Suisun song sparrows are associated with tidal marsh habitats dominated by *Sarcocornia*[1], *Spartina*, and *Grindelia*. In brackish marsh habitats, these types are interspersed mostly with *Schoenoplectus*[2], *Typha*, and *Juncus*. Dense vegetation is required for nesting sites, song perches, and refuge from predators (Marshall 1948). There is also an association with tidal channels in areas where *Sarcocornia* or *Spartina* are the dominant landscape cover and *Grindelia* or shrubs occur along the edges of the channels, providing nesting and perching habitat (Spautz and Nur 2008). The association with channels is weaker in brackish marshes with extensive cover of *Schoenoplectus* and *Typha* (Spautz and Nur 2008).

While dense vegetation is characteristic, exposed ground is important for foraging. The song sparrow is the only obligate ground foraging bird in the tidal brackish marsh, and the species occupies an uncontested niche by foraging on the surface of the mud (Larsen 1989). In tidal marsh habitats, openings in the dense *Sarcocornia*, created by small mammals or tidal action, are required for foraging access. In *Schoenoplectus/Typha*-dominated habitats, plant spacing needs to be sufficient to provide openings for foraging and movement on the ground (Marshall 1948).

Spautz et al. (2006) analyzed abundance with a series of vegetation and habitat variables. They found a positive correlation with shrub cover, particularly *Gindelia stricta* and *Baccharis pilularis* (coyote bush), marsh size, and proportion of adjacent natural upland. In general, they found that song sparrows tend to be denser along upland edges of large marshes, especially where shrubs are present (Spautz et al. 2006). Abundance ranges from approximately 3 to 15 birds per hectare (2.5 acres), depending on habitat quality (Marshall 1948, Marshall and Dedrick 1994, Spautz and Nur 2008).

Nesting territories are established linearly every 10 to 50 meters (33 to 164 feet) along sloughs or other channels or along upland edges of marshes. Open marshes away from meandering channels are usually avoided. Each territory requires sufficient area for nesting and foraging, including tidally exposed mud, water, and vegetation suitable for nesting and cover (Walton 1975).

Nests are constructed in a variety of substrates, including *Schoenoplectus americanus*, *S. maritimus*, *S. acutus*, *Grindelia stricta*, *Lepidium latifolium*, *Sarcocornia pacifica*, and *Distichlis spicata*, among others (Spautz and Nur 2008). Nest heights average 36 centimeters (1.2 feet) (Herzog et al. 2004, Spautz et al. 2006) and are usually placed at a height in the vegetation where they can clear flood tide levels while still having cover from taller plants to minimize exposure to predation (Johnston 1956).

[1] Formerly known as *Salicornia*.
[2] Formerly known as *Scirpus*.

A19.4 LIFE HISTORY

Description. The Suisun song sparrow is a small passerine with a large head and plump build, conical bill, short rounded wings, and slender tail with a blunt tip (Arcese et al. 2002). Plumage is characterized by a dark streaked breast and mantle, usually well-defined on a gray or whitish background. The longitudinal streaks align into rows on the back and ventrally gather into a variably defined spot on the chest, leaving the lower belly largely unstreaked. Eyebrows are grayish, and a broad, dark stripe borders the whitish throat. Legs and feet are a pinkish color. The Suisun song sparrow is the darkest of the three subspecies occurring in the San Francisco Bay estuary. Coloration on the back is dark reddish-brown, which distinguishes it from the olive-brown of *M.m. samuelis* and the yellowish gray or plain gray of *M.m. pusillula* (Larsen 1989). The Suisun song sparrow also has a larger, thicker bill than the other neighboring subspecies (Marshall 1948).

Seasonal Patterns. The Suisun song sparrow is non-migratory and occupies the same territory year-round.

Reproduction. The Suisun song sparrow begins breeding relatively early in the spring, an adaptation thought to avoid the highest spring tides, which is a mortality factor for eggs and young (Johnston 1954). Breeding generally occurs from March to June, but this species can produce more than one brood per year and construct up to three nests each year. These activities are influenced by tidal activity and associated habitat and food availability and the outcome of the initial nesting attempt (Johnston 1954). Clutch size averages 3.2 eggs per nest; over the breeding season, the average total number of eggs per pair ranges from 7.5 to 9.1 (Johnston 1956). Productivity per pair over the season varies from 2.0 to 5.8 fledglings per pair per season (Johnston 1956).

Home Range/Territory Size. During the breeding season, the Suisun song sparrow occupies small territories (approximately 0.04 hectares [0.1 acre] in optimal habitat), usually adjacent to the territories of other Suisun song sparrows in a single linear arrangement along the edges of sloughs and bays. Each pair remains within its limited territory during the breeding season. All requirements for nesting and foraging, including tidally exposed mud, water, light, and vegetation suitable for nesting and cover is met within the territory. During the fall and winter, adults and young may range up to 183 meters (600 feet) from the territory and occupy adjacent seasonal marshes or grasslands, but continue to occupy the same general area and return to the same breeding territory each year (Marshall 1948, Walton 1975).

Foraging Behavior and Diet. Suisun song sparrows forage on the bare surface of tidally exposed mud and along slough margins in the salt and brackish marshes of Suisun Bay during low tides. They feed on *Schoenoplectus* and other seeds once they have fallen to the ground, insects (mostly mosquito larvae and flies), and other invertebrates exposed during low tides (Marshall 1948, Walton 1975). While foraging, the Suisun song sparrow hops along the ground with both feet together, scratches leaf litter by pushing both feet simultaneously, or flycatches using hopping and darting motions with outstretched wings for balance (Bent 1968).

A19.5 Threats and Stressors

Habitat Loss and Fragmentation. Habitat loss and fragmentation, caused by diking, levee construction, channelization, invasive species, and urbanization, is considered the primary threat to the continued existence of the Suisun song sparrow (Larsen 1989, Spautz and Nur 2008). Throughout most of the Suisun Marsh, the tidal marsh has been reduced to small fragments that are separated by dispersal barriers or only connected by very narrow strips of vegetation remaining along the banks of tidal sloughs, reducing dispersal, gene flow, and reproduction (Larsen 1989). Large-scale habitat loss can also occur through the effects of global climate change and the resulting rise in sea level. With a projected 0.4-meter (1.3-foot) rise in sea level (IPCC 2001), large areas of tidal marsh in the Suisun Marsh could be inundated, thus making them unsuitable for the Suisun song sparrow (Spautz and Nur 2008). This may be of particular concern in the Suisun Marsh and similar areas where urbanization around the marsh perimeter has removed adjacent natural habitat and thus restricted potential expansion of the marsh in response to sea level rise over time (Orr et al. 2003).

Nest Predation. Spautz and Nur (2008) note that reproductive failure caused by high levels of nest predation may also be a significant threat to the Suisun song sparrow. Nonnative predators include the house cat *(Felix catus)*, Norway rat *(Rattus norvegicus)*, and red fox *(Vulpes fulva)*. Native predators include the American crow *(Corvus brachyrynchos)* and common raven *(Corvus corax)*.

Toxics. While there are regulations that protect most of the remaining tidal marshes inhabited by Suisun song sparrows, the urbanization of the surrounding area contributes to other threats that may alter water salinity and introduce toxins into the system, such as oil spills, chemical contamination, sewage, and other waste. Shipping activities along major channels, including oil tanker traffic and the presence of toxic waste dumps in the area, pose potential contamination issues (Larsen 1989).

Diking, channelization, development, and a substantial decrease in freshwater outflow from the Sacramento-San Joaquin Delta have greatly reduced the habitat that supports this subspecies. The remaining habitat is highly fragmented, existing in thin strips along the inside edges of tidal sloughs.

Salinity Changes. Normal salinity of the Suisun Marsh is a function of the amount of freshwater outflow it receives from the Sacramento-San Joaquin Delta. Disruption of normal outflows can have a detrimental effect on this species. While the Suisun song sparrow has the ability to adapt to short-term changes in water salinity, the species requires a relatively narrow range of saline conditions for long-term survival. Significant alterations in the salinity content can result in undesirable habitat changes, lower reproductive output, competition, and genetic dilution from neighboring subspecies that have a greater range of tolerance (Larsen 1989).

A19.6 RELEVANT CONSERVATION EFFORTS

The Suisun Marsh has been the subject of various conservation efforts for many years, particularly with respect to development and issues related to water quality within its boundaries. The California Department of Water Resources (DWR) Suisun Marsh Program (http://www.iep.water.ca.gov/suisun/program/index.html) summarizes the major agreements, management plans, and legislation that have directed management of the Suisun Marsh since the mid-1970s. These efforts focus on the preservation and restoration of tidal marsh habitats.

The Nejedly-Bagley-Z'Berg Suisun Marsh Preservation Act (1974). The California Legislature enacted the Suisun Marsh Preservation Act to protect the marsh from urban development. It required the San Francisco Bay Conservation and Development Commission (BCDC) to develop a plan for the marsh and provides for various restrictions on development within marsh boundaries.

Suisun Marsh Protection Plan (1976). This plan was developed by the BCDC and defines and limits development within primary and secondary management areas for the "future of the wildlife values of the area as threatened by potential residential, commercial and industrial development." It recommends that the state purchase 1,800 acres (728 hectares) and maintain water quality. While the focus of the plan is on maintaining waterfowl habitat, it also addresses the importance of tidal wetlands and recommends restoring historical marsh areas to wetland status (managed or tidal).

The Suisun Marsh Protection Act (1977). This bill adopts and calls for implementation of the Suisun Marsh Protection Plan. Assembly Bill (AB) 1717 designates the BCDC as the state agency with regulatory jurisdiction of the marsh and calls for the Suisun Resource Conservation District to have responsibility for water management in the marsh. The bill identifies (and focuses on) actions for the preservation of waterfowl needs, along with the retention of the diversity of wildlife. It states that land within the Suisun Marsh should be acquired for public use or resource management if it is suitable for restoration to tidal or managed marsh, but that such restoration cannot be required as a condition of private development.

State Water Resources Control Board (SWRCB) Water Rights Decision 1485 (1978). SWRCB adopted the Water Quality Control Plan for the Sacramento-San Joaquin Delta and issued Water Rights Decision 1485. The decision sets channel water salinity standards for the period from October to May and preserves the area as brackish water tidal marsh. It sets water quality standards in the marsh as a condition of export pumping. These come from the California Department of Fish and Game's (DFG's) recommendations, which were based on (1) the relative value of marsh plants as duck food; (2) the influence of soil salinity and other factors on distribution and growth of marsh plants; and (3) the relationships between channel water salinity and soil salinity. DFG concluded that improved management practices, improved drainage, water control facilities, and adequate quality of water were needed to achieve desired soil salinity conditions for waterfowl food plants.

Plan of Protection for the Suisun Marsh (1984). DWR and the U.S. Bureau of Reclamation (USBR) developed and began implementing the Plan of Protection (POP) in accordance with Water Rights Decision 1485. The POP implementation strategy was to construct large facilities and distribution systems to meet salinity standards (lower channel water salinity), in lieu of significant Central Valley Project/State Water Project storage releases estimated as high as 2 million acre-feet in dry/critical water years. The six-phase POP was the programmatic blue print (required by the SWRCB and embodied in the original Suisun Marsh Preservation Agreement). Two of the six phases were completed, including the Initial Facilities and the Suisun Marsh Salinity Control Gates.

Suisun Marsh Preservation Agreement (SMPA) (1987). This contractual agreement between DWR, USBR, DFG, and Suisun Resource Conservation District contains provisions for DWR and USBR to mitigate the effects on Suisun Marsh channel water salinity from the State Water Project and Central Valley Project operations and other upstream diversions. The SMPA requires DWR and USBR to meet salinity standards, sets a timeline for implementing the POP, and delineates monitoring and mitigation requirements. The Suisun Marsh Monitoring Agreement and the Suisun Marsh Mitigation Agreement were also signed at this time. The Suisun Marsh Mitigation Agreement defines habitat requirements to mitigate effects of facilities and operations, and the Suisun Marsh Monitoring Agreement defines requirements for monitoring salinity and species in the Suisun Marsh.

Bay-Delta Accord (1994). On December 15, 1994, federal and state agencies, working with agricultural, environmental and urban stakeholders, reached an agreement on water quality standards and related provisions that would remain in effect for 3 years. This agreement, known as the Bay-Delta Accord, was based on a proposal developed by the stakeholders. Elements of the agreement include the following:

- Springtime export limits expressed as a percentage of Delta inflow;
- Regulation of the salinity gradient in the estuary so that a salt concentration of two parts per thousand is positioned where it may be more beneficial to aquatic life;
- Specified springtime flows on the lower San Joaquin River to benefit Chinook salmon; and
- Intermittent closure of the Delta Cross Channel gates to reduce entrainment of fish into the Delta.

SWRCB Water Quality Control Plan (1995–1998). In 1994, wildlife and fishery agencies and urban water users expressed concerns about the appropriateness of western Suisun Marsh channel water salinity standards. In May of 1995, the SWRCB modified the Suisun Marsh salinity objectives in the Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary. Modeling analysis by the Suisun Marsh Planning Program showed that Suisun Marsh standards would be met most of the time at all Suisun Marsh compliance stations. Some standard exceedances would be expected in the western Suisun Marsh that participants in the SMPA agreed could be mitigated by more-active water control by landowners.

SWRCB Water Rights Decision 1641 (1999). The SWRCB issued Decision 1641 in December 1999, which updated salinity standards for Suisun Marsh. Increased outflow and salinity requirements for the Bay-Delta provided indirect benefits to the Suisun Marsh. DWR proposed that the SWRCB adopt the Amendment Three actions for Suisun Marsh in this decision. However, the SWRCB was unable to adopt Amendment Three actions because the Section 7 consultation with the U.S. Fish and Wildlife Service (USFWS) had not concluded. However, the SWRCB did relieve USBR and DWR of their responsibility to meet salinity objectives at S-35 and S-97 in the western Suisun Marsh.

Suisun Marsh Charter Implementation Plan (2001). The Suisun Marsh Charter was completed in 2001, and development of an Implementation Plan commenced. Charter participants collaborated on a joint presentation to the State of the Estuary Conference on the principles of the Charter Plan, including coordinated water quality, endangered species, and heritage value protection in the Suisun Marsh.

Habitat Management, Preservation, and Restoration Plan (2003). The Charter process was expanded to include additional federal and state agencies to develop a Suisun Marsh Plan that will balance the goals and objectives of the Bay-Delta Program, SMPA, and other management and restoration programs within the Suisun Marsh in a manner that is responsive to the concerns of all stakeholders and is based upon voluntary participation by private landowners.

In addition, several facilities have been constructed in the Suisun Marsh to protect and improve water quality and protect and enhance wildlife habitat, including:

- Roaring River Distribution System (1979–80);
- Morrow Island Distribution System (1979–80;
- Goodyear Slough Outfall (1979–80);
- Suisun Marsh Salinity Control Gates (1988); and
- Cygnus and Lower Joyce Facilities (1991).

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy (MSCS) designation for Suisun song sparrow is “Recovery” (CALFED Bay-Delta Program 2000). This means that the ERP has established a goal to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

The Suisun song sparrow is also proposed for coverage under the Solano County Multispecies Habitat Conservation Plan.

A19.7 Species Habitat Suitability Model

Model Approach. BDCP Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information systems (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which are incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and revise the vegetation input data as necessary.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements, and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate, as well as overestimate, the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small, isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; instead, the models indicate that non-habitat areas have a much lower probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percentage cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf (2007). Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers; connectivity between habitat types; and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or underestimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The Suisun song sparrow model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), USDA 2005 aerial photography, and DWR 2007 land use survey of the Delta and Suisun Marsh area-version. Using these data sets, the model maps the distribution of suitable Suisun song sparrow habitat in the Plan Area. Vegetation types were assigned based on the species requirements, as described above, and the assumptions described below.

Breeding Habitat. Suisun song sparrow habitat consists of all *Salicornia*[3]-dominated tidal brackish emergent wetland and all *Typha*-, *Scirpus*[4]-, and *Juncus*-dominated tidal freshwater emergent wetland within the Plan Area west of Sherman Island.

Suisun song sparrow habitat in the Delta consists of the following types from the BDCP composite vegetation layer:

- Managed wetland
    - o *Scirpus*[6] spp. in managed wetlands.
- Alkali seasonal wetland complex
    - o *Distichlis spicata – Salicornia virginica*[5]*;*
    - o *Distichlis spicata – Juncus baltica;*
    - o *Juncus bufonius* (salt grasses);
    - o *Juncus balticus* – meadow vegetation;
    - o Pickleweed *(Salicornia virginica);* and
    - o *Salicornia virginica – Cotula coronopifolia.*
- Freshwater perennial emergent wetland
    - o Broad-leaf cattail *(Typha latifolia).*
- Tidal freshwater emergent wetland and tidal brackish emergent wetland
    - o Mixed *Scirpus* mapping unit;
    - o Mixed *Scirpus*/floating aquatics complex;

---

[3] Currently known as *Sarcocornia*.
[4] Currently known as *Schoenoplectus*.
[5] Currently known as *Sarcocornia pacifica*.

- Mixed *Scirpus*/submerged aquatics complex;
- Hard-stem bulrush *(Scirpus acutus);*
- *Scirpus acutus* pure;
- *Scirpus acutus – Typha angustifolia;*
- *Scirpus acutus – Typha latifolia;*
- *Scirpus acutus – (Typha latifolia) – Phragmites australis;*
- California bulrush *(Scirpus californicus);*
- *Scirpus californicus – Eichhornia crassipes;*
- *Scirpus californicus – Scirpus acutus;*
- American bulrush *(Scirpus americanus);*
- Narrow-leaf cattail *(Typha angustifolia);* and
- *Typha angustifolia – Distichlis spicata.*

Suisun song sparrow habitat in the Suisun Marsh consists of the following types from the BDCP composite vegetation layer:

- Bulrush – cattail freshwater marsh NFD super alliance;
- *Grindelia stricta* var. *stricta;*
- *Juncus balticus;*
- *Juncus balticus/Conium;*
- *Juncus balticus/Lepidium;*
- *Juncus balticus/Potentilla;*
- *Ledidium* (generic);
- *Lepidum/Distichlis;*
- *Salicornia* (generic);
- *Salicornia virginica;*
- *Salicornia/*annual grasses;
- *Salicornia/Atriplex;*
- *Salicornia/Cotula;*
- *Salicornia/Crypsis;*
- *Salicornia/Polygonum-Xanthium-Echinochloa;*
- *Salicornia/Sesuvium;*
- *Scirpus (californicus* or *acutus)-Typha* spp.;

- *Scirpus (californicus* or *acutus)-Rosa;*
- *Scirpus (californicus* or *acutus)/*wetland herb;
- *Scirpus americanus* (generic);
- *Scirpus americanus/Lepidium;*
- *Scirpus americanus/Potentilla;*
- *Scirpus americanus/S. Californicus-S. acutus;*
- *Scirpus californicus/S. acutus;*
- *Scirpus maritimus;*
- *Scirpus maritimus/Salicornia;*
- *Scirpus maritimus/Sesuvium;*
- *Typha angustifolia* (dead stalks);
- *Typha angustifolia/Distichlis;*
- *Typha angustifolia/Phragmites;*
- *Typha angustifolia/Polygonum-Xanthium-Echino;*
- *Typha angustifolia/S. americanus;* and
- *Typha* species (generic).

Assumptions. Suisun song sparrows are found exclusively in tidal marshes of the Suisun Bay and as far east as Kimbal Island in the western Delta (Spautz and Nur 2008). They nest and forage in tidal brackish emergent wetland habitats dominated by *Spartina*, *Salicornia*, and *Grindelia* spp. and tidal freshwater emergent wetland habitats dominated by *Scirpus*, *Typha*, and *Juncus* spp. and, to an increasing extent, *Lepidium latifolium* (Spautz and Nur 2008). Specific habitat elements, including proximity to tidal channels, percentage of shrub cover, and site-specific vegetation associations that could potentially refine the extent of the suitable habitat conditions were not sufficiently identified in the GIS databases, and thus were not used in the model. Therefore, the model likely overestimates the extent of potentially occupied tidal marsh habitat.

A19.8 Recovery Goals

A USFWS recovery plan has not been prepared for this species, and no recovery goals have been established; however, the CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for Suisun song sparrow is "Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP has established a goal to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

APPENDIX A20. YELLOW-BREASTED CHAT (*ICTERIA VIRENS*)

A20.1 LEGAL STATUS

The yellow-breasted chat *(Icteria virens)* is designated as a state Bird Species of Special Concern by the California Department of Fish and Game (DFG) (Shuford and Gardali 2008). In California, nests are protected under *Fish and Game Code*, Section 3503. The yellow-breasted chat has no federal regulatory status; however, the species is protected under the federal Migratory Bird Treaty Act.

A20.2 SPECIES DISTRIBUTION AND STATUS

A20.2.1 Range and Status

The yellow-breasted chat is a neotropical migrant songbird that breeds in North America and winters in Central America, primarily in Mexico and Guatemala, although a few birds winter in southern California (Small 1994). The species' range includes most of the continental United States and Mexico. Yellow-breasted chats are widespread summer residents of eastern North America; however, they have a much more fragmented distribution in western North America (USFS 2008). In western North America, their range includes the Cascade Range; central Oregon valleys; southern Idaho and northern Nevada; and portions of California, Utah, western Colorado, and central Arizona (USFS 2008).

Grinnell and Miller (1944) reported that chats bred over the entire length and breadth of California exclusive of higher mountains and coastal islands, and were more numerous toward the interior. In migration, chats were similarly widespread with fewer restrictions as to habitat (dense riparian plant growth). In California, the species' current range is not completely known because of population declines (Small 1994); however, the species is thought to inhabit most of its historical range, with the exception of most of the Central Valley (Comrack 2008) (Figure A-20a).

This species was formerly a common summer resident in coastal southern and central California, along the Colorado River, and throughout the Central Valley (Grinnell and Miller 1944). However, the species is currently reported as an uncommon resident in riparian habitats on the Modoc Plateau, Klamath Mountain region, along the north and south Coast Ranges, in the Sierra Nevada foothills, and in the Transverse and Peninsular Ranges (Small 1994, Eckerle and Thompson 2001). It appears to be extirpated from the San Joaquin and Sacramento valleys, but still occurs along some foothill tributaries.

DRAFT

Figure A-20a. Yellow-Breasted Chat Statewide Range and Recorded Occurrences

Few data are available regarding population decreases or increases over large sections of the species' range (Eckerle and Thompson 2001). California Breeding Bird Survey data from 1966 through 1998 show an increasing trend of 1.1 percent per year (Sauer et al. 1999, Ricketts and Kus 2000). However, these data are not considered statistically significant and should be interpreted with caution (Ricketts and Kus 2000). The species has apparently declined dramatically in southern California (Garrett and Dunn 1981).

A20.2.2 Distribution and Status in the Plan Area

Comrack (2008) includes the central Delta within the current breeding range of the yellow-breasted chat. There are few breeding records of yellow-breasted chat from this area or elsewhere within the Plan Area (Figure A-20b). Most are fall and winter migrants found along Putah Creek near the northern edge of the Plan Area in Yolo and Solano Counties or along the Cosumnes River within the Cosumnes River Preserve. The National Audubon Society (2008) notes that several pairs of yellow-breasted chat have been recorded at several locations in the Sacramento-San Joaquin Delta, including Liberty Island, Sherman Island, and Piper Slough. However, no additional information was found to confirm nesting activity at these locations. Comrack (2008) also reported breeding records from the Contra Costa Breeding Bird Atlas within the Delta and additional breeding records from White Slough in San Joaquin County. Recent Delta Habitat Conservation and Conveyance Program (DHCCP) field surveys have confirmed late-spring and summer occurrences of chats within the Plan Area. While breeding has not yet been confirmed, this suggests a reasonable possibility that the species is breeding within the Plan Area.

A20.3 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

Yellow-breasted chats nest and forage in dense riparian thickets of willows, vines, and brush associated with streams and other wetland habitats (Small 1994). The species has been classified as an open-canopy obligatory species (i.e., it prefers open overstory and brushy understory), with population density directly related to shrub density to a height of 4.5 meters (14.8 feet) (Crawford et al. 1981). Some taller trees, such as tall willows (*Salix* spp.), cottonwood (*Populus* spp.), and sycamore (*Platanus* spp.) are also required for song perches (Dunn and Garrett 1997). Several studies indicate a strong association with early successional vegetation, including clearcut areas and powerline corridors with dense shrubby vegetation such as Himalayan blackberry (*Rubus discolor*), wild grape (*Vitis* spp.), and/or willows (*Salix* spp.), with sapling-sized trees as opposed to mature riparian forest (Kroodsma 1982, Melhop and Lynch 1986, Annand and Thompson 1997, Comrack 2008). Kroodsma (1982) also reported a preference for blackberry (*Rubus* spp.) thickets and avoidance of areas with a high percentage of grass cover.

Yellow-breasted chats occur up to 1,463 meters (4,800 feet) in valley foothill riparian habitats and up to 1,981 meters (6,499 feet) east of the Sierra Nevada in desert riparian habitats (DeSante and Ainley 1980, Garrett and Dunn 1981, Gaines 1992). Nests are usually constructed low to the ground (usually within 1 meter) in dense shrubs (Barber and Martin 1997, Ricketts 1999).

DRAFT

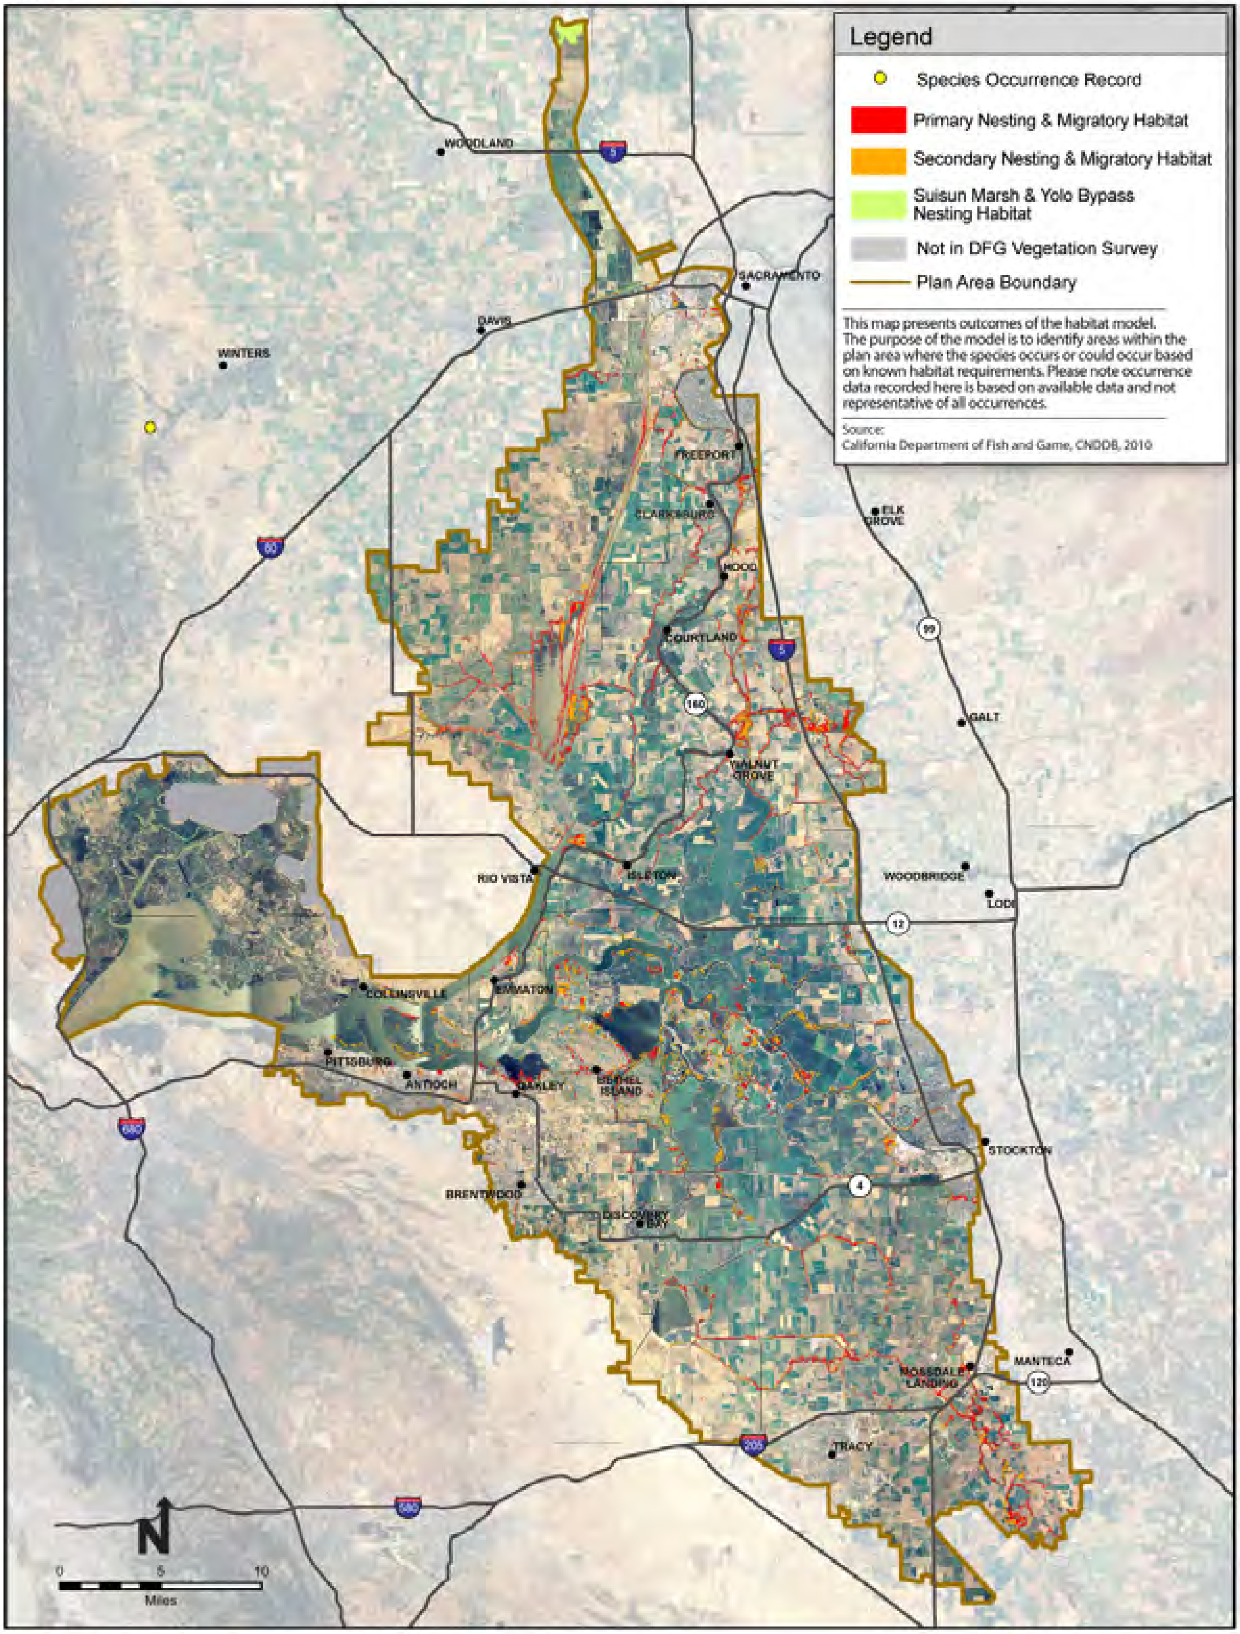

Figure A-20b. Yellow-Breasted Chat Habitat Model and Recorded Occurrences

A variety of trees and shrubs are used as nest substrate, including willow; alder; and several shrub species, including blackberry. At the Lower Clear Creek Floodway in Shasta County, Burnett and DeStaebler (2003) found that most chat nests were associated with Himalayan blackberry. Other species used for nesting include California blackberry, California wild rose *(Rosa californica),* and pipevine *(Aristolochia macrophylla)* (Ricketts and Kus 2000). Additionally, chats have been found to use saltcedar preferentially to native habitat (Hunter et al. 1988). During migration, yellow-breasted chats use habitat similar to their breeding habitat (Dunn and Garrett 1997).

