loboschefsky et al. 2009, Miranda et al. 2010). Upstream gravel pits and flooded ponds such as those that occur on the San Joaquin River and its tributaries, attract non-native predators because of their depth and lack of cover for juvenile steelhead (DWR 2005). Non-native aquatic vegetation, such as Brazilian waterweed and water hyacinth, provide suitable habitat for non-native predators (Brown and Michniuk 2007). The low spatial complexity of channelized waterways (e.g., riprap-lined levee that provide virtually no cover protection from predators) and general low habitat diversity elsewhere in the Delta reduces refuge cover and protection of steelhead from predators (Raleigh et al. 1984, Missildine et al. 2001, 70 FR 52488). A major concern is the potential invasion of the Delta by the highly predatory northern pike. The pike, recently present in Lake Davis on the Feather River, is currently the target of a major eradication effort (California Department of Fish and Game [DFG] 2007a). If eradication fails and pike were to escape downstream to the Delta, they would likely be present in areas frequently inhabited by Central Valley steelhead.

Predation by native species such as the Sacramento pikeminnow in the Sacramento River at locations such as the RBDD has also been identified as a potentially significant source of mortality on juvenile steelhead.

Harvest. Steelhead have been, and continue to be, an important recreational fishery within inland rivers throughout the Central Valley. Although there are no commercial fisheries for steelhead, inland steelhead fisheries include tribal and recreational fisheries. In the Central Valley, recreational fishing for steelhead of hatchery origin is popular, but harvest is restricted to only visibly marked fish of hatchery origin (adipose fin clipped). Unmarked steelhead (adipose fin intact) must be released, reducing the take of naturally spawned wild fish. The impacts of illegal harvest occurring in the Delta and tributary rivers is thought to be relatively minor for Chinook salmon and steelhead. The effects of recreational fishing and the unknown level of illegal harvest on the abundance and population dynamics of wild Central Valley steelhead have not been quantified.

Reduced genetic diversity/integrity. Artificial propagation programs for steelhead in Central Valley hatcheries present multiple threats to the wild steelhead population, including mortality of natural steelhead in fisheries targeting hatchery origin steelhead, competition for prey and habitat, predation by hatchery origin fish on younger natural fish, disease transmission, and impediments to fish passage imposed by hatchery facilities. It is now recognized that Central Valley hatcheries are a significant and persistent threat to wild Chinook salmon and steelhead populations and fisheries (NMFS 2009a). One major concern with hatchery operations is the genetic introgression by hatchery origin fish that spawn naturally and interbreed with local natural populations (USFWS 2001, USBR 2004, Goodman 2005). Such introgression introduces maladaptive genetic changes to the wild steelhead stocks (McEwan and Jackson 1996, Myers et al. 2004). Impacts to fitness in Chinook salmon have been detected due to hatchery operations (Araki et al. 2007). Taking eggs and sperm from a large pool of individuals is one method for ameliorating genetic introgression, but artificial selection for traits that assure individual success in a hatchery setting (e.g., rapid growth and tolerance to crowding) are unavoidable (USBR 2004).

Entrainment. Juvenile steelhead migrating downstream through the Delta are vulnerable to entrainment and salvage at the SWP and CVP export facilities, primarily between March and May (see Table A-1a). There are also multiple factors that can influence the vulnerability of juvenile steelhead to entrainment by State Water Project (SWP) and Central Valley Project (CVP) export facilities, including the geographic distribution of steelhead within the Delta and hydrodynamic factors such as reverse flows in Old and Middle rivers, which are a function of export operations relative to San Joaquin River inflows, and southward flows of Sacramento River water towards pumps through an open Delta Cross Channel and Georgiana Slough. SWC and CVP exports have been shown to affect the tidal hydrodynamics (e.g., water current velocities and direction). The magnitude of these hydrodynamic effects varies in response to a variety of factors including tidal stage and magnitude of ebb and flood tides, the rate of SWP and CVP exports, operation of the Clifton Court Forebay (CCF) radial gate opening, and inflow from upstream tributaries. Steelhead respond behaviorally to hydraulic cues (e.g., water currents) during both upstream adult and downstream juvenile migration through the Delta. Changes in these hydraulic cues as a result of SWP and/or CVP export operations during the period when steelhead are migrating through Delta channels may contribute to attraction to false migration pathways, delays in migration, or increased movement of migrating steelhead toward the export facilities where there is an increase in the risk fish will be entrained into the salvage facilities. DWR and U.S. Bureau of Reclamation (USBR) (1999) found significant relationships between total monthly exports in January through May and monthly steelhead salvage at SWP and CVP facilities, suggesting the risk of steelhead entrainment is related, in part, to export rates. During the past several years, additional investigations have been designed using radio or acoustically-tagged juvenile and adult (post spawning adults) steelhead to monitor their migration behavior through the Delta channels and to assess the effects of changes in hydraulic cues and SWP and CVP export operations on migration (Holbrook et al. 2009, Perry et al. 2010, San Joaquin River Group Authority 2010). These studies are ongoing. Studies have also been recently conducted to assess the potential losses of juvenile steelhead, primarily as a result of predation by adult striped bass, during passage through CCF (Clark et al. 2008). Results of these studies have estimated that pre-screen losses of juvenile steelhead within CCFare greater than 80 percent.

In addition to SWP and CVP export facilities, there are over 2,200 small water diversions within the Delta, of which the majority are unscreened (Herren and Kawasaki 2001). The risk of entrainment is a function of the size of juvenile fish and the slot opening of the screen mesh (Tomljanovich et al. 1978, Schneeberger and Jude 1981, Zeitoun et al. 1981, Weisberg et al. 1987, C. Hanson unpubl. data). Although entrainment/salvage of steelhead at the SWP and CVP export facilities is well documented, it is unclear how many juvenile steelhead are entrained at other unscreened Delta diversions. Because steelhead are moderately large (greater than 200 mm fork length) and relatively strong swimmers when out-migrating, the effects of small in-Delta agricultural water diversions are thought to be lower than those of other Central Valley salmonids. In addition, many of the juvenile steelhead migrate downstream through the Delta during the late winter or early spring before many of the agricultural irrigation diversions are operating. Power plants within the Plan Area have the ability to impinge juvenile steelhead on the existing intake screens. However, use of cooling water is currently low with the retirement of older units. Furthermore, newer units are equipped with a closed cycle cooling system that virtually eliminates the risk of impingement of juvenile steelhead.

Exposure to toxins. Toxic chemicals are widespread throughout the Delta and may occur on a more localized scale in response to episodic events (e.g., stormwater runoff, point source discharges, etc.). These toxic substances include mercury, selenium, copper, pyrethroids, and endocrine disruptors with the potential to impact fish health and condition, and negatively impact steelhead distribution and abundance directly or indirectly. Some loads of toxics, such as selenium, are much higher in the San Joaquin River than the Sacramento River because they are naturally occurring in the alluvial soils and have been leached by irrigation water and concentrated by evapotranspiration (Nichols et al. 1986). This may indicate that the potential effects of chronic exposure could be greater for steelhead of San Joaquin River origin. Additionally, agricultural return flows that may contain toxic chemicals are widely distributed throughout the Sacramento and San Joaquin rivers and the Delta, although dilution flows from the rivers may reduce chemical concentrations to sublethal levels. Sublethal concentrations of toxics may interact with other stressors on salmonids, such as increasing their vulnerability to predation or disease (Werner 2007). For example, Clifford et al. (2005) found in a laboratory setting that juvenile fall-run Chinook salmon exposed to sublethal levels of a common pyrethroid, esfenvalerate, were more susceptible to infectious hematopoietic necrosis virus than those not exposed to esfenvalerate. Although not tested on steelhead, a similar response is likely, however juvenile steelhead generally migrate through the Delta in a comparatively shorter time period to Chinook salmon. The short duration may decrease juvenile steelhead exposure and susceptibility to toxic substances in the Delta. Adult migrating steelhead may be less affected by toxins in the Delta because they are not feeding, and thus not bioaccumulating toxic exposure, and they are moving rapidly through the system.

Iron Mountain Mine, located adjacent to the upper Sacramento River, has been a source of trace elements that are known to adversely affect aquatic organisms (Upper Sacramento River Fisheries and Riparian Habitat Advisory Council 1989). Storage limitations and limited availability of dilution flows have caused downstream copper and zinc levels to exceed salmonid tolerances and resulted in documented fish kills in the 1960s and 1970s (USBR 2004). The U.S. Environmental Protection Agency's Iron Mountain Mine remediation program has removed toxic metals in acidic mine drainage from the Spring Creek watershed with a state-of-the-art lime neutralization plant. Contaminant loading into the Sacramento River from Iron Mountain Mine has shown measurable reductions since the early 1990s.

Increased water temperature. Water temperature is among the physical factors that affect quality of habitat for salmonid adult holding, spawning and egg incubation, juvenile rearing, and migration. Adverse sublethal and lethal effects can result from exposure to elevated water temperatures at sensitive lifestages, such as during incubation or rearing. Water temperature criteria for various lifestages of salmonids in the Central Valley have been developed by NMFS (2009). The tolerance of steelhead water temperatures depends on life stage, acclimation history, food availability, duration of exposure, health of the individual, and other factors such as predator avoidance (Myrick and Cech 2004, USBR 2004). Higher water temperatures can lead to physiological stress, reduced growth rate, reduced spawning success, and increased mortality of steelhead (Myrick and Cech 2001). Temperature can also indirectly influence disease incidence and predation (Waples et al. 2008). Exposure to seasonally elevated water temperatures may occur as a result of reductions in flow as a result of upstream reservoir operations, reductions in riparian vegetation, channel shading, local climate and solar radiation. The installation of the Shasta Temperature Control Device in 1998, in combination with reservoir management to maintain the cold water pool, has reduced many of the temperature issues on the Sacramento River. During dry years, however, the release of cold water from Shasta Dam is still limited. As the river flows further downstream, particularly during the warm spring, summer, and early fall months, water temperatures continue to increase until they reach thermal equilibrium with atmospheric conditions. As a result of the longitudinal gradient of seasonal water temperatures, the coldest water and, therefore, the best areas for steelhead spawning and rearing are typically located immediately downstream of the dam.

Increased temperature can also arise from a reduction in shade over rivers by tree removal (Watanabe et al. 2005). Because river water is typically in thermal equilibrium with atmospheric conditions by the time it enters the Delta (C. Hanson, unpubl. data), this issue is caused primarily from actions upstream of the Delta. As a result of the relatively wide channels that occur within the Delta, the effects of additional riparian vegetation on reducing water temperatures.

A1.6 RELEVANT CONSERVATION EFFORTS

Because steelhead biology is similar to that of Chinook salmon, few conservation actions are specific to steelhead. Efforts by DFG to restore Central Valley steelhead are described in the "Steelhead Restoration and Management Plan for California" (McEwan and Jackson 1996). Measures to protect steelhead throughout the State of California have been in place since 1998 and a wide range of measures have been implemented including 100 percent marking of all hatchery steelhead, zero bag limits for unmarked steelhead, gear restrictions, closures, and size limits designed to protect rearing juveniles and smolts. The Central Valley Steelhead Project

Work Team, an interagency technical working group led by DFG, drafted a proposal to develop a comprehensive steelhead monitoring plan that was selected by the CALFED Ecosystem Restoration Program (ERP) Implementing Agency Managers for directed action funding. Long-term funding for implementation of the monitoring plan still needs to be secured.

Biological opinions for SWP and CVP operations (e.g., NMFS 2009b) and other federal projects involving irrigation and water diversion and fish passage, for example, have improved or minimized adverse impacts on steelhead in the Central Valley. In 1992, an amendment to the authority of the CVP through the Central Valley Project Improvement Act (CVPIA) was enacted to give protection of fish and wildlife equal priority with other Central Valley Project objectives. From this Act arose several programs that have benefited listed salmonids. The USFWS's Anadromous Fish Restoration Program (AFRP) is engaged in monitoring, education, and restoration projects designed to contribute toward doubling the natural populations of select anadromous fish species residing in the Central Valley. Restoration projects funded through the AFRP include fish passage, fish screening, riparian easement and land acquisition, development of watershed planning groups, instream and riparian habitat improvement, and gravel replenishment. The AFRP combines federal funding with State and private funds to prioritize and construct fish screens on major water diversions mainly in the upper Sacramento River. The goal of the Water Acquisition Program is to acquire water supplies to meet the habitat restoration and enhancement goals of the CVPIA, and to improve the ability of the U.S. Department of the Interior to meet regulatory water quality requirements. Water has been used to improve fish habitat for Central Valley steelhead by maintaining or increasing instream flows on Butte and Mill creeks and the San Joaquin River at critical times. Additionally, salmonid entrainment at the SWP and CVP export facilities is decreased through reducing seasonal diversion rates during periods when protected fish species are vulnerable to export related losses.

Two programs included under CALFED, the Ecosystem Restoration Program (ERP) and the Environmental Water Account, were created to improve conditions for fish, including steelhead, in the Central Valley. Restoration actions implemented by the ERP include the installation of fish screens, modification of barriers to improve fish passage, habitat acquisition, and instream habitat restoration. The majority of these actions address key factors affecting listed salmonids and emphasis has been placed in tributary drainages with high potential for Central Valley steelhead and spring-run Chinook salmon production. Additional ongoing actions include efforts to enhance fishery monitoring and directly support salmonid production through hatchery releases. The Environmental Water Account has been under scrutiny recently as to its success in meeting its original goal.

A major CALFED ERP action currently underway is the Battle Creek Salmon and Steelhead Restoration Project. The project will restore 77 km (48 miles) of habitat in Battle Creek to support steelhead and Chinook salmon spawning and juvenile rearing at a cost of over $90 million. The project includes removal of five small hydropower diversion dams, construction of new fish screens and ladders on another three dams, and construction of several hydropower facility modifications to ensure the continued hydropower operations. It is thought that this restoration effort is the largest cold water restoration project to date in North America.

The Delta Regional Ecosystem Restoration Implementation Plan (DRERIP) was formed to guide the implementation of CALFED Ecosystem Restoration Plan elements within the Delta (DFG 2007b). The DRERIP team has created a suite of ecosystem and species conceptual models, including steelhead, that document existing scientific knowledge of Delta ecosystems. The DRERIP Team has used these conceptual models to assess the suitability of actions proposed in the Ecosystem Restoration Plan for implementation. DRERIP conceptual models were used in the analysis of proposed BDCP conservation measures.

Oroville Dam Federal Energy Regulatory Commission (FERC) relicensing efforts on the Feather River have considered instream flows and temperature management for steelhead spawning and juvenile rearing downstream of the dam.

Multiple fish passage projects have been recently implemented for steelhead and other salmonids in the Sacramento and San Joaquin Watersheds. Multiple large diversions on the Sacramento River (e.g., Glenn-Colusa Irrigation District, RD108, RD1004, Sutter Mutual, and Wilkins Slough) have been equipped with positive barrier fish screens to reduce entrainment of steelhead and other salmonids. The Woodbridge Irrigation District Dam on the Mokelumne River was designed to improve upstream and downstream passage of steelhead and other salmonids by installing fish screens and fish ladders at the dam.

Mitigation under the Delta Fish Agreement has increased the number of wardens enforcing harvest regulations for steelhead and other fish in the Bay-Delta and upstream tributaries by creating the Delta Bay Enhanced Enforcement Program (DBEEP). Initiated in 1994, DBEEP currently consists of nine wardens and a supervisor.

Many smaller tributaries to the Sacramento and San Joaquin rivers have local watershed conservancies with master plans to contribute to conservation and recovery of steelhead and other salmonids.

A1.7 Recovery Goals

The Public Draft Recovery Plan for Central Valley salmonids, including steelhead, was released by NMFS on October 19, 2009. Although not final, the overarching goal in the public draft is the removal of, among other listed salmonids, the Central Valley steelhead DPS from the Federal List of Endangered and Threatened Wildlife (NMFS 2009a). Several objectives and related criteria represent the components of the recovery goal, including the establishment of at least two viable populations within each historical diversity group, as well as other measurable biological criteria.

APPENDIX A2. SACRAMENTO RIVER WINTER-RUN CHINOOK SALMON (*ONCORHYNCHUS TSHAWYTSCHA*)

A2.1 LEGAL STATUS

The Sacramento River winter-run Chinook salmon Evolutionarily Significant Unit (ESU) was originally listed as a threatened species in August 1989, under emergency provisions of the Federal Endangered Species Act (ESA), and was formally listed as threatened in November 1990 (55 FR 46515). The ESU consists of only one population confined to the upper Sacramento River in California's Central Valley. The ESU was reclassified as endangered under the federal ESA on January 4, 1994 (59 FR 440), due to increased variability of run sizes, expected weak returns as a result of two small year classes in 1991 and 1993, and a 99 percent decline between 1966 and 1991. The Sacramento River winter-run Chinook salmon ESU includes all naturally spawned winter-run Chinook salmon in the Sacramento River and its tributaries as well as two artificial propagation programs: winter-run Chinook salmon produced from the Livingston Stone National Fish Hatchery and released as juveniles into the Sacramento River and winter-run Chinook salmon held in a captive broodstock program maintained at Livingston Stone National Fish Hatchery (70 FR 37160, June 28, 2005) (see Figure A-2a).

The National Marine Fisheries Service (NMFS) reaffirmed the listing of Sacramento River winter-run Chinook salmon as endangered on June 28, 2005 (70 FR 37160) and included the Livingston Stone National Fish Hatchery population within the listed population.

Winter-run Chinook salmon was listed as endangered under the California Endangered Species Act on September 22, 1989.

A2.2 SPECIES DISTRIBUTION AND STATUS

A2.2.1 Range and Status

The distribution of winter-run Chinook salmon spawning and rearing was limited historically to the upper Sacramento River and tributaries, where cool spring-fed streams supported successful adult holding, spawning, egg incubation, and juvenile rearing (Slater 1963, Yoshiyama et al. 1998). The headwaters of the McCloud, Pit, and Little Sacramento Rivers, Hat and Battle creeks , provided clean, loose gravel, cold, well-oxygenated water, and year-round flow in riffle habitats for spawning and incubation (see Figure A-2a). These areas also provided the cold, productive waters necessary for egg and fry survival, and juvenile rearing over summer. Construction of Shasta Dam in 1943 and Keswick Dam in 1950 blocked access to all of these upstream waters except Battle Creek, which is blocked by a weir at the Coleman National Fish Hatchery and other small hydroelectric facilities (Moyle et al. 1989, NMFS 1997).

DRAFT

Figure A-2a. Sacramento River Winter-Run Chinook Salmon Inland Range in California

Primary spawning and rearing habitats for winter-run Chinook salmon are now confined to the cold water areas between Keswick Dam and Red Bluff Diversion Dam (RBDD)(see Figure A-2a). The lower reaches of the Sacramento River, Delta, and San Francisco Bay serve as migration corridors for the upstream migration of adult and downstream migration of juvenile winter-run Chinook salmon.

Estimates of the Sacramento River winter-run Chinook salmon population (including both male and female salmon) reached nearly 100,000 fish in the 1960s before declining to under 200 fish in the 1990s (Good et al. 2005). Abundance of returning adult spawners generally increased between the mid-1990s and 2006 (see Figure A-2b). However, recent population estimates of winter-run Chinook salmon spawning upstream of the RBDD have dropped off since the 2006 peak (DFG 2010).

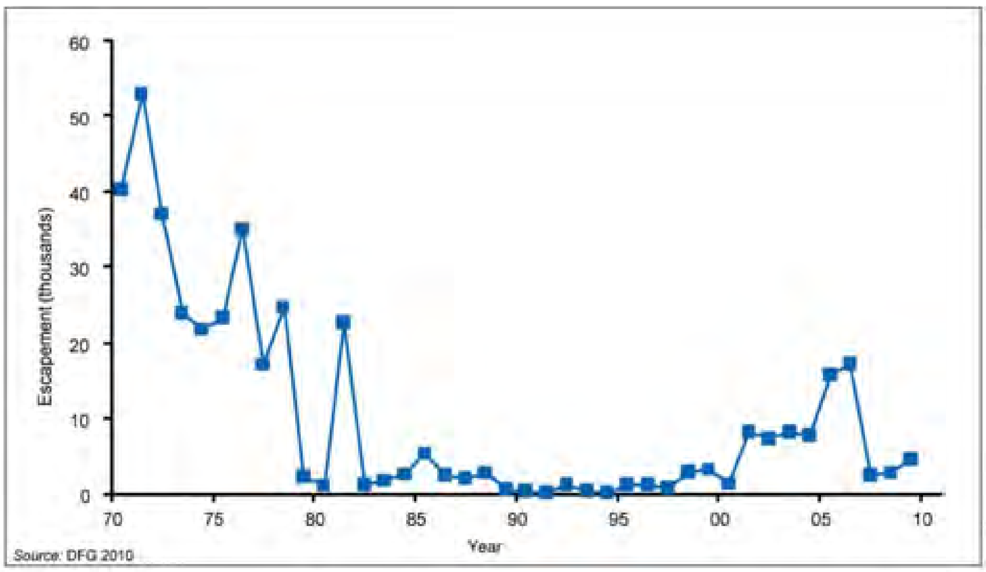

Figure A-2b. Estimate Historical Spawner Escapement of Sacramento River Winter-Run Chinook Salmon (1970-2009)

Two methods are currently used to estimate the juvenile production of Sacramento River winter-run Chinook salmon: the juvenile production index method (using rotary screw traps) and the juvenile production estimate method (using carcass surveys). Average juvenile population of Sacramento River winter-run Chinook salmon inhabiting the upper Sacramento River at the RBDD is 4,230,378 juveniles per year using the juvenile production index method between 1995 and 2007 (excluding 2000 and 2001 when rotary screw trapping was not conducted) (Poytress and Carillo 2010). Using the juvenile production estimate method, average production is estimated to be 5,034,921 juveniles exiting the upper Sacramento River at the RBDD in all years between 1996 and 2007 (Poytress and Carillo 2010).

Although the abundance of the Sacramento River winter-run Chinook salmon population has on average been growing since the 1990s (despite recent declines since 2007), there is only one population and it depends heavily on cold-water releases from Shasta Dam (Good et al. 2005).

Lindley et al. (2007) considers the Sacramento River winter-run Chinook salmon population at a moderate risk of extinction primarily due to the risks associated with only one existing population. The viability of an ESU that is represented by a single population is vulnerable to changes in the environment through a lack of spatial geographic diversity and genetic diversity that result from having only one population. A single catastrophic event with effects persisting for four or more years could extirpate the entire Sacramento River winter-run Chinook salmon ESU, which puts the population at a high risk of extinction over the long-term (Lindley et al. 2007). Such potential catastrophes include volcanic eruption of Mt. Lassen; prolonged drought, which depletes the cold water pool in Lake Shasta or some related failure to manage cold water storage; a spill of toxic materials with effects that persist for four years; regional declines in upwelling and productivity of near-shore coastal marine waters resulting in reduced food supplies for juvenile and sub-adult salmon, reduced growth, and/or increased mortality; or a disease outbreak. Another vulnerability to an ESU that is represented by a single population is the limitation in life history and genetic diversity that would otherwise increase the ability of individuals in the population to withstand environmental variation.

Although NMFS recently proposed that this ESU be downgraded from endangered to threatened status, NMFS decided in its Final Listing Determination (June 28, 2005, 70 FR 37160) to continue to list the Sacramento River winter-run Chinook salmon ESU as endangered because the population remains below the draft recovery goals established for the run (NMFS 1997) and the naturally-spawned component of the ESU is dependent on one extant population in the Sacramento River.

A2.2.2 Distribution and Status in the Plan Area

The entire population of the Sacramento River winter-run Chinook salmon must pass through the Plan Area as migrating adults and emigrating juveniles. Because winter-run Chinook salmon use only the Sacramento River system for spawning, it has been hypothesized that adults are attracted to, and migrate upstream primarily along, the western edge of the Delta through the Sacramento River corridor. Because juvenile winter-run salmon have been collected at various locations within the Delta (including the State Water Project [SWP] and the Central Valley Project [CVP] south Delta export facilities), it has been hypothesized that juveniles likely use a wider range of the Delta for migration and rearing than adults. Studies using acoustically tagged juvenile and adult Chinook salmon are ongoing to further investigate the migration routes, migration rates, reach-specific mortality rates, and the effects of hydrologic conditions (including the effects of SWP and CVP export operations) on salmon migration through the Delta (Lindley et al. 2008, MacFarlane et al. 2008a, Michel et al. 2008, Perry et al. 2008). Juvenile winter-run Chinook salmon likely inhabit Suisun Marsh for rearing and may inhabit the Yolo Bypass when flooded, although use of these two areas is not well understood.

Results of fishery monitoring using a combination of adult counts at the RBDD fish ladder and carcass surveys have been used to estimate annual adult escapement of winter-run Chinook salmon on the mainstem Sacramento River. The estimated annual adult escapement over the period from 1970 through 2010 is shown in Figure A-2b. During the late 1960s and throughout the 1970s, winter-run Chinook salmon abundance declined significantly from a high of approximately 120,000 adults to several thousand adults. Population abundance remained low through the mid-1990s, with adult abundance in some years less than 500 fish. Beginning in the mid-1990s and continuing to date, adult escapement has shown a trend of increasing abundance, approaching 20,000 fish in 2006. A variety of factors have been identified that are thought to have contributed to the recent increasing trend in adult abundance. These factors, include but are not limited to, improved water temperatures and temperature management in the Shasta Reservoir and the mainstem river downstream of Keswick Dam, improvements in the operations of the RBDD (keeping holding gates open for a longer period), favorable hydrological and ocean rearing conditions, habitat enhancements, reductions in loading of toxic chemicals, improved fish screens on major water diversions, and changes in ocean commercial and recreational angling to reduce harvest mortality.

Adult winter-run Chinook salmon escapement to the Sacramento River declined substantially in 2007, with an estimated 2,542 adults retuning to spawn (see Figure A-2b). As discussed below, it has been hypothesized that the substantial decline in adult winter-run Chinook salmon escapement was the result of reduced productivity of near-shore coastal waters and reduced prey availability resulting in poor juvenile salmon growth and high mortality during the juvenile ocean rearing phase (MacFarlane et al. 2008b). A similar substantial decline in abundance of retuning fall-run Chinook salmon (and other salmon populations in California) was observed in 2007. Adult escapement remained low during 2008 and 2009. In response to the low numbers of adult Chinook salmon returning to the Central Valley, commercial and recreational fishing for salmon has been curtailed since 2007.

A2.3 Habitat Requirements and Special Considerations

Critical habitat for the winter-run Chinook ESU was designated under the ESA on June 16, 1993 (58 FR 33212). Designated critical habitat includes: the Sacramento River from Keswick Dam (RM 302) to Chipps Island (RM 0) at the westward margin of the Sacramento-San Joaquin Delta, all waters from Chipps Island westward to Carquinez Bridge, including Honker, Grizzly, and Suisun bays, and Carquinez Strait, all waters of San Pablo Bay westward of San Pablo Bay westward of the Carquinez Bridge, and all waters of San Francisco Bay (north of the San Francisco/Oakland Bay Bridge) from San Pablo Bay to the Golden Gate Bridge (59 FR 440, January 4, 1994) (see Figure A-2c). In the Sacramento River, critical habitat includes the river water column, river bottom, and adjacent riparian zone used by fry and juveniles for rearing. In the areas westward of Chipps Island, critical habitat includes the estuarine water column and essential foraging habitat and food resources used by Sacramento River winter-run Chinook salmon as part of their juvenile emigration or adult spawning migration.

Figure A-2c. Sacramento River Winter-Run Chinook Salmon Inland Designated Critical Habitat in California

Habitat of Sacramento River winter-run Chinook salmon is also protected under the Magnuson-Stevens Fishery Conservation and Management Act as Essential Fish Habitat (EFH). Those waters and substrate necessary to support Sacramento River winter-run Chinook salmon spawning, breeding, feeding, or growth are included as EFH (see Figure A-2d). Critical Habitat and EFH are managed differently from a regulatory standpoint, but are biologically equivalent with regard to conservation.

The PCEs considered essential for the conservation of Sacramento River winter-run Chinook salmon are: (1) freshwater spawning sites, (2) freshwater rearing sites, (3) freshwater migration corridors, (4) estuarine areas, (5) nearshore marine areas, and (6) offshore marine areas.

A2.3.1 Spawning Habitat

Spawning habitat for Sacramento River winter-run Chinook salmon is restricted to the Sacramento River primarily between RBDD and Keswick Dam.

Spawning sites for Sacramento River winter-run Chinook salmon include those stream reaches with water movement, velocity, depth, temperature, and substrate composition that support spawning, egg incubation, and larval development. Water velocity and substrate conditions are more critical to the viability of spawning habitat than depth. Incubating eggs and embryos buried in gravel require sufficient water flow through the gravel to supply oxygen and removal of metabolic wastes (Resources Agency et al. 1998). Spawning occurs in gravel substrate in relatively fast-moving, moderately shallow riffles or along banks with relatively high water velocities. The gravel must be clean and loose, yet stable for the duration of egg incubation and the larval development.

Substrate composition has other key implications to spawning success. The embryos and alevins (newly hatched fish with the yolk sac still attached) require adequate water movement through the substrate; however, this movement can be inhibited by the accumulation of fines and sand. Generally, the redd should contain less than 5 percent fines (Resources Agency et al. 1998).

Water velocity in Chinook salmon spawning areas typically ranges from 1.0 to 3.5 feet per second and optimum velocity is 1.5 feet per second (Resources Agency et al. 1998). Spawning occurs at depths between 1 to 5 feet with a maximum depth observed of 20 feet. A depth of less than 6 inches can be restrictive to Chinook salmon movement.

DRAFT

Figure A-2d. Sacramento River Winter-Run Chinook Salmon Inland Essential Fish Habitat in California

A2.3.2 Freshwater Rearing Habitat

Freshwater salmon rearing sites are those with sufficient water quantity and floodplain connectivity to form and maintain physical habitat conditions that support juvenile growth and mobility; suitable water quality; availability of suitable forage species that support juvenile salmon growth and development; and cover such as shade, submerged and overhanging large wood, log jams, beaver dams, aquatic vegetation, large rocks and boulders, side channels, andundercut banks. Both spawning areas and migratory corridors also function as rearing habitat for juveniles, which feed and grow before and during their outmigration. Non-natal, intermittent tributaries also may be used for juvenile rearing. Rearing habitat quality is strongly affected by habitat diversity and complexity, food supply, and fish and avian predators. Some of these more complex and productive habitats with floodplains are still found in the system (e.g., the lower Cosumnes River, Sacramento River reaches with set-back levees [i.e., primarily located upstream of the City of Colusa]). The channeled, leveed, and rip-rapped river reaches and sloughs common along the Sacramento River and throughout the Delta, however, typically have low habitat complexity, low abundance of food organisms, and offer little protection from predation by fish and birds. Freshwater rearing habitat has a high conservation value as the juvenile life stage of salmonids is dependent on the function of this habitat for successful survival and recruitment into the adult population.

A2.3.3 Freshwater Migration Corridors

Freshwater migration corridors for winter-run Chinook salmon, including river channels, channels through the Delta, and the Bay-Delta estuary, support mobility, survival, and food supplies for juveniles and adults. Migration corridors should be free from obstructions (passage barriers and impediments to migration), provide favorable water quantity (instream flows) and quality conditions (seasonal water temperatures), and contain natural cover such as submerged and overhanging large wood, native aquatic vegetation, large woody debris, rocks and boulders, side channels, and undercut banks. Migratory corridors for winter-run Chinook salmon are located downstream of the spawning areas and include the lower Sacramento River, the Delta, and the San Francisco Bay complex extending to coastal marine waters. These corridors allow the upstream passage of adults and the downstream emigration of juvenile salmon. Migratory corridor conditions are strongly affected by the presence of passage barriers, which can include dams, unscreened or poorly screened diversions, and degraded water quality. For freshwater migration corridors to function properly, they must provide adequate passage, provide suitable migration cues, limit false attraction, provide low vulnerability to predation, and not contain impediments and delays in both upstream and downstream migration.

Results of mark-recapture studies conducted using juvenile Chinook salmon (typically hatchery-reared late fall-run Chinook salmon that are considered to be representative of juvenile winter-run salmon) released into the Sacramento River have shown high mortality during passage downstream through the rivers and Delta (Brandes and McLain 2001, Newman and Rice 2002, Hanson 2008). Mortality is typically greater in years when spring flows are reduced and water temperatures are increased. Results of survival studies have shown that closing the Delta Cross Channel gates to reduce the movement of juvenile salmon into the Delta, contributes to improved survival of emigrating juvenile Chinook salmon (Brandes and McLain 2001, Manly 2004, Low and White undated). Observations at the SWP and CVP fish salvage facilities have shown that very few of the marked salmon (typically less than 1 percent [Hanson 2008]) are entrained and salvaged at the export facilities. Results of estimating incidental take of juvenile winter-run Chinook salmon at the SWP and CVP fish salvage facilities based on comparison of the juvenile production estimates for winter-run emigrating from the upper Sacramento River rearing areas (e.g., estimated based on results of spawning carcass surveys and environmental conditions and/or fishery monitoring at RBDD) show a similar low magnitude to direct losses of juvenile winter-run Chinook salmon at the fish salvage facilities. Although the factors contributing to the high juvenile mortality have not been quantified, results of acoustic tagging experiments and anecdotal observations suggest that exposure to adverse water quality conditions leading to mortality (e.g., elevated water temperatures, potentially toxic chemicals) and vulnerability to predation mortality are two of the factors contributing to the high juvenile mortality observed in the Sacramento River and Delta.

A2.3.4 Estuarine Areas

Estuarine migration and juvenile rearing habitats should be free of obstructions (i.e., dams and other barriers) and provide suitable water quality, water quantity (river and tidal flows), and salinity conditions to support juvenile and adult physiological transitions between fresh and salt water. Natural cover, such as submerged and overhanging large wood, native aquatic vegetation, and side channels, provide juvenile foraging habitat and cover from predators. Tidal wetlands and seasonally inundated floodplains have also been identified as high value foraging and rearing habitats for juvenile salmon migrating downstream through the estuary. Estuarine areas contain a high conservation value because they function to support juvenile Chinook salmon growth, smolting, avoidance of predators, and provide a transition to the ocean environment.

A2.3.5 Ocean Habitats

Although ocean habitats are not part of the critical habitat listings for Sacramento River winter-run Chinook salmon, biologically productive coastal waters are an important habitat component for the species. Juvenile Chinook salmon inhabit near-shore coastal marine waters for a period of typically two to four years before adults return to Central Valley rivers to spawn. During their marine residence, Chinook salmon forage on krill, squid, and other marine invertebrates as well as a variety of fish such as northern anchovy and Pacific herring. These features are essential for conservation because, without them, juveniles cannot forage and grow to adulthood.

The variation in ocean productivity off the West Coast can be high both within and among years. Changes in ocean currents and upwelling have been identified as significant factors affecting nutrient availability, phytoplankton, and zooplankton production and the availability of other forage species in near-shore surface waters. Ocean conditions during a salmon’s ocean residency period can be important, as indicated by the effect of the 1983 El Niño on the size and fecundity of Central Valley fall-run Chinook salmon (Wells et al. 2006). Although the effects of ocean conditions on Chinook salmon growth and survival have not been investigated extensively, recent observations since in 2007 have shown a significant decline in the abundance of adult Chinook salmon and coho salmon returning to California rivers and streams (fall-run adult returns to the Sacramento and San Joaquin rivers were the lowest on record) (Pacific Fishery Management Council 2008) that has been hypothesized to be the result of declines in ocean productivity and associated high mortality rates during the period when these fish were rearing in near-shore coastal waters (MacFarlane et al. 2008b). The importance of changes in ocean conditions on growth, survival, and population abundance of Central Valley Chinook salmon is currently undergoing further investigation.

A2.4 LIFE HISTORY

Chinook salmon exhibit two generalized freshwater life history types (Healey 1991). Stream-type adults enter freshwater months before spawning and juveniles reside in freshwater for a year or more following emergence, whereas ocean-type adults spawn soon after entering freshwater and juveniles migrate to the ocean as fry or parr within their first year. Winter-run Chinook salmon are somewhat anomalous in that they have characteristics of both stream- and ocean-type races (Healey 1991). Adults enter freshwater in winter or early spring, and delay spawning until spring or early summer (stream-type). However, juvenile winter-run Chinook salmon migrate to sea after only 4 to 7 months of river life (ocean-type). Adequate instream flows and cool water temperatures are more critical for the survival of Chinook salmon exhibiting a stream-type life history due to over-summering by adults and/or juveniles.

Sacramento River winter-run Chinook salmon adults enter the Sacramento River basin between December and July; the peak occurring in March (see Table A-2a) (Yoshiyama et al. 1998, Moyle 2002). Spawning occurs from mid-April to mid-August, peaking in May and June, in the Sacramento River reach between Keswick Dam and RBDD (Vogel and Marine 1991). The majority of Sacramento River winter-run Chinook salmon spawners are three years old. Adult winter-run Chinook salmon tend to enter freshwater as sexually immature fish, migrate far upriver, and delay spawning for weeks or months. Pre-spawning activity requires an area of 200 to 650 square feet. The female digs a nest, called a redd, with an average size of 165 square feet, in which she buries her eggs after they are fertilized by the male (Resources Agency et al. 1998).

Sources: [1]Yoshiyama *et al.* 1998; Moyle 2002; [2]Myers *et al.* 1998; [3]Martin *et al.* 2001; [4]Snider and Titus 2000; [5]USFWS 2006

Sacramento River winter-run Chinook salmon fry begin to emerge from the gravel in late June to early July and continue through October (Fisher 1994), with emergence generally occurring at night. Fry then seek lower velocity nearshore habitats with riparian vegetation and associated substrates important for providing aquatic and terrestrial invertebrates, predator avoidance, and slower velocities for resting (NMFS 1996). Emigrating juvenile Sacramento River winter-run Chinook salmon pass the RBDD beginning as early as mid-July, typically peaking in September, and can continue through March in dry years (Vogel and Marine 1991, NMFS 1997). From 1995 to 1999, all Sacramento River winter-run Chinook salmon outmigrating as fry passed the RBDD by October, and all outmigrating pre-smolts and smolts passed the RBDD by March (Martin et al. 2001).

Juvenile Sacramento River winter-run Chinook salmon occur in the Delta primarily from November through early May based on data collected from trawls in the Sacramento River at West Sacramento (RM 55; USFWS 2006). The timing of migration varies somewhat due to changes in river flows, dam operations, seasonal water temperatures, and hydrologic conditions (water year type). Winter-run Chinook salmon juveniles remain in the Delta until they reach a fork length of approximately 118 mm and are between five and 10 months of age. It has been hypothesized that changes in habitat conditions within the Delta over the past century have resulted in a reduction in extended juvenile salmon rearing when compared to periods when habitat for juvenile salmon rearing was more suitable. Emigration to the ocean begins as early as November and continues through May (Fisher 1994, Myers et al. 1998). The importance of the Delta in the life history of Sacramento River winter-run Chinook salmon is not well understood.

Data from the Pacific States Marine Fisheries Commission Regional Mark Information System database indicate that Sacramento River winter-run Chinook salmon adults are not as broadly distributed along the Pacific Coast as other Central Valley Chinook salmon runs and concentrate in the region between San Francisco and Monterey. This localized distribution may indicate a unique life history strategy related to the fact that Sacramento River winter-run Chinook salmon also mature at a relatively young age (Myers et al. 1998). Sacramento River winter-run Chinook salmon remain in the ocean environment for two to four years.

A2.5 Threats and Stressors

The following have been identified as important threats and stressors to winter-run Chinook salmon (without priority).

Reduced staging and spawning habitat. Access to much of the historical upstream spawning habitat for winter-run Chinook salmon (see Figure A-2a) has been eliminated or degraded by man-made structures (e.g., dams and weirs) associated with water storage and conveyance, flood control, and diversions and exports for municipal, industrial, agricultural, and hydropower purposes (Yoshiyama et al. 1998). The construction and operation of Shasta Dam reduced the winter-run Chinook salmon ESU from four independent populations to just one. The remaining available habitat for natural spawners is currently maintained with cool water releases from Shasta and Keswick dams, thereby significantly limiting spatial distribution of this ESU within the reach of the mainstem Sacramento River immediately downstream of the dam.

Upstream diversions and dams have decreased downstream flows and altered seasonal hydrologic patterns, which have been identified as factors resulting in delayed upstream migration by adults and increased mortality of out-migrating juveniles (Yoshiyama et al. 1998, DWR 2005). Dams and reservoir impoundments and associated reductions in peak flows have blocked gravel recruitment and reduced flushing of sediments from existing gravel beds, reducing and degrading natal spawning grounds. Furthermore, reduced flows can lower attraction cues for adult spawners, causing straying and delays in spawning (DWR 2005). Adult salmon migration delays can reduce fecundity and increase susceptibility to disease and harvest (McCullough 1999).

The RBDD, located on the Sacramento River, has been identified as a barrier and impediment to adult winter-run Chinook salmon upstream migration. Although the RBDD is equipped with fish ladders, migration delays occur when the dam gates are closed. Mortality as a result of increased predation by Sacramento pikeminnow on juvenile salmon passing downstream through the fish ladder has also been identified as a factor affecting abundance of salmon produced on the Sacramento River (Hallock 1991). The construction and operation of the RBDD has been identified as one of the primary factors contributing to the decline in winter-run Chinook salmon abundance that lead to listing of the species under the ESA.

Reduced rearing and out-migration habitat. Juvenile winter-run Chinook salmon prefer natural stream banks, floodplains, marshes, and shallow water habitats to utilize as rearing habitat during out-migration. Channel margins throughout the Delta have been leveed, channelized, and fortified with riprap for flood protection and island reclamation, reducing and degrading the quality of natural habitat available for juvenile Chinook salmon rearing (Brandes and McLain 2001). Man-made barriers further reduce and degrade rearing and migration habitat and delay juvenile out-migration. Juvenile out-migration delays can reduce fitness and increase susceptibility to diversion screen impingement, entrainment, disease, and predation. Modification of natural flow regimes from upstream reservoir operations has resulted in dampening and altering the seasonal timing of the hydrograph, reducing the extent and duration of seasonal floodplain inundation and other flow-dependent habitat used by migrating juvenile Chinook salmon (70 FR 52488, Sommer et al. 2001, DWR 2005). Recovery of floodplain habitat in the Central Valley has been found to contribute to increased production in fall-run Chinook salmon (Sommer et al. 2001), but little is known about the potential benefits of recovered floodplains during the migration period for winter-run. Reductions in flow rates have resulted in increased seasonal water temperature. The potential adverse effects of dam operations and reductions in seasonal river flows, such as delays in juvenile emigration and exposure to a higher proportion of agricultural return flows, have all been identified as factors that could affect the survival and success of winter-run Chinook salmon inhabiting the Sacramento River in the future.

Predation by non-native species. Predation on juvenile salmon by non-native fish has been identified as an important threat to winter-run Chinook salmon in areas with high densities of non-native fish (e.g., small and large mouth bass, striped bass, and catfish) that prey on out-migrating juveniles (Lindley and Mohr 2003). Water temperatures are generally lower during out-migration of winter-run compared to other salmonids, and may ameliorate predation pressures that can increase with increasing water temperature. In addition, non-native aquatic vegetation, such as Egeria and water hyacinth, provide suitable habitat for non-native predators (Nobriga et al. 2005, Brown and Michniuk 2007). Predation risk may covary with increased temperatures. Metabolic rates of non-native, predatory fish increase with increasing water temperatures based on bioenergetic studies (Loboschefsky et al. 2009, Miranda et al. 2010). The low spatial complexity and reduced habitat diversity (e.g., lack of cover) of channelized waterways within the Sacramento River and Delta reduces refuge space of salmon from predators (Raleigh et al. 1984, Missildine et al. 2001, 70 FR 52488). A major concern is the potential invasion of the Delta by the highly predatory northern pike. The pike, recently present in Lake Davis on the Feather River, was the target of a major eradication effort (DFG 2007a). If eradication fails and pike escape downstream to the Delta, they would likely be present in areas inhabited by juvenile winter-run Chinook salmon.

Increased predation mortality by native fish species, such as Sacramento pikeminnow at the RBDD, has also been identified as a factor affecting the survival of juvenile salmon within the Sacramento River and Delta.

Harvest. Commercial and recreational harvest of winter-run Chinook salmon in the ocean and inland fisheries has been a subject of management actions by the California Fish and Game Commission and the Pacific Fishery Management Council. The primary concerns focus on the effects of harvest on wild Chinook salmon produced in the Central Valley, as well as the incidental harvest of winter-run Chinook salmon as part of the fall-run and late fall-run salmon fisheries. Naturally reproducing winter-run Chinook salmon are less able to withstand high harvest rates when compared to hatchery-based stocks because of differences in survival rates for incubating eggs and rearing and emigrating juvenile salmon produced in streams and rivers (relatively low survival rates) compared to Central Valley salmon hatcheries (relatively high survival rates) (Knudsen et al. 1999). As a result of recent changes in fishing regulations and restrictions on harvest, commercial and recreational fishing does not appear to have a significant impact on winter-run Chinook salmon populations, but continued assessment is warranted. Commercial fishing for salmon in West Coast ocean waters is managed by the Fishery Management Council and is constrained by time and area closures to meet the Sacramento River winter-run ESA consultation standard and restrictions requiring minimum size limits and use of circle hooks for anglers. Ocean harvest restrictions since 1995 have led to reduced ocean harvest of winter-run Chinook salmon (i.e., Central Valley Chinook salmon ocean harvest index, ranged from 0.55 to nearly 0.80 from 1970 to 1995, and was reduced to 0.27 in 2001). Major restrictions in the commercial fishing industry in California and Oregon during the past two years were enforced to protect Klamath River coho salmon stocks. Because the fishery is mixed, these restrictions have likely reduced harvest of winter-run Chinook salmon, as well. The DFG, NMFS, and Pacific Fishery Management Council continually monitor and assess the effects of harvest of winter-run Chinook salmon, such that regulations can be refined and modified as new information becomes available.

Because adult winter-run Chinook salmon hold in the mainstem Sacramento River until spawning during the summer months, they are particularly vulnerable to illegal (poaching) harvest. Various watershed groups have established public outreach and educational programs in an effort to reduce poaching. In addition, DFG wardens have increased enforcement against illegal harvest of winter-run Chinook salmon. The level and effect of illegal harvest on adult winter-run Chinook salmon abundance and population reproduction is unknown.

Reduced genetic diversity/integrity. Artificial propagation programs conducted for winter-run Chinook salmon conservation purposes (i.e., Livingston Stone National Fish Hatchery) were developed to increase the abundance and diversity of winter-run Chinook salmon and to protect the species from extinction in the event of a catastrophic failure of the wild population. It is unclear what the effects of the hatchery propagation program are on the productivity and spatial structure of the winter-run Chinook salmon ESU (i.e., genetic fitness and productivity). One of the primary concerns with hatchery operations is the genetic introgression by hatchery origin fish that spawn naturally and interbreed with local natural populations (USFWS 2001, USBR 2004, Goodman 2005). It is now recognized that Central Valley hatcheries are a significant and persistent threat to wild Chinook salmon and steelhead populations and fisheries (NMFS 2009a). Such introgression introduces maladaptive genetic changes to the wild winter-run stocks and may reduce overall fitness (Myers et al. 2004, Araki et al. 2007). Taking egg and sperm from a large number of individuals is one method to ameliorate genetic introgression, but artificial selection for traits that assure individual success in a hatchery setting (e.g., rapid growth and tolerance to crowding) are unavoidable (USBR 2004). Investigations are continuing to evaluate the genetic characteristics of winter-run Chinook salmon, improve genetic management of the artificial propagation program, evaluate the minimum viable population size that would maintain genetic integrity within the population, and explore methods for establishing additional independent winter-run Chinook salmon populations as part of recovery planning and conservation of the species.

Entrainment. The vulnerability of juvenile winter-run Chinook salmon to entrainment and salvage at SWP and CVP export facilities varies in response to multiple factors, including the seasonal and geographic distribution of juvenile salmon within the Delta, operation of Delta Cross Channel gates, hydrodynamic conditions occurring within the central and southern regions of the Delta (e.g., Old and Middle rivers), and export rates. The loss of fish to entrainment mortality has been identified as an impact to Chinook salmon populations (Kjelson and Brandes 1989). Juvenile winter-run Chinook salmon tend to be distributed within the central and southern Delta where they have an increased risk of entrainment/salvage between February and April (see Table A.X.1). The effect of changing hydrodynamics within Delta channels, such as reversed flows in Old and Middle rivers resulting from SWP and CVP export operations, has the potential to increase attraction of emigrating juveniles into false migration pathways, delay emigration through the Delta, and directly or indirectly increase vulnerability to entrainment at unscreened diversions. In addition, there is an increase the risk of predation and duration of exposure to seasonally elevated water temperatures and other water quality conditions. SWP and CVP exports have been shown to affect the tidal hydrodynamics (e.g., water current velocities and direction). The magnitude of these hydrodynamic effects vary in response to a variety of factors including tidal stage and magnitude of ebb and flood tides, the rate of SWP and CVP exports, operation of the Clifton Court Forebay (CCF) radial gate opening, and inflow from the upstream tributaries. Chinook salmon behaviorally respond to hydraulic cues (e.g., water currents) during both upstream adult and downstream juvenile migration through the Delta. Changes in these hydraulic cues as a result of SWP and/or CVP export operations during the period that salmon are migrating through Delta channels may contribute to use of false migration pathways, delays in migration, or increased movement of migrating salmon toward the export facilities leading to an increase in entrainment risk. During the past several years, additional investigations have been designed using radio or acoustically-tagged juvenile Chinook salmon to monitor migration behavior through the Delta channels and to assess the effects of changes in hydraulic cues and SWP and CVP export operations on migration (Holbrook et al. 2009, Perry et al. 2010, San Joaquin River Group Authority 2010). These studies are ongoing.

Incidental take of juvenile winter-run Chinook salmon at the SWP and CVP export fish salvage facilities is routinely monitored and reported as part of export operations. Salvage monitoring and the protocol for identifying juvenile winter-run Chinook salmon from other Central Valley Chinook salmon have been refined over the past decade. Run identification was originally determined based on the length of each fish and the date when it was collected. Subsequent genetic testing has been used to refine species identification. Methods for estimating juvenile winter-run Chinook salmon production each year (year class strength) have been developed that take into account the number of adults spawning in the river from carcass surveys, hatching success based on a consideration of water temperatures and other factors, and estimated juvenile survival. Authorized incidental take can then be adjusted each year (1-2 percent of juvenile production) to reflect the relative effect of take at a population level rather than based on a predetermined level that does not reflect year-to-year variation in juvenile production within the Sacramento River.

In addition to SWP and CVP exports, there are more than 2,200 small water diversions throughout the Delta, including unscreened diversions located on the tributary rivers (Herren and Kawasaki 2001). The risk of entrainment is a function of the size of juvenile fish and the slot opening of the screen mesh (Tomljanovich et al. 1978, Schneeberger and Jude 1981, Zeitoun et al. 1981, Weisberg et al. 1987, C. Hanson unpubl. data). Many juvenile winter-run Chinook salmon migrate downstream through the Delta during the late winter or early spring when many of the agricultural irrigation diversions are not operating or are only operating at low levels. Juvenile winter-run Chinook salmon also migrate primarily in the upper part of the water column, reducing their vulnerability to unscreened diversions located near the channel bottom. No quantitative estimates have been developed to assess the potential magnitude of entrainment losses for juveniles migrating through the rivers and Delta, or the effects of these losses on the overall population abundance of returning adult Chinook salmon. The effect of entrainment mortality on the population dynamics and overall adult abundance of winter-run Chinook salmon is not well understood.

Power plants within the Plan Area have the ability to impinge and entrain juvenile Chinook salmon on the existing cooling water system intake screens. However, use of cooling water is currently low with the retirement of older units. Furthermore, newer units are being equipped with a closed cycle cooling system that virtually eliminates the risk of impingement of juvenile salmon.

Besides direct mortality, salmon fitness may be affected by delays in out-migration of smolts caused by reduced or reverse flows. Delays in migration due to water management related to the SWP and CVP operations can make juvenile salmonids more susceptible to many of the threats and stressors discussed in this section, such as predation, entrainment, angling, exposure to poor water quality, and disease. The quantitative relationships among changes in Delta hydrodynamics, the behavioral and physiological response of juvenile salmon, and the increase or decrease in risk associated with other threats is unknown, but currently the subject of a number of investigations and analyses.

Exposure to toxins. Inputs of toxics into the Delta watershed include agricultural drainage and return flows, municipal wastewater treatment facilities, and other point and non-point discharges (Moyle 2002). These toxic substances include mercury, selenium, copper, pyrethroids, and endocrine disruptors with the potential to impact fish health and condition, and adversely impact salmon distribution and abundance. Toxic chemicals have the potential to be widespread throughout the Sacramento River and Delta, or may occur on a more localized scale in response to episodic events (e.g., stormwater runoff, point source discharges, etc.). Agricultural return flows are widely distributed throughout the Sacramento River and the Delta, although dilution flows from the rivers may reduce chemical concentrations to sublethal levels. Toxic algae (e.g., Microcystis) have also been identified as a potential factor adversely affecting salmon and other fish. Exposure to these toxic materials has the potential to directly and indirectly adversely impact salmon distribution and abundance. Concern regarding exposure to toxic substances for Chinook salmon includes both waterborne chronic and acute exposure, but also bioaccumulation and chronic dietary exposure. For example, selenium is a naturally occurring constituent in agricultural drainage water return flows from the San Joaquin River that is then dispersed downstream into the Delta (Nichols et al. 1986). Exposure to selenium in the diet of juvenile Chinook salmon has been shown to result in toxic effects (Saiki 1986, Saiki and Lowe 1987, Hamilton et al. 1986, 1990, Hamilton and Buhl 1990). Selenium exposure has been associated with agricultural and natural drainage within the San Joaquin River basin and refining operations adjacent to San Pablo and San Francisco bays. Other contaminants of concern for Chinook salmon include, but are not limited to, mercury, copper, oil and grease, pesticides, herbicides, ammonia, and localized areas of depressed dissolved oxygen (e.g., Stockton Deep Water Ship Channel, return flows from managed freshwater wetlands, etc.). As a result of the extensive agricultural development within the Central Valley, exposure to pesticides and herbicides has been identified as a significant concern for salmon and other fish species within the Plan Area (Bennett et al. 2001). In recent years, changes have been made in the composition of herbicides and pesticides used on agricultural crops in an effort to reduce potential toxicity to aquatic and terrestrial species. Modifications have also been made to water system operations and discharges related to agricultural wastewater discharges (e.g., agricultural drainage water system lock-up and holding prior to discharge) and municipal wastewater treatment and discharges. Concerns remain, however, regarding the toxicity of contaminants such as pyrethroids that adsorb to sediments and other chemicals (e.g., including selenium and mercury, as well as other contaminants) on salmon.

Mercury and other metals such as copper have also been identified as contaminants of concern for salmon and other fish as a result of direct toxicity and impacts such as those related to acid mine runoff from sites such as Iron Mountain Mine (EPA 2006). The potential problems include tissue bioaccumulation that may adversely impact the fish, but also represents a human health concern (Gassel et al. 2008). These materials originate from a variety of sources including mining operations, municipal wastewater treatment, agricultural drainage within the tributary rivers and Delta, non-point runoff, natural runoff and drainage within the Central Valley, agricultural spraying, and a number of other sources.

The State Water Resources Control Board (SWRCB), Central Valley Regional Water Quality Control Board (CVRWQCB), U.S. Environmental Protection Agency (EPA), U.S. Geological Survey (USGS), DWR, and others have ongoing monitoring programs designed to characterize water quality conditions and identify potential toxicants and contaminant exposure to Chinook salmon and other aquatic resources within the Plan Area. Programs are in place to regulate point source discharges as part of the National Pollutant Discharge Elimination System (NPDES) program as well as programs to establish and reduce total daily maximum loads of various constituents entering the Delta. Changes in regulations have also been made to help reduce chemical exposure and reduce the adverse impacts to aquatic resources and habitat conditions within the Plan Area. These monitoring and regulatory programs are ongoing. Regulations and changes in monitoring and management of agricultural pesticide and herbicide chemicals and their application, education on the effects of urban runoff and chemical discharges, and refined treatment processes have been adopted over the past several decades in an effort to reduce the adverse effects of chemical pollutants on salmon and other aquatic species.

In the final listing determination of the ESU, acid mine runoff from Iron Mountain Mine, located adjacent to the upper Sacramento River, was identified as one of the main threats to winter-run Chinook salmon (Upper Sacramento River Fisheries and Riparian Habitat Advisory Council 1989). Acid mine drainage, including elevated concentrations of metals, produced from the abandoned mine degraded spawning habitat of winter-run Chinook salmon and resulted in high mortality. Storage limitations and limited availability of dilution flows have caused downstream copper and zinc levels to exceed salmonid tolerances and resulted in documented fish kills in the 1960s and 1970s (USBR 2004). The EPA's Iron Mountain Mine remediation program and 2002 restoration plan has removed toxic metals in acidic mine drainage from the Spring Creek watershed with a state-of-the-art lime neutralization plant. Contaminant loading into the Sacramento River from Iron Mountain Mine has shown measurable reductions since the early 1990s. Pollution from Iron Mountain Mine is no longer considered to be a main factor threatening the winter-run Chinook salmon ESU.

Concern has been expressed regarding the potential to resuspend toxic materials into the water column where they may adversely affect salmon through seasonal floodplain inundation, habitat construction projects, channel and harbor maintenance dredging, and other means. For example, mercury deposits exist at a number of locations within the Central Valley and Delta, including the Yolo Bypass. Seasonal inundation of floodplain areas, such as within the Yolo Bypass, has the potential to create anaerobic conditions that contribute to the methylation of mercury, which increases toxicity. Additionally, there are problems with scour and erosion of these mercury deposits by increased seasonal flows. Similar concerns exist regarding creating aquatic habitat by flooding Delta islands or disturbance created by levee setback construction or other habitat enhancement measures. The potential to increase toxicity as a result of habitat modifications designed to benefit aquatic species is one of the factors that needs to be considered when evaluating the feasibility of habitat enhancement projects within the Central Valley.

Sublethal concentrations of toxics may interact with other stressors on salmonids, such as increasing their vulnerability to mortality as a result of exposure to seasonally elevated water temperatures, predation or disease (Werner 2007). For example, Clifford et al. (2005) found in a laboratory setting that juvenile fall-run Chinook salmon exposed to sublethal levels of a common pyrethroid, esfenvalerate, were more susceptible to infectious hematopoietic necrosis virus than those not exposed to esfenvalerate. Although not tested on winter-run Chinook salmon, a similar response is likely.

Increased water temperature. Water temperature is among the physical factors that affect quality of habitat for salmonid adult holding, spawning and egg incubation, juvenile rearing, and migration. Adverse sublethal and lethal effects can result from exposure to elevated water temperatures at sensitive lifestages, such as during incubation or rearing. The Central Valley is the southern limit of Chinook salmon geographic distribution and increased water temperatures are often recognized as an important stressor to California populations. Water temperature criteria for various lifestages of salmonids in the Central Valley have been developed by NMFS (2009). The tolerance of winter-run Chinook salmon to water temperatures depends on life stage, acclimation history, food availability, duration of exposure, health of the individual, and other factors, such as predator avoidance (Myrick and Cech 2004, USBR 2004). Higher water temperatures can lead to physiological stress, reduced growth rates, pre-spawning mortality, reduced spawning success, and increased mortality of salmon (Myrick and Cech 2001). Temperature can also indirectly influence disease incidence and predation (Waples et al. 2008). Exposure to seasonally elevated water temperatures may occur as a result of reductions in flow, as a result of upstream reservoir operations, reductions in riparian vegetation, channel shading, local climate and solar radiation. The installation of the Shasta Temperature Control Device in 1998, in combination with reservoir management to maintain the cold water pool within Shasta Reservoir, has reduced many of the temperature issues on the Sacramento River. Water temperature management on the Sacramento River has been specified in the NMFS biological opinion and has been identified as one of the factors contributing to the observed increase in adult winter-run Chinook salmon abundance in recent years. During dry years, however, the release of cold water from Shasta Dam is still limited. As the river flows further downstream, particularly during the warm spring, summer, and early fall months, water temperatures continue to increase until they reach thermal equilibrium with atmospheric conditions. As a result of the longitudinal gradient of seasonal water temperatures, the coldest temperatures and best areas for winter-run Chinook salmon spawning and rearing are typically located immediately downstream of Keswick Dam.

Increased temperature can also arise from a reduction in shade over rivers by tree removal (Watanabe et al. 2005). Because river water is typically in thermal equilibrium with atmospheric conditions by the time it enters the Delta, this issue is caused primarily from actions upstream of the Delta. As a result of the relatively wide channels that occur within the Delta, the effects of additional riparian vegetation on reducing water temperatures within the Delta are minimal.

The effects of climate change and global warming patterns, in combination with changes in precipitation and seasonal hydrology in the future, have been identified as important factors that may adversely affect the health and long-term viability of Sacramento River winter-run Chinook salmon (Crozier et al. 2008). The rate and magnitude of these potential future environmental changes, and their effect of habitat quality and availability for winter-run Chinook salmon, however, are subject to a high degree of uncertainty.

A2.6 Relevant Conservation Efforts

Since the listing of Sacramento River winter-run Chinook salmon, several habitat and harvest-related problems that were identified as factors contributing to the decline of the species have been addressed and improved through restoration and conservation actions. The impetus for initiating restoration actions stems primarily from the following: (1) ESA section 7 consultation Reasonable and Prudent Alternatives on temperature, flow, and operations of the CVP and SWP (NMFS 2009b); (2) Regional Water Quality Control Board decisions requiring compliance with Sacramento River water temperature objectives which resulted in the installation of the Shasta Temperature Control Device in 1998; (3) a 1992 amendment to the authority of the CVP through the Central Valley Improvement Act to give fish and wildlife equal priority with other CVP objectives; (4) fiscal support of habitat improvement projects from the California Bay Delta Authority (CALFED) Bay-Delta Program (e.g., installation of a fish screen on the Glenn-Colusa Irrigation District diversion); (5) establishment of the CALFED Environmental Water Account ; (6) EPA actions to control acid mine runoff from Iron Mountain Mine; and, (7) ocean harvest restrictions implemented in 1995.

Results of monitoring at the CVP and SWP fish salvage facility and extensive experimentation over the past several decades have lead to the identification of a number of management actions designed to reduce or avoid the potentially adverse impacts of SWP and CVP export operations on salmon. Many of these actions have been implemented through SWRCB water quality permits (D-1485, D-1641), biological opinions issued on project export operations by NMFS, USFWS, and DFG, as part of CALFED programs (e.g., Environmental Water Account), and as part of Central Valley Project Improvement Act actions. As a result of these requirements, multiple conservation efforts exist to enhance habitat and reduce entrainment of Chinook salmon by the SWP and CVP export facilities.

The artificial propagation program for winter-run Chinook salmon at Livingston Stone National Fish Hatchery, located on the mainstem of the Sacramento River, has operated for conservation purposes since the early 1990s. The increased natural escapement over the last several years has led to the termination of both captive broodstock programs located at University of California at Davis' Bodega Marine Laboratory and Livingston Stone National Fish Hatchery.

Biological opinions for SWP and CVP operations (e.g., NMFS 2009b) and other federal projects involving irrigation and water diversion and fish passage, for example, have improved or minimized adverse impacts to salmon in the Central Valley. In 1992, an amendment through the Central Valley Project Improvement Act gave protection of fish and wildlife equal priority with other CVP objectives. From this act arose several programs that have benefited listed salmonids. The Anadromous Fish Restoration Program is engaged in monitoring, education, and restoration projects designed to contribute toward doubling the natural populations of select anadromous fish species residing in the Central Valley. Restoration projects funded through the Anadromous Fish Restoration Program include fish passage, fish screening, riparian easement and land acquisition, development of watershed planning groups, instream and riparian habitat improvement, and gravel replenishment. The Anadromous Fish Screen Program combines federal funding with state and private funds to prioritize and construct fish screens on major water diversions mainly in the upper Sacramento River. The goal of the Water Acquisition Program is to acquire water supplies to meet the habitat restoration and enhancement goals of the Central Valley Project Improvement Act, and to improve the ability of the U.S. Department of the Interior to meet regulatory water quality requirements. Water has been used to improve fish habitat for Central Valley salmon, with the primary focus on listed Chinook salmon and steelhead, including winter-run Chinook salmon, by maintaining or increasing instream flows (e.g., Environmental Water Account) on the Sacramento River at critical times, and to reduce salmonid entrainment at the SWP and CVP export facilities through reducing seasonal diversion rates during periods when protected fish species are vulnerable to export related losses.

Two programs included under CALFED, the Ecosystem Restoration Program (ERP) and the Environmental Water Account, were created to improve conditions for fish, including winter-run Chinook salmon, in the Central Valley. As part of developing the ERP, a series of conceptual models (DRERIP) have been constructed to provide a framework for identifying and assessing the potential benefits and/or consequences of potential restoration actions. The DRERIP models are being used to evaluate potential BDCP conservation measures, as well as restoration actions as part of the ERP. Restoration actions implemented by the ERP include the installation of fish screens, modification of barriers to improve fish passage, habitat acquisition, and instream habitat restoration. The majority of these actions address key factors and stressors affecting listed salmonids. Additional ongoing actions include efforts to enhance fishery monitoring, and improvements to hatchery management to support salmonid production through hatchery releases.

A major CALFED ERP action currently underway is the Battle Creek Salmon and Steelhead Restoration Project. Although winter-run Chinook salmon do not currently inhabit Battle Creek, they occurred there historically. CALFED is funding the establishment of a second independent population of winter-run Chinook salmon in the upper Battle Creek watershed using the artificial propagation program as a source of fish. The project will restore 77 km (48 miles) of habitat in Battle Creek to support steelhead and Chinook salmon spawning and juvenile rearing at a cost of over $90 million. The project includes removal of five small hydropower diversion dams, construction of new fish screens and ladders on another three dams, and construction of several hydropower facility modifications to ensure the continued hydropower operations. It is thought that this restoration effort is the largest cold water restoration project to date in North America.

As part of CALFED and CVPIA programs, many of the largest water diversions located on the Sacramento River and Delta (e.g., Glenn Colusa Irrigation District, Reclamation District 1001 Princeton diversion, RD 108 Wilkins Slough pumping plant, Sutter Mutual Water Company Tisdale pumping plant, Contra Costa Water District's Old River and Alternative Intake Project intake, and others) have been equipped with positive barrier fish screens, although the majority of smaller water diversions located on the Sacramento River and Delta remain unscreened. Reclamation District 108 has also designed and constructed a new fish screen and pumping plant (Poundstone Pumping Plant) located on the Sacramento River that consolidates and eliminates three currently existing unscreened water diversions. These fish screening projects are specifically intended to reduce and avoid entrainment losses of juvenile winter-run Chinook salmon and other fish inhabiting the river.

The Delta Regional Ecosystem Restoration Implementation Plan (DRERIP) was formed to guide the implementation of CALFED Ecosystem Restoration Plan elements within the Delta (DFG 2007b). The DRERIP team has created a suite of ecosystem and species conceptual models, including winter-run Chinook salmon, that document existing scientific knowledge of Delta ecosystems. The DRERIP Team has used these conceptual models to assess the suitability of actions proposed in the Ecosystem Restoration Plan for implementation. DRERIP conceptual models were used in the analysis of proposed BDCP conservation measures.

The Central Valley Salmonid Project Work Team, an interagency technical working group led by DFG, drafted a proposal to develop a Chinook salmon escapement monitoring plan that was selected by the CALFED ERP Implementing Agency Managers for directed action funding. Long-term funding for implementation of the monitoring plan still needs to be secured.

Recent habitat restoration initiatives sponsored and funded primarily by the CALFED ERP have funded 29 projects (approximately $24 million) designed to restore ecological function to 9,543 acres (8,091 acres within the Bay Region and the remaining acres located in the Delta and Eastside Tributaries Regions of the CALFED action area) of shallow-water tidal and marsh habitats within the Bay-Delta. Restoration of these areas primarily involves flooding lands previously used for agriculture, thereby creating additional rearing habitat for juvenile salmonids. Similar habitat restoration is imminent adjacent to Suisun Marsh (i.e., at the confluence of Montezuma Slough and the Sacramento River) as part of the Montezuma Wetlands project, which is intended to provide for commercial disposal of material dredged from San Francisco Estuary in conjunction with tidal wetland restoration.

The U.S. EPA's Iron Mountain Mine remediation involves the removal of toxic metals in acidic mine drainage from the Spring Creek Watershed with a state-of-the-art lime neutralization plant. Contaminant loading into the Sacramento River from Iron Mountain Mine, and other mining operations, has shown measurable reductions since the early 1990s. Decreasing the heavy metal contaminants that enter the Sacramento River should increase the survival of salmonid eggs and juveniles. However, during periods of heavy rainfall upstream of the Iron Mountain Mine, Reclamation substantially increases Sacramento River flows to dilute heavy metal contaminants being spilled from the Spring Creek debris dam. This rapid change in flows can cause juvenile salmonids to become stranded or isolated in side channels below Keswick Dam.

In 2001, a new fish screen was constructed at the Anderson Cottonwood Irrigation District Diversion Dam and a state-of-the-art fish ladder was installed to address the threats caused by the diversion dam. As described in the final listing determination for the ESU (70 FR 37160), the flashboard gates and inadequate fish ladders at the diversion dam blocked passage for upstream migrant winter-run Chinook salmon. The seasonal operation of the dam created unsuitable habitat upstream of the dam by reducing flow velocity over the incubating eggs, reducing egg survival. Evaluation of the fish ladder is ongoing.

To help reduce the effects of the RBDD operation on migration of adult and juvenile salmonids and other species, management has changed in recent years to maintain the dam gates in the open position for a longer period of time and thereby facilitate greater upstream and downstream migration. Changes in dam operations have benefited both upstream and downstream migration by salmon and have contributed to a reduction in juvenile predation mortality. In 2009, USBR received funding for the Fish Passage Improvement Project at the RBDD to build a pumping facility to provide reliable water supply for high-valued crops in Tehama, Glenn, Colusa, and northern Yolo counties while providing year-round unimpeded fish passage. This project, which is expected to be completed in late 2012, will eliminate passage issues for winter-run Chinook salmon and other migratory species.

DWR’s Delta Fish Agreement Program has approved approximately $49 million for projects that benefit salmon and steelhead production in the Sacramento-San Joaquin basins and Delta since the agreements inception in 1986. Delta Fish Agreement projects that benefit Sacramento River winter-run Chinook salmon include enhanced law enforcement efforts from San Francisco Estuary upstream into the Sacramento River, spawning gravel augmentations, and habitat enhancement projects. Through the Delta-Bay Enhanced Enforcement Program (DBEEP), initiated in 1994, a team of 10 wardens focus their enforcement efforts on salmon, steelhead, and other species of concern from the San Francisco Estuary upstream into the Sacramento and San Joaquin River basins. Enhanced enforcement programs are believed to have had significant benefits to Chinook salmon attributed to DFG, although results have not been quantified.

Harvest protective measures for Sacramento River winter-run Chinook salmon include seasonal constraints on sport and commercial fisheries south of Point Arena in an effort to reduce harvest of winter-run Chinook salmon. Ocean harvest restrictions since 1995 have led to reduced ocean harvest of winter-run Chinook salmon (i.e., Central Valley Chinook salmon ocean harvest index ranged from 0.55 to nearly 0.80 from 1970 to 1995, and was reduced to 0.27 in 2001). The state of California has established specific in-river fishing regulations and no-retention prohibitions designed to protect Sacramento River winter-run Chinook salmon. DFG has implemented enhanced enforcement efforts to reduce illegal harvests.

A2.7 RECOVERY GOALS

The Public Draft Recovery Plan for Central Valley salmonids, including Sacramento River winter-run Chinook salmon, was released by NMFS on October 19, 2009. Although not final, the overarching goal in the public draft is the removal of, among other listed salmonids, Sacramento River winter-run Chinook salmon from the federal list of Endangered and Threatened Wildlife (NMFS 2009a). Several objectives and related criteria represent the components of the recovery goal, including the establishment of at least two viable populations within each historical diversity group, as well as other measurable biological criteria.

APPENDIX A3. CENTRAL VALLEY SPRING-RUN CHINOOK SALMON (*ONCORHYNCHUS TSHAWYTSCHA*)

A3.1 LEGAL STATUS

The Central Valley spring-run Chinook salmon evolutionarily significant unit (ESU) is listed as a threatened species under the federal Endangered Species Act (ESA). The ESU includes all naturally spawned populations of spring-run Chinook salmon in the Sacramento River and its tributaries in California, including the Feather River (see Figure A-3a). The ESU was listed as threatened on September 16, 1999 (64 FR 50394).

In June 2004, the National Marine Fisheries Service (NMFS) proposed that Central Valley spring-run Chinook salmon remain listed as threatened (69 FR 33102). This proposal was based on the recognition that, although Central Valley spring-run Chinook salmon productivity trends were positive, the ESU continued to face risks from having a limited number of remaining populations (i.e., three existing populations from an estimated 17 historical populations), a limited geographic distribution, and potential hybridization with Feather River Hatchery spring-run Chinook salmon. Until recently, Feather River Hatchery spring-run Chinook salmon were not included in the ESU, yet these fish are genetically distinct from other populations in Mill, Deer, and Butte creeks.

On June 28, 2005, NMFS issued its final decision to retain the status of Central Valley spring-run Chinook salmon as threatened (70 FR 37160). This decision also included the Feather River Hatchery spring-run Chinook salmon population as part of the Central Valley spring-run Chinook salmon ESU.

Spring-run Chinook salmon was listed as a threatened species under the California ESA on February 5, 1999.

A3.2 SPECIES DISTRIBUTION AND STATUS

A3.2.1 Range and Status

Historically, spring-run Chinook salmon were predominant throughout the Central Valley occupying the upper and middle reaches (1,000 to 6,000 feet) of the San Joaquin, American, Yuba, Feather, Sacramento, McCloud and Pit rivers, with smaller populations in most tributaries with sufficient habitat for adult salmon holding over the summer months (see Figure A-3a) (Stone 1874, Rutter 1904, Clark 1929). Completion of Friant Dam extirpated the native spring-run Chinook salmon population from the San Joaquin River and its tributaries. Naturally-spawning populations of Central Valley spring-run Chinook salmon with consistent spawning returns are currently restricted to Butte Creek, Deer Creek, and Mill Creek (Good et al. 2005).

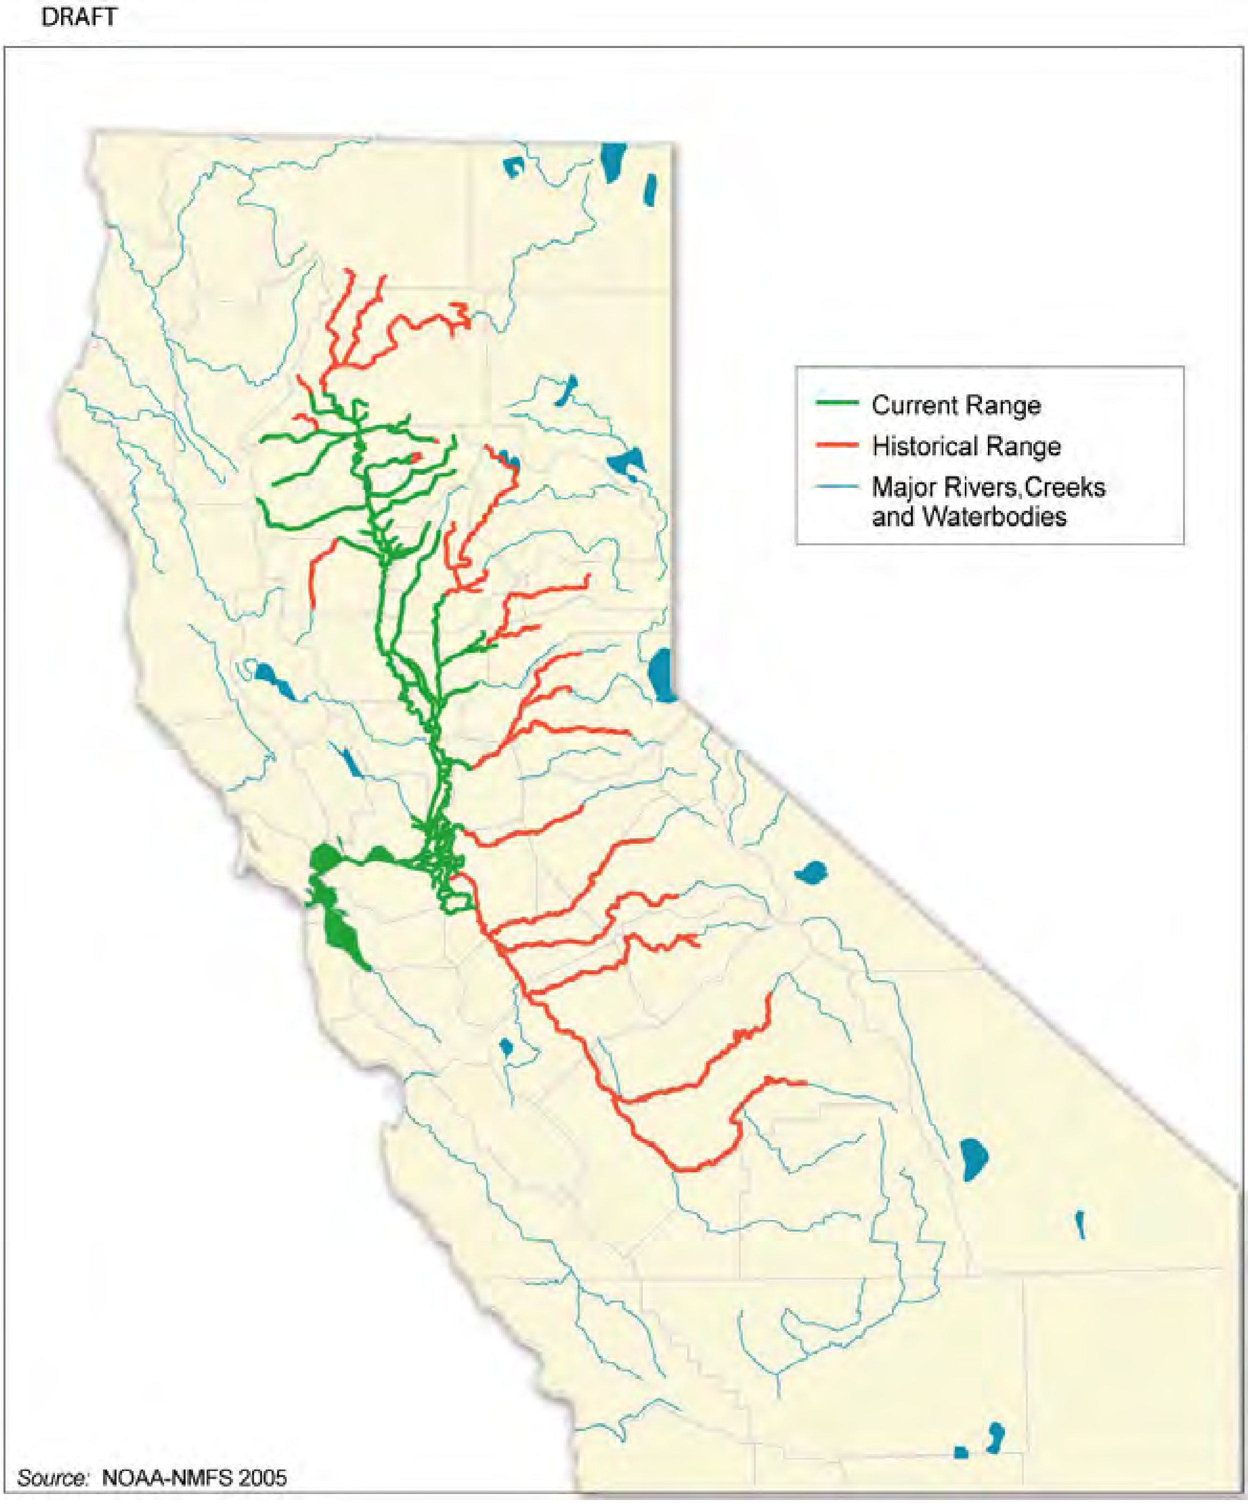

Figure A-3a. Central Valley Spring-Run Chinook Salmon Inland Range in California

There is a small spawning population that has been documented in Clear Creek (Newton and Brown 2004). In addition, the upper Sacramento River and Yuba River support small populations, but their status is not well documented. The Feather River Hatchery produces spring-run Chinook salmon on the Feather River.

Central Valley spring-run Chinook salmon were once the most abundant run of salmon in the Central Valley (Campbell and Moyle 1992). The Central Valley drainage as a whole is estimated to have supported spring-run Chinook salmon runs as large as 600,000 fish between the late 1880s and 1940s (California Department of Fish and Game [DFG] 1998). More than 500,000 Central Valley spring-run Chinook salmon were caught in the Sacramento-San Joaquin commercial fishery in 1883 (Yoshiyama et al. 1998). Population estimates of returning spring-run Chinook salmon for the years immediately preceding and after the closure of Friant Dam in February 1944 are: 35,000 in 1943, 5,000 in 1944, 56,000 in 1945, 30,000 in 1946, 6,000 in 1947, and 2,000 in 1948 (Fry 1961, Yoshiyama et al. 1998). There were occasional records of returning spring-run Chinook salmon during the 1950s and 1960s in wet years. The San Joaquin River population was essentially extirpated by the late 1940s. Populations in the upper Sacramento, Feather, and Yuba rivers were eliminated with the construction of major dams during the 1950s and 1960s.

The Central Valley spring-run Chinook salmon ESU has displayed broad fluctuations in adult abundance between 1961 and 2009 (see Figure A-3b). Adult spring-run salmon escapement to the Sacramento River system in 2009 was 3,802 fish. Sacramento River tributary populations in Mill, Deer, and Butte creeks are probably the best trend indicators for the Central Valley spring-run Chinook ESU as a whole because these streams contain the primary independent populations within the ESU. Generally, there was a positive trend in escapement in these waterways between 1992 and 2005, at which time there was a steep decline (see Figure A-3c). Estimated adult spring-run salmon escapement to Mill, Deer, and Butte creeks in 2009 was only 2,492 fish. Escapement numbers are dominated by Butte Creek returns, which represented nearly 75 percent of fish returning to these three creeks since 2000. Adult spring-run salmon escapement to Butte Creek in 2009 was approximately 2,059 fish, or 83 percent of escapement to these three creeks. During the period between 1992 and 2009, there have been significant habitat improvements in these watersheds, including the removal of several small dams and increases in summer flows, as well as reduced ocean salmon harvest and a favorable terrestrial and marine climate. The significant recent declines in adult fall-run Chinook salmon escapement has resulted in significant curtailment of the commercial and recreational salmon fisheries, which is expected to also increase the level of protection and benefit the Central Valley spring-run Chinook salmon population.

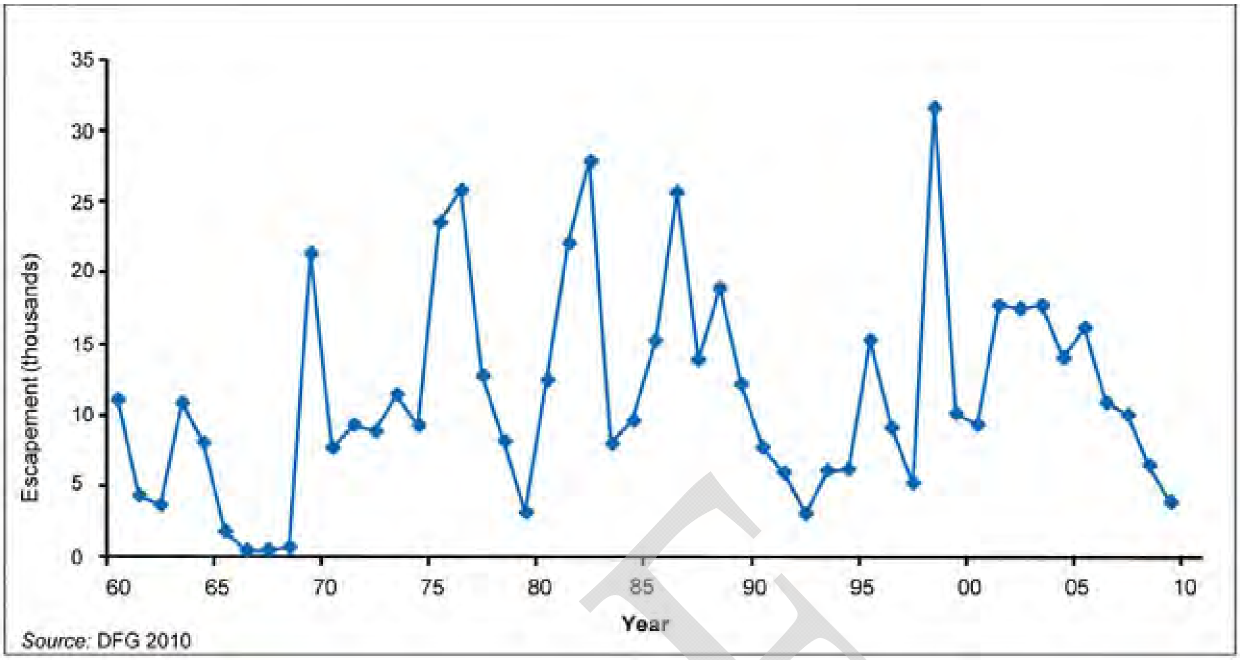

Figure A-3b. Estimate Historical Spawner Escapement of Spring-Run Chinook Salmon throughout the Central Valley (1960-2009)

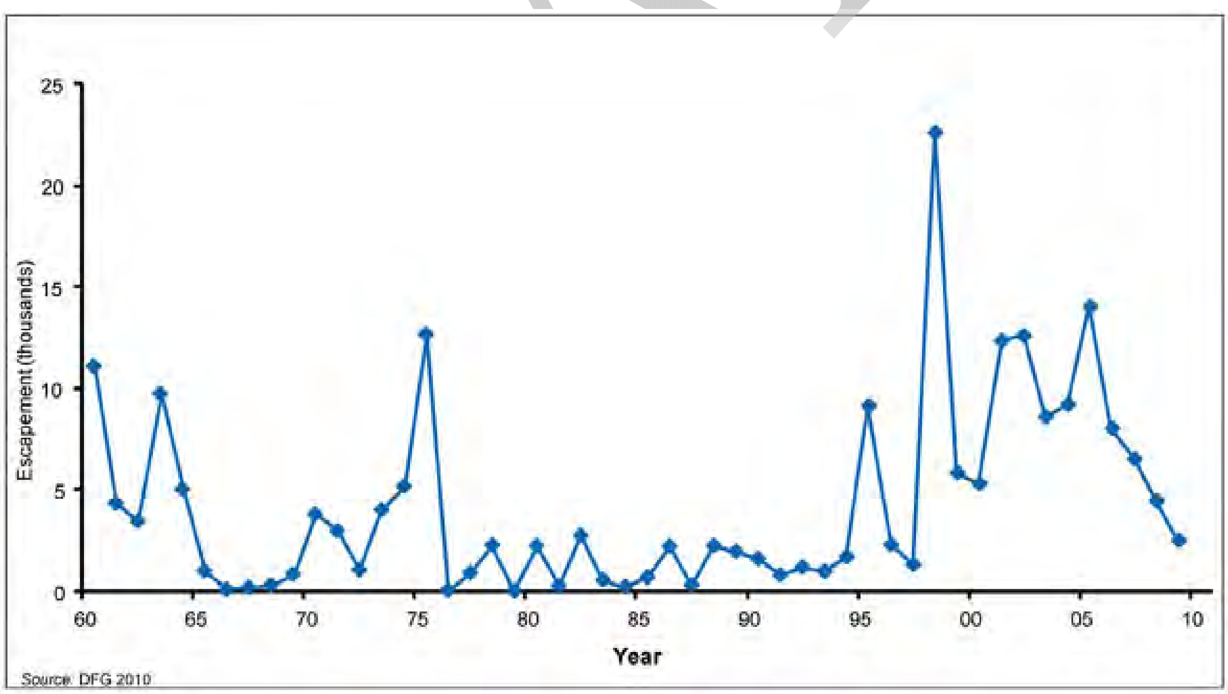

Figure A-3c. Estimated Historical Spawner Escapement of Spring-Run Chinook Salmon in Mill, Deer, and Butte Creeks (1960-2009)

On the Feather River, significant numbers of spring-run Chinook salmon, as identified by run timing, return to the Feather River Hatchery. However, coded-wire tag information from these hatchery returns and results of genetic testing indicate that substantial introgression has occurred between fall-run and spring-run Chinook salmon populations within the Feather River due to hatchery practices and the geographic and temporal overlap with spawning fall-run in the river.

