<u>Progress Report on the Bay Delta Conservation Plan</u>
April 28, 2006 - November 18, 2010

The members of the Bay Delta Conservation Plan (BDCP) Steering Committee provide this memorandum reporting on our progress in developing a plan to achieve the co-equal goals of restoring the ecosystem and water supply reliability of the Sacramento-San Joaquin River Delta. The November 18, 2010 draft of the plan, which is a work in progress as described in paragraph 4 below, is attached. This is the first time the draft plan has been compiled in one place and provides an opportunity for the Steering Committee and members of the public to review and formulate opinions about how to best proceed with further development and revisions of the plan in 2011.

1. Under our Planning Agreement (2006, amended 2009), the BDCP is intended to establish a conservation strategy for the Delta infrastructure and operations of the State Water Project and Central Valley Project, as well as the powerplant operations of Mirant Corporation. It is specifically intended to assure that these and any other covered activities comply with the requirements of the federal and state Endangered Species Act, Natural Community Conservation Planning Act, and other applicable laws, over a plan term up to 50 years.

2. The Steering Committee consists of the California Department of Water Resources, the U.S. Bureau of Reclamation, federal (*ex officio* members) and state permitting agencies, water contractors, environmental organizations, and other stakeholders. Pursuant to the Delta Reform Act of 2009, the Delta Stewardship Council participates as an Interested Observer. As provided in the Planning Agreement, meetings of the Steering Committee are open to the public. Since formation, the Steering Committee has met 122 times to review scientific analyses, other planning documents, and draft plan chapters, while taking public comments into account. The Steering Committee convened various subcommittees and workgroups, and commissioned independent scientific reviews, which substantially assisted in plan development. On a parallel track, lead State and Federal agencies initiated environmental review under the National Environmental Policy Act and California Environmental Quality Act. The cumulative investment by members, consultants, other stakeholders and members of the public in this planning process exceeds several hundred thousand hours of time, reflecting the extraordinary importance – and difficulty – of preparing such a complex conservation plan that includes redesigning the Delta water supply infrastructure (built several generations ago) to advance co-equal goals in this highly altered ecosystem.

3. The November 18, 2010 draft represents the progress toward a conservation strategy intended to achieve the co-equal goals, as described in "Points of Agreement" (2007) and "An Overview of the Draft Conservation Strategy for the BDCP" (2009). The approach includes integrated elements: new conveyance infrastructure and operational criteria, restoration of habitat for covered species and their communities, measures to address stressors other than water supply operations, and provisions for adaptive management over the plan term.

4. The Steering Committee has reviewed various drafts of most plan chapters over the course of the past four years. As of November 18, 2010, the draft plan includes chapters and sub-chapters

that have undergone varying levels of input and review by the Steering Committee, including portions that have been reviewed and revised multiple times as well as new and revised language that has not yet been reviewed. On the whole, some elements of this plan are clearly defined, while others are incomplete, disputed among members, or otherwise under development, as indicated in editorial notes to reviewers in the chapters.

5. The Steering Committee believes that we have made substantial progress towards a complete plan. As stated in the Points of Agreement and Overview, and again in this draft, an integrated conservation strategy that addresses habitat and other stressors, as well as operational rules for the water supply projects, will be necessary to restore the ecosystem.

6. Recognizing the vital importance of this effort, the Steering Committee will continue to work on the remaining elements of this plan. Editorial notes in the plan chapters highlight those elements. One critical task is resolution of scientific issues related to the complex set of analytical methods to evaluate the benefits for covered species (Chapter 5). Once these issues are resolved, the analysis will be used to test the effectiveness and indicate the need for potential modifications of the conservation strategy. Related tasks include further development of plan objectives for ecosystem benefits (Chapter 3.3), regulatory assurances (Chapter 6.3), and iterative use of the effects analysis to refine the conservation measures. In addition, the Steering Committee must review and revise the current draft to assure that all prior comments on all chapters have been adequately addressed and resolved.

7. Our Planning Agreement as amended in 2009 provides that the draft plan and the associated draft Environmental Impact Statement/Report will be completed in 2011. The members of the Steering Committee commit to continue to work in a cooperative and open process to assist in the expeditious completion of a science-based and legally sufficient draft plan that will achieve the co-equal goals of Delta ecosystem restoration and water supply reliability.

Working Draft

Bay Delta Conservation Plan

November 18, 2010

*[**Note to Reviewers**: This November 18, 2010 working draft of the Bay Delta Conservation Plan (BDCP) contains chapters and major chapter sections that are in different stages of development by the SAIC Consultant Team and review by the BDCP Steering Committee. The BDCP Steering Committee members have submitted comments to various drafts of the chapters and chapter sections during development, which may or may not have been incorporated into this November 18, 2010 draft. Addressing such comments will be part of the continuing process of developing the BDCP. While the text of this document is subject to change and revision as the BDCP planning process progresses, the document has been drafted and formatted to appear as it may in a completed draft HCP/NCCP. Although the document includes declarative statements (e.g., the Implementation Office will…), it is nonetheless a "working draft" that will undergo further modification based on input from the BDCP Steering Committee, state and federal agencies, and the public.]*

TABLE OF CONTENTS

CHAPTER 1. INTRODUCTION
1.1 Background 1-1
1.1.1 BDCP Steering Committee and the Planning Agreement 1-3
1.2 BDCP Planning Goals and Conservation Objectives 1-6
1.3 Regulatory Context 1-7
1.3.1 Regulatory Purpose of the BDCP 1-7
1.3.2 The Federal Endangered Species Act 1-9
1.3.3 Natural Community Conservation Planning Act 1-12
1.3.4 California Endangered Species Act 1-13
1.3.5 The National Environmental Policy Act 1-13
1.3.6 The California Environmental Quality Act 1-14
1.3.7 Relationship with Existing Biological Opinions 1-14
1.3.8 Recent California Legislation Relating to Water and the Sacramento-San Joaquin Delta 1-14
1.3.9 Relationship between the BDCP and Other Federal and State Laws and Regulations 1-15
1.4 Scope of the BDCP 1-20
1.4.1 Geographic Scope of the Plan Area 1-20
1.4.2 Natural Communities 1-21
1.4.3 Covered Species 1-22
1.4.4 Covered Activities and Associated Federal Actions 1-29
1.4.5 Permit Duration 1-30
1.5 Overview of the Planning Process 1-30
1.5.1 Role of the Steering Committee 1-30
1.5.2 Public Participation and Engagement 1-31
1.5.3 Integration of Science 1-33
1.6 Organization of the BDCP 1-37

CHAPTER 2. EXISTING ECOLOGICAL CONDITIONS
2.1 Introduction 2-1
2.2 Historical Conditions 2-3
2.2.1 Hydrologic and Geomorphic Conditions 2-3
2.2.2 Biological Conditions 2-6
2.3 Existing Ecological Conditions 2-8
2.3.1 Data Sources and Natural Community Classification 2-8
2.3.2 Ecosystem Processes 2-13
2.3.3 Physical Environment 2-23
2.3.4 Natural Communities 2-51
2.3.5 Covered Species 2-134
2.4 Biological Diversity 2-136

CHAPTER 3. CONSERVATION STRATEGY

3.1 Introduction ... 3-1
3.1.1 Biological Goals and Objectives ... 3-5
3.1.2 Conservation Measures ... 3-5
3.1.3 Monitoring, Research, and Adaptive Management ... 3-7
3.2 Methods and Approaches Used to develop the Conservation Strategy ... 3-7
3.2.1 Framework for the Conservation Strategy ... 3-7
3.2.1.1 The Importance of Adaptive Management, Monitoring, and Research ... 3-10
3.2.1.2 The Timing and Interrelatedness of Conservation Measures ... 3-11
3.2.2 Identifying Conservation Zones and Restoration Opportunity Areas ... 3-12
3.2.3 Development of the Aquatic Resources Component of the Conservation Strategy ... 3-34
3.2.3.1 Aquatic Resources Conservation Strategy Development Process ... 3-36
3.2.3.2 Stressors Affecting Covered Fish Species ... 3-37
3.2.3.3 Water Facilities and Operations ... 3-39
3.2.3.4 Physical Habitat Restoration ... 3-41
3.2.3.5 Measures to Address Other Stressors ... 3-42
3.2.4 Development of the Terrestrial Resources Component of the Conservation Strategy ... 3-43
3.2.4.1 Conservation Targets ... 3-44
3.2.4.2 Assembly of Conservation Lands ... 3-52
3.3 Biological Goals and Objectives ... 3-64
3.3.1 Framework for the Goals and Objectives ... 3-68
3.3.2 Goal and Objective Statements ... 3-71
3.3.2.1 Ecosystem Goals and Objectives ... 3-71
3.3.2.2 Natural Community Goals and Objectives ... 3-75
3.3.2.3 Covered Fish Species Goals and Objectives ... 3-140
3.3.2.4 Covered Wildlife and Plant Species Goals and Objectives ... 3-153
3.4 Conservation Measures ... 3-288
3.4.1 Development Process ... 3-300
3.4.2 Ecosystem-Level Conservation Measures ... 3-301
3.4.2.1 CM1 Water Facilities and Operation ... 3-302
3.4.2.2 CM2 Yolo Bypass Fishery Enhancement ... 3-333
3.4.2.3 CM3 Natural Communities Protection ... 3-343
3.4.3 Natural Community-Level Conservation Measures ... 3-359
3.4.3.1 CM4 Tidal Habitat Restoration ... 3-360
3.4.3.2 CM5 Seasonally Inundated Floodplain Restoration ... 3-374
3.4.3.3 CM6 Channel Margin Habitat Enhancement ... 3-379
3.4.3.4 CM7 Riparian Habitat Restoration ... 3-383
3.4.3.5 CM8 Grassland Communities Restoration ... 3-386
3.4.3.6 CM9 Vernal Pool Complex Restoration ... 3-388
3.4.3.7 CM10 Nontidal Marsh Restoration ... 3-391
3.4.3.8 CM11 Natural Communities Enhancement and Management ... 3-393
3.4.4 Species Level Other Stressor Conservation Measures ... 3-403
3.4.4.1 CM12 Methylmercury Management ... 3-404

3.4.4.2 CM13 Nonnative Aquatic Vegetation Control ... 3-407
3.4.4.3 CM14 Stockton Deep Water Ship Channel Dissolved Oxygen Levels ... 3-412
3.4.4.4 CM15 Predator Control ... 3-414
3.4.4.5 CM16 Non-Physical Fish Barriers ... 3-417
3.4.4.6 CM17 Hatchery and Genetic Management Plans ... 3-421
3.4.4.7 CM18 Illegal Harvest ... 3-424
3.4.4.8 CM19 Conservation Hatcheries ... 3-425
3.4.5 Avoidance and Minimization Measures ... 3-428
3.4.5.1 General Avoidance and Minimization Measures ... 3-429
3.4.5.2 Avoidance and Minimization Measures for Covered Natural Communities ... 3-436
3.4.5.3 Species-Specific Avoidance and Minimization Measures ... 3-438
3.5 Potential Conservation Measures to Address Other Stressors ... 3-446
3.5.1 Introduction ... 3-446
3.5.2 Implementation of Potential Conservation Measures to Address Other Stressors ... 3-447
3.5.3 Descriptions of Potential Conservation Measures to address Other Stressors ... 3-448
3.6 Monitoring and Research Program ... 3-448
3.6.1 Responsibility for the Monitoring and Research Program ... 3-451
3.6.2 Monitoring Framework ... 3-452
3.6.3 Integration of Monitoring and Research with Other Programs ... 3-453
3.6.4 Types of Monitoring ... 3-455
3.6.4.1 Preconstruction Surveys ... 3-455
3.6.4.2 Construction Monitoring ... 3-456
3.6.4.3 Compliance Monitoring ... 3-456
3.6.4.4 Baseline Surveys ... 3-456
3.6.4.5 Effectiveness Monitoring ... 3-457
3.6.5 Potential BDCP Monitoring Actions and Metrics ... 3-459
3.6.6 Development of Specific Monitoring Plans ... 3-460
3.6.7 Research Program ... 3-461
3.6.8 Database Development and Maintenance ... 3-462
3.6.9 Monitoring and Research Schedule ... 3-463
3.6.10 Reporting and Science Communication ... 3-464
3.7 Adaptive Management Program ... 3-569
3.7.1 Adaptive Management Process Framework ... 3-571
3.7.1.1 Plan Objectives and the Knowledge Base ... 3-575
3.7.1.2 Collect and Manage Data ... 3-575
3.7.1.3 Analyze Data, Assimilate Information, and Develop and Recommend Adjustments to Implementation. ... 3-576
3.7.1.4 Implement Modified Conservation Measures, Tools, Metrics, and Targets ... 3-578
3.7.2 Adaptive Management Decision Making Process ... 3-580
3.7.2.1 Roles and Responsibilities ... 3-580
3.7.2.2 Adaptive Management Decisions and Responses (Not Related to Water Operations) ... 3-581
3.7.2.3 Internal Scientific Review ... 3-583

3.7.2.4 External Independent Scientific Review 3-583
3.7.3 Concept of a "Defined Adaptive Range" and Water Operations Adaptive Management 3-583
3.7.3.1 Water Operations Adaptive Range 3-584
3.7.3.2 Decision Process for Adjusting Water Operations within the Adaptive Range 3-584
3.7.4 Concept of Adaptive Management Triggers 3-585
3.7.5 Adaptive Management Experiments 3-586
3.7.5.1 Targeted Research 3-586
3.7.5.2 Management-Oriented Conceptual Models 3-586
3.7.6 Database Development and Reporting 3-588
3.7.7 Program Status Reviews 3-588
3.7.8 Public Involvement 3-588

CHAPTER 4. DESCRIPTION OF COVERED ACTIVITIES AND ASSOCIATED FEDERAL ACTIONS

4.1 Introduction 4-1
4.1.1 History and Overview of the SWP and CVP 4-3
4.1.2 Overview of Covered Activities and Associated Federal Actions 4-7
4.2 Covered Activities 4-8
4.2.1 Operations and Maintenance of Existing SWP Facilities 4-9
4.2.2 New Water Facilities Construction, Operations and Maintenance 4-14
4.2.3 Power Generation Water Use - Mirant Delta, LLC 4-22
4.2.4 Habitat Restoration, Enhancement, and Management Activities 4-26
4.2.5 Activities to Reduce Contaminants 4-29
4.2.6 Activities to Reduce Predators and Other Sources of Direct Mortality 4-29
4.2.7 Monitoring and Research Programs 4-30
4.2.8 Other Conservation Actions 4-30
4.2.9 Emergency Actions 4-30
4.3 Federal Actions Associated with the BDCP 4-31
4.3.1 CVP Operations and Maintenance 4-31
4.4 Joint Federal and Non-federal Actions 4-37
4.4.1 Joint Point of Diversion Operations 4-37
4.4.2 Operations of New Water Intake and Conveyance Facilities 4-38
4.4.3 Transfers 4-39
4.4.4 Suisun Marsh Facilities Operations and Maintenance 4-39

CHAPTER 5. OVERVIEW OF THE EFFECTS ANALYSIS

5.1 Introduction 5-2
5.1.1 Regulatory Scope 5-4
5.1.2 Spatial Scope 5-4
5.1.3 Actions Evaluated 5-5
5.1.4 Existing Biological Conditions 5-5
5.1.5 Temporal Scope 5-5
5.1.6 Approach to the Analysis 5-6
5.2 Status of the Effects Analysis 5-8
5.3 Methodology 5-11
5.3.1 Analytical Tools and Assumptions 5-13

5.3.2 System-Level Analysis Approach to Support Assessments 5-18
5.3.3 Fish Species Assessment Methods... 5-21
5.3.4 Killer Whale Analysis Methods.. 5-24
5.3.5 Natural Community Assessment Methods.. 5-25
5.3.6 Covered Wildlife and Plant Species Assessment Methods.............................. 5-27
5.4 Summary of Results 5-28
5.4.1 Covered Fish Species 5-28
5.4.2 Natural Communities 5-72
5.4.3 Covered Wildlife and Plant Species 5-83

CHAPTER 6. PLAN IMPLEMENTATION

6.1 Plan Implementation Schedule 6-2
6.1.1 Ecosystem-Level Conservation Measures 6-7
6.1.2 Natural Community-Level Conservation Measures 6-12
6.1.3 Species-Level Other Stressors Conservation Measures.................................. 6-21
6.2 Compliance and Progress Reporting... 6-22
6.2.1 Annual Workplan and Budget 6-24
6.2.2 Annual Water Operations Plan 6-24
6.2.3 Annual Progress Report 6-25
6.2.4 Annual Water Operations Report... 6-28
6.2.5 6.2.5 Five-Year Comprehensive Review 6-28
6.2.6 Five Year Implementation Plan 6-30
6.3 Regulatory Assurances and Changed Circumstances and Unforeseen Circumstances 6-30
6.3.1 Regulatory Assurances... 6-30
6.3.2 Changed Circumstances... 6-32
6.3.3 Unforeseen Circumstances... 6-44
6.3.4 Applicability of Other Federal Endangered Species Act Issues to the BDCP 6-45
6.4 Permit Duration and Renewal, Plan Amendments, Permit Suspension and Revocation 6-46
6.4.1 Permit Duration and Extension.. 6-46
6.4.2 BDCP Administrative Actions That Do Not Require Modification or Amendment.. 6-46
6.4.3 Minor Modifications or Revisions... 6-47
6.4.4 Formal Amendment 6-48
6.4.5 Suspension of the Federal Permits... 6-49
6.4.6 Suspension or Revocation of the State Permit.. 6-51

CHAPTER 7. IMPLEMENTATION STRUCTURE

7.1 Roles and Responsibilities of Entities Involved in BDCP Implementation 7-2
7.1.1 The BDCP Program Manager and Implementation Office.............................. 7-2
7.1.2 Authorized Entities 7-7
7.1.3 Implementation Board 7-9
7.1.4 DWR and Reclamation: Operation of the SWP and CVP 7-11

7.1.5 Permitting Agencies: Fish and Wildlife Agencies 7-11
7.1.6 Other Regulatory Agencies 7-13
7.1.7 Implementation Facilitation Team 7-13
7.1.8 Supporting Entities 7-14
7.1.9 BDCP Stakeholder Committee 7-15
7.1.10 The General Public 7-16
7.2 Implementation Office Administration 7-16
7.2.1 Establishing Administrative Capacity 7-17
7.2.2 Preparing Budgets and Managing Expenditures 7-17
7.2.3 Contracting for Services 7-17
7.2.4 Securing, Holding, and Managing Funds to Support Implementation Actions 7-18
7.2.5 Coordinating with the Authorized Entities and Supporting Entities 7-18
7.2.6 Coordinating with Regulatory Agencies – Facilitation Team 7-18
7.2.7 Coordinating with the Delta Stewardship Council, Delta Science Program, and Delta Conservancy 7-18
7.2.8 Coordinating with Local Governments, Delta Protection Commission, and Other Public Agencies 7-19
7.2.9 Coordinating with Flood Control Agencies 7-19
7.2.10 Protecting and Defending Against Legal Challenges 7-19
7.2.11 Overseeing Plan Amendments 7-20
7.2.12 Implementing Mitigation Measures Identified in BDCP-related Environmental Documentation under NEPA and CEQA 7-20
7.2.13 Undertaking Other Responsibilities 7-20
7.3 Implementation of the Conservation Strategy 7-20
7.3.1 Implementation of the Habitat Protection and Restoration Conservation Measures 7-20
7.3.2 Implementation of Water Operations Conservation Measures 7-22
7.3.3 Implementation of All Other Conservation Measures 7-25
7.3.4 Management of Biological Monitoring, Scientific Research, and Reporting Programs 7-26
7.3.5 Management of the Adaptive Management Program 7-27
7.3.6 Implementation of Measures in Response to Changed Circumstances 7-27
7.4 Regulatory Compliance Related to BDCP Implementation 7-28
7.4.1 Maintaining Permits/Authorizations and Obtaining Amendments 7-28
7.4.2 Obtaining Additional Regulatory Authorizations 7-28
7.5 Public Outreach 7-29

CHAPTER 8. IMPLEMENTATION COSTS AND FUNDING SOURCES

8.1 Introduction 8-1
8.1.1 Scope and Purpose of the Cost Analysis 8-2
8.1.2 Organization of Chapter 8-4
8.2 Common Assumptions for Cost Estimation 8-4
8.2.1 Cost Periods 8-4

8.2.2 Cost Ranges 8-4
8.2.3 Cost Contingency 8-5
8.2.4 Financial Assumptions 8-5
8.2.5 Delta Real Estate Values 8-5
8.2.6 Transaction Costs Associated with the Acquisition of Interests in Land 8-7
8.2.7 Employee Salary Costs and Benefits Multiplier 8-8
8.3 Cost Estimate for Conservation Measures 8-8
8.3.1 CM1: Water Facilities and Operation 8-8
8.3.2 CM2: Yolo Bypass Fisheries Enhancements 8-16
8.3.3 CM3: Natural Communities Protection 8-21
8.3.4 CM4: Tidal Habitat Restoration 8-23
8.3.5 CM5: Seasonally Inundated Floodplain Restoration 8-28
8.3.6 CM6: Channel Margin Habitat Enhancement 8-32
8.3.7 CM7: Riparian Habitat Restoration 8-32
8.3.8 CM8: Grassland Communities Resotration 8-34
8.3.9 CM9: Vernal Pool Complex Restoration 8-35
8.3.10 CM10: Nontidal Marsh Restoration 8-37
8.3.11 CM11: Natural Communities Enhancement and Management 8-38
8.3.12 CM12: Methylmercury Management 8-39
8.3.13 CM13: Nonnative Aquatic Vegetation Control 8-41
8.3.14 CM14: Stockton Deep Water Ship Channel Dissolved Oxygen Levels 8-42
8.3.15 CM15: Predator Control 8-43
8.3.16 CM16: Non-Physical Fish Barriers 8-45
8.3.17 CM17: Hatchery and Genetic Management Plans 8-45
8.3.18 CM18: Illegal Harvest 8-47
8.3.19 CM19: Conservation Hatcheries 8-48
8.4 Plan Administration Cost Estimate 8-49
8.5 Monitoring/Research and Avoidance and Minimization Measures Cost Estimate 8-52
8.6 Adaptive Management Program Cost Estimate 8-52
8.7 Changed Circumstances Cost Estimate 8-52
8.8 Mitigation Measures Cost Estimate 8-56
8.9 Summary of Program Costs 8-56
8.10 Net BDCP Costs 8-61
8.11 Funding Sources and Assurances 8-61

CHAPTER 9. ALTERNATIVES TO TAKE

9.1 Introduction 9-1
9.1.1 Regulatory Standard and Evaluation Criteria 9-1

CHAPTER 10. INTEGRATION OF INDEPENDENT SCIENCE IN BDCP DEVELOPMENT

10.1 Background and Regulatory Requirements 10-1
10.2 Independent Science Advisory Process 10-2
10.3 Independent Science Reviews 10-3
10.3.1 Initial BDCP Independent Science Advisors 10-3
10.3.2 Independent Science Advisors for Non-Aquatic Resources 10-6
10.3.3 Independent Science Advisors on Adaptive Management 10-7

10.3.4 Independent Science Input on Logic Chain Approach 10-9
10.3.5 DRERIP Evaluation Process 10-10

CHAPTER 1. INTRODUCTION

1.1 BACKGROUND

The Bay Delta Conservation Plan (BDCP or "Plan") addresses the increasingly significant and intensifying conflict between the ecological needs of a number of at-risk species adversely affected by a range of human activities and the need for adequate and reliable water supplies from the Sacramento-San Joaquin River Delta (Delta) for people, communities, agriculture, and industry. The Plan sets out a comprehensive conservation strategy for the Delta designed to advance the co-equal planning goals of restoring ecological functions of the Delta and improving water supply reliability to large portions of the state of California. The BDCP reflects the outcome of a multi-year collaboration between public water agencies, state and federal fish and wildlife agencies, non-governmental organizations, agricultural interests, and the general public.

The BDCP is expected to result in long-term regulatory authorizations under state and federal endangered species laws for the operations of the State Water Project (SWP) and the Central Valley Project (CVP), as well as the operations of certain power plants owned by Mirant Delta LLC (Mirant). The Plan will further provide the basis for durable regulatory assurances. Specifically, the goal of the BDCP is to serve as a natural community conservation plan (NCCP) under the state's Natural Community Conservation Planning Act (NCCPA),[1] and a habitat conservation plan (HCP) under Section 10 of the federal Endangered Species Act (ESA). The Plan will also provide the basis for biological assessments that support new ESA Section 7 consultations between the Bureau of Reclamation (Reclamation), the U.S. Fish and Wildlife Service (USFWS), and the National Marine Fisheries Service (NMFS). The BDCP is further intended to meet the standards set out in the recently-enacted Sacramento-San Joaquin Delta Reform Act, which provides for the incorporation of the BDCP in a comprehensive management plan for the Delta (known as the "Delta Plan").[2]

Unlike past regulatory approaches, which have relied almost exclusively on iterative adjustments to the operations of the SWP and CVP, the BDCP prescribes actions that will produce fundamental, systemic and long-term physical changes to the Delta. These changes will involve substantial alterations to water conveyance infrastructure and water management regimes in combination with extensive restoration of habitat and actions to reduce the impacts of various biological stressors. It is expected that these actions will significantly enhance Delta productivity and ecological processes so as to provide for the conservation of multiple species and natural communities, while improving water supply reliability for the export contractors. To further advance this holistic approach and enhance opportunities for success, the BDCP has been designed to accommodate and respond over time to new information and greater scientific understanding of the Delta.

[1] The BDCP has also been designed to meet the regulatory standards of the California Endangered Species Act.
[2] Add citation for the Delta Reform Act.

The BDCP sets out an integrated Conservation Strategy to achieve the overarching planning goals of ecosystem restoration and water supply reliability (Section 1.2, *BDCP Planning Goals and Conservation Objectives*) and meet a range of specific biological goals and objectives (Section 3.3, *Biological Goals and Objectives*). The BDCP includes a description of each element of the Conservation Strategy and the rationale for its inclusion in the Plan. The BDCP further describes the expected contribution of each plan element toward advancing both the overall planning goals and specific biological goals and objectives. The Conservation Strategy was informed by findings and conceptual models developed over time through prior scientific efforts, including those conducted by the CALFED Science Program, and supplemented by data and analysis developed through the BDCP process. The Conservation Strategy is based on the best available science and was built upon the following scientific tenets:

- Increase the quality, availability, spatial diversity, and complexity of aquatic habitat within the Delta;
- Create new opportunities to restore the ecological health of the Delta by modifying the water infrastructure to convey water around the Delta, reducing reliance on conveyance of water through artificial and natural channels in the Delta to export pumping plants in the southern Delta;
- Directly address key ecosystem drivers unrelated to freshwater flow patterns rather than manipulation of Delta flow patterns alone;
- Improve connectivity among aquatic habitats, facilitate migration and movement of covered fish among habitats, and provide transport flows for the dispersal of planktonic material (organic carbon), phytoplankton, zooplankton, macroinvertebrates, and fish eggs and larvae;
- Improve synchrony between environmental cues and conditions and the life history of covered fish and their food resources within the upstream rivers, Delta, and Suisun Bay, including the hydrologic seasonal synchrony within the watershed, seasonal water temperature gradients, salinity gradients, turbidity, and other environmental cues;
- Reduce sources of direct mortality and other stressors on the covered fish and the aquatic ecosystem within the Delta;
- Improve habitat conditions for covered fish in upstream river reaches, within the Delta, and downstream within the low salinity zone of the estuary in Suisun Bay through the integration of water operations with physical habitat enhancement and restoration;
- Minimize adverse effects on terrestrial wildlife and plants resulting from implementation of measures to benefit aquatic species;
- Expand the extent and enhance the functions of existing natural communities and habitat of covered wildlife and plants that is permanently protected;

- Restore habitat to expand the populations and distributions of covered wildlife and plant species; and
- Rely, to the extent possible, on natural physical habitat and biological processes to support and maintain covered species and their habitat.

The BDCP covers the Sacramento-San Joaquin Delta, as defined by California Water Code Section 12220 (“statutory Delta”), as well as certain additional areas in which conservation measures set out in the Conservation Strategy will be implemented (Section 1.4.1 *Geographic Scope of the Plan Area*) (Figure 1-1). The geographic scope of the Plan Area also encompasses the areas in which the activities that have been proposed for regulatory coverage under the Plan are expected to occur.

Because the infrastructure of the state and federal water projects, however, form an integrated system that extends beyond the boundaries of the Delta, the implementation of the BDCP will affect water operations and species and habitat both inside and outside of the Delta. While the geographic scope of Plan Area generally does not include areas upstream and downstream of the Delta, the Plan will take into account and address the upstream and downstream effects of covered activities, both beneficial and adverse.

1.1.1 BDCP Steering Committee and the Planning Agreement

In January 2006, a number of stakeholders with diverse interests in the Delta, including public water agencies, environmental and conservation organizations, and other parties, agreed to a Statement of Principles that called for the development of a comprehensive conservation plan for the Delta[3]. The parties to that agreement envisioned a plan that would advance the recovery of fish and wildlife species affected by certain water supply-related activities and provide long-term assurances regarding the operation of existing and future water-related facilities and other activities associated with the SWP and the CVP.

In July 2006, several of these parties entered into a memorandum of agreement (MOA) entitled For Supplemental Funding for Certain Ecosystem Actions and Support for Implementation of Near-Term Water Supply, Water Quality, Ecosystem, and Levee Action.[4] The MOA set out the financial commitments of the parties to carry out actions to satisfy existing regulatory requirements related to the operation of the SWP and the CVP and to develop a conservation plan for the Delta that would support new regulatory authorizations under state and federal endangered species laws for current and future activities related to the SWP and CVP.

[3] Appendix H1, Jan 2006 Statement of Principles

[4] Appendix H2, MOA For Supplemental Funding for Certain Ecosystem Actions and Support for Implementation of Near-Term Water Supply, Water Quality, Ecosystem, and Levee Action, July 2006.)

DRAFT

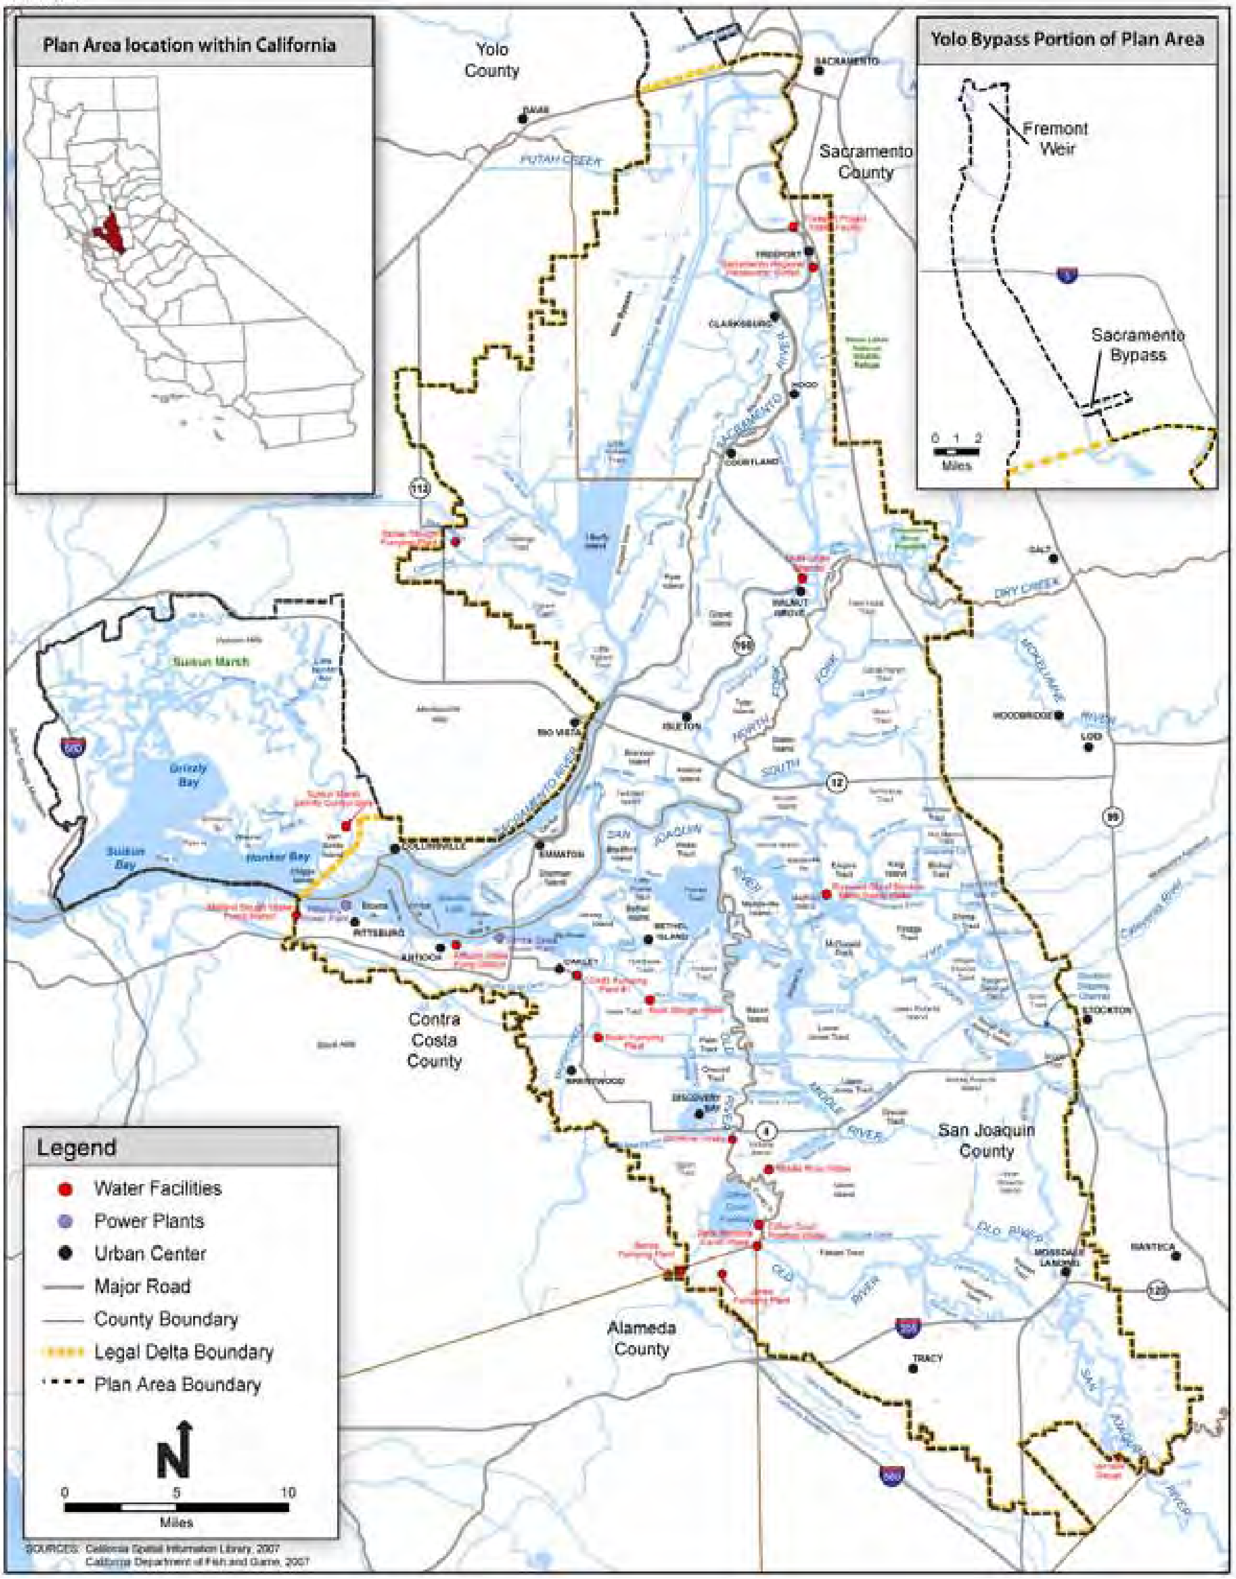

Figure 1-1. BDCP Plan Area

1

At the same time, the California Resources Agency (currently the "California Natural Resources Agency") convened a diverse group of stakeholders and regulatory agencies to help guide the development of a comprehensive conservation plan for the Delta, which became known as the BDCP. The resulting BDCP Steering Committee consisted of parties to the Statement of Principles and MOA as well as other interested groups and additional state and federal agencies, all of whom indicated their commitment to engage in a process to advance the co-equal goals of ecosystem restoration and water supply reliability (Table 1-1). The meetings of the BDCP Steering Committee were intended to serve as the principal forum within which key policy and strategy issues pertaining to the development of the BDCP would be discussed and considered. In December 2006, the original members of the Steering Committee entered into a formal Planning Agreement, consistent with requirements of the NCCPA,[5] for the development of the BDCP. The Steering Committee was expanded after December 2006, as noted in Table 1-1. The Planning Agreement, among other things, defined the goals, commitments, and expectations of the parties regarding the BDCP planning process. It also reiterated the goal of the Steering Committee to develop a conservation plan that would meet the requirements of the ESA and the NCCPA. Section 1.5, *Overview of the Planning Process*, provides a summary of the role of the Steering Committee and the various groups and teams that supported the Committee.

1.2 BDCP Planning Goals and Conservation Objectives

The overarching goals of the BDCP are to advance the restoration of the ecological functions and productivity in the Delta and improve the reliability of water supplies provided by the SWP and CVP, as first stated in the Statement of Principles and reaffirmed in the BDCP Planning Agreement. The Planning Agreement further articulated specific planning goals to guide the development of the BDCP and further ensure its consistency with the broader goals of the program. The planning goals for the BDCP are as follows:

- Provide for the conservation and management of covered species within the Plan Area;
- Preserve, restore and enhance aquatic, riparian and associated terrestrial natural communities and ecosystems that support covered species within the Plan Area through conservation partnerships;
- Allow for projects to proceed that restore and protect water supply, water quality, and ecosystem health within a stable regulatory framework;
- Provide a means to implement covered activities in a manner that complies with applicable state and federal fish and wildlife protection laws, including the California Endangered Species Act (CESA) and ESA, and other environmental laws, including the California Environmental Quality Act (CEQA) and National Environmental Policy Act (NEPA);
- Provide a basis for permits necessary to lawfully take covered species;
- Provide a comprehensive means to coordinate and standardize mitigation and compensation requirements for covered activities within the Plan Area;
- Provide a less costly, more efficient project review process which results in greater conservation values than project-by-project, species-by-species review; and
- Provide clear expectations and regulatory assurances regarding covered activities occurring within the Plan Area.

Throughout the planning process, the Steering Committee worked to develop a plan consistent with these planning goals. The BDCP reflects these goals and provides the basis for conservation and regulatory outcomes identified in the Planning Agreement.

The BDCP process was also guided by a preliminary set of conservation objectives that were first expressed in the Planning Agreement. These preliminary conservation objectives included the following:

- Provide for the protection of covered species and associated natural communities and ecosystems that occur within the Plan Area;
- Preserve the diversity of fish, wildlife, plant and natural communities within the Plan Area;
- Minimize and mitigate, as appropriate, the take of proposed covered species;
- Preserve and restore habitat and contribute to the recovery of covered species;
- Reduce the need to list additional species;
- Set forth species-specific goals and objectives;
- Set forth specific habitat-based goals and objectives;
- Implement an adaptive management and monitoring program to respond to changing ecological conditions; and
- Avoid actions that are likely to jeopardize the continued existence of covered species or result in the destruction or adverse modification of critical habitat.

These planning goals and preliminary conservation objectives set the initial direction for the BDCP planning process. As the planning process progressed, the Steering Committee began to identify specific biological goals and objectives that the BDCP would be expected to meet during its implementation. These specific biological goals and objectives are described in Section 3.3, *Biological Goals and Objectives*, and are set out in a hierarchical framework that distinguishes between ecosystem-level goals and objectives, natural community goals and objectives, and species-specific goals and objectives. The biological goals reflect broad principals while the biological objectives identify more specific targets that the Plan should meet to achieve its overall biological goals. These objectives include measureable metrics or criteria to enable ongoing assessment of the Plan's effectiveness throughout its implementation.

1.3 Regulatory Context

1.3.1 Regulatory Purpose of the BDCP

The BDCP provides the basis for regulatory compliance with ESA and the NCCPA for a range of activities related to the operation of the SWP, CVP, and the Mirant power plants that occur within the Plan Area, including the diversion and export of water from the Delta and its tributaries. The BDCP advances a comprehensive solution to the persistent regulatory challenges that have faced the SWP and CVP. This comprehensive solution includes systemic changes to water conveyance infrastructure and broad-scale restoration and enhancement of ecological resources. This approach is intended to result in long-term regulatory stability for the state and federal water projects, while furthering the goals of water supply reliability and ecological restoration.

The BDCP has been prepared as a joint HCP/NCCP, which will support the issuance of incidental take authorizations from USFWS and NMFS pursuant to Section 10 of the ESA and take authorizations from the California Department of Fish and Game (DFG) under Section 2835 of the NCCPA to the non-federal applicants.[6] The BDCP has also been designed to meet the standards of Section 2081 of the California Endangered Species Act (CESA). The BDCP will further provide the basis for biological assessments (BA) to support the issuance of incidental take authorizations from USFWS and NMFS to Reclamation pursuant to Section 7 of the ESA, for its actions in the Delta.[7]

To meet these regulatory objectives, the BDCP sets out a comprehensive Conservation Strategy that will address the adverse effects of SWP and CVP actions that occur within the Plan Area on aquatic and terrestrial species, including those listed under the ESA or CESA as threatened, endangered, or candidates for listing, as well as on critical habitat, if any, that has been designated for these species pursuant to the ESA (Chapter 3 *Conservation Strategy*). The biological assessment for CVP-related activities in the Delta will adopt the BDCP Conservation Strategy as it relates to those federal actions and will serve as a companion document to the BDCP. It should be noted that the BDCP does not attempt to distinguish precisely between the effects on covered species attributable to the CVP covered activities and those of the SWP. Rather, the BDCP includes a comprehensive analysis of the effects associated with both the SWP and the CVP within the Plan Area and proposes a Conservation Strategy that adequately addresses the totality of those effects. On the basis of the BDCP and the companion biological assessment, USFWS and NMFS are expected to issue Section 10 permits and a new joint biological opinion that supersedes biological opinions existing at that time as they relate to SWP and CVP actions covered by the BDCP.

The BDCP affords an opportunity to move beyond the cycle of litigation that has compelled incremental and disruptive adjustments to the operations of the existing water supply infrastructure and toward a stable regulatory environment. The succession of federal court decisions over the past several years regarding the intersection of the federal and state endangered species acts and the operation of the state and federal water projects did little to settle conflicts over species conservation and water supply needs. Rather, these decisions translated into additional restrictions on water supplies to 25 million Californians in the Bay Area, Central Valley, and Southern California. These water supplies had been previously constrained because of a worsening environmental crisis in the Delta, prior court-ordered pumping restrictions, and state-wide drought conditions. The recent legal proceedings are but part of a history of legal

---

[6] 16 U.S.C. § 1539.; California Fish and Game Code (Fish & Game Code) § 2835 *et seq*.

battles that have served to further reinforce the need for comprehensive, legally-defensible regulatory solutions to the environmental and water supply challenges associated with the Delta.

1.3.2 The Federal Endangered Species Act

The United States Congress passed the Endangered Species Act (ESA) in 1973 to provide a means for conserving the ecosystems that endangered and threatened species require in order to prevent species extinctions. The ESA has three major components relevant to the BDCP: the Section 7 requirement that federal agencies ensure, in consultation with the federal fish and wildlife agencies, that their actions are not likely to jeopardize the continued existence of species or result in modification or destruction of critical habitat; the Section 9 prohibition against the "taking" of listed species; and the Section 10 provisions that provide for the permitting of non-federal entities for the incidental take of listed species.

Section 7 of the ESA provides that each federal agency must ensure, in consultation with the Secretary of the Interior or Commerce, that any actions authorized, funded, or carried out by the agency are not likely to jeopardize the continued existence of any endangered or threatened species or result in the destruction or adverse modification of areas determined to be critical habitat.[8] Section 7 requires federal agencies to engage in formal consultation with USFWS or NMFS for any proposed actions that are likely to adversely affect listed species. A biological opinion is issued by USFWS or NMFS at the completion of formal consultation. The biological opinion can conclude that the project as proposed is either likely or not likely to jeopardize the continued existence of the species. If the biological opinion concludes "no jeopardy," the action can proceed as proposed. If the biological opinion concludes "jeopardy," USFWS or NMFS will identify "reasonable and prudent alternatives" to the proposed action that would avoid jeopardizing the species. Included in the biological opinion is an incidental take statement that authorizes a specified level of take anticipated to result from the proposed action. The incidental take statement contains "reasonable and prudent measures" that are designed to minimize the level of incidental take and that must be implemented as a condition of the take authorization.[9]

Section 9(a)(1)(B) of the ESA prohibits the take by any person of any endangered fish or wildlife species; take of threatened fish or wildlife species is prohibited by regulation. The ESA prohibits the take of any listed threatened fish or wildlife species in violation of any regulation promulgated by the USFWS or NMFS. "Take" is defined broadly to mean harass, harm, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to engage in any such conduct.[10] "Harm" is defined by regulation to mean an act which actually kills or injures wildlife, including those activities that cause significant habitat modification or degradation resulting in the killing or injuring of wildlife by significantly impairing essential behavior patterns, including breeding,

[8] 16 U.S.C. § 1536(a)(2).

[9] 50 C.F.R. § 402.14(i)(5).

[10] 16 U.S.C. § 1532 (1988).

feeding, or sheltering.[11] The take prohibitions of the ESA apply unless take is otherwise specifically authorized or permitted pursuant to the provisions of Section 7 or Section 10 of the ESA. The protections for listed plant species under the ESA are more limited than for fish and wildlife. [12]

Section 10 of the ESA specifically addresses the authorization for take by non-federal entities through the development of a HCP. For those actions for which no federal nexus exists, private individuals, corporations, state and local government agencies, and other non-federal entities who wish to conduct otherwise lawful activities that may incidentally result in the take a listed species must first obtain a Section 10 incidental take permit from USFWS or NMFS. The non-federal entity is required to develop an HCP as part of the permit application process.

Under Section 10(a)(1)(B) of the ESA, the Services may permit the incidental take of listed species that may occur as a result of an otherwise lawful activity. To obtain a Section 10(a)(1)(B) permit, an applicant must prepare an HCP that meets the following five criteria: (1) the taking will be incidental to an otherwise lawful activity; (2) the applicant will, to the maximum extent practicable, minimize and mitigate the impacts of such taking; (3) the applicant will ensure that adequate funding for the plan will be provided; (4) the taking will not appreciably reduce the likelihood of the survival and recovery of the species in the wild; and (5) other measures, if any, which the Services require as being necessary or appropriate for purposes of the plan will be met. [13]

The BDCP is intended to meet all regulatory requirements necessary for USFWS and NMFS to issue Section 10 permits to allow incidental take of all proposed covered species as a result of covered activities undertaken by the California Department of Water Resources (DWR), certain SWP contractors, and Mirant Corporation, and to issue Section 7 biological opinions to authorize incidental take for covered actions undertaken by Reclamation and CVP contractors. The BDCP assessment of direct and indirect effects (Chapter 5 *Effects Analysis*) on covered species and critical habitat provides the analyses and information necessary for Reclamation, USFWS, and NMFS to meet the analytical requirements of Section 7.

1.3.2.1 Compliance with the Services' Five-Point Policy Guidance

In June 2000, the USFWS and NMFS adopted a five-point policy designed to clarify elements of the habitat conservation planning program as they relate to biological goals, adaptive management,

[11] 50 C.F.R. § 17.3. NMFS has a similar definition that adds the concepts of spawning and migrating to examples of injury. NMFS defines "harm" as "an act which actually kills or injures fish or wildlife. Such an act may include significant habitat modification or degradation which actually kills or injures fish or wildlife by significantly impairing essential behavioral patterns, including, breeding, spawning, rearing, migrating, feeding or sheltering.' (50 C.F.R § 222.102).

[12] Section 9(a)(2)(B) of the ESA prohibits removal, possession, or malicious damage or destruction of endangered plants in areas under federal jurisdiction, as well as actions that remove, cut, dig up, damage, or destroy endangered plants in areas outside of federal jurisdiction in violation of any state law or regulation, including state criminal trespass law. Protection for threatened plant species is limited to areas under federal jurisdiction. 50 C.F.R. § 17.71(a). The ESA section 7(a)(2) prohibition against jeopardy applies to plants, wildlife, and fish equally, and USFWS and NMFS may not issue a section 10(a)(1)(B) permit if the issuance of that permit would result in jeopardy to any listed species.

[13] 16 U.S.C. § 1539(a)(2)(A).

monitoring, permit duration, and public participation.[14] The five-point policy directs that the following elements be addressed in the development of habitat conservation plans:

Biological Goals and Objectives. HCPs are required to define biological goals and objectives that the plan is intended to achieve. Biological goals and objectives clarify the purpose and direction of the plan's conservation program. The BDCP sets out extensive biological goals and objectives, including specific measurable targets that the Plan is designed to meet. These targets were developed on the basis of the best available scientific information and have been used as parameters and benchmarks to guide the conservation strategies for the species and natural communities covered by the Plan. The biological goals and objectives of the BDCP are described in Section 3.3, *Biological Goals and Objectives*.

Adaptive Management. The five-point policy encourages the inclusion of adaptive management strategies in HCPs in appropriate circumstances to address uncertainty related to species covered by a plan. The agencies describe adaptive management as a "method for examining alternative strategies for meeting measurable biological goals and objectives, and then if necessary, adjusting future conservation management actions according to what is learned."[15] The BDCP incorporates an adaptive management process that is designed to facilitate and improve decision-making during the implementation of the Plan and identify adjustments and modifications, as defined in the Plan, to the conservation strategy as new information becomes available over time. The framework for the BDCP adaptive management program is set out in Section 3.7, *Adaptive Management Program*.

Monitoring. HCPs are required to include provisions for monitoring to gauge the effectiveness of the plan in meeting the biological goals and objectives and to verify that the terms and conditions of the plan are being properly implemented. The biological and compliance monitoring provisions of the BDCP are found in Section 3.6, *Monitoring and Research Program*.

Permit Duration. Consistent with the five-point policy, the USFWS and NMFS consider several factors in determining the term of an incidental take permit. The agencies, for instance, take into account the expected duration of the activities proposed for coverage and the anticipated positive and negative effects on covered species that will likely occur during the course of the plan. The agencies also factor in the level of scientific and commercial data underlying the proposed operating conservation program, the length of time necessary to implement and achieve the benefits of the operating conservation program, and the extent to which the program incorporates adaptive management strategies. The duration of the permits to be issued pursuant to the BDCP is anticipated to be 50 years.

Public Participation. Under the five-point policy, the federal fish and wildlife agencies have sought to increase public participation in the HCP process, including greater opportunity for the public to assess, review, and analyze HCPs and associated NEPA documentation. As part of this

[14] Final Addendum to the Handbook for Habitat Conservation Planning and Incidental Take Permitting, 65 FR 106, June 1, 2000 (hereinafter referred to as the "Five Point Policy")

[15] Five-Point Policy for HCPs, 65 FR 106, June 1, 2000

effort, the agencies have encouraged greater engagement of the public for most HCPs, particularly those with regional scopes. As described in Section 1.5.2, the BDCP process afforded extensive opportunities for public involvement and input throughout the development of the Plan.

1.3.3 Natural Community Conservation Planning Act

The Natural Community Conservation Planning Act (NCCPA) provides a mechanism for compliance with state endangered species regulatory requirements through the development of comprehensive, broad-scale conservation plans that focus on the needs of natural communities and the range of species that inhabit them.[16] The NCCP program has provided the basis for successful collaborations throughout California between state and federal agencies, local governments, community groups, and private interests that have resulted in long-term, habitat-based protections for regional biodiversity and related ecosystems. It has also proved to be an effective tool in achieving these protections while reducing conflicts between conservation goals and the reasonable use of natural resources and lands for economic development. The BDCP adopts the approaches set out in the NCCPA and incorporates those elements necessary to meet regulatory requirements of the Act.

Specifically, the BDCP has been developed in a manner consistent with the process identified in its Planning Agreement, including processes to ensure ample public participation and engagement throughout Plan development and review, extensive input from independent scientists, and coordination with federal fish and wildlife agencies with respect to ESA requirements. Consistent with the requirements of the NCCPA, the Plan further provides a multi-faceted approach to provide for the conservation and management of covered species and their habitats, incorporating a conservation strategy that provides for the protection of habitat, natural communities, and species diversity on an ecosystem level; establishes conservation measures, including measures sufficient to fully mitigate the effects of covered activities; integrates adaptive management strategies that can be modified based on new information developed through monitoring; and sets out a detailed implementation program, including provisions that ensure adequate funding to carry out the Plan.

The BDCP addresses all of the requirements of the NCCPA for aquatic, wetland, and terrestrial covered species of fish, wildlife, and plants and Delta natural communities affected by BDCP actions. On that basis, DFG may issue permits for the taking of the species proposed for coverage under the Plan.[17]

[16] Fish & Game Code § 2800 *et. seq*.

[17] Fish & Game Code § 2835.

1.3.4 California Endangered Species Act

The California Endangered Species Act (CESA) prohibits the take of wildlife or plant species designated as threatened or endangered by the California Fish and Game Commission.[18] "Take" is defined as any action or attempt "to hunt, pursue, catch, capture, or kill."[19] Like the ESA, CESA allows for exceptions to the take prohibitions for otherwise lawful activities. The requirements of an application for incidental take under CESA are described in Section 2081 of the Fish and Game Code. Incidental take of endangered, threatened, or candidate species may be authorized if an applicant demonstrates, among other things, that the impacts of the proposed take will be minimized and fully mitigated.[20]

Although the BDCP has been designed to comply with the NCCPA, and take authorizations are being sought under Section 2835 of the Fish and Game Code, the Plan's provisions have also been developed to be consistent with the regulatory standards of CESA. Specifically, the BDCP Conservation Strategy incorporates measures that adequately minimize and fully mitigate the effects of Covered Activities on state-listed species and includes other such measures as required by CESA. As such, the actions set out in the BDCP are expected to be sufficient to allow for findings to be made by DFG to support the issuance of incidental take authorizations under CESA.

1.3.5 The National Environmental Policy Act

The purpose of NEPA is to ensure that federal agencies consider the environmental impacts of their actions and decisions.[21] NEPA requires that the federal government use all practicable means and measures to protect environmental values and makes environmental protection a part of the mandate of every federal agency and department. To accomplish this goal, NEPA establishes a process and approach to analysis to determine the environmental impacts associated with proposed federal actions that significantly affect the quality of the human environment.

The permitting and implementation of the BDCP involve several federal actions and decisions that are subject to review under NEPA. Reclamation's actions include changes in the operation of the Delta Cross Channel, an expected agreement with DWR to provide for wheeling of CVP water through a new isolated conveyance facility, and the implementation of certain conservation measures through the BDCP Implementation Office. USFWS and NMFS will make decisions regarding the issuance of incidental take permits under Section 10(a)(1)(B) of the ESA. Reclamation, USFWS, and NMFS are joint lead agencies for the preparation of the BDCP Environmental Impact Statement (EIS). The U.S. Army Corps of Engineers (USACE) and the U.S. Environmental Protection Agency (EPA) are participating in the NEPA process as cooperating federal agencies.

[18] Fish & Game Code § 2080.

[19] Fish & Game Code § 86.

[20] Fish & Game Code § 2081(b)(2).

[21] 42 U.S.C. § 4371 *et seq*.

1.3.6 The California Environmental Quality Act

The CEQA serves as a counterpart to NEPA, and applies to all discretionary activities proposed to be carried out or approved by California public agencies. CEQA requires state and local agencies to identify significant environmental impacts of their actions and to take all feasible steps to avoid or mitigate those impacts. CEQA sets forth both procedural and substantive requirements and its procedures are intended to ensure adequate public participation and input into the decision-making process.

The BDCP is a project subject to CEQA, as are numerous BDCP-related actions that will be implemented over the term of the plan.[22] DWR serves as the lead agency for the preparation of the Environmental Impact Report (EIR), which will include analyses of DWR's proposed adoption of the plan, as well as its implementation of certain projects covered by the BDCP. Among the BDCP-related projects that will undergo review are the construction of new conveyance facilities and several identifiable habitat restoration actions, which are all described in the BDCP. DFG is participating in the preparation of the EIR as both a responsible and trustee agency. The EIR will also serve as the CEQA document for the purpose of regulatory permits issued by DFG pursuant to the BDCP.

The state and federal lead agencies will prepare a joint BDCP EIR/EIS to satisfy CEQA and NEPA concurrently.

1.3.7 Relationship with Existing Biological Opinions

The operations of the SWP and the CVP are currently subject to the terms and conditions of biological opinions issued by the USFWS and NMFS pursuant to Section 7 of the federal ESA. The biological opinion to be jointly issued by USFWS and NMFS on the basis of the BDCP and its companion biological assessments will supersede USFWS and NMFS biological opinions that exist at the time of the approval of the BDCP as they relate to the coordinated operation of the CVP and SWP to the extent that the BDCP addresses activities covered by these existing biological opinions.

1.3.8 Recent California Legislation Relating to Water and the Sacramento-San Joaquin Delta

In November 2009, the state of California enacted comprehensive legislation to address the range of challenges facing the Delta, including those involving water supply reliability and ecosystem health. The legislation advances several broad goals of the state with regards to the Delta and specifies a range of actions to be implemented to meet those goals. Among the several goals stated in the legislation is the following:

[22] California Public Resources Code (CPRC) section 21000 *et seq*. and CEQA Guidelines 14 CCR 15000 *et seq*.

> *Achieve the two co-equal goals of providing for a more reliable water supply for the California and protecting, restoring, and enhancing the Delta ecosystem. The co-equal goals shall be achieved in a manner that protects and enhances the unique cultural, recreational, natural resource, and agricultural values of the Delta as an evolving place.*[23]

The codification of these co-equal goals has served to reinforce the nearly-identical BDCP planning goals adopted by the Steering Committee and used throughout the planning process to help guide the development of the Plan.

The Delta legislation includes the Sacramento-San Joaquin Delta Reform Act of 2009,[24] which provides for the establishment of an independent state agency, the Delta Stewardship Council, to further the co-equal goals of ecosystem restoration and a reliable water supply. The Council, which became operational on February 3, 2010, is charged with the development and implementation of a comprehensive management plan for the Delta (Delta Plan), and is vested with the authority to review actions of state and local agencies and advise on their consistency with the Delta Plan.

The Council is also required to consider the inclusion of the BDCP in the Delta Plan. The Delta Reform Act sets out the conditions under which the Council is to incorporate the BDCP into the Delta Plan. To be considered for inclusion in the Delta Plan, the BDCP must comply with the requirements of the NCCPA and CEQA, which includes a review and analysis of various specified alternatives to the proposed Plan. Upon approval of the BDCP as an NCCP and as an HCP under the ESA, the Council is required to incorporate the BDCP into the Delta Plan. However, the determination by DFG that the BDCP meets the requirements of the NCCPA may be appealed to the Council.

1.3.9 Relationship between the BDCP and Other Federal and State Laws and Regulations

The BDCP has been developed as a conservation plan that complies with state and federal endangered species laws. However, the Plan or the actions described herein will need to conform to the requirements of various other state and federal laws and regulations not specifically addressed by the Plan. Prior to the implementation of many of the conservation actions set out in the BDCP, regulatory authorizations and approvals will need to be obtained from state and federal under applicable laws. Such authorizations will likely involve some or all of the following statutes: California Water Code sections 1000 *et seq*. (water rights), Water Code sections 13000 *et seq*. (water quality), California Fish and Game Code sections 1600 *et seq*. and 5900 *et seq*. (channel modification, fish screens), Clean Water Act Section 404 (placement of dredge and fill), Rivers and Harbors Act Section 408 (work on levees), Rivers and Harbors Act Section 10 (navigation), and the Migratory Bird Treaty Act (migratory birds).

[23] SBX 7 1.

[24] Division 35, California Water Code.

1.3.9.1 Section 404 of the Clean Water Act

In 1972, Congress passed the Federal Water Pollution Control Act, commonly known as the Clean Water Act (CWA), with the goal of “restor[ing] and maintain[ing] the chemical, physical, and biological integrity of the Nation’s waters.”[25] In furtherance of this goal, the CWA prohibits the discharge of any pollutants into navigable waters, except as allowed by permit issued under certain sections of the CWA.[26] Specifically, Section 404 authorizes USACE to issue permits for and regulate the discharge of dredged or fill materials into wetlands or other “waters of the United States.” Under the CWA and its implementing regulations, “waters of the United States” are broadly defined to consist of rivers, creeks, streams, and lakes extending to their headwaters, including adjacent wetlands.[27]

Responsibility for the implementation of Section 404 of the CWA is shared by the U.S. EPA and USACE. EPA is generally responsible for establishing policy and guidance regarding the implementation of the program. For instance, EPA developed the guidelines that are used to evaluate the sufficiency of Section 404 permit applications, and has played the lead role in determining the scope of the federal government’s jurisdiction over aquatic resources, including the reach of the term “waters of the United States.” EPA also determines the eligibility of a state to assume responsibility for portions of the Section 404 program.[28] On the other hand, USACE is responsible for the day-to-day administration of the Section 404 permit program.
Many of the actions that will be implemented under the BDCP will result in the discharge of dredged or fill materials into “waters of the U.S.” and will need to be authorized by USACE. These BDCP actions will receive such authorizations through both General Permits and Individual Permits. Typically, General Permits apply to specific classes of activities that have been determined to cause no more than minimal impact to the aquatic environment (e.g., construction of road crossings, installation of utility lines, and operations and maintenance activities).[29] Individual Permits are designed for activities that have the potential to have more than a minimal effect on jurisdictional waters or that otherwise do not qualify under the conditions of a General Permit. Substantively, USACE must evaluate applications for Individual Permits to determine their consistency with the requirements of the Section 404(b)(1) Guidelines[30] and USACE’ regulations.[31]

[25] 33 U.S.C. § 1251(a).

[26] *See* 33 U.S.C. §§ 1311, 1342, and 1344.

[27] 33 C.F.R. § 328.3(a)(3).

[28] The 1977 amendments to the CWA provided that States can assume the federal 404 program provided that the State has a “comparable” program. State program assumption of 404 is only available for non-navigable waters so that even in States where the program has been assumed, the federal government retains control over activities in navigable waters. Only two States, Michigan and New Jersey, have assumed the 404 program to date. In States with assumed 404 programs, the State authorization is the only one required.

[30] 40 C.F.R. Part 230.

[31] 33 C.F.R. Part 325.

1.3.9.2 Section 401 of the Clean Water Act

Pursuant to Section 401, states can certify or deny federal permits or licenses that might result in a discharge to state waters, including wetlands.[32] Section 404 permit applicants must obtain a "water quality certification" from the state water quality agency indicating that the proposed activity complies with all applicable state water quality standards, limitations, and restrictions. In California, the Regional Water Quality Control Boards (RWQCB) issue water quality certifications within their jurisdictions. Appeals to the decisions of the RWQCBs are heard by the SWRCB.

1.3.9.3 Section 10 of the Rivers and Harbors Act

Certain BDCP actions will require authorizations under Section 10 of the Rivers and Harbors Act of 1899 (33 U.S.C. 403) which requires authorization from the Secretary of the Army for the construction of any structure in or over any navigable water of the United States or the construction of structures or alteration of capacity in any port, canal, navigable river, or other water of the United States.[33] "Navigable waters" under Section 10 of the Rivers and Harbors Act are defined as "those waters of the United States that are subject to the ebb and flow of the tide shoreward to the mean high water mark and/or are presently used, or have been used in the past, or may be susceptible to use to transport interstate or foreign commerce."[34]

1.3.9.4 Section 14 of the Rivers and Harbors Act ("Section 408")

Section 14 of the Rivers and Harbors Act of 1899 (33 U.S.C. 408; commonly referred to as "Section 408") provides protection for federal projects in waterways such as sea walls, dikes, levees, and piers from being moved, altered, or destroyed, in a manner that impairs the usefulness of the structure. Under Section 408, the Chief of Engineers may grant permission to alter an existing federal project if it is not injurious to the public interest and does not impair the usefulness of the project. Certain BDCP actions, such as those that affect federal project levees and weirs, will require authorizations under Section 408.

1.3.9.5 California Fish and Game Code Section 1600 et seq.

California has adopted regulations to address impacts to many of the resources subject to Section 404 of the CWA. Although not entirely overlapping, these programs intersect frequently. Project proponents are required to obtain separate authorizations from USACE and DFG.

Section 1602 of the California Fish and Game Code requires any person, state or local governmental agency to provide advance written notification to DFG prior to initiating any activity that would: (1) divert or obstruct the natural flow of, or substantially change or remove material from the bed, channel, or bank of any river, stream, or lake; (2) result in the disposal or

[32] 33 U.S.C. § 1341.

[33] 33 C.F.R. § 401 *et seq*.

[34] 33 C.F.R. § 329.4

deposition of debris, waste, or other material into any river, stream, or lake.[35] The State definition of "lake, rivers, and streams" includes all rivers or streams that flow at least periodically or permanently through a bed or channel with banks that support fish or other aquatic life, and watercourses with surface or subsurface flows that support or have supported riparian vegetation.[36]

Certain actions that will be implemented under the BDCP will require Streambed Alteration Agreements under Section 1602. As part of that process, DFG will review notifications submitted by the BDCP Implementation Office to determine if the proposed project would impact existing fish and wildlife resources that are directly dependent on a lake, river, or stream. If DFG determines that the proposed activity will not substantially adversely affect an existing fish and wildlife resource, it will notify the Implementation Office that no Streambed Alteration Agreement is required and the project may proceed.[37] If DFG determines that the project may substantially adversely affect an existing fish and wildlife resource, it will require, as part of a Streambed Alteration Agreement, reasonable measures necessary to protect the fish and wildlife resource.[38]

1.3.9.6 Migratory Bird Treaty Act

The Migratory Bird Treaty Act (MBTA) of 1918 implements four international treaties for the conservation and management of bird species that may migrate through more than one country.[39] The MBTA makes it unlawful to take, possess, buy, sell, purchase, or barter any migratory bird listed in 50 Code of Federal Regulations (CFR) Part 10, including feathers or other parts, nests, eggs, or products, except as allowed by implementing regulations.[40] For federally listed migratory bird species covered under the BDCP for which an ESA Section 10(a) permit has been issued, the Implementation Office may also obtain an MBTA permit for those species.

1.3.9.7 Water Rights under the California Water Code

The California Water Code[41] prescribes detailed procedures that govern the appropriation of water from a lake, river, stream, or creek. After the enactment of the State Water Commission Act in 1914, the state required any person or agency seeking to use surface water, without an existing riparian right, to apply for and receive approval for such use from the State Water Resources Control Board (SWRCB). Water rights permits granted by the SWRCB include detailed descriptions of the amounts, conditions, and construction timetables under which the proposed water project must comply. Prior to permit issuance, the SWRCB must take into account all prior rights and the availability of water in the basin. The Board must also consider

[35] Fish & Game Code § 1602.

[36] 14 C.C.R. § 1.72.

[37] Fish & Game Code § 1602(a)(4)(A)(i).

[38] Fish & Game Code § 1603(a).

[39] 16 U.S.C. § 703 *et seq*.

[40] 50 C.F.R. § 21.

[41] Division 2, Wat. Code section 1000 *et seq*.

the flows needed to preserve instream uses such as recreation and fish and wildlife habitat. The Board may impose additional conditions to ensure that these criteria are satisfied and it may use its continuing authority to enforce and revise the conditions of water right permits over time. The SWRCB is also empowered to revoke a permit or issue cease and desist orders if conditions of the permit are not being met.

At any time after receiving a water right permit, a permittee may seek permission from the SWRCB to change the point of diversion, place of use, or purpose of use from that specified in the permit. The proposed change cannot involve a new right or cause injury to any other legal user of water. The implementation of the BDCP will require a change in points of diversion specified in the DWR and Reclamation water right permits. As such, DWR and Reclamation will need to petition the SWRCB to change the point of diversion. Prior to approving these petitions, the SWRCB must find that the change will not cause injury to any legal user of the water involved or result in harm fish or wildlife. Other right holders and the public will have an opportunity to object to the proposed change by filing a protest form with the SWRCB. If a protest is filed, the Board must hold a hearing on the petition and will either grant or refuse permission to make the change, as the facts may warrant. Because the SWRCB has discretion to approve the requested petition, it must comply with the California Environmental Quality Act.

1.3.9.8 Porter-Cologne Water Quality Control Act

The Porter-Cologne Water Quality Control Act (Porter-Cologne)[42] sets out a comprehensive regulatory, planning, and management program to protect water quality and beneficial uses of the state's water. The Act established the State Water Resources Control Board's authority to preserve and enhance the quality of California's water resources, and to ensure proper allocation and efficient use of water.

Under Porter-Cologne, the SWRCB is required to prepare a Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary (Bay-Delta Plan). While the Regional Water Boards have primary responsibility for formulating and adopting water quality control plans for their respective regions, the SWRCB also is authorized to develop and adopt water quality control plans. In such instances, the water quality control plan adopted by the SWRCB supersedes regional plans developed for the same waters, to the extent they conflict.

The Bay-Delta Plan consists of three primary components: (1) the beneficial uses (of water) to be protected; (2) the water quality objectives for the estuary; and (3) the implementation programs to meet the water quality objectives. Beneficial uses include uses such as domestic, agricultural and industrial supply; power generation; recreation and aesthetic use; navigation; and preservation and enhancement of fish, aquatic, and wildlife resources. Water quality objectives or standards reflect the levels of water quality constituents that have been determined to be necessary to protect beneficial uses. Implementation plans describe actions to be taken to achieve the objectives and set out programs for monitoring, management, and enforcement.

42 Water Code § 13000 *et seq*.

The SWRCB is vested with primary regulatory authority over flows, water quality, and other water rights issues in the Bay-Delta. As such, many of the actions described in the BDCP, including modifications to the water conveyance system, will require the approval of the SWRCB. The SWRCB's participation in the development of the BDCP and in the environmental review process is intended to ensure consistency between the actions described in the BDCP and those required by the SWRCB as part of its water quality control planning and implementation activities.

1.4 SCOPE OF THE BDCP

This section describes the geographic scope of the BDCP, the types of activities that the Plan covers, and the duration sought for regulatory permits that are issued by the Fish and Wildlife agencies pursuant to the Plan.

1.4.1 Geographic Scope of the Plan Area

The geographic scope of the Plan Area encompasses the Sacramento-San Joaquin Delta and additional areas in which conservation measures may be implemented pursuant to the Plan. Take authorizations issued under the BDCP will extend to covered activities that occur within the Plan Area.

The BDCP Conservation Strategy is primarily focused on the statutory Delta, as defined in California Water Code Section 12220. However, certain areas outside the statutory Delta contain desirable locations for conservation actions that advance the goals and objectives of the Plan (Figure 1-1).[43] Areas such as Suisun Marsh, Suisun Bay, and upstream areas of the upper Yolo Bypass and the area that encompasses the Fremont Weir, for instance, provide important sites for habitat restoration to support goals and objectives for natural communities and covered species (Figure 1-1). In addition, the Conservation Strategy includes measures that will be implemented outside of the statutory Delta to support or complement regional conservation planning efforts underway in Yolo, Solano, Contra Costa, San Joaquin, and Sacramento counties. As such, the geographic scope of the Plan Area will also encompass habitat lands that are conserved through BDCP actions taken in conjunction with these other regional conservation programs. To the extent appropriate, these conservation actions will be implemented through cooperative agreements, or similar mechanisms, between the BDCP Implementation Office and local agencies, interested non-governmental organizations, landowners, or other parties.

To accommodate the range of conservation measures necessary to meet the goals and objectives of the BDCP, the scope of the Plan Area may be expanded during the implementation of the Plan. The flexibility to expand the boundaries of the Plan during plan implementation will allow for greater opportunity to maximize conservation benefits associated with the measures set out in

[43] The BDCP Planning Agreement, recognized the likelihood that the BDCP Conservation Strategy would include actions that would be implemented outside of the Statutory Delta to further advance the goals and objectives of the plan

the Conservation Strategy. Adjustments to the Plan Area, however, would occur only under certain defined circumstances and within identified areas, as set out in the Conservation Strategy.

Because the SWP and CVP water infrastructure is operated as an integrated system, the effects of implementing the BDCP will extend beyond the Delta, both upstream and downstream, and will implicate water operational parameters as well as species and their habitats. Therefore, the BDCP effects analysis (Chapter 5 *Effects Analysis*) takes into account these upstream and downstream effects, both positive and negative, to ensure that the overall effects of the BDCP are sufficiently described, analyzed and addressed. Areas potentially affected by the implementation of the BDCP located outside of the geographic scope of the plan, have been included in the analysis of effects to ensure that all of the potential effects within the "action area," as defined by Section 7 of the ESA, have been adequately assessed.

1.4.2 Natural Communities

Natural communities are distinct and reoccurring assemblages of plants and animals associated with specific physical environmental conditions and ecological processes. A natural community occurs across a landscape where similar ecological conditions exist. The Wildlife and Natural Areas Conservation Act defines natural community as "a distinct, identifiable, and recurring association of plants and animals that are ecological interrelated" (California Fish and Game Code subsection 2702[d]). Individual species occur within the context of natural communities and it is within these communities that species interact with other species and the physical environment. The NCCPA states that the purpose of natural community conservation planning is "to sustain and restore those species and their habitat …that are necessary to maintain the continued viability of those biological communities impacted by human changes to the landscape." [44]

To adequately address the natural communities in the Delta that support covered species and native biodiversity, the BDCP includes measures that sustain and enhance ecological processes and provide for the protection and restoration of a broad range of natural communities. Conservation measures have been designed to improve ecological functions and restore species habitat in the following natural communities:

- Tidal Perennial Aquatic;
- Tidal Mudflat;
- Tidal Brackish Emergent Wetland;
- Tidal Freshwater Emergent Wetland;
- Valley/Foothill Riparian;
- Nontidal Perennial Aquatic;
- Nontidal Freshwater Perennial Emergent Wetland;

[44] Fish & Game Code § 2801(h)(i).

- Alkali Seasonal Wetland Complex;
- Vernal Pool Complex;
- Other Natural Seasonal Wetland;
- Managed Wetland;
- Grassland; and
- Inland Dune Scrub.

Although not considered a natural community, cultivated croplands are nonetheless taken into account in the BDCP Conservation Strategy because, in certain instances, they provide value as habitat for covered species. Cultivated croplands addressed by the BDCP have been divided into subtypes, each of which provide varying benefits to different covered species or groups of covered species. These cultivated cropland subtypes are as follows:

- Alfalfa;
- Irrigated Pasture;
- Rice;
- Other cultivated crops;
- Orchards; and
- Vineyards.

Collectively, the covered natural communities encompass the habitat used by covered species within the Plan Area.

1.4.3 Covered Species

The ESA and the NCCPA set forth specific criteria that must be satisfied to support the issuance of regulatory authorizations that provide for the incidental take of species. The term “covered species” refers to those species for which incidental take authorizations may be issued under the BDCP pursuant to state and federal endangered species laws. The proposed BDCP covered species are identified in Table 1-2.

The BDCP seeks regulatory coverage for those species that will potentially be adversely affected by those activities covered by the Plan. As such, the list of species proposed for coverage is limited to those species currently protected under state or federal wildlife laws, and those species that are likely to receive the protection of those laws in the future. The list of covered species is not intended to include all species that occur within the Plan Area or all species and habitats that will directly or indirectly benefit from implementation of the BDCP. Rather, the covered species list reflects the range of species for which regulatory authorizations are needed under state and/or federal law for any take associated with the activities covered by the BDCP. Species not covered under the BDCP will benefit from the measures that provide for the conservation of natural communities that encompass both common and rare species.

1.4.3.1 Species Evaluated for Coverage

The species evaluated for potential coverage under the BDCP include a broad range of fish and wildlife species that are likely to occur within the geographic scope of the Plan and are currently considered to be rare, sensitive, threatened or imperiled, or likely to be so in the future (Appendix C, *Evaluation of Species Considered for Coverage*). Many of the species on the list have been granted protected or special status, including those that have been listed under the state and/or federal endangered species acts or other laws or regulations. This list further included species that have been recognized by the scientific community as warranting concern due to their rarity or ecological importance. Among the species included on the list are those with the following special status:

- Listed as threatened or endangered under the ESA;
- Proposed or candidates for listing under ESA;
- Listed as threatened or endangered under CESA;
- Candidates for listing under CESA;
- California species of special concern identified by DFG;
- California fully protected species under California Fish & Game Code sections 3511 (birds), 4700 (mammals), 5050 (reptiles and amphibians), and 5515 (fish);
- USFWS birds of conservation concern;
- NMFS species of concern;
- Plants listed as rare under the California Native Plant Protection Act (NPPA); or
- Plants included in the California Native Plant Society (CNPS) List 1A, 1B, or 2.

1.4.3.2 Evaluation and Selection Criteria

The evaluation process relied primarily on four criteria to determine which special-status species would be included on the list of species proposed for coverage under the BDCP. The selection criteria, which are discussed in detail in Appendix C, *Evaluation of Species Considered for Coverage*, are as follows:

- Listing status of the species.
- Likelihood that the species is present in the Plan Area or other areas within the geographic scope.
- Potential for the species to be adversely affected by BDCP covered activities, including the implementation of conservation measures.

- Level of information available to determine potential impacts to species and to identify effective conservation measures.

Those species that met all four of these criteria are proposed for coverage under the BDCP (Table 1-2). The results of the evaluations conducted for each species are set out in Appendix C, *Evaluation of Species Considered for Coverage*.

Table 1-2. BDCP Proposed Covered Species and Associated Habitats

[***Note to reviewers:*** *This table provides the current list of proposed covered species. Additional species may be added and some of the species presented here may be removed from the covered species list as per continuing development of the BDCP.]*

No.	***Common Name/ Scientific Name***	***Status (Federal/ State/CNPS)***[1]	***Natural Communities Supporting Species Habitat***

1.4.4 Covered Activities and Associated Federal Actions

The BDCP is intended to provide the basis for the issuance of regulatory authorizations under the ESA and the NCCPA for a broad range of ongoing and anticipated activities in the Plan Area that are associated with the operations of the SWP and the CVP, as well as for actions related to the operation of Mirant power plants. Covered Activities and Associated Federal Actions encompass all actions that are proposed for coverage under take authorizations that are expected to be issued by the state and/or federal Fish and Wildlife Agencies on the basis of the BDCP.

These actions have been designated as either "Covered Activities," which encompass those actions that will be undertaken by non-federal parties, or "Associated Federal Actions," which refer to those actions that are authorized, funded, or carried out by Reclamation. The BDCP Covered Activities and Associated Federal Actions are described in Chapter 4, *Description of Covered Activities and Associated Federal Actions*.

1.4.4.1 Covered Activities

The BDCP Covered Activities consist primarily of activities related to the development and operation of water conveyance infrastructure associated with the SWP that will occur within the Plan Area. Specifically, those SWP-related actions covered by the BDCP involve: (1) the operation of existing and future Delta facilities to transport and deliver water for SWP purposes; (2) the construction of new water conveyance infrastructure and other facilities; and (3) the maintenance and monitoring of water infrastructure and other facilities.

The BDCP also covers the operation of the Pittsburg and Contra Costa power plants owned by Mirant. The Plan covers activities related to the intake and discharge of water from the Delta necessary to operate the plants as well as certain other maintenance activities required to ensure continued proper operation of the existing facilities.

The BDCP Covered Activities also include the conservation measures described in the Conservation Strategy for the Plan. These actions are covered by the BDCP because they may potentially impact species protected under state and/or federal endangered species laws. Such conservation actions include the restoration of aquatic and terrestrial habitats, construction of facilities, monitoring of Covered Species, and research and study of species and habitats.

1.4.4.2 Associated Federal Actions

The BDCP associated federal actions comprise those activities that are authorized, funded, or carried out by Reclamation within the Plan Area and relate to the operation of the CVP's Delta facilities. These actions include: (1) operation of existing CVP Delta facilities to convey and export water to meet project purposes; and (2) associated maintenance and monitoring activities. While the CVP and SWP are separate systems, the projects function in an integrated and coordinated manner pursuant to the Coordinated Operations Agreement (COA). As such, Reclamation and/or the CVP contractors will utilize a portion of the conveyance capacity of a new tunnel/pipeline facility.

1.4.5 Permit Duration

DWR is seeking take permits from the state and federal Fish and Wildlife Agencies that remain in effect for a term of 50 years. A 50 year term is necessary to allow for the full implementation of the BDCP Conservation Strategy and to maximize the ecological benefits of the Plan. Moreover, the nature and scope of the actions to be permitted require a permit duration of 50 years.

1.5 Overview of the Planning Process

1.5.1 Role of the Steering Committee

The BDCP reflects input from a range of interested parties, public agencies, stakeholder groups, independent scientists, and the general public. The development of the Plan was primarily guided by the BDCP Steering Committee, whose membership is set out in Table 1-1, with direction from a Management Team. The Steering Committee provided direction on a range of technical, regulatory, and policy matters that shaped the Plan. The Management Team served the role of establishing agendas and facilitating meetings of the Steering Committee. The state and federal fish and wildlife agencies participated on the Steering Committee in an *ex officio* capacity. The proceedings of the Steering Committee, including the schedule and notice of meetings, topics for inclusion in meeting agendas, and the course of deliberations, were facilitated by the California Natural Resources Agency.

The Steering Committee formed a number of standing "Working Groups" and "Technical Teams," as well as ad hoc groups, to focus on approaches and solutions to specific issues related to Plan development. The focus of these groups is described below. The Working Groups dealt primarily with broad topics related to such matters as biological goals and objectives, conservation strategies, water conveyance, other stressors, and governance, and developed recommendations which were presented to the Steering Committee for consideration. Each Working Group was co-chaired by members of the Steering Committee. Technical Teams were tasked with responsibility for developing proposed approaches to technical and scientific issues. These teams were co-chaired by subject-matter experts who represented Steering Committee members, and were staffed by technical experts from both inside and outside the Steering Committee. All of these subgroups of the Steering Committee were composed of or were informed by technical experts representing a broad range of disciplines relevant to various aspects of plan development. Meetings of the Working Groups and Technical Teams were noticed on the BDCP website and open to the public.

The Working Groups and Technical Teams included the following:

- Conservation Strategy Working Group
- Biological Goals and Objectives Working Group
- Conveyance Working Group
- Other Stressors Working Group
- Implementation Structure/Governance Working Group
- Analytical Tools Technical Team
- Fish Facilities Technical Team
- Habitat and Operations Technical Team
- Habitat Restoration Program Technical Team
- Terrestrial Resources Subgroup
- Synthesis Team
- Integration Team
- Logic Chain and Metrics Technical Group

1.5.2 Public Participation and Engagement

The NCCPA requires the establishment of a process for public participation and outreach throughout the development of a plan.[45] Similarly, policies governing the ESA emphasize the importance of public involvement in the development of large-scale HCPs and encourage plan participants to facilitate the engagement of the public.[46] At the initial stage of the BDCP planning process, an outreach program was developed to provide the public a wide range of opportunities to learn about the various elements of the Plan and provide input during the course of its development.

The BDCP Steering Committee was established in May 2006, and met on a regular and ongoing basis throughout the planning process. All meetings of the Steering Committee, as well as Working Groups and Technical Teams, were open to the public. Such meetings could also be attended by teleconference, with live or archived access to presentations provided through the internet. Initially, a group email list was compiled and used to provide Steering Committee members and interested parties with Steering Committee meeting dates, times, and handouts. Later, an electronic listserv was developed and maintained to ensure that interested members of the public were notified of upcoming meetings and that draft documents pertaining to the planning process were distributed as they became available. All documents discussed by the Steering Committee, including its Working Groups and Technical Teams, were made available

[45] Fish & Game Code § 2815.

[46] 65 FR at X.

to the public on the BDCP website. At BDCP meetings, both oral and written public comments were received by the Steering Committee, and those comments received in writing were posted to the website. The notes of Steering Committee meetings also reflected comments and input offered by the public.

Throughout the planning process, representatives of the BDCP conducted approximately 200 briefings for community organizations, local jurisdictions within and adjacent to the Plan Area, environmental organizations, urban and agricultural water users groups, and recreational and commercial fishing organizations. Public presentations were made throughout the state, and information about the BDCP was regularly distributed, including updated "fact sheets" explaining the purpose of the Plan and describing its various components. To further facilitate the dissemination of information, the BDCP maintained a project website at: www.baydeltaconservationplan.com. Additional public outreach and involvement activities were conducted around major milestones in the planning process, and in compliance with NEPA and CEQA environmental review processes.

In 2008, DWR, Reclamation, NMFS, and USFWS, the lead agencies in the CEQA and NEPA environmental review processes, hosted ten scoping meetings throughout California. These meetings occurred at locations within the Sacramento Valley, the primary watershed through which stored water supplies are conveyed to and through the Delta to Project pumping facilities; other Delta communities; the San Francisco Bay Area; the San Joaquin Valley; and Southern California. Within the same year, DWR held eight landowner workshops in various Delta communities that focused in particular on the Temporary Entry Permit process and on updating these communities on the status of the BDCP planning process, and the environmental review process associated with the plan. In addition, the California Natural Resources Agency convened town hall meetings in Sacramento, Stockton, and Walnut Grove to further inform Delta communities about the BDCP and to respond to questions about the broader array of public agency efforts underway in the Delta, including the BDCP, pertaining to land use, flood protection, ecosystem restoration and governance.

In the spring of 2009, the BDCP produced and distributed a summary update about the development of the Plan to interested members of the public, including details of individual conservation measures that were being considered as part of the BDCP conservation strategy. NEPA and CEQA lead agencies also conducted 12 additional scoping meetings throughout California, seeking public input about the scope of BDCP actions and potential alternatives to the proposed action. Six of these scoping meetings were held in communities in or in close proximity to the Plan Area including Brentwood, Clarksburg, Davis, Fairfield, Sacramento, and Stockton. A Webinar was hosted in advance of these meetings to provide more in depth information about the BDCP process and to afford individuals unable to attend the workshops in person an opportunity to access to this information and interact with the BDCP representatives.

During the fall of 2009, after the release of a draft of a partial conservation strategy, four technical workshops were held in the Delta communities of Brentwood, Stockton, Walnut Grove, and West Sacramento to solicit input about the planning assumptions, biological rationale, and feasibility of draft conservation measures, as well as to seek recommendations for additional or different conservation measures. Input from the workshops was compiled and conveyed to the BDCP Steering Committee for its consideration and posted on the BDCP website. Three fact sheets were distributed that described the status of the Plan's development, the draft conservation strategy generally, and proposed water conveyance and flow and habitat restoration conservation measures more specifically.

Throughout 2010, BDCP representatives continued to conduct community briefings throughout the state, but primarily with organizations and local jurisdictions located within the Delta. As a result of these ongoing briefings, important working relationships were established with community leaders, further facilitating local engagement. In addition, informational materials about the BDCP, including fact sheets and issue summaries, evolved over time to ensure that the public was kept up-to-date with BDCP developments.

1.5.3 Integration of Science

The BDCP is built upon and reflects the extensive body of scientific investigation, study, and analysis of the Delta compiled over several decades,[47] including the results and findings of numerous studies initiated under the CALFED Bay-Delta Science program and Ecosystem Restoration Program, the long-term monitoring programs conducted by the Interagency Ecological Program (IEP), research and monitoring conducted by state and federal resource agencies, and research contributions of academic investigators.

In addition, the BDCP Steering Committee considered a number of other recent reports on the Delta, including reports of the Governor's Delta Vision Blue Ribbon Task Force (January and October 2008) and several recent reports of the Public Policy Institute of California.[48] Many elements of the BDCP conservation strategy parallel the recommendations of these other reports.

1.5.3.1 Independent Science Advisory Process

To ensure that the BDCP would be based on the best scientific and commercial data available, the Steering Committee also sought input and advice from independent scientists on the key elements of the Plan. Early in the planning process, the Steering Committee established a group of "Science Liaisons" to recommend approaches to ensure an appropriate level of independent scientific input into the development of the BDCP and to coordinate with facilitators tasked with responsibility for arranging and overseeing the independent science process. Consistent with the requirements of the NCCPA and the policy directives of the Five-Point Policy,[49] the BDCP Steering Committee directed the facilitators to convene independent scientists at several key stages of the BDCP planning process, enlisting well-recognized experts in ecological and biological sciences to produce recommendations on a range of relevant topics, including

[47] See The State of Bay-Delta Science (2008).
[48] For example, *Comparing Futures for the Sacramento-San Joaquin Delta* (Public Policy Institute of California 2008).
[49] 65 Fed. Reg. 35242.

approaches to conservation planning for aquatic and terrestrial species in the Delta and developing adaptive management and monitoring programs. Among other things, the independent scientists provided recommendations and guidance on such matters as:

- Scientifically sound conservation strategies for species and natural communities proposed to be covered by the Plan;
- A set of reserve design principles that addresses the needs of species, landscapes, ecosystems, and ecological processes in the Plan Area proposed to be addressed by the Plan;
- Management principles and conservation goals that could be used in developing a framework for the monitoring and adaptive management component of the Plan; and
- Identification of data gaps and uncertainties so that risk factors may be adequately evaluated.

Reports prepared by independent science advisors to the BDCP are provided in Appendix G, *Independent Science Advisors Reports*.

The Steering Committee assembled five different groups of independent science advisors during the development of the BDCP. The first group gathered in September 2007, to provide guidance on approaches to planning for the conservation of aquatic species and ecosystem processes in the Delta. Specifically, the group advised the Steering Committee on the following elements of the BDCP:

- The application of conservation planning principles within the Plan Area;
- Geographic and temporal scope of the BDCP;
- Addressing facets of Delta ecosystem dynamics;
- Analytical methods used in BDCP formulation, methods of analysis; and
- Adaptive management and monitoring considerations.

A second group of science advisors was convened in September 2008 to consider approaches to planning for the conservation of non-aquatic resources in the Plan Area. The group provided recommendations to the Steering Committee on such issues as:

- Non-aquatic species to be considered for regulatory coverage under the BDCP;
- Terrestrial natural communities that should be addressed under the BDCP;
- Landscape-level approaches to conservation planning for non-aquatic resources;
- Additional sources of information that should be developed to support the non-aquatic resource elements of the BDCP; and

- Conservation strategies that may be considered for addressing terrestrial and non-tidal wetland communities and dependent wildlife and plant species.

The third group of science advisors met in December 2008 and focused on matters related to the development of an adaptive management decision making process for the BDCP informed by data and information generated by monitoring and research efforts. This group built upon guidance on adaptive management that followed from the first of the independent science workshops, offering more specific advice based on progress that had since been made in the development of the BDCP.

The Delta Science Program provided assistance in assembling a fourth group of independent science advisors in February-March 2010 and a fifth group in July-August 2010 to evaluate and provide recommendations on the "Logic Chain" planning structure. The Logic Chain has been proposed as a framework for linking recovery goals for covered fish species with BDCP goals, objectives, conservation measures, monitoring, and adaptive management. Two science reports on the Logic Chain were prepared.

In the first report, dated March 19, 2010 (Appendix G5), the group assessed the value of the Logic Chain as a tool, its internal consistency, and next steps for input of information into the Logic Chain. The group stated that the Logic Chain was a useful tool for clearly articulating and linking goals, objectives, actions, and outcomes, but recommended an alternate approach that clarifies the links in the chain and reduces areas of ambiguity; distinguish between order-of-magnitude approximations of goals and objectives that are acceptable in early planning and the more detailed descriptions developed later; frame projected outcomes as testable hypotheses linked to specific conservation measures; use metrics to evaluate the success of outcomes that clearly link to biological functions and consider the judicious use of surrogate metrics; consider constraints to implementation of conservation measures; consider the potential impacts of system dynamics, variation, and change over time; and provide more detail to the adaptive management framework. As next steps, the group recommended developing logic chains for a few species initially; leaving recovery goal development to responsible regulatory agencies; focusing on development of the BDCP biological goals and objectives; and convening a workshop to develop monitoring metrics.

In the second report, dated August 23, 2010 and revised September 6, 2010 (Appendix G6 and G7), the group assessed the populated logic chains to evaluate internal logic, measurability, and linkages, and consistency in approach; recommended alternative strategies and metrics for goals and objectives and alternative ways of framing goals and objectives to be more practicable; and provided advice on constructing an integrated monitoring program linked to the logic chains. Recommendations of this science group included: simplifying the logic chain structure to reduce the number of objective statements and to focus on BDCP objectives; identify stressors that are outside of BDCP management; focus BDCP objectives on measures of individual and population-level performance, such as habitat-specific estimates of growth and survivorship, quantitative estimates of abundance, and quantitative measures of movement and/or distribution;

take care in populating the compliance and performance monitoring actions and consider three monitoring levels separately, the global goal, the "covered activity" level, and compliance; and to link implementation of conservation measures, through monitoring and evaluation, to the adaptive management program.

1.5.3.2 DRERIP Evaluation Process

The BDCP Steering Committee undertook a rigorous process to incorporate new and updated information and to evaluate a wide variety of issues and approaches as it formulated a cohesive, comprehensive BDCP conservation strategy. This effort included an evaluation conducted early in 2009 by multiple teams of experts of draft BDCP conservation measures, using the CALFED Bay-Delta Ecosystem Restoration Program's (ERP) Delta Region Ecosystem Restoration Implementation Plan (DRERIP) Scientific Evaluation Process.

In October 2008, the Steering Committee developed early drafts of BDCP conservation measures related to water operations, habitat restoration, and other stressors. The DRERIP evaluation process was used to evaluate these draft conservation measures. The DRERIP process was specifically developed to aid in planning and decision making regarding potential ecosystem restoration projects in the Delta. The process entails engaging teams of experts to work through a structured, step-by-step examination of the scientific efficacy of proposed restoration actions by analyzing both potential positive and negative outcomes which might result from a given action.

To conduct the DRERIP evaluations, the Steering Committee engaged 52 technical experts assembled into five teams to address related groupings of conservation measures. The DRERIP Technical Team meetings were limited to specific technical experts trained in the DRERIP evaluation process. The teams conducted DRERIP evaluations, from January-April 2009, on 32 draft conservation measures that could be evaluated using the process. The evaluations were conducted using a series of peer-reviewed DRERIP ecosystem and species conceptual models developed specifically for the Delta and additional relevant sources of information (e.g., published literature, recently collected data). The conceptual models describe the current scientific understanding regarding how the Delta ecosystem works and were designed to serve as a foundation for the evaluation process. A description of the BDCP DRERIP evaluations and evaluation results are presented in Appendix F, *DRERIP Evaluation Results*.

Results include an assessment of the likely magnitude of the ecological outcomes and the certainty of those outcomes that could be associated with implementation of each evaluated conservation measure. However, because the DRERIP process is designed to evaluate restoration actions independently, it does not provide for a direct assessment of the combined magnitude and certainty of positive and negative ecological outcomes that would be associated with the contemporaneous implementation of multiple conservation measures under BDCP. To address this need, the Steering Committee established a Synthesis Team comprised of Steering Committee member representatives and technical experts that participated in the DRERIP evaluations to conduct an assessment of the likely synergistic ecological effects of simultaneous implementation of multiple conservation measures based on the evaluation results for individual conservation measures. The Synthesis Team conducted the evaluation during March-April 2009 and provided recommendations to the Steering Committee for refining conservation measures, sequencing implementation of conservation measures, and adjusting DRERIP results for individual conservation measures based on their synergistic effects with implementation of other conservation measures.

DRERIP evaluation results were also used to inform development of the effectiveness monitoring for conservation measures (Section 3.6, *Monitoring and Research Program*). DRERIP evaluation results include assessments and sources of uncertainty surrounding the magnitude of ecological outcomes that could be expected with the implementation of each conservation measure. Based on these assessments, effectiveness monitoring was developed to collect the information necessary to address these sources of uncertainty and to inform the need for future adjustments to conservation measures to improve their performance over time through the BDCP adaptive management decision making process (Section 3.7, *Adaptive Management Program*).

1.6 ORGANIZATION OF THE BDCP

The BDCP consists of an Executive Summary, 12 chapters, and 14 appendices. Specifically, the plan includes the following components:

The BDCP includes an executive summary, which provides an overview of the BDCP, including descriptions of the background, purpose, covered activities, conservation strategy, and approach to plan implementation. Chapter 1 sets the context for the development of the BDCP, including the purpose and scope of the plan, the planning and conservation goals and objectives, and the expected regulatory outcomes. Chapter 1 also describes the process that guided the development of the Plan. Chapter 2 describes existing environmental conditions within the Plan Area, providing the context in which the BDCP and its various elements have been developed. Chapter 3 sets out the BDCP conservation strategy, including the biological goals and objectives of the Plan, approach to conservation adopted by the Plan, the range of conservation measures for aquatic and terrestrial species and habitats, and the monitoring and adaptive management plans.

Chapter 4 identifies the activities proposed for regulatory coverage, including existing and future actions. Chapter 5 includes an analysis of the beneficial and adverse effects of the BDCP on covered natural communities and covered species. The chapter also describes the indirect effects resulting from the implementation of the BDCP conservation strategy and the covered activities. Chapter 6 addresses matters relating to the implementation of the BDCP, including the schedule for the implementation of actions, the reporting process to ensure compliance, regulatory assurances anticipated by the entities seeking authorizations, measures to address changed circumstances, and the approach to unforeseen circumstances. Chapter 7 sets out a governance structure to ensure successful long-term implementation of the Plan. Chapter 8 estimates the costs of Plan implementation and identifies the sources of funding that will be relied on to implement the Plan.

Chapter 9 sets out the alternatives to take that were developed and considered and the reasons why they were not adopted. Chapter 10 describes the independent science advisory process and the recommendations provided by these scientists. Chapter 11 lists the preparers of the BDCP, and Chapter 12 lists the sources cited in the Plan.

CHAPTER 2. EXISTING ECOLOGICAL CONDITIONS

Table of Contents

2.1 Introduction 2-5
2.2 Historical Conditions 2-7
2.2.1 Hydrologic and Geomorphic Conditions 2-7
2.2.2 Biological Conditions 2-10
2.3 Existing Ecological Conditions 2-12
2.3.1 Data Sources and Natural Community Classification 2-12
2.3.1.1 Data Sources 2-12
2.3.1.2 Natural Community Classification in the Legal Delta 2-13
2.3.1.3 Natural Community Classification in Suisun Marsh 2-14
2.3.1.4 Natural Community Classification in the Upper Yolo Bypass 2-16
2.3.1.5 Vernal Pool Complex Dataset Development 2-16
2.3.2 Ecosystem Processes 2-17
2.3.2.1 Aquatic Ecosystem Processes 2-18
2.3.2.2 Physical Processes 2-18
2.3.2.3 Chemical Processes 2-19
2.3.2.4 Geomorphic Processes 2-21
2.3.2.5 Biological Processes 2-22
2.3.2.6 Effects of Anthropogenic Influence and Future Climate Change 2-24
2.3.2.7 Terrestrial Ecosystem Processes 2-26
2.3.3 Physical Environment 2-27
2.3.3.1 Geomorphic Setting 2-27
2.3.3.2 Climate 2-40
2.3.3.3 Hydrologic Conditions 2-41
2.3.3.4 Tides 2-49
2.3.3.5 Non-Water Supply Plan Area Infrastructure and Uses 2-54
2.3.4 Natural Communities 2-55
2.3.4.1 Tidal Perennial Aquatic 2-65
2.3.4.2 Tidal Mudflat 2-74
2.3.4.3 Tidal Brackish Emergent Wetland 2-75
2.3.4.4 Tidal Freshwater Emergent Wetland 2-80
2.3.4.5 Valley/Foothill Riparian 2-86
2.3.4.6 Nontidal Perennial Aquatic 2-93
2.3.4.7 Nontidal Freshwater Perennial Emergent Wetland 2-97
2.3.4.8 Alkali Seasonal Wetland Complex 2-101
2.3.4.9 Vernal Pool Complex 2-105
2.3.4.10 Managed Wetland 2-111
2.3.4.11 Other Natural Seasonal Wetland 2-116
2.3.4.12 Grassland 2-119
2.3.4.13 Inland Dune Scrub 2-125
2.3.4.14 Agricultural Habitats 2-129
2.3.5 Covered Species 2-138
2.4 Biological Diversity 2-140

CHAPTER 2. EXISTING ECOLOGICAL CONDITIONS

[***Note to Reviewers****: This is a revised version of BDCP Chapter 2, Existing Ecological Conditions. The last draft of Chapter 2 was presented to the Steering Committee at the October 7, 2010 meeting. Revisions have been made throughout the text to address comments received, to clarify concepts, and to bring the document up to date with the progress on various components of the BDCP in 2010. The BDCP Steering Committee members have submitted comments to various drafts of this chapter during development, which may or may not have been incorporated into this November 18, 2010 draft. While the text of this chapter is subject to change and revision as the BDCP planning process progresses, the chapter has been drafted and formatted to appear as it may in a completed draft HCP/NCCP. Although the chapter includes declarative statements (e.g., the Implementation Office will…), it is nonetheless a "working draft" that will undergo further modification based on input from the BDCP Steering Committee, state and federal agencies, and the public.*]

2.1 INTRODUCTION

This chapter describes the existing ecological conditions present in the Bay Delta Conservation Plan (BDCP) Plan Area, including specific information to meet the requirements of the federal Endangered Species Act (ESA) and the California Natural Community Conservation Planning Act (NCCPA). The Plan Area encompasses approximately 858,372 acres, and includes the statutory Delta as defined in the California Water Code, Section 12220, Suisun Marsh (approximately 107,837 acres), and the upper Yolo Bypass (approximately 16,762 acres) (Figure 2-1).

Section 2.2, *Historical Conditions*, provides a brief summary of the physical and biological conditions that were historically present within the Plan Area, as well as historical conditions upstream and downstream of the Delta as they relate to supporting conditions of the historical Delta. Current physical and biological conditions of the Plan Area are described in Section 2.3, *Existing Ecological Conditions,* which provides descriptions of natural processes in the Plan Area, its physical environment, and its biological communities. Section 2.4, *Biological Diversity*, provides a summary of the biological diversity within the Plan Area. Appendix A, *Covered Species Account*s, contains detailed accounts of the covered species, including information on life history characteristics, habitat requirements, and threats and stressors that are relevant to conservation efforts and recovery goals. The ecological information presented in this chapter and that provided in Appendix A provide support for the evaluation of the potential effects of covered activities on proposed covered species and natural communities and for the development of measures to address the conservation of covered species and natural communities. Common and scientific names of species mentioned in the text are provided in Appendix B, *Common and Scientific Names of Fish, Wildlife, and Plants Mentioned in the Text*.

2.2 HISTORICAL CONDITIONS

This section provides a brief overview of historical physical and biological environmental conditions of the Plan Area and environmental conditions present upstream and downstream of the Plan Area as they relate to supporting the description of conditions within the Plan Area.

2.2.1 Hydrologic and Geomorphic Conditions

Much of the broad scale geology of the Central Valley, Delta, and Suisun Marsh was formed before the Pleistocene epoch (>2 million years ago), while finer details wrought by younger geologic formations, including the recent uplift and movement of the Coast Range and the deposition of broad alluvial fans along both sides of the Central Valley, formed during the Pleistocene epoch from 2 million to 15,000 years ago (Loudeback 1951, Olmsted and Davis 1961, Lydon 1968, Shelmon 1971, Atwater et al. 1979, Marchandt and Allwardt 1981, Helley and Harwood 1985, Sarna-Wojcicki et al. 1985, Weber-Band 1998, Unruh and Hector 1999, Graymer et al. 2002, Weissmann et al. 2005, Unruh and Hitchcock 2009). Approximately 21,000 years ago, the last glacial maximum ended and the eustatic (worldwide) sea level began to rise from the lowstand (lowest sea level bathymetric position or depth during a geologic time) of -394 feet (-120 m) in a series of large meltwater pulses interspersed by periods of constant rising elevation. The rise continued until the Laurentide ice sheet had completely melted 6,500 years ago and the rate of sea level rise slowed dramatically (Edwards 2006, Peltier and Fairbanks 2006). During this change from glacial to interglacial period, runoff brought enormous quantities of sediment from the Sierra Nevada and Coast Range that formed alluvial fans and altered stream channels in the Central Valley (Olmsted and Davis 1961, Shelmon 1971, Marchandt and Allwardt 1981, Helley and Harwood 1985, Weissmann et al. 2005).

The modern Delta formed sometime between 10,000 and 6,000 years ago when the rising sea level inundated a broad valley that occupied the Plan Area region. Despite its name, the Sacramento-San Joaquin Delta is not simply the merging of two river deltas, but is instead an elongated and complex network of deltas and flood basins with flow sources that include Cache Creek, Putah Creek, Sacramento River, Mokelumne River, San Joaquin River, and Marsh Creek. Based on current unimpaired flow estimates, the Sacramento River is the largest source of flows and has contributed an average of 73 percent of historical inflows into the Delta; the east-side tributaries including the Mokelumne River contribute about 6 percent, and the San Joaquin River contributes 21 percent (Dayflow 2007). Currently, during flood stages, approximately 82 percent of flows from the Sacramento River pass through the Yolo Bypass (Roos 2006). The flood stage flows can have many sources, including direct flows from tributaries such as the Feather and American rivers, as well as through a system of passive and active weirs (James and Singer 2008, Singer et al. 2008, Singer and Aalto 2009). The Yolo Bypass also serves as a conduit for Cache Creek and Putah Creek as their waters do not reach the Sacramento River until they pass through Cache Slough at the southern end of the Yolo Bypass. The San Joaquin River discharges into a broad network of sloughs and channels, and the Mokelumne River delta merges with the San Joaquin River delta on the eastern side of the Delta. On the southwest side of the Delta, the Marsh Creek delta merges with the San Joaquin River delta.

While flooding has always been a regular occurrence along the Sacramento River (Thompson 1957, Thompson 1960, Thompson 1961, Thompson 1965), the natural geomorphic processes and hydrological regimes were completely disrupted through the enormous increase in sediment and debris supply generated by hydraulic mining operations in the central Sierra Nevada from 1853 to 1884 (Gilbert 1917, Mount 1995). Large volumes of mining sediment remain in the tributaries today (James 2004a, 2004b). The portion of the estimated 1.5 billion cubic feet of sediment that poured into the Sacramento Valley filled river channels and increased flooding severity and peak flows (Gilbert 1917, Kelley 1989, Mount 1995, James 2004a, Hitchcock et al. 2005, William Lettis & Associates 2005, James 2006, CVRWQCB 2008, James and Singer 2008, James et al. 2009). In the 1900s another pulse of mining sediment was discharged into the Sacramento River watershed (James 1999). While it is often assumed the mining sediment has already passed through the Delta or is stored behind dams, large amounts remain within the system (James 1999, 2004a, 2004b, 2006, James and Singer 2008, James et al. 2009). Other Central Valley streams, such as the Cosumnes River, have been impacted to a lesser extent by similar mining or agriculture-derived sources of sediment (Florsheim and Mount 2003). The initial pulse of sediment made its way into the San Francisco Estuary where it filled shallow tidal bays, but with current reduced sediment loads these sediments are being eroded and transported into the Pacific Ocean (Cappiella et al. 1999, Ganju and Schoellhamer 2010).

Soils in the Plan Area are extremely variable in texture and chemical composition. Delta soils away from its margins are generally a combination of peat beds in the center of islands with relatively coarse textured inorganic sediments deposited in the channels and along the margins of the islands (William Lettis & Associates 2005, Unruh and Hitchcock 2009, Deverel and Leighton 2010). There are some ancient dune deposits on the islands and shoreline of the western Delta in the vicinity of the San Joaquin River that predate the peat beds (Carpenter and Cosby 1939, SFEI 2010). The soils in the Suisun Marsh area are generally peat or fine textured mineral soils in and along the islands closest to Suisun Bay, and fine textured mineral soils are found closer to the border of the marsh where it abuts the uplands. The soils of the Cache Slough area are primarily mineral soils that are either fine-textured and of local origin, or coarse-textured material that is a legacy of gold mining in the Sierra Nevada and streams leading from the Sierra Nevada. The uplands north of Suisun Marsh and west of the Sacramento River are generally alkaline clays (Mann et al. 1911, Bryan 1923, Thomasson Jr. et al. 1960, State of California 1987, Graymer et al. 2002). The soils of the Yolo Basin are alkaline clays on the west side, a mixture of clay, sand and peat on the bottom of the basin, and silts with sand splays on the natural levee of the Sacramento River (Anonymous 1870, Mann et al. 1911, Andrews 1970). The soils along the southwestern border of the Delta are sands to the north and alkaline clays to the south (Carpenter and Cosby 1939, Natural Resources Conservation Service [NRCS] 2009, SFEI 2010). Along the eastern border of the Plan Area, the soils are heterogeneous patches of clays, loams, and peat (Florsheim and Mount 2003, NRCS 2009).

It is estimated that prior to reclamation actions, nearly 60 percent of the Delta was inundated by daily tides. The tidal portion of the Delta consisted of backwater areas, tidal sloughs, and a network of channels that supported highly productive freshwater tidal marsh and other wetland habitats (CALFED 2000). Similar complex drainage networks, ponds, and salt panes existed in tidal brackish marshes in Suisun Marsh and along the north shore of east Contra Costa County (Suisun Ecological Workgroup 2001, Brown 2004, Grossinger 2004, SFEI 2010). The soils in these marshes were generally peat beds that accumulated and were preserved under anoxic conditions. In contrast, soils in channels and along the higher energy channel margins of islands tend to be comprised primarily of mineral sediment (William Lettis & Associates 2005, Unruh and Hitchcock 2009).

Vast areas in the Delta, Yolo Basin, Suisun Marsh, and the south shore of Suisun Bay were reclaimed (filled, leveed, diked, and drained) between the 1850s and the early 1930s, completely transforming their physical structure (Thompson 1957, 1965, Suisun Ecological Workgroup 2001, Brown 2004, Grossinger 2004, SFEI 2010). Levee ditches were built to drain land for agriculture, human habitation, mosquito control, and other human uses while channels were straightened, widened, and dredged to improve shipping access to the Central Valley and to improve downstream water conveyance for flood control. An estimated 95 percent of original tidal wetlands and many miles of sloughs in the Delta were removed by channelization and levee construction (CALFED 2000).

Under natural conditions, inflows from both the Sacramento and San Joaquin rivers were much lower from July through November compared to the December to June period (The Bay Institute 1998) and in drought periods likely lead to salinity intrusions. This difference was more dramatic in the San Joaquin River. The San Joaquin River has an upper watershed consisting of impermeable granitic rock that does not support dry season groundwater discharge. In contrast, the upper watershed of the Sacramento River is composed of permeable volcanic rock. As a result, groundwater discharge from this volcanic system historically maintained a summer base flow at Red Bluff of approximately 4,000 cfs without which the Sacramento River would have nearly dried up each fall (The Bay Institute 1998).

Water diversions in the San Joaquin Valley began earlier than those in the Sacramento Valley; and by 1870, flows of the San Joaquin River were significantly reduced (DWR 1931, Jackson and Paterson 1977). Sacramento River diversions, particularly those in late spring and summer diversions for rice irrigation, increased dramatically from 1912 to 1929, and the combination of significant drought periods and increased diversion during the annual low flow period resulted in an unprecedented salinity intrusion into the Delta in the fall of 1918 (DWR 1931, Jackson and Patterson 1977, The Bay Institute 1998, CCWD 2010). The economic impacts of these diversion-caused salt water intrusions ultimately led to the creation of the Central Valley Project (CVP) and the construction of dams for the release of freshwater flow to prevent salinity intrusion (Jackson and Patterson 1977). Construction of dams and diversions on all major rivers contributing to the Delta between the 1930s and 1960s resulted in substantial changes to Delta hydrodynamics (The Bay Institute 1998, CCWD 2010). Four dams (Shasta, Oroville, Trinity, and

Monticello) in the Sacramento Valley have a storage capacity greater than 1 million acre feet (maf) (12 maf total); an additional four dams (New Melones, Don Pedro, New Exchequer, and Pine Flat) with storage capacity greater than 1 maf (6.5 maf total) drain into the San Joaquin Valley (DWR 1993).

The main effect of this upstream water development was the dampening of the seasonal high and low flows into the Plan Area (CCWD 2010). Reclamation of the Delta and upstream water development also accentuated salinity intrusions into the Plan Area. Current water management regulations have reduced the annual fluctuations in salt water intrusion, but have also shifted the boundary between fresh and salt water significantly further into the Delta (CCWD 2010). In combination with dam construction, flood control and water operations have greatly transformed the geometry and hydrology of the Delta, as well as for downstream locations including Suisun Bay and Suisun Marsh (Section 2.3.2, *Ecosystem Processes*).

2.2.2 Biological Conditions

Prior to the Gold Rush era (c. 1850), the predominant vegetation of the Delta consisted of bulrushes and tules (*Schoenoplectus*[1] spp.), which are adapted to the range of salinity present in the Delta from freshwater to as high as 2 parts per thousand (ppt) in the western Delta in the later summer (Thompson 1957, Atwater and Belknap 1980). The area was described as a vast, sea-level “swamp” with tracts of intertidal wetland and a network of channels of various sizes. The characterization of the historical Delta as a vast tule marsh, however, is an oversimplification from an ecological standpoint, and fails to reflect the considerable habitat complexity and diversity that allowed the Delta ecosystem to support such an unusually rich and diverse native biological community (The Bay Institute 1998). Generally, the current vegetation of the Delta correlates with the historical vegetation, and the vegetation of the tidal freshwater areas of the central Delta down to about 18 inches below mean lower low water (MLLW) falls into two general categories. Tules (generally *Schoenoplectus californicus*), cattails (*Typha* spp.), and willows (*Salix* spp.) dominate the vegetation along the Sacramento River, while throughout the San Joaquin River area of the Delta bulrushes (generally *Schoenoplectus acutus*), tules, common reed (*Phragmites australis*), and willows are more often the dominant species (Atwater 1980, Simenstad et al. 2000, Watson 2006, EDAW 2007b, Hickson and Keeler-Wolf 2007, Watson and Byrne 2009).

Further west, from about the vicinity of Collinsville, the tidal brackish marsh vegetation is characterized by bulrush, tules, common reed, and cattail (Culberson 2001, Suisun Ecological Workgroup 2001, Watson and Byrne 2009, SFEI 2010). These same large species occur as clumps in the tidal channel to the marsh plain transition zone and share that zone with many other species such as saltgrass (*Distichlis spicata*), Baltic rush (*Juncus balticus*), and seaside arrowgrass (*Triglochin maritima*). The borders of the smallest channels (first order channels and mosquito ditches) are also habitat for Suisun thistle (*Cirsium hydrophilum* var. *hydrophilum*), which is a

[1] The genus was formerly *Scirpus.*

BDCP covered species. The boundary between the distant edge of the transition zone and marsh plain is gradual as there is very little change in the elevation of the marsh plain; and this is where soft bird's-beak (*Cordylanthus mollis* ssp. *mollis*), a BDCP covered species, occurs with pickleweed (*Sarcocornia pacifica,* formerly *Salicornia virginica*), saltgrass, salt marsh dodder (*Cuscuta salina*), and spearscale (*Atriplex triangularis*). The marsh plain proper is dominated by a variable mixture of pickleweed and saltgrass.

Historically, the perimeter of the Plan Area consisted of tidal and nontidal wetlands and mudflats that merged with upland vegetation types that included nontidal wetlands, meadows, oak savanna, alkali grasslands, vernal pools, and alkali sink scrub. Due to their productivity and heterogeneity, vegetation in the uplands formed complex physical habitats that consisted of herbaceous species (grasses and dicots), shrub species (willows, blackberries [*Rubus*], wild roses [*Rosa*]), and a mixture of tree species such as oak (*Quercus*), sycamore (*Platanus*), alder (*Alnus*), walnut (*Juglans*), and cottonwood (*Populus*). Mammals using these upland habitats included tule elk (*Cervus canadensis nannodes*), mule deer (*Odocoileus hemionus*), pronghorn (*Antilocapra americana*), grizzly (*Ursus arctos*), coyote (*Canis latrans*), American badger (*Taxidea taxus*), ground squirrel (many spp.), pocket gopher (*Thomomys*), cottontail (*Sylvilagus audubonii*), and black-tailed jackrabbit (*Lepus californicus*) in drier areas (Grinnell et al. 1937, Thompson 1957). Much of this flora and fauna was severely reduced with reclamation and the development of agriculture that began in the early 1850s.

High tule productivity combined with the rich organic sediments of the basins along the Sacramento and San Joaquin rivers and the channels and channel-to-marsh plain transition zones of Suisun Marsh provided large amounts of organic matter support for the aquatic food web. This organic matter input probably resulted in abundant biomass of zooplankton (detritivores, scavengers, and filter-feeding planktivores) (The Bay Institute 1998). The large and complex food web also likely supported an abundant assemblage of fishes.

Because the Delta environment and its fish species assemblage has changed significantly and was not documented prior to the changes, there is limited knowledge of the ecology of native fishes in the past (Moyle 2002). It is known that the historical assemblage of fish in the Delta was very different from the current assemblage. For example, thicktail chub was driven to extinction in the 1950s, most likely due to marsh reclamation impacts and the introduction of nonnative fish species (Schulz and Simons 1973). Also, the Sacramento perch, once very abundant in sloughs off main channels, was extirpated from the Delta for the same reasons (Rutter 1908). Conversely, a large number of nonnative species of fish have been deliberately introduced (e.g., striped bass [*Morone saxatilis*], channel catfish [*Ictalurus punctatus*], and largemouth bass [*Micropterus salmoides*]), or introduced into the system as cast offs (e.g., goldfish [*Carassius auratus auratus*]). Further, the abundance of many species of native fish was much greater historically than currently. For example, Chinook salmon (*Oncorhynchus tshawytscha*) were once very abundant throughout the Delta and Sacramento and San Joaquin rivers and tributaries, but today their abundance is low for many reasons (Appendices A2 through A4). The freshwater range of anadromous fish, such as salmonids (Salmonidae) and sturgeon (*Acipenser*) was much greater historically before the construction of dams, and the degradation of suitable habitat below dams significantly reduced the extent of spawning habitat. Fish likely fed on dominant crustaceans, such as the mysid *Neomysis*, the amphipod *Corophium*, and cyclopoid copepods (Moyle 2002), which have been replaced as dominant species by multiple nonnative copepod species, including *Limnoithona*, *Pseudodiaptomus*, and *Acanthomysis* (Sommer 2007).

2.3 Existing Ecological Conditions

2.3.1 Data Sources and Natural Community Classification

2.3.1.1 Data Sources

Background data for the BDCP were collected through an extensive search of various sources including current scientific literature, reports, technical documents, agency maintained data (e.g., CALFED Interagency Ecological Program, California Department of Fish and Game [DFG], and DWR), and BDCP documents (e.g., BDCP Independent Science Advisors Report [Reed et al. 2007]). A full list of sources of background data used for this report is provided in Chapter 12, *References*. Where data were not available, or where significant uncertainties were identified through initial data gathering and synthesis, technical experts were engaged to provide unpublished data and best professional scientific judgment. Various technical experts participated in developing, writing, and reviewing the descriptions of the natural communities (Section 2.3.4) and the accounts of covered species (Appendix A, *Covered Species Accounts*). Citations and references pertaining to individual covered species are embedded in species accounts in Appendix A.

Map data layers were compiled from existing spatial data sets, primarily produced by state and federal agencies and available on their websites, or by data transfer. The sources and types of spatial information used in this report are presented in Table 2-1.

Natural communities (Section 2.3.4) were defined and described using the CALFED Bay-Delta Program Ecosystem Restoration Program (ERP) Volume 1 and the Multiple Species Conservation Strategy (CALFED 2000), and were further refined and augmented by input from DFG staff participating in the BDCP Terrestrial Resources subgroup in 2009. In addition to the BDCP vegetation cover dataset, a vernal pool complex natural community dataset was separately generated to more effectively capture the vernal pool complex (pools and supporting uplands) community present within the Plan Area. Vernal pool complex areas that were deemed to have been significantly altered were retained as a degraded vernal pool complex vegetation type which generally falls into the grassland and the natural seasonal wetland BDCP covered natural communities (Appendix L2, *Vernal Pool Complex Mapping for the BDCP*).

2.3.1.2 Natural Community Classification in the Legal Delta

The natural communities were delineated within most of the statutory Delta portion of the Plan Area using the Vegetation and Land Use Classification map of Sacramento-San Joaquin River Delta and associated GIS shape files (Hickson and Keeler-Wolf 2007). Vegetation was classified and mapped by the California Department of Fish and Game (DFG) within the legal Delta, excluding Chipps Island and Van Sickle Island in the far western portion of the Delta, during 2005-2006 for use in conjunction with the Delta Regional Ecosystem Restoration Implementation Plan. Vegetation sampling was conducted using the California Native Plant Society Rapid Assessment Protocol.

Land cover features were mapped by DFG using minimum mapping units (MMU) as follows:

- Landuse: MMU = 2 acres (minimum width of 25 meters);
- Isolated Landuse: MMU = 1 acres (minimum width of 10 meters);
- Water: MMU = 1 acre (minimum width of 10 meters);

- Vegetation: MMU = 2 acres (minimum width of 10 meters); and
- Critical veg: MMU = 1 acre (minimum width of 10 meters).

Features were occasionally mapped below MMU or minimum width because those features were so distinct or important compared to their surroundings that omitting them would have distorted the representation of the area.

In the area sampled, a total of 377 Rapid Assessments were conducted in the field and subsequently used to develop a quantitative classification based on cluster analysis. A total of 52 vegetation alliances were identified by the clustering algorithm, including 45 plant associations defined by Sawyer and Keeler-Wolf (1995). These classification units were either directly or indirectly used to develop 129 fine-scale to mid-scale vegetation mapping units. Mapping was undertaken using heads-up digitizing, in which polygons of vegetation were delineated on-screen. Each polygon was then coded with both a vegetation type and one of 25 land use types. Base imagery used to map the vegetation was true color 1-foot resolution aerial photography from spring 2002. Additional marginal areas of the mapped area were supplemented by true color 1-meter resolution photography from summer 2005. The mapped polygons were then compared with a fine-scale vegetation mapping product of nearby Suisun Marsh to measure efficiency and accuracy for future mapping efforts in the Bay-Delta Region. A more detailed description of the classification and mapping process is available in Hickson and Keeler-Wolf (2007).

The vegetation categories produced by DFG were combined into the corresponding broad biological community classifications used in the BDCP. Polygons from the fine-scale DFG map were combined using GIS. The portion of the Plan Area not sampled by DFG during the Delta mapping project was delineated by SAIC ecologists into a GIS using U.S. Department of Agriculture National Agriculture Imagery Program 1-m resolution color aerial photography (USDA 2005). This imagery was photographically interpreted to identify the natural communities present in portions of the Plan Area that were not sampled by DFG.

2.3.1.3 Natural Community Classification in Suisun Marsh

Natural communities were delineated within Suisun Marsh using the Vegetation Mapping of Suisun Marsh, Solano County California GIS dataset from 2006 (Boul and Keeler-Wolf 2008). DFG classified and mapped vegetation within Suisun Marsh, as well as Chipps Island and Van Sickle Island. The Manual of California Vegetation (Sawyer and Keeler-Wolf 1995) was used as the classification protocol and is based on the National Vegetation Classification System (Grossman et. al. 1998). The vegetation classification process described by Keeler-Wolf and Vaghti (2000) was reapplied in 2003 and 2006 in an effort to document vegetation changes within the Suisun Marsh. The 2006 Suisun Marsh Vegetation Mapping Change Detection GIS dataset represents the most recent data, and thus was used to define vegetation cover occurring within the Suisun Marsh region. It should be noted that this dataset has registration issues when comparing it to the National Agriculture Imagery Program (NAIP) or the U.S. Geologic Survey

(USGS) standardized regional imagery. The original dataset was developed in 1999. It involved registering and "rubber sheeting" over 100 1:9,600 true color photos. The airphotos were rectified to a registered SPOT base satellite image and the mapping was then tied to these registered and mosaiced photos. Users will observe that internal alignment inconsistencies are present when comparing the mapped land cover features to standardized imagery (e.g., USGS Digital Orthophoto Quarter Quadrangles [DOQQ], NAIP). Currently, there is no work planned to refine the alignment inconsistencies at this time (pers. com. T. Keeler-Wolf 2009). This dataset represents the most comprehensive and detailed vegetation survey available for the Suisun Marsh region.

Developing the relationships and equivalencies between the Suisun Marsh mapped vegetation cover types and the corresponding natural community classifications used in the Plan Area proved problematic. Science Applications International Corporation (SAIC) staff ecologists observed that the classification of communities within the Suisun Marsh was primarily driven by changes in species compositions due to wetland management strategies being applied in the region. Because of the presence of these management strategies, vegetation classes could be found to occur within multiple BDCP natural communities types. For example, the *Distichlis spicata* vegetation type was often found within both the managed wetland and the tidal brackish emergent wetland communities. Therefore, instead of developing a procedure to link the Suisun Marsh vegetation classes to the BDCP natural communities, the spatial extents of wetland management strategies were used to categorize the 2006 Suisun Marsh mapped vegetation.

The San Francisco Estuary Institutes' EcoAtlas (SFEI 1998) GIS dataset provides a reasonable estimate of land use classifications, and was used to support the categorization of the Suisun Marsh vegetation classes into the BDCP natural communities. The SFEI EcoAtlas GIS dataset mapped the Suisun Marsh using general categories that were loosely lumped into high elevation tidal marsh, low/mid elevation tidal marsh, muted tidal marsh, managed marsh, diked marsh, farmed bayland, grazed bayland, ruderal, storage basins, deep bay or ocean, shallow bay, and tidal mudflat. These land use categories were grouped into the equivalent BDCP natural community types (Table 2-2). DFG Suisun Marsh vegetation cover types located within any of the EcoAtlas 'tidal marsh' classified areas were determined to be tidal brackish emergent wetland. DFG Suisun Marsh vegetation cover types located within areas classified as either "managed marsh," "diked marsh," or "storage basin" by the EcoAtlas dataset were determined to be managed wetland. DFG Suisun Marsh vegetation cover types located within areas classified as "farmed bayland" or "ruderal" by the EcoAtlas dataset were determined to be agriculture. DFG Suisun Marsh vegetation cover types located within areas classified as "deep bay or ocean," "shallow bay," or "tidal mudflat" by the EcoAtlas dataset were determined to be tidal perennial aquatic. Lastly, DFG Suisun Marsh vegetation cover types located within areas classified as "grazed bayland" by the EcoAtlas dataset were determined to be grasslands. The resulting categorized Suisun Marsh vegetation dataset was then visually compared to NAIP 2005 aerial imagery by SAIC ecologists and refined as necessary (USDA- FSA 2005).

Table 2-2. EcoAtlas Land Use Classifications and Equivalent BDCP Natural Community Type

EcoAtlas Land Use Classification	*Equivalent Designation of BDCP Natural Community Type*
Tidal Marsh	Tidal Brackish Emergent Wetland
Managed Marsh Diked Marsh Storage Basin	Managed Wetland
Farmed Bayland Ruderal	Agriculture
Deep Bay or Ocean Shallow Bay Tidal Mudflat	Tidal Perennial Aquatic
Grazed Bayland	Grasslands

2.3.1.4 Natural Community Classification in the Upper Yolo Bypass

The Yolo County Natural Heritage Program's Regional Vegetation GIS dataset (TAIC 2008) was used to define vegetation cover for the upper Yolo Bypass that extends from the north legal Delta boundary northward to the Sacramento River. The dataset was clipped to the boundaries established for the Yolo Bypass. The vegetation classification categories assigned to the Yolo County dataset were evaluated by SAIC ecologists to determine the appropriate corresponding BDCP natural community with which each vegetation category should be associated.

The Delta vegetation cover dataset, the Suisun Marsh vegetation cover dataset, and the Upper Yolo Bypass vegetation cover dataset were merged to generate a single compilation vegetation cover dataset for the Plan Area.

2.3.1.5 Vernal Pool Complex Dataset Development

In addition to the BDCP vegetation cover dataset, a vernal pool complex natural community dataset was separately generated to more effectively capture vernal pool characteristics present within the Plan Area. On the east side of the Delta, the potential region of the vernal pool complex near Stone Lakes was identified using existing vernal pool GIS data sets, CNDDB records, management plans, South Sacramento HCP vernal pool maps, expert knowledge, and Google Earth aerial imagery (DWR 2007a, Kleinschmidt Associates 2008, DFG 2007, Google Inc. 2009). The areas of the region that were not clearly impacted by intensive agriculture or development were then inspected using Light Detection and Ranging (LiDAR) imagery to determine the extent of ground disturbance and the presence of appropriate pool and swale microtopography. The entire area identified within field boundaries was then digitized as vernal pool complex. Mapping of the remainder of the Delta, Yolo Bypass, and areas along the northern edge of Suisun Marsh was accomplished by identifying areas with alkaline soils and the appropriate geomorphic characteristics and drainage condition. Those areas were cross-checked through CNDDB records, maps produced for the East Contra Costa HCP/NCCP, and various management plans and then intersected with the appropriate vegetation type.

Google Earth and LiDAR imagery were then used to identify areas with the appropriate microtopography (Leigh Fisher Associates 2005, DWR 2007a, DFG 2007, Google Inc. 2009). The appropriate areas within fields, ditches, or other clear edges were classified as Vernal Pool Complex. A few areas with vernal pool signatures that were not identified by the soil-vegetation intersection were digitized as vernal pool complex. No MMU or scale was used during the process as the goal was to be as inclusive as possible of these often very small features. GPS-linked photographs taken during BDCP floristic field surveys in the spring and summer of 2009 were used to assess the accuracy of the mapping at several sites (DWR file data 2009). The excluded areas of low quality ephemeral habitat ranged from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, disking, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pasture. These areas were retained as a vegetation type that generally fell within the BDCP other seasonal wetlands community. For more detail on the vernal pool complex dataset development, see Appendix L2, *Vernal Pool Complex Mapping for the BDCP*.

2.3.2 Ecosystem Processes

The ecosystems of the Plan Area are dynamic and driven by a complex set of interacting physical, chemical, geomorphical, and biological processes that originate from internal and external causes (Figure 2-2). These processes vary at multiple spatial and temporal scales, typically along gradients rather than at well defined boundaries (Kimmerer 2004). Organisms that evolved in these ecosystems are adapted to this variability as it historically existed. Anthropogenic factors have altered the ecosystems in many ways and global climate change is expected to alter it further.

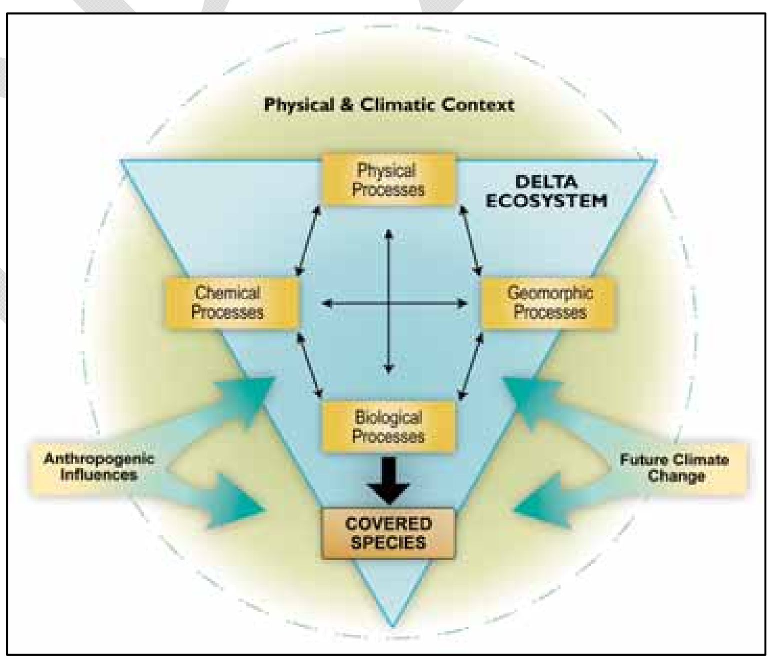

Figure 2-2. Ecosystem Processes in the Delta

2.3.2.1 Aquatic Ecosystem Processes

2.3.2.1.1 Physical Processes

Major physical factors driving ecological conditions in the Plan Area include water flow, salinity, and turbidity. The most conspicuous physical forcing factor is water flow, which varies daily, seasonally, and annually. Water flow directly or indirectly influences nearly all other ecosystem processes in the Plan Area. Large scale hydrodynamics in the Plan Area are driven largely by tides, flows, water exports, cumulative effects of local diversions, and atmospheric forcing. Local hydrodynamics are driven by water depth, channel geometry, and bathymetry at bends and channel junctions. Local conditions are not static and the cross-sections and beds of most Delta channels are dynamic and change in response to flow rates, wind, and other physical drivers.

Flow patterns are driven by the interaction between upstream (freshwater) flows entering the Delta and oceanic tides moving in and out of the Delta twice a day. While tidal flows drive the large majority of water movement in the Delta (Kimmerer 2004), they contribute little to net flow out of the Plan Area. Average tidal flow rates are 170,000 cfs, but can exceed 300,000 cfs during high tidal flow events (Mount 1995). In contrast, inflows from the upstream rivers average an order of magnitude lower. The average daily total Delta outflow from 1955-2007 was 33,715 cfs and has been as low as 4,200 cfs during dry periods (DayFlow, unpubl. data). While tidal influence dissipates at approximately the same location upstream on both the Sacramento and San Joaquin rivers (at approximately river mile [rm] 50), because freshwater inflow from the Sacramento River is much larger than inflow from the San Joaquin River (Section 2.3.3.3, *Hydrologic Conditions*) a much larger tidally driven volume of water or tidal prism moves in and out of the San Joaquin River. The overall pattern shows that hydrodynamic processes (e.g., transport, dispersion, etc.) in the western portion of the Delta are governed primarily by tidal exchange, while hydrodynamics in the northern and southern portions of the Delta are governed primarily by river flow.

In the region where fresh and oceanic waters first mix a longitudinal salinity gradient is formed. This gradient is intensively monitored and is spatially indexed by X_2, which is the distance (in kilometers [km]) from the Golden Gate Bridge at which channel bottom water salinity is 2 ppt (Jassby et al. 1995). The spatial and temporal characteristics of this gradient vary daily and seasonally and are driven by freshwater inflow and tidal action. The location of X_2 shifts upstream during a flood tide and downstream during an ebb tide. Similarly, X_2 is located farther downstream during high Delta outflows and farther upstream during periods of low outflows. Theoretically, within the salinity gradient, an estuarine salinity field and density gradient, also called a salt wedge, may form in which denser salt water is located at the bottom farther upstream and freshwater is located at the surface farther downstream; however, due to turbulent mixing, this rarely occurs in the Delta or Suisun Bay (Kimmerer 2004).

Temporal and spatial patterns in flow can directly affect the concentration and distribution of nutrients and contaminants, water density, salinity gradients, and floodplain inundation frequency and duration (Kimmerer 2004). Flow patterns also directly affect the transport of dissolved and suspended particles, including nutrients, gases, organic matter, toxics, sediment, and organisms (Kimmerer 2002, Jassby 2008). Although concentrations of particles do not necessarily increase with higher flows (but often do because of resuspension), the overall load (i.e., delivery) of particles increases with higher flow rates. The residence time of particles, the duration that they occur in a defined area, is inversely related to water flow rates. There are both positive and negative effects of increased residence time, depending on the effect of the particle on the biological process. Longer residence time of nutrients and organic matter may have beneficial effects on biological processes, whereas longer residence time of toxics may have deleterious effects on biological processes. When residence time is too great, biological consumption of dissolved oxygen at particular depths in the water column may exceed oxygen supply rates that are driven by atmospheric exchange processes and mixing at different depths and lead to anoxic conditions which are lethal for many organisms. Short residence time of nutrients and organic matter in the Delta may not provide organisms with sufficient time to use primary and secondary production that arises from these nutrients and organic matter.

Turbidity is an indirect method for quantifying how the transmission of light through water is attenuated by particles and dissolved substances, and is influenced primarily by suspended sediments and secondarily by suspended and dissolved organic material and plankton (Kimmerer 2004). Although still high relative to other aquatic ecosystems, turbidity in the western region of the Delta (in and near the Low Salinity Zone [LSZ]) has declined tenfold over the past three decades (Lehman 2000, Kimmerer 2004). This may be due to reduced sediment supply, reduced phytoplankton biomass, or the localized trapping of particles caused by an increase in the extent of submerged aquatic vegetation, particularly the nonnative and highly invasive Brazilian waterweed (Grimaldo and Hymanson 1999, Kimmerer 2004). This decrease is an indicator of extensive changes in the aquatic food web that may be manifested in a number of ways. Regardless of current declines in turbidity, primary productivity in the Delta is thought to be limited due to low light transmission through the still relatively turbid water column (Cole and Cloern 1984, Kimmerer 2004).

2.3.2.1.2 Chemical Processes

Major chemical processes driving ecological conditions in the Delta include the cycling of nutrients, carbon, and other organic matter. Some important dissolved inorganic nutrients include, but are not limited to, nitrogen in the form of nitrate, nitrite, and ammonium/ammonia (chemical species varies with pH), phosphorus in the form of phosphate, and silicate (Kimmerer 2004). Dissolved organic nitrogen and phosphorus are also present in the system and can be easily recycled by the consumption of organic material by animals and microbes. Sources of nitrogen and phosphorus to the Delta include sewage, urban runoff, oceanic inputs, and agricultural runoff. As noted above, it is generally accepted that, for most of the year in most locations of the Delta, primary productivity is not nutrient-limited; instead, turbitity appears to limit primary productivity as a result of low light levels (Section 2.3.2.5, *Biological Processes*) (Cole and Cloern 1984, Kimmerer 2004). High nutrient concentrations in the Delta are not necessarily beneficial and can cause blooms of harmful phytoplankton species that pose risks to both the aquatic ecosystem and humans, as has occurred in other estuaries (Anderson et al. 2002). For example, blooms of the toxic cyanobacteria, *Microcystis*, have increased since it was first documented in the Delta in 2003 (Lehman et al. 2005), and the blooms may contribute to the reduced concentrations of zooplankton (Pelagic Organism Decline [POD]) (Resources Agency et al. 2007). However, recent work suggests that nutrient concentration explains a small percentage of *Microcystis* abundance patterns (Lehman et al. 2008).

The primary sources of organic carbon for the Delta are its upstream tributaries (Jassby and Cloern 2000). Secondary sources include local phytoplankton and bacterial production and agricultural drainage within the Delta. Most organic carbon from agricultural drainage is derived from peat soils (Jassby et al. 2003). Tertiary sources include discharges from wastewater treatment plants, exports from tidal marsh areas, and possibly aquatic macrophyte production. Benthic microalgal production, urban run-off, and other sources appear to be negligible throughout the Delta.

Organic carbon concentrations are generally reported as particulate until below a threshold size, where they are considered dissolved. Within the Delta, biological production of particulate organic carbon is derived primarily from phytoplankton, although heterotrophic bacteria may contribute a significant proportion of organic carbon to the food web, particularly in the Delta and Suisun Marsh where phytoplankton biomass has declined over the past three decades (Parker et al. 2007). Unlike particulate organic carbon, most dissolved organic carbon (i.e., extremely small particles of organic matter) must be consumed and transformed into larger particles by bacteria before it can be consumed by larger organisms. Since it is a transformation of existing organic carbon and not the production of new organic carbon through photosynthesis by cyanobacteria or phytoplankton, the bacterial transformation of dissolved organic carbon does not add new organic carbon to the food web (Jassby et al. 2003).

Seasonally inundated floodplains such as those in the Yolo Bypass and adjacent to the Cosumnes River provide an allochthonous (export) subsidy of organic matter to other regions of the Delta. Some of this floodplain-generated organic carbon, such as phytoplankton, is especially labile (available to organisms) (Jassby & Cloern 2000, Moyle et al. 2007). Also, since these floodplains are shallower, have longer residence times, and are generally warmer than the mainstem river, they have greater rates of phytoplankton production than do the channels of the rivers (Sommer et al. 2001a).

The oxygen concentration of the aquatic environment is influenced by exchange with the atmosphere, photosynthesis, aerobic and anaerobic respiration, vertical exchange, water temperature, and wind and wave action (Kimmerer 2004). In general, the water in the channels of the Delta is saturated (at equilibrium with the atmosphere) with dissolved oxygen in most areas during most of the year. One common exception occurs during late summer and early fall in the Stockton Deep Water Ship Channel (DWSC) on the San Joaquin River. At that particular location the combination of low river flows, high concentrations of oxygen-demanding organisms (algae from upstream, bacterial uptake of effluent from the City of Stockton Regional Wastewater Control Facility, and other unknown sources), and channel geometry causes rates of biological oxygen demand to exceed rates of gas exchange with the atmosphere and results in a sag (locally depleted concentration) in dissolved oxygen concentration in the Stockton DWSC (Lee and Jones-Lee 2002, Kimmerer 2004, Jassby and Van Nieuwenhuyse 2005). An oxygen diffuser experiment is currently being conducted in the Stockton DWSC to meet Total Maximum Daily Load (TMDL) objectives for dissolved oxygen concentrations established by the Central Valley Regional Water Quality Control Board (2005) (above 6.0 mg/L from September 1 through November 30 and above 5.0 mg/L at all times). Low dissolved oxygen concentrations have also been documented in Old River near the Tracy Boulevard Bridge and occur in multiple dead-end sloughs near Stockton (e.g., Pixley Slough, Mosher Slough, and Five Mile Slough) (CVRWQCB 2009).

Chemical processes can also be important drivers of physical process. For example, low oxygen concentrations in areas with dense growth of tidal emergent vegetation leads to peat formation which allows the surface of the submerged soil to accumulate peat at a rate that maintains its surface at the same relative elevation to sea level. Prior to reclamation activities, natural peat formation was widespread in the Plan Area, and it remains important for maintaining the elevation of the marsh plain of Suisun Marsh. Additionally, in tidal areas of the western Delta and Suisun Marsh, salinity levels and water and soil water oxygen concentrations are both responsive to the frequency and timing of inundation and are the primary factors that determine the physical structure and species composition of tidal marsh plant communities and the rate of peat accumulation. In the Suisun Marsh, changes in salinity cause corresponding changes in species composition, which in turn cause different rates of belowground productivity that then leads to different rates of peat accumulation in the marsh plain (Culberson 2001, Culberson et al. 2004). Variation in peat accumulation rates is likely to result in variation in the rate the marsh can respond to sea level rise.

2.3.2.1.3 Geomorphic Processes

Major geomorphic processes driving ecological conditions in the Delta include sediment transport and erosion. Fluvial and tidal forces (hydrodynamics) directly influence terrestrial as well as aquatic communities. Geomorphic attributes of the Delta are largely determined by the interactions among sediment sources, water flow, and aquatic and terrestrial biota.

The rate of sediment transport into the Delta depends on the magnitude of upstream erosion and downstream transport. Sediment loads increase with higher flows both because the delivery rate is higher and because sediment concentrations in the water column increase due to greater turbulent mixing and scour, leading to resuspension of sediment (Ruhl and Schoellhamer 2004, McKee et al. 2006). Sediment can act as a sink of multiple biologically active materials, including toxics such as pyrethroids and mercury that have settled into or are bound to the sediment. These biologically active materials are then moved with resuspended sediment. Sediment inputs in the Delta are not in equilibrium with exports to the San Francisco Bay and Pacific Ocean, and there are active areas of erosion within the Delta (Ruhl and Schoellhamer

2004, McKee et al. 2006 Cappiella et al. 1999, Ganju and Schoellhamer 2010). Local sediment deposition occurs in low velocity waters, such as near emergent vegetation or in shallower backwaters. These relatively stable deposits can provide suitable substrate for colonization by plants and ultimately may develop into an emergent vegetation community that traps sediment at greater rates by impeding flow and reducing wave energy (pers. comm. C. Simenstad 2007). This vegetation-sedimentation feedback loop leads to gradients of natural community types that correspond to characteristic bathymetric profiles.

Sediment yields have declined by about 50 percent since 1957 through the depletion of erodible sediments that were deposited by mining activity in the 1800s and 1900s, sediment trapping within reservoirs, riverbank erosion protection, levees, and altered land uses (e.g., agriculture) (James 1999, 2004a, 2004b, Wright and Schoellhamer 2004, James 2006, McKee et al. 2006, James and Singer 2008, Singer et al. 2008, James et al. 2009, Singer and Aalto 2009, Ganju and Schoellhamer 2010). This sediment supply reduction may become particularly problematic under predicted future climate change models as it may prevent marsh surface elevations from tracking sea level rise (Section 2.3.2.6, *Effects of Anthropogenic Influence and Future Climate Change*).

2.3.2.1.4 Biological Processes

This section focuses on aquatic environments in the main channels of the tidal waters of the Delta (biological processes for each of the BDCP communities are discussed in the *Natural Communities* section [2.3.4] below). Primary and secondary productivity and energy transfer to higher trophic levels are the biological processes that fuel the ecosystems of the Delta. In the channel waters of the Delta, phytoplankton biomass and production are low relative to other larger estuaries around the world (Jassby et al. 2002). Historically, chlorophyll concentration, a measure of phytoplankton biomass, decreased significantly in each season except spring (April-June) from 1975-1995 (Jassby et al. 2002, 2003), and remains low (Kimmerer 2004). A major driver of this decline may be the 1986 invasion of the overbite clam (Kimmerer and Orsi 1996) (Section 2.3.2.6, *Effects of Anthropogenic Influence and Future Climate Change*). There are spatial gradients within the Delta as chlorophyll concentrations are greater in the southern and eastern Delta, presumably due to longer residence time and greater water clarity (Kimmerer 2004).

In the absence of other factors such as the overbite clam, nutrients do not limit the development of primary producers in the Delta; instead, light levels within the water column appear to control primary productivity (Cole and Cloern 1984, Kimmerer 2004). Light penetration through the water column has an inverse exponential relationship with suspended particulate matter at a given depth. Therefore, the large majority of phytoplankton production occurs near the surface. If the current pattern holds and water clarity continues to increase in the Delta as it has done over the past few decades (Lehman 2000), higher phytoplankton production is expected. However, the growth rate, depth distribution, and extent of Brazilian waterweed and other nonnative invasive aquatic plants may respond positively to increasing water clarity due to reduced particulate matter concentrations and their dense and extensive canopies may drive down light levels (Kimmerer 2004). High concentrations of ammonia and ammonium, which are derived primarily from wastewater treatment plants, may also contribute to reduced productivity in the Delta and bays of the Plan Area by suppressing the uptake of nitrate by diatoms and phytoplankton (Dugdale et al. 2007, Dugdale 2008). It has been hypothesized that this mechanism may have contributed to the unexplained long term decline in primary productivity in the Delta (Kimmerer 2008). Preliminary research supports this hypothesis (Parker et al. 2010). Glibert (in press) has found evidence that spatio-temporal patterns in ratios of ammonia, nitrate, and phosphate concentrations can explain spatial and temporal patterns in algal functional groups (i.e., diatoms, and flagellates), and cyanobacteria in the Delta, and may also explain zooplankton and pelagic fish abundance.

A high abundance of benthic microalgae occurs in shallow subtidal habitat and intertidal mudflats which compose a significant portion of aquatic habitats in the Delta. While this appears to be a potential source of primary productivity, the actual contribution of benthic microalgae to overall organic carbon production appears to be small (Jassby and Cloern 2000, Kimmerer 2004).

Benthic dwelling filter-feeders, particularly the overbite clam, may be responsible for major inter- and intra-annual variation in phytoplankton abundance in the brackish water areas of the western Plan Area. Similarly, in the freshwater areas of the central and eastern Delta the abundance of the Asian clam is inversely related to phytoplankton biomass in subsided islands that have flooded. Together, the combined grazing impacts of these clams may have a major influence in the Delta food web (Lucas et al. 2002). Conversely, grazing on phytoplankton by zooplankton does not appear to be a major sink for primary production in the Delta (Kimmerer 2004).

Within the Delta the general food web is highly complex and variable at multiple spatial and temporal scales, and no attempt has been made to fully reconstruct it. Zooplankton play a critical role in the food web as they represent an important link between primary producers and higher trophic levels. Zooplankton population sizes are very dynamic at short time scales (i.e., weeks to months) (Kimmerer 2004). They are also dynamic over longer time scales as there has been a large decline in zooplankton abundance throughout the Delta since the mid-1970s, and it is hypothesized that the decline is due to a combination of factors that include reduced organic inputs, increased water exports, reduced phytoplankton biomass, and toxic substances in the water (Kimmerer 2004).

Zooplankton community composition varies spatially where copepods are numerically dominant in the brackish water region of the Plan Area, while cladocerans dominate the freshwater region. In the LSZ between those two regions, macrozooplankton, including mysids and epibenthic amphipods, are important food items for many fish species (Kimmerer 2004) as most fish species consume zooplankton for at least part of their lives. Changes in the composition and abundance of the zooplankton community of the Plan Area that are driven by biological invasions and changing water conditions have forced native fish species to adapt to new prey species and caused a reduction of overall carrying capacity of fish in the Plan Area (Bennett 2005).

Both fish and larger epibenthic invertebrates (e.g., crabs and shrimp) have complex life cycles, and their abundances are regulated by multiple environmental factors (Kimmerer 2004). For example, many fish species, due to their anadromous life history, respond to both oceanic and

Delta conditions and transfer energy between both food webs. Additionally, a diverse species assemblage of birds, mammals, amphibians, and reptiles comprise higher trophic levels of the Delta's aquatic food web and consume a variety of invertebrate and fish species. While predation impacts by these species are significant, their overall impact on prey populations is thought to be less important than other sources of mortality (Sommer 2007).

2.3.2.1.5 Effects of Anthropogenic Influence and Future Climate Change

This section focuses on aquatic environments in the main channels of the tidal waters of the Plan Area (biological processes for each of the BDCP communities are discussed in Section 2.3.4, *Natural Communities*).

Ecosystem processes within the Delta have been greatly modified by a variety of anthropogenic influences and are predicted to continue to be modified with future sea level rise and climatic changes. The large extent of wetland reclamation, flood control infrastructure, and channel modifications have transformed the geometry of the Delta from one with a complex structure of branching channels to one of interconnected channels around leveed and diked islands. These channels have created linear and circular flow patterns that are different from the dendritic channel structure that existed before these modifications occurred (Grossinger 2004, Grossinger et al. 2008). Flow rates through the modified channels tend to be greater than in dendritic channels, reducing residence time and leading to a reduction in overall productivity of the Delta. Levees have removed important elevational gradients that historically existed at the interface between aquatic and terrestrial ecosystems.

The construction of dams and reservoirs has dampened the variation that was present in the historical hydrograph of the Delta and has changed the timing of flows through the Delta. Upstream diversions reduce flows into the Delta and in-Delta diversions, including CVP/SWP facilities and over 2,200 non-project diversions, have reduced flow out of the Delta. Operations of the CVP and SWP facilities (including the Delta Cross Channel [DCC], Victoria Canal, and the pumping stations) have altered in-Delta hydrodynamics by altering the direction of water flow such that east to west flows are lower than they were historically, and north to south flows are greater than they were historically.

Return flows from wastewater treatment plants, island drainage, and groundwater seepage have introduced toxic substances into the Delta. Barriers and new channels that were constructed and are operated to maintain water quality (e.g., Head of Old River barrier, and DCC) have significantly altered flow, transport, and mixing of suspended particles, dissolved gases, and dissolved salts in the Delta.

In conjunction with the depletion of erodible sediments from mining, riverbank protection and levees, and altered land uses, the dams and reservoirs have also greatly reduced loads of sediment transported to the Delta and suspended in the water column. Lower sediment load is of particular concern in relation to future climate change because current sediment loads may be insufficient to support a rate of accretion that will keep pace with projected sea level rise.

Nonnative invasive species introductions and population expansions have altered a variety of ecosystem processes in the Delta. The overbite clam has, since its introduction in 1986, had a substantial impact on the aquatic ecosystem (Kimmerer and Orsi 1996, Kimmerer 2004) and that impact has had a greater effect on the Delta's food web than any other known invasion since long-term monitoring in the Delta began. As described above, the clam has caused a loss of summertime phytoplankton in Suisun Bay, declines in phytoplankton in the Delta, reductions in turbidity in both regions, changes in species composition and abundance of zooplankton, alterations of pathways and efficiencies of energy transfer through the food web, and restructuring of the benthic community in downstream bays. Serial invasions and numerical dominance of multiple zooplankton species (e.g., copepods and mysids) have changed the diet composition and breadth of multiple fish species. The introductions of multiple centrarchids species (e.g., largemouth bass and sunfishes) are thought to have directly contributed to the local extinction of Sacramento perch in the Delta (Cohen and Carlton 1995). The introduction of two nonnative invasive aquatic plants, water hyacinth and Brazilian waterweed, has reduced habitat quantity and quality for many native fishes in the Plan Area. Because water hyacinth forms dense floating mats that greatly reduce light penetration into the water column, it can significantly reduce primary productivity in the underlying water column (NMFS 2004). Brazilian waterweed grows along the margins of channels in dense stands that prohibit access by native juvenile fish to shallow water habitat. In addition, the thick cover of these two invasive plants provides excellent habitat for nonnative ambush predators, such as bass and sunfish, which prey on native fish species. Brazilian waterweed is thought to reduce turbidity through a reduction in water velocity, resulting in higher local particle sediment rates, which has been hypothesized to increase predation rates on native fish (Brown and Michniuk 2007).

Toxic substances can interfere with ecosystem processes by reducing growth, reproduction, and survival of species. Herbicide applications can locally limit phytoplankton growth and production rates (Jassby et al. 2003). Many of the pesticides used to control agricultural pests are also toxic to zooplankton. Other sources of flows of toxic substances in the ecosystems of the Plan Area include wastewater treatment plants, urban run-off, and upstream sources. Although there is considerable uncertainty regarding the effects of some of these toxics on fish, at least three mechanisms have been identified through which toxics could affect fish. First, direct exposure to toxics could have negative impacts on fish, especially to more vulnerable life stages such as eggs and larvae. Second, toxic substance-induced mortality of zooplankton, a source of food for nearly all fish species at one or more life stages, could limit food to fish species and result in reduced growth rates, reproductive output, and survival rates. Third, the bioaccumulation of toxics such as mercury and selenium by the overbite clam is well documented. Because some fish (e.g., sturgeon and splittail) and aquatic birds (e.g., surf scoter, American coot, and scaup) forage on the clam, their tissue can bioaccumulate these toxics, thus reducing growth, reproduction, and survival (Luoma and Presser 2000).

If the reduced dry season flows into the Delta and increased sea level due to global climate change occur as predicted by climate models, they will combine to cause salt water intrusion and tidal influence to shift farther upstream. This shift will likely affect biological processes that are dependent on salinity (e.g., rearing habitat for delta native fishes). Reduced flow into the Delta during summer and fall could lead to substantial increases in residence time during those seasons, which would increase water temperature and reduce dissolved oxygen levels to the detriment of native fish and other organisms. With reduced flows into and out of the Delta, toxic substances may accumulate to a greater extent in channels during the summer and fall. The predicted effects of global climate change are discussed in more detail in Section 2.3.3.2, *Climate*.

2.3.2.2 Terrestrial Ecosystem Processes

Terrestrial ecosystems dominate the Plan Area. The present extent of the aquatic ecosystem, as defined by the tidal perennial aquatic natural community, is a relatively small 86,240 acre portion (11 percent) of the 858,372 acre Plan Area. Most of the terrestrial portion of the Plan Area, however, is dominated by human-modified landscape. Intensively managed agricultural lands and managed wetlands comprise 572,623 acres (73 percent) of the Plan Area. Grassland, which is primarily comprised of managed non-natural grasslands on Delta islands and levees, constitutes another 62,880 acres. Together, these three human-managed communities constitute 81 percent of the Plan Area. The ecosystem processes of these communities are almost entirely controlled by human management activities that include disturbance by tilling and disking; regulation of the water cycle by irrigation; chemical enhancement of soil fertility with fertilizers; and control of species composition with herbicides, pesticides, and cultivation.

Agricultural lands retain some natural ecosystem functions. For example, flooded rice fields provide surrogate wetland habitats for species such as the giant garter snake, a BDCP covered species. Hay crops and some annually-cultivated crops provide important foraging habitat for raptors. Winter-flooded croplands provide essential foraging and roosting habitat for the greater sandhill crane, a BDCP covered species, as well as waterfowl and shore birds. Managed wetlands provide productive seasonal wetlands interspersed with permanent wetlands. These wetlands feed large populations of waterfowl and shorebirds through the production of seeds and invertebrates; and their structure is managed to provide nesting and resting, or loafing areas. The majority of the grassland natural community is managed as vacant, typically abandoned crop lands, while a small portion is managed as a source of primary productivity to feed domestic grazing animals and for its small herbivore productivity to sustain birds of prey.

The other terrestrial and wetland natural communities in the Plan Area support more natural ecological processes and native species but constitute only a small portion of the Plan Area relative to human-managed communities. The Plan Area supports 17,338 acres of valley/foothill riparian natural community and 17,298 acres of combined tidal freshwater and tidal brackish emergent wetlands. These three natural communities constitute 4 percent of the Plan Area. The valley/foothill riparian natural community provides a number of ecological functions. It serves as the hydrologic connection between terrestrial uplands and aquatic ecosystems and provides water quality benefits by processing and filtering runoff. It is a source for organic material (e.g., falling leaves), insect food, and woody debris in waterways, and can influence channel dynamics.

Riparian forest and scrub provides habitat for the greatest diversity of wildlife of any community in the Plan Area. In the Delta, these riparian functions are greatly diminished as most riparian habitat is present on levees and within agricultural lands separated from floodplains and natural hydrodynamics and substrates. Tidal freshwater and brackish emergent wetland communities provide ecosystem functions as wildlife habitat, natural chemical filters, and buffers to wave action, and also provide resources to adjacent aquatic ecosystems through their contributions of nutrients and organic material to the shared food web. Tidal wetlands also accumulate peat, which controls the surface elevation and productivity of the Delta's wetlands. Tidal freshwater and brackish emergent wetland vegetation provides rearing habitat for fish species.

Several specialized natural communities of limited distribution in the Plan Area and statewide provide unique ecological conditions that support unique assemblages of plants and wildlife, including many rare species that are covered species under the BDCP. These communities include vernal pool complex, alkali seasonal wetlands complex, and inland dune scrub; collectively they constitute approximately 1 percent of the Plan Area.

2.3.3 Physical Environment

2.3.3.1 Geomorphic Setting

The Delta, Yolo Bypass, and Suisun Marsh are the expression of numerous spatial and temporal variations in regional and local physical processes that, in combination, have established the hydrologic and geomorphic conditions that are present today. One of the most visually-apparent physical features is the enormous north-south trending Central Valley that is almost completely surrounded by mountains and has a single westerly outlet near its midpoint. In and around this valley, tectonic activity has assembled a diverse mixture of elements and minerals, raised the surrounding mountains, and elevated or subsided various sections of the valley floor and regulated its connection to the ocean.

The Central Valley and its surrounding mountains are perched on the Sierra Nevada/Great Valley tectonic microplate, which is more or less solidly attached to the North American tectonic plate to its east. Its western boundary is being distorted by friction caused by the contrary motion of the North American and Pacific tectonic plates as they slide past and buffet each other with the microplate trapped in between (Argus and Gordon 2001, Fay and Humphreys 2008). The distortion of the western margin of the microplate has led to bursts of mountain building in the Coast Range as well as extensive networks of faults that serve to release the built up strains. Both the Coast Range and faults are features that are expressed by the microplate through a thick pavement of oddly shaped and sized blocks composed of shallower and younger layers of the earth's crust. Two of these blocks, the Suisun and the Montezuma Hills, together gave birth to the current opening of the Central Valley to the Pacific Ocean approximately 500,000 years ago and have maintained the opening in the face of extensive tectonic activity in the Coast Range on either side of the gap in the mountains (Loudeback 1951, Sarna-Wojcicki et al. 1985, Weber-Band 1998). The floor of the microplate is not uniform in thickness or rigidity and can roughly be divided into the subsiding south San Joaquin Valley, the stable north San Joaquin Valley, the subsiding Delta region, and the stable Sacramento Valley (Saleeby and Foster 2004, Mikhailov et al. 2006).

The geology of the mountain ranges that surround the Central Valley is extremely complex and beyond the scope of this document (Jennings et al. 1977, Alt and Hyndman 2000, USGS 2005). However, generally described, the geology and rock of the bordering mountains differ when comparing the southern San Joaquin Valley with the northern San Joaquin and Sacramento valleys. The Sierra Nevada range to the east of southern San Joaquin Valley consists primarily of granitic rock while the Coast Range to the west is composed of marine sedimentary rock. Northward, the Sierra Nevada is composed of volcanic lahars near the valley floor, metamorphic and mixed types of igneous rock in the foothills, granitic rocks in the mountains, and a cap of volcanic rock along the crest of the Sierra Nevada. The Coast Range consists of two bands of very different rock. Immediately along the border of the valley is the Great Valley sequence of marine sedimentary rock whereas to the west is the Franciscan complex consisting of marine sedimentary rock, metamorphic rock, igneous rock, and patches of volcanic rock.

Sediment is produced in the mountains and delivered to the Central Valley as locally and regionally heterogeneous mixtures that correspond to the geology of the four mountainous regions described above (Wakabayashi and Sawyer 2001, Curtis et al. 2005). These sediments have different physical and chemical attributes that directly affect the geomorphology of the rivers and streams both upstream and within the Delta, as well as the quality of the water that they deliver to the Delta. Additionally, the rate at which the sediments are delivered to the Delta is partially determined by whether they are detained or trapped in a subsiding region of the Valley floor. Precipitation, which produces and transports the sediment, occurs less in the south and varies from east to west as the parallel set of north-south trending mountain ranges along the longitudinal axis of the valley creates precipitation shadows on their lee faces and large orographic increases on their windward faces (Dettinger et al. 2004, National Atlas of the United States 2009). The amount and type of precipitation intercepted by the mountains is also greatly influenced by glacial/interglacial climatic variation and by periodic deviations from seasonal averages. When precipitation accumulates high in the southern and north-central Sierra Nevada as glaciers, the glaciers grind away at the granitic rock, which is delivered to the Valley as fine material in glacial meltwaters. In contrast, during warm humid periods, chemical weathering of the granitic rock leads to deep and unstable deposits of a sand-like material called grus that is delivered to the valley as deep and permeable alluvial fans (Wahrhaftig 1965, Weissmann et al. 2005). In the central and northern Sierra Nevada, glacial effects have been smaller and erosion is the primary force that delivers material from its diverse rock types to the Valley (James et al. 2002, James 2003, Curtis et al. 2005) and supplies sediment from a diversity of rock types to the Sacramento River (Singer and Dunne 2001). Along the entire Coast Range, erosion attacks the southern marine mudstone and sandstone, Great Valley sequence, and Franciscan complex and delivers fine clay material and a mixture of dissolved elements (mercury, chrome, sodium, magnesium, boron, and selenium) to the Central Valley where they settle out in broad and relatively impermeable alkaline clay plains (U. S. Bureau of Soils 1909, California State Mining Bureau 1918, Bryan 1923, Belitz 1988, Deverel and Gallanthine 1989, Peters 1991, Donnelly-

Nolan et al. 1993, Davisson et al. 1994, Graymer et al. 1994, Graymer et al. 2002, The Natural Heritage Institute 2003, Domagalski et al. 2004a, Domagalski et al. 2004b, Williamson et al. 2005, Hothem et al. 2007, Sommer et al. 2008).

Subtle surface and hidden subsurface factors also directly control the rate and type of sediment and dissolved chemical delivery to the Delta. Underlying the more recent alluvium in the San Joaquin Valley and southernmost region of the Sacramento Valley to near the Dunnigan Hills is the thick and impermeable Corcoran clay that formed the bed of Corcoran Lake which covered the San Joaquin Valley and southernmost Sacramento Valley until it drained through the new opening of the Central Valley to the Pacific Ocean approximately 500,000 years ago (Thomasson Jr. et al. 1960, Sarna-Wojcicki et al. 1985, Belitz 1988). This relatively shallow clay layer controls groundwater/surface water interactions that affect the hydrology and selenium content of the overlying San Joaquin River. Underlying the majority of the Sacramento Valley is the thick and relatively permeable Tuscan Formation that was derived from volcanic ash and mud flows (Olmsted and Davis 1961, Lydon 1968, Jennings et al. 1977, Helley and Harwood 1985, Page 1985, USGS 2005). Because the Tuscan Formation lies on top of the surface of the lower Sierra Nevada foothills before steeply dipping under the Sacramento Valley, and because it is permeable, it intercepts and stores some surface flow as well as deeply percolating water from local sources. Both the Corcoran Clay and the Tuscan Formation contain or control regional aquifers that are used as alternatives to surface flows. Because of tectonic controls and alluvial deposition that are associated with the Sierra Nevada, the San Joaquin River flows northward over its sandy bed along the western border of its valley to the Delta (Weissmann et al. 2005). In contrast, the Sacramento River shifts back and forth across its valley as it flows southward along the Willows Fault, is deflected to the east by the subsurface Colusa Dome, and is deflected to the east again by the delta of Cache Creek (Larsen et al. 2002, Singer 2008, Singer et al. 2008). Gravels are largely trapped upstream of the Colusa Dome while sand and finer sediment are carried downstream (Singer 2008).

Due to its lesser gradient, greater proportion of sand to finer sediment, and smaller flows, the San Joaquin River is a braided river with numerous sloughs as it flows northward toward the Delta. In contrast, the Sacramento River is bordered by broad and high natural levees that isolate it from seven adjacent flood basins as it flows southward to the Delta, and its single channel becomes increasingly stable as it approaches and enters the Delta (Hitchcock et al. 2005, Singer et al. 2008). The natural levees were formed when overbank flow deposited suspended sediment. When the deposits were made into floodplain waters at equal elevation to the main channel, the result was steep levees with coarse material that rapidly graded into fine deposits in the floodplain (Adams et al. 2004). Alternatively, when sediment was deposited by floodplain waters at lower levels than the main channel, the result was more gently sloped broad levees where sediment texture fined less rapidly (Adams et al. 2004). The banks of the levees can be stabilized by vegetation (Thompson 1961, Stainstreet and McCarthy 1993, Larsen et al. 2002, Adams et al. 2004) and channels or crevasses connecting the channel to the river can exist for hundreds to thousands of years (Rowland et al. 2009). The Sacramento River levee from the upper end of the Yolo Basin to Cache Slough has a number of crevasses with characteristic sand splays and connecting sloughs (Thompson 1960, Robertson 1987, Hitchcock et al. 2005, Singer et al. 2008). Both Cache Creek and Putah Creek discharge into the Yolo Basin, and their waters do not join the channel of the Sacramento River until Cache Slough near the center of the Delta. Under historical flood conditions, the combined flow through Cache Slough was often greater than the flow in the Sacramento River Channel and under natural conditions created a hydraulic dam at their confluence which backed up the Sacramento River (Thompson 1960, Roos 2006, James and Singer 2008, Singer et al. 2008). The Mokelumne River discharges into the San Joaquin River on the eastern side of the Delta and only became tidally influenced within the last 1,000 years compared to approximately 6,000 years ago for the rest of the Delta (Shelmon 1971, Brown and Pasternack 2005). Marsh Creek, on the southwestern edge of the delta, has migrated back and forth across its broad alkaline clay alluvial plain and has discharged at different points into that area of the Delta (The Natural Heritage Institute 2003, SFEI 2010).

Approximately 21,000 years ago, the last glacial maximum ended and eustatic sea level began to rise from the lowstand of -394 feet (-120 m) in a series of large meltwater pulses interspersed by periods of constant rising elevation until the Laurentide ice sheet had completely melted 6,500 years ago and the rate of sea level rise slowed dramatically (Edwards 2006, Peltier and Fairbanks 2006). The modern Delta formed sometime between 10,000 and 6,000 years ago when rising sea level flooded a broad valley. The inlet elevation to the valley is constrained by river-cut notches in the bedrock under the Carquinez Strait and the east end of Sherman Island at depths of -131 feet (-40 m) and -121 feet (-37 m) below current sea level respectively, which are elevations that would have been flooded by rising sea levels approximately 10,000 years ago (Shelmon 1971, Peltier and Fairbanks 2006, Drexler et al. 2009a). Until approximately 6,700 years ago, sediment deposits in the central and western Delta were primarily composed of mineral alluvium. Since that time, peat has accumulated from depths of approximately -30 feet (-9 m) to the current sea level (Goman and Wells 2000, Drexler et al. 2009a). These deposits could have only accumulated under anaerobic conditions present in a permanently flooded Delta, likely maintained by high sea levels (Drexler et al. 2009a). This hypothesis is supported by fluctuating levels of oceanic-derived salinity as indicated by shifts in the dominance of aquatic plant species that are adapted to either brackish or freshwater conditions (Goman and Wells 2000, Byrne et al. 2001, Malamud-Roam and Ingram 2004, Malamud-Roam et al. 2006, Malamud-Roam et al. 2007, Watson and Byrne 2009).

At Browns Island in the western Delta, the transition to peat was apparently interspersed with periods dominated by fine mineral sediments, whereas peat developed abruptly and continuously in the central Delta (Drexler et al. 2009a). Sea level would have been approximately -13 ft (-4 m) below its current level 6,000 years ago (Peltier and Fairbanks 2006). There is currently no explanation for the approximately 13 ft (4 m) of additional peat in the central Delta, the difference between sea level 6,000 years ago and peat deposits that extend to a depth of approximately -26 ft (-8 m) (Drexler et al. 2009a), although at least a portion of this difference could be attributed to tectonic subsidence as there is a 10-ft high scarp along the Midland Fault in this area (Unruh and Hitchcock 2009).

Although the geomorphology of the Delta has often been described as a typical "bird's foot" delta, this description inaccurately describes the complex system of alluvial fans and flood basins that were converted into multiple deltas when they were drowned by rising sea level and that are visually apparent when viewing historical maps and aerial photographs (Hitchcock et al. 2005, Grossinger et al. 2008). The complex geomorphology of sea level induced deltas is just beginning to be studied and understood (Shelmon 1971, Blum and Tornqvist 2000, Parker et al. 2008). Under these dynamic conditions, deltas can be single thread linear channels, large fans, or complex combinations of different forms (Atwater et al. 1979, Blum and Tornqvist 2000, Hitchcock et al. 2005, Kim et al. 2009, Van Dijk et al. 2009).

Suisun Marsh lies immediately to the west of the Delta in a subsiding basin (Unruh and Hector 1999) between the bedrock notches of Carquinez Strait and Sherman Island, and because the base elevation of Suisun Bay is controlled by the bedrock notches upstream and downstream, it probably was flooded by rising sea level at the same time as the central Delta. Two studies conducted at Rush Ranch, which is at the northern end of the marsh and distant from the main channel that runs from Suisun Bay to the San Francisco Bay, indicate that marsh vegetation at that location established between approximately 3,000 and 2,500 years ago (Byrne et al. 2001, Malamud-Roam and Ingram 2004). Suisun Marsh is unique in that its water is brackish with salinities that have varied from fresh at its eastern end to nearly saline at its western end depending on the combined flow volume of the Sacramento and San Joaquin rivers (Goman and Wells 2000, Byrne et al. 2001, Malamud-Roam and Ingram 2004, Malamud-Roam et al. 2006, Malamud-Roam et al. 2007, Watson and Byrne 2009). Additionally, flows into the north end of the marsh from Green Valley Creek can reach 5,000 cfs and can affect the salinity of the water both in the channels and on the marsh plain (Burau 2004). Increasing salinity levels can shift the species composition from highly productive freshwater-adapted plants to much less productive salt-adapted plants (Byrne et al. 2001, Culberson 2001, Boul and Keeler-Wolf 2008, Watson and Byrne 2009), influencing the rate of peat bed development and the elevation of the marsh surface above sea level (Culberson et al. 2004). Early charts of the marsh display classic tidal channel geomorphology with channels interspersed with ponds and the boundary of the upper margin of the marsh traced with salt pannes (Grossinger 2004). A salinity gradient exists as salt accumulates in areas more distant from channels that are not flushed by the tides during the rainless summer months (Sanderson et al. 2000, Culberson 2001, Culberson et al. 2004, Watson and Byrne 2009). The duration of tidal inundation also affects the distribution of plant species at the upper margin of the marsh (Culberson 2001, Watson and Byrne 2009) and establishes bare mudflats at the lowest areas of the marsh adjacent to Suisun Bay (Cappiella et al. 1999).

The natural geomorphology of the Delta, Yolo Bypass, and Suisun Marsh has been greatly altered by anthropogenic changes in sediment supply, flood control projects including levee building and draining, mosquito ditches in Suisun Marsh, and by large water dam and diversion projects throughout its watershed. The impact of the enormous pulse of sediment produced by hydraulic mining from 1853-1884 has been well-documented (Gilbert 1917, Kelley 1989, Mount 1995, Kimmerer 2004, Shvidchenko et al. 2004, James and Singer 2008, Keller 2009), but it is less well-known that additional mining sediment was produced between 1893-1953, and that large quantities of sediment still remain in reaches below dams (James 1999, 2006, James et al. 2009). The initial pulse of sediment increased flooding along the Sacramento River and built extensive mudflats on the outer margin of Suisun Marsh as the sediment made its way to the San Francisco Bay (Gilbert 1917, Kelley 1989, Mount 1995, Keller 2009). Current sediment supply rates are too low to sustain those mudflats and other features that were created prior to the building of large debris dams and water storage dams, and those features have been eroding for many years (Cappiella et al. 1999, Kimmerer 2004, Wright and Schoellhamer 2004, McKee et al. 2006, Ganju and Schoellhamer 2010). Levee building has affected the Plan Area in diverse ways. Upstream of the Delta along the Sacramento River and in the various flood basins, levee building has both trapped and sped the delivery of sediment to the Delta (James 1999, Singer and Dunne 2001, James 2004a, 2004b, 2006, Mikhailov et al. 2006, James and Singer 2008, Singer 2008, Singer et al. 2008, James et al. 2009, Singer and Aalto 2009). In the Delta proper, levees and various land uses have reduced the depth of peat soils within the confines of the levees to depths of -24 feet (-7.25 m) (Drexler et al. 2009b), which creates an enormous volume of accommodation space that, in the event of a levee break, will bring saline and brackish water from the west further into the Delta (Mount and Twiss 2005).

As noted above, the alluvium underlying the Sacramento-San Joaquin Delta is dominated by Quaternary alluvial deposits in the channels and on the levees and peat beds in the center of the islands (Figure 2-3). The peat beds, combined with historical floodwater alluvial deposits of fine mineral particles, have provided highly fertile and productive soils to support the agriculture industry throughout the Plan Area (Figure 2-4). The smaller extent of mineral soils, including soils in the map units Zamora-Rincon-Capay-Brentwood, Veritas-Tinnin-Delhi, and Willows-Waukena-Pescadero-Fresno, are located primarily along the western and southern edges of the Plan Area (Figure 2-4).

Prior to reclamation for agriculture, much of the vegetation of the Delta (approximately 380,000 acres; 1538 km^2) was dominated by tidal marshes (Atwater 1980, The Bay Institute 1998). By 1930, island reclamation was complete, and by 1980, only about 16,000 acres (65 km^2) of marshes remained (Atwater 1980, The Bay Institute 1998). Today, these areas of former tidal marshes consist primarily of channelized waterways surrounding highly productive row-cropped agricultural islands that are protected from flooding by over 1,300 miles (2,093 km) of levees. Dewatering of the marshes and plowing the peat soils for farming have led to peat oxidation losses, soil compaction, and erosion of the islands, resulting in surface subsidence. The result is that the interiors of many Delta islands have substantially subsided and are now depressions well below the level of the surrounding water, protected only by a ring of levees (Figures 2-5 through 2-9).

2.3.3.2 Climate

The climate in the Sacramento-San Joaquin Delta region is spatially variable, but is generally characterized as hot Mediterranean (Köppen climate classification) (McKnight and Hess 2005). The general climate becomes milder from east to west due to marine influence as it is affected by influxes of winds off of the Pacific Ocean.

Summers are hot with average daily highs from June through September in the upper 80s degrees Fahrenheit (°F) to lower 90s °F with very little to no precipitation and low humidity. Heat waves are common in summer months, during which temperatures can reach triple digits for consecutive days. Periodically, a "Delta breeze" of cool and humid air from the ocean moves onshore and cools the Central Valley in the vicinity of the Delta by up to 7°F (3.9 degrees Celsius [°C]) (Pierce and Gaushell 2005). Winters are mild (average daily highs during November through March are in the mid-50s to mid-60s °F) and wet. Approximately 80 percent of annual precipitation occurs between November and March. The primary origin of precipitation is the seasonal arrival of low pressure systems from the Pacific Ocean. Very dense ground fog (tule fog) is common between periods of precipitation in the Plan Area from November through March.

The climate of the Plan Area is predicted to change in complex ways. Although there is high uncertainty, temperatures in the Plan Area are projected to increase at an accelerating pace from 3.6 to 9°F (2 to 5°C) by the end of the century (Cayan et al. 2009). Depending upon the general-circulation model used, there are variable predictions for precipitation change, with most models simulating a slight decrease in average precipitation (Dettinger 2005, California Climate Change Center 2006). The Mediterranean seasonal precipitation experienced in the Plan Area is expected to continue, with most precipitation falling during the winter season and originating from North Pacific storms. Although the amount of precipitation is not expected to change dramatically over the next century, seasonal and interannual variation in precipitation will likely increase as it has over the past century (DWR 2006). This could lead to more intense winter flooding, greater erosion of riparian habitats, and increased sedimentation in wetland habitats (Field et al. 1999, Hayhoe et al. 2004).

Global sea level rise predictions vary. One model predicts that by the end of this century, global sea level will increase by 7 to 23 inches (18 to 59 cm); with an additional 6 inches (15 cm) of sea level rise if the rate of Greenland ice-melt intensifies (Intergovernmental Panel on Climate Change 2007). Another model projection for sea level rise has produced mid-range estimates from 28 to 39 inches (70 to 100 cm) by the end of this century, with a full range of variability from 20 to 55 inches (50 to 140 cm) (Rahmstorf 2007). Recently issued U.S. Army Corps of Engineers guidance on incorporation of sea level rise in civil works projects suggests end of century sea level rise in the range of 20 to 59 inches (50 to 150 cm) (USACE 2009).

Predicted warmer temperatures will affect the rate of snow accumulation and melting in the snowpack of the Sierra Nevada. Some projections predict reductions in the Sierra Nevada spring snowpack of as much as 70-90 percent by the end of the century (California Climate Change Center 2006). Knowles and Cayan (2002) estimated that a projected warming of 3°F (1.6°C) by 2060 would cause the loss of one-third of the watershed's total April snowpack, whereas a 4°F (2.1°C) warming by 2090 would reduce April snowpack by 50 percent. The loss of snowpack is predicted to be greater in the northern Sierra Nevada than in the southern Sierra Nevada because of differences in the relative amounts of low- and mid-elevation snowpack (DWR 2006). Measurements taken to track the water content of snow (snow water equivalent [SWE]) since 1930 show that peak snow mass in the Sierra Nevada has been occurring earlier in the year by 0.6 days per decade (Kapnick and Hall 2009). These predicted changes in the dynamics of the snowpack will influence the timing, duration, and magnitude of inflow from the Sacramento and San Joaquin River watersheds. For example, with more precipitation falling as rain instead of snow and the snowpack melting earlier, greater peak flows will result during the rainy season and lower flows during the dry season. Knowles and Cayan (2004) predict that inflows will increase by 20 percent from October through February and decrease by 20 percent from March through September. Storm surges (tidal and wind-driven) associated with the more intense storms predicted for the future will also exacerbate Delta flooding.

2.3.3.3 Hydrologic Conditions

2.3.3.3.1 River Hydrology

The hydrology of the Plan Area is primarily influenced by freshwater inflows from the Sacramento River from the north and the San Joaquin River from the south. East-side streams, particularly the Mokelumne River, also contribute inflows to the Plan Area. Numerous upstream dams and diversions greatly influence the timing and volume of water flowing into the Delta. There are multiple upstream tributaries to the Sacramento and San Joaquin rivers that influence flow into the Plan Area. The Feather and American rivers and many large creeks drain directly into the Sacramento River while the Cache and Putah creeks drain into the Yolo Bypass which joins the Sacramento River in the Cache Slough area (Figure 2-10). The Yuba and Bear rivers drain into the Feather River before its confluence with the Sacramento River. The Calaveras, Stanislaus, Tuolumne, Merced, and Kings rivers drain into the San Joaquin River upstream of the Delta. The Cosumnes River drains directly into the Mokelumne River, and both drain into the San Joaquin River after entering the Delta. In addition to the Sacramento and San Joaquin deltas, the Mokelumne delta in some ways can be viewed as a third important river delta.

Regardless of water-year type, the large majority of unimpaired upstream flow into the Delta originates from the Sacramento River and its tributaries, and a lesser extent originates from the San Joaquin River and its tributaries (Figure 2-11). The Cosumnes and Mokelumne rivers and other smaller tributaries, collectively called the "Eastside Tributaries" in Figure 2-11, contribute only a small percentage of inflows. Upstream diversions reduce the total inflow from upstream rivers and tributaries. Only a small proportion of water, relative to upstream flows, enters the Plan Area through precipitation. In the 2000 Water Year, an above normal water year, nearly 70 percent of water entering the Delta passed through the system as outflow, 6 percent was consumed within the Delta, less than 1 percent was diverted via the North Bay Aqueduct and

Contra Costa Water Districts, and 24 percent was exported via SWP and CVP facilities (Figure 2-12). Additional water was taken upstream of the Delta in upstream diversions and reservoirs that accounted for an additional 7525 thousand acre feet (TAF) (Governor's Delta Vision Blue Ribbon Task Force 2008). These values vary by water year type and the inflows associated with the water year (Figures 2-12 and 2-13). For example, in the 2001 water year, a dry year, approximately 54 percent of water entering the Delta passed through the system as outflow, 13 percent was consumed within the Delta, and 39 percent was exported via SWP and CVP facilities (Figure 2-13). Because exports and in-Delta use are relatively consistent among years, inflows affect Delta outflow most significantly, with a lower proportion of water exiting the system as outflow during drier years and a higher proportion during wetter years.

The hydrograph of the Delta is highly variable both within and among years (Figure 2-14). Within years, water flow is generally greatest in winter and spring with inputs of wet season precipitation and snowpack melt from the Sierra Nevada and lowest during fall and early winter before significant rainfall. The construction of upstream dams and reservoirs for flood protection and water supply has dampened the seasonal variation in flow rates. Water is released from reservoirs year-round, and flooding is much less common than it was before dam and levee construction. As a result, the frequency of small- to moderate-sized floods has been significantly reduced since major dam construction, although the magnitude and frequency of large floods has not been significantly altered; additionally, because of climatic changes there have been more large floods in the last 50 years than the previous 50 years. Among years, wet and dry periods (defined as periods during which unimpaired runoff was above or below average, respectively, for three or more years) occurred numerous times in the last 100 years; although the duration and magnitude of the wet and dry periods have increased in the last 30 years, including the 6-year drought of 1987 to 1992 and the prolonged periods of wetness in the early- to mid-1980s and the mid- to the late-1990s (Dayflow 2007). The wet and dry periods recorded over the last 150 years, however, are less severe and shorter than the prolonged wet and dry periods of the previous 1,000 years.

The Yolo Bypass is an important physical feature affecting river hydrology during high flow events in the Sacramento River watershed. The bypass is a 59,280-acre engineered floodplain that conveys flood flows from the Sacramento River, Feather River, American River, Sutter Bypass, and western tributaries and drains (Figure 2-15) (Harrell and Sommer 2003). The leveed Bypass protects Sacramento and other nearby communities from flooding during high water events. Most water enters the Yolo Bypass by spilling over the Fremont and Sacramento weirs and returns to the Sacramento River in the Delta approximately 5 miles upstream of Rio Vista. The Yolo Bypass floods seasonally in approximately 60 percent of years (Sommer et al. 2001b) and can convey up to 80 percent of flow from the Sacramento basin during high water events (Sommer et al. 2001a).

2.3.3.4 Tides

The Delta, lower portion of the Yolo Bypass, and Suisun Marsh are tidally influenced by the Pacific Ocean, although tidal range and influence decreases with increasing distance from the San Francisco Bay (Kimmerer 2004, Siegel 2007). Tides are mixed semidiurnal with two highs and two lows each day, one large magnitude high and low, and one lower magnitude high and low. A typical diurnal range is 3.3 to 4.6 feet (1 to 1.4 m) in the western Delta (Orr et al. 2003). The entire tidal cycle is superimposed upon the larger 28-day lunar cycle with more extreme highs and lows during spring tides and depressed highs and lows during the neap tides. In addition, there is an annual cycle in which tidal elevation is greatest in February and August. The multiple temporal scales at which these cycles occur causes significant variation in draining and filling of the Delta, and therefore, in patterns of mixing of the waters (Kimmerer 2004). Additionally, variation in sea level can also be caused by changes in atmospheric pressure and winds.

2.3.3.4.1 Water Supply Facilities and Facility Operations

There are over 3,000 diversions that remove water from upstream and in-Delta waterways for agricultural, municipal, and industrial uses; 722 of these are located in the mainstem San Joaquin and Sacramento rivers and 2,209 diversions are in the Delta (Herren and Kawasaki 2001). In the Delta, the Central Valley Project (CVP) managed by the Bureau of Reclamation and the State Water Project (SWP) managed by DWR use the Sacramento and San Joaquin rivers and other Delta channels to transport water from river flows and reservoir storage to two water export facilities in the south Delta (Figure 2-16). The C.W. “Bill” Jones Pumping Plant (herein referred to as the Jones Pumping Plant) is operated by the CVP and the Harvey O. Banks Delta Pumping Plant (herein referred to as the Banks Pumping Plant) is operated by the SWP. Water from these facilities is exported for urban and agricultural water supply demands throughout the San Joaquin Valley, Southern California, the central coast, and the southern and eastern San Francisco Bay area.

Water enters the Banks Pumping Plant via the Clifton Court Forebay (CCF) (Figure 2-16). Large radial arm gates control inflows to CCF during the tidal cycle to reduce approach velocities, prevent scouring of adjacent channels, and by allowing water to enter the CCF at times other than low tide, reducing water level fluctuation in the south Delta (USFWS 2005). The Banks Pumping Plant operates to move water from CCF into the 440-mile (708-km) California Aqueduct. Water in the California Aqueduct travels to O’Neill Forebay; where a portion of the water is diverted to the joint-use SWP/CVP San Luis Reservoir for storage. The remaining water flows southward via the joint-use San Luis Canal.

Water from Old River in the Delta is pumped by the Jones Pumping Plant into the Delta-Mendota Canal. The Jones Pumping Plant facility does not have an associated forebay. The Delta-Mendota Canal sends water southward, providing irrigation water along the way, towards the O’Neill Forebay where a portion of the water is diverted into the San Luis Reservoir. The remaining water continues in the Delta-Mendota Canal, providing irrigation water along the way, until it reaches the Mendota Pool, where water is returned to the San Joaquin River to replenish downstream flows.

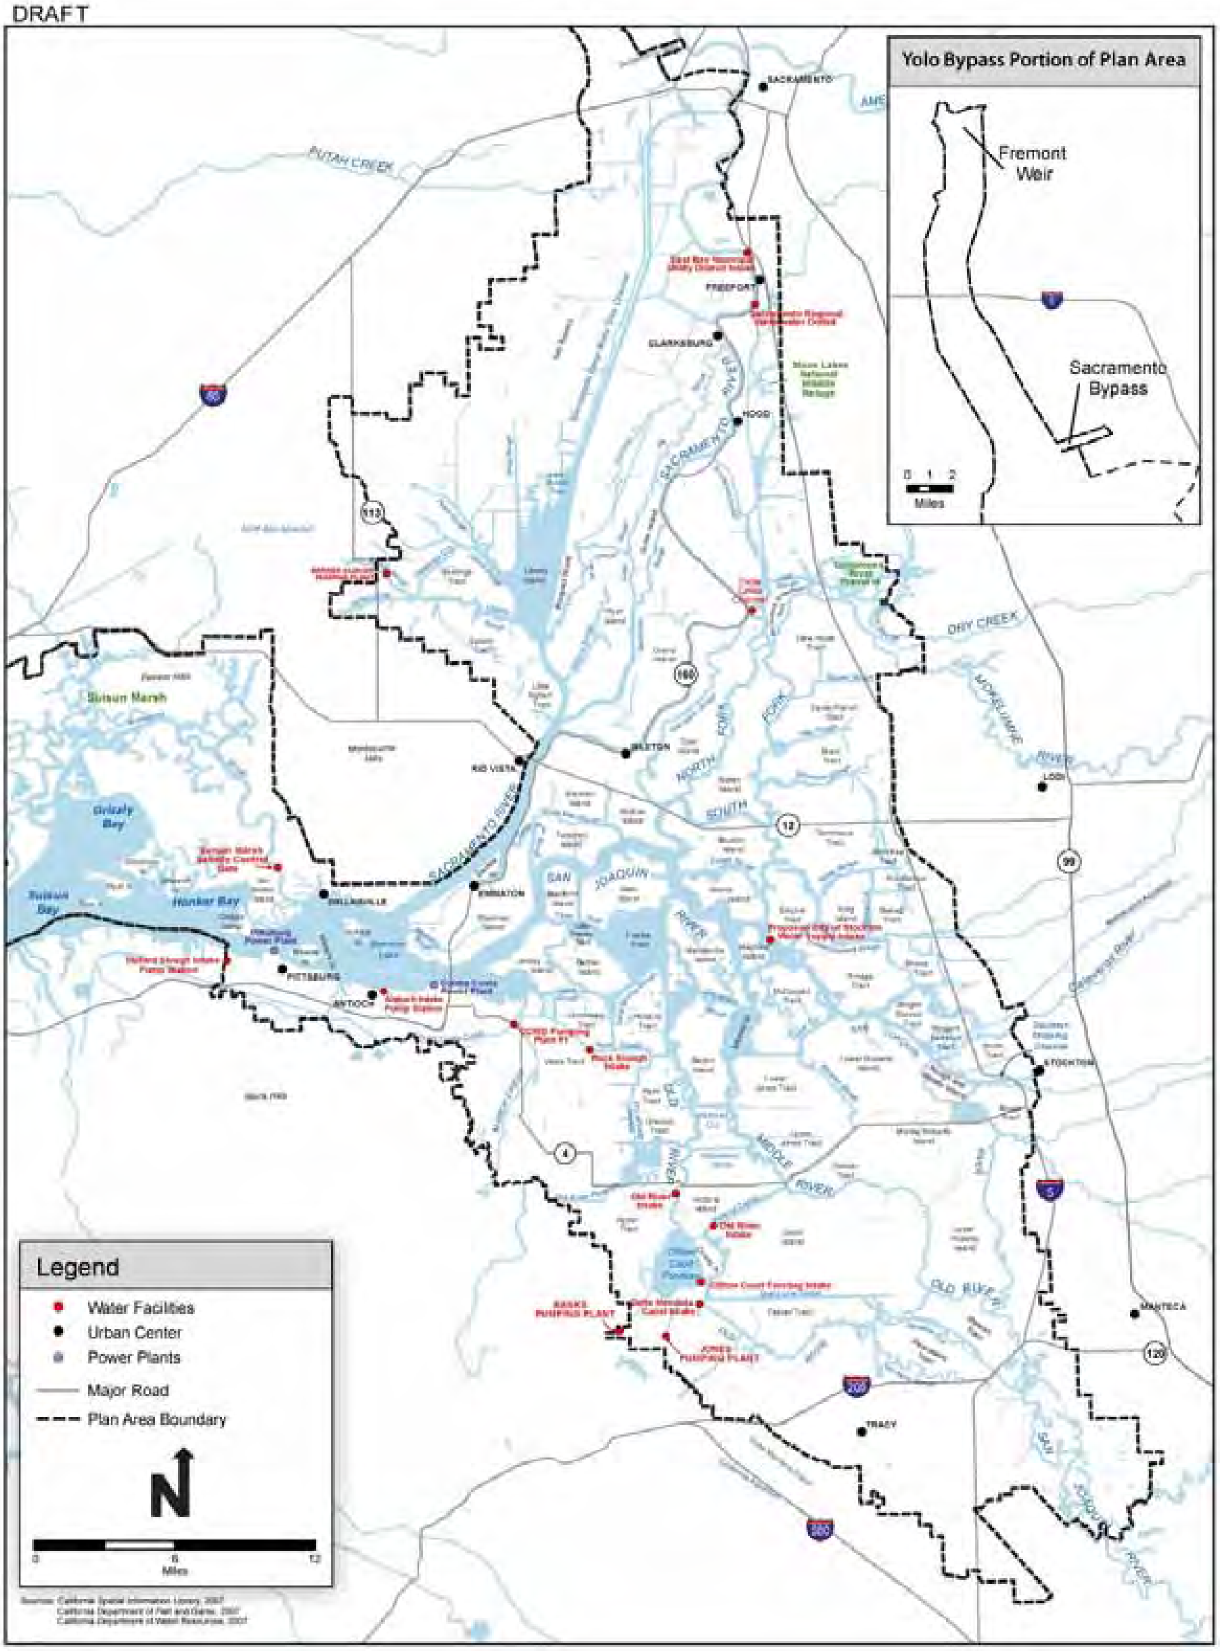

Figure 2-16. Water Facilities in the BDCP Plan Area

The Delta Cross Channel (DCC) is operated by the Bureau of Reclamation to improve through-Delta flows from the Sacramento River towards the pumping facilities in the south Delta (Figure 2-16). Water is diverted into Snodgrass Slough, a tributary of the Mokelumne River, through which it travels into the central Delta. Two large radial gates on the DCC can open or close to control flows into the central Delta. Reasons for closure include reduction in scour in the channels on the downstream side of the DCC, reduction in flood flows into the Mokelumne River, and fish protection.

The Barker Slough Pumping Plant is operated by the SWP and draws water from Barker Slough into the North Bay Aqueduct (Figure 2-16). The intake is located just upstream of where Barker Slough empties into Lindsey Slough, which is approximately 10 miles (16 km) from the mainstem Sacramento River. Water from the Barker Slough Pumping Plant is delivered to Napa and Solano counties for municipal and industrial uses. The North Bay Aqueduct (NBA) is operated by DWR as part of the SWP and delivers wholesale water to the Solano County Water Agency and the Napa County Flood Control and Water Conservation District. The 27.6 mile NBA extends from Barker Slough to the end of the Napa Turnout Reservoir. Water is pumped from the Delta at the Barker Slough Pumping Plant, which is located 7 river miles upstream from the confluence of Barker Slough with the Sacramento River in southeast Solano County. Water is then diverted to the Travis Surge Tank where it flows by gravity through the NBA to the Cordelia Pumping Plant.

The South Delta Temporary Barriers project consists of the installation of four rock barriers each spring in south Delta channels: the head of Old River, Old River at Tracy, Grant Line Canal, and Middle River. The head of Old River barrier is also installed during the fall for dissolved oxygen reasons. The head of Old River barrier is considered a fish barrier because it is installed to keep migrating juvenile Chinook salmon in the San Joaquin River. The other three barriers are agricultural barriers; meaning they are installed to maintain water quality for agricultural uses in the south Delta. The head of Old River barrier was not installed in spring of 2009 or 2010 as the 2008 USFWS Biological Opinion prohibited the installation of the barrier for the protection of delta smelt. The rock barriers are not installed in years when San Joaquin River flows are high, such as during 1998.

The Contra Costa Water District (CCWD) diverts water from the Delta to the Contra Costa Canal and the Los Vaqueros Reservoir using four intake locations: Rock Slough, Old River, Mallard Slough, and Middle River (on Victoria Canal) (Figure 2-16). The Contra Costa Canal and its pumping plants have a capacity of 350 cfs and were built by the U.S. Bureau of Reclamation from 1937 to 1948 as part of the CVP. The Contra Costa Canal is owned by the Bureau of Reclamation but operated and maintained by CCWD. The screened Old River Pump Station (250 cfs capacity) was built in 1997 as part of the Los Vaqueros Project to improve water quality for CCWD. The Old River pump station connects via pipelines to a transfer pump station (200 cfs) used to pump water into Los Vaqueros Reservoir (100,000 af [acre feet] capacity) and from the transfer station via gravity pipeline to the Contra Costa Canal. The screened Mallard Slough intake (39 cfs capacity) was constructed in the 1920s and rebuilt to make it seismically protected in 2001. It is used primarily in winter and spring during wet periods when water quality is sufficiently high. The screened Middle River intake and pump station (250 cfs capacity) were completed in 2010 to provide additional operational flexibility and improved water quality. The Middle River intake connects to the Old River Pump Station via pipe that crosses Victoria Island and tunnels underneath Old River. The Middle River intake is used primarily in late summer and fall to provide better water quality than is obtainable from the other three intakes.

East Contra Costa Irrigation District provides water supplies to the city of Brentwood, portions of Antioch and Oakley, the unincorporated community of Knightsen, and surrounding unincorporated rural areas (Dudek 2007). The East Contra Costa Irrigation District operates a diversion located at Indian Slough on Old River in combination with canals and pumping stations for distribution within the service area. The primary purpose of the diversion is to provide raw water for irrigation of agricultural lands, landscape, and recreational uses (e.g., golf courses). The district has agreements with CCWD and City of Brentwood to make surplus water available for municipal use.

The city of Antioch, located in eastern Contra Costa County, supplies water through diversions directly from the San Joaquin River, raw water purchased from CCWD that is delivered through the Contra Costa Canal, and treated water delivered through CCWD's Multi-Purpose Pipeline (Dudek 2007). Antioch receives approximately 85 percent of its water supplies from CCWD. The majority (76 percent in 2004) of the water is provided for municipal/residential use, with industrial (11 percent) and agricultural (13 percent) uses in the service area.

Byron Bethany Irrigation District provides water for agricultural, industrial, and municipal uses to portions of Alameda, Contra Costa, and San Joaquin counties (San Joaquin County Planning Division 2008). The district maintains two water diversions from the Delta under a pre-1914 appropriative water right and a riparian water right on Old River. Water diversions occur from the SWP intake channel, located between the Skinner Fish Protection Facility and the Banks Pumping Plant. Two diversions serve the Byron Division and the Bethany Division. The District also operates a series of pumping stations and canals for water distribution.

East Bay Municipal Utility District's Mokelumne Aqueduct traverses the Delta, carrying water from Pardee Reservoir on the Mokelumne River to the East Bay (Figure 2-16). East Bay Municipal Utility District, in partnership with Sacramento County, constructed a major new diversion from the Sacramento River at Freeport. This new diversion, sized at 185 million gallons/day capacity, will feed into the Mokelumne Aqueduct and the Vineyard Surface Water Treatment Plant for central Sacramento County use.

There are over 2,200 water diversions in the Delta, most of which are unscreened and used for in-Delta agriculture irrigation (Figure 2-17) (Herren and Kawasaki 2001). Industrial diversions in the Plan Area include the Mirant Power plants at Pittsburg and Antioch. Water from these diversions cools generators producing electric power at the plants.

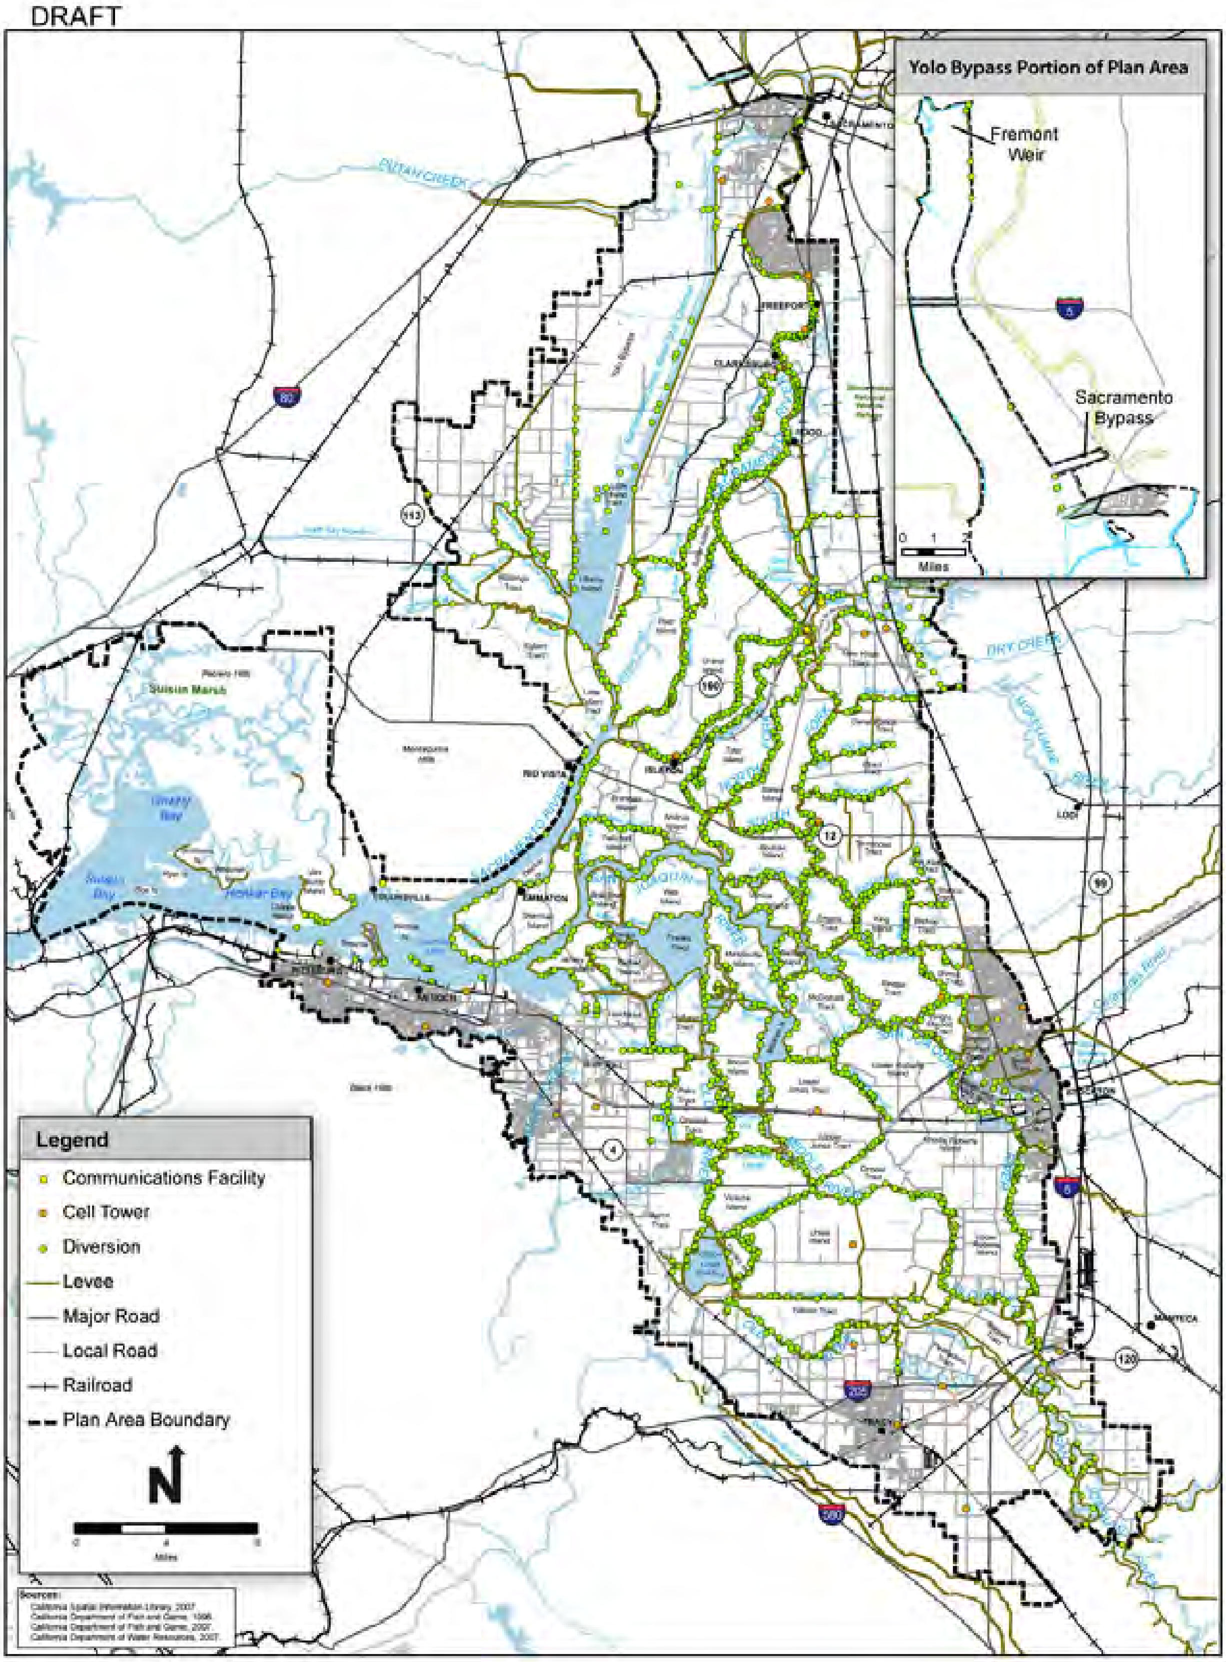

Figure 2-17. Infrastructure within the BDCP Plan Area

Suisun Bay and Suisun Marsh are important ecosystems connected to the Delta, and habitat conditions and facility operations in Suisun Bay and Marsh can affect ecosystem conditions in the Delta (Figure 2-16 and Figure 2-17). A system of levees, canals, gates, and culverts in Suisun Marsh was constructed in 1979-80 and is currently operated by DWR to lower salinity in privately managed wetlands in the marsh. The Suisun Marsh Salinity Control Gates are composed primarily of a set of radial gates that extend across the entire width of Montezuma Slough. The control gates are used to reduce salinity from Collinsville through Montezuma Slough and into the eastern and central parts of Suisun Marsh and to reduce intrusion of saltwater from downstream into the western part of Suisun Marsh. In addition to radial gates, the Suisun Marsh Salinity Control Gates consist of permanent barriers adjacent to the levee on either side of the channel, flashboards, and a boat lock. The gates have been operated historically from September to May and open and close twice a day during full operation to take advantage of tidal flows. The gates are opened during ebb tides to allow freshwater from the Sacramento River to flow into Montezuma Slough and are closed during flood tides to prevent higher salinity water from downstream from entering Montezuma Slough. Gate operations have been curtailed in recent years.

2.3.3.5 Non-Water Supply Plan Area Infrastructure and Uses

The Plan Area supports a substantial amount of infrastructure related to urban development, transportation, agriculture, recreation, energy, and other uses (Figure 2-17). Portions of six counties are included in the legal Delta: Yolo, Sacramento, Solano, Contra Costa, Alameda, and San Joaquin (DWR 2006).

The major land use for the Plan Area is agriculture, which represents approximately two-thirds of all surface area. There is increasing residential, commercial, and industrial land use in the Plan Area, most of which occurs around the periphery of the Delta. Major urban development within the cities of Sacramento, West Sacramento, Stockton, Tracy, Antioch, Brentwood, and Pittsburg are in the Plan Area. Small towns located wholly within the Delta include Clarksburg, Hood, Walnut Grove, Isleton, Collinsville, Courtland, Locke, Ryde, Bethel Island, and Discovery Bay. Much of this development occurs in the secondary zone of the Delta (as defined in *Section 12220* of the Water Code).

Several interstate highways (I-5, I-80, I-205/580, and I-680) and one state highway (State Route [SR] 99) are on the periphery of the Delta, and three state highways (SR 4, SR 12, and SR 160) and multiple county roads cut across the Delta (Figure 2-17). Three major railways cross through the Delta. The Plan Area contains a network of electrical transmission lines (over 500 miles [805 km]) and gas pipelines (over 100 lines). Natural gas extraction and storage is another important Plan Area use. In addition to approximately 95 public and private marinas (Lund et al. 2007), two major ports (Stockton and Sacramento) and their associated maintained ship channels are in the Delta. These ports can handle high tonnage (55,000 ton class) ships to move cargo to and from the Pacific Ocean. Much of the Plan Area, including 635 miles (1022 km) of boating waterways, is used for a variety of recreational purposes including water sports, fishing, hunting, and wildlife viewing (Lund et al. 2007).

2.3.4 Natural Communities

The natural communities in the Plan Area are tidal perennial aquatic, tidal mudflat, tidal brackish emergent wetland, tidal freshwater emergent wetland, nontidal freshwater perennial emergent wetland, nontidal perennial aquatic, valley/foothill riparian, grassland, alkali seasonal wetland complex, vernal pool complex, managed wetland, other natural seasonal wetland, inland dune scrub, and agricultural habitats (Figures 2-18 through 2-22).

The descriptions of the natural communities are generally based on broad community descriptions that were developed for the CALFED Bay-Delta Program's Multi-Species Conservation Strategy (MSCS) (CALFED 2000). These broad community types were further refined and augmented by input from DFG staff participating in the BDCP Terrestrial Resources subgroup in 2009. In addition to the natural communities, a finer scale delineation of vegetation within the Plan Area was used to model the habitat of covered species, based on a more detailed land cover type classification used by DFG to prepare its Vegetation and Land Use Classification map of the Sacramento-San Joaquin River Delta and the 2006 Vegetation Map Update for Suisun Marsh, Solano County, California (Hickson and Keeler-Wolf 2007, Boul and Keeler-Wolf 2008). The methods used to produce maps of the natural communities are described in Section 2.3.1, *Data Sources and Natural Community Classification***.**

A primary focus of the BDCP Conservation Strategy is habitat restoration in the tidal and riparian natural communities of the Plan Area that support covered fish species: tidal perennial aquatic, tidal mudflat, tidal freshwater emergent wetland, tidal brackish emergent wetland, and valley/foothill riparian. The tidal perennial aquatic natural community includes deepwater aquatic (greater than 10 ft [3 m] deep from mean lower low tide), shallow aquatic (less than or equal to 10 ft [3 m] deep from mean lower low tide). It also coexists spatially with unvegetated intertidal zones of estuarine bays, river channels, and sloughs of the Plan Area that characterize the tidal mudflat community. The tidal freshwater emergent wetland natural community consists of intertidal zones of the Plan Area that support emergent wetland plant species that are intolerant of saline or brackish water. Freshwater emergent vegetation is generally found in water shallower than 6 ft (2 m) deep (Cowardin et al. 1979). The tidal brackish emergent wetland natural community supports similar species as the tidal freshwater emergent wetland in and near channels, and shorter stature, salt-tolerant plants on the marsh plains. It is found from the westernmost tip of Sherman Island westward to the tidal areas of Suisun Marsh and Suisun Bay. The valley/foothill riparian natural community includes all successional stages of woody riparian vegetation, commonly dominated in the Plan Area by willows, Fremont cottonwood, alder, and valley oak. The valley/foothill riparian natural community and the tidal communities are spatially intermingled with the tidal mudflat natural community. A generalized schematic of the distribution of natural communities in the Plan Area relative to tidal levels and representative species associated with each of the communities is depicted in Figure 2-23. All of the communities and covered species are discussed in more detail in the following sections and in Appendix A, *Covered Species Accounts*.

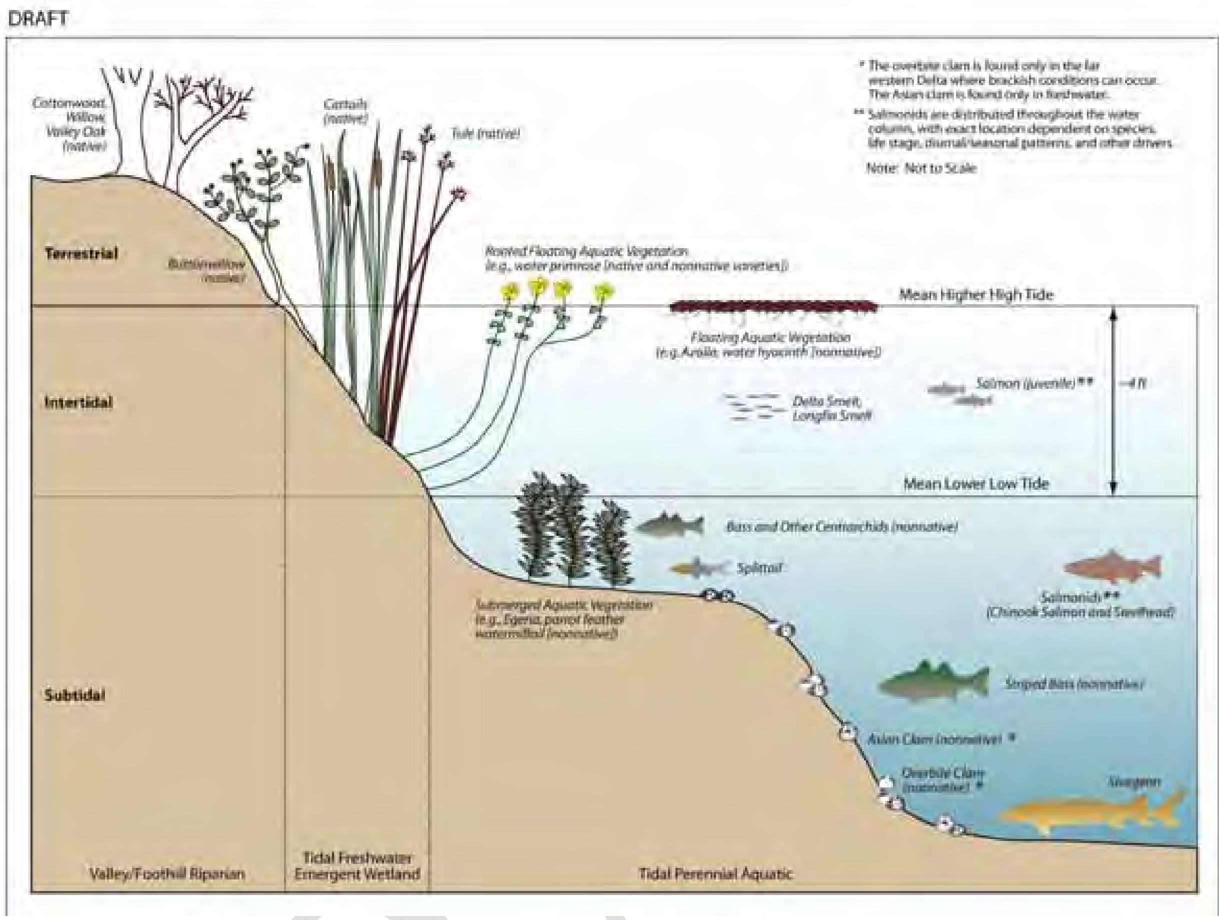

Figure 2-23. Generalized Schematic of Valley/Foothill Riparian, Tidal Freshwater Emergent Wetland, and Tidal Perennial Aquatic Natural Communities

The extent of each natural community within the Plan Area is presented in Table 2-3. The distribution of natural communities in the Plan Area is presented in Figures 2-18 through 2-22.

The following sections describe physical and biological attributes associated with each natural community.

Table 2-3. Extent of Natural Communities in the Plan Area (acres)

Tidal Perennial Aquatic	86,240
Tidal Mudflat	NA[1]
Tidal Brackish Emergent Wetland	8,351
Tidal Freshwater Emergent Wetland	8,947
Valley/Foothill Riparian	17,338
Nontidal Perennial Aquatic	5,341
Nontidal Freshwater Perennial Emergent Wetland	1,134
Alkali Seasonal Wetland Complex	3,722
Vernal Pool Complex	6,959
Managed Wetland	64,844
Other Natural Seasonal Wetland	264
Grassland	62,880
Inland Dune Scrub	20
Agricultural Habitats	503,779
Developed	70,174
No Data[2]	18,379
Total	**858,372**

[1]Tidal mudflats are included in tidal perennial aquatic (upper edge) and tidal freshwater and brackish emergent wetlands.
[2]No data available for upland portions of Suisun Marsh (e.g., Petrero Hills).

These natural communities provide habitat for animals and plants that are covered under the Plan Area. Covered fish, wildlife, and plant species that are present or could be present within these natural communities in the Plan Area are presented in Table 2-4.

Natural community codes:
TPA = Tidal perennial aquatic
TM = Tidal mudflat
TBE = Tidal brackish emergent wetland
TFE = Tidal freshwater emergent wetland
V/FR = Valley/foothill riparian
NPA = Nontidal perennial aquatic
NFPE = Nontidal freshwater perennial emergent wetland
ASW = Alkali seasonal wetland complex
VPC = Vernal pool complex
MW = Managed wetland
ONS = Other natural seasonal wetland
G = Grassland
IDS = Inland dune scrub
AL = Agricultural habitats

2.3.4.1 Tidal Perennial Aquatic

The tidal perennial aquatic natural community includes deep water aquatic (greater than 10 ft [3 m] deep from mean low low tide (lowest of the low tide in a day), shallow aquatic (less than or equal to 10 ft [3 m] deep from mean low low tide), and unvegetated intertidal (i.e. mudflat) zones of estuarine bays, river channels, and sloughs (CALFED 2000). Under present water operation conditions in the Plan Area, tidal perennial aquatic is mainly freshwater, with brackish and saline conditions occurring in Suisun Bay at times of high tides and low flows. The distribution of the tidal perennial aquatic natural community in the Plan Area is shown in Figure 2-24.

DRAFT

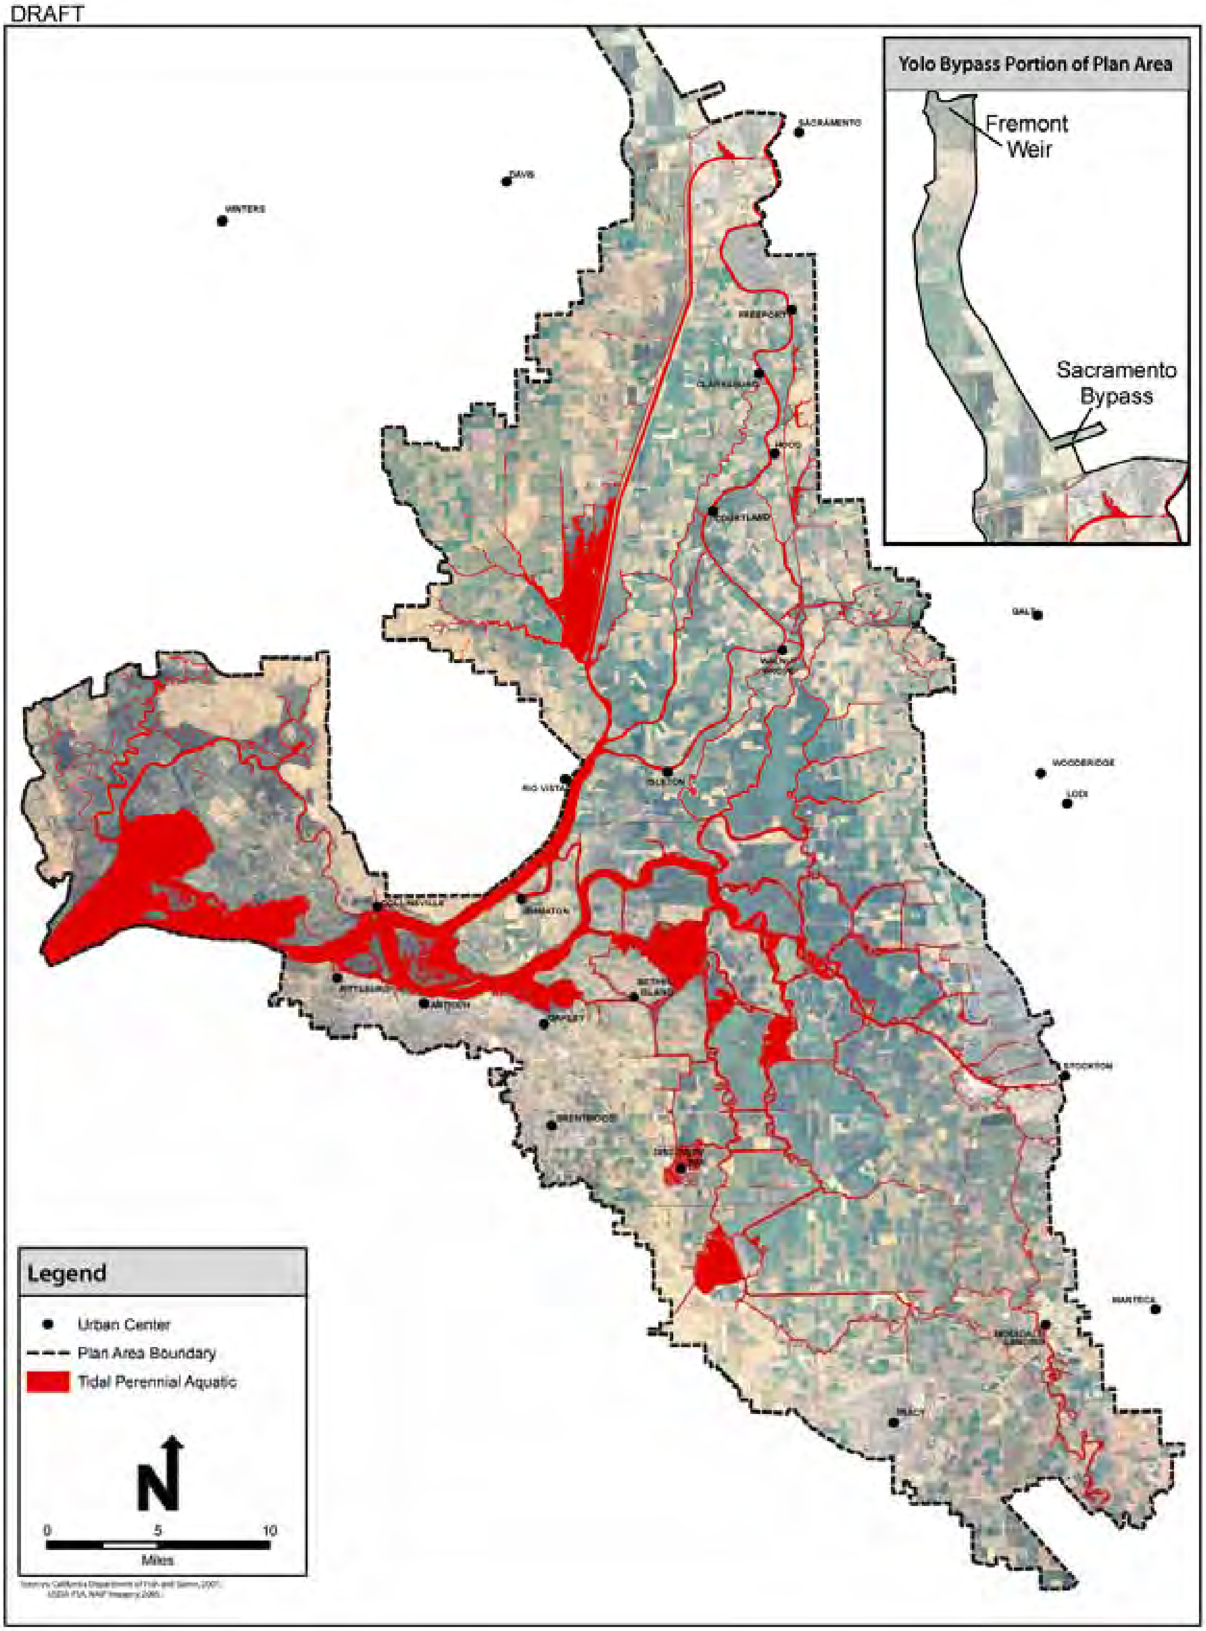

Figure 2-24. Distribution of Tidal Perennial Aquatic Natural Community in the BDCP Plan Area

2.3.4.1.1 Vegetation

The tidal perennial aquatic natural community is largely unvegetated. Where vegetation exists, it can be separated into two categories: submerged aquatic vegetation and floating vegetation (both rooted and unrooted) (Cowardin et al. 1979). The plant associations present and their extent within the tidal perennial aquatic natural community are shown in Table 2-5. The geographic extent of this vegetation is highly dynamic through time and space because it is largely dependent on physical factors that are highly variable, such as depth, turbidity, water flow, salinity, substrate, and nutrient availability.