A20.4 LIFE HISTORY

Description. The yellow-breasted chat is the largest of the North American warblers (average total length equals 13.3 centimeters [cm] [5.2 inches]; average wing length equals 17.8 cm [7.0 inches]; average weight equals 11 grams [0.39 ounces]). The sexes are similar, with plain olive-green to olive-gray upperparts, a deep yellow throat and breast, and a grayish face with black lores, white supercilium, and whitish spectacles contrasting with the surrounding feathers (Dunn and Garrett 1997, Eckerle and Thompson 2001).

Seasonal Patterns. Yellow-breasted chats are migratory and usually arrive at California breeding grounds in April from their wintering grounds in Mexico and Guatemala (Green 2005). Northern populations may arrive at breeding grounds from late April to early May (Ricketts and Kus 2000). In the Sierra Nevada, they may move upslope after breeding (Gaines 1992). Departure for wintering grounds occurs from August to September (Ricketts and Kus 2000). Spring migration occurs from March to May (Dunn and Garrett 1997).

Little information is available on juvenile dispersal. Banding studies in Indiana showed that many juveniles moved away from the forests where they were born. Data on post-breeding dispersal are also scarce. Data from the eastern United States indicate an extremely low fidelity to breeding sites between years; however, in southern California, the limited amount of available habitat may foster a higher level of breeding site fidelity (Eckerle and Thompson 2001).

Reproduction. Yellow-breasted chats breed from early May to early August, with peak breeding activity occurring in June (Green 2005). Males arrive at breeding grounds before females (Eckerle and Thompson 2001). Pairs are monogamous, although pairs may nest near one another in loose colonies (Ehrlich et al. 1988). Following arrival at the breeding grounds, nests are constructed and three to six eggs are laid from mid-May to mid-July (Thompson and Nolan 1973). Females incubate eggs for 11 to 15 days (Green 2005). Once eggs hatch, both sexes tend to the nestlings until they fledge (Harrison 1978). Approximately 8 to 11 days are required for fledging (Petrides 1938, Green 2005). They will occasionally produce a second brood in the season. Of 24 females nesting in southern Indiana for which all nesting attempts within a single year were known, only 2 (8 percent) had a second brood (Thompson and Nolan 1973). Survival rates of fledglings are unknown.

Foraging Behavior and Diet. Chats forage by foliage gleaning, consuming insects and berries about equally (Ehrlich et al. 1988, Green 2005). Adults feed on a variety of arthropods, including beetles and weevils, true bugs, ants, bees, caterpillars, and spiders. Nestlings are typically fed a diet of soft-bodied orthopterans (e.g., grasshoppers) and larval lepidopterans (Petrides 1938). In late summer and fall, chats feed largely on small fruits, such as the fruits of honeysuckle, wild strawberry, blackberry, mulberry, chokecherry, sumac, and nightshade (Dunn and Garrett 1997).

Home Range/Territory Size. Yellow-breasted chats typically nest in loose colonies, although males usually defend distinct territories (Ehrlich et al. 1988). Territorial defense appears to be less effective as population densities increase (Eckerle and Thompson 2001). Territory size ranges from 0.3 to 3.2 acres (0.1 to 1.3 hectares) (Zeiner et al. 1990). Thompson and Nolan (1973) reported 28 territories averaging 3.2 acres (1.3 hectares) in Indiana and reported that territory sizes decreased as more males arrived. Brewer (1955) reported territories averaging 0.3 acres (0.1 hectares) and varying from 0.1 to 0.7 acres (0.04 to 0.3 hectares) in Illinois. Dennis (1958) reported territory varying from 1.2 to 2.5 acres (0.5 to 1.0 hectares) in Virginia. Territory sizes have not been measured in California, but Gaines (1974) reported a breeding density from the Sacramento Valley of one chat per 10 acres (4 hectares). Although some known breeding sites are consistently active each year, some data suggest low site fidelity (Thompson and Nolan 1973).

A20.5 Threats and Stressors

Habitat Loss and Alteration. A major factor leading to declines in populations of yellow-breasted chats is the loss and degradation of riparian woodland habitat throughout the species' range (Remsen 1978, Rosenberg et al. 1991). Habitat loss and degradation can occur through clearing of vegetation for agriculture, timber harvest, development, or flood control.

Flood control and river channelization eliminates early successional riparian habitat (willow/alder shrub habitats with a dense understory) that chats (and many other riparian focal species) use for breeding.

Timber harvest may have initial negative impacts on nesting chats; however, Annand and Thompson (1997) noted that chats preferred clearcut areas, suggesting that timber harvest impacts may be temporary and could ultimately have a beneficial impact in some situations.

Grazing can also have a significant effect on riparian vegetation (Sedgwick and Knopf 1987). Cattle and other livestock can trample vegetation and eat seedlings, saplings, shrubs, and herbaceous plants. This can lead to a reduction in cover and nesting sites and affect insect prey populations.

Cowbird Parasitism. Brown-headed cowbirds *(Molothrus ater)* may also significantly impact yellow-breasted chats by laying eggs in chats' nests in a phenomenon called brood parasitism

(Gaines 1974, Remsen 1978). The chat is among the 17 hosts most parasitized by cowbirds (Ricketts and Kus 2000). In a 3-year study in Missouri, 31 percent of nests were parasitized by cowbirds (Burhans and Thompson 1999). While data are limited on the extent of cowbird parasitism on yellow-breasted chats in California, it could have a significant impact on local reproductive performance.

Predation. Yellow-breasted chats are also subject to occasional predation by accipiters, small mammals, and snakes (Green 2005). Potential nest predators in California include western scrub-jays *(Aphelocoma californica)*, American crows *(Corvus brachyrhynchos)*, common ravens *(Corvus corax)*, black rats *(Rattus rattus)*, dusky-footed woodrats *(Neotoma fuscipes)*, raccoons *(Procyon lotor)*, and several species of snakes (Ricketts and Kus 2000). Predation of nests may be intensified where insufficient riparian scrub cover or insufficient riparian width occurs, potentially reducing reproduction and recruitment.

A20.6 Relevant Conservation Efforts

There have been few conservation efforts directed toward yellow-breasted chats in California. Efforts to protect and restore riparian systems can potentially preserve or create habitat for this species. Some regional habitat conservation planning efforts may also protect the species, primarily through preserving existing occupied habitat. Neighboring HCP/NCCP finalized or in-progress plans that include the yellow-breasted chat as a covered species include the following: Yolo County Natural Heritage Program Plan, Solano County Multispecies Habitat Conservation Plan, San Joaquin County Multi-Species Habitat Conservation and Open Space Plan, the South Sacramento County Habitat Conservation Plan, and the Butte Regional Habitat Conservation Plan and Natural Community Conservation Plan.

A20.7 Species Habitat Suitability Model

Model Approach. BDCP Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which are incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and revise the vegetation input data as necessary.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements, and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate, as well as overestimate, the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small, isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; instead, the models indicate that non-habitat areas have a much lower probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percentage cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf (2007). Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers; connectivity between habitat types; and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified, and each vegetation type or association is identified, along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or underestimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The yellow-breasted chat model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), USDA 2005 aerial photography, and California Department of Water Resources 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable yellow-breasted chat nesting and migratory habitat in the Plan Area using two qualitative parameters, primary habitat and secondary habitat. Vegetation types were assigned based on the species requirements, as described above, and the assumptions described below.

Nesting and Migratory Habitat. Nesting and migratory habitat in the Delta consists of the following valley riparian types from the BDCP composite vegetation layer:

Primary Habitat

- White alder *(Alnus rhombifolia)*;
- *Alnus rhombifolia/Salix exigua (Rosa californica)*;
- *Acer negundo-Salix gooddingii*;
- Hinds walnut *(Juglans hindsii)*;
- Black willow *(Salix gooddingii)*;
- *Salix gooddingii-Populus fremontii (Quercus lobata-Salix exigua-Rubus discolor)*;
- *Salix gooddingii/Rubus discolor*;
- Coast live oak *(Quercus agrifolia)*;
- *Quercus lobata/Rosa californica (Rubus discolor-Salix lasiolepis/Carex* spp.*)*;
- *Quercus lobata – Acer negundo*;
- *Quercus lobata – Alnus rhombifolia (Salix lasiolepis-Populus fremontii-Quercus agrifolia)*;
- *Quercus lobata – Fraxinus latifolia*;
- *Salix lasiolepis* – Mixed brambles *(Rosa californica-Vitis californica-Rubus discolor)*; and
- *Salix exigua (Salix lasiolepis – Rubus discolor – Rosa californica)*.

Secondary Habitat

- *Alnus rhombifolia/Cornus sericea*;
- Oregon ash *(Fraxinus latifolia)*;
- Box elder *(Acer negundo)*;
- Fremont cottonwood *(Populus fremontii)*;
- *Salix gooddingii*/wetland herbs;
- *Salix gooddingii – Quercus lobata*/wetland herbs;
- Coyote bush *(Baccharis pilularis)*;
- Blackberry *(Rubus discolor)*;
- California wild rose *(Rosa californica)*;
- Mexican elderberry *(Sambucus mexicana)*;
- California dogwood *(Cornus sericea)*;

- *Cornus sericea – Salix exigua*;
- *Cornus sericea – Salix lasiolepis/(Phragmites australis)*;
- Arroyo willow *(Salix lasiolepis)*;
- *Salix lasiolepis – Cornus sericea/Scirpus*[1] spp. – complex unit;
- Shining willow *(Salix lucida)*; and
- Narrow-leaf willow *(Salix exiqua)*.

Nesting and migratory habitat in the Suisun Marsh and Yolo Basin consists of the following valley riparian types from the BDCP composite vegetation layer:

- *Fraxinus latifolia*;
- Fremont cottonwood-Valley oak-Willow riparian forest;
- Mixed Fremont cottonwood – Willow;
- Mixed willow super alliance;
- *Quercus agrifolia*;
- *Rosa californica*;
- *Rosa/Baccharis*;
- *Rubus discolor*;
- *Salix laevigata/S. lasiolepis*;
- *Salix lasiolepis/Quercus agrifolia*;
- Valley oak alliance – Riparian; and
- Willow trees.

Yellow-breasted chat nesting and migratory habitat consists of all valley riparian types with a shrub component that includes blackberry, California wild rose, dogwood, coyote bush, willow, and other shrub species, and an overstory component that includes valley oak, coast live oak, Fremont cottonwood, white alder, box elder, Oregon ash, willow, or walnut. Distinguishing primary from secondary habitat within the Delta was based on a qualitative assessment of the suitability of the understory and overstory layers within each type. Types that are classified as primary habitat support a greater percentage of cover of a suitable shrub layer, particularly blackberry and California wild rose, and also have an open to moderately dense overstory canopy. Determining whether a riparian habitat was considered primary or secondary habitat in the Delta was done through a review of the species associations and ranges of percentage cover from Hickson and Keeler-Wolf (2007). Because this information was not available in the Suisun

[1] Currently known as *Schoenoplectus*.

Marsh data set (Boul and Keeler-Wolf 2008), suitable habitat types were not similarly differentiated.

Assumptions. Yellow-breasted chats nest and forage in dense riparian thickets of willows, vines, and brush associated with streams and other wetland habitats (Small 1994). Population density is directly related to shrub density (Crawford et al. 1981), with a preference for blackberry noted in several studies (Kroodsma 1982, Burnett and DeStaebler 2003), although a variety of other shrubs and thickets are considered suitable, including wild grape, willows, and California wild rose (Melhop and Lynch 1986, Annand and Thompson 1997, Ricketts and Kus 2000, Comrack 2008). Some taller overstory trees are also required for song perches (Dunn and Garrett 1997), but the mature and dense overstory canopies are apparently avoided (Kroodsma 1982, Melhop and Lynch 1986, Annand and Thompson 1997, Comrack 2008).

While uncommon, there are historical and several relatively recent breeding records of chats within the Plan Area, and late spring and summer occurrences of chats have been confirmed by DHCCP surveys. Chats are known to migrate through the Plan Area. Vegetation types that are listed as primary habitat are considered to have a higher probability of breeding activity, and while chats generally use similar habitat during the breeding and non-breeding seasons, both the primary and secondary types are considered suitable migratory habitat.

The model does not distinguish suitability on the basis of riparian width or patch size. Zeiner et al. (1990) reported chat territory sizes from 0.3 to 3.2 acres (0.1 to 1.3 hectares). Because the minimum mapping unit (1 acre) is above the minimum territory size, the model is not restricted on the basis of patch size, but may in fact underestimate the extent of suitable habitat. Note however, that Gaines (1974) reported a breeding density from the Sacramento Valley of one chat per 10 acres, which suggests a possible overestimate of suitable habitat. Riparian width may be an important factor related to yellow-breasted chat occurrence. Narrow widths may make chats more susceptible to brown-headed cowbird parasitism (Gaines 1974, Ricketts and Kus 2000) and predation (Green 2005). The model may also overestimate suitable habitat for chats by not restricting the distribution of suitable habitat based on riparian width.

A20.8 Recovery Goals

A USFWS recovery plan has not been prepared for this species, and no recovery goals have been established.

APPENDIX A21. LEAST BELL'S VIREO (*VIREO BELLII PUSILLUS*)

A21.1 LEGAL STATUS

The least Bell's vireo (*Vireo bellii pusillus*) is state and federally listed as endangered. The species was listed by the California Fish and Game Commission pursuant to the California Endangered Species Act (Fish and Game Code, Sections 2050 et seq.) on October 2, 1989, and by the U.S. Fish and Wildlife Service (USFWS) pursuant to the federal Endangered Species Act on May 2, 1986 (51 FR 16474). Critical habitat was designated for this species pursuant to the federal Endangered Species Act on February 2, 1994 (59 FR 4845).

A21.2 SPECIES DISTRIBUTION AND STATUS

A21.2.1 Range and Status

The least Bell's vireo is one of four subspecies of Bell's vireo and is the only subspecies that breeds entirely in California and northern Baja California. Arizona Bell's vireo (*V. bellii arizonae*) is found along the Colorado River and may occur on the California side, but otherwise occurs throughout Arizona, Utah, Nevada, and Sonora, Mexico.

A riparian obligate, the historical distribution of the least Bell's vireo extended from coastal southern California through the San Joaquin and Sacramento valleys as far north as Tehama County near Red Bluff (Figure A-21a). The Sacramento and San Joaquin valleys were considered the center of the species' historical breeding range supporting 60-80 percent of the historical population (51 FR 16474). The species also occurred along western Sierra foothill streams and in riparian habitats of the Owens Valley, Death Valley, and Mojave Desert (Cooper 1861 and Belding 1878 in Kus 2002a, Grinnell and Miller 1944). The species was reported in Grinnell and Miller (1944) from elevations ranging from -175 feet in Death Valley to 4,100 feet at Bishop, Inyo County. These and other historical accounts described the species as common to abundant, but no reliable population estimates are available prior to the species' federal listing in 1986.

Coinciding with widespread loss of riparian vegetation throughout California (Katibah 1984), Grinnell and Miller (1944) began to detect population declines in the Sacramento and San Joaquin Valley region by the 1930s. Surveys conducted in late 1970s (Goldwasser et al. 1980) detected no least Bell's vireos in the Sacramento-San Joaquin Valleys, and the species was considered extirpated from the region. By 1986, the USFWS determined that least Bell's vireo had been extirpated from most of its historical range and numbered approximately 300 pairs statewide (51 FR 16474).

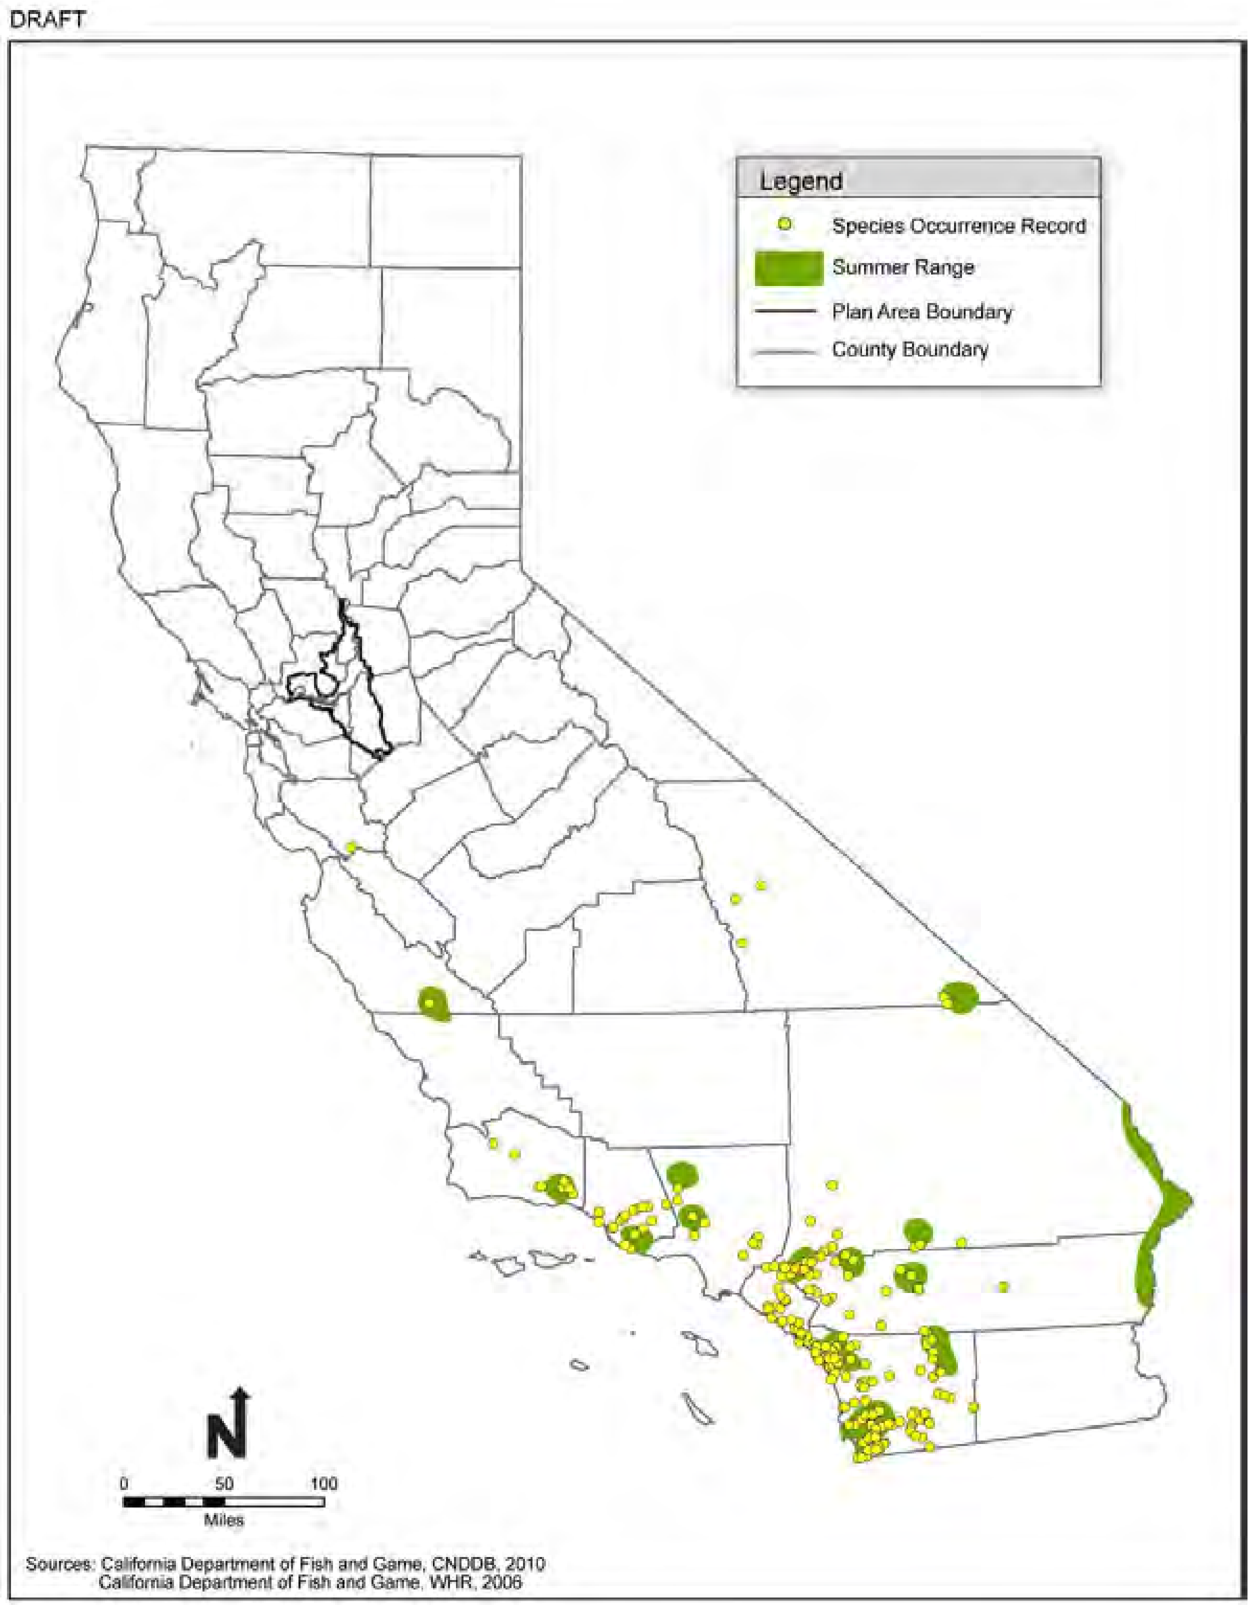

Figure A-21a. Least Bell's Vireo Statewide Range and Recorded Occurrences

The historical range was reduced to six California counties south of Santa Barbara, with the majority of breeding pairs in San Diego County (77 percent), Riverside County (10 percent), and Santa Barbara County (9 percent) (51 FR 16474).

Since federal listing in 1986, populations have gradually increased and the species has re-colonized portions of its historical range. Increases have been attributed primarily to riparian restoration and efforts to control the brood parasite brown-headed cowbird (Kus 1998 and Kus and Whitfield 2005 in Howell et al. in press). By 1998, the total population was estimated at 2,000 pairs and recolonization was reported along the Santa Clara River in Ventura County, the Mojave River in San Bernardino County, sites in Monterey and Inyo counties (Kus and Beck 1998, Kus 2002a, USFWS 2006), and a single nest reported from Santa Clara County near Gilroy in 1997 (Roberson et al. 1997). Still, the distribution remained largely restricted to San Diego County (76 percent) and Riverside County (16 percent) (USFWS 2006).

By 2005, the population had reached an estimated 2,968 breeding pairs (USFWS 2006) with increases in most Southern California counties and San Diego County (primarily Camp Pendleton Marine Corps Base) supporting roughly half of the current population (USFWS 2006).

Two singing least Bell's vireo males were detected, positively identified, and photographed in the southern portion of the Yolo Bypass Wildlife Area in Yolo County in mid-April 2010 (J. P. Galván pers. comm.). As of late-May the two males are still present and have been viewed by a large number of people. The next closest sighting occurred in June 2005 when least Bell's vireos were detected nesting at the San Joaquin River National Wildlife Refuge, west of Modesto in Stanislaus County, the first nesting record of the species in the Central Valley in over 50 years (Howell et al. in press). A single breeding pair nested at the refuge in 2005, 2006, and 2007. The pair successfully nested in 2005 and 2006. The nest was depredated in 2007. No least Bell's vireos were detected in 2008 or 2009 (Howell et al. in press).

A21.2.2 Distribution and Status in the Plan Area

There are no records of least Bell's vireos breeding in the Plan Area since at least the 1970's (Figure A-21b). Two singing males were detected in the Yolo Bypass Wildlife Area in mid-April 2010. The next-nearest most recent record (noted above) is approximately 7 miles south of the Plan Area at the San Joaquin River National Wildlife Refuge in the San Joaquin and Tuolumne River floodplain (Howell et al. in press). Because of the recent sighting of least Bell's vireo in the Plan Area and because the Plan Area may support suitable riparian habitat for a breeding pair, the species may potentially re-colonize the Plan Area.

DRAFT

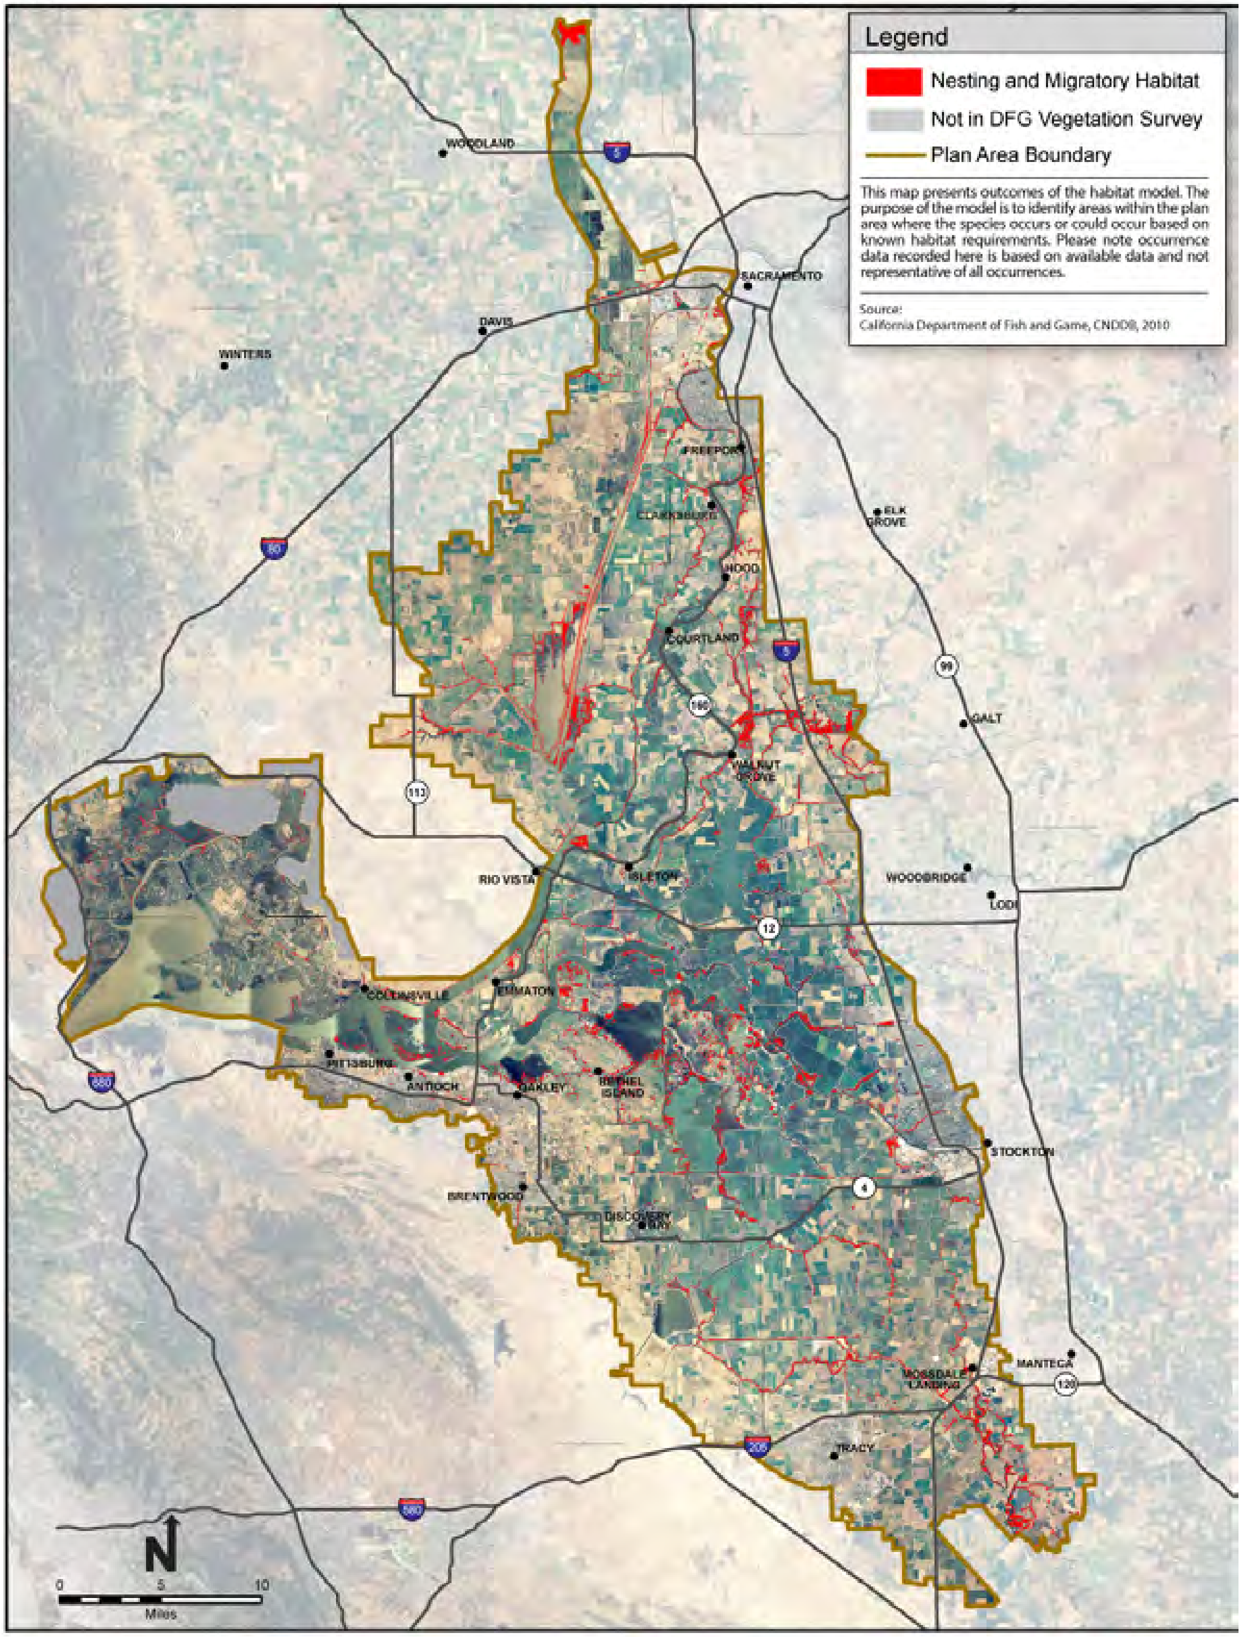

Figure A-21b. Least Bell's Vireo Habitat Model

A21.2.3 Habitat Requirements and Special Conditions

The least Bell's vireo is an obligate riparian breeder that typically inhabits structurally diverse woodlands, including cottonwood-willow woodlands/forests, oak woodlands, and mule fat scrub (USFWS 1998). Two features appear to be essential for breeding habitat: (1) the presence of dense cover within 3-6 feet (1-2 meters) of the ground, where nests are typically placed; and (2) a dense stratified canopy for foraging (Goldwasser 1981, Gray and Greaves 1981, Salata 1981 & 1983, RECON 1989). While least Bell's vireo typically nests in willow-dominated areas, plant species composition does not seem to be as important a factor as habitat structure.