Although recent Central Valley spring-run Chinook salmon population trends are negative, annual abundance estimates display a high level of variation. The overall number of Central Valley spring-run Chinook salmon remains well below estimates of historical abundance. Central Valley spring-run Chinook salmon have some of the highest population growth rates in the Central Valley, but other than Butte Creek and the hatchery-influenced Feather River, population sizes are very small relative to fall-run Chinook salmon populations (Good et al. 2005).

The viability of an ESU that is essentially represented by three populations located within the same ecoregion is vulnerable to changes in the environment through a lack of spatial geographic diversity. The current geographic distribution of viable populations makes the Central Valley spring-run Chinook salmon ESU vulnerable to catastrophic disturbance (Lindley et al. 2007). Such potential catastrophes include volcanic eruption of Mt. Lassen, prolonged drought conditions reducing coldwater pool adult holding habitat, and a large wildfire (approximately 30 km maximum diameter) encompassing the Deer, Mill and Butte creek watersheds. The Central Valley spring-run Chinook salmon ESU remains at a moderate to high risk of extinction because: (1) the ESU is spatially confined to relatively few remaining streams within its historical range; (2) the population continues to display broad fluctuations in abundance; and, (3) a large proportion of the population (i.e., in Butte Creek) faces the risk of high mortality rates due to high water temperatures during the adult holding period.

A3.2.2 Distribution and Status in the Plan Area

The entire population of the Central Valley spring-run Chinook salmon ESU must pass through the Plan Area as migrating adults and emigrating juveniles. Adult Central Valley spring-run Chinook salmon migrate primarily along the western edge of the Delta through the Sacramento River corridor, and juvenile spring-run Chinook salmon use the Delta, Suisun Marsh, and Yolo Bypass for migration and rearing.

A3.3 Habitat Requirements and Special Considerations

Critical habitat for spring run Chinook salmon ESU was updated on September 2, 2005 with an effective date of January 2, 2006 (70 FR 52488). Designated critical habitat includes 1,158 miles of stream habitat in the Sacramento River basin and 254 square miles of estuarine habitat in the San Francisco-San Pablo-Suisun Bay complex (70 FR 52488, Figure A-3d). Critical habitat includes stream reaches such as those of the Feather and Yuba rivers, Big Chico, Butte, Deer, Mill, Battle, Antelope, and Clear creeks, and the Sacramento River and Delta.

DRAFT

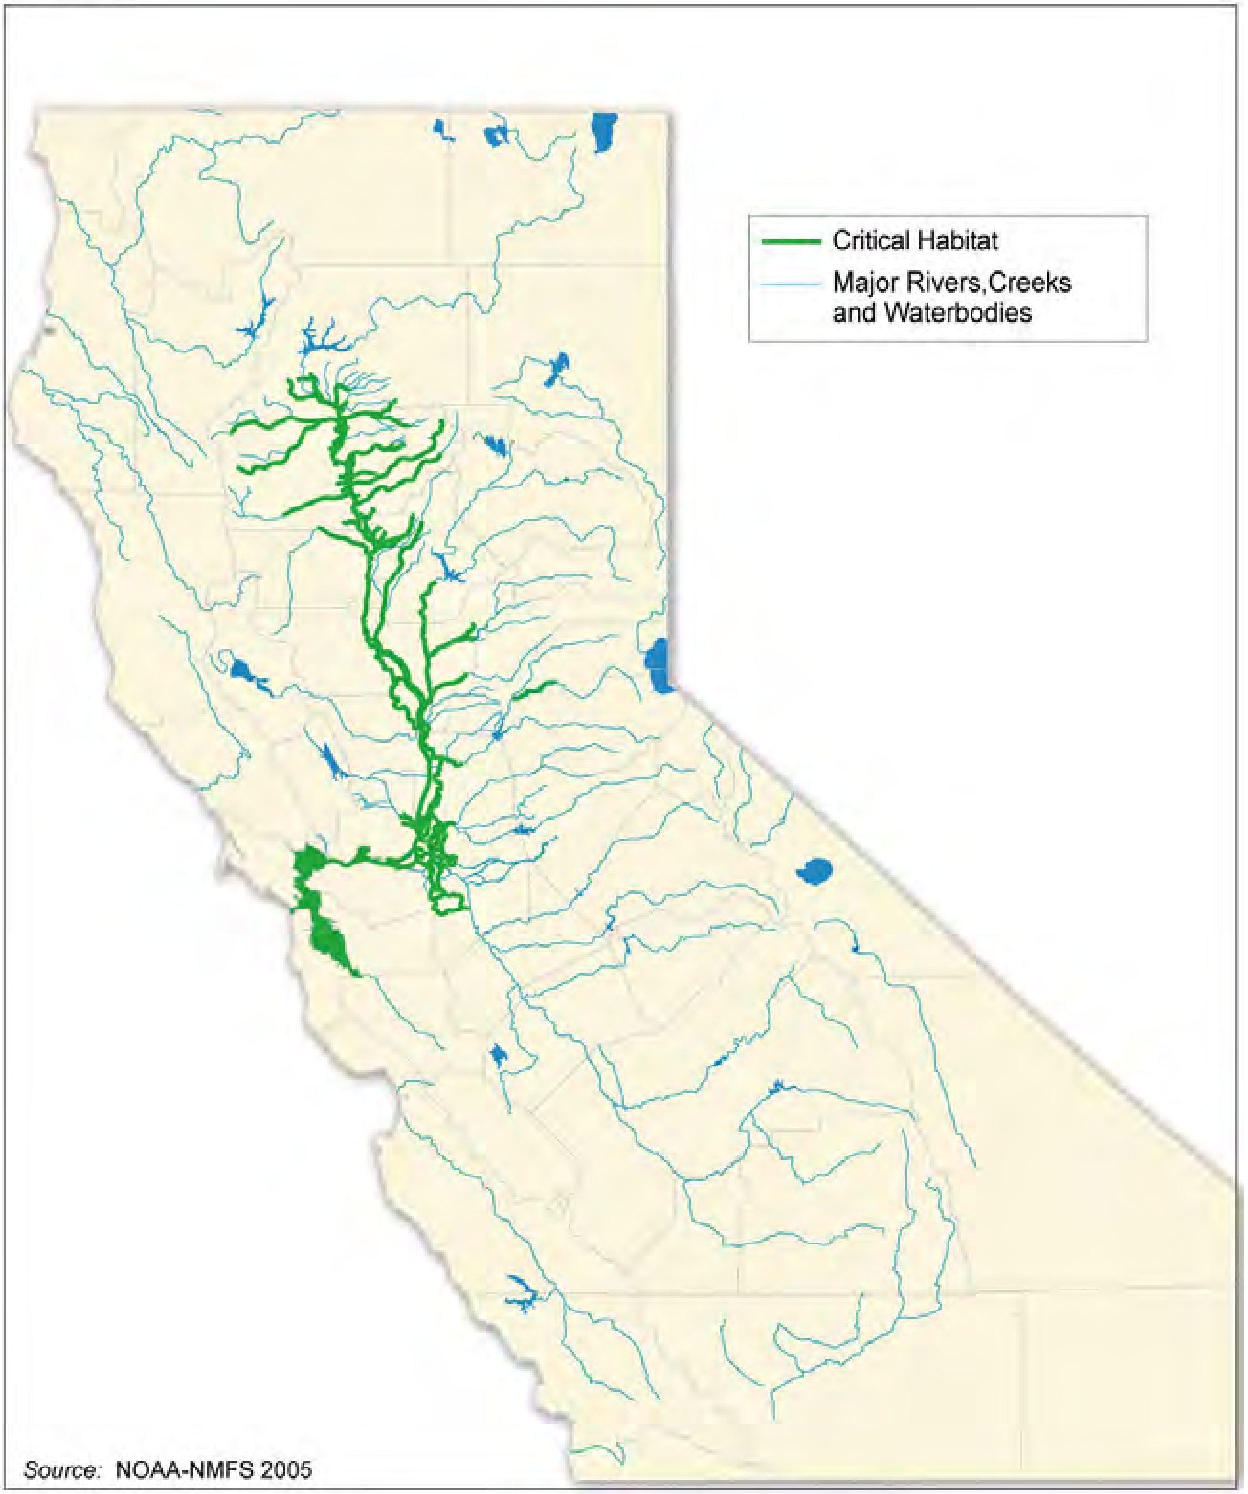

Figure A-3d. Central Valley Spring-Run Chinook Salmon Inland Designated Critical Habitat in California

This habitat is comprised of physical and biological features considered essential to the conservation of the species, including space for individual and population growth and for normal behavior; cover; sites for breeding, reproduction, and rearing of offspring; and habitats protected from disturbance or are representative of the historical geographical and ecological distribution of the species.

Central Valley spring-run Chinook salmon habitats are also protected under the Magnuson-Stevens Fishery Conservation and Management Act as Essential Fish Habitat (EFH). Those waters and substrate necessary to spring-run Chinook salmon for spawning, breeding, feeding, or growth to maturity are included as EFH and are presented in Figure A-3e. Critical Habitat and EFH are managed differently from a regulatory standpoint, but are biologically equal for the conservation of Central Valley spring-run Chinook salmon.

The Primary Constituent Elements (PCEs) considered essential for conservation are: (1) freshwater spawning sites, (2) freshwater rearing sites, (3) freshwater migration corridors, (4) estuarine rearing and migration areas, (5) nearshore marine areas, and (6) offshore marine areas.

A3.3.1 Freshwater Spawning Habitat

Freshwater spawning sites are those stream reaches with water quantity (instream flows) and quality conditions (e.g., water temperature and dissolved oxygen) and substrate suitable to support spawning, egg incubation, and larval development. Most spawning habitat in the Central Valley for spring-run Chinook salmon is located in areas directly downstream of dams containing suitable environmental conditions for spawning and incubation. Historically, spring-run Chinook salmon migrated upstream into high elevation steep gradient reaches of the rivers and tributaries for spawning. Access to the majority of these historical spawning areas has been blocked by construction of major Central Valley dams and reservoirs. Currently, Central Valley spring-run Chinook salmon spawn on the mainstem Sacramento River between the Red Bluff Diversion Dam (RBDD) and Keswick Dam, and in tributaries such as the Feather River and Mill, Deer, and Butte creeks. There is currently an effort underway to re-establish a self-sustaining population of spring-run Chinook salmon on the San Joaquin River downstream of Friant Dam. Spawning habitat has a high conservation value as its function directly affects the spawning success and reproductive potential of listed salmonids.

A3.3.2 Freshwater Rearing Habitat

Freshwater rearing sites are those with water quantity and floodplain connectivity to form and maintain physical habitat conditions and support juvenile growth and mobility; suitable water quality; availability of suitable prey and forage to support juvenile growth and development; and natural cover such as shade, submerged and overhanging large wood, log jams, beaver dams, aquatic vegetation, large woody debris, rocks and boulders, side channels, and undercut banks. Both spawning areas and migratory corridors comprise rearing habitat for juveniles, which feed and grow before and during their outmigration.

DRAFT

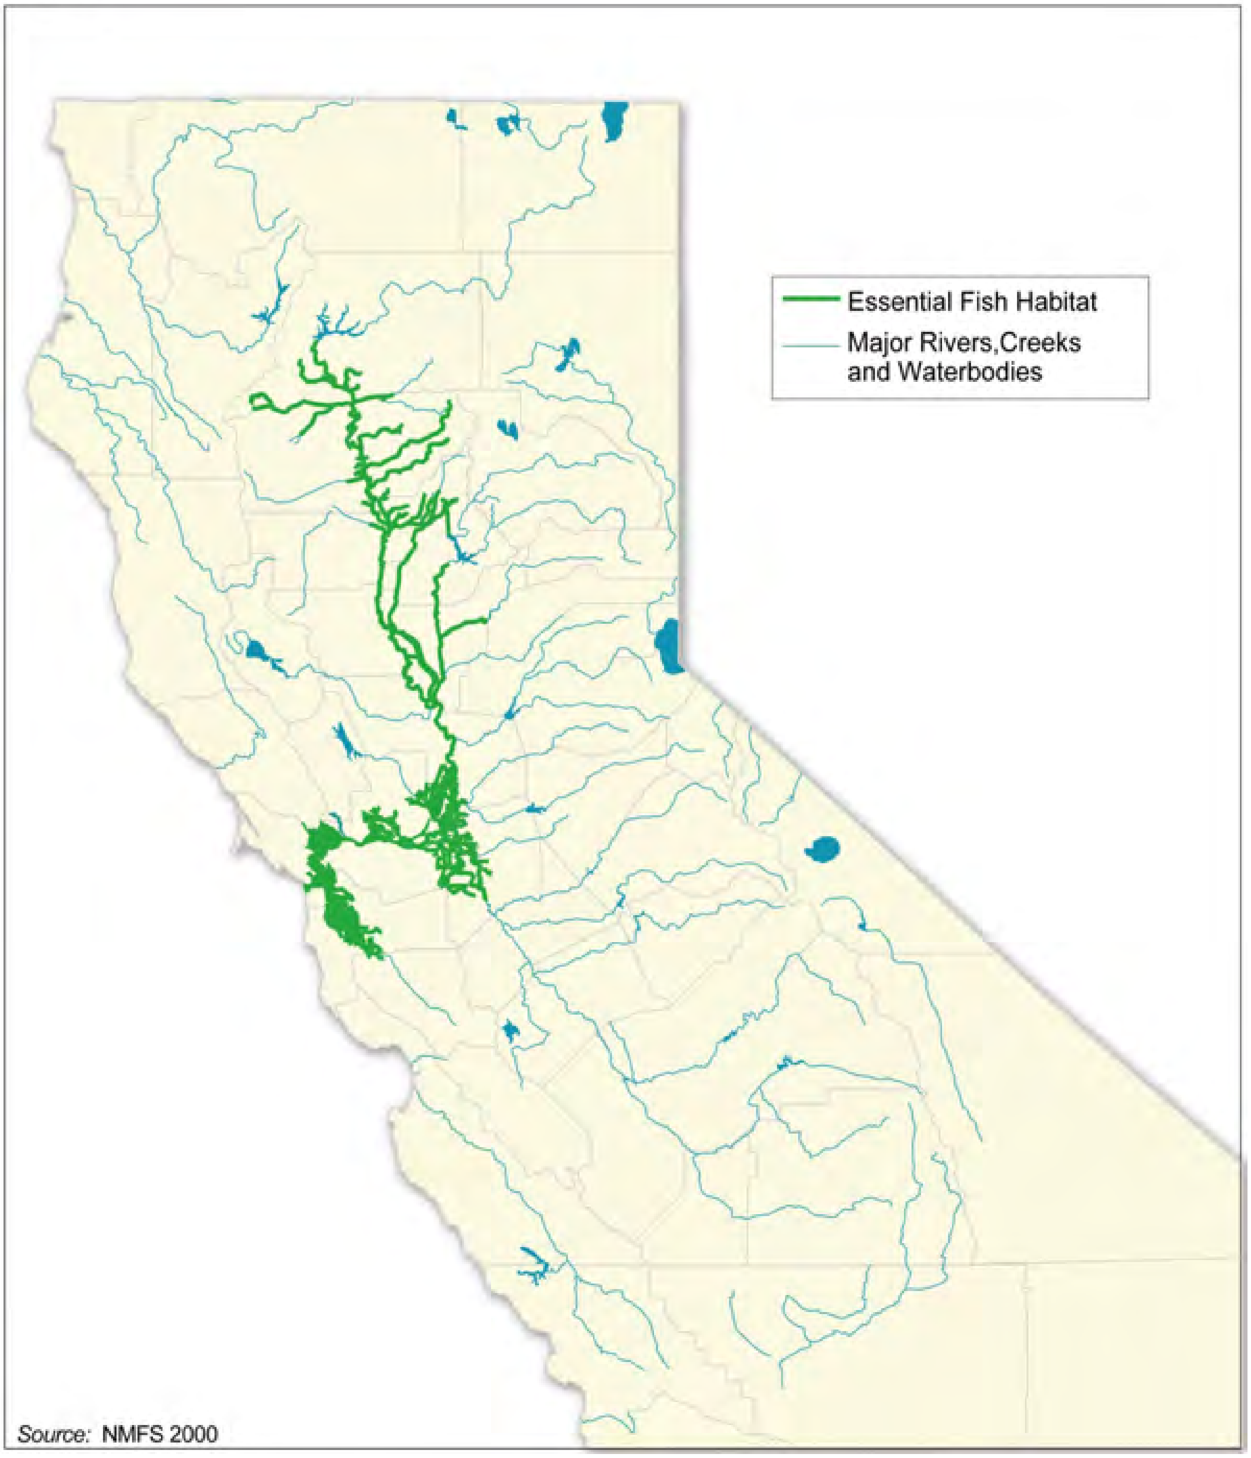

Figure A-3e. Central Valley Spring-Run Chinook Salmon Inland Essential Fish Habitat in California

Non-natal, intermittent tributaries are also used for juvenile rearing. Rearing habitat condition is strongly affected by habitat diversity and complexity, food supply, and presence of predators. Some of these more complex, productive habitats with floodplain connectivity are still present in limited amounts within the Central Valley (e.g., the lower Cosumnes River, Sacramento River reaches with set-back levees [i.e., primarily located upstream of the City of Colusa]). However, the channeled, leveed, and riprapped river reaches and sloughs that are common along the Sacramento and San Joaquin rivers and throughout the Delta typically have low habitat complexity, low abundance of food organisms, and offer little protection from predatory fish and birds. Freshwater rearing habitat also has a high conservation value, as the juvenile life stage of salmonids is dependent on the function of this habitat for successful survival and recruitment to the adult population.

A3.3.3 Freshwater Migration Corridors

Freshwater migration corridors for spring-run Chinook salmon, including river channels, channels through the Delta, and the Bay-Delta estuary, support mobility, survival, and food supplies for juveniles and adults. Migration corridors should be free from obstructions (passage barriers and impediments to migration), have favorable water quantity (instream flows) and quality conditions (seasonal water temperatures), and contain natural cover such as submerged and overhanging large wood, native aquatic vegetation, large rocks and boulders, side channels, and undercut banks. Migratory corridors for spring-run Chinook salmon are located downstream of the spawning areas and include the lower Sacramento River, lower Feather River, tributaries providing suitable adult holding and spawning habitat, the Delta, and the San Francisco Bay complex extending to coastal marine waters. Efforts are currently underway to re-establish a spring-run salmon population on the San Joaquin River downstream of Friant Dam that would use the lower river and Delta as part of the migration corridor. These corridors allow the upstream passage of adults and the downstream emigration of juvenile salmon. Migratory corridor conditions are strongly affected by the presence of passage barriers, which can include dams, unscreened or poorly screened diversions, and degraded water quality. For freshwater migration corridors to function properly, they must provide adequate passage, provide suitable migration cues, reduce false attraction, avoid areas where vulnerability to predation is increased, and avoid impediments and delays in both upstream and downstream migration. For this reason, freshwater migration corridors are considered to have a high conservation value.

Results of mark-recapture studies conducted using juvenile Chinook salmon (typically fall-run or late fall-run Chinook salmon, which are considered to be representative of juvenile spring-run salmon) released into both the Sacramento and San Joaquin rivers have shown high mortality during passage downstream through the rivers and Delta (Brandes and McLain 2001, Newman and Rice 2002, Manly 2004, San Joaquin River Group Authority 2007, Hanson 2008, Low and White undated). Mortality for juvenile salmon is typically greater in the San Joaquin River than in the Sacramento River (Brandes and McLain 2001). In both rivers, mortality is typically greater in years when spring flows are reduced and water temperatures are increased. Results of survival studies have shown that closing the Delta Cross Channel gates and installation of the Head of Old River Barrier to reduce the movement of juvenile salmon into the Delta contribute to improved survival of emigrating juvenile Chinook salmon (Brandes and McLain 2001, Manly 2004, San Joaquin River Group Authority 2010, Low and White undated). Observations at the State Water Project (SWP) and Central Valley Project (CVP) fish salvage facilities have shown that very few of the marked salmon (typically fewer than 1 percent) are entrained and salvaged at the export facilities (San Joaquin River Group Authority 2007, Hanson 2008, California Department of Water Resources [DWR] and U.S. Bureau of Reclamation [USBR] unpubl. data). Although the factors contributing to high juvenile mortality have not been quantified, results of acoustic tagging experiments and anecdotal observations suggest that exposure to adverse water quality conditions (e.g., elevated water temperatures, toxic chemicals) and vulnerability to predation are two of the factors contributing to the high juvenile mortality observed in the rivers and Delta (San Joaquin River Group Authority 2007). Additional acoustic tagging experiments are currently underway to better assess factors affecting migration pathways, migration rates, effects of SWP and CVP exports on migration, and reach-specific survival rates for emigrating juvenile Chinook salmon (Lindley et al. 2008, MacFarlane et al. 2008a, Michel et al. 2008, Perry et al. 2008).

A3.3.4 Estuarine Areas

Estuarine migration and juvenile rearing habitats should be free of obstructions (i.e., dams and other barriers) and provide suitable water quality, water quantity (river and tidal flows), and salinity conditions to support juvenile and adult physiological transitions between fresh and salt water. Natural cover, such as submerged and overhanging large wood, native aquatic vegetation, and side channels, provide juvenile foraging habitat and cover from predators. Tidal wetlands and seasonally inundated floodplains have also been identified as high value foraging and rearing habitats for juvenile salmon migrating downstream through the estuary. Estuarine areas contain a high conservation value as they function to support juvenile Chinook salmon growth, smolting, avoidance of predators, and provide a transition to the ocean environment.

A3.3.5 Ocean Habitats

Although ocean habitats are not part of the critical habitat listing for Central Valley spring-run Chinook salmon, biologically productive coastal waters are an important habitat component for the ESU. Juvenile Chinook salmon inhabit near-shore coastal marine waters for a period of typically two to four years before adults return to Central Valley rivers to spawn. During their marine residence Chinook salmon forage on krill, squid, and other marine invertebrates as well as a variety of fish such as northern anchovy and Pacific herring. These features are essential for conservation because, without them, juveniles cannot forage and grow to adulthood.

Results of oceanographic studies have shown the variation in ocean productivity off the West Coast within and among years. Changes in ocean currents and upwelling have been identified as significant factors affecting nutrient availability, phytoplankton and zooplankton production and the availability of other forage species in near-shore surface waters. Ocean conditions during the salmon's ocean residency period can be important, as indicated by the effect of the 1983 El Niño on the size and fecundity of Central Valley fall-run Chinook salmon (Wells et al. 2006). Although the effects of ocean conditions on Chinook salmon growth and survival have not been investigated extensively, recent observations since 2007 have shown a significant decline in the abundance of adult Chinook salmon and coho salmon returning to California rivers and streams (fall-run adult returns to the Sacramento and San Joaquin rivers were the lowest on record; Pacific Fishery Management Council 2008) that is thought to be the result of declines in ocean productivity and associated high mortality rates during the period when these fish were rearing in near-shore coastal waters (MacFarlane et al. 2008b). The importance of changes in ocean conditions on growth, survival, and population abundance of Central Valley Chinook salmon is currently undergoing further investigation.

A3.4 LIFE HISTORY

Chinook salmon typically mature between two and six years of age (Myers et al. 1998). Freshwater entry and spawning timing generally are thought to be related to local water temperature and flow regimes. Runs are designated on the basis of adult migration timing; however, distinct runs also differ in the degree of maturation at the time of river entry, thermal regime and flow characteristics of their spawning site, and the actual time of spawning (Myers et al. 1998). Spring-run Chinook salmon tend to enter freshwater as immature fish, migrate far upriver, hold in cool water pools for a period of months during the spring and summer, and delay spawning until the early fall.

Information on the migration rates of Central Valley spring-run Chinook salmon in freshwater is scant, but a general description of migration rates can be found in Appendix A4, *Central Valley fall-/late fall-run Chinook salmon.*

Adult Central Valley spring-run Chinook salmon begin their upstream migration in late January and early February (DFG 1998) and enter the Sacramento River between March and September, primarily in May and June (Table A-3a) (Yoshiyama et al. 1998, Moyle 2002). Lindley et al. (2006) reported that adult Central Valley spring-run Chinook salmon enter native tributaries from the Sacramento River primarily between mid-April and mid-June. Typically, spring-run Chinook salmon utilize mid- to high-elevation streams that provide appropriate seasonal water temperatures and sufficient flow, cover, and pool depth to allow over-summering while conserving energy and allowing their gonadal tissue to mature (Yoshiyama et al. 1998).

Chinook salmon spawn in clean, loose gravel in swift, relatively shallow riffles or along the margins of deeper reaches where suitable water temperature, depth, and velocity favor redd construction and adequate oxygenation of incubating eggs. Chinook salmon spawning typically occurs in gravel beds located at the tails of holding pools (U.S. Fish and Wildlife Service [USFWS] 1995). Fry emergence generally occurs at night. Upon emergence, fry swim or are displaced downstream (Healey 1991). The daily migration of juvenile spring-run Chinook salmon passing RBDD is highest in the four hour period prior to sunrise (Martin et al. 2001).

Fry may continue downstream to the estuary and rear, or may take up residence in the stream for a period from weeks to a year (Healey 1991). Fry seek streamside habitats containing beneficial characteristics such as riparian vegetation and associated substrates that provide aquatic and terrestrial invertebrates, predator avoidance cover, and slower water velocities for resting (NMFS 1996).

Spring-run Chinook salmon fry emerge from the gravel from November to March (Moyle 2002) and the emigration timing is highly variable, as they may migrate downstream as young-of-the year or as juveniles or yearlings. The modal size of fry migrants at approximately 40 mm between December and April in Mill, Butte, and Deer creeks reflects a prolonged emergence of fry from the gravel (Lindley et al. 2006). Studies in Butte Creek found that the majority of Central Valley spring-run Chinook salmon migrants are fry occurring primarily during December, January, and February, and that fry movements appeared to be influenced by flow (Ward et al. 2002, 2003, McReynolds et al. 2005). Small numbers of Central Valley spring-run Chinook salmon remained in Butte Creek to rear and migrated as yearlings later in the spring. Juvenile emigration patterns in Mill and Deer creeks are very similar to patterns observed in Butte Creek, with the exception that juveniles from Mill and Deer creeks typically exhibit a later young-of-the year migration and an earlier yearling migration (Lindley et al. 2006).

Once juveniles emerge from the gravel they initially seek areas of shallow water and low velocities while they finish absorbing the yolk sac (Moyle 2002). Many also disperse downstream during high-flow events. As is the case with other salmonids, there is a shift in microhabitat use by juveniles to deeper faster water as they grow. Microhabitat use can be influenced by the presence of predators, which can force juvenile salmon to select areas of heavy cover and suppress foraging in open areas (Moyle 2002). Peak movement of juvenile Central Valley spring-run Chinook salmon in the Sacramento River at Knights Landing occurs in December, and again in March and April; however, juveniles were also observed between November and the end of May (Snider and Titus 2000).

As juvenile Chinook salmon grow, they move into deeper water with higher current velocities, but still seek shelter and velocity refugia to minimize energy expenditures (Healey 1991). Catches of juvenile salmon in the Sacramento River near West Sacramento by the USFWS (1997) showed that larger juvenile salmon were captured in the main channel and smaller sized fry were typically captured along the channel margins. When the channel of the river is greater than 9 to 10 feet in depth, juvenile salmon tend to inhabit surface waters (Healey 1980). Stream flow changes and/or turbidity increases in the upper Sacramento River watershed are thought to stimulate juvenile emigration (Kjelson et al. 1982, Brandes and McLain 2001).

Within the Delta, juvenile Chinook salmon forage in shallow areas with protective cover, such as tidally influenced sandy beaches and shallow water areas with emergent aquatic vegetation (Meyer 1979, Healey 1980). Cladocerans, copepods, amphipods, and larval dipterans, as well as small arachnids and ants are common prey items (Kjelson et al. 1982, Sommer et al. 2001a, MacFarlane and Norton 2002). Though the bulk of production in Butte and Big Chico creeks emigrate as fry, yearlings can enter the Delta as early as February and as late as June (DFG 1998). Yearling-sized spring-run Chinook salmon migrants appear at Chipps Island (entrance to Suisun Bay) between October and December (Brandes and McLain 2001, USFWS 2001). It has been hypothesized that changes in habitat conditions within the Delta over the past century may have resulted in a reduction in extended juvenile salmon rearing when compared to periods when habitat for juvenile salmon rearing was more suitable.

Central Valley spring-run Chinook salmon begin their ocean life in the coastal marine waters of the Gulf of the Farallones. Upon reaching the ocean, juveniles feed on larval and juvenile fishes, plankton, and terrestrial insects (Healey 1991, MacFarlane and Norton 2002). Juveniles grow rapidly in the ocean environment with growth rates dependent on water temperatures and food availability (Healey 1991). The first year of ocean life is considered a critical period of high mortality for Chinook salmon that largely determines survival to harvest or spawning (Beamish and Mahnken 2001, Quinn 2005).

A3.5 THREATS AND STRESSORS

The following have been identified as important threats and stressors to spring-run Chinook salmon (without priority).

Reduced staging and spawning habitat. Access to most of the historical upstream spawning habitat for spring-run Chinook salmon (see Figure A-3a) has been eliminated or degraded by man-made structures (e.g., dams and weirs) associated with water storage and conveyance, flood control, and diversions and exports for municipal, industrial, agricultural, and hydropower purposes (Yoshiyama et al. 1998). Current spawning and juvenile rearing habitat is restricted to the mainstem and a few tributaries to the Sacramento River. Suitable summer water temperatures for adult and juvenile spring-run Chinook salmon holding and rearing are thought to occur at elevations over 492-1,640 feet (150-500 m), most of which are now blocked by impassible dams. Habitat loss has resulted in a reduction in the number of natural spawning populations from an estimated 17 to 3 (Good et al. 2005).

Upstream diversions and dams have decreased downstream flows and altered the seasonal hydrologic patterns. These factors have been identified as resulting in delayed upstream migration by adults, increased mortality of out-migrating juveniles, and are responsible for making some streams uninhabitable by spring-run salmon (Yoshiyama et al. 1998, DWR 2005). Dams and reservoir impoundments and associated reductions in peak flows have blocked gravel recruitment and reduced flushing of sediments from existing gravel beds, thereby reducing and degrading natal spawning grounds. Further, reduced flows may decrease attraction cues for adult spawners, causing migration delays and increases in straying (DWR 2005). Adult salmon migration delays can reduce fecundity and increase susceptibility to disease and harvest (McCullough 1999).

Dams and other passage barriers also limit the geographic locations where spring-run Chinook salmon can spawn. Within areas such as the Sacramento and Feather rivers, restrictions to upstream movement and spawning site selection for spring-run salmon may increase the risk of hybridization with fall-run salmon, as co-occurrence contributes to an increased risk of redd superimposition. In creeks that are not affected by dams, such as Deer and Mill creeks, adult spring-run Chinook salmon have a greater opportunity to migrate upstream into areas where geographic separation from fall-run salmon reduces the risk of hybridization.

The RBDD located on the Sacramento River has been identified as a barrier and impediment to adult spring-run Chinook salmon upstream migration. Although the RBDD is equipped with fish ladders, migration delays were reported when the dam gates are closed. Mortality from increased predation by Sacramento pikeminnow on juvenile salmon passing downstream through the fish ladder also affects abundance of salmon produced on the Sacramento River (Hallock 1991). To help reduce the effects of dam operation on migration of adult and juvenile salmonids and other species, management changes have occurred in recent years to maintain the dam gates in the open position for a longer period of time and thereby facilitate greater upstream and downstream migration. Changes in dam operations have benefited both upstream and downstream migration of salmon and have contributed to a reduction in juvenile predation mortality.

Reduced rearing and out-migration habitat. Juvenile spring-run Chinook salmon prefer natural stream banks, floodplains, marshes, and shallow water habitats to utilize as rearing habitat during out-migration. Channel margins throughout the Delta have been leveed, channelized, and fortified with riprap for flood protection and island reclamation, reducing and degrading the quality of natural habitat available for juvenile Chinook salmon rearing (Brandes and McLain 2001). Man-made barriers further reduce and degrade rearing and migration habitat and delay juvenile out-migration. Juvenile out-migration delays can reduce fitness and increase susceptibility to diversion screen impingement, entrainment, disease, and predation. Modification of natural flow regimes from upstream reservoir operations has resulted in dampening and altering the seasonal timing of the hydrograph, reducing the extent and duration of seasonal floodplain inundation and other flow-dependent habitat used by migrating juvenile Chinook salmon (70 FR 52488, Sommer et al. 2001a, DWR 2005). Recovery of floodplain habitat in the Central Valley has been found to contribute to increases in production in Chinook salmon (Sommer et al. 2001b), but little is known about the potential benefit available to migrating spring-run. Reductions in flow rates have resulted in increased seasonal water temperature. The potential adverse effects of dam operations and reductions in seasonal river flows, delays in juvenile emigration, exposure to a higher proportion of agricultural return flows, and exposure to reduced dissolved oxygen concentrations (e.g., Stockton Deep Water Ship Channel) have all been identified as factors that could affect the survival and success of re-establishing spring-run Chinook salmon on the San Joaquin River in the future (Regional Water Resources Control Board 2003).

Predation by non-native species. Predation on juvenile salmon by non-native fish has been identified as an important threat to spring-run Chinook salmon in areas with high densities of non-native fish (e.g., small and large mouth bass, striped bass, and catfish) that prey on out-migrating juveniles (Lindley and Mohr 2003). Non-native aquatic vegetation, such as Brazilian waterweed and water hyacinth, provide suitable habitat for non-native predators (Nobriga et al. 2005, Brown and Michniuk 2007). Predation risk may covary with increased temperatures. Metabolic rates of non-native, predatory fish increase with increasing water temperatures based on bioenergetic studies (Loboschefsky et al. 2009, Miranda et al. 2010). The low spatial complexity and reduced habitat diversity (e.g., lack of cover) of channelized waterways within the rivers and Delta reduces refuge space of salmon from predators (Raleigh et al. 1984, Missildine et al. 2001, DWR 2005, 70 FR 52488). A major concern among managers is the potential invasion of the Delta by the highly predatory northern pike. The pike, recently present in Lake Davis on the Feather River, was the target of a major eradication effort (DFG 2007a). If pike escape downstream to the Delta, they would likely be present in areas inhabited by spring-run Chinook salmon.

Increased predation mortality by native fish species, such as Sacramento pikeminnow at the RBDD, has also been identified as a factor affecting the survival of juvenile salmon within the rivers and Delta.

Harvest. Commercial and recreational harvest of spring-run Chinook salmon in the ocean and inland fisheries has been a subject of management actions by the California Fish and Game Commission and Pacific Fishery Management Council. The primary concerns focus on the effects of harvest on wild Chinook salmon produced in the Central Valley as well as the incidental harvest of listed salmon as part of the fall-run and late fall-run salmon fisheries. Naturally reproducing spring-run Chinook salmon are less able to withstand high harvest rates when compared to hatchery-based stocks. Due to reduced survivorship in incubating eggs and rearing and emigrating individuals wild salmon relative to hatchery-reared individuals, naturally reproducing populations are less able to withstand high harvest rates compared to hatchery based stocks (Knudsen et al. 1999). Because of recent changes in fishing regulations and restrictions on harvest, commercial and recreational fishing does not appear to have a significant impact on spring-run Chinook salmon populations, but continued assessment is warranted. Commercial fishing for salmon in West Coast ocean waters is managed by the Pacific Fishery Management Council, and is constrained by time and area closures to meet the Sacramento River winter-run ESA consultation standard and restrictions requiring minimum size limits and use of circle hooks for anglers. Ocean harvest restrictions since 1995 have led to reduced ocean harvest of spring-run Chinook salmon (i.e., Central Valley Chinook salmon ocean harvest index, ranged from 0.55 to nearly 0.80 from 1970 to 1995, and was reduced to 0.27 in 2001). DFG, NMFS, and Pacific Fishery Management Council are continuing to monitor and assess the effects of harvest of spring-run Chinook salmon, such that regulations can be refined and modified as new information becomes available.

Because adult spring-run Chinook salmon hold in pool habitat within a stream during the summer months they are vulnerable to illegal harvest (poaching). Various watershed groups have established public outreach and educational programs in an effort to reduce poaching. In addition, DFG wardens have increase enforcement against illegal harvest of spring-run Chinook salmon. The level and effect of illegal harvest on adult spring-run Chinook salmon abundance and population reproduction is unknown.

Reduced genetic diversity/integrity. Interbreeding of wild spring-run Chinook salmon with both wild and hatchery fall-run Chinook salmon has the potential to dilute and eventually eliminate the adaptive genetic distinctiveness and diversity of the few remaining naturally reproducing spring-run Chinook salmon populations (DFG 1995, Sommer et al. 2001b, Araki et al. 2007). Central Valley spring- and fall-run Chinook salmon spawning areas were historically isolated in time and space (Yoshiyama et al. 1998). However, the construction of dams has eliminated access to historical upstream spawning areas of spring-run salmon in the upper tributaries and streams of many river systems. Restrictions to upstream access, particularly on the Sacramento and Feather rivers has forced spring-run individuals to spawn in lower elevation areas also used by fall-run individuals, potentially resulting in hybridization of the two races. Hybridization between spring- and fall-run salmon has been identified as a particular concern on the Feather River where both runs co-occur and as a potential concern for restoration of salmon on the San Joaquin River downstream of Friant Dam. Management of the Feather River hatchery and brood stock selection practices have been modified in recent years (e.g., tagging early returning adult salmon showing phenotypic and run timing characteristics of spring-run Chinook salmon for subsequent use as selected brood stock and genetic testing of potential brood stock) in an effort to reduce potential hybridization as a result of hatchery operations. Consideration has also been given to using a physical weir to help segregate and isolate adults showing spring-run characteristics and later arriving fish showing characteristics of fall-run fish to reduce the risk of hybridization and redd superimposition within spawning areas of the river.

Investigations have been undertaken to assess the potential habitat quality and availability for spring-run Chinook salmon spawning and juvenile rearing within the reaches of the Feather River upstream of Oroville Dam that could potentially be used to expand the geographic range of spring-run salmon using trap and haul techniques. On many of the other Central Valley tributaries, such as Deer and Mill creeks, the risk of hybridization is reduced by the ability of the runs to segregate geographically within the watersheds.

Further, in an effort to improve juvenile survival and the contribution of the Feather River Hatchery to the adult spring-run Chinook salmon population, the spring-run salmon program at the hatchery has released juvenile spring-run salmon far downstream of the hatchery (San Pablo Bay) in the past, which has increased the rate of straying adults migrating back upstream (DFG 2001). Recent changes in hatchery management by DFG, however, have modified juvenile planting with a greater number of juvenile fish released into the Feather River in an effort to improve imprinting and reduce straying, which may reduce potential for hybridization with spring-run salmon in other watersheds (McReynolds et al. 2006). Half of the juvenile spring-run Chinook salmon produced at the hatchery are now released in the Feather River at Live Oak as part of an experimental program designed to improve hatchery management.

Entrainment. The vulnerability of juvenile spring-run Chinook salmon to entrainment and salvage at the SWP and CVP export facilities varies in response to multiple factors, including the seasonal and geographic distribution of juvenile salmon within the Delta, operation of Delta Cross Channel gates, hydrodynamic conditions occurring within the central and southern regions of the Delta (e.g., Old and Middle rivers), and export rates. The losses of fish to entrainment mortality has been identified as an impact to Chinook salmon populations (Kjelson and Brandes 1989). Juvenile spring-run Chinook salmon tend to be distributed within the central and southern Delta where they have an increased risk of entrainment/salvage between February and May (see Table A.-3a). The effect of changing hydrodynamics within Delta channels, such as reversed flows in Old and Middle rivers resulting from SWP and CVP export operations, has the potential to increase attraction of emigrating juveniles into false migration pathways, delay emigration through the Delta, directly or indirectly increase vulnerability to entrainment at unscreened diversions, increase the risk of predation, increase movement of migrating salmon toward the export facilities, increase the risk that these fish will be entrained into the fish salvage facilities, and increase the duration of exposure to seasonally-elevated water temperatures and other depressed water quality conditions. SWP and CVP exports have been shown to affect the tidal hydrodynamics (e.g., water current velocities and direction), and the magnitude of these effects varies in response to a variety of factors, including tidal stage and magnitude of ebb and flood tides, the rate of SWP and CVP exports, operation of the Clifton Court Forebay radial gate opening, and inflow from the upstream tributaries. Chinook salmon behaviorally respond to hydraulic cues (e.g., water currents) during both upstream adult and downstream juvenile migration through the Delta. Over the past several years additional investigations have been designed using radio or acoustically-tagged juvenile Chinook salmon to monitor their migration behavior through the Delta channels and to assess the effects of changes in hydraulic cues and SWP and CVP export operations on migration. These studies are continuing (San Joaquin River

Group Authority 2007, Brandes et al. 2008, Lindley et al. 2008, MacFarlane et al. 2008a, Michel et al. 2008, North Delta Hydrodynamic and Juvenile Salmon Migration Study 2008, Perry et al. 2008).

In addition to SWP and CVP exports, over 2,200 small water diversions exist throughout the Delta, in addition to unscreened diversions located on the tributary rivers (Herren and Kawasaki 2001). The risk of entrainment is a function of the size of juvenile fish and the slot opening of the screen mesh (Tomljanovich et al. 1978, Schneeberger and Jude 1981, Zeitoun et al. 1981, Weisberg et al. 1987, C. Hanson unpubl. data). Many of the juvenile salmon migrate downstream through the Delta during the late winter or early spring when many of the agricultural irrigation diversions are not operating or are only operating at low levels. Juvenile salmon also migrate primarily in the upper part of the water column and therefore their vulnerability to an unscreened diversion located near the channel bottom is reduced. No quantitative estimates have been developed to assess the potential magnitude of entrainment losses for juvenile Chinook salmon migrating through the rivers and Delta, and the effects of these losses on the overall population abundance of returning adult Chinook salmon is unknown. Many of the larger water diversions located within the Central Valley and Delta (e.g., Glenn Colusa Irrigation District, Reclamation District 108 Wilkins Slough, Poundstone, and Sutter Mutual Water Company Tisdale pumping plants, Contra Costa Water District Old River and Alternative Intake Project, and others) have been equipped with positive barrier fish screens to reduce and avoid the loss of juvenile Chinook salmon and other fish species.

Power plants within the Plan Area have the ability to impinge juvenile Chinook salmon on the existing cooling water system intake screens. However, use of cooling water is currently low with the retirement of older units. Further, newer units are being equipped with a closed cycle cooling system that virtually eliminates the risk of impingement of juvenile salmon.

Besides direct mortality, salmon fitness may be affected by entrainment at these diversions and delays in out-migration of smolts caused by reduced or reverse flows. Delays in migration due to water management related to the SWP and CVP operations can make juvenile salmonids more susceptible to many of the threats and stressors discussed in this section, such as predation, entrainment, angling, exposure to poor water quality and toxics, and disease. The quantitative relationships among changes in Delta hydrodynamics, the behavioral and physiological response of juvenile salmon, and the increase or decrease in risk associated with other threats are unknown, but currently the subject of a number of investigations and analyses.

Exposure to toxins. Toxic chemicals have the potential to be widespread throughout the Delta, or may occur on a more localized scale in response to episodic events (i.e., stormwater runoff, point source discharges, etc.). These toxic substances include mercury, selenium, copper, pyrethroids, and endocrine disruptors with the potential to impact fish health and condition, and adversely impact salmon distribution and abundance. Concern regarding exposure to toxic substances for Chinook salmon includes both waterborne chronic and acute exposure, but also bioaccumulation and chronic dietary exposure. For example, selenium is a naturally occurring constituent in agricultural drainage water return flows from the San Joaquin River that is then dispersed downstream into the Delta (Nichols et al. 1986). Exposure to selenium in the diet of juvenile Chinook salmon has been shown to result in toxic effects (Saiki 1986, Saiki and Lowe 1987, Hamilton et al. 1986, 1990, Hamilton and Buhl 1990). Selenium exposure has been associated with agricultural and natural drainage within the San Joaquin River basin and refining operations adjacent to San Pablo and San Francisco bays. Other contaminants of concern for Chinook salmon include, but are not limited to, mercury, copper, oil and grease, pesticides, herbicides, ammonia, and localized areas of depressed dissolved oxygen (e.g., Stockton Deep Water Ship Channel, return flows from managed freshwater wetlands, etc.). As a result of the extensive agricultural development within the Central Valley exposure to pesticides and herbicides has been identified as a significant concern for salmon and other fish species within the Plan Area (Bennett et al. 2001). In recent years changes have been made in the composition of herbicides and pesticides used on agricultural crops in an effort to reduce potential toxicity to aquatic and terrestrial species. Modifications have also been made to water system operations and discharges related to agricultural wastewater discharges (e.g., agricultural drainage water system lock-up and holding prior to discharge) and municipal wastewater treatment and discharges. Concerns remain, however, regarding the toxicity of contaminants such as pyrethroids that adsorbed to sediments and other chemicals (e.g., including selenium and mercury, as well as other contaminants) on salmon.

Mercury and other metals such as copper have also been identified as contaminants of concern for salmon and other fish as a result of direct toxicity and impacts such as those related to acid mine runoff from sites such as Iron Mountain Mine (U.S. Environmental Protection Agency [EPA] 2006). There are problems with tissue bioaccumulation that may adversely impact the fish, but also represents a human health concern (Gassel et al. 2008). These materials originate from a variety of sources including mining operations, municipal wastewater treatment, agricultural drainage within the tributary rivers and Delta, non-point runoff, natural runoff and drainage within the Central Valley, agricultural spraying, and a number of other sources. The State Water Resources Control Board (SWRCB), Central Valley Regional Water Quality Control Board (CVRWQCB), U.S. EPA, U.S. Geological Survey (USGS), DWR, and others have ongoing monitoring programs designed to characterize water quality conditions and identify potential toxicants and contaminant exposure to Chinook salmon and other aquatic resources within the Plan Area. Programs are in place to regulate point source discharges as part of the National Pollutant Discharge Elimination System (NPDES) program as well as efforts to establish and reduce total daily maximum loads (TMDL) of various constituents entering the Delta. Changes in regulations have also been made to help reduce chemical exposure and reduce the adverse impacts to aquatic resources and habitat conditions within the Plan Area. These monitoring and regulatory programs are ongoing.

Sublethal concentrations of toxics may interact with other stressors on salmonids, such as increasing their vulnerability to mortality as a result of exposure to seasonally elevated water temperatures, predation, or disease (Werner 2007). For example, Clifford et al. (2005) found in a laboratory setting that juvenile fall-run Chinook salmon exposed to sublethal levels of a common pyrethroid, esfenvalerate, were more susceptible to infectious hematopoietic necrosis virus than those not exposed to esfenvalerate. Although not tested on spring-run Chinook salmon, a similar response is likely due to the physiological similarity.

Iron Mountain Mine, located adjacent to the upper Sacramento River, has been a source of trace elements and metals that are known to adversely affect aquatic organisms (Upper Sacramento River Fisheries and Riparian Habitat Advisory Council 1989). Storage limitations and limited availability of dilution flows have caused downstream copper and zinc levels to exceed salmonid tolerances and resulted in documented fish kills in the 1960s and 1970s (USBR 2004). The Environmental Protection Agency's Iron Mountain Mine remediation program has removed toxic metals in acidic mine drainage from the Spring Creek watershed with a state-of-the-art lime neutralization plant. Contaminant loading into the Sacramento River from Iron Mountain Mine has shown measurable reductions since the early 1990s.

Increased water temperature. Water temperature is among the physical factors that affect quality of habitat for salmonid adult holding, spawning and egg incubation, juvenile rearing, and migration. Adverse sublethal and lethal effects can result from exposure to elevated water temperatures at sensitive lifestages, such as during incubation or rearing. The Central Valley is the southern limit of spring-run Chinook salmon geographic distribution, so increased water temperatures are often recognized as an important stressor to California populations. Water temperature criteria for various lifestages of salmonids in the Central Valley have been developed by NMFS (2009). The tolerance of spring-run Chinook salmon to water temperatures depends on life stage, acclimation history, food availability, duration of exposure, health of the individual, and other factors such as predator avoidance (Myrick and Cech 2004, USBR 2004). Higher water temperatures can lead to physiological stress, reduced growth rate, pre-spawning mortality, reduced spawning success, and increased mortality of salmon (Myrick and Cech 2001). Temperature can also indirectly influence disease incidence and predation (Waples et al. 2008). Exposure to seasonally elevated water temperatures may occur as a result of reductions in flow, upstream reservoir operations, reductions in riparian vegetation, channel shading, local climate and solar radiation. The installation of the Shasta Temperature Control Device in 1998, in combination with reservoir management to maintain the cold water pool, has reduced many of the temperature issues on the Sacramento River. During dry years, however, the release of cold water from Shasta Dam is still limited. As the river flows further downstream, particularly during the warm spring, summer, and early fall months, water temperatures continue to increase until they reach thermal equilibrium with atmospheric conditions. As a result of the longitudinal gradient of seasonal water temperatures, the coldest temperatures and best areas for salmon spawning and rearing are typically located immediately downstream of the dam.

Increased temperature can also arise from a reduction in shade over rivers by tree removal (Watanabe et al. 2005). Because river water is typically in thermal equilibrium with atmospheric conditions by the time it enters the Delta, this issue is caused primarily from actions upstream of the Delta. As a result of the relatively wide channels that occur within the Delta, the effects of additional riparian vegetation on reducing water temperatures are minimal.

Adult and juvenile spring-run Chinook salmon hold and rear within pools at higher elevations within the watershed. On several tributaries, pre-spawning adult mortality has been reported for adults that accumulate in high densities within a pool and are then exposed to elevated summer water temperatures. Flow reductions, resulting from natural hydrologic conditions during the summer, evapotranspiration, or surface and groundwater extractions may all contribute to exposure to elevated temperatures and increased levels of stress or mortality. In some areas groundwater wells have been used to pump cooler water into the stream to reduce oversummer temperatures. Dense riparian vegetation, streams incised into canyons that provide shading, cool water springs, and availability of deep holding pools are factors that affect summer holding and rearing conditions for spring-run Chinook salmon.

The effects of climate change and global warming patterns, in combination with changes in precipitation and seasonal hydrology in the future have been identified as important factors that may adversely affect the health and long-term viability of Central Valley spring-run Chinook salmon (Crozier et al. 2008). The rate and magnitude of these potential future environmental changes, and their effect of habitat quality and availability for spring-run Chinook salmon, however, are subject to a high degree of uncertainty.

A3.6 Relevant Conservation Efforts

Results of salvage monitoring and extensive experimentation over the past several decades have lead to the identification of a large number of management actions designed to reduce or avoid the potentially adverse impacts of SWP and CVP export operations on salmon. Many of these actions have been implemented through SWRCB water quality permits (D-1485, D-1641), biological opinions issued on project export operations by NMFS, USFWS, and DFG, as part of CALFED programs (e.g., Environmental Water Account [EWA]), and as part of actions associated with Central Valley Project Improvement Act (CVPIA). As a result of these requirements multiple conservation efforts exist to enhance habitat and reduce entrainment of Chinook salmon by the SWP and CVP export facilities.

Several habitat problems that contributed to the decline of Central Valley salmonid species are being addressed and improved through restoration and conservation actions Such actions are related to ESA Section 7 consultation, Reasonable and Prudent Alternatives, addressing temperature, flow, and operations of the Central Valley and State Water Projects; EPA actions to control acid mine runoff from Iron Mountain Mine; and the CVRWB decisions requiring compliance with Sacramento River water temperature objectives. These decisions resulted in the installation of the Shasta Temperature Control Device in 1998.

Biological opinions for SWP and CVP operations (e.g., NMFS 2009a) and other federal projects involving irrigation and water diversion and fish passage, for example, have improved or minimized adverse impacts to salmon in the Central Valley. In 1992, an amendment to the authority of the CVP through the CVPIA was enacted to give protection of fish and wildlife equal priority with other CVP objectives. From this act arose several programs that have benefited listed salmonids. The Anadromous Fish Restoration Program (AFRP) is engaged in monitoring, education, and restoration projects designed to contribute toward doubling the natural populations of select anadromous fish species residing in the Central Valley. Restoration projects funded through the AFRP include fish passage, fish screening, riparian easement and land acquisition, development of watershed planning groups, instream and riparian habitat improvement, and gravel replenishment. The Anadromous Fish Screen Program combines federal funding with state and private funds to prioritize and construct fish screens on major water diversions mainly in the upper Sacramento River. The goal of the Water Acquisition Program is to acquire water supplies to meet the habitat restoration and enhancement goals of the Central Valley Improvement Act, and to improve the ability of the U.S. Department of the Interior to meet regulatory water quality requirements. Water has been used to improve fish habitat for Central Valley salmon, with the primary focus on listed Chinook salmon and steelhead, by maintaining or increasing instream flows (EWA) on the Sacramento River at critical times, and to reduce salmonid entrainment at the SWP and CVP export facilities through reducing seasonal diversion rates during periods when protected fish species are vulnerable to export related losses.

Two programs included under CALFED, the Ecosystem Restoration Program (ERP) and the EWA, were created to improve conditions for fish, including spring-run Chinook salmon, in the Central Valley. The ERP Implementing Agency Managers selected a proposal for directed action funding written by the Central Valley Salmonid Project Work Team, an interagency technical working group led by DFG, to develop a spring-run Chinook salmon escapement monitoring plan. Long-term funding for implementation of the monitoring plan must still be secured.

A major CALFED ERP action currently underway is the Battle Creek Salmon and Steelhead Restoration Project. The project will restore 48 miles (77 km) of habitat in Battle Creek to support steelhead and Chinook salmon spawning and juvenile rearing at a cost of over $90 million. The project includes removal of five small hydropower diversion dams, construction of new fish screens and ladders on another three dams, and construction of several hydropower facility modifications to ensure the continued hydropower operations. It is thought that this restoration effort is the largest cold water restoration project to date in North America.

The Delta Regional Ecosystem Restoration Implementation Plan (DRERIP) was formed to guide the implementation of CALFED ERP elements within the Delta (DFG 2007b). The DRERIP team has created a suite of ecosystem and species conceptual models, including spring-run Chinook salmon, that document existing scientific knowledge of Delta ecosystems. The DRERIP team has used these conceptual models to assess the suitability of actions proposed in the ERP for implementation. DRERIP conceptual models were used in the analysis of proposed BDCP conservation measures.

Recent habitat restoration initiatives sponsored and funded primarily by the ERP have resulted in plans to restore ecological function to 9,543 acres of shallow-water tidal and marsh habitats within the Delta. Restoration of these areas primarily involves flooding lands previously used for agriculture, thereby creating additional rearing habitat for juvenile salmonids. Similar habitat restoration is adjacent to Suisun Marsh (i.e., at the confluence of Montezuma Slough and the Sacramento River) as part of the Montezuma Wetlands project, which is intended to provide for commercial disposal of material dredged from San Francisco Estuary in conjunction with tidal wetland restoration.

The Vernalis Adaptive Management Program (VAMP) has implemented migration flow augmentation for the San Joaquin River basin to improve juvenile and adult migration for fall-run Chinook salmon (San Joaquin River Group Authority 2007). The VAMP program also includes seasonal reductions in SWP and CVP export rates that may benefit juvenile spring-run Chinook salmon during their emigration period. The program has been designed within the framework of adaptive management to improve the survival of juvenile salmonids migrating from the river through the Delta while providing an experimental framework to quantitatively evaluate the contribution of each action to salmonid survival. The incremental contribution of the VAMP conditions to overall spring-run salmon survival and adult abundance is uncertain. The VAMP experimental design and results of survival testing conducted to date is currently undergoing peer review and will also be the subject of a review conducted by the SWRCB. Based on results and recommendations from these technical reviews, the VAMP experimental design and testing program is expected to be refined.

The U.S. EPA's Iron Mountain Mine remediation involves the removal of toxic metals in acidic mine drainage from the Spring Creek Watershed with a state-of-the-art lime neutralization plant. Contaminant loading into the Sacramento River from Iron Mountain Mine has shown measurable reductions since the early 1990s. Decreasing the heavy metal contaminants that enter the Sacramento River should increase the survival of salmonid eggs and juveniles. However, during periods of heavy rainfall upstream of the Iron Mountain Mine, Reclamation substantially increases Sacramento River flows to dilute heavy metal contaminants being spilled from the Spring Creek debris dam. This rapid change in flows can cause juvenile salmonids to become stranded or isolated in side channels below Keswick Dam.

DWR's Delta Fish Agreement Program has approved approximately $49 million for projects that benefit salmon and steelhead production in the Sacramento-San Joaquin basins and Delta since the agreements inception in 1986. Delta Fish Agreement projects that benefit Central Valley spring-run Chinook salmon include water exchange programs on Mill and Deer creeks; enhanced law enforcement efforts from San Francisco Estuary upstream to the Sacramento and San Joaquin rivers and their tributaries; design and construction of fish screens and ladders on Butte Creek; and, screening of diversions in Suisun Marsh and San Joaquin River tributaries. The Spring-Run Salmon Increased Protection Project provides overtime wages for DFG wardens to focus on reducing illegal take and illegal water diversions on upper Sacramento River tributaries and adult holding areas, where the fish are vulnerable to poaching. This project covers Mill, Deer, Antelope, Butte, Big Chico, Cottonwood, and Battle creeks, and has been in effect since 1996. Through the Delta-Bay Enhanced Enforcement Program (DBEEP), initiated in 1994, a team of 10 wardens focus their enforcement efforts on salmon, steelhead, and other species of concern from the San Francisco Estuary upstream into the Sacramento and San Joaquin River basins. These two enhanced enforcement programs have likely had significant benefits to spring-run Chinook salmon attributed to DFG, although results have not been quantified.

The Mill and Deer Creek Water Exchange projects are designed to provide new wells that enable diverters to bank groundwater in place of stream flow, thus leaving water in the stream during critical migration and oversummering periods. On Mill Creek several agreements between Los Molinos Mutual Water Company, Orange Cove Irrigation District, DFG, and DWR allows DWR to pump groundwater from two wells into the Los Molinos Mutual Water Company canals to pay back Los Molinos Mutual Water Company water rights for surface water released downstream for fish. Although the Mill Creek Water Exchange project was initiated in 1990 and the agreement allows for a well capacity of 25 cfs, only 12 cfs has been developed to date. In addition, it has been determined that a base flow of greater than 25 cfs is needed during the April through June period for upstream passage of adult spring-run Chinook salmon in Mill Creek. In some years, water diversions from the creek are curtailed by amounts sufficient to provide for passage of upstream migrating adult spring-run Chinook salmon and downstream migrating juvenile steelhead and spring-run Chinook salmon.

The Feather River Hatchery is making efforts to segregate spring-run from fall-run Chinook salmon to enhance and restore the genotype of spring-run Chinook salmon in the Feather River (DFG 2001, McReynolds et al. 2006).

To help reduce the effects of the RBDD operation on migration of adult and juvenile salmonids and other species, management has changed in recent years to maintain the dam gates in the open position for a longer period of time and thereby facilitate greater upstream and downstream migration. Changes in dam operations have benefited both upstream and downstream migration by salmon and have contributed to a reduction in juvenile predation mortality. In 2009, USBR received funding for the Fish Passage Improvement Project at the RBDD to build a pumping facility to provide reliable water supply for high-valued crops in Tehama, Glenn, Colusa, and northern Yolo counties while providing year-round unimpeded fish passage. This project, which is expected to be completed in late 2012, will eliminate passage issues for spring-run Chinook salmon and other migratory species.

Seasonal constraints on sport and commercial fisheries south of Point Arena benefit spring-run Chinook salmon. DFG has implemented enhanced enforcement efforts to reduce illegal harvests. Central Valley spring-run Chinook salmon is a state listed fish that is protected by specific in-river fishing regulations.

A3.7 Recovery Goals

The Public Draft Recovery Plan for Central Valley salmonids, including spring-run Chinook salmon, was released by NMFS on October 19, 2009. Although not final, the overarching goal in the public draft is the removal of, among other listed salmonids, spring-run Chinook salmon from the federal list of Endangered and Threatened Wildlife (NMFS 2009b). Several objectives and related criteria represent the components of the recovery goal, including the establishment of at least two viable populations within each historical diversity group, as well as other measurable biological criteria.

APPENDIX A4. CENTRAL VALLEY FALL- AND LATE FALL-RUN CHINOOK SALMON (*ONCORHYNCHUS TSHAWYTSCHA*)

A4.1 LEGAL STATUS

The Central Valley fall- and late fall-run Chinook salmon Evolutionarily Significant Unit (ESU) includes all naturally spawned populations of fall- and late fall-run Chinook salmon in the Sacramento and San Joaquin River basins and their tributaries east of Carquinez Strait, California (64 FR 50394) (see Figure A-4a and Figure A-4b, respectively). On September 16, 1999, after reviewing the best available scientific and commercial information, the National Marine Fisheries Service (NMFS) determined that listing Central Valley fall- and late fall-run Chinook salmon was not warranted. On April 15, 2004, the Central Valley fall- and late fall-run Chinook salmon ESU was identified by NMFS as a Species of Concern (69 FR 19975).

The Central Valley fall-/late fall-run Chinook salmon ESU are not listed under the California Endangered Species Act. Fall-run/late fall-run Chinook salmon are identified as a California Species of Special Concern (Moyle et al. 1995).

A4.2 SPECIES DISTRIBUTION AND STATUS

A4.2.1 Range and Status

Central Valley fall-run Chinook salmon historically spawned in all major tributaries, as well as the mainstem of the Sacramento and San Joaquin rivers (see Figure A-4a). The historical geographic distribution of Central Valley late fall-run Chinook salmon is not well understood, but is thought to be less extensive than that of fall-run (see Figure A-4b). A large percentage of fall-run Chinook spawning areas in the Sacramento and San Joaquin rivers historically inhabited the lower gradient reaches of the rivers downstream of sites now occupied by major dams, such as Shasta and Friant dams. As a result of the geographic distribution of spawning and juvenile rearing areas, fall-run Chinook salmon populations in the Central Valley were not as severely affected by early water projects that blocked access to upstream areas as were spring- and winter-runs of Chinook salmon and steelhead that used higher elevation habitat for spawning and rearing (Reynolds et al. 1993, McEwan 2001). Changes in seasonal hydrologic patterns resulting from operation of upstream reservoirs for water supplies, flood control, and hydroelectric power generation have altered instream flows and habitat conditions for fall-run Chinook salmon and other species downstream of the dams (Williams 2006).

DRAFT

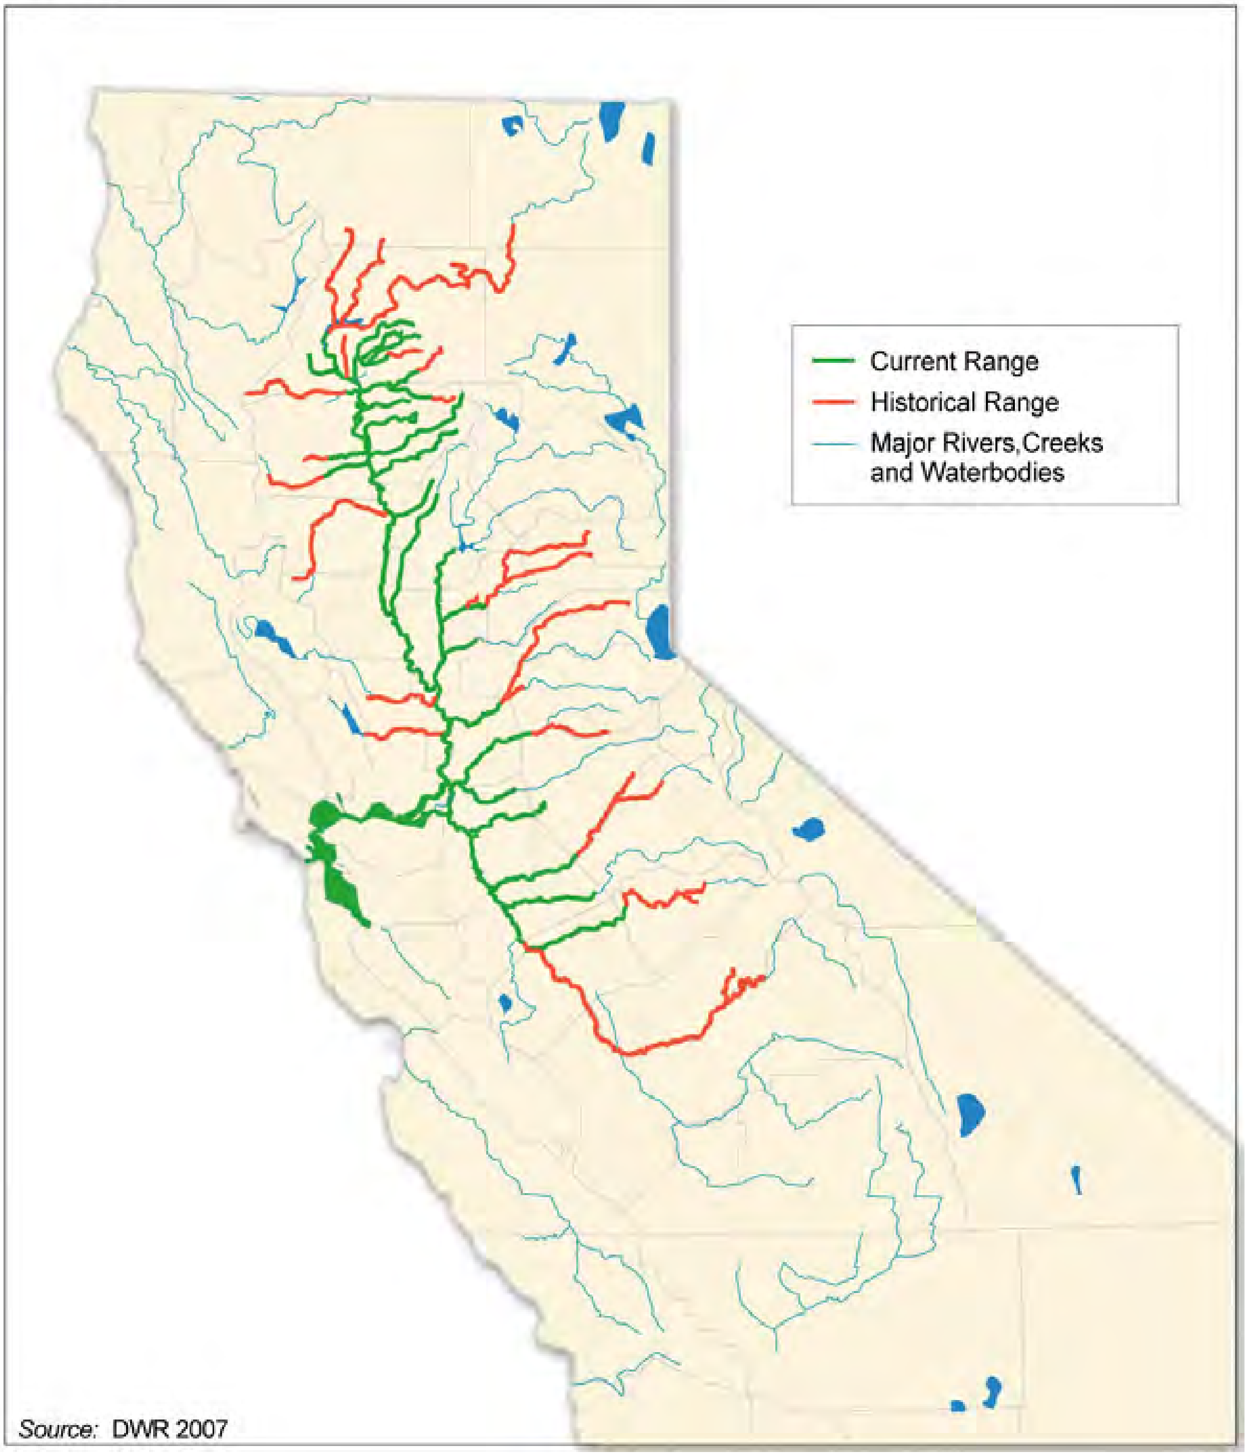

Figure A-4a. Central Valley Fall-Run Chinook Salmon Inland Range in California

Figure A-4b. Central Valley Late Fall-Run Chinook Salmon Inland Range in California

The abundance of Central Valley fall- and late fall-run Chinook salmon escapement before 1952 is poorly documented. Reynolds et al. (1993) estimated that production of fall- and late fall-run Chinook salmon on the San Joaquin River historically approached 300,000 adults and probably averaged approximately 150,000 adults. Calkins et al. (1940) estimated fall- and late fall-run Chinook salmon abundance at 55,595 adults in the Sacramento River Basin during the period 1931-1939. In the early 1960s, adult fall- and late fall-run Chinook salmon escapement was estimated to be 327,000 fish in the Sacramento River basin (U.S. Department of Fish and Game [DFG] 1965). In the mid-1960s, fall- and late fall-run Chinook salmon escapement to the San Joaquin River Basin was estimated to be about 2,400 fish, which spawned in the San Joaquin River tributaries – the Stanislaus, Tuolumne, and Merced rivers.

Long-term trends in adult fall-run Chinook salmon escapement indicate that abundance in the Sacramento River has been consistently higher than abundance in the San Joaquin River (see Figure A-4c). Escapement on the Sacramento River has been characterized by relatively high interannual variability ranging from approximately 100,000 to over 800,000 fish. Sacramento River escapement showed a marked increase in abundance between 1990 and 2003 followed by a decline in abundance over the period from 2004 through present. In 2009 adult fall-run Chinook salmon returns to the Central Valley rivers showed a substantial decline within both the Sacramento and San Joaquin river systems. Similar declines in adult escapement were also observed for coho salmon and Chinook salmon returning to other river systems in California (MacFarlane et al. 2008).

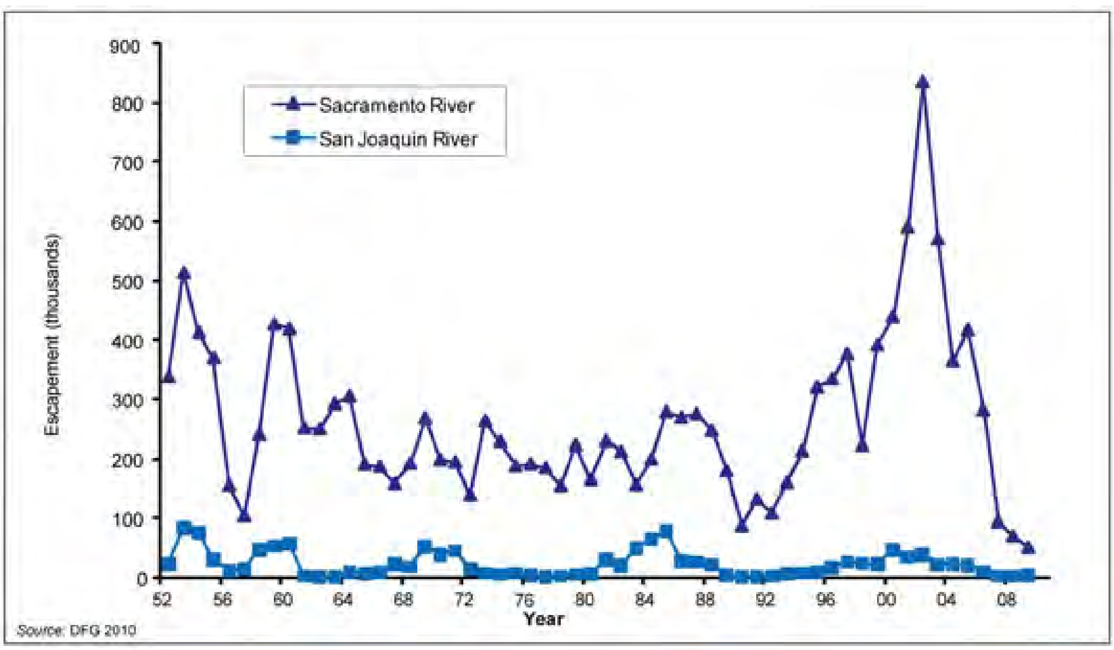

Figure A-4c. Estimated Historical Spawner Escapement of Central Valley Fall-Run Chinook Salmon (1952-2009)

A variety of factors are thought to have influenced adult escapement on both rivers, including hydrological conditions for migration, spawning, and juvenile rearing, ocean conditions, and management actions that have been implemented since the early 1990s to improve seasonal water temperatures, streamflows, modifications to Red Bluff Diversion Dam (RBDD) gate operations, improved fish passage, construction of positive barrier fish screens on larger diversions, and improved habitat conditions.

Trends in adult fall-run Chinook salmon escapement on the San Joaquin River and tributaries has been relatively low since the 1950s, ranging from several hundred adults to approximately 100,000 adults (see Figure A-4c). Results of escapement estimates have shown a relationship between adult escapement in one year and spring flows on the San Joaquin River 2.5 years earlier when the juvenile within the cohort were rearing and migrating downstream through the Delta. Adult escapement appears to be cyclical and may be related to hydrology during juvenile rearing and migration period, among other factors (San Joaquin River Group Authority 2007, DFG 2008).

Population estimates for late fall-run Chinook salmon on the San Joaquin River system are not available, but it is thought that late fall-run Chinook salmon do not regularly spawn in the tributaries of the San Joaquin River (Moyle et al. 1995). Adult escapement estimates for late fall-run Chinook salmon returning to the Sacramento River over the period from 1971 through 2009 have ranged from several hundred adults to over 40,000 adults. Adult escapement showed a general trend of declining abundance between 1971 and 1997 (see Figure A-4d). During the late 1990s and continuing through 2006 escapement has increased substantially but is characterized by high interannual variability. The 2008 and 2009 escapement estimates were lower than the previous 4 years, but were not characterized by the massive decline observed for fall-run Chinook salmon (see Figure A-4c). A number of factors have been identified that may be contributing to the observed trends and patterns in late fall-run Chinook salmon escapement to the upper Sacramento River and its tributaries.

A4.2.2 Distribution and Status in the Plan Area

The entire population of the Central Valley fall-/late fall-run Chinook salmon ESU must pass through Plan Area as adults migrating upstream and as juveniles emigrating downstream. Adult Central Valley fall-/late fall-run Chinook salmon migrating into the Sacramento River and its tributaries primarily use the western and northern portions of the Delta, whereas adults entering the San Joaquin River system to spawn use the western, central, and southern Delta as a migration pathway. Young fall-/late fall-run Chinook salmon must migrate through the Delta towards the Pacific Ocean and use the Delta, Suisun Marsh, and the Yolo Bypass for rearing to varying degrees, depending on their life stage (fry vs. juvenile) and size, river flows, and time of year.

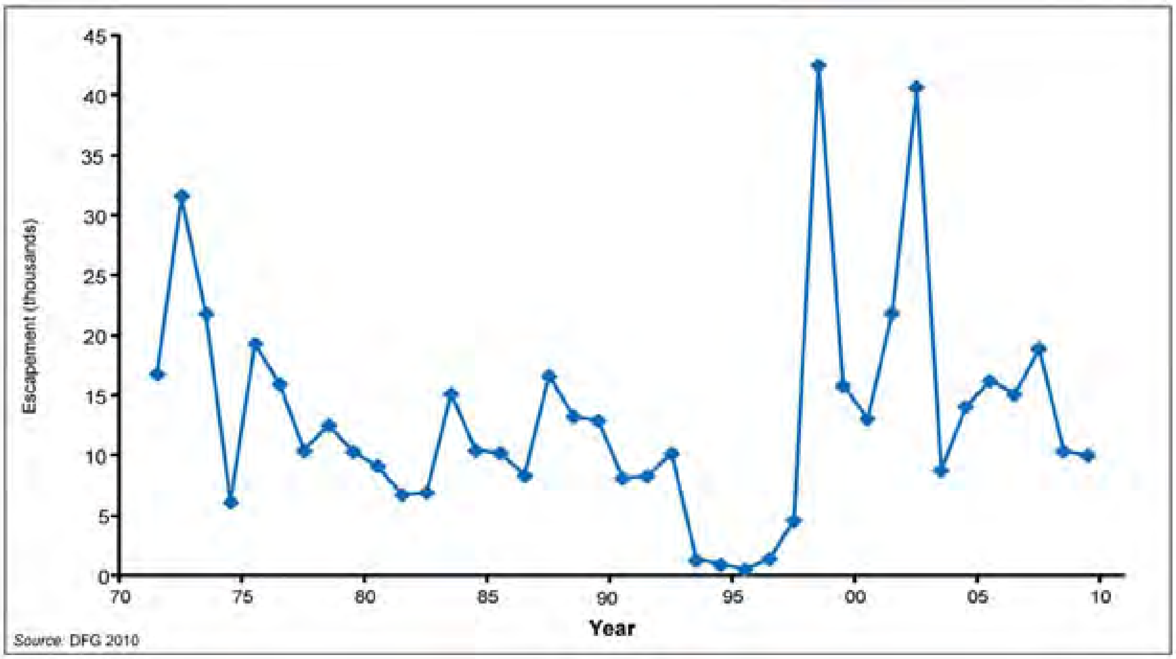

Figure A-4d. Estimated Historical Spawner Escapement of Central Valley Late Fall-Run Chinook Salmon (1971-2009) in the Sacramento River

A4.3 HABITAT REQUIREMENTS AND SPECIAL CONSIDERATIONS

Critical Habitat has not been designated for either fall-run or late fall-run Chinook salmon because the ESU is not listed under the Endangered Species Act. However, Central Valley fall- and late fall-run Chinook salmon habitats are protected under the Magnuson-Stevens Fishery Conservation and Management Act as Essential Fish Habitat. Those waters and substrate that support fall- and late fall-run Chinook salmon growth to maturity are included as Essential Fish Habitat (fall-run: see Figure A-4e; late fall-run: see Figure A-4f).

The Primary Constituent Elements (PCEs) considered essential for the conservation of Central Valley salmonids are: (1) freshwater spawning sites, (2) freshwater rearing sites, (3) freshwater migration corridors, (4) estuarine areas, (5) nearshore marine areas, and (6) offshore marine areas.

A4.3.1 Spawning Habitat

Chinook salmon spawning sites include those stream reaches with instream flows, water quality, and substrate conditions suitable to support spawning, egg incubation, and larval development. Central Valley fall-run Chinook salmon currently spawn downstream of dams on every major tributary within the Sacramento and San Joaquin river systems (with the exception of the San Joaquin River downstream of Friant Dam which is currently the subject of a settlement agreement and salmonid restoration program) in areas containing suitable environmental conditions for spawning and egg incubation.

DRAFT

Figure A-4e. Central Valley Fall-Run Chinook Salmon Inland Essential Fish Habitat in California

DRAFT

Figure A-4f. Central Valley Late Fall-Run Chinook Salmon Inland Essential Fish Habitat in California

Late fall-run Chinook salmon spawning is limited to the mainstem and tributaries of the Sacramento River. No Chinook salmon spawning habitat is known to occur within the Plan Area.

A4.3.2 Freshwater Rearing Habitat

Fall-/late fall-run Chinook salmon rear in streams and rivers with sufficient water flow and floodplain connectivity to form and maintain physical habitat conditions that support growth and mobility, provide suitable water quality (e.g., seasonal water temperatures) and forage species that support juvenile salmon growth, and cover such as shade, submerged and overhanging large wood, log jams, beaver dams, aquatic vegetation, large rocks and boulders, side channels, and undercut banks. Both spawning areas and migratory corridors might also function as rearing habitat for juveniles, which feed and grow before and during their outmigration. Non-natal, intermittent tributaries and seasonally inundated flood control bypasses such as the Yolo Bypass also support juvenile rearing (Sommer et al. 2001). Rearing habitat quality is strongly affected by habitat complexity, food supply, and vulnerability to predators. Some of these more complex and productive habitats with floodplains are still present in limited amounts within the Central Valley (e.g., the lower Cosumnes River, Sacramento River reaches with set-back levees [i.e., primarily located upstream of the City of Colusa]). The channeled, leveed, and riprapped river reaches and sloughs common in the Sacramento-San Joaquin River and throughout the Delta typically have low habitat diversity and complexity, low abundance of food organisms, and offer little protection from predation by fish and birds. Freshwater rearing habitat has a high conservation value because the juvenile life stage of salmonids is dependent on the function of this habitat for successful growth, survival, and recruitment to the adult population.

A4.3.3 Freshwater Migration Corridors

Freshwater migration corridors for fall-run and late fall-run Chinook salmon, including river channels, channels through the Delta, and the Bay-Delta estuary, support mobility, survival, and food supply for juveniles and adults. Migration corridors should be free from obstructions (passage barriers and impediments to migration), favorable water quantity (instream flows) and quality conditions (seasonal water temperatures), and contain natural cover such as submerged and overhanging large wood, aquatic vegetation, large rocks and boulders, side channels, and undercut banks. Migratory corridors are typically downstream of the spawning area and include the lower Sacramento and San Joaquin rivers, the Delta, and the San Francisco Bay complex extending to coastal marine waters. These corridors allow the upstream passage of adults and the downstream emigration of juvenile salmon. Migratory corridor conditions are strongly affected by the presence of passage barriers, which can include dams, unscreened or poorly screened diversions, and degraded water quality. For freshwater migration corridors to function properly, they must provide adequate passage, provide suitable migration cues, reduce false attraction, avoid areas where vulnerability to predation is increased, and avoid impediments and delays in both upstream and downstream migration. For this reason, freshwater migration corridors are considered to have a high conservation value. Results of mark-recapture studies conducted using juvenile Chinook salmon released into both the Sacramento and San Joaquin rivers have shown high mortality during passage downstream through the rivers and Delta. Mortality for juvenile salmon is typically greater on the San Joaquin River than for those fish emigrating from the Sacramento River. On both rivers, mortality is typically greater in years when spring flows are reduced and water temperatures are increased. Results of survival studies have shown that closing the Delta Cross Channel gates and installation of the Head of Old River Barrier, to reduce the movement of juvenile salmon into the Delta, contribute to improved survival of emigrating juvenile Chinook salmon. Observations at the State Water Project (SWP) and the Central Valley Project (CVP) fish salvage facilities have shown that very few of the marked salmon are entrained and salvaged at the export facilities. Although factors contributing to the high juvenile mortality have not been quantified, results of anecdotal observations and results of acoustic tagging experiments suggest the exposure to adverse water quality conditions leading to mortality and vulnerability to predation mortality are two of the factors contributing to the high juvenile mortality observed in the rivers and Delta.

A4.3.4 Estuarine Areas

Estuarine migration and juvenile rearing habitats should be free of obstructions (i.e., dams and other barriers) and provide suitable water quality, water quantity (river and tidal flows), and salinity conditions to support juvenile and adult physiological transitions between fresh and salt water. Natural cover, such as submerged and overhanging large wood, aquatic vegetation, and side channels, provide juvenile and adult foraging. Estuarine areas contain a high conservation value as they function to support juvenile Chinook salmon growth, smolting, avoidance of predators, and provide a transition to the ocean environment.

A4.3.5 Ocean Habitats

Biologically productive coastal waters are an important habitat component for Central Valley fall- and late fall-run Chinook salmon. Juvenile fall-run and late fall-run Chinook salmon inhabit near-shore coastal marine waters for a period of typically 2 to 4 years before adults return to Central Valley rivers to spawn . During their marine residence Chinook salmon forage on krill, squid, and other marine invertebrates as well as a variety of fish such as northern anchovy and Pacific herring. These features are essential for conservation because, without them, juveniles cannot forage and grow to adulthood.