Table 2-5. Plant Alliances within the Tidal Perennial Aquatic Natural Community in the Plan Area

[1]Some of the mapping units provided here are newly described associations or alliances. For more detailed information concerning these mapping units and plant associations/alliances, as well as on methods of classification used, see Hickson and Keeler-Wolf (2007) and Boul and Keeler Wolf (2008).
[2]DFG vegetation types were combined to form this mapping unit in order to condense the list.

Submerged aquatic vegetation consists of aquatic plants that cannot tolerate drying, and as a result, maintain leaves at or below the water surface. Submerged vascular plant species in the tidal perennial aquatic natural community include native water primrose and the highly abundant and invasive nonnative Brazilian waterweed. The introduction of Brazilian waterweed has been detrimental to native fishes in the Plan Area (Section 2.3.4.1.3, *Nonnative Species*). Another common submerged nonnative invasive plant is the Eurasian watermilfoil. In addition to plants, algae and cyanobacteria can be common during summer and fall months in areas with clear water and little shade. Blooms of the nonnative floating toxic cyanobacteria, *Microcystis*, were first documented in the Delta in 2003, and its distribution has subsequently expanded eastward (Lehman et al. 2005). Periphyton, a thin layer of organisms (mostly diatoms and bacteria) and their exudates, forms on substrates throughout this community. The ecologically important eel grass grows in soft sediment in the subtidal estuarine habitat, primarily in the far western Suisun Bay where salinities are sufficiently high for this brackish/saltwater species. Dense eel grass beds can provide suitable habitat for young fish and other aquatic organisms and are an important food source for waterfowl, although their occurrence in the Plan Area is very limited.

Floating aquatic vegetation in this habitat generally consists of free-floating beds of plants at the surface or in the water column. Wind and water movement can be important factors in determining its distribution. Species in this group include native duckweed, native floating water fern, and nonnative invasive water hyacinth. Reddish carpets of native floating water fern occur in calm waters of sloughs supporting tidal perennial aquatic. This water fern has a symbiotic relationship with a nitrogen fixing bacteria that lives within its tissues (Armstrong 1979). Water hyacinth grows in dense mats that can have harmful effects on native fish species (Section 2.3.4.1.3, *Nonnative Species*).

2.3.4.1.2 Fish and Wildlife

Zooplankton are one of the primary consumers of phytoplankton in the food web of the tidal perennial aquatic natural community and are important both as prey to consumers, such as fish and macroinvertebrates, and as consumers of phytoplankton and detritus. Water salinity is a major factor that influences the distribution of zooplankton species in the tidal perennial aquatic natural community. In the brackish portions of the Plan Area, calanoid copepods (*Eurytemora*, *Pseudodiaptomus*) and cyclopoid copepods (*Limnoithona*) are the primary zooplankton species, and mysid shrimp (*Neomysis*) is the dominant macrozooplankton. In freshwater regions, cladocerans (*Daphnia*) and calanoid copepods (*Diaptomus*, *Limnocalanus*) are the dominant zooplankton present (Kimmerer & Orsi 1996, Kimmerer 2004, Gewant & Bollens 2005, Winder & Jassby in press).

The tidal perennial aquatic natural community supports over 50 species of fish, approximately one-half of which are native (Table 2-6). It is used as habitat by fish for foraging, spawning, egg incubation and larval development, juvenile nursery areas, and migratory corridors. Most species spend their entire lives in the community while others may spend certain seasons or part of their lives in habitats outside of the tidal perennial aquatic natural community depending on the state of physical factors such as salinity, turbidity, dissolved oxygen, flow rates, and water temperature.

Table 2-6. Native and Nonnative Fish Species Found in the Plan Area

Family	*Common name*	*Scientific name*
Native Species		
Acipenseridae	Green Sturgeon	*Acipenser medirostris*
	White Sturgeon	*Acipenser transmontanus*
Atherinopsidae	Topsmelt	*Atherinops affinis*
Catostomidae	Sacramento Sucker	*Catostomus occidentalis*
Clupeidae	Pacific Herring	*Clupea pallasii*
Cottidae	Prickly Sculpin	*Cottus asper*
	Pacific Staghorn Sculpin	*Leptocottus armatus*
Cyprinidae	California Roach	*Hesperoleucus symmetricus*
	Hitch	*Lavinia exilicauda*
	Hardhead	*Mylopharodon conocephalus*
	Sacramento Blackfish	*Orthodon microlepidotus*
	Sacramento Splittail	*Pogonichthys macrolepidotus*
	Sacramento Pikeminnow	*Ptychocheilus grandis*
Embiotocidae	Tule Perch	*Hysterocarpus traskii*
Engraulidae	Northern Anchovy	*Engraulis mordax*
Gasterosteidae	Threespine Stickleback	*Gasterosteus aculeatus*
Gobiidae	Chameleon Goby	*Tridentiger trigonocephalus*
Osmeridae	Delta Smelt	*Hypomesus transpacificus*
	Longfin Smelt	*Spirinchus thaleichthys*
Petromyzontidae	River Lamprey	*Lampetra ayresii*
	Pacific Lamprey	*Entosphenus tridentatus* (formerly *Lampetra tridentata)*
Pleuronectidae	Starry Flounder	*Platichthys stellatus*
Salmonidae	Rainbow / Steelhead Trout	*Oncorhynchus mykiss*
	Chinook Salmon	*Oncorhynchus tshawytscha*
Nonnative Species		
Atherinopsidae	Inland Silverside	*Menidia beryllina*
Centrarchidae	Pumpkinseed	*Lepomis gibbosus*

	White Catfish	*Ameiurus catus*
	Channel Catfish	*Ictalurus punctatus*
Moronidae	Striped Bass	*Morone saxatilis*
Osmeridae	Wakasagi	*Hypomesus nipponensis*
Percidae	Bigscale Logperch	*Percina macrolepida*
Poeciliidae	Western Mosquitofish	*Gambusia affinis*

Source: USFWS, Stockton Office, unpublished data

In addition to its value as habitat for fish, the tidal perennial aquatic natural community provides reproduction, feeding, and resting habitat for many species of mammals and birds. Open water areas supply habitat for rest and foraging by water birds, especially during heavy winter storms when open coastal waters become rough. Bird species that use open water include loons, pelicans, gulls, cormorants, and diving ducks (CALFED 2000). A number of state and federally listed birds feed on fish in the tidal perennial aquatic natural community, including bald eagle, California brown pelican, and California least tern.

2.3.4.1.3 Nonnative Species

The tidal perennial aquatic natural community has been heavily impacted on nearly every trophic level by the introductions of a number of nonnative species. These nonnative species have had substantial adverse effects on the physical habitat and the food web, ultimately impacting the growth and survival of the species covered under the BDCP. Successful nonnatives tend to be better suited than natives to anthropogenic changes to the tidal perennial aquatic natural community. Successful nonnatives generally do not experience the same population controls (i.e., competition, predation, parasitism, and disease) that were present in their place of native origin, resulting in rapid population expansion where they are introduced.

The introduction of two nonnative invasive aquatic plants, water hyacinth and Brazilian waterweed, has reduced habitat quantity and quality for many native fishes in the Plan Area. Under ideal conditions, water hyacinth is capable of extremely rapid growth and can tolerate wide ranges in nutrient concentration, pH, and temperature (Batcher 2000). The species grows as dense floating mats that can greatly reduce primary productivity within the water column (NMFS 2004). Brazilian waterweed grows along the margins of channels and in shallow bays as dense stands that restrict the access of juvenile fish to shallow water habitat within the community. In addition, the thick vegetation of these two invasive species provides excellent habitat for nonnative ambush predators, such as bass and sunfish. Brazilian waterweed is also thought to reduce turbidity through a reduction in water velocity, resulting in higher local precipitation of suspended matter from the water column which results in better hunting conditions for nonnative ambush predators (Brown and Michniuk 2007).

The nonnative copepod, *Pseudodiaptomus*, established after the decline in the abundance of the native copepod, *Eurytemora*, resulted from the introduction of the highly efficient filter-feeding overbite clam (Kimmerer and Orsi 1996). *Eurytemora* can still be abundant during spring, but its populations are replaced by *Pseudodiaptomus* in late spring. Although native fishes, including delta smelt and larval longfin smelt, can switch between these two copepod prey species, because *Pseudodiaptomus* is more elusive than *Eurytemora*, a decrease in the abundance of *Eurytemora* can lead to lower fish foraging efficiency leading to reduced growth rates and the starvation of native fishes (Moyle 2002). More recently, the cyclopoid copepod, *Limnoithona*, has rapidly become the most abundant copepod in the Delta after its introduction in 1993 (Hennessey and Hieb 2007). This species is hypothesized to be a low quality food source and intraguild predator of calanoid copepods such as *Eurytemora* and *Pseudodiaptomus* (Resources Agency et al. 2007).

A variety of macroinvertebrates have been introduced into the tidal perennial aquatic natural community with varying impacts. The Chinese mitten crab experienced a population bloom in 1997 that overwhelmed the fish screening facilities associated with the Jones and Banks pumping plants, but has been uncommon since then. Other potential adverse effects of Chinese mitten crab include: physical impacts, because the crabs burrow into soft sediment and reduce levee stability; ecological impacts, because the crabs are omnivorous, voracious, and experience population blooms; and economic impacts, because the crabs are known to eat rice shoots. The introductions of two clams from Asia, the overbite clam and the Asian clam, have led to major alterations in the food web in the Delta. The overbite clam is most abundant in brackish and saline water while the Asian clam is most abundant in freshwater; therefore, the overbite clam is most abundant in Suisun Bay and the western Delta, and the Asian clam is most abundant in the central Delta. These species are highly efficient filter feeders that significantly reduce phytoplankton and zooplankton concentrations in the water column, which results in reduced food availability for native fishes, such as delta smelt and young Chinook salmon (Kimmerer and Orsi 1996, NMFS 2004, Center for Biological Diversity 2007). In addition to its adverse effects on *Eurytemora*, the overbite clam has been implicated in the reduction of the native opossum shrimp, *Neomysis*, a preferred food of Delta native fishes such as Sacramento splittail and longfin smelt (Feyrer 1999, Moyle 2002).

A large number of nonnative fishes have been introduced into the tidal perennial aquatic natural community of the Delta. Many of the species were introduced for sportfish (striped bass, largemouth bass, smallmouth bass, bluegill, and sunfish); as forage for sportfish (threadfin shad, golden shiner, and fathead minnow); for human food use (common carp, brown bullhead, and white catfish); and from either deliberate or indeliberate release from the aquarium trade or from ballast water release (yellowfin goby, shimofuri goby, and shokihaze goby) (Moyle 2002). Although no introduction of a nonnative fish has unambiguously caused the extinction of a native species in the Bay-Delta (Cohen and Carlton 1995), it is suspected that nonnative introductions have significantly contributed to the decline of some native species due to predation and competition for shared resources. For example, smallmouth bass have been associated with the decline in hardhead, a native minnow found in the Delta, and introductions of several centrarchid species (sunfish and black basses) have been associated with the extirpation of the native Sacramento perch from the Delta.

2.3.4.1.4 Ecosystem Functions

The physical habitat provided by the tidal perennial aquatic natural community supports much of the aquatic Delta food web. This is an extremely complex system, and many details are provided in the Delta Regional Ecosystem Restoration Implementation Plan (DRERIP) Food Web Model (Durand 2008). Use of the habitat by individual species is often determined by multiple physical factors (e.g. flow, water salinity, wind, tide, and temperature), many of which vary at multiple temporal scales (Kimmerer 2004). Phytoplankton and zooplankton spend their entire lives in the water medium. As described above, resident and migratory fish use tidal perennial aquatic habitat for spawning, rearing, foraging, and escape cover (CALFED 2000). Young steelhead and Chinook salmon forage in these productive waters as fry and juveniles to put on critical weight before entering the ocean. Changes in physical attributes of the water column, such as flow and water temperature, provide environmental cues for some species to trigger the timing of biological events, such as migration and spawning.

The tidal perennial aquatic natural community is used for foraging, resting, and escape cover by shorebirds, wading birds, and waterfowl. River otters and beavers use this habitat for much of their semi-aquatic lives. The tidal perennial aquatic natural community supports a soft sediment community consisting primarily of invertebrates, including mollusks, crustaceans, and worms.

The tidal perennial aquatic natural community plays a primary role in the formation and maintenance of tidal wetlands (Culberson et al. 2004). As sediments accumulate in the tidal aquatic bed, areas of shallow water increase, and the opportunity for establishment of emergent vegetation increases. Over time, this vegetation may give rise to wetland and riparian communities.

2.3.4.1.5 Environmental Gradients

The tidal perennial aquatic natural community includes an ecologically-important water depth gradient. Many species of phytoplankton, zooplankton, macroinvertebrates, and fish occupy different depths along this gradient depending on their individual physical needs (e.g., light level, temperature, and water velocity). The tidal perennial aquatic natural community also serves as an important link between upstream and downstream ecosystems. Much of the productivity, organic matter, and inorganic sediment from upstream waterways and marshes eventually move into this community and moves downstream to the Pacific Ocean. In the Plan Area, saline water from coastal oceanic water is diluted by flowing freshwater of rivers (Ellison 1983). This mixture of fresh and oceanic water forms a salinity gradient that varies by area and location with seasonal variations in freshwater outflow and tidal action. This gradient drives the location of species that depend on a specific salinity level. The location of this gradient varies on multiple time scales: daily tides, monthly lunar cycle, intra-annual (seasonal) flow patterns, interannual flow variation from interannual rainfall variation, and long-term global climate change (see *Future Conditions with Climate Change* section below) (Kimmerer 2004). Historically, the salinity gradient was generally farther downstream than it now occurs under similar precipitation and unimpaired flow conditions (CCWD 2010).

The tidal perennial aquatic natural community extends shoreward to shallower subtidal zone habitat where light penetrates to the bottom under normal conditions. In this habitat, a distinct benthic flora and fauna exist that rely on light for energy.

2.3.4.1.6 Future Conditions with Climate Change

As described in Section 2.3.3.2, *Climate*, temperatures are projected to increase at an accelerating pace from 3.6 to 9°F (2 to 5°C) by the end of the century (Cayan et al. 2009). Depending upon the general-circulation model used, there are variable predictions for precipitation change, with most models simulating a slight decrease in average precipitation (Dettinger 2005, California Climate Change Center 2006). The Mediterranean-type climate seasonal precipitation experienced in the Plan Area is expected to continue, with most precipitation falling during the winter season and originating from North Pacific storms. Although the amount of precipitation is not expected to change dramatically over the next century, seasonal and interannual variations in precipitation will likely increase as it has over the past century (DWR 2006). With more precipitation falling as rain instead of snow and the snowpack melting earlier, greater peak flows will result during the rainy season and lower flows during the dry season. Knowles and Cayan (2004) predict that inflows will increase by 20 percent from October through February and decrease by 20 percent from March through September. This change in the annual hydrograph could affect species in the tidal perennial aquatic natural community in a number of ways. Many species that inhabit the tidal perennial aquatic natural community have evolved to use environmental cues, such as changes in flows and temperature, to trigger the timing of biological events, such as migration and spawning. Changes in these factors due to global climate change may lead to confusion by these species as to the timing of these natural events and may affect their growth, production, and survival. Reduced outflow from the Delta during the dry season and rising sea level would increase the extent of saltwater intrusion into the Delta (Knowles and Cayan 2002, 2004). Such changes could relocate the extent of tidal influence and the low salinity zone (LSZ) farther upstream. This relocation of the LSZ could influence the amount of rearing habitat available to native estuarine species (USFWS 2004). Reduced flow into the Delta during summer and fall could also lead to increased residence time during these seasons, likely exacerbating high water temperature and low dissolved oxygen problems that already occur in localized areas of the Delta. Toxic substances may also accumulate during the summer and fall as the flow-driven flushing action decreases.

Sea level rise could have negative effects on fish that rely on shallow water habitat by deepening preferred shallow water areas of the Delta and changing them to non-preferred deep water zones. However, sea level rise may create more shallow water and floodplain areas that inundate more readily, thus providing a benefit to species that use floodplains as rearing habitat.

Sea level rise is predicted to be an especially significant factor in the Plan Area, where much of the land has subsided to below sea level and is currently protected from flooding by levees. The current subsided island condition, combined with higher sea level, increased winter river flooding, and more intense winter storms, will significantly increase the hydraulic forces on the levees. With sea level rise exacerbating current conditions, a powerful earthquake in the region could collapse levees, leading to major seawater intrusion and flooding throughout the reclaimed lands of the Delta, altering the tidal prism, and causing substantial changes to the tidal perennial aquatic natural community (Mount and Twiss 2005).

Warmer water temperatures from future climate change would be detrimental to temperature-dependent native fish species in the tidal perennial aquatic natural community by altering the timing of optimal temperature regimes needed for fish spawning, rearing, and migration (Bennett 2005, Lindley et al. 2007). High temperatures can also cause sublethal (e.g., heat shock proteins) and lethal effects to specific life stages of some fish and other organisms in the community. Warmer temperatures could promote the success of nonnative species, such as centrarchids (e.g., black basses, sunfish) and cyprinids (e.g., carp), that spawn during periods with warmer water temperatures (Moyle 2002).

2.3.4.2 Tidal Mudflat

The tidal mudflat natural community typically occurs as mostly unvegetated sediment deposits in the intertidal zone between the mean higher high tide and the mean lower low water (MLLW). The community is typically associated with the tidal freshwater and tidal brackish emergent wetland communities at its upper edge and the tidal perennial aquatic community at its lower edge. The tidal mudflat natural community is ephemeral and owes its physical existence to sediment erosion and deposition processes that differ throughout the Delta and Suisn Marsh, and its biological characteristics to plant succession (Golden and Fiedler 1991, Fiedler and Zebell 1993, Witham and Kareofelas 1994, Zebell and Fiedler 1996, Cappiella et al. 1999, Meisler 2002, Ruhl and Schoellhamer 2004, McKee et al. 2006, Witham 2006). Inflows to the Delta import suspended sediment, and the resuspension and deposition of that sediment are critical accretion factors. Wave energy dissipation and levee maintenance are typical erosion factors. The rate of plant succession on the sediments will vary depending on the supply of plant propagules and the distance to plants that can colonize the sediment by extending their root systems.

The tidal mudflat natural community was not mapped separately in the GIS datasets used for the BDCP. Instead, it was subsumed within the mapped areas of tidal freshwater emergent wetland, tidal brackish emergent wetland, and tidal perennial aquatic natural communities. GIS models were used to estimate the extent of habitat for species that use mudflats (Appendix A, *Covered Species Accounts*).

2.3.4.2.1 Vegetation

The tidal mudflat natural community is generally not vegetated when considered at fine scales, but patches of two small BDCP covered plant species, Mason’s lilaeopsis and Delta mudwort, are found in this community type with the former being more abundant in brackish areas and the latter more abundant in freshwater areas (Golden and Fiedler 1991, Fiedler and Zebell 1993, Zebell and Fiedler 1996, Meisler 2002, Fiedler et al. 2007).

2.3.4.2.2 Fish and Wildlife

An important wildlife habitat function of the tidal mudflat natural community is as foraging habitat for probing shorebirds, including godwits, willets, and sandpipers. This habitat function only exists for shorebirds when the area of mudflat is exposed by the tides. This community supports an extensive invertebrate community that consists of benthic and interstitial species (crustaceans, bivalves, gastropods, aquatic insects, and polychaetes) that provide forage to shorebirds. Other wildlife may access the tidal mudflat natural community occasionally, but there is little habitat value for these species.

When the tidal mudflat natural community is inundated, it serves as shallow open water habitat for several pelagic fish species, including splittail, salmonids, and sturgeon. These species can use tidal mudflat habitat as a shallow water refugia from predators and also forage on benthic invertebrates. Smaller benthic fish species, such as gobies, flatfish, and sculpin inhabit the tidal mudflat natural community at low tide if depressions in the mud support pooled water.

2.3.4.2.3 Nonnative Species

There are no available data regarding the impacts of nonnative invasive species on this community. Where tidal mudflat exists within the valley/foothill riparian natural community, problematic plant species are likely to include giant reed (*Arundo donax*) and perennial pepperweed (*Lepidium latifolium*).

2.3.4.2.4 Ecosystem Functions

At lower intertidal elevations, the tidal mudflat natural community functions as foraging area for waterfowl and shorebirds; and at higher intertidal elevations, it also functions as unoccupied sediment that can be colonized by small stature plant species such as Mason's lilaeopsis and Delta mudwort which are covered species.

2.3.4.2.5 Environmental Gradients

The tidal mudflat natural community occupies a narrow transition zone between tidal perennial aquatic and tidal brackish emergent wetland, tidal freshwater emergent wetland, or valley/foothill riparian. In general, it provides habitat in the lower portion of the tidal range between the mean low tide and extreme low tide where emergent plants typically cannot establish. However, in disturbed sediment depositional areas along natural and artificial levees it provides ephemeral microhabitats within other natural communities when vegetation is removed.

2.3.4.2.6 Future Conditions with Climate Change

Sea level rise is expected to shift the tidal mudflat natural community to higher elevations in areas where the topography rises gradually; however, where steep levee sides are present, it would diminish in areal extent. The tidal mudflat natural community is sensitive to sedimentation and erosion processes (Ruhl and Schoellhamer 2004). If sediment delivery rates do not match sediment export rates, the extent of the tidal mudflat natural community will change until a steady state between supply and export is reached. It is unclear how climate change will affect these processes, but a lack of sediment supply to the Delta and Suisun Marsh will likely decrease the extent of this community (Cappiella et al. 1999, Ganju and Schoellhamer 2010).

2.3.4.3 Tidal Brackish Emergent Wetland

The tidal brackish emergent wetland natural community is a transitional community between the tidal perennial aquatic and terrestrial upland communities. In the Plan Area, tidal brackish emergent wetland exists from near Collinsville westward to the Carquinez Strait. While it is also present on the south side of Suisun Bay and on islands in mid-channel, most of its extent is within Suisun Marsh. The distribution of the tidal brackish emergent wetland natural community in the Plan Area is shown in Figure 2-25 and the constituent plant associations are provided in Table 2-7.

DRAFT

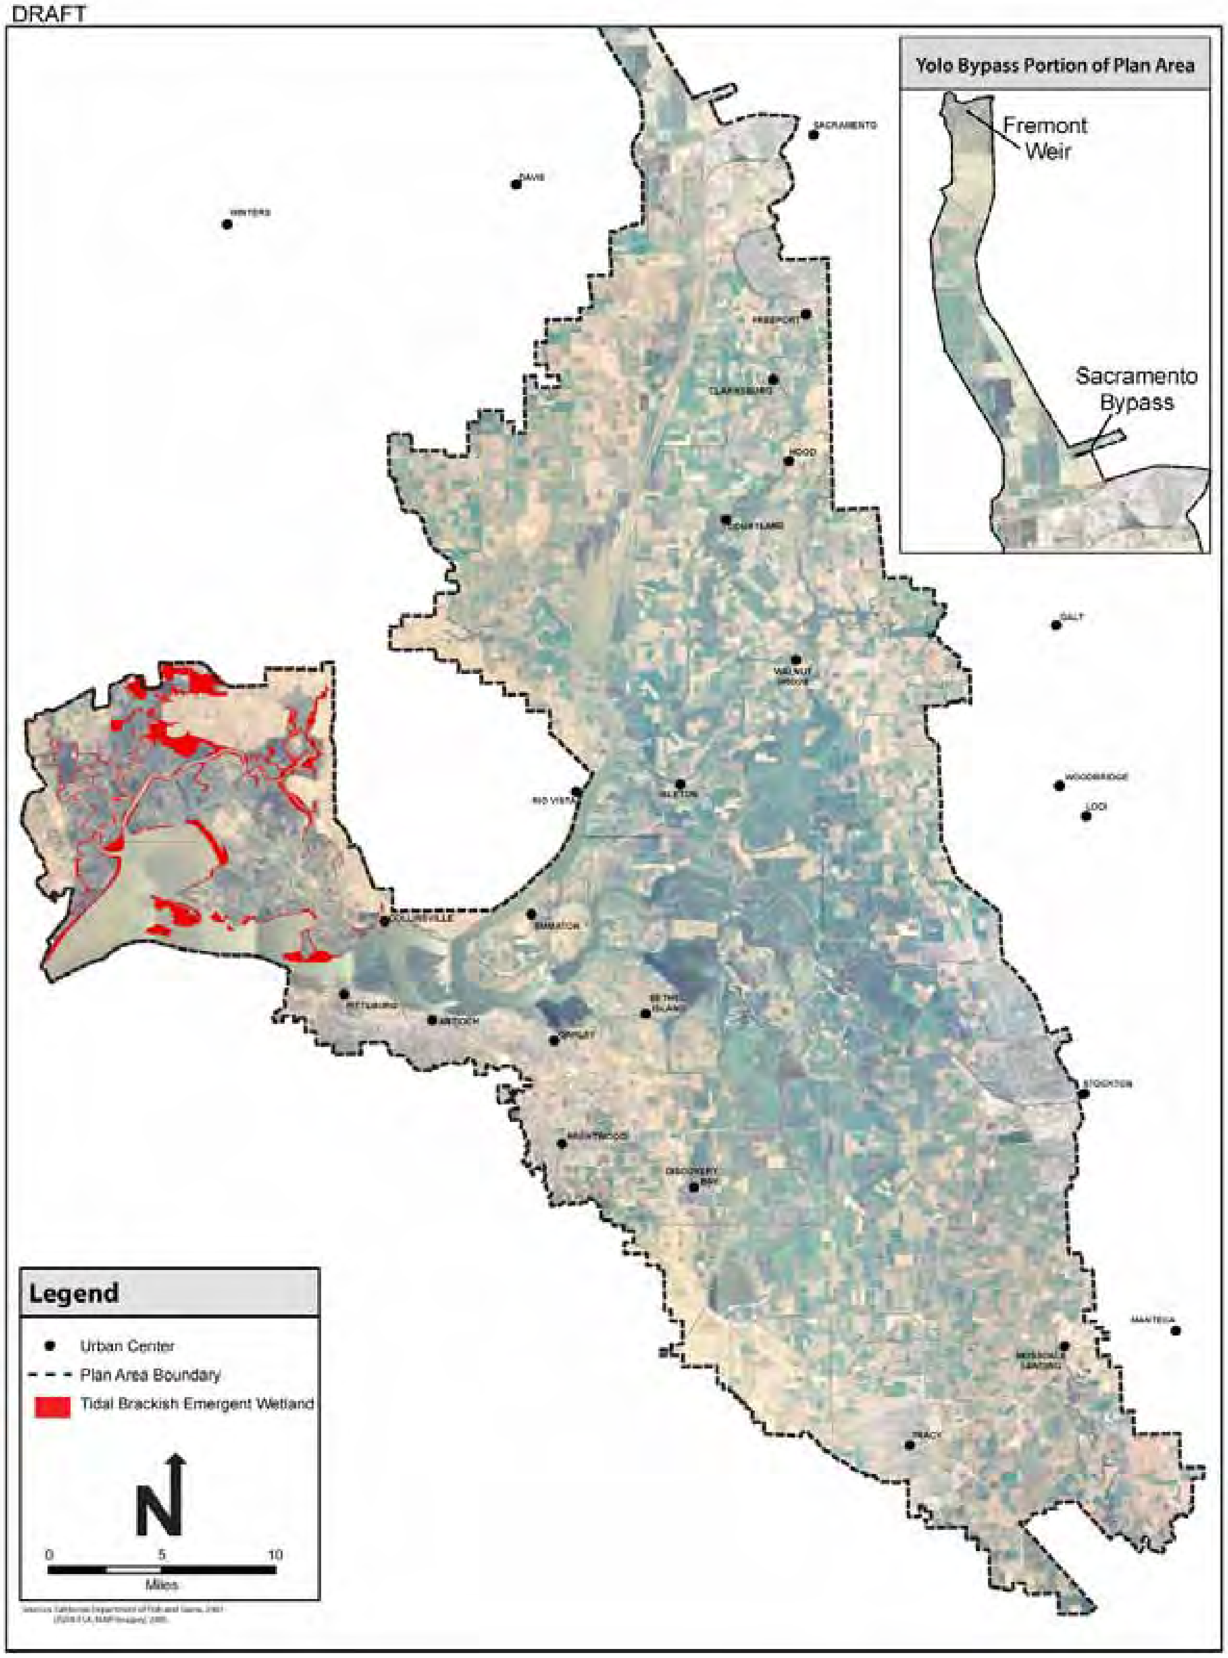

Figure 2-25. Distribution of Tidal Brackish Emergent Wetland Natural Community in the BDCP Plan Area

Table 2-7. Plant Alliances within Tidal Brackish Emergent Wetland Natural Community in the Plan Area

Mapping Unit[1]	*Plant Alliance (Sawyer and Keeler-Wolf 1995)*	*Acreage*
Delta		
Schoenoplectus[2] - *Typha* - *Phragmites*	-	304
Distichlis – Juncus - Sarcocornia[3]	-	2
Other	-	37
Suisun Marsh		
Schoenoplectus - Typha - Phragmites	-	6,048
Distichlis – Juncus – Sarcocornia - Atriplex	-	688
Annual grasses	-	341
Lepidium latifolium	-	181
Other	-	750
Total		**8,351**[3]

[1]Due to the large number of very fine scale mapping units the units shown here are the totals based on the dominant species. Additionally, for Suisun Marsh SFEI (2005) tidal data were used and intersected with the Boul and Keeler-Wolf (2008) vegetation data. For detailed information on these mapping units and plant associations/alliances, as well as on methods of classification used, see Hickson and Keeler-Wolf (2007) and Boul and Keeler-Wolf (2008).
[2]Formerly known as *Scirpus*.
[3]Formerly known as *Salicornia*.

The tidal brackish emergent wetland natural community in the Plan Area is found in undiked areas of Suisun Marsh such as Rush Ranch and Hill Slough, along undiked shorelines on the south shore of Suisun Bay, and on undiked in-channel islands such as Brown's Island. Prior to anthropogenic hydrological modifications, the tidal brackish emergent wetland natural community comprised an estimated 69,000 acres of Suisun Marsh (Boul and Keeler-Wolf 2008) but only 12 percent, or 8,351 acres, remain. At any particular place within this community, the composition of the dominant plant species are controlled by salinity in the channel water and in soil pore water (Culberson 2001, Culberson et al. 2004). Salinity levels in the channels are controlled by local sources of freshwater, seasonal outflow through the Delta and long term climatic variations, semidiurnal tides, and through the operation of a number of water control structures (Byrne et al. 2001, Culberson 2001, Suisun Ecological Workgroup 2001, Brown 2004, Culberson et al. 2004, Malamud-Roam and Ingram 2004, Malamud-Roam et al. 2006, Malamud-Roam et al. 2007, Watson and Byrne 2009).

The effects of channel water salinity are attenuated with distance away from the channel as evapotranspiration through the dry season drives increases in soil pore water salinity that is not flushed away by tidal influences (Culberson 2001, Culberson et al. 2004, Watson and Byrne 2009). This results in higher salinity in the soil pore water of the channel/marsh transition zone and highest salinity levels in the marsh plain (Culberson 2001, Culberson et al. 2004). Additionally, within the marsh plain, depressions and small ponds may support vegetation adapted to less saline conditions (Suisun Ecological Workgroup 2001). Because soil pore water salinity and distance from channel, and not elevation, are the primary drivers of vegetation composition in these brackish marshes, the distributions of saltgrass and pickleweed in the marsh plain proper are driven by subtle differences in inundation duration (Culberson 2001, Culberson et al. 2004, Watson and Byrne 2009). Because the extent of the community is determined by dynamic salinity gradients, the vegetation is also naturally spatially and temporally variable and this variability leads to high plant diversity compared to tidal saline marshes (Watson and Byrne 2009).

Soils underlying the tidal brackish emergent wetland natural community are heavily influenced by suspended sediment along the channels and by the formation of peat beds away from the channels (Culberson 2001, Culberson et al. 2004). The rate of peat accumulation in the marsh plain is slow due to the low productivity of the small stature dominant plants, but has been sufficiently rapid to maintain its surface with increases in sea level (Culberson et al. 2004).

2.3.4.3.1 Vegetation

The tidal brackish emergent wetland natural community in the Plan Area is characterized by tall herbaceous hydrophytes that line the channels down to approximately 18 inches below mean lower low water (MLLW) with species that include hard-stem bulrush (*Schoenoplectus acutus*), California bulrush (*Schoenoplectus californicus*), common reed (*Phragmites australis*), and cattail (*Typha* spp.) (Culberson 2001, Suisun Ecological Workgroup 2001, Watson and Byrne 2009). The borders of first order channels and mosquito ditches, which mimic small channels, are also habitat for Suisun thistle (*Cirsium hydrophilum* var. *hydrophilum*), a BDCP covered species (USFWS 2009a). These same large species occur as clumps in the channel to marsh transition zone and share the zone with many other species such as saltgrass (*Distichlis spicata*), Baltic rush (*Juncus balticus*), and seaside arrow grass (*Triglochin maritima*). The boundary between the distant edge of the transition zone and marsh plain is gradual, and this is where the soft bird's-beak (*Cordylanthus mollis* ssp. *mollis*), a BDCP covered species, occurs with pickleweed (*Sarcocornia pacifica,* formerly *Salicornia virginica*), saltgrass, salt marsh dodder (*Cuscuta salina*), and spearscale (*Atriplex triangularis*) (Grewell 2005, USFWS 2009b). The marsh plain proper is dominated by a variable mixture of pickleweed and saltgrass.

2.3.4.3.2 Fish and Wildlife

The tidal brackish emergent wetland natural community in the Plan Area is productive wildlife habitat. The vegetation and associated waterways provide food and cover for numerous species of birds (e.g., waterfowl, wading birds), mammals, reptiles, and emergent aquatic insects. Many species rely on these emergent wetlands for their entire life cycle. Covered species that depend on the tidal brackish emergent wetland natural community include California black rail, California clapper rail, Suisun song sparrow, salt marsh harvest mouse, and Suisun shrew (Table 2-4).

When inundated, the tidal brackish emergent wetland natural community provides high quality fry and juvenile rearing habitat for a variety of fish species adapted to low salinities, such as splittail, salmonids, and sturgeon. In addition, organic material is exported from the community to provide food to nearby pelagic species, such as delta and longfin smelt.

2.3.4.3.3 Nonnative Species

The tidal brackish emergent wetland natural community and native plant and wildlife species present in the community have been, and continue to be, significantly impacted by invasive nonnative taxa. Invading plant species can potentially alter the species composition of the vegetation, its structure, and its chemical characteristics. Invasions of perennial pepperweed, which are often accompanied by fennel (*Foeniculum vulgare*), are one of the most serious threats to this community (Brown 2004, Vaghti and Keeler-Wolf 2004, Grewell 2005, SFEI 2006, ESA 2007, Fiedler et al. 2007, Hickson and Keeler-Wolf 2007, Boul and Keeler-Wolf 2008, Andrew and Ustin 2009, USFWS 2009a, USFWS2009b). This tall species commonly forms dense patches that exclude native species including BDCP covered species such as soft bird's-beak and Suisun thistle (Grewell 2005, Fiedler et al. 2007, USFWS 2009a, USFWS2009b). Other large stature invasive plant species that are problematic include pampas grass (*Cortaderia selloana*), giant reed (*Arundo donax*), and the nonnative genotype of common reed (*Phragmites australis*). These species commonly establish and spread along channels, in the marsh plain transition zone, and along the upland/marsh transition zone. Additionally, small nonnative annual grasses, particularly barbgrass (*Hainardia cylindrical*) and rabbitsfoot grass (*Polypogon monspeliensis*), have significantly impacted BDCP covered soft bird's-beak by functioning as ineffective host plants to this hemiparasite (Grewell 2005).

A number of nonnative animals are serious predators of native wildlife and have been shown to significantly reduce populations of salt marsh harvest mouse, California black rail, and California clapper rail which are covered species (Suisun Ecological Workgroup 2001, Brown 2004). These invasive and high impact nonnative wildlife species include red fox (*Vulpes vulpes*), feral cats (*Felis domesticus*), and rats (*Rattus* spp.) (Brown 2004, Takekawa et al. 2006). Additionally, ground disturbances caused by foraging by feral pigs (*Sus scrofa*) are significantly impacting the covered Suisun thistle (Fiedler et al. 2007, USFWS 2009a).

2.3.4.3.4 Ecosystem Functions

Because it is connected to the Plan Area through the semi-diurnal tidal cycle, the tidal brackish emergent wetland natural community has both local ecosystem characteristics and is also part of other ecosystems through its contribution to the shared food web. Local effects are dominated by vegetation productivity and decomposition rates which affect tidal channel morphology and tidal plain elevation (Culberson 2001, Culberson et al. 2004, Pearce 2004). Because the soil away from the immediate channel margins is primarily peat, a dynamic equilibrium exists between sea level changes, underground biomass production, and decomposition rates that controls the extent of emergent vegetation (Culberson 2001, Culberson et al. 2004). Additionally, the structure of the vegetation provides cover for aquatic species in the channels and over the transition zone and marsh plain when high tides flood the marsh (Brown 2004). Organic carbon and invertebrates produced within this community are transported to the channels and then to the Delta where they contribute significantly to the greater food web (Brown 2004).

2.3.4.3.5 Environmental Gradients

The tidal brackish emergent wetland natural community exists at the intersection of many gradients that are spatially and temporally variable. The gradients are primarily determined by tidal flows which range from 300,000-600,000 cfs between Chipps Island and Carquinez Strait and 6,500-50,000 cfs in Montezuma Slough (Brown 2004). These large flows create fast currents in the smaller channels, but the transport of materials into and out of the community depends on complex flow dynamics (Brown 2004). The tidal surges create a large scale salinity gradient that is manifested by brackish water conditions that exist because of the mixing of freshwater from the Delta and local creeks with oceanic water from San Francisco Bay. The longitudinal boundary between fresh and brackish water is not discrete but generally occurs over a distance of several miles from Sherman Island to the Carquinez Strait with smaller local boundaries where tributaries enter the northern portion of Suisun Marsh. There is no clear definition of brackish water, but a salinity range of 5-15 ppt generally describes the channel water salinity in the areas where the tidal brackish emergent wetland natural community is found (Conomos et al. 1985, Goman and Wells 2000, Culberson 2001, Kimmerer 2004). The amount of freshwater available to dilute oceanic water is generally determined by water management operations, sewage effluent discharge, and by winter creek and Sacramento River flows. Within this community, a secondary soil pore water salinity gradient develops between the channels and the marsh plain during the dry season as salts accumulate away from the channels through evapotranspiration (Culberson 2001). An elevational gradient also exists between the channels and the marsh plain with the dividing elevation at mean higher high water (MHHW) (Goman and Wells 2000). Below MHHW, large clonal species dominate, while above MHHW are mixtures of various large and small species. The combination of the salinity and elevational gradients creates a wide range of physical habitats that lead to a high diversity of species compared to salt and freshwater marshes (Watson and Byrne 2009).

2.3.4.3.6 Future Conditions with Climate Change

As with all intertidal communities, the tidal brackish emergent wetland natural community is by definition directly linked to sea level as well as the ratio of salt to freshwater. As a result, it is particularly sensitive to long-term sea level rise associated with global climate change and changes in Delta discharge. In order to persist, the tidal brackish emergent wetland natural community must be able to accrete sediments at high enough rates to keep their surfaces intertidal (Watson and Byrne 2009); that rate will depend upon how changing salinity and inundation duration affects the species composition of the wetland (Culberson et al. 2004, Watson and Byrne 2009).

2.3.4.4 Tidal Freshwater Emergent Wetland

The tidal freshwater emergent wetland natural community is typically a transitional community between the tidal perennial aquatic, and valley/foothill riparian and various terrestrial upland communities across a range of hydrologic and edaphic conditions. In the Plan Area, the tidal freshwater emergent wetland natural community often occurs at the shallow, slow-moving or stagnant edges of freshwater waterways in the intertidal zone and is subject to frequent long duration flooding. The distribution of the tidal freshwater emergent wetland natural community in the Plan Area is shown in Figure 2-26, and the constituent plant associations are provided in Table 2-8.

[1]Some of the mapping units provided here are newly described associations or alliances. For more detailed information concerning these mapping units and plant associations/alliances, as well as on methods of classification used, see Hickson and Keeler-Wolf (2007) and Boul and Keeler-Wolf (2008).

[2]Extent of this natural community present in the Plan Area for which DFG did not delineate plant alliances. As described in Section 2.3.1, *Data Sources and Natural Community Classification*, these areas were delineated as this natural community type from aerial photography interpretation.

Note: Acreage total accommodates for rounding.

The tidal freshwater emergent wetland natural community is distributed in narrow, fragmented bands along island levees, in-channel islands, shorelines, sloughs, and shoals. Prior to the 1860s, it comprised an estimated 87 percent of the Delta, with extensive marshes forming dense stands of vegetation bisected by meandering channels (The Bay Institute 1998, Grossinger et al. 2008). Today, remnant patches of this community are found in the western portion of the Delta near the confluence of the Sacramento and San Joaquin rivers, along Lindsey Slough and the Yolo Bypass, along the mainstem and several channels of the San Joaquin, Old, and Middle rivers, Lost Slough, and the area where the Cosumnes and Mokelumne rivers join the Delta. The loss and degradation of its historical extent is due to its conversion to agriculture as well industrial and urban development; and those losses have led to dramatic reductions in habitat that is available for associated fish and wildlife species (The Bay Institute 1998, CALFED 2000). Channelization, levee-building, removal of vegetation to stabilize levees, and upstream flood control have also reduced the extent of this community and altered its ecological function through changes to flooding frequency, inundation duration, and quantity of alluvial material deposition.

The tidal freshwater emergent wetland natural community occurs along a hydrologic gradient in the transition zone between open water and riparian vegetation or upland terrestrial vegetation such as grasslands or woodlands. In the Plan Area, there are often abrupt transitions to agricultural habitats and managed wetland natural communities and also along the boundaries formed by levees and other artificial landforms. The environmental conditions that support the tidal freshwater emergent wetland natural community are dynamic with frequent flooding disturbances and geomorphologic changes (i.e., alluvial deposition and scouring). Its constituent species composition and ecosystem functions are consequently variable in space and time (The Bay Institute 1998). As a result of the different sources of variability and the anthropogenically restricted area in which it can occur, the community vegetation may be distributed in small patches or in occasional large areas.

Soils underlying the tidal freshwater emergent wetland natural community are heavily influenced by inundation period, water flow, and alluvial deposition. They are hydric soils and when mineral-based, their texture can vary from clay to sand; and when based on organic material, can form peat beds (Goman and Wells 2000, Hitchcock et al. 2005, Drexler et al. 2009a). The soils are typically anaerobic due to frequent or permanent saturation with slow decomposition rates resulting in the accumulation of organic debris in various stages of decomposition. The composition of the vegetation is limited to relatively few dominant species that are tolerant of inundation and anaerobic soil conditions and typically are not tolerant of saline or brackish conditions (Holland and Keil 1995).

The natural topography of the Plan Area that supports this community is virtually flat, draining gradually toward the center of the Delta and then westward toward Suisun Bay. Under natural hydrological conditions, deposits of alluvial material sometimes shifted due to scouring and redeposition, and elevational differences of the vegetation from place to place were a function of alluvium elevation and tidal inundation levels (Grossinger et al. 2008). Today, artificial levees provide topographic barriers adjacent to waterways, and the inboard areas of many of the leveed islands that historically supported this community have subsided below sea level (CALFED 2000). In some cases, where levees have been breached and not repaired, portions of the islands that have not significantly subsided support tidal freshwater emergent wetland (e.g., northern Liberty Island); however, other deeply subsided islands that have flooded and have not been reclaimed support the tidal perennial aquatic natural community due to deeper inundation by floodwaters (e.g., Franks Tract, southern Liberty Island).

2.3.4.4.1 Vegetation

The tidal freshwater emergent wetland natural community is characterized by erect herbaceous hydrophytes (Holland and Keil 1995). There are 17 plant community alliances (i.e., unique species assemblages) mapped in the Plan Area that fall within the tidal freshwater emergent wetland natural community (Table 2-8) (Sawyer and Keeler-Wolf 1995, Hickson and Keeler-

Wolf 2007). The typical vegetation of this type, as mapped by DFG and adopted for vegetation mapping purposes, is dominated by tall, perennial monocots that reproduce by seed as well as vegetatively through rhizomes. However, the DFG vegetation classification was based on vegetation structure and species composition and did not consider ecosystem functions such as location within or above the intertidal region along drainages. In many areas of what is functionally tidal freshwater emergent wetland, woody species, especially willows (*Salix* spp.), occur in the intertidal region and co-dominate the vegetation (Atwater 1980, Watson 2006, EDAW 2007b, Watson and Byrne 2009). These intertidal areas with woody vegetation were not distinguishable in the DFG data set.

Cattails (*Typha* spp.) dominate the vegetation of this community along the Sacramento River; while throughout the San Joaquin River area, bulrushes (*Schoenoplectus americanus* and *Bolboschoenus maritimus*), tules (*Schoenoplectus californicus* and *S. acutus*), and common reed (*Phragmites australis*) are more often the dominant species (Atwater 1980, Watson 2006, EDAW 2007, Hickson and Keeler-Wolf 2007, Watson and Byrne 2009). In the far western portion of the Delta, where tidal waters are generally fresh but may be brackish during periods of low outflow, saltgrass becomes common (Boul and Keeler-Wolf 2008). Numerous native and nonnative dicots and rooted aquatics also commonly occur in the tidal freshwater emergent wetland natural community. Covered plant species associated with the tidal freshwater emergent wetland natural community are presented in Table 2-4.

2.3.4.4.2 Fish and Wildlife

The tidal freshwater emergent wetland natural community provides productive habitat for wildlife. Its vegetation and associated waterways provide food and cover for numerous species of birds (e.g., waterfowl, wading birds), mammals, reptiles, emergent aquatic insects, and amphibians. BDCP covered wildlife species associated with the tidal freshwater emergent wetland natural community are presented in Table 2-4.

Although the remaining areas of tidal freshwater emergent wetlands in the Plan Area are highly altered, they remain critical wintering grounds for migratory birds. A small number of wetland-associated species, such as waterfowl and egrets, have successfully adapted to foraging on some types of croplands that were converted from historical wetland areas (DFG 2005).

Many of the species of fish that use the tidal perennial aquatic natural community for habitat will also use the tidal freshwater emergent wetland natural community as habitat when it is inundated. Younger stages (e.g., larvae and fry) of some species rear in shallow waters that support emergent vegetation. Further, many fish species use emergent vegetation as refuge from predation and high flows (The Bay Institute 1998).

2.3.4.4.3 Nonnative Species

One important invasive nonnative species that has become established in the tidal freshwater emergent wetland natural community is giant reed (*Arundo donax*). This species grows as dense monocultures which shade and crowd out native plant species in this community (Dudley 2000).

Giant reed is found growing along natural and artificial watercourses throughout the Plan Area, but the acreage of the invasion is unknown (Hickson and Keeler-Wolf 2007). By eliminating native plants, giant reed reduces food and habitat for a number of birds, insects, and other wildlife.

2.3.4.4.4 Ecosystem Functions

The tidal freshwater emergent wetland communities provide critical biogeochemical, hydrologic, and geomorphic functions, as well as habitat for a variety of fish and wildlife; however, island reclamation throughout the Delta, channelization, and anthropogenic changes to flow patterns have dramatically altered the ecosystem function and habitat value of these wetlands in the Plan Area (DFG 2005). The tidal freshwater emergent wetland natural community in the Delta provides habitat for microorganisms, macroinvertebrates, and insects that form the base of the aquatic food chain. The vegetation also releases organic debris ("drift") into the waterways that is a source of nutrients and cover. The warm, shallow water and dense vegetation that is often present in this community provides cover for some species and can be a key source of aquatic food or prey for birds and larger wildlife (The Bay Institute 1998). Additionally, it provides allochthonous sources of food and prey for fish and other aquatic species.

The tidal freshwater emergent wetland natural community also naturally absorbs or processes influxes of nutrients that find their way into the aquatic system ("nutrient transformation"), thereby acting as a biogeochemical buffer and contributing to the aquatic food web.

2.3.4.4.5 Environmental Gradients

The tidal freshwater emergent wetland natural community provides habitat on virtually all exposures and slopes provided the surface is saturated or at least periodically flooded by tidal action. However, level topography dominates in the Plan Area, and on the water-side of levees from a depth of approximately 18 inches below mean lower low water (MLLW), the community occurs as a distinct transition to the levee bank upland vegetation. The upland limit of the habitat is generally the boundary between hydric soils supporting predominantly hydrophytic vegetation and non-hydric soils on the levees with primarily non-aquatic vegetation (Cowardin et al. 1979). The boundary between habitat associated with the tidal freshwater emergent wetland natural community and deep water habitats is approximately 18 inches below MLLW (Atwater et al. 1979, Simenstad et al. 2000).

Where brackish conditions occur at the western edge of the Delta, Suisun Bay, and Suisun Marsh, the tidal freshwater emergent wetland natural community merges into the tidal brackish emergent wetland natural community that supports plant and wildlife that are tolerant of brackish water or saline soil conditions. Physical factors that drive the location of gradients between community types include elevation, salinity, and flow patterns at multiple temporal scales (e.g., daily tidal, lunar, seasonal, inter-annual) (Culberson 2001, Watson 2006, Watson and Byrne 2009).

2.3.4.4.6 Future Conditions with Climate Change

As with all intertidal communities, the tidal freshwater emergent wetland natural community is by definition directly linked to sea level. As a result, it is particularly sensitive to long-term sea level rise associated with global climate change (Nicholls et al. 1999). Higher sea level will relocate the natural community to higher elevations in the Delta. Further, tidally influenced waterways would be relocated upstream, thus shifting the tidal freshwater emergent wetland natural community farther upstream. Because much of the Delta is armored with levees, the sea level driven relocation of the intertidal zone would be primarily vertical and not horizontal, likely resulting in a reduction in the extent of the tidal freshwater emergent wetland natural community as it is replaced by deep water habitat (i.e., tidal perennial aquatic natural community) adjacent to steep-sided levees. The greatest increase in the extent of this natural community will primarily occur along the periphery of the Delta where there are gently sloping areas of upland (Knowles 2006).

In order for its extent to remain constant the tidal freshwater emergent wetland natural community must accrete sediments, both influxes of mineral soil as well as local accumulations of peat, at a rate high enough to keep its lowest surface above an elevation of 18 inches below MLLW (Atwater et al. 1979, Simenstad et al. 2000, Kimmerer 2004). Given the reductions in sediment loads over the past half century (Section 2.3.2, *Ecosystem Processes*) (Cappiella et al. 1999, Wright and Schoellhamer 2004, Ganju and Schoellhamer 2010), and the likely inability of peat accumulation to keep pace with accelerating sea level rise (Orr unpublished data) it is likely that the extent of this community will be reduced where its vegetation cannot colonize newly inundated uplands.

2.3.4.5 Valley/Foothill Riparian

Broadly defined, the valley/foothill riparian natural community is often found as a transition zone between aquatic and terrestrial habitats and often expresses a wide range of environmental conditions (e.g., variable light and nutrient availability) (Holland and Keil 1995, The Bay Institute 1998, Vaghti and Greco 2007). In the Plan Area, the valley/foothill riparian natural community occurs along the margins of low-gradient perennial and intermittent waterways, floodplains, tidal areas, or where the water table is sufficiently high to provide water to plants year-round (e.g., oxbows) (CALFED 2000, Vaghti and Greco 2007). The distribution of the valley/foothill riparian natural community is shown in Figure 2-27, and the extent of its constituent vegetation associations is presented in Table 2-9.

The valley/foothill riparian natural community usually occurs in the Plan Area as long, linear patches separating other terrestrial biological communities and agricultural or urban land, or in low-lying, flood-prone patches near river bends, canals, or breached levees (Figures 2-18 through 2-22). Such areas are located along many of the major and minor waterways, oxbows, and levees in the Plan Area, including the Sacramento River, Deep Water Ship Channel, Yolo Bypass, and channels of the San Joaquin River and the Delta. Patches of riparian vegetation are also found on the interior of leveed Delta islands, along drainage channels and pond margins, and in abandoned low-lying fields.

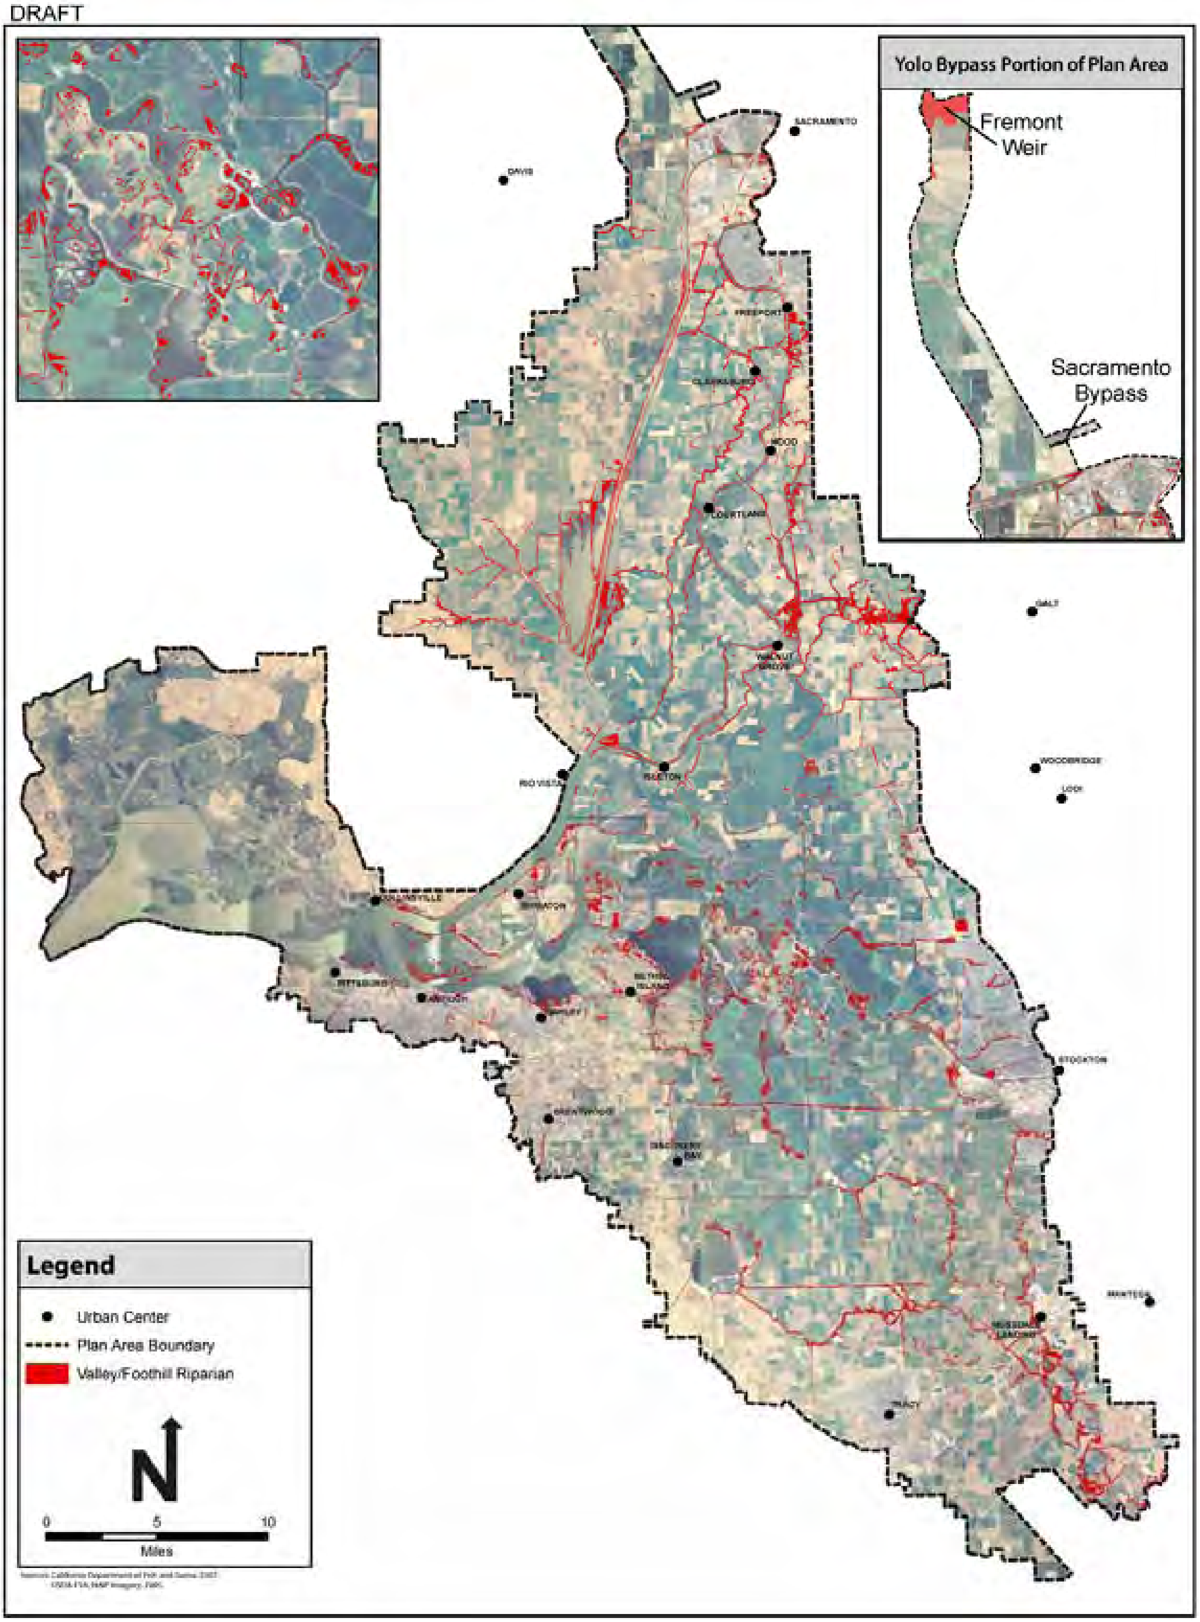

Figure 2-27. Distribution of Valley/Foothill Riparian Natural Community in the BDCP Plan Area

The current extent of the valley/foothill riparian natural community represents only a small proportion of its historical extent in the Plan Area (Thompson 1961, The Bay Institute 1998). Historically, valley oak (*Quercus lobata*) and cottonwood (*Populus fremontii*) occurred on coarser textured soils along natural levees and ranged from scraggy trees in the vicinity of Brannan Island to larger trees upriver (Thompson 1957). Similarly, in mineral soil areas of the south Delta, valley oak occurred sporadically as scraggy trees near drainage channels (Norris 1851). In contrast to historical conditions, these species occur on man-made levees sporadically throughout the Delta where vegetation control has not been a constant practice. In contrast to valley oak, under both historical and current conditions, extensive stands of willows occur throughout the Delta with box elder (*Acer negundo*), red alder (*Alnus rubus*), Redosier dogwood (*Cornus sericea*) and Oregon ash (*Fraxinus latifolia*), becoming increasingly common upstream from the Lower Sherman Island (Atwater 1980, EDAW 2007, Hickson and Keeler-Wolf 2007). The loss of riparian vegetation throughout California is estimated to be between 85-95 percent, and was caused by human activities such as river and stream channelization, levee building, removal of vegetation to stabilize levees, and extensive agricultural and urban development (Riparian Habitat Joint Venture 2004).

2.3.4.5.1 Vegetation

DFG identified 41 plant community alliances (i.e., unique species assemblages) in the Delta that fall within the valley/foothill riparian natural community (Table 2-9) (Sawyer and Keeler-Wolf 1995, Hickson and Keeler-Wolf 2007). The most common riparian plant associations in the Plan Area are dominated by valley oak, Fremont cottonwood, and Gooding’s black willow in the overstory and Himalayan blackberry, narrow-leaf willow, arroyo willow, and California wild rose in the understory or as riparian scrub. A recent Delta DFG survey discovered areas of valley/foothill riparian vegetation dominated by Redosier dogwood (*Cornus sericea*). Other native trees and shrubs that may be locally-dominant or important include white alder, California sycamore, buttonbush, California dogwood, Oregon ash, red willow, Pacific willow, box elder, Mexican elderberry, and Hinds’ walnut. California wild grape is a vine commonly found climbing upon other riparian vegetation.

Due to the wide range of abiotic environmental conditions in which the valley/foothill riparian natural community is found (e.g., substrate, flood frequency and duration, groundwater level, salinity), species composition and vegetation density and structure varies widely, from tall-canopied riparian forests dominated by deciduous, broad-leaved trees, to riparian scrub dominated by shorter stature trees, shrubs, and brambles. Species composition overlaps among the various riparian vegetation associations, and the structure and density of vegetation may vary even at relatively small spatial scales. The vegetation alliances, which make up the valley/foothill riparian natural community as identified by DFG in the Plan Area, can be placed into riparian forest, woodland, and scrub categories, based largely on the canopy height and the structure of the dominant plant taxa (Holland and Keil 1995). Riparian forest is dominated by broad-leaved, winter deciduous trees, such as valley oak and Fremont cottonwood, that form closed canopies up to 115 feet (35 m) tall (Griggs et al. 1993, Tu 2000, Griggs and Golet 2002, Trowbridge 2002, Trowbridge et al. 2005). This type of riparian vegetation is typically found along perennial or intermittent streams and tends to consist of relatively even-aged trees that reproduce episodically after flood events (Trowbridge 2005, Vaghti and Greco 2007). Riparian woodland may have similar species composition to the forests and are also typically dominated by tall, broad-leaved, winter deciduous trees. However, woodland canopies tend to be more open, likely due to hydrologic conditions and the species adaptations to the flooding regime. These conditions are found in few areas in the Delta today. Thickets dominated by one or more shorter stature willows (typically narrow leaf willow or arroyo willow) are categorized as riparian scrub, and are common along newly or frequently flooded waterways. Riparian scrub may contain saplings of riparian trees, other fast-growing shrubs, and vines that recolonize quickly following flood disturbance.

[1]Some of the mapping units provided here are newly described associations or alliances. For more detailed information concerning these mapping units and plant associations/alliances, as well as on methods of classification used, see Hickson and Keeler-Wolf (2007) and Boul and Keeler-Wolf (2008).

[2]Extent of this natural community present in the Plan Area for which DFG did not delineate plant alliances. As described in Section 2.3.1, *Data Sources and Natural Community Classification*, these areas were delineated as this natural community type from aerial photography interpretation.

Note: Acreage total accommodates for rounding.

The understory in riparian forest and woodland may contain immature canopy species and species commonly found in the riparian scrub community. All three structural types of the valley/foothill riparian natural community typically contain diverse mixtures of herbaceous plant species in the understory, often including graminoids such as rushes, bulrushes, sedges, flat-sedges, and grasses, as well as forbs such as monkeyflowers, stinging nettle, and watercress. Woody vines or lianas are also common and may form a dense understory composed of species such as honeysuckles, poison oak, and California wild grape (Holland and Keil 1995, Vaghti and Greco 2007).

BDCP covered plant species found or likely to be found in the valley/foothill riparian natural community in the Plan Area are listed in Table 2-4.

2.3.4.5.2 Wildlife

Although significantly altered and reduced in extent since initial European settlement (Katibah 1984), riparian habitats continue to support the greatest diversity of wildlife species of any habitat in California. The rich and complex vegetation composition and structure present in the valley/foothill riparian natural community provides habitat for over 225 bird, mammal, and reptile species (Riparian Habitat Joint Venture 2004). Over 80 percent of all wildlife species in the Sacramento Valley use riparian areas during a part of their life cycle for nesting, movement, cover, or forage (Riparian Habitat Joint Venture 2004). BDCP covered wildlife species associated with the valley/foothill riparian natural community are listed in Table 2-4.

Mammals that use the valley/foothill riparian natural community as habitat or movement corridors include ringtails, muskrats, raccoons, deer, coyotes, mountain lions, bobcats, woodrats, and mice. Two covered mammal species, riparian brush rabbit and riparian woodrat, are dependent upon the valley/foothill riparian natural community in the Plan Area. Riparian brush rabbit, a federally-listed endangered species, relies on the community for its entire lifecycle. The riparian woodrat (aka San Joaquin Valley woodrat), federally-listed as endangered and a state species of concern, inhabits riparian areas in the Plan Area. Bats are also found in greater densities near riparian areas feeding on the abundant swarms of aquatic insects and also use riparian areas for roosting habitat.

Abundant micro- and macro-invertebrate wildlife inhabit both the belowground and aboveground portions of the valley/foothill riparian natural community, contribute to ecosystem function and food web diversity. Soil invertebrates are a critical factor controlling decomposition and nutrient cycling (Power and Rainey 2000).

Riparian habitat is considered the most important habitat to landbird species in California (Manly and Davidson 1993, Davidson 1995). Migratory birds use riparian areas as stopover points. Major direct and indirect anthropogenic and non-anthropogenic impacts on this community in the Plan Area that affect avian species include degradation and fragmentation of habitat, nest parasitism, disruption of hydrologic processes by levees, clearing for agricultural and urban development, and biological invasions. Special-status bird species that are riparian habitat specialists include Swainson’s hawk, bank swallow, yellow warbler, common yellowthroat, Wilson’s warbler, yellow-breasted chat, and tricolored blackbird.

2.3.4.5.3 Nonnative Species

Riparian environments, with their high edge-to-area ratios and frequent disturbance regime, are prone to biological invasions (Planty-Tabacchi et al. 1996). In the valley/foothill riparian systems, introduced nonnative woody and herbaceous plant species may replace native species, and once established, can be extremely difficult to control or eradicate. Problematic nonnative invasive plant species in riparian areas include tree-of-heaven, *Sesbania*, Chinese tallowtree, black locust, tamarisk, Russian olive, bluegum eucalyptus, Himalayan blackberry, palm trees (multiple genera), giant reed, and perennial pepperweed. For example, the introduction of giant reed has negatively impacted the valley/foothill riparian natural community because the species grows in very dense monocultures, displacing natives and changing hydrological regimes (Dudley 2000). By eliminating native plants, giant reed removes food and habitat for a number of birds, insects, and other wildlife.

Many nonnative invasive wildlife species such as red-eared sliders and black rats have also impacted the valley/foothill riparian natural community. Feral domestic cats are another important nonnative species that can impact many native bird species in this community.

2.3.4.5.4 Ecosystem Function

The valley/foothill riparian natural community provides disproportionately higher ecosystem services and wildlife habitat compared to other terrestrial communities (National Research Council 2002). Riparian areas serve as the hydrologic connection between terrestrial uplands and aquatic ecosystems, receiving water from precipitation, overland runoff, groundwater discharge, and flow from an adjacent water body or alluvial aquifer (Vaghti and Greco 2007). They provide benefits to water quality by processing and filtering runoff, retaining and recycling nutrients, and trapping sediments (National Research Council 2002). Within the Plan Area, these ecosystem functions have been substantially negatively impacted due to the destruction and fragmentation of the community.

Although the covered fish species do not rely primarily on riparian habitat because they are aquatic species, they are directly and indirectly supported by the habitat services and food sources provided by the highly productive riparian ecosystem, particularly during flood flows when riparian habitats are inundated. Riparian vegetation is a source for organic material (e.g., falling leaves), insect food, and woody debris in waterways and can influence the course of water flows and structure of in-stream habitat. This debris is an important habitat and food source for fish, amphibians, and aquatic insects (Opperman 2005).

2.3.4.5.5 Environmental Gradients

Due to its location in the transition zone between aquatic and terrestrial ecosystems, the valley/foothill riparian natural community is characterized by biotic (e.g., species composition) and abiotic (e.g., hydrologic) gradients (Vaghti and Greco 2007). These gradients interact to form highly diverse and complex communities, both structurally and functionally. They also interact strongly with and influence the aquatic, emergent, and upland habitats along their edges.

The valley/foothill riparian natural community is associated with active and remnant hydrologic features in the Plan Area, as well as areas with a high water table that are periodically inundated. Plant community composition and structure is tightly coupled with fluvial processes (Strahan 1984). Vegetation density is inversely related to frequency of flooding; low-stature annual and perennial species on frequently-inundated sandbars and low-elevation ground give way to taller, longer-lived species further upland. In the Plan Area, there are abrupt transitions to agricultural cover, managed wetlands, or boundaries formed by levees and other man-made landforms.

Although the valley/foothill riparian vegetation is found on a range of soil types, the vast majority are primarily mineral or intermixed with peat in the Plan Area (Figure 2-4) (Hitchcock et al. 2005, Unruh and Hitchcock 2009). Soil conditions associated with this vegetation type are also typically influenced by current and past hydrologic conditions (Figure 2-10).

2.3.4.5.6 Future Conditions with Climate Change

Future climate change (Section 2.3.3.2, *Climate*) is expected to alter the valley/foothill riparian natural community in a variety of ways. Rising sea level will affect the location, extent, and composition of the valley/foothill riparian natural community as a result of increased water elevation and increased salt water intrusion. As water levels rise, riparian vegetation at the water's edge will become more frequently flooded, and many species intolerant of this longer inundation will migrate upslope if suitable habitat and hydrologic regimes are present. The ability to colonize new ground by shifting away from water's edge will depend on the availability of space in adjacent higher elevation areas and the ability of individual riparian species to colonize any new spaces (e.g., via seed dispersal or clonal growth).

Future vegetation composition and extent of the valley/foothill riparian natural community will also depend on the tolerance levels of individual plant species to the higher salinity associated with saltwater intrusion. Changes in channel water salinity may cause species shifts in the lower Delta by eliminating non-willow tree species, but the effect will be difficult to determine even qualitatively due to the inherent variability of the system.

Changes to the timing, duration, and magnitude of Delta inflows associated with future climate change are anticipated to result in more intense winter flooding and greater erosion of riparian habitats (Field et al. 1999, Hayhoe et al. 2004). The hydrodynamics of stream channels and the width of riparian corridors will be altered, resulting in losses or shifts in species composition of riparian vegetation.

Increased variability in precipitation is expected to produce prolonged droughts that make riparian vegetation more prone to fires. Thus, the frequency of wildfires in the valley/foothill riparian natural community is expected to increase in the future.

2.3.4.6 Nontidal Perennial Aquatic

The nontidal perennial aquatic natural community in the Delta can range in size from small ponds in upland areas to small lakes, such as the North and South Stone Lakes. The nontidal perennial aquatic natural community can be found in association with any terrestrial habitat and often transitions into nontidal freshwater perennial emergent wetland and valley/foothill riparian. The distribution of nontidal perennial aquatic is shown in Figure 2-28. The littoral zone of the nontidal perennial aquatic community is defined as the portion of the water column penetrable by light and that occurs at the edges of lakes and throughout most ponds (Moss 1998, Scheffer 2004). The limnetic zone extends below the littoral zone to the deepest part of the water body. Light penetration is inversely related to turbidity. Water temperature varies with depth; colder water generally occurs deeper due to the inverse relationship between water temperature and density. The oxygen concentration in nontidal perennial aquatic waters is low relative to that of flowing water. Only a small portion of water is in direct contact with air at the surface, where gas exchange with the atmosphere occurs. Dead organic material typically sinks to the bottom and decomposes, increasing biological oxygen demand near the bottom of some water bodies. Because of the stratification of these physical variables, there is a distinct zonation in plants and animals living in the nontidal perennial aquatic natural community (DFG 2005).

2.3.4.6.1 Vegetation

The plant associations present and their extent within the nontidal perennial aquatic natural community are described in Hickson and Keeler-Wolf (2007) (Table 2-10). Non-plant primary producers such as diatoms, desmids, and filamentous green algae often form the base of the food web where they dominate open water habitat. Plant species found in this community vary with inundation depth and distance from shore, from submerged aquatics (e.g., pondweed and Brazilian waterweed) to floating aquatic vegetation (e.g., duckweed and water hyacinth) that are found closer to shore and which may increase the rates of sediment and organic matter accumulation (DFG 2005).

Table 2-10. Plant Alliances within the Nontidal Perennial Aquatic Natural Community in the Plan Area

DRAFT

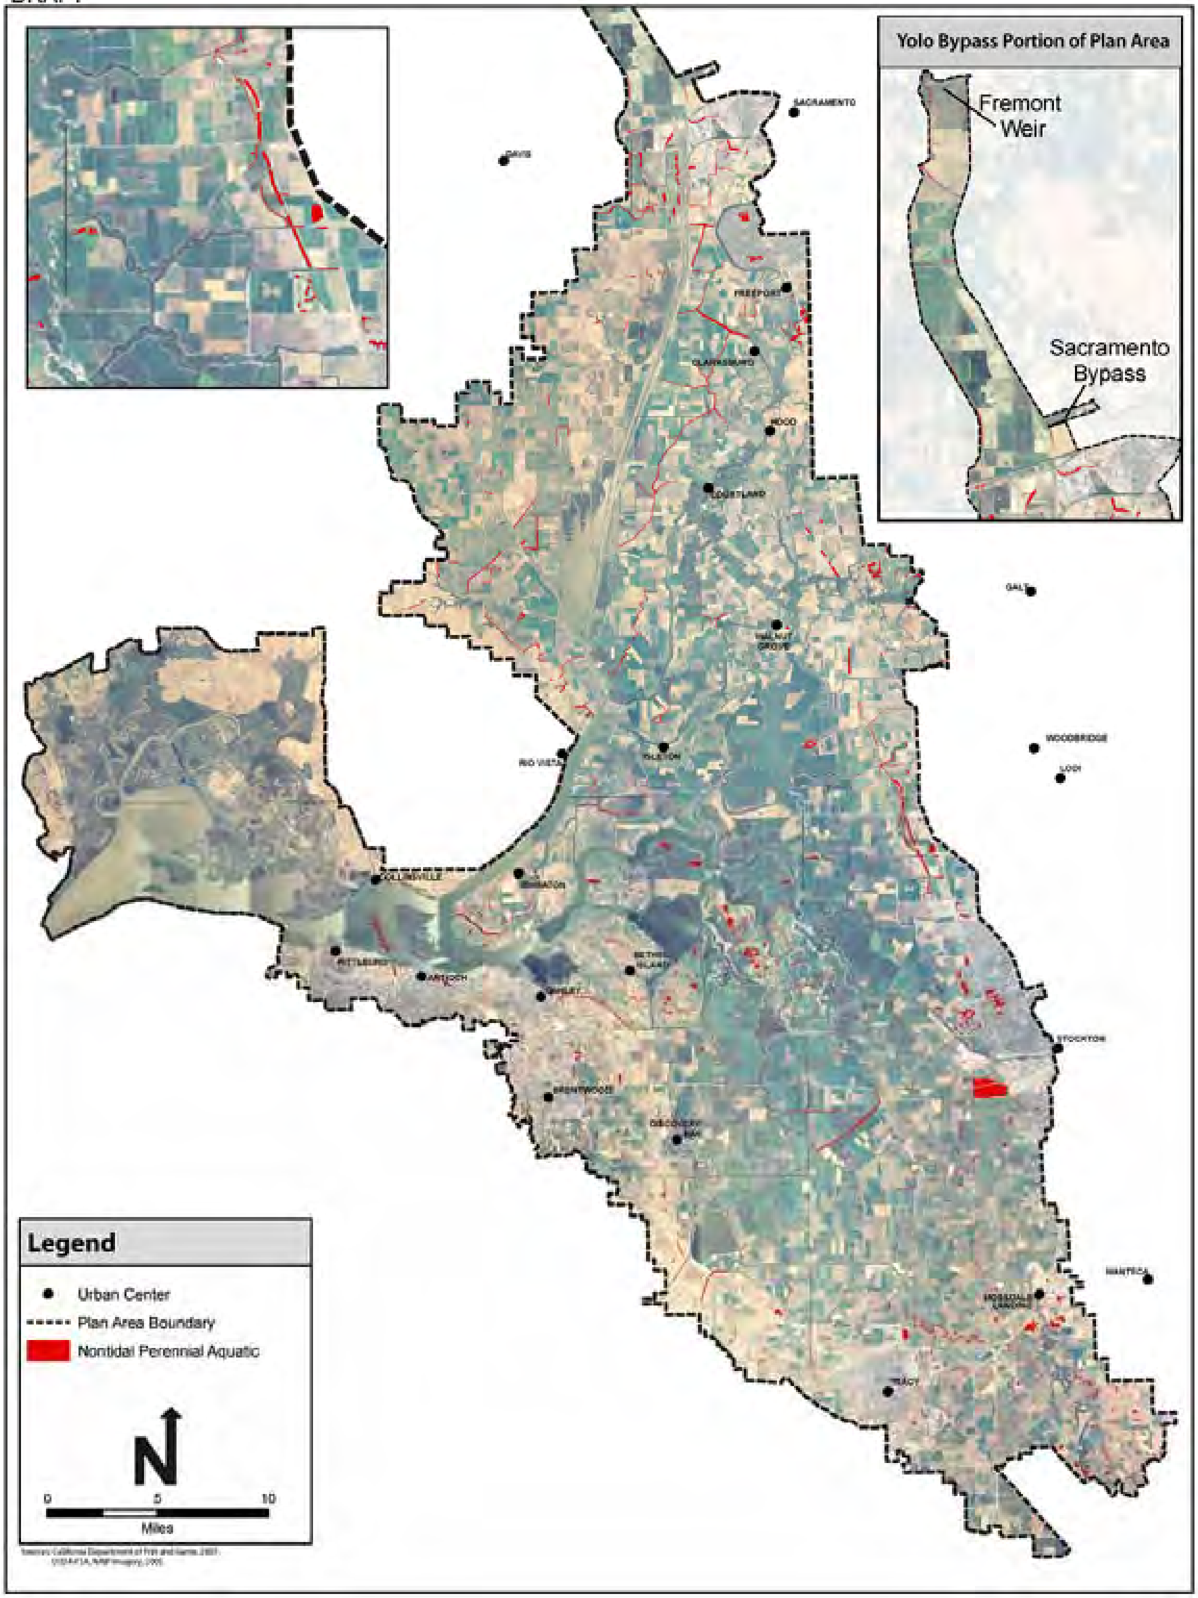

Figure 2-28. Distribution of Nontidal Perennial Aquatic Natural Community in the BDCP Plan Area

Shallow bodies of water, such as ponds and small lakes, generally are found in either a clear-water state with rooted and floating aquatic plants or in a turbid-water state dominated by algae with very few aquatic plants (Moss 1998, Scheffer 2004). These states can be stable or can oscillate between each other depending on a large number of factors that primarily affect the density of *Daphnia* zooplankton populations (Moss 1998, Scheffer 2004). The submerged portions of the plants provide a substrate for smaller algae and cover for smaller aquatic animals, including fish. Floating aquatics provide food and support for herbivorous crustaceans and mollusks (Smith 1974). Vegetation cover in the nontidal perennial aquatic natural community ranges from continuous to open (CALFED 2000). Covered plant species associated with the nontidal perennial aquatic natural community are presented in Table 2-4.

2.3.4.6.2 Fish and Wildlife

A thin layer of floating duckweed often covers the surface of shallow nontidal perennial aquatic waters. Desmids, diatoms, protozoans, crustaceans, hydras, and snails live on the under-surface of the layer, whereas mosquitoes and other aquatic insect larvae may live in between the plants.

Zooplankton, such as rotifers, copepods, and cladocerans, live suspended in the water column and graze on phytoplankton (Smith 1974). Together with phytoplankton, these organisms compose the base of the nontidal perennial aquatic food web. A variety of aquatic insects (e.g., dipterans, coleopterans, chironomids, trichopterans, plecopterans, and ephemeropterans) and collembolans use the nontidal perennial aquatic habitat for their larval stage. Native fish that can (or could in the past) be found in some nontidal perennial aquatic communities include the Sacramento perch, hitch, and tule perch (Moyle 2002).

A variety of wildlife species use the nontidal perennial aquatic natural community for resting and foraging, including waterfowl, shorebirds, semi-aquatic mammals (e.g., beaver, muskrat, and river otter), piscivorous birds (e.g., bald eagles and osprey), and insectivorous birds and bats that prey on insects that gather over open water. Ponds and other small bodies of open water also serve as important brooding habitat for ducks nesting in nearby upland habitats. Many water-dependent species (e.g., western pond turtle) require adjacent upland, riparian woodlands, or emergent wetlands for cover or nesting habitat. BDCP covered fish and wildlife species associated with the nontidal perennial aquatic natural community are presented in Table 2-4.

2.3.4.6.3 Nonnative Species

Many nonnative species have invaded the nontidal perennial aquatic community. Common invasive plants found in this habitat include Brazilian waterweed, Eurasian watermilfoil, and water hyacinth (DBW 2006, 2008). These plants form thick mats that exclude native vegetation and associated wildlife (SFEI 2003).

The nontidal perennial aquatic natural community in the Plan Area supports many nonnative freshwater fish species, including centrarchids, common carp, inland silverside, fathead minnow, and western mosquitofish. Additionally, the nonnative bullfrog is frequently present. These nonnative species prey on or compete with native fish and amphibian species both directly and indirectly for resources, including the BDCP covered California red-legged frog and California tiger salamander.

2.3.4.6.4 Ecosystem Functions

The nontidal perennial aquatic natural community is embedded in other communities, and generally the most significant ecosystem functions include providing an alternative source of primary productivity through its aquatic food web and an aquatic habitat for native fish, amphibians, and reptiles such as giant garter snake, a BDCP covered species. As described above, the source of primary productivity can either be algal phytoplankton or aquatic plants depending on whether the body of water is in a turbid- or clear-water state. The identity of the primary consumers and their feedback effects on the ecosystem depend in complex ways on many factors and cause impacts on the secondary consumers such as planktivorous or benthivorous (cyprinids) fish (Scheffer 2004).

2.3.4.6.5 Environmental Gradients

Within the water column of the nontidal perennial aquatic natural community there are gradients of light, oxygen and other chemicals, pH, and temperature which combine in various ways and result in a range of micro-habitat types (Moss 1998, Scheffer 2004). External gradients to terrestrial ecosystems always exist at the boundary of this community and vary from direct transitions to riparian forest, grassland, or agricultural lands in the Plan Area.

2.3.4.6.6 Future Conditions with Climate Change

Ongoing and future climate change (Section 2.3.3.2, *Climate*) is expected to alter the nontidal perennial aquatic natural community. Where this community exists at elevations at or below current sea level, rising sea level will alter its location, extent, and composition and potentially result in increased saltwater intrusion through an altered tidal hydrological regime. Also, where this community exists in flooded depressions in upland areas, which presumably already support the nontidal perennial aquatic community, it is not likely that natural processes could replace the area that will be lost.

2.3.4.7 Nontidal Freshwater Perennial Emergent Wetland

The nontidal freshwater perennial emergent wetland natural community is composed of perennially saturated wetlands, including meadows, dominated by emergent plant species that do not tolerate perennial saline or brackish conditions (CALFED 2000). Nontidal freshwater perennial emergent wetland communities in the Plan Area occur in small fragments along the edges of the nontidal perennial aquatic and valley/foothill riparian natural communities (Figure 2-29). Soils are predominantly silt and clay, although coarser sediments and organic material may be intermixed (Cowardin et al. 1979). In some areas, organic soils (peat) may constitute the primary growth medium (USACE 1978).

DRAFT

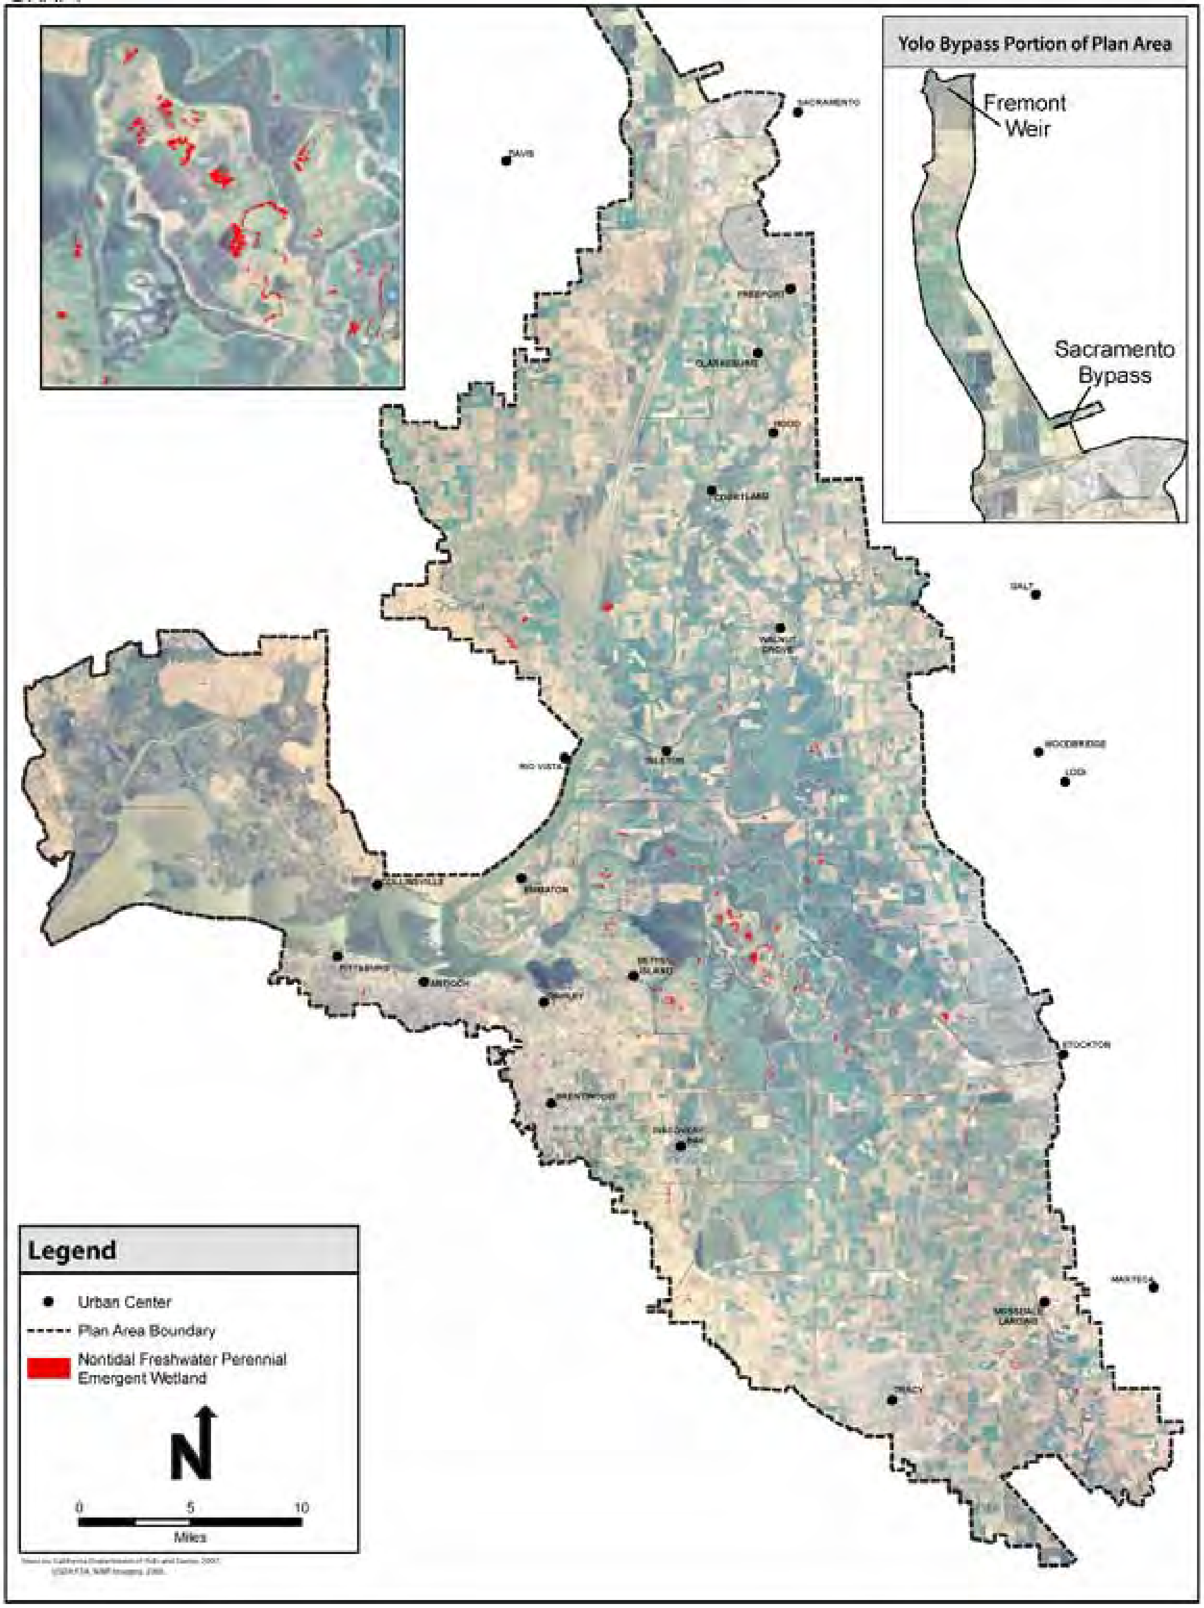

Figure 2-29. Distribution of Nontidal Freshwater Perennial Emergent Wetland Natural Community in the BDCP Plan Area

The extent of nontidal freshwater perennial emergent wetland in California, including the Delta, has declined dramatically over the past century due to reclamation and conversion of the habitat to other uses, primarily agriculture (Gilmer et al. 1982, The Bay Institute 1998). Only 1,134 acres of this natural community remain within the Plan Area. The extent of this natural community in the Delta has been dramatically reduced in the past century, with a corresponding reduction in its function as habitat for associated fish and wildlife species (The Bay Institute 1998).

2.3.4.7.1 Vegetation

The nontidal freshwater perennial emergent wetland natural community is distinguished by environmental conditions that support erect, rooted herbaceous plant species that can tolerate long inundation periods. All patches of these wetlands mapped in the Plan Area are dominated by broad-leaf cattail (Table 2-11) (Hickson and Keeler-Wolf 2007). This plant community frequently includes tules, bulrushes, sedges, rushes, and other emergent plant species. BDCP covered plant species associated with nontidal freshwater perennial emergent wetlands are presented in Table 2-4.

Table 2-11. Plant Alliances within the Nontidal Freshwater Perennial Emergent Wetland Natural Community in the Plan Area

[1]Some of the mapping units provided here are newly described associations or alliances. For more detailed information concerning these mapping units and plant associations/alliances, as well as on methods of classification used, see Hickson and Keeler-Wolf (2007) and Boul and Keeler-Wolf (2008).
[2]Extent of this natural community present in the Plan Area for which DFG did not delineate plant alliances. As described in Section 2.3.1, *Data Sources and Natural Community Classification*, these areas were delineated as this natural community type from aerial photography interpretation.
[3]DFG vegetation types were combined to form this mapping unit in order to condense the list.
[4]The genus of pickleweed is now *Sarcocornia* instead of *Salicornia*.
Note: Acreage total accommodates for rounding.

2.3.4.7.2 Wildlife

The nontidal freshwater perennial emergent wetland natural community is among the most productive wildlife habitat in California (DFG 2005). It provides food, cover, and water for numerous mammals, reptiles, amphibians, and birds. Many species rely on fresh emergent wetlands for their entire life cycle (e.g., giant garter snake). Others use the habitat primarily for breeding (e.g., California red-legged frog), feeding and hunting (e.g., bald eagle), or foraging and loafing habitat (e.g., migrating waterfowl). Within the Plan Area, the ecological functions provided by nontidal freshwater perennial emergent wetlands in support of wildlife are very limited because this community is highly fragmented and occurs in small patches (e.g., the 1,134 acres of this natural community are distributed among 159 mapped polygons). BDCP covered wildlife species that may use nontidal freshwater perennial emergent wetlands are presented in Table 2-4.

2.3.4.7.3 Nonnative Species

Many nonnative species have invaded the nontidal freshwater perennial emergent wetland natural community. Common invasive plants found in this habitat include Brazilian waterweed, Eurasian watermilfoil, and water hyacinth (DBW 2006, 2008). These plants form thick mats that exclude native vegetation and associated wildlife (SFEI 2003).

Nontidal freshwater perennial emergent wetland natural community in the Plan Area supports many nonnative freshwater fish species, including centrarchids, common carp, inland silverside, fathead minnow, and western mosquitofish. Additionally, the nonnative bullfrog is frequently present. These nonnative species prey on or compete with native fish and amphibian species both directly and indirectly for resources.

2.3.4.7.4 Ecosystem Functions

Nontidal freshwater perennial emergent wetland natural community generally forms the boundary around the nontidal perennial aquatic natural community, and with that community is embedded in other communities. Generally, its most significant ecosystem functions include providing an alternative source of primary productivity through its aquatic food web and providing an aquatic habitat for native fish, amphibians, and reptiles such as giant garter snake, a BDCP covered species. Its importance as a source of primary productivity can increase or decrease if the body of water is dominated by algal phytoplankton or aquatic plants depending on whether the body of water is in a turbid- or clear-water state. The contribution of primary consumers and their feedback effects on the ecosystem depend on many factors and cause impacts to the secondary consumers such as planktivorous or benthivorous (cyprinids) fish (Scheffer 2004). Additionally, this community provides the structural substrate for predator avoidance and nesting of wildlife.

2.3.4.7.5 Environmental Gradients

Within the water column of the nontidal freshwater perennial emergent wetland natural community there are gradients of light, oxygen and other chemicals, pH, and temperature which combine in various ways and result in a range of micro-habitat types (Moss 1998, Scheffer 2004). External gradients to terrestrial ecosystems always exist at the boundary of this community because it is the boundary that lies between open water habitat and ecotonal transitions into riparian forest, grassland, or agricultural lands in the Plan Area.

2.3.4.7.6 Future Conditions with Climate Change

Ongoing and future climate change (Section 2.3.3.2, *Climate*) is expected to alter the nontidal freshwater perennial emergent wetland natural community. Sea level rise will affect the location, extent, and composition of this community in places where it exists at or below current sea level as a result of increased water elevation, increased saltwater intrusion, and the tidal hydrological regime. Nontidal freshwater perennial emergent wetland locations that exist at the water's edge will become more deeply immersed, or in the case of overtopped levees, deeply flooded. Where this community exists in flooded depressions in upland areas, which presumably already support the nontidal freshwater perennial emergent wetland natural community, it is not likely that natural processes could replace the area that will be lost.

2.3.4.8 Alkali Seasonal Wetland Complex

The alkali seasonal wetland complex natural community occurs on fine-textured soils that contain a relatively high concentration of dissolved salts. This natural community includes both saturated wetlands, sometimes with areas of shallow ponding during the wet season, and a surrounding matrix of various types of vegetation. It is typically found either at the historical locations of seasonal ponds in the Yolo Basin in and around the California Department of Fish and Game Tule Ranch Preserve (Witham 2003, EDAW 2007) where salts accumulated through evaporation, or in upland situations such as basin rims and seasonal drainages that receive salts in runoff from upslope salt-bearing bedrock such as areas near Suisun Marsh and the Clifton Court Forebay (CCF). Associations dominated by saltgrass cover the largest extent of the alkaline wetland alliances in the Plan Area (Hickson and Keeler-Wolf 2007), and the area of undetermined vegetation adjacent to Suisun Marsh is also likely dominated by saltgrass (Table 2-12). Vegetation associations containing salt-adapted shrubs and subshrubs, generally located in the CCF area (SFEI 2010), constitute most of the remaining acreage. Depending on its location, this community often transitions into other natural communities such as tidal brackish emergent wetland, vernal pool complex, grassland, valley/foothill riparian, and agricultural habitats. The distribution of the alkali seasonal wetland complex natural community in the Plan Area is shown in Figure 2-30.

2.3.4.8.1 Vegetation

Dominant species in the alkali seasonal wetland complex natural community include saltgrass, Baltic rush, pickleweed, iodine bush, and alkali heath (Table 2-12) (Hickson and Keeler-Wolf 2007). Other abundant plant species include toad rush, bush seepweed, brass buttons, gum plant, and perennial pepperweed. Annual grasses associated with this natural community include the native Pacific foxtail as well as nonnative grasses such as rabbitsfoot grass, swamp timothy, and Italian ryegrass. In associations that are dominated by woody plants in the Clifton Court Forebay area, shrubs characteristic of desert regions such as iodine bush (*Allenrolfea occidentalis*) may form an open shrub cover with an intermittent herbaceous strata that is dominated by saltgrass, wild barley, and curved sicklegrass (Hickson and Keeler-Wolf 2007).

[1]Some of the mapping units provided here are newly described associations or alliances. For more detailed information concerning these mapping units and plant associations/allicances, as well as on methods of classification used, see Hickson and Keeler-Wolf (2007) and Boul and Keeler-Wolf (2008).
[2]*Salicornia virginica* is now *Sarcocornia pacifica.*
[3]Extent of this natural community present in the Plan Area for which DFG did not delineate plant alliances. As described in Section 2.3.1, *Data Sources and Natural Community Classification*, these areas were delineated as this natural community type from aerial photography interpretation.
Note: Acreage total accommodates for rounding.

Covered plant species that occur in this community include Delta button-celery growing on alluvium in the Discovery Bay area, San Joaquin saltbush on basin rims, brittlescale and heartscale growing in alkaline drainages; and growing in the vernal pool complex natural community, which is sometimes interspersed within this community, are alkali milk-vetch, dwarf downingia, Boggs Lake hedge-hyssop, legenere, and Heckard's pepper-grass (Table 2-4).

2.3.4.8.2 Fish and Wildlife

In the Plan Area, the alkali seasonal wetland complex natural community, and in particular saltgrass-dominated grassland, supports breeding and/or foraging habitat for covered vertebrate species including California tiger salamander, western spadefoot toad, giant garter snake, Swainson's hawk, tricolored blackbird, western burrowing owl, white-tailed kite, Townsend's big-eared bat, and San Joaquin kit fox (Table 2-4). The vernal pool complex natural community, which is sometimes scattered within this community, supports covered invertebrate species including several fairy shrimp species and vernal pool tadpole shrimp.

2.3.4.8.3 Nonnative Species

The primary problematic nonnative plant species in this community are perennial pepperweed (Witham 2006, EDAW 2007, ESA 2007) and annual ryegrass (*Lolium multiflorum*) (Dawson et al. 2007) which form dense patches that exclude many native plant species. There are no data describing their effects on wildlife.

2.3.4.8.4 Ecosystem Functions

The alkali seasonal wetland complex natural community is found on relatively impermeable clay alluvial soils (Graymer et al. 2002, Water Resources & Information Management Engineering Inc. 2006, NRCS 2009) that remain saturated throughout the wet season and during the early part of the dry season. The two contrasting types of typical vegetation, either dominated by the perennial saltgrass as is the case in most areas, or the woody iodine bush scrub near the Clifton Court Forebay, largely control the ecosystem functions of this community. Saltgrass-dominated areas are generally vegetated more or less uniformly and provide a very simple and herbaceous physical structure with relatively fast nutrient and carbon cycling. In contrast, iodine bush-dominated areas tend to have a patchy distribution of shrubs that provide more structural variation and sequester nutrients and carbon for longer periods of time. Saltgrass areas are typically grazed by native wildlife and domestic livestock and function as grasslands. They are also relatively open habitat that provides foraging habitat for raptors. Iodine bush habitat provides open areas for foraging by wildlife as well as closed canopy areas for cover.

2.3.4.8.5 Environmental Gradients

The alkali seasonal wetland complex natural community transitions into wetter areas such as the tidal brackish emergent wetland natural community in the Suisun Marsh area (Collins and Grossinger 2004, Grossinger 2004) and the tidal freshwater emergent wetland in the Delta (Grossinger et al. 2008) and often has vernal pool inclusions in areas with depressions. In other areas, such as near the Montezuma Hills, it transitions into the drier grassland natural community (Collins and Grossinger 2004, Grossinger 2004, Grossinger et al. 2008).

2.3.4.8.6 Future Conditions with Climate Change

Ongoing and future climate change (Section 2.3.3.2, *Climate*) is expected to alter the alkali seasonal wetland complex natural community. Because this community is generally located well above sea level it will not be directly impacted by rising sea level except at locations where it abuts tidal communities which will move upslope, thus reducing its extent. The primary impact of climate change on this community is predicted to be driven by changes in the hydrological regime due to increased variability in precipitation. The species present in this community are adapted to existing hydrological conditions such that increased variability of precipitation would likely lead to a shorter and more variable wet season or similar changes in the inundation period. It is not known how the increased variability in seasonal hydrology will affect the plants and animals inhabiting this community, but because these species are adapted to current conditions, the impacts will likely result in changes to species composition. In addition, rising average temperatures could result in increased evapotranspiration rates and therefore more extended dry periods for this community; the impacts of which are expected to be adverse to native plants and wildlife.

2.3.4.9 Vernal Pool Complex

The vernal pool complex natural community is characterized by interconnected and isolated groups of vernal pools and seasonal swales that are generally within a matrix of either grassland or alkali seasonal wetland vegetation. This natural community is rare in the Plan Area and is generally found only in a few locations along the very margin of the Plan Area (Figure 2-31). The vernal pool complex natural community was mapped specifically for the BDCP using a range of methods because there were no available data sets with the appropriate level of detail or spatial extent. Details of the methods used to map vernal pool complex are presented in Section 2.3.1.5, *Vernal Pool Complex Dataset Development*, and an in-depth discussion is presented in Appendix L2, *Vernal Pool Complex Mapping for the BDCP*. Regions of the Central Valley to the east and west of the Plan Area support large areas of vernal pool complex natural community, especially in San Joaquin, Sacramento, and Solano counties.

In the Plan Area, vernal pools are found west of the Sacramento River from Putah Creek south to the gently sloped terraces immediately to the north and east of the Montezuma Hills, east of the Sacramento River in the Stone Lakes area, and west of the San Joaquin River from Byron to Discovery Bay (Witham 2003, ESA 2005, Leigh Fisher Associates 2005, Williamson et al. 2005, Witham 2006, Baraona et al. 2007, Kleinschmidt Associates 2008, Rains et al. 2008, SFEI 2010). The pools on the west side of the Delta formed on clay soils with relatively high salt content, while those on the east side formed on clays with little salt content. The plant species in vernal pools are generally adapted to a hydrological regime of standing water in winter and spring and desiccated soils in summer (CALFED 2000, Solomeshch et al. 2007). Vernal pools in California are also known for providing habitat for a number of endemic and rare species (Jain 1979, Jones and Stokes Associates 1990, Skinner and Pavlik 1994, Solomeshch et al. 2007). A single vernal pool may support over 100 species of native plants and animals (USFWS 2007). The conversion of large extents of the vernal pool complex natural community to agriculture and developed areas has led directly to greatly reduced population sizes of species covered in the BDCP such as alkali milk-vetch, Heckard’s pepper-grass, and legenere (Table 2-4).

[1]Some of the mapping units provided here are newly described associations or alliances. For more detailed information concerning these mapping units and plant associations/alliances, as well as on methods of classification used, see Hickson and Keeler-Wolf (2007) and Boul and Keeler-Wolf (2008).
[2]*Salicornia virginica* is now *Sarcocornia pacifica.*
[3]Extent of this natural community present in the Plan Area for which DFG did not delineate plant alliances. As described in Section 2.3.1, *Data Sources and Natural Community Classification*, these areas were delineated as this natural community type from aerial photography interpretation.

Vernal pools are uniquely defined by their hydrology and by the presence of endemic plant and invertebrate species (Keeley and Zedler 1998). The hydrological regime has three components: 1) the source of water; 2) the durations of the inundated and the waterlogged soil phases; and 3) the seasonal timing of these phases. In general, rainfall is the primary source of water to vernal pools as it falls directly into the vernal pool or is transported a short distance across the watershed of the vernal pool. This direct rainfall and watershed model is the simplest case, but there may be groundwater transport to the vernal pool through a shallow perched aquifer or a combination of rainfall and creek flooding (ESA 2005, Williamson et al. 2005, Rains et al. 2008). The duration and timing of the inundation and waterlogged soil phases are also variable with hardpan vernal pools generally having shorter phases centered during the middle of the wet season while claypan and clay vernal pools have longer phases extending earlier and later into the wet season (ESA 2005, Williamson et al. 2005, Rains et al. 2008). Similar complications occur in determining the presence of the characteristic endemic species. Using endemic plants as an example, the cover of many of them can vary by orders of magnitude from season to season, and they may only be present in the soil seed bank in some years (Barbour et al. 2007). These unique characteristics can also be blurred to varying degrees by human-driven impacts such as land leveling and ripping, altering the supply of water through flood irrigation, or through the intentional or inadvertent introduction of exotic plant species.

Note that the vernal pool complex natural community was mapped separately from the other vegetation data used for the BDCP and the mapped polygons of the community overlay of DFG vegetation types that are described in this chapter. There are 6,959 acres of the vernal pool complex natural community (including both wetted surface and upland matrix) within the Plan Area, of which 4,730 acres are found in annual grassland vegetation, 1,673 acres are found in saltgrass vegetation, 233 acres are found in iodine bush scrub, and 196 acres were mapped as vernal pools by DFG.

2.3.4.9.1 Vegetation

The flora of vernal pools has adapted in different ways to the unique physical and chemical constraints imposed by the inundated lacustrian phase. The duration of inundation has been found to be strongly correlated with two clear functional groups (Zedler 1987, 1990, Barbour et al. 2003, 2005, Barbour et al. 2007). An edge-of-pool plant functional group is adapted to the fluctuating hydrology of shallow vernal pools or to the edges of deep vernal pools, while the long inundation functional group is adapted to the deeply inundated basins of vernal pools. The edge or saturated soil species are especially prone to elimination by competition with upland exotic grass species or through thatch accumulation (Barry 1995, Griggs 2000, Marty 2005), while the basins are prone to invasion by low mannagrass (Gerlach et al. 2009).

The vernal pool complex natural community in the Plan Area can be classified into four fairly uniform types: annual grassland vernal pool complexes in the Stone Lakes area; clay alluvium vernal pools and playa pools running from Putah Creek south to Cache Slough; Montezuma Block vernal pools and playa pools in the Jepson Prairie/Montezuma Hills area; and alkaline sink/meadow vernal pools near the Byron/Clifton Court Forebay area.

Annual grassland vernal pool complexes have uplands that are dominated by Eurasian annual grasses with a varying mixture of native grasses and herbs depending on the farming history of the site. These vernal pools are found in the lowest local topographic positions on soils that were deposited in and alongside ancient stream channels and are underlain by a discontinuous claypan (Williamson et al. 2005, Rains et al. 2008) or clay alluvial lens. The endemic plant species present in the vernal pools are generally considered to be adapted to non-alkaline soils, but some characteristic species of alkaline vernal pools, such as Heckard's pepper-grass or saline clover, may be present. Typical plant species found in these vernal pools are: Pacific foxtail (*Alopecurus saccatus*), bristled downingia (*Downingia bicornuta* var. *bicornuta*), low mannagrass (*Glyceria declinata*), rayless goldfields (*Lasthenia glaberrima*), shining peppergrass (*Lepidium nitidum* var. *nitidum*), small stipitate popcorn-flower (*Plagiobothrys stipitatus* var. *micranthus*), Sacramento mesamint (*Pogogyne zizyphoroides*), and woolly marbles (*Psilocarphus brevissimus*).

Clay alluvium vernal pools and playa pools have uplands that are dominated in the spring by either Eurasian annual grasses or a variable mixture of saltgrass and native herbs, and are dominated in the summer by native tarweeds or the exotic yellow starthistle. These vernal pools and playa pools can be found on extremely thick clay alluvium (Bryan 1923, Thomasson Jr. et al. 1960, State of California 1987) in a range of topographic positions, from scoured areas above the main flood distribution channels of Putah Creek to mid-elevations where a swale may connect a series of vernal pools (ESA 2005), to low elevation playas in the Yolo Bypass that are periodically flooded by the Sacramento River (Witham 2003), to much older vernal pools and playa pools in the greater Jepson Prairie area (Bryan 1923, Thomasson Jr. et al. 1960, Witham and Kareofelas 1994, Williamson et al. 2005, Witham 2006, Baraona et al. 2007, Rains et al. 2008). The rare endemic species found in these vernal pools and playa pools include Solano grass, Colusa grass, alkali milk-vetch, San Joaquin spearscale, dwarf downingia, legenere, and Heckard's pepper-grass.

Montezuma Block vernal pools and playa pools have uplands that are similar to those of the clay alluvium vernal pools and playa pools, but extensive areas are also in agricultural production as dry-farmed wheat. These vernal pools and playa pools can also be found in a range of topographic positions from intermittent stream channels in the Montezuma Hills, to the mid-elevation divide that is characteristic of the Jepson Prairie area, to the near tidal elevation vernal pools found along Cache Slough (Witham and Kareofelas 1994) and upland of Suisun Marsh (Wildlands Inc. 2005, SFEI 2006). The rare endemic species found in these vernal pools and playa pools include Colusa grass, alkali milk-vetch, San Joaquin spearscale, dwarf downingia, legenere, and Heckard's pepper-grass.

Alkaline sink/meadow vernal pools, as the name implies, are found scattered within alkaline meadows and alkaline sinks near the Byron/Clifton Court Forebay area (Carpenter and Cosby 1939, SFEI 2010). Hydrologically, these vernal pools are similar to the clay alluvium vernal pools and playa pools as their hydrology is a mixture of local rainfall, groundwater flow, and long distance stream transport. The surrounding vegetation is unique as it is typically dominated by native grasses such as saltgrass and alkali ryegrass, or by woody shrubs like iodine bush (*Allenrolfea occidentalis*) and subshrubs such as bush seepweed (*Suaeda moquinii*) and alkali heath (*Frankenia salina*). Recent BDCP field surveys (DWR 2009 and 2010 unpublished data) found that the herbaceous vernal pool species include: Pacific foxtail (*Alopecurus saccatus*), brass-buttons (*Cotula coronopifolia*), rayless goldfields (*Lasthenia glaberrima*), alkali peppergrass (*Lepidium dictyotum* var. *dictyotum*), small stipitate popcorn-flower (*Plagiobothrys stipitatus* var. *micranthus*), and Sacramento mesamint (*Pogogyne zizyphoroides*).

2.3.4.9.2 Wildlife

Much less is known about the adaptations of animals to vernal pool conditions than about the adaptations of vernal pool plants. Most animals that are endemic to vernal pools have a combination of behavioral, structural, and physiological adaptations to avoid, resist, or tolerate desiccation during the dry season or during long droughts. Amphibians such as California tiger salamander and western spadefoot toad use vernal pools for breeding, but otherwise are essentially terrestrial animals. The six crustacean species covered under the BDCP (California linderiella, midvalley fairy shrimp, Conservancy fairy shrimp, longhorn fairy shrimp, vernal pool fairy shrimp, and vernal pool tadpole shrimp) tend to occur in separate vernal pools with different inundation periods (Table 2-4). These species are typically not found in vernal pools that have been heavily invaded by low mannagrass, as the fauna of these invaded vernal pools is typically dominated by mosquito and midge larvae (Rogers 1998). Waterfowl may forage in vernal pools during the wet season with ducks and shorebirds consuming invertebrates and geese consuming vegetation (Medeiros 1976, Reiner and Swenson 2000).

The upland watersheds associated with the vernal pool complex natural community provide foraging habitat for BDCP covered species such as western burrowing owl, Swainson's hawk, white-tailed kite, and San Joaquin kit fox (Table 2-4).

2.3.4.9.3 Nonnative Species

Vernal pools in the vernal pool complex natural community are invaded by different nonnative species at different points along the moisture gradient. The margins of vernal pools throughout the Central Valley are often dominated by the nonnative annual ryegrass. The deeper portions of many pools are being rapidly invaded by low mannagrass (Gerlach et al. 2009). Other parts of vernal pool complexes are being invaded by perennial pepperweed (Swiecki and Bernhardt 2002, Witham 2003, ESA 2005, Witham 2006, ESA 2007).

2.3.4.9.4 Ecosystem Functions

This is essentially an amphibious ecosystem with greatly differing functions depending on whether it is in its flooded or dry stages. When flooded, this community supports an aquatic food web that is functionally similar to that found in shallow lakes (Alexander 1976, Barclay and Knight 1981, Scheffer 2004, Williams 2006). As the water recedes, its ecosystem characteristics change from those of a fully aquatic system to those of a wetland and then to those of a terrestrial ecosystem (Williams 2006), and its food web linkages break down as the community becomes more integrated with the terrestrial landscape in which it is embedded. When flooded, it teems with a variety of ephemeral pond-adapted invertebrates, the immature stages of amphibians, and waterfowl. When dry, it is integrated with the surrounding terrestrial ecosystems and provides foraging habitat for native wildlife, and is typically managed as rangeland and grazed by sheep or cattle.

2.3.4.9.5 Environmental Gradients

The dominant environmental gradient in the vernal pool complex natural community is driven by the different chemical and physical attributes of water versus air. Water is a polar solvent that is important in many chemical exchanges, and those exchanges control pH and the oxidation state of many chemicals and compounds. It also has a high heat capacity so temperature changes are buffered, and it is extremely viscous compared to air so exchanges between the air and water as well as movement within the water are very slow (Scheffer 2004, Williams 2006). Ecological gradients in vernal pools are characterized by depth and ponding/saturation duration from the pool center to the surrounding grassland community.

2.3.4.9.6 Future Conditions with Climate Change

Ongoing and future climate change (Section 2.3.3.2, *Climate*) is expected to alter the vernal pool complex natural community. Because this community is generally located at elevations that will not be directly impacted by rising sea level, the primary impact of climate change is predicted to be driven by changes in the hydrological regime due to increased variability in precipitation. The species present in this community are adapted to existing hydrological conditions such that increased variability of precipitation would likely lead to a shorter and more variable wet season or similar changes in the inundation period. It is not known how increased variability in pool hydrology would affect the plants and animals inhabiting them, but because these species are adapted to current conditions, the impacts will likely result in changes to species composition. In addition, rising average temperatures could result in increased evapotranspiration rates and therefore shorter wetted periods for vernal pools; the impacts of which are expected to be adverse to native plants and wildlife.

2.3.4.10 Managed Wetland

The managed wetland natural community consists of areas that are intentionally flooded and managed during specific seasonal periods to enhance habitat values for specific wildlife species (CALFED 2000). Ditches and drains associated with this community are also included. The managed wetland natural community includes some areas of the CALFED Ecosystem Restoration Program "managed seasonal wetlands" habitat, and it fits into the "fresh emergent wetland" classification from the California Wildlife Habitat Relationships (DFG 2005).

Soils are composed predominantly of silts and clays, although coarser sediments and organic material may be intermixed. In some areas, such as Suisun Marsh, organic soils (peat) may constitute the primary growth medium.

Managed wetland is distributed largely in the northern, central, and western portions of the Delta, as well as in Suisun Marsh (Boul and Keeler-Wolf 2006, Hickson and Keeler-Wolf 2007). Substantial acreage of this type occurs in the Yolo Bypass, Stone Lakes National Wildlife Refuge, Cosumnes River Preserve, and Suisun Marsh (Suisun Ecological Workgroup 1997, Suisun Ecological Workgroup 2001, Brown 2004, EDAW 2007, USFWS 2007, Kleinschmidt Associates 2008). Several islands in the central Delta support large areas of this community type, including Mandeville Island, Medford Island, Holland Tract, and Bradford Island. The far western edge of the Delta, including Van Sickle and Chipps islands, and Suisun Marsh also includes managed wetland (Figure 2-32). Water at the far western border of the Plan Area and in the Suisun Marsh can be more brackish compared to other portions of the Delta where this community occurs (Suisun Ecological Workgroup 1997, Suisun Ecological Workgroup 2001, Brown 2004).

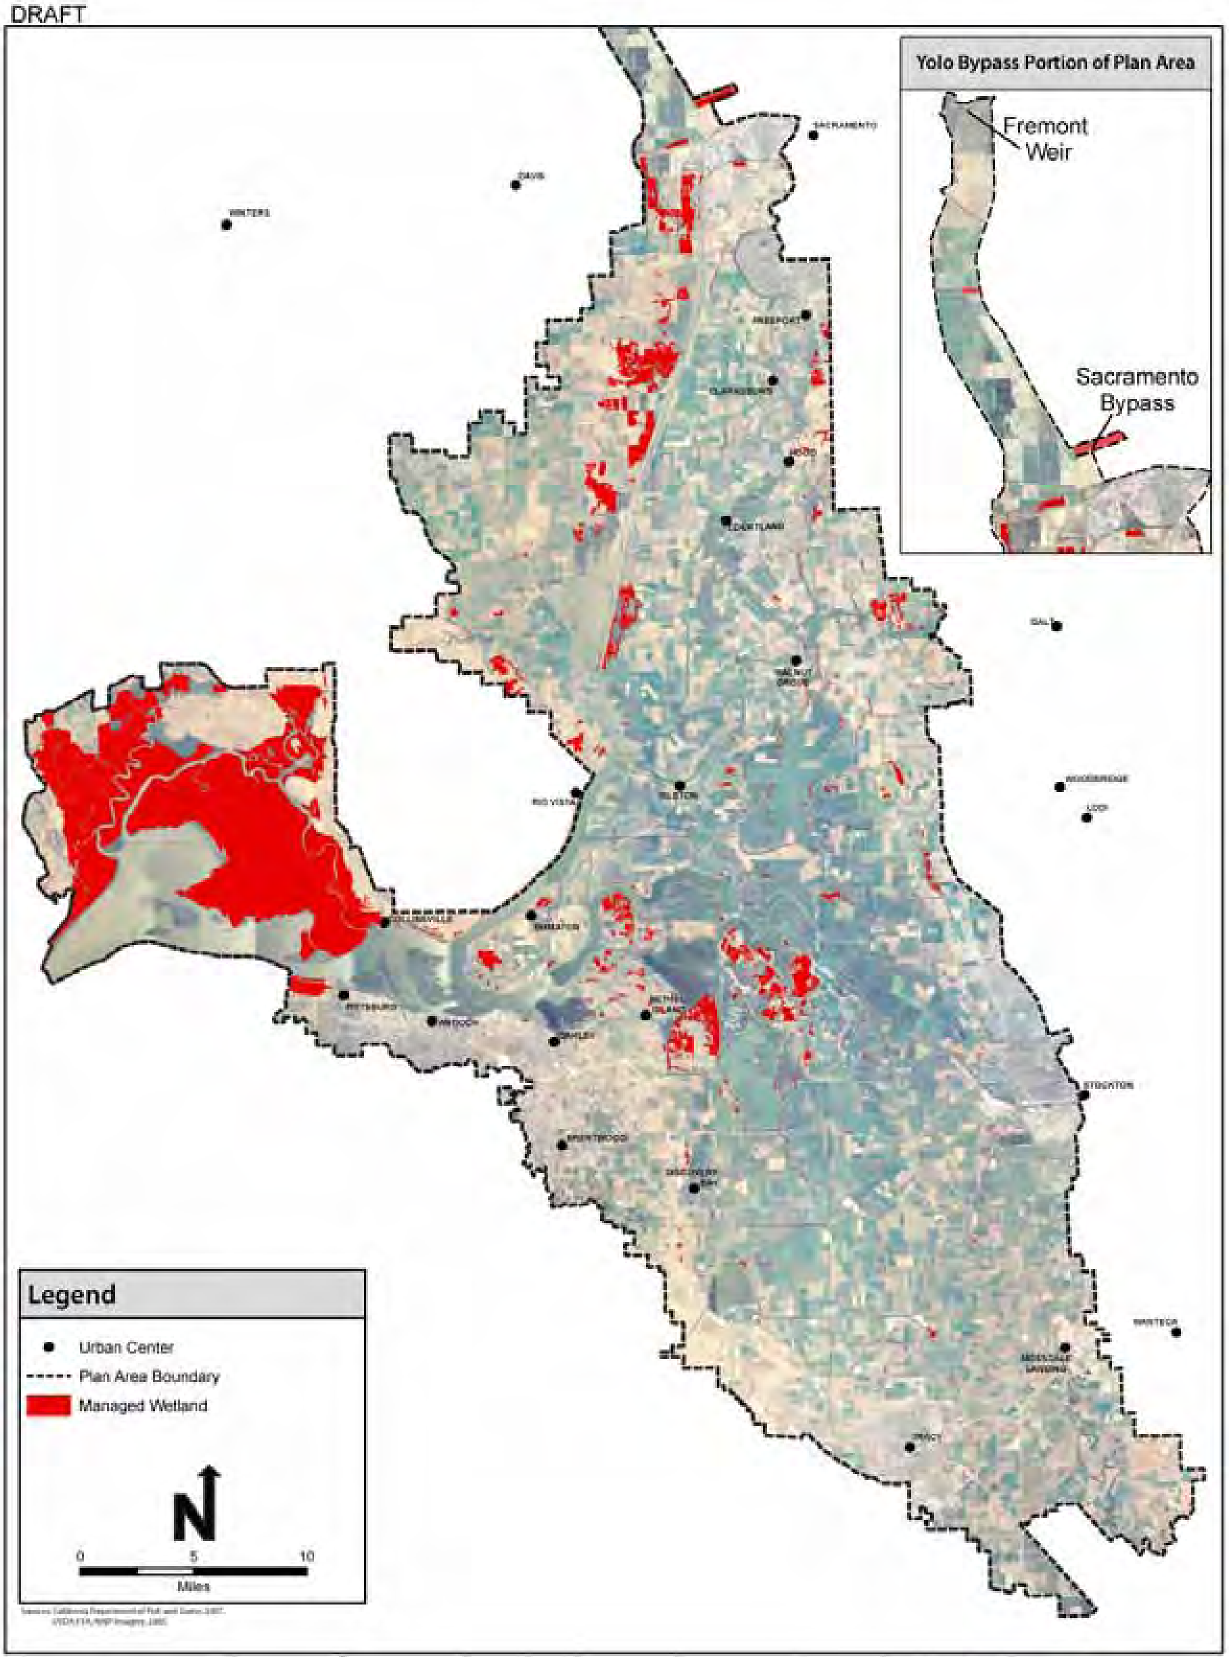

Figure 2-32. Distribution of Managed Wetland Natural Community in the BDCP Plan Area

The typical hydrologic management regime includes flooding during the winter in anticipation of the arrival of migratory birds followed by a slow drawdown of water to manage plant seed production (Fredrickson and Taylor 1982, Naylor 2002) and to control mosquito populations (Kwasny et al. 2004). Summer irrigation may also be conducted (USFWS 2007). The management of Suisun Marsh is unique as water salinity is a significant management issue, and water use is tightly regulated (Suisun Ecological Workgroup 1997, Suisun Ecological Workgroup 2001, Brown 2004).

2.3.4.10.1 Vegetation

The managed wetland natural community is characterized by robust, perennial emergent vegetation and annual-dominated moist-soil grasses and forbs in freshwater areas (Fredrickson and Taylor 1982, Naylor 2002, Hickson and Keeler-Wolf 2007) and often by pickleweed and brass buttons in brackish water areas. The plant associations present and their extent within the managed wetland natural community are shown in Table 2-14. Vegetation that is important to waterfowl includes alkali bulrush, grand redstem, brass buttons, smartweed, barnyard grass, burhead, and swamp timothy (Fredrickson and Taylor 1982, Suisun Ecological Workgroup 1997, Suisun Ecological Workgroup 2001, Naylor 2002, Brown 2004). During periods when water is drained from the habitat, a wide variety of annual grasses and forbs germinate and grow beneath and in the interstitial space around the emergent plants.

[1]Some of the mapping units provided here are newly described associations or alliances. Additionally, for Suisun Marsh SFEI (2005) tidal data were used to determine the nontidal areas and were intersected with the Boul and Keeler-Wolf (2008) vegetation data. For more detailed information concerning these mapping units and plant associations/alliances, as well as on methods of classification used, see Hickson and Keeler-Wolf (2007); TAIC (2008); SAIC 2009 reclassification of Boul and Keeler-Wolf (2008).

[2]Currently known as *Schoenoplectus*.

[3]Extent of this natural community present in the Plan Area for which DFG did not delineate plant alliances. As described in Section 2.3.1, *Data Sources and Natural Community Classification*, these areas were delineated as this natural community type from aerial photography interpretation.

[4]DFG vegetation types were combined to form this mapping unit in order to condense the list.

[5]The genus of pickleweed is now *Sarcocornia* instead of *Salicornia*.

Note: Acreage total accommodates for rounding.

2.3.4.10.2 Fish and Wildlife

Managed wetland is managed specifically to promote use by wildlife, particularly birds, and as a result, a wide variety of waterfowl and other birds migrating along the Pacific Flyway use the habitat when inundated (Fleskes et al. 2005, EDAW 2007, USFWS 2007, Kleinschmidt 2008). Sandhill cranes forage and roost, and many ducks, geese, wading birds, and shorebirds commonly forage and loaf in managed wetland in the Plan Area (USFWS 2007). This natural community includes abundant and diverse plant assemblages and invertebrate populations that provide important food resources for migrating waterfowl, bats, and many other wildlife species that forage in and over these wetlands. During winter flood flow inundation, the managed wetland areas in the Yolo Bypass floodplain can provide spawning and rearing habitat for Sacramento splittail and refuge habitat for other fish species (Feyrer et al. 2006, Sommer et al. 2007). In Suisun Marsh, managed wetland provides habitat for waterfowl, rails, Suisun song sparrow, and salt marsh harvest mouse (Suisun Ecological Workgroup 1997, Suisun Ecological Workgroup 2001, Brown 2004).

Covered wildlife species that are associated with the managed wetland natural community within the Plan Area include salt marsh harvest mouse, greater sandhill crane, Swainson’s hawk, and giant garter snake (Table 2-4).

2.3.4.10.3 Nonnative Species

Managed wetland is subjected to the same invasive nonnative plant taxa as tidal brackish emergent wetland and tidal freshwater emergent wetland natural communities; however, because management operations include discing and the manipulation of flooding duration, there are more control opportunities. Perennial pepperweed (*Lepidium latifolium*) is one of the most serious threats to this community. It is difficult to control and may be spread through discing (Brown 2004, Vaghti and Keeler-Wolf 2004, EDAW 2007, ESA 2007, Boul and Keeler-Wolf 2008). Other large stature invasive plant species that are problematic include pampas grass (*Cortaderia selloana*), giant reed (*Arundo donax*), and the nonnative genotype of common reed (*Phragmites australis*) (Vaghti and Keeler-Wolf 2004, Boul and Keeler-Wolf 2008). Managed wetland supports nonnative animals, including red fox (*Vulpes vulpes*), feral cats (*Felis domesticus*), and rats (*Rattus* spp.) (Brown 2004, Takekawa et al. 2006), that are predators of native wildlife and have been shown to significantly reduce populations of BDCP covered species including salt marsh harvest mouse, California black rail, and California clapper rail (Suisun Ecological Workgroup 2001, Brown 2004).

2.3.4.10.4 Ecosystem Functions

As a surrogate for natural marshes, managed wetland is managed to support highly productive seasonal wetlands interspersed with permanent wetlands to sustain large populations of waterfowl and shorebirds through the production of seed and invertebrates (Brown 2004, EDAW 2007). The structure of the community is managed to provide nesting and resting or loafing areas. The nutrients and primary productivity are often transferred to adjacent natural wetlands through water management activities (Brown 2004) and by the daily and seasonal movements of waterfowl and shorebirds.

2.3.4.10.5 Environmental Gradients

Because they are often confined behind levees, environmental gradients in managed wetland are generally controlled through management actions. Discing and soil contouring provide a variety of ponding depths and widths of shallow water habitat (Brown 2004, EDAW 2007). Flooding timing, duration, and water quality controls species composition, primary productivity, water temperature, salinity, and the timing of exports of primary productivity.

2.3.4.10.6 Future Conditions with Climate Change

The managed wetland community is particularly sensitive to increased variability in precipitation associated with global climate change (Nicholls et al. 1999). Reduced and more variable water flows through the Central Valley are likely to reduce the amount of water available for management actions that require the flooding of the managed wetland community at precise times of the season to provide habitat and food for waterfowl. Additionally, sea level rise is expected to be especially significant in the Delta, where much of the land has subsided to below sea level and is currently protected from flooding by levees. The current subsided island condition, combined with higher sea level, increased winter river flooding, and more intense winter storms, will significantly increase the hydraulic forces on the levees. With sea level rise exacerbating current conditions, a powerful earthquake in the region could collapse levees, leading to major seawater intrusion and flooding throughout the Delta if flows were sufficiently low, altering the tidal prism, and causing substantial changes to the community (Mount and Twiss 2005). Areas within the levees that are currently covered by the managed wetland community would be lost.

2.3.4.11 Other Natural Seasonal Wetland

The other natural seasonal wetland natural community encompasses all the remaining natural (not managed) seasonal wetland communities that are not the vernal pool complex and alkali seasonal wetland complex natural communities (Figure 2-33). The vegetation types included in the other natural seasonal wetland natural community, as mapped by DFG (Hickson and Keeler-Wolf 2007), include seasonally ponded, flooded, or saturated soils dominated by grasses, sedges (*Carex* spp.), or rushes (*Juncus* spp.), and DFG-mapped vernal pools that were not included in the vernal pool complex natural community because they do not support characteristic vernal pool hydrology or vegetation (Table 2-15) (see Section 2.3.1.5, *Vernal Pool Complex Dataset Development*). A review of the aerial photography (Google Inc. 2009) indicated that approximately half of the other natural seasonal wetland natural community consists of seasonally ponding areas in agricultural fields, and the other half consists of a temporarily flooded perennial forbs vegetation type that is exclusively found in a field near the Cosumnes River that has been the subject of restoration efforts through a levee breach and the creation of two ponds (Trowbridge 2005, Trowbridge et al. 2005) (Figure 2-33).

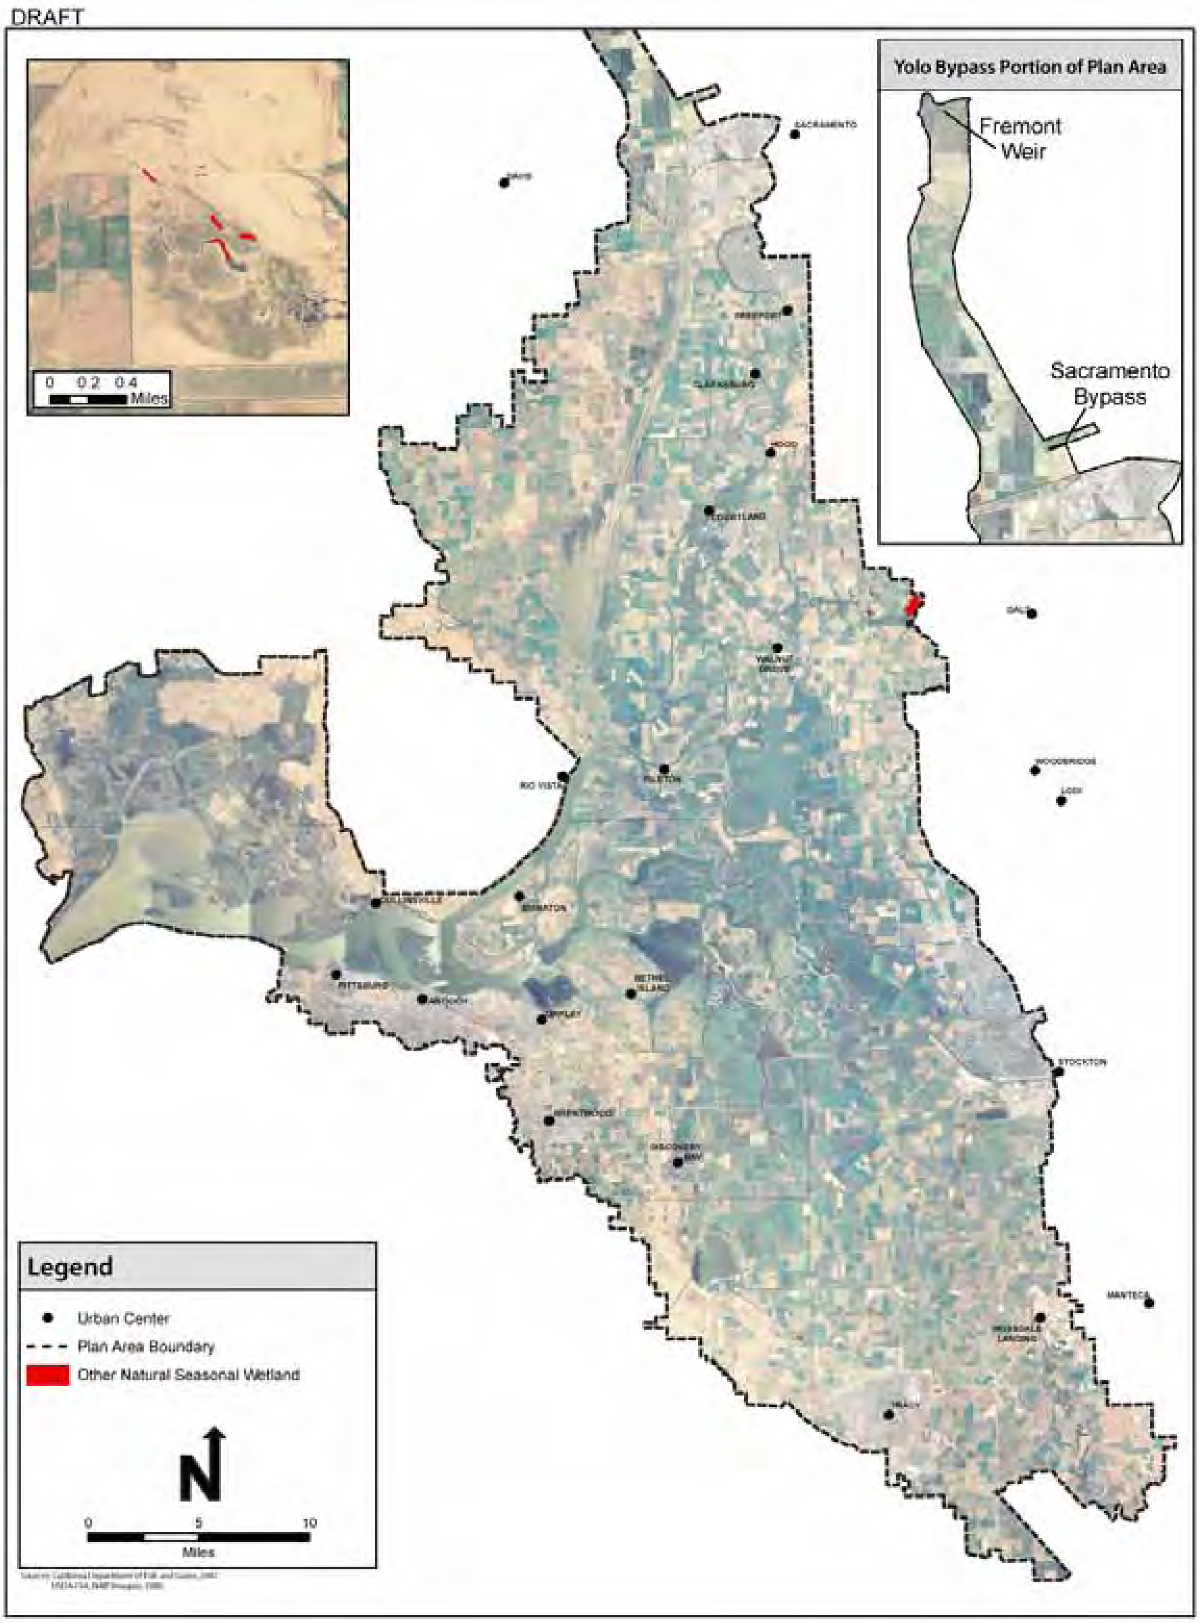

Figure 2-33. Distribution of Other Natural Seasonal Wetland Natural Community in the BDCP Plan Area

Table 2-15. Plant Alliances within the Other Natural Seasonal Wetland Natural Community

Mapping Unit[1]	*Plant Alliance (Sawyer and Keeler-Wolf 1995)*	*Acreage in Plan Area*
Carex barbarae Alliance	Santa Barbara Sedge (*Carex barbarae*) Stands	15
Seasonally flooded temperate or subpolar grassland	Seasonally Flooded Grasslands	36
Juncus bufonius non-classified stands	*Juncus bufonius* (salt grasses)	6
Vernal Pool stands[1]	Vernal Pools	9
-	Degraded Vernal Pool Complex	13
Temporarily Flooded Perennial Forbs	-	185
Total		**264**

[1]Vernal pool stands identified here were mapped by DFG (Hickson and Keeler-Wolf 2007) for the Delta vegetation layer, however, a separate vernal pool complex natural community mapping was conducted by SAIC that overlaid and expanded on DFG's more coarse-level vernal pool mapping. See Section 2.3.1.5 *Vernal Pool Complex Dataset Development.*

2.3.4.11.1 Vegetation

Vegetation found in the other natural seasonal wetland natural community consists of a mixture of exotic and native perennial forbs, grasses, sedges, and rushes tolerant of temporary flooding, ponding, or soil saturation during winter and spring months.

2.3.4.11.2 Fish and Wildlife

The other natural seasonal wetland natural community supports common invertebrates that are the main source of food for waterfowl and shorebirds (Silveira 1998) which also use the wetlands in their dry state as resting and seed foraging areas (USFWS 2007, Kleinschmidt Associates 2008).

2.3.4.11.3 Nonnative Species

Problematic invasive nonnative plant species in the other natural seasonal wetland natural community include low mannagrass, Italian ryegrass, and perennial pepperweed (Hogle et al. 2006, Dawson et al. 2007, Gerlach et al. 2009).

2.3.4.11.4 Ecosystem Functions

When flooded, this natural community supports an aquatic food web that is functionally similar to undisturbed vernal pools (Alexander 1976, Barclay and Knight 1981, Scheffer 2004, Williams 2006). As the water recedes, its ecosystem characteristics change from a fully aquatic system to a terrestrial ecosystem (Williams 2006), and its food web linkages break down as the community becomes more integrated with the terrestrial landscape in which it is embedded.

2.3.4.11.5 Environmental Gradients

The dominant environmental gradient in the other natural seasonal wetland community is driven by the different chemical and physical attributes of water versus air. Water is a polar solvent that is important in many chemical exchanges, and those exchanges control pH and the oxidation state of many chemicals and compounds. It also has a high heat capacity so temperature changes are buffered; and it is extremely viscous compared to air, so exchanges between the air and water as well as movement within the water are very slow (Scheffer 2004, Williams 2006). The ecological gradient between seasonal wetlands and surrounding terrestrial communities is marked by transitions in plant and wildlife species and is most pronounced during the wetted phase.

2.3.4.11.6 Future Conditions with Climate Change

Ongoing and future climate change (see Section 2.3.3.2, *Climate*) is expected to alter the other natural seasonal wetland natural community. The primary impact of climate change is predicted to be driven by changes in the hydrological regime due to increased variability in precipitation. The species present in this community are adapted to existing hydrological conditions, therefore increased variability of precipitation would likely lead to a shorter and more variable wet season or similar changes in the inundation period. It is not known how the increased variability in seasonal hydrology would affect the plants and animals inhabiting this community; however, because these species are adapted to current conditions, the impacts will likely result in changes to species composition. Additionally, rising average temperatures could result in increased evapotranspiration rates and therefore shorter wetted periods for this community; the impacts of which are expected to be adverse to native plants and wildlife.

2.3.4.12 Grassland

The grassland natural community encompasses a management spectrum ranging from natural to intensively managed vegetation dominated by grasses. At the more natural end of the spectrum, it is comprised of upland vegetation associations dominated by introduced or native annual and perennial grasses and forbs (non-grass herbaceous species) (D'Antonio et al. 2007, Keeler-Wolf et al. 2007). At the intensively managed end of the spectrum, it includes non-irrigated pasturelands (CALFED 2000). The grassland natural community is often found adjacent to wetland and riparian habitats and is the dominant community on managed levees in the Plan Area (Hickson and Keeler-Wolf 2007). The distribution of the grassland natural community in the Plan Area is shown in Figure 2-34.

The extent of this community in its natural landscape position around the periphery of the Plan Area has declined over the past century due to land conversion to intensive agriculture and losses to urban development (CALFED 2000, SFEI 2010). Anthropogenic changes to the natural disturbance regimes (e.g., dry-land grain farming, grazing, and diseases) since European settlement have also eliminated many native plant communities (D'Antonio et al. 2007, SFEI 2010). Depending upon how intensively and how long a natural variant of the grassland natural community has been impacted, its suite of native species may have largely been replaced by nonnative species (D'Antonio et al. 2007) and is often dominated by near monocultures of nonnative annual grasses and forbs (D'Antonio et al. 2007, USFWS 2007). In the historical tidal areas of the Delta, grassland has expanded on the dry land created on and behind levees.

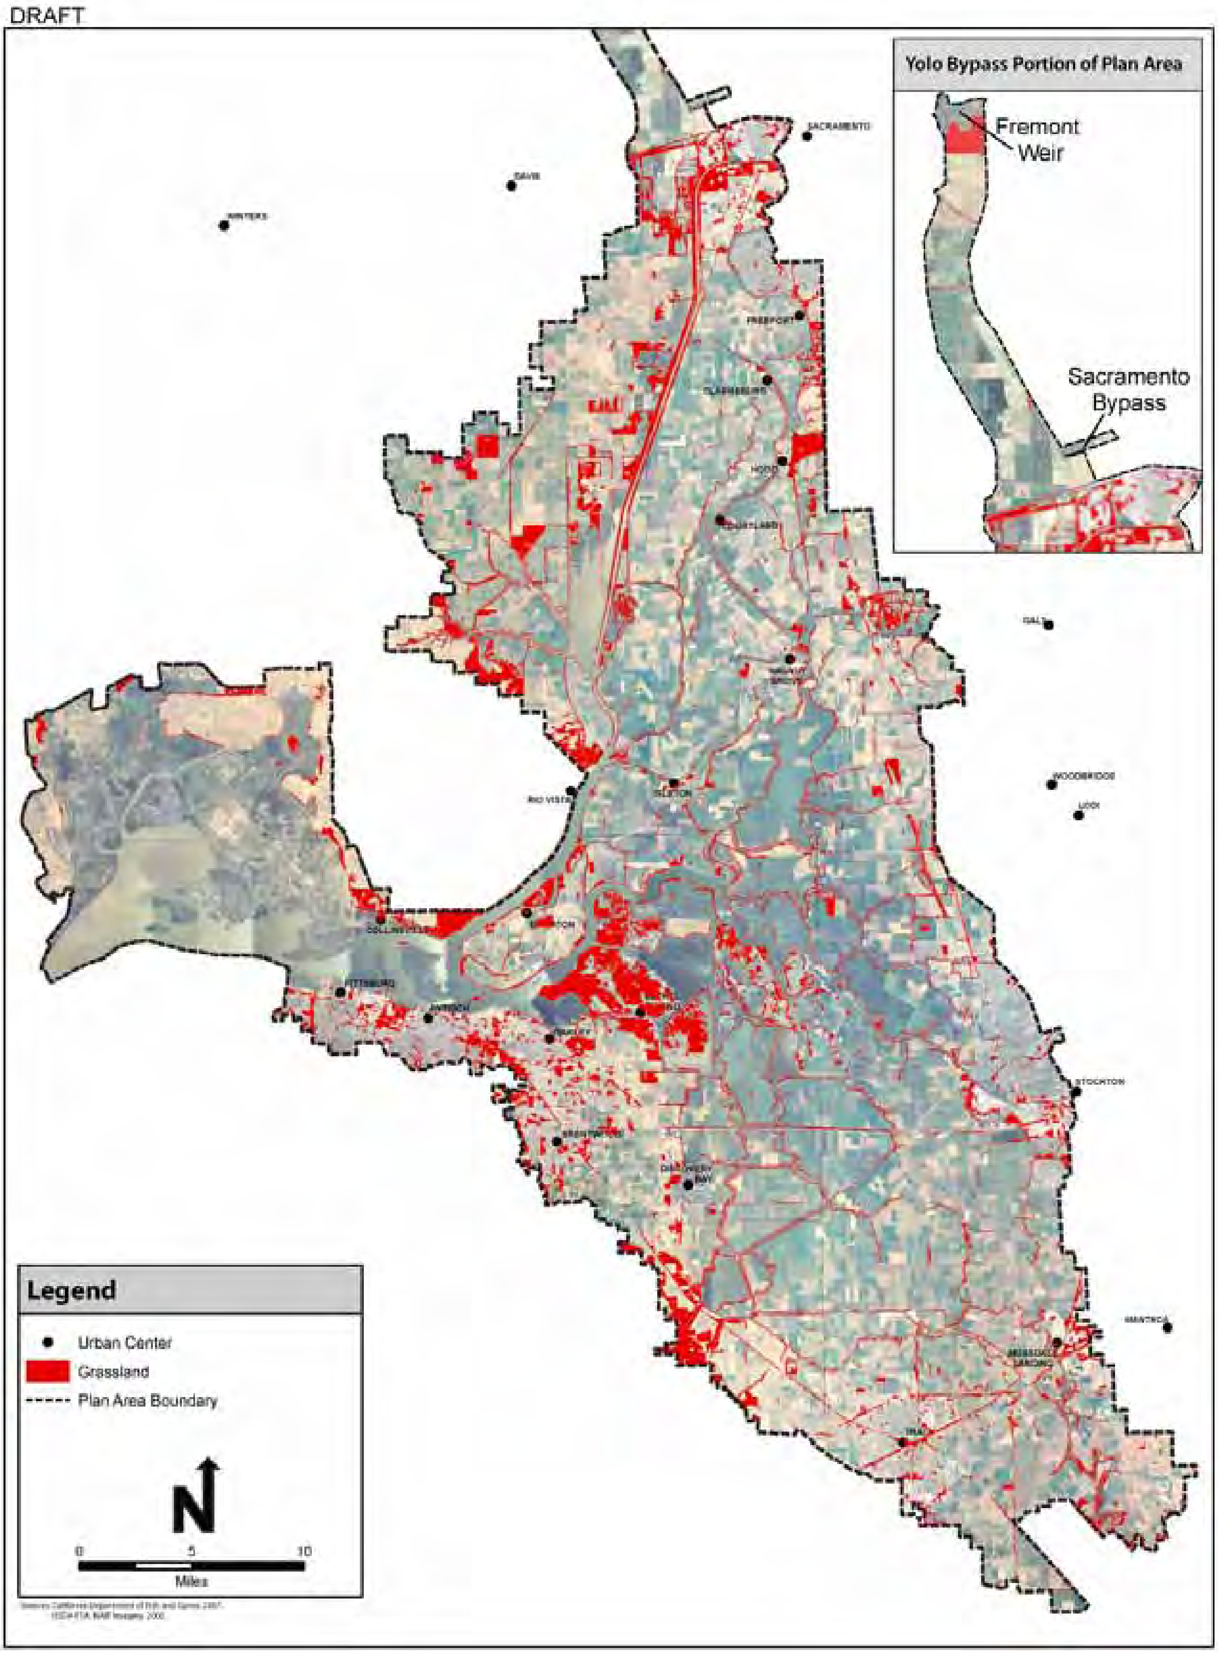

Figure 2-34. Distribution of Grassland Natural Community in the BDCP Plan Area

Vegetation types dominated by native grasses in the Plan Area were historically limited to a narrow border of either alkaline or freshwater meadows on clay rich soils in the uplands, adjacent to either marshes or alkaline sink scrub and dominated by saltgrass (*Distichlis spicata*). In higher topographic positions on coarser textured soils, there was a unique community with a significant component of native perennial and annual grasses (*Distichlis*, *Elymus*, *Melica*, *Nassella*, *Poa,* and *Vulpia*), geophytes (*Calochortus*, *Chlorogalum*, *Dichelostemma*, and *Triteleia*), and a phenological succession of many species of early spring-, spring-, and summer-flowering annual dicots (Bryan 1923, Thomasson Jr. et al. 1960, Collins and Grossinger 2004, Grossinger 2004, Grossinger et al. 2008, SFEI 2010).

In the southwestern portion of the Plan Area, from the Clifton Court Forebay to Oakley, there was a narrow band of alkali meadow dominated by saltgrass which was sandwiched between tidal marshes and alkaline sink scrub on one side and oak savanna on the other (Carpenter and Cosby 1939, SFEI 2010). Similar conditions occurred around the Montezuma Hills (Collins and Grossinger 2004). Using the historical conditions of the south San Francisco Bay, old charts, and current floras to reconstruct the vegetation, along the borders of Suisun Marsh and the Cache Slough area there were alkali meadows dominated by saltgrass located between the marshes with the unique seasonal community in higher topographic positions (Collins and Grossinger 2004, Grossinger 2004).

Along the west side of the Yolo Basin from the Cache Slough area to the current sinks of Putah Creek, there was a unique landform called the Putah Plain that consisted of numerous small floodwater distributaries of Putah Creek (Bryan 1923, Thomasson Jr. et al. 1960, Graymer et al. 2002, Witham 2003, Grossinger et al. 2008, Gerlach 2009). The distributaries were aligned perpendicular to the Yolo Basin as a continuous parallel repeating geomorphic series of shallow basin, low natural levee, channel, low natural levee, shallow basin features. These hydrological features disappear at lower elevations in the Yolo Basin because they were periodically eroded away by large Sacramento River flood events into the Yolo Basin. The channels were, and where they are still intact, are dominated by vernal pool species characteristic of non-alkaline, short inundation period, clay-bottom, swale/pool complexes. Good examples are the relatively undisturbed channels at the DFG Tule Ranch. The basins in topographically higher positions than the channels were likely highly alkaline areas that resulted from the accumulation of salts transported by floodwaters from west of the Yolo Basin. These basins are dominated by saltgrass, tarweeds, tarplants, and seepweed at higher elevation edges and by typical clay-bottom vernal pools species and salt pans species at their bottoms. These bottoms are the local habitat of Solano grass and Colusa grass; a good example is found at the Yolo County Grasslands Regional Park (Witham 2003, ESA 2005, Gerlach 2009).

Along the east side of the Plan Area in the vicinity of Stone Lakes NWR there are areas of the unique seasonal community interspersed with partially filled former tidal drainages of the Cosumnes Basin that grade upslope into claypan vernal pool/swale complex as reflected in the current flora and aerial imagery (USFWS 2007, Google Earth 2010). These communities abut tidal and reclaimed former tidal marshes and are periodically cut by small creeks and tidal channels running down to the Cosumnes Basin.

Direct and indirect anthropogenic influences on the landscape of the Plan Area have resulted in the reduction, conversion, and fragmentation of the meadows and unique seasonal communities. These changes have led to diminished ecological conditions necessary for sustaining well-functioning grassland natural community. In the Plan Area, the grassland natural community currently comprises one of the most common natural communities, but a large portion of this grassland is in areas that were historically tidal marsh and the vegetation is dominated by invasive nonnative grasses. While many native plant species have been reduced in abundance or distribution through these processes, they persist and coexist with nonnative plant species where the meadows and unique seasonal community once existed. Some animal species have also adjusted well to the new type of grassland community. Thus, the current grassland natural community still offers valuable habitats to many grassland-dependent species.

2.3.4.12.1 Vegetation

The plant associations present and their extent within the grassland natural community are shown in Table 2-16. Common nonnative annual grass species in this natural community include Italian ryegrass, soft chess, ripgut brome, red brome, wild barley, wild oats, and foxtail fescue. Native perennial grasses are generally found only in areas that have not been plowed and include creeping wildrye, blue wildrye, saltgrass, California melic, California brome, meadow barley, tuffed hairgrass, one-sided bluegrass, and purple needlegrass (Witham 2003, 2006, Keeler-Wolf 2007, USFWS 2007). If unplowed, the grassland natural community can be rich in species in the lily family that may include Ithuriel's spear, white hyacinth, harvest brodiaea, gold nugget, paper onion, blue dicks, common muilla, and narrow-leaved soap plant. In some parts of the Plan Area, the grassland natural community is interspersed with the vernal pool complex, alkali seasonal wetland complex, and other natural seasonal wetland natural community types (Witham 2003, 2006, Baraona et al. 2007). The Manual of California Vegetation (Sawyer et al. 2009) recognizes the broad spectrum of grassland types and includes vegetation types that are completely dominated by nonnative annual grasses to grasslands that are dominated by perennial native grasses. Plant species that can sometimes be found within grassland that contains patches of other natural communities covered by the BDCP include alkali milk-vetch, Heckard's pepper-grass, and San Joaquin spearscale (Table 2-4).

Table 2-16. Plant Alliances within the Grassland Natural Community in the Plan Area

Mapping Unit[1]	*Plant Alliance (Sawyer and Keeler-Wolf 1995)*	*Acreage*

Total		**62,880**

[1]Because of the fine scale mapping of many slightly different vegetation units in the Delta, Yolo Bypass, and Suisun Marsh plant alliances dominated by the same groups of species, nonnative annual grasses for example, were combined into a composit mapping unit. For more detailed information concerning the original mapping units and plant associations/alliances, as well as on methods of classification used, see Hickson and Keeler-Wolf (2007), Boul and Keeler-Wolf (2008), and TAIC 2008. The degraded vernal pool mapping unit was generated from existing vegetation types using the methods described in Section 2.3.1.5, *Vernal Pool Dataset Development*.
[2]Now known as *Sarcocornia*.
[3]Now known as *Schoenoplectus*.
[4]Extent of this natural community present in the Plan Area for which DFG did not delineate plant alliances. As described in Section 2.3.1, *Data Sources and Natural Community Classification*, these areas were delineated as this natural community type from aerial photography interpretation.
Note: Acrege total accommodates for rounding.

2.3.4.12.2 Wildlife

The grassland natural community provides important breeding and foraging habitat for many species of wildlife. Common mammals found in grasslands include mule deer, California ground squirrel, California vole, pocket gopher, desert cottontail, black-tailed jackrabbit, coyote, and badger. Grasslands are important to raptors and nesting waterfowl (CALFED 2000). Raptors for which grasslands provide important foraging habitat include Swainson’s hawk, white-tailed kite, red-tailed hawk, northern harrier, golden eagle, American kestrel, burrowing owl, great horned owl, and barn owl. Common songbirds that use the grasslands include loggerhead shrike, horned lark, water pipit, western bluebird, savannah sparrow, and western kingbird. Common reptiles and amphibians in the grasslands include gopher snake, common garter snake, California king snake, western fence lizard, Pacific tree frog, and western toad.

Grasslands provide habitat for many BDCP covered wildlife species, including California tiger salamander, California red-legged frog, Swainson's hawk, greater sandhill crane, and San Joaquin kit fox (Table 2-4).

2.3.4.12.3 Nonnative Species

California's grasslands have been invaded by a large number of exotic plant species which were primarily introduced and spread through farming and ranching agricultural practices (D'Antonio et al. 2007). A large number of exotic annual grass species dominate non-irrigated grasslands (D'Antonio et al. 2007, Keeler-Wolf et al. 2007) with annual ryegrass, medusahead (*Taeniatherum caput-medusae*) and barbed goatgrass (*Aegilops triuncialis*) being the most problematic in the Plan Area (Swiecki and Bernhardt 2002, Witham 2003, ESA 2005, USFWS 2007, Hopkinson et al. 2008). Dicot species that are especially problematic include Italian thistle (*Carduus pycnocephalus*), purple starthistle (*Centaurea calcitrapa*), yellow starthistle (*Centaurea solstitialis*), and perennial pepperweed (*Lepidium latifolium*) (Swiecki and Bernhardt 2002, Witham 2003, ESA 2005, Witham 2006, USFWS 2007, Hopkinson et al. 2008). Much of the grassland natural community in the Plan Area is classified as "ruderal" vegetation because it is dominated by nonnative opportunistic plants on disturbed soils such as levees and old tilled fields.

Problematic vertebrate exotic species that adversely affect wildlife in the grassland natural community include feral dogs (*Canis lupus familiaris*) and feral cats (*Felis silvestris*) (USFWS 2007).

2.3.4.12.4 Ecosystem Functions

The grassland natural community in the Plan Area is primarily managed for its function as a source of primary productivity to feed domestic grazing animals (Jackson and Bartolome 2007) and for its small herbivore productivity to sustain birds of prey such as Swainson's hawk. Burrows excavated by small rodents provide terrestrial habitat for California tiger salamander and nesting habitat for California burrowing owl (Witham 2006, EDAW 2007, USFWS 2007). Other ecosystem functions include effects on carbon sequestration and on the water and nutrient cycles by the grassland natural community (Eviner and Firestone 2007, Jackson, Potthoff et al. 2007, Reever-Morghan et al. 2007).

2.3.4.12.5 Environmental Gradients

Because of its extensive distribution in California, the grassland natural community often serves as the matrix in which other natural communities are embedded. In the Plan Area, it is generally located in higher topographic positions with steep environmental gradients to lower and wetter communities such as the alkali seasonal wetland complex and valley/foothill riparian natural community. A less obvious gradient exists between subsurface environments such as rodent burrows which maintain high humidity for California tiger salamander during the hot dry season (Storer 1925, Loredo and Van Vuren 1996, Petranka 1998, Trenham 1998).

2.3.4.12.6 Future Conditions with Climate Change

Ongoing and future climate change (see Section 2.3.3.2, *Climate*) may negatively impact the grassland natural community; although, there is no consensus on what the impacts will be (Dukes and Shaw 2007, Jackson et al. 2009). Because this community is generally located at elevations that will not be directly impacted by rising sea level, the primary impact of climate change is predicted to be driven by the increased variability in precipitation. The species present in this community are adapted to the existing precipitation regime, and an increase in the variability of precipitation is likely to lead to a shorter and more variable wet season. It is uncertain how the community or its individual species may respond to this increased variability (Dukes and Shaw 2007).

2.3.4.13 Inland Dune Scrub

Inland dune scrub is a dense to open shrub and sub-shrub dominated community of remnant dune soils with a unique mix of rare, endemic species of plants and insects. Inland dune scrub occurs only on the disturbed remnants of the former dune that existed along the southern shore of the San Joaquin River, immediately east of the city of Antioch (Figure 2-35). The 190-acre dune paralleled the shore for 2 miles, and was 0.15 mile wide and 120 ft tall (Howard and Arnold 1980, SFEI 2010). Beginning in 1865, the sand of the dune was mined to manufacture pottery, and in the late 1880s the sand was mined to manufacture bricks. The rate of sand mining greatly accelerated after the 1906 San Francisco earthquake for the manufacturing of bricks to rebuild the city. In the 1920s, mining increased again for the manufacture of asphalt and concrete. Sand mining then continued at a declining rate until World War II when it increased again.

After World War II, extensive commercial development spread across the area where the dune had been mined away, and sand mining continued eastward. The mining continued on the last two parcels of the dune even as USFWS was negotiating to establish the 55-acre Antioch Dunes National Wildlife Refuge (NWR). By the time the purchase was complete, the highest elevations of the remains of the dune were only 50 feet above mean higher high water (MHHW) of the San Joaquin River, with a slightly more dune-like area on an adjacent 12-acre Pacific Gas and Electric (PG&E) transmission line corridor 80 feet above MHHW (Howard and Arnold 1980, USFWS 1984, 2001, SFEI 2010). When measured from the landward side, the highest point on the Antioch Dunes NWR is 30 ft; the PG&E elevation is 60 ft.

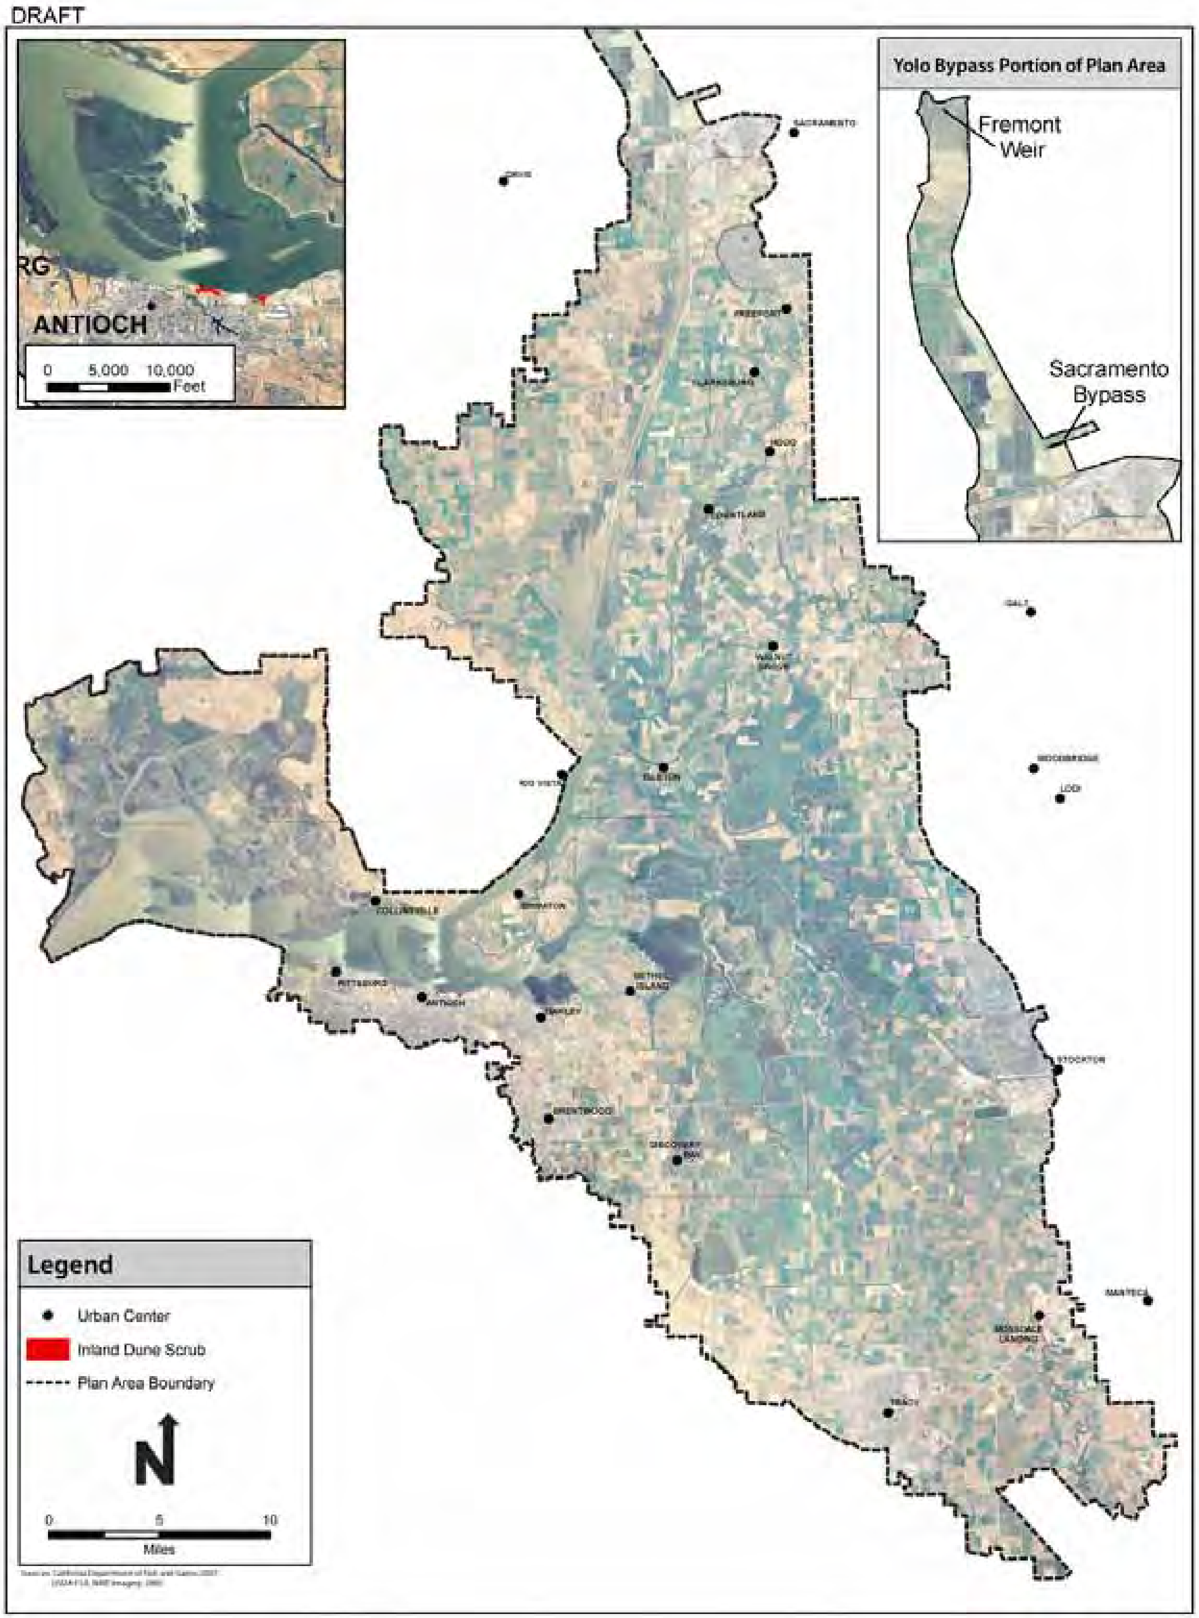

Figure 2-35. Distribution of Inland Dune Scrub Natural Community in the BDCP Plan Area

A description of the combined area of the Antioch Dunes NWR and PG&E properties with dune-like characteristics at the time of acquisition stated that “only an extremely small percentage of the area is in the configuration of a dune” (USFWS 1984). Management actions to increase the dune-like characteristics of Antioch Dunes NWR have included creating small dunes with 7,000 cubic yards of dredged sand material that had been stockpiled on the PG&E property (which proved unsuitable due to its clay content), and bulldozing the residual sand on the Antioch Dunes NWR into the shape of small dunes (USFWS 1984, 2001).

The geological origin of the dune has not been determined; however, regardless of its original source, the sand was sorted from a mixture of fine- and coarse-textured material and redeposited by wind (not water), as indicated by its extremely low clay content (soil survey), and it appears to have had a deep, older layer as well as a more recent layer (USFWS 2001). It has been speculated that the sand was brought to the location by the San Joaquin River approximately 140,000 years ago, and that the most recent dune probably established prior to the post-ice age sea level rise approximately 15,000 years ago (USFWS 1984, 2001).

Most accounts incorrectly describe the sand as the result of glaciation even though glaciated material would consist of very fine clay and silt like particles (glacial milk). Instead, the sand probably originated during warm humid periods as the granitic rock of the southern Sierra Nevada was chemically transformed into grus and then transported to the San Joaquin Valley during enormous slope failures (Wahrhaftig 1965, Twidale and Vidal Romaní 2005, Graham et al. 2010). While the dune was a unique formation, the sand is distributed southwestward from the dune in a 5.5 mile by 2 mile oblong patch (Carpenter and Cosby 1939, SFEI 2010).

In the 1933 soil survey of the area, the sand was classified as the Oakley sand soil series, and it was determined to be infertile, slightly acidic, and consisting of 2 percent coarse sand, 65 percent fine sand and 1 percent clay (Carpenter and Cosby 1939). In contrast, the much more heterogeneous riverine deposit of Piper fine sandy loam on the low islands of the nearby Delta is slightly alkaline and consists of 12 percent coarse sand, 45 percent fine sand, and 4 percent clay.

2.3.4.13.1 Vegetation

The plant associations present and their extent within the inland dune scrub natural community are shown in Table 2-17. Inland dune scrub is more similar to the vegetation of sandy soils in the San Joaquin Valley and Mohave Desert than to coastal scrub communities (Howard and Arnold 1980). Unfortunately, the pre-disturbance species composition of the vegetation was never well described before the sand mining and extensive oak cutting in the early 1900s and post-World War II (USFWS 2001). Based on early charts and a postcard dating from the early 1900s, the vegetation contained widely scattered large valley oaks, live oaks, various shrub species, and numerous herbaceous species (Howard and Arnold 1980, SFEI 2010). Very similar vegetation occurred 1.5 miles southeast of the dune as a 3-mile by 1.5-mile, 3,000-acre oblong patch on the Oakley sand soil southwest of Oakley (SFEI 2010). That area of chaparral/scrub was described as nearly impenetrable, but was cleared for grain production, later planted as almond orchards, and now is almost entirely developed (SFEI 2010).

Antioch Dunes NWR vegetation surveys conducted by Susan Bainbridge of the UC Berkeley Jepson Herbarium and the California Native Plant Society (CNPS) were used by DFG (Hickson and Keeler-Wolf 2007) to map two Antioch Dunes unique vegetation types that have one or more shrubs in the overstory which may have very sparse cover. The data were not formally analyzed by the DFG Delta mapping project, and the BDCP inland dune scrub community is defined by the presence of either of the two vegetation types. One vegetation type consists of a broadleaf shrubland that was classified as the *Lupinus albifrons* Antioch Dunes alliance (5 acres), and the other is a dwarf shrub vegetation type classified as the *Lotus scoparius* Antioch Dunes alliance (15 acres). Given that *L. albifrons* is primarily a coastal species, while the vegetation of the dune is primarily the northern-most expression of desert vegetation, it is more likely the species is the *L. excubitus*, an interior and desert species that is indistinguishable from *L. albifrons* (Rosatti ed. 2010). Other plant species present include ripgut brome (*Bromus diandrus*), yellow starthistle (*Centaurea solstitialis*), elegant clarkia (*Clarkia unguiculata*), naked stem buckwheat (*Eriogonum nudum* var. *auriculatum*), Contra Costa wallflower (*Erysimum capitatum* var. *angustatum*), California poppy (*Eschscholzia calfornica*), California croton (*Croton californicus*), Grindelia (*Grindelia* spp.), California matchweed (*Gutierrezia californica*), telegraph weed (*Heterotheca grandiflora*), Antioch Dunes evening-primrose (*Oenothera deltoides* ssp. *howellii*), vetch (*Vicia* spp.), and Russian thistle (*Salsola tragus*) (USFWS 2001). Contra Costa wallflower and Antioch Dunes evening-primrose are rare, endemic dune species and are BDCP covered species.

2.3.4.13.2 Wildlife

Recent observations of wildlife on the Antioch Dunes NWR include coyote *(Canis latrans)*, long-tailed weasel *(Mustela frenata)*, muskrat *(Ondatra zibethica)*, raccoon *(Procyon lotor)*, Townsend's mole *(Scapanus townsendi)*, Beechy ground squirrel *(Otospermophilus beecheyi)*, black-tailed jackrabbit *(Sylvilagus bachmani)*, Botta's pocket gopher *(Thomomys bottae)*, gray fox *(Urocyon cinereoargenteus)*, red fox *(Vulpes vulpes)*, racers *(Coluber constrictor)*, gopher snake *(Pituophis melanoleucus)*, western fence lizard (*Sceloporus occidentalis*), and common side-blotched lizard (*Uta stansburiana*). Numerous bird species have been observed on the Antioch Dunes NWR (migratory and resident), and gadwalls *(Anas strepera)* and mallards *(A. platyrhynchos)* have nested there. Historically, the dunes represented the northernmost occurrences for reptiles adapted to arid conditions, including the California legless lizard (*Anniella pulchra*), glossy snake (*Arizona elegans*), San Joaquin whipsnake (*Masticophis flagellum ruddocki*), and side-blotched lizard (*Uta stansburiana*) (Howard and Arnold 1980, USFWS 1984, 2001, 2008).

2.3.4.13.3 Invertebrates

The Antioch Dunes have been known as an entomological hotspot since the 1930s when research entomologists began collecting in what is now the Sardis Unit of the Antioch Dunes NWR (Howard and Arnold 1980, Arnold 1983). The area attracted extensive academic attention for its large and colorful species with desert affinities. In the 1930s, many species of wasps and flies, particularly the giant flower-loving fly (*Thaphiomydas trochilus*), were completely new to the region's collectors. A total of 27 taxa were described from the Antioch Dunes during that decade. Eight of those taxa are endemic to the Antioch Dunes; four are now extinct, three are of uncertain status, and one is the federally and state endangered Lange's metalmark butterfly (*Apodemia mormo langei*). Lange's metalmark is a covered species under the BDCP.

Table 2-17. Plant Associations within the Inland Dune Scrub Natural Community in the Plan Area

Mapping Unit[1]	*Plant Association (Sawyer and Keeler-Wolf 1995)*	*Acreage*
Plan Area		
Lupinus albifrons Antioch Dunes Association	Antioch Dunes Unique Association	15
Lotus scoparius Antioch Dunes Association	Antioch Dunes Unique Association	5
Total		**20**

[1]The mapping units provided here are newly described associations. For more detailed information concerning these mapping units, plant associations, and methods of classification used, see Hickson and Keeler-Wolf (2007).

2.3.4.13.4 Nonnative Species

The primary problematic nonnative plant species in this community are annual grasses such as ripgut brome, vetches, and yellow starthistle (*Centaurea solstitialis*) which form dense patches that crowd native plant species and reduce habitat quality for wildlife and invertebrates (USFWS 2001).

2.3.4.13.5 Ecosystem Functions

The inland dune scrub natural community is found on infertile sandy soil that historically was a large dune. There are only two patches totaling 20 acres of this natural community currently in existence, all of which have been severely degraded by a century of sand mining. Currently, the degraded remnants of the community are being managed exclusively for the three endangered species for which the Antioch Dunes NWR was established to protect.

2.3.4.13.6 Environmental Gradients

Inland dune scrub transitions into the tidal brackish emergent wetland natural community along its border with the San Joaquin River (USFWS 1984, 2001). Its other three sides are bordered by commercial developments.

2.3.4.13.7 Future Conditions with Climate Change

Because this community is generally located at elevations that will not be directly impacted by rising sea level, the primary impact of climate change is predicted to be driven by changes in the hydrological regime due to increased variability in precipitation. The species present in this community are adapted to a highly variable precipitation, and it is uncertain how they will be affected by increased variability.

2.3.4.14 Agricultural Habitats

The majority of lands in the Delta are currently in agricultural use (Figure 2-36). Major Delta region crops and cover types in agricultural production include small grains (such as wheat and barley), field crops (such as corn, sorghum, and safflower), truck crops (such as tomatoes and sugar beets), forage crops (such as hay and alfalfa), pastures, orchards, and vineyards (CALFED

2000, DWR 2007b). Of the total Plan Area, 66 percent is in agricultural use. Of the total acreage of irrigated land in the Delta, which encompasses both seasonally flooded and upland cropland agriculture, corn is currently the predominant cover type (28 percent), followed by alfalfa (21 percent), pasture (12 percent), and tomatoes (8 percent). Orchards cover 4 percent of the total irrigated land acreage in the Delta, and asparagus covers 3 percent (DWR 2007b). The distribution of seasonal crops in the Plan Area varies annually, depending upon crop-rotation patterns and market forces. Vegetable crops are the most abundant crops in the region (Fleskes et al. 2005). Changes in agricultural crops in the Delta over the past 30-40 years have shown dramatic trends, including a six-fold reduction in asparagus acreage (lowering it from the number one crop to the number eight crop in acreage grown), a two-fold increase in corn acreage (making it the number one crop in acreage grown), and an 18-fold increase in vineyards (DWR 2007b). These changes can have substantial effects on the habitat value of agricultural habitats for wildlife, particularly for birds.

2.3.4.14.1 Vegetation

Vegetation in the agricultural habitats community is variable and dynamic in terms of structure, growth, and harvesting patterns. Croplands do not conform to natural habitat successional stages. Instead, cropland is regulated by the artificial crop cycle. Vegetation can be either annual or perennial and can germinate at various times of the year. The largest proportion of the Plan Area landscape includes annually cultivated irrigated croplands that are seasonally or annually rotated to conserve soil nutrients and maintain soil productivity. This portion of the landscape, which includes most field, truck, and grain crops, changes seasonally as crops grow, are harvested, and with the rotational sequence of different crop types. These changes influence the value and use of cultivated habitats to covered wildlife species on a seasonal basis. Other cover types, such as orchards, vineyards, rice, and irrigated pasture remain uncultivated for many years and are considered perennial crop types because they do not seasonally or annually rotate to other crop or cover types. Still other crops, particularly alfalfa and other hay crops, while regularly harvested, may remain uncultivated for multiple years, but eventually are rotated to other uses and are thus referred to as semi-perennial crop types.

While planting timeframes are variable, most annually cultivated croplands are planted in spring and harvested in late summer or early fall. Much of the Plan Area remains unplanted and bedded during the winter season, although a second crop may be planted during the same growing season in some areas. Cropland vegetation is grown as a monoculture, using tillage or herbicides to eliminate unwanted vegetation.

However, interspersed within the agricultural landscape are small patches or linear corridors of natural vegetation and other natural features, such as riparian woodland and scrub, wetlands, ponds, hedgerows, tree rows, and small patches of isolated native or nonnative trees. Agricultural habitats in the Plan Area are not known to support any covered plant species (Table 2-4). Soil often dictates the type of crops grown in the Plan Area. Corn, for instance, requires better soil than barley, which can grow in poor quality soil; and rice does well in clay soil not suitable for other crops. Leaching can remove contaminants in areas of high salt or alkali levels, making the soil highly productive. Local climate variation also influences the type of crops grown (DFG 2005).

DRAFT

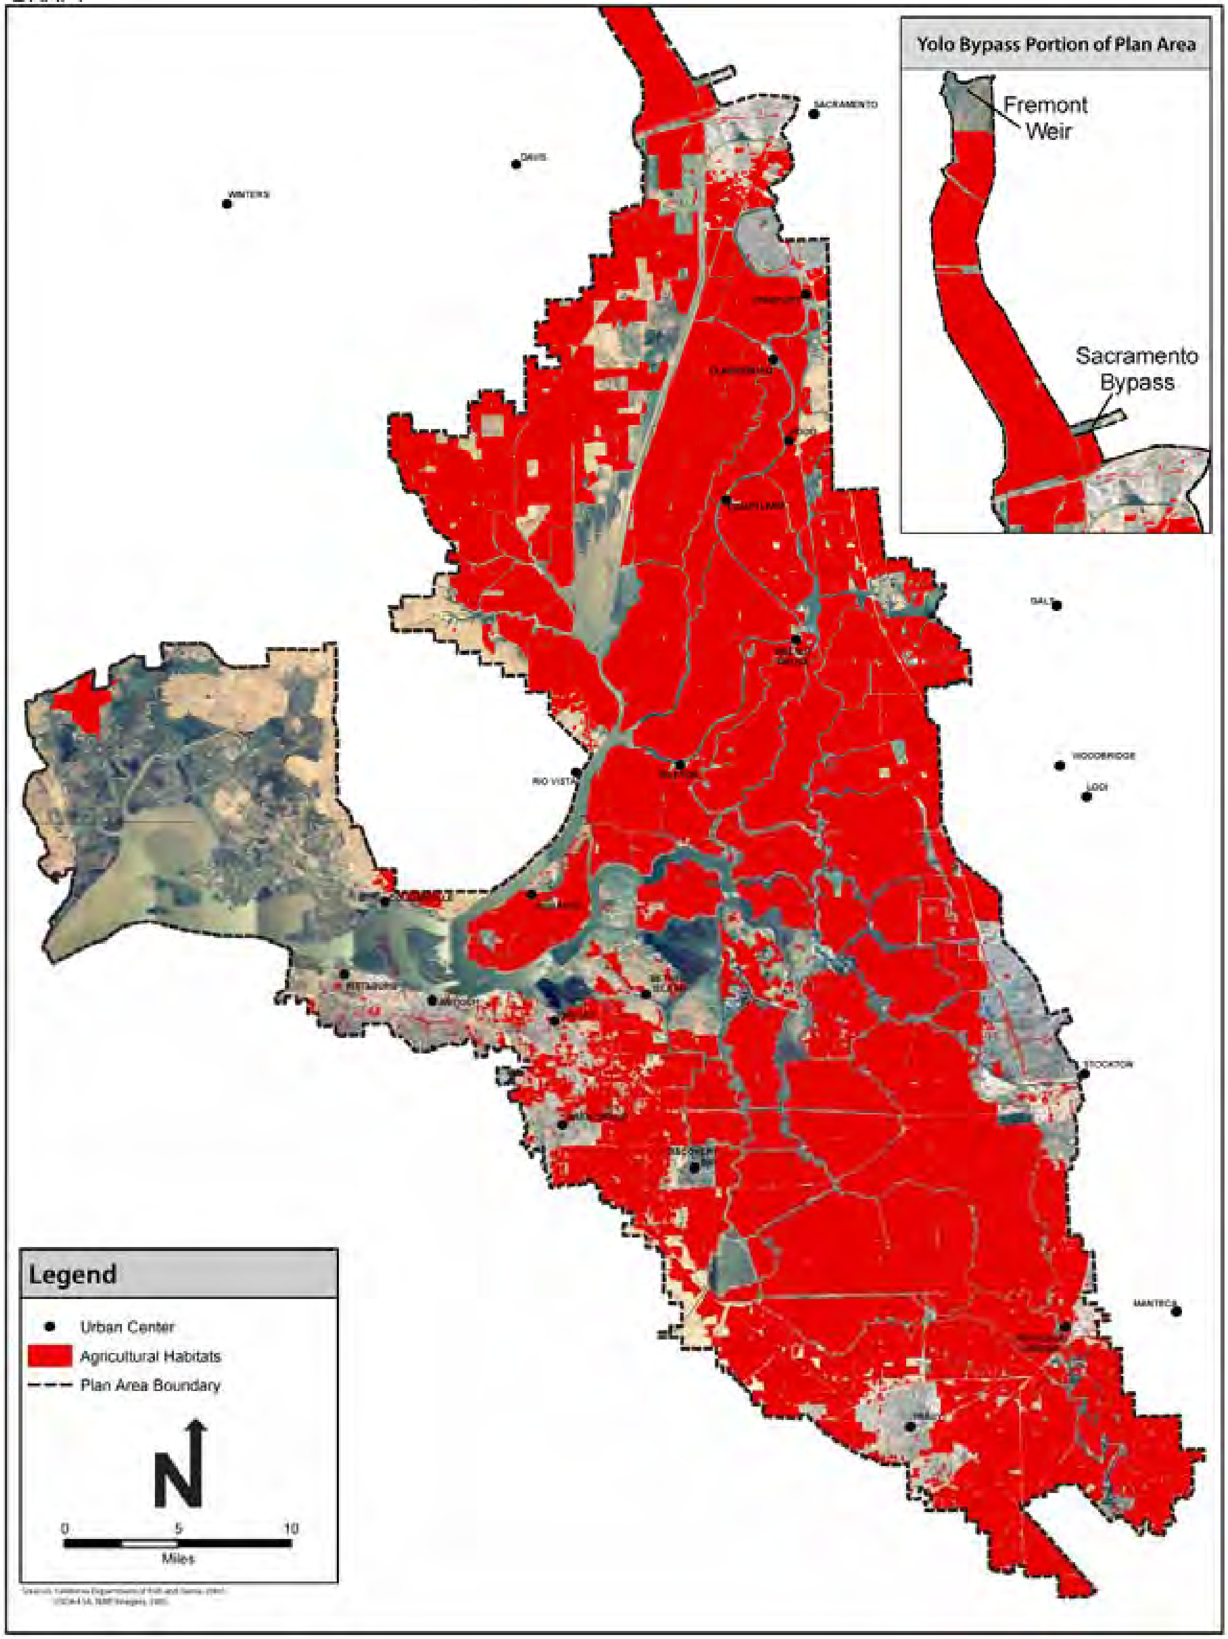

Figure 2-36. Distribution of Agricultural Habitats in the BDCP Plan Area

Orchard crops are categorized as deciduous or evergreen, with deciduous orchards far more common in the Delta region than evergreen orchards. Deciduous orchards include commercially productive tree crops in which the trees lose their leaves at some point in the year and include fruit and nut trees (e.g., pear and walnut), and bush crops. Bush crops are similar to orchards, but they may be configured in rows rather than a matrix, and are much shorter in height. Evergreen orchards include commercially productive tree crops, including citrus, avocado, and olive groves, in which the trees retain their leaves throughout the year (Hickson and Keeler-Wolf 2007). Agricultural habitats also include eucalyptus, tree-of-heaven, and other exotic vegetation stands (Table 2-18).

[1]Some of the mapping units provided here are newly described associations or alliances. For more detailed information concerning these mapping units and plant associations/alliances, as well as on methods of classification used, see Hickson and Keeler-Wolf (2007); TAIC (2008); SAIC 2009 reclassifications of Boul and Keeler-Wolf (2008).
[2]Extent of this natural community present in the Plan Area for which DFG did not delineate plant alliances. As described in Section 2.3.1, *Data Sources and Natural Community Classification*, these areas were delineated as this natural community type from aerial photography interpretation.
[3]FG vegetation types were combined to form this mapping unit in order to condense the list.
[4]The genus of pickleweed is now *Sarcocornia* instead of *Salicornia*.

2.3.4.14.2 Fish and Wildlife

Agricultural habitats in the Plan Area formerly consisted of extensive wetlands, open grasslands, broad riparian systems, and oak woodlands. The conversion of natural vegetation to agriculture has eliminated large areas of these native habitats. However, although they generally support a less diverse community of wildlife compared with most native habitats, agricultural systems continue to support abundant wildlife and provide essential breeding, foraging, and roosting habitat for many resident and migrant wildlife species (Fleskes et al. 2005, EDAW 2007, USFWS 2007, Kleinschmidt 2008). Agricultural habitats in the Plan Area provide habitat for several federal and California listed species covered by the BDCP, including Swainson's hawk, giant garter snake, and greater sandhill crane (Table 2-4).

Agricultural habitats in the Delta provide essential upland habitat for many wildlife species. Crop patterns that include a variety of hay, grain, and row crops support abundant rodent populations. Field edges, woodlots, and watercourses that support riparian habitat also provide breeding sites and refugia for prey species and other wildlife. Because of this abundance of food, the Central Valley supports one of the largest concentrations of raptors during the winter and breeding seasons. Raptors, such as red-tailed hawk, Swainson's hawk and white-tailed kite, nest throughout the Central Valley and forage in a variety of agricultural crop types including hay, grain, row crops and irrigated pastures. Conversion of pastures, row crops, and similar agricultural habitats to orchards and vineyards has been noted as a factor affecting raptors such as Swainson's hawk (Estep in prep). Grain, corn, and rice fields also provide important foraging habitats for sandhill cranes, waterfowl, wading birds, and shorebirds. Upland and seasonally flooded agricultural habitats and wetlands of the Delta support an estimated 10 percent of the waterfowl population that winter annually in California (CALFED 1998).

The Yolo Bypass Wildlife Area is an example of an area that utilizes agriculture to manage wildlife habitats while providing income from agriculture (EDAW 2007). Many agricultural practices occurring in the Yolo Bypass Wildlife Area provide habitat for a diverse assemblage of wildlife species. Rice is grown, harvested, and flooded to provide food for thousands of waterfowl. Corn fields are harvested to provide forage for geese and cranes. Working with local farmers, the Yolo Bypass Wildlife Area provides fields of grain sorghum, corn and sudan grass specifically for wildlife forage purposes. Crops such as safflower are cultivated and mowed to provide seed for upland species such as ring-necked pheasant and mourning dove (EDAW 2007).

When inundated, the Yolo Bypass provides habitat for at least 42 fish species, including delta smelt, splittail, Chinook salmon, steelhead, and white sturgeon (Sommer et al. 2001a, 2007, Feyrer et al. 2006). Evidence suggests that splittail and Chinook salmon benefit substantially from floodplain inundation because of increased food supply, lower water velocity, and warmer water. Further, extensive grading of the Yolo Bypass for agricultural drainage and relatively slow water stage decreases has likely contributed to reduced stranding of juvenile salmonids and splittail.

Native and nonnative vegetation growing along field margins and riparian vegetation growing along permanent agricultural ditches also provides habitat for migrant and resident songbirds, raptors, reptiles, amphibians, and small mammals. Filter strips of vegetation planted in agricultural areas to improve water quality also provide wildlife habitat. Natural seasonal wetlands associated with agricultural drainage and irrigation channels provide habitat for a number of wildlife and fish species.

The wildlife habitat value of agricultural cover types is a function of several variables, including accessibility to prey, prey density, and proximity to other habitat types. However, due to the dynamic nature of the agricultural landscape, to best evaluate the wildlife value of agricultural cover types in the Plan Area over a long timeframe, cover types can be characterized at a broad scale according to seasonal or perennial condition. Although perennial or semi-perennial cover types can be evaluated independently, seasonal crop types are best evaluated more generally by combining all seasonally and annually cultivated crop types into a single category. Specific crop type requirements or preferences can be addressed at the species-specific or preserve management level. Agricultural habitats in the Plan Area are thus characterized and evaluated according to subtypes presented in Figure 2-37, and acreages for each subtype are shown in Table 2-19[2]. Characteristics and wildlife use of each agricultural subtype are described below.

Table 2-19. Acreages of Agricultural Habitats Categories in the Plan Area

Agricultural Habitats Subtype	*Acreage*		
	Plan Area	*Upper Yolo Bypass*	*Suisun Marsh*
Alfalfa	82,280	3	0
Irrigated Pasture	49,205	0	489
Rice	5,034	7,603	0
Orchards	18,020	0	0
Vineyards	28,901	0	0
Other Cultivated Crops	223,676	6,151	1

Source: DWR Land Use 2007

Alfalfa. Alfalfa is an ungrazed irrigated hay crop used for livestock feed. Alfalfa is regarded as a semi-perennial crop type typically remaining uncultivated for 4 to 5 years, and occasionally longer. During this time, it is not rotated to other crop types. Alfalfa is considered to be the agricultural cover type with the highest foraging value to Swainson's hawk and the white-tailed kite, and is an important foraging cover type for the greater sandhill crane and tricolored blackbird. Its value is largely a function of its relatively low vegetation structure, and the practice of regular mowing and flood irrigating during the spring and summer, which enhances prey accessibility for foraging birds. This crop type is distributed throughout the Plan Area, including portions of the Yolo Bypass.

Irrigated Pasture. Irrigated pastures are irrigated grasses or hays grazed by livestock and periodically cut for hay. They include large pasturelands found in the Yolo Bypass, Sherman Island, and other Delta islands, and smaller pastures associated with farm residences or smaller cattle operations. While smaller irrigated pastures may be rotated to other cover types periodically, most irrigated pasturelands remain intact for many years. Like alfalfa, irrigated pastures provide foraging value to several covered species, including Swainson's hawk, white-tailed kite, burrowing owl, greater sandhill crane, and tricolored blackbird.

[2] The source data for this graphic and table, DWR Land Use 2007, is different from the source data for Figure 2-36 and Table 2-18, DFG 2007.

DRAFT

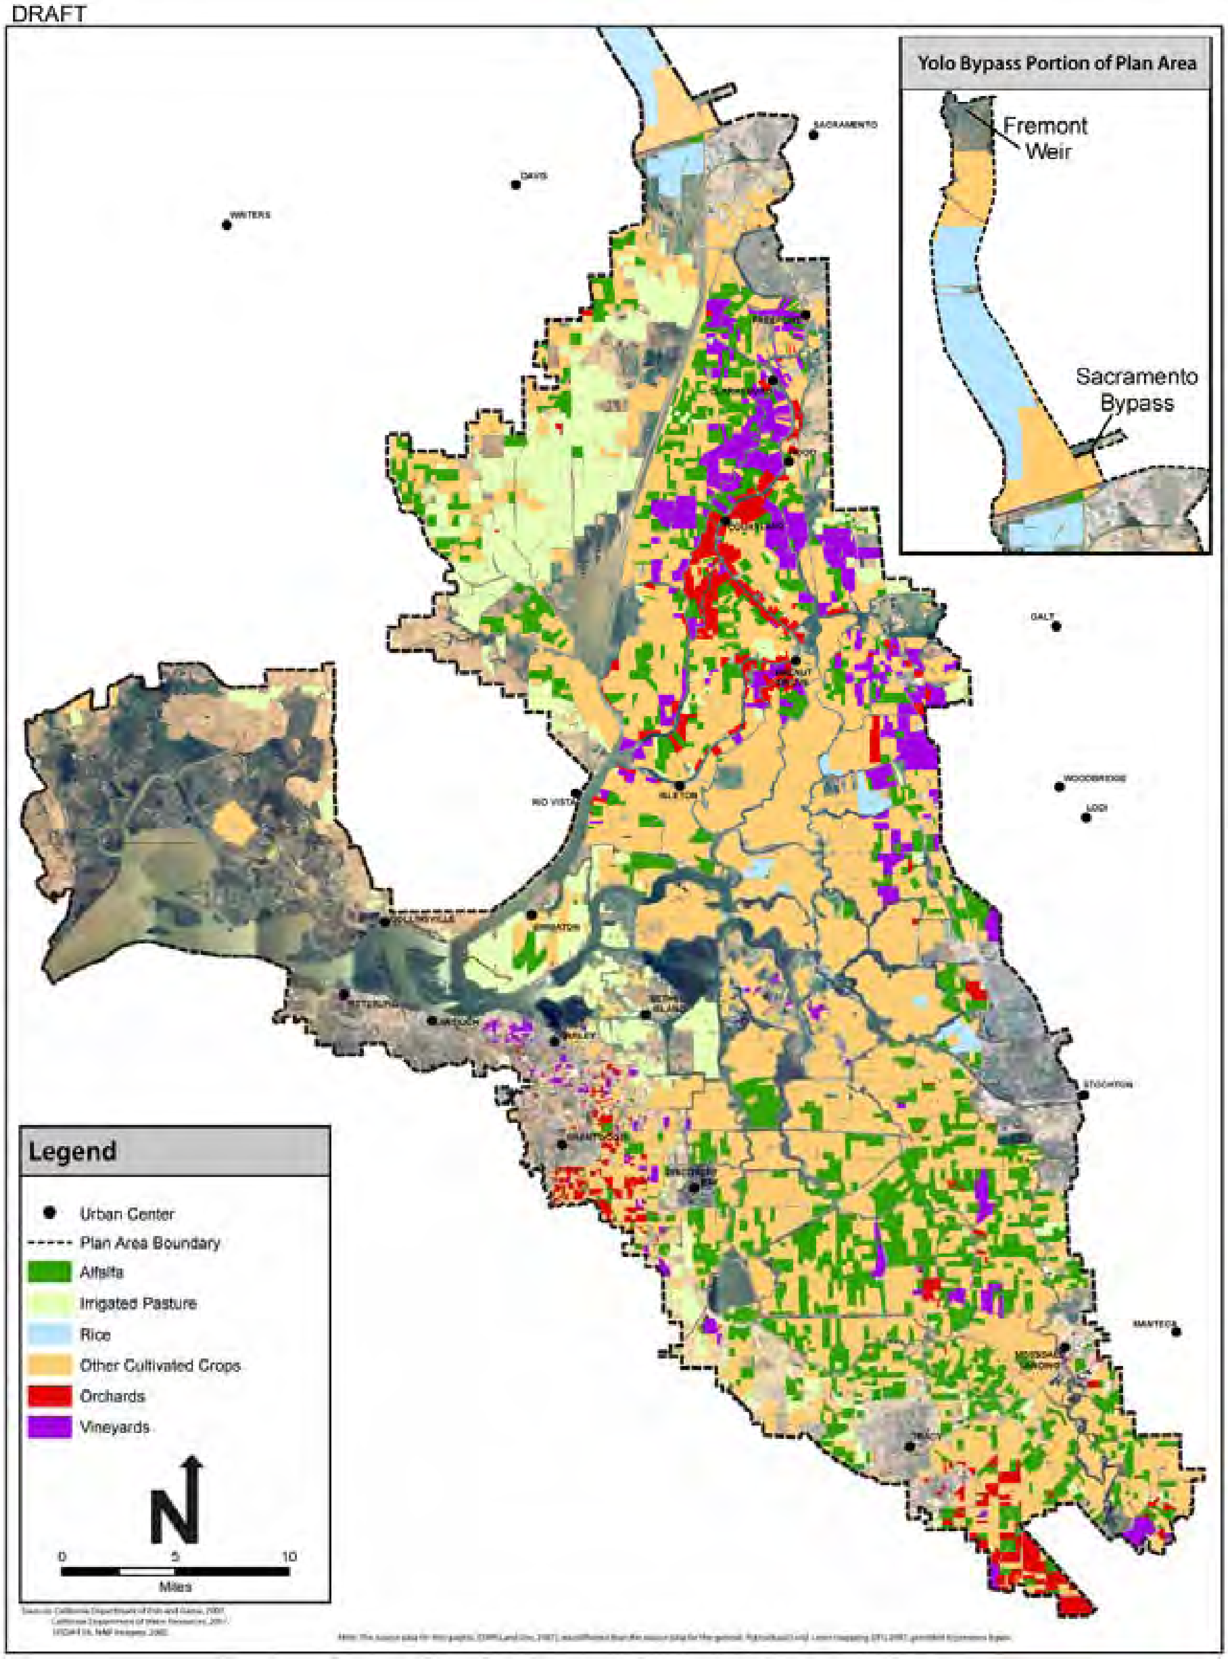

Figure 2-37. Distribution of Agricultural Habitats Subtypes in the BDCP Plan Area

Rice. Because rice cultivation requires a narrow range of soil conditions and because of the infrastructure required to effectively manage ricelands, this crop is not typically rotated and remains for many consecutive years, sometimes decades. Thus, rice is also considered a perennial crop type. Rice fields are active beginning as early as March when fields are initially flooded, to September and October when fields are drained and harvested. During the fall and winter, some rice fields are flooded to provide habitat for wintering waterfowl. Rice fields provide important aquatic habitat for giant garter snakes during the active season, as well as foraging habitat for many bird species during the active and inactive seasons.

Orchards. Orchards are perennial crops that provide limited wildlife value, particularly to covered species. Orchards develop a vegetation overstory that generally precludes access by foraging Swainson's hawks, white-tailed kites, burrowing owls, and other agricultural land-associated covered species. Orchards are planted in rows and eventually develop a dense overstory canopy. Some bats and birds find roosting and nesting opportunities in orchard trees, but overall, orchard trees receive limited use and are of negligible value to covered species.

Vineyards. Like orchards, the structure of vineyards also limits use by covered species and most other wildlife. This crop type also remains for many consecutive years and is considered a perennial cover type. Planted in rows, a relatively dense overstory develops that prohibits use by most agriculture-associated wildlife species. The increase in vineyard acreage in the Plan Area has removed other agricultural habitats more suitable to wildlife.

Other Cultivated Crops. This type is defined as areas dominated by crop patterns that involve annual or seasonal cultivation and rotation. This is the dominant cover type in the Plan Area and consists of most of the field, truck, and grain crops. These types are generally characterized as having seasonal or fluctuating habitat value depending on the planting and harvesting regime and vegetation structure. Thus, there is substantial variation in habitat value among the many crop types included within this category. Because they are seasonally or annually rotated, the value of individual fields changes each year. In addition, lands that are farmed to rotated irrigated crops generally have periods – usually during the fall post-harvest and winter months – when the fields are disked or bedded and support no vegetation. Therefore, for purposes of general classification and modeling habitat value, these crop types are not differentiated based on their individual seasonal value but are instead combined into a category of seasonally rotated croplands.

2.3.4.14.3 Nonnative Species

The agricultural landscape within the Plan Area supports primarily nonnative cultivated crops interspersed with small linear features (e.g., riparian corridors) or small patches (e.g., wetlands) that support native vegetation. The modified and disturbed conditions inherent to agricultural habitats have also encouraged a variety of undesirable nonnative species, commonly referred to as agricultural weeds, that occur around the perimeter of agricultural fields and that rapidly germinate in idle fields. These nonnative agricultural weeds usually require ground disturbance, such as tillage and irrigation, to establish and persist. Many have been persistent in the agricultural landscape for generations. Active and ongoing agricultural activity, including regular cultivation and herbicide application, is required to suppress expansion in active fields.

Agricultural habitats also attract a variety of nonnative wildlife species, particularly where patches of natural habitat persist within the landscape that provides refuge from regularly cultivated lands. Nonnative birds, such as the European starling and house sparrow, and nonnative mammals such as the Norway rat and house mouse commonly occur in agricultural habitats and adjacent riparian and wetland habitats in the Delta and throughout the Central Valley. These and other nonnative wildlife species are not unique to agricultural habitats, but also occur in many natural habitats. In an agricultural landscape, nonnative species are generally considered with respect to their impacts on cropland productivity and agricultural economics; however, some species can also invade adjacent riparian and wetland habitats.

2.3.4.14.4 Ecosystem Functions

While important for providing essential human services (e.g., food, fuel, fiber), agricultural landscapes are generally considered detrimental to most ecosystem functions. The regular and intensive cultivation of lands within the Delta can be contrary to the natural patterns of nutrient cycling, soil and sediment retention, water flow and water quality regulation, climate and air quality regulation, flood protection, and the protection of biodiversity. While some elements of ecosystem function can be partially retained, such as providing flooded habitat for wintering waterfowl and other waterbirds, a more comprehensive approach to agricultural land management that incorporates natural systems and functions is generally required to retain or enhance most ecosystem functions, such as incorporation of small patches or linear corridors of natural vegetation or wetlands.

The native Delta landscape was an extensive tidal marsh complex made up of freshwater and brackish marshes. By the mid-1800s, reclamation of wetlands began to transform the Delta into an agricultural region with a complex system of channelized waterways and Delta “islands.” This transformation of the Delta into an intensively managed agricultural landscape has substantially reduced its ecosystem functions and led to the development of several major resource issues that have affected agricultural productivity and stability of the Delta environment including flooding, salinity intrusion, and subsidence.

Agricultural habitats can, however, provide important habitats for wildlife; and if appropriately managed, can serve as surrogate habitats for native grasslands and wetlands that were converted to an agricultural landscape. Several covered species rely on agricultural habitats to meet life requisites. For example, flooded rice fields provide surrogate wetland habitats for the giant garter snake and western pond turtle during the spring and summer, hay crops and some annually cultivated crops provide important foraging habitat for Swainson’s hawk and the white-tailed kite, and winter-flooded croplands provide essential foraging and roosting habitat for the greater sandhill crane as well as waterfowl and other waterbirds along the Pacific Flyway.

2.3.4.14.5 Environmental Gradients

In general, agricultural habitats have a detrimental effect on natural gradients due to the removal of native habitats, grading and leveling of land, and changes in both groundwater and surface water movement. As a result, environmental gradients associated with agricultural habitats tend to be abrupt. The majority of the Plan Area consists of agricultural habitats with little to no topographic relief. These lands transition to grassland habitats in several areas, including portions of the southwestern, northeastern, and western edges of the Plan Area, and portions of the Yolo Basin. Tidal perennial aquatic habitats occur within the agricultural landscape, such as Franks Tract, Clifton Court Forebay, and the Sacramento and San Joaquin rivers; however, because these areas are confined by levees and water flow is highly regulated, there is little natural transition between these features and agricultural habitats. Agricultural habitats also transition to some wetland habitats, primarily in the Yolo Basin.

2.3.4.14.6 Future Conditions with Climate Change

Agricultural habitats may be particularly sensitive to long-term sea level rise associated with global climate change (see Section 2.3.3.2, *Climate)* (Nicholls et al. 1999). More variable flows through the Central Valley could reduce the reliability of water supply available for irrigating crops at critical times of the year. With sea level rise exacerbating current conditions, a powerful earthquake in the region could collapse levees; leading to major saltwater intrusion and flooding throughout the Delta if flows were sufficiently low, altering the tidal prism and causing substantial changes to agricultural areas (Mount and Twiss 2005). Areas within levees that are currently farmed would be impacted by the floodwaters.

Crop types are anticipated to change with elevated ambient temperatures. Jackson et al. (2009) asserted that over the next 50 years, cultivation of some warm season crops, such as tomatoes, cucumbers, sweet corn, and peppers, is expected to decline; whereas cultivation of hot season crops, including melons and sweet potatoes, are expected to increase as a result of climatic changes.

2.3.5 Covered Species

A total of 63 species are proposed for coverage under the BDCP, listed in Table 2-20. Detailed information about each of these species is provided in Appendix A, *Covered Species Accounts*, including life history characteristics, historical and current distribution, designated critical habitat, essential habitat, and key stressors that affect species distribution and abundance.

Table 2-20. Species Proposed for Coverage under the BDCP

Common name	*Scientific Name*
Fish	
Central Valley steelhead	*Oncorhynchus mykiss*
Sacramento River winter-run Chinook salmon	*Oncorhynchus tshawytscha*
Central Valley spring-run Chinook salmon	*Oncorhynchus tshawytscha*
Central Valley fall- and late fall-run Chinook salmon	*Oncorhynchus tshawytscha*
Longfin smelt	*Spirinchus thaleichthys*
Delta smelt	*Hypomesus transpacificus*
Sacramento splittail	*Pogonichthys macrolepidotus*
White sturgeon	*Acipenser transmontanus*
North American green sturgeon	*Acipenser medirostris*
Pacific lamprey	*Entosphenus tridentatus* (formerly *Lampetra tridentata*)
River lamprey	*Lampetra ayresii*
Mammals	
San Joaquin kit fox	*Vulpes macrotis mutica*
Riparian woodrat	*Neotoma fuscipes riparia*
Salt marsh harvest mouse	*Reithrodontomys raviventris*
Riparian brush rabbit	*Sylvilagus bachmani riparius*
Townsend's big-eared bat	*Corynorhinus townsendii*
Suisun shrew	*Sorex ornatus sinuosus*
Birds	
Tricolored blackbird	*Agelaius tricolor*
Suisun song sparrow	*Melospiza melodia maxillaris*
Yellow breasted chat	*Icteria virens*
Least Bell's vireo	*Vireo bellii pusillus*
Western burrowing owl	*Athene cunicularia hypugaea*
Western yellow-billed cuckoo	*Coccyzus americanus occidentalis*
California least tern	*Sternula antillarum browni*
Greater sandhill crane	*Grus canadensis tabida*
California black rail	*Laterallus jamaicensis coturniculus*
California clapper rail	*Rallus longirostris obsoletus*
White-tailed kite	*Elanus leucurus*
Swainson's hawk	*Buteo swainsoni*
Reptiles	
Giant garter snake	*Thamnophis gigas*
Western pond turtle	*Actinemys* (formerly *Emys* and *Clemmys*) *marmorata*
Amphibians	
California red-legged frog	*Rana draytonii*
Western spadefoot toad	*Spea hammondii*
California tiger salamander	*Ambystoma californiense*
Invertebrates	
Lange's metalmark butterfly	*Apodemia mormo langei*
Valley elderberry longhorn beetle	*Desmocerus californicus dimorphus*
Vernal pool tadpole shrimp	*Lepidurus packardi*
Conservancy fairy shrimp	*Branchinecta conservatio*
Longhorn fairy shrimp	*Branchinecta longiantenna*
Vernal pool fairy shrimp	*Branchinecta lynchi*
Midvalley fairy shrimp	*Branchinecta mesovallensis*
California linderiella	*Linderiella occidentalis*

Table2-20. Species Proposed for Coverage under the BDCP (continued)

Common name	*Scientific Name*
Plants	
Alkali milk-vetch	*Astragalus tener* var. *tener*
Heartscale	*Atriplex cordulata*
Brittlescale	*Atriplex depressa*
San Joaquin spearscale	*Atriplex joaquiniana*
Slough thistle	*Cirsium crassicaule*
Suisun thistle	*Cirsium hydrophilum* var. *hydrophilum*
Soft bird's-beak	*Cordylanthus mollis* ssp. *mollis*
Dwarf downingia	*Downingia pusilla*
Delta button-celery	*Eryngium racemosum*
Boggs Lake hedge-hyssop	*Gratiola heterosepala*
Carquinez goldenbush	*Isocoma arguta*
Delta tule pea	*Lathyrus jepsonii* var. *jepsonii*
Legenere	*Legenere limosa*
Heckard's pepper-grass	*Lepidium latipes* var. *heckardii*
Mason's lilaeopsis	*Lilaeopsis masonii*
Delta mudwort	*Limosella subulata*
Side-flowering skullcap	*Scutellaria lateriflora*
Suisun Marsh aster	*Symphyotrichum lentum*
Caper-fruited tropidocarpum	*Tropidocarpum capparideum*
Antioch Dunes evening-primrose	*Oenothera deltoides* spp. *howellii*
Contra Costa wallflower	*Erysimum capitatum* var. *angustatum*

2.4 BIOLOGICAL DIVERSITY

California is considered a global hotspot for biological diversity, where species diversity, endemism, and threats to this diversity are particularly high (Myers et al. 2000, Stein et al. 2000). California is particularly rich in unique plant species and contains globally important sites of plant diversity (Davis et al. 1997).

By most measures of biological diversity, California stands out as unique in North America. For example, California contains more native biological diversity than any other state, including more endemic species than any other state (1,295 species) (Stein 2002). Compared to other states, California is ranked first in the United States in the number of endemic species of freshwater fish, vascular plants, amphibians, reptiles, and mammals (Stein et al. 2000). In terms of total species, California supports approximately one-third of all species of vascular plants and reptiles in the United States, 47 percent of mammal species, and 56 percent of bird species (DFG 2003).

The Plan Area supports a great diversity of habitats. DFG has identified over 100 different plant associations, as defined by Sawyer and Keeler-Wolf (1995), in the Plan Area within the general biological communities of aquatic, seasonal wetlands, tidal and nontidal perennial wetlands, grasslands, riparian, and agricultural lands (Hickson and Keeler-Wolf 2007). The Delta is part of the Pacific flyway, one of the major north-south migratory routes for avifauna in the Americas. Surveys of the California Central Valley, including the Delta, document that it is one of the most important regions in western North America to migratory and wintering shorebirds (Shuford et al. 1998).

One measure of the degree of biological diversity in the Plan Area is the number of species known to inhabit the Delta and surrounding uplands. Based on information from various sources, an estimated 345 species of vertebrates could occur in the biological communities of the Plan Area, representing approximately 40 percent of all the vertebrate species known to occur in California (Table 2-21). Table 2-21 presents the number and percentage of species found in the Plan Area compared to the entire State of California by taxonomic group. The Plan Area represents less than one percent of the land area of California but is disproportionately rich in fish and bird species. Nearly 50 percent of all of California's bird species potentially use the Plan Area, a testament to its importance as part of the Pacific flyway. The Plan Area has a high diversity of native fish species with 61 percent of California's native fish species found in the Delta (31 of 51 species) (see list of all Delta fish species in Table 2-6). Of all fish species found in California, both native and nonnative, nearly half can be found in the Delta.

Over 300 taxa (species, subspecies, and varieties) of native and nonnative (naturalized) vascular plants were recorded in sampled vegetation stands in the Plan Area by DFG during its vegetation mapping effort (Hickson and Keeler-Wolf 2007). Since this mapping effort only sampled at various specific sites across the Plan Area, the total number of vascular plant taxa in the Plan Area is certainly much higher.

Table 2-21. Number of Vertebrate and Plant Species Present in the Plan Area

Taxonomic Group	*Number of Species in Plan Area*	*Number of Species in California*[6]	*Percent of California Species in Plan Area*
Vertebrates	345	876	39%
Mammals	58[1]	197	29%
Birds	200[2]	433	46%
Reptiles	22[3]	84	26%
Amphibians	9[3]	51	18%
Fish	55[4]	111[7]	49%
Vascular Plants	Over 300[5]	6,272	Over 4%
Total	**Over 643**	**7,231**	**Over 8%**

CHAPTER 3. CONSERVATION STRATEGY

[***Note to Reviewers****: This is a revised version of BDCP Chapter 3, Conservation Strategy prepared by the Consultant. The drafts of various subsections of Chapter 3 were provided by the Consultant to the Steering Committee between July 2009 and November 2010. This version of Chapter 3 combines the various subsections for the first time. Revisions to draft subsections have been made throughout the text to address comments received, to clarify concepts, and to bring the document up to date with the progress on the subsections. The BDCP Steering Committee members have submitted comments to various drafts subsections of this chapter during development, which may or may not have been incorporated into this November 18, 2010 draft. While the text of this chapter is subject to change and revision as the BDCP planning process progresses, the chapter has been drafted and formatted to appear as it may in a completed draft HCP/NCCP. Although the chapter includes declarative statements (e.g., the Implementation Office will…), it is nonetheless a "working draft" that will undergo further modification based on input from the BDCP Steering Committee, state and federal agencies, and the public.*

Chapter 3 includes statements that describe the anticipated results of the Effects Analysis. As stated in the note to reviewer in Chapter 5, Effects Analysis, the effects analysis is not complete and is ongoing. Statements in Chapter 3 regarding the Effects Analysis may need to be revised once the Effects Analysis is complete. The Steering Committee may revise, add, or delete one or more conservation measures to better achieve goals specified in the planning agreement and objectives may be revised or developed through the logic chain process.

The most recent draft of the Terrestrial Resources Conservation Strategy was provided to the Steering Committee on November 4, 2010. Work is continuing with Steering Committee representatives to further refine the Terrestrial Resource Goals and Objectives and Conservation Strategy. Due to the ongoing development and refinement of the Terrestrial Conservation Strategy, the terrestrial effects analysis will need to be revisited to reflect any changes in the strategy.]

3.1 INTRODUCTION

This chapter sets out the BDCP Conservation Strategy, which consists of multiple components that are designed collectively to achieve the BDCP overall planning goals and objectives of ecosystem restoration and water supply and reliability. The chapter further describes the Plan's intended biological outcomes and details the means by which these outcomes will be achieved. The Conservation Strategy includes the BDCP's biological goals and objectives, and identifies a set of conservation measures necessary to provide for the conservation and management of covered species and natural communities upon which they depend, and to avoid, minimize, and compensate for the potential impacts of covered activities on these resources (*see* Chapter 4, *Description of Covered Activities and Associated Federal Actions*). The Conservation Strategy also includes comprehensive programs for monitoring, research, and adaptive management. The

BDCP Conservation Strategy has been developed to meet the regulatory standards of Sections 7 and 10 of the federal Endangered Species Act (ESA), the state's Natural Community Conservation Planning Act (NCCPA), and, as appropriate, the California Endangered Species Act.

The Conservation Strategy responds to the challenge of restoring key ecosystem functions in the highly altered environment of the Delta. The Delta was once a vast marsh and floodplain intersected by meandering channels and sloughs that provided habitat for a rich diversity of fish, wildlife, and plants. The Delta of today is a system of artificially channeled and dredged waterways constructed into static geometries, initially designed to support farming and, later, urban development. These channels also serve to convey water supplies across the Delta for export to cities and farms in the San Francisco Bay Area, San Joaquin Valley and southern California. Physical disturbances within the Delta, the introduction of nonnative species that have disrupted the foodweb, and multiple other environmental challenges to the ecosystem have contributed to declines in native fish, wildlife, and plant species and other organisms. In recent years, these factors have caused a significant drop in the population of key native fish species.

There is a growing urgency to address the challenges of the Delta from both an ecological and water supply perspective. At-risk species have become further imperiled, litigation contesting the adequacy of existing approaches to meet conservation and water supply objectives has intensified and regulatory requirements governing the water system have continuously shifted in response, resulting in increasing unpredictability. To further compound these challenges, fundamental changes to the Delta are certain to occur, as the Delta is not a static ecological system. The anticipated effects of climate change will result in elevated sea levels, altered annual and inter-annual hydrological cycles, changed salinity and water temperature regimes, and accelerated shifts in species composition and distribution in and around the Delta. In addition, the risk of significant flood events has greatly increased, in part because of the likelihood that significant seismic events will occur over the next several decades. These expected environmental changes add to the difficulty of resolving the increasingly intensifying conflict between the ecological needs of a range of at-risk Delta species and natural communities and the need to provide adequate and reliable water supplies for people, communities, agriculture, and industry. Anticipating, preparing for, and adapting to these changes are key underlying drivers for the BDCP.

The approach embodied in the BDCP and its Conservation Strategy reflects a significant departure from the manner in which at-risk Delta fish species and their habitats have been managed in the past. The BDCP will contribute to the restoration of the health of the Delta's ecological systems by focusing on ecological functions and processes at a broad landscape scale, rather than by focusing on discrete parts. Unlike past regulatory approaches that have relied almost exclusively on iterative adjustments to the operations of the State Water Project (SWP) and the Central Valley Project (CVP), including those reflected in recent biological opinions issued by the U.S. Fish and Wildlife Service (USFWS)[1] the National Marine Fisheries Service (NMFS),[2] the BDCP proposes actions that will allow for fundamental, systemic, long-term physical changes to the Delta, including substantial alterations to water conveyance infrastructure and water management regimes and extensive restoration of habitat. These ecosystem-wide changes are intended to enhance substantially the productivity of ecological processes and advance the conservation of multiple species and communities that depend upon them.

The geographic scope of the BDCP Plan Area includes the statutory Sacramento-San Joaquin Delta, as defined in California Water Code Section 12220; Suisun Marsh; and the Yolo Bypass (see Section 1.4.1 *Geographic Scope of the Plan Area*). The boundaries of the Plan Area may also encompass over time additional areas within Delta counties that are protected through BDCP actions to advance the Plan's goals and objectives for terrestrial species and habitats. Because the state and federal water infrastructure operates as an integrated system, the effects of the BDCP will extend beyond the Plan Area, both upstream and downstream, and will implicate both water operational parameters and species and their habitats. Therefore, the BDCP will take into account these upstream and downstream effects, both positive and negative, to ensure that the overall effects of the BDCP are fully analyzed and understood.

While the initial focus of the BDCP was to address the conservation of Delta fish species that are currently at very low population levels, such as delta smelt, longfin smelt, winter-run Chinook salmon, spring-run Chinook salmon, and green sturgeon, the Conservation Strategy has evolved to include measures to address a broad range of species and habitats. The Conservation Strategy will provide for the conservation and management of 63 species of fish, wildlife, and plants (Section 1.4.3, *Covered Species*) and 14 natural communities (Section 1.4.2, Covered *Natural Communities*) in the Plan Area. The strategy sets forth actions to reduce the effects of environmental stressors on these biological resources at various ecological scales, including ecosystem-level actions to address physical and chemical processes and foodwebs; natural community-level actions to address the habitats of many species, and species-level actions to address individual populations and occurrences of species.

The Conservation Strategy is built upon and reflects the extensive body of scientific investigation, study, and analysis of the Delta compiled over several decades (see The State of Bay-Delta Science, 2008). The BDCP Steering Committee, for instance, took into account the results and findings of numerous studies initiated under the CALFED Bay-Delta Science program (now the Delta Science Program) and Ecosystem Restoration Program (ERP), the long-term monitoring programs conducted by the Interagency Ecological Program (IEP), research and monitoring conducted by state and federal resource agencies, and research contributions of academic investigators. In addition, the Steering Committee considered a number of other recent

[1] Formal Endangered Species Act Consultation on the Proposed Coordinated Operations of the Central Valley Project (CVP) and State Water Project (SWP) (U.S. Fish and Wildlife Service 2008).

[2] Biological Opinion and Conference Opinion on the Long-Term Central Valley Project and State Water Project Operations Criteria and Plan (National Marine Fisheries Service 2004, 2009).

reports on the Delta, including reports of the Governor's Delta Vision Blue Ribbon Task Force (January and October 2008) and several recent reports of the Public Policy Institute of California.[3] Many elements of the BDCP Conservation Strategy parallel the recommendations of these other reports and reflect broad agreement that the Delta is dysfunctional from both an ecological and water supply reliability perspective and that fundamental change is necessary.

To ensure that the BDCP would be based on the best scientific and commercial data available, the BDCP Steering Committee also undertook a rigorous process to develop new and updated information and to evaluate a wide variety of issues and approaches as it formulated a cohesive, comprehensive Conservation Strategy. This effort included an evaluation, early in 2009, conducted by multiple teams of experts of BDCP conservation options using the CALFED Bay-Delta Ecosystem Restoration Program's DRERIP[4] evaluation process (results are provided in Appendix F, *DRERIP Evaluation Results*). Reflecting the requirements of the NCCPA planning process, the Steering Committee also sought and utilized independent scientific advice at several key stages of the planning process, enlisting well-recognized experts in ecological and biological sciences to produce recommendations on a range of relevant topics, including approaches to conservation planning for both aquatic and terrestrial species, establishing adaptive management and monitoring programs, and devising biological goals and objectives (see Appendix G, *Independent Science Advisors Reports*).[5]

In the fall of 2009, the Steering Committee conducted a "mini" effects analysis that focused on the expected effects of draft water operations conservation measures on salmonids, smelt, and sturgeon. The results of the mini effects analysis informed decisions to revise proposed water operations criteria to further increase benefits to fish species consistent with water supply goals. Early in 2010, the BDCP Steering Committee initiated a full analysis of the likely effects of the draft Conservation Strategy and proposed covered activities on species and habitats covered by the Plan (see Chapter 4, *Description of Covered Activities*). The BDCP effects analysis was comprehensive in scope, identifying the beneficial and adverse effects that would be expected to occur through the implementation of covered activities and conservation measures (Chapter 5, *Effects Analysis*). Through an iterative process, the results and conclusions from the effects analysis provided the basis for multiple adjustments, modifications, and revisions to be made to the conservation measures to enhance their likely effectiveness.

This chapter sets out the Conservation Strategy for the BDCP. The chapter begins with a description of the overall approach to the development of a strategy sufficient to provide for the conservation and management of key Delta species and their habitats (Section 3.2). In Section 3.3, the biological goals and objectives of the Plan are identified. Section 3.4 sets out the specific conservation measures that will be implemented to achieve those biological goals and objectives. Section 3.5 identifies "potential conservation measures" that may later be adopted

through the adaptive management program to further address the adverse effects of various stressors on the aquatic system. The biological monitoring and research program is described in Section 3.6, and the adaptive management program is described in Section 3.7.

3.1.1 Biological Goals and Objectives

The BDCP biological goals and objectives reflect the expected ecological outcomes of the Plan. The biological goals set out the broad principles that were established to guide the development of the Conservation Strategy; the biological objectives express specific, measurable targets that the conservation measures are designed to meet. Progress toward achieving objectives will be generally measured on the basis of outcomes related to ecological processes, habitat conditions, and species distribution.

BDCP biological goals and objectives are expressed in an ecological-scale hierarchy with ecosystem-level, natural community-level, and species-specific goals and objectives. For example, the Plan includes an ecosystem goal to "improve hydrodynamic conditions to support the movement of adult life stages of native fish species to natal spawning habitats"; a natural community goal to "protect, enhance, and restore natural communities to provide habitat and ecosystem functions to increase the natural production (reproduction, growth, and survival), abundance, and distribution of native Delta species;" and a species goal to "create conditions that support a self-sustaining population of delta smelt in the Delta and Suisun Bay." As such, the goals and objectives reflect the comprehensive scope of the BDCP, including its focus on both broad-scale ecological processes and species-specific needs.

3.1.2 Conservation Measures

The BDCP conservation measures comprise the specific actions that will be implemented to achieve the biological goals and objectives of the Plan. The conservation measures have been grouped into the same ecological hierarchy as the biological goals and objectives. Ecosystem-level conservation measures are designed to improve the method, timing, and amount of flow and quality of water into and through the Delta for the benefit of covered species and covered natural communities. They are also focused on the establishment of an interconnected system of conservation lands across the Plan Area. Natural community-level conservation measures include actions to restore physical habitat to expand the extent and quality of intertidal, floodplain, and other habitats. Species-level "other stressors" conservation measures are designed to reduce the adverse effects of various stressors on covered species, including toxic contaminants, nonnative predators, illegal harvest, and genetic threats. This comprehensive suite of actions is expected to significantly contribute to the conservation of covered species and to the restoration of ecosystem processes in the Delta, while providing for a reliable water supply for human use.