Early successional riparian habitat typically supports the dense shrub cover required for nesting and a diverse canopy for foraging. While least Bell's vireo tends to prefer early successional habitat, breeding site selection does not appear to be limited to riparian stands of a specific age. If willows and other species are allowed to persist, within 5-10 years they form dense thickets and become suitable nesting habitat (Goldwasser 1981, Kus 1998). Tall canopy tends to shade out the shrub layer in mature stands, but least Bell's vireo will continue to use such areas if patches of understory exist. In mature habitat, understory vegetation consists of species such as California wild rose (*Rosa californica*), posion oak (*Toxicodendron diversiloba*), California blackberry (*Rubus ursinus*), grape (*Vitis californica*), and perennials that can conceal nests. Nest site characteristics are highly variable and no features have been identified that distinguish nest sites from the remainder of the territory (Hendricks and Rieger 1989, Olson and Gray 1989, RECON 1989).

Least Bell's vireo use upland habitat, in many cases coastal sage scrub, adjacent to riparian habitat. These areas provide migratory stopover grounds, foraging habitat, and dispersal corridors for non-breeding adults and juveniles (Kus and Miner 1989, RHJV 2004). Vireos along the edges of riparian corridors maintain territories that incorporate both habitat types, and a significant proportion of pairs with territories encompassing upland habitat place at least one nest there (Kus and Miner 1989).

Little is known about least Bell's vireo wintering habitat requirements. They are not exclusively associated with riparian habitat during winter, and can occur in mesquite scrub vegetation to a greater degree than riparian areas in winter (Kus unpubl. data in USFWS 2006). Least Bell's vireo may also occur in palm groves or along hedgerows associated with agriculture and rural residential areas.

A21.2.4 Life History

Description. Least Bell's vireo is the smallest subspecies of the Bell's vireo (*Vireo bellii*). The Bell's vireo can range from 4.3-4.7 inches (11-12 centimeters [cm]) in length and has a wingspan of 7.1 inches (18 cm). It weighs approximately 0.2-0.4 oz (7-10 g) (Brown 1993). It is drably colored and indistinctly marked. The least Bell's vireo is the grayest subspecies of Bell's vireo and has very little yellow or green in its plumage.

Seasonal Patterns. Least Bell's vireos are migratory and usually arrive to their California breeding grounds in mid-March to early April from their wintering grounds in Mexico. Observations of banded birds suggest that returning adult breeders may arrive earlier than first-year birds by a few weeks (Kus unpubl. data in USFWS 2006). Least Bell's vireos begin departing for their wintering grounds by late July but are generally present on their breeding grounds until late September (Garrett and Dunn 1981, Salata 1983).

Nest Site Selection. Nests are typically placed in the fork of a tree or shrub branch in dense cover within 3-6 feet (1-2 meters) of the ground. Both members of the pair construct the cup-shaped nest from leaves, bark, willow catkins, spider webs, and other material, in about 4-5 days. The female selects the nest site (Bent 1950, Barlow 1962). Nests are placed in a wide variety of plant species, but the majority are placed in willows (*Salix* spp.) and mule fat (*Baccharis glutinosa*). Nests tend to be placed in openings along the riparian edge, where exposure to sunlight allows the development of shrubs.

Reproduction. Egg-laying begins 1-2 days after nest completion. Typically 3-4 eggs are laid. Average clutch sizes of nonparasitized nests observed with complete clutches have ranged from 3.1-3.9 in recent years. Both parents share in incubation which takes approximately 14 days. After hatching, nestlings are fed by both parents for 10-12 days until fledging (USFWS 1998). Adults continue to care for the young at least two weeks after fledging when territorial boundaries may be relaxed as family groups range over larger areas. Fledglings usually remain in the territory or its vicinity for most of the season. Least Bell's vireo pairs may attempt up to five nests in a breeding season, although most fledge young from only one or two. Few nests are initiated after mid-July. Long term annual rates of hatching success (the percentage of eggs laid that hatch) have ranged from 53-83 percent in the major study populations at the San Luis Rey, Santa Margarita, and Tijuana Rivers. The annual average number of fledglings produced per pair has ranged from 0.9-4.5, with long term averages ranging between 1.8 and 3.2 (USFWS 1998).

Home Range/Territory Size. Territory size ranges from 0.5-7.5 acres (0.2-3 hectares), but on average are between 1.5 and 2.5 acres (0.6 and 1 hectares) in southern California (USFWS 1998). Newman (1992) investigated the relationship between territory size, vegetation characteristics, and reproductive success for populations in San Diego County, but found no significant factors that could account for the variability in territory size found at his sites. Spatial differences in riparian habitat structure, patch size, and numerous other factors result in differences in the density of territories within and between drainages. Embree (1992) concluded that patch size and crowding did not influence least Bell's vireo reproductive success, at least not through the mechanisms of singing rates and attraction of predators.

Foraging Behavior and Diet. Least Bell's vireos are insectivorous and prey on a wide variety of insects, including bugs, beetles, grasshoppers, moths, and especially caterpillars (Chapin 1925, Bent 1950). They obtain prey primarily by foliage gleaning (picking prey from leaf or bark substrates) and hovering (removing prey from vegetation surfaces while fluttering in the air). Foraging occurs at all levels of the canopy but appears to be concentrated in the lower to mid-strata, particularly when pairs have active nests (Grinnell and Miller 1944, Goldwasser 1981, Gray and Greaves 1981, Salata 1983, Miner 1989). Miner (1989) determined that least Bell's vireo foraging time across heights was not simply a function of the availability of vegetation at those heights, but rather represented an actual preference for the 3-6 m zone. Foraging occurs most frequently in willows (Salata 1983, Miner 1989), but occurs on a wide range of riparian species and even some non-riparian plants that may host relatively large proportions of large prey (Miner 1989).

A21.2.5 Threats and Stressors

Habitat Loss and Fragmentation. A major factor leading to declines in populations of least Bell's vireo is the loss and degradation of riparian woodland habitat throughout the species' range. Habitat loss and degradation can occur through clearing of vegetation for agriculture, timber harvest, development, or flood control.

Flood control and river channelization eliminates early successional riparian habitat that least Bell's vireo (and many other riparian focal species) use for breeding. Dams, levees and other flood control structures hinder riparian reestablishment, creating more "old-growth" conditions (dense canopy and open understory) that are unfavorable to breeding vireos. Finally, habitat degradation encourages nest predation and parasitism. Agricultural land uses and water projects not only directly destroy habitat, but may also reduce water tables to levels that inhibit the growth of the dense vegetation least Bell's vireo prefer (RJHV 2004).

Grazing can also have a significant effect on riparian vegetation (Sedgwick and Knopf 1987). Cattle and other livestock can trample vegetation and eat seedlings, saplings, shrubs, and herbaceous plants. This can lead to a reduction in cover and nesting sites, and affect insect prey populations.

Cowbird Parasitism. Brood parasitism from brown-headed cowbirds (*Molothrus ater*) has a major negative impact on least Bell's vireo. Livestock grazing has reduced and degraded the lower riparian vegetation favored by the Least Bell's Vireo (Overmire 1962) and provided foraging areas for the brown-headed cowbird. Sharp & Kus (2005) suggest that microhabitat cover around the nest is the most important habitat feature influencing brood parasitism of least Bell's vireo nests. They found unparasitized nests had fewer trees >8 cm (3 inches) diameter at breast height within 11.3 meters (37 feet) of the nest and had less canopy cover within 5 meters (16 feet) than parasitized nests. They also suggest that cover near the nest reduces the chance that a cowbird will observe nesting activity and later parasitize the nest.

Row crops and orchards also provide feeding grounds for the parasite. Young and Hutto (1997) found that distance to agriculture was the strongest predictor of cowbird presence and abundance. Riparian habitat that is fragmented by agriculture is therefore highly susceptible to cowbird brood parasitism. By as early as 1930, nearly every least Bell's vireo nest found in

California hosted at least one cowbird egg (USFWS 1998). Since a parasitized nest rarely fledges any vireo young, nest parasitism of least Bell's vireo results in drastically reduced nest success (Goldwasser 1978, Goldwasser et al. 1980, Franzreb 1989, Kus 1999, Kus 2002b).

Predation. Predation is a major cause of nest failure in areas where brown-headed cowbird nest parasitism is infrequent or has been reduced by cowbird trapping programs. Most predation occurs during the egg stage. Predators likely include western scrub jays (*Aphelocoma californica*), Cooper's hawks (*Accipiter cooperii*), gopher snakes (*Pituophis melanoleucus*) and other snake species, raccoons (*Procyon lotor*), opossums (*Didelphis virginiana*), coyotes (*Canis latrans*), long-tailed weasels (*Mustela frenata*), dusky-footed woodrats (*Neotoma fuscipes*), deer mice (*Peromyscus maniculatus*), rats (*Rattus* spp.), and domestic cats (*Felis domesticus*) (Franzreb 1989).

A21.3 Relevant Conservation Efforts

The least Bell's vireo is federally and state-listed as endangered. Critical habitat for the least Bell's vireo was designated in 1994, and a Draft Recovery Plan was published in 1998. Aside from the protections and regulations offered under these plans, the Clean Water Act, Migratory Bird Treaty Act of 1918, and a Memorandum of Understanding (MOU) between the USFWS and Camp Pendleton Marine Corps Base for the purpose and objective of managing and perpetuating the least Bell's vireo on Camp Pendleton, also offer the least Bell's vireo regulatory protection. The least Bell's vireo is also listed as a covered species in 16 Habitat Conservation Plans, including the Coachella Valley Multi-species Habitat Conservation Plan, San Diego Multi-Species Conservation Plan, Orange County Natural Community Conservation Plan / Habitat Conservation Plan, and Western Riverside Multi-Species Habitat Conservation Plan.

Riparian habitat creation and restoration is underway throughout California (RHJV 2004). The Santa Clara River Enhancement and Management Plan is an especially significant effort to protect the ecological integrity of the longest unchannelized river in the South Coast bioregion. Current efforts to develop along the Santa Clara and its tributaries may endanger the integrity of the plan.

Brown-headed cowbird trapping has proven to be an effective method of increasing the reproductive success of least Bell's vireo on a local scale. At Camp Pendleton, nest parasitism dropped from 47 percent to <1 percent in less than 10 years as a result of cowbird trapping efforts (USFWS 1998). However, cowbird trapping should be considered as a temporary and complementary aid to long-term restoration and habitat enhancement and preservation efforts.

Continued research and monitoring of key least Bell's vireo populations at Camp Pendleton and other southern California riparian areas provides important information on population trends and allows for the employment of appropriate adaptive conservation techniques. Point Reyes Bird Observatory's Geographic Information System (GIS) database of California Partners in Flight (CalPIF) riparian study sites is a useful tool in identifying where riparian research is occurring.

The Riparian Bird Conservation Plan (RHJV 2004) offers a comprehensive vision of conservation, education, and research activities necessary to conserve and restore the riparian habitats that least Bell's vireo requires.

A21.3.1 Species Habitat Suitability Model

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing GIS data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf 2007. Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers, connectivity between habitat types, and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The least Bell's vireo model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), and USDA 2005 aerial photography. Using these data sets, the model maps the distribution of suitable least Bell's vireo nesting and migratory habitat in the Plan Area. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Nesting and Migratory Habitat. Nesting and migratory habitat in the Delta includes the following valley riparian types from the BDCP composite vegetation layer:

- Black willow (*Salix gooddingii*);
- *Salix gooddingii-Populus fremontii* (*Quercus lobata-Salix exigua-Rubus discolor*);
- *Salix gooddingii/Rubus discolor;*
- *Salix lasiolepis* – Mixed brambles (*Rosa californica-Vitis californica-Rubus discolor*);
- *Salix exigua* – (*Salix lasiolepis* – *Rubus discolor* – *Rosa californica*);
- *Salix gooddingii*/wetland herbs;
- *Salix gooddingii* – *Quercus lobata*/wetland herbs;
- Arroyo willow (*Salix lasiolepis*);
- *Salix lasiolepis* – *Cornus sericea/Scirpus*[1] spp. – complex unit;
- Shining willow (*Salix lucida*);
- Narrow-leaf willow (*Salix exiqua*);
- Fremont cottonwood (*Populus fremontii*);
- White alder (*Alnus rhombifolia*);
- *Alnus rhombifolia/Salix exigua* (*Rosa californica*);
- Oregon ash (*Fraxinus latifolia*);
- Box elder (*Acer negundo*);
- *Acer negundo-Salix gooddingii;*
- Hinds walnut (*Juglans hindsii*);
- Coyotebush (*Baccharis pilularis*);

[1] Currently known as *Schoenoplectus*.;

- California wild rose (*Rosa californica*);
- *Cornus sericea – Salix exigua;*
- *Cornus sericea – Salix lasiolepis/(Phragmites australis*);
- Coast live oak (*Quercus agrifolia*);
- *Quercus lobata – Alnus rhombifolia* (*Salix lasiolepis-Populus fremontii-Quercus agrifolia*);
- *Quercus lobata/Rosa californica* (*Rubus discolor-Salix lasiolepis/Carex* spp.);
- *Quercus lobata – Acer negundo;*
- *Quercus lobata – Fraxinus latifolia;*
- Blackberry (*Rubus discolor*);
- Mexican elderberry (*Sambucus mexicana*); and
- California dogwood (*Cornus sericea*).

Nesting and migratory habitat in the Suisun Marsh and Yolo Basin includes the following valley riparian types from the BDCP composite vegetation layer:

- Fremont cottonwood-Valley oak-Willow riparian forest;
- Mixed Fremont cottonwood – Willow;
- Mixed willow super alliance;
- *Salix laevigata/S. lasiolepis;*
- *Salix lasiolepis/Quercus agrifolia;*
- *Rosa californica;*
- *Rosa/Baccharis;*
- *Fraxinus latifolia;*
- *Quercus agrifolia;*
- *Rosa californica;*
- *Rosa/Baccharis;*
- *Rubus discolor;*
- Valley oak alliance – Riparian; and
- Willow trees.

Assumptions. The least Bell's vireo is an obligate riparian breeder. While it can use adjacent non-riparian scrub habitats for foraging or dispersal (Kus and Miner 1989, RHJV 2004), suitable non-riparian habitats are largely absent from the Plan Area, which is primarily agricultural. Therefore, the habitat model is restricted to riparian vegetation. While least Bell's vireo typically nests in willow-dominated habitats, plant species composition does not seem to be as important a factor as habitat structure. Early successional riparian habitat typically supports the dense shrub cover required for nesting and a diverse canopy for foraging. While least Bell's vireo tends to prefer early successional habitat, breeding site selection does not appear to be limited to riparian stands of a specific age. Therefore, in addition to all willow-dominated types, all other riparian habitats that may consist of a dense shrub layer are included.

A21.3.2 Recovery Goals

The Draft Recovery Plan (USFWS 1998) includes the following criteria that constitute the recovery goals for this species:

Reclassification to Threatened may be considered when Criterion 1 has been met for a period of 5 consecutive years.

Criterion 1: Stable or increasing least Bell's vireo populations/metapopulations, each consisting of several hundred or more breeding pairs are protected and managed at the following sites: Tijuana River, Dalzura Creek/Jamul Creek/Otay River, Sweetwater River, San Diego River, San Luis Rey River, Camp Pendleton/Santa Margarita River, Santa Ana River, an Orange County/Los Angeles County metapopulation, Santa Clara River, Santa Inez River, and an Anzo Borrego Desert metapopulation.

Delisting may be considered when the species meets the criterion for downlisting and the following criteria have been met for 5 consecutive years:

Criterion 2: Stable or increasing least Bell's vireo populations/metapopulations, each consisting of several hundred or more breeding pairs, have become established and are protected and managed at the following sites: Salinas River, a San Joaquin Valley metapopulation, and a Sacramento Valley metapopulation.

Criterion 3: Threats are reduced or eliminated so that least Bell's vireo populations/metapopulations listed above are capable of persisting without significant human intervention, or perpetual endowments are secured for cowbird trapping and exotic plant control in riparian habitat occupied by least Bell's vireo.

APPENDIX A22. WESTERN BURROWING OWL (*ATHENE CUNICULARIA HYPUGAEA*)

A22.1 LEGAL STATUS

The western burrowing owl (*Athene cunicularia hypugaea*) is designated as a state Bird Species of Special Concern (Shuford and Gardali 2008) by the California Department of Fish and Game (DFG). Nests are protected in California under Fish and Game Code Section 3503.5.

The burrowing owl has no federal regulatory status; however, the species is protected under the federal Migratory Bird Treaty Act and is designated as a Bird of Conservation Concern by the U.S. Fish and Wildlife Service (USFWS 2002).

A22.2 SPECIES DISTRIBUTION AND STATUS

A22.2.1 Range and Status

There are two subspecies of burrowing owls in North America (Clark 1997, Haug et al. 1993). The breeding range of *A. cunicularia floridana* is restricted to Florida and adjacent islands. The breeding range of *Athene cunicularia hypugaea* extends south from southern Canada throughout most of the western half of the United States and south to central Mexico. The winter range extends from Central California southeastward through Arizona, New Mexico, and Texas and south into northern and central Mexico and coincides with southern breeding range where the species is resident year-round (Haug et al. 1993).

Burrowing owls were once widespread and generally common over western North America in treeless, well-drained grasslands, steppes, deserts, prairies, and agricultural lands (Haug et al. 1993). The owl's range has contracted in recent decades, and populations have been generally diminished in some areas.

In California, burrowing owls are widely distributed in suitable habitat throughout the lowland portions of the state (Figure A-22a); however, occupied sites have ranged from 200 feet below sea level at Death Valley, to above 12,000 feet at Dana Plateau in Yosemite (DFG 2000). In southern California, the species is fairly common along the Colorado River Valley (Rosenberg et al. 1991) and in the agricultural region of the Imperial Valley. Only small, scattered populations are thought to occur in the Great Basin and the desert regions of southern California (DeSante et al. 2007). Burrowing owl breeding populations have greatly declined along the California coast, including the southern coast to Los Angeles, where these owls have been eliminated from virtually all private land and occur only in small populations on some federal lands (Garrett and Dunn 1981, DeSante et al. 2007, Kidd et al. 2007). Breeding populations in Central California include the southern San Francisco Bay between Alameda and Redwood City, the interior valleys and hills in the Livermore area, and the Central Valley (DeSante et al. 1997).

DRAFT

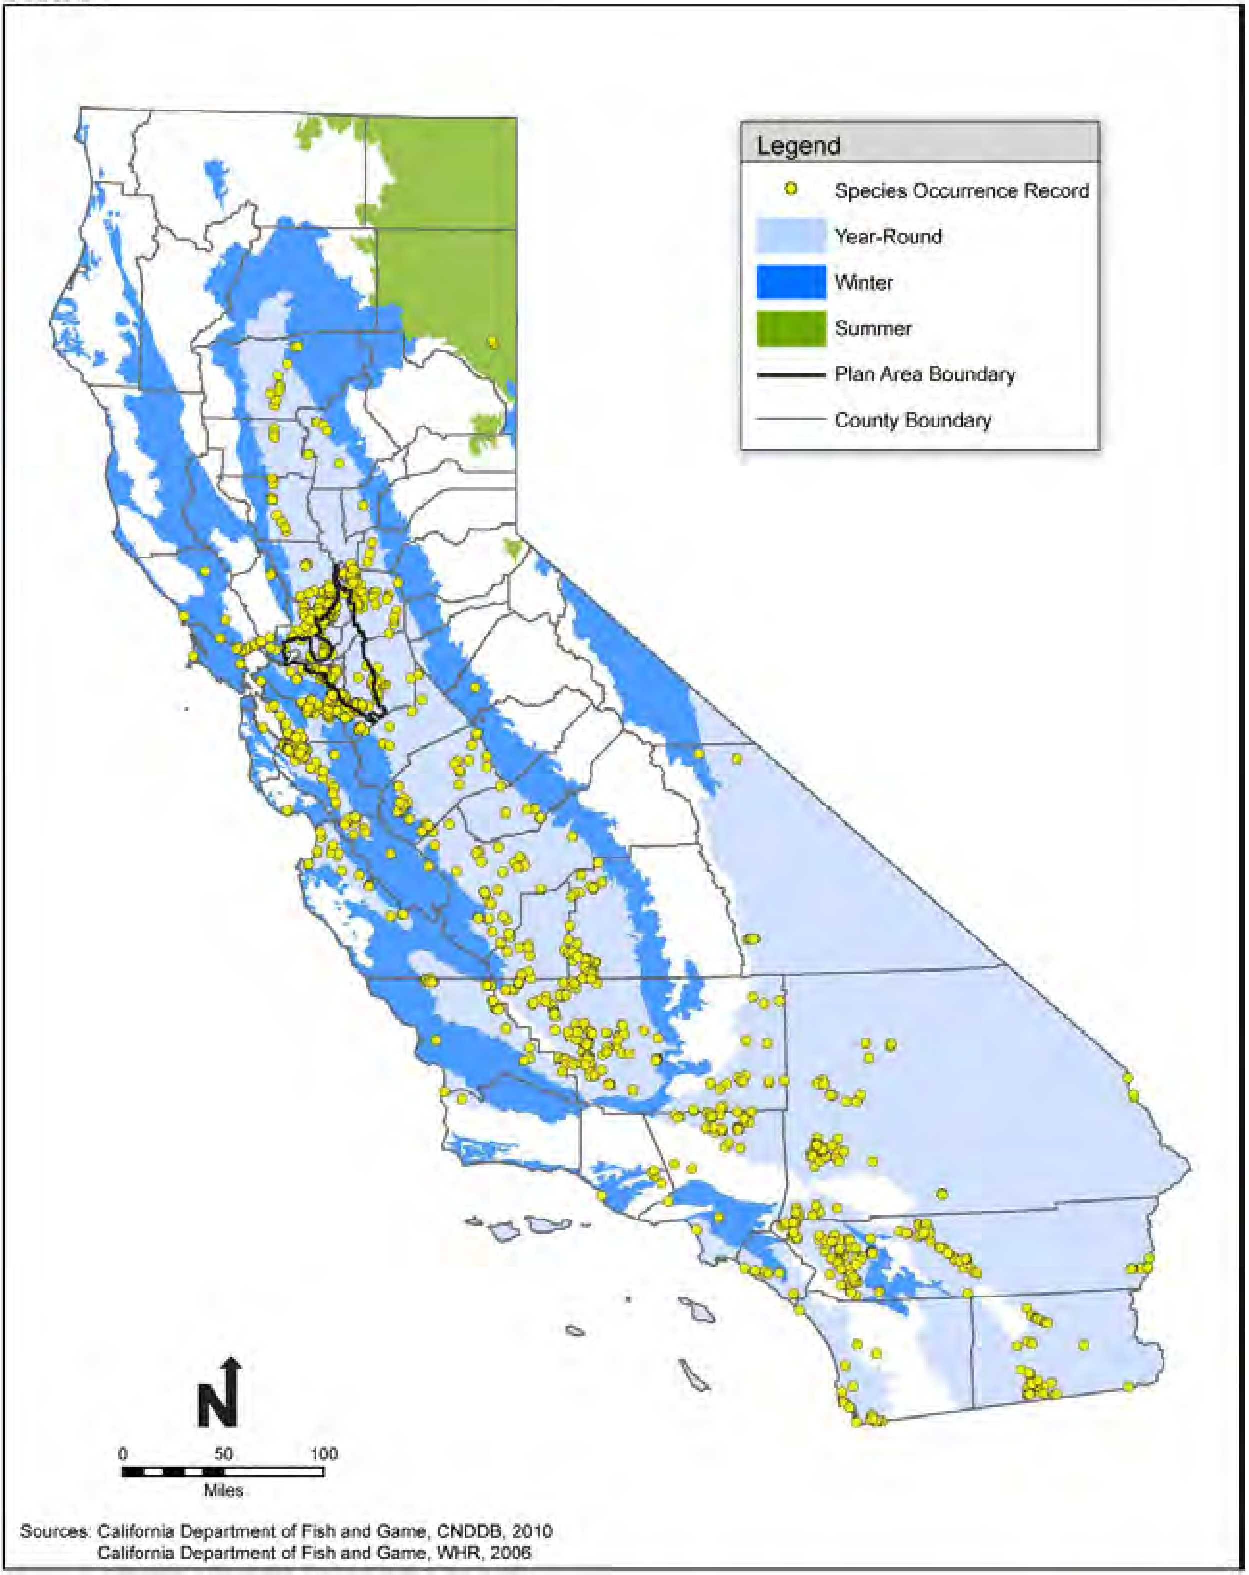

Figure A-22a. Western Burrowing Owl Statewide Range and Recorded Occurrences

1

Burrowing owls appear to be resident year-round throughout much of central and southern California; however, migratory patterns remain unclear (Haug et al. 1993).

Overall population trends throughout the western burrowing owl's North American range are reportedly declining (James and Espie 1997, Klute et al. 2003). James (1993) reports that 54 percent of the areas sampled reported declining burrowing owl populations. Breeding Bird Surveys conducted between 1980 and 1989 also report significant declines in many areas (Haug et al. 1993).

Burrowing owls were formerly common or abundant throughout much of California, but noticeable declines have been reported since the 1940s (Grinnell and Miller 1944) and continue to the present time (DeSante et al. 2007, Shuford and Gardali 2008). The decline has been almost universal throughout California. Conversion of grasslands and pasturelands to incompatible crop types and the destruction of ground squirrel colonies have been the main factors causing the decline of the burrowing owl population (Zarn 1974). Assimilation of poisons applied to ground squirrel colonies may also affect burrowing owl population levels (James et al. 1990).

Surveys in California in 1986-91 found population decreases of 23 to 52 percent in the number of breeding groups and 12 to 27 percent in the number of breeding pairs of owls (DeSante et al. 1997). Nearly 60 percent of burrowing owl colonies that existed in the 1980s reportedly disappeared by the early 1990s (DeSante and Ruhlen 1995, DeSante et al. 1997).

DeSante et al. (2007) estimated a statewide population of 9,266 breeding pairs, most occurring in four main population areas: the Imperial Valley, the Central Valley, the Southern California coast, and the San Francisco Bay area. An estimated 167 nesting pairs (1.8 percent of California's population) occur in the Bay area, where the species often uses burrows created by the California ground squirrel (*Spermophilus beecheyi*) and resides in undeveloped grassland remnants amid a rapidly expanding human population. In the southern California coastal population, burrowing owls have been almost entirely extirpated from private lands and were found only on a few undeveloped federal lands, where an estimated 260 nesting pairs (3 percent of California's population) persist (DeSante et al. 2007, Kidd et al. 2007). An estimated 2,224 nesting pairs exist in the Central Valley (24 percent of California's population), where the species is also subject to widespread habitat loss from urbanization. This population also often uses burrows created by the California ground squirrel and resides in remaining patches of grassland, along the grassland edges of canals and levees, and along the edges of pastures and some agricultural fields. An estimated 6,570 nesting pairs (71 percent of California's population) occur in the Imperial Valley, where burrowing owls are almost completely relegated to irrigation canal banks and where they most often use burrows created by the round-tailed ground squirrel (*Spermophilus tereticaudus*) (DeSante et al. 2007).

Although California has a significant burrowing owl population, development pressures and recent population trends suggest that the species may continue to be extirpated from large portions of its range in California during the next decade. Coastal areas, in particular, have experienced extirpations or near extirpations in recent years presumably from habitat loss (Desante et al. 2007). While burrowing owls in the Central Valley have exhibited strong site fidelity even with increasing habitat fragmentation, the species has been extirpated from many historically occupied areas due to increasing urbanization and related causes.

A22.2.2 Distribution and Status in the Plan Area

Reported occurrence data indicates that within the Plan Area, burrowing owls are concentrated mostly in the grassland/pastureland areas west of the Sacramento Deep Water Ship Channel in Yolo and Solano counties, and in the grassland habitats along the western edge of the Plan Area between roughly Brentwood/Antioch and Tracy (Figure A-22b). These mostly uncultivated areas support larger and more stable populations of California ground squirrels and are less likely to be disturbed by regular cultivation and other ground disturbances. The species is a year-round resident in the Plan Area; however, local migratory patterns and the extent to which migrants occupy the Plan Area during the non-breeding season are unclear.