Results of oceanographic studies have shown the variation in ocean productivity off the West Coast within and among years. Changes in ocean currents and upwelling have been identified as significant factors affecting nutrient availability, phytoplankton and zooplankton production and the availability of other forage species in near-shore surface waters. Ocean conditions at the end of the salmon’s ocean residency period can be important, as indicated by the effect of the 1983 El Niño on the size and fecundity of Central Valley fall-run Chinook salmon (Wells et al. 2006). Although the effects of ocean conditions on Chinook salmon growth and survival have not been investigated extensively, recent observations since 2007 have shown a significant decline in the abundance of adult Chinook salmon and coho salmon returning to California rivers and streams (fall-run adult returns to the Sacramento and San Joaquin rivers were the lowest on record [Pacific Fishery Management Council 2008]) that has been hypothesized to be the result of declines in ocean productivity and associated high mortality rates during the period when these fish were rearing in near-shore coastal waters (MacFarlane et al. 2008). The importance of changes in ocean conditions on growth, survival, and population abundance of Central Valley Chinook salmon is currently undergoing further investigation.

A4.4 LIFE HISTORY

The following life history information was summarized primarily from the Final Restoration Plan for the Anadromous Fish Restoration Program (2001).

Chinook salmon exhibit two characteristic freshwater life history types (Healey 1991). Stream-type adult Chinook salmon enter freshwater months before spawning, and their offspring reside in freshwater one or more years following emergence. Ocean-type Chinook salmon, in contrast, spend significantly less time in freshwater: spawning soon after entering freshwater as adults and migrating to the ocean as juvenile fry or parr within their first year. Adequate stream flows and cool water temperatures are more critical for the survival of Chinook salmon exhibiting the stream-type life history behaviors due to their residence in freshwater both as adults and juveniles over the warmer summer months.

Central Valley fall-run Chinook salmon exhibit an ocean-type life history. Adult fall-run Chinook salmon migrate through the Delta and into Central Valley rivers from July through December and spawn from October through December (see Table A-4a). Peak spawning activity usually occurs in October and November. The life history characteristics of late fall-run Chinook salmon are not well understood; however, they are thought to exhibit an ocean-type life history. Adult late fall-run Chinook salmon migrate through the Delta and into the Sacramento River from October through April and may wait one to three months before spawning from January through April (Table A-4b). Peak spawning activity occurs in February and March. Chinook salmon typically mature between 2 and 6 years of age (Myers et al. 1998). The majority of Central Valley fall-run Chinook salmon spawn at age 3.

Information on the migration rates of Chinook salmon in freshwater is scant, most of which is taken from the Columbia River basin where migration behavior information is used to assess the effects of dams on salmon travel times and passage (Matter et al. 2003). Adult Chinook salmon upstream migration rates ranged from 29 to 32 km per day in the Snake River, a Columbia River tributary (Matter et al. 2003). Keefer et al. (2004) found migration rates of adult Chinook salmon in the Columbia River ranging between approximately 10 km per day to greater than 35 km per day. Adult Chinook salmon with sonic tags have been tracked throughout the Delta and the lower Sacramento and San Joaquin rivers (CALFED Science Program 2001).

These fish exhibited substantial upstream and downstream movement in a random fashion while migrating upstream several days at a time. Adult salmonids migrating upstream, particularly larger salmon such as Chinook, as described by Hughes (2004), are assumed to make greater use of pool and mid-channel habitat than they are of channel margins (Stillwater Sciences 2004). Adult salmon are thought to exhibit crepuscular behavior during their upstream migrations, primarily migrating during twilight hours (Hallock et al. 1970).

Chinook salmon spawn in clean, loose gravel in swift, relatively shallow riffles; or along the margins of deeper river reaches where suitable water temperatures, depths, and velocities favor redd construction and oxygenation of incubating eggs. Chinook salmon spawning typically occurs in gravel beds located at the tails or downstream ends of holding pools (U.S. Fish and Wildlife Service [USFWS] 1995). Egg incubation for Central Valley fall-run Chinook salmon begins with spawning in October and can extend into March. Egg incubation for late fall-run salmon occurs from January through June.

Fry emergence generally occurs at night. Upon emergence from the gravel, fry swim or are displaced downstream (Healey 1991). Fry seek streamside habitats containing beneficial aspects such as riparian vegetation and associated substrates that provide aquatic and terrestrial invertebrates, predator avoidance cover, and slower water velocities for resting (NMFS 1996). These shallow water habitats have been described as more productive juvenile salmon rearing habitat than the deeper main river channels. Higher juvenile salmon growth rates, partially due to greater prey consumption rates, as well as favorable environmental temperatures have been associated with shallow water habitats (Sommer et al. 2001).

Central Valley fall-run Chinook salmon fry (i.e., juveniles shorter than two inches long) generally emerge from December through March, with peak emergence occurring by the end of January. In general, fall-run Chinook salmon fry abundance in the Delta increases following high winter flows. Most fall-run Chinook salmon fry rear in freshwater from December through June, with emigration as smolts occurring from April through June (see Table A-4a). Smolts that arrive in the estuary after rearing upstream migrate quickly through the Delta and Suisun and San Pablo Bays. A very small number (generally considered less than 5 percent) of fall-run juveniles spend over a year in fresh water and emigrate as yearling smolts the following November through April.

Central Valley late fall-run Chinook salmon fry generally emerge from April through June. Late fall-run fry rear in freshwater from April through the following April and emigrating as smolts from November through April (see Table A-4b). Juvenile fall-run Chinook salmon outmigration through the Delta is thought to be primarily a diurnal activity, whereas outmigration of juvenile late fall-run salmon through the Delta is thought to occur primarily at night (Wilder and Ingram 2006). There are a variety of possible explanations for the difference in diel activity between races, including size of fish, water temperature, flow rate, and water clarity during downstream migration. Once downstream movement has commenced, individuals may continue this movement until reaching the estuary or they may reside in the stream for a time period that varies from a few weeks to a few months (Healey 1991). Juvenile Chinook salmon migration rates vary considerably and likely depend on physiological stage of the fish and hydrologic conditions. Kjelson et al. (1982) found Chinook salmon fry traveled downstream as fast as 30 km per day in the Sacramento River. Sommer et al. (2001) found rates ranging from approximately 1 km to greater than10 km per day in the Yolo Bypass. As juvenile Chinook salmon grow, they move into deeper water with higher current velocities, but still seek shelter and velocity refugia to minimize energy expenditures (Healey 1991). Catches of juvenile salmon in the Sacramento River near West Sacramento by the USFWS (1997) indicate that larger juveniles were captured in the main channel and smaller sized fry along the channel margins. Where the river channel is greater than 9 to 10 feet in depth, juvenile salmon tend to inhabit the surface waters (Healey 1980). Stream flow and/or turbidity increases in the upper Sacramento River basin are thought to stimulate juvenile emigration (Kjelson et al. 1982, Brandes and McLain 2001).

As Chinook salmon begin to smolt (i.e., make the physiological changes necessary for life in salt water), they are found rearing further downstream where ambient salinity reaches 1.5 to 2.5 parts per thousand (Healey 1980, Levy and Northcote 1981, USFWS unpubl. data). Within the Delta, juvenile Chinook salmon forage in shallow areas with protective cover, such as tidally influenced sandy beaches and shallow vegetated zones (Meyer 1979, Healey 1980). Cladocerans, copepods, amphipods, and dipteran larvae dipteral, as well as small arachnids and ants, are common prey items (Kjelson et al. 1982, Sommer et al. 2001).

Juvenile Chinook salmon movements within the estuarine habitat are dictated by the interaction between tidally driven saltwater intrusions through the San Francisco Bay and fresh water outflow from the Sacramento and San Joaquin rivers. Juvenile Chinook salmon follow rising tides into shallow water habitats from the deeper main channels, and return to the main channels when the tides recede (Levy and Northcote 1981, Healey 1991). Juvenile Chinook salmon were found to spend about 40 days migrating through the Delta to the mouth of San Francisco Bay and grew little in length or weight until they reached the Gulf of the Farallones Islands (MacFarlane and Norton 2002). Based on the mainly ocean-type life history observed (i.e., fall-run Chinook salmon), MacFarlane and Norton (2002) concluded that unlike other salmonid populations in the Pacific Northwest, Central Valley Chinook salmon smolts currently show little estuarine dependence and may benefit from expedited ocean entry. However, this may not be the case for emigrating fry that rear for a longer period within the Delta and estuary before emigrating to coastal marine waters. In addition, it has been hypothesized that changes in habitat conditions within the Delta over the past century may have resulted in a reduction in extended juvenile salmon rearing when compared to periods during which habitat for juvenile fall-run and late fall-run salmon rearing was more suitable.

Central Valley Chinook salmon begin their ocean life in the coastal marine waters of the Gulf of the Farallones from where they distribute north and south along the continental shelf primarily between Point Conception and Washington State (Healey 1991). Upon reaching the ocean, juvenile Chinook salmon feed on larval and juvenile fishes, plankton, and terrestrial insects (Healey 1991, MacFarlane and Norton 2002). Chinook salmon grow rapidly in the ocean environment with growth rates dependent on water temperatures and food availability (Healey 1991). The first year of ocean life is considered a critical period of high mortality for Chinook salmon that largely determines survival to harvest or spawning (Beamish and Mahnken 2001, Quinn 2005).

Recovery of coded-wire tagged Chinook salmon from the Feather River Hatchery in the ocean recreational and commercial fisheries (Pacific States Marine Fisheries Commission Regional Mark Information System database) indicates that Central Valley fall-run Chinook salmon adults are broadly distributed along the Pacific Coast from Northern Oregon to Monterey. Recovery of late fall-run coded-wire tagged Chinook salmon from the Coleman Hatchery in the ocean recreational and commercial fisheries (Pacific States Marine Fisheries Commission Regional Mark Information System database) indicates that Central Valley late fall-run Chinook salmon adults are the most broadly distributed along the Pacific Coast of the Central Valley salmon, ranging from British Columbia to Monterey.

Like other ocean-type Chinook salmon, Central Valley fall- and late fall-run Chinook salmon remain near the coast throughout their ocean life (Healey 1983, 1991, Myers et al. 1984). Central Valley fall- and late fall-run Chinook salmon remain in the ocean for 2 to 5 years. Fall-run Chinook salmon mature in the ocean before returning to freshwater to spawn. Late fall-run Chinook salmon may return to freshwater as immature adults as indicated by a 1 to 3 month delay in spawning once reaching the spawning grounds.

A4.5 THREATS AND STRESSORS

The following have been identified as important threats and stressors to fall- and late fall-run Chinook salmon (without priority). Additionally, recent record low numbers of fall-run Chinook salmon adult returns to the Central Valley (Pacific Fishery Management Council 2008) suggest that ocean conditions may be an important stressor to the ESU (MacFarlane et al. 2008), although the mechanisms driving this potential effect are not well understood.

Reduced staging and spawning habitat. Access to the upper extent of the historical upstream spawning habitat for fall- and late fall-run Chinook salmon (see Figures A-4a and A-4b, respectively) has been eliminated or degraded by man-made structures (e.g., dams and weirs) associated with water storage and conveyance, flood control, and diversions and exports for, municipal, industrial, agricultural, and hydropower purposes (Yoshiyama et al. 1998). Because spawning locations of fall- and late fall-run Chinook salmon are typically in the lower reaches of rivers, fall-/late fall-run Chinook salmon have been less affected by dam construction relative to other Central Valley salmonids. Spawning habitat for fall- and late fall-run Chinook salmon is still widely distributed within the Sacramento River basin, but more limited within the San Joaquin River basin.

Upstream diversions and dams have decreased downstream flows and altered the seasonal hydrologic patterns. These factors have been identified as contributing to delays in upstream migration by adults, increased mortality of out-migrating juveniles, and responsible for making some streams uninhabitable by fall-/late fall-run salmon (Yoshiyama et al. 1998, California Department of Water Resources [DWR] 2005). Dams and reservoir impoundments and associated reductions in peak flows have blocked gravel recruitment and reduced flushing of sediments from existing gravel beds, reducing and degrading natal spawning grounds. Further, reduced flows can lower attraction cues for adult spawners, causing straying and delays in spawning (DWR 2005). Adult salmon migration delays can reduce fecundity and increase susceptibility to disease and harvest (McCullough 1999) Because fall-run Chinook salmon spawn shortly after entering freshwater, a delay in migration can have large impacts to pre-spawning mortality and spawning success relative to other races of Chinook salmon.

The RBDD located on the Sacramento River has been identified as a barrier and impediment to adult upstream migration. Although the RBDD is equipped with fish ladders, migration delays were reported when the dam gates are closed. Mortality as a result of increased predation by Sacramento pikeminnow on juvenile salmon passing downstream through the fish ladder has also been identified as a factor affecting abundance of salmon produced on the Sacramento River (Hallock 1991). To help reduce the effects of dam operation on migration of adult and juvenile salmonids and other species, management changes have occurred in recent years to maintain the dam gates in the open position for a longer period of time, facilitating greater upstream and downstream migration. Changes in dam operations have benefited both upstream and downstream migration and have contributed to a reduction in juvenile predation mortality.

Reduced rearing and out-migration habitat. Natural migration corridors for juvenile fall- and late fall-run Chinook salmon consist of a mosaic of complex habitat types, including stream banks, floodplains, marshes, and shallow water areas which are used as rearing habitat during out-migration. Much of the Sacramento and San Joaquin river corridor and Delta have been leveed, channelized, and modified with riprap for flood protection, thereby reducing and degrading the quality and availability of natural habitat for rearing and emigrating juvenile Chinook salmon (Brandes and McLain 2001). Juvenile out-migration delays associated with man-made passage impediments can reduce fitness and increase susceptibility to diversion screen impingement, entrainment, disease, and predation. Modification of natural flow regimes from upstream reservoir operations has resulted in dampening of the hydrograph, reducing the extent and duration of seasonal floodplain inundation and other flow-dependent habitat used by migrating juvenile Chinook salmon (70 FR 52488, Sommer et al. 2001, DWR 2005). Recovery of floodplain habitat in the Central Valley has been found to contribute to increases in production in Chinook salmon (Sommer et al. 2001). Reductions in flow rates have resulted in increased water temperature and residence time, and reduced dissolved oxygen levels in localized areas of the Delta (e.g., Stockton Deep Water Ship Channel). Reduced dissolved oxygen levels in the San Joaquin River during summer and fall have been identified as a water quality barrier to salmon migration (Central Valley Regional Water Quality Control Board 2007).

Predation by non-native species. Predation on juvenile salmon by non-native fish has been identified as an important threat to fall- and late fall-run Chinook salmon in areas with high densities of non-native fish (e.g., small and large mouth bass, striped bass, and catfish) that prey on out-migrating juvenile salmon (Lindley and Mohr 2003). Non-native aquatic vegetation, such as Brazilian waterweed and water hyacinth, provide suitable habitat for non-native predators (Nobriga et al. 2005, Brown and Michniuk 2007). Predation risk may covary with increased temperatures. Metabolic rates of non-native, predatory fish increase with increasing water temperatures based on bioenergetic studies (Loboschefsky et al. 2009, Miranda et al. 2010). Upstream gravel pits and flooded ponds attract non-native predators because of their depth and lack of cover for juvenile salmon (DWR 2005). The low spatial complexity and reduced habitat diversity (e.g., lack of cover) of channelized waterways within the rivers and Delta reduces refuge space of salmon from predators (Raleigh et al. 1984, Missildine et al. 2001, 70 FR 52488). A major concern is the potential invasion of the Delta by the highly predatory northern pike. The pike, recently present in Lake Davis on the Feather River, is currently the target of a major eradication effort (DFG 2007a). If eradication fails and pike escape downstream to the Delta, they would likely be present in areas inhabited by fall- and late fall-run Chinook salmon.

Predation by native species, such as the Sacramento pikeminnow, in the Sacramento River at locations such as the RBDD has also been identified as a potentially significant source of mortality on juvenile salmonids.

Harvest. Commercial or recreational harvest of fall- and late fall-run Chinook salmon populations in the ocean and inland fisheries has been a subject of management actions by the California Fish and Game Commission and the Pacific Fishery Management Council. Coastal marine waters offshore of San Francisco Bay are a mixed stock fishery comprised of both wild and hatchery produced salmon. As a result of differences in survival rates for eggs incubation, rearing, and emigration, juvenile salmon produced in streams and rivers have relatively low survival rates compared to Central Valley salmon hatcheries, which have relatively high survival rates. Therefore, naturally reproducing Chinook salmon populations are less able to withstand high harvest rates compared to hatchery-based stocks (Knudsen et al. 1999). The ocean fishery for fall- and late fall-run Chinook salmon is supplemented by hatchery enhancement programs (USFWS 1999, Williams 2006). The Coleman National Fish Hatchery produces approximately 12 million fall-run and one million late fall-run Chinook salmon juveniles each year to mitigate for habitat loss from construction of Shasta and Keswick dams (Williams 2006). Fall-run Chinook salmon are also produced at hatcheries on the Feather, American, Mokelumne, and Merced rivers (Williams 2006). Harvest as a result of the commercial and recreational fisheries may ultimately be having detrimental effects to wild spawners in this mixed stock fishery, but few data are available. Commercial fishing for salmon is managed by the Pacific Fishery Management Council and is constrained by time and area to meet the Sacramento River winter-run ESA consultation standard and restrictions requiring minimum size limits and use of circle hooks for anglers.

Beginning in 2007, Central Valley hatcheries have implemented a proportional marking program (tagging a set percentage of salmon produced in each hatchery) that is designed to provide improved information on the effects of harvest on various stocks of Chinook salmon. The program also provides information on ocean migration patterns, growth and survival for fish released at various lifestages and locations, the contribution of hatcheries to the adult population, straying among hatcheries and watersheds, the relative contribution of in-river versus hatchery production, and other data that will assist managers in refining harvest regulations. Results of coded wire tag (CWT) mark-recapture studies and data from the proportional marking program are continually being reviewed and analyzed each year and used to modify harvest regulations and Central Valley salmon management.

Reduced genetic diversity/integrity. Artificial propagation programs (hatchery production) for fall- and late fall-run Chinook salmon in the Central Valley present multiple threats to wild (in-river spawning) Chinook salmon populations, including genetic introgression by hatchery origin fish that spawn naturally and interbreed with local wild populations (USFWS 2001, U.S. Bureau of Reclamation [USBR] 2004, Goodman 2005). It is now recognized that Central Valley hatcheries are a significant and persistent threat to wild Chinook salmon and steelhead populations and fisheries (NMFS 2009a). Interbreeding with hatchery fish contributes directly to reduced genetic diversity and introduces maladaptive genetic changes to the wild population (DFG 1995, CALFED 2004, Myers et al. 2004, Araki et al. 2007). In addition, releasing hatchery smolts downstream of hatcheries has resulted in an increase in straying rates, further reducing genetic diversity among populations (Williamson and May 2005). Central Valley hatcheries are currently undergoing a detailed review by NMFS and DFG as part of a comprehensive hatchery master plan process. Various techniques and actions have been identified for reducing the effects of hatchery production on the genetic characteristics of Chinook salmon as part of the hatchery review. These include, but are not limited to, seasonally selecting brood stock for use in the hatchery in proportion to adult escapement to the river, selecting brood stock from various age classes (including grilse) that represents the age structure of the wild population, use of tagging and genetic testing to select brood stock, increasing the number of adults used as brood stock to increase genetic diversity, reduce interbasin transfer of eggs and fry, and imprinting juveniles to reduce straying among watersheds. These and other hatchery management methods (e.g., reduction of the use of antibiotics, juvenile release strategies to reduce impacts to wild rearing juveniles, volitional releases, etc.) are expected to reduce the potential risk of hatchery production on the genetics and success of wild populations; however, artificial selection for traits that assure individual success in a hatchery setting (e.g., rapid growth and tolerance to crowding) are difficult to avoid (USBR 2004).

The potential for inter-breeding between Central Valley spring- and fall-run salmon stocks is generally identified as a genetic concern (Yoshiyama et al. 1998), however some studies indicate no evidence of natural hybridization among Chinook salmon runs despite the spatial and temporal overlap (Banks et al. 2000). Spring- and fall-run Chinook salmon were historically isolated in time and space during spawning; however, the construction of dams and reduction in flows has eliminated access to historical spawning areas of spring-run salmon in the upper tributaries and streams, forcing spring-run salmon to spawn in lower elevation areas also used by fall-run salmon (Yoshiyama et al. 1998). Although hybridization between spring- and fall-run salmon has been identified as a particular concern on the Feather River where both runs co-occur and as a potential concern for future restoration of salmon on the San Joaquin River downstream of Friant Dam, the genotypic proportions in the Butte Creek spring-run cluster farther from the fall-run versus the spring-run from Deer and Mill creeks, not closer as expected under the hybridization hypothesis (Banks et al. 2000). Deer and Mill creeks, as many of the other Central Valley tributaries, has a reduced risk of hybridization by the ability of the runs to segregate geographically within the watersheds.

Entrainment. The vulnerability of fall- and late fall-run Chinook salmon to entrainment and salvage at the SWP and CVP export facilities varies in response to multiple factors, including the seasonal and geographic distribution of juvenile salmon within the Delta, operation of Delta Cross Channel gates and Head of Old River Barrier, hydrodynamic conditions occurring within the central and southern regions of the Delta (e.g., Old and Middle rivers), and export rates. The losses of fish to entrainment mortality has been identified as an impact to Chinook salmon populations (Kjelson and Brandes 1989). Juvenile fall-run Chinook salmon tend to be distributed within the central and southern Delta where they have an increased risk of entrainment/salvage between January and April (see Table A-4a). Juvenile late fall-run Chinook salmon tend to be distributed within the Delta primarily between December and January and again between April and May (see Table A-4b). The effect of changing hydrodynamics within Delta channels, such as reversed flows in Old and Middle rivers resulting from SWP and CVP export operations, has the potential to increase attraction of emigrating juveniles into false migration pathways, delay emigration through the Delta, and directly or indirectly increase vulnerability to entrainment at unscreened diversions, risk of predation, and the duration of exposure to seasonally elevated water temperatures and other water quality conditions. SWP and CVP exports have been shown to affect the tidal hydrodynamics (e.g., water current velocities and direction). The magnitude of these hydrodynamic effects vary in response to a variety of factors that include the tidal stage and magnitude of ebb and flood tides, the rate of SWP and CVP exports, operation of the Clifton Court Forebay radial gate opening, and inflow from the upstream tributaries. Chinook salmon behaviorally respond to hydraulic cues (e.g., water currents) during both upstream adult and downstream juvenile migration through the Delta. During the past several years additional investigations have been designed using radio or acoustically-tagged juvenile Chinook salmon to monitor their migration behavior through the Delta channels and assess the effects of changes in hydraulic cues and SWP and CVP export operations on migration (Holbrook et al. 2009, Perry et al. 2010, San Joaquin River Group Authority 2010). These studies are ongoing

Besides direct mortality, salmon fitness may be affected by entrainment at diversions and delays in out-migration of smolts caused by reduced or reverse flows. Delays in migration due to water operations related to SWP and CVP export facilities can make juvenile salmonids more susceptible to many of the threats and stressors discussed in this section, such as predation, entrainment, harvest, exposure to toxins, etc. The quantitative relationships among changes in Delta hydrodynamics, the behavioral and physiological response of juvenile salmon, and the increase or decrease in risk associated with other threats is unknown, but the subject of a number of current investigations and analyses.

In addition to SWP and CVP exports, over 2,200 small water diversions exist throughout the Delta, in addition to unscreened diversions located on the tributary rivers (Herren and Kawasaki 2001). The risk of entrainment is a function of the size of juvenile fish and the slot opening of the screen mesh (Tomljanovich et al. 1978, Schneeberger and Jude 1981, Zeitoun et al. 1981, Weiserg et al. 1987, C. Hanson unpubl. data). Many of the juvenile salmon migrate downstream through the Delta during the late winter or early spring when many of the agricultural irrigation diversions are not operating or are only operating at low levels. Juvenile salmon also migrate primarily in the upper part of the water column and, as a result, their vulnerability to an unscreened diversion located near the channel bottom is reduced. No quantitative estimates have been developed to assess the potential magnitude of entrainment losses for juvenile Chinook salmon migration through the rivers and Delta, or the effects of these losses on the overall population abundance of returning adult fall-run and late fall-run Chinook salmon. Many of the larger water diversions located within the Central Valley and Delta (e.g., Glenn Colusa Irrigation District, Reclamation District 108 Wilkins Slough and Poundstone pumping plants, Sutter Mutual Water Company Tisdale pumping plant, Contra Costa Water District Old River and Alternaitve Intake Project intake, and others) have been equipped with positive barrier fish screens to reduce and avoid the loss of juvenile Chinook salmon and other fish species.

Power plants within the Plan Area have the ability to impinge juvenile Chinook salmon on the existing cooling water system intake screens. However, use of cooling water is currently low with the retirement of older units. Further, newer units are being equipped with a closed cycle cooling system that virtually eliminates the risk of impingement of juvenile salmon.

Exposure to toxins. Toxic chemicals have the potential to be wide spread throughout the Delta, or may occur on a more localized scale in response to episodic events (stormwater runoff, point source discharges, etc.). These toxic substances include mercury, selenium, copper, pyrethroids, and endocrine disruptors with the potential to impact fish health and condition, and adversely impact salmon distribution and abundance. Concern regarding exposure to toxic substances for Chinook salmon includes waterborne chronic and acute exposure, as well as bioaccumulation and chronic dietary exposure. For example, selenium is a naturally occurring constituent in agricultural drainage water return flows from the San Joaquin River that is subsequently dispersed downstream into the Delta (Nichols et al. 1986). Exposure to selenium in the diet of juvenile Chinook salmon has been shown to result in toxic effects (Saiki 1986, Hamilton et al. 1986, 1990, Saiki and Lowe 1987, Hamilton and Buhl 1990). Selenium exposure has been associated with agricultural and natural drainage within the San Joaquin River basin and refining operations adjacent to San Pablo and San Francisco bays. Other contaminants of concern for Chinook salmon include, but are not limited to: mercury, copper, oil and grease, pesticides, herbicides, and ammonia. As a result of the extensive agricultural development within the Central Valley, exposure to pesticides and herbicides has been identified as a significant concern for salmon and other fish species within the Plan Area (Bennett et al. 2001). Mercury and other metals such as copper have also been identified as contaminants of concern for salmon and other fish as a result of direct toxicity and tissue bioaccumulation adversely impacting fish (U.S. Environmental Protection Agency [EPA] 2006), as well as representing a human health concern

(Gassel et al. 2008). These materials originate from a variety of sources including mining operations, municipal wastewater treatment, agricultural drainage within the tributary rivers and Delta, non-point runoff, natural runoff and drainage within the Central Valley, agricultural spraying, and a number of other sources. The State Water Resources Control Board (SWRCB), Central Valley Regional Water Quality Control Board (CVRWQCB), U.S. EPA, U.S. Geological Survey (USGS), DWR, and others have ongoing monitoring programs designed to characterize water quality conditions and identify potential toxicants and contaminant exposure to Chinook salmon and other aquatic resources within the Plan Area. Programs are in place to regulate point source discharges as part of the National Pollutant Discharge Elimination System (NPDES) as well as programs to establish and reduce total daily maximum loads (TMDL) of various constituents entering the Delta. Changes in regulations have also been made to help reduce chemical exposure and reduce the adverse impacts to aquatic resources and habitat conditions within the Plan Area. These monitoring and regulatory programs are ongoing.

Sublethal concentrations of toxins may interact with other stressors to cause adverse effects to salmonids, such as increasing their vulnerability to mortality as a result of exposure to seasonally elevated water temperatures, predation, or disease (Werner 2007). For example, Clifford et al. (2005) found in a laboratory setting that juvenile fall-run Chinook salmon exposed to sublethal levels of a common parathyroid, esfenvalerate, were more susceptible to infectious hematopoietic necrosis virus than those not exposed to esfenvalerate. Juvenile Chinook salmon have a relatively extended period of Delta and estuarine residence of several months (Quinn 2005), which increases exposure and susceptibility to toxic substances in these areas. Adult migrating Chinook salmon may be less affected by these toxins because they are not feeding, and thus not bioaccumulating toxic exposure, and they are moving rapidly through the system.

Iron Mountain Mine, located adjacent to the upper Sacramento River, has been a source of trace elements and metals that are known to adversely affect aquatic organisms (Upper Sacramento River Fisheries and Riparian Habitat Advisory Council 1989). Storage limitations and limited availability of dilution flows have caused downstream copper and zinc levels to exceed salmonid tolerances and resulted in documented fish kills in the 1960s and 1970s (USBR 2004). The Environmental Protection Agency's Iron Mountain Mine remediation program has removed toxic metals in acidic mine drainage from the Spring Creek watershed with a state-of-the-art lime neutralization plant. Contaminant loading into the Sacramento River from Iron Mountain Mine has shown measurable reductions since the early 1990s.

Increased water temperature. Water temperature is among the physical factors that affect quality of habitat for salmonid adult holding, spawning and egg incubation, juvenile rearing, and migration. Adverse sublethal and lethal effects can result from exposure to elevated water temperatures at sensitive lifestages, such as during incubation or rearing. The Central Valley is the southern limit of Chinook salmon geographic distribution. As a result, increased water temperatures are often recognized as a particularly important stressor to California populations. Water temperature criteria for various lifestages of salmonids in the Central Valley have been developed by NMFS (2009). The tolerance of fall-run and late fall-run Chinook salmon to water temperatures depends on life stage, acclimation history, food availability, duration of exposure, health of the individual, and other factors such as predator avoidance (Myrick and Cech 2004, USBR 2004). Higher water temperatures can lead to physiological stress, reduced growth rate, delayed passage, *in vivo* egg mortality of spawning adults, pre-spawning mortality, reduced spawning success, and increased mortality of salmon (Myrick and Cech 2001). Temperature can also indirectly influence disease incidence and predation (Waples et al. 2008). Exposure to seasonally elevated water temperatures may occur as a result of reductions in flow as a result of upstream reservoir operations, reductions in riparian vegetation, channel shading, local climate and solar radiation. The installation of the Shasta Temperature Control Device in 1998, in combination with reservoir management to maintain the cold water pool, has reduced many of the temperature issues on the Sacramento River. During dry years, however, the release of cold water from Shasta Dam is still limited. As the river flows further downstream, particularly during the warm spring, summer, and early fall months, water temperatures continue to increase until they reach thermal equilibrium with atmospheric conditions. As a result of the longitudinal gradient of seasonal water temperatures, the coldest water and, therefore, the best areas for salmon spawning and rearing are typically located immediately downstream of the dam.

Increased temperature can also arise from a reduction in shade over rivers by tree removal (Watanabe et al. 2005). Because river water is typically in thermal equilibrium with atmospheric conditions by the time it enters the Delta, this issue is caused primarily from actions upstream of the Delta. As a result of the relatively wide channels that occur within the Delta, the effects of additional riparian vegetation on reducing water temperatures are minimal. The effects of climate change and global warming patterns, in combination with changes in precipitation and seasonal hydrology in the future have been identified as important factors that may adversely affect the health and long-term viability of Central Valley spring-run Chinook salmon (Crozier et al. 2008). The rate and magnitude of these potential future environmental changes, and their effect of habitat quality and availability for fall- and late fall-run Chinook salmon, however, are subject to a high degree of uncertainty.

A4.6 RELEVANT CONSERVATION EFFORTS

Results of salvage monitoring and extensive experimentation over the past several decades have led to identification of a large number of management actions designed to reduce or avoid the potentially adverse impacts of SWP and CVP export operations on salmon. Many of these actions have been implemented through SWRCB water quality permits (D-1485, D-1641), biological opinions issued on project export operations by NMFS, USFWS, and DFG, as part of CALFED programs such as the Environmental Water Account (EWA), and as part of CVPIA actions. As a result of these requirements, multiple conservation efforts exist to reduce entrainment of Chinook salmon by the SWP and CVP export facilities.

Several habitat problems that contributed to the decline of Central Valley salmonid species are being addressed and improved through restoration and conservation actions related to Endangered Species Act (ESA) Section 7 consultation, Reasonable and Prudent Alternatives, addressing temperature, flow, and operations of the Central Valley and State Water Projects, the Central Valley Regional Water Board decisions requiring compliance with Sacramento River water temperature objectives that resulted in installation of the Shasta Temperature Control Device in 1998, and EPA actions to control acid mine runoff from Iron Mountain Mine.

Biological opinions for SWP and CVP operations (e.g., NMFS 2009b) and other federal projects involving irrigation and water diversion and fish passage, for example, have improved or minimized adverse impacts to salmon in the Central Valley. In 1992, an amendment to the authority of the CVP through the Central Valley Project Improvement Act was enacted to give protection of fish and wildlife equal priority with other Central Valley Project objectives. From this act arose several programs that have benefited listed salmonids. The Anadromous Fish Restoration Program (AFRP) is engaged in monitoring, education, and restoration projects designed to contribute toward doubling the natural populations of select anadromous fish species residing in the Central Valley. Restoration projects funded through the AFRP include fish passage, fish screening, riparian easement and land acquisition, development of watershed planning groups, instream and riparian habitat improvement, and gravel replenishment. The Anadromous Fish Screen Program combines federal funding with state and private funds to prioritize and construct fish screens on major water diversions mainly in the upper Sacramento River. The goal of the Water Acquisition Program is to acquire water supplies to meet the habitat restoration and enhancement goals of the Central Valley Project Improvement Act (CVPIA), and to improve the ability of the U.S. Department of the Interior to meet regulatory water quality requirements. Water has been used to improve fish habitat for Central Valley salmon, with the primary focus on listed Chinook salmon and steelhead that provide incidental benefits to fall-run and late fall-run Chinook salmon by maintaining or increasing instream flows (Environmental Water Account) on the Sacramento River and the San Joaquin River at critical times, and to reduce salmonid entrainment at the SWP and CVP export facilities through reducing seasonal diversion rates during periods when protected fish species are vulnerable to export related losses.

Two programs included under CALFED, the Ecosystem Restoration Program (ERP) and the Environmental Water Account (EWA), were created to improve conditions for fish, including fall-run and late fall-run Chinook salmon, in the Central Valley. Restoration actions implemented by the ERP include the installation of fish screens, modification of barriers to improve fish passage, habitat acquisition, and instream habitat restoration. The majority of these actions address key factors and stressors affecting listed salmonids that incidentally benefit fall-run and late fall-run Chinook salmon. Additional ongoing actions include efforts to enhance fishery monitoring, and improvements to hatchery management to support salmonid production through hatchery releases.

A major CALFED ERP action currently underway is the Battle Creek Salmon and Steelhead Restoration Project. The project will restore 48 miles (77 km) of habitat in Battle Creek to support steelhead and Chinook salmon spawning and juvenile rearing at a cost of over $90 million. The project includes removal of five small hydropower diversion dams, construction of new fish screens and ladders on another three dams, and construction of several hydropower facility modifications to ensure the continued hydropower operations. It is thought that this restoration effort is the largest cold water restoration project to date in North America.

The Delta Regional Ecosystem Restoration Implementation Plan (DRERIP) was formed to guide the implementation of CALFED ERP elements within the Delta (DFG 2007b). The DRERIP team has created a suite of ecosystem and species conceptual models, including fall-/late fall-run Chinook salmon, that document existing scientific knowledge of Delta ecosystems. The DRERIP team has used these conceptual models to assess the suitability of actions proposed in the ERP for implementation. DRERIP conceptual models were used in the analysis of proposed BDCP conservation measures.

The Vernalis Adaptive Management Program (VAMP) has implemented migration flow augmentation for the San Joaquin River basin to improve juvenile and adult migration for fall-run Chinook salmon (San Joaquin River Group Authority 2010). The VAMP program also includes seasonal reductions in SWP and CVP export rates and installation of the Head of Old River Barrier to further improve the survival of downstream migrating salmon. The program has been designed within the framework of adaptive management to improve the survival of juvenile salmon migrating from the river through the Delta while also providing an experimental framework to quantitatively evaluate the contribution of each action to fall-run Chinook salmon survival. Preliminary results of the VAMP survival studies have shown evidence that juvenile Chinook salmon survival is positively correlated with San Joaquin River flows during the spring emigration period, however no statistically significant relationship between juvenile salmon survival and SWP/CVP exports has been detected. The range of flows and SWP/CVP export rates that can be tested under the VAMP experimental design is relatively small (e.g., river flows from approximately 2000 to 7000 cfs with SWP and CVP export rates ranging from 1500 to 3000 cfs). In addition, during the experimental period installation of the Head of Old River Barrier has been precluded by federal court order to protect delta smelt. As a result of these and other factors, the level of additional protection that the VAMP has provided to naturally produced Chinook salmon during emigration downstream from the San Joaquin River and Delta, and the incremental contribution of the VAMP conditions to overall salmon survival and adult abundance, is uncertain. The VAMP experimental design and results of survival testing conducted to date is currently undergoing peer review and will also be the subject of a review conducted by the SWRCB. Based on results and recommendations from these technical reviews, the VAMP experimental design and testing program, as well as flow management for juvenile salmon migration on the San Joaquin River, is expected to be refined.

A4.7 RECOVERY GOALS

Because fall-run and late fall-run Chinook salmon are not listed for protection under either the federal or California ESA formal recovery goals will not be established. As part of other fishery management programs, such as the CVPIA and the SWRCB salmon doubling goal, goals and objectives have been established for Central Valley Chinook salmon.

APPENDIX A5. DELTA SMELT *(HYPOMESUS TRANSPACIFICUS)*

A5.1 LEGAL STATUS

The U.S. Fish and Wildlife Service (USFWS) determined that delta smelt warranted listing as a threatened species under the federal Endangered Species Act (ESA) effective April 5, 1993. The listing decision was based on a substantial reduction in delta smelt abundance within the Bay-Delta estuary in a variety of fishery sampling programs, threats to its habitat, and the inadequacy of regulatory mechanisms to protect delta smelt (58 FR 12863). The delta smelt was listed as a threatened species under the California ESA on December 9, 1993. The Sacramento-San Joaquin Delta Native Fishes Recovery Plan, which includes delta smelt, was completed in 1996 (USFWS 1996). The recovery plan identified a number of specific criteria related to delta smelt abundance and geographic distribution that had to be met as a condition for assessing whether the species could be considered to have recovered and be eligible for potential de-listing. During the late 1990s and early 2000s, delta smelt met the criteria set out in the recovery plan. In response to several law suits, the USFWS conducted a five-year status review for delta smelt and, on March 31, 2004, concluded that delta smelt abundance remained relatively low compared to historical levels and that many of the threats to the species identified at the time of listing were still in existence, precluding de-listing of the species (USFWS 2004). Subsequent indices of delta smelt abundance based on results of California Department of Fish and Game (DFG) fishery sampling have shown that the abundance of delta smelt, in addition to other pelagic fish species, has declined substantially in recent years (collectively referred to as pelagic organism decline [POD]), reaching record low levels of abundance. In March 2006, the Center for Biological Diversity, the Bay Institute, and the Natural Resources Defense Council filed an emergency petition with USFWS requesting that the status of delta smelt be elevated from threatened to endangered under the federal ESA (Center for Biological Diversity et al. 2006). The emergency petition was not approved by USFWS. However, the USFWS on July 10, 2008 announced in a 90-day finding that consideration for reclassification of delta smelt was warranted and, after an information collection stage, a status review would be initiated (73 FR 39639). On April 7, 2010, the USFWS ruled that the change in status from threatened to endangered was warranted, but precluded by other higher priority listing actions (75 FR 17667).

An emergency petition was filed in February 2007 to the California Fish and Game Commission to elevate the status of delta smelt from threatened to endangered under the California ESA (the Bay Institute et al. 2007). On March 4, 2009, the California Fish and Game Commission elevated the status of delta smelt to endangered under the California ESA.

A5.2 SPECIES DISTRIBUTION AND STATUS

A5.2.1 Range and Status

Delta smelt are endemic to the Bay-Delta estuary (see Figure A-5a) (Moyle 2002). The geographic distribution of delta smelt occurs primarily downstream of Isleton on the Sacramento River, downstream of Mossdale on the San Joaquin River, and Suisun Bay and Suisun Marsh. Delta smelt have also been collected in the Petaluma and Napa rivers. Delta smelt adults occur primarily in the tidally influenced low salinity region of Suisun Bay and the freshwater regions of the Delta and the Sacramento and San Joaquin rivers (Moyle 2002). The downstream location of the low salinity habitat for delta smelt is typically located in Suisun Bay, extending further to the west in response to high delta outflows and further to the east in response to low delta outflows. Delta smelt have been collected in Carquinez Strait, the Napa River, and even as far downstream as San Pablo Bay in wet years (Moyle 2002). In September or October, adults begin upstream movement towards freshwater sloughs and channels of the western Delta to spawn. Spawning takes place between February and July, but appears to be greatest during mid-April and May (Bennett 2005). Spawning can occur in the Sacramento River as far upstream as Sacramento, the Mokelumne River system, and the Cache Slough region (Moyle 2002). Since 1982, the center of adult delta smelt abundance in the fall has been the northwestern Delta in the channel of the Sacramento River near Decker Island. In any month, two or more life stages (adult, larvae, and juveniles) of delta smelt have the potential to be present in Suisun Bay (Wang 1991, DWR and USBR 1994, Moyle 2002). Delta smelt are also found seasonally in Suisun Marsh.

Results of multiple long-term monitoring programs that include a variety of sampling methods have consistently shown that the abundance of delta smelt inhabiting the Bay-Delta system has been extremely low since 2001 (see Figure A-5b). The observed decline in delta smelt abundance is consistent with declines of other pelagic species in the Delta. The decline in pelagic fish species abundance within the estuary has prompted a large set of investigations funded by the Interagency Ecological Program (IEP), CALFED, and other sources to identify and examine various factors that may be causing these declines (Resources Agency 2007). Indices of delta smelt abundance in the fall, as reflected in the DFG fall mid-water trawl (FMWT) surveys were the lowest on record in 2006 (see Figure A-5b).

A5.2.2 Distribution and Status in the Plan Area

Delta smelt occur throughout the Delta, Suisun Bay and Suisun Marsh, and within the Napa and Petaluma rivers (see Figure A-5a). Multiple permanent sites sampled by DFG and USFWS using many different collection methods intended to sample various life history stages of delta smelt provide a basis for examining trends in abundance of delta smelt under different hydrologic conditions as well as the temporal and geographic distribution of the species within and among years (see Figure A-5c).

DRAFT

Figure A-5a. Delta Smelt Inland Range in California

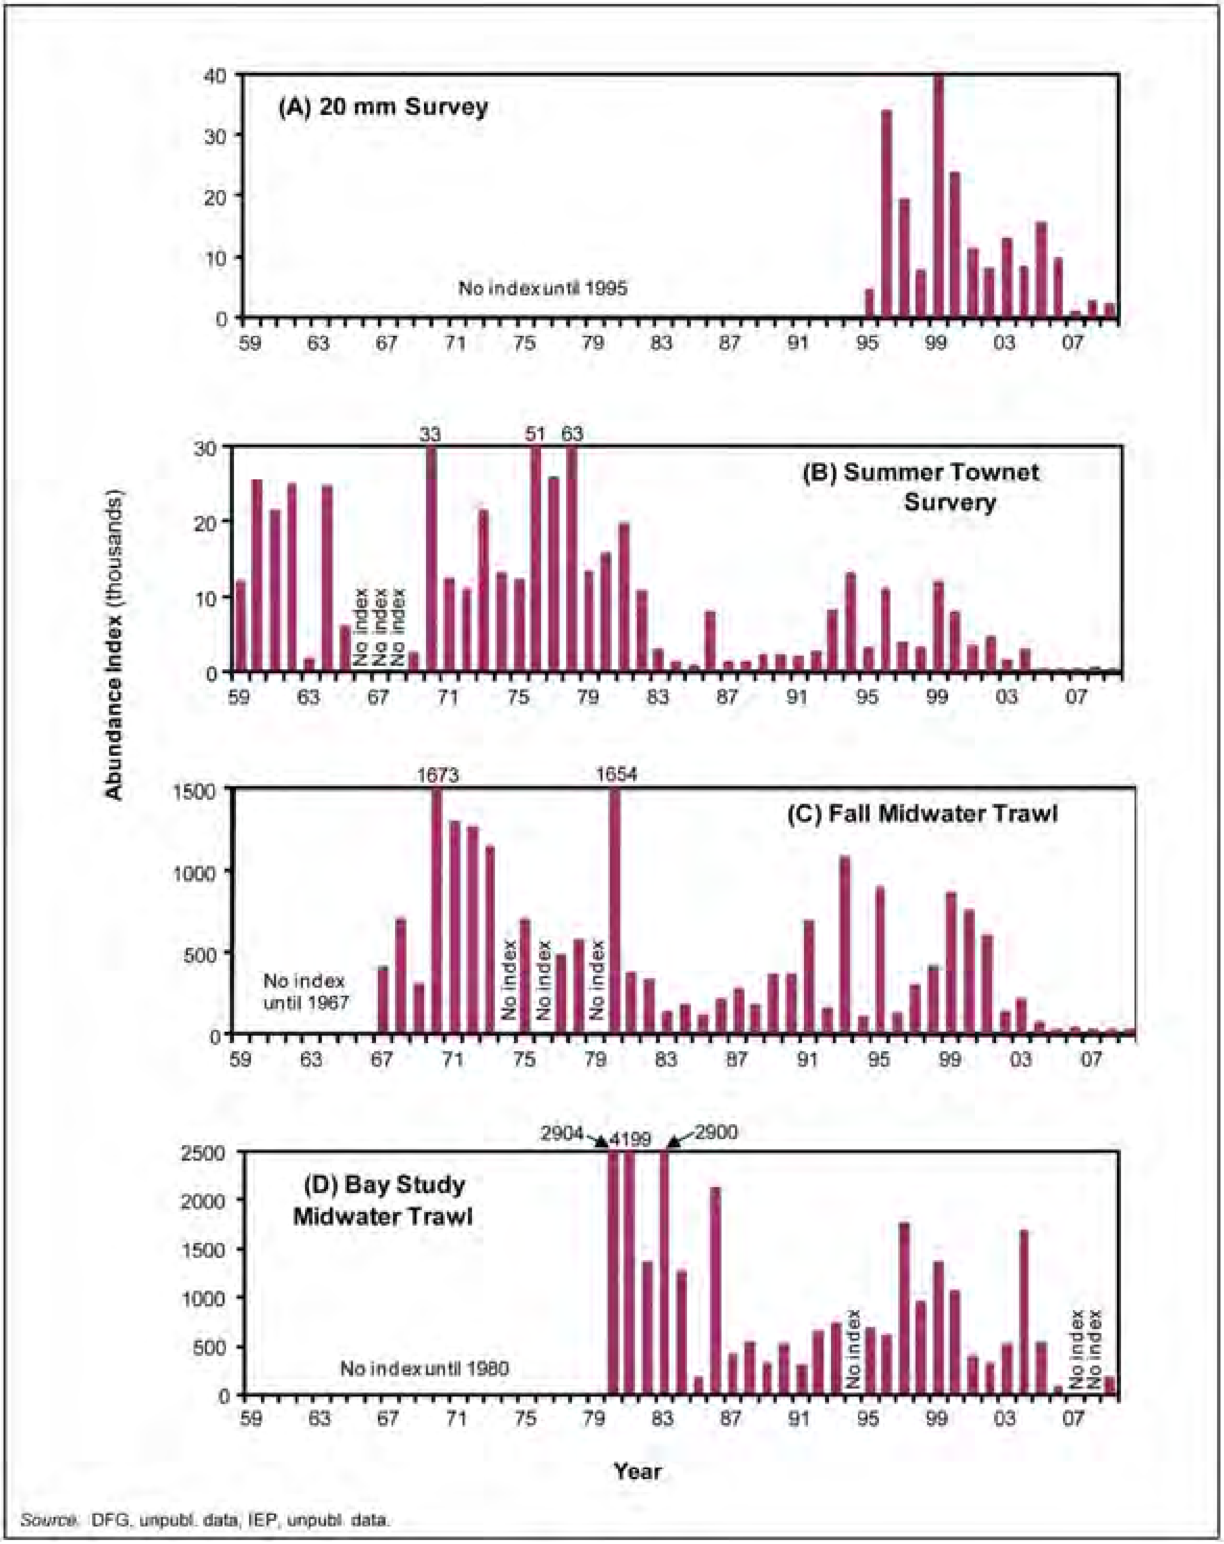

Figure A-5b. Annual Abundance Indices of Delta Smelt from 1959-2009 in (A) 20-mm Trawl Survey, (B) Summer Townet Survey, (C) Fall Midwater Trawl, and (D) Bay Study Midwater Trawl

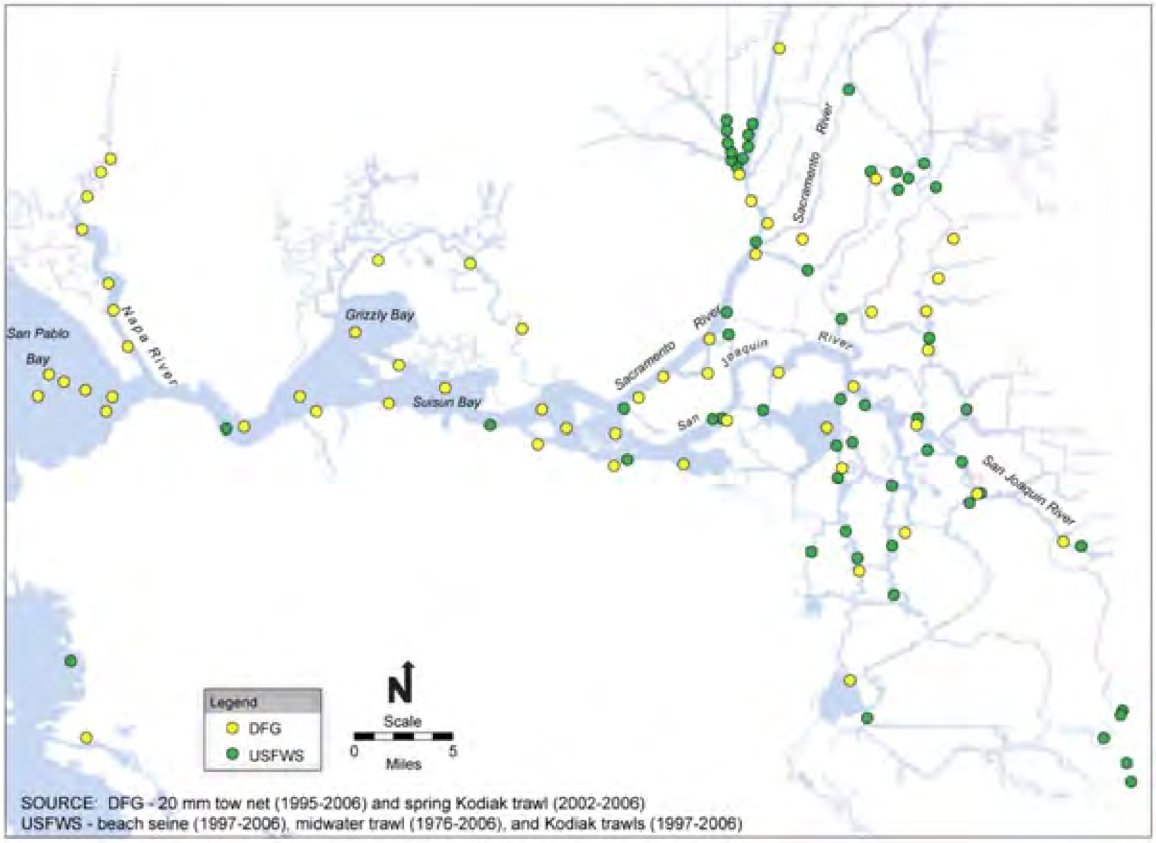

Figure A-5c. Historical Sampling Locations where Delta Smelt Have Been Captured Since 1976

Results of these fishery surveys, in addition to past records and habitat conditions for delta smelt, have been used to determine the current trends in abundance (see Figure A-5b). Trends in all four indices shown in Figure A-5b indicate that delta smelt population size has been at historical lows over the past several years.

Recent evidence suggests that a fairly large proportion of the delta smelt population over-summers in the Cache Slough region (Sommer et al. 2009). It is suspected that turbidity and prey abundance in the region are sufficient to preclude young delta smelt to migrate downstream towards the south and western Delta.

A5.3 HABITAT REQUIREMENTS AND SPECIAL CONSIDERATIONS

Critical habitat was designated by USFWS for the delta smelt under the federal ESA effective January 18, 1995 (59 FR 65256). The designated critical habitat extends throughout Suisun Bay (including Grizzly and Honker bays), the length of Goodyear, Suisun, Cutoff, first Mallard and Montezuma sloughs, and the contiguous waters of the legal Delta (see Figure A-5d) (59 FR 65256).

DRAFT

Figure A-5d. Delta Smelt Designated Critical Habitat

Designation of critical habitat for delta smelt was intended to provide additional protection under section 7 of the ESA with regard to activities that require federal agency action.

Delta smelt inhabit the low salinity (brackish water/fresh water interface) waters in the upper Bay-Delta estuary. Bennett (2005) found that over 90 percent of juvenile and pre-adult delta smelt caught in the DFG Summer Townet Survey and DFG Fall Midwater Trawl Survey, respectively, were collected in salinities lower than 6 practical salinity units (psu) (Bennett 2005).

Because the location of the low salinity zone is determined by the interaction of river outflow and tidal inflow of marine water from San Francisco Bay, the daily distribution of adult delta smelt can vary by many kilometers (Bennett 2005) in response to the tidal dynamics of the estuary. The location of the low salinity zone during the late winter and spring (e.g., February-June), commonly referred to as the X2 location (location of the 2 parts per thousand [ppt] bottom salinity isohaline), has been used as an indicator of habitat conditions for delta smelt and other estuarine fish and macroinvertebrates. The location of X2, which varies seasonally and inter-annually, is used as one of the parameters in assessing the effects of changes in freshwater outflow on estuarine habitat conditions.

Delta smelt are most often collected in shallow, low-salinity water upstream of the low salinity zone (about 0.5-6 psu) (Kimmerer 2004), except during spawning (K. Fleming, DFG, pers. comm.). Moyle et al. (1992) reported that delta smelt were collected primarily from waters with a mean salinity of 2 ppt and having a mean temperature of 15 °C (59 °F), but were found in salinities ranging from 0-14 ppt and at temperatures ranging from 6 °C to 23 °C (43 °F to 73 °F). A correlation has also been observed between the geographic distribution and occurrence of sub-adult and adult delta smelt in the State Water Project (SWP) and Central Valley Project (CVP) fish salvage and turbidity within the Delta (D. Fullerton unpubl. data.). Sub-adult and adult delta smelt densities are positively correlated with turbidity. Two hypotheses have been suggested for the observed correlation that include: (1) greater feeding ability; and (2) greater predator avoidance in higher turbidity. Delta smelt larvae require high microzooplankton densities during the spring months to support rapid growth and development (Miller 2007).

A5.4 LIFE HISTORY

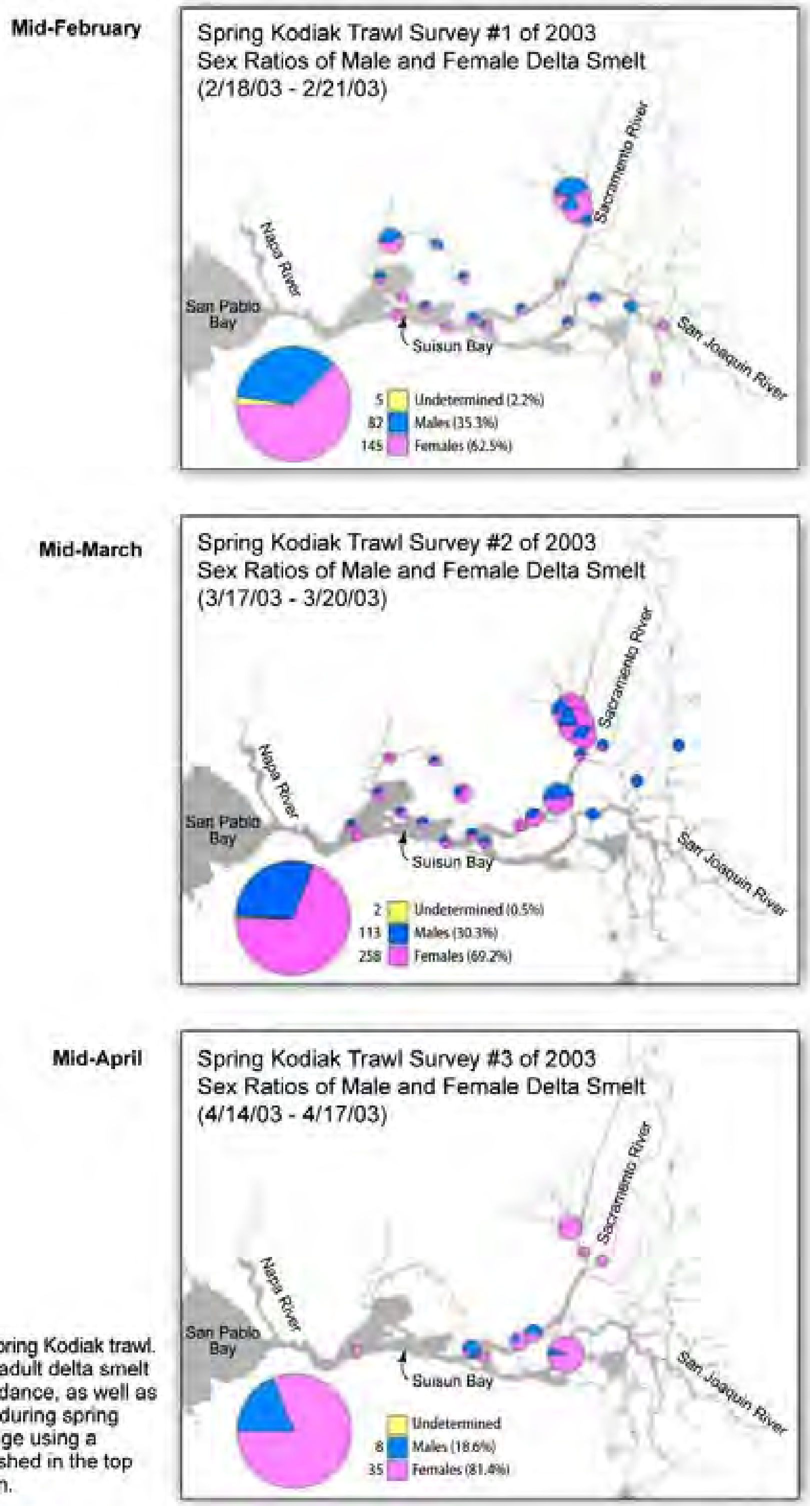
Delta smelt inhabit open surface waters of the Delta and Suisun Bay, where they may gather together in loose aggregations. Delta smelt are semi-anadromous, spawning in freshwater areas within the Delta and tributaries (the exact spawning location of delta smelt is unknown) from February to July at water temperatures ranging from approximately 7°C to 22°C (45°F to 72°F; Wang 1986, Bennett 2005). Shortly before spawning, adult smelt migrate upstream to disperse widely into river channels and tidally-influenced backwater sloughs (Radtke 1966, Wang 1991, Moyle 2002). Although the exact location of delta smelt spawning is unknown, sampling of larval smelt in the Delta suggests spawning occurs in the Sacramento River, Barker, Lindsey, Cache, Georgiana, Prospect, Beaver, Hog, and Sycamore sloughs, in the San Joaquin River off Bradford Island including Fisherman's Cut, False River along the shore zone between Frank's and Webb tracts, and possibly other areas (Wang 1991). Recent DFG sampling has suggested that spawning is often centered in Cache Slough and the lower end of the Sacramento Deep-Water Ship Channel (DFG 2007a). Although delta smelt spawning behavior has not been observed in the wild (Moyle et al. 1992), it is thought that their adhesive, demersal eggs attach to substrates such as cattails, tules, tree roots, and submerged branches in shallow waters (Wang 1991, Moyle 2002). Laboratory experiments indicate that delta smelt spawn mainly at night, broadcasting their eggs while swimming against the current. Cultured delta smelt broadcast eggs mainly over gravel, but preferred substrates in the wild are unknown. Eggs incubate from eight to fifteen days, depending upon water temperature (Bennett 2005). Temperatures that are optimal for survival of embryos and larvae have not yet been determined, although survival of newly spawned larvae and older delta smelt appear to decrease at temperatures over 20 °C (68 °F) (Swanson and Cech 1995, Bennett 2005). Delta smelt of all sizes are found in the main channels of the Delta and Suisun Marsh and the open waters of Suisun Bay, where the waters are well oxygenated and temperatures are relatively cool, usually lower than 20-22 °C (68-72 °F) in summer. Although delta smelt tolerate a wide range of temperatures (less than 6 °C [43 °F] to greater than 25 °C [77 °F]), warmer water temperatures restrict their distribution more than colder water temperatures (Swanson and Cech 1995). Over 90 percent of juvenile and pre-adult delta smelt caught in the DFG Summer Townet Survey and DFG FMWT Survey, respectively, were collected at water temperatures lower than 20 °C (68 °F; Bennett 2005). When not spawning, delta smelt tend to concentrate near the low salinity zone, where primary productivity and zooplankton densities are typically greatest (Knutson and Orsi 1983, Orsi and Mecum 1986). Other than newly hatched larvae, all life stages of delta smelt are found in greatest abundance in the top 2 m of the water column and are not usually in close association with the shoreline (Moyle 2002).

Newly hatched delta smelt larvae have a large oil globule that makes them semi-buoyant, allowing the larvae to maintain themselves just off the bottom (R. Mager, unpublished data), where they feed on rotifers and other microscopic prey. Once the swim bladder develops, larvae become more buoyant and rise higher in the water column. It is thought that, at this stage (16-18 mm total length), delta smelt take advantage of tidal flows to move downstream until they reach the low salinity zone or the area immediately upstream of it. Net downstream flows are thought to be important for physical transport of planktonic larval delta smelt towards suitable rearing habitat in the western Delta and Suisun Bay. Prior to 2004, intermediate outflow years tended to produce the greatest abundance of delta smelt, although production was highly variable among years and in response to environmental conditions such as Delta outflow (Moyle 2002, Bennett 2005). It has been hypothesized that very low flows into and through the Delta were insufficient to transport larvae downstream to suitable rearing habitat where sufficient food resources were available to support growth and development. It has also been hypothesized that very high delta outflows may have flushed larval delta smelt downstream into the western region of Suisun Bay or San Pablo Bay where larval and juvenile rearing conditions and habitat suitability are reduced. In recent years, however, low flows appear to provide better habitat conditions for delta smelt than in earlier years (Bennett pers. comm. 1).

Feeding success is highly dependent upon prey densities (Nobriga 2002). Miller and Mongan (2006) have shown a strong correlation between the spatial and temporal co-occurrence of early lifestages of delta smelt and densities of suitable zooplankton for forage and subsequent delta smelt abundance at older lifestages. Growth is rapid and juveniles grow to 40-50 mm total length by early August (Erkkila et al. 1950; Ganssle 1966; Radtke 1966). Delta smelt reach 55-70 mm standard length in 7-9 months (Moyle 2002). Growth during the next 3 months slows down considerably (only 3-9 mm total), presumably because most of the energy ingested is directed towards gonadal development (Erkkila et al. 1950; Radtke 1966).

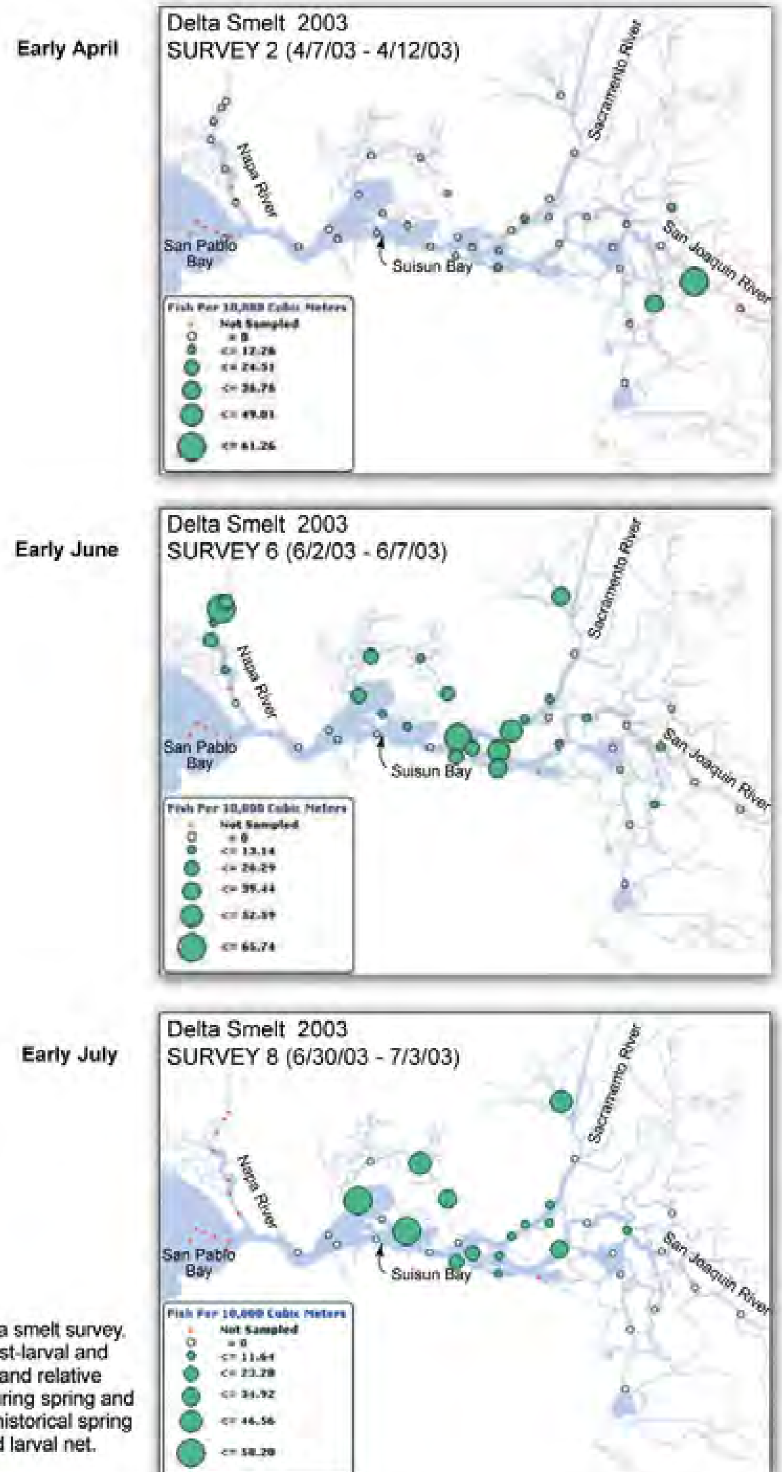
Yearly surveys by DFG (e.g., spring Kodiak trawl and 20 mm survey) provide the ability to track the geographic distribution of delta smelt within the estuary. Kodiak trawls target adult spawning delta smelt in spring months; the 20 mm townet survey targets post-larval and juvenile delta smelt from approximately March-August. Spatial patterns in the abundance of adults from the Spring Kodiak trawl and post-larval/juveniles from the 20 mm survey are shown in Figures A-5e and A-5f, respectively, based on sampling results from surveys conducted in 2003, which was a normal water year. Results of fishery surveys suggest that the geographic distribution of pre-spawning adult delta smelt in the winter and early spring does not vary substantially in response to seasonal and inter-annual variation in inflows to the Delta. Instead, it has been hypothesized that the distribution of pre-spawning delta smelt is a response to staging and foraging prior to spawning and associations with suitable habitat conditions, such as substrate, for spawning. The geographic distribution of larval and early juvenile lifestages of delta smelt appears to be influenced by freshwater inflows to the Delta during the late winter and spring. It has been hypothesized that higher Delta inflows result in faster larval planktonic transport rates from the upstream spawning habitat to the downstream estuarine portions of the Delta. In addition, when Delta inflows are high, the location of the low salinity zone is further west (downstream) and larval and early juvenile delta smelt are frequently observed further downstream within Suisun Bay. Fecundity of delta smelt is relatively low. Mager (1996) reported a length/fecundity range spanning 1,196 eggs for a 56-mm female to 1,856 eggs for a 66-mm female. Captive-reared females may be more fecund than the same size wild female; however, the variability in the length-fecundity relationship also appears to be greater for captive females (B. Baskerville-Bridges, pers. comm. as cited in Bennett 2005). The abrupt change from a single-age, adult cohort during spawning in spring to a population dominated by juveniles in summer suggests strongly that most adults die after they spawn (Radtke 1966, Moyle 2002). However, a small unknown fraction of the adult delta smelt population may survive to become two-year-old fish and spawn in the subsequent year (Moyle 2002). It has been hypothesized that because of their larger size and increased fecundity, two-year-old adults may exert a small or intermittent, but important, reproductive influence in years following poor recruitment (Bennett 2005).

In a near-annual fish like delta smelt, maximizing recruitment success is vital to the long-term persistence of the population. However, investigations using the Beverton-Holt model have found that stock-recruitment relationships accounted for only approximately one quarter of the variability observed in recruitment (Sweetnam and Stevens 1993, Bennett 2005).



Source: DFG 2003, 20 mm Spring Kodiak trawl. This annual survey monitors adult delta smelt distribution and relative abundance, as well as sex ratio and gonadal stage, during spring throughout their historical range using a variable mesh Kodiak trawl fished in the top 6 feet (1.8 m) of water column. For more information see http://www.delta.dfg.ca.gov/data/skt/

Figure A-5e. Example of Distribution of Adult Delta Smelt in Spring-Summer of a Representative Above Normal Water Year



Source: DFG 2003, 20 mm delta smelt survey. This annual survey monitors post-larval and juvenile delta smelt distribution and relative abundance every two weeks during spring and early summer throughout their historical spring range using a 1600 µm egg and larval net. For more information see http://www.delta.dfg.ca.gov/data/20mm/description.asp

Figure A-5f. Example of Distribution of Post-Larval/Juvenile Delta Smelt in Spring-Summer of a Representative Above Normal Water Year

The weak stock-recruitment relationship does indicate, however, that factors affecting the numbers of spawning adults (e.g., entrainment, toxics, and predation) can influence delta smelt abundance (cohort strength) the following year.

Results of more recent evaluations suggest that density-dependent mortality may influence the number of juveniles that reach pre-adulthood in some years, even at the current low level of abundance (Bennett 2005).

Delta smelt feed primarily on planktonic copepods, cladocerans, amphipods, and, to a lesser extent, on insect larvae. Larger delta smelt may also feed on the mysid shrimp, *Neomysis*. The most important food organism for all sizes of delta smelt appears to be the euryhaline copepod, *Eurytemora*, although the non-native *Pseudodiaptomus* has become a major part of the diet since its introduction (Moyle et al. 1992, Nobriga 2002). Nobriga (2002) noted that decades-long declines in the abundance of zooplankton prey organisms such as *Eurytemora* and *Pseudodiaptomus* indicate that delta smelt prey densities have also declined. Recent unpublished analyses by Miller and Mongan (2006) suggest that a decline in the co-occurrence of juvenile delta smelt and their prey may have contributed to their decline in abundance.

A5.5 THREATS AND STRESSORS

There are multiple threats and stressors to delta smelt that appear to act in complicated and synergistic ways to influence the distribution and abundance of delta smelt (Moyle 2002). Individual stressors affect delta smelt at different times based on environmental conditions. Delta smelt are particularly vulnerable to these threats and stressors because of their short life span, low fecundity, low current abundance, and limited geographic range.

Reduced food availability. Reduced food availability in the Bay-Delta estuary has been identified as a major stressor to delta smelt (Resources Agency 2007). The co-occurrence of suitable food supplies (zooplankton) and various life stages of delta smelt (e.g., larval and juvenile life stages) as appears to be an important factor affecting delta smelt survival and abundance (Feyrer et al. 2007, Miller 2007). Histological examination of liver and other tissue collected from delta smelt has shown evidence of necrosis and pathology related to reduced foraging and depleted energy reserves. Furthermore, the size of delta smelt has declined through time. There are at least seven mechanisms briefly described here (without priority) that potentially contribute to the observed reduction in zooplankton prey densities.

First, levee construction, island reclamation, and channelization within the Delta has resulted in a substantial reduction in intertidal and shallow-water subtidal wetland/emergent marshes and open water habitat throughout the Delta. Historically, Delta wetlands and shallow-water habitat was expansive and provided large areas of estuarine and freshwater habitat that was highly productive. The significant reduction in tidal and shallow-water subtidal habitat, and an associated reduction in emergent vegetation, nutrient cycling, and the production of phytoplankton, zooplankton, macroinvertebrates, and other aquatic organisms that provide food resources for delta smelt has been identified as a major factor affecting habitat conditions within the Delta for species such as delta smelt.

Second, much of the seasonally inundated floodplain habitat in the Delta and tributary rivers has been eliminated by levees and reclamation. As a result of levee construction, flood control, and increased reservoir storage, the frequency of inundation on floodplains that still exist has been reduced (Resources Agency 2007). Floodplains are highly productive due to their shallow, warm, low velocity water (Sommer et al. 2001a, b) and input of organic material and nutrients from the terrestrial community (Booth et al. 2006). Floodplains are a key source of nutrients and organic material for the Bay-Delta estuary (Sommer et al. 2001a, Harrell and Sommer 2003).

Third, hydraulic residence time in the Delta has declined as a result of increased channelization and passage of Sacramento River water through the Delta Cross Channel into the central and southern Delta to meet water quality standards and supplies for the SWP and CVP exports. The decreased hydraulic residence time reduces the time available for production of phytoplankton and zooplankton that provide food for delta smelt and other aquatic species and for bacteria to use nutrients and organic carbon (Jassby et al. 2002, Kimmerer 2002a, 2004, Resources Agency 2007).

Fourth, the presence of non-native species has reduced the abundance of food available to delta smelt. The efficient filter feeding and high abundance of the overbite clam has dramatically reduced phytoplankton and zooplankton abundance in Suisun Bay, the western Delta, and Suisun Marsh since its introduction in the mid 1980s (Kimmerer and Orsi 1996). The Asian clam has also reduced phytoplankton abundance in the Delta, which likely reduced zooplankton abundance (Jassby et al. 2002, Thompson 2007). Other non-native zooplanktivores that likely compete for limited available food resources with delta smelt include threadfin shad, inland silverside, and wakasagi.

Fifth, the zooplankton community inhabiting the Bay-Delta estuary has changed multiple times since the 1970s as non-native species have established and outcompeted other zooplankton species (Resources Agency 2007, Sommer 2007). These changes in the zooplankton species composition have affected the quality of food resources available to delta smelt because some of the non-native species do not appear to be as suitable a food resource as the native species (Resources Agency 2007). Most recently, *Limnoithona*, a non-native cyclopoid copepod, invaded the Delta. This copepod is smaller than preferred forage species, *Pseudodiaptomus* and *Eurytemora* (Lott 1998), may be protected from predators by spines (Orsi and Ohtsuka 1999), and, therefore, is thought to be lower quality food for delta smelt (Resources Agency 2007). Preliminary laboratory work by Sullivan et al. (2007, 2008) indicates that larval delta smelt consume these copepods according their size. Also, adult delta smelt, which are larger and need greater amounts of food, may prefer the larger *Pseudodiaptomus* and *Eurytemora* over *Limnoithona*. A decrease in foraging efficiency and/or the availability of suitable prey for various lifestages of delta smelt would result in reduced growth, survival, and reproductive success contributing to reduced population abundance.

Sixth, SWP and CVP exports and the over 2,200 in-Delta agricultural diversions (Herren and Kawasaki 2001) export phytoplankton, zooplankton, nutrients, and organic material that would otherwise support the base of the food web in the Delta, thus reducing food availability for delta smelt (Jassby and Cloern 2000, Resources Agency 2007).

Seventh, it has been hypothesized that exposure of phytoplankton and zooplankton to toxics (e.g., pesticides, herbicides) that enter the Delta from point and non-point sources contribute to the observed low abundance of zooplankton prey species for delta smelt and other species inhabiting the Bay-Delta (Weston et al. 2004, Luoma 2007, Werner 2007). In addition to direct impacts of toxics on delta smelt, such as liver damage and other pathologic symptoms, the indirect effect of toxics on reducing zooplankton and phytoplankton abundance is thought to result in reduced availability of food resources for delta smelt.

Municipal wastewater treatment plants, particularly the Sacramento Regional County Sanitation District's wastewater treatment plant, discharges high loads of ammonia directly into the Sacramento River in the North Delta (Jassby 2008). Results of a recent investigations suggest that high concentrations of ammonium, the ionized form of ammonia, can inhibit diatom production in San Francisco and San Pablo bays (Wilkerson et al. 2006, Dugdale et al. 2007), which could disrupt the foodweb, ultimately resulting in reduced food for delta smelt and other Delta fish species. The source of this ammonium in the bays is unknown, but could come from wastewater treatment plants. Recent preliminary investigations have also examined the role of ammonium in inhibiting freshwater diatom production in the Delta, although results are inconclusive (Parker and Dugdale 2008).

Reduced rearing habitat. Availability of rearing habitat for delta smelt is less dependent on physical substrate and more dependent on water column conditions. There is evidence that the availability and suitability of delta smelt rearing habitat varies with location of the low salinity zone, measured as X2 (Moyle et al. 1992) , although there is no long-term trend indicating that X2 has changed nor is there strong evidence that X2 predicts delta smelt abundance (Armor et al. 2006). Guerin et al. (2006) reported correlations between reductions in fall delta outflow, salinity changes, and indices of delta smelt abundance. State Water Board Decision 1641 (D1641, State Water Resources Control Board [SWRCB] 2000) establishes criteria for maintenance of X2 at specific locations within Suisun Bay and the western Delta by month and water year type. The maintenance of this standard substantially affects when water can be exported from the Delta at the CVP and SWP pumps. SWP and CVP exports were reduced to protect aquatic resources in the spring with a resulting increase in export operations during the summer and fall.

The location of the low salinity zone within Suisun Bay and the western Delta varies in response to the magnitude of freshwater outflow from the Delta and saltwater intrusion from San Francisco and San Pablo bays. The low salinity zone, when positioned over shallow water shoal areas in Suisun Bay in response to Delta outflows, is thought to result in highly productive conditions (Moyle et al. 1992, Bennett et al. 2002, Kimmerer 2004, Bennett 2005). Aasen

(1999) observed higher abundance of delta smelt in shallow water shoal habitat compared to adjacent deep water channels and Hobbs et al. (2006) found evidence that the health and survival of delta smelt were greater in habitats associated with shallow water. When located upstream of the confluence of the Sacramento and San Joaquin rivers, however, the low salinity zone is confined to the deep river channels, resulting in a smaller total surface area, few shoal areas, swifter, more turbulent water currents, and lower zooplankton productivity (USFWS 2004).

Feyrer et al. (2007) developed an index of fall habitat quality for delta smelt based on statistical regression models of delta smelt catches in DFG fishery sampling at specific sampling locations throughout the Delta and Suisun Bay and water quality parameters (salinity, turbidity, and water temperature) measured for each sample. There is substantial debate over whether this index is meaningful to the delta smelt population.

As the geographic distribution of delta smelt shifts upstream with X2, individuals may become more vulnerable to entrainment by the SWP and CVP export facilities and other diversions within the interior of the Delta.

The Suisun Marsh Salinity Control Gates function to decrease salinity in managed wetlands of Suisun Marsh to support crops that attract waterfowl to duck clubs located throughout the marsh. When in operation, generally from October through May, the control gates near Collinsville divert up to 2,500 cubic feet per second (cfs) of freshwater from upstream flows into the marsh. Because the minimum outflow standard during fall months is 5,000 cfs, a significant proportion of total Delta outflow (up to 50 percent) does not flow through the eastern Suisun Bay region. This diversion moves X2 upstream resulting in a measurable increase in salinity in eastern Suisun Bay, which may correspond to a decrease in low salinity habitat for delta smelt (Fullerton 2007)

Elevated water temperatures. Delta smelt are sensitive to exposure to elevated water temperatures (Swanson and Cech 1995). During the late spring, summer, and early fall months water temperatures within the central and southern regions of the Delta typically exceed 25 °C (77 °F), which has been found to be close to the incipient lethal temperature for delta smelt. During these warmer periods of the year, results of fishery sampling have shown that delta smelt avoid inhabiting the central and southern regions of the Delta and are typically located downstream in Suisun Bay and Suisun Marsh. It is generally thought that water temperatures within the Delta vary in response to seasonal air temperatures and solar radiation, and are largely independent of freshwater inflow to the Delta during the summer months (flow rate has been identified as a factor affecting water temperatures in the rivers; however, the influence decreases with distance downstream in the lower rivers and Delta). As a result of coastal fog and marine conditions along the coast and within San Francisco Bay, water temperatures during the summer typically decrease within Suisun Bay when compared to conditions further upstream within the Delta. Although water temperatures are cooler within Suisun Bay during the summer months, water temperatures in excess of 20 °C (68 °F) are typical. Under these warmer summer conditions, delta smelt rearing in Suisun Bay and Suisun Marsh would be stressed by exposure to elevated water temperatures and experience higher metabolic demands and a greater demand for food supplies to maintain individual health and a positive growth rate. Stresses experienced by rearing delta smelt during the warmer summer months, which include the synergistic effects of salinity and seasonally elevated water temperatures, have been hypothesized to be a potentially significant factor affecting delta smelt survival, abundance, and subsequent reproductive success within the Bay-Delta estuary.

Reduced turbidity. Delta smelt appear to have specific turbidity requirements that can influence predation risk and foraging efficiency. Turbidity is a significant predictor of delta smelt occurrence in the Delta (Feyrer et al. 2007, Resources Agency 2007, Nobriga et al. 2008, Grimaldo et al. 2009). That is, delta smelt occurrence increases with higher turbidity. Fullerton (unpubl. data) has demonstrated a correlation between the occurrence of delta smelt and elevated levels of turbidity (above approximately 12 nephelometric turbidity units). It is thought that delta smelt require turbidity for both successful foraging (Baskerville-Bridges et al. 2004) and predator escape (Feyrer et al. 2007), and that turbidity is an important cue for delta smelt spawning migrations (Grimaldo et al 2009). Results of laboratory studies indicate that, in low turbidity waters, delta smelt move to the edge of aquaria and stop swimming, presumably to reduce vulnerability to predation (D. Fullerton unpubl. data). Results of laboratory studies have also demonstrated that delta smelt reduce or stop foraging when turbidity is low and actively forage when turbidity is increased. It was hypothesized that increased turbidity levels provide a more favorable background and contrast that allows delta smelt a better opportunity to detect and effectively capture zooplankton prey.

Turbidity levels have declined in the Bay-Delta estuary since the 1970s (Kimmerer 2004, Wright and Schoellhamer 2004, Feyrer et al. 2007, Fullerton 2007). This trend can be attributed to multiple causes. First, upstream sediment inputs have been reduced due to a range of anthropogenic actions (Jassby et al. 2002, Kimmerer 2004), including depletion of erodable sediments from hydraulic mining in the 1800s, river bank protection, trapping of sediments by dams and reservoirs, levee construction that has reduced floodplain inundation and channel meanders, and changes in land use (Wright and Shoellhamer 2004). Wright and Shoellhamer (2004) estimated that the yield of suspended sediments from the Sacramento River declined by approximately one half from 1957 to 2001.

Second, the distribution and abundance of non-native aquatic plant species, particularly Brazilian waterweed (*Egeria*), have increased dramatically over the past 20 years (Nobriga et al. 2005, Brown and Michniuk 2007). Brazilian waterweed can reduce turbidity by reducing local water velocities and trapping fine suspended sediments (Grimaldo and Hymanson 1999, Nestor et al. 2003, Hobbs et al. 2006).

Third, the high filtering efficiency of the overbite clam has dramatically reduced phytoplankton and zooplankton abundance in the western Delta and Suisun Bay since its introduction (Kimmerer and Orsi 1996, Jassby et al. 2002, Kimmerer 2002b, 2004). The reduction in phytoplankton in the water column may contribute to increased water clarity and reduced turbidity in the Delta.

Fourth, hydraulic residence time in the Delta has declined as a result of increased channelization and the movement of water from the Sacramento River into the interior Delta channels to improve water quality and provide increased supplies to the SWP and CVP exports. SWP and CVP export operations have also directly resulted in changes in the hydrodynamics within Delta channels such as Old and Middle rivers which affect hydraulic residence time. Reduced hydraulic residence time reduces the ability of phytoplankton and bacteria to incorporate nutrients and carbon, ultimately reducing the abundance of these organisms in the water column (Jassby et al. 2002, Kimmerer 2002a, 2004, Resources Agency 2007). This reduction in phytoplankton and zooplankton abundance reduces the turbidity within the Bay-Delta estuary.

The observed reduction in Bay-Delta turbidity has the potential, in combination with other factors such as the effects of non-native species, to fundamentally alter the trophic dynamics of the estuary for species such as delta smelt.

Reduced spawning habitat. Although delta smelt spawning has not been observed within the Bay-Delta estuary, it is generally thought that spawning occurs in shallow, low-salinity upstream areas with sand or gravel substrate on which to deposit adhesive egg sacs (Moyle et al. 2004). Such habitat could occur in Cache Slough or in shallow shoals located in the Deep Water Ship Channel (Bennett 2007). The primary causes of reduced spawning habitat are believed to be reclamation, channelization, and riprapping of historical intertidal and shallow subtidal wetlands.

Non-native species. Predation by introduced species has been identified as a potential stressor on smelt populations (Sommer et al. 2007, Baxter et al. 2008), but the importance of predation on delta smelt abundance is thought to be low (Stevens 1966 as cited in Nobriga and Feyrer 2008, Feyrer et al. 2003, Nobriga and Feyrer 2007, 2008, Nobriga 2009a, Hanson 2009). There are several potential non-native fish predators of delta smelt that have been introduced into the Delta (Bennett 2005). Delta smelt have historically been a minor prey item of juvenile and subadult striped bass in the Delta (Stevens 1966, Bennett 2005), although predation does occur (M. Nobriga, pers. comm.). More recent studies indicate that delta smelt are rarely found in the stomachs of striped bass, largemouth bass or other nearshore predators (Feyrer and Nobriga 2008, Nobriga and Feyrer 2008). Delta smelt have also been reported from the stomach contents of white catfish and black crappie in the Delta (Turner and Kelley 1966). Threadfin shad and inland silversides, both planktivores, possibly eat delta smelt eggs, larvae, and small juveniles. Dense aggregations of silversides occur in shoreline habitats where delta smelt are thought to spawn and may consume delta smelt eggs and larvae (Bennett 2005). The largest single source of predation on delta smelt is thought to occur at or near the SWP and CVP south Delta pumping facilities (Sommer et al. 2007), and especially at Clifton Court Forebay. This predation is related to the number of smelt that are drawn to this area because of export-related changes in hydrology (Grimaldo et al. 2009, Kimmerer et al. 2009).