The conservation measures were developed in the context of the time frame governing the implementation of the BDCP, which has been designed as a fifty year conservation plan. Under the scope of the BDCP, the type of water conveyance infrastructure for SWP and CVP operations serves to demarcate near-term and long-term components of the Plan. Specifically, the near-term component of the BDCP encompasses those actions related to the operations of the projects under existing water conveyance infrastructure, including conservation measures associated with this operational framework. The long-term component of the BDCP comprises those actions related to project operations under new isolated conveyance infrastructure, including the construction of and operation of the infrastructure and the implementation of an array of conservation measures. A number of conservation measures cannot be implemented until the north Delta diversion is operational and therefore are considered to be long-term actions. Those measures that are not dependent on operations of the new facilities will largely be initiated in the near-term phase. These actions include habitat restoration to accelerate new productivity in the Delta, the installation of non-physical barriers to divert young salmonids from high risk areas, removal of habitat features that promote nonnative predators, and enhancement of the Yolo Bypass floodplain habitat. Prompt and decisive implementation of these measures pending the completion of systemic changes in the water conveyance system is likely to be central to the success of the BDCP Conservation Strategy.

The conservation measures address biological needs on a broad spatial scale, an important feature of the overall Conservation Strategy. The Delta-wide focus of the Plan requires that restoration actions be implemented in proper sequence and timing across the northern, western, eastern and southern regions of the Delta. These restoration actions must also be closely integrated with the measures affecting water facilities and operations to ensure that the flow and physical habitat parameters are all met.

Under the BDCP, certain conservation measures are also covered activities. In some cases, actions that are intended to advance the biological objectives of the Plan may also result in the incidental take of covered species. Certain activities may provide benefits for some covered species, and have either no effect or some limited negative effect on other species. For instance, the restoration of tidal habitats to provide new physical habitat and enhanced food production for covered fish species and certain covered wildlife and plants, will necessarily remove terrestrial habitat that supports other covered wildlife and plant species. Another example is the proposed construction and operation of a new isolated conveyance system, which may provide substantial benefits to certain aquatic species over the existing system, but will also entail adverse impacts on terrestrial wildlife and plants. Consequently, these conservation measures are characterized as covered activities to ensure their coverage under the regulatory authorizations issued under the BDCP and enable their implementation.

This chapter also identifies “potential conservation measures,” which do not qualify as conservation measures at present, but may during the implementation of the BDCP be adopted as conservation measures through the adaptive management program. The efficacy of these potential conservation measures will be evaluated over time by the Implementation Office to determine whether they should be incorporated into the Conservation Strategy as conservation measures (see Section 3.5, *Potential Conservation Measures to Address Other Stressors*).

3.1.3 Monitoring, Research, and Adaptive Management

The monitoring, research and adaptive management components of the Conservation Strategy are intended to inform decision-making during plan implementation, provide indicators of progress, enable modifications to be made to improve the efficiency and effectiveness of the conservation measures in achieving the BDCP biological goals and objectives, and to allow for adjustments to be made to conservation measures as more is learned about the Delta. The monitoring and research program, described in Section 3.6, *Monitoring and Research Program*, includes a combination of system-wide and conservation measure-specific monitoring and research to provide information on the effectiveness of conservation actions.

Adaptive management is central to the success of the Plan. The adaptive management program described in Section 3.7, *Adaptive Management Program*, will integrate new data, knowledge, and scientific information to enhance the efficacy of the BDCP conservation measures. The adaptive management program will provide the mechanism by which conservation measures can be modified or discontinued in response to results from BDCP monitoring and research programs and other new scientific information.

3.2 METHODS AND APPROACHES USED TO DEVELOP THE CONSERVATION STRATEGY

This section describes the methods and the approaches used to develop the BDCP Conservation Strategy. Section 3.2.1, *Framework for the Conservation Strategy,* describes the regulatory and temporal contexts for the Conservation Strategy. It also describes the role of the adaptive management and monitoring programs in reinforcing the effectiveness of the Conservation Strategy over time. The Conservation Strategy addresses two ecologically interconnected categories of species, habitats, and natural communities: aquatic resources, encompassing the aquatic ecosystem and the covered fish species, and terrestrial resources, encompassing nontidal natural communities and covered wildlife and plant species. The approach to the development of the aquatic resources component of the Conservation Strategy is described in Section 3.2.3, *Development of the Aquatic Resources Component of the Conservation Strategy*. The approach to the development of the terrestrial resources component is described in Section 3.2.4, *Development of the Terrestrial Resources Component of the Conservation Strategy*. While these approaches are described separately, the two are closely interrelated and together are reflected in the overall BDCP Conservation Strategy. Background on the planning process for the major elements of Conservation Strategy is provided Appendix D, *Background on the Process of Developing the BDCP Conservation Measures*.

3.2.1 Framework for the Conservation Strategy

The Conservation Strategy is designed to meet the regulatory requirements of federal ESA and the NCCPA. Consistent with the requirements of the NCCPA, the Conservation Strategy will provide for the conservation and management of covered species through the protection, restoration, and enhancement of ecosystem processes, natural communities, and species habitat. Specifically, the Conservation Strategy will achieve the following:

- Conserve, restore, and provide for the management of representative natural and seminatural[6] landscapes;
- Establish reserves that provide for conservation of covered species within the BDCP geographic area and linkages to adjacent habitat outside the study area;
- Protect and maintain habitat areas that are large enough to support sustainable populations of covered species;
- Incorporate in the reserves, a range of environmental gradients and high habitat diversity to provide for shifting species distributions in response to changing circumstances; and
- Sustains the effective movement and interchange of organisms between habitat areas in a manner that maintains the ecological integrity of the system of BDCP conservation lands.

Of the 63 species covered under the BDCP (see descriptions of these species in Appendix A, *Covered Species Accounts*), 11 are fish and 52 are wildlife and plants (including 6 mammal species, 12 birds species, 5 reptile and amphibian species, 8 invertebrate species, and 21 plant species). The Conservation Strategy, which is based on the best scientific and commercial data available (see Chapter 2, *Existing Ecological Conditions*, and Appendix A, *Covered Species Accounts*), has been developed to achieve BDCP biological goals and objectives for ecosystems, natural communities, and covered species. Biological goals and objectives for aquatic resources were developed using an approach that took into account desired biological outcomes as well as an assessment of feasible conservation measures that would meet the dual objectives of the Plan[7] (see Section 3.2.3.1, *Aquatic Resources Conservation Strategy Development Process*). With respect to terrestrial species, goals and objectives were developed using approaches that appear in several recently-approved terrestrial HCPs and NCCPs and following technical guidance provided by DFG and USFWS.

The BDCP Conservation Strategy reflects a multi-scale ecological approach to conservation guided by principles of conservation biology. At the broadest scale, biological goals and objectives were developed that describe intended outcomes related to ecological processes, environmental gradients, biological diversity, and regional landscape connectivity. Conservation measures were developed to achieve these large scale, or “ecosystem-level,” goals and objectives. At the middle of the ecological scale, biological goals and objectives and conservation measures were developed for natural communities, many of which are focused on the enhancement, restoration, and management of physical habitat. This middle-level scale is referred to as the “natural community level.” At the smallest scale, biological goals and

[6] A seminatural landscape is defined as one that is disturbed by human activity but still provides important habitat for a variety of native species.

[7] The “logic chain” is a process relationship of linkages among the various components of the conservation strategy, including environmental stressors, biological goals and objectives, metrics, conservation measures, and expected outcomes developed specifically for the BDCP covered fish species.

objectives and conservation measures were identified for covered species. These "species-level" conservation actions were developed to supplement actions that are directed at ecosystem-level and natural community-level goals and objectives to ensure that the needs of covered species are addressed. This framework is discussed in greater detail in Section 3.3, *Biological Goals and Objectives*.

Biological goals and objectives and conservation measures were developed at the ecosystem level first to take into account the needs of the broadest array of covered natural communities and covered species as practicable. Next, each natural community was examined to determine additional conservation measures that would advance the biological goals and objectives for natural communities. Finally, each covered species was evaluated to determine whether species-specific measures would provide additional benefits to the species beyond those that would result from the ecosystem-level and natural-community-level conservation measures. Using this hierarchical approach, conservation measures associated with the ecosystem and natural community levels were generally considered to be sufficient to provide for the conservation of the individual covered species. In certain case, species-specific measures were adopted to ensure that the goals and objectives for the species would be met.

The BDCP conservation measures are set out in Section 3.4, *Conservation Measures*, and have been categorized by ecosystem level, natural community level, and species level. The Conservation Strategy includes several types of conservation measures, as decribed below:

- Water operations measures, through the management of flows, will support ecosystem functions associated with aquatic resources;
- Habitat protection measures will afford protection of existing functioning natural communities that are not currently protected;
- Habitat restoration/creation measures will provide for the physical restoration of natural communities in areas that do not currently support those communities;
- Habitat enhancement measures will result in improvements to habitat functions within existing natural communities;
- Habitat management measures will provide for ongoing management of natural communities and habitat to maximize the functional values of BDCP conservation areas over the long term;
- Other stressors measures will reduce the adverse effects of various stressors on fish species (aside from habitat and operations-related stressors), including the impacts of predation, toxic contaminants, and illegal harvest; and
- Avoidance and minimization measures will ensure that adverse effects of covered activities on covered species will be avoided or minimized to the maximum extent practicable.

All of the BDCP conservation measures have been developed at a sufficient level of detail and specificity to ensure their implementation. Because of the broad scope of the BDCP and its extended timeframe for implementation, a degree of flexibility has been built into many of the measures to accommodate changes in conditions and methods over time. For example, natural community–level actions provide broad management guidelines and principles such that land managers may implement specific techniques on the ground best suited to site conditions. Preserving this flexibility is an important part of the Conservation Strategy and is articulated in Section 3.7, *Adaptive Management Program*.

Implementation of habitat protection, enhancement, and restoration conservation measures will require the preparation of site-specific implementation documents. These site plans, as well as any additional environmental documentation, will be prepared in accordance with the schedule for the implementation of specific actions.

3.2.1.1 The Importance of Adaptive Management, Monitoring, and Research

Monitoring and adaptive management will play important roles in the implementation of the BDCP because of the inherently dynamic nature of the Delta ecosystems, the expected changes in these dynamics over time (e.g., effects of climate change on sea level and watershed hydrology), and uncertainties related to the likely response of certain covered species to certain conservation measures. To further support plan implementation, the BDCP provides for the establishment of a research program that will yield data and information over time that support adjustments and modifications to the conservation measures to increase their effectiveness.

The Conservation Strategy anticipates the potential for changes to occur in Delta conditions that result from climate change, seismic events, changes in land use, and other factors. The BDCP recognizes that monitoring, research, and adaptive management are necessary to allow for the incorporation of any new information and insight regarding actual changes and new projections of changing futures into plan implementation. As more is understood about the Delta ecosystem, refinements to the BDCP conservation measures may be necessary to enhance their effectiveness.

Information gathered through the BDCP monitoring and research program (Section 3.6, *Monitoring and Research Program*) and other research efforts will guide decision-making during implementation. The BDCP monitoring and research program is designed to establish cause and effect relationships between implementation of specific conservation measures and the type and magnitude of species and ecosystem responses to those measures, as well as species and ecosystem responses to the implementation of combinations of conservation measures. Should strong cause and effect relationships be established, adaptive management will provide the mechanism to concentrate efforts on the implementation of conservation measures that have been demonstrated to be more effective and to de-emphasize or discontinue implementation of conservation measures that prove to be less effective at achieving the BDCP biological goals and objectives.

As described in Section 3.7, *Adaptive Management Program*, all conservation measures will be implemented using an adaptive management approach that is informed by monitoring and research (Section 3.6, *Monitoring and Research Program*).

3.2.1.2 The Timing and Interrelatedness of Conservation Measures

The Conservation Strategy is divided into near-term and long-term implementation stages. The near-term implementation lasts until the north Delta diversion and tunnel/pipeline conveyance facilities are constructed and operational. This division of the implementation period was used because dual operation of separate diversions in the north and south Delta will bring significant flexibility and ecological changes to the system; hence, the interrelatedness of many of the conservation measures with operations of the new conveyance facility.

The implementation of conservation measures associated with the near-term will provide for immediate responses to degraded ecological conditions, while building the foundation to improve long-term ecological productivity. These near-term measures include early restoration actions for tidal habitats, implementation of conservation measures that address other stressors on covered fish species, and acquisition of terrestrial and wetland habitat to provide conservation for covered wildlife and plant species.

Completion and operation of the north Delta intakes and isolated tunnel/pipeline conveyance facility will facilitate the implementation of other key conservation measures, including restoration of tidal and floodplain habitat in the east and south Delta associated with the Mokelumne, Cosumnes, Middle, Old, and San Joaquin rivers. The close integration of conservation actions across both time and geography is central to the success of the BDCP Conservation Strategy. A complex web of important interrelationships exists among the conservation measures. There are interrelationships and interdependencies among all the water operations parameters because changes in water operations in any one part of the Delta affect hydrodynamics in other parts of the Delta. For example, diversions in the north Delta reduce Delta outflow but also reduce the need to export at the south Delta diversions, thereby reducing reverse flows in Old and Middle rivers. The coordinated operations of new and existing water facilities in a flexible and adaptable plan will allow for the optimal combination of improvements to aquatic habitat and reliability of water supply.

Restoration of large portions of the Delta to tidal habitat will affect the hydrodynamics and water quality in immediately surrounding channels and, in some cases channels distant from the restoration site, by increasing the tidal prism and reducing the tidal range. For example, restoration of tidal habitats in the Cache Slough area is projected to result in reduced tidal range and greater unidirectional flows in Sutter and Steamboat sloughs, which may reduce the risk of predation on juvenile salmonids migrating through these sloughs by speeding transport time. The reduction in contaminants, such as pesticides and herbicides that will result from restoring habitat on agricultural lands, is expected to interact synergistically with improvements in organic and nutrient input from restored tidal marsh and floodplains to benefit the aquatic food web. Hence, understanding the interconnections amongst the BDCP conservation measures across program elements, across the wide geography of the Delta, and across time is an important aspect of the strategy. In short, the Conservation Strategy is intended to be more than the sum of its parts.

The BDCP Implementation Office will also time and sequence the acquisition of conservation lands to protect and restore habitats to ensure that these conservation actions occur in a manner that is roughly proportional to and temporally aligned with the impacts of covered activities (see Chapter 6, *Plan Implementation*).

3.2.2 Identifying Conservation Zones and Restoration Opportunity Areas

To facilitate development of habitat protection and restoration elements of the Conservation Strategy, the Plan Area was subdivided into 11 Conservation Zones within which conservation targets for natural communities and covered species' habitats were established (Figure 3-1). Conservation Zones were delineated based on conservation opportunities afforded by different geographic locations.

Conservation Zones were delineated primarily on the basis of landscape characteristics and logical geographic or landform divisions to create a more structured organizational approach to how and where conservation actions will be carried out within the Plan Area. Conservation Zones were used as a planning tool to ensure that targets identified for natural communities and covered species habitat will be spatially distributed to achieve biological goals.

Criteria used to establish each Conservation Zone included:

- Distribution of covered species within and adjacent to the Plan Area;
- Distribution of natural communities supporting covered species habitats;
- Differences in the function of covered species habitats supported by natural communities in different portions of the Plan Area (e.g., high, medium, and low function as habitat for covered species);
- Natural features (e.g., watercourses);
- Locations of barriers to covered species movement among habitats; and
- Connectivity with existing habitat areas adjacent to the Plan Area.

A different set of planning units, Restoration Opportunity Areas (ROAs), were also established to assist in the development of the Conservation Strategy (Figure 3-2). ROAs are different from, but overlap with, the Conservation Zones. ROA's encompass those locations considered to be the most appropriate for the restoration of tidal habitats within the Plan Area and within which restoration goals for tidal and associated upland natural communities will be achieved (see Section 3.4.3.1, *CM4 Tidal Habitat Restoration*, for a description of ROAs and tidal habitat restoration conservation actions).

The extent of each natural community and covered species habitat in each of the Conservation Zones is presented in Tables 3-1a-c and Tables 3-2a-c, respectively. The existing distribution of natural communities within each of the Conservation Zones is presented in Figure 3-3 through Figure 3-8.

3.2.3 Development of the Aquatic Resources Component of the Conservation Strategy

The aquatic component of the BDCP Conservation Strategy is designed to support the restoration of ecological productivity of the Delta and adjacent areas to contribute to the conservation of covered fish species and the tidal natural communities upon which they depend, consistent with the water supply and reliability goals of the Plan. Over the course of the BDCP planning process, the Steering Committee convened independent scientists on several occasions to solicit their advice and recommendations regarding a number of concepts that were used to help guide the Conservation Strategy for aquatic resources, including:

- Land use changes within the Delta have reduced the quality and availability of aquatic habitat suitable for various life stages of covered fish – the conservation strategy should contribute to an increase in the quality, availability, spatial diversity, and complexity of aquatic habitat within the Delta.
- Achieving the goals of the BDCP will require more than manipulation of Delta flow patterns alone. A number of key ecosystem drivers are unrelated to freshwater flow patterns, and these drivers must also be addressed directly.
- The conservation strategy should improve connectivity among aquatic habitats, facilitate migration and movement of covered fish among habitats, and provide transport flows for the dispersal of planktonic material (organic carbon), phytoplankton, zooplankton, macroinvertebrates, and fish eggs and larvae.
- Synchrony between environmental cues and conditions and the life history of covered fish and their food resources within the upstream rivers, Delta, and Suisun Bay is important. The conservation strategy should consider hydrologic seasonal synchrony within the watershed, seasonal water temperature gradients, salinity gradients, turbidity, and other environmental cues.
- There are currently a number of stressors and sources of mortality affecting covered fish within the Delta – the conservation strategy should identify and implement actions to reduce sources of direct mortality and other stressors on the covered fish and the aquatic ecosystem within the Delta.
- Hydrology and SWP and CVP operations within the Delta are integrated with conditions both upstream and downstream of the Delta – the conservation strategy should consider effects on habitat conditions for covered fish in upstream river reaches, within the Delta, and downstream within the low salinity zone of the estuary in Suisun Bay.
- To the extent possible, the conservation strategy should rely on natural physical habitat and biological processes to support and maintain covered fish species and their habitat.

These concepts informed the development of the aquatic component of the Conservation Strategy. Underlying the BDCP Conservation Strategy is the widely-accepted assumption that the existing water conveyance system is fundamentally flawed and that continued reliance on the system as it currently exists is incompatible with the long-term restoration needs of the Delta. Given the inability of the existing conveyance system to meet ecological and water supply goals, and in light of the ongoing and anticipated changing conditions of the Delta brought on by climate change, anticipated seismic events, nonnative species, and other stressors, the BDCP provides for wholesale, systemic modifications to the Delta. Modifying the water conveyance infrastructure to allow for both north and south Delta diversions is essential to creating new opportunities to restore the ecological health of the Delta and to achieve improvements in water supply reliability. The BDCP provides for dual operations of north and south Delta intakes that allow for flexibility of operations to:

- Improve passage of fish within and through the Delta by improving hydrodynamic and water quality conditions that can create barriers to movement;
- Allow for restoration of tidal habitats in the east and south Delta by reducing the risk for entrainment of food produced in restored habitat and life stages of covered fish species using this habitat; and
- Reduce the risk of entrainment of covered fish species by conveying water from either the north or south Delta, depending on the seasonal distribution of their sensitive life stages.

The Conservation Strategy for aquatic resources identifies conservation actions to be implemented under both existing and future water conveyance facilities and operational regimes that can effectively reverse or reduce the adverse effects of environmental stressors on the aquatic ecosystem, covered fish species, and other native aquatic organisms. In addition to the water facilities and operations, the Conservation Strategy provides for habitat restoration actions to improve rearing, spawning, and migration habitat conditions for the covered fish species and to improve aquatic food web processes and actions to address specific stressors on the covered fish species, including impediments to fish passage, sources of unnatural mortality, and the adverse effects on the genetic integrity of covered fish species.

To improve habitat and food web conditions for the covered fish species, the Conservation Strategy provides for the restoration of 75,000 acres of tidal habitats, seasonally inundated floodplains, and adjacent transition uplands; 20 miles of channel margin habitat; and enhancement of seasonally inundated floodplain habitats of the Yolo Bypass through operation of a modified Fremont Weir. These restored natural communities will account for a substantial increase in the extent and quality of physical habitat available for covered fish species. For example, the ROAs described in Section 3.2.2, *Identifying Conservation Zones and Restoration Opportunity Areas*, (see Figure 3-2) were selected specifically to encompass areas most suitable for the restoration of tidal habitats and the most beneficial locations for covered fish species that use main channels, distributaries, and sloughs of the Sacramento, San Joaquin, and Mokelumne rivers and the channels and sloughs of Suisun Marsh. Prior to completion of the new conveyance facility, tidal habitat restoration actions will be focused on the Cache Slough and

Suisun Marsh ROAs, which are minimally affected by through-Delta conveyance operations. Expansion of tidal habitat in these ROAs will benefit delta smelt and longfin smelt. The expansion of tidal area will affect flows in the Sacramento River and its distributaries to the benefit of Sacramento River salmonids. Constructing the new north Delta diversions and isolated tunnel/pipeline facility will open up significant additional tidal habitat restoration opportunities that do not now exist. Accordingly, the long-term phase of the physical habitat restoration program will emphasize restoration of tidal and floodplain habitats in the northeast and south Delta to benefit San Joaquin, Mokelumne, and Cosumnes river salmonids as well as sturgeon, splittail, and lamprey. As described in Section 3.2.4, *Development of the Terrestrial Resources Component of the Conservation Strategy*, these restoration actions will also benefit covered wildlife and plant species that use tidal marsh and riparian habitats.

A third component of the aquatic strategy consists of actions to reduce the direct and indirect adverse effects of other stressors on the ecological functions of the Delta and the covered fish species. A number of factors have been identified that adversely affect covered fish species, either directly or by affecting food resources or habitat quality. Many of these conservation measures address other stressors that are not related directly to water operations or habitat restoration activities, but offer significant opportunities to reduce adverse impacts on covered species and otherwise improve productivity. These other stressors include poor water quality (e.g., low dissolved oxygen), nonnative predator species, illegal harvest activities, and the genetic effects of hatchery-raised fish. Implementation of conservation measures addressing these other stressors is expected to reduce adverse effects on covered species productivity.

Because there are some uncertainties regarding the likely responses of the aquatic ecosystem and covered fish species to some of the measures to address these other stressors, the monitoring and adaptive management programs will be used to ensure that such measures can be refined over time to improve their effectiveness.

3.2.3.1 Aquatic Resources Conservation Strategy Development Process

The process of developing the BDCP Conservation Strategy was complicated by the challenges associated with ecological requirements that vary among the covered fish species, the physical complexity of the Delta, and uncertainties about the nature and strength of certain cause-effect relationships operating in this aquatic ecosystem. Furthermore, the ecosystem experiences ongoing changes, some of which are relatively well understood (e.g., sea level rise), others incompletely understood (e.g., pelagic organism decline), and some that are entirely unknown. As part of the process of developing the Conservation Strategy, the linkages between key plan elements were identified in process referred to as the “logic chain,” which was used to help organize and address the elements of this complex system. Biological goals and objectives for the covered fish species were identified and monitoring metrics were assigned to assess the effectiveness of conservation actions toward achieving the biological goals and objectives.

The logic chain is intended to add specificity and clarity with respect to the relationships between stressors affecting covered fish species, biological goals and objectives, the assumptions underlying conservation approaches, the conservation measures and their projected outcomes, and the appropriate metrics to monitor the success of the Conservation Strategy. Understanding these key linkages helped to facilitate the evaluation of the Plan components and their likely effectiveness as they are implemented over time. As a result, the Conservation Strategy uses a comprehensive approach that accounts for the relationships between what the BDCP is trying to accomplish and how it intends to achieve its objectives.

3.2.3.2 Stressors Affecting Covered Fish Species

A key step in the development of the Conservation Strategy for aquatic resources was the identification of significant environmental stressors on each of the covered fish species. Biological objectives for the Conservation Strategy were developed on the basis of identified stressors on covered fish species and their habitats. Conservation measures were developed to address the biological goals and objectives. Table 3-3 identifies the primary stressors on covered fish species and indicates those stressors that will be addressed by BDCP conservation measures and those that will not.

Table 3-3. Stressors on Covered Fish Species and their Relationship to Biological Objectives

No.	*Applicable species*[8]	*Stressors*	*Description*	*Biological objectives that Address the Stressor*[2]
9	SASP RILA PALA	Stranding	Effects on productivity and abundance from incidences of stranding associated with water management activities. Splittail are floodplain spawners. Design of the restored floodplain may influence potential for stranding.	PALA1.2 RILA1.2 SASP1.1 SASP1.3
10	GRST WHST	Dredging	Disturbance of benthos and direct and indirect effects of physical disturbances of substrates used for rearing from dredging activities associated with BDCP construction and maintenance activities.	GRST1.6 WHST1.6
11	CHSA STEE	Access to historical spawning habitat	Barriers to historical spawning habitat are predominately located outside of the BDCP planning area. In-delta migration and barriers addressed in Stressor # 4 above.	NA
12	CHSA STEE	Climate Change	Increases in ambient air temperatures resulting in increased water temperatures with negative effects on habitat suitability. Effects of climate change are considered but no specific objectives proposed. Changes in water temperature as applicable to BDCP covered activities are addressed under stressor # 5 above.	NA
13	RILA PALA	Disease	Disease may influence lamprey health with effects on reproduction and survival.	NA
14	RILA PALA	Ocean conditions	Reductions in the availability of host/food species may be affecting lamprey survival and growth.	NA

[1] Species abbreviations are defined as follows:
Note: objectives for Delta Smelt and Longfin Smelt are not included
CHSA = Chinook salmon all runs
STEE = Central Valley steelhead
SASP = Sacramento splittail
GRST = Green sturgeon
WHST = White sturgeon
RILA = River Lamprey
PALA = Pacific Lamprey
[2] Species-specific objectives are presented in Section 3.3, *Biological Goals and Objectives.*

3.2.3.3 Water Facilities and Operations

The BDCP Conservation Strategy includes conservation measures that provide for the development and operation of new water conveyance infrastructure and the establishment of operational parameters associated with both existing and new facilities. Central to the

[9] Stressors not addressed by BDCP objectives are associated with conditions outside the Plan Area and/or not under the control of BDCP Authorized Entities

Conservation Strategy is the development and operation of new north Delta facilities that will be located along the Sacramento River and divert water to the south Delta through an isolated tunnel/pipeline. The combination of moving freshwater via an isolated tunnel/pipeline facility in conjunctions with the existing south Delta facilities (referred to as "dual operations") is expected to provide flexibility sufficient to substantially improve conditions for covered fish species. The operation of these dual facilities as set out in the BDCP is expected to benefit different species at different times and under a variety of conditions. Dual operation of new and existing diversion facilities is expected to reduce levels of entrainment of native fish at the south Delta SWP/CVP facilities, particularly delta and longfin smelt.

To minimize the potential for entrainment of fish (particularly juvenile Sacramento River salmonids and splittail) at the new diversion facilities on the Sacramento River, state-of-the-art positive-barrier fish screens will be constructed at each of five intakes and flexible operational methods in the timing and rate of diversion will be coordinated among the intake facilities. Constructing state-of-the-art positive barrier fish screens on in-river and on-river intakes along the Sacramento River and employing flexible operational scenarios will ensure that fish mortality at the new north Delta diversion sites is minimized to the maximum extent practicable. The positive barrier fish screens will be designed and operated in accordance with design criteria (e.g., screen mesh size, approach velocity) currently used by CDFG, NMFS, and USFWS. These operational measures have been devised to ensure that any potential risks to migrating salmonids from the operation of the new north diversion facility will be avoided or otherwise minimized.

The water operations conservation measures establish parameters for water diversion rates and bypass flows in the Sacramento River at the diversions that reflect seasonal movement patterns of covered fish species, including specific responses during periods in which fish species are present in the vicinity of the diversions. These parameters have been developed to better reflect seasonal synchrony with hydrologic conditions within the river and upstream watersheds. Bypass criteria set out in the water operations conservation measures reflect the variation in the seasonal periods of hydrology. The criteria includes "pulse flow" operations, minimum river flow requirements, and flow requirements based on a percentage of the river flow that would pass by the diversions ("bypass flows"). Extensive hydrologic simulation modeling has been used to evaluate and develop the range of water diversion criteria included in the Conservation Strategy. Detailed information on the Sacramento River bypass and diversion operations criteria is presented in Section 3.4.2.1, *CM1 Water Facilities and Operation*.

Proposed water operations measures include actions to improve flows through the Yolo Bypass floodplain, ensure sufficient water for fish transport in the Sacramento River (i.e., north Delta diversion or Hood "bypass flows"), prevent fish from being drawn into the central Delta through the Delta Cross Channel, provide quality habitat for delta smelt and longfin smelt in the Delta and Suisun Bay, and minimize entrainment of fish at the south Delta SWP/CVP diversions. The flexibility associated with the operation of dual facilities in the north and south Delta is expected to allow for physical habitat restoration to be implemented in the western, eastern, and southern

Delta. Some of the enhanced production of carbon, zooplankton and phytoplankton generated from these restored habitats is expected to pass through the interior Delta, while some should also be consumed by fish within and adjacent to the marshes. The flexibility of this dual approach will also allow for substantial reductions in fish entrainment at the south Delta facilities, while meeting the water supply and reliability goals of the BDCP.

The BDCP conservation measures also include the modification of Fremont Weir (lowering a portion of the weir and installing an operable gate facility) and changes to its operations to improve the inundation regime in the Yolo Bypass. Research suggests that covered fish species, particularly splittail and Chinook salmon, would benefit significantly from optimizing the frequency, duration, and timing of seasonal inundation of the Yolo Bypass floodplain habitat (Sommer et al. 1997, 2001a, 2001b, 2004a, 2004b). In addition, the measures is also designed to increase levels of phytoplankton, zooplankton, and other organic material transported from the Yolo Bypass floodplain to Cache Slough, the lower Sacramento River, the western Delta, and Suisun Bay, which will increase the food supply for delta smelt and longfin smelt in those areas.

The BDCP also includes operational criteria that set seasonal limits based on Old and Middle River (OMR) reverse flows. To reduce the risk that south Delta SWP and CVP exports cause direct losses or salvage of covered fish or increases in the export of nutrients and food resources produced in restored southern and eastern Delta marshes, the water operations conservation measures provide for seasonally adjusted year-round limits on OMR reverse flows. Detailed information on OMR operations criteria is presented in CM1 *Water Facilities and Operations,* in Section 3.4, *Conservation Measures.*

The western Delta and Suisun Bay system functions as an estuarine mixing zone for freshwater passing downstream from the tributary rivers and saltwater intrusion from coastal waters through San Francisco Bay. Suisun Bay and the western Delta serve as the low salinity mixing area that has been found to be important rearing and foraging habitat for the covered fish species. The estuarine habitat is also important to the production of phytoplankton and zooplankton as well as many other fish that are the prey of covered fish. The dynamics of the estuarine zone are determined largely by tides and the balance of the magnitude of Delta inflow and Delta outflow. Habitat conditions and salinity gradients in the Suisun Bay and western Delta are most important to covered fish species during the winter and spring months. Consequently, the Conservation Strategy includes, as part of the water operations conservation measures, seasonally adjusted Delta flows designed to better maintain the functions of the estuarine habitat.

3.2.3.4 Physical Habitat Restoration

A second major component of the Conservation Strategy for aquatic resources is the protection, enhancement, and restoration of habitats and natural communities that support covered species. Habitat restoration actions will involve both the reestablishment of habitat in locations that historically supported such habitat and the creation of habitat on altered landscapes where no such habitat previously existed. Habitat enhancement refers to the improvement of ecological functions of existing habitat; habitat protection refers to the preservation of existing habitat susceptible to changes in use by human activity.

The habitat restoration conservation measures include commitments to restore natural habitats at a substantial scale. These actions will restore natural habitat mosaics and gradients to levels that have not been present in the Delta for at least 70 years. Specifically, these conservation measures provide for the restoration of 65,000 acres of tidal wetland and associated estuarine and upland habitats distributed across the Delta, but primarily located within Suisun Marsh and the north Delta Cache Slough complex; restoration of 10,000 acres of new floodplain habitat along major channels; and enhancement of floodplain in the Yolo bypass. ROAs have been identified within the Delta and Suisun Marsh that are characterized by physical conditions suitable for tidal marsh restoration (see Figure 3-2). The ROAs encompass potential restoration areas that could support covered fish species that use main channels, distributaries, and sloughs of the Sacramento, San Joaquin, and Mokelumne rivers in the Delta and the channels and sloughs of Suisun Marsh. Within the floodplain and tidal restoration areas, 5,000 acres of riparian habitat restoration will be implemented. These conservation actions will result in the restoration of large tracts of Delta tidal marsh, estuarine, and seasonal floodplain habitats of sufficient size to substantially increase the extent of physical habitat for covered species (including cover, rearing habitat, nesting habitat, and food resources) and improve overall food web productivity in the restoration areas and adjacent aquatic habitat.

3.2.3.5 Measures to Address Other Stressors

An important third component of the Conservation Strategy for aquatic resources consists of measures to reduce the direct and indirect adverse effects of other stressors on the ecological functions of the Delta and on covered species and natural communities. A number of factors have been identified that adversely affect covered fish species and their habitats. These other stressors include nonnative predators, localized low dissolved oxygen, and genetic issues in hatchery fish.

Specific other stressors conservation measures include actions to reduce predator levels through removal of predator habitat, such as submerged and floating aquatic vegetation and abandoned structures and vessels, particularly in reaches important to juvenile salmonid migration. New non-physical barriers are proposed to direct certain covered species away from areas that pose a higher risk of predation and entrainment. Other measures include actions to improve dissolved oxygen conditions in specific problem areas important to salmonid migration, and to develop new and expanded conservation hatcheries for delta smelt and longfin smelt for the purpose of establishing refugial populations.

3.2.4 Development of the Terrestrial Resources Component of the Conservation Strategy

The Conservation Strategy for terrestrial resources comprises a comprehensive program that provides for the protection of existing functioning natural communities, restoration of new areas of specific natural communities, enhancement of the function of natural communities for covered species habitat, establishment and long term management of geographically distributed conservation lands, and monitoring and adaptive management actions. The Conservation Strategy reflects well-established principles of conservation biology. The approach is designed to maximize opportunities to preserve and restore natural communities sufficient to achieve the goals and objectives for the terrestrial covered species. The natural community level measures include specific targets for habitat protection and restoration, including requirements relating to preserve size, habitat corridors and linkages, and preserve management. Where the goals and objectives for a covered species are may not be fully achieved through implementation of the natural community conservation measures, species-specific conservation measures have been included to ensure appropriate outcomes for species and habitats.

Because of the diverse species habitat requirements and highly altered nature of the Delta, the covered wildlife and plant species are distributed unevenly in the Plan Area, often in discrete, disconnected patches of habitat. A few of the wildlife and plant species are distributed broadly across the Plan Area, but many of the covered wildlife and plant species are found only at the margins of the Plan Area or in local parts of the Plan Area. For some of these species, the Plan Area includes only low-quality or marginal habitat and for others the Plan Area provides the key resources required for conservation. Hence, the conservation approaches for covered wildlife and plant species vary because of the large variation in the importance and quality of habitat in the Plan Area for these species.

Each natural community supports habitat for multiple covered wildlife and plant species, and the suite of species' habitats supported by some communities are similar. Conservation of each natural community is addressed based on the specific spatial, temporal and structural attributes of those communities.

The Conservation Strategy includes measures to provide connectivity between areas that are important for sustaining and improving ecosystem functions and providing for species conservation. For some species and natural communities this interconnection will be achieved through large-scale restoration of aquatic and wetland communities, such as tidal habitats concentrated in the Delta and Suisun Marsh and riparian forest and scrub. For covered species that occur in terrestrial natural communities along the periphery of the Plan Area (e.g., San Joaquin kit fox, California red-legged frog), opportunities for habitat interconnection will be mostly between existing and newly protected terrestrial habitat in the Plan Area and protected terrestrial habitat adjacent to the Plan Area (mostly associated with adjacent or surrounding HCPs and NCCPs).

The geographic pattern of habitat protection and restoration in the Plan Area will result in a system of core habitat patches linked by ribbons of habitat along channels, sloughs, and floodplains. This approach can be thought of as a "node and network" approach. In core species habitat areas, patches or "nodes" of protected and restored habitat will be established to address site-specific species needs. The Plan provides for large-scale preservation and restoration of habitat along the channels, floodplains, and sloughs of the Delta and Suisun Marsh that will provide a "network" of habitat connections among the nodes of protected and restored core habitats. Steps to establish a connectivity network for covered species within the Plan Area will be informed and guided by the California Essential Habitat Connectivity project (Spencer et al. 2010).

Many of the natural communities addressed by the BDCP share common characteristics that are related to spatial proximity on the landscape, shared ecosystem process (exchanges of nutrients through daily tidal cycles or seasonal flooding regimes), similarity of habitat structural characteristics (herbaceous versus woody vegetation), and some are dominated by human land use practices (managed wetlands or agricultural lands). For example, tidal freshwater emergent wetland, tidal mudflat, and tidal perennial aquatic communities are typically spatially contiguous along a tidal elevation gradient and are linked through ecosystem processes such as energy and nutrient flows. Another example is the spatial distribution of grassland, alkali seasonal wetland complex, and vernal pool complex communities that, within the Plan Area, are typically intermingled with each other to the extent that these communities form a complex mosaic on the landscape that defines the mapping of each community as discrete land cover units. While grassland in the Plan Area can occur in discrete patches that can be mapped, it often occurs intermixed with the alkali seasonal wetland complex and vernal pool complex natural communities. On fine spatial scales, the seasonal wetland communities are embedded as "islands" within a larger matrix of the grassland community, and for the BDCP development those areas were mapped as complexes of communities.

3.2.4.1 Conservation Targets

Conservation targets have been established for the natural communities and the covered wildlife and plant species habitats they support. Conservation targets represent the extent and distribution of habitat to be protected, enhanced, and restored/created to achieve the biological goals and objectives. Under the monitoring program, the effectiveness of habitat enhancement, restoration, and management actions will be assessed and potential adjustments to conservation actions can be identified to maintain or improve habitat functions over time (see Section 3.6, *Monitoring and Research Program*). The habitat conservation targets have been developed to satisfy mitigation requirements associated with the impacts of covered activities on covered species and provide for the conservation of those species.

The conservation targets for natural communities and the covered wildlife and plant species are presented in Table 3-4 and Table 3-5, respectively. The process used to develop conservation targets is presented in Figure 3-9. The information used to develop the conservation targets included the:

- Distribution and extent of each natural community within the Plan Area (Figure3-3 through Figure 3-8);
- Distribution and extent of each covered species' modeled habitat that is located within the Plan Area (Figure 3-14 through Figure 3-51 in Section 3.3.2.4, *Covered Wildlife and Plant Species Goals and Objectives*);
- Primary threats and stressors for each of the covered species (Appendix A, *Covered Species Accounts*);
- Location of habitat areas known to be occupied by each of the covered species (Appendix A, *Covered Species Accounts*);
- The distribution and extent of existing protected patches of each natural community and covered species habitat (Figures 3-3 through 3-8 and 3-14 through 4-51); and
- Potential for increasing connectivity with conserved habitat areas adjacent to the Plan Area (from documents of HCP/NCCPs approved or under development for lands that are adjacent to the Plan Area).

To establish the conservation targets, this information was evaluated for each of the following variables.

- The patch size and connectivity of each natural community with other protected and unprotected natural community patches and connectivity with existing protected natural communities was evaluated. The conservation targets were formulated to include large patches of connected natural communities and not small fragmented patches;
- The extent of modeled habitat for covered species that is supported by each natural community within each of the Conservation Zones was evaluated. The conservation targets were formulated to include natural communities in locations that support modeled habitat for multiple species and exclude areas that support modeled habitat for no or a relatively small number of species, except where patches are important for conserving a particular species;
- The habitat value of patches of natural communities for associated covered species and ability to maintain habitats into the future was evaluated. The conservation targets minimize protecting low value habitats (e.g., patches of grassland on levee slopes) and habitat areas at risk for future loss to natural events (e.g., habitats on subsided lands that may be lost to future levee failures associated with flood and seismic events);

Draft

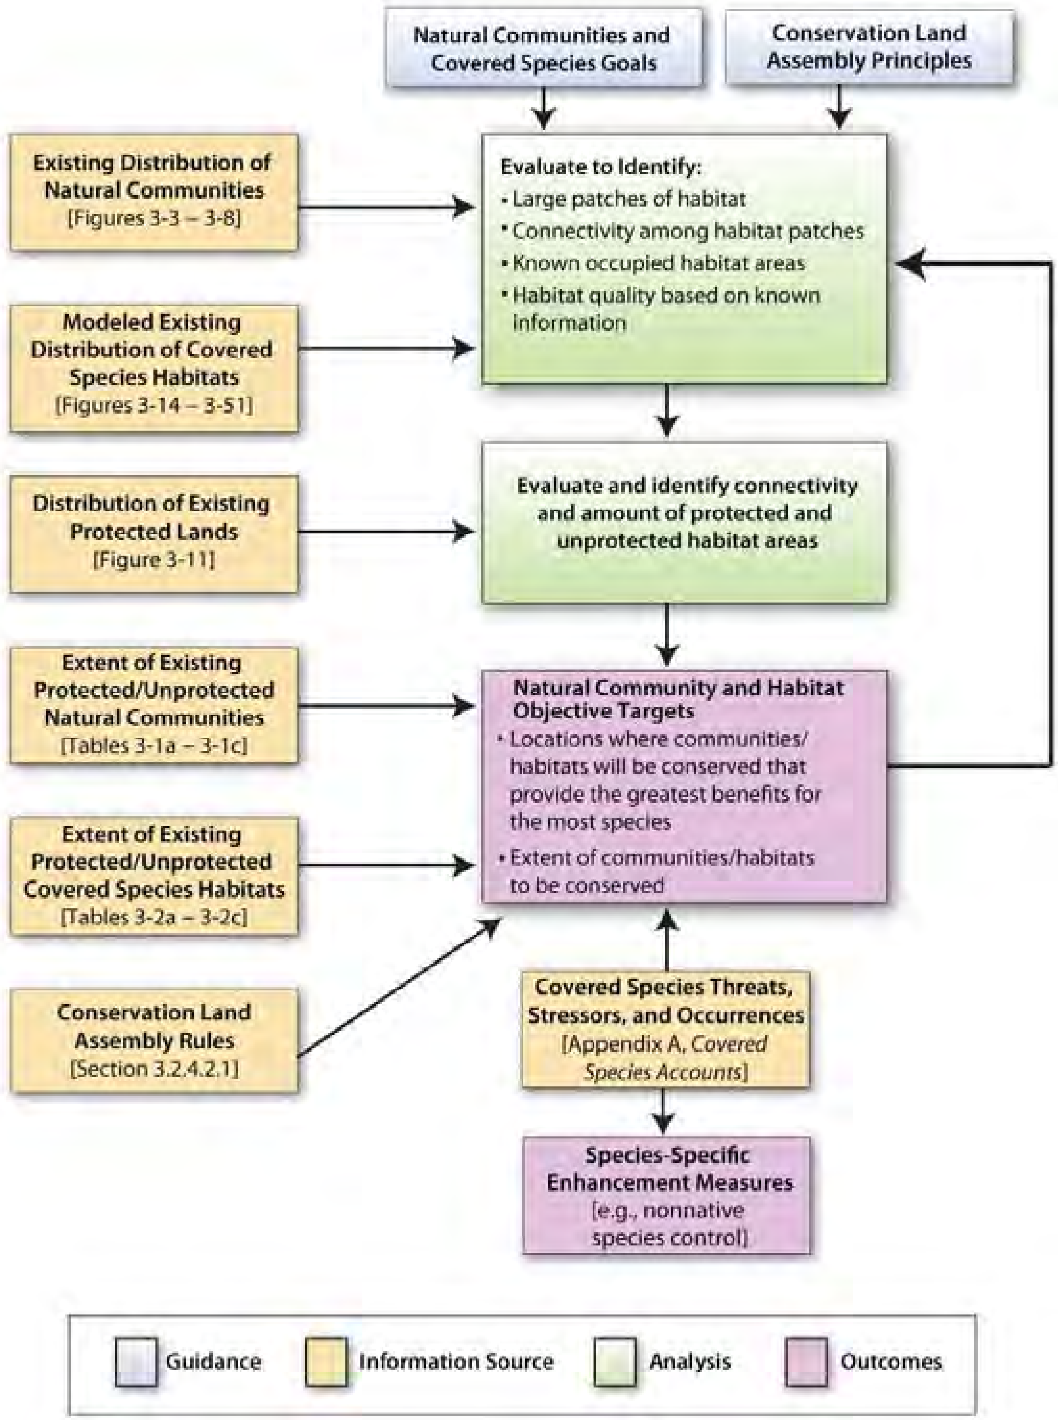

Figure 3-9. Process for Establishing Natural Community and Covered Species Habitat Targets and Species-Specific Measures

- The patch size and connectivity of each covered species' modeled habitat to other patches of modeled protected and unprotected species habitat within the Plan Area and habitat adjacent to the Plan Area was evaluated. The conservation targets were formulated to include large patches of connected modeled habitat for each of the covered species rather than small fragmented patches;
- Location of important known covered wildlife species population centers and covered plant species occurrences was evaluated. The conservation targets were formulated to protect a proportion of these habitat areas such that these populations and occurrences will be conserved;
- Proximity of modeled covered species habitats to known occupied habitats was evaluated. The conservation targets were formulated to protect occupied habitats and unoccupied habitat areas that are connected to known occupied habitat areas such that, with implementation of enhancement measures, unoccupied habitats can be occupied in the future; and
- Based on the evaluation of these variables for each natural community and covered wildlife and plant species, the conservation targets were established such that, once they are achieved, the largest and highest quality patches of natural communities and associated covered species habitats remaining in the Plan Area will be protected. The rationale for how the natural community conservation targets presented in Table 3-4 address the conservation needs for each of the covered species is presented in Section 3.3.2.4, *Covered Wildlife and Plant Species Goals and Objectives*.

Actions that provide for the conservation of the covered species and their habitats include habitat protection, enhancement, restoration, and management. Conservation actions also include targeted species-specific actions, some of which reflect approaches identified in approved recovery plans and approved conservation plans overlap with the Plan Area.

Table 3-4. Natural Community Conservation Targets by Conservation Zone

Natural Community	*Conservation Target (acres)* Restored	Protected/ Enhanced	*Total Conserved Land Base (acres)*	*Applicable Conservation Zones*	*Covered Species Habitats Supported by Conserved Natural Communities*
Tidal	65,000	0	65,000	1, 2, 4, 5, 6, 7, and 11	Chinook salmon (all runs), steelhead, delta smelt, longfin smelt, splittail, salt marsh harvest mouse, Townsend's western big-eared bat, Suisun shrew, tricolored blackbird, Suisun song sparrow, California black rail, California clapper rail, giant garter snake, western pond turtle, Suisun thistle, soft bird's-beak, delta tule pea, Mason's lilaeopsis, delta mudwort, and Suisun marsh aster.
Valley/foothill riparian	5,000	0	5,000	1-9 and/or 11	Chinook salmon (all runs), steelhead, splittail, riparian woodrat, riparian brush rabbit, Townsend's big-eared bat, yellow-breasted chat, white-tailed kite, Swainson's hawk, western pond turtle, and valley elderberry longhorn beetle.
Grassland	2,000	8,000	10,000	1, 8, and 11	San Joaquin kit fox, Townsend's big-eared bat, tricolored blackbird, western burrowing owl, white-tailed kite, Swainson's hawk, giant garter snake, western pond turtle, western spadefoot toad, California red-legged frog, and California tiger salamander.
Nontidal freshwater perennial emergent wetland and nontidal perennial aquatic	400	0	400	2 and 4	Townsend's big-eared bat, tricolored blackbird, giant garter snake, and western pond turtle
Alkali seasonal wetland complex	0	400	400	1, 8, and 11	San Joaquin kit fox, Townsend's big-eared bat, tricolored blackbird, western burrowing owl, white-tailed kite, Swainson's hawk, giant garter snake, western pond turtle, western spadefoot toad, California red-legged frog, and California tiger salamander.
Vernal pool complex	200	300	500	1, 8, and 11	San Joaquin kit fox, Townsend's big-eared bat, tricolored blackbird, western burrowing owl, white-tailed kite, Swainson's hawk, giant garter snake, western pond turtle, western spadefoot toad, and California red-legged frog.
Other natural seasonal wetlands	0	0	0	Not applicable.	None
Inland dune scrub	To be determined.	To be determined.	To be determined.	To be determined.	To be determined.
Agricultural habitats	0	16,620-32,640	16,620-32,640	1-9	San Joaquin kit fox, Townsend's western big-eared bat, Swainson's hawk, tricolored blackbird, greater sandhill crane, western burrowing owl, white-tailed kite, giant garter snake, and western pond turtle.
Total	**Up to 72,600**	**Up to 25,320-41,340**	**Up to 97,920-113,940**		

Table 3-5. Covered Species Habitat Conservation Targets

Covered species	*Conservation Provided by Conservation Zone (CZ)*	
	Preservation/ Enhancement (acres[2])	**Restoration (acres[2])**

[1]Initial estimate prior to the full BDCP effects analysis.

[2]Values above 10 are rounded to the nearest 10 acres.

[3]Suisun Marsh/Upper Yolo Bypass Nest and Migratory Habitat acreage totals have been assumed to be equivalent to Primary Habitat and have been combined with the Primary Habitat acreage totals. For further definition of the Suisun Marsh/Upper Yolo Bypass Nest and Migratory Habitat, refer to Yellow-breasted Chat species account documented within Appendix A, *Covered Species Accounts*.

3.2.4.2 Assembly of Conservation Lands

Conservation lands include all areas of land and water included within BDCP protected, restored, and created natural communities in the Plan Area at full BDCP implementation. Upon full assembly of conservation lands over the term of BDCP implementation coupled with the continued operations of water facilities and management of habitats and other stressors conservation actions, all natural community and species goals and objectives are expected to be achieved. This section provides a discussion of the considerations associated with the assembly of conservation lands and guidance for selecting lands for conservation during implementation of the BDCP. Included are discussions of: (1) conservation land assembly principles; (2) existing protected lands and their relationship to conservation land assembly; (3) conservation actions that may occur outside the Plan Area; and (4) the relationship between other regional conservation planning programs and the BDCP Conservation Strategy.

3.2.4.2.1 Conservation Land Assembly Principles

The following conservation land assembly principles describe considerations used to distribute the conservation of natural communities and covered species habitats among the Conservation Zones to ensure the greatest biological benefits. These assembly principles provide guidance to the BDCP Implementation Office for selecting conservation lands.

1. Protect, enhance, and restore the full ecological diversity of natural communities and covered species habitats at the periphery of the Plan Area on lands most likely to accommodate future sea level rise and less likely to be flooded as a result of levee failures (i.e., terrestrial habitat conservation areas should be located where there is a low risk of future flooding).
2. Maintain a range of contiguous ecological gradients and provide connectivity between estuarine/wetland and upland communities inside and outside the Plan Area.
3. Design reserves to appropriately scale the ecological gradient and emphasize compatibility between restored native communities and working landscapes (e.g., agricultural lands).
4. Design reserves of sufficient size to ensure the intended conservation benefits for the target covered species.
5. Design reserves of sufficient size and configuration to ensure that they can be effectively managed given site constraints.
6. Maximize connections between preserve lands within and outside of the Plan Area.
7. Protect the highest quality natural communities and covered species' habitats available consistent with the BDCP implementation schedule.

The following are important implementation concepts that will be used by the BDCP Implementation Office to guide the design and timing of restoration actions and selection of sites for habitat protection and restoration.

1. During the BDCP near-term implementation period, focus restoration and enhancement of covered fish species habitats in north Delta locations to generate improvements in productivity consistent with continued operations of the south Delta SWP and CVP pumping facilities.
2. Identify restoration areas and design actions to accommodate and to integrate with BDCP water operations (see CM1 Water Facilities and Operation) to optimize primary and secondary productivity, spawning and rearing, and other aquatic functions that support covered species.
3. During the BDCP long-term implementation period, expand the restoration and enhancement of covered fish species habitats to include the Mokelumne and San Joaquin River deltas to provide benefits to covered fish species found in each of those areas.
4. Implement conservation measures for terrestrial and nontidal wetland communities and covered wildlife and plants in a manner that complements, as appropriate, the conservation strategies of approved and developing conservation plans for areas adjacent to and overlapping the Plan Area.
5. Restore habitat in large patches to increase the likelihood of providing the desired levels of ecological function and to support large numbers of covered species.
6. Distribute restored and enhanced habitats throughout the Delta to minimize the risk of loss of habitat benefits to catastrophic events in one part of the Delta.
7. Distribute and design restored habitats to withstand potential changes in Delta conditions associated with future sea level rise and changes in stream hydrographs.
8. Design tidal habitats to withstand effects that could be associated with Delta levee failures.
9. Restore habitat in patch sizes that are equal to or greater than the patch sizes required by the covered species that use the habitat.
10. Juxtapose restored habitats with existing habitats to improve and maintain habitat corridors and connectivity among covered species habitats.
11. Locate and design restored habitats to provide beneficial hydrodynamic effects on adjacent channel systems (e.g., increased tidal flows that may result in decreased bidirectional flow in upstream channels or provide greater mixing in adjacent channels).
12. Locate and design restored habitats to create natural gradients in the Delta that historically transitioned from shallow subtidal aquatic habitats, to riverine floodplain habitats, and to transitional upland habitats (seasonal wetland, riparian, grassland).

13. Design tidal marsh and seasonally inundated floodplain habitats to provide access and egress for covered fish species in a manner that avoids stranding or trapping of fish.

14. Locate and design restored habitats to minimize potential effects of other stressors that could degrade intended covered species benefits (e.g., effects of nearby diversions, discharges of low quality water).

3.2.4.2.2 Existing Protected Lands

An important consideration in the assembly of BDCP conservation lands is the extent and distribution of existing protected lands that conserve natural communities and covered species habitats. The BDCP Protected Lands GIS dataset identifies existing protected lands within the Plan Area. The dataset was compiled from various public sources. Ownership information was collected and organized into attributes which included: County, County Assessor's Parcel Number (APN), Management Level, Management Agency, Alias (if known), Type (type of ownership), and Data Source. Although the boundaries depicted within the data do not represent legal boundaries, they represent the best available information and were considered to be sufficient to guide development of the conservation measures for the system of conservation lands at a landscape level.

The public dataset sources used to generate the BDCP Protected Lands GIS data layer included:

- DFG Lands GIS data layer 2010;
- California Protected Areas Database March 2009;
- Central Valley Farmland Trust 2009;
- Yolo County Assessors Data 2009;
- Yolo County Natural Heritage Program 2009;
- Delta Parcels data created by DWR for SAIC 2008;
- Delta Wetlands Program website 2008;
- DWR ownership layer created for SAIC 2008;
- Sacramento Bee, 2008;
- Wildlife Conservation Board, 2008;
- GreenInfo 2007;
- Solano County Water Agency 2007;
- CaSIL Conservation Lands data layer 2005;
- USGS Oil & Gas Assessment Program 2003; and
- CA Public, Conservation and Trust Lands, v5.2.

The data layer was created by overlaying source data on top of county parcel boundary data. Parcels identified as protected lands via source datasets were then attributed with the appropriate information.

Based on the ownership information derived from the above sources, the data was evaluated and grouped into three primary categories defined as follows.

- **Category 1 protected lands:** Lands that are subject to irrevocable protection against a change in primary land use through local, state, or federal authority and with a primary management goal related to ecological protection.
- **Category 2 protected lands:** Lands that are subject to irrevocable protection against a change in primary land use through local, state, or federal authority with a primary land management goal assessed to be that of open space for mixed use in a manner that maintains ecological value.
- **Category 3 protected lands:** Lands that are subject to irrevocable protection against a change in primary land use through local, state, or federal authority. However, these lands are not managed primarily for ecological protection nor are they managed as open space for mixed use in a way that maintains ecological value.

Properties excluded from consideration included those owned by the Department of Defense and city parks. Figure 3-10 illustrates a decision matrix that was applied to assign protection categories.

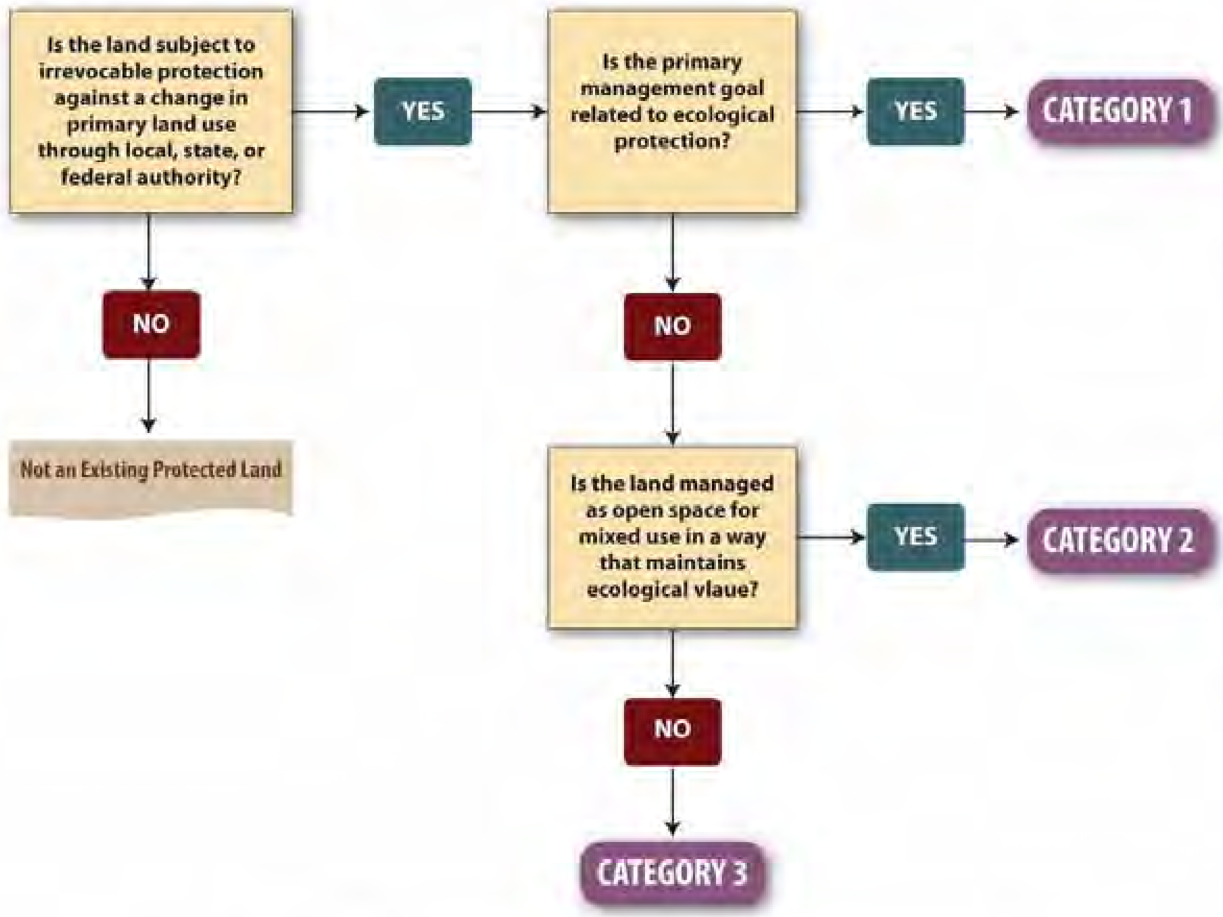
The distribution of existing protected lands by Conservation Zone is presented in Figure 3-11. The extent of each natural community and covered species habitat in each of the Conservation Zones is presented in Table 3-1a-c and Table 3-2-c, respectively.

3.2.4.2.3 Conservation Actions that May Occur Outside the Plan Area

Initially, the Plan Area will encompass the Sacramento-San Joaquin Delta, Suisun Marsh, and the upper Yolo Bypass. However, additional areas may be incorporated into the Plan Area during plan implementation to accommodate conservation actions that advance the biological goals and objectives of the BDCP. Such conservation actions are limited to the preservation and/or restoration of habitat for terrestrial species located within any of the six Delta counties.[10] In particular, BDCP conservation actions will likely be directed to areas that would support both the BDCP Conservation Strategy and regional conservation planning efforts underway in the Delta counties.

[10] The Delta counties are: Sacramento, San Joaquin, Yolo, Solano, Contra Costa, and Alameda.

DRAFT



PROTECTED LANDS	
CATEGORY 1	Land use is protected with a primary management goal related to ecological protection.
CATEGORY 2	Land use is protected with a primary management goal related to maintaining open space for mixed use in a manner that maintains ecological value.
CATEGORY 3	Land use is protected, but not managed as open space for mixed use in a way that maintains ecological value.

Figure 3-10. Decision Matrix for Assigning Protection Status Categories for Compiled Protected Lands Database

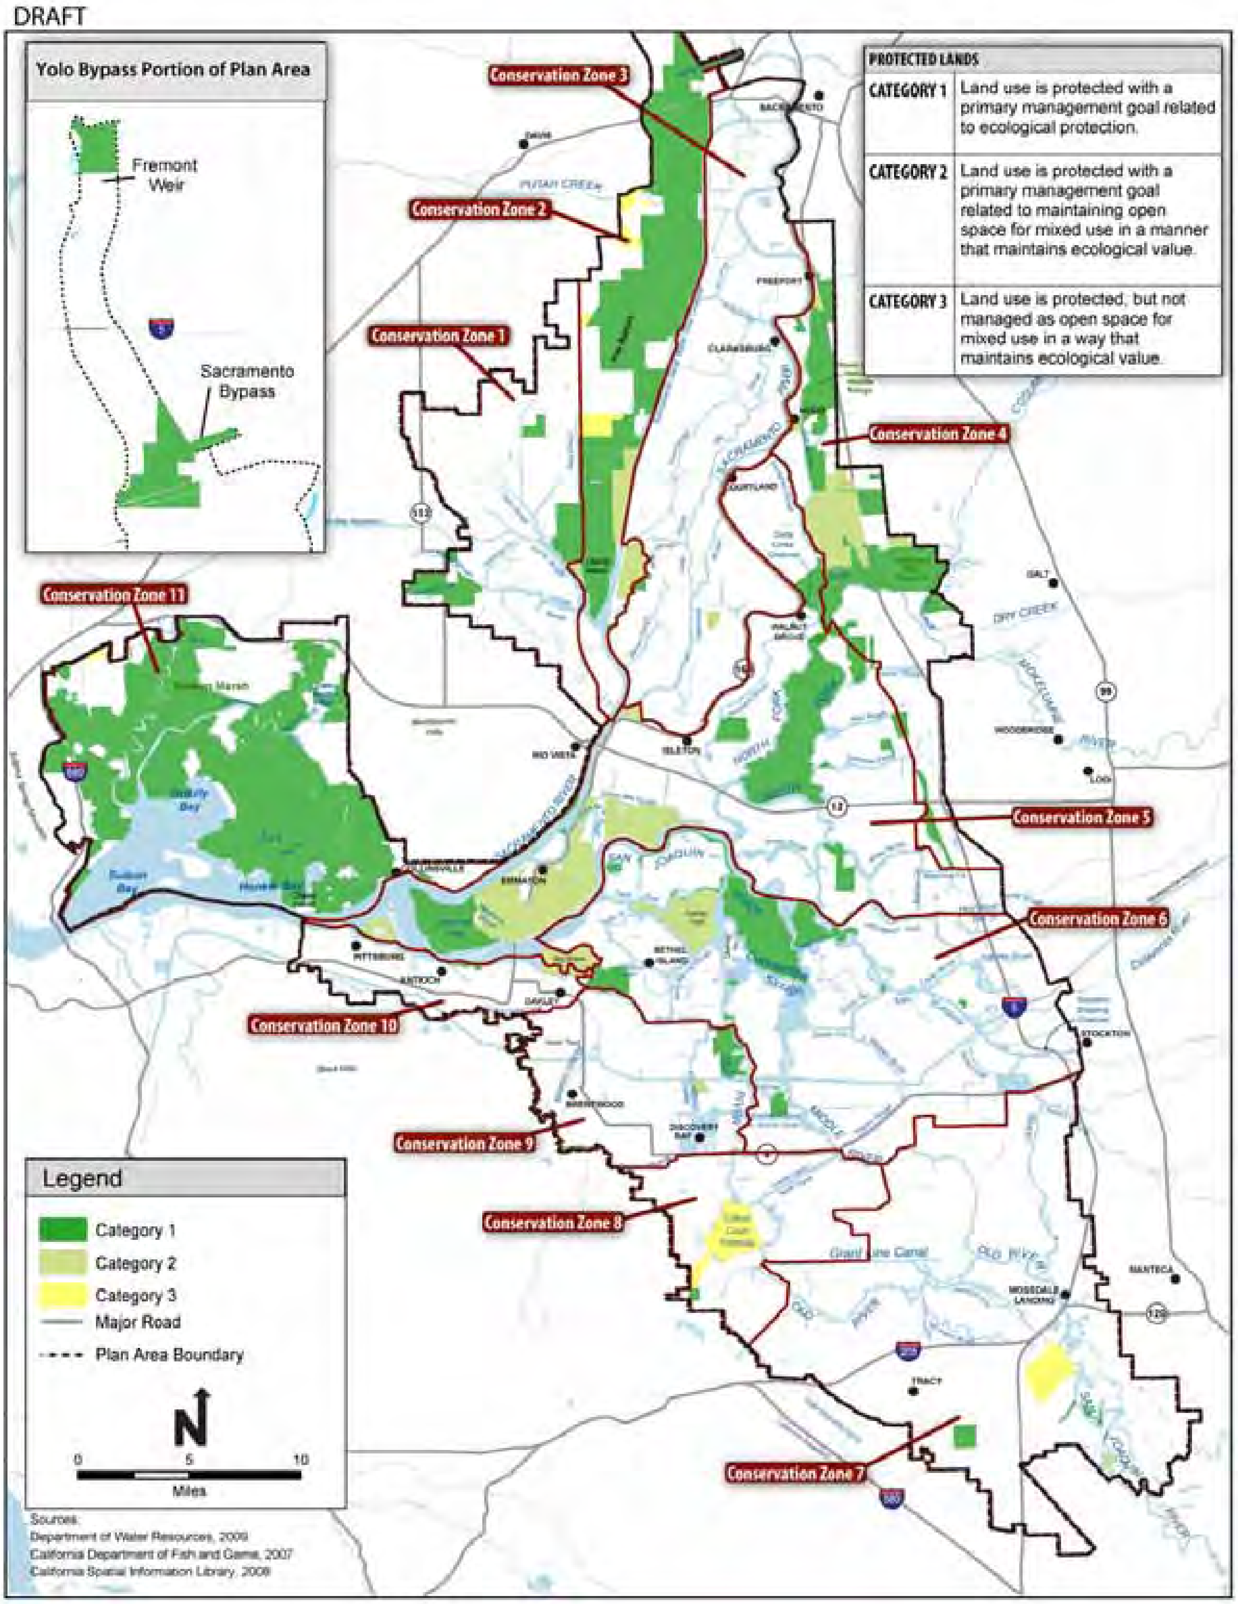


Figure 3-11. Distribution of Protected Lands and Conservation Zones 1-11

•

Most of the habitat for covered wildlife and plant species is found at the margins of the Plan Area or in distinct portions of the Plan Area. For some species, the Plan Area includes only low functioning habitat. The approach to conservation for these species varies reflecting the fragmented distribution of their habitats within the Plan Area, the extent and connectivity of those habitats within and adjacent to the Plan Area, and the distribution and abundance of each of the species. Conservation measures to address species such as giant garter snake, San Joaquin kit fox, and vernal pool invertebrates may more effectively be implemented on lands just outside of the Plan Area in the Delta counties.

3.2.4.2.4 Relationship between other Regional Conservation Planning Programs and the BDCP Conservation Strategy

Several regional conservation plans have been approved in the vicinity of the Delta and others are in the process of being developed. These plans are generally sponsored by local governments and special districts to address the mitigation and conservation needs of terrestrial and wetland wildlife and plant species. The regional conservation plans that overlap with BDCP, listed in rank order of amount of physical overlap, are:

- San Joaquin County HCP (approved);
- East Contra Costa County HCP/NCCP (approved);
- Solano County HCP (in development);
- Yolo County HCP/NCCP (in development);
- Suisun Marsh Habitat Restoration and Management Plan (in development);
- South Sacramento County HCP (in development); and
- East Alameda County Conservation Strategy (in development).

The San Joaquin County HCP has the largest amount of overlap with the BDCP Plan Area with more than 300,000 acres of land in common. The East Alameda County Conservation Strategy has the least amount of overlap with the BDCP Plan Area with less than 5,000 acres of land in common. An additional plan, the approved Natomas Basin HCP in Sacramento County, is adjacent to the Upper Yolo Bypass area that is included in the BDCP Conservation Strategy. Most of the BDCP wildlife and plant covered species are also covered or proposed for coverage by at least one of these other plans (Table 3-6). There are BDCP covered species that occur in surrounding plan areas that are not covered by those plans and species covered in these other plans that are not covered under the BDCP. The geographic and species overlap with surrounding plans provides an opportunity for collaboration and partnership in the implementation of conservation actions common to these plans and the BDCP.

Opportunities exist for joint implementation of conservation actions for covered species and natural communities both inside and outside of the BDCP Plan Area. The BDCP Implementation Office may partner with willing regional conservation planning sponsors to jointly implement conservation actions that complement each plan and provide economies of scale and efficiencies. These partnerships would be guided by the following criteria.

- BDCP is responsible for the mitigation of its impacts; and the mitigation actions and the mitigation requirements of the BDCP must be additive to the mitigation obligations of other plans (i.e., BDCP mitigation cannot supplant the mitigation obligations of other plans); and

Conservation actions implemented by another conservation program within the BDCP Plan Area on behalf of the BDCP could be funded by the BDCP to cover the costs of initial implementation, long-term management, long-term monitoring, and remedial actions.

3.3 BIOLOGICAL GOALS AND OBJECTIVES

This section describes the biological goals and objectives of the BDCP. Biological goals are defined as broad guiding principles for development of the Conservation Strategy that can be parsed into more manageable subsets of biological objectives. These objectives, in turn, provide measurable metrics by which to measure progress in meeting plan goals and help inform the adaptive management process. The BDCP biological goals and objectives are consistent with the guidance provided in the federal Five-Point Policy for Habitat Conservation Plans[15] and with the BDCP Planning Agreement conservation goals and objectives. BDCP biological goals are intended to be broad principles designed to guide the conservation strategy to meet the statutory criteria of the NCCPA and Sections 7 and 10 of the ESA. BDCP objectives may be either habitat or species based, and they are described as specific, measurable objectives.[16] Specific biological goals and objectives set parameters and benchmarks for the development and implementation of BDCP conservation measures and help frame the monitoring and adaptive management programs.

The biological goals and objectives are purposefully framed to reflect and respond to the significant ecological complexity of the Delta and associated scientific uncertainties. They are designed to serve several important functions in the Conservation Strategy. The first is to describe the desired biological outcomes of the Conservation Strategy, and how those outcomes will contribute to the long-term conservation of covered species and their habitats. The second is to serve as important yardsticks by which to measure progress in achieving those outcomes across multiple temporal and spatial scales. A third, closely related function, is to provide the context and framework for the monitoring program and monitoring metrics by which to evaluate the effectiveness of the conservation measures themselves, and to inform the adaptive

[15] See 65 FR No. 106 at 35242 (June 1, 2000)

[16] According to the federal Five Point HCP Policy, "the Services and the applicants must determine the appropriate unit of measure such as numbers of individuals at a particular life stage, all life stages, or quantity or quality of habitat." 65 Fed. Reg. 35242, 35244 (June 1, 2000).

management program through which adjustments to the Conservation Strategy may occur over the course of its implementation.

As is standard practice in conservation planning, these biological goals and objectives are themselves not intended to constitute permit conditions or otherwise serve as required regulatory targets for the permittees/authorized entities. Rather, the purpose of biological goals and objectives is to guide the development and implementation of the conservation strategy. As long as permittees/authorized entities properly implement the Conservation Strategy elements, they will be fulfilling their plan obligations in compliance with their Section 10 and Section 2835 permits.[17]

The ecological complexity of the Delta and the extent of scientific uncertainty associated with this complexity require a conservation strategy that is flexible, testable, and scientifically grounded. A rationale that identifies the general underlying problems is provided with each of the biological goals and objectives statements. The BDCP Conservation Strategy is built on a set of core hypotheses about how to restore the ecological processes and functions necessary to achieve biological goals and objectives over time. Core hypotheses are articulated as problem statements that are associated with each of the conservation measures and are intended to provide an orderly, scientifically-disciplined approach to managing complexity and uncertainty. These core hypotheses will be tested and evaluated, verified or adjusted during BDCP implementation through an adaptive management process. The biological goals and objectives are part of this overall approach. They are designed in a conceptual hierarchy, the components of which are measurable, transparent and verifiable. They are intended to be consistent with the goals and objectives of existing recovery plans and other regional species plans goals that have been established for the covered species, so that implementation of the BDCP contributes to the long-term conservation of covered species and their habitats.

The biological goals and objectives are organized hierarchically on the basis of the following ecological scale:

- **Ecosystem Goals and Objectives.** Ecosystem goals and objectives are focused on the extent, distribution, and connectivity among habitats and improvements to the overall condition of hydrological, physical, chemical, and biological processes in the Plan Area in support of achieving goals and objectives for natural communities and covered species.
- **Natural Community Goals and Objectives.** Natural community goals and objectives are focused on maintaining or enhancing ecological functions and values of natural communities. Achieving natural community goals and objectives also serve to conserve habitat of associated covered species and other native species.
- **Species-Specific Goals and Objectives.** Species-specific goals and objectives address species-specific stressors and habitat needs that are not addressed under the higher order

[17] As the federal fish and wildlife agencies have stated, "[w]hether the HCP is based on prescriptions, results, or both, the permittee's obligation for meeting the biological goals and objectives is proper implementation of the operating conservation program. In other words, under the No Surprises assurances, a permittee is required only to implement the HCP, IA, if any, and terms and conditions of the permit." 65 Fed. Reg. at 35251.

ecosystem and natural community goals and objectives. For covered fish species, goals and objectives may be life stage specific.

These goals and objectives are intended to encompass the ecological functions within the Plan Area that are important for covered species. They thus relate directly to the functions of habitats within the Plan Area that have been designated as "critical habitats" for covered species by the U.S. Fish and Wildlife Service and the National Marine Fisheries Service. Table 3-7 correlates these goals and objectives to the elements of critical habitats within the Plan Area deemed important by both agencies for species proposed to be covered by the BDCP.

Table 3-7. Goals and Objectives that Address Primary Constituent Elements of Critical Habitat Designated for Covered Species

Primary Constituent Element of Critical Habitat	*Goals and Objectives that Address Primary Constituent Elements*	
	Goals	**Objectives**
California tiger salamander critical habitat[7]		
Standing bodies of fresh water (including natural and manmade (e.g., stock)) ponds, vernal pools, and other ephemeral or permanent water bodies which typically support inundation during winter rains and hold water for a minimum of 12 weeks in a year of average rainfall.	VPNC1; VPNC2; ONSW1	VPNC1.1; VPNC2.1; ONSW1.1
Upland habitats adjacent and accessible to and from breeding ponds that contain small mammal burrows or other underground habitat that California tiger salamander depend upon for food, shelter, and protection from the elements and predation.	GRNC1; GRNC2; ONSW1	GRNC1.1; GRNC1.2; GRNC2.2; GRNC2.3; GRNC2.4; ONSW1.1
Accessible upland dispersal habitat between occupied locations that allow for movement between such sites.	GRNC1; GRNC2	GRNC1.1; GRNC1.2; GRNC2.1; GRNC2.2; GRNC2.3; GRNC2.4
Vernal pool tadpole shrimp, Conservancy fairy shrimp, and vernal pool fairy shrimp critical habitat[8]		
Topographic features characterized by mounds and swales, and depressions within a matrix of surrounding uplands that result in complexes of continuously, or intermittently, flowing surface water in the swales connecting the pools described in PCE (ii), providing for dispersal and promoting hydroperiods of adequate length in the pools.	VPNC1; VPNC2; GRNC1	VPNC1.1; VPNC2.1; GRNC1.1; GRNC1.2
Depressional features including isolated vernal pools with underlying restrictive soil layers that become inundated during winter rains and that continuously hold water for a minimum of 41 days (vernal pool tadpole shrimp), 19 days (Conservancy fairy shrimp, and 18 days for vernal pool fairy shrimp (Helm 1998), in all but the driest years; thereby providing adequate water for incubation, maturation, and reproduction. As these features are inundated on a seasonal basis, they do not promote the development of obligate wetland vegetation habitats typical of permanently flooded emergent wetlands.	VPNC1; VPNC2; GRNC1	VPNC1.1; VPNC2.1; GRNC1.1; GRNC1.2
Sources of food, expected to be detritus occurring in the pools, contributed by overland flow from the pools' watershed, or the results of biological processes within the pools themselves, such as single-celled bacteria, algae, and dead organic matter, to provide for feeding.	VPNC1; VPNC2; GRNC1	VPNC1.1; VPNC2.1; VPNC2.2; GRNC1.1; GRNC1.2

Table 3-7. Goals and Objectives that Address Primary Constituent Elements of Critical Habitat Designated for Covered Species (continued)

Primary Constituent Element of Critical Habitat	*Goals and Objectives that Address Primary Constituent Elements*	
	Goals	**Objectives**
Structure within the pools described in PCE (ii), consisting of organic and inorganic materials, such as living and dead plants from plant species adapted to seasonally inundated environments, rocks, and other inorganic debris that may be washed, blown, or otherwise transported into the pools, that provide shelter.	VPNC1; VPNC2; GRNC1	VPNC1.1; VPNC2.1; VPNC2.2; GRNC1.1; GRNC1.2
Suisun thistle[9]		
Persistent emergent, intertidal, estuarine wetland at or above the mean high-water line (as extended directly across any intersecting channels).	BMNC1	BMNC1.1
Open channels that periodically contain moving water with ocean-derived salts in excess of 0.5 percent.	BMNC1	BMNC1.1
Gaps in surrounding vegetation to allow for seed germination and growth.	BMNC1; BMNC2; SUTH1	BMNC1.1; BMNC2.1; SUTH1.2
Soft bird's-beak[9]		
Persistent emergent, intertidal, estuarine wetland at or above the mean high-water line (as extended directly across any intersecting channels).	BMNC1	BMNC1.1
Rarity or absence of plants that naturally die in late spring (winter annuals)	BMNC1; BMNC2	BMNC1.1; BMNC2.1
Partially open spring canopy cover (approximately 790 nMol/m2/s) at ground level, with many small openings to facilitate seedling germination.	BMNC1; BMNC2; SOBB1	BMNC1.1; BMNC2.1; SOBB1.2

[8]From Final Rule, Federal Register, Vol. 72, No. 70, April 12, 2007. pp. 18517-18553.
[9]From Final Rule, Federal Register, Vol. 72, No. 70, April 12, 2007. pp. 18518-18553.

Monitoring metrics and metric values or targets that may be associated with these monitoring metrics accompany objectives and are described in Section 3.6, *Monitoring and Research Program*. The purpose of the metrics and targets is to describe how progress will be measured towards or away from these goals and objectives over the course of BDCP implementation. They are intended to enable the BDCP Implementation Office and other interested parties to track how the implementation of the conservation measures may be effectuating improvements in the system as a whole at the larger scale of these objectives. In some cases, these metrics may be identical to those used to track the effectiveness of individual conservation measures; in other cases, the metrics may be broader than those established for conservation measures.

The metrics for these biological objectives are described in Section 3.6, *Monitoring and Research Program*. These metrics will likely change over the term of the BDCP as new capabilities emerge to track performance in achieving the objectives and as the scientific understanding of the ecological and biological functions of the Bay Delta evolve. They are intended to serve as an essential component of the monitoring and adaptive management program for the Plan, and may be changed through the BDCP adaptive management decision making process (Section 3.7, *Adaptive Management Program*).

3.3.1 Framework for the Goals and Objectives

To address the many uncertainties associated with conserving covered fish species, the aquatic biological goals and objectives were shaped within the framework of the "logic chain" architecture as described in Section 3.2.3.1, *Aquatic Resources Conservation Strategy Development Process*. The logic chain captures the underlying rationale and assumptions for the conservation measures and establishes benchmarks against which progress can be measured. This clear articulation of hypotheses and expected outcomes of implementing the conservation measures facilitates the effective assessment of progress towards achieving the goals and objectives and the effectiveness of the conservation measures during Plan implementation.

Figure 3-12 and Figure 3-13 illustrate these hierarchical relationships between broad, general goals at the species and ecosystem levels, BDCP biological goals and objectives, conservation measures that are designed to achieve the biological goals and objectives (see Section 3.4, *Conservation Measures*), and the monitoring and adaptive management components of the Conservation Strategy (Section 3.6, *Monitoring and Research Program*, and Section 3.7, *Adaptive Management Program*). Figure 3-12 depicts the relationship among the different tiers of the BDCP goals and objectives themselves, and how these tiers tie back into the viability attributes. Figure 3-13 depicts the relationship between overall general species conservation and recovery goals – at the top of the pyramid – and the key substantive components of the BDCP plan itself: the biological goals and objectives for the BDCP, the conservation measures of the BDCP, and the monitoring and adaptive management actions for the BDCP. It also describes the key attributes of long-term species viability in terms of abundance, diversity, spatial distribution and growth rates so as to demonstrate graphically how the BDCP goals and objectives and its conservation measures are intended to contribute to the achieving of these attributes. Together, these two figures are intended to illustrate the tiered conceptual hierarchy both within the BDCP itself and how it will contribute to the larger conservation goals for those species covered by the plan.

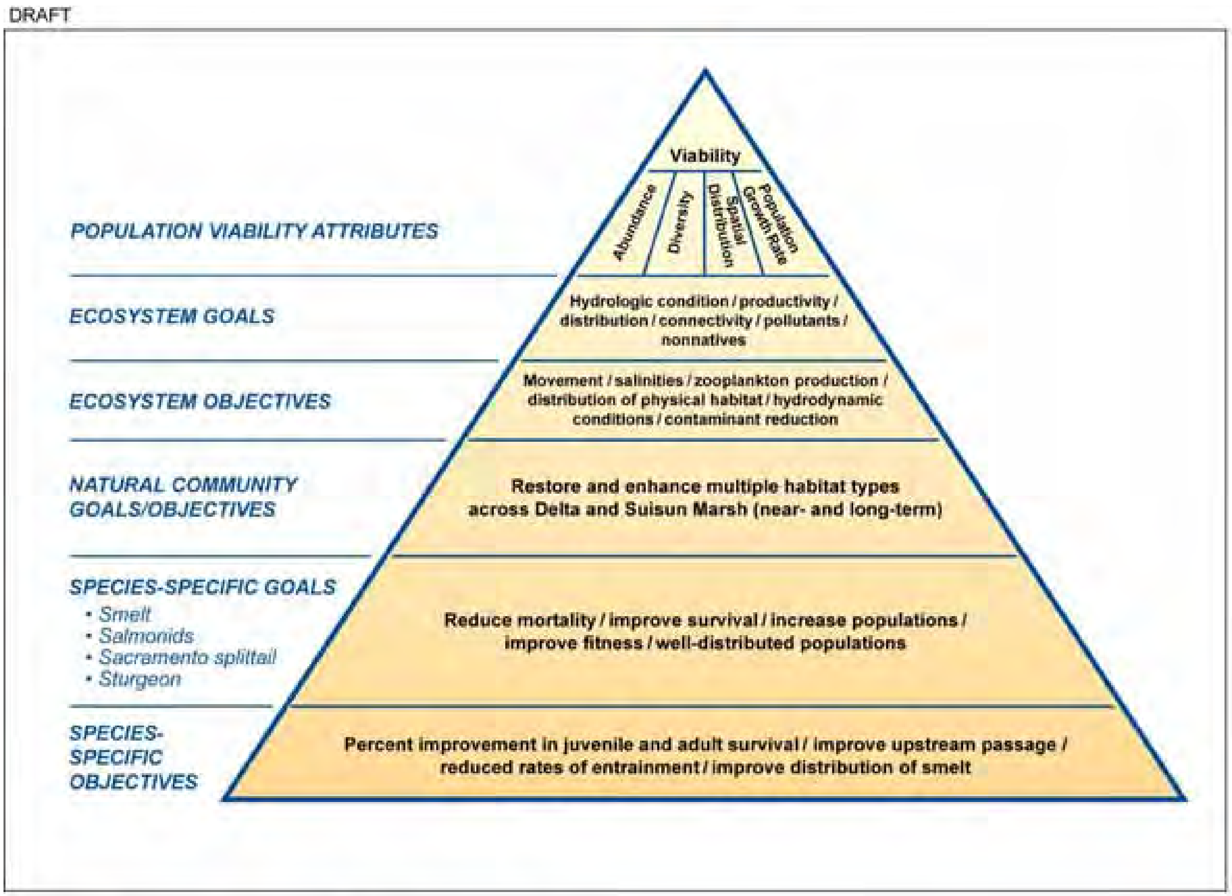

Figure 3-12. Relationships Among Goals and Objectives Tiers

DRAFT

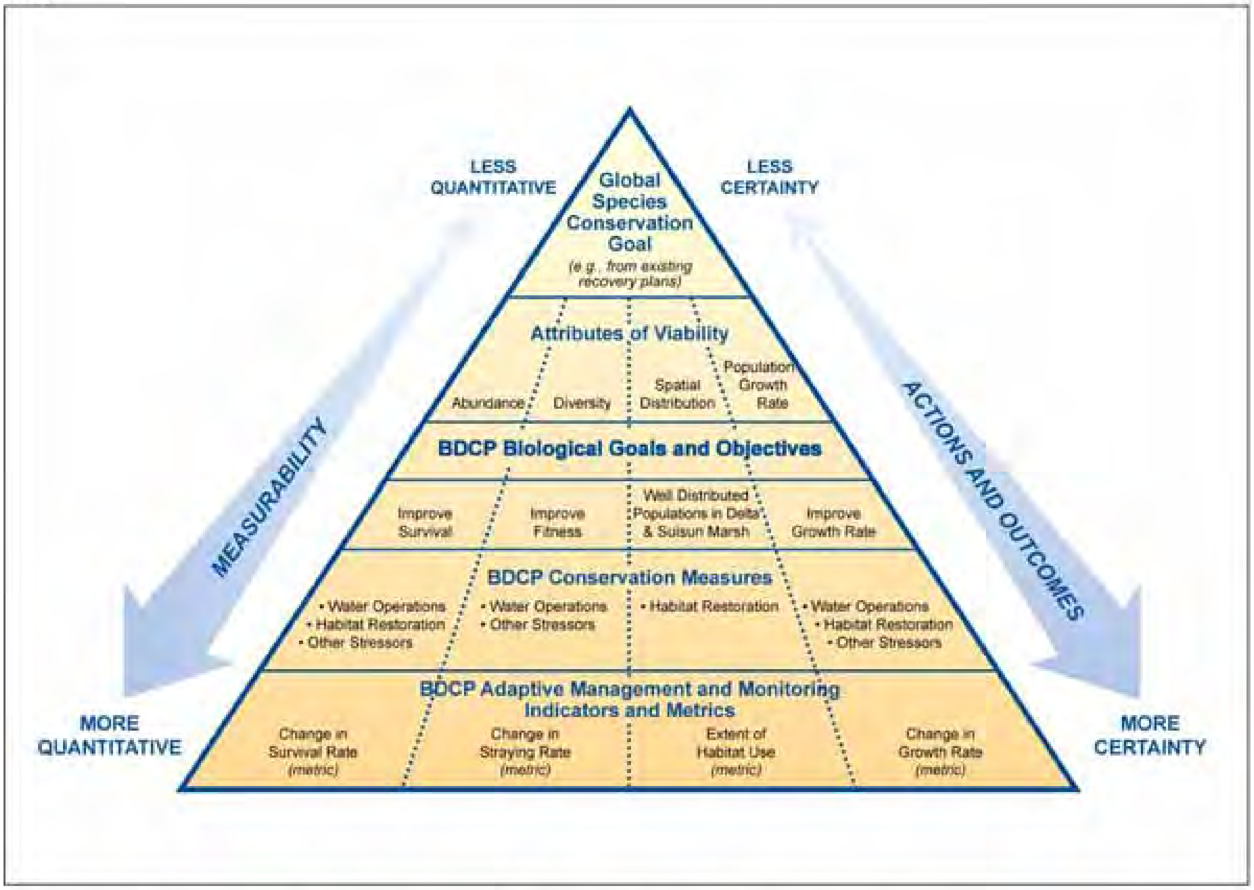

Figure 3-13. Biological Goals and Objectives: Relationships with Broader Goals, Conservation Measures, Adaptive Management, and Monitoring

There is generally greater certainty associated with conservation approaches to covered wildlife and plant species than for covered fish species. The development of goals and objectives for natural communities and covered wildlife and plant species followed a well established approach based on the frameworks used in other HCP/NCCPs and USFWS recovery plans that address the same species and communities. HCP and NCCP programs with plan areas that overlap with the BDCP Plan Area were used as sources of information in developing goals and objectives for the BDCP natural communities and covered wildlife and plants. Based on guidance from and in collaboration with the USFWS and DFG, the biological goals and objectives were developed. The goals and objectives are intended to guide the conservation strategy and meet the statutory criteria for the NCCPA and Sections 7 and 10 of the ESA. Through a collaborative and iterative process, goals and objectives for each covered natural community and covered species were formulated on the basis of specific biological rationale based on the ecological setting, species biology, threats to communities and species, and the potential effects of covered activities. Conservation measures and avoidance and minimization measures were designed to achieve the broad-based goals and the more specific or measureable objectives. The monitoring, research, and adaptive management programs will provide new information and program flexibility to improve the conservation actions to meet goals and objectives during Plan implementation.

3.3.2 Goal and Objective Statements

This section presents the ecosystem, natural community, and species-specific biological goals and objectives. Each goal and objective is assigned a unique alpha-numeric code that is used throughout the BDCP document and that will assist with monitoring of implementation of the BDCP Conservation Strategy. A rationale is associated with each of the biological goals and objectives statements. These rationales identify the general underlying problems that the conservation measures (that are designed to achieve each of the biological objectives) are intended to address.

3.3.2.1 Ecosystem Goals and Objectives

Ecosystem goals and objectives were developed to follow the principles of conservation biology and the requirements of NCCPA. For the covered fish species, the ecosystem goals and objectives are designed to address major stressors of ecosystem processes and functions that support the covered species. These goals and objectives address the hydrodynamic and water quality functions of habitat, movement, and food production for each of the life stages of the covered fish species using the Plan Area, as well as the effects of nonnative predator and competitor species. For the covered wildlife and plant species, these goals and objectives address the desired extent, distribution, connectivity, and ecological function of ecosystems supporting their habitats and life requirements within the BDCP landscape.

3.3.2.1.1 Landscapes and Ecological Gradients

Goal ECSY1: Protect and restore large landscapes representing a range of physical and biological attributes (e.g., hydrology, soil, and plant associations) necessary to sustain viable populations of covered species and to preserve native species biodiversity.

> **Objective ECSY1.1:** Protect 25,000-41,000 acres of existing natural communities that support covered species.

> **Objective ECSY1.2:** Protect a range of environmental gradients (e.g., hydrology, elevation, and soils) across a diversity of natural communities.

> **Objective ECSY1.3:** Restore or create up to 65,000 acres of tidally influenced habitat consisting of subtidal, mudflat, tidal marsh, and transitional upland habitat for sea level rise accommodation that supports a gradient of natural communities and habitat for covered species.

> **Objective ECSY1.4:** Restore or create up to 10,000 acres of seasonally inundated floodplain and 20 miles of channel margin habitat.

> **Objective ECSY1.5:** Manage protected and restored or created habitats to enhance habitat functions for associated covered and other native species over the term of the BDCP.

Goal ECSY2: Provide hydrodynamic conditions within Delta waterways that are more reflective of natural patterns of flow within the BDCP Plan Area and Suisun Marsh.

> **Objective ECSY2.1:** Support the movement of larval and juvenile life stages of native fish species to downstream rearing habitats.

> **Objective ECSY2.2:** Support the movement of adult life stages of native fish species to natal spawning habitats.

> **Objective ECSY 2.3:** Promote water quality conditions within the Delta that help restore native fish habitat.

> **Objective ECSY2.4:** Maintain or increase life history diversity of native fishes and a diversity of rearing conditions for native fishes over time.

> **Objective ECSY 2.5:** Promote greater connectivity between low salinity zone habitats and upstream freshwater habitats, and availability of spawning habitats for native pelagic species.

Rationale

Habitat loss, fragmentation, and degradation within and outside of the Plan Area have disrupted the ecosystem function and large-scale habitat connectivity that are necessary for sustaining covered and other native species and maintaining biodiversity. Protecting and restoring large swaths of connected habitat will enhance ecosystem processes and connectivity and help increase the abundance, distribution, and diversity of covered and other native species.

3.3.2.1.2 Connectivity

Goal ECSY3: Provide for connectivity among protected lands to provide for the movement of native organisms among habitat areas and to facilitate genetic exchange among populations.

> **Objective ECSY3.1:** Protect corridors of habitat that provide linkages among protected habitat areas within and adjacent to the Plan Area.

> **Objective ECSY3.2:** Improve habitat corridors that allow covered and other native species to move into protected habitats from adjacent areas and to move among habitat areas within protected lands.

Rationale

The destruction of habitat for native species has both reduced the extent of habitat and fragmented more extensive areas of habitat into isolated patches of habitat. These impacts to habitat have disrupted the historical movement and dispersal patterns of individuals and their genetics and threaten the health and existence of the species. Maintaining habitat connectivity also makes it more likely that individuals can disperse into and colonize new habitat or territories as those areas become available. Achievement of this goal will benefit all covered and other native species within the Plan Area.

3.3.2.1.3 Ecosystem Processes

Goal ECSY4: Promote ecosystem processes that support natural communities, covered species, other native species, and the habitats of those species.

> **Objective ECSY4.1**: Maintain and improve disturbance regimes and other processes that support functioning natural communities.

Goal ECSY5: Increase aquatic primary and secondary production in the Delta, Yolo Bypass and Suisun Marsh to increase the abundance and availability of food for native aquatic organisms.

> **Objective ECSY5.1:** Over the term of the BDCP, increase the abundance and productivity of zooplankton that provide food and support food production for covered fish species in Delta waterways.

Objective ECSY5.2: Over the term of the BDCP, increase the abundance and productivity of aquatic invertebrate species that provide food and support food production for covered fish species in Delta waterways.

Goal ECSY6: Reduce the adverse predation effects of nonnative species on covered fish species.

Objective ECSY6.1: Manage the distribution and abundance of established nonnative predators in the Delta to reduce predation on native covered fishes.

Objective ECSY6.2: Manage the distribution of covered fish species to minimize movements into high predation risk areas of the Delta.

Rationale

The variability and range of ecosystem characteristics such as disturbance regimes and dynamic ecosystem physical and chemical processes such as tidal and nontidal inundation dynamics, seasonal fluvial flooding and low flow dynamics, and nutrient flows have been drastically altered or eliminated in the Plan Area due to the modification of ecosystem hydrology, the conversion of natural habitat to agricultural systems, residential and commercial development, and other anthropogenic effects. These ecosystem physical and chemical processes drive many biological processes and contribute towards sustaining viable populations of covered and other native species. Maintaining and restoring these ecosystem processes will sustain and increase the extent of natural communities which support the abundance, distribution, and diversity of covered and other native species, which are expected to increase or maintain as described in this Plan. .

3.3.2.1.4 Climate Change

Goal ECSY7: Protect lands with a sufficient range of habitat conditions to accommodate anticipated shifts in the distributions of covered species and natural communities in response to climate change.

Objective ECSY7.1: Protect sufficient upland transitional habitat area adjacent to restored brackish and freshwater tidal emergent wetland to permit the future upslope natural establishment of tidal emergent wetland communities with sea level rise.

Rationale

The effects of climate change on the Plan Area are expected to have far-reaching and potentially dramatic impacts on native species and natural communities. Sea level rise will inundate some subsided and low-lying terrestrial areas, while other effects of climate change are expected to be more complex. For example, changes in temperature range and precipitation patterns may cause some areas of suitable habitat to become unsuitable for some species; while other areas of currently unsuitable habitats may become suitable for other species. Many habitats and species are expected to be affected and their temporal dynamics and spatial distributions will change in unpredictable ways. Faced with such large, uncertain, and dynamic responses, it is important that a broad range of elevation, connectivity, and other habitat characteristics be protected to ensure that while some current habitat may be lost to species due to global climate change, sufficient suitable habitat will remain available to sustain both covered and non-covered species. Achievement of this goal will benefit all covered and other native species within the Plan Area.

3.3.2.2 Natural Community Goals and Objectives

Natural community goals and objectives were developed following the principles of conservation biology and the requirements of the NCCPA. Natural community goals and objectives were developed to address:

- Protecting each natural community in quantities and locations that contribute to the conservation of associated covered and other native species;
- Maintaining and enhancing the habitat functions supported by preserved habitats to provide for sustaining and increasing the abundance and distribution of associated covered and other native species; and
- Restoring or creating natural communities to increase the extent and availability of covered and other native species habitats to accommodate increases in abundance and distribution.

Information used to develop the natural community goals and objectives included:

- Current spatial distribution and extent of each natural community within the Conservation Zones (Figure 3-3 through Figure 3-8);
- Preliminary estimates of the extent of each natural community that could be affected by the implementation of BDCP covered activities and conservation measures;
- Condition of habitat functions supported by existing patches of natural communities;
- Function of existing patches of natural communities as habitat corridors supporting the movement of covered and other native species among habitat areas inside and outside of the Conservation Zones;
- Spatial distribution of patches of natural communities relative to existing preserved areas;
- The spatial distribution of covered species habitats within Conservation Zones and the distribution of known occurrences of covered species; and
- The habitat-related conservation needs of covered and other native species within and adjacent to the Conservation Zones.

Each natural community supports habitat for multiple covered species and multiple natural communities may provide habitat functions for a particular covered species. Table 3-8 describes the habitat functions that are provided by each of the natural communities that primarily support each species in the Plan Area. Table 3-9 identifies all of the natural communities that support habitat for each of the covered species as described in each species' habitat model (see Appendix A, *Covered Species Accounts*). For example, grassland supports foraging habitat for the Swainson's hawk and breeding and foraging habitat for the western burrowing owl. Agricultural lands also support foraging habitat for both of these species. Consequently, conservation of foraging habitat for these species can be accomplished by preserving, enhancing, and/or restoring a specified quantity of either grassland or agricultural land or a combination of both. The strategy for the conservation of natural communities is based on the need to provide a distributed and heterogeneous spatial arrangement of habitat for each covered species.

Natural community goals and objectives are outlined below. The approach and rationale used to establish each objective follows for each natural community. Conservation measures designed to meet all objectives are found in Section 3.4. Table 3-10 presents the expected extent of each natural community that will be protected and restored in the Plan Area with full BDCP implementation.

3.3.2.2.1 Tidal Perennial Aquatic

Tidal perennial aquatic natural community includes both deep and shallow aquatic environments (deep is greater than 10 ft [approximately 3 m] depth from mean lower low tide [lowest of the low tide in a day]; shallow is from mean lower low tide to 10 ft [3 m] depth) (CALFED 2000). Under current water operation conditions in the Plan Area, the tidal perennial aquatic natural community is predominantly fresh water with brackish conditions occurring in Suisun Bay at times of high tides and low river flows.

The tidal perennial aquatic natural community is an important link between upstream and downstream ecosystems. Much of the productivity, organic matter, and inorganic sediment from upstream waterways and marshes eventually moves into the tidal perennial aquatic community and subsequently moves downstream to the Pacific Ocean. In the Plan Area, saline oceanic water mixes with freshwater from rivers in the western region of the tidal perennial aquatic natural community. This mixing establishes a salinity gradient, which varies by area and location with seasonal variations in freshwater outflow and tidal action and which drives the location of species that require specific salinity ranges. Historically, in most seasons, the salinity gradient was generally farther downstream than it now occurs under similar precipitation and unimpaired flow conditions (Contra Costa Water District 2010). See Section 2.3.4.1, *Tidal Perennial Aquatic* in Chapter 2, *Existing Ecological Conditions*, for more detail on the current state of the tidal perennial aquatic natural community.

The historical functions of the tidal perennial aquatic natural community in the Delta have been substantially reduced through the destruction of tidal communities and the loss and fragmentation of aquatic habitats, and the alteration of natural tidal regimes.

[1] Riparian brush rabbits will also use small grassland and seasonal wetlands that occur immediately adjacent to or as openings within riparian communities.

[2] Occurs along the upper margins of vernal pools, playa pools, and in swales in the clay alluvium vernal pools and playas, Montezuma Block vernal pools and playas, and alkaline sink/meadow vernal pools in the BDCP vernal pool complex regions.

[3] Occurs along intermittent and perennial drainages and along the borders of playa pools in the clay alluvium vernal pools and playas, Montezuma Block vernal pools and playas, and alkaline sink/meadow vernal pools in the BDCP vernal pool complex regions. Also occurs in alkali seasonal wetland complex in the same areas.

[4] Occurs in more saline or disturbed areas in the clay alluvium vernal pools and playas, Montezuma Block vernal pools and playas, and alkaline sink/meadow vernal pools in the BDCP vernal pool complex regions. Also occurs in grassland and alkali seasonal wetland complex in the same areas.

[5] Not known to occur in the Plan Area or ROAs.

[6] In the southern San Joaquin Valley it occurs in the scoured and overflow areas of stream channels on alkaline soils. In the northern San Joaquin Valley the historical occurrences have been along tidal river channels or in wetland inclusions in agricultural fields.

[7] Endemic to the Suisun Marsh where it occurs adjacent to first-order channels or mosquito control ditches that link to first-order channels.

[8] In Suisun Marsh soft bird's-beak is distributed in bands at the lower margin of the brackish high marsh that are not correlated with elevation, but with soil pore water salinity during the dry season which is determined by distance to channel and varies from season to season depending on freshwater flows from creeks draining into the marsh. Where the topography is more complex, such as areas with ridges or mounds and on levee banks, soft bird's-beak can be found in a variety of patch shapes.

[9] Delta button celery occurs in two habitat types. One habitat type is seasonally scoured and inundated swales, depressions, and clay flats in the floodplain of the San Joaquin River and the other alkaline clay deltas of Coast Range tributaries that are deposited immediately above the flood basin of the San Joaquin River where plant cover is typical alkaline sink vegetation.

[10] Carquinez goldenbush occurs along seasonal drainages, adjacent to the margins of alkaline playa pools, and in association with vegetation that is transitional between the brackish marsh and the grasslands within the 3.4-4.3 meter NAVD88 elevation band along the eastern border of Suisun Marsh.

[11] Occurrences in open vegetation in freshwater areas are on the landward side of the landward boundary of Tidal Freshwater Emergent Wetland and in brackish water areas in and near Suisun Marsh, within a range of tidal elevations that are generally near drainages.

[12] Occurs in all BDCP vernal pool complex regions on alkaline clays soils in areas that are not deeply inundated.

[13] Occurs on open areas of tidal mudflats that are susceptible to scour and deposition and it colonizes new areas through water transported seed and vegetative parts.

[14] Occurrences in open vegetation in freshwater areas are on the landward side of the landward boundary of Tidal Freshwater Emergent Wetland and in brackish water areas in and near Suisun Marsh, within a range of tidal elevations that are generally near drainages. It is also found in less densely vegetated areas of valley/foothill riparian vegetation.

[1]Tidal mudflats are not delineated within the BDCP land cover type GIS data base, but are subsumed in acreages shown for tidal communities.

[2]Restored tidal habitat acreage ranges are a component of the 65,000 acre target for restored tidal habitat. Acreage ranges are based on the results of hydrodynamic modeling of realistic hypothetical restoration designs. While these ranges are not the acreage targets for restored tidal habitats, but rather the results of modeling, the hypothetical designs provided verification of the practicability of achieving restoration targets.

Tidal Perennial Aquatic Goals and Objectives

Goal TANC1: The expected outcome is tidal perennial aquatic natural community that supports habitats for covered and other native species and that supports aquatic food web processes.

> **Objective TANC1.1**: Restore or create 10,000 to 20,000 acres of tidal perennial aquatic in the BDCP Restoration Opportunity Areas (Conservation Zones 1, 2, 4, 5, 7, and 11) that supports aquatic food production and habitat for covered and other native species.

Goal TANC2: The expected outcome is biologically diverse tidal perennial aquatic natural community that is enhanced for native species and sustained by natural ecological processes.

> **Objective TANC2.1:** Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal perennial aquatic community for covered and other native species over the term of the BDCP.

Rationale for Goals and Objectives

Tidal Perennial Aquatic Natural Community Extent and Connectivity

The tidal perennial aquatic natural community influences the establishment and persistence of other natural communities. As sediment accumulates in this community, the elevation of the surface of the bottom eventually increases to the point that it is shallow enough to be colonized by emergent vegetation, and the colonized areas may become tidal emergent wetland or valley/foothill riparian natural communities.

Native Biodiversity and Tidal Perennial Aquatic Function

Biologically Diverse Tidal Perennial Aquatic. The tidal perennial aquatic natural community is largely unvegetated; however, where vegetation exists, it is either rooted and frequently submerged or unrooted and floating. Submerged aquatic plant species include native water primrose and eel grass. Dense eel grass beds provide habitat for young fish and other aquatic organisms and are an important food source for waterfowl, although their occurrence in the Plan Area is very limited. Invasive submerged nonnative plant species include Brazilian waterweed and Eurasian watermilfoil. Brazilian waterweed grows in dense stands along the margins of channels and across shallow bays and significantly restricts the access of juvenile fish to shallow water habitat. It also provides excellent habitat for nonnative ambush predators, such as bass and sunfish, by reducing water velocity, resulting in lower levels of suspended matter in the water column which increases water clarity and produces better hunting conditions for nonnative ambush predators (Brown and Michniuk 2007).

Native floating aquatic plant species include duckweed and floating water fern, and generally occur as free-floating beds of plants at the surface or suspended in the water column. Because floating aquatic plants are not rooted, wind and water movement determine distribution and density. In contrast to the smaller native species, water hyacinth, an invasive species, grows in dense mats that can greatly reduce primary productivity within the water column (NMFS 2004) and provide habitat for nonnative ambush predators, such as bass and sunfish.

The flow of primary productivity through food webs has been greatly affected by the introduction of nonnative species. The native copepod, *Eurytemora*, is an important food source for delta smelt and larval longfin smelt. For example, after the introduction of the highly efficient filter-feeding overbite clam into the Delta (Kimmerer and Orsi 1996), this native copepod declined in abundance. This has allowed for increased colonization of the Delta by nonnative copepods, *Pseudodiaptomus* and *Limnoithona* which have lower fish foraging efficiency. Introduced clams in the tidal perennial aquatic natural community, the Asian clam and overbite clam, are highly efficient filter feeders that significantly reduce phytoplankton and zooplankton concentrations in the water column, resulting in reduced food availability for native fishes, such as delta smelt and young Chinook salmon (Kimmerer and Orsi 1996, NMFS 2004, Center for Biological Diversity 2007).

The tidal perennial aquatic natural community supports over 50 species of fish, approximately one-half of which are native. It is used as habitat by fish for foraging, spawning, egg incubation and larval development, juvenile nursery areas, and migratory corridors. Most species spend their entire lives in the tidal perennial aquatic natural community while others may spend certain seasons or parts of their lives in habitats outside of the tidal perennial aquatic natural community, depending on the state of physical factors such as salinity, turbidity, dissolved oxygen, flow rates, and water temperature. The tidal perennial aquatic community also supports many wildlife species including some covered species. For example, where this community borders tidal freshwater emergent wetland community and contains structural elements such as woody debris as basking sites, giant garter snake and western pond turtle may occur.

Nonnative fish species that have been introduced into the tidal perennial aquatic natural community include striped bass, largemouth bass, smallmouth bass, bluegill sunfish, threadfin shad, golden shiner, fathead minnow, common carp, brown bullhead, white catfish, yellowfin goby, shimofuri goby, and shokihaze goby. No introduction of a nonnative fish species has clearly caused the extinction of a native fish species in the Bay-Delta (Cohen and Carlton 1995); however, nonnative introductions may have significantly contributed to the decline of some native species due to predation and competition for shared resources. For example, smallmouth bass has been associated with the decline of hardhead, a native minnow found in the Delta; and introductions of several centrarchid species (sunfish and black basses) have been associated with the extirpation of the native Sacramento perch from the Delta.

Species Protection. Resident and migratory fish use the tidal perennial aquatic natural community for purposes of spawning, rearing, foraging, and escape cover (CALFED 2000). Young steelhead and Chinook salmon forage in the tidal perennial aquatic natural community as fry and juveniles to put on critical weight before entering the ocean.

In addition to its value as habitat for fish, the tidal perennial aquatic natural community provides reproduction, feeding, and resting habitat for many species of mammals and birds. The tidal perennial aquatic natural community is used by shorebirds, wading birds, and waterfowl for foraging, resting, and escape cover, including BDCP covered California least tern that feeds on fish in the tidal perennial aquatic natural community.

Restoring 2,100 acres of tidal freshwater emergent wetland, with inclusions of the tidal perennial aquatic natural community, in Conservation Zone 4 will provide habitat for giant garter snake and provide the potential for future expansion and colonization from nearby giant garter snake populations (Badger Creek and Coldani Marsh/White Slough subpopulations) into the Delta. It will also provide additional protected tidal perennial aquatic habitat to facilitate the north-south movement of giant garter snakes between the Coldani Marsh/White Slough subpopulation and Stone Lakes National Wildlife Refuge. Restoring 5,000 acres of tidal freshwater emergent wetland in Conservation Zone 7 will provide additional giant garter snake habitat and facilitate the expansion of existing populations into the South Delta.

Tidal Perennial Aquatic and Climate Change

Warmer water temperatures from future climate change would be detrimental to temperature-dependent native fish species in the tidal perennial aquatic natural community due to alterations of the timing of optimal temperature regimes required for fish spawning, rearing, and migration (Bennett 2005, Lindley et al. 2007). High water temperatures can also cause lethal and sublethal effects on some species of fish and other organisms in the community during specific life stages. Warmer water temperatures may also promote the success of nonnative species, such as centrarchids (e.g., black basses, sunfish) and cyprinids (e.g., carp), that spawn during periods with warmer water temperatures (Moyle 2002).

Climate change is predicted to cause more precipitation to fall as rain instead of snow and cause earlier melting of the snowpack. These changes would lead to greater peak flows during the rainy season and lower flows during the dry season. Knowles and Cayan (2004) predict that inflows will increase by 20 percent from October through February and decrease by 20 percent from March through September. Such changes could affect species in the tidal perennial aquatic natural community by altering environmental cues, such as changes in flows and temperature that trigger the timing of biological events such as migration and spawning. Changes in these cues could lead to confusion in the timing of migration and spawning which could ultimately affect the growth, fecundity, and survival of individuals.

A combination of reduced outflow from the Plan Area during the dry season and a rising sea level would increase the extent of saltwater intrusion into the Plan Area (Knowles and Cayan 2002, 2004) and could shift the low salinity zone farther upstream, which would influence the amount of rearing habitat available to native estuarine species (USFWS 2004). Reduced flow into the Plan Area during summer and fall could also lead to increased residence time, which could exacerbate the high water temperature and low dissolved oxygen problems that already occur in some portions of the Plan Area. Concentrations of toxic substances may also increase during the summer and fall as flow-driven flushing and dilution decrease.

Sea level rise could negatively affect fish species that rely on shallow water habitat by deepening preferred shallow water areas of the Plan Area and changing them to deep water zones. Conversely, sea level rise may create more shallow water and floodplain areas that inundate more readily, thus providing a benefit to species that use floodplains as rearing habitat.

Conservation Measures for Tidal Perennial Aquatic

- CM4 Tidal Habitat Restoration
- CM11 Natural Communities Enhancement and Management

3.3.2.2.2 Tidal Mudflat

Tidal mudflat is an ephemeral, mostly unvegetated habitat that usually occurs as patches in areas of disturbance or sediment deposition associated with various intertidal elevations of tidal brackish and tidal freshwater emergent wetlands, and with the upper elevations of the tidal perennial aquatic natural community. It also occupies sediment depositional areas along natural and artificial levees that are ephemeral microhabitats within the valley/foothill riparian natural community, as well as in specific habitats such as seasonal floodplain and channel margin habitats.

The extent of tidal mudflat within the Plan Area has been substantially reduced with the construction of levees and dikes, the channelization of waterways, and the conversion of tidal marshes to agricultural and other land uses. This reduction in the extent of tidal mudflat has reduced the availability of foraging habitat that supports shorebird migrations along the Pacific Flyway and has reduced the extent of silt substrates at the interface of tidal perennial aquatic and tidal emergent wetland that supports habitat for covered species. See Section 2.3.4.2, *Tidal Mudflat* in Chapter 2, *Existing Ecological Conditions*, for more detail on the current state of this natural community.

An increase in extent of tidal mudflat habitat is expected to occur through the restoration of tidal brackish and freshwater emergent wetland community, valley/foothill riparian community, and channel margin enhancement in areas that respond to the dynamic processes that lead to disturbance or deposition events that produce tidal mudflat. This restoration of tidal mudflat habitat will provide foraging habitat for shorebirds and wading birds and will create patches of suitable habitat for several BDCP covered plant species.

Tidal Mudflat Goals and Objectives

Goal MFNC1: The expected outcome is areas of tidal mudflat that provide foraging habitat for shorebirds and wading birds, and substrates suitable for the natural establishment of BDCP covered plant species.

Objective MFNC1.1: Restore or create 20 linear miles of edge areas within other natural communities that serve as tidal mudflat substrate and which will support habitat for tidal mudflat-associated species as a component of BDCP restored tidal brackish emergent wetland and tidal freshwater emergent wetland natural communities and channel margin enhancement.

Objective MFNC1.2: Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal mudflat as a component of BDCP restored brackish and freshwater tidal habitat and channel margin enhancement for covered and other native species over the term of the BDCP.

Rationale for Goals and Objectives

Tidal Mudflat Natural Community Extent and Connectivity

The tidal mudflat natural community generally occupies a narrow transition zone in the intertidal zone of various natural communities in the Plan Area. Tidal mudflat is ephemeral and is sustained through disturbances to other nearby communities or through the deposition of mineral soil within the intertidal zone. Tidal mudflats are typically located in a transition area near brackish and freshwater tidal emergent wetland. These wetlands experience disturbances to their vegetation via the restoration of natural tidal and salinity regimes in brackish areas and through flow and sediment related disturbances in freshwater areas.

Under the tidal mudflat goals and objectives, 20 linear miles of edge areas within brackish and freshwater tidal emergent wetland that could support tidal mudflat will be restored, and tidal mudflat will be allowed to develop under natural processes. Restoration of the tidal mudflat natural community is expected to occur through the BDCP efforts to restore brackish and freshwater tidal emergent wetland communities and other natural communities. The restoration of larger extents of brackish and freshwater tidal emergent wetland, valley/foothill riparian communities and the restoration of seasonal floodplain and channel margin habitats will provide more extensive and frequent disturbances than currently occur and will support a greater extent of tidal mudflat community. Tidal mudflat is expected to develop along the narrow transition zone between the tidal perennial aquatic natural community and the brackish and freshwater tidal emergent wetland natural communities and in sediment depositional areas along artificial and natural levees within the valley/foothill riparian natural community. For the implementation schedule of tidal habitat restoration, see the BDCP implementation schedule presented in Chapter 6, *Plan Implementation.*

Native Biodiversity and Tidal Mudflat Function

Biologically Diverse Tidal Mudflat. When exposed at low tide, lower elevation tidal mudflats serve as foraging habitat for waterfowl and shorebirds which consume crustaceans, bivalves, gastropods, aquatic insects, and polychaetes that live in tidal mudflats. When covered at high tide, these same areas serve as shallow open water habitat for several BDCP covered pelagic fish species, including splittail, salmonids, and sturgeon. These species use the area as a shallow water refuge from predators and also forage on benthic invertebrates.

Tidal mudflat is expected to develop naturally from the effective management of brackish and freshwater tidal emergent wetland and will not be specifically enhanced or managed. Most of the physical processes that will be designed into the restoration of tidal emergent wetland are expected to evolve naturally and will produce ephemeral patches of tidal mudflat. Some biological processes in tidal marsh habitats may require active management, such as the control of invasive species; however, there is little current knowledge about the effects of invasive species on tidal mudflat habitats. This uncertainty is expected to be resolved through baseline surveys, effectiveness monitoring, and targeted research.

Species Protection. Two BDCP covered plant species, Mason's lilaeopsis and Delta mudwort, can be found on higher elevation tidal mudflat. Mason's lilaeopsis is more abundant in brackish areas, while Delta mudwort is more abundant in freshwater (Golden and Fiedler 1991, Fiedler and Zebell 1993, Zebell and Fiedler 1996, Meisler 2002, Fiedler et al. 2007). The rate of plant colonization and succession on tidal mudflat depends on the supply of propagules and the distance to clonal plants. Restoration of tidal mudflat will also create patches of suitable habitat for BDCP covered plant species Delta tule pea and Suisun Marsh aster.

Tidal Mudflat and Climate Change

It is expected that sea level rise will shift tidal mudflats to higher elevations in areas with a gradual topographic incline. Where steep levee sides occur, the areal extent of tidal mudflats could be diminished as a result of sea level rise. Additionally, tidal mudflat extent is affected by rates of sedimentation and erosion. If sediment deposition does not match sediment export, the extent of tidal mudflats could change; and it is not clear how climate change will affect sediment deposition and export rates. However, implementation of BDCP tidal mudflat goals and objectives can improve the extent, and thus potential resilience, of this natural community in the face of climatic changes.

Conservation Measures for Tidal Mudflat

- CM4 Tidal Habitat Restoration
- CM11 Natural Communities Enhancement and Management

3.3.2.2.3 Tidal Brackish Emergent Wetland

The tidal brackish emergent wetland natural community is a transitional community between the tidal perennial aquatic natural community and terrestrial upland natural communities; it can also exist as isolated patches on islands (e.g., islands within Suisun Bay). In the Plan Area, tidal brackish emergent wetland natural community currently persists at the following locations: Suisun Marsh, the south side of Suisun Bay, and along the shore and on islands in the saltwater/freshwater mixing zone that extends from near Collinsville westward to the Carquinez

Strait. However, despite its large potential extent, most tidal brackish emergent wetland is present in undiked areas of Suisun Marsh, such as Rush Ranch and Hill Slough. Smaller patches also occur along undiked shorelines on the south shore of Suisun Bay, and on undiked in-channel islands such as Brown's Island. See Section 2.3.4.3, *Tidal Brackish Emergent Wetland* in Chapter 2, *Existing Ecological Conditions,* for more detail on the current state of this natural community.

Substantial reductions in the extent, distribution, and condition of the historical tidal brackish emergent wetland natural community in Suisun Marsh have reduced the extent and diversity of tidal brackish emergent wetland for associated covered and other native species. Prior to extensive anthropogenic modifications of Suisun Marsh that included dike building and drainage, the tidal brackish emergent wetland natural community comprised an estimated 69,000 acres of what was the largest tidal brackish water marsh complex in the western United States (Boul and Keeler-Wolf 2008). Today, only 8,351 acres (12 percent) remain; 5102 acres (61 percent) of which is currently under protected status.

Conservation of the tidal brackish emergent wetland natural community will be achieved by increasing the extent and connectivity of the community, by establishing connectivity with other natural communities along an environmental gradient from aquatic to upland areas, by reestablishing ecological conditions and processes that sustain the community, and by enhancing native biodiversity. Tidal brackish emergent wetland restoration will be implemented in Suisun Marsh through the breaching of dikes around unsubsided areas of the marsh and through site-specific contouring to speed the establishment of natural tidal channels. Restoring tidal brackish marsh habitats along an environmental gradient extending from the tidal perennial aquatic natural community to upland natural communities is expected to increase the abundance and distribution of associated native species, improve connectivity among habitat areas within Suisun Marsh and Suisun Bay, provide nutrients and food to adjacent subtidal aquatic habitat, and to contribute to the long-term conservation of tidal brackish marsh-associated covered species.

Tidal Brackish Emergent Wetland Goals and Objectives

Goal BMNC1: The expected outcome is restored large expanses and interconnected patches of tidal brackish emergent wetland natural community.

> **Objective BMNC1.1:** Restore or create 3,600 to 4,800 acres of tidal brackish emergent wetland in the Suisun Marsh ROA (Conservation Zone 11).

Goal BMNC2: The expected outcome is biologically diverse tidal brackish emergent wetland that is enhanced for native species and sustained by natural ecological processes.

> **Objective BMNC2.1:** Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal brackish emergent wetland for covered and other native species over the term of the BDCP.

Rationale for Goals and Objectives

Tidal Brackish Emergent Wetland Natural Community Extent and Connectivity

The conservation of tidal brackish emergent wetland focuses on restoration and management rather than on protection because of the very limited extent of this community compared to historical conditions, and because most of the existing natural community has been protected or is unlikely to be developed. Two of the largest patches of tidal brackish emergent wetland in Conservation Zone 11, Rush Ranch and Hill Slough, are owned by the Department of Fish and Game and are actively managed for their natural resource values. Much of the remaining area of tidal brackish emergent wetland natural community in Conservation Zone 11 is protected from future development under the Suisun Marsh Protection Plan. Areas of this natural community in Conservation Zone 5, although not under formal protection, occur on mid-channel islands that are subject to strong tidal forces, wave action, and are isolated from roadways. These factors render tidal emergent wetlands in Conservation Zone 5 largely unsuitable for development and therefore, protection is not a priority.

Under the tidal habitat restoration goals and objectives, 65,000 acres of tidal habitat will be restored; of which at least 7,000 acres will be in brackish areas of Suisun Marsh. A portion of the restored area (3,600 to 4,800 acres) will be restored tidal brackish emergent wetland natural community. The extent of acres targeted for Suisun Marsh is in part a function of the potential for wetland restoration based on historical and current conditions. Restoration sites will be chosen based on appropriate marsh plain elevations, hydrodynamic conditions, and environmental gradients. Priority for restoration will be given to sites that were former tidal brackish emergent wetland, that fall within intertidal tidal elevations, and that are suitable for creating a gradient from subtidal habitats to upland habitats through the breaching of dikes. Consideration will also be given to sites that will increase connectivity among preserve lands or that will accommodate sea-level rise. Restoration of tidal brackish emergent wetland natural community in Suisun Marsh will increase the extent and connectivity of an already established network of habitat and will improve foraging and/or dispersal dynamics for a variety of wildlife species. The implementation schedule of tidal habitat restoration is described in the BDCP implementation schedule presented in Chapter 6, *Plan Implementation.*

Native Biodiversity and Tidal Brackish Emergent Wetland Function

Biologically Diverse Tidal Brackish Emergent Wetland. Implementation of tidal brackish emergent wetland natural community restoration actions will aid in the recovery of natural tidal fluctuation that is essential to improve the function of the natural community. Restoration of tidal influence affects water accessibility, soil oxygen status, and soil salinity, all of which are critical factors for the wetland vegetation. Endemic plant species located within and near the intertidal area in this community, such as BDCP covered species Suisun thistle, Suisun Marsh aster, and soft bird's-beak, will benefit from the restoration of tidal influence.

The target restoration goal for the tidal brackish emergent wetland natural community includes the relatively brackish channel margin habitat with tall bulrushes, tules, and cattails; the more brackish transition zone with species-rich vegetation containing a diversity of structural habitats; and the marsh plain that is dominated by low stature salt-tolerant species such as pickleweed and saltgrass and may include bare patches of very saline soil.

Directing the restoration of tidal brackish emergent wetland natural community to the Suisun Marsh is expected to provide the greatest possible benefit for BDCP covered aquatic and terrestrial species and for the tidal brackish emergent wetland natural community which the species depend upon for habitat and food web support. Vegetated marsh plains are also expected to filter non-point source pollution from surface runoff or subsurface infiltration that otherwise would flow into Suisun Bay. The potential restoration areas in Suisun Marsh are extensive and interconnected and will allow for the foraging and dispersal dynamics of a wide range of BDCP covered and other native species.

Enhancing and managing the natural community to maintain variation in inundation, composition, and structure will be critical for maintaining the value of tidal brackish emergent wetland as habitat. Natural physical processes will be restored through the design of the restoration sites and natural site evolution will be allowed. In contrast, some biological processes will require active management. For example, both the transition zone and marsh plain are frequently invaded by nonnative species such as perennial pepperweed and fennel in the intertidal zone and annual grasses immediately above the MHHW line. Tall nonnative plant species form dense patches, excluding native species; and some small nonnative annuals, such as barbgrass (*Hainardia cylindrical*) and rabbitsfoot grass (*Polypogon monspeliensis*), impact BDCP covered soft bird's-beak (a hemiparasite) by functioning as ineffective host plants (Grewell 2005). These invasive species significantly degrade the habitat value of this community and will require active management methods to reduce and prevent increases of their cover at levels that will minimize their negative effects on the community. While methods have been developed to reduce the cover of these species in the short term, there are no long term control solutions; and effective management of invasive species will require focused studies to develop those methods.

The tidal brackish emergent wetland community is frequently invaded by nonnative animals such as feral pigs. Pigs can have significant adverse effects on marsh vegetation, especially BDCP covered Suisun thistle (Fiedler et al. 2007, USFWS 2009a). Other nonnative animals that have been shown to significantly reduce populations of BDCP covered salt marsh harvest mouse, California black rail, and California clapper rail (Suisun Ecological Workgroup 2001) include red fox, feral cats, and rats (Brown 2004, Takekawa et al. 2006). Management methods to reduce or eliminate populations of invasive animals will be developed and implemented.

The range of potential restoration sites vary by past disturbance regime and location in Suisun Marsh. Therefore, this community will be enhanced using techniques that are tailored to each specific restoration site. The combination of unknown past effects and variable current condition means that there will be a broad range of uncertainty in implementing the enhancement techniques, frequencies, and intensities of application that will be informed by baseline surveys, effectiveness monitoring, and targeted research studies.

Species Protection. When fully restored, this community will provide habitat for covered terrestrial species, and will provide structure as well as nutrient and energy flows to the aquatic food web that supports covered fish species that rear and spawn in the channels of the marsh. BDCP covered species expected to benefit from tidal brackish emergent wetland restoration include delta smelt, longfin smelt, all runs of Chinook salmon, Central Valley steelhead, salt marsh harvest mouse, Suisun shrew, Suisun song sparrow, California black rail, California clapper rail, white-tailed kite (foraging), western pond turtle, Suisun thistle, soft bird's-beak, Delta tule pea, Suisun Marsh aster, Delta mudwort, and Mason's lilaeopsis. Restoration of tidal brackish emergent wetland will also provide breeding and wintering habitat for a variety of waterfowl, shorebirds, and other waterbirds in an ecologically functioning landscape within the Suisun Marsh complex.

Tidal Brackish Emergent Wetland and Climate Change

The tidal brackish emergent wetland natural community is directly linked to salinity gradients and sea level. Delta wetlands are particularly sensitive to long-term sea level rise associated with global climate change and changes in Delta sediment discharge. In order to be maintained, the tidal brackish emergent wetland natural community must have the ability to accrete sediments at rates high enough to keep its surfaces intertidal (Watson and Byrne 2009). That accretion rate will in turn depend on how changing salinity and inundation duration affect the species composition of the wetland (Culberson et al. 2004, Watson and Byrne 2009).

The potential restoration sites in Suisun Marsh are generally located on unsubsided mineral soils and are adjacent to upland communities so that restoration actions will be efficient and relatively resilient to the effects of global sea level rise. Additionally, a 900-acre area of similar unsubsided mineral soils will be restored just beyond the eastern limit of the brackish water area in Conservation Zone 5, which could function as refugia for species adapted to brackish conditions from the effects of global climate change.

Conservation Measures for Tidal Brackish Emergent Wetland

- CM4 Tidal Habitat Restoration
- CM11 Natural Communities Enhancement and Management

3.3.2.2.4 Tidal Freshwater Emergent Wetland

The tidal freshwater emergent wetland natural community is typically a transitional community between the tidal perennial aquatic natural community and valley/foothill riparian or terrestrial upland communities, such as grasslands and agricultural lands. In the Plan Area, the tidal freshwater emergent wetland natural community occurs across a range of hydrologic and soil conditions, often occurring at the shallow, slow-moving or stagnant edges of freshwater waterways in the intertidal zone. It frequently experiences long duration flooding.

Prior to the 1860s, the tidal freshwater emergent wetland natural community covered an estimated 87 percent of the Delta, with extensive marshes forming dense stands of vegetation bisected by meandering channels (The Bay Institute 1998). Today, the distribution of the tidal freshwater emergent wetland natural community in the Plan Area is limited to narrow fragmented bands or small patches along island levees, in-channel islands, shorelines, sloughs, and shoals. A total of 8,947 acres of this natural community remain within the Plan Area, 4,990 acres (56 percent) of which is currently under protected status.

Channelization, levee-building, agricultural conversion, urban development, removal of vegetation to stabilize levees, and upstream flood control have reduced the extent of the tidal freshwater emergent wetland natural community and altered its ecological function through changes to flooding frequency, inundation, depth, and duration, and the quantity of sediment deposition. These substantial reductions in the extent, distribution, and condition of tidal freshwater marshes that historically covered most of the Delta have reduced the extent and diversity of tidal freshwater habitats for associated covered and other native plant and wildlife species. See Section 2.3.4.4, *Tidal Freshwater Emergent Wetland* in Chapter 2, *Existing Ecological Conditions*, for more detail on the current state of this natural community.

When fully restored, tidal freshwater emergent wetland will support a complex habitat structure composed of bulrushes, tules, cattails, and other emergent marsh species that will provide habitat for covered terrestrial species and provide nutrient and energy flows to the aquatic food web that supports covered fish species that rear in the channels of the marsh.

Tidal Freshwater Emergent Wetland Goals and Objectives

Goal FMNC1: The expected outcome is restored large, interconnected patches of tidal freshwater emergent wetland natural community.

> **Objective FMNC1.1:** Restore or create 13,900 to 21,600 acres of tidal freshwater emergent wetland in the Cache Slough, West Delta, Cosumnes-Mokelumne, and South Delta ROAs (Conservation Zones 1, 2, 4, 5, 6, and 7).

Goal FMNC2: The expected outcome is biologically diverse tidal freshwater emergent wetland that is enhanced for native species and sustained by natural ecological processes.

> **Objective FMNC2.1:** Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal freshwater emergent wetlands for covered and other native species over the term of the BDCP.

Rationale for Goals and Objectives

Tidal Freshwater Emergent Wetland Natural Community Extent and Connectivity

A total of 65,000 acres of tidal habitats will be restored by the BDCP, of which 13,900 to 21,600 acres will be tidal freshwater emergent wetland. Remnant patches of tidal freshwater emergent wetlands can currently be found near the confluence of the Sacramento and San Joaquin rivers, along Cache and Lindsey sloughs and the Yolo Bypass, along the mainstem and several channels of the San Joaquin, Old, and Middle rivers, Dutch Slough, Lost Slough, and near the confluence of the Cosumnes and Mokelumne rivers.

Tidal freshwater emergent wetland restoration will be implemented across a wide geography in the Delta with most of the restored acreage occurring in the Cache Slough area and in the south Delta. Sites will be selected for restoration based on their spatial distribution, extent, location, and configuration of restored tidal habitat, the ability to minimize impacts to existing habitats or infrastructure, the ability to restore appropriate tidal range to a site, the potential for a site to produce and export productivity to sustain aquatic food webs in the river channels, and the potential to accommodate sea-level rise. Priority will be given to sites that will increase connectivity among preserve lands.

The modification of natural Delta hydrology through levees, drainage, and water exports has reduced the extent and diversity of tidal freshwater habitats for associated covered and other native plant and wildlife species. Tidal brackish emergent wetland restoration will be implemented through the breaching of levees around unsubsided areas of the marsh, combined with site specific contouring to speed the establishment of natural tidal channel morphology and sinuosity. Restoring tidal freshwater marsh habitats along an environmental gradient extending from the subtidal perennial aquatic natural community to upland natural communities is expected to increase the abundance and distribution of associated native wildlife and plant species, improve connectivity among habitat areas within the Plan Area, provide nutrients and food to adjacent subtidal perennial aquatic habitat, and contribute to the long-term conservation of tidal freshwater marsh-associated covered species.

Because the tidal freshwater emergent wetland restoration areas are distributed throughout the Delta, there will be extensive site to site variation in physical and biological characteristics. Given this variability, enhancement actions will use techniques that are tailored to each specific restoration site. The inherent variability among potential restoration sites also means that there will likely be a broad range of uncertainty in implementing the restoration and enhancement techniques. Therefore, restoration and enhancement techniques and effective application frequencies and intensities will be informed by baseline surveys, effectiveness monitoring, and targeted research. For the implementation schedule of tidal habitat restoration, see the BDCP implementation schedule presented in Chapter 6, *Plan Implementation.*

Native Biodiversity and Tidal Freshwater Emergent Wetland Function

Biologically Diverse Tidal Freshwater Emergent Wetland. There are 17 plant community alliances (i.e., unique species assemblages) mapped in the Plan Area that fall within the tidal freshwater emergent wetland natural community (Table 2-8) (Sawyer and Keeler-Wolf 1995, Hickson and Keeler-Wolf 2007). In tidal freshwater emergent wetlands, tules, cattails, and willows (*Salix* spp.) dominate the vegetation along the Sacramento River; while throughout the San Joaquin River area of the Delta, bulrushes, tules, common reed (*Phragmites australis*), and willows are more often the dominant species (Atwater 1980, Watson 2006, EDAW 2007, Hickson and Keeler-Wolf 2007, Watson and Byrne 2009). In some areas of the Delta, generally freshwater areas may become brackish during periods of low flows. These potential salinity changes are driven by the incursion of higher salinity oceanic water from Suisun Bay up the Sacramento and San Joaquin rivers and from salinity transported by the San Joaquin River into the Delta. There may also be local sources of salinity in the vicinity of Lindsey and Cache sloughs that might become less diluted by Sacramento River water under periods of low flows, causing a shift to more salt-adapted species.

The vegetation and associated waterways of the tidal freshwater emergent wetland natural community in the Plan Area provide food and cover for numerous species of birds (e.g., waterfowl, shorebirds, wading birds), mammals, reptiles, emergent aquatic insects, and amphibians. Many tidal freshwater emergent wetlands remaining in the Plan Area are highly altered. This has substantially reduced its value as habitat for many plant and wildlife species. However, the remaining tidal freshwater emergent wetlands are essential wintering grounds for migratory birds.

Some species, such as waterfowl and egrets, have adapted to foraging on certain types of Delta cropland that were converted from historical wetland areas (DFG 2005). These and other species are expected to benefit from restoration of ecologically functioning tidal freshwater emergent wetlands. Many fish in the tidal perennial aquatic natural community will also use tidal freshwater emergent wetland habitat when it is inundated. Younger stages (e.g., larvae, fry) of some fish species rear in shallower waters that support the emergent vegetation of the tidal freshwater emergent wetland natural community; and some fish species use the emergent vegetation as refuge from predation and high flows (The Bay Institute 1998).

In tidal freshwater emergent wetlands, emergent vegetation releases organic debris (“drift”) into the waterways, providing nutrients and cover, and forms the base of the aquatic food chain supporting primary consumers such as microorganisms, macroinvertebrates, and insects.. The tidal freshwater emergent wetland natural community also processes influxes of nutrients that find their way into the aquatic system (“nutrient transformation”), thereby contributing further to the aquatic food web.

Enhancing and managing tidal freshwater marsh to maintain variation in tidal inundation, species composition, and vegetation structure will be critical for supporting the value of tidal freshwater marsh as habitat. Natural physical processes will be restored through the careful design and implementation of habitat restoration. As part of the restoration, natural geomorphology will be allowed to develop.

However, some biological process will require active management. For example, the area immediately above MHHW is often invaded by species such as perennial pepperweed and giant reed (*Arundo donax*), and both species grow as dense monocultures which eliminate native plant species in both riparian and tidal wetland habitats. Invasive species significantly degrade the habitat value of this community and only management actions to reduce and limit their cover to low levels will minimize their adverse effects on the community. For example, the giant reed eliminates native plants, resulting in the reduction of food and habitat for a number of native birds, insects, and other wildlife. While methods have been developed to reduce the cover of invasive species in the short-term, there are no long-term control solutions and effective management of invasive species will require an uninterrupted long-term commitment.

The tidal freshwater emergent wetland community has also been invaded by nonnative animals such as cowbirds and feral cats that can have significant negative effects native wildlife. Management methods to reduce or eliminate populations of nonnative animals will be developed and implemented.

Species Protection. When fully restored, this community will provide habitat for covered terrestrial species, as well as structure and nutrient and energy flows to the aquatic food web that supports covered fish species that rear and spawn in the channels of the marsh. The augmented productivity and structural diversity of the restored tidal freshwater emergent wetland will create a diversity of nesting and foraging habitat for California black rail, greater sandhill crane, tricolored blackbird, giant garter snake, western pond turtle, and several species of waterfowl and shorebirds. It will also provide patches of suitable habitat for covered plant species, such as Delta tule pea, Suisun Marsh aster, Delta mudwort, and Mason's lilaeopsis.

Restoring 2,100 acres of tidal freshwater emergent wetland in Conservation Zone 4 will provide habitat for giant garter snake and provide the potential for future expansion and colonization from nearby giant garter snake populations (Badger Creek and Coldani Marsh/White Slough subpopulations). It will also provide additional protected tidal freshwater emergent wetlands to facilitate the north-south movement of giant garter snakes between the Condani Marsh/White Slough subpopulation and Stone Lakes National Wildlife Refuge. Restoring 5,000 acres of tidal freshwater marsh complex in Conservation Zone 7 will provide additional giant garter snake habitat and facilitate expansion of existing populations into the south Delta.

Greater sandhill crane is also expected to benefit from the restoration of 2,100 acres of tidal freshwater marsh complex in Conservation Zone 4 by providing additional roosting, resting, and foraging habitat within the species' primary use area where the tidal range is sufficiently narrow. Restoration of 5,000 acres of tidal freshwater emergent wetland in Conservation Zone 7 will provide suitable roosting and foraging habitat south of the current primary use area and facilitate expansion of the wintering range.

Tidal Freshwater Emergent Wetland and Climate Change

Since it is intertidal, the tidal freshwater emergent wetland natural community is directly affected by sea level and will be particularly sensitive to the predicted long-term sea level rise associated with global climate change (Nicholls et al. 1999). To persist in the face of rising sea levels the tidal freshwater emergent wetland natural community will have to maintain a maximum MLLW inundation depth of -35 cm by shifting its distribution upslope where it can or by accumulating mineral and organic sediment at a rate that will match that of sea level rise. The upslope shift will also shift tidal freshwater emergent wetland vegetation farther upstream as the tidal area migrates upstream.

Much of the area occupied by tidal freshwater emergent wetland is along armored levees; therefore, the relocation of the intertidal zone would be primarily vertical to the extent that the levees remain above sea level. In areas where sedimentation rates do not match sea level rise or where levees in subsided areas are breached or overtopped, there will be a reduction in the extent of tidal freshwater emergent wetland as it is replaced by the tidal perennial aquatic community. The implementation of BDCP tidal freshwater emergent wetland goals and objectives will increase the extent of this natural community and help ensure its persistence through climatic changes.

Conservation Measures for Tidal Freshwater Emergent Wetland

- CM4 Tidal Habitat Restoration
- CM11 Natural Communities Enhancement and Management
- CM13 Nonnative Aquatic Vegetation Control

3.3.2.2.5 Nontidal Freshwater Perennial Emergent Wetland

The nontidal freshwater perennial emergent wetland natural community is composed of permanently saturated wetlands, including meadows, dominated by emergent plant species that cannot tolerate permanent saline or brackish conditions. It generally occurs with and forms the boundary around the nontidal perennial aquatic natural community, and both are embedded in other natural communities (e.g., agricultural, grassland). Conservation of nontidal freshwater perennial emergent wetland will occur primarily in conjunction with the creation and protection of nontidal perennial aquatic natural community (see below under *Nontidal Perennial Aquatic*).

Historically, nontidal emergent wetland occurred primarily in the Yolo, American, and Cosumnes basins and in depressions along the margins of the Plan Area that ponded water long enough to support emergent aquatic vegetation such as tules, bulrushes, cattails, and other native vegetation. This community was among the most ecologically productive in the Delta, providing important nesting, feeding, and cover habitat for many native species, including BDCP covered species.

The extent of nontidal freshwater perennial emergent wetlands in California, including the Delta, has declined dramatically over the past century due to reclamation and conversion of the natural community to other uses, primarily agriculture (Gilmer et al. 1982, The Bay Institute 1998). Substantial reductions in the extent, distribution, and condition of historical nontidal freshwater perennial emergent wetland that resulted from agricultural conversion and the deterioration of natural hydrology has reduced the extent and diversity of freshwater marsh communities for associated covered and other native plant and wildlife species.

Today, nontidal freshwater perennial emergent wetland in the Plan Area is largely an artifact of agricultural practices or sites managed to maintain waterfowl habitat. Additionally, because of habitat loss and substitution, many native species that historically used tidal marsh habitats in the Delta are now dependent on remnant or created patches of nontidal emergent wetlands. See Section 2.3.4.7, *Nontidal Freshwater Perennial Emergent Wetland* in Chapter 2, *Existing Ecological Conditions,* for more detail on the current state of this natural community.

There are currently only 1,134 acres of nontidal freshwater perennial emergent wetland in the Plan Area, and most of it occurs as small fragmented patches along the edges of channels in the nontidal perennial aquatic and valley/foothill riparian natural communities. Approximately 36 percent of this area (408 acres) is already under a protected status. Creating additional freshwater marsh in association with nontidal perennial aquatic habitat in strategic areas; protecting aquatic habitat migration corridors such as canals and drains; and protecting associated upland habitat are expected to maintain or increase the abundance of native associated wildlife and plant species, improve connectivity among habitat areas within and adjacent to the Plan Area, and contribute to the long-term conservation of freshwater marsh-associated covered species.

Nontidal Freshwater Perennial Emergent Wetland Goals and Objectives

Goal NWNC1: The expected outcome is nontidal freshwater perennial emergent wetland natural community that supports habitat for covered and other native species.

> **Objective NWNC1.1**: Create 400 acres of nontidal freshwater marsh (including components of nontidal perennial aquatic and perennial emergent wetland communities) that functions as habitat for the giant garter snake, tricolored blackbird, and western pond turtle within or adjacent to habitat occupied by the Caldoni Marsh/White Slough giant garter snake subpopulation in Conservation Zone 4 and the Yolo/Willow Slough giant garter snake subpopulation in Conservation Zone 2.

Goal NWNC2: The expected outcome is biologically diverse nontidal freshwater perennial emergent wetland communities that are enhanced for native species and sustained by ecological processes.

> **Objective NWNC2.1**: Maintain and enhance the habitat functions of protected and created nontidal freshwater perennial emergent wetlands for covered and other native species over the term of the BDCP.

Rationale for Goals and Objectives

Nontidal Freshwater Perennial Emergent Wetland Natural Community Extent and Connectivity

Conservation of nontidal freshwater perennial emergent wetland will occur through the protection and management of agricultural and grassland landscapes throughout the Plan Area that include remnant patches of nontidal emergent wetland, associated canals and streams, and associated upland habitat. Focused conservation will include the creation of 400 additional acres of nontidal freshwater perennial emergent wetland and associated nontidal perennial aquatic habitat within a larger protected landscape. This approach will focus on the protection and expansion of two existing giant garter snake subpopulation centers.

While nontidal freshwater emergent wetland natural community will be protected throughout much of the Plan Area in coordination with the protection of other natural communities (e.g., agricultural lands, grasslands), the conservation strategy for nontidal freshwater perennial emergent wetland and nontidal perennial aquatic natural communities is focused on restoring these communities in areas where the greatest benefit to covered species can be achieved. The strategy involves protecting, enhancing, and restoring these communities primarily for the benefit of two giant garter snake subpopulation centers: the Caldoni Marsh/White Slough subpopulation in Conservation Zone 4 and the Yolo/Willow Slough subpopulation in Conservation Zone 2.

Emergent marsh and associated open water habitat will be created in association with existing occupied habitats to protect and allow for expansion of these subpopulations. Surrounding agricultural lands will be targeted for acquisition in order to build larger contiguous preserves in these areas that support a network of irrigation canals and other aquatic features in addition to the restored wetland habitats within the agricultural matrix of these two areas. In this way, the protected landscape and restored wetland habitats will provide additional aquatic habitat and protect associated movement corridors and upland habitats for these subpopulations.

As these conservation areas are designed, agricultural parcels will be selected based on their proximity and connectivity to occupied sites and opportunities for restoration and enhancement. Restored habitats will be created with appropriate patch sizes and within the existing agricultural matrix to maximize connectivity and the potential for expansion and dispersal. This approach is designed to protect the existing subpopulation centers and create opportunities for the expansion of these subpopulations.

With targeted conservation of 400 acres of nontidal freshwater perennial emergent wetland and perennial aquatic natural communities under the BDCP, approximately 1,948 acres of the combined communities would be protected, an 18 percent increase in the extent of protected habitat of these types. Additional protection will occur in conjunction with the conservation of other natural communities and through enhancement and management of those natural communities. For the implementation schedule of nontidal marsh restoration, see the BDCP implementation schedule presented in Chapter 6, *Plan Implementation.*

Native Biodiversity and Nontidal Freshwater Perennial Emergent Wetland Function

Biologically Diverse Nontidal Freshwater Perennial Emergent Wetland. All patches of nontidal freshwater perennial emergent wetland natural community mapped in the Plan Area are dominated by broad-leaf cattail (Hickson and Keeler-Wolf 2007). Other plant species frequently found in Plan Area nontidal freshwater perennial emergent wetlands include tules, bulrushes, sedges, rushes, and other emergent plant species.

The nontidal freshwater perennial emergent wetland natural community is among the most productive wildlife habitat in California (DFG 2005) providing primary productivity through its aquatic food web; aquatic habitat for native fish, amphibians, and reptiles; food, cover, and water for mammals, reptiles, amphibians, and birds; and vegetation structure for predator avoidance and nesting of wildlife. Some species, such as BDCP covered giant garter snake, rely on freshwater emergent wetlands for their entire life cycle. The BDCP covered California red-legged frog uses this natural community as breeding habitat; and migrating waterfowl use it as foraging and loafing habitat.

These ecological functions provided by nontidal freshwater perennial emergent wetlands in the Plan Area are limited by habitat fragmentation and small patch sizes. Protection and creation of this natural community will focus on reestablishing these functions within the two giant garter snake preserves and elsewhere on preserved BDCP lands.

Created and protected nontidal freshwater perennial emergent wetland areas will be actively managed to promote high value wetland habitat. These areas will require regular monitoring and periodic manipulation of herbaceous emergent vegetation and possibly floating aquatic vegetation to maintain the appropriate balance of open water and vegetation components that will benefit BDCP covered species. Because the sites occur within agricultural areas, they will require careful management and monitoring of some agricultural practices, such as aerial application of pesticides and fertilizers, water control, and maintenance of buffers. Nonnative centrarchid fish (bass and sunfish) and bullfrog are known predators of giant garter snake and western pond turtle, and their populations may need to be periodically controlled. Additionally, the nontidal freshwater perennial emergent wetland community may be invaded by nonnative animals such as cowbirds and feral cats, as well as nonnative plants, such as ludwigia, that can have adverse effects on native wildlife. Management methods to reduce or eliminate populations of nonnative animals and plants will be developed and implemented.

Species Protection. Agricultural lands surrounding two existing giant garter snake subpopulation centers will be targeted for acquisition in an effort to establish two 1,000-acre preserves to provide for the conservation of giant garter snake and other nontidal freshwater perennial emergent wetland and agriculture-associated covered species. Freshwater marsh creation will occur within the preserves in selected areas, and the marsh will be designed to build off of existing occupied giant garter snake sites to improve connectivity among habitat areas within and adjacent to the Plan Area. Creation and protection of the preserves is also expected to increase the abundance of other covered species, such as western pond turtle and tricolored blackbird and contribute to the long-term conservation of nontidal freshwater perennial emergent wetland-associated covered species.

Nontidal Freshwater Perennial Emergent Wetland and Climate Change

Sea level rise will affect the location, extent, and composition of the nontidal freshwater perennial emergent wetland natural community, in places where the natural community exists at or below current sea level, as a result of increased water elevation, increased saltwater intrusion, and a tidal hydrological regime. Nontidal freshwater perennial emergent wetland locations existing at water's edge will become more deeply immersed or, in the case of overtopped levees, deeply flooded. Flooded depressions in upland areas presumably already support this natural community, and it is not likely that natural processes in these upland areas would replace the area that will be lost closer to sea level. Implementation of BDCP nontidal freshwater perennial emergent wetland goals and objectives will increase the extent of this natural community and associated habitat services, despite potential losses of this natural community resulting from climate change.

Conservation Measures for Nontidal Freshwater Perennial Emergent Wetland

- CM3 Natural Communities Protection
- CM10 Nontidal Marsh Restoration
- CM11 Natural Communities Enhancement and Management

3.3.2.2.6 Nontidal Perennial Aquatic

The nontidal perennial aquatic natural community can be found in association with any terrestrial community and can occur as isolated ponds or as the open water component of nontidal freshwater perennial emergent wetland and valley/foothill riparian communities. Conservation of nontidal perennial aquatic natural community will occur primarily in conjunction with the creation and protection of nontidal freshwater perennial emergent wetland (See above under *Nontidal Freshwater Perennial Emergent Wetland*).

Historically, the nontidal perennial aquatic natural community occurred primarily in the Yolo, American, and Cosumnes basins and in depressions along the margins of the Plan Area that ponded water for sufficient duration and depth to support areas of open water among emergent aquatic vegetation such as tules, bulrushes, cattails, and other native vegetation. This community provided important open water habitat for waterfowl, other water birds, and many other native species.

The distribution and historical functions of the Delta nontidal perennial aquatic community have been substantially reduced from historical conditions through the effects of agricultural conversion and land management practices resulting in the loss of natural hydrology. Today, the nontidal perennial aquatic community in the Plan Area is largely an artifact of agricultural practices or sites managed to maintain waterfowl habitat. Additionally, because of habitat loss and conversion, many native species that historically used tidal marsh habitats in the Delta are now dependent on remnant or created patches of nontidal perennial aquatic habitat. See Section 2.3.4.6, *Nontidal Perennial Aquatic* in Chapter 2, *Existing Ecological Conditions*, for more detail on the current state of this natural community.

There are currently 5,341 acres of the nontidal perennial aquatic natural community in the Plan Area, most of which occurs as small fragmented patches along the edges of channels. Approximately 23 percent of this area (1,239 acres) is already under a protected status. Creating additional nontidal perennial aquatic habitat in association with nontidal freshwater perennial emergent wetland in strategic areas, protecting aquatic habitat migration corridors such as canals and drains, and protecting associated upland habitat are expected to maintain or increase the abundance of native associated wildlife and plant species, improve connectivity among habitat areas within and adjacent to the Plan Area, and contribute to the long-term conservation of nontidal perennial aquatic-associated covered species.

Conservation of nontidal perennial aquatic will occur through the protection and management of agricultural and grassland landscapes throughout the Plan Area that include remnant patches of nontidal emergent wetland, associated canals and streams, and associated upland habitat. Focused conservation will include the creation of 400 additional acres of nontidal freshwater perennial emergent wetland (See Objective NWCN1.1) that includes the emergent wetland and associated nontidal perennial aquatic habitat components within a larger protected landscape. This approach will focus on the protection and expansion of two existing giant garter snake subpopulation centers. Agricultural lands surrounding these subpopulation centers will be targeted for acquisition in an effort to establish two 1,000-acre preserves to provide for the conservation of giant garter snake and other freshwater emergent wetland and agriculture-associated covered species. Nontidal freshwater perennial emergent wetland creation will occur within the preserves in selected areas designed to build off of existing occupied giant garter snake sites and improve connectivity among habitat areas within and adjacent to the Plan Area. Creation and protection of the preserves is also expected to increase the abundance of other covered species, such as western pond turtle and tricolored blackbird and contribute to the long-term conservation of nontidal perennial aquatic-associated covered species.

Nontidal Perennial Aquatic Goals and Objectives

Goal NANC1: The expected outcome is nontidal perennial aquatic communities that support habitat for covered and other native species.

Objective NANC1.1. Restore 400 acres of nontidal marsh as per Objective NWNC1.1

Goal NANC2: The expected outcome is biologically diverse nontidal perennial aquatic communities that are enhanced for native species and sustained by ecological processes.

> **Objective NANC2.1**: Maintain and enhance the habitat functions of protected and created nontidal open water habitats for covered and other native species over the term of the BDCP.

Rationale for Goals and Objectives

Nontidal Perennial Aquatic Natural Community Extent and Connectivity

While the nontidal perennial aquatic natural community will be protected throughout much of the Plan Area in coordination with the protection of other natural communities (e.g., agricultural habitats, grasslands), the conservation strategy for nontidal perennial aquatic and nontidal freshwater perennial emergent wetland natural communities is focused on restoring these communities in areas where the greatest benefit to covered species can be achieved. The strategy involves protecting, enhancing, and restoring these communities primarily for the benefit of two giant garter snake subpopulation centers: the Caldoni Marsh/White Slough subpopulation in Conservation Zone 4 and the Yolo/Willow Slough subpopulation in Conservation Zone 2.

Nontidal freshwater perennial emergent wetland and associated open water habitat will be created in association with existing occupied habitats to protect and allow for expansion of these subpopulations. Surrounding agricultural lands will be targeted for acquisition in order to build larger contiguous preserves in these areas that support a network of irrigation canals and other aquatic features in addition to the restored wetland habitats within the agricultural matrix of these two areas. In this way, the protected landscape and restored wetland habitats will provide additional aquatic habitat and protect associated movement corridors and upland habitats for these subpopulations.

As these conservation areas are designed, agricultural parcels will be selected based on their proximity and connectivity to occupied sites and opportunities for restoration and enhancement. Restored habitats will be created with appropriate patch sizes and within the existing agricultural matrix to maximize connectivity and the potential for expansion and dispersal. This approach is designed to protect existing subpopulation centers and create opportunities for the expansion of these subpopulations.

With the additional conservation of 400 acres of nontidal freshwater perennial emergent wetland and perennial aquatic natural communities under the BDCP, approximately 1,948 acres of the combined communities would be protected, an 18 percent increase in the extent of protected habitat of these types. Protection of giant garter snake upland refuge habitat will be expanded in appropriate areas adjacent to the habitat creation sites. For the implementation schedule of nontidal marsh restoration, see the BDCP implementation schedule presented in Chapter 6, *Plan Implementation.*

Native Biodiversity and Nontidal Perennial Aquatic Function

Biologically Diverse Nontidal Perennial Aquatic. A significant ecosystem function of the nontidal perennial aquatic natural community is primary productivity through its aquatic food web. The nontidal perennial aquatic natural community provides habitat for a variety of species, from single-celled organisms to semi-aquatic mammals. There are non-plant primary producers such as diatoms, desmids, and filamentous green algae that often form the base of the nontidal perennial aquatic food web. Zooplankton (e.g., rotifers, copepods, and cladocerans) also live suspended in the water column, grazing on phytoplankton.

Plant species vary with inundation depth and distance from shore. There are submerged aquatics (e.g., native pondweed and invasive nonnative Brazilian waterweed) and floating aquatics (e.g., native duckweed and invasive nonnative water hyacinth). The submerged portions of these plants provide a substrate for smaller algae and cover for smaller aquatic animals, including fish; however, the invasive Brazilian waterweed, Eurasian watermilfoil, and water hyacinth form thick mats that exclude native vegetation and associated wildlife (SFEI 2003).

A variety of aquatic insects use the nontidal perennial aquatic natural community for their larval stage. Wildlife species that use the nontidal perennial aquatic natural community for resting and foraging include waterfowl, shorebirds, semi-aquatic mammals (e.g., beaver, muskrat, and river otter), piscivorous birds (e.g., bald eagles and osprey), and insectivorous birds and bats that prey on insects that gather over open water. Small ponds of the nontidal perennial aquatic natural community can also serve as brooding habitat for ducks nesting in nearby upland habitats. Some water-dependent species, such as BDCP covered western pond turtle, require adjacent upland, riparian woodlands, or emergent wetlands for cover or nesting habitat.

Species Protection. Created and protected nontidal perennial aquatic habitat will be actively managed to promote high habitat function for giant garter snake and western pond turtle. These areas will require regular monitoring and periodic manipulation of herbaceous emergent vegetation and possibly floating aquatic vegetation to maintain the appropriate balance of open water and vegetative components. Because the sites occur within agricultural areas they will require the careful management and monitoring of some agricultural practices, such as aerial application of pesticides and fertilizers, water control, and maintenance of buffers. Nonnative centracharid fish (bass and sunfish) and bullfrog are known predators of giant garter snake and western pond turtle and their populations may need to be periodically controlled. Additionally, the nontidal perennial aquatic habitat may be invaded by nonnative plants, such as ludwigia, that can have adverse negative effects on native wildlife. Management methods to reduce or eliminate populations of the nonnative animals and plants will be developed and implemented.

While designed specifically to meet the ecological requirements of giant garter snake, restored freshwater marshes will also provide habitat for other aquatic and marsh-associated covered species, such as the western pond turtle and tricolored blackbird.

Nontidal Perennial Aquatic and Climate Change

Sea level rise will affect the location, extent, and composition of the nontidal perennial aquatic natural community, in places where the natural community exists at or below current sea level, as a result of increased water elevation, increased saltwater intrusion, and a tidal hydrological regime. Flooded depressions in upland areas presumably already support this natural community, and it is not likely that natural processes in these upland areas would replace the area that will be lost closer to sea level. Implementation of BDCP nontidal perennial aquatic goals and objectives will increase the extent of the natural community and associated habitat services, despite potential losses of this natural community resulting from climate change.

Conservation Measures

- CM3 Natural Communities Protection
- CM10 Nontidal Marsh Restoration
- CM11 Natural Communities Enhancement and Management

3.3.2.2.7 Valley/Foothill Riparian

Valley/foothill riparian natural community historically occurred above the tidal zone along the margins of the Delta, except in the Cache Slough area and eastern Contra Costa County, on the eastern margin of the Yolo Basin, and along channels and sloughs of the Sacramento and San Joaquin rivers. Since reclamation and levee construction began under the Swamp and Overflow Land Act of 1850, substantial reductions in the extent, distribution, and condition of valley/foothill riparian communities from agricultural conversion, stream channelization, and urbanization have reduced the extent and diversity of valley/foothill riparian natural community for associated covered and other native plant and wildlife species.

Currently, the valley/foothill riparian natural community represents less than 4 percent of the total acreage in the Plan Area. In general, riparian communities do not occur in large patches as do other vegetation types. Instead, they tend to be distributed across the landscape as narrow corridors along watercourses or as isolated remnant patches near watercourses. The majority of the valley/foothill riparian natural community occurs as blackberry scrub, or willow/blackberry scrub with occasional patches of cottonwood, willow and oak trees. The largest patches are associated with levee blowouts on Delta Islands that lead to the establishment of isolated patches of willow scrub.

The main riparian corridors in the Plan Area are found along the San Joaquin, Sacramento, Old, Middle, and Mokelumne rivers, with the Sacramento River currently supporting the smallest extent of valley/foothill riparian natural community due to extensive engineered levees. Some smaller drainages, such as Putah Creek and Elk Slough, retain relatively continuous but narrow corridors of riparian woodland. These remnant riparian communities, while highly degraded relative to their historical occurrence, continue to provide habitat for several BDCP covered species, including riparian brush rabbit, Swainson's hawk, white-tailed kite, yellow-breasted chat, yellow-billed cuckoo, and valley elderberry longhorn beetle.

Valley/foothill riparian natural community currently covers a total of 17,338 acres in the Plan Area. Most of this acreage is distributed among Conservation Zones 2 through 7, with smaller amounts in the other 5 conservation zones. In Conservation Zones 2 and 4, most of the acreage of existing valley/foothill riparian natural community is already protected. In Conservation Zone 3, however, less than 1 percent of the total 2,080 acres of valley/foothill riparian natural community is currently protected. Of the total 17,338 acres of valley/foothill riparian natural community existing in the Plan Area, 5,339 acres (30.8 percent) are under protected status. See Section 2.3.4.5, *Valley/Foothill Riparian* in Chapter 2, *Existing Ecological Conditions*, for more detail on the current state of this natural community.

Conservation of valley/foothill riparian natural community will be achieved through the restoration of 5,000 acres of riparian forest and scrub in Conservation Zones 1, 2, 4, 5, 7, and/or 11. Riparian habitat will be restored in conjunction with tidal habitat, floodplain habitat, and channel margin restoration activities and through directed planting to restore habitat specifically for riparian brush rabbit.

Riparian Natural Community Goals and Objectives

Goal VRNC1: The expected outcome is restored large expanses and interconnected corridors of valley/foothill riparian natural community.

> **Objective VRNC1.1**: Restore or create 5,000 acres of valley/foothill riparian in Conservation Zones 1, 2, 4, 5, 6, 7, and/or 11.

Goal VRNC2: The expected outcome is biologically diverse valley/foothill riparian natural community that supports native species and is sustained by natural ecological processes.

> **Objective VRNC2.1**: Maintain and enhance the habitat and ecosystem functions of BDCP restored valley/foothill riparian and patches of riparian forest and scrub present on BDCP preserved lands over the term of the BDCP.

> **Objective VRNC2.2**: Establish seasonal buffers around riparian habitats occupied by covered species to minimize disturbance during the breeding season.

> **Objective VRNC2.3**: Restore connectivity of valley/foothill riparian corridors along linear watercourses to enhance habitat for covered species and facilitate wildlife movement.

Rationale for Goals and Objectives

Riparian Natural Community Extent and Connectivity

Restoration of valley/foothill riparian natural community will occur in restored floodplains and along main channels. This is expected to establish a more natural ecological gradient extending from shallow subtidal aquatic to upland transitional habitats. Along with BDCP conservation of other natural communities, valley/foothill riparian restoration will increase the abundance and distribution of associated native wildlife and plant species; improve connectivity among habitat areas within and adjacent to the Plan Area; improve genetic interchange among native riparian-associated species' populations; provide nutrients and food to adjacent aquatic habitats; and contribute to the long-term conservation of riparian-associated BDCP covered species.

Priority for restoration will be given to sites that provide a range of environmental gradients; increase connectivity between preserve lands; and provide additional habitat for species with currently very limited distributions. Under the goals and objectives for valley/foothill riparian natural communities, 5,000 acres will be restored with the aim of providing a full range of seral stages. Riparian restoration will be conducted in association with the restoration of tidal and nontidal wetlands, seasonally inundated floodplains, and channel margin enhancement, reestablishing a greater degree of hydrological connectivity with riparian areas, naturally promoting the regeneration and establishment of native plants, including willow-dominated scrub.

Most of the riparian restoration in the Plan Area will be in restored seasonally inundated floodplain habitat and associated with tidal restoration in Conservation Zone 7, where currently only 4.5 percent is under protected status. Restoration will also be implemented in Conservation Zones 1-6 associated with tidal habitat restoration and channel margin enhancement. On restored floodplains, restoration will be in large patches (typically over 100 acres) while restoration associated with tidal habitat and channel margins will be mostly long and narrow patches. Following restoration and other BDCP actions, the amount of valley/foothill riparian natural community in the Plan Area under protected status will be increased by 80 percent. For the implementation schedule of valley/foothill restoration, see the BDCP implementation schedule presented in Chapter 6, *Plan Implementation.*

Native Biodiversity and Valley/Foothill Riparian Function

Biologically Diverse Riparian Communities. Under a regime of natural disturbances, primarily flooding, riparian natural communities tend to vary widely in terms of both vegetation composition and structure. For example, willow thickets and mature riparian gallery forests represent riparian communities at different seral stages. Obligate and facultative riparian species may use all or only a subset of riparian communities. For example, least Bell's vireo is more likely to occur in willow-dominated riparian; yellow-breasted chat is more likely to occur in dense riparian scrub with a relatively sparse overstory; and yellow-billed cuckoo is more likely to occur in a relatively dense cottonwood/willow forest. To meet the ecological requirements of riparian-associated covered species, habitat management activities will focus on maintaining the full range of riparian communities and processes that support those communities. Existing riparian natural communities protected in BDCP conservation lands are expected to be somewhat degraded due to past or current land use practices and the spread of nonnative plants. Riparian communities will be enhanced using techniques tailored to vegetation type and site. Enhancement techniques and frequencies and intensities of application will be informed by baseline surveys, effectiveness monitoring, and targeted studies. Techniques that could be used to enhance riparian communities include but are not limited to cattle exclusion, selective application of herbicides, mowing, mechanical removal, and supplemental seeding of natives. Enhancing riparian communities within the BDCP conservation lands will likely require applying a number of these management techniques simultaneously at different sites.

Riparian passerine birds including least Bell's vireo have been adversely affected by habitat loss and cowbird parasitism. Management of riparian natural communities will address the impact of cowbird parasitism, based on site-specific conservation objectives, the documented extent of parasitism, and its impacts on the locally-occurring native species. Management of cowbird parasitism may involve cowbird trapping as appropriate.

Species Protection. Riparian restoration will create additional habitat and potential for local range expansion of several species including riparian woodrat, riparian brush rabbit, Townsend's big-eared bat (roosting and foraging), yellow-breasted chat, least Bell's vireo, western yellow-billed cuckoo, Swainson's hawk (nesting), white-tailed kite (nesting), western pond turtle, valley elderberry longhorn beetle, slough thistle, Delta button-celery, Suisun Marsh aster, and side-flowering skullcap, delta smelt, all runs of Chinook salmon, and Central Valley steelhead.

Several of the covered terrestrial wildlife species are riparian obligate birds and mammals. This is true of the riparian woodrat and the riparian brush rabbit among mammals, and the yellow-breasted chat, yellow-billed cuckoo, and least Bell's vireo among birds. Other terrestrial wildlife species use riparian natural communities extensively. Swainson's hawk and white-tailed kite forage in open country, but nest in tall trees, often in patches of riparian forest.

For all of the BDCP covered species listed above, as well as numerous other native riparian species, population declines and/or range contractions have been linked mainly or exclusively to loss of riparian habitat. The restoration of 5,000 acres of riparian natural communities in the Plan Area represents an important, positive development toward the conservation of all those species. Crucial to the conservation of the riparian woodrat and the riparian brush rabbit in particular is habitat restoration and management in Conservation Zone 7, where most of the riparian restoration will be implemented with most of it in large patches.

Restoration and protection of riparian natural communities with connectivity between them will provide an opportunity for some species to recolonize some of their historical distribution. These riparian corridors will also provide important connectivity for wildlife movement among various other natural communities within and adjacent to the Plan Area.

Riparian and Climate Change

Future climate change can affect the valley/foothill riparian natural community in a number of ways. Increased variability in precipitation will change the timing, duration, and magnitude of Delta inflows, resulting in more intense winter flooding and greater erosion of riparian habitats (Field et al. 1999, Hayhoe et al. 2004). Increased variability in precipitation can also produce prolonged droughts, making riparian vegetation more prone to fires.

A rise in sea level can affect the valley/foothill riparian natural community through increased water elevation and increased salt water intrusion. As water levels rise, riparian vegetation at the water's edge will become more frequently flooded, causing species intolerant of longer inundation periods to migrate upslope if suitable habitat is present. Changes in channel water salinity may also cause species shifts. Implementation of BDCP valley/foothill riparian goals and objectives can improve the extent, and thus potential resilience, of this natural community in the face of climate change.

Conservation Measures for Valley-Foothill Riparian

- CM3 Natural Communities Protection
- CM4 Tidal Habitat Restoration
- CM5 Seasonally Inundated Floodplain Restoration
- CM6 Channel Margin Habitat Enhancement
- CM7 Riparian Habitat Restoration
- CM11 Natural Communities Enhancement and Management

3.3.2.2.8 Grassland

Although California native grassland originally covered one-quarter of the land mass of the state (Barbour et al. 2007, Stromberg 2010), it has recently been identified as one of the twenty most endangered ecosystems in the United States (Noss et al. 1995). Once occurring in the Central Valley as widespread, species-rich prairies (Keeler-Wolf et al. 2007) with a high density of perennial grasses, valley grasslands today are highly-fragmented and dominated by nonnative annual grasses and other species. In the Plan Area, valley grassland comprises one of the two most common natural or seminatural vegetation communities, occupying approximately one-fourth of non-cultivated lands.

Direct and indirect anthropogenic influences on this landscape have resulted in the reduction, conversion, and fragmentation of valley grassland. These changes in turn have led to diminished ecological conditions necessary to sustain a well-functioning grassland natural community. Degradation of grassland quality and quantity has contributed to almost complete conversion of the vegetation community from perennial to annual grasses in less than two centuries.

Many native grassland species have been reduced in abundance or distribution through these processes. However, native plant species remain rich in number, persisting and coexisting with nonnative plants in traditional locations within remaining grasslands. Some animal species have also adjusted well to the new type of grassland. Thus, the current grassland community still offers highly valuable habitats to many grassland dependent species. See Section 2.3.4.12, *Grassland* in Chapter 2, *Existing Ecological Conditions*, for more detail on the current state of this natural community.

Conservation of grassland has three general intentions: increase grassland extent and connectivity to improve habitat quantity; recover native biodiversity at every level; and restore ecological functions necessary to sustain this natural community.

Grassland Goals and Objectives

Goal GRNC1: The expected outcome is grassland comprised of large interconnected patches or contiguous expanses.

> **Objective GRNC1.1**: Protect a minimum of 8,000 acres of grassland in Conservation Zones 1, 8, and 11. At least 1,000 acres will be protected in Conservation Zone 8, with the remainder distributed throughout these three Conservation Zones.

> **Objective GRNC1.2**: Restore 2,000 acres of grassland to connect fragmented patches of protected grassland.

Goal GRNC2: The expected outcome is biologically diverse grassland managed to enhance native species and sustained by natural ecological processes.

> **Objective GRNC2.1**: Restore and sustain a mosaic of grassland vegetation alliances, reflecting local water availability, soil chemistry, soil texture, topography, and disturbance regimes, with consideration of historical states.

> **Objective GRNC2.2**: Increase the relative cover of native grasses and forbs in native grassland vegetation alliances.

> **Objective GRNC2.3**: Increase opportunities for wildlife movement through grassland habitat.

> **Objective GRNC2.4**: Increase burrow availability for burrow-dependent species.

> **Objective GRNC2.5**: Increase prey, especially small mammals and insects, for grassland-foraging species.

Rationale for Goals and Objectives

Grassland Natural Community Extent and Connectivity

In determining the aerial extent and spatial configuration of grasslands to be conserved, the following criteria were considered: habitat value of the grasslands that currently exist within the Plan Area; ecological and evolutionary processes that sustain grasslands; spatial and functional needs of covered grassland species, including genetic exchange; and projected impacts on grasslands resulting from implementation of the BDCP.

Large contiguous grasslands within the Plan Area are present in Conservation Zones 1, 2, 4, 6, 8, and 11. Zones 3, 5 and 7 contain few large patches of grassland and Zones 9 and 10 have many small fragments of grassland distributed throughout a matrix of urban and agricultural land cover. Of those zones with areas of large existing grasslands, grassland in Zones 2 and 4 have largely been protected. 76 percent of the grassland in Zone 2 (Yolo Bypass Wildlife Area) and 67 percent of the grassland in Zone 4 (Stone Lakes NWR and Cosumnes River Preserve) are currently protected.

Zone 6 contains large areas of unprotected grasslands, but the zone is in the deeply subsided portion of the Delta and is intersected by large channels that make connection to adjacent islands impossible. The fact that the grasslands occur on deeply subsided areas also makes them susceptible to future levee failures and does not allow for the establishment of natural environmental gradients of uplands to marsh and aquatic habitats. Grasslands in this zone do not support many covered species.

Most critical for grassland conservation are Zones 1, 8, and 11. These zones are situated at the periphery of the Delta where elevations are suitable for upland habitats adjacent to restored tidal habitats. Protection and enhancement of grasslands adjacent to restored tidal marsh habitats would reestablish one of the most important historical environmental gradients (along the water-land interface) that has been largely lost due to construction of levees and reclamation of wetlands. These areas will also be more able to adapt to changes in sea level because they are at higher elevations. Grasslands in these zones also often co-occur with vernal pool complex or alkali seasonal wetland natural communities. Some protected grasslands in Zones 1 and 11 can be conserved to build upon existing and planned preserves between these two zones in Solano County. Protection of additional grasslands in this area will protect an important connection between Suisun Marsh and the Cache Slough area. Zone 8 has little protected grassland but is located near important areas for conservation that were identified in the East Contra Costa County HCP/NCCP. Habitats in these three zones support a variety of BDCP covered species and are especially important areas in the Plan Area for vernal pool plant and animal species, California tiger salamander, western burrowing owl, and rare grassland plant species. In addition to providing habitat for these species, Zone 8 supports and is adjacent to the best habitats in the Plan Area for California red-legged frog and San Joaquin kit fox.

Currently approximately 17 percent of grassland in Zones 1, 8, and 11 is protected. With the additional conservation of 8,000 acres of grassland that is proposed under the BDCP, approximately 74 percent would be protected. This would put habitat conservation in these areas on par with Zones 2 and 4 (76 percent and 67 percent, respectively).

Priority for restoration will be given to sites that provide a range of environmental gradients and increase connectivity between preserve lands. Under the BDCP, 65,000 acres of tidal habitats will be restored which include subtidal, intertidal, and transitional upland habitats. Lands acquired for restoration of these tidal habitats will include regions of higher elevation lands that would accommodate sea level rise and would also contribute to the goals and objectives for the grassland natural community. These lands would be considered high priority for grassland restoration. For the implementation schedule of grassland restoration and protection, see the BDCP implementation schedule presented in Chapter 6, *Plan Implementation.*

Native Biodiversity and Grassland Function

Biologically Diverse Grasslands. Valley grassland is species-rich, with 50 plant species commonly found in 30 x 30 m plots (Heady et al. 1991). Grassland plant species exist in patches of plant communities called (vegetation) alliances, which are unevenly spread throughout the grassland and sometimes extend into other nearby natural communities as well. Valley grassland is an extremely productive natural community, but is still not well understood.

Before the introduction of livestock grazing and modern agriculture practices, alliances characterized by perennial grasses were common in the Central Valley. Barry (1972) estimated that 99 percent of the pre-contact purple needlegrass (*Nassella pulchra*) alliance has disappeared in the valley grassland community. While its historical extent and abundance are still under debate (and classification of sub-communities (associations) under this alliance remains incomplete), it is assumed that various patches of perennial grasses, many in bunch form, and associated forbs, were widely distributed in the Central Valley (D'Antonio et al. 2007) before changes in land use affected this natural community. Native grassland vegetation alliances are likely to be found within the BDCP conservation lands, but these grasslands are expected to be degraded (i.e., low relative cover of native species) due to past and current land uses practices (e.g., deep soil disturbance and heavy grazing) and the competitive spread of nonnative plants.

Many grasslands to be conserved in the Plan Area will require intensive management that mimics natural pressures on the system; however, where possible, natural ecological processes will be allowed to influence grassland structure, succession, and heterogeneity. Historically, herbivory and fire determined native grass vigor and distribution. Wind exacerbates arid conditions characteristic of valley grasslands, and wind spreads fire, which likely maintained historical grassland extent and distribution, and contributed to the mosaic of vegetation alliances and structure, in turn determining patch dynamics of animal habitats. Natural ecological processes should be allowed to drive structure and dynamics in BDCP grasslands as much as possible.

Species Protection. In the Plan Area, there is now a limited distribution of purple needlegrass, along with several other alliances of perennial grass. Another bunchgrass, alkali sacaton (*Sporobolus airoides*), is often found on alkali or sodic stratum. In contrast, stolonous (non-bunching) creeping rye-grass (*Leymus triticoides*) covers wetter areas at the margins of riparian and emergent wetland communities. Valley grasslands, in this sense, exist as transitional zones which reflect underlying environmental gradients and create ecotones in the Bay Delta region.

Recent studies show that purple needlegrass influences soil chemistry and soil structure and contributes to underground soil heterogeneity (Parker and Schimel 2010), which is already enriched by critical microorganisms (fungi, bacteria, nematodes) and bioturbation by burrowing rodents. In native grasslands, these subterranean processes in turn contribute to diversity of flora composition above ground. On the other hand, local homogenization of soil properties caused by annual nonnative grasses are thought to create a feedback loop that encourages their invasion.

Grassland communities in the Plan Area exhibit complexity and diversity at all spatial scales, and perennial grasses and related ecological processes play a pivotal role in dynamically sustaining that complexity. Successful restoration of grassland alliances, especially those comprised of native perennial grasses will likely benefit not only the characteristic species, but valley grasslands as integrated communities (as well as nearby natural communities) by promoting essential ecological functions.

The grassland flora of the Central Valley and Bay Delta evolved under the influence of prehistoric herbivores, for example large herds of deer, elk, pronghorn, and other grazing animals. Although dense concentrations of most of these large mammals and their predators are no longer present, deer and medium-sized carnivores (e.g., gray fox, coyote) still inhabit the Plan Area. Herbivores and carnivores with a propensity to move widely will especially benefit from increases in the extent and connectedness of grasslands. This goal is underscored by the California Essential Wildlife Connectivity Project (Spencer et al. 2010), an interagency, multi-stakeholder effort steered by DFG and Caltrans to identify, map, and implement wildlife movement corridors and habitat linkages throughout the State. Twenty-four of the 192 “Essential Connectivity Areas” identified by this project occur in the Central Coast Ecoregion of the state with six of these in or adjacent to the Plan Area. In the Central Coast Ecoregion, the landcover in the identified Essential Connectivity Areas is 25 percent grassland or herbaceous, second only to the Great Central Valley in the representation of this landcover type within important wildlife movement corridors.

A large proportion of animal species that inhabit grasslands are either fossorial or burrow-dependent, attributes which provide access to constant underground habitats, presumably for temperature regulation and for protection from fire and predators. Some fossorial grassland mammals can be considered keystone species because the burrows they dig are critical to the survival of many other species and essential for a well-functioning grassland community. For example, California ground squirrels excavate burrows that provide substantial benefits to native covered species, including San Joaquin kit fox (den sites), western burrowing owl (nesting and roosting habitat), and California red-legged frog, California tiger salamander, and western spadefoot toad (upland aestivation sites). Unfortunately, ground squirrels have been the target of widespread poisoning campaigns in California where they threaten levees or are perceived as pests. Loss and fragmentation of grasslands have also reduced ground squirrel distribution and abundance. By increasing the extent of grassland, and the abundance and distribution of host burrowers, many native species will benefit.

Grasslands in the Plan Area provide foraging habitat for predators by supporting populations of small animals (mice, voles, rabbits, insects, amphibians, reptiles) on which they prey. Sufficient prey populations are critical to the health and persistence of predator populations. Enhancing the extent and abundance of rodent, lagomorph, and insect (e.g., grasshopper) populations will increase the prey base for San Joaquin kit fox and other carnivores, and raptor species, including Swainson's hawk, western burrowing owl, and white-tailed kite. Grassland conservation and restoration will also help to offset impacts to agricultural lands that produce prey for covered species.

Other ecological factors, in addition to the size and density of rodent populations, may limit populations of covered species in the Plan Area. For example, the population of San Joaquin kit fox may be limited by mortality from road kill, poisoning, coyote predation, or competition from nonnative red foxes (U.S. Fish and Wildlife Service 1998). However, there is evidence in other parts of the kit fox range that abundance of prey affects reproductive success (Egoscue 1975; White and Ralls 1993). Although research to date suggests that prey abundance is important, a lack of studies in the northern portion of the kit fox range contributes to uncertainty about the efficacy of this conservation measure in BDCP grasslands.

Because of this uncertainty, adaptive management and targeted studies are required to understand factors controlling kit fox and other predator populations and to improve management techniques. Pilot studies of management methods that enhance the rodent prey base will be conducted through the Adaptive Management Program, and effective management measures will be incorporated into grassland management actions.

Grasslands and Climate Change

The most decisive factor determining grassland presence or absence is soil water accessibility (Bartoleme et al. 2007). In the Plan Area, precipitation greatly influences soil water level and accessibility at any given location. Seasonal and annual variations in rainfall amount and pattern are vast in this region, and valley grasslands respond significantly to such stochastic fluctuations. For example, an area dominated by lush grasses in a rainy year may exhibit a vivid display of wildflowers the following spring. Therefore, it is expected that valley grasslands will be influenced, perhaps in unexpected ways, by near-future and long-term climate change. Implementation of all BDCP goals and objectives for grassland, especially promotion of underground processes, is expected to substantially improve the flexibility and resilience of this natural community and contribute to its persistence.

Conservation Measures for Grasslands

- CM3 Natural Communities Protection;
- CM8 Grassland Communities Restoration; and
- CM11 Natural Communities Enhancement and Management.

3.3.2.2.9 Alkali Seasonal Wetland Complex

The alkali seasonal wetland complex natural community is distributed within or adjacent to grasslands and adjacent to tidal marshes and oak savanna. It is associated with seasonally saturated alkali soils along the northwestern and southwestern margins of the Delta and around the perimeter of Suisun Marsh. Alkali seasonal wetland complex was once very common in the Central Valley and portions of the Plan Area; however, conversion of land to agriculture, waterfowl habitat, and commercial and urban land use has eliminated or degraded the habitat functions of the alkali seasonal wetland complex natural community through direct removal of vegetation, removal of watershed topography by leveling of the land, and the establishment of nonnative plants. For example, in east Contra Costa County the historical extent of this community has been reduced from 8,800 acres to 2,720 acres, 30 percent of its historical extent (SFEI 2010). These reductions in the extent, distribution, and condition of alkali seasonal wetland complex have reduced the diversity of native plant species uniquely associated with alkali soils and habitat for associated covered and other native wildlife species.

There are approximately 3,723 acres of alkali seasonal wetland complex natural community in the Plan Area that generally exist as two contrasting DFG vegetation types. One type, which is by far the most extensive, is dominated by perennial saltgrass (*Distichlis spicata*); while the other type is rare, covers approximately 260 acres, and is dominated by woody iodine bush shrubs. Saltgrass grasslands are typically characterized by having low productivity and are grazed by both native wildlife and domestic livestock. Because saltgrass is a prostrate grass it creates a visually open habitat that provides foraging habitat for raptors. Iodine bush habitat provides a structurally diverse habitat with open areas of salt scalds and very low herbaceous vegetation for foraging by wildlife as well as closed canopy shrub-dominated areas for cover. See Section 2.3.4.8, *Alkali Seasonal Wetland Complex* in Chapter 2, *Existing Ecological Conditions*, for more detail on the current state of this natural community.

Currently 2,769 acres (74 percent) of alkali seasonal wetland complex natural community in the Plan Area are in a protected status. Protecting and enhancing additional alkali seasonal wetland complex natural community in conjunction with adjoining natural communities is expected to maintain or increase the abundance of native wildlife and plant species, improve connectivity among habitat areas within and adjacent to the Plan Area, and contribute to the long-term conservation of alkali seasonal wetland complex and grassland natural communities associated covered species.

Alkali Seasonal Wetland Goals and Objectives

Goal AWNC1: The expected outcome is protected alkali seasonal wetland complex natural community that represents a range of environmental conditions and is adjacent to other conserved lands.

> **Objective AWNC1.1**: Protect 400 acres of alkali seasonal wetland complex natural community in Conservation Zones 1, 8, and/or 11.

Goal AWNC2: The expected outcome is biologically diverse alkali seasonal wetland complex natural community with improved native biodiversity, habitat heterogeneity, and the ability to support populations of covered and other native species.

> **Objective AWNC2.1**: Maintain and, where habitat functions for covered species can be increased, increase the diversity and relative cover of native grasses and forbs.

Rationale for Goals and Objectives

Alkali Seasonal Wetland Natural Community Extent and Connectivity

In determining the extent and spatial configuration of alkali seasonal wetland complex natural community to be conserved, the following criteria were considered: the habitat value of alkali seasonal wetland complex that currently exists within the Plan Area; the spatial and functional needs of covered species that use alkali seasonal wetland complex; and the projected impacts on alkali seasonal wetland complex resulting from the implementation of the BDCP. Under the alkali seasonal wetland complex natural community goals and objectives, 400 acres of the community will be protected in Conservation Zones 1, 8, and/or 11, which correspond to the same areas where impacts will occur.

Additionally, alkali seasonal wetland complex natural community in Conservation Zones 1, 8, and 11 is situated at elevations that are suitable for serving as upland habitats adjacent to restored tidal habitats; and in Conservation Zones 1 and 11 can be protected to enhance the spatial extent and connectivity of existing and planned preserves in Solano County that span tidal and upland habitats. Further, the protection of additional alkali seasonal wetland complex natural community in this area will protect the habitat connectivity between Suisun Marsh and Cache Slough and maintain its function as a movement corridor for wildlife.

Protection of 400 acres of alkali seasonal wetland complex natural community under the BDCP will prevent the removal or degradation of these alkali seasonal wetlands from future changes in land use. Even though 74 percent of the current extent of this natural community is protected, it is a rare community that warrants further protection. Its current extent is only a small fraction of its historical extent before it was converted to other land uses; therefore, preserving as much remaining area as possible is important for preserving the biota and preserving the hydrological function of the alkali seasonal wetland complex natural community which requires a more extensive watershed than the vernal pool complex natural community. Following full implementation of the BDCP, the extent of protected alkali seasonal wetland complex natural community in the Plan Area will be increased from 2,769 acres to 3,112 acres, a 12 percent net increase accounting for the loss of 57 acres of protected alkali seasonal wetland complex. For the implementation schedule of alkali seasonal wetland complex protection, see the BDCP implementation schedule presented in Chapter 6, *Plan Implementation.*

Native Biodiversity and Alkali Seasonal Wetland Complex Natural Community Function

Biologically Diverse Alkali Seasonal Wetland Complex. While alkali seasonal wetland complex natural community may be perennial grassland that is dominated by saltgrass or woody scrub dominated by iodine bush, it typically has a diverse forb component that consists of spring vernal pool-like vegetation in areas of heavy clay or salt scalds followed by summer flowering tarweeds, tarplants (*Hemizonia* and *Holocarpha* spp.), *Atriplex* (*Atriplex* spp.) and perennial gumplant (*Grindelia* spp.). They also support diverse assemblages of native ground-nesting bees and other important pollinators for both native and agricultural plant species. Saltgrass is found in most areas of alkali seasonal wetland complex natural community, while the iodine bush shrub is found within the Plan Area only near the Clifton Court Forebay. The saltgrass-dominated areas generally provide a lower, non-woody physical structure with relatively fast nutrient and carbon cycling. The iodine bush-dominated areas tend to have a patchy distribution of shrubs, providing greater structural variation and relatively slower carbon cycling

Enhancement and management of protected alkali seasonal wetland complex natural community is expected to improve native biodiversity and enhance the function of this natural community for covered and other species. Careful planning will be required to resolve uncertainties regarding appropriate management regimes for this community type in the context of a larger diverse and managed landscape. Alkali seasonal wetland complex natural community in the Plan Area is generally interspersed with or adjacent to grassland and vernal pool complex, and all three communities are generally managed together within large pastures. There is very little information available regarding the appropriate management of alkali seasonal wetland complex per se, but there is one long-term grazing study available for mixed exotic annual and saltgrass perennial grassland for the Jepson Prairie area (Swiecki and Bernhardt 2008). To resolve this general lack of information, enhancement techniques and effective application frequencies and intensities will be informed by baseline surveys, effectiveness monitoring, and targeted research. Techniques that could be used to enhance alkali seasonal wetland complex within the context of the other communities include but are not limited to: appropriate grazing regimes including grazing exclusion, prescribed burning, and the appropriate use of herbicides to control invasive nonnative plant species. Enhancing the alkali seasonal wetland complex natural community will likely require applying multiple management techniques simultaneously and the spatial separation of some of the techniques.

Species Protection. Brittlescale and heartscale habitat consists of ephemeral drainages within the alkali seasonal wetland complex natural community, while Delta button-celery occupies clay flats that periodically flood. Specific habitat acreage requirements for brittlescale, heartscale, and Delta button-celery are necessary to ensure that the specific habitat conditions required by these species are included within the alkali seasonal wetland complex natural community that will be protected (see Species Goals and Objectives). Other BDCP covered species expected to benefit from alkali seasonal wetland complex natural community protection and enhancement include San Joaquin kit fox, Townsend's big-eared bat, tricolored blackbird, Suisun song sparrow, western burrowing owl, Swainson's hawk, white-tailed kite, giant garter snake, western pond turtle, California red-legged frog, California tiger salamander, western spadefoot toad, and Carquinez goldenbush. For the implementation schedule of alkali seasonal wetland complex natural community protection and enhancement, see the BDCP implementation schedule presented in Chapter 6, *Plan Implementation.*

Alkali Seasonal Wetland Complex and Climate Change

Alkali seasonal wetland complex natural community is generally located at elevations that will not be directly inundated by rising sea level, but could be subjected to vegetation changes through altered hydrology in adjacent tidal areas. Another potential impact of climate change would be driven by increased variability in precipitation. The species present in this community are adapted to variable precipitation; and increased variability could lead to changes of the vegetation within the community. Implementation of BDCP alkali seasonal wetland complex natural community goals and objectives can improve the extent, and thus potential resilience, of this community in the face of climatic changes.

Conservation Measures for Alkali Seasonal Wetland Complex

- CM3 Natural Communities Protection
- CM11 Natural Communities Enhancement and Management

3.3.2.2.10 Vernal Pool Complex

The vernal pool complex natural community is characterized by both isolated and interconnected groups of vernal pool wetlands and seasonal swales within the matrix of grassland or alkali seasonal wetland natural communities. Vernal pools in California provide habitat for a number of endemic and rare species (Jain 1979, Jones and Stokes Associates 1990, Skinner and Pavlik 1994, Solomeshch et al. 2007). A single vernal pool may support over 100 species of native plants and animals (USFWS 2005).

Within the Plan Area, there are 6,954 acres of vernal pool complex, of which 68 percent is found in the grassland natural community, 31 percent is found in the alkali seasonal wetland complex, and 1 percent is found in other natural community types. The vernal pool complex is uncommon in the Plan Area, found only in a few locations along the very margin of the Plan Area. Vernal pools are found west of the Sacramento River from Putah Creek south to the gently sloped terraces immediately to the north and east of the Montezuma Hills; on the north and eastern margins of Suisun Marsh; east of the Sacramento River in the Stone Lakes area; and west of the San Joaquin River from Byron to Discovery Bay (Witham 2003, ESA 2005, Leigh Fisher

Associates 2005, Williamson et al. 2005, Witham 2006, Baraona et al. 2007, Kleinschmidt Associates 2008, Rains et al. 2008). See Section 2.3.4.9, *Vernal Pool Complex* in Chapter 2, *Existing Ecological Conditions*, for more detail on the current state of this natural community.

Conversion of land for agricultural and urban uses has eliminated or degraded the habitat functions and value of vernal pool complex natural community through direct the removal of vegetation, the elimination of vernal pool watershed topography with land leveling, and disruption of natural seasonally hydrology by flood irrigation. The reduction in the extent, distribution, and condition of vernal pools has reduced the diversity of native vernal pool plant species such as BDCP covered alkali milk-vetch, Heckard's peppergrass, and legenere. It has also eliminated habitat for associated covered and other native wildlife species such as BDCP covered vernal pool shrimp species.

Of the 6,958 acres of vernal pool complex in the Plan Area, 4,379 acres (63 percent) is currently under protected status. Preserving, restoring, and enhancing additional remaining vernal pool complex in conjunction with surrounding grassland habitats is expected to further maintain or increase the abundance of native wildlife and plant species, improve connectivity among habitat areas within and adjacent to the Plan Area, and contribute to the long-term conservation of vernal pool- and grassland-associated covered species, including western spadefoot toad, California tiger salamander, vernal pool shrimp species, and various vernal pool plant species.

Vernal Pool Complex Goals and Objectives

Goal VPNC1: The expected outcome is protected vernal pool complex natural community that represents a range of environmental conditions and is adjacent to other conserved lands.

> **Objective VPNC1.1**: Protect 300 acres of vernal pool complex in Conservation Zones 1, 8, and 11.

Goal VPNC2: The expected outcome is restored biologically diverse vernal pool complex natural community with improved native biodiversity, habitat heterogeneity, and the ability to support populations of covered and other native species.

> **Objective VPNC2.1**: Restore 200 acres of vernal pool complex natural community in Conservation Zones 1, 8, and/or 11 within patches of protected grassland that supports habitat for the western spadefoot toad, California tiger salamander, and the covered vernal pool shrimp and plant species.

> **Objective VPNC2.2**: Maintain and, where habitat functions for covered species can be enhanced, increase the diversity and relative cover of native grasses and forbs.

Rationale for Goals and Objectives

Vernal Pool Complex Natural Community Extent and Connectivity

In determining the extent and spatial configuration of vernal pool complex natural community to be conserved, the following criteria were considered: the habitat value of the community that currently exists within the Plan Area; the extent and distribution of the community that is currently under protected status; the spatial and functional needs of covered species that use the community as habitat; and the projected impacts on the community resulting from implementation of the BDCP. Under the vernal pool complex natural community goals and objectives, 300 acres of vernal pool complex will be protected and 200 acres of vernal pool complex will be restored in Conservation Zones 1, 8, or 11.

Vernal pool complex natural community is distributed within or adjacent to a variety of natural communities on relatively impermeable soils in shallow basins and drainages on level terrain along the margins of the Plan Area. In the Plan Area, the vernal pool complex natural community consists of four fairly uniform types: annual grassland vernal pools in the Stone Lakes area; clay alluvium vernal pools and playa pools running from Putah Creek south to Cache Slough; Montezuma Block vernal pools and playa pools in the Jepson Prairie/Montezuma Hills area; and alkaline sink/meadow vernal pools in the Byron/Clifton Court Forebay area.

These areas are generally at the margins of the species distributions where the vernal pool complex natural community transitions into other natural communities such as tidal brackish or tidal freshwater emergent wetland. The community can also grade into the agricultural habitat natural community where its unique characteristics are blurred to varying degrees by human driven impacts such as land leveling and ripping, altering the supply of water through flood irrigation.

BDCP actions will increase the amount of extant vernal pool complex natural community in protected status in the Plan Area by 300 acres from a current 4,379 acres, or 63 percent, to 4,679 acres, or 67 percent of the total 6,959 acres of vernal pool complex. The BDCP will also restore and additional 200 acres of vernal pool complex natural community in the Plan Area. The net increase in area of both restored and protected vernal pool complex, accounting for a small loss of lower quality vernal pool complex, will result in a total of 4,849 acres vernal pool complex in protected status.

All of the vernal pool complex natural community in the Plan Area is found within Conservation Zones 1, 4, 8, 9, and 11. Most of the community present in Conservation Zone 4 is already protected; while in Conservation Zone 9, it consists of small patches that are isolated among developed areas and agricultural land. Vernal pool complex natural community in Conservation Zones 1, 8, and 11 is situated at elevations that are suitable for serving as upland habitats adjacent to restored tidal habitats and additionally, in Conservation Zones 1 and 11, can be protected to build upon existing and planned preserves in Solano County between these conservation zones. Protection of additional vernal pool complex natural community in this area will protect an important connection between Suisun Marsh and the Cache Slough area. Vernal pool complex natural community in Conservation Zone 8 consists of relatively rare alkaline sink/meadow vernal pools that warrant protection. For the implementation schedule of vernal pool complex natural community protection and restoration, see the BDCP implementation schedule presented in Chapter 6, *Plan Implementation.*

Native Biodiversity and Vernal Pool Complex Function

Biologically Diverse Vernal Pool Complex. The restoration of 200 acres of vernal pool complex natural community will enhance native biodiversity and habitat heterogeneity within the Plan Area. Priority for restoration will be given to sites that display clear vernal pool signatures on aerial imagery, possesses relatively natural hydrology, provide a range of environmental gradients, and that will increase connectivity between protected lands. Under the vernal pool complex natural community goals and objectives, 200 acres of vernal pool complex will be restored in Conservation Zones 1, 8, or 11; and 300 acres will be protected in those conservation zones.

Vernal pool complex natural community in the Plan Area is generally interspersed with the grassland and alkali seasonal wetland complex natural communities; and all three communities are generally managed together, although there is very little experience in managing and alkaline sink/meadow vernal pools.

There is very little information available regarding the appropriate management of the types of vernal pool complex found in the Plan Area but there is one long-term grazing study available for mixed exotic annual and saltgrass perennial grassland for the Jepson Prairie area. To resolve this general lack of information, restoration and enhancement techniques and effective application frequencies and intensities will be informed by baseline surveys, effectiveness monitoring, and targeted research. Techniques that could be used to enhance vernal pool complex within the context of the other communities include but are not limited to: appropriate grazing regimes including grazing exclusion; prescribed burning; and the appropriate use of herbicides to control invasive nonnative plant species. Enhancing vernal pool complex will likely require applying multiple management techniques simultaneously and the spatial separation of some of the techniques.

The vernal pool complex is essentially an amphibious ecosystem with differing functions dependent upon whether it is in a flooded or dry stage. When flooded, it contains ephemeral aquatic invertebrates, the immature stages of amphibians, and hosts waterfowl. As the water recedes, the ecosystem services first change from those of a fully aquatic system to a wetland, and then to a terrestrial ecosystem (Williams 2006). Through this process the food web linkages break down as the community becomes more integrated with the terrestrial landscape around it. When dry, it is integrated with the surrounding terrestrial ecosystems and provides foraging habitat for native wildlife, and is typically managed as rangeland and grazed by sheep or cattle.

Vernal pools are defined in large part by their hydrology, which has three components: 1) the source of water; 2) the duration of inundation and waterlogged soil phases; and 3) the seasonal timing of these phases. Rainfall is the primary source of water to vernal pools as it falls directly into the vernal pool or is transported a short distance across the watershed of the vernal pool; however, there can be groundwater transport to a vernal pool through a shallow perched aquifer or a combination of rainfall and creek flooding (ESA 2005, Williamson et al. 2005, Rains et al. 2008). The duration and timing of the inundation and waterlogged soil phases also vary; with hard-pan vernal pools having shorter phases centered during the middle of the wet season, while clay-pan and clay vernal pools have longer phases extending earlier and later into the wet season (ESA 2005, Williamson et al. 2005, Rains et al. 2008).

Vernal pool plant species are generally adapted to survive standing water throughout winter and spring and dry soils in summer (CALFED 2000, Solomeshch et al. 2007). Duration of inundation correlates with two clear functional plant groups (Zedler 1987, 1990, Barbour et al. 2003, Barbour et al. 2005, Barbour et al. 2007). Plants found at the edge of pools are adapted to the fluctuating hydrology of shallow vernal pools or to the edges of deep vernal pools. These species are prone to elimination by competition with upland exotic grass species or through thatch accumulation (Barry 1995, Griggs 2000, Marty 2005). The second functional plant group is adapted to the longer inundation periods of the pool basins.

Vernal pool plant species also vary among the four types of vernal pool complex in the Plan Area. The annual grassland type found in the Stone Lakes area is dominated by Eurasian annual grasses with a varying mixture of native grasses and herbs depending on the farming history of the site. The clay alluvium vernal pools and playa pools type from Putah Creek south to Cache Slough is dominated in the spring by either Eurasian annual grasses or a variable mixture of saltgrass and native herbs and dominated in the summer by native tarweeds, or the exotic yellow starthistle. The Montezuma Block vernal pools and playa pools type in the Jepson Prairie/Montezuma Hills area is similar to the clay alluvium vernal pools and playa pools type, but extensive areas are also in agriculture production as dry-farmed wheat. The alkaline sink/meadow vernal pools type in the Byron/Clifton Court Forebay area has surrounding vegetation that is typically dominated by native grasses such as saltgrass and alkali ryegrass or by woody shrubs like iodine bush and subshrubs such as bush seepweed and alkali heath.

In the Plan Area, nonnative species invade and degrade the vernal pool complex at various points along the moisture gradient. The margins of vernal pools are often dominated by the nonnative Italian ryegrass, while the deeper portions of hardpan pools are invaded by low mannagrass (Gerlach et al. 2009). Other parts of vernal pool complexes are often invaded by perennial pepperweed (Swiecki and Bernhardt 2002, Witham 2003, ESA 2005, Witham 2006, ESA 2007, Gerlach et al. 2009).

Species Protection. The vernal pool complex natural community is utilized as habitat by a number of wildlife species. Some use the community only for a specific part of their life history. For example, amphibians such as California tiger salamander and western spadefoot toad use vernal pools and playa pools for breeding, but are otherwise essentially terrestrial animals. Some waterfowl forage in vernal pools and playa pools during the wet season, consuming invertebrates (ducks and shorebirds) and vegetation (geese) (Medeiros 1976, Reiner and Swenson 2000). Some species spend their entire lives in vernal pools and playa pools, for example the five crustacean species covered under the BDCP (mid-valley fairy shrimp, Conservancy fairy shrimp, longhorn fairy shrimp, vernal pool fairy shrimp, vernal pool tadpole shrimp, and California linderiella).

Vernal pool complex natural community protection and restoration will provide habitat for BDCP covered western spadefoot toad, California tiger salamander, mid-valley fairy shrimp, Conservancy fairy shrimp, longhorn fairy shrimp, vernal pool fairy shrimp, vernal pool tadpole shrimp, California linderiella, alkali milk-vetch, heartscale, brittlescale, San Joaquin spearscale, dwarf downingia, Delta button-celery, Boggs Lake hedge-hyssop, legenere, and Heckard's peppergrass. Most of the BDCP covered vernal pool plant species are generally confined to small scattered populations growing in vernal pools and swales on alkaline clay soils. When they occur on unprotected land they are especially vulnerable to agriculture intensification or development. BDCP tidal restoration activities could also potentially affect some occurrences. In such cases, surveying for and protecting individual occurrences of these species is an effective conservation strategy that can yield population level benefits.

Vernal Pool Complex and Climate Change

Climate change is expected to alter the vernal pool complex natural community. Because this natural community is generally located at elevations that will not be directly impacted by rising sea level, the primary impact of climate change is predicted to be driven by changes in the hydrological regime due to increased variability in precipitation. The species present in this community are adapted to existing hydrological conditions, such that increased variability of precipitation would likely lead to a shorter and more variable wet season or similar changes in the inundation period. It is not known how increased variability in pool hydrology would affect the plants and animals inhabiting them, but because these species are adapted to current conditions, the impacts will likely be negative. In addition, rising average temperatures could result in increased evapotranspiration rates and therefore shorter wetted periods for vernal pools, the impacts of which are expected to be adverse to native plants and wildlife. The implementation of BDCP vernal pool complex natural community goals and objectives will increase the extent of this natural community and help ensure its persistence through climatic changes.

Conservation Measures for Vernal Pool Complex

- CM3 Natural Communities Protection
- CM9 Vernal Pool Complex Restoration
- CM11 Natural Communities Enhancement and Management

3.3.2.2.11 Inland Dune Scrub

Inland Dune Scrub occurs in only one location in the Plan Area. It is found along the south shore of the San Joaquin River immediately east of the city of Antioch within the Antioch Dunes National Wildlife Refuge (ADNWR) and on two adjacent (PG&E) properties. These areas of inland dune scrub are fully protected by ownership or conservation Memoranda of Understanding (MOUs). These protected lands are completely isolated from other terrestrial habitats by development to the west, south, and east, and by the San Joaquin River to the north.

Historically, the 190-acre dune paralleled the San Joaquin River shore for 2 miles and was 0.15 mile wide and 120 feet tall (Howard and Arnold 1980, SFEI (San Francisco Estuary Institute) 2010). Mining of the sand in the late 19^{th} and early 20^{th} century for the manufacture of pottery, bricks, asphalt and concrete reduced the extent of the dunes. After WWII, commercial development occurred in the area where the dune had been mined, and the sand mining moved eastward. The USFWS negotiated a purchase to establish the 55-acre Antioch Dunes National Wildlife Refuge (ADNWR) with the sand dunes that remained in 1980. See Section 2.3.4.13, *Inland Dune Scrub* in Chapter 2, *Existing Ecological Conditions*, for more detail on the current state of this natural community.

To increase the level of conservation benefits provided to inland dune scrub species, the BDCP inland dune scrub conservation will be implemented through the funding of appropriate management actions and studies.

<u>Inland Dune Scrub Goals and Objectives</u>

Goal IDSC1: The expected outcome is support for funding of the USFWS management and enhancement of the inland dune scrub natural community on the Antioch Dunes National Wildlife Refuge.

> **Objective IDSC1.1:** The BDCP will support the funding of the USFWS program for management, enhancement, and monitoring of inland dune scrub natural community on the Antioch Dunes National Wildlife Refuge at an annual amount of $XX.XX for X years.

<u>Rationale for Goals and Objectives</u>

Inland Dune Scrub Natural Community Extent and Connectivity

Currently, the degraded remnants of the inland dune scrub natural community are being managed exclusively for the three endangered species which the ADNWR was established to protect. The inland dune scrub natural community transitions into tidal brackish emergent wetland along its border with the San Joaquin River (USFWS (United States Fish & Wildlife Service 1984, 2001); and its other three sides are bordered by commercial developments. Management actions to increase the dune-like characteristics of ADNWR have included creating small dunes with dredged sand material (USFWS 1984a, 2001). Additionally there are captive breeding and propagation reintroduction program for Lange's metalmark, Contra Costa wallflower, and Antioch Dunes evening primrose (Johnson et al. 2007, USFWS 2008).

Native Biodiversity and Inland Dune Scrub Function

Biologically Diverse Inland Dune Scrub. Inland dune scrub is more similar to the vegetation of sandy soils in the San Joaquin Valley and Mojave Desert than to coastal scrub communities (Howard and Arnold 1980). The pre-disturbance species composition of the vegetation was not well described; however, based on early charts and a postcard dating from the early 1900s, the vegetation contained widely scattered large valley oaks, live oaks, various shrub species, and numerous herbaceous species (Howard and Arnold 1980, SFEI (San Francisco Estuary Institute) 2010).

The BDCP inland dune scrub natural community is defined by the presence of two vegetation types. One vegetation type consists of a broadleaf shrubland that was classified as the *Lupinus albifrons* (silver bush lupine) Antioch Dunes alliance (5 acres), and the other is a dwarf shrub vegetation type classified as the *Lotus scoparius* (deerweed) Antioch Dunes alliance (15 acres).

The primary problematic nonnative plant species in this community are annual grasses such as ripgut brome, vetches, and yellow starthistle (*Centaurea solstitialis*) (USFWS 2001a) which form dense patches that crowd out native plant species and reduce habitat quality for wildlife and invertebrates. The current management plan for the Antioch Dunes NWR invasive nonnative plant species control efforts includes hand pulling of individual invasive plants through the efforts of volunteers, targeted herbicide application, controlled burns, the restoration of some dune-like topography, and planting of nursery-grown nakedstem buckwheat (USFWS 2001a, 2008).

The Antioch Dune has also been known as an entomological hotspot since the 1930s when research entomologists began collecting in what is now the Sardis Unit of the ADNWR (Howard and Arnold 1980, Arnold 1983). A total of 27 taxa were described from Antioch Dunes during that decade. Eight of those taxa are endemic to the Antioch Dune. Four are now extinct, three are of uncertain status, and the eighth is the federally and state endangered Lange's metalmark butterfly (*Apodemia mormo langei*).

Species Protection. The BDCP conservation actions for the inland dune scrub natural community are consistent with and help to achieve the recovery objectives for Lange's metalmark butterfly identified in the 5-year Review (USFWS 2008). The Lange's metalmark butterfly captive breeding and release program will include the nursery propagation and out-planting of the white-flowered, sand-associated, ecotype of nakedstem buckwheat and the management of the nakedstem buckwheat to create dense patches of older plants with an extensive layer of leaf litter. The required sizes of self-sustainable Lange's metalmark butterfly populations have not yet been determined, but may be revealed as the controlled propagation studies proceed.

Lange's metalmark butterfly is endemic to areas of Oakley sand soil in east Contra Costa County that support nakedstem buckwheat which is its larval host plant and its adult nectar plant (Arnold 1983). Contra Costa wallflower and Antioch Dunes evening primrose are microendemics that only occur on the Antioch Dune itself. Lange's metalmark butterfly is entirely dependent on a particular white-flowered, sand-associated, ecotype of nakedstem buckwheat (*Eriogonum nudum* ssp. *auriculatum*) that has a later and longer blooming season than ecotypes growing on rocky areas nearby on Mt. Diablo. Additionally, its dependence on the plant extends to the leaf litter that accumulates near the base of large plants growing in large clumps (Arnold 1983).

Historically, nakedstem buckwheat occurred on the 190-acre Antioch Dune; in an area 1.5 miles southeast of the Antioch Dune as a 3-mile long by 1.5-mile wide 3,000-acre oblong patch on the Oakley sand soil southwest of Oakley; and in an unknown location near Brannan Island (Howard and Arnold 1980, Arnold 1983, 2005, SFEI (San Francisco Estuary Institute) 2010). The dune habitat has been reduced to 20 acres by sand mining, and the rest of the habitat was lost through development and agriculture. The remaining 20 acres of habitat has been further degraded by nonnative invasive plants such as vetches and annual grasses, and older dense stands of nakedstem buckwheat have been lost to wildfires (United States Fish & Wildlife Service 2001, 2008).

Inland Dune Scrub and Climate Change

The primary impact of climate change on the inland dune scrub natural community is predicted to be driven by changes in the hydrological regime due to increased variability in precipitation. The species present in this community are adapted to variable precipitation, and it is uncertain how they will be affected by increased variability. The inland dune scrub natural community is generally located at elevations that will not be directly impacted by rising sea level. Implementation of BDCP inland dune scrub goals and objectives will help ensure propagation of sensitive inland dune scrub species.

Conservation Measures for Inland Dune Scrub

- CM11 Natural Communities Enhancement and Management

3.3.2.2.12 Agricultural Habitats

The majority of lands in the Delta are currently used for agriculture. Agricultural habitats in the Plan Area formerly consisted of extensive brackish and freshwater wetlands, open grasslands, broad riparian systems, and oak woodlands. By the mid-1800s, reclamation of wetlands began to transform the Delta into an agricultural region with a complex system of channelized waterways and Delta "islands." The conversion of natural vegetation to agriculture eliminated large areas of native habitats. Nevertheless, some agricultural systems continue to support abundant wildlife and provide essential breeding, foraging, and roosting habitat for many resident and migrant wildlife species; although they generally support a less diverse community of wildlife compared with most native habitats (Fleskes et al. 2005, EDAW 2007, USFWS 2007a, Kleinschmidt 2008).

The agricultural landscape within the Plan Area is a dynamic matrix of a variety of land cover types, including perennial, semi-perennial, and seasonally or annually rotational crops. The large extent of the rotational crops results in a cover type matrix that is subject to change annually based primarily on agricultural economic conditions. This dynamic land management regularly changes habitat values at the field level for agriculture-associated BDCP covered species, while the overall landscape habitat values may change more slowly. See Section 2.3.4.14*, Agricultural Habitats* in Chapter 2, *Existing Ecological Conditions,* for more detail on the current state of this natural community.

Some BDCP covered species utilize agricultural habitats and in some cases have come to rely on the habitat value of certain agricultural landscapes, practices, and crop types. A reduction in agricultural acreage in the Plan Area will occur largely as a result of restoring tidal and nontidal wetland habitats. These restored habitats will incorporate a range of ecological gradients and will thus include associated grassland, open water, riparian, and other habitats. The removal of agricultural habitats through restoration of wetlands and associated communities will reduce the extent of upland agricultural habitats. However, the reduction in cropland acreage will be largely offset by 1) the value of restored wetlands and associated communities that will provide higher value habitat to some agriculture-associated species such as giant garter snake, greater sandhill crane, white-tailed kite, and tricolored blackbird; and 2) the stabilization of higher value agricultural cover types on BDCP protected lands.

Agricultural Habitat Goals and Objectives

Goal ALNC1: The expected outcome is increased habitat functions for covered and other native species that are supported by agricultural land cover types and management practices.

> **Objective ALNC1.1**: Maintain and protect the functions of 4,600 acres of rice lands as habitat for giant garter snake, western pond turtle, tricolored blackbird, white-tailed kite, waterfowl, and migrant shorebirds in Conservation Zone 2. This objective may be partially or fully achieved by maintaining an equivalent extent of natural or managed lands that support habitat functions similar to rice lands for associated covered and other native wildlife species.

> **Objective ALNC1.2**: Maintain and protect the functions of 12,020 to 28,040 acres of non-rice agricultural lands as foraging habitat for Swainson's hawk, white-tailed kite, and tricolored blackbird that are located within 8 miles of occupied Swainson's hawk nesting habitat.

> **Objective ALNC1.3**: Of the maintained 12,020 to 28,040 acres of non-rice agricultural lands, maintain at least 3,000 acres of pasture that supports western burrowing owl foraging habitat. This objective may be partially or fully achieved through preservation of other land cover types that provide moderate-value or greater habitat function for the western burrowing owl.

Objective ALNC1.4: Of the maintained 12,020 to 28,040 acres of non-rice agricultural lands, maintain at least 4,800 acres that supports greater sandhill crane foraging habitat within its Winter Use Area and within 2 miles of known roosting sites in Conservation Zones 3, 4, 5 and/or 6.

Objective ALNC1.5: Of the maintained 12,020 to 28,040 acres of non-rice agricultural lands and 4,600 acres of rice lands, maintain and protect 1,000 acres within or adjacent to habitat occupied by the Yolo/Willow Slough giant garter snake subpopulation in Conservation Zone 2.

Objective ALNC1.6: Of the maintained 12,020 to 28,040 acres of non-rice agricultural lands, maintain and protect 1,000 acres within or adjacent to habitat occupied by the Caldoni Marsh/White Slough giant garter snake subpopulation in Conservation Zone 4.

Objective ALNC1.7: Target agricultural land conservation to provide connectivity between other protected lands.

Objective ALNC1.8: Maintain and protect the small patches of important wildlife habitats associated with agricultural lands that occur within BDCP conserved agricultural lands, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, and wetlands.

Rationale for Goals and Objectives

Agricultural Habitats Extent and Connectivity

Delta crop types include small grains such as wheat and barley, field crops such as corn, sorghum, and safflower, truck crops such as tomatoes and sugar beets, forage crops such as hay and alfalfa, pastures, orchards, and vineyards (CALFED 2000, DWR 2007). The distribution of crop types in production in the Plan Area varies, depending on crop-rotation patterns and market forces. For example, over the past few decades there has been a two-fold increase in acreage used to produce corn, making it the number one crop in acreage grown; and an 18-fold increase in vineyards (DWR 2007).

Changes in crop production can have substantial effects on the habitat value of agricultural habitats for wildlife, particularly birds. Hay, grain, row crops, and irrigated pastures support abundant rodent populations, providing foraging habitat for bird species such as Swainson's hawk, white-tailed kite, and burrowing owl. Conversion of pastures, row crops, and similar agricultural habitats to orchards and vineyards has been noted as a factor affecting raptors such as Swainson's hawk (Estep 2008).

Irrigated pastures, alfalfa, and annually cultivated irrigated cropland provide foraging habitat for BDCP covered Swainson's hawk, white-tailed kite, western burrowing owl, greater sandhill crane, and tricolored blackbird. Grain, corn, and rice fields provide foraging habitats for sandhill cranes, waterfowl, wading birds, and shorebirds. Upland and seasonally flooded agricultural habitats and wetlands of the Delta support an estimated 10 percent of the waterfowl population that annually winter in California (CALFED 1998). Rice fields provide foraging habitat for many bird species as well as important aquatic habitat for giant garter snakes and western pond turtle. Orchards and vineyards, conversely, provide limited wildlife value, particularly to BDCP covered species. Orchards and vineyards develop a dense overstory canopy that generally precludes access by foraging Swainson's hawks, white-tailed kites, western burrowing owls, and other agricultural land-associated covered species.

While the agricultural landscape of the Delta is important to BDCP covered and other native species, only a portion of the landscape is utilized in any give year due to conversions and crop rotations that result in long-term (i.e., orchards, vineyards) or short-term reductions in habitat value. The use of conservation easements and fee title to protect the wildlife habitat functions for BDCP covered species will maximize habitat functions and eliminate the dynamic fluctuations in habitat functions of 4,600 acres of rice land and 12,020 to 28,040 acres of non-rice agricultural lands under BDCP conservation protection. Agricultural land placed under conservation protection under the BDCP will increase from the current 11 percent to a range of between 14 to 18 percent.

While some agriculture-associated covered species, such as Swainson's hawk are highly mobile and do not necessarily require connectivity of large preserved habitat patches, other species, such as giant garter snake and western pond turtle, will benefit from acquiring contiguous agricultural parcels that facilitate expansion of existing populations and dispersal and other movements between occupied areas and connectivity to suitable unoccupied areas. For example, connectivity of protected agricultural habitats (and restored tidal marsh and nontidal marsh) in Conservation Zone 4 will provide additional connectivity to Stone Lakes National Wildlife Refuge and facilitate northward expansion of the Coldani Marsh/White Slough giant garter snake subpopulation.

The reduction in agricultural acreage in the Plan Area will occur largely as a result of restoring tidal habitats. These restored habitats will incorporate the range of ecological gradients and will thus include associated grassland, open water, riparian, and other habitats. Most of the covered species associated with agricultural habitats including giant garter snake, Townsend's big-eared bat, white-tailed kite, tricolored blackbird, and greater sandhill crane, will use the restored habitats and benefit from the restoration activities. The distribution and abundance of these species is unlikely to be affected, and may benefit, as a result of the conversion of agricultural acreage to restored tidal marsh communities. For the implementation schedule of agricultural habitat preservation, see the BDCP implementation schedule presented in Chapter 6, *Plan Implementation.*

Native Biodiversity and Agricultural Habitats Function

Biologically Diverse Agricultural Habitats. Although cropland vegetation is grown as a monoculture using tillage or herbicides to eliminate unwanted vegetation, interspersed within the agricultural landscape are small patches or linear corridors of natural vegetation and other natural features, such as riparian woodland and scrub, wetlands, ponds, hedgerows, tree rows, and small patches of isolated native or nonnative trees that provide habitat for songbirds, raptors, reptiles, amphibians, and small mammals. Maintenance of these small but important wildlife habitats can benefit BDCP covered wildlife species. Agricultural habitats in the Plan Area are not known to support any BDCP covered plant species.

Covered wildlife species that use agricultural habitats use other habitats to meet life requirements. For example, agricultural lands are used primarily for foraging by several species that nest in riparian areas, roadside trees, or isolated trees and groves. Wetlands, streams, ponds, hedge rows, groves, and other remnant natural or created habitats are key to providing the full range of habitat elements necessary to support BDCP covered species in agricultural habitats. These native and sometimes nonnative (e.g., eucalyptus groves) are important elements within the agricultural matrix that provide essential habitat for these agricultural-associated covered species. Management of protected lands will therefore focus on the protection and enhancement of these key elements.

*Species Protection***.** Several covered species and many other native species (e.g., shorebirds, waterfowl) are associated with agricultural lands, which are used as surrogate landscapes for native communities that they replaced. Some of these species, such as Swainson's hawk and white-tailed kite, use agricultural lands as foraging habitat while they find nesting habitat in remnant patches or riparian habitat or other native and nonnative trees occurring within the agricultural matrix. Agricultural lands meet other life requirements for other covered species, such as giant garter snake and western pond turtle.

There are two primary components of giant garter snake conservation under BDCP: 1) the establishment of agricultural land preserves that will include nontidal freshwater perennial emergent wetland restoration associated with two existing subpopulations; and 2) protection of existing rice land values in the Yolo Bypass to minimize the effects of increased inundation duration and extent. Protection of other agricultural lands and restoration of tidal wetlands in Conservation Zones 4 and 7 will also benefit giant garter snake.

Although dependent on the aquatic environment, the giant garter snake occurs within the agricultural landscape where it uses interconnected watercourses (primarily irrigation canals) and associated freshwater emergent wetland habitat and rice lands during the active season and adjacent uplands during the inactive season. Maintaining an agricultural matrix that includes suitable interconnected canals with reliable water and associated emergent vegetation and adjacent upland habitats is essential for conservation of this species. Protection and management of agricultural lands within and adjacent to existing subpopulations will provide security for these occupied habitats and allow for additional expansion into adjacent protected areas. A 1,000 acre preserve is considered sufficient to protect and allow for expansion of these subpopulations. Agricultural lands within the preserves are also expected to be compatible with other BDCP covered species, including Swainson's hawk, white-tailed kite, greater sandhill crane, tricolored blackbird, and Townsend's big-eared bat.

In addition, the protection of 4,600 acres (the existing extent of rice land acres potentially affected by BDCP actions in the Yolo Bypass) of rice land or lands with equivalent value will help to sustain or increase giant garter snake use of the Yolo Bypass.

Swainson's hawk and white-tailed kite find the highest value foraging habitat on agricultural lands within the Plan Area. However, as noted above, only a portion of the landscape is suitable in any given year due to crop rotations and conversions to unsuitable cover types. The protection and management of between 12,020 and 28,040 acres of non-rice agricultural land distributed throughout the agricultural landscape within the Plan Area will ensure long-term stability of high value foraging habitat for these wider-ranging species.

Greater sandhill crane is also closely associated with agricultural lands in the Delta and will benefit from the protection of at least 4,000 acres of agricultural land within its primary use area (refer to species model in Appendix A, *Covered Species Accounts*). Agricultural lands managed as crane foraging habitat will include high value crops such as corn, wheat, alfalfa, and irrigated pasture. Close proximity to known roosts increases the opportunity for foraging use.

While not providing optimal habitat conditions, the burrowing owl also uses some agricultural habitats including hay crops and irrigated pastures. These are considered moderate value cover types for burrowing owl (refer to species model in Appendix A, *Covered Species Accounts*). Agricultural land conservation will also include the protection of at least 3,000 acres of pastureland suitable for western burrowing owl. This cover type is compatible with Swainson's hawk, white-tailed kite, and greater sandhill crane use.

Also, as noted above, many of the BDCP covered species associated with agricultural habitats, including giant garter snake, Townsend's big-eared bat, white-tailed kite, tricolored blackbird, and greater sandhill crane, will use the BDCP restored habitats and benefit from the restoration activities. The distribution and abundance of these species is unlikely to be affected, and may benefit, as a result of the conversion of agricultural acreage to restored tidal marsh communities.

Agricultural Habitats and Climate Change

Agricultural habitats may be particularly sensitive to precipitation changes and long-term sea level rise associated with global climate change. Increased variability in precipitation is likely to reduce the reliability of water supply available for irrigating crops at critical times of the year; and crop types cultivated may change with elevated ambient temperatures. With sea level rise exacerbating current conditions, a powerful earthquake in the region could collapse levees, leading to major saltwater intrusion and flooding throughout the Delta if flows were sufficiently low, altering the tidal prism and causing substantial changes to the agricultural areas (Mount and Twiss 2005). Areas within levees that are currently farmed could be impaired. Climate change impacts on agricultural habitats and its potential effect on covered species is addressed primarily by restricting the extent of conservation that occurs within areas that are currently below sea level in the Central Delta.

Conservation Measures for Agricultural Habitats

- CM3 Natural Communities Protection
- CM11 Natural Communities Enhancement and Management

3.3.2.2.13 Managed Wetland

The managed wetland natural community consists of areas that are intentionally flooded and managed (including associated ditches and drains) during specific seasonal periods to enhance habitat values for specific wildlife species. Typically, managed wetlands are flooded during the winter in anticipation of the arrival of migratory birds. This is followed by a slow draw down of the water to manage plant seed production and control mosquito populations. Some summer irrigation may also be conducted. Salinity of managed wetlands is determined by their proximity to the more brackish waters of the western Delta.

Currently, distribution of the managed wetland natural community in the Plan Area is largely in the northern, central, and western portions of the Delta, as well as in Suisun Marsh. Substantial acreage of this natural community can be found in the Yolo Bypass, the Stone Lakes National Wildlife Refuge, the Cosumnes River Preserve, and in Suisun Marsh. Delta islands that support areas of managed wetland include Mandeville, Medford, Bradford, Van Sickle and Chipps islands, and Holland Tract.