Burrowing owls continue to persist locally in the vicinity of Stockton where they are typically found along levees, canals, field edges, and some ruderal habitats or idle fields. Burrowing owls are also known to occur in the grassland habitats in the vicinity of Stone Lakes. While relatively few burrowing owls have been reported from this area, the grassland habitats could potentially support a larger population. In recognition of this, enhancement of burrowing owl habitat, including the installation of 80 artificial nest boxes, reintroduction of the California ground squirrel, and adjustment of land management activities, is ongoing on the Stone Lakes National Wildlife Refuge. These activities are part of an agreement with the Sacramento Area Flood Control Agency and Sacramento County to use the refuge for purposes of burrowing owl mitigation because of impacts from the South Sacramento Streams Group Project (SAFCA, Resolution Number 07058).

Few burrowing owls have been reported from the central portion of the Delta and the northern Delta east of the Sacramento Deep Water Ship Channel (Figure A-22b), probably due to regular cultivation, lack of undisturbed habitats, and lack of ground squirrel populations. Active sites in this area are generally restricted to levee embankments and along irrigation canals.

Burrowing owls persist in low numbers in grassland habitats around the perimeter of Suisun Marsh. Gervais et al. (2008) note that populations in the vicinity of Suisun Marsh and San Pablo Bay are declining.

Remaining populations in the vicinity of Stockton, Brentwood/Antioch, and Tracy are subject to continued land use changes from urbanization and populations are likely to decline over time as suitable habitat is removed. Populations in Yolo and Solano counties west of the Deep Water Ship Channel are less subject to land use changes and thus may be more likely to persist.

DRAFT

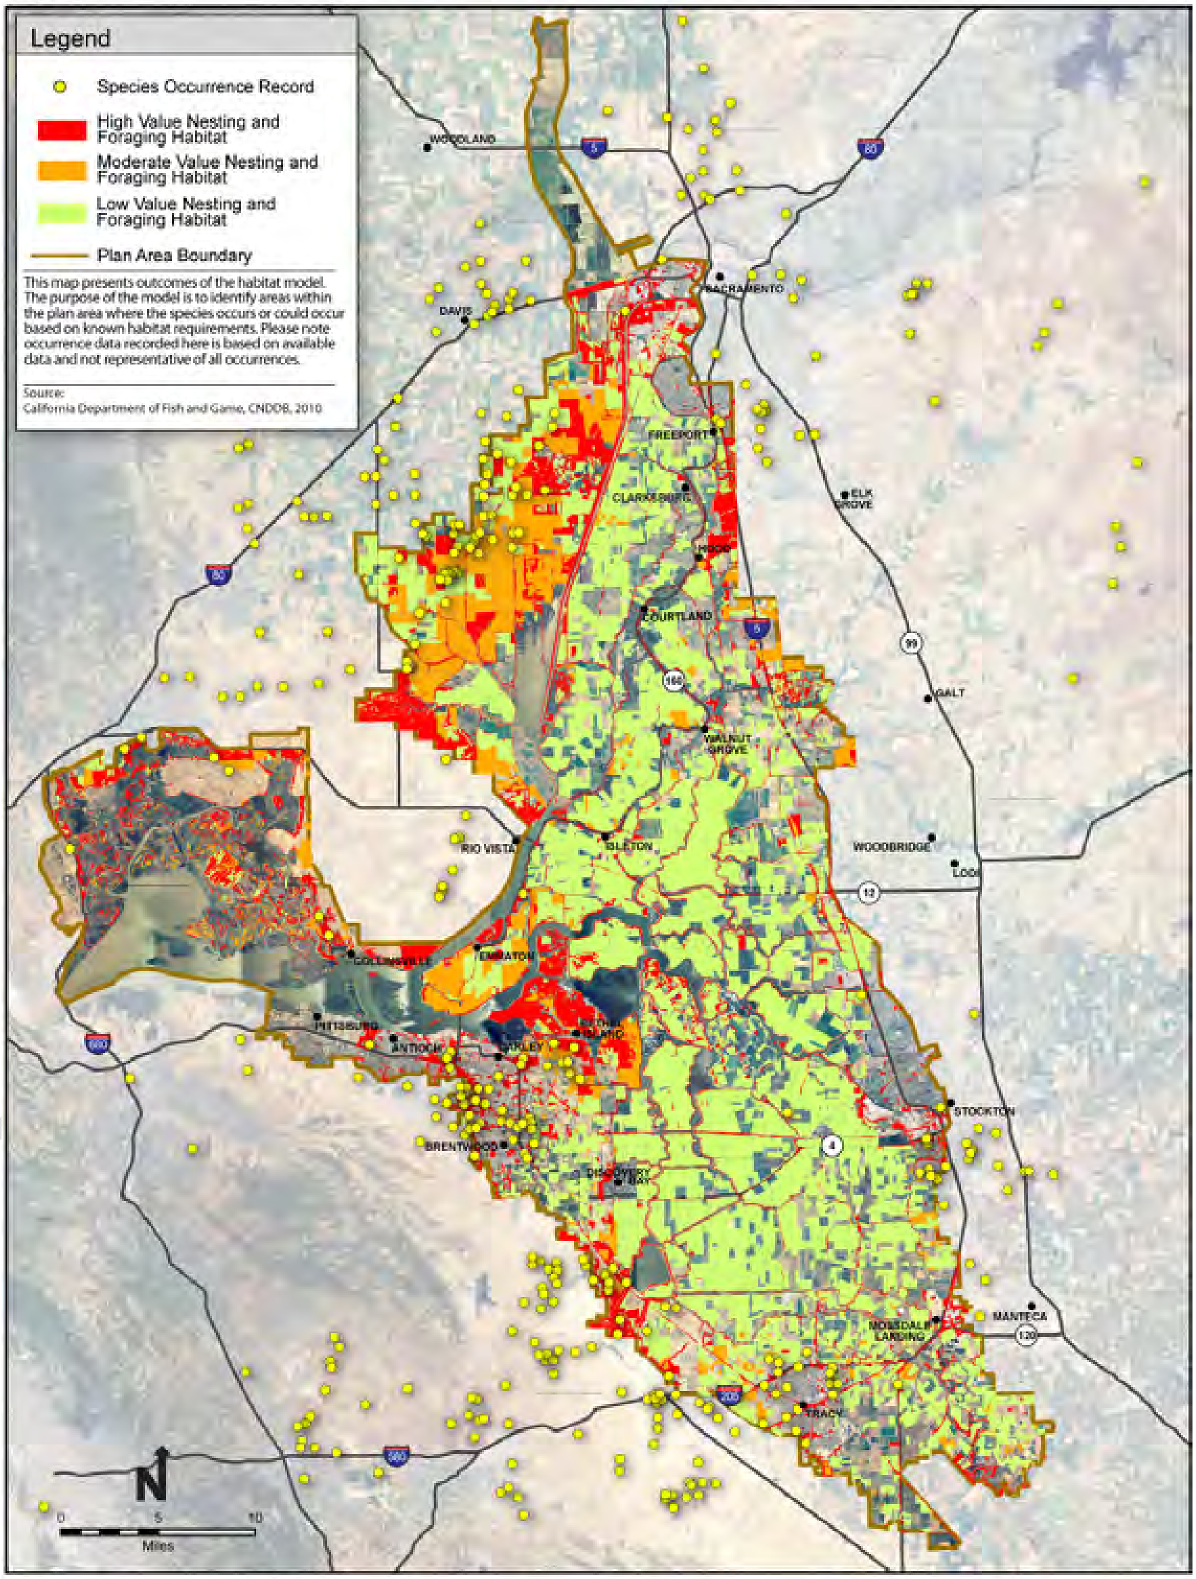

Figure A-22b. Western Burrowing Owl Habitat Model and Recorded Occurrences

A22.3 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

Burrowing owls are found in open, well-drained grasslands, agricultural and range lands, and desert habitats often associated with burrowing animals (Klute et al. 2003). They also occupy golf courses, airports, road and levee embankments, and other disturbed sites where there is sufficient friable soil for burrows (Haug et al. 1993). Because they typically use the burrows created by other species, particularly the California ground squirrel, presence of these species is usually a key indicator of potential occurrence of burrowing owl.

Nesting. In northern California, most reported nest sites occur in abandoned ground squirrel burrows; however, other mammal burrows and various burrow surrogates, such as culverts, pipes, rock piles, and artificially-constructed burrows are also used. Burrowing owls may select sites in habitats that allow for modification of burrows and maximize drainage. In addition to providing nesting, roosting, and escape burrows, ground squirrels improve habitats for burrowing owls in other ways. Burrowing owls favor areas with short, sparse vegetation, which is typical around active sciurid colonies (Coulombe 1971, Haug and Oliphant 1990, Plumpton and Lutz 1993b) to facilitate detection of predators and hunting. Additionally, burrowing owls may select areas with a high density of burrows (Plumpton and Lutz 1993b). Typical habitats are treeless, with minimal shrub cover and woody plant encroachment, and have low vertical density of vegetation and low foliage height diversity (Plumpton and Lutz 1993b). While occupied burrows are sometimes found in flat landscapes – often in elevated mounds created by burrowing activity – they are also commonly found on hillsides, levee slopes, or other steep cut banks, probably to facilitate drainage and maximize visibility. Nest sites are also often associated with nearby perches, including stand pipes, fences, or other low structures.

Burrowing owls are tolerant of human-altered open spaces, such as areas surrounding airports, golf courses, and military lands where burrows may be readily adopted (Thomsen 1971, Barclay 2007). Burrowing owls may use burrows in open areas adjacent to unimproved and improved roads (Brenckle 1936, Ratcliff 1986); a modest volume of vehicle traffic does not appear to significantly affect behaviors or reproductive success (Plumpton and Lutz 1993c), but presumably may also be a source of collision-related mortality. In the south San Francisco Bay region and in the Sacramento area, burrowing owls nest and winter in highly human-affected environments and can habituate to human activity if breeding and foraging habitat remains in a suitable condition.

The dimensions of the nest burrow vary with location, age of burrow, and the species that originally excavated it. Typical burrows constructed by ground squirrels are from 3 to 6 inches (7.6 to 15.2 centimeters [cm]) in diameter and extend underground at a gradual downward slope from 3 to 20 feet (0.9 to 6.1 meters) with an enlarged cavity at the end of a tunnel. Feathers, pellets, and white wash are often present at active burrow entrances. The burrow is often lined with grass or other material (Haug et al. 1993).

Burrowing owls may nest solitarily but many nest in loose colonies – usually from 4 to 10 pairs (Zarn 1974); however, larger colonies have been documented. Most pairs occupy a natal burrow, and several satellite burrows where available.

As semi-colonial raptors, colony size is indicative of habitat quality and quantity. Colony size is also positively correlated with annual site reuse by breeding burrowing owls; larger colonies (those with more than five nesting pairs) are more likely to persist over time than colonies containing fewer pairs or single nesting pairs (DeSante et al. 1997). Nest burrow reuse by burrowing owls has been well documented (Martin 1973, Gleason 1978, Rich 1984, Plumpton and Lutz 1993b, Lutz and Plumpton 1999). Former nest sites may be more important to continued reproductive success than are mates from previous nest attempts (Plumpton and Lutz 1994). Past reproductive success may influence future site re-occupancy by burrowing owls. Female burrowing owls with large broods tend to return to previously occupied nest sites; while females that fail to breed, or produced small broods, may change nest territories in subsequent years (Lutz and Plumpton 1999).

In general, burrowing owls show a high degree of nest site fidelity and reuse the same nesting burrows and satellite burrows for many years if left undisturbed.

Foraging. Burrowing owls forage in open grasslands, pasturelands, agricultural fields and field edges, fallow fields, and along the edges of roads and levees. Low vegetation aids in maximizing visibility and access. Short perches, such as fence posts are often used to enhance visibility. While they will defend the immediate vicinity of the nest, burrowing owls will often forage in common areas (Haug et al. 1993).

A22.4 LIFE HISTORY

Description. This small owl stands about 9 inches (23 cm) tall. The sexes are similar (although females are slightly smaller and often slightly darker than males) with distinct oval facial ruff, white supercilium, yellow eyes, and long legs. Wingspan is relatively broad (20 to 24 inches [51 to 61 cm]) and wings are somewhat rounded. The owl is sandy-colored with pale tan spots on the back and upperparts of the wings and white-to-cream with barring on the breast and belly (Haug et al. 1993).

Seasonal Patterns. Burrowing owls are resident in the Central Valley and other portions of central California. The breeding season (defined as from pair bonding to fledging) generally occurs from February to August with peak activity occurring from April through July (Haug et al. 1993). Pairs may be resident at breeding sites throughout the year or disperse out of the breeding area during the non-nesting season. Some individual birds only winter in the region. Burrowing owls have a strong affinity for previously occupied nesting and wintering habitats. They often return to burrows used in previous years, especially if they had been reproductively successful (Lutz and Plumpton 1999). Additionally, burrowing owls often return as breeding adults to the general area in which they were born. For these reasons, efforts that enhance productivity help to ensure continued use of burrows and territories.

Reproduction. Adults begin pair bonding and courtship in February through March. Following pair formation, a nest is established in the natal burrow and females lay a clutch of 6 to 11 eggs. Average clutch size is 7 to 9 eggs. Eggs are incubated entirely by the female for a period of between 28 and 30 days. Incubation begins prior to the clutch being complete, which causes asynchronous hatching. During this time, the female is provisioned with food by the male. Following hatching, the young remain in the natal burrow for 2 weeks after which they begin to emerge from the burrow and roost at the burrow entrance. The female begins hunting as soon as the young begin thermoregulation and no longer require continuous brooding. Adults and nestlings will also relocate to satellite burrows presumably to reduce the risk of predation (Desmond and Savidge 1998) and possibly to avoid nest parasites (Dechant et al. 2003). After approximately 44 days, young leave the natal burrow and by 49 to 56 days begin to hunt live insects. On average, three to five young fledge, but fledging rates can range from a single fledgling to as many as eight or nine (Lutz and Plumpton 1999). During this time, the juveniles expand their range and may find cover in satellite burrows. The juveniles continue to be provisioned by the adults until mid-August when they molt into adult plumage and begin to disperse (Landry 1979). King and Belthoff (2001) report that dispersing young use satellite burrows in the vicinity of their natal burrows for about two months after hatching before departing the natal area.

Home Range/Territory Size. Few valid measures of territory or home range size of burrowing owls have been published; home range has not often been measured directly (e.g., via telemetry studies) and is highly subject to observer bias or equipment effect. Accordingly, caution is warranted when interpreting home range estimates. Gervais et al. (unpublished 2000 report in Yolo Natural Heritage Program 2008) estimated that the mean minimum convex polygon (MCP) home range estimates for 22 burrowing owls in Fresno and Kings counties in California was 467 acres (189 hectares). Haug and Oliphant (1990) estimated that the mean MCP for six owls in Saskatchewan was 595 acres (241 hectares) (Yolo Natural Heritage Program 2008).

In Colorado, Plumpton and Lutz (D. Plumpton pers. comm. in Yolo Natural Heritage Program 2008) recorded densities of nesting burrowing owls that ranged from 21 to 34 pairs on roughly 2,240 acres (906 hectares) of available habitat (i.e., 106 and 65 acres [43 and 26 hectares]/pair, respectively). Thomsen (1971) estimated territory size based on nearest-neighbor distances between nest burrows, producing a result of six pairs of owls averaging 2 acres (0.8 hectares), with a range of between 0.1 to 4.0 acres (0.04 to 1.6 hectares). The preceding values demonstrate the disparity among studies, the different values attained when using different methods of estimating abundance, and the risk in relying on the results of a single study (Yolo Natural Heritage Program 2008).

Foraging Behavior and Diet. Although there are seasonal differences, burrowing owls are active during the day and night and will hunt throughout the 24-hour day, but are mainly crepuscular, hunting mostly at dusk and dawn, and are less active midday. During the fall and winter, they become more nocturnal, and during the breeding season they may hunt all times of the 24-hour day depending on the temperature, number of young, stage of breeding cycle, and other factors. They tend to hunt insects in daylight and small mammals at night. They usually hunt by walking, running, hopping along the ground, flying from a perch, hovering, and fly-catching in midair.

Burrowing owls tend to be opportunistic feeders. Large arthropods, mainly beetles and grasshoppers, comprise a large portion of their diet. In addition, small mammals, especially mice and voles (*Microtus*, *Peromyscus*, and *Mus* spp.) are also important food items. Other prey animals include reptiles and amphibians, young cottontail rabbits (*Sylvilagus audubonii*), bats, and birds, such as sparrows and horned larks (*Eremophila alpestris*). Consumption of insects increases during the breeding season (Zarn 1974, Tyler 1983, Thompson and Anderson 1988, Green et al. 1993, John and Romanow 1993, Plumpton and Lutz 1993a). Productivity may increase in proportion to the amount of mice and voles in the diet (D. Plumpton, unpublished data in Yolo Natural Heritage Program 2008).

As with most raptors, burrowing owls select foraging areas based on prey availability as well as prey abundance. Prey availability (the ability of a raptor to detect prey) decreases with increasing vegetation cover and thus foraging habitat suitability decreases with increasing grass height or vegetation density.

A22.5 THREATS AND STRESSORS

Urbanization/Habitat Fragmentation. Urbanization, including residential and commercial development and infrastructure development (roads and oil, water, gas, and electrical conveyance facilities) is one of the principal causes of habitat loss for burrowing owls and is a continuing threat to remaining northern California populations. Urbanization permanently removes habitat and has led to permanent abandonment of many burrowing owl colonies in the developing portions of the Central Valley, Bay Area, and throughout the state.

Interestingly, while urbanization is considered a key cause for population declines, burrowing owls are known to exhibit strong site fidelity (Johnson 1997). They have shown a relatively high level of tolerance for human encroachment, degradation of native habitats, and fragmentation of habitats (Schultz 1997, Trulio 1997). Active breeding colonies have been reported in small parcels or narrow strips of disturbed habitat along levees or utility corridors and surrounded by urban development. Colonies have also been reported along the edges of airport runways, around the perimeter fences of prisons, and in other urbanized or highly disturbed habitats (Thomsen 1971, Barclay 2007). Disturbances may depress reproductive potential in urban settings as compared with more natural habitats (Thomsen 1971). However, owls will often continue to occupy traditional sites as long as essential habitat elements remain present, until the disturbances force the owls out, or until the extent of available habitat is reduced below habitat requirements (Millsap and Bear 1988).

Agricultural Crop Conversion. Some burrowing owls nest on the edges of agricultural areas and forage in suitable agricultural fields (Gervais et al. 2003), such as recently harvested fields, alfalfa and other hay fields, irrigated pastures, and fallow fields. The conversion of these fields to incompatible crop types, such as orchards, vineyards, and other crops that are not conducive to burrowing owl foraging, reduce available foraging habitat and lead to abandonment of traditional nesting areas. Road and ditch maintenance in agricultural areas can also damage or destroy active nesting and wintering burrows.

Levee Maintenance. Many burrowing owl nests are known to occur along the outside slope of levees (Desante et al. 2004, Rosenburg and Haley 2004). Levee stability practices for flood control, including vegetation removal, grading, and reinforcing with rock can destroy burrowing owl nesting habitat (Catlin and Rosenburg 2006).

Rodent Control. Rodent control, particularly along levees and roadsides, can decimate ground squirrel populations and ultimately reduce available nesting and cover habitat for burrowing owls.

Other Human Disturbances. Although burrowing owls can exhibit a tolerance of some human activities, human-related impacts such as shooting and burrow destruction adversely affect this species (Zarn 1974, Haug et al. 1993). Artificially enhanced populations of native predators (e.g., gray foxes [*Urocyon cinereoargenteus*], coyotes [*Canis latrans*]) and introduced predators (e.g., red foxes [*Vulpes vulpes*], cats, dogs) near burrowing owl colonies can also be a significant local problem. Burrowing owls also get tangled in loose fences, abandoned wire, fishing line, rat traps, and other materials.

The overall effect of population-level threats (e.g., habitat conversion or ground squirrel eradication) is of much greater concern than sources of individual mortality (e.g., shooting or vehicle collisions), as these former forces operate at a population, regional, and/or range-wide level. As obligate burrow nesters that do not typically excavate their own burrows, burrowing owls are largely dependent on burrowing mammals that have no legal status or protection, and are commonly and purposefully eradicated by humans. Whereas, individual mortality cumulatively represents a significant number of individuals, a population that is stable and productive can offset these losses. Conversely, populations that are failing because of population-level effects cannot be sustained even in the absence of direct sources of individual mortality. In California, significant economic development pressures exist, and habitat conversion for human purposes continues to degrade the abundance and quality of owl nesting habitat (Barclay et al. 1998). Few provisions exist to protect habitats over time. As a result, burrowing owls appear to be declining throughout most of California.

A22.6 RELEVANT CONSERVATION EFFORTS

Few conservation efforts have been undertaken to conserve burrowing owl populations. The lack of state or federal listing, and the rejection of recent efforts to list the species at the state and federal levels, limits the extent of regulatory influence. There remain several significant data gaps regarding population status and trends, migration, dispersal from nesting sites, and other aspects of annual movements.

Protection typically occurs at the local project level through implementation of the guidelines prepared by DFG (1994). While the guidelines address protection of active sites and compensation for impacts, they do not address conservation or protection at a regional level. DFG is currently developing a statewide conservation strategy for the burrowing owl.

Regional conservation efforts have focused on the development and implementation of habitat conservation plans/natural community conservation plans. These regional conservation approaches can be an effective tool to manage and sustain burrowing owl populations if they protect sufficient suitable and occupied habitat. The majority of the Plan Area overlaps with other conservation planning efforts that are either currently being implemented or are in development. These include the San Joaquin County Multi-species Habitat Conservation and Open Space Plan, the East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan, the Natomas Basin Habitat Conservation Plan, the South Sacramento County Habitat Conservation Plan, the Solano County Multispecies Habitat Conservation Plan, the Yolo County Natural Heritage Program Plan, and the Butte Regional Conservation Plan. If effectively coordinated, these efforts can be a valuable tool in managing burrowing owl populations in the region.

A22.7 SPECIES HABITAT SUITABILITY MODEL

Model Approach. BDCP Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information systems (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided by Hickson and Keeler-Wolf (2007). Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include soils data, incorporating buffers, connectivity between habitat types, and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The western burrowing owl model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), USDA 2005 aerial photography, DWR Central Valley Levees 2001, DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3, and the Yolo County 1997 land use survey. Using these data sets, the model maps the distribution of suitable burrowing owl habitat in the Plan Area in three suitability categories: high, moderate, and low. Vegetation types were assigned to a suitability category based on the species requirements as described above and the assumptions described below.

Nesting and Foraging. Nesting and foraging habitat for burrowing owls has been split into three categories: high value, moderate value, and low value. Value is generally determined on the basis of major vegetation type (grasslands, pastures and seasonal wetlands, agricultural lands).

High value nesting and foraging habitat in the Delta includes the following types using the BDCP composite vegetation layer:

- Grasslands
  - California annual grasslands (California annual grassland/herbaceous alliance);
  - Ruderal herbaceous grasses and forbs (*Cynodon dactlyon* alliance and ruderal herbaceous [nonnative annual forbland]);
  - *Bromus diandrus – Bromus hordeaceus;*
  - Degraded vernal pool complex – California annual grasslands; and
  - Degraded vernal pool complex – Ruderal herbaceous grasses and forbs.
- Vernal pool complex
  - California annual grasslands; and
  - Ruderal herbaceous grasses and forbs.

High value habitat in the Suisun Marsh and Yolo Basin includes the following types using the BDCP composite vegetation layer:

- Annual grasses generic;
- Annual grasses/weeds; and
- Perennial grass.

Additional high value habitat also includes the following types using the DWR 2007 and Yolo County 1997 land use survey data:

- Native vegetation-Grassland

Moderate value nesting and foraging habitat in the Delta includes the following types using the BDCP composite vegetation layer:

- Grasslands
  - Italian rye-grass (*Lolium multiflorum* alliance); and
  - Degraded vernal pool complex – Italian rye-grass (*Lolium multiflorum*).
- Vernal pool complex
  - Italian rye-grass (*Lolium multiflorum* alliance)
- Alkali seasonal wetland complex
  - *Distichlis spicata* – annual grasses

Moderate value habitat in the Suisun Marsh and Yolo Basin includes the following types using the BDCP composite vegetation layer:

- Medium upland graminoids;
- Short upland graminoids;
- Bare ground;
- Pasture;
- Upland annual grasslands and forbs formation;
- Upland herbs; and
- Medium upland herbs.

Additional moderate value habitat also includes the following types using the DWR 2007 Survey data:

- Native pasture;
- Miscellaneous grasses; and
- Mixed pasture.

Levee slopes in managed and natural seasonal wetlands were also included as Moderate value habitat. DWR's Central Valley Levees data was buffered by 100 feet on either side; all managed wetland and natural seasonal wetland types from the BDCP composite vegetation layers situated within the buffered region were included as moderate value habitat.

Low value nesting and foraging habitat in the Delta includes the following types using the BDCP composite vegetation layer:

- Managed wetlands (when not flooded)
    - Temporarily flooded grasslands;
    - Rabbitsfoot grass;
    - Intermittently flooded perennial forbs;
    - Managed annual wetland vegetation (non-specific grasses and forbs);
    - Shallow flooding with minimal vegetation;
    - Seasonally flooded undifferentiated annual grasses and forbs;
    - Managed alkali wetland; and
    - Intermittently or temporarily flooded undifferentiated annual grasses and forbs.

- Alkali seasonal wetland complex and other seasonal wetlands (when not flooded)
  - Saltgrass (*Distichlis spicata*);
  - Seasonally flooded annual grasslands;
  - Vernal pools;
  - Degraded vernal pool complex-vernal pools; and
  - Temporarily flooded perennial forbs.

Low value habitat in the Suisun Marsh and Yolo Basin includes the following types using the BDCP composite vegetation layer:

- *Baccharis*/annual grasses;
- *Bromus* spp./*Hordeum;*
- Cultivated annual graminoid;
- *Cynodon dactylon;*
- *Hordeum*/*Lolium;*
- *Lolium* (generic);
- *Lolium*/*Rumex;*
- *Lotus corniculatus;* and
- Short wetland graminoids.

Low value nesting and foraging habitat also include the following agricultural types from the DWR 2007 Land Use survey and Yolo County 1997 Land use survey. These types represent the typical agricultural cover types in the Plan Area and Upper Yolo Bypass that are included in the DWR 2007 and 1997 Yolo County land use surveys. Rotational crop types that are not common to the Plan Area are not included here. Pasture types are mostly perennial; alfalfa is semi-perennial (3 to 7 years); and all other types are annually or seasonally rotated irrigated crops, only some of which provide suitable foraging habitat for burrowing owl.

- Grain and hay crops
  - Barley;
  - Wheat;
  - Oats; and
  - Miscellaneous and mixed grain and hay.
- Field crops

- Safflower;
- Sugar beets;
- Corn;
- Grain sorghum;
- Sudan;
- Beans;
- Miscellaneous field; and
- Sunflowers.

- Pasture
  - Alfalfa and alfalfa mixtures; and
  - Clover.
- Truck, nursery and berry crops
  - Asparagus;
  - Beans;
  - Onions and garlic;
  - Tomatoes; and
  - Peppers.
- Idle
  - Land not cropped the current or previous crop season, but cropped within the past three years; and
  - New lands being prepped for crop production.

Interior grassy slopes of levees surrounding central Delta islands were also considered low value habitat for burrowing owls. DWR's Central Valley Levees data was buffered by 100 feet on either side; BDCP composite vegetation layer for Agriculture and Valley/Foothill Riparian Natural Community types that fell within this buffer were included as low value habitat.

Assumptions. Western burrowing owls require habitat with three attributes: open, well-drained terrain; short, sparse vegetation; and underground burrows or burrow facsimiles (Klute et al. 2003). In Northern California, most nest sites occur in ground squirrel burrows; however, other mammal burrows and various artificial sites, such as culverts, pipes, and rock piles are also used (Haug et al. 1993). Optimal nesting locations are within an open landscape with level to gently sloping topography, sparse or low grassland or pasture cover, and a high density of burrows.

However, nest locations also include disturbed habitats within this landscape, including roadside berms, levee slopes, and debris piles.

Western burrowing owls occur primarily in open grassland habitats where vegetation is low to maximize visibility and access. Thus, open grassland habitats are ranked as high value for burrowing owls. Moderate value foraging and nesting habitat includes native and irrigated pasture types that maintain a relatively constant vegetation structure; and berms, road edges, and fence rows around the perimeter of fields; and levee slopes in managed and natural seasonal wetland types. Low value nesting and foraging habitat includes seasonal wetland types that are dry during the breeding season and types (e.g., irrigated crops) that exhibit periodic or seasonal foraging value due to management activities and changes in vegetation structure. A variety of irrigated crop types may be used; however, use is generally associated with low vegetation structure and thus occurs primarily during pre-planting or post-harvesting seasons. Because most irrigated crop types (Grain and hay; Field; and Truck, nursery and berry crop types listed above) are rotated seasonally or annually, the distribution of suitable types will also vary seasonally and annually. Thus, this model overestimates the extent of these lower value agricultural foraging habitats in any given year.

A22.8 RECOVERY GOALS

A USFWS recovery plan has not been prepared for this species and no recovery goals have been established.

APPENDIX A23. WESTERN YELLOW-BILLED CUCKOO (COCCYZUS AMERICANUS OCCIDENTALIS)

A23.1 LEGAL STATUS

The western yellow-billed cuckoo (*Coccyzus americanus occidentalis*) is listed as an endangered species under the California Endangered Species Act. The western yellow-billed cuckoo (*C. americanus*) is currently a candidate for federal listing. Despite the evidence of population declines within the range of *C. a. occidentalis*, taxonomic debate related to the division of the two subspecies (*C. a. occidentalis* and *C. a. americanus*) contributed to the initial determination by the United States Fish and Wildlife Service (USFWS) that there was insufficient evidence to support federal listing. Following a second petition to list the species in 1998, the USFWS initially agreed that listing may be warranted and issued a 90-day Finding for Petition to list as endangered and commencement of a status review (65 FR 8104).

Additional information gathered during the status review suggested that there was insufficient differentiation to justify division into the two subspecies; thus, the USFWS determined that on the basis of the status of eastern populations, there was insufficient information to list the species. In 2001, however, the USFWS determined that there was sufficient information to consider the range of *C. a. occidentalis* as a distinct population segment (DPS), and thus found that there was sufficient evidence to list the yellow-billed cuckoo western DPS (66 FR 38611). The USFWS also determined, however, that the listing was precluded by higher priority listing actions and that the immediacy of the threat to the species was non-imminent. Thus, the species was added to the list of candidate species subject to future federal listing.