Competition with inland silversides could have a potentially large impact on delta smelt. Silversides are highly abundant throughout the delta smelt geographic range, their diet range encompasses that of delta smelt, and they spawn repeatedly throughout late spring, summer, and fall, thus providing silversides with a competitive advantage over delta smelt (Bennett 2005).

Wakasagi can occur in the delta smelt geographic range and have similar life requirements. Thus, they likely compete for food and spawning sites. Wakasagi have a higher tolerance to salinity and temperature and a wider geographic range than delta smelt, suggesting that they have a competitive advantage over delta smelt. Furthermore, the introduction of wakasagi has created the potential for a loss of genetic integrity of delta smelt, although the probability that hybridization could be successful is low (Moyle 2002). The two species are not closely related genetically and, although first generation hybrids have been collected, all of them have been sterile (Stanley et al. 1995, Trenham et al. 1998). If wakasagi abundance in delta smelt habitat were to increase dramatically, the risk of genetic introgression would be enhanced (Bennett 2005), although this does not appear to be a large concern at this time (K. Fisch pers. comm.). The recent decline in delta smelt abundance has likely made the species vulnerable to inbreeding and genetic drift, leading to decreased genetic variation and reduced evolutionary fitness (Center for Biological Diversity et al. 2006). However, no estimates currently exist for the minimum viable population size of delta smelt, nor have studies been conducted to evaluate changes in genetic diversity.

It has been hypothesized that the greatest impact of a non-native species on delta smelt is that resulting from colonization of the Bay-Delta estuary by the overbite clam. The clam has been identified as one of the major causes of the dramatic changes observed in the composition and abundance of the delta smelt zooplankton prey base. Because of its high filtration efficiency and dense populations in the western Delta and Suisun Bay, the clam has reduced phytoplankton and zooplankton abundance throughout the region (Kimmerer and Orsi 1996). The euryhaline copepod, *Eurytemora*, was historically the primary prey for all life stages of delta smelt. After the introduction of the overbite clam, the abundance of *Eurytemora* declined sharply, being replaced over much of its range by *Pseudodiaptomus* (Kimmerer and Orsi 1996, Bennett 2005). Although *Eurytemora* is still abundant during early spring, the population is replaced by *Pseudodiaptomus* in later spring, creating a period of low copepod abundance. Low food abundance can cause poor feeding success by larval and juvenile delta smelt, leading to slow growth, liver abnormalities associated with starvation, and, ultimately, reduced survival for cohorts that begin feeding during the period of low copepod abundance (Bennett 2005). In addition to the low copepod abundance period, *Pseudodiaptomus* are faster swimmers than *Eurytemora* and may lead to lower foraging efficiency, starvation, and reduced growth rates for delta smelt (Moyle 2002). Recent evidence suggests that the overbite clam may further negatively impact delta smelt by reducing their foraging efficiency by filtering large quantities of phytoplankton from the water column and increasing water clarity, potentially leading to the inability of delta smelt to forage effectively (Herbold, pers. comm.). The increase in water clarity may also increase the vulnerability of delta smelt to visual predators.

Brazilian waterweed and water hyacinth are fast growing and abundant aquatic plants that have had detrimental effects to the Bay-Delta aquatic ecosystem (Grimaldo and Hymanson 1999, Brown and Michniuk 2007, Feyrer et al. 2007). These non-native plant species grow in dense aggregations can indirectly affect delta smelt by reducing dissolved oxygen levels and reducing nearby flow rates, resulting in local reductions in suspended sediment concentrations and turbidity within the water column. Furthermore, because of the three dimensional structure and shade they provide, these aquatic plants likely create excellent habitat for non-native predators of delta smelt, primarily centrarchids (Nobriga et al. 2005). Because Brazilian waterweed has recently spread by as much as 10 percent per year in areal coverage (Ustin et al. 2008), its negative impacts on delta smelt may increase in future years.

Entrainment. Despite the number of delta smelt that have been entrained by the SWP and CVP export facilities and over 2,200 smaller diversions in the Delta (Herren and Kawasaki 2001), the direct impacts of water diversions on the overall population dynamics of delta smelt is not well understood and there is disagreement among experts about the magnitude of these impacts (Bennett 2005).

Several studies have been conducted that show correlative relationships between SWP and CVP exports and indices of delta smelt abundance, suggesting that entrainment may negatively impact delta smelt abundance (USFWS 2008). These relationships do not establish causality, but they are an indicator that salvage should be considered. Kimmerer (2008) reported results of an analysis of the potential effects of SWP and CVP entrainment losses on larval and adult delta smelt. Results of these analyses suggest that losses of adult delta smelt had a median value of 15 percent (range 1-50 percent) while the seasonal losses for juvenile delta smelt had a median value of 13 percent (range of 0-25 percent). Kimmerer (2008) concluded that the effect of these losses on population abundance of delta smelt was obscured by a 50-fold variation in the overall survival of delta smelt survival between summer and fall.

Guerin et al. (in review) found significant correlations between SWP winter salvage of adult smelt and subsequent FMWT index of delta smelt with 1 and 2 year lags over the past 12 years. More recent work shows that SWP winter salvage of adult delta smelt normalized to the prior FMWT correlates strongly with subsequent FMWT for delta smelt over a longer record.

Bennett (unpubl. data) found a significant negative correlation between winter and early spring salvage and delta smelt survival estimates (Brown and Kimmerer 2001). Swanson (2005) found that winter exports (December through March) were significantly negatively correlated with both the juvenile delta smelt abundance index from DFG summer townet surveys and the sub-adult and adult delta smelt abundance index from DFG FMWT surveys, although SWP and CVP exports explained only 15.5 and 2.4 percent of variation in juvenile and sub-adult/adult abundance indices, respectively. Herbold et al. (2005) reported that delta smelt salvage density relative to apparent abundance has increased markedly since 2002, concurrent with the POD. Manly and Chotkowski (unpubl. data) found a statistically significant correlation between delta smelt abundance and total exports, but the relationship explained only a small proportion of overall variation in delta smelt abundance (Miller 2007). As a result, Manly and Chotkowski assert that exports do not appear to play a large role in controlling delta smelt population abundance relative to other stressors (e.g., reduced food availability).

The risk of entrainment to delta smelt varies seasonally and among years. The most important entrainment risk has been hypothesized to occur during winter when pre-spawning adults migrate into the Delta in preparation for spawning (Moyle 2002, Bureau of Reclamation 2004). Patterns in SWP and CVP salvage data support this hypothesis (DFG, unpubl. data). Bennett (2005) has hypothesized that larger female delta smelt spawn earlier in the winter and are, therefore, more vulnerable to entrainment by export facilities. Larger females are more fecund, spawn repeatedly, and can produce more offspring with higher fitness than smaller females. As a result, Bennett hypothesized that entrainment during winter months may have a disproportionately large impact on the overall population dynamics of delta smelt than entrainment during other periods of the year.

Analyses conducted by P. Smith (unpubl. data) and J. Johns (unpubl. data) present results of an analysis of the relationship between the magnitude of reverse flows in Old and Middle rivers during the winter (January-February) and salvage of pre-spawning delta smelt at the SWP and CVP export facilities. Smith found a linear relationship between reverse flows and delta smelt salvage for January and February combined. Johns found a non-linear relationship between reverse flows and delta smelt salvage separately by month. Results of the non-linear model were statistically significant and showed that delta smelt salvage remained relatively low when reverse flows in Old and Middle rivers were below approximately -5,000 cfs. As reverse flows increased to greater than 5,000 cfs, delta smelt salvage increased substantially. Results of these analyses were used as the basis for a 2007 federal court decision regarding interim operational restrictions on SWP and CVP exports (Wanger decision) and the December 2008 delta smelt biological opinion for SWP and CVP operations by the USFWS (2008).

Entrainment risk for delta smelt has largely been based on analyses of SWP and CVP fish salvage. The fish salvage operation, however, only identifies and counts those individual fish greater than 20 mm in length. As a result, larval delta smelt smaller than 20 mm are not included in fish salvage estimates. Results of several preliminary estimates of the potential magnitude of larval delta smelt entrainment at the SWP and CVP export facilities have been made, as well as estimates of the population size of delta smelt that are intended to put entrainment losses into an population-level framework for evaluation (Hanson unpublished data). Estimates of entrainment losses for larval delta smelt and estimates of population abundance have been based on extrapolations from results of the DFG 20 mm delta smelt survey. These preliminary estimates have been criticized on the basis of a number of assumptions that are required to make the population and entrainment loss estimates that have not been tested or validated. Recognizing that larval delta smelt are vulnerable to SWP and CVP entrainment losses that may vary in magnitude and potential effect on the population among years, the federal district court ordered that a study be conducted beginning in 2008 to monitor the densities of larval delta smelt vulnerable to SWP and CVP entrainment losses for use in the future in determining whether or not additional protective measures would be required to reduce potentially adverse impacts associated with larval delta smelt entrainment.

Nobriga and Matica (2000) and Nobriga et al. (2004) found low and inconsistent entrainment of juvenile delta smelt by small agricultural diversions near Sherman Island; the low entrainment rates were hypothesized to be the result of juvenile delta smelt occurring offshore of the intake location and in the upper portions of the water column. Cook and Buffaloe (1998) also reported that unscreened agricultural diversions entrained low numbers of delta smelt. However, many agricultural diversions are located within primary delta smelt habitat and could potentially entrain delta smelt for a large proportion of the year. It has been hypothesized that, although juvenile and adult delta smelt may avoid entertainment at unscreened water diversions, planktonic larvae are expected to be distributed within the water column and have weak swimming performance. Therefore, larvae may be vulnerable to higher entrainment losses than predicted by results of investigations of juvenile and adult smelt. Therefore, the combined effect of location, abundance, and duration of agricultural diversions on delta smelt survival could be high.

Power plants located within the Plan Area at Pittsburg and Antioch have the potential to entrain large numbers of fish, including delta smelt and other covered fish species, particularly because these species may be located near these facilities for much of the year (Matica and Sommer 2005, C. Hanson unpubl. data). However, use of cooling water is currently low with the retirement of older units. According to recent regulations by the SWRCB, units at these two plants must be equipped with a closed cycle cooling system by 2017that eliminates fish entrainment.

Exposure to toxins. Exposure of delta smelt to toxic substances can result from point and non-point sources associated with agricultural, urban, and industrial land uses. The Delta serves as the receiving waters for a wide variety and large volume of toxic substances, including agricultural pesticides, herbicides, endocrine disruptors, heavy metals, and other agricultural and urban products (Thompson et al. 2000, Moyle 2002). Kuivila and Moon (2004) sampled pesticide concentrations within the Delta and west to Chipps Island for 3 years (1998-2000) during April-June. Their water samples contained multiple pesticides, but at individual concentrations well below lethal 96-hr LC50 concentrations for fishes. A reported toxic event in the winter of 2007 (toxicity was demonstrated using water samples collected from the Delta under laboratory conditions; no tests were performed using delta smelt) coincided temporally and spatially with delta smelt spawning in the Cache Slough region of the Delta and was also detected further downstream in the lower Sacramento River near Sherman Island (DWR, unpubl. data). Indications of toxicity also were detected within Suisun Bay during the summer of 2007 (S. Ford pers comm.). Although no specific causal link has been established, these toxic events coincided with low abundance indices of larval and juvenile delta smelt observed in the 2007 DFG 20 mm townet and summer townet surveys. Bioassay studies conducted as part of the POD studies found two instances of significant larval delta smelt mortality in samples collected from the Sacramento River in June and July 2007 that had relatively low turbidity and salinity and moderate levels of ammonia (Werner unpublished data, as cited in Baxter et al. 2008) . There have been multiple studies indicating that toxics have little direct effect on delta smelt (Resources Agency 2007, Werner et al. 2007, Bennett unpubl. data).

The short life span (1-2 years) and location of their food source in the food web (zooplankton are primary consumers) reduce the ability of toxic chemicals to bioaccumulate in the tissue of delta smelt (Moyle 2002). Their location in the upper portion of the water column may further reduce the probability of some toxic impacts by those chemicals that are sequestered quickly by sediments (i.e., pyrethroids; B. Herbold pers. comm).

Ammonia discharged from municipal wastewater treatment plants may contribute to localized toxicity in delta smelt, although results are highly variable. Werner et al. (2008) found that water samples near the Sacramento Regional County Sanitation District's wastewater treatment plant effluent reduced 4-day survival of larval delta smelt in 2006, but did not affect survival even after 7 days in 2007. Furthermore, there were two instances of significant larval delta smelt mortality from POD bioassays collected from the Sacramento River in June and July 2007 that had relatively low turbidity and salinity and moderate levels of ammonia (Werner unpubl. data, as cited in Baxter et al. 2008). The form and toxicity of ammonia/um changes based on pH and it has been hypothesized that changes in pH of the Delta receiving waters may change in response to algal growth, discharges from managed wetlands and duck clubs, and agricultural return flows that result in ammonia toxicity. These potential water quality interactions and the effects of discharging ammonia from a number of wastewater treatment plants located throughout the Sacramento and San Joaquin rivers, Delta, Suisun Bay and Suisun Marsh on the health and survival of delta smelt and other aquatic species are under investigation.

Consistent evidence of direct toxicity of contaminants to smelt within the Delta is lacking (Werner et al. 2008); however, there is growing evidence that toxics may have indirect effects on delta smelt. For example, invertebrate prey of delta smelt are affected by toxics (Weston et al. 2004, Luoma 2007, Werner 2007), reducing food availability. Additionally, the nitrate uptake by and production of phytoplankton, the base of the food web that supports delta smelt, may be inhibited by ammonia concentrations in the North Delta as has been demonstrated for phytoplankton in San Francisco and San Pablo bays (Dugdale et al. 2007). There is also evidence that toxics may cause sublethal impacts to delta smelt that make them more vulnerable to other sources of mortality (Werner 2007). Most, if not all, pyrethroids are potent neurotoxicants (Bradbury and Coats 1989, Shafer and Meyer 2004) and have immunosuppressive effects (Madsen et al. 1996, Clifford et al. 2005). In addition, these compounds and their breakdown products can act as endocrine disrupting compounds by disrupting hormone-related functions (Go et al. 1999, Tyler et al. 2000, Perry et al. 2006, Sun et al. 2007). Esfenvalerate, a common pyrethroid insecticide, has been shown to increase the susceptibility of juvenile fall-run Chinook salmon to infectious hematopoietic necrosis virus (Clifford et al. 2005), and reduce swimming ability and increase susceptibility to predation in larval fathead minnows (Floyd et al. 2008). In delta smelt, exposure to environmentally relevant pyrethroid concentrations resulted in significant swimming abnormalities, which were strongly linked with downregulation of genes involved in neuromuscular activity (Connon et al. 2009).

Exposure to copper contamination can also result in significant sublethal effects on Delta fish species, with implications for their vulnerability to other stressors. Environmentally relevant copper concentrations are shown to result in significant immunosuppressive effects (Hetrick et al. 1979) and impair olfactory function and eliminate the predator avoidance response in fish (Sandahl et al. 2006; Werner et al. in press). Swimming abnormalities have been observed after exposure to copper concentrations as low as one quarter of the chemical's LC50 values (Little and Finger 1990; Oros and Werner 2005). Dissolved copper causes acute toxicity to the calanoid copepod, *Eurytemora affinis*, in the north and south Delta (Teh 2009) and impairs the sensory function of juvenile salmonids (Hecht et al. 2007), specifically related to predator avoidance behavior. Moreover, specific concentrations of dissolved copper correspond to sublethal endpoints such as primary production and salmonid growth (Hecht et al. 2007). Delta smelt may be affected in a similar way. Additionally, negative synergistic effects have been documented such that the presence of copper in combination with ammonia is more toxic to aquatic organisms than either toxicant individually (Herbert and Vandyke 1964).

A5.6 Relevant Conservation Efforts

Pursuant to the CALFED objective of ecosystem restoration, the CALFED agencies developed the Ecosystem Restoration Plan (ERP) and the Environmental Water Account (EWA) for the purpose of restoring habitat and recovering at-risk populations like delta smelt in the Bay-Delta estuary (CALFED 2000). The ERP was intended to improve aquatic and terrestrial habitats and natural processes to support stable, self-sustaining populations through an adaptive management process, and the EWA was intended to provide increased water supply reliability while assuring the availability of sufficient water to meet fishery protection and restoration and recovery needs, as part of the overall ERP. Additional enhancement and protective actions are also being identified as part of mitigation programs for various projects, biological opinions, and regional conservation planning efforts.

The Delta Regional Ecosystem Restoration Implementation Plan (DRERIP) was formed to guide the implementation of CALFED ERP elements within the Delta (DFG 2007b). The DRERIP team has created a suite of ecosystem and species conceptual models, including a conceptual model for delta smelt, that document existing scientific knowledge of Delta ecosystems. The DRERIP team has used these conceptual models to assess the suitability of actions proposed in the ERP for implementation. DRERIP conceptual models have been used in the analysis of proposed BDCP conservation measures.

Various projects exist to benefit delta smelt and several other native fish species. For example, in 2007, Westlands Water District acquired land located in the southern end of the Yolo Bypass that is thought to be high value habitat for delta smelt. Designs for potential habitat enhancement projects within the Yolo Bypass are being developed and evaluated. Objectives of these potential actions include enhancing the frequency and duration of access to seasonally inundated floodplain habitat to benefit species such as juvenile Chinook salmon and splittail, as well as to increase nutrient cycling and food production for delta smelt and other species. Wildlands, Inc. has established a mitigation bank to offset site-specific impacts to fish species, such as delta smelt, near Kimball Island in the western Delta. Access to aquatic habitats, such as the waters adjacent to Kimball Island, may provide direct benefits to delta smelt, as well as indirect benefits associated with increased nutrient cycling, phytoplankton and zooplankton production, and an associated increase in food supplies for delta smelt and other aquatic resources. Furthermore, work funded by CALFED and implemented by the Natural Heritage Institute and DWR is intended to improve and protect habitat in Dutch Slough for delta smelt, splittail, and juvenile salmonids.

The Delta Smelt Working Group is a group of scientists under the auspices of the Interagency Ecological Program, Bureau of Reclamation, and DWR that makes recommendations on water operations for the protection of delta smelt. The group uses a delta smelt risk assessment matrix, which consists of month by month criteria that, when exceeded, will trigger a meeting of the group and possible management recommendations.

In January 2005, the Interagency Ecological Program established the Pelagic Organism Decline (POD) work team to investigate the causes of the observed rapid decline in populations of pelagic organisms, including delta smelt, in the upper San Francisco Bay estuary (Baxter et. al. 2008). Since then, numerous studies have been conducted to determine the cause of the POD. Based on results of these studies and relevant studies undertaken by others, the work team has developed conceptual models to discern an understanding of the factors causing POD and to provide a basis from which to identify actions to address POD. Resources Agency has also prepared a Pelagic Fish Action Plan in March 2007 to address POD (Resources Agency 2007). The action plan identifies 17 actions that are being implemented or that are under active evaluation to help stabilize the Delta ecosystem and improve conditions for pelagic fish.

In 2007, the Federal District Court, Eastern District of California, Fresno Division (Judge Wanger) issued a court order for interim actions to protect delta smelt pending completion of a new biological opinion by the USFWS on SWP and CVP operations. The court ruling remained in effect until the new biological opinion was approved in December 2008. In the interim period, export operations of the SWP and CVP during the winter and spring months were restricted based on the magnitude of reverse flows in Old and Middle rivers and the geographic distribution and risk to delta smelt of entrainment at the export facilities. During the winter and spring months, SWP and CVP exports were limited to reverse flows of not greater than -5,000 cfs and may be reduced to as low as -2,000 cfs when delta smelt are at high risk of being entrained. These operating restrictions were intended to provide protection to delta smelt, reduce the potential risk of entrainment losses to the overall abundance, and reduce the effects of operations on population viability of delta smelt. The operating restrictions, in combination with other export limitations (e.g., SWRCB D-1641, operations to reduce the incidental take of winter-run and spring-run Chinook salmon and steelhead) have resulted in reductions in water supply deliveries to SWP and CVP contractors.

In December 2008, the USFWS released a biological opinion on the proposed operations of DWR and USBR, indicating that "coordinated operations of CVP and SWP diversion facilities, as proposed, are likely to jeopardize the continued existence of delta smelt" (USFWS 2008). The new biological opinion supplanted the 2007 Judge Wanger court decision when approved. The biological opinion details reasonable and prudent alternative actions to reduce the likelihood of jeopardy that include improvements to flow conditions, restoration of tidal marsh and associated subtidal habitat in the Delta and Suisun Marsh, and a comprehensive monitoring plan.

A5.7 Recovery Goals

The USFWS recovery strategy for delta smelt is contained in the Sacramento-San Joaquin Delta Native Fishes Recovery Plan (USFWS 1996), which also includes the longfin smelt, Sacramento splittail, green sturgeon, Sacramento perch, and three races of Chinook salmon. The objective of the Delta Native Fishes Recovery Plan for delta smelt is to remove delta smelt from the federal list of threatened species through restoration of its abundance and geographic distribution. The basic strategy for recovery is to manage the estuary in such a way that it provides better habitat for native fish in general and delta smelt in particular. The Recovery Plan defines restoration as a return of the population to pre-decline levels.

Based on the available information at the time, the 1996 recovery plan outlined a number of measurable criteria that could be used to evaluate the status of delta smelt. Delta smelt were to be considered restored when its population dynamics and distribution pattern within the estuary were similar to those that existed in the pre-decline 1967-1981 period. Restoration was to be assessed when the species satisfied both distributional and abundance criteria. The abundance criteria outlined in the 1996 recovery plan for delta smelt were met and the USFWS conducted a status review of the species in compliance with the terms of a settlement agreement. After reviewing the available information, the USFWS concluded that significant threats to the population recovery of delta smelt remain and that delta smelt should continue to be listed as a threatened species under the federal ESA.

Since 1996, new significant findings regarding the status and biology of and threats to delta smelt have emerged. The USFWS has the responsibility to review and update the recovery plan for these species. To accomplish this task, USFWS has formed the Delta Native Fishes Recovery Team to assist in the preparation of this updated recovery plan. An updated recovery plan is currently expected to be released in the near future.

APPENDIX A6. LONGFIN SMELT *(SPIRINCHUS THALEICHTHYS)*

A6.1 LEGAL STATUS

Longfin smelt is not currently listed under the federal Endangered Species Act (ESA). However, the species was recently listed as threatened under the California ESA. The Bay-Delta population of longfin smelt was petitioned for threatened status under the Federal ESA in 1992. However, the petition was denied because the population was surviving well in areas outside the Bay-Delta estuary. The population was deemed insignificant to the entire species and was not deemed sufficiently reproductively isolated to warrant ESA listing (59 FR 869). More recent evidence from electrophoretic analysis has shown minor differences in allele frequencies between longfin smelt populations inhabiting Lake Washington in Washington state and those in the San Francisco Bay-Delta estuary, but gene frequencies differed enough to suggest that current gene flow between these two populations is restricted (Stanley et al. 1995). The Bay-Delta population appears to be more geographically isolated from other West Coast longfin smelt populations than previously thought (Moyle 2002). In 2007, the Bay Institute, Center for Biological Diversity, and Natural Resources Defense Council (2007a, b) petitioned to have the Bay-Delta longfin smelt population listed as a threatened species under both the California and Federal ESAs. On May 6, 2008, the U.S. Fish and Wildlife Service (USFWS) ruled that a status review for longfin smelt was warranted (73 FR 24911). On April 9, 2009, the USFWS determined that the Bay-Delta population did not meet the legal criteria for protection as a species subpopulation under the ESA (74 FR 16169).

In December 2007, the California Department of Fish and Game (DFG) completed a preliminary review of the longfin smelt petition (DFG 2007a) and concluded that there was sufficient information to warrant further consideration by the California Fish and Game Commission. On February 7, 2008 the California Fish and Game Commission designated the longfin smelt as a candidate for potential listing under the California ESA. On June 26, 2009, the California Fish and Game Commission ruled to list the status of longfin smelt as threatened under the California ESA.

A6.2 SPECIES DISTRIBUTION AND STATUS

A6.2.1 Range and Status

Populations of longfin smelt occur along the Pacific Coast of North America, from Hinchinbrook Island, Prince William Sound, Alaska to the San Francisco estuary (Lee et al. 1980). Although individual longfin smelt have been caught in Monterey Bay (Moyle 2002), there is no evidence of a spawning population south of the Golden Gate. The Bay-Delta population is the southernmost, and also the largest, spawning population in California (see Figure A-6a).

DRAFT

Figure A-6a. Longfin Smelt Range in California

Small and perhaps ephemeral longfin smelt spawning populations have been documented or suspected to exist in Humboldt Bay, the Eel River estuary, the Klamath River estuary, the Eel River drainage, and the Russian River (Moyle 2002, Pinnix et al. 2004).

Longfin smelt seasonally inhabit the entire Bay-Delta estuary, typically in the lower Sacramento River downstream of Rio Vista and the lower San Joaquin River downstream of Medford Island, Suisun Bay, San Pablo Bay, and San Francisco Bay including South San Francisco Bay (see Figure A-6b). During non-spawning periods, individuals are most often concentrated in Suisun, San Pablo and north San Francisco bays (Baxter 1999, Moyle 2002). The species is also common in nearshore coastal marine waters outside the Golden Gate Bridge in late summer and fall (Baxter 1999, Sakuma, pers. comm. 2003). Longfin smelt are periodically caught in nearshore ocean surveys (City of San Francisco, unpublished data, Sakuma pers. comm.), suggesting that some individuals emigrate from or immigrate into the estuary.

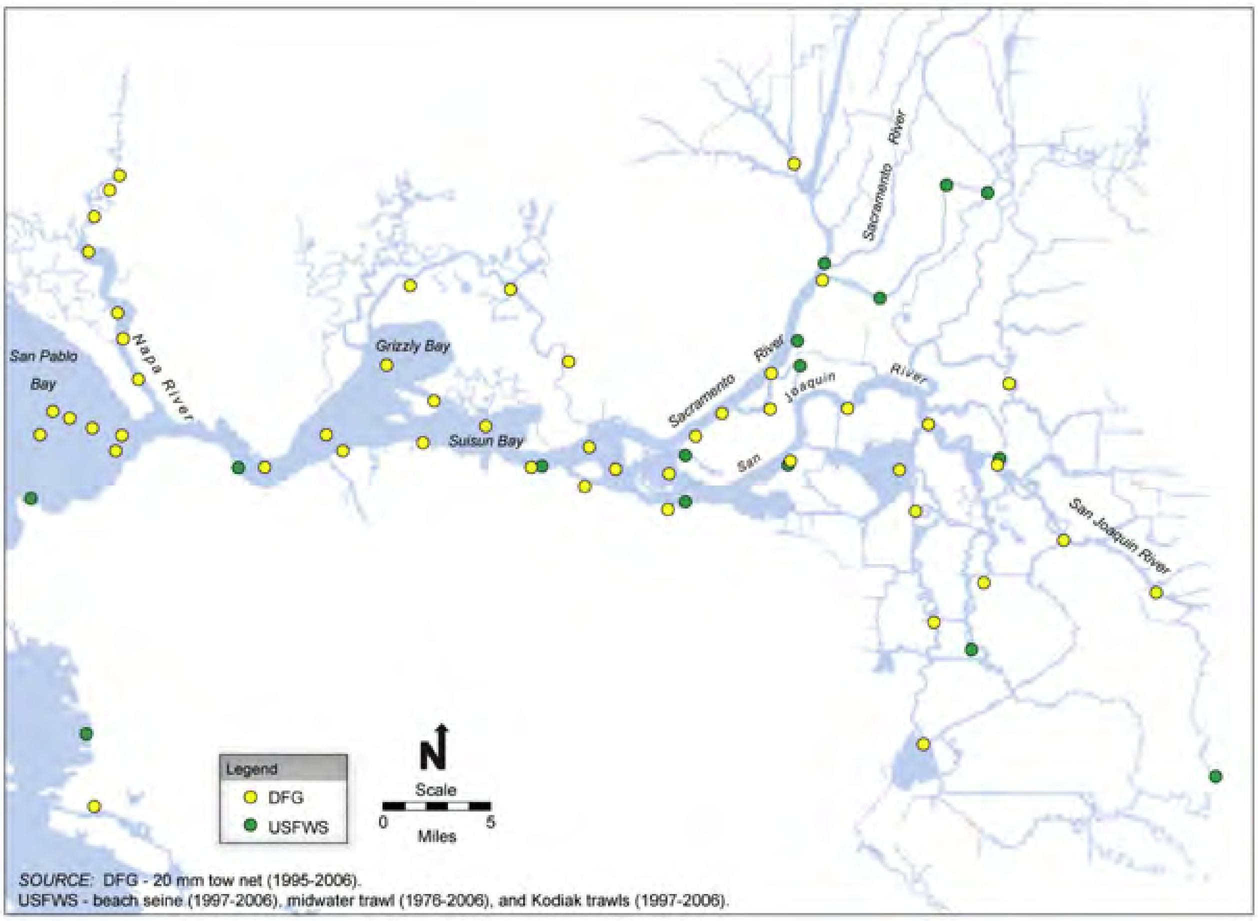

Figure A-6b. Historical Sampling Locations Where Longfin Smelt Have Been Captured Since 1976

Longfin smelt abundance within the Bay-Delta estuary has been highly variable as reflected in the DFG fall midwater trawl surveys and Bay study surveys (see Figure A-6c). The DFG fall midwater trawl samples approximately 100 locations throughout the Bay-Delta system during the period from September through December each year. The survey has been conducted since 1967 and is considered to represent the best long-term record of the index of longfin smelt abundance in the Bay-Delta estuary. Additional information on trends in abundance of longfin smelt inhabiting the estuary is available from the DFG Bay fishery surveys that have sampled monthly since 1980 at a wide range of locations using both an otter trawl and midwater trawl. Since the fall midwater trawl surveys and Bay fishery surveys show similar trends in abundance of longfin smelt (Hieb et al. 2005), the following description of trends in the status of longfin smelt is based on results of the long-term DFG fall midwater trawl surveys.

Indices of longfin smelt abundance (see Figure A-6c) are characterized by high variability among years. Abundance indices were greatest in 1967 and 1969 followed by a second peak in abundance in 1980 and 1982. High abundance indices have generally been associated with years when spring Delta outflow has been high. Abundance indices have typically been low in years when Delta outflow in the spring is low, such as the drought conditions that occurred in 1976 and 1977 and during the early 1990s drought. The trends in longfin abundance also show a general pattern of declining abundance over the 1967 through 2009 survey period. In recent years, longfin smelt abundance was greatest in 1995 followed by a general decline in abundance between 1998 and 2009. The abundance index based on the DFG fall midwater trawl survey conducted in 2007 was the lowest on record over the 1967 to 2009 survey period. Fall midwater trawl abundance indices suggest that abundance of longfin smelt within the Bay-Delta estuary has declined by over 95 percent since the survey began.

Correlations between longfin smelt abundance indices and various environmental parameters suggest that freshwater outflow from the Delta during the longfin smelt larval and early juvenile period (January-June) has a strong influence on longfin smelt abundance (see Figure A-6d) (Moyle 2002).

Although there was a four-fold decline in longfin smelt abundance after the 1987 invasion of the overbite clam, there was no change in the slope of the relationship between freshwater outflow and longfin smelt abundance (see Figure A-6d) Kimmerer 2002a, Sommer et al. 2007). Furthermore, although Delta outflow conditions were relatively high in 2003, 2005, and 2006, reflecting wet and above normal hydrologic conditions, longfin smelt abundance did not increase (as would be expected based on the 1987 to 2000 relationship; Sommer et al. 2007). There appears to be yet a further reduction in the height of the abundance-flow relationship since 2001, although the slope of the relationship remains unchanged (see Figure A-6d). This finding suggests that an additional factor or factors may now be limiting the Bay-Delta population response. When longfin smelt abundance is low, it becomes more difficult to accurately assess their geographic distribution and abundance.

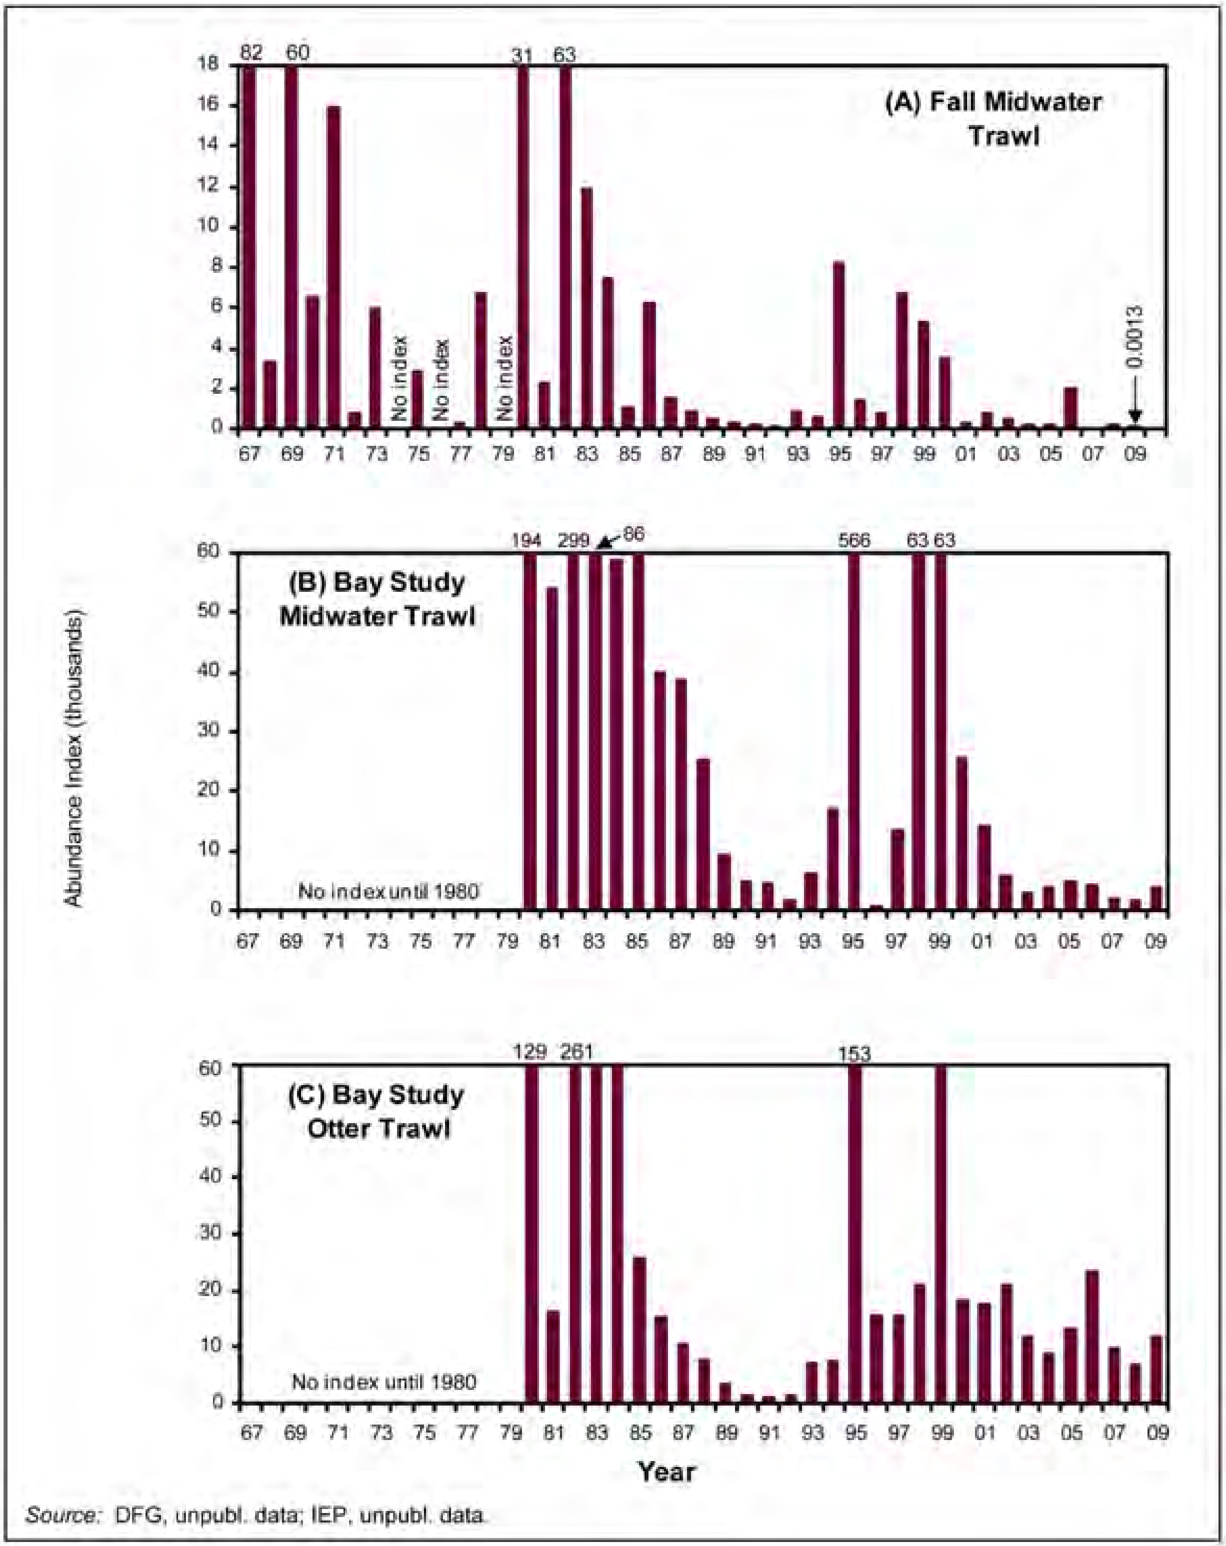

Figure A-6c. Annual Abundance Indices of Longfin Smelt from 1967-2009 in (A) Fall Midwater Trawl, (B) Bay Study Midwater Trawl, and (C) Bay Study Otter Trawl

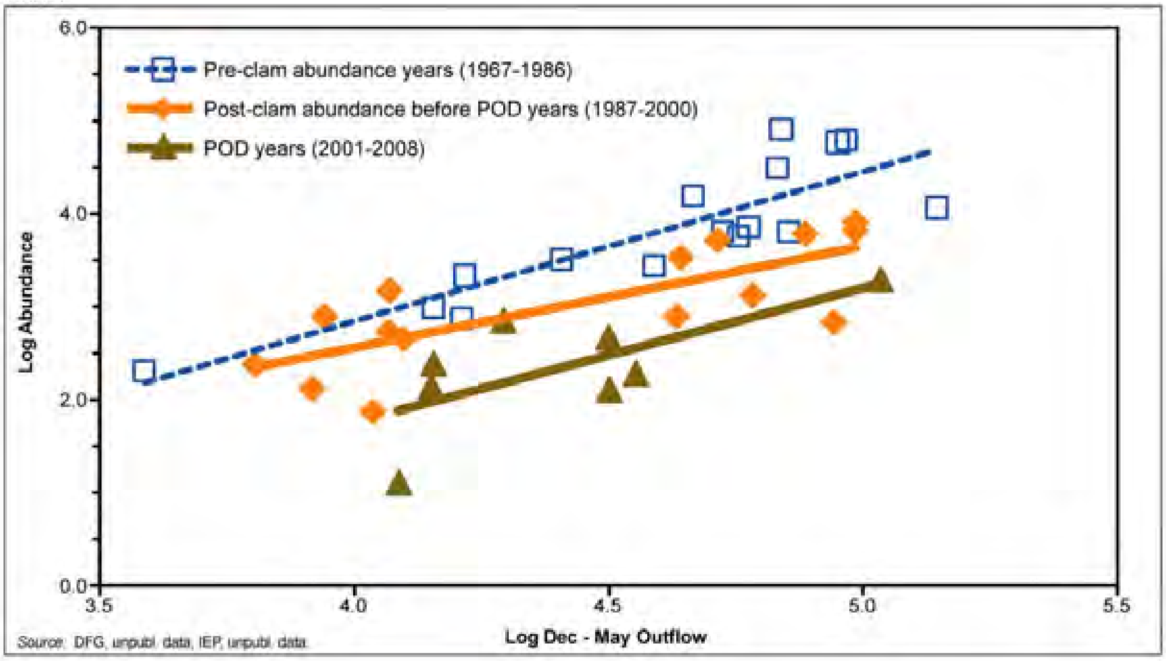

Figure A-6d. Longfin Smelt Abundance ($\log_{10}$) from DFG Fall Midwater Trawl Survey as a Function of Mean Delta Outflow from December through May ($\log_{10}$)

Longfin smelt migration patterns and geographic distribution patterns within the Bay-Delta estuary have remained the same throughout the period of record (1967-present, fall midwater trawl; 1980-present, Bay Study trawls). Results of fishery surveys suggest that the geographic distribution of pre-spawning adult longfin smelt in the winter and early spring does not vary substantially in response to seasonal and inter-annual variation in inflows to the Delta. It has been hypothesized that the pre-spawning longfin smelt distribution is determined by staging and foraging prior to spawning and associations with suitable habitat conditions for spawning. The geographic distribution of larval and early juvenile lifestages of longfin smelt may be influenced by freshwater inflows to the Delta during the late winter and spring, possibly influencing larval planktonic transport rates from the upstream spawning habitat to the downstream estuarine portions of the Delta. In addition, when Delta inflows are high the location of the low salinity zone is further west (downstream) and larval and early juvenile delta smelt are frequently observed further downstream within Suisun Bay.

No spawning habitats have been specifically identified for longfin smelt, but based on the collection of larvae, most spawning is believed to take place in the Sacramento River near or downstream of Rio Vista, and downstream of Medford Island on the San Joaquin River (Wang 1986). Historically, spawning longfin smelt were also common in Suisun Marsh; in recent years, very few adult, spawning-age longfin smelt have been collected in Suisun Marsh (DFG, unpubl. data). Larval longfin smelt have been found concentrated off the mouth of Coyote Creek, indicating that spawning can take place in tributaries of South San Francisco Bay during periods when freshwater runoff and Delta outflow are high, such as conditions that occurred in 1982 and

1983 (Baxter 1999). Collection of small larvae in the Interagency Ecological Program (IEP) 20 mm tow net surveys suggests spawning regularly occurs in the Napa River.

Larval longfin smelt are typically collected in the region of the estuary extending from the western Delta into San Pablo Bay, but their distribution shifts upstream or downstream in response to Delta outflow (Baxter 1999, Dege and Brown 2004). In years when winter-spring Delta outflow is low, few larvae are transported to San Pablo Bay. In years when winter-spring Delta outflow is high, few larvae remain in the western Delta, but are abundant in San Pablo Bay and may reach northern San Francisco Bay (Baxter 1999, Dege and Brown 2004). Longfin smelt larvae are distributed broadly into all open water habitats and into marsh sloughs (Baxter 1999, Meng and Matern 2001).

The initial distribution of young juveniles correlates positively with that of larvae, both vertically within the water column and geographically. During their first year, juveniles disperse broadly downstream, eventually inhabiting Suisun, San Pablo, and Central and South San Francisco bays and moving into near shore coastal marine habitats in most years (see Figure A-6e) (Baxter 1999, Dege and Brown 2004, Hieb and Baxter 1993, Moyle 2002). Juveniles move from offshore shoals into channels during summer and fall (Rosenfield and Baxter 2007).

Longfin smelt in their second year of life (age 1) are typically distributed from the western Delta through South San Francisco Bay during January through March. Their distribution then moves toward the Central San Francisco Bay, such that by August and September few, if any, are collected outside of Central San Francisco Bay (Baxter 1999). During the summer longfin smelt are also common in nearshore coastal waters (City of San Francisco unpubl. data, Sakuma pers. comm.). As longfin smelt begin to mature in the fall, they re-inhabit the entire estuary and begin migrating upstream toward freshwater (Baxter 1999, Rosenfield and Baxter 2007).

A6.2.2 Distribution and Status in the Plan Area

Longfin smelt occur primarily in the lower Sacramento River (downstream of Rio Vista), lower San Joaquin River, and western Delta and Suisun Bay within the Plan Area (see Figure A-6a). Longfin smelt occur in relatively low abundance in the south Delta as reflected in results of DFG fishery sampling and fish salvage monitoring at the State Water Project (SWP) and Central Valley Project (CVP) export facilities. The typical distribution of juvenile and adult longfin smelt (brackish water and coastal marine waters of San Pablo and San Francisco bays) is downstream of the Plan Area.

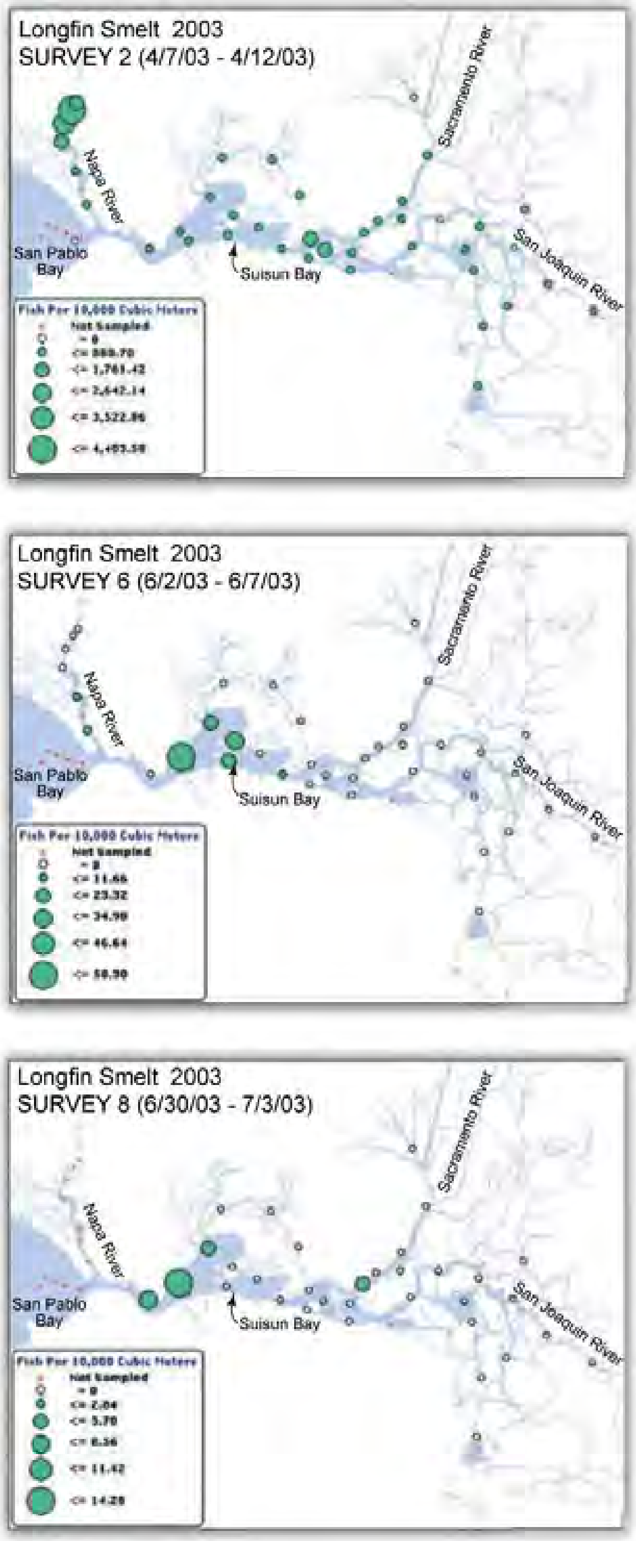
A6.3 Habitat Requirements and Special Considerations

Longfin smelt inhabiting the Bay-Delta estuary are thought to spawn in freshwater or slightly brackish water over sandy or gravel substrates at temperatures ranging from 7 to 14.5 °C (44.6 to 58.1 °F) (Moyle 2002).

Early April

Early June

Early July



Source: CDFG 2003, 20 mm Longfin smelt survey. This annual survey monitors post-larval and juvenile longfin smelt distribution and relative abundance every two weeks during spring and early summer throughout their historical spring range using a 1600 μm egg and larval net. For more information see http://www.delta.dfg.ca.gov/data/20mm/description.asp

Figure A-6e. Example of Distribution of Post-Larval and Juvenile Longfin Smelt in Spring-Summer of a Representative Above Normal Water Year

Other populations of longfin smelt inhabiting West Coast waters are present in coastal estuaries or may complete their entire life cycle in freshwater (Dryfoos 1965, Moulton 1974), indicating that there is no lower limit to salinity tolerance for any life stage. Collections of larval and juvenile longfin smelt smaller than 50 mm fork length (FL) within the Bay-Delta showed that 90 percent of the individuals inhabited areas with salinities lower than 18 parts per thousand (ppt) (Baxter 1999). Healthy individuals 20 mm FL and larger have been captured in salinities of 32 ppt (ocean water) and along the open coast, suggesting that high salinity may be limiting the geographic distribution for only a small portion of their lifecycle, if at all (Baxter, unpubl. data).

Spawning in the Bay-Delta estuary occurs immediately before, and for several months after, the coldest water temperatures of the year (Baxter 1999, Orsi 1999). Movement patterns based on catches in DFG fishery sampling suggest that longfin smelt actively avoid water temperatures greater than 22 °C (72 °F) (see Figure A-6d). Longfin smelt do not occupy areas with temperatures greater than 22 °C (72 °F) in combination with salinities greater than 26 ppt. These conditions occur between August and September almost annually in South San Francisco Bay and periodically in shallower portions of San Pablo Bay. Spawning is thought to occur in freshwater over sand, gravel, rocks, or aquatic vegetation (Wang 1991).

The effect of turbidity on longfin smelt geographic distribution or habitat preferences is unknown. However, longfin smelt larvae hatch coincident with annual peak Delta outflows, which typically coincide with high turbidity. Also, larval and older life stages of longfin smelt possess a well developed olfactory system. The development of the olfactory system at an early lifestage suggests its use in food acquisition (S. Foott, pers. comm.).

A6.4 LIFE HISTORY

An unknown fraction of the longfin smelt population migrates to the marine environment during both their first and second years of life; some may remain in the marine environment from their first year until they return to the estuary to spawn near the end of their second year (rarely their third). It is unknown whether marine residence is necessary for proper egg development, but the extremely limited number of age1 smelt captured upstream of Central San Francisco Bay during fall suggests that salinity or, more likely, higher temperatures may be a factor affecting the seasonal distribution of smelt within the estuary.

Upon hatching from adhesive eggs (primarily January-April), buoyant longfin smelt larvae rise toward the surface and are transported downstream by surface currents resulting from both river flow and tidal mixing of fresh and marine waters. Flow rates are positively related to downstream transport of the planktonic larvae (Hieb and Baxter 1993, Baxter 1999, Dege and Brown 2004). Larval longfin smelt remain in the upper part of the water column until they reach 10 to 15 mm, after which they move to the middle and bottom parts of the water column (Hieb and Baxter 1993, Bennett et al. 2002, Moyle 2002).

Larval and small juvenile longfin smelt feed on copepods and other small crustaceans (Moyle 2002). In Suisun Bay, at low salinities, the non-native copepods, *Pseudodiaptomus* and *Acanthocyclops,* dominate the diet of small juvenile smelt in summer (Hobbs et al. 2006). Mysid shrimp become important in the diets of larger juvenile and adult longfin smelt (Moyle 2002, Feyrer et al. 2003, Rosenfield and Baxter 2007). Since the decline of *Neomysis* following the invasion of the overbite clam in the late 1980s, subadult and adult longfin smelt have fed on a broader variety of organisms, but mysids remain their primary food item (Moyle 2002, Feyrer et al. 2003). In fall 2006, a high outflow year, longfin smelt fed predominantly on the introduced mysid, *Acanthomysis*, but consumed other mysids, as well as the copepod *Pseudodiaptomus* and amphipod, *Corophium* (DFG, unpubl. data).

During their first year, juvenile longfin smelt disperse broadly downstream, eventually inhabiting Suisun, San Pablo, and Central and South San Francisco bays, as well as nearshore coastal marine habitat in most years (Hieb and Baxter 1993, Baxter 1999, Moyle 2002, Dege and Brown 2004). Juveniles move from offshore shoals into channels during the summer and fall (Rosenfield and Baxter 2007). This movement may be a response to increasing water temperatures (greater than 20 °C [68 °F]), as does the late summer emigration from South San Francisco Bay (Baxter 1999).

A6.5 THREATS AND STRESSORS

Reduced spawning habitat. A primary mechanism responsible for the reduction in spawning habitat for longfin smelt has been the reclamation, channelization, and riprapping of historical freshwater intertidal and shallow subtidal wetlands. Furthermore, reductions of winter and spring Delta outflows over the past several decades as a result of water exports, reservoir storage, and upstream diversions have repositioned the low salinity region of the estuary (X2 location) farther upstream, possibly forcing spawning adult longfin smelt to migrate farther upstream to reach suitable spawning habitat.

Reduced access to rearing habitat. Access to suitable rearing habitat, which is centered in the low salinity zone (Dege and Brown 2004), has likely declined as a result of reductions in Delta outflow over the past 40 years. Reduced access to rearing habitat can result from low net downstream flows slowing the transport of planktonic larval longfin smelt downstream towards suitable rearing habitat in the western Delta and Suisun Bay. The documented correlation between the abundance of longfin smelt in the FMWT and the location of X2 in the winter and spring months (Dec-May; Kimmerer 2002, Kimmerer et al. 2009) is hypothesized to relate to the transport of larval longfin smelt out of the Delta to rearing habitats downstream.

The low salinity zone, when positioned over shallow shoal areas in Suisun Bay in response to high Delta outflows, is thought to be highly productive (Moyle et al. 1992, Bennett et al. 2002). When located upstream, the low salinity zone is confined to the deep river channels, is smaller in total surface area, contains very few shoal areas, may have swifter, more turbulent water currents, and may lack high zooplankton productivity. Hobbs et al. (2006) found evidence that the health and survival of longfin smelt were greater in habitats associated with shallow water. Furthermore, as the distribution of longfin smelt shifts upstream, individuals may become more vulnerable to entrainment by the SWP and CVP export facilities and other diversions within the interior of the Delta.

The Suisun Marsh Salinity Control Gates function to decrease salinity in managed wetlands of Suisun Marsh to support crops that attract game birds for the many duck clubs located throughout the marsh. When in operation, generally from October through May, the control gates near Collinsville divert up to 2,500 cubic feet per second (cfs) of freshwater from upstream flows into the marsh. Because the minimum outflow standard during fall months is 5,000 cfs, a significant proportion of total Delta outflow (up to 50 percent) does not flow through the eastern Suisun Bay region. This diversion has resulted in a measurable increase in salinity in eastern Suisun Bay, which may correspond to a decrease in low salinity habitat for longfin smelt (Fullerton 2007).

Reduced food availability. Reduced food availability for longfin smelt can result from at least seven impact mechanisms.

First, the presence of non-native species has reduced the abundance of food available to longfin smelt. Efficient filter feeding and high abundance of the overbite clam have dramatically reduced phytoplankton and zooplankton abundance in Suisun Bay, the western Delta, and Suisun Marsh since its introduction in the mid 1980s (Kimmerer and Orsi 1996). The Asian clam has also reduced phytoplankton abundance in the Delta, which likely reduced zooplankton abundance (Jassby et al. 2002, Thompson 2007). Other non-native zooplanktivores that may compete for limited available food resources with longfin smelt include threadfin shad, inland silversides, and wakasagi.

Second, much of the floodplain habitat in the Delta and tributary rivers has been eliminated by levees and reclamation. As a result of levee construction, flood control, and increased reservoir storage the frequency of inundation on floodplains that still exist has been reduced (Resources Agency 2007). Floodplains are highly productive due to their shallow, warm, low-velocity water (Sommer et al. 2001a, b) and input of organic material and nutrients from the terrestrial community (Booth et al. 2006). Floodplains are a key source of nutrients and organic material for the Bay-Delta estuary (Sommer et al. 2001a, Harrell and Sommer 2003).

Third, levee construction, island reclamation, and channelization within the Delta have resulted in a substantial reduction in intertidal and shallow-water subtidal wetland/emergent marshes and open water habitat throughout the Delta. Historically, Delta wetlands and shallow-water habitat was expansive and provided large areas of estuarine and freshwater habitat that was highly productive. The significant reduction in tidal and shallow-water subtidal habitat, and an associated reduction in emergent vegetation, nutrient cycling, and the production of phytoplankton, zooplankton, macroinvertebrates, and other aquatic organisms that provide food resources for delta smelt, have been identified as a major factor affecting habitat conditions within for Delta species, such as longfin smelt.

Fourth, SWP and CVP exports and the over 2,200 in-Delta agricultural diversions (Herren and Kawasaki 2001) export zooplankton, nutrients, and organic material that would otherwise support the base of the food web in the Delta, thus reducing food availability for the longfin smelt (Jassby and Cloern 2000, Resources Agency 2007).

Fifth, hydraulic residence time in the Delta has declined as a result of increased channelization and passage of Sacramento River water through the Delta Cross Channel into the central and southern Delta to meet water quality standards and supplies for in-Delta exports. The decreased hydraulic residence time reduces the time available for bacteria to use nutrients and organic carbon and for production of phytoplankton and zooplankton that provide food for longfin smelt and other aquatic species (Jassby et al. 2002, Kimmerer 2002a, 2004, Resources Agency 2007).

Sixth, exposure of phytoplankton and zooplankton to toxics (e.g., pesticides, herbicides) that enter the Delta from point and non-point sources may contribute to the observed low abundance of zooplankton prey species for longfin smelt and other species inhabiting the Bay-Delta (Weston et al. 2004, Luoma 2007, Werner 2007). Although direct impacts of toxics on longfin smelt have not been extensively studied, the indirect effect of toxics on reducing zooplankton and phytoplankton abundance is thought to result in reduced availability of food resources to longfin smelt (Johnson et al. 2010, Werner et al. in press).

Seventh, in addition to the discharge of toxic contaminants, municipal wastewater treatment plants, particularly the Sacramento Regional County Sanitation District's Wastewater Treatment Plant, discharge high loads of ammonia directly into the Sacramento River in the North Delta (Jassby 2008). High concentrations of ammonium, the ionized form of ammonia, may inhibit phytoplankton production in the Sacramento and San Joaquin rivers, as has been found downstream in the Suisun, San Pablo and Central bays (Wilkerson et al 2006, Dugdale et al. 2007), which could result in reduced food production for longfin smelt. Additional research is ongoing to determine if and to what extent, ammonia/um may affect phytoplankton production.

Non-native species. The effect of non-native predators, such as inland silversides, largemouth bass, striped bass, and other fish on the longfin smelt population is largely unknown, but may be important (Bennett and Moyle 1996, Moyle 2002). The establishment of the highly invasive and fast growing aquatic plants, such as the Brazilian waterweed and water hyacinth, has provided habitat for non-native predatory fish, such as centrarchids and striped bass, although no population level effects on longfin smelt have been detected or quantified (Nobriga et al. 2005). These aquatic plants may have had other potentially detrimental impacts to longfin smelt, including competition with native vegetation and reducing dissolved oxygen concentrations and turbidity within their immediate vicinity (Grimaldo and Hymanson 1999, Brown and Michniuk 2007, Feyrer et al. 2007).

The overbite clam has caused dramatic changes to the composition and abundance of phytoplankton and zooplankton communities in the aquatic food web since its introduction into the Bay-Delta estuary (Kimmerer and Orsi 1996). Kimmerer (2002a) asserted that these changes likely reduced food availability for a large assemblage of organisms, leading to reduced recruitment success of longfin smelt and a four-fold reduction in the abundance of longfin smelt (Rosenfield and Baxter 2007).

Reduced turbidity. The observed change in Bay-Delta turbidity has the potential, in combination with other factors, such as non-native species, to fundamentally alter the trophic dynamics of the estuary for species such as longfin smelt. Based on the similarities in life history, seasonal and geographic distribution, pelagic foraging and diet, it has been hypothesized that longfin smelt may have a similar relationship to turbidity as that observed for delta smelt (S. Foot unpubl. data, R. Baxter pers. comm.). Enlarged olfactory organs in longfin smelt suggest that they are well adapted to high turbidity conditions during foraging. As a result, longfin smelt may lose their competitive advantage in foraging to other zooplanktivores when turbidity is low.

Turbidity has decreased over the past several decades in the Delta as a result of a variety of factors (Kimmerer 2004, Wright and Shoellhamer 2004, Feyrer et al. 2007, Fullerton 2007). First, upstream sediment inputs have been reduced due to a range of anthropogenic actions (Jassby et al. 2002, Kimmerer 2004), including depletion of erodible sediments from hydraulic mining in the 1800s, river bank protection, trapping of sediments by dams and reservoirs, levee construction that reduced flood plain inundation and channel meanders, and changes in land use (Wright and Shoellhamer 2004). Wright and Shoellhamer (2004) estimated that the yield of suspended sediments from the Sacramento River declined by approximately one half from 1957 to 2001.

Second, the distribution and abundance of non-native aquatic plant species, particularly *Egeria* and water hyacinth, has increased dramatically over the past 20 years (Nobriga et al. 2005, Brown and Michniuk 2007). Both plants can reduce turbidity by reducing water velocity and trapping fine suspended sediments (Grimaldo and Hymanson 1999, Jassby et al. 2002, Nestor et al. 2003, Hobbs et al. 2006).

Third, the high filtering efficiency of the overbite clam has dramatically reduced phytoplankton and zooplankton abundance in the western Delta and Suisun Bay since its introduction (Kimmerer and Orsi 1996, Jassby et al. 2002, Kimmerer 2002b, 2004). The reduction in phytoplankton in the water column may contribute to increased water clarity and reduced turbidity in the Delta.

Fourth, hydraulic residence in the Delta has declined as a result of increased channelization and the movement of water from the Sacramento River into the interior Delta channels to improve water quality and provide increased supplies to in-Delta exports. SWP and CVP export operations have also directly resulted in changes in the hydrodynamics within Delta channels such as Old and Middle rivers which affect hydraulic residence time. Reduced hydraulic residence time reduces the ability of phytoplankton and bacteria to incorporate nutrients and carbon (Jassby et al. 2002, Kimmerer 2002a, 2004, Resources Agency 2007). This reduction in phytoplankton and zooplankton production contributes directly to reduced turbidity within the Bay-Delta estuary.

Reduced food quality. The zooplankton community inhabiting the Bay-Delta estuary has changed multiple times in response to multiple introductions of non-native species. These changes in the zooplankton species composition have affected the quality of food resources available to longfin smelt because some of the non-native species do not appear to be as suitable of a food resource as the native species (Resources Agency 2007, Sommer 2007). For example, the non-native copepod *Limnoithona* (Orsi and Ohtsuka 1999) is described as lower quality prey for longfin smelt because they are small and have sufficient swimming ability to avoid capture (Orsi and Ohtsuka 1999, B. Herbold pers. comm.). As a result, foraging efficiency of longfin smelt may have decreased (Resources Agency 2007). A decrease in foraging efficiency and/or the availability of suitable prey for various life stages of longfin smelt may have resulted in reduced growth, survival, and reproductive success contributing to reduced population abundance.

Entrainment. The effect of entrainment on the population dynamics and abundance of longfin smelt remains largely unquantified. Because longfin smelt tend to be mostly estuarine, they likely spend most of their life (approximately 1.5 years) downstream of the influences of the SWP/CVP facilities (see Figure A-6e). However, entrainment during winter months when spawners move upstream may be higher and particularly detrimental to the population because it results in mortality of not only pre-spawning and spawning adults, but also their potential progeny. Guerin et al (2008, in review) found significant correlations for longfin smelt as reported earlier for delta smelt between SWP winter salvage of adult smelt and subsequent fall mid-water trawl (FMWT) index of smelt with 1 and 2 year lags over the past 12 years. More recent work shows that SWP winter salvage of adult smelt normalized to the prior FMWT correlates strongly with subsequent FMWT for delta smelt over a longer record. These relationships do not establish causality, but they are an indicator that winter salvage at the SWP may be a factor to be considered.

The relationship between Delta outflow during the late winter and spring and the DFG fall midwater trawl longfin smelt index (see Figure A-6d) may be partially explained by entrainment vulnerability relative to the geographic distribution of the longfin smelt population. In high outflow years, salvage rates are lower, suggesting that longfin smelt may not be vulnerable to the SWP and CVP exports when the population is located farther west in Suisun Bay and further downstream.

There are over 2,200 small agricultural diversions in the Delta (Herren and Kawasaki 2001). Although these diversions generally take water near the bottom, the intakes may entrain water near the surface at low tide; therefore, the vulnerability of a pelagic species such as juvenile and adult longfin smelt may be reduced. Planktonic larval longfin smelt may have a greater vulnerability to entrainment into diversions than older life stages that have greater swimming ability and may inhabit areas further offshore and in the upper portions of the water column. It has been hypothesized that, although juvenile and adult longfin smelt may avoid entertainment at unscreened water diversions, planktonic longfin smelt larvae are expected to be distributed within the water column and have weak swimming performance and, therefore, may be vulnerable to entrainment losses in larger numbers than suggested by results of investigations of juvenile and adult smelt. Many agricultural diversions are located within longfin smelt spawning and larval rearing habitat. The impact of entrainment mortality at these diversions on the longfin smelt population abundance has not been quantified.

Power plants in Antioch and Pittsburg have the ability to entrain large numbers of longfin smelt, particularly because longfin smelt tend to be located near these facilities for most of the year (Matica and Sommer 2005, C. Hanson unpubl. data). However, use of cooling water is currently low with the retirement of older units. According to recent regulations by the State Water Resources Control Board, units at these two plants must be equipped with a closed cycle cooling system by 2017 that eliminates fish entrainment.

Exposure to toxins. Exposure of longfin smelt to toxic substances can result from point and non-point sources associated with agricultural, urban, and industrial land uses. Longfin smelt can potentially be exposed to these toxic materials, including pesticides, herbicides, endocrine disrupting compounds, and metals, during their period of residence within the Bay-Delta. There are no known studies that directly link mortality of longfin smelt with exposure to toxic chemicals within the Bay-Delta estuary (S. Foott unpubl. data, R. Baxter pers. comm., Resources Agency 2007). However, longfin smelt spawn during winter months when non-point runoff of pesticides tends to be the greatest. The pesticide diazinon is known to reduce growth and increase spinal deformities in Sacramento splittail (Teh et al. 2004), but effects of diazinon on longfin smelt have not been investigated. Reports during January 1997 indicated that flooding along the Feather River dispersed fuel and agricultural chemicals into the water column during a period when longfin smelt larvae were hatching in high numbers; the subsequent 1997 year class was low given the high winter outflow, although a direct cause and effect linkage with exposure to toxics was not documented. Kuivila and Moon (2004) sampled pesticide concentrations within the Delta and west to Chipps Island for 3 years (1998-2000) during April-June. Their water samples contained multiple pesticides, but at individual concentrations well below lethal 96-hr LC50 concentrations for fishes. In 1999 and 2000, sizable, but uncalculated fractions of the longfin smelt population overlapped their pesticide sampling area (see http://www.delta.dfg.ca.gov/data/20mm/CPUE_map.asp), although no known direct link between chemical concentration and larval mortality was established.

The short life span (less than 3 years) and location of their food source in the food web (zooplankton are primary consumers) reduce the ability of toxic chemicals to bioaccumulate in the tissue of longfin smelt (Moyle 2002). Their location in the water column may further reduce the probability of some toxic impacts by those chemicals that are sequestered quickly by sediments (i.e., pyrethroids; B. Herbold pers. comm). Additional research is needed to investigate the potential risk of exposure to toxic chemicals at concentrations and exposure durations typical of Bay-Delta conditions on various life stages of longfin smelt. To date, no formal risk assessment has been performed on the potential lethal and sublethal effects of toxics to longfin smelt population dynamics, although investigations of the toxicity of contaminants to larval delta smelt (Werner unpubl. data, as cited in Baxter et al. 2008) are being undertaken as part of the Interagency Ecological Program's studies of pelagic organism decline.

Ammonia discharged from municipal wastewater treatment plants may contribute to localized toxicity in longfin smelt. Werner et al. (2008) found that water samples near the Sacramento Regional County Sanitation District's wastewater treatment plant effluent reduced 4-day survival of larval delta smelt in 2006, but did not affect survival even after 7 days in 2007. Furthermore, there were two instances of significant larval delta smelt mortality from POD bioassays collected from the Sacramento River in June and July 2007 that had relatively low turbidity and salinity and moderate levels of ammonia (Werner unpubl. data, as cited in Baxter et al. 2008). Exposure to ammonia may have similar effects on longfin smelt. The form and toxicity of ammonia/um changes based on pH and it has been hypothesized that changes in pH of the Delta receiving waters may change in response to algal growth, discharges from managed wetlands and duck clubs, and agricultural return flows that result in ammonia toxicity. These potential water quality interactions and the effects of discharging ammonia from a number of wastewater treatment plants located throughout the Sacramento and San Joaquin rivers, Delta, Suisun Bay and Suisun Marsh on the health and survival of delta smelt and other aquatic species are under investigation.

Consistent evidence of direct toxicity of contaminants to smelt within the Delta is lacking (Werner et al. 2008); however, there is growing evidence that toxics may have indirect effects on longfin smelt. For example, invertebrate prey of longfin smelt are affected by toxics (Weston et al. 2004, Luoma 2007, Werner 2007), reducing food availability of longfin smelt. Additionally, the nitrate uptake by and production of phytoplankton, the base of the food web that supports longfin smelt, may be inhibited by ammonia concentrations in the North Delta as has been demonstrated for phytoplankton in San Francisco and San Pablo bays (Dugdale et al. 2007). There is also evidence that toxics may cause sublethal impacts to longfin smelt that make them more vulnerable to other sources of mortality (Werner 2007). Most, if not all, pyrethroids are potent neurotoxicants (Bradbury and Coats 1989, Shafer and Meyer 2004) and have immunosuppressive effects (Madsen et al. 1996, Clifford et al. 2005). In addition, these compounds and their breakdown products can act as endocrine disrupting compounds by disrupting hormone-related functions (Go et al. 1999, Tyler et al. 2000, Perry et al. 2006, Sun et al. 2007). Esfenvalerate, a common pyrethroid insecticide, has been shown to increase the susceptibility of juvenile fall-run Chinook salmon to infectious hematopoietic necrosis virus (Clifford et al. 2005), reduce swimming ability, and increase susceptibility to predation in larval fathead minnows (Floyd et al. 2008). In delta smelt, exposure to environmentally relevant pyrethroid concentrations resulted in significant swimming abnormalities, which were strongly linked with downregulation of genes involved in neuromuscular activity (Connon et al. 2009).

Exposure to copper contamination can also result in significant sublethal effects on Delta fish species, with implications for their vulnerability to other stressors. Environmentally relevant copper concentrations are shown to result in significant immunosuppressive effects (Hetrick et al. 1979) and impair olfactory function and eliminate the predator avoidance response in fish (Sandahl et al. 2006; Werner et al. in press). Swimming abnormalities have been observed after exposure to copper concentrations as low as 0.25 of the chemical's LC50 values (Little and Finger 1990; Oros and Werner 2005). Dissolved copper causes acute toxicity to the calanoid copepod, *Eurytemora affinis,* in the north and south Delta (Teh 2009) and impairs the sensory function of juvenile salmonids (Hecht et al. 2007), specifically related to predator avoidance behavior. Moreover, specific concentrations of dissolved copper correspond to sublethal endpoints such as primary production and salmonid growth (Hecht et al. 2007). Longfin smelt may be affected in a similar manner. Additionally, negative synergistic effects have been documented such that the presence of copper in combination with ammonia is more toxic to aquatic organisms than either toxicant individually (Herbert and Vandyke 1964).

Predation. Predation by introduced predators, such as inland silversides, striped bass, and centrarchids, has been identified as a potential stressor on smelt populations (Sommer et al. 2007, Rosenfield 2010), but the importance of predation for longfin smelt abundance is thought to be low (Nobriga and Feyrer 2008, Rosenfield 2010). Information regarding the impact of predation on longfin smelt is limited; however, inland silversides are believed to prey on larval longfin smelt, and predation by striped bass adults likely results in mortality for the juvenile and adult lifestages (Rosenfield 2010). Larval longfin smelt are not strong swimmers, and are thus particularly vulnerable to predation (Wang 1986). Various factors such as turbidity, outflows, and exposure to contaminants are likely to influence the susceptibility of longfin smelt to predation (Rosenfield 2010).

Predation has been implicated as an important factor affecting production of juvenile longfin smelt, in part due to the correspondence between freshwater flows, the volume of turbid habitat, and the young-of-year class size for longfin smelt (Rosenfield 2010). The coincidence of the increase in inland silverside abundance and decline in longfin smelt abundance also provides evidence of the potential importance of predation as a stressor to longfin smelt. However, increases in predation are not believed to be responsible for the most recent decline in the longfin smelt population. Although striped bass are likely to be major predators of longfin smelt, their populations have declined substantially in recent years and any impact they have on longfin smelt populations is also expected to have declined (Rosenfield 2010). In addition, inland silversides are predatory, but they prefer shallow-water habitats where juvenile and sub-adult longfin smelt are rare. Consequently, their impact as predators of juvenile longfin smelt is likely limited (Rosenfield 2010).

Elevated water temperature. Temperature affects the metabolic requirements and physiological processes of longfin smelt. Beyond a certain threshold, temperature increases are expected to cause increases in longfin smelt mortality. The temperature limitations and sublethal impacts of temperature variation on longfin smelt are unknown. Given the northerly distribution of longfin smelt and their probable derivation from a marine ancestor, it is possible that longfin smelt distribution and abundance in the Estuary are limited by high temperatures, particularly during summer months. Rosenfield and Baxter (2007) noted several aspects of their distribution patterns that would be consistent with temperature limitation. Temperatures below the longfin smelt minimum temperature threshold are not likely to occur in this estuary.

Low dissolved oxygen. In order to respire, longfin smelt require sufficient dissolved oxygen concentrations. Below a certain threshold, longfin smelt mortality would be expected to increase rapidly with decreasing dissolved oxygen levels (or increased time of exposure to low dissolved oxygen levels). No studies on the dissolved oxygen requirements of longfin smelt are available. Given the species' range (and limited historical exposure to high temperature/low dissolved oxygen conditions) and distribution within this ecosystem, this fish may be expected to have fairly high requirements for dissolved oxygen concentrations. For example, longfin smelt requirements for dissolved oxygen are expected to equal or exceed those of Delta smelt because the latter species specializes in the warmer habitats with lower dissolved oxygen. Given their pelagic distribution, regular exposure to low dissolved oxygen conditions is unlikely. Low dissolved oxygen conditions may limit longfin smelt use of the lower San Joaquin as DO levels are frequently extremely low in that area.

A6.6 RELEVANT CONSERVATION EFFORTS

The CALFED Multi-Species Conservation Strategy (CALFED 2000) designates longfin smelt as an "R" species and states that the goal is to "achieve recovery objectives identified for longfin smelt in the recovery plan for the Sacramento/San Joaquin Delta native fishes" (USFWS 1996). However, no conservation efforts in the recovery plan specifically target longfin smelt; all are referenced to delta smelt.

The Delta Regional Ecosystem Restoration Implementation Plan (DRERIP) was formed to guide the implementation of CALFED Ecosystem Restoration Plan elements within the Delta (DFG 2007b). The DRERIP team has created a suite of ecosystem and species conceptual models, including longfin smelt that document existing scientific knowledge of Delta ecosystems. The DRERIP Team has used these conceptual models to assess the suitability of actions proposed in the Ecosystem Restoration Plan for implementation. DRERIP conceptual models have been used in the analysis of proposed BDCP conservation measures. Additional enhancement and protective actions are also being identified as part of mitigation programs for various projects, biological opinions, and regional conservation planning efforts.

Modifications in the seasonal timing of SWP and CVP export operations on the longfin smelt population are currently being evaluated.

The Environmental Water Account (EWA) is intended to contribute to the protection, restoration, and recovery needs of fish, including longfin smelt, while still providing water supply reliability. However, analysis of the biological response of longfin smelt and other fish species to EWA actions in the past have failed to demonstrate significant protection or benefits to the overall populations of longfin smelt and other fish species.

In January 2005, the Interagency Ecological Program established a new Pelagic Organism Decline (POD) work team to investigate the causes of the recently observed rapid decline in populations of pelagic organisms, including longfin smelt, in the upper San Francisco Bay estuary (Baxter et al. 2008). Since that time, numerous studies have been conducted to determine the cause of the POD. Based on results of these studies and relevant studies undertaken by others, the work team has developed conceptual models to further the understanding POD. The Resources Agency prepared a Pelagic Fish Action Plan in March 2007 to address POD (Resources Agency 2007). The action plan identifies 17 actions that are being implemented or that are under active evaluation to help stabilize the Delta ecosystem and improve conditions for pelagic fish.

A6.7 RECOVERY GOALS

Longfin smelt is included in the 1996 Sacramento-San Joaquin Delta Native Fishes Recovery Plan, which also includes the delta smelt, Sacramento splittail, green sturgeon, Sacramento perch, and three races of Chinook salmon. The USFWS has the responsibility to review and update the recovery plan for these species. To accomplish this task, the USFWS has formed the Delta Native Fishes Recovery Team to assist in the preparation of this updated recovery plan. An updated recovery plan is expected to be completed in the near future.

APPENDIX A7. SACRAMENTO SPLITTAIL (*POGONICHTHYS MACROLEPIDOTUS*)

A7.1 LEGAL STATUS

The Sacramento splittail was listed as threatened under the federal Endangered Species Act (ESA) on February 8, 1999 (64 FR 5963). This ruling was challenged by two lawsuits (San Luis & Delta-Mendota Water Authority v. Anne Badgley et al. and State Water Contractors et al. v. Michael Spear et al.). On June 23, 2000, the Federal Eastern District Court of California found the ruling to be unlawful and on September 22 of that same year remanded the determination back to the U.S Fish and Wildlife Serviuce (USFWS) for re-evaluation of their original listing decision. Upon further evaluation, splittail was removed from the ESA on September 22, 2003 (68 FR 55139). On August 13, 2009, the Center for Biological Diversity (2009) challenged the 2003 decision to remove splittail from the ESA. However, on October 7, 2010, the USFWS found that listing of splittail was not warranted (75 FR 62070).

The splittail is designated as a species of special concern by the California Department of Fish and Game (DFG).

A7.2 SPECIES DISTRIBUTION AND STATUS

A7.2.1 Range and Status

The Sacramento splittail is endemic to the San Francisco Estuary and watershed. Splittail regularly inhabit the Sacramento River upstream to the Red Bluff Diversion Dam at river mile (rm) 243 and the San Joaquin River upstream to the mouth of Mud Slough at rm 125 (plus an additional 10.5 miles into Mud Slough) (see Figure A-7a). Splittail also inhabit the Napa and Petaluma River drainages (upper documented range: rm 18 and 17, respectively) and marshes. Splittail inhabiting these drainages have been found to be genetically distinct from splittail inhabiting the Sacramento and San Joaquin rivers (Baerwald et al. 2007). Splittail from the Petaluma River exhibited a higher degree of differentiation from the Sacramento-San Joaquin population than did Napa River splittail, suggesting high salinities in San Pablo Bay and Carquinez Strait isolated these populations to differing degrees from the larger Sacramento-San Joaquin population. Spawning occurs in the Petaluma and Napa rivers, but spawning locations within these rivers remain unknown (Moyle et al. 2004, Feyrer et al. 2005). No populations of splittail exist outside of the Central Valley rivers and the Bay-Delta estuary. Splittail range and selected observations in the lower portions of Sacramento River and tributaries include: the American River to rm 12, in the Feather River to rm 58 and from just below the Thermalito Afterbay outlet (B. Oppenheim pers. comm., A. Seesholtz pers. comm.), and in Butte Creek/ Sutter Bypass to vicinity of Colusa State Park.

DRAFT

Figure A-7a. Sacramento Splittail Inland Range in California

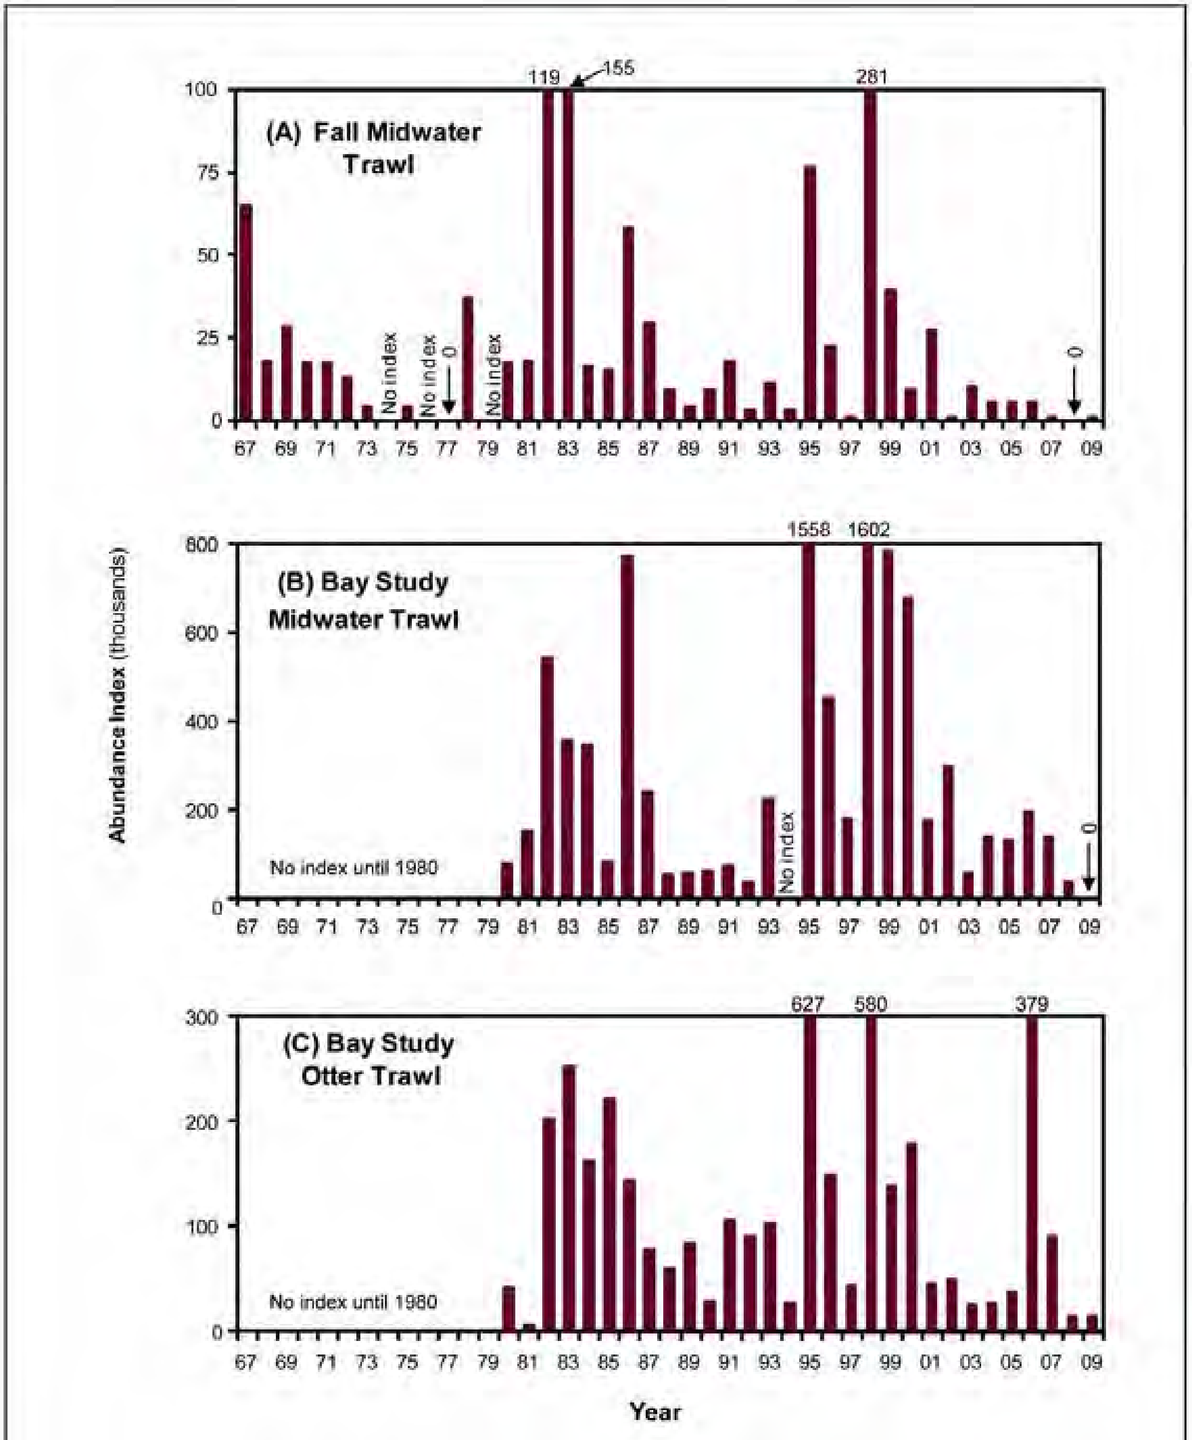
Long-term beach seine sampling data for age 0 splittail (less than or equal to 50 mm fork length) in the Sacramento River spanning 32 years (1976-2008) indicates that the farthest location upstream where juvenile splittail have been collected was 144 to 184 miles upstream of the confluence of the Sacramento and San Joaquin rivers (USFWS, unpublished data). The consistency in the upstream range of juvenile splittail found in these long-term studies supports a finding that there has been no decrease in distribution during this period (Feyrer et al. 2005).