As a surrogate for natural marshes, managed wetlands provide productive seasonal wetlands interspersed with permanent wetlands in an effort to support large populations of waterfowl and shorebirds with the production of seeds and invertebrates. Managed wetlands are also maintained to provide nesting and resting or loafing areas. Some of the nutrients and primary productivity of managed wetlands can be transferred to adjacent natural wetlands through water management activities and movements of waterfowl and shorebirds. See Section 2.3.4.10, *Managed Wetland* in Chapter 2, *Existing Ecological Conditions,* for more detail on the current state of managed wetlands.

BDCP restoration of tidal wetlands will replace some existing managed wetlands that currently provide habitat for wintering and breeding waterfowl and migrant shorebirds. While tidal restoration is expected to replace most of the habitat functions removed through this conversion, it could potentially affect the distribution and abundance of some species.

Managed Wetland Goals and Objectives

Goal MWNC1: The expected outcome is maintenance of the current level of habitat functions provided by existing managed wetlands in the Plan Area through enhancement and restoration of natural communities on BDCP conservation lands, such that those wildlife functions do not preclude achievement of the Central Valley Joint Venture (CVJV) Implementation Plan's waterfowl and shorebird conservation targets for the Delta and Yolo Basin.

Objective MWNC1.1: Maintain the level of wintering and breeding waterfowl habitat functions currently supported by habitats in the Plan Area through protection, restoration, and management of habitat of equivalent function on BDCP conservation lands.

Objective MWNC1.2: Maintain the current level of migrant shorebird habitat functions currently supported by habitats in the Plan Area through protection, restoration, and management of habitat of equivalent function on BDCP conservation lands.

Goal MWNC2: The expected outcome is biologically diverse managed wetlands that are enhanced for native species.

Objective MWNC2.1: Maintain and enhance the habitat functions of BDCP managed wetlands present on BDCP preserved lands over the term of the BDCP.

Rationale for Goals and Objectives

Managed Wetland Extent

The Central Valley Joint Venture (CVJV) has developed wetland acreage goals for nine basins within the Central Valley. The acreage goals for the Suisun basin have been surpassed while the restoration goal for wetlands in the Delta basin is 19,000 acres. The intent of BDCP is to maintain or increase the habitat functions for wintering and breeding waterfowl and migrant and breeding shorebirds supported by the Plan Area habitats to ensure that BDCP actions will not impede attainment of the goals established by the CVJV Implementation Plan for the Delta and Yolo Basin.

Biodiversity and Managed Wetland Function

Biologically Diverse Managed Wetlands. Managed wetlands are managed primarily to promote use by birds. A wide variety of waterfowl and other birds migrating along the Pacific Flyway use the managed wetland natural community when inundated. In the Plan Area, BDCP covered greater sandhill cranes forage and roost in managed wetlands; many ducks, geese, wading birds, and shorebirds forage and loaf in managed wetlands. Abundant and diverse plant and invertebrate populations in managed wetlands provide important food resources for migrating waterfowl, bats, and many other wildlife species that forage in and over these wetlands.

Managed wetland vegetation typically consists of robust, perennial emergent vegetation and annual-dominated moist-soil grasses and forbs in freshwater areas and pickleweed and brass buttons in brackish water areas. The managed wetland natural community is subjected to the same invasive nonnative plant species as the tidal brackish emergent wetland and tidal freshwater emergent wetland natural communities. However, because management operations include discing and the manipulation of flooding duration, there are more opportunities to control invasive species. One managed wetland invasive, perennial pepperweed (*Lepidium latifolium*), is a serious threat that may be spread through discing; adding complexity to land management. Other problematic invasive plant species include pampas grass (*Cortaderia selloana*), giant reed (*Arundo donax*), and the nonnative genotype of common reed (*Phragmites australis*).

Because they are often confined behind levees, environmental gradients in managed wetlands are generally controlled through active management actions such as discing and soil contouring to provide a variety of ponding depths and widths. Variations in flooding timing, duration, and water quality are used to control species composition, primary productivity, water temperature, salinity, and the timing of exports of primary productivity.

Species Protection. Managed to appropriate depths and interspersed with berms and other upland edges, managed wetlands can provide high value roosting habitat for greater sandhill cranes. Creation of additional crane roosting habitat within the crane's traditional use area will provide additional roosting opportunities, allow for greater dispersal within the use area, and facilitate use of foraging habitats that may currently be underused due to the lack of roosting habitat. Crane roosting habitat may also provide additional managed wetland habitat for waterfowl and shorebirds.

Managed Wetland and Climate Change

Seasonal changes in precipitation and sea level rise are the aspects of climate change that will most affect managed wetlands. Potential reductions of and changes in timing of flows through the Central Valley will likely reduce the amount of water available for managed wetlands management actions, such as flooding at precise times of the season to provide habitat and food for waterfowl. Additionally, the managed wetland natural community may be impacted by sea level rise as much of it is near or below sea level and protected from flooding by levees. Higher sea level, increased winter river flooding, and more intense winter storms will significantly increase the hydraulic forces acting on the levees, threatening managed wetlands.

Conservation Measures for Managed Wetland

- CM3 Natural Communities Protection
- CM11 Natural Communities Enhancement and Management

3.3.2.2.14 Other Natural Seasonal Wetland

The other natural seasonal wetlands natural community encompasses all remaining natural (i.e., not managed) seasonal wetland communities other than the vernal pool complex and alkali seasonal wetland complex natural communities. The other natural seasonal wetlands natural community includes seasonally ponded, flooded, or saturated soils dominated by grasses, sedges (*Carex* spp.), or rushes (*Juncus* spp.) including degraded vernal pools that were not included in the vernal pool complex natural community.

In the Plan Area, this natural community generally occurs on degraded sites consisting primarily of seasonally ponding areas in agricultural fields. It also occurs as a temporarily flooded perennial forb vegetation type that is exclusively found in a field near the Cosumnes River. While small, isolated, and degraded, these sites may still provide some habitat value to covered species (e.g., vernal pool fairy shrimp) and other native species. In some cases, other natural seasonal wetlands provide opportunities for restoration and in other cases retention of these sites within the agricultural matrix can provide important refugia for a variety of BDCP covered and other native species. See Section 2.3.4.11, *Other Natural Seasonal Wetlands* in Chapter 2, *Existing Ecological Conditions*, for more detail on the current state of this natural community.

Other Natural Seasonal Wetlands Goals and Objectives

Goal ONSW1: The expected outcome is increased habitat functions that support BDCP covered species in other natural seasonal wetland natural community within maintained and protected agricultural habitat areas.

> **Objective ONSW1.1**: Integrate management of other natural seasonal wetland natural community with management of BDCP maintained and protected agricultural lands to increase habitat functions for covered species.

Rationale for Goals and Objectives

Other Natural Seasonal Wetlands Biodiversity and Function

The ecological gradient observable between seasonal wetlands and surrounding terrestrial natural communities is marked by transitions in plant and wildlife species; this is most pronounced during the wetted phase. When flooded, the other natural seasonal wetlands natural community supports an aquatic food web that may be functionally similar to that found in undisturbed vernal pools and natural seasonal wetlands (Alexander 1976, Barclay and Knight 1981, Scheffer 2004, Williams 2006). As the water recedes, its ecosystem characteristics change from those of a fully aquatic system to those of a terrestrial ecosystem (Williams 2006), and its food web linkages break down as the community becomes more integrated with the terrestrial landscape in which it is embedded.

Plant species found in the other natural seasonal wetlands natural community consist of a mixture of exotic and native perennial forbs, grasses, sedges, and rushes that are tolerant of temporary flooding, ponding, or soil saturation during winter and spring months. Problematic invasive plant species in this natural community include low mannagrass, Italian ryegrass, and perennial pepperweed. Invertebrates of the other natural seasonal wetlands natural community are the main source of food for waterfowl and shorebirds (Silveira 1998) which also use the wetlands in their dry state for resting and seed foraging areas (USFWS 2007a, Kleinschmidt Associates 2008).

In some cases other natural seasonal wetlands may provide, or have the potential for providing value to some covered and other native species. Agricultural lands managed under BDCP for agriculture-associated species may contain small patches of other natural seasonal wetland. These sites may provide current habitat value as refugia for species that otherwise occur within the agricultural matrix, or they may provide opportunities for restoration (e.g., vernal pools).

Other Natural Seasonal Wetlands and Climate Change

Climate change is expected to impact the other natural seasonal wetlands natural community primarily through changes in the hydrological regime brought about by increased variability in precipitation. The species present in this natural community are adapted to existing hydrological conditions. Increased variability in precipitation could lead to a shorter more variable wet season, bringing changes to the inundation period. It is unknown how increased variability in seasonal wetland hydrology would affect the plants and animals inhabiting them, but because these species are adapted to current conditions, the impacts will likely be negative. In addition, rising average temperatures could result in increased evapotranspiration rates, and therefore shorter wetted periods for seasonal wetlands; the impacts of which are expected to be adverse to native plants and wildlife.

Conservation Measures for Other Natural Seasonal Wetland

- CM11 Natural Communities Enhancement and Management

3.3.2.3 Covered Fish Species Goals and Objectives

[Note to Reviewers: *The BDCP consultants most recently provided preliminary covered fish species goals and objectives in July 2009. Those objectives are being developed, refined, and revised using the logic chain process, which has been informed by independent science review. The logic chain process is intended to inform plan development and implementation. It is not intended to identify regulatory requirements, nor will every objective developed using the logic chain be incorporated into the BDCP conservation strategy. The objectives below reflect the current work in progress from the consultants. The level of detail for longfin smelt, for example, represents the level of detail the logic chain process will ultimately develop for other species. The objectives below do not represent a consensus position of the Steering Committee regarding the objectives of the BDCP.*

Ecosystem- and natural community-level goals and objectives, which were not addressed by the Logic Chain Group, are provided in Sections 3.3.2.1 and 3.3.2.2 and were derived from the July 2009 draft Conservation Strategy and the November 2010 Terrestrial Conservation Strategy.

Next Steps for Completing Goals and Objectives

The following outlines recommended steps for continuing and completing the development of objectives and metrics in accordance with the Logic Chain process as revised per input from the August 2010 Logic Chain independent review panel. These next steps are intended to build on *the discussions and subsequent work products from the logic chain workshop held on October 26-27, 2010.*

1. ***Complete Logic Chain Objective Worksheets** – convene additional technical workshops to complete specific species worksheets.*

   a. *Convene subteam for focused meetings to discuss and finalize the worksheets.*

   b. *Where existing information is insufficient to establish numeric targets, the subteams will identify specific study needs to develop such information, including a timeframe for conducting such.*

   c. *Where there is disagreement regarding an objective, or metric, the details of the disagreement will be documented for resolution at a policy level.*

   ***Timeframe:** The goal is to be done by end of January 2011.*

2. ***Revise Community Goals –**review and revise ecosystem and natural community goals as necessary to be consistent with the species objectives.*

   ***Timeframe:** The goal is to be done by end of January 2011.*

3. ***Review Proposed Conservation Measures in Light of Consensus Objectives** – once objectives have been agreed to, review existing conservation measures to identify gaps and make changes as needed.*

   ***Timeframe:** The goal is to be done by end of February 2011.*

4. ***Refine Proposed Metrics** – based on #1,#2, #3 above, refine or revise the draft metrics proposed in Section 3.6.*

   ***Timeframe:** To the extent possible, refinements should be complete by the end of February in order to allow inclusion in the complete draft plan. It has not been determined at this time the level of detail necessary prior to BDCP authorization/permitting and the additional refinements that could be developed after the plan has been authorized/permitted.*

5. ***Develop Recommendations for the Monitoring and Adaptive Management Program** – based on all of the above.*

   ***Timeframe**: Some changes may be recommended after February for inclusion in the draft plan in 2011, but it is also likely that additional refinements in both programs would be made after BDCP authorization/permitting.]*

3.3.2.3.1 Delta Smelt

[***Note to Reviewers:*** *Draft goals and objectives for delta smelt have not been discussed by the logic chain team and therefore are not included herein. Goals and objectives for delta smelt will be developed in accordance with the next steps noted above]*

3.3.2.3.2 Longfin Smelt

Stressor: Physical Spawning Habitat Loss and Modification.

BDCP Objective: Increase extent and availability of quality longfin smelt physical spawning habitat.

Relation to Global Objectives: Increasing the extent/availability and quality of spawning habitat for longfin smelt may have positive effects on productivity and abundance.

Indicator: Spatial extent of quality habitats available for longfin smelt spawning. Attributes of "quality spawning habitat (i.e. what makes a habitat "quality spawning habitat") remain to be defined as they are largely unknown at this time. The position and extent of spawning habitat is believed to track the position of the low salinity zone.

Locations: Suisun Bay, Suisun Marsh, West Delta, lower Sacramento River, lower San Joaquin (historical spawning area)

Timing (e.g. seasonality) of stressor reduction: Spawning season roughly ~December - April

Attribute: Spatial Extent: Acreage of accessible habitat

Quality: Undefined as micro-habitat requirements are unknown. Further research in this ecosystem needed.

Quantity or State: Maintain/improve existing, and increase the areal extent of longfin smelt spawning habitat that meets certain quality specifications (may be divided into "high", "medium" and "low" quality or accessibility) by ________% or by ___ acres

Confidence that "Quantity or State" are sufficient to attain objective Unknown as the hypothesis that longfin smelt are limited by physical spawning habitat substrate is undocumented and attributes of spawning micro-habitat are undefined.

Time Frame (defined herein as the time from implementation of CM's or suites of CM's until Objective may reasonably be attained). Use of newly created or improved spawning habitat substrate by spawning adults and larvae could be assessed within a few years. Attainment of Objective would be assessed after implementation of habitat restoration and following several years (~5) years in which conditions would have been expected to limit spawning habitat prior to restoration.

Stressor: Degraded pelagic habitat for larval and early life stage longfin smelt.

BDCP Objective: Increase the extent (overlap of acceptable parameters of key habitat variables) and improve quality of the physical/chemical attributes of longfin smelt pelagic habitat.

Relation to Global Objectives: Increasing the extent and improving the quality of the physical/chemical attributes of longfin smelt pelagic habitat (including transport/retention dynamics) will increase longfin smelt abundance and productivity.

Indicator(s):

1) Volume of longfin smelt's preferred pelagic habitat conditions (e.g. temperature, depth, turbidity, salinity) during critical winter and spring periods;
2) Magnitude and duration of flows that promote transport and retention of longfin smelt (e.g. gravitational circulation) in the LSZ.

These are well-indexed by the variable "X2" (the 2ppt bottom isohaline) – the frequency distribution of X2 values in different months indicates the state of longfin smelt pelagic habitat over time.

Locations: Low Salinity Zone (i.e. location changes depending on hydrology of a given year).

Timing (e.g. seasonality) of stressor reduction: Winter-Spring (December-June)

Attribute: TBD

Quantity or State: TBD

Confidence that "Quantity or State" are sufficient to attain Objective: TBD

Time Frame: TBD

Stressor: Increased food Limitation due to food web suppression.

BDCP Objective: Increased density of longfin smelt preferred prey.

Relation to Global Objectives: Abundance and productivity are expected to increase with an increasing longfin smelt food supply

Indicator: 1) longfin smelt preferred prey items (mysids, Eurytemora, amphipods, *Psuedodiaptomous*, etc)(additional system-wide indicators include: 1) individual growth rates or condition index to understand extent of food limitation and 2) diet studies -- to determine if the longfin smelt diet has been affected by restoration-related impacts to food supplies).

Locations: the low salinity zone (0-6psu)

Timing (e.g. seasonality) of stressor reduction: TBD

Attribute: Density of prey and at least one of the following

1) individual growth rates or proportion of maximum ration attatined (Pmax)
2) condition index and
3) diet studies -- to determine if the increase in food translates to decrease in food limitation

Quantity or State: A 10x increase in prey density would be required, at a minimum, on the basis of rough approximations of trophic transfer relationships found in many food webs. [Importantly, the committee did not determine what level of increase in the longfin smelt population would be required].

Alternative basis for quantity/state of this objective might be to identify prey density during historical period of desired longfin smelt abundance (e.g. 1967-1984) and establish this as the objective.

Time Frame: Expectation of time required to attain objective varies with type of conservation measure employed.

Confidence that "Quantity or State" are sufficient to attain Objective:

Differs depending on the conservation measures employed

Potential covariate in unmanaged stressors: unimpaired hydrology (food abundance sensitive to outflow). In other words, effectiveness of non-flow related measures is evaluated against expectation of food web productivity given the relationship between prey density and hydrology in a given year (modifications to actual hydrology as well as other physical habitats are both expected to play a role in food web productivity).

Stressor #: Increased toxin concentrations (pyrethroids, Organophosphates, surfactants).

BDCP Objective: Reduce toxic compound concentrations to below identified thresholds that impede productivity of the longfin smelt food supply (ie, that produce detectable effects on those things that longfin smelt eat).

Indicator: Concentrations of identified toxins and zooplankton bioassays

Locations: Will vary by toxin. They should be measured where they would potentially effect longfin smelt. Pyrethroids would be measured in sediment, organophosphates in the water column, etc. Some (but not all) potential toxins might be measured as concentration in fish tissues; in this case it would be necessary to correlate body-burden with fish condition, performance, and fertility.

Timing (e.g. seasonality) of stressor reduction: Step 1: determine when/where food limitation is occurring. Step 2: evaluate water toxicity indicators at those times/places relative to other areas

Attribute: Intentionally left blank [unknown]

Quantity or State: Intentionally left blank [unknown]

Time Frame: Intentionally left blank [unknown]

Confidence that "Quantity or State" are sufficient to attain Objective: The current effect of toxins on the populations of organisms that longfin smelt eat is unknown.

Stressor #: Increased nutrient concentrations (ammonium) and/or altered N:P ratios.

BDCP Objective: Reduce nutrient concentrations to below identified thresholds that impede productivity of the longfin smelt food supply (ie, that produce detectable effects on those things that longfin smelt eat) and/or that support levels of toxic organisms (e.g. microsystis) that inhibit attainment of longfin smelt distribution objectives.

Relation to Global Objectives: Limitation of the food supply potentially constrains longfin smelt abundance and productivity. If the limitation is regionally specific, foodweb limitations may constrain longfin smelt distribution as well.

Nutrient levels that encourage growth of toxic organisms like *microcystis* may be limited longfin smelt distribution.

Indicator: Concentrations of identified nutrients; intensity of Microcystis bloom? Restoration of spring-summer diatom blooms…

Locations: Suisun Bay in the late spring-fall.

Timing (e.g. seasonality) of stressor reduction: May-October

Attribute: Diatom blooms, zooplankton population responses

Quantity or State: Intentionally left blank [unknown]

Time Frame: May-Octoberish [unknown]

Confidence that "Quantity or State" are sufficient to attain Objective: The current effect of nutrients on the populations of organisms that longfin smelt eat is unknown. Some research has indicated levels of ammonium that may inhibit production at the base of the food web (phytoplankton), though if/how improving phytoplankton growth in certain years will transfer to longfin smelt is unknown. The ammonium threshold (~4 umolar?) is fairly certain; concentrations below this are not expected to inhibit primary production.

Stressor #: Entrainment

BDCP Entrainment Objective (A): For winter protection of reproductive adults: combined SWP and CVP December through February salvage of juvenile and adult longfin smelt shall not exceed ___ times the value of the Fall Midwater Trawl longfin smelt index (all ages) from the previous September through December.

For winter spring protection of larvae and early juveniles: Larvae entrainment modeled by surface oriented particles (DSM2 particle tracking model) shall not exceed ___ of surface oriented particles from the sampling stations ___, while longfin smelt larvae are being detected at ___ of ___ sampling locations in the San Joaquin River and south Delta .

Relation to Global Objectives: Reducing entrainment of reproductive, larval, and early juvenile longfin smelt will increase productivity (survival and total egg production)

Indicator: See above

Locations: Salvage measured at Project Diversions and impingement (or relevant measure) at Mirant Power Plant. Stock of spawning aged fish measured by FMWT and/or other survey at existing survey stations.

Timing (e.g. seasonality) of stressor reduction: Dec-June. longfin smelt entrainment is a greater concern during low outflow periods when X2 is nearer the south Delta export facilities.

Attribute: X2 OMR and other flow variables

Quantity or State: See above.

Time Frame: Measure efficacy should be detectable in first few years after implementation in which low outflow conditions would make longfin smelt susceptible to entrainment. Attainment of objective would be evaluated after several years of "susceptible conditions".

Confidence that "Quantity or State" are sufficient to attain Objective: Needs further documentation – see K. Newman Life Cycle model? In particular, pre-screen mortality estimates for longfin smelt should be studied.

BDCP Entrainment Objective (B): Spawning and larval migration spatial extent will not be limited by entrainment mortality or diversion-related impacts to habitat

Relation to Global Objectives: Reducing entrainment of spawning, larval, and early juvenile longfin smelt in the lower San Joaquin River will allow for increased spatial distribution of spawning

Indicator: X2 and OMR flows

Locations: Old and Middle River flow gauges on either side of Bacon Island and QWEST – the flow estimate for the San Joaquin River at Jersey Point in the DAYFLOW database (where flow is currently measured)

Timing (e.g. seasonality) of stressor reduction: Dec-June. longfin smelt entrainment is a greater concern in years when outflow conditions place X2 close to the south Delta export facilities.

Attribute: Net average flow in Old and Middle River and at Jersey Point

Quantity or State: OMR Flows not to be more negative than ___ cfs December – June (spawning-larval period)

Time Frame: Measure efficacy could be modeled prior to plan implementation. Ground-truthing this estimate in the field requires some substantial new sampling/monitoring. Effect would be expected to materialize in concert with restoration efforts in the south Delta including improved flows and reduction in *Egeria*.

Confidence that "Quantity or State" are sufficient to attain Objective: Conceptual model for longfin smelt indicates that continued entrainment-related mortality in the South Delta could be a factor in declining detection for spawning activity in that region. Research needs re: longfin smelt reproductive site fidelity.

3.3.2.3.3 Chinook Salmon

Stressors Addressed: Habitat loss; flow alterations; predation;; impingement and entrainment; passage impediments; and illegal harvest

Stressors Not Addressed: Contaminants; ocean conditions; and access to historical spawning habitat.

Goal CHSA1: Contribute to conditions that will support increased abundance, increased spatial extent of key lifestages, restore genetic diversity and increase productivity of all runs of Chinook salmon.

Objective CHSA1.1: Increase habitat extent, availability, and quality for juvenile Chinook salmon of all runs, including presence of suitable food resources.

Stressor: Habitat loss, food limitation, and passage impediments.

Objective CHSA1.2: Increase growth rates of juvenile Chinook salmon of all runs while rearing in the Plan Area.

Stressor: See CHSA1.1

Objective CHSA1.3: Help to maintain adequate dissolved oxygen levels in the Stockton Deep Water Ship Channel to avoid blocking migration of adult fall-run Chinook salmon and spring-run Chinook salmon once a viable run is established in the San Joaquin River.

Stressor: Low dissolved oxygen concentrations on the San Joaquin River near Stockton

Objective CHSA1.5: Increase immigration success by __% and reduce migratory delays by __%

Stressor: Altered flow conditions, poor water quality, exposure to unscreened water diversions, entrainment

Objective CHSA1.6: The total percentage of juvenile Chinook salmon entrained at the CVP and SWP pumps shall not exceed __% of the Juvenile Production Estimate (JPE) (methods for determining JPE and target entrainment percentages to be determined for each run including an analysis of data by water year type to scale the targets accordingly)

Stressor: Entrainment of juvenile salmon at unscreened water diversions and CVP and SWP pumping plants.

Objective CHSA1.7: Reduce illegal harvest of adult Chinook salmon (all runs).

Stressor: Illegal take of covered species.

Objective CHSA1.8: Reduce susceptibility to, and impact of predation by nonnative predatory fish on juvenile outmigrants by _%.

Stressor: High densities of nonnative fish that prey on outmigrating salmon (NMFS 2009).

Objective CHSA1.9: Manage salmonid hatchery operations to minimize genetic affects on all naturally producing Chinook salmon run.

Stressor: Threats of hatchery programs in the Central Valley to spring-run Chinook salmon stock genetic integrity.

3.3.2.3.4 Central Valley Steelhead

Stressors Addressed: Habitat loss; flow alterations; predation;; impingement and entrainment; passage impediments; and illegal harvest.

Stressors Not Addressed: Contaminants; access to historical spawning habitat.

Goal STEE1: Contribute to conditions that will support increased abundance, increased spatial extent of key lifestages, restore genetic diversity and increase productivity of Central Valley steelhead.

Objective STEE1.1: Increase extent, availability, and quality of migration habitat for juvenile steelhead.

Stressor: Flow alterations, predation, poor water quality, habitat loss

Objective STEE1.2: Increase growth rates of juvenile steelhead while rearing in the Plan Area.

Stressor: See STEE1.1

Objective STEE1.3: Improve upstream and downstream passage for steelhead. Increase immigration success by __%.

Stressor: Passage impediments, flow alterations, low dissolved oxygen concentrations on the San Joaquin River near Stockton

Objective STEE1.4: Increase survival of outmigrating smolts by **__**%

Stressor: Flow alterations

Objective STEE1.5: The total percentage of juvenile steelhead entrained at the CVP and SWP pumps shall not exceed **__**% (methods for determining the percentage of entrainment and target entrainment levels to be determined with targets scaled according to water year type)

Stressor: Entrainment at unscreened water diversions and CVP and SWP pumping plants

Objective STEE1.6: Reduce illegal harvest of adult steelhead

Stressor: Illegal take of covered species.

Objective STEE1.7: Reduce susceptibility to, and impact of predation by nonnative predatory fish on juvenile outmigrants

Stressor: Predation caused by high densities of nonnative predatory fish

Objective STEE1.8: Manage salmonid hatchery operations to minimize genetic effects on all naturally producing steelhead run.

Stressor: Threats to natural steelhead posed by hatchery programs, including: (1) mortality of natural steelhead in fisheries targeting hatchery-origin steelhead; (2) competition for prey and habitat; (3) predation by hatchery-origin fish on younger natural fish; (4) genetic introgression by hatchery-origin fish that spawn naturally and interbreed with local natural populations; and (5) disease transmission (NMFS 2009).

3.3.2.3.5 Sacramento Splittail

Stressors Addressed: Habitat loss and food limitations, entrainment, predation by nonnative predators;

Stressors Not Addressed: Toxins and Contaminants

Goal SASP1: Contribute to conditions that will support the increased abundance and productivity of of Sacramento splittail in the Plan Area.

Objective SASP1.1: Increase access to, and availability of suitable spawning, rearing and foraging habitat for splittail. Increase the total surface area of inundated floodplain habitat by ___% when Delta inflow is __ cfs. [**Note to Reviewers**: *Look at the acreage to flow curve relationship. Look for opportunities to maximize the flooding for 30 days.]*

Stressor: Habitat loss, particularly loss of floodplain and channel margin habitat

Objective SASP1.2: Increase food availability for all life stages of Sacramento splittail by ___%.

Stressor: Food limitation

Objective SASP1.3: Help to maintain multiple spawning cohorts of Sacramento splittail as part of the breeding population.

Objective SASP1.4: The total percentage of splittail entrained at the CVP and SWP pumps shall not exceed __% (methods for determining the percentage of entrainment and target entrainment levels to be determined with targets scaled according to water year type)

Stressor: Entrainment

Objective SASP1.5: Reduce predation of splittail by centrachids and other predators.

Stressor: Predation by nonnative fish

3.3.2.3.6 Green Sturgeon

Stressors Addressed: Habitat loss; flow alterations; passage impediments; entrainment; dredging and illegal harvest.

Stressors Not Addressed: Contaminants, invasive species.

Goal GRST1: Contribute to conditions that will support the increased abundance, productivity, distribution and life-history and genetic diversity of green sturgeon in the Plan Area.

Objective GRST1.1: Improve rearing habitat for green sturgeon. [***Note to Reviewers:*** *Logic Chain Objective* #5)

Stressor: Habitat loss.

Objective GRST1.3: Improve upstream passage success for adult green sturgeon through the Fremont Weir and other operational gates/barriers. [***Note to Reviewers:*** *Logic Chain Objective #2]*

Stressor: Passage impediments.

Objective GRST1.4: The total percentage of green sturgeon entrained at the CVP and SWP pumps shall not exceed __% (methods for determining the percentage of entrainment and target entrainment levels to be determined with targets scaled according to water year type)

Stressor: Entrainment.

Objective GRST1.5: Determine through targeted studies the significance of poaching to the population and based upon study results, reduce poaching of adult green sturgeon in the Plan Area.

Stressor: Poaching green sturgeon

Objective GRST1.6: Avoid and minimize adverse effects of construction or maintenance dredging related to BDCP activities on green sturgeon.

Stressor: Construction or maintenance dredging related to BDCP activities.

3.3.2.3.7 White Sturgeon

Stressors Addressed: Habitat loss; flow alterations; passage impediments; entrainment; dredging and illegal harvest.

Stressors Not Addressed: Contaminants, , invasive species

Goal WHST1: Contribute to conditions that will increase the abundance, productivity and distribution of white sturgeon in the Plan Area.

Objective WHST1.1: Improve rearing habitat conditions for white sturgeon.

Stressor: Habitat loss, invasive plant species *[**Note to Reviewers:** Tidal marsh allocanthous support of clams and other macro-crustaceans contribute to the prey base of sturgeon]*

Objective WHST1.3: Improve upstream passage success for adult white sturgeon through the Fremont and Lisbon weirs and other operational gates.

Stressor: The Fremont Weir is a documented barrier to white sturgeon (Z. Matica, Department of Water Resources, pers. comm.).

Objective WHST1.4: The total percentage of white sturgeon entrained at the CVP and SWP pumps shall not exceed __% (methods for determining the percentage of entrainment and target entrainment levels to be determined with targets scaled according to water year type) [***Note to Reviewers:** Entrainment is a low magnitude stressor for sturgeon, currently. This should be addressed during real-time operations*]

Stressor: White sturgeon entrainment from agricultural operations, power plants, and the state and federal water project facilities

Objective WHST1.5: Reduce poaching of adult white sturgeon in the Plan Area

Stressor: Poaching of adult white sturgeon.

Objective WHST1.6: Avoid and minimize adverse effects of construction or maintenance dredging related to BDCP activities on white sturgeon.

Stressor: Construction or maintenance dredging related to BDCP activities

3.3.2.3.8 River Lamprey

Stressors Addressed: Habitat loss; flow alterations; passage impediments; and illegal harvest.

Stressors Not Addressed: Contaminants, predation by nonnative species, and dredging

Goal RILA1: Contribute to conditions that will support the maintenance and restoration of river lamprey distribution and abundance to higher levels than present.

Objective RILA1.1: Restore and/or enhance river lamprey rearing habitat.

Stressor: Habitat loss.

Objective RILA1.3: Identify impediments/barriers to upstream passage of adult river lamprey and implement lamprey-specific passage and protection measures.

Stressor: Passage impediments. **Objective RILA1.4**: Help maintain flow conditions that facilitate outmigration of juvenile river lampreys.

Stressor: Flow alterations.

3.3.2.3.9 Pacific Lamprey

Stressors Addressed: Habitat loss; flow alterations; passage impediments and illegal harvest.

Stressors Not Addressed: Contaminants, predation by nonnative species and dredging

Goal PALA1: Contribute to conditions that will support the maintenance and restoration of Pacific lamprey distribution and abundance to higher levels than present.

Objective PALA1.1: Restore and/or enhance Pacific lamprey rearing habitat.

Stressor: Habitat loss.

Objective PAILA1.2: Reduce stranding of Pacific lamprey ammocoetes

Stressor: Passage impediment caused by dewatering of channels

Objective PALA1.4: Help maintain flow conditions that facilitate outmigration of juvenile Pacific lampreys.

Stressor: Flow alterations.

3.3.2.4 Covered Wildlife and Plant Species Goals and Objectives

This section presents goals and objectives that provide for the conservation of covered wildlife and plant species. Conservation for covered species is addressed primarily through ecosystem and natural community goals and objectives. For some species, additional species-specific goals and objectives were deemed necessary for conservation and are included below. This section lists the applicable natural community and species-specific goals and objectives for each covered species and presents the rationale and conservation approach that will be used to achieve them. Table 3-11 presents the expected extent of each covered wildlife and plant species' habitat that will be protected and restored in the Plan Area with full BDCP implementation.

Table 3-11. Expected Extent of Conserved Species Habitat Types in Conservation Zones 1-11 with BDCP Implementation

Covered Species	*Total Extent (acres)*	*Total Existing Preserved (acres)*	*Percent Existing Preserved (acres)*	*BDCP Preserved (acres)* **A**	*BDCP Restored (acres)* **B**	*BDCP Conserved (acres)* **A+B**	*Total Conserved with BDCP Implementation* **(Existing +BDCP)**	*Percent Conserved with BDCP Implementation*

3.3.2.4.1 San Joaquin Kit Fox

In Northern California, the San Joaquin kit fox is a year-round resident of grassland habitats (Swick 1973, Hall 1983, Bell 1994), although it may also sometimes forage in fallow fields and irrigated row crops (Bell 1994). Its home range size is highly variable and tends to be related to prey abundance (White and Ralls 1993, White and Garrott 1999); its territories range from less than 2.6 square kilometers (sq km) (1 square mile [sq mi]) up to approximately 31 sq km (12 sq mi) (Morrell 1972, Knapp 1978, Zoellick et al. 1987b, Paveglio and Clifton 1988, Spiegel and Bradbury 1992, White and Ralls 1993). Habitat loss and fragmentation due to urbanization and agricultural expansion are the principal factors that have been implicated in the decline of the San Joaquin kit fox in the San Joaquin Valley (Laughrin 1970, Jensen 1972, Morrell 1975, Knapp 1978). By 1979, only an estimated 6.7 percent of the San Joaquin Valley floor's original native habitat south of Stanislaus County remained untilled and undeveloped (USFWS 1983). In its northern range, continued urbanization, primarily in Contra Costa and Alameda counties, water storage and conveyance projects, road construction, energy development, and other activities continue to reduce and fragment its remaining grassland habitat and contribute to kit fox declines through displacement, isolation of populations, creation of barriers to movement, direct and indirect mortality, and the reduction of prey populations (USFWS 1998a).

Applicable Natural Community Goals and Objectives

Goal GRNC1: The expected outcome is grassland comprised of large interconnected patches or contiguous expanses.

> **Objective GRNC1.1**: Protect a minimum of 8,000 acres of grassland in Conservation Zones 1, 8, and 11. At least 1,000 acres will be protected in Conservation Zone 8, with the remainder distributed throughout these three Conservation Zones.

Goal GRNC2: The expected outcome is biologically diverse grassland managed to enhance native species and sustained by natural ecological processes.

> **Objective GRNC2.1**: Restore and sustain a mosaic of grassland vegetation alliances, reflecting local water availability, soil chemistry, soil texture, topography, and disturbance regimes, with consideration of historical states.

> **Objective GRNC2.2**: Increase the relative cover of native grasses and forbs in native grassland vegetation alliances.

> **Objective GRNC2.3**: Increase opportunities for wildlife movement through grassland habitat.

> **Objective GRNC2.4**: Increase burrow availability for burrow-dependent species.

> **Objective GRNC2.5**: Increase prey, especially small mammals and insects, for grassland-foraging species.

Rationale and Conservation Approach

Since the primary stressor on the kit fox is the loss and fragmentation of its grassland habitat through urban and agricultural expansion, protection of grassland habitat is considered the most effective approach to the kit fox's conservation (Figure 3-14). In the recovery plan for the San Joaquin kit fox and other San Joaquin Valley upland species (USFWS 1998a), the recommended conservation strategy is centered on establishing a network of conservation areas and reserves. During the implementation of BDCP, conservation of the kit fox will similarly be provided through habitat protection, with an emphasis on protecting the largest remaining contiguous patches of habitat, and ensuring habitat connectivity with adjacent occupied areas. Because kit fox habitat within the Plan Area is located along the margin, rather than in the core, of the species' range, the possibility exists that BDCP conservation measures will be implemented outside the boundaries of the Plan Area, but this will occur only if and where conservation measures are expected to maximize the benefit for kit fox conservation. This contingency would be selected should a specific opportunity arise for conservation in a core kit fox habitat area, consistent with conservation plans for those locations as described in Section 3.2.4, *Development of the Terrestrial Resources Component of the Conservation Strategy*.

Conservation of San Joaquin kit fox in the Plan Area will focus on the preservation and enhancement of 1,000 acres of its grassland breeding, foraging, and dispersal habitat (Table 3-5).

Protection of kit fox habitat will focus in particular on acquiring the largest remaining contiguous patches of unprotected grassland breeding habitat, which are located in Conservation Zone 8 south of Highway 4 (see Appendix A, *Covered Species Accounts*). Conservation Zone 8 supports 74 percent of the modeled kit fox grassland breeding habitat in the Plan Area (Table 3-11). Following BDCP implementation, the percent of modeled kit fox breeding, foraging, and dispersal habitat protected in Conservation Zone 8 will increase from 16 percent to 42 percent.

Kit fox home ranges are large; therefore, habitat connectivity is key to the conservation of the species. Breeding habitat present in Conservation Zones 7, 9, and 10 occurs only in small fragmented patches, which by themselves are likely to be of limited value to the kit fox (see Appendix A, *Covered Species Accounts*). Even protected grassland habitat in Conservation Zone 8 is unlikely to encompass an entire home range. For this reason, protected habitat will be acquired in locations that provide connectivity to existing protected breeding habitats in Conservation Zone 8 and to other adjoining kit fox habitat within and adjacent to the Plan Area. Connectivity to occupied habitat adjacent to the Plan Area will help ensure the movement of kit fox to larger habitat patches outside of the Plan Area.

Declines in prey abundance associated with ground squirrel poisoning programs have been identified as a stressor contributing to reduced kit fox abundance (see habitat model in Appendix A, *Covered Species Accounts*). Consequently, protected grassland will be managed and enhanced to increase the abundance and distribution of kit fox mammalian prey species (e.g., discontinued use of pesticides, manipulation of topography, mowing for increasing ground squirrel densities).

In summary, the Plan Area lies along the margin of the kit fox's distribution, where conservation measures might provide only limited benefits. However, should the proposed kit fox habitat conservation actions be implemented in the Plan Area, they are still expected to maintain sufficient habitat area to sustain or increase the existing Plan Area kit fox population. The same proposed habitat conservation actions are also expected to maintain connectivity with occupied core populations that are adjacent to the Plan Area and are covered under adjacent and overlapping HCP/NCCPs. Conservation measures may be implemented outside rather than within the Plan Area. Such a conservation approach would be selected only where conservation benefits are expected to be greater than from conservation measures implemented within the Plan Area.

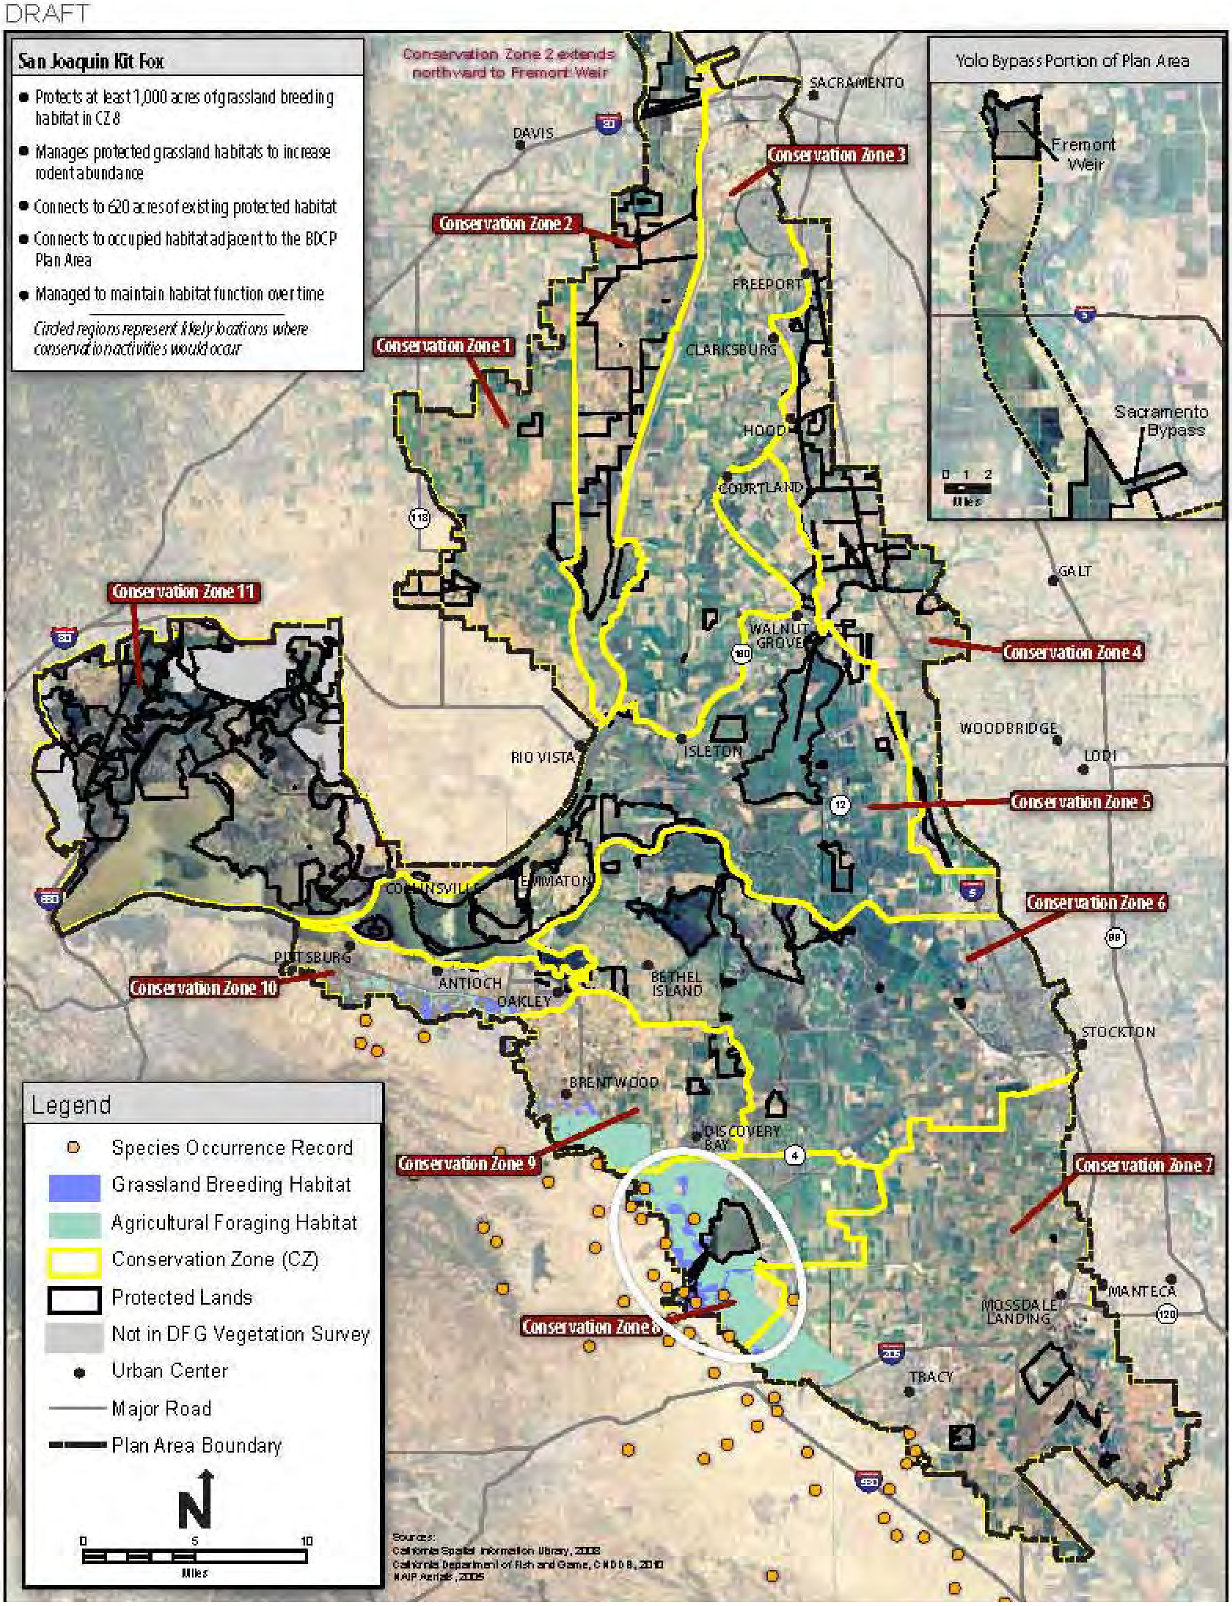

Figure 3-14. San Joaquin Kit Fox Habitat Distribution and Conservation Strategy

3.3.2.4.2 Riparian Woodrat

The riparian woodrat (*Neotoma fuscipes riparia*) is a subspecies of the dusky-footed woodrat that occurs in riparian woodland with an overstory canopy of trees and a moderate to dense shrub understory, reaching its highest densities in willow thickets growing under a canopy of valley oaks (Williams 1986, USFWS 1998a). It is not known to occur in the Plan Area, but the only verified extant population of riparian woodrat is only 2 miles east of the Plan Area in Caswell Memorial State Park along the Stanislaus River (Williams 1986, 1993). Small patches of potentially occupied valley oak riparian forest occur along the San Joaquin River from the southern tip of the Plan Area north to approximately the Interstate 5 overcrossing near Lathrop (Appendix A, *Covered Species Accounts*).

The riparian woodrat is a federally listed species and a state species of special concern (Williams 1986). Once occupying a larger range, it is now confined to the lower portions of the San Joaquin and Stanislaus rivers in northern San Joaquin County (Williams 1986, 1993, USFWS 1998a). Habitat loss and fragmentation are considered the main causes for the riparian woodrat's range contraction. There has been a nearly 90 percent reduction in the extent of riparian communities along major streams flowing onto the floor of the northern San Joaquin Valley (Katibah 1983), much of the loss is due to habitat conversion to agricultural lands and the construction of large dams and canals (Appendix A, *Covered Species Accounts*).

Applicable Natural Community Goals and Objectives

Goal VRNC1: The expected outcome is restored large expanses and interconnected corridors of valley/foothill riparian natural community.

> **Objective VRNC1.1**: Restore or create 5,000 acres of valley/foothill riparian in Conservation Zones 1, 2, 4, 5, 6, 7, and/or 11.

Goal VRNC2: The expected outcome is biologically diverse valley/foothill riparian natural community that supports native species and is sustained by natural ecological processes.

> **Objective VRNC2.1**: Maintain and enhance the habitat and ecosystem functions of BDCP restored valley/foothill riparian and patches of riparian forest and scrub present on BDCP preserved lands over the term of the BDCP.

> **Objective VRNC2.3**: Restore connectivity of valley/foothill riparian corridors along linear watercourses to enhance habitat for covered species and facilitate wildlife movement.

Species-Specific Goals and Objectives

Goal RIWR1: The expected outcome is restored and protected habitat for the riparian woodrat.

> **Objective RIWR1.1:** Of the 5,000 acres of restored valley/foothill riparian, restore and manage 300 acres to meet the ecological requirements of the riparian woodrat in Conservation Zone 7.

Rationale and Conservation Approach

Habitat protection and, where appropriate, habitat restoration, is the central component of the conservation strategy recommended in the Recovery Plan for the riparian woodrat and other upland species of the San Joaquin Valley (USFWS 1998a). The Recovery Plan establishes an overall goal of establishing three riparian woodrat populations based on conservation actions aimed at protecting and restoring riparian habitat, together with species reintroduction (USFWS 1998a). The overall BDCP biological goal for the riparian woodrat is to restore suitable riparian woodrat habitat to provide for the species' conservation; this is congruent with the Recovery Plan (Figure 3-15) (see Appendix A, *Covered Species Accounts*). Conservation will be directed towards restoring valley/foothill riparian within the Plan Area to provide habitat that could allow for future reintroduction or expansion of the existing riparian woodrat population into the Plan Area. The 5,000 acres of valley/foothill riparian to be restored under the Plan is expected to include patches of riparian vegetation that supports riparian woodrat habitat. These patches will increase the likelihood of future colonization of Plan Area habitats by the riparian woodrat.

Additionally, of the 5,000 acres of riparian habitat to be restored under the Plan, BDCP will restore and manage 300 acres of riparian vegetation with specific riparian woodrat habitat attributes, including a willow understory and oak overstory. Riparian woodrat habitat would be restored in patches of at least 25 acres, which is believed to exceed the minimum habitat patch size requirements for the species. The extent of existing known occupied habitat is approximately 250 acres (see Appendix A, *Covered Species Accounts*). Restoration of 300 acres of additional habitat is expected to contribute to conservation of the riparian woodrat by substantially increasing the extent of available and protected habitat.

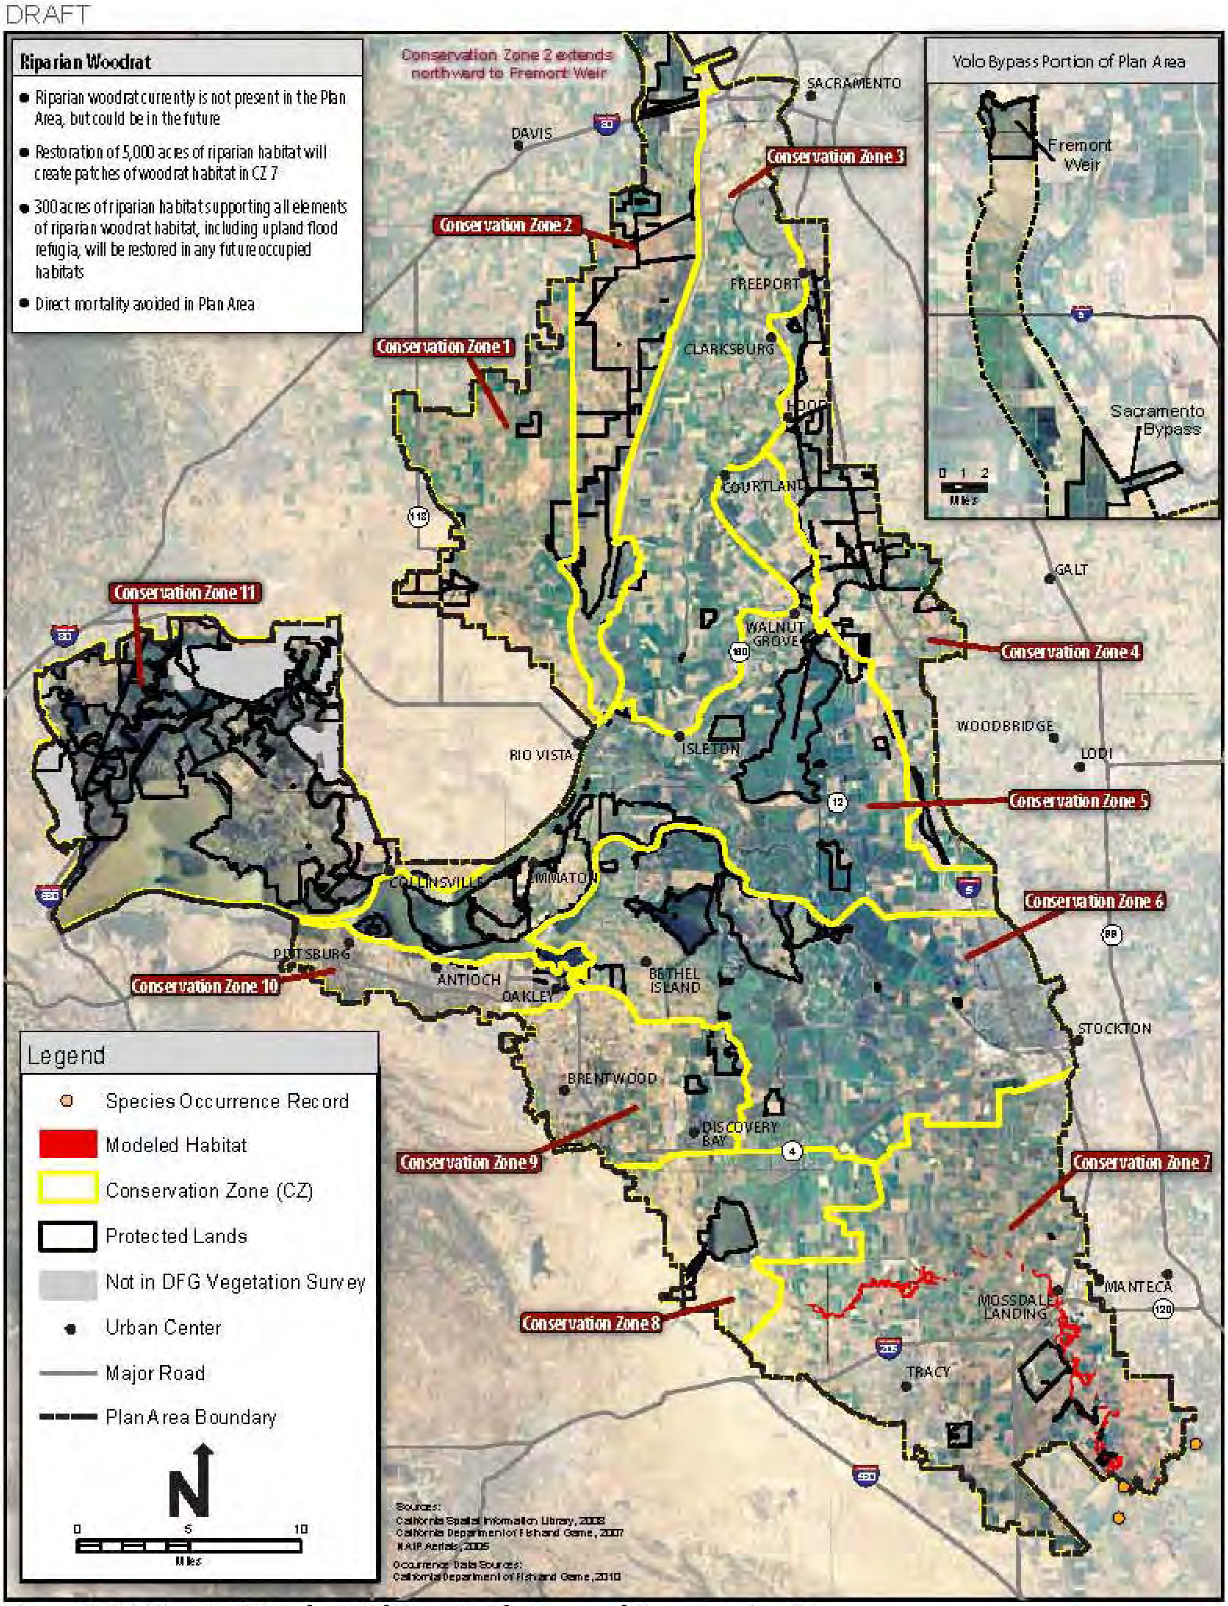

Figure 3-15. Riparian Woodrat Habitat Distribution and Conservation Strategy

3.3.2.4.3 Salt Marsh Harvest Mouse

The salt marsh harvest mouse is a small rodent endemic to the salt and brackish marshes of San Francisco, San Pablo, and Suisun Bays (USFWS 2001b). It depends on salt marshes as its optimal habitat and is primarily found in vegetation dominated by pickleweed. Upland refugia are important during high tide events so that it can escape flooded low-lying marshlands (see Appendix A, *Covered Species Accounts*). Much of the occupied habitat in Suisun Marsh consists of suitable patches of tidal brackish emergent wetland within a nontidal managed and diked wetland complex (including upland grasslands used as refugia during high tide events) that the mouse has adapted to following the reclamation of historical Suisun Bay tidal marshes. The size of salt marsh harvest mouse populations in Suisun Marsh are likely limited by habitat fragmentation.

The recovery plan for this state and federally endangered species was completed in 1984 and is currently under revision (Appendix A, *Covered Species Accounts*). The historical range of the species likely included most of the marshland in the San Francisco Bay Area. Today, the species might occupy an area representing only approximately 15 percent of the historical salt marsh habitat formerly found in the San Francisco Bay Area (Dedrick 1989). Much of this remaining habitat is isolated by dikes and landfill, is subject to backfilling, subsidence, and vegetation changes, and as a result is unlikely to support salt marsh harvest mouse (Shellhammer 1989). Thus, the remaining populations are small and separated by large areas of unsuitable habitat, and the loss and degradation of tidal marsh habitats continue to be the most significant threat to the salt marsh harvest mouse and other tidal marsh species.

Applicable Natural Community Goals and Objectives

Goal BMNC1: The expected outcome is restored large expanses and interconnected patches of tidal brackish emergent wetland natural community.

> **Objective BMNC1.1:** Restore or create 3,600 to 4,800 acres of tidal brackish emergent wetland in the Suisun Marsh ROA (Conservation Zone 11).

Goal BMNC2: The expected outcome is biologically diverse tidal brackish emergent wetland that is enhanced for native species and sustained by natural ecological processes.

> **Objective BMNC2.1:** Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal brackish emergent wetland for covered and other native species over the term of the BDCP.

Rationale and Conservation Approach

Because the primary stressor on the salt marsh harvest mouse is loss of its tidal marsh habitat due to urban and agricultural expansion, the recovery plan for the salt marsh harvest mouse emphasizes habitat protection, enhancement, and restoration as essential to the conservation and recovery of the species (USFWS 1984b). BDCP-proposed restoration, enhancement, and management of tidal habitat and associated refugia in Suisun Marsh is consistent with the 1984 Recovery Plan for the salt marsh harvest mouse (Figure 3-16). It also helps to achieve the salt marsh harvest mouse objectives of the draft tidal marsh ecosystems recovery plan (USFWS 2010) and the objectives of the Suisun Marsh Restoration Plan (under development).

Restoration of tidal habitat will remove and degrade patches of tidal brackish emergent wetland that are currently occupied by salt marsh harvest mouse; therefore, restoration will be sequenced and located in a manner that minimizes any initial, temporary loss of habitat. Approaches for restoring tidal habitat to support salt marsh harvest mouse habitat are described in Conservation Measure CM4 Tidal Habitat Restoration. Restored tidal habitats will be designed to the extent practicable within site constraints to provide the full range of environmental gradients from tidal areas to uplands that existed under historical conditions in Suisun Marsh. This approach is expected to result in restoration of patches of salt marsh harvest mouse habitat within a mosaic of larger marsh plain habitat. A total of between 3,600 and 4,800 acres[24] of tidal wetland and 350 to 700 acres of associated upland habitat is expected to be restored in the Suisun Marsh (Conservation Zone 11) and provide high value habitat for the salt marsh harvest mouse. It is anticipated that following completion of all tidal habitat restoration in Suisun Marsh, tidal marsh plain habitats will be restored in patches larger than currently found (characterized by habitat fragmentation by dikes, roads, and other infrastructure, as well as unsuitable habitat). These larger unfragmented patches are expected to be of higher ecological value to the salt marsh harvest mouse and facilitate population expansion and growth in Suisun Marsh. The transitional upland component of restored tidal habitats will be designed to provide flood refugia (grassland) habitat during high tide events.

BDCP actions are expected to initially impact salt marsh harvest mouse wetland habitat in Suisun Marsh, but most marshes to be impacted will be managed wetlands. Over the full course of BDCP implementation, BDCP actions will preserve and restore a greater amount of tidal marsh than will be impacted, and thus significantly advance the conservation of the salt marsh harvest mouse.

Nonnative predators (e.g., feral cats) are believed to be an important stressor on the salt marsh harvest mouse. Therefore, the design and management of restored habitat will include control of nonnative predators (e.g., through direct removal of predators or through design of restored habitats that minimize access of predators into occupied habitats).

<u>*Applicable Conservation Measures*</u>

- CM3 Natural Communities Protection
- CM4 Tidal Habitat Restoration
- CM11 Natural Communities Enhancement and Management

[24] Restored tidal habitat acreage ranges are a component of the 65,000 acre target for restored tidal habitat. Acreage ranges are based on the results of hydrodynamic modeling of realistic hypothetical restoration designs. While these ranges are not the acreage targets for restored tidal habitats, but rather the results of modeling, the hypothetical designs provided verification of the practicability of achieving restoration targets.

DRAFT

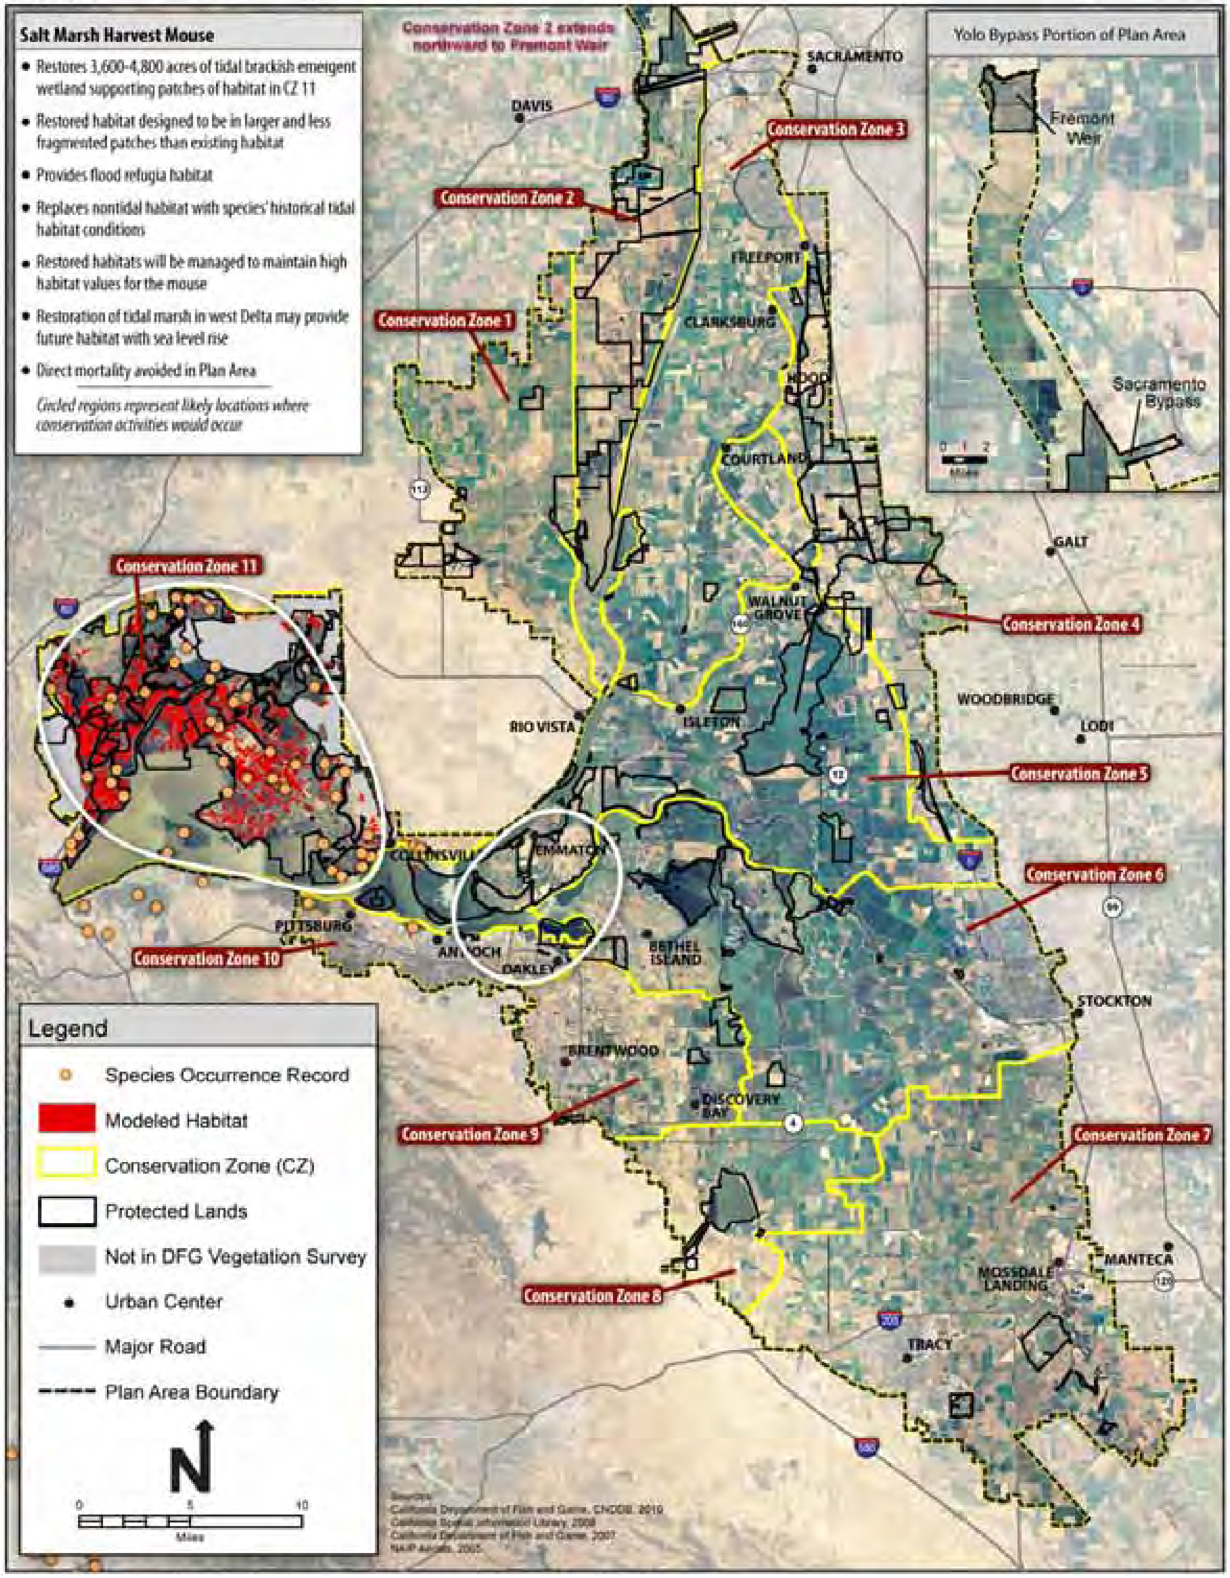

Figure 3-16. Salt Marsh Harvest Mouse Habitat Distribution and Conservation Strategy

3.3.2.4.4 Riparian Brush Rabbit

One of eight subspecies of brush rabbit in California, the riparian brush rabbit (*Sylvilagus bachmani riparius*) occupies a range that is disjunct from that of other brush rabbits, near sea level on the floor of the San Joaquin Valley (USFWS 1998a). Riparian brush rabbits inhabit valley riparian forests or forest patches, where they are closely associated with dense shrub vegetation (Williams et al. 2008). Occupied sites tend to be in riparian settings with an open overstory canopy of valley oak (*Quercus lobata*) or savannah-like settings that support extensive patches of low-growing willow (*Salix* spp.), wild rose (*Rosa californica*), wild grape (*Vitis californica*), or blackberry (*Rubus* spp.) (Williams et al. 2008). The brush rabbits move through the dense brush and thickets by creating tunnels through the vegetation. Seasonally available weedy/ruderal cover, including patches of tall grass, forbs, and pepperweed (*Lepidium latifolium*) is also used, particularly where it connects to more suitable woody cover (Williams et al. 2008). Generally, riparian forests that support a closed overstory canopy lack sufficient understory shrubs to support riparian brush rabbits (USFWS 1998a). Small herbaceous openings in close proximity to cover are also required for foraging, and higher elevation areas are required to sustain populations during floods (USFWS 1998a).

Due to drastic declines in brush rabbit numbers since the 1940s, the riparian brush rabbit (*Sylvilagus bachmani riparius*) is listed as endangered under the state and federal endangered species acts. The riparian brush rabbit's historical distribution may have extended along portions of the San Joaquin River and its tributaries on the valley floor from at least as south as Stanislaus County to the Delta (Orr 1935 in USFWS 1998a). Populations are known to have historically occurred in riparian forests along the San Joaquin and Stanislaus rivers and some tributaries to the San Joaquin River on the valley floor (USFWS 1998a). One population estimate within this historical range was about 110,000 individuals (USFWS 1998). The dramatic decline of the riparian brush rabbit began with the building of dams constructed for irrigation and flood control, on the major rivers of the Central Valley. Protection from flooding resulted in conversion of floodplains to croplands and the consequent reduction and fragmentation of remaining riparian communities. By the mid-1980s, the riparian forest within the species' former range had been reduced to a few small and widely scattered fragments totaling about 5,189 acres (USFWS 1998a).

As a result of habitat loss, remaining populations of riparian brush rabbits occur in only two areas of San Joaquin County. The first is a patch of approximately 258 acres in Caswell Memorial State Park (CMSP) on the Stanislaus River. The second population, which was only confirmed in late 1998, occupies approximately 270 acres in several small, isolated or semi-isolated patches along Paradise Cut and Tom Paine Slough and channels of the San Joaquin River in the southern Plan Area (Williams et al. 2002a, Williams et al. 2008).

In 2005, a captive-bred population of approximately two-dozen animals was introduced to the Faith Ranch along the San Joaquin River in Stanislaus County adjacent to the San Joaquin River National Wildlife Refuge. The recovery plan for the brush rabbit (and other upland species of the San Joaquin Valley) is focused on riparian restoration and protection, together with population reintroductions.

Applicable Natural Community Goals and Objectives

Goal VRNC1: The expected outcome is restored large expanses and interconnected corridors of valley/foothill riparian natural community.

> **Objective VRNC1.1**: Restore or create 5,000 acres of valley/foothill riparian in Conservation Zones 1, 2, 4, 5, 6, 7, and/or 11.

Goal VRNC2: The expected outcome is biologically diverse valley/foothill riparian natural community that supports native species and is sustained by natural ecological processes.

> **Objective VRNC2.1**: Maintain and enhance the habitat and ecosystem functions of BDCP restored valley/foothill riparian and patches of riparian forest and scrub present on BDCP preserved lands over the term of the BDCP.

> **Objective VRNC2.3**: Restore connectivity of valley/foothill riparian corridors along linear watercourses to enhance habitat for covered species and facilitate wildlife movement.

Species-Specific Goals and Objectives

Goal RIBR1: The expected outcome is restored and protected habitat for riparian brush rabbit.

> **Objective RIBR1.1:** Of the 5,000 acres of riparian restoration, restore and manage at least 300 acres to meet the ecological requirements of the riparian brush rabbit in Conservation Zones 7 or 8.

Rationale and Conservation Approach

BDCP implementation will be congruent with and help achieve the goals of the recovery plan. Specifically, conservation within the Plan Area will be directed towards restoring riparian forest and scrub to provide habitat compatible with future reintroduction efforts or expansion of the existing riparian brush rabbit population into the Plan Area. Approaches for restoring riparian communities that support riparian brush rabbit habitat are described in the conservation approaches for conserving the Valley/foothill riparian natural community.

Conservation of riparian brush rabbit will be provided through restoration of 300 acres of riparian vegetation that supports brush rabbit habitat attributes within the species' historical range along Old River, Middle River, and/or the San Joaquin River or suitable tributaries in Conservation Zones 7 and 8 (Figure 3-17). Habitat will be restored in patches of at least 25 acres, which is believed to exceed the minimum habitat patch size requirements for the species.

Connectivity with currently occupied or potentially occupied habitat will be a primary factor in the selection of restoration sites. In addition to the species' limited distribution and abundance, flooding and predation are primary stressors on this species. The restored riparian brush rabbit habitat will be designed to incorporate flood refugia habitat (i.e., bunny mounds) and will be designed and managed to control predation. The extent of existing known occupied habitat is approximately 270 acres (Appendix A, *Covered Species Accounts*) and restoration of 300 acres of additional habitat located adjacent to occupied or potentially occupied habitat areas will result in a substantial increase in the extent of available habitat. Additionally, a portion of the remaining 4,500 acres riparian habitat to be restored and distributed amongst Conservation Zones 1, 4, 5, 7, and/or 11 is expected to also support riparian brush rabbit habitat over the term of the BDCP. Thus, the proposed restoration and management of riparian brush rabbit habitat are expected to sustain the existing population. Riparian habitat conservation efforts within Conservation Zones 7 and 8 will serve to accommodate any future expansion of the existing population or provide habitat for future introductions of the species.

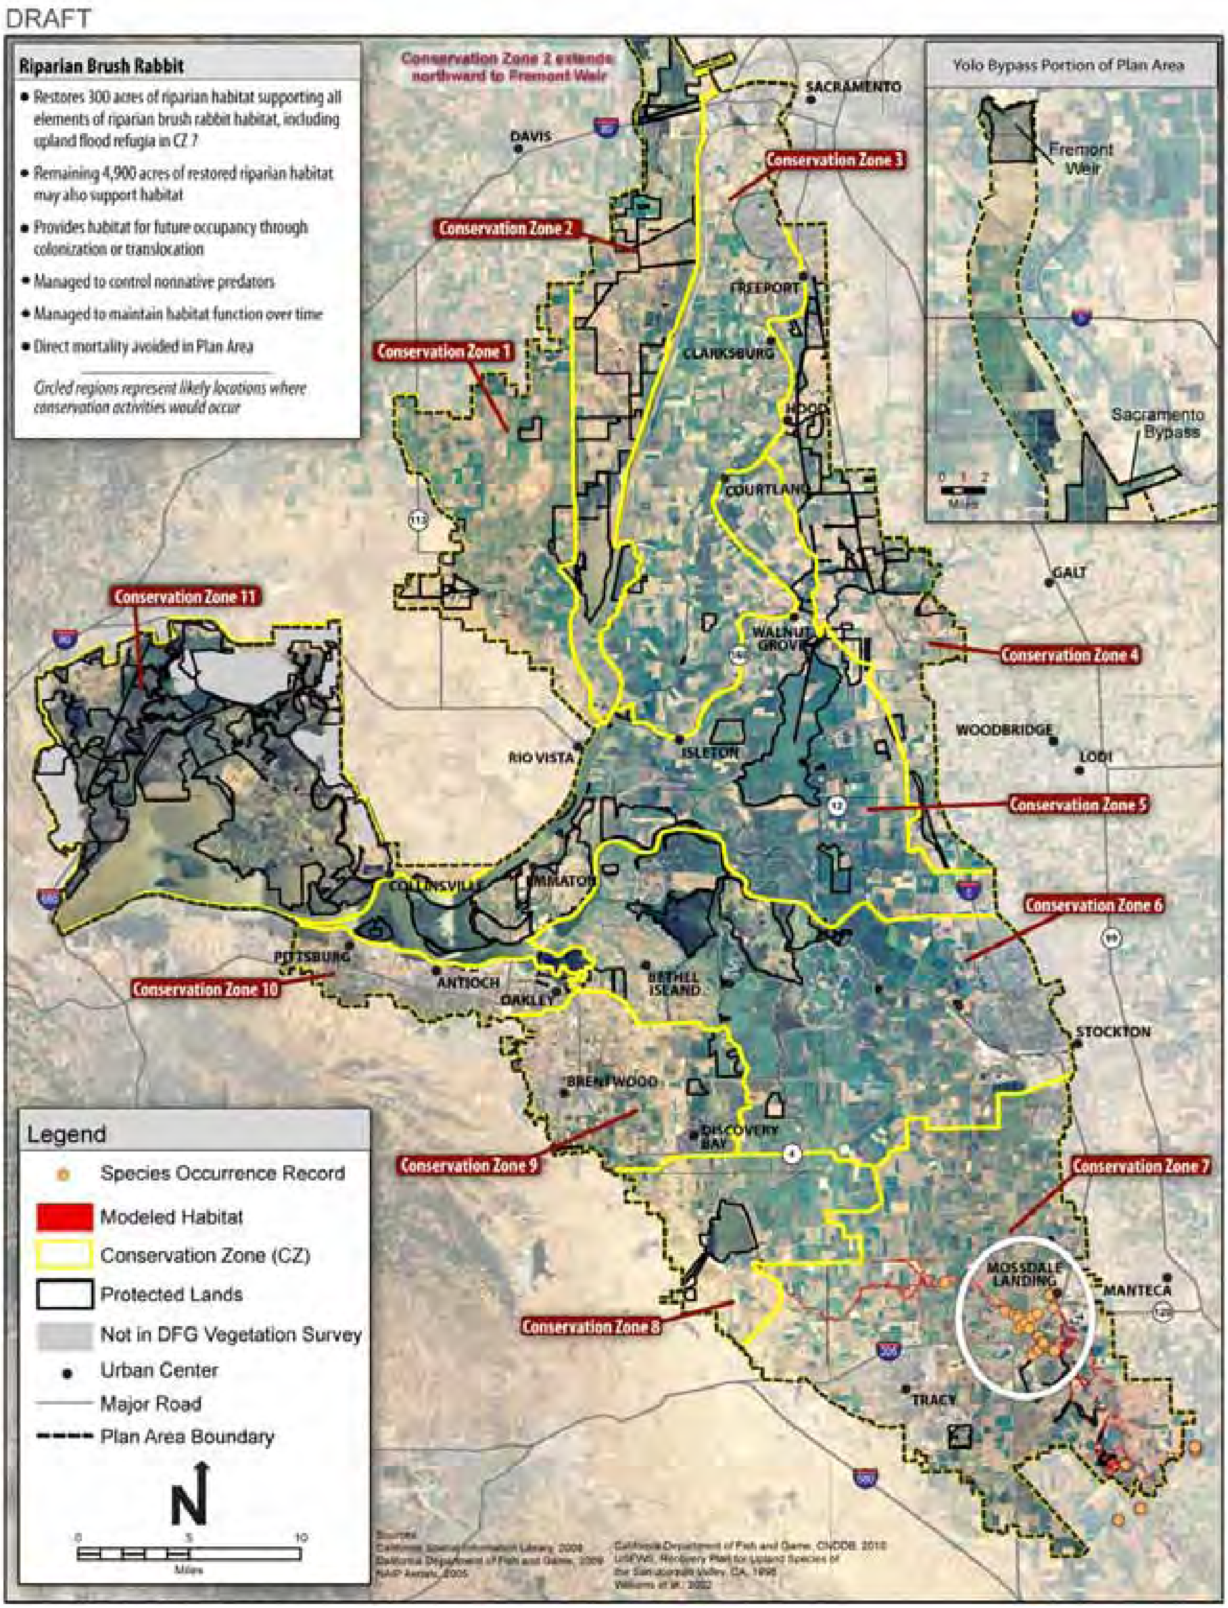

Figure 3-17. Riparian Brush Rabbit Habitat Distribution and Conservation Strategy

3.3.2.4.5 Townsend's Big-Eared Bat

Townsend's big-eared bat occurs in many habitats including active agricultural areas, riparian vegetation communities, coastal habitat types, oak woodland, conifer forest, desert scrub, and native prairies. Roosting habitat is mainly limited to caves, mines, tunnels, and other features that mimic caves, such as large tree hollows, abandoned buildings with cave-like attics, water diversion tunnels, and internal spaces in bridges. Pierson and Rainey (1998a) suggested that the species' distribution appears to be constrained primarily by the availability of suitable roosting sites and the degree of human disturbance at roosts.

According to Pierson and Rainey (1998a), there has been a 52 percent loss in the number of maternity colonies during the last 40 years, a 45 percent decline in the number of available roosts, a 54 percent decline in the total number of animals, and a 33 percent decrease in the average size of remaining colonies for the species as a whole across California. Townsend's big-eared bats have declined notably in San Francisco Bay area counties where native habitat and rural land have been converted to agriculture (i.e., wine production) or suburban/urban development. The cause of local population declines is most likely the disturbance and the destruction of roost sites. Vulnerability to human disturbance is indicated by findings that colonies have abandoned roost sites after human visitation (Humphrey and Kunz 1976). In addition to the disturbance or destruction of winter roosts, Pierson et al. (1999) also reported that Townsend's big-eared bats are threatened by the loss of clean water and the loss of roosting and foraging habitat. The impacts of pesticides and herbicides on insect prey availability may also threaten populations of this species.

No Townsend's big-eared bat has been documented in the Plan Area. However, the species is known to occur at nearby Central Valley locations and presumably could be present in the Plan Area (see Appendix A, *Covered Species Accounts*).

Applicable Natural Community Goals and Objectives

Goal VRNC1: The expected outcome is restored large expanses and interconnected corridors of valley/foothill riparian natural community.

> **Objective VRNC1.1**: Restore or create 5,000 acres of valley/foothill riparian in Conservation Zones 1, 2, 4, 5, 6, 7, and/or 11.

Goal ALNC1: The expected outcome is increased habitat functions for covered and other native species that are supported by agricultural land cover types and management practices.

> **Objective ALNC1.1**: Maintain and protect the functions of 4,600 acres of rice lands as habitat for giant garter snake, western pond turtle, tricolored blackbird, white-tailed kite, waterfowl, and migrant shorebirds in Conservation Zone 2. This objective may be partially or fully achieved by maintaining an equivalent extent of natural or managed lands that support habitat functions similar to rice lands for associated covered and other native wildlife species.

Objective ALNC1.2: Maintain and protect the functions of 12,020 to 28,040 acres of non-rice agricultural lands as foraging habitat for Swainson's hawk, white-tailed kite, and tricolored blackbird that are located within 8 miles of occupied Swainson's hawk nesting habitat.

Goal BMNC1: The expected outcome is restored large expanses and interconnected patches of tidal brackish emergent wetland natural community.

Objective BMNC1.1: Restore or create 3,600 to 4,800 acres of tidal brackish emergent wetland in the Suisun Marsh ROA (Conservation Zone 11).

Goal FMNC1: The expected outcome is restored large, interconnected patches of tidal freshwater emergent wetland natural community.

Objective FMNC1.1: Restore or create 13,900 to 21,600 acres of tidal freshwater emergent wetland in the Cache Slough, West Delta, Cosumnes-Mokelumne, and South Delta ROAs (Conservation Zones 1, 2, 4, 5, 6, and 7).

Goal GRNC1: The expected outcome is grassland comprised of large interconnected patches or contiguous expanses.

Objective GRNC1.1: Protect a minimum of 8,000 acres of grassland in Conservation Zones 1, 8, and 11. At least 1,000 acres will be protected in Conservation Zone 8, with the remainder distributed throughout these three Conservation Zones.

Rationale and Conservation Approach

Conservation of Townsend's big-eared bat under BDCP focuses on the restoration of valley/foothill riparian as roosting and primary foraging habitat. Woody vegetation is particularly important for foraging as well as for roosting because Townsend's big-eared bats forage through both aerial hawking and substrate gleaning. Restored areas of valley/foothill riparian are anticipated to be located primarily within Conservation Zones 1, 4, 7, and/or 11 (Figure 3-18). Secondary foraging habitats are comprised of all other land cover types present in the Plan Area (e.g., cultivated lands) and will be protected through actions that provide conservation for other covered species (e.g., preservation of Swainson's hawk foraging habitat) and the restoration of tidal emergent wetland, tidal perennial aquatic, nontidal wetland, and valley/foothill riparian. The production of flying insects and, consequently the function of restored habitats as bat foraging habitat is expected to be greater in restored habitats than in cultivated land foraging habitats. Restored habitats will provide a diversity of microhabitats conducive to a greater production and availability of flying insects compared to the homogenous microhabitat conditions associated with cultivated lands that are subject to routine application of pesticides. Additionally, protected and restored habitats will be monitored to assess occupancy by the species and managed to minimize human disturbances that could affect roosting bats.

Based on model projections, the restoration of valley/foothill riparian areas will increase the extent of Townsend's big-eared bat roosting and primary foraging habitat within the Plan Area by approximately 28 percent (see detailed description of habitat requirements and habitat model assumptions in Appendix A, *Covered Species Accounts*). The substantial increase in this species' core habitat in combination with the protection and enhancement of its secondary foraging habitats is expected to sustain the existing abundance and distribution of Townsend's big-eared bat and provide for the future growth of its population.

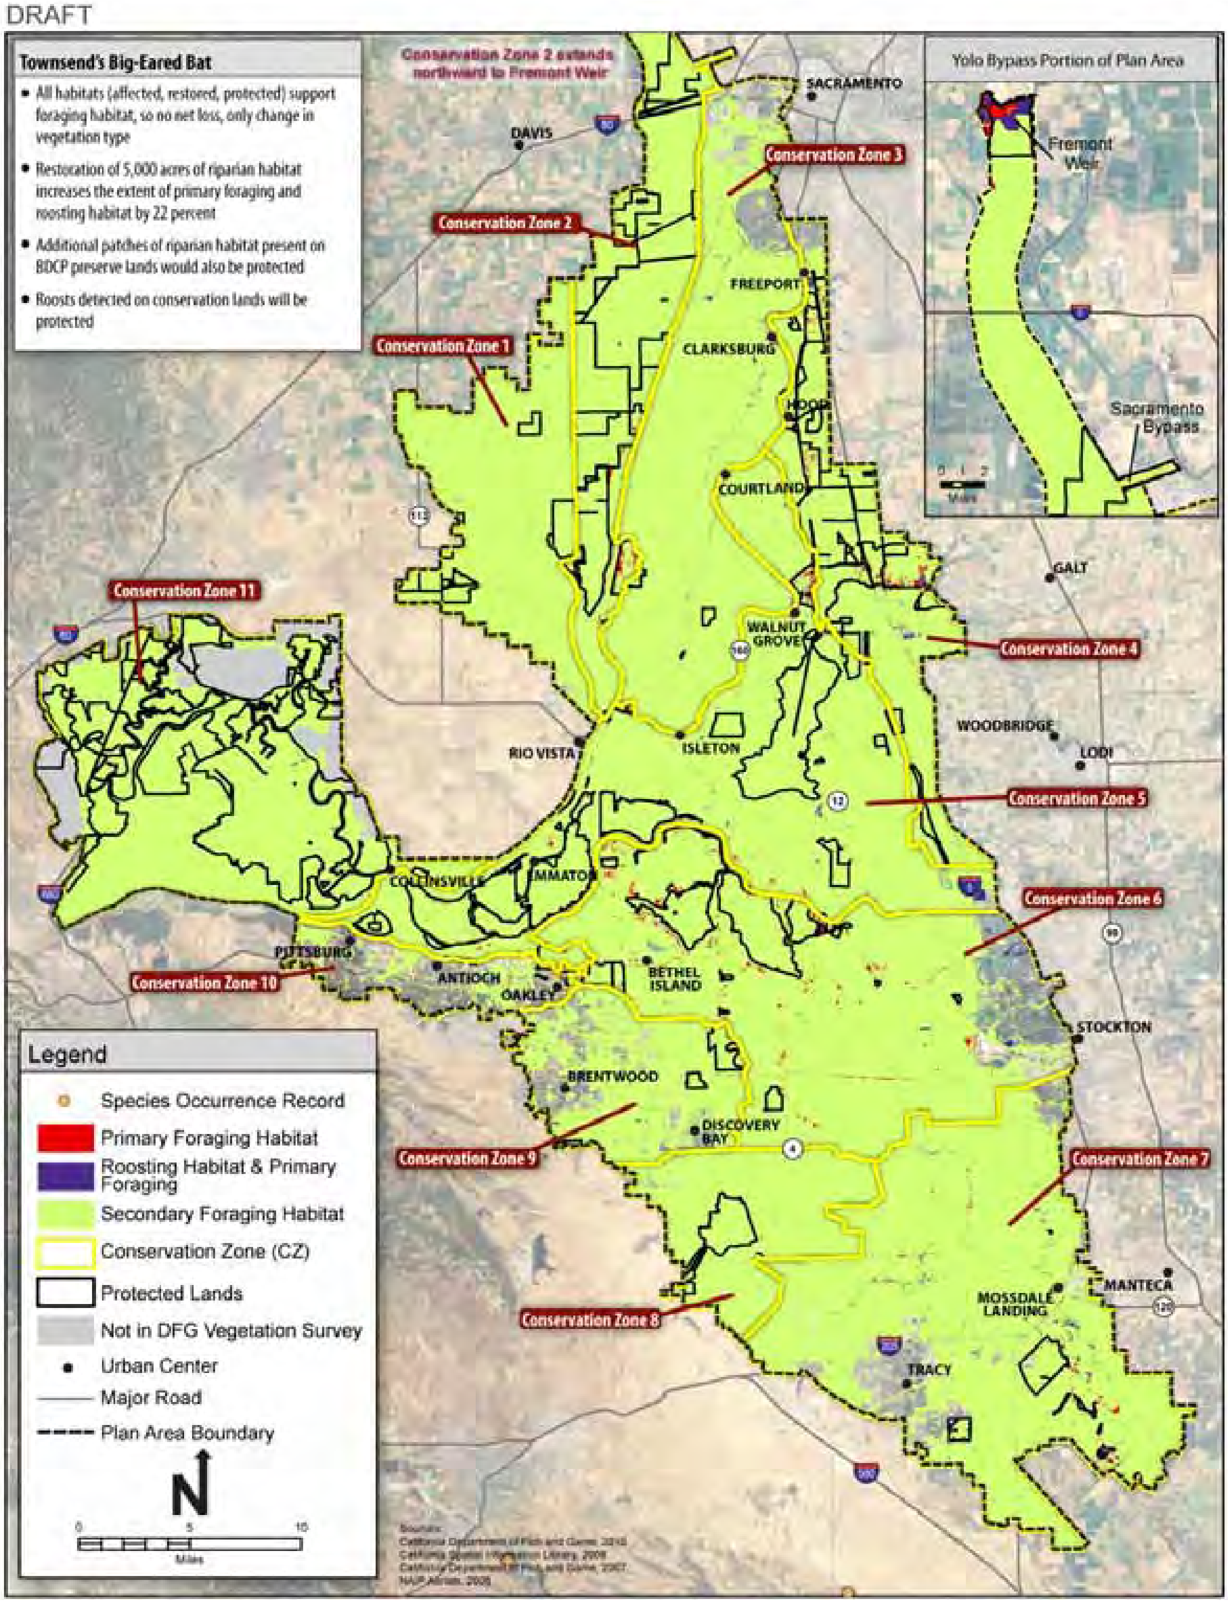

Figure 3-18. Townsend's Big-Eared Bat Habitat Distribution and Conservation Strategy

3.3.2.4.6 Suisun Shrew

The Suisun shrew is one of several subspecies of the ornate shrew and is endemic to the tidal saline and brackish salt marshes of Solano, Napa, and eastern Sonoma counties. Its current distribution is restricted to isolated remnants of natural tidal and brackish marshes along the northern borders of San Pablo and Suisun bays, including a number of locations in Suisun Marsh, Southampton Marsh, and the Napa Marshes, extending as far east as Grizzly Island and as far west as Sonoma Creek and Tubbs Island (Brown and Rudd 1981, Western Ecological Services 1986). There are no reported occurrences of Suisun shrew from within the Plan Area except in Suisun Marsh. Degradation of tidal marsh habitats continues to be the most significant threat to Suisun shrews and other tidal marsh species. Tidal marshes have been reduced by 84 percent since historical times (Dedrick 1989). The fragmentation of suitable habitats has isolated populations and reduced dispersal opportunities.

Applicable Natural Community Goals and Objectives

Goal BMNC1: The expected outcome is restored large expanses and interconnected patches of tidal brackish emergent wetland natural community.

> **Objective BMNC1.1:** Restore or create 3,600 to 4,800 acres of tidal brackish emergent wetland in the Suisun Marsh ROA (Conservation Zone 11).

Goal BMNC2: The expected outcome is biologically diverse tidal brackish emergent wetland that is enhanced for native species and sustained by natural ecological processes.

> **Objective BMNC2.1:** Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal brackish emergent wetland for covered and other native species over the term of the BDCP.

Rationale and Conservation Approach

Because the primary stressor on the Suisun shrew is loss of its tidal marsh habitat, Suisun shrew conservation and recovery efforts are aimed at protecting and restoring tidal marsh habitat (e.g., CALFED Bay-Delta Program 2000). Congruent with those conservation efforts, BDCP will restore tidal marsh habitat to provide for the conservation of the Suisun shrew. Suisun shrew inhabits tidal brackish emergent wetland. Much of Suisun shrew occupied habitat is supported by suitable patches of vegetation within nontidal managed wetland complex that the mouse has adapted to following the reclamation of historical Suisun Bay tidal marshes. Conservation will be directed towards restoring tidal brackish emergent wetland, on which the species was historically dependent to produce a net increase in Suisun shrew habitat. Because restoration of tidal brackish emergent wetland will remove and degrade patches of nontidal managed wetland complex that are currently occupied by Suisun shrew, restoration will be sequenced and located in a manner that minimizes the extent of any temporary loss of habitat. Approaches for restoring tidal brackish emergent wetland to support Suisun shrew habitat are described in the conservation approach for conserving the tidal brackish emergent wetland natural community.

In the Plan Area, the Suisun shrew is only present in Suisun Marsh in Conservation Zone 11. Conservation of Suisun shrew will be provided through the restoration and management of tidal brackish emergent wetland in Suisun Marsh and associated preserved upland refugia habitats. A total of between 3,600 and 4,800 acres[25] of tidal wetland and 350 to 700 acres of associated upland habitat is expected to be restored in the Suisun Marsh (Conservation Zone 11) and provide high value habitat for the Suisun shrew (Figure 3-19). Restored marsh plain habitats will be designed to the maximum extent practicable within site constraints to provide the full range of tidal exchange that occurred under historical Suisun Bay conditions. This approach is expected to result in the establishment of patches of Suisun shrew habitat within a mosaic of larger marsh plain habitats. Restoration designs will also include the preservation and enhancement of adjacent uplands in sufficient quantity and width to function as flood refugia habitat during high tidal events. This upland habitat will be designed and managed to minimize exposure to predation during flood events. The proposed restoration of tidal brackish emergent wetland in Suisun Marsh is consistent with and helps achieve the Suisun shrew objectives of the draft tidal marsh ecosystems recovery plan (USFWS 2010) and the objectives of the Suisun Marsh Restoration Plan (under development).

Suisun shrew habitat will be restored in a sequenced manner that minimizes disturbance of existing habitat between the time that restoration actions are initiated and when restored tidal brackish emergent wetland develops as Suisun shrew habitat. Direct removal of existing tidal brackish emergent wetland will be minimized to be consistent with achieving overall BDCP wetland restoration objectives, although some existing tidal brackish emergent wetland is expected to be desiccated or inundated as a result of changes in the existing tidal range following the breaching of dikes and levees. It is anticipated that following completion of all tidal habitat restoration in Suisun Marsh, tidal brackish emergent wetland will be restored in larger patches than the existing patches of habitat that are currently fragmented by dikes, roads, unsuitable habitat areas, and other infrastructure. These larger, unfragmented patches are expected to provide higher-value habitat that will facilitate the expansion and growth of Suisun shrew populations in the Suisun Marsh.

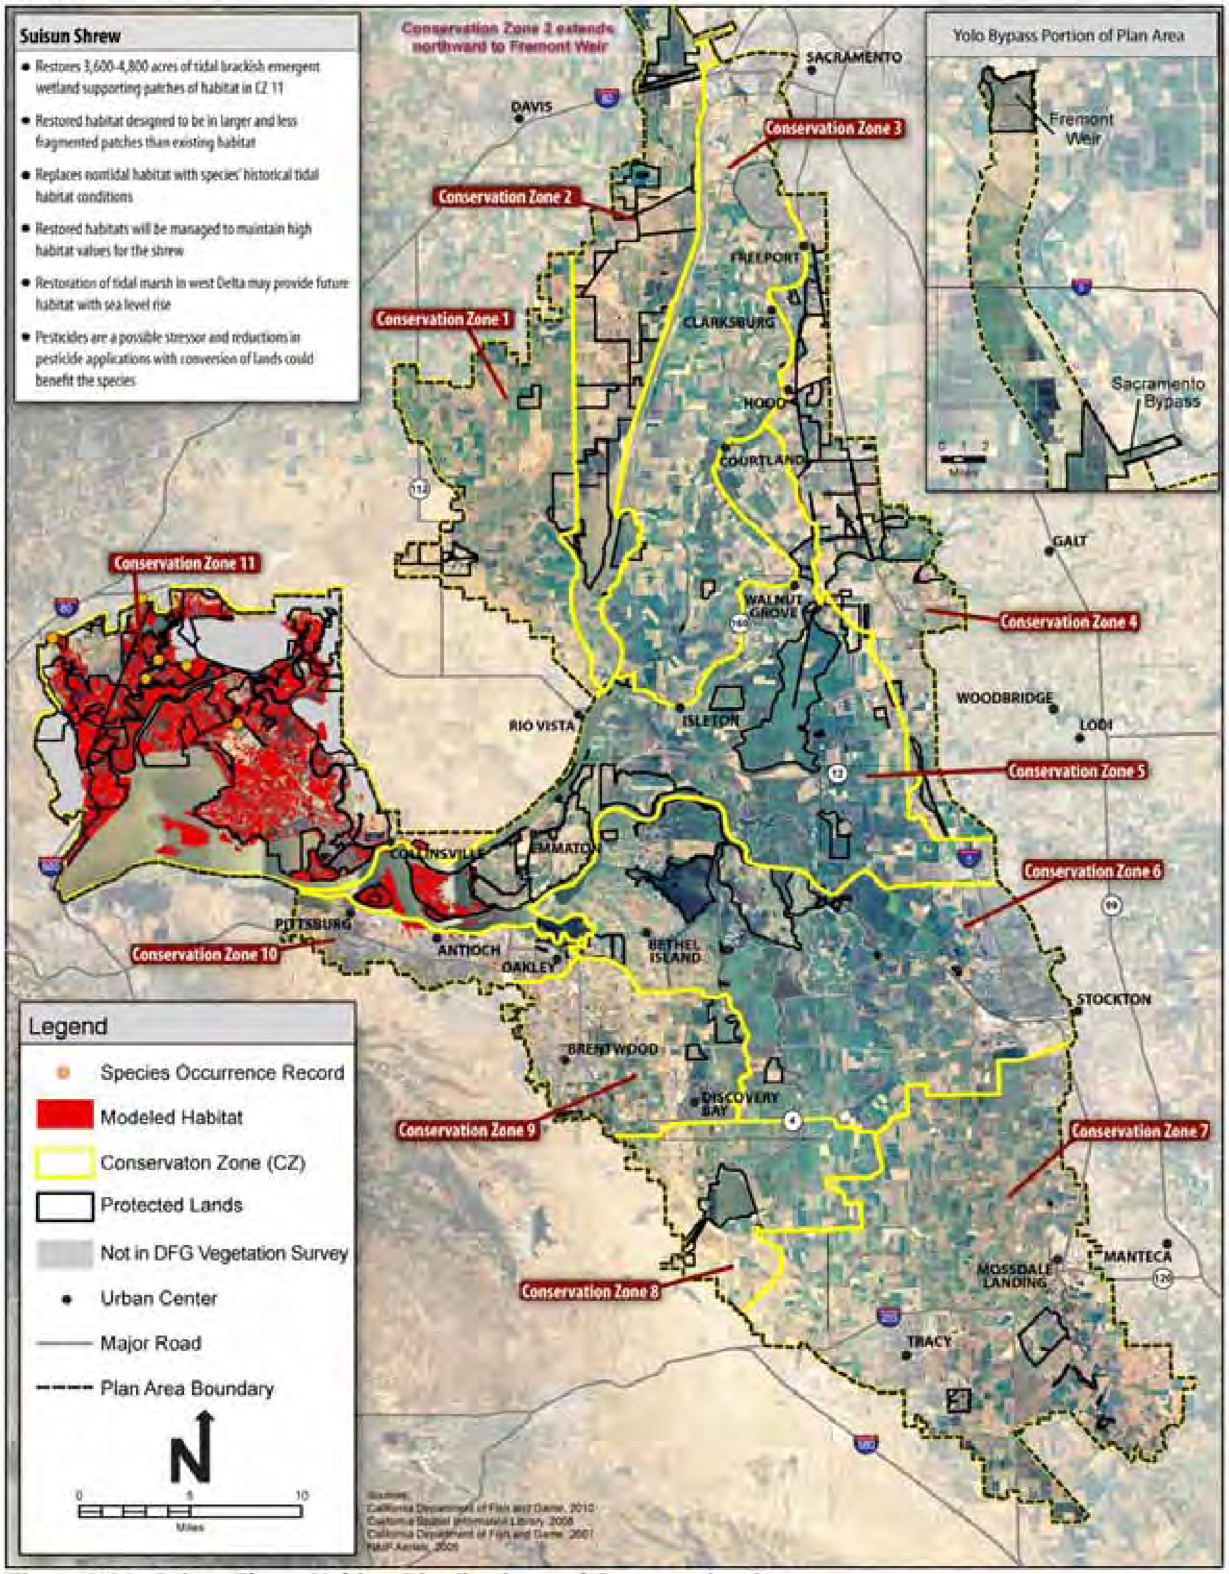

Figure 3-19. Suisun Shrew Habitat Distribution and Conservation Strategy

3.3.2.4.7 Tricolored Blackbird

Tricolored blackbirds form the largest colonies of any North American passerine bird (Beedy and Hamilton 1999) and are largely endemic to California. The state is home to more than 95 percent of the global population and more than 75 percent of the breeding population occurs in the Central Valley in any given year (Hamilton 2000). Tricolored blackbirds nest in areas with open accessible water, a protected nesting substrate (e.g., flooded, thorny, or spiny vegetation), and suitable foraging habitat (e.g., pastures, dry seasonal pools, agricultural fields such as alfalfa and rice, feedlots, and dairies) providing adequate insect prey within a few miles of the nesting colony. As many as 30,000 nests have been recorded in cattail (Typha spp.) marshes of 10 acres or less (Neff 1937, DeHaven et al. 1975). The Bay Delta is recognized as a major wintering area for tricolored blackbirds (Hamilton 2004, Beedy 2008), though there are few records of breeding colonies in the Delta (see Appendix A, *Covered Species Accounts*).

While the overall range of the species is largely unchanged since the 1930s (Neff 1937, DeHaven et al. 1975, Beedy et al. 1991, Hamilton 1998), there are now large gaps in the species' former range encompassing entire counties (e.g., Kings, San Joaquin, Riverside, San Bernardino counties). Recent surveys (Hamilton et al. 1995, Beedy and Hamilton 1997, Hamilton 2000) indicate a significant declining trend in populations in California since the 1930s and a particularly dramatic decline since 1994. Hamilton (2000) reports a 56 percent statewide decline between 1994 and 2000 (from 369,359 to 162,508 adults), and a 69 percent decline in the Sacramento Valley during that period (from 98,362 to 30,979 adults). The most significant historical and ongoing threat to the tricolored blackbird is habitat loss and alteration (e.g., (Cook 1999, DeHaven 2000, Hamilton 2004, Yolo Natural Heritage Program 2008). The initial conversion from native landscapes to agriculture removed vast wetland areas in the state and caused initial declines in populations. The more recent conversion of suitable agricultural lands to urbanization has permanently removed historical breeding and foraging habitat for this species. In urbanizing areas, habitat fragmentation and proximity to human disturbances has also led to abandonment of large historical colonies (Beedy and Hamilton 1999).

Applicable Natural Community Goals and Objectives

Goal FMNC1: The expected outcome is restored large, interconnected patches of tidal freshwater emergent wetland natural community.

> **Objective FMNC1.1:** Restore or create 13,900 to 21,600 acres of tidal freshwater emergent wetland in the Cache Slough, West Delta, Cosumnes-Mokelumne, and South Delta ROAs (Conservation Zones 1, 2, 4, 5, 6, and 7).

Goal NWNC1: The expected outcome is nontidal freshwater perennial emergent wetland natural community that supports habitat for covered and other native species.

> **Objective NWNC1.1**: Create 400 acres of nontidal freshwater marsh (including components of nontidal perennial aquatic and perennial emergent wetland communities)

that functions as habitat for the giant garter snake, tricolored blackbird, and western pond turtle within or adjacent to habitat occupied by the Caldoni Marsh/White Slough giant garter snake subpopulation in Conservation Zone 4 and the Yolo/Willow Slough giant garter snake subpopulation in Conservation Zone 2.

Goal GRNC1: The expected outcome is grassland comprised of large interconnected patches or contiguous expanses.

Objective GRNC1.1: Protect a minimum of 8,000 acres of grassland in Conservation Zones 1, 8, and 11. At least 1,000 acres will be protected in Conservation Zone 8, with the remainder distributed throughout these three Conservation Zones.

Goal ALNC1: The expected outcome is increased habitat functions for covered and other native species that are supported by agricultural land cover types and management practices.

Objective ALNC1.1: Maintain and protect the functions of 4,600 acres of rice lands as habitat for giant garter snake, western pond turtle, tricolored blackbird, white-tailed kite, waterfowl, and migrant shorebirds in Conservation Zone 2. This objective may be partially or fully achieved by maintaining an equivalent extent of natural or managed lands that support habitat functions similar to rice lands for associated covered and other native wildlife species.

Objective ALNC1.2: Maintain and protect the functions of 12,020 to 28,040 acres of non-rice agricultural lands as foraging habitat for Swainson's hawk, white-tailed kite, and tricolored blackbird that are located within 8 miles of occupied Swainson's hawk nesting habitat.

Rationale and Conservation Approach

Because the primary stressor on tricolored blackbird is the loss of its wetland nesting habitat due to urban and agricultural expansion (e.g., DeHaven et al. 1975, Cook and Toft 2005), restoration of wetland nesting habitat likely represents the most effective approach to the species' long-term conservation. Conservation of tricolored blackbird within the Plan Area is directed at substantially increasing the extent of its tidal and nontidal emergent wetland nesting habitat in conjunction with protection of nearby foraging habitats (Figure 3-20). Restoration of brackish and freshwater tidal emergent wetland is expected to support large patches of emergent vegetation suitable for nesting within Conservation Zones 1, 2, 4, 5, 6, 7, and 11. Because nesting habitat will be restored in large contiguous patches in these areas, restored nesting habitat is expected to provide higher nesting habitat functions than existing patches of nesting habitat, which are generally small, fragmented, and subject to disturbance during the breeding season. The proposed restoration of up to between 17,500 to 26,400 acres of tidal emergent wetland and 400 acres of nontidal marsh habitat suitable for tricolored blackbird nesting and foraging is expected to increase the extent of available nesting habitat in the Plan Area several-fold.

Protection of foraging habitats within a few miles of nesting habitat will provide food resources necessary for successful rearing and fledging of young and all protected foraging habitats will support wintering birds. The proposed protection of agricultural habitat, grassland, and vernal pool complex foraging habitat will increase the extent of currently preserved habitat from 19 percent to up to approximately 26 percent within the Plan Area.

The protection of active nesting colonies is also essential for successful breeding. Tricolored blackbirds are sensitive to human disturbances, and establishing no-disturbance buffers around nesting colonies during the breeding season will increase the opportunities for reproductive success. No disturbance buffers will be established through implementation of Avoidance and Minimization Measures (See AMM13).

In summary, proposed BDCP restoration of nesting habitat and protection of foraging habitats are expected to be sufficient to sustain the existing breeding and wintering population(s) of tricolored blackbirds in the Plan Area. Because the Plan Area corresponds to a major wintering area yet supports only a small number of nesting colonies (largely or mainly in the Yolo Bypass; see Appendix A, *Covered Species Accounts*), restoration of wetland nesting habitat in particular has the potential to provide for future increases in of tricolored blackbird abundance and distribution.

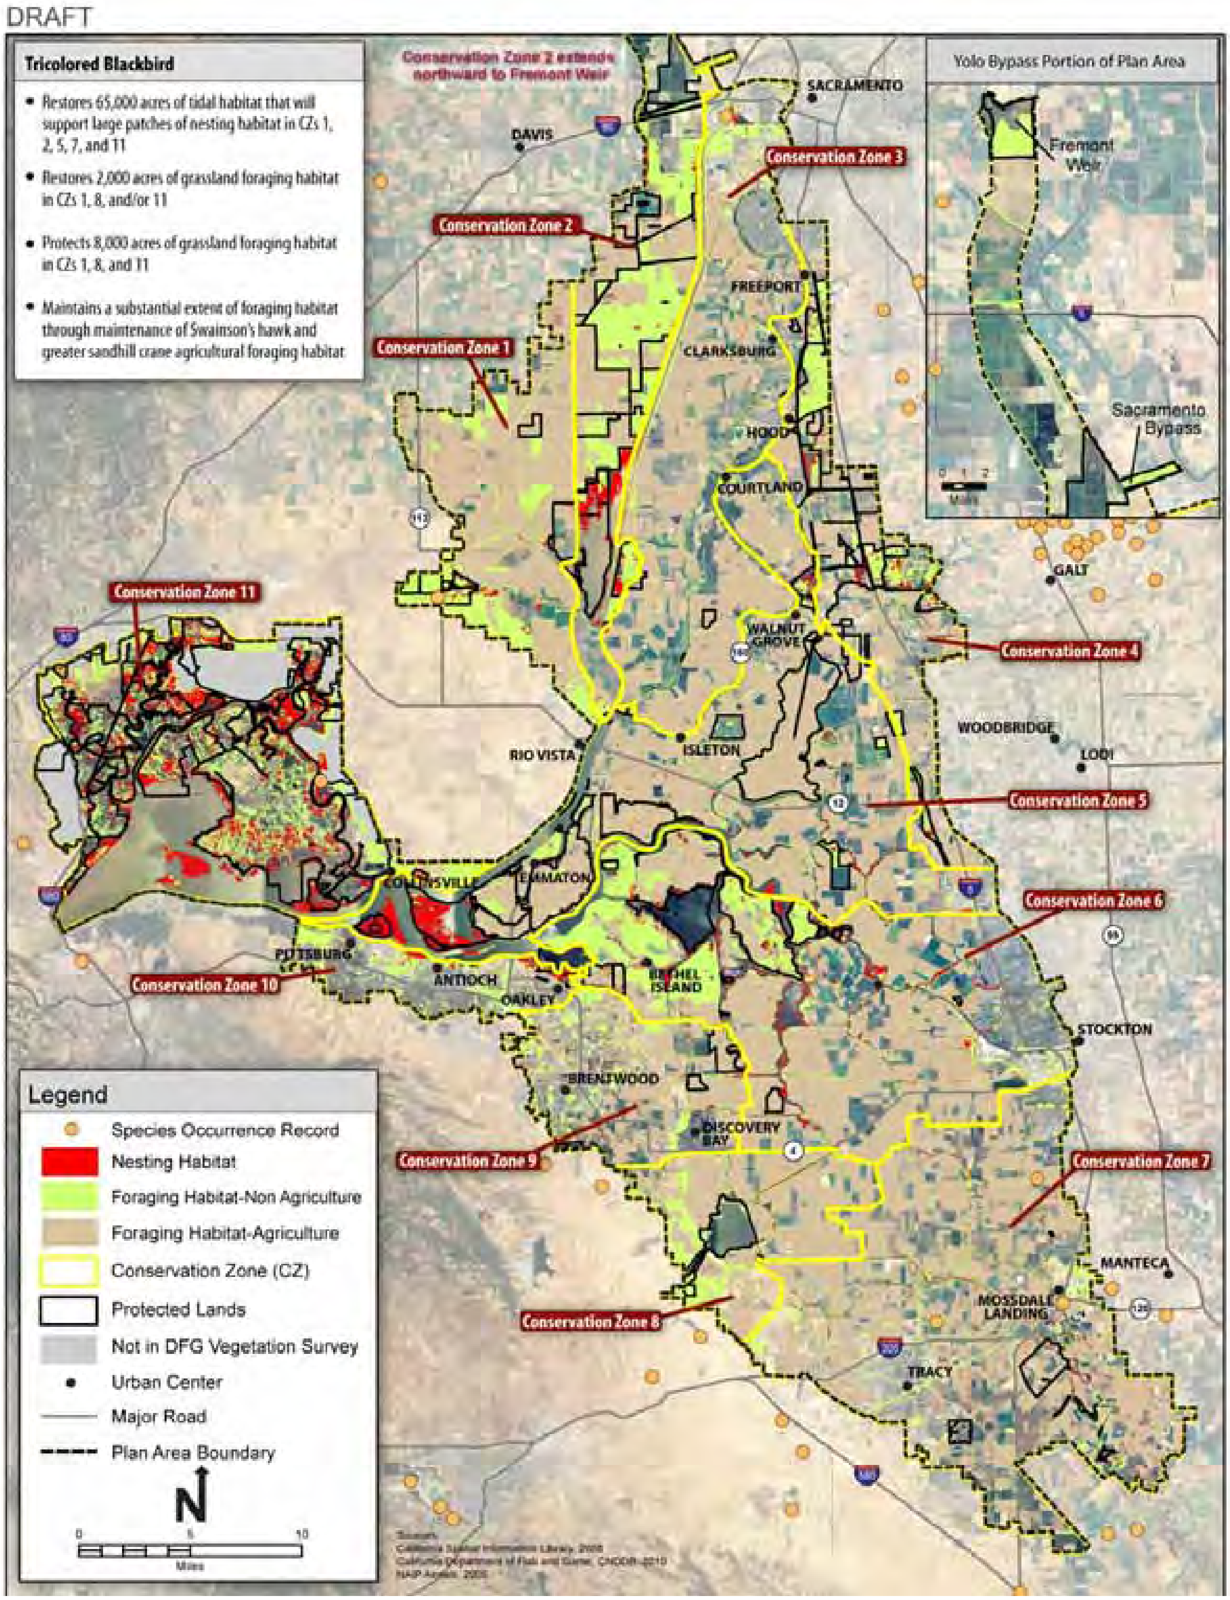

Figure 3-20. Tricolored Blackbird Habitat Distribution and Conservation Strategy

3.3.2.4.8 Suisun Song Sparrow

The Suisun song sparrow is endemic to the salt marshes of Suisun Bay and while it has been confirmed to be phenotypically distinct from neighboring subspecies (Patten 2001), genetic differentiation has not been confirmed (Chan and Arcese 2002). The Suisun song sparrow is associated with tidal marsh habitats characterized by dense vegetation with bare areas that support foraging. Its distribution extends into the Plan Area to approximately Kimbal Island; however, the majority of the range of the species is included within the Suisun Marsh. Spautz and Nur (2008), citing unpublished data from the Point Reyes Bird Observatory (PRBO), estimate the total population of Suisun song sparrows as 43,000 to 66,000 breeding pairs, approximately one-third of the estimated historical population size (Spautz and Nur 2008). Habitat loss and fragmentation, caused by diking, levee construction, channelization, invasive species, and urbanization, is considered the primary threat to the continued existence of the Suisun marsh sparrow (Larsen 1989, Spautz and Nur 2008). Throughout most of the Suisun Marsh, tidal marsh has been reduced to small fragments that are separated by dispersal barriers or only connected by very narrow strips of vegetation remaining along the banks of tidal sloughs, reducing dispersal, gene flow, and reproduction (Larsen 1989).

Applicable Natural Community Goals and Objectives

Goal BMNC1: The expected outcome is restored large expanses and interconnected patches of tidal brackish emergent wetland natural community.

> **Objective BMNC1.1:** Restore or create 3,600 to 4,800 acres of tidal brackish emergent wetland in the Suisun Marsh ROA (Conservation Zone 11).

Goal BMNC2: The expected outcome is biologically diverse tidal brackish emergent wetland that is enhanced for native species and sustained by natural ecological processes.

> **Objective BMNC2.1:** Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal brackish emergent wetland for covered and other native species over the term of the BDCP.

Rationale and Conservation Approach

Because the primary stressor on the Suisun song sparrow is loss of tidal marsh habitat, the restoration of this habitat type is considered the most effective approach to the conservation of the sparrow. Under BDCP, the conservation of Suisun song sparrow will be provided through restoration and management of brackish tidal emergent wetland habitats that historically supported Suisun song sparrow habitat in Suisun Marsh (Figure 3-21). Much of the still-existing Suisun song sparrow habitat consists of patches of nontidal managed wetlands that the sparrow has adapted to following reclamation of historically Suisun Bay tidal marshes. Because restoration of tidal brackish emergent wetland will remove and degrade patches of nontidal managed wetlands that are currently occupied by Suisun song sparrow, restoration will be sequenced and located in a manner that minimizes any temporary, initial loss of habitat.

Direct removal of existing tidal brackish emergent wetland will be minimized consistent with achieving overall wetland restoration objectives, although some existing tidal brackish emergent wetland is expected to be desiccated or inundated as a result of changes in the existing tidal range following the breaching of dikes and levees. Approaches for restoring tidal brackish emergent wetland to support Suisun song sparrow habitat are described in the conservation approach for conserving the tidal brackish emergent wetland natural community.

Suisun Marsh is included in Conservation Zone 11. Restored marsh plain habitat in Conservation Zone 11 (3,600 to 4,800 acres[26]) will be designed to the maximum extent practicable within site constraints to provide the full range of tidal conditions that were associated with historical Suisun Bay tidal marsh. This approach is expected to result in restoration of patches of sparrow habitat within a mosaic of extensive brackish tidal emergent wetland.

Restored habitat will be designed to include channel habitat edges that support high functioning Suisun song sparrow nesting habitat and tidal brackish emergent wetland away from channels that is dominated by *Salicornia*, *Spartina*, and *Grindelia*.

Nonnative predators (e.g., feral cats) are believed to be an important stressor on the Suisun song sparrow. The design and management of restored habitat will include the control of nonnative predators to help maintain the species abundance (e.g., through direct removal of predators or through the design of restored habitats that minimize access of predators into occupied habitats).

The proposed restoration of tidal brackish emergent wetland in Suisun Marsh is consistent with and helps achieve the Suisun song sparrow objectives of the draft tidal marsh ecosystems recovery plan (USFWS 2010) and the objectives of the Suisun Marsh Restoration Plan (under development). It is anticipated that following completion of all tidal habitat restoration in Suisun Marsh, tidal brackish emergent wetland will be restored in larger patches than the existing patches of habitat currently fragmented by dikes, roads, infrastructure, or other unsuitable habitat. These larger unfragmented patches are expected to provide higher-value habitat and facilitate the expansion and growth of Suisun song sparrow populations in Suisun Marsh.

Applicable Conservation Measures

[26] Restored tidal habitat acreage ranges are a component of the 65,000 acre target for restored tidal habitat. Acreage ranges are based on the results of hydrodynamic modeling of realistic hypothetical restoration designs. While these ranges are not the acreage targets for restored tidal habitats, but rather the results of modeling, the hypothetical designs provided verification of the practicability of achieving restoration targets.

Figure 3-21. Suisun Song Sparrow Habitat Distribution and Conservation Strategy

3.3.2.4.9 Yellow-breasted Chat

The Yellow-breasted chat is a neotropical migrant that breeds throughout much of North America and winters primarily in Mexico and Central America, with a few birds also wintering in California (Small 1994). According to Grinnell and Miller (1944), the species' breeding distribution included the entire length and breadth of California exclusive of the higher mountains and coastal islands. The yellow-breasted chat is still present in most of its historical range with the exception of most of the Central Valley (Comrack 2008). In particular, nesting populations have been extirpated from the San Joaquin and Sacramento valleys except along foothill tributaries. The yellow-breasted chat occurs in the Plan Area mainly as a spring and fall migrant. During the breeding season, however, it is sparsely distributed across the Plan Area (Appendix A, *Covered Species Accounts*).

Yellow-breasted chats nest and forage in streamside, shrubby thickets of willows, vines, and brush (Small 1994). The species has been classified as an open-canopy obligatory species (i.e., preferred open overstory and brushy understory), with population density directly related to shrub density to a height of 4.5 meters (14.8 feet) (Crawford et al. 1981). Habitat loss is implicated in yellow-breasted chat population declines throughout much of the species' range (e.g., Remsen 1978, Rosenberg et al. 1991). Shuford and Gardali's (2008) list of management recommendations includes the preservation of existing, healthy riparian habitat and the restoration of degraded riparian habitat. Also listed by Shuford and Gardali (2008) is the need to maintain and/or promote a dense shrub layer in riparian habitat and create a shrub layer in the early stages of restoration projects. Zeiner et al. (1990) report that yellow-breasted chat territory size ranges from 0.3 to 3.2 acres (0.1 – 1.3 hectare). Small territory size suggests the potential for large-scale restoration of valley/foothill riparian to promote the establishment of sizeable chat populations.

Applicable Natural Community Goals and Objectives

Goal VRNC1: The expected outcome is restored large expanses and interconnected corridors of valley/foothill riparian natural community.

> **Objective VRNC1.1**: Restore or create 5,000 acres of valley/foothill riparian in Conservation Zones 1, 2, 4, 5, 6, 7, and/or 11.

Goal VRNC2: The expected outcome is biologically diverse valley/foothill riparian natural community that supports native species and is sustained by natural ecological processes.

> **Objective VRNC2.1**: Maintain and enhance the habitat and ecosystem functions of BDCP restored valley/foothill riparian and patches of riparian forest and scrub present on BDCP preserved lands over the term of the BDCP.

Objective VRNC2.2: Establish seasonal buffers around riparian habitats occupied by covered species to minimize disturbance during the breeding season.

Objective VRNC2.3: Restore connectivity of valley/foothill riparian corridors along linear watercourses to enhance habitat for covered species and facilitate wildlife movement.

Rationale for Conservation Approach

Within the Plan Area, modeled yellow-breasted chat habitat is divided into primary and secondary habitat based on a qualitative assessment of shrub and tree densities in riparian areas. Primary habitat includes a dense shrub layer such as typically found within chat breeding territories (Figure 3-22). Secondary habitat is riparian habitat with a less developed shrub layer. BDCP yellow-breasted chat conservation is directed at increasing the extent of primary and secondary riparian nesting and migratory habitats to ensure that: (1) chat numbers in the Plan Area at a minimum remain stable; and (2) sufficient valley/foothill riparian habitat is maintained to support potential future increases in the species' abundance and distribution.

Of the 5,000 acres of BDCP riparian habitat to be restored, it is expected that a substantial amount will provide the structure, species composition, and overstory suitable as yellow-breasted chat breeding habitat. It is also anticipated that much of the restored valley/foothill riparian habitat will be restored in large patches that will minimize the potential for cowbird nest parasitism, which is believed to be a stressor on the species (see Appendix A, *Covered Species Accounts*). The proposed restoration of yellow-breasted chat riparian habitat is expected to increase the extent of available habitat in the Plan Area by approximately 35 percent and, following BDCP implementation, approximately 51 percent of the species' habitat is expected to be under protected status.

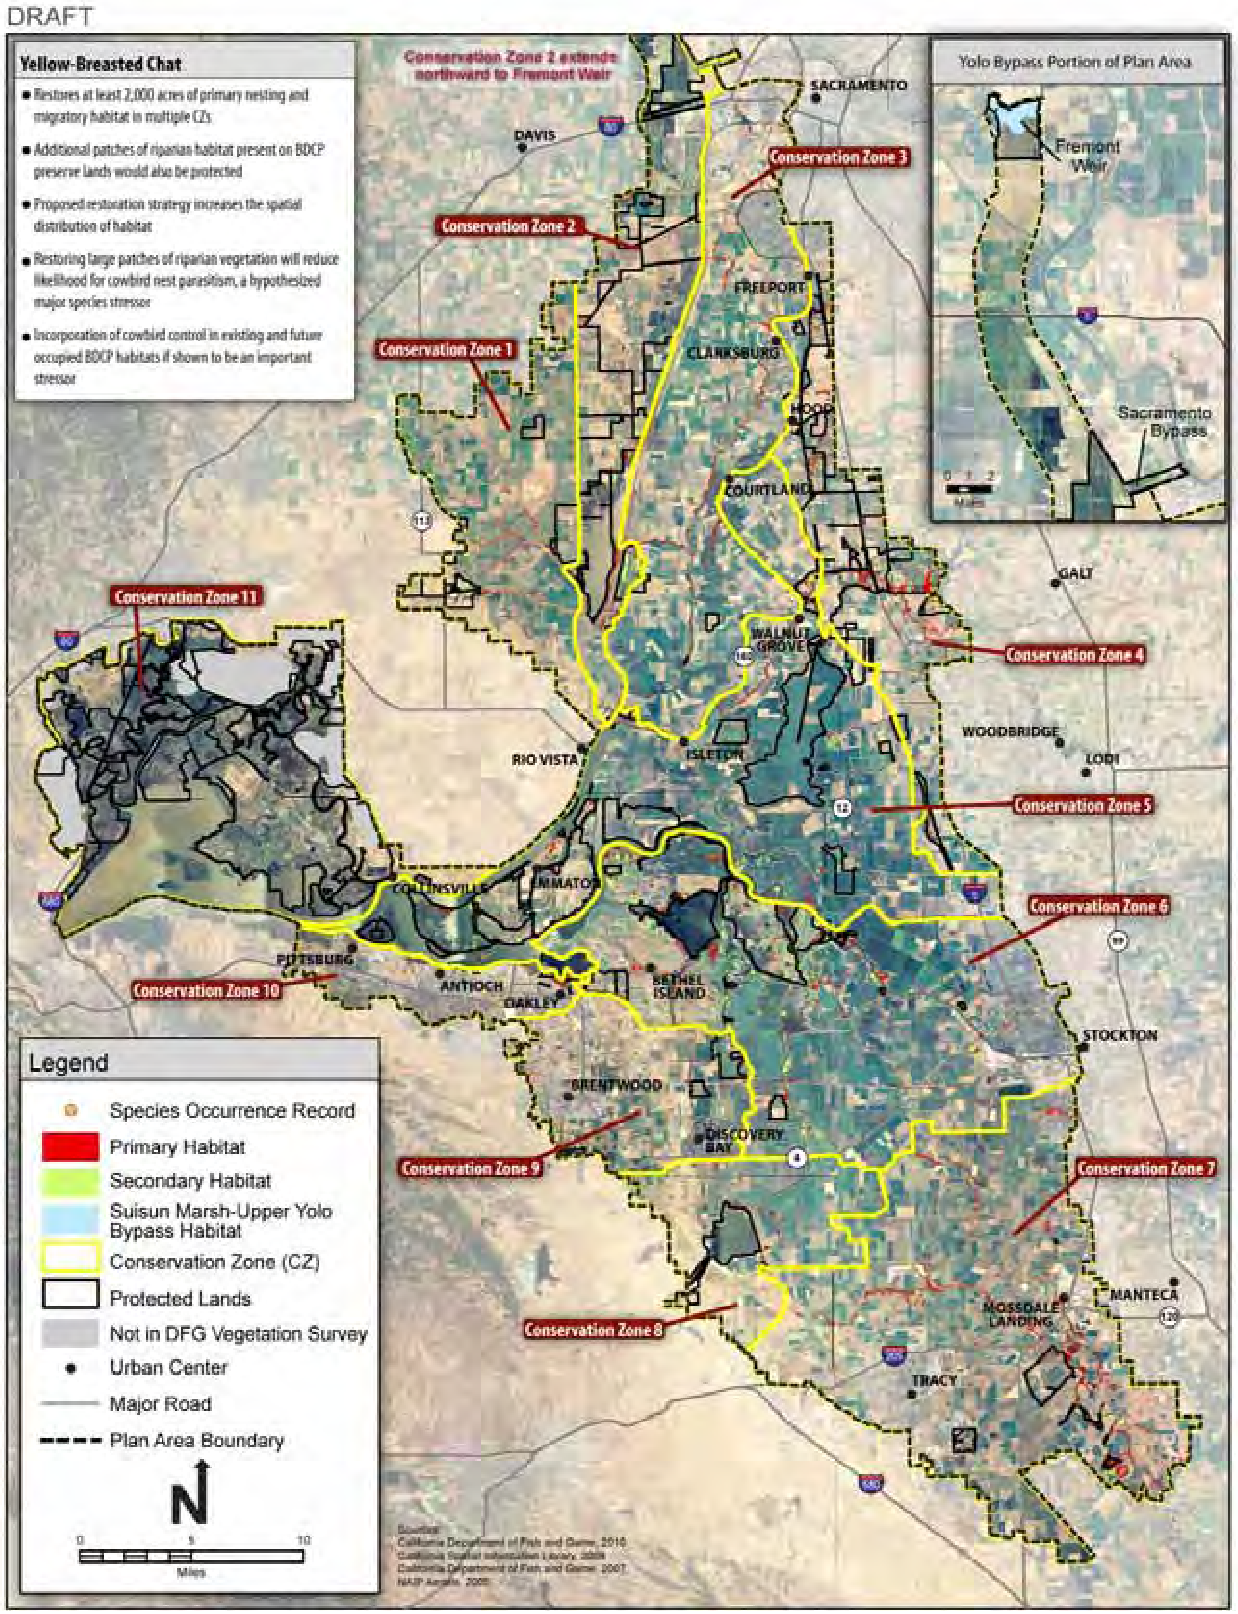

Figure 3-22. Yellow-Breasted Chat Habitat Distribution and Conservation Strategy

3.3.2.4.10 Least Bell's Vireo

A neotropical migrant, the least Bell's vireo is the only subspecies of the Bell's vireo that breeds entirely in California and northern Baja California. The least Bell's vireo's historical breeding distribution once extended from coastal southern California through the San Joaquin and Sacramento valleys as far north as Tehama County near Red Bluff. The Sacramento and San Joaquin valleys were considered the center of the species' historical breeding range supporting 60-80 percent of the historical population (51 FR 16474). Coinciding with widespread loss of riparian vegetation throughout California (Katibah 1984), Grinnell and Miller (1944) began to detect population declines in the Sacramento and San Joaquin Valley region by the 1930s. Surveys conducted in late 1970s (Goldwasser et al. 1980) detected no least Bell's vireos in the Sacramento-San Joaquin Valleys, and the species was considered extirpated from the region. By 1986, the USFWS determined that least Bell's vireo had been extirpated from most of its historical range and numbered approximately 300 pairs statewide (51 FR 16474). However, recent occurrences have suggested a northward expansion of the breeding range, including nest sites reported from the San Joaquin River National Wildlife Refuge and recent (2010) occurrences from the Yolo Bypass Wildlife Area.

The least Bell's vireo is an obligate riparian breeder that typically inhabits structurally diverse woodlands, including cottonwood-willow woodlands/forests, oak woodlands, and mule fat scrub (USFWS 1998b). Two features appear to be essential for breeding habitat: (1) the presence of dense cover within 3-6 ft. (1-2 m.) of the ground, where nests are typically placed; and (2) a dense stratified canopy for foraging (Goldwasser 1981, Gray and Greaves 1981, Salata 1981 & 1983, RECON 1989). While least Bell's vireo typically nests in willow-dominated areas, plant species composition does not seem to be as important a factor as habitat structure. Least Bell's vireo territories can range in size from 0.5-7.2 acres, but common territory sizes in Southern California range from 1.5-2.5 acres.

Critical habitat for this state and federally endangered species was designated in 1994, and a Draft Recovery Plan emphasizing the need for habitat protection and restoration was published in 1998 (USFWS 1998b). Riparian habitat creation and restoration are underway throughout California (RHJV 2004), and the least Bell's vireo is listed as a covered species in 16 Habitat Conservation Plans (HCPs), including the Coachella Valley Multi-species HCP, San Diego MSCP, Orange County NCCP/HCP, and Western Riverside MSHCP. Conservation actions under all of those habitat conservation plans and BDCP have the potential to act in synergy toward partial recovery of the vireo. The recent documentation of the species in the Yolo Bypass has heightened awareness of the species' conservation potential within the Plan Area.

Applicable Natural Community Goals and Objectives

Goal VRNC1: The expected outcome is restored large expanses and interconnected corridors of valley/foothill riparian natural community.

> **Objective VRNC1.1**: Restore or create 5,000 acres of valley/foothill riparian in Conservation Zones 1, 2, 4, 5, 6, 7, and/or 11.

Goal VRNC2: The expected outcome is biologically diverse valley/foothill riparian natural community that supports native species and is sustained by natural ecological processes.

> **Objective VRNC2.1**: Maintain and enhance the habitat and ecosystem functions of BDCP restored valley/foothill riparian and patches of riparian forest and scrub present on BDCP preserved lands over the term of the BDCP.

> **Objective VRNC2.2**: Establish seasonal buffers around riparian habitats occupied by covered species to minimize disturbance during the breeding season.

> **Objective VRNC2.3**: Restore connectivity of valley/foothill riparian corridors along linear watercourses to enhance habitat for covered species and facilitate wildlife movement.

Rationale and Conservation Approach

Because the primary stressor on the least bell's vireo is loss and fragmentation of its riparian habitat through urban and agricultural expansion, the protection and restoration of riparian areas is considered the most effective approach to the vireo's conservation. In the Plan Area, the conservation of least Bell's vireo will be provided through the restoration of 5,000 acres of valley/foothill riparian (of which more than 2,000 acres is expected to support least Bell's vireo) (Table 3-5) (Figure 3-23).

The least Bell's vireo is not known to presently breed in the Plan Area, but two singing males were detected in the Yolo Bypass Wildlife Area in mid-April 2010. A single breeding pair recently nested for multiple years immediately south of the Plan Area along the San Joaquin River, and because the Plan Area may support suitable riparian habitat, the species may re-establish itself within the Plan Area. Approaches for restoring valley/foothill riparian communities that support least Bell's vireo habitat are described in the conservation approaches for conserving the valley/foothill riparian natural community.

Patches of least Bell's vireo habitat are expected to be restored as a component of BDCP actions to restore 5,000 acres of valley/foothill riparian. A substantial amount of willow-dominated riparian is expected to be restored that will meet the ecological requirements of the least Bell's vireo. It is anticipated that much of the restored riparian habitat will occur in large wide patches that will minimize the potential for cowbird nest parasitism, which is a stressor on the species (see Appendix A, *Covered Species Accounts*). Given the relatively small territory size of least Bell's vireo and the large acreage of riparian habitat to be restored, BDCP riparian restoration efforts have the potential to significantly increase the likelihood of population re-establishment in the region.

- CM7 Riparian Habitat Restoration
- CM11 Natural Communities Enhancement and Management

DRAFT

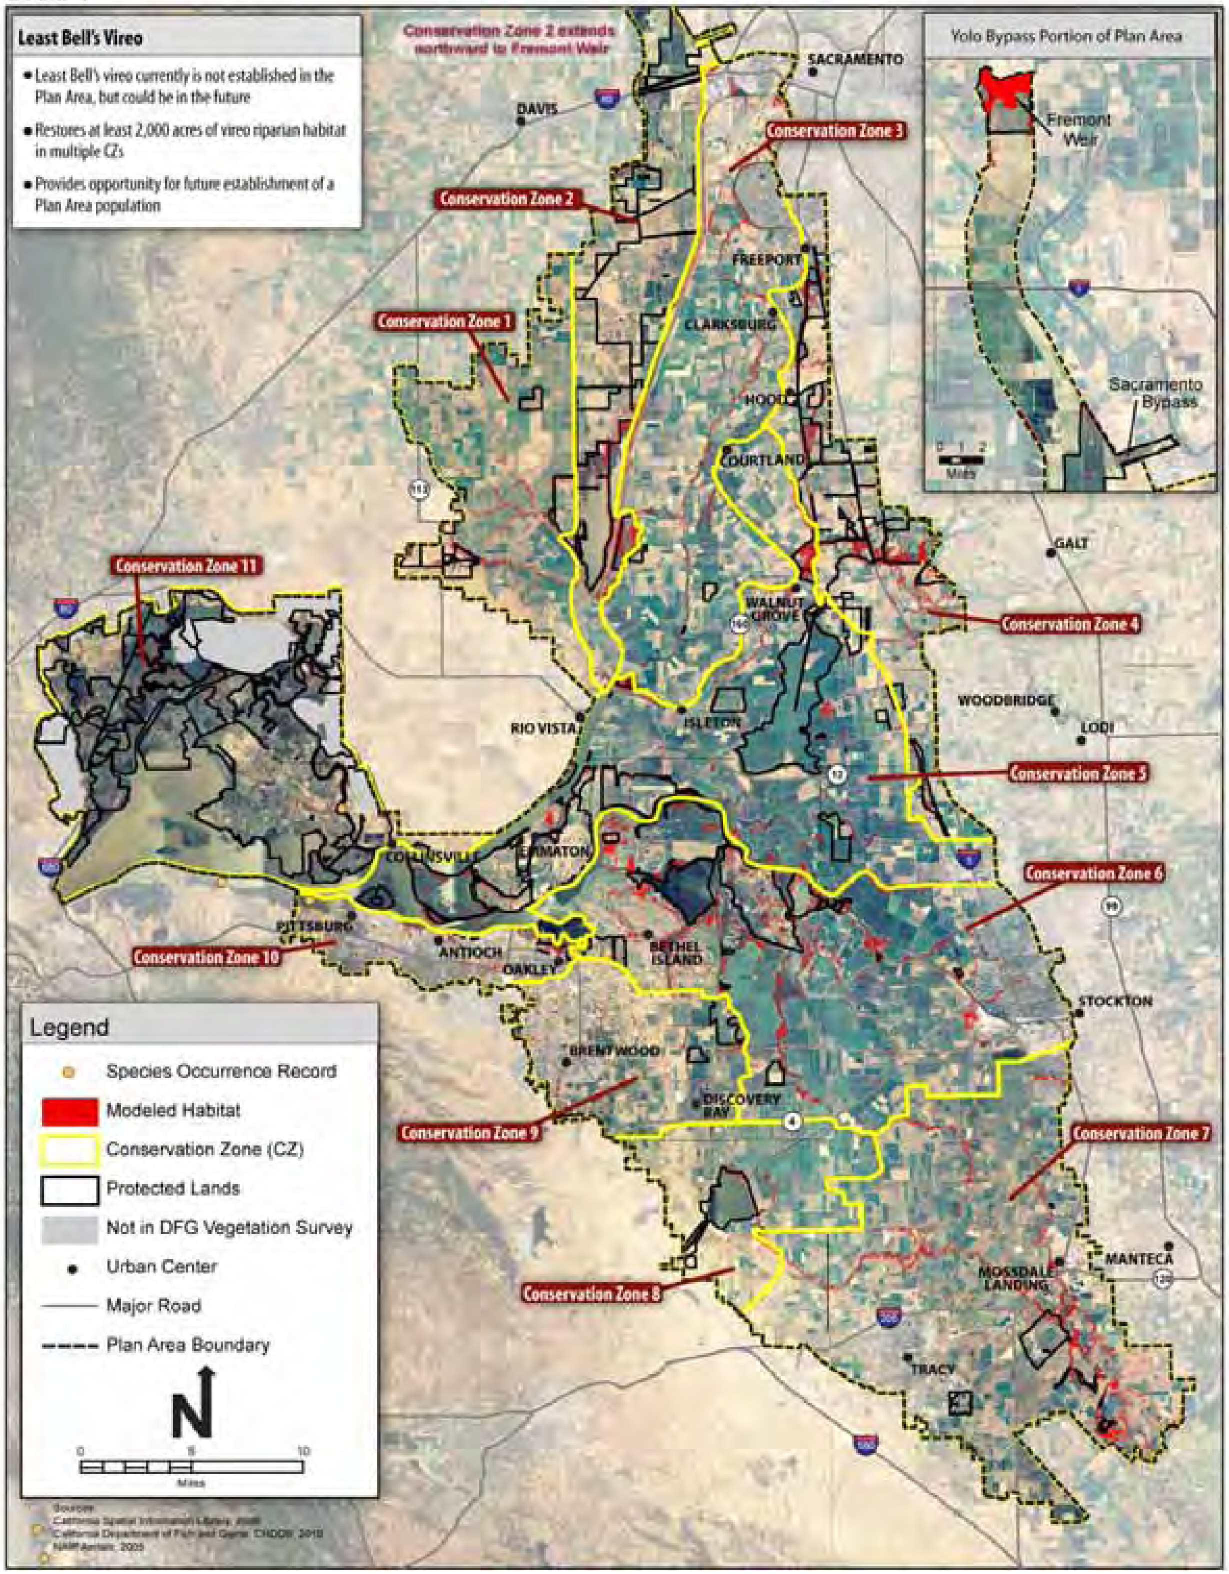

Figure 3-23. Least Bell's Vireo Habitat Distribution and Conservation Strategy

3.3.2.4.11 Western Burrowing Owl

Western burrowing owl occurrences in the Plan Area are a mix of year-round and winter residents, where habitat consists of grasslands, managed wetlands, and cultivated lands (see Appendix A, *Covered Species Accounts*). Throughout much of the species' range, and including in California, burrowing owl populations have been declining largely as a result of loss, degradation, or fragmentation of foraging and nesting habitat (Zarn 1974, Haug et al. 1993, Klute et al. 2003, DeSante et al. 2007, Desmond 2010). Causal factors are numerous, ranging from urbanization to poisoning of sciurid rodents whose burrows are used by the owls (Klute et al. 2003, DeSante et al. 2007, Desmond 2010). The majority of burrowing occurrences in the Plan Area are from the grassland/pastureland/cultivated matrix in Conservation Zones 1 and 2. However, the species is known to persist in low densities in more isolated locations where suitable burrowing habitat exists, including grassy levee slopes, remnant patches of grassland, and debris piles, roadside edges, and field edges in cultivated landscapes. The focus of BDCP on habitat for the western burrowing owl directly addresses the primary regional threat to the species (DeSante et al. 2007).

Applicable Natural Community Goals and Objectives

Goal GRNC1: The expected outcome is grassland comprised of large interconnected patches or contiguous expanses.

> **Objective GRNC1.1**: Protect a minimum of 8,000 acres of grassland in Conservation Zones 1, 8, and 11. At least 1,000 acres will be protected in Conservation Zone 8, with the remainder distributed throughout these three Conservation Zones.

> **Objective GRNC1.2**: Restore 2,000 acres of grassland to connect fragmented patches of protected grassland.

Goal GRNC2: The expected outcome is biologically diverse grassland managed to enhance native species and sustained by natural ecological processes.

> **Objective GRNC2.4**: Increase burrow availability for burrow-dependent species.

> **Objective GRNC2.5**: Increase prey, especially small mammals and insects, for grassland-foraging species.

Goal ALNC1: The expected outcome is increased habitat functions for covered and other native species that are supported by agricultural land cover types and management practices.

> **Objective ALNC1.3**: Of the maintained 12,020 to 28,040 acres of non-rice agricultural lands, maintain at least 3,000 acres of pasture that supports western burrowing owl foraging habitat. This objective may be partially or fully achieved through preservation

of other land cover types that provide moderate-value or greater habitat function for the western burrowing owl.

Objective ALNC1.8: Maintain and protect the small patches of important wildlife habitats associated with agricultural lands that occur within BDCP conserved agricultural lands, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, and wetlands.

Rationale and Conservation Approach

Conservation of western burrowing owl focuses on maintaining a landscape of suitable habitat across the Plan Area and on adjacent lands through strategic acquisition and management of grassland and agricultural preserves (Figure 3-24). In terms of burrowing owl habitat, the Plan Area's grasslands, managed wetlands, and cultivated lands range in value (or quality) from high to low (see Appendix A, *Covered Species Accounts*). Specifically, BDCP implementation will result in the protection and restoration of large patches of moderate-to-high-value natural grassland foraging and breeding habitats.

Protected grassland will also be connected to burrowing owl habitats adjacent to the Plan Area to preclude further fragmentation of important habitats. The distribution of high and moderate value habitat in the Plan Area is consistent with the observed current distribution of burrowing owls. Few western burrowing owls have been documented from low-value habitat areas. Habitat will be protected in large patches that are connected to existing protected habitats and located within or near known occupied habitat. It will also be managed to increase the availability of nesting burrows and prey species through a combination of measures (e.g., discontinued use of pesticides, manipulation of topography, mowing). An estimated 33 percent of the high-value habitat, 31 percent of the moderate-value habitat, and 11 percent of the low-value habitat are currently protected, respectively. Following BDCP implementation, 46 percent of the highest value existing habitat and 39 percent of the moderate value habitat in the Plan Area will be protected. The implementation of the proposed conservation actions is expected to sustain existing burrowing owl populations within and adjacent to the Plan Area and to provide an acreage of suitable habitat large enough to allow for any future population growth.

- CM8 Grassland Communities Restoration
- CM9 Vernal Pool Complex Restoration
- CM11 Natural Communities Enhancement and Management

DRAFT

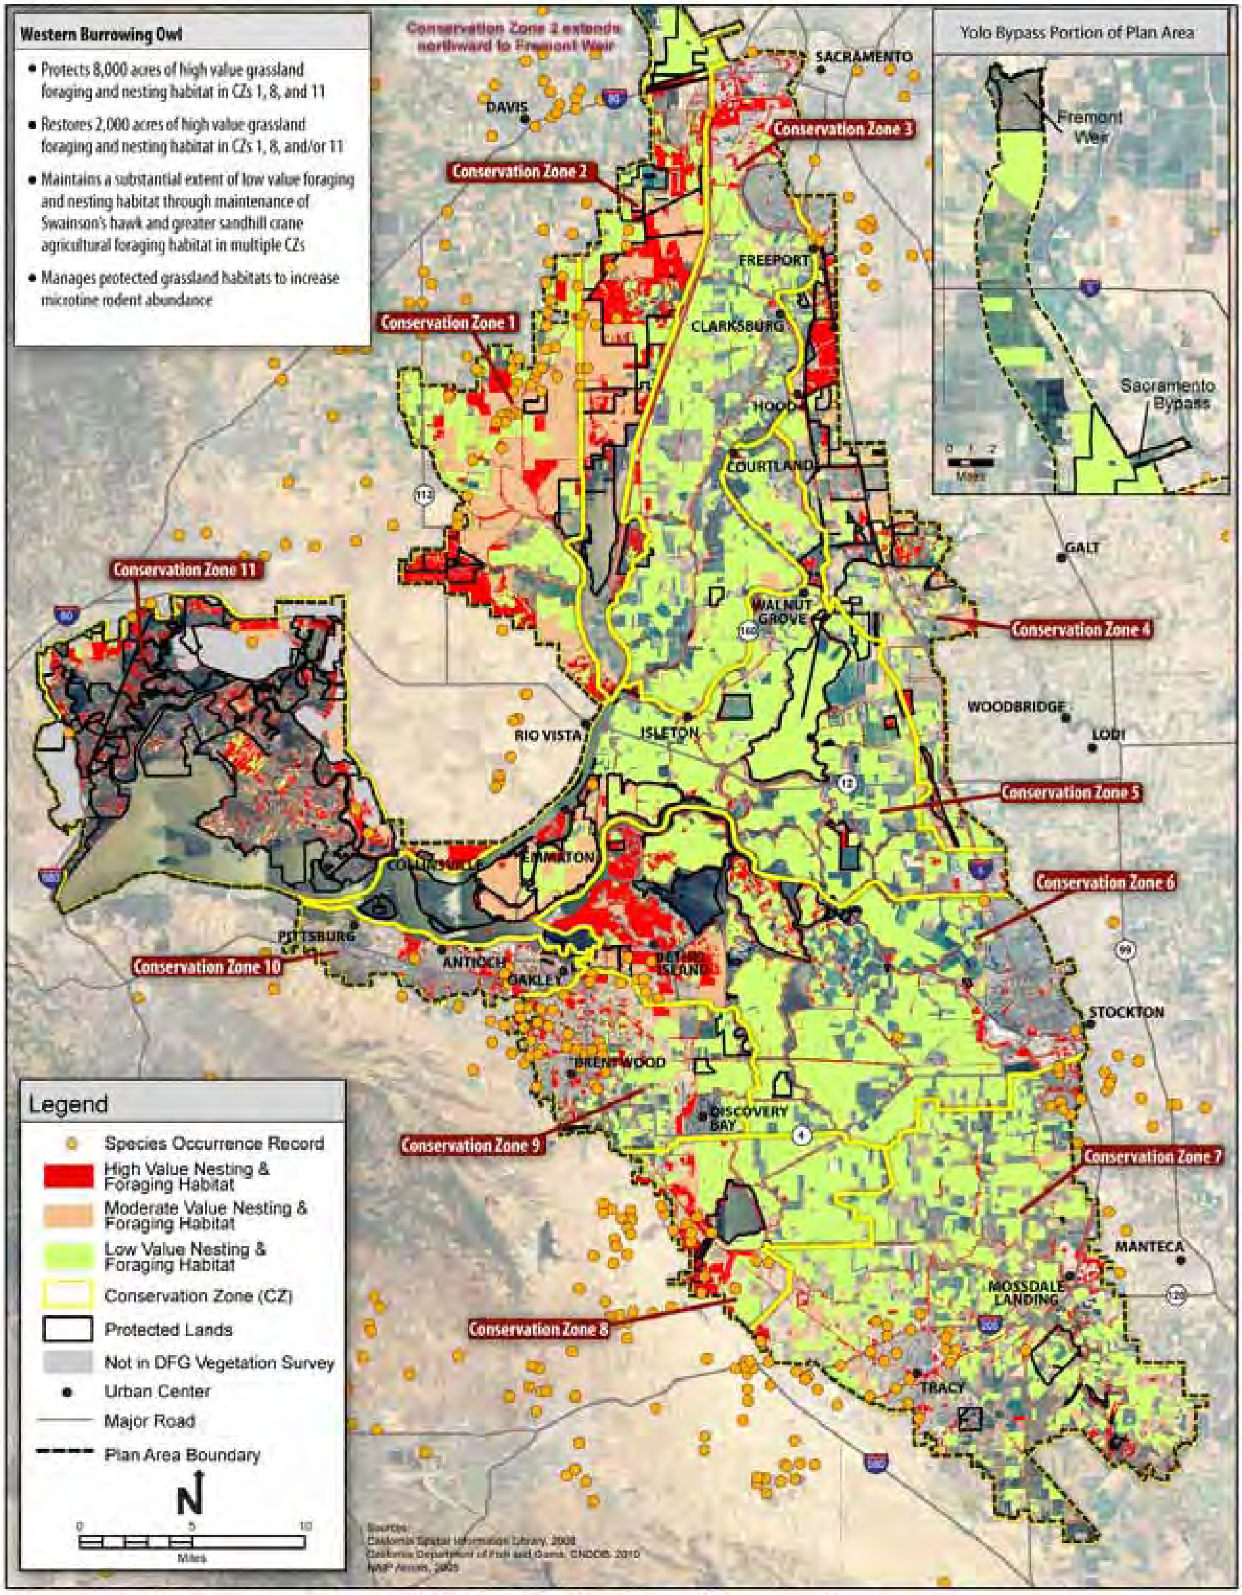

Figure 3-24. Western Burrowing Owl Habitat Distribution and Conservation Strategy

3.3.2.4.12 Western Yellow-billed Cuckoo

The yellow-billed cuckoo is a Neotropical migrant that breeds in North America and winters in South America. The range of the western yellow-billed cuckoo historically extended from southern British Columbia south to the Rio Grande in northern Mexico, and east to the Rocky Mountains (Bent 1940). Currently, the only known populations of breeding western yellow-billed cuckoo are in several disjunct locations in California, Arizona, and western New Mexico (Halterman 1991). Declines in numbers of the yellow-billed cuckoo in California are the result of the "removal widely of essential habitat conditions," as described by Grinnell and Miller (1944). Population declines in California have continued primarily in the San Joaquin Valley and along the north coast and central coast (where the populations had been extirpated by 1977) (Gaines and Laymon 1984), while the species was also nearly extirpated in the Lower Colorado River Valley by 1999. In the Sacramento Valley, only 1 percent of the species' historical habitat remains to support a small population estimated at only 50 pairs in 1987 and 19 pairs in 1989 (Laymon and Halterman 1989), most of these from Sutter, Yuba, and Butte Counties. There are no records of the species breeding in the Plan Area; however, an individual cuckoo was documented in the Central Delta during breeding season surveys conducted in 2009.

Estimates of yellow-billed cuckoo territory size on the south fork of the Kern River ranged from 8-40 hectares (20-100 acres) (Laymon and Halterman 1985), but on the Colorado River were as small as 4 hectares (10 acres) (Laymon and Halterman 1989). Patch size, type and quality of habitat, and prey abundance largely determine the size of territories (Halterman 1991). Laymon and Halterman (1989) classify a willow-cottonwood forest patch greater than 604 meters (1,980 ft) wide and greater than 81 hectares (200 acres) as optimum habitat.

Applicable Natural Community Goals and Objectives

Goal VRNC1: The expected outcome is restored large expanses and interconnected corridors of valley/foothill riparian natural community.

> **Objective VRNC1.1**: Restore or create 5,000 acres of valley/foothill riparian in Conservation Zones 1, 2, 4, 5, 6, 7, and/or 11.

Goal VRNC2: The expected outcome is biologically diverse valley/foothill riparian natural community that supports native species and is sustained by natural ecological processes.

> **Objective VRNC2.1**: Maintain and enhance the habitat and ecosystem functions of BDCP restored valley/foothill riparian and patches of riparian forest and scrub present on BDCP preserved lands over the term of the BDCP.

> **Objective VRNC2.2**: Establish seasonal buffers around riparian habitats occupied by covered species to minimize disturbance during the breeding season.

Objective VRNC2.3: Restore connectivity of valley/foothill riparian corridors along linear watercourses to enhance habitat for covered species and facilitate wildlife movement.

Rationale and Conservation Approach

The primary stressor on the yellow-billed cuckoo is the loss and fragmentation of its riparian habitat through urban and agricultural expansion, bank stabilization, and flood control projects; therefore, the restoration of this habitat type is considered to be the most effective approach to its conservation. In the Plan Area, the conservation of western yellow-billed cuckoo will be provided through the restoration of 5,000 acres of valley/foothill riparian habitat (Table 3-5) (Figure 3-25). The western yellow-billed cuckoo has been sighted several times migrating through the Plan Area, but there have been no recently confirmed nesting records in the Plan Area or vicinity. Since most riparian corridors in the Plan Area do not support sufficiently large riparian patches for cuckoo breeding, conservation will be directed towards restoring riparian forest within the Plan Area to provide habitat that could allow for the future reintroduction or expansion of the existing yellow-billed cuckoo population into the Plan Area. Approaches for restoring valley/foothill riparian that supports western yellow-billed cuckoo habitat are described in the conservation approaches for conserving the valley/foothill riparian natural community.

Western yellow-billed cuckoo nesting habitat is located in expansive stands of riparian cottonwood-willow forests, but other species such as alder (*Alnus rhombifolia*) and box elder (*Acer negundo*) may be an important habitat element in some areas (see Appendix A, *Covered Species Accounts*). Patches of this habitat are expected to be restored as a component of BDCP actions to restore 5,000 acres of valley/foothill riparian. The large amount of valley/foothill riparian that will be restored as a result of the BDCP is expected to significantly advance conservation for the western yellow-billed cuckoo. These restoration actions could increase the likelihood for the western yellow-billed cuckoo to continue to migrate through and potentially re-initiate breeding in the Plan Area.

DRAFT

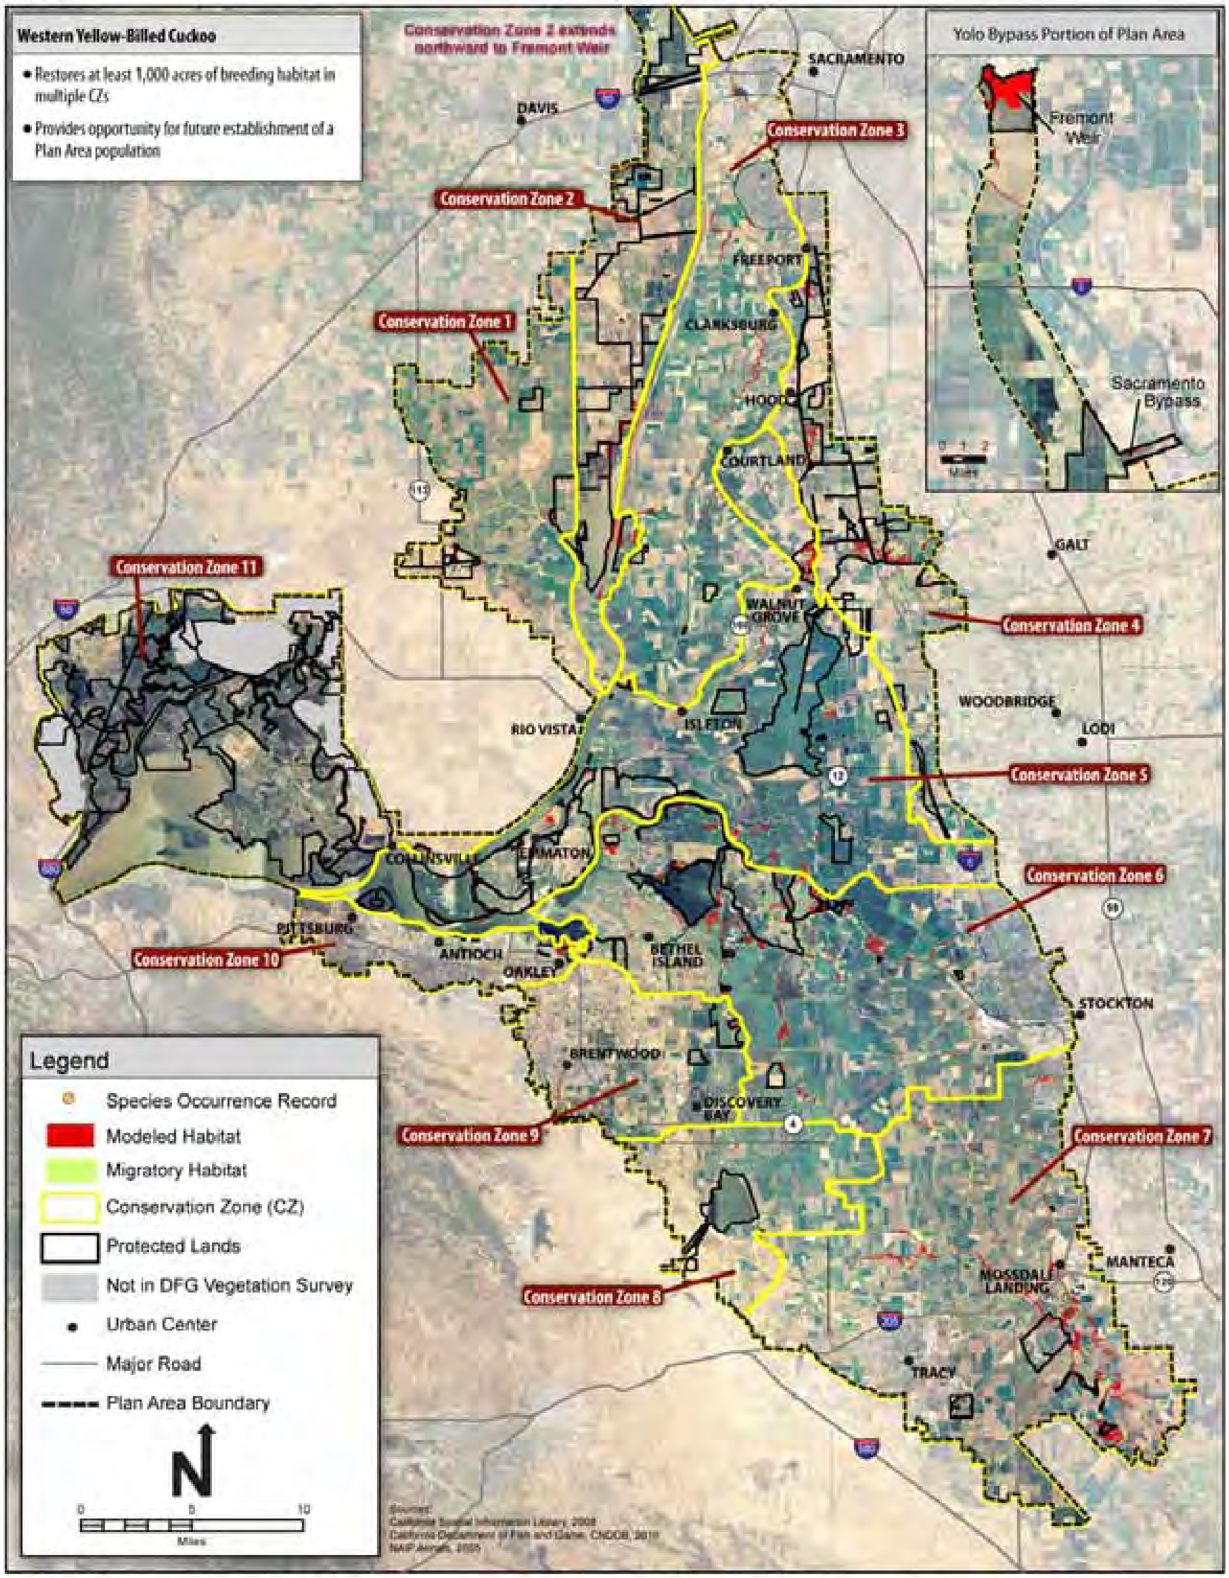

Figure 3-25. Western Yellow-Billed Cuckoo Habitat Distribution and Conservation Strategy

3.3.2.4.13 California Least Tern

California least tern is a migratory species present in California only during the breeding season; arriving in mid-April and departing in late September (Massey 1974, Cogswell 1977, Anderson and Rigney 1980, Patton 2002). Habitat loss is the primary reason for the population declines of California terns from historical levels (USFWS 2006). Since federal and state listing of the California least tern, nesting populations have increased dramatically from only a few pairs in the late 1960s to approximately 7,000 pairs at present (Marschalek 2009). However, the population size and distribution of the least California tern remains limited by the lack of natural nesting habitat (USFWS 2006). Two known breeding occurrences within the Plan Area are both on artificial substrates and virtually no natural breeding habitat exists within the Plan Area.

Applicable Natural Community Goals and Objectives

Goal TANC1: The expected outcome is tidal perennial aquatic natural community that supports habitats for covered and other native species and that supports aquatic food web processes.

> **Objective TANC1.1**: Restore or create 10,000 to 20,000 acres of tidal perennial aquatic in the BDCP Restoration Opportunity Areas (Conservation Zones 1, 2, 4, 5, 6, 7, and 11) that supports aquatic food production and habitat for covered and other native species.

Goal TANC2: The expected outcome is biologically diverse tidal perennial aquatic natural community that is enhanced for native species and sustained by natural ecological processes.

> **Objective TANC2.1:** Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal perennial aquatic community for covered and other native species over the term of the BDCP.

Species-Specific Goals and Objectives

Goal CALT1: The expected outcome is an expanded California least tern population in the Plan Area.

> **Objective CALT1.1:** Create two patches of California least tern nesting habitat during restoration of tidal marsh communities.

Rationale and Conservation Approach

BDCP conservation of California least tern is directed at expanding high value foraging habitat and protecting and creating future nesting sites in the Plan Area (Figure 3-26). Currently, there are only two nesting sites associated with the Plan Area, one at the Montezuma Wetlands and one in the City of Pittsburg (see Appendix A, *Covered Species Accounts*). Neither site consists of natural nesting habitat. Overall, there is little to no natural nesting habitat available in the Plan Area. While much of the tidal perennial aquatic habitat (open water) is suitable for tern foraging, nesting habitat is a function of the availability and suitability of artificial features, such as gravel piles or unused gravel roads in the immediately vicinity of open water habitats. Because of its rarity throughout its range and particularly within the Plan Area, protection and creation of least tern nesting habitat will aid in the expansion of this species' distribution and contribute to its recovery. Tidal habitat restoration in the ROAs is projected to result in the development of 24,913 to 31,622 acres[27] of subtidal aquatic habitat based on the hypothetical restoration designs (exceeding the objective of 10,000 to 20,000 acres), much of which will be suitable as least tern foraging habitat.

Applicable Conservation Measures

- CM3 Natural Communities Protection
- CM11 Natural Communities Enhancement and Management

[27] Restored tidal habitat acreage ranges are a component of the 65,000 acre target for restored tidal habitat. Acreage ranges are based on the results of hydrodynamic modeling of realistic hypothetical restoration designs. While these ranges are not the acreage targets for restored tidal habitats, but rather the results of modeling, the hypothetical designs provided verification of the practicability of achieving restoration targets.

1

3.3.2.4.14 Greater Sandhill Crane

There are an estimated 500,000 sandhill cranes in North America, of which an estimated 62,600 are greater sandhill cranes. An estimated 8,500 of these belong to the Central Valley Population (Littlefield and Ivey 2000). Greater sandhill cranes are winter residents in the Plan Area, where they depend on certain types of agricultural fields (e.g., corn stubble fields) and on grasslands and managed wetlands for foraging; field edges, levees, rice-checks, ditches, alfalfa fields, and pastures for loafing; and inundated fields and wetlands for roosting (Appendix A, *Covered Species Accounts*).

The most significant threat to wintering greater sandhill cranes is the loss of traditional winter habitat from urbanization and agricultural conversion (Littlefield and Ivey 2000). While relatively limited urbanization has occurred to date within key crane areas, surrounding development and increased levels of human disturbances may threaten the long-term sustainability of important wintering lands. In the Delta region, the conversion of suitable agricultural foraging and roosting habitats to unsuitable cover types, particularly orchards and vineyards, has removed key habitats and altered the distribution and behavior of wintering greater sandhill cranes.

Applicable Natural Community Goals and Objectives

Goal ALNC1: The expected outcome is increased habitat functions for covered and other native species that are supported by agricultural land cover types and management practices.

> **Objective ALNC1.2**: Maintain and protect the functions of 12,020 to 28,040 acres of non-rice agricultural lands as foraging habitat for Swainson’s hawk, white-tailed kite, and tricolored blackbird that are located within 8 miles of occupied Swainson’s hawk nesting habitat.

> **Objective ALNC1.4**: Of the maintained 12,020 to 28,040 acres of non-rice agricultural lands, maintain at least 4,800 acres that supports greater sandhill crane foraging habitat within its Winter Use Area and within 2 miles of known roosting sites in Conservation Zones 3, 4, 5, and/or 6.

Goal MWNC2: The expected outcome is biologically diverse managed wetlands that are enhanced for native species.

> **Objective MWNC2.1**: Maintain and enhance the habitat functions of BDCP managed wetlands present on BDCP preserved lands over the term of the BDCP.

Goal FMNC1: The expected outcome is restored large, interconnected patches of tidal freshwater emergent wetland natural community.

> **Objective FMNC1.1:** Restore or create 13,900 to 21,600 acres of tidal freshwater emergent wetland in the Cache Slough, West Delta, Cosumnes-Mokelumne, and South Delta ROAs (Conservation Zones 1, 2, 4, 5, 6, and 7).

Goal FMNC2: The expected outcome is biologically diverse tidal freshwater emergent wetland that is enhanced for native species and sustained by natural ecological processes.

> **Objective FMNC2.1:** Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal freshwater emergent wetlands for covered and other native species over the term of the BDCP.

Species-Specific Goals and Objectives

Goal GSHC1: The expected outcome is expansion and protection of greater sandhill crane winter range.

> **Objective GSHC1.1**: Create 320 acres of seasonally managed greater sandhill crane roosting habitat within Conservation Zones 3, 4, 5, or 6.

Rationale and Conservation Approach

Conservation of greater sandhill crane proposed under BDCP is directed at preserving and restoring wintering habitat sufficient to sustain current wintering population numbers and provide for any future growth of the population. In particular, at least 4,800 acres of protected high functioning foraging habitat will be located within the winter use area.

Protected foraging habitat will primarily be comprised of agricultural habitats with high crane foraging value (e.g., corn, grains, irrigated pasture, alfalfa), but may include grassland and managed wetlands. Protected lands will be managed to provide high-quality foraging habitat and to minimize human disturbances during the crane's wintering period. A total of at least 4,800 acres of high value foraging habitat will be preserved and protected in Conservation Zones 3, 4, 5 and/or 6 (Figure 3-27). Preserved foraging habitat patches will be at least 160 acres in size (or less if adjacent to other protected habitat) to minimize the potential effects of human-associated visual and noise disturbances adjacent to preserved foraging habitat. The majority of foraging habitat within the winter use area is located below sea level and potentially subject to future loss with levee failures. As part of the conservation strategy, the BDCP Implementation Office will therefore consider opportunities for acquisition of lands at elevations above sea level.

In addition, the conversion from agricultural lands with uncertain or variable suitability (due to crop rotations or that are subject to conversion to unsuitable perennial crops such as orchards and vineyards) to tidal freshwater wetlands is expected to increase the habitat value of the restored lands. Restored tidal freshwater wetlands within the crane's primary use area (2,100 acres in

Conservation Zone 4) will include shallow water habitats, berms, and grassland edges and may provide suitable roosting and foraging habitat for greater sandhill cranes. Additional restored tidal freshwater wetlands south of the crane's primary use area (5,000 acres in Conservation Zone 7) is expected to provide suitable roosting, resting, and foraging habitat that may facilitate expansion of the wintering range.

Additional agricultural land preserved for other covered species including Swainson's hawk and white-tailed kite (primarily alfalfa and irrigated pasture cover types) within the crane use area will also be available to wintering greater sandhill cranes. Following implementation of BDCP actions, more than 19 percent of greater sandhill crane foraging habitat will be protected (Table 3-5). Protection and management of existing foraging habitats and restoration and management of roost sites are expected to ensure that the existing abundance of wintering cranes in the Plan Area is maintained and are expected to provide sufficient wintering habitat to accommodate potential future expansions of the crane population.

Greater sandhill crane winter roosting habitats are limited within the Plan Area and roosting cranes are intolerant of disturbances and readily will abandon roosts if disturbed. Lack of permanent roosting habitat limits the ability of cranes to use foraging habitats. To address this species' requirement, 320 acres of land will be managed specifically to meet the ecological requirements of greater sandhill crane roosting habitat will be created to ensure the future availability of sufficient winter roosting habitat. Roost sites will be at least 80 acres in size (or less if adjacent to other existing roosting habitat or otherwise meet criteria for roosting and are considered to have exceptionally high value) and will be located within the Delta winter range of the species, but with consideration of the potential for sea level rise. Roost sites will be located in areas that are not subject to disturbances and will be designed to minimize predator accessibility. Location of roost sites will also consider opportunities for expanding the range of the species by placing roosts within suitable, but underused foraging habitats due to the lack of roost sites.

- CM11 Natural Communities Enhancement and Management

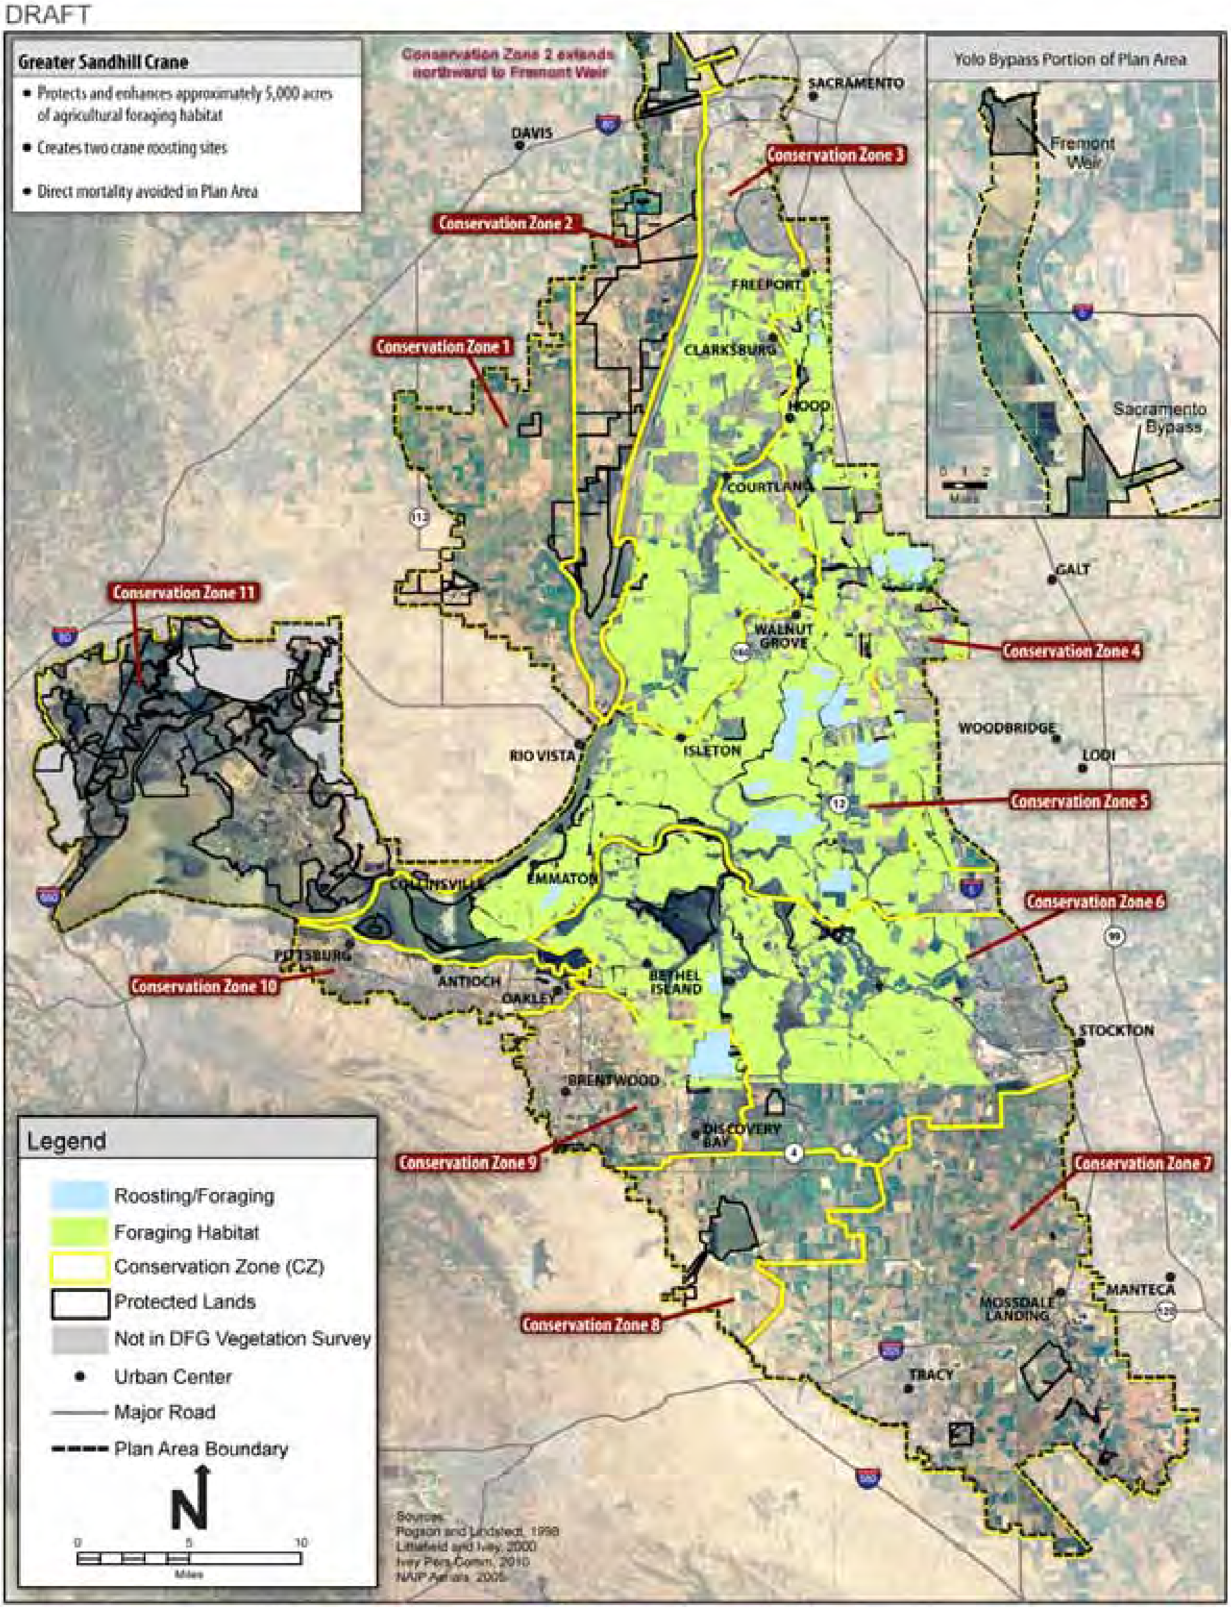

Figure 3-27. Greater Sandhill Crane Habitat Distribution and Conservation Strategy

3.3.2.4.15 California Black Rail

California black rail inhabits tidal saltwater, tidal brackish, and tidal freshwater marshes (Grinnell and Miller 1944, Manolis 1978, Spautz et al. 2005). Declines in populations of the California black rail in California and the extirpation of the rail from much of its historical coastal range are the result of tidal marsh habitat loss and degradation along with an increase in exotic predators such as black rats and red foxes (Manolis 1978, Garrett and Dunn 1981 as cited in DWR 2001, Evens et al. 1991). Currently, the species is confined to mostly pristine remnants of historical tidal marshlands, including throughout parts of Suisun Bay, which serves as one of the last large refuge areas for a viable population (Evens et al. 1991, Spautz et al. 2005). The proposed restoration of California black rail habitat in the Plan Area is consistent with and helps achieve the California black rail objectives of the draft tidal marsh ecosystems recovery plan (USFWS 2010) and objectives of the Suisun Marsh Restoration Plan (under development). Black rails also occur in lower densities in the patches of tidal freshwater marsh found along the margins of waterways in the Central Delta.

Applicable Natural Community Goals and Objectives

Goal BMNC1: The expected outcome is restored large expanses and interconnected patches of tidal brackish emergent wetland natural community.

> **Objective BMNC1.1:** Restore or create 3,600 to 4,800 acres of tidal brackish emergent wetland in the Suisun Marsh ROA (Conservation Zone 11).

Goal BMNC2: The expected outcome is biologically diverse tidal brackish emergent wetland that is enhanced for native species and sustained by natural ecological processes.

> **Objective BMNC2.1:** Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal brackish emergent wetland for covered and other native species over the term of the BDCP.

Goal FMNC1: The expected outcome is restored large, interconnected patches of tidal freshwater emergent wetland natural community.

> **Objective FMNC1.1:** Restore or create 13,900 to 21,600 acres of tidal freshwater emergent wetland in the Cache Slough, West Delta, Cosumnes-Mokelumne, and South Delta ROAs (Conservation Zones 1, 2, 4, 5, 6, and 7).

Goal FMNC2: The expected outcome is biologically diverse tidal freshwater emergent wetland that is enhanced for native species and sustained by natural ecological processes.

> **Objective FMNC2.1:** Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal freshwater emergent wetlands for covered and other native species over the term of the BDCP.

Rationale and Conservation Approach

Under BDCP, the conservation of the California black rail is directed at restoring tidal marsh conditions that historically supported habitat in the Plan Area (Figure 3-28). Outside of Suisun Marsh, existing habitat is limited primarily to small and isolated remnant patches of tidal emergent wetland vegetation along Delta channels. Because opportunities for conserving species habitats along existing tidal channels are limited by levees, conservation will be provided through the restoration of large tracts of brackish and freshwater tidal emergent wetland throughout Suisun Marsh and elsewhere in the Plan Area where such restoration is practicable. A total of between 17,500 and 26,400 acres of tidal emergent wetland (freshwater and brackish) will be restored in Conservation Zones 1, 2, 4, 5, 6, 7, and 11. Restored tidal brackish emergent wetland and tidal freshwater emergent wetland will be designed to the extent practicable within site constraints to provide the full range of environmental gradients from tidal areas to uplands that existed under historical conditions in Suisun Bay and the Delta. This approach is expected to result in restoration of patches of rail habitat within a mosaic of larger marsh plain habitats. Approaches for restoring habitat to support California black rail habitat are described in the conservation approaches for conserving the tidal brackish emergent wetland and the tidal freshwater emergent wetland natural communities.

In Suisun Marsh, tidal emergent wetland will be restored in a sequenced manner that minimizes the disturbance of existing habitats between the initiation of restoration actions and the point at which restored tidal emergent wetland develops as California black rail habitat. Direct removal of existing tidal brackish emergent wetland will be minimized consistent with achieving overall wetland restoration objectives, although some tidal brackish emergent wetland is expected to be desiccated or inundated as a result of changes in the existing tidal range following the breaching of dikes and levees. It is anticipated that following completion of all tidal habitat restoration in Suisun Marsh, tidal brackish emergent wetland will be restored in larger patches than the existing patches of habitat that are currently fragmented by dikes, roads, unsuitable habitat areas, and other infrastructure. These larger unfragmented patches are expected to provide higher-value habitat and facilitate population expansion and growth of California black rail populations in Suisun Marsh.

Restoration of tidal freshwater emergent wetland in the Delta will occur primarily on existing agricultural land and is expected to expand the range of suitable California black rail habitat. Nonnative predators (e.g., feral cats) are believed to be an important stressor on the California black rail. The design and management of restored habitat will include control of nonnative predators to help maintain the species abundance (e.g., through direct removal of predators or through design of restored habitats that minimize access of predators into occupied habitats).

DRAFT

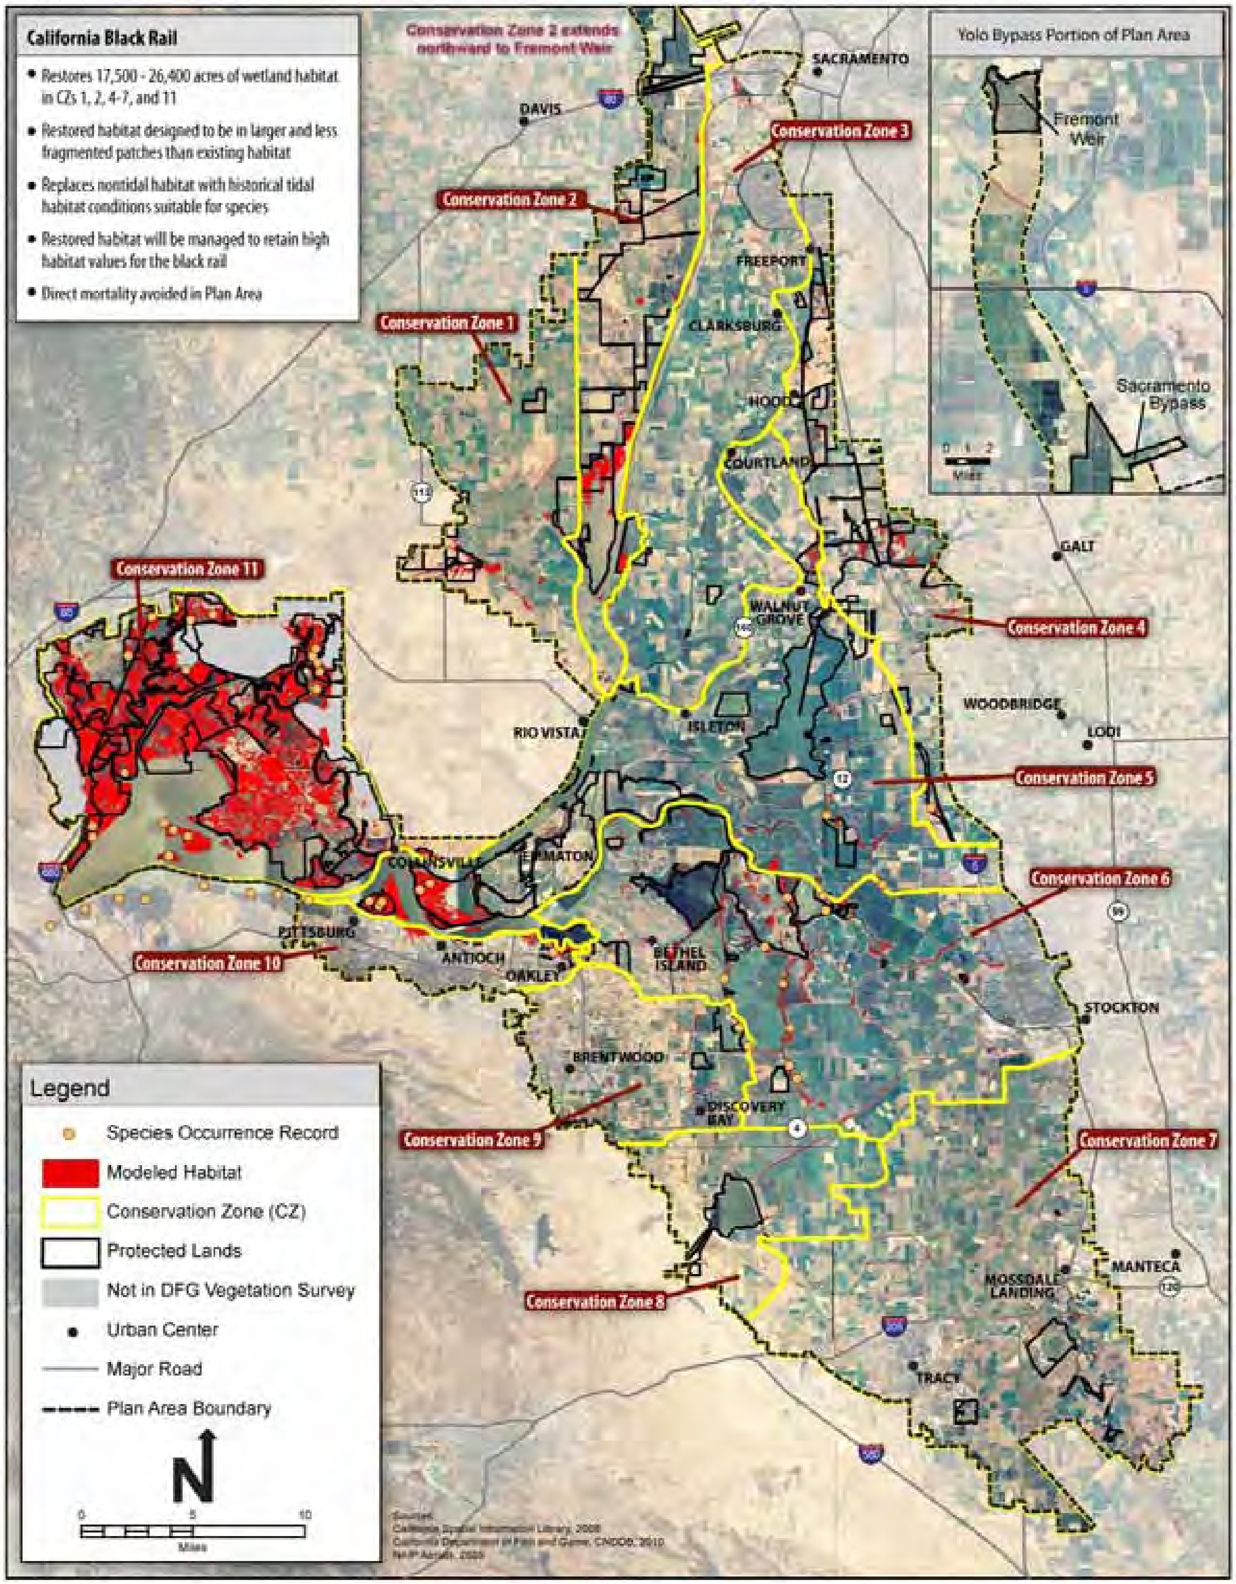

Figure 3-28. California Black Rail Habitat Distribution and Conservation Strategy

3.3.2.4.16 California Clapper Rail

The California clapper rail is a year-round resident of tidal salt and brackish marshes (Albertson 1995 as cited in LSA 2007, USFWS 1998c), occurring in higher population densities where habitat exceeds 100 ha (247 acres) in size (LSA 2007). Its current range is limited to the San Francisco Bay (extending to Suisun Bay), but the California clapper rail once ranged over much of coastal northern California (DWR 1994, USFWS 1998c, LSA 2007). The main significant threat to the California clapper rail continues to be the degradation of its tidal marsh habitat (Williams 1985, Ohlendorf and Fleming 1988, Ohlendorf et al. 1989, Harvey 1990, Lonzarich et al. 1990, Foerster and Takekawa 1991, Leipsic-Baron 1992, DFG 2000 as cited in LSA 2007). Tidal marsh habitat has been reduced by up to 84 percent in the San Francisco Bay since the mid-1800s (Dedrick 1989).

Applicable Natural Community Goals and Objectives

Goal BMNC1: The expected outcome is restored large expanses and interconnected patches of tidal brackish emergent wetland natural community.

> **Objective BMNC1.1:** Restore or create 3,600 to 4,800 acres of tidal brackish emergent wetland in the Suisun Marsh ROA (Conservation Zone 11).

Goal BMNC2: The expected outcome is biologically diverse tidal brackish emergent wetland that is enhanced for native species and sustained by natural ecological processes.

> **Objective BMNC2.1:** Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal brackish emergent wetland for covered and other native species over the term of the BDCP.

Rationale and Conservation Approach

The primary focus of the Recovery Plan for the California clapper rail (USFWS 1984b) is to restore and enhance tidal marsh habitat as a means to increase population numbers and expand the distribution of the rail. BDCP implementation will tie in with existing conservation and enhancement efforts for Suisun Marsh, where more extensive patches of suitable habitat should support larger rail numbers.

The tidal brackish emergent wetland habitat of the California clapper rail is primarily in Suisun Marsh, which is encompassed by Conservation Zone 11. A small portion of the western edge of Conservation Zone 5 (western edge of Sherman Island) is also considered potential habitat for California clapper rail, although no occurrences have been documented there (Appendix A, *Covered Species Accounts*). Conservation will be directed towards restoring tidal brackish emergent wetland in Conservation Zone 11 such that of 3,600 to 4,800 acres[28] of restored tidal

[28] Restored tidal habitat acreage ranges are a component of the 65,000 acre target for restored tidal habitat. Acreage ranges are based on the results of hydrodynamic modeling of realistic hypothetical restoration designs. While these ranges are not the acreage targets for restored tidal habitats, but rather the results of modeling, the hypothetical designs provided verification of the practicability of achieving restoration targets.

habitat will serve as California clapper rail habitat based on the analysis of the hypothetical restoration design (Figure 3-29). Tidal habitat restoration that will be implemented in the West Delta ROA (see Conservation Measure CM4, Tidal Habitat Restoration), may also support California clapper rail in future years with sea level rise if salinity increases in the west Delta such that freshwater tidal habitats convert to brackish tidal habitat.

Because restoration of tidal habitat will remove and degrade patches of tidal brackish emergent wetland that are currently occupied by California clapper rail, restoration will be sequenced and located in a manner that minimizes any initial, temporary loss of habitat. Approaches for restoring tidal habitat to support California clapper rail habitat are described in Conservation Measure CM4 Tidal Habitat Restoration. Restored tidal habitats will be designed to the extent practicable within site constraints to provide the full range of environmental gradients from tidal areas to uplands that existed under historical conditions in Suisun Bay. This approach is expected to result in the restoration of patches of California clapper rail habitat within a mosaic of tidal emergent wetland. It is anticipated that following completion of all tidal habitat restoration in Suisun Marsh, tidal emergent wetland will be restored in larger patches than the existing patches of habitat that are currently fragmented by dikes, roads, unsuitable habitat areas, and other infrastructure. These larger unfragmented patches are expected to provide higher ecological value that will facilitate the expansion and growth of California clapper rail populations in the Suisun Marsh. The transitional upland component of restored tidal habitats will be designed to provide flood refugia habitat during high water events.

Nonnative predators (e.g., feral cats) are believed to be an important stressor on the California clapper rail. The design and management of restored habitat will include control of nonnative predators to help maintain the species abundance (e.g., through design of restored habitats that minimize access of predators to occupied habitats and/or through direct removal of predators or). Restored habitat will also be monitored to assess the status of the species and will be adaptively managed to ensure high habitat function for the clapper rail is maintained over time. The proposed restoration of tidal habitat in Suisun Marsh is consistent with and helps achieve the California clapper rail objectives of the draft tidal marsh ecosystems recovery plan (USFWS 2010) and objectives of the Suisun Marsh Restoration Plan (under development).

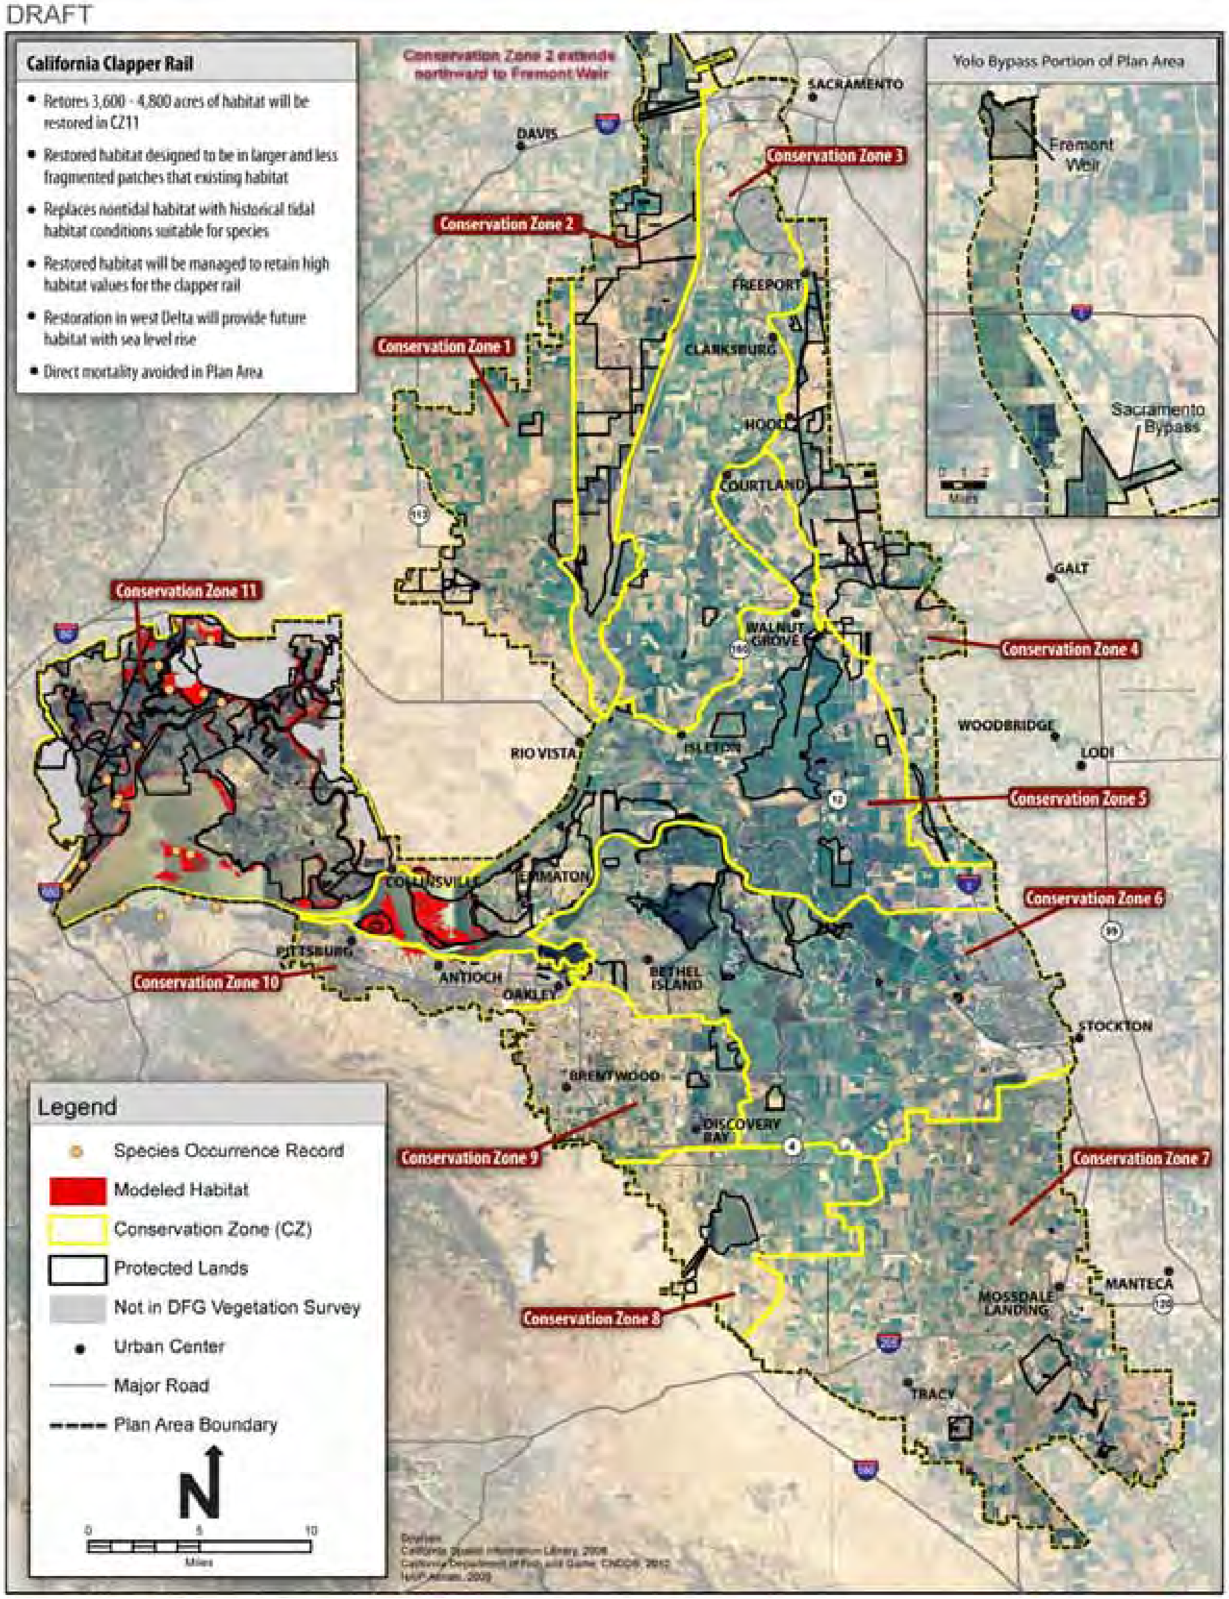

Figure 3-29. California Clapper Rail Habitat Distribution and Conservation Strategy

3.3.2.4.17 Swainson's Hawk

Nesting Swainson's hawks are widely distributed throughout the Plan Area and surrounding lands (Figure 3-30). Of the 314 nesting records since 2000, at least 220 of these are considered independent and are potentially active in any given year. They hunt primarily for rodent prey in agricultural and grassland habitats, and they nest in trees, mainly along stringers of remnant riparian forest along drainages (Estep 1984, Schlorff and Bloom 1984, England et al. 1997) as well as in isolated trees, tree rows, and other nesting habitats. Swainson's hawk population declines in California are thought to be the result of the loss of nesting and foraging habitat due to urban development and conversion to unsuitable agriculture, such as orchards and vineyards (Schlorff and Bloom 1984, England et al. 1995, 1997). Within the Bay/Delta region, high densities of nesting Swainson's hawk nesting pairs have been reported from remnant habitat patches, indicating the potential for large-scale riparian restoration to be of substantial benefit to the species (Estep 1989, 2008).

Applicable Natural Community Goals and Objectives

Goal VRNC1: The expected outcome is restored large expanses and interconnected corridors of valley/foothill riparian natural community.

> **Objective VRNC1.1**: Restore or create 5,000 acres of valley/foothill riparian in Conservation Zones 1, 2, 4, 5, 6, 7, and/or 11.

Goal VRNC2: The expected outcome is biologically diverse valley/foothill riparian natural community that supports native species and is sustained by natural ecological processes.

> **Objective VRNC2.1**: Maintain and enhance the habitat and ecosystem functions of BDCP restored valley/foothill riparian and patches of riparian forest and scrub present on BDCP preserved lands over the term of the BDCP.

> **Objective VRNC2.2**: Establish seasonal buffers around riparian habitats occupied by covered species to minimize disturbance during the breeding season.

> **Objective VRNC2.3**: Restore connectivity of valley/foothill riparian corridors along linear watercourses to enhance habitat for covered species and facilitate wildlife movement.

Goal GRNC1: The expected outcome is grassland comprised of large interconnected patches or contiguous expanses.

> **Objective GRNC1.1**: Protect a minimum of 8,000 acres of grassland in Conservation Zones 1, 8, and 11. At least 1,000 acres will be protected in Conservation Zone 8, with the remainder distributed throughout these three Conservation Zones.

Goal GRNC2: The expected outcome is biologically diverse grassland managed to enhance native species and sustained by natural ecological processes.

> **Objective GRNC2.5**: Increase prey, especially small mammals and insects, for grassland-foraging species.

Goal ALNC1: The expected outcome is increased habitat functions for covered and other native species that are supported by agricultural land cover types and management practices.

> **Objective ALNC1.2**: Maintain and protect the functions of 12,020 to 28,040 acres of non-rice agricultural lands as foraging habitat for Swainson's hawk, white-tailed kite, and tricolored blackbird that are located within 8 miles of occupied Swainson's hawk nesting habitat.

> **Objective ALNC1.8**: Maintain and protect the small patches of important wildlife habitats associated with agricultural lands that occur within BDCP conserved agricultural lands, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, and wetlands.

Rationale and Conservation Approach

The conservation of Swainson's hawk will be provided by restoring 5,000 acres of valley/foothill riparian nesting habitat, a substantial amount of which is expected to provide suitable nesting habitat for Swainson's hawk; and by preserving 20,020 to 36,040 acres of agricultural and grassland foraging habitat (Figure 3-30). These actions are expected to sustain the current local Swainson's hawk population and provide for any future increases in Swainson's hawk numbers in the Plan Area. Breeding densities are high in some areas, particularly the north, east, and south Delta, and less so in the Central Delta and south Yolo Bypass. Nesting occurs in riparian habitats as well as roadside trees, isolated trees, and groves where trees support appropriate height and structure (see Appendix A, *Covered Species Accounts*).

The majority of the land within the Plan Area supports Swainson's hawk foraging habitat; however, habitat value varies in agricultural habitats depending on annual and seasonal crop patterns and practices, which influences prey accessibility due to the growth and structure of vegetation, and prey abundance. Because of the dynamic nature of the agricultural landscape and the variability of crop patterns and conditions seasonally and annually, only a proportion of the agricultural landscape is suitable or available for foraging in any given season or year. To account for this variability and to more accurately represent the value of Plan Area-wide foraging habitat, acres of Swainson's hawk foraging habitat were converted to habitat units by placing different crop types and other foraging habitats that traditionally occur in the Plan Area into crop value classes and assigning relative values to those classes (See Species Model in Appendix A, *Covered Species Accounts*). This approach, used to calculate foraging habitat impacts to Swainson's hawk, will also be used to ensure that similar habitat value or better is consistently maintained on BDCP protected lands during the permit period.

The majority of protected foraging habitat will be located at elevations above sea level to ensure that foraging habitat is maintained for Swainson's hawks should potential future Delta levee failures result in large-scale inundation. It is anticipated that all of the restored riparian habitat will be located within flight distance to protected foraging habitat, thus increasing the functions of both types of habitat for the species. Furthermore, patches of nesting habitat located within lands protected for other purposes will also be maintained and all protected habitats supporting active nest sites will be managed to minimize human disturbances during the breeding season.

Protected grassland and agricultural lands will be managed to provide high value Swainson's hawk foraging habitat. Conservation will occur in cooperation and in conjunction with neighboring and overlapping HCP/NCCPs to ensure that conservation actions are implemented where they most benefit the regional Swainson's hawk population and where they are compatible with conservation of other agricultural and riparian-associated species. It is also expected that ongoing agricultural land uses within and adjacent to the Plan Area will also continue to support foraging habitat for Swainson's hawks in the Plan Area.

An estimated 17 percent of Swainson's hawk foraging habitat within the Plan Area is currently protected on state and federal wildlife refuges, other state-owned lands, and mitigation banks and is expected to remain suitable Swainson's hawk foraging habitat. Following implementation of BDCP actions, between 22 and 26 percent of the total available foraging habitat will be preserved, and the extent of nesting habitat will be increased by approximately 28 percent. The proposed conservation is expected to sustain the existing population of Swainson's hawk and provide for future increases in its abundance and distribution within and adjacent to the Plan Area.

DRAFT

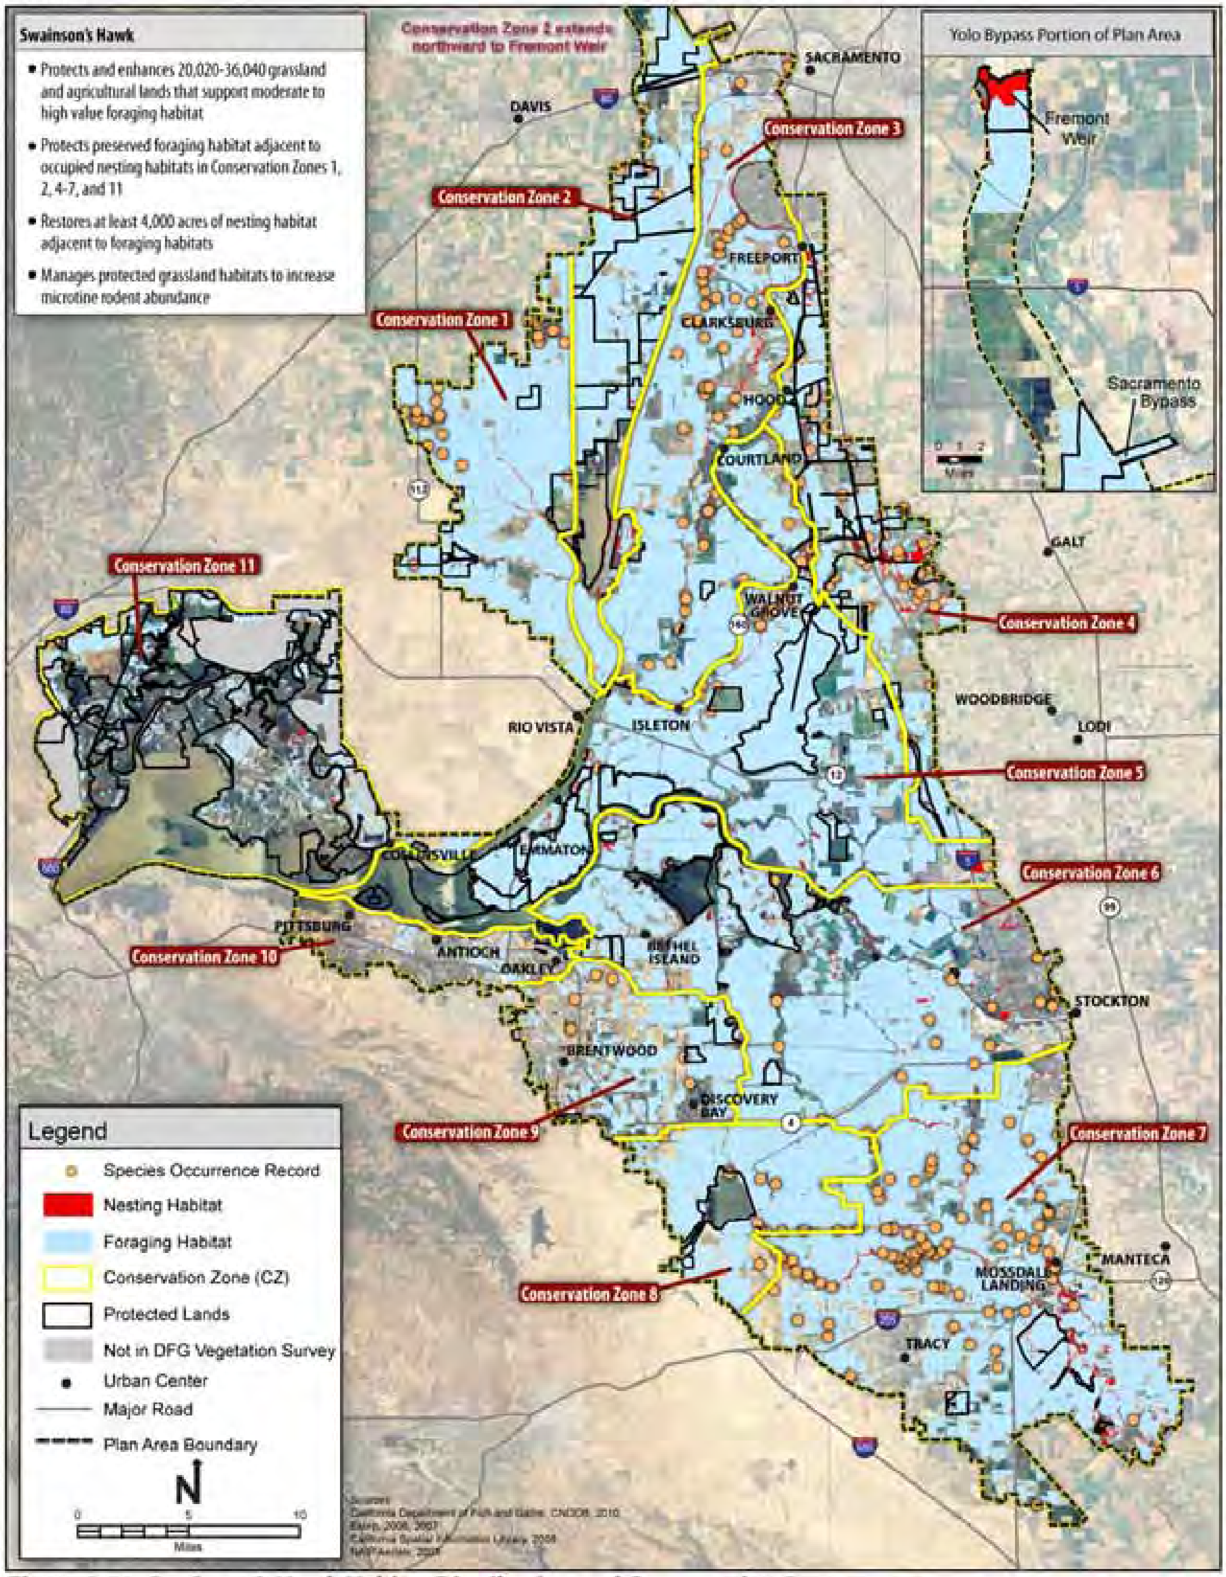

Figure 3-30. Swainson's Hawk Habitat Distribution and Conservation Strategy

3.3.2.4.18 White-Tailed Kite

The white-tailed kite inhabits or uses low elevation, open grasslands, savannah-like habitats, agricultural areas, wetlands, and oak woodlands (Dunk 1995). California is currently considered the stronghold of the white-tailed kite's breeding distribution in North America, with nearly all areas up to the western Sierra Nevada foothills and southeastern deserts occupied (Small 1994, Dunk 1995). It is an uncommon to common year-round resident in the Central Valley and other lowland valleys, and along the entire length of the coast (Dunk 1995). The white-tailed kite occurs year-round in the Plan Area, where it nests in trees, often in riparian areas, and forages in agricultural areas with accessible rodent prey populations (see Appendix A, *Covered Species Accounts*). It is designated as a state Fully Protected species pursuant to California Department of Fish and Game Code Section 3511.

Pronounced population declines and increases have been documented throughout the species' distribution in North America, in many cases the apparent result of changes in prey rodent densities caused by weather or anthropogenic habitat alteration (Ruth and Krueper 2010).

Applicable Natural Community Goals and Objectives

Goal VRNC1: The expected outcome is restored large expanses and interconnected corridors of valley/foothill riparian natural community.

> **Objective VRNC1.1**: Restore or create 5,000 acres of valley/foothill riparian in Conservation Zones 1, 2, 4, 5, 6, 7, and/or 11.

Goal VRNC2: The expected outcome is biologically diverse valley/foothill riparian natural community that supports native species and is sustained by natural ecological processes.

> **Objective VRNC2.1**: Maintain and enhance the habitat and ecosystem functions of BDCP restored valley/foothill riparian and patches of riparian forest and scrub present on BDCP preserved lands over the term of the BDCP.

> **Objective VRNC2.2**: Establish seasonal buffers around riparian habitats occupied by covered species to minimize disturbance during the breeding season.

> **Objective VRNC2.3**: Restore connectivity of valley/foothill riparian corridors along linear watercourses to enhance habitat for covered species and facilitate wildlife movement.

Goal GRNC1: The expected outcome is grassland comprised of large interconnected patches or contiguous expanses.

> **Objective GRNC1.1**: Protect a minimum of 8,000 acres of grassland in Conservation Zones 1, 8, and 11. At least 1,000 acres will be protected in Conservation Zone 8, with the remainder distributed throughout these three Conservation Zones.

Objective GRNC1.2: Restore 2,000 acres of grassland to connect fragmented patches of protected grassland.

Goal GRNC2: The expected outcome is biologically diverse grassland managed to enhance native species and sustained by natural ecological processes.

Objective GRNC2.5: Increase prey, especially small mammals and insects, for grassland-foraging species.

Goal ALNC1: The expected outcome is increased habitat functions for covered and other native species that are supported by agricultural land cover types and management practices.

Objective ALNC1.1: Maintain and protect the functions of 4,600 acres of rice lands as habitat for giant garter snake, western pond turtle, tricolored blackbird, white-tailed kite, waterfowl, and migrant shorebirds in Conservation Zone 2. This objective may be partially or fully achieved by maintaining an equivalent extent of natural or managed lands that support habitat functions similar to rice lands for associated covered and other native wildlife species.

Objective ALNC1.2: Maintain and protect the functions of 12,020 to 28,040 acres of non-rice agricultural lands as foraging habitat for Swainson's hawk, white-tailed kite, and tricolored blackbird that are located within 8 miles of occupied Swainson's hawk nesting habitat.

Objective ALNC1.8: Maintain and protect the small patches of important wildlife habitats associated with agricultural lands that occur within BDCP conserved agricultural lands, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, and wetlands.

Rationale and Conservation Approach

Habitat loss and fragmentation represent threats to the species in California (see Appendix A, *Covered Species Accounts*), and BDCP conservation of white-tailed kite is directed at maintaining a landscape of suitable nesting and foraging habitat across the Plan Area and adjacent lands. This goal is to be accomplished through strategic acquisition and management of between 22,000 and 40,000 acres of grassland and agricultural preserves (as foraging habitat) and through restoration of 5,000 acres of riparian habitat (Figure 3-31). The majority of protected foraging habitat will be located at elevations above sea level to ensure that foraging habitat is maintained for white-tailed kites should potential future Delta levee failures result in extensive, permanent inundation of the lowest-lying areas. It is anticipated that all of the restored valley/foothill riparian will be located within foraging flight distance to protected foraging habitat, thus increasing the value of both types of habitat for the species. Furthermore, patches of nesting habitat located within lands protected for other purposes will also be maintained and all protected habitats supporting active nest sites will be managed to minimize human disturbance during the breeding season.

Protected grasslands and agricultural lands will be managed to provide high value white-tailed kite foraging habitat. An estimated 21 percent of white-tailed kite foraging habitat within the Plan Area is currently protected on state and federal wildlife refuges, other state-owned lands, and mitigation banks and is expected to remain suitable white-tailed kite foraging habitat. Following implementation of BDCP actions, an estimated 26 to 31 percent of the total available foraging habitat will be protected, and the extent of nesting habitat will be increased by approximately 29 percent.

White-tailed kite conservation will occur in cooperation and in conjunction with neighboring and overlapping HCP/NCCPs to ensure that conservation actions occur where they most benefit the regional white-tailed kite population and where they are compatible with conservation of other agricultural and riparian-associated species. It is also expected that ongoing agricultural land uses within and adjacent to the Plan Area will continue to support foraging habitat for white-tailed kite nesting and wintering in the Plan Area. BDCP's proposed white-tailed kite conservation strategy is expected to sustain the existing population of white-tailed kites and provide for future increases in its abundance and distribution within and adjacent to the Plan Area.

DRAFT

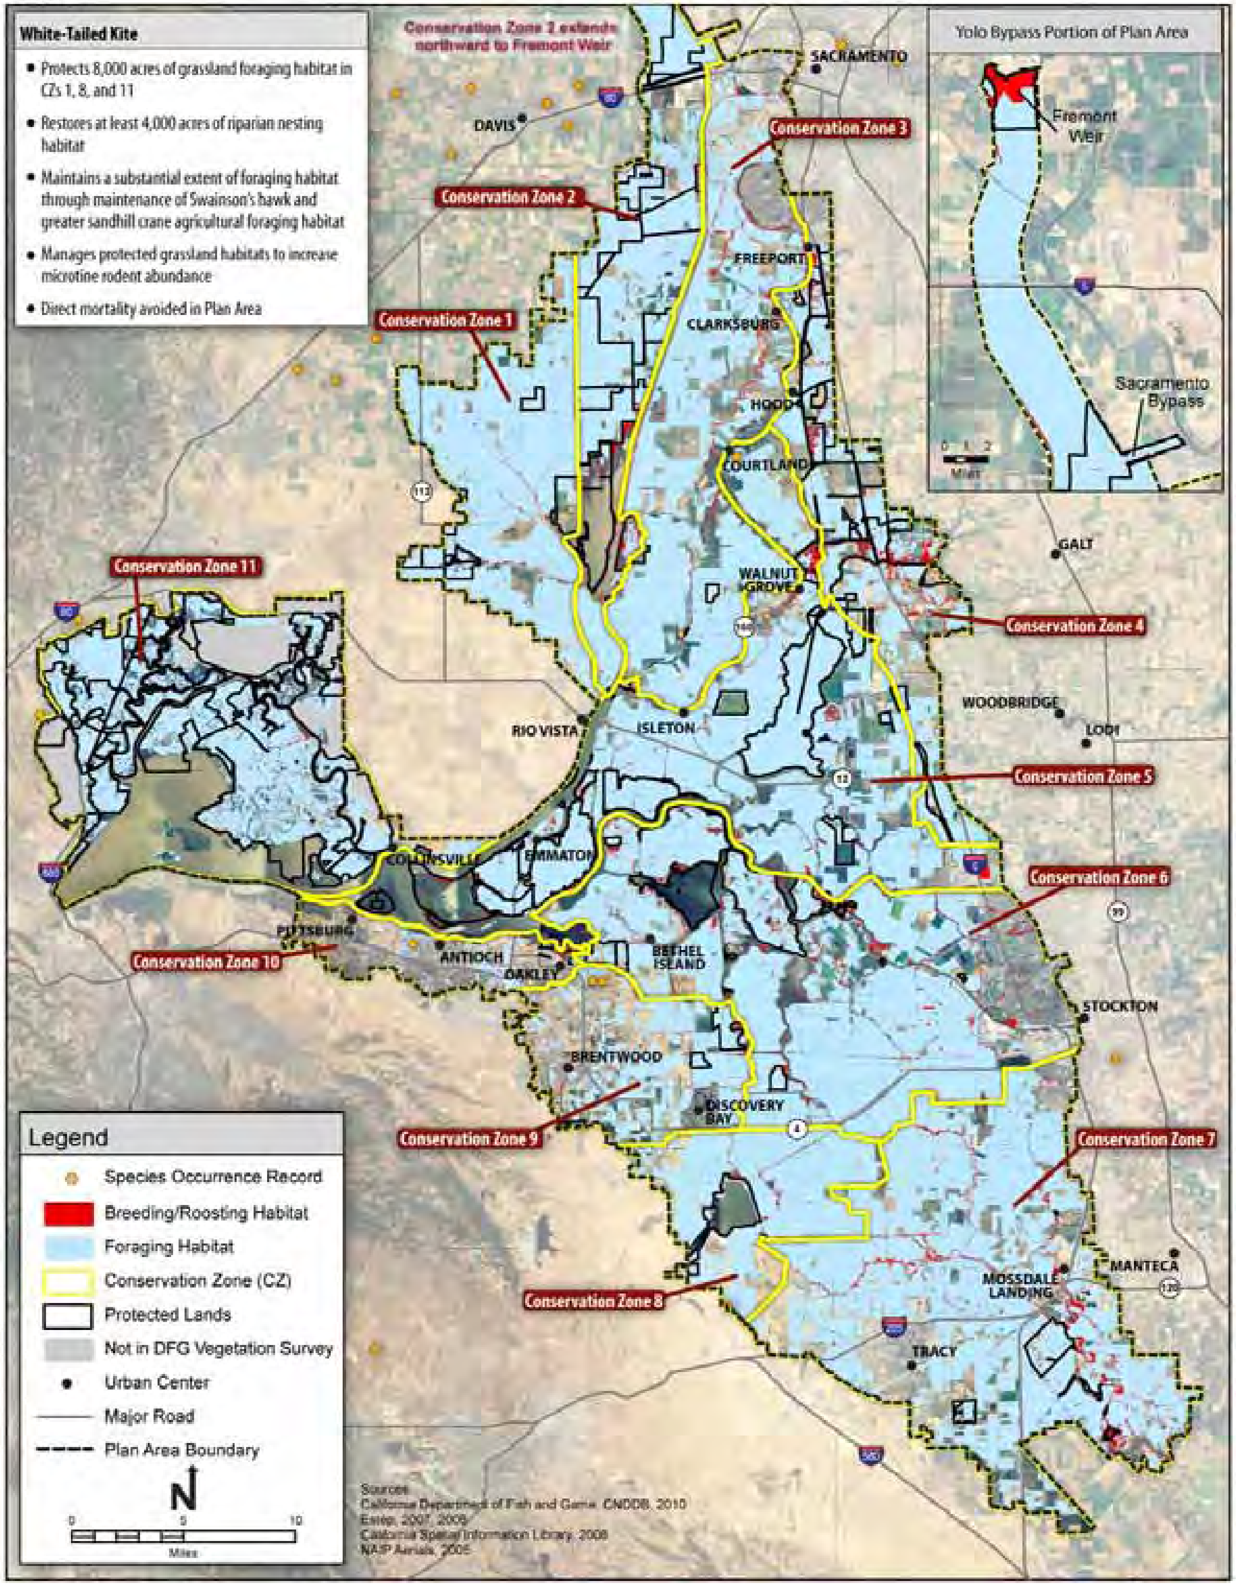

Figure 3-31. White-Tailed Kite Habitat Distribution and Conservation Strategy

3.3.2.4.19 Giant Garter Snake

The giant garter snake is endemic to wetlands in the Sacramento and San Joaquin valleys and was historically distributed throughout the San Joaquin Valley (Hansen and Brode 1980). The current distribution extends from near Chico in Butte County south to the Mendota Wildlife Area in Fresno County. The Plan Area is within the Mid-Valley Recovery Unit identified in the Draft Recovery Plan, and three of the thirteen giant garter snake populations identified by the USFWS occur within the Plan Area in Yolo Basin – Willow Slough, Yolo Basin – Liberty Farms, and Coldani Marsh – White Slough (USFWS 1999a).

Giant garter snakes utilize a wide variety of aquatic habitats including marshes, ponds, sloughs, small lakes, low gradient streams, and other waterways, including agricultural wetlands such as irrigation and drainage canals, rice fields, and the adjacent uplands. Important giant garter snake habitat elements include: adequate water during the snake's active season (early-spring through mid-fall) to provide food and cover, emergent herbaceous wetland vegetation accompanied by vegetated banks for escape cover and as foraging habitat during the active season, basking habitat of grassy banks and openings in waterside vegetation, and higher elevation uplands for cover and refuge from flood waters during the snake's dormant season in the winter. Home range size varies by location, with median home range estimates averaging 23 acres (range [10.3 to 203 ac], n = 8) (9 hectares, range = 4.2 to 82 ha) in a semi-native perennial marsh system and 131 acres (range [3.2 to 2,792 ac], n = 29) (53 hectares, range = 1.3 to 1130 ha) in a managed refuge (USFWS 1999a). Continued loss of wetland or other suitable habitat resulting from agricultural and urban development constitutes the greatest threat to this species' survival. Conversion of Central Valley wetlands for agriculture and urban uses has resulted in the loss of as much as 95 percent of historical habitat for the giant garter snake (Wylie et al. 1997).

Applicable Natural Community Goals and Objectives

Goal TANC1: The expected outcome is tidal perennial aquatic natural community that supports habitats for covered and other native species and that supports aquatic food web processes.

> **Objective TANC1.1**: Restore or create 10,000 to 20,000 acres of tidal perennial aquatic in the BDCP Restoration Opportunity Areas (Conservation Zones 1, 2, 4, 5, 7, and 11) that supports aquatic food production and habitat for covered and other native species.

Goal FMNC1: The expected outcome is restored large, interconnected patches of tidal freshwater emergent wetland natural community.

> **Objective FMNC1.1:** Restore or create 13,900 to 21,600 acres of tidal freshwater emergent wetland in the Cache Slough, West Delta, Cosumnes-Mokelumne, and South Delta ROAs (Conservation Zones 1, 2, 4, 5, 6, and 7).

Goal FMNC2: The expected outcome is biologically diverse tidal freshwater emergent wetland that is enhanced for native species and sustained by natural ecological processes.