A23.2 SPECIES DISTRIBUTION AND STATUS

A23.2.1 Range and Status

There are two currently recognized subspecies, *C. a. occidentalis*, found west of the Rocky Mountains and *C. a. americanus*, found in deciduous forests east of the Rocky Mountains. There is a continuing debate over the taxonomic separation of the two subspecies, which is based primarily on morphological and plumage differences (Banks 1988, Franzreb and Laymon 1993), and more recently on genetics studies initiated by the USFWS during the status review for federal listing.

The range of western yellow-billed cuckoo historically extended from southern British Columbia to the Rio Grande River in northern Mexico, and east to the Rocky Mountains (Bent 1940). Currently, the only known populations of breeding western yellow-billed cuckoo are in several disjunct locations in California, Arizona, and western New Mexico (Halterman 1991). Yellow-billed cuckoos winter in South America from Venezuela to Argentina after a southern migration that extends from August to October (Laymon and Halterman 1985). They migrate north in late June and early July (de Schauensee 1970).

Studies conducted since the 1970s indicate that there may be fewer than 50 breeding pairs in California (Gaines 1974, Halterman 1991, Laymon et al. 1997). While a few occurrences have been detected elsewhere recently, including the Eel River, the only locations in California that currently sustain breeding populations include the Colorado River system in Southern California, the South Fork Kern River east of Bakersfield, and isolated sites along the Sacramento River in northern California (Figure A-23a) (Laymon and Halterman 1989, Laymon 1998).

Declines in numbers of the yellow-billed cuckoo in California are a result of “removal widely of essential habitat conditions,” as described by Grinnell and Miller (1944). These declines have continued primarily in the San Joaquin Valley, north coast, and central coast (where the populations had been extirpated by 1977) (Gaines and Laymon 1984), and the species was nearly extirpated in the Lower Colorado River Valley by 1999. In the Sacramento Valley, only 1 percent of the species’ historical habitat remains to support a small population estimated at only 50 pairs in 1987 and 19 pairs in 1989 (Laymon and Halterman 1989). Population estimates based on surveys conducted in 1999 are similar to those from the 1980s (USFWS 2001). Because no surveys have been conducted since 1999, the current status of the Sacramento Valley population is not known.

A23.2.2 Distribution and Status in the Plan Area

The historical distribution of yellow-billed cuckoo extended throughout the Central Valley, where the species was considered common (Belding 1890). In the mid-1940s, Grinnell and Miller (1944) still considered the Central Valley distribution to extend from Bakersfield to Redding. While there are few historical records from the Plan Area, presumably the species nested along the Sacramento, San Joaquin, and Mokelumne rivers and along smaller tributary drainages including Lost Slough, White Slough, and Disappointment Slough (Figure A-23b).

Gaines (1974) reports several sightings of cuckoos in the vicinity of the Plan Area between 1962 and 1973. The Yolo Audubon Society also reports several sightings from Yolo County, including one from the Putah Creek Sinks in 2005. All of these are presumed to be of migrating birds. There are no recently confirmed breeding locations from the Plan Area or vicinity. In summer 2009, DWR detected one and possibly two yellow-billed cuckoos in a remnant patch of riparian forest in the vicinity of Mandeville Island. Breeding status was not confirmed.

Most riparian corridors in the Plan Area do not support sufficiently large riparian patches for cuckoo breeding; however, the species likely continues to migrate along the Sacramento River and other drainages to northern breeding sites in the Sutter Basin and Butte County. The Plan Area supports several remnant riparian patches in the vicinity of Mandeville and Medford islands that provide suitable riparian vegetation for cuckoos, but may not provide sufficiently large patch size to support breeding cuckoos.

DRAFT

Figure A-23b. Western Yellow-Billed Cuckoo Habitat Model and Recorded Occurrences

1

A23.3 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

The yellow-billed cuckoo is a riparian obligate species. Its primary habitat association is willow-cottonwood riparian forest, but other species such as alder (*Alnus glutinosa*) and box elder (*Acer negundo*) may be an important habitat element in some areas, including occupied sites along the Sacramento River (Laymon 1998). Nests are primarily in willow (*Salix* spp.) trees; however, other tree species are occasionally used, including cottonwood (*Populus fremontii*) and alder. Along the Sacramento River, English walnut (*Juglans regia*) trees have also been reportedly used for nesting (Laymon 1980). Nest site height in willow trees average 14 feet (4.3 meters), but those in cottonwood trees have been reported at 100 feet (30.5 meters). Canopy cover is typically dense (averaging 96.8 percent at the nest), and large patch sizes (generally greater than 50 acres [20.23 hectares]) are typically required (Laymon 1998).

While yellow-billed cuckoos nest primarily in willow (*Salix* spp.) trees, cottonwood (*Populus fremontii*) trees are important foraging habitat, particularly as a source of insect prey. All studies indicate a highly significant association with relatively expansive stands of mature cottonwood-willow forests; however, yellow-billed cuckoos will occasionally occupy a variety of marginal habitats, particularly at the edges of their range (Laymon 1998). Continuing habitat succession has also been identified as important in sustaining breeding populations (Laymon 1998). Meandering streams that allow for constant erosional and depositional processes create habitat for new rapidly-growing young stands of willow, which create preferred nesting habitat conditions. Channelized streams or levied systems that do not allow for these natural processes become over-mature and, presumably, less optimal.

Occupied habitat in Butte County was described by Halterman (1991) as great valley cottonwood riparian forest and great valley mixed riparian forest, including willows, box elder, and white alder. On the Sacramento River, nests have been found in willows, cottonwoods, and box elders. Nests have also been found rarely in orchards including prune, English walnut, and almond. Several nests on the Sacramento River were draped with wild grape (Gaines and Laymon 1984, Laymon 1998). Potential habitat also occurs in valley marshland with willow riparian corridors, such as that found in the Llano Seco area of Butte County.

Primary factors influencing nest site selection in the Butte County population included the presence of cottonwood/willow riparian forest; patch size; and density of understory vegetation (Halterman 1991). Laymon and Halterman (1989) found a significant trend toward increased occupancy with increased patch size. In California, away from the Colorado River, cuckoos occupied 9.5 percent of 21 sites 20-40 hectares (49-99 acres) in extent, 58.8 percent of 17 sites 41-80 hectares (101-198 acres) in extent, and 100 percent of 7 sites greater than 80 hectares (198 acres) in extent (Laymon and Halterman 1989). On the Sacramento River, Halterman (1991) found that the extent of patch size was the most important variable in determining occupancy.

A habitat model developed by Gaines (1974) for the yellow-billed cuckoo in the Sacramento Valley includes the following: patch size of at least 25 acres, at least 100.5 meters (330 feet) wide and 302 meters (990 feet) long, within 100.5 meters (330 feet) of surface water, and dominated by cottonwood/willow gallery forest with high-humidity microclimate. Laymon and Halterman (1989) further refined the model by classifying habitat patch sizes for suitability. A willow-cottonwood forest patch greater than 604 meters (1,980 feet) wide and greater than 81 hectares (200 acres) is classified as optimum habitat; a patch 201-603.5 meters (660-1,980 feet) wide and 41.5-81 hectares (102.5-200 acres) is suitable; a patch 100.5-201 meters (330-660 feet) wide and 20 to 40 hectares (50-100 acres) is marginal, and smaller patches are unsuitable. Management objectives for the Sacramento Valley include six subpopulations of 25 pairs each to maintain viable populations sizes (Laymon 1998). To achieve this goal, it would be necessary to establish or preserve at least 6,070 hectares (15,000 acres) of optimum/suitable habitat. As of 1998, only 2,367 hectares (5,850 acres) of habitat were considered suitable (Laymon 1998).

A23.4 LIFE HISTORY

Description. The yellow-billed cuckoo is a medium-sized bird about 30 centimeters (cm) (11.8 inches) in length with a wingspan of 38-43 cm (15-17 inches). The species has a slender, long-tailed profile, with a fairly stout and slightly down-curved bill, which is blue-black with yellow on the base of the lower mandible. Plumage is grayish-brown above and white below, with red primary flight feathers. The tail feathers are boldly patterned with characteristic rows of large white spots on the underside. The legs are short and bluish-gray. Adults have a narrow, yellow eye ring. Juveniles resemble adults, except the tail patterning is less distinct, and the lower bill may have little or no yellow (Hughes 1999).

Seasonal Patterns. In northern California, birds typically arrive onto breeding territories and pair formation occurs from late June to mid-July following the northward migration from South America, which is followed by nest building and raising of young (Halterman 1991). The species is restricted to the mid-summer period for breeding, presumably due to a seasonal peak in large insect abundance (Rosenberg et al. 1982). To accommodate this, development of young is very rapid with a breeding cycle of 17 days from egg-laying to fledging. Following a relatively short period of post-fledging juvenile dependency, cuckoos migrate out of California from approximately mid-August to early September. The species migrates to South America during the non-breeding season and, thus, does not occur in California between approximately October and May.

Nest Site Selection. Primary factors influencing nest site selection include the presence of cottonwood/willow riparian forest, patch size, and density of understory vegetation. Little information is known about nesting density and spacing; however, along the Sacramento River, in an area of extensive foraging habitat (cottonwoods) and extremely restricted nesting habitat (willows and English walnuts), nests were placed as close as 200 feet apart, showing that they are capable of nesting in close proximity to one another (Laymon 1980).

Reproduction. The pair constructs a flimsy twig nest which is typically 5 to 40 feet above the ground in dense canopy cover. Clutch size is usually three to four eggs, rarely five (Bent 1940). Both the female and the male perform incubation of the eggs, which lasts for 10 to 11 days (Hamilton and Hamilton 1965). Both parents also share brooding duties and provision young with food. Young develop very rapidly and fledge from six to eight days post-hatching. Parental care continues for an additional three to four weeks before the southern migration begins (Halterman 1991).

In the well-studied Kern River population, it was found that 70 percent of yellow-billed cuckoo pairs were monogamous, while the remaining 30 percent included a helper at the nest (Laymon 1998). When prey is abundant, cuckoos increase clutch size and may lay eggs in nests of other yellow-billed cuckoo pairs and other nests of other species (Fleischer et al. 1985, Laymon 1998, Hughes 1999). Further, the Kern River studies determined that cuckoos tend to lay more eggs when they are able to feed nestlings a high percentage diet of katydids, and they tend to fledge more young when prey are easily and quickly captured (Laymon 1998).

Home Range/Territory Size. Limited information is available on home range and territory size. Territory size at the South Fork Kern River ranged from 8-40 hectares (20-100 acres) (Laymon and Halterman 1985), and on the Colorado River as small as 4 hectares (10 acres) (Laymon and Halterman 1989). Patch size, type and quality of habitat, and prey abundance largely determine the size of territories (Halterman 1991).

Yellow-billed cuckoos are loosely territorial and do not defend territories, but given uniform habitat they are regularly spaced throughout the landscape (Laymon 1998). Laymon (1980) found nests placed as close as 60 meters (197 feet) apart along the Sacramento River in an area where foraging habitat was abundant but nesting habitat was extremely limited. Breeding densities at the South Fork Kern River from 1985 to 1996 averaged 0.85 pairs/40 hectares and ranged from a low of 0.15 pairs/40 hectares in 1990 to a high of 1.4 pairs/40 hectares in 1993 (Laymon unpublished data *in* Laymon 1998).

Foraging Behavior and Diet. Food resources vary greatly from year to year and significantly affect reproductive success (Laymon et al. 1997). Cuckoos forage within the riparian canopy primarily on slow-moving insects. The principal food item is green caterpillar (primarily sphinx moth larvae) (44.9 percent), with lesser amounts of katydids (21.8 percent), tree frogs (23.8 percent), and grasshoppers (8.7 percent). The diet also includes cicadas, dragonflies, butterflies, moths, beetles, and spiders (Laymon et al. 1997). Primary food items, particularly sphinx moth larvae, are associated with cottonwood trees and likely explain high reported use of cottonwood trees as foraging habitat for cuckoos (Laymon and Halterman 1985).

Yellow-billed cuckoos are primarily foliage gleaners (Laymon 1998). The typical strategy is to slowly hop from limb to limb in the canopy searching for movement of prey. They also sally from perches to catch flying insects or drop to the ground to catch grasshoppers or tree frogs (Laymon 1998).

A23.5 Threats and Stressors

Habitat Loss and Fragmentation. Historical declines have been due primarily to the removal of riparian forests in California for agricultural and urban expansion. Habitat loss and degradation continues to be the most significant threat to remaining populations. Habitat loss continues as a result of bank stabilization and flood control projects, urbanization along edges of watercourses, agricultural activities, and river management that alter flow and sediment regimes. Nesting cuckoos are also sensitive to habitat fragmentation that reduces patch size (Hughes 1999).

Pesticides. Pesticide use associated with agricultural practices may also pose a long-term threat to cuckoos. Pesticides may affect behavior and cause death or potentially affect prey populations (Hughes 1999).

Predation. Predation is a significant source of nest failures, which have been recorded at 80 percent in some areas (Hughes 1999). Fragmentation of occupied habitats could make nest sites more accessible and more vulnerable to predation. Nestlings and eggs are vulnerable to predation by snakes, small mammals, and birds.

A23.6 Relevant Conservation Efforts

There have been few conservation efforts directed toward yellow-billed cuckoos in California. The most significant conservation and research efforts have occurred at Audubon California's Kern River Preserve and actions associated with the Lower Colorado River Multi-Species Conservation Program (MSCP). Efforts to protect and restore riparian systems can potentially preserve or create habitat for this species. Some regional habitat conservation planning efforts may also provide protections, primarily through protection of existing occupied habitat. Western yellow-billed cuckoo is also a covered species in other neighboring regional conservation plans including the approved San Joaquin County Multi-species Habitat Conservation and Open Space Plan and the in-progress Yolo County Natural Heritage Program Plan and Butte Regional Conservation Plan.

A23.7 Species Habitat Suitability Model

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models, and as necessary, revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements, and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf 2007. Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers, connectivity between habitat types, and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described, and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The yellow-billed cuckoo model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), USDA 2005 aerial photography, and DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable yellow-billed cuckoo nesting and migratory habitat in the Plan Area. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Breeding and Migratory Habitat. Breeding and migratory habitat in the Delta includes the following valley riparian types from the BDCP composite vegetation layer. Breeding habitat is restricted to patches greater than 10 ha (25 ac); migratory habitat has no size restriction.

Fremont cottonwood (*Populus fremontii*);

White alder (*Alnus rhombifolia*);

Oregon ash (*Fraxinus latifolia*);

Box elder (*Acer negundo*);

Hinds walnut (*Juglans hindsii*);

Black willow (*Salix gooddingii*);

Arroyo willow (*Salix lasiolepis*);

Shining willow (*Salix lucida*);

Narrow-leaf willow (*Salix exiqua*);

Alnus rhombifolia/*Salix exigua* (*Rosa californica*);

Alnus rhombifolia/*Cornus sericea*;

Acer negundo-Salix gooddingii;

Salix gooddingii-Populus fremontii (*Quercus lobata-Salix exigua-Rubus discolor*);

Salix gooddingii/*Rubus discolor*;

Salix lasiolepis – Mixed brambles (*Rosa californica-Vitis californica-Rubus discolor*);

Salix exigua – (*Salix lasiolepis – Rubus discolor – Rosa californica*);

Salix gooddingii/wetland herbs;

Salix goodingii – Quercus lobata/wetland herbs;

Salix lasiolepis – Cornus sericea/*Scirpus*[1] spp. – complex unit;

Cornus sericea – Salix exigua;

Cornus sericea – Salix lasiolepis/(*Phragmites australis*);

Quercus lobata/*Rosa californica* (*Rubus discolor-Salix lasiolepis*/*Carex* spp.);

Quercus lobata – Acer negundo; and

Quercus lobata – Alnus rhombifolia (*Salix lasiolepis-Populus fremontii-Quercus agrifolia*).

Nesting and migratory habitat in the Suisun Marsh and Yolo Basin includes the following valley riparian types from the BDCP composite vegetation layer:

Mixed Fremont cottonwood – willow;

Fremont cottonwood-valley oak-willow riparian forest;

Mixed willow super alliance;

Fraxinus latifolia;

Salix laevigata/*S. lasiolepis*;

Salix lasiolepis/*Quercus agrifolia*;

Valley oak alliance – Riparian; and

Willow trees.

Assumptions. The yellow-billed cuckoo is a riparian obligate species. Its primary habitat association is willow-cottonwood riparian forest, but other species such as alder (*Alnus rhombifolia*) and box elder (*Acer negundo*) may be an important habitat element in some areas, including occupied sites along the Sacramento River (Laymon 1998). Canopy cover is typically dense (averaging 96.8 percent at the nest) and large patch sizes (generally greater than 50 acres [20.23 ha]) are typically required (Laymon 1998). Cuckoos may also nest in smaller patches of habitat. Gaines (1974) reports a 25 acre (10 hectare) minimum patch size. Therefore, a patch size of at least 25 acres was selected based on values from Gaines (1974) and used for the Lower Colorado River Multi-Species Conservation Strategy (LCR MSCP 2004).

1 Currently known as *Schoenoplectus.*

A23.8 RECOVERY GOALS

A USFWS recovery plan has not been prepared for this species and no recovery goals have been established.

APPENDIX A24. CALIFORNIA LEAST TERN (*STERNULA ANTILLARUM BROWNI*)

A24.1 LEGAL STATUS

The California least tern (*Sternula antillarum browni*) is state and federally listed as endangered. The species was listed by the California Fish and Game Commission pursuant to the California Endangered Species Act (Fish and Game Code, Sections 2050 et seq.) on June 27, 1971, and by the U.S. Fish and Wildlife Service (USFWS) pursuant to the federal Endangered Species Act on October 13, 1970 (35 FR 8491). Critical habitat has not been designated for this species.

A24.2 SPECIES DISTRIBUTION AND STATUS

A24.2.1 Range and Status

The California least tern, the smallest of the five recognized North American subspecies of *S. antillarum*, is the only subspecies that occurs in California (Thompson et al. 1997). The historical breeding range of the California least tern was described as extending along the Pacific Coast from approximately Moss Landing to the southern tip of Baja California (Grinnell and Miller 1944). However, since about 1970, colonies have been reported north to San Francisco Bay (USFWS 2006). The nesting range in California is somewhat discontinuous due to the availability of suitable estuarine shorelines, where California least terns often establish breeding colonies (Figure A-24a). Marschalek (2006) identifies six geographic population clusters along the Pacific Coast in California including San Diego, Camp Pendleton, Los Angeles/Orange County, Ventura County, San Luis Obispo/Monterey County, and San Francisco Bay. The majority of the California population is concentrated in three counties: San Diego, Orange, and Los Angeles.

There is little reliable historical information on breeding populations. The first statewide surveys were conducted in 1969-70 (Craig 1971). Annual breeding surveys began in 1973 (Bender 1974) and continue to present (Marschalek 2009). Recent statewide surveys estimated between 6,744 and 6,989 breeding pairs in California, with approximately 85 percent of the breeding colonies occurring in Southern California and only a small percentage (6.3 percent) occurring in the San Francisco Bay area (Marschalek 2009). Statewide, the trend in the breeding population has been dramatic since state and federal listing of the California least tern, from only several pairs in the late 1960s to a current estimate of 6,998 and 7,698 pairs (Marschalek 2009).

Marschalek (2009) monitored six active breeding colonies in the San Francisco Bay area in 2008 with a total number of breeding pairs estimated at approximately 443.

Figure A-24a. California Least Tern Statewide Range and Recorded Occurrences

1

Colony sites included Alameda Point, Hayward Regional Landing, and Eden Landing on the western edge of Alameda County, Green Island at the southern tip of Napa County, the Pittsburg Power Plant in northern Contra Costa County, and the Montezuma Wetlands at the southern edge of Solano County. Approximately 73 percent (323) of the breeding pairs were documented at the Alameda Point site. The remaining sites included between 2 and 57 breeding pairs (Marschalek 2009).

A24.2.2 Distribution and Status in the Plan Area

Recently, several California least tern nesting sites have been reported from the vicinity of the Plan Area, two of which (Montezuma Hills and Pittsburg Power Plant) are within the Plan Area. California least terns have nested at the Montezuma Wetlands on the eastern edge of Suisun Marsh near Collinsville since 2006 (Figure A-24b). This colony site was unintentionally created as part of a wetlands restoration project that requires increasing the elevation of certain areas prior to flooding (Marschalek 2008). A pile of sand and shells, formed during excavation of the wetland restoration site, attracted terns to the site, which to date has prohibited completion of the restoration project. Marschalek (2009) reports 35 breeding pairs, 35 nests, and 11 to 18 fledglings from this breeding colony in 2008. California least terns also recently began nesting at the Pittsburg Power Plant in Pittsburg, although with less success. In 2008, Marschalek (2009) documented 10 breeding pairs, but no successful nests.

Two additional locations were recently reported from just outside the Plan Area, including Green Island on the Napa River east of the San Pablo Bay National Wildlife Refuge and northwest of American Canyon, where 19 least terns and two successful nests were reported in 2007 (Marschalek 2008); and along a gravel road between two treatment ponds at the Sacramento Regional Wastewater Treatment Plant (Bufferlands) east of Interstate-5, where a single unsuccessful nest was documented in 2008 (Marschalek 2009).

A24.3 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

California least terns nest in loose colonies on barren or sparsely vegetated sandy or gravelly substrates above the high tide line along the coastline and in lagoons and bays of the California coast. Coastal colonies are typically located on sandy shorelines that are kept free of vegetation from tidal action. Colonies are always near water that provides foraging opportunities. Foraging typically occurs in shallow estuaries or lagoons (Thompson et al. 1997, USFWS 2006).

In the San Francisco Bay area, nesting colonies are typically located in abandoned salt ponds and along estuarine shores, often using artificially or incidentally created habitat (Rigney and Granholm 2005, Marschalek 2008). Foraging occurs in the bay or large river estuaries.

California least terns roost on the ground. Prior to egg-laying, adults generally roost away from nest sites, from 0.25 miles at coastal sites to several miles at estuarine sites. This behavior is thought to be in response to predator avoidance (USFWS 2006).

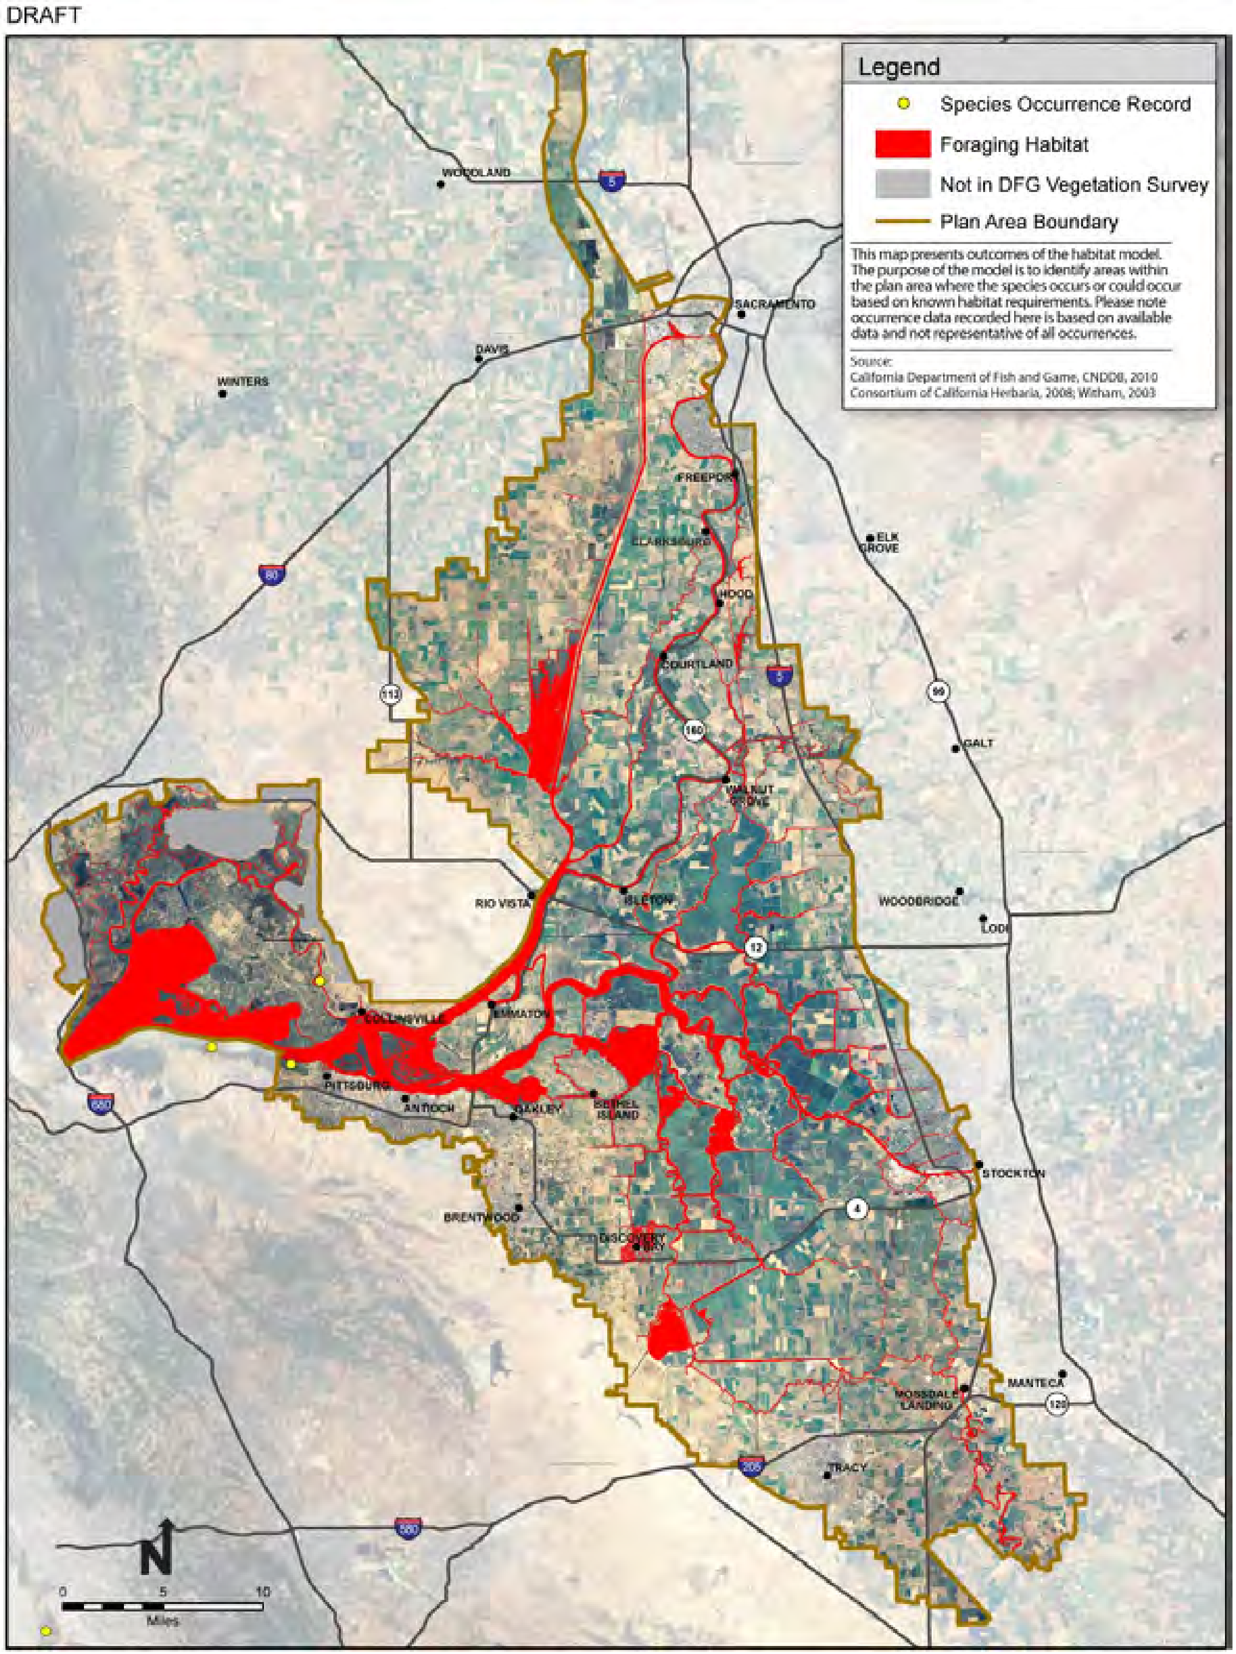

Figure A-24b. California Least Tem Habitat Model and Recorded Occurrences

California least terns are very gregarious and nest, feed, roost, and migrate in colonies. California least terns are highly sensitive to nest disturbance and will readily abandon nest sites if disturbed (Davis 1974).

A24.4 LIFE HISTORY

Description. The California least tern is a small seabird measuring approximately 10 inches (25 centimeters [cm]) in length with a 30-inch (76-cm) wingspan. It has long, tapered wings and a forked tail. Its distinctive black cap and black-tipped pale gray wings contrast with the white body. It has a white forehead, black-tipped yellow bill, and yellowish feet.

Seasonal Patterns. California least terns are migratory. Present at nesting areas from mid-April to late September (Massey 1974, Cogswell 1977, Anderson and Rigney 1980, Patton 2002). Wintering areas are largely unknown, but are suspected to be along the Pacific Coast of Central and South America (Massey 1977).

Nest Site Selection. Nesting colony sites are selected that are free of human or predatory disturbance. The availability of such sites is a limiting factor for the species. Nest sites are shallow depressions without nesting material, typically in barren sandy or gravelly substrate near water.

Reproduction. Courtship generally occurs during April-May and usually takes place away from the nesting area on exposed tidal flats or beaches. Nesting begins by mid-May (Massey 1974). Clutch size ranges from 1 to 4 eggs and is usually 2-3, with a single brood raised each year. Incubation is usually 20-25 days and young are fledged by 28 days, but continue to depend on adults for an additional two weeks (Rigney and Granholm 2005).

Home Range/Territory Size. No information is available on home range size. Nests are typically spaced 1 to 5 meters (3 to 16 feet) apart, and an approximately 1-meter radius area around the nest is defended by the adults (Thompson et al. 1997).

Foraging Behavior and Diet. The California least tern feeds in shallow estuaries and lagoons for small fish including anchovies (*Engraulis* spp.), silversides (*Atherinops* spp.), and shiner surfperch (*Cymatogaster aggregata*) (Rigney and Granholm 2005). It hovers above the water, then plunges, but does not completely submerge. It will also forage in the shallow tidal zone of the open ocean and in bays (Cogswell 1977, Rigney and Granholm 2005).