Splittail range in other rivers includes:

- San Joaquin River – into Salt Slough (rm 135; Moyle 2002) and Mud Slough at the highway 140 bridge (R. Tibstra, pers. comm.);
- Cosumnes River – just above the confluence with the Mokelumne River (Crain et al. 2004);
- Mokelumne River – observed above Woodbridge Diversion Dam to rm 60;
- Stanislaus River – no confirmed sightings, but, based on observations from other tributaries, splittail probably inhabit low gradient portions of the lower river;
- Tuolumne River – rm 17 (Legion Park, Modesto, T. Ford pers. comm.) and several annually at rm 5 during 1999-2002 (T. Heyne, pers. comm.); and
- Merced River – rm 13 several annually 1999-2001 (1 mile upstream of Hagaman Park, M. Horvath pers. comm.; T. Heyne pers. comm.).

Near Mud and Salt Sloughs, splittail can access historical valley floodplains and apparently use them for spawning in wet years (e.g., 1995 and 1998; Baxter 1999, Moyle et al. 2004). Splittail occasionally extend their range farther southward into central and southern San Francisco Bays using freshwater and low salinity habitats created during high outflow years (DFG unpubl. data; Moyle et al. 2004). After high outflow years in the early 1980s and mid-1990s, splittail were captured in the estuary of Coyote Creek, South San Francisco Bay (M. Stevenson, pers. comm.). There is no recent information on the status or persistence of these south Bay populations.

The abundance of juvenile splittail (young-of-the-year) is highly variable from one year to the next and positively correlated with hydrologic conditions within the rivers and Delta during the late-winter and spring spawning period and the magnitude and duration of floodplain inundation (Sommer et al. 1997). Because splittail are a long-lived species (5 to 7 years; Moyle 2002), the abundance of juveniles in a given year may not be a good predictor of adult splittail abundance. Results of DFG fall midwater trawl surveys indicate a marked decline in overall splittail abundance and consistently low population levels since 2002 (see Figure A-7b). In addition, Bay study indices were extremely low.



Source: DFG, unpubl. data; IEP, unpubl. data.

A7.2.2 Distribution and Status in the Plan Area

Adult splittail spawn within the mainstem rivers and major tributaries to the Delta upstream of the Plan Area. Adult splittail spawn in the Plan Area on inundated floodplains of the Yolo Bypass and Cosumnes River. Collection of larvae and young juveniles indicates that inundation of terrestrial habitat within the levees of the San Joaquin River also provides suitable spawning habitat (Moyle et al. 2004). Larvae and young juveniles begin their migration downstream through the Delta with rising water temperatures during the spring; such migrations often occur in late-April, May, or even June of high flow years (Moyle et al. 2004). In low flow years, juvenile splittail are most abundant in the northern and western regions of the Delta; in high flow years, their distribution is more even throughout the Delta (Sommer et al. 1997). Most late stage juveniles and non-reproductive adults inhabit moderately shallow (less than 4 m) brackish and freshwater tidal sloughs and shoals, such as those found in Suisun Marsh and the margins of the lower Sacramento River (Moyle et al. 2004, Feyrer et al. 2005). Figure A-7c indicates the geographic distribution of splittail over the past 34 years throughout the Delta region and Figure A-7d indicates seasonal variation in the abundance of post-larval and juvenile splittail throughout their range.

No population level estimates currently exist for Sacramento splittail. However, because much of the overall distribution of splittail occurs in the Plan Area, population status and trends in the Plan Area are expected to be very similar to overall population status and trends.

A7.3 Habitat Requirements and Special Considerations

Spawning and Early Rearing. Splittail spawning is known to take place from February to July in freshwater on inundated floodplains in the Yolo and Sutter Bypasses and along the Cosumnes River (Sommer et al. 1997, 2001, 2002, Crain et al. 2004, Moyle et al. 2004). Limited collections of ripe adults and early stage larvae indicate splittail spawn in shallow water (less than 2 m deep) over flooded vegetated habitat (cockle burr, other annual terrestrial vegetation, and perennial vegetation like willow) with a detectable water flow (Moyle et al. 2004). Turbidity is typically high under these conditions, but decreases rapidly as flows diminish. On floodplains, complex topography slows water velocities, creating eddies, and increasing hydraulic residence time. Increased hydraulic residence time promotes phytoplankton and zooplankton production on seasonally inundated floodplains. Copepods are an important first food for larval splittail (Kurth and Nobriga 2001). Floodplain inundation initiates egg development of an aquatic fly (chironomids) that, as late stage larva or pupa, is an important food of late stage larval splittail (Kurth and Nobriga 2001). Relatively warm temperatures and an abundance of food allow young splittail to grow and develop rapidly on floodplains so that they are physically prepared to leave floodplains when water levels recede. Increased water temperatures and reduced water levels may cue floodplain emigration of juvenile splittail. Many of these ecosystem benefits are dependent upon the frequency, duration, and timing of the floodplain inundation.

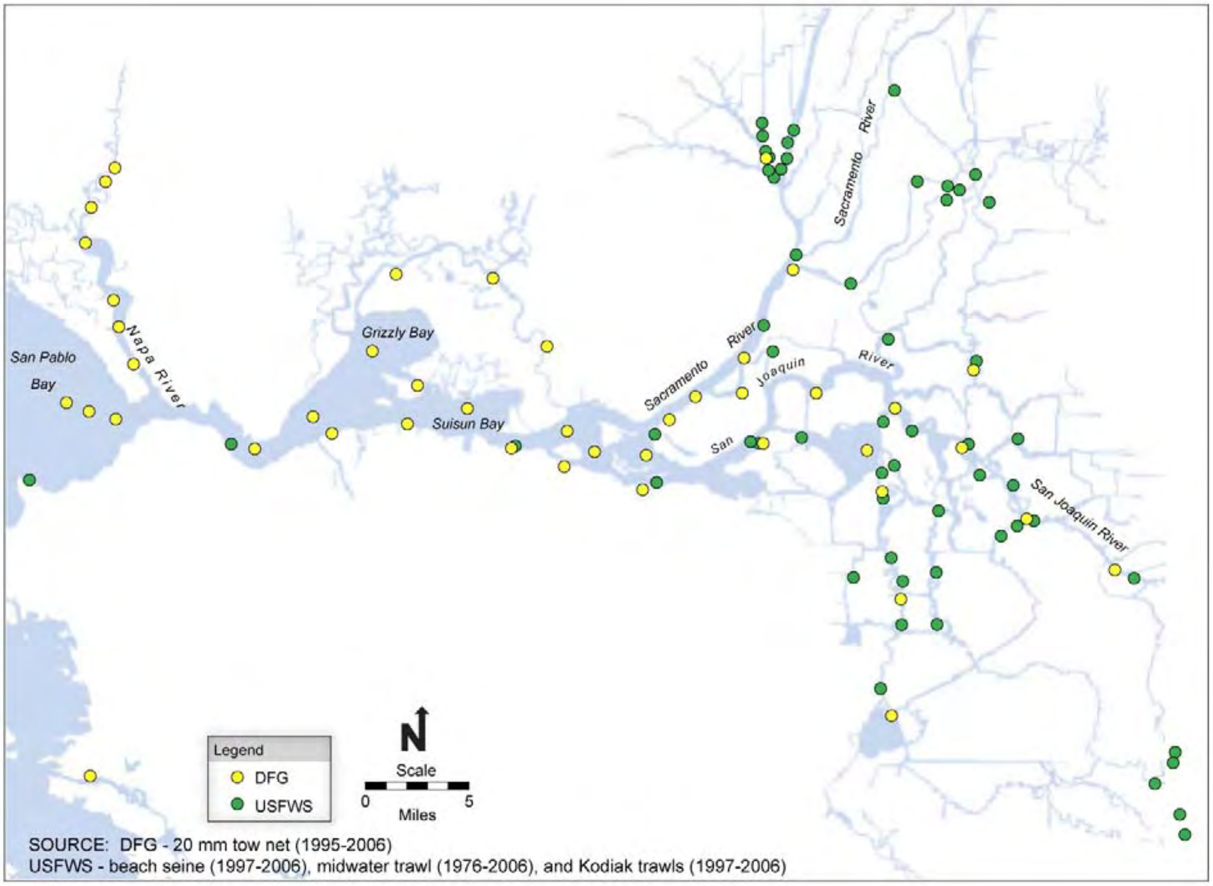

Figure A-7c. Historical Sampling Locations where Splittail have been Captured Since 1976

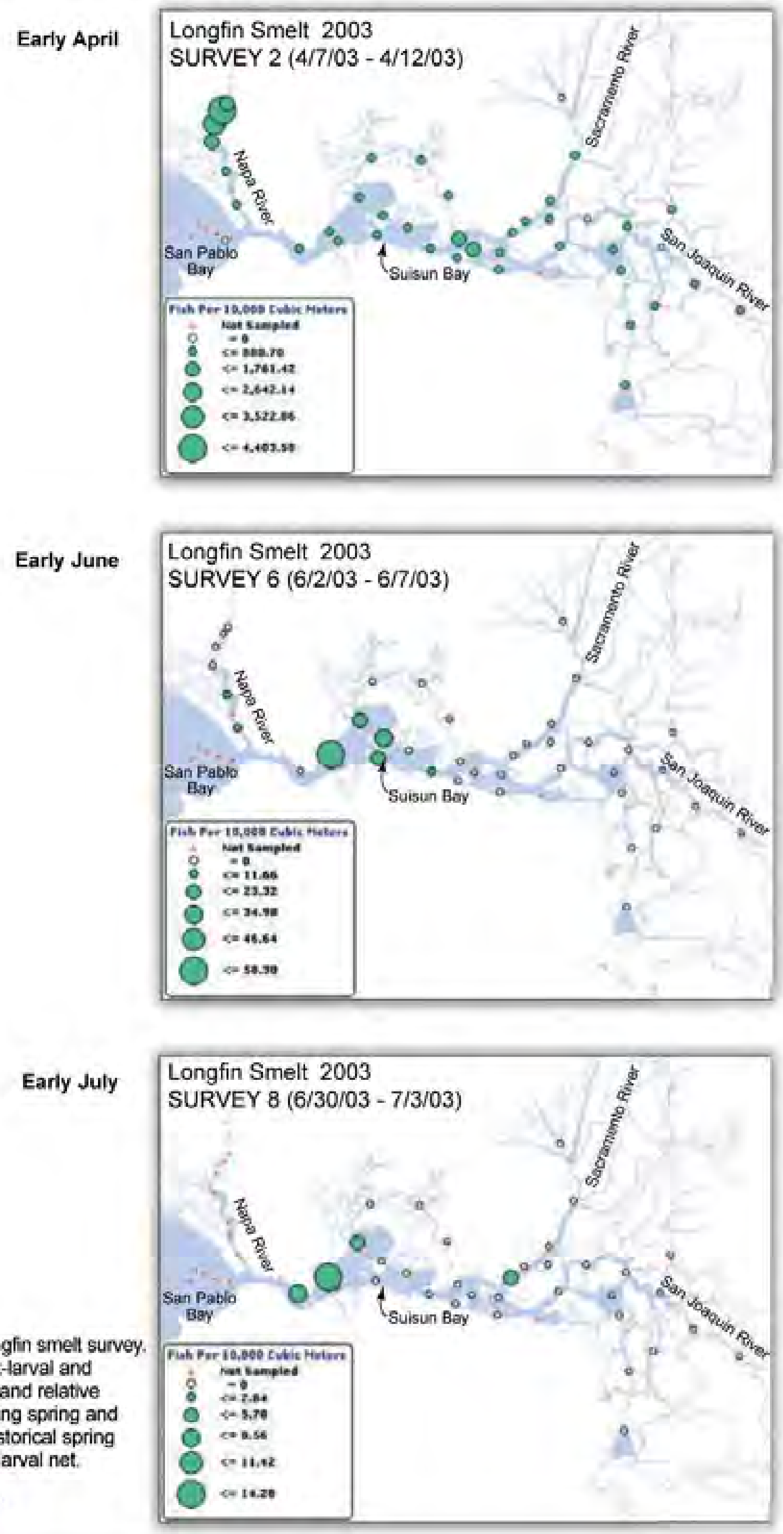
When floodplain inundation does not occur in the Yolo or Sutter Bypasses, adult splittail migrate farther upstream to suitable habitat along channel margins or flood terraces; spawning in such locations occurs in all water year types (Feyrer et al. 2005). Although evidence from DFG fishery surveys demonstrates that splittail spawn in all years, spawning success, as reflected in juvenile abundance, is typically greatest in wet years.

Juveniles and Adults. Although some larval and juvenile splittail are swept off floodplains and downstream by flood currents (Baxter et al. 1996), many splittail larvae and juveniles remain in riparian or annual vegetation along shallow edges on floodplains as long as water temperatures remain cool (Sommer et al. 2002, Moyle et al. 2004). Juvenile and subadult splittail commonly inhabit regions of the estuary characterized by salinities of 10 to 18 parts per thousand (ppt) (Meng and Moyle 1995; Sommer et al. 1997). Salinity tolerance increases with size (and age) such that adult splittail can survive salinities up to 29 ppt for brief periods of time (Young and Cech 1996). Splittail inhabit a broad range of temperatures, 5 to 24°C (41 to 75.2 °F) depending upon season, and acclimated fish can tolerate 29 to 33°C (84.2 to 91.4 °F) for short periods (Young and Cech 1996).



Source: CDFG 2003, 20 mm Longfin smelt survey. This annual survey monitors post-larval and juvenile longfin smelt distribution and relative abundance every two weeks during spring and early summer throughout their historical spring range using a 1600 µm egg and larval net. For more information see http://www.delta.dfg.ca.gov/data/20mm/description.asp

Figure A-7d. Example of Distribution of Post-Larval and Juvenile Longfin Smelt in Spring-Summer of a Representative Above Normal Water Year

Complementing their temperature and salinity tolerances, splittail of all sizes can tolerate low dissolved oxygen levels (less than 1 mg O_2 L^{-1}, Moyle et al. 2004), making them well suited to slow moving sections of sloughs and rivers. In Suisun Marsh during summer, splittail commonly inhabit areas with salinities of 6 to 10 ppt and temperatures of 15 to 23 °C (59 to 73.4 °F; Meng and Moyle 1995). Juveniles are most abundant in shallow (less than 2 m), turbid water with a current, and are often m) with incoming tide to feed. Napa and Petaluma River stocks may possess a higher salinity tolerance than the Central Valley stock (Baerwald et al. 2007).

Two early life history strategies occur in juvenile splittail produced in the Sacramento River system: the dominant strategy is characterized by juveniles migrating downstream in late spring and early summer to the Delta, Suisun Bay, and Suisun Marsh; a less well studied strategy is to remain upstream through the summer into the next fall or spring and migrate downstream as a subadult (Baxter 1999, Moyle et al. 2004). This latter strategy occurs in Butte Creek and the mainstem Sacramento River. As water recedes further, juveniles remaining in upstream riverine habitats and congregate in large eddies for feeding (R. Baxter, unpubl.data).

Channel margin and backwater habitats can be critical to the survival of young-of-year (YOY) splittail, as well as the population as a whole (Moyle et al. 2004, Feyrer et al. 2005). Such habitats provide refugia from predatory fishes and feeding sites as fish grow in upstream regions before and during downstream migration. Many backwater habitats are associated with the complex topography of remnant riparian habitats and are ephemerally created in response to increases in river stage (water surface elevation); others are synthetic creations such as cut channels, boat ramps, or agricultural pump intakes. This contrasts with major floodplain inundation typically associated with large splittail year classes (Meng and Moyle 1995, Baxter et al. 1996, Sommer et al. 1997), which may require an 8 to 10 m increase in river stage (typically associated with flood flow events). In the Sacramento River, levees constrain river meander from rm 194 at Chico Landing downstream to Collinsville (rm 0) and restrict the riparian zone accessible via the river channel.

Levee configuration differs through three reaches downstream of Chico Landing and has important implications in terms of splittail spawning and rearing habitat: (1) the river reach from Chico Landing to Colusa (rm 144) is characterized by setback levees enclosing remnant floodplain (flood terraces) and a narrowly meandering river channel; (2) the reach from Colusa to Verona (rm 80) is tightly leveed and contains fewer and much narrower flood terraces, many of which are actively eroding and targeted for rip-rap; and (3) the reach from Verona to Collinsville (rm 0) is also tightly leveed and contains extensive, narrow flood terraces between Verona and Sacramento, but is almost completely rip-rapped from Sacramento to Collinsville (Feyrer et al. 2005).

Maintaining and increasing this seasonally inundated floodplain habitat suitable for splittail spawning and juvenile rearing throughout the species range has been identified as a factor that will help maintain successful reproduction and increase juvenile abundance and genetic diversity during prolonged drought events and avoid a genetic “bottleneck.”

A7.4 LIFE HISTORY

Phenology. Adult splittail begin a gradual upstream migration towards spawning areas sometime between late November and late January. The relationship between migrations and river flows is poorly understood, but it is likely that splittail have a positive behavioral response to increases in flows. Feeding in flooded riparian areas in the weeks just prior to spawning may be important for later success of spawning and for post-spawning survival. Not all splittail make significant movements prior to spawning, as indicated by evidence of spawning in Suisun Marsh (Meng and Matern 2001) and the Petaluma River. The upstream movement of splittail is closely linked with flow events during February-April that inundate floodplains and riparian areas (Garman and Baxter 1999, Harrell and Sommer 2003). Seasonal inundation of shallow floodplains provides both spawning and foraging habitat for splittail (Caywood 1974, Daniels and Moyle 1983, Baxter et al. 1996, Sommer et al. 1997). Evidence of splittail spawning on floodplains has been found on both the San Joaquin and Sacramento rivers. In the San Joaquin River drainage, spawning has apparently taken place in wet years in the region where the San Joaquin River is joined by the Tuolumne and Merced rivers (T. Ford, pers. comm.). Spawning has also been documented on flooded areas along the lower Cosumnes River (Crain et al. 2004). Spawning may take place elsewhere in the Delta (e.g., on mid-channel islands) but it has not been documented. In the Sacramento River drainage, the most important spawning areas appear to be the Yolo and Sutter Bypasses, which are extensively flooded during wet years (Sommer et al. 1997, 2001). However, some spawning takes place every year along the river edges and backwaters created by small increases in flow.

In the eastern Delta, the floodplain along the lower Cosumnes River appears to be important as spawning habitat. Ripe splittail have been observed in areas flooded by levee breaches, in association with cool temperatures (less than 15 °C [59 °F]), turbid water, and flooded terrestrial vegetation (P. Moyle, unpubl. data).

Life Cycle. Splittail spawning occurs between late February and early July (Wang 1986). Fecundity is highly variable; females lay between 5,000 to 100,000 eggs. Egg incubation lasts for 3 to 7 days depending on water temperature (Moyle 2002). Newly hatched larvae are typically 6.5 to 8 mm (fork length) (Wang 1986). Larvae remain in shallow weedy areas near spawning areas for 10 to 14 days (Meng and Moyle 1995). When juveniles reach a length of approximately 29 mm (fork length), they move into deeper habitats (Sommer et al. 2002). Splittail grow to a typical length of 110 mm (standard length) during their first year, 170 mm during their second year, 250 mm during their third year, and 35 mm/year during remaining years (Moyle 2002). Maturity is typically reached at the end of their second year (Daniels and Moyle 1983).

Diet. The diet of splittail larvae up to 15 mm in length is dominated by zooplankton, primarily cladocerans with some copepods, chironomids, and rotifers present in small amounts; chironomids become important after splittail reach 15 mm in length (Kurth and Nobriga 2001, Moyle 2002). For age 1+ splittail, detritus is the dominant item found in fish collected from the estuary; various macroinvertebrates, including amphipods, clams, and mysid shrimp, are the most common non-detrital items (Caywood 1974, Daniels and Moyle 1983, Feyrer et al. 2003). During upstream migration to spawning areas, adult splittail captured near inundated shorelines along the Sacramento River were found to contain oligochaetes (earth worms) as well as smaller amounts of dipterans and cladocerans (Caywood 1974).

A7.5 THREATS AND STRESSORS

The following have been identified as important threats and stressors to Sacramento splittail (not in order of priority).

Reduced juvenile/adult rearing habitat. Reclamation of Delta islands and wetlands during the 19th and early 20th centuries removed or degraded large areas of high quality juvenile/adult rearing habitat. This habitat consisted of shallow, low velocity areas throughout the Delta, and particularly in the western Delta and Suisun Marsh (Moyle et al. 2004). In the 1960s and 1970s, the U.S. Army Corps of Engineers (USACE) increased downstream water conveyance and reinforced levees by clearing and rip-rapping levees along the lower Sacramento River. These actions further reduced or eliminated suitable rearing habitat for splittail from the city of Sacramento downstream by removing large areas of shallow channel margins. Current efforts are under way to improve flood protection for communities along much of the lower Sacramento River and several other valley rivers. Actions being proposed and conducted include removal of trees and riparian vegetation and armoring with riprap. USACE's current policy is for removal of all large trees and brush from levees to improve detection of weak points and potential levee failures.

Reduced spawning/larval rearing habitat. Reclamation and levee construction along the majority of Delta waterways and upstream riverine habitats has degraded or eliminated large areas of seasonally inundated floodplains that once served as spawning and larval rearing habitat for splittail. Although some spawning occurs on shallow margins of the main channels every year, floodplains are highly productive and, when inundated, are used more heavily by splittail than channel margin habitat for spawning and larval rearing.

Changes in river stage resulting from upstream diversions and reservoir storage has not been well studied, but, during low and moderate runoff years, water management may affect access of splittail to floodplains and their ability to emigrate successfully after spawning and early rearing (Moyle et al. 2004). Reservoir operations are designed to reduce peak flows during winter and spring months that historically would have resulted in seasonal inundation of floodplains.

Reduced food. There are multiple mechanisms that may cause reductions in food supplies for juvenile and adult splittail, including competition with non-native species and reductions in primary and secondary productivity (Jassby et al. 2002, Resources Agency 2007). The overbite clam is a highly efficient filter feeder that has reduced zooplankton populations in the Delta and Suisun Bay (Kimmerer and Orsi 1996). Zooplankton, particularly mysid shrimp, were the principal component of the splittail diet prior to the invasion of the estuary by the overbite clam, and the introduction of the clam has reduced the availability of mysids to splittail (Feyrer et al. 2003). However, the effect of the overbite clam on food availability to splittail is mixed because splittail also consume the clams (Feyrer et al. 2003).

Reductions in productivity within the estuary have been attributed to changes in hydrology associated with upstream reservoir operations, in-Delta water diversions, and reduced hydraulic residence time in the Delta. Upstream reservoir operations have reduced seasonal variability in Delta and river hydrology, resulting in fewer and shorter high flow events and, therefore, reduced frequency and duration of floodplain inundation (Sommer et al. 1997, 2002, Meng and Matern 2001, Feyrer et al. 2005, 2006). Floodplains are highly productive and are a source of large amounts of organic carbon (Schemel et al. 1996, Sommer et al. 2001, Schemel et al. 2004, Lehman et al. 2008).

The State Water Project (SWP) and Central Valley Project (CVP) export facilities and the over 2,200 in-Delta agricultural diversions (Herren and Kawasaki 2001) export nutrients, organic material, phytoplankton, and zooplankton from the Delta that would otherwise support the base of the food web (Jassby et al. 2002, Resources Agency 2007).

Reductions in hydraulic residence time in the central Delta have resulted, in part, from the need to maintain high water quality in the Delta for agricultural uses and SWP/CVP exports. Higher quality water from the Sacramento River is conveyed southward through the Delta via the Delta Cross Channel, creating a hydraulic barrier against salt water that may otherwise enter the Delta from the west. As a result, water movement has increased and hydraulic residence time has declined in the central Delta. Reduced hydrologic residence time is thought to reduce productivity in the Delta because nutrients and organics are transported downstream and out of the Delta before stimulating phytoplankton or zooplankton production (Jassby et al. 2002, Kimmerer 2002a,b, Resources Agency 2007). Increased hydraulic residence time allows more opportunity for bacterial activity and phytoplankton and zooplankton production.

Exposure to toxins. Although there is strong support from laboratory studies that toxics can be lethal to splittail (Teh et al. 2002, 2004a,b, 2005), there is little information about the chronic or acute toxicity of contaminants within the Delta (e.g., Greenfield et al. 2008). The longevity of splittail relative to most other covered fish species (5 to 7 years, Moyle 2002) enables their tissue to bioaccumulate toxicants to higher concentrations than these other species. This makes splittail particularly vulnerable to heavy metals, such as mercury, and other fat-soluble chemicals. Perhaps the greatest concern among the impacts of contaminants on splittail relates to selenium. Tissues of splittail collected in Suisun Bay had sufficiently high selenium concentrations to potentially cause physiological impacts, in particular reproductive abnormalities (Stewart et al. 2004). Adult splittail feed on the overbite clam, which bioaccumulates and transfers selenium in high concentrations (Luoma and Presser 2000). With the decline of the mysid shrimp, *Neomysis,* in the estuary, juvenile and adult splittail have increased foraging on benthic macroinvertebrates such as clams (Feyrer et al. 2003). Teh et al. (2004b) found that young splittail that were fed a diet high in selenium grew significantly slower and had higher liver and muscle selenium concentrations after nine months of testing.

Kuivila and Moon (2004) documented dissolved pesticides in the Sacramento-San Joaquin Delta during April-June (1998-2000) when young, growing splittail were migrating into the Delta and estuary. The use of pyrethroid pesticides has increased substantially in the Central Valley since the early 1990s (Oros and Werner 2005). Though relatively non-toxic to mammals, these chemicals are highly toxic to aquatic organisms, including fishes. Also, pesticide use on row crops (including rice) commonly grown in the Yolo and Sutter Bypasses and their proclivity to adhere to sediment particles suspended in water and deposited on the bottom provide a dietary pathway to splittail ingestion along with detritus during feeding (see Diet section above) (Werner 2007). Exposure to pesticides and other chemical contaminants may occur while splittail forage on inundated floodplains or in the estuary after the pesticides have entered Delta channels through agricultural drainage and have been transported to and settled in the Delta.

Non-native species. Splittail have persisted in the estuary through numerous invasions of non-native fish and invertebrates. Some, such as the invasion of the mysid shrimp, *Acanthomysis*, may have been beneficial to splittail, as the native mysid, *Neomysis*, was already on a steep decline in abundance. Both mysid species are eaten by splittail. The invasive overbite clam also became a food item, but with potential detrimental effects, such as bioaccumulation of selenium and reduction in overall phytoplankton and zooplankton abundance (see above).

Major non-native predatory fish introduced into the Bay-Delta estuary, such as striped bass and largemouth bass, have resided in the Delta for over a century (Dill and Cordone 1997), and splittail have persisted. However, reduced turbidity in the Delta combined with increased habitat for non-native predatory species provided by Brazilian waterweed and water hyacinth has enhanced both largemouth bass abundance and their ability to visually forage, thus increasing predation risk to splittail (Toft et al. 2003, Brown and Michniuk 2006).

A major concern is the potential invasion of the Delta by the highly predatory northern pike. The pike, recently present in Lake Davis on the Feather River, is currently the target of a major eradication effort (DFG 2007a). If eradication fails and pike escape downstream to the Delta, they would likely to become abundant in many of the same habitats as splittail (Moyle 2002).

Entrainment. Splittail are salvaged year-round in the SWP and CVP fish salvage facilities, with the greatest occurrence during May-July. The majority of splittail observed in fish salvage monitoring are early juveniles. Although juvenile splittail are collected in SWP and CVP fish salvage, there is no evidence that juvenile entrainment mortality has a significant population level effect on splittail (Sommer et al. 1997). Splittail salvage rates at the SWP and CVP facilities are high when splittail populations are at high levels. Young-of-the-year splittail have critical swimming velocities that are similar to water velocities occurring at the SWP and CVP diversions and are entrained at these facilities (Young and Cech 1996). Because salvage rates are high when splittail abundance is high, the effect of entrainment at the SWP and CVP export facilities on the overall population of splittail is not expected to be great. However, prolonged drought and subsequent reduction in adult splittail abundance could eventually cause a proportionally large effect on the population, particularly if the geographic distribution of the splittail population were to occur near the export facilities (Sommer et al. 1997).

Increases in export rates during the winter and total water exports from the south Delta have been associated with increased salvage of a wide variety of upper estuary fishes since 2000 (Herbold et al. 2005). The majority of splittail salvage at the SWP and CVP export facilities is composed of age 0 fish in May-July during years with high outflows that persist into the March-April splittail spawning period (Sommer et al. 1997). For example, splittail salvage increased substantially in both 2005 and 2006, corresponding to high levels of juvenile production within the system, reaching a record high of over 5 million fish at the CVP Tracy Fish Collection Facility (Gartz 2007).

There are no studies that quantitatively examine splittail mortality during the SWP or CVP fish salvage process, but it is thought to be high. Mortality to young splittail may occur as a result of overcrowding within transport tanks and predation at release locations within the Delta. Furthermore, adults that are salvaged are returned to an area downstream of the export facilities, which is expected to increase the energy expenditure needed to reach their upstream spawning sites and could reduce their ability to spawn successfully (Moyle et al. 2004).

In addition to SWP and CVP export facilities, there are over 2200 small water diversions within the Plan Area, the majority of which are unscreened (Herren and Kawasaki 2001). Results of surveys at unscreened diversions (Nobriga et al. 2004) have shown that a variety of fish species (e.g., threadfin shad, silversides, striped bass, etc.), primarily larval and juvenile lifestages, are vulnerable to entrainment. Based on results of this and similar studies conducted on unscreened diversions, it has been hypothesized that early juvenile splittail would be vulnerable to entrainment from these smaller diversions. The available information, however, is insufficient to fully assess the potential magnitude of the entrainment risk, how the risk varies among areas and seasonally, and the cumulative effect of entrainment losses on the population dynamics of splittail. Water velocities at these relatively small agricultural pumps and siphons are low enough that larger fish are able to avoid entrainment. No comprehensive quantitative estimates have been developed for the level of potential entrainment mortality that may occur as a result of diversions from the rivers and Delta.

Power plants within the Plan Area have the ability to entrain large numbers of fish. However, use of cooling water is currently low with the retirement of older units. Furthermore, recent State Water Resources Control Board (SWRCB) regulations require that units at these plants be equipped with a closed cycle cooling system by 2017.

Harvest. The legal fishery for splittail is thought to be substantial, despite poor documentation (Moyle et al. 2004). Subadult and adult splittail are harvested by recreational anglers for consumption, as well as for use as bait by striped bass anglers. There is no evidence that splittail are affected at a population level by the fishery, but there is insufficient evidence to conclude this with confidence.

A7.6 RELEVANT CONSERVATION EFFORTS

The Ecosystem Restoration Program (ERP) (CALFED 2000) lists splittail as “r,” contribute to recovery, and includes the following prescription to achieve the species goal:

> *Species recovery objectives will be achieved when 2 of the following 3 criteria are met in at least 4 of every 5 years for a 15 year period: 1) the fall mid-water trawl survey numbers must be 19 or greater for 7 of 15 years. 2) Suisun Marsh catch per trawl must be 3.8 or greater and the catch of young-of-year must exceed 3.1 per trawl for 3 of 15 years, and 3) Bay Study otter trawls must be 18 or greater AND catch of young-of-year must exceed 14 for 3 out of 15 years.*

The CALFED ERP has funded the Yolo Bypass Watershed Restoration Strategy. The purpose of this project is to develop a local implementation strategy for a broad landscape level of restoration and rehabilitation for the Yolo Bypass, which should have direct benefits to splittail.

The ERP has also funded a feasibility study for flood protection and ecosystem restoration at Hamilton City. The feasibility study identified constructing an 11 km (6.8 mile) setback levee with varying heights. To accomplish ecosystem restoration within the project area, the majority of the existing “J” levee would be removed to reconnect the river to the floodplain, allowing overbank flooding and increasing capacity in the Sacramento River. Native vegetation would be restored on all project lands waterside of the new setback levee. Existing orchards in the proposed restoration areas would be removed and native vegetation planted. The native vegetation would be riparian species, scrub, oak savannah, and grassland species.

Connectivity to and restoration of floodplain habitat were achieved along the Cosumnes River through breaching of levees on the Cosumnes River Preserve during the 1990s (Booth et al. 2006). The Cosumnes River Preserve is managed by a coalition of state, federal, and non-profit organizations, such as The Nature Conservancy California. The Cosumnes River floodplain is now thought to be used for spawning by splittail (Crain et al. 2004, Moyle et al. 2004).

There are several conservation activities planned to improve shallow subtidal habitat in the Delta that should provide benefit to splittail. The CALFED ERP Suisun Marsh Land Acquisition and Tidal Marsh Restoration project will restore 500 acres within the Suisun Marsh to tidal wetland. The Suisun Marsh/North San Francisco Bay Ecological Zone Biological Restoration and Monitoring project will restore, maintain, and monitor the biology of at least three major eastern San Pablo Bay and southern Suisun Bay areas within a single CALFED-defined ecological zone (Suisun Bay/North San Francisco Bay), and compare and improve these restoration efforts through an integrated monitoring program. Construction in Ponds 3, 4, and 5 in the Napa-Sonoma Marsh will restore three commercial salt ponds along the Napa River that are expected to provide habitat benefits for splittail and other aquatic species. Restoration of Pond 3 will provide tidal habitat, whereas restoration actions in Ponds 4 and 5 will reduce salinity in preparation for tidal habitat restoration. The overall goal of this project is to restore tidal influence and re-create natural/historic elevations/topography, soil conditions, and plant communities throughout the entire elevational range to restore tidal marsh habitat.

Using ERP funds**,** construction of the Sutter Mutual Water Company Tisdale positive barrier fish screen and pumping plant has been completed. This diversion is located 45 miles north of Sacramento on the Sacramento River and will eliminate entrainment losses while maintaining Sutter Mutual Water Company's diversions.

Construction is ongoing for the Reclamation District 108 Poundstone Intake Consolidation and Positive Barrier Fish Screen Project in Colusa County. This project will construct an 81 foot long positive barrier fish screen at the entrance to a new water diversion site on the Sacramento River (rm 110.5) in Colusa County. The new diversion will consolidate and allow removal of three existing unscreened diversions. Other projects (e.g., Reclamation District 1004 intake screens, RD 108 Wilkins Slough Positive Barrier Fish Screen) have been constructed on the Sacramento River to reduce entrainment of splittail and other fish.

A new integrated monitoring and outreach program to evaluate fish contamination issues has recently been funded by ERP. This project will monitor mercury levels in sport fish and biosentinel indicators for three years throughout the watershed. The monitoring will evaluate spatio-temporal variability and gather information needed for management decisions.

The Delta Regional Ecosystem Restoration Implementation Plan (DRERIP) was formed to guide the implementation of CALFED ERP elements within the Delta (DFG 2007b). The DRERIP team has created a suite of ecosystem and species conceptual models, including splittail, that document existing scientific knowledge of Delta ecosystems. The DRERIP Team has used these conceptual models to assess the suitability of actions proposed in the Ecosystem Restoration Plan for implementation. DRERIP conceptual models were used in the analysis of proposed BDCP habitat restoration actions.

The Sacramento River Conservation Area Forum, DWR, USFWS, DFG, the Department of Parks and Recreation, the Wildlife Conservation Board, nonprofit organizations such as the Nature Conservancy and the Sacramento River Partners, and many other stakeholders conduct conservation and restoration activities in the middle and upper reaches of the Sacramento River. The Sacramento River Conservation Area Forum developed guidelines for all stakeholders to follow in directing their restoration and conservation actions. These guidelines "ensure that riparian habitat management along the river addresses the dynamics of the riparian ecosystem and the reality of the local agricultural economy." Sacramento River Conservation Area Forum goals include preserving remaining riparian habitat and reestablishing a continuous riparian ecosystem along the river. Restoration activities generally fall into one of two categories:

- Actions aimed to protect and maintain existing healthy habitat and natural processes; or
- Actions aimed to restore and recover lost habitat and disrupted processes.

The Sacramento River Conservation Area Forum recommends preserving existing riparian habitat and reestablishing a continuous band of riparian vegetation along the river. Most conservation actions to date embrace this goal and were initiated to offset habitat fragmentation as a significant threat to declining fish and wildlife populations. The most flood-prone land parcels with less productive soils and more rapid bank erosion have been bought from willing sellers and restored first.

On December 10, 2009, the California Fish and Game Commission adopted DFG's proposal to establish fishing regulations on splittail in an effort to reduce the potential effects of harvest on the splittail population. Effective March 1, 2010, there is a year-round two fish daily bag and possession limit.

A7.7 Recovery Goals

Although splittail is not listed, it is included in the USFWS 1996 Sacramento-San Joaquin Delta Native Fishes Recovery Plan, which also includes the delta smelt, longfin smelt, green sturgeon, Sacramento perch, and three races of Chinook salmon (USFWS 1996). The USFWS has the responsibility to review and update the recovery plan for these species. To accomplish this task, the Service has formed a new Delta Native Fishes Recovery Team to assist in the preparation of this updated plan. An updated recovery plan from USFWS is expected to be completed soon.

Ford, Tim (Biologist, Turlock and Modesto Irrigation Districts) Fax and phone call to Randall Baxter (DFG) documenting splittail catches in the Tuolumne and lower San Joaquin rivers 1986-1992. February 16, 1994.

Heyne, Tim (Biologist, DFG) email to Randall Baxter (DFG) documenting splittail counts from the Tuolumne (rm 5) and Merced (rm 13) rotary screw traps 1999-2003. October 3, 2003.

Horvath, Mike (Fish and Wildlife Technician, DFG) email to Randall Baxter (DFG) describing the catch in a screw trap of a gravid female splittail the previous day. April 16, 1999,

Oppenheim, Bruce (Biologist, NMFS) email report to Randall Baxter (DFG) of a fresh angler killed adult splittail thrown up on a river bank just below the Thermalito outlet. September 15, 2003.

Seesholtz , Alicia (Environmental Scientist, DWR) phone conversation with Rick Wilder about fish use of the Feather River. September 20, 2007

Stevenson, Marty (Biologist/Consultant, Kinetic Laborary for South Bay Dischargers) to Randall Baxter (DFG) describing juvenile splittail collected in Coyote Creek and adjacent, Guadalupe Slough in 1983 and 1984. May 16, 1997.

Tibstra, Robert (Biologist, DFG) email to Randall Baxter (DFG) describing splittail collected electrofishing at 3 sites: in the San Joaquin River upstream of the Merced River confluence and downstream of the Mud Slough confluence (RKM 191); in the SJR upstream of the Mud Sl. confluence, 100m downstream of the highway 140 bridge (RKM 201); and in Mud Slough (north) downstream of the discharge of the San Luis Drain at hwy 140 bridge. November 15, 2002.

APPENDIX A8. WHITE STURGEON (*ACIPENSER TRANSMONTANUS*)

A8.1 LEGAL STATUS

The white sturgeon is not listed under the Federal or California Endangered Species Acts (ESA).

A8.2 SPECIES DISTRIBUTION AND STATUS

A8.2.1 Range and Status

White sturgeon inhabit three major drainages on the west coast of North America including the California Central Valley, Columbia (Washington), and Fraser River (British Columbia) systems. In California, white sturgeon are most abundant in the Sacramento River and San Francisco Bay-Delta estuary (Figure A-8a) (Moyle 2002). White sturgeon have been reported from the San Joaquin River system, particularly in wet years (DFG 2002, Beamesderfer et al. 2004).

Historical spawning range of white sturgeon extended upstream of Shasta Dam before its construction in the 1940s (Figure A-8a). It is thought that white sturgeon also spawned farther upstream on the San Joaquin River before major water diversions existed (Moyle 2002).

In the Central Valley, white sturgeon populations have declined from an estimated 144,000 adults in 1994 to 10,000 adults in 2005 (Bland 2006). The number of adults fluctuates annually and appears to be the result of highly variable juvenile production; the population is dominated by a few strong year classes associated with high spring outflows (Moyle 2002).

A8.2.2 Distribution and Status in the Plan Area

The Delta and Suisun Bay serve as a migratory corridor, feeding area, and juvenile rearing area for white sturgeon. White sturgeon move from coastal marine waters into the Delta and lower Sacramento River during the late fall and winter. Larval and juvenile white sturgeon inhabit the lower reaches of the Sacramento and San Joaquin rivers and the Delta (Stevens and Miller 1970). Adult white sturgeon have also been documented in the Yolo Bypass (Webber et al. 2007; M. Marshall, pers. comm.).

DRAFT

Figure A-8a. White Sturgeon Inland Range in California

A8.3 HABITAT REQUIREMENTS AND SPECIAL CONSIDERATIONS

As anadromous fish, sturgeon inhabit riverine, estuarine, and marine habitats at various life stages during their long life. White sturgeon spawn preferably in the Sacramento River in the reach between the Red Bluff Diversion Dam (RBDD) and Jelly's Ferry Bridge (River Mile [rm] 267) in areas characterized by swift currents and deep pools with gravel (USFWS 1995, Schaffter 1997, DFG 2002, Moyle 2002). Habitats for migration of white sturgeon are downstream of spawning areas and include the mainstem Sacramento River, Delta, and San Francisco Bay estuary. These corridors allow the upstream passage of adults and the downstream emigration of juveniles. It has been hypothesized that migratory habitat conditions are affected by a variety of factors that may include the presence of barriers and impediments to passage (e.g., dams, gates such as the RBDD gates). Rearing habitat condition and function may be affected by annual and seasonal variation in flow and water temperatures.

A8.4 LIFE HISTORY

White sturgeon spend most of their lives in brackish portions of the estuary, although a small number of individuals move extensively in the ocean (Moyle 2002, Surface Water Resources, Inc. 2004, Welch et al. 2006). Individuals tend to concentrate in deeper areas of the estuary with soft mud and sand substrate (Pacific States Marine Fisheries Council 1996, Moyle 2002). Individuals can live over 100 years and can grow to over 19.7 feet (6 m), but sturgeon greater than 27 years old and over 6.6 feet (2 m) are rare (Moyle 2002).

Male white sturgeon reach sexual maturity at 10 to 12 years old and females reach sexual maturity at 12 to 16 years old (Moyle 2002). Maturation is thought to be a function of both photoperiod and temperature (Birstein et al. 1997). White sturgeon can spawn multiple times throughout their life. Males are believed to spawn every 1 to 2 years, whereas females spawn every 2 to 4 years (Moyle 2002). Females can produce 100,000 to several million eggs (PSMFC 1996), although typical females will produce approximately 200,000 eggs (Moyle 2002). Spawning typically occurs between February and June when temperatures are 46 to 66 °F (8 to 19 °C; Moyle 2002). Maximum spawning occurs at 58 °F (14.4 °C) in the Sacramento River (Kohlhorst 1976). It is thought that adults broadcast spawn in the water column in areas with swift current. Fertilized eggs sink and attach to the gravel bottom, where they hatch. Eggs hatch after four days at 61 °F (16 °C; Beer 1981), but may take up to 2 weeks at lower water temperatures (PSMFC 1996).

Spawning success varies from year to year. Newly hatched larvae are 7.5 to 19.5 mm in length (Kohlhorst 1976) and generally remain in the gravel for 7 to 10 days before emergence into the water column (Moyle 2002). Newly emerged larvae are pelagic for approximately seven to 10 days until their yolk-sac is absorbed, at which time they begin actively feeding on amphipods and other small benthic macroinvertebrates (Wang 1986). Juvenile white sturgeon feed primarily on algae, aquatic insects, small clams, fish eggs, and crustaceans, but their diet becomes more varied with age (Wang 1986, PSMFC 1996, Moyle 2002). Since the invasion by the overbite clam in the western Delta and Suisun Bay during the late 1980s, the clam has become a major component of the diet of juvenile and adult white sturgeon.

A8.5 THREATS AND STRESSORS

The following have been identified as important threats and stressors to white sturgeon inhabiting the Bay-Delta estuary (without priority).

Harvest. As long-lived, late maturing fish, white sturgeon are particularly susceptible to threats from overfishing (Musick 1999). White sturgeon are a popular game species within the Bay-Delta estuary and Sacramento River and support commercial fisheries within estuaries in Oregon and Washington. White sturgeon are also vulnerable to illegal (poaching) harvest. Catches of white sturgeon occur during all years, with the greatest catches typically occurring in wet years. The California Fish and Game Commission has recently adopted more restrictive sport fishing regulations designed to reduce the effects of angler harvest on white sturgeon inhabiting the Bay-Delta estuary.

Due to limits imposed on the sport fishery by DFG (2007a), only white sturgeon between 46 and 66 inches may be retained by sport fisherman with a daily bag limit of one fish in possession. Current regulations, initially implemented by DFG in 2007, require that anglers carry an annual sturgeon report card that limits annual harvest of white sturgeon to three fish per year. DFG (2002) indicates high sturgeon vulnerability to the fishery in areas where sturgeon are concentrated, such as the region between the Delta and San Pablo Bay in late winter and the upper Sacramento River during the spawning migration. In addition, the trophy status of white sturgeon and the consequent incentive for retaining oversized (greater than 66 inches [167.6 cm]) fish is another impetus for active enforcement of sturgeon angling regulations (DFG 2002).

Poaching (illegal harvest) of white sturgeon is known to occur in the Sacramento River, particularly in areas where sturgeon have been stranded (e.g., Fremont Weir) (M. Marshall, pers. comm.), as well as throughout the Bay-Delta estuary. Poaching rates in the estuary, Sacramento River, San Joaquin River and Feather River are unknown.

Furthermore, the effects of legal and illegal harvest on the population dynamics and abundance of white sturgeon within the Bay-Delta estuary are largely unknown. The small population of white sturgeon inhabiting the San Joaquin River experiences heavy fishing pressure, particularly from illegal fishing (U.S. Fish and Wildlife Service [USFWS] 1995). In addition, areas just downstream of Thermalito Afterbay Outlet, Cox's Spillway, and several barriers impeding sturgeon migration on the Feather River, may be areas of high adult mortality from high fishing effort and poaching. Poaching of white sturgeon females for roe has increased over the past 10 years despite increased enforcement efforts by DFG (L. Schwall, pers. comm.). This type of poaching is particularly detrimental to the white sturgeon population because it targets the oldest and largest adults with the highest fecundity, which affects both current and future stocks.

Reduced spawning habitat. Access to historical spawning habitat has been reduced by construction of barriers to upstream migration that block or impede access to spawning and juvenile rearing habitat. Major dams include Keswick Dam on the Sacramento River and Oroville Dam on the Feather River (Lindley et al. 2004, National Marine Fisheries Service [NMFS] 2005). White sturgeon adults have been observed periodically in the Feather River (USFWS 1995, Beamesderfer et al. 2004). Habitat modeling by Mora (2006) suggests there is suitable habitat for sturgeon in the upstream reaches of the Feather River that have been blocked by Oroville Dam. This modeling also suggests that suitable conditions are present in the San Joaquin River upstream of Friant Dam, and in the tributaries such as Stanislaus, Tuolumne, and Merced rivers upstream to their respective dams.

Other potential migration barriers include structures such as the RBDD, Sacramento Deep Water Ship Channel locks, Sutter Bypass, and Delta Cross Channel Gates on the Sacramento River, and Shanghai Bench and Sunset Pumps on the Feather River (70 FR 17386). The RBDD is an important migration barrier for sturgeon on the Sacramento River (USFWS 1995). Adult sturgeon can migrate past the RBDD when gates are raised between mid-September and mid-May to allow passage of winter-run Chinook salmon. However, tagging studies by Heublein et al. (2006) found that, when the gates were closed, a substantial portion of tagged adult green sturgeon failed to use the fish ladders at the dam and were, therefore, unable to access upstream spawning habitats. The same behavioral response may be true for white sturgeon. A set of locks at the end of the Sacramento River Deep Water Ship Channel at the connection with Sacramento River “blocks the migration of all fish from the deep water ship channel back to the Sacramento River” (California Department of Water Resources [DWR] 2005).

The Fremont Weir is located at the upstream end of the Yolo Bypass, a 40 mile (64 km) long basin that functions as a flood control facility on the Sacramento River. When the Yolo Bypass is inundated by flood water, white sturgeon are attracted into the Bypass and become trapped behind Fremont Weir, which acts as a barrier and impediment to upstream migration (DWR 2005). Sturgeon that are trapped by the weir are then subject to heavy legal and illegal fishing pressure, or become stranded behind the flashboards when the flows recede (M. Marshall, pers. comm.). Sturgeon can also be attracted to small pulse flows and trapped during the descending hydrograph (Harrell and Sommer 2003). Methods to reduce stranding and increase passage have been investigated by DWR and DFG (J. Navicky, pers. comm.).

It has been hypothesized that white sturgeon use the same migratory routes as Chinook salmon. Tagging studies have been designed and initiated to track sturgeon movement and migration patterns (P. Klimley, pers. comm.). Delta Cross Channel gate closures occur during the winter and early spring months (February through May) during sturgeon migration. The seasonal closure of the Delta Cross Channel gates is required by the State Water Resources Control Board D-1641 as a measure designed to improve the survival of downstream migrating juvenile Chinook salmon. Upstream migrating adult Chinook salmon are known to use the Delta Cross Channel as a migratory pathway when the gates are open (Hallock et al. 1970). When the gates are open, Sacramento River water flows into the central Delta providing migration cues. It is likely that attraction to flows passing into the central Delta from the Sacramento River cause migration delays and straying of white sturgeon, as it does to Chinook salmon (CALFED Science Program 2001, McLaughlin and McLain 2004). Gate closures completely block juvenile and adult sturgeon migration.

Exact white sturgeon spawning locations in Feather River are unknown; however, based on angler catches, most spawning is believed to occur downstream of Thermalito Afterbay and upstream of Cox's Spillway, just downstream of Gridley Bridge. Potential physical barriers to upstream migration include the rock dam associated with Sutter Extension Water District's sunrise pumps, shallow water caused by a head cut at Shanghai Bend, and several shallow riffles between the confluence of Honcut Creek upstream to the Thermalito Afterbay Outlet (USFWS 1995). These structures are likely to present barriers or impediments during low flow periods that block and or delay upstream sturgeon migration to spawning habitat.

Exposure to toxins. Water quality in the Sacramento and San Joaquin rivers and the Delta is influenced by a variety of point and non-point source pollutants from urban, industrial, and agricultural land uses. Runoff from residential, agricultural, and industrial areas introduces pesticides, oil, grease, heavy metals, other organics, and nutrients that contaminate drainage waters and deteriorate the quality of aquatic habitats necessary for white sturgeon survival (NMFS 1996, California Regional Water Quality Control Board-Central Valley Region 1998). Organic contaminants from agricultural returns, urban and agricultural runoff from storm events, and high concentrations of trace elements, such as boron, selenium, and molybdenum, have been identified as factors that decrease sturgeon early life-stage survival, causing abnormal development and high mortality in yolk-sac fry sturgeon at concentrations of only a few parts per billion (USFWS 1995, California Regional Water Quality Control Board 2004). Principal sources of organic contamination in the Sacramento River are rice field discharges from Butte Slough, Reclamation District 108, Colusa Basin Drain, Sacramento Slough, and Jack Slough (USFWS 1995). In recent years, changes have been made in the composition of herbicides and pesticides used on agricultural crops in an effort to reduce potential toxicity to aquatic and terrestrial species. Modifications have also been made to water system operations and discharges related to agricultural wastewater discharges (e.g., agricultural drainage water system lock-up and holding prior to discharge) and municipal wastewater treatment and discharges. Concerns remain, however, regarding the toxicity to sturgeon of contaminants that adsorb to sediments, such as pyrethroids, and other chemicals including selenium and mercury.

The extent to which toxic pollution has affected the population of white sturgeon is unknown. Sturgeon are a long-lived species that feed on invertebrates, such as clams and shrimp, and are vulnerable to the effects of toxicant bioaccumulation on the health and condition of sub-adult and adult sturgeon and their reproductive success within the estuary. However, sturgeon do not readily concentrate lipid-soluble toxins such as polychlorinated biphenyls (PCBs). Greenfield et al. (2003) found that dichlorodiphenyltrichloroethane (DDT) and chlordane concentrations in white sturgeon tissues have declined since the 1980s while selenium concentrations have remained elevated. High levels of selenium can also be found in some white sturgeon prey

(Johns and Luoma 1988, White et al. 1988), including Corbula (Urquhart and Regalado 1991), as well as in sturgeon muscle, liver, and eggs (White et al. 1987, 1988, 1989, Kroll and Doroshov 1991, Urquhart and Regalado 1991). Doroshov et al. (2007) found selenium incorporation into the plasma vitellogenin and egg yolk proteins after exposing gravid females to a selenium enriched diet. The accumulation of selenium in egg yolk to a level greater than or equal to 15 µg g-1 resulted in severe deformities and mortalities of newly hatched larvae, and the amount of selenium measured in the ovaries of recently caught wild white sturgeon has approached or exceeded these levels (Doroshov et al. 2007). Early life history stages are especially sensitive to contaminant uptake, and Kruse and Scarnecchia (2002) showed moderately increased mortality rates of white sturgeon embryos to concentrations of trace metals and other contaminants found in the Kootenai River environment. The effects on the different life history stages of white sturgeon of contaminants, other than selenium, at concentrations found in the San Francisco Bay Estuary are unknown, as are any additive or synergistic effects of multiple contaminants.

Water quality in the San Joaquin River has degraded significantly since the late 1940s (California Regional Water Quality Control Board 2004). Discharges of agricultural return flows and other point and non-point discharges have resulted in increased loading of various water quality constituents to the river and subsequently the Delta. In an effort to improve water quality, habitat, and reduce stressors on fish species such as sturgeon, water quality monitoring and management programs have been implemented on the San Joaquin River and its tributaries to reduce the loading of salt, selenium, and other water quality contaminants.

Acidic water discharges from Iron Mountain Mine, located adjacent to the upper Sacramento River, have been identified as a factor affecting the survival of fish downstream of Keswick Dam and storage limitations and limited availability of dilution flows cause high levels of downstream copper, cadmium, and zinc (Environmental Protection Agency [EPA] 2007). The EPA's Agency's Iron Mountain Mine remediation has removed toxic metals in acidic mine drainage from the Spring Creek Watershed with a state-of-the-art lime neutralization plant. Contaminant loading into the Sacramento River from Iron Mountain Mine has shown measurable reductions since the early 1990s.

Since the invasion of the overbite clam and its rapid increase in abundance within Suisun Bay, the diet of white sturgeon has shifted such that the clam is now the main component of their diet (State Water Resource Control Board 1999). The overbite clam, due to its high filtration efficiency, accumulates selenium in high concentrations and loses it slowly (Luoma and Presser 2000, Linville et al. 2002, Doroshov et al. 2007). As a result, concentrations of selenium in white sturgeon have been observed at greater than threshold levels at which toxic effects have been observed in other fish species (Lemly 2002). Dietary selenium in high concentrations can adversely affect white sturgeon survival, activity, and growth (Tashjian et al. 2006).

Reduced rearing habitat. Historical reclamation of wetlands and islands has reduced and degraded suitable in- and off-channel rearing habitat for white sturgeon. Furthermore, the channelization and hardening of levees with riprap has reduced in- and off-channel intertidal and subtidal rearing habitat as well as seasonal inundation of floodplains. The resulting changes to river hydraulics, riparian cover, and geomorphology affect important ecoystem functions (Sweeney et al. 2004). Because juvenile and adult white sturgeon feed primarily on benthic organisms such as clams and shrimp, habitat related impacts of reclamation, channelization, and riprapping would be expected to contribute to ecosystem related impacts, such as changes in the availability of food source and altered predator densities. The impacts of channelization and riprapping are thought to affect larval, post-larval, juvenile, and adult stages of sturgeon, as these life stages are dependent on the freshwater and estuarine food webs within the rivers and Bay-Delta estuary.

Increased water temperature. While juvenile and adult white sturgeon are tolerant of higher temperatures, although they appear to show signs of stress at temperatures at and above 68 °F (20 °C) (Cech et al. 1984, Geist et al. 2005). Exposure to water temperatures greater than 63 °F (17.2 °C) has also been shown to increase sturgeon egg and larval mortality (Pacific States Marine Fisheries Commission 1992).

Water temperatures in the upper Sacramento River near the RBDD historically occurred within optimum ranges for sturgeon reproduction; however, temperatures downstream, especially later in the spawning season, were reported to be frequently above 63 °F (17.2 °C; USFWS 1995). Concern regarding exposure to high temperatures in the Sacramento River during the February to June period has been reduced in recent years as temperatures in the upper Sacramento River are actively managed for Sacramento River winter-run Chinook salmon. The Shasta temperature control device, which was installed at Shasta Dam in 1997, cold water pool management within Lake Shasta, and management to maintain higher reservoir storage have all contributed to improving cool water temperature conditions within the upper Sacramento River where white sturgeon spawning and juvenile rearing are thought to occur.

Water temperatures in the lower Feather River may be inadequate for sturgeon spawning and egg incubation as the result of releases of warmed water from Thermalito Afterbay (Surface Water Resources, Inc. 2003). The warmed water may be one reason that neither green nor white sturgeon are found in the river in low-flow years (DFG 2002). Exposure to elevated water temperatures within the Feather River downstream of Thermalito Afterbay is expected to be a factor affecting habitat quality and availability for sturgeon spawning and juvenile rearing on the lower Feather River (DFG 2002).

Reduced flow on the San Joaquin River resulting from dam and diversion operations and agricultural return flows contribute to seasonally elevated water temperatures in the mainstem San Joaquin River, particularly during late summer and fall. Although these effects are difficult to measure, water temperatures in the lower San Joaquin River continually exceed preferred temperatures for sturgeon migration and development during spring months. Temperatures at Stevenson on the San Joaquin River near the Merced River confluence as recorded on May 31 (spawning typically occurs February-June) between 2000 and 2004 ranged from 77 to 82 °F (25 to 27.8 °C; California Data Exchange Center 2007). Juvenile sturgeon are also exposed to increased water temperatures in the Delta during the late spring and summer, as a result in part of the loss of riparian shading, and by thermal inputs from municipal, industrial, and agricultural discharges. Seasonally elevated water temperature on the San Joaquin River and within the Delta has been identified as a factor affecting habitat quality and availability for sturgeon migration, spawning, and juvenile rearing.

Non-native species. White sturgeon have been impacted, both positively and negatively, by the introduction of non-native species into the Bay-Delta estuary. Changes in the species composition of fish and macroinvertebrates have altered trophic interactions and dynamics for juvenile and adult white sturgeon. Many of the recent introductions of invertebrates have greatly affected the benthic fauna in the Delta and Suisun Bay and non-native species such as the overbite clam and Asian clam are now a major component of the diet of white sturgeon (DFG 2002). The overbite clam and other introduced clams are benthic filter feeders that can accumulate various toxic substances , such as selenium, mercury, and other compounds, in their tissue. Sturgeon, which are long-lived species, may bioaccumulate these toxics by foraging on these clams, which may adversely impact the health and survival of sub-adult and adult sturgeon and their reproduction (Doroshov et al. 2007).

DFG (2002) reviewed many of the recent non-native invasive species introductions and the potential consequences to white sturgeon. The most notable species responsible for altering the trophic system of the Sacramento-San Joaquin Delta and Suisun Bay include overbite and Asian clams, and the Chinese mitten crabs. Sturgeon regularly consume both clam species, which is of particular concern because of the high bioaccumulation rates of these clams (Doroshov et al. 2007). Although Chinese mitten crabs may be eaten by adult white sturgeon, it is possible they prey upon sturgeon eggs. The Chinese mitten crab population within the Bay-Delta system has undergone a substantial decline since 2002 and currently occurs in very low abundance (Hieb, pers. comm. 2008) and, therefore, may currently not be a major factor affecting white sturgeon.

Introductions of non-native invasive plant species such as water hyacinth and Brazilian waterweed have altered habitat within the Delta and Suisun Bay and have affected local assemblages of fish within the Bay-Delta estuary (Nobriga et al. 2005). Nobriga et al. (2005) found significant differences in water clarity and fish communities in those areas where submerged aquatic vegetation (SAV) was abundant when compared to open water habitats where SAV was not abundant. The occurrence of dense concentrations of SAV has been hypothesized to result in a number of potential effects on aquatic habitat including raising temperatures, reducing turbidity and dissolved oxygen levels, and inhibiting access to shallow water habitat by fish intolerable to these conditions. The presence of non-native centrarchid species is strongly associated with the occurrence of Brazilian waterweed (Brown and Michniuk 2007). Brazilian waterweed forms thick “walls” along the margins of channels and shallow water habitat in the Delta. This growth may prevent juvenile sturgeon from accessing shallow water habitat along channel edges. Water hyacinth creates dense floating mats that can impede river flows and alter the aquatic environment beneath mats. By reducing water velocities near plants, these species reduce turbidity in the water column, potentially exposing sturgeon to higher predation risk.

Dissolved oxygen levels beneath the mats often drop below suitable levels for fish due to the increased amount of decaying vegetative matter produced from the overlying mat and diel respiration by aquatic plants. Like Brazilian waterweed, water hyacinth is often associated with the margins of the Delta waterways in its initial colonization, but can eventually cover the entire channel if conditions permit. High levels of infestation by non-native aquatic plants may produce barriers to white sturgeon movement within the Delta, although there is no evidence that this occurs.

Dredging. Hydraulic dredging is a common practice in the navigational channels within San Francisco, San Pablo, and Suisun bays, the Delta, and the Sacramento and San Joaquin rivers to allow commercial and recreational vessel traffic. White sturgeon are at risk of entrainment from dredging, with young-of-the-year fish at greatest risk (Boysen and Hoover 2009).. Studies by Buell (1992) reported approximately 2,000 sturgeon entrained in the removal of one million tons of sand from the bottom of the Columbia River at depths of 60 to 80 feet (18 to 24 m). In addition, dredging operations can result in the resuspension of toxics such as ammonia, hydrogen sulfide, and copper as a result of both dredging and dredge spoil disposal, and alter channel bathymetry and current patterns (NMFS 2006).

Reduced turbidity. Turbidity levels in the Delta have decreased over the past few decades (Jassby et al. 2002). This reduction may have had detrimental effects to white sturgeon. Gadomski and Parsley (2005) found that larval white sturgon predation by prickly sculpin was greater with reduced turbidity. However, larval sturgeon are found close to spawning locations generally upstream of the Delta, where turbidity is already lower than the Delta.

The relationship between turbidity and the vulnerablity of various life stages of white sturgeon to predation has not been established within the Delta. As discussed above, the dense colonization of local areas within the Delta by SAV such as the Brazilian waterweed (*Egeria densa*) has been shown to be associated with increased water clarity (e.g., resuting from trapping and settlement of suspended sediments). Increased water clarity may contribute to increased vulnerablity of sturgeon to predation. Juvenile white sturgeon are expected to be less vulnerable to predation than other estuarine fish due to their scutes and protective armoring. In addition, the large size of sub-adult and adult white sturgeon further reduces their vulnerablity to predation. As a result of these factors, the potential increase in vulnerability to predation due to localized reductions in turbidity is expected to be minor relative to other covered fish species.

Stranding. White sturgeon that are attracted to high flows when the Yolo Bypass is inundated by flood waters from the Sacramento River will move onto the floodplain and eventually concentrate behind Fremont Weir, where they are blocked from further upstream migration (DWR 2005). As Bypass flows recede, these sturgeon become stranded behind the weir (Harrell and Sommer 2003) and are then subject to both legal and illegal harvest (M. Marshall, pers. comm.). Methods to reduce stranding and increase sturgeon passage are have been previously developed (J. Navicky, pers. comm.) but have been stalled (Z. Matica, pers. comm.).

Entrainment. There is little evidence that the overall population of white sturgeon is influenced by entrainment. Adults are not likely to be entrained due to their large size and benthic habits. Larval sturgeon are more susceptible to entrainment from water diversion facilities as a result of their migratory behavior within the water column and reduced swimming perfomance capability. Herren and Kawasaki (2001) documented 431 water diversions located on the Sacramento River between Sacramento and Shasta Dam. In the Feather River, there are eight diversions greater than 10 cubic feet per second (cfs) and approximately 60 small diversions between 1 to 10 cfs between the Thermalito Afterbay outlet and the confluence with the Sacramento River (USFWS 1995). White sturgeon have been reported in low numbers in fish salvage at both the SWP and CVP export facilities. White sturgeon observed in fish salvage have predominantly been juvenile and sub-adult life stages. Occasionally, adult white sturgeon have been observed impinged on the trash racks at the CVP intake; it has been hypothesized that these large adults were in weakened conditions or had previously died from stresses associated with spawning, angler mortality, or other causes before being impinged at the export intake. Given the large number of diversions, it is possible that larval white sturgeon are vulnerable to entrainment at these diversions; however, actual entrainment mortality and potential effects on the abundance and population dynamics of white sturgeon are unknown.

A8.6 RELEVANT CONSERVATION EFFORTS

The Central Valley Project Improvement Act's Anadromous Fish Restoration Program (AFRP) have a goal of supporting efforts that lead to doubling the natural production of anadromous fish in the Central Valley at a sustainable, long-term basis, at levels not less than twice the average abundance reported during the period of 1967 to 1991. Though most efforts of the AFRP have focused on Chinook salmon as a result of their listing history and status, sturgeon may receive some unknown incidental amount of benefit from these restoration efforts. For example, the acquisition of water for flow enhancement on tributaries to the Sacramento River, spawning gravel augmentation, fish screening for the protection of Chinook salmon and Central Valley steelhead, or riparian revegetation and instream restoration projects would likely have ancillary benefits to sturgeon.

Many beneficial actions have originated and been funded by the CALFED program including such projects as floodplain and instream restoration, riparian habitat protection, fish screening and passage projects, research regarding non-native invasive species and contaminants, restoration methods, watershed stewardship, education, and outreach programs. Prior Federal Register notices have reviewed the details of Central Valley Project Improvement Act (CVPIA) and CALFED programs and potential benefits for anadromous fish, particularly Chinook salmon and Central Valley steelhead (69 FR 33102). Projects potentially benefiting sturgeon primarily consist of fish screen evaluation and construction projects, restoration evaluation and enhancement activities, contamination studies, and dissolved oxygen investigations related to the San Joaquin River Deep Water Ship Channel.

The Delta Regional Ecosystem Restoration Implementation Plan (DRERIP) was formed to guide the implementation of CALFED Ecosystem Restoration Plan elements within the Delta (DFG 2007b). The DRERIP team has created a suite of ecosystem and species conceptual models, including white sturgeon, that document existing scientific knowledge of Delta ecosystems. The DRERIP Team has used these conceptual models to assess the suitability of actions proposed in the Ecosystem Restoration Plan for implementation. DRERIP conceptual models were used in the analysis of proposed BDCP conservation measures.

New sport fishing regulations adopted over the past several years specifically to protect and reduce harvest of sturgeon and increased law enforcement are expected to further reduce illegal fishing practices, and reduce the effects of harvest of white sturgeon by recreational anglers, throughout the range of the species.

A8.7 RECOVERY GOALS

No recovery plan has been prepared for white sturgeon because the species is not listed under the California or Federal ESA.

APPENDIX A9. NORTH AMERICAN GREEN STURGEON *(ACIPENSER MEDIROSTRIS)*

A9.1 LEGAL STATUS

The North American green sturgeon is composed of two Distinct Population Segments (DPS): the northern DPS, which includes all populations in the Eel River and northward; and the southern DPS, which includes all populations south of the Eel River. Only the southern DPS is found in the Plan Area of the Bay Delta Conservation Plan (BDCP).

After a status review was completed in 2002 (Adams et al. 2002), the National Marine Fisheries Service (NMFS) determined that the southern DPS of the North American green sturgeon did not warrant listing as threatened or endangered but should be identified as a Species of Concern. The "not warranted" determination was challenged on April 7, 2003. The National Marine Fisheries Service (NMFS) updated their status review on February 22, 2005, and determined that the southern DPS should be listed as threatened under the Federal Endangered Species Act (Biological Review Team 2005). NMFS published a final rule on April 7, 2006 that listed the southern DPS as threatened, which took effect on June 6, 2006 (71 FR 17757). Included in the listing are the spawning population in the Sacramento River and fish living in the Sacramento River, the Sacramento-San Joaquin Delta, and the San Francisco Estuary.

California Department of Fish and Game has identified green sturgeon as a Species of Special Concern (California Department of Fish and Game [DFG] 2003).

A9.2 SPECIES DISTRIBUTION AND STATUS

A9.2.1 Range and Status

Green sturgeon range from Ensenada, Mexico to the Bering Sea, Alaska (Colway and Stevenson 2007, Moyle 2002). Green sturgeon are currently known to spawn in two California basins: the Sacramento and Klamath rivers. These reproducing populations are genetically distinct and occupy the Southern and Northern DPS, respectively (Adams et al. 2002, Israel et al. 2004). Adult populations in the less-altered Klamath and Rogue rivers are fairly constant with a few hundred spawning adults typically being harvested annually by tribal fisheries. In the Sacramento River, the green sturgeon population is believed to have declined over the last two decades with less than 50 spawning green sturgeon being sighted annually in the best spawning habitat (Richard Corwin, Bureau of Reclamation, pers. comm.). In the Umpqua, Feather, Yuba, and Eel rivers green sturgeon sightings are extremely limited and spawning has not been recently recorded. In the San Joaquin and South Fork Trinity rivers, the green sturgeon population appears extirpated (see Figure A-9a).

DRAFT

Figure A-9a. Green Sturgeon Inland Range in California

Green sturgeon have been recorded in the Feather River (Beamesderfer et al. 2004), and may spawn there during high flow years (DFG 2002), although no indication of spawning has been documented despite intensive sampling efforts (Niggemyer and Duster 2003). No juvenile green sturgeon have been documented in the San Joaquin River, although Moyle (2002) suggests that reproduction may have taken place in the San Joaquin River because adults have been captured at Santa Clara Shoal and Brannan Island. Additionally, two unidentified juvenile sturgeon have been caught on the Mokelumne River, a tributary to the San Joaquin River (J. Smith, pers. comm.).

Green sturgeon are anadromous and pass through the San Francisco Bay to the ocean where they primarily move northward and commingle with other sturgeon populations, spending much of their lives in the ocean or in Oregon and Washington estuaries (DFG 2002; Kelly et al. 2007). Subadult and adult green sturgeon are thought to potentially migrate thousands of miles along the coasts of northern California and the Pacific Northwest. Relatively large concentrations of sturgeon occur in the Columbia River estuary, Willapa Bay, and Grays Harbor, with smaller aggregations in the San Francisco estuary (Emmett et al. 1991, Moyle et al. 1992, Israel 2006).

Although NMFS indicates that absolute population abundance of green sturgeon is currently not determinable (74 FR 52,300), some information on the population abundance of the southern DPS of North American green sturgeon is available, and is described in NMFS status reviews (Adams et al. 2002, 2007, NMFS 2005). Musick et al. (2000) noted that the abundance of North American green sturgeon populations has declined by 88 percent throughout much of its range. DFG (2002) estimated that green sturgeon abundance within the Bay-Delta estuary ranged from 175 to more than 8,000 adults between 1954 and 2001 with an annual average of 1,509 adults. Fish monitoring efforts at Red Bluff Diversion Dam (RBDD) and the Glenn-Colusa Irrigation District pumping facility on the upper Sacramento River have recorded between zero and 2,068 juvenile North American green sturgeon per year (Adams et al. 2002). Catches of sub-adult and adult North American green sturgeon by the Interagency Ecological Program (IEP) between 1996 and 2004 ranged from one to 212 green sturgeon per year, with the highest catch in 2001 (Samantha Vu, pers. comm.). Because these fish were primarily captured in San Pablo Bay, where both northern and southern DPSs exist, the proportion of fish captured in IEP sampling from the southern DPS is unknown.

Green sturgeon are long-lived (up to 60 to 70 years) and late maturing (sexual maturity is reached at approximately 15 to 20 years) (Moyle 2002). They have a low fecundity rate (59,000 to 242,000 eggs per female) relative to white sturgeon (180,000 to 590,000 eggs per female) and spawn only periodically (Doroshov 1983, Moyle 2002, Van Eenennaam et al. 2006). These characteristics make them particularly susceptible to habitat degradation and overharvest (Musick 1999). With only one population in the Central Valley, the viability of the southern DPS is vulnerable to changes in the environment and catastrophic events through a lack of spatial geographic diversity. As a result of low abundance, the population has limited genetic diversity, which decreases the ability of individuals in the green sturgeon population to withstand environmental variation.

A9.2.2 Distribution and Status in the Plan Area

The Delta serves as a migratory corridor, feeding area, and juvenile rearing habitat for North American green sturgeon in the southern DPS. Adults migrate upstream primarily through the western edge of the Delta into the lower Sacramento River between March and June (Adams et al. 2002). Green sturgeon spawning is thought to occur primarily in the upper reaches of the Sacramento River, although some spawning may also occur in tributaries. Larvae and post-larvae are present in the lower Sacramento and North Delta between May and October, primarily in June and July (DFG 2002). Juvenile green sturgeon have been captured in the Delta during all months of the year (Borthwick et al. 1999, DFG 2002, BDAT 2007). Adult green sturgeon have been documented in the Yolo Bypass (M. Marshall, pers. comm.) and rear in Suisun Bay and marsh.

A9.3 Habitat Requirements and Special Considerations

On October 9, 2009, NMFS (74 FR 52,300) designated critical habitat for the green sturgeon Southern DPS throughout most of its occupied range, including: coastal marine waters from Monterey Bay to the Washington/Canada border; coastal bays and estuaries in California, Oregon, and Washington; and fresh water rivers in the Central Valley, California. The essential physical and biological habitat features identified for the Southern DPS include prey resources (benthic invertebrates and small fish), water quality, water flow (particularly in freshwater rivers), water depth, substrate types (i.e., appropriate spawning substrates within freshwater rivers), sediment quality, and migratory corridors (see Figure A-9b). Proposed inland critical habitat in the Sacramento and San Joaquin River basins includes the Sacramento River downstream of Keswick Dam, the Feather River downstream of Oroville Dam, and the Yuba River downstream of Daguerre Dam; portions of Sutter and Yolo Bypasses; the legal Delta, excluding Five Mile Slough, Seven Mile Slough, Snodgrass Slough, Tom Paine Slough and Trapper Slough; and San Francisco, San Pablo, and Suisun bays.

As anadromous fish, North American green sturgeon rely on riverine, estuarine, and marine habitats during their long life. Freshwater habitat of green sturgeon of the southern DPS varies in function, depending on location within the Sacramento River watershed. Spawning areas currently are limited to accessible reaches of the Sacramento River upstream of Hamilton City and downstream of Keswick Dam (see Figure A-9a) (DFG 2002). Preferred spawning habitats are thought to contain large cobble in deep and cool pools with turbulent water (DFG 2002, Moyle 2002, Adams et al. 2002). Sufficient flows are needed to sufficiently oxygenate and limit disease and fungal infection of recently laid eggs (Deng et al. 2002; Parsley et al. 2002). Within the Sacramento River, spawning appears to be triggered by large increases in water flow during spawning (Brown 2007). However, within the Rogue River, Erickson et al. (2002) found that green sturgeon were most often found at depths greater than 5 m with low or no currents during summer and fall months.

DRAFT

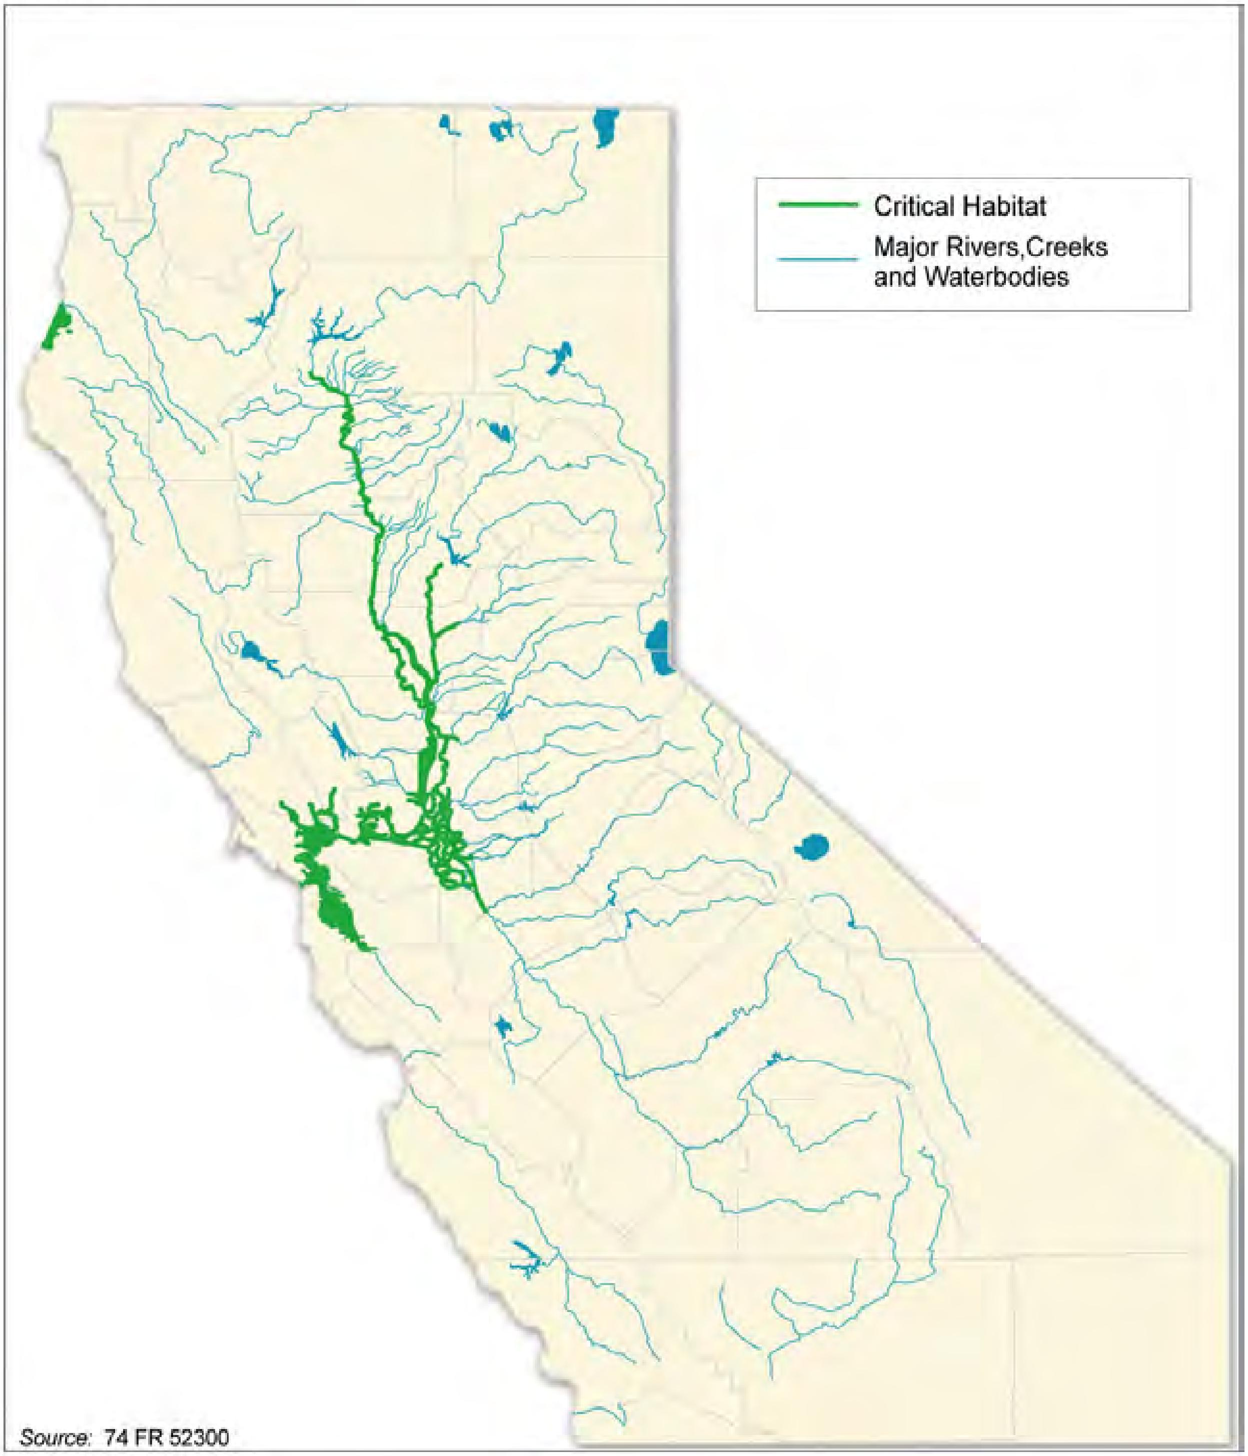

Figure A-9b. Green Sturgeon Inland Critical Habitat in California

In addition, acoustic tagging studies by Erickson et al. (2002) indicate that adult green sturgeon hold for as long as six months in deep (greater than 5 m), low gradient reaches or off-channel sloughs or coves of the river during summer months when water temperatures were between 15 and 23 °C (59 and 73.5 °F). When ambient temperatures in the river dropped in fall and early winter (less than 10 °C [50 °F]) and flows increased, fish moved downstream and into the ocean. Water temperatures in spawning and egg incubation areas are critical; temperatures greater than 19 °C (66.2 °F) are lethal to green sturgeon embryos (Cech et al. 2000, Mayfield and Cech 2004, Van Eenennaam et al. 2005, Allen et al. 2006).

Habitats for migration are downstream of spawning areas and include the mainstem Sacramento River, Delta, and San Francisco Bay estuary. These corridors allow the upstream passage of adults and the downstream emigration of juveniles (NMFS 2006a). Migratory habitat conditions are strongly affected by the presence of barriers and impediments to migration (e.g., dams), unscreened or poorly screened diversions, and degraded water quality. Heublein et al. (2009) found two different patterns of "spawning migration" and out-migration for green sturgeon in the Sacramento River. Results of this study found six individuals potentially spawned, over-summered and moved out of the river with the first fall flow event, nine individuals promptly moved out of the Sacramento River before September 1. While some green sturgeon appeared to be impeded on their upstream movement by closure of the RBDD in mid-May, at least five individuals passed under the dam gates during their downstream migration. Both spawning areas and migratory corridors comprise rearing habitat for juvenile green sturgeon, which feed and grow up to three years in freshwater. Stomach contents from adult and juvenile green sturgeon captured in the Delta point to the importance of habitat that supports shrimp, mollusks, amphipods, and small fish (Radtke 1966, Houston 1988, Moyle et al. 1992). Rearing habitat condition and function may be affected by variation in annual and seasonal flow and water temperatures (NMFS 2006a).

Nearshore marine habitats must provide adequate food resources, suitable water quality conditions, and natural cover for juvenile green sturgeon to successfully forage and grow to adulthood. Offshore marine habitats are also important for supporting growth and maturation of sub-adult green sturgeon.

A9.4 LIFE HISTORY

There is relatively little known about the North American green sturgeon, particularly for those that spawn in the Sacramento River (the Nature Conservancy et al. 2008). Adult North American green sturgeon are believed to spawn every 3 to 5 years, but can spawn as frequently as every 2 years (Lindley and Moser pers. comm., as cited in NMFS 2005) and reach sexual maturity at an age of 15 to 20 years. Adult green sturgeon begin their upstream spawning migrations into the San Francisco Bay in March, reach Knights Landing during April, and spawn between March and July (Heublein et al. 2006). Based on the distribution of sturgeon eggs, larvae, and juveniles in the Sacramento River, DFG (2002) concluded that green sturgeon spawn in late spring and early summer upstream of Hamilton City, and possibly to Keswick Dam.

Peak spawning is believed to occur between April and June (Table A-9a). Adult female green sturgeon produce between 59,000-242,000 eggs, depending on body size, with a mean egg diameter of 4.3 mm (Moyle et al. 1992, Van Eenennaam et al. 2006).

Sources: [1]USFWS 2002, [2]Moyle et al. 1992, [3]Adams et al. 2002 and NMFS 2005, [4]Kelly et al. 2007, [5]DFG 2002, [6]BDAT, fall midwater trawl green sturgeon captures from 1969 to 2003, [7]Nakamoto et al. 1995, [8]Heublein et al. 2006

Newly hatched green sturgeon are approximately 12.5 to 14.5 mm in length. Green sturgeon are strongly oriented to the river bottom and exhibit nocturnal activity patterns (Cech et al. 2000). After six days, the larvae exhibit nocturnal swim-up activity (Deng et al. 2002) and nocturnal downstream migrational movements (Kynard et al. 2005). Juvenile green sturgeon continue to exhibit nocturnal behavior beyond the metamorphosis from larval to juvenile stages. After approximately 10 days, larvae begin feeding and growing rapidly, and young green sturgeon appear to rear for the first one to two months in the Sacramento River between Keswick Dam and Hamilton City (DFG 2002). Length measurements estimate juveniles to be two weeks old (24 to 34 mm fork length) when they are captured at RBDD (DFG 2002, USFWS 2002), and three weeks old when captured further downstream at the Glenn-Colusa facility (DFG, unpubl. data, Van Eenennaam et al. 2001). Growth is rapid as juveniles reach up to 30 cm the first year and over 60 cm in the first 2 to 3 years (Nakamoto et al. 1995).

Juveniles appear to spend 1 to 4 years in freshwater and estuarine habitats before they enter the ocean (Nakamoto et al. 1995). According to Heublein (2006), all adults leave the Sacramento River prior to September. Lindley (2006) found frequent large-scale migrations of green sturgeon along the Pacific coast. Kelly et al. (2007) reported that green sturgeon enter the San Francisco estuary during the spring and remain until fall. Juvenile and adult green sturgeon enter coastal marine waters after making significant long-distance migrations with distinct directionality thought to be related to resource availability.

Little is known about juvenile and adult green sturgeon feeding and diet within the ocean. On entering the highly productive ocean environment, green sturgeon grow at a rate of approximately 7 cm per year until they reach maturity. Male green sturgeon mature at an earlier age and are smaller than females (Van Eenennaam et al. 2006). Green sturgeon spend 3-13 years in the ocean before returning to freshwater to spawn.

A9.5 THREATS AND STRESSORS

The following have been identified as important threats and stressors to the southern DPS of green sturgeon (without priority).