Objective FMNC2.1: Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal freshwater emergent wetlands for covered and other native species over the term of the BDCP.

Goal NWNC1: The expected outcome is nontidal freshwater perennial emergent wetland natural community that supports habitat for covered and other native species.

Objective NWNC1.1: Create 400 acres of nontidal freshwater marsh (including components of nontidal perennial aquatic and perennial emergent wetland communities) that functions as habitat for the giant garter snake, tricolored blackbird, and western pond turtle within or adjacent to habitat occupied by the Caldoni Marsh/White Slough giant garter snake subpopulation in Conservation Zone 4 and the Yolo/Willow Slough giant garter snake subpopulation in Conservation Zone 2.

Goal NWNC2: The expected outcome is biologically diverse nontidal freshwater perennial emergent wetland communities that are enhanced for native species and sustained by ecological processes.

Objective NWNC2.1: Maintain and enhance the habitat functions of protected and created nontidal freshwater perennial emergent wetlands for covered and other native species over the term of the BDCP.

Goal NANC2: The expected outcome is biologically diverse nontidal perennial aquatic communities that are enhanced for native species and sustained by ecological processes.

Objective NANC2.1: Maintain and enhance the habitat functions of protected and created nontidal open water habitats for covered and other native species over the term of the BDCP.

Goal ALNC1: The expected outcome is increased habitat functions for covered and other native species that are supported by agricultural land cover types and management practices.

Objective ALNC1.1: Maintain and protect the functions of 4,600 acres of rice lands as habitat for giant garter snake, western pond turtle, tricolored blackbird, white-tailed kite, waterfowl, and migrant shorebirds in Conservation Zone 2. This objective may be partially or fully achieved by maintaining an equivalent extent of natural or managed lands that support habitat functions similar to rice lands for associated covered and other native wildlife species.

Objective ALNC1.2: Maintain and protect the functions of 12,020 to 28,040 acres of non-rice agricultural lands as foraging habitat for Swainson's hawk, white-tailed kite, and tricolored blackbird that are located within 8 miles of occupied Swainson's hawk nesting habitat.

Objective ALNC1.5: Of the maintained 12,020 to 28,040 acres of non-rice agricultural lands and 4,600 acres of rice lands, maintain and protect 1,000 acres within or adjacent to habitat occupied by the Yolo/Willow Slough giant garter snake subpopulation in Conservation Zone 2.

Objective ALNC1.6: Of the maintained 12,020 to 28,040 acres of non-rice agricultural lands, maintain and protect 1,000 acres within or adjacent to habitat occupied by the Caldoni Marsh/White Slough giant garter snake subpopulation in Conservation Zone 4.

Objective ALNC1.7: Target agricultural land conservation to provide connectivity between other protected lands.

Objective ALNC1.8: Maintain and protect the small patches of important wildlife habitats associated with agricultural lands that occur within BDCP conserved agricultural lands, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, and wetlands.

Species-Specific Goals and Objectives

Goal GGSN1: The expected outcome is high quality upland and aquatic habitat containing a mosaic of features provided for extant giant garter snake populations.

Objective GGSN1.1: Create functional landscapes on giant garter snake preserves that include a mosaic of restored freshwater marsh intermixed with protected agricultural lands and interconnected water conveyance canals and natural drainages.

Goal GGSN2: The expected outcome is protected giant garter snake corridors facilitating movement and linking populations.

Objective GGSN2.1: Establish connectivity between giant garter snake preserve lands, restored tidal wetlands, and protected agricultural lands in Conservation Zone 4 to facilitate movement into unoccupied portions of the Delta and with the Badger Creek subpopulation.

Objective GGNS2.2: Establish a giant garter snake north-south corridor that includes protected agricultural lands and restored tidal and nontidal wetlands between Coldani Marsh/White Slough and the Stone Lakes National Wildlife Refuge.

Rationale and Conservation Approach

Because the primary stressor on the giant garter snake is loss and fragmentation of its aquatic and terrestrial cover habitat through urban and agricultural expansion, the focus of this conservation strategy is to protect habitat, protect and restore connectivity, and enhance habitat function, key elements of the species' Recovery Plan (USFWS 1999a).

There are four components of giant garter snake conservation under BDCP (Figure 3-32):

- The establishment of agricultural land preserves that will include nontidal freshwater marsh restoration associated with two existing subpopulations in Conservation Zones 2 and 4;
- Protection of existing rice land values in Conservation Zone 2;
- Protection, connectivity, and management of non-rice agricultural habitats in the Plan Area; and
- Restoration of freshwater tidal marshes.

Protecting and expanding existing giant garter snake subpopulations is considered the most effective approach to conservation of this species in the Plan Area. The majority of the Plan Area is considered low value habitat for this species (Appendix A, *Covered Species Accounts*); however, extant subpopulations occur along the eastern edge of the Plan Area boundary in the vicinity of White Slough (Caldoni Marsh/White Slough subpopulation) and near the northwestern edge of the Plan Area in the vicinity of Willow Slough (Yolo/Willow Slough subpopulation).

The Caldoni Marsh/White Slough and Yolo/Willow Slough subpopulations support the highest densities of giant garter snakes in the Plan Area and habitat preservation, enhancement, and restoration actions for these populations are directed at securing habitats supporting these populations from potential threats (e.g., change in land uses), expanding and enhancing these habitat areas to allow for increases in their abundance and distribution, and to help to meet USFWS recovery goals for these designated subpopulations.

The Caldoni Marsh/White Slough subpopulation is centered within the White Slough Wildlife Area and is comprised of approximately 830 acres, of which approximately 50 acres represent core giant garter snake wetland habitat. The Yolo/Willow Slough subpopulation includes unprotected habitat areas and habitat preserved within the Yolo Wildlife Area.

The conservation strategy for these subpopulations includes creation of 400 acres of nontidal marsh that will be divided between two 1,000 acre agricultural preserves in each of these subpopulation areas to help ensure their continued existence. This additional restoration of nontidal marsh (comprised of a mix of nontidal perennial aquatic and nontidal permanent emergent communities) distributed between the two subpopulation habitat areas will substantially increase connectivity among existing occupied habitat areas and provide the basis for future expansion of their distribution and abundance.

Although dependent on the aquatic environment, the giant garter snake occurs within the agricultural landscape where it uses interconnected watercourses (primarily irrigation canals) and associated freshwater emergent wetland habitat and rice lands during the active season and adjacent uplands during the inactive season. Maintaining an agricultural matrix that includes suitable interconnected canals with reliable water, associated emergent vegetation and adjacent upland habitats is essential for conservation of this species. As these conservation areas are designed, agricultural parcels will be selected based on their proximity and connectivity to occupied sites and opportunities for restoration and enhancement. Restored marsh habitats will be created in appropriate patch sizes and within the existing agricultural matrix to maximize connectivity and the potential for expansion and dispersal. This approach is designed to protect the existing subpopulation centers and create opportunities for the expansion of these subpopulations.

Protected agricultural habitats will be managed to enhance habitat conditions for giant garter snake and to minimize potential adverse effects of agricultural operations on giant garter snake in occupied habitat areas (e.g., upland buffers adjacent to aquatic habitats; timing maintenance of agricultural ditches that support aquatic and movement habitat to periods the snake is not present). Protection and management of upland and agricultural habitat areas adjacent to core wetland habitats will also be aimed at preventing potential impacts associated with adjacent land uses. If site-specific planning to design the subpopulation preserves indicates that the extent of the proposed preservation is not necessary to sustain and expand these populations, some of the proposed preservation and restoration may be directed towards securing populations adjacent to the Plan Area (e.g., the Badger Creek population) consistent with achieving objectives of adjacent conservation plans.

In addition to the creation of the giant garter snake preserves, protection of other natural communities within the Plan Area will also benefit the giant garter snake. Lands protected for Swainson’s hawk and greater sandhill crane that occur within the range of the giant garter snake will provide additional protected landscape to support existing or future populations. These lands will include water conveyance systems, patches of freshwater marsh, and other aquatic habitats that will be managed to promote use by giant garter snake and other covered species. Protection of cultivated habitats in Zones 2 and 4 for Swainson’s hawk and greater sandhill crane conservation are expected to provide additional opportunities for enhancing north-south movement corridors for the Yolo/Willow Slough subpopulation within the Yolo Bypass and for the Caldoni Marsh/White Slough subpopulation between Stone Lakes National Wildlife Refuge and the Caldoni Marsh/White Slough area.

The restoration of freshwater tidal marsh habitat in the Plan Area is also expected to create or enhance habitat conditions for giant garter snake and provide potential for dispersal and expansion of populations. Restoration of 13,900-21,600 acres of tidal freshwater emergent wetland and portions of 10,000-20,000 acres of adjacent tidal aquatic habitat will provide opportunities for giant garter snake expansion into areas where they are currently absent (e.g., Conservation Zone 7). Restoration of tidal habitats, particularly in potentially occupied habitat areas in Conservation Zones 2 and 4 will increase the extent of suitable giant garter snake breeding and foraging habitat in locations with narrow tidal ranges. Restoration of tidal habitats in Conservation Zone 4 will also help in providing connectivity between the Caldoni Marsh/White Slough subpopulation and the Badger Creek subpopulation. Meeting the tidal marsh restoration objectives is expected to substantially increase aquatic and associated upland habitat for giant garter snake throughout the Plan Area.

Within the Yolo Bypass, preservation of the existing extent of rice lands that could be affected by proposed Fremont Weir operations or restoration of wetlands to replace any lost habitat functions of rice lands will sustain the abundance and distribution of snakes known to inhabit cultivated portions of the Bypass. Preservation of cultivated habitats will also preserve and enhance upland aestivation habitat for giant garter snake within its Primary Habitat Area.

Consistency with USFWS Draft Recovery Plan

Guidance in the USFWS draft giant garter snake recovery plan was used in the development of the giant garter snake conservation strategy. The following links recovery action priorities for the Southern Sacramento Valley recovery unit to individual goals and objectives for giant garter snake.

Protect Existing Populations. The following objectives address protection of existing populations.

- Objectives NWNC1.1 and 2.1; NANC2.1; ALNC1.1, 1.5,1.6, and GGSN1.1 will contribute to the priority need as identified in the Draft Recovery Plan by protecting and managing habitat currently occupied by the species. These objectives will shelter the population from potential threats, increase habitat quantity, and increase habitat quality; which will lead to increased population size of the Caldoni Marsh/White Slough and Yolo/Willow Slough subpopulations.
- Objectives FMNC2.1, NWNC2.1, NANC2.1, ALNC1.8, and GGNS1.1 will contribute to the priority need as identified in the Draft Recovery Plan by increasing the quality and functionality of managed lands in or adjacent to occupied habitat. Implementing management plans and guidelines for the species on managed lands is anticipated to reduce injury and mortality associated with incompatible land uses.
- Objectives ALNC1.5 and 1.6, NWNC1.1, TANC 1.1, FMNC1.1, and GGNS1.1 and 1.2 will contribute to the priority need as identified in the Draft Recovery Plan by protecting (previously unprotected) and/or enhancing corridor habitat. Increasing the connectivity between populations and within meta-populations is expected to enhance gene flow, increase distribution, and ultimately make the populations more resilient to catastrophic events.

Restore Habitat. The following objectives address restoration of giant garter snake habitat.

- Objectives TANC1.1 and FMNC1.1 will restore 10,000-20,000 acres of tidal perennial aquatic in Conservation Zones 1, 2, 4, 5, 6, 7, and 11 and 13,900-21,600 acres of tidal freshwater marsh to Conservation Zones 1, 2, 5, and 7. The majority of these lands are currently non-functional or low functioning lands for giant garter snake and will be restored to enhance existing conditions. Of the total acres of tidal marsh restoration, 1,500 acres is planned for Conservation Zone 4, which will provide additional habitat, contribute to connectivity, and facilitate movement between the Caldoni/White Slough subpopulation northward toward the Cosumnes River Preserve and Stone Lakes National Wildlife Refuge.

- Objective NWNC1.1 will restore 400 acres of nontidal freshwater marsh habitat in Conservation Zones 2 and 4 to support security and expansion of the Yolo/Willow Slough and Caldoni Marsh/White Slough subpopulations.
- Objectives FMNC2.1, NWNC2.1, NANC2.1, ALNC1.8, and GGNS1.1 will protect and manage essential habitat elements within restored habitats, including upland buffers, and ensure that management actions are consistent with giant garter snake protection.

Ensure dependable water supply. The following goals address ensuring a dependable water supply for restored giant garter snake habitats.

- Goals TANC1, FMNC1, and NWNC1 seek to meet the priority need identified in the Draft Recovery Plan to provide a dependable water supply for giant garter snake populations in the Delta region. Conservation actions will include provisions for a perennial water supply with particular importance placed on the active season.

Buffer land supporting giant garter snake populations from the effects of urbanization and highway expansion. The following objectives address protecting giant garter snake populations.

- Objectives FMNC2.1, NWNC2.1, NANC2.1, ALNC1.8, and GGNS1.1 will protect, enhance, and manage essential habitat elements within restored habitats to ensure protection of giant garter snake habitat and populations. While these are general objectives that address the range of management actions for all covered species, they also include establishing and maintaining appropriate buffers between giant garter snake habitat and incompatible land uses.

Restore and maintain connectivity between populations and protected lands. The following objectives address habitat connectivity.

- Objectives TANC 1.1, FMNC 1.1, and GGSN2.1 will promote connectivity between the Caldoni Marsh/White Slough subpopulation and the Badger Creek subpopulation; and
- ALNC1.2 and GGSN2.2 will protect cultivated habitats in Zones 2 and 4 for Swainson's hawk and greater sandhill crane, which will provide opportunities for enhancing north-south movement corridors for the Yolo/Willow Slough subpopulation within the Yolo Bypass and for Caldoni Marsh/White Slough subpopulation between Stone Lakes National Wildlife Refuge and the Caldoni Marsh/White Slough area.

Development management plans and guidelines for conservation lands. Developing site-specific management plans for BDCP lands is an essential element of all goals and objectives. The following objectives specifically target the need for the development of management plans.

- Objectives FMNC2.1, NWNC2.1, NANC2.1, and ALNC1.8 will require the development of site-specific management plans for all BDCP lands, which will protect, enhance, and manage essential habitat elements for all covered species including giant garter snake.

Restore connectivity to the Northern Sacramento Valley Recovery Unit. The following objectives address connectivity throughout the Northern Sacramento Valley Recovery Unit.

- ALNC1.5 and 1.6, NWNC1.1, and GGSN1.1 and 1.2 will increase connectivity outside of the Plan Area by protecting and enhancing habitat around the Yolo/Willow Slough and Caldoni Marsh/White Slough subpopulations.;
- TANC1.1 and FMNC1.1 will create substantial additional habitat for giant garter snake and promote connectivity between the Plan Area and habitats outside the Plan Area; and
- ALNC1.2 will protect substantial cultivated habitats that will promote connectivity between the Plan Area and habitats outside the Plan Area.

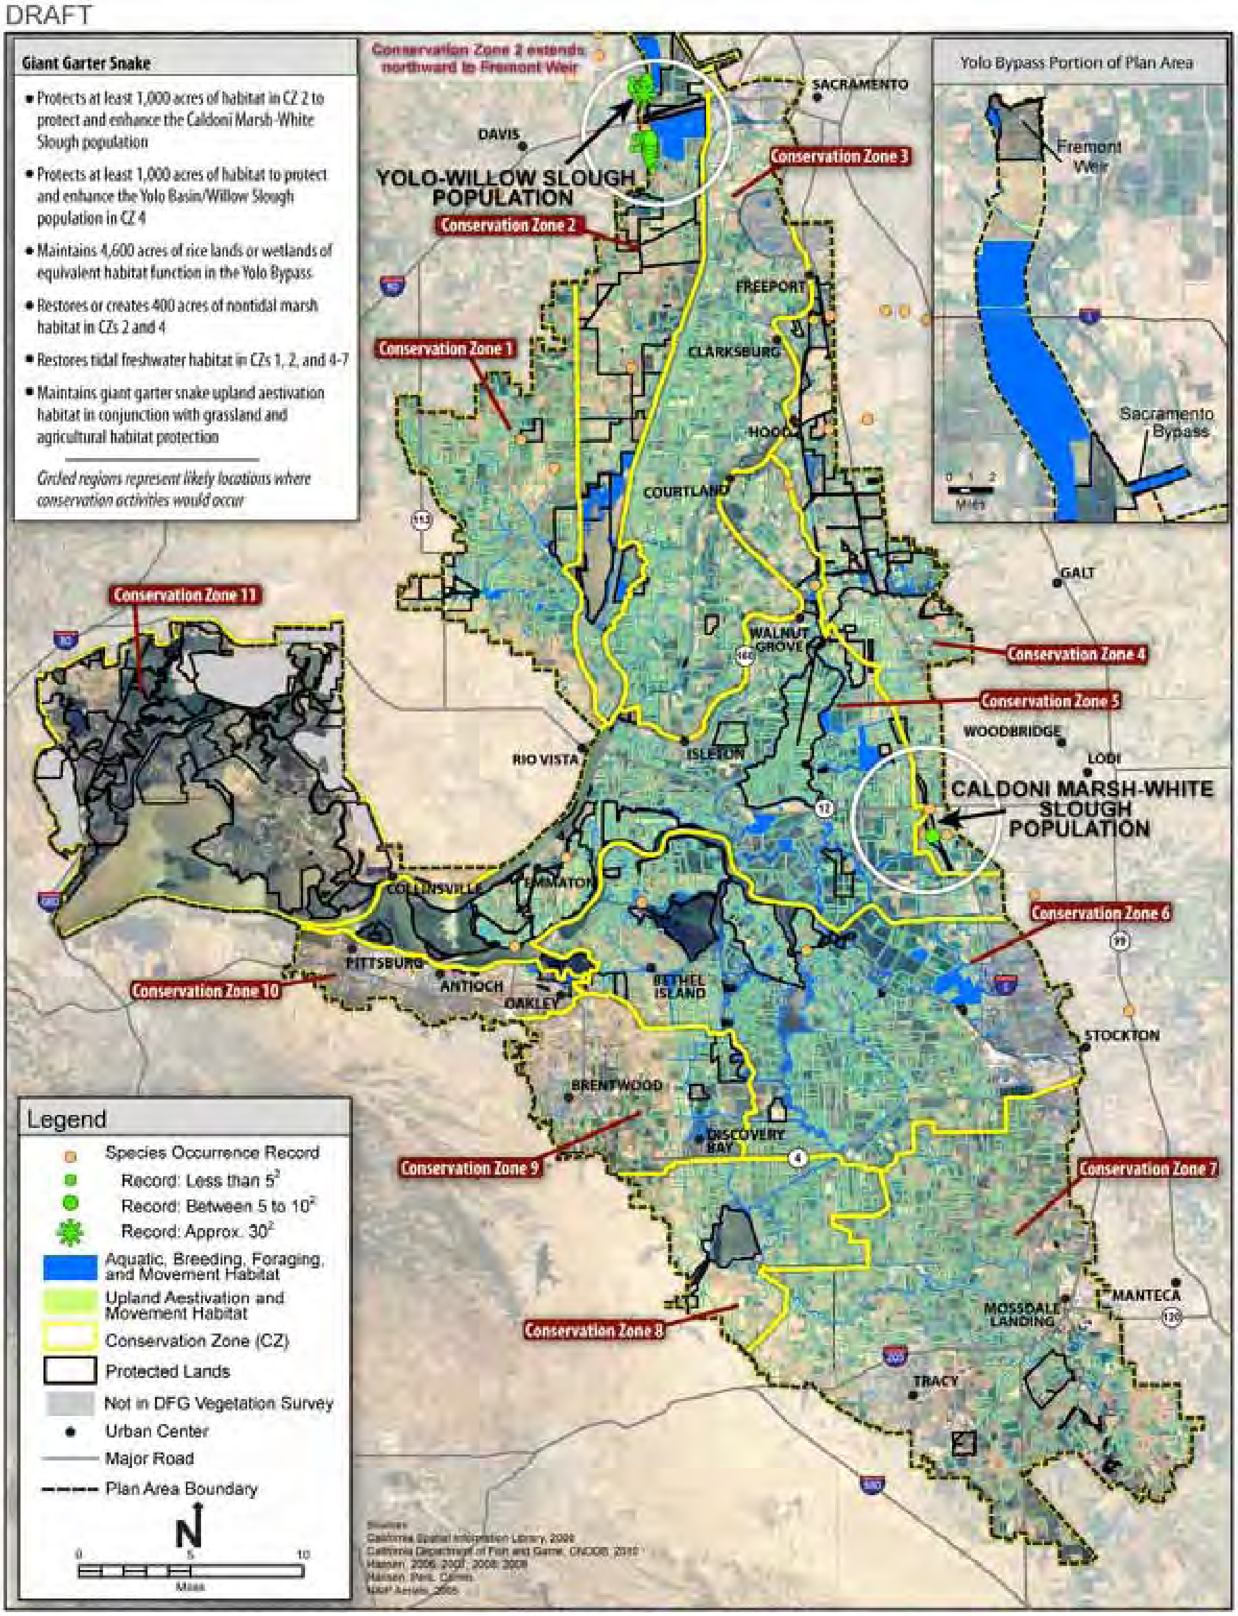

Figure 3-32. Giant Garter Snake Habitat Distribution and Conservation Strategy

3.3.2.4.20 Western Pond Turtle

The western pond turtle is a California Species of Special Concern and occurs in the Pacific states of North America from Baja California, north through Washington, and possibly into southernmost British Columbia, Canada (Bury and Germano 2008). The California Natural Diversity Database (CNDDB) reports several occurrences spread throughout the Plan Area in Sacramento, San Joaquin, and Contra Costa counties (CNDDB 2009); however, it is likely that this species is underreported and underrepresented in CNDDB. While primarily found in natural aquatic habitats, it also inhabits impoundments, irrigation ditches, and other artificial and natural water bodies (Ernst et al. 1994). The species is usually found in stagnant or slow-moving freshwater habitats, but brackish habitats are also utilized (Ernst et al. 1994). An upland habitat component is also used for movement, dispersal, and overwintering. Bury (1972) found adult males had the largest home ranges in his study (0.98 ha [2.42 ac]), followed by juveniles (0.36 ha [0.89 ac]) and adult females (0.25 ha [0.62 ac]) (Yolo Natural Heritage Program 2009). Most populations throughout the range have exhibited some declines. In California, Jennings and Hayes (1994) consider the western pond turtle as endangered from the Mokelumne River south and threatened elsewhere within the state. Loss of habitat is the most significant factor in western pond turtle declines. Over 90 percent of the historical wetlands in California have been drained, filled, or diked to support agricultural and urban development (Frayer et al. 1989).

Applicable Natural Community Goals and Objectives

Goal TANC1: The expected outcome is tidal perennial aquatic natural community that supports habitats for covered and other native species and that supports aquatic food web processes.

> **Objective TANC1.1**: Restore or create 10,000 to 20,000 acres of tidal perennial aquatic in BDCP Restoration Opportunity Areas (Conservation Zones 1, 2, 4, 5, 7, and 11) that supports aquatic food production and habitat for covered and other native species.

Goal BMNC1: The expected outcome is restored large expanses and interconnected patches of tidal brackish emergent wetland natural community.

> **Objective BMNC1.1:** Restore or create 3,600 to 4,800 acres of tidal brackish emergent wetland in the Suisun Marsh ROA (Conservation Zone 11).

Goal FMNC1: The expected outcome is restored large, interconnected patches of tidal freshwater emergent wetland natural community.

> **Objective FMNC1.1:** Restore or create 13,900 to 21,600 acres of tidal freshwater emergent wetland in the Cache Slough, West Delta, Cosumnes-Mokelumne, and South Delta ROAs (Conservation Zones 1, 2, 4, 5, 6, and 7).

Goal FMNC2: The expected outcome is biologically diverse tidal freshwater emergent wetland that is enhanced for native species and sustained by natural ecological processes.

Objective FMNC2.1: Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal freshwater emergent wetlands for covered and other native species over the term of the BDCP.

Goal NWNC1: The expected outcome is nontidal freshwater perennial emergent wetland natural community that supports habitat for covered and other native species.

Objective NWNC1.1: Create 400 acres of nontidal freshwater marsh (including components of nontidal perennial aquatic and perennial emergent wetland communities) that functions as habitat for the giant garter snake, tricolored blackbird, and western pond turtle within or adjacent to habitat occupied by the Caldoni Marsh/White Slough giant garter snake subpopulation in Conservation Zone 4 and the Yolo/Willow Slough giant garter snake subpopulation in Conservation Zone 2.

Goal NWNC2: The expected outcome is biologically diverse nontidal freshwater perennial emergent wetland communities that are enhanced for native species and sustained by ecological processes.

Objective NWNC2.1: Maintain and enhance the habitat functions of protected and created nontidal freshwater perennial emergent wetlands for covered and other native species over the term of the BDCP.

Goal NANC2: The expected outcome is biologically diverse nontidal perennial aquatic communities that are enhanced for native species and sustained by ecological processes.

Objective NANC2.1: Maintain and enhance the habitat functions of protected and created nontidal open water habitats for covered and other native species over the term of the BDCP.

Goal VRNC1: The expected outcome is restored large expanses and interconnected corridors of valley/foothill riparian natural community.

Objective VRNC1.1: Restore or create 5,000 acres of valley/foothill riparian in Conservation Zones 1, 2, 4, 5, 6, 7, and/or 11.

Goal VRNC2: The expected outcome is biologically diverse valley/foothill riparian natural community that supports native species and is sustained by natural ecological processes.

Objective VRNC2.1: Maintain and enhance the habitat and ecosystem functions of BDCP restored valley/foothill riparian and patches of riparian forest and scrub present on BDCP preserved lands over the term of the BDCP.

Objective VRNC2.3: Restore connectivity of valley/foothill riparian corridors along linear watercourses to enhance habitat for covered species and facilitate wildlife movement.

Goal ALNC1: The expected outcome is increased habitat functions for covered and other native species that are supported by agricultural land cover types and management practices.

> **Objective ALNC1.1**: Maintain and protect the functions of 4,600 acres of rice lands as habitat for giant garter snake, western pond turtle, tricolored blackbird, white-tailed kite, waterfowl, and migrant shorebirds in Conservation Zone 2. This objective may be partially or fully achieved by maintaining an equivalent extent of natural or managed lands that support habitat functions similar to rice lands for associated covered and other native wildlife species.

> **Objective ALNC1.8**: Maintain and protect the small patches of important wildlife habitats associated with agricultural lands that occur within BDCP conserved agricultural lands, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, and wetlands.

Rationale and Conservation Approach

Because the primary stressor on the western pond turtle is loss of its aquatic and upland habitat due to urban and agricultural expansion, the preservation, enhancement, and restoration of these habitat types is considered to be the most effective approach to its conservation. Conservation of western pond turtle will be provided through the preservation and enhancement of 4,000 acres of its dispersal habitat, over 5,000 acres of its upland nesting and overwintering habitat, and restoration of 5,000 acres of overwintering and nesting habitat and between 27,900 and 46,800 acres of its aquatic habitat (Figure 3-33). The preservation and restoration of such large habitat areas is expected to significantly advance the conservation of western pond turtle in the region. Western pond turtle aquatic, dispersal, and upland nesting and overwintering occurs throughout the Plan Area.

Western pond turtle utilize a wide variety of aquatic habitats. Although primarily found in natural aquatic habitats, it also inhabits impoundments, irrigation ditches, and other artificial and natural water bodies. Western pond turtle is usually found in stagnant or slow-moving freshwater habitats, but brackish habitats are also utilized. Conservation of aquatic habitat will be provided through the restoration of tidal marsh plain and adjacent shallow subtidal habitats within Restoration Opportunity Areas (ROAs) that are expected to support extensive patches of western pond turtle habitat and _ acres of nontidal wetland that will be located in occupied giant garter snake habitat areas.

Western pond turtle upland nesting and overwintering habitat includes riparian areas and grassland. Nesting sites are typically placed about 100 m from aquatic habitat. Conservation of western pond turtle upland nesting and overwintering habitat will be provided mainly through a combination of grassland protection and riparian habitat restoration within ROAs, with grassland restoration and vernal pool complex restoration having the potential to also benefit the species. Vernal pools in particular have been shown to be used during dispersal between nesting and overwintering sites (Reese and Welsh 1997) and vernal pool complex restoration may increase the ability of western pond turtles to disperse across the BDCP landscape. A substantial amount of restored riparian habitat is expected to be adjacent to restored tidal wetland and subtidal aquatic habitat, thus ensuring proximity of nesting and overwintering habitat to aquatic habitat. Dispersal habitat consists of agricultural land and is ubiquitous within the Plan Area (see Appendix A, *Covered Species Accounts*). Protection of cultivated habitats to achieve habitat conservation targets for other covered species (e.g., protection of Swainson's hawk foraging habitat) will also preserve western pond turtle dispersal habitat.

Following BDCP implementation, restoration of pond turtle aquatic habitat is expected to increase the extent of this habitat type in the Plan Area by up to 68 percent relative to current conditions. The proposed habitat conservation actions are expected to maintain sufficient habitat area to sustain or increase the existing Plan Area population of western pond turtle and to maintain connectivity with populations adjacent to the Plan Area that are covered under adjacent and overlapping HCP/NCCPs.

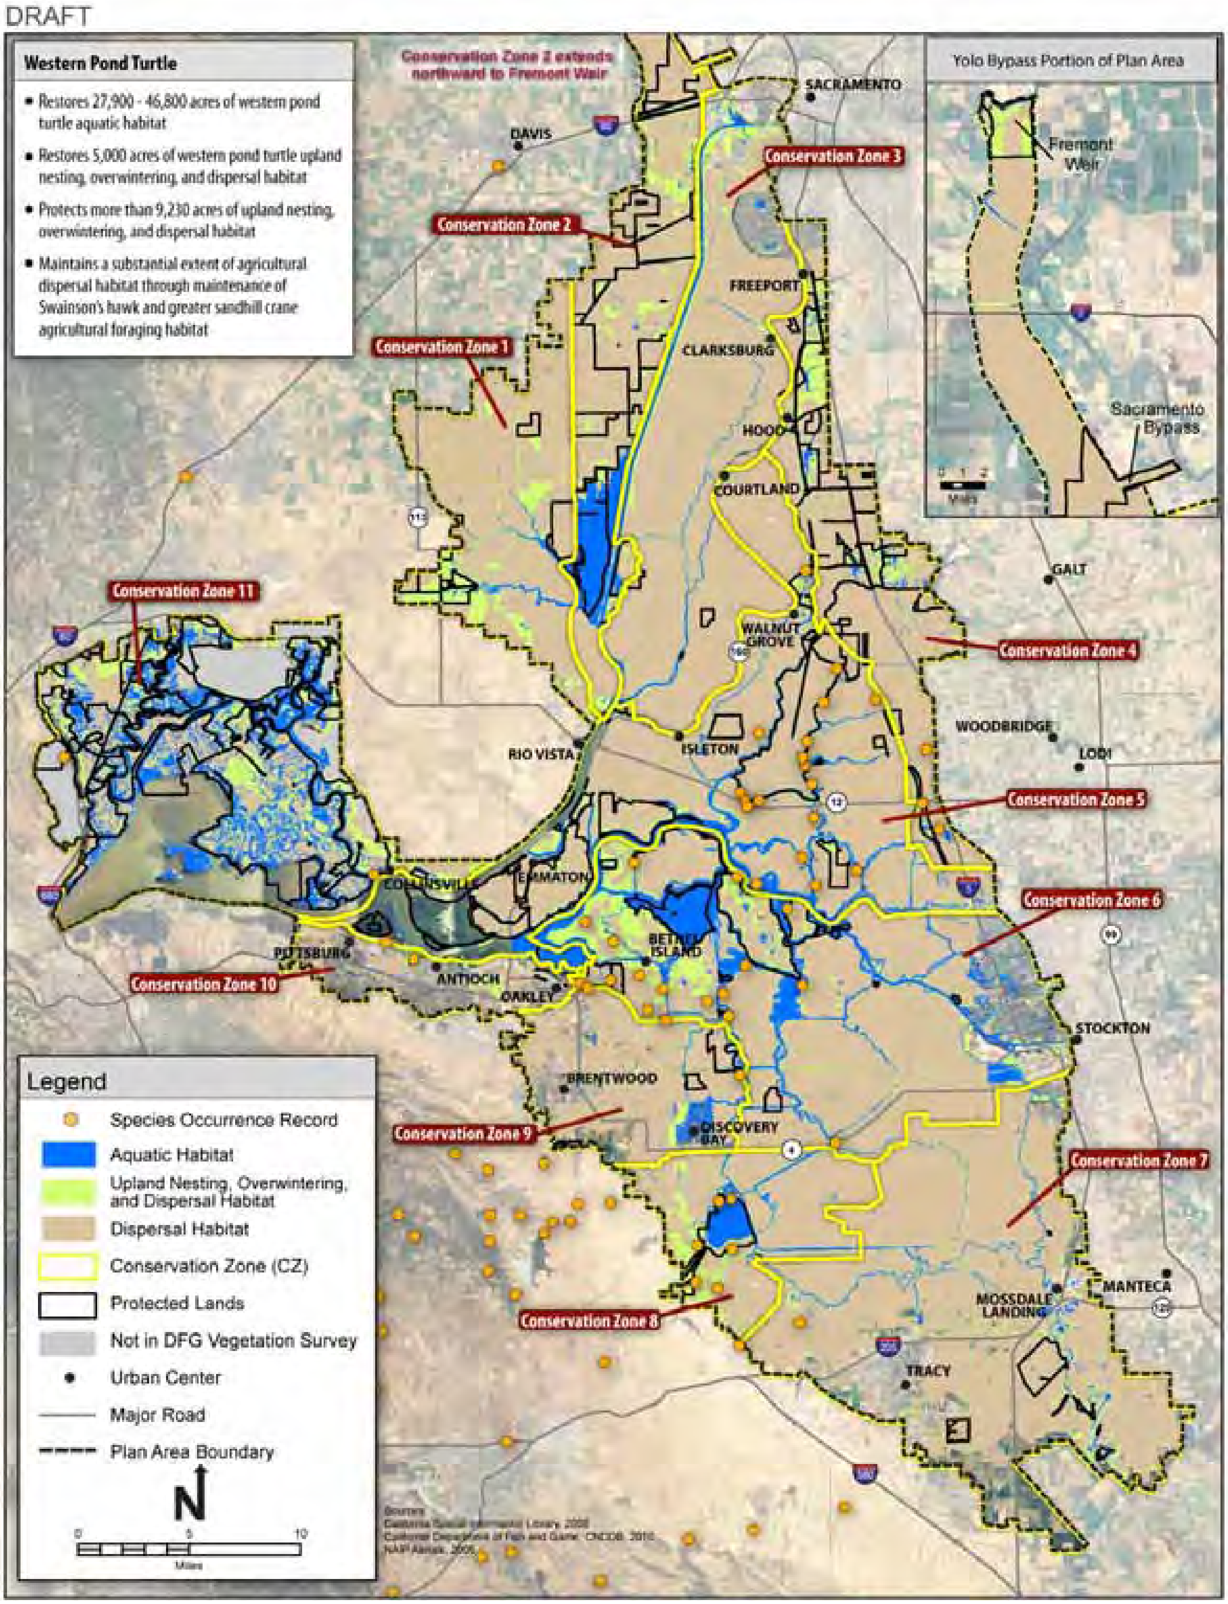

Figure 3-33. Western Pond Turtle Habitat Distribution and Conservation Strategy

3.3.2.4.21 California Red-Legged Frog

The historical range of the California red-legged frog is generally characterized as extending south along the coast from the vicinity of Point Reyes National Seashore and inland from the vicinity of Redding, southward along the interior Coast Ranges and Sierra Nevada foothills to northwestern Baja California (USFWS 2007b). Habitat typically consists of deep water ponds and pools, streams, and other aquatic habitat along with grasslands that provide movement corridors and aestivation sites. The USFWS (2002) estimates that the species has lost approximately 70 percent of its former range, with severe declines occurring primarily in the Central Valley and Southern California (Jennings and Hayes 1994). The principal factors contributing to the decline of the California red-legged frog are the loss of habitat due to urban development, the conversion of native habitats to agricultural lands, the introduction of nonnative predators, and pesticide use (Fisher and Shaffer 1996, Hobbs and Mooney 1998, Davidson et al. 2002).

Within the Plan Area, this species is restricted to the grassland natural community and associated aquatic habitats (stock ponds and small streams) in Conservation Zone 8 along the southwest periphery of the Plan Area.

Applicable Natural Community Goals and Objectives

Goal GRNC1: The expected outcome is grassland comprised of large interconnected patches or contiguous expanses.

> **Objective GRNC1.1**: Protect a minimum of 8,000 acres of grassland in Conservation Zones 1, 8, and 11. At least 1,000 acres will be protected in Conservation Zone 8, with the remainder distributed throughout these three Conservation Zones.

Goal GRNC2: The expected outcome is biologically diverse grassland managed to enhance native species and sustained by natural ecological processes.

> **Objective GRNC2.1**: Restore and sustain a mosaic of grassland vegetation alliances, reflecting local water availability, soil chemistry, soil texture, topography, and disturbance regimes, with consideration of historical states.

> **Objective GRNC2.2**: Increase the relative cover of native grasses and forbs in native grassland vegetation alliances.

> **Objective GRNC2.3**: Increase opportunities for wildlife movement through grassland habitat.

> **Objective GRNC2.4**: Increase burrow availability for burrow-dependent species.

Species-Specific Goals and Objectives

Goal CRLF1: The expected outcome is enhanced breeding California red-legged frog populations in the Plan Area.

> **ObjectiveCRLF1.1**: Enhance stock ponds in grassland in Conservation Zone 8 through partial livestock exclusion and predator control.

Rationale and Conservation Approach

Because a primary stressor on the California red-legged frog is the loss of its aquatic and upland habitat due to urban and agricultural expansion, the protection and enhancement of these habitat types are key elements of the U.S. Fish and Wildlife Service's Recovery Plan for the species and considered to be the most effective approach to its conservation. Conservation of California red-legged frog will be provided through the preservation of 1,000 acres of grassland natural community in Conservation Zone 8 (Figure 3-34). Habitat will be preserved and enhanced in the largest possible patch sizes adjacent to occupied habitat within and adjacent to the Plan Area and will be managed to enhance habitat functions for California red-legged frog. Conservation Zone 8 is the only location within the Plan Area where California red-legged frog is present or expected to occur. Conservation of California red-legged frog is focused on protecting its intact riparian and upland cover and dispersal habitat linking to its aquatic breeding habitat within the Plan Area and to occupied habitat areas adjacent to the Plan Area in Conservation Zone 8 south of Highway 4.

California red-legged frog upland habitat will be preserved in Conservation Zone 8. Upland habitats are comprised of grassland that supports aestivation and movement habitat to and from aquatic breeding habitats. Approximately 3,830 acres of upland cover and dispersal habitat is present in Conservation Zone 8 of which approximately 620 acres (16 percent) are currently protected. The proposed protection of grassland would be located such that it encompasses ponds and stream corridors that support breeding habitat. Protected habitat will be managed to increase the abundance of ground squirrel burrows to increase the availability of cover and aestivation sites and to increase the habitat function of any riparian habitat adjacent to preserved stream channels by providing dense stands of overhanging willows and a fringe of cattails between the willow roots and overhanging willow limbs. Stock ponds will also be enhanced by excluding livestock from a portion of the stock pond and allowing freshwater emergent vegetation to grow, facilitating red-legged frog occupancy.

California red-legged frog habitat within the Plan Area is located on the margin of its range and as such is not considered to support core habitat area for the species. Consequently, to increase the level of conservation benefits provided to California red-legged frog relative to benefits that would be provided by implementing the conservation actions within the Plan Area, the red-legged frog conservation actions may be implemented within core red-legged frog habitat areas that are located outside of the Plan Area consistent with conservation plans for those locations as described in Section 3.2.4, *Development of the Terrestrial Resources Component of the Conservation Strategy*.

Following BDCP implementation, approximately 33 percent of modeled California red-legged frog habitat in Conservation Zone 8 that links to occupied habitat outside the Plan Area would be preserved. The proposed habitat conservation actions are expected to preclude potential future fragmentation of the highest functioning frog habitat in the Plan Area and maintain sufficient habitat area to sustain or increase the existing Plan Area population of California red-legged frog and to maintain connectivity with occupied core populations adjacent to the Plan Area that are covered under adjacent and overlapping HCP/NCCPs.

- CM8 Grassland Communities Restoration
- CM11 Natural Communities Enhancement and Management

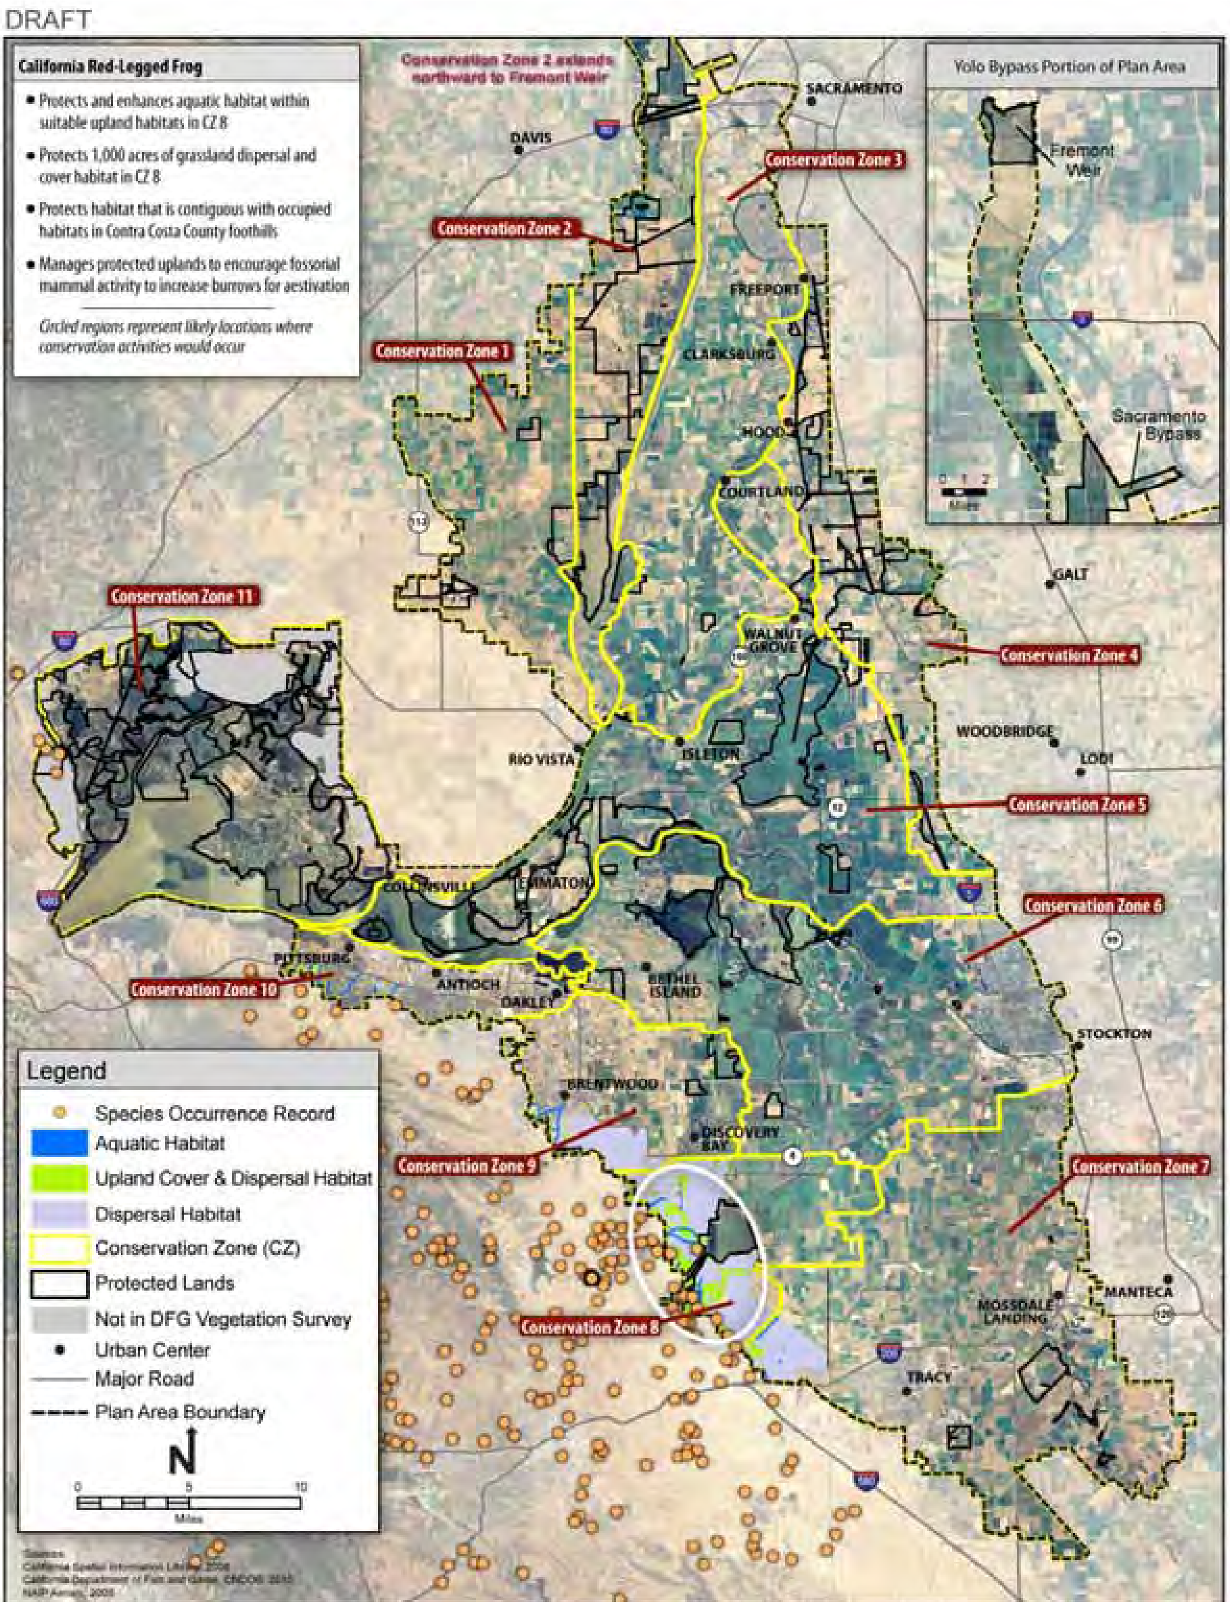

Figure 3-34. California Red-Legged Frog Habitat Distribution and Conservation Strategy

3.3.2.4.22 Western Spadefoot Toad

The western spadefoot toad is a state Species of Special Concern whose range includes portions of California, extending south to Mesa de San Carlos in Baja California, Mexico (Stebbins 1985, Jennings and Hayes 1994, California Academy of Sciences 2008, Museum of Vertebrate Zoology 2008). In California, the current range of the western spadefoot toad includes portions of the Central Valley and bordering foothills, and the Coast Ranges south of Monterey Bay (Stebbins 2003). The western spadefoot toad has been extirpated throughout most of the lowlands of southern California (Stebbins 1985) and from many historical locations within the Central Valley (Jennings and Hayes 1994, Fisher and Shaffer 1996). Fisher and Shaffer (1996) state that the western spadefoot toad populations have declined severely in the Sacramento Valley, and their density has been reduced in eastern San Joaquin Valley. Optimal habitat consists of vernal pool breeding habitat surrounded by grassland upland cover habitat. Western spadefoot toad also typically inhabits other lowland habitats such as washes, floodplains of rivers, alluvial fans, playas, and alkali flats (Stebbins 1985). Its range extends into the foothills and mountains to an elevation of 1,360 m (4,462 feet) (Jennings and Hayes 1994). The principal factors contributing to the decline of the western spadefoot are loss of habitat due to urban development, conversion of native habitats to agricultural lands, introduction of nonnative predators, and pesticide use (Fisher and Shaffer 1996, Hobbs and Mooney 1998, Davidson et al. 2002). The loss of vernal pool or other seasonal pool habitats due to land conversion is likely the greatest threat to the western spadefoot toad. More than 80 percent of occupied habitat in southern California and more than 30 percent in northern California have been lost to development or other incompatible land uses (Jennings and Hayes 1994).

Applicable Natural Community Goals and Objectives

Goal GRNC1: The expected outcome is grassland comprised of large interconnected patches or contiguous expanses.

> **Objective GRNC1.1**: Protect a minimum of 8,000 acres of grassland in Conservation Zones 1, 8, and 11. At least 1,000 acres will be protected in Conservation Zone 8, with the remainder distributed throughout these three Conservation Zones.

> **Objective GRNC1.2**: Restore 2,000 acres of grassland to connect fragmented patches of protected grassland.

Goal GRNC2: The expected outcome is biologically diverse grassland managed to enhance native species and sustained by natural ecological processes.

> **Objective GRNC2.1**: Restore and sustain a mosaic of grassland vegetation alliances, reflecting local water availability, soil chemistry, soil texture, topography, and disturbance regimes, with consideration of historical states.

> **Objective GRNC2.2**: Increase the relative cover of native grasses and forbs in native grassland vegetation alliances.

Objective GRNC2.3: Increase opportunities for wildlife movement through grassland habitat.

Objective GRNC2.4: Increase burrow availability for burrow-dependent species.

Goal VPNC1: The expected outcome is protected vernal pool complex natural community that represents a range of environmental conditions and is adjacent to other conserved lands.

Objective VPNC1.1: Protect 300 acres of vernal pool complex in Conservation Zones 1, 8, and 11.

Goal VPNC2: The expected outcome is restored biologically diverse vernal pool complex natural community with improved native biodiversity, habitat heterogeneity, and the ability to support populations of covered and other native species.

Objective VPNC2.1: Restore 200 acres of vernal pool complex natural community in Conservation Zones 1, 8, and/or 11 within patches of protected grassland that supports habitat for the western spadefoot toad, California tiger salamander, and the covered vernal pool shrimp and plant species.

Objective VPNC2.2: Maintain and, where habitat functions for covered species can be enhanced, increase the diversity and relative cover of native grasses and forbs.

Rationale and Conservation Approach

Because a primary stressor on the western spadefoot toad is the loss of its vernal pool breeding and upland habitat due to urban and agricultural expansion, the preservation, enhancement, and restoration of these habitat types is considered to be the most effective approach to its conservation. Conservation of western spadefoot toad will be provided mainly through the preservation and enhancement of 300 acres and restoration of 200 acres of its vernal pool complex breeding habitat and the preservation and enhancement of 8,400 acres of its grassland and associated alkali seasonal wetland cover habitat (Figure 3-35). Additionally, grassland restoration will be conducted in the Plan Area and has the potential to benefit the western spadefoot where vernal pools occur within dispersal distance. Although there are no records of western spadefoot toad occurring within the Plan Area (CNDDB 2009), potentially suitable habitat exists and the expected range extends through the Plan Area. Habitat will be preserved and restored in the largest possible patch sizes and management of preserved and restored vernal pool complex (e.g., livestock grazing) will be designed to enhance habitat functions for western spadefoot toad and other associated covered vernal pool-associated species. Western spadefoot toad breeding and upland habitat is present in Conservation Zones 1, 2, 4, 8, 9, and 11. Conservation of western spadefoot toad habitat is focused on preserving, enhancing, and restoring vernal pool complex and associated grassland habitats where opportunities for large scale conservation of western spadefoot toad habitat exist in Conservation Zones 1, 8, and 11. Breeding and associated grassland habitat in Conservation Zones 2 and 4 is almost entirely under protected status (99 percent) and vernal pool complex in Conservation Zone 9 (approximately

120 acres) is located in the vicinity of Discovery Bay and is largely fragmented by development and cultivated lands.

While western spadefoot toad lays its eggs in a variety of permanent and temporary wetlands, including rivers, creeks, pools in intermittent streams, vernal pools, temporary rain pools (CNDDB 2009) and stock ponds, optimal habitat consists of vernal pools and other temporary wetlands free of fish and other nonnative predators. Restored vernal pool complex will be designed to meet optimal habitat criteria and provide high breeding habitat function. Habitat will be restored at sites within Conservation Zones 1, 8, and 11 that historically supported fully functioning vernal pool habitats. Management of protected vernal pool complex (e.g., livestock grazing) will be designed to enhance western spadefoot toad breeding habitat functions. Habitat will preserved in conjunction with protected grassland and alkali seasonal wetlands in these same Conservation Zones.

Western spadefoot toad upland terrestrial cover and aestivation habitat will be preserved in Conservation Zones 1, 8, and 11. Upland habitat will be comprised of grassland and alkali seasonal wetland that encompasses protected aquatic breeding habitats and are within or connected to potentially occupied western spadefoot toad habitat. Connections to potentially occupied habitat will be of sufficient width to provide for the movement of western spadefoot toad to and from occupied habitat areas. Protected grassland will be managed to provide appropriate vegetative conditions to facilitate spadefoot movement and reduce predation exposure and to maintain or increase the abundance of ground squirrels and other fossorial mammal species to improve the availability of suitable aestivation sites.

Western spadefoot toad habitat within the Plan Area is located on the margin of its range and as such is not considered to support core habitat area for the species. Consequently, to maximize the level of conservation benefits provided to western spadefoot toad, conservation actions may be implemented within core western spadefoot toad habitat areas that are located outside of the Plan Area consistent with conservation plans for those locations as described in Section 3.2.4, Development of the Terrestrial Resources Component of the Conservation Strategy.

Following BDCP implementation, approximately 69 percent of modeled western spadefoot toad vernal pool complex breeding habitat and 99 percent of its modeled upland habitat will be preserved within the Plan Area. The proposed habitat conservation actions are expected to maintain sufficient habitat area to sustain or increase the potential Plan Area population of western spadefoot toad and to maintain connectivity with occupied core populations adjacent to the Plan Area and covered under adjacent and overlapping HCP/NCCPs.

- CM9 Vernal Pool Complex Restoration
- CM11 Natural Communities Enhancement and Management

DRAFT

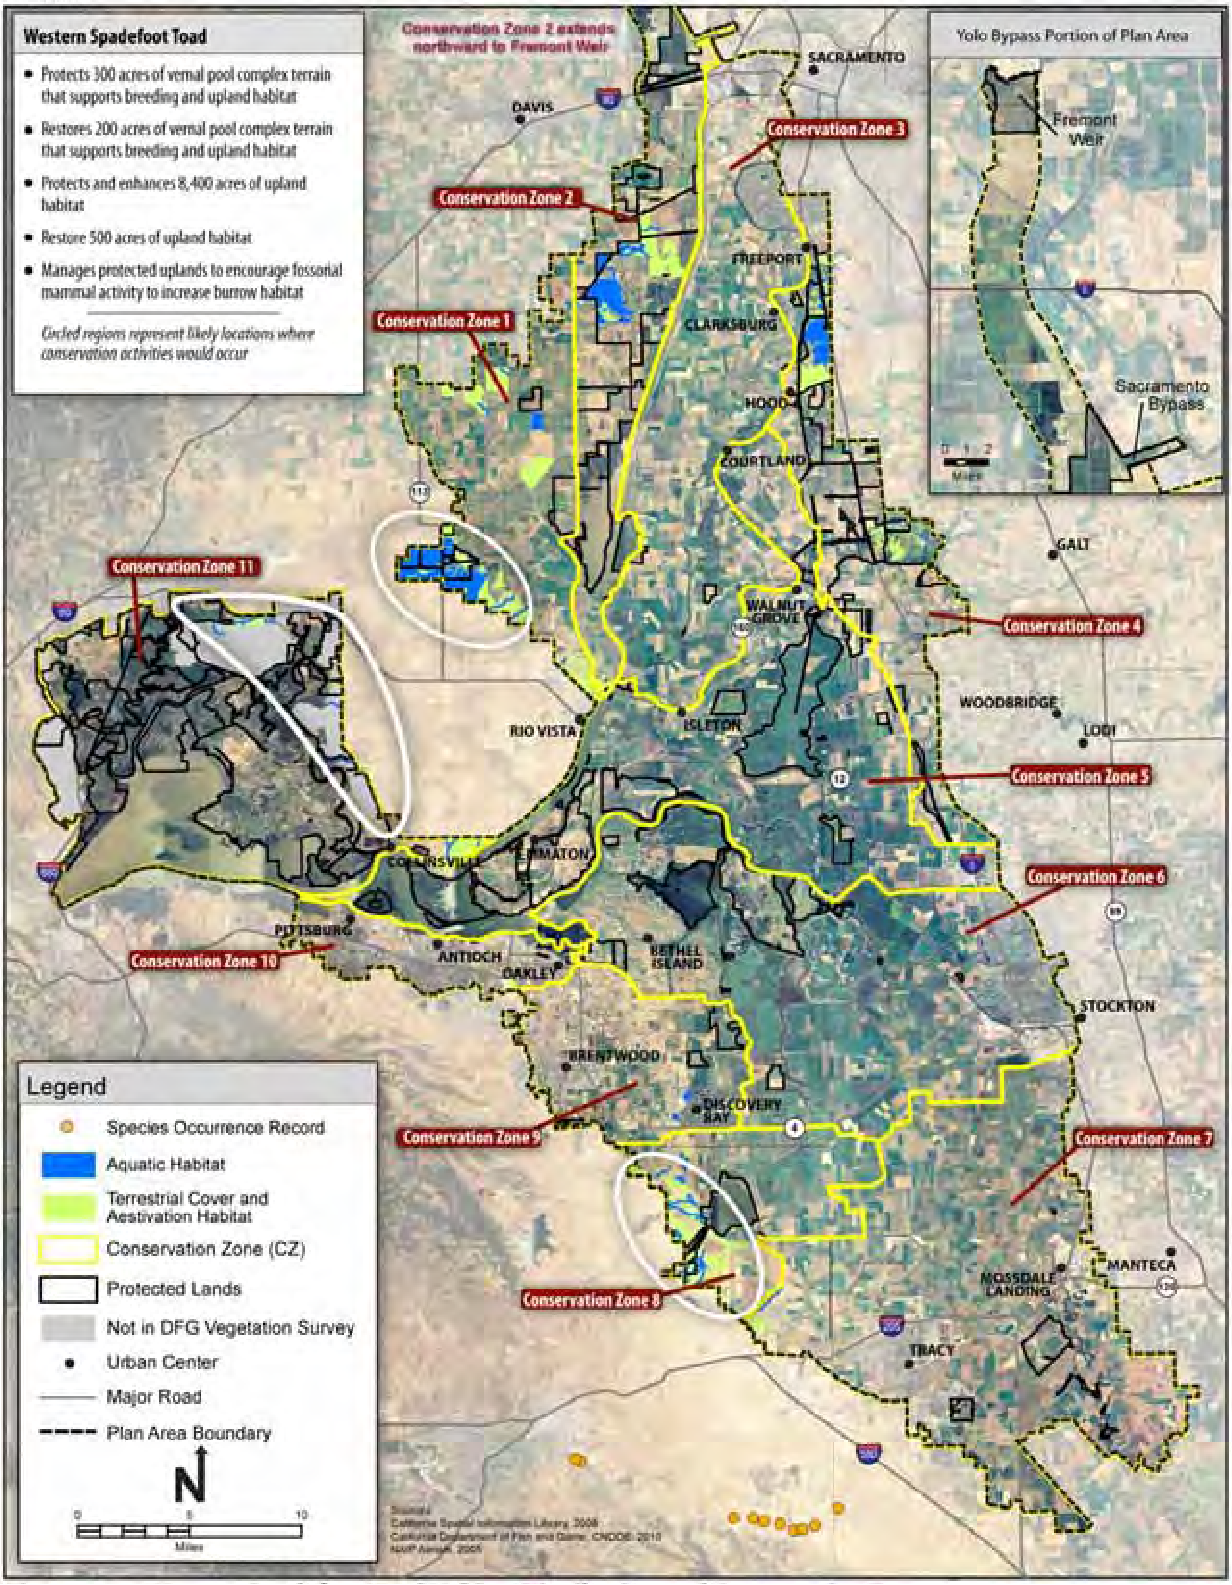

Figure 3-35. Western Spadefoot Toad Habitat Distribution and Conservation Strategy

3.3.2.4.23 California Tiger Salamander

The California tiger salamander is endemic to California, where its range is limited primarily by the availability of burrows and winter breeding habitat, primarily open grassland landscapes with vernal pools and playa pools and with burrowing squirrels and pocket gophers (Barry and Shaffer 1994). Extant populations of California tiger salamanders are believed to be declining as a result of habitat loss (Shaffer et al. 1993, Barry and Shaffer 1994, Holland 1998). In particular, an estimated 80 percent of the species' historical natural aquatic (i.e., vernal pool) habitat has been lost (Holland 1998) and the species has been eliminated from 55 to 58 percent of historical breeding sites (Barry and Shaffer 1994). There is no recovery plan for the species, but critical habitat has been designated for the species, and California tiger salamander conservation relies primarily on the preservation, enhancement, and restoration of its vernal pool complex breeding and grassland cover habitat (Appendix A, *Covered Species Accounts*). The focus on California tiger salamander habitat by BDCP not only addresses the species' primary need but also ties in with other regional conservation efforts such as the acquisition of land occupied by tiger salamander near the Bay Regional Parks District west of the Plan Area in Contra Costa and Alameda counties.

Applicable Natural Community Goals and Objectives

Goal GRNC1: The expected outcome is grassland comprised of large interconnected patches or contiguous expanses.

> **Objective GRNC1.1**: Protect a minimum of 8,000 acres of grassland in Conservation Zones 1, 8, and 11. At least 1,000 acres will be protected in Conservation Zone 8, with the remainder distributed throughout these three Conservation Zones.

> **Objective GRNC1.2**: Restore 2,000 acres of grassland to connect fragmented patches of protected grassland.

Goal GRNC2: The expected outcome is biologically diverse grassland managed to enhance native species and sustained by natural ecological processes.

> **Objective GRNC2.1**: Restore and sustain a mosaic of grassland vegetation alliances, reflecting local water availability, soil chemistry, soil texture, topography, and disturbance regimes, with consideration of historical states.

> **Objective GRNC2.2**: Increase the relative cover of native grasses and forbs in native grassland vegetation alliances.

> **Objective GRNC2.3**: Increase opportunities for wildlife movement through grassland habitat.

> **Objective GRNC2.4**: Increase burrow availability for burrow-dependent species.

Goal VPNC1: The expected outcome is protected vernal pool complex natural community that represents a range of environmental conditions and is adjacent to other conserved lands.

> **Objective VPNC1.1**: Protect 300 acres of vernal pool complex in Conservation Zones 1, 8, and 11.

Goal VPNC2: The expected outcome is restored biologically diverse vernal pool complex natural community with improved native biodiversity, habitat heterogeneity, and the ability to support populations of covered and other native species.

> **Objective VPNC2.1**: Restore 200 acres of vernal pool complex natural community in Conservation Zones 1, 8, and/or 11 within patches of protected grassland that supports habitat for the western spadefoot toad, California tiger salamander, and the covered vernal pool shrimp and plant species.

> **Objective VPNC2.2**: Maintain and, where habitat functions for covered species can be enhanced, increase the diversity and relative cover of native grasses and forbs.

Rationale and Conservation Approach

Conservation of California tiger salamander will be provided through the preservation and enhancement of 300 acres and the restoration of 200 acres of its vernal pool complex breeding habitat and the preservation, enhancement, and restoration of 8,400 acres of its grassland and associated alkali seasonal wetland cover habitat (Figure 3-36). Habitat will be protected and restored in the largest possible patch sizes and management of preserved and restored vernal pool complex (e.g., livestock grazing) will be designed to enhance habitat functions for California tiger salamander and other associated covered vernal pool-associated species. California tiger salamander breeding and upland habitat is present in Conservation Zones 1, 2, 4, 8, 9, and 11. Breeding and associated grassland habitat in Conservation Zones 2 and 4 is almost entirely under protected status (99 percent) and vernal pool complex in Conservation Zone 9 (approximately 120 acres) is located in the vicinity of Discovery Bay and is largely fragmented by development and cultivated lands. Preserved habitat will be acquired in locations that provide connectivity to existing protected and occupied habitat.

Optimal California tiger salamander breeding habitat consists of large vernal pools, playa pools, or ephemeral ponds that hold water until at least May. Pools and ponds with this long ponding duration prevent the establishment of nonnative predators, enable salamander larvae to metamorphose, and contain enough prey to allow for high breeding productivity (P. Trenham, pers. comm.). Restored vernal pool complex will be designed to meet all such California tiger salamander habitat criteria and provide high breeding habitat function. Additionally, it will be restored on sites within Conservation Zones 1, 8, and 11 that historically supported fully functioning vernal pool habitats. Management of preserved vernal pool complex (e.g., livestock grazing) will be designed to enhance tiger salamander breeding habitat functions. Habitat will be preserved in conjunction with preserved grassland and alkali seasonal wetland complex that will also be preserved in these Conservation Zones. Connections to occupied habitat will be of sufficient width to provide for the movement of salamanders to and from occupied areas.

California tiger salamander habitat within the Plan Area is located on the margin of the species' range and as such is not considered to support core habitat area for the species. Consequently, to maximize the level of conservation benefits provided to California tiger salamander, conservation actions may be implemented within core California tiger salamander habitat areas that are located outside of the Plan Area consistent with conservation plans for those locations as described in Section 3.2.4, *Development of the Terrestrial Resources Component of the Conservation Strategy*.

Following BDCP implementation, approximately 68 percent of modeled California tiger salamander vernal pool complex breeding habitat and 99 percent of its modeled upland habitat will be protected within the Plan Area. The proposed habitat conservation actions are expected to maintain sufficient habitat area to sustain or increase the existing Plan Area population of California tiger salamander and to maintain connectivity with occupied core populations adjacent to the Plan Area and covered under adjacent and overlapping HCP/NCCPs.

- CM8 Grassland Communities Restoration
- CM9 Vernal Pool Complex Restoration
- CM11 Natural Communities Enhancement and Management

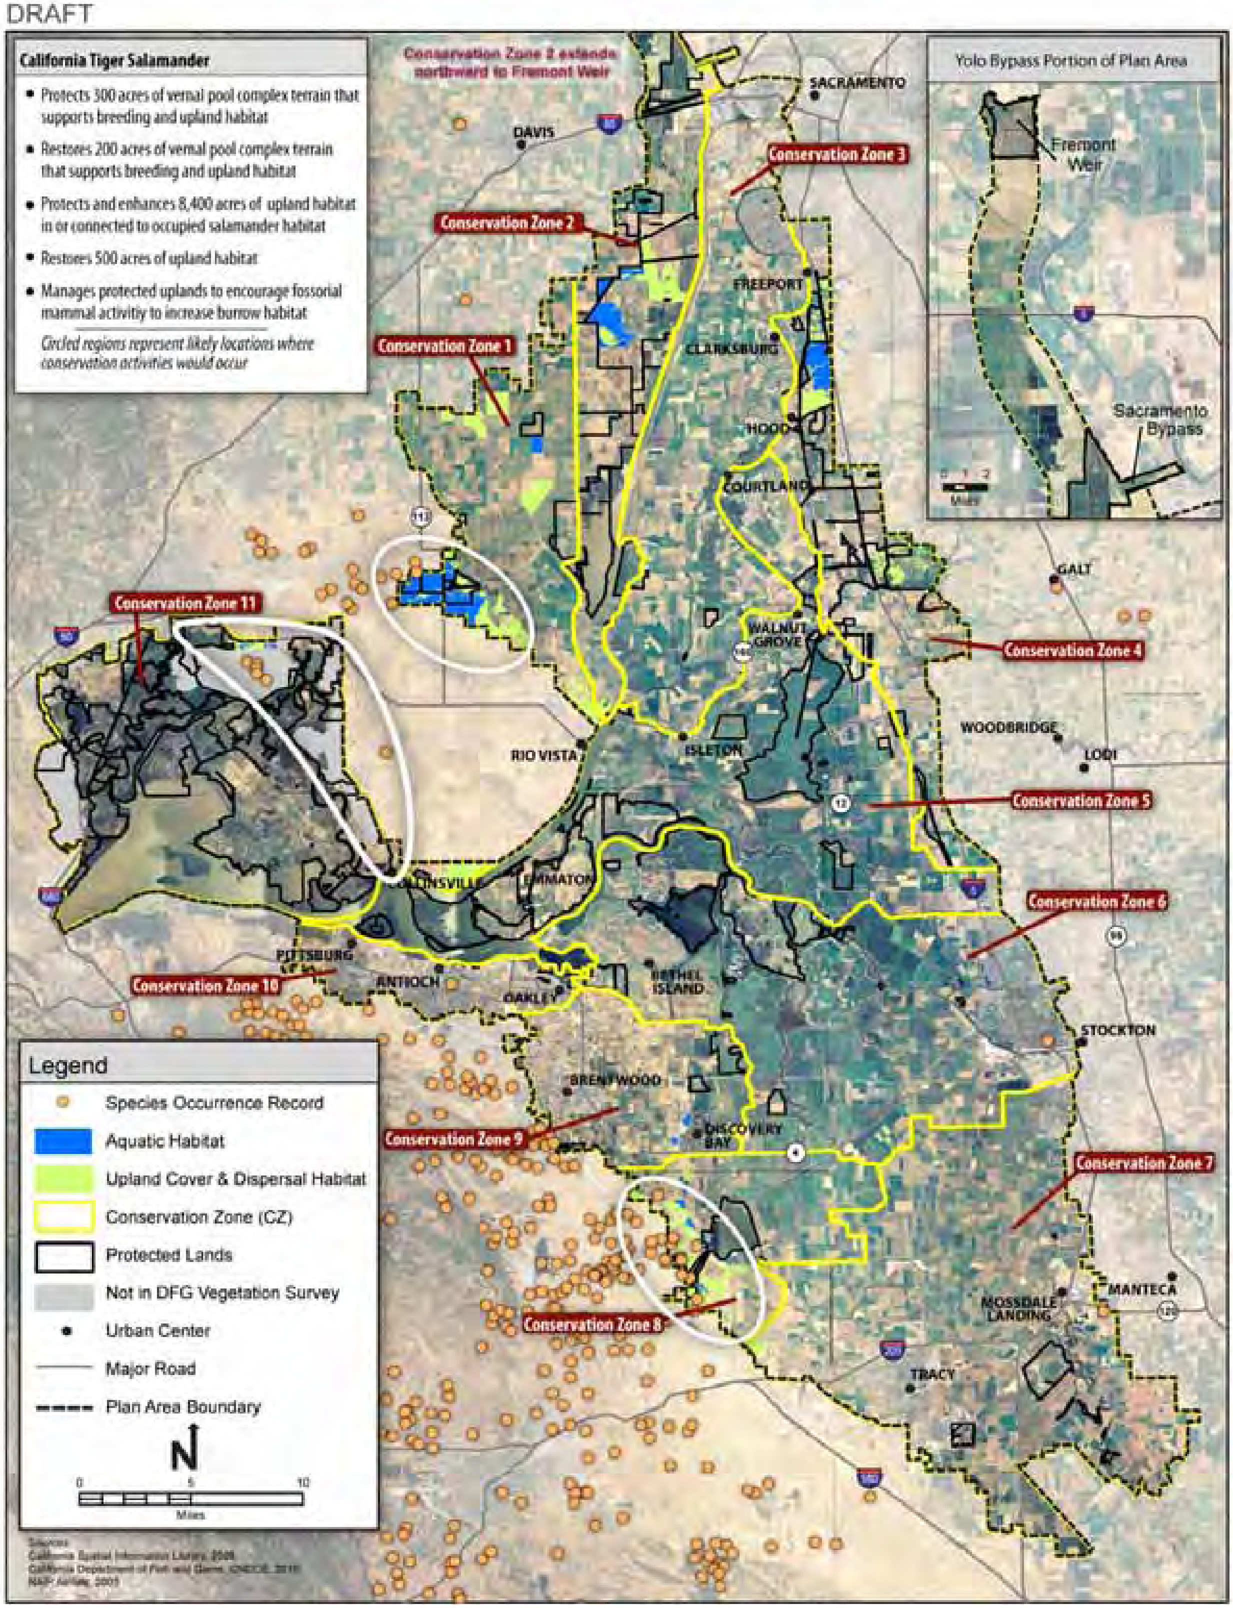

Figure 3-36. California Tiger Salamander Habitat Distribution and Conservation Strategy

3.3.2.4.24 Lange's Metalmark Butterfly

Lange's metalmark butterfly is endemic to areas of Oakley sand soil in east Contra Costa County that support nakedstem buckwheat which is its larval host plant and its adult nectar plant. It is entirely dependent on a particular white-flowered, sand-associated, ecotype of nakedstem buckwheat that grows only on the remnant of the Antioch Dune. Its dependence on the plant extends to the leaf litter that accumulates near the base of large plants growing in large clumps. The extent of the former dune has been reduced to 20 acres plus an unknown amount on two Pacific Gas & Electric (PG&E) parcels that total 12 acres. The 20-acre known extent is protected on the Antioch Dunes National Wildlife Refuge (ADNWR), while the PG&E parcels are being managed under an MOU with USFWS. All the existing habitat has been degraded by nonnative invasive plant species while some older dense stands of nakedstem buckwheat have been lost to wildfires.

The current USFWS management plan for the ADNWR provides for invasive nonnative plant species control efforts that include hand pulling of individual invasive plants through the efforts of volunteers, targeted herbicide application, the restoration of some dune-like topography, and planting of nursery-grown nakedstem buckwheat. Additionally, there is a captive breeding and reintroduction program for Lange's metalmark butterfly and a propagation and out-planting program for its host plant.

The known occurrences of Lange's metalmark butterfly within the Plan Area are located exclusively within the ADNWR and on the two adjacent PG&E properties and are fully protected by ownership and conservation MOUs. These protected lands are completely isolated from other terrestrial habitats by development to the west, south, and east, and by the San Joaquin River to the north. Consequently, to increase the level of conservation benefits provided to inland dune scrub species, inland dune scrub conservation will be implemented through funding support for appropriate management actions and studies.

<u>Applicable Natural Community Goals and Objectives</u>

Goal IDSC1: The expected outcome is support for funding of the USFWS management and enhancement of the inland dune scrub natural community on the Antioch Dunes National Wildlife Refuge.

> **Objective IDSC1.1:** The BDCP will support the funding of the USFWS program for management, enhancement, and monitoring of inland dune scrub natural community on the Antioch Dunes National Wildlife Refuge at an annual amount of $XX.XX for X years.

Species-Specific Goals and Objectives

Goal LMMB1: The expected outcome is funding support for the USFWS captive breeding and reintroduction program for Lange's metalmark butterfly.

Objective LMMB1.1: The BDCP will provide funding to support the USFWS program for the captive breeding and release of Lange's metalmark butterfly at an annual amount of $XX.XX for X years.

Rationale and Conservation Approach

Lange's metalmark butterfly is listed as endangered under the Federal Endangered Species Act but critical habitat has not been designated. The CALFED Bay-Delta Ecosystem Restoration Program Plan's Multi-Species Conservation Strategy designation for Lange's metalmark is "Recovery." After the recent 5-year review of the recovery plan by USFWS found that Lange's metalmark was declining significantly at the ADNWR and appeared to be headed towards extinction, a captive breeding and release program was begun in 2006. The current management plan is designed to meet the recovery needs for the species on the ADNWR, provides for invasive nonnative plant species control efforts, restores dune-like topography, and oversees the out-planting of nursery-grown nakedstem buckwheat.

Conservation of Lange's metalmark butterfly will be provided through the support of funding for the USFWS captive breeding program and its management of the ADNWR (Figure 3-37). The program will include the nursery propagation and out-planting of the white-flowered, sand-associated, ecotype of nakedstem buckwheat and the management of the nakedstem buckwheat to create dense patches of older plants with an extensive layer of leaf litter. The required sizes of self-sustainable Lange's metalmark butterfly populations have not yet been determined, but may be revealed as the controlled propagation studies proceed.

Applicable Conservation Measures

DRAFT

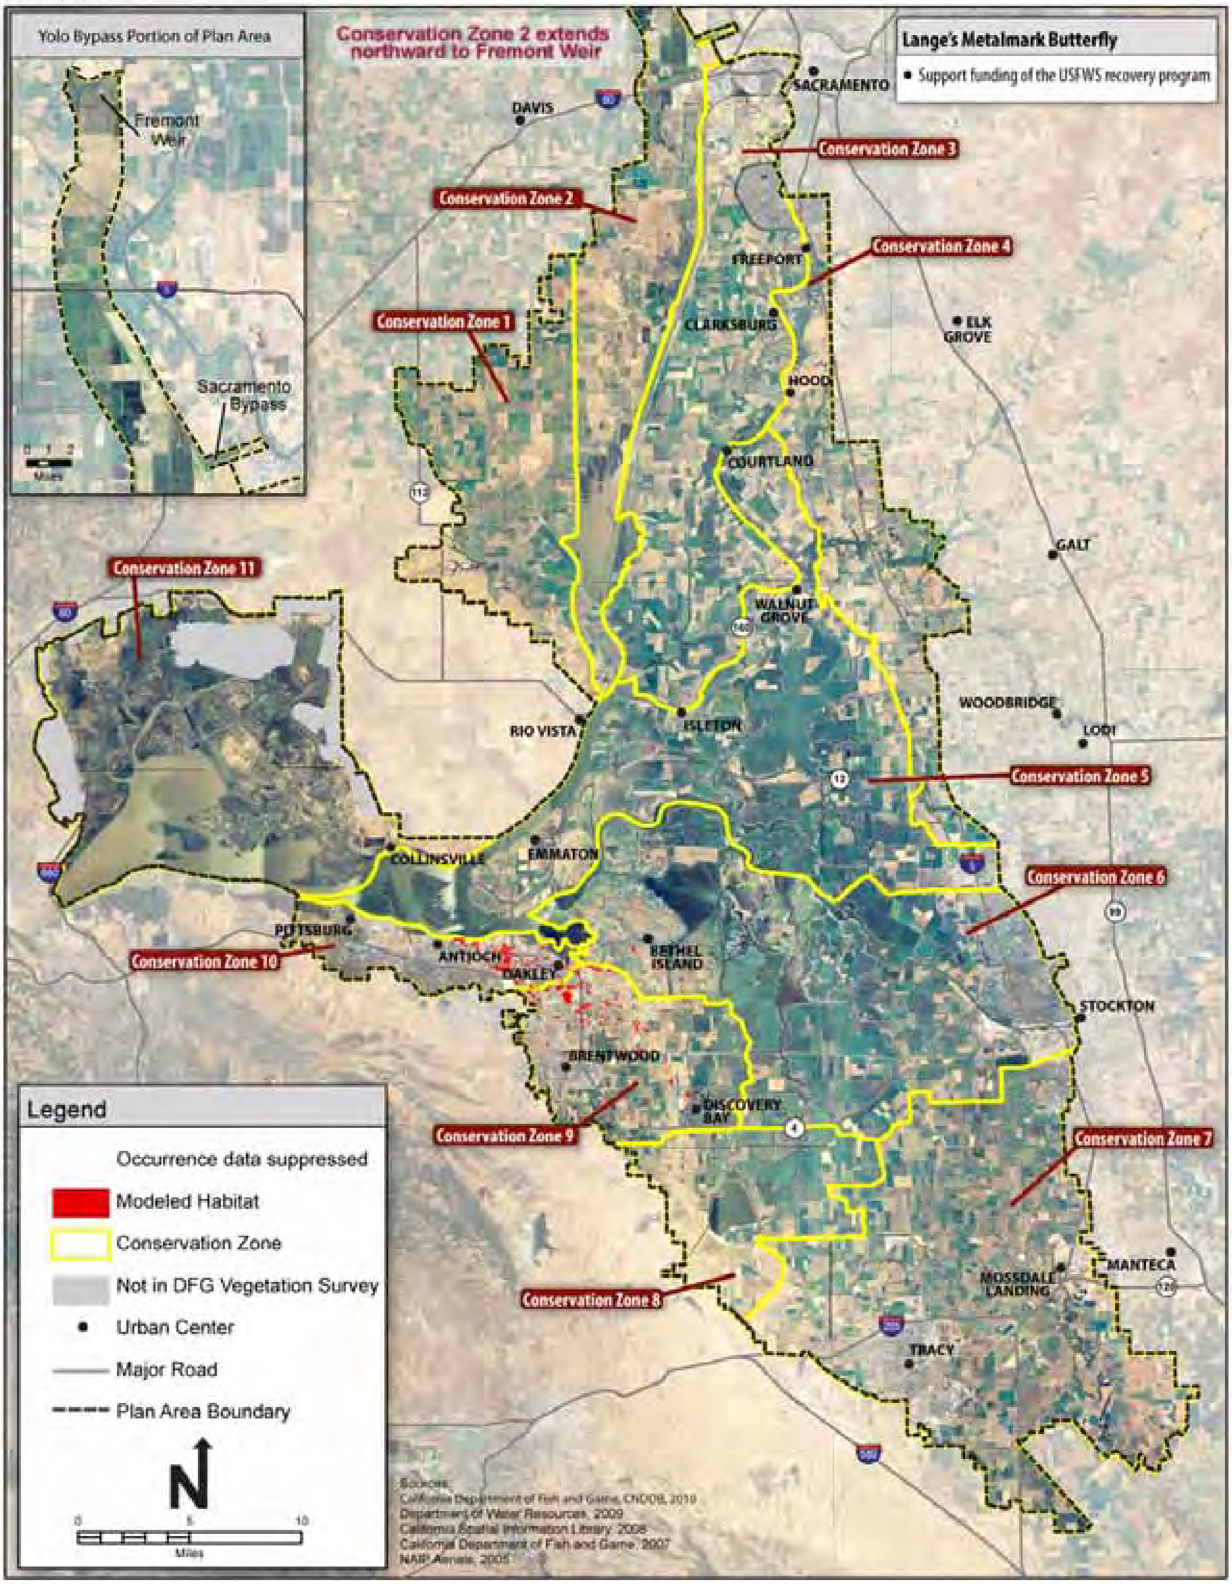

Figure 3-37. Lange's Metalmark Butterfly Habitat Distribution and Conservation Strategy

3.3.2.4.25 Valley Elderberry Longhorn Beetle

One of two subspecies of the longhorn beetle (*Desmocerus californicus*), the valley elderberry longhorn beetle is endemic to moist valley/foothill riparian corridors in the lower Sacramento and lower San Joaquin valleys (USFWS 1984c). Historically, valley elderberry longhorn beetle presumably occurred throughout the Central Valley of California. Little is known about the historical abundance of valley elderberry longhorn beetle, but the extensive destruction of its habitat suggests that the beetle's range has been largely reduced and fragmented (USFWS 1984c). Valley elderberry longhorn beetle is closely associated with a few species of elderberry (*Sambucus* spp.) that are obligate host plants for valley elderberry longhorn beetle larvae and are necessary for the completion of the beetle's life cycle (Linsley and Chemsak 1972, 1997, Eng 1984, Barr 1991, Collinge et al. 2001). The two main species of elderberry utilized by the valley elderberry longhorn beetle are the blue elderberry and red elderberry, two shrubs found in remnant riparian forests throughout the Central Valley.

Applicable Natural Community Goals and Objectives

Goal VRNC1: The expected outcome is restored large expanses and interconnected corridors of valley/foothill riparian natural community.

> **Objective VRNC1.1**: Restore or create 5,000 acres of valley/foothill riparian in Conservation Zones 1, 2, 4, 5, 6, 7, and/or 11.

Goal VRNC2: The expected outcome is biologically diverse valley/foothill riparian natural community that supports native species and is sustained by natural ecological processes.

> **Objective VRNC2.1**: Maintain and enhance the habitat and ecosystem functions of BDCP restored valley/foothill riparian and patches of riparian forest and scrub present on BDCP preserved lands over the term of the BDCP.

> **Objective VRNC2.3**: Restore connectivity of valley/foothill riparian corridors along linear watercourses to enhance habitat for covered species and facilitate wildlife movement.

Rationale and Conservation Approach

The valley elderberry longhorn beetle is listed as threatened under the federal Endangered Species Act (45 FR 52803). Critical habitat has been designated, but neither of the two sites with critical habitat is located within the boundaries of the Plan Area. Conservation guidelines for the valley elderberry longhorn beetle were established by the USFWS in 1999 to mitigate development-related impacts on valley elderberry longhorn beetle habitat (USFWS 1999b). Valley elderberry longhorn beetle conservation has also been addressed in several regional conservation plans. The valley elderberry longhorn beetle is a covered species under the approved San Joaquin County Multi-species Habitat Conservation and Open Space Plan and the Natomas Basin Habitat Conservation Plan. It is proposed for coverage under the South

Sacramento Habitat Conservation Plan, the Solano County Multispecies Habitat Conservation Plan, the Yolo County Natural Heritage Program Plan, and the Butte Regional Conservation Plan. Valley elderberry longhorn beetle conservation under BDCP will therefore tie in with conservation efforts under those other habitat conservation plans.

Conservation of valley elderberry longhorn beetle will be provided through the restoration of 5,000 acres of valley/foothill riparian distributed among Conservation Zones 1, 4, 6, 7, and/or 11 (Figure 3-38). Plantings of elderberry shrubs, including shrubs translocated as mitigation, will be incorporated into the design of restored habitat. Valley/foothill riparian will be provided in large patches that will be managed to control the establishment of undesirable nonnative vegetation that can affect the health of the beetle's host plants, mainly blue elderberry and red elderberry. Based on model projections, restoration of 5,000 acres of valley/foothill riparian, including elderberry shrubs, will increase the extent of the riparian habitat that will support the valley elderberry longhorn beetle's host plant by 29 percent relative to existing conditions (see detailed description of species habitat and model assumptions in Appendix A, *Covered Species Accounts*). This projected increase is expected to be sufficient to sustain beetle populations in the Plan Area while also allowing for any future increase in the distribution and abundance of the species. Numeric targets for preservation of existing habitat are not established; however, elderberry shrubs that are present within BDCP preserved habitat areas will be preserved and maintained.

Applicable Conservation Measures

- CM3 Natural Communities Protection
- CM7 Riparian Habitat Restoration

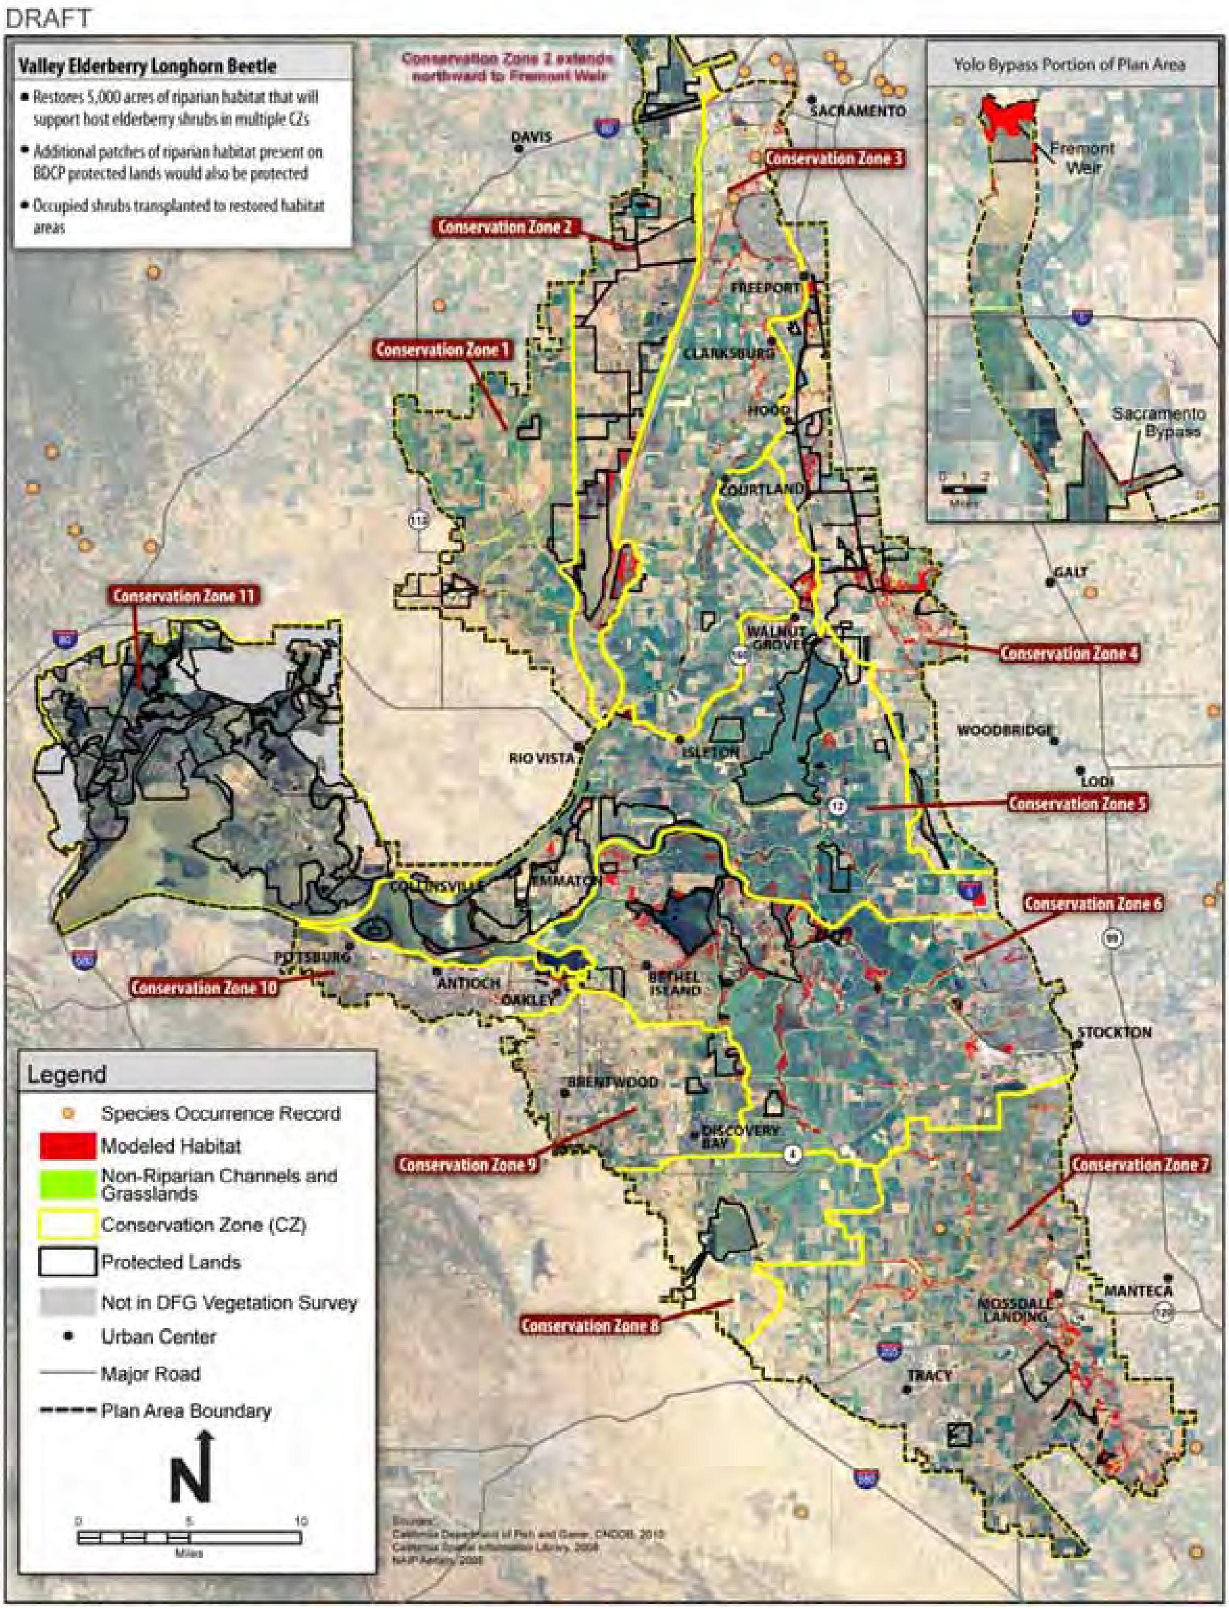

Figure 3-38. Valley Elderberry Longhorn Beetle Habitat Distribution and Conservation Strategy

3.3.2.4.26 Vernal Pool Shrimp Species (Vernal Pool Tadpole Shrimp, Conservancy Fairy Shrimp, Longhorn Fairy Shrimp, Vernal Pool Fairy Shrimp, Midvalley Fairy Shrimp, and California Linderiella)

Several vernal pool shrimp species (vernal pool tadpole shrimp, conservancy fairy shrimp, longhorn fairy shrimp, vernal pool fairy shrimp, midvalley fairy shrimp, and California linderiella) are found in the vernal pool complex natural community in California. While specific hydrological requirements, water chemistry, and water temperature requirements may vary somewhat between the species, within the Plan Area, all are closely associated with the vernal pool complex natural community. Development, conversion of the community to agriculture, and exotic plant species are considered to be the primary stressors on these species (Showers 1996, Witham 2003, EDAW 2004, ESA 2005, Dawson et al. 2007, CNDDB 2009, CNPS 2009).

Applicable Natural Community Goals and Objectives

Goal VPNC1: The expected outcome is protected vernal pool complex natural community that represents a range of environmental conditions and is adjacent to other conserved lands.

> **Objective VPNC1.1**: Protect 300 acres of vernal pool complex in Conservation Zones 1, 8, and 11.

Goal VPNC2: The expected outcome is restored biologically diverse vernal pool complex natural community with improved native biodiversity, habitat heterogeneity, and the ability to support populations of covered and other native species.

> **Objective VPNC2.1**: Restore 200 acres of vernal pool complex natural community in Conservation Zones 1, 8, and/or 11 within patches of protected grassland that supports habitat for the western spadefoot toad, California tiger salamander, and the covered vernal pool shrimp and plant species.

> **Objective VPNC2.2**: Maintain and, where habitat functions for covered species can be enhanced, increase the diversity and relative cover of native grasses and forbs.

Goal ONSW1: The expected outcome is increased habitat functions that support BDCP covered species in other natural seasonal wetland natural community within maintained and protected agricultural habitat areas.

> **Objective ONSW1.1**: Integrate management of other natural seasonal wetland natural community with management of BDCP maintained and protected agricultural lands to increase habitat functions for covered species.

Rationale and Conservation Approach

Vernal pool complex natural community supporting vernal pool shrimp habitat is present in Conservation Zones 1, 2, 4, 8, 9, and 11 along the margins of the Delta. Opportunities for large scale conservation of vernal pool shrimp species within the Plan Area, however, are located only in Conservation Zones 1, 8, and 11 (Figure 3-39). Vernal pool complex natural community in

Conservation Zones 2 and 4 is almost entirely under protected status (99 percent) and in Conservation Zone 9 (approximately 120 acres) is located in the vicinity of Discovery Bay and is largely fragmented by development and cultivated lands. Conservation of vernal pool fairy shrimp species habitat will be provided through the protection and restoration of vernal pool complex natural community that supports vernal pool shrimp species and will be protected and managed in conjunction with protected grassland and alkali seasonal wetland complex natural communities that will also be protected in these conservation zones. Habitat will be protected and restored in the largest possible patch sizes and management of protected and restored vernal pool complex natural community (e.g., invasive species control and livestock grazing) will be implemented to enhance habitat functions for vernal pool shrimp species and other associated covered vernal pool species.

It is important to conserve vernal pool complex natural community areas that encompass a range of environmental variation for the purpose of vernal pool shrimp reproduction. While Helm found no difference in the time to reproduce among fairy shrimp (Helm 1998), field data (Gallagher 1996, Alexander 2007) suggests that the average time to reproduce for California linderiella, conservancy fairy shrimp, longhorn fairy shrimp, vernal pool fairy shrimp is approximately 8 weeks; while average time for midvalley fairy shrimp is approximately 2 weeks, and the minimum time to reproduce may be correlated with vernal pool hydrology. Field observations also suggest that the various shrimp species are seldom found inhabiting the same vernal pools.

The proposed protection and restoration of vernal pool complex natural community, in conjunction with existing protected natural communities and habitat, is expected to sustain vernal pool shrimp populations within the Plan Area and to increase the distribution and abundance of covered vernal pool shrimp species. Following completion of conservation actions, approximately 69 percent of vernal pool shrimp species vernal pool complex will be preserved. The conservation actions are consistent with and help to achieve the recovery objectives for Conservancy fairy shrimp, longhorn fairy shrimp, vernal pool fairy shrimp, midvalley fairy shrimp, and vernal pool tadpole shrimp as identified in the Vernal Pool Recovery Plan (USFWS 2005).

Vernal pool shrimp habitat within the Plan Area is located on the margin of the distribution of the Central Valley vernal pool complex natural community and as such is not considered to support core habitat area for these species. Consequently, to increase the level of conservation benefits provided to vernal pool shrimp species relative to benefits that would be provided by implementing the conservation actions within the Plan Area, the vernal pool shrimp species conservation actions may be implemented within core vernal pool shrimp species habitat areas that are located outside of the Plan Area consistent with conservation plans for those locations.

Applicable Conservation Measures

- CM3 Natural Communities Protection
- CM9 Vernal Pool Complex Restoration
- CM11 Natural Communities Enhancement and Management

DRAFT

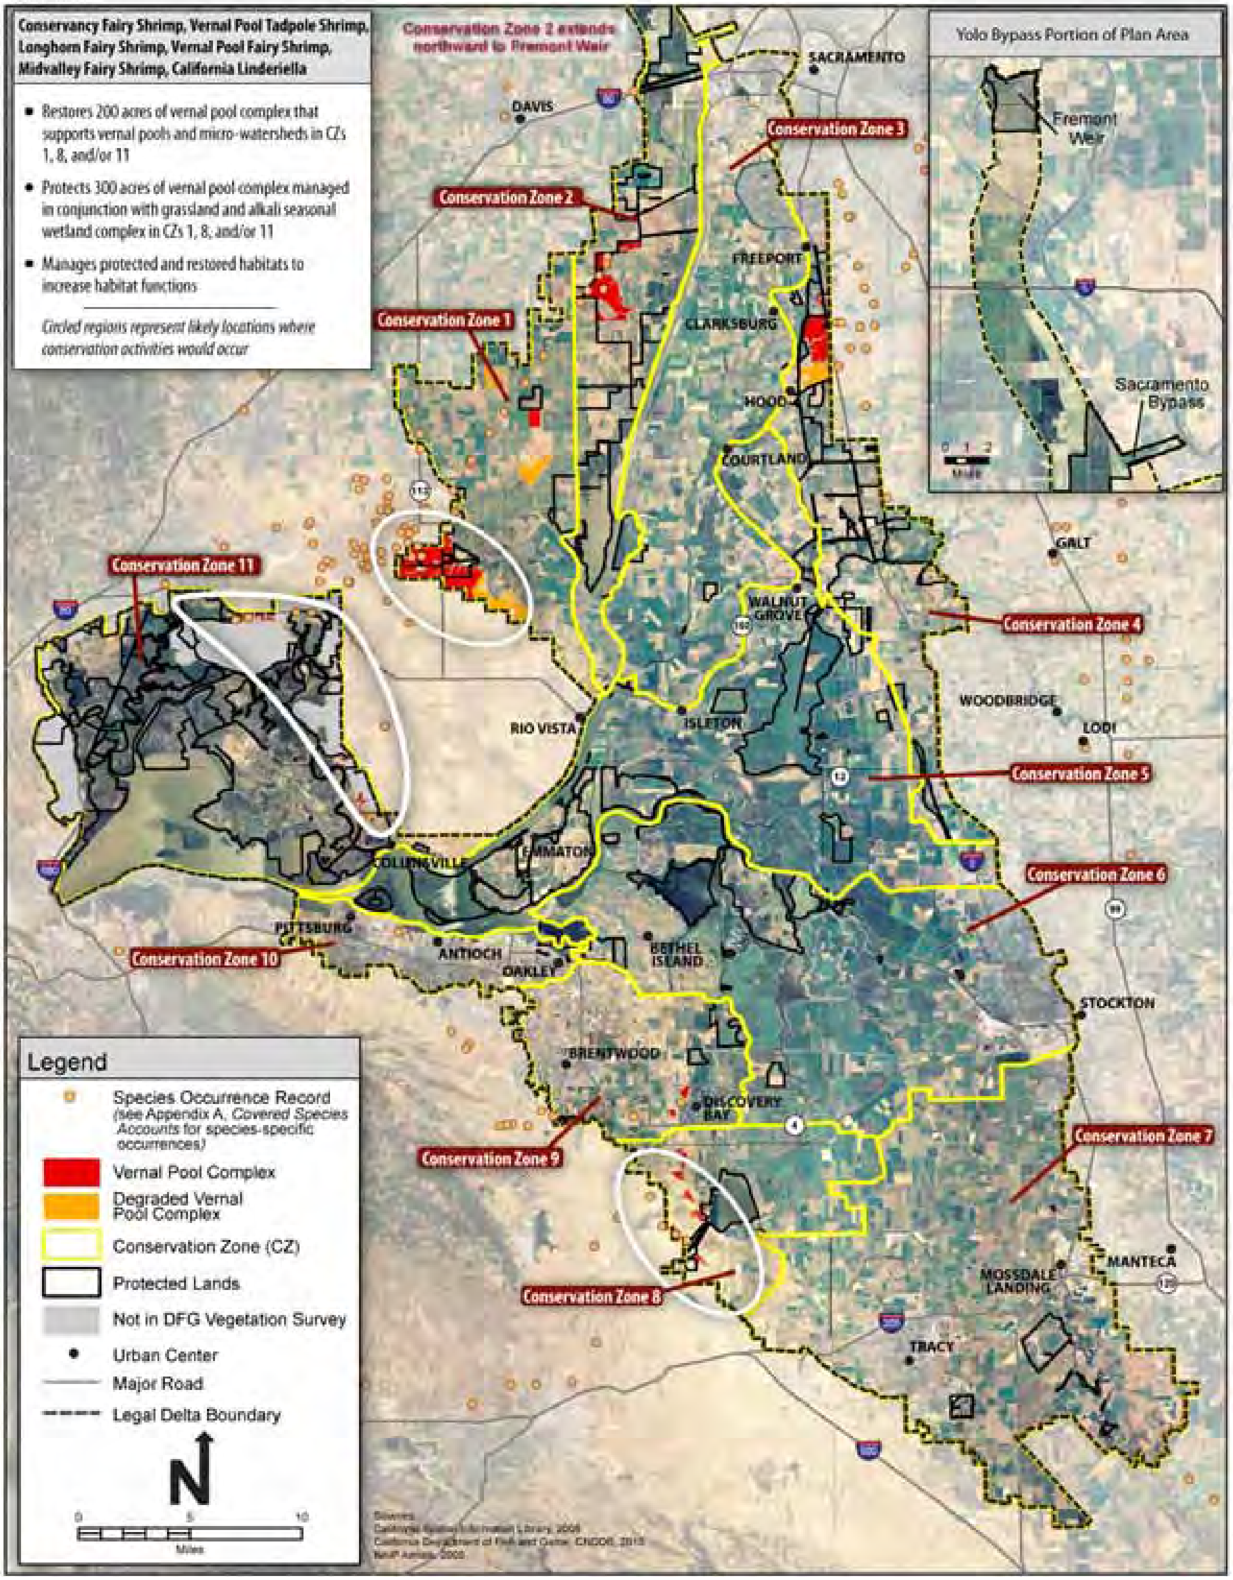

Figure 3-39. Vernal Pool Shrimp Species Habitat Distribution and Conservation Strategy

3.3.2.4.27 Vernal pool plant species (alkali milk-vetch, San Joaquin spearscale, dwarf downingia, Boggs Lake hedge-hyssop, legenere, and Heckard's peppergrass)

Several vernal pool plant species (alkali milk-vetch, San Joaquin spearscale, Boggs Lake hedge-hyssop, Heckard's peppergrass, and legenere) are endemic to California. While specific soil requirements and micro-habitat restrictions vary somewhat between species, within the Plan Area, all are closely associated with the vernal pool complex natural community. Development, agricultural conversion, and exotic plant species are considered to be the primary stressors on these species (Showers 1996, Witham 2003, EDAW 2004, ESA 2005, Dawson et al. 2007, CNDDB 2009, CNPS 2009).

Applicable Natural Community Goals and Objectives

Goal VPNC1: The expected outcome is protected vernal pool complex natural community that represents a range of environmental conditions and is adjacent to other conserved lands.

> **Objective VPNC1.1**: Protect 300 acres of vernal pool complex in Conservation Zones 1, 8, and 11.

Goal VPNC2: The expected outcome is restored biologically diverse vernal pool complex natural community with improved native biodiversity, habitat heterogeneity, and the ability to support populations of covered and other native species.

> **Objective VPNC2.1**: Restore 200 acres of vernal pool complex natural community in Conservation Zones 1, 8, and/or 11 within patches of protected grassland that supports habitat for the western spadefoot toad, California tiger salamander, and the covered vernal pool shrimp and plant species.

> **Objective VPNC2.2**: Maintain and, where habitat functions for covered species can be enhanced, increase the diversity and relative cover of native grasses and forbs.

Species-Specific Goals and Objectives

Goal ALMV1: The expected outcome is protected and enhanced alkali milk-vetch populations.

> **Objective ALMV1.1**: Protect at least 3 unprotected occurrences of alkali milk-vetch in Conservation Zones 1 and/or 11.

> **Objective ALMV1.2:** Maintain and enhance the habitat functions of preserved alkali milk-vetch habitat over the term of the BDCP.

Goal HEPE1: The expected outcome is protected and enhanced Heckard's peppergrass populations.

> **Objective HEPE 1.2**: Protect at least 2 unprotected occurrences of Heckard's peppergrass in Conservation Zones 1, 8, or 11.

> **Objective HEPE1.2:** Maintain and enhance the habitat functions of preserved Heckard's peppergrass habitat over the term of the BDCP.

Rationale and Conservation Approach

Because habitat loss and exotic species are the primary stressors on vernal pool plants, protecting, enhancing, and restoring vernal pool complex natural community is expected to help maintain and potentially increase the abundance and distribution of these species. Conservation of vernal pool plant species will be directed at preserving and enhancing 300 acres and restoring 200 acres of vernal pool complex natural community (Figure 3-40) to improve habitat conditions for these species. Additionally, at least 3 unprotected occurrences of alkali milk-vetch and 2 unprotected occurrences of Heckard's peppergrass will be preserved and enhanced. Protection of vernal pool complex natural community will be achieved through the preservation and restoration of clay alluvium vernal pools and playa pools, Montezuma Block vernal pools and playa pools, and alkaline sink/meadow vernal pools (see Section 2.3.4.9, *Vernal Pool Complex*) that support vernal pool plant species in Conservation Zones 1, 8, and 11 (Figure 3-40) and will be conducted in conjunction with the preservation, enhancement, and restoration of grassland and alkali seasonal wetland complex natural communities in those conservation zones. To the extent practicable, vernal pool complex natural community will be protected and restored in the largest possible patch sizes and management of protected and restored vernal pool complex natural community (e.g., control of nonnative invasive species, restoration of natural hydrological regime, spatial linkages between patches of vernal pool complex natural community, etc.) will be designed to enhance habitat functions for vernal pool plant species and other covered vernal pool associated species.

The proposed protection and restoration of vernal pool complex natural community, in conjunction with existing protected habitat, is expected to sustain vernal pool plant species populations within the Plan Area and increase the distribution and abundance of covered vernal pool plant species. While vernal pool complex natural community supporting vernal pool plant species habitat is present in Conservation Zones 1, 2, 4, 8, 9, and 11 along the margins of the Plan Area, opportunities for the large scale conservation of vernal pool plant species within the Plan Area are located only in Conservation Zones 1, 8, and 11. Vernal pool complex natural community in Conservation Zones 2 and 4 is almost entirely under preserved status (99 percent) and vernal pool complex natural community in Conservation Zone 9 (approximately 120 acres) is located in the vicinity of Discovery Bay and is largely fragmented by development and cultivated lands.

The areas of vernal pool complex natural community within the Plan Area are located in areas that are transitional between tidal wetland communities and uplands and generally contain fragmented and degraded vernal pool complex natural community compared to areas immediately outside of the Plan Area. Because of this transitional location and due to a history of relatively intensive agricultural land uses, those areas contain little of the community that is occupied by robust populations of vernal pool plant species. Consequently, to increase the level of conservation benefits provided to vernal pool plant species relative to benefits that would be provided by implementing the conservation actions within the Plan Area, the vernal pool plant species conservation actions may be implemented within vernal pool plant species habitat core areas that are located outside of the Plan Area when consistent with conservation plans for those locations.

Following full implementation of the BDCP, 69 percent of the modeled vernal pool complex natural community in the Plan Area will be preserved (Table 3-10).

The conservation actions are consistent with and help to achieve the recovery objectives for alkali milk-vetch, Boggs Lake hedge-hyssop, and legenere identified in the Vernal Pool Recovery Plan (USFWS 2005).

Applicable Conservation Measures

- CM9 Vernal Pool Complex Restoration
- CM11 Natural Communities Enhancement and Management

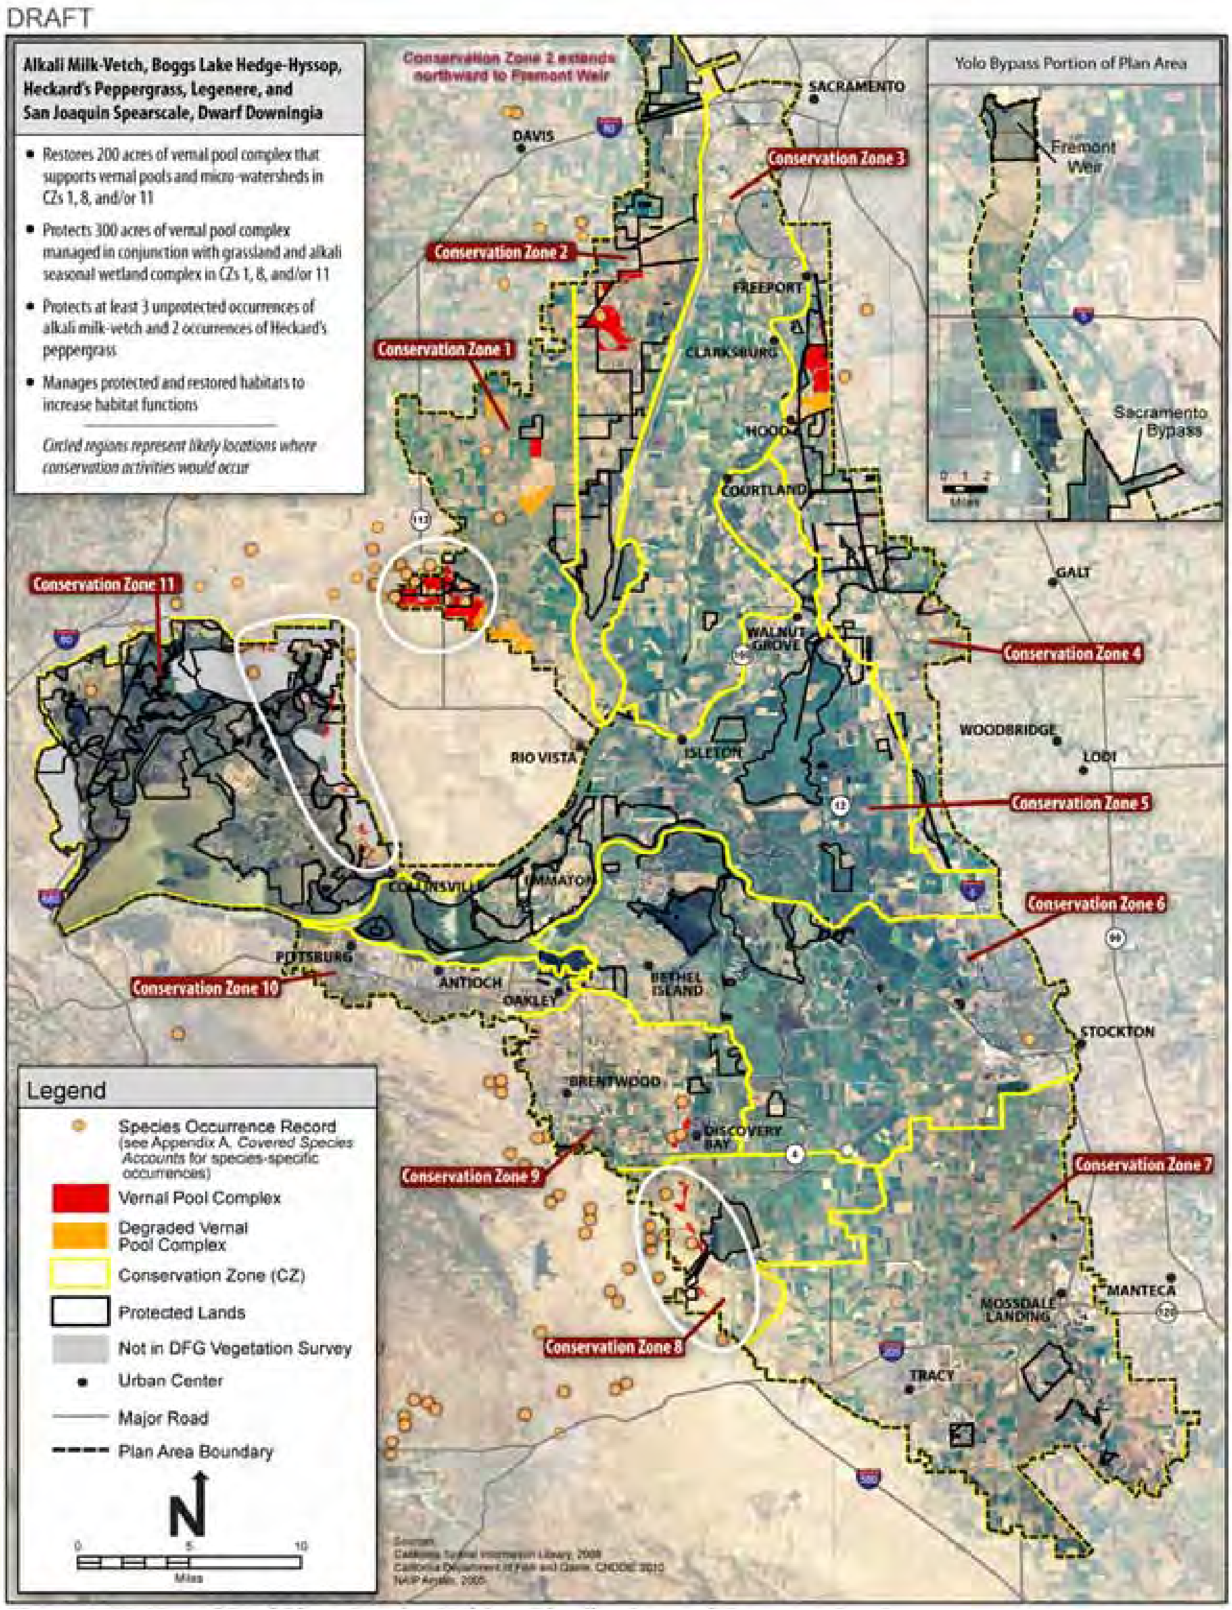

Figure 3-40. Vernal Pool Plant Species Habitat Distribution and Conservation Strategy

3.3.2.4.28 Heartscale and Brittlescale

Heartscale and brittlescale are found only in very limited habitat types in close proximity to hydrological features such as stream corridors and playa pools which are located on either alluvium associated with the Montezuma Block along the western boundary of the Plan Area or on alluvium associated with tertiary formations located along the southwest boundary of the Plan Area. The population sizes of the occurrences tend to be very small. Throughout its range it has been impacted by development, agricultural intensification, conversion of habitat to waterfowl habitat, and invasive species. BDCP tidal restoration activities could potentially affect some occurrences.

Applicable Natural Community Goals and Objectives

Goal GRNC1: The expected outcome is grassland comprised of large interconnected patches or contiguous expanses.

> **Objective GRNC1.1**: Protect a minimum of 8,000 acres of grassland in Conservation Zones 1, 8, and 11. At least 1,000 acres will be protected in Conservation Zone 8, with the remainder distributed throughout these three Conservation Zones.

> **Objective GRNC1.2**: Restore 2,000 acres of grassland to connect fragmented patches of protected grassland.

Goal GRNC2: The expected outcome is biologically diverse grassland managed to enhance native species and sustained by natural ecological processes.

> **Objective GRNC2.1**: Restore and sustain a mosaic of grassland vegetation alliances, reflecting local water availability, soil chemistry, soil texture, topography, and disturbance regimes, with consideration of historical states.

> **Objective GRNC2.2**: Increase the relative cover of native grasses and forbs in native grassland vegetation alliances.

Goal AWNC1: The expected outcome is protected alkali seasonal wetland complex natural community that represents a range of environmental conditions and is adjacent to other conserved lands.

> **Objective AWNC1.1**: Protect 400 acres of alkali seasonal wetland complex natural community in Conservation Zones 1, 8, and/or 11.

Goal AWNC2: The expected outcome is biologically diverse alkali seasonal wetland complex natural community with improved native biodiversity, habitat heterogeneity, and the ability to support populations of covered and other native species.

> **Objective AWNC2.1**: Maintain and, where habitat functions for covered species can be increased, increase the diversity and relative cover of native grasses and forbs.

Goal VPNC1: The expected outcome is protected vernal pool complex natural community that represents a range of environmental conditions and is adjacent to other conserved lands.

> **Objective VPNC1.1**: Protect 300 acres of vernal pool complex in Conservation Zones 1, 8, and 11.

Goal VPNC2: The expected outcome is restored biologically diverse vernal pool complex natural community with improved native biodiversity, habitat heterogeneity, and the ability to support populations of covered and other native species.

> **Objective VPNC2.1**: Restore 200 acres of vernal pool complex natural community in Conservation Zones 1, 8, and/or 11 within patches of protected grassland that supports habitat for the western spadefoot toad, California tiger salamander, and the covered vernal pool shrimp and plant species.

> **Objective VPNC2.2**: Maintain and, where habitat functions for covered species can be enhanced, increase the diversity and relative cover of native grasses and forbs.

Species-Specific Goals and Objectives

Goal HART/BRIT1: The expected outcome is protected and expanded alkali seasonal wetland complex natural community-associated covered species populations.

> **Objective HART/BRIT1.1:** Of the 400 acres of protected alkali seasonal wetland complex natural community, protect 150 acres that support heartscale and brittlescale habitat.

> **Objective HART/BRIT1.2**: Protect at least 3 unprotected occurrences of heartscale in Conservation Zones 1 and /or 11.

> **Objective HART/BRIT1.3**: Protect at least 3 unprotected occurrences of brittlescale in Conservation Zones 1, 8, or 11.

> **Objective HART/BRIT1.4**: Maintain and enhance the habitat functions of preserved heartscale and brittlescale habitat over the term of the BDCP.

Rationale and Conservation Approach

Heartscale and brittlescale are both endemic to California and within the Plan Area are found in meadows, seeps, and vernal pools with alkaline clay soils (CNPS 2009). The primary stressors to these species are agricultural intensification, development, nonnative plants, overgrazing, and trampling (CNDDB 2009, CNPS 2009). Because habitat loss and incompatible land management practices are the primary stressors on these species, preserving and enhancing heartscale and brittlescale habitat is expected to help maintain and potentially increase the abundance and distribution of these species.

Conservation of heartscale and brittlescale will be directed at known occurrences and protecting and enhancing currently unprotected heartscale and brittlescale habitat that supports the known elements (e.g., soils, hydrology) of their habitat. Priority will be given to protecting three unprotected occurrences and protecting habitat that supports species occurrences or is within the watersheds that support known occurrences. Conservation will be provided through protecting and enhancing 150 acres of stream corridors and appropriate buffers on alkaline soils in the same general locations as clay alluvium vernal pools and playa pools, Montezuma Block vernal pools and playa pools, and alkaline sink/meadow vernal pools and associated grassland and alkali seasonal wetland complex (see Section 2.3.4.9, *Vernal Pool Complex*) that support heartscale and brittlescale habitat in Conservation Zones 1, 8, and 11 (Figure 3-41).

Protection and enhancement of their habitat will be conducted in conjunction with the protection, enhancement, and restoration of grassland, alkali seasonal wetland complex, and vernal pool complex natural communities in those Conservation Zones. To the extent practicable, heartscale and brittlescale habitat will be protected in the largest possible linear corridor extents, and management of protected habitat (e.g., control of nonnative invasive species, restoration of natural hydrological regime, appropriate grazing intensity, etc.) will be designed to enhance habitat functions for heartscale, brittlescale and other covered associated species. Following full implementation of the BDCP, 277 acres (56 percent) of the modeled heartscale and brittlescale habitat in the Plan Area will be protected (Table 3-10).

Applicable Conservation Measures

- CM3 Natural Communities Protection
- CM8 Grassland Communities Restoration
- CM9 Vernal Pool Complex Restoration
- CM11 Natural Communities Enhancement and Management

DRAFT

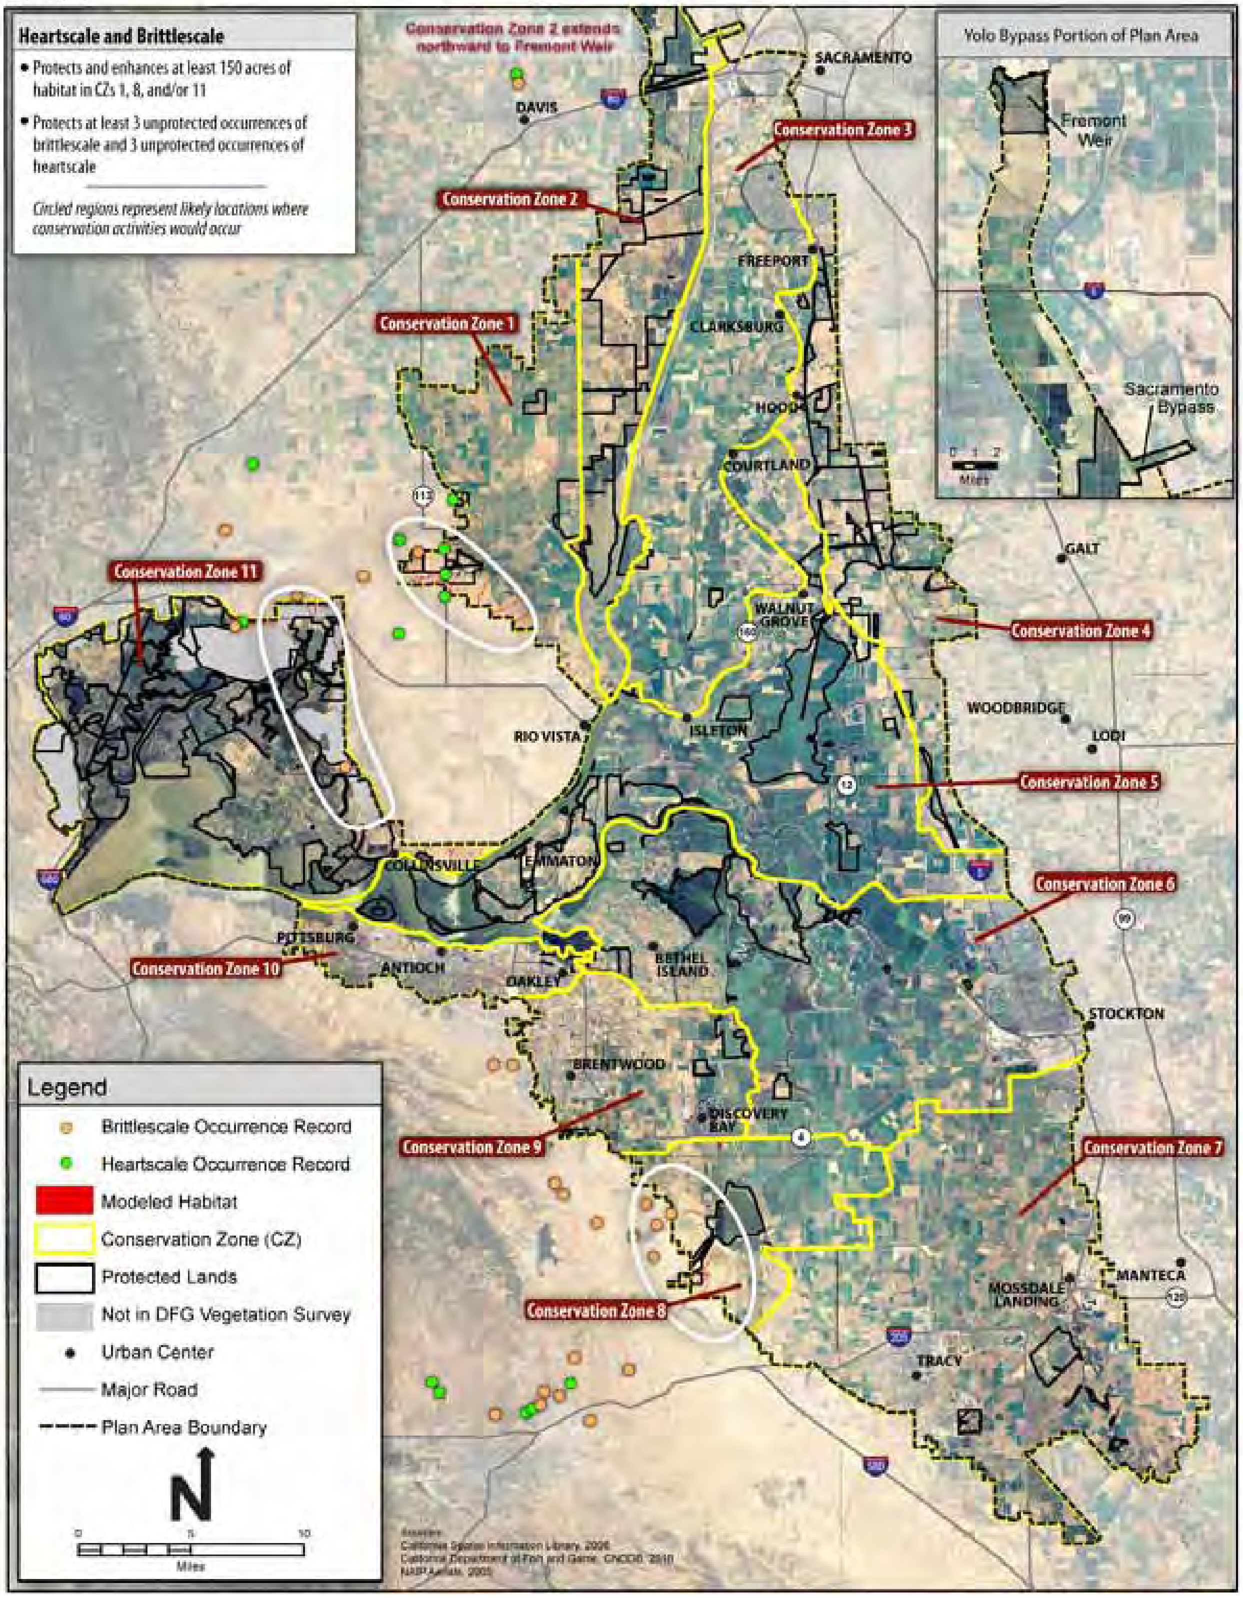

Figure 3-41. Heartscale and Brittlescale Habitat Distribution and Conservation Strategy

3.3.2.4.29 Slough Thistle

Slough thistle is endemic to the San Joaquin Valley and has been reported from San Joaquin County in the north and in Kings and Kern counties in the south (CNPS 2009). Slough thistle occurs in the southern end of the Plan Area in the San Joaquin River. There are seven records from near Lathrop and Vernalis; all but two of which have been extirpated by agriculture or urbanization (CNDDB 2009). The locations reported in the southern San Joaquin Valley are all along or adjacent to high flood flow areas (CNDDB 2009). Historically slough thistle was likely present in lesser flow channels as well. It is generally found within the portions of river channels that flood at high water and on the banks of flood water conveyance canals and drains (T. Griggs pers. comm. 2009, R. Hansen pers. comm. 2009). Historical and current records of this species indicate that its distribution within the Plan Area is limited to the floodplain of the San Joaquin River (Figure 3-42). Based on its distribution in the southern San Joaquin Valley, its habitat is likely to be areas along the river that have been disturbed by flood events and are being colonized by willow scrub vegetation.

Conversions of suitable habitat to agricultural land uses and competition from nonnative plants have been reported as the primary threats to slough thistle (CNPS 2009). In the southern San Joaquin Valley, other threats include removing vegetation from the banks of drains and canals, and weed control efforts (T. Griggs pers. comm. 2009, R. Hansen pers. comm. 2009).

Slough thistle has been reported from freshwater marshes and swamps, and in chenopod scrub and riparian scrub habitats (CNPS 2009). Under natural conditions, it almost always occurs in wetlands (Calflora 2009). The locations reported in the southern San Joaquin Valley are all along or adjacent to high flood flow areas (CNDDB 2009) such as the Hacienda Spillway where high flows from the Kern River broke through the Sand Ridge and flowed into Tulare Lake (R. Hansen pers. comm. 2009). Because these high flow areas have been preserved, albeit in a modified condition, for floodwater conveyance, some habitat has been preserved in what is now an area of intensive agricultural production. Historically slough thistle was likely present throughout the Tulare Basin in lesser flow channels as well. It is generally found within the portions of channels that flood at high water and on the banks of flood water conveyance canals and drains (T. Griggs pers. comm. 2009, R. Hansen pers. comm. 2009).

Applicable Natural Community Goals and Objectives

Goal VRNC1: The expected outcome is restored large expanses and interconnected corridors of valley/foothill riparian natural community.

> **Objective VRNC1.1**: Restore or create 5,000 acres of valley/foothill riparian in Conservation Zones 1, 2, 4, 5, 6, 7, and/or 11.

Goal VRNC2: The expected outcome is biologically diverse valley/foothill riparian natural community that supports native species and is sustained by natural ecological processes.

> **Objective VRNC2.1**: Maintain and enhance the habitat and ecosystem functions of BDCP restored valley/foothill riparian and patches of riparian forest and scrub present on BDCP preserved lands over the term of the BDCP.

> **Objective VRNC2.3**: Restore connectivity of valley/foothill riparian corridors along linear watercourses to enhance habitat for covered species and facilitate wildlife movement.

Rationale and Conservation Approach

Conservation of slough thistle will be directed at restoring floodplain habitat along the San Joaquin River that provides slough thistle habitat which consists of seasonally scoured areas within the floodplain and corresponding channel morphology (Figure 3-42). Reestablishing patterns of flood flows to floodplain that were historically occupied by this species is expected to sustain the species within the Plan Area and provide for increases in species distribution and abundance.

Applicable Conservation Measures

- CM3 Natural Communities Protection
- CM5 Seasonally Inundated Floodplain Restoration
- CM7 Riparian Habitat Restoration
- CM11 Natural Communities Enhancement and Management

DRAFT

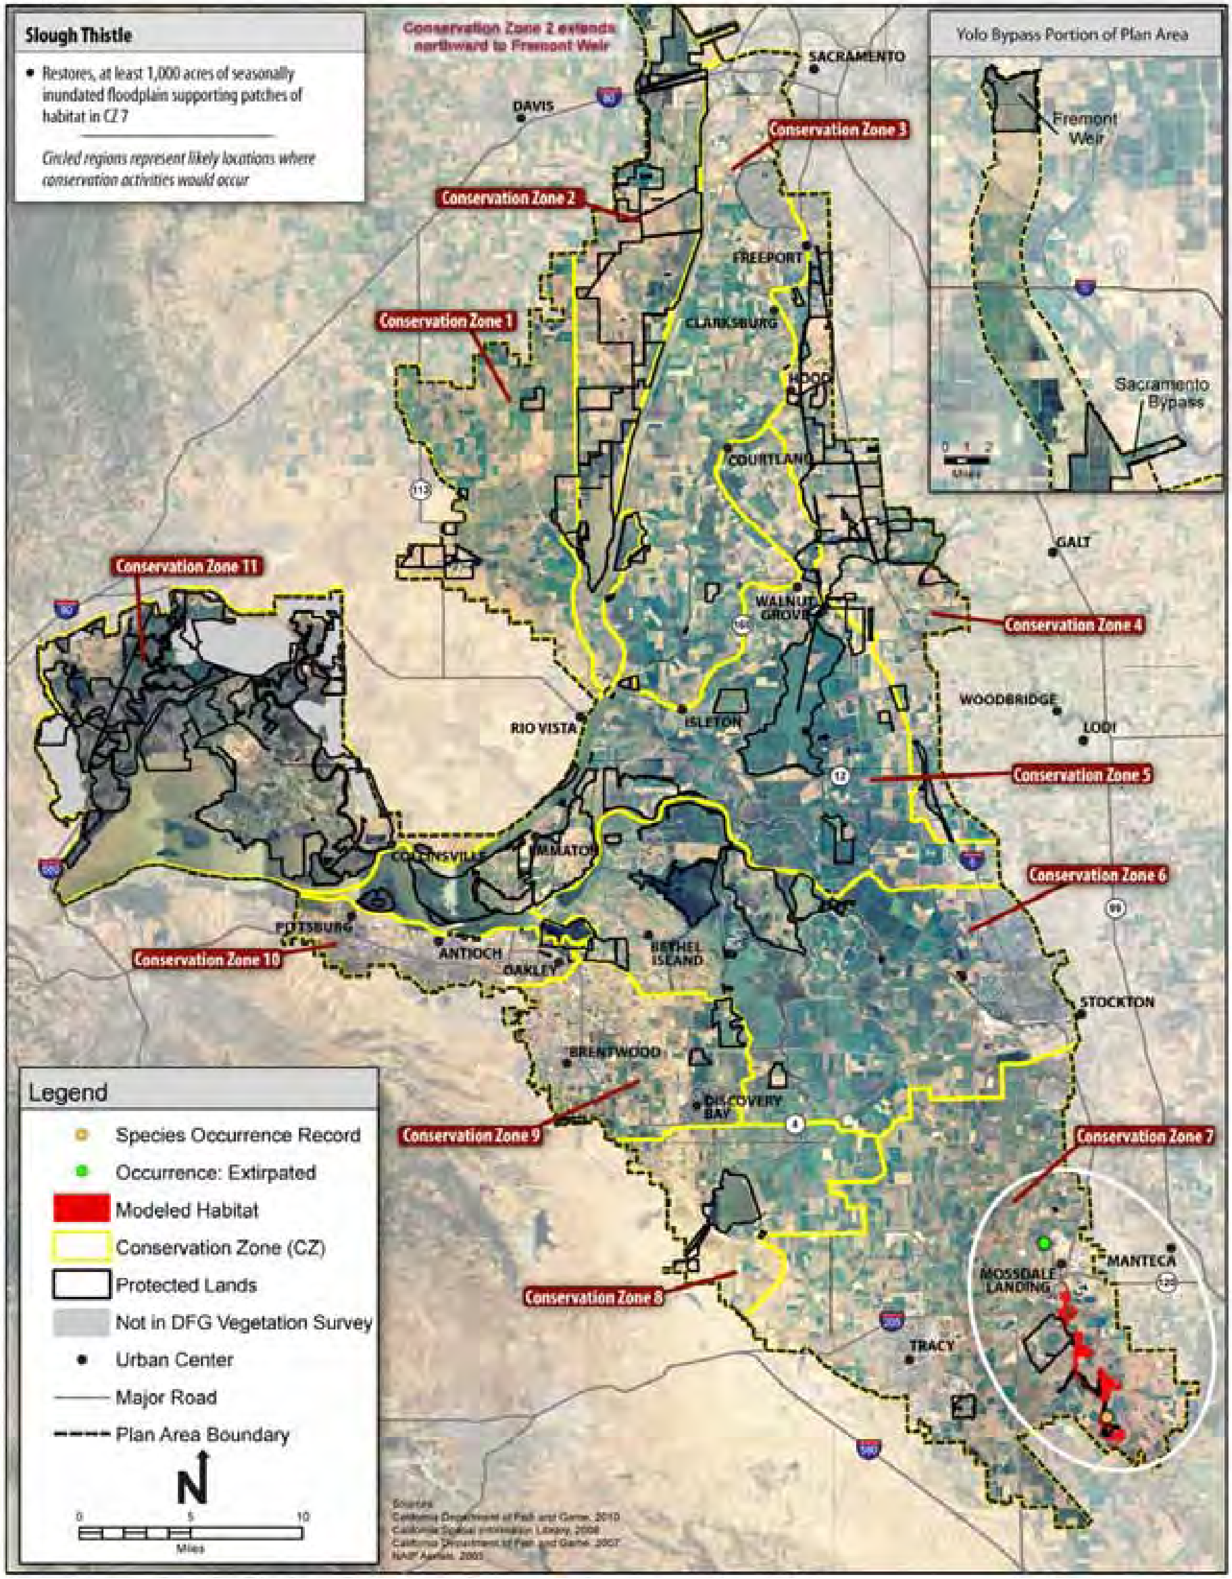

Figure 3-42. Slough Thistle Habitat Distribution and Conservation Strategy

3.3.2.4.30 Suisun Thistle and Soft Bird's-beak

Suisun thistle and soft bird's-beak co-occur in Suisun Marsh. Suisun thistle is found only in the tidal brackish marshes of Suisun Marsh (62 FR 61916, USFWS 2009a, b) and is almost always found adjacent to first-order channels or mosquito control ditches that link to first-order channels (Fiedler et al. 2007, USFWS 2009a, b). In 1975, Suisun thistle was presumed to be extinct because it had not been observed for 15 years (62 FR 61916, USFWS 2009a); however, extensive surveys conducted at Suisun Marsh in 1989 rediscovered this species at two locations. Historically, the range of soft bird's-beak extended from tidal marshes of Napa and Solano counties in the north, Contra Costa County in the south, Sonoma and Marin counties in the west, and Sacramento and San Joaquin counties in the east. It is now believed to be extirpated from Marin, San Joaquin, Sonoma, and Sacramento counties; and extant in Napa, Solano, and Contra Costa counties (CNDDB 2010).

The tidal brackish emergent wetland natural community that is suitable habitat for Suisun thistle and soft bird's-beak has been lost mostly through development, dredge disposal, waterfowl habitat creation, agricultural conversion, and diking of tidal marshes. Diked marshes generally lack rare tidal marsh species. It is believed that the conditions brought about by dikes favor robust generalist species that can better tolerate the long inundation periods in diked managed wetlands (Goals Project 2000). Current threats to Suisun thistle include: the nonnative and highly invasive perennial pepperweed, feral pigs, and fire during sensitive periods of the species' lifecycle (Fiedler et al. 2007, USFWS 2009a). Other potential but unquantified threats specific to Suisun thistle include hybridization with bull thistle and seed predation by the introduced biocontrol thistle weevil (Fiedler et al. 2007, USFWS 2009a). Threats specific to soft bird's-beak include overgrazing and trampling by livestock and the invasion of its habitat by nonnative annual plants that are inappropriate hosts, and invasion of its habitat by perennial pepperweed (Grewell et al. 2003, Grewell 2005, Fiedler et al 2007, CNDDB 2008, USFWS 2009b, USFWS 2010).

Applicable Natural Community Goals and Objectives

Goal BMNC1: The expected outcome is restored large expanses and interconnected patches of tidal brackish emergent wetland natural community.

> **Objective BMNC1.1**: Restore or create 3,600 to 4,800 acres of tidal brackish emergent wetland in the Suisun Marsh ROA (Conservation Zone 11).

Goal BMNC2: The expected outcome is biologically diverse tidal brackish emergent wetland that is enhanced for native species and sustained by natural ecological processes.

> **Objective BMNC2.1:** Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal brackish emergent wetland for covered and other native species over the term of the BDCP.

Species-Specific Goals and Objectives

Goal SUTH1: The expected outcome is protected and expanded Suisun thistle populations.

> **Objective SUTH1.1:** Protect 3 unprotected occurrences of Suisun thistle in Suisun Marsh in Conservation Zone 11.

> **Objective SUTH1.2**: Maintain and enhance the habitat functions of preserved Suisun thistle habitat over the term of the BDCP.

Goal SOBB1: The expected outcome is protected and expanded soft bird's-beak populations.

> **Objective SOBB1.1:** Protect 3 unprotected occurrences of soft bird's-beak in Suisun Marsh in Conservation Zone 11.

> **Objective SOBB1.2**: Maintain and enhance the habitat functions of preserved soft bird's-beak habitat over the term of the BDCP.

Rational and Conservation Approach

Conservation of Suisun thistle and soft bird's-beak will be directed at protecting 3 unprotected occurrences of each species and restoring 3,600-4,800 acres[29] of tidal brackish emergent wetland that supports the known elements (e.g., soils, hydrology, etc.) of their habitat (Figures 3-43 and 3-44). The conservation actions are consistent with and help to achieve the draft recovery objectives for Suisun thistle and soft bird's-beak identified in the Draft Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (USFWS 2010).

Applicable Conservation Measures

- CM3 Natural Communities Protection
- CM4 Tidal Habitat Restoration
- CM11 Natural Communities Enhancement and Management

[29] Restored tidal habitat acreage ranges are a component of the 65,000 acre target for restored tidal habitat. Acreage ranges are based on the results of hydrodynamic modeling of realistic hypothetical restoration designs. While these ranges are not the acreage targets for restored tidal habitats, but rather the results of modeling, the hypothetical designs provided verification of the practicability of achieving restoration targets.

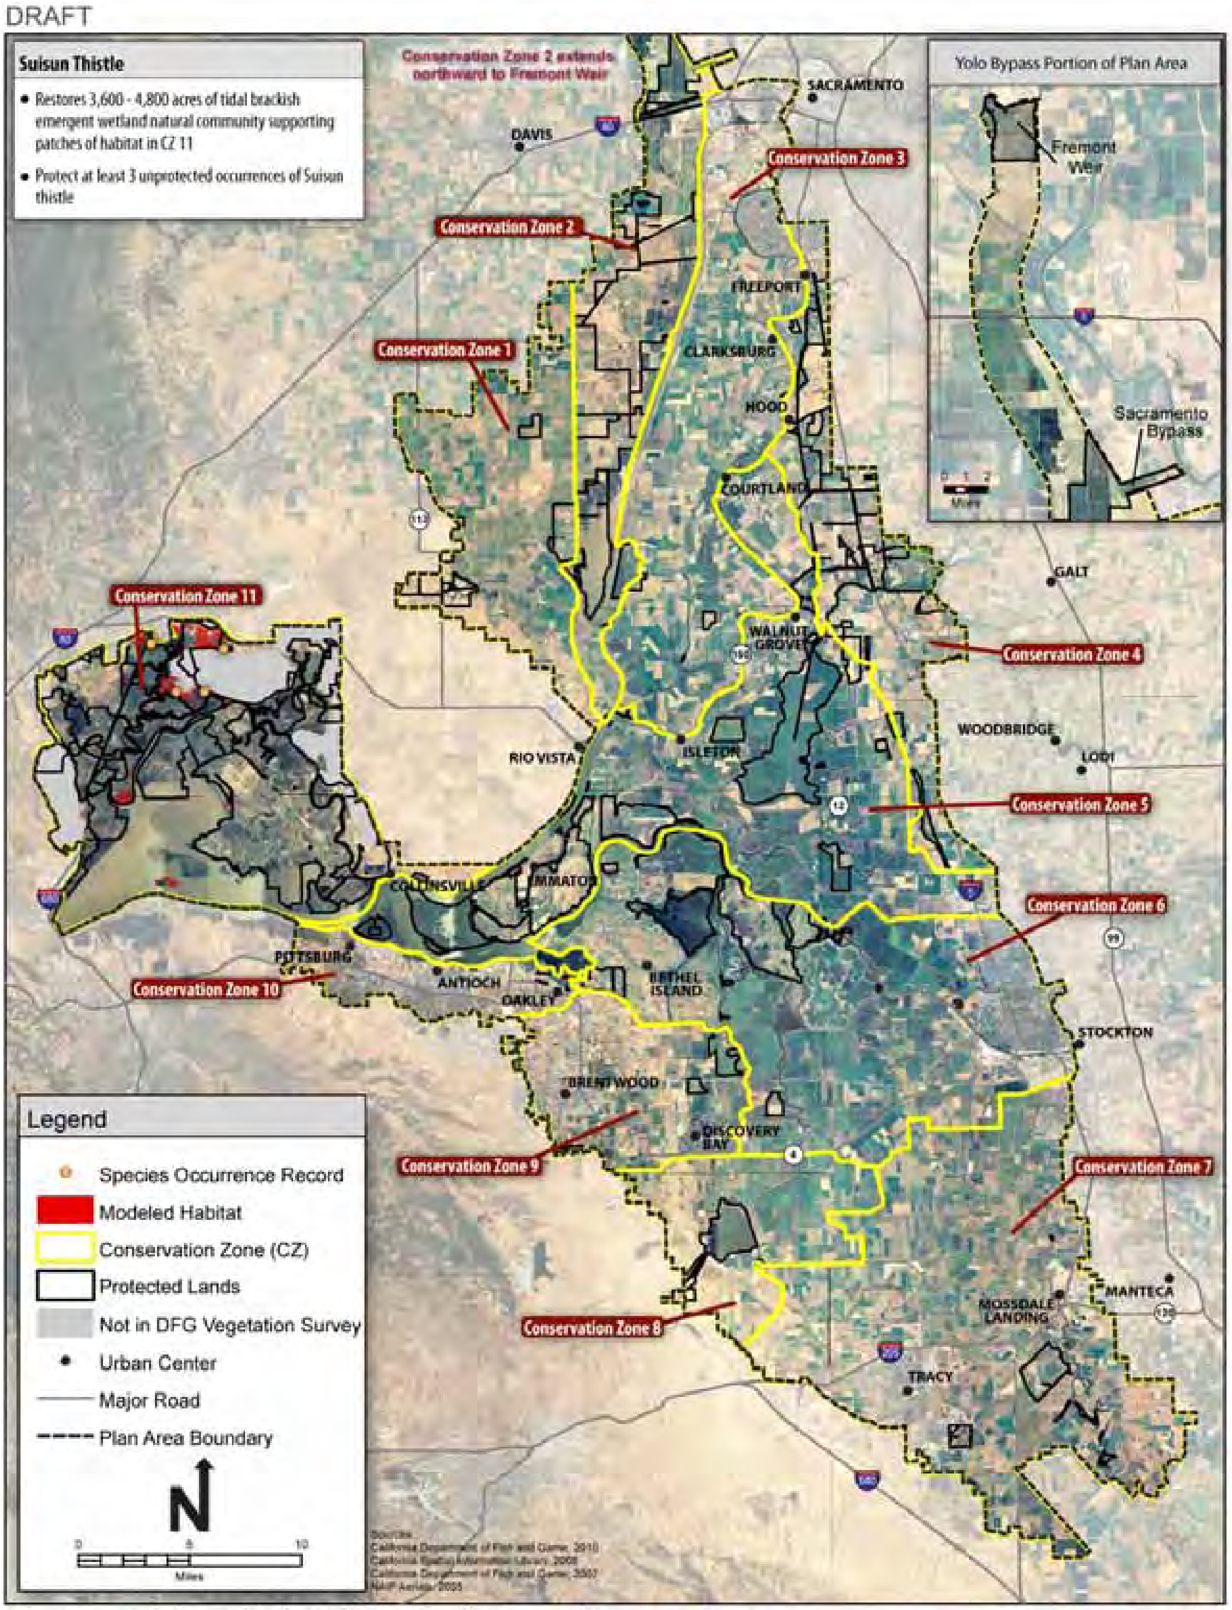

Figure 3-43. Suisun Thistle Habitat Distribution and Conservation Strategy

DRAFT

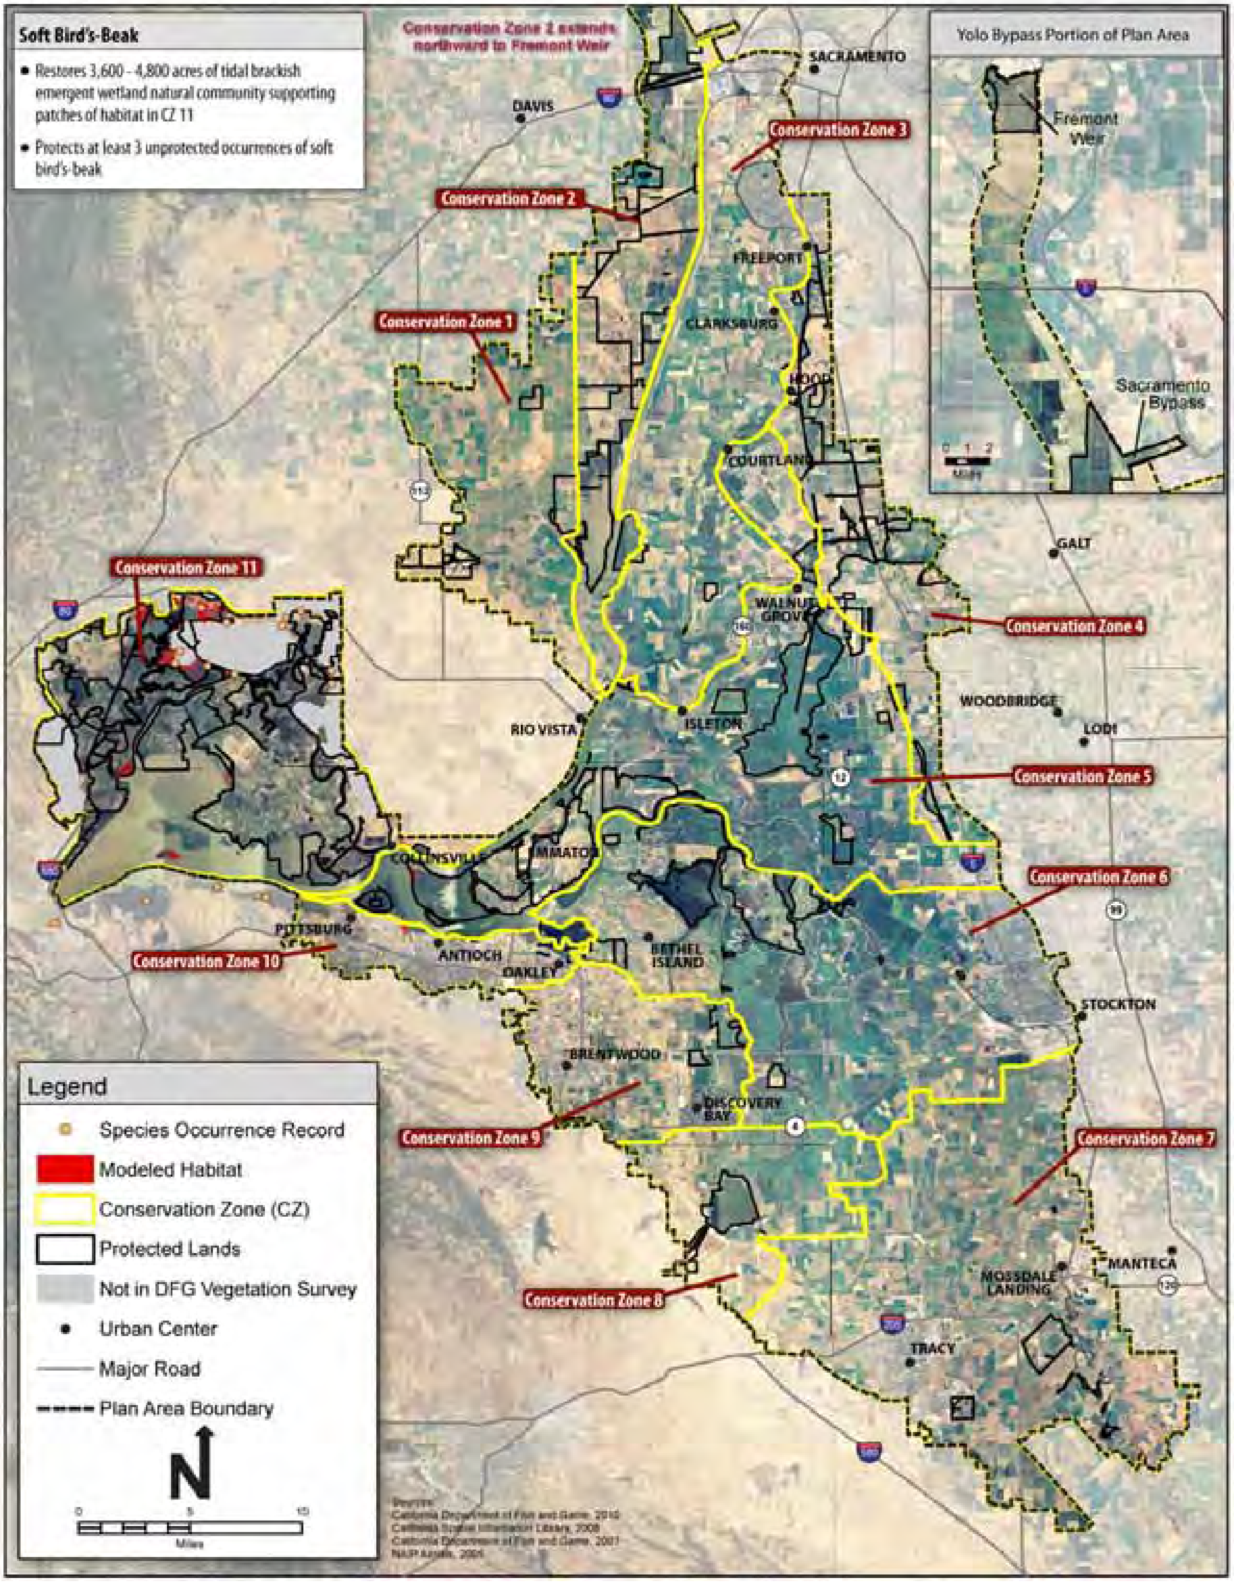

Figure 3-44. Soft Bird's-Beak Habitat Distribution and Conservation Strategy

3.3.2.4.31 Delta Button-celery

Delta button-celery is endemic to the San Joaquin Valley of California and is listed as endangered under the California Endangered Species Act (see Appendix A, *Covered Species Accounts*). It occurs in two habitat types: (1) seasonally scoured and inundated swales, depressions, and clay flats in the floodplain of the San Joaquin River (D. Woolington pers. comm.); (2) alkaline clay deltas of Coast Range tributaries that are deposited immediately above the flood basin of the San Joaquin River where plant cover is typical alkaline sink vegetation (NatureServe 2008). The primary threats to Delta button-celery include habitat loss through agricultural habitat conversion, channelization and channel maintenance activities and other impacts that include overgrazing, invasive nonnative plant species. Six of all 26 recorded occurrences have been extirpated by agricultural expansion and disturbance (NatureServe 2008). Thus, where the Delta button-celery still occurs – including both locations where it has been recorded in the Plan Area, land preservation is important to protect it from any further extirpation. BDCP implementation will tie in with habitat preservation on public lands such as Caswell Memorial State Park and the San Joaquin County Multi-species Habitat Conservation and Open Space Plan.

Applicable Natural Community Goals and Objectives

Goal VRNC1: The expected outcome is restored large expanses and interconnected corridors of valley/foothill riparian natural community.

> **Objective VRNC1.1**: Restore or create 5,000 acres of valley/foothill riparian in Conservation Zones 1, 2, 4, 5, 6, 7, and/or 11.

Goal VRNC2: The expected outcome is biologically diverse valley/foothill riparian natural community that supports native species and is sustained by natural ecological processes.

> **Objective VRNC2.1**: Maintain and enhance the habitat and ecosystem functions of BDCP restored valley/foothill riparian and patches of riparian forest and scrub present on BDCP preserved lands over the term of the BDCP.

> **Objective VRNC2.3**: Restore connectivity of valley/foothill riparian corridors along linear watercourses to enhance habitat for covered species and facilitate wildlife movement.

Goal AWNC1: The expected outcome is protected alkali seasonal wetland complex natural community that represents a range of environmental conditions and is adjacent to other conserved lands.

> **Objective AWNC1.1**: Protect 400 acres of alkali seasonal wetland complex natural community in Conservation Zones 1, 8, and/or 11.

Goal AWNC2: The expected outcome is biologically diverse alkali seasonal wetland complex natural community with improved native biodiversity, habitat heterogeneity, and the ability to support populations of covered and other native species.

Objective AWNC2.1: Maintain and, where habitat functions for covered species can be increased, increase the diversity and relative cover of native grasses and forbs.

Species-Specific Goals and Objectives

Goal DEBC1: The expected outcome is protected and expanded Delta button-celery populations.

Objective DEBC1.1: Of the 400 acres of protected alkali seasonal wetland complex natural community, protect at least 100 acres that support Delta button-celery habitat.

Objective DEBC1.2: Maintain and enhance the habitat functions of preserved Delta button-celery habitat over the term of the BDCP.

Rationale and Conservation Approach

Conservation of Delta button-celery will be directed at preserving at least 100 acres of currently unprotected alkali seasonal wetland complex that supports the known elements (e.g., soils, hydrology, etc.) of one of its habitat types and restoring at least 1,000 acres of floodplain habitat along the San Joaquin River that provide its other form of habitat which consists of seasonally scoured areas within the floodplain and channel (Figure 3-45). Protection of existing unprotected habitat will occur in Conservation Zone 8 and priority will be given to protecting habitat that supports occurrences or which will connect patches of occupied habitat. Restored floodplain habitat will be restored in Conservation Zone 7 and will be designed and managed to support patches of suitable habitat (e.g., soils, flood disturbance regime, etc.) (Figure 3-45). If appropriate, this species may be translocated to establish new occurrences within restored habitat. Protecting remaining occupied habitat areas and reestablishing patterns of flood flows to floodplain historically occupied by this species is expected to sustain the species within the Plan Area and provide for increases in the species distribution and abundance.

Applicable Conservation Measures

- CM3 Natural Communities Protection
- CM5 Seasonally Inundated Floodplain Restoration
- CM7 Riparian Habitat Restoration
- CM11 Natural Communities Enhancement and Management

DRAFT

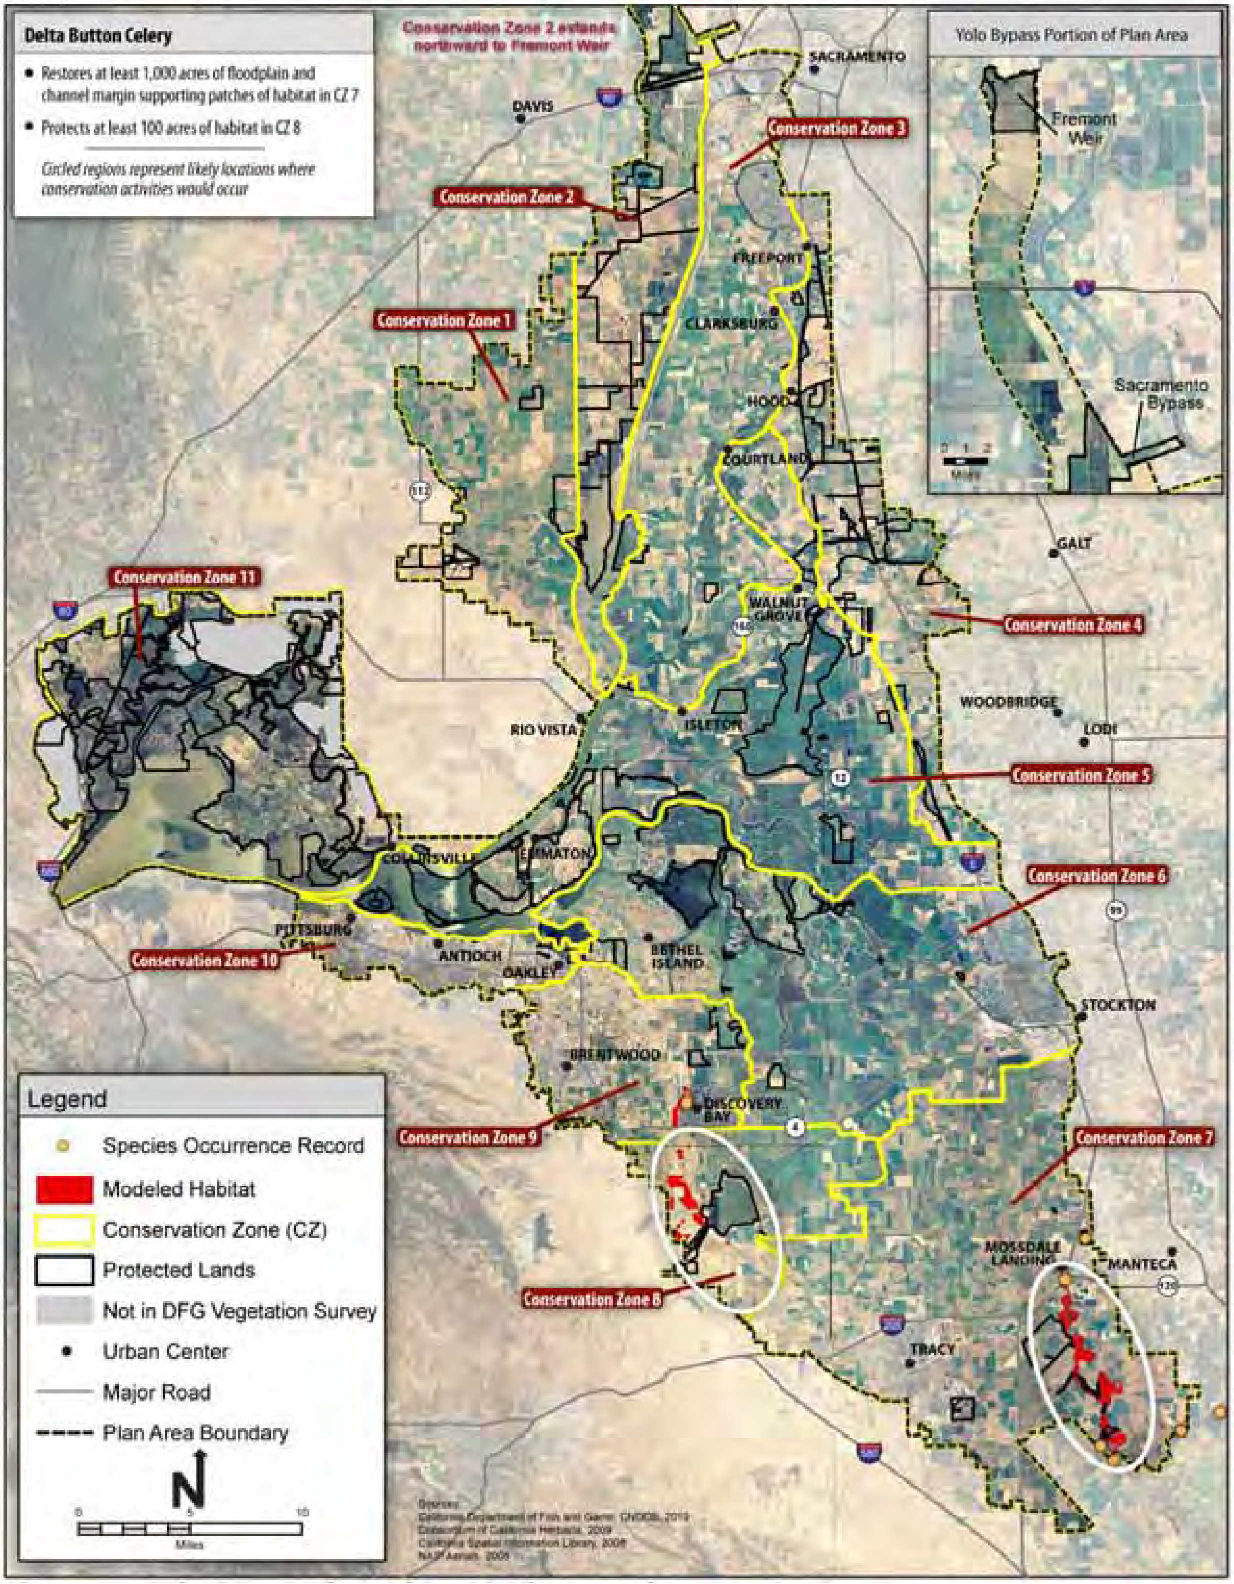

Figure 3- 45. Delta Button Celery Habitat Distribution and Conservation Strategy

3.3.2.4.32 Contra Costa Wallflower and Antioch Dunes Evening Primrose

Contra Costa wallflower and Antioch Dunes evening primrose are listed as endangered under both the federal Endangered Species Act and the California Endangered Species Act. They are endemic to the former Antioch Dune and persist on the small remnant of the dune. The extent of the former dune has been reduced to 20 acres plus an unknown amount on two Pacific Gas & Electric (PG&E) parcels that total 12 acres. The 20-acre known extent is protected on the Antioch Dunes National Wildlife Refuge (ADNWR) while the PG&E parcels are being managed under an MOU with USFWS. All existing habitat has been degraded by nonnative invasive plant species.

The current USFWS management plan for the ADNWR provides for invasive nonnative plant species control efforts that include hand pulling of individual invasive plants through the efforts of volunteers, targeted herbicide application, the restoration of some dune-like topography, and the planting of nursery grown stock and seed of Contra Costa wallflower and Antioch Dunes evening primrose.

The known natural occurrences of Contra Costa wallflower and Antioch Dunes evening primrose within the Plan Area are located exclusively within the ADNWR and on the two adjacent PG&E properties and are fully protected by ownership and conservation MOUs. These protected lands are completely isolated from other terrestrial habitats by development to the west, south, and east, and by the San Joaquin River to the north. Consequently, to increase the level of conservation benefits provided to inland dune scrub species, the inland dune scrub conservation will be implemented through the funding support of appropriate management actions and studies.

Applicable Natural Community Goals and Objectives

Goal IDSC1: The expected outcome is support for funding of the USFWS management and enhancement of the inland dune scrub natural community on the Antioch Dunes National Wildlife Refuge.

> **Objective IDSC1.1:** The BDCP will support the funding of the USFWS program for management, enhancement, and monitoring of inland dune scrub natural community on the Antioch Dunes National Wildlife Refuge at an annual amount of $XX.XX for X years.

Species-Specific Goals and Objectives

Goal CCWF/ADEP1: The expected outcome is funding support for the USFWS implementation of the propagation and out-planting program for Contra Costa wallflower and Antioch Dunes evening primrose.

> **Objective CCWF/ADEP1.1:** The BDCP will support the funding of the USFWS program for propagation and out-planting program for Contra Costa wallflower and Antioch Dunes evening primrose at an annual amount of $XX.XX for X years.

Rationale and Conservation Approach

After the recent 5-year review of the recovery plan by USFWS found that Contra Costa wallflower and Antioch Dunes evening primrose were declining significantly at the ADNWR and appeared to be headed towards extinction, USFWS began an out-planting of nursery grown stock and direct seeding into restored sandy habitat in 2005 and 2006 which appears to have stopped the decline. However, the populations are not yet considered to be self-sustaining because of invasive species problems (USFWS 2008). The current ADNWR management plan is designed to meet the recovery needs for the species of the ADNWR and provides for invasive nonnative plant species control efforts, restoration of dune-like topography, and the out-planting of nursery-grown stock and seed.

Conservation of Contra Costa wallflower and Antioch Dunes evening primrose will be provided through the support of funding for the USFWS planting and seeding program and its management of the ADNWR (Figure 3-46).

Applicable Conservation Measures

- CM11 Natural Communities Enhancement and Management

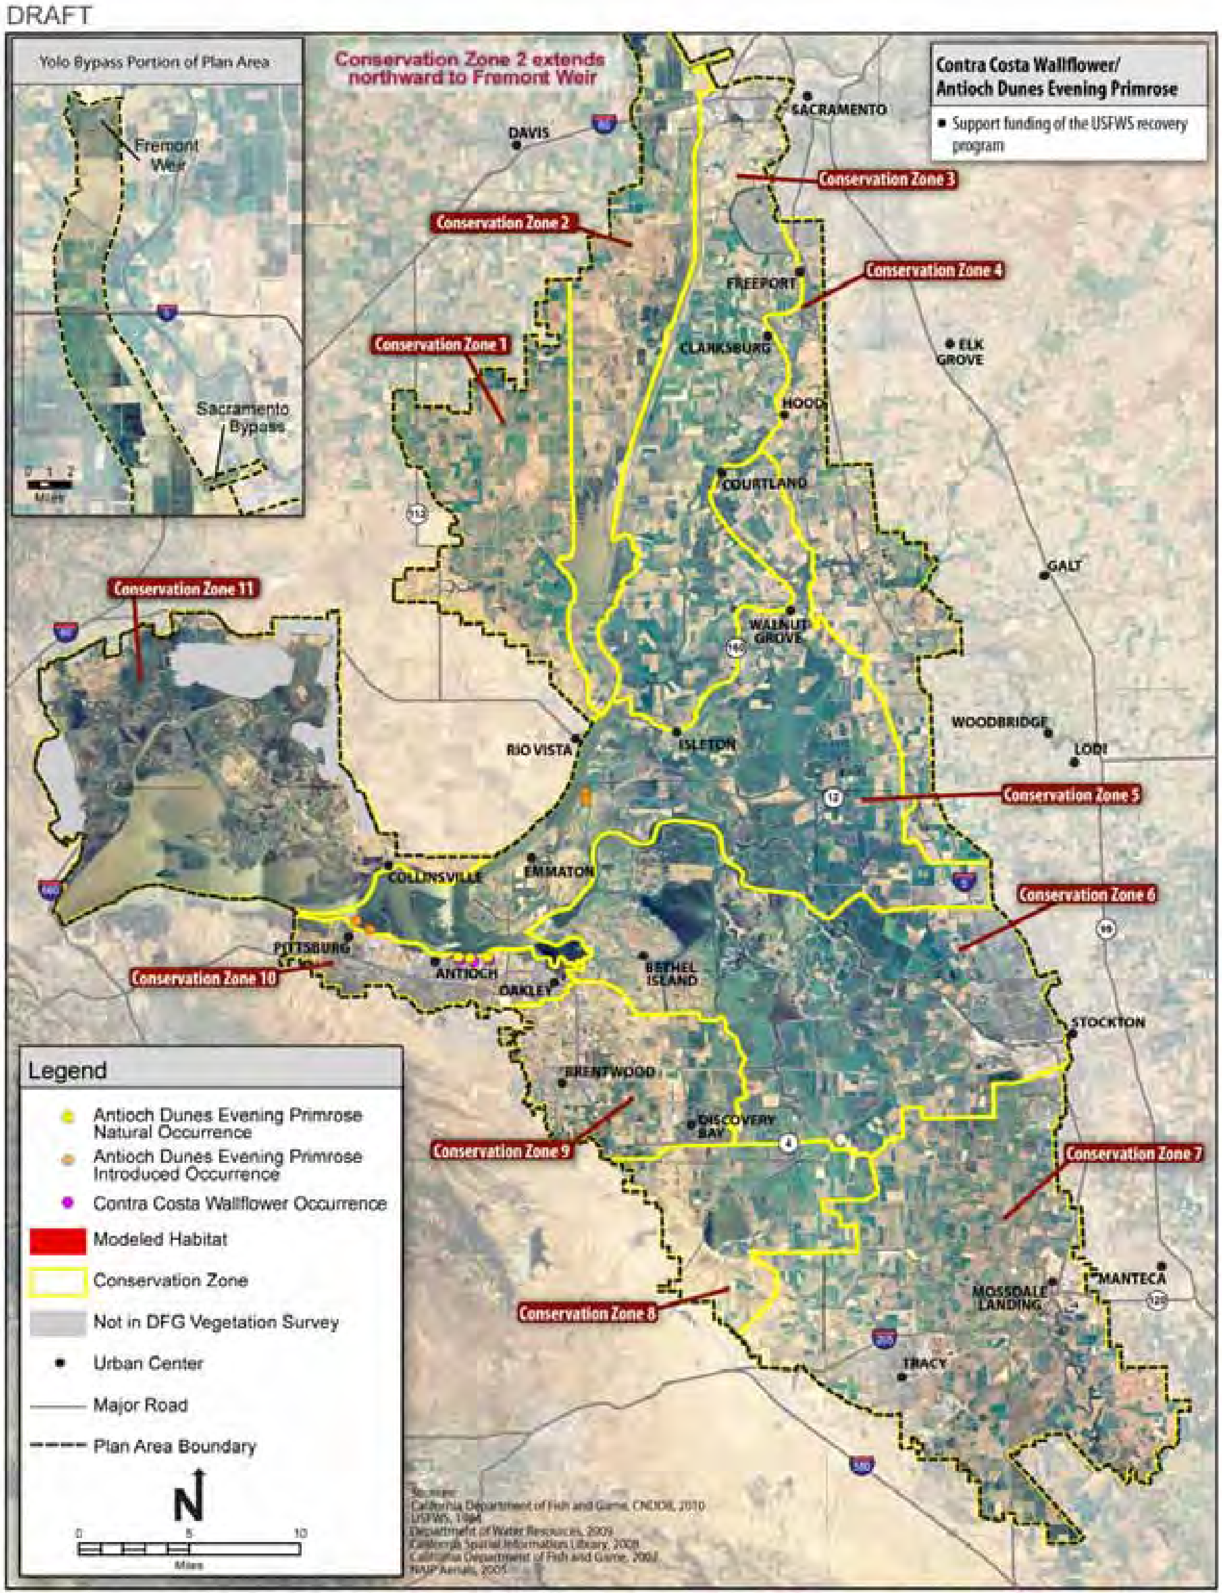

Figure 3- 46. Contra Costa Wallflower and Antioch Dunes Evening Primrose Habitat Distribution and Conservation Strategy

3.3.2.4.33 Carquinez Goldenbush

Carquinez goldenbush is known only from a very limited geographic range in Solano County, California (Nesom 1991, Hickman 1993, CNDDB 2009, CNPS 2009). It appears to be restricted to alluvial soils along ephemeral drainages associated with the Tehama geological formation and the Montezuma Block north and west of the Montezuma Hills in Solano County (Hickman 1993, Graymer et al. 2002, CNPS 2009, NRCS 2009). Carquinez goldenbush has been affected by agricultural land conversion, grazing, road widening, and development (CNPS 2009). Because Carquinez goldenbush is known only from 13 occurrences and its small populations are within the potential Impacts Area and in adjacent area immediately outside of the Plan and Impacts Areas, the emphasis of BDCP conservation measures will be on the protection of land with potential Carquinez goldenbush habitat.

Applicable Natural Community Goals and Objectives

Goal GRNC1: The expected outcome is grassland comprised of large interconnected patches or contiguous expanses.

> **Objective GRNC1.1**: Protect a minimum of 8,000 acres of grassland in Conservation Zones 1, 8, and 11. At least 1,000 acres will be protected in Conservation Zone 8, with the remainder distributed throughout these three Conservation Zones.

> **Objective GRNC1.2**: Restore 2,000 acres of grassland to connect fragmented patches of protected grassland.

Goal GRNC2: The expected outcome is biologically diverse grassland managed to enhance native species and sustained by natural ecological processes.

> **Objective GRNC2.1**: Restore and sustain a mosaic of grassland vegetation alliances, reflecting local water availability, soil chemistry, soil texture, topography, and disturbance regimes, with consideration of historical states.

> **Objective GRNC2.2**: Increase the relative cover of native grasses and forbs in native grassland vegetation alliances.

Goal AWNC1: The expected outcome is protected alkali seasonal wetland complex natural community that represents a range of environmental conditions and is adjacent to other conserved lands.

> **Objective AWNC1.1**: Protect 400 acres of alkali seasonal wetland complex natural community in Conservation Zones 1, 8, and/or 11.

Goal AWNC2: The expected outcome is biologically diverse alkali seasonal wetland complex natural community with improved native biodiversity, habitat heterogeneity, and the ability to support populations of covered and other native species.

> **Objective AWNC2.1**: Maintain and, where habitat functions for covered species can be increased, increase the diversity and relative cover of native grasses and forbs.

Species-Specific Goals and Objectives

Goal CAGB1: The expected outcome is protected and expanded Carquinez goldenbush populations.

> **Objective CAGB1.1:** Protect at least 3 unprotected occurrences of Carquinez goldenbush in Conservation Zones 1 and/or 11.

> **Objective CAGB1.2**: Maintain and enhance the habitat functions of preserved Carquinez goldenbush habitat over the term of the BDCP.

Rationale and Conservation Approach

Conservation of Carquinez goldenbush will be directed at preserving 300 acres of currently unprotected habitat that supports the known elements (e.g., soils, hydrology, etc.) of its habitat and 3 unprotected occurrences (Figure 3-47). Priority will be given to protecting habitat that supports occurrences or are connected to occupied habitat in Conservation Zones 1 and 11 (Figure 3-47). Protection of Carquinez goldenbush habitat will be achieved through the preservation and enhancement of its habitat in stream corridors with appropriate buffers and in localized patches along the margin of Suisun Marsh in the same general locations as Montezuma Block vernal pools and playa pools and associated grassland and alkali seasonal wetland complex natural communities (see Section 2.3.4.9, *Vernal Pool Complex*) in Conservation Zones 1 and 11 (Figure 3-47).

Protection and enhancement of Carquinez goldenbush habitat will be conducted in conjunction with the protection, enhancement, and restoration of grassland and alkali seasonal wetland complex natural communities in that conservation zone. To the extent practicable, Carquinez goldenbush habitat will be protected in the largest possible linear corridor extents and management of protected habitat (e.g., control of nonnative invasive species, restoration of natural hydrological regime, appropriate grazing intensity, etc.) will be designed to enhance habitat functions for Carquinez goldenbush and other covered associated species.

Protected habitat will be incorporated within larger patches of protected grassland and vernal pool complex habitats that will complement their wetland habitat functions and will be managed to improve habitat conditions for these species (e.g., control of invasive nonnative plant species). If desirable and consistent with adjacent conservation plans, unpreserved occupied habitat may be protected adjacent to the Plan Area.

The protection of Carquinez goldenbush habitat is expected to help maintain and provide the basis for potentially increasing the distribution and abundance Carquinez goldenbush in the Plan Area. Following implementation of BDCP actions, approximately 67 percent of the species' habitat will be preserved in the Plan Area.

Applicable Conservation Measures

- CM3 Natural Communities Protection
- CM8 Grassland Communities Restoration
- CM9 Vernal Pool Complex Restoration
- CM11 Natural Communities Enhancement and Management

DRAFT

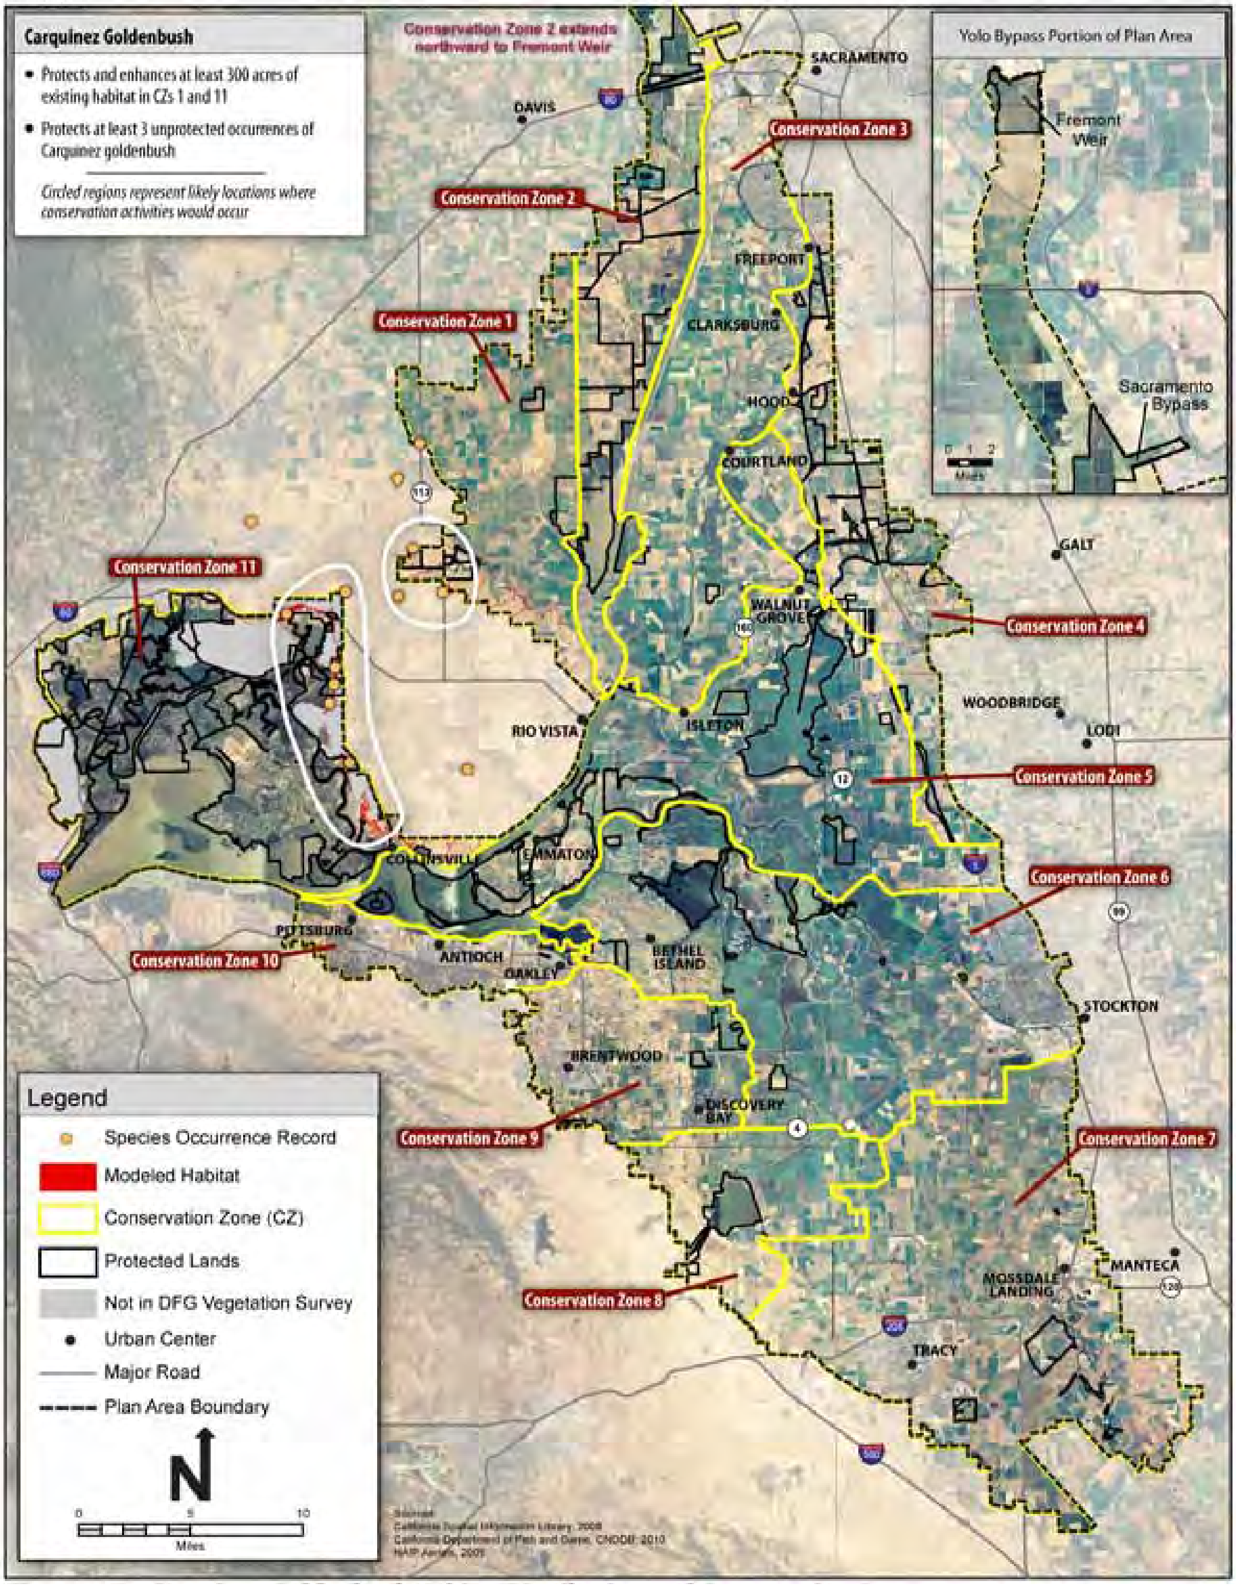

Figure 3- 47. Carquinez Goldenbush Habitat Distribution and Conservation Strategy

3.3.2.4.34 Delta Tule Pea and Suisun Marsh Aster

Delta tule pea and Suisun Marsh aster occur from Sacramento and Solano counties in the north, Napa and Sonoma counties in the west, and Contra Costa and San Joaquin counties in the south. Historically, Suisun Marsh aster was also known from marshes in the East Bay portion of San Francisco Bay (California State Coastal Conservancy 2003). Within the Plan Area, these species occur in tidal areas throughout Suisun Marsh and the west and central Delta with scattered occurrences in the north and south Delta (Figure 3-48). Typically they occur on the upper margins of tidal brackish and tidal freshwater marshes, river channels, creek channels, and sloughs in the ecotone with terrestrial habitats (Goals Project 2000). The tidal marsh habitat and channel margin habitat suitable for Delta tule pea and Suisun marsh aster has been lost mostly through development, dredge disposal, waterfowl habitat creation, agricultural conversion, and levee and dike building.

Applicable Natural Community Goals and Objectives

Goal MFNC1: The expected outcome is areas of tidal mudflat that provide foraging habitat for shorebirds and wading birds, and substrates suitable for the natural establishment of BDCP covered plant species.

> **Objective MFNC1.1:** Restore or create 20 linear miles of edge areas within other natural communities that serve as tidal mudflat substrate and which will support habitat for tidal mudflat-associated species as a component of BDCP restored tidal brackish emergent wetland and tidal freshwater emergent wetland natural communities and channel margin enhancement.

> **Objective MFNC1.2:** Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal mudflat as a component of BDCP restored brackish and freshwater tidal habitat and channel margin enhancement for covered and other native species over the term of the BDCP.

Goal BMNC1: The expected outcome is restored large expanses and interconnected patches of tidal brackish emergent wetland natural community.

> **Objective BMNC1.1:** Restore or create 3,600 to 4,800 acres of tidal brackish emergent wetland in the Suisun Marsh ROA (Conservation Zone 11).

Goal BMNC2: The expected outcome is biologically diverse tidal brackish emergent wetland that is enhanced for native species and sustained by natural ecological processes.

> **Objective BMNC2.1:** Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal brackish emergent wetland for covered and other native species over the term of the BDCP.

Goal FMNC1: The expected outcome is restored large, interconnected patches of tidal freshwater emergent wetland natural community.

> **Objective FMNC1.1:** Restore or create 13,900 to 21,600 acres of tidal freshwater emergent wetland in the Cache Slough, West Delta, Cosumnes-Mokelumne, and South Delta ROAs (Conservation Zones 1, 2, 4, 5, 6, and 7).

Goal FMNC2: The expected outcome is biologically diverse tidal freshwater emergent wetland that is enhanced for native species and sustained by natural ecological processes.

> **Objective FMNC2.1:** Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal freshwater emergent wetlands for covered and other native species over the term of the BDCP.

Goal VRNC1: The expected outcome is restored large expanses and interconnected corridors of valley/foothill riparian natural community.

> **Objective VRNC1.1**: Restore or create 5,000 acres of valley/foothill riparian in Conservation Zones 1, 2, 4, 5, 6, 7, and/or 11.

Goal VRNC2: The expected outcome is biologically diverse valley/foothill riparian natural community that supports native species and is sustained by natural ecological processes.

> **Objective VRNC2.1**: Maintain and enhance the habitat and ecosystem functions of BDCP restored valley/foothill riparian and patches of riparian forest and scrub present on BDCP preserved lands over the term of the BDCP.

Rationale and Conservation Approach

Because habitat loss and exotic species are the primary stressors on Delta tule pea and Suisun Marsh aster, protecting, enhancing, and restoring tidal natural communities is expected to help maintain and potentially increase the abundance and distribution of these species. Conservation of Delta tule pea and Suisun Marsh aster will be directed at restoring a total of between 16,970 and 26,470 acres of tidal freshwater emergent wetland, floodplain, and valley/foothill riparian habitat in Conservation Zones 1, 2, 5, 6, 7, and 11 (Figure 3-48). The conservation actions are consistent with and help to achieve the draft recovery objectives for Delta tule pea identified in the Draft Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (USFWS 2010).

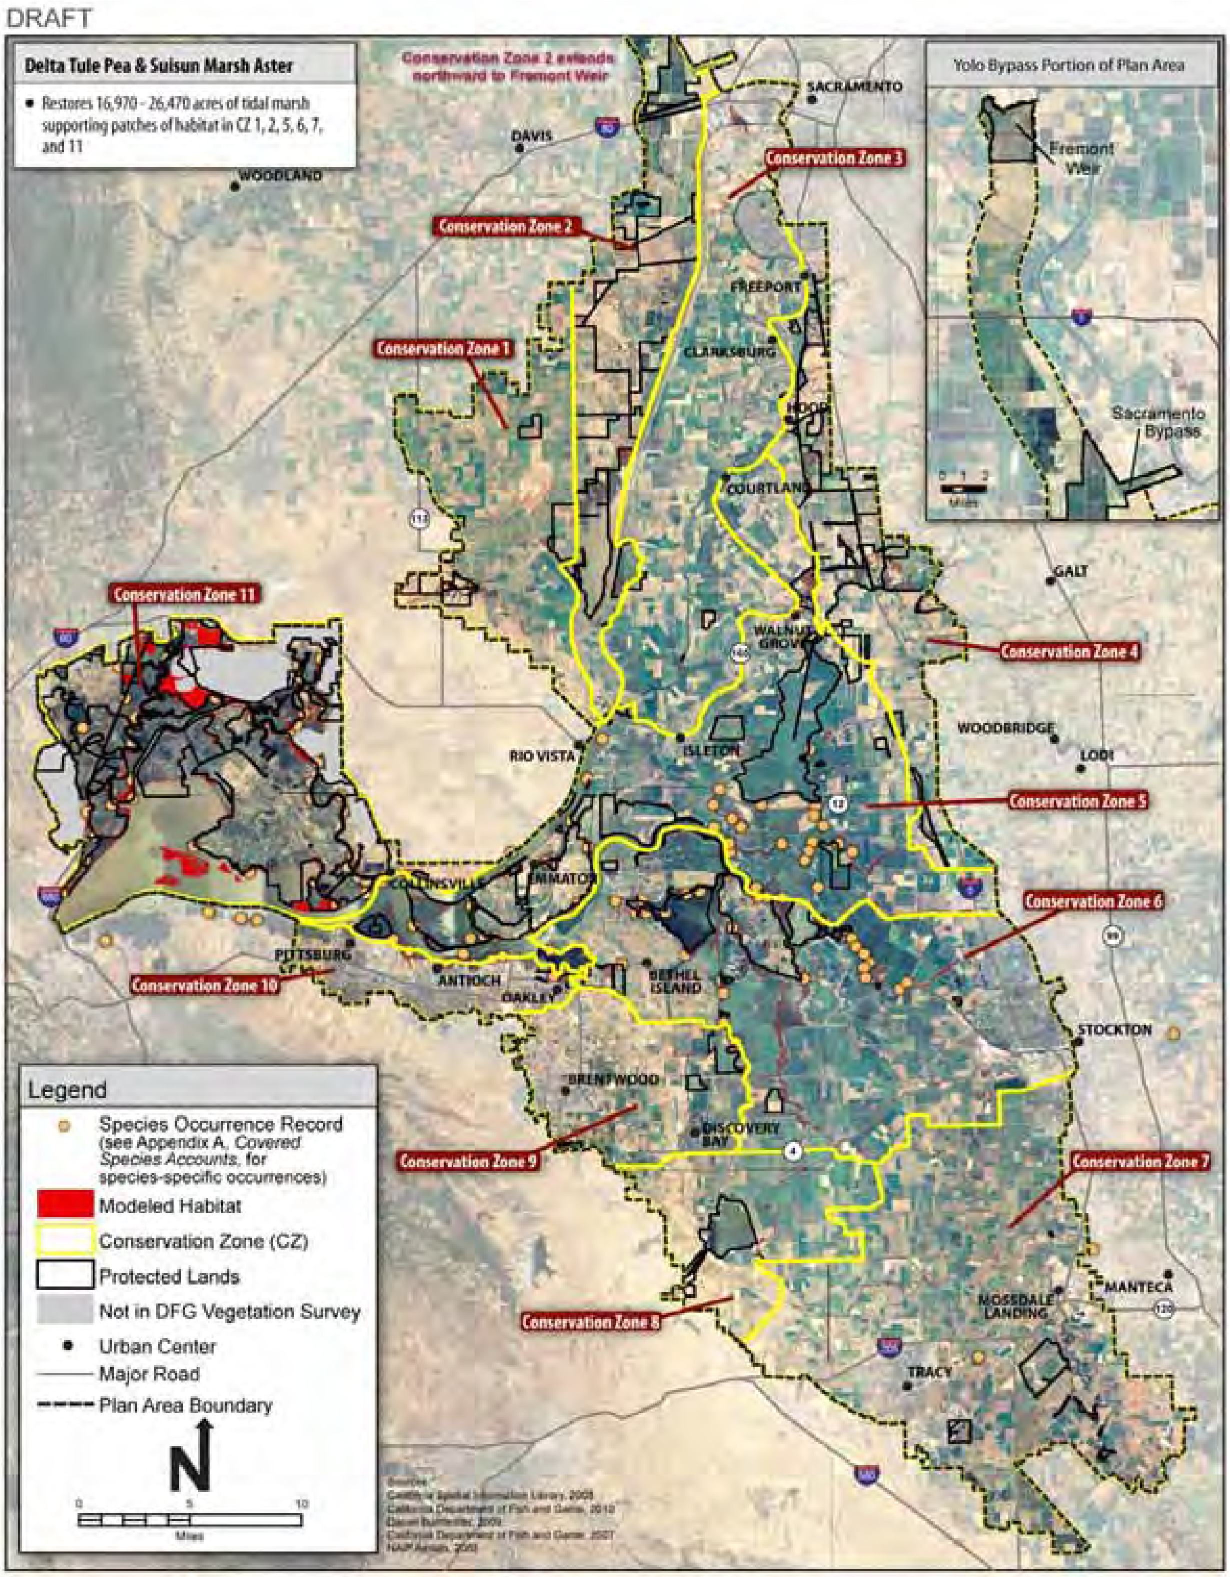

Figure 3-48. Delta Tule Pea and Suisun Marsh Aster Habitat Distribution and Conservation Strategy

3.3.2.4.35 Mason's Lilaeopsis and Delta Mudwort

Mason's lilaeopsis is endemic to California (Calflora 2007) while Delta mudwort can be found outside of California in British Columbia, on the east coast of North America, and in Europe (Hickman 1993). The range of Mason's lilaeopsis extends from Napa and Solano counties in the north, to Contra Costa and Alameda counties in the south, to Marin County in the west, and Sacramento and San Joaquin counties in the east while Delta mudwort only extends as far west as Suisun Marsh (CNDDB 2008).

Both species are found in relatively unvegetated areas within tidal brackish or tidal freshwater habitats that are inundated by waves or tides such as estuarine wetlands and immediately below the banks of tidal sloughs, rivers, and creeks (Golden and Fiedler 1991, Fiedler and Zebell 1993, DFG 2000, CNPS 2008). They are colonizing species that establish on newly deposited or exposed sediments (CNPS 2008) and prefer low tidal mudflats on clayey or silty soils (Witham and Kareofelas 1994).

The tidal marsh and tidal channel margin habitats suitable for Mason's lilaeopsis and Delta mudwort has been lost mostly through development, dredge disposal, waterfowl habitat creation, agricultural conversion, and levee and dike building.

Applicable Natural Community Goals and Objectives

Goal MFNC1: The expected outcome is areas of tidal mudflat that provide foraging habitat for shorebirds and wading birds, and substrates suitable for the natural establishment of BDCP covered plant species.

> **Objective MFNC1.1:** Restore or create 20 linear miles of edge areas within other natural communities that serve as tidal mudflat substrate and which will support habitat for tidal mudflat-associated species as a component of BDCP restored tidal brackish emergent wetland and tidal freshwater emergent wetland natural communities and channel margin enhancement.

> **Objective MFNC1.2:** Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal mudflat as a component of BDCP restored brackish and freshwater tidal habitat and channel margin enhancement for covered and other native species over the term of the BDCP.

Goal BMNC1: The expected outcome is restored large expanses and interconnected patches of tidal brackish emergent wetland natural community.

> **Objective BMNC1.1:** Restore or create 3,600 to 4,800 acres of tidal brackish emergent wetland in the Suisun Marsh ROA (Conservation Zone 11).

Goal BMNC2: The expected outcome is biologically diverse tidal brackish emergent wetland that is enhanced for native species and sustained by natural ecological processes.

> **Objective BMNC2.1:** Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal brackish emergent wetland for covered and other native species over the term of the BDCP.

Goal FMNC1: The expected outcome is restored large, interconnected patches of tidal freshwater emergent wetland natural community.

> **Objective FMNC1.1:** Restore or create 13,900 to 21,600 acres of tidal freshwater emergent wetland in the Cache Slough, West Delta, Cosumnes-Mokelumne, and South Delta ROAs (Conservation Zones 1, 2, 4, 5, 6, and 7).

Goal FMNC2: The expected outcome is biologically diverse tidal freshwater emergent wetland that is enhanced for native species and sustained by natural ecological processes.

> **Objective FMNC2.1:** Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal freshwater emergent wetlands for covered and other native species over the term of the BDCP.

Rationale and Conservation Approach

Because habitat loss and exotic species are the primary stressors on Mason's lilaopsis and Delta mudwort, protecting, enhancing, and restoring tidal natural communities is expected to help maintain and potentially increase the abundance and distribution of these species. Conservation of Mason's lilaopsis and Delta mudwort will be directed at restoring between 16,980 and 26,560 acres of tidal marsh, floodplain, and riparian habitat in Conservation Zones 1, 2, 4, 5, 6, 7, and 11 (Figure 3-49).

- CM4 Tidal Habitat Restoration
- CM11 Natural Communities Enhancement and Management

DRAFT

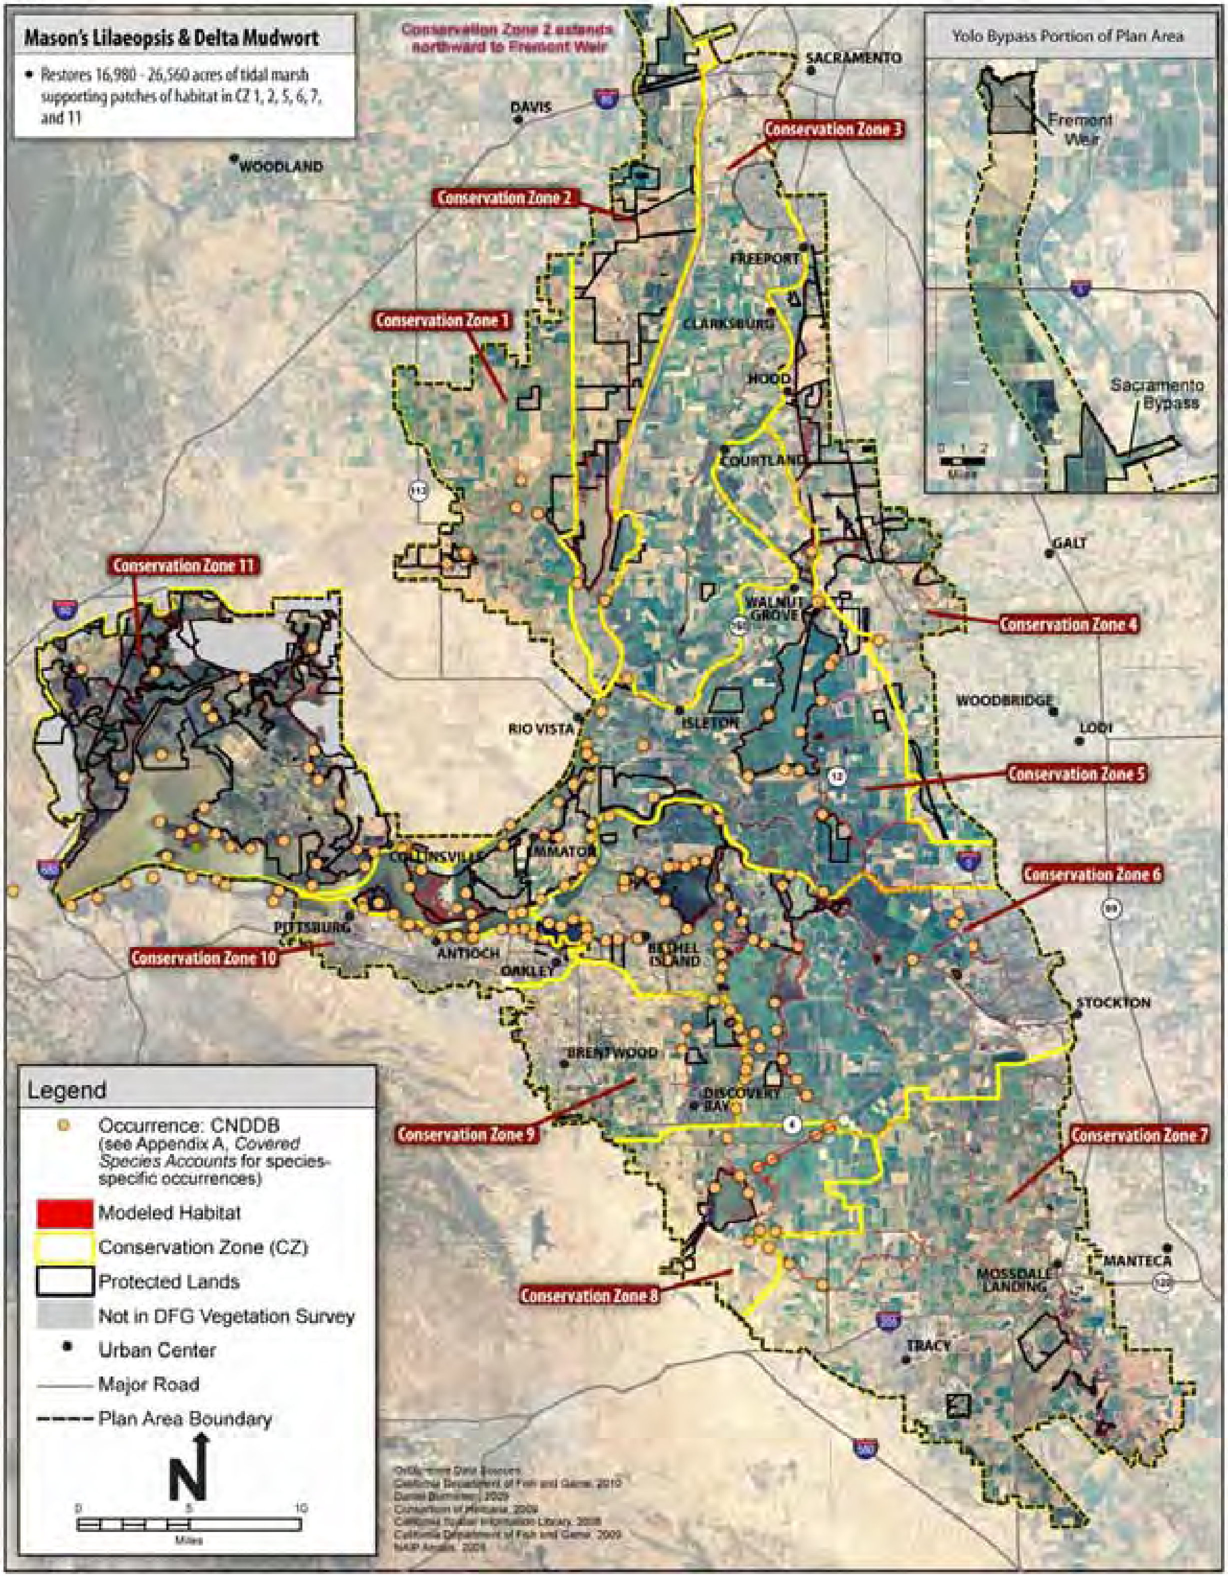

Figure 3- 49. Mason's Lileaopsis and Delta Mudwort Habitat Distribution and Conservation Strategy

3.3.2.4.36 Side-flowering Skullcap

Side-flowering skullcap is known only from a very limited geographic range in California, all of which are in the Delta around Bouldin Island in San Joaquin County, Delta Meadows State Park area, and Sycamore Slough (CNDDB 2010). The Bouldin Island location was recorded in 1892, and the exact location of the collection is unknown. The Delta Meadows State Park occurrence was recorded in 1993. During botanical surveys of the Plan Area conducted by DWR/DHCCP in the summer of 2009, side-flowering skullcap was found growing on rotting pilings and stumps in and along the channels of Snodgrass Slough, Lost Slough, and the Mokelumne River. In the Pacific Northwest it is found on similar coarse woody debris substrates.

Applicable Natural Community Goals and Objectives

Goal FMNC1: The expected outcome is restored large, interconnected patches of tidal freshwater emergent wetland natural community.

> **Objective FMNC1.1:** Restore or create 13,900 to 21,600 acres of tidal freshwater emergent wetland in the Cache Slough, West Delta, Cosumnes-Mokelumne, and South Delta ROAs (Conservation Zones 1, 2, 4, 5, 6, and 7).

Goal FMNC2: The expected outcome is biologically diverse tidal freshwater emergent wetland that is enhanced for native species and sustained by natural ecological processes.

> **Objective FMNC2.1:** Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal freshwater emergent wetlands for covered and other native species over the term of the BDCP.

Goal VRNC1: The expected outcome is restored large expanses and interconnected corridors of valley/foothill riparian natural community.

> **Objective VRNC1.1**: Restore or create 5,000 acres of valley/foothill riparian in Conservation Zones 1, 2, 4, 5, 6, 7, and/or 11.

Goal VRNC2: The expected outcome is biologically diverse valley/foothill riparian natural community that supports native species and is sustained by natural ecological processes.

> **Objective VRNC2.1**: Maintain and enhance the habitat and ecosystem functions of BDCP restored valley/foothill riparian and patches of riparian forest and scrub present on BDCP preserved lands over the term of the BDCP.

Rationale and Conservation Approach

Most side-flowering skullcap plants found in the Plan Area are located within or directly adjacent to Delta Meadows State Park, a California State Park that was established to preserve and protect one of the last remaining areas of the northern Sacramento-San Joaquin River Delta that possesses large stands of fairly mature valley/foothill riparian vegetation (California State Parks 2010). Historically, it may have existed on decaying fallen trees and stumps along riparian channels and sloughs at the lower margin of valley/foothill riparian and the upper margin of tidal freshwater emergent wetland natural communities.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for side-flowering skullcap is "Maintain" (CALFED Bay-Delta Program 2000). This designation indicates that the ERP will undertake actions to maintain the species by avoiding, minimizing, and compensating for any adverse effects to the species created by ERP restoration actions. It also means that the species' population and habitat are unlikely to be affected by ERP actions.

As part of valley/foothill riparian restoration and channel margin enhancement, coarse woody debris substrate will be made available for side-flowering skullcap establishment. Where side-flowering skullcap is found to already be present on stumps or other substrate, the movement and transplantation of the substrate and plants to appropriate sites in the immediate vicinity will be used to minimize impacts (Figure 3-50).

Applicable Conservation Measures

- CM3 Natural Communities Protection
- CM4 Tidal Habitat Restoration
- CM6 Channel Margin Habitat Enhancement
- CM7 Riparian Habitat Restoration
- CM11 Natural Communities Enhancement and Management

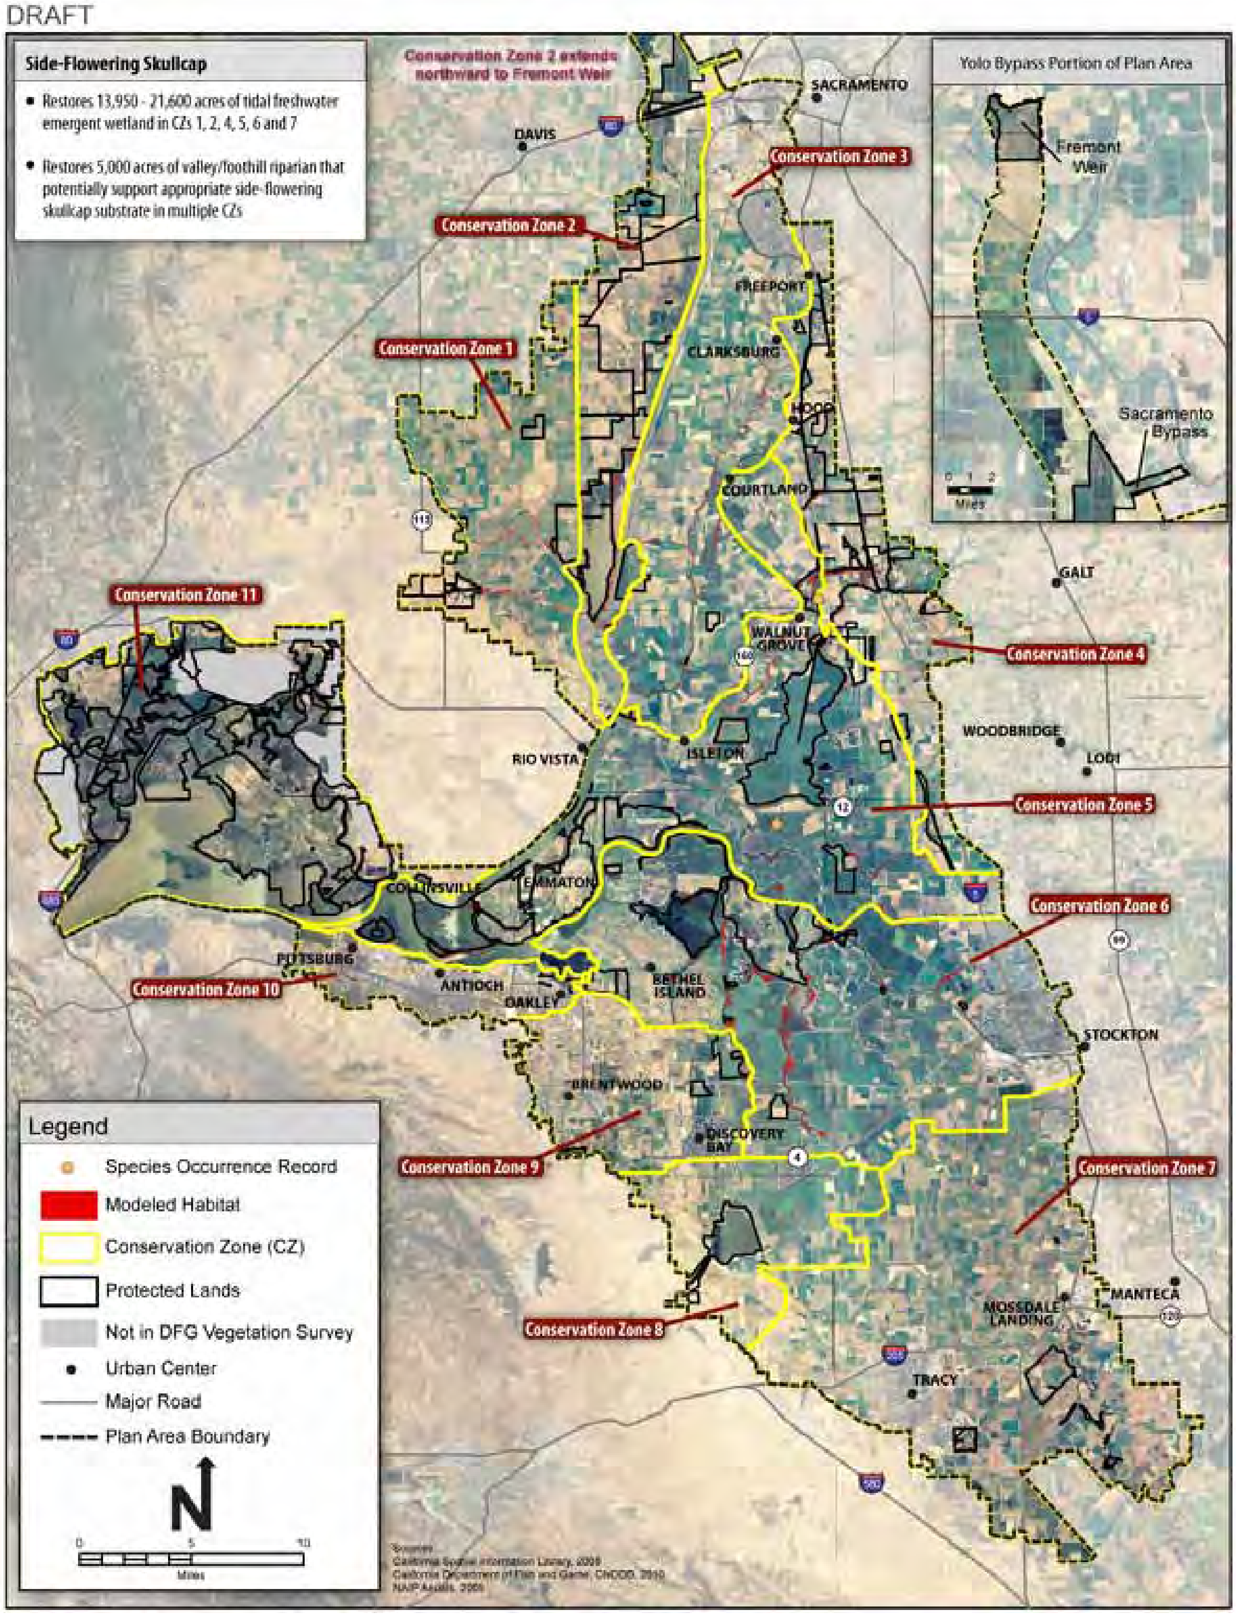

Figure 3-50. Side-Flowering Skullcap Habitat Distribution and Conservation Strategy

3.3.2.4.37 Caper-Fruited Tropidocarpum

Caper-fruited tropidocarpum is endemic to California, where its distribution is extremely limited (Appendix A, *Covered Species Accounts*). With only 19 observations of this plant and most known occurrences facing threats, caper-fruited tropidocarpum is considered by the California Native Plant Society to be seriously endangered (CNPS 2009). The reasons for its limited abundance and distribution are not known, but based on its historical distribution in the Plan Area, most impacts appear to have occurred through intensive agriculture and urbanization or other development activities. Caper-fruited tropidocarpum occurs on valley and foothill grassland habitats on moderately alkaline soils (CNPS 2009) or in foothill oak woodland on slightly alkaline clay soils (CNDDB 2009).

The protection of caper-fruited tropidocarpum habitat in the Plan Area is expected to provide the basis for potentially increasing the species' distribution and abundance. Caper-fruited tropidocarpum was historically distributed along the southwestern boundary of the Plan Area, but today may only reside as seeds in a long-lived soil seed bank. It is sporadically distributed in the inner southern Coast Range. Its potential habitat in the Plan Area ranges from pastures to abandoned dry-farmed grainlands to areas that were not farmed, but which have been invaded by nonnative annual grasses. Based on its historical distribution in the Plan Area, most impacts have occurred through intensive agriculture and urbanization or other development activities. The protection of caper-fruited tropidocarpum habitat in the Plan Area is expected to provide the basis for potentially increasing the species' distribution and abundance.

Applicable Natural Community Goals and Objectives

Goal GRNC1: The expected outcome is grassland comprised of large interconnected patches or contiguous expanses.

> **Objective GRNC1.1**: Protect a minimum of 8,000 acres of grassland in Conservation Zones 1, 8, and 11. At least 1,000 acres will be protected in Conservation Zone 8, with the remainder distributed throughout these three Conservation Zones.

> **Objective GRNC1.2**: Restore 2,000 acres of grassland to connect fragmented patches of protected grassland.

Goal GRNC2: The expected outcome is biologically diverse grassland managed to enhance native species and sustained by natural ecological processes.

> **Objective GRNC2.1**: Restore and sustain a mosaic of grassland vegetation alliances, reflecting local water availability, soil chemistry, soil texture, topography, and disturbance regimes, with consideration of historical states.

> **Objective GRNC2.2**: Increase the relative cover of native grasses and forbs in native grassland vegetation alliances.

Species-Specific Goals and Objectives

Goal CFTR1: The expected outcome is protection and expansion of caper-fruited tropidocarpum populations.

Objective CFTR1.1: Protect occurrences of caper-fruited tropidocarpum that reestablish on BDCP conservation lands.

Objective CFTR1.2: Maintain and enhance the habitat functions of protected caper-fruited tropidocarpum occurrences over the term of the BDCP.

Objective CFTR1.3: Protect and maintain 100 acres of unprotected caper-fruited tropidocarpum grassland habitat in Conservation Zone 8.

Rationale and Conservation Approach

Conservation of caper-fruited tropidocarpum will include protecting and maintaining 100 acres of its remaining unprotected grassland habitats in Conservation Zone 8 (Figure 3-51). All caper-fruited tropidocarpum occurrences have apparently been extirpated in the Plan Area although the species may be present as a persistent seed bank. Protected habitat will be contiguous with and managed in conjunction with other protected habitats in Conservation Zone 8. Protected habitat will be monitored to determine if plants germinate in future years and any located occurrences will be protected and managed to encourage the expansion of such occurrences. Based on the level of BDCP habitat effects, the proposed preservation of caper-fruited tropidocarpum habitat is expected to provide for the conservation of caper-fruited tropidocarpum.

3.4 CONSERVATION MEASURES

This section presents the BDCP conservation measures that will be implemented by the BDCP Implementation Office to protect and improve the ecological function of natural communities; avoid, minimize, and compensate for impacts on covered species associated with implementation of covered activities; and provide for the conservation of covered species. Collectively the conservation measures are expected to achieve the BDCP biological goals and objectives. As described in Section 3.3, *Biological Goals and Objectives*, conservation measures address conveyance and water operations; protection, enhancement, and restoration of physical habitats that support covered species; and reductions in the effect of other stressors on covered species. Conservation measures were developed to address stressors at three ecological scales: ecosystem, natural community, and species-specific. Ecosystem-level conservation measures are presented in Section 3.4.2, natural community-level and species-specific conservation measures are presented in Sections 3.4.3 and 3.4.4, and avoidance and minimization measures for covered wildlife and plant species are presented in Section 3.4.5.

A summary list of BDCP conservation measures and the biological goals and objectives they serve is provided in Table 3-12. As is demonstrated in Table 3-12, many of the conservation measures address multiple goals and objectives. The following information is provided with each conservation measure, as appropriate, in Sections 3.4.2-3.4.4.

- **Problem Statement.** This section describes the ecological problems that are intended to be addressed by the conservation measure.
- **Hypothesized Benefits.** This section describes the hypotheses that justify the approach reflected in the conservation measure. Uncertainties and risks that could be associated with DRERIP-evaluated conservation measures are described in Appendix F, *DRERIP Evaluation Results*.