A24.5 THREATS AND STRESSORS

Habitat Loss and Fragmentation. The degradation and disturbance of suitable estuarine shoreline habitat is the primary reason for the historical reduction of California least tern populations. Most extant colonies occur on small patches of degraded nesting habitat surrounded on all sides by human activities. The majority of colony sites are in areas that were incidentally created during development projects. There is no other available natural habitat for expansion or dispersal other than artificial or incidentally created nesting habitat. Further expansion and recovery of the California least tern population may require the creation or restoration of habitat (USFWS 2006).

Human Disturbance. Human disturbance was noted as early as the mid-1920s as a factor in causing colony abandonment and population declines (Schneider 1926 in: Rigney and Granholm 2005), and is still considered a major threat to remaining colonies (Garrett and Dunn 1981, Marschalek 2009). There is no suitable natural habitat in California that is free of development, military, or recreation-related human disturbances; thus, opportunities for the species to develop new breeding territories are mostly restricted to artificially or incidentally created habitat. Fencing has been used to prohibit entry into colony sites, but this also restricts the movement of birds and has led to nesting failures (USFWS 2006).

Predation. Predation is regarded as the most significant threat to existing colonies. Marschalek (2009) reports 45 avian and mammalian predators or suspected predators of California least tern colonies in 2008. Most depredated terns were taken by American crow (*Corvus brachyrhynchos*), gull-billed tern (*Sterna nilotica*), common raven (*Corvus corax*), and coyote (*Canis latrans*). Peregrine falcon (*Falco peregrinus*), American kestrel (*Falco sparverius*), burrowing owl (*Athene cunicularia*), northern harrier (*Circus cyaneus*), and black skimmer (*Rynchops niger*) were also responsible for a significant proportion of predation events. Marschalek (2009) calculated that 1686-1693 eggs, 304-443 chicks, 73-100 fledglings, and 28 adults were lost to predation events in 2008.

A24.6 Relevant Conservation Efforts

In addition to the guidance provided by the federal recovery plan (USFWS 1985), which establishes 23 coastal management areas, and state and federal laws and regulations, conservation efforts include:

- U.S. Marine Corps, Camp Pendleton Integrated Natural Resources Management Plan. Provides specific direction regarding least tern protection and conservation on the military base.
- San Diego Unified Port District. Conducts monitoring and management of least tern colonies on their properties around San Diego Bay as well as public information programs.
- San Diego Multiple Species Conservation Program. Addresses conservation of California least tern within its planning area.
- Feeding ecology and monitoring studies at the Alameda Point colony by the Point Reyes Bird Observatory.

- Predator control programs – cooperative agreements and efforts by Navy, Marine Corps, and the USFWS and Animal Damage Control.
- California Coastal Management Program, administered by the California Coastal Commission in accordance with the Coastal Zone Management Act, requires a review, permit, and appeal process; implementation of local coastal programs; and a federal consistency review to guide development along the coast.
- Protection under the Migratory Bird Treaty Act of 1918.
- Audubon efforts to use decoys and recorded calls to lure terns to protected habitat that offer a better chance at breeding success.
- Los Angeles trash removal and invasive plant control at nesting sites by local community groups and government agencies.

A24.7 Species Habitat Suitability Model

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and revise the vegetation input data as necessary.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf 2007. Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers, connectivity between habitat types, and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association (i.e., breeding, foraging, or movement/dispersal habitat). Finally, the assumptions used in the formulation of the model are described, and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The California least tern model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta]; Boul and Keeler-Wolf 2008 [Suisun Marsh]; TAIC 2008 [Yolo Basin]); USDA 2005 aerial photography; and DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable California least tern nesting and migratory habitat in the Plan Area. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Breeding and Foraging Habitat. Foraging habitat includes all areas mapped as tidal perennial aquatic. Nesting habitat is not mapped but is assumed to potentially occur along the perimeter of tidal perennial aquatic habitat.

Assumptions. As evidenced by recent breeding occurrences at the Montezuma Wetlands, Pittsburg Power Plant, and the Bufferlands, California least tern has potential to nest in shoreline habitat adjacent to large permanent water bodies within the Plan Area. It is assumed that continued range expansion could occur in association with suitable tidal perennial aquatic habitat throughout the Plan Area. While most of the shoreline habitat has been modified or is artificial, nesting colonies are often in artificially or incidentally created habitat (Rigney and Granholm 2005, Marschalek 2008) such as gravel roads, debris piles, and other conditions that mimic a natural sandy or gravelly substrate. It is assumed that foraging can occur in large river estuaries, such as the Sacramento and San Joaquin rivers, and other tidal perennial aquatic habitat throughout the Plan Area and Restoration Opportunity Area (ROAs). However, because little if any natural nesting habitat occurs and future breeding occurrences may occur incidentally around these water bodies, it is not possible to accurately determine locations of suitable breeding habitat. Therefore, it is assumed that breeding sites could occur in the future adjacent to tidal perennial aquatic habitat.

A24.8 RECOVERY GOALS

A recovery plan for the California least tern was published in 1980 and revised in 1985 (USFWS 1985). Recovery criteria included (1) at least 1,200 breeding pairs distributed in at least 20 of 23 coastal management areas; (2) each of the 20 management areas must have at least 20 breeding pairs; (3) each of the 20 management areas must have a 5-year mean reproductive rate of at least 1.0 young fledged per breeding pair; and (4) San Francisco Bay, Mission Bay, and San Diego Bay must be included within the 20 secure management areas with 4, 6, and 6 secure colonies respectively.

The most recent 5-year review (USFWS) indicated that while the gross number of pairs was six times the number identified in the criteria, this was the only recovery goal that has been fully met (USFWS 2006). The review also indicated that substantial new information was available that should be used to revise the recovery plan. While the 5-year review recommends a downlisting of status to "threatened," it also recommends the following:

- Revisit and revise the California least tern recovery plan;
- Continued management of existing nest sites;
- Monitoring of nest sites; and
- Creation of new nest sites and site expansion at existing sites.

APPENDIX A25. GREATER SANDHILL CRANE (*GRUS CANADENSIS TABIDA*)

A25.1 LEGAL STATUS

The greater sandhill crane (*Grus canadensis tabida*) is listed as a state-threatened species under the California Endangered Species Act (Fish and Game Code, Sections 2050 et seq.). The species was listed by the California Fish and Game Commission in 1983. The greater sandhill crane is also designated as a state Fully Protected species. The greater sandhill crane has no federal regulatory status.

A25.2 SPECIES DISTRIBUTION AND STATUS

A25.2.1 Range and Status

The greater sandhill crane is one of six subspecies of sandhill crane in North America; three of which are non-migratory and occupy ranges in the southeastern United States and Cuba (Littlefield and Ivey 2000). The remaining three are migratory and include the lesser and greater subspecies, both of which are further divided into distinct populations. The greater sandhill crane is divided into five migratory populations, all of which return to the same breeding territory and wintering sites each year. These include: the Eastern Population, the Prairie Population, the Rocky Mountain Population, the Lower Colorado River Population, and the Central Valley Population. The Central Valley Population breeds in northeastern California (Figure A-25a), central and eastern Oregon, southwestern Washington, and southern British Columbia; and winters in the Central Valley of California (Littlefield and Ivey 2000).

Breeding Range. There are an estimated 500,000 sandhill cranes in North America, of which an estimated 62,600 are greater sandhill cranes. An estimated 8,500 of these belong to the Central Valley Population (Littlefield and Ivey 2000). The most recent breeding surveys have recorded 1,151 breeding pairs in Oregon, 465 breeding pairs in California, 20 pairs in Washington, and 11 pairs in Nevada (Engler and Brady 2000 as cited in Ivey and Herziger 2001, Ivey and Herziger 2000). The exact number of breeding pairs in British Columbia remains unknown; however, Littlefield and Ivey (2000) estimate approximately 2,500 individuals.

Within California, the breeding distribution is restricted to a six-county area in the northeastern corner of the state, including Siskiyou, Modoc, Shasta, Lassen, Plumas, and Sierra counties (Figure A-25a) (Littlefield 1982, Littlefield 1989, Ivey and Herziger 2001). Ivey and Herziger (2001) conducted the most recent surveys and found that the greatest number of breeding pairs are in Modoc County (54 percent) followed by Lassen County (26 percent). A total of 91 percent of the breeding pairs were found in Modoc, Lassen, and Siskiyou counties (Ivey and Herziger 2001).

DRAFT

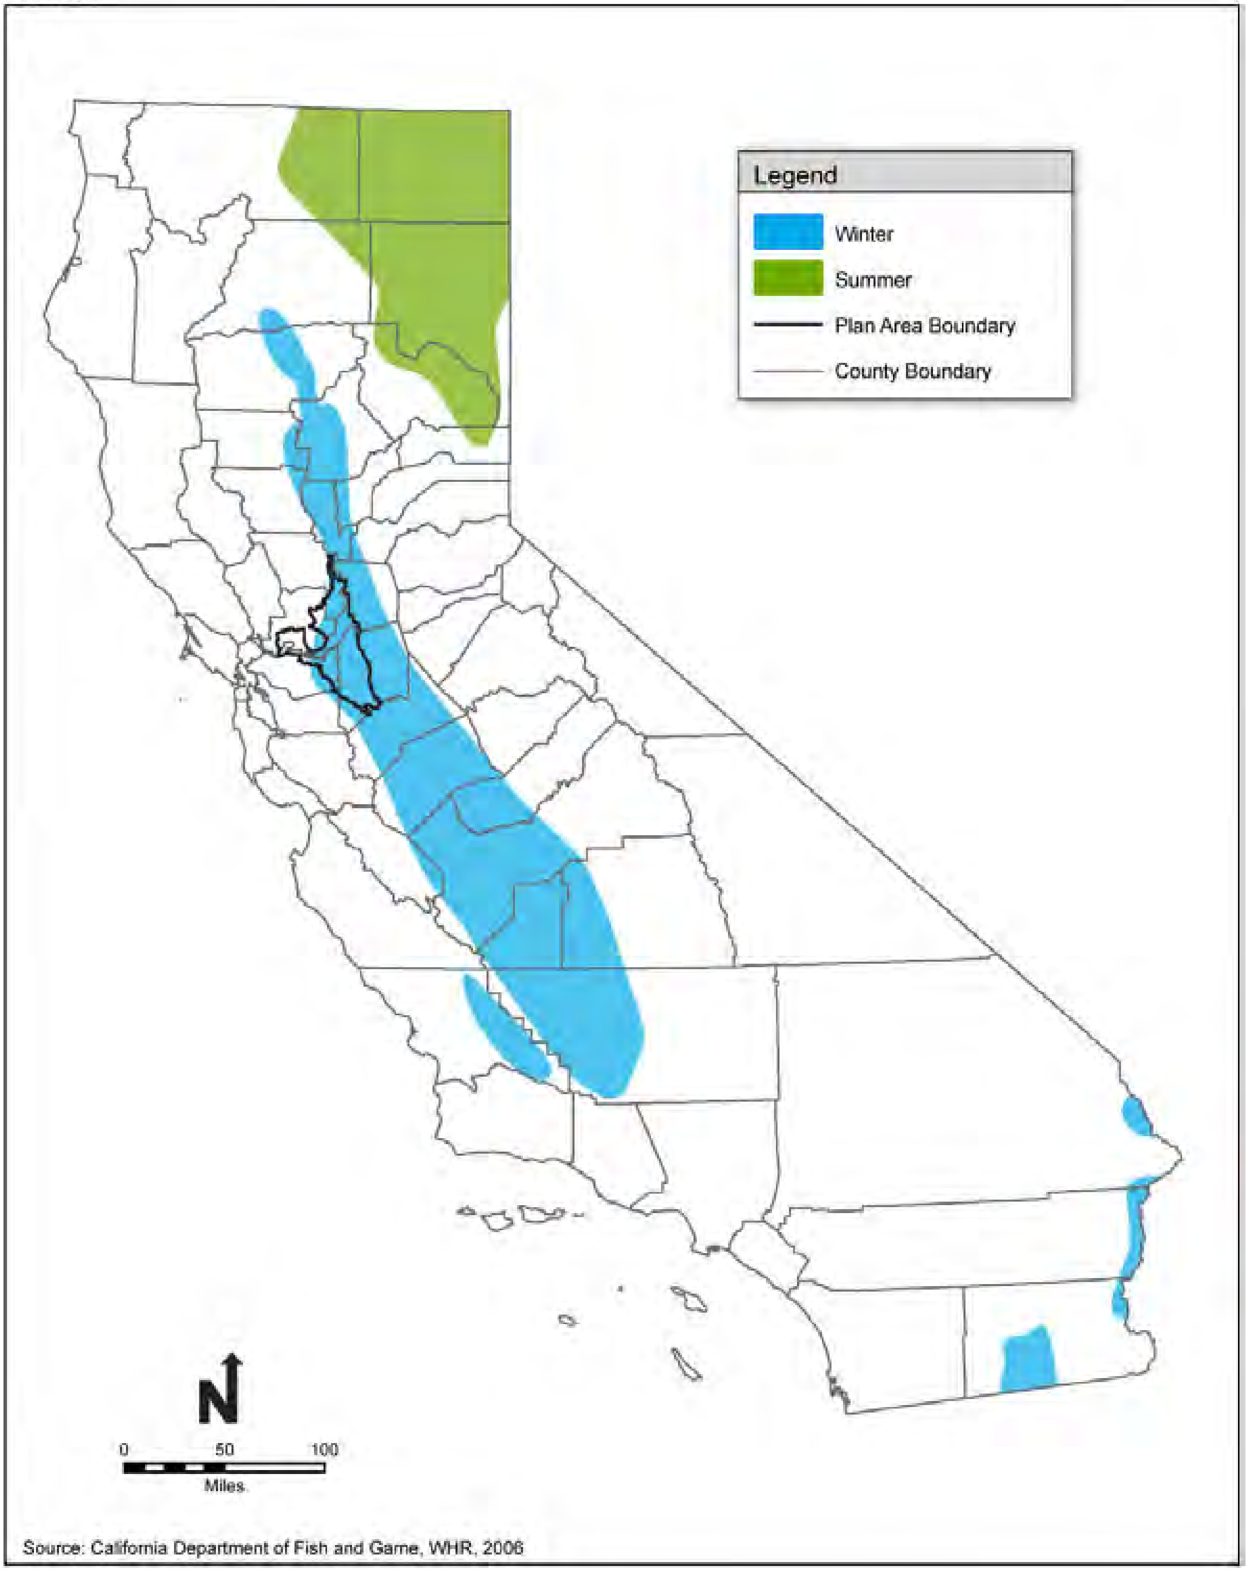

Figure A-25a. Greater Sandhill Crane Statewide Range and Recorded Occurrences

Prior to the early 1970s, survey efforts were insufficient to accurately estimate the breeding population of greater sandhill crane; however, major population declines have been noted and attributed to the widespread destruction of essential wetland habitats between 1870 and 1915 (Walkinshaw 1949). The first comprehensive surveys were conducted in 1971 (112 pairs), followed by surveys in 1981 (129 pairs) and 1988 (170 pairs), indicating a positive trend in the breeding population during that period (Littlefield 1982, Littlefield 1989). The next subsequent, and most recent, survey was conducted in 2000 (Ivey and Herziger 2001) when 465 pairs were reported, an increase of 68 percent since the 1988 survey. Much of this increase may be attributable to protection of traditional nesting areas on state and national wildlife refuges, lack of hunting, and a variety of management practices.

Wintering Range. Pogson and Lindstedt (1991) identified eight distinct wintering locations in the Central Valley from Chico/Butte Sink in the north to Pixley National Wildlife Refuge near Delano in the south, with over 95 percent occurring within the Sacramento Valley between Butte Sink and the Sacramento-San Joaquin River Delta (Figure A-25a). Use varies seasonally within this area probably as a function of the winter flooding regime and food resources. The Butte Sink has been reported to support a large segment of the population (>50 percent) during October and November. Use then shifts to the Delta and the Cosumnes River floodplain during December and January, where an estimated two-thirds of the population resides the remainder of the winter (Pogson and Lindstedt 1988, Littlefield and Ivey 2000).

The first exhaustive winter survey was conducted in the mid-1980s (Pogson and Lindstedt 1988), which estimated a wintering population of 6,000 birds. This was adjusted in the early 1990s to 8,500 birds as a result of additional follow-up survey work in the Sacramento Valley (Littlefield 1993). Although portions of the wintering population have been monitored periodically prior to and since the mid-1980s, no other comprehensive survey has been conducted and information has been insufficient to reliably detect trends.

A25.2.2 Distribution and Status in the Plan Area

Figure A-25b illustrates the distribution of the greater sandhill crane in the Plan Area. The entire Delta winter range of the species (defined here as including the Delta and Cosumnes River floodplain), as defined by Pogson and Lindstedt (1988), Littlefield and Ivey (2000), and most recently by Ivey (2010 pers. comm.) occurs within the Plan Area with the exception of the eastern portion of the Cosumnes River floodplain area. Greater sandhill cranes begin arriving in the Delta in October and from 3,000 to 4,000 cranes are in the Delta region in October and November. As noted above, the population peaks in December and January as cranes move into the Delta from the Butte Basin. An estimated two-thirds (from 5,000 to 6,000 cranes) of the population resides in the Delta the remainder of the winter (Pogson and Lindstedt 1988, Littlefield and Ivey 2000).

DRAFT

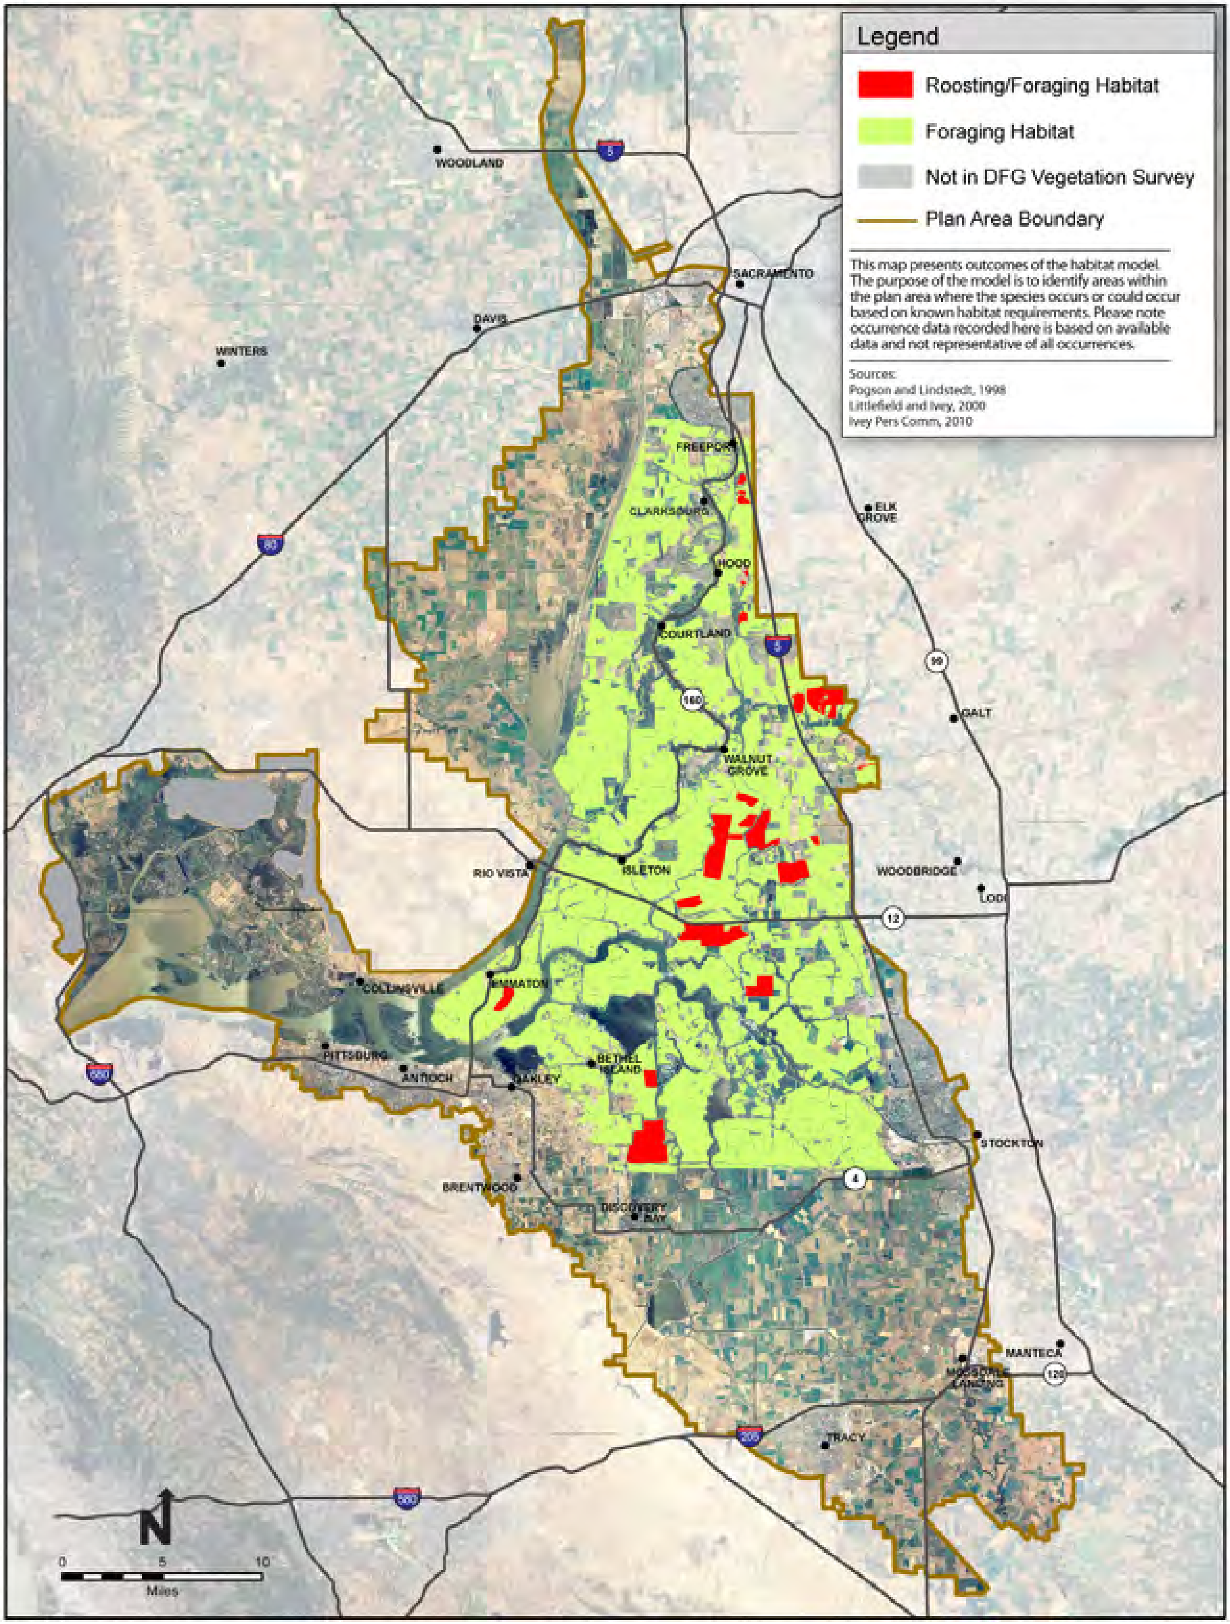

Figure A-25b. Greater Sandhill Crane Habitat Model

While populations have shifted over the years in response to changing agricultural patterns, particularly the increase of vineyards, the islands and tracts traditionally receiving the highest crane use include Staten Island, Terminous Island, Canal Ranch, and New Hope Tract. Other areas receive less and from occasional to regular use, including Bouldin Island, Empire Tract, King Island, Grand Island, Tyler Island, Ryer Island, Brannan Island, Twitchell Island, Bradford Island, Venice Island, Manderville Island, and Webb, Holland, and Palm tracts (Pogson 1990, Littlefield and Ivey 2000). More recently, greater sandhill cranes have also been found occasionally using Ridge, Bacon, and Roberts islands (Bradbury pers. comm.); and on lands west of the Sacramento River, in the west Delta in the vicinity of Sherman Island, and in the vicinity of the Stone Lakes National Wildlife Refuge (Ivey 2010 pers. comm.). Areas receiving the highest use are generally associated with the location of active roost sites. Highest levels of use are typically within approximately 2 miles of known roosts, and use (measured as a function of observed crane density) decreases beyond approximately 2 miles from roosts (Ivey 2010 pers. comm.).

The Cosumnes River floodplain, much of it protected within The Nature Conservancy's Cosumnes River Preserve, also supports significant winter crane use. Use may have increased in this area as continued conversion to vineyards on Delta Islands has reduced habitat availability in that area (Littlefield and Ivey 2000).

As noted, crane use is entirely dependent on agricultural crop patterns. Conversion to unsuitable crop types effectively eliminates crane habitat. Over the last two decades, a substantial amount of conversion to vineyards has occurred on Delta Islands and is considered among the most important conservation issues for greater sandhill crane (Littlefield and Ivey 2000). Several important traditionally used areas, such as portions of the Thompson-Folger Ranch along Peltier Road, have been converted to vineyards. Habitat loss from agricultural conversion and disturbances from increasing recreational activities in some areas threaten the long-term sustainability of key wintering areas for this species.

A25.3 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

Greater sandhill cranes are primarily birds of open freshwater wetlands. In California, nesting typically occurs in open grazed meadows. Most of these are bulrush or sedge meadows adjacent to grasslands or short vegetation uplands (Littlefield and Ryder 1968, Littlefield 1982). While breeding sites occur on state and federal refuges or U.S. Forest Service lands, more than 60 percent occur on private lands (Ivey and Herzinger 2001).

Wintering habitat is found almost entirely in agricultural fields and edges. Wintering habitat consists of three primary elements: foraging habitat, loafing habitat, and roosting habitat. There are two principal foraging habitat types used during winter. In the Delta, harvested corn fields are the most commonly used foraging habitat along with winter wheat, alfalfa, pasture, and fallow fields (Pogson and Lindstedt 1988). Ivey (pers. comm. in Sacramento County 2008) rated foraging habitat cover types in the Delta region in the following order of importance to greater sandhill cranes: harvested corn, winter wheat, irrigated pasture, and alfalfa fields. In the Butte Basin, harvested rice fields are the most commonly used foraging habitat along with winter wheat, harvested and unharvested corn, fallow fields, and grasslands (Pogson and Lindstedt 1988, Littlefield 2002).

Loafing generally occurs mid-day when birds loosely congregate along agricultural field borders, levees, rice-checks, ditches, or in alfalfa fields or pastures. Cranes will often loaf in rocky uplands or along gravel roads where they collect grit, which is important in the digestion of grain seeds. During the late afternoon and evening, cranes begin to congregate into large, dense communal groups where they remain until the following morning. Providing protection from predators during the night, roost sites are typically within two to three miles from foraging and loafing areas and thus available roosting sites are an essential component of winter habitat. Roosting habitat typically consists of shallowly flooded open fields of variable size (1 to 300 acres) or wetlands interspersed with uplands. Water depth is important and averages 4.5 inches. Littlefield (1993) reported cranes abandoning roosting sites when water depth reached 8 to 11 inches. He recommended roost sites be a minimum of 20 acres in size with water maintained from early September to mid-March. If properly managed, roost sites are often used for many years.

Greater sandhill cranes are considered intolerant of excessive human disturbances and the level of disturbance may play a role in habitat selection (Lovvorn and Kirkpatrick 1981).

Excessive disturbances have caused cranes to abandon foraging and roosting sites; and repeated disturbance may affect their ability to feed and store the energy needed for survival. Ivey and Herziger (2003) documented disturbances of greater sandhill cranes on Staten Island, a high use area, and found that aircraft, vehicles, hunting, and recreational activities (e.g., birding, walking, horseback riding, bicycling, boating) can cause cranes to run or fly away. Ivey (pers. comm. in Sacramento County 2008) found that cranes generally avoid suitable agricultural foraging habitat near occupied dwellings, and foraging areas within 100 yards of occupied dwellings should not be considered suitable (Sacramento County 2008).

A25.4 Life History

Description. The greater sandhill crane is the largest of the six sandhill crane subspecies. It stands up to 4.9 feet and has a wing span from 5.9 to 6.9 feet. Adult males and females are similar in appearance with gray plumage, whitish face, chin, and upper throat, and a bare red forehead and crown. Greater sandhill cranes sometimes preen iron-rich mud into their feathers leaving a rusty-brown hue that can last throughout the summer months and sometimes remains detectable during the early winter. Juveniles are easily detectable through their first winter by their smaller size and cinnamon-brown plumage, which changes to gray during their first year (Tacha et al. 1992).

Seasonal Patterns. Nesting generally begins in April and May and extends from July through August. By September, the Central Valley population begins their migration and arrives onto the wintering grounds by late September, where they remain until approximately late February to early March, when they begin their northward migration back to the breeding grounds (Pogson 1990, Tacha et al. 1992). Local winter movements continue throughout the winter season in response to changes in flooded habitat and available food resources. For example, Pogson and Lindstedt (1988) and Littlefield (2002) report extensive use of the Butte Basin during the early part of the winter season in October and November and movement of a large segment of the population into the Delta during December and January.

Nest Site Selection. Nesting areas are selected on the basis of meadow size, flooding regime, condition of meadow and presence of cattle, vegetation composition, available food resources, and proximity to human disturbances (Armbruster 1987). Nests are usually constructed as mounds in shallow water (generally less than 12 inches deep), typically in wetland vegetation. The nest is constructed by plucking and stacking the dominant vegetation in the nesting area to form a mound. These are often very large, 2 to 3 feet high and up to 6 feet in diameter. They often use all of the vegetation from several feet around the nest creating a distinctive circular unvegetated ring around the nest mound (Smith 1999). Nests are also constructed on dry ground.

Reproduction. Females usually lay two eggs. Both the male and female incubate the eggs; incubation lasts from 29 to 32 days. One or two young fledge from successful nests. Young fledge at 67 to 75 days. Juveniles remain with the adults during the first year in family groups and do not disperse until they return to the breeding areas the following year (Tacha et al. 1992).

Foraging Behavior and Diet. Sandhill cranes are omnivorous and primarily search for subsurface food items by probing soil with their bill. They also glean seeds and other foods on the surface (Walkinshaw 1973, Tacha 1987).

Sandhill crane diet consists of tubers, seeds, grains (particularly corn and rice), small vertebrates (e.g., mice and snakes) and a variety of invertebrates.