Reduced spawning habitat. Access to historical spawning habitat has been reduced by construction of migration barriers, such as major dams, that block or impede access to the spawning habitat. Major dams include Keswick Dam on the Sacramento River and Oroville Dam on the Feather River (Lindley et al. 2004, NMFS 2005). The Feather River is likely to have supported significant spawning habitat for the green sturgeon population in the Central Valley before dam construction (see Figure A-9a) (DFG 2002). Green sturgeon adults have been observed periodically in the lower Feather River (USFWS 1995, Beamesderfer et al. 2004). Results of habitat modeling by Mora (2006) suggest there is potential habitat on the Feather River upstream of Oroville Dam that would have been suitable for sturgeon spawning and rearing prior to construction of the dam. This modeling also suggests sufficient conditions are present in the San Joaquin River to Friant Dam, and in the tributaries such as Stanislaus, Tuolumne, and Merced rivers upstream to their respective dams, although it is unknown whether green sturgeon ever inhabited the San Joaquin River or its tributaries (Beamesderfer et al. 2004).

NMFS (2006a) reports several potential migration barriers, including structures such as the RBDD, Sacramento Deep Water Ship Channel locks, Sutter Bypass, and Delta Cross Channel gates on the Sacramento River, and Shanghai Bench and Sunset Pumps on the Feather River (). In the Central Valley, approximately 4.6 percent of the total river kilometers have spawning habitat characteristics similar to where Northern DPS green sturgeon spawn, with only 12 percent of this habitat is currently occupied by sturgeon (Neuman et al. 2007). Of the 88 percent that is unoccupied (approx. 4000 km), 44.2 percent is currently inaccessible due to dams Neuman et al. (2007).

The RBDD has been identified as a major barrier and impediment to sturgeon migration on the Sacramento River (USFWS 1995). Adult sturgeon can migrate past RBDD when gates are raised between mid-September and mid-May to allow passage for winter-run Chinook salmon. However, tagging studies by Heublein (2006) found that, when the gates were closed, a substantial portion of tagged adult green sturgeon failed to use fish ladders at the dam and were, therefore, unable to access upstream spawning habitats. A set of locks at the end of the Sacramento River Deep Water Ship Channel at the connection with the Sacramento River "blocks the migration of all fish from the deep water ship channel back to the Sacramento River" (DWR 2005).

The Fremont Weir is located at the upstream end of the Yolo Bypass, a 40 mile (64 km) long basin that functions as a flood control project on the Sacramento River. Green sturgeon are attracted by high floodwater flows into the Yolo Bypass basin and then concentrate behind Fremont Weir, which they cannot effectively pass (DWR 2005). Green sturgeon that concentrate behind the weir are subject to heavy illegal fishing pressure or become stranded behind the flashboards when high flood flows recede (M. Marshall, pers. comm.). Sturgeon can also be attracted to small pulse flows and trapped during the descending hydrograph (Harrell and Sommer 2003). Methods to reduce stranding and increase passage have been investigated by the California Department of Water Resources (DWR) and DFG (DWR 2007, J. Navicky, pers. comm.).

It is thought that adult and juvenile green sturgeon use the same migratory routes as Chinook salmon. Delta Cross Channel gate closures occur during the winter and early spring months sturgeon migration period (February through May) as required by State Water Resources Control Board (SWRCB) D-1641. Upstream migrating adult Chinook salmon are known to use the Delta Cross Channel as a migratory pathway when the gates are open (Hallock et al. 1970). When the gates are open, Sacramento River water flows into the central Delta and the Mokelumne and San Joaquin rivers providing migration cues. It is possible that attraction to water passing from the Sacramento River into the interior Delta causes delays and straying of green sturgeon, as it does to Chinook salmon (CALFED Science Program 2001, McLaughlin and McLain 2004). The Delta Cross Channel completely blocks juvenile and adult sturgeon migration to and from the interior Delta when the gates are closed.

Exposure to toxins. Exposure of green sturgeon to toxics has been identified as a factor that can lower reproductive success, decrease early life stage survival, and cause abnormal development, even at low concentrations (USFWS 1995, Environmental Protection Information Center et al. 2001, Klimley 2002). Water discharges containing metals from Iron Mountain Mine, located adjacent to the Sacramento River, have been identified as a factor affecting survival of sturgeon downstream of Keswick Dam and storage limitations and limited availability of dilution flows cause downstream copper and zinc levels to exceed salmonid tolerances. Treatment processes and improved drainage management in recent years have reduced the toxicity of runoff from Iron Mountain Mine to acceptable levels. Although the impact of trace elements on green sturgeon reproduction is not completely understood, negative impacts similar to those of salmonids are suspected.

Green sturgeon consume overbite and Asian clams, which are known to bioaccumulate selenium rapidly and lose selenium slowly (Linville et al. 2002, Doroshov 2006). Selenium is transferred to the egg yolk where it can cause mortality of larvae. Although chronic and acute exposure to toxics has been identified as a factor adversely affecting various lifestages of green sturgeon, the severity, frequency, geographic locations, and population level consequences of exposure to toxics have not been quantified (Linville et al. 2002, Doroshov 2006). However, Linville (2006) observed larvae to have increased skeletal deformities and mortality associated with maternal effects of selenium exposure, while smaller quantities (about 20mg/kg) decreased feeding efficiency and larger quantities (greater than 20mg/kg) reduced growth rates after four weeks (Lee et al. 2008a).

Methylmercury is another toxic substance that could potentially affect sturgeon development and survival. Between 2002 and 2006, sediment concentrations of methylmercury was highest in the Central Bay, while shallower parts of San Pablo Bay and Suisun Bay also contained levels greater than 0.2 parts per billion (ppb) (San Francisco Estuary Institute [SFEI] 2007). The amount of methylmercury resulting in the death of juvenile green sturgeon lies between 20 to 40mg/kg, with greater consumption increasing mortality significantly (Lee et al. 2008b).

Harvest. As a long-lived, late maturing fish with relatively low fecundity and periodic spawning, the green sturgeon is particularly susceptible to threats from overfishing (Musick 1999). Commercial harvest for green sturgeon occurs primarily along the Oregon and Washington coasts and within their coastal estuaries, with almost all catch being entirely in bycatch of three fisheries: white sturgeon commercial and sport fisheries, Klamath Tribal salmon gill-net fisheries, and coastal groundfish fisheries trawl fisheries (Adams et al. 2007). Total captures of green sturgeon in the Columbia River Estuary in commercial fisheries between 1985 and 2003 ranged from 46 fish per year to 6,000 (Adams et al. 2007). However, a high proportion of green sturgeon present in the Columbia River, Willapa Bay, and Grays Harbor (as high as 80 percent in the Columbia River) may be from the southern DPS (DFG 2002, Israel 2006).

Green sturgeon are also vulnerable to recreational sport fishing with the Bay-Delta estuary and Sacramento River, as well as other estuaries located in Oregon and Washington. Green sturgeon are primarily captured incidentally in California by sport fishermen targeting the more desirable white sturgeon, particularly in San Pablo and Suisun bays (Emmett et al. 1991).

Since the listing of the southern DPS of green sturgeon, new federal and state regulations, including the June 2, 2010 NMFS take prohibition (75 FR 30714), mandate that no green sturgeon can be taken or possessed in California (DFG 2007a). If green sturgeon are caught incidentally and released while fishing for white sturgeon, it must be reported to DFG. The level of hooking mortality that results following release of green sturgeon by anglers is unknown. Sport fishing captures have declined through time; however, it is not known whether this is a result of reduced abundance, changed fishing regulations, or other factors. DFG (2002) indicates that sturgeon are highly vulnerable to the fishery in areas where sturgeon are concentrated, such as the Delta and Suisun and San Pablo Bays in late winter and the upper Sacramento River during spawning migration. Because many sturgeon in the Columbia River, Willapa Bay, and Grays Harbor are likely from the southern DPS, additional harvest closures in these areas would likely benefit the southern DPS.

Poaching (illegal harvest) of sturgeon is known to occur in the Sacramento River, particularly in areas where sturgeon have been stranded (e.g., Fremont Weir) (M. Marshall, pers. comm.), as well as throughout the Bay-Delta (L. Schwall, pers. comm.). Catches of sturgeon are thought to occur during all years, especially during wet years. The small population of green sturgeon inhabiting the San Joaquin River experiences heavy fishing pressure, particularly from illegal fishing (U.S. Fish and Wildlife Service [USFWS] 1995). Areas just downstream of Thermalito Afterbay outlet, Cox's Spillway, and several barriers impeding migration on the Feather River may be areas of high adult mortality from increased fishing effort and poaching. Poaching rates in the rivers and estuary and the impact of poaching on green sturgeon abundance and population dynamics are unknown.

Reduced rearing habitat. Historical reclamation of wetlands and islands have reduced and degraded the availability of suitable in- and off-channel rearing habitat for green sturgeon. Further, channelization and hardening of levees with riprap has reduced in- and off-channel intertidal and subtidal rearing habitat. The resulting changes to river hydraulics, riparian cover, seasonal floodplain inundation, and geomorphology affect important ecoystem functions (Sweeney et al. 2004). The impacts of channelization and riprapping are thought to affect larval, post-larval, juvenile, and adult stages of sturgeon, as these life stages are dependent on the food web in freshwater and low salinity regions of the Bay-Delta.

Increased water temperature. Exposure to water temperatures greater than 63 ºF (17.2 °F) can increase mortality of sturgeon eggs and larvae (Pacific States Marine Fisheries Commission 1992) and temperatures above 69 °F (20.6 °C) are lethal to embryos (Cech et al. 2000). Temperatures near the RBDD on the Sacramento River historically occur within optimum ranges for sturgeon reproduction; however, temperatures downstream, especially later in the spawning season, were reported to be frequently above 63 °F (17.2 °F; USFWS 1995). High temperatures in the Sacramento River during the February to June period no longer appear to be a major concern for green sturgeon spawning, egg incubation, and juvenile rearing, as temperatures in the upper Sacramento River are actively managed for Sacramento River winter-run Chinook salmon. The Shasta temperature control device, installed at Shasta Dam in 1997, in combination with improved cold water pool management and storage within Lake Shasta, have resulted in improved cool water stream conditions within the upper Sacramento River.

Water temperatures in the Feather River may be inadequate for spawning and egg incubation as the result of releases of warmed water from Thermalito Afterbay (Surface Water Resources, Inc. 2003). Warmed water may be one reason why neither green nor white sturgeon are found in the river during low flow years (DFG 2002). It is not expected that water temperatures will become more favorable in the near future and this temperature problem will continue to be a factor affecting habitat quality for green sturgeon on the lower Feather River (DFG 2002).

The lack of flow in the San Joaquin River from dam and diversion operations and agricultural return flows contribute to higher temperatures in the mainstem San Joaquin River, offering less water to keep temperatures cool for sturgeon, particularly during late summer and fall. Though these effects are difficult to measure, temperatures in the lower San Joaquin River continually exceed preferred temperatures for sturgeon migration and development during spring months. Temperatures at Stevenson on the San Joaquin River near the Merced River confluence recorded on May 31 (spawning typically occurs during April-June; see Table A-9a) between 2000 and 2004 ranged from 77 to 82 °F (25 to 27.8 °C; California Data Exchange Center 2007). Juvenile sturgeon are also exposed to increased water temperatures in the Delta during the late spring and summer due to the loss of riparian shading and by thermal inputs from municipal, industrial, and agricultural discharges.

Non-native species. Green sturgeon have been impacted, both positively and negatively, by non-native species introductions through changes in trophic dynamics within the Delta and Suisun Bay. Many of the recent introductions of invertebrates have greatly affected the benthic fauna in the Delta and Suisun Bay. DFG (2002) reviewed many of the recent non-native invasive species introductions and the potential consequences to green sturgeon. The most notable species responsible for altering the trophic system of the Sacramento-San Joaquin Delta include the overbite clam and the Chinese mitten crab. Sturgeon regularly consume overbite and Asian clams, which is of particular concern because of the high bioaccumulation rates of these clams (Doroshov 2006). Although Chinese mitten crabs may be eaten by adult green sturgeon, it is possible they prey upon sturgeon eggs. However, the Chinese mitten crab population within the Bay-Delta system has undergone a substantial decline since 2002 and currently occurs in very low abundance (K. Hieb, pers. comm.) and, therefore, has not been a major factor affecting green sturgeon during this period.

Introductions of non-native invasive plant species such as water hyacinth and Brazilian waterweed have altered habitat and have affected local assemblages of fish within the Bay-Delta estuary (Nobriga et al. 2005). Nobriga et al. (2005) found significant differences in water clarity and fish communities in those areas where submerged aquatic vegetation (SAV) was abundant when compared to open water habitats where SAV was not abundant. The occurrence of dense concentrations of SAV has been hypothesized to result in a number of potential effects on aquatic habitat including raising temperatures, reducing turbidity and dissolved oxygen levels, and inhibiting access to shallow water habitat by fish that cannot tolerate these conditions. The presence of non-native centrarchid species is strongly associated with the occurrence of Brazilian waterweed (Brown and Michniuk 2007). Brazilian waterweed forms thick “walls” along the margins of channels in the Delta. This growth is thought to prevent juvenile sturgeon from accessing shallow water habitat along channel edges. Water hyacinth creates dense floating mats that can impede river flows and alter the aquatic environment beneath the mats. By reducing water velocities near plants, these species reduce turbidity in the water column, potentially exposing young sturgeon to higher predation risk. Several investigators (Abrahams and Kattenfeld 1997, Utne-Palm 2002; cited in Nobriga and Feyrer 2007) observed that various lifestages of estuarine fish may use turbidity as a form of cover from predators. High densities of SAV have been observed to trap suspended sediments and reduce local water velocities resulting in reduced turbidity and increased water clarity associated with SAV. Although there is no direct evidence of a relationship between turbidity and vulnerability of species such as juvenile green sturgeon to predation mortality, Nobriga et al. (2005) found that an inverse relationship between SAV and water clarity, as well as an increase in the occurrence of several predatory fish species in association with SAV within the estuary, which potentially may increase the vulnerability of juvenile sturgeon to predation mortality.

Dissolved oxygen levels beneath mats of aquatic vegetation often drop below suitable levels for fish possibly due to the increased amount of decaying vegetative matter produced from the overlying mat as well as diel respiration by aquatic plants. Like Brazilian waterweed, water hyacinth is often associated with the margins of Delta waterways in its initial colonization, but can eventually cover the entire channel if conditions permit. This level of infestation may produce barriers to green sturgeon migration and access to rearing and foraging habitat within the Delta, although there is no evidence that this occurs.

Dredging. Hydraulic dredging is a common practice in the Sacramento and San Joaquin rivers, navigation channels within the Delta, and Suisun, San Pablo, and San Francisco bays to allow commercial and recreational vessel traffic. Such dredging operations pose risks to bottom oriented fish such as green sturgeon. Studies by Buell (1992) reported approximately 2,000 sturgeon entrained in the removal of one million tons of sand from the bottom of the Columbia River at depths of 60 to 80 feet (18 to 24 m). In addition, dredging operations can decrease the abundance of locally available prey species, and contribute to resuspension of toxics such as ammonia, hydrogen sulfide, and copper during dredging and dredge spoil disposal, and alter bathymetry and water movement patterns (NMFS 2006b).

Reduction in turbidity. Turbidity levels in the Delta have been reduced over the past few decades (Jassby et al. 2002). This reduction may have had detrimental effects to green sturgeon. Although little is known about the effects of reduced turbidity on green sturgeon, Gadomski and Parsley (2005) have found that larval white sturgon predation by prickly sculpin was greater in water with lower turbidity. Because green and white sturgeon larvae may have similar behavior and morphology, this effect likely applies to green sturgeon, as well. However, larval sturgeon are found close to spawning locations generally upstream of the Delta, where turbidity is already lower than the Delta.

Entrainment. Larval sturgeon are susceptible to entrainment from non-project water diversion facilities as a result of their migratory behavior and habitat selection within the rivers and Bay-Delta estuary. The overall impact of entrainment of fish populations is typically unknown (Moyle and Israel 2005), however there is enough descriptive information to predict where green sturgeon may be entrained. Herren and Kawasaki (2001) documented 431 non-project diversions located on the Sacramento River between Sacramento and Shasta Dam. Entrainment information regarding larval and post-larval individuals of the green sturgeon is unreliable because entrainment at these diversions has not been monitored and field identification of green sturgeon larvae is difficult. USFWS staff are working on identification techniques and are optimistic that green sturgeon greater than 40 mm can be identified in the field (Poytress 2006). Sturgeon collected at the Glenn-Colusa Irrigation District diversion located on the upper Sacramento River are not identified to species, but are assumed to primarily consist of green sturgeon because white sturgeon are known to spawn primarily downstream (Schaffter 1997). Although screens at the Glenn-Colusa Irrigation District diversion satisfy both the NMFS and DFG screening criteria for salmonids, the effectiveness of these criteria is unknown for sturgeon. Low numbers of green sturgeon have also been identified and entrained at the Red Bluff Research Pumping Plant (Borthwick et al. 1999).

In the Feather River, there are 8 large diversions greater than 10 cfs and approximately 60 small diversions between 1 and 10 cfs between the Thermalito Afterbay outlet and the confluence with the Sacramento River (USFWS 1995). Based on potential entrainment problems of green sturgeon elsewhere in the Central Valley and the presence of multiple screened and unscreened diversions on the Feather River, it is thought that operation of unscreened water diversions on the Feather River are a possible threat to juvenile green sturgeon.

Presumably, as green sturgeon juveniles grow, they become less susceptible to entrainment as their swimming ability and capacity to escape diversions improves. The majority of North American green sturgeon captured in the Bay-Delta are between 200 and 500 mm in length (DFG 2002). Herren and Kawasaki (2001) inventoried water diversions in the Delta finding a total of 2,209 diversions of various types; only 0.7 percent of which were screened. The majority of these diversions were between 12 and 24 inches in diameter. The vulnerability of juvenile green sturgeon to entrainment at these unscreened diversions is largely unknown. Results of limited entrainment studies at diversions within the Delta suggest that larger juvenile green sturgeon have a lower risk of entrainment mortality. The largest diversions within the Delta are the State Water Project (SWP) and Central Valley Project (CVP) export facilities, located in the southern Delta, where a low number of juvenile green sturgeon have been recorded as part of fish salvage monitoring (DFG 2002). The average number of green sturgeon taken per year at the SWP Skinner Fish Facility was 87 individuals between 1981 and 2000, and 20 individuals from 2001 through 2007 (M. Donnellan, unpublished data). At the CVP Tracy Fish Collection Facility, green sturgeon counts averaged 246 individuals per year between 1981 and 2000, and 53 individuals per year between 2001 and 2007 (M. Donnellan, unpublished data). This reduction in salvage is consistent with a significant reduction in white sturgeon take at the salvage facilities within the same time periods (NMFS 2005).

Stranding. Green sturgeon that are attracted by high flows in the Yolo Bypass move onto the floodplain and eventually concentrate behind Fremont Weir, where they are blocked from further upstream migration (DWR 2005). As the Bypass recedes, these sturgeon become stranded behind the flashboards of the weir and can be subjected to heavy illegal fishing pressure (M. Marshall, USFWS, pers. comm.). Sturgeon can also be attracted to small pulse flows and trapped during the descending hydrograph (Harrell and Sommer 2003). Methods to reduce stranding and increase passage have been investigated (J. Navicky, pers. comm.).

A9.6 Relevant Conservation Efforts

The Central Valley Project Improvement Act's Anadromous Fish Restoration Program has a goal of supporting efforts that lead to doubling the natural production of anadromous fish in the Central Valley at a sustainable, long-term basis, at levels not less than twice the average levels attained during the period of 1967 to 1991. Although most efforts of the Anadromous Fish Restoration Program have focused on Chinook salmon as a result of their listing history and status, sturgeon may receive some unknown amount of incidental benefit from these restoration efforts. For example, the acquisition of water for flow enhancement on tributaries to the Sacramento River, fish screening for the protection of Chinook salmon and Central Valley steelhead, spawning gravel augmentation, or riparian revegetation and instream restoration projects would likely have some ancillary benefits to sturgeon. The Anadromous Fish Restoration Program has also invested in a green sturgeon research project that has helped improve our understanding of the life history requirements and temporal patterns of the southern DPS of North American green sturgeon.

Many beneficial actions have originated from and been been funded by the CALFED program including such projects as floodplain and instream restoration, riparian habitat protection, fish screening and passage projects, research on non-native invasive species and contaminants, restoration methods, watershed stewardship, and education and outreach programs. Prior Federal Register notices have reviewed the details of the Central Valley Project Improvement Act (CVPIA) and CALFED programs and potential benefits for anadromous fish, particularly Chinook salmon and Central Valley steelhead (69 FR 33102). Projects potentially benefiting sturgeon primarily consist of fish screen evaluation and construction projects, restoration evaluation and enhancement activities, and contaminant studies. Two evaluation projects specifically addressed green sturgeon while the remaining projects primarily address listed salmonids and fishes of the area in general. The new information developed through these research investigations will be used to enhance the understanding of the risk factors affecting population dynamics and recovery, thereby improving the ability to develop effective management measures.

The Delta Regional Ecosystem Restoration Implementation Plan (DRERIP) was formed to guide the implementation of CALFED Ecosystem Restoration Plan elements within the Delta (DFG 2007b). The DRERIP team has created a suite of ecosystem and species conceptual models, including green sturgeon, that document existing scientific knowledge of Delta ecosystems. The DRERIP team is in the process of using these conceptual models to assess the suitability of actions proposed in the Ecosystem Restoration Plan for implementation. DRERIP conceptual models have been used in the analysis of proposed BDCP conservation measures.

In response to passage impediment concerns to green sturgeon and other migratory species, operations of the RBDD have been modified since its construction in 1964 to reduce the "gates-in" period. In 2009, U.S. Bureau of Reclamation received funding for the Fish Passage Improvement Project at the RBDD to build a pumping facility to provide reliable water supply for high-valued crops in Tehama, Glenn, Colusa, and northern Yolo counties while providing year-round unimpeded fish passage. This project, which is expected to be completed in late 2012, will eliminate passage issues for sturgeon and other migratory species.

The combination of increased law enforcement and new sport fishing regulations adopted over the past several years specifically to protect sturgeon and reduce their harvest is expected further reduce illegal fishing practices as well as the effects of incidental harvest of green sturgeon by recreational anglers throughout the range of the species. Mitigation under the Delta Fish Agreement has increased the number of wardens enforcing harvest regulations for steelhead and other fish in the Bay-Delta and upstream tributaries by creating the Delta Bay Enhanced Enforcement Program (DBEEP).

A9.7 Recovery Goals

On November 12, 2009, NMFS announced its intent to develop a recovery plan for the Southern DPS of North American green sturgeon (*Acipenser medirostris*) and has requested information from the public (74 FR 58245). This plan has not yet been developed.

APPENDIX A10. PACIFIC LAMPREY (*ENTOSPHENUS TRIDENTATUS*)

A10.1 LEGAL STATUS

The Pacific lamprey is not listed under the California or federal Endangered Species Acts (ESA).

A broad group of West Coast conservation organizations petitioned the U.S. Fish and Wildlife Service (USFWS) on January 27, 2003 to list Pacific lamprey, along with three other lamprey species on the West Coast, as threatened or endangered Klamath-Siskiyou Wildlands Center 2003). However, the petition was declined in a 90-day finding on December 27, 2004, citing insufficient evidence that listing was warranted (69 FR 77158).

A10.2 SPECIES DISTRIBUTION AND STATUS

A10.2.1 Range and Status

The Pacific lamprey is the most widely distributed lamprey species on the west coast of the United States. The species occurs from Hokkaido Island, Japan (Morrow 1980) along the Pacific Rim to Rio Santo Domingo, Baja California, Mexico (Ruiz-Campos and Gonzalez-Guzman 1996). A single individual was caught in 1889 offshore of Clarion Island, Revillagigedo Islands, Mexico, approximately 386 km southwest of Cabo San Lucas (Renaud 2008). Individuals inhabit major river systems, including the Columbia, Fraser-Trinity, Klamath, Eel, and Sacramento-San Joaquin rivers, as well as smaller coastal streams (see Figure A-10a). In general, populations south of San Luis Obispo are scattered and irregular (Swift et al. 1993). Populations may exist in other rivers, but are easily overlooked and have been the subject of few targeted sampling efforts (Moyle 2002). The species is usually absent from highly-altered or polluted streams within its geographic range, although appears to be persistent in currently occupied suitable streams (Moyle 2002).

In the Central Valley, Pacific lamprey occur in both the lower Sacramento and San Joaquin Rivers (Moyle 2002) and many of their tributaries including the Stanislaus, Tuolumne, Merced, and King Rivers (Brown and Moyle 1993, 69 FR 77158).

Population trends are unknown in California, although anecdotal evidence indicates that populations have been in decline (Moyle 2002, 69 FR 77158).

DRAFT

Figure A-10a. Pacific Lamprey Inland Range in California

A10.2.2 Distribution and Status in the Plan Area

Individuals outmigrating from Sacramento and San Joaquin River watersheds pass through the Plan Area during winter and spring on their way to the Pacific Ocean. Emigrating adults pass through the Plan Area on their way upstream towards spawning grounds primarily between March and June. It is unknown to what extent Pacific lamprey use the Plan Are for purposes other than a migration corridor.

Status and trend data are extremely sparse and unreliable. There are no monitoring programs that target Pacific lamprey in the Delta and those that catch Pacific lamprey do not catch them regularly enough to establish trends through time. In addition, Pacific lamprey are inconspicuous, often overlooked, and ammocoetes can be difficult to distinguish from ammocoetes of the co-occurring river lamprey (H. Webb, pers. comm).

A10.3 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

The habitat requirements of Pacific lamprey have not been well studied. It is thought that adults need clean, gravelly riffles in permanent streams to spawn successfully and that these requirements are thought to be similar to those of salmonids (Moyle 2002). Ammocoetes live in silty backwaters and eddies with muddy or sandy substrate into which they burrow. Ammocoetes require water temperatures that are lower than 25 °C (76 °F) (Moyle et al. 1995). Meeuwig et al. (2004) found significant death or deformation of eggs and early stage ammocoetes in water greater than 72 °F (22 °C). Lamprey can pass barriers that other fish cannot, although large dams and other habitat modifications remain barriers to migration. Oceanic adults are thought to remain relatively close to the mouths of their home spawning streams where host/prey concentrations may be higher (Moyle 2002).

A10.4 LIFE HISTORY

Pacific lamprey are anadromous, beginning their migration into freshwater towards upstream spawning areas primarily between early March and late June (Moyle 2002). Most upstream migration occurs at night and occurs in pulses. Spawning habitat requirements are thought to be similar to those of salmonids. There is some evidence that Pacific lamprey in larger river systems, such as the Klamath and Eel Rivers, have distinct runs similar to Chinook salmon (Moyle 2002). Both sexes contribute to nest construction by removing larger stones from a gravelly substrate, creating a shallow depression. These simple nests occur in gravelly substrata at a depth of 30-150 cm with moderately swift currents and water temperatures typically of 12-18 °C (53.6 to 64.4 °F) (Moyle 2002). External fertilization of eggs occurs just in front of the nest, after which the fertilized eggs are washed into the nest. Fecundity is unknown, but has been estimated at 98,000 to 238,400 eggs per female (Kan 1975 as cited in Close et al. 2002). Spawning is repeated until both individuals are spent. Adults typically die after spawning.

Eggs hatch into ammocoetes after approximately 19 days at 15 °C, spend a short time in the nest, and then drift downstream to suitable areas in sand or mud (Moyle 2002). Ammocoetes remain in freshwater for approximately 5 to 7 years, where they bury into silt and mud and feed on algae, organic material, and microorganisms. Ammocoetes change locations during this stage.

Ammocoetes begin metamorphosis into macropthalmia (juveniles) when they reach 14-16 cm total length (TL). Individuals develop external features (eyes, oral disc, and color changes) and experience internal and physiological changes that prepare them for their predatory life stage in the ocean (McPhail and Lindsey 1970). Downstream migration begins upon completion of this metamorphosis, generally coinciding with high flow events in winter and spring (Moyle 2002).

Adults spend 3-4 years in the ocean in British Columbia, but this length is thought to be shorter in more southern areas (Moyle 2002). Adult remain close to the mouths of the rivers from which they came, likely because their prey is most abundant in estuaries and other coastal areas (Moyle 2002). Individuals attack a wide variety of fishes, include salmon, Pacific herring, and flatfishes, in the ocean (Beamish 1980). Pacific lamprey are thought to be preyed upon in the ocean by sharks, other fish, otters, seals, and sea lions (Roffe and Mate 1984, Moyle 2002).

A10.5 Threats and Stressors

Evaluation of the threats and stressors to Pacific lamprey has been limited. Therefore, much of the following discussion is based on a recent workshop to identify the state of knowledge, including knowledge gaps, on the biology, population structure, habitat of and threats to Pacific lamprey (Luzier et al. 2009).

Reduced Access (Passage) to Spawning Habitat. Artificial barriers, including dams, culverts, water diversions, tidal gates, and other barriers, can impede or completely block the upstream migration of adults to spawning grounds, resulting in impacts to the distribution and abundance of lamprey (Klamath-Siskiyou Wildlands Center et al. 2003, Luzier et al. 2009). Lamprey adults may have difficulty passing over barriers using ladders and other passage structures designed for salmonids, possibly due to high water velocity, sharp angles, culverts with drop-offs, or insufficient resting areas (Kostow 2002). Hydroelectric projects and water diversions may entrain or impinge weak-swimming macropthalmia (Moursund et al. 2000).

Reduced Access (Passage) to Downstream Habitat. Artificial barriers, including dams, culverts, water diversions, tidal gates, and other barriers, can impede or completely block the downstream migration of ammocoetes and macropthalmia towards the ocean, resulting in impacts to the distribution and abundance of lamprey (Luzier et al. 2009). Lamprey tend to outmigrate deeper in the water column such that traditional spill gates meant to aid migration of salmonids may not be effective on lamprey and may block passage (Moursund et al. 2003). Pacific lamprey populations cannot persist for more than a few years above impassable barriers (Beamish and Northcote 1989).

Stranding. Rapid changes in stream flows as a result of reservoir management can dewater stream beds and strand ammocoetes residing in the substrate. Water diversions and instream construction projects, such as culvert replacements, may also dewater reaches of streams and strand ammocoetes (Streif 2007). Because Pacific lamprey ammocoetes burrow in upstream sediments for 5-7 years in high densities, a dewatering event may affect multiple age classes burrowing together in a single stream reach (Luzier et al. 2009).

Dredging. Dredging associated with channel or irrigation screen maintenance and mining may affect many age classes at once due to their "colonial" nature and long upstream life stage (5-7 years) (Luzier et al. 2009). Beamish and Youson (1987) found that only 3-26 percent of lamprey that pass through a dredge survive. Further, it has been suggested that suction dredge mining was responsible for the decline or even loss of populations in some basins (Kostow 2002).

Chemical Poisoning and Toxins. Ammocoetes spend 5-7 years living in silty areas that are known to accumulate high levels of toxins. As a result, lamprey tend to have high body burdens of toxins relative to other fish species (Haas and Ichikawa 2007, Bettaso and Goodman 2008). Despite this apparent tolerance for high levels of toxins, lamprey are thought to be susceptible to toxins (Kostow 2002).

Ocean Conditions. Reductions the availability of host/prey organisms in the ocean (e.g., salmon and flatfishes) as a result of poor ocean conditions may negatively affect lamprey survival and growth, although very little is known about the oceanic stage of Pacific lamprey (Luzier et al. 2009).

Water Temperature. Elevated water temperature (greater than 22 °C [72 °F]) can cause mortality or significant deformation of eggs and young ammocoetes in laboratory conditions (Meeuwig et al. 1999). Degraded streams with a water temperature greater than 22 °C during early/mid-summer while lamprey spawn and young ammocoetes develop may be common (Luzier et al. 2009).

Disease. Pacific lamprey disease incidence is not well understood, but it is thought that disease may impact lamprey health to the point at which their ability to reproduce and survive is reduced (Luzier et al. 2009).

Overutilization. The extent to which harvest affects the population level effect on Pacific lamprey has not been well studied, but could represent a large proportion of spawning adults. Pacific lamprey adults and ammocoetes are harvested for use as bait to catch other species (Luzier et al. 2009). In addition, the fish is important to tribes in the Pacific Coast for sustenance, medicine, and ceremonial purposes (Close et al. 2002). Pacific lamprey for food and commercial purposes has declined from historical levels and Washington and Oregon have banned harvest for bait. However, harvest has not declined in California, where there are no regulations on lamprey harvest (69 FR 77158).

Predation. Mammals, birds, and other fish species consume lamprey at all life stages (Luzier et al. 2009). Ammocoetes are consumed by terrestrial mammal and birds, fish, and other species. Adult lamprey are consumed by otters, pinnipeds, and sturgeon.

Stream and Floodplain Degradation. The high density and limited mobility of lamprey ammocoetes in streams can potentially make them more vulnerable to channel alterations such as channelization, loss of riffle and side channel habitat, and scouring (Streif 2007, Luzier et al. 2009). Loss or alteration of habitat can also limit spawning if occurring in spawning reaches.

Non-Native Species. Non-native species, including striped bass, centrarchids, and catfish, are believed to consume juvenile and adult lamprey and may pose a threat to population sizes of lamprey (Streif 2007, Luzier et al. 2009). Many of these non-native species have become established within the range of Pacific lamprey in the Central Valley and have populations that are thriving despite recent declines in many native species (Baxter et al. 2008).

Translocation. It is unknown whether migrating adults cue solely on ammocoete pheromones or on other upstream cues to guide them to natal streams to spawn. If an ammocoete pheromone cue does not drive adult migration, translocation of individuals to an area previously extirpated would not affect adult migration cues.

Climate Change. Future climate change is expected to further increase water temperatures and modify the timing of flow-related environmental cues upon which Pacific lamprey rely for life history events (e.g., outmigration, spawning, etc.) (Luzier et al. 2009).

Extirpation. It is unknown whether migrating adults cue solely on ammocoete pheromones or on other upstream cues to guide them to natal streams to spawn. If they cue solely on ammocoete pheromones, extirpation of local populations would have large effects on recolonization of natal streams (Luzier et al. 2009).

A10.6 RELEVANT CONSERVATION EFFORTS

Along with several tribes, state and federal agencies are increasingly incorporating Pacific lamprey into management and monitoring plans to increase the overall body of knowledge and conserve the species.

There have been very few efforts to conserve Pacific lamprey in the Central Valley of California. The CALFED Ecosystem Restoration Program (ERP) designated the entire lamprey family as “Enhance and/or Conserve” (CALFED Bay-Delta Program 2000). This designation indicates that the ERP will undertake actions to conserve and enhance their abundance and distribution and the community diversity in which they live for their long-term stability.

There has been work in the Columbia River basin to modify new or existing ladders and structures to facilitate lamprey passage, such as creating holding areas where lamprey can rest (Columbia River Basin Lamprey Technical Workgroup 2004).

The Pacific Lamprey Conservation Initiative, led by the USFWS, was initiated in 2007 to “facilitate communication and coordination relative to the conservation of Pacific lampreys throughout their range” (USFWS 2007). The goal of the initiative is to restore Pacific lamprey populations and improve their habitat. Anticipated actions from the Initiative include: development of a Pacific Lamprey Conservation Plan, identification of funding for implementation of the Initiative and Plan, development of a network of interested parties, funding immediate conservation actions, and improvements in communication of Pacific lamprey conservation efforts.

A10.7 Recovery Goals

A recovery plan has not been prepared for this species and no recovery goals have been established because the species is not listed under the Federal or California ESA.

APPENDIX A11. RIVER LAMPREY (*LAMPETRA AYRESII*)

A11.1 LEGAL STATUS

The river lamprey is not listed under the state or federal Endangered Species Acts (ESA).

A broad group of West Coast conservation organizations petitioned the U.S. Fish and Wildlife Service (USFWS) on January 27, 2003 to list river lamprey, along with three other lamprey species on the West Coast, as threatened or endangered (Klamath-Siskiyou Wildlands Center 2003). However, the petition was declined in a 90-day finding on December 27, 2004, citing insufficient evidence that listing was warranted (69 FR 77158).

A11.2 SPECIES DISTRIBUTION AND STATUS

A11.2.1 Range and Status

The river lamprey occurs from near Juneau, Alaska, to San Francisco Bay, California (Moyle 2002). Outside of California, there are widely scattered and isolated populations throughout its range. River lamprey are common in British Columbia, the center of their geographic range. Within California, river lamprey can be found in the Central Valley, Napa River, Sonoma Creek, Alameda Creek, Salmon Creek, and in tributaries of the lower Russian River (see Figure A-11a). In the Central Valley, river lamprey are found in the lower Sacramento and San Joaquin River drainages, including the Stanislaus and Tuolumne Rivers. They may exist in other tributaries of these rivers, but are easily overlooked and have been the subject of few targeted sampling efforts (Moyle 2002). The species appears to be more abundant in the lower Sacramento-San Joaquin River system than in other streams in California.

Population trends are unknown in California, although declines are thought to have occurred synonymously with freshwater habitat degradation (Moyle 2002).

A11.2.2 Distribution and Status in the Plan Area

Individuals outmigrating from Sacramento and San Joaquin River watersheds pass through the Delta on their way to the Pacific Ocean and emigrating adults pass through the Plan Area on their way upstream towards spawning grounds. The extent to which river lamprey use the Plan Area for purposes other than a migration corridor is unknown. However, outmigrating lamprey macropthalmia in the final stages of metamorphosis to adults hold just upstream of salt water until late spring. Depending on the position of X2, this location could be within the Plan Area.

DRAFT

Figure A-11a. River Lamprey Inland Range in California

Status and trend data are extremely sparse and unreliable. There are no monitoring programs that target river lamprey in the Delta and those that catch river lamprey do not catch them regularly enough to establish trends through time. River lamprey are inconspicuous, often overlooked, and ammocoetes can be difficult to distinguish from ammocoetes of the co-occurring Pacific lamprey (H. Webb, pers. comm).

A11.3 Habitat Requirements and Special Conditions

The habitat requirements of river lamprey have not been well studied. It is thought that adults need clean, gravelly riffles in permanent streams to spawn successfully. These requirements are thought to be similar to those of salmonids. Ammocoetes live in silty backwaters and eddies with muddy or sandy substrate into which they burrow (Moyle et al. 1995). Ammocoetes require water temperatures that are lower than 25 °C (77 °F; Moyle et al. 1995). Lamprey can pass barriers that other fish cannot, although large dams and other habitat modifications remain barriers to migration. Lamprey may have difficulty passing over barriers using ladders and other passage structures designed for salmonids, possibly due to high water velocity, sharp angles, culverts with drop-offs, or insufficient rest areas (Kostow 2002). There has been some work in the Columbia River basin to modify new or existing ladders and structures to facilitate lamprey passage, such as creating holding areas where lamprey can rest (Columbia River Basin Lamprey Technical Workgroup 2004).

Although generally considered anadromous, river lamprey can live in freshwater as adults. For example, the population of river lamprey living in land-locked Sonoma Creek spend their entire life in freshwater.

A11.4 Life History

The biology of the river lamprey has not been well studied in California. As a result, much of this section is derived from information known for river lamprey from British Columbia. The potential exists for dissimilar life histories between fish in these two locations due to differences in physical factors (e.g., temperature, hydrology).

River lamprey are anadromous, beginning their migration into freshwater in the fall towards suitable spawning areas upstream (Moyle et al. 1995, Moyle 2002). Exact spawning locations are not known, although spawning habitat requirements are thought to be similar to those of salmonids. Fidelity to natal streams is also unknown. Spawning occurs from February through May in gravelly riffles in which individuals dig saucer-shaped depressions (Moyle 2002). Adults die after spawning. Fecundity is not well documented, but a study of two females in Cache Creek reported that one female (23 centimeters [cm; 9.1 inches] total length) produced approximately 11,400 eggs and the other (17.5 cm [6.9 inches] total length) produced approximately 37,300 eggs (Vladykov and Follett 1958). The eggs hatch into ammocoetes that remain in freshwater for approximately 3 to 5 years in silty or sandy low-velocity backwaters or stream edges where they bury into the substrate and filter-feed on algae, detritus, and microorganisms (Moyle 2002).

Ammocoetes begin metamorphosis into macropthalmia and then adults during summer at approximately 12 cm total length. This process takes nine to ten months during which individuals may shrink in length by up to 20 percent (Moyle 2002). Prior to entering the ocean, macropthalmia congregate just upstream of salt water until their esophagus opens (Beamish and Youson 1987). Once the esophagus is opened, new adults can properly osmoregulate and can then enter the ocean (Moyle 2002). Adults spend approximately 3 to 4 months in the ocean where they grow rapidly to 25 to 31 cm total length. If the ammocoete stage is 3 to 5 years, the total life span of river lamprey is estimated to be 6 to 7 years (Moyle et al. 1995).

River lamprey adults are parasitic during both freshwater and saltwater phases. Adults feed on a variety of host fish species that are small to intermediate size (4 to 12 inches total length) (Moyle et al 1995), the most common of which are thought to be herring and salmon (Beamish and Youson 1987). In Canada, river lamprey predation is considered to be a significant source of salmon mortality (Beamish and Neville 1995). Individuals feed by attaching to the back of their prey above the lateral line and eating the muscle tissue, even after the host fish dies (Moyle 2002). More than one lamprey can attach to a host salmon (Beamish and Youson 1987).

A11.5 THREATS AND STRESSORS

There have been no formal evaluations conducted that assess the threats and stressors to river lamprey. Therefore, much of the following discussion is based on limited resources or has been derived from the co-occurring Pacific lamprey as part of the Pacific Lamprey Conservation Initiative. The primary threat to river lamprey is thought to be loss or degradation of habitat through dams, diversions, toxics, stream channelization, dredging, and urbanization (Moyle et al. 1995, Luzier et al. 2009). Dams have altered flows in channels and limited access to spawning grounds. Toxics may have both lethal and sublethal effects on individuals. Stream channelization, dredging, and diversions have altered flow patterns and rates in channels. Urbanization has degraded habitat by increasing loads of certain toxics, changing runoff patterns, and altering the configuration of some channels. Future climate change is expected to further increase water temperatures and modify the timing of flow-related environmental cues upon which Pacific lamprey rely for life history events (e.g., outmigration, spawning, etc.).

A11.6 RELEVANT CONSERVATION EFFORTS

There have been very few efforts to conserve river lamprey in the Central Valley of California. The CALFED Ecosystem Restoration Program (ERP) designated the entire lamprey family as “Enhance and/or Conserve” (CALFED Bay-Delta Program 2000). This designation indicates that the ERP will undertake actions to conserve and enhance their abundance and distribution and the community diversity in which they live for their long-term stability.

River lamprey is currently listed as a covered species under the Butte County Habitat Conservation Plan, but specific conservation measures have not yet been written.

A11.7 Recovery Goals

A recovery plan has not been prepared for this species and no recovery goals have been established because the species is not listed under the Federal or California ESA.

APPENDIX A12. SAN JOAQUIN KIT FOX (*VULPES MACROTIS MUTICA*)

A12.1 LEGAL STATUS

The San Joaquin kit fox (*Vulpes macrotis mutica*) is a state and federally-listed species. It was listed by the U.S. Fish and Wildlife Service as an endangered species in 1967 and as a threatened species pursuant to the California Endangered Species Act in 1971. No critical habitat rules have been published for the San Joaquin kit fox.

A12.2 SPECIES DISTRIBUTION AND STATUS

A12.2.1 Range and Status

Grinnell et al. (1937) initially described the range of the San Joaquin kit fox prior to 1930 as extending from southern Kern County as far north as eastern Contra Costa County. Grinnell et al. (1937) note that by 1930 the range had been reduced by more than half, with the largest portion of the occupied range remaining in the western and southern parts of the valley. They considered the species largely absent from the eastern and central parts of the valley.

Although no complete surveys have been conducted of the historical range, kit foxes are currently thought to inhabit suitable habitat on the San Joaquin Valley floor and in the surrounding foothills of the coastal ranges, Sierra Nevada, and Tehachapi Mountains north to Contra Costa, Alameda, and San Joaquin counties on the west side of the valley, and near La Grange, Stanislaus County, on the east side of the Valley (USFWS 1998) (Figure A-12a). Kit foxes have been found on all the larger, scattered islands of natural land on the Valley floor in Kern, Tulare, Kings, Fresno, Madera, San Benito, Merced, Stanislaus, San Joaquin, Alameda, and Contra Costa counties. They also occur in the interior basins and ranges in Monterey, San Benito, San Luis Obispo, and, possibly, Santa Clara counties and in the upper Cuyama River watershed in northern Ventura and Santa Barbara counties and southeastern San Luis Obispo County (Laughrin 1970, Jensen 1972, Swick 1973, Morrell 1975).

USFWS (1998) reports that the largest extant populations of kit foxes are in western Kern County on and around the Elk Hills and Buena Vista Valley, Kern County, and in the Carrizo Plain National Area, San Luis Obispo County. Other relatively large populations have been reported to occur in the Central Coast around Fort Hunter Liggett, Monterey County, and Camp Roberts, Monterey, and San Luis Obispo counties. Occurrences further north are fewer and less frequent and include several in the Los Vaqueros watershed and surrounding area in Contra Costa County in the early 1990s (USFWS 1998, CNDDB 2009).

DRAFT

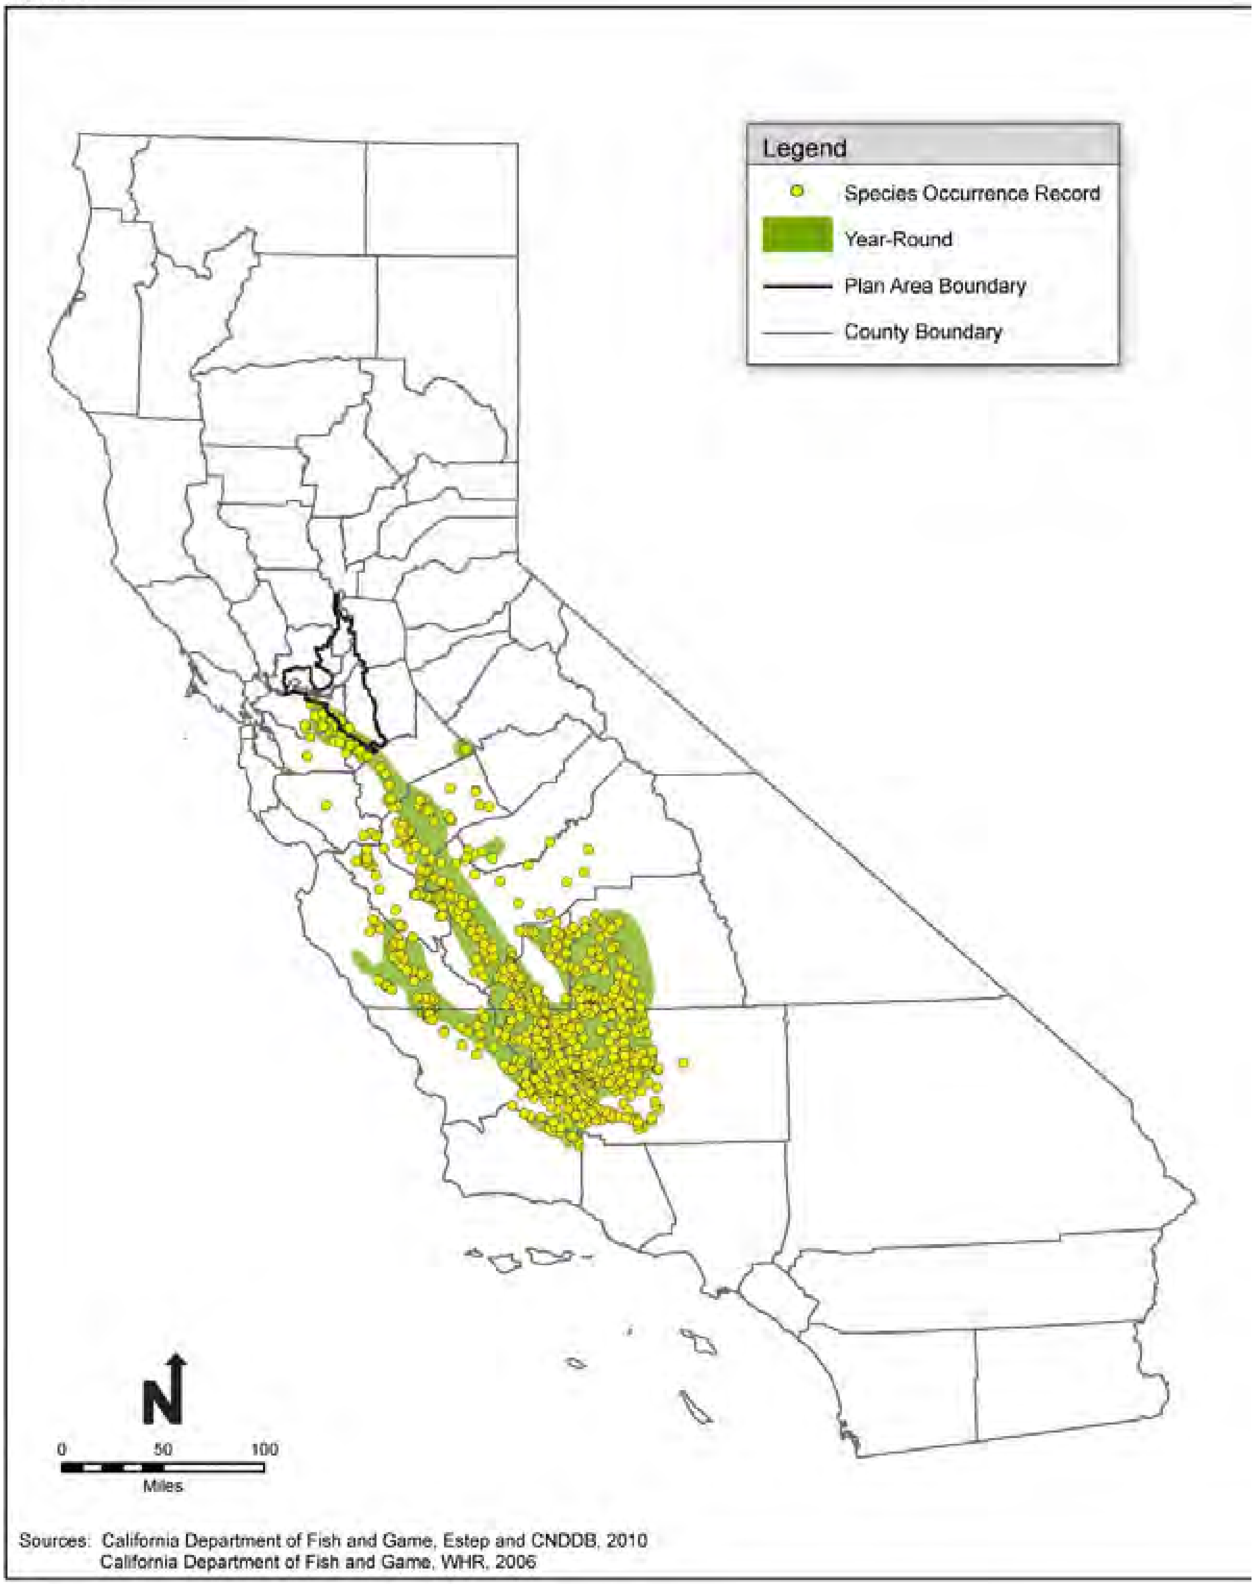

Figure A-12a. San Joaquin Kit Fox Statewide Range and Recorded Occurrences

Habitat loss, particularly on the San Joaquin Valley floor, has constrained the distribution of San Joaquin kit fox. Morrell (1975) reported that approximately 85 percent of the fox population in 1975 was found in only six counties (Kern, Tulare, Kings, San Luis Obispo, Fresno, and Monterey), and over half the population occurred in two of those counties: Kern (41 percent) and San Luis Obispo (10 percent). The 1983 recovery plan (USFWS 1983) estimated that the population of adult kit foxes over the entire range prior to 1930 may have been between 8,667 and 12,340. The estimate presented in the 1983 recovery plan was 6,961 adult foxes, representing a possible population decline of 20 to 43 percent.

More recently, Constable et al. (2009) found persistent but low populations in Merced County south of Santa Nella, but also questioned the viability and presence of kit fox populations north of Santa Nella due to habitat loss and fragmentation; declining populations of preferred prey, particularly kangaroo rats; low densities; and lack of reported population persistence.

Within this constrained, fragmented, and largely disturbed landscape, Cypher et al. (2000) showed that (1) population growth rates vary positively with reproductive success, (2) population density is positively related to both the current and the previous year's prey availability, and (3) prey abundance is strongly related to the previous years' effective precipitation (October to May). White and Garrott (1999) note that two density-dependent mechanisms may also regulate kit fox population patterns: (1) the rate of juvenile recruitment, which is inversely related to the density of adult foxes because higher proportions of juveniles are killed by coyotes at high fox densities and (2) kit fox populations are bounded by their territorial spacing behavior, which limits recruitment at high densities.

A12.2.2 Distribution and Status in the Plan Area

CNDDB (2009) reports eight occurrences of San Joaquin kit fox in the Plan Area. All occurrences are within the grassland landscape along the extreme western edge of the Plan Area south of Brentwood (Figure A-12b). This is considered the extreme northeastern edge of the San Joaquin kit fox range (USFWS 1998). The species has not been detected, nor is it expected to occur elsewhere within the Plan Area. Most of the reported occurrences are from the late-1980s to the mid-1990s. There have been very few reported occurrences of this species within the far northern portion of its range (Alameda, Contra Costa, and San Joaquin counties) since the mid-1990s. Of the 53 recorded occurrences in Contra Costa County between 1967 and 1997, only 15 were documented since 1986 (Duke et al. 1997). A recent survey of Contra Costa and Alameda counties within the known range of the kit fox found no evidence of recent occupancy (Clark et al. 2003). While recent survey results do not necessarily indicate absence of the species, they do indicate very low density of San Joaquin kit fox and suggest a declining population within the northern range of the species.

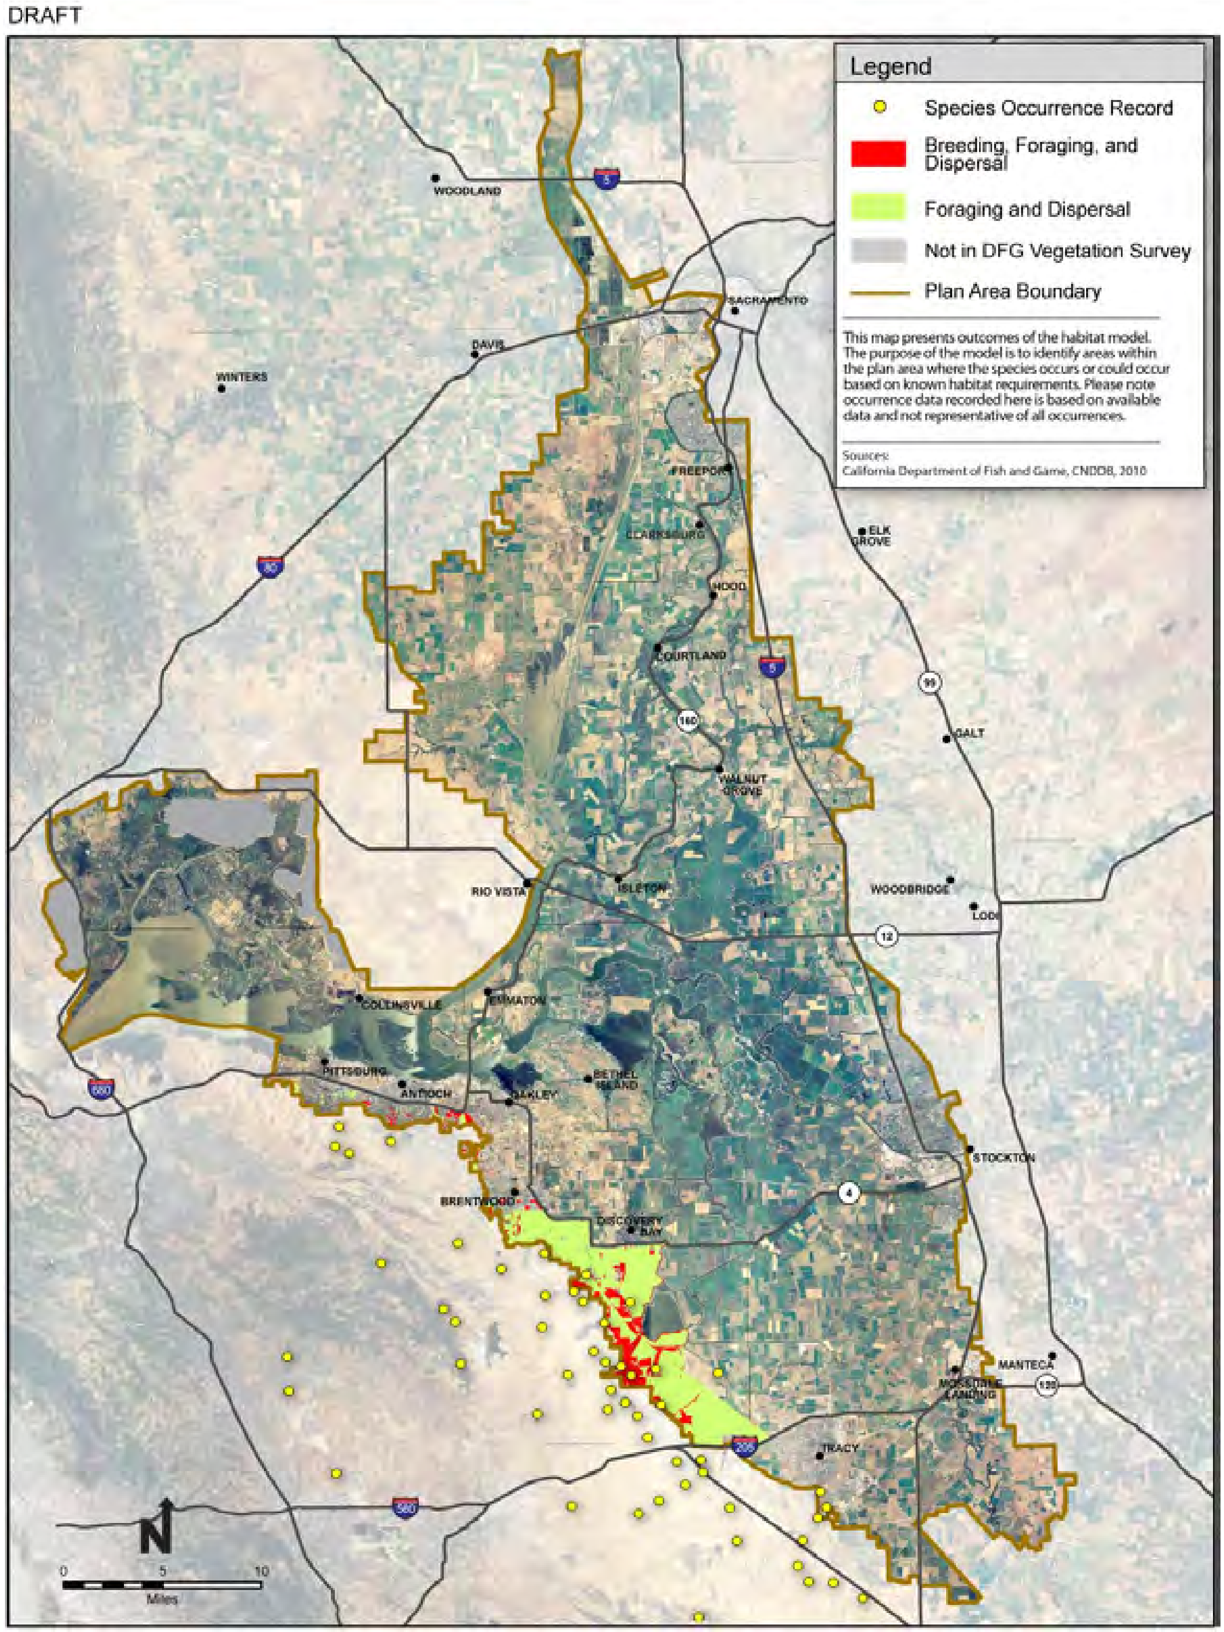

Figure A-12b. San Joaquin Kit Fox Habitat Model and Recorded Occurrences

A12.3 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

In the northern part of the range, the San Joaquin kit fox is associated primarily with foothill annual grasslands (Swick 1973, Hall 1983, Bell 1994) and sometimes with valley oak savanna and alkali grasslands (Bell 1994). In the vicinity of the Plan Area, San Joaquin kit foxes inhabit grazed grasslands and grasslands with associated wind farms and sometimes occur adjacent to and forage in tilled and fallow fields and irrigated row crops (Bell 1994). In the central and southern portions of the range, kit foxes are also found in remnant patches of native valley floor scrubland (e.g., valley sink scrub, valley saltbush scrub, Upper Sonoran subshrub, Interior Coast Range saltbush scrub), as well as grazed grasslands, agricultural lands, petroleum fields, and some urban areas (USFWS 1998). Remaining patches of northern hardpan vernal pool, northern claypan vernal pool, alkali meadow, and alkali playa types also provide foraging habitat when in association with grasslands or other suitable denning habitats.

Dens are typically in relatively flat terrain or in gently sloping hills, in washes, drainages, and roadside berms. Occupied habitats are usually associated with loose-textured soils to facilitate den construction (Grinnell et al 1937, Egoscue 1962, Morrell 1972). Shallow soils with close proximity to bedrock, soils with high water tables, and impenetrable hardpan layers are generally avoided (Morrell 1972, O'Farrell and Gilbertson 1979, O'Farrell et al. 1980, McCue et al. 1981). However, kit foxes will also modify burrows dug by other animals, such as California ground squirrel (*Otospermophilus beecheyi*[1]). Where this is common, particularly in the northern part of the range, dens may be found in soils with high clay content (Orloff et al. 1986). Kit foxes have also been documented using agricultural lands where adjacent uncultivated land occurs and provides suitable denning sites and a prey base (Jensen 1972, Kato 1986, Orloff et al. 1986).

A12.4 LIFE HISTORY

Description. The San Joaquin kit fox is the largest of eight subspecies of kit foxes, the smallest canid species in North America. Kit foxes have a small, slim body; long, slender legs; large ears set close together; a narrow nose; and a long, bushy tail tapering slightly toward the tip, which is typically carried low and straight (USFWS 1998). Males average 80.5 centimeters (cm) (2.64 feet) in total length and 29.5 cm (11.6 inches) in tail length; females average 76.9 cm (2.52 feet) in total length and 28.4 cm (11.2 inches) in tail length (Grinnell et al. 1937). The average weight of adult males is 2.3 kilograms (5.1 lbs); that of adult females is 2.1 kilograms (4.6 lbs) (Morrell 1972).

The color and texture of the coat of kit foxes vary geographically and seasonally. The most commonly described colorations are buff, tan, grizzled, or yellowish-gray dorsal coats (McGrew

[1] Formerly *Spermophilus beecheyi*

1979). Two distinctive coats develop each year: a tan summer coat and a silver-gray winter coat (Morrell 1972). The undersides vary from light buff to white (Grinnell et al. 1937), with the shoulders, lower sides, flanks, and chest varying from buff to a rust color. The ear pinna (external ear flap) is dark on the back side, with a thick border of white hairs on the forward-inner edge and inner base. The tail is distinctly black-tipped (USFWS 1998).

Activity. San Joaquin kit foxes are primarily nocturnal and active throughout the year (Grinnell et al. 1937, Morrell 1972). Adults and pups are sometimes observed resting and playing near the den entrance in the afternoons, but most aboveground activities begin near sunset and continue sporadically throughout the night (USFWS 1998). Morrell (1972) reported that hunting occurred only at night. However, this may not be true for populations that rely on diurnal ground squirrels as their principal prey, such as those in the northern range. This suggests that kit foxes are not entirely nocturnal and appear to adapt to the activities of available prey (Balestreri 1981, Hall 1983, Orloff et al. 1986, O'Farrell et al. 1987).

Reproduction. Kit foxes are capable of breeding at age one, but may not breed until their first year of adulthood (Morrell 1972). Adult pairs remain together all year, sharing the home range but not necessarily the same den (USFWS 1998). During September and October, adult females begin to clean and enlarge natal or pupping dens, usually selecting dens with multiple openings (Morrell 1972). Mating and conception take place between late-December and early-March (Egoscue 1956, Morrell 1972, Zoellick et al. 1987a). The median gestation period is estimated to range from 48 to 52 days (USFWS 1998). The majority of litters, of from two to six pups, are born sometime between mid-February and late-March (Egoscue 1962, Morrell 1972, Zoellick et al. 1987a).

During the time the female is lactating, she rarely hunts and is provisioned by the male. The pups emerge above ground at slightly more than 1 month of age and may already be weaned. After 4 to 5 months, usually in August or September, the family bonds begin to dissolve and the young begin dispersing. Occasionally a juvenile female will remain with the adult female for several more months (O'Neal et al. 1992). Koopman et al. (2000) found that 33 percent of juveniles disperse from their natal territory, with more males (49 percent) than females (24 percent). Others remain in their natal area. Dispersal was associated with mean annual litter size in males and prey abundance in females.

Home Range/Territory Size. Home ranges appear to be highly variable, from less than 2.6 square kilometers (sq km) (1 square mile [sq mi]) up to approximately 31 sq km (12 sq mi) (Morrell 1972, Knapp 1978, Zoellick et al. 1987b, Paveglio and Clifton 1988, Spiegel and Bradbury 1992, White and Ralls 1993). Morrell (1972) reported home ranges between 2.6 and 5.2 sq km (1 and 2 sq mi). Differences in home range size among study sites tend to be related to prey abundance (White and Ralls 1993, White and Garrott 1999). The USFWS (1999) mentions large kit fox home ranges in the northern range; however, little data are available for home range size in the northern portion of the range.

Foraging Behavior and Diet. San Joaquin kit fox diet varies geographically, seasonally, and annually based on variation in abundance of potential prey (USFWS 1998). In the southern and central portions of their range, kangaroo rats, pocket mice, white-footed mice (*Peromyscus* spp.), and other nocturnal rodents are key prey items. California ground squirrels, black-tailed hares, San Joaquin antelope squirrels, desert cottontails, ground-nesting birds, and insects are also taken (Jensen 1972, Scrivner et al. 1987a, Archon 1992). In the northern part of their range, kit foxes most frequently consume California ground squirrels (Orloff et al. 1986). Cottontails, black-tailed hares, pocket mice, and kangaroo rats are also eaten (Hall 1983).

A12.4.1 Threats and Stressors

Habitat Loss and Fragmentation. Habitat loss and fragmentation from urbanization and agricultural expansion is the principal factor in the decline of the San Joaquin kit fox in the San Joaquin Valley (Laughrin 1970, Jensen 1972, Morrell 1975, Knapp 1978). By 1979, an estimated 6.7 percent of the San Joaquin Valley floor's original native habitat south of Stanislaus County remained untilled and undeveloped (USFWS 1983). In the northern range, continued urbanization, primarily in Contra Costa and Alameda counties; water storage and conveyance projects; road construction; energy development; and other activities continue to reduce and fragment remaining grassland habitats. These land conversions contribute to kit fox declines through displacement, isolation of populations, creation of barriers to movement, direct and indirect mortality, and reduction of prey populations (USFWS 1998).

Grazing. While livestock grazing is not necessarily detrimental and may in fact be beneficial (Morrell 1975, Balestreri 1981, Orloff et al. 1986), intensive overgrazing that destroys shrub cover and reduces prey abundance may be detrimental (O'Farrell et al. 1980, O'Farrell and McCue 1981, USFWS 1983, Kato 1986).

Rodent Control. The use of pesticides and rodenticides also threatens kit foxes. Ground squirrel control programs in the 1970s severely reduced California ground squirrel populations in Contra Costa County and are thought to have contributed to kit fox declines in the northern range (Bell et al. 1994, USFWS 1998). Kit fox is also susceptible to secondary poisoning from rodenticides (Berry et al. 1992, Standley et al. 1992).

Predation. Human activities, including urbanization, agricultural expansion, and agricultural and grazing practices, may have increased some predator populations that are more adaptable to disturbed environments, including coyote and red fox, two primary predators of the San Joaquin kit fox. This, in turn, can result in increased competition for resources and additional human-induced predation affecting kit fox populations.

A12.5 Relevant Conservation Efforts

A recovery plan that proposed interim objectives of halting the decline of the San Joaquin kit fox and increasing population sizes above 1981 levels was approved in 1983 (USFWS 1983).

Subsequent to the recovery plan, the most significant conservation efforts have included land acquisitions by federal, state, and private agencies and organizations, including the U.S. Bureau of Land Management, USFWS, and The Nature Conservancy. Key acquisitions include the Carrizo Plain, Ciervo-Panoche Natural Area, and the Lokern Natural Area in the southern range. Other lands have been protected as mitigation for land conversions.

Past and continuing research, particularly on the Naval Petroleum Reserves in Kern County, provides data on a variety of topics that assist with long-term management and conservation of kit fox, including dispersal, mortality, movements and home ranges, habitat enhancement, relocation, supplemental feeding, and coyote control (Berry et al. 1987a, 1987b, Scrivner et al 1987b, Zoellick et al. 1987a, Cypher and Scrivner 1992, EG&G Energy Measurements 1992), as well as various survey efforts and life history studies (Hall 1983, Orloff et al. 1986, Archon 1992, Spiegel and Bradbury 1992, White and Ralls 1993, Bell et al. 1994, White et al. 1994).

The San Joaquin kit fox is a covered species in the San Joaquin County Multi-Species Habitat Conservation and Open Space Plan and the East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan, which limit or prohibit removal of occupied habitat that could potentially affect the species as a result of the implementation of covered activities.

A12.6 SPECIES HABITAT SUITABILITY MODEL

Model Approach. BDCP Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information systems (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which are incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and revise the vegetation input data as necessary.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements, and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate, as well as overestimate, the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small, isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; instead, the models indicate that non-habitat areas have a much lower probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf (2007). Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers; connectivity between habitat types; and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified, and each vegetation type or association is identified, along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or underestimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The San Joaquin kit fox model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), U.S. Department of Agriculture (USDA) 2005 aerial photography, and California Department of Water Resources (DWR) 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable San Joaquin kit fox habitat in the Plan Area. Vegetation types were assigned based on the species requirements, as described above, and the assumptions described below.

Upland Breeding, Foraging, and Dispersal Habitat. Upland breeding, foraging, and dispersal habitat includes grassland and agricultural habitats within the area south and west of Highway 4 from Antioch (Bypass Road to Balfour Road to Brentwood Boulevard), to Old River; then south along Old River to Clifton Court Forebay; along the western and southern sides of Clifton Court Forebay to Old River; then south along the county line to Byron Highway; then west of Byron Highway to I-205, north of I-205 to I-580, and west of I-580.

Upland Breeding, Foraging, and Dispersal Habitat from the BDCP composite vegetation layer consists of the following:

- Grassland

- Ruderal herbaceous grasses and forbs;
- California annual grasslands – herbaceous;
- *Bromus diandrus – Bromus hordeaceus;*
- Degraded vernal pool complex – California annual grasslands; and
- Degraded vernal pool complex – Ruderal herbaceous grasses and forbs.

- Vernal pool complex
  - Ruderal herbaceous grasses and forbs; and
  - California annual grasslands – herbaceous.

Upland Foraging and Dispersal Habitat from the BDCP composite vegetation layer consists of the following:

- Agricultural land – all types

Assumptions. Within the Plan Area, the San Joaquin kit fox has been detected only in grassland and adjoining agricultural habitats within the grassland landscape along the extreme southwestern edge of the Plan Area from approximately Brentwood to Tracy. This area is the northeasternmost edge of the San Joaquin kit fox range. The species is not known to or expected to occur elsewhere in the Plan Area.

In the northern part of the range, the San Joaquin kit fox is associated primarily with foothill annual grasslands (Swick 1973, Hall 1983, Bell 1994) and sometimes with valley oak savanna and alkali grasslands (Bell 1994). In the vicinity of the Plan Area, San Joaquin kit foxes inhabit grazed grasslands and sometimes occur adjacent to and forage in tilled and fallow fields and irrigated row crops (Bell 1994). Agricultural lands are likely used infrequently and inconsistently due to crop rotations and differences in suitability; thus, this model overestimates the extent of suitable agricultural foraging and dispersal habitat.

A12.6.1 Recovery Goals

The 1998 recovery plan for upland species of the San Joaquin Valley (USFWS 1998) incorporates and expands on the strategy provided in the initial 1983 San Joaquin kit fox recovery plan (USFWS 1983). The goal of the 1998 recovery plan is to establish and maintain a viable complex of kit fox populations (i.e., viable metapopulations) on private and public lands throughout the species' geographic range. The plan hinges on the enhanced protection and management of three geographically distinct core populations and a number of smaller satellite populations. The three core populations inhabit the Carrizo Plan Natural Area in San Luis Obispo County, natural lands of western Kern County (i.e., Elk Hills, Buena Vista Hill, Buena Vista Valley, Lokern Natural Area, and adjacent natural land), and the Ciervo-Panoche Natural

Area of western Fresno and eastern San Benito counties (USFWS 1998). Protection of smaller satellite populations will connect isolated natural lands to core and other populations.

The plan also includes a series of recovery actions that focus on land protection and maintenance or reestablishment of habitat corridors that link all occupied portions of the range. While there are no identified core populations in the northern range, the Habitat Protection and Population Interchange recovery actions (USFWS 1998) include:

> *Protect existing kit fox habitat in the northern, northeastern, and northwestern segments of their geographic range and existing connections between habitat in those areas and habitat farther south.*

Additional Ecology and Recovery Actions include determining habitat restoration and management prescriptions; determining the current geographic range of the species; monitoring populations; investigating use of farmlands; measuring movements between populations; determining the effects of rodent control; and evaluating the interactions between kit foxes and other canids.

APPENDIX A13. RIPARIAN WOODRAT (*NEOTOMA FUSCIPES RIPARIA*)

A13.1 LEGAL STATUS

The riparian woodrat (*Neotoma fuscipes riparia*) is a federally listed species and a state species of special concern (Williams 1986). It was listed pursuant to the federal Endangered Species Act as endangered on February 23, 2000 (65 FR 8881). Critical habitat has not been designated for this species.

A13.2 SPECIES DISTRIBUTION AND STATUS

A13.2.1 Range and Status

The riparian woodrat is 1 of 11 recognized subspecies of the dusky-footed woodrat (*Neotoma fuscipes*). The species range extends from the Columbia River and the Willamette Valley in Oregon to northwestern Baja California. It is generally found in dense chaparral, oak and riparian woodland, and mixed coniferous forest that has a well-developed understory. Generally preferring fairly moist habitats, *N. fuscipes* is also found in drier communities, such as pinyon-juniper woodland, and favors brushy habitat or woodland that has an oak component (USFWS 1998).

The riparian woodrat has a limited distribution associated primarily with valley oak (*Quercus lobata*)-dominated riparian habitats of the Central Valley (Figure A-13a). Historical records indicate the subspecies was distributed along the San Joaquin, Stanislaus, and Tuolumne rivers, and possibly Corral Hollow, in San Joaquin, Stanislaus, and Merced counties, although Hooper (1938) thought the distribution could have extended south to northern Fresno County. The current distribution is highly restricted and is limited to riparian habitats along the lower portions of the San Joaquin and Stanislaus rivers in northern San Joaquin County. Riparian woodrat is found in a 100-hectare (247-acre) patch of riparian forest on the Stanislaus River in Caswell Memorial State Park (Williams 1986), and in San Joaquin River National Wildlife Refuge (P. Kelly pers. comm.). Williams (1993) estimated the population at Caswell State Park at 437 individuals. Since confirming their presence at San Joaquin River National Wildlife Refuge in 2003, more than 30 individual riparian woodrats have been captured at this location (P. Kelly pers. comm.).

Figure A-13a. Riparian Woodrat Statewide Range and Recorded Occurrences

1

A13.2.2 Distribution and Status in the Plan Area

There are no current records of riparian woodrat occurrences in the Plan Area. However, while occupancy has not been verified, the recorded occurrences northeast of Vernalis along the San Joaquin River, which is near the extreme southeastern tip of the Plan Area, are considered extant by CNDDB (2008) (Figure A-13b). The Caswell Memorial State Park population along the Stanislaus River is approximately 2 miles east of the Plan Area. The population of riparian woodrats at San Joaquin River National Wildlife Refuge is directly adjacent the Plan Area.

Small patches of potentially occupied valley oak riparian forest occur along the San Joaquin River from the southern tip of the Plan Area north to approximately the Interstate 5 overcrossing near Lathrop. Sufficiently large patches of oak-dominated riparian forest are lacking elsewhere in the Plan Area. A survey effort coordinated by DWR is currently ongoing to determine the presence or absence of the species in the Plan Area.

A13.3 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

The riparian woodrat occurs in riparian woodland with an overstory canopy of trees and a moderate-to-dense shrub understory with abundant dead branches and downed woody material (Williams 1986). Riparian woodrats are found primarily where there is a valley oak overstory and are most numerous in areas of dense shrub cover. While they will also occur in riparian habitats with other dominant overstory species, such as Oregon ash (*Fraxinus latifolia*), box elder (*Acer negundo*), and Hinds' walnut (*Juglans hindsii*) (Patrick Kelly pers. comm.), highest densities of woodrats and their houses have been found in willow thickets with an oak overstory (USFWS 1998).

The riparian woodrat typically lives in colonies of conical stick houses constructed with sticks, bark, plant cuttings, and other objects (Collins 1998), which range in size from 60 to 150 centimeters (cm) (24 to 59 inches) in height, and can be 120 to 240 cm (47 to 94 inches) in basal diameter. Williams (1993) reports similar house construction for riparian woodrat; however, unlike other subspecies that may construct arboreal houses, riparian woodrat houses appear to be mainly terrestrial. Houses typically are placed on the ground against or straddling a log or exposed roots of a standing tree and are often located in dense brush. With their general dependence on terrestrial stick houses, riparian woodrats may be vulnerable to flooding. While the woodrat itself can be arboreal and can escape flooding, its terrestrial houses, which are essential for survival, can be affected by flooding and thus potentially affect population viability (USFWS 1998).

DRAFT

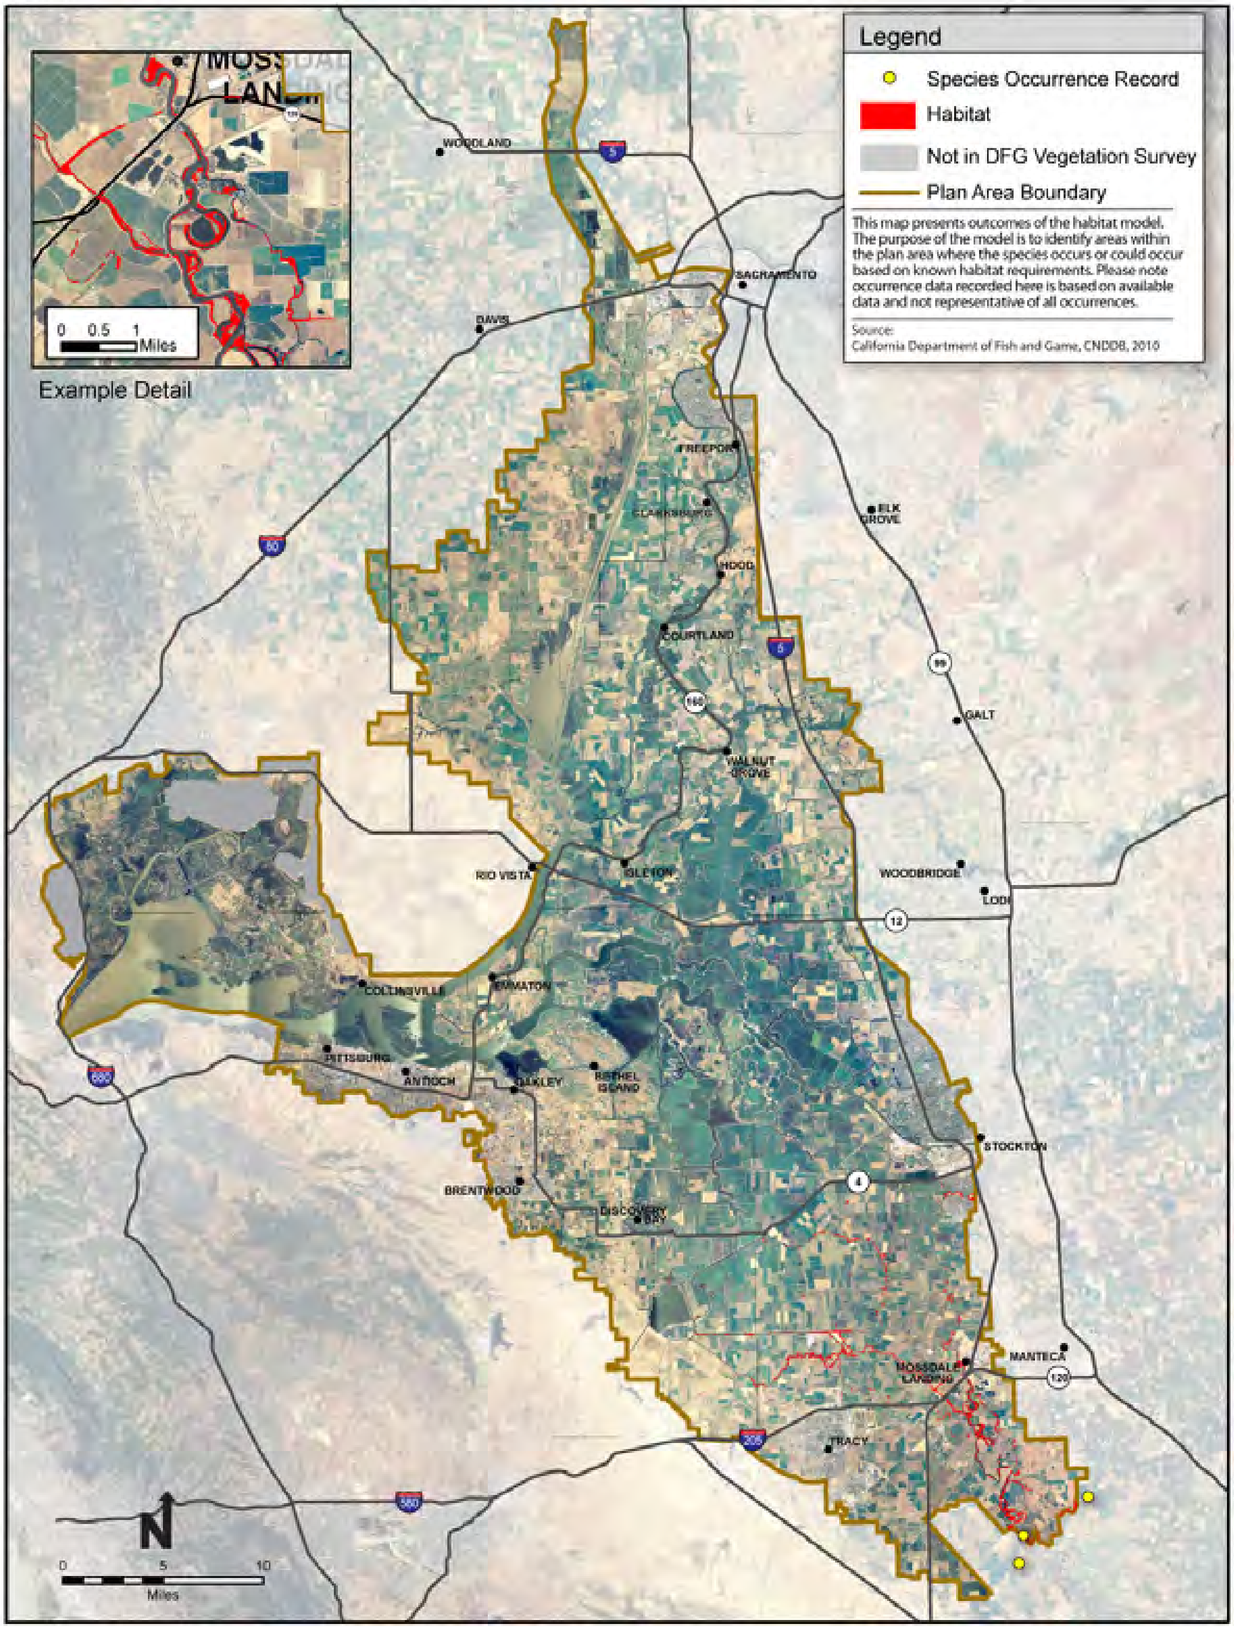

Figure A-13b. Riparian Woodrat Habitat Model and Recorded Occurrences

A13.4 LIFE HISTORY

Description. The riparian woodrat is a medium-sized rodent, with total length ranging from 434 to 452 millimeters (mm) (17.1 to 17.8 inches), tail length ranging from 207 to 217 mm (8.2 to 8.5 inches), and average weight of 243 grams (8.57 oz) in females and 266 grams (9.38 oz) in males (Hooper 1938). It is distinguished from other subspecies of woodrats by its larger size, more grayish color, white hind feet, and a more bicolored tail, which is lighter below contrasting with the darker dorsal color. The riparian woodrat's tail is well-furred and not scaled.

Activity and Social Structure. Riparian woodrats are primarily nocturnal, with peak activity at dawn and dusk. While riparian woodrat houses are generally constructed on the ground, woodrats may be found on the ground or in the foliage of trees and shrubs (Linsdale and Tevis 1951).

There is little information on the social structure of riparian woodrats. Assuming their activity and social structure is similar to *N. fuscipes*, they probably live in loosely cooperative societies and have a matrilineal (mother-offspring associations; through the maternal line) social structure that results in populations that are female-biased and in which adjacent females are closely related (Kelly 1990, *in litt*.). Females remain at their natal site throughout their lives. Males disperse away from their birth den and are highly territorial and aggressive, especially during the breeding season. Males mate with more than one female in a single breeding season; this is known as a polygynous mating system. The effective population size (i.e., successful breeders) is generally much smaller than the actual population size. This breeding system, in combination with the small size of the only known extant population, means that the riparian woodrat is at an increased risk of extinction because of inbreeding depression. Small, isolated populations are more susceptible to genetic, demographic, and environmental stochasticity than large, widely distributed populations (USFWS 1998).