Table 3-12. Conservation Measures that Meet BDCP Conservation Strategy Goals and Objectives

Goals and Objectives	*Applicable Conservation Measures*
Ecosystem-Level Goals and Objectives	
Goal ECSY1: Protect and restore large landscapes representing a range of physical and biological attributes (e.g., hydrology, soil, and plant associations) necessary to sustain viable populations of covered species, and to preserve native species biodiversity.	
Objective ECSY1.1: Protect 25,000-41,000 acres of existing natural communities that support covered species.	CM3 Natural Communities Protection CM6 Channel Margin Habitat Enhancement
Objective ECSY1.2: Protect a range of environmental gradients (e.g., hydrology, elevation, and soils) across a diversity of natural communities.	CM3 Natural Communities Protection
Objective ECSY1.3: Restore or create up to 65,000 acres of tidally influenced habitat consisting of subtidal, mudflat, tidal marsh, and transitional upland habitat for sea level rise accommodation that supports a gradient of natural communities and habitat for covered species.	CM4 Tidal Habitat Restoration
Objective ECSY1.4: Restore or create up to 10,000 acres of seasonally inundated floodplain and 20 miles of channel margin habitat.	CM5 Seasonally Inundated Floodplain Restoration CM6 Channel Margin Habitat Enhancement
Objective ECSY1.5: Manage protected and restored or created habitats to enhance habitat functions for associated covered and other native species over the term of the BDCP.	CM11 Natural Communities Enhancement and Management
Goal ECSY2: Provide hydrodynamic conditions within Delta waterways that are more reflective of natural patterns of flow within the BDCP Plan Area and Suisun Marsh.	
Objective ECSY2.1: Support the movement of larval and juvenile life stages of native fish species to downstream rearing habitats.	CM1 Water Facilities and Operation CM2 Yolo Bypass Fisheries Enhancements CM16 Non-Physical Fish Barriers
Objective ECSY2.2: Support the movement of adult life stages of native fish species to natal spawning habitats.	CM1 Water Facilities and Operation CM2 Yolo Bypass Fisheries Enhancements
Objective ECSY 2.3: Promote water quality conditions within the Delta that help restore native fish habitat.	CM12 Methylmercury Management CM14 Stockton Deep Water Ship Channel Dissolved Oxygen Levels
Objective ECSY2.4: Maintain or increase life history diversity of native fishes and a diversity of rearing conditions for native fishes over time.	CM1 Water Facilities and Operation CM2 Yolo Bypass Fisheries Enhancements CM4 Tidal Habitat Restoration CM5 Seasonally Inundated Floodplain Restoration CM6 Channel Margin Habitat Enhancement CM7 Riparian Habitat Restoration
Objective ECSY 2.5: Promote greater connectivity between low salinity zone habitats and upstream freshwater habitats, and availability of spawning habitats for native pelagic species.	CM1 Water Facilities and Operation CM4 Tidal Habitat Restoration

Table 3-12. Terrestrial Conservation Measures that Meet BDCP Conservation Strategy Goals and Objectives (continued)

Goals and Objectives	*Applicable Conservation Measures*
Ecosystem-Level Goals and Objectives	
Goal ECSY3: Provide for connectivity among protected lands to provide for the movement of native organisms among habitat areas and to facilitate genetic exchange among populations.	
Objective ECSY3.1: Protect corridors of habitat that provide linkages among protected habitat areas within and adjacent to the Plan Area.	CM3 Natural Communities Protection
Objective ECSY3.2: Improve habitat corridors that allow covered and other native species to move into protected habitats from adjacent areas and to move among habitat areas within protected lands.	CM3 Natural Communities Protection CM4 Tidal Habitat Restoration CM5 Seasonally Inundated Floodplain Restoration CM6 Channel Margin Habitat Enhancement CM7 Riparian Habitat Restoration CM8 Grassland Communities Restoration CM11 Natural Communities Enhancement and Management
Goal ECSY4: Promote ecosystem processes that support natural communities, covered species, other native species, and the habitats of those species.	
Objective ECSY4.1: Maintain and improve disturbance regimes and other processes that support functioning natural communities.	CM4 Tidal Habitat Restoration CM5 Seasonally Inundated Floodplain Restoration CM11 Natural Communities Enhancement and Management
Goal ECSY5: Increase aquatic primary and secondary production in the Delta, Yolo Bypass and Suisun Marsh to increase the abundance and availability of food for native aquatic organisms.	
Objective ECSY5.1: Over the term of the BDCP, increase the abundance and productivity of zooplankton that provide food and support food production for covered fish species in Delta waterways.	CM2 Yolo Bypass Fisheries Enhancements CM4 Tidal Habitat Restoration CM5 Seasonally Inundated Floodplain Restoration CM6 Channel Margin Habitat Enhancement
Objective ECSY5.2: Over the term of the BDCP, increase the abundance and productivity of aquatic invertebrate species that provide food and support food production for covered fish species in Delta waterways.	CM2 Yolo Bypass Fisheries Enhancements CM4 Tidal Habitat Restoration CM5 Seasonally Inundated Floodplain Restoration CM6 Channel Margin Habitat Enhancement
Goal ECSY6: Reduce the adverse predation effects of non-native species on covered fish species.	
Objective ECSY6.1: Manage the distribution and abundance of established non-native predators in the Delta to reduce predation on native covered fishes.	CM13 Nonnative Aquatic Vegetation Control CM15 Predator Control
Objective ECSY6.2: Manage the distribution of covered fish species to minimize movements into high predation risk areas of the Delta.	CM1 Water Facilities and Operation CM2 Yolo Bypass Fisheries Enhancements CM16 Non-Physical Fish Barriers
Goal ECSY7: Protect lands with a sufficient range of habitat conditions to accommodate anticipated shifts in the distributions of covered species and natural communities in response to climate change.	
Objective ECSY7.1: Protect sufficient upland transitional habitat area adjacent to restored brackish and freshwater tidal emergent wetland to permit the future upslope natural establishment of tidal emergent wetland communities with sea level rise.	CM3 Natural Communities Protection CM4 Tidal Habitat Restoration

Table 3-12. Terrestrial Conservation Measures that Meet BDCP Conservation Strategy Goals and Objectives (continued)

Goals and Objectives	*Applicable Conservation Measures*
Natural Community Goals and Objectives	
Tidal Perennial Aquatic	
Goal TANC1: The expected outcome is tidal perennial aquatic natural community that supports habitats for covered and other native species and that supports aquatic food web processes.	
Objective TANC1.1: Restore or create 10,000 to 20,000 acres of tidal perennial aquatic in the BDCP Restoration Opportunity Areas (Conservation Zones 1, 2, 4, 5, 7, and 11) that supports aquatic food production and habitat for covered and other native species.	CM4 Tidal Habitat Restoration
Goal TANC2: The expected outcome is biologically diverse tidal perennial aquatic natural community that is enhanced for native species and sustained by natural ecological processes.	
Objective TANC2.1: Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal perennial aquatic community for covered and other native species over the term of the BDCP.	CM4 Tidal Habitat Restoration
Tidal Mudflat	
Goal MFNC1: The expected outcome is areas of tidal mudflat that provide foraging habitat for shorebirds and wading birds, and substrates suitable for the natural establishment of BDCP covered plant species.	
Objective MFNC1.1: Restore or create 20 linear miles of edge areas within other natural communities that serve as tidal mudflat substrate and which will support habitat for tidal mudflat-associated species as a component of BDCP restored tidal brackish emergent wetland and tidal freshwater emergent wetland natural communities and channel margin enhancement.	CM4 Tidal Habitat Restoration CM6 Channel Margin Habitat Enhancement
Objective MFNC1.2: Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal mudflat as a component of BDCP restored brackish and freshwater tidal habitat and channel margin enhancement for covered and other native species over the term of the BDCP.	CM1 Water Facilities and Operation CM11 Natural Communities Enhancement and Management
Tidal Brackish Emergent Wetland	
Goal BMNC1: The expected outcome is restored large expanses and interconnected patches of tidal brackish emergent wetland natural community.	
Objective BMNC1.1: Restore or create 3,600 to 4,800 acres of tidal brackish emergent wetland in the Suisun Marsh ROA (Conservation Zone 11).	CM4 Tidal Habitat Restoration
Goal BMNC2: The expected outcome is biologically diverse tidal brackish emergent wetland that is enhanced for native species and sustained by natural ecological processes.	
Objective BMNC2.1: Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal brackish emergent wetland for covered and other native species over the term of the BDCP.	CM11 Natural Communities Enhancement and Management

Table 3-12. Terrestrial Conservation Measures that Meet BDCP Conservation Strategy Goals and Objectives (continued)

Goals and Objectives	*Applicable Conservation Measures*
Natural Community Goals and Objectives	
Tidal Freshwater Emergent Wetland	
Goal FMNC1: The expected outcome is restored large, interconnected patches of tidal freshwater emergent wetland natural community.	
Objective FMNC1.1: Restore or create 13,900 to 21,600 acres of tidal freshwater emergent wetland in the Cache Slough, West Delta, Cosumnes-Mokelumne, and South Delta ROAs (Conservation Zones 1, 2, 4, 5, 6, and 7).	CM4 Tidal Habitat Restoration
Goal FMNC2: The expected outcome is biologically diverse tidal freshwater emergent wetland that is enhanced for native species and sustained by natural ecological processes.	
Objective FMNC2.1: Maintain and enhance the habitat and ecosystem functions of BDCP restored tidal freshwater emergent wetlands for covered and other native species over the term of the BDCP.	CM11 Natural Communities Enhancement and Management
Nontidal Freshwater Perennial Emergent Wetland	
Goal NWNC1: The expected outcome is nontidal freshwater perennial emergent wetland natural community that supports habitat for covered and other native species.	
Objective NWNC1.1: Create 400 acres of nontidal freshwater marsh (including components of nontidal perennial aquatic and perennial emergent wetland communities) that functions as habitat for the giant garter snake, tricolored blackbird, and western pond turtle within or adjacent to habitat occupied by the Caldoni Marsh/White Slough giant garter snake subpopulation in Conservation Zone 4 and the Yolo/Willow Slough giant garter snake subpopulation in Conservation Zone 2.	CM10 Nontidal Marsh Restoration
Goal NWNC2: The expected outcome is biologically diverse nontidal freshwater emergent wetland communities that are enhanced for native species and sustained by ecological processes.	
Objective NWNC2.1: Maintain and enhance the habitat functions of protected and created nontidal freshwater emergent wetlands for covered and other native species over the term of the BDCP.	CM11 Natural Communities Enhancement and Management
Nontidal Perennial Aquatic	
Goal NANC1: The expected outcome is nontidal perennial aquatic communities that support habitat for covered and other native species. ***Note:*** *The objective for nontidal perennial aquatic community Goal NANC1 is the same as that described under nontidal freshwater emergent wetland Goal NWNC1*.	
Objective NANC1.1: Restore 400 acres of nontidal marsh as per Objective NWNC1.1.	CM10 Nontidal Marsh Restoration
Goal NANC2: The expected outcome is biologically diverse nontidal perennial aquatic communities that are enhanced for native species and sustained by ecological processes.	
Objective NANC2.1: Maintain and enhance the habitat functions of protected and created nontidal open water habitats for covered and other native species over the term of the BDCP.	CM11 Natural Communities Enhancement and Management

Table 3-12. Terrestrial Conservation Measures that Meet BDCP Conservation Strategy Goals and Objectives (continued)

Goals and Objectives	*Applicable Conservation Measures*
Natural Community Goals and Objectives	
Valley/Foothill Riparian	
Goal VRNC1: The expected outcome is restored large expanses and interconnected corridors of valley/foothill riparian natural community.	
Objective VRNC1.1: Restore or create 5,000 acres of valley/foothill riparian in Conservation Zones 1, 2, 4, 5, 6, 7, and/or 11.	CM7 Riparian Habitat Restoration
Goal VRNC2: The expected outcome is biologically diverse valley/foothill riparian natural community that supports native species and is sustained by natural ecological processes.	
Objective VRNC2.1: Maintain and enhance the habitat and ecosystem functions of BDCP restored valley/foothill riparian and patches of riparian forest and scrub present on BDCP preserved lands over the term of the BDCP.	CM11 Natural Communities Enhancement and Management
Objective VRNC2.2: Establish seasonal buffers around riparian habitats occupied by covered species to minimize disturbance during the breeding season.	CM7 Riparian Habitat Restoration
Objective VRNC2.3: Restore connectivity of valley/foothill riparian corridors along linear watercourses to enhance habitat for covered species and facilitate wildlife movement.	CM7 Riparian Habitat Restoration
Grassland	
Goal GRNC1: The expected outcome is grassland comprised of large interconnected patches or contiguous expanses.	
Objective GRNC1.1: Protect a minimum of 8,000 acres of grassland in Conservation Zones 1, 8, and 11. At least 1,000 acres will be protected in Conservation Zone 8, with the remainder distributed throughout these three Conservation Zones.	CM3 Natural Communities Protection
Objective GRNC1.2: Restore 2,000 acres of grassland to connect fragmented patches of protected grassland.	CM8 Grassland Communities Restoration
Goal GRNC2: The expected outcome is biologically diverse grassland managed to enhance native species and sustained by natural ecological processes.	
Objective GRNC2.1: Restore and sustain a mosaic of grassland vegetation alliances, reflecting local water availability, soil chemistry, soil texture, topography, and disturbance regimes, with consideration of historical states.	CM8 Grassland Communities Restoration
Objective GRNC2.2: Increase the relative cover of native grasses and forbs in native grassland vegetation alliances.	CM8 Grassland Communities Restoration
Objective GRNC2.3: Increase opportunities for wildlife movement through grassland habitat.	CM8 Grassland Communities Restoration
Objective GRNC2.4: Increase burrow availability for burrow-dependent species.	CM8 Grassland Communities Restoration
Objective GRNC2.5: Increase prey, especially small mammals and insects, for grassland-foraging species.	CM8 Grassland Communities Restoration

Table 3-12. Terrestrial Conservation Measures that Meet BDCP Conservation Strategy Goals and Objectives (continued)

Goals and Objectives	***Applicable Conservation Measures***
Natural Community Goals and Objectives	
Alkali Seasonal Wetland Complex	
Goal AWNC1: The expected outcome is protected alkali seasonal wetland complex natural community that represents a range of environmental conditions and is adjacent to other conserved lands.	
Objective AWNC1.1: Protect 400 acres of alkali seasonal wetland complex natural community in Conservation Zones 1, 8, and/or 11.	CM3 Natural Communities Protection
Goal AWNC2: The expected outcome is biologically diverse alkali seasonal wetland complex natural community with improved native biodiversity, habitat heterogeneity, and the ability to support populations of covered and other native species.	
Objective AWNC2.1: Maintain and, where habitat functions for covered species can be increased, increase the diversity and relative cover of native grasses and forbs.	CM11 Natural Communities Enhancement and Management
Vernal Pool Complex	
Goal VPNC1: The expected outcome is protected vernal pool complex natural community that represents a range of environmental conditions and is adjacent to other conserved lands.	
Objective VPNC1.1: Protect 300 acres of vernal pool complex in Conservation Zones 1, 8, and 11.	CM3 Natural Communities Protection
Goal VPNC2: The expected outcome is restored biologically diverse vernal pool complex natural community with improved native biodiversity, habitat heterogeneity, and the ability to support populations of covered and other native species.	
Objective VPNC2.1: Restore 200 acres of vernal pool complex natural community in Conservation Zones 1, 8, and/or 11 within patches of protected grassland that supports habitat for the western spadefoot toad, California tiger salamander, and the covered vernal pool shrimp and plant species.	CM9 Vernal Pool Complex Restoration
Objective VPNC2.2: Maintain and, where habitat functions for covered species can be enhanced, increase the diversity and relative cover of native grasses and forbs.	CM8 Grassland Communities Restoration CM9 Vernal Pool Complex Restoration
Inland Dune Scrub	
Goal IDSC1: The expected outcome is support for funding of the USFWS management and enhancement of the inland dune scrub natural community on the Antioch Dunes National Wildlife Refuge.	
Objective IDSC1.1: The BDCP will support the funding of the USFWS program for management, enhancement, and monitoring of inland dune scrub natural community on the Antioch Dunes National Wildlife Refuge at an annual amount of $XX.XX for X years.	CM11 Natural Communities Enhancement and Management

Table 3-12. Terrestrial Conservation Measures that Meet BDCP Conservation Strategy Goals and Objectives (continued)

Goals and Objectives	*Applicable Conservation Measures*
Agricultural Habitats	
Goal ALNC1: The expected outcome is increased habitat functions for covered and other native species that are supported by agricultural land cover types and management practices.	
Objective ALNC1.1: Maintain and protect the functions of 4,600 acres of rice lands as habitat for giant garter snake, western pond turtle, tricolored blackbird, white-tailed kite, waterfowl, and migrant shorebirds in Conservation Zone 2. This objective may be partially or fully achieved by maintaining an equivalent extent of natural or managed lands that support habitat functions similar to rice lands for associated covered and other native wildlife species.	CM3 Natural Communities Protection
Objective ALNC1.2: Maintain and protect the functions of 12,020 to 28,040 acres of non-rice agricultural lands as foraging habitat for Swainson's hawk, white-tailed kite, and tricolored black bird that are located within 8 miles of occupied Swainson's hawk nesting habitat.	CM3 Natural Communities Protection
Objective ALNC1.3: Of the maintained 12,020 to 28,040 acres of non-rice agricultural lands, maintain at least 3,000 acres of pasture that supports moderate-value western burrowing owl foraging habitat. This objective may be partially or fully achieved through preservation of other land cover types that provide moderate-value or greater habitat function for the western burrowing owl.	CM3 Natural Communities Protection
Objective ALNC1.4: Of the maintained 12,020 to 28,040 acres of non-rice agricultural lands, maintain at least 4,800 acres that supports greater sandhill crane foraging habitat within its Winter Use Area and within 2 miles of known roosting sites in Conservation Zones 3, 4, 5 and/or 6.	CM3 Natural Communities Protection
Objective ALNC1.5: Of the maintained 12,020 to 28,040 acres of non-rice agricultural lands and 4,600 acres of rice lands, maintain and protect 1,000 acres within or adjacent to habitat occupied by the Yolo/Willow Slough giant garter snake subpopulation in Conservation Zone 2.	CM3 Natural Communities Protection
Objective ALNC1.6: Of the maintained 12,020 to 28,040 acres of non-rice agricultural lands, maintain and protect 1,000 acres within or adjacent to habitat occupied by the Caldoni Marsh/White Slough giant garter snake subpopulation in Conservation Zone 4.	CM3 Natural Communities Protection
Objective ALNC1.7: Target agricultural land conservation to provide connectivity between other protected lands.	
Objective ALNC1.8: Maintain and protect the small patches of important wildlife habitats associated with agricultural lands that occur within BDCP conserved agricultural lands, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, and wetlands.	CM3 Natural Communities Protection

Table 3-12. Terrestrial Conservation Measures that Meet BDCP Conservation Strategy Goals and Objectives (continued)

Goals and Objectives	***Applicable Conservation Measures***
Managed Wetland	
Goal MWNC1: The expected outcome is maintenance of the current level of habitat functions provided by existing managed wetlands in the Plan Area through enhancement and restoration of natural communities on BDCP conservation lands, such that those wildlife functions do not preclude achievement of the Central Valley Joint Venture (CVJV) Implementation Plan's waterfowl and shorebird conservation targets for the Delta and Yolo Basin.	
Objective MWNC1.1: Maintain the level of wintering and breeding waterfowl habitat functions currently supported by habitats in the Plan Area through protection, restoration, and management of habitat of equivalent function on BDCP conservation lands.	CM3 Natural Communities Protection CM4 Tidal Habitat Restoration CM8 Grassland Communities Restoration
Objective MWNC1.2: Maintain the current level of migrant shorebird habitat functions currently supported by habitats in the Plan Area through protection, restoration, and management of habitat of equivalent function on BDCP conservation lands.	CM3 Natural Communities Protection CM4 Tidal Habitat Restoration
Goal MWNC2: The expected outcome is biologically diverse managed wetlands that are enhanced for native species.	
Objective MWNC2.1: Maintain and enhance the habitat functions of BDCP managed wetlands present on BDCP preserved lands over the term of the BDCP.	CM11 Natural Communities Enhancement and Management
Other Natural Seasonal Wetland	
Goal ONSW1: The expected outcome is increased habitat functions that support BDCP covered species in other natural seasonal wetland natural community within maintained and protected agricultural habitat areas.	
Objective ONSW1.1: Integrate management of other natural seasonal wetland natural community with management of BDCP maintained and protected agricultural lands to increase habitat functions for covered species.	CM3 Natural Communities Protection
Species-Specific Goals and Objectives *[**Note to Reviewers:** This table will be revised to indlcude the covered fish species pending further development of the covered fish species goals and objectives.]*	
Riparian Woodrat	
Goal RIWR1: The expected outcome is restored and protected habitat for the riparian woodrat.	
Objective RIWR1.1: Of the 5,000 acres of restored valley/foothill riparian, restore and manage 300 acres to meet the ecological requirements of the riparian woodrat in Conservation Zone 7.	CM7 Riparian Habitat Restoration
Riparian Brush Rabbit	
Goal RIBR1: The expected outcome is restored and protected habitat for riparian brush rabbit.	
Objective RIBR1.1: Of the 5,000 acres of riparian restoration, restore and manage at least 300 acres to meet the ecological requirements of the riparian brush rabbit in Conservation Zones 7 or 8.	CM7 Riparian Habitat Restoration
California Least Tern	
Goal CALT1: The expected outcome is an expanded California least tern population in the Plan Area.	
Objective CALT1.1: Create two patches of California least tern nesting habitat during restoration of tidal marsh communities.	CM11 Natural Communities Enhancement and Management

Table 3-12. Terrestrial Conservation Measures that Meet BDCP Conservation Strategy Goals and Objectives (continued)

Goals and Objectives	*Applicable Conservation Measures*
Species-Specific Goals and Objectives	
Greater Sandhill Crane	
Goal GSHC1: The expected outcome is expansion and protection of greater sandhill crane winter range.	
Objective GSHC1.1: Create 320 acres of seasonally managed greater sandhill crane roosting habitat within Conservation Zones 3, 4, 5, or 6.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management
Giant Garter Snake	
Goal GGSN1: The expected outcome is high quality upland and aquatic habitat containing a mosaic of features provided for extant giant garter snake populations.	
Objective GGSN1.1: Create functional landscapes on giant garter snake preserves that include a mosaic of restored freshwater marsh intermixed with protected agricultural lands and interconnected water conveyance canals and natural drainages.	CM3 Natural Communities Protection CM4 Tidal Habitat Restoration CM10 Nontidal Marsh Restoration CM11 Natural Communities Enhancement and Management
Goal GGSN2: The expected outcome is protected giant garter snake corridors facilitating movement and linking populations.	
Objective GGSN2.1: Establish connectivity between giant garter snake preserve lands, restored tidal wetlands, and protected agricultural lands in Conservation Zone 4 to facilitate movement into unoccupied portions of the Delta and with the Badger Creek subpopulation.	CM3 Natural Communities Protection CM4 Tidal Habitat Restoration CM10 Nontidal Marsh Restoration CM11 Natural Communities Enhancement and Management
Objective GGNS2.2: Establish a giant garter snake north-south corridor that includes protected agricultural lands and restored tidal and nontidal wetlands between Coldani Marsh/White Slough and the Stone Lakes National Wildlife Refuge.	CM3 Natural Communities Protection CM4 Tidal Habitat Restoration CM10 Nontidal Marsh Restoration CM11 Natural Communities Enhancement and Management
California Red-Legged Frog	
Goal CRLF1: The expected outcome is enhanced breeding California red-legged frog populations in the Plan Area.	
ObjectiveCRLF1.1: Enhance stock ponds in grassland in Conservation Zone 8 through partial livestock exclusion and predator control.	CM11 Natural Communities Enhancement and Management
Lange's Metalmark Butterfly	
Goal LMMB1: The expected outcome is funding support for the USFWS captive breeding and reintroduction program for Lange's metalmark butterfly.	
Objective LMMB1.1: The BDCP will provide funding to support the USFWS program for the captive breeding and release of Lange's metalmark butterfly at an annual amount of $XX.XX for X years.	CM11 Natural Communities Enhancement and Management
Vernal Pool Plant Species **(**Alkali Milk-vetch, San Joaquin Spearscale, Dwarf Downingia, Boggs Lake Hedge-hyssop, Legenere, and Heckard's Peppergrass**)**	
Goal ALMV1: The expected outcome is protected and enhanced alkali milk-vetch populations.	
Objective ALMV1.1: Protect at least 3 unprotected occurrences of alkali milk-vetch in Conservation Zones 1 and/or 11.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management
Objective ALMV1.2: Maintain and enhance the habitat functions of preserved alkali milk-vetch habitat over the term of the BDCP.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management

Table 3-12. Terrestrial Conservation Measures that Meet BDCP Conservation Strategy Goals and Objectives (continued)

Goals and Objectives	*Applicable Conservation Measures*
Species-Specific Goals and Objectives	
Vernal Pool Plant Species **(**Alkali Milk-vetch, San Joaquin Spearscale, Dwarf Downingia, Boggs Lake Hedge-hyssop, Legenere, and Heckard's Peppergrass**)**	
Goal HEPE1: The expected outcome is protected and enhanced Heckard's peppergrass populations.	
Objective HEPE 1.2: Protect at least 2 unprotected occurrences of Heckard's peppergrass in Conservation Zones 1, 8, or 11.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management
Objective HEPE1.2: Maintain and enhance the habitat functions of preserved Heckard's peppergrass habitat over the term of the BDCP.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management
Heartscale and Brittlescale	
Goal HART/BRIT1: The expected outcome is protected and expanded alkali seasonal wetland complex natural community-associated covered species populations.	
Objective HART/BRIT1.1: Of the 400 acres of protected alkali seasonal wetland complex natural community, protect 150 acres that support heartscale and brittlescale habitat.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management
Objective HART/BRIT1.2: Protect at least 3 unprotected occurrences of heartscale in Conservation Zones 1 and /or 11.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management
Objective HART/BRIT1.3: Protect at least 3 unprotected occurrences of brittlescale in Conservation Zones 1, 8, or 11.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management
Objective HART/BRIT1.4: Maintain and enhance the habitat functions of preserved heartscale and brittlescale habitat over the term of the BDCP.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management
Suisun Thistle and Soft Bird's-Beak	
Goal SUTH1: The expected outcome is protected and expanded Suisun thistle populations.	
Objective SUTH1.1: Protect 3 unprotected occurrences of Suisun thistle in Suisun Marsh in Conservation Zone 11.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management
Objective SUTH1.2: Maintain and enhance the habitat functions of preserved Suisun thistle habitat over the term of the BDCP.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management
Goal SOBB1: The expected outcome is protected and expanded soft bird's-beak populations.	
Objective SOBB1.1: Protect 3 unprotected occurrences of soft bird's-beak in Suisun Marsh in Conservation Zone 11.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management
Objective SOBB1.2: Maintain and enhance the habitat functions of preserved soft bird's-beak habitat over the term of the BDCP.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management
Delta Button-Celery	
Goal DEBC1: The expected outcome is protected and expanded Delta button-celery populations.	
Objective DEBC1.1: Of the 400 acres of protected alkali seasonal wetland complex natural community, protect at least 100 acres that support Delta button-celery habitat.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management
Objective DEBC1.2: Maintain and enhance the habitat functions of preserved Delta button-celery habitat over the term of the BDCP.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management

Table 3-12. Terrestrial Conservation Measures that Meet BDCP Conservation Strategy Goals and Objectives (continued)

Goals and Objectives	***Applicable Conservation Measures***
Species-Specific Goals and Objectives	
Contra Costa Wallflower and Antioch Dunes Evening Primrose	
Goal CCWF/ADEP1: The expected outcome is funding support for the USFWS implementation of the propagation and out-planting program for Contra Costa wallflower and Antioch Dunes evening primrose.	
Objective CCWF/ADEP1.1: The BDCP will support the funding of the USFWS program for propagation and out-planting program for Contra Costa wallflower and Antioch Dunes evening primrose at an annual amount of $XX.XX for X years.	CM11 Natural Communities Enhancement and Management
Carquinez Goldenbush	
Goal CAGB1: The expected outcome is protected and expanded Carquinez goldenbush populations.	
Objective CAGB1.1: Protect at least 3 unprotected occurrences of Carquinez goldenbush in Conservation Zones 1 and/or 11.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management
Objective CAGB1.2: Maintain and enhance the habitat functions of preserved Carquinez goldenbush habitat over the term of the BDCP.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management
Caper-Fruited Tropidocarpum	
Goal CFTR1: The expected outcome is protection and expansion of caper-fruited tropidocarpum populations.	
Objective CFTR1.1: Protect occurrences of caper-fruited tropidocarpum that reestablish on BDCP conservation lands.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management
Objective CFTR1.2: Maintain and enhance the habitat functions of protected caper-fruited tropidocarpum occurrences over the term of the BDCP.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management
Objective CFTR1.3: Protect and maintain 100 acres of unprotected caper-fruited tropidocarpum grassland habitat in Conservation Zone 8.	CM3 Natural Communities Protection CM11 Natural Communities Enhancement and Management

3.4.1 Development Process

The BDCP conservation measures were developed on the basis of the best available scientific and commercial information, including input of a broad range of technical experts and an extensive body of scientific study and analysis compiled over the past several decades. The conservation measures further reflect the recommendations of independent scientists with extensive knowledge of Delta ecological issues. The conservation measure development process, including descriptions of technical evaluations, is described in Appendix D, *Background on the Process of Developing the BDCP Conservation Measures.* On several occasions, the Steering Committee convened these scientists to provide guidance and insight on a range of issues important to the development of a comprehensive conservation strategy for the BDCP, the recommendations of which are are reflected in many of the conservation measures set out in this section (see Appendix G, *Independent Science Advisors Reports*).

The BDCP conservation measures were initially developed to address the conservation needs of the covered fish species and the aquatic ecosystem by groups of technical experts convened by the Steering Committee. To guide initial development of potential conservation measures, these experts, based on review of the body of relevant scientific information and input from the Fishery Agencies and topical experts, identified important environmental stressors affecting the covered fish species and aquatic ecosystem. The groups then identified the range of potential conservation measures that could reduce or remove the effects of these stressors on the covered fish species. The conservation measure development process was informed through application of several tools and processes described in the following paragraphs. Following development of a range of potential conservation measures, the groups iteratively screened and refined the conservation measures based on evaluations of their likely biological effectiveness and implementability.

A large body of information on the Delta ecosystem and approaches to ecosystem and species conservation has been developed over many years that provided a starting point for the development of the BDCP conservation measures. Important sources of scientific information and conservation approach ideas included the CALFED Bay Delta Program, particularly the Science Program and Ecosystem Restoration Program; the Interagency Ecological Program; two reports on the Delta prepared by the California Public Policy Institute; the Delta Vision Program, various plan and technical documents; and the Delta Risk Management Strategy. Building on this knowledge base, the BDCP conservation measures to address aquatic resources were developed using additional investigations, state-of-the-art physical models, specially developed conceptual models, and expert input from a large number of scientists and resource managers.

At several stages in the development of the conservation measures, interim evaluations where conducted to assess the potential for measures under consideration to improve ecological conditions within the Delta for the covered fish species. Central to these assessments were the conceptual ecological models and detailed evaluation processes that were developed under the CALFED Ecosystem Restoration Program to gauge the likely effect of potential actions on Delta fish and ecosystem processes. This process, known as the Delta Regional Ecosystem Restoration

Implementation Plan (DRERIP) Scientific Evaluation Process, was used to evaluate draft BDCP conservation measures in December 2008-March 2009 (see Appendix F, *DRERIP Evaluation Results*). Under the DRERIP process, potential conservation measures were evaluated individually to assess their benefits and drawbacks without factoring in potential synergies with other actions. To account for interrelationships with other potential measures, the BDCP Synthesis Team was established to review the results of the DRERIP process and identify instances in which combinations of measures would likely provide benefits greater than the sum of the individual measures. The Synthesis Team assessed potential synergies and conflicts between various measures and suggested modifications to the draft conservation measures to improve the overall effectiveness of measures. Based on input from the DRERIP Evaluation and the Synthesis Team, the conservation measures were revised to improve their potential effectiveness.

Following development of draft conservation measures for the aquatic ecosystem and covered fish species, the Steering Committee assembled a team of technical experts to develop conservation measures to address the nontidal natural communities and covered wildlife and plant species. These experts reviewed and refined the draft habitat restoration measures intitially developed to address aquatic resources to ensure that the measures included elements that would also support high functioning habitat for the associated covered wildlife and plant species. Using the best available information, additional conservation measures to protect, enhance, restore, and manage nontidal habitats were developed based on assessments of each covered wildlife and plant species conservation needs. These assessments included consideration for each species distribution within the Plan Area, known species stressors, the extent and distribution of existing protected and unprotected habitat areas, effects of implementing the BDCP actions on each species and their habitats, opportunities to protect and improve habitat corridors, and opportunities to improve habitat connectivity among habitat areas within and adjacent to the Plan Area in accordance with the principles of conservation biology.

3.4.2 Ecosystem-Level Conservation Measures

Ecosystem-level conservation measures include water operations and the spatial distribution of landscape-scale protection and restoration of natural communites to improve the processes and ecological functions supported by the Plan Area's aquatic and terrestrial ecosystems. Water operations are designed to enhance aquatic foodweb processes to improve food abundance and availability and to improve the hydrodynamic and water quality conditions that support the habitat and movement of the covered fish and other native aquatic organisms. Large-scale protection and restoration of connected natural communities are designed to maintain and increase the extent of high functioning habitat areas for the covered and other native wildlife and plant species and that support the movements of covered and other native wildlife. Because these conservation measures will have a systemic effect on ecosystem condtions within the Plan Area, they are designed to complement and guide implementation of the natural community-level conservation measures described in Section 3.4.3, *Natural Community-Level Conservation Measures*.

3.4.2.1 CM1 Water Facilities and Operation

*[**Note to Reviewers:** On January 29, 2010 the BDCP Steering Committee approved, for the purposes of the detailed Effects Analysis, a set of BDCP initial long-term operating criteria. A table of these criteria can be found in the February 11 Steering Committee agenda packet on the BDCP web site. A companion document titled "Aquatic Conservation Measures Proposed for Effects Analysis under BDCP" can also be found in the February 11 agenda packet and describes the steps that were used to develop this set of criteria. These criteria reflected the thinking of the Steering Committee at that time for the purpose of a comprehensive Effects Analysis. The Steering Committee noted that these criteria might become the final criteria or they might be modified based on the results of the Effects Analysis, evaluation of alternatives under CEQA and NEPA, or efforts to optimize them and permit achievement of the ecosystem and water supply goals of the BDCP. The Steering Committee envisioned an iterative process to refine the conservation strategy, including the development of the final set of initial long-term operating criteria and the adaptive range for these criteria.*

An effects analysis has been underway by the SAIC team over the past 10 months and the Steering Committee has been given several presentations on the preliminary results of that analysis. The Effects Analysis continues to be reviewed by the technical staff of the Steering Committee representatives and will be revised as necessary. To date, several issues have been identified that necessitate analysis of potential changes to the initial long-term operating criteria by January 2011. These include:

- *North Delta intake configuration related to predation concerns (in-river vs on-bank)*
- *Spring-run salmon egg mortality on the Sacramento River in the fall*
- *Reduced Sacramento River flows downstream of the north Delta intakes*
- *Refinement of April-May south Delta operations*
- *Winter-spring X2 and outflow effects on longfin smelt*
- *Summer and fall X2 and delta smelt abiotic habitat*

A process has begun to evaluate how modifications to some of the conservation measures, including initial long-term operating criteria, might address some of these issues in a manner that provides a refined approach to fishery protection while being sensitive to the water supply goals. This will lead to an iteration process that will take place for the purpose of describing the final conservation strategy and the initial long-term operating criteria for complete evaluation in the effects analysis. Also, as part of this process, an adaptive range for the operational criteria will be developed.]

This conservation measure provides for significant proposes changes to water operations in the Delta under the BDCP. This conservation measure includes two major components: (1) construction of new water facilities, and (2) operations of new operational control facilities or changes to the operations of existing operational control facilities. The evaluation of proposed new conveyance facilities (or changes to existing facilities) addresses two core issues that are separate and distinct, but are also closely interrelated. The first is the design issue associated with the new facility; that is, whether the new facility itself may enable improvements in flows and hydrodynamics if operated properly, and how to design the facility to achieve those improvements. The second issue is the operational issue; that is, what types of operational parameters would be most appropriate for the new facility to contribute to BDCP goals and objectives. It is important to recognize that these two aspects of proposed new water conveyance facilities are separate and distinct yet also closely joined, and must be evaluated as such.

The proposed new north Delta diversion facility offers an instructive example of this distinction. The appropriateness of the north Delta facility as a major new conservation measure for the BDCP demonstrates how both issues must be addressed together. There is a relatively broad agreement within the fisheries conservation community that a properly operated new north Delta facility will provide substantial benefits for certain listed species over the existing system, for all of the reasons enumerated below. The far more energetic debate focuses on what constitutes the proper operating parameters for the new facility, and less on the design parameters of the north Delta facility itself – although both are essential components of the proposal. Determining the appropriateness of the north Delta facility, therefore, considers the operational parameters that will govern it as much as the reliability of the governance structures that will apply those parameters. Hence, clearly distinguishing the design features from the operational features is important for an accurate appraisal of the merits of the measure overall.

The lower Sacramento River, Delta, and Suisun Bay and Marsh provide habitat for a diverse and complex assemblage of resident and migratory fish and other aquatic organisms. Section 3.2.3 *Development of the Aquatic Resources Component of the Conservation Strategy*, describes the BDCP approach to conservation and outlines the basic principles governing the approach. Several of these principles apply directly to the design of the conservation measure proposed in this section and are, therefore, expanded upon here. Development of water operations conservation measure as part of the BDCP is based, in large part, on the balance of seasonal and interannual variation in hydrologic conditions occurring within the watershed, and seasonal variation in the habitat requirements and geographic distribution of each of the lifestages of the covered fish within the estuary and tributary rivers, as well as many other factors. These include the beneficial interactions between establishing new aquatic habitats and hydrodynamics, a variety of flow-based and other mechanisms affecting the habitat quality and availability for these species and their food supplies, growth, survival, reproduction, and overall population dynamics in response to implementation of conservation measures. In addition, the water operations conservation measure is designed to provide a reliable water supply in a manner that avoids and reduces adverse effects to covered species and their habitat.

The proposed water operations also reflect the fact that the covered fish and other aquatic species have evolved in the Central Valley rivers and Delta. Their life histories are keyed to seasonal changes that naturally occur in flows, water temperatures, and other environmental cues that affect processes such as the seasonal timing of juvenile emigration downstream through the Delta, seasonal timing of reproduction, seasonal patterns in phytoplankton and zooplankton production that are food for covered fish and other aquatic species, seasonal inundation of floodplain habitat, and other important biological mechanisms.

One factor considered in the development of the water operations conservation measure is unidirectional downstream sweeping flows across the new fish screens proposed for the lower Sacramento River as part of long-term dual facility operations. Another consideration is the downstream transport of planktonic fish eggs and larvae, organic material, phytoplankton, and zooplankton from the lower Sacramento River into the Delta and Suisun Bay. A third factor is the consideration of sufficient flows in the lower Sacramento River during the primary migration period for juvenile Chinook salmon, steelhead, and other species (December-June) to reduce the frequency of bidirectional tidal flows in areas like Sutter and Steamboat Sloughs that are thought to reduce migration rates and increase the risk of juvenile fish to mortality from sources such as predation. Another factor that is taken into account is the provision of operations to maintain and improve habitat quality and availability for aquatic species in areas such as the Cache Slough complex, the lower Sacramento River, Delta and the low salinity zone located in the western Delta and Suisun Bay. The long-term water operations described below were developed to meet these and other biological objectives, water supply objectives, and water quality objectives of the BDCP.

In addition to reducing direct entrainment loss as a result of BDCP covered activities, the new water facilities and operations are designed to reduce other sources of harm to listed species, both direct and indirect (e.g. stranding, loss of homing ability, and reduced predation). In addition, implementation will be adaptively managed to optimize benefits to covered species while maintaining water supply reliability (see Section 3.7, *Adaptive Management Program*). Uncertainties concerning these actions will be managed through ongoing monitoring and research under the BDCP monitoring and adaptive management programs.

Water operations in the Delta are an integrated collection of actions that affect flow and water quality. This water facilities and operational conservation measure is closely intertwined with other components of the conservation strategy, including measures that will restore habitat and address other stressors to covered species. For example, the ability of habitat restoration in the south Delta to increase the amount of biological productivity transported to the western Delta and Suisun Bay will be realized only after preferential operation of the north Delta diversion facility over south Delta facilities begins (i.e., long-term operations).

Where applicable, criteria (quantitative values) are identified here for each parameter for specific times of year and specific water year types.

Water Facilities

This section presents an introduction to and summary of the proposed new and existing water facilities operated by the SWP and CVP within and near the Plan Area (Figure 3-52). These facilities include physical control structures such as gates, intakes, and pumps that can modify flows and affect Delta hydrodynamics in the immediate vicinity of the structure and often across large portions of the surrounding Delta. The physical construction and modification of these facilities are described and evaluated separately from the operations of the facilities under the BDCP.

The following is a list of new and existing water facilities and brief description of their functions:

1. North Delta Diversion Facilities and Tunnel/Pipeline – The north Delta diversion facilities will include five new intakes along the Sacramento River between Freeport and Courtland (Figure 3-52). Intakes will be equipped with state-of-the-art positive barrier fish screens to reduce entrainment of fish and will connect to tunnel/pipeline to carry water to a new regulating forebay adjacent and connected to existing south Delta SWP and CVP export facilities. More detail on specific features of the tunnel/pipeline facility is provided in Chapter 4, *Covered Activities. [**Note to Reviewers**: The design and location of the new intakes and conveyance facilities to be included in the proposed BDCP have not been determined.]*
2. Fremont Weir Operable Gates – New operable gates on the Fremont Weir will allow for the control of the timing, duration, and frequency of inundation of the Yolo Bypass during periods when the Sacramento River would not currently spill over the Fremont Weir into the Yolo Bypass. Operations for Fremont Weir Operable Gates are described in Section 3.4.2.2. *CM2 Yolo Bypass Fishery Enhancement*.
3. Delta Cross Channel Gates – Delta Cross Channel Gates are existing radial gates that control the flow of Sacramento River water through the Delta Cross Channel into the interior Delta.
4. Montezuma Slough Salinity Control Gate – Existing gate at the eastern opening of Montezuma Slough that controls the flow of fresh and salt water into Montezuma Slough.
5. South Delta Diversions – Two existing diversion facilities, the CVP Jones Pumping Plant and the SWP Banks Pumping Plant, divert water from the south Delta to meet water supply demands outside the Delta.

   In addition to the above listed facilities, the existing Barker Slough Pumping Plant diverts water from Barker Slough into the North Bay Aqueduct (NBA) for delivery in Napa and Solano counties. New diversion from the Sacramento River proposed as the North Bay Aqueduct Alternative Intake would operate in conjunction with the existing North Bay Aqueduct intake at Barker Slough.

<u>*Near-Term Water Operations*</u>

*[**Note to Reviewers**: At this time, BDCP does not have proposed near-term operations.]*

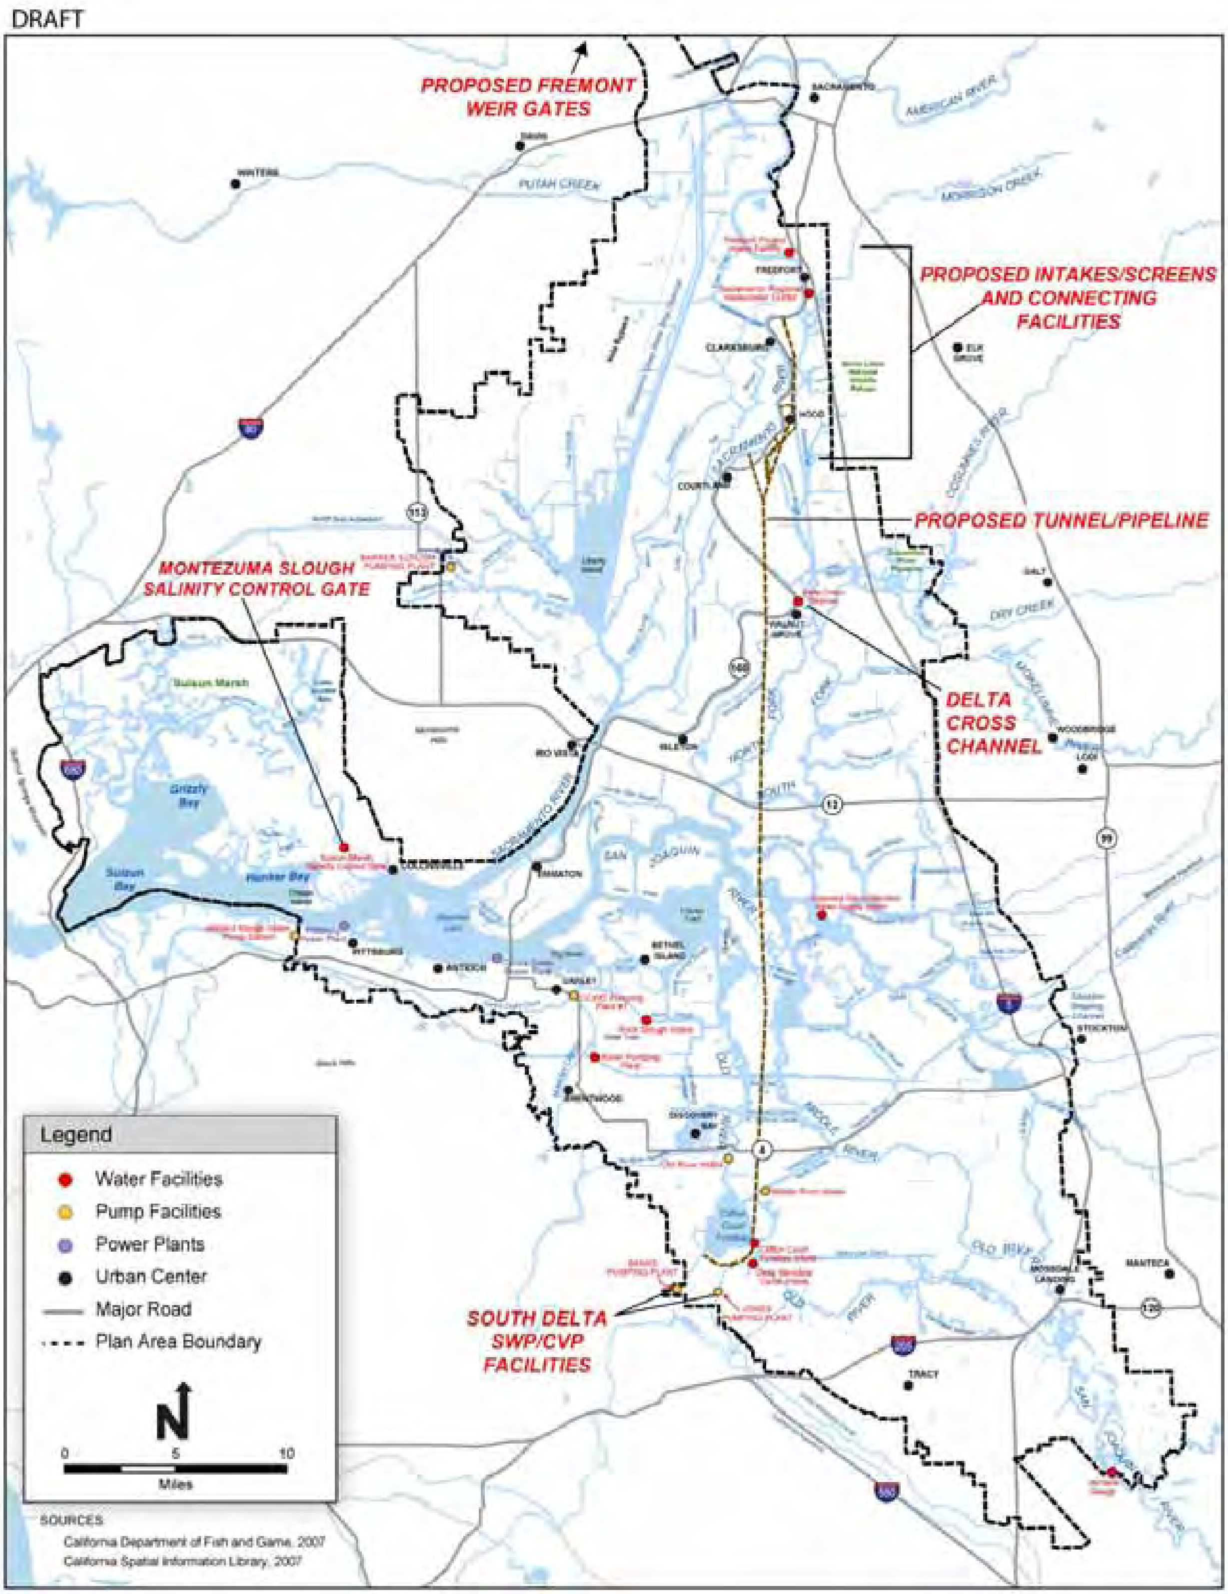

Figure 3-52. Water Operations Facilities in the Delta (Existing and Proposed)

Long-Term Water Operations

This section provides descriptions of the long-term water operations for multiple parameters across the Delta. Long-term operations are made possible by facilities constructed during the near-term implementation period (e.g., new north Delta diversions, tunnel/pipeline, and new gates at Fremont Weir). In the long-term implementation period, dual operations of the existing south Delta diversion facilities and the new north Delta diversion facilities will provide greater flexibility to benefit covered fish and water exports not possible during the near-term implementation period. Long-term operations under the dual facility will allow water to be diverted from the lower Sacramento River using state-of-the-art positive barrier fish screens that are expected to substantially reduce the risk of entrainment of covered fish and other aquatic organisms, but will also provide positive benefits resulting from a reduction in the rate of water diversions occurring from the south Delta when covered fish species are present. Long-term water operations described in this section will replace certain near-term water operations once the new north Delta diversions and the new tunnel/pipeline are completed and functional.

Construction and Preferential Operation of a New Water Diversion Facility in the North Delta.

Five new water diversion facilities with 3,000 cfs capacity each (combined 15,000 cfs capacity) will be constructed and operated on the Sacramento River in the north Delta to minimize impacts on fish at the SWP and CVP south Delta diversion facilities. A tunnel/pipeline facility with a 15,000 cfs capacity will be constructed to convey water from the new diversion facilities to the south Delta, where it will join existing SWP and CVP diversion facilities. The capacity of the new facilities will be 15,000 cfs, which is approximately the capacity of existing export pumps at SWP and CVP facilities in the southern Delta. The new tunnel/pipeline will follow a route through the Delta (Figure 3-52). Each new intake will be screened with state-of-the-art positive barrier fish screens and have a pump station, power lines, access roads, and other associated infrastructure.

Five locations for intakes have been identified in the north Delta (Figure 3-52). Selection of locations is based on multiple considerations including, but not limited to, maximizing function and effectiveness of screens; minimizing impacts to in-channel, on-bank, and terrestrial resources; applicable navigational and flood conveyance regulations; channel geometry and bathymetry; location relative to tidal influence and ranges of covered fish; future climate change and sea level rise; and proximity to other infrastructure (e.g., Sacramento Regional Wastewater outfall, existing developed land, and other intakes). Each intake will be engineered to allow variable rate pumping to handle variation in the location of covered fish and tidally-induced flows, as well as sea level rise from climate change. The influence of tides, which could produce reverse or stagnant flows in channels, attenuates upstream such that the most northern intakes are expected to be less influenced by tides than downstream intakes, particularly during higher river flow.

After the comprehensive evaluation of three types of intake/screens structures (on-bank, near-shore, and in-channel screens) for flood control, effects to covered fish species, and feasibility, it was concluded that on-bank structures would best meet these criteria for this reach of the river Fish screens will be designed to NMFS, DFG, and USFWS criteria to include specific screen mesh sizes (1.75 mm open area), a maximum approach velocity of 0.2 feet per second (ft/sec), sweeping velocity of at least two times the approach velocity (0.4 ft/sec), screen cleaning mechanisms, and monitoring systems. Three types of screening materials are currently being investigated: stainless steel, copper-nickel, and plastic. The advantages and disadvantages of each will be considered in the ultimate decision by the Implementation Office of which material to use. Further, with the high risk of invasion into the Delta by quagga and zebra mussels in the future, the use of anti-fouling material or alternative cleaning systems is also being considered.

The tunnel/pipeline will route water through the Delta to a new 600-acre forebay on Byron Tract (Figure 3-52). Water will be conveyed from the five intakes via pipelines to either an intake tunnel or a 750-acre Intermediate Forebay. A 33.5-mile tunnel will convey water from the Intermediate Forebay to the Byron Tract Forebay, where it will tie into existing SWP and CVP facilities.

Although construction of the new north Delta facility and associated infrastructure will be initiated as early as practicable following BDCP authorization, operation of the new facility will not start until and defines the beginning of the long-term implementation period (estimated at implementation year 10). The north Delta diversion facility will be operated in conjunction with, but preferentially to (except during summer months and at other times where necessary to meet the goals of fish conservation and water supply), existing south Delta SWP and CVP diversion facilities to minimize adverse effects on fish in the Delta while maintaining water supply reliability as described in Chapter 4, *Covered Activities*. The quantity and timing of diversions will be affected by specific parameters described in this chapter.

The new intake facilities will be operated to maintain flows in the Sacramento River to meet five primary objectives for flows at and downstream of the new north Delta facilities:

1. Maintain fish screen sweeping velocities,
2. Minimize undesirable upstream transport of water and aquatic resources from downstream channels,
3. Support fish transport to regions of suitable habitat,
4. Minimize predation effects downstream, and
5. Maintain or improve rearing habitat in the north Delta.

These north Delta facilities “bypass flows” represent the rate of flow at which the Sacramento River must pass downstream of the new diversion points. Bypass flows are intended to serve as an operational parameters to limit or otherwise manage water diversions from the new north Delta diversion facilities to minimize and reduce the effects of those diversions on downstream hydrodynamics (e.g., reduce Sacramento River flow downstream of the point of diversion) needed to support functions within and downstream of the river. Bypass flows for the Sacramento River act as an operational criteria in which water diversions will only occur when flows are maintained above the minimum criteria. The minimum bypass flow rates act as restrictions on water diversions during those years and seasons when flow in the Sacramento River is low. To meet water supply goals (see Chapter 4, *Description of Covered Activities*), constraints on the amount of water diverted from north Delta facilities may require commensurate increases in diversions from the south Delta SWP and CVP facilities. To maintain water quality in the south and central Delta during low flow periods on the San Joaquin River in summer months (July-September), existing south Delta pumps will be preferentially operated up to 3000 cfs (see *Delta water quality maintenance* below).

In addition to establishing the minimum bypass flow rates as one set of operating criteria, two additional operating criteria will be implemented in response to low river flow conditions. The first operational condition is preferential operation of the new diversion facilities located the farthest upstream to reduce the effects of low Sacramento River flow on tidal reversal in the vicinity of the diversion (maintain positive downstream flows across the intake structures and reduce the likelihood that larval and juvenile fish will move upstream into the area of potential entrainment/impingement at the diversion). Results of hydrodynamic modeling indicate that a higher level of Sacramento River flow needs to be maintained to avoid tidal flow reversal downstream (e.g., near Walnut Grove) when compared to the flow needed to maintain downstream river flows at more upstream sites. A second operational response to low Sacramento River flow conditions is to implement preferential diversion operations in response to tidal conditions (e.g., divert water during ebb tide stage to maintain sweeping velocity and avoid tidal flow reversal) and then reduce or curtail diversion during the flood tide stage.

Factors considered in developing north Delta diversion bypass flows included:

- Seasonal timing of various life stages of covered fish inhabiting the Sacramento River in the vicinity of the proposed water diversion locations;
- Changes in the biological processes and relationship in response to river flow that occur seasonally (e.g., differences in the biological processes of phytoplankton and zooplankton production between winter-spring and summer-fall);
- The relationship between bypass flows and hydrologic synchrony of flows and environmental cues within the Sacramento River watershed;
- The relationship between river bypass flow rate and constraints on water diversions and water supplies;
- The relationship between downstream transport rate of planktonic particles (simulating larval delta and longfin smelt transport between the upstream spawning areas, such as Cache Slough, and the downstream estuarine habitat where first feeding and juvenile rearing occur) and river flow rate;

- The relationship between river flow and downstream transport of phytoplankton, zooplankton, and organic material;
- The relationship between fall river flows and attraction and migration flows in the mainstem river for adult upstream migration by fall-run and late fall-run Chinook salmon, steelhead, delta and longfin smelt, splittail, and other upstream migrating adults;
- Relationships between river flow rate and juvenile transit time through the lower river (a factor thought to affect vulnerability to predation mortality), juvenile survival rates, and river flow;
- Relationships between river flow and habitat conditions for predatory fish (e.g., largemouth bass, smallmouth bass, pikeminnow, and striped bass) in the river and sloughs;
- The relationship between river flow rate and tidal dynamics (e.g., changes in water velocity and direction in response to flood and ebb tide conditions) and the river flows at various potential diversion locations that maintain a net unidirectional downstream flow over all tidal conditions;
- The relationship between mainstem river flows and seasonal flows into a floodplain habitat such as the Yolo Bypass and the resultant effects on hydrodynamic conditions in the river at the points of diversion;
- The relationship between existing and expanded tidal marsh habitat within the Cache Slough complex and tidal hydrodynamics within the river at various potential points of diversion;
- The relationships between seasonal timing of juvenile winter-run Chinook salmon downstream migration and pulse flows down the lower Sacramento River (del Rosario and Redler 2010); and
- The relationship between river flow, channel geometry, and resulting sweeping velocities across a positive barrier fish screen at each potential diversion location. Sweeping velocity is intended to transport fish downstream in a timely manner to reduce their exposure to entrainment and impingement at the diversion and to help remove accumulated debris from the fish screen surface to maintain approach velocities.

Analysis of seasonal timing of juvenile winter-run Chinook salmon migration (del Rosario and Redler 2010) suggests that pulse flows provide an environmental cue that stimulates the downstream migration of juvenile winter-run Chinook salmon into the Delta and subsequently their migration into coastal marine waters. Pulse flows provide a change in river flow over a short time period and are also typically associated with increases in turbidity and suspended sediments within the water column. Increased turbidity has been identified as an important environmental condition affecting pre-spawning adult delta smelt geographic distribution within the Delta and lower reaches of the Sacramento River. Therefore, bypass operations include provisions for operations in response to seasonal pulse flow events.

Operational Criteria and Adaptive Limits. The north Delta facilities operations and bypass flow requirements will apply in the BDCP long-term implementation period following completion of facilities construction. Specifics on the operational criteria and adaptive range of north Delta facilities bypass flows are provided in Table 3.13. The bypass operations will be based on three parameters “Constant Low Flow Pumping,” “Initial Pulse Protection,” and “Post-Pulse Operations.” Table 3.14 provides post-pulse flows criteria.

To allow for flexible and responsive implementation of the BDCP, several conservation measures include a defined “adaptive range” that establishes the parameters within which a conservation measure may be adjusted to improve its effectiveness or respond to changing biological conditions. Adaptive Ranges are specifically established upper and lower boundaries and limits that govern the scope of changes that can be made to water operations criteria for specific operational parameters under this conservation measure pursuant to the adaptive management program. These adaptive ranges are expected to be included within the bounds of BDCP regulatory authorizations and provide for both flexibility to change operation criteria to improve conservation or water supply performance and limitations to clearly define the confines of the Plan. Adjustments to the water operations criteria set out in the BDCP and reflected in its associated authorizations, and within the adaptive range for water operations described Tables 3-13 and 3-14, may only be conducted through the process identified in Section 3.7.3.2, *Decision Process for Adjusting Water Operations within the Adaptive Range*.

[***Note to Reviewers:*** *Adaptive range limits have not been determined at this time. Tables 3-13 and 3-14 provide “analytical ranges” used in the BDCP Effects Analysis as a step in the process of development of adaptive ranges.]*

Problem Statement: For decades, water has been diverted directly from the south Delta through SWP and CVP facilities to meet agricultural and urban water demands south and west of the Delta. These diversions both require and create an artificial north-to-south flow of water through the Delta (as opposed to the natural general east-to-west flow pattern) and have resulted in the development of reverse flows in major Delta channels that result in entrainment of fish, invertebrates, nutrients, and other organic material. Existing diversion facilities are equipped with louvers that guide juvenile and larger fish into salvage facilities. Salvaged fish are subsequently transported to release locations on the lower Sacramento and San Joaquin Rivers where they are subject to high predation pressure (Miranda et al. 2010). Planktonic eggs, larvae, and small juveniles are not effectively salvaged and do not survive when carried into conveyance facilities. Smelt and juvenile salmonids that are drawn into Clifton Court Forebay are subject to predation from the large populations of predatory fish that are present there as well as other sources of mortality (Gingras 1997, Clark et al. 2009, Castillo et al. 2009).

Table 3-13. Proposed Long-Term Operational Criteria and Adaptive Range Limits

*[**Note to Reviewers:** Table 3-13 and table 3-14 provide the proposed BDCP long term water operations for evaluation in the BDCP Effects Analysis. The criteria in these tables do not represent criteria agreed to by the Steering Committee; its purpose is for use in the Effects Analysis. These two tables are the same as the tables provided to the Steering Committee in February 2010. The operational criteria identified in these tables are the criteria agreed to by the BDCP Steering Committee on January 29, 2010 as documented in the handout titled: "SAIC Consultant Team Recommendations for Long Term Operations (January 29, 2010 draft D) – revised version based on SC input.]*

North Delta Diversion Bypass Flows		
Objectives include flows of the functional equivalent thereof to (1) maintain fish screen sweeping velocities, (2) reduce upstream transport from downstream channels, (3) support salmonid and pelagic fish transport to regions of suitable habitat, (4) reduce predation effects downstream, and (5) maintain or improve rearing habitat in the north Delta.		
Analytical Range A Operational Criteria[30]	**Initial Operational Criteria**	**Analytical Range B Operational Criteria[1]**
Constant Low-Level Pumping (Dec-Jun): • Diversions up to 10% of river flow for flows greater than 5,000 cfs. No more than 300 cfs at any one intake.	**Constant Low-Level Pumping (Dec-Jun):** • Diversions up to 6% of river flow for flows greater than 5,000 cfs. No more than 300 cfs at any one intake.	**Constant Low-Level Pumping (Dec-Jun):** • Diversions up to 2% of river flow for flows greater than 5,000 cfs. No more than 300 cfs at any one intake.
Initial Pulse Protection: • No pulse flow protection criteria implemented.	**Initial Pulse Protection:** • Low level pumping maintained through the initial pulse period. For the purpose of monitoring, the initiation of the pulse is defined by the following criteria: (1) Wilkins Slough flow changing by more than 45% over a five day period and (2) flow greater than 12,000 cfs. Low-level pumping continues until (1) Wilkins Slough returns to pre-pulse flows (flow on first day of 5-day increase), (2) flows decrease for 5 consecutive days, or (3) flows are greater than 20,000 cfs for 10 consecutive days. After pulse period has ended, operations will return to the bypass flow table (Table 3-6). These parameters are for modeling purposes. Actual operations will be based on real-time monitoring of fish movement. • If the first flush begins before Dec 1, May bypass criteria must be initiated following first flush and the second pulse period will have the same protective operation.	**Initial Pulse Protection:** • No range. (Same as initial operations)
Post-Pulse Operations: • After initial flush(es), go to Level I post-pulse bypass rule (see Table 3-6) until **10** total days of bypass flows above 20,000 cfs. Then go to the Level II post-pulse bypass rule until **20** total days of bypass flows above 20,000 cfs. Then go to the Level III post-pulse bypass rule.	**Post-Pulse Operations:** • After initial flush(es), go to Level I post-pulse bypass rule (see Table 3-6) until **15** total days of bypass flows above 20,000 cfs. Then go to the Level II post-pulse bypass rule until **30** total days of bypass flows above 20,000 cfs. Then go to the Level III post-pulse bypass rule.	**Post-Pulse Operations:** • After initial flush(es), go to Level I post-pulse bypass rule (see Table 3-6) until **20** total days of bypass flows above 20,000 cfs. Then go to the Level II post-pulse bypass rule until 45 total days of bypass flows above 20,000 cfs. Then go to the Level III post-pulse bypass rule.

[30] Analytical ranges represent the operational range limits for which the Effects Analysis will evaluate operational parameters. These analytical ranges are part of the process of identifying adaptive management ranges. It is expected that the eventual adaptive management range limits would fall within these analytical ranges.

Table 3-13. Proposed Long-Term Operational Criteria and Adaptive Range Limits (continued)

South Delta Channel Flows

Minimize take at south Delta pumps by reducing incidence and magnitude of reverse flows during critical periods for pelagic species.

* Values are monthly average for use in modeling. December 20-31 targets are -5000 cfs (W, AN), -3500 cfs (BN, D), and -3000 cfs (C), and are averaged with an assumed background of -8000 cfs for December 1-19. Values are reflective of the "most likely" operation under the FWS Delta Smelt Biological Opinion. Values for modeling may be updated based on review by fishery agencies.

South Delta Export – San Joaquin Inflow Ratio[31]

- Sliding scale for flows above the established OMR to share additional SJR flows between export and environment; export share would increase at higher flows
- Time value of benefit; crediting outside of period in which flows are acquired
- [Note that Conveyance WG/HOTT recommends continuing to evaluate the concept of isolating Old River to address south Delta channel flows.][32]

Analytical Range B Operational Criteria

OMR Flows

- Old and Middle River flows same as proposed Operations during December, January, and June
- Old and Middle River flows no less than -5,000 cfs between July and November

South Delta Export – San Joaquin Inflow Ratio

- 50% Feb & Mar
- 25% April & May

[31] The effects of potential increased San Joaquin River inflows on BDCP goals and objectives will be evaluated separately from the BDCP Effects Analysis.

Table 3-13. Proposed Long-Term Operational Criteria and Adaptive Range Limits (continued)

Fremont Weir/Yolo Bypass		
Considerations include (1) increasing spawning and rearing habitat for splittail and rearing habitat for salmonids for >30 days, (2) providing alternate migration corridor to the mainstem Sacramento River, and (3) increasing effectiveness of habitat and food transport in Cache Slough.		
Analytical Range A Operational Criteria	**Initial Operational Criteria**	**Analytical Range B Operational Criteria**
No Range.	• Sacramento Weir - No change in operations; improve upstream fish passage facilities • Lisbon Weir - No change in operations; improve upstream fish passage facilities • Fremont Weir – Improve fish passage at existing weir elevation; construct opening and operable gates at elevation 17.5 feet with fish passage facilities; construct opening and operable gates at a smaller opening with fish passage enhancement at elevation 11.5 feet	No Range.
Fremont Weir – Improve fish passage at existing weir elevation; construct opening and operable gates at elevation 17.5 feet with fish passage facilities		No Range.
Fremont Weir Gate Operations		
December 1-March 30 open the 17.5 foot elevation gates when Sacramento River flow at Freeport is greater than 25,000 cfs (provides local and regional flood control benefit and coincides with pulse flows and juvenile salmonid migration cues) to provide Yolo Bypass inundation of 3,000 to 6,000 cfs depending on river stage. Operating the gates to allow Yolo Bypass inundation when Sacramento River flow is greater than 25,000 cfs will reduce impacts to water supply associated with Hood bypass flow constraints. Potential impacts to water supply would be avoided or minimized through an operations plan.	December 1-March 30 (extend to May 15, depending on hydrologic conditions and measures to minimize land use and ecological conflicts) open the 17.5 foot and 11.5 foot elevation gates when Sacramento River flow at Freeport is greater than 25,000 cfs (provides local and regional flood control benefit and coincides with pulse flows and juvenile salmonid migration cues, provides seasonal floodplain inundation for food production, juvenile rearing, and spawning) to provide Yolo Bypass inundation of 3,000 to 6,000 cfs depending on river stage. Operating the gates to allow Yolo Bypass inundation when Sacramento River flow is greater than 25,000 cfs will reduce impacts to water supply associated with Hood bypass flow constraints. Potential impacts to water supply would be avoided or minimized through an operations plan.	No Range.
Close the 17.5 foot elevation gates when Sacramento River flow at Freeport recedes to less than 25,000 cfs	Close the 17.5 foot elevation gates when Sacramento River flow at Freeport recedes to less than 20,000 cfs but keep 11.5 foot elevation gates open to provide greater opportunity for fish within the bypass to migrate upstream into the Sacramento River; close 11.5 foot elevation gates when Sacramento River flow at Freeport recedes to less than 15,000 cfs	No Range.

[32] The concept of isolating Old River to address south Delta channel flows will be evaluated separately from the BDCP Effects Analysis.

Table 3-13. Proposed Long-Term Operational Criteria and Adaptive Range Limits (continued)

Delta Inflow & Outflow		
Considerations include (1) Provide sufficient outflow to maintain desirable salinity regime downstream of Collinsville during the spring, (2) explore range of approaches toward providing additional variability to Delta inflow and outflow.		
Analytical Range A Operational Criteria	**Initial Operational Criteria**	**Analytical Range B Operational Criteria**
Delta Outflow: Jul-Jan: Per D-1641 Feb-Jun: Per D-1641*, except no Roe Island triggering * Current relaxation of Collinsville standard to 4,000 cfs in May and June revised to state when the Eight River Index is 10.0 or less as established on May 1. ** Proportional Reservoir Release concept will continue to be evaluated to the extent that it provides similar response to outflow, inflow, and upstream storage conditions	**Delta Outflow:** Jul-Jan: Per D-1641 Feb-Jun: Per D-1641 * Proportional Reservoir Release concept will continue to be evaluated to the extent that it provides similar response to outflow, inflow, and upstream storage conditions	**Delta Outflow:** **Summer, Winter, and Fall:** Jul-Aug & Dec-Jan: Per D-1641 Sep-Nov: Fall X2 per FWS Smelt BO **Spring:** Feb-Jun: NGO X2-Eight River Index approach in all years (storage off-ramps in all year types will be refined to avoid upstream coldwater storage impacts on all reservoirs). * Proportional Reservoir Release concept will continue to be evaluated to the extent that it provides similar response to outflow, inflow, and upstream storage conditions ** Continue analysis of NGO watershed unimpaired runoff approach as it relates to PREs and parties outside of BDCP. Carry into “related action” alternative.
Delta Cross Channel Gate Operations		
Considerations include (1) reduce transport of outmigrating Sacramento River fish into central Delta, (2) maintain flows downstream on Sacramento River, (3) and providing sufficient Sacramento River flow into interior Delta when water quality for M&I and AG may be of concern.		
No Range.	Oct-Nov: DCC gate closed if fish are present (assume 15 days per month; may be open longer depending on presence of fish) Dec-Jun: DCC gate closed Jul-Sep: DCC gate open	No Range.
Rio Vista Minimum Instream Flows		
Maintain minimum flows for outmigrating salmonids and smelt.		
No Range.	Sep-Dec: Per D-1641 Jan-Aug: Minimum of 3,000 cfs	No Range.

Table 3-13. Proposed Long-Term Operational Criteria and Adaptive Range Limits (continued)

Operations for Delta Water Quality and Residence Time		
Considerations include (1) maintain a minimum level of pumping from the south Delta during summer to provide limited flushing for general water quality conditions (reduce residence times), (2) for M&I and AG salinity improvements, and (3) to allow operational flexibility during other periods to operate either north or south diversions based on real-time assessments of benefits to fish and water quality.		
Analytical Range A Operational Criteria	**Initial Operational Criteria**	**Analytical Range B Operational Criteria**
No Range.	**Assumptions for analysis:** Jul-Sep: Prefer south delta pumping up to 3,000 cfs before diverting from north Oct-Jun: Prefer north delta pumping (real-time operational flexibility)	No Range.
In-Delta Agricultural and Municipal & Industrial Water Quality Requirements		
Existing M&I and ag salinity requirements.		
No Range.	Existing D-1641 North and Western Delta AG and MI standards EXCEPT move compliance point from Emmaton to Three Mile Slough juncture. Maintain all water quality requirements contained in the NDWA/ DWR Contract and other DWR contractual obligations.[33]	No Range.

[33] The results of the water quality modeling from the effects analysis will be used to determine if other actions are needed to address water quality issues that may arise, including water quality in the southern and central Delta for both Agricultural and M*I due to the BDCP long-term operations.

Table 3-14. Post-Pulse Operations for North Delta Diversion Bypass Flows

*[**Note to Reviewers:** Table 3-13 and table 3-14 provide the proposed BDCP long term water operations for evaluation in the BDCP Effects Analysis. The criteria in these tables do not represent criteria agreed to by the Steering Committee; its purpose is for use in the Effects Analysis. These two tables are the same as the tables provided to the Steering Committee in February 2010. The operational criteria identified in these tables are the criteria agreed to by the BDCP Steering Committee on January 29, 2010 as documented in the handout titled: "SAIC Consultant Team Recommendations for Long Term Operations (January 29, 2010 draft D) – revised version based on SC input.]*

Level I Post-Pulse Operations

Based on the objectives stated above, it is recommended to implement the following operating criteria:

- Bypass flows sufficient to prevent upstream tidal transport at two points of control: (1) Sacramento River upstream of Sutter Slough and (2) Sacramento River downstream of Georgiana Slough. These points are used to prevent upstream transport toward the proposed intakes and to prevent upstream transport into Georgiana Slough.

Dec - Apr

If Sacramento River flow is over--	But not over--	The bypass is:
0 cfs	5,000 cfs	100% of the amount over 0 cfs
5,000 cfs	15,000 cfs	Flows remaining after constant low level pumping (see main table)
15,000 cfs	17,000 cfs	15,000 cfs plus 80% of the amount over 15,000
17,000 cfs	20,000 cfs	16,600 cfs plus 60% of the amount over 17,000 cfs
20,000 cfs	no limit	18,400 plus 30% of the amount over 20,000 cfs

Level II Post-Pulse Operations

Based on the objectives stated above, it is recommended to implement the following operating criteria:

- Bypass flows sufficient to prevent upstream tidal transport at two points of control: (1) Sacramento River upstream of Sutter Slough and (2) Sacramento River downstream of Georgiana Slough. These points are used to prevent upstream transport toward the proposed intakes and to prevent upstream transport into Georgiana Slough.

Dec - Apr

If Sacramento River flow is over--	But not over--	The bypass is:
0 cfs	5,000 cfs	100% of the amount over 0 cfs
5,000 cfs	11,000 cfs	Flows remaining after constant low level pumping (see main table)
11,000 cfs	15,000 cfs	11,000 cfs plus 60% of the amount over 11,000
15,000 cfs	20,000 cfs	13,400 cfs plus 50% of the amount over 15,000 cfs
20,000 cfs	no limit	15,900 cfs plus 20% of the amount over 20,000 cfs

Level III Post-Pulse Operations

Based on the objectives stated above, it is recommended to implement the following operating criteria:

- Bypass flows sufficient to prevent upstream tidal transport at two points of control: (1) Sacramento River upstream of Sutter Slough and (2) Sacramento River downstream of Georgiana Slough. These points are used to prevent upstream transport toward the proposed intakes and to prevent upstream transport into Georgiana Slough.

Dec - Apr

If Sacramento River flow is over--	But not over--	The bypass is:
0 cfs	5,000 cfs	100% of the amount over 0 cfs
5,000 cfs	9,000 cfs	Flows remaining after constant low level pumping (see main table)
9,000 cfs	15,000 cfs	9,000 cfs plus 50% of the amount over 9,000
15,000 cfs	20,000 cfs	12,000 cfs plus 20% of the amount over 15,000 cfs
20,000 cfs	no limit	13,000 cfs plus 0% of the amount over 20,000 cfs

Table 3-14. Post-Pulse Operations for North Delta Diversion Bypass Flows (continued)

Level I Post-Pulse Operations

May

If Sacramento River flow is over--	But not over--	The bypass is:
0 cfs	5,000 cfs	100% of the amount over 0 cfs
5,000 cfs	15,000 cfs	Flows remaining after constant low level pumping (see separate table)
15,000 cfs	17,000 cfs	15,000 cfs plus 70% of the amount over 15,000
17,000 cfs	20,000 cfs	16,400 cfs plus 50% of the amount over 17,000 cfs
20,000 cfs	no limit	17,900 plus 20% of the amount over 20,000 cfs

Jun

If Sacramento River flow is over--	But not over--	The bypass is:
0 cfs	5,000 cfs	100% of the amount over 0 cfs
5,000 cfs	15,000 cfs	Flows remaining after constant low level pumping (see separate table)
15,000 cfs	17,000 cfs	15,000 cfs plus 60% of the amount over 15,000
17,000 cfs	20,000 cfs	16,200 cfs plus 40% of the amount over 17,000 cfs
20,000 cfs	no limit	17,400 plus 20% of the amount over 20,000 cfs

Jul-Sep: 5,000 CFS
Oct-Nov: 7,000 cfs

Level II Post-Pulse Operations

May

If Sacramento River flow is over--	But not over--	The bypass is:
0 cfs	5,000 cfs	100% of the amount over 0 cfs
5,000 cfs	11,000 cfs	Flows remaining after constant low level pumping (see separate table)
11,000 cfs	15,000 cfs	11,000 cfs plus 50% of the amount over 11,000
15,000 cfs	20,000 cfs	13,000 cfs plus 35% of the amount over 15,000 cfs
20,000 cfs	no limit	14,750 cfs plus 20% of the amount over 20,000 cfs

Jun

If Sacramento River flow is over--	But not over--	The bypass is:
0 cfs	5,000 cfs	100% of the amount over 0 cfs
5,000 cfs	11,000 cfs	Flows remaining after constant low level pumping (see separate table)
11,000 cfs	15,000 cfs	11,000 cfs plus 40% of the amount over 11,000
15,000 cfs	20,000 cfs	12,600 cfs plus 20% of the amount over 15,000 cfs
20,000 cfs	no limit	13,600 cfs plus 20% of the amount over 20,000 cfs

Jul-Sep: 5,000 CFS
Oct-Nov: 7,000 CFS

Level III Post-Pulse Operations

May

If Sacramento River flow is over--	But not over--	The bypass is:
0 cfs	5,000 cfs	100% of the amount over 0 cfs
5,000 cfs	9,000 cfs	Flows remaining after constant low level pumping (see separate table)
9,000 cfs	15,000 cfs	9,000 cfs plus 40% of the amount over 9,000
15,000 cfs	20,000 cfs	11,400 cfs plus 20% of the amount over 15,000 cfs
20,000 cfs	no limit	12,400 cfs plus 0% of the amount over 20,000 cfs

Jun

If Sacramento River flow is over--	But not over--	The bypass is:
0 cfs	5,000 cfs	100% of the amount over 0 cfs
5,000 cfs	9,000 cfs	Flows remaining after constant low level pumping (see separate table)
9,000 cfs	15,000 cfs	9,000 cfs plus 30% of the amount over 9,000
15,000 cfs	20,000 cfs	10,800 cfs plus 20% of the amount over 15,000 cfs
20,000 cfs	no limit	11,800 cfs plus 0% of the amount over 20,000 cfs

Jul-Sep: 5,000 CFS
Oct-Nov: 7,000 CFS

The Sacramento River, in addition to its upstream tributaries, is the primary migration corridor and spawning/rearing habitat for Chinook salmon, Central Valley steelhead, green and white sturgeon, and Pacific and river lamprey spawning in the Sacramento River watershed. Further, both delta smelt and longfin smelt are thought to spawn in the lower Sacramento River (Wang 1986, Bennett 2005). Important fishery issues with respect to seasonal river flows include: (1) adult Chinook salmon, steelhead, green and white sturgeon, and Pacific and river lamprey attraction flows and upstream migration; (2) juvenile Chinook salmon, steelhead, and Pacific and river lamprey downstream migration and survival; (3) downstream transport of planktonic fish eggs and larvae; (4) downstream transport of food and other organic material; and (5) habitat for both resident and migratory covered fish species within the lower Sacramento River. The importance of river flows to each life stage of the covered fish species varies seasonally depending life history and habitat requirements for each species. Because of the importance of the Sacramento River as a migration route and habitat for covered fish species, maintaining sufficient flows within the river to support this function is an important operational objective for covered fish species.

Hypotheses: Relocation and operation of the primary point of SWP and CVP water diversions from the south Delta to multiple facilities on the Sacramento River between Freeport and Courtland and conveying water through a tunnel/pipeline facility are hypothesized to provide a broad range of benefits to covered fish species, the Delta ecosystem, and water supply if operated according to an appropriate set of operational parameters, which are described as part of this conservation measure. The following hypotheses provide the justification for the relocation of the primary point of diversion:

1. Relocation and operation of the primary point of diversion to the north Delta will substantially reduce entrainment of the larvae of covered fish species by reducing the spatial overlap of diversion intakes and covered fish species. The location of the existing south Delta export facilities is within the influence of all covered fish species for at least part of the year. However, the population centers of resident estuarine species, particularly delta and longfin smelt, are downstream of the reach of the Sacramento River where the north Delta intakes could be installed (Wang 1986, Bennett 2005).

2. Equipping facility intakes with state-of-the-art positive barrier fish screens will substantially reduce entrainment and impingement losses of juveniles and adults of covered fish species. These screens will be engineered to provide a maximum approach velocity coupled with a minimum unidirectional sweeping velocity to protect covered fish species when fish are within the vicinity of intakes.

3. Constructing multiple intakes (rather than one or few) along the Sacramento River between Freeport and Courtland will substantially reduce entrainment and impingement losses of juveniles and adults of covered fish species. Multiple intakes will reduce the distance fish must travel past each fish screen, allowing individuals to

rest between intake locations. Early estimates indicated that, if one 15,000 cfs intake were constructed, a single fish screen nearly a mile long will need to be constructed to meet approach and sweeping velocity criteria. This distance would expose fish to screens for longer periods, potentially exhausting them, reducing their swimming ability, and increasing their vulnerability to impingement.

4. Reducing water diversions in the tidal region of the Delta will substantially reduce entrainment and impingement losses of juveniles and adults of covered fish species. Reverse flows associated with tidal oscillations increase the zone of influence of existing diversion facilities in many south Delta channels, potentially increasing the risk of entrainment of covered fish species. Relocating the primary point of diversion farther upstream will reduce the tidal influence on diversions, which will reduce entrainment of covered fish species. Further, for positive barrier fish screens to function properly to minimize fish entrainment and impingement risk, a minimum unidirectional sweeping velocity must be maintained. Opportunities for such velocity improve as tidal influence decreases farther upstream.

5. Relocation and operation of the primary point of diversion to the north Delta will reduce the export of nutrients, phytoplankton, zooplankton, macroinvertebrates, and other organic material from the estuary. The location of existing south Delta diversion facilities is thought to be in an area that exports higher concentrations of nutrients, phytoplankton, zooplankton, macroinvertebrates, and other organic material than will occur with the new proposed reach of the Sacramento River. As a result, the loss of Delta productivity may be lower if water is diverted at north Delta facilities compared to existing south Delta facilities.

6. Improving hydrodynamics within Delta channels will improve fishery and aquatic habitat within the Delta. Existing flow patterns in the Delta have been altered to maintain high water quality in the south Delta for project exports, as well as for local agricultural and other urban water uses. Such alterations include north to south flows through the man-made Delta Cross Channel and reverse flows in Old and Middle Rivers, generating adverse effects on fish and aquatic processes.

7. Relocation and operation of the primary point of diversion to the north Delta will reduce or eliminate mortality of covered fish species associated with collection, handling, transport, and release of salvaged fish from the existing export facilities and predation within these facilities. A north Delta diversion facility will be designed to avoid altogether the need to salvage fish by constructing in-river or on-river facilities.

8. Relocation and operation of the primary point of diversion to the north Delta will improve water supply reliability and flexibility under conditions of future environmental change. Because of their location, new diversion facilities could withstand predicted future sea level rise in ways that existing diversion facilities will not. Multiple intakes will add flexibility in operations to handle variation in the location of covered fish and tidally-induced flows.

9. Reducing artificial north-to-south through-Delta flows when covered fish are present will increase hydraulic residence time and improve aquatic productivity in the interior Delta. Existing Delta operations promote north-to-south flow of water via the Delta Cross Channel to offset high salinities and lower inflows from the San Joaquin River. By reducing South Delta diversions, less water will move from north to south, resulting in increased residence time of nutrients and organic matter, allowing these materials to be assimilated into the Delta food web.

10. Reducing the reliance on through-Delta conveyance via the Delta Cross Channel and intakes in the south Delta will provide greater opportunity for effective physical habitat restoration and enhancement in the western, eastern, and southern Delta. Decreased south Delta pumping will reduce the export of primary and secondary ecological production that may result from restored habitat, which would other reduce or eliminate the expected benefits of the habitat restoration also proposed by the BDCP. Restoration in these parts of the Delta, as well as Delta-wide hydrodynamic changes expected from a north Delta diversion, will reestablish ecosystem complexity by improving aquatic ecosystem processes, distribution, connectivity, migration, transport, and residence time in ways that the current water conveyance system cannot accommodate.

11. Reducing the reliance on through-Delta conveyance via the Delta Cross Channel and intakes in the south Delta will substantially reduce the effects of existing water projects on salmonids in the San Joaquin River system and tributaries, Mokelumne River, and other east side tributaries. Such artificial flow patterns are thought to entrain outmigrating juvenile salmonids in these channels towards the pumps and confuse the upstream migration cues of adults. Although the potential for adverse effects on Sacramento River salmonids may increase, these effects are predicted to be avoided or minimized by the positive fish screen and sweeping and approach velocity criteria (see #2-4 above) and other operational parameters.

12. Relocation and operation of the primary point of diversion to the north Delta will facilitate the implementation of some other conservation measures focused on non-flow and non-habitat related stressors.

13. Relocation and operation of the primary point of diversion to the north Delta will allow for the emulation of more natural physical patterns (e.g., salinity regimes, flow patterns) and processes in the Delta under which native resident species evolved. For example, a change in the hydrograph could favor native species by providing proper timing of biological processes from physical cues, such as those needed to initiate upstream or downstream migration, and create conditions that disfavor non-native species, such as reduced summer inflows, which are currently higher than would occur naturally.

The following hypotheses provide the basis for maintaining bypass flows past the proposed new north Delta diversions:

1. Maintaining bypass flows will maintain adequate flows in the mainstem Sacramento River and distributaries downstream of the points of diversion for covered fish species. Of particular interest are flow rates within Sutter and Steamboat Sloughs. These sloughs are existing channels that convey water from the Sacramento River in the general vicinity of Courtland downstream to approximately Rio Vista where they re-enter the lower Sacramento River. Both channels currently have a hydraulic capacity greater than 500 cfs. Benefits maintaining adequate flows in Sutter and Steamboat Sloughs include:

    - Providing an alternative migration route for salmonids (Perry and Skalski 2008) and possibly splittail, sturgeon, and lamprey that circumvents the Delta Cross Channel and Georgiana Slough, thereby reducing the likelihood of covered fish species moving into the interior Delta where they may be exposed to higher predation pressure and entrainment into the south Delta pumps.
    - Providing high quality juvenile rearing habitat and adult holding habitat for salmonids, sturgeon, and splittail. Both slough channels support substantially more woody riparian vegetation and greater habitat diversity (e.g., water depths, velocities, in-channel habitat, etc.) than is present along the mainstem Sacramento River between Courtland and Rio Vista.
    - Providing high quality spawning habitat for splittail during dry periods without floodplain inundation.

    Despite these anticipated benefits, Perry and Skalski (2009) and Perry et al. (2010) indicate that survival rates of juvenile Chinook salmon in Sutter and Steamboat sloughs are highly variable relative to the mainstem Sacramento River; in their studies, they have found that survival has been higher than, lower than, and similar to survival rates in the mainstem Sacramento River rates. Recent hydrodynamic modeling indicates that substantial habitat restoration in the Cache Slough area (see Section 3.4.3.2), in combination with bypass flow requirements for the north Delta diversions, will enhance downstream flows in Sutter and Steamboat sloughs substantially above those present under current conditions without facility north Delta diversion facility (A. Munevar unpubl. data). Further, the BDCP proposes to enhance channel margin habitat in Sutter and Steamboat sloughs in part to create habitat that is unfavorable to non-native predators that may be reducing survival of Chinook salmon, and likely other covered species in these sloughs. Therefore, in combination with these other conservation measures, maintaining bypass flows is expected to improve survival of salmonids, sturgeon, and splittail in Sutter and Steamboat sloughs.

2. Maintaining bypass flows will provide transport flows necessary for downstream movement of delta and longfin smelt. Newly hatched larval delta and longfin smelt, called yolk-sac larvae, have a yolk sac attached to them with an oil globule (Wang

1986). The yolk sac provides nourishment for delta smelt larvae for approximately 4 to 6 days (Bennett 2005) and is thought to be similar for longfin smelt. These larvae are very weak swimmers and drift downstream with flows from the Sacramento River to the low salinity zone, where they can find suitable prey. To avoid starvation, this downstream movement must take place before the entire yolk sac is absorbed. Because downstream yolk-sac larval movement is driven nearly entirely by downstream flows, a minimum bypass flow criteria that allows this movement to occur is necessary.

3. Maintaining minimum bypass flows will provide downstream transport of food and organic material. The Sacramento River is used as a major corridor through which food and other organic material from upstream are transported downstream to the Delta and bays. The Delta and bays acquire production from upstream habitats to support their ecosystems.

4. Maintaining minimum bypass flows will provide necessary attraction flows for upstream migration of adult Chinook salmon, steelhead, and green and white sturgeon, including attraction flows through Sutter and Steamboat Sloughs.

5. Maintaining minimum bypass flows will minimize tidally driven bidirectional flows near diversion intakes, reducing the exposure duration of covered fish species to predators that will likely reside near intake structures. Unidirectional flows past intakes may also affect local current patterns and hydrodynamics in the vicinity of the screen surface that may affect fish entrainment or impingement, debris loading, effectiveness of fish screen cleaning mechanisms in removing debris from the screen surface, and maintaining a uniform approach velocity within the screen design criterion.

Developing bypass flow criteria for the north Delta diversion facilities involved consideration of the seasonal timing of various life stages of covered fish species within the lower Sacramento River, relationships between river flow, water velocity, transport time, and residence time, and the growth, survival, and distribution of various life stages of the covered species.

Adaptive Management Considerations: Results of the biological monitoring would be used adaptively in a variety of ways that include, but are not limited to: (1) changes in diversion operations within a range of adopted diversion parameters that are based on "real-time" monitoring of the occurrence of covered fish in the area; (2) selectively operating diversions based on the geographic distribution of covered fish within the river; and (3) changing diversion operations based on tidal velocity and river flows to increase sweeping velocity and the rate of fish movement past fish screens.

Results of both biological and operational monitoring throughout the Delta could be used within the BDCP adaptive management framework to refine and modify river bypass flow rates. For example, additional information on the actual timing of fish migration downstream within the Sacramento River within a given year could result in modification to the river bypass flows to facilitate migration past the points of diversion and fish screens. The adaptive management ranges provided for operational criteria under this conservation measure (Tables 3-13 and 3-14) provide flexibility to incorporate new knowledge gained through monitoring and research and to respond to changes in the system.

South Delta Diversion Operations and Old and Middle River Flows.

To reduce the impacts of south Delta diversions on covered fish species and the Delta environment, Old and Middle River reverse flows will meet the operational criteria described in Table 3-13. These rivers are subject to reduced or reverse flows as a result of low San Joaquin River inflow, flood tides, and water exports at SWP and CVP facilities. These flow conditions can result in increased risk of entrainment of fish, invertebrates, phytoplankton, and other organic material.

Diversions from the south Delta SWP and CVP facilities will be reduced considerably during wetter periods with dual operation of new north Delta diversion facilities. During wetter periods in the BDCP long-term implementation period, water will be diverted from the south Delta to augment north Delta diversions and may be diverted in appropriate circumstances to improve circulation and maintain water quality conditions in the interior and southern Delta.

Operational Criteria and Adaptive Limits. The operational criteria for south Delta operations and Old and Middle River flows during the BDCP long-term implementation periods are described in Table 3-13.

With operation of north Delta diversion facilities in the long-term implementation period, the existing south Delta SWP and CVP export facilities will be operated as part of a dual conveyance facility and exports from the south Delta will be substantially reduced (the north Delta diversion facilities will be equipped with state-of-the-art positive barrier fish screens and will be the primary point of long-term diversion during wetter periods). The dual export system will be operated to meet water supplies.

> **Problem Statement:** Export operations of the SWP and CVP diversion facilities in the South Delta, in combination with San Joaquin and Sacramento River flows, tidal effects, and substantially reduced inflows into the Delta, have been identified as primary factors in altering hydrodynamic conditions within Delta channels and associated fishery habitat (DWR 2006, Baxter et al. 2008). Export operations of the SWP and CVP pumping plants contribute to local changes in water current patterns, water quality, and direct entrainment and losses of fish, macroinvertebrates, nutrients, phytoplankton, and zooplankton from the Delta environment (DWR 2006).
>
> Although the response of various lifestages of covered species to flows within Old and Middle rivers is dynamic and variable within and among species, there is a positive relationship between the magnitude (average monthly) of reverse flows within Old and Middle rivers and the occurrence of pre-spawning adult delta smelt in SWP and CVP fish

salvage during the winter months (Kimmerer 2008, USFWS 2009c). Further, particle tracking model simulations predict that there is a greater risk that planktonic early lifestages of covered fish species (e.g., larval delta smelt) will be vulnerable to entrainment at the SWP and CVP export facilities when reverse flows within Old and Middle rivers increase. In addition, a number of the covered fish, including the juvenile and adult lifestages of Chinook salmon, steelhead, delta smelt, longfin smelt, sturgeon, lamprey, and splittail are expected to use hydrodynamic cues (e.g., channel flow direction and magnitude) to help guide movement through the Delta. Reverse flows in Delta channels are thought to contribute to false attraction to migration cues, longer migration routes that may expose fish to sources of mortality such as predation, exposure to seasonally elevated water temperatures and other stressors, and increased vulnerability to entrainment at the SWP and CVP south Delta export facilities.

Reverse flows within the channels of Old and Middle rivers are also hypothesized to affect local and regional habitat conditions for covered fish and other aquatic species. Changes in channel velocity and flow patterns affect hydraulic residence time in the area and the production of phytoplankton and zooplankton that are important to the diet of covered fish. Channel velocities, scour, and deposition patterns affect habitat for benthic organisms and other macroinvertebrates. Changes in tidal hydrodynamics, especially channel velocity, affect habitat suitability for covered fish and other aquatic species in the area.

Relationships between the magnitude of reverse flows in Old and Middle rivers and corresponding changes in salvage of various covered fish, such as juvenile Chinook salmon, steelhead, splittail, longfin smelt, lamprey, and sturgeon, are highly variable. Analyses and evaluations are ongoing to further assess the potential biological benefits of managing SWP and CVP south Delta exports based on direct diversion rates or changes in the magnitude of reverse flows in Old and Middle rivers.

Hypotheses: Reducing diversions in the South Delta are hypothesized to:

- Reduce the risk of entrainment mortality of salmonids, smelt, splittail, sturgeon and lamprey;
- Reduce the risk of predation mortality of salmonids, smelt, lamprey, and splittail in Clifton Court Forebay; and
- Reduce the risk of entrainment of organic matter and food for salmonids, smelt, splittail, and sturgeon.

Adaptive Management Considerations: Results of biological monitoring will be used within the BDCP adaptive management framework to refine and modify seasonal operations of Old and Middle River flows. The adaptive management ranges provided for operational criteria under this conservation measure (Tables 3-13 and 3-14) provide flexibility to incorporate new knowledge gained through monitoring and research and to respond to changes in the system.

Delta Cross Channel Gate Operations

The Delta Cross Channel gates will be operated during the long-term implementation period to improve fish migration, hydrodynamics (including hydraulic residence time), and food and organic material transport while minimizing changes to water quality for agriculture, municipal, and industrial uses in the interior and southern Delta.

Delta Cross Channel gates are located on the Sacramento River near Walnut Grove (Figure 3-52). The Delta Cross Channel serves as a conveyance facility for water to move from the Sacramento River into the interior Delta. Water quality in the central and south Delta can degrade during low San Joaquin River flows. The Delta Cross Channel was constructed to move higher quality Sacramento River towards the central and south Delta to improve water quality there. Juvenile Chinook salmon, and presumably a number of other fish species, move from the Sacramento River into the interior Delta when the gate is open (Brandes and McLain 2001). Results of survival studies using coded wire tagged and radio tagged fish suggest that survival juvenile Chinook salmon passing into the Delta through the Delta Cross Channel is lower than survival of those migrating down the mainstem Sacramento River (Brandes and McLain 2001, Perry and Skalski 2009, Perry et al. 2010). Based on results of these studies, closure of Delta Cross Channel gates between February 1 and May 20 was established under D-1641 for fish benefits.

Operational Criteria and Adaptive Limits. The operational criteria for the Delta Cross Channel gates during the BDCP long-term implementation period are described in Table 3-13.

Problem Statement: When the Delta Cross Channel is open, fish move into the interior Delta with Sacramento River water (Brandes and McLain 2001). Survival of juvenile Chinook salmon, and likely other fish species, within the interior Delta is lower than survival in the mainstem Sacramento River (Baker and Morhardt 2001, Brandes and McLain 2001, CALFED 2001, Perry and Skalski 2009, Perry et al. 2010), although it is unknown whether this reduced survival has a population level effect on Chinook salmon (Manly 2002, 2008).

Current seasonal operations of the Delta Cross Channel gates designated by D-1641 are designed to prohibit the migration of juvenile fish from the Sacramento River into the interior Delta through the Delta Cross Channel during the spring. However, adverse effects of an open DCC operation to anadromous fish, and other fish, also occur outside of this closure period. Furthermore, open gates decrease velocities and increase bi-directional flows in the Sacramento River and its distributaries, slowing the migration of covered species and increasing their vulnerability to predation or mortality from poor habitat. Therefore, lengthening the closure period or operating on a tidal or daily cycle may improve survival of salmonids and other covered fish species.

Hypotheses: Revised operations of Delta Cross Channel gates are hypothesized to:

- Increase the survival of juvenile Chinook salmon and possibly other covered fish species by: (1) improving downstream migration of fish in the Sacramento River and tributaries, which will reduce their risk to predation and other sources of mortality; and (2) reducing the proportion of fish entering the interior Delta, where survival of juvenile Chinook salmon is lower (Baker and Morhardt 2001, Brandes and McLain 2001, CALFED 2001, Perry and Skalski 2009, Perry et al. 2010). Several hypotheses have been suggested to explain reduced survival of juvenile Chinook salmon in the interior Delta relative to the mainstem Sacramento River, including, but not limited to: (1) increased exposure to unscreened water diversions within the Delta channels; (2) exposure to seasonally elevated water temperatures and potentially toxic contaminants; (3) increased residence time and longer migration routes leading to longer exposure to environmental conditions within the Delta and increased vulnerability to predation mortality; (4) delayed migration as a result of altered hydrologic conditions in Delta channels as a result of SWP and CVP export operations; and (5) direct losses as a result of entrainment, predation, or salvage mortality at the south Delta SWP and CVP export facilities (Baxter et al. 2008).

- maintain sufficient water quality in the south Delta in combination with minimal year-round pumping in the south Delta (see Section 3.4.2.1, CM1). Seasonally elevated water temperatures and an accumulation of toxics can occur in the central and south Delta, likely as a result of high residence times associated with low inflows from the San Joaquin River. These impairments can have lethal and sublethal effects on covered fish species inhabiting the south and central Delta. In addition, modeling results indicate that drinking water quality standards for the south Delta under D-1641 would not be violated under this revised set of operational criteria (A. Munevar pers. comm.).

- Improve the strength of migration cues and avoid false cues for adult migrating steelhead, Chinook salmon, and sturgeon on the Sacramento and San Joaquin Rivers. When the Delta Cross Channel is open, water from the Sacramento River mixes with water from the Mokelumne, Cosumnes, and San Joaquin Rivers, reducing the strength of migration cues to salmonids and sturgeon migrating upstream. Therefore, increasing the duration of Delta Cross Channel closure will allow more anadromous fish below the Delta Cross Channel to directly sense migration cues to upstream habitat, thus increasing the ability to move upstream and reducing delays to spawning; and

- Improve downstream flows and downstream transport of fish eggs, larvae, juveniles, food, and organic material within the Sacramento River into the Delta.

Adaptive Management Considerations: Results of biological monitoring will be used within the BDCP adaptive management framework to refine and modify seasonal operations of Delta Cross Channel gates.

Rio Vista Flows

Sufficient Rio Vista flows will be maintained during the long-term implementation period for the benefit of covered fish species. The lower Sacramento River serves as an important part of the aquatic habitat within the Delta. Diversion of water at new north Delta Diversion Facilities, as well as diversion of water from the mainstem river into side channels (e.g., Delta Cross Channel) or seasonally inundated floodplain habitat (e.g., Yolo Bypass), has a direct effect on flow rates in the Sacramento River at Rio Vista. Identification of a minimum flow requirement at Rio Vista is intended to support fishery and aquatic habitat in the reach of the Sacramento River located between Sacramento and Rio Vista. Flow in the mainstem Sacramento River at Rio Vista is augmented by the flow contribution from Cache Slough, the Yolo Bypass, Sutter and Steamboat Sloughs, and other local tributaries. Minimum river flows at Rio Vista in the fall are included in current regulations (D-1641, biological opinions).

Operational Criteria and Adaptive Limits. The operational criteria for Rio Vista flows during the BDCP long-term implementation periods are described in Table 3-13.

Problem Statement: The Sacramento River, in addition to its upstream tributaries, is the primary migration corridor in the Delta for Chinook salmon, Central Valley steelhead, sturgeon, and lamprey from the Sacramento River basin. In addition, both delta and longfin smelt likely spawn in the lower river in the general vicinity of Rio Vista. Key fishery issues with respect to seasonal river flows at Rio Vista have primarily focused on adult Chinook salmon and steelhead attraction and upstream migration flows during the fall months. The importance of river flows to each of the species and lifestages of covered fish species varies seasonally depending on the life history and habitat requirements of the species.

Hypotheses: Maintaining sufficient flows past Rio Vista is hypothesized to:

- Maintain sufficient attraction and upstream migration flows for adult salmonids, sturgeon, and lamprey in the Sacramento River;
- Maintain sufficient downstream migration of juvenile Chinook salmon, steelhead, and lamprey from the Sacramento River basin;
- Maintain sufficient downstream transport of planktonic fish eggs and larvae;
- Maintain sufficient downstream transport of organic material, phytoplankton, and zooplankton; and
- Provide high quality habitat for both resident and migratory species within the lower river.

Adaptive Management Considerations: Results of biological monitoring will be used within the BDCP adaptive management framework to refine and modify the seasonal river flow criteria at Rio Vista.

Delta Outflows

Sufficient Delta outflows will be maintained during the long-term for the benefit of covered fish species. Delta outflows provide for downstream transport of fish and other aquatic organisms as well as organic material and prey for covered species into the lower reaches of the Delta and Suisun Bay. In balance with upstream salinity intrusion from the bay, Delta outflows also control the location of the low salinity region of the estuary (Baxter et al. 1999, Kimmerer 2004). The abundance of life stages of a number of fish species, including some covered fish species (longfin smelt), has been positively correlated with the location of the low salinity zone (generally measured as X2) within the estuary (Baxter et al. 1999, Kimmerer 2004). Suisun Bay and the western Delta represent important low salinity habitat areas within the estuary. Open water habitat in this region serves as larval and juvenile rearing, adult holding, and foraging habitat for resident and anadromous fish and a wide variety of other aquatic and wildlife species, and as a migration corridor for anadromous species such as salmon, steelhead, sturgeon, and lamprey. Based on the information regarding the relationship between fish abundance and X2 location, the State Water Quality Control Board's D-1641 and the USFWS Biological Opinion include requirements for maintaining the X2 location during the late winter and spring within Suisun Bay.

Operational Criteria and Adaptive Limits. The operational criteria for Delta outflow during the BDCP long-term implementation period are described in Table 3-13.

Problem Statement: Fishery monitoring studies conducted by DFG (Baxter et al. 1999) suggest that abundances of juvenile lifestages of many fish (e.g., starry flounder, splittail, longfin smelt, and striped bass) and macroinvertebrates are correlated with the location of the low salinity zone during the late winter and spring (e.g., February through June [Kimmerer 2004]). For example, longfin smelt juvenile abundance indices increased as the location of X2 moved further downstream (west) within Suisun Bay (Kimmerer 2004). Recent analyses have suggested that previous correlations between X2 location and fish abundance indices have changed (Kimmerer 2004). The changes observed in these relationships have been hypothesized to be the result of the introduction and rapid colonization of Suisun Bay by the filter feeding Asian overbite clam (*Corbula*) and a subsequent reduction in phytoplankton and zooplankton as food supplies for juveniles within Suisun Bay (Kimmerer 2004). Another change in this relationship has occurred since 2001 in conjunction with the pelagic organism decline, although the cause of this change is currently unknown (Baxter et al. 2008).

Factors that may contribute to the relationship between Delta outflow (as well as X2 location) and juvenile fish abundance are heavily debated, but may include increased productivity and availability of high quality habitat within Suisun Bay; downstream transport of fish, food, and organic matter; reduced temperature and/or toxics exposure with lower X2; inundation of backwater and floodplains with high flows; and the distribution of early lifestages of fish into habitats that are located further downstream with decreased vulnerability to direct and indirect effects of south Delta SWP and CVP export operations.

Hypotheses: Allowing Delta outflow in the adaptable range above is hypothesized to:

- Provide for downstream transport of fish and other aquatic organisms into the lower reaches of the Delta and Suisun Bay;
- Provide sufficient flushing of the Delta to avoid and prolonged exposure to high water temperatures and toxics by covered fish species;
- Provide a suitable location for the low salinity zone; and
- Provide for downstream transport of organic material and prey for covered species into the lower reaches of the Delta and Suisun Bay.

Adaptive Management Considerations: Based on results and analysis of monitoring data, adaptive modifications to management of Delta outflow under the BDCP adaptive management framework could occur by modifying operational criteria by season or water-year type (hydrology) or by addressing other stressors and factors that may affect the survival or abundance of a covered fish species.

Delta Water Quality Maintenance.

Dual conveyance facilities in the Delta will be operated during the long-term implementation period to balance flows and exports for fish protection and water quality for both fish and humans while maintaining water supply reliability. Preferential south Delta operations during summer months when flows in the San Joaquin River are lowest will provide flushing the south and central Delta water with fresh Sacramento River water, thus reducing hydraulic residence time and improving water quality for fish, agriculture, and M&I uses in the south and central Delta.

Considerations regarding dual operations of conveyance facilities include: (1) providing limited flushing for general water quality conditions (reduce residence times) during low San Joaquin River flow periods, (2) maintaining adequate M&I and agricultural salinity in the central and south Delta, and (3) allowing operational flexibility during other periods to operate either north or south Delta diversions based on real-time assessments of benefits to fish, water quality, and operational constraints.

Operational Criteria and Adaptive Limits. The operational criteria for dual conveyance operations, including operations to maintain Delta water quality, during the BDCP long-term implementation periods are described in Table 3-13.

Problem Statement: The balance of fish protection, water supply reliability, and water quality for both fish and humans is dependant, in part, on hydrologic and water quality (e.g., salinity, dissolved oxygen, etc.) conditions occurring within Delta channels, densities of covered fish in the general region of the central and south Delta, and the magnitude of effect of south Delta exports on reverse flows in Old and Middle rivers.

Hypotheses: Dual operation of conveyance facilities in the long-term implementation period according to the operational criteria in Table 3-13 is hypothesized to:

- Reduce entrainment mortality of all covered fish species at south Delta facilities;
- Reduce toxic-related mortality and sublethal effects to all covered fish species in the central and south Delta;
- Reduce the effects of the proliferation of noxious algae, such as Microcystis, in the central and south Delta. Microcystis tends to grow in warm, slowly moving water (Lehman et al. 2008). Microcystis is known to disrupt the food web by being toxic to zooplankton and macroinvertebrates (Resources Agency 2007, Baxter et al. 2008); and
- Reduce the effects of the proliferation of SAV, such as Egeria, in shallow areas of the central and south Delta. Egeria tends to establish and grow at faster rates in warm, slowly moving water (Barko and Smart 1981, Gantes and Caro 2001) (see Section 3.4.3.10 *SAV/FAV Control* for detail on effects to these covered species),

Adaptive Management Considerations: Effectiveness monitoring of water quality parameters, including EC, temperature, selenium, and other toxics as deemed necessary by the BDCP Implementation Office, in central and south Delta before and after preferential south Delta operations begin will inform adaptive management decisions to change pumping rates at the south Delta.

In-Delta Agricultural, Municipal, and Industrial Water Quality Requirements.

In the long-term implementation period, D-1641 North and Western Delta agricultural and municipal and industrial (M&I) standards will be maintained, except that the D-1641 compliance point will be moved from Emmaton to the Three Mile Slough juncture. All water quality requirements contained in the North Delta Water Agency/DWR Contract and other DWR contractual obligations will be maintained.

Operational Criteria and Adaptive Limits. The operational criteria for in-Delta agricultural, municipal, and industrial water quality requirements during the BDCP long-term implementation period are described in Table 3-13.

Problem Statement. Salinity in the Delta is primarily a function of freshwater flowing from tributary rivers and saltwater intrusion from the Pacific Ocean. Areas located downstream such as Suisun Bay and further west are characterized by increasing salinity gradients. The northern and eastern Delta is characterized by primarily freshwater aquatic habitats. The lower San Joaquin River and southern Delta are characterized by low salinity waters, primarily resulting from saline agricultural drainage returns with elevated salt concentrations discharging into the San Joaquin River (DWR et al. 2006). If salinity increases to levels above standards dictated in D-1641, agricultural and M&I use of exported water can be severely limited.

Hypotheses. Maintaining existing D-1641 North and Western Delta agricultural and municipal and industrial (M&I) standards and all water quality requirements contained in the North Delta Water Agency/DWR Contract and other DWR contractual obligations would permit existing agricultural and M&I uses of water in these areas.

Adaptive Management Considerations. Within the BDCP framework of adaptive management, the BDCP Implementing Entity will monitor and adaptively manage salinity in the Delta in response to any adverse impacts resulting from the operational criteria described above

Montezuma Slough Salinity Control Gate Operations.

Coordination will occur with the Suisun Marsh Charter Group over the term of the BDCP to seek amendments to the Suisun Marsh Plan (in development) that will provide for reducing the long-term operation of the Montezuma Slough Salinity Control Gate. This action will allow more water to flow past Chipps Island and will improve access of covered fish species to existing and future restored intertidal marsh habitats.

Suisun Marsh is currently managed largely to provide seasonal freshwater wetland habitat, primarily to support waterfowl habitat and recreation. There are approximately 150 waterfowl hunting clubs in the Suisun Marsh, and wetland managers flood their ponds in early October and drain them after the end of the waterfowl season in January. The Montezuma Slough Salinity Control Gate was originally installed and operated as a tidal pump to reduce salinity within the marsh: the one-way gates were opened on the ebb tide to allow freshwater from upstream to enter the slough and closed on the flood tide to prohibit saline water from entering the slough. Operation of the gates also results in a net flow of water from east to west. The salinity control structure (the gates and associated flashboards) not only alters local hydrodynamics and water quality conditions but also impedes the migration and passage of various fish species. The gates are operated on average 10 days every year, all during the period of early October through May (B. Burkhard, pers. comm.). Operation of the gates is based on tidal stage and triggered by high salinity readings in the marsh. DWR and USBR are required to meet water salinity standards for the Suisun Marsh established by the SWRCB under D-1641.

Operational Criteria and Adaptive Limits. In the beginning of BDCP implementation, Montezuma Slough Salinity Control Gates will continue to operate in the same way as existing standards. However, as land use changes during the 50 year implementation period, the gates may stay open for longer up to possibly remaining open year-round, as determined through adaptive management (see Section 3.7 *Adaptive Management*).

Problem Statement. The Montezuma Slough Salinity Control Gate has been identified as an impediment to migration and passage of species such as Chinook salmon, steelhead, and green sturgeon through Montezuma Slough (Fujimura et al. 2000). In addition, existing operations of the control structure alter local current patterns and tidal hydrodynamics within Montezuma Slough, in large regions of Suisun Marsh, and in the main river channel between the control gate and Suisun Bay (DWR 1999). For example, operation of the control structure during the late fall in dry years can cause a significant upstream shift in X_2 location, potentially increasing the risk of entrainment at the SWP/CVP export facilities of smelt and other species that are situated near X_2 location (D. Fullerton pers. comm. 1). These changes in environmental conditions are thought to have resulted in adverse effects on covered species and other aquatic resources within the area.

As levees are breached for tidal restoration, salinity levels may increase through much of Suisun Marsh, complicating the feasibility of discontinuing the operation of the salinity control gates, or eliminating the gates. First, rising salinity could negatively affect the managed wetlands of the remaining waterfowl hunting clubs. Secondly, salinity standards at the Suisun Marsh may have to be revised. Assuming that the Suisun Marsh's current salinity standards are maintained, tidal restoration could even lead to an increase in the operation of the salinity control gates under the Suisun Marsh Plan (S. Chappell pers. comm.).

Hypotheses: A reduction in operation of the Montezuma Slough Salinity Control Gate is hypothesized to:

- Reduce delays in outmigration of juvenile salmonids and sturgeon by allowing more water and fish to flow past Chipps Island; and
- Improve access of splittail, salmonids, and sturgeon to existing and future restored intertidal marsh habitats in Suisun Marsh.

Adaptive Management Considerations: As land use changes over the period of the Plan, monitoring and adaptive management could be used to alter operations of the salinity control gates.

3.4.2.2 CM2 Yolo Bypass Fishery Enhancement

*[**Note to Reviewers:** Yolo County has proposed specific edits to the content of this conservation measure that will be posted to the BDCP website. These proposed edits will be considered in subsequent versions of this conservation measure developed prior to the release of the public draft of the BDCP in 2011.]*

The purpose of this conservation measure is to improve upstream and downstream fish passage, reduce straying and stranding of native fish, increase availability of floodplain fish rearing and spawning habitat, and stimulate the food web in the Yolo Bypass and to investigate the potential for food web export from the Yolo Bypass to the Delta. The conservation measure requires the preparation and implementation of a Yolo Bypass Fishery Enhancement Plan (YBFEP) that details the specific actions to be implemented to achieve the biological objectives of this measure. Key benefits to covered fish species include reduced migratory delays and loss of salmon, steelhead, and sturgeon at Fremont Weir and other structures; enhanced rearing habitat for Sacramento River Basin salmonids; enhanced spawning and rearing habitat for splittail; and potential improvement of food sources of Delta smelt in habitat downstream of the Bypass. The YBFEP will:

- Evaluate alternative actions to restore passage and reduce stranding, including, but not limited to, physical modifications to the Fremont Weir and Yolo Bypass to manage the timing, frequency, and duration of inundation of the Yolo Bypass (Figure 3-53) with gravity flow from the Sacramento River, and to improve upstream fish passage past barriers including Fremont and Lisbon Weirs;
- Based on the evaluation, identify the actions, including, but not limited to, the physical modifications to the Fremont Weir and the Yolo Bypass, that will be implemented;
- Describe the YBFEP's biological objectives, performance goals, and monitoring metrics in detail;
- Ensure compatibility with the flood control functions of the Yolo Bypass;
- Identify specific funding sources from the BDCP funding commitments;
- Discuss regulatory and legal constraints and how the constraints will be addressed; and
- Provide an implementation schedule with milestones for key actions.

The BDCP Implementing Entity will consult with the U.S. Army Corps of Engineers, DWR, DFG, NMFS, and USFWS in development of the YBFEP and will coordinate with Yolo and Solano counties, affected reclamation districts, other flood control entities, and the Yolo Bypass Working Group on a wide range of issues during preparation of the YBFEP. During implementation of this conservation measure, the BDCP Implementing Entity will coordinate with the U.S. Army Corps of Engineers, DWR, reclamation districts, and other flood control entities, as appropriate, to ensure that fish passage improvements, bypass improvements, and Fremont Weir improvements and operations are constructed in accordance with the YBFEP and particularly the compatibility with the flood control functions of the Yolo Bypass.

The YBFEP analysis of alternative actions will focus on the construction of physical improvements and modifications from Fremont Weir downstream to the Lisbon Weir to (1) reduce migratory delays and loss of salmonids and sturgeon at Fremont Weir; and (2) enhance seasonal floodplain habitats for salmonids, splittail, and other covered aquatic species. The YBFEP will also evaluate the need for actions that may be necessary to optimize the number of juvenile salmonids entering the bypass when the water is being diverted through the modified Fremont Weir. In addition, a gated channel that could provide flows from the Sacramento River, Colusa Basin Drain, Knights Landing Ridge Cut, or other sources into the Yolo Bypass along the west side will be evaluated.

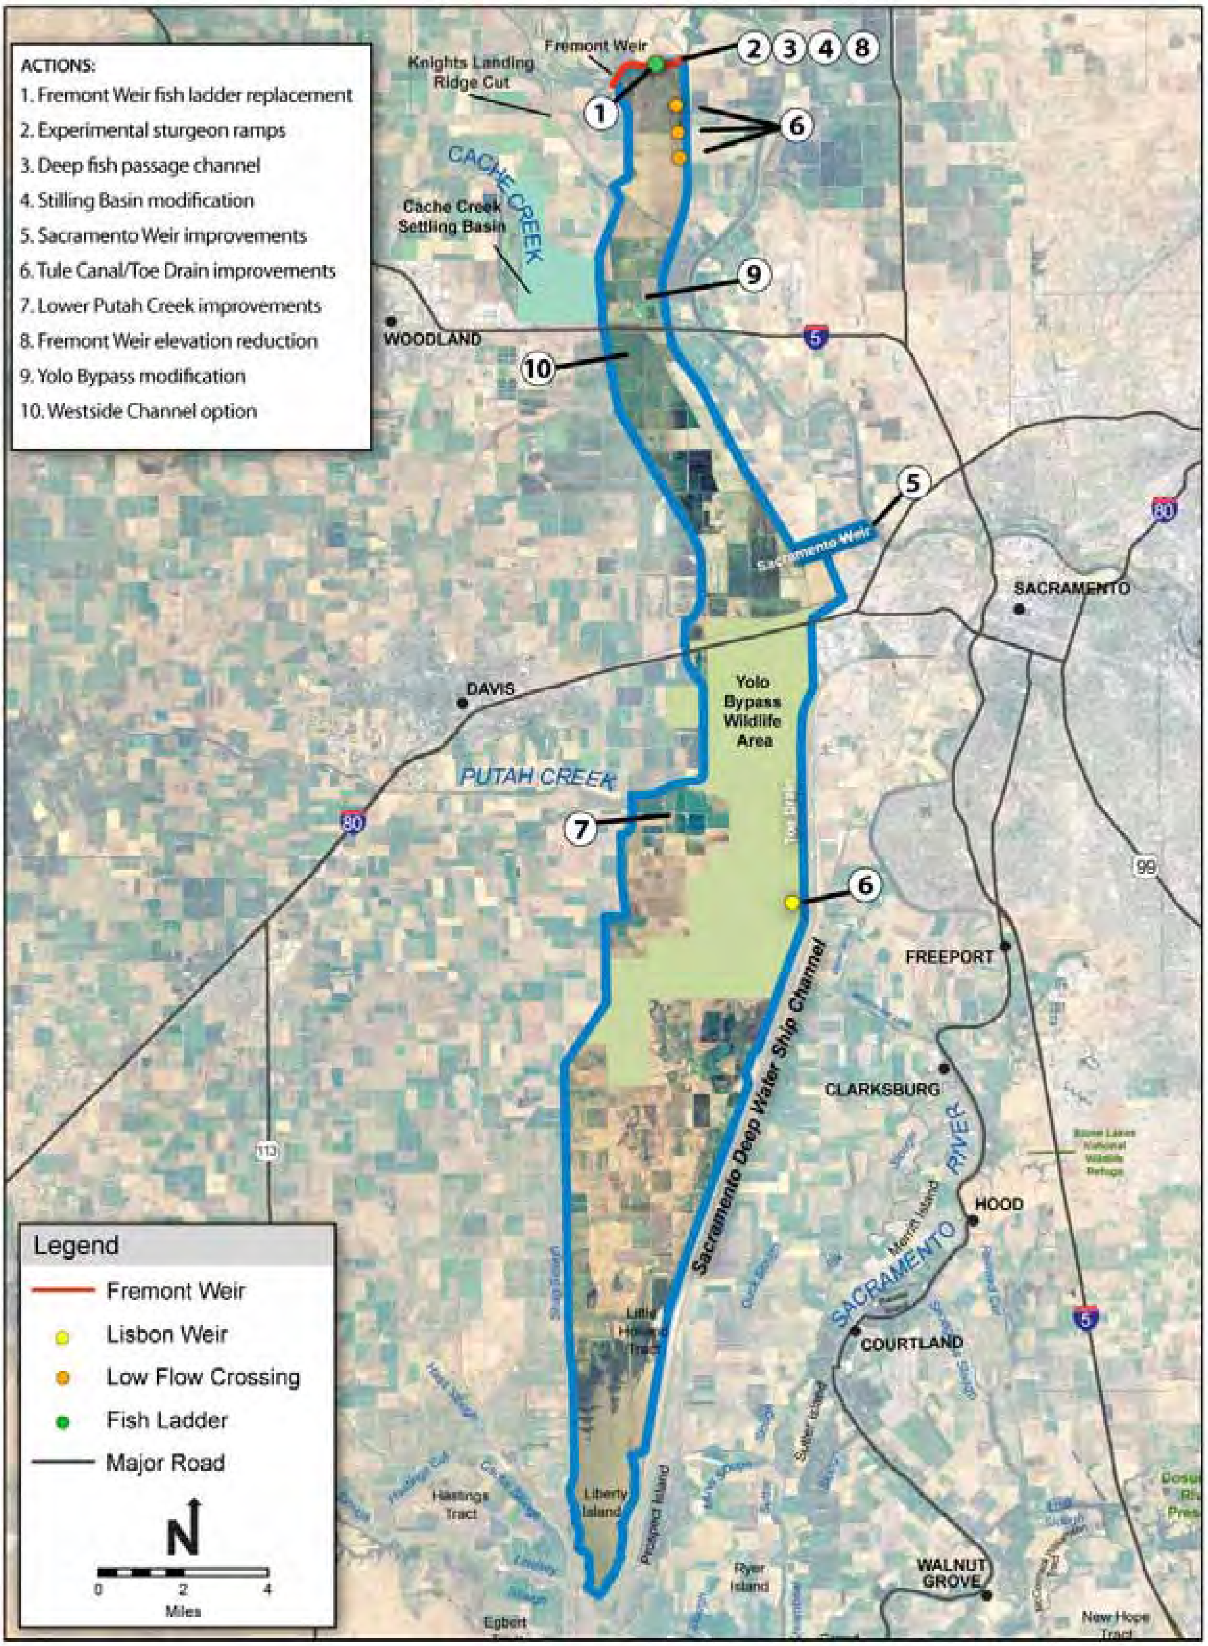

Figure 3-53. Yolo Bypass Fishery Enhancement Conservation Measure (CM2)

All of the actions identified below will be evaluated in the YBFEP. If supported by the evaluation (i.e., would achieve the biological objectives of this conservation measure), all of these actions will be further developed in the YBFEP and implemented. If the YBFEP evaluation does not support implementation of one or more of the actions--because the action would not be effective, is not needed because of the effectiveness of other actions, would have unacceptable effects on flood control, or for other reasons--the action will not be implemented. However, the YBFEP will identify for implementation specific actions that together are sufficient to achieve the biological objectives identified in the YBFEP.

Actions to Reduce Migratory Delays and Loss of Salmonids and Sturgeon at Fremont Weir

1. Fremont Weir Fish Ladder Replacement. The existing Fremont Weir Denil fish ladder will be removed and replaced with new salmonid passage facilities designed to allow for the effective passage of adult salmonids and sturgeon from the Yolo Bypass past the Fremont Weir and into the Sacramento River when the river overtops the weir. Specific design criteria of the ladder have not yet been determined. This facility will incorporate monitoring technologies to allow for collection of information to evaluate its efficacy at passing adult fishes.

2. Experimental Sturgeon Ramps. An experimental ramp(s) will be constructed at the Fremont Weir to allow for the effective passage of adult sturgeon and lamprey from the Yolo Bypass over the Fremont Weir and into the Sacramento River at flows when the new Fremont Weir Fish Ladder will also be operated when the river overtops the weir by approximately 3 feet (Figure 3-54). Specific design criteria of ramps have not yet been determined. This facility will incorporate monitoring technologies to allow for collection of information to evaluate its efficacy at passing adult fishes.

3. Deep Fish Passage Gates and Channel. To enhance adult fish passage through the Fremont Weir, as part of modifications to the Fremont Weir (see action #8, below), a deep fish passage notch will be cut through a much smaller section of the Fremont Weir to an elevation of 11.5 feet (NAVD88). This notch will be fitted with operable “fish passage gates” that will allow controlled flow into the Yolo Bypass when the Sacramento River stage is between 11.5 and 17.5 feet (NAVD88). A “fish passage channel” will be excavated to convey water from the Sacramento River to the new fish passage gates, and from the fish passage gates to the Tule Canal to convey water from the Sacramento River, through the gates, and to the Tule Canal and Toe Drain.

4. Stilling Basin Modification. Modifications will be made to the existing Fremont Weir stilling basin to ensure that the basin drains sufficiently into the deep fish passage channel. Effective drainage of the stilling basin will prevent stranding of juvenile and adult fish that are attracted to pooled water in the stilling basin during drainage of the floodplain.

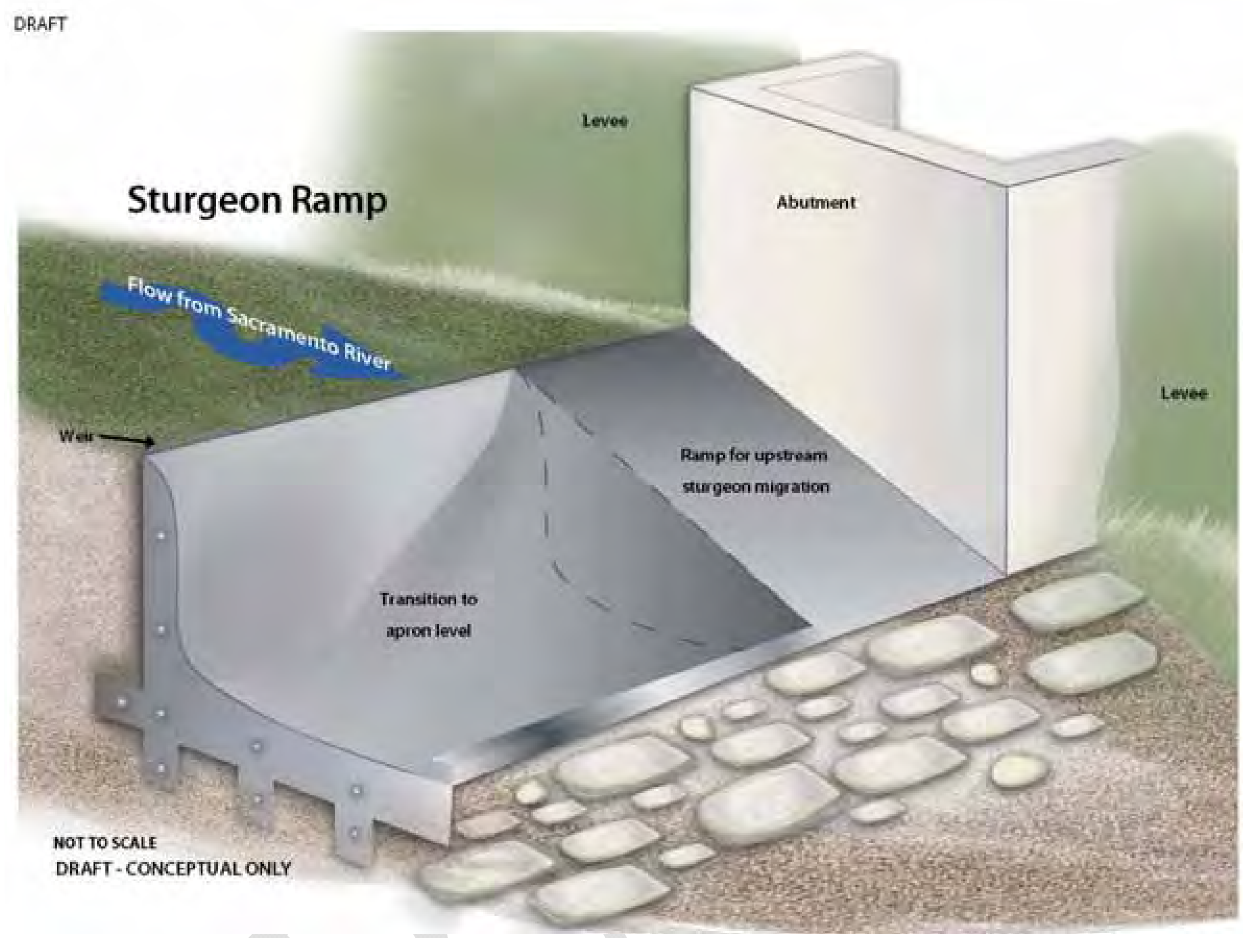

Figure 3-54. Conceptual Design for Experimental Sturgeon Ramp (CM2)

5. Sacramento Weir Improvements. Modifications will be made to reduce leakage at the Sacramento Weir and therefore reduce attraction of fish from the Yolo Bypass to the weir where they are blocked and could become stranded. For comparative analysis purposes, the plan will review the benefits and necessity of constructing fish passage facilities at the Sacramento Weir to reduce juvenile fish stranding and improve upstream adult fish passage. This action may require excavation of a channel to convey water from the Sacramento River to the Sacramento Weir and from the Sacramento Weir to the Toe Drain, construction of new gates at a portion of the weir, and minor modifications to the stilling basin of the weir to ensure proper basin drainage. Specific design criteria of ramps would need to be determined.

6. Tule Canal/Toe Drain and Lisbon Weir Improvements. The YBFEP will include physical modifications to passage impediments, including road crossings and agricultural impoundments in the Tule Canal/Toe Drain to improve fish passage and survival. The plan will evaluate the benefits of replacing three existing structures at the northern end of the Tule Canal with bridges or other structures to allow adult fish passage. Lisbon Weir will be redesigned to improve fish passage while maintaining or improving water capture efficiency for irrigation.

7. Lower Putah Creek Improvements. The YBFEP will include a realignment of Lower Putah Creek. The YBFEP will include a realignment sufficient to improve upstream and downstream passage of Chinook salmon and steelhead in Putah Creek and floodplain habitat restoration to provide benefits for multiple species on existing public lands. This action will be designed so that it will not create stranding or migration barriers for juvenile salmon.

Actions to Increase Seasonal Floodplain Habitats for Salmonids, Splittail, and other Covered Aquatic Species

1. Fremont Weir Modification. The YBFEP will include engineering designs to physically modify the Fremont Weir to manage the timing, frequency, and duration of inundation of the Yolo Bypass with Sacramento River flows. In the BDCP Effects Analysis, it was assumed a section of the Fremont Weir will be lowered to 17.5 feet (NAVD88) (lower elevations may be considered if necessary to satisfy inundation targets or fish passage needs) and fitted with operable gates that will allow for controlled flow into the Yolo Bypass when the Sacramento River stage at the weir exceeds 17.5 feet. Separate operable gates will be designed and operated to provide for the efficient upstream and downstream passage of sturgeon and salmonids to and from the Yolo Bypass into the Sacramento River (as described in action #3 above). The YBFEP will explain how this modification will provide significantly increased acreage of seasonal floodplain rearing habitat with biologically appropriate durations and magnitudes on a return rate of one to three years, depending on water year type.

2. Yolo Bypass Modification. Grading, removal of existing berms, levees, and water control structures, construction of berms or levees, re-working of agricultural delivery

channels, and earthwork or construction of structures to reduce Tule Canal/Toe Drain channel capacities will be conducted to the extent necessary to improve the distribution (e.g., wetted area) and hydrodynamic characteristics (e.g., residence times, flow ramping, and recession) of water moving through the Yolo Bypass. The YBFEP will include modifications that will allow water to inundate in certain areas of the bypass to maximize biological benefits and keep water away from other areas to reduce stranding of covered fish species in isolated ponds, minimize impacts to terrestrial covered species, including giant garter snake, and accommodate other existing land uses (e.g., wildlife, public, and agricultural use areas). If necessary, lands will be acquired, in fee-title and through conservation or flood easements.

3. Westside Option. The YBFEP will include a feasibility study and evaluation of a gated channel to provide flows into Yolo Bypass along the west side. Potential flow sources are the Sacramento River, Colusa Basin Drain or Sacramento River flows through Knights Landing Ridge Cut, or augmentation of other western tributaries. Some modification of the existing configuration of the discontinuous channels along the western edge of the Yolo Bypass may also be required. If effective at meeting biological objectives, this option could be included in the implementation of the conservation measure.

Operational Criteria and Adaptive Limits

The YBFEP will include operational criteria as well as a strategy for adaptive management. The YBFEP will describe how a modified Fremont Weir will be operated to manage the timing and increase the frequency and duration of inundation of a portion of the Yolo Bypass with Sacramento River flows via the Fremont Weir to achieve the biological goals and objectives. The YBFEP will take into account both Weir and tributary inflows.

In the Effects Analysis, inundation timing, frequency, and duration in the Yolo Bypass within the period of December 1 through March 31 (with occasional extension to May 15, depending on hydrologic conditions and measures to minimize land use and ecological conflicts) at the reduced weir elevation of 17.5 feet was considered. In evaluating this scenario, target flows into the bypass were between 3,000 and 6,000 cfs. In the Effects Analysis, flow through modified Fremont Weir gates was limited to maximum spills of 6,000 cfs when the Sacramento River was not spilling over the 33 foot crest of the weir. For the Effects Analysis, no management of the gates was assumed to limit lower flows (e.g., <3,000 cfs). The YBFEP will further refine these operational criteria to provide the specific biological objectives, restoration actions, and locations necessary to meet performance goals including habitat attributes, juvenile and adult metrics, and inundation depth and duration criteria. The YBFEP will include criteria for rare situations to limit flooding when, as determined by the BDCP Implementing Entity, inundation could cause more harm than benefit to covered species. Gates will remain closed in such situations

Under existing conditions the Fremont Weir is overtopped and spills into the Yolo Bypass in about 70 percent of years. The proposed notch and gates could increase that frequency to about 75-95 percent of years with a modified weir height of 17.5 feet (NAVD88) compared to the existing weir height of 33 feet (NAVD88). The frequency of Fremont Weir spills of at least 30 days at 3,000 cfs between 1984 and 2007 would double with a modified weir height of 17.5 feet compared to the existing weir height of 33 feet (Table 3-15). Once the targeted duration of inundation is achieved and the river is below the top of the Fremont Weir, the weir gates could be operated to reduce diversion of flow from the Sacramento River to allow for drainage of the Bypass while still allowing for fish passage. The basic flood control functions of the Fremont Weir will not be changed; at flood stage, the weir will overtop as it does currently.

Table 3-15 Number of Floodwater Spills Overtopping the Fremont Weir under Current and Proposed Weir Elevations.

	Events during Water Years 1984-2008[1]		*Events during Water Years 1929-2008*[1]	
	Current Weir[2]	**Proposed Notch**[2]	**Current Weir**[2]	**Proposed Notch**[2]
Less than 30 days	17[3] (10)[4]	42[3] (20)[4]	48[3] (29)[4]	137[3] (62)[4]
At least 30 days	9 (9)	18 (14)	11 (10)	70 (52)
At least 45 days	4 (4)	11 (11)	5 (5)	46 (41)

[1]Flows between October 1, 1929 and December 31, 1983 have been reconstructed from the hydrologic record

[2]Current weir elevation = 33 ft NAVD88; Proposed weir elevation = 17.5 ft NAVD88.

[3]Number of events with consecutive spills producing at least 3,000 cfs over the Fremont Weir. Assumes no more than a 7-day gap in flooding to count as the same event

[4]Number of water years in which events took place with spills producing at least 3,000 cfs over the Fremont Weir. Water Year is defined as August 1 of the previous year through July 31 of the current year. For example, Water Year 2005 is August 1, 2004 to July 31, 2005.

Problem Statement

The majority of historical floodplain in the Sacramento and San Joaquin River systems have been lost, particularly floodplains that flow directly into the Delta. This loss of floodplains has resulted in a reduction of highly productive rearing habitat for juvenile salmon and spawning and rearing habitat for other native species such as splittail. Loss of floodplain habitat has reduced the seasonal input of organic and inorganic material and food resources into adjoining riverine habitat and the downstream bay and estuary. Inundation of the Yolo Bypass from the Sacramento River is currently limited to times when the Fremont Weir is overtopped, limiting the availability of habitat for covered fish species and inputs to the food web from the Yolo Bypass.

The current configuration of the Yolo Bypass and Fremont Weir creates passage impediments and potential stranding for adult Chinook salmon, steelhead, green and white sturgeon, and river and Pacific lamprey and stranding hazards for juvenile Sacramento splittail, sturgeon, Chinook salmon, and steelhead. First, the Denil fish ladder at the Fremont Weir, designed for adult salmonid passage, is not effective at passing salmon, adult sturgeon and lamprey. Second, the stilling basins immediately downstream of the Sacramento and Fremont weirs have higher stranding rates of juvenile Chinook salmon than do earthen ponds as floodwater recedes (Sommer et al. 2005). Third, there are road crossings and agricultural impoundments in the Tule Canal/Toe Drain that block hydrologic connectivity, and therefore, fish passage. Fourth, the Lisbon Weir, which was built to impound agricultural water in the Toe Drain upstream of the weir, creates a passage impediment for fish at low stage when riprap is exposed or shallowly submerged.

Putah Creek is used for spawning habitat by a small population of Chinook salmon and steelhead. The Los Rios Check Dam, an irrigation impoundment structure, is seasonally removed but remains in place for several months while adult salmon and steelhead are attempting to migrate upstream. The reach of channel downstream of the check dam runs through a straight ditch to the Toe Drain. Putah Creek often breaks through its bank a short distance upstream of the Los Rios Check Dam, requiring periodic road maintenance at the Yolo Bypass Wildlife Area.

Hypothesized Benefits

Modifying the Fremont Weir and its operations and improving fish passage will reduce the adverse effects of stressors related to food availability, habitat availability, passage, harvest, stranding, predation, and entrainment for some of the covered fish species. Specifically, this conservation measure will:

- Create additional spawning habitat for Sacramento splittail (Sommer et al. 2001a, 2002, 2007b, 2008, Moyle 2002, Moyle et al. 2004, Feyrer et al. 2006). Because splittail are primarily floodplain spawners, successful spawning is predicted to increase with increased floodplain inundation;
- Create additional juvenile rearing habitat for Chinook salmon, Sacramento splittail, and possibly steelhead (Sommer et al. 2001a,b, 2002, 2007b, 2008, Moyle 2002, Moyle et al. 2004, Feyrer et al. 2006). Growth and survival of larval and juvenile fish is higher in the floodplain compared to those rearing in the mainstem Sacramento River (Sommer et al. 2001b);
- Increase downstream juvenile passage of Chinook salmon, Sacramento splittail, river and Pacific lamprey, and possibly steelhead. An inundated Yolo Bypass is used as an alternative to the mainstem Sacramento River for downstream migration of salmonids, splittail, river lamprey, and sturgeon. Sommer et al. (2003, 2004a) found that, other than steelhead and Pacific lamprey, juveniles from all of these species inhabit the Yolo Bypass during periods of inundation. Based on the timing and life history traits of steelhead relative to Chinook salmon, steelhead likely also benefit from inhabiting the Yolo Bypass. Similarly, based on the timing and life history traits of Pacific lamprey relative to river lamprey, Pacific lamprey likely also benefit from inhabiting the Yolo Bypass
- Increase adult upstream passage of fall-, late fall-, winter-, and spring-run Chinook salmon, steelhead, green and white sturgeon, and river and Pacific lamprey. It is thought that an inundated Yolo Bypass is used as an alternative route by upstream migrating adults of these species when Fremont Weir is spilling ;

- Increase food production for rearing salmonids, splittail, and other covered species on the floodplain (Sommer et al. 2001a,b, 2002, 2007b, 2008, Moyle 2002, Moyle et al. 2004, Feyrer et al. 2006). During periods when the bypass is flooded, there is relatively high production of zooplankton and macroinvertebrates that serve, in part, as the forage base for many of the covered fish species (Benigno and Sommer 2008);
- Increase the availability and production of food in the Delta, Suisun Marsh, and bays downstream of the bypass, including restored habitat in Cache Slough, for delta smelt, longfin smelt, and other covered species by exporting organic material and phytoplankton, zooplankton, and other organisms produced from the inundated floodplain into the Delta (Schemel et al 1996, Jassby and Cloern 2000, Mitsch and Gosselink 2000, Moss 2007, Lehman et al. 2008). The co-occurrence of suitable food supplies (zooplankton) and various life stages of delta smelt (e.g., larval and juvenile life stages) has been assumed to be an important factor affecting delta smelt survival and abundance (Feyrer et al. 2007a, Miller 2007b). The relationship between longfin smelt abundance and Delta outflow has experienced two step-declines: one after the invasion of *Corbula* and one during the POD years, although the slope of the relationship has not changed, suggesting that longfin smelt are food-limited (Baxter et al. 2008). Hobbs et al. (2006) found evidence of food limitation in early-stage juvenile longfin smelt, although spatially and temporally variable;
- Increase the duration that the floodplain is inundated during periods that the Yolo Bypass is receiving water from both the Fremont Weir and the westside tributaries (e.g., Cache and Putah Creeks);
- Reduce losses of adult Chinook salmon, sturgeon, and other fish species to stranding and illegal harvest by improving upstream passage at the Fremont Weir. When flows in the Sacramento River recede, the Fremont Weir stops spilling, trapping fish downstream of the weir. Many of these fish remain in the shallow water near the weir, providing easy access to illegal harvesters. Under this conservation measure, the Fremont Weir will be modified to reduce stranding when Sacramento River flows recede;
- Reduce the exposure and risk of outmigrating juvenile fish migrating from the Sacramento River into the interior Delta through the Delta Cross Channel and Georgiana Slough, thus decreasing the risk for predation losses (Brandes and McLain 2001);
- Reduce the exposure of outmigrating juvenile fish to entrainment or other adverse effects associated with the intakes of the proposed north Delta water diversion facilities by passing juvenile fish into the Yolo Bypass upstream of the proposed intake locations; and
- Improve fish passage, and possibly increase and improve seasonal floodplain habitat availability, by retrofitting Los Rios Check Dam with a fish ladder, or creating another, fish-passable route for water from Putah Creek to reach the Toe Drain.

Increasing the frequency and duration of inundation within the Yolo Bypass is the largest opportunity for enhancing seasonally inundated floodplain habitat in the Central Valley . The

Yolo Bypass provides the only opportunity for increasing the frequency and duration of inundation of a floodplain in the Planning Area without restoration of historical floodplain surfaces presently in more highly developed, year-round land uses.

Adaptive Management Considerations

Implementation of this conservation measure by the Management Entity will be informed through effectiveness monitoring that will be conducted as described in Section 3.6, *Monitoring and Research Program,* and the adaptive management process described in Section 3.7, *Adaptive Management Program*. Results of both biological and operational monitoring in the Yolo Bypass and the mainstem Sacramento River will be used within the BDCP adaptive management framework to refine and modify project structures and operations and fish passage improvements.

Timeline for Implementation

The Yolo Bypass Fishery Enhancement Plan will be completed within 6 months of approval of BDCP. The Plan shall include: (1) specific biological objectives, restoration actions, and locations; (2) specific operational criteria; (3) a timeline with key milestones, (4) performance goals and associated monitoring, including habitat attributes, juvenile and adult metrics, and inundation depth and duration criteria; (5) specific actions to minimize stranding or migration barriers for juvenile salmon; and (6) identification of regulatory and legal constraints that may delay implementation, and a strategy to address those constraints. Construction of capital improvements identified in the Plan will be completed within five years of completion of the Plan.

3.4.2.3 CM3 Natural Communities Protection

This conservation measure provides the mechanism and guidance for the acquisition of lands and the establishment of a system of conservation lands in the Plan Area necessary to meet natural community and species habitat protection objectives established in Section 3.3, *Biological Goals and Objectives*. This system of conservation lands will be built over the term of the BDCP implementation to protect and enhance areas of existing natural communities and covered species habitat, protect and maintain occurrences of selected plant species with very limited distributions, provide sites suitable for restoration of natural communities and covered species habitat, and provide habitat connectivity among the various BDCP conservation land units in the system. This conservation measure describes the overall approach to land acquisition procedures including the extent of land acquisition, a discussion of pre-acquisition surveys, as well as site selection criteria.

Approach to Land Acquisition

The BDCP Implementation Office will establish a system of conservation lands that encompasses all BDCP protected and restored natural communities. Lands may be acquired through the following mechanisms:

- Purchase in fee title;
- Permanent conservation easements;
- Limited term conservation easements;
- Change to more protective land use designation on federal or state owned lands ;
- Permanent agreements with state, federal, and local flood control agencies that enable the restoration, enhancement, and management of floodplain and channel margin habitats along levees and lands under flood easements; and
- Purchase of mitigation credits from private mitigation banks.

The BDCP Implementation Office may acquire conservation lands in partnership with other conservation organizations or through grants of land from participating entities where such lands will serve to achieve the biological goals and objectives of the Plan. The conservation lands system will be comprised of: 1) conservation areas (lands that are under direct management of the Implementation Office or a Supporting Entity and lands protected through permanent conservation easements); and 2) lands that are covered by limited term conservation easements.

It is anticipated that lands acquired for habitat restoration and enhancement actions will primarily be those that are currently in public ownership or those that are acquired in fee title because these conservation measures could preclude other land uses. Lands acquired for the protection and maintenance of existing habitat functions may be acquired through conservation easements that specify the range of permitted land uses and practices that will maintain the intended habitat functions of the acquired lands. Limited-term conservation easements may be used to conserve agricultural habitats for a specified period, after which the easement would expire and the Implementation Office will be required to conserve additional habitat to replace the habitat that was protected through the expired conservation easement.

The BDCP habitat conservation target acreage commitments for the natural communities are presented in Table 3-4. Acquisition of these lands will also fulfill the target acreage requirements for each of the covered species for which habitat conservation targets are established (Table 3-5). These targets represent the minimum extent of land that will be acquired; the actual extent that will be acquired will likely be greater because acquired parcels may not be comprised wholly of habitat types that contribute towards achieving conservation target acreage.

Pre-acquisition Surveys and Assessments

The BDCP Implementation Office will develop and implement protocols for assessing physical and biological resources and infrastructure present on lands being considered for acquisition to determine the degree to which they are suitable for achieving habitat protection and restoration objectives. Pre-acquisition surveys would be conducted by qualified biologists and other qualified scientists or technical experts as appropriate under agreements with the landowners. Surveys will assess the physical and biological attributes of the lands, including, but not limited to:

- The extent and quality of existing covered species habitats;
- Connectivity with other habitat areas;
- Presence of covered species;
- Infrastructure supporting existing habitats or necessary to restore habitats;
- Potential constraints to long-term management and maintenance of habitats; and
- Other conservation-related opportunities and constraints.

The BDCP Implementation Office will apply, and revise when necessary, the following criteria for evaluating and prioritizing acquisition of lands for achieving habitat protection and restoration targets. Criteria for evaluating the suitability of lands supporting grassland, alkali seasonal wetland complex, and vernal pool complex include:

- Level of benefits the acquisition will provide for covered species;
- Presence and abundance of covered species;
- Presence of uncommon site specific attributes (e.g., soil types) required by covered species with narrow range of habitat requirements;
- Likely effects of adjacent land uses on the ability to maintain or improve desired ecological functions into the future;
- Habitat patch size relative to the habitat patch size of the covered species intended to benefit from the habitat;
- Opportunities for effectively implementing management actions to enhance ecological functions;
- Level of contribution for maintaining local and regional ecological processes;
- Level of connectivity provided between and among existing preserved habitat areas;
- Level of contribution for preserving natural environmental gradients;
- Level of contribution towards establishment of large preserve areas;
- Likely effects of climate change on future ecological functions;

- Role in maintaining and complementing the habitat functions of adjoining natural communities for covered and other native species;
- Level of contribution towards protection of a heterogeneous mix of natural communities and native species, including native grasses and forbs;
- Effectiveness in contributing towards achieving multiple biological goals and objectives;
- Likely contribution towards achieving biological objectives for approved and planned HCPs and NCCPs overlapping or adjacent to the Plan Area; and
- Additionally, restoration of vernal pool complex will only be permitted on lands that historically supported vernal pools and that currently support suitable soils for restoration.

Criteria for the selection of agricultural habitats to be maintained under the Plan include:

- Proximity to active Swainson's hawk nesting territories;
- Proximity to greater sandhill crane roost sites;
- Ability to support crops that provide high value Swainson's hawk and/or greater sandhill crane foraging habitat;
- Proximity to habitat occupied by the Caldoni Marsh/White Slough and Yolo Bypass/Willow Slough giant garter snake populations;
- Opportunities to incorporate riparian corridors into agricultural preserves; and
- Opportunities to preserve patches of other high value non-agricultural habitats (e.g., oak groves, wetlands, tree and hedge rows) that are supported among farmed fields.

For acquisition of land for restoring tidal, riparian, nontidal marsh, and seasonally inundated floodplain habitats, the BDCP Implementation Office will develop site selection criteria based on the ability of lands under consideration to:

- Achieve biological goals and objectives;
- Suitability and cost effectiveness for restoring target habitats;
- Suitability for supporting the restored habitat over time; and
- Level of management necessary to maintain desired ecological functions into the future.

Lands acquired for protection of existing habitats must be acquired within the Conservation Zones indicated in Table 3-4 to be credited as contributing towards achieving the biological goals and objectives. Land acquired for restoration of tidal habitat is expected to be located within the ROAs as indicated in CM4 Tidal Habitat Restoration, but may occur elsewhere if suitable lands are available. Seasonally inundated floodplain restoration and channel margin habitat enhancement may be located at appropriate sites within the geographic boundaries indicated in CM6 Channel Margin Habitat Enhancement and CM5 Seasonally Inundated Floodplain Restoration. Riparian habitats are expected to be restored within tidal habitat restoration, channel margin habitat enhancement, and seasonally inundated floodplain restoration sites (see CM7 Riparian Habitat Restoration). The Implementation Office is committed to the acquisition of a sufficient extent of land to achieve the seasonally inundated floodplain, channel margin habitat, and riparian habitat conservation targets described in CM5 (*Seasonally Inundated Floodplain Restoration*), CM6 (*Channel Margin Habitat Enhancement*), and CM7 (*Riparian Habitat Restoration*); these commitments, however, are not tied to specific Conservation Zones, but rather to the geographies identified in the conservation measures and therefore are not described in the Conservation Zone acquisition requirements described below.

The existing extent of unprotected and protected natural communities and their distribution within each of the Conservation Zones are presented in Tables 3-1a through 3-1c.

Conservation Zone 1 Acquisition Requirements

Land acquisition (includes fee title and easement) requirements for Conservation Zone 1 are directed at protecting and restoring grassland and associated seasonal wetlands, acquiring lands necessary for the restoration of tidal and associated riparian habitats, protecting cultivated agricultural foraging habitats, and protecting occurrences of selected plant species with very limited distributions.

Tidal Aquatic and Wetland Natural Communities. Lands sufficient to restore at least 5,000 acres of tidal habitat within the Cache Slough Complex ROA, which includes lands in Conservation Zones 1and 2, will be acquired. Additional lands will be acquired to the extent that additional restoration of tidal habitat is needed in this Conservation Zone to achieve the total conservation target of restoring 65,000 acres of tidal habitat. Restored tidal habitat includes restored gradient of habitats ranging from shallow subtidal aquatic habitat, to mudflat, emergent marsh plain, riparian (in suitable locations) and transitional uplands. Transitional uplands will include sufficient land to accommodate future upslope establishment of marsh plain vegetation with sea level rise and will support habitat for grassland associated species. Restored tidal aquatic, marsh plain and associated transitional upland habitats are expected to support habitat for the California black rail; aquatic and possible upland nesting habitat for the California least tern; nesting habitat for the tricolored blackbird; upland and aquatic habitat for the giant garter snake where a narrow tidal range exists; and upland and aquatic habitat for the western pond turtle. The restoration of tidal marsh communities in CZ1 may help achieve the recovery objectives for giant garter snake identified in the giant garter recovery plan (USFWS 1999a). Tidal marsh plain and mudflat habitats are also expected to support substrates suitable for colonization and establishment of Delta tule pea and Suisun Marsh aster, Mason's lilaeopsis, and Delta mudwort.

Grasslands and Associated Seasonal Wetland Natural Communities. The grassland and associated seasonal wetland community group is comprised of the grassland, alkali seasonal wetland complex, and vernal pool complex natural communities. A portion of the 300 acres of existing vernal pool complex, 400 acres of existing alkali seasonal wetland, and 8,000 acres of existing grassland to be protected under the BDCP will be acquired and protected in Conservation Zone 1. The goal of these acquisitions is to protect lands in large contiguous grassland landscapes that encompass the range of vegetation, hydrologic, and soil conditions that characterize these communities within the Conservation Zone. The extent of existing protected and unprotected grassland, alkali seasonal wetland complex, and vernal pool complex is shown in Figure 3-1a.

Conserved lands will be located to maintain habitat connectivity with protected grassland landscapes immediately adjacent to the Plan Area (e.g., Jepson Prairie Preserve) and with transitional uplands associated with tidal habitats restored in the Cache Slough Complex ROA. Specific land acquisition requirements include the protection of at least two occurrences of Heckard's peppergrass. This approach to the conservation of these natural communities will conserve foraging habitat for the tricolored blackbird, western burrowing owl, Swainson's hawk, and white-tailed kite; upland habitat for the giant garter snake and western pond turtle; breeding and upland habitat for the western spadefoot toad and California tiger salamander; and habitat for the covered vernal pool shrimp species, alkali milk-vetch, San Joaquin spearscale, dwarf downingia, Boggs Lake hedge-hyssop, Heckard's peppergrass, legenere, heartscale, brittlescale, Delta button-celery, and Carquinez goldenbush (see details on benefits to each of these species in Section 3.3, *Biological Goals and Objectives*).

These conserved lands will be evaluated and managed to maintain and enhance their existing habitat functions for these species over the term of the BDCP (see Conservation Measure CM11, Natural Communities Enhancement and Management). The protection and restoration of vernal pool complex will help achieve the recovery objectives for Conservancy fairy shrimp, longhorn fairy shrimp, vernal pool fairy shrimp, mid- valley fairy shrimp, vernal pool tadpole shrimp, alkali milk-vetch, Boggs Lake hedge-hyssop, and legenere identified in the Vernal Pool Recovery Plan (USFWS 2005).

Some or all of the 2,000 acres of grassland and 200 acres of vernal pool complex to be restored under the Plan may be restored within Conservation Zone 1. Lands that are suitable for the restoration of these habitats as described in Conservation Measures CM9 Vernal Pool Complex Restoration, and CM8 Grassland Communities Restoration will be acquired. Lands acquired for grassland restoration will be located such that they will increase connectivity among currently fragmented patches of grassland and seasonal wetlands and/or provide high value transitional upland habitat adjacent to restored tidal marsh plain habitats. Lands acquired for vernal pool complex restoration will be located on lands that historically supported vernal pools and will be inoculated with seeds of vernal pool plants, and soil inoculum where the donor vernal pools are free of exotic species such as swamp timothy, perennial pepperweed, and Italian ryegrass, collected from vernal pools in Conservation Zones 1 and/or 2. These restored habitats are expected to support habitat for the covered species described above for lands acquired to protect grassland and associated seasonal wetlands.

*Agricultural Lands and Managed Wetlands***.** Agricultural lands will be acquired in Conservation Zone 1 to achieve a substantial proportion of the overall agricultural habitat conservation target established for the Plan Area (Table 3-4). Agricultural lands will be acquired that support foraging habitat for tricolored blackbird, Swainson's hawk, and other agricultural-associated species. These conserved lands will be located within 8 miles of Swainson's hawk foraging flight distances from riparian nesting habitats to ensure that conserved habitats function as foraging habitat for the species. Individual agricultural land acquisitions will be at least 80 acres in size unless high value sites are contiguous or potentially contiguous with other conserved lands; with the intent of creating contiguous agricultural preserves of at least 400 acres. As indicated in CM11 agricultural lands will be managed to provide high value foraging habitat for Swainson's hawk, white-tailed kite, and tricolored blackbird. A portion of the conserved agricultural lands will be maintained as pasture to also meet the foraging habitat requirements of burrowing owl. Other habitat elements on protected agricultural lands (e.g., wetlands, riparian corridors, grasslands, hedgerows, tree rows and groves, and isolated trees) will be retained and enhanced as needed as covered species habitat within the agricultural matrix. The specific parcels of conserved agricultural habitat will vary among years to the extent that they are acquired through limited term conservation easements.

*Plant Species Occurrences***.** Protect and enhance at least 3 occurrences of alkali milk-vetch, brittlescale, and heartscale in Conservation Zones 1, 8, and/or 11. Protect and enhance 2 occurrences of Heckard's peppergrass in Conservation Zones 1, 8, and/or 11. Preserve at least 3 occurrences of Carquinez goldenbush in Conservation Zones 1 and/or 11.

Conservation Zone 2 Acquisition Requirements

Land acquisition (includes fee title and easement) requirements for Conservation Zone 2 are directed at protecting and restoring grassland and associated seasonal wetlands, acquiring lands necessary for the restoration of tidal and associated riparian habitats and nontidal wetlands, and protecting cultivated agricultural foraging habitats.

Tidal Aquatic and Wetland Natural Communities. Lands sufficient to restore at least 5,000 acres of tidal habitat within the Cache Slough Complex ROA, which includes lands in Conservation Zones 1and 2, will be acquired. The criteria for restoring tidal habitat and the anticipated benefits for associated covered species are the same as described above for restoration of tidal habitat in Conservation Zone 1.

*Grasslands and Associated Seasonal Wetland Natural Communities***.** There is no specific acquisition target for grassland and associated seasonal wetlands established for Conservation Zone 2. However, acquisitions may occur if there are high value grassland or seasonal wetland habitats that connect to existing protected grassland landscapes (e.g., Yolo Bypass Wildlife Area). Conserved lands will be evaluated and managed to maintain and enhance their existing habitat functions for covered species over the term of the BDCP. In addition, small and fragmented patches of grassland associated with maintained agricultural habitats (e.g., vegetated levee slopes), however, may be protected that will serve as upland habitat for giant garter snake and western pond turtle, and foraging habitat for Swainson's hawk and white-tailed kite. Grassland conservation in Conservation Zone 2 will conserve habitat for the tricolored blackbird, western burrowing owl, Swainson's hawk, white-tailed kite, giant garter snake, and western pond turtle (see details on benefits to each of the species in Section 3.3, *Biological Goals and Objectives*).

*Nontidal Aquatic and Wetland Natural Communities***.** The nontidal aquatic and wetland natural communities group is comprised of nontidal freshwater perennial emergent wetland and nontidal aquatic natural communities. Lands will be acquired in Conservation Zone 2 to restore up to 200 acres of nontidal marsh that functions as aquatic habitat for the giant garter snake. Nontidal freshwater marsh will be restored in locations to benefit the Yolo/Willow Slough subpopulation of giant garter snake. The specific amount of marsh that will be restored will be determined based on results of site-specific habitat assessments of the Yolo/Willow Slough and Caldoni Marsh/White Slough (Conservation Zone 4) subpopulations to determine the extent of marsh needed to be restored in each location to maximize conservation benefits for the species. Marsh will be restored within or adjacent to habitats occupied by these subpopulations and within larger patches of protected giant garter snake upland and agricultural habitats. The BDCP Implementation Office will consult with species experts and use guidance provided in the giant garter snake recovery plan (USFWS 1999a) to determine specific locations, patch sizes, and develop specific restoration design criteria and implementation guidance (e.g., vegetation associations, edge habitat, bank slopes, wetland to upland ratio, etc.). In addition to benefiting the giant garter snake, restored tidal marsh habitats are expected to provide nesting habitat for tricolored blackbird and aquatic habitat for the western pond turtle. Increased flying insect production associated with restored marshes relative to the existing upland habitats that will be restored to marsh is expected to improve foraging habitat conditions for the Townsend's Big-eared Bat.

*Agricultural Lands and Managed Wetlands***.** Agricultural lands will be acquired in Conservation Zone 2 to achieve a substantial proportion of the overall agricultural habitat conservation target established for the Plan Area (Table 3-4). Agricultural lands will be acquired that support foraging habitat for tricolored blackbird, Swainson's hawk, giant garter snake, and other agricultural-associated species. A total of 4,600 acres will be maintained in rice or equivalent habitat value to provide habitat for the giant garter snake. Other conserved agricultural lands will be located within 8 miles of Swainson's hawk foraging flight distances from riparian nesting habitats to ensure that conserved habitats function as foraging habitat for the species. Agricultural lands will be managed to provide high value foraging habitat for Swainson's hawk, white-tailed kite, and tricolored blackbird. Other habitat elements on protected agricultural lands (e.g., wetlands, riparian corridors, grasslands, hedgerows, tree rows and groves, and isolated trees) will be retained and enhanced as needed as covered species habitat within the agricultural matrix. Criteria for acquisition of agricultural lands to provide habitat for Swainson's hawk are the same as described above for Conservation Zone 1. A portion of the conserved agricultural lands may also be maintained as pasture to meet the foraging habitat requirements of western burrowing owl.

A portion of the conserved agricultural lands will need to be acquired and maintained within or adjacent to habitat occupied by the Yolo/Willow Slough subpopulation of giant garter snake to establish a 1,000-acre preserve for this subpopulation. The Implementation Office will consult with giant garter snake species experts to determine appropriate agricultural land acquisitions relative to the proximity of the existing subpopulation, proximity and connectivity with existing and restored nontidal freshwater marsh, and opportunities for population protection and expansion. The specific parcels of conserved agricultural habitat will vary among years to the extent that they are acquired through limited term conservation easements.

Conservation Zone 3 Acquisition Requirements

No specific conservation land acquisition targets are identified for Conservation Zone 3. Agricultural lands that support Swainson's hawk and greater sandhill crane foraging habitats, which may be conserved in multiple Conservation Zones to achieve the objectives for these species, may be acquired in Conservation Zone 3. Any acquired Swainson's hawk foraging habitat will be located within 8 miles of its riparian nesting habitat and acquired greater sandhill crane foraging habitat will be located within 2 miles of roosting habitat to ensure that conserved habitats function as foraging habitat for these species.

Conservation Zone 4 Acquisition Requirements

Land acquisition (includes fee title and easement) requirements for Conservation Zone 4 are directed at acquiring lands necessary for the restoration of tidal and associated riparian habitats and nontidal wetlands, and protecting cultivated agricultural habitats.

Tidal Aquatic and Wetland Natural Communities. Lands sufficient to restore at least 1,500 acres of tidal habitat within the Cosumnes/Mokelumne ROA in Conservation Zone 4 will be acquired. The criteria for restoring tidal habitat and the anticipated benefits for associated covered species are the same as described above for restoration of tidal habitat in Conservation Zone 1. The restoration of tidal marsh communities in CZ4 may help achieve the recovery objectives for giant garter snake identified in the giant garter snake recovery plan (USFWS 1999a) by providing additional habitat connectivity between the Caldoni Marsh/White Slough subpopulation and the Stone Lakes National Wildlife Refuge lands to the north and additional connectivity between the Delta and the Badger Creek giant garter snake subpopulation to the east.

Grasslands and Associated Seasonal Wetland Natural Communities. There is no specific acquisition target for grassland and associated seasonal wetlands established for Conservation Zone 4 because high value grassland habitats in the Conservation Zone are currently protected. Small and fragmented patches of grassland associated with maintained agricultural habitats (e.g., vegetated levee slopes), however, may be protected that will serve as upland habitat for giant garter snake and western pond turtle, and foraging habitat for Swainson's hawk and white-tailed kite.

*Nontidal Aquatic and Wetland Natural Communities***.** Lands will be acquired in Conservation Zone 4 to restore up to 200 acres of nontidal marsh that functions as aquatic habitat for the giant garter snake. Nontidal marsh will be restored in locations to benefit the Caldoni Marsh/White Slough giant garter snake subpopulation. The criteria for restoring nontidal marsh and the anticipated benefits for associated covered species are the same as described above for restoration of nontidal marsh in Conservation Zone 2.

*Agricultural Lands and Managed Wetlands***.** Agricultural lands will be acquired in Conservation Zone 4 to achieve a proportion of the overall agricultural habitat conservation target established for the Plan Area (Table 3-4). Agricultural lands will be acquired that support habitat for tricolored blackbird, Swainson's hawk, greater sandhill crane, and giant garter snake. Other habitat elements on protected agricultural lands (e.g., wetlands, riparian corridors, grasslands, hedgerows, tree rows and groves, and isolated trees) will be retained and enhanced as needed as covered species habitat within the agricultural matrix. Criteria for acquisition of agricultural lands to provide habitat for Swainson's hawk are the same as described above for Conservation Zone 1. Protection of agricultural lands in Conservation Zone 4 will also focus on increasing the connectivity of protected lands along the eastern edge of the Plan Area to further facilitate movement and expansion of giant garter snake and other covered species populations between the Stone Lakes National Wildlife Refuge and the Caldoni Marsh/White Slough giant garter snake subpopulation.

A portion of the conserved agricultural land in Conservation Zone 4 will need to be acquired and managed as foraging habitat for the greater sandhill crane to meet the requirements of 4,000 conserved acres within the crane's primary zone. In addition, a portion of the 300 acres of greater sandhill crane managed wetland roosting habitat can be acquired in Conservation Zone 4. Individual agricultural land and managed wetland acquisitions for greater sandhill crane foraging and roosting habitat will be at least 80 acres in size unless high value sites are contiguous or potentially contiguous with other conserved lands. The BDCP Implementation Office will consult with species experts to determine the suitability of potential acquisitions relative to proximity to foraging habitats within the primary zone, and to establish restoration design criteria for crane roosting habitat.

A portion of the conserved agricultural lands will also need to be acquired and permanently maintained within or adjacent to habitat occupied by the Caldoni Marsh/White Slough subpopulation of giant garter snake to establish a 1,000 acre preserve for this subpopulation. The Implementation Office will consult with giant garter snake species experts to determine appropriate agricultural land acquisitions relative to the proximity of the existing subpopulation, proximity and connectivity with existing and restored nontidal perennial freshwater emergent wetland, and opportunities for population protection and expansion. The specific parcels of conserved agricultural habitat will vary among years to the extent that they are acquired through limited term conservation easements.

Conservation Zone 5 Acquisition Requirements

Land acquisition (includes fee title and easement) requirements for Conservation Zone 5 are directed at acquiring lands necessary for the restoration of tidal habitat. Agricultural lands that support Swainson's hawk and greater sandhill crane foraging habitats, which may be conserved in multiple Conservation Zones to achieve the objectives for these species may also be acquired in Conservation Zone 5 if needed to achieve the overall agricultural habitat conservation target (Table 3-4). The extent of subsided lands that may be acquired in Conservation Zone 5, however, is limited to the extent of existing Swainson's hawk and greater sandhill crane foraging habitat located below sea level that would be removed by BDCP actions.

Tidal Aquatic and Wetland Natural Communities**.** Lands sufficient to restore at least 2,100 acres of tidal habitat within the West Delta ROA will be acquired. The criteria for restoring tidal habitat and the anticipated benefits for associated covered species are the same as described above for restoration of tidal habitat in Conservation Zone 1.

Agricultural Lands. Agricultural lands may be acquired in Conservation Zone 5 to achieve a proportion of the overall agricultural habitat conservation target established for the Plan Area (Table 3-4). Agricultural lands would be acquired that support habitat for tricolored blackbird, Swainson's hawk, greater sandhill crane, and giant garter snake. Other habitat elements on protected agricultural lands (e.g., wetlands, riparian corridors, grasslands, hedgerows, tree rows and groves, and isolated trees) will be retained and enhanced as needed as covered species habitat within the agricultural matrix. Criteria for acquisition of agricultural lands to provide habitat for Swainson's hawk and greater sandhill crane are the same as described above for Conservation Zone 1 and 4, respectively.

In addition, lands necessary to create a portion of the 320 acres of greater sandhill crane roosting habitat can be acquired in Conservation Zone 5. Criteria for acquisition is the same as described above for Conservation Zone 4.

Conservation Zone 6 Acquisition Requirements

No specific conservation land acquisition targets are identified for Conservation Zone 6. This Conservation Zone encompasses deeply subsided islands of the Delta that are dominated by agricultural habitats and generally only support small fragmented patches of non-agricultural habitats. Some tidal habitat restoration could occur in Conservation Zone 6 in the West Delta ROA. Agricultural lands that support Swainson's hawk and greater sandhill crane foraging and roosting habitats, which may be conserved in multiple Conservation Zones to achieve the objectives for these species, may be acquired in Conservation Zone 6. Criteria for acquisition of agricultural lands to provide habitat for Swainson's hawk and greater sandhill crane are the same as described above for Conservation Zone 4. The extent of subsided lands that may be acquired in Conservation Zone 6, however, is limited to the extent of existing Swainson's hawk and greater sandhill crane foraging habitat located below sea level that would be removed by BDCP actions.

Conservation Zone 7 Acquisition Requirements

Land acquisition (includes fee title and easement) requirements for Conservation Zone 7 are directed at acquiring lands necessary for the restoration of tidal and associated riparian habitats, restoration of seasonally inundated floodplains and associated riparian habitat, restoration of riparian habitats specifically to support riparian brush rabbit, and protecting cultivated agricultural habitats.

*Tidal Aquatic and Wetland Natural Communities***.** Lands sufficient to restore at least 5,000 acres of tidal habitat within the South Delta ROA will be acquired. The criteria for restoring tidal habitat and the anticipated benefits for associated covered species are the same as described above for restoration of tidal habitat in Conservation Zone 1. In addition, tidal wetland restoration in Conservation Zone 7 is also expected to benefit the greater sandhill crane by providing potential foraging and roosting habitats and facilitating possible expansion of the species' winter range southward.

*Riparian Natural Community***.** Lands sufficient to restore a substantial portion of the 10,000-acre seasonally inundated floodplain target included within would be most of the 5,000-acre riparian natural community target will be acquired. Floodplain habitat and associated riparian habitat would be restored by setting back levees on major river channels including the San Joaquin, Old, and Middle rivers. Riparian habitat restoration would support habitat for riparian brush rabbit, riparian woodrat, Townsend's Big-eared Bat, yellow-breasted chat, white-tailed kite, Swainson's hawk, and valley elderberry longhorn beetle.

Of the 5,000 acres of restored riparian, 300 acres will be specifically restored to meet the ecological requirements of the riparian brush rabbit and 300 additional acres will be restored to meet the ecological requirements of the riparian woodrat. The BDCP Implementation Office will consult with species experts to determine appropriate restoration locations, minimum patch size, species composition, and to develop other restoration design criteria and implementation guidance.

*Grasslands and Associated Seasonal Wetland Natural Communities***.** There is no specific acquisition target for grassland and associated seasonal wetlands established for Conservation Zone 7. Small and fragmented patches of grassland associated with maintained agricultural habitats (e.g., vegetated levee slopes), however, may be protected that will serve as upland habitat for giant garter snake and western pond turtle, and foraging habitat for Swainson's hawk and white-tailed kite.

*Agricultural Lands and Managed Wetlands***.** Agricultural lands will be acquired in Conservation Zone 7 to achieve a substantial proportion of the overall agricultural habitat conservation target established for the Plan Area (Table 3-4). Agricultural lands will be acquired that support foraging habitat for Swainson's hawk and habitat for other agricultural-associated covered species. Other habitat elements on protected agricultural lands (e.g., wetlands, riparian corridors, grasslands, hedgerows, tree rows and groves, and isolated trees) will be retained and enhanced as needed as covered species habitat within the agricultural matrix. Criteria for acquisition of agricultural lands to provide habitat for Swainson's hawk are the same as described above for Conservation Zone 1. The specific parcels of conserved agricultural habitat will vary among years to the extent that they are acquired through limited term conservation easements.

Conservation Zone 8 Acquisition Requirements

Land acquisition (includes fee title and easement) requirements for Conservation Zone 8 are directed at protecting and restoring grassland and associated seasonal wetlands, and protecting occurrences of selected plant species with very limited distributions. Agricultural lands may also be acquired in this Conservation Zone to provide habitat for Swainson's hawk and other agricultural-associated covered species as described above for Conservation Zone 3.

*Grasslands and Associated Seasonal Wetland Natural Communities***.** At least 1,000 acres of existing grassland will be acquired and protected in Conservation Zone 8; and a portion of the 300 acres of existing vernal pool complex and 400 acres of existing alkali seasonal wetland to be protected under the BDCP will be acquired and protected in Conservation Zone 8. The goal of these acquisitions is to protect lands in large contiguous grassland landscapes that encompass the range of vegetation, hydrologic, and soil conditions that characterize these communities within the Conservation Zone south of Highway 4. Conserved lands will be located to maintain habitat connectivity with protected grassland landscapes within and immediately adjacent to the Plan Area. Protection of these habitat areas will maintain connectivity with lands that have been protected or may be protected in the future under the East Contra Costa HCP/NCCP.

This approach to conservation of these natural communities will conserve habitat for the San Joaquin kit fox, tricolored blackbird, western burrowing owl, Swainson's hawk, white-tailed kite, western pond turtle, western spadefoot toad, California red-legged frog, California tiger salamander, the covered vernal pool shrimp species, alkali milk-vetch, San Joaquin spearscale, dwarf downingia, Boggs Lake hedge-hyssop, Heckard's peppergrass, legenere, heartscale, brittlescale, Delta button-celery, and caper-fruited tropidocarpum (see details on benefits to each of these species in Section 3.3, *Biological Goals and Objectives*). Protection and management of grasslands and associated seasonal wetlands in Conservation Zone 8 will help achieve recovery plan objectives for the San Joaquin kit fox (USFWS 1998a), the California red-legged frog (USFWS 2002), Conservancy fairy shrimp, longhorn fairy shrimp, vernal pool fairy shrimp, mid-valley fairy shrimp, vernal pool tadpole shrimp, alkali milk-vetch, Boggs Lake hedge-hyssop, and legenere (USFWS 2005). These conserved lands will be evaluated and managed to maintain and enhance their existing habitat functions for these species over the term of the BDCP. Following full BDCP implementation, an estimated __ percent of grassland, vernal pool complex, and alkali seasonal wetland remaining in Conservation Zone 8 will be protected.

*Plant Species Occurrences***.** Protect and enhance at least 3 occurrences of alkali milk-vetch, brittlescale, heartscale in Conservation Zones 1, 8, and/or 11. Protect and enhance 2 occurrences of Heckard's peppergrass in Conservation Zones 1, 8, and/or 11. Protect occurrences of caper-fruited tropidocarpum that reestablish in Conservation Zone 8.

Conservation Zone 9 Acquisition Requirements

No specific conservation land acquisition targets are identified for Conservation Zone 9. This Conservation Zone is comprised primarily of urban lands (e.g., Brentwood and Discovery Bay are located in this zone) and non-urban areas are dominated by agricultural habitats. Non-agricultural habitats generally are present in small patches that are fragmented and disconnected from other natural habitats. Agricultural lands that support Swainson's hawk foraging habitat, which may be conserved in multiple Conservation Zones to achieve the objectives for this species, may be acquired in Conservation Zone 9 as described above for Conservation Zone 3.

Conservation Zone 10 Acquisition Requirements

No conservation land acquisition targets are identified for Conservation Zone 10. This Conservation Zone encompasses the City of Antioch and is comprised almost entirely of urban lands.

Conservation Zone 11 Acquisition Requirements

Land acquisition (includes fee title and easement) requirements for Conservation Zone 11 are directed at protection of grassland and associated seasonal wetland habitats, acquiring lands necessary for the restoration of tidal habitats, and protecting occurrences of selected plant species with very limited distributions.

*Grasslands and Associated Seasonal Wetland Natural Communities***.** A portion of the 300 acres of existing vernal pool complex, 400 acres of existing alkali seasonal wetland, and 8,000 acres of existing grassland to be protected under the BDCP will be acquired and protected in Conservation Zone 11. These communities are located along the upland fringe of Suisun Marsh and the goal of these acquisitions is to protect these lands to maintain connectivity with much larger protected (e.g., Jepson Prairie Preserve) and unprotected grassland landscapes that are immediately adjacent to the zone. Specific land acquisition requirements include the protection of at least three occurrences of alkali milk-vetch. This approach is expected to result in conservation of a gradient of natural habitats that range from grassland upland communities down slope to existing and restored tidal wetland communities.

Grassland, vernal pool complex, and alkali seasonal wetland complex communities fringing Suisun Marsh support several rare plant species that will be brought under protection and management through these acquisitions. This approach to conservation of these natural communities will serve to conserve habitat for the tricolored blackbird, western burrowing owl, Swainson's hawk, white-tailed kite, giant garter snake, western pond turtle, western spadefoot toad, California tiger salamander, the covered vernal pool shrimp species, alkali milk-vetch, San Joaquin spearscale, dwarf downingia, Boggs Lake hedge-hyssop, Heckard's peppergrass, legenere, heartscale, brittlescale, and Carquinez goldenbush (see details on benefits to each of these species in Section 3.3, *Biological Goals and Objectives*). These conserved lands will be evaluated and managed to maintain and enhance their existing habitat functions for these species over the term of the BDCP. The protection and restoration of vernal pool complex will help achieve the recovery objectives for Conservancy fairy shrimp, longhorn fairy shrimp, vernal pool fairy shrimp, mid- valley fairy shrimp, vernal pool tadpole shrimp, alkali milk-vetch, Boggs Lake hedge-hyssop, and legenere identified in the Vernal Pool Recovery Plan (USFWS 2005). Following full BDCP implementation, an estimated __ percent of grassland, vernal pool complex, and alkali seasonal wetland remaining in Conservation Zone 11 will be protected.

*Tidal Aquatic and Wetland Natural Communities***.** Lands sufficient to restore at least 7,000 acres of tidal habitat, including 3,000 acres of tidal brackish emergent wetland will also be acquired in Conservation Zone 11 within the Suisun Marsh ROA. Restored tidal habitat includes restored gradient of habitats ranging from shallow subtidal aquatic habitat, to mudflat, emergent marsh plain, and transitional uplands. Transitional uplands will include sufficient land to accommodate future upslope establishment of marsh plain vegetation with sea level rise and will support habitat for grassland associated species. Restored tidal marsh plains and mudflats are expected to support habitat for the salt marsh harvest mouse, Suisun shrew, Townsend's big-eared bat, tricolored blackbird, Suisun song sparrow, California black rail, California clapper rail, western pond turtle, Suisun thistle, soft bird's-beak, Delta tule pea, Suisun marsh aster, Mason's lilaeopsis, and Delta mudwort. Restoration and protection of transitional uplands will provide flood refugia habitat for salt marsh harvest mouse, Suisun shrew, California black rail, and California clapper rail during high water events. Restoration of shallow subtidal aquatic habitat will also support California least tern foraging habitat and aquatic habitat for the western pond turtle.

*Plant Species Occurrences***.** Protect and enhance at least three occurrences of alkali milk-vetch, brittlescale, heartscale in Conservation Zones 1, 8, and/or 11. Protect and enhance 2 occurrences of Heckard's peppergrass in Conservation Zones 1, 8, and/or 11. Protect and enhance 3 occurrences each of Suisun thistle and soft bird's-beak in Suisun Marsh Conservation Zones 11. Preserve at least 3 occurrences of Carquinez goldenbush in Conservation Zones 1 and/or 11.

Inter-Conservation Zone Connectivity

In addition to the spatial distribution requirements among the Conservation Zones for protection of natural communities and covered species, conservation lands will also need to be distributed within and among some Conservation Zones to provide connectivity for some covered species habitats across specific segments within or adjacent to the Plan Area. Specific efforts will focus on two ecological corridors described below. It is expected that the corridors can be established through meeting the natural community conservation targets presented in Table 3-4. Corridor width will follow the recommendations from the *California Essential Habitat Connectivity Project* (DFG/CALTRANS 2010), to the extent that it is practicable and within the natural community conservation targets.

Grassland/Vernal Pool Complex Corridor. Vernal pool complex natural community in Conservation Zones 1 and 11 are situated at elevations that are suitable for serving as upland habitats adjacent to restored tidal habitats and can be protected to build upon existing and planned preserves in Solano County between these conservation zones. Protection of additional vernal pool complex natural community in this area will protect an important connection between Suisun Marsh and the Cache Slough area. Establishing a protected corridor in this area will also facilitate movement of several covered species including California tiger salamander and western spadefoot toad from occupied habitats in the Montezuma Hills and Jepson Prairie into the grassland and vernal pool complex habitats in Conservation Zone 1.

The Implementation Office will explore opportunities through coordination with Solano County to acquire and protect additional lands between Suisun Marsh and the Cache Slough area in order to establish a protected corridor comprised of contiguous patches of grassland, vernal pool complex, tidal wetlands, and other seasonal wetlands.

Giant Garter Snake Corridor. Habitat connectivity, particularly hydrologic connectivity that supports giant garter snake movement and dispersal, is essential for protection of giant garter snake populations, and is a key element of the species' recovery plan (USFWS 1999a). Focusing agricultural land conservation along a north-south corridor within Conservation Zone 4 along with restoration of tidal wetlands in that area, will enhance connectivity and facilitate giant garter snake movement between the Coldani Marsh-White Slough subpopulation north to the Cosumnes River Preserve and to Stone Lakes National Wildlife Refuge.

A corridor will be protected that is comprised of contiguous patches of agricultural, restored tidal and nontidal wetlands, grassland, vernal pool complex, and other seasonal wetlands between the Coldani Marsh/White Slough giant garter snake subpopulation area north to Stone Lakes National Wildlife Refuge and to the extent possible connecting the Cosumnes River Preserve. The corridor will be configured such that there is contiguous giant garter snake movement habitat along this north-south corridor. To serve as a movement corridor to meet the needs of the giant garter snake, the width of the corridor may not be less than 3,200 feet wide in any location.

Invasive Species Control Program

The BDCP Implementation Office will develop and implement a plan for the control of invasive animal and plant species that could substantially degrade the functions of protected natural communities as habitat for covered and other native species on BDCP lands.

Elements of the plan will include:

- Protocols for periodically surveying for and assessing the abundance of nonnative predators and competitors on BDCP lands;
- Protocols for periodically surveying for and assessing the occurrence and abundance of invasive nonnative plants on BDCP lands;

- A brown-headed cowbird monitoring and control program (see discussion below);
- Methods for assessing degree of biological effect nonnative species have on covered and other native species within BDCP lands;
- Methods for assessing threats of establishment of nonnative animals and plants on lands adjacent to BDCP lands;
- Methods for assessing threats of the spread of nonnative plants from BDCP lands onto adjacent lands;
- A decision-making process for determining the need for implementing management actions to control nonnative species;
- A description of potential nonnative species control methods; and
- A process for developing and implementing monitoring necessary to assess the effectiveness of implemented control methods.

Monitoring and control requirements that may be developed for specific preserve lands will be incorporated into preserve-specific management plans (see CM11 Natural Communities Enhancement and Management).

Examples of nonnative plant species currently of concern include waxy mannagrass, Italian ryegrass, barbed goatgrass, medusahead grass, yellow starthistle, Himalayan blackberry, giant reed, and parrot feather. Animal species that could degrade the habitat functions for covered species include feral domesticated animals (e.g., feral cat predation on ground-nesting birds) and brown-headed cowbirds.

The brown-headed cowbird is a native species that has expanded its range substantially with conversion of historical Central Valley habitats to agriculture. The brown-headed cowbird is a frequent brood parasite of yellow-breasted chats and other native birds and can affect local reproduction of chats. On conserved lands that support nesting yellow-breasted chats, surveys will be conducted to identify and monitor brown-headed cowbird populations, the extent of brood parasitism of yellow-breasted chats, and the reproductive trend of nesting yellow-breasted chats. If it is determined that cowbirds are substantially affecting nesting success of yellow-breasted chats such that local populations are or could decline, cowbird control measures will be implemented to reduce local cowbird populations.

3.4.3 Natural Community-Level Conservation Measures

Natural community conservation measures include the protection, restoration, enhancement, and management of natural communities and the covered species that are dependent upon them. The overarching goal of restoration and protection of natural communities is to create and maintain an ecologically functioning landscape that successfully combines both native and working landscape elements and that meets natural community and species goals and objectives. Natural community conservation measures provide the mechanisms for achieving restoration and protection goals and objectives using the following the guiding principles:

- Restore natural communities such that they contribute to and enhance an ecologically functional landscape;
- Manage and enhance working landscapes (e.g., agricultural lands) such that they protect covered species habitat values and facilitate expansion of covered species populations while maintaining their agricultural production and economic value;
- Emphasize natural ecological gradients and connectivity among and between restored and existing natural communities that provide a range of conditions to provide for shifting or expanding species distributions; and
- Protect, restore, and enhance habitats for covered species such that implementation of the BDCP provides a significant contribution to their long-term conservation in the Plan Area.

3.4.3.1 CM4 Tidal Habitat Restoration

BDCP implementation will provide for the restoration of 65,000 acres of freshwater and brackish tidal habitat within the BDCP ROAs (Figure 3-3). The extent of restored tidal habitat includes a contiguous habitat gradient encompassing restored shallow subtidal aquatic habitat[34], restored tidal mudflat, restored tidal marsh plain habitat[35], and adjoining transitional upland habitat. This upland habitat will accommodate approximately 3 feet of sea level rise that could function as tidal marsh plain at some future time, if necessary. Additional upland habitat, however, would be protected and enhanced to provide habitat for terrestrial species.

Of the 65,000-acre restoration target, 22,000 acres will be distributed among the ROAs as described below in Minimum Restoration Targets for Freshwater Tidal Habitat in ROAs and Minimum Restoration Target for Brackish Tidal Habitat in the Suisun ROA. The remaining 43,000 acres of the target total will be distributed among the ROA's at the discretion of the BDCP Implementation Office based on land availability, biological value, and practicability considerations. The freshwater and brackish tidal habitat restoration targets will be achieved on the following time schedule:

- 14,000 acres developed[36] within the first 10 years of plan implementation;
- 25,000 acres (cumulative) developed by year 15 of plan implementation; and
- 65,000 acres (cumulative) developed by year 40 of plan implementation.

[34] Restored shallow subtidal habitat extends approximately from the mean lower low water [MLLW] elevation to 9 feet below the MLLW elevation.

[35] Restored tidal marsh plain extends from the MLLW elevation to the mean higher high water [MHHW] elevation.

[36] In achieving these targets the term "developed" means the completion of reintroduction of tidal inundation to areas expected to develop as tidal habitat. These target values represent the habitat area developed at the points in time identified. Development of fully functioning restored habitat may take years subsequent to initial tidal inundation through the effects of natural processes on the constructed surface.

Actions to restore freshwater and brackish tidal habitat, as appropriate to site-specific conditions, will include:

- Acquiring lands, in fee-title or through conservation easements, suitable for restoration of tidal habitats and protecting sufficient adjacent uplands to accommodate 3 feet of future sea level rise;
- Consulting with covered species experts to assist with the design and implementation of avoidance and minimization measures;
- Breaching and lowering levees and dikes to reintroduce tidal exchange to currently leveed former tidelands;
- Reconnecting disconnected remnant sloughs to Suisun Bay and removing remnant slough levees to reintroduce tidal connectivity to slough watersheds;
- Constructing new or enhancing existing levees to provide flood protection for adjacent landowners and protecting existing land use against seepage and erosion of existing levees;
- Constructing new levees to isolate deeply subsided lands from tidal flooding;
- Restoring natural remnant meandering tidal channels;
- Excavating channels to encourage the development of dendritic channel networks within restored marsh plain;
- Modifying ditches, cuts, and levees to encourage more natural tidal circulation and better flood conveyance based on local hydrology;
- Restoring tributary stream functions to establish more natural patterns of sediment transport to improve spawning conditions for delta smelt and other fish and macroinvertebrates;
- Prior to breaching, re-contouring the surface to maximize the extent of surface elevation suitable for establishment of tidal marsh vegetation ("marsh plain") by scalping higher elevation land to provide fill for placement on subsided lands to raise surface elevations;
- Prior to breaching, importing dredge or fill and placing it in shallowly subsided areas to raise ground surface elevations to a level suitable for establishment of tidal marsh vegetation ("marsh plain");
- Prior to breaching, cultivating stands of tules through flood irrigation for sufficiently long periods to raise subsided ground surface to elevations suitable to support marsh plain and breaching levees when target elevations are achieved; and
- Designing levee and dike breaches to maximize the development of tidal marsh plain and minimize hydrodynamic conditions that favor nonnative predatory fish.

Measures for addressing the potential for methylation of mercury in restored tidal habitats will be addressed through implementation of CM12 Methylmercury Management.

Freshwater Tidal Habitat Restoration

Freshwater tidal habitats will be restored to provide the ecological benefits for covered species described under *Hypothesized Benefits* below. Freshwater tidal habitats will be restored by breaching or removing levees along Delta waterways to reestablish tidal connectivity to reclaimed lands. Tidal habitat restored on deeply subsided Delta tracts and islands may require construction of cross levees or berms to isolate deeply subsided lands from inundation, avoiding the creation of large areas of subtidal habitats that could favor nonnative predator/competitor species and disfavor covered fish species. Where required, levees or berms will be constructed to prevent inundation of adjacent lands.

Where practicable and appropriate, portions of restoration sites will be raised to elevations that will support tidal marsh vegetation following breaching. Depending on the degree of subsidence and location, lands may be elevated by grading higher elevations to fill subsided areas, importing dredged or fill material from other locations, or planting tules or other appropriate vegetation to raise elevations in shallowly subsided areas over time through organic material accumulation. Surface grading will provide for a shallow elevation gradient from the marsh plain to the upland transition habitat. Based on assessments of local hydrodynamic conditions, sediment transport, and topography, restoration activities may be designed and implemented in a manner that accelerates the development of tidal channels within restored marsh plains. Following reintroduction of tidal exchange, tidal marsh vegetation is expected to establish naturally at suitable elevations relative to the tidal range. Depending on site-specific conditions and monitoring results, patches of native emergent vegetation may be planted to accelerate the establishment of native marsh vegetation on restored marsh plain surfaces. A conceptual illustration of restored freshwater tidal habitat is presented in Figure 3-55.

Restoration variables that will be considered by the BDCP Implementation Office in the design of restored freshwater tidal habitat include:

- Spatial distribution of restored tidal marsh habitats within the Delta;
- Extent, location, and configuration of restored tidal habitat areas;
- Predicted tidal range at tidal habitat restoration sites following reintroduction of tidal exchange;
- Size and location of levee breaches;
- Cross sectional profile of tidal habitat restoration sites (elevation of marsh plain, topographic diversity, depth, and slope); and
- Density and size of restored tidal habitat channels appropriate to each restoration site.

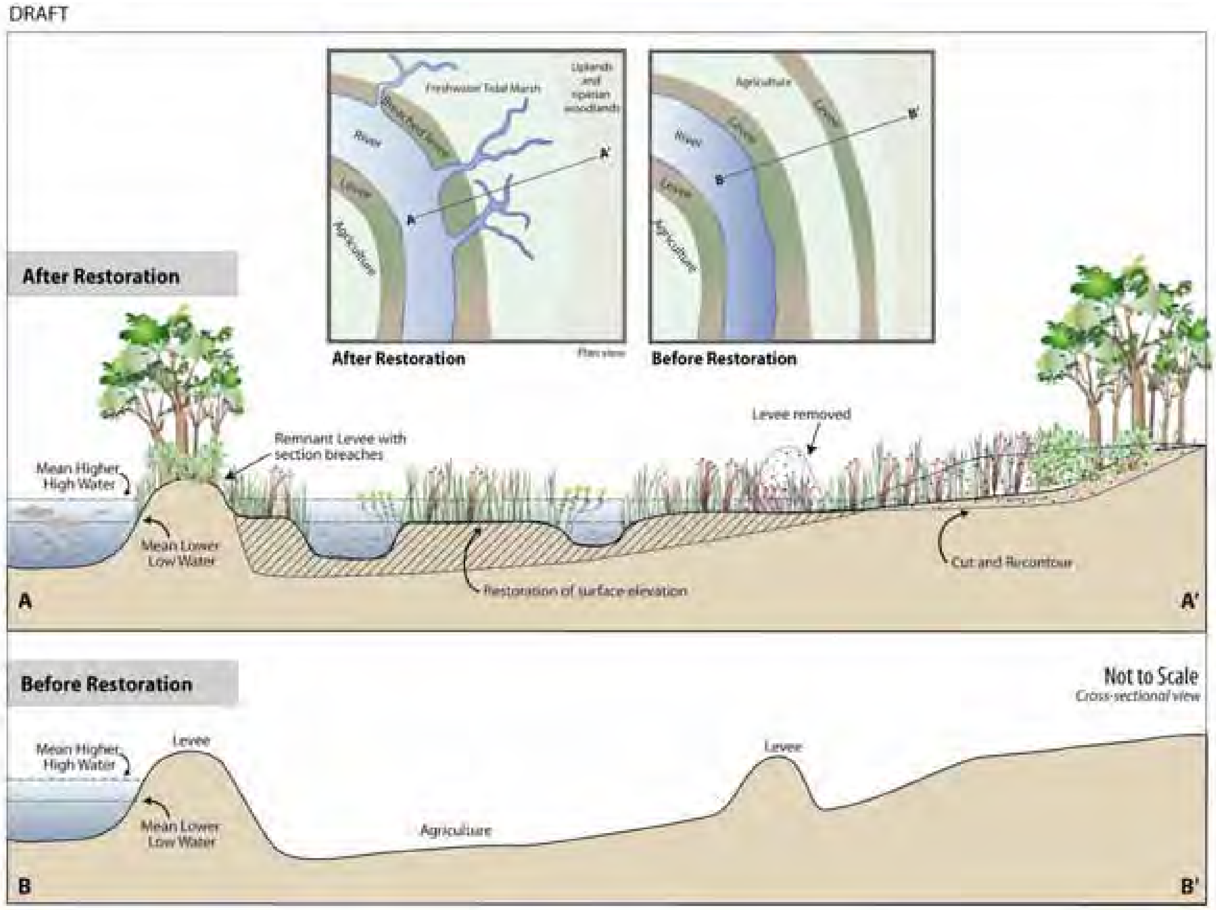

Figure 3-55. Conceptual Design for Restored Freshwater Tidal Marsh Habitat (CM4)

Restoration design considerations for freshwater tidal habitat will include the following.

*Marsh Plain Vegetation***.** To provide for high functioning habitat, restored tidal marsh plains will be vegetated primarily with tules and other native freshwater emergent vegetation to reflect the historical composition and densities of Delta tidal marshes. Following establishment of tidal exchange, restored habitat will be monitored to assess the establishment of native and invasive nonnative plants. If indicated by monitoring results, the Implementation Office will implement invasive plant control measures to help ensure the establishment of native marsh plain plant species.

*Hydrodynamic Conditions***.** Tidal habitat restoration will be designed, within restoration site constraints, to produce sinuous, high density, dendritic networks of tidal channels that promote effective tidal exchange throughout the marsh plain and provide foraging habitat for covered fish species. Effective tidal exchange is expected to enhance ecological functions that support covered species, including:

- The export of productivity from the marsh plain into adjacent Delta waterways in support of aquatic food web processes;
- Production and export of phytoplankton and zooplankton from tidal channels into adjacent Delta waterways in support of the aquatic food web; and
- Maintenance of cooler localized water temperatures preferred by covered fish species through nocturnal thermal exchange on marsh plains.

Marsh channels and levee breaches will also be designed to maintain flow velocities that minimize conditions favorable to the establishment of nonnative submerged and floating aquatic vegetation and habitat for nonnative predatory fish.

Following breaching and reintroduction of tidal action to restoration sites, tidal action will begin the natural process of sediment movement and the restored bottom contours will evolve. A discussion of such the types of changes expected is provided in Appendix N-4 [*marsh evolution document*].

*Environmental Gradients***.** As determined by site-specific constraints, tidal habitat restoration actions will be designed to provide an ecological gradient among subtidal, tidal mudflat, tidal marsh plain, riparian, and upland habitats to accommodate the movement of fish and wildlife species and provide flood refuge habitat for marsh-associated wildlife species during high water events. In addition, by protecting higher elevation lands adjacent to restored marsh plains, these areas will be available for future marsh establishment that may occur as a result of sea level rise.

*Shallow subtidal aquatic habitat***.** Restored shallow subtidal aquatic habitat is expected to support, depending on location, delta smelt, longfin smelt, juvenile salmonid rearing, sturgeon, and lamprey habitat. Shallow freshwater subtidal aquatic habitat in some portions of the Delta support large numbers of nonnative predatory fish and extensive beds of nonnative submerged aquatic vegetation that adversely affect covered fish species. In other portions of the Delta, shallow subtidal habitat provides suitable habitat for native species, such as delta smelt in the Liberty Island/Cache Slough region, and does not promote the growth of nonnative submerged aquatic vegetation. Because it may generate habitat for nonnative predators, it is not a goal of the BDCP to restore large areas of shallow subtidal aquatic habitat; rather, shallow subtidal aquatic habitat will result as part of the restoration of freshwater tidal marsh plain where land surface elevations within restoration sites are subsided below elevations that would support tidal marsh vegetation. Tidal habitat restoration projects will be designed to minimize the likelihood of establishment of nonnative submerged aquatic vegetation, which may serve as habitat for nonnative predators. Early restoration projects will be monitored to assess the response of nonnative species to restoration designs and local environmental conditions. This information will be used to modify restoration designs and implementation methods, if necessary, over time to further improve habitat conditions for covered fish species. As described in CM13 Nonnative Aquatic Vegetation Control, the BDCP Implementation Office will engage in active removal of submerged and floating aquatic vegetation in subtidal portions of tidal restoration sites to reduce the levels of establishment of nonnative predators.

*Minimum Restoration Targets for Freshwater Tidal Habitat in ROAs***.** At a minimum, the BDCP Implementation Office will restore the following amounts of tidal habitat in each of the Delta ROAs (Figure 3-2) as described below.

- **Restore at least 5,000 acres of freshwater tidal habitat within the Cache Slough Complex ROA**. The BDCP Implementation Office will restore a minimum of 5,000 acres of freshwater tidal habitat in the Cache Slough Complex ROA. Areas suitable for restoration include, but are not limited to, Haas Slough, Hastings Cut, Lindsey Slough, Barker Slough, Calhoun Cut, Liberty Island, Little Holland, the Westlands property ("Yolo Ranch"), Shag Slough, Little Egbert Tract, and Prospect Island. The Cache Slough Complex has been recognized as possibly the best functioning existing tidal habitat area of the Delta. The complex includes Liberty Island, which is likely the best existing model for freshwater tidal habitat restoration in the Delta for native fishes. The Complex supports multiple covered fish species and may be one of the last areas where Delta smelt spawn and rear successfully. Restoring the target amount of freshwater tidal habitat within the Cache Slough Complex ROA and protecting associated upland habitat would benefit multiple covered species and the Delta ecosystem. In conjunction with floodplain enhancement in the Yolo Bypass, the habitat restoration in the Cache Slough ROA will re-establish the ecological gradient from river to floodplain to tidal estuary and to provide tidal wetland adjacent to open channel habitat that is characteristic of less altered estuaries. Hydrodynamic modeling indicates that increased tidal exchange in the Cache Slough area resulting from 5,000-10,000 acres of tidal habitat restoration will reduce bidirectional flows in Steamboat and Sutter Sloughs and the mainstem Sacramento River compared to tidal action under present conditions, thus significantly enhancing movement of juvenile salmonids through these waterways and potentially reducing their exposure to predators.

Additionally, the Cache Slough Complex encompasses a substantial area of land with elevations suitable for freshwater tidal habitat restoration that would involve few impacts on existing infrastructure or permanent crops relative to other areas of the north Delta. The Cache Slough Complex provides an excellent opportunity to expand habitat supporting multiple aquatic and terrestrial covered species. Restoration of freshwater tidal habitat will be designed to support the physical and biological attributes that benefit covered species. Based on existing land elevations, approximately 21,000 acres of public and private lands in the area are potentially suitable for restoration of tidal habitat. Areas for restoration would be identified by working with interested landowners.

- **Restore at least 1,500 acres of freshwater tidal habitat within the Cosumnes-Mokelumne ROA.** The BDCP Implementation Office will restore a minimum of 1,500 acres of freshwater tidal habitat in the Cosumnes/Mokelumne ROA. Areas suitable for restoration within the Cosumnes-Mokelumne ROA (Figure 3-2) include McCormack-Williamson Tract, New Hope Tract, Canal Ranch Tract, Bract Tract, Terminous Tract north of State Highway 12, and lands adjoining Snodgrass Slough, South Stone Lake, and Lost Slough. Depending on site-specific conditions, levees may be constructed to avoid inundation of deeply subsided lands.
- **Restore at least 2,100 acres of tidal habitat within the West Delta ROA.** The BDCP Implementation Office will restore a minimum of 2,100 acres of freshwater tidal habitat in the West Delta ROA. The west Delta includes multiple small areas where tidal habitat can be restored. Areas suitable for restoration include Dutch Slough, Decker Island, portions of Sherman Island, Jersey Island, Bradford Island, Twitchell Island, Brannon Island, Grand Island, and along portions of the north bank of the Sacramento River where elevations and substrates are suitable. The purpose of restoring tidal habitat in the west Delta is to provide a continuous reach of tidal marsh and subtidal aquatic habitat associated with food productivity between current and future restored habitats in the Cache Slough Complex and Suisun Marsh and Bay and to provide tidal marsh plain habitat within the anticipated future eastward position of the biologically important low salinity zone of the estuary with sea level rise.
- **Restore at least 5,000 acres of tidal habitat within the South Delta ROA.** The BDCP Implementation Office will restore a minimum of 5,000 acres of freshwater tidal habitat in the South Delta ROA. To maximize benefits associated with restoration of tidal habitat in the south Delta, tidal habitat will not be restored until the north Delta diversion facilities become operational. Potential sites for restoring freshwater tidal habitat include Fabian Tract, Union Island, Middle Roberts Island, and Lower Roberts Island. Sites selected for restoration would be dependent on the location and design of the selected conveyance pathway and operations for the through-Delta component of the dual conveyance facility. Selected sites would be those that would provide substantial species and ecosystem benefits with the selected through-Delta conveyance configuration and most effectively avoid potential adverse effects of south Delta SWP/CVP operations. In conjunction with dual conveyance operations, tidal habitat restoration in the South Delta

ROA may support the expansion of the current distribution of delta smelt into formerly occupied habitat areas.

Tidal habitat restoration sites will be designed to support habitat mosaics and an ecological gradient of shallow subtidal aquatic, tidal mudflat, tidal marsh, transitional upland and riparian habitats, and uplands (e.g., grasslands, agricultural lands) for sea level rise accommodation, as appropriate to specific restoration sites.

Problem Statement

The majority of historical freshwater tidal marsh in the Sacramento/San Joaquin Delta has been lost. Historically, approximately 350,000 acres of tidal marsh was present in the Delta, of which less than 10,000 acres of freshwater tidal marsh remains. This loss of tidal marsh has greatly reduced the availability and quality of spawning and rearing habitat for many native fish species, by reducing the input of organic and inorganic material and food resources into adjoining deep water habitats (sloughs and channels) and the downstream bay and estuary. This loss of freshwater tidal marsh has also greatly reduced the extent and quality of habitat for native wildlife and plants adapted to the tidal marsh environment, including many of the covered species.

Hypothesized Benefits

Restoration of freshwater tidal habitat is hypothesized to provide a range of ecosystem and covered species benefits. These anticipated benefits are described below for the freshwater tidal habitat restoration proposed in each of the ROAs. As described in Chapter 5, *Effects Analysis*, and Appendix F, *DRERIP Evaluation Results*, however, there are a number of uncertainties regarding the level of benefits that may be provided by tidal habitat restored in each of the ROAs as well as risks for adverse consequences. These uncertainties will be addressed through effectiveness monitoring, research, and the adaptive management program (see Sections 3.6 and 3.7).

Restoring freshwater tidal habitat within the Cache Slough ROA is expected to:

- Increase rearing habitat area for Chinook salmon (Sacramento River runs), Sacramento splittail, white sturgeon, and green sturgeon (Healey 1991, Brown 2003, Appendix F, *DRERIP Evaluation Results*);
- Increase the local production of food for rearing salmonids, splittail, delta smelt, green and white sturgeon (Kjelson et al. 1982, Siegel 2007);
- Increase the export of food in the Delta downstream of Rio Vista available to juvenile salmonids, splittail, delta smelt, white sturgeon, and green sturgeon by exporting organic material from the marsh plain and phytoplankton, zooplankton, and other organisms produced in tidal channels into the Delta and Suisun Marsh (Siegel 2007);
- Expand habitat available for colonization by Mason's lilaeopsis, Suisun Marsh aster, Delta mudwort, and Delta tule pea; and

- Expand habitat for tricolored blackbird, California black rail, and giant garter snake (in locations with a muted tidal range).

Restoring freshwater tidal habitat within the Cosumnes/Mokelumne River ROA is expected to:

- Increase rearing habitat area for Cosumnes/Mokelumne fall-run Chinook salmon, steelhead, delta smelt, and Sacramento splittail (Healey 1991, Brown 2003);
- Increase the local production of food for Cosumnes/Mokelumne fall-run Chinook salmon, steelhead, delta smelt, and Sacramento splittail migrating to and from the Cosumnes and Mokelumne Rivers (Kjelson et al. 1982, Siegel 2007);
- Increase the availability and production of food in the east and central Delta available to juvenile salmonids, splittail, delta smelt, white sturgeon, and green sturgeon by exporting organic material from the marsh plain and phytoplankton, zooplankton, and other organisms produced in tidal channels into the Delta (Siegel 2007);
- Increase the extent of habitat available for colonization by side-flowering skullcap, Mason's lilaeopsis, Suisun Marsh aster, and Delta tule pea; and
- Expand habitat for tricolored blackbird, California black rail, greater sandhill crane, and giant garter snake (in locations with a muted tidal range).

Restoring freshwater tidal habitat in the West Delta ROA is expected to:

- Increase rearing habitat area for Chinook salmon (Sacramento, San Joaquin, and Mokelumne river runs), Sacramento splittail, and possibly steelhead (Healey 1991, Brown 2003);
- Improve future rearing habitat areas for delta smelt and longfin smelt within the anticipated eastward movement of the low salinity zone with sea level rise;
- Increase the local production of food for rearing salmonids, splittail, and other covered species (Kjelson et al. 1982; Siegel 2007);
- Increase the availability and production of food in the western Delta and Suisun Bay by exporting organic material via tidal flow from the marsh plain and organic carbon, phytoplankton, zooplankton, and other organisms produced in tidal channels into adjacent open water areas (Siegel 2007);
- Provide an important linkage between current and future upstream restored habitat with downstream habitat in Suisun Marsh and Bay;
- Provide additional refugial habitat for migrating and resident covered species;
- Increase the extent of habitat available for colonization by Mason's lilaeopsis, Suisun Marsh aster, Delta mudwort, and Delta tule pea; and
- Expand habitat for tricolored blackbird, California black rail, and giant garter snake (in locations with a muted tidal range).

Restoring freshwater tidal habitat in the South Delta ROA is expected to:

- Increase rearing habitat area for Sacramento splittail, Chinook salmon produced in the San Joaquin River and other eastside tributaries, and possibly steelhead (Healey 1991, Brown 2003);
- Increase the local production of food for rearing salmonids, splittail, and other covered species (Kjelson et al. 1982, Siegel 2007);
- Increase the availability and production of food in the Delta and Suisun Bay by export from the south Delta of organic material via tidal flow from the new marsh plain and organic carbon, phytoplankton, zooplankton, and other organisms produced in new tidal channels (Siegel 2007);
- Increase the extent of habitat available for colonization by Mason's lilaeopsis, Delta mudwort, and Delta tule pea; and
- Expand habitat for tricolored blackbird, California black rail, greater sandhill crane, and giant garter snake (in locations with a muted tidal range).

Adaptive Management Considerations

Implementation of freshwater tidal habitat restoration actions and subsequent management of restored tidal habitats by the BDCP Implementation Office will be informed through effectiveness monitoring that will be conducted for this conservation measure as described in Section 3.6, *Monitoring and Research Program*, and the adaptive management process described in Section 3.7, *Adaptive Management Program*. Based on analysis of monitoring results, likely elements of this measure that could be adjusted through the adaptive management process include considerations for selecting restoration locations and sequencing restoration of tidal habitat among the ROAs; methods for establishing marsh plain vegetation, including the establishment of marsh-associated covered plant species; methods and designs for elevating subsided land surfaces to increase restored marsh plain area; design and location of levee breaches; designs for encouraging the development of a high functioning network of tidal channels; and nonnative vegetation and wildlife control techniques.

Brackish Tidal Habitat Restoration

Brackish tidal habitat will be restored within Suisun Marsh ROA in coordination with the Suisun Marsh Habitat Restoration and Management Plan, currently under development. Brackish tidal habitat will be restored to provide the ecological benefits for covered species described under Hypothesized Benefits below. Brackish tidal habitat will be restored by breaching or removing dikes along Montezuma and other Suisun Marsh sloughs and channels and Suisun Bay to reestablish tidal connectivity to reclaimed lands. Tidal habitat restored adjacent to farmed lands or lands managed as freshwater seasonal wetlands may require construction of dikes to maintain those land uses. Where appropriate, portions of restoration sites will be raised to elevations that would support tidal marsh vegetation.

Depending on the degree of subsidence, location, and likelihood for natural accretion through sedimentation, lands may be elevated by grading higher elevations to fill subsided areas, importing dredged or fill material from other locations, or planting appropriate native vegetation to raise elevations in shallowly subsided areas over time through organic material accumulation prior to breaching dikes. Surface grading will be designed to result in a shallow elevation gradient from the marsh plain to the upland transition habitat. Remnant disconnected tidal channels will be restored if present within restoration sites to accelerate development of marsh functions. Existing tidal channels may also be deepened and or widened if necessary to increase tidal flow. Based on assessments of local hydrodynamic conditions, sediment transport, and topography, restoration sites may be graded to accelerate the development of tidal channels within restored marsh plains. Following reintroduction of tidal exchange, tidal marsh vegetation would be expected to naturally establish at suitable elevations relative to the tidal range. Depending on site-specific conditions and monitoring results, patches of native emergent vegetation may be planted to accelerate the establishment of native marsh vegetation on restored marsh plain surfaces. A conceptual illustration of restored brackish tidal habitat is presented in Figure 3-56.

Restoration variables that will be considered by the BDCP Implementation Office in the design of restored brackish tidal habitat include:

- Extent, location, and configuration of other existing and proposed restored tidal habitat areas;
- Distribution of restored tidal habitats along salinity gradients to optimize the range of habitat conditions for covered species and food production;
- Predicted tidal range at tidal habitat restoration sites following reintroduction of tidal exchange;
- Size and location of dike breaches;
- Cross sectional profile of tidal habitat restoration sites (elevation of marsh plain, topographic diversity, depth, and slope);
- Density and size of tidal marsh plain channels appropriate to each restoration site; and
- Potential hydrodynamic and water quality effects on other areas of the Delta.

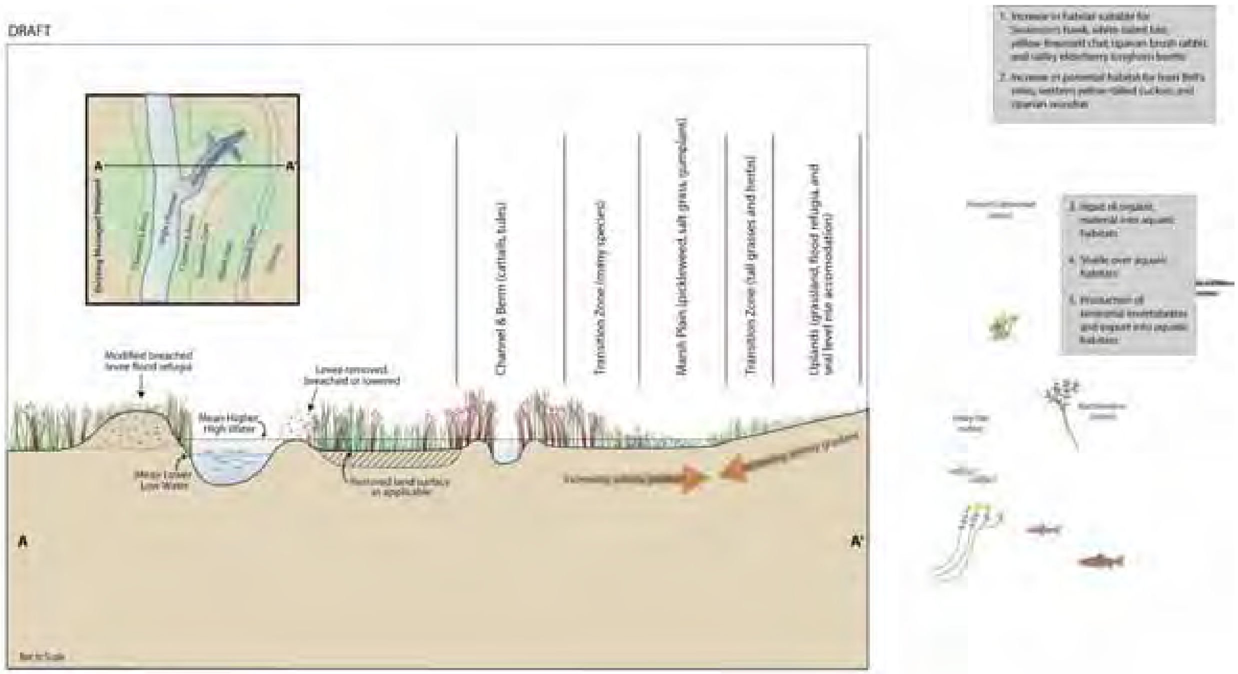

Figure 3-56. Conceptual Design for Restored Brackish Tidal Marsh Habitat (Suisun Marsh ROA) (CM4)

Restoration design considerations for brackish tidal habitat include the following.

*Marsh Plain Vegetation***.** To provide high functioning habitat, restored tidal marsh plains will be dominated by native brackish marsh vegetation (e.g., pickleweed, saltgrass) appropriate to marsh plain elevations, mimicking the composition and densities of historical Suisun Bay brackish tidal marshes. Vegetated marsh plains will also be expected to filter non-point source pollution from surface or subsurface infiltration that otherwise would flow into Suisun Bay. Following establishment of tidal exchange, restored habitat will be monitored to assess the establishment of invasive nonnative plants. If indicated by monitoring results, the BDCP Implementation Office will implement invasive plant control measures to help ensure the establishment of native marsh plain plant species.

*Hydrodynamic Conditions***.** Restored brackish tidal habitat will be designed to provide hydrodynamic conditions similar to those described for freshwater tidal habitat. In addition to desired biological and ecological attributes, the selection and design of restored tidal habitat in Suisun Marsh will need to consider potential hydrodynamic and water quality effects of the proposed restoration, including the effect on salinity intrusion, tidal mixing, and Delta salinity.

*Environmental Gradients***.** Restored brackish tidal habitat will be designed to provide environmental gradients similar to those described for freshwater tidal habitat. Because land surface elevations within Suisun Marsh are relatively homogenous, opportunities to provide linkages to upland habitats are limited to restoration sites that are located along the fringe of Suisun Marsh. Dikes constructed to restore tidal habitat in the interior of Suisun Marsh will be designed with low gradient slopes supporting high marsh and upland vegetation to provide flood refuge habitat. Where appropriate, higher elevation islands of upland habitat within restored tidal habitat may also be created to provide flood refuge for marsh wildlife.

Minimum Restoration Targets for Brackish Tidal Habitat in Suisun ROA. The BDCP Implementation Office will restore at least the following amount of brackish tidal habitat in the Suisun Marsh ROA.

*Restore at least 7,000 acres of brackish tidal habitat within the Suisun Marsh Restoration Opportunity Area***.** The BDCP Implementation Office will restore a minimum of 7,000 acres of brackish tidal habitat in the Suisun Marsh ROA. Restored brackish tidal habitat will be designed to support the physical and biological attributes described above in Brackish Tidal Marsh Habitat Restoration. Restored tidal habitat will be designed to create ecological gradients that support a mosaic of tidal marsh, tide flat, shallow subtidal aquatic, and transitional upland habitats as appropriate to specific restoration sites. The Suisun Marsh ROA encompasses a substantial area with elevations suitable for tidal habitat restoration that would have minimal effect on infrastructure or permanent crops relative to other suitable lands within the Delta.

The Suisun Marsh Habitat Restoration and Management Plan (currently under development) will include an evaluation of alternatives, including options that contemplate the restoration of up to

7,000 acres of brackish tidal habitat. Much of Suisun Marsh is currently at elevations that could be restored to tidal habitat.

Hydrodynamic modeling conducted for the Suisun Marsh Restoration Plan (J. DeGeorge pers. comm.) indicates that restoring tidal habitat north of Montezuma Slough would shift the low salinity zone westward and restoring tidal habitat at sites adjacent to Suisun Bay would shift the low salinity zone eastward, potentially adversely affecting delta smelt habitat and water quality in the west Delta. Consequently, implementation of tidal habitat restoration projects in north and south Suisun Marsh will be sequenced such that these potential effects would be minimized.

As described in CM1 *Water Facilities and Operation*, future reoperation of the Montezuma Slough Salinity Control Gate will increase the benefits of restoring brackish tidal habitat in Suisun Marsh by increasing access for covered fish species to existing and restored tidal aquatic habitat within a large area of Suisun Marsh.

Problem Statement

Suisun Marsh is the largest brackish water marsh complex in the western United States. The majority of historical brackish tidal marsh has been lost, of which approximately 8,300 acres remains in Suisun Marsh. This loss of tidal marsh has greatly reduced the availability and quality of spawning and rearing habitat for many native species, by reducing the input of organic and inorganic material and food resources into adjoining deep water habitats (sloughs and channels) and the downstream bay and estuary. This loss of brackish tidal marsh has also greatly reduced the extent and quality of habitat for native wildlife and plants adapted to the tidal marsh environment, including many of the covered species.

Hypothesized Benefits

Restoration of brackish tidal habitat in Suisun Marsh is hypothesized to provide a range of ecosystem and covered species benefits. As described in Chapter 5, *Effects Analysis,* and Appendix F, *DRERIP Evaluation Results*, however, there are a number of uncertainties regarding the level of benefits that may be provided by tidal habitat restored as well as risks for adverse consequences. These uncertainties will be addressed through effectiveness monitoring, research, and the adaptive management program (see Sections 3.6 and 3.7).

Restoring brackish tidal habitat within the Suisun Marsh ROA is expected to:

- Increase rearing habitat area for Chinook salmon, Sacramento splittail, and possibly steelhead (Healey 1991, Siegel 2007);
- Increase the local production of food for rearing salmonids, splittail, and other covered species (Kjelson et al. 1982);
- Provide an important linkage between current and future upstream restored habitat, such as Yolo Bypass/Cache Slough with Suisun Marsh/Bay;

- Increase the availability and production of food in Suisun Bay for delta and longfin smelt by exporting organic material via tidal flow from the marsh plain and phytoplankton, zooplankton, and other organisms produced in tidal channels into the Bay;
- Locally provide areas of cool water refugia for delta smelt (C. Enright pers. comm.);
- Reduce periodic low dissolved oxygen events associated with the discharge of waters from lands managed as seasonal freshwater wetlands that would be restored as brackish tidal habitat (Siegel 2007, C. Enright pers. comm.);
- Increase the extent of habitat available for colonization by Suisun marsh aster and soft-bird's-beak; and
- Enhance and increase the extent of salt marsh harvest mouse, Suisun shrew, California clapper rail, California black rail, and Suisun song sparrow habitat.

Adaptive Management Considerations

Implementation of brackish tidal habitat restoration actions and subsequent management of restored brackish tidal habitats by the BDCP Implementation Office will be informed through effectiveness monitoring that will be conducted for this conservation measure as described in Section 3.6, *Monitoring and Research Program*, and the adaptive management process described in Section 3.7, *Adaptive Management Program*. Based on analysis of monitoring results, likely elements of this measure that could be adjusted through the adaptive management process include considerations for selecting restoration locations and sequencing restoration of tidal habitat within Suisun Marsh to maintain desirable salinity gradients; methods for establishing marsh plain vegetation, including the establishment of marsh-associated covered plant species; methods and designs for elevating subsided land surfaces to increase restored marsh plain area; design and location of dike breaches; designs for encouraging the development of a high functioning network of tidal channels; and nonnative vegetation and wildlife control techniques.

3.4.3.2 CM5 Seasonally Inundated Floodplain Restoration

The BDCP Implementation Office will provide for the restoration of 10,000 acres of seasonally inundated floodplain habitat within the north, east, and/or south Delta. Because of the long-lead time needed to plan for and implement floodplain restoration it is not expected that new floodplain would be restored in the first 10 years of Plan implementation. The following are the temporal targets for seasonally inundated floodplain restoration:

- At least 1,000 acres restored by year 15 of plan implementation; and
- 10,000 acres (cumulative) restored by year 40 of plan implementation.

Although seasonally inundated floodplain may be restored along channels in many locations in the north, east, and south Delta, the most promising opportunities for large-scale restoration are in the south Delta along the San Joaquin River, Old River, and Middle River channels based on benefits to covered fish species, practicability considerations, and compatibility with potential flood control projects. Criteria that will be considered in selecting seasonally inundated floodplain restoration sites include:

- Relative importance of the adjacent channel as migration pathways for juvenile salmonids;
- Estimated frequency and duration of inundation periods; and
- Compatibility with flood control programs and level of flood control benefits provided relative to other potential restoration sites.

Actions to restore seasonally inundated floodplain habitats, as appropriate to site-specific conditions, include but are not limited to:

- Acquiring lands, in fee-title or through conservation easements, suitable for restoration of seasonally inundated floodplain;
- Setting back levees along the selected river corridor and removing the existing levees or sections of the existing levees;
- Removing existing riprap along channel banks to allow for channel meander between the set-back levees through the natural processes of erosion and sedimentation;
- Grading restored floodplain surfaces to provide for drainage of over bank flood waters such that the potential for fish stranding is minimized ;
- Lowering the elevation of restored floodplain surfaces to increase inundation frequency and duration and to establish elevations suitable for the establishment of riparian vegetation;
- Discontinuing farming within the setback levees and allowing riparian vegetation to naturally establish on the floodplain;
- Where farming is continued consistent with achieving biological and flood control objectives, engaging in farming practices and crop types that provide high benefits for covered fish species; and
- Actively establishing riparian habitat where necessary to accelerate formation of habitat for specific covered species (see the description of CM7 Riparian Habitat Restoration).

Measures for addressing the potential for methylation of mercury in restored tidal habitats will be addressed through implementation of CM12 Methylmercury Management.

A conceptual illustration of restored seasonally inundated floodplain is presented in Figure 3-57. Because restoration requires modification of levees that serve flood control functions, restored floodplain habitats will be implemented such that flood control functions are maintained or improved.

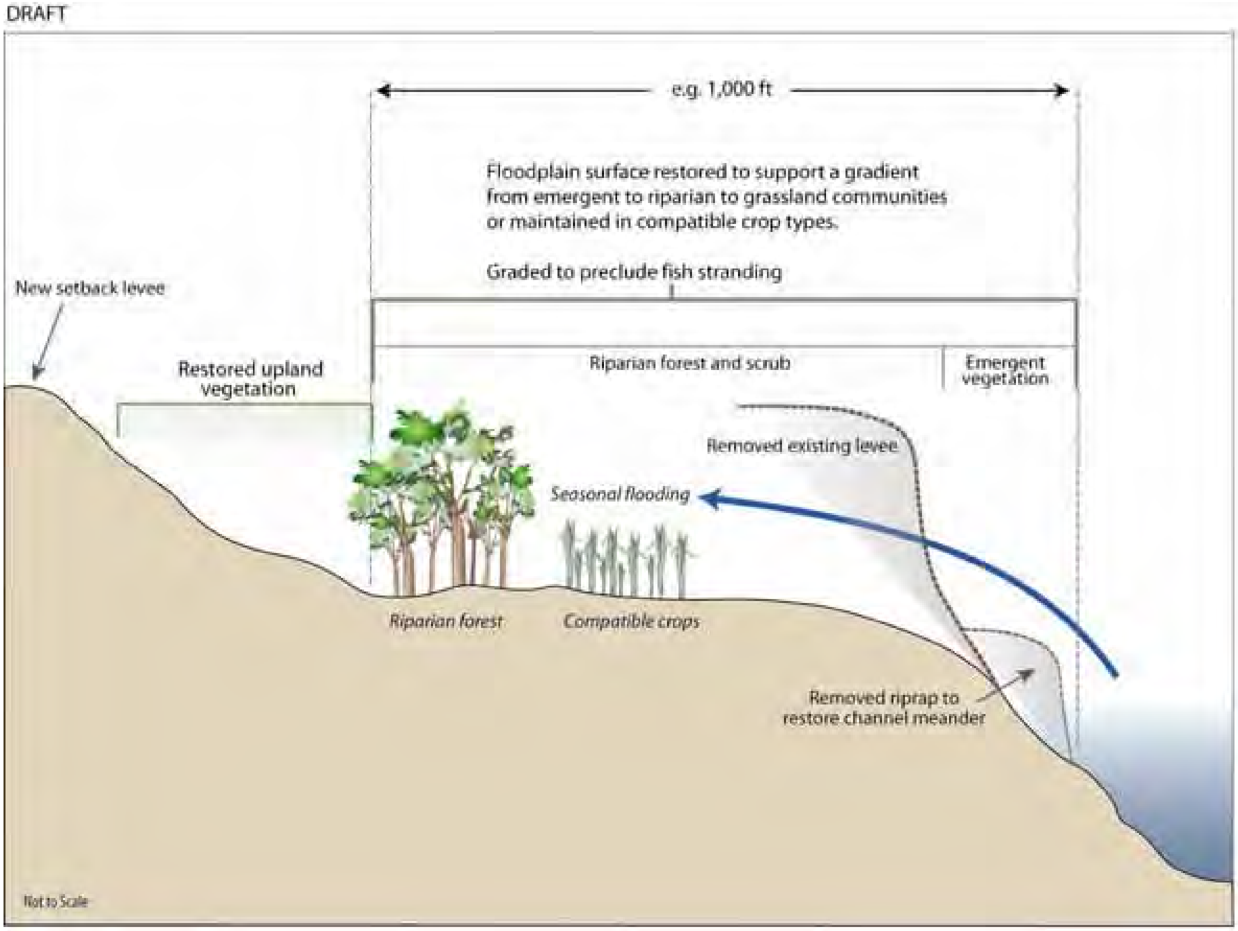

Figure 3-57. Conceptual Design for Restored Seasonally Inundated Floodplain Habitat (CM5)

The BDCP Implementation Office will coordinate floodplain restoration planning with the flood control planning efforts of USACE, DWR, the Central Valley Flood Protection Board, and other flood control agencies to assess the desirability and feasibility for setting back levees in potentially suitable locations. Seasonally inundated floodplain habitat will be designed to support the physical and biological attributes described below in Seasonally Inundated Floodplain Habitat Restoration Concepts and to provide the ecological benefits for covered species described below in Hypothesized Benefits.

Seasonally Inundated Floodplain Habitat Restoration Concepts

Restoration variables that will be considered in the design of restored seasonally inundated floodplain habitat include:

- Modeled timing, duration, interannual frequency, and spatial extent of inundation;
- Connectivity with tidal marsh and channel habitats;
- Accessibility to migrating fish;
- Stranding risk and effects on fish passage;
- Vegetation type and cover;
- Dry season land use (compatible farming practices); and
- Topography and slope.

Restoration design considerations for seasonally inundated floodplain habitat include the following.

Floodplain Topography. Where appropriate, the topography of restored floodplains would be sculpted to reduce the risk for fish stranding by improving drainage and to provide topographic variability to increase hydrodynamic complexity.

Connectivity. Where suitable landform is present, restored floodplains will be located and designed such that flows exiting the floodplain would pass through existing or restored tidal marsh to recreate historical landscape relationships and to provide for connectivity with adjacent uplands that result in transitional habitats and accommodate species movement.

Habitat Restoration on Restored Floodplains. Riparian forest and scrub vegetation will be actively and passively established in restored floodplain areas to the extent consistent with floodplain land uses and flood control requirements. Restored floodplains provide the largest area for meeting the 5,000-acre target for restoration of woody riparian habitat under CM7 Riparian Habitat Restoration, and it is expected that about four-fifths of the riparian habitat restoration will occur at these restored floodplain sites. Established woody riparian vegetation would support habitat for riparian-associated covered species and provide cover and hydrodynamic complexity for covered fish species during inundation periods. Riparian vegetation would also serve as sources of instream woody material for fish habitat, organic carbon in support of the aquatic food web, and macroinvertebrates (e.g., insects) that provide food for covered fish species.