Home Range/Territory Size. Ivey and Herziger (2003) estimated average winter home range sizes of greater sandhill cranes in the Delta to be 0.66/square miles, varying from 0.07 to 2.12 square miles. Average distance between roost sites and feeding areas was estimated by Pogson (1990) to be 1.74 miles and by Ivey and Herziger (2003) to be 0.88 miles (range 0.17 to 1.89 miles).

A25.5 THREATS AND STRESSORS

On the breeding grounds, threats include changes in water regime that lowers the water table and eliminates nesting areas; cattle grazing that can degrade habitat, destroy nests, and disturb nesting birds; and mowing and haying operations that can kill young cranes.

Threats on the wintering grounds include changes in water availability; flooding fields for waterfowl, which reduces foraging habitat for cranes; conversion of cereal cropland to vineyards or other incompatible crop types; human disturbances; collision with power lines and other structures; disease; and urban encroachment (Littlefield and Ivey 2000).

Habitat Loss and Alteration. The most significant threat to wintering greater sandhill cranes is the loss of traditional winter habitat from urbanization and agricultural conversion. While relatively limited urbanization has occurred to date within key crane areas, surrounding development and increased levels of human disturbances may threaten the long-term sustainability of important wintering lands. In the Delta region, the conversion of suitable agricultural foraging and roosting habitats to unsuitable cover types, particularly orchards and vineyards, has removed key habitats and altered the distribution and behavior of wintering greater sandhill cranes.

Disturbance of Foraging and Roosting Areas. Greater sandhill cranes are sensitive to human presence and do not tolerate regular disturbances, including low-level recreational disturbances. Types of disturbances include hunting, birding, photography, operating equipment for habitat management, boating, and aircraft. Disturbances cause birds to abandon otherwise suitable habitats, and may cause birds to deplete important energy stores needed for survival during wintering and migration. Only one pre-dawn disruption is usually necessary before cranes abandon a site (Littlefield and Ivey 2000). Disturbance from hunting also poses a threat to cranes. Hunters accessing hunt areas during pre-dawn hours flush cranes from their roosts and hunter presence can keep cranes from roosting or foraging in an area (Ivey and Herziger 2003). Flooding of agricultural fields for waterfowl hunting also reduces available foraging habitat for wintering cranes.

A25.6 Relevant Conservation Efforts

Several significant efforts have been made to protect and enhance wintering habitat for greater sandhill cranes. In 1985, the California Department of Fish and Game (DFG) acquired and continues to manage the Woodbridge Ecological Reserve. Purchased specifically to manage as a crane roosting area, this site has been a traditional crane roost for decades and continues to be one of the most important crane roosts for this wintering population.

Management of Staten Island has also provided substantial benefit to greater sandhill cranes. The island has been managed for several decades to provide benefit to wildlife in conjunction with agricultural production. Crane use of the island has increased particularly since the 1980s and 1990s under the successful management of the private landowners and continues to be among the most significant crane use areas in the Delta (Littlefield and Ivey 2000). In 2002, The Nature Conservancy established the Conservation Farms and Ranches program to provide oversight management of Staten Island and to ensure long-term conservation of crane habitat on the island.

Beginning in 1984, a cooperative effort between The Nature Conservancy, the Bureau of Land Management, the California Department of Fish and Game, the Wildlife Conservation Board, and Ducks Unlimited also began acquiring lands that today encompass approximately 40,000 acres on the Cosumnes River Preserve. Portions of the preserve are managed specifically for winter crane use and have attracted up to 20 percent of the greater sandhill crane wintering population at certain times of the wintering season (Littlefield and Ivey 2000).

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designates the greater sandhill crane as a "Contribute to Recovery" species (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its control and within its scope that are necessary to contribute to the recovery of the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

Greater sandhill crane is a covered species under the approved San Joaquin County Multi-species Habitat Conservation and Open Space Plan. It is also proposed for coverage under the South Sacramento County Habitat Conservation Plan and the Butte Regional Conservation Plan.

A25.7 SPECIES HABITAT SUITABILITY MODEL

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf 2007. Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers, connectivity between habitat types, and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The greater sandhill crane model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), USDA 2005 aerial photography, and DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable winter roosting and foraging greater sandhill crane habitat in the Plan Area. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Winter Roosting and Foraging Habitat. Greater sandhill crane winter roosting and foraging habitat includes selected grasslands, managed seasonal wetlands, natural seasonal wetlands, rice lands, pasturelands, hay crops, and annually rotated agricultural crops that occur within the defined winter range. Natural vegetation types designated as species habitat in this model correspond to the mapped vegetation associations in the BDCP composite vegetation data layer. Agricultural crop types designated as species habitat correspond to DWR 2007 land use survey data.

The Delta winter range is defined by traditional use areas as described by Pogson and Lindstedt (1988, 1991) and most recently mapped by Littlefield and Ivey (2000) and Ivey (2010 pers. comm.), along with additional observations of occasional use areas (Bradbury pers. comm.).

Winter roosting and foraging habitat in the Delta includes the following types from the BDCP composite vegetation layer:

- Grassland
  - Ruderal herbaceous grasses and forbs;
  - California annual grasslands;
  - *Bromus diandrus-Bromus hordeaceus;*
  - Italian rye-grass (*Lolium multiflorum*);
  - *Lolium multiflorum-Convolvulus arvensis;*
  - Degraded vernal pool complex – California annual grasslands;
  - Degraded vernal pool complex – Ruderal herbaceous grasses and forbs; and
  - Degraded vernal pool complex – Italian rye-grass (*Lolium multiflorum*).
- Vernal pool complex
  - Ruderal herbaceous grasses *and forbs;*
  - *Califor*nia annual grasslands;
  - Italian rye-grass (*Lolium multiflorum*);
  - *Distichlis spicata* – annual grasses;
  - *Distichlis*/annual grasses;
  - Seasonally-flooded grasslands;
  - Vernal pools;
  - Annual grasses generic; and
  - Annual grasses/weeds.
- Managed wetland
  - Temporarily flooded grasslands;
  - Rabbitsfoot grass (*Polypogon monspeliensis*);
  - Intermittently flooded perennial forbs;
  - Managed annual wetland vegetation (non-specific grasses and forbs);
  - Shallow-flooding with minimal vegetation;
  - Seasonally flooded undifferentiated annual grasses and forbs;
  - Managed alkali wetland (*Crypsis*);
  - Intermittently or temporarily flooded undifferentiated annual grasses and forbs;

    - *Scirpus*[1] spp. in managed wetlands; and
    - Smartweed *Polygonum* spp. – mixed forbs.
- Alkali seasonal wetland complex and other seasonal wetlands
    - *Distichlis spicata* – annual grasses;
    - Seasonally-flooded grasslands;
    - Vernal pools;
    - Degraded vernal pool complex-vernal pools;
    - Temporarily flooded perennial forbs; and
    - *Juncus balticus* – Meadow vegetation.

Agriculture. The following DWR 2007 Land Use survey types are included as suitable agricultural roosting and foraging habitats. These types represent the typical agricultural cover types in the Plan Area that are included in the DWR 2007 land use survey. Rotational crop types that are not common to the Plan Area are not included here. Pasture types are mostly perennial; alfalfa is semi-perennial (3 to 7 years); and all other types are annually or seasonally rotated irrigated crops, only some of which (italicized) provide high value habitat for greater sandhill cranes.

- Grain and hay crops
    - Barley;
    - *Wheat;*
    - Oats; and
    - Miscellaneous and mixed grain and hay.
- Field crops
    - Safflower;
    - Sugar beets;
    - *Corn;*
    - Grain sorghum;
    - Sudan;
    - Beans;
    - Miscellaneous field; and

[1] Currently known as *Schoenoplectus*.

   - Sunflowers.
- Pasture
   - *Alfalfa and alfalfa mixtures;*
   - Clover;
   - *Mixed pasture;*
   - *Native pasture;*
   - Induced high water table native pasture; and
   - Miscellaneous grasses.
- Truck, nursery and berry crops
   - Asparagus;
   - Beans;
   - Onions and garlic;
   - Tomatoes; and
   - Peppers.
- Idle
   - Land not cropped the current or previous crop season, but cropped within the past three years; and
   - New lands being prepped for crop production.

Assumptions. Greater sandhill crane does not breed in the Plan Area, but the Plan Area contains one of the most important wintering areas of this state threatened species (Figure A-25b) (Pogson and Lindstedt 1988). The Delta winter range is defined by traditional use areas as described by Pogson and Lindstedt (1988, 1991) and most recently mapped by Littlefield and Ivey (2000) and supplemented with new information by Ivey (2010 pers. comm.). The Littlefield and Ivey (2000) and Ivey (2010 pers. comm.) map along with modifications based on recent crane use in the Stone Lakes area are used here to define the geographic winter range of the species within the Plan Area.

Throughout their wintering range in the Delta, cranes roost in shallowly flooding seasonal wetlands and forage primarily in harvested corn fields, winter wheat fields, alfalfa fields, seasonal wetlands, irrigated pastures, and grasslands (Pogson and Lindstedt 1988, 1991, Littlefield and Ivey 2000). Suitable foraging habitat is likely also a function of patch size. However, because there is insufficient data on winter habitat patch size and because, in general, field size within the Delta winter range are probably sufficiently large to support foraging cranes, all suitable cover types are considered suitable irrespective of patch size. Because annually rotated crop types could convert to a more suitable or less suitable cover type in any given year, all crop types that are or could potentially rotate into a suitable cover type (Grain and hay; Field; and Truck, nursery and berry crop types listed above) are included here as potentially suitable habitat. Therefore, these crop types are not differentiated based on their seasonal value and are instead combined into a category of seasonally rotated croplands. As a result, this model overestimates the extent of available agricultural roosting/foraging habitat in any given year.

It is assumed that under appropriate management, all cover types could function as roosting habitat. However, known roosting sites indicated on Figure A-25b are provided by Ivey (2010 pers. comm.).

The model also does not differentiate habitat value based on observed crane use patterns within the overall use area. The model only differentiates potential use based on the presence or absence of suitable cover types as defined above irrespective of geography within the overall use area. While the distance from roost sites is an important factor that influences use of surrounding foraging habitats, using this criterion to further define use patterns assumes knowledge of all roost sites in the crane use area and assumes the stability of roost site locations over time.

Habitat Units. As described, greater sandhill cranes are closely associated with agricultural lands in the Plan Area. Most of the land within the Delta use area consists of agricultural land, and much is considered to have some value as foraging habitat for greater sandhill cranes. While the species is traditional to winter use areas, the agricultural landscape throughout the crane's use area is dynamic and subject to seasonal and annual changes in crop types. Because the greater sandhill crane is closely associated with specific agricultural crop types and patterns, use areas are also subject to change as crop patterns change. Because of the dynamic nature of the agricultural landscape and the variability of crop patterns and conditions seasonally and annually, only a portion of the agricultural landscape is suitable or available for foraging in any given season. To account for this variability and to more accurately represent the value of Plan Area-wide foraging habitat, acres of greater sandhill crane foraging habitat can be converted to habitat units.

Sufficient information is available on the use of different agricultural crops to generally categorize crops based on their value as foraging habitat. By placing different crop types and other foraging habitats that traditionally occur in the Plan Area into crop value classes and assigning relative values to those classes (e.g., 0.1, 0.5, 0.75, and 1.0), the habitat acres can be converted to habitat units. Habitat units, in addition to acres, can then be used to describe and calculate impacts to crane foraging habitat using this index of habitat value. Table A-25a provides the rationale for assigning crop types and other agricultural land uses to habitat value categories. Figure A-25c displays the distribution of habitat and the assigned habitat values within the Plan Area.

Table A-25a. Greater Sandhill Crane Foraging/Roosting Habitat Suitability Model

Foraging Habitat Value Class	*Assigned Agricultural Crops/ Habitats*	*Rationale for Assignment of Agricultural Crop Class*	*Information Sources[1]*
1.0-Very High	Corn, managed wetland	The primary food of sandhill cranes in agricultural areas is waste grain. Within the Delta wintering area, waste corn from harvested fields is generally regarded as the highest value forage for cranes. Fields traditionally planted to corn in the central Delta and therefore considered to have the highest value ranking relative to other agricultural cover types. Managed wetlands also provide high value invertebrate prey and potential roosting sites if they meet crane roosting habitat needs (e.g., appropriate water depth, vegetation type, availability of berms and other adjacent uplands, and proximity to agricultural foraging habitats) and are thus also regarded as having the highest value ranking.	Reinecke and Krapu 1979, Pogson and Lindstedt (1991), Ivey (pers. comm.); Littlefield and Ivey (2000)
.75-High	Alfalfa, irrigated pasture, wheat	Alfalfa, irrigated pasture, and winter wheat also provide high value foraging habitat for cranes. However, these types are generally used on a more temporary basis based on crop growth, harvesting, irrigation, and grazing regimes. For example, use of alfalfa fields increases following cutting and during flood irrigation events. Wheat, while available during November and December following initial planting, decreases in value during January and February as the vegetation height increases.	Pogson and Lindstedt (1991), Ivey (pers. comm.); Littlefield and Ivey (2000)
.5-Medium	Other grain crops, grassland	Other grain crops including rice and barley also provide foraging value but are traditionally less abundant in the Delta (e.g., rice) or the growth/harvest regime is not optimal for crane foraging use (e.g., barley, oats).	Pogson and Lindstedt (1991), Ivey (pers. comm.); Littlefield and Ivey (2000)
.25-Low		There are a variety of other agricultural cover types in the Delta, many of which may be occasionally used by foraging cranes. However, in most cases they are regarded as having significantly lower value in terms of relative suitability/use than those noted in the Very High, High, and Medium categories, and are therefore placed in the Marginal category below.	
.10-Marginal	Other irrigated crops, natural seasonal wetland, idle cropland	A variety of other irrigated crops may receive occasional use by cranes during the winter if fields have been left idle following harvest or immediately following planting. Some types of natural seasonal wetland may also provide suitable foraging habitat for cranes. These types, however, are dependent on vegetation type and structure, flooding, and food availability (waste grain, invertebrates, etc.) and are considered less predictable than the types identified in the Very High, High, and Medium categories.	Pogson and Lindstedt (1991), Ivey (pers. comm.); Littlefield and Ivey (2000)

A25.8 Recovery Goals

In 1997 the California Endangered Species Act was amended, explicitly requiring the California Department of Fish and Game to develop a recovery strategy pilot program for the greater sandhill crane (DFG 2001). A recovery strategy team was assembled with representatives from state and federal agencies, local landowners, environmental groups, and species experts; and it produced a draft recovery strategy. The strategy included long-term recovery goals, and a range of alternative management goals and activities. The overall goal was to improve the status of the species through a variety of specific habitat protections and other actions so the protections of the California Endangered Species Act are no longer necessary, and therefore, delisting can be proposed (DFG 2005). The draft recovery strategy has not been finalized or implemented.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designates the greater sandhill crane as "Contribute to Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its control and within its scope that are necessary to contribute to the recovery of the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

APPENDIX A26. CALIFORNIA BLACK RAIL (*LATERALLUS JAMAICENSIS COTURNICULUS*)

A26.1 Legal Status

The California black rail (*Laterallus jamaicensis coturniculus*) is listed as a threatened species under the California Endangered Species Act. It was listed by the California Fish and Game Commission in 1971. It is also designated as a Fully Protected species in California.

Black rail has no federal regulatory status; however, it is on the U.S. Fish and Wildlife Service (USFWS) Region 1 list of Birds of Conservation Concern (BCC). BCC species are those that the USFWS considers potential candidates for federal listing.

A26.2 Species Distribution and Status

A26.2.1 Range and Status

The California black rail is one of two subspecies of black rail that inhabit North America. The range of the California black rail extends throughout portions of California and Arizona. The Eastern black rail (*Laterallus jamaicensis jamaicensis*) is found along the eastern seaboard, along the Gulf Coast, and rarely at inland sites in the Midwest (Eddleman et al. 1994).

The historical range of the California black rail extended from the San Francisco Bay, throughout the Sacramento-San Joaquin Delta, along the coast to northern Baja California, at other Southern California locales such as the Salton Sea, and along the lower Colorado River. Breeding records existed early in the century of black rail populations existing on coastal marshes in San Diego, Los Angeles, and Santa Barbara counties. Loss of tidal marsh habitat has extirpated populations from much of its coastal range, particularly in Southern California and much of the San Francisco Bay since the 1950s (Manolis 1978, Garrett and Dunn 1981 as cited in DWR 2001).

Figure A-26a illustrates documented occurrences of California black rail in California. The species persists in remaining tidal marshes in the northern San Francisco Bay estuary, Tomales Bay, Bolinas Lagoon, the Sacramento-San Joaquin Delta, Morro Bay, the Salton Sea, and the lower Colorado River (Manolis 1978, Evens et al. 1991, Eddleman et al. 1994). Several small, isolated populations also still exist in southeastern California and western Arizona (Evens et al. 1991). The species has also been found more recently at several inland freshwater sites in the Sierra Nevada foothills in Butte, Yuba, and Nevada counties (Aigner et al. 1995, Tecklin 1999), and most recently in Clover Valley (City of Rocklin) in southern Placer County (The California Black Rail Project 2006). Additional detections have been made recently at the Cosumnes River Preserve in South Sacramento County and Bidwell Park in Chico, Butte County (Central Valley Bird Club Site Guides).

DRAFT

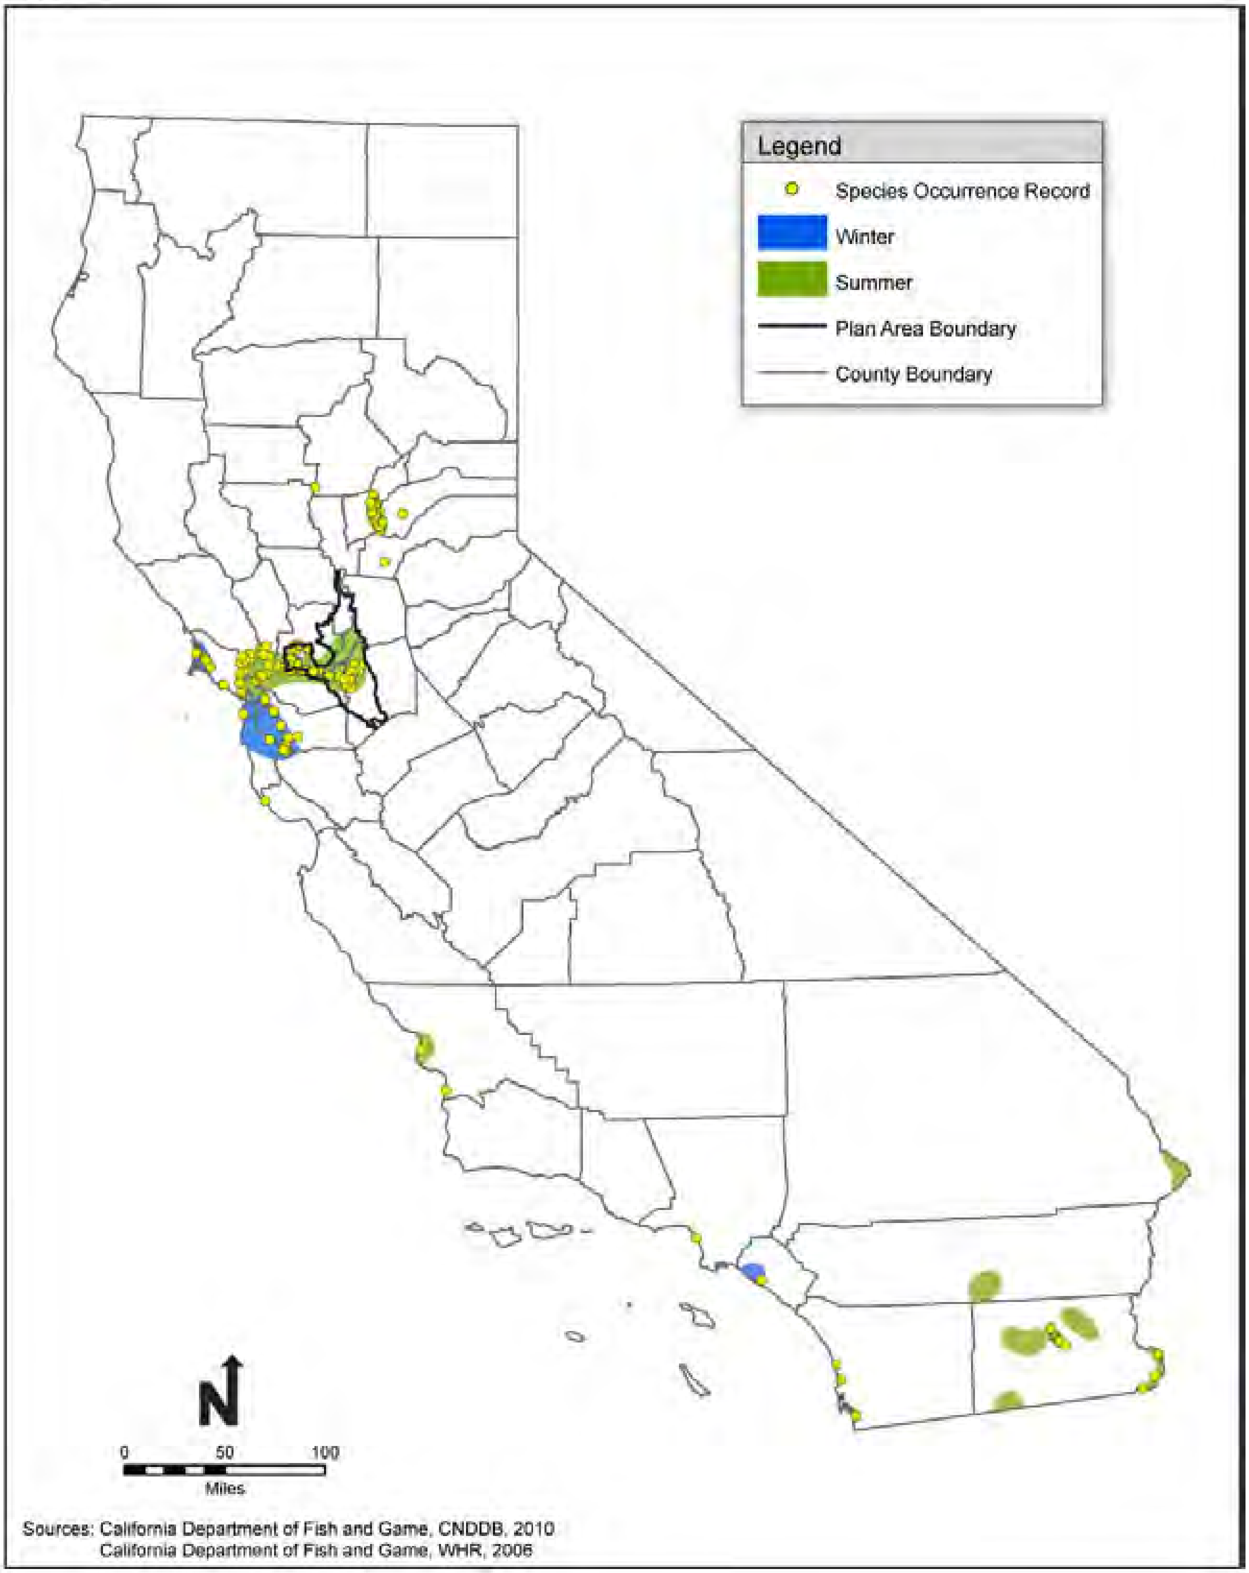

Figure A-26a. California Black Rail Statewide Range and Recorded Occurrences

1

Additional recent unconfirmed sightings from rice fields in the Butte Sink and Sutter County suggest that there may be down slope movement from the foothill breeding population.

Until 1994, the black rail was unknown from the Sacramento Valley except for a single winter record at the California Department of Fish and Game's (DFG) Gray Lodge Wildlife Area in Butte County. In 1994, a population of the rail was found occupying a freshwater marsh at the University of California's Sierra Field Station in Yuba County (Aigner et al. 1995). Further examination revealed that the species could be breeding at four separate freshwater marsh ponds within approximately 3.7 miles (6 kilometers) of each other. As a result, the DFG provided funding for a more regional survey effort that resulted in additional occurrences in Butte, Yuba, and Nevada Counties (Tecklin 1999). Since then, the University of California has continued with a study, the California Black Rail Study Project, that locates additional subpopulations in their Sierra Nevada foothill study area and examines how each of these isolated subpopulations are functioning as a metapopulation.

As of 2005, this ongoing study included 168 wetland sites in their sample, with 54 percent of these occupied by black rails (The California Black Rail Project 2005). These populations, and presumably others that remain undetected in the region, are considered to be year-round residents. Given the geographic extent of this metapopulation and the consistently high occupancy rate detected over the last five years, it is likely that additional subpopulations occur elsewhere in the Sacramento Valley and Sierra Nevada foothills.

Declines in populations of the black rail in California are a result of habitat loss and degradation along with an increase in exotic predators such as black rats and red foxes (Evens et al. 1991). However, because there were no estimates of historical population levels, the extent of population declines is not fully understood. Evens et al. (1991) examined relative abundance of rails at various locations within the species' range and determined that more than 80 percent of the remaining population is confined to the northern reaches of the San Francisco Bay estuary. They also determined that the species was subject to continuing and ongoing population decline due to habitat loss and/or degradation.

A26.2.2 Distribution and Status in the Plan Area

Within the San Francisco Bay and Sacramento-San Joaquin River Delta region, California black rail populations are restricted primarily to the remaining tidal marshlands of the northern San Francisco Bay estuary, and the vicinity of Suisun and Napa marshes (Figure A-26b). In Suisun Marsh, a high abundance of black rails have been found at east Mallard Island and moderate abundances at South Joice Island, Pacheco Creek, East Peyton Slough, Cutoff Island, Peytonia Slough, and Southampton Bay (Spautz et al. 2005). It is possible that a small population occurs in the vicinity of Little Honker Bay and on the north shore of Nurse Slough. In moderate abundances, black rails were found in the northern reaches of Suisun Bay in undiked marshes along the northern bank of Cutoff Slough from Beldonís Landing west to Suisun Slough.

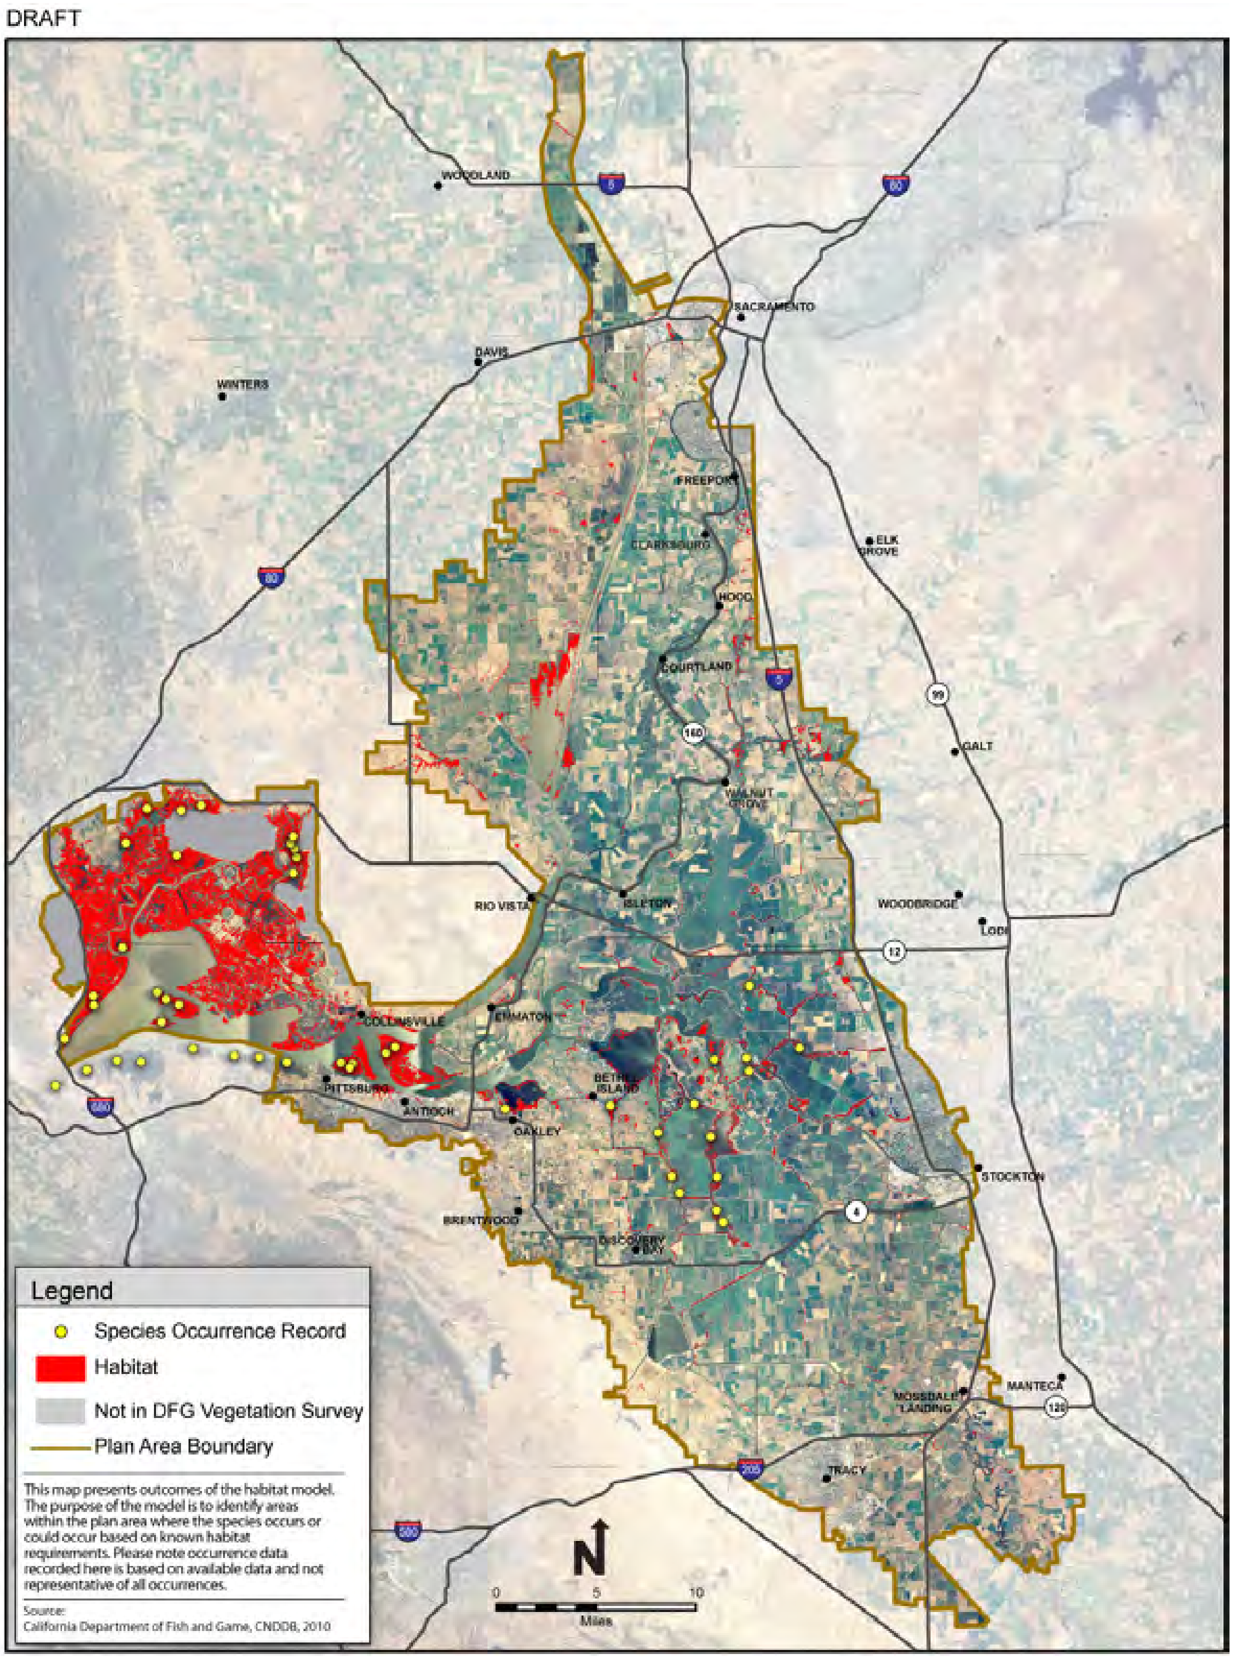

Figure A-26b. California Black Rail Habitat Model and Recorded Occurrences

Surveys conducted by DFG in the early 1990's found small numbers of black rails at several locations in the central Delta, including White, Little Potato, Disappointment, and Whiskey sloughs; mid-Channel Islands in Middle and San Joaquin rivers; Holland and Palm tracts; and Mildred, Bacon, and Mandeville islands (CNDDB 2008).