Reproduction. There is also little information available on reproduction and dispersal of riparian woodrat. Again, assuming it is similar to *N. fuscipes*, the subspecies likely breeds from December to September, with the majority of litters born in mid-spring (Carraway and Verts 1991, *in litt.*). Following a gestation period of 28 to 33 days (Carraway and Verts 1991, *in litt.*), females give birth to one annual litter (Vestal 1938, *in litt.*). Litter size averages 2.6 young per litter, but ranges from 1 to 4 (Carraway and Verts 1991, *in litt.*). Juveniles rarely disperse more than 50 feet to establish home ranges in or adjacent to the maternal range (Linsdale and Tevis 1951, Collins 1998).

Diet. Woodrats as a group are generalist herbivores, consuming a wide variety of nuts and fruits, fungi, foliage, and some forbs (Linsdale and Tevis 1951). Riparian woodrat may be considered to be more specialized feeders, but there are no available studies on riparian woodrat diet.

A13.5 THREATS AND STRESSORS

Loss of Genetic Variability. Because there is only one known extant population of riparian woodrat of limited size and occupancy, it is at increased risk of harm or extinction because of genetic, demographic, and naturally occurring catastrophic events (e.g., drought, flooding, fire), that threaten small, isolated populations. In addition, because of its breeding behavior, the effective size of woodrat populations is generally much smaller than the actual population size, which increases the risk of inbreeding depression.

Habitat Loss and Fragmentation. There has been a nearly 90 percent reduction of historical riparian communities throughout the riparian forests along major streams flowing onto the floor of the northern San Joaquin Valley (Katibah 1983). The extent to which this reduction of available habitat has affected populations of riparian woodrat is unknown. However, loss and fragmentation of habitat are considered the principal reasons for the decline of this subspecies. Much of this loss was the result of conversion to agricultural land uses and the construction of large dams and canals, which diverted water for the irrigation of crops and permanently altered the hydrology of valley streams. Historically, cattle also probably impacted riparian woodrat populations since the thick undergrowth, which is particularly important to woodrats, is sensitive to trampling, browsing, and grazing by livestock (USFWS 1998).

Flooding and Fire. The increase of habitat conversion to agriculture, combined with construction of dams, has altered the timing, frequency, duration, and intensity of flooding. Although woodrats can easily climb trees and avoid drowning, their nests, which are essential to survival, can be destroyed (USFWS 1998). Wildfires are also of great concern because of habitat degradation and loss of individuals unable to avoid the fire. A catastrophic fire at Caswell Memorial State Park could potentially eliminate the only known occupied site for this species.

Other Threats. Other threats that could potentially affect the remaining occupied site for this subspecies include disease, predation, the use of rodenticides, and trampling by grazing animals.

A13.6 RELEVANT CONSERVATION EFFORTS

Although the only known population has some protection by residing in Caswell Memorial State Park, there are currently no conservation efforts under way specifically to benefit the riparian woodrat. The California Department of Parks and Recreation, however, has supported some general small-mammal studies and studies on the woodrat population at the park (Cook 1992, Williams 1993) and has developed a fire management plan to protect habitat within it.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-species Conservation Strategy designates the riparian woodrat as a "Contribute to Recovery" species (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its

control and within its scope that are necessary to contribute to the recovery of the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

The riparian woodrat is a covered species in the San Joaquin County Multi-species Habitat Conservation and Open Space Plan, which prohibits removal or disturbance of occupied riparian habitat that could potentially affect the subspecies as a result of the implementation of covered activities.

A13.7 Species Habitat Suitability Model

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which are incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and revise the vegetation input data as necessary.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements, and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate, as well as overestimate, the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small, isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; instead, the models indicate that non-habitat areas have a much lower probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf (2007). Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers; connectivity between habitat types; and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified, and each vegetation type or association is identified, along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or underestimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The riparian woodrat model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), USDA 2005 aerial photography, and DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable riparian woodrat habitat in the Plan Area. Vegetation types were assigned based on the species requirements, as described above, and the assumptions described below.

Habitat. Potentially occupied riparian woodrat habitat consists of the following valley riparian types from the BDCP composite vegetation layer in Conservation Zone 7:

- Valley oak – *Quercus lobata;*
- *Quercus lobata – Salix exigua-Rubus discolor;*
- *Salix gooddingii – Quercus lobata*/wetland herbs;
- *Salix gooddingii – Populus fremontii* (*Quercus lobata-Salix exigua-Rubus discolor*);
- *Quercus lobata/Rosa californiaca* (*Rubus discolor – Salix lasiolepis/Carex* spp.);
- *Quercus lobata – Acer negundo;*
- *Quercus lobata – Alnus rhombifolia (Salix lasiolepis – Populus fremontii – Quercus agrifolia*);
- *Quercus lobata – Fraxinus latifolia;*
- Box elder (*Acer negundo*);
- *Acer negundo – salix goodingii*);
- *Alnus rhombifolia/Cornus sericea;*
- *Alnus rhombifolia/Salix exigua (Rosa californica*);

- Black willow (*Salix gooddingii*) – Valley oak (*Quercus lobata*) restoration);
- Fremont cottonwood (*Populus fremontii*);
- Hinds' walnut (*Juglans hindsii*);
- Oregon ash (*Fraxinus latifolia*);
- Valley oak (*Quercus lobata*) restoration;
- White alder (*Alnus rhombifolia*); and
- White alder (*Alnus rhombifolia*) – Arroyo willow (*Salix lasiolepis*) restoration.

Some areas supporting the above vegetation types were excluded from the final model, based on landscape-scale selection criteria. In particular, riparian areas along smaller drainages (Paradise Cut, Tom Paine Slough) and some of the larger streams in the northern section of Conservation Zone 7 were excluded from the riparian woodrat habitat model due to a lack of trees and/or the narrow width of the riparian corridor. The final riparian woodrat habitat model is found south of State Route 4 and Old River Pipeline along the Stanislaus, San Joaquin, Old, and Middle rivers.

Assumptions. The riparian woodrat occurs in riparian woodland with an overstory canopy of trees and a moderate-to-dense shrub understory with abundant dead branches and downed woody material (Williams 1986). Riparian woodrats are found primarily where there is a valley oak overstory, but will also occur with other overstory species and are most numerous in areas of dense shrub cover. In riparian areas, highest densities of woodrats and their houses have been found in willow thickets with a valley oak overstory (USFWS 1998).

The current distribution is highly restricted and is limited to valley oak riparian habitats along the lower portions of the San Joaquin and Stanislaus rivers in northern San Joaquin County. A 100-hectare (247-acre) patch of riparian forest on the Stanislaus River in Caswell Memorial State Park is the only verified extant population of the riparian woodrat (Williams 1986). There are insufficient data on patch size or riparian width requirements for this species; however, the species has only been reported to occur in large, intact riparian patches associated with larger watercourses. While it may greatly overestimate the extent of potentially occupied habitat for this species – but to avoid including small, narrow patches of riparian along smaller streams in the Plan Area – for purposes of this model, it is assumed that all mapped instances of the riparian categories listed above that occur south of State Route 4 and Old River Pipeline along the Stanislaus, San Joaquin, Old, and Middle rivers are potentially occupied. It is also assumed that the species is absent north of north of State Route 4 and Old River Pipeline even where suitable habitat occurs. While somewhat arbitrary, for purposes of this model, this boundary is considered to represent the northern extent of all potentially-occupied habitat within the Plan Area based on the known distribution of the species and results of recent surveys in the Plan

Area. While survey access was not permitted within some portions of this area, it may also greatly overestimate the extent of potentially occupied habitat for this species.

A13.8 Recovery Goals

A recovery strategy for the riparian woodrat is included in the Recovery Plan for the Upland Species of the San Joaquin Valley, California (USFWS 1998). The recovery plan has not been updated since the 2000 listing of the riparian woodrat.

The recovery plan establishes an overall goal of three or more areas of occupied habitat, each supporting 400 or more individuals, with a total population of 5,000 or more independent individuals (i.e., excluding dependent young) during average precipitation years. The following initial conservation actions are included in the recovery plan to help achieve these goals.

1. Survey and map all riparian areas along the San Joaquin River and its major tributaries; this is the highest priority of the proposed conservation actions. A cost-effective survey can be carried out through a combination of aerial photo interpretation, selective truthing of photos on the ground, and judicious trapping where permission is required and given.
2. Develop an incentive program for preserving cover and riparian vegetation in collaboration with owners of riparian land and local levee-maintenance districts.
3. Develop a plan for the restoration of riparian habitat; the establishment of riparian corridors; and the reintroduction, if necessary, of riparian woodrats to suitable habitat.
4. Initiate a genetic study of the Caswell Memorial State Park woodrats, and any other riparian woodrat populations that can be sampled, to determine inbreeding levels, and devise a procedure for ensuring that translocations neither reduce genetic diversity in the parent population nor unduly restrict it in the translocated population.
5. Establish conservation agreements with willing landowners that do not already have conservation easements, as appropriate and necessary, to accomplish habitat restoration, linkage, and reintroduction goals.
6. Begin efforts to restore and link riparian habitat, and reintroduce woodrats, as appropriate.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan’s Multi-Species Conservation Strategy designates the riparian woodrat as a “Contribute to Recovery” species (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its control and within its scope that are necessary to contribute to the recovery of the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

APPENDIX A14. SALT MARSH HARVEST MOUSE (*REITHRODONTOMYS RAVIVENTRIS*)

A14.1 LEGAL STATUS

The U.S. Fish and Wildlife Service listed the salt marsh harvest mouse *(Reithrodontomys raviventris)* as endangered in 1970 (35 FR 16047). The State of California listed the mouse as endangered in 1971 (Fish and Game Code, Sections 2050 et seq.). The salt marsh harvest mouse is also designated as a state Fully Protected species. A recovery plan for the species was prepared in 1984 and is currently under revision. Critical habitat has not been designated for this species.

A14.2 SPECIES DISTRIBUTION AND STATUS

A14.2.1 Range and Status

The salt marsh harvest mouse is a small, native rodent endemic to the salt marshes of San Francisco, San Pablo, and Suisun Bays (Figure A-14a). The historical range of the species likely included most of the marshland in the San Francisco Bay Area. Closely associated with saline habitats, the species' eastern distribution is generally considered to extend as far as approximately Collinsville. The waters of wetlands and marshes east of this point are currently considered too fresh to support the habitat of this species (USFWS 2001).

The species has been divided into two subspecies. The southern subspecies *(R.r. raviventris)* occurs in the marshes of Corte Madera, Richmond, and South San Francisco Bay. The northern subspecies *(R.r. halicoetes)* is found in the marshes of San Pablo and Suisun bays, from San Rafael Bridge to approximately Collinsville on the north and from Martinez to Pittsburg on the south (USFWS 2001).

Today, the species potentially occupies an area representing approximately 15 percent of the historical salt marsh habitat that formerly occurred in the San Francisco Bay Area (Dedrick 1989). Much of this remaining habitat, isolated by dikes and landfill, is subject to backfilling, subsidence, and vegetation changes, making it unable to support harvest mice (Shellhammer 1989). Thus, remaining populations are small and separated by large areas of unsuitable habitat.

A14.2.2 Distribution and Status in the Plan Area

Reported occurrences of the salt marsh harvest mouse in the Plan Area are restricted to salt and brackish diked and tidal wetlands and adjacent uplands from Suisun Marsh eastward along the northern edge of the Sacramento River and the southern edge of the San Joaquin River as far east as the vicinity of Collinsville and Antioch, west of Sherman Island (Figure A-14b).

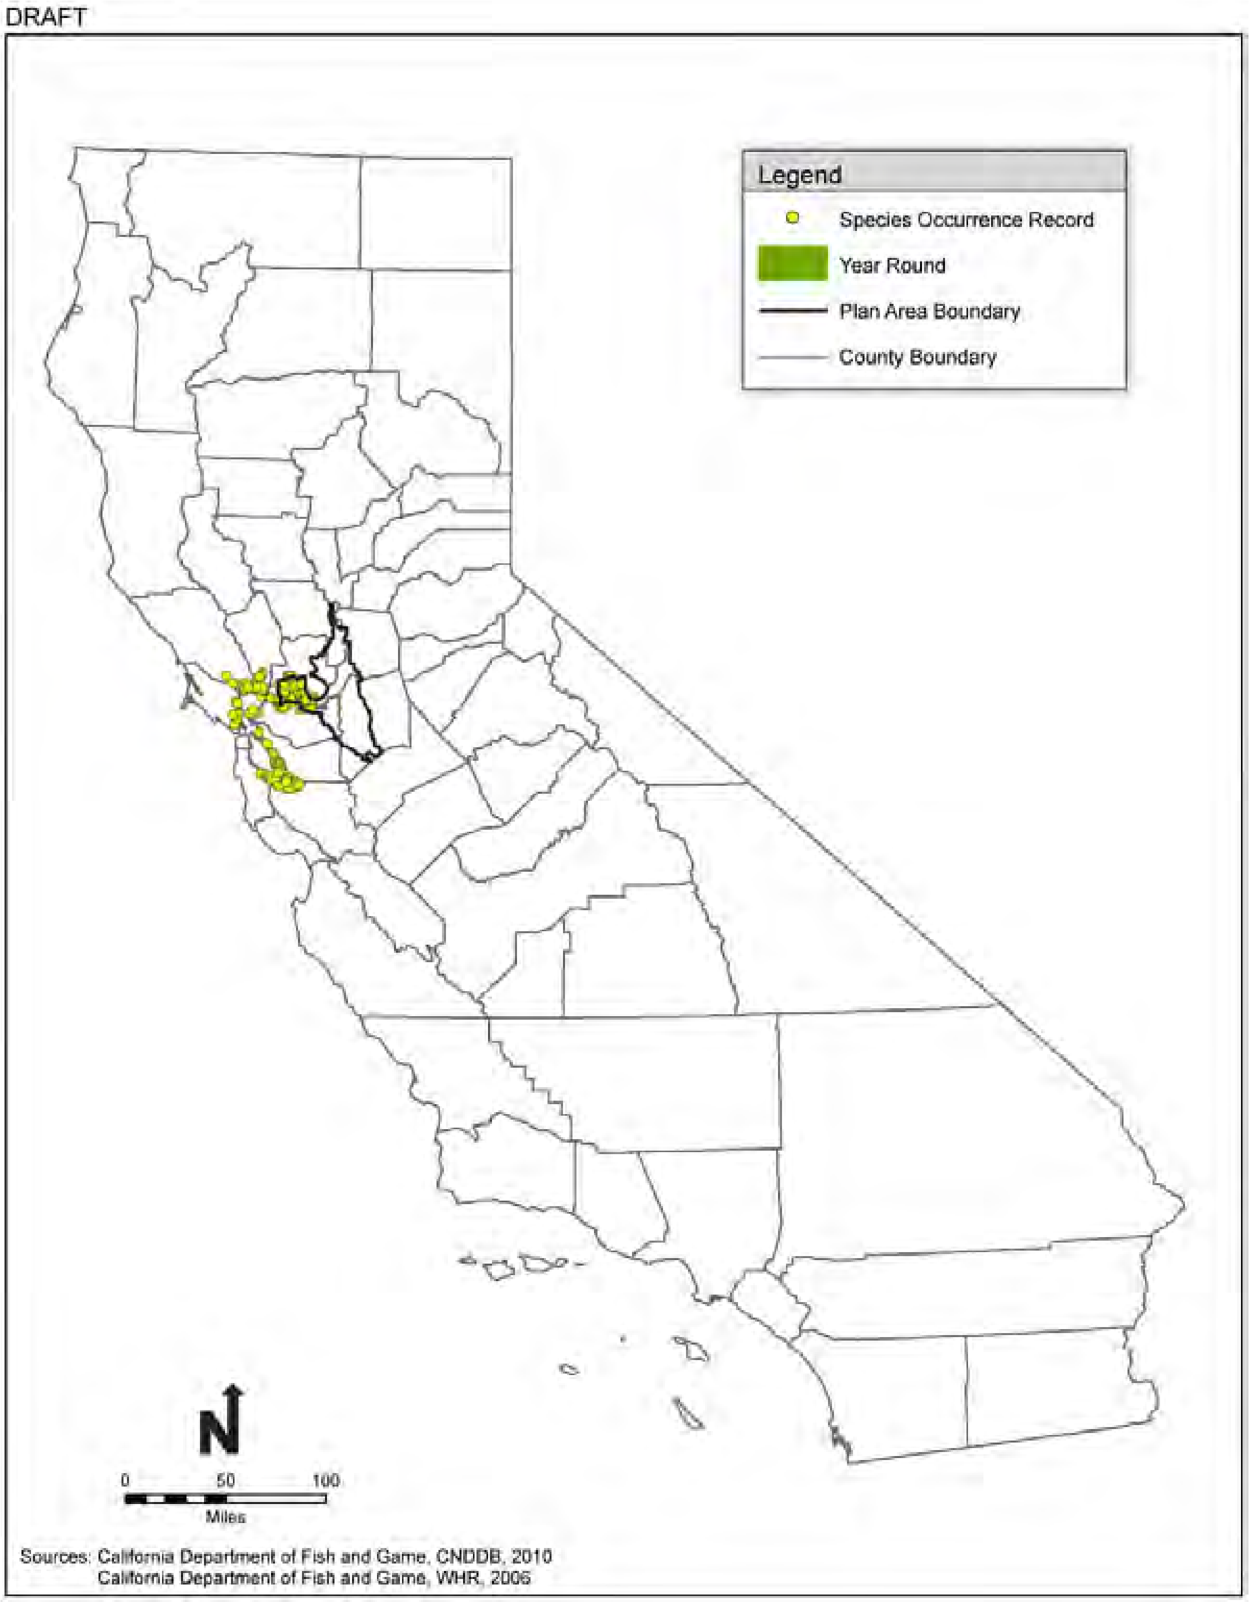

Figure A-14a. Salt Marsh Harvest Mouse Statewide Range and Recorded Occurrences

DRAFT

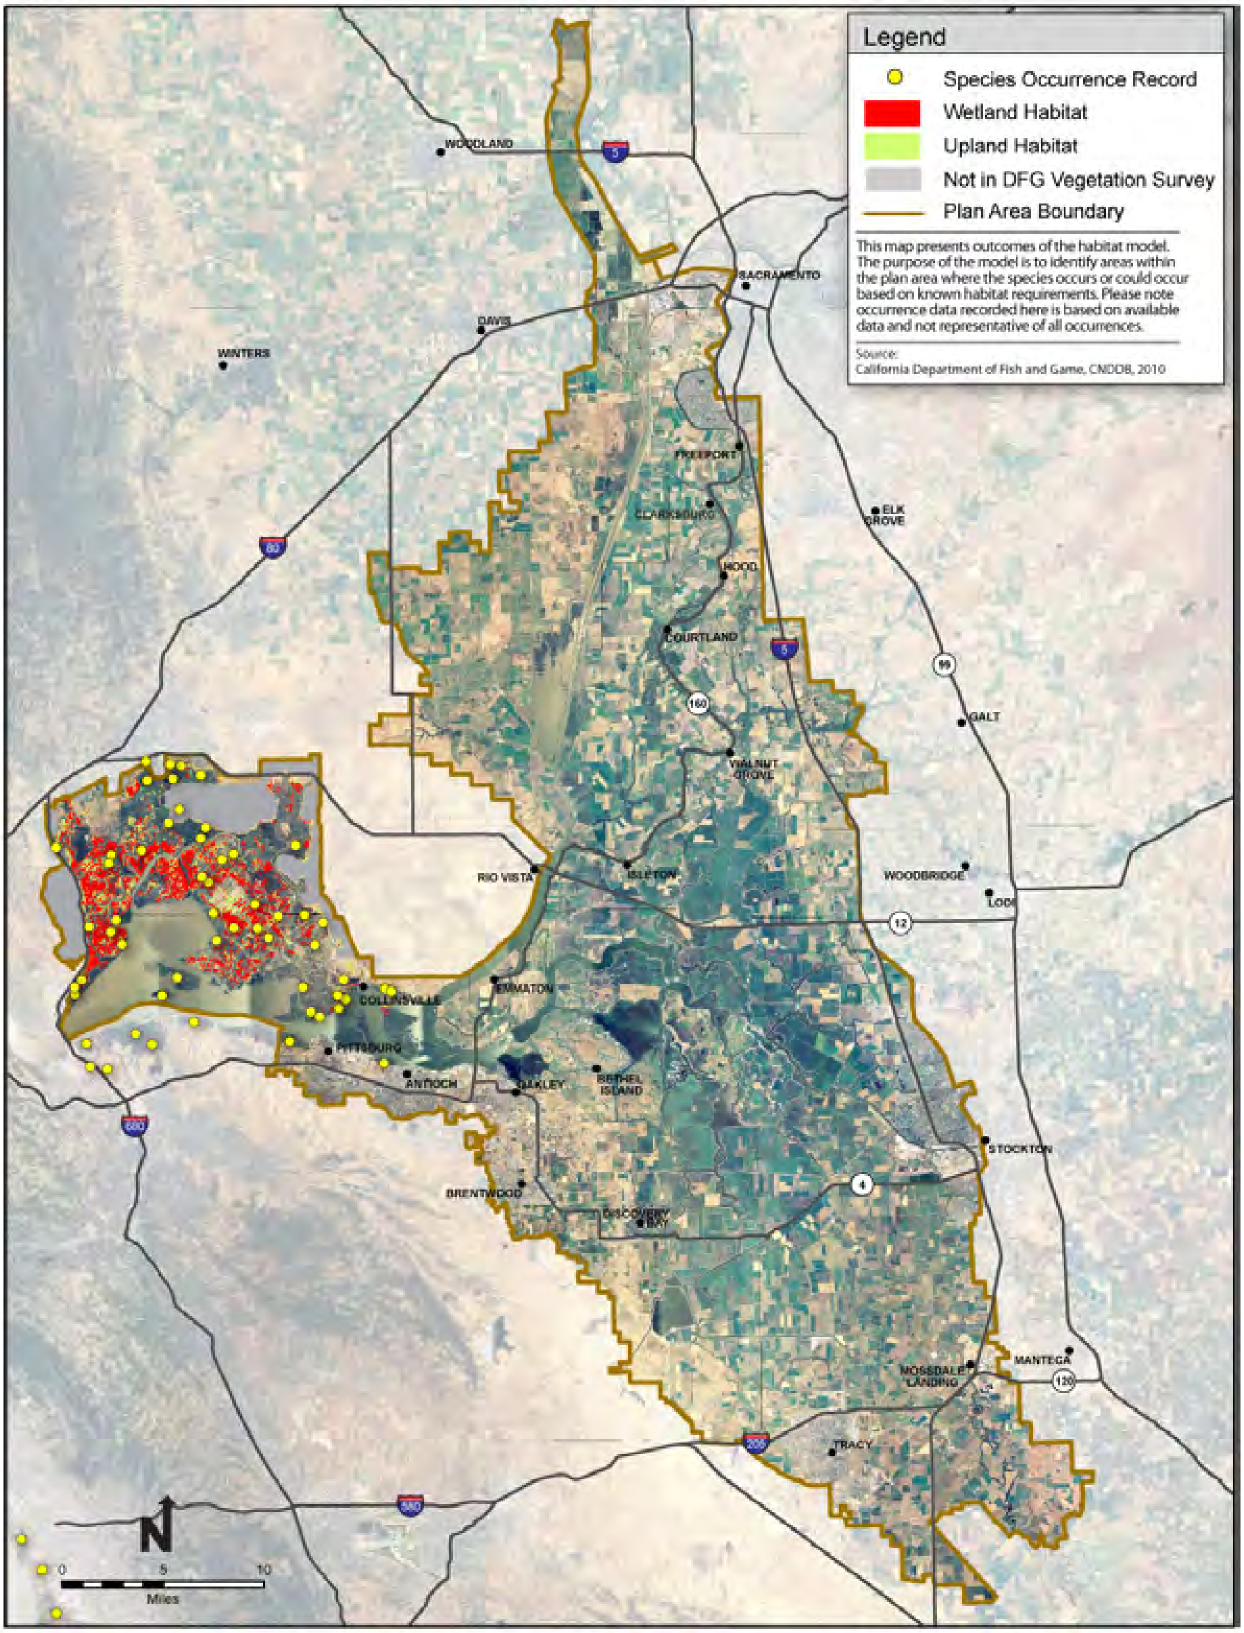

Figure A-14b. Salt Marsh Harvest Mouse Habitat Model and Recorded Occurrences

This is consistent with the range of the species as described by USFWS (2001).

A14.3 Habitat Requirements and Special Conditions

Salt marsh harvest mice depend on dense cover of native halophytes (salt-tolerant plants). Pickleweed (*Sarcocornia pacifica*, formerly *Salicornia virginica*) is the species' primary habitat (Shellhammer 1977). Deep (60–75 centimeters) and dense pickleweed, intermixed with fat hen *(Atriplex patula)* and alkali heath *(Frankenia grandifolia)*, is preferred. Salt marsh harvest mice are rarely found in alkali bulrush *(Schoenoplectus maritimus*[1]*)*, pure stands of salt grass *(Disticlis spicata)*, or cordgrass (*Spartina* spp.) (Shellhammer et al. 1982), which can displace pickleweed. However, more-recent research has documented the species in dense stands of three-square bulrush *(Schoenoplectus americanus)* in densities similar to that found in pickleweed (Patterson pers. comm.). Non-submerged escape cover is also required during high tides (Shellhammer et al. 1982). Fisler (1965) reported that populations can be concentrated on high marsh levels during periods of high tides. They have also been found in the top zone of tidal marshes and in transitional zones, which rarely flood (Shellhammer 1989). They will also move into adjacent grasslands during high tides. Fisler (1965) and Shellhammer et al. (1982) reported that the species will occupy adjoining grasslands during the highest winter tides and will occasionally use grasslands during spring and summer, when new growth affords sufficient cover. WESCO (1991) also reported use of nontidal uplands up to 150 feet from the wetland edge.

Within the Suisun Marsh, salt marsh harvest mice apparently respond well to carefully managed diked wetlands and have been reported in densities equal to that found in tidal wetlands (Patterson pers. comm.).

Salt marsh harvest mice have shown an ability to disperse considerable distances (Geissel et al. 1988); however, they apparently do not move through unvegetated areas, and thus, fragmentation of salt marsh habitats has limited salt marsh harvest mouse dispersal opportunities. A corridor of suitable vegetation is required for movement and dispersal into adjacent habitats.

A14.4 Life History

Description. The salt marsh harvest mouse is buff or brownish in color and has a long bicolored tail, large ears, and grooves in the outer surface of its upper incisors. The underside is variable, ranging from white to a cinnamon- or rufous-colored belly. Adult salt marsh harvest mice are 118 to 175 millimeters (mm) in length and weigh between 0.28 and 0.42 ounces (8 and 12 grams).

[1] Formerly known as *Scirpus maritimus*.

Activity. The maximum life expectancy for salt marsh harvest mice is generally considered to be approximately 1 year; however, California Department of Water Resources (DWR) data indicate that the life expectancy can be longer (Patterson pers. comm.). A generally solitary animal outside of the breeding season, this species typically remains beneath the canopy of dense low-lying vegetation and will sometimes use the ground runways of other rodents. Active year-round and primarily at night, this species responds to tidal action and can escape tidal or seasonal flooding by swimming or climbing, and will move into adjoining grasslands during the highest winter tides. Grasslands are otherwise used as habitat primarily when new grass growth affords suitable cover in spring and summer months. These movements probably occur only on a daily basis and do not represent a seasonal shift in habitat use. Young are able to disperse considerable distances, but can be restricted with fragmentation of suitable marsh habitats (Fisler 1965, Shellhammer et al. 1982 in LSA Associates 2007).

Reproduction. Salt marsh harvest mice breed from spring through autumn, with females reproductively active from March to November. The breeding season for *R. r. raviventris* usually begins in March, while the breeding for *R. r. halicoetes* begins approximately 2 months later, in May (Fisler 1965). Adults typically construct an aboveground nest of grasses and sedges about 150 to 175 mm (6 to 7 inches) in diameter. They sometimes construct the nest on top of bird nests and have been reported to use the nests of song sparrows. Females have a relatively low reproductive potential, bearing an average of four young per litter, following a gestation period of 21 to 24 days. Also, while *R. r. raviventris* often produces two litters per year, *R. r. halicoetes* usually produces only one due to the shorter breeding season (Fisler 1965). Adults make up the majority of the population.

Reproduction can also be suppressed by increasing populations of California meadow voles *(Microtus californicus)*, which respond to decreasing salinities and vegetation cover. In years when *Microtus* populations are high, breeding for salt marsh harvest mice is suppressed further into the spring. If *Microtus* populations are high enough in a given area, populations of harvest mice can be reduced to the point of local extirpation. However, when water salinities and vegetation cover increase, harvest mice have a competitive edge due to their ability to withstand higher salinities in the water and food, and populations can recover (Geissel et al. 1988).

Diet. The diet of the salt marsh harvest mouse consists of seeds, grasses, forbs, and insects. During winter, fresh green grasses are preferred. During the rest of the year, the stems and leaves of pickleweed and saltgrass are main food sources (Fisler 1965). As noted, salt marsh harvest mice can tolerate high salinities in both food and drink intake, which can give them a competitive advantage over *Microtus* when the salinity of the marsh increases (Geissel et al. 1988).

A14.5 THREATS AND STRESSORS

Loss and degradation of tidal marsh habitats continue to be the most significant threat to the salt marsh harvest mouse and other tidal marsh species. Tidal marshes have been reduced by 84 percent since historical times (Dedrick 1989). The loss and fragmentation of suitable habitats from commercial and residential development have isolated populations and reduced dispersal opportunities. The loss of tidal marsh habitat through filling and diking has largely been curtailed. However, other current factors associated with declining populations include the conversion of salt marshes to brackish marshes due to freshwater discharges from sewage treatment plants; introduction of nonnative cordgrass, saltgrass, and other plant species; predation by nonnative red foxes and feral cats; and invasion of runoff, industrial discharges, and sewage effluent (Shellhammer et al. 1982, DFG 2000, LSA Associates 2007). Probably the most significant long-term issue is the predicted sea level rise as high as 1.2 meters within this century.

A14.6 Relevant Conservation Efforts

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designates the salt marsh harvest mouse as a "Contribute to Recovery" species (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its control and within its scope that are necessary to contribute to the recovery of the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

The Suisun Marsh has been the subject of various conservation efforts for many years, particularly with respect to issues related to development and water quality within its boundaries. The California Department of Water Resources Suisun Marsh Program (http://www.iep.water.ca.gov/suisun/program/index.html) summarizes the major agreements, management plans, and legislation that have directed management of the Suisun Marsh since the mid-1970s. These efforts focus on the preservation and restoration of tidal marsh habitats.

The Nejedly-Bagley-Z'Berg Suisun Marsh Preservation Act (1974). The California Legislature enacted the Suisun Marsh Preservation Act to protect the marsh from urban development. It required the San Francisco Bay Conservation and Development Commission to develop a plan for the marsh and provides for various restrictions on development within marsh boundaries.

Suisun Marsh Protection Plan (1976). This plan was developed by the Bay Conservation and Development Commission (BCDC) and defines and limits development within primary and secondary management areas for the "future of the wildlife values of the area as threatened by potential residential, commercial and industrial development." It recommends that the state purchase 1,800 acres and maintain water quality. While the focus of the plan is on maintaining waterfowl habitat, it also addresses the importance of tidal wetlands and recommends restoring historical marsh areas to wetland status (managed or tidal).

The Suisun Marsh Protection Act (1977). This bill adopts and calls for implementation of the Suisun Marsh Protection Plan. AB 1717 designates the BCDC as the state agency with regulatory jurisdiction of the marsh and calls for the Suisun Resource Conservation District to have responsibility for water management in the marsh. The bill identifies (and focuses on) actions for the preservation of waterfowl needs, along with the retention of the diversity of wildlife. It states that land within the Suisun Marsh should be acquired for public use or resource management if it is suitable for restoration to tidal or managed marsh, but that such restoration cannot be required as a condition of private development.

State Water Resources Control Board (SWRCB) Water Rights Decision 1485 (1978). SWRCB adopted the Water Quality Control Plan for the Sacramento-San Joaquin Delta and issued Water Rights Decision 1485. The decision sets channel water salinity standards for the period from October to May and preserves the area as brackish water tidal marsh. It sets water quality standards in the marsh as a condition of export pumping. These come from the California Department of Fish and Game's (DFG's) recommendations, which were based on (1) the relative value of marsh plants as duck food; (2) the influence of soil salinity and other factors on distribution and growth of marsh plants; and (3) the relationships between channel water salinity and soil salinity. DFG concluded that improved management practices, improved drainage, water control facilities, and adequate quality of water were needed to achieve desired soil salinity conditions for waterfowl food plants.

Plan of Protection for the Suisun Marsh (1984). DWR and the U.S. Bureau of Reclamation (USBR) developed and began implementing the Plan of Protection (POP) in accordance with Water Rights Decision 1485. The POP implementation strategy was to construct large facilities and distribution systems to meet salinity standards (lower channel water salinity), in lieu of significant Central Valley Project/State Water Project storage releases estimated as high as 2 million acre-feet in dry/critical water years. The six-phase POP was the programmatic blue print (required by the SWRCB and embodied in the original Suisun Marsh Preservation Agreement). Two of the six phases were completed, including the Initial Facilities and the Suisun Marsh Salinity Control Gates.

Suisun Marsh Preservation Agreement (1987). This contractual agreement between DWR, USBR, DFG, and Suisun Resource Conservation District contains provisions for DWR and USBR to mitigate the effects on Suisun Marsh channel water salinity from the State Water Project and Central Valley Project operations and other upstream diversions. The Suisun Marsh Preservation Agreement requires DWR and USBR to meet salinity standards, sets a timeline for implementing the POP, and delineates monitoring and mitigation requirements. The Suisun Marsh Monitoring Agreement and the Suisun Marsh Mitigation Agreement were also signed at this time. The Suisun Marsh Mitigation Agreement defines habitat requirements to mitigate effects of facilities and operations, and the Suisun Marsh Monitoring Agreement defines requirements for monitoring salinity and species in the Suisun Marsh.

Bay-Delta Accord (1994). On December 15, 1994, federal and state agencies, working with agricultural, environmental, and urban stakeholders, reached an agreement on water quality standards and related provisions that would remain in effect for 3 years. This agreement, known as the Bay-Delta Accord, was based on a proposal developed by the stakeholders. Elements of the agreement include the following:

- Springtime export limits expressed as a percentage of Delta inflow;
- Regulation of the salinity gradient in the estuary so that a salt concentration of two parts per thousand is positioned where it may be more beneficial to aquatic life;
- Specified springtime flows on the lower San Joaquin River to benefit Chinook salmon; and
- Intermittent closure of the Delta Cross Channel gates to reduce entrainment of fish into the Delta.

SWRCB Water Quality Control Plan (1995–1998). In 1994, wildlife and fishery agencies and urban water users expressed concerns about the appropriateness of western Suisun Marsh channel water salinity standards. In May of 1995, the SWRCB modified the Suisun Marsh salinity objectives in the Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary. Modeling analysis by the Suisun Marsh Planning Program showed that Suisun Marsh standards would be met most of the time at all Suisun Marsh compliance stations. Some standard exceedances would be expected in the western Suisun Marsh that participants in the Suisun Marsh Preservation Agreement (SMPA) agreed could be mitigated by more-active water control by landowners.

SWRCB Water Rights Decision 1641 (1999). The SWRCB issued Decision 1641 in December 1999, which updated salinity standards for Suisun Marsh. Increased outflow and salinity requirements for the Bay-Delta provided indirect benefits to the Suisun Marsh. DWR proposed that the SWRCB adopt the Amendment Three actions for Suisun Marsh in this decision. However, the SWRCB was unable to adopt Amendment Three actions because the Section 7 consultation with the USFWS had not concluded. However, the SWRCB did relieve USBR and DWR of their responsibility to meet salinity objectives at S-35 and S-97 in the western Suisun Marsh.

CALFED Multi-species Conservation Strategy and Record of Decision (2000). In August 2000, the Programmatic Record of Decision for the CALFED Bay-Delta Program was signed by 13 federal and state agencies with management and regulatory responsibilities in the San Francisco Bay estuary. Based on the analysis in the MSCS and the final programmatic environmental impact statement/environmental impact report, the CALFED agencies fulfilled the regulatory requirement for programmatic evaluation of the CALFED program.

Suisun Marsh Charter Implementation Plan (2001). The Suisun Marsh Charter was completed in 2001, and development of an Implementation Plan commenced. Charter participants collaborated on a joint presentation to the State of the Estuary Conference on the principles of the Charter Plan, including coordinated water quality, endangered species, and heritage value protection in the Suisun Marsh.

Habitat Management, Preservation, and Restoration Plan (2003). The Charter process was expanded to include additional federal and state agencies to develop a Suisun Marsh Plan that will balance the goals and objectives of the Bay-Delta Program, SMPA, and other management and restoration programs within the Suisun Marsh in a manner that is responsive to the concerns of all stakeholders and is based upon voluntary participation by private landowners.

In addition, several facilities have been constructed in the Suisun Marsh to protect and improve water quality and protect and enhance wildlife habitat including:

- Roaring River Distribution System (1979–80);
- Morrow Island Distribution System (1979–80);
- Goodyear Slough Outfall (1979–80);
- Suisun Marsh Salinity Control Gates (1988); and
- Cygnus and Lower Joyce Facilities (1991).

Several tidal marsh restoration projects are also planned or being implemented within the range of the salt marsh harvest mouse. These projects, implemented through the direction or support of the San Francisco Bay National Wildlife Refuge, National Biological Service, East Bay Regional Park District, Regional Water Quality Control Board, California Department of Fish and Game, and the City of San Jose include the following:

- Restoration of the 1,500-acre Napa Marsh Unit in the Napa River in the north bay;
- Restoration of the Knapp Property, a 452-acre former salt pond in the Alviso area, on the edge of the bay, between Alviso and Guadalupe Sloughs.
- Enhancement of the 325-acre Oro Loma Marsh, an area of diked salt marsh and adjacent uplands located along the shore of Hayward. The area will be restored to tidal marsh and seasonal wetland habitat.
- Restoration of the Baumberg Tract, an 835-acre inactive salt evaporator in Hayward, to tidal marsh and seasonal wetlands.
- Restoration of the Moseley Tract, located just north of the west approach to the Dumbarton Bridge from the Port of Oakland.

Salt marsh harvest mouse is also proposed for coverage under the Solano County Multispecies Habitat Conservation Plan.

A14.7 SPECIES HABITAT SUITABILITY MODEL

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which are incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and revise the vegetation input data as necessary.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements, and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate, as well as overestimate, the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small, isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; instead, the models indicate that non-habitat areas have a much lower probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percentage cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf (2007). Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers, connectivity between habitat types, and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified, and each vegetation type or association is identified, along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or underestimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The salt marsh harvest mouse model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and

Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), U.S. Department of Agriculture (USDA) 2005 aerial photography, and DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable salt marsh harvest mouse habitat in the Plan Area. Vegetation types were assigned based on the species requirements, as described above, and the assumptions described below.

Habitat. Salt marsh harvest mouse habitat consists of *Salicornia*[2]-dominated natural seasonal wetlands, other non-flooded wetlands, and upland habitats within 150 feet of the wetland edge west of the western edge of Sherman Island.

Salt marsh harvest mouse habitat in the Delta consists of the following wetland types from the BDCP composite vegetation layer:

- Tidal brackish emergent wetland, managed wetland, and alkali seasonal wetland complex;
- *Distichlis spicata – Salicornia virginica*[3];
- Pickleweed *(Salicornia virginica)*;
- *Salicornia virginica – Cotula coronopifolia*;
- *Salicornia virginica – Distichlis spicata*; and
- Alkali heath *(Frankenia salina)*.

And the following grassland types that occur within 150 feet of the wetland edge:

- Grassland;
- Ruderal herbaceous grasses and forbs;
- California annual grasslands – herbaceous;
- *Bromus diandrus – Bromus hordeaceus*; and
- Degraded vernal pool complex.

And the following vernal pool complex types that occur within 150 feet of the wetland edge:

- Vernal pool complex;
- Ruderal herbaceous grasses and forbs; and
- California annual grasslands – herbaceous.

---

[2] Currently known as *Sarcocornia*.

[3] Currently known as *Sarcocornia pacifica.*

Salt marsh harvest mouse habitat in the Suisun Marsh includes the following vegetation types from the BDCP composite vegetation layer:

- *Distichlis*/*Salicornia*;
- *Salicornia* (generic);
- *Salicornia virginica*;
- *Salicornia*/*Atriplex*;
- *Salicornia*/*Cotula*;
- *Salicornia*/annual grasses;
- *Salicornia*/*Crypsis*;
- *Salicornia*/*Polygonum-Xanthium-Echinochloa*; and
- *Salicornia*/*Sesuvium*.

And the following upland types within 150 feet of the wetland edge:

- Annual grasses generic;
- Annual grasses/weeds;
- *Atriplex lentiformis* (generic);
- *Atriplex triangularis*;
- *Atriplex*/annual grasses;
- *Atriplex*/*Districhlis*;
- *Atriplex*/*S. Maritimus*;
- *Atriplex*/*Sesuvium*;
- *Baccharis*/annual grasses;
- *Bromus* spp./*Hordeum*;
- *Hordeum*/*Lolium*; and
- Perennial grass.

Assumptions. Historical and current records of this species indicate that its distribution extends eastward to approximately Collinsville and Antioch (Figure A-14a). This species is dependent on dense cover of native halophytes (salt-tolerant plants) and prefers pickleweed-dominated *(Sarcocornia pacifica* [formerly *Salicornia virginica*]) saline emergent wetlands and mixed-halophyte wetlands as its habitat (Shellhammer et al. 1982, Patterson pers. comm.). The species also uses adjacent upland habitats during periods of high tides (Fisler 1965, Shellhammer et al.

1982, WESCO 1991). For purposes of this model, all *Sarcocornia*- (formerly *Salicornia*)-dominated habitats along the western edge of Sherman Island westward are included within the potential range of the species. Some non-flooded mixed-halophyte wetlands and other vegetation associations where the species has been detected, including *Schoenoplectus americanus*, could not be sufficiently determined from the vegetation database, and thus the model may underestimate the extent of potentially occupied habitat in the Suisun Marsh. Suitability of habitat may also be dependent on other factors, such as patch size, tidal connectivity (diked marshes), and proximity to other land uses. However, data regarding the effects of these factors on potential occupancy for the salt marsh harvest mouse are insufficient. Thus, potential habitat for the salt marsh harvest mouse is not further restricted in this habitat model on the basis of these factors; in this respect, the model may overestimate potentially occupied habitat for the salt marsh harvest mouse.

A14.8 Recovery Goals

The Salt Marsh Harvest Mouse and California Clapper Rail Recovery Plan was finalized in 1984. It is considered outdated and is under revision by the USFWS. Both species will be covered under the Tidal Marsh Ecosystem Recovery Plan.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's MSCS designates the salt marsh harvest mouse as a "Contribute to Recovery" species (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its control and within its scope that are necessary to contribute to the recovery of the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

APPENDIX A15. RIPARIAN BRUSH RABBIT (*SYLVILAGUS BACHMANI RIPARIUS*)

A15.1 LEGAL STATUS

The riparian brush rabbit (*Sylvilagus bachmani riparius*) is listed as endangered under the state and federal endangered species acts. It was initially listed as endangered by the State of California on May 29, 1994. The U.S. Fish and Wildlife Service (USFWS) proposed the species for endangered species protection on November 21, 1997, and reopened the proposal for further public input on April 13, 1998, to include survey data from the 1998 winter floods in its final determination on whether or not to list the species. The USFWS issued its final determination to list the species as endangered on February 23, 2000 (65 FR 8881).

Critical habitat has not been designated for this species because the USFWS believed it would not provide any additional benefit beyond that provided through being listed as endangered since the species was only known to occur within Caswell Memorial State Park (65 FR 8881). Subsequent rulings allow critical habitat to be designated post-listing following further analysis.

A15.2 SPECIES DISTRIBUTION AND STATUS

A15.2.1 Range and Status

One of eight species of brush rabbit in California, the riparian brush rabbit occupies a range that is disjunct from other brush rabbits, near sea level on the floor of the San Joaquin Valley (USFWS 1998). Documented occurrences are shown in Figure A-15a. Its historical distribution may have extended along portions of the San Joaquin River and its tributaries on the valley floor from at least Stanislaus County to the Delta (Orr 1935 in USFWS 1998). Populations are known to have historically occurred in riparian forests on the valley floor along the San Joaquin and Stanislaus rivers and some tributaries of the San Joaquin River (USFWS 1998). One population estimate within this historical range was about 110,000 individuals (USFWS 1998).

The dramatic decline of the riparian brush rabbit began in the 1940s with the building of dams constructed for irrigation and flood control on the major rivers of the Central Valley. Protection from flooding resulted in conversion of floodplains to croplands and the consequent reduction and fragmentation of remaining riparian communities. By the mid-1980s, the riparian forest within the species' former range had been reduced to a few small and widely scattered fragments totaling about 5,189 acres (2100 hectares) (USFWS 1998).

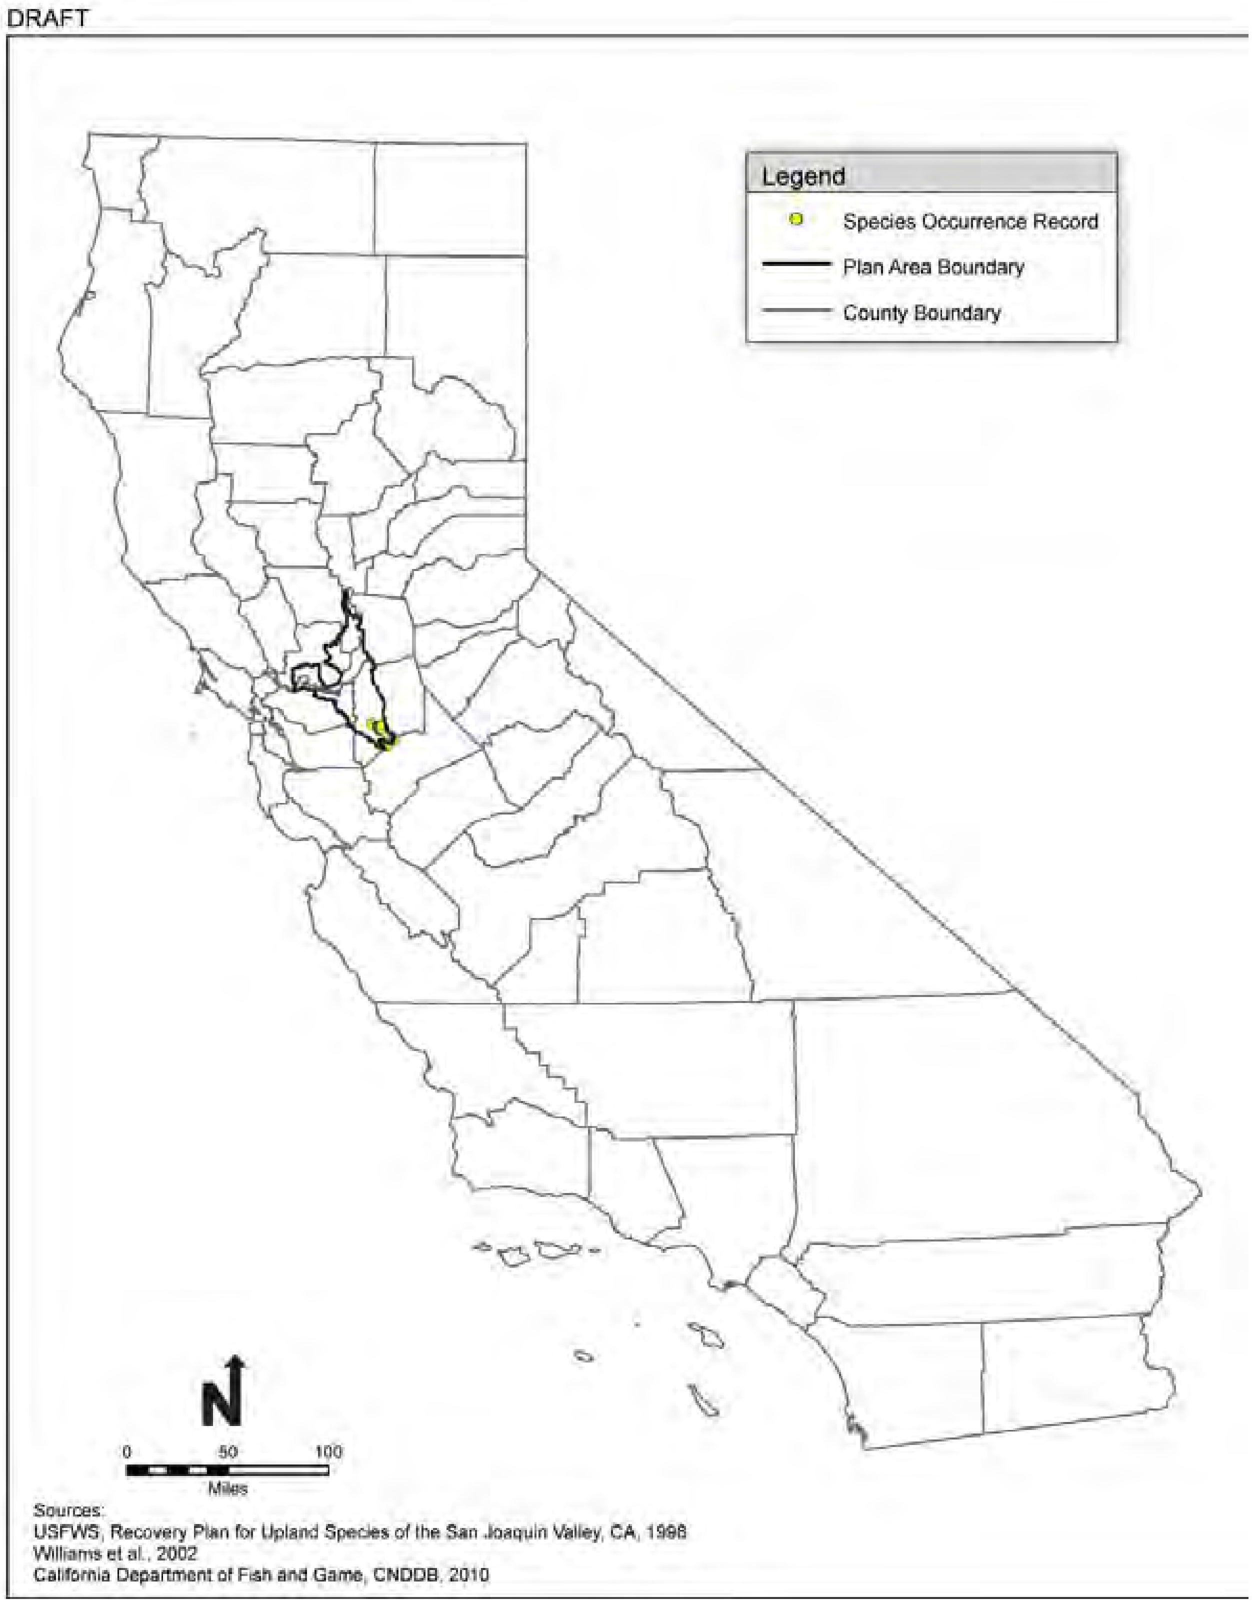

Figure A-15a. Riparian Brush Rabbit Statewide Range and Recorded Occurrences

Within this area, remaining populations of riparian brush rabbits occur in only two areas of San Joaquin County: an approximately 258-acre (104-hectare) patch in Caswell Memorial State Park on the Stanislaus River immediately southeast of the Plan Area; and in several small, isolated or semi-isolated patches totaling approximately 270 acres (109 hectares) along Paradise Cut and Tom Paine Slough and channels of the San Joaquin River in the south Delta within the Plan Area (Williams et al. 2002a, Williams et al. 2008).

While the Caswell Memorial State Park population has been known and considered to be the last occupied location for riparian brush rabbit for many years, the latter location has been known only since 1998 (Williams et al. 2008). While recent surveys conducted by staff at the Endangered Species Recovery Program have not detected additional occurrences within the Plan Area, researchers have identified additional suitable habitat and some potentially occupied un-surveyed areas (Patrick Kelly and Tristan Edgarian pers. comm.).

In 2005, a captive-bred population of approximately two-dozen animals was introduced to the Faith Ranch along the San Joaquin River in Stanislaus County adjacent to the San Joaquin River National Wildlife Refuge.

The most serious ongoing problem has been the lack of suitable habitat above the level of regular floods where the animals could find food and cover for protection from weather and predators. Flooding during the 1970s resulted in additional population declines, with estimates of the extant population ranging from just 15 to 20 individuals (DFG 2000). In January 1993, Caswell Memorial State Park was thought to support the only extant population, with an estimate of between 213 and 312 individuals. Flooding of the park in 1996 inundated more than 80 percent of the park, which contributed to additional population declines. The 1993 census was the last for which a reliable population estimate could be generated for the Caswell Memorial State Park population. Surveys conducted in 2002 (Williams et al. 2002a) resulted in the highest number of captures since the 1993 census, but are still not sufficient to generate a population estimate.

Access restrictions to the south Delta population prevent sufficient sampling to reliably estimate the population size; however, based on trapping conducted during 1998–99, this population is estimated to include between 25 and 100 individuals (Williams et al. 2002b).

A15.2.2 Distribution and Status in the Plan Area

Of the two extant populations of riparian brush rabbit, only the south Delta population (Paradise Cut and Tom Paine Slough) occurs within the Plan Area (Figure A-15b). As indicated above, occurrence locations in this area are on private land, and watercourses are managed for flood control, not wildlife management. Surveys conducted by the Endangered Species Recovery Program under contract with the California Department of Water Resources have not detected other occurrences within the Plan Area; however, surveys are incomplete due to the lack of property access.

DRAFT

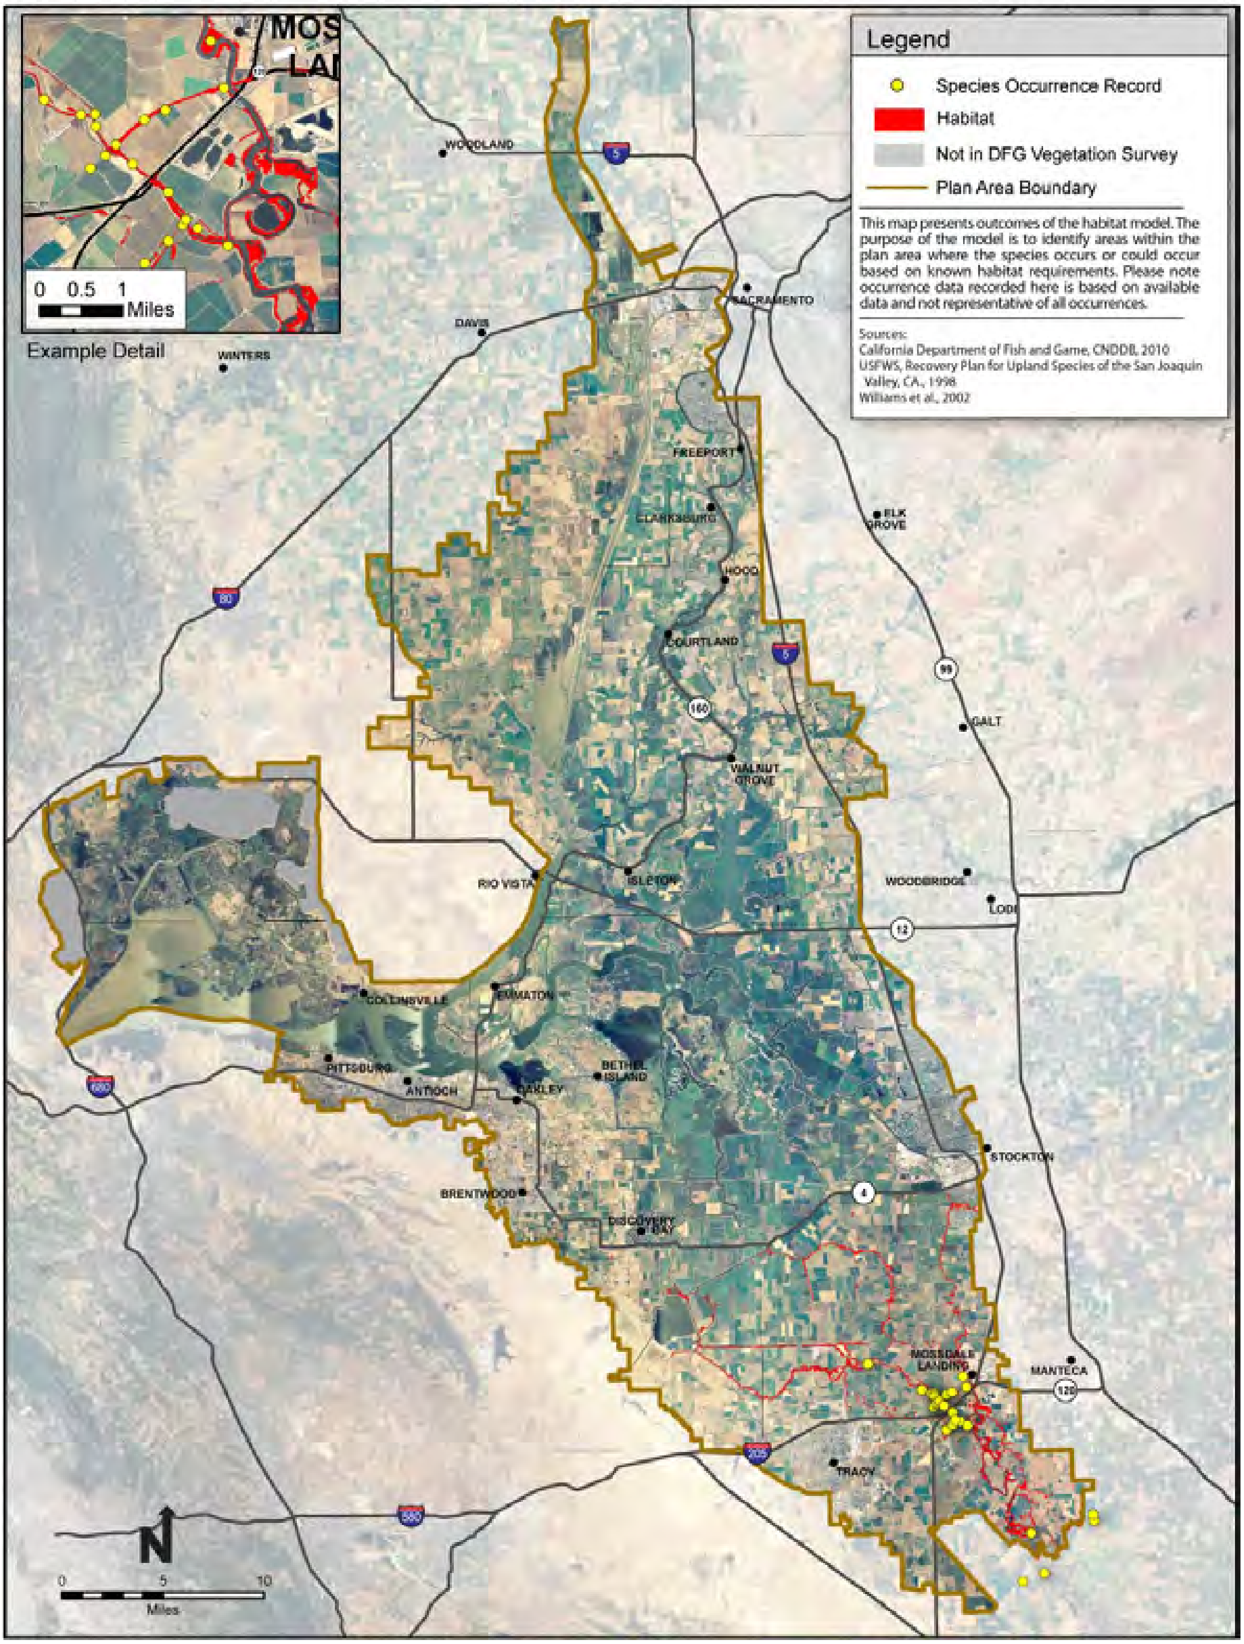

Figure A-15b. Riparian Brush Rabbit Habitat Model and Recorded Occurrences

A15.3 Habitat Requirements and Special Conditions

Riparian brush rabbits inhabit the brushy understory shrub layer of valley riparian forests. Closely associated with dense shrub vegetation, occupied sites tend to be in riparian settings with an open overstory canopy of valley oak (*Quercus lobata*) or savannah-like settings that support extensive patches of low-growing willow (*Salix* spp.), wild rose (*Rosa californica*), wild grape (*Vitis californica*), or blackberry (*Rubus* spp.) (Williams et al. 2008). The brush rabbits move through the dense brush and thickets by creating tunnels through the vegetation. Seasonally available weedy/ruderal cover, including patches of tall grass, forbs, and pepperweed (*Lepidium latifolium*) is also used, particularly where it connects to more-suitable woody cover (Williams et al. 2008). Generally, riparian forests that support a closed overstory canopy lack sufficient understory shrubs to support riparian brush rabbits (USFWS 1998). Small herbaceous openings in close proximity to cover are also required for foraging, and higher elevation areas are required to sustain populations during floods (USFWS 1998).

Sites inhabited by riparian brush rabbits usually have a mix of roses, blackberries, coyote bush (*Baccharis pilularis*), and grape vines, with high volumes of roses and coyote bushes (*Baccharis* spp.) in comparison to uninhabited sites (Williams 1988, Basey 1990, USFWS 1998). Williams and Basey (1986) also note that brush rabbit sites support significantly more ground litter and surface area of roses and significantly fewer willows in the canopy and understory than sites occupied by desert cottontails. This condition may indicate the presence of higher elevation areas that are not flooded regularly or heavily, an important element of brush rabbit habitat (Williams and Basey 1986).

Patch size is important, and fragmentation of intact riparian forests is a major issue restricting occupancy and overall distribution of the species. Brushy clumps smaller than 0.08 acre (0.03 hectare) are rarely occupied.

Flooding is a key issue for this species and is thought to be responsible for major population declines. Riparian brush rabbits are closely tied to brushy cover and will generally not cross large, open areas. They are thus unable to disperse beyond the dense brush, making them susceptible to mortality during flood events (Williams 1988, USFWS 1998).

A15.4 Life History

Description. The riparian brush rabbit is a small, brownish cottontail-like rabbit with a white belly; relatively short ears; and a small, inconspicuous tail. The hind legs are short and hind feet are slender and not covered with long or dense hair. The white belly and ventral tail hairs are gray near the skin, and the ears lack dark tips (Orr 1940, Ingles 1965, Chapman 1974). Adult riparian brush rabbits are about 13 inches (33 centimeters) long and can be distinguished from other subspecies by their relatively pale color, gray sides, darker back (Orr 1935), restricted range and habitat requirements, and skull characteristics. When looking down at the head from above, the riparian brush rabbit cheeks protrude outward rather than being straight or curving inward as in other subspecies (Orr 1935, 1940).

Features that distinguish the riparian brush rabbit from the desert cottontail (*S. audubonii*) include size and coloration. The riparian brush rabbit is smaller and darker grayish-brown, though populations of desert cottontails living along Central Valley rivers are about the same color as the riparian brush rabbit (which is lighter colored than many of the other subspecies). The tail of the brush rabbit is small and inconspicuous compared with the desert cottontail, and its ears are uniformly colored. The tail of the desert cottontail shows much white when viewed from behind, and the inner (medial) tips of the ears are black. When looked at from above, the cheeks of the brush rabbit protrude, whereas those of the desert cottontail are slightly concave (Sandoval et al. 2006)

Activity. Riparian brush rabbits are active throughout the year and are most active during the twilight hours around dawn and dusk. Depending on season, the main activity periods generally last from 2 to 4 hours. The period of least activity is from about 1030 hours to 1600 hours (10:30 am to 4:00 pm) (Chapman 1974).

Riparian brush rabbits typically remain hidden under protective shrub cover. They seldom venture more than 1 meter from cover. They often remain motionless while searching for signs of danger before moving short distances. When pursued, they leap back into the cover of shrubs instead of heading into open ground (Chapman 1974). Williams (1988) reported that they will generally not cross large, open areas, and hence are unable to disperse beyond the dense brush of the riparian forest. More recent observations, however, have suggested a somewhat more elastic range of conditions and that in some settings riparian brush rabbits will use larger, more exposed herbaceous habitats (Patrick Kelly and Tristan Edgarian pers. comm.).

Riparian brush rabbits have a limited ability to climb into bushes and trees. This trait probably has significant survival value, given that the riparian forests that are its preferred habitat are subject to inundation by periodic flooding (Chapman 1974, Williams 1988). Prolonged flooding of riparian areas can dramatically impact riparian brush rabbit populations (Kelly pers. comm.).

When weather conditions are appropriate, individuals may spend time in the early mornings and afternoons basking in the sun on a log or a dry form (a resting place for a rabbit). Ideal basking sites are a few inches from cover no more than about 18 inches (46 cm) above ground, with a partial, low-overstory canopy (Williams 1988, USFWS 1998).

Reproduction. The breeding season is generally from approximately January to May, although it can extend through the late summer (Kelly pers. comm.). The gestation period for brush rabbits is about 27 days, the usual litter size is three to four, and the females may produce three to four litters during the season. Females average 9 to 16 offspring per year, which remain in the nest for about 24 days. Although this is a relatively high reproductive rate, 5 out of 6 rabbits do not survive to the next breeding season (Mossman 1955, Chapman and Harman 1972). Their eyes open at 10 days, but they remain in the nest for another 2 weeks. The nest is a shallow burrow or depression (3–4 inches deep [7.6-10.2 cm]) lined with grasses and fur and covered by a plug of residual vegetation. Young mature at approximately 4 months old (Williams 1988, Larsen 1993, USFWS 1998).

Home Range/Territory Size. Data from studies being conducted at the San Joaquin National Wildlife Refuge (in preparation for publication) indicate that average home range size varies from year to year but ranges from 3.1 to 7.4 acres (1.3 to 3 hectares). Breeding season ranges are typically larger than non-breeding ranges, and male ranges are usually larger than female ranges, but not dramatically so. The average core area is typically less than half of the home range area (1.2–1.9 acres [0.5 to 0.8 hectares]) (Kelly pers. comm.). Home ranges generally conform to the size of the available brushy habitat (USFWS 1998). Individuals are intolerant of each other when they come too close, but there is no well-defined territoriality. Young are more tolerant of approach by another rabbit than are adults (Chapman 1974, USFWS 1998).

Foraging Behavior and Diet. Riparian brush rabbits feed at the edges of shrub cover rather than in large openings. Their diet consists of herbaceous vegetation, such as grasses, sedges, clover, and forbs and buds, bark, and leaves of woody plants. They consume herbaceous plants found along trails, firebreaks, or at the edge of brushy areas, and they eat the leaves, bark, and buds of many types of woody shrubs and vines within and at the edges of thickets. Grasses and other herbs are the most important food for brush rabbits, but shrubs such as California wild rose, coyote bush, and blackberry (*Rubus* spp.) also are eaten. When available, green clover (*Trifolium wormskioldii*) is preferred over all other foods (Orr 1940, Larsen 1993, USFWS 1998, Sandoval et al. 2006).

A15.5 THREATS AND STRESSORS

Restricted Range and Habitat Availability. The primary threats to the survival of the riparian brush rabbit are the limited extent of its existing habitat, extremely low numbers of individual animals, and few extant populations. The small size of its remaining population, the behavior of the species, and the highly limited and fragmented nature of remaining habitat restrict natural dispersal and put the species at risk from a variety of environmental factors. The existing population size does not meet the minimum population sizes that Thomas (1990) suggests are required to assure the medium- to long-term persistence of birds or mammals (i.e., the geometric mean of population size should be 1,000 for species with normally varying numbers and about 10,000 for species exhibiting a high variability in population size). The species is therefore considered at a high risk of imminent extinction from several consequent threats related to population genetics and dynamics and environmental variability (USFWS 1998).

Flooding. Periodic flooding still occurs along all major rivers in the Valley (Kindle 1984). With behavioral restrictions on its freedom of movement (low mobility) and the dearth of habitat suitably protected from frequent floods downstream of Caswell Memorial State Park, there is little chance that individuals that escape drowning or predation will meet mates or reproduce (USFWS 1998).

Predation. Limited and fragmented habitats and flooding increase the risk and extent of predation on riparian brush rabbits. The increased predation to which they are exposed while taking refuge on cleared levees or in exposed bushes or trees contributes directly to population decline and an elevated risk of extinction. Predators of riparian brush rabbits include red-tailed hawks (*Buteo jamaicensis*), Swainson's hawks (*B. swainsoni*), red-shouldered hawks (*B. lineatus*), great-horned owls (*Bubo virginianas*), gray foxes (*Urocyon cinereoargenteus*), coyotes (*Canis latrans*), dogs, and feral cats (Nolan 1984, USFWS 1998).

Fire. Wildfire also poses a major threat. Long-term fire suppression of Caswell Memorial State Park, combined with prolonged drought, has caused the buildup of high fuel loads from dead leaves; woody debris; and decadent, flammable shrubs. The dense, brushy habitat to which the rabbits are restricted is thus highly susceptible to catastrophic wildfire that would cause both high mortality and severe destruction of habitat. Recovery of the riparian brush rabbit population from such a devastating event would be improbable (USFWS 1998).

Disease. Like most rabbits, the riparian brush rabbit is subject to a variety of common diseases, including tularemia, plague, myxomatosis, silverwater, encephalitis, listeriosis, Q-fever, and brucellosis. These contagious, and generally fatal, diseases could be transmitted easily to riparian brush rabbits from neighboring populations of desert cottontails. In a widespread, genetically heterogeneous population, such an outbreak would be of minimal concern. However, in this small remnant brush rabbit population, this kind of epidemic could quickly eliminate the entire population (Williams 1988, USFWS 1998).

A15.6 Relevant Conservation Efforts

The Recovery Plan for Upland Species of the San Joaquin Valley, California (USFWS 1998) describes conservation efforts undertaken through the end of the 1990s.

In 1986, after surveys along rivers within its historical range indicated that there was only a single, small extant population in Caswell Memorial State Park (Williams and Basey 1986), the riparian brush rabbit was designated as a "Mammalian Species of Special Concern" by the DFG Wildlife Management Division. It was given Federal category-1 candidate status by USFWS in 1985 and remained a candidate for listing in USFWS's most recent Notice of Review (61 FR 7596). The riparian brush rabbit was proposed for listing by the USFWS on November 21, 1997 (62 FR 62276). The subspecies was listed as endangered by the State of California in May 1994 (Title 14, Division 1, California Administrative Code, Section 670.5, Animals of California declared to be endangered or threatened).

In addition to the passive protection afforded to the species by the status of Caswell as a State Park, the California Department of Parks and Recreation funded a study of ecology and habitat management of riparian brush rabbits (Williams 1988, Basey 1990) and a small mammal inventory (Cook 1992). California Department of Parks and Recreation, Bureau of Reclamation, and USFWS, through the Endangered Species Recovery Program, funded a population assessment in the winter of 1993 and 1996–1997 (Williams 1993). The California Department of Parks and Recreation has expanded fire trails in Caswell Memorial State Park, which provides additional edge habitat for rabbits and better access to fight fires. The agency also has an ongoing control program for feral animals, has curtailed measures intended to control ground squirrels (brush rabbits will eat treated bait meant for ground squirrels), and is involved in ongoing planning for habitat protection for wildlife in the park.

In 1999, the Endangered Species Recovery Program at California State University Stanislaus began implementing a Controlled Propagation and Reintroduction Plan for the Riparian Brush Rabbit (Williams et al. 2002a), which was recommended in the Recovery Plan for Upland Species of the San Joaquin Valley, California (USFWS 1998). The primary goal of the program is to prevent extinction by providing animals for reintroduction to establish new populations or augment existing populations. This effort is ongoing.

In response to development activities in the city of Lathrop, mitigation lands have been acquired along the San Joaquin River and Paradise Cut for purposes of preserving and restoring habitat for the riparian brush rabbit. The San Joaquin River Oxbow Preserve is a 30-acre (12-hectare) riparian forest established in 2004 as mitigation for the Union Pacific Homes development in Lathrop; this preserve is currently under ownership and management of the Center for Natural Lands Management. The preserve was established primarily to protect the riparian brush rabbit. The River Islands project also intends to implement a plan to manage and restore riparian and other wetland habitats in the Paradise Cut in part to enhance habitat for the riparian brush rabbit.

In 2005, the USFWS and the Endangered Species Recovery Program at California State University Stanislaus introduced a captive-bred population of approximately two-dozen animals to the Faith Ranch along the San Joaquin River in Stanislaus County adjacent to the San Joaquin River National Wildlife Refuge.

The riparian brush rabbit is a covered species under the San Joaquin County Multi-Species Habitat Conservation and Open Space Plan, which prohibits removal or disturbance of occupied riparian habitat that could potentially affect the subspecies as a result of the implementation of covered activities.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan’s Multi-Species Conservation Strategy (MSCS) designates the riparian brush rabbit as a “Contribute to Recovery” species (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its control and within its scope that are necessary to contribute to the recovery of the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

A15.7 SPECIES HABITAT SUITABILITY MODEL

Model Approach. BDCP Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information systems (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which are incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and revise the vegetation input data as necessary.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements, and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate, as well as overestimate, the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small, isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; instead, the models indicate that non-habitat areas have a much lower probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percentage cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf (2007). Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers; connectivity between habitat types; and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified, and each vegetation type or association is identified, along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or underestimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The riparian brush rabbit model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), USDA 2005 aerial photography, and DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable riparian brush rabbit habitat in the Plan Area. Vegetation types were assigned based on the species requirements, as described above, and the assumptions described below.

Habitat. Riparian brush rabbit habitat includes the following valley/foothill riparian and coastal scrub types from the BDCP composite vegetation layer:

- White alder *(Alnus rhombifolia)*;
- Box elder *(Acer negundo)*;
- Oregon ash (*Fraxinus latifolia*);
- White alder (*Alnus rhombifolia*) – Arroyo willow (*Salix lasiolepis*) restoration;
- *Alnus rhombifolia*/*Salix exigua (Rosa californica)*;
- *Acer negundo-Salix gooddingii*;
- Hinds walnut *(Juglans hindsii)*;
- Black willow *(Salix gooddingii)*;
- *Salix gooddingii-Populus fremontii (Quercus lobata-Salix exigua-Rubus discolor)*;
- *Salix gooddingii*/*Rubus discolor*;
- *Salix goodingii/*wetland herbs;
- *Salix lasiolepis – (Cornus sericea)/Scirpus spp.- (Phragmites australis – Typha spp.)* complex unit;
- Valley Oak (*Quercus lobata*);
- Valley Oak (*Quercus lobata*) restoration;
- *Quercus lobata*/*Rosa californica (Rubus discolor-Salix lasiolepis/Carex spp.)*;
- *Quercus lobata – Acer negundo*;
- *Quercus lobata – Alnus rhombifolia (Salix lasiolepis-Populus fremontii-Quercus agrifolia)*;
- *Quercus lobata – Fraxinus latifolia*;
- *Salix lasiolepis* – Mixed brambles *(Rosa californica-Vitis californica-Rubus discolor)*;

- *Salix exigua – (Salix lasiolepis – Rubus discolor – Rosa californica)*;
- Coyote bush *(Baccharis pilularis)*;
- *Baccharis pilularis*/Annual Grasses and Herbs;
- California wild rose *(Rosa californica)*;
- Blackberry *(Rubus discolor)*;
- Buttonbrush (*Cephalanthus occidentalis*);
- California Dogwood (*Cornus sericea*);
- *Cornus sericea – Salix exigua;*
- *Cornus sericea – Salix lasiolepis/ (Phargmites australis*);
- Microphyllous shrubland;
- Intermittently or Temporarily Flooded Deciduous Shrublands;
- Arroyo willow *(Salix lasiolepis)*;
- Mexican elderberry *(Sambucus mexicana)*;
- Fremont cottonwood *(Populus fremontii)*;
- *Alnus rhombifolia*/*Cornus sericea*;
- *Salix goodingii – Quercus lobata*/wetland herbs;
- Narrow-leaf willow *(Salix exiqua)*;
- Shining willow *(Salix lucida)*; and
- Black willow (*Salix gooddingii*) – Valley Oak (*Quercus lobata*) restoration.

The vegetation types were selected based on a review of understory and overstory composition from Hickson and Keeler-Wolf (2007) and species habitat requirements, but were not further differentiated based on percentage composition or species associations. Thus, the list includes lower- and high-quality vegetation associations. Potentially occupied habitat is restricted to the above types with a minimum patch size of 0.05 acre (0.02 hectare).

Assumptions. The current distribution is highly restricted. There are only two known extant populations, one of which occurs within the Plan Area near Paradise Cut and Tom Paine Slough in the south Delta. Riparian brush rabbits inhabit the brushy understory shrub layer of valley riparian forests. Closely associated with dense shrub vegetation, occupied sites tend to be in riparian settings with an open overstory canopy or savannah-like settings that support patches of low-growing wild rose, wild grape, blackberry, and coyote bush, where the brush rabbits move through the dense brush and thickets by creating tunnels through the vegetation. Generally, riparian forests that support a closed overstory canopy lack sufficient understory shrubs to support riparian brush rabbits (Williams 1988, Basey 1990, USFWS 1998).

Patch size is important, and fragmentation of intact riparian forests is a major issue restricting occupancy and overall distribution of the species. Brushy clumps smaller than 0.08 acre (0.03 hectare) are rarely occupied. A minimum patch size of 0.05 acre (0.02 hectare) is used to ensure all potential habitat is included.

While it may greatly overestimate the extent of potentially occupied habitat for this species, for purposes of this model, it is assumed that all mapped occurrences of the riparian categories listed above using a minimum patch size of 0.05 acre (0.02 hectare) are potentially occupied. Modeled habitat is geographically constrained to qualifying habitat south of State Route 4 and Old River Pipeline. While somewhat arbitrary, for purposes of this model, this boundary is considered to represent the northern extent of all potentially-occupied habitat within the Plan Area based on the known distribution of the species and results of recent surveys in the Plan Area. While survey access was not permitted within some portions of this area, it may also greatly overestimate the extent of potentially occupied habitat for this species.

A15.8 Recovery Goals

The following recovery actions for the riparian brush rabbit were outlined in the Recovery Plan for Upland Species of the San Joaquin Valley, California (USFWS 1998).

Because of the small size of remaining blocks of potential habitat and the severely limited dispersal capability of the riparian brush rabbit, the species is likely to require continuing special protection of its habitat and population. Realization of these limitations should remove barriers to the rapid establishment of as many populations in remnant habitat as possible and sustainment of these populations by reintroduction should any one become extinct. In furtherance of these objectives, the following actions are needed:

1. Establish an emergency plan and monitoring system to provide swift action to save individuals and habitat at Caswell Memorial State Park in the event of flooding, wildfire, or a disease epidemic.
2. Develop and implement a cooperative riparian brush rabbit conservation program that will include, at a minimum:
    a) Identifying and obtaining biological information needed in management decisions; researching captive breeding methodology using surrogate species; conducting genetic composition analysis on the riparian brush rabbit population prior to any captive breeding or introduction/reintroduction (the objective is to ensure the establishment of new populations neither depletes the genetic diversity of the source population nor unduly restricts diversity in the newly established population); and implementing the captive breeding program.
    b) Creating a riparian brush rabbit management plan for Caswell Memorial State Park that will incorporate elements detailed by Williams (1988) relating to predator and pest control; fire lines and access roads; campground, picnic, and recreation areas;

brush and fuel control; mosquito abatement; habitat enhancement; and expansion of the park.

c) Establishing at least three additional wild populations in the San Joaquin Valley in restored and expanded suitable habitat within the rabbit's historical range.
d) Creating a monitoring program of all riparian brush rabbit populations to assess population trends and status.
e) Creating a long-term reintroduction preplan for the prompt reestablishment of eliminated populations.
f) Establishing a cooperative program, to take effect once the minimum of four protected populations are established, to place excess young (or other animals as appropriate) from populations at carrying capacity onto private parcels with suitable habitat where owners are willing to enter into a management agreement.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy (MSCS) designates the riparian brush rabbit as a "Contribute to Recovery" species (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its control and within its scope that are necessary to contribute to the recovery of the species. Recovery is equivalent to the requirements of delisting a species under Federal and state endangered species acts.

APPENDIX A16. TOWNSEND'S BIG-EARED BAT (*CORYNORHINUS TOWNSENDII*)

A16.1 LEGAL STATUS

The Townsend's big-eared bat (*Corynorhinus townsendii*) is designated as a state Mammal Species of Special Concern (Williams 1986) by the California Department of Fish and Game (DFG). The two subspecies occurring in California have no Federal regulatory status; however, the species was formerly listed as a United States Fish and Wildlife Service (USFWS) category 2 candidate (59 FR 58988) under the Endangered Species Act.

A16.2 SPECIES DISTRIBUTION AND STATUS

A16.2.1 Range and Status

Townsend's big-eared bats occur throughout most of western North America from British Columbia to central Mexico, east to the Black Hills of South Dakota, and across Texas to the Edwards Plateau (Hall 1981, Kunz and Martin 1982). There are five subspecies of Townsend's big-eared bat: *C.t. ingens, C.t. virginianus, C.t. pallescens, C.t. townsensii*, and *C.t. australis.* Two of these (*C.t. ingens* and *C.t. virginianus*) are found in isolated, relictual populations in the southern Great Plains and the Ozark and Appalachian Mountains and are listed as federally endangered. In California, the two subspecies found are *C.t. pallescens* and *C.t. townsendii*; the boundary between them is generally described as running north-south through the central portion of the Central Valley, with *C.t. townsendii* on the west side (Hall 1981).

In California, Townsend's big-eared bat populations have been concentrated primarily in the limestone formations of the Sierra Nevada and Klamath mountain ranges, the volcanic formations in the Columbian Plateau (e.g., Lava Beds National Monument), and throughout mining districts (Figure A-16a). The species also occurs throughout much of the northern and central Coast Ranges, including the San Francisco Bay Area, and in southern California.

Pierson and Rainey (1998a) reported on the distribution, status, and management of this species in California. They found that during the previous 40 years, there had been a 52 percent loss in the number of maternity colonies, a 45 percent decline in the number of available roosts, a 54 percent decline in the total number of animals, and a 33 percent decrease in the average size of remaining colonies for the species as a whole across the state. The populations that have shown the most marked declines are along the coast, in the Mother Lode country, and along the Colorado River. Townsend's big-eared bats have declined notably in San Francisco Bay Area counties, where native habitat and rural land have been converted to agriculture (i.e., wine production) or suburban/urban development.

DRAFT

Figure A-16a. Townsend's Big-Eared Bat Statewide Range and Recorded Occurrences

At the Homestake Mine near the Yolo County line, an adult female population of 140 and a winter population of both males and females of 166 that had been recorded in 1950 had declined to 105 and 27, respectively, by 1987–1991 (Pierson and Rainey 1998a). Depressed populations may recover when roost sites are protected (e.g., gating a mine to prevent human entry) if suitable foraging habitat remains.

A16.2.2 Distribution and Status in the Plan Area

There are no documented occurrences of Townsend's big-eared bat in the Plan Area or in the immediate vicinity of the Plan Area (Figure A-16b). The nearest recorded occurrences are in northwestern Yolo County, where the species is documented (CNDDB 2008) at three mine sites in the Little Blue Ridge and at two sites in Alameda County, one near Calaveras Reservoir and the other in the hills south of Livermore (CNDDB 2008). The Plan Area does not support caves, mines, or other similar natural roosting habitat for this species. However, some populations of Townsend's big-eared bat may be located in buildings and other anthropogenic structures such as tunnels and bridges, and individuals have been reported to use basal hollows in large trees as roost sites. The species could potentially forage and roost in larger riparian corridors in the Plan Area. While no occurrences have been reported, potential roosting habitat in the Plan Area may include old barns and other buildings with suitable interior structure, and possibly bridges.

A16.3 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

In California, this species occurs in many habitats, including active agricultural areas, riparian communities, coastal habitat types, oak woodland, conifer forest, desert scrub, and native prairies. Pierson and Rainey (1998a) suggested that its distribution appears to be constrained primarily by the availability of suitable roosting sites and the degree of human disturbance at roosts.

Roosting. The roosting behavior of the Townsend's big-eared bat leaves it highly vulnerable to disturbance. Roosting habitat is mainly limited to caves, mines, tunnels, and other features that mimic caves, such as large tree hollows, abandoned buildings with cave-like attics, water diversion tunnels, and internal spaces in bridges. For example, of the six maternity colonies known along the California coast, five colonies are in the attics of old buildings and one colony is in a cave-like feature of a bridge (Fellers and Pierson 2002). Open spaces under bridges are often used as night roosts by individual animals. Within these features (caves, mines, other structures), bats typically roost in highly visible areas on open surfaces, rarely seeking shelter in crevices as many other bat species do (Dalquest 1947, Barbour and Davis 1969). The distribution of the Townsend's big-eared bat is limited to regions with appropriate roosting habitat.