*Land Use on Restored Floodplains***.** Restored floodplains will be managed for ongoing agricultural uses or to support native wildlife habitats. Farmed floodplains will be managed to minimize the use of persistent herbicides and pesticides that are toxic to aquatic organisms and to provide structure and types of residual crop biomass to provide cover and hydrodynamic complexity for fish and provide sources of organic carbon in support of aquatic food web processes during inundation periods.

Problem Statement

Extensive channelization and levee construction has disconnected river channels from their historical floodplains over much of the Central Valley, including the Planning Area, resulting in substantial reduction in the availability of high functioning spawning and rearing habitats that historically support several of the covered fish species. Restoring connectivity of Delta river channels to their historical floodplains will substantially increase the extent of floodplain that can be inundated by overbank flows, thus restoring high functioning spawning and rearing habitat for Sacramento splittail and rearing habitat for salmonids. The restoration of floodplain habitat would allow for establishment of riparian forest and scrub natural community that would support habitat for a large number of covered wildlife and plant species.

Hypothesized Benefits

Restoration of seasonally inundated floodplain habitat is hypothesized to provide the ecosystem and covered species benefits described below. As described in Chapter 5, *Effects Analysis*, and Appendix F, *DRERIP Evaluation Results*, however, there are a number of uncertainties regarding the level of benefits that may be provided by restored floodplain habitats as well as risks for adverse consequences. These uncertainties will be addressed through effectiveness monitoring, research, and the adaptive management program (Sections 3.6 and 3.7).

Restoring seasonally inundated floodplain habitat is expected to:

- Increase spawning habitat for Sacramento splittail by expanding floodplain habitat area and providing in-channel spawning habitat by creating backwaters (Sommer et al. 2001a, 2002, 2007b, 2008, Moyle 2002, Moyle et al. 2004, Feyrer et al. 2006).
- Depending on the location of restored floodplain, increase rearing habitat for Sacramento and San Joaquin Basin runs of Chinook salmon, Sacramento splittail, and possibly steelhead (Sommer et al. 2001a,b, 2002, 2007, 2008, Moyle 2002, Moyle et al. 2004, Feyrer et al. 2006).

- Increase the production of food for rearing salmonids, splittail, and other covered species (Sommer et al. 2001a,b, 2002, 2007b, 2008, Moyle 2002, Moyle et al. 2004, Feyrer et al. 2006).
- Increase the availability and production of food in Delta channels downstream of restored floodplain habitat for delta smelt, longfin smelt, and other covered species by exporting organic material and phytoplankton, zooplankton, and other organisms produced from the inundated floodplain into Delta channels (Mitsch and Gosselink 2000, Moss 2007).
- Increase in nesting habitat for Swainson's hawk and white-tailed kite and habitat for yellow-breasted chat, least Bell's vireo, yellow-billed cuckoo, and valley elderberry longhorn beetle associated with riparian forest and scrub established in floodplain restoration sites.
- Increase in habitat for riparian brush rabbit and riparian woodrat within riparian scrub established in the south Delta restored floodplains (CITATION).
- Increase in habitat area for the establishment of slough thistle and Delta button-celery depending on the location of restored floodplain.

Adaptive Management Considerations

Implementation of seasonally inundated floodplain restoration actions and subsequent management of restored floodplain habitats by the Implementation Office will be informed through effectiveness monitoring that will be conducted for this conservation measure as described in Section 3.6, *Monitoring and Research Program*, and the adaptive management process described in Section 3.7, *Adaptive Management Program*. Based on analysis of monitoring results, likely elements of this measure that could be adjusted through the adaptive management process include modifications to floodplain surfaces to increase inundation frequency and duration, reduce the potential for fish stranding, and changes in floodplain vegetation to increase functions related to food production and habitat conditions during periods of inundation.

3.4.3.3 CM6 Channel Margin Habitat Enhancement

The BDCP Implementation Office will provide for the enhancement of 20 linear miles of channel margin habitat in the Delta. This conservation measure is directed at improving habitat conditions for covered fish, wildlife, and plant species along Delta channel banks (as measured along one bank line of channels) by improving channel geometry and restoring riparian, marsh, and mudflat habitats along levees. Channel margin habitat will be enhanced only along channels that serve as important rearing and outmigration habitat for juvenile salmonids. Although channel margin enhancements are intended to provide specific benefits for salmonids, enhancement of these habitats is also expected to improve or restore habitat for other species of covered fish, wildlife, and plants that inhabit channel margin habitats. This measure will be implemented along channels protected by federal Project and/or non-Project levees within the

Plan Area. Channel margin habitat enhancements associated with Project levees will be not be implemented on the levee, but rather on benches to the outboard side of such levees (Figure 3-X [*to come*]). Based on results of effectiveness monitoring for this conservation measure, the BDCP Implementation Office may elect to enhance up to an additional 20 miles of channel margin (for a total of 40 miles) through the adaptive management decision making process. Channel margin habitat enhancement is measured along one side of a channel.

Channel margin enhancement actions will be located along channels that serve as primary rearing and outmigration habitat for juvenile salmonids. These locations include the Sacramento River between Freeport and Walnut Grove, the San Joaquin River between Vernalis and Mossdale, and Steamboat and Sutter Sloughs that are protected by federal Project levees and salmonid migration channels in the interior Delta, such as the North and South Forks of the Mokelumne River, that are protected by non-Project levees. The following are minimum geographic requirements for the 20 miles of channel margin enhancement under this measure:

- At least 5 miles will be located along the Sacramento River between Freeport and Walnut Grove;
- At least 5 miles will be located along the San Joaquin River between Vernalis and Mossdale; and
- The remaining 10 miles will be distributed among the channels described in the preceding paragraph.

The following are the temporal targets for implementation of the 20 miles of channel margin habitat enhancements:

- At least 5 miles enhanced by year 10 of Plan implementation;
- At least 5 miles enhanced by year 20 of Plan implementation;
- At least 5 miles enhanced by year 25 of Plan implementation; and
- At least 5 miles enhanced by year 30 of Plan implementation.

Actions to enhance channel margin habitats, as appropriate to site-specific conditions include, but are not limited to:

- Modifying the outboard side of levees or setting back levees to create low floodplain benches designed with variable surface elevations to create hydrodynamic complexity and that support emergent vegetation to provide an ecological gradient of habitat conditions, and higher elevation benches that support riparian vegetation;
- Planting riparian and emergent wetland vegetation on created benches;
- Installing large woody material (e.g., tree trunks and stumps) could be anchored into constructed low benches or into existing riprapped levees to provide similar habitat functions;

- Removing riprap from channel margins where levees are setback to restore seasonally inundated floodplain habitat under CM5 Seasonally Inundated Floodplain Restoration; and
- Modifying channel geometry in unconfined channel reaches or along channels where levees are setback to restore seasonally inundated floodplain habitat under CM5 Seasonally Inundated Floodplain Restoration, to create backwater salmonid and splittail rearing and splittail spawning habitat.

A conceptual depiction of how channel margin habitat may be enhanced is presented in Figure 3-X [*to come*].

Because channel margin habitat enhancement is expected to require modification of channels and levees that serve flood control functions, channel margin habitat enhancements will be implemented such that flood control functions are maintained or improved. The BDCP Implementation Office will coordinate channel margin habitat enhancement planning with the flood control planning efforts of USACE, DWR, the Central Valley Flood Protection Board, and other flood control agencies to assess the desirability and feasibility for channel modifications. Channel margin habitat enhancements will be designed to support the ecological benefits for covered species described below in *Hypothesized Benefits*.

Restoration variables that will be considered in the location and design of enhanced channel margin habitat include:

- The length of habitat that can be practicably enhanced along channel margins;
- Connectivity with existing channel margin habitats supporting high functioning salmonid rearing habitat;
- The cross sectional profile of enhanced channels (elevation of habitat, topographic diversity, width, variability in edge and bench surfaces, depth, and slope);
- The amount and distribution of installed woody debris along enhanced channel margins; and
- The extent of shaded riverine aquatic overstory and understory vegetative cover needed to provide future input of large woody debris.

Problem Statement

Primary Delta channels serve as movement corridors for the covered fish species and support splittail spawning and salmonid, sturgeon, and splittail rearing habitat. These channels are now leveed and, as such, channel margin habitats lack the diversity and complexity of habitat conditions associated with unmodified channels. Increasing the diversity and complexity of channel margin habitats is expected to increase their function as habitat for covered fish species. Specifically, providing for channel margin habitat complexity along migration corridors for outmigrating juvenile Chinook salmon may increase survivorship through reductions in predation and increases in food availability.

Hypothesized Benefits

Enhancement of channel margin habitat is hypothesized to provide the following ecosystem and covered species benefits. As described in Chapter 5, *Effects Analysis,* and Appendix F, *DRERIP Evaluation Results*, however, there are a number of uncertainties regarding the level of benefits that may be provided by enhancing channel margin habitat as well as risks for adverse consequences. These uncertainties will be addressed through effectiveness monitoring, research, and the adaptive management program (Sections 3.6 and 3.7).

Enhancing channel margin habitats is expected to:

- Increase the quality of rearing habitat area for Chinook salmon, sturgeon, and possibly steelhead (Sommer et al.2001a,b, 2002, 2007b, 2008, Moyle 2002, Moyle et al. 2004, Feyrer et al. 2006);
- Reducing the risk for predation on covered fish species by nonnative fish predators;
- Increase the extent of shaded riverine aquatic cover and increase instream cover by through contributions of instream woody material (USFWS 2004);
- Increasing connectivity among salmonid rearing and outmigration habitat areas;
- Provide inputs of organic material (e.g., leaf and twig drop) in support of aquatic foodweb processes;
- Increase production and export of terrestrial invertebrates into the aquatic ecosystem (Nakano and Murakami 2001);
- Create additional spawning habitat for Sacramento splittail by creating low velocity backwater habitats (Sommer et al. 2001a, 2002, 2007b, 2008, Moyle 2002, Moyle et al. 2004, Feyrer et al. 2006); and
- Create tidal mudflat substrate suitable for the establishment of Suisun Marsh aster, Mason's lilaeopsis, Delta mudwort, and Delta tule pea and coarse woody debris substrate suitable for side-flowering skullcap.

Restoration of riparian forest and scrub that is incorporated into channel margin enhancements is also expected to support habitat for valley elderberry longhorn beetle, Swainson's hawk, white-tailed kite, and potentially, depending on vegetative structure and patch size, yellow-breasted chat and least Bell's vireo. Increasing the extent of large woody material will enhance habitat for western pond turtle.

Adaptive Management Considerations

Implementation of channel margin habitat enhancement actions by the BDCP Implementation Office will be informed through effectiveness monitoring that will be conducted for this conservation measure as described in Section 3.6, *Monitoring and Research Program*, and the adaptive management process described in Section 3.7, *Adaptive Management Program*. Based on analysis of monitoring results, likely elements of this measure that could be adjusted through the adaptive management process include adjusting the design of subsequent channel margin restoration actions to improve habitat functions for covered fish species and increasing the effectiveness of emergent and riparian vegetation establishment techniques.

3.4.3.4 CM7 Riparian Habitat Restoration

The BDCP Implementation Office will restore 5,000 acres of riparian forest and scrub. It is anticipated that riparian forest and scrub will be restored primarily in association with the restoration of tidal and floodplain habitats and channel margin habitat enhancements. The following are the temporal targets for riparian restoration:

- 400 acres restored by year 15 of Plan implementation; and
- 5,000 acres (cumulative) restored by year 40 of Plan implementation.

Anticipated actions to restore riparian forest and scrub, as appropriate to site-specific conditions, include, but are not limited to:

- Acquiring lands, in fee-title or through conservation easements, suitable for restoration of riparian forest and scrub;
- Allowing for the natural establishment of riparian vegetation;
- Site preparation, planting of native riparian vegetation, and maintenance of plantings;
- Irrigation of plantings; and
- Control of nonnative plants.

Patches of restored riparian forest and scrub are expected to support the range of riparian habitat conditions necessary to support habitat for each of the riparian-associated covered wildlife species. Once established, it is expected that restored riparian forest and scrub will be self-sustaining and will be monitored to determine if subsequent management actions may be required to ensure successful regeneration of native riparian plant species.

Riparian Restoration in Restored Floodplains

To the extent consistent with flood control requirements, restored floodplain habitat areas (Figure 3-57 and CM5) will allow for the natural establishment and growth of woody riparian vegetation on portions of restored floodplains that support appropriate soils and hydrology and along channels within restored floodplains. Restored floodplain riparian vegetation is expected to establish in large extensive patches relative to the typically narrow stringers of riparian vegetation that exist along channels and agricultural water conveyance features within much of the Plan Area.

Native riparian vegetation (e.g., Fremont cottonwood, Goodings' willow, box elder) will be planted if site-specific restored floodplain conditions indicate that such plantings will substantially increase the establishment of riparian forest and scrub. Elderberry shrubs will be a component of such plantings to provide habitat for the valley elderberry longhorn beetle. The development of riparian vegetation will be monitored to determine if nonnative vegetation needs to be controlled to facilitate the establishment of native riparian vegetation or if restoration success could be improved with supplemental plantings of native riparian vegetation. If indicated by monitoring, nonnative vegetation control measures and supplemental plantings will be implemented.

Riparian Restoration in Restored Tidal Habitats

Woody riparian vegetation will be allowed to naturally reestablish along the upper elevation margins of restored tidal marsh habitats within ROAs (Figure 3-2 and CM4) where soils and hydrology are suitable, including segments of stream channels that drain into restored marshes. Suitable soils for restoration are expected to be most extensive in the Cosumnes/Mokelumne, East Delta, West Delta, and South Delta ROAs. In these ROAs, riparian vegetation is expected to generally form as a band of riparian forest and scrub of variable width depending on site-specific soil and hydrologic conditions between high marsh vegetation and herbaceous uplands.

Soil salinity in the Suisun Marsh ROA and extensive clayey soils in the Cache Slough ROA are expected to limit the extent of riparian vegetation that will become established. In these ROAs, riparian vegetation is expected to generally establish in narrow stringers (e.g., along dikes) and small patches where suitable soil conditions are present. Additionally, where conditions are appropriate woody riparian vegetation will be planted on new levees that are constructed by the BDCP Implementation Office within ROAs to provide for the restoration of tidal habitat. As described for riparian restored in floodplains, native riparian vegetation may planted to initiate establishment of riparian forest and scrub and restoration areas will be monitored to determine the need for vegetation control and supplemental plantings.

Riparian Restoration on Channel Margins

Where compatible with site-specific channel margin habitat objectives, native woody riparian vegetation, including elderberry shrubs, will be planted along channel margins on benches outboard of existing levees (Figure 3-X [to come] and CM6) to enhance covered fish and wildlife species habitat. Riparian vegetation restored in these locations is expected to form narrow stringers of riparian forest and scrub along enhanced channel margins.

Directed Riparian Restoration. At least 300 acres of the 5,000 acres of restored riparian forest and scrub will be located in Conservation Zone 7 and/or 8 (Figure 3-5) within or contiguous with occupied or potentially occupied riparian brush rabbit habitat along the San Joaquin River, Old River, and/or Middle Rivers or suitable tributaries. This restored habitat will be designed and managed to specifically support riparian scrub with an open overstory that includes dense brush and thickets of wild rose, wild grape, and blackberry that supports this species habitat. An additional 300 acres will be restored in similar locations within Conservation Zone 7 to provide suitable habitat for the riparian woodrat. This restored habitat will be designed and managed to specifically support riparian habitat that includes a moderately dense midstory of willow scrub and an overstory of valley oak.

Problem Statement

Substantial reduction in the extent, distribution, and condition of Valley/foothill riparian communities that historically occurred along the upper elevational margins of the Delta and along natural levees along Delta and Suisun Marsh channels has reduced the extent and diversity of valley/foothill riparian habitats for associated covered and other native species. Most existing levees were not designed (e.g., steep banks, rip-rap) to incorporate riparian vegetation that support habitat for covered fish and wildlife species and have created increased habitat for nonnative predatory fish and thus contribute to increased predation losses of covered fish species.

A lack of riparian habitat associated with existing and restored tidal aquatic and marsh habitats limits the ecological benefits to fish and wildlife by limiting important ecological gradients and ecosystem functions that a full suite of these habitats would provide. Restoring Valley/foothill riparian habitats to establish a more natural ecological gradient extending from shallow subtidal aquatic to upland transitional habitats is expected, along with BDCP conservation of other natural communities, to increase the abundance and distribution of associated covered and other native species, improve connectivity among habitat areas within and adjacent to the Planning Area and Suisun Bay, improve genetic interchange among native riparian-associated species' populations, and contribute to the long-term conservation of riparian-associated covered species.

Hypothesized Benefits

Restoration of valley/foothill riparian forest and scrub is hypothesized to provide the following ecosystem and covered species benefits described below. As described in Appendix F, DRERIP Evaluations, however, there are a number of uncertainties regarding the level of benefits that may be provided by restored riparian habitats as well as risks for adverse consequences. These uncertainties will be addressed through effectiveness monitoring, research, and the adaptive management program (Sections 3.6 and 3.7).

Restoring valley/foothill riparian forest and scrub is expected to:

- Provide inputs of organic material (e.g., leaf and twig drop) where riparian forest and scrub is restored adjacent to channels resulting in increased production of phytoplankton, zooplankton, and macroinvertebrates that serve as or support production food for covered fish species;
- Increase the extent of shaded riverine aquatic cover and increase instream cover where riparian forest and scrub is restored adjacent to channels through contributions of instream woody material (U.S. Fish and Wildlife Service 2004);
- Increase in the production and export of terrestrial invertebrates into the aquatic ecosystem (Nakano and Murakami 2001) where riparian forest and scrub is restored adjacent to channels;
- Increase the extent of riparian brush rabbit, riparian woodrat, Swainson's hawk, white-tailed kite, yellow-breasted chat, and valley elderberry longhorn beetle habitat; and
- Increase the extent of least Bell's vireo, western yellow-billed cuckoo, and riparian woodrat for potential future occupancy by these species through future expansion of their range; and
- Create coarse woody debris substrate suitable for side-flowering skullcap.

Adaptive Management Considerations

Implementation of riparian restoration actions and subsequent management of restored riparian habitats by the BDCP Implementation Office will be informed through effectiveness monitoring that will be conducted for this conservation measure as described in Section 3.6, *Monitoring and Research Program*, and the adaptive management process described in Section 3.7, *Adaptive Management Program*. Based on analysis of monitoring results, likely elements of this measure that could be adjusted through the adaptive management process include riparian vegetation establishment methods, locations selected for restoration of riparian forest and scrub, and post-restoration management actions that may be need to be implemented to ensure that intended habitat functions of restored riparian habitats are maintained over time.

3.4.3.5 CM8 Grassland Communities Restoration

The BDCP Implementation Office will provide for the restoration of 2,000 acres of grassland within the BDCP CZs 1, 8, and/or 11 (Figure 3-6). The restored grassland habitat will be designed and located such that it supports habitat for associated covered species, improves connectivity among existing patches of grassland and other natural habitats, and improves the native wildlife habitat functions of transitional uplands adjacent to BDCP restored tidal habitats. Opportunities for improving connectivity and increasing the habitat functions of existing grassland habitats include linking or providing wildlife movement corridors to much larger habitat areas immediately outside of the Plan Area. The most strategically important areas are a connection between CZs 1 and 11 in the Jepson Prairie area and connecting BDCPs CZ 8 to other high quality grassland habitat to the west and southwest of the Plan Area.

Anticipated actions to restore grassland habitat, as appropriate to site-specific conditions, will include, but not be limited to:

- Acquiring lands, in fee-title or through conservation easements, that have site characteristics (e.g., soils, proximity to high value habitat areas) that support restoration of high functioning grassland high value habitat.
- Restoring grassland by sowing native species using a variety of techniques that include seed drilling, native hay spreading, and plugs as appropriate. Seed sown on the sites will be from collections or increases from seed collected at the nearest practicable natural site with similar ecological conditions. Restoration actions my require the recontouring of graded land as appropriate and should generally be targeted to parcels with low soil fertility and which have not been used for intensive crop production. These areas could also function as seed nurseries to produce seed that could be planted on other portions of the site.
- Potentially restoring grazing grassland habitat to modify its vegetation; this is a complex management problem if the grassland contains native bunchgrasses, geophytes, vernal pool complex, or alkali seasonal wetland complex and will require site and pasture specific solutions like those described in CM9 Vernal Pool Complex Restoration.

Problem Statement

Implementation of BDCP actions will result in the removal of grassland natural community. Restoration of grasslands, therefore, is necessary to ensure that the current habitat functions supported by affected grasslands for associated covered and other native species are maintained.

Hypothesized Benefits of BDCP Actions

Grassland habitat is distributed around the upland margin of the Sacramento/San Joaquin Delta and Suisun Bay system, and much has been lost to development and conversion to agriculture. Restoration of grassland habitat will increase the extent and quality of grassland habitat available for use by covered and other native associated species and thus contribute to their conservation. BDCP covered species predicted to benefit from restored grasslands include San Joaquin kit fox, salt marsh harvest mouse, riparian brush rabbit, Townsend's big-eared bat, tricolored blackbird, western burrowing owl, greater sandhill crane, Swainson's hawk, white-tailed kite, giant garter snake, western pond turtle, California red-legged frog, western spadefoot toad, California tiger salamander, heartscale, brittlescale, San Joaquin spearscale, Carquinez goldenbush, and caper-fruited tropidocarpum (see *Appendix A, Covered Species*, for specific life history requirements met by the grasslands natural community).

<ins>*Adaptive Management Considerations*</ins>

Implementation of grassland habitat restoration actions will be informed through effectiveness monitoring that will be conducted for this conservation measure as described in Section 3.6 *Monitoring and Research Program*, and the adaptive management process described in Section 3.7, *Adaptive Management Program*. Based on analysis of monitoring results and data compiled from other sources, likely elements of this measure that could be adjusted through the adaptive management process include considerations for selecting restoration locations; methods for establishing and maintaining the desired plant species in restored grasslands, and nonnative vegetation control techniques.

3.4.3.6 CM9 Vernal Pool Complex Restoration

The BDCP will provide for the restoration of 200 acres of vernal pool complex within Conservation Zones 1, 8, and/or 11 (Figure 3-6). The extent of restored vernal pool complex will include a matrix of grassland or alkali seasonal wetland complex in which vernal pools, swales, and saturated alkaline soil areas are adjacent or interspersed and which are found in habitat gradients that vary by Conservation Zone and include tidal freshwater or tidal brackish emergent wetlands, adjoining transitional upland habitat, grassland, alkali seasonal wetlands, and agriculture. The 200 acres will be distributed in Conservation Zones 1, 8, and 11 in a manner that will achieve conservation objectives for associated covered species. The BDCP Implementation Office will select specific restoration sites within these Conservation Zones based on the suitability of available lands for restoration, biological value, and practicability considerations.

Anticipated actions to restore vernal pool complex habitat, as appropriate to site-specific conditions, include but are not limited to:

- Acquiring lands, in fee-title or through conservation easements, suitable for restoration of vernal pool complex habitat;
- Restoring remnant natural vernal and swale topography by excavating or recontouring historical vernal pools and swales to natural bathymetry based on their characteristic visual signatures on historical aerial photographs, other historical data, and on the arrangement and bathymetry of natural reference vernal pools and swales;
- Restoring and maintaining natural hydrology by removing impediments to natural runoff such as roads, berms, field drains, storm drains, etc.;
- Restoring and maintaining natural hydrology by removing non-natural supplemental sources of surface water originating from flood irrigation, drainage and irrigation canal turnouts, impermeable surfaces, leaking stock ponds, culverts, etc.;
- Restoring and maintaining natural salt and suspended clay concentrations in vernal pool water;

- Significantly reducing or preventing the deposition of substances that increases the fertility of the habitat such as manure, runoff from cattle or sheep congregation areas, runoff from dairies, etc.;
- Controlling the cover of invasive nonnative plant species such as perennial pepperweed, swamp timothy, Italian ryegrass, etc.;
- Adjusting livestock grazing regimes in vernal pool complexes to improve habitat functions of vernal pools for covered and other native vernal pool species;
- Preventing the introduction of the propagules of invasive species during restoration, maintenance, outreach, and other activities that occur on the site; and
- Hand collecting seed and vernal pool invertebrates from the vicinity of the vernal pools to be restored will be used to establish native species. Soil inoculum should not be used to establish vernal pool plants and animals in these Conservation Zones unless the source vernal pools are free of perennial pepperweed, swamp timothy, and Italian ryegrass which establish more rapidly than native species and create dense populations that are likely to reduce the establishment success of the native plants and also create thatch problems in the vernal pools (see Barona et al. 2007 for problems of nonnative species thatch buildup due to soil inoculum).

Restored vernal pool complex habitat will be designed and managed to provide the ecological benefits for covered species described under the Hypothesized Benefits section below. Habitat will be restored on sites that historically supported vernal pool complex, thus ensuring that soil types that support vernal pools are present.

Restoration variables that will be considered by the BDCP Implementation Office in the design of restored vernal pool complex habitat include:

- The spatial distribution of existing restored vernal pool complex habitat within the Delta;
- The distribution of soils that historically supported vernal pool complex;
- An analysis of historical aerial photography, survey records, or other information and vernal pool and swale restoration will be limited to the visual signatures indicated in that data and contoured using bathymetry data from similar vernal pools in the same Conservation Zone; and
- The predicted tidal range adjacent to tidal habitat restoration sites in Conservation Zone 1 and 11.

Restoration design considerations for vernal pool complex habitat will include the following:

Vernal Pool Complex Vegetation. To provide for high functioning habitat, restored vernal pool complex will be vegetated with hand collected seed from appropriate areas within the same Conservation Zone as the planned restoration action. Soil inoculum will not be used unless the source vernal pools are free of perennial pepperweed, swamp timothy, and Italian ryegrass.

However, prior to any seed collection actions occurring, where physical restoration actions such as excavation are undertaken to restore the hydrology of vernal pool complex habitat, the hydrographs, inundation depths, and water chemistry (particularly salt and boron concentrations) of the restored vernal pool complex will be compared with reference vernal pool complex habitat in the same areas. Following establishment of restored habitat will be monitored to assess the establishment of invasive nonnative plants. If indicated by monitoring results, the BDCP Implementation Office will implement invasive plant control measures to help ensure the establishment of native vernal pool plant species.

Vernal Pool Complex Invertebrates. Propagules of covered vernal pool invertebrate species may be introduced into the restored vernal pools through the movement of individuals. Introductions will not be made through the use of soil inoculum unless the source vernal pools are free of perennial pepperweed, swamp timothy, and Italian ryegrass.

Hydrological Conditions. Vernal pool complex habitat restoration will be designed based on the historical patterns of vernal pools and swales present on the restoration site as indicated by aerial photography and vernal pool bathymetry will be based on natural undisturbed vernal pools in the same area.

Problem Statement

Implementation of BDCP actions will result in the removal of vernal pool complex. Restoration of vernal pool complex, therefore, is necessary to ensure that the current habitat functions supported by affected vernal pools for associated covered and other native species are maintained.

Hypothesized Benefits

Restoration of vernal pool complex habitat will increase the extent of habitat for vernal pool complex-dependent covered species.

Adaptive Management Considerations

Implementation of vernal pool complex habitat restoration actions and subsequent management of restored vernal pool complex habitats by the BDCP Implementation Office will be informed through effectiveness monitoring that will be conducted for this conservation measure as described in Section 3.6, *Monitoring and Research Program*, and the adaptive management process described in Section 3.7, *Adaptive Management Program*. Based on analysis of monitoring results and data compiled from other sources, likely elements of this measure that could be adjusted through the adaptive management process include considerations for selecting restoration locations within the distribution of vernal pool complex habitat among CZs 1 and 8, methods for restoring and maintaining the necessary hydrology and water chemistry, methods for establishing the desired species in the habitat, and nonnative vegetation and wildlife control techniques.

3.4.3.7 CM10 Nontidal Marsh Restoration

The BDCP will provide for the restoration of 400 acres of nontidal freshwater marsh within Conservation Zones 2 and 4 (Figure 3-4). Restored habitat will be distributed in patches of at least 25 acres and associated with occupied giant garter snake habitat within the proposed 1,000-acre giant garter snake preserves designed to enhance the Caldoni Marsh/White Slough and the Yolo Basin/Willow Slough giant garter snake populations.

Restored nontidal wetlands will also be designed and managed to support other native wildlife functions including waterfowl foraging, resting, and brood habitat and shorebird foraging and roosting habitat. Restored habitat will include preserved transitional upland habitat to provide upland habitat for giant garter snake and western pond turtle, and nesting habitat for waterfowl.

Though not a conservation target, patches of existing nontidal freshwater perennial emergent wetland present on lands acquired to protect other natural communities will also be protected and enhanced to improve habitat functions and values for covered and other native species.

Anticipated actions to restore nontidal freshwater perennial emergent wetland, as appropriate to site-specific conditions, include, but are not limited to:

- Acquiring lands, in fee-title or through conservation easements, suitable for restoration of nontidal freshwater perennial emergent wetland;
- Securing sufficient annual water to sustain habitat function;
- Creating complex habitat with open water and edge habitats, tule-dominated vegetation, bank slopes with variable angles, adjacent upland with open canopy and elevational gradient to promote mammal burrows and higher elevation refugia;
- Establishing connectivity with the existing water conveyance system and habitats occupied by giant garter snakes;
- Allowing for the natural establishment of marsh vegetation;
- Site preparation, planting of native marsh vegetation, and maintenance of plantings; and
- Control of nonnative plants.

Patches of restored nontidal freshwater perennial emergent wetland are expected to support the range of habitat conditions necessary to support habitat for each of the nontidal freshwater perennial emergent wetland-associated covered wildlife species. Once established, it is expected that restored nontidal freshwater perennial emergent wetland will be self-sustaining and will be monitored to determine if subsequent management actions may be required to ensure successful regeneration of native marsh plant species.

Nontidal freshwater perennial emergent wetland will be established where soils and hydrology are suitable through conversion of existing agricultural lands to a freshwater marsh-perennial aquatic complex. Restored marshes will also occur in association with adjacent grassland, pastureland, or cultivated uplands. Grading will be required to establish an elevation gradient to support both open water perennial aquatic habitat intermixed with shallower marsh habitat. Marsh vegetation will be allowed to naturally reestablish along the edges of perennial aquatic habitat, but will also be planted as needed to facilitate marsh development and to manage species composition. The development of marsh vegetation will be monitored to determine if nonnative vegetation needs to be controlled to facilitate the establishment of native marsh vegetation or if restoration success could be improved with supplemental plantings of native species. If indicated by monitoring, nonnative vegetation control measures and supplemental plantings will be implemented.

Problem Statement

The ecological function of nontidal freshwater perennial emergent wetland is limited because it occurs in highly fragmented and small patches within the Planning Area and adjacent lands. Associated with nontidal permanent aquatic and riparian communities, a substantial reduction in the extent, distribution, and condition of nontidal freshwater perennial emergent wetland communities that historically occurred throughout the Central Valley and along the perimeter of the Delta has reduced the extent and diversity of nontidal freshwater perennial emergent wetland habitats for many native species including the giant garter snake (Gilmer et al. 1982, The Bay Institute 1998).

While there are records of giant garter snake in tidal marshes within the Central Delta, the species is known primarily from nontidal freshwater perennial emergent wetland within the interior of the Central Valley including along the eastern perimeter of the Sacramento-San Joaquin Delta. Agricultural conversion and stream channelization have removed nontidal freshwater perennial emergent wetlands, leading to widespread giant garter snake population declines and restricting extant populations to remaining degraded or suboptimal habitats, such as irrigation channels and rice fields. A lack of nontidal freshwater perennial emergent wetland limits the ecological benefits to fish and wildlife by limiting important ecological gradients and ecosystem functions that these habitats would provide, particularly in association with other native habitats including nontidal permanent aquatic, grassland, and riparian habitats. Restoring nontidal freshwater perennial emergent wetland to re-establish a more natural ecological gradient and incorporating aquatic, riparian, and upland transitional habitats is expected, along with BDCP conservation of other natural communities, to increase the abundance and distribution of associated covered and other native species, improve connectivity among habitat areas within and adjacent to the Plan Area, improve genetic interchange among native freshwater perennial emergent wetland species' populations, and contribute to the long-term conservation of giant garter snake and other native species.

Hypothesized Benefits

Restoring nontidal freshwater perennial emergent wetland is expected to:

- Provide essential marsh and aquatic habitat for giant garter snake and western pond turtle;
- Enhance the Caldoni Marsh-White Slough and Yolo Basin-Willow Slough giant garter snake populations by increasing the extent and quality of available habitat;
- Provide nesting habitat for tricolored blackbird; and
- Increase the spatial extent and distribution of habitat available to associated covered and other native wildlife and will increase the diversity and complexity of the mosaic of habitats supported in the Plan Area and adjacent lands.

Adaptive Management Considerations

Implementation of nontidal freshwater perennial emergent wetland restoration actions and subsequent management of restored marsh habitats by the BDCP Implementation Office will be informed through effectiveness monitoring that will be conducted for this conservation measure as described in Section 3.6, *Monitoring and Research Program*, and the adaptive management process described in Section 3.7, *Adaptive Management Program*. Based on analysis of monitoring results, likely elements of this measure that could be adjusted through the adaptive management process include marsh vegetation establishment methods, locations selected for restoration of nontidal freshwater perennial emergent wetland, and post-restoration management actions that may need to be implemented to ensure that intended habitat functions of restored nontidal freshwater perennial emergent wetland are maintained over time.

3.4.3.8 CM11 Natural Communities Enhancement and Management

Site-Specific Management Plans

The BDCP Implementation Office will prepare and implement management plans for protected natural communities and covered species habitats that are found within those communities. Management plans may be prepared for specific reserves or multiple reserve areas within a specified geographic area. Management plans will provide the information necessary to guide habitat enhancement and management actions necessary to achieve the biological objectives established for the conserved lands addressed by each plan. Within two years of acquisition of conserved parcels, the Implementation Office will conduct surveys to collect the information necessary to assess the level of ecological condition and function of conserved species habitats and supporting ecosystem processes. Based on results of the assessment, the Implementation Office will identify habitat enhancement actions to be implemented to enhance habitat functions for the target covered species and any subsequent ongoing management actions that are necessary to maintain habitat functions over time. Survey data will also collect the information necessary to establish base ecological conditions from which the effectiveness of enhancement and management measures can be evaluated through subsequent effectiveness monitoring.

The content of management plans will include, but not be limited to, a description of:

- The biological goals and objectives to be achieved with the preservation and management of the parcels;
- Base ecological conditions (e.g., habitat maps, assessment of covered species habitat functions, occurrence of covered and other native wildlife species, vegetation structure and composition, assessment of nonnative species abundance and effect on habitat functions, occurrence and extent of nonnative species);
- Vegetation management actions that: benefit covered communities, habitats, and species and reduce fuel loads as appropriate; are necessary for implementing community conservation measures; and are necessary for implementing species specific conservation measures;
- The incorporation of a fire management plan developed in coordination with the appropriate agencies and to the extent practicable, consistent with achieving the biological objectives of the BDCP;
- Infrastructure, hazards, and easements;
- Existing land uses and management practices and their relationship to covered species habitat functions;
- Applicable permit terms and conditions;
- Terms and conditions conservation easements when applicable;
- Management actions and schedules;
- Monitoring requirements and schedules;
- Established data acquisition and analysis protocols;
- Established data and report preservation, indexing, and repository protocols;
- The adaptive management approach; and
- Any other information relevant to management of the preserved parcels.

Management plans will be periodically updated to incorporate changes in maintenance, management, and monitoring requirements as they may occur over the term of the BDCP.

Based on the assessment of existing site conditions (e.g., soils, hydrology, vegetation, occurrence of covered species) and site constraints (e.g., location and size), and depending on biological objectives of the conserved lands, management plans will specify measures for enhancing and maintaining habitat as appropriate.

Management Actions

Listed below are enhancement and management actions for the natural communities described in Section 3.3.2.2, *Natural Community Goals and Objectives*. The application of these or other management actions will depend on site-specific conditions and targeted biological values. Specific management actions will be included in each site-specific management plan described above. Management actions are designed to meet the biological goals and objectives of each natural community and covered species.

Tidal Aquatic and Wetland Natural Communities

Approximately 65,000 acres of tidal habitat restoration is planned for the Plan Area. This includes 7,000 acres of brackish tidal habitat in the Suisun Marsh ROA in Conservation Zone 11 and approximately 14,000 acres of freshwater tidal habitat distributed among 4 ROAs, including 5,000 acres in the Cache Slough ROA in Conservation Zones 1 and 2; 1,500 acres in the Cosumnes/Mokelumne ROA in Conservation Zone 4; 2,100 acres in the West Delta ROA in Conservation Zones 5 and 6; and 5,000 acres in the South Delta ROA in Conservation Zone 7. This restoration will create and protect substantial habitat for several covered species including salt marsh harvest mouse, Suisun shrew, California clapper rail, California black rail, Suisun song sparrow, California least tern, Mason's lilaeopsis, Suisun Marsh aster, Delta tule pea, Delta mudwort, and soft bird's-beak. Tidal wetland restoration in Conservation Zones 4, 5, 6, and 7 is also expected to provide additional habitat for tricolored blackbird, greater sandhill crane, and giant garter snake. The following measures will be implemented to manage and enhance the tidal wetland conservation lands.

- Create or maintain upland areas that can serve as refugia during high tide events (e.g., grassland patches for salt marsh harvest mouse);
- Create two nesting habitat areas consisting of gravel or sandy elevated mounds for California least terns along the margins of tidal perennial aquatic natural community areas on BDCP lands. The BDCP Implementation Office will collaborate with species experts to determine appropriate locations, materials, and dimensions of created sites.
- Restore brackish marsh habitats in a sequenced manner to minimize disturbance to adjacent habitats;
- Maintain habitat connectivity and corridors for species' movement between restored sites and restored and existing habitats;
- Maintain appropriate habitat patch sizes for covered species. The BDCP Implementation Office will consult with species experts to determine appropriate patch sizes and other elements of restoration design relevant to covered species;
- Nonnative predatory species are an important stressor for several covered species (e.g., California black and clapper rails). The establishment and abundance of nonnative predatory species will be controlled with habitat manipulating techniques or trapping;

- Where California least terns or tricolored blackbirds are found nesting, and to the extent feasible, protect and establish appropriate buffer zones around occupied sites to minimize disturbance;
- Reduce and then maintain the population size of feral pigs in Suisun Marsh to levels at which their rooting impacts on tidal marsh plain vegetation does not significantly impact covered species;
- Exclude cattle grazing from Suisun thistle and soft bird's-beak habitat;
- Reduce and then maintain the cover of nonnative invasive plant species such as perennial pepperweed, bull thistle, and annual grasses in Suisun Marsh to levels that do not significantly impact covered species;
- Conduct research to determine if fire is beneficial for tidal marsh management and its effects on covered communities and species; and
- Conduct research to determine effective methods for increasing the extent of Suisun thistle and soft bird's-beak in Suisun Marsh.

*[**Note to reviewers:** Additional management tools to address fisheries habitat will be added to this section.]*

Nontidal Aquatic and Wetland Natural Communities

In association with the development of two 1,000 acre preserves for the giant garter snake, 400 acres of nontidal freshwater marsh will be restored. A portion of the 400 acres will be restored to support the protection and expansion of the Yolo/Willow Slough subpopulation in Conservation Zone 2 and a portion will be restored to support the protection and expansion of the Caldoni Marsh/White Slough subpopulation in Conservation Zone 4. The BDCP Implementation Office, through consultation with species experts will determine the number of acres that will be restored in each area based on the level of existing protection and available habitat, and restoration opportunities. The marsh restoration, which will include both emergent wetland and open water habitats, will be coordinated with acquisition of agricultural lands that will make up the 1,000 acre preserves. It is expected that agricultural lands within the preserves, in additional to providing the water conveyance system that will be managed as suitable giant garter snake aquatic habitat and adjacent upland habitat, will also provide suitable foraging habitat for Swainson's hawk, white-tailed kite, and tricolored blackbird. It is also expected that the restored nontidal wetland will provide habitat for nesting tricolored blackbirds and aquatic and cover habitat for western pond turtle. Management plans will be prepared for the Coldani Marsh/White Slough and the Yolo/Willow Slough giant garter snake preserves to guide nontidal wetland restoration activities and associated agricultural land management. The Implementation Office will consult with species experts to develop these plans that will describe site selection, configuration and channel design, water management, vegetation composition, and long-term management of the preserves. The following measures will be addressed in the management plans and implemented to manage and enhance the nontidal wetland and associated giant garter snake preserves.

- Vegetation density and composition, water depth, and other habitat elements will be managed to enhance habitat values for giant garter snakes;
- Upland refugia (islands or berms) will be created and maintained within the restored marsh;
- Permanent buffer zones at least 200 feet wide will be established around all developed wetland habitats to provide undisturbed (uncultivated) upland cover and aestivation habitat immediately adjacent to aquatic habitat;
- Bank slopes and upland buffer habitats will be managed to enhance giant garter snake use, provide cover, and encourage burrowing mammals for purposes of creating aestivation sites for giant garter snake;
- Establish seasonal buffer zones around aquatic habitats to reduce disturbance and improve foraging habitat for tricolored blackbirds;
- Control human and pet access into wetland areas;
- Nontidal and wetland communities may be dominated by bullfrogs and other nonnative predatory species limiting the abundance of covered amphibians and reptiles. Habitat management and enhancement will include trapping and other techniques to control the establishment and abundance of nonnative predators; and
- Limit cattle access to wetland vegetation to the extent necessary to prevent significant deterioration of habitat of covered species.

Riparian Natural Community

Over 5,000 acres of riparian scrub and woodland will be restored in the Plan Area. The majority is expected to develop in Conservation Zone 7 associated with the San Joaquin, Old, and Middle River systems, but riparian habitat will also develop in other Conservation Zones in association with tidal habitat, floodplain, and channel margin restoration. Restored valley/foothill riparian is expected to provide substantial habitat for several riparian-associated covered species. Yellow-breasted chat, least Bell's vireo, riparian brush rabbit, and riparian woodrat will benefit from the establishment of willow scrub and early successional riparian habitats that are expected to develop in association with tidal habitat and floodplain restoration; yellow-billed cuckoo, Swainson's hawk, and white-tailed kite will benefit from the future development of cottonwood-willow forest; and Swainson's hawk and white-tailed kite will benefit from all mature riparian habitats that provide suitable nesting structure. Nesting habitat for Swainson's hawk and white-tailed kite is expected to develop in association with tidal habitat and floodplain restoration and from the restoration of planted riparian habitats along channel margins. Riparian brush rabbit and riparian woodrat will also benefit from directed riparian restoration along channel margins. The following measures include those that will apply to all conserved riparian communities and where noted others apply to lands acquired to manage species-specific values.

- Control nest parasitism (e.g., through cowbird trapping);

- Control the establishment and abundance of nonnative predatory species (e.g., bullfrogs);
- Plant native plant species to improve habitat functions for covered and other native species (e.g., blue elderberry for valley elderberry longhorn beetle, willows for yellow-breasted chat);
- Establish buffers along riparian habitats to minimize the disturbance affects to nesting covered species;
- Establish uncultivated buffers adjacent to riparian habitats to protect the integrity of the stream corridor and associated riparian vegetation and to promote regeneration of riparian species;
- Manage the structure and composition of restored riparian areas to meet the habitat objectives established for riparian brush rabbit, riparian woodrat, Swainson's hawk, white-tailed kite, yellow-breasted chat, least Bell's vireo, and yellow-billed cuckoo;
- Install woody debris in stream channels to create pools to increase the diversity of micro-habitats;
- Where appropriate, remove riprap along channel banks and alter stream channel geomorphology to improve hydrologic conditions that support the regeneration of riparian vegetation and improve habitat functions for aquatic species;
- Prepare a restoration plan for the restoration of 300 acres of riparian habitat for the riparian brush rabbit and 300 acres for the riparian woodrat. Consult with species experts to determine appropriate location, species composition, structure, and patch size, and to develop management guidelines;
- Within riparian brush rabbit restoration areas, create upland refugia (i.e., bunny mounds) to provide protection against flooding. Consult with species experts to determine appropriate location, size, and composition.
- Establish and implement a nonnative species control program to control species such as Himalayan blackberry, giant reed, perennial pepperweed, black locust, and fig where their presence is undesirable; and
- Limit cattle access to riparian and other wetland vegetation to the extent necessary to prevent significant deterioration of habitat of covered species.

Grasslands and Associated Seasonal Wetland Natural Communities

Over 10,000 acres of grassland, vernal pool complex, and alkali seasonal wetland will be protected or restored in Conservation Zones 1, 8, and 11 to support and protect San Joaquin kit fox, Swainson's hawk, white-tailed kite, tricolored blackbird, California red-legged frog, California tiger salamander, and western spadefoot toad populations. The following measures include those that will apply to all conserved grassland communities and where noted others apply to lands acquired to manage species-specific values.

- To minimize uncertainty about the appropriate management regime necessary to maintain and enhance each grassland type, pilot experiments will be conducted to test the effects of management actions. The experiments will be designed to test a range of reasonable management alternatives under appropriate spatial scales and seasonal weather patterns. Long term monitoring programs will also include experimental plots that generate information describing the long term trends of management actions, and include experimental treatments for most likely management alternatives, and appropriate controls.

- Where appropriate, manipulate topography or manage vegetation to attract ground squirrels and other small mammals to: (1) increase the availability of aestivation and nesting burrows for California red-legged frog and California tiger salamander; and (2) increase prey availability for San Joaquin kit fox, Swainson's hawk, white-tailed kite, and other native wildlife predators.

- Reduce rodent control (e.g., poisoning, hunting, and trapping), where appropriate, in conserved grasslands. Note that rodent control measures will likely remain necessary in certain areas where dense rodent populations may compromise important infrastructure (e.g., levees, pond berms, road embankments, and water conveyance structures).

- Fence portions of stock ponds in Conservation Zone 8 to prevent livestock entry, encourage emergent wetland growth, and facilitate California red-legged frog and California tiger salamander use.

- Develop management protocols for stock ponds (e.g., seasonal draining) in Conservation Zone 8 grassland habitats to control bullfrogs and predatory fish and facilitate use by California red-legged frogs and California tiger salamanders.

- Protect grassland movement corridors between aquatic and upland California red-legged frog and California tiger salamander aestivation sites.

- Where lands neighboring preserves require ground squirrel management to protect agricultural uses or public health, establish a buffer zone in the preserve within which ground squirrel colonies will not be encouraged or may be controlled. The width of this buffer will be determined by the preserve manager in consultation with neighboring landowners and BDCP Implementation Office scientists. The buffer width will depend on site conditions, the size and density of the local ground squirrel population, and the intensity of control methods used adjacent to the preserve.

- Where appropriate, install artificial nesting burrows or create elevated berms, mounds, or debris piles for western burrowing owl to facilitate use of unoccupied areas.

- Install perching structures to facilitate use by western burrowing owl, Swainson's hawk, and white-tailed kite.

- For vernal pool complex and alkali seasonal wetland complex, restore and maintain natural hydrology and eliminate supplemental sources of water and structures that increase or decrease the duration of natural vernal pools. If grazed, provide grazing animals with supplemental sources of water located in the uplands away from vernal pools.

- Livestock grazing can be used to manage vegetation for purposes of maintaining and improving habitat conditions for resident plants and animals and to reduce fuel loads for wildfires. Different grazers and different grazing intensities result in different impacts on vegetation. BDCP will develop an appropriate grazing program for enhancing and maintaining habitat for covered species for each protected area based on site specific characteristics of the community and covered species, the spatial location of important ecological features in each pasture, the history of grazing on the site, species composition of the site, grazer vegetation preference, and other relevant information. Grazing exclusion should be used as a management alternative where appropriate. Grazing practices in effect in each pasture for the 5 years prior to acquisition should be continued unless there is a specific conservation related immediate need to alter them or site specific data is acquired through scientific studies suggests that alternate management actions would better advance the sites conservation goals. Grazing in certain native grassland communities, however, may need to be reduced to maintain or enhance these communities. Note that midsummer grazing may be effective in controlling exotic grassland plant species because most native perennial grasses would be dormant in summer and not substantially damaged by grazing.
- Prescribed burning can be used to mimic short interval fire regimes. Late-spring and fall prescribed burning may be used in some grassland areas to increase native species cover in grasslands and reduce the cover of exotic species, repeating treatment on site as needed. Grazing will be used in conjunction with prescribed burns where appropriate to control exotic grasses as they germinate after winter rains.
- Herbicide application may be necessary to control heavy infestations of nonnative plants and re-seed with native species.
- Any seed supplements in native grasslands must use locally derived genetic stock. To maximize the success of seed addition, pretreatments (e.g., burning one year prior to seeding to reduce weed seeds on the surface and in litter) can be utilized.

Inland Dune Scrub

The BDCP Implementation Office will support ongoing efforts to manage and enhance inland dune scrub and to reestablish dune scrub-associated covered species populations through the following actions:

- Support the funding of the USFWS program for management, enhancement, and monitoring of inland dune scrub natural community at the Antioch Dunes National Wildlife Refuge at an annual amount of $XX.XX for X;
- Provide funding to support the USFWS program for the captive breeding and release of Lange's metalmark butterfly at an annual amount of $XX.XX for X years; and

- Support the funding of the USFWS program for propagation and out-planting programs for Contra Costa wallflower and Antioch Dunes evening primrose at an annual amount of $XX.XX for X years.

No acquisition of lands to protect inland dune scrub natural community is proposed.

Agricultural Lands and Managed Wetlands

Agricultural lands will be acquired and managed to support and protect Swainson's hawk, white-tailed kite, greater sandhill crane, tricolored blackbird, and giant garter snake populations. Between 12,000 and 28,000 acres of non-rice agricultural lands and 4,600 acres of rice lands are included in the conservation strategy and that will be managed to provide value to targeted covered species. Agricultural land acquisition is expected to occur throughout the Plan Area, but primarily in Conservation Zones 1, 2, 4, 5, and 7. The following measures include those that will apply to all conserved agricultural lands and where noted others apply to lands acquired to manage species-specific values.

- Minimize or discontinue pesticide use to reduce negative impacts on wildlife including direct, lethal toxicity, reproductive failures, and teratogenic effects.
- Retain hedgerows, wetlands, riparian communities, grassland edges, ponds, and other natural communities and habitat features that occur within the agricultural matrix.
- Retain tree rows, wood lots or other tree groves, and isolated trees to provide nesting habitat for Swainson's hawk and white-tailed kite.
- Retain or create grassland edges, levee slopes, berms, or patches that provide opportunities for burrowing owl breeding or wintering burrows.
- Enhance burrowing owl habitat along agricultural edges by managing vegetation height, installing perches and artificial nesting structures, where appropriate, and encouraging ground squirrel activity.
- Plant hedgerows on agricultural preserves to provide refugia for rodents, thus increasing rodent prey populations for both the Swainson's hawk and the white-tailed kite.
- Plant small woodlots in field corners or tree rows along field borders to provide nesting habitat for Swainson's hawk and white-tailed kite.
- On agricultural lands managed for Swainson's hawk conservation, crop types will be selected and rotated such that sufficient high value foraging habitat is maintained within the agricultural matrix and that meet the requirements for maintaining the target number of habitat units for this species. This will ensure that Swainson's hawk agricultural foraging value is consistently maintained during the term of the BDCP. To the extent practicable, conserved agricultural lands will focus on the highest value foraging habitat (i.e., alfalfa), but include other crop type rotations and agricultural land uses (e.g.,

irrigated pastures) in order to meet the habitat unit requirement (see species model in Appendix A, *Covered Species Accounts*).

- On agricultural land managed for greater sandhill cranes, crop types will be used that provide high value foraging habitat in order to meet the target number of habitat units for this species. Managed agricultural foraging habitat for cranes will include corn, wheat, alfalfa, and irrigated pasture cover types.
- To increase the value of agricultural lands for sandhill cranes, where feasible, habitat management will include deferment of the tilling of corn and grain fields until later in the fall to increase the amount and availability of forage for sandhill cranes. Also where feasible, a portion of corn or grain fields will be left unharvested to increase the quantity of forage available to sandhill cranes (forage would gradually become available as senescent plant stalks fall over as a result of weathering).
- To increase the foraging and roosting value of agricultural lands for greater sandhill cranes, shallow flooding of some corn, grain, and irrigated pastures during fall and winter will also be used. This will also improve foraging conditions for waterfowl and shorebirds.
- Create and manage two greater sandhill crane roost sites located within Conservation Zones 4, 5, and/or 6. Management actions will include 1) establishing appropriate seasonal wetland vegetation that supports crane roosting habitat; 2) incorporating upland berms situated throughout the seasonal wetland; and 3) maintaining water levels that support crane roosting habitat during the crane winter season. The BDCP Implementation Office will consult with species experts to develop specific design and management criteria for crane roost sites.
- Enhance roosting habitat for greater sandhill cranes by controlling public use.
- Establish seasonal or permanent buffers around riparian and wetland habitats to reduce disturbance of nesting tricolored blackbirds, yellow-breasted chats, and least Bell's vireo.
- Establish upland buffers around canals and ditches that support giant garter snake to reduce disturbance and possible mortality.
- Maintain water in canals and ditches during the activity period (early spring through mid-fall) for the giant garter snake, western pond turtle, and other covered species using waterways.
- Maintain and enhance emergent vegetation in irrigation and other water conveyance canals to provide basking and escape cover for giant garter snakes.
- Where managed wetlands exist, habitat management and enhancement will focus on improving and maintaining site hydrology by grading, excavating, replacing, or installing water control infrastructure.
- On agricultural lands within the giant garter snake preserves (Yolo-Willow subpopulation and Caldoni Marsh-White Slough subpopulation), and other conserved agricultural land

that potentially supports giant garter snake, retain or create connectivity of the water conveyance system to facilitate dispersal and other movement of giant garter snakes.

- To enhance protected lands for wintering waterfowl and shorebird use, where feasible flood harvested corn fields during the fall and winter months.

Results of effectiveness monitoring of enhancement and management actions will provide the information necessary to identify future changes in management of conserved lands to ensure that biological objectives are achieved over the term of the BDCP.

3.4.4 Species Level Other Stressor Conservation Measures

[***Note to Reviewers***: *The text of this section of Chapter 3, including the other stressors conservation measures described, is subject to change and revision as the BDCP planning process progresses. This section, however, has been drafted and formatted to appear as it may in a draft HCP/NCCP. Although this section includes declarative statements (e.g., the Implementation Office will…), it is nonetheless a "working draft" that will undergo further modification based on input from the BDCP Steering Committee, state and federal agencies, and the public.*]

This section describes BDCP conservation measures that address other factors potentially affecting covered fish species. These factors, collectively titled "Other Stressors," go beyond issues associated with water operations and physical habitats to address toxic contaminants, other water quality issues (e.g., dissolved oxygen), non-native species, hatcheries, harvest, and non-project diversions that are individually and collectively affecting the productivity of the Delta. As discussed more fully in the Introduction (Section 3.1) and the Methods and Approaches Used to Develop the Conservation Strategy (Section 3.2), the inclusion of these measures into the BDCP reflects the comprehensive nature of the approach to conservation that underlies the BDCP.

A number of these conservation measures address activities that are not currently within the direct control of the BDCP Implementation Office and therefore are proposed to be implemented through agreements with third parties. These agreements will establish reliable mechanisms for the execution and success of these measures by those third parties. In instances where a third party is proposed to implement the conservation measure funded by the BDCP, the BDCP Implementation Office will enter into binding Memoranda of Agreement (MOA) or similarly binding instruments with the third party. These MOAs will describe respective roles and obligations for funding and implementing conservation measures as identified through the process described in each conservation measure. Specific elements of the MOA will describe:

- the specific activities or improvements that would be funded by BDCP;
- the preparation of annual work plans for these activities and improvements;
- the expected benefits of the action for covered species and the aquatic ecosystem;
- the performance metrics that will be measured to verify that the action being implemented has the expected benefit;

- provisions for monitoring, reporting, and documenting work performed; and
- provisions for modifying or terminating MOAs.

The third party will develop annual work plans, acceptable to the BDCP Implementation Office and the fish and wildlife agencies, that describe activities or capital improvements to be funded by BDCP over the course of that year. The third party will be responsible for implementing the scope of work and submitting reports as specified in the MOA that demonstrate that work plans have been successfully implemented. The third party will also be responsible for demonstrating the effectiveness of the funded activities to meet objectives as specified in the MOA.

The BDCP Implementation Office and the fish and wildlife agencies will review progress or other relevant reports prepared by the third party to assess program effectiveness and to identify adjustments to funding levels, management practices, or other related aspects of the program that will improve the biological effectiveness of the program. Such changes will be effected through the BDCP adaptive management process and will be included in the subsequent annual work plans.

3.4.4.1 CM12 Methylmercury Management

*[**Note to Reviewers:** This completely revised version of CM12 Methylmercury Management was provided to the Steering Committee on November 18, 2010, and the Steering Committee has not had the opportunity to review it at this time.]*

The purpose of this conservation measure is to minimize the potential for habitat restoration actions, implemented under the BDCP (CM4 *Tidal Habitat Restoration*, CM5 *Seasonally Inundated Floodplain Restoration*, and CM6 *Channel Margin Habitat Enhancement*), to increase the bioaccumulation of methylmercury in covered and other native species. It is also intended to reduce potential negative effects of methylmercury on important native species that maintain natural communities through herbivory, physical disturbance activities, predator-prey interactions, and other species interactions, or through species regulation of ecosystem processes.

The BDCP Implementation Office will:

1) Conduct pre-acquisition surveys to characterize the mercury content in the soil and other factors that could lead to high rates of methylation in potential habitat restoration areas;
2) After evaluating site characteristics and site conservation goals, prepare habitat restoration designs using measures that, to the extent practicable, will minimize the bioaccumulation of methylmercury in covered and other native species;
3) Conduct monitoring, to the extent practicable, to provide data that will enable the Implementation Office to track the effects of the restoration actions on the bioaccumulation of methylmercury in covered and other native species; and

4) Implement adaptive management actions when monitoring data indicate it is necessary, to the extent practicable, to reduce the bioaccumulation of methylmercury in covered and other native species resulting from tidal habitat and floodplain restoration actions.

The Implementation Office will coordinate with DWR, DFG, the Central Valley Regional Water Quality Control Board (CVRWQCB), and other entities to identify and implement methods for minimizing the methylation of mercury in BDCP restoration areas and the bioaccumulation of methylmercury in covered and other native species.

Problem Statement

There are high concentrations of mercury in the Plan Area due to the continual transport and deposition of historical gold and mercury mining sediment through Delta tributaries. In aquatic systems, anaerobic organisms transform mercury from an inorganic state to a bioavailable and toxic form of mercury (methylmercury). The consumption and bioaccumulation of methylmercury may cause adverse effects to BDCP covered fish and wildlife species. Methylmercury bioaccumulates within individuals and biomagnifies in higher food chain level consumers (CVRWQCB 2010). Biomagnification results in approximately four-fold increases in tissue concentration with each prey-to-predator step up the food chain (Marvin-DiPasquale et al. 2007). As a result, toxic effects of methylmercury are manifested strongly in upper trophic level organisms.

Most of the covered fish species are exposed to methylmercury primarily through the consumption of pelagic prey, and secondarily through direct exposure to high concentrations in the water column; although the latter is substantially lower than the former (Alpers et al. 2008). In addition to their pelagic food web exposure, white sturgeon, North American green sturgeon, and Sacramento splittail are most likely to be affected by high methylmercury concentrations in benthic prey. These fish species are long lived and thereby may accumulate high levels of methylmercury.

Wildlife may be affected by consuming fish or other aquatic organisms that have bioaccumulated methylmercury, or by consuming tidal marsh vegetation that contains methylmercury. Patterns of methylmercury concentration in tidal marsh plant species are complex, as are the grazing dynamics of the wildlife that feed on tidal marsh plants. These factors make it difficult to predict the effects tidal marsh and floodplain restoration actions may have on wildlife species.

Effects of dietary methylmercury on fish include, but are not limited to, endocrine and reproductive problems, liver necrosis, brain lesions, and altered behavior that can result in an increased risk of predation. Bioaccumulation rates in fish may depend on a number of environmental factors in addition to methylmercury concentrations in the water column and/or prey (Alpers et al. 2008); these include growth rate (e.g., seasonality with respect to methylation cycles and/or varied prey availability), foraging in habitats (e.g., preferences can result in foraging in areas with increased propensity for methylation), and food web structure (e.g., temporal and spatial variability in trophic transfer linkages).

High concentrations of methylmercury also have negative effects on birds and terrestrial wildlife (Wolfe et al. 1998). Deleterious effects on bird species from methylmercury consumption include reproductive impairment and reduced juvenile survival (Heinz 1979, Evers et al. 2004, Albers et al. 2007, Ackerman et al. 2008). Methylmercury consumption effects on mammals include anorexia, ataxia, and death (O'Connor and Nielsen 1981, Wren et al. 1987).

Methylmercury is produced by the bacterial mediated chemical synthesis of inorganic mercury with an organic compound under fluctuating oxidation/reduction conditions. Inorganic mercury is widely distributed throughout the Delta, both from mercury mining in the Coast Range and as a legacy from the gold-mining in the Sierras where mercury was used in the mining process. Conditions most conducive to the methylation of mercury typically occur at shallow depths within inundated sediments but can also occur in anaerobic open water. Methylmercury can be lost to the atmosphere through de-methylation or be buried deeply in sediment. Net methylation, the balance between methylation and de-methylation, is controlled by an extensive set of chemical and biological factors which are not well understood, limiting the ability of current science to predict changes resulting from tidal habitat and floodplain restoration. Even less is known about how methylmercury enters the benthic and pelagic food webs and the rates at which enters. It is also not well understood how or if methylmercury is transferred between the benthic and pelagic food webs.

While the data are still being refined and augmented, the general pattern in the Plan Area is that the total mercury and methylmercury of the sediment are not tightly correlated with methylmercury content in fish and clam tissue. Sentinel species tissue concentrations in the Dutch Slough area are among the lowest in the Plan Area despite high sediment concentrations (Grassetti Environmental Consulting 2008). Perhaps the best available data are from the Blacklock dike breach restoration site in Suisun Marsh from 2006-2009 which shows that tissue concentrations of methylmercury in inland silverside (a fish) decreased in adjacent Nurse Slough despite the continual increase of methlymercury in the sediment (M. Stephensen unpublished data). Additionally, the amount of methylmercury generated by existing land use activities is highly variable with waterfowl management actions in Suisun Marsh generating more methylmercury in managed wetlands than is generated in tidal marsh habitat (USDI et al. 2010).

Methods for minimizing methylation in sediments are being developed and include capping mercury-containing sediment with uncontaminated sediment (as at the Montezuma Wetlands Restoration Project) and the addition of ferrous iron or activated carbon granules to the sediment. Continued transport of contaminated sediment into and within the Plan Area would likely limit the effectiveness of capping, and the addition of chemicals is experimental and would likely be limited to relatively small areas.

Hypothesized Benefits

Through the use of appropriate site selection protocols, design measures, construction techniques, and management actions, tidal habitat and floodplain restoration is hypothesized to:

- Minimize adverse effects of methylmercury on white sturgeon, North American green sturgeon, and Sacramento splittail;
- Minimize, and potentially reduce, adverse effects of methylmercury on covered wildlife such as salt marsh harvest mouse, Suisun shrew, and California least tern in Suisun Marsh as a result of the conversion of managed wetlands to tidal wetlands;

Adaptive Management Considerations

Implementation of this conservation measure will be informed through effectiveness monitoring that will be conducted as described in Section 3.6, *Monitoring and Research Program*, and the adaptive management process described in Section 3.7, *Adaptive Management Program*. Results from the long-term monitoring of sentinel species and covered species tissue concentrations of methylmercury and of sediment concentrations of methylmercury will be used to assess the effects of tidal habitat and floodplain restoration on achieving the methylmercury management objective. Effectiveness monitoring results will be used to determine whether tidal marsh and floodplain restoration actions increase tissue concentrations of methylmercury in sentinel and covered fish and wildlife species.

The following four types of monitoring and research actions could be implemented to inform the adaptive management program: (1) quantification of existing mercury and methylmercury sources; (2) remediation of mercury source areas; (3) quantification of ecological and human health effects of methylmercury in the system; and (4) testing of possible management approaches. Many of these action areas are being addressed by ongoing efforts through regional agencies, research institutions, and stakeholders, such as characterization of mercury and methylmercury in sediment and biota throughout the Plan Area, evaluation of solutions for the Cache Creek Settling Basin, research on methylmercury flux and bioaccumulation in various Delta environments, and pilot studies on management approaches such as application of ferrous iron amendments.

3.4.4.2 CM13 Nonnative Aquatic Vegetation Control

The BDCP Implementation Office will control the growth of Brazilian waterweed (*Egeria densa*), water hyacinth (*Eichhornia crassipes*), and other nonnative submerged and floating aquatic vegetation (SAV and FAV) in BDCP tidal habitat restoration areas (Figure 3-58). To implement this conservation measure, the Implementation Office will apply existing methods used by the Department of Boating and Waterways (DBW) *Egeria densa* and Water Hyacinth Control Programs. Control methods currently employed by DBW include application of herbicides and mechanical removal. BDCP methods of removal will be dictated by site-specific conditions and intended outcome or goal. Application of herbicides or other means to control SAV/FAV will be timed to eliminate or minimize potential negative effects of SAV/FAV removal on covered species.

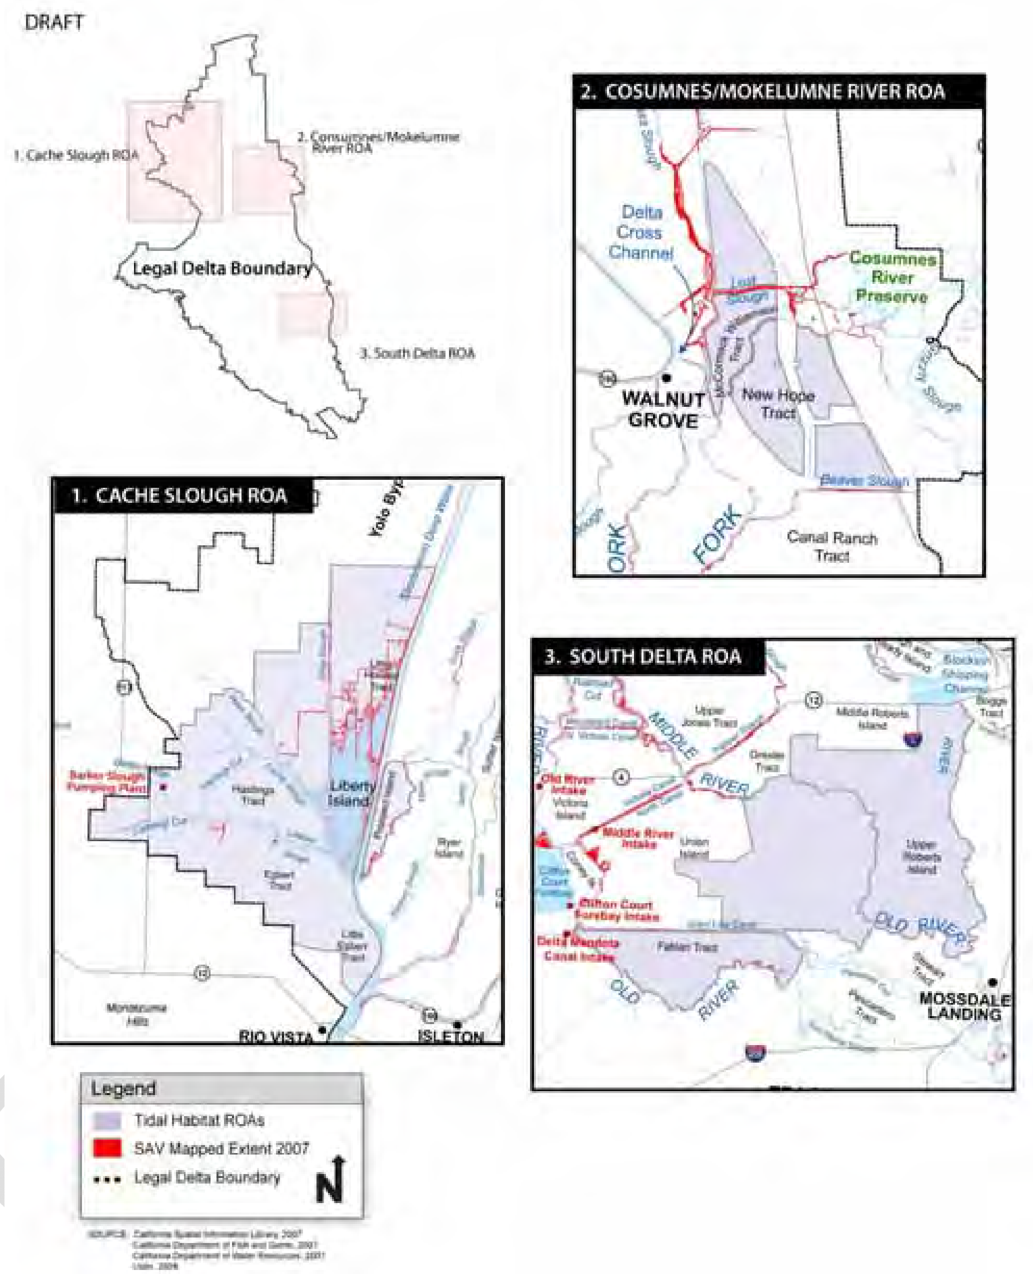

Figure 3-58. Overlap of Submerged Aquatic Vegetation in 2007 and Tidal Habitat Restoration Opportunity Areas (CM13)

Problem Statement

Although the historical extent of native SAV and FAV in the Delta ecosystem is unknown, invasive SAV and FAV species have recently colonized large areas of the Delta (Brown 2003, DFG 2008a, Ustin et al. 2008) and are continuing to expand into a greater proportion of channels and new areas (IEP 2008b). The widest spread nonnative FAV species, water hyacinth, was introduced into the Delta over 100 years ago, and severe infestations were experienced by the 1980s. The majority of the surface cover of SAV detected through the recent use of airborne hyperspectral imagery is Brazilian waterweed, although the SAV vegetation frequently contains a mixture of three invasive nonnative species: Brazilian waterweed, *Potamogeton crispus* (curlyleaf pondweed), and *Myriophyllum spicatum* (Eurasian watermilfoil) (Ustin et al. 2008). Of the 55,000 acres of the Delta surveyed in 2007, SAV cover has been estimated to be between 5,500 and 10,000 acres (Ustin et al. 2008). Nonnative SAV and FAV are thought to cause multiple negative effects on the Delta ecosystem, including providing habitat for nonnative predators of covered fish species (Brown 2003, Nobriga et al. 2005), reducing food abundance and feeding ability of covered fish species by reducing light and turbidity (Brown and Michniuk 2007), and blocking rearing habitat for juvenile salmon and splittail (IEP 2008a).

The DBW Water Hyacinth Control Program, which began in 1982, has been effective in reducing hyacinth from Delta waterways by using chemical and mechanical removal methods. DBW has developed and operated the *Egeria densa* Control Program since 2001 in response to AB 2193, which amended the Harbors and Navigation Code to designate DBW as the lead agency for the control of Brazilian waterweed in the Delta (DBW 2006, 2008). Initially, the program focused control efforts in a number of locations where Brazilian waterweed impeded navigation, tested a range of mechanical and chemical control techniques, and conducted an extensive suite of toxicology and water quality tests and sampling that were required by the terms of its National Pollution Discharge Elimination System permit and under biological opinions issued by USFWS and NOAA Fisheries (DBW 2008). In 2006, DBW concluded that its current approach was not effective at stopping the expansion of SAV in the Delta and proposed expanding the treatment area to sites across most of the legal Delta between 2006-2010 and concentrating on Franks Tract between 2006-2008 (DBW 2006).

Hypothesized Benefits

Removing nonnative SAV and FAV from tidal habitat restoration areas is hypothesized to provide benefits to covered fish species through the following mechanisms:

1. Reducing predation mortality on juvenile salmon, steelhead, and splittail by reducing habitat for nonnative predatory fish (see Appendix F, *DRERIP Evaluation Results*). SAV provides relatively high quality habitat for nonnative piscivores and is spread across large portions of the Delta in or adjacent to significant migration corridors and pelagic and subtidal open water habitat for covered species (Figure 3-59). The interior of SAV stands is good habitat for larval and juvenile centrarchids (Brown and Michniuk 2007), whereas

adult striped bass forage immediately outside of the SAV bed and feed on juvenile Chinook salmon, steelhead, splittail, delta smelt, and longfin smelt (Stevens 1966, Temple et al. 1998, Nobriga and Feyrer 2007b, 2008);

2. Reducing predation mortality of delta smelt by increasing turbidity levels (IEP 2008a, Appendix F, *DRERIP Evaluation Results*). SAV and FAV are thought to reduce local flow rates and cause suspended solids to precipitate out of the water column, resulting in a localized reduction in turbidity levels (Grimaldo and Hymanson 1999). Increased turbidity is hypothesized to improve the predator avoidance abilities of delta and longfin smelt. In addition, improved turbidity may reduce the hunting efficiency of nonnative piscivores (Nobriga et al. 2005);

3. Increasing food consumption by delta and longfin smelt by increasing turbidity levels. SAV and FAV are thought to reduce local flow rates and cause suspended particles to precipitate out of the water column, resulting in a localized reduction in turbidity levels (Grimaldo and Hymanson 1999). A reduction in turbidity is hypothesized to reduce the foraging ability of delta and longfin smelt;

4. Increasing rearing habitat for juvenile salmon (all races), steelhead, and splittail (Appendix F, *DRERIP Evaluation Results*). Dense patches of SAV and FAV physically obstruct covered fish species' access to habitat (IEP 2008a) that would become available with SAV and FAV removal and control; and

5. Increasing food availability for all covered fish species near removal locations by increasing light levels below vegetation. Phytoplankton growth is hypothesized to be light-limited in the Delta (Cole and Cloern 1984). The presence of SAV/FAV is more light-limiting for phytoplankton growth, through shading, than anticipated increases in water turbidity resulting from SAV/FAV removal. The reduction in light levels near nonnative SAV and FAV are thought to reduce local growth of phytoplankton, which can affect the local abundance of zooplankton that forms the food base for covered fish species near patches of SAV and FAV.

Adaptive Management Considerations

Implementation of this conservation measure by the BDCP Implementation Office will be informed through effectiveness monitoring that will be conducted as described in Section 3.6, *Monitoring and Research Program*, and the adaptive management process described in Section 3.7, *Adaptive Management Program*. The Implementation Office will monitor the effectiveness of BDCP-funded elements of the nonnative aquatic vegetation control in successfully controlling SAV and FAV. The Implementation Office will adjust control strategies and funding levels through the BDCP adaptive management process as appropriate based on review of program reports.

DRAFT

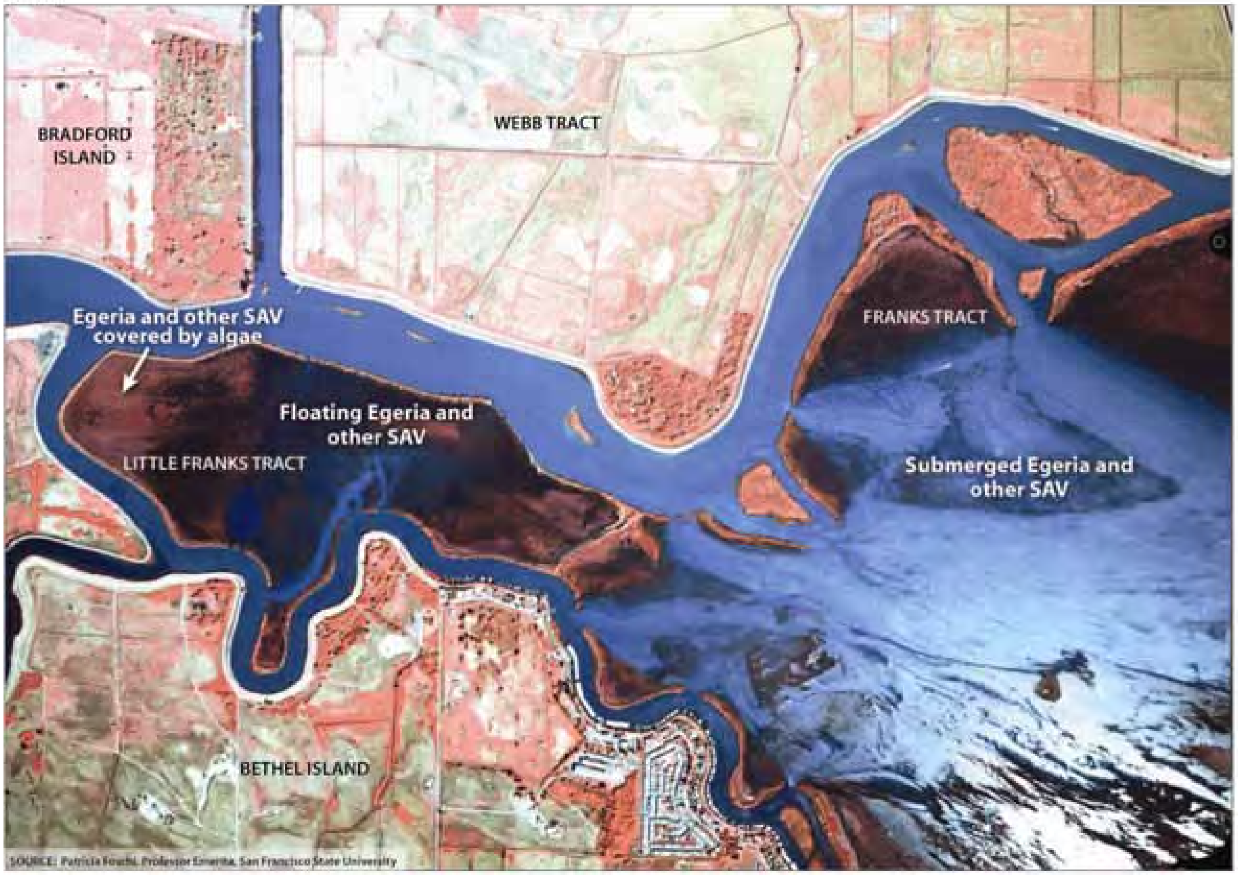

Figure 3-59. Examples of Delta Areas with Submerged Aquatic Vegetation (SAV) Infestations (CM13)

The Implementation Office will use results of effectiveness monitoring to determine if controlling SAV and FAV results in measurable benefits to covered fish species and to identify adjustments to funding levels, control methods, or other related aspects of the program that would improve the biological effectiveness of the program. Such changes, once approved through the adaptive management decision-making process, will be effected through subsequent annual work plans.

If results of monitoring indicate that removing and controlling SAV and FAV does not substantially and cost-effectively benefit covered fish species, the Implementation Office, in coordination with Fishery Agencies, may terminate this conservation measure. If terminated, remaining funding would be deobligated from this conservation measure and reallocated to augment funding for other more effective conservation measures identified in coordination with the Fishery Agencies through the BDCP adaptive management

3.4.4.3 CM14 Stockton Deep Water Ship Channel Dissolved Oxygen Levels

The purpose of this conservation measure is to maintain dissolved oxygen concentrations above levels that impair covered fish species in the Stockton Deep Water Ship Channel during periods when covered fish species are present. The BDCP Implementation Office will operate and maintain an oxygen aeration facility in the Stockton Deep Water Ship Channel to increase dissolved oxygen concentrations between Turner Cut and Stockton to meet Total Maximum Daily Load (TMDL) objectives established by the Central Valley Regional Water Quality Control Board (CVRWQCB) (2005) (above 6.0 mg/L from September 1 through November 30 and above 5.0 mg/L at all times). The existing aeration facility will be modified as necessary and, if necessary, additional aerators and associated infrastructure would be added to optimize oxygen delivery to the river, contingent upon results of an ongoing demonstration project conducted by DWR and effectiveness monitoring during implementation.

The Implementation Office will be responsible for developing annual work plans in coordination with Fishery Agencies that specify the extent of dissolved oxygen improvements to be implemented and will be responsible for monitoring the effectiveness of dissolved oxygen enhancement measures in improving dissolved oxygen levels.

Problem Statement

The Stockton Deep Water Ship Channel has been identified as an impaired waterway by the State Water Resources Control Board because of low dissolved oxygen concentrations during late summer and early fall (CVRWQCB 2005). The combination of low flows, high loads of oxygen-demanding substances (algae from upstream, effluent from the City of Stockton Regional Wastewater Control Facility, and other unknown sources), and channel geometry contribute to low oxygen levels in the Stockton Deep Water Ship Channel (CVRWQCB 2005). The Stockton Deep Water Ship Channel often fails to meet water quality objectives established by the Regional Board for dissolved oxygen (CVRWQCB 2007). The 7.5-mile low dissolved oxygen area of the ship channel creates a barrier for upstream migration of adult fall-run

Chinook salmon and Central Valley steelhead on the mainstem of the San Joaquin River (Hallock et al. 1970). Further, low dissolved oxygen levels can cause physiological stress on and mortality of fish, including Chinook salmon and steelhead (Jassby and Van Nieuwenhuyse 2005), and other aquatic organisms (CVRWQCB 2007). Once spring-run Chinook salmon are re-established in the San Joaquin River under the San Joaquin River Litigation Settlement, dissolved oxygen sags in the Deep Water Ship Channel will likely have similar effects on this run if sags were to occur during their adult migration period (expected to be approximately March-September). In addition, juvenile white sturgeon, which rear in the San Joaquin River, exhibit reduced foraging and growth rates at dissolved oxygen levels below 58 percent saturation (5.8 mg/l at 15 °C) (Cech and Crocker 2002).

One potential solution to dissolved oxygen sags in the Stockton Deep Water Ship Channel, a dissolved oxygen aeration system, has been installed and is currently undergoing field testing by DWR. Results suggest that the aeration facility is effective at raising dissolved oxygen levels in much of the channel. Long-term funding for operations and maintenance has not yet been secured and there are currently no mandates by the CVRWQCB that require contributors to the sag to fund the project. Under this conservation measure, the BDCP would share in funding the long term operation and maintenance costs associated with the project.

Hypothesized Benefits

Increasing dissolved oxygen concentrations in the Stockton Deep Water Ship Channel in accordance with TMDL objectives is hypothesized to result in:

- Reduced delay and inhibition of upstream and downstream migration of fall-run Chinook salmon, steelhead, white sturgeon, river and Pacific lamprey, and, once they are re-established in the San Joaquin River, spring-run Chinook salmon (Hallock et al. 1970); and
- Reduced physical stress and mortality of fall-run Chinook salmon, steelhead, white sturgeon, river and Pacific lamprey, and, once they are re-established in the San Joaquin River, spring-run Chinook salmon.

Adaptive Management Considerations

Implementation of this conservation measure by the BDCP Implementation Office will be informed through effectiveness monitoring that will be conducted as described in Section 3.6, *Monitoring and Research Program*, and the adaptive management process described in Section 3.7, *Adaptive Management Program*. Results from monitoring of dissolved oxygen levels at various distances from the diffuser(s) will be used to assess the performance of the facilities operations at achieving the water quality objective. The Implementation Office will use effectiveness monitoring results to determine whether aeration facility operations result in measurable benefits to covered fish species.

Based on review of performance and effectiveness monitoring results, the Implementation Office will adjust funding levels, oxygen diffuser methods, or other related aspects that will improve the performance and/or biological effectiveness of the project through the BDCP adaptive management process as appropriate. Such changes will be effected through the BDCP adaptive management process and would be included in the subsequent annual work plans.

If results indicate that the aeration facility does not substantially and cost-effectively benefit covered fish species, the BDCP Implementation Office, in coordination with Fishery Agencies, may terminate this conservation measure. If terminated, remaining funding will be deobligated from this conservation measure and reallocated to augment funding for other more effective conservation measures identified in coordination with the Fishery Agencies through the BDCP adaptive management process.

3.4.4.4 CM15 Predator Control

The purpose of this conservation measure is to reduce local effects of predators on covered fish species by conducting focused predator control in high predator density locations. The BDCP Implementation Office will reduce the local effects of predators on covered fish species by conducting focused predator control using a variety of methods in locations in the Delta that are known to have high densities of predators ("hot spots").

The Implementation Office will examine existing fish monitoring data, bathymetry data, and radio and acoustic tagging study results to determine the locations and causes of predator hot spots throughout the Delta (Figure 3-X [to come]). Locations of hot spots in which focused predator control will occur include:

1. Old structures in or hanging over Delta waterways, such as pier pilings or other man-made structures, that are no longer functional or have been abandoned but affect flow fields or provide shade (target: 10-20 structures removed per year);
2. Boats that have been abandoned throughout the Delta (target: 5-10 boats removed per year);
3. New intake structures of the North Delta Diversions (target: daily focused removal when sensitive lifestages of covered fish species are present);
4. The deep hole just downstream of the Head of Old River in the San Joaquin River (target: daily focused removal when sensitive lifestages of covered fish species are present. Additional control efforts may be needed in conjunction with operation of non-physical barriers, as described in CM16);
5. Specific locations in Georgiana Slough, as identified by Fishery Agencies (target: daily focused removal in up to 3 specific locations when sensitive lifestages of covered fish species are present);

6. Specific locations in Sutter and Steamboat sloughs, as identified by Fishery Agencies (target: daily focused removal of predators in up to 2 specific locations per slough when sensitive lifestages of covered fish species are present); and
7. Release sites of salvaged fish from CVP/SWP facilities (target: weekly focused removal at each salvage release site when sensitive lifestages of covered fish species are being salvaged).

The Implementation Office will use a variety of methods to control predator populations in hot spots, including removal of predator hiding spots, modification of channel geometry, targeted removal of predators, and/or other focused methods as dictated by site-specific conditions and the intended outcome or goal. Preference for which hot spots to address will be given to areas of high overlap with covered fish species, such as major migratory routes or spawning and rearing habitats.

Site-specific control plans will be developed in consultation with the Fishery Agencies, and will include expected benefits, methods, and a monitoring design that will provide information necessary to determine the effectiveness of the action.

<u>*Problem Statement*</u>

Although a natural part of the estuarine ecosystem, predation in the Delta has been identified as a stressor to BDCP covered fish species (Appendix F, *DRERIP Evaluation Results*). Habitat for fish predators generally consists of a specific suite of attributes that allow them to forage more efficiently, such as dark locations adjacent to light locations or deep pools that allow the predator to hide and ambush their prey. There are multiple locations in the Delta that contain these physical attributes and attract predatory fish that prey upon covered fish species.

<u>*Hypothesized Benefits*</u>

Conducting localized predator control at hot spots in the Delta using a variety of control methods is expected to reduce local predator abundance, thus reducing localized predation mortality of Chinook salmon (Temple et al. 1998, Lindley and Mohr 2003), steelhead (Temple et al. 1998), Sacramento splittail (Moyle et al. 2004), and delta smelt (Stevens 1966, Thomas 1967, Moyle 2002); and possibly longfin smelt (Nowak et al. 2004), green sturgeon (J. Israel pers. obs.), and white sturgeon.

Within the Columbia River system, a predator removal program was investigated in the 1980's for the control of juvenile salmonid predators benefiting from the existence of multiple hydropower dams located along this system. The principle predators for juvenile salmonids within the Columbia River are the northern pikeminnow (*Ptychocheilus oregonensis*), and two nonindigenous species: smallmouth bass (*Micropterus dolomieu*) and walleye (*Sander vitreus*). Northern pikeminnow greater than ~10 inches were considered the primary predator of juvenile salmonids in slower moving portions of the Columbia River (i.e., near hydropower facilities).

The program, designed to reduce predation rates in these areas utilizing a bounty program, net fisheries, professional fishers, and fishing areas adjacent to hatcheries, was initiated in 1990. The bounty program targets the removal of 10 to 20 percent of the larger pikeminnow to control size classes that have the greatest juvenile salmonid predation rates, while still maintaining a sustained pikeminnow population. By maintaining a sustained pikeminnow population, the program was designed to avoid compensatory responses of other juvenile salmonid predators in the system (smallmouth bass and walleye) filling the void created by pikeminnow removal. Through the first 16 years of the program there were no indications of compensatory responses. In 2006, however, there were possible indications of localized compensatory responses, although there is insufficient data to determine whether there is a system-wide compensatory response (Takata et al. 2007, Van Dyke 2010).

Prior to the initiation of this program, Beamesderfer et al. (1996) estimated that approximately 16.4 million juvenile salmonids of the estimated 200 million downstream migrants were consumed by northern pikeminnow in the Columbia system. Another study estimated that northern pikeminnow accounted for 10 to 20 percent of juvenile salmonid mortality (as cited in Young 1997). Predation rates are greatest in the vicinity of each of the eight Columbia and Snake River reservoirs ("pools"). Within the John Day pool, it was estimated that a northern pikeminnow exploitation rate of 10 to 20 percent could reduce their predation on juvenile salmonids by 50 percent (as cited in Young 1997). From 1990 through 2008, the Northern Pikeminnow Sports Reward Fishery removed 3.3 million reward-sized (≥9 inches) northern pikeminnow from the Columbia system. From 1991-1998, system-wide exploitation rates of northern pikeminnow averaged 11.7 percent (Hankin and Richards 2000). The removal program estimates northern pikeminnow predation has been reduced by 37 percent (Northern Pikeminnow Sports Reward Fishery 2009). Although the program does not provide an estimated annual number of juvenile salmonids "spared" due to predator removal, model estimates for a reduction of 50 percent predation rate range from 5.2 to 8.2 million juvenile salmonids annually (Hankin and Richards 2000).

Adaptive Management Considerations

Implementation of this conservation measure by the BDCP Implementation Office will be informed through effectiveness monitoring that will be conducted as described in Section 3.6, *Monitoring and Research Program*, and the adaptive management process described in Section 3.7, *Adaptive Management Program*. Monitoring will consist of assessing the abundance, distribution, and size of predator species before and immediately after implementation of predator control actions in each hot spot to determine the performance of the action. In addition, potential changes in survival rate of covered species will be monitored using acoustic tagging studies where possible or similar techniques.

The Implementation Office, in consultation with the Fishery Agencies, will use results of effectiveness monitoring to determine whether the actions result in measurable benefits to covered fish species, and to identify adjustments to funding levels, methods, or other related aspects of the program that would improve its biological effectiveness. Such changes, once approved through the adaptive management decision-making process, will be effected through subsequent annual work plans. If results of monitoring indicate that the action does not substantially and cost-effectively benefit covered fish species, the BDCP Implementation Office, in coordination with Fishery Agencies, may terminate this conservation measure. If terminated, remaining funding will be deobligated from this conservation measure and reallocated to augment funding for other more effective conservation measures identified in coordination with the Fishery Agencies through the BDCP adaptive management process.

3.4.4.5 CM16 Non-Physical Fish Barriers

The purpose of this conservation measure is to improve the survival of outmigrating juvenile salmonids by using non-physical barriers to re-direct them away from channels in which survival is lower (Figure 3-60). The BDCP Implementation Office will install non-physical barriers at the junction of channels with low survival of outmigrating juvenile salmonids to deter fish from entering these channels[37]. Non-physical barrier placement locations will include the Head of Old River, the Delta Cross Channel, Georgiana Slough, and could possibly include Turner Cut, Columbia Cut, the Delta Mendota Canal intake, and Clifton Court Forebay (Figure 3-61). Other locations may be considered in the future by the Implementation Office if, for example, future research demonstrates differential rates of survival in Sutter and Steamboat sloughs relative to the mainstem Sacramento River, or in the Yolo Bypass relative to the mainstem Sacramento River. Non-physical barriers will include a combination of sound, light, and bubbles similar to the three-component non-physical barrier used in the 2009 DWR Head of Old River Test Project (Bowen et al. 2009). Non-physical barriers will be installed and operated during October to June or when Fishery Agencies monitoring determines that salmonid smolts are present in the areas when barriers are to be installed. Non-physical barrier placement may also be accompanied by methods to reduce local predator abundance described in CM15 above if monitoring finds that barriers attract predators. Barriers will be removed and stored off-site while not in operation (M. Holderman pers. comm.).

Problem Statement

Juvenile salmonids experience low survival rates while migrating through the Delta towards the ocean. Survival rates vary among routes taken through the Delta (Brandes and McLain 2001, Perry and Skalski 2008, 2009, Holbrook et al. 2009, Perry et al. 2009) as a result of differential exposure to predation, entrainment mortality at state and federal water export facilities and small agricultural diversions, and other factors (SJRGA 2006, J. Burau pers. comm.).

[37] Previous evidence suggests that, under a non-physical barrier configuration that was effective in deterring salmon smolts, the non-physical barrier was not effective in deterring delta smelt (Bowen et al. 2008). It is currently not known whether this was a result of the configuration (e.g., sound frequency) of the non-physical barrier or the poor swimming ability of delta smelt that was swamped by high flows (Bowen et al. 2008). Reclamation is currently studying whether there are sound frequencies that deter delta smelt (M. Holderman pers. comm.). If demonstrated to be effective in deterring delta smelt and longfin smelt and deemed necessary by the Fishery Agencies, non-physical barriers could also be installed at the mouths of Old and Middle rivers and in Three Mile Slough (if salinity manipulation is not also needed) to deter these species from moving into these channels where survival is thought to be lower when present, as determined by Fishery Agencies monitoring.

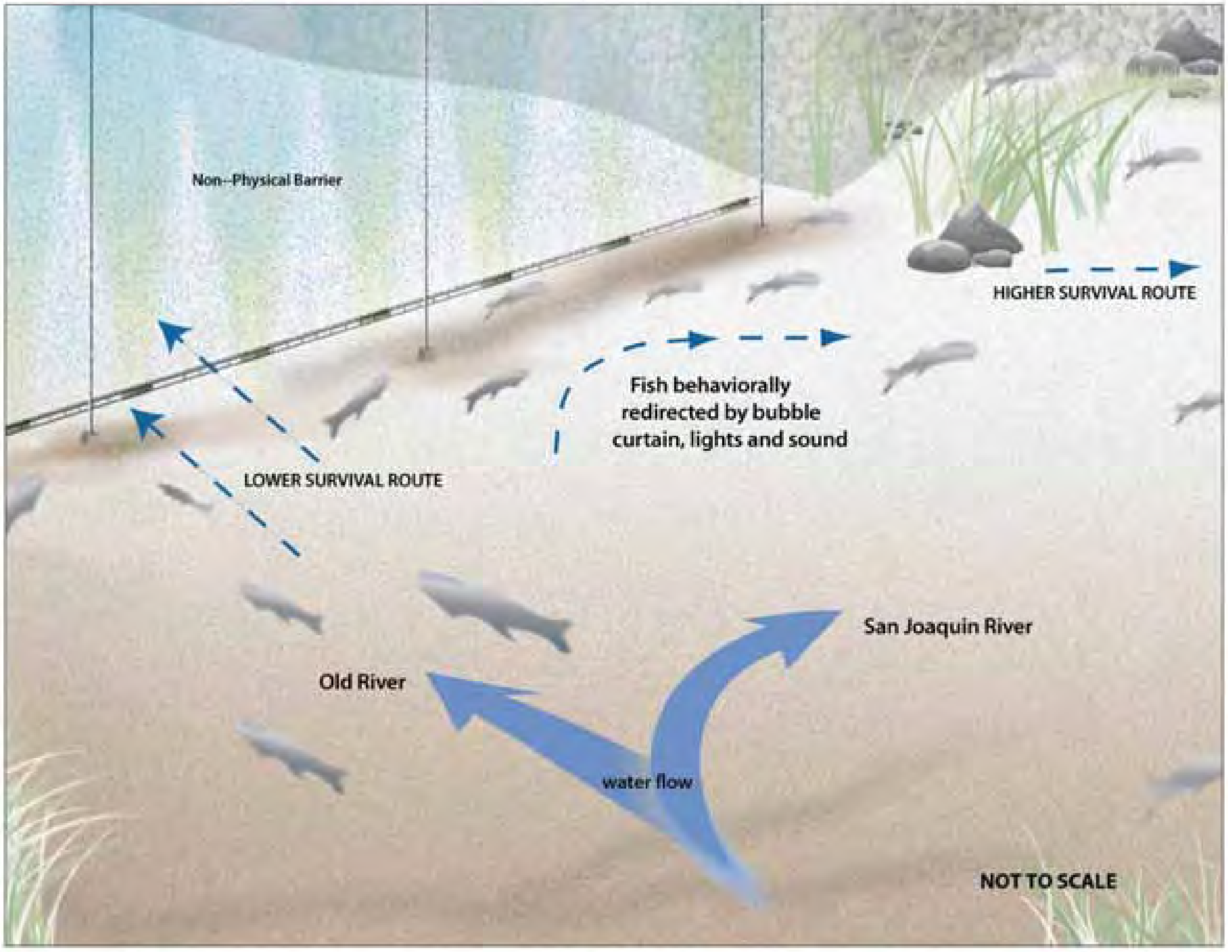

Figure 3-60. Schematic of Non-Physical Fish Barrier (CM16)

DRAFT

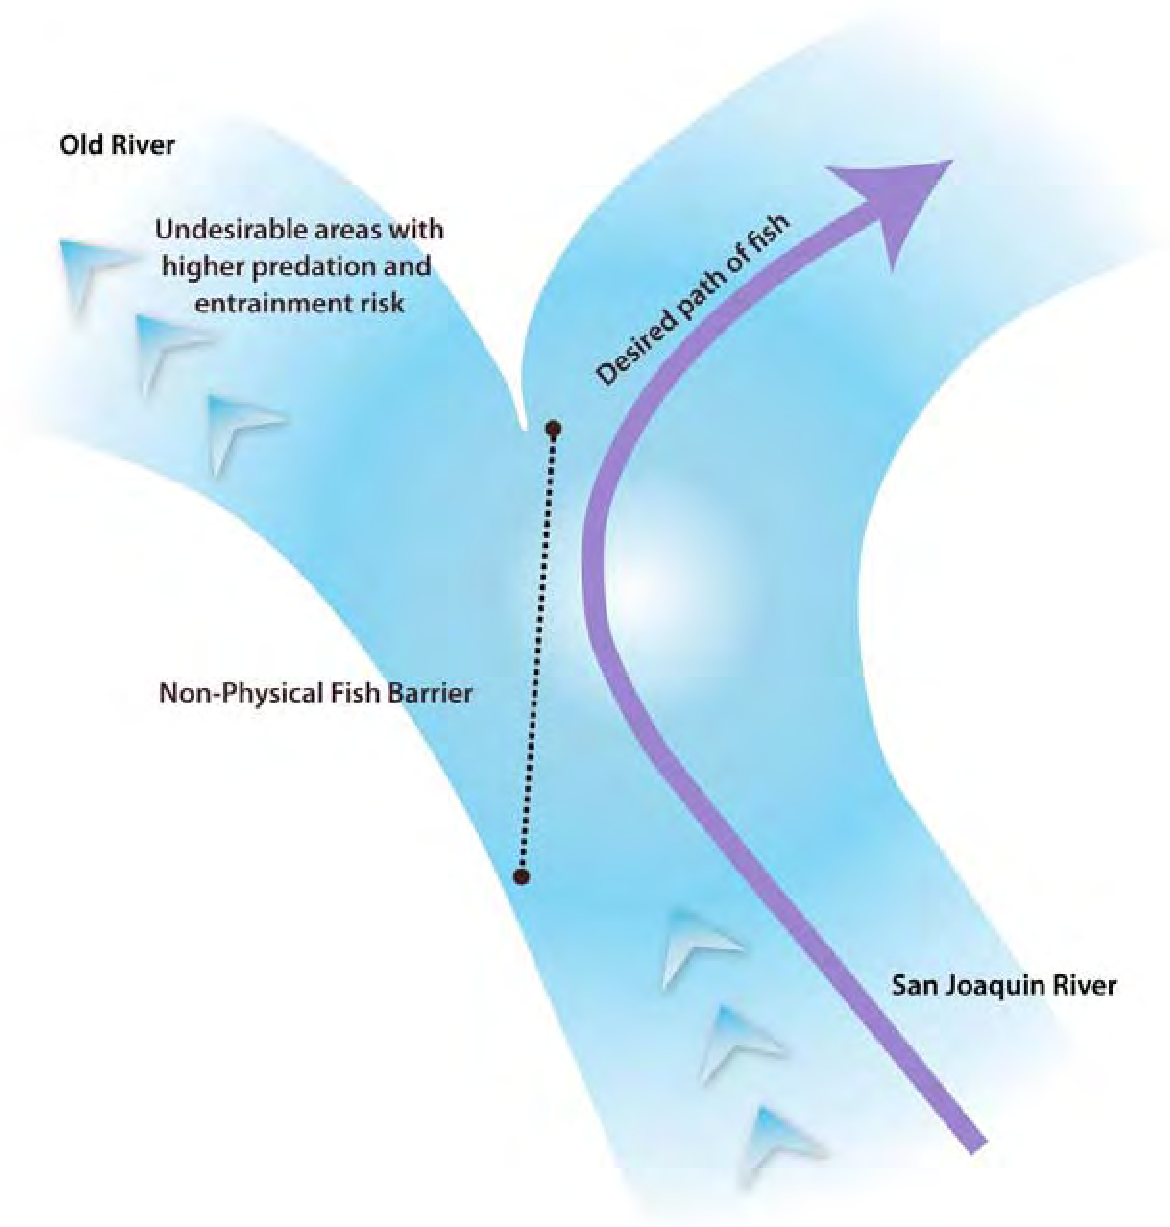

Figure 3-61. Conceptual Location of Non-Physical Fish Barrier (CM16)

Survival for routes through the interior Delta was at most 35 percent that of survival for fish remaining in the Sacramento River (Perry et al. 2010). Such low probability of survival when migrating through the interior Delta indicates that significant population level impacts could result if a sizable portion of the salmon population passed through this area. Perry and Skalski (2009) found that 19.8 to 34.5 percent of tagged salmon used Sutter and Steamboat sloughs during migration, while 26.7 percent to nearly one-third of the population entered the interior area. Low survival probabilities and high proportions of the population migrating through the interior Delta combine to significantly reduce salmon survival through the Delta during migration. Physical barriers have been used in the Delta, such as the Delta Cross Channel gates and the rock barrier at the Head of Old River, to prohibit the entry of fish into channels where survival rates are low. Physical barriers are effective at prohibiting entry of salmonids into channels, but also alter flow dynamics in these channels, likely affecting tidal flows, sediment loads, bathymetry, water supply reliability, potential for noxious algal blooms, toxic concentrations, and other water quality parameters. However, operation of non-physical barriers is predicted to cause smaller changes in the physical configuration of the channel, thus reducing flow-related effects, while improving survival of salmonids by deterring them from entering channels with a higher risk of mortality.

Hypothesized Benefits

Installation and seasonal operation of non-physical barriers is hypothesized to improve survival of juvenile salmonids migrating downstream by guiding fish into channels in which they experience higher survival rates (Welton et al. 2002, Bowen et al. 2009). The three component non-physical barrier has shown promising results in laboratory experiments on Chinook salmon emulating the Sacramento River/Georgiana Slough flow split (Bowen et al. 2008) and a field experiment on Atlantic salmon (*Salmo salar*) smolts in the River Frome, UK (Welton et al. 2002). In addition, preliminary evidence suggests that the three-component barrier was effective in deterring acoustically-tagged Chinook salmon juveniles from entering the head of Old River during a 2009 pilot study (Bowen et al. 2009). Non-physical barriers that utilize only one component, such as sound or light, have demonstrated only limited success in deterring fish during field trials. For example, out of 25 separate single-component sound and light systems placed in 21 different locations in Europe and the United States to affect the behavior of salmonids near water intakes and canals, fewer than 50 percent were effective in altering fish behavior (USBR 2006). The three-component Non-physical Barrier Test Project at the confluence of Old River and the San Joaquin River in the Sacramento-San Joaquin Delta has demonstrated greater success, successfully deterring 81.4 percent of tagged Chinook salmon smolts from entering Old River compared to conditions without the barrier operating that deterred 25.4 percent of tagged salmon smolts (Bowen et al. 2009). Sound is known to affect the behavior of salmonids (Vanderwalker 1967, Knudsen et al. 1992, 1994).

Adaptive Management Considerations

Implementation of this conservation measure by the BDCP Implementation Office will be informed through effectiveness monitoring that will be conducted as described in Section 3.6, *Monitoring and Research Program*, and the adaptive management process described in Section 3.7, *Adaptive Management Program*. The Implementation Office will conduct and review monitoring to assess the effectiveness of using non-physical barriers. The Implementation Office will use results of effectiveness monitoring to determine whether operations of non-physical barriers result in measurable benefits to juvenile salmonids and to identify adjustments to funding levels, methods, or other related aspects of the program that would improve the biological effectiveness of the program. Uncertainty regarding the potential attraction of predators to non-physical barriers and the effectiveness of barriers in higher flow areas must be resolved. Such changes, once approved through the adaptive management decision-making process, will be effected through subsequent annual work plans. If results of monitoring indicate that operations of non-physical barriers do not substantially and cost-effectively benefit covered fish species, the Implementation Office, in coordination with Fishery Agencies, may terminate this conservation measure. If terminated, remaining funding will be deobligated from this conservation measure and reallocated to augment funding for other more effective conservation measures identified in coordination with the Fishery Agencies through the BDCP adaptive management process.

3.4.4.6 CM17 Hatchery and Genetic Management Plans

[*Note to Reviewers*: *SAIC is in discussion with hatchery coordinators to determine the funding needs for this conservation measure. This measure will be updated as new information becomes available via continued coordination.***]**

The purpose of this conservation measure is to develop and implement hatchery and genetic management plans to minimize the potential for genetic and ecological impacts of hatchery-reared salmonids on wild salmonid stocks. The BDCP Implementation Office will minimize potential adverse effects of hatchery-reared salmonids on wild salmonid stocks by supporting the accelerated development and implementation of Hatchery and Genetic Management Plans (HGMPs) for all state Chinook salmon and steelhead hatcheries in the Central Valley. HGMPs would be implemented to reduce adverse ecological and genetic effects of hatcheries on wild fish and to be consistent with conservation and protection for listed fish species.

The Implementation Office will provide funding to:

- Expand and finalize steering groups for each hatchery HGMP process, in part to aid in determining hatchery function;
- Support DFG staff and DFG contractors to prepare HGMPs under DFG and NMFS direction;

- Staff a DFG HGMP Coordinator, a position dedicated to coordinating HGMPs from beginning through implementation. HGMP implementation and adaptive management will be an ongoing task for the life of each hatchery;
- Staff hatcheries sufficiently to carry out changes necessary to meet ESA requirements, including providing regional support for fishery biologists at each hatchery;
- Improve efforts to minimize several categories of hatchery impacts including trucking, inter-basin egg transfers, genetic stock management, monitoring (especially hatchery natural proportions and impacts of hatcheries on natural stocks), and conservation hatcheries; and
- Provide support for staffing and analysis associated with a genetic parental-based tagging system.

Funding of these efforts will be higher during development of the plans and should decline as plans are completed. The BDCP Implementation Office will enter into binding Memoranda of Agreement or similar instruments with DFG as described in Section 3.4.4, *Species Level Other Stressors Conservation Measures*.

Problem Statement

Hatchery-reared Chinook salmon and steelhead are believed to have negative effects on wild Chinook salmon and steelhead, including competition for space and food as juveniles and for spawning habitat as adults. Fish reared in hatcheries can be selected for traits that are different from those in nature, such as those that allow them to survive in an artificial, contained environment (e.g., fast growth, large size). This could result in reduced genetic isolation of hatchery fish from wild fish. It is thought that these hatchery fish outcompete their smaller wild-reared conspecifics (individuals of the same species) for food and space in natural waterways (Williams 2006). Also, as adults, straying by hatchery-reared salmon into natural spawning grounds may lead to competition for spawning habitat and genetic introgression, where offspring of wild salmon are “genetically polluted” with hatchery-selected genes, thereby reducing the fitness of wild population (ISAB 2003, Goodman 2005, Hey et al. 2005).

To address these concerns, hatcheries have begun reforming their management practices to minimize the effects that hatchery fish may have on wild fish. HGMPs serve as the foundation of hatchery management and reform to minimize genetic and ecological impacts to wild fish. HGMPs are developed to devise and evaluate practices of a hatchery to ensure the hatchery contributes to the conservation and recovery of listed salmonids.

Although required, the development of HGMPs in Central Valley hatcheries has been slow to date. The following provides a summary of the status of the progress made toward completion of HGMPs at Central Valley hatcheries (M. Lacy pers. comm.):

- Nimbus Hatchery - Draft HGMPs for both fall Chinook salmon and winter steelhead have been completed. Updates and minor revisions were made during 2008 to initial drafts. Reclamation and DFG staff are currently reviewing subsequent drafts.
- Feather River Hatchery - Draft HGMPs for spring and fall Chinook salmon and Central Valley steelhead were completed in late 2008. DWR is reviewing the spring Chinook salmon draft HGMP; fall Chinook salmon and steelhead HGMPs are both still in development by consultant staff. Updates and DWR comments are being incorporated into all drafts as appropriate.
- Mokelumne River Hatchery - A revised draft HGMP for the steelhead program was completed at the end of 2008 and has been reviewed by hatchery staff. A draft HGMP for the fall Chinook salmon is 50 percent complete.
- Merced River Hatchery - There has been no progress towards beginning work on this HGMP.
- Coleman National Fish Hatchery and Livingston Stone National Fish Hatchery - All of the necessary HGMP information for Coleman and Livingston Stone National Fish Hatcheries are contained in the 2001 Biological Assessment (plus a subsequent addendum for Section 10 coverage for winter Chinook and amendments to respond to operational changes at Coleman National Fish Hatchery) submitted to NMFS. The Biological Opinion, including updates to the BA, is in process.

Hypothesized Benefits

Accelerating the development and implementation of HGMPs at Central Valley hatcheries is hypothesized to:

- Improve the genetics and fitness of wild salmonids (ISAB 2003, Goodman 2005, Hey et al. 2005); and
- Reduce competition for rearing and spawning habitat and food with hatchery-reared salmonids (Flagg et al. 2000, Goodman 2005).

Adaptive Management Considerations

Implementation of this conservation measure by the BDCP Implementation Office will be informed through effectiveness monitoring that will be conducted as described in Section 3.6, *Monitoring and Research Program*, and the adaptive management process described in Section 3.7, *Adaptive Management Program*. The Implementation Office will review annual reports or other relevant reports to assess the performance of the HGMP teams in the accelerated development and implementation of HGMPs. The Implementation Office will coordinate with the individual hatcheries to adjust HGMP strategies and funding levels through the BDCP adaptive management process as appropriate, based on review of performance monitoring results and other relevant reports.

The Implementation Office will use effectiveness monitoring results to determine whether HGMP development and implementation results in measurable benefits to covered fish species and to identify adjustments to funding levels or other related aspects of the program that would improve the biological effectiveness of the program. Such changes will be effected through the BDCP adaptive management process and will be included in the subsequent annual work plans.

If results of review indicate that HGMP development and implementation does not substantially and cost-effectively benefit covered fish species, the Implementation Office, in coordination with Fishery Agencies, may terminate this conservation measure. If terminated, remaining funding will be deobligated from this conservation measure and reallocated to augment funding for other more effective conservation measures identified in coordination with the Fishery Agencies through the BDCP adaptive management process.

3.4.4.7 CM18 Illegal Harvest

The purpose of this conservation measure is to reduce illegal harvest of Chinook salmon, Central Valley steelhead, green sturgeon, and white sturgeon in the Delta, bays, and upstream waterways. The BDCP will provide funding over the term of the BDCP to increase the enforcement of fishing regulations in the Delta and bays to reduce illegal harvest of covered salmonids and sturgeon. The BDCP Implementation Office will provide funds to DFG to hire and equip 17 additional Game Wardens and 5 supervisory and administrative staff in support of the existing field wardens assigned to the Delta-Bay Enhanced Enforcement Program over the term of the BDCP.

The DFG Delta-Bay Enhanced Enforcement Program (DBEEP) is a 10-Warden squad that was formed specifically to increase enforcement on poaching of anadromous fish species in Bay-Delta waterways. The program is funded by water contractors through the Delta Fish Agreement. The BDCP would contribute directly to this existing program by expanding its size to improve enforcement against poaching of covered species.

The BDCP Implementation Office will enter into Memoranda of Agreement or similar binding instruments with DFG as described in Section 3.4.4, *Species Level Other Stressors Conservation Measures*.

Problem Statement

California has the lowest Game Warden to population ratio in the nation with fewer than 200 field wardens for the entire state. The Delta is a particular hot spot for poaching because of the large number of sport fish, particularly gravid female white sturgeon, whose roe are used for caviar (Lt. L. Schwall, pers. comm.). Illegal harvest is thought to have high impacts on sturgeon populations, particularly white sturgeon (Beamsderfer et al. 2007). Illegal harvest of juvenile and adult Chinook salmon and steelhead in the Delta and bays is also common (DBEEP 2007).

Hypothesized Benefits

It is hypothesized that enhanced enforcement on poaching will reduce mortality, and potentially increase population sizes, of green sturgeon (Beamesderfer et al. 2007, DFG unpublished, Boreman 1997, D. Tanner pers. comm., DFG 2007b, Appendix F, *DRERIP Evaluation Results*); white sturgeon (Bay-Delta Oversight Council 1995, Boreman 1997, Schaffter & Kohlhorst 1999, Beamesderfer et al. 2007, DFG 2007b, DFG 2008c, M. Gingras pers. comm., Z. Matica pers. comm., CDFG unpubl. data, Appendix F, *DRERIP Evaluation Results*); Chinook salmon (all races) (Bay-Delta Oversight Council 1995, Williams 2006); and steelhead (DFG 2007b, DFG 2007c, DFG 2008d, Moyle et al. 2008, Appendix F, *DRERIP Evaluation Results*). Spring-run Chinook salmon are hypothesized to experience the greatest benefit because they are more susceptible to poaching than other runs due to over-summer holding and ease of locating them (Appendix F, *DRERIP Evaluation Results*). Due to the recent establishment of daily bag limits for Sacramento splittail by the Fish and Game Commission, it is hypothesized that this conservation measure will also reduce mortality and potentially increase population size of splittail.

Magnitudes of population-level benefits of this measure are expected to vary inversely with the population size of each covered species (Bay-Delta Oversight Council 1995, Begon et al. 1996, Futuyma 1998, Moyle et al. 2008).

Adaptive Management Considerations

Implementation of this conservation measure by the BDCP Implementation Office will be informed through effectiveness monitoring that will be conducted as described in Section 3.6, *Monitoring and Research Program*, and the adaptive management process described in Section 3.7, *Adaptive Management Program*. The Implementation Office will coordinate with DFG to adjust enforcement strategies and funding levels through the BDCP adaptive management process as appropriate based on review of DBEEP annual reports.

3.4.4.8 CM19 Conservation Hatcheries

The purpose of this conservation measure is to establish new and expand existing conservation propagation programs for delta and longfin smelt. The BDCP Implementation Office will support: (1) the development of a delta and longfin smelt conservation hatchery by the USFWS to house a delta smelt refugial population and provide a source of delta and longfin smelt for supplementation or reintroduction, if deemed necessary by Fishery Agencies; and (2) the expansion of the refugial population of delta smelt and establishment of a refugial population of longfin smelt at the University of California, Davis Fish Conservation and Culture Laboratory to serve as a population safeguard in case of a catastrophic event in the wild.

The new facility proposed by the USFWS will house genetically-managed refugial populations of delta and longfin smelt (Clarke 2008). Further, the facility will provide fish to supplement the wild population and provide fish stocks for reintroduction, as necessary and appropriate. State-of-the-art genetic management practices will be implemented to avoid hatchery-produced fish becoming genetically different from wild fish. The facility will be designed with the ability to add other species if necessary in the future. Due to space limitations, the facility as planned will consist of two sites: a science oriented genetic refuge and research facility on the edge of the Sacramento River, and a larger supplementation production facility nearby (B. Clarke pers. comm.) (Figure 3-62). Specific rules will be established to discontinue housing refugial populations of delta and longfin smelt at the hatchery if and when populations of these species are considered recovered by the Fishery Agencies.

In addition, the UC Davis Fish Conservation and Culture Laboratory (FCCL) is in need of additional space and funds to expand the refugial population of delta smelt and establish a refugial population of longfin smelt. The FCCL and the Genomic Variation Laboratory (GVL) at UC Davis are and will be, the primary entities developing and implementing genetic management of the delta smelt refugial population over the period 2009-2015 or longer and may then play a secondary role in keeping a back-up population(s).

At both facilities, genetic management practices will be implemented to maintain wild genetic diversity, minimize genetic adaptation to captivity, minimize mean kinship, and equalize family contributions. Furthermore, genetic monitoring of wild populations will proceed to minimize risks such as genetic swamping from the hatchery population, reduction in effective population size, and changes in the census population-to-breeder population ratio over time.

The BDCP Implementation Office will enter into binding Memoranda of Agreement or similar instruments with the USFWS and University of California, Davis similar to that described in Section 3.4.4, *Species Level Other Stressors Conservation Measures*. In addition, if and when populations of these species are considered recovered by the Fishery Agencies, the Implementation Office will terminate funding for the propagation of the species and either fund propagation of an additional BDCP covered fish species, if necessary and feasible, or deobligate funds to this conservation measure and reallocate them to augment funding other conservation measures identified in coordination with the Fishery Agencies through the BDCP adaptive management process.

Problem Statement

Populations of both delta and longfin smelt have dramatically declined recently (IEP 2008a, b). Although a variety of stressors are suspected, there is not a clear understanding of why these populations have declined (IEP 2008a, b). There is evidence that delta smelt continue to decline and that very low population size could result in an Allee effect causing an even more rapid decline of the species (Mueller-Solger 2007). As a result, the risk of extinction of delta smelt is hypothesized to be increasing. Longfin smelt abundance has followed a similar trend to delta smelt (IEP 2008a, b).

Figure 3-62. Potential USFWS Conservation Hatchery Facility Locations (CM19)

Hypothesized Benefits

Artificial propagation and maintenance of refugial populations of delta and longfin smelt are hypothesized to:

- Provide a safeguard against the possible extinction of delta and/or longfin smelt by maintaining a captive population that is genetically similar to the wild population (Lande 1988, Hedrick et al. 1995, Sveinsson & Hara 1995, Carolsfeld 1997, Sorensen 1998, USFWS 2003, Hedgecock et al. 2000, Kowalski et al. 2006, Turner et al. 2007, Nobriga 2008, Turner & Osborne 2008, B. Clarke, pers. comm., Appendix F, *DRERIP Evaluation Results*);
- Improve the knowledge base regarding threats to and management of delta and longfin smelt by increasing the ability to study the effects of various stressors on these species using hatchery-reared specimens (Appendix F, *DRERIP Evaluation Results*); and
- Contribute to increasing population sizes of delta smelt (Lande 1988, Deblois & Leggett 1991, Sveinsson & Hara 1995, Carolsfeld 1997, Sorensen 1998, USFWS 2003, Flagg et al. 2000, Richards et al. 2004, Kowalski et al. 2006, Purchase et al. 2007, Nobriga 2008, B. Clarke, pers. comm.) and longfin smelt (Sveinsson & Hara 1995, Carolsfeld 1997, Sorensen 1998, USFWS 2003, Flagg et al. 2000, Richards et al. 2004, Kowalski et al. 2006, Nobriga 2008) to self-sustaining levels in the wild when combined with effective habitat restoration and other measures to improve conditions in their natural environment.

Adaptive Management Considerations

Implementation of this conservation measure by the BDCP Implementation Office will be informed through effectiveness monitoring that will be conducted for this conservation measure as described in Section 3.6, *Monitoring and Research Program*, and the adaptive management process described in Section 3.7, *Adaptive Management Program*. Based on review of performance and effectiveness monitoring results in USFWS and UC Davis annual reports, the Implementation Office, in coordination with Fishery Agencies and UC Davis, will adjust funding levels, hatchery operations, or other related aspects that will improve the performance and/or biological effectiveness of the program through the BDCP adaptive management process as appropriate. Such changes will be effected through the BDCP adaptive management process and would be included in the subsequent annual work plans.

3.4.5 Avoidance and Minimization Measures

As required by Section 10 of the ESA, the BDCP includes avoidance and minimization measures that will be implemented by the BDCP Implementation Office to avoid and minimize adverse impacts of covered activities on the covered species. Careful design and implementation of covered activities will help avoid take of covered species, but specific avoidance and minimization measures may be required during implementation to fully meet this requirement. It is the responsibility of the Implementation Office to design and implement projects in compliance with these measures.

Biological surveys are an essential first step that will be used to assess the location, extent, and quality of suitable habitat or occurrences of covered species on BDCP project sites. Three levels of surveys, described in greater detail in the following sections, may be required for implementation of covered activities and conservation measures: planning surveys, preconstruction surveys, and construction-period monitoring.

- **Planning Surveys.** Planning surveys are used to identify the natural communities that are present in a BDCP project site, to determine whether suitable habitat for covered species is present, and to determine whether additional surveys are required to establish occupancy by covered species. Planning survey maps are used in assessing project effects on natural communities by identifying the extent of natural communities in BDCP project sites.
- **Preconstruction Surveys**. Preconstruction surveys are used to determine whether covered species are present in a BDCP project site, and whether species-specific avoidance and minimization measures must be implemented to ensure compliance with the HCP/NCCP. Agency-approved protocols are available for surveying some covered species; survey procedures for other species will be developed in cooperation with USFWS and DFG.
- **Construction Monitoring.** Construction monitoring ensures that necessary avoidance and minimization measures are implemented properly during construction activities.

3.4.5.1 General Avoidance and Minimization Measures

Avoidance and Minimization Measure (AMM) 1. Conduct planning surveys for covered wildlife and plant species. Planning surveys are reconnaissance level surveys that are intended to identify the habitats that are present in BDCP project sites, and what, if any, more intensive survey effort should be made to accurately determine the status of covered species and natural communities on the sites. Planning surveys are required for all covered activities and implementation of conservation measures. Results of planning surveys will inform project design and be used, if avoidance is not possible, to preserve the species and implement relevant conservation measures.

Planning surveys will use existing data on natural community and habitat distribution and covered species occurrences gathered during the development of the BDCP GIS mapping layers and covered species models (Appendix A, *Covered Species Accounts*) and other sources of information to assess the location, quantity, and quality of suitable habitat for covered wildlife and plant species on and near the project site. Results of planning surveys will be used to determine whether more intensive preconstruction and construction monitoring surveys are necessary. For example, if suitable habitat is not present for one of the covered species, the BDCP Implementation Office will not be required to conduct preconstruction surveys or construction monitoring for that species. For covered plant species, it is expected that follow-up floristic surveys (see AMM2) will be needed if the covered species are likely to be present on the project site but cannot be reliably identified to species at the time of the planning survey.

A survey report with the following information for the project site will be included with project application documents for covered activities and implementation of conservation measures:

- Description of the types of natural communities present in the project site, including the extent of each community;
- Description and map of locations of suitable habitat and/or habitat features for covered wildlife species;
- Description and map of potential habitat for covered plant species (e.g., vernal pools) based on soil type and land cover types;
- Map of all reported Covered Species occurrences;
- CNDDB California Native Species Field Survey Forms for all covered plants found on the site; and
- A description of the applicable avoidance and minimization measures required by the HCP/NCCP (e.g., preconstruction surveys).

Results of the planning survey will provide permit applicants with the information necessary to comply with the HCP/NCCP. Applicable avoidance and minimization measures described in this section must be incorporated into the project design and submitted with the application package. The BDCP Implementation Office will review and approve all planning survey reports before approving coverage under the HCP/NCCP. The Implementation Office will enter all relevant information in the survey reports into a database and use these data to monitor plan compliance.

*AMM2: Conduct preconstruction surveys for covered wildlife and plant species***.** If planning surveys for covered species identify suitable habitat and specific habitat elements (e.g. nest sites) described in the species habitat models (Appendix A, *Covered Species Accounts*), and if impacts cannot be avoided by modifying project design or project implementation, preconstruction surveys will be conducted. Preconstruction surveys are intended to determine the presence, status and likely impacts to covered species on the site. Results are used to identify or refine the site-specific measures required to avoid and minimize take. Permit applicants will be responsible for contracting with qualified biologists to conduct preconstruction surveys.

In general, preconstruction surveys will be conducted not less than 30 days or more than 6 months prior to commencement of construction activities on specific proposed construction sites, with the exception that preconstruction surveys may be completed up to one year in advance of construction if the sole period for reliable detection of a covered species is between May 1 and December 31. Detailed survey requirements are available for some covered species in existing

USFWS survey protocols, which will be used for the species listed in Table 3-16 (survey protocols are presented in Appendix I). It is expected that USFWS and DFG will refine these survey protocols and develop new protocols for other listed species in the future. In this case, the latest protocols and guidance from agencies will be followed.

Table 3-16. USFWS Preconstruction Survey Protocols

Covered Species	*Survey Protocol*
San Joaquin kit fox	USFWS San Joaquin Kit Fox Survey Protocol for the Northern Range (1999)
Riparian woodrat	USFWS Draft Habitat Assessment Guidelines and Survey Protocol for the Riparian Brush Rabbit and the Riparian Woodrat
Riparian brush rabbit	USFWS Draft Habitat Assessment. Guidelines and Survey Protocol for the Riparian Brush Rabbit and the Riparian Woodrat
California red-legged frog	USFWS Guidance on Site Assessments and Field Surveys for the California Red-legged Frog (2005)
California tiger salamander	USFWS Interim Guidance on Site Assessment and Field Surveys for Determining Presence or a Negative Finding of the California Tiger Salamander (2003)
Valley elderberry longhorn beetle	Document shrub and habitat conditions according to USFWS conservation guidelines

The BDCP Implementation Office will coordinate with USFWS and DFG to develop preconstruction survey protocols for the remaining covered wildlife and plant species. Components of preconstruction survey protocols for selected wildlife species are presented in Table 3-17.

Table 3-17. Preconstruction Survey Protocol Elements for Selected Wildlife Species

Covered Species	*Survey Protocol Element*
Salt marsh harvest mouse	Identify suitable habitat within 0.25 miles of the project footprint limits. Conduct preconstruction surveys of suitable habitat using USFWS and DFG approved survey protocols.
Townsend's big-eared bat	Identify suitable roost sites within 0.25 miles of the project footprint limits. Conduct preconstruction surveys of hibernation roosts and nursery roosts using USFWS and DFG approved survey protocols.
Suisun shrew	Identify suitable habitat within 0.25 miles of the project footprint limits for projects in the Suisun Marsh ROA and West Delta ROA. Conduct preconstruction surveys of suitable habitat using USFWS and DFG approved survey protocols.
Tricolored blackbird	Conduct preconstruction surveys in breeding habitat within 0.25 miles of BDCP project footprint limits (covered activities and habitat restoration projects). Preconstruction surveys will be conducted during the breeding season (approximately early April through late-August) prior to project activity, and during the construction year.
Suisun song sparrow, yellow-breasted chat, least Bell's vireo, and western yellow-billed cuckoo	Conduct preconstruction surveys of potentially-occupied breeding habitat within 0.25 miles from the project footprint limit (covered activities and habitat restoration projects). Preconstruction surveys will be conducted during the breeding season prior to project activity, and during the construction year.
Western burrowing owl	Conduct preconstruction surveys of breeding and wintering habitat within __ feet of the BDCP project footprint limit (covered activities and habitat restoration projects). Preconstruction surveys will be conducted during the breeding season (approximately March through August) or wintering season (approximately September through February) prior to project activity, and during the construction year.

Table 3-17. Preconstruction Survey Protocol Elements for Selected Wildlife Species (continued)

Covered Species	*Survey Protocol Element*
Greater sandhill crane	Conduct preconstruction surveys within the identified greater sandhill crane winter use area to determine the presence of occupied winter roost sites within 0.5 miles of the project footprint limits during late-October/early-November of each construction year.
California black rail California clapper rail	Identify suitable habitat within 0.25 miles of the project footprint limits. Conduct preconstruction surveys of suitable habitat using USFWS and DFG approved survey protocols.
White-tailed kite	Conduct preconstruction surveys of potentially-occupied breeding habitat within 0.25 miles from the project footprint limits and within 0.25 miles of planned restoration sites to locate active white-tailed kite nest sites. Preconstruction surveys will be conducted early (March-April) during the breeding season (March 1 to September 1), prior to project activity, and during the planned construction year.
Swainson's hawk	Conduct preconstruction surveys of potentially-occupied breeding habitat within 0.5 miles from the project footprint limits (covered activities and habitat restoration projects) to locate active Swainson's hawk nest sites. Preconstruction surveys will be conducted early (March 15 to April 20) during the breeding season (March 15 to September 1), prior to project activity, and during the planned construction year.
Giant garter snake	Identify suitable aquatic habitat (wetlands, ditches, canals) within project footprint limits. Conduct preconstruction surveys during active period (May 1 to September 30) of suitable habitat and 200 feet into adjacent uplands using USFWS and DFG approved survey protocols.
Western pond turtle	Identify suitable aquatic habitat and upland nesting and overwintering habitat within 0.25 miles of the project footprint limits. Conduct preconstruction surveys of suitable aquatic habitat using USFWS and DFG approved survey protocols.
Western spadefoot toad	Identify suitable aquatic habitat (vernal pools, ponds, pools along intermittent streams) for spadefoot toad within 0.25 miles of the project footprint limits. Conduct preconstruction surveys of suitable aquatic habitat during the breeding season (January to May) using USFWS and DFG approved survey protocols.

Additional survey requirements will apply to vernal pool habitats and associated plant and animal species. Surveys will be scheduled as specified in USFWS and DFG guidelines to ensure that vernal pool habitat is present. Vernal pools in BDCP project sites will be described, mapped and characterized in terms of duration, depth of ponding, and source of hydrology. Descriptive information for the site will include topography, drainage patterns and the extent of vegetative cover. Assessments should be made in consideration of "normal or average" conditions, if possible. Wildlife surveys following protocols listed in Tables 3-16 and 3-17 will include giant garter snake, western pond turtle, California red-legged frog, California tiger salamander and western spadefoot toad. The fairy shrimp and tadpole shrimp species surveys will follow USFWS-approved guidelines (USFWS Interim Survey guidelines to Permittees for Recovery Permits under Section 10(a)(1)(A) of the Endangered Species Act for the Listed Vernal Pool Branchiopods (1996)). Vernal pool plant species will be inventoried by floristic surveys following DFG Protocols for Surveying and Evaluating Impacts to Special Status Native Plant Populations and Natural Communities (2009) and USFWS Guidelines for Conducting and

Reporting Botanical Inventories for Federally Listed, Proposed and Candidate Plants (1996). In addition to requirements listed below for survey reports, vernal pool survey reports will include estimates of the size and acreage of direct and indirect impacts (as defined by seasonal inundation and other hydrology indicators, and the presence of hydric soils) on species that occur in the pool/pool complex.

Preconstruction surveys of other covered plant species will be conducted in suitable natural communities, using general habitat distribution models for these species (Appendix A, *Covered Species Accounts*). Surveys will be conducted during the appropriate season for identification of these species (i.e. floristic surveys). If covered plants or populations are found, the location, extent, and condition of all occurrences will be documented in the survey report. Any new records of sensitive plant species will be submitted to the CNDDB.

The BDCP Implementation Office will prepare a report with results of the preconstruction surveys and recommended minimization measures, and submit it to t the USFWS and DFG. The survey report will include the following elements:

- Survey dates, methods, timing and intensity;
- Map of survey area showing proposed BDCP project footprint and locations of covered wildlife and plant species occurrences;
- Description of status of wildlife species in occupied sites, (e.g. breeding);
- Description of special habitat features used by covered species (e.g. nest trees, caves, buildings);
- CNDDB field survey forms and maps for all covered animals and plants encountered on the site;
- A description of the applicable avoidance and minimization measures required by the HCP/NCCP and incorporated into project design or project implementation (e.g., construction timing, buffer width, buffer location); and
- Occurrences of covered species and other listed species will be documented in CNDDB forms.

*AMM3: Conduct Construction Monitoring***.** Construction-period monitoring by qualified biologists focuses on the covered natural communities and species identified during planning and preconstruction surveys, and is intended to ensure proper implementation of specific avoidance and minimization measures that have been integrated into the project design and permit requirements. Construction monitoring is the responsibility of the BDCP Implementation Office.

Before implementing an approved project, the BDCP Implementation Office will prepare a construction monitoring plan. The construction monitoring plan will include the following elements:

- Summaries or copies of planning and preconstruction surveys (if applicable) for covered natural communities and species;
- Description of avoidance and minimization measures to be implemented, including a description of project-specific measures or additional measures not included in the HCP/NCCP;
- Descriptions of monitoring activities, including the specific activities to be monitored (e.g. grading activities), monitoring frequency and duration; and
- Description of the onsite authority of the monitoring biologist to modify construction activity and protocols for consultation with DFG and USFWS, if needed.

*AMM4: Implement construction best management practices***.** Construction activities have the potential to affect covered species by removing natural habitat (i.e. vegetation), disturbing soils, and transporting sediments and pollutants, creating visual and noise disturbance, and introducing invasive and exotic species. In order to avoid and minimize these impacts, best management practices (BMPs) will be used to minimize new disturbances during construction and monitoring. These measures generally apply to all covered natural communities. BMPs include, but are not limited to:

- Construction activities will be staged to avoid, as much as possible, the sensitive time period for covered species that have been determined, through preconstruction surveys, to occur on the site. The sensitive time periods are defined in avoidance and minimization measures for each species in Section 3.4.5.3, *Species-Specific Avoidance and Minimization Measures*.
- Disturbance to existing grades and vegetation will be limited to the project site and necessary access routes. Placement of roads, staging areas, and other facilities will avoid and limit disturbance to stream bank or stream channel habitat as much as possible. When possible, existing egress points will be used and/or work will be performed from the top of stream banks. Upon completion, the contours of stream channels will be restored to pre-construction or better.
- Construction by-products and pollutants such as petroleum products, chemicals, cement, or other harmful materials will not be discharged into aquatic habitats, and will be collected and transported to an authorized disposal area.
- A plan for the emergency clean up of any spills of fuel or other material will be prepared and implemented, as needed.
- Water contained mud or silt from construction activities will be treated by filtration or retention in a settling pond to prevent turbid water from entering live streams.
- Equipment will be refueled and serviced at designated construction staging areas away from aquatic habitats. All construction material and fill will be stored and contained in a designated area that is located away from aquatic habitats. A silt fence will be installed to collect any discharge, and adequate materials for spill cleanup will be maintained on site.

- Construction vehicles and equipment will be maintained to prevent contamination of soil or water from external contaminants (i.e. grease and oil) or from leaking hydraulic, fluid, fuel, oil, and grease.
- Building material storage areas containing hazardous or potentially toxic materials will have an impermeable membrane between the ground and the hazardous materials and will be bermed to prevent the discharge of pollutants to ground water and storm water runoff.
- Project proponents will implement environmentally sound practices, utilize safer alternative products such as biodegradable hydraulic fluids, where feasible, and conduct employee training programs. Employee training will emphasize prevention and reduction of pollutant discharge from construction activities to aquatic habitats, and the appropriate measures to take should a spill occur.
- In-channel work will take place only in dry channels.
- If a work site is to be temporarily de-watered or filled, the de-watering and other required maintenance will be conducted during time frames specified for covered species (i.e. giant garter snake, California red-legged frog, California tiger salamander), see AMMs 20, 21, 22.

*AMM5: Establish setbacks and buffer zones***.** To the extent practicable, buffer zones dominated by native vegetation will be established between construction activities and covered natural communities, and nest, den or roost sites or covered species. Required buffers proposed by this measure are designed to maintain existing habitat value for covered species, reduce disturbance of species that use habitats protected by buffers, and provide wildlife movement corridors. With regard to streams and wetlands, buffer widths must be compatible with standards and requirements of existing regulatory programs, including the Clean Water Act and State regulations. Avoidance and minimization measures specific to buffers for covered riparian and aquatic communities include the following:

- Establish construction buffers for streams, measured horizontally from the top of the bank and extending the entire length of perennial, intermittent, and ephemeral streams (or linear wetland) within the boundaries of the project site.
- Stream buffer widths will be a function of stream order (e.g. first order), duration of flow, and location (i.e., agricultural, natural, or urban locations). Buffers will be determined in consultation with permitting agencies, and may be reduced with the concurrence of the permitting agencies if the reduction will not result in an adverse impact to the covered species or reduction in the biological values of the riparian or aquatic habitat. No setbacks are required on irrigation ditches, underground stream reaches, or on drainages and swales that lack a defined bed and bank or evidence of scour or sediment transport. The buffer must be marked throughout construction with stakes, fencing or other materials that will be visible to construction workers.

- Require appropriate erosion control measures (e.g. hay bales, filter fences, vegetative buffer strips or other equivalents) to reduce siltation and contaminated runoff from project sites. Brush, loose soils, or other debris materials will not be stockpiled within stream channels or on adjacent banks.
- Silt fencing or other sediment trapping method will be installed downgradient from construction activities to minimize the transport of sediment off site.
- Temporary stream diversions, if required, will use sand bags or other approved methods that minimize instream impacts and effects on wildlife.
- Limit removal of native vegetation as much as possible.
- Locate roadways and other facilities perpendicular to waterways wherever practical to reduce the total riparian area disturbed.
- Locate bridge and road footings outside of high water zones and riparian habitats where practical.
- Construction monitoring will be conducted throughout the construction period to ensure that buffers, BMPs, and other restrictions are being implemented properly.

3.4.5.2 Avoidance and Minimization Measures for Covered Natural Communities

*AMM6: Avoid and minimize impacts on vernal pool complex and alkali seasonal wetland complex***.** Natural community goals and objectives of the BDCP Conservation Strategy include the protection of vernal pool complex and alkali seasonal wetland complex and managed wetlands in and adjacent to the Plan Area that support habitat for associated native species. BDCP projects should avoid and minimize the fill of seasonal wetlands, vernal pools, and associated uplands, in particular the high value sites identified through implementation of Conservation Measure CM3 *Natural Communities Protection*. If planning surveys indicate that these communities are present in areas where fill is proposed, areas specified for avoidance will be protected with vegetated buffers that protect the wetland community and provide habitat for covered species and other native species. General buffer criteria are outlined in AMM5. Additional avoidance and minimization measures specific to vernal pool, vernal swale, alkali meadow, and alkali sink habitats, including their watersheds, and managed wetlands are as follows:

- Establish buffers measured horizontally from the edge of hydrophytic vegetation associated with the vernal pool;
- Vegetated buffers will consist of valley floor grassland and/or other natural vegetation communities (i.e, oak savanna/woodland, coastal marsh or riparian habitats);
- Buffer width will be sufficient to prevent significant adverse changes in water quality due to adjacent upland sources, or the inflow of water that could change the timing and duration of inundation of the wetland;

- Buffer width must be adequate to provide upland habitat for pollinators, amphibian species and terrestrial species;
- Buffer width must be adequate to provide connectivity between individual aggregations of vernal pools within a larger complex; and
- Buffer width must be adequate to protect the wetland and associated upland habitat from edge effects associated with surrounding land uses.

Buffer widths of 500 feet or greater will be presumed to meet these criteria. If avoidance is not practicable, the BDCP Implementation Office will provide documentation to USFWS and DFG explaining why avoidance is not practicable and/or would not contribute to the conservation goals and objectives of the BDCP. Smaller proposed buffer distances must be supported by assessments of the project's compliance with water quality/quantity criteria and assessments of habitat-related criteria.

AMM7: Avoid and minimize impacts on riparian communities. Natural community goals and objectives of the BDCP Conservation Strategy include increasing the extent and spatial distribution of riparian forest and scrub within the Planning Area to support habitat and food production for associated native species and increase connectivity among native habitats within and adjacent to the Plan Area. If planning surveys indicate that riparian communities are present in areas affected by BDCP projects, areas specified for enhancement, restoration or other actions under BDCP conservation measures will be protected by avoidance or minimization measures. General avoidance and minimization measures for riparian communities include establishing buffer zones (AMM5), construction period best management practices (AMM4), and construction period monitoring (AMM3). Additional avoidance and minimization measures specific to riparian communities include the following:

- Design project elements including roadways and other facilities perpendicular, rather than parallel to riparian zones and waterways whenever possible; and
- Locate bridge and road footings outside of high water zones and riparian habitats.

Except as noted below for covered wildlife species that inhabit riparian communities, riparian buffer widths will extend at a minimum to the outer dripline of riparian vegetation.

*AMM8: Implement Construction Best Management Practices for Fish Species***.** Construction of the proposed intake facilities in the North Delta have the potential to affect fish species, including covered species, by creating noise levels above ambient conditions during construction activities such as mobilization and demobilization of equipment, development of staging/storage areas and construction zones, creation of temporary detour roads, earthwork, deep excavation, shoring and bracing, levee construction, slurry cut-off walls, and coffer-damming, trenching, and other construction activities. In addition to increased noise, fish species could be affected by increased suspended sediments from pile installation, levee breaching, and dredging by decreasing visibility for foraging activities or impairing oxygen exchange due to clogged gills

(USEPA 1993). Moreover, the greatest effects from suspended sediments are to fish eggs, larvae, and juveniles (USACE 1992).

Best management practices (BMPs) will be used to avoid and minimize these impacts during construction. Although most fishes would likely move out of disturbed areas during construction and could return after these activities are completed, a number of protection measures would be used to further reduce affects to fish species, including:

- Preparing, maintaining, and implementing a Stormwater Pollution Prevention Plan (SWPPP) that contains all of the BMPs that would apply to all aspects of project construction.
- Placing and maintaining silt fences, coir logs, straw bale dikes, silt fences, and other siltation barriers so that silt or other deleterious materials does not enter the river.
- Settling, filtering, or otherwise treating construction-related water before discharge to minimize turbidity and siltation.
- Preventing raw cement and concrete, concrete wash water, bentonite, petroleum products, or other products that could be hazardous to aquatic life from contaminating soils, and/or entering streams, sloughs, or the river.
- Setting work windows during which the most sensitive lifestages of covered fish species are not generally found in the vicinity of the construction area.
- Dredging in front of the intake structure should be performed during a low river flow period, if possible, and a temporary silt screen should be provided to minimize suspended sediment movement into the river. This should coincide with the work windows set in the previous bullet.
- Vegetate or otherwise protect all disturbed surfaces to prevent erosion.

3.4.5.3 Species-Specific Avoidance and Minimization Measures

This section provides descriptions of avoidance and minimization measures for specific covered species. Several covered species are designated as fully protected by the California Fish and Game Code (§3511 and §4700), as DFG cannot issue permits for take of these species. Fully protected species in the Plan Area are: salt marsh harvest mouse, greater sandhill crane, California black rail, California clapper rail, and white-tailed kite.

Many of the avoidance and minimization measures described in this section are designed to provide opportunities for individual wildlife to avoid or escape construction areas.

AMM9: Avoid and minimize impacts on and mortality of San Joaquin kit fox. The BDCP Implementation Office will implement the 1999 USFWS Standardized Recommendations for Protection of the San Joaquin Kit Fox Prior to or During Ground Disturbance (see Appendix I) to avoid and minimize impacts on occupied kit fox sites. If preconstruction surveys (AMM2) identify a kit fox den in the proposed development footprint of a BDCP project site, the den will be monitored for 3 days by an agency-approved biologist using a tracking medium or an infrared beam camera to determine if the den is currently being used. Unoccupied dens should be destroyed to prevent subsequent use. If kit fox activity is observed at a den during the initial monitoring period, the den will be monitored for an additional 5 consecutive days from the time of the first observation. If an active natal or pupping den is found, USFWS and DFG will be notified immediately. The den will be excavated after the pups and adults have vacated and then only after further consultation with USFWS and DFG. For dens other than natal or pupping dens, use of the den can be discouraged by partially plugging the entrance with soil such that any resident animals can easily escape. Once the den is determined to be unoccupied it may be excavated under the direction of the biologist. Alternatively, if the animal is still present after 5 or more consecutive days of plugging and monitoring, the den may have to be excavated when, in the opinion of the biologist, it is temporary vacant (i.e. during the animal's normal foraging activities.).

If dens are identified outside the proposed disturbance footprint of a BDCP project site, exclusion zones around each den entrance or cluster of entrances will be demarcated. No construction-related activities will be allowed within the exclusion zone. Exclusion zone radius for potential or atypical kit fox dens will be at least 50 feet and 250 feet for all known occupied dens. The exclusion zone will be marked with flagged stakes.

*AMM10: Avoid and minimize impacts on and mortality of riparian woodrat and riparian brush rabbit***.** If preconstruction protocol surveys (AMM2) identify occupied riparian woodrat or riparian brush rabbit habitat along BDCP project construction corridors, avoid mortality by 1) reducing the corridor width to avoid occupied habitat, 2) if feasible, consider tunneling beneath the occupied riparian corridor, and 3) if appropriate, coordinate with the USFWS and DFG to develop a trapping and relocation program. All trapped animals will be relocated to approved sites prior to construction activities. If occupied habitat is present within proposed habitat restoration sites, avoid mortality and minimize impacts on individuals by 1) selecting alternative unoccupied restoration sites; or 2) designing the habitat restoration to avoid direct impacts on individuals, minimize impacts on habitat, and include riparian woodrat and riparian brush rabbit habitat in the restoration project design.

Implementation of avoidance and minimization measures for riparian habitat (see AMM7) will be considered sufficient to avoid take of these species in unoccupied potential habitat. Limited take of up to 3 acres of potential habitat (i.e. habitat conversion) for these species may occur under the HCP/NCCP for covered projects under the following conditions: 1) no individuals are encountered in preconstruction surveys, 2) the impact is less than 0.25 acres of habitat on a per-project basis, and 3) actions result in no harm, injury, or harassment of individuals.

*AMM11: Avoid and minimize impacts on Townsend's Big-eared Bat***.** If initial planning surveys, CNDDB search and habitat models (Appendix A, *Covered Species Accounts*) indicate suitable breeding or roosting sites for Townsend's big-eared bat are present on BDCP project sites, an agency-approved wildlife biologist will conduct preconstruction surveys to determine if they are occupied by the species. If the site is occupied, the BDCP permit applicant will avoid impacts to the extent practicable by relocating impacts at least 500 feet away from the occupied breeding or roosting site, and postponing construction activities that could disturb active roost sites while sites are occupied. Construction is allowed either prior to or after the hibernation season (November to March) for hibernation sites and prior to or after the breeding season (April to August 15) for nursery colonies. Avoidance and minimization measures will be incorporated into the project design.

If the project design cannot fully avoid impacts to roost sites, sealing the sites while they are unoccupied will allow bats to reestablish elsewhere. In this case, monitoring surveys will be conducted immediately prior to construction to determine if the sites are occupied or whether they show signs of recent previous occupation. If bats are discovered or if evidence of recent prior occupation is established in these surveys, construction will be scheduled such that it minimizes impacts on the bats. Unoccupied hibernation sites with evidence of prior occupation will be sealed before the hibernation season, and nursery sites will be sealed before the breeding season.

*AMM12: Avoid mortality of salt marsh harvest mouse***.** The salt marsh harvest mouse is a fully protected species under the California Fish and Game Code and direct mortality must be avoided. All construction activities will be done between May 1 and October 15, and locations of activities, such as levee breaches, will be sited to avoid potential salt marsh harvest mouse habitat. Salt marsh harvest mouse surveys using approved protocols will be conducted at the breach locations prior to excavation according the protocol specified by the USFWS. Surveys will be conducted for 7 consecutive days. If salt marsh harvest mouse is present at specific breach locations the captured animals will be relocated to a suitable alternate location on the property and surveys will continue until no mice are captured for 5 consecutive days. Vegetation will then be hand-removed, followed by another trapping sequence. To avoid the loss of individual salt marsh harvest mice from construction activities in suitable habitat, vegetation removal will be limited to the minimum extent necessary to permit the construction activity to occur. A sufficient extent of habitat, as determined by a DFG and USFWS approved biologist, will be allowed to remain adjacent to the construction area to provide refugia for displaced salt marsh harvest mice. Construction can commence after salt marsh harvest mice are not detected for 5 consecutive days following vegetation removal. If salt marsh harvest mice are not present, vegetation will be removed (by hand) from breach locations immediately following surveys. A qualified (with necessary permits from USFWS) biologist will walk in front of the excavator as it moves down the levee towards the breach location to flush any salt marsh harvest mice that may be in the vegetation on the levee crown and shoulders. No pets will be allowed on the work site and all persons will stay within the boundaries of the work site, which is the top of the levees and the water side levee slopes.

*AMM13: Avoid and minimize impacts on and mortality of Suisun shrew***.** Conduct preconstruction surveys to identify occupied habitat for the Suisun shrew within the area that could be impacted by BDCP actions in the Suisun Marsh Restoration Opportunity Area and potentially occupied habitats in the West Delta Restoration Opportunity Area. If Suisun shrews are present on project sites, avoid mortality and minimize impacts on individuals by 1) designing the habitat restoration to avoid the potential for mortality or 2) remove Suisun shrews from locations that could be affected by habitat restoration activities using DFG-approved methods and relocating them to DFG-approved sites. Direct mortality will be avoided by establishing a 200 foot buffer adjacent to suitable tidal marsh habitats, in which no construction activity or disturbance is permitted.

AMM14: Avoid and minimize impacts on tricolored blackbird. Conduct preconstruction surveys within known or suitable nesting habitat no more than 30 days prior to scheduled construction to identify active tricolored blackbird colonies within a BDCP project site. Avoid mortality and minimize impacts by creating a 500-foot no-disturbance buffer around each active colony and allow no entry of any kind into the buffer while the colony site is occupied during the breeding season (approximately mid-March through mid-August). Entry into the buffer may be granted if a qualified biologist, with concurrence from USFWS and DFG, determines through monitoring surveys that healthy young have fledged and nest sites are no longer active, or nesting birds do not exhibit significant adverse reaction to construction activities.

AMM15: Avoid and minimize impacts on Suisun song sparrow and California least tern. Conduct preconstruction surveys of potential breeding habitat for the Suisun song sparrow and California least tern within 0.25 miles from the project footprint limit of habitat restoration projects in the Suisun Marsh Restoration Opportunity Area and potentially occupied habitats in the West Delta Restoration Opportunity Area. Preconstruction surveys will be conducted during the breeding season prior to project activity. If an active Suisun song sparrow nest is present, avoid mortality and minimize impacts by creating a minimum 500-foot no-disturbance buffer around the nest site and allow no entry of any kind into the buffer while the site is occupied during the breeding season (approximately early April through late August). Entry into the buffer may be granted if a qualified biologist, with concurrence from USFWS and DFG, determines through monitoring surveys that healthy young have fledged and nest sites are no longer active, or nesting birds do not exhibit significant adverse reaction to construction activities.

AMM16: Avoid and minimize impacts on yellow-breasted chat, least Bell's vireo, and western yellow-billed cuckoo. Conduct preconstruction surveys of potential breeding habitat for the yellow-breasted chat, least Bell's vireo, and western yellow-billed cuckoo within 0.25 miles from the project footprint limit of habitat restoration. Preconstruction surveys will be conducted during the breeding season prior to project activity. If an active yellow-breasted chat nest site is present, avoid mortality and minimize impacts by creating a 1,300-foot no-disturbance buffer around the nest site and allow no entry of any kind into the buffer while the site is occupied during the breeding season (approximately early April through late-August). Entry into the buffer may be granted if a qualified biologist, with concurrence from USFWS and DFG, determines that healthy young have fledged and nest sites are no longer active, or nesting birds do not exhibit significant adverse reaction to construction activities.

*AMM17: Avoid and minimize impacts on nesting and wintering burrowing owls***.** If preconstruction surveys identify occupied breeding burrows within a BDCP project site, establish a 250-foot no-disturbance buffer around each occupied breeding burrow and allow no entry of any kind into the buffer while the site is occupied during the breeding season (approximately February 1 through August 31). The buffer may be reduced through consultation with a qualified biologist and with concurrence from USFWS and DFG based on line-of-sight, topography, land uses, type of disturbance, and other relevant factors. Entry into the buffer is granted when a qualified biologist, with concurrence from USFWS and DFG, determines that healthy young have fledged, are capable of independent survival, and nest sites are no longer active.

Avoid disturbance to winter burrows by creating a 160-foot no-disturbance buffer around each occupied wintering burrow and allow no entry of any kind into the buffer while the site is occupied during the winter season (approximately September 1 through January 31). The buffer can be reduced through consultation with a qualified biologist and with concurrence from USFWS and DFG based on line-of-sight, topography, land uses, type of disturbance, monitoring of the site to evaluate reaction to disturbances, and other issues. If direct impacts to active winter burrows cannot be avoided and the site is also used for breeding, implement standard DFG guidelines for passive relocation by installing one-way doors on active winter burrows (see Appendix I).

*AMM18: Avoid and minimize impacts on and avoid mortality of greater sandhill cranes***.** The greater sandhill crane is fully protected under the California Fish and Game Code and direct mortality must be avoided. If preconstruction surveys determine that a greater sandhill crane roost site is located within or adjacent to a BDCP project site, a 0.5 mile no-disturbance buffer will be established around each identified roost area. Construction and other work activity in the buffer will be restricted based on crane use patterns of the roost while the site is occupied during the winter season (approximately October 1 through February 28). During the roosting season, construction equipment greater than 50 feet in height will avoid locations that could lead to strikes by greater sandhill crane. When locating permanent facilities that could pose a bird strike hazard for greater sandhill crane, specific site locations will be chosen that minimize bird strike hazard to greater sandhill crane. Bird strike risk to greater sandhill crane will be considered when locating transmission, sub-transmission, and distribution power lines and conductor and ground lines will be fitted with flight diverters in compliance with the best available practices such as those specified in the USFWS Avian Protection Guidelines.

*AMM19: Avoid and minimize impacts on and avoid mortality of California black rail and California clapper rail***.** The California black rail and the California clapper rail are fully protected species under the California Fish and Game Code and direct mortality must be avoided. In areas with habitat for California black rail or the California clapper rail, as determined by planning surveys, work will be conducted outside of the breeding season during the period from September 1 to January 31, and no buffers will be required. To avoid the loss of individual rails, construction or other work activities within or adjacent to rail habitat will not be allowed in the time period within two hours before or two hours after local mean higher high tide to allow fleeing rails to reach cover. This restriction may be modified in consultation with DFG and USFWS if mean higher high tides during work periods are not sufficient to increase the likelihood for affecting individual birds. Activities conducted during the breeding season will implement the specific avoidance and minimization measures. If preconstruction surveys, using agency accepted protocols, determine that California black rail or California clapper rail are nesting within or adjacent to BDCP project sites, a 500-foot buffer will be established within which no activities will be allowed that could disturb the nesting pair or their young. The size of the no-disturbance buffer zone may be reduced if a qualified biologist determines, in consultation with DFG and USFWS, that the birds would be unaffected by project-related activities. An example in which a buffer distance would be reduced is in instances in which a major slough channel or other substantial physical barrier exists between the rail nest site and the activity. Buffers will be maintained until the young have fledged and are capable of flight (typically prior to September 15).

*AMM20: Avoid and minimize impacts on white-tailed kite and Swainson's hawk and avoid mortality of white-tailed kites***.** The white-tailed kite is a fully protected species under the California Fish and Game Code and direct mortality must be avoided. Preconstruction surveys will be conducted for active raptor nest sites (i.e. trees) within and adjacent to (within 0.5 miles) BDCP project sites. For construction scheduled during the breeding season of white-tailed kite and Swainson's hawk (March 15-September 15), surveys will take place no more than 30 days prior to the start of construction. A 1,000-foot radius no-disturbance buffer will be established around each active white-tailed kite nest site and at 0.25 mile radius around each Swainson's hawk nest site. No entry of any kind related to the BDCP construction activity will be allowed in the buffer while a nest site is occupied by white-tailed kite or Swainson's hawk during the breeding season. The buffer size may be reduced on the determination of a qualified biologist and with concurrence from USFWS and DFG based on line-of-sight, topography, land use, type of disturbance, existing ambient noise and disturbance levels, and other relevant factors. Entry into the buffer will be granted when a qualified biologist, with concurrence from USFWS and DFG, determines that the young have fledged and are capable of independent survival and the nest site is no longer active. If nest tree removal is necessary, tree removal will occur only during the non-breeding season (September through February).

*AMM21: Avoid and minimize impacts on giant garter snake***.** To the extent practicable, implement BDCP project site-specific measures approved by USFWS and DFG to avoid and minimize impacts on giant garter snake, as follows: Limit habitat disturbance to the period May 1 to September 30 (the active period for snakes) to minimize direct mortality, and dewater irrigation ditches, canals or other aquatic habitat, if needed, between April 15 and September 30. Dewatered areas must remain dry for at least 15 consecutive days prior to excavation or filling the habitat. If a site cannot be completely dewatered, netting and salvage of prey items may be necessary to discourage use by giant garter snakes.

Impacts to giant garter snakes may be minimized by the following measures: (1) From October to April, construction should be limited to in-channel work below OHWM and channel banks should not be disturbed. (2) During the dormant period, dredged or excavated material should be hauled off-site to discourage use by overwintering snakes. (3) Clearing of vegetation in aquatic habitats and channel banks should be limited to the minimum necessary to facilitate construction. (4) Movement of heavy equipment should be confined to existing roads and tops of channel banks. (5) No erosion control material containing nylon mesh or monofilament may be used within 200 feet of suitable giant garter snake aquatic habitat.

AMM22: Avoid and minimize impacts to western pond turtle and California red-legged frog. Conduct preconstruction USFWS and DFG-approved surveys to determine if suitable aquatic habitat is present for California red-legged frog and western pond turtle within one mile of BDCP project sites. The survey period for red-legged frogs extends from January to September, and surveys should be conducted two weeks prior to the beginning of construction activities during this period. The survey period for western pond turtle will be determined in consultation with the agencies. Guidelines for sampling habitats and site occupancy of western pond turtles are in preparation (Bury 2009, pers. comm.), and may be implemented with agency approval.

If occupied sites consist of isolated pools or ponds, avoid disturbance to these sites within or near the project footprint to the extent feasible and minimize the loss of occupied and potentially occupied aquatic habitat and grassland vegetation through adjustments in project design, as practicable. If occupied sites are along streams or other channels, install temporary aquatic barriers and relocate and exclude animals from the work area. A 500 foot buffer will be established on both sides of creeks and wetlands occupied by red-legged frogs or western pond turtles, and entry will be restricted during the construction period. Buffers may be reduced if a qualified biologist determines, in consultation with DFG and USFWS, that 1) the reduction would not affect habitat (e.g., a stream crossing project is directionally bored under the occupied habitat), or 2) the reduction will not result in an adverse impact to the species or reduction in the biological values of the habitat.

Direct mortality for California red-legged frogs and western pond turtles in irrigation ditches and canals can be minimized by implementing de-watering measures described for giant garter snake (AMM20), screening water intakes, and removing predators such as crayfish, bullfrogs and warm-water fish from aquatic habitats in the project site. Construction activities should avoid creation of perennial ponds in occupied sites that could result in the expansion of predator populations. Permit applicants will coordinate with the USFWS and DFG to develop a trapping and relocation program and to develop appropriate seasonal restrictions to minimize mortality. Individuals found within the construction footprint will be captured and relocated to designated relocation habitat approved by USFWS and DFG.

*AMM23: Avoid and minimize impacts on western spadefoot toad and California tiger **salamander**.* Conduct preconstruction USFWS approved surveys to determine if California tiger salamanders or western spadefoot toads are present in suitable aquatic and upland habitat within

1.24 miles of BDCP project sites. Aquatic larval sampling for California tiger salamanders is conducted in March, April, and May; upland sampling of adults is conducted from October through March. The survey period for western spadefoot toads will be determined in consultation with the agencies.

Avoid disturbance to occupied sites within or near the project footprint to the extent feasible and minimize the loss of occupied and potentially occupied seasonal pool and grassland vegetation through adjustments in project design, as practicable. As needed, permit applicants will coordinate with the USFWS and DFG to develop appropriate seasonal restrictions to minimize mortality. Dewatering of aquatic habitats will take place outside of the breeding season (December to June). Construction activities should avoid creation of perennial ponds in occupied sites that could result in the expansion of predator populations. Permit applicants will coordinate with the USFWS and DFG to develop a trapping and relocation program. Individuals found within the construction footprint will be captured and relocated to designated relocation habitat approved by USFWS and DFG. .

*AMM24: Avoid and minimize impacts on valley elderberry longhorn beetle***.** Avoid disturbance to elderberry shrubs large enough to support beetle habitat within or near the project footprint to the extent practicable through adjustments in project design. For ground-disturbing activities within 100 ft around elderberry shrubs with stems > 1 inch, establish a 20 ft buffer from the dripline of each plant. No harmful chemicals will be applied within 100 ft of the buffer. Protected elderberry bushes may be trimmed during the dormant period (November to mid-February), and grasses may be mowed within the buffer from July to April.

*AMM25: Avoid impacts on covered plant species associated with tidal mudflats, tidal emergent wetlands, and valley/foothill riparian communities***.** If occurrences of side-flowering skullcap slough thistle, Suisun thistle, soft bird's-beak, Delta tule pea, Mason's lilaeopsis, Delta mudwort, or Suisun marsh aster could be affected by BDCP actions, to the extent practicable, implement the proposed BDCP actions to avoid the direct loss of plants. Establish a 100 foot buffer around known populations of covered plants, and place temporary fences around plants to be avoided during construction. Minimization of impacts to side-flowering skullcap, where side-flowering skullcap is present on stumps or other substrate, may occur through the movement and transplantation of the substrate and plants to appropriate sites in the immediate vicinity.

*AMM26: Avoid and minimize impacts on covered plant species associated with alkali seasonal wetland complex, vernal pool complex, other natural seasonal wetlands, and grassland habitats***.** If occurrences of alkali milk-vetch, heartscale, brittlescale, San Joaquin spearscale, slough thistle, Delta button-celery, Boggs Lake hedge-hyssop, Carquinez goldenbush, Legenere, Heckard'pepper-grass, or caper-fruited tropidocarpum are detected within BDCP project sites, design and implement proposed BDCP actions to avoid the direct loss of any of these covered plants. To the extent practicable, implement project site-specific measures approved by the USFWS and DFG to avoid and minimize impacts on these species. Avoidance of impacts may require case-by-case review with DFG and/or USFWS. Impacts to plants that occur in vernal pool habitat may be avoided or minimized by implementing measures provided in AMM6. For plants occurring in other covered communities, establish a 250 foot buffer around covered plant populations, and avoid disturbance to adjacent areas that support the hydrological regime of the plants.

*AMM27: Avoid and minimize impacts on soft bird's-beak and Suisun thistle***.** If occurrences of soft bird's-beak and Suisun thistle are detected within BDCP project sites, design and implement proposed BDCP actions to avoid the direct loss of any of these covered plants. Implement project site-specific measures approved by the USFWS and DFG to avoid and minimize impacts on these species. Avoidance of impacts may require case-by-case review with DFG and/or USFWS. Establish site appropriate buffers with approval of USFWS and DFG around covered plant populations.

3.5 Potential Conservation Measures to Address Other Stressors

*[**Note to Reviewers:** As the BDCP Conservation Strategy is refined over the next several months, the Potential Conservation Measures described in this section will be further evaluated to determine whether they should be included as conservation measures in the initial BDCP or remain as potential actions that may be adopted as conservation measures at a later date, pursuant to the adaptive management program. The Steering Committee believes that the concepts reflected in these potential conservation measures may effectively address a number of other stressors, but that they require further development before they can serve as conservation measures. As such, Potential Conservation Measures will not be used by the fish and wildlife agencies to provide the basis for the issuance of regulatory authorizations for the BDCP.]*

3.5.1 Introduction

The BDCP Conservation Strategy includes a number of conservation measures that address environmental stressors not related to water operations or physical habitat restoration, preservation, or management. Such measures, which are referred to as "other stressor conservation measures," have the potential to improve the quality of Delta's ecological conditions to the benefit of covered fish species. Some other stressor conservation measures are described in Section 3.4.4, *Species Level Other Stressor Conservation Measures*. The Steering Committee indentified additional actions that address other stressors, referred to as "important related actions" (IRAs) that could potentially become conservation measures.

Because of these potential conservation measures could reduce other stressors to benefit ecological conditions in the Delta, the BDCP establishes the requirement that the BDCP Program Manager take the steps necessary, through the adaptive management process, to determine whether these potential conservation measures identified in this section should ultimately be adopted as new conservation measures. The following are potential conservation measures to address other stressors:

- Ammonia Load Reduction;
- Endocrine Disrupting Compounds Load Reduction;
- Agricultural Pesticides and Herbicides Runoff Reduction;
- Stormwater and Urban Runoff Toxic Contaminants Reduction;
- Nonnative Aquatic Organisms Introduction Risk Reduction;
- Nonnative Species Introduction Detection and Response Improvement;
- Nonnative Predatory Fish Harvest Increase;
- Mark-Selective Fishery Implementation; and
- Non-Project Diversions Entrainment Reduction.

The approach to the implementation of these potential conservation measures under the BDCP is described in Section 3.5.2, *Implementation of Potential Conservation Measures to Address Other Stressors*. Descriptions of these additional other stressor conservation measures are provided in Section 3.5.3, *Descriptions of Potential Conservation Measures to Address Other Stressors*.

3.5.2 Implementation of Potential Conservation Measures to Address Other Stressors

The potential conservation measures described in Section 3.5.3, below, may be enacted during the course of Plan implementation through the BDCP adaptive management program (Section 3.7 *Adaptive Management Program*). As monitoring and research improve scientific knowledge about the effects of other stressors on covered fish species, the level of uncertainty will diminish regarding the importance of such stressors for the fish and the effectiveness of actions to reduce such stressors. Through the adaptive management process, measures to address other stressors that are proven to be effective in the conservation of covered fish species will be more fully developed and implemented by the BDCP Program Manager or the Program Manager will seek to have the measures implemented by other entities that has the authority to do so.

In certain instances, the Program Manager may identify mechanisms to create intergovernmental partnerships between BDCP authorized entities and the agencies that have jurisdiction over the environmental effects that the other stressor measures would address. These interagency partnerships may be used to advance studies, actions, and enforcement to reduce the adverse effects of the stressors on fish. The Program Manager, through the BDCP Science Manager, may work with the Delta Independent Science Board, Delta Science Program, State Water Resources Control Board, Regional Water Quality Control Boards, and others to support research necessary to clarify the science and assure implementation of corrective actions related to other stressors.

The Program Manager, BDCP Implementation Board, and BDCP Stakeholder Committee members will work to encourage all state and federal agencies, boards, and commissions that have regulatory authority in the Plan Area to exercise that authority to reduce the impact of other stressors on the covered species and will encourage those entities to provide funding to support those activities in their annual budgets. The Program Manager, Implementation Board, and Stakeholder Committee members will encourage state and federal agencies to seek opportunities to take or support actions that implement BDCP conservation measures that address other stressors. The Program Manager and Implementation Board may consider incorporating new other stressors measures into the BDCP, through the adaptive management process, as they are identified by the state and federal agencies.

The Program Manager, through the Science Manager, will advocate and pursue research to continue evaluation of other stressors and engage the regulatory agencies to take actions based upon improved scientific understanding to reduce the effects of these stressors on the health of at risk fish species in the Delta. The Program Manager will initially focus on ammonia effects on covered fish species and regulatory actions to eliminate those effects.

3.5.3 Descriptions of Potential Conservation Measures to address Other Stressors

*[**Note to Reviewers:** This section will include descriptions of potential conservation measures to address other stressors, i.e., all the Important Related Actions (IRAs).]*

3.5.3.1 Ammonia Load Reduction

3.5.3.2 Endocrine Disrupting Compounds Load Reduction

3.5.3.3 Agricultural Pesticides and Herbicides Runoff Reduction

3.5.3.4 Stormwater and Urban Runoff Toxic Contaminants Reduction

3.5.3.5 Nonnative Aquatic Organisms Introduction Risk Reduction

3.5.3.7 Nonnative Species Introduction Detection and Response Improvement

3.5.3.8 Nonnative Predatory Fish Harvest Increase

3.5.3.9 Mark-Selective Fishery Implementation

3.5.3.11 Non-Project Diversions Entrainment Reduction

3.6 MONITORING AND RESEARCH PROGRAM

*[**Note to Reviewers:** This draft of the Monitoring and Research Program is revised from the July 27, 2009 draft. The two large monitoring actions tables included in this section are initial drafts that will be revised and refined, as described in the Note to Reviewers in Section 3.3. It is expected that a section will be added in future drafts, specifying in more detail the issues to be addressed by the research program and focus for additional research needs.]*

The BDCP Conservation Strategy provides flexibility for adjustments to be made over time as additional information becomes available about the ecological systems and processes of the Delta and the effect of the BDCP conservation measures on those systems and processes. Monitoring and research are critical elements of adaptive management, providing the data and analysis needed to inform decision-making. Information gained through monitoring and research also provides the basis for determining the effectiveness of the Conservation Strategy over time. A well-designed monitoring and research program is essential for the success of BDCP.

Monitoring will play four crucial roles in the implementation of the BDCP. First, it will provide basic information necessary to track Plan commitments and compliance with the terms and conditions of regulatory authorizations. Second, it will provide information about the current state of the system against which change can be assessed. Third, it will provide information about the changing state of the system as conservation actions are implemented that can be used to assess system response and progress toward achieving the Plan's goals and objectives over time. Finally, monitoring provides important information about implementation of conservation measures that can be used to increase their effectiveness.

Program evaluation involves compiling and synthesizing monitoring data to evaluate program success and support adjustments over time, including revising program objectives and actions. Program evaluation will also be used to support the Implementation Office's efforts to communicate information to the public about the status of the BDCP (Section 3.7, *Adaptive Management Program*, discusses the program evaluation).

Information derived from research efforts will provide the basis for addressing key uncertainties and testing hypotheses that underpin various conservation measures. Research supports learning, a better understanding of the processes driving the system, and an improved knowledge base upon which informed decisions can be made regarding management interventions. Given the complexities of the Delta ecosystem, and the uncertainties regarding the outcomes that will result from the implementation of certain conservation measures, research and other information-gathering efforts will help ensure the success of the Plan.

This section describes key elements of the BDCP monitoring and research program, including: the parties responsible for implementing the monitoring program; the framework for integrating monitoring data to support program evaluation and reporting; the manner in which the BDCP monitoring program will interface with other monitoring programs; the types of monitoring that will be conducted; the process that will be used to develop site-specific monitoring plans; and the process that will be used to develop a research program. For more information on the Adaptive Management Program, including the role of monitoring and research in the adaptive management process, see Section 3.7, *Adaptive Management Program*.

Site-specific monitoring plans for each conservation measure, as well as a specific research agenda, will be prepared as part of the BDCP implementation process. These plans will be reviewed on a regular basis and adjustments made in response to new information and/or identified research needs. Plan implementation, monitoring, analysis and research, are all part of an overall adaptive management process. This process is not intended to be a stand-alone process, but rather one that integrates information to facilitate decision making, including decisions to adjust the design and implementation of conservation measures, and the type and extent of monitoring associated with those measures, as the Plan is implemented.

Because the Delta reflects a highly altered ecosystem, with limited reference sites for historical conditions, the monitoring program and the evaluation framework will rely heavily on Before/After and Control/Impact (BACI) design approaches to assess ecosystem change (Green 1979, Underwood 1992, Underwood 1994). Although the BACI approach is typically presented as a means for testing whether an impact to the system has occurred, it is technically a model that tests for changes in conditions. The model may also be used to evaluate conservation and restoration projects (Michener 1997 and Lincoln-Smith et al 2006) and test if conditions are improving. These types of monitoring approaches are commonly used in restoration ecology, particularly where numerous natural and anthropogenic disturbances represent unplanned, uncontrollable events that cannot be replicated or studied using traditional experimental approaches and statistical analyses. Ultimately, experience in restoration ecology suggests using a broad mix of appropriate research approaches (e.g., long-term studies, large-scale comparative studies, space-for-time substitution, modeling, manipulative experiments, and focused experimentation) and analytical tools (e.g., observational, spatial, and temporal statistics) (Michener 1997).

Evaluating discernable changes in environmental conditions is often difficult, due to the multitude of interacting factors. It is often not clear which environmental component will be affected by a stressor reduction and what type of change will result. A changing environment is natural and variation due to natural effects may be great (Smith 2002). To account for this, BDCP monitoring designs will be informed by the location and timing of effects expected to occur (both spatially and temporally), what organisms are expected to be affected (fish, wildlife, plants, aquatic invertebrates, etc.), what the expected benefits are (magnitude, duration), potential mitigating factors (including distribution and exposure), and how various factors may alter exposure and effect.

The BDCP monitoring program will be conducting sufficient baseline monitoring to establish the "before" condition against which change can be compared. This will entail both assessing existing data bases and determining what new measurements will be useful prior to the implementation of a conservation measure.

The monitoring program outlined in this chapter is consistent with the guidance provided by the U.S. Fish and Wildlife Service and the National Marine Fisheries Service in the "Five-Point Policy" for Habitat Conservation Plans (HCP)[38] and provisions of the Natural Community Conservation Planning Act (NCCPA)[39] . As described in the Five-Point Policy, the monitoring

[38] 65 FR 106, June 1, 2000

[39] Fish and Game Code Sections 2810(a)(7)

program of a conservation plan should generate information sufficient to guide plan implementation, particularly with respect to the following matters:

> *"(1) assess the implementation and effectiveness of the HCP terms and conditions (e.g., financial responsibilities and obligations, management responsibilities, and other aspects of the incidental take permit, HCP, and the IA, if applicable); (2) determine the level of incidental take of the covered species; (3) determine the biological conditions resulting from the operating conservation program (e.g., change in the species' status or a change in the habitat conditions); and (4) provide any information needed to implement an adaptive management strategy, if utilized. An effective monitoring program is flexible enough to allow modifications, if necessary, to obtain the appropriate information."*[40]

The BDCP research program will be implemented to address specific scientific questions regarding: (1) covered species; (2) natural communities; and (3) ecosystem processes to increase the base of knowledge about these resources such that conservation measures can be adaptively implemented to advance biological goals and objectives. Specifically, the BDCP monitoring and research program will be conducted primarily to:

- Document compliance with terms and conditions of BDCP regulatory authorizations, including limits established for the incidental take of covered species;
- Increase and refine scientific understanding of the effects of the covered activities (Chapter 4, *Description of Covered Activities*) on covered species and natural communities;
- Collect data necessary to effectively implement conservation measures;
- Document and evaluate the effectiveness of conservation measures in achieving BDCP biological goals and objectives;
- Test the scientific hypotheses on which the assessment of effects and effectiveness are based; and
- Assess progress towards achieving the biological goals and objectives both specific to conservation actions and Delta-wide.

3.6.1 Responsibility for the Monitoring and Research Program

The Implementation Office (IO) Science Manager, under the direction of the BDCP Program Manager, will be responsible for the overall management and oversight of the BDCP monitoring and research programs, including the implementation of monitoring-related activities (see Section 7.3.4, *Management of Biological Monitoring, Scientific Research, and Reporting Programs*). The Science Manager, with the support of the Interagency Ecological Program (IEP), will be responsible for developing and overseeing the implementation of the monitoring

[40] 65 FR 106, June 1, 2000; 35254

and research program activities. The Science Manager may further utilize the Delta Science Program and Independent Science Board to review and provide input on aspects of the monitoring and research program. The IO may look to the Authorized Entities and Supporting Entities (see Chapter 7, *Implementation Structure*) to conduct monitoring activities on specific conservation actions, as appropriate.

The BDCP Science Manager will be responsible for ensuring that the BDCP science activities, reporting, and reviews are coordinated with other science activities being conducted in the Delta. The Science Manager will seek the assistance of the Lead Scientist of the IEP and the Chief Scientist for the Delta Science Program to ensure that BDCP science activities, reporting, and reviews are coordinated with other science activities being conducted in the Delta.

3.6.2 Monitoring Framework

The following outlines a framework for integrating monitoring data to support program evaluation and reporting. The BDCP Evaluation Framework is described in Section 3.7, *Adaptive Management Program*. Specific types of monitoring (baseline, compliance, effectiveness, and system-wide) that will feed the evaluation framework (as well as other plan reporting requirements) are described in more detail in Section 3.6.4, *Types of Monitoring*.

The BDCP monitoring framework as presented herein is modeled after the successful Ecosystem Health Monitoring Program used as part of the Healthy Waterways Initiative in South East Queensland, Australia (South East Queensland Healthy Waterways Partnership 2007). The framework tracks indicators for five basic ecological conditions that collectively reflect the overall health of the ecosystem. For the BDCP, the monitoring and evaluation framework is divided into five ecological categories: (1) ecological processes; (2) physical and chemical conditions (including nutrients); (3) food webs; (4) natural communities; and (5) fish, wildlife, and plants. A select set of key indicators for these five characteristics will be measured for the appropriate geographic area to assess status and trends. Specific indicators, metrics and sampling designs will vary depending on the regional area.

Table 3-18 illustrates how the BDCP monitoring and evaluation framework could be structured. An example of all likely possible monitoring elements was developed for the implementation of a project at Suisun Marsh under the CM4, *Tidal Habitat Restoration*. It is expected that frameworks for other conservation measures will be developed and refined during plan implementation using this as an example of the types of elements that could be included.

Table 3-18. Example Framework For Southern Suisun Marsh Monitoring and Metrics

*[**Note to Reviewers:** Table in development. To come]*

3.6.3 Integration of Monitoring and Research with Other Programs

Monitoring of covered species and many ecosystem conditions that are relevant to BDCP implementation is currently undertaken by a number of entities, including IEP, Delta Science Program, California State University Endangered Species Recovery Program, USGS, DFG, DWR, USFWS, Reclamation, NOAA Fisheries Science Center, and UC Davis. As an example of the types of monitoring data that are currently being collected, Table 3-19 lists some of the fisheries monitoring data that is coordinated by the IEP.[41]

In addition to fish monitoring, there is a considerable amount of water quality monitoring that is currently being conducted in the Delta. The Environmental Monitoring Program (which also monitors lower trophic levels) is part of the IEP, while programs tracking environmental contaminants currently are not. The new Delta Regional Monitoring Program is intended to coordinate these programs.[42] [43]

Most of the existing Delta monitoring efforts are being implemented as conditions of existing regulatory authorizations and many are coordinated under the IEP umbrella. The IEP has been instrumental in coordinating Delta monitoring and research activities conducted by State and federal agencies and other science partners for 40 years. IEP monitoring activities are generally carried out in compliance with Water Right Decision and Endangered Species Act permit conditions. Most of the existing IEP-coordinated monitoring focuses on open water areas and the major Delta waterways conveying water to the SWP and CVP facilities in the south Delta. A new regional monitoring program intended to coordinate Delta water quality monitoring in compliance with Clean Water Act permit conditions is currently under development by the Central Valley Regional Water Quality Control Board. A similar regional monitoring program already exists for San Francisco Bay and is carried out by the San Francisco Estuary Institute, a non-profit research organization.

Due to their permit-driven nature, none of the existing long-term monitoring programs focus explicitly on monitoring ecological processes and habitats. Perhaps as a result, there has never been an integrative "Ecosystem Health" assessment similar to the Australian example mentioned in Section 3.6.2, Monitoring Framework. The "Are Our Aquatic Ecosystems Healthy?" portal[44] currently under development by the California Water Quality Monitoring Council (WQMC) may provide an opportunity to better organize, integrate, evaluate, and communicate data and information about the health of the Delta relative to other aquatic ecosystems in California and changes in Delta ecosystem health associated with the BDCP and other programs. The WQMC is based on an interagency MOU mandated by California Senate Bill 1070 (Kehoe, 2006) and

[41] A more complete summary of the IEP fish monitoring programs can be found at: http://www.water.ca.gov/iep/docs/IEP_FishMonitoring_final.pdf.

[42] For information on this new Delta Regional Monitoring Program see http://www.swrcb.ca.gov/rwqcb5/water_issues/delta_water_quality/comprehensive_monitoring_program/index.shtml).

[43] A recent summary of existing water quality monitoring programs can be found at http://www.swrcb.ca.gov/rwqcb5/water_issues/delta_water_quality/comprehensive_monitoring_program/draftfinal_deltamon_25nov09.pdf

[44] See the portal at http://www.waterboards.ca.gov/mywaterquality/

requires the boards, departments and offices within the California Environmental Protection Agency (Cal/EPA) and the California Natural Resources Agency to integrate and coordinate their water quality and related ecosystem monitoring, assessment, and reporting.

The Science Manager will coordinate with the IEP and other entities involved in monitoring programs and will use data collected through these programs, as appropriate, to support evaluation of the effectiveness of the BDCP Conservation Strategy in achieving biological goals and objectives and to assess the long-term status and trends of covered species populations and ecosystem conditions.

Table 3-19. Sample Listing of Existing Bay-Delta Fish Monitoring Programs Coordinated through the Interagency Ecological Program (IEP)

Monitoring Program	*Agency*	*Primary Purpose*	*Available Data for BDCP*
Spring Kodiak trawl	DFG	Monitors spawning adult delta smelt distribution, relative abundance, and reproductive status, January-May, 2002-present	Spawning abundance index, distribution, sex ratios, reproductive status (e.g., pre-spawn, mature, or spent)
20 mm tow net survey	DFG	Monitors post larval-juvenile delta smelt distribution and relative abundance, March-June, 1995-present	Post larval and juvenile abundance index, distribution, length frequency
Summer tow net survey	DFG	Monitors striped bass and delta smelt abundance indices, July-August, 1959-present	Delta smelt: juvenile delta smelt abundance index, distribution, and length frequency. Longfin smelt: post larval juvenile longfin smelt abundance index, distribution, and length frequency. Sacramento splittail: YOY splittail, distribution, and length frequency
Fall midwinter trawl	DFG	Monitors striped bass and delta smelt abundance indices, September-December, 1967-present	Delta smelt: Pre-adult delta smelt abundance index. Longfin smelt: Pre-adult longfin smelt abundance index. Sacramento splittail: Abundance of all size classes
Smelt larval study	DFG	Monitors longfin smelt larvae distribution and relative abundance, January 2009-present	Larval abundance index and distribution
Bay Study	DFG	Monitors abundance indices for a variety of species in South San Francisco and Suisun Bays, Year-round, 1980-present	Delta smelt: Juveniles-adult delta smelt abundance index. Longfin smelt: Juveniles-adult longfin smelt abundance index. Sacramento splittail: Young of year and older splittail abundance.
Suisun Marsh fisheries monitoring program	UC Davis	Monitors abundance of all fish species in Suisun Marsh, Year-round, 1979-present	Delta smelt: Juveniles-adult delta smelt abundance, distribution within Suisun Marsh. Longfin smelt: Juveniles-adult longfin smelt abundance, distribution within Suisun Marsh. Sacramento splittail: Abundance of all size classes, distribution within Suisun Marsh.
Fish salvage monitoring	DWR, DFG, USBR	Monitors entrainment and salvage of all fish species, Year-round, 1979-present	Delta and longfin smelt: 20 mm post larvae-adult smelt abundance. Sacramento splittail: Abundance of all size classes >20 mm and length frequency. Almonds: >20 mm larvae-adults abundance. Sturgeon: >20 mm juvenile sturgeon abundance.

Table 3-19. Sample Listing of Existing Bay-Delta Fish Monitoring Programs Coordinated through the Interagency Ecological Program (IEP) (continued)

Monitoring Program	*Agency*	*Primary Purpose*	*Available Data for BDCP*
Chips Island, Mossdale, and Sacramento trawls	USFWS	Monitors fish abundance and distribution in mid-channel at surface at Chips Island, Moss dale (RM 54), and Sacramento (RM 55), and survival through the Delta, targets Chinook salmon, Year-round, 1976-present	Almonds: juvenile abundance, distribution, length frequency, survival indices (of hatchery tagged fish) to Chips Island Delta smelt: >25 mm abundance, distribution, and length frequency. Longfin smelt: >25 mm abundance and distribution, and length frequency. Sacramento splittail: >25 mm abundance and distribution, and length frequency.
Beach seines	USFWS	Monitors fish abundance and distribution throughout the Delta, upstream Sacramento River, northern San Francisco and San Pablo Bays, targets Chinook salmon, Year-round, 1976-present	Sacramento splittail: >25 mm young of year splittail abundance, distribution, and size frequency. Almonds: juvenile almonds, abundance, distribution, and size frequency.
Chinook salmon escapement estimates (Grand tab database)	DFG, DWR	Grand tab collects all races of Chinook salmon escapement	Almonds: adult returns to spawning grounds by race and location
Suisun March otter trawl	UC Davis	Monitors abundance of all fish species in Suisun Marsh, Year-round, 1979-present	Chinook salmon: juvenile abundance and distribution within Suisun Marsh
Adult sturgeon tagging study	DFG	Tag-recapture (via creel surveys) of green (prior to being listed) and white sturgeon for abundance and population dynamics	White and green sturgeon: abundance, distribution, population dynamics, length frequency, annual harvest rates, and migration rates.

3.6.4 Types of Monitoring

The Implementation Office will conduct and/or coordinate several types of monitoring to ensure the success of the Conservation Strategy. The general types of monitoring required are described in this section.

3.6.4.1 Preconstruction Surveys

As specified in Section 3.4.5, *Avoidance and Minimization Measures*, preconstruction surveys are required for specifically identified covered species, prior to the implementation of certain covered activities and conservation measures (e.g., water facilities construction or tidal habitat restoration actions that would remove existing terrestrial habitat) that may affect covered species or their habitats.

The potentially affected area will be surveyed to determine if covered species are present and likely to be affected by the activity. Survey results will be used by the Implementation Office to determine the need to implement measures described in Section 3.4.5 to avoid and minimize impacts on covered species and natural communities related to the covered activity or conservation measure. Preconstruction surveys may also be used in measure and record the level of take for a specific action as part of compliance monitoring, discussed below.

Preconstruction surveys may be coupled with baseline surveys, discussed below, as appropriate.

3.6.4.2 Construction Monitoring

Monitoring of construction activities will be conducted during the construction of various proposed facilities (both covered activities and conservation measures), including habitat restoration projects. Construction monitoring is required to ensure that avoidance and minimization measures are properly carried out where specific sensitive occurrences of covered species (e.g., an active nesting site for a covered bird species or a population of a highly restricted covered plant species) have been identified at or adjacent to a construction site. The Implementation Office will: (1) monitor implementation of covered activities to ensure that any applicable avoidance and/or minimization measure is properly and effectively implemented, and (2) ensure that conservation measures are implemented in accordance with specifications and plans.

3.6.4.3 Compliance Monitoring

The purpose of compliance monitoring is to: (1) track progress of BDCP implementation in accordance with established timetables, and (2) ensure compliance with terms and conditions of the BDCP and its associated permits. Compliance monitoring will be undertaken for all conservation measures, whether implemented directly by the BDCP Implementation Office or by other supporting entities through contracts, memoranda of agreement, or other agreements with the BDCP Implementation Office. Compliance monitoring will be conducted to ensure that conservation measures are meeting specified permit terms.

3.6.4.4 Baseline Surveys

Surveys to establish existing baseline conditions are critical to conducting a "before" and "after" comparison of biological and physical conditions related to the implementation of conservation actions and to the evaluation of the effectiveness of those conservation actions (refer to Section 3.6.4.5, *Effectiveness Monitoring*, below). Appropriate statistical designs for baseline surveys and effectiveness monitoring will be established as part of development of action-specific monitoring plans (Section 3.6.6, *Development of Specific Monitoring Plans*). Baseline surveys will be performed prior to implementation of conservation actions with sufficient lead time to allow future detection of changes in trajectories for the expected outcomes after implementation. For example, zooplankton sampling would be conducted in channels adjacent to tidal restoration sites in all seasons for multiple years prior to levee breaching to set the baseline condition. Monitoring sampling of zooplankton would be conducted at the same channel locations immediately following the levee breaching and throughout the natural development period of the restored tidal habitat, to quantify changes in the zooplankton community related to increased food availability.

Baseline and monitoring survey results will be used as the basis for BACI designs intended to evaluate program effectiveness. In some cases baseline monitoring may involve monitoring at reference (control) sites inside or outside the BDCP area (e.g., habitat use in unaffected habitat areas). BACI design approaches may be used where reference sites are limited.

3.6.4.5 Effectiveness Monitoring

Effectiveness monitoring assesses ecosystem, natural community, and covered species responses to the implementation of conservation measures and monitors progress made toward achieving biological goals and objectives. Effectiveness monitoring will occur at two scales: (1) a local scale focused on evaluating the effectiveness of specific individual conservation measures; and (2) a system-wide scale focused on the status and trends in species populations, natural communities, and ecosystem processes within the Plan Area. Each of these effectiveness monitoring scales are described in more detail below.

Effectiveness monitoring will be closely coordinated with baseline monitoring and the BDCP research program to support adaptive management. It is anticipated that the extent of effectiveness monitoring will be reduced over time as causal relationships between the implementation of conservation measures and the responses of covered species and ecosystems to those measures are better understood (as a result of knowledge gained under the BDCP monitoring and research program and other research programs). For example, if relationships between restoration of tidal marsh and zooplankton production are established through monitoring and research on initially restored tidal marshes, then effectiveness monitoring for assessing the production of zooplankton associated with subsequent restoration of tidal marsh may be reduced or no longer required. Effectiveness monitoring will also be spatially stratified to establish the effectiveness of the conservation measures in each Conservation Zone or ecologically relevant portions of the Plan Area.

Conservation Measure Monitoring. Monitoring focused on specific conservation measures will be undertaken for water operations, physical habitat restoration and enhancement, and other stressors conservation measures implemented by the BDCP Implementation Office and Supporting Entities. BDCP covered species will be monitored to assess individual, population, and community responses directly associated with specific conservation measures. Specific attributes of the aquatic ecosystem that are necessary for the survival and recovery of covered fish species will also be monitored as they relate to specific conservation measures. Monitoring at the local scale will also be used to determine whether any desirable or undesirable consequences are occurring in association with the implementation of specific conservation measures.

System-Wide Monitoring. Together with the BDCP research program, system-wide monitoring is intended to complement conservation measure monitoring by evaluating the status of ecological processes, natural communities, and covered species across the Plan Area, and in some cases outside of the Plan Area. Information within the scope of system-wide monitoring includes overall status, distribution of organisms, and trends related to covered species populations. Together with the conservation measure monitoring, system-wide monitoring is intended to help determine causality when examining a potential biological response, or lack thereof, to BDCP actions. System-wide monitoring allows for the evaluation of the collective effects of multiple conservation measures through time and provides information specific to the measuring metrics and the achievement of biological goals.

Consistent with the BDCP goals and objectives, system-wide monitoring will focus on three levels of ecological scale: (1) ecosystem processes (ecological processes, physical and chemical conditions, and food webs), (2) natural communities (including the ecological functions they provide for covered species), and (3) covered species. Each of these is described below.

Ecosystem Processes. Within the BDCP conservation lands and the Plan Area, the Implementation Office will monitor the structure and function of the aquatic ecosystems and the processes that influence these attributes at appropriate time intervals and at appropriate locations, over the term of the BDCP. Monitoring of aquatic ecosystem processes and conditions will provide the BDCP Implementation Office with information necessary to track long-term changes affecting the aquatic ecosystem (e.g., covered activities, climate viability and change, activities of others) and to document the contribution of the BDCP toward maintaining and improving aquatic ecosystem attributes in support of the covered fish species.

The BDCP Implementation Office will use the best available scientific understanding and datasets associated with the Delta aquatic ecosystem to establish markers from which to assess future changes in ecosystem processes, structure and function. Depending on the type and extent of data gaps, the BDCP Implementation Office will at the outset of Plan implementation collect necessary additional information to better understand existing conditions. If strong relationships between the response of specific ecosystem functions and conservation measures are established, the frequency of system monitoring for those monitoring elements of the Plan may be modified by the BDCP Implementation Office.

Natural Communities. The BDCP Implementation Office will monitor the extent and distribution of natural communities within the BDCP conservation lands and within the Plan Area at appropriate intervals over the term of the BDCP, depending on the type of community. Monitoring of covered natural communities will provide the BDCP Implementation Office with information sufficient to track long-term changes in the distribution and extent of covered natural communities attributable to any of a number of factors that may affect the communities (e.g., covered activities, climate variability and change, and activities of others). The results of these monitoring efforts will also provide documentation of the contribution of the BDCP towards maintaining and improving the extent, distribution, and continuity of natural communities. The baseline conditions from which changes in the range and distribution of natural communities will be assessed are the conditions described in Chapter 2, *Existing Ecological Conditions* and Appendix A, *Covered Species Accounts* and in baseline data collected by the Implementation Office early in the implementation period.

Covered Species. The status, distribution, and trends in populations of covered fish, wildlife, and plant species will be monitored within the BDCP Plan Area over the term of the BDCP. This level of monitoring will provide the BDCP Implementation Office with information sufficient to track long-term changes attributable to factors such as covered activities, physical and chemical changes, and climate variability and change that may affect covered species. The results of these monitoring efforts will document the contribution of the BDCP toward the conservation of covered species and inform system-level assessments of status, trends, and distribution. The baseline conditions from which changes in the range and distribution of covered species will be assessed are the conditions described in Chapter 2, *Existing Ecological Conditions* and Appendix A, *Covered Species Accounts* and in baseline data collected by the Implementation Office early in the implementation period.

As part of the covered species monitoring, the BDCP Implementation Office will also review relevant scientific data collected for covered species whose range and life stage distribution extends beyond the BDCP Plan Area as this information becomes available. Review of information gathered outside of the BDCP Plan Area will be sought to further inform assessments of the status and trends relating to covered species within the BDCP Plan Area and for making adjustments to BDCP implementation through the adaptive management process.

Species monitoring will be particularly important for covered fish and wildlife species that are migratory, nomadic, or otherwise highly mobile (i.e., dispersing readily in and out of the Plan Area). For these species, factors external to the Plan Area can readily obscure the type and extent of response to the implementation of the BDCP. For example, it may be that a conservation measure intended to restore habitat for a covered species is not followed by use of that habitat. The apparent lack of response, however, may be due to a population decline of the covered species caused by increased mortality outside the Plan Area. To establish causality, a number of monitoring metrics are needed, making use of cross-system comparisons.

3.6.5 Potential BDCP Monitoring Actions and Metrics

Potential monitoring actions and metrics to be implemented by the BDCP Implementation Office are divided into the same ecological hierarchy as the biological goals and objectives and conservation measures. Potential effectiveness monitoring actions and metrics for conservation measures are presented in Table 3-20 and potential monitoring actions and metrics for system-wide monitoring are presented in Table 3-21. Each potential monitoring action includes a description of existing programs that are currently implementing a portion or all of the monitoring action and how the monitoring information is expected to inform adaptive management decision making. All types of monitoring identified in Section 3.6.4, *Types of Monitoring*, are addressed in these tables. Tables 3-20 and 3-21 illustrate the types of monitoring actions and metrics that could be implemented, however, the Implementation Office will have the flexibility to determine the specific methods for gathering monitoring information and to change monitoring actions and metrics through the adaptive management process (see Section 3.6.6, *Development of Specific Monitoring Plans*, and Section 3.7, *Adaptive Management Program*).

3.6.6 Development of Specific Monitoring Plans

The BDCP Implementation Office will prepare detailed monitoring plans tailored to specific conservation measures and to system-wide monitoring needs based on the monitoring actions and metrics in Tables 3-20 and 3-21. These monitoring plans will be developed prior to implementation of the applicable conservation measures and the plans will include specific experimental and statistical designs to allow analysis of the status and trends of the selected metrics using approaches such as BACI analyses (see the discussion of target research in Section 3.7.5, *Adaptive Management Experiments)*. The monitoring plans will include survey protocols for efforts related to preconstruction, construction, compliance, effectiveness, and system-wide monitoring. In most instances, existing and generally accepted monitoring protocols (e.g., USFWS survey protocols for listed species, and protocols for monitoring status and trends in abundance and distribution of covered fish species) will be adopted by the BDCP Implementation Office, as appropriate. In some cases, however, the Implementation Office will need to develop specific monitoring protocols to assess a conservation measure.

The specific contents of each specific monitoring plan may vary depending on its purpose. The monitoring plans, however, will generally include the following types of information:

- Description of the purpose and objectives of the monitoring (e.g., assessing progress towards achieving a biological objective);
- Description of monitoring protocols, including sampling design and justification supporting the validity of monitoring methods and sampling design;
- Analytical methods for assessing monitoring results;
- Procedures for validating monitoring data and methods;
- Monitoring schedule, duration, and rationale;
- Spatial sampling scheme;
- Content requirements and submission schedule for monitoring reports;
- Monitoring data storage and management procedures;
- Analytical methods for the assessment of data and presentation of results;
- References, including printed references and personal communications;
- Provisions for documenting subsequent revisions to the monitoring plan; and
- Other information pertinent to specific monitoring plans.

Monitoring provides the necessary information to make adjustments in the implementation of the Plan and to measure progress toward achieving the BDCP biological goals and objectives; therefore, monitoring plans must be based on the best available information and subject to rigorous standards, including statistically sound sampling designs. To ensure defensibility of the

BDCP monitoring plans, protocols, and sampling designs, the Implementation Office will provide for internal science-based review of these monitoring elements as a routine matter and the overall plans will be examined by external science review as necessary and appropriate.

3.6.7 Research Program

While habitat conservation plans and natural community conservation plans are not specifically required to include research programs, the ecological complexity of the Delta and the level of uncertainty regarding the level of anticipated beneficial outcomes for covered species resulting from some of the conservation measures highlight the need for targeted research to better inform BDCP implementation and monitoring and adaptive management decision making. Existing research programs (particularly those funded under the IEP and Delta Science Program) have produced a broad range of valuable information. The BDCP Science Manager will identify research priorities to address specific uncertainties and provide funding for research to support more effective implementation of the Conservation Strategy. The Science Manager will coordinate with other entities, including IEP and the Delta Science Program to identify research needs and priorities. Many of the uncertainties and research needs are stated within the BDCP conservation measures in Section 3.4, *Conservation Measures*.

The following provides a preliminary description of how the BDCP will approach its research program. Additional details regarding the research program will be developed as proposed conservation measures are further refined and site-specific designs are developed, including the development of experimental designs to be incorporated with program implementation to support the adaptive management process.

BDCP Implementation Office may undertake or contract focused research to develop information necessary to better inform BDCP implementation. The types of research that may be conducted include those related to resolving BDCP-specific questions and needs related to:

- Key ecological processes and controls on these processes;
- Technologies and methods for effectively implementing and measuring the outcome of conservation measures;
- Development of new and more sensitive indicators and metrics;
- Improving understanding of the ecological requirements of covered species as they relate to effective implementation of conservation measures;
- Modeling and assessing responses of covered species to conservation measures;
- Determining causal relationships between ecological stressors and drivers and changes in natural communities and covered species; and
- Identify and evaluate tradeoffs among conservation measures.

Each conservation measure in Section 3.4, *Conservation Measures*, include discussions of hypothesized benefits of the measures that are testable under the either the monitoring program or the research program. Results of research would also be used to help direct and prioritize subsequent implementation of conservation measures through the adaptive management process.

The BDCP Implementation Office will use and maintain existing analytical tools (e.g., the DRERIP conceptual models and hydrologic models such as CALSIM, DSM2, and RMA), as appropriate, may also develop or participate in the development of models and other analytical tools to help inform BDCP implementation and support the adaptive management process. These analytical tools include current models and development or improvement of relevant deterministic, statistical, and conceptual models and exploring correlations and the cause and effect relationships between various components of the Delta ecosystem. To develop these modeling and analytical tools, the BDCP Implementation Office may conduct studies to collect information necessary for development of the tools. Additionally, it is anticipated that the BDCP Implementation Office will also participate in revising and improving existing tools (e.g., hydrologic and hydrodynamic models, DRERIP conceptual models) as new capabilities become available over the term of the BDCP.

3.6.8 Database Development and Maintenance

The BDCP Implementation Office will develop and maintain a comprehensive spatially-linked database to track implementation of all aspects of the BDCP. The database would be structured to be "user friendly" and to allow for future expansion and integration with external databases (e.g., linkage to databases of the Delta Science Program, and California Water Quality Monitoring Council). The database would look to other well recognized database management examples such as the Consortium of Universities for the Advancement of Hydrologic Science and the U.S. Long Term Ecological Research Network, which are leaders in multiple facets of data management in the environmental sciences. Functions that the BDCP database would be expected to support include:

- Data documentation such that future users can determine why, how, and where data were collected (i.e., metadata);
- Quality assurance and control of the data and data entry;
- Access to and use of the most current information for analysis and decision making; and
- Evaluation of data by all users, as appropriate, and incorporation of corrections and improvements in the data.

Major types of information expected to be maintained within the database include:

- Monitoring, research, and adaptive management experiment data and results;
- Modeling inputs, outputs, and results;

- Status of covered activities, including implementation and impacts;
- Implementation status of conservation measures;
- Implementation status of research and adaptive management experiments;
- Adopted changes to BDCP implementation through the adaptive management process; and
- All reports and documents generated by the Implementation Office and relevant data and reports generated by other entities.

The BDCP Implementation Office may choose to develop a web-linked database to facilitate controlled transference of information into and out of the database by other entities. If the BDCP Implementation Office chooses to allow access to the database by others, the database will incorporate strict controls and monitoring to ensure the integrity of the database is maintained.

The BDCP Implementation Office will ensure quality control of all monitoring data and will adopt procedures to maintain high standards of quality. Steps will be instituted to maintain the accuracy and functionality of gages, meters, and other devices, and protocols will be established to govern the collection, transcription, and storage of data. All monitoring data will be entered into database software and will be made readily available online once quality control analyses have been conducted.

The BDCP Implementation Office will use standard analytical procedures where such procedures exist. Particular analyses would be specific to individual monitoring parameters and would consist of classical parametric or non-parametric hypothesis testing and statistical models (e.g., t-tests, ANOVAs, correlations, regressions, etc.) to the extent practicable. If advanced statistical methods are necessary (e.g., multivariate ANOVAs, principal components analysis, Bayesian statistics, etc.), the BDCP Implementation Office would consult with experts to ensure proper analyses are being conducted. For many parameters, due to high environmental variability, time series analyses will be necessary to assess with confidence whether a trend in a parameter depicts a change that has occurred as a result of a BDCP action. Results of the analysis of monitoring data will feed back into the BDCP adaptive management process to modify and refine conservation measures to maximize benefits to and minimize unanticipated adverse effects on covered species and other components of the aquatic community.

3.6.9 Monitoring and Research Schedule

Following the signing of the Implementing Agreement and authorization of the BDCP, the Implementation Office will develop detailed monitoring plans and schedules for compliance and effectiveness monitoring. In addition, site-specific monitoring schedules will be developed for each BDCP conservation area as they are protected, enhanced, and restored.

3.6.10 Reporting and Science Communication

Requirements for the Reporting of monitoring results are provided in Chapter 6, *Plan Implementation.* The BDCP Implementation Office will regularly prepare implementation reports that describe survey, monitoring, research, and experimental activities and results over the term of the BDCP. Regular reporting requirements are described in Section 6.2, *Compliance and Progress Reporting*. The Implementation Office will also support peer-reviewed publications, seminars, and conferences like the Delta Science Conference and State of the Estuary Conference as additional mechanisms for communicating information and results. These approaches tend to foster the level of synthesis and integration needed to support an adaptive management approach.