DRAFT

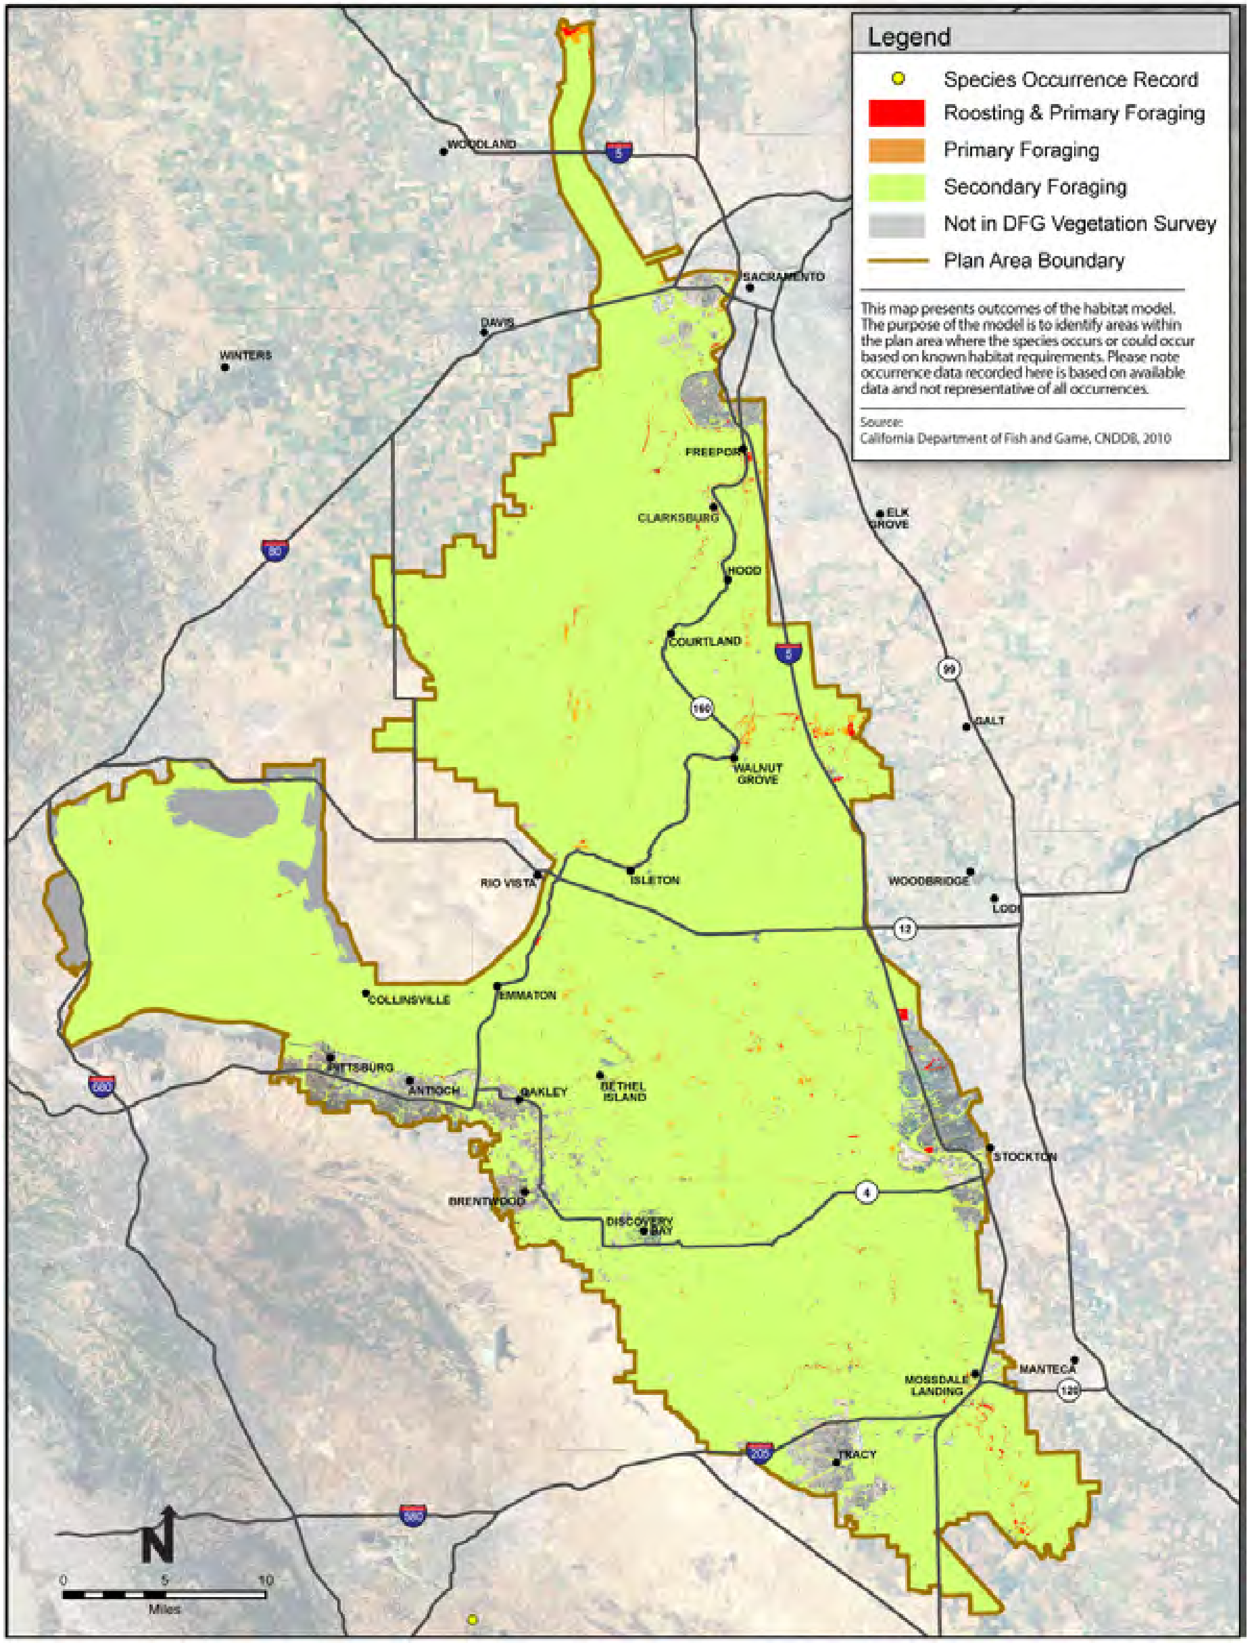

Figure A-16b. Townsend's Big-Eared Habitat Model and Recorded Occurrences

Foraging. Foraging occurs primarily along edges of wooded habitats and along streams (Kunz and Martin 1982). This species feeds both in the air and gleans insects off leaf surfaces. Radio-tracking and light-tagging studies have also documented it feeding in closed forest and woodland settings, within the canopy of oaks (Pierson and Rainey 1998b), particularly along vegetated stream corridors; over corn and alfalfa fields (Fellers and Pierson 2002); and occasionally over hay crops and vineyards. Telemetry studies found that commuting distances (from roost site to primary foraging area) varied from 1–13 kilometers (0.6–8.1 miles); because some individuals were not found, it is possible that they traveled even further (Fellers and Pierson 2002). Commuting distances vary among individuals and within the species based on season, sex, reproductive condition, and the availability of suitable foraging habitat (Fellers and Pierson 2002). Over 90 percent of the diet of the Townsend's big-eared bat consists of moths and butterflies.

A16.4 LIFE HISTORY

Description. The Townsend's big-eared bat is a medium-sized (8–14 grams [0.28–0.49 oz]) bat with rabbit-like ears; a small, indistinct face; and overall brownish coloration. This species is related in appearance to only one other bat with very large ears, the pallid bat (*Antrozous pallidus*), which is larger overall, light-colored, with large eyes and a distinct muzzle.

Seasonal Patterns. The life history of the Townsend's big-eared bat centers on reproduction and meeting the energetic demands of a small, insectivorous mammal. Its annual cycle includes an approximately 7- to 8-month period of peak activity in spring and summer when insects are most available and reproduction occurs. Pregnant females gather in maternity colonies that range in size from a few to several hundred individuals. Males usually roost elsewhere, singly or in small numbers. Maternity colonies form between March and June (based on local climatic factors), with a single pup born between May and July (Pearson et al. 1952). Maternity colonies cluster tightly together to share body heat, and the appearance of the cluster is characteristic of this species. Although roost site fidelity is variable in areas with many potential roost sites, it is quite high in California, where roosting habitat is scarce (Sherwin et al. 2003).

The Townsend's big-eared bat uses daily and seasonal periods of hibernation to conserve energy when it is inactive. In winter months, when insect prey is less available, this species extends hibernation over weeks or months, and it may migrate locally to suitable hibernation sites. In the Sacramento Valley, bats may hibernate, migrate, or reside year-round and alternate between activity and hibernation depending on weather and insect availability.

Reproduction. Females arrive at maternity roost sites in early spring and give birth to a single offspring in late spring or early summer after an approximately 3-month gestation period (Pearson et al. 1952). In California, young are born over a 3- to 5-week period beginning in late May. Maternity colonies disperse in fall, and mating occurs in fall and winter. The peak of copulation occurs from November through February, although some females apparently mate before arriving at hibernacula (Kunz and Martin 1982). Females are sexually mature and mate in their first autumn. However, as in most bats, females store sperm, and ovulation does not occur until early spring (Pearson et al. 1952). Ovulation may occur either before or after females leave hibernation. Young grow rapidly, reaching adult size in approximately 1 month, and are capable of flight in 2.5 to 3 weeks. They are fully weaned by 6 weeks (Pearson et al. 1952).

A16.5 Threats and Stressors

The cause of local population declines is most likely disturbance and destruction of roost sites. Activities such as recreation in caves and mines, abandoned mine closure, and renewed mining at historical sites have all contributed to this species' decline. For example, roosting habitat in historical mine shafts is lost when renewed mining uses open pit methods. Dependence on abandoned mines puts this species at risk if mine reclamation and renewed mining projects do not mitigate for roost loss, or do not conduct adequate biological surveys prior to mine closure.

The Townsend's big-eared bat is vulnerable to human disturbance; colonies have abandoned roost sites after human visitation (Humphrey and Kunz 1976). Pierson et al. (1999) also reported that Townsend's big-eared bats are threatened by the loss of clean water, the loss of roosting and foraging habitat, and the disturbance or destruction of winter roosts. The impacts on insect prey availability from the use of pesticides and herbicides may also threaten populations of this species.

A16.6 Relevant Conservation Efforts

A species conservation assessment and conservation strategy for the Townsend's big-eared bat (Pierson et al. 1999) was produced as part of efforts to allow opportunities for federal and state agencies and other interested parties to stabilize and recover this species and its ecosystems. This species is at risk of being listed as threatened or endangered under the Endangered Species Act. The conservation strategy addressed cave and mine management; pesticides; vegetation conversions; timber harvest; and inventory, monitoring, and research protocols.

Monitoring is needed to determine current population trends and status. More information is needed to help determine the seasonal home ranges and movements, particularly during winter months, and the foraging requirements in different habitats. In addition, information is needed to determine the amount of relatedness within and between different populations to help conserve populations.

Townsend's big-eared bat is a covered species in the permitted East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan and the in-progress Yolo County Natural Heritage Program Plan. These plans include a conservation strategy that conserves habitat and protects occupied roosting locations for this species.

A16.7 SPECIES HABITAT SUITABILITY MODEL

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which are incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and revise the vegetation input data as necessary.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements, and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate, as well as overestimate, the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small, isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; instead, the models indicate that non-habitat areas have a much lower probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percentage cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf (2007). Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers; connectivity between habitat types; and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified, and each vegetation type or association is identified, along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or underestimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The Townsend's big-eared bat model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), USDA 2005 aerial photography, and DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable Townsend's big-eared bat habitat in the Plan Area according to the species' two primary life requisite parameters, roosting habitat and foraging habitat. Vegetation types were assigned based on the species requirements, as described above, and the assumptions described below.

Roosting Habitat. Natural roosting habitat for Townsend's big-eared bat in the Plan Area is limited to (1) riparian habitats that support mature valley oak, walnut, coast live oak, and cottonwood riparian woodland and (2) mature eucalyptus stands, which would most likely be used by solitary or small groups of roosting males.

Roosting habitat in the Delta consists of the following vegetation types from the Hickson and Keeler-Wolf (2007) vegetation layer:

- Valley/foothill riparian
    - Hinds walnut (*Juglans hindsii*);
    - Fremont cottonwood *(Populus fremontii)*;
    - *Salix gooddingii-Populus fremontii (Quercus lobata-Salix exigua-Rubus discolor)*;
    - Coast live oak *(Quercus agrifolia)*;
    - Valley oak *(Quercus lobata)*;
    - *Quercus lobata – Rosa californica*;
    - *Quercus lobata – Acer negundo*;
    - *Quercus lobata – Alnus rhombifolia*; and
    - *Quercus lobata – Fraxinus latifolia*.
- Agricultural land
    - Eucalyptus.

Roosting habitat in the Suisun Marsh and Yolo Basin consists of the following vegetation types from the Boul and Keeler-Wolf (2008) and TAIC (2008) vegetation layers:

- Eucalyptus;
- *Eucalyptus globules*;

- Oaks;
- *Quercus agrifolia*;
- Fremont cottonwood-valley oak-willow (ash-sycamore) riparian forest NFD association; and
- Valley oak alliance – riparian.

Other roosting habitat in the Plan Area may include manmade features that mimic caves, including abandoned barns and other buildings, tunnels, and bridges.

Assumptions. Townsend's big-eared bat roosting habitat is limited to caves, mines, tunnels, and other features that mimic caves, such as large tree hollows, abandoned buildings with cave-like attics, water diversion tunnels, and internal spaces in bridges. Natural roosting habitat in the Plan Area is limited to large trees. Open spaces under bridges are often used as night roosts by individual animals. Within these features (caves, mines, other structures), bats typically roost in highly visible areas on open surfaces, rarely seeking shelter in crevices as many other bat species do (Dalquest 1947, Barbour and Davis 1969).

Foraging Habitat. The entire Plan Area is considered suitable foraging habitat for Townsend's big-eared bat. Modeled foraging habitat is divided into primary and secondary foraging habitat.

Primary foraging habitat in the Delta consists of the following valley riparian types from the BDCP composite vegetation layer:

- Valley/foothill riparian – all types.

Primary foraging habitat in the Suisun Marsh and Yolo Basin consists of the following riparian types from the BDCP composite vegetation layer:

- *Fraxinus latifolia*;
- Fremont cottonwood-Valley oak-Willow riparian forest;
- Mixed Fremont cottonwood – Willow;
- Mixed willow super alliance;
- *Quercus agrifolia*;
- *Salix lasiolepis/Quercus agrifolia*; and
- Valley oak alliance – Riparian.

Secondary foraging habitat in the Delta includes the following types from the BDCP composite vegetation layer:

- Agricultural land – All types;
- Alkali seasonal wetland complex – All types;

- Grassland – All types;
- Managed wetland – All types;
- Other natural seasonal wetlands – All types;
- Nontidal freshwater perennial emergent – All types;
- Tidal freshwater emergent wetland – All types;
- Tidal perennial aquatic – All types; and
- Vernal pool complex – All types.

Secondary foraging habitat in the Suisun Marsh and Yolo Basin consists of the following vegetation types from the Boul and Keeler-Wolf (2008) and TAIC (2008) vegetation layers:

- All non-riparian types.

Assumptions. Foraging occurs primarily along edges of wooded habitats and along streams (Kunz and Martin 1982). This species both feeds in the air and gleans insects off leaf surfaces. Radio-tracking and light-tagging studies have also documented it feeding in closed forest and woodland settings, within the canopy of oaks (Pierson and Rainey 1998b), particularly along vegetated stream corridors, over corn and alfalfa fields (Fellers and Pierson 2002); and occasionally over hay crops and vineyards. The Townsend's big-eared bat has also been captured while flying over damp, marshy patches of meadow and in willow riparian vegetation. There are no reported occurrences of this species in the Plan Area; thus, this model likely significantly overestimates the extent of potentially occupied habitat.

A16.8 Recovery Goals

A USFWS recovery plan has not been prepared for this species, and no recovery goals have been established.

APPENDIX A17. SUISUN SHREW (*SOREX ORNATUS SINUOSUS*)

A17.1 LEGAL STATUS

The Suisun shrew *(Sorex ornatus sinuosus)* is a California Department of Fish and Game Species of Special Concern (Williams 1986). The Suisun shrew has no federal regulatory status.

A17.2 SPECIES DISTRIBUTION AND STATUS

A17.2.1 Range and Status

The Suisun shrew, one of several subspecies of the ornate shrew, is endemic to the tidal saline and brackish salt marshes of Solano, Napa, and eastern Sonoma counties. While the historical range of the Suisun shrew is unknown, its current range was defined by Brown and Rudd (1981), who separated it from the ornate shrew *(S.o. californicus)*, which is found west of Sonoma Creek and Tubbs Island. The species' current distribution is restricted to isolated remnants of natural tidal and brackish marshes along the northern borders of San Pablo and Suisun bays, including a number of locations in Suisun Marsh, Southampton Marsh, and the Napa Marshes, and as far east as Grizzly Island, and as far west as Sonoma Creek and Tubbs Island (Figure A-17a) (Brown and Rudd 1981, Western Ecological Services 1986).

Western Ecological Services (1986) identified nine additional sites with a high probability of supporting Suisun shrew populations, including Skaggs Island, Appleby Bay/Coon Island, Steamboat Slough, Vallejo, Morrow Island, Cordelia Slough (Rush Ranch, Peytonia Slough), Hammond Island, Simmons/Wheeler Islands, and Collinsville.

Limited information exists on population densities. Newman (1970) estimated densities of 111 shrews per hectare (2.5 acres) in good quality habitat. Hays (1990) estimated densities from 10 to 100 shrews per acre at Rush Ranch in Solano County, depending on the presence or absence of large aggregations (one male with several females) of shrews. Hays (1990) found that shrews often occur in aggregations consisting of one dominant male and several females. Individuals, mainly subdominant males, were dispersed between these aggregations and returned in early spring to compete with resident males during the breeding season. Dispersing males may also occupy the deeper tidal marsh areas that were not considered in Hays (1990) (LSA Associates 2007).

DRAFT

Figure A-17a. Suisun Shrew Statewide Range and Recorded Occurrences

A17.2.2 Distribution and Status in the Plan Area

The only reported occurrences of Suisun shrew in the Plan Area are from the Suisun Marsh Restoration Opportunity Area (Figure A-17b), where there is a substantial amount of suitable habitat west of Sherman Island and throughout the Suisun Marsh (Figure A-17b). With the possible exception of portions of Kimble and Sherman islands on the western edge of the Plan Area, there is little available tidal marsh habitat within the Delta with potential to support the Suisun shrew.

A17.3 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

Suisun shrews inhabit tidal marshes characterized by pickleweed *(Sarcocornia pacifica*[1]*)*, cordgrass *(Spartina foliosa)*, and gumplant *(Grindelia cuneifolia)*. The species also occurs in brackish tidal marshes dominated by California bulrush *(Schoenoplectus californicus*[2]*)* and cattail *(Typha latifolia)* (Rudd 1955). Rudd (1955) also noted that plant community structure, rather than species composition, was the primary factor determining occupancy. The species appears to prefer dense, low-lying vegetation where invertebrates are abundant. However, suitability apparently decreases with increased inundation frequency. Williams (1983) suggests the importance of marsh habitat that is not regularly flooded and is 6 to 8 feet (2 to 2.5 meters) above sea level. Adjacent upland habitats are also important in providing cover and sources of food particularly during prolonged flooding of marshes and dikes (Williams 1983). Driftwood and other litter above the mean high tide line may also be important for nesting and foraging sites (MacKay 2000).

Hays (1990) determined that shrews alter their microhabitat use seasonally. During the fall when the weather was hot and tides high, he noted that shrews were typically found under dense layers of matted plant material beneath large clumps of succulents such as *Sarcocornia* and *Jaumea*. During winter and early spring when tides were low and succulents above the line of frequent flooding died back, shrews were seen foraging mostly among arrowgrass *(Triglochin maritinum)*.

Once abundant around San Pablo and Suisun Bays, the availability of suitable tidal marsh habitat for Suisun shrew and other tidal marsh species has declined dramatically. Western Ecological Services (1986) estimated that natural tidal marsh in this area has decreased from 100,000 acres (40,469 hectares) to around 12,000 acres (4,856 hectares). Most of the remaining tidal marsh habitat occurs in small, isolated units, the largest of these in the Suisun Marsh.

---

[1] Formerly known as *Salicornia virginica*.
[2] Formerly known as *Scirpus californicus*.

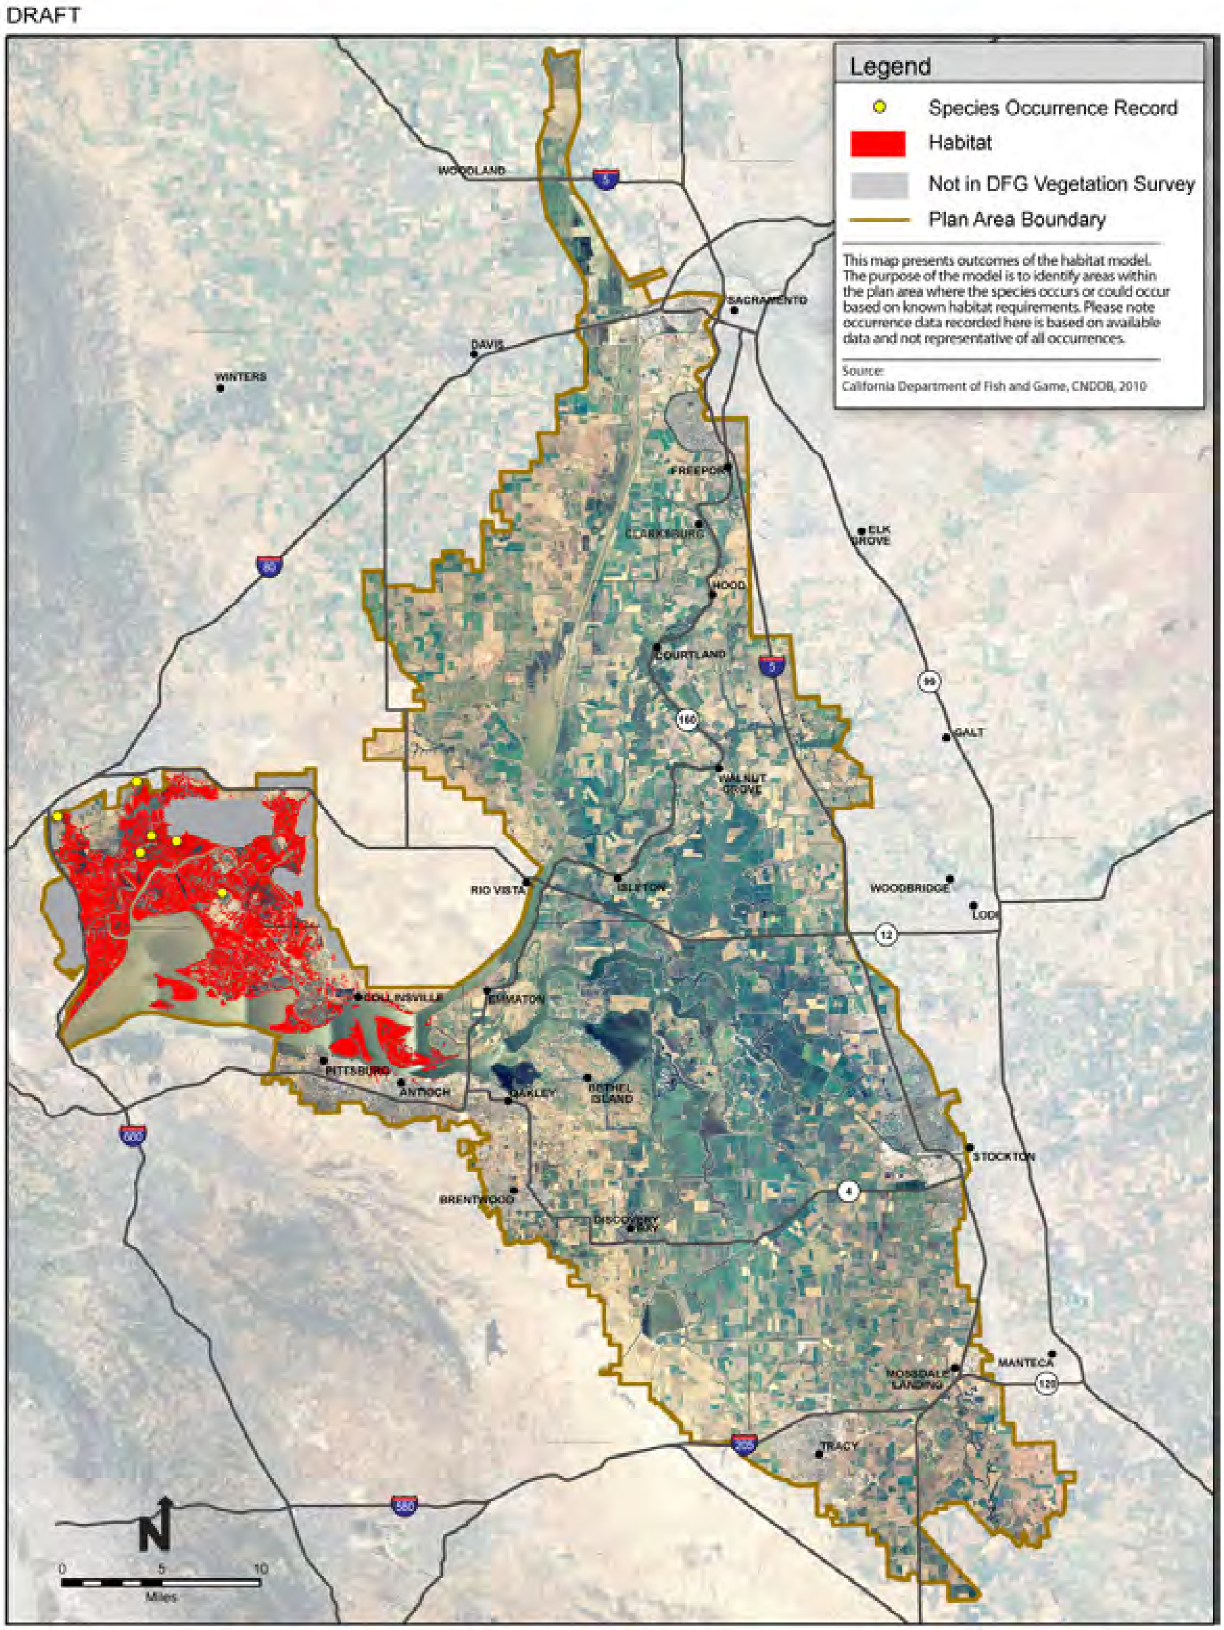

Figure A-17b. Suisun Shrew Habitat Model and Recorded Occurrences

A17.4 LIFE HISTORY

Description. The Suisun shrew is a small (98 to 106 millimeters [mm] [3.9 to 4.2 inches]), dark mammal with a long, pointed nose, an elongate, relatively narrow skull, and a 37- to 41-mm (1.5- to 1.6-inch) long scaly tail (Engles 1965). It is distinguished from other shrews by its darker pelage (fur) and localization to tidal marshes in and near San Pablo and Suisun bays. The skull is elongate, relatively narrow, and fragile (Rudd 1955).

Activity. With their high metabolic rate, Suisun shrews spend much of their time foraging. Genoud and Vogel (1989) reported that between 60 and 200 percent of their body mass is eaten daily; during peak lactation, females can consume up to 300 percent of body mass.

They access their territories by constructing shallow subterranean tunnels (Hays 1990) or share burrows and runways with harvest mice (*Reithrodontomys* spp.) and meadow mice (*Microtus* spp.).

Males are apparently more subject to local movements than females. While young females typically remain in their natal area, subdominant males intersperse within the aggregations of single dominant males and several females. Hays (1990) also concluded that dispersing shrews will most likely occupy and overwinter in deeper tidal marsh areas rather than in upland habitats.

As with all other *Sorex* species, the life span of shrews is short, with 16 months being considered the maximum age (Rudd 1955); thus, most individuals do not live to breed in a second season. Most die shortly after the breeding season, with females generally living slightly longer than males.

Reproduction. In early March, males reach sexual maturity and begin to migrate into population foci. The harem-structured population foci are reestablished within a narrow band of preferred habitat. Breeding occurs from April through October, with the reproductive peak in May (Newman and Rudd 1978). After breeding occurs, each population focus is left with one dominant male, several breeding females, and several immature females (Hays 1990).

Shrews construct domed, cup-like nests composed of paper scraps and dead plant material. Nests are directly on the soil surface below driftwood or wooden planks and are situated above the high tide line (Western Ecological Services 1986). Gestation is approximately three weeks, and two to nine young are produced. Another 3 weeks of altricial dependency occurs prior to weaning. Suisun shrews are capable of producing two litters in 1 year, but this is apparently rare (Rudd 1955).

Diet. The diet of Suisun shrews consists almost entirely of animal prey, including amphipods, isopods, and other invertebrate species (Hays 1990).

A17.5 Threats and Stressors

Habitat Degradation. Degradation of tidal marsh habitats continues to be the most significant threat to Suisun shrews and other tidal marsh species. Tidal marshes have been reduced by 84 percent since historical times (Dedrick 1989). The fragmentation of suitable habitats has isolated populations and reduced dispersal opportunities. While the loss of tidal marsh habitat through filling and diking has largely been curtailed, other current factors may be associated with declining populations, including the management of marshes in and around the Suisun, which may favor the growth of bulrush (LSA Associates 2007). Contaminants accumulated in the food chain, such as polychlorinated biphenyls (PCBs), heavy metals, and pesticides, may also degrade habitat conditions and threaten Suisun shrews (Western Ecological Services 1986).

A17.6 Relevant Conservation Efforts

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designates the Suisun shrew as "Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP has established a goal to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

The Suisun Marsh has been the subject of various conservation efforts for many years, particularly with respect to development and issues related to water quality within its boundaries. The California Department of Water Resources (DWR) Suisun Marsh Program (http://www.iep.water.ca.gov/suisun/program/index.html) summarizes the major agreements, management plans, and legislation that have directed management of the Suisun Marsh since the mid-1970s. These efforts focus on the preservation and restoration of tidal marsh habitats.

The Nejedly-Bagley-Z'Berg Suisun Marsh Preservation Act (1974). The California Legislature enacted the Suisun Marsh Preservation Act to protect the marsh from urban development. It required the San Francisco Bay Conservation and Development Commission (BCDC) to develop a plan for the marsh and provides for various restrictions on development within marsh boundaries.

Suisun Marsh Protection Plan (1976). This plan was developed by the BCDC and defines and limits development within primary and secondary management areas for the "future of the wildlife values of the area as threatened by potential residential, commercial and industrial development." It recommends that the state purchase 1,800 acres and maintain water quality. While the focus of the plan is on maintaining waterfowl habitat, it also addresses the importance of tidal wetlands and recommends restoring historical marsh areas to wetland status (managed or tidal).

The Suisun Marsh Protection Act (1977). This bill adopts and calls for implementation of the Suisun Marsh Protection Plan. Assembly Bill (AB) 1717 designates the BCDC as the state agency with regulatory jurisdiction of the marsh and calls for the Suisun Resource Conservation District to have responsibility for water management in the marsh. The bill identifies (and focuses on) actions for the preservation of waterfowl needs, along with the retention of the diversity of wildlife. It states that land within the Suisun Marsh should be acquired for public use or resource management if it is suitable for restoration to tidal or managed marsh, but that such restoration cannot be required as a condition of private development.

State Water Resources Control Board (SWRCB) Water Rights Decision 1485 (1978). SWRCB adopted the Water Quality Control Plan for the Sacramento-San Joaquin Delta and issued Water Rights Decision 1485. The decision sets channel water salinity standards for the period from October to May and preserves the area as brackish water tidal marsh. It sets water quality standards in the marsh as a condition of export pumping. These come from the California Department of Fish and Game's (DFG's) recommendations, which were based on (1) the relative value of marsh plants as duck food; (2) the influence of soil salinity and other factors on distribution and growth of marsh plants; and (3) the relationships between channel water salinity and soil salinity. DFG concluded that improved management practices, improved drainage, water control facilities, and adequate quality of water were needed to achieve desired soil salinity conditions for waterfowl food plants.

Plan of Protection for the Suisun Marsh (1984). DWR and the U.S. Bureau of Reclamation (USBR) developed and began implementing the Plan of Protection (POP) in accordance with Water Rights Decision 1485. The POP implementation strategy was to construct large facilities and distribution systems to meet salinity standards (lower channel water salinity), in lieu of significant Central Valley Project/State Water Project (CVP/SWP) storage releases estimated as high as 2 million acre-feet in dry/critical water years. The six-phase POP was the programmatic blue print (required by the SWRCB and embodied in the original Suisun Marsh Preservation Agreement). Two of the six phases were completed, including the Initial Facilities and the Suisun Marsh Salinity Control Gates.

Suisun Marsh Preservation Agreement (SMPA) (1987). This contractual agreement between DWR, USBR, DFG, and Suisun Resource Conservation District contains provisions for DWR and USBR to mitigate the effects on Suisun Marsh channel water salinity from the CVP/SWP operations and other upstream diversions. The SMPA requires DWR and USBR to meet salinity standards, sets a timeline for implementing the POP, and delineates monitoring and mitigation requirements. The Suisun Marsh Monitoring Agreement and the Suisun Marsh Mitigation Agreement were also signed at this time. The Suisun Marsh Mitigation Agreement defines habitat requirements to mitigate effects of facilities and operations, and the Suisun Marsh Monitoring Agreement defines requirements for monitoring salinity and species in the Suisun Marsh.

Bay-Delta Accord (1994). On December 15, 1994, federal and state agencies, working with agricultural, environmental, and urban stakeholders, reached an agreement on water quality standards and related provisions that would remain in effect for 3 years. This agreement, known as the Bay-Delta Accord, was based on a proposal developed by the stakeholders. Elements of the agreement include the following:

- Springtime export limits expressed as a percentage of Delta inflow;
- Regulation of the salinity gradient in the estuary so that a salt concentration of two parts per thousand is positioned where it may be more beneficial to aquatic life;
- Specified springtime flows on the lower San Joaquin River to benefit Chinook salmon; and
- Intermittent closure of the Delta Cross Channel gates to reduce entrainment of fish into the Delta.

SWRCB Water Quality Control Plan (1995–1998). In 1994, wildlife and fishery agencies and urban water users expressed concerns about the appropriateness of western Suisun Marsh channel water salinity standards. In May of 1995, the SWRCB modified the Suisun Marsh salinity objectives in the Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary. Modeling analysis by the Suisun Marsh Planning Program showed that Suisun Marsh standards would be met most of the time at all Suisun Marsh compliance stations. Some standard exceedances would be expected in the western Suisun Marsh that participants in the SMPA agreed could be mitigated by more-active water control by landowners.

SWRCB Water Rights Decision 1641 (1999). The SWRCB issued Decision 1641 in December 1999, which updated salinity standards for Suisun Marsh. Increased outflow and salinity requirements for the Bay-Delta provided indirect benefits to the Suisun Marsh. DWR proposed that the SWRCB adopt the Amendment Three actions for Suisun Marsh in this decision. However, the SWRCB was unable to adopt Amendment Three actions because the Section 7 consultation with the U.S. Fish and Wildlife Service (USFWS) had not concluded. However, the SWRCB did relieve USBR and DWR of their responsibility to meet salinity objectives at S-35 and S-97 in the western Suisun Marsh.

CALFED Multi-species Conservation Strategy and Record of Decision (2000). In August 2000, the Programmatic Record of Decision for the CALFED Bay-Delta Program was signed by 13 federal and state agencies with management and regulatory responsibilities in the San Francisco Bay estuary. Based on the analysis in the multi-species conservation strategy and the final programmatic environmental impact statement/environmental impact report, the CALFED agencies fulfilled the regulatory requirement for programmatic evaluation of the CALFED program.

Suisun Marsh Charter Implementation Plan (2001). The Suisun Marsh Charter was completed in 2001, and development of an Implementation Plan commenced. Charter participants collaborated on a joint presentation to the State of the Estuary Conference on the principles of the Charter Plan, including coordinated water quality, endangered species, and heritage value protection in the Suisun Marsh.

Habitat Management, Preservation, and Restoration Plan (2003). The Charter process was expanded to include additional federal and state agencies to develop a Suisun Marsh Plan that will balance the goals and objectives of the Bay-Delta Program, SMPA, and other management and restoration programs within the Suisun Marsh in a manner that is responsive to the concerns of all stakeholders and is based upon voluntary participation by private landowners.

In addition, several facilities have been constructed in the Suisun Marsh to protect and improve water quality and protect and enhance wildlife habitat, including:

- Roaring River Distribution System (1979–80);
- Morrow Island Distribution System (1979–80;
- Goodyear Slough Outfall (1979–80);
- Suisun Marsh Salinity Control Gates (1988); and
- Cygnus and Lower Joyce Facilities (1991).

Several tidal marsh restoration projects are also planned or being implemented within the range of the Suisun shrew. These projects, implemented through the direction or support of the San Francisco Bay National Wildlife Refuge, National Biological Service, East Bay Regional Park District, Regional Water Quality Control Board, DFG, and the City of San Jose include the following:

- Restoration of the 1,500-acre Napa Marsh Unit in the Napa River in the north bay.
- Restoration of the Knapp Property, a 452-acre former salt pond in the Alviso area, on the edge of the bay, between Alviso and Guadalupe Sloughs.
- Enhancement of the 325-acre Oro Loma Marsh, an area of diked salt marsh and adjacent uplands located along the shore of Hayward. The area will be restored to tidal marsh and seasonal wetland habitat.
- Restoration of the Baumberg Tract, an 835-acre inactive salt evaporator in Hayward, to tidal marsh and seasonal wetlands.
- Restoration of the Moseley Tract, located just north of the west approach to the Dumbarton Bridge) from the Port of Oakland.

The Suisun shrew is also proposed for coverage under the Solano County Multispecies Habitat Conservation Plan.

A17.7 Species Habitat Suitability Model

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which are incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and revise the vegetation input data as necessary.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements, and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate, as well as overestimate, the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small, isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; instead, the models indicate that non-habitat areas have a much lower probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percentage cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf (2007). Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers; connectivity between habitat types; and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or underestimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The Suisun shrew model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), USDA 2005 aerial photography, and DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable Suisun shrew habitat in the Plan Area. Vegetation types were assigned based on the species requirements, as described above, and the assumptions described below.

Habitat. Suisun shrew habitat consists of all *Salicornia*[3]-dominated natural seasonal wetlands and *Scirpus*[4]/*Typha*-dominated tidal freshwater emergent wetlands located west of State Highway 160 on Sherman Island (Figure A-17b). Vegetation types designated as species habitat in this model correspond to the mapped vegetation associations in the BDCP GIS vegetation data layer.

Suisun shrew habitat in the Delta consists of the following types from the BDCP composite vegetation layer:

- Alkali seasonal wetland complex
- Managed wetlands
- Nontidal freshwater perennial emergent wetland
  - Broad-leaf cattail *(Typha latifolia)*
- Tidal freshwater emergent wetland and tidal brackish emergent wetland
  - Mixed *Scirpus* mapping unit;
  - Mixed *Scirpus*/floating aquatics complex;
  - Mixed *Scirpus*/submerged aquatics complex;
  - Hard-stem bulrush *(Scirpus acutus)*;
  - *Scirpus acutus* pure;
  - *Scirpus acutus* – *Typha angustifolia*;

[3] Currently known as *Sarcocornia*.
[4] Currently known as *Schoenoplectus*.

   - *Scirpus acutus – Typha latifolia*;
   - *Scirpus acutus – (Typha latifolia) – Phragmites australis*;
   - California bulrush *(Scirpus californicus)*;
   - *Scirpus californicus – Eichhornia crassipes*;
   - *Scirpus californicus – Scirpus acutus*;
   - American bulrush *(Scirpus americanus)*;
   - Narrow-leaf cattail *(Typha angustifolia)*; and
   - *Typha angustifolia – Distichlis spicata*.

Suisun shrew habitat in the Suisun Marsh consists of the following types from the BDCP composite vegetation layer:

- *Scirpus* (*californicus* or *acutus*)/Rosa;
- *Scirpus* (*californicus* or *acutus*)/wetland herb;
- *Scirpus* (*californicus* or *acutus*)-Typha spp.;
- *Scirpus americanus* (generic);
- *Scirpus americanus*/Lepidium;
- *Scirpus americanus*/Potentilla;
- *Scirpus californicus*/*S. acutus*;
- *Scirpus maritimus*;
- *Scirpus maritimus*/Salicornia;
- *Typha angustifolia*/Distichlis;
- *Typha angustifolia*/*S. americanus*;
- *Typha* species (generic);
- Bulrush - cattail fresh water marsh NFD super alliance;
- *Scirpus americanus*/*S. Californicus-S. acutus*;
- *Scirpus maritimus*/*Sesuvium*;
- *Typha angustifolia*;
- *Typha angustifolia*/*Phragmites*;
- *Typha angustifolia*/*Polygonum-Xanthium-Echino*;
- *Typha angustifolia/S. americanus*;

- *Distichlis*/*Salicornia*;
- *Salicornia* (generic);
- *Salicornia virginica*;
- *Salicornia/Atriplex*;
- *Salicornia/Cotula*;
- *Salicornia*/annual grasses;
- *Salicornia*/*Crypsis*;
- *Salicornia*/*Polygonum-Xanthium-Echinochloa*; and
- *Salicornia*/*Sesuvium*.

Assumptions. Historical and current records of this species indicate that its known distribution extends eastward to approximately Grizzly Island. For purposes of this model, the potential range of the Suisun shrew occurs in suitable habitats west of the western edge of Sherman Island. Suisun shrews are restricted to pickleweed *(Sarcocornia,* formerly *Salicornia)* and cordgrass *(Spartina foliosa)*-dominated saline tidal marshes and *Schoenoplectus* (formerly *Scirpus)/Typha*-dominated brackish marshes (Rudd 1955, Williams 1986). Suitability of habitat may also be dependent on other factors, such as patch size, tidal connectivity (diked marshes), and proximity to other land uses. However, data regarding the effects of these factors on potential occupancy for the Suisun shrew are insufficient. Thus, potential habitat for the Suisun shrew is not further restricted in this habitat model on the basis of these factors. Therefore, the model likely overestimates the extent of potentially occupied tidal marsh habitat.

A17.8 Recovery Goals

A USFWS recovery plan has not been prepared for this species, and no recovery goals have been established; however, the CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designates the Suisun shrew as "Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP has established a goal to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

APPENDIX A18. TRICOLORED BLACKBIRD (*AGELAIUS TRICOLOR*)

A18.1 LEGAL STATUS

The tricolored blackbird *(Agelaius tricolor)* is designated as a state Bird Species of Special Concern by the California Department of Fish and Game (DFG) (Shuford and Gardali 2008). Nests are protected in California under *Fish and Game Code*, Section 3503.

The tricolored blackbird has no federal regulatory status; however, the species is protected under the federal Migratory Bird Treaty Act and is designated as a Bird of Conservation Concern by the U.S. Fish and Wildlife Service (USFWS 2002). A petition for federal listing was submitted in 2004. In 2006, the USFWS denied the petition based on insufficient scientific evidence to warrant listing the species under the federal Endangered Species Act.

A18.2 SPECIES DISTRIBUTION AND STATUS

A18.2.1 Range and Status

Tricolored blackbirds form the largest colonies of any North American passerine bird, and these colonies may consist of tens of thousands of breeding pairs (Beedy and Hamilton 1999). Tricolored blackbirds are largely endemic to California; the state is home to more than 95 percent of the global population, with breeding documented in 46 counties (Figure A-18a). More than 75 percent of the breeding population occurs in the Central Valley in any given year (Hamilton 2000). Recent surveys indicate that the overall range of the species is largely unchanged since the 1930s (Neff 1937, DeHaven et al. 1975, Beedy et al. 1991, Hamilton 1998). However, while the overall geographic distribution of the species may not have changed since historical times, there are now large gaps in their former range encompassing entire counties (e.g., Kings, San Joaquin, Riverside, and San Bernardino counties).

Historical population sizes are unknown, but by the mid-1930s, following the removal of most major wetland areas in the state, populations still likely exceeded 1.1 million adult birds (Hamilton 1998). In the first systematically conducted range-wide surveys, Neff (1937) documented 252 colonies of tricolored blackbirds in 26 California counties, including over 700,000 adults in just eight Central Valley counties. Surveys conducted in the 1960s and 1970s indicate that range-wide populations declined by more than 50 percent during the 30- to 35-year period following Neff's surveys in the 1930s (Orians 1961, Payne 1969, DeHaven et al. 1975).

More recently, the USFWS, DFG, and California Audubon cosponsored systematic tricolored blackbird surveys throughout California in 1994, 1997, 1999, and 2000 (Hamilton et al. 1995, Beedy and Hamilton 1997, Hamilton 2000).

DRAFT

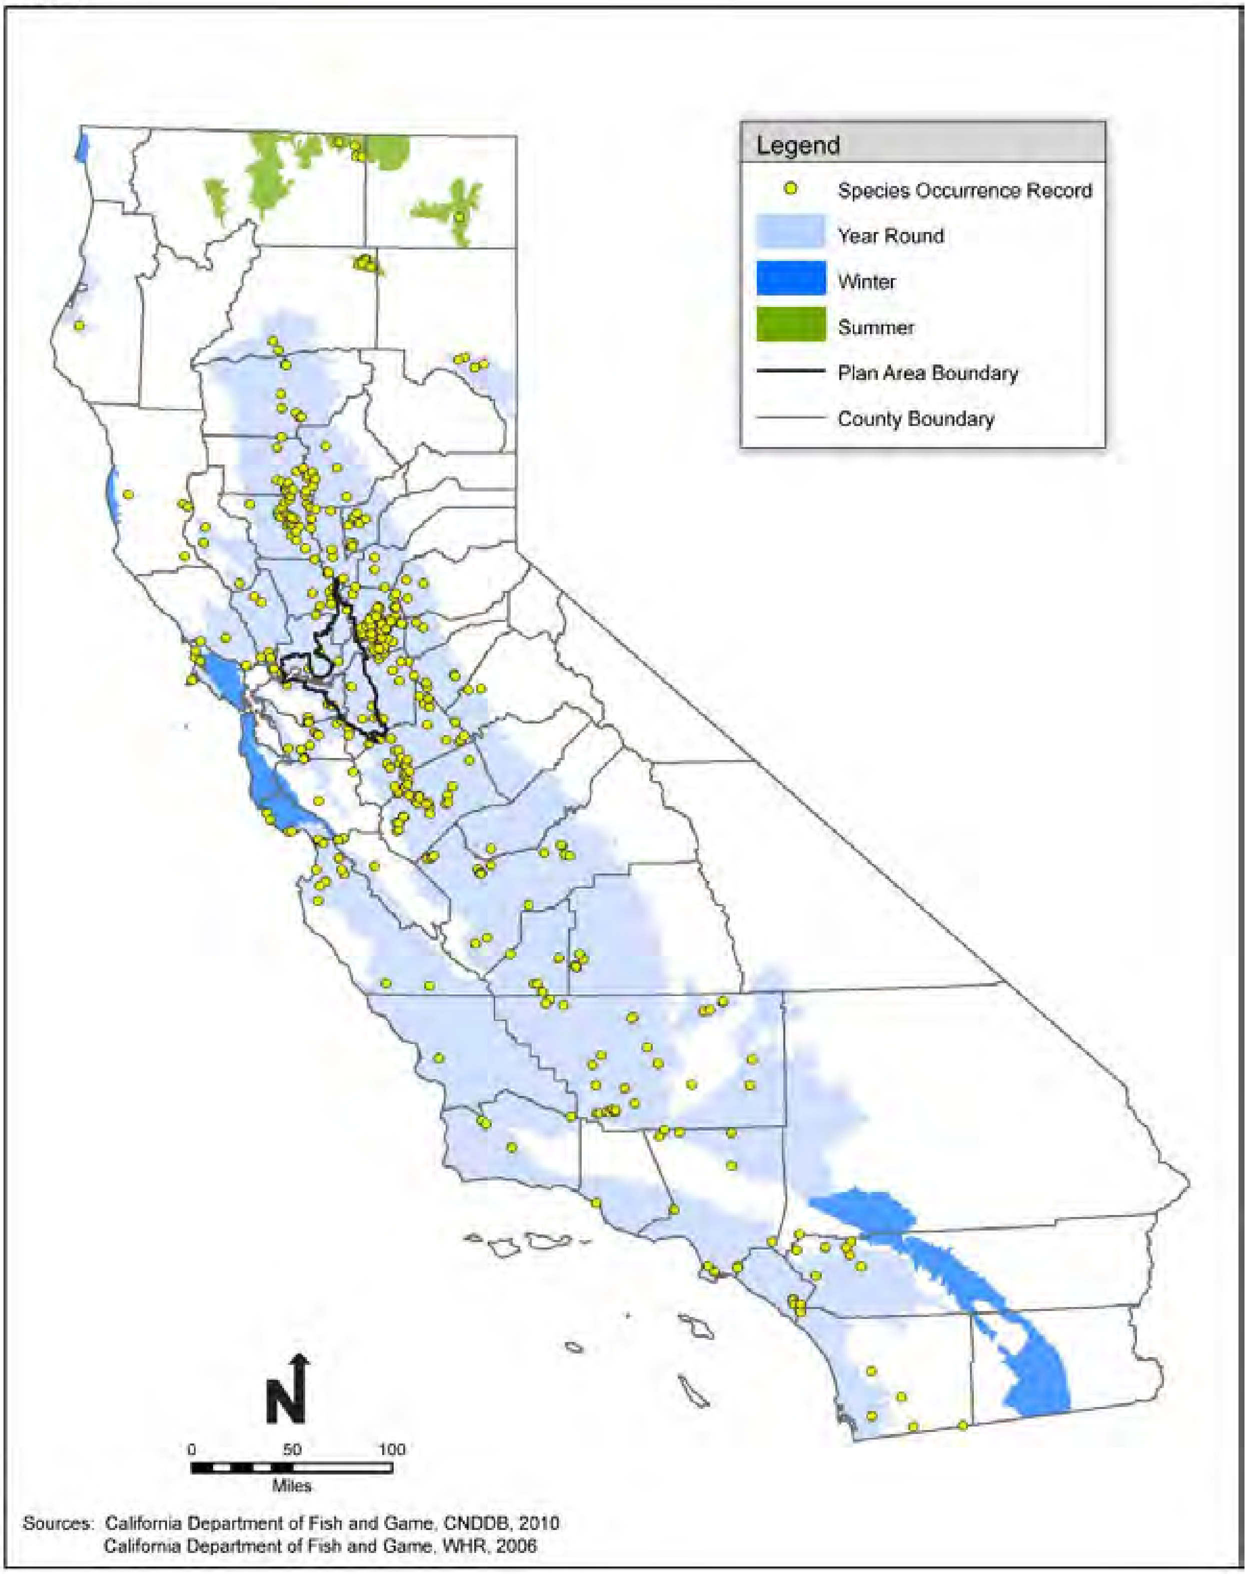

Figure A-18a. Tricolored Blackbird Statewide Range and Recorded Occurrences

Results of these surveys indicate a significantly declining trend in populations in California since the 1930s and a particularly dramatic decline since 1994. Hamilton (2000) reported a 56 percent statewide decline between 1994 and 2000 (from 369,359 to 162,508 adults) and a 69 percent decline in the Sacramento Valley during that period (from 98,362 to 30,979 adults).

The most recent statewide surveys have been coordinated by the Point Reyes Bird Observatory and California Audubon with assistance from Partners in Flight, USFWS, and DFG. Surveys conducted in 2008 included 35 counties from San Diego County to Shasta County. A total of 395,321 birds were estimated, with Kern, Tulare, and Merced counties in the San Joaquin Valley accounting for 314,936 (79.7 percent) of the total (University of California Davis 2008).

While survey results over the past several years may suggest a stable or possibly increasing population in the state, the data also indicate that populations continue to decline in several areas of the state where the species was formerly common, particularly in Southern California and several Central Valley counties, including San Joaquin County, where no active colonies were documented in 2008. Thus, while the number of birds may have increased statewide, they have concentrated into a significantly smaller effective range (University of California, Davis 2008).

A18.2.2 Distribution and Status in the Plan Area

There are few reported tricolored blackbird nesting colonies in the Plan Area (Figure A-18b). The 2009 California Department of Water Resources (DWR) surveys identified two confirmed breeding sites, one in the central Delta and one north and west of the Sacramento River in the north Delta, and numerous other detections of foraging or roosting tricolored blackbirds.

Beedy et al. (1991) reported historical occurrences at Stone Lakes and at sites near Tracy, near Durham Ferry, and at Birds Landing (from Neff 1937). California Natural Diversity Database reported occurrences in and near the Yolo Bypass; near Stockton, Manteca, and Tracy in the southeastern corner of the Plan Area; and along the eastern edge of the Suisun Marsh; however, few of these are recent reports. Statewide surveys conducted in 2008 reported no active colonies within the Plan Area. However, surveys in 2007 revealed a highly successful colony of more than 30,000 breeding adults in milk thistle on the Conaway Ranch in the Yolo Bypass. This was one of only three documented colonies statewide that were large and successful, and this colony was estimated to have produced about 30,000 young (Meese 2007). Other than the DWR 2009 survey results, the nearest reported active colonies were west of Byron at Marsh Creek Reservoir (University of California, Davis 2008) and in the Yolo Bypass (Feliz pers. comm.). Thus, the species is generally considered an uncommon breeder in the Plan Area; historical nesting activity was generally restricted to the northern and southern ends of the Plan Area.

The Delta is also recognized as a major wintering area for tricolored blackbirds (Hamilton 2004, Beedy 2008). Large wintering flocks have been reported on Sherman Island.

DRAFT

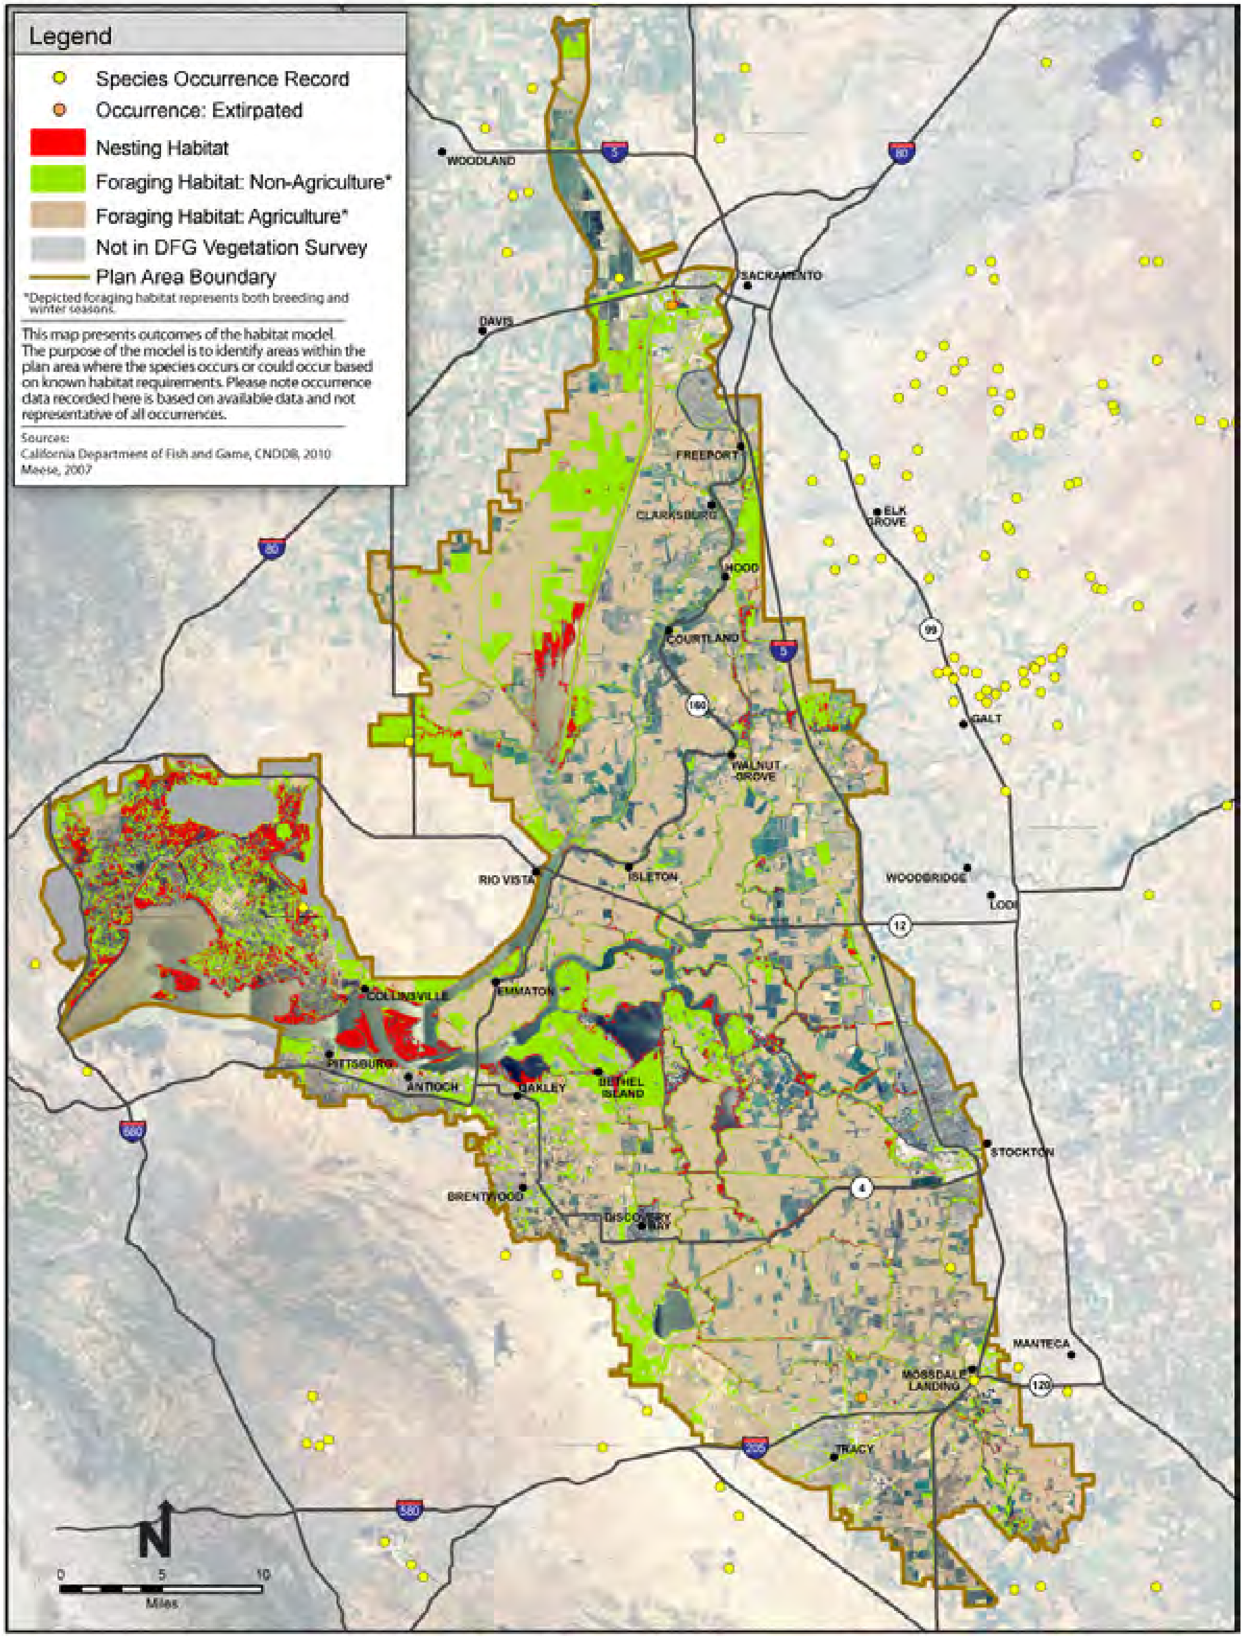

Figure A-18b. Tricolored Blackbird Habitat Model and Recorded Occurrences

1

A18.3 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

Tricolored blackbirds are among the most colonial of North American passerine birds (Bent 1958, Orians 1961, Payne 1969, Beedy and Hamilton 1999). The species' highly synchronized and colonial breeding system may have adapted to exploit a rapidly changing environment in which the locations of secure nesting habitat and rich insect food supplies were ephemeral and likely to change each year (Orians 1961, Collier 1968, Payne 1969).

Nesting. Tricolored blackbirds have three basic requirements for selecting their breeding colony sites: (1) open, accessible water; (2) a protected nesting substrate, including flooded, thorny, or spiny vegetation; and (3) a suitable foraging space providing adequate insect prey within a few miles of the nesting colony (Hamilton et al. 1995, Beedy and Hamilton 1999).

As many as 30,000 nests have been recorded in cattail (*Typha* spp.) marshes of 10 acres or less, with individual nests less than 0.5 meters from each other (Neff 1937, DeHaven et al. 1975). Nest heights range from a few centimeters (cm) to about 1.5 meters above water or ground at colony sites in freshwater marshes (Neff 1937) and up to 3 meters in the canopies of willows (*Salix* spp.) and other riparian trees; nests are rarely built on the ground. The species typically selects breeding sites adjacent to open, accessible water and places its nests in a protected nesting substrate, often including flooded, thorny, or spiny vegetation. Breeding colonies must have suitable foraging space providing adequate insect prey within a few kilometers (Beedy and Hamilton 1999).

Males initially select breeding sites and establish nesting territories. Females select the nest site location. The first nests in a colony generally occur in the densest vegetation, usually in the interior of the nesting habitat. As the colony forms, nests are added in concentric circles gradually or in synchronous pulses (Collier 1968).

Over time, the selection of nesting habitat has changed dramatically as freshwater marsh habitat has been removed. Almost 93 percent of the 252 breeding colonies reported by Neff (1937) were in freshwater marshes dominated by tules (*Schoenoplectus*[1] spp.) and cattails (*Typha* spp.). The remaining colonies in Neff's study were in willows (*Salix* spp.), blackberries (*Rubus* spp.), thistles (*Cirsium* and *Centaurea* spp.), or nettles (*Urtica* spp.). In contrast, only 53 percent of the colonies reported during the 1970s were in cattails and tules (DeHaven et al. 1975).

An increasing percentage of colonies in the 1980s and 1990s were reported in Himalaya blackberry *(Rubus discolor)* (Beedy et al. 1991), and some of the largest recent colonies are in silage and grain fields (Hamilton et al. 1995, Beedy and Hamilton 1997, Hamilton 2000). Other substrates where tricolored blackbirds have been observed nesting include giant cane *(Arundo donax)*, safflower *(Carthamus tinctorius)* (DeHaven et al. 1975), tamarisk trees (*Tamarix* spp.),

[1] Formerly known as *Scirpus*.

elderberry/poison oak (*Sambucus* spp. and *Toxicodendron diversilobum*), and riparian scrublands and forests.

Foraging. Tricolored blackbirds forage in areas that provide abundant insects, including pastures, dry seasonal pools, agricultural fields planted with crops such as alfalfa and rice, feedlots, and dairies. Tomatoes may occasionally be used as foraging habitat. With the loss of the natural flooding cycle and most native wetland and upland habitats in the Central Valley, breeding tricolored blackbirds now forage primarily in anthropogenic habitats. Tricolored blackbirds have been able to exploit foraging conditions created when shallow flood irrigation, mowing, or grazing keeps the vegetation at an optimal height (less than 15 cm). Preferred foraging habitats include crops such as rice, alfalfa, sunflowers, irrigated pastures, and ripening or cut grain fields (e.g., oats, wheat, silage), as well as annual grasslands and shrublands.

In recent years, an increasing percentage and now large majority of adults have foraged on grains provided to livestock, for example, in cattle feedlots and dairies. Tricolored blackbirds also forage in remnant native habitats, including wet and dry vernal pools and other seasonal wetlands, riparian scrub habitats, and open marsh borders. Vineyards, orchards, and row crops (sugar beets, corn, peas, beets, onions, etc.) do not provide suitable nesting substrates or foraging habitats for tricolored blackbirds (Beedy and Hamilton 1999). Both adults feed the nestlings; adults feeding young typically forage within 3 miles of the colony, but can range up to 8 miles from the colony (Beedy and Hamilton 1999).

Some small breeding colonies may occur at private and public lakes, reservoirs, and parks, provided that they are near suitable foraging habitats. Many of these colonies are surrounded by shopping centers, subdivisions, and other urban development; adults from such colonies forage in undeveloped uplands nearby.

Wintering tricolored blackbirds are associated primarily with open rangeland and dairies in the Sacramento-San Joaquin Delta (Hamilton 2004).

A18.4 LIFE HISTORY

Description. The tricolored blackbird is a medium-sized passerine (8.8 inches [22 cm] in length with 14-inch [36 cm] wingspan) that closely resembles the red-winged blackbird *(Agelaius phoeniceus)*, with subtle differences in coloration, bill shape, and overall morphology (Beedy and Hamilton 1999). The adult male is black, with shades of glossy blue, and has a bright red patch on the wing (an epaulet), similar to that of a red-winged blackbird. However, the epaulet of tricolored blackbirds is deeper red with a white lower border, as opposed to an orange-red patch with a yellowish border or no border at all. The adult females are brownish and black, streaked with gray, with small reddish epaulets (rarely visible in the field) and a pale gray or whitish chin and throat. Tricolored blackbirds have longer, slightly narrower wingtips and thinner bills than red-winged blackbirds (Beedy and Hamilton 1999).

Seasonal Patterns. Many tricolored blackbirds reside throughout the year in the Central Valley of California. However, local populations can move considerable distances, and some are migratory and move from inland breeding locations to wintering habitats in the Sacramento-San Joaquin River Delta and coastal areas. During the first breeding effort of the season, most birds nest in the San Joaquin Valley and in Sacramento County. They may later move northward throughout the Sacramento Valley, northeast California, and southern Oregon to nest again (Hamilton 1998). Thus, individual tricolored blackbirds may occupy and breed at several sites, or renest at the same site, during a given breeding season, depending on environmental conditions and their previous nesting success (Hamilton 1998, Beedy and Hamilton 1999, Meese 2006). In the fall, after the nesting season, large roosts form at managed wildlife refuges and other marshes near abundant food supplies such as rice *(Oryza sativa)* and water grass *(Echinochloa crusgalli)* (Beedy and Hamilton 1997). During winter, many tricolored blackbirds move out of the Sacramento Valley to the Sacramento–San Joaquin River Delta. Large flocks also winter in the central and southern San Joaquin Valley and at the dairy farms in coastal areas such as Point Reyes and Monterey County (Beedy and Hamilton 1997). From early March to early April, these flocks move from wintering areas to their breeding colonies in Sacramento County and the San Joaquin Valley (Beedy and Hamilton 1997).

Reproduction. Tricolored blackbirds nest colonially, enabling them to synchronize their timing of nest building and egg laying (Beedy and Hamilton 1999). A few breeding colonies documented during fall months (September to November) had more-protracted nest-building periods that led to asynchronous egg laying and fledging of young (Orians 1960). In the Central Valley, adults typically arrive on the breeding grounds from early March to early April (Hamilton 2004). Females usually breed in their first year, but most males apparently defer breeding until they are at least 2 years old (Payne 1969). Females typically lay three to four eggs and incubate them for 11 to 14 days (Emlen 1941, Orians 1961); then both parents feed young until they fledge 9 to 14 days after hatching (Beedy and Hamilton 1999).

Tricolored blackbird young transition from hatchlings to fledglings in approximately 24 days. Thus, a successful nesting effort requires approximately 45 days from nest initiation to independence of young (Hamilton et al. 1995). However, because birds may continue to be recruited into the nesting colony following the initial nest establishment, the colony itself remains active and in various stages of the breeding cycle for an extended period. This period may sometimes last more than 90 days, but generally requires a minimum of 50 days for a complete breeding cycle of a less-asynchronous colony (Beedy and Hamilton 1997).

Foraging Behavior and Diet. Like other blackbirds, tricolored blackbirds often forage in flocks. They usually forage on the ground by walking, hopping, or taking short flights. Most forage within 3 miles of their colony sites (Orians 1961).

Diets of adult tricolored blackbirds are dependent on geographic location and the availability of local insect foods. Among the most important prey for adults provisioning nestlings include Coleopterans (beetles), Orthopterans (grasshoppers, locusts), Hemipterans (true bugs), other larval insects, and Arachnids (spiders and allies) (Crase and DeHaven 1977, Beedy and Hamilton 1999). The primary diet of a colony depends on the local food availability (large hatches of dragonflies [Odonata] are especially favorable to this species [Meese pers. comm. as cited in: Yolo Natural Heritage Program 2008]). Individuals are also attracted to large outbreaks of grasshoppers (Orians 1961). Adult females require insects to form eggs, and nestlings require insects because they are unable to digest plant materials until they are at least 9 days old and ready to leave their nests (Beedy and Hamilton 1999). During the non-breeding season, tricolored blackbirds often congregate at dairy feedlots to consume grains and other livestock feed, while others forage on insects, grains, and other plant material in grasslands and agricultural fields (Skorupa et al. 1980, Beedy and Hamilton 1999).

A18.5 Threats and Stressors

Habitat Loss and Alteration. The most significant historical and ongoing threat to the tricolored blackbird is habitat loss and alteration. The initial conversion from native landscapes to agriculture removed vast wetland areas in the state and caused initial declines in populations. The more-recent conversion of suitable agricultural lands to urban areas has permanently removed historical breeding and foraging habitat for this species.

In urbanizing areas, habitat fragmentation and proximity to human disturbances has also led to abandonment of large historical colonies (Beedy and Hamilton 1999).

In Sacramento County, a historical breeding center of this species, the conversion of grassland and pastures to vineyards expanded from 7,537 acres in 1996, to 13,171 acres in 1998 (DeHaven 2000), to 16,709 acres in 2003 (California Agricultural Statistics Service, http://www.nass.usda.gov/ca). Conversions of pastures and grasslands to vineyards in Sacramento County and elsewhere in the species' range in the Central Valley have resulted in the recent loss of several large colonies and the elimination of extensive areas of suitable foraging habitat for this species (Cook 1999, DeHaven 2000, Hamilton 2004, Yolo Natural Heritage Program 2008).

Direct Mortality During Crop Harvest. Entire colonies (up to tens of thousands of nests) in cereal crops and silage are often destroyed by harvesting and plowing of agricultural lands (Beedy and Hamilton 1999, Hamilton 2004, Cook and Toft 2005). While adult birds can fly away, eggs and fledglings cannot. The concentrations of a high proportion of the known population in a few breeding colonies increases the risk of major reproductive failures, especially in vulnerable habitats such as active agricultural fields (Yolo Natural Heritage Program 2008).

Predation. Historical accounts documented the destruction of nesting colonies by a diversity of avian, mammalian, and reptilian predators (Beedy and Hamilton 1999). Recently, especially in perennial freshwater marshes of the Central Valley, entire colonies have been lost to black-crowned night-herons *(Nycticorax nycticorax)* and common ravens *(Corvus corax)*. Recently, cattle egrets *(Bubulcus ibis)* have been observed preying on tricolored blackbird nests, and at one colony in Tulare County, more than 125 egrets were present throughout the breeding season (Meese 2007). Some large colonies (up to 100,000 adults) may lose greater than 50 percent of nests to coyotes *(Canis latrans)*, especially in silage fields, but also in freshwater marshes when water is withdrawn (Hamilton et al. 1995). Thus, water management by humans often has the effect of increasing predator access to active colonies (Yolo Natural Heritage Program 2008).

Human Disturbances. Tricolored blackbird colonies are highly sensitive to human disturbances. Close proximity to urbanizing areas can cause colonies to be permanently abandoned. Increases in noise, loose pets, and human presence can cause nest abandonment. Even entry into colonies for management or scientific purposes can cause disturbances and should be avoided (Beedy and Hamilton 1999).

Poisoning and Contamination. Various poisons and contaminants have caused mass mortality of tricolored blackbirds. McCabe (1932) described the strychnine poisoning of 30,000 breeding adults as part of an agricultural experiment. Neff (1942) considered poisoning to regulate numbers of blackbirds preying upon crops (especially rice) to be a major source of mortality. This practice continued until the 1960s, and thousands of tricolored blackbirds and other blackbirds were exterminated to control damage to rice crops in the Central Valley. Beedy and Hayworth (1992) observed a complete nesting failure of a large colony (about 47,000 breeding adults) at Kesterson Reservoir in Merced County; selenium toxicosis was diagnosed as the primary cause of death. At a colony in Kern County, all eggs sprayed by mosquito abatement oil failed to hatch (Beedy and Hamilton 1999). Hosea (1986) attributed the loss of at least two colonies to aerial herbicide applications (Yolo Natural Heritage Program 2008).

Other Conservation Issues. Important information gaps in the ecology of the species include the effects of land use changes on the reproductive success of colonies and on the distribution of wintering birds; the relationship of invertebrate prey abundance and brood size; winter distribution, diet, and survival rates; and measures of suitable foraging habitat (Beedy and Hamilton 1999, Meese 2007).

Tricolored blackbirds have been the focus of recent management concern due to population decline, very limited global range, and vulnerability of large breeding colonies to habitat losses, predation, and human-induced impacts.

A18.6 Relevant Conservation Efforts

There are no statewide, regional, or local conservation efforts that are specific to the conservation of the tricolored blackbird. However, a conservation strategy for this species was prepared recently (Tricolored Blackbird Working Group 2007). Recommendations for the species conservation (Beedy and Hamilton 1999, Hamilton 2004) include frequent monitoring of breeding and wintering population sizes, colony locations, and reproductive success; protection of colony locations and foraging habitats; protection of colonies on farmland by avoiding harvesting/tilling until young have fledged; providing adequate protection in Habitat

Conservation Plans; focusing on dairy dependence for breeding and wintering populations; developing or restoring breeding habitat near reservoirs, rice fields, alfalfa fields, and other optimal foraging habitats; and managing major predators in or near breeding colonies, including common ravens, black-crowned night-herons, cattle egrets, and coyotes when feasible.

The tricolored blackbird is also a covered species in other neighboring regional conservation plans, including the approved San Joaquin County Multi-species Habitat Conservation and Open Space Plan, the East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan, and the Natomas Basin Habitat Conservation Plan. It is proposed for coverage in the in-progress South Sacramento County Habitat Conservation Plan, the Solano County Multispecies Habitat Conservation Plan, the Yolo County Natural Heritage Program Plan, and the Butte Regional Conservation Plan.

A18.7 Species Habitat Suitability Model

Model Approach. BDCP Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which are incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and revise the vegetation input data as necessary.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements, and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate, as well as overestimate, the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small, isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; instead, the models indicate that non-habitat areas have a much lower probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percentage cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf (2007). Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers; connectivity between habitat types; and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or underestimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The tricolored blackbird model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), USDA 2005 aerial photography, and DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable tricolored blackbird habitat in the Plan Area according to the species' two primary life requisites, nesting habitat and foraging habitat. Vegetation types were assigned to a suitability category based on the species requirements, as described above, and the assumptions described below.

Nesting Habitat. There are few reported historical occurrences of tricolored blackbird breeding colonies within the Plan Area (Neff 1937, Beedy et al. 1991, CNDDB 2008), and few recent occurrences (University of California, Davis 2008). This is likely due in part to the lack of breeding habitat throughout most of the Delta. The 2009 California Department of Water Resources (DWR) surveys identified two confirmed breeding sites, one in the central Delta and one north and west of the Sacramento River in the north Delta. A large colony of over 30,000 breeding adults was also found in the Yolo Bypass north of Interstate 80 in 2007 (Meese 2007).

Potentially suitable breeding habitat within the Plan Area consists of all bulrush (*Scirpus*[2] spp.) and cattail (*Typha* spp.) alliances and blackberry (*Rubus* spp.) brambles located within 500 m of open water. Nesting habitat in the Delta consists of the following types from the BDCP composite vegetation layer:

- Managed wetlands

[2] Currently known as *Schoenoplectus*.

- o *Scirpus* spp. in managed wetlands.
- Freshwater perennial emergent wetlands
    - o Broad-leaf cattail *(Typha latifolia).*
- Tidal freshwater emergent wetland and tidal brackish emergent wetland
    - o Mixed *Scirpus* mapping unit;
    - o Mixed *Scirpus*/floating aquatics complex;
    - o Mixed *Scirpus*/submerged aquatics complex;
    - o Hard-stem bulrush *(Scirpus acutus);*
    - o *Scirpus acutus* pure;
    - o *Scirpus acutus – Typha angustifolia;*
    - o *Scirpus acutus – Typha latifolia;*
    - o *Scirpus acutus – (Typha latifolia) – Phragmites australis;*
    - o California bulrush *(Scirpus californicus);*
    - o *Scirpus californicus – Eichhornia crassipes;*
    - o *Scirpus californicus – Scirpus acutus;*
    - o American bulrush *(Scirpus americanus);*
    - o Narrow-leaf cattail *(Typha angustifolia);* and
    - o *Typha angustifolia – Distichlis spicata.*
- Nontidal freshwater perennial emergent
    - o American bulrush (*Scirpus americanus*);
    - o Hard-stem bulrush (*Scirpus acutus*);
    - o Mixed *Scirpus*/floating aquatics (*Hydrocotyle – Eichhornia*) complex;
    - o Mixed *Scirpus*/submerged aquatics (*Egeria-Cabomba-Myriophyllum* spp.) complex;
    - o Mixed *Scirpus* mapping unit;
    - o Broad-leaf cattail *(Typha latifolia);*

- *Salix gooddingii*/*Rubus discolor;* and
- Giant cane *(Arundo donax).*

Nesting habitat in the Suisun Marsh and Yolo Basin consists of the following types from the BDCP composite vegetation layer:

- *Scirpus (californicus or acutus)/rosa;*
- *Scirpus (californicus or acutus)*/wetland herb;
- *Scirpus (californicus or acutus)-Typha* spp.;
- *Scirpus americanus* (generic);
- *Scirpus americanus/Lepidium;*
- *Scirpus americanus/Potentilla;*
- *Scirpus californicus/S. acutus;*
- *Scirpus maritimus;*
- *Scirpus maritimus/Salicornia*[3]*;*
- *Typha angustifolia/Distichlis;*
- *Typha angustifolia/S. americanus;*
- *Typha* species (generic);
- Bulrush - Cattail freshwater marsh NFD super alliance;
- *Scirpus americanus/S. californicus-S. acutus;*
- *Scirpus maritimus/Sesuvium;*
- *Typha angustifolia;*
- *Typha angustifolia/Phragmites;*
- *Typha angustifolia/Polygonum-Xanthium-Echino;* and
- *Typha angustifolia/S. americanus.*

[3] Currently known as *Sarcocornia*.

Assumptions. Beedy et al (1991) reported breeding colonies occupying sites as small as 0.1 acre. Therefore, all potentially suitable vegetation types are considered potential breeding habitats regardless of patch size. The mapping unit size of 1 acre may contribute to underestimating the extent of suitable breeding habitat in the Plan Area. Hamilton (2004) reported that open water within 500 m of nesting substrate is a requirement for colony settlement.

Other important factors regarding the selection of breeding sites include the condition of the vegetation and the extent of open water associated with emergent vegetation along canals. For example, Hamilton (2004) suggests that cattail marsh that has not been recently burned may be too dense and preclude settlement. Hamilton (2004) also suggests that strips of emergent vegetation along canals that are less than 10 m wide may be avoided due to insufficient open water habitat. However, because these factors cannot be adequately identified using the available mapping tools, for purposes of this model, all potentially suitable vegetation types are considered potential breeding habitats, regardless of condition, and all potentially suitable habitat along canals is considered potential breeding habitat, regardless of canal width. Thus, this aspect of the model may contribute to overestimating potentially suitable breeding habitat.

Foraging Habitat. Breeding season foraging habitat consists of all grassland, managed wetland, and natural seasonal wetland categories, and most agricultural lands, with the exception of vineyards and orchards and other perennial crops within 13 km (8 miles) of potentially suitable breeding habitat. Winter season foraging habitat consists of all of these categories without distance restrictions.

Non-agricultural foraging habitat in the Delta consists of the following types from the BDCP composite vegetation layer:

- Grassland
    - All types.
- Managed wetland
    - All types.
- Alkali seasonal wetland complex
    - All types.
- Other natural seasonal wetland
    - All types.
- Vernal pool complex
    - Annual grasses generic;
    - Annual grasses/weeds;

  - California annual grasslands;
  - *Distichlis* (generic);
  - *Distichlis spicata;*
  - *Distichlis spicata* – annual grasses;
  - *Distichlis*/annual grasses;
  - *Distichlis*/*S. Maritimus;*
  - Ruderal herbaceous grasses and forbs;
  - Italian rye-grass *(Lolium multiflorum);*
  - *Salicornia virginica*[4]*;* and
  - *Salicornia*/annual grasses.

Non-agricultural foraging habitat in the Suisun Marsh and Yolo Basin consists of the following types from the BDCP composite vegetation layer:

- *Bromus* spp./*Hordeum;*
- *Crypsis schoenoides;*
- *Crypsis* spp. – wetland grasses – wetland forbs;
- Cultivated annual graminoid;
- *Cynodon dactylon;*
- *Distichlis*/annual grasses;
- *Distichlis* (generic);
- *Distichlis spicata;*
- *Distichlis*/annual grasses;
- *Distichlis/Cotula;*
- *Distichlis/Juncus;*
- *Distichlis/Lotus;*
- *Distichlis/S. americanus;*
- *Distichlis/S. maritimus;*
- *Distichlis/Salicornia;*
- *Distichlis-Juncus-Triglochin-Glaux;*
- *Hordeum/Lolium;*

[4] Currently known as *Sarcocornia pacifica*.

- *Lotus corniculatus;*
- Medium upland herbs;
- Medium wetland graminoids;
- Medium wetland herbs;
- Pasture;
- Perennial grass;
- Short upland graminoids;
- Short wetland graminoids;
- Tall wetland graminoids;
- Upland annual grasslands and forbs formation; and
- Upland herbs.

A18.7.1 Agriculture

The following DWR 2007 land use survey types are included as suitable agricultural foraging habitats for tricolored blackbirds. These types represent the typical agricultural crop types and uses in the Plan Area that are included in the DWR 2007 land use survey. Rotational crop types that are not common to the Plan Area are not included here. Pasture types are mostly perennial; alfalfa is semi-perennial (3 to 7 years); and all other types are annually or seasonally rotated irrigated crops, only some of which provide suitable habitat for tricolored blackbirds.

- Grain and hay crops
    - Barley;
    - Wheat;
    - Oats; and
    - Miscellaneous and mixed grain and hay.
- Field crops
    - Safflower;
    - Sugar beets;
    - Corn;
    - Grain sorghum;
    - Sudan;
    - Beans;
    - Miscellaneous field; and
    - Sunflowers.
- Pasture

  - Alfalfa and alfalfa mixtures;
  - Clover;
  - Mixed pasture;
  - Native pasture;
  - Induced high water table native pasture; and
  - Miscellaneous grasses.
- Truck, nursery, and berry crops
  - Asparagus;
  - Beans;
  - Onions and garlic;
  - Tomatoes; and
  - Peppers.
- Idle
  - Land not cropped the current or previous crop season, but cropped within the past three years; and
  - New lands being prepped for crop production.
- Semiagricultural and incidental to agricultural
  - Livestock feed lots; and
  - Dairies.

Assumptions. During the breeding season, tricolored blackbirds usually forage within 5 km (3.1 miles) of the colony, but can range up to 13 km (8 miles) from the colony (Beedy and Hamilton 1999). However, during the winter, the species forages widely throughout the Plan Area without regard to proximity of colony sites or breeding habitats.

Suitable agricultural lands generally include pasturelands, grain and hay crops, safflower and sorghum, and certain other annually rotated irrigated crops. Tricolored blackbirds also forage in livestock feedlots, dairies, and poultry farms. Not all agricultural crop types are considered suitable for foraging, but because the Grain and hay; Field; and Truck, nursery, and berry crop types listed above are seasonally rotated, the value of individual fields changes each year. Therefore, these crop types are not differentiated based on their seasonal value and are instead combined into a category of seasonally rotated croplands. As a result, this model overestimates the extent of available agricultural foraging habitat in any given year.

A18.8 RECOVERY GOALS

A USFWS recovery plan has not been prepared for this species, and no recovery goals have been established.

Feliz, Dave. California Department of Fish and Game, Refuge Manager – Yolo Bypass Wildlife Area. Comments from earlier draft report.

APPENDIX A19. SUISUN SONG SPARROW (*MELOSPIZA MELODIA MAXILLARIS*)

A19.1 LEGAL STATUS

The Suisun song sparrow *(Melospiza melodia maxillaris)* has no federal legal status. A petition for listing it as a federal endangered species was submitted in 1987, but the U.S. Fish and Wildlife Service (USFWS) considered the petition unwarranted.

The species is a third priority California Bird Species of Special Concern (Spautz and Nur 2008).

A19.2 SPECIES DISTRIBUTION AND STATUS

A19.2.1 Range and Status

The Suisun song sparrow is one of 24 subspecies of *Melospiza melodia*, and one of three that occur in the San Francisco Bay estuary (Modesto song sparrow *[M.m. mailliardi]* may be a fourth subspecies; however, its taxonomic status is currently under review, and further research is necessary to determine its status as a valid subspecies [Gardali 2008]). *M.m. samuelis* occurs in salt marshes of north San Francisco and San Pablo bays, and *M.m. pusillula* occurs in salt marshes of south San Francisco Bay. The Suisun song sparrow is endemic to the salt marshes of the Suisun Bay, and while it has been confirmed to be phenotypically distinct from neighboring subspecies (Patten 2001), genetic differentiation has not been confirmed (Chan and Arcese 2002). Its year-round range is confined to tidal salt and brackish marshes of the Suisun Bay area from the Carquinez Strait east to Antioch at the confluence of the San Joaquin and Sacramento rivers (Grinnell and Miller 1944, Spautz and Nur 2008). The current range remains relatively unchanged since Grinnel and Miller's (1944) description. However, the current distribution of the species within this area is defined by the extent of remaining tidal marsh habitats, which occur primarily along the fringes of the Carquinez Strait and Suisun Bay (Figure A-19a).

Spautz and Nur (2008), citing unpublished data from the Point Reyes Bird Observatory, estimated the total population of Suisun song sparrows as 43,000 to 66,000 breeding pairs, approximately one-third of the estimated historical population size (Spautz and Nur 2008). The subspecies occurs in virtually every tidal marsh in Suisun Bay; however, densities differ widely based on habitat conditions and suitability (Spautz and Nur 2008).

A19.2.2 Distribution and Status in the Plan Area

The range of the Suisun song sparrow extends into the Plan Area to approximately Kimbal Island. However, the majority of the range of the species is included within the Suisun Marsh Restoration Opportunity Area (Figure A-19b). There are several reported occurrences from Kimbal Island, Browns Island, and in the Suisun Marsh in the western portion of the Plan Area.