*[**Note to Reviewers:** This table presents in-progress draft potential effectiveness monitoring actions for each BDCP conservation measure. This table will continue to be refined and populated to ensure that all of the effectiveness monitoring, including incorporation of metrics from the logic chain, are addressed.]*

Table 3-20. Potential Effectiveness Monitoring Actions for Conservation Measures

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Ecosystem-Level Conservation Measures				
CM1: Water Facilities and Operation				
Monitoring Action CM1-1. Document the operation of the new water diversion facility in the north Delta with multiple intakes and fish screens and an isolated conveyance facility while maintaining sufficient bypass flows for covered fish species.				
Base condition: As-built construction drawings. **Approach**: Record amounts and timing of water diversion and conveyance, record bypass flows at automated monitoring stations downstream of the last intake. **Schedule:** real-time data compiled for daily summaries.	**Existing Programs:** 1. Continuous Multi-parameter Monitoring, Discrete Physical /Chemical Water Quality Sampling (Environmental Monitoring program; IEP) 2.Continuous Recorder Sites (DWR, USBR) 3. National Pollutant Discharge Elimination System (NPDES) Self Monitoring Program (Central Valley Water Board) 4. Delta Flows Network and National Water Quality Assessment Program (USGS) 5. other (DWR, SRCSD, SWAMP, Central Valley Water Board, State Water Board, SFEI, etc) **Potential Program Additions:** add automatic water monitoring stations at each intake as needed.	1. Hourly Intake (cfs) 2. Bypass flow (cfs) downstream of last intake	This monitoring action will provide real-time data on the amount of water diverted by the north Delta diversion facility, and the amount of water that bypasses the facility. This information will be used by the Implementing Office to determine of water operations adhere to existing target levels. The monitoring schedule may be adjusted to better estimate diversion and bypass flows.	ECSY2.1 ECSY2.2 ECSY2.3 ECSY2.4 ECSY2.5 CHSA1.5 GRST1.1 RILA1.4 PALA1.4

Table 3-20. Potential Effectiveness Monitoring Actions for Conservation Measures (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM 1-2: Record and quantify the number of fish impinged at intakes of the new water diversion facility in the north Delta.				
Base condition: As-built construction drawings. **Approach**: Time stratified sampling; record number, size, species and life stage, reproductive status of impinged fish at intake screens; Install underwater monitoring cameras at fish screens to examine fish behavior at intake screens **Schedule:** Daily	**Existing Programs:** Protocols, equipment and skilled personnel working at CVP and SWP facilities (south Delta) **Potential Program Additions:** Equipment and staff to monitor north Delta diversion facility using identical protocols; protocols for analyzing video sequences of underwater cameras	1.Number of fish 2. Species 3. Life stage 4. Reproductive status	This monitoring action will provide data on impingement of covered fish species at the North Delta facilities. This information will be used by the Implementing Office to determine if the existing fish screens perform to meet target thresholds. It will also provide insights in fish behavior at intakes and will be used to evaluate and redesign fish screens if necessary. The monitoring schedule may be intensified if large numbers of fish are impinged at any given time/season.	CHSA1.6 STEE1.5 SASP1.4 GRST1.4 WHST1.4
Monitoring Action CM 1-3: Record and quantify the number of fish entrained at the south Delta SWP and CVP pumping facilities.				
Base Condition: Current levels of entrainment **Approach:** Use existing protocols and sampling procedures, continue to collect entrainment and salvage data at CVP and SWM pumping stations. **Schedule:** ongoing, daily	**Existing Programs:** Ongoing fish sampling at pumping facilities, IEP Monitoring (Fishery Improvements) coordinated with DWR, DFG, USBR, UCD, and other federal, state, and local agencies. **Potential Program Additions:** None	1. Monthly salvage density (fish/cubic foot per second [cfs] 2. Estimated entrainment (numbers) 3. Estimated impingement (numbers) 4. Species composition 5. Size distribution of individual species	This monitoring provides information about the seasonal distribution and amount of fish losses due to entrainment at pumping facilities The Implementation Office will use this information as input in population and life-cycle models of covered fish, and to determine if fish salvage and screening perform at expected target levels. This monitoring activity is already adaptively scheduled by adjusting sampling according to the number of fish entrained and by flow. Modification of this sampling is not expected. Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM1-4: Document diversion operations to ensure target flows in Old and Middle Rivers.				
Base Condition: Pre-implementation flows of Old and Middle Rivers. **Approach:** Use existing network of fixed-site sampling stations to collect time-histories of water quality variables. Derive flux between regions in the Delta through these key channels. **Schedule:** Within 1 year of initiation of the South Delta Diversion Operational Limits, operate monitoring sites and track flow on a daily basis.	**Existing Programs:** 1. Continuous Multi-parameter Monitoring, Discrete Physical /Chemical Water Quality Sampling (Environmental Monitoring program; IEP) 2.Continuous Recorder Sites (DWR, USBR) 3. National Pollutant Discharge Elimination System (NPDES) Self Monitoring Program (Central Valley Water Board) 4. Delta Flows Network and National Water Quality Assessment Program (USGS) 5. other (DWR, SRCSD, SWAMP, Central Valley Water Board, State Water Board, SFEI, etc) **Potential Program Additions:** **1.** If needed, add complementary stations to track water flows within Old and Middle River. see also Monitoring Action CM4-4 and Monitoring Action CM4-6.	1. Flow dynamics (velocity and volume of flows, direction) in Old and Middle River	This monitoring action will provide information regarding the effectiveness of adaptive operational changes of Old and Middle River flows (by modifications in export rates and reverse flows). The Implementing Office will use this information to determine if flow rates are within adaptive range limits. The schedule for monitoring may be changed if flow dynamics are found not to be within not adaptive range limits.	ECSY2.1 ECSY2.2 ECSY2.3 ECSY2.4 ECSY2.5 CHSA1.5 STEE1.3 PALA1.4 RILA1.4

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM1-5: Document fish migration and hydrodynamics (including hydraulic residence time) resulting from Delta Cross Channel operations (increasing the duration of Delta Cross Channel closure).				
Baseline Condition: Current knowledge of migration routes of covered fish species; if necessary determine proportion of covered juvenile fish (salmonids and sturgeon) migrating through the interior Delta and the mainstem of the Sacramento River. **Approach**: Conduct tracking (e.g., radio-telemetry, acoustic tracking, or other appropriate methods) of juvenile winter-run Chinook salmon, green and white sturgeon, and other species as appropriate to determine the proportion of fish migrating through the mainstem Sacramento River and tributaries and the interior of the delta and their survival. Compare water quality and organic food indices among migration routes and under different flow regimes and Cross Channel gate operation. **Schedule**: During migration track marked fish daily. Aggregate data by month and derive mortality estimates for fish in each migration route (mainstem vs interior).	**Existing Programs:** 1. Previous salmon survival and migration studies (e.g., USFWS, Perry et al. 2010), ultrasonic recorder stations (USGS & California Bay-Delta Authority). 2. Water quality monitoring sites within the Delta (see CM1-1). **Potential Program Additions:** Implement a routine juvenile fish migration and survival tracking program by experimentally releasing tagged fish to determine the effects of Cross Channel Closure on survival.	1. Migration routes (% individuals moving through the mainstem) by juvenile salmon and sturgeon 2. route- and species-specific survival estimates 3. Hydraulic residence time 4. Flows and downstream transport of fish eggs, larvae, juveniles, organic material, phytoplankton, and zooplankton, within the Sacramento River into the Delta.	This monitoring will provide information on the effectiveness of Delta Cross Channel closure to increase covered fish survival and by improving downstream transport of fish eggs, larvae, juveniles and organic food resources. Results of this monitoring will be used within the BDCP adaptive management framework to refine and modify seasonal operations of Delta Cross Channel gates. The schedule of monitoring may be adaptively altered if data resolution requirements are not met or when a clear relationship between Delta Cross channel operation, covered species survival and transport, and tidal flows is established and can be predicted robustly and with low uncertainty. Monitoring Action CM1-6: Document achievement of minimum flow requirements at Rio Vista to support fishery and aquatic habitat in the reach of the Sacramento River between Sacramento and Rio Vista.				
Base Condition: Existing data and modeling results for flow statistics of the Sacramento river between Sacramento and Rio Vista **Approach:** Using the existing network of fixed-site sampling stations, collect time-histories of water quality variables. Derive flow rates. **Schedule:** Operate monitoring sites and track flow on a continuous basis for at least 5 years or until a robust predictive model can be derived from the monitoring data that allows forecasting of flow rates as a product of operational and other variables.	**Existing Programs:** 1. Continuous Multi-parameter Monitoring, Discrete Physical /Chemical Water Quality Sampling (Environmental Monitoring program; IEP) 2.Continuous Recorder Sites (DWR, USBR) 3. National Pollutant Discharge Elimination System (NPDES) Self Monitoring Program (Central Valley Water Board) 4. Delta Flows Network and National Water Quality Assessment Program (USGS) 5. other (DWR, SRCSD, SWAMP, Central Valley Water Board, State Water Board, SFEI, etc) **Potential Program Additions:** 1. If needed, add complementary stations to track water flows within The Sacramento River between Sacramento and Rio Vista. see also Monitoring Action CM4-4 and Monitoring Action CM4-6.	1. Flow dynamics (cfs) of the Sacramento River reach between Sacramento and Rio Vista.	This monitoring action will provide information regarding the effectiveness of adaptive operational changes to ensure minimum flows at Rio Vista to support fishery and aquatic habitat in the reach of the Sacramento River between Sacramento and Rio Vista. The Implementing Office will use this information to determine if flow rates are within adaptive range limits. The schedule for monitoring may be changed if flow dynamics are found not to be within not adaptive range limits.	ECSY2.1 ECSY2.2 ECSY2.3 ECSY2.4 ECSY2.5 CHSA1.5 STEE1.3 GRST1.1 RILA1.4 PALA1.4

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM1-7: Monitor Delta outflows during the near-term implementation period for environmental benefits.				
Base Condition: Current Delta Outflows; seasonal position of 350 µS/cm EC isohaline (X2). **Approach**: Continue monitoring salinity via the fixed water quality stations throughout the Delta. Obtain Daily and seasonal dynamics to determine if and when Delta outflows are below target levels. **Schedule:** Daily monitoring via fixed station network.	**Existing Programs:** 1. IEP Monitoring Data– daily average surface salinity at fixed stations along the Sacramento River interpolated to determine the location of 350 µS/cm EC isohaline. 2. DSM2 Simulations – daily average, depth-averaged salinity at fixed locations (every DSM2 node) along the Sacramento River is interpolated to determine the location of 350 µS/cm EC isohaline. **Potential Program Additions:** none	1. Daily average surface salinity at fixed stations. 2. Interpolated position of the isohaline (X2), expressed in miles from the Golden Gate Bridge. 3. Net Delta Outflow Index	This monitoring action will provide information on the magnitude of Delta outflow and related parameters (salinity intrusion). It will track the position of the isohaline Based on results and analysis of monitoring data, adaptive modifications to management of Delta outflow under the BDCP adaptive management framework could occur by modifying operational criteria by season or water-year type (hydrology). The schedule of monitoring actions may be altered to improve precision and accuracy of estimating the position of the isohyaline.	ECSY2.1 ECSY2.2 ECSY2.3 ECSY2.4 ECSY2.5 CHSA1.5 STEE1.3 GRST1.1 RILA1.4 PALA1.4
Monitoring Action CM1-8: Record in-Delta agricultural, municipal, and industrial water quality.				
Base condition: Current water quality monitoring **Approach**: Continue current water quality monitoring as mandated by existing D-1641 North and Western Delta agricultural and municipal and industrial (M&I) standards and all water quality requirements contained in the North Delta Water Agency/DWR Contract and other DWR contractual obligations. **Schedule:** as currently implemented.	**Existing Programs:** 1. Continuous Multi-parameter Monitoring, Discrete Physical /Chemical Water Quality Sampling (Environmental Monitoring program; IEP) 2.Continuous Recorder Sites (DWR, USBR) 3. National Pollutant Discharge Elimination System (NPDES) Self Monitoring Program (Central Valley Water Board) 4. Delta Flows Network and National Water Quality Assessment Program (USGS) 5. other (DWR, SRCSD, SWAMP, Central Valley Water Board, State Water Board, SFEI, etc)	1. EC (salinity) 2. Water temperature (°C) 3. mg/L dissolved oxygen 4. Turbidity (NTUs) 5. Concentration (µg/L) of ammonia, pyrethroids, copper, organophosphates 6. pH 7. mg methylmercury/L	This monitoring action is intended to collect data necessary to determine if salinity conditions are meeting contractual and legal requirements. This information will be used to address deviations from salinity target conditions, and design modifications and/ research studies to address uncertainty in salinity control. The monitoring schedule may be adjusted in response to monitoring results to better understand causal relationships between water management and salinity.	CHSA1.3

Table 3-20. Potential Effectiveness Monitoring Actions for Conservation Measures (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM 1-9: Document and quantify effects of modified/reduced operations the Montezuma Slough Salinity Control Gate for covered fish species passage and salinity				
Base Condition: current operation and flows (local current patterns and tidal hydrodynamics). **Approach**: continue to monitor and calculate water quality and flow parameters through Suisun March and at Chipps Island (Delta Net outflow index), continue IEP Suisun Marsh fish monitoring (otter trawls and beach seines) **Schedule**: instantaneous automatic 15 min interval recording of salinity data, Seasonal fish abundance as currently conducted by IEP.	**Existing Programs:** IEP coordinated programs: 1. Suisun Marsh Water Quality Monitoring and Compliance (five compliance stations); 2. Aquatic Monitoring by University of California Davis (UCD) and DFG in Suisun Marsh (otter trawls and beach seine) **Potential Program Additions:** none	1. Catch per unit effort (CPUE) and % change (over baseline conditions) of outmigrating juvenile salmonids and sturgeon in Suisun Marsh; 2. Catch per unit effort (CPUE) and % change (over baseline conditions) of splittail, salmonids, and sturgeon in existing and future restored intertidal marsh habitats in Suisun Marsh (see also CM 4-5). 3. Salinity levels within Suisun marsh and in adjacent Delta channels 4. Flow (cfs) in Montezuma Slough	This monitoring action provides information on the effects of changing or eliminating salinity control gate operations in Montezuma Slough on covered fish species and salinity levels within the Delta. In the event that the control structure remains in place and the gates are opened, results of monitoring could be used in the future to adaptively manage the control gates (resume gate operations) if unexpected undesirable consequences are detected. If the control structure is removed, adaptive management of salinity regimes will require modifications of Delta outflow to manage salinity within the marsh. The monitoring schedule may be adjusted to better inform management decisions if deemed necessary.	CHSA1.1 STEE1.1 STEE1.3 RILA1.4 PALA1.4

Monitoring Action CM2-3: Document the effects of the Yolo Bypass modifications to improve distribution (e.g., wetted area) and hydrodynamic characteristics (e.g., residence times, flow ramping, and recession) of water moving through the Yolo Bypass.				
Base conditions: as-built construction drawings; current extent of Yolo bypass inundation and hydroperiod **Approach:** Document and quantify grading, removal of existing berms, levees, and water control structures, construction of berms or levees, re-working of agricultural delivery channels, and earthwork or structures by remote sensing data and field observations entered into GIS. Record and quantify the hydrodynamic characteristics of the Yolo basin by flood and spill gages and satellite imagery LANDSAT or similar to estimate extent of wetted area). Develop correlation between the extent wetted, hydrodynamic indicators and flood gage measurements. Update GIS database if lands are acquired in fee-title or through conservation or flood easements. **Schedule:** Daily monitoring of flood gauges, weekly acquisition of remote sensing data, until a correlation can be established between stage at various flood gauges and hydrodynamic measures.	**Existing Programs:** Yolo bypass inundation gauging stations at Fremont weir (USGS), Sacramento Weir (USGS) and Lisbon (DWR). Potential GIS capability with DWR IISS section within DWR-DES **Potential Program Additions:** Development of spatial databases and mapping capabilities including photo-interpretation (GIS lab)	1. Yolo bypass wetted area 2. Residence times 3. Flow ramping rate (change of water flow cmps/hr hour) 4. Recession timelines	This monitoring action will provide information on the relationships between the hydrological conditions within the Yolo bypass as they pertain to fish habitat, and flood gage information provided throughout the basin. This information will be used to determine the operational constraints and effectiveness of gate and spill operations of the Fremont weir and flow obstruction removals within the floodplain. It will also be used to assess if additional floodplain modifications are necessary to reduce flow and inundation impediments, and to address erosion and other issues. The monitoring schedule may modified once robust, statistically significant and precise correlations have been verified. Monitoring Action CM2-5: Document Stilling Basin Modification and assess risk of covered fish stranding.				
Base conditions: As-built construction drawings **Approach**: Document the physical changes in stilling basin topography. Estimate the number of fish stranding in the stilling basin as flows are receding by electro-fishing, beach seining or other appropriate method. **Schedule:** Sample if standing water remains within the basin after weir spills have ceased and floodplain drainage has begun.	**Existing Programs:** Intermittent and historical IEP and USFWS beach seine and trawling methods within the Yolo and Sutter bypasses **Potential Program Additions:** Fish sampling of stilling basin to verify stranding. See CM5-2	Number of fish Size species	This monitoring action will provide information to assess if the basin drains sufficiently into the deep fish passage channel and thus will prevent stranding of juvenile and adult fish. Information from this monitoring action will be used by the Implementing Office to assess the risk of stranding at the stilling basin, and to guide the redesign if necessary, if significant numbers of fish are found to be stranded in the basin after re-contouring. The monitoring schedule will be reduced to annual visits at the end of the inundation period once fish escape of from the basin has been verified with low uncertainty. Monitoring Action CM 2-11: Determine zooplankton and invertebrate production rates during periods the Fremont Weir is operated.				
Base Condition: existing data on Yolo Bypass zooplankton productivity **Approach:** Establish monitoring stations at inflow and outflow locations and within the inundated floodplain of the Yolo bypass. Take weekly grab samples and measurements of chlorophyll a and zooplankton. **Schedule:** Conduct sampling for the first 5 years following reestablishment of tidal flow and every 5 years thereafter.	**Existing Programs:** Environmental Monitoring Program (EMP, under IEP) **Potential Program Additions:** **1.** Additional sampling stations in the Yolo Bypass floodplains t reflect the before-after-control-impact design. Locations of some added stations will be fixed during the duration of the plan (systemwide monitoring to detect increase on food availability in delta waterways), others are added to account for different flow rates and inundation depth in dry vs wet years to track how food production develops over time. Sampling stations will also provide water quality data (e.g., temperature, turbidity, pH for ammonia conversion, amount of organic carbon) Invertebrate sampling should be adaptively adjusted to changes in fish diets – see also: Monitoring Action CM4-4, CM4-6, and CM16-5	1. Phytoplankton species composition/relative abundance 2. Phytoplankton density (mg/L chlorophyll a) 3. Zooplankton species composition/relative abundance 4. Zooplankton density (number/1,000 m^3)	This monitoring action is intended to collect data necessary to determine and quantify the degree to which the Yolo bypass is producing and exporting phytoplankton and zooplankton into the Delta. This information, in combination with evaluation of other foodweb-related monitoring and research data, will provide the basis for : 1. Identifying sources of uncertainty and the design of management experiments and/ research studies, to address uncertainty. 2. evaluating underlying conceptual models and hypotheses (source-sink dynamics, variability and uncertainty in primary production response) 3. evaluating restoration design options to increase the production and export of primary production inundated floodplains 4. Implementing additional management actions to improve production and export of primary production from the floodplain. The monitoring schedule will be modified if uncertainty or variances do not support a clear causal relationship between floodplain inundation and food production and - exports. Table 3-20. Potential Effectiveness Monitoring Actions for Conservation Measures (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM 2-12: Determine growth rates of juvenile salmonids entering the Yolo Bypass during periods of Fremont Weir operation.				
Base condition: Current studies and knowledge about salmon growth and survival in the Delta and the Yolo bypass. **Approach**: Conduct routine mark-recapture and radio-telemetry tagging experiments by marking juvenile salmon within the Yolo bypass and measuring survival and growth rates at Chipps Island **Schedule**: annually mark and radio-tag individual Chinook for at least 5 years. Repeat mark-recapture monitoring every 5th year	**Existing Programs:** IEP mid-water trawl at Chipps Island, previous salmon survival studies (Perry et al 2009) **Potential Program Additions:** 1. routine radio-tracking and mark recapture program	1. survival rates 2. growth rates (mm/d)	This monitoring action provides information on the effectiveness of modifying the Fremont weir to benefit survival and growth rates of juvenile outmigrating Chinook salmon. The implementing Office will use this information to determine if operation of the Fremont weir is achieving target levels of survival and growth. The information will also ser as a basis to determine f additional research should be conducted, and if initial models and hypotheses are supported by monitoring data. The monitoring schedule may be extended if survival and growth data are inconclusive to determine that survival and growth has achieved target levels or of substantial environmental variability has increased the level of uncertainty associated with predicted outcomes. Monitoring Action CM 2-16: Determine the distribution and abundance of giant garter snake in the Yolo Bypass.				
Base Condition: none **Approach**: Using accepted survey protocols, conduct randomized, stratified surveys to detect presence of GGS in the Yolo Bypass, especially using known or historical locations as starting points and radiating outwards from there. **Schedule**: Annual surveys during periods of GGS activity. Continue for at least 5 inundation years. Repeat every 5 years, focusing on verifying presence in previously established occurrences.	**Existing Programs:** historical surveys, research projects, approved sampling protocols. **Potential Program Additions:** 1. Standardized surveys for Giants Garter Snake 3. Establishment of new sampling points/grids/stations as habitat patches are restored and populations expand See Monitoring Action CM4-8 , 4-14	1. Presence and sex/age distribution of Giant Garter Snake 2. Estimated population trend Giant Garter Snakes in restored habitats (source or sink?)	This monitoring action is intended to collect data on the distribution and population trend of giant garter snake in the Yolo Bypass. Monitoring results will be used to determine if habitat restoration has a source or sink effect on the abundance of giant garter snake in the Yolo Bypass This information is necessary to determine if adaptive changes to the implementation schedule or additional measures may be necessary to increase the abundance and viability of giant garter snake populations in the Yolo Bypass	TANC1.1 FMNC1.1 FMNC2.1 NANC2.1 NWNC2.1 ALNC1.2 ALNC1.5 ALNC1.7 ALNC1.8 GGSN1.1 GGSN2.1
Monitoring Action CM 2-17: Determine abundance of wintering waterfowl and shorebirds in the Yolo Bypass during years the Fremont Weir is operated.				
Base Condition: Current waterfowl monitoring as conducted by USFWS, CDFG and CWA **Approach**: Continue USFWS and CDFG special fall and midwinter aerial surveys. The midwinter survey, the longest running population assessment, focuses on all ducks, geese, swans, and coots. **Schedule**: Annual mid-winter surveys as currently implemented by USFWS.	**Existing Programs:** USFWS midwinter waterfowl surveys **Potential Program Additions:** none	1. Number 2. Species 3. sex/age composition (if possible)	This monitoring action provides information on the abundance of wintering waterfowl. The Implementation office will use this information to determine the effectiveness of inundation of the Yolo bypass ion providing wintering habitat for waterfowl. The Monitoring schedule may be changed if necessary to improve accuracy and/or precision of waterfowl estimates.	MWNC1.1 MWNC1.2

CM3: Protect Natural Communities				
Action CM3-1 Record the acquisition or protection of parcels by conservation zone, natural community, and covered species habitat.				
Base Condition: Pre-acquisition parcel information. **Approach**: Document and record in a suitable database the characteristics of protected land as they are added to the conservation lands system **Schedule:** Update maps and database of conservation lands annually to reflect status of each parcel as they are added to the conservation land system.	**Existing Programs:** DWR IISS section within DWR-DES (potentially) **Potential Program Additions:** 1. Development of spatial databases and mapping capabilities including photo-interpretation (GIS lab)	Acres of land protected by Conservation Zone / ROA and natural community Linear miles of edge within tidal mudflat habitats as habitat for tidal-mudflat associated species (e.g., Delta tule pea, Suisun marsh aster)	This monitoring action will provide the means to track how the Implementing Office is adding conservation lands in each Conservation Acquisition zone. This information will be used to assess progress and determine if conservation targets in each CAZ and natural community have been met.	ECSY1.1 ECSY1.2 GRNC1.1 VPNC1.1 ALNC1.1-1.6
Monitoring Action CM 3-2: Record, quantify and delineate occurrences of covered plant species.				
Base Condition: Pre-acquisition parcel information. Baseline survey of parcels at acquisition **Approach**: Document and record in a suitable database the characteristics of rare species occurrences on BDCP protected lands **Schedule**: Survey once every 5 years to document presence and condition/abundance of special status plants	**Existing Programs:** DWR IISS section within DWR-DES (potentially) **Potential Program Additions:** 1. Development of spatial databases and mapping capabilities including photo-interpretation (GIS lab) 2. Special status surveys and species verifications by a qualified botanist	Species occurrences: 1. Location 2. Species 3. Habitat 4. Number of individuals 5. Land use 6. Threats	This monitoring action will provide information on the presence and status of special-status plants on conservation lands within the BDCP Plan Area. This information will be used in the development of specific management plans for each parcel to ensure that management and protection activities are compatible with special-status plants and these plants are protected and maintained. The monitoring schedule will be altered for species that are dependent on specific climatic events or conditions (i.e. vernal pool plans require "wet" years to emerge)	ALMV1.1 AWNC1.1 CAGB1.1 CFTR1.1 DEBC1.1 HART/ BRIT1.1 HEPE1.1 SOBB1.1 SUTH1.1

Monitoring Action CM 3-3: Document habitat connectivity among the various BDCP conservation land units in the conservation land system.				
Base Condition: Pre-acquisition parcel information. Baseline documentation **Approach**: Document and record in a suitable database evidence of connectivity and movement of animals and plants across conservation land habitats. **Schedule**: Update maps and database of conservation lands annually to reflect the conservation status of adjacent lands and the location of newly arriving species of interest.	**Existing Programs:** DWR IISS section within DWR-DES (potentially) **Potential Program Additions:** 1. Development of spatial databases and mapping capabilities including photo-interpretation (GIS lab)	Land status and changes in natural communities on adjacent parcels Species occurrence of newly arriving species Observed shifts in species distribution and use of the parcel.	This monitoring action will identify how well the protected lands are connected with adjacent habitats to enable species to move across the landscape. This information will be used to determine where uncertainties and knowledge gaps exists regarding the connectivity of habitats within the BDCP Plan Area, and where corridors for covered and invasive species exist. This information will be used to determine appropriate management strategies to support covered species and reduce the likelihood of dispersal of non-native invasive species. The monitoring schedule may be reduced to every 5 or even 10 years once conservation targets have been met within a Conservation Zone.	ECSY3.1 ECSY7.1 ALNC1.7 VRNC2.3

Natural Community-Level Conservation Measures				
CM4: Tidal Habitat Restoration				
Monitoring Action CM4-1. Document the extent of tidal habitat restored.				
Base Condition: As-built construction drawings. **Approach:** Delineate the extent of subtidal aquatic, unvegetated mudflat, vegetated marsh plain by vegetation type, and transitional upland by vegetation type. **Schedule:** Annually delineate habitat components for the first 5 years following reestablishment of tidal flow and every 5 years thereafter.	**Existing Programs:** DWR IISS section within DWR-DES (potentially) **Potential Program Additions:** 1. Development of spatial databases and mapping capabilities including photo-interpretation (GIS lab) 2. Vegetation sampling (on-the ground) for field verification to increase mapping accuracy (aquatic botanist) See Monitoring Action CM4-2, CM16-1	1. Extent, distribution, and channel order of tidal perennial aquatic natural community on restoration sites. 2. Percentage of subtidal aquatic habitat in areas of subsidence 3. Extent, distribution and persistence of high-functioning tidal mudflat community	This monitoring action provides information regarding the development of restored habitat components over time. Results will be used to evaluate if targets and objectives have been met, parameterize and evaluate conceptual models and other analytical tools, and to prioritize potential actions according to certainty, magnitude and timeliness of benefit. This information will also provide the basis for determining if there is a need to modify subsequent restoration designs to improve their ecosystem and habitat functions, or if it is necessary to alter management actions to support the development of desired habitat functions (e.g., control of non-native vegetation, planting of native emergent vegetation to improve development of marsh functions). The monitoring schedule may be adjusted for a particular project in response to monitoring results and the intensity of monitoring for subsequent projects may be decreased if causal relationships between restoration actions and outcomes are established. Monitoring Action CM4-2. Document the progress of vegetation community establishment and the extent of covered species habitat provided by restored tidal habitats.				
Base Condition: As-built construction drawings. **Approach:** For the first 5 years following completion of tidal marsh restoration projects, annually conduct aerial and/or field surveys in October to map the extent of tidal vegetation establishment. Evaluate and quantify the extent of each covered species habitat based on evaluation of data collected under Monitoring Action CM4-1. **Schedule:** Annually quantify the extent of restored covered, species habitats for the first 5 years following reestablishment of tidal flow and every 5 years thereafter.	**Existing Programs:** DWR IISS section within DWR-DES (potentially) **Potential Program Additions:** 1. Development of spatial databases and mapping capabilities including photo-interpretation (GIS lab) 2. Vegetation sampling (on-the ground) for field verification to increase mapping accuracy (aquatic botanist/ field personnel; see Monitoring Action CM4-1, CM16-1)	1. Extent, distribution and persistence of high-functioning tidal mudflat community 2. Linear extent of restored or created tidal mudflat substrate as part of the restored brackish and freshwater tidal habitat and channel margin enhancement. 3. Acres of covered species habitat 4. presence of key habitat correlates and requisites/attributes for covered species 5. Percent absolute and relative cover 6. Extent, distribution, cover, and species composition of non-native invasive species within establishing tidal mudflats on restoration sites	This monitoring action is intended to provide information regarding the development of habitat covered species in restored tidal habitats over time. This information will provide the basis for determining if there is a need to modify subsequent restoration designs to improve the development of habitat functions for target covered species. The monitoring schedule may be adjusted for a particular project in response to monitoring results and the intensity of monitoring for subsequent projects may be decreased if causal relationships between restoration actions and outcomes are established. Monitoring Action CM4-3. Quantify the primary production exported from restored tidal marsh plain into adjacent restored subtidal aquatic habitat areas.				
Base Condition: Seasonal abundances of phytoplankton and zooplankton in channels adjacent to restoration sites. Sample restored subtidal prior to breaching of levees, measured for at least one year prior to restoring tidal habitat. **Approach:** Establish monitoring stations at inflow and outflow locations and within restored subtidal habitat. Take weekly grab samples and measurements of chlorophyll a and zooplankton. **Schedule:** Conduct sampling for the first 5 years following reestablishment of tidal flow and every 5 years thereafter.	**Existing Programs:** Environmental Monitoring Program (EMP, under IEP) **Potential Program Additions:** **1.** Additional sampling stations in connection with restored tidal marsh plains to reflect the before-after-control-impact design. Locations of some added stations will be fixed during the duration of the plan (systemwide monitoring to detect increase on food availability in delta waterways), others are added as levees are breached and sites are flooded to track how food production in individual wetlands develops over time (i.e., flux from wetland restoration sites) Sampling stations will also provide water quality data (e.g., temperature, turbidity, pH for ammonia conversion, amount of organic carbon) Invertebrate sampling should be adaptively adjusted to changes in fish diets – see also: Monitoring Action CM4-4, CM4-6, and CM16-5	1. Phytoplankton species composition/relative abundance 2. Phytoplankton density (mg/L chlorophyll a) 3. Zooplankton species composition/relative abundance 4. Zooplankton density (number/1,000 m^3)	This monitoring action is intended to collect data necessary to determine and quantify the degree to which restored tidal habitats are producing and exporting phytoplankton and zooplankton into restored subtidal habitats. This information, in combination with evaluation of other foodweb-related monitoring and research data, will provide the basis for : 1. Identifying sources of uncertainty and the design of management experiments and/ research studies, to address uncertainty. 2. evaluating underlying conceptual models and hypotheses (source-sink dynamics, variability and uncertainty in primary production response) 3. evaluating restoration design options to increase the production and export of primary production from restored tidal marsh plains 4. Implementing additional management actions to improve production and export of primary production from restored tidal marsh plains The monitoring schedule will be modified if uncertainty or variances do not support a clear causal relationship between tidal marsh restoration and food production and exports. The intensity of monitoring for subsequent projects may be decreased if causal relationships between restoration actions and outcomes are established. Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM4-4. Document the export of organic carbon produced in restored tidal marsh plain into existing Plan Area channels.				
Base Condition: Not applicable. **Approach:** Determine the extent of organic carbon produced in restored tidal marsh plains that is exported from restored tidal habitats to downstream locations either through modeling (e.g., particle tracking modeling) or direct observation (e.g., isotope marking). **Schedule:** To be determined based on an assessment of the sufficiency of phytoplankton and zooplankton production levels determined under CM4-3. Conduct once to establish the extent of organic carbon that is exported and repeat as needed if hydrodynamic conditions change sufficiently in the future such that export rates might be affected.	**Existing Programs:** Environmental Monitoring program (EMP, under IEP) **Potential Program Additions:** See Monitoring Action CM4-3. 1.Possible adaptive expansion of the monitoring program to include isotope particle marking and tracking to determine organic carbon exports downstream locations	1. Amount of organic carbon produced in restored tidal marsh 2. Proportion of total organic carbon produced in restored tidal marsh plain that is exported to specified downstream locations.	This monitoring action is intended to collect complimentary and additional data necessary to determine if and how much restored tidal habitats are producing and exporting phytoplankton and zooplankton to downstream locations. This monitoring is an adaptive contingency monitoring action in case actions under CM-4 suggest a high degree of uncertainty or suggest inadequacy of conceptual models. This monitoring action will be implemented as targeted research project to address uncertainty in food production pathways and the magnitude and dynamics of exports into Delta water ways. It will be adaptively applied to sites, seasons and identified portions of the Delta.	ECSY5.1

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM4-5. Determine the extent of covered fish species habitat restored by life stage.				
Base Condition: Not applicable. **Approach:** Based on the current understanding of life stage requirements of each covered fish species and key environmental correlates, delineate the extent of habitat restored for each covered species life stage based on bathymetry (determined from as-build drawings), substrate (assessed before levee breaching), and water quality parameters determined through CM-11. **Schedule:** Annually for the first 10 years and every 5 years thereafter.	**Existing Programs:** Current knowledge on life history and biology of covered fishes in the Delta, life history models. **Potential Program Additions:** 1. Development of spatial databases and mapping capabilities including photo-interpretation (GIS lab)	1. Extent of restored habitat 2. extent of spawning habitat 3. extent of rearing habitat 4. portion of restored habitat within migration routes/corridors	This monitoring action will provide information on the amount of habitat that is being restored through BDCP conservation measures and how it pertains to requirements for stage-specific life history events of covered species. The implementing Office will use this information to determine if restored habitat effectively addresses habitat limitations. The monitoring action will be intensified of modeling or field observations suggest that certain habitats are in short supply and that restoration and protection targets should be modified through the adaptive decision making process. Monitoring Action CM4-6. Determine covered fish species use of restored subtidal aquatic habitat.				
Base Condition: Estimated existing seasonal abundances of relevant life stages of covered fish species in channels adjacent to restoration sites based on existing information (IEP fish sampling). **Approach:** Conduct surveys for each covered fish species using standardized existing or improved methods. **Schedule:** Conduct sampling for the first 5 years following reestablishment of tidal flow and at least every 5 years thereafter.	**Existing Programs:** IEP –coordinated fish surveys: 1. CDFG 20 mm Survey 2. CDFG Delta smelt larva study 3. USFWS Spring Kodiak Trawl and "Supplemental Surveys", Mossdale trawl 4. USFWS Midwater trawl 5. USFWS beach seine 6. CDFG Summer townet survey 7. UCD/IEP Suisun Marsh otter trawl **Potential Program Additions:** 1. Expanded sampling location array to reflect changed food availability, diversion and flow regimes (e.g., North delta and Ship Channel); additional sampling areas should be located near restored subtidal habitat to determine fish response to restored habitats. Stratify sampling by project and systemwide variables.	1. Seasonal distribution of covered fish species 2. Type of use (e.g., rearing, spawning) 3. Duration of use 4. species, age composition and sizes of covered fish species 5. CPUE	This monitoring action will provide information to determine and quantify use of restored subtidal aquatic habitat by covered fish species. This information in combination with evaluation of other covered fish species-related monitoring and research data, will be used to evaluate underlying models and hypotheses about the predicted benefits of restored subtidal aquatic habitat to covered fish species. This information will aid in identifying sources of uncertainty and will guide the design of further management experiments and/ research studies to address uncertainty. The Implementing Office will use this information to evaluate restoration design options and additional management actions to increase the benefits of restored tidal marsh plains to covered species. The monitoring schedule and methods may be adjusted for a particular project in response to monitoring results and the intensity of monitoring for subsequent projects may be decreased if causal relationships between restoration actions and outcomes are established. This information in combination with evaluation of other non-native fish species-related monitoring and research data, will be used to evaluate underlying models and hypotheses about the predicted use of restored subtidal aquatic habitat by nonnative fish species. This information will aid in identifying sources of uncertainty and will guide the design of further management experiments and/ research studies to address uncertainty. The Implementing Office will use this information to evaluate restoration design options and additional management actions to minimize the use of restored tidal marsh plains to nonnative species. The monitoring schedule and methods may be adjusted for a particular project in response to monitoring results and the intensity of monitoring for subsequent projects may be decreased if causal relationships between restoration actions and outcomes are established.	ECSY6.1

Table 3-20. Potential Effectiveness Monitoring Actions for Conservation Measures (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM4-8. Determine the extent of nonnative submerged (SAV) and floating aquatic vegetation (FAV) in subtidal aquatic habitats.				
Implemented through Monitoring Action CM13-1. *Also see Monitoring Action SY 5-2. Determine the abundance and species composition of non-native, submerged and floating aquatic vegetation (Table 3-20)*				ECSY6.1
Monitoring Action CM4-9. Determine the extent and patterns of establishment of nonnative clams in restored subtidal aquatic habitats.				
Base conditions: ongoing benthic monitoring by IEP throughout the Estuary. **Approach**: Benthic monitoring will be conducted at up to 20 sites within the estuary, with four benthic samples and one sediment sample taken at each site. Samples are analyzed by a contracting lab. Samples will be collected using a hydraulic winch and Ponar dredge or other appropriate grab sampler. **Schedule**: Quarterly	**Existing Programs:** Benthic monitoring component of IEP's Environmental Monitoring Program (EMP) **Potential Program Additions:** Increase the number of benthic sampling stations to up to 20 sites as a representatively sample of the entire BDCP plan area. Database to track observation and incidental records of non-native bivalves to estimate their habitat use and range expansion in the Delta	1. Species of non-native bivalves 2. Total number of individuals counted 3. Size distribution of clams	This monitoring activity provides information on the non-native clams of the estuary, changes in their presence, abundance and distribution. Data collected from the benthic monitoring program is also used to detect newly introduced species in the estuary. The Implementing Office will use this information to determine the status and change of benthic communities over the term of the BDCP and to evaluate possible causal relationships between physical factors and benthic invertebrate communities. This information will also provide important indicators of invasive species progress, impacts of toxics and water operations, and other changes within the Delta. The monitoring schedule may be adjusted to provide data at a higher temporal or spatial resolution of deemed necessary.	ECSY6.1

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM4-11. Determine water quality conditions for covered fish species in restored subtidal aquatic habitats.				
Base Condition: Existing seasonal water quality conditions in channels adjacent to restoration sites based on existing information (see Applicable IEP and other Resources). Upon breaching, establish base conditions by paired sampling within restored habitat and at outflow channel locations. **Approach:** Establish water quality sampling stations in restored subtidal habitat area. Monthly, collect and analyze water grab samples at representative depths for: 1) water temperature, 2) dissolved oxygen, 3) turbidity, 4) salinity, 5) ammonia and 6) methylmercury. **Schedule:** Sample monthly for 1) the first 2 years following reestablishment of tidal flow, 2) quarterly for the following 10 years, 3) and quarterly every 5 years thereafter.	**Existing Programs:** 1. Continuous Multiparameter Monitoring, Discrete Physical /Chemical Water Quality Sampling (Environmental Monitoring program; IEP) 2.Continuous Recorder Sites (DWR, USBR) 3. National Pollutant Discharge Elimination System (NPDES) Self Monitoring Program (Central Valley Water Board) 4. Delta Flows Network and National Water Quality Assessment Program (USGS) 5. other (DWR, SRCSD, SWAMP, Central Valley Water Board, State Water Board, SFEI, etc) **Potential Program Additions:** **1.** There are over 100 water quality sampling sites within the Delta providing a baseline of water quality data. If needed, additional localized sampling stations may be added to reflect the before-after-control-impact design (grab samples in project locations). Locations of some stations will be added as levees are breached and sites are flooded to track water quality changes at restoration sites.	1. Water temperature (^{o}C) 2. mg/L dissolved oxygen 3. Turbidity (NTUs) 4. Salinity (EC) 5. pH 6. mg methylmercury/L	This monitoring action is intended to collect data necessary to determine if water quality conditions in restored tidal marshes are suitable for supporting covered fish species. It will also be used to determine the possible impact on water quality in adjacent channels and habitats. This information will be used to evaluate underlying models and hypotheses of water quality responses to tidal marsh restoration. This information will aid in identifying sources of uncertainty and will guide the design of further management experiments, design modifications and/ research studies to address uncertainty. The monitoring schedule may be adjusted for a particular project in response to monitoring results and the intensity of monitoring for subsequent projects may be decreased if causal relationships between restoration actions and outcomes are established.	CHSA1.3

Table 3-20. Potential Effectiveness Monitoring Actions for Conservation Measures (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM4-12. Determine the response and status of salt marsh harvest mouse, Suisun shrew, Suisun song sparrow, and California clapper rail, California black rail to loss of existing Suisun Marsh habitats that are restored as tidal habitat.				
Base Condition: The existing distribution and abundance of Suisun Marsh covered mammal and bird species based on existing information and additional surveys if needed. **Approach:** Conduct surveys, transects, mark-recapture or other methods to evaluate the response and status of Suisun Marsh populations of covered mammal and bird species following the conversion of existing species habitat areas to tidal habitat. Map upland refugia during high tide events, survey for presence/use of salt marsh harvest mouse during high tide **Schedule:** Conduct at least annual sampling of covered species distribution and abundance for 5 years following each tidal habitat restoration project until use of restored tidal habitats by covered mammal and bird species is established.	**Existing Programs:** IEP's Suisun marsh program (triennial vegetation surveys, GIS map identifying 103 vegetation classifications, change detection analysis, Salt Marsh Harvest Mouse Monitoring program on Conservation Areas), Point Reyes Bird Observatory (PRBO) San Francisco Bay Tidal Marsh Project, some historical surveys, research projects, approved sampling protocols. **Potential Program Additions:** 1. Regular mark-recapture program for SMHM and Suisun shrew (trapping grids) in Suisun marsh 2. Standardized surveys for Clapper rail, Suisun song sparrow and black rail (using PRBO San Francisco Bay Tidal Marsh Project protocols as appropriate) 3. Establishment of new sampling points/grids/stations as habitat patches are restored See Monitoring Action CM4-9	1. Abundance (N) of each species in Suisun Marsh 2. Population trend (λ) of each species in Suisun Marsh 3. Distribution and range of each species in Suisun Marsh 4. Extent and distribution of upland refugia for salt marsh harvest mouse during high tide.	This monitoring action is intended to test the hypothesis that restoring tidal marshes will have no effect on the status and population size of covered species in Suisun Marsh. Monitoring results will be used to determine how much habitat restoration has affected the distribution and abundance of Suisun Marsh covered mammal and bird species. This information is necessary to determine if adaptive changes to the implementation schedule (i.e., timing and extent of tidal habitat restoration projects in Suisun Marsh) are necessary to maintain viability of covered species populations in Suisun Marsh. Monitoring frequency and intensity may be adjusted to provide monitoring that addresses uncertainties effectively.	TANC1.1 BMNC1.1

Monitoring Action CM4-13. Determine covered wildlife species use of restored tidal habitats in Suisun Marsh.				
Base Condition: The existing distribution and abundance of covered marsh-associated wildlife species in Suisun Marsh based on existing information and additional surveys if needed. Not applicable to restoration sites in the Delta. **Approach:** Conduct standardized surveys using established methods to determine the abundance and type of use (e.g., foraging, nesting) of marsh plain and transitional upland habitats by covered wildlife species. Conduct standard vegetation transects and monitoring of incidental reports of newly established clones of covered plants, tracking of growth, survival and cover of covered plant species. **Schedule:** Conduct surveys for each species during each species' active period for 5 years following the development of habitat functions for each species as determined through data collected under CM4-2 and every 5 years thereafter.	**Existing Programs:** IEP's Suisun marsh program, some historical surveys, research projects, approved sampling protocols. **Potential Program Additions:** 1. Intensive mark-recapture program for SMHM and Suisun shrew in Suisun marsh 2. Standardized surveys (breeding, winter) for Clapper rail, Suisun song sparrow and black rail 3. standard surveys of covered plant species 3. Establishment of new sampling points/grids/stations as habitat patches are restored and populations expand See Monitoring Action CM4-8	1. Estimated abundance of each species in using restored habitat 2. estimated populations trend in restored habitats (source or sink?) 3. Presence and population size of covered plant species (e.g., bird's beak, Mason's lilaeopsis, Delta mudwort, Delta tule pea Slough thistle,and Suisun Marsh aster)	This monitoring action is intended to collect data on the distribution and population trend of covered species in Suisun Marsh restored habitats. Monitoring results will be used to determine if habitat restoration has a source or sink effect on the abundance of Suisun Marsh covered mammal and bird species This information is necessary to determine if adaptive changes to the implementation schedule (i.e., timing and extent of tidal habitat restoration projects in Suisun Marsh) are necessary to maintain populations of these covered species in Suisun Marsh and to increase the utility of restored habitats to covered species	ECSY1.5 TANC1.1 MFNC1.1 MFNC1.2 BMNC1.1 BMNC2.1

Monitoring Action CM4-14. Determine covered wildlife species use of restored tidal habitats in the Delta.				
Base Condition: The existing distribution and abundance of covered marsh-associated wildlife species, specifically giant garter snake (Conservation Zone 4 and 5), western pond turtles, and California least tern foraging sites. **Approach:** Conduct standardized surveys using established methods to determine the abundance and type of use (e.g., foraging, nesting) of marsh plain and transitional upland habitats by covered wildlife species. Conduct standardized surveys using established methods to determine the abundance and type of use (e.g., foraging, nesting) of Giant Garter snake (Conservation Zone 4 and 5), western pond turtles, and California least tern sites. **Schedule:** Conduct surveys for each species during each species' active period for 5 years following the development of habitat functions for each species as determined through data collected under CM4-2 and every 5 years thereafter.	**Existing Programs:** historical surveys, research projects, approved sampling protocols. **Potential Program Additions:** 1. Standardized surveys for Giants Garter Snake, western pond turtles and California least tern 3. Establishment of new sampling points/grids/stations as habitat patches are restored and populations expand See Monitoring Action CM4-8	1. Presence and sex/age distribution of Giant Garter Snake 2. Presence and sex/age distribution of western pond turtles 3. Estimated populations trend of covered species in restored habitats (source or sink?)	This monitoring action is intended to collect data on the distribution and population trend of covered species in restored habitats. Monitoring results will be used to determine if habitat restoration has a source or sink effect on the abundance of covered mammal and bird species. This information is necessary to determine if adaptive changes to the implementation schedule (i.e., timing and extent of tidal habitat restoration projects) are necessary to maintain populations of these covered species and to increase the utility of restored habitats to covered species. CM5: Seasonally Inundated Floodplain Restoration				
Monitoring Action CM 5-1: Develop inundation rating curves to quantify the relationship between discharge and inundation dynamics of floodplain habitat for covered species.				
Base condition: As-built restored habitat elevations and river stage elevations**.** **Approach:** The Implementing Office will develop inundation rating curves for inundation depth and extent of restored inundated floodplain habitat area and will record floodplain inundation events and period of inundation by automatic water depth monitoring gages and other appropriate methods. **Schedule**: monitoring of inundation depth and extent of inundated area will continue until a sufficient inundation rating curve can be established with reasonable uncertainty.	**Existing Programs:** California Bay Delta Authority Science Program - Integrated Regional Wetlands Monitoring (historical pilot program) **Potential Program Additions:** 1. Installation and monitoring of automated monitoring devices or other appropriate measures to determine inundation depth, stage and frequency.	1. Inundation frequency 2. Inundation duration	This monitoring element will provide information on the relationship between inundation depth and inundation period and extent to guide the design of floodplain projects and/or operation of flood control structures. This information will be used to guide and if necessary, change the design of floodplain restoration projects and if applicable, the operation of flood control structures to effectively control the period of inundation in seasonal floodplains under an variable flow regimes. The monitoring schedule may be adjusted in response to uncertainty of the established ratings curve.	CHSA1.1 STEE1.1 SASP1.2

Monitoring Action CM5-2: Record and quantify incidences and locations of stranded covered fish species at the end of the inundation period in restored floodplains.				
Base Condition: none **Approach**: Visual and other surveys (e.g., beach seining) immediately following inundation periods in restored floodplain habitats as flows are receding from the floodplain to document stranding locations and magnitude. **Schedule**: Annual surveys for the first five years after restoration. Once documented, monitoring will be discontinued and a more limited monitoring effort to be determined by the Implementing Office would be conducted every 5th year that restored floodplains are inundated to document any changes in stranding location and magnitude that may result from changes in floodplain topography (e.g., formation of scour holes or sedimentation that create isolated pools).	**Existing Programs:** Intermittent and historical IEP and USFWS beach seine and trawling methods within the Yolo and Sutter bypasses **Potential Program Additions:** **1.** Weekly surveys of restored floodplains to identify areas suddenly dewatered by lower river conditions which may contain stranded fish. 2. Follow-up on the ground, dip netting, beach seining or electro-shocking of remnant puddles to verify stranding. On-the-ground mapping of standing locations to guide re-contouring.	1. locations of covered fish species stranding 2. number, species, length, and age/sex distribution of stranded fish 3. type of stranding pool (i.e., erosion, topography, man-made, etc.)	This monitoring action will provide information on the extent and magnitude of fish strandings at the end of the inundation period in restored floodplains. This information will be used to determine the severity of fish stranding and their locations within the restored floodplain. Results of monitoring will be used to determine if modifications to floodplain surfaces are needed to reduce stranding risk (e.g., grading). The schedule of the monitoring action may be adjusted to reflect changes in management. In locations where floodplain topography was altered to reduce fish stranding, monitoring will continue for at least 3 years to document reduction in stranding incidences.	CHIN1.1 STEE1.1 SASP1.1

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM5-3. Quantify presence and abundance of juvenile salmonids in restored floodplain habitats during inundation periods.				
Base Condition: Concurrent presence and abundance of juvenile salmonids in adjacent Delta waterways **Approach**: Visual and non-lethal fish sampling (e.g., beach seining, electrofishing) of representative, randomly selected sections of restored floodplain habitats during the inundation period and in adjacent Delta waterways. **Schedule**: During the first 5 floodplain inundation events that coincide with rearing/outmigration periods of juvenile salmonids, conduct biweekly sampling of the inundated floodplain as long as the floodplain is inundated. Subsequently monitor every fifth flood event over the term of the BDCP.	**Existing Programs:** Historical sampling, USFWS weekly beach seining survey of juvenile salmonids (49 permanent locations Delta wide) **Potential Program Additions:** 1. Add sampling locations to include restored floodplain and adjacent channel habitats to ensure statistical representative sampling effort	1. Abundance, size, and race of salmonid species in the inundated restored floodplain habitat and in adjacent Delta waterways.	This monitoring action will provide information on the presence and abundance and relative use of restored floodplains compared to adjacent delta waterways. Results of monitoring will be assessed to determine if floodplain habitats attract more salmonids than adjacent waterways and if fish abundance, age and size distributions differ among restored floodplains and adjacent waterways of the Delta. Results will be used to determine if subsequent design or locations of restored floodplains need to be adjusted to improve their function as juvenile salmonid habitat. The schedule of the monitoring action may be adjusted to reflect changes in management or research results on fish presence in inundated floodplains.	CHSA1.1 CHSA1.2 STEE1.1 STEE1.2

Monitoring Action CM5-4: Delineate and quantify Sacramento splittail spawning and rearing in relationship to restored seasonally inundated floodplain habitat.				
Base condition: Conduct surveys of splittail adults, larvae, and eggs in slow-moving sections of rivers and sloughs and dead-end sloughs adjacent to projected floodplains to determine the abundance of splittail larvae and early juveniles present during the reproductive period. **Approach:** Conduct fish sampling surveys in restored floodplain habitats and adjacent slow-moving sections of rivers and sloughs and dead-end sloughs during inundation periods to determine the change in densities of larvae and juveniles relative to base conditions and in-channel spawning. **Schedule:** Weekly fish sampling will be conducted in spawning habitat within restored habitats and in adjacent channel habitats during the first 5 floodplain inundation periods during the splittail spawning season. Subsequently monitor every fifth flood event over the term of the BDCP.	**Existing Programs:** USFWS rotary screw traps USFWS beach seine **Potential Program Additions:** 1. Add sampling locations to include restored floodplain and adjacent channel habitats to ensure statistical representative sampling effort	1. Production of Sacramento splittail (number of larval and early juvenile splittail/10,000 m^3) during floodplain inundation periods	This monitoring action will provide information on productivity of Sacramento splittail populations and the contribution of inundated restored floodplains on spawning and rearing of splittail. This information will be used by the Implementing Office to decide if the production of splittail during floodplain inundation periods has increased significantly from base conditions. If monitoring results do not support conceptual models and hypotheses predicting increasing splittail spawning, the Implementing Office will conduct additional studies to determine 1. uncertainties and competing hypotheses 2. other factors/stressors that affect splittail spawning and rearing in restored habitats, and 3. restoration design modifications to increase splittail productivity. If causes are related to inundation duration, experimental management of flood control structures and floodplain topography may used to address uncertainties. The monitoring schedule may be extended or intensified if uncertainties of causal relationships persist.	SASP1.1

Table 3-20. Potential Effectiveness Monitoring Actions for Conservation Measures (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM5-5: Quantify abundance of nonnative fish species in restored floodplain habitats during inundation periods.				
Base Condition: Concurrent abundance of nonnative fish species in adjacent Delta waterways **Approach**: Visual and non-lethal fish sampling (e.g., beach seining, electrofishing) of representative, randomly selected sections of restored floodplain habitats during the inundation period and in adjacent Delta waterways. **Schedule**: During the first 5 floodplain inundation events that coincide with rearing/outmigration periods of juvenile salmonids, conduct biweekly sampling of the inundated floodplain as long as the floodplain is inundated. Subsequently monitor every fifth flood event over the term of the BDCP.	**Existing Programs:** Historical sampling, USFWS weekly beach seining (49 locations Delta wide) **Potential Program Additions:** 1. Add sampling locations to include restored floodplain and adjacent channel habitats to ensure statistical representative sampling effort	1. Abundance, size, and race of salmonid species in the inundated restored floodplain habitat and in adjacent Delta waterways.	This monitoring action will provide information on the presence, abundance, and relative use of restored floodplains compared to adjacent delta waterways. Results of monitoring will be assessed to determine if floodplain habitats attract more salmonids than adjacent waterways and if fish abundance, age and size distributions differ among restored floodplains and adjacent waterways of the Delta. Results will be used to determine if subsequent design or locations of restored floodplains need to be adjusted to improve their function as juvenile salmonid habitat. The schedule of the monitoring action may be adjusted to reflect changes in management or research results on fish presence in inundated floodplains.	ECSY6.1 CHSA1.8 STEE1.7 SASP1.5

Table 3-20. Potential Effectiveness Monitoring Actions for Conservation Measures (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM5-6: Identify types and quantities of aquatic food production for covered fish species.				
Base Condition: Aquatic food production in adjacent channel habitat prior to restoration activities. Take weekly samples and measurements during inundation period for zooplankton and pelagic macroinvertebrates in Delta waterways adjacent to floodplain restoration sites for a least one year before habitat is restored to establish base conditions. **Approach:** Sample and measure zooplankton and pelagic macroinvertebrates abundance weekly at inflow, outflow and interior sampling points/transects within restored floodplains during inundation periods, and compare these with in-channel samples of zooplankton and pelagic macroinvertebrates taken in adjacent waterways. Assess measurements of zooplankton and pelagic macroinvertebrates to establish relationships between restored floodplain habitat during inundation periods and production of zooplankton and and pelagic macroinvertebrate forage species for covered fish. **Schedule** : Once these relationships have been established, annual monitoring of aquatic food production may be discontinued and a more limited monitoring effort to be determined by the Implementing Office may be conducted every 5th year to document any changes in zooplankton and macroinvertebrates production during floodplain inundation periods over the term of the BDCP.	**Existing Programs:** Zooplankton monitoring conducted by Environmental Monitoring Program (EMP under IEP umbrella) also includes monitoring of water quality, benthos, phytoplankton and exotic species **Potential Program Additions:** 1. Additional sampling stations to reflect the before-after-control-impact design. Locations of some added stations will be fixed during the duration of the plan (systemwide monitoring to detect increase on food availability in delta waterways), others are added as levees are breached and sites are flooded to track how food production in individual wetlands develops over time (i.e., flux from wetland restoration sites) Sampling stations will also provide water quality data (e.g., temperature, turbidity, pH for ammonia conversion, amount of organic carbon) Invertebrate sampling should be adaptively adjusted to changes in fish diets – see also Monitoring Action CM4-4 and Monitoring Action CM4-6.	1. Zooplankton species composition/relative abundance 2. Zooplankton density (number/1,000 m^3) 3. Pelagic macroinvertebrate species composition / relative abundance 4. Pelagic macroinvertebrate density (number/1,000 m^3)	The monitoring action will provide information to test hypotheses on the role that the restored floodplain plays in providing additional aquatic food resources for covered fish in and outside the restoration areas. The monitoring will provide quantitative assessments to determine how much of this food enters the aquatic system through outflows from the floodplain. This information will be used by the Implementing Office to determine if and how much restored floodplains contribute to increased food availability for covered fish species. This information will be used to guide the development of alternative models, hypotheses, management strategies and additional research studies to resolve uncertainties about hypotheses or models. For example, if production of zooplankton and macroinvertebrates does not exceed production relative to base conditions or is not trending towards achieving those production levels, the Implementing Office may conduct investigations to determine causes for insufficient production of zooplankton and macroinvertebrates. Depending on the causes, potential actions could include the experimental modification of floodplain surfaces to increase inundation duration or vegetation structure, or installing water control structures at inflow and outflow locations. CM6: Channel Margin Habitat Restoration				
Monitoring Action CM6-1 Extent of channel margin enhanced to provide habitat for covered fish species.				
Base Condition: As-built restoration designs. Baseline documentation for acquired parcels **Approach:** Extent of enhanced habitat following restoration actions will be delineated, including habitat type (e.g., submerged bench, channel margin emergent vegetation, overhead shaded riverine cover) and vegetation communities. **Schedule**: Annually delineate habitat components for the first 5 years following restoration actions.	**Existing Programs:** DWR IISS section within DWR-DES (potentially) **Potential Program Additions:** 1. Development of spatial databases and mapping capabilities including photo-interpretation (GIS lab) 2. Vegetation sampling (on-the ground) for field verification to increase mapping accuracy (aquatic botanist/ field personnel) See Monitoring Action CM4-1, CM4-2, CM6-2)	1. Linear feet of enhanced habitat by habitat type	This monitoring action will provide information about the progress and spatial extent of channel habitat enhancement. This information will be used to determine if subsequent restoration designs can or should be modified to improve habitat conditions for covered fish species. It will also serve to guide and design management actions to increase or maintain enhancement results (see Monitoring Action CM16-2). The monitoring schedule may be adjusted for a particular project in response to monitoring results. The intensity of monitoring for subsequent projects may be decreased if causal relationships between restoration actions and outcomes are established.	MFNC1.1 MFNC1.2 CHSA1.1 STEE1.1 SASP1.1

CM6-2: Quantify the extent and dynamics of establishment of emergent vegetation .				
Base Condition: As-built restoration designs. Targets for the establishment of emergent vegetation as identified in habitat enhancement design specifications for each channel margin enhancement site. Baseline documentation for acquired parcels. **Approach:** Percent absolute vegetative cover and extent of vegetated channel will be determined in years 1, 2, and 5 following enhancement. Enhancement sites will be monitored at least every 5 years to assess the extent of established non-native invasive vegetation.	**Existing Programs:** DWR IISS section within DWR-DES **Potential Program Additions:** 1. Development of spatial databases and mapping capabilities including photo-interpretation (GIS lab) 2. Vegetation sampling (on-the ground) for field verification to increase mapping accuracy (aquatic botanist/ field personnel) See Monitoring Action CM4-1, CM4-2, CM6-1)	1. Percent absolute vegetation cover over time 2. Linear extent of vegetated channel margin 3. Presence and extent of non-native invasive vegetation	This monitoring action is intended to provide information regarding the development of habitat structure and vegetation community structure in enhanced channel margin habitats over time. This information will provide the basis for determining if there is a need to modify subsequent enhancement designs to improve the development of emergent vegetation over time. It also may guide development of management actions to improve the establishment of emergent plant communities in enhanced channel margin habitats, including additional studies to identify such actions. The monitoring schedule may be adjusted for a particular project in response to monitoring results and the intensity of monitoring for subsequent projects may be decreased if causal relationships between restoration actions and outcomes are established. CM6-3: Quantify the presence and abundance of covered and nonnative fish species using enhanced channel margin habitats.				
Base condition: If sufficient existing information is not available, conduct monthly fish sampling surveys along existing channel margin habitats to be enhanced for a least one year before enhancement is implemented using appropriate survey methods to be determined by the Implementing Office to establish base conditions. **Approach:** Following enhancement, initiate comparable surveys within enhanced channel margin habitats and continue surveys **Schedule**: Continue surveys until a relationship between the abundance of each covered fish species/non-native predatory fish species and the extent and function of enhanced habitat is established (at least 5 years). Subsequently, surveys will be conducted at least every 5 years to document any changes that may occur in use of enhanced channel margin habitats over the term of the BDCP.	**Existing Programs:** fish surveys 1. CDFG 20 mm Survey 2. CDFG delta smelt larva study 3. USFWS Spring Kodiak Trawl and 'Supplemental Surveys", Mossdale trawl 4. USFWS Midwater trawl 5. USFWS beach seine 6. CDFG Summer townet survey 7. UCD/IEP Suisun Marsh otter trawl **Potential Program Additions:** Expanded sampling location array to sampling locations along channel margin and within channel margin habitats. Beach seining to reflect micro-habitats and shallow areas not sampled by trawls. Trawl or townet surveys if channel margin extends too deep for beach seine sampling.	1. Presence of covered fish species by life stage in enhanced channel margin habitats 2. Abundance and length of covered fish species per unit area of habitat 3. Abundance of nonnative fish per unit area of habitat 4. Ratio of nonnative predatory fish to native fish	This monitoring action will provide quantitative information about the effectiveness of the enhanced channel margins to provide habitat for different life stages of covered fish species and their spatial response (presence and density) to these enhancements. Monitoring results will be used to evaluate if targets and objectives have been met, parameterize and evaluate conceptual models and other analytical tools, and to prioritize potential actions according to certainty, magnitude and timeliness of benefit. The information provided will also support decisions on potential modification of enhancement design and techniques. It will guide management actions to maintain enhanced habitats. It will also be used to determine if additional research activities or special survey technology should be developed. The monitoring schedule may be adjusted if the relationship between the abundance of each covered fish species/non-native predatory fish species and the extent and function of enhanced habitat cannot be established with acceptable certainty over the first 5 years, especially in cases where designs and enhancement techniques are changed through the adaptive management process. In these cases, annual monitoring will continue for 10 years post enhancement, and then be repeated every 5 years.	ECSY6.1 CHSA1.8 STEE1.7 SASP1.5 CHSA1.1 STEE1.1 SASP1.1

CM8: Grassland Community Restoration				
Monitoring Action CM8-1. Document the extent of grassland habitat restored.				
Base Condition: As-built construction drawings. **Approach:** Delineate the extent of grassland habitat by vegetation type, vegetation structure, and dominant species composition. **Schedule:** Annually delineate habitat components for the first 5 years following the implementation of individual grassland restoration projects.	**Existing Programs:** DWR IISS section within DWR-DES (potentially) **Potential Program Additions:** 1. Development of spatial databases and mapping capabilities including photo-interpretation (GIS lab) including terrestrial data 2. Vegetation sampling (on-the ground) for field verification to increase mapping accuracy (terrestrial botanist/ field personnel) See also Monitoring Action CM4-1, CM4-2, CM16-1, CM16-2)	1. Acres of each component of restored grassland habitat. 2. Percent absolute vegetation cover. 3. Percent relative cover of native plant species.	This monitoring action is intended to provide information about the development of grassland attributes in restored grassland habitat parcels over time. Monitoring results will be used to determine if subsequent restoration designs should be modified to improve their ecosystem and habitat functions. It will also guide adaptive management actions to improve development of desired habitat attributes (e.g., re-seeding, planting of native vegetation, control of non-native vegetation). The monitoring schedule may be adjusted for a particular project in response to monitoring results, especial the rangeland health assessment. The intensity of monitoring for subsequent projects may be decreased if strong causal relationships between restoration actions and grassland community responses are established. Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM8-2. Document the ecosystem functions of restored grassland habitat in comparison with site potential.				
Base Condition: Post-restoration conditions determined under CM8-1). Reference sheet for ecological site(s) – to be developed if necessary. **Approach:** Apply the "Interpreting Indicators of Rangeland Health" protocol to conduct rapid, qualitative assessment of soil/site stability, hydrologic function, and biotic integrity of restored grassland sites against a reference condition (ecological site; see Appendix I-xx, "Interpreting Indicators of Rangeland Health- version 3.0"). **Schedule:** Conduct rangeland health assessment in year 5 and every 10 years thereafter	**Existing Programs:** 1. NRCS National Grazing Lands Team, 2. County RCDs 3. NRCS local and regional offices **Potential Program Additions:** 1. ESD reference sheets for all restored grassland sites 2. Rangeland health assessment capabilities (terrestrial botanist, collaboration with NRCS soil specialists)	Rangeland health indicators: 1. Rills 2. Water Flow Patterns 3. Pedestals and/or Terracettes 4. Bare Ground 5. Gullies 6. Wind Scour or deposition 7. Litter Movement 8. Soil Surface Resistance to Erosion 9. Soil Surface Loss & Degradation 10. Plant Community Composition and Distribution Relative to Infiltration and Runoff 11. Compaction 12. Functional/Structural Groups 13. Plant Mortality and Decadence 14. Litter Amount 15. Annual Production 16. Invasive Plants 17. Reproductive Capability of Perennial Plants	This monitoring action is intended to provide information about the development of ecosystem functions in restored grassland habitat components over time. This information will provide the basis for addressing whether subsequent restoration designs should be modified to improve their ecosystem and habitat functions. It also will establish if adaptive management actions or interventions are required to halt deteriorative processes (erosion, invasive weeds). Furthermore, the information may provide reasons for additional research studies to address and resolve uncertainties in understanding ecosystem processes in restored grassland habitats. The monitoring schedule may be adjusted for a particular project in response to monitoring results. The intensity of monitoring for subsequent projects may be decreased if strong causal relationships between restoration actions and grassland community responses are established. Monitoring Action CM8-3. Document the extent of covered species habitat supported by restored grassland natural communities.				
Base Condition: Post-restoration conditions determined under CM8-1). **Approach:** Evaluate and quantify the extent of each covered species habitat based on evaluation of data collected under Monitoring Action CM8-1. **Schedule:** Annually quantify the extent of restored, covered species habitats for the first 5 years following the implementation of every grassland restoration project and every 5 years thereafter.	**Existing Programs:** 1. USGS Breeding bird survey routes (partial) 2. historical and intermittent research studies **Potential Program Additions:** 1. Breeding bird surveys (USGS protocol) at additional locations in restored grassland habitats 2. randomized camera trap, track, scat or spotlight surveys for mammals 3. Randomized amphibian an reptile surveys during peak activity times in restored habitats and adjacent remnant riparian habitats (control sites).	1. Acres of each covered species habitat restored.	This monitoring action is intended to provide information regarding the development of habitat functions for covered species in restored grassland habitats over time. This information will provide the basis for determining if there is a need to modify subsequent restoration designs to improve the development of habitat functions for target covered species. The information will also be used to determine what management actions (e.g., prescribed burning, controlled livestock grazing, weed control) are appropriate and indicated to advance progress towards achieving conservation targets. The monitoring schedule may be adjusted for a particular project in response to monitoring results and the intensity of monitoring for subsequent projects may be decreased if strong causal relationships between restoration actions and outcomes are established. Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM 10-3. Document the functionality and condition of restored nontidal marsh habitats over time.				
Base Condition: As-built construction drawings. Comprehensive ecological baseline documentation **Approach:** Conduct a California Rapid Assessment Method for Wetlands (CRAM, Appendix I-X "California Rapid Assessment Method for Wetlands version 5.0.2") to (a) evaluate wetland conditions and stressors and determine the need for intensive monitoring; (2) evaluate performance of restored nontidal marsh; and (3) assess progress of restoration relative to ambient conditions, reference conditions, and expected ecological trajectories. **Schedule:** Conduct a CRAM assessment 5 years after project implementation and every 5 years thereafter.	**Existing Programs:** none **Potential Program Additions:** **1.** develop CRAM capability either per contract with consultant or by training botanical staff.	1. Buffer and Connectivity Metrics 2. Water Source, Hydroperiod, Hydrologic Connectivity 3. Physical Patch Richness 4. Topographic Complexity 5. Organic Matter Accumulation 6. Biotic Patch Richness 7. Vertical Structure 8. Interspersion and zonation 9. Percent Invasive Plant Species 10. Native Plant Species Richness	This monitoring action is intended to provide information regarding the functionality, condition and self-sustainability of restored non-tidal marsh habitats and their ecological dynamics over time. The use of CRAM for ambient monitoring will, over time, help the Implementing Office to quantify the relative influence of anthropogenic stress, management actions, and natural disturbance on the spatial and temporal variability in reference conditions. This information can then be used in the design, management, and assessment of similar wetland projects. The monitoring schedule may be adjusted for a particular project in response to monitoring results and the intensity of monitoring for subsequent projects may be decreased if causal relationships between restoration actions and outcomes are established. If the causes are not readily apparent, then research might be recommended to determine the causes and to what extent they can be managed. If the causes are deemed natural, then management actions may not be warranted.	NANC2.1 NANC2.2 NWNC2.1 NWNC2.2

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM10-4. Determine covered wildlife species use of restored non-tidal marsh habitats.				
Base Condition: The existing distribution and abundance of covered wildlife species, especially giant garter snake, in restored and existing nontidal marsh habitats patches based on existing information and additional surveys if/where needed. **Approach:** Conduct standardized surveys using established methods to determine the abundance and type of use (e.g., foraging, resting) of giant garter snake; reconnaissance level surveys and incidental records of other covered species (primarily tricolored blackbird, western pond turtle) and non-native predators or competitors **Schedule:** Conduct surveys for each species during each species' active period for 5 years following the implementation of each restoration project as determined through data collected under CM4-2 and every 5 years thereafter.	**Existing Programs:** USGS studies of Giant Garter Snakes at four sites in the Sacramento Valley (1996–2006), USGS Natomas HCP Monitoring. **Potential Program Additions:** 1. Add the USGS Giant Garter Snake monitoring team under the IEP program for routine GGS effectiveness monitoring. Conduct, possibly localized mark-recapture /and radio-telemetry studies to determine habitat use patterns within proposed 1,000-acre giant garter snake conservation lands designed to enhance the Caldoni Marsh/White Slough and the Yolo Basin/Willow Slough giant garter snake populations. 2. Annual wildlife surveys for covered species.	1. Estimated abundance of each covered target species in created non-tidal, freshwater perennial emergent wetlands 2. Estimated extent of occupied covered species habitat in each created non-tidal, freshwater perennial emergent wetland 3. Acreage of created nontidal marsh that functions as habitat for the giant garter snake within or adjacent to habitat occupied by the Caldoni Marsh/White Slough and Yolo/Willow Slough giant garter snake subpopulations in Conservation Zones 2 and 4 3. Connectivity of water conveyance and habitat for giant garter snake 4. Acreage of created nontidal marsh that functions as habitat for the tricolored blackbird 4 5. Acreage of created nontidal marsh that functions as habitat for the western pond turtle 6. Abundance of feral pigs, cats and other non-native predators (non-native centrarchid fish and bullfrog) or competitors (non-native turtles), abundance of nest predators and parasites (brown-headed cowbirds)	This monitoring action is intended to provide information regarding the use and functionality of restored habitats for covered species, particularly the giant garter snake. This information will provide the basis for determining if there is a need to modify subsequent restoration designs to improve the development of habitat functions for target covered species. It will also determine if additional research studies are needed to assess the contribution of restored non-tidal marsh habitats to the viability of covered species. The monitoring schedule may be adjusted annually for a particular project in response to variable water levels and habitat conditions, marsh maintenance and enhancement activities, grazing or other circumstances that necessitate changes in the sampling schedule and/or protocol. Sampling intensity may take into account garter snake activity (and therefore detectability), unfavorable habitat conditions (i.e., lack of water), maintenance activities, trap theft and/or tampering, or other circumstances. Monitoring for subsequent projects may be decreased if causal relationships between restoration actions and outcomes are established.	NANC2.1 NANC2.2 NWNC2.1 NWNC2.2

CM11 Enhance and Manage Preserved Natural Communities				
Monitoring Action CM11-1. Document the planning and implementing progress for the development of Site-Specific Management Plans				
Base Condition: N/A **Approach**: Document completion of site-specific management plans for conservation lands in annual plans **Schedule**: Within 1 year of each conservation land acquisition.	**Existing Programs:** None **Potential Program Additions:** Project management database	Management plans	This monitoring action is intended to provide information to assess the progress the Implementing Office is making towards developing long-term guidance for site-specific management of each acquired BDCP conservation lands. The information in each management plan will provide the menu of actions to be undertaken and related implementation schedules.	

Table 3-20. Potential Effectiveness Monitoring Actions for Conservation Measures (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM11-2 Quantify covered species habitat availability, function, and suitability of conservation lands				
Base Condition: Baseline condition reports, existing conditions (see Chapter 2, *Existing Ecological Conditions* and Appendix A, *Covered Species Accounts*). **Approach**: Inventory key habitat correlates and requisites for each covered species associated with natural communities to determine the extent and suitability of covered species habitat on conservation lands over time (e.g., percent of riparian with suitable structure and vegetation associations to support riparian brush rabbit; percent of agricultural habitat suitable for Swainson's hawk or greater sandhill crane foraging). Conduct comprehensive field surveys, map extent, and document conditions. **Schedule**: Conduct complete baseline survey the first year following implementation of Site-Specific Management Plan, then repeat biannually for 10 years, followed by 5-year interval surveys.	**Existing Programs:** DWR IISS section within DWR-DES (potentially) **Potential Program Additions:** 2. Vegetation and habitat sampling (on-the ground) for field verification to increase mapping accuracy (botanist) 3. Capabilities to determine habitat quality and presence of key habitat correlates for covered species (terrestrial ecologist) See also CM 7-1, CM 8-1, CM 10-1	1. Extent, distribution, age structure, size structure, canopy structure, vegetation associations, and species composition of each natural community on restoration sites 2. Presence of species-specific requisites (e.g., basking sites, roost and nest trees, foraging sites, burrows, cover) 3. Estimated abundance of suitable habitat for each targeted covered species. 4. occurrences of Suisun Thistle 5. proximity of non-rice agricultural lands to occupied Swainson's hawk nesting habitat 6. relative cover of native grasses and forbs in Alkali seasonal wetlands and grasslands 5. acres of greater sandhill foraging habitat within its winter use area and within 2 miles of known roosting sites in CZ 3,4,5, and/or 6 6. Prey abundance for grassland foraging species, especially insects, small mammals 7. Extent and severity of detrimental agricultural practices and disturbance from adjacent sites 7. extent of seasonal buffers around riparian habitats	This action is intended to provide information on the abundance of suitable habitat and habitat functions that addresses any or all life requisites for each covered species on all BDCP protected lands. The information will provide the basis of tracking specific habitat elements and habitat function throughout the Plan Area that is essential for Covered Species occurrence, including riparian structure and composition, functionality of water conveyance canals and associated wetlands, woodlots, tree and hedge rows, vegetation and winter water depth of created managed wetland, and the proportion of agricultural lands with suitable cover types that meet foraging habitat objectives for agriculture-associated covered species. . This monitoring is subject to modification if acquisition proceeds more slowly than expected and the periodicity can be extended. Monitoring Action CM11-5. Increase habitat function for covered species				
Base Condition: Pre-acquisition condition. **Approach**: Each Site-Specific Management Plan will include specific enhancement objectives to increase habitat function by supporting or increasing specific key environmental correlates and habitat requisites for covered species depending on the location, existing habitat function, and opportunities for enhancement. For example, in grassland habitats where burrowing animals are determined to be limited based on results from implementation of Monitoring Action CM11.3, actions will be undertaken (e.g., manipulation of topography, reduction in rodent control programs, non-native predator control, etc.) to increase ground squirrel and small mammal populations. Another example is postponing tilling of harvested corn fields to increase available forage for wintering greater sandhill cranes. **Schedule**: Variable and ongoing.	**Existing Programs:** None **Potential Program Additions:** 1. Survey methodology to inventory habitat functions and stressors for individual covered species on conservation land 2. Database on non-native predator records on conservation lands (observations, surveys, control measures)	1. Burrowing owl occupancy of artificial burrows. 2. Swainson's hawk and white-tailed occupancy of planted trees. 3. Ground squirrel and rodent activity (burrows per acre). 4. Greater sandhill crane occupancy of created roosts. 5. Activity and reproductive performance of tricolored blackbird colonies. 6. Estimated abundance of California red-legged frogs in enhanced stockponds. 7. Extent of grazing activity in vernal pools 8. Condition of rangeland (cover and composition). 9. Percent cover of native grasses 10. Number of created riparian brush rabbit "bunny mounds" 11. Activity , reproductive success and percent of parasitized nests of tricolored blackbird and yellow-breasted chat breeding colonies, and least Bell's vireo and yellow-billed cuckoo nests. 12. Extent of upland refugia in restored marshes. 13. Documented predation events at nesting colonies. 14. Trend in predator populations. 15. Estimated abundance of feral pigs in Suisun Marsh and other conservation lands. 16. presence /abundance of black rats in suitable riparian woodrat habitat in Conservation Zone 7 17. Acres of each agricultural cover type. 18. Forage value of greater sandhill crane winter foraging habitat (lbs per acre). 19. Covered aquatic invertebrate occupancy of vernal pools. 20. Estimated abundance of giant garter snake	This action is intended to enhance the function of BDCP protected lands to meet specific covered species requirements. This information will provide the basis for determining the functioning of conservation lands with respect to meeting covered species objectives. Management actions are undertaken based on the guidance in the Site-Specific Monitoring Plan, which is subject to modification based on site-specific conditions, opportunities unforeseen at the onset of implementation, or to adjust to the progress of other site specific management plans and the need to meet overall Plan Area-wide goals. CM12: Methylmercury Management				
Monitoring Action CM12-1: Determine the trend in load of methylmercury or precursors discharged from treated sources				
Base conditions: Mercury concentrations in soils to be restored as tidal habitat before levees are breached based on survey information collected under Conservation Measure *CM4, Tidal Habitat Restoration*. **Approach**: Testing of monthly water and sediment samples in restored subtidal habitat areas for methylmercury concentrations. **Schedule**: Monitor monthly for five years or until relationships between restoration of tidal habitats at different locations in the Plan Area and methylmercury concentrations are understood. After the initial five year monitoring period, every 10 years monitor methylmercury concentrations bimonthly for one year.	**Existing**: 1. Environmental Monitoring program (IEP) 2. National Pollutant Discharge Elimination System (NPDES) Self Monitoring Program 3.Continuous Recorder Sites (USBR) 4. Delta Flows network and National Water Quality Assessment Program (USGS) 5. other (DWR, SFEI, etc) 6. UC Davis Biosentinel Hg Monitoring Program **Potential Program Additions:** 1. Establishment and monitoring of methylmercury monitoring stations in restored subtidal habitat areas. See also Monitoring Action CM4-4 and Monitoring Action CM4-6. 2. Expand UC Davis Biosentinel Hg Monitoring Program to include entire Delta and restored floodplain and tidal habitats.	Concentration of methylmercury and precursors	This monitoring is designed to determine the effectiveness of tidal habitat restoration designs in avoiding or reducing methylmercury concentrations in restored subtidal habitats. This information will be used by the Implementing Office to determine if adjustments in tidal habitat restoration designs are necessary to further reduce methylation of mercury. The monitoring schedule may be adjusted based on assessments of initial monitoring results at each restoration site.	TANC1.1 BMNC1.1 FMNC1.1

Monitoring Action CM12-2: Determine the extent of methylmercury exported into Delta channels.				
Base conditions: 1) Methylmercury concentrations in the water column and sediments in channels adjacent tidal marsh restoration sites before levees are breach based on existing data or survey data collected for this purpose. 2) Methylmercury concentrations in restored subtidal habitats from data collected under CM12-2. **Approach**: Testing of monthly water and sediment samples in channels adjacent to restored subtidal habitat areas for methylmercury concentrations in conjunction with sampling implemented under CM12-1. **Schedule**: Monitor monthly for five years or until relationships between restoration of tidal habitats at different locations in the Plan Area and export of methylmercury into adjacent channels are understood. After the initial five year monitoring period, every 10 years monitor methylmercury concentrations bimonthly for one year.	**Existing**: 1. Environmental Monitoring program (IEP) 2. National Pollutant Discharge Elimination System (NPDES) Self Monitoring Program 3. Continuous Recorder Sites (USBR) 4. Delta Flows network and National Water Quality Assessment Program (USGS) 5. Other (DWR, SFEI, etc) 6. UC Davis Biosentinel Hg Monitoring Program **Potential Program Additions:** 1. Establishment and monitoring of sampling stations in channels adjacent to restored subtidal habitats	Concentration of methylmercury and precursors	This monitoring is designed to determine the effectiveness of tidal habitat restoration designs in avoiding or reducing export of methylmercury into existing Plan Area tidal aquatic habitats. This information will be used by the Implementing Office to determine if adjustments in tidal habitat restoration designs are necessary to further reduce methylation of mercury. The monitoring schedule may be adjusted based on assessments of initial monitoring results.	TANC1.1 BMNC1.1 FMNC1.1

CM13: Nonnative Aquatic Vegetation Control				
Monitoring Action CM13-1: Detect and document the establishment of non-native submerged (SAV) and floating aquatic vegetation (FAV) in subtidal aquatic habitats in restored tidal habitat areas.				
Base Condition: The current extent of SAV and FAV present in channels adjacent to tidal habitat restoration sites before breaching of levees based on existing information or field surveys. **Approach**: Monthly monitoring to detect and delineate the extent of SAV and FAV in newly restored tidal habitat areas to detect SAV and FAV establishment, conditions under which it establishes, and patterns of establishment. Monitoring data will be evaluated relative to water quality, hydrodynamic, and other physical parameters collected under other monitoring actions or by others to establish relationships between SAV/FAV establishment and restoration design and site conditions. **Schedule:** Monitoring will occur for five years at each site until relationships between tidal habitat restoration designs and SAV/FAV establishment are well understood.	**Existing Programs:** Department of Boating and Waterways is the lead agency for controlling aquatic weeds in the Delta **Potential Program Additions:** 1. SAV/FAV surveys of restored subtidal habitats	Temporal progress of SAV/FAV establishment Spatial extent of SAV/FAV within a restored subtidal habitat project area	This monitoring is designed to determine the SAV/FAV establishment process relative restoration design and parameters related to Plan Area location (e.g., water quality constituents, hydrodynamic conditions, wind patterns). This information will be used to determine if subsequent restoration designs should be adjusted to reduce the likelihood of establishment and extent of SAV/FAV in restored subtidal habitats and to help guide development of more effective SAV/FAV control methods. The duration of monitoring may be increased or decreased as indicated from evaluation of monitoring results.	ECSY6.1 TANC1.1

Monitoring Action CM13-2: Determine the need for implementation of SAV/FAV control actions and the effectiveness of SAV/FAV control actions.				
Base condition: the extent and distribution of SAV/FAV in restored subtidal habitat areas before implementation of control actions. **Approach**: Monthly surveys of restored subtidal habitats from [month] to [month] to assess the extent of SAV/FAV for use in determining need to implement control actions. Weekly surveys to document changes in extent and distribution of SAV/FAV relative to base conditions following implementation of control actions. **Schedule:** Monthly surveys to determine the need to implement control actions over the term of BDCP. Monitoring following control actions continues until monitoring indicates that the response of SAV/FAV has stabilized or SAV/FAV is determined to be spreading.	**Existing Programs:** Department of Boating and Waterways is the lead agency for controlling aquatic weeds in the Delta **Potential Program Additions:** 1. SAV/FAV surveys of restored subtidal habitats in conjunction with control actions	Areal extent of SAV/FAV or other appropriate measure (e.g., biovolume) Distribution of SAV/FAV in restored habitat	This monitoring action is designed to provide the information necessary to determine the need to implement control actions, the effectiveness of SAV/FAV control techniques over time, and to help determine the frequency with which control actions will need to be implemented in future years. Monitoring frequency and duration to determine the need to implement control actions may be adjusted if relationships between SAV/FAV establishment and need for control actions is established. Monitoring Action CM13-3: Determine the effectiveness of SAV/FAV control actions in reducing the risk for nonnative predatory fish predation on covered fish species.				
Base condition: Nonnative predatory fish abundance before implementation of control actions as determined through CM15 or surveys conducted specifically for this purpose. **Approach:** Bimonthly surveys of control areas following control actions to determine the abundance and distribution of non-native predatory fish. **Schedule:** Monitoring following control actions continues until monitoring indicates that the response of nonnative predatory fish has stabilized or there abundance and distribution increases.	**Existing Programs:** DFG, USFWS, and NMFS fish monitoring programs **Potential Program Additions:** 1. Non-predatory surveys of restored subtidal habitats	Number of nonnative predatory fish per unit area	This monitoring action is designed to provide the information necessary to determine the need to implement control actions, the effectiveness of SAV/FAV control techniques over time, and to help determine the frequency with which control actions will need to be implemented in future years.	ECSY6.1 TANC1.1 CHSA1.8 SASP1.5 STEE1.7
Monitoring Action CM13-4: Determine if non-native SAV/FAV control results in measurable increase in turbidity.				
Base condition: Turbidity of the water column at sampling locations within restored subtidal habitat areas before implementation of SAV/FAV control actions. **Approach**: Weekly turbidity measurements at sampling sites within restored subtidal habitat areas following implementation of control actions. Conducted in conjunction with monitoring under CM2 **Schedule**: see Monitoring Action CM13-1	**Existing:** 1. Environmental Monitoring program (IEP) 2. National Pollutant Discharge Elimination System (NPDES) Self Monitoring Program 3.Continuous Recorder Sites (USBR) 4. Delta Flows network and National Water Quality Assessment Program (USGS) 5. other (DWR, SFEI, etc) **Potential Program Additions:** **1.** Establishment sampling stations and monitoring of turbidity in restored subtidal habitat areas	Turbidity (NTU, TSS)	This monitoring approach will provide information necessary to determine if removal of nonnative aquatic vegetation will increase turbidity of the water column to improve habitat conditions for delta smelt. Species-Level Measures				
CM14: Stockton Deep Water Ship Channel Dissolved Oxygen Levels				
Monitoring Action CM14-1 Operate and maintain an oxygen aeration facility in the Stockton Deep Water Ship Channel (DWSC) to increase dissolved oxygen concentrations between Turner Cut and Stockton to meet Total Maximum Daily Load (TMDL) objectives(above 6.0 mg/L from September 1 through November 30 and above 5.0 mg/L at all times).				
Base condition: Existing aeration operations **Approach:** Keep daily operational and maintenance records for the oxygen aeration facility, tracking hours of operation, amount of Oxygen (lbs) injected, sensor operations and system failures or shutdowns. **Schedule:** Daily operational logs and maintenance records, DWSC Demonstration Dissolved Oxygen Aeration Facility monthly reports.	**Existing Programs:** DWR's Stockton DWSC Demonstration Dissolved Oxygen Project, Bay-Delta Office. **Potential Program Additions:** None	Operational statistics 1. hours of operation 2. lbs of dissolved oxygen 3. failures & shutdowns 4. operational costs 5. maintenance and repair records	This monitoring activity ensures that the operation of the DWSC dissolved Oxygen aeration facility is recorded accurately and operational data are publicly available. The Implementing Office will use this information to determine if system modifications need to be implemented based on system performance and cost/benefit ratios. The monitoring schedule may be adjusted if the existing aeration facility will be modified or additional aerators and associated infrastructure are added to optimize DO delivery to the river.	CHSA1.3

Table 3-20. Potential Effectiveness Monitoring Actions for Conservation Measures (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM14-2 Measure levels of dissolved oxygen (DO) delivered to the river within the 7.5 mile low dissolved oxygen area of the ship channel				
Base condition: As built construction drawings **Approach:** measure dissolved oxygen levels at various distances from the diffuser(s) and depths via remote monitoring stations. Current DO sensors are placed at a depth of about 10 ft (at low tide) and record 15-minute data. Additional sensors will be installed concurrent with addition of diffuser facilities. **Schedule:** Measure minimum DO levels per 15 min interval at each DO sensor station over a 25 hr tidal cycle. Compile Monthly Dissolved Oxygen Data Reports.	Existing Programs: **1.** Demonstration Dissolved Oxygen (DO) Aeration Facility remote monitoring stations (NA 40, 42, 43 and 48), handheld instrument data, California Data Exchange Center (CDEC) Rough and Ready Island (RRI) station data, and CDEC San Joaquin River at Garwood Bridge (SJG) station data Potential Program Additions: Possibly additional remote monitoring stations Possible additional diffusers	1. diffused oxygen (mg/L)	Results from this monitoring will be used to assess the performance of the facilities operations at achieving the water quality objective. The BDCP Implementing Office will use this information to determine whether aeration facility operations result in measurable benefits to water quality of the DWSC. Based on review of performance and effectiveness monitoring results, the BDCP Implementing Office will adjust funding levels, oxygen diffuser methods, or other related aspects that will improve the performance and/or biological effectiveness of the project through the BDCP adaptive management process as appropriate. Such changes will be effected through the BDCP adaptive management process and would be included in the subsequent annual work plans.	CHSA1.3

Table 3-20. Potential Effectiveness Monitoring Actions for Conservation Measures (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM14-3 Determine if aeration increases the use of the Stockton DWSC as a migration route for covered fish species.				
Baseline Condition: existing knowledge and study results on fish migration routes and channel-specific survival rates **Approach**: Through tracking of marked fish (e.g., acoustic tags, radiotelemetry or other suitable method), determine the proportion of tagged fish that successfully migrate through the DWSC. Determine the residence time within DWSC. **Schedule**: Implement covered fish species tracking until a precise (+- 5%) estimate of permeability can be established by species, location and season. Once permeability rates have been estimated, fish tracking can be discontinued for 5 years. Every 5 years thereafter, the Implementing Office will estimate permeation rates and residence times for covered fish species for at least 2 months.	**Existing Programs:** USFWS Delta Juvenile Fish monitoring program (DJFMP), various DFG fish survival and migration tracking studies. Potential Program Additions: Coordinate DJFMP with juvenile fish mortality tracking projects in coordination with operation of DWSC aeration facilities. Separate tracking of tagged adults	Permeation rates (% of tracked fish) Residence time of tracked fish within the DWSC Survival of tagged fish (see also CM 16-3)	This monitoring action is designed to provide information on the effects of DO aeration of the DWSC in enhancing migration of covered species through the DWSC. The Implementing Office will use this information to determine if oxygen diffusion is effective in the re-routing of migrating covered fish species. The monitoring action may be reduced if permeation rates are found to have minimal seasonal and location-dependent variance and are highly precise (+-5%). Results from tracking studies every 5 years will determine if increasing monitoring activities are necessary (i.e., if permeation rates fall below the initially determine value).	CHSA1.3 STEE1.3

Table 3-20. Potential Effectiveness Monitoring Actions for Conservation Measures (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
CM15: Predator Control				
Monitoring Action CM15-1: Document the extent and locations of fish predator hotspots within the Delta.				
Base Condition: Estimated existing locations and types of predator hotspots such as abandoned structures, boats, deep holes , etc. where predators have an above-average effect on sensitive life stages of covered fish species, based on existing information. **Approach:** Using a combination of existing knowledge (e.g., survey of fishermen about striped bass catch locations), aerial surveys (e.g., during mapping of nonnative FAV/SAV), and direct observations (IEP and agency staff on boats within the Delta waterways), inventory and map all known and suspected predator hotspots within Delta waterways where sensitive lifestages of covered fish species are present. **Schedule:** Within 3 years and prior to implementing any predator control measures at hotspots, conduct complete mapping of all major fish-rearing habitats within each waterway to identify and rank potential hotspots of predators. Continue adding new hotspots as they become known.	**Existing Programs:** Extant knowledge of hotspots by fishery biologists, game wardens and agency staff.: DWR IISS section within DWR-DES (potential data warehouse and GIS repository) **Potential Program Additions:** **1.** Development of spatial databases and mapping capabilities including photo-interpretation (GIS lab) 2. tracking of incidental information of predator hotpots from agency staff	1.Location 2. Size 3. Type 4. Structural elements 5. Abundance and type of predatory fish present and relative threat to covered fish species	This monitoring action is designed to provide information on the location and extent of predator hotspots within Delta waterways. The Implementing Office will use this information to schedule removal/amelioration of structures and channel geometry to reduce favorable spots for predatory fish. It also will allow the Implementing Office to estimate costs and technical constraints in removing certain hotspots and adaptively prioritize these for removal. This information will be updated annually and the scheduling of removal/amelioration activities will be adjusted adaptively based on this information The schedule may be adjusted in response to unscheduled events that add significant hiding cover into the channel (floods, windthrow, etc), and to the removal and decelerating need of removals as the channels are being cleared.	ECSY6.1 CHSA1.8 SASP1.5 STEE1.7

Table 3-20. Potential Effectiveness Monitoring Actions for Conservation Measures (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM15-2: Document the extent of predator hotspot removals/ameliorations.				
Base condition: Completed predator hotspot inventory and map (see CM15-1). **Approach**: Annually update the database by identifying removed hotspots. Track costs and disposal of removed materials. **Schedule**: Annual.	**Existing Programs:** none **Potential Program Additions:** **1.** Responsibility to track progress as predator hotspots are removed or ameliorated	Change in number of hotspots Type of hotspots removed/ ameliorated (abandoned structure, boat, etc.)	See CM 15-1	ECSY6.1 CHSA1.8 SASP1.5 STEE1.7
Monitoring Action CM15-3: Document the extent of predator removal activities within Delta hotspots				
Base condition: Existing knowledge of agency staff and experts pertaining to predator hotspots (see CM 15-1). Prior to predator control measures, the relative abundance (species, size and age composition) of predatory fish species must be sampled (non-lethally) at least twice per hotspot to establish baseline conditions. **Approach**: Implement localized predator control actions (e.g., electro-shocking, seining, gill netting or other appropriate methods) to remove targeted predators of covered fish species **Schedule**: Upon establishing baseline conditions and after implementing control measures, continue localized control measures each year at various locations throughout the Delta. Each hotspot will be treated several times (not more than 10 days apart) until predator numbers removed have declined and show a significant asymptotic trend (leveling off). Resample and retreat hotspots every 3-5 years.	**Existing Programs:** IEP fish predator control studies **Potential Program Additions:** Predatory fish control program to reduce localized predator densities and thus reduce covered fish mortality	Predators removed: Species number Size, age Location Diet (gut content)	This monitoring action will provide a estimate of the magnitude of the predator control efforts (Treatment size). This information will be used by the Implementing Office to estimate the effectiveness of controlling predators on sensitive lifestages of covered fish species in open systems (waterways of the delta). It will also provide insight in the life history of predatory fish and will allow addressing potential efficiency issues in an adaptive manner. The Implementing Office will also use these data to address cost effectiveness and to guide additional research, This schedule may be changed upon careful review of results to better encapsulate the response time of predator populations to control measures.	ECSY6.1 CHSA1.8 SASP1.5 STEE1.7

Table 3-20. Potential Effectiveness Monitoring Actions for Conservation Measures (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM15-4: Determine the survival of covered fish species in response to predator control actions.				
Base condition: Baseline studies of predatory fish abundance and mortality levels of covered species due to predation prior to predator control measure implementation. **Approach**: Implement an adaptive experimental management program using a BACI approach to determine the existence and importance of compensatory predation mortality in sensitive lifestages of covered fish species. Specifically, this program investigates under which environmental conditions mortality of covered fish is additive and hence can be affected by localized predator control. Using a combination of fish tagging, sampling and radio- or acoustic telemetry tracking approaches, the Implementing Office will determine mortality rates due to predators at local predation hotspots in comparison to earlier (unmanaged) circumstances (before) and adjacent, randomly selected non-hotspot sites (control sites) **Schedule**: Annually, until uncertainty regarding predator management effectiveness (and density dependence) can be reduced and robust correlations between environmental conditions and predator control effectiveness can be established.	**Existing Programs:** USFWS Delta Juvenile Fish monitoring program (DJFMP), Delta smelt mortality monitoring, DFG hatchery fish radio tracking and acoustic tagging studies. **Potential Program Additions:** Coordinate DJFMP with fish mortality tracking projects in coordination with predator removal projects.	1. Survival rates of sensitive lifestages of covered fish species	This monitoring action is designed to provide information on the effects of predator removals on juvenile fish of covered species. The Implementing Office will use this information to determine if predator removal is effective in increasing the survival of juvenile covered fish species (i.e., mortality is not compensatory / juvenile fish are not regulated by density-dependent factors). To remove uncertainty regarding the role of varying habitat quality and spawning success, the Implementing Office will determine if targeted research or management experiments are needed to determine the conditions under which predator removal an effective management tool to support survival of sensitive lifestages of covered fish species.	ECSY6.1 CHSA1.8 SASP1.5 STEE1.7

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
CM16: Non-Physical Fish Barriers				
Monitoring Action CM16-1 Document the installation of non-physical fish barriers.				
Baseline Condition: As-built construction drawings. **Approach**: Document the installation and seasonal operation of non-physical fish barriers. **Schedule**: ongoing as barriers are installed.	**Existing Programs:** 2009 pilot study (Bowen et al. 2009), various research data. **Potential Program Additions:** 1. Fish barrier database that tracks seasonal operation, cost and incidental observations	Location Hours and dates of operations Performance/Failures and operational statistics of the three components (light, sound, bubbles) Other incidental observations Cost of operations	This monitoring action will provide information on the operation of non-physical fish barriers. This information will be used by the Implementing Office to schedule operations, redesign failing or faulty equipment, or implement other corrective measures as needed to ensure the continuous operation. The monitoring schedule will be adjusted to reflect additional data needs	CHSA1.5 STEE1.3

Table 3-20. Potential Effectiveness Monitoring Actions for Conservation Measures (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM16-2: Determine the permeability of non-physical barriers for outmigrating juvenile salmonids.				
Baseline Condition: existing knowledge and study results on fish migration routes and channel-specific survival artes **Approach**: Through tracking of marked fish (e.g., acoustic tags, radiotelemetry or other suitable method), determine the proportion of tagged fish that penetrate non-physical fish barriers. Determine the residence time at or near barriers. **Schedule**: Implement juvenile salmonid tracking prior or at least simultaneously with the initiation of operation of each physical barrier. Continue tracking fish until a precise (+- 5%) estimate of permeability can be established by species, location and season. Use occasional failures as "experiments" to determine "control" values. Once permeability rates have been estimated, fish tracking can be discontinued for 5 years. Every 5 years thereafter, the Implementing Office will randomly select 3 non-physical fish barriers and estimate permeation rates and residence times for outmigrating juvenile salmonids for at least 2 months.	**Existing Programs:** USFWS Delta Juvenile Fish monitoring program (DJFMP), DFG hatchery fish radio tracking and acoustic tagging studies. **Potential Program Additions:** Coordinate DJFMP with fish mortality tracking projects in coordination with operation of non-physical fish barriers.	Permeation rates (% of tracked fish) Residence time of tracked fish within 500 ft of the barriers Lifestage of tracked fish Survival of tagged fish (see also CM16-3)	This monitoring action is designed to provide information on the effects of non-physical fish barriers in deterring juvenile fish of covered species to enter "low survival" channels. The Implementing Office will use this information to determine if non-physical fish barriers are effective in the re-routing of migrating juvenile covered fish species. This information will also be used to determine if outmigrating juvenile salmonids "pool" at the barriers. Intermittent replications of fish tracking will ensure that non-physical fish barriers are still functional and effective. The monitoring action may be reduced if permeation rates are found to have minimal seasonal and location-dependent variance and are highly precise (+-5%). Results from tracking studies at 3 randomly selected barriers every 5 years will determine if increasing monitoring activities are necessary (i.e., if permeation rates fall below the initially determined value).	CHSA1.5 STEE1.3

Table 3-20. Potential Effectiveness Monitoring Actions for Conservation Measures (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM16-3 Determine the abundance of predators and their effect on the survival of outmigrating juvenile salmonids at non-physical fish barriers.				
Base condition: Baseline studies of predatory fish abundance and mortality levels of covered species due to predation.. **Approach**: Using a combination of fish tagging, sampling and radio- or acoustic telemetry tracking approaches, or visual sampling (underwater cameras) the Implementing Office will determine the abundance and composition of predator guilds at non-physical fish barriers in comparison to earlier (unmanaged) circumstances (before) and adjacent, randomly selected non-hotspots sites (control sites). In conjunction with CM16-3, estimate predation mortality to juvenile salmonids. Also, investigate if there are correlations between residence time of marked juvenile salmonids and predation risk and survival at barriers. **Schedule**: Annually, until uncertainty regarding predation rates can be reduced and robust correlations between residence time and survival of marked juvenile salmonids can be established	**Existing Programs:** USFWS Delta Juvenile Fish Monitoring Program (DJFMP), DFG hatchery fish radio tracking and acoustic tagging studies. **Potential Program Additions:** Coordinate DJFMP with fish mortality tracking projects in coordination with operation of non-physical fish barriers.	Survival of tracked juvenile salmonids (a) within 500 feet of non-physical fish barriers, and (b) for the entire migration (by migration route)	This monitoring action is designed to provide information on the effects of non-physical fish barriers in increasing total survival of outmigrating juvenile fish of covered species. The Implementing Office will use this information to determine to what degree survival of migrating juvenile covered fish species increases as a function of non-physical fish barriers. It will also use these data to determine if predation in the immediate vicinity of barriers increases due to juvenile fish aggregations at the barriers, and to what extent predation at the barriers alters survival during the entire outmigration This information will also be used to determine if predator control activities (see CM15) may be indicated. Results from intermittent replications of fish tracking will determine if non-physical fish barriers are still functional and effective. The monitoring action may be reduced if predation rates are found to have estimable, minimal seasonal and location-dependent variance and are highly precise (+-5%). Results from tracking studies at 3 randomly selected barriers every 5 years will determine if increasing monitoring activities are necessary (i.e., if predation rates increase above the initially determined value). Monitoring Action CM16-4: Determine change in survivorship of outmigrating juvenile salmonids redirected by non-physical barriers.				
Baseline Condition: existing survivorship of outmigrating salmonids using existing migration pathways **Approach**: Through tracking of marked fish (e.g., acoustic tags, radiotelemetry or other suitable method), determine change in outmigration success relative to existing conditions **Schedule**: Annually during peak outmigration periods of affected runs until relationships between barrier operations and outmigration success are understood	**Existing Programs:** USFWS Delta Juvenile Fish monitoring program (DJFMP), DFG hatchery fish radio tracking and acoustic tagging studies. **Potential Program Additions:** Implementation of targeted studies to assess change in survivorship relative to barrier operations.	Change in proportion of outmigrating salmonids passing Chipps Island	This action is designed to provide the Implementing Office with information necessary to determine the effectiveness of non-physical barriers and barrier operations in improving juvenile salmonid survival by directing migration pathways.	CHSA1.5 CHSA1.8 STEE1.3 STEE1.7 SASP1.5
CM17: Hatchery and Genetic Management Plans				
Monitoring Action CM17-1 Document development and implementation of hatchery and genetic management plans for salmonid stocks.				
Base condition: Existing HGMPs and hatchery operations **Approach:** BDCP will evaluate progress towards HGMPs for each hatchery through annual accomplishment reports plans, fiscal accounting reports and interagency agreements and work plans. **Schedule:** within the first 5 years BDCP will have funded and achieved the development of HGMPs for each hatchery within the BDCP area. Updates of HGMPs are conducted every 10 years for the duration of the BDCP.	**Existing Programs:** Existing HGMPs and drafts (Nimbus Hatchery , Feather River Hatchery, Mokelumne River Hatchery) and Coleman National Fish Hatchery and Livingston Stone National Fish Hatchery 2001 Biological Assessment **Potential Program Additions:** none	Annual fiscal /accounting reports Interagency workplans HGMPs as they are developed	This monitoring action will provide information on the progress the BDCP Implementing Office is making towards the implementation of HGMPs for all salmonid hatcheries affected by BDCP. This information will be used by the Implementing Office to determine if modifications to targets or schedules are necessary, and how modifications will be implemented. Such changes will be effected through the BDCP adaptive management process and will be included in the subsequent annual work plans.	CHSA1.9 STEE1.8

Table 3-20. Potential Effectiveness Monitoring Actions for Conservation Measures (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM17-2 Determine if HGMP development and implementation substantially and cost-effectively benefit covered salmonid stocks.				
Base condition: HGMPs as developed and implemented, research hypotheses and models. **Approach**: With funding from BDCP, the Implementing Office will collaborate in the Design and Evaluation of targeted studies, conducted by collaborating agencies that explicitly test the hypothesis that implemented HGMPs are reducing negative effects on wild Chinook salmon and steelhead. **Schedule:** 10 years after implementation of the BDCP, the Implementing Office will have completed a comprehensive meta-analysis and evaluation of the HGMP program.	**Existing Programs:** DFG and USFWS expert staff, UCD genetics lab, hatchery personnel and facilities **Potential Program Additions:** review and analysis capability (either in house or under contract) to comprehensively and rigorously evaluate studies and data on the impacts of hatchery fish on wild salmonid stocks.	Population viability of wild salmonid stocks Competition indices and models Genetic integrity of hatchery and wild stocks	This monitoring action will provide information on the cost-benefit relationship of implementing HGMPs to benefit wild salmonids. If results of review indicate that HGMP development and implementation does not substantially and cost-effectively benefit covered fish species, the BDCP Management Entity in coordination with Fishery Agencies may terminate this conservation measure. If terminated, remaining funding will be deobligated from this conservation measure and reallocated to augment funding for other more effective conservation measures identified in coordination with the Fishery Agencies through the BDCP adaptive management process. The monitoring schedule may be extended for up to 5 years if longer time series are needed to determine conclusively the effects of HGMPs on wild salmonid stocks.	CHSA1.10 STEE1.9

CM18: Illegal Harvest				
Monitoring Action CM18-1: Determine if hiring target of 17 additional game wardens for the BDCP Plan Area has been met				
Base Condition: Current staffing levels of CDFG enforcement officers within the BDCP Plan Area. **Approach:** Review annual employment reports provided by DFG to determine success in filling vacant game warden positions and to determined why positions were not filled (if applicable) **Schedule:** Annual monitoring until the 5-year deadline has been met	**Existing Programs:** none Potential Program Additions: 1. Collaborative data exchange with DFG enforcement and Human Resources	1. Hiring of 17 additional game wardens for the BDCP Plan Area	This monitoring action is intended to provide information regarding achieving enhanced enforcement of fishery regulations for covered species. This information will provide the basis for determining if there is a need to modify the hiring process. The monitoring schedule may be extended beyond the initial 5 year period if necessary.	CHSA1.7 STEE1.6 SASP1.3 GRST1.5 WHST1.5
Monitoring Action CM18-2: Determine the game warden's contact rate with the public				
Base Condition: Current 5-year average contact rate for Game wardens in the BDCP Plan Area **Approach:** The Implementing Office will review annual reports of enforcement statistics for the BDCP plan area, which details the number of contacts, warnings and citations issued per game warden **Schedule:** Annual monitoring of game warden contact rates	**Existing Programs:** Existing analytical methods for assessing effectiveness of contact rates **Potential Program Additions:** 1. Collaborative data exchange with DFG enforcement	1. Rates of contacts, warnings and citations by game warden	This monitoring action is intended to provide information regarding the achievement of enhanced enforcement of fishery regulations for covered species. This information will provide the basis for determining if there is a need provide additional training of game wardens. The monitoring schedule may be altered if necessary. Table 3-20. Potential Effectiveness Monitoring Actions for Conservation Measures (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
Monitoring Action CM18-3: Determine compliance ratios in routine enforcement activities				
Base Condition: 5-year average compliance ratios for Game wardens in the Bay Delta and similar areas **Approach:** The total number of contacts with the public and the total number of warnings and citations issued per year will be recorded annually, consistent with current game warden practices. **Schedule:** Annual monitoring of compliance ratios	**Existing Programs:** Existing analytical methods for assessing compliance effectiveness **Potential Program Additions:** 1. Collaborative data exchange with DFG enforcement	1. % change in compliance ratios (trend) 2. Annual deviation from the 5 year running average compliance ratio.	This monitoring action will provide an assessment of routine enforcement activity and effectiveness of enforcement to reduce illegal harvest This monitoring action will provide the basis for determining if enforcement actions and staffing levels are sufficient to reduce illegal harvest of covered fish in the BDCP Plan Area. The monitoring schedule may be reduced once compliance ratios have declined and are at satisfactory levels	
Monitoring Action CM18-4: Determine success of undercover and non-routine operations				
Base Condition: Current 5-year average arrest ratios for undercover and special enforcement actions in the BDCP Plan Area. **Approach:** The total number of contacts with the public and the total number of warnings and citations issued per year will be recorded annually, consistent with current game warden practices. **Schedule:** Annual monitoring of compliance ratios	**Existing Programs:** Existing analytical methods for assessing success of special enforcement operations **Potential Program Additions:** 1. Collaborative data exchange with DFG enforcement	1. Number of arrests in special undercover enforcement operations 2. Annual deviation (% change) from the 3 year running average of number of arrests per person-hour	This monitoring action will provide an assessment of undercover and non-routine enforcement activity and effectiveness of enforcement to reduce illegal harvest. This monitoring action will provide the basis for determining if undercover and special enforcement actions are sufficient to reduce illegal harvest of covered fish in the BDCP Plan Area. The monitoring schedule may be reduced once arrests/person-hour ratios have declined and are at satisfactory levels.	CHSA1.7 STEE1.6 SASP1.3 GRST1.5 WHST1.5

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Objectives addressed*
CM19: Conservation Hatcheries				
Monitoring Action CM19-1: Support the development of a delta and longfin smelt conservation hatchery by USFWS to house a delta smelt refugial population and provide a source of delta and longfin smelt for supplementation or reintroduction, if deemed necessary by Fishery Agencies.				
Base condition: MOU **Approach**: IEP will 1) document the establishment of functional hatchery facilities and 2) track the funds expended towards implementing a collaborative development of conservation hatcheries by USFWS through its annual reports, financial and operational records. **Schedule**: Annually	**Resources:** 1. USFWS proposals **Potential Program Additions:** 1. Conservation hatchery program budget, 2. Conservation hatchery administration staff	1. Annual progress reports	This monitoring action will provide a detailed accounting of expenses and other support provided to USFWS to develop and operate Conservation hatcheries. This information will be used by the Implementing Office to determine if funding levels and expected benefits are within target levels. The annual reporting schedule is maintained for the duration of the conservation hatchery program.	
Monitoring Action CM19-2: Support the expansion of the refugial population of delta smelt and establishment of a refugial population of longfin smelt at the University of California, Davis Fish Conservation and Culture Laboratory to serve as a population safeguard in case of a catastrophic event in the wild.				
Base condition: MOU. **Approach**: IEP will 1) review annual reports to determine if hatchery operations are successful in establishing and maintaining sufficient refugial populations to meet BDCP objectives and 2) track the funds expended towards expanding refugial population of Delta smelt and longfin smelt at the University of California, Davis Fish Conservation and Culture Laboratory through its annual reports, financial and operational records. **Schedule**: Annually	Resources: 1. University of California, Davis Fish Conservation and Culture Laboratory Potential Program Additions: 1. Conservation hatchery program budget 2. Conservation hatchery administration staff	1. Annual progress reports	This monitoring action will provide a detailed accounting of expenses and other support provided to expanding refugial populations of Delta smelt and longfin smelt at the University of California, Davis Fish Conservation and Culture Laboratory. This information will be used by the Implementing Office to determine if funding levels and expected benefits are within target levels. The annual reporting schedule is maintained for the duration of the conservation hatchery program.	

*[**Note to Reviewers:** This table presents in-progress draft potential system-wide monitoring actions based on the five ecological characteristics described in Section 3.6.2, Monitoring Framework. This table will continue to be refined and populated to ensure that all of the system-wide monitoring actions, including incorporation of metrics from the logic chain, are addressed.]*

Table 3-21. Potential System-Wide Monitoring Actions

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Biological Goals and Objectives Addressed*
Ecosystem Monitoring Element: Foodweb				
Element 1: Primary and Secondary Production				
Monitoring Action SY1-1: Determine the seasonal abundance, distribution, and composition of phytoplankton and zooplankton in Delta and Suisun Marsh/Bay waterways.				
Condition: Seasonal abundances of phytoplankton and zooplankton in Delta and Suisun Marsh channels and waterways as currently sampled. **Approach:** Establish monitoring stations that are representative of different reaches of the Delta and Suisun marsh Take monthly grab samples and measurements of chlorophyll a and zooplankton. Invertebrate sampling should be adaptively adjusted to changes in fish diets. Plankton monitoring tracks changes in phyto- and zooplankton diversity, abundance, and distribution associated with physical and other biological factors in the Delta. Salinity and other water quality variables are monitored at all plankton sites. **Schedule:** Conduct sampling monthly every year for the first 10 years, then randomly sample 30% of all sampling stations annually for the duration of the BDCP.	**Existing Programs:** Ongoing discrete sampling through Environmental Monitoring Program (EMP, under IEP) **Potential Program Additions:** **1.** Additional sampling stations to represent the entire system by individual reach or major channel system. Locations of added stations will be fixed during the duration of the plan to detect increase on food availability in delta waterways. Note that additional stations are added under Monitoring Actions CM 4-3, CM4-4 , CM4-6, and CM16-5 as levees are breached and sites are flooded to track how food production in individual wetlands develops over time (i.e., flux from wetland restoration sites) Sampling stations will also provide water quality data (e.g., temperature, turbidity, pH for ammonia conversion, amount of organic carbon.	1. Phytoplankton: -mg/L chlorophyll a - species composition - relative abundance 2. Zooplankton: - number/1,000 m^3 - species composition - relative abundance 3. variations in oxygen concentration 4. organic carbon-14 content 5. Stable isotopes of Oxygen (16O, 18O and 17O	This monitoring action is intended to collect data necessary to determine and quantify the overall production and export of phytoplankton and zooplankton throughout the Delta This information, in combination with evaluation of other project-specific foodweb-related monitoring and research data, will provide the basis for : 1. Identifying sources of uncertainty and the design of management experiments and/ research studies, to address uncertainty. 2. evaluating underlying conceptual models and hypotheses (source-sink dynamics, variability and uncertainty in primary production response) 3. evaluating restoration design options to increase the production and export of primary production from restored tidal marsh plains 4. Implementing additional management actions to improve production and export of primary production within the Delta. The monitoring schedule will be modified if uncertainty or variances do not support current conceptual models and hypotheses	ECSY5.1 CHSA1.2 STEE1.2 SASP1.2 GRST1.2 WHST12

Table 3-21. Potential System-Wide Monitoring Actions (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Biological Goals and Objectives Addressed*
Monitoring Action SY1-2: Determine the seasonal abundance, distribution, and composition of benthic invertebrates in Delta and Suisun Marsh/Bay waterways.				
Base conditions: ongoing benthic monitoring by IEP throughout the Estuary. **Approach**: Benthic monitoring will be conducted at up to 20 sites within the estuary, with four benthic samples and one sediment sample taken at each site. Samples are analyzed by a contracting lab. Samples will be collected using a hydraulic winch and Ponar dredge or other appropriate grab sampler. **Schedule**: Quarterly	**Existing Programs:** Benthic monitoring component of IEP's Environmental Monitoring Program (EMP) **Potential Program Additions:** Increase the number of benthic sampling stations to up to 20 sites as a representatively sample of the entire BDCP plan area.	1. Species of macro-benthic organisms identified 2. Total number of individuals counted	This monitoring activity provides information on the benthic communities of the estuary, changes in benthic fauna presence, and abundance and distribution associated physical factors in the estuary. Data collected from the benthic monitoring program is also used to detect newly introduced species in the estuary. The Implementing Office will use this information to determine the status and change of benthic communities over the term of the BDCP and to evaluate possible causal relationships between physical factors and benthic invertebrate communities. This information will also provide important indicators of invasive species progress, impacts of toxics and water operations, and other changes within the Delta. The implementing office will use this information to address changes and modifications to conservation measures through the adaptive decision making process. The monitoring schedule may be adjusted to provide data at a higher temporal or spatial resolution of deemed necessary.	ECSY5.1 ECSY5.2 CHSA1.2 STEE1.2 SASP1.2 GRST1.2 WHST12

Table 3-21. Potential System-Wide Monitoring Actions (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Biological Goals and Objectives Addressed*
Ecosystem Monitoring Element: Physical/Chemical/Nutrient Processes				
Element 2: Water Quality				
Monitoring Action SY2-1: Determine the seasonal and spatial variability of water quality within the Plan Area.				
Condition: Existing seasonal water quality conditions based on existing information (see Applicable IEP and other Resources **Approach:** Continue current water quality monitoring as mandated by existing D-1641 North and Western Delta agricultural and municipal and industrial (M&I) standards and all water quality requirements contained in the North Delta Water Agency/DWR Contract and other DWR contractual obligations. **Schedule:** as currently implemented.	**Existing Programs:** 1. Continuous Multiparameter Monitoring, Discrete Physical /Chemical Water Quality Sampling (Environmental Monitoring program; IEP) 2.Continuous Recorder Sites (DWR, USBR) 3. National Pollutant Discharge Elimination System (NPDES) Self Monitoring Program (Central Valley Water Board) 4. Delta Flows Network and USGS)National Water Quality Assessment Program (, Toxic Substances Hydrology Program 5.. other (DWR, SRCSD, SWAMP, Central Valley Water Board, State Water Board, SFEI, etc) **Potential Program Additions:** **1.** There are over 100 water quality sampling sites within the Delta providing a baseline of water quality data. If needed, additional sampling stations may be added to reflect system-wide representative sampling efforts. Additional water quality sampling stations will be added as levees are breached and sites are flooded to track water quality changes at restoration sites. 2. Expand UC Davis Biosentinel Hg Monitoring Program to include entire Delta. see also Monitoring Action CM4-4 and Monitoring Action CM4-6.	1. Water temperature (^{o}C) 2. mg/L dissolved oxygen 3. NTUs 4. EC 5. pH 6. mg methylmercury/L 7. other nutrients and/or toxicants (e.g., Ammonia, Major Cations (Na, K, Ca, Mg), Metals (Cd, Co, Cu, Fe, Mn, Pb, Zn), inorganic Nitrate, pyrethrins,) 8. Derived location of X2 (isohyaline)	This monitoring action is intended to collect data necessary to determine if salinity conditions are meeting contractual and legal requirements. It also provides data necessary to determine if water quality conditions in the different portions of the Delta remain suitable or improve for supporting covered fish species. This information will also used as a reference condition to determine the possible impact of restoration activities on water quality. This information will be used to address deviations from salinity target conditions, and design modifications and/ research studies to address uncertainty in salinity control. This information will be used to evaluate underlying models and hypotheses of water quality responses conservation measures. This information will aid in identifying sources of uncertainty and will guide the design of further management experiments, design modifications and/ research studies to address uncertainty. The monitoring schedule may be adjusted in response to monitoring results to better understand causal relationships between water management and water quality. Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Biological Goals and Objectives Addressed*
Ecosystem Element 3: Hydrodynamics				
Monitoring action SY 3-1: Determine daily flow characteristics throughout the BDCP Plan area.				
Base Condition: Temporal and spatial patterns of flow throughout the Delta region; DAYFLOW, SI3D predictions. **Approach**: Continue monitoring Delta flow and hydrological dynamics through IEP's EMP,. Continue to monitor and calculate flow parameters through Suisun March and at Chipps Island (Delta Net outflow index), **Schedule**: as currently implemented	**Existing Programs:** 1. Delta Flows network (USGS) (21 continuously operating flow stations) 2. IEP EMP sampling station network (15 sites sampled monthly) 3. Flow models (e.g., DAYFLOW, SI3D) **Potential Program Additions:** Expand the USGS network to 29 stations as planned	1. Flow (CFS) 2. Salinity (EC) 3. Water temperature (C^o)	This monitoring action will provide data that will be used by water project operators to assess compliance with target flow levels. They provide a framework for understanding how the tidal currents, river inflows, water project exports, temporary barriers, and DCC gate operations impact transport within the upper estuary. These data are also used routinely for numerical model calibration and validation and are regularly leveraged into large interdisciplinary process-based studies.	ECSY2.1 ECSY2.2 ECSY2.3 ECSY2.4 ECSY2.5, ECSY0.1 CHSA1.5 GRST1.1, RILA1.4, PALA1.4
Ecosystem Element 4: Climate Change				
Monitoring action SY 4-1 Determine the long term dynamics of hydrological characteristics (water level, temperature, salinity) throughout the BDCP Plan area.				
Base Condition: Current monitoring conducted by the interagency network of recorder stations. **Approach**: Continue existing continuous USGS and other agency monitoring programs of Bay Delta water levels, salinity and water temperature; continue modeling of **Schedule**: as currently implemented	**Existing Programs:** Delta Flows network (USGS) comprised of 21 continuously operating flow stations **Potential Program Additions:** Expand the network to 29 stations as planned; See Monitoring Action SY4-1	1. Water level (m) 2. Salinity (EC) 3. Water temperature (C^o)	This monitoring action will provide the Implementing Office with information to determine the magnitude and direction of climate-driven environmental change within the Delta. This information will be used to (a) calibrate models and modify hypotheses as necessary, (b) determine if goals, objectives, or conservation measures are no longer linked with underlying models or hypotheses and thus should be adjusted, modified or eliminated, and (c) if and where changes to planned restoration activities should be considered and managed through the adaptive decision making framework. Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Biological Goals and Objectives Addressed*
Ecosystem Monitoring Element: Ecological Processes				
Element 5: Nonnative Species				
Monitoring Action SY 5-1: Determine the seasonal abundance, distribution, and composition of established nonnative fish predators and competitors with native fishes.				
Base condition: Existing fish surveys and harvest statistics for non-native fish predators/competitors. **Approach:** Annual surveys of non-native fish populations to detect long-term trends. Continue representative sampling of non-native predators in trawls and fish surveys. Estimate harvest rate, population size (CPUE) and age distribution of non-native predatory fish caught in sport fisheries (mark-recapture). **Schedule**: annual	**Existing Programs:** fish surveys 1. CDFG 20 mm Survey 2. CDFG Delta smelt larva study 3. USFWS Spring Kodiak Trawl and 'Supplemental Surveys", (e.g., Mossdale trawl) 4. USFWS Midwater trawl 5. USFWS beach seine 6. CDFG Summer townet survey 7. UCD/IEP Suisun Marsh otter trawl 8. DFG striped bass mark-recapture program 9. IEP fish predator control studies **Potential Program Additions:** Expanded sampling location array to create representative systemwide monitoring network of fish populations. Beach seining to reflect micro-habitats and shallow areas not sampled by trawls. Creel surveys or mandatory harvest reporting for non-native sport fish	1.Abundance, density and diet of non-native predatory centrarchids species (e.g., largemouth bass and sunfishes) in size classes that prey on covered fish species in Delta channels 2. Abundance of non-native predatory fish per unit area of habitat 4. Ratio of non-native fish to native fish 5. Change in harvest success and size of non-native fish caught in sport fisheries	This monitoring action will provide quantitative information about the effectiveness of the conservation measures to reduce predator and competitor populations for different life stages of covered fish species and their spatial response (presence and density) to these enhancements. Monitoring results will be used to evaluate if targets and objectives have been met, parameterize and evaluate conceptual models and other analytical tools, and to prioritize potential actions according to certainty, magnitude and timeliness of benefit. The information provided will also support decisions on potential modification to conservation measures, goals and objectives. It will also be used to determine if additional research activities or special survey technology should be developed.	ECSY6.1 TANC1.2 CHSA1.8 STEE1.7 SASP1.5

Table 3-21. Potential System-Wide Monitoring Actions (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Biological Goals and Objectives Addressed*
Monitoring Action SY 5-2. Determine the abundance and species composition of non-native, submerged and floating aquatic vegetation.				
Base Condition: Existing knowledge/surveys/data by resource managers (DBW) will be used to delineate and estimate nonnative SAV and FAV extent in the Delta. **Approach**: This monitoring is implemented as a two-stage sampling: 1. determine the extent and locations of SAV/FAV by remote sensing or other appropriate methods; 2. Randomized stratified water column sampling. Once a close correlation has been established between actual vegetation samples and remote sensing, physical vegetation samples can be eliminated from the sampling protocol. **Schedule:** Every 3 years delineate areas of nonnative invasive aquatic vegetation and conduct Delta wide paired sampling.	**Existing Programs:** Department of Boating and Waterways (DBW) Aquatic Pest Control Program (DBW is the lead agency for controlling Water Hyacinth and Egeria in the Delta) **Potential Program Additions:** 1. Collaboration with DBW on delineation and inventory of aquatic weed extent 2. Remote sensing or aerial imagery acquisition multiple times throughout the growing season (additional delineation via GPS/GIS from vessels etc.) 3. Vessel-based subsampling to estimate composition of aquatic species See also Monitoring Actions CM 13-1, SY3.3	Extent (acres) of nonnative SAV and FAV Maps of the distribution of nonnative SAV and FAV Species composition of nonnative aquatic vegetation	This monitoring is designed to determine the extent of nonnative SAV and FAV in the waterways and floodplains of the BDCP. The BDCP Implementing Office will use results of plan-area wide monitoring to determine if and where controlling SAV and FAV is achievable and sustainable. This information will be used to determine if non-native aquatic vegetation control measures are sufficient to sustainably reduce their impact in important portions of the Delta. The results will also be used by the Implementing Office to determine if control activities should be adaptively adjusted to changing nonnative SAV/FAV extent. The Implementing Office will also use these results to address uncertainties with research studies and adaptive management experiments. The monitoring schedule may be adjusted to reflect changes in non-native aquatic control efforts.	ECSY6.1 TANC1.2 CHSA1.8, SASP1.5, STEE1.7

Table 3-21. Potential System-Wide Monitoring Actions (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Biological Goals and Objectives Addressed*
Monitoring Action SY5-3. Determine the status and distribution of nonnative clams.				
Base conditions: ongoing benthic monitoring by IEP throughout the Estuary. **Approach**: Benthic monitoring will be conducted at up to 20 sites within the estuary, with four benthic samples and one sediment sample taken at each site. Samples are analyzed by a contracting lab. Samples will be collected using a hydraulic winch and Ponar dredge or other appropriate grab sampler. **Schedule**: Quarterly	**Existing Programs:** Benthic monitoring component of IEP's Environmental Monitoring Program (EMP) **Potential Program Additions:** Increase the number of benthic sampling stations to up to 20 sites as a representatively sample of the entire BDCP plan area. Database to track observation and incidental records of non-native bivalves to estimate their habitat use and range expansion in the Delta	1. Species of non-native bivalves 2. Total number of individuals counted	This monitoring activity provides information on the non-native clams of the estuary, changes in their presence, abundance and distribution. Data collected from the benthic monitoring program is also used to detect newly introduced species in the estuary. The Implementing Office will use this information to determine the status and change of benthic communities over the term of the BDCP and to evaluate possible causal relationships between physical factors and benthic invertebrate communities. This information will also provide important indicators of invasive species progress, impacts of toxics and water operations, and other changes within the Delta. The implementing office will use this information to address changes and modifications to conservation measures through the adaptive decision making process. The monitoring schedule may be adjusted to provide data at a higher temporal or spatial resolution of deemed necessary.	ECSY6.1 TANC1.2

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Biological Goals and Objectives Addressed*
Monitoring Action SY5-3. Determine the status and distribution of Microcystis blooms.				
Base Condition: existing data on Delta microcystis abundance, productivity and correlations with water quality parameters **Approach:** Establish additional fixed monitoring stations as needed in areas where microcystis blooms are observed or likely to occur given water conditions. Take weekly grab samples and measurements of chlorophyll a. **Schedule:** Conduct sampling for the first 5 years following first detection and every 5 years thereafter.	**Existing Programs:** Environmental Monitoring Program (EMP, under IEP) **Potential Program Additions:** **1.** Locations of added stations will be fixed during the duration of the plan to detect increase on microcystis abundance and blooming activity in delta waterways Sampling stations will also provide water quality data (e.g., temperature, turbidity, pH for ammonia conversion, amount of organic carbon) *See Monitoring Actions CM 4-3, CM4-4 , CM4-6, and CM16-5*	1. Phytoplankton species composition/relative abundance 2. Phytoplankton density (mg/L chlorophyll a) 3. microcystis colony structure 4. Water temperature 5. $NH4^+$ concentration 6. EC 7. presence of non-native clams (see SY5-3)	This monitoring action is intended to collect data necessary to determine and quantify the degree of microcystis spread and toxic blooms in the Delta. This information, in combination with evaluation of other foodweb-related monitoring and research data, will provide the basis for : 1. Identifying sources of uncertainty and the design of management experiments and/ research studies, to address uncertainty. 2. evaluating underlying conceptual models and hypotheses (e.g., excessive N loading . grazing effects by clams, salinity and temperature limiting factors) 3. evaluating restoration design options to increase the production and export of primary production inundated floodplains 4. Implementing additional management actions to improve production and export of primary production from the floodplain.	ECSY6.1

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Biological Goals and Objectives Addressed*
Natural Community Monitoring Element				
Element 6: Landscape change				
Monitoring SY6-1: Determine the long-term changes in the location, extent, distribution and juxtaposition of Natural Communities within the Plan Area.				
Base Condition: Current landscape composition (see Chapter 2, *Existing Ecological Conditions*). **Approach**: GIS coverages of natural communities will be updated by remote sensing or other appropriate methods to provide estimates of the change occurring within natural communities and landscapes of the BDCP Planning Area. Classification will be field-checked using BDCP conservation lands as verification sites. **Schedule**: Every five years	**Existing Programs:** GIS database (BDCP) Agency databases (CASIL) **Potential Program Additions:** GIS and spatial analysis capability	1. Extent (acres) 2. Location (boundaries) 3. Distribution (number of parcels, parcel size) 4. Neighborhood spatial statistics	This monitoring action will provide the Implementing Office with a Planning Area-wide assessment of how landscapes change over time. This provides an important framework for assessing the effectiveness of the conservation lands system and its functionality and role within the overall landscape. It also indicates to what degree landscape change follows anticipated shifts in the distributions of covered species and natural communities in response to climate change. The Implementing Office will use this information to determine if current models and hypotheses on landscape and climate change are supported or need to be modified. It further will use this information to examine the context of conservation measures and to address conservation targets through the adaptive decision making process. For example, if certain natural community types become unexpectedly rare, the Implementing Office can adaptively respond by increasing acquisition of conservation lands of the rarest community type. The monitoring schedule may be adjusted if landscape change accelerates.	ECSY1.1 ECSY1.2

Table 3-21. Potential System-Wide Monitoring Actions (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Biological Goals and Objectives Addressed*
Monitoring Action SY6-2: Determine structural connectivity and identify corridors and landscape barriers of the BDCP Plan Area				
Base Condition: Current landscape composition (see Chapter 2, *Existing Ecological Conditions*). **Approach**: Connectivity will be evaluated from Planning Area -wide GIS mapping by calculating structural connectivity measures (e.g., mean inter-patch distance and other connectivity measures) and species specific functional connectivity assessments (e.g., least-cost corridor analyses, circuit theory). Connectivity maps will be produced to identify gaps and breaks in structural and functional connectivity throughout the BDCP Planning Area. **Schedule**: Every 10 years.	**Existing Programs:** GIS databases (BDCP) Agency databases (CASIL) **Potential Program Additions:** 1. GIS and spatial analysis capability 2. Connectivity assessment and analysis (including species modeling)	1. Landscape statistics (e.g., contagion, diversity, elevation, area-perimeter ratios)	This monitoring action will provide the Implementing Office with a Planning Area-wide assessment of structural and functional connectivity of habitats for covered species over time. This provides an important framework for assessing the effectiveness of the conservation lands system and its functionality in connecting habitats and improving covered species movement across the landscape. The Implementing Office will use this information to determine the locations where additional conservation land acquisitions are need to increase landscape connectivity. The monitoring schedule may be adjusted if landscape change accelerates or if major, landscape-altering events occur (floods, fire, seismic events).	ECSY3.1 ECSY3.2

Table 3-21. Potential System-Wide Monitoring Actions (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Biological Goals and Objectives Addressed*
Element 7: Biodiversity				
Monitoring Action SY7-1: Determine the diversity of native species within the BDCP Area.				
Base Condition: Current species occurrence and predicted habitat (see Appendix 1, Covered Species and Chapter 2, *Existing Ecological Conditions*). **Approach**: Calculate the change in the number of present covered species, based on (a) updated maps of natural communities (see Monitoring Action SY6-1), (b) actual surveys of conservation lands, (c) species occurrence databases (e.g., CNDDB) and other agency records. **Schedule**: Every 10 years.	**Existing Programs:** 1. GIS databases 2. CNDDB	1. Number of species 2. Acres of habitat per species	This monitoring action will provide information to the Implementing Office whether the presence/occurrence and diversity of covered species may have changed for the Planning Area. The Implementing Office will use this information to evaluate if conservation lands acquisition should be redesigned or modified. It will also use this information to initiate targeted research to determine causal relationships for this change. This monitoring schedule may be intensified to a 5-year interval if rapid change in biodiversity is indicated or following a major, planning area – wide disturbance (flood, seismic event, etc).	ECSY1.1

Table 3-21. Potential System-Wide Monitoring Actions (continued)

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Biological Goals and Objectives Addressed*
Fish, Wildlife, and Plant Monitoring Elements				
Element 8: Abundance and distribution of covered fish species.				
Monitoring Action SY8-1: Determine the distribution and abundance of juvenile salmonid abundance for each run.				
Base Condition: Current knowledge of presence and abundance of juvenile salmonids in Delta waterways **Approach**: Visual and non-lethal fish sampling (e.g., beach seining, electrofishing) of representative, randomly selected sections in Delta rearing habitats during the. **Schedule**: Annually during rearing/outmigration periods of juvenile salmonids, conduct biweekly sampling	**Existing Programs:** Historical sampling, USFWS weekly beach seining survey of juvenile salmonids (49 permanent locations Delta wide) **Potential Program Additions:** 1. Add sampling locations to ensure statistical representative sampling effort See also *Monitoring Action CM5-3.*	1. Abundance 2 . size 3. race 4. location	This monitoring action will provide information on the presence and abundance and relative use of delta waterways by juvenile salmonids. Results of monitoring will be assessed to determine if salmonid distribution and abundance is responding to increasing habitat and food availability as restoration progresses. The information will be used test and evaluate numerous models and hypotheses on stressors and limiting factors for salmonids in the Delta. The schedule of the monitoring action may be adjusted to reflect changes in management or research results on fish presence in inundated floodplains.	CHSA1.5 STEE1.3
Monitoring Action SY8-2: Determine the seasonal abundance and distribution of juvenile and adult delta smelt.				
[Text to come.]	[Text to come.]	[Text to come.]	[Text to come.]	
Monitoring Action SY8-3: Determine the location of delta smelt spawning habitats.				
[Text to come.]	[Text to come.]	[Text to come.]	[Text to come.]

Base Conditions, Approach, and Schedule	*Applicable IEP and other Programs and Potential Additions to those Programs*	*Metrics*	*Adaptive Management Considerations*	*Biological Goals and Objectives Addressed*
Monitoring Action SY8-4: Determine the seasonal abundance and distribution of juvenile and adult Sacramento splittail.				
Base condition: Conduct surveys of splittail adults, larvae, and eggs to determine the abundance of splittail larvae, juveniles and adult present during the reproductive period. **Approach:** Conduct fish sampling surveys to determine the change in densities of larvae and juveniles relative to base conditions and in-channel spawning. **Schedule:** Weekly fish sampling will be conducted in spawning habitat during the first 5 floodplain inundation periods during the splittail spawning season. Subsequently monitor every fifth flood event over the term of the BDCP.	**Existing Programs:** USFWS rotary screw traps USFWS beach seine **Potential Program Additions:** 1. Add sampling locations to include restored floodplain and adjacent channel habitats to ensure statistical representative sampling effort	1. Production of Sacramento splittail (number of larval and early juvenile splittail/10,000 m^3) during floodplain inundation periods	This monitoring action will provide information on productivity of Sacramento splittail populations and the contribution of inundated restored floodplains on spawning and rearing of splittail. This information will be used by the Implementing Office to decide if the production of splittail during floodplain inundation periods has increased significantly from base conditions. If monitoring results do not support conceptual models and hypotheses predicting increasing splittail spawning, the Implementing Office will conduct additional studies to determine 1. uncertainties and competing hypotheses 2. other factors/stressors that affect splittail spawning and rearing in restored habitats, and 3. restoration design modifications to increase splittail productivity. If causes are related to inundation duration, experimental management of flood control structures and floodplain topography may used to address uncertainties. The monitoring schedule may be extended or intensified if uncertainties of causal relationships persist.	SASP1.1 SASP1.3

3.7 ADAPTIVE MANAGEMENT PROGRAM

[***Note to Reviewers****: The text of this section of Chapter 3 on adaptive management was revised based on comments by Steering Committee members following the October 21, 2010 meeting. This section is subject to change and revision based on further input from the BDCP Steering Committee.*]

The BDCP Adaptive management program is premised on the concept that, as new information and insight is gained during the implementation of a conservation plan, adjustments can be made to the conservation actions to further advance the goals and objectives of the plan. The Natural Community Conservation Planning Act (NCCPA) recognizes this function, defining adaptive management as a process whereby "the results of new information gathered through the monitoring program of the plan and from other sources [is applied] to adjust management strategies and practices to assist in providing for the conservation of covered species."[45] Similarly, the U.S. Fish and Wildlife Service (USFWS) and National Marine Fisheries Service (NMFS) describe adaptive management as a "method for examining alternative strategies for meeting measurable biological goals and objectives, and then if necessary, adjusting future conservation management actions according to what is learned."[46]

Consistent with these definitions, the BDCP adaptive management program will provide the basis for: (1) key gaps in data and knowledge to be identified and steps to be taken to close such gaps; ; (2) alternative approaches to conservation actions to be developed that would enhance the effectiveness of conservation measures; (3) new information gathered through monitoring and targeted research programs to be evaluated; and (4) analytical processes and feedback loops to be instituted to better inform decisions regarding adaptive changes. Outcomes of the adaptive management decision making process could include changes in conservation measures, biological objectives and targets, monitoring actions and metrics, and analytical tools within the boundaries established by the BDCP.

The Program Manager, through the Science Manager, will be responsible for the administration and implementation of the BDCP adaptive management program. The BDCP Implementation Board will oversee the Implementation Office's implementation of the program. The roles and responsibilities of the Implementation Office, the Implementation Board, the fish and wildlife agencies, and the Authorized Entities in the adaptive management program are summarized in Section 3.7.2 *Adaptive Management Decision Making Process.*

The conservation measures described in Section 3.4, *Conservation Measures*, are based on the best scientific and commercial information and data available and have been designed to address the biological goals and objectives of the Plan. As the BDCP is being implemented, however, new data and information will be developed through the monitoring and research program described in Section 3.6, *Monitoring and Research Program*, as well as through other efforts, that

[45] Fish and Game Code Section 2805(a)
[46] Five-Point Policy for HCPs, 65 FR 106, June 1, 2000

will further inform the Implementation Office on a number of matters affecting plan implementation.

Information gained through monitoring and research will help inform investigations into such matters as: maximizing the efficacy of conservation measures and understanding the factors that may account for poorer than expected ecological responses to the implementation conservation measures; the synergistic and cumulative effects associated with multiple conservation measures; the influence of factors present outside the BDCP Plan Area, including those associated with other conservation planning efforts; and the effects of operational criteria on ecosystem conditions. Additionally, monitoring and research conducted under the BDCP and other programs produce information and data regarding the effects of climate change on Delta conditions (e.g., sea level rise, hydrology in the Delta watershed, and increased water temperatures), seismic events, projected large-scale changes in land use, and other circumstances that fall outside of the scope of the BDCP to address.

As more is understood about the Delta ecosystem, modifications to the BDCP conservation measures may be necessary. Conservation measures may initially prove to be less effective than expected, but as more is learned through the adaptive management process, certain adjustments may be possible to increase the effectiveness of measures. Alternatively, conservation measures may prove initially effective, but changing conditions in the Plan Area may necessitate changes in the manner in which conservation measure are implemented or require a shift to more effective measures. The adaptive management process will afford the Implementation Office, in coordination with the Implementation Board, the flexibility to address the shortcomings of conservation measures in meeting BDCP goals and objectives by making adjustments to these measures. Specifically, adaptive management changes may include modifications to the conservation measures, their elimination altogether, or the addition of new measures. The adaptive management program may also indicate refinements to the biological goals and objectives and targets; changes in the priorities for implementation of conservation measures, including the shifting of funds among measures; and changes to the monitoring program as indicated by new scientific information. Should strong cause and effect relationships be established, the adaptive management program will provide the mechanism to concentrate efforts on the implementation of conservation measures that have been demonstrated to be effective and to de-emphasize or discontinue implementation of conservation measures that have proven to be less effective at achieving desired outcomes.

To address uncertainty regarding Delta ecological processes and species biology, to provide for flexibility in the Conservation Strategy through time as ecological knowledge expands, and to ensure that the BDCP becomes increasingly more effective over time and responsive to changing ecological conditions in the Delta, the BDCP adaptive management program has been developed with the following elements:

- **Process Framework –** the process by which the BDCP adaptive management program will be implemented, including gathering data through monitoring and targeted research, analyzing data, assimilating new knowledge, and making adjustments to the strategy (Section 3.7.1, *Adaptive Management Process Framework*);

- **Decision Making Process –** a decision making process that effectively uses new information in a timely manner to make adaptive management changes and that allows for sufficient input from various participants (Section 3.7.2, *Adaptive Management Decision Making Process*; see also Chapter 7, *Implementation Structure*) under the governance structure of the BDCP;
- **Adaptive Ranges –** specifically established upper and lower boundaries and limits that govern the scope of changes that can be made to conservation measures, including water operations criteria, pursuant to the adaptive management program. These ranges are reflected in the BDCP and its associated regulatory authorizations. (Section 3.7.3, *Concept of a "Defined Adaptive Range" and Water Operations Adaptive Management*);
- **Targeted Research** – experiments and pilot studies specifically designed to test uncertainties and the hypotheses underlying conservation measures, and to rapidly gain knowledge that could improve performance (Section 3.7.5, *Adaptive Management Experiments*);
- **Status Reviews –** required regular reviews of the Conservation Strategy's performance, achievement of goals and objectives, and status of covered species (Section 3.7.7, *Program Status Reviews*; see also Section 6.2, *Compliance and Progress Reporting*).

This adaptive program of knowledge expansion and implementation flexibility is central to the BDCP Conservation Strategy and the achievement of the BDCP biological goals and objectives.

3.7.1 Adaptive Management Process Framework

The process framework for the BDCP adaptive management program is depicted in Figure 3-63.

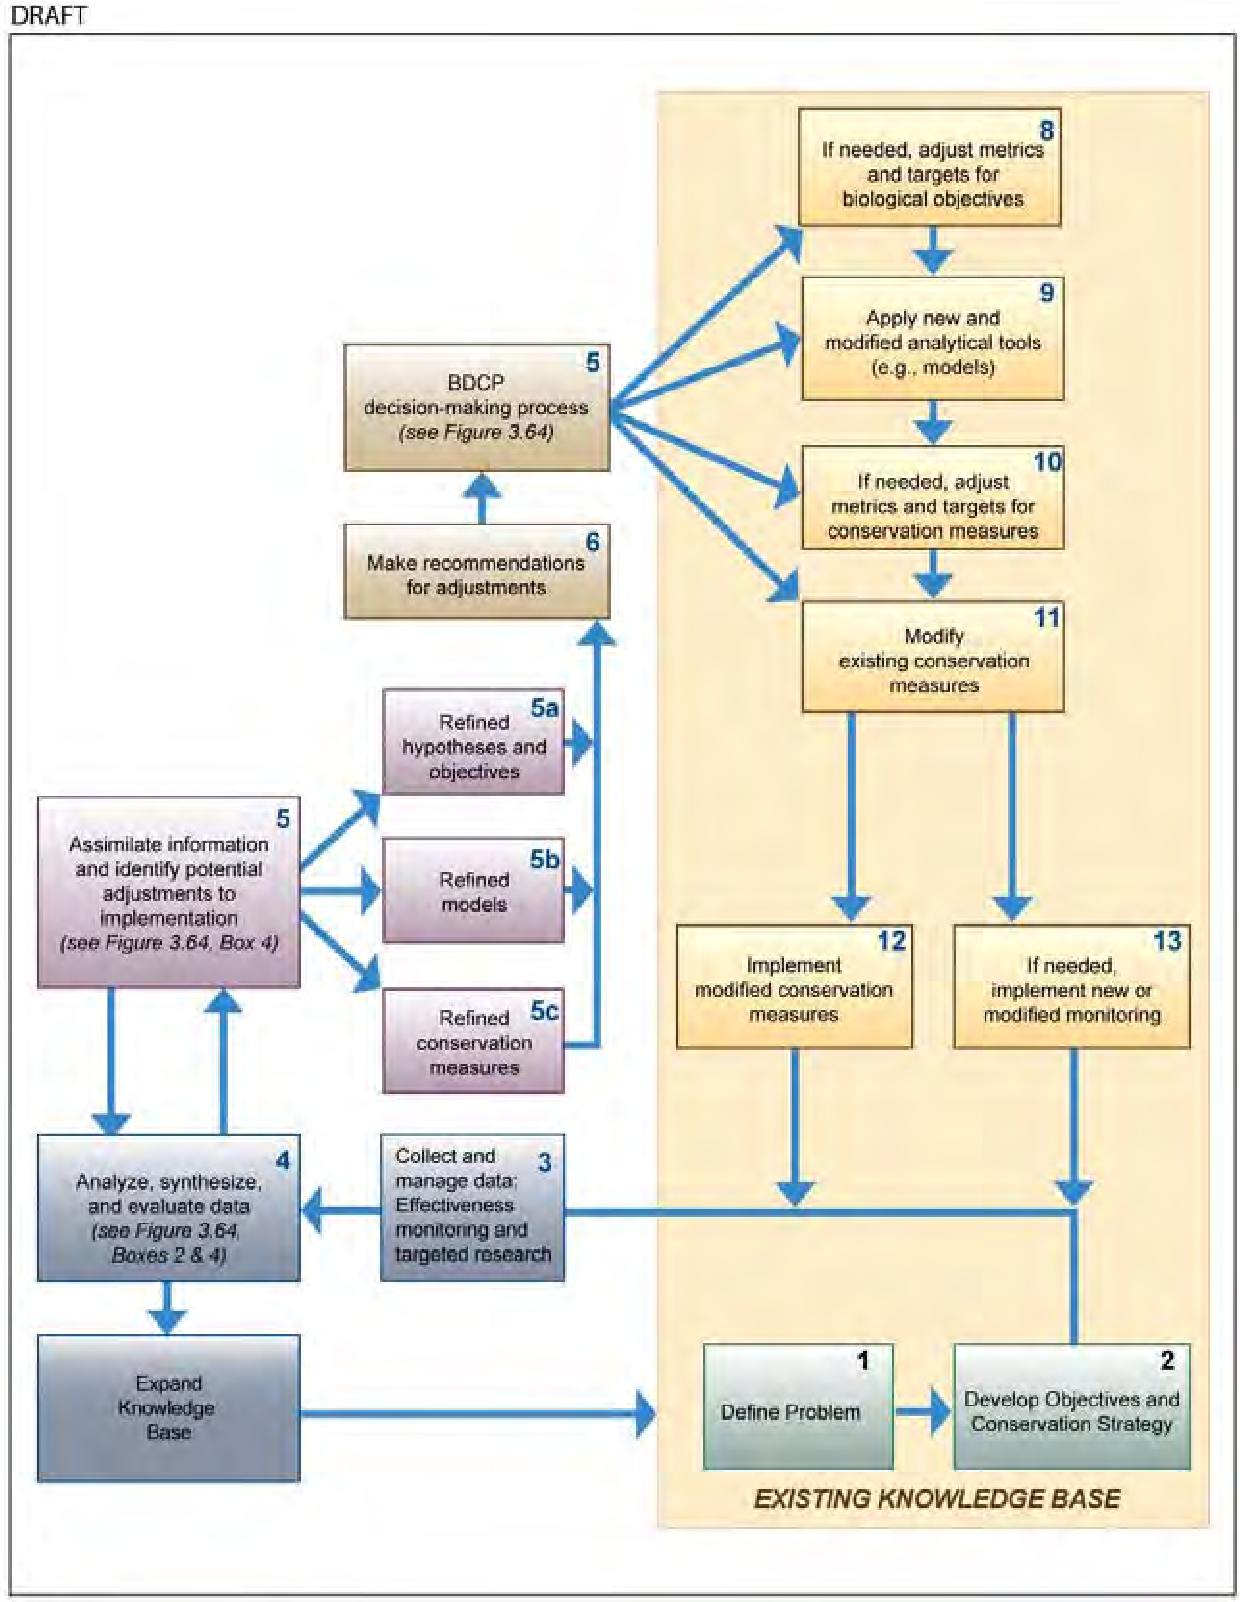

Figure 3-63. BDCP Adaptive Management Process Framework

To ensure development of a scientifically-based BDCP adaptive management program, independent science advisors were engaged to provide expert input on best approaches to adaptive management. The results of the deliberations of these scientists are reflected in the *BDCP Independent Science Advisors Report on Adaptive Management, February 2009* (Appendix G). The report set out the following principles for effective adaptive management:

1. The scope and degree of reversibility of each proposed action (i.e., conservation measure) determines the form of adaptive management that can be applied (e.g., “active” or versus “passive” adaptive management)[47].
2. The knowledge base about the ecosystem is key to decisions about what to do and what to monitor, and includes all relevant information, not just that derived from monitoring and analysis within the context of BDCP.
3. Program goals should relate directly to the problems being addressed and provide the intent behind the conservation measures; objectives should correspond to measurable, predicted outcomes.
4. Models should be used to formalize the knowledge base, develop expectations of future conditions and conservation outcomes that can be tested by monitoring and analysis, assess the likelihood of various outcomes, and identify tradeoffs among conservation measures.
5. Monitoring should be targeted at specific mechanisms thought to underlie the conservation measures, and must be integrated with an explicitly funded program for assessing the resulting data.
6. Prioritization and sequencing of conservation measures should be assessed at multiple steps in the adaptive management cycle.
7. Specifically targeted institutional arrangements are required to establish effective feedback mechanisms to inform decisions about whether to retain, modify, or replace conservation measures.
8. A dedicated, highly skilled agent (person, team, office) is essential to assimilate knowledge from monitoring and technical studies and make recommendations to senior decision makers regarding programmatic changes.

The advisors report included an adaptive management process framework. The BDCP adaptive management process depicted in the flow diagram in Figure 3-64 follows the recommendations provided in the independent science advisors report.

47 Active adaptive management is experimental, involving manipulations intended to achieve conservation goals but also to improve knowledge. Passive adaptive management is not experimental, but is nevertheless approached from a scientific perspective to improve knowledge and adapt strategies during project implementation.

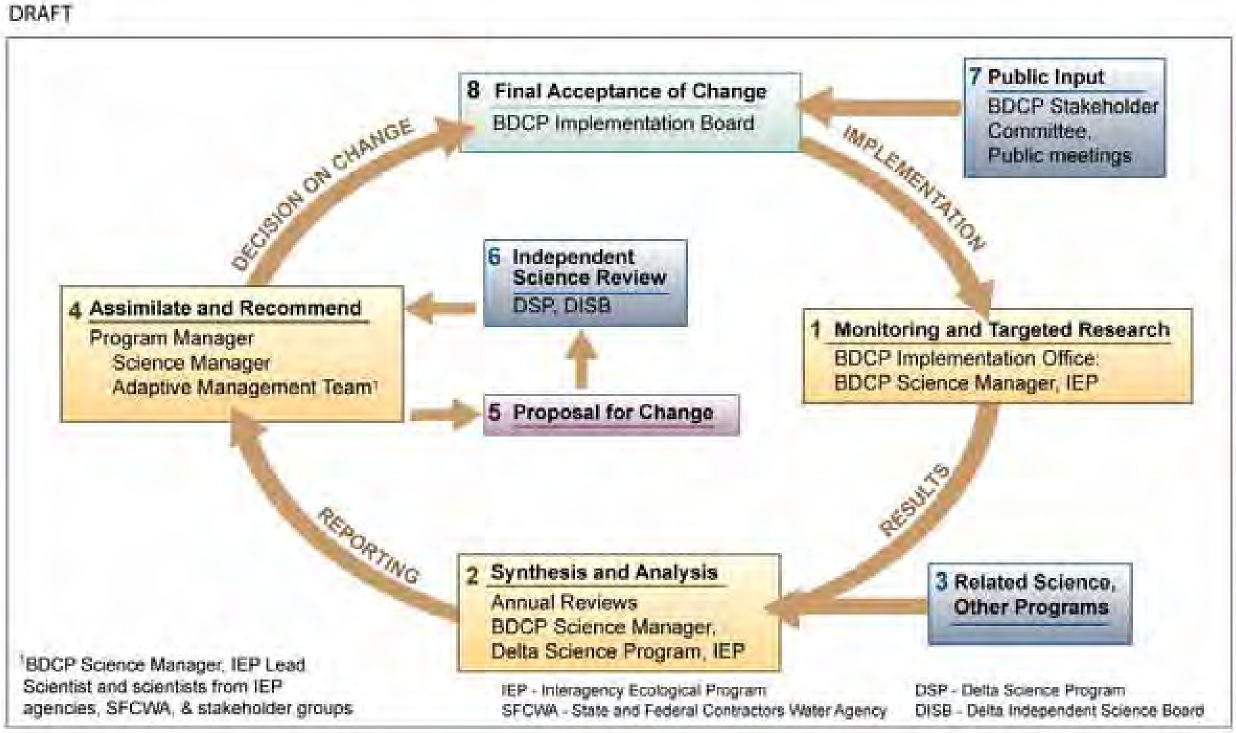

Figure 3-64. BDCP Adaptive Management – Decision-Making Process

3.7.1.1 Plan Objectives and the Knowledge Base

The starting point for the BDCP adaptive management process is with the definition of global problems and the identification of BDCP-specific, measurable and practical biological goals and objectives (see Figure 3-63, Boxes 1 and 2). BDCP objectives are based on the best available information about covered species, natural communities, ecosystem function in the Delta, and about the environmental stressors affecting these biological resources, and anticipated ecological and species responses to the conservation measures. The current information about system function and stressors comprises the existing "knowledge base" (see large shaded box underlying the right side of Figure 3-63). The adaptive management process is designed to use new information (i.e. contributions to the knowledge base) to inform a systematic and integrated critical review, at regular intervals, of the entire Conservation Strategy, including BDCP objectives, conservation measures, hypotheses relating to predicted outcomes and targets. As the knowledge base is expanded, and biological models are revised, changes may be made to the BDCP objectives and associated hypotheses, metrics, targets, and monitoring metrics (Figure 3-63, Box 5; see Section 3.7.1.3). The Science Manager, within the BDCP Implementation Office, is responsible for ensuring that the adaptive management program is focused on the achievement of BDCP biological goals and objectives and that the program draws from be best scientific and commercial information available to support adaptive management decisions.

3.7.1.2 Collect and Manage Data

Critical to the adaptive management process is the collection and management of existing and new data (see Figure 3-63, Box 3) to assess conservation measure performance and the achievement of biological goals and objectives. Monitoring and targeted research data collection and management will be the responsibility of the Science Manager within the BDCP Implementation Office with assistance from the Interagency Ecological Program (IEP), and in coordination with the Delta Science Program and other science and monitoring programs (see Section 3.6, *Monitoring and Research Program*). Monitoring actions and metrics are described in Section 3.6, *Monitoring and Research Program*. In addition, results of targeted research and scientific modeling conducted by programs other than the BDCP will contribute to the knowledge base to support understanding of ecological cause and effect relationships. Monitoring data and research results will provide the BDCP Implementation Office with information to help determine the effectiveness of conservation measures in providing benefits to species and habitats, the effectiveness of adjusting or modifying approaches to the implementation of the measures, and the effectiveness of combinations of measures to achieve desired objectives. Because new data provide the foundation for making effective adjustments to plan implementation over time through the adaptive management process, collected data will undergo quality assurance reviews. Recommendations to modify implementation of conservation measures will be guided by information gathered through the monitoring and research program and other research sources (Figure 3-63, Box 3, see also Figure 3-64, Box 3). The BDCP monitoring and research program is designed to establish cause and effect relationships between implementation of specific conservation measures and the type and magnitude of ecosystem and species responses to those measures, as well as responses to the implementation of combinations of conservation measures.

The Implementation Office will establish processes and procedures to govern the systematic control and management of information obtained through BDCP monitoring and research. Specifically, the Implementation Office will ensure that all information is appropriately classified, stored, secured, and shared. This includes:

- Ensure that records of permanent value are preserved.
- Ensure the security and protection of regulatory, statutory or business importance from unauthorized access and/or modification.
- Ensure that all BDCP data is of the highest quality (accuracy and precision).
- Ensure responsive and transparent sharing of data across the widest-possible spectrum of users, including scientists, government agencies, non-governmental organizations and the public.

3.7.1.3 Analyze Data, Assimilate Information, and Develop and Recommend Adjustments to Implementation.

The science advisors report on adaptive management (Appendix G) pointed out that the weakest aspect of most adaptive management plans is in the sequence of steps required to link the knowledge gained from implementation monitoring and research and other sources to decisions about whether to continue, modify, or stop actions, refine objectives, or alter monitoring (Figure 3-63, Box 5 and Box 6; Figure 3-65). See the discussion of internal and external science review in the 3.7.2, *Adaptive Management Decision Making*.

Collected data will be analyzed and synthesized at appropriate intervals by the Implementation Office, in coordination with Delta Science Program and IEP, and these results will be evaluated by the Adaptive Management Team. The BDCP Science Manager may utilize IEP, the Delta Science Program, and other expertise to support the evaluation of monitoring and research data. Results will include information related to cause and effect relationships between conservation measures and ecological processes, covered species, and natural communities; the status of ecosystem conditions and covered species; and the effectiveness of the conservation measures and the monitoring program (Figure 3-63, Box 5). The results will also clearly identify the inferential reliability of this knowledge (sensu Romesburg 1981), statistical performance measures (e.g. power accuracy, precision) and, if appropriate, alternative hypotheses generated from the results. Information gained through this process may indicate the need to redefine hypotheses underlying biological objectives and conservation measures; refine, discontinue, or expand conservation measures; or develop and implement new conservation measures within limits set by the plan and its associated regulatory authorizations.

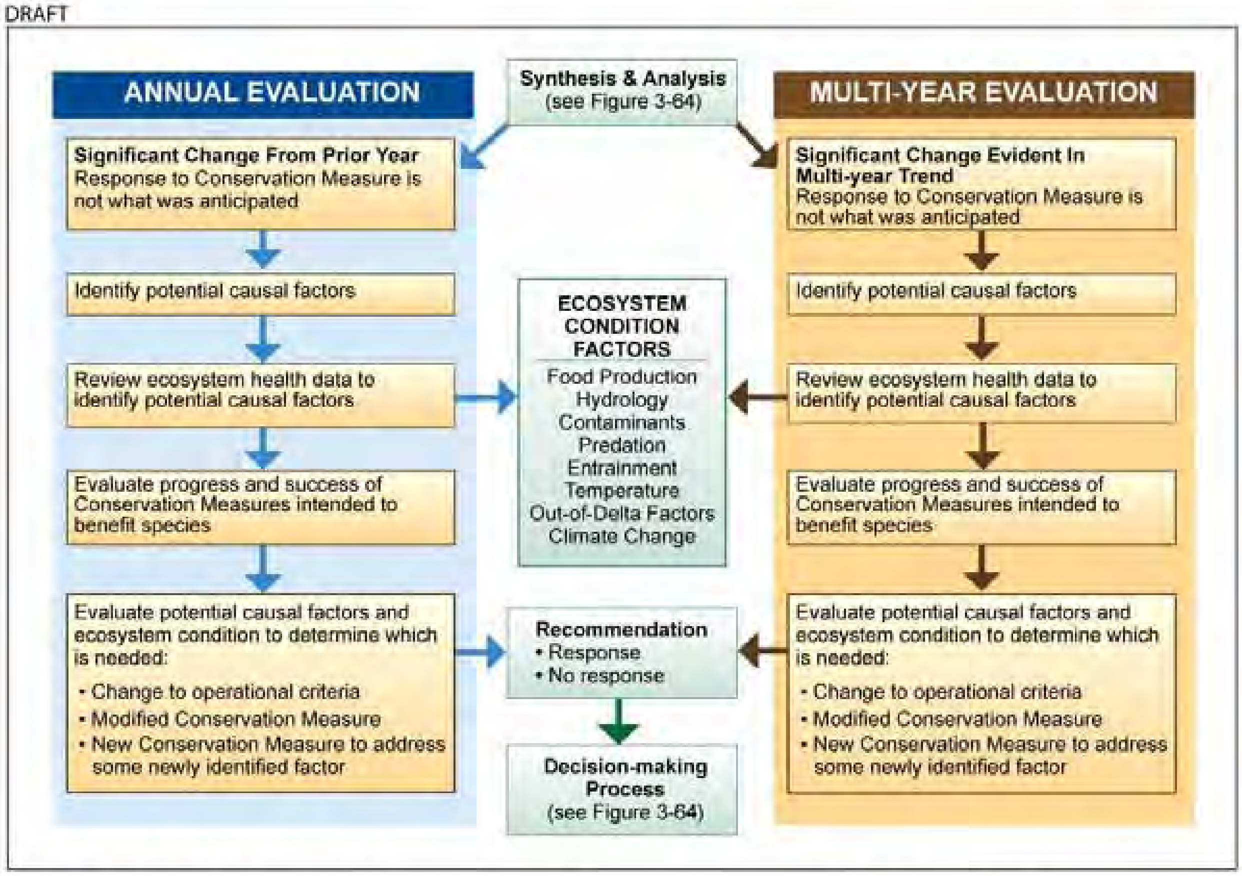

Figure 3-65. BDCP Adaptive Management Process: Response to a Significant Declining Trend in Covered Species

The science advisors also emphasized the need to integrate the evaluation of the efficacy of conservation measures across suites of measures that are inter-related, and to use and expand upon the existing (and new) modeling capabilities to assist in that integrated evaluation. New data will therefore also be used to update models (e.g., conceptual, statistical, and process models) and other analytical tools that are useful in assessing the performance of both individual conservation measures and suites of interrelated measures in helping to achieve the goals and objectives of the plan as the magnitude of stressors are better understood and uncertainties are resolved. New data and modeling work will also help predict the magnitude and trajectory of ecosystem and covered species responses to conservation measures and identify the need for new models and tools (Figure 3-63, Box 5 which corresponds to Box 4 of decision making process illustrated in Figure 3-64). Ecological models (either conceptual or mathematical) are extremely valuable for formalizing the link between objectives and proposed conservation measures to clarify how and why each conservation measure is expected to contribute to objectives and are a key element of adaptive management. Models will be used to formalize knowledge about the system and to predict the outcomes of and design modifications to conservation measures.

Based on assimilation of new information, the Adaptive Management Team (see Section 3.7.2.1, *Roles and Responsibilities*) working with the IEP, Real Time Operations Response Team (see Chapter 7, *Implementation Structure*) and the Implementation Facilitation Team (see Chapter 7, *Implementation Structure*), as appropriate, will formulate recommended new approaches for BDCP implementation intended to increase the effectiveness of conservation measures, the monitoring program, analytical tools, and metrics in meeting the biological goals and objectives of the BDCP (see Figure 3-63, Box 6). The BDCP Program Manager may include such recommendation in the Annual Workplan and Budget (see Section 6.2, *Compliance and Progress Reporting*). Recommended new approaches to conservation actions would be considered, and potentially adopted, through the BDCP adaptive management decision making process (Figure 3-64).

3.7.1.4 Implement Modified Conservation Measures, Tools, Metrics, and Targets

BDCP Implementation Office through the adaptive management program, and within the limits of the adaptive ranges set out in the BDCP and reflected in the associated regulatory authorizations, would implement adaptive changes to the BDCP Conservation Strategy that may include:

- **Adjustments to metrics and targets for biological objectives** (Figure 3-63, Box 8) – Metrics and targets for BDCP biological objectives were developed based on the existing knowledge base. New information developed during the BDCP implementation could result in the need to revise metrics and targets for these objectives (as allowable under the authorizing permits).
- **Development and application of new analytical tools** (Figure 3-63, Box 9) – As knowledge grows over time, new analytical tools are expected to be developed including monitoring technologies and techniques, physical and biological models, statistical

relationships, etc. These new tools would be applied to the monitoring and evaluation of implementation of the BDCP Conservation Strategy as they become available.

- **Adjustments to metrics and targets for conservation measures** (Figure 3-63, Box 10) – Specific metrics and targets have been identified for BDCP conservation measures based on existing knowledge. As understanding of the Delta ecosystem improves, revisions would be made to these metrics and targets to reflect this new knowledge, as appropriate.

- **Modification of conservation measures** (Figure 3-63, Box 11) – The adaptive management program guides the modification of BDCP conservation measures to improve effectiveness in meeting BDCP goals and objectives. The adaptive management program can also modify priorities and timetables for implementing conservation measures based on new knowledge.

- **Discontinuance of ineffective conservation measures** (Figure 3-63, Box 11) – The adaptive management program allows for the elimination of unsuccessful conservation measures. The funds allocated to these measures may be reallocated to expand successful measures.

- **Identification of new conservation measures** (Figure 3-63, Box 11) – As a result of BDCP monitoring and research and new knowledge, new stressors may be identified which are drivers of ecosystem change and species response. The adaptive management program may be used, subject to the limits established in the Plan, to incorporate new conservation measure to address these stressors in the Conservation Strategy. [***Note to Reviewers****: Could refer to Section 3.5, Potential Conservation Measures to Address Other Stressors, depending on the approach decided for those potential conservation measures.]*

- **Implementation of new or modified monitoring methods** (Figure 3-63, Box 13) – The adaptive management program will inform and guide the subjects of monitoring, monitoring metrics, and the duration and scope of monitoring. Monitoring technology and techniques improve through time and as new methods are developed they will be incorporated into the BDCP monitoring program. The adaptive management program would also identify and implement modifications to the research program and adaptive management experiments to address new uncertainties and fill knowledge gaps.

BDCP actions related to SWP and CVP water operations remain under the authority and are the responsibility of DWR and Reclamation, not the Implementation Office. Adjustments to the water operations criteria set out in the BDCP and reflected in its associated authorizations, and within the adaptive range for water operations described in CM1 *Water Facilities and Operations*, may only be conducted through the process identified in Section 3.7.3.2, *Decision Process for Adjusting Water Operations within the Adaptive Range.*

3.7.2 Adaptive Management Decision Making Process

This section describes the process by which adaptive management decisions will be made, including those that result in adjustments to conservation measures, operational criteria, biological objectives, metrics and targets, the monitoring program including monitoring methods, and analytical tools, as warranted by new information. This section describes the relationships among, and coordination between, the entities that comprise the governance structure (Chapter 7, *Implementation Structure*) in the context of the adaptive management decision-making process (Figure 3-64).

3.7.2.1 Roles and Responsibilities

3.7.2.1.1 Science Manager

The BDCP Implementation Office, under the direction of the BDCP Program Manager, is responsible for Plan implementation, including the monitoring, research, and adaptive management programs. The BDCP Science Manager, under the direction of the Program Manager, is the primary Implementation Office staff responsible for ensuring the proper implementation of these programs.

3.7.2.1.2 Adaptive Management Team

The Science Manager may create an “Adaptive Management Team” and will serve as the chair of and recommend membership for the BDCP Adaptive Management Team to the Program Manager. Membership of the Adaptive Management Team will be reviewed and approved by the BDCP Program Manager and the BDCP Implementation Board. The Adaptive Management Team may include:

- BDCP Science Manager (chair);
- IEP Lead Scientist;
- Senior scientists from IEP member agencies[48];
- SFWCA scientists;
- Other scientists; and
- Scientists from the Stakeholder Committee, as appropriate.

Adaptive Management Team members may change as necessary depending on specific the technical issues that need to be addressed (e.g., fisheries, terrestrial wildlife, habitat restoration, water operations).

[48] IEP has ten member agencies: three State (DWR, DFG, and State Water Resources Control Board); six Federal (USFWS, Reclamation, U.S. Geological Survey, USACE, NMFS, and U.S. Environmental Protection Agency), and one non-government organization (The San Francisco Estuarine Institute).

The Science Manager will utilize the Adaptive Management Team to support the conduct of annual and multi-year reviews, in coordination with the Delta Science Program, including efforts to identify issues that may benefit from independent science advice; consider potential adaptive management actions that may be indicated by the results of monitoring and research efforts; and identify research that may be useful to effectively address uncertainties. The Adaptive Management Team will make recommendations to the Program Manager for adaptive management changes to the BDCP Conservation Strategy.

The Science Manager may utilize the Adaptive Management Team to support the synthesis and presentation of current scientific knowledge on relevant Delta resources to the Program Manager and BDCP Implementation Board.

3.7.2.2 Adaptive Management Decisions and Responses (Not Related to Water Operations)

The Program Manager will manage the BDCP adaptive management program through the Science Manager. The Program Manager will facilitate and coordinate discussion and consideration of adaptive management issues among the various participating entities, including the authorized entities, fish and wildlife agencies, and the Implementation Board to facilitate decision-making regarding changes in the implementation of the Plan. Adaptive management decisions to take new actions within the BDCP Plan Area will take into account and be coordinated with changes that may be made to upstream operations, which may result from changes made pursuant to existing or future biological opinions for the CVP/SWP project operations outside the Delta. The decision-making process described in this section does not apply to changes or modifications to water operations that may be made by DWR and USBR. The process for adaptive management decisions affecting water operations is set out in Section 3.7.3.2, *Decision Process for Adjusting Water Operations within the Adaptive Range*. The approach depicted in Figure 3-64 will be used to make adaptive management decisions relating to BDCP actions that are not related to water operations.

1. Monitoring and targeted research (Figure 3-64, box 1) will be conducted under the direction of the Science Manager, with support provided by the IEP.

2. The BDCP Science Manager, in coordination with the IEP, Adaptive Management Team, and the Delta Science Program, will assemble, synthesize, and analyze the results of BDCP monitoring and targeted research (Figure 3-64, box 2) efforts and integrate the results of new and relevant scientific research and studies conducted by other parties (Figure 3-64, box 3).

3. Based on this information and the advice of independent scientists, as appropriate (Figure 3-64, boxes 5 and 6), the Adaptive Management Team, through the Science Manager, will provide recommended program changes to the Program Manager (Figure 3-64, Box 4), either as part of the annual and five year workplan development process or on an *ad hoc* basis, where an adaptive change should occur on a shorter than annual timeframe.

4. The Program Manager will recommend adaptive management changes to the Implementation Board (Figure 3-64, Box 4). The Implementation Board will provide an opportunity for stakeholder input (Figure 3-64, box 7). The Implementation Board will review the Program Manager's recommendation and make final acceptance of the proposed adaptive management changes (Figure 3-64, Box 8).

The BDCP Implementation Board will receive information on the implementation of the BDCP generally, and will review major aspects of the adaptive management program described in the Annual Workplan. Members of the Board will have the right to object to adaptive management proposals made by the Program Manager on the basis that the proposed change, a) will not adequately contribute to achievement of the goals and objectives of the BDCP, or, b) is inconsistent with the requirements of the Plan or the permits/authorizations. If changes are accepted by the Board, they will be implemented by the Implementation Office under the accepted timetable. If the Board cannot come to agreement on an adaptive management change, the dispute resolution process described in Chapter 7, *Implementation Structure,* will be used.

As the BDCP is being implemented, it is expected that some changes in implementation actions and some adaptive management decisions will be considered to be minor. These minor decisions will not be subject to the formal adaptive management decision process as described above. Once such a type or category of change is accepted as minor by the Implementation Board, the Program Manager will be able to undertake such minor adjustments to conservation measures, without the need for extensive coordination with the other entities, thereby encouraging efficiency and timeliness in the implementation process. Such changes to the manner in which actions are implemented under the Plan include, for example, refinements to techniques used to restore habitat or to remove invasive species.

Plan implementation and adaptive management responses that will require full review as part of the adaptive management process include:

- Any change in the water operating criteria within the adaptive range;
- Discontinuation of a conservation measure;
- Expansion of a conservation measure;
- Addition of a new conservation measure;
- Decisions to reallocate available funding or resources away from ineffective conservation measures and toward more promising ones; or
- Any change to BDCP goals and objectives.

The Program Manager will consult with the Implementation Facilitation Team, the Real Time Operations Response Team and Adaptive Management Team regarding ongoing implementation issues which may require changes to broad elements of the Plan or specific actions to determine if such changes should be considered through the adaptive management process. Changes to the

Plan would be subject to the limits, boundaries, parameters and sideboards established for adaptive management actions, including funding caps established to implement the BDCP Conservation Strategy.

In some instances, a significant change in population trends for a covered species may occur, necessitating responsive actions (Figure 3-65). Efforts to respond to such circumstances would be conducted within the framework of the adaptive management program, as appropriate.

3.7.2.3 Internal Scientific Review

The Program Manager will use the Adaptive Management Team to provide internal scientific review (internal to the Implementation Office) on specific technical issues of immediate importance to the success of the adaptive management program and the Conservation Strategy implementation. The Adaptive Management Team will also assess on a regular basis the overall efficacy of the adaptive management program, including the results of effectiveness monitoring, selection of research and adaptive management experiments, and relevance of new scientific information developed by others (e.g., universities, Delta Science Program) to determine whether changes in the implementation of the conservation measures and the monitoring program would improve the effectiveness of the BDCP in achieving its biological goals and objectives

Recommendations made by the Adaptive Management Team and by other scientists and experts will be memorialized in a standardized format and will include a description of the recommended change in implementation; a description of the justification for the recommended change; an assessment of effects the change may have on other elements of BDCP implementation, if any; and any other relevant information in support of the recommendation. The rationale for rejection of adaptive management recommendations made during the internal science review process will also be documented.

3.7.2.4 External Independent Scientific Review

Working in coordination with the Delta Science Program and the Adaptive Management Team, the Program Manager will from time to time seek additional science input on specific implementation and adaptive management-related issues. The Program Manager may convene, at its discretion, experts on selected topics that are not affiliated with the Implementation Office, permit holders, or fish and wildlife agencies. The Program Manager will consult with the Implementation Board regarding the selection of scientists to provide advice on specific matters.

3.7.3 Concept of a “Defined Adaptive Range” and Water Operations Adaptive Management

[***Note to Reviewers**: The process for making adjustments to water operations within the adaptive range needs to be consistent with the process in Section 3.7.2.2, with recognition that these kinds of changes will likely be made more frequently.*]

To allow for flexible and responsive implementation of the BDCP, several conservation measures include a defined "adaptive range" that establishes the parameters within which a conservation measure may be adjusted to improve its effectiveness or respond to changing biological conditions. For example CM6 *Channel Margin Habitat Enhancement* identifies a target of 20 linear miles of enhancement of channel margins in areas important to salmonid outmigration and identifies an adaptive range that allows for an additional 20 miles of margin enhancement through the adaptive management program should this measure prove to be highly effective.

3.7.3.1 Water Operations Adaptive Range

Defined adaptive ranges are included in the BDCP Conservation Strategy for a number of operational criteria established for water operations (see CM1 *Water Facilities and Operations* in Section 3.4 *Conservation Measures*). For example, initial operational criteria (to be implemented once new facilities become operational) are identified in CM1 for Sacramento River bypass flows at the north Delta diversions, along with a defined adaptive range. This adaptive range includes allowance for increasing the bypass flows, through the adaptive management process, should an initial flow criterion prove to be less effective than expected (as defined by the Plan; *e.g.*, objectives established to protect covered fish species). Similarly, a lower limit to the defined adaptive range includes an allowance for narrowing the bypass criteria (allowing increased diversions) should flows or other conservation measures prove more effective in meeting objectives than expected, as defined by a standard or measure set out in the biological objectives and monitoring program.

3.7.3.2 Decision Process for Adjusting Water Operations within the Adaptive Range

SWP and CVP water operations are under the authority and are the responsibility of DWR and Reclamation, not the Implementation Office. Accordingly, DWR and Reclamation will implement the BDCP water operations conservation measures, under CM1 *Water Facilities and Operations*. Adjustments of the water operations criteria within the adaptive range for water operations, established at the time of BDCP authorization and described in CM1 *Water Facilities and Operations,* may only be conducted through the following process.

1. **Proposal to change operating criteria within the adaptive range provided to Program Manager -** Proposals to change the criteria for water operations are likely to come primarily from the IO staff, but may come from an outside body. However, proposed changes may also be requested by member of the Stakeholder Committee. All proposals related to changes in the water operations criteria will be submitted to the Program Manager. A proposal to change the real time operational range within the adaptive range will be identified in the draft Annual Water Operations Strategy and the draft Annual Workplan and Budget. Out-of-cycle proposals for changes may be requested, if necessary, to address biological objectives in situations that are time sensitive.

2. **Review of proposed change** - The Program Manager, through the Science Manager, will solicit independent science input on the proposed change from the Delta Science Program, Independent Science Board, and other appropriate independent scientists with expertise in the resources and operational change proposed.

3. **Submittal of proposal for change by Program Manager to the "Decision Body" –** The Program Manager will submit the proposed change to the "Decision Body" for review as part of the draft Annual Workplan and Budget. Out-of-cycle proposals for changes may be submitted, if necessary to address biological objectives in situations that are time sensitive. [***Note to Reviewers****: The placeholder "Decision Body" is used here until the appropriate entity(ies) is/are identified to serve in the role*.]

4. **Review of proposal for change by "Decision Body" -** The program manager will facilitate a review by the "Decision Body." The "Decision Body" will review the proposed operational change and determine if it is acceptable.

5. **Resolutions of disputes among directors –** If the "Decision Body" cannot reach consensus, then the decision on the proposed change will be elevated to the "Higher Level Decision Body" for joint resolution.

6. **Establish the changed criteria** - Once changes are agreed to by the "Decision Body" or through the dispute resolution process, they will be incorporated into the Annual Water Operations Strategy by DWR and Reclamation and implemented under the accepted timetable. These changed criteria will become the new operational criteria for the conservation measure within which the Real Time Operations Response Team may make real time operational decisions.

The process described above applies only to changes in operational criteria that are within the bounds of the operational adaptive range established at the time of BDCP authorization and described in CM1 *Water Facilities and Operations*. .

3.7.4 Concept of Adaptive Management Triggers

The Program Manager, with Implementation Board concurrence, may elect to develop adaptive management triggers for specific parameters and metrics during Plan implementation as a tool to support the adaptive management program, should the development of such triggers prove valuable to the program. Adaptive management triggers are quantified thresholds established for objectives or conservation measures that, if exceeded, would identify the need for an analysis of cause and effect and development of alternative actions to improve effectiveness of the conservation measure. Adaptive management triggers related to effectiveness identify specific conditions in which targets are not likely to be achieved and therefore adaptive changes should be considered and undertaken.

3.7.5 Adaptive Management Experiments

Because the biological outcome of many management actions is uncertain, the adaptive management program is based on scientific principles that guide continual refinement of conservation efforts in order to achieve the biological goals of the plan. The adaptive management program will develop alternative management strategies and test the effectiveness of these strategies. To that end, there is a continuum of management actions that incorporate scientific principles of adaptive management to varying degrees. The simplest studies involve monitoring effects once a conservation action has been taken, without replication, controls, or comparison of management treatments. At the other end of the spectrum is targeted research that tests a hypothesis in a manner that can be validated through statistical inference.

3.7.5.1 Targeted Research

There are a number of key uncertainties surrounding covered species, ecological processes, and biotic/abiotic interactions, and regarding the effectiveness of the conservation measures (see discussions of hypothesized benefits for individual conservation measures in Section 3.4, *Conservation Measures).* Some of these key uncertainties are expected to be resolved using adaptive management targeted research and others may be resolved by studies outside BDCP.

The Implementation Office may undertake or fund targeted research through the BDCP research program to provide information necessary to adaptively implement the BDCP (see Section 3.6, *Monitoring and Research Program*). This research should answer specific management-related questions that arise based on results of monitoring and to address data gaps to provide information necessary to successfully implement the conservation measures.

Results of research will inform management decisions to and increase the effectiveness of conservation measures. It is expected that most or all targeted research will be conducted by or in partnership with outside scientists from academic institutions, consulting firms, and non-profit organizations. It is anticipated that funding provided by the Implementation Office for targeted research could be matched or supplemented by other entities to increase the level of research and to achieve results that integrate with broader issues in the research community. The amount of targeted research will be limited by funding available to the Implementation Office.

In addition to targeted research undertaken by the Implementation Office, it is also expected that scientists within the Implementation Office will develop partnerships with academic institutions to encourage academic research that could inform and improve management and monitoring techniques.

3.7.5.2 Management-Oriented Conceptual Models

Conceptual models describe our current understanding of a functioning ecosystem. They provide a framework for learning about a system and help formulate hypotheses about cause-and-effect relationships. Conceptual models are useful for management because they can help to identify which factors may be important in a system, which of these factors may be influenced by management, and hence which attribute (component or condition) of the system should be assessed. Conceptual models can inform the research program in several important ways: by providing a basis from which to test assumptions about the relative importance of certain processes, by helping to identify threats or stressors, by identifying species or other attributes that function as ecosystem indicators, and by serving as a repository of our changing understanding of the system as more data become available. Conceptual models can also be used to communicate understanding of the system to other scientists and the public and to facilitate review. For a multi-species, ecosystem-process-based and habitat-based conservation plan such as the BDCP, models provide a useful framework for understanding how individual species react to the same management actions. Therefore, models must be sufficiently complex as to capture the relationships that drive the system and translate these relationships to covered species, but streamlined enough to be useful as management and monitoring tools. Models are only as good as the information used to develop them. Several types of conceptual models have been used in the development of the BDCP Conservation Strategy, and other models may be developed as more data become available, and as more efficient tools are developed.

The Delta Regional Ecosystem Restoration Implementation Plan (DRERIP) Conceptual Models developed by the CALFED Ecosystem Restoration Program are a suite of process, habitat, and species models incorporating the current scientific understanding of the Delta. These conceptual models describe the relationship of life history components to known drivers or stressors, and include categorical evaluations of the relative importance, predictability and level of understanding of the linkages between these drivers/stressors and outcomes. The DRERIP Evaluation Process was used to evaluate the relative magnitude and certainty of effects of proposed BDCP conservation measures on aquatic covered species (i.e., fish and aquatic plants), aquatic and estuarine natural communities, and related ecosystem processes using these DRERIP models and other available data (see Section 10.3.5, *DRERIP Evaluation Process* and Appendix F, *BDCP DRERIP Evaluation Results of Draft Conservation Measures.*). The DRERIP process was also used to explicitly identify key data gaps that should be filled through directed research or other exploratory studies. In most cases these models consist of diagrams that show the hypothesized relationships that characterize the ecosystem and are supplemented by written materials. There is also a need to develop full life history model for all of the covered fish species to facilitate plan implementation and guide adaptive management decision making process. Additional models may be developed as needed during the development and refinement of detailed monitoring plans. As new information becomes available, the DRERIP models will be updated to improve confidence in model parameters.

Species-habitat models have been developed for terrestrial Covered Species and natural communities; (see Appendix A, *Covered Species Accounts*). Species-habitat models, which can also be considered conceptual models, are useful tools that make explicit the assumptions about the relationship between species and habitat type. Species-habitat models were developed for the BDCP to hypothesize a relationship between land cover type and other habitat components and the distribution of covered species. These models have served as the basis for identifying current habitat distribution, predicting habitat distribution after restoration-related conservation measures are implemented, estimating impacts of conservation measure implementation, and prioritizing land acquisition. Information from pre-acquisition surveys and the planning surveys for covered activities will further refine these models such that they can be used to more accurately predict distribution, occupancy, and assess population trends.

3.7.6 Database Development and Reporting

Proper data management, analysis, and reporting are critical to the success of the adaptive management program. Data on monitoring methods, results, and analysis must be managed, stored, and made available to Implementation Office staff, decision-makers, scientific advisors, and other appropriate persons. A database and clear reporting procedure is also required for permit compliance. See Section 3.6.8, *Database Development and Maintenance,* for a discussion of the proposed database structure.

3.7.7 Program Status Reviews

Requirements for annual and five year reports and work plans by the Implementation Office that include discussions of implementation results and adaptive management changes are described in Section 6.2, *Compliance and Progress Reporting*.

3.7.8 Public Involvement

Public involvement is an especially important component of successful adaptive management. The responsibility for public outreach by the Implementation Office is described in Section 7.5, *Public Outreach*.

CHAPTER 4. DESCRIPTION OF COVERED ACTIVITIES AND ASSOCIATED FEDERAL ACTIONS

Table of Contents

4.1 Introduction 4-1
4.1.1 History and Overview of the SWP and CVP 4-3
4.1.2 Overview of Covered Activities and Associated Federal Actions 4-7
4.2 Covered Activities 4-8

CHAPTER 4. DESCRIPTION OF COVERED ACTIVITIES AND ASSOCIATED FEDERAL ACTIONS

[***Note to Reviewers****: This is a revised version of BDCP Chapter 4, Covered Activities. The last draft of Chapter 4 was presented to the Steering Committee at the October 7, 2010 meeting. Revisions have been made throughout the text to address comments received, to clarify concepts, and to bring the document up to date with the progress on various components of the BDCP in 2010. The BDCP Steering Committee members have submitted comments to various drafts of this chapter during development, which may or may not have been incorporated into this November 18, 2010 draft. While the text of this chapter is subject to change and revision as the BDCP planning process progresses, the chapter has been drafted and formatted to appear as it may in a completed draft HCP/NCCP. Although the chapter includes declarative statements (e.g., the Implementation Office will…), it is nonetheless a "working draft" that will undergo further modification based on input from the BDCP Steering Committee, state and federal agencies, and the public.]*

4.1 INTRODUCTION

*[**Note to reviewers**: Issues relating to take authorization for the State and federal water contractors are still under discussion.]*

The BDCP is intended to provide the basis for the issuance of regulatory authorizations under the federal Endangered Species Act (ESA) and the California Natural Community Conservation Planning Act (NCCPA) for a broad range of ongoing and anticipated activities that are associated with the operations of the State Water Project (SWP) in the Sacramento-San Joaquin River Delta, as well as for actions related to the operation of certain power plants located in the Plan Area (Figure 4-1). Additionally, the BDCP is intended to provide the basis for a Section 7 consultation. This chapter identifies and describes the activities that are addressed by the BDCP. The chapter further categorizes these activities on the basis of the party chiefly responsible for their implementation, characterizing activities as either "covered activities" for those actions undertaken by non-federal parties or as "associated federal actions" for those actions that are authorized, funded, or carried out by the Bureau of Reclamation (Reclamation). The potential effects of all of these activities on covered species, their habitats, and natural communities have been evaluated as part of an overall assessment of the effects of the BDCP, as described in Chapter 5, *Effects Analysis*. All construction and maintenance activities included as covered activities and actions would comply with the avoidance and minimization measures described in Chapter 3, *Conservation Strategy*, to avoid or reduce adverse effects on covered species and natural communities.

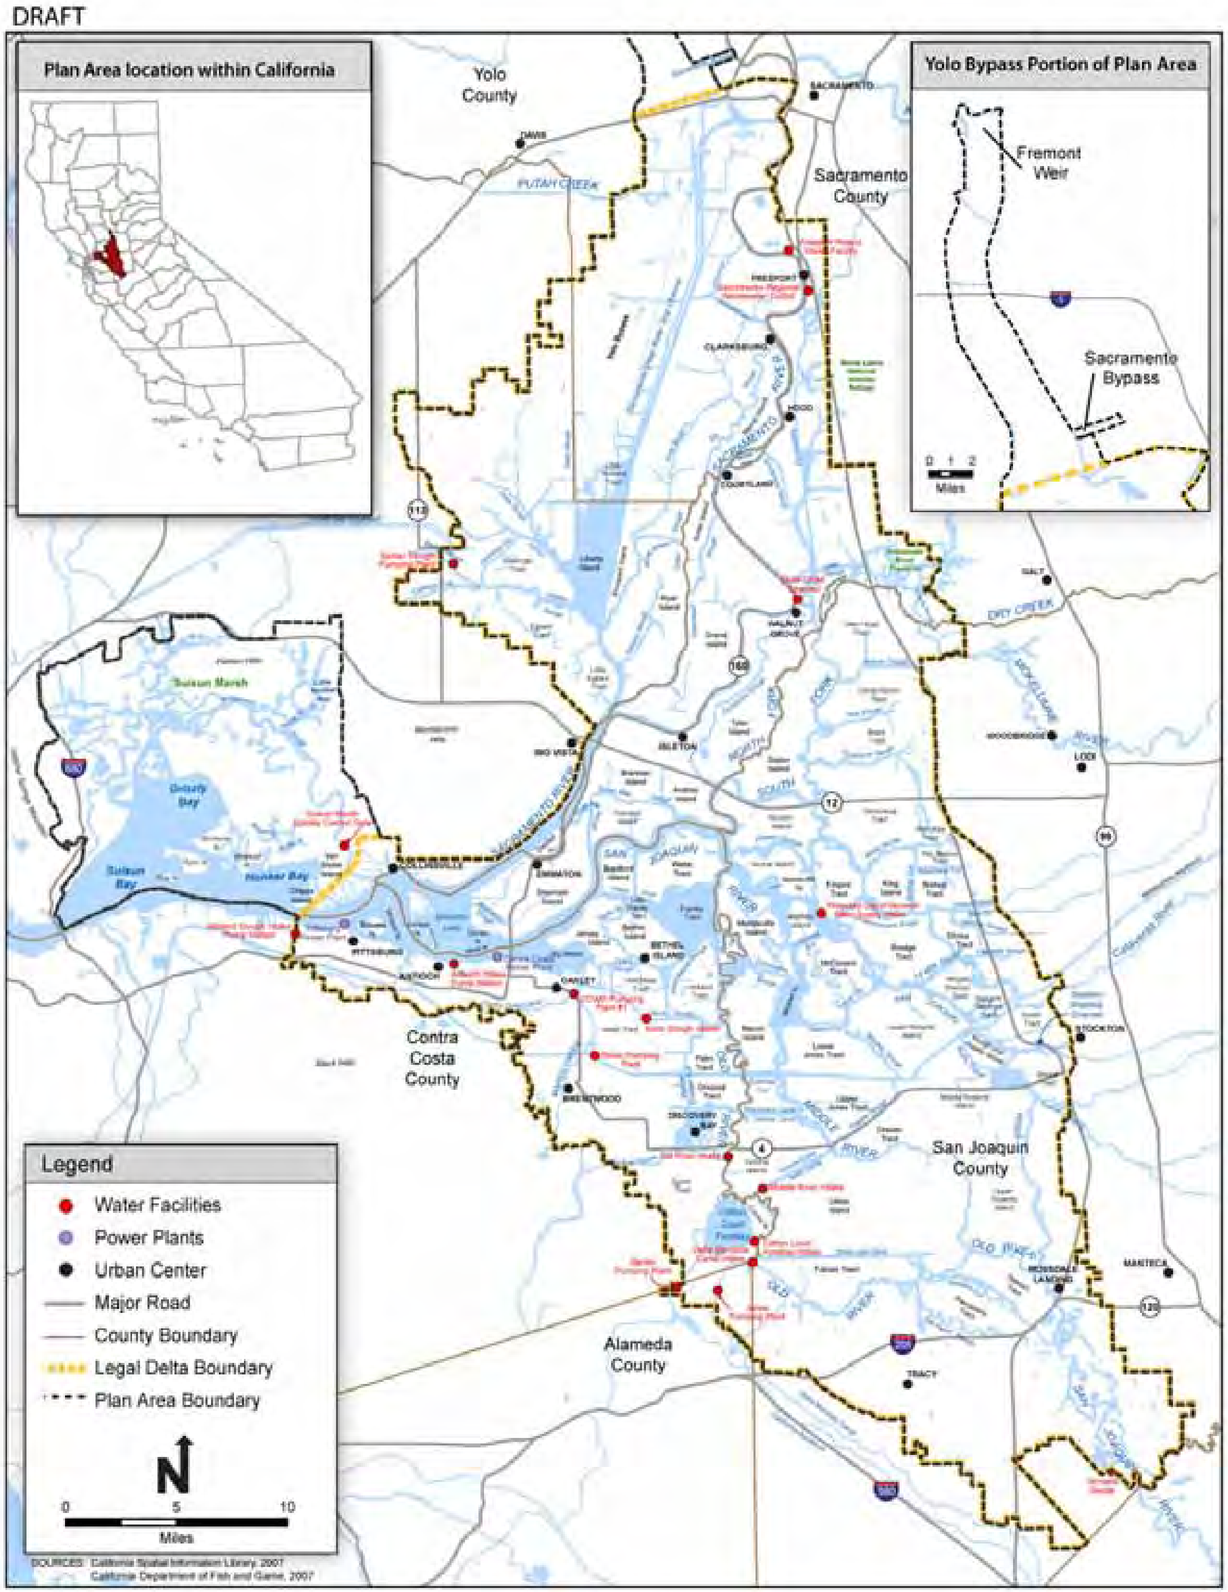

Figure 4-1. BDCP Plan Area Location

As a joint HCP/NCCP, the BDCP has been designed to meet the requirements of both State and federal endangered species laws and provide the basis for non-federal entities to obtain take authorizations from the U.S. Fish and Wildlife Service (FWS) and the National Marine Fisheries Service (NMFS) pursuant to Section 10 of the ESA and from the California Department of Fish and Game (DFG) under Section 2835 of the NCCPA, and potentially under Section 2081 of the California Endangered Species Act (CESA).[1]

Specifically, the Department of Water Resources (DWR), certain SWP contractors, and Mirant Delta LLC (Mirant) are seeking regulatory coverage under the ESA and the NCCPA to ensure that their activities within the geographic scope of the Plan, including conveyance, diversions, exports, or use of water from the Delta associated with energy generation, comply with these laws. The BDCP further provides the basis for the biological assessment (BA) to facilitate consultation under Section 7 of the ESA.

*[**Note to Reviewers:** The regulatory mechanism of the ESA that will be used to provide regulatory coverage to the CVP contractors has yet to be determined. Also, it has not yet been determined if coverage will be provided or what mechanism may be used to provide coverage for other diversions in specific areas of the Delta.]*

To meet these regulatory objectives, the BDCP sets out a comprehensive conservation strategy that addresses the effects of SWP, CVP, and Mirant existing and future actions that may occur within the Plan Area on aquatic and terrestrial species, including those listed under the ESA or CESA as threatened, endangered, or candidates for listing, as well as on critical habitat, if any, that has been designated for these species (see Chapter 3, *Conservation Strategy*). The BA for federal actions in the Delta will incorporate the BDCP Conservation Strategy as it relates to those actions and will serve as a companion document to the BDCP. The BDCP does not attempt to distinguish precisely between the effects on covered species and their habitat attributable to the CVP-related federal actions and to covered activities associated with the SWP. Rather, the BDCP includes a comprehensive analysis of the effects related to both the SWP and the CVP within the Plan Area and sets out a conservation strategy that adequately addresses the totality of those effects. On the basis of the BDCP and the companion BA, it is expected that the FWS and NMFS will issue Section 10 permits and a new joint biological opinion that supersede biological opinions existing at that time as they relate to SWP and CVP actions addressed by the BDCP, as well as CVP and SWP operations affected by BDCP that occur upstream of the Delta.

4.1.1 History and Overview of the SWP and CVP

This section provides an overview and a summary of the history of the SWP and the CVP. Additional detail may be found at: http://www.water.ca.gov/swp/.

[1] The BDCP has also been developed to meet the permit issuance standards of CESA for the activities described in this chapter.

4.1.1.1 SWP

The SWP is currently operated to provide water for agricultural, municipal, industrial, recreational, and environmental purposes, and to control flooding. As conditions of the water right permits and licenses, the State Water Board requires that the SWP meet specific water quality, quantity, and operational criteria within the Delta. The development of the SWP was necessitated by the tremendous population growth that occurred in California after the Second World War. The State recognized at the time that local water supplies alone would not be sufficient to meet future regional demands, prompting the legislature in 1945 to commission an investigation of statewide water needs. That investigation resulted in recommendations for substantial new water infrastructure, including the development of various aqueducts and channels, a multipurpose dam and reservoir near Oroville on the Feather River, and an aqueduct to carry water from the Delta to the San Joaquin Valley and Southern California (http://www.water.ca.gov/swp/history.cfm).

In 1960, California voters authorized the first phase of the SWP, which enabled water deliveries from watersheds of Northern California to the cities of Southern California and to farmers in the Tulare Basin that were beyond the reach of the CVP. After the SWP was passed by voters in 1960, the California Aqueduct, the main conveyance for the SWP, Clifton Court Forebay (CCF), and Harvey O. Banks Pumping Plant west of Tracy were constructed (Figures 4-1 and 4-2 depict both CVP and SWP facilities).

Today, the SWP consists of 34 storage facilities (reservoirs and lakes), 20 pumping plants, four pumping-generating plants, five hydroelectric power plants, and about 701 miles of open canals and pipelines. It provides water which supplements local sources for approximately 20 million Californians and about 660,000 acres of irrigated farmland (http://www.water.ca.gov/swp/).

The SWP distributes water to 29 urban and agricultural water suppliers in Northern California, the San Francisco Bay Area, the San Joaquin Valley, the Central Coast, and Southern California. These suppliers, known as the State Water Project contractors, receive specified annual amounts of water as provided by contracts with DWR.[2] These contracts are subject to renewal during the period 2035 through 2042. Of the total water supply under contract, 70 percent is allocated to urban users and 30 percent to agricultural users. (http://www.water.ca.gov/swp/)

[2] Under existing contract conditions, DWR is currently (2010) obligated to make 4.167 MAF/year of water available to its contractors, except under certain conditions specified in the contract, including shortage of supply availability, under which a lesser amount may be made available.

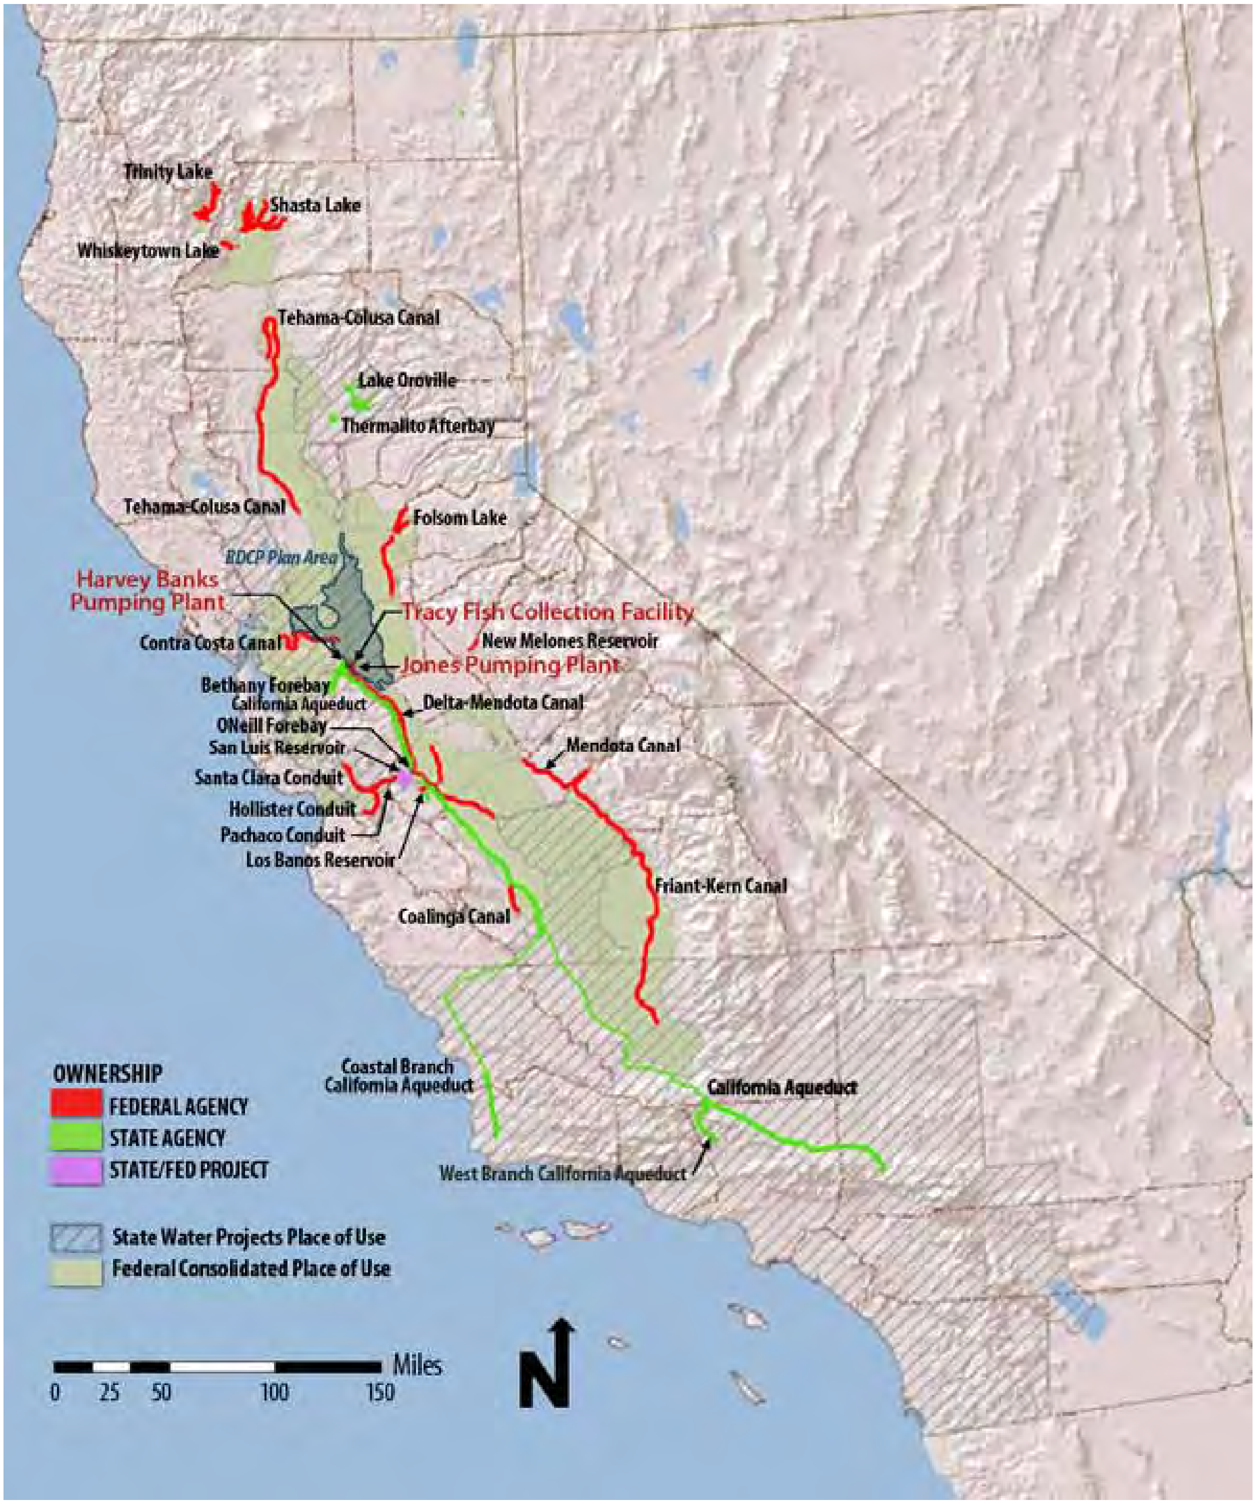

Figure 4-2. CVP and SWP Facilities

4.1.1.2 CVP

Beginning in the late 1800s, the State of California recognized the potential to deliver surplus water from the Sacramento River to the dry, but potentially productive, San Joaquin Valley (Alexander et al. 1874). The State further recognized, as reflected in the 1930 State Water Plan (Department of Public Works 1930), that the development of upstream storage capacity along the Sacramento River could simultaneously resolve two major water problems facing the State: water shortages in the San Joaquin Valley, where pumping in excess of natural groundwater recharge was occurring; and salinity intrusion into the Delta, which could be addressed with a hydraulic salinity barrier created through controlled releases of water from upstream storage (Lund et al. 2007). This water plan served as a blueprint for the eventual CVP.

In 1933, the State legislature and the voters of California approved the CVP. Shortly thereafter, California ceded control of the project to the federal government to maximize federal financial contributions during the Great Depression. Construction of Shasta Dam, one of the primary components of the CVP, began in 1938. In the 1940s, federal agencies agreed on an approach to divert water from the Sacramento River, which relied on a small cross-channel to move water through the Delta. This channel, which was constructed by Reclamation in 1944, is known as the Delta Cross Channel.

Following the construction of the Friant Dam (1942) and the Friant-Kern Canal (1948), the CVP began diverting San Joaquin River water to supply irrigators on the east side of the San Joaquin Valley. Subsequent projects on the west side of the Sacramento Valley, notably the Tehama-Colusa Canal (1980), increased capacity for upstream diversions from the Sacramento River. The CVP's major water storage facilities are located at the Shasta, Trinity, Folsom, and New Melones dams (USBR 2008) (Figure 4-2). The primary water pumping facility for the CVP is the Jones Pumping Plant, which is located west of the City of Tracy.

The CVP presently consists of 20 dams and reservoirs, 11 powerplants, and 500 miles of major canals, as well as conduits, tunnels, and related facilities. These facilities provide sufficient quantities of water to irrigate approximately one-third of the agricultural land of California and to provide for municipal and industrial use to support close to 1 million households for one year (http://www.usbr.gov/projects/Project.jsp?proj_Name=Central%20Valley%20Project). Over 250 contractors in 29 out of 58 counties in California have entered into long-term contracts for CVP water (http://www.water.ca.gov/swp/cvp.cfm).

The Central Valley Project Improvement Act (CVPIA) of 1992 mandated that the CVP be partly managed for the protection, restoration, and enhancement of fish and wildlife. The CVPIA provided for annual allocations of water to support fish and wildlife resources, a habitat restoration fund financed by water and power users, and a moratorium on new water contracts until such time as fish and wildlife goals are achieved (http://www.usbr.gov/mp/cvpia/index.html).

4.1.2 Overview of Covered Activities and Associated Federal Actions

4.1.2.1 SWP and CVP

The SWP and CVP function as two inter-basin water storage and delivery systems that divert and re-divert water from the southern portion of the Delta. The SWP and CVP utilize major reservoirs upstream of the Delta to store water, and use natural watercourses and canal systems to transport water to areas south and west of the Delta. The CVP also includes facilities and operations on the Stanislaus and San Joaquin rivers, such as the New Melones and Friant dams.

The Projects are permitted by the State Water Board to store water during wet periods, divert water that is surplus to the Delta, and re-divert Project water that has been stored in upstream reservoirs. Both Projects operate pursuant to water right permits and licenses issued by the State Water Board that allow for the appropriation of water by diverting to storage or by directly diverting to use and re-diverting releases from storage later in the year. As conditions of their water right permits and licenses, the State Water Board requires that the CVP and SWP meet specific water quality, quantity, and operational criteria within the Delta.[3] Reclamation and DWR closely coordinate their management of the operations of the CVP and SWP to meet these conditions.

The BDCP covered activities consist of activities in the Plan Area associated with the conveyance and export of water supplies from the SWP's Delta facilities and with the implementation of the BDCP Conservation Strategy. Each of these activities falls into one of four categories: 1) operation of existing and new Delta facilities used to transport and deliver water for Project purposes; 2) construction of new facilities; 3) facility maintenance, monitoring and other associated ongoing activities; and 4) implementation of certain BDCP conservation measures and the biological monitoring and adaptive management programs.

The BDCP associated federal actions comprise those activities that are authorized, funded, or carried out by Reclamation within the Plan Area and relate to the operation of the CVP's Delta facilities to meet CVP purposes. These actions include: 1) operation of existing CVP Delta facilities to convey and export water for project purposes; and 2) associated maintenance and monitoring activities. The CVP is operated in coordination with the SWP under the Coordinated Operations Agreement (COA). While the CVP and SWP are separate systems, they function in an integrated and coordinated manner. Reclamation, and/or the CVP contractors may seek to wheel CVP water through a new conveyance facility.

Under the BDCP, the type of water conveyance infrastructure in use serves to demarcate the near-term and long-term components of the Plan. Specifically, the near-term component of the BDCP encompasses those actions related to the operations of the projects under existing water conveyance infrastructure, including conservation measures associated with this operational

[3] DWR has a separate contract to provide water to NDWA and that contract has separate water quality standards.

framework. The long-term component of the BDCP comprises those actions related to project operations under new isolated conveyance infrastructure, including the construction of and operation of the infrastructure and the implementation of an array of conservation measures.[4] The actions that will be implemented during the near-term and long-term periods will involve both covered activities and associated federal actions.

Other actions associated with the CVP and SWP are not within the scope of the BDCP. These actions occur upstream of the Delta, outside of the Plan Area, and include the operations of certain reservoirs and the diversion and delivery of certain water supplies. Although these other activities are not addressed by the BDCP, the effect of the BDCP on those activities and the effects of those activities on listed species will be analyzed and addressed in the joint biological opinion to be issued pursuant to the BDCP or in subsequent biological opinions that cover project-related activities that are outside of the Plan Area.

4.1.2.2 Mirant Delta, LLC Power Plants

The operation of Mirant's power plants, which are located in the cities of Pittsburg and Antioch (referred to as the "Pittsburg Power Plant" and the "Contra Costa Power Plant" and collectively as the "Delta Plants"), requires the diversion of water from the Delta. Mirant's generating units burn natural gas and are cooled with Delta water. As described below, Mirant's current operational parameters are set by (1) its Clean Water Act (CWA) National Pollution Discharge Elimination System (NPDES) permits, which include requirements pursuant to Section 316(b); (2) incidental take permits issued by the National Marine Fisheries Service and U.S. Fish and Wildlife Service pursuant to the Endangered Species Act; and (3) a Memorandum of Understanding with the California Department of Fish and Game authorizing incidental take of species listed under the California Endangered Species Act.

The BDCP covers those Mirant activities associated with the generation of power at its Pittsburg and Contra Costa power plants. These activities involve either (1) current power generation activities and water intake and discharge flows associated with those activities; or (2) recurrent maintenance activities required to ensure continued proper operation of those existing facilities.

4.2 COVERED ACTIVITIES

The activities described in this section are considered to be "covered activities" under the BDCP. Covered activities are those actions that are carried out by non-federal entities, such as DWR and Mirant, and are expected to be covered by regulatory authorizations under Section 10 of the ESA and Section 2835 of the NCCPA. Covered activities are distinguished from "associated federal actions," which are those BDCP-related actions that are carried out, funded, or authorized by Reclamation and will be authorized under Section 7 of the ESA.

[4] The activities related to the development of a tunnel/pipeline facility are included in the long-term component of the BDCP. As such, the period associated with the long-term component of the BDCP will likely overlap with the near-term period as development of a tunnel/pipeline facility will occur during the implementation of the near-term operational regime.

4.2.1 Operations and Maintenance of Existing SWP Facilities

This section describes covered activities carried out by DWR to operate and maintain the existing SWP facilities in the Delta. These activities involve the daily operation of water diversion, conveyance, and delivery systems, and appurtenant facilities within the Plan Area. The near-term and long-term criteria and adaptive ranges set out in Chapter 3, *Conservation Strategy,* establish parameters under which certain operations-related actions identified in this chapter will be carried out.

The SWP's facilities within the Plan Area consist of the Clifton Court Forebay; Banks Pumping Plant; Skinner Delta Fish Protective Facility; the installation, operation and removal of the temporary barriers in the south Delta; the northern portion of the California Aqueduct; Barker Slough Pumping Plant; and the eastern portions of the North Bay Aqueduct (Figures 4-1 and 4-2). These SWP facilities are used to export water from the south Delta (Banks Pumping Plant) and from the north Delta (Barker Slough Pumping Plant) into canals and pipelines that carry it to municipal and industrial (M&I) and agricultural water contractors in the San Francisco Bay Area and Southern California. These facilities are integral components of the SWP and contribute to the functional capacity of the overall system. This section describes these facilities, their operational requirements, and the actions necessary to maintain their viability. The manner in which these facilities are operated and maintained is not only integral to the proper functioning of the water supply system, but intertwined with the actions in the BDCP Conservation Strategy to provide for the conservation of the aquatic ecosystem and covered fish species.

The existing SWP facilities described in this section will continue to operate under both the near-term and long-term components of the BDCP, but will be subject to different operating criteria following completion of new water conveyance facilities. The BDCP near-term and long-term operational criteria and adaptive operational ranges are described in Chapter 3, *Conservation Strategy*, and include descriptions of operations of SWP facilities in the Plan Area.

The following descriptions of SWP-related covered activities are intended to be sufficiently broad to cover all aspects of the development, operation, and maintenance of identified SWP facilities that may potentially affect resources covered by this Plan, including covered species and their habitats. The measures to address the effects of these covered activities on covered resources are set out in the BDCP Conservation Strategy (see Chapter 3, *Conservation Strategy*).

4.2.1.1 Clifton Court Forebay

4.2.1.1.1 Background

Water for the SWP is diverted into Clifton Court Forebay (CCF) and pumped at Banks Pumping Plant (Banks). Clifton Court Forebay is a 31,000-acre-foot regulatory reservoir located in the southwestern edge of the Delta, about 10 miles northwest of the City of Tracy. Inflows to the Forebay from surrounding channels are controlled by radial gates, which are generally operated based on the tidal cycle to reduce approach velocities, prevent scour in adjacent channels, and minimize water level fluctuation in the south Delta by taking water in through the gates at times other than low tide. When a large head differential (difference in water surface elevation) exists between the outside and the inside of the gates, theoretical inflow can be as high as 15,000 cfs for a short time.

4.2.1.1.2 Activity

See Chapter 3, *Conservation Strategy*, for description of BDCP near- and long-term operations criteria and adaptive range for south Delta operations of the SWP and CVP to provide for protection of covered fish species in conjunction with water conveyance and diversion. DWR is seeking ESA Section 10 and NCCPA Section 2835 permits for all existing and future operations and maintenance of Clifton Court Forebay.

4.2.1.2 Harvey O. Banks Pumping Plant

4.2.1.2.1 Background

The Banks Pumping Plant is in the south Delta, about 8 miles northwest of Tracy and marks the beginning of the California Aqueduct. By means of 11 pumps, including two rated at 375-cfs capacity, five at 1,130-cfs capacity, and four at 1,067-cfs capacity, the Banks Pumping Plant provides the initial lift of water 244 feet into the aqueduct. The nominal capacity of the Banks Pumping Plant is 10,300 cfs. The pumps can be operated at full capacity to enable diversions to utilize power in off-peak periods.

4.2.1.2.2 Activity

Chapter 3, *Conservation Strategy*, includes a description of the near-term and long-term operations criteria and adaptive ranges for south Delta operations of the SWP and CVP. These measures have been designed to address the effect on covered fish species of water conveyance and diversion actions associated with the Banks Pumping Plant. As such, the BDCP provides the basis for federal and State regulatory authorizations under the ESA and NCCPA for coverage of all existing and future operations and maintenance activities of the Banks Pumping Plant. Refer to the background discussion above with respect to existing operations, to Chapter 3, *Conservation Strategy* for the near-term and long-term operations criteria and adaptive ranges for south Delta operations of the SWP and CVP, and refer to Section 4.2.1.7 below for a description of the types of maintenance activities that may occur. DWR is seeking ESA Section 10 and NCCPA Section 2835 permits for all existing and future operations and maintenance of Banks Pumping Plant.

4.2.1.3 John E. Skinner Delta Fish Protective Facility

4.2.1.3.1 Background

The John E. Skinner Delta Fish Protective Facility is located at the head of the Intake Channel that connects Clifton Court Forebay to the Banks Delta Pumping Plant. The Skinner Fish

Facility screens fish away from the pumps. Debris is directed away from the pumps by a 388-foot-long trash boom. Fish are diverted from the intake channel into bypasses by a series of metal louvers, while the main flow of water continues through the louvers and toward the pumps. These fish pass through a secondary system of screens and pipes into seven holding tanks, where they are later counted and recorded. The salvaged fish are then returned to the Delta in oxygenated tank trucks.

4.2.1.3.2 Activity

Chapter 5, *Effects Analysis*, describes the level of take associated with the operations of the Skinner Fish Facility. DWR is seeking ESA Section 10 and NCCPA Section 2835 permits for all existing and future operations and maintenance of the Skinner Fish Facility not otherwise restricted by the BDCP Conservation Strategy. Refer to the background description above with respect to operations of this facility, and to Section 4.2.1.7 for a description of the types of maintenance activities that may occur.

4.2.1.4 Barker Slough Pumping Plant and North Bay Aqueduct

4.2.1.4.1 Background

The Barker Slough Pumping Plant diverts water from Barker Slough into the North Bay Aqueduct (NBA) for delivery in Napa and Solano counties. The NBA intake is located approximately 10 miles from the mainstem Sacramento River at the end of Barker Slough. The maximum pumping capacity is 175 cfs (pipeline capacity). During the last few years, daily pumping rates have ranged between 0 and 140 cfs. Each of the 10 NBA pump bays is individually fitted with a positive barrier fish screen consisting of a series of flat, stainless steel, wedge-wire panels with a slot width of 3/32 inch. This configuration is designed to exclude fish 25 millimeters (mm) or larger from being entrained. The bays tied to the two smaller units have an approach velocity of about 0.2 ft/sec. The larger units were designed for a 0.5-ft/sec approach velocity, but actual approach velocity is about 0.44 ft/sec. The screens are routinely cleaned to prevent excessive head loss, thereby minimizing increased localized approach velocities.

4.2.1.4.2 Activity

DWR is seeking ESA Section 10 and NCCPA Section 2835 permits for all existing and future operations and maintenance of the Barker Slough Pumping Plant not otherwise restricted by the BDCP operating criteria. Combined operations of a new intake on the Sacramento River (described below in Section 4.2.2.3) and the existing intake at Barker Slough would be included under BDCP covered activities for future peak demand of up to 240 cfs.

4.2.1.5 State Water Project Diversions

4.2.1.5.1 Background

The amount of water delivered by the SWP in any year has been and will continue to be variable, but in any year, will be equal to the amount of water that is hydrologically available and that can be diverted under current contractual rights consistent with the terms and conditions of the BDCP and existing permits and regulations. SWP "project water" is water made available for delivery to the contractors by the project conservation and transportation facilities included in the system. Under existing contract conditions, DWR is currently (2010) obligated to make 4.167 MAF/year of water available to its contractors, except under certain conditions specified in the contract, including shortage of supply availability, under which a lesser amount may be made available. The obligation incrementally increases to a maximum amount of 4.173 MAF/year in 2021. This quantity may be exceeded if DWR determines surplus water is available above and beyond that needed to satisfy all regulations, permits, and operational requirements.

The California Water Code requires the State to allow the use of SWP facilities to convey non-Project water as long as the conveyance will not interfere with SWP operations. During drier years, conveyance capacity is available in SWP facilities for the transfer of water by other entities. Non-Project water for Drought Water Banks, Dry Water Purchase Programs, and individual transfers has been conveyed through SWP facilities in the past and is expected to continue into the future. SWP facilities are also used to support groundwater banking programs, such as the Semitropic Water Banking and Exchange Program.

4.2.1.5.2 Activity

Chapter 3, *Conservation Strategy*, includes a description of the near-term and long-term operations criteria and adaptive ranges for the SWP and CVP under the BDCP. These measures have been designed to address the effect on covered fish species of water conveyance and diversion actions associated with the SWP and CVP. As such, the BDCP provides the basis for federal and State regulatory authorizations under the ESA and NCCPA for coverage of all existing and future diversion activities of the SWP in the Plan Area.

4.2.1.6 Temporary Barriers in the South Delta

4.2.1.6.1 Background

The South Delta Temporary Barriers Project consists of four barriers across south Delta channels for the purpose of benefitting southern Delta agricultural diverters by increasing water levels, improving circulation, and improving water quality, and for the purpose of benefiting San Joaquin River fall-run Chinook salmon by keeping them away from the export facilities. The existing South Delta Temporary Barriers Project consists of the annual installation and removal of temporary barriers at the following locations:

- Middle River near Victoria Canal, about 0.5 mile south of the confluence of Middle River, Trapper Slough, and North Canal;
- Old River near Tracy, about 0.5 mile east of the Delta-Mendota Canal intake;
- Grant Line Canal near Tracy Boulevard Bridge, about 400 feet east of the Tracy Boulevard Bridge; and
- At the Head of Old River (in Old River near its divergence from the San Joaquin River).

The barriers on Middle River, Old River near Tracy, and Grant Line Canal are tidal control facilities composed of rock and gated culverts designed to improve water levels and circulation for agricultural diversions and are in place during the growing season.

A rock barrier may be installed during the fall at the Head of Old River to improve flow quality for salmon migration in the San Joaquin River. In the past, the barrier has been installed at the direction of the Department of Fish and Game.[5] The objective of the barrier is to improve dissolved oxygen levels by reducing the amount of flow diverted into Old River and, therefore, keeping more flow moving downstream in the San Joaquin River. A non-physical or physical (rock) barrier may also be installed at the Head of Old River in the spring. This barrier would be designed to discourage salmonids migrating downstream in the San Joaquin River from entering Old River and being exposed to the effects of the export pumps. Since 2009, a non-physical barrier utilizing sound, light, and a “bubble curtain” has been tested at this location in the spring to determine its effectiveness at discouraging fish passage. Depending upon the observed effectiveness of this barrier under various operational conditions, its installation may continue as part of Conservation Measure number 7 (*CM16 Non-physical Fish Barriers* [see Chapter 3, *Conservation Strategy*]). If the monitoring program indicates that the non-physical barrier is not effective at addressing passage concerns relating to the out-migrating salmonids under certain operational conditions, a rock barrier may be tested as an alternative means of minimizing fish passage into Old River. [6]

4.2.1.6.2 Activity

These barriers will likely continue to be utilized in the near-term in conjunction with the BDCP near-term conservation measures. The four barriers are generally installed beginning in early April. The barrier at the Head of Old River is operated mid-April through mid-May and,

[5] The Department of Fish and Game has been responsible for directing DWR to install the fall barrier. Both DWR and DFG monitor the dissolved oxygen levels in the Stockton Deep Water Ship Channel. If dissolved oxygen is at a level that inhibits or prevents salmon from migrating up the San Joaquin River, then DFG directs DWR to install the barrier. This is a covered activity under BDCP and, therefore, can continue on into the future.

[6] The 2008 National Marine Fisheries Service Biological Opinion for the Temporary Barriers Project required that a three-year fisheries monitoring program using biotelemetry techniques be established to examine the movements and survival of juvenile salmon and juvenile steelhead through the channels of the south Delta. The biological opinion also required that predation effects associated with the project be examined. A pilot-scale biotelemetry study was conducted March-July 2009 to develop an understanding of the movement and survival of salmonids through the south Delta with specific focus at the three agricultural barrier locations. The pilot study was designed to identify movement patterns of predatory fish within the south Delta. Information gained from the pilot study was used to develop the 2010 and 2011 experimental design for the full-scale, mark-recapture, salmonid survival study. To meet these objectives, Hydroacoustic Technology Incorporated (HTI) acoustic tags and receivers were used as steelhead, salmon, largemouth bass, striped bass, and white catfish were tagged, released, and tracked in south Delta channels.

possibly, into June. The barriers in Middle River, Old River at Tracy and Grant Line Canal are partially operated through the end of May while delta smelt are in south Delta channels. During June, once the risk to delta smelt has passed, those barriers are allowed to begin full operations and continue full operations through the remaining summer and fall. Removal of the barriers begins in early November. All barriers are completely removed by November 30. Long-term use of the barriers will be evaluated under the BDCP adaptive management program.

4.2.1.7 Maintenance and Monitoring Activities

4.2.1.7.1 Background

Maintenance activities are covered activities under the BDCP. Maintenance activities include actions necessary to maintain the capacity and operational features of the existing water diversion and conveyance facilities, as described in this chapter, including Banks Pumping Plant, Clifton Court Forebay, the Temporary Barriers Project, Barker Slough Pumping Plant, North Bay Aqueduct, and Skinner Fish Facility. Maintenance activities also include canal maintenance; placement of riprap for bankline protection and erosion control; vegetation management and weed control; and operation and maintenance of electrical power supply facilities. Maintenance activities also include repair and replacement as needed to ensure continued operations of facility or system components.

Monitoring activities for the operation of the SWP are included under BDCP covered activities. This includes water quality and other SWP monitoring activities. For BDCP fish and other biological monitoring activities, see Section 4.2.7, *Monitoring and Research Program* below. DWR's Division of Operations and Maintenance conducts monitoring of chemical, physical and biological parameters to evaluate conditions of concern for drinking water, recreation, and fish and wildlife. Fish monitoring may also be conducted by DWR for the Temporary Barriers Project.

4.2.1.7.2 Activity

All SWP maintenance and monitoring described in this section that could affect species or modify critical habitat protected under ESA or CESA are covered activities, and the effects of those activities are addressed by the BDCP (see Chapter 3, *Conservation Strategy* and Chapter 5, *Effects Analysis*).

4.2.2 New Water Facilities Construction, Operations and Maintenance

*[**Note to reviewers**: The tunnel/pipeline conveyance facility is described here as the new BDCP conveyance approach to allow for dual operations of the new north and existing south Delta diversions, however, it has not been decided if the conveyance facility would be a tunnel/pipeline or, alternatively, a canal facility.]*

4.2.2.1 Tunnel/Pipeline Facility Construction and Operations

4.2.2.1.1 Background

DWR is planning to construct new diversion and conveyance facilities that will be designed and operated to improve protections for fish by bringing water from the Sacramento River around the Delta to the existing water export pumping plants in the south Delta. This new tunnel/pipeline facility would allow for reductions in diversions from the existing SWP and CVP south Delta facilities and hence reduced entrainment of covered fish species. For a more detailed description of the biological benefits of the tunnel/pipeline see Chapter 3, *Conservation Strategy*. The new facility will include five intake structures located on the Sacramento River between Freeport and Courtland. These intakes will be fitted with state-of-the-art positive barrier fish screens. The conveyance would consist of a tunnel/pipeline system that will convey water diverted from the Sacramento River to a new regulating forebay. The conveyance would follow an alignment generally through the central portion of the Delta to a new forebay located adjacent to and south of the existing Clifton Court Forebay. Water would be conveyed to the existing Banks and Jones pumping plants serving the SWP and CVP, respectively. The tunnel/pipeline system would improve protections for water supplies from flood, earthquake, and sea level rise.

The system design would include:

- Five intake facilities, each with fish screens and pumping plants;
- 7.8 miles of twin 16 ft diameter cut and cover intake pipelines to convey water from intake pumping plants to the intake tunnel or the Intermediate Forebay
- 5 miles of tunnel (29 ft inside diameter) to convey water from intake pipelines to an Intermediate Forebay;
- 750-acre Intermediate Forebay and an intermediate pumping plant with a gravity bypass system;
- 33.5 miles of twin-bore tunnel (33 ft inside diameter each) connecting the Intermediate Forebay to the Byron Tract Forebay;
- 600-acre Byron Tract Forebay; and

Other actions necessary to support the development and operation of a new tunnel/pipeline facility are covered under the BDCP. They include activities to improve local drainage systems affected by the new conveyance infrastructure, upgrade existing utilities and develop new utility infrastructure, establish temporary construction staging sites, install temporary and permanent roads, and dispose of spoils on certain sites. More detail on specific features of the tunnel/pipeline facility is provided in Appendix M, *Facilities Design Information*.

New intake and conveyance facilities specifications are summarized in Table 4-1.

Chapter 3, *Conservation Strategy*, includes a description of the long-term operations criteria and adaptive ranges for SWP and CVP with dual operations, including the new intakes and tunnel/pipeline facilities. These measures have been designed to minimize the potential effects of water conveyance and diversion actions associated with the new intakes and tunnel/pipeline facilities on covered fish species and their habitat.

The proposed intake facilities will require routine or periodic adjustment and tuning to ensure operations are managed consistent with design intentions. Facility maintenance includes activities such as painting, cleaning, repairs, and other routine tasks that ensure the facilities are operated in accordance with design standards after construction and commissioning. Activities will involve performing routine, preventive, predictive, scheduled, and unscheduled maintenance aimed at preventing equipment/facility failure or deterioration.

Continuous general inspections will be important for monitoring and logging performance; recording the history of facility conditions and deterioration, and preventing mechanical and structural failures of project elements. Sediment removal will be carried out through suction dredging, mechanical excavation, and dewatering to remove sediment buildup. If large debris is found to have accumulated around intakes, removal would require underwater diving crews, boom trucks or rubber wheel cranes, and possibly a small barge and crew to rig the leads to the debris. While cleaning frequency will need to be varied for screen operations commensurate with debris load conditions in the river, the continuous traveling brush mechanisms, or other screen cleaning technologies applied, are expected to maintain a relatively clean screen face and adequate open area. Over time, biofouling can occlude the screens and jeopardize function. The key design provision for intake facilities is that all mechanical elements can be removable from the top surface for convenience of inspection, cleaning, and repairs, as needed. The intakes will feature top-side gantry crane systems for removal and insertion of screen panels, louver assemblies, and bulkheads. It is expected that all panels will require annual removal (at a minimum) for pressure washing. Additionally, individual intake bays will require dewatering (one pair at a time) for inspection and assessment of biofoul growth rates. Dewatering is accomplished by closing off portals with pre-fabricated bulkheads. Metalwork in intakes is expected to consist of plastics and austenitic steels (stainless); therefore, corrosion is not expected to be detrimental to the life of the facilities. Maintenance associated with these systems consists of replacing sacrificial (zinc) anodes at multi-year intervals.

Table 4-1. Summary of Tunnel/Pipeline Facility Physical Characteristics

Feature Description	*Approximate Characteristics*
Overall Project	
Conveyance Capacity (cfs)	15,000 cfs
Overall Length (miles)	45 miles
Intake Facilities	
Number of Fish-Screened Intakes	5 intakes
Flow Capacity at Each Intake (cfs)	3,000 cfs
Intake Pumping Plants	
6 Pumps per Intake plus one spare, Capacity per Pump (cfs)	500 cfs
Total Dynamic Head (ft)	30 to 57ft
Total Electric Load (MW)	65 MW
Intake Pipelines	
Intake Pipelines connect each Intake Pumping Plant to the Intake Tunnel or the Intermediate Forebay	
Total Pipeline Length (ft)	41,000 ft
Number of Pipelines	2 each side by side
Pipeline Finished Inside Diameter (ft)	16 ft
Tunnels	
Intake Tunnel connecting Intakes #1and #2 to Intermediate Forebay, maximum flow 6,000 cfs	
Tunnel Length (ft)	27,260 ft
Number of Tunnel Bores; Number of Shafts (total)	1 bores; 2 shafts
Tunnel Finished Inside Diameter (ft)	29 ft
Main Conveyance Tunnel connecting Intermediate Pumping Plant to Byron Tract Forebay, maximum flow 15,000 cfs	
Tunnel Length (ft)	176,000 ft
Number of Tunnel Bores; Number of Shafts (total)	2 bores; 14 shafts
Tunnel Finished Inside Diameter (ft)	33 ft
Intermediate Forebay	
Water Surface Area (acres)	750 acres
Active Storage Volume (AF)	5,250 AF
Intermediate Pumping Plant	
In Reach 2, at southern end of Intermediate Forebay	
Number of Pumps, Capacity per Pump (cfs)	10 at 1,500 (high head) 6 at 1,500 (low head)
Total Dynamic Head (ft)	0 to 90 ft
Total Electric Load (MW)	136 MW
Byron Tract Forebay	
Water Surface Area (acres)	600 acres
Active Storage Volume (AF)	4,200 AF
Power Requirements	
Total Conveyance Electric Load (MW)	210 MW

Intake, Screen, and Tunnel/Pipeline Facilities Maintenance Activities

Impact damage incurred by the intake facilities (such as boat collisions, debris impact, stone and sediment abrasion, etc.) may require repairs.

The only systems associated with the intakes involving power-driven and routinely moving parts are the screen cleaning systems and gantry crane hoist systems. Lubrication of bearings, continuity checks of limit/torque switches, and periodic inspections of equipment per manufacturer recommendations are the primary O&M tasks expected for these systems. Strip brushes for the screen cleaning systems will need replacement every several years.

Maintenance would be needed for the intake pumping plants, sedimentation basins, and solids lagoons. This includes service based on a schedule recommended by the manufacturers, mussel and solids removal, and checking and replacing worn parts. Major equipment repairs and overhauls will be conducted at a centralized maintenance shop. Routine site maintenance would include landscape maintenance, trash collection, and outdoor lighting repair or replacement.

Some of the critical considerations in terms of tunnel/pipeline maintenance will include evaluating whether the tunnel/pipeline needs to be taken out of service for inspection and, if so, how frequently this will be required. Typically, new water conveyance pipelines are inspected at least every 10 years for the first 50 years and more frequently after 50 years of age. Dewatering of the tunnel/pipeline facility for maintenance purposes is expected to be conducted but it is assumed that only one of the tunnel/pipelines at a time would be dewatered, allowing continued north Delta diversions to the Intermediate Forebay. Depending on the monthly demands diversion needs could be met or may be temporarily reduced. The entire dewatering and non-routine maintenance process would likely be complete in a month and can be timed for low diversion periods. Dewatering for maintenance would be conducted approximately once every 5, 10 or 20 years. This type of non-regular maintenance would require an additional set of pumps, temporarily located at either the Byron Tract Forebay or at one of the shafts along the tunnel/pipeline route. While these pumps will have some noise associated with them, their operation would be less than a month and would occur at 5, 10 or 20 year intervals. Use of remotely operated vehicles for inspection of the tunnel/pipeline would be inside the tunnel/pipeline with a crane at the shaft site to launch and retrieve the vehicle and possibly a portable generator to supply power. All work would be within the right-of-way at the shaft.

Forebay maintenance considerations would include regular harvesting of pond weed to maintain flow and forebay capacity, the installation of automatic trash raking equipment and disposal facilities, and potential sediment dredging approximately every 50 years. Maintenance requirements for the forebay embankments would include control of vegetation and rodents, embankment repairs in the event of island flooding and wind wave action, and monitoring of seepage flows. Maintenance requirements for the spillway would include the removal and disposal of any debris blocking the outlet culverts. Debris in the stilling basin would also have to be removed to ensure normal water flow through outlet culverts.

Additional activities may include maintenance of: powerlines (insulator washing and routine tower/pole maintenance and replacement) and interconnection substations; permanent roads and fencing; pipelines that could require excavation; back-up power supplies (e.g., testing); general buildings and facilities; and any permanent marine facilities such as barge uploading facilities that provide access to tunnel/pipeline shaft locations (may require localized dredging and other maintenance work, such as painting, decking replacement/repair, and removing barnacles).

4.2.2.1.2 Activity

All construction, operations and maintenance of the new intakes, screens, pumps, and conveyance facilities described in this section are covered activities and the effects of those activities are addressed by the BDCP (see Chapter 3, *Conservation Strategy* and Chapter 5, *Effects Analysis*). DWR is seeking ESA Section 10 and NCCPA Section 2835 permits for all maintenance of these new facilities not otherwise restricted by the BDCP Conservation Strategy.

4.2.2.2 Fremont Weir and Yolo Bypass Improvements and Maintenance

4.2.2.2.1 Background

The purpose of this activity is to modify the Fremont Weir and Yolo Bypass and operate the Fremont Weir to increase the availability of floodplain habitat for spawning and rearing for covered fish species, enhance food production within and downstream of the Yolo Bypass, and improve fish passage within and nearby the Yolo Bypass (see *CM2 Yolo Bypass Fish Habitat Improvements* in Chapter 3, *Conservation Strategy*). Specifically, the Fremont Weir and Yolo Bypass modifications and operations (1) improve rearing and spawning habitat for covered fish species; (2) provide for a higher frequency and duration of inundation of the targeted portion of the Yolo Bypass; and (3) improve fish passage in the Yolo Bypass, Putah Creek, and past the Fremont and Sacramento weirs.

Ten physical modifications to the Fremont Weir, Yolo Bypass and the Sacramento Weir and their resulting effects are proposed as covered activities and are listed below (additional details may be found in Chapter 3). While not all of these actions would occur, some combination of the actions would be implemented and, therefore, are all proposed as covered activities.

1. Replace the Fremont Weir fish ladder. The covered activities include removing and replacing the existing Fremont Weir Denil fish ladder with new experimental fish passage facilities designed to allow for the effective passage of all covered fish species including adult sturgeon and salmonids.
2. Install experimental sturgeon ramps. The covered activities include constructing experimental ramps at the Fremont Weir to allow for the effective passage of adult sturgeon and lamprey.
3. Construct a deep fish passage gates and channel. The covered activities include removing a section of the Fremont Weir, soil excavation, fitting the remaining notch with operable “fish passage gates” that allow controlled flow into the Yolo Bypass, and excavation of a deeper “fish passage channel” to convey water from the Sacramento River to the new fish passage gates, and from the fish passage gates to the Tule Canal to convey water from the Sacramento River, through the gates, and to the Tule Canal.

4. Modify the existing Fremont Weir stilling basin. The covered activities include modifications to the existing Fremont Weir stilling basin to ensure that the basin drains sufficiently into the deep fish passage channel.

5. Make improvements to the Sacramento Weir. The covered activities include excavation of a channel to convey water from the Sacramento River to the Sacramento Weir and from the Sacramento Weir to the Tule Canal/Toe Drain, construction of new gates at a portion of the weir, and minor modifications to the stilling basin of the weir to ensure proper basin drainage.

6. Make improvements to the Tule Canal/Toe Drain and Lisbon Weir. The covered activities include physical modifications to passage impediments in the Tule Canal and Toe Drain (e.g., road crossings and agricultural impoundments) and redesigning Lisbon Weir to improve fish passage while maintaining or improving water capture efficiency for irrigation.

7. Realign Lower Putah Creek. The covered activities include realigning Lower Putah Creek to improve upstream and downstream passage of Chinook salmon and steelhead in Putah Creek, and restoring floodplain habitat to provide benefits of seasonal floodplain habitat.

8. Create a notch in the Fremont Weir and a connecting channel. These covered activities include the addition of new operable gates on the weir that allow for the control of the timing, duration, magnitude and frequency of inundation of the Yolo Bypass during non-flood stage periods of the Sacramento River.

9. Modify the Yolo Bypass. The covered activities include grading, removal of existing berms, levees, and water control structures, construction of berms or levees, re-working of agricultural delivery channels, and earthwork or construction of structures to reduce Tule Canal/Toe Drain channel capacities.

10. Create a gated westside channel. The covered activities include the creation of a gated channel to provide flows into Yolo Bypass along the west side, and potential modification of the existing configuration of the discontinuous channels along the western edge of the Yolo Bypass to reduce diversion of Delta water for Yolo Bypass irrigation while maintaining or improving fish passage for all covered fish species.

Maintenance of Fremont Weir and Yolo Bypass Improvements

Routine maintenance of the Fremont Weir and Yolo Bypass are covered activities. Vegetation maintenance activities may include mowing, discing, livestock grazing, dozing, spraying, and/or hand-cutting of young willow groves, cottonwoods, arundo, brush, debris, and young selected oak trees. Trees with a trunk diameter of four inches or greater may be pruned up six feet from the ground. Clearing of areas will be done in stripes to open areas for water flow and to avoid islands and established growth. On a non-routine, but periodic basis, sediment will be removed from the Fremont Weir area using graders, bulldozers, excavators, dump trucks, or other machinery. Outside of the new channel, sediment removal of approximately one million cubic-yards (MCY) within one mile of the weir can be reasonably expected to occur on an average of approximately every five years based on recent maintenance history. Primarily inside the new channel, an additional one million cubic yards every other year of sediment removal is anticipated as a conservative estimate of sediment management. Where feasible, work will be conducted under dry conditions; if necessary some dredging may be required to maintain connection along the deepest part of the channel for fish passage. Where agreements can be made with landowners, sediment may be disposed of on properties in the immediate vicinity of the Fremont Weir area. It may also be used as source material for levee or restoration projects, or otherwise beneficially reused.

The spatial extent of the maintenance activities would be expected to be from the Sacramento River to the Fremont Weir, the Fremont Weir to the southern end of the Yolo Bypass, and between the associated levees.

4.2.2.2.2 Activity

All activities related to the construction, maintenance, replacement, and operations of the facilities described in this section, as well as access road improvements, are covered by the BDCP. In addition, construction of facilities necessary to provide electrical power to these facilities will also be covered by the Plan. The operations of the new Fremont Weir gates under the near- and long-term criteria and adaptive range as described in Chapter 3, *Conservation Strategy*, are also covered by the BDCP.

4.2.2.3 North Bay Aqueduct Alternative Intake Project

4.2.2.3.1 Background

The BDCP will cover all operational components of the North Bay Aqueduct Alternative Intake Project. The project includes an additional intake on the Sacramento River that will operate in conjunction with the existing North Bay Aqueduct intake at Barker Slough (described in Section 4.2.1, *Operations and Maintenance of Existing SWP Facilities*). The project would be used to accommodate projected future peak demand of up to 240 cfs. The construction of any new facilities (any intakes, pipelines, and supporting facilities) associated with the North Bay Aqueduct Alternative Intake Project is not covered under the BDCP. Consequently, any such State and/or federal regulatory compliance requirements that would be applicable to the development of the project would be addressed through processes separate and apart from the BDCP.

Combined operations of a new intake on the Sacramento River and the existing intake at Barker Slough would be included under BDCP covered activities for future peak demand of up to 240 cfs. Operations of the North Bay Aqueduct Sacramento River intake will conform, in combination with the new BDCP intake facilities on the Sacramento River, to the water operations criteria and adaptive range as described in Chapter 3, *Conservation Strategy*. The North Bay Aqueduct Alternative Intake Project may also consider an alternative that would involve the export of water from the Sacramento River through the proposed BDCP North Delta facilities.

4.2.2.3.2 Activity

The BDCP will cover all water operations components of implementing the North Bay Aqueduct Alternative Intake Project.

4.2.3 Power Generation Water Use - Mirant Delta, LLC

Mirant Delta's covered activities are those activities associated with the generation of power at its Pittsburg and Contra Costa power plants (the “Delta Plants”). These activities can be divided into two categories: 1) current power generation activities, and water intake and discharge flows associated with those activities; and 2) recurrent maintenance activities required to ensure continued operation of those existing facilities.

4.2.3.1 Existing and Future Plant Operations

4.2.3.1.1 Background

The Pittsburg Power Plant is located on the southern shore of Suisun Bay near Pittsburg, California (Figure 4-1), and the Contra Costa Power Plant is located 12 miles upstream on the southern bank of the San Joaquin River near Antioch, California (Figure 4-1).

The Delta Plants have a total generating capacity of 2,090 gross megawatts (1,985 net megawatts). Mirant's generating units burn natural gas and are designed to be cooled by water from the Sacramento-San Joaquin River Delta. Cooling water is drawn into the plants through 9.5 mm (3/8 inch) screens, pumped to condensers, used to cool spent steam and then discharged immediately back into the Delta. Source waters for the Delta Plants' cooling water systems are characteristic of this part of the Bay-Delta that separates the upstream, freshwater Delta from the downstream, saltwater bays.

Pittsburg Power Plant