The National Audubon Society's Important Bird Areas Report for the Sacramento-San Joaquin Delta reports that California black rail occurs on most in-stream islands greater than 15 acres (6 hectares) that support marsh vegetation elevated above the high tide and wave line (National Audubon Society 2008).

Larger concentrations of black rail occur in the western portion of the Plan Area in the vicinity of Little Honker Bay and Kimble Island, and smaller concentrations on small in-channel islands, and other wetlands within the central Delta between State Route 12 (SR-12) and SR-4 (Figure A-26b). Overall, habitat availability is restricted to remnant wetland sites that are generally unavailable for agricultural uses. Insufficient data have been collected to estimate black rail populations within the Plan Area; however, the small populations found in the central Delta portion of the Plan Area likely represent a relatively small proportion of the San Francisco Bay/Sacramento-San Joaquin River Delta region. Regardless, these small populations that persist east of the Suisun Marsh are important relative to the overall range and dispersal capabilities of the species.

A26.3 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

California black rails inhabit tidal saltwater and brackish marshes, and freshwater marshes (Grinnell and Miller 1944, Manolis 1978, Spautz et al. 2005). A highly secretive and rarely observed bird, there appears to be a preference in coastal areas for tidal salt marshes dominated by dense pickleweed (*Sarcocornia*[1] spp.) with an open structure below. This provides a dense canopy for protective cover while providing nesting habitat and accessibility below the canopy (Evens and Page 1983). Rails are susceptible to predation by herons, egrets, northern harriers, short-eared owls, and several mammalian predators. A dense canopy that provides optimal cover is essential for survival.

Black rails tend to be associated with areas where *Schoenoplectus*[2] spp. and *Sarcocornia* border each other. Evens et al. (1991) found rails where there was a mosaic of *Juncus* (40 percent), *Schoenoplectus* (30 percent), *Triglochin* (10 percent), *Grindelia* (<10 percent), *Distichlis* (<10 percent), and *Typha* (<10 percent). In Suisun Marsh, presence of black rails occurs in conjunction with a pickleweed-alkali heath-American bulrush plant association in the high marsh zone. Data from Spautz et al. (2005) indicate that black rails prefer marshes that are close to water (bay or river), large, away from urban areas, and saline to brackish with a high proportion

[1]Formerly known as *Salicornia*.
[2]Formerly known as *Scirpus*.

of *Sarcocornia*, *Grindelia*, *Schoenoplectus maritimus*, *Juncus*, and *Typha*. Escape cover is critical to these birds. Rail nests consist of loosely-made, deep cups either at ground level or slightly elevated. Nests are concealed in dense marsh vegetation near the upper limits of tidal flooding (DWR 2001).

Away from coastal estuaries and salt marshes, black rails are restricted to breeding in freshwater marshes with stands of tule, cattail, bulrush, and sedge (*Carex* spp.) (Eddleman et al. 1994). These sites are very shallow (usually less than 3 centimeters [cm]), but require a perennial water source. A relatively narrow range of conditions is required for occupancy and successful breeding. Water depth is an important parameter for successful nest sites as rising water levels can prevent nesting or flood nests and reduce access to foraging habitat (Eddleman et al. 1994). Too little water will lead to abandonment of the site until the water source is reestablished. Primary factors determining their presence are annual fluctuations in water levels and shallow water depth (<3 cm) (Rosenberg et al. 1991, Eddleman et al. 1994, Conway et al. 2002). There is no information on minimum patch size for the California black rail in the Central Valley and Delta Region; however, in the foothills of the central Sierra Nevada, rails are in marshes ranging from 0.5 to 25 acres (0.2 to 10.1 hectares) in size, with 32 percent of occupied sites in wetlands less than 0.75 acres (0.3 hectares) (Tecklin 1999). The discovery of these Sierra Nevada populations suggest that the species is able to colonize isolated habitat patches (Aigner et al. 1995, Trulio and Evens 2000).

Black rails occur in marshland only, a habitat mostly destroyed or modified in the western United States since the mid-1800s (Atwater et al. 1979, Zedler 1982, Josselyn 1983, Nichols et al. 1986 as cited in DWR 2001). Populations and numbers have and will continue to decline as loss and alteration of habitat continues. Currently, the species is confined to mostly pristine remnants of historical tidal marshlands, mainly along the large tributaries and shoreline of northern San Pablo Bay, along the Carquinez Strait, and throughout parts of Suisun Bay (Evens et al. 1991, Spautz et al. 2005). The marshes of San Pablo and Suisun bays are important in that they are the last large refuge areas for a viable population. There is no evidence that black rails recolonize restored marshes for breeding (Evens et al. 1989).

A26.4 Life History

Description. The California black rail is a small (12- to 15-cm [4.7- to 5.9-inch]), secretive, marsh-associated species (Eddleman et al. 1994). They are black to gray in color with a small black bill, sides and back speckled with white, and a nape of deep chestnut brown (DFG 1999). Difficult to observe, rails are usually identified by their call.

Seasonal Patterns. Very little information is available on seasonal patterns, timing of reproduction, dispersal, or other activities. The breeding season begins as early as February with pair formation and extends through approximately early-to-mid June. Egg-laying peaks around May 1 (Eddleman et al. 1994). The species is generally known as a medium-distance migrant that winters in Mexico and Central America; however, recently discovered inland populations in California are thought to be year-round residents. At these locations, seasonal movements including juvenile dispersal and adult relocation to other wetland breeding sites occur each year sometime during the non-breeding season between approximately August and February (Tecklin 1999).

Reproduction. Black rails are monogamous birds. They build cup nests with a woven canopy in dead or new emergent vegetation over shallow water less than 3 cm (1.2 inches) in depth (Eddleman et al. 1994). They initiate egg-laying within a few days after nest construction is complete. Rails in California usually lay one single brood with an average clutch size of 6 eggs (range equals 3 to 8 eggs) (Eddleman et al. 1994). The incubation period ranges from 17 to 20 days and both adults apparently incubate the eggs (Flores and Eddleman 1993); however, there is very limited data. After hatching, the semi-precocial young leave the nest within a day, but at least one parent continues to brood the young for several additional days (Eddleman et al. 1994). There is limited information on length of brooding period, timing of fledging, parental care, or reproductive success.

Home Range/Territory Size. California black rails have small home ranges in the breeding season. In north San Francisco Bay tidal marshes, fixed-kernel home ranges (representing 95 percent utilization distribution) averaged 1.5 acres (0.6 hectare) and core use areas (representing the 50 percent utilization distribution) averaged 0.3 acre (0.1 hectare) (Tsao et al. in press). Using a different calculation method, Flores and Eddleman (1991) found that California black rail minimum convex polygon (MCP) home ranges in Arizona averaged 1.1 acres (0.4 hectare). For comparison, MCP home ranges for San Francisco Bay black rails averaged 0.6 acre (0.2 hectare) (Tsao et al. in press). Studies of other rail species showed increased home range sizes outside of the breeding season (Bookhout and Stenzel 1987, Conway 1990); however, black rails in Arizona, where water levels remain steady throughout the year, showed no difference in home range size across seasons (Flores and Eddleman 1991).

Foraging Behavior and Diet. Very little information is available on the foraging behavior of the black rail. The species is assumed to be an opportunistic daytime feeder that forages exclusively within the wetland habitat, presumably on or near the ground at the edges of emergent vegetation. Their diet consists of insects, small mollusks, amphipods, and other invertebrates, and seeds from bulrushes (*Schoenoplectus* spp.) and cattails (*Typha* spp.) (Eddleman et al. 1994).

A26.5 Threats and Stressors

Throughout its range, the primary threat to California black rail is the loss and fragmentation of habitat from urbanization, flood control projects, agricultural practices, and hydrologic changes that affect water regimes. The most significant historical threat was the draining of tidal marshes, which may be responsible for over 90 percent of the population declines of this species, and which is still occurring in some areas, albeit at a slower rate.

At inland sites, agricultural practices, livestock grazing, and urbanization may threaten individual subpopulations. Use of pesticides, including those used for mosquito control programs may also have unintended consequences for black rails. These isolated subpopulations are also susceptible to metapopulation dynamics and stochastic variables (Evens et al. 1991). Other potential threats include increased predation by domestic cats and by native predators as a result of hydrologic and vegetation changes that increase black rail susceptibility to predation; pollution and its effect on freshwater marshes; and collisions with automobiles and utility lines.

There are significant data gaps relating to many aspects of the ecology of the black rail. Data gaps include minimum patch size for successful breeding colonies, parameters of population sinks, sources of mortality, site fidelity and movement in winter, as well as winter diet and foraging ecology.

Since black rails reside year-round in tidal marshes throughout the San Francisco Bay-Delta region where sediment methylmercury (MeHg) production is high (Marvin-DiPasquale et al. 2003), they may be particularly vulnerable to MeHg contamination. Black rails at north San Francisco Bay tidal marshes had lower MeHg concentrations than other waterbirds at San Francisco Bay (Ackerman et al. 2007, Tsao et al. 2009), likely due to their low-trophic-level invertebrate diet (Eddleman et al. 1994) However, 78 percent of black rail feather samples were above levels associated with adverse reproductive effects in mallards and ring-necked pheasants (Heinz 1979, Eisler 2000); and 9 percent of blood samples fell within the range for moderate risk of reproductive effects in common loons (Evers et al. 2008). Since MeHg sensitivity varies widely among species, the effects of MeHg contamination on the San Francisco Bay black rail population are unclear.

A26.6 Relevant Conservation Efforts

The California black rail is a covered species in several neighboring regional habitat conservation plans/natural communities conservation plans, including the approved San Joaquin County Multi-species Habitat Conservation and Open Space Plan and the proposed Solano County Multispecies Habitat Conservation Plan, the Yolo County Natural Heritage Program Plan, and the Butte Regional Conservation Plan. Several management plans have outlined threats to California black rails and provided recommendations for conservation (Trulio and Evens 2000). Recommendations focus primarily on protection of high-quality habitats. However, few actual habitat protection or species conservation efforts specific to the California black rail have been undertaken to date.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designates the California black rail as "Contribute to Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its

control and within its scope that are necessary to contribute to the recovery of the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

A26.7 SPECIES HABITAT SUITABILITY MODEL

Model Approach. BDCP Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf 2007. Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers, connectivity between habitat types, and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The California black rail model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), USDA 2005 aerial photography, and DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable California black rail habitat in the Plan Area. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Habitat. In the central Delta portion of the Plan Area, California black rail may be found in remaining patches of tidal freshwater emergent wetland found along the perimeter of sloughs and on in-channel islands of larger watercourses. (Figure A-26b) (National Audubon Society 2008, Gifford pers. comm.). These are remnant wetland sites that are generally unavailable for agricultural uses. Primary habitat for this species in the Suisun Marsh is *Sarcocornia*-dominated tidal marshlands (Trulio and Evens 2000, Spautz and Nur 2002). However, the remaining patches of this habitat type within the Plan Area west of Sherman Island are considered too small and fragmented to support this species and are thus excluded from this model.

Potentially suitable habitat within the Plan Area includes all *Schoenoplectus* and *Typha*-dominated Tidal and Nontidal Freshwater Emergent Wetland in patches greater than 0.5 acres. Within the Suisun Marsh, suitable habitat includes all *Schoenoplectus* and *Typha*-dominated, and *Saarcornia*-dominated patches greater than 0.5 acres. Patches less than 5 acres that are within 100 feet of larger patches are also included.

Black rail habitat in the Delta includes the following types from the BDCP composite vegetation layer:

- Alkali seasonal wetland complex
  - *Distichlis spicata – Salicornia virginica;*[3]
  - Pickleweed (*Salicornia virginica*); and
  - *Salicornia virginica – Cotula coronopifoli.*

[3] Currently known as *Sarcocornia pacifica*.

- Nontidal freshwater perennial emergent wetlands
    - Broad-leaf cattail (*Typha latifolia*);
    - American bulrush (*Scirpus americanus*);
    - Hard-stem bulrush (*Scirpus acutus*);
    - Mixed *Scirpus*/floating aquatics (*Hydrocotyle – Eichhorinia*) complex;
    - Mixed *Scirpus*/submerged aquatics (*Egeria-Cabomba-Myriophyllum* spp.) complex;
    - Mixed *Scirpus* mapping unit;
    - Narrow-leaf cattail (*Typha angustifolia*);
    - *Salicornia*[4]/annual grasses;
    - *Scirpus acutus – Typha latifolia – Phragmites australis*;
    - *Scirpus acutus – Typha angustifolia*;
    - *Scirpus acutus* pure; and
    - *Scirpus acutus – Typha latifolia*.
- Tidal freshwater emergent wetland and tidal brackish emergent wetland
    - Mixed *Scirpus*[5] mapping unit;
    - Mixed *Scirpus*/floating aquatics complex;
    - Mixed *Scirpus*/submerged aquatics complex;
    - Hard-stem bulrush (*Scirpus acutus*);
    - *Scirpus acutus* pure;
    - *Scirpus acutus – Typha angustifolia;*
    - *Scirpus acutus – Typha latifolia;*
    - *Scirpus acutus* – (*Typha latifolia*) – *Phragmites australis;*
    - California bulrush (*Scirpus californicus*);
    - *Scirpus californicus – Eichhornia crassipes;*
    - *Scirpus californicus – Scirpus acutus;*
    - American bulrush (*Scirpus americanus*);
    - Narrow-leaf cattail (*Typha angustifolia*); and
    - *Typha angustifolia – Distichlis spicata.*

---

[4] Currently known as *Sarcocornia*.
[5] Currently known as *Schoenoplectus*.

Black rail habitat in the Suisun Marsh and Yolo Basin includes the following types from the BDCP composite vegetation layer:

- *Scirpus* (*californicus or acutus*)*/Rosa;*
- *Scirpus* (*californicus or acutus*)/wetland herb;
- *Scirpus* (*californicus or acutus*)-*Typha* spp.;
- *Scirpus americanus* (generic);
- *Scirpus americanus/Lepidium;*
- *Scirpus americanus/Potentilla;*
- *Scirpus californicus/S. acutus;*
- *Scirpus maritimus;*
- *Scirpus maritimus/Salicornia*[6]*;*
- *Typha angustifolia/Distichlis;*
- *Typha angustifolia/S. americanus;*
- *Typha* species (generic);
- Bulrush - Cattail freshwater marsh NFD super alliance;
- *Scirpus americanus/S. Californicus-S. acutus;*
- *Scirpus maritimus/Sesuvium;*
- *Typha angustifolia;*
- *Typha angustifolia/Phragmites;*
- *Typha angustifolia/Polygonum-Xanthium-Echino;*
- *Typha angustifolia/S. americanus;*
- *Distichlis/Salicornia;*
- *Salicornia* (generic);
- *Salicornia virginica;*
- *Salicornia/Atriplex;*
- *Salicornia/Cotula;*
- *Salicornia*/annual grasses;
- *Salicornia/Crypsis;*

[6] Currently known as *Sarcocornia*.

- *Salicornia/Polygonum-Xanthium-Echinochloa;* and
- *Salicornia/Sesuvium.*

Assumptions. There is limited information available on minimum habitat patch size for black rail in the Delta region. Spautz and Nur (2002) and Spautz et al. (2005) determined that larger intact marshes in the San Francisco Bay estuary were required for occupancy; however, they did not establish a minimum patch size. Tsao et al. (in press) calculated an average home range size of 1.5 acres and average core use areas (representing the 50 percent utilization distribution) of 0.3 acres for the San Francisco Bay estuary. Recently discovered Sierra Nevada foothill populations occur in emergent marsh habitats as small as 0.5 acres (Tecklin 1999). However, the extent to which minimum habitat patch size corresponds to home range size is unknown. The California Department of Fish and Game conducted surveys for California black rail in the central Delta in the early 1990s and found occupancy on in-channel islands that were at least 15 acres and not subject to agricultural or other disturbances and that supported marsh vegetation elevated above the high tide and wave line (Gifford pers. comm.). However, while the occupied islands were at least 15 acres, suitable habitat may have covered only a portion of the islands. The extent to which habitat conditions or requirements in the San Francisco Bay estuary or the Sierra Nevada foothills may not be transferable to the rather unique habitat conditions in the Delta is unclear. However, for purposes of this model, a minimum patch size of 0.5 acres is used, relying on data from Tecklin (1999) and Tsao et al. (*in press*). However, this may result in an overestimate of potentially occupied habitat for black rails. To address habitats fragmented by roads or channels, we also assume that patches that are smaller than 5 acres but are within 100 feet of larger patches are potentially occupied.

Other important factors that determine occupancy include water depth and a perennial water source. Very shallow water (usually <1.2 inches) is required. In general, a relatively narrow range of conditions is required for occupancy and successful breeding (Eddleman et al. 1994). For purposes of this model, it is assumed that these conditions are met in all *Schoenoplectus* and *Typha*-dominated tidal freshwater emergent wetlands or tidal brackish emergent wetlands greater than 0.5 acres. This also likely results in an overestimate of potentially occupied habitat for this species.

A26.8 RECOVERY GOALS

A USFWS recovery plan has not been prepared for this species and no recovery goals have been established; however, the CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designates the California black rail as "Contribute to Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its control and within its scope that are necessary to contribute to the recovery of the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

APPENDIX A27. CALIFORNIA CLAPPER RAIL (*RALLUS LONGIROSTRIS OBSOLETUS*)

A27.1 LEGAL STATUS

The California clapper rail (*Rallus longirostris obsoletus*) is state and federally listed as endangered. The species was listed by the California Fish and Game Commission pursuant to the California Endangered Species Act (Fish and Game Code, Sections 2050 et seq.) on June 27, 1971, and by the U.S. Fish and Wildlife Service (USFWS) pursuant to the federal Endangered Species Act on October 13, 1970 (35 FR 16047). The California clapper rail is also designated as a state Fully Protected species.

Critical habitat has not been designated for this species.

A27.2 SPECIES DISTRIBUTION AND STATUS

A27.2.1 Range and Status

The California clapper rail is one of three subspecies of clapper rail (including light-footed clapper rail [*R.l. levipes*] and Yuma clapper rail [*R.l. yumanensis*]) listed as endangered under both state and federal endangered species acts.

The historical range of the California clapper rail extended within the coastal California tidal marshes from Humboldt Bay southward to Elkhorn Slough and Morro Bay, and estuarine marshes of San Francisco Bay and San Pablo Bay to the Carquinez Strait. Historically, the highest densities of California clapper rails existed in south San Francisco Bay (DWR 1994, USFWS 1998, LSA 2007).

The current distribution is limited to San Francisco Bay, San Pablo Bay, Suisun Bay, and tidal marshes associated with estuarine sloughs draining into these bays (Figure A-27a) (USFWS 1998, Albertson and Evens 2000, DFG 2000). The USFWS reports that there are populations in all of the larger tidal marshes in South San Francisco Bay, and the distribution in the North Bay is patchy and discontinuous, primarily in small, isolated habitat fragments (USFWS 1998). Small populations are widely distributed throughout San Pablo Bay and at various locations throughout the Suisun Marsh Area (Carquinez Strait to Browns Island, including tidal marshes adjacent to Suisun, Honker, and Grizzly bays) (USFWS 1998).

California clapper rails were historically abundant throughout much of the San Francisco Bay estuary. Sport and market hunting significantly reduced populations in the late nineteenth and early twentieth centuries. Population levels recovered following passage of the Migratory Bird Treaty Act in 1913; however, with increasing loss and fragmentation of tidal marshes for salt ponds, agricultural land, and bayfill, available habitat continued to be reduced.

DRAFT

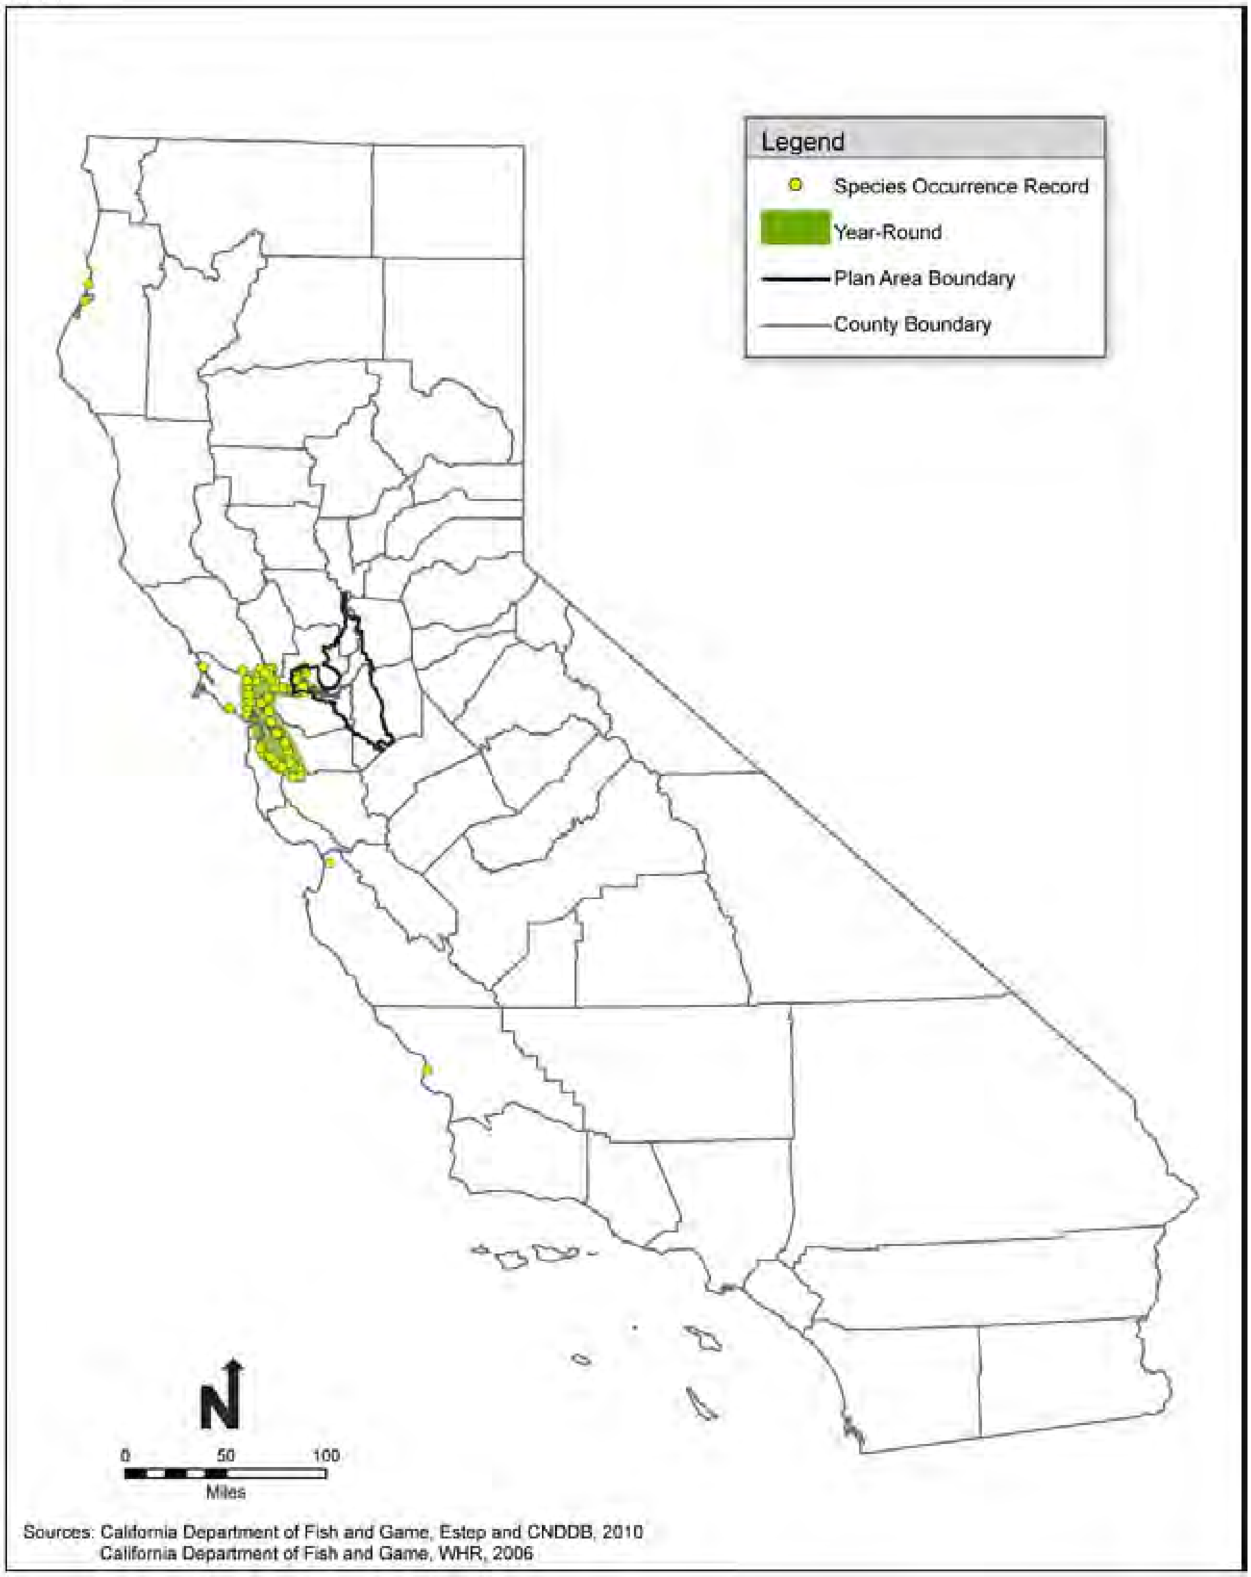

Figure A-27a. California Clapper Rail Statewide Range and Recorded Occurrences

1

Of the 193,800 acres of tidal marsh that bordered San Francisco Bay in 1850, about 30,100 acres currently remain (Dedrick 1989), representing an 84 percent reduction of available habitat.

In the early 1970s, California clapper rail populations were estimated at 4,200 to 6,000 individuals (Gill 1979). Loss and fragmentation of habitat continued over the following two decades resulting in a total rail population of approximately 500 birds in 1991, 300 of which are estimated to occur in the South San Francisco Bay (USFWS, unpubl. data).

Since then, management activities, including predator management, have resulted in population increases with the current estimate at approximately 450 to 600 pairs (USFWS unpubl. data). Of these, 195 to 282 pairs are estimated to occur in the North San Francisco Bay population, which includes the Suisun Marsh (Collins et al. 1994).

A27.2.2 Distribution and Status in the Plan Area

There are no reported occurrences of California clapper rail within the Plan Area (Figure A-27b); however, there are numerous reported occurrences in and around the Suisun Marsh Restoration Opportunity Area (ROA). Isolated patches of suitable habitat may occur within the Plan Area as far east as the western edge of Sherman Island.

Harvey (1980) reported the first California clapper rail in the Suisun Marsh at Cutoff Slough in 1978, which extended their range east of the San Francisco Bay area. A coordinated clapper rail survey was conducted by the San Francisco Bay Bird Observatory throughout the estuary between 1983 and 1986, resulting in two detections at the upper end of First Mallard Branch. Additional detections were made in 1986 at the Concord Naval Weapons Station (O'Neil 1988). Subsequent surveys, conducted by DFG and DWR, confirmed presence of the species in several locations in the Suisun Marsh including: Hill Slough, Cutoff Slough, First and Second Mallard branches, Suisun Slough from Goodyear Slough to Suisun Bay, Suisun Bay shoreline at the Suisun Marsh Reserve Fleet, Ryer Island, Point Edith Marsh, mouth of Boynton Slough, Union Creek, McCoy Creek and Suisun Slough at Morrow Island (DWR 1994).

A27.3 Habitat Requirements and Special Conditions

Throughout their distribution, California clapper rails occur within a range of salt and brackish marshes. In south and central San Francisco Bay and along the perimeter of San Pablo Bay, rails typically inhabit salt marshes dominated by pickleweed (*Sarcocornia pacifica*[1]) and Pacific cordgrass (*Spartina foliosa*). Pacific cordgrass dominates the middle marsh zone throughout the south and central Bay (USFWS 1998).

[1]Formerly known as *Salicornia virginica.*

DRAFT

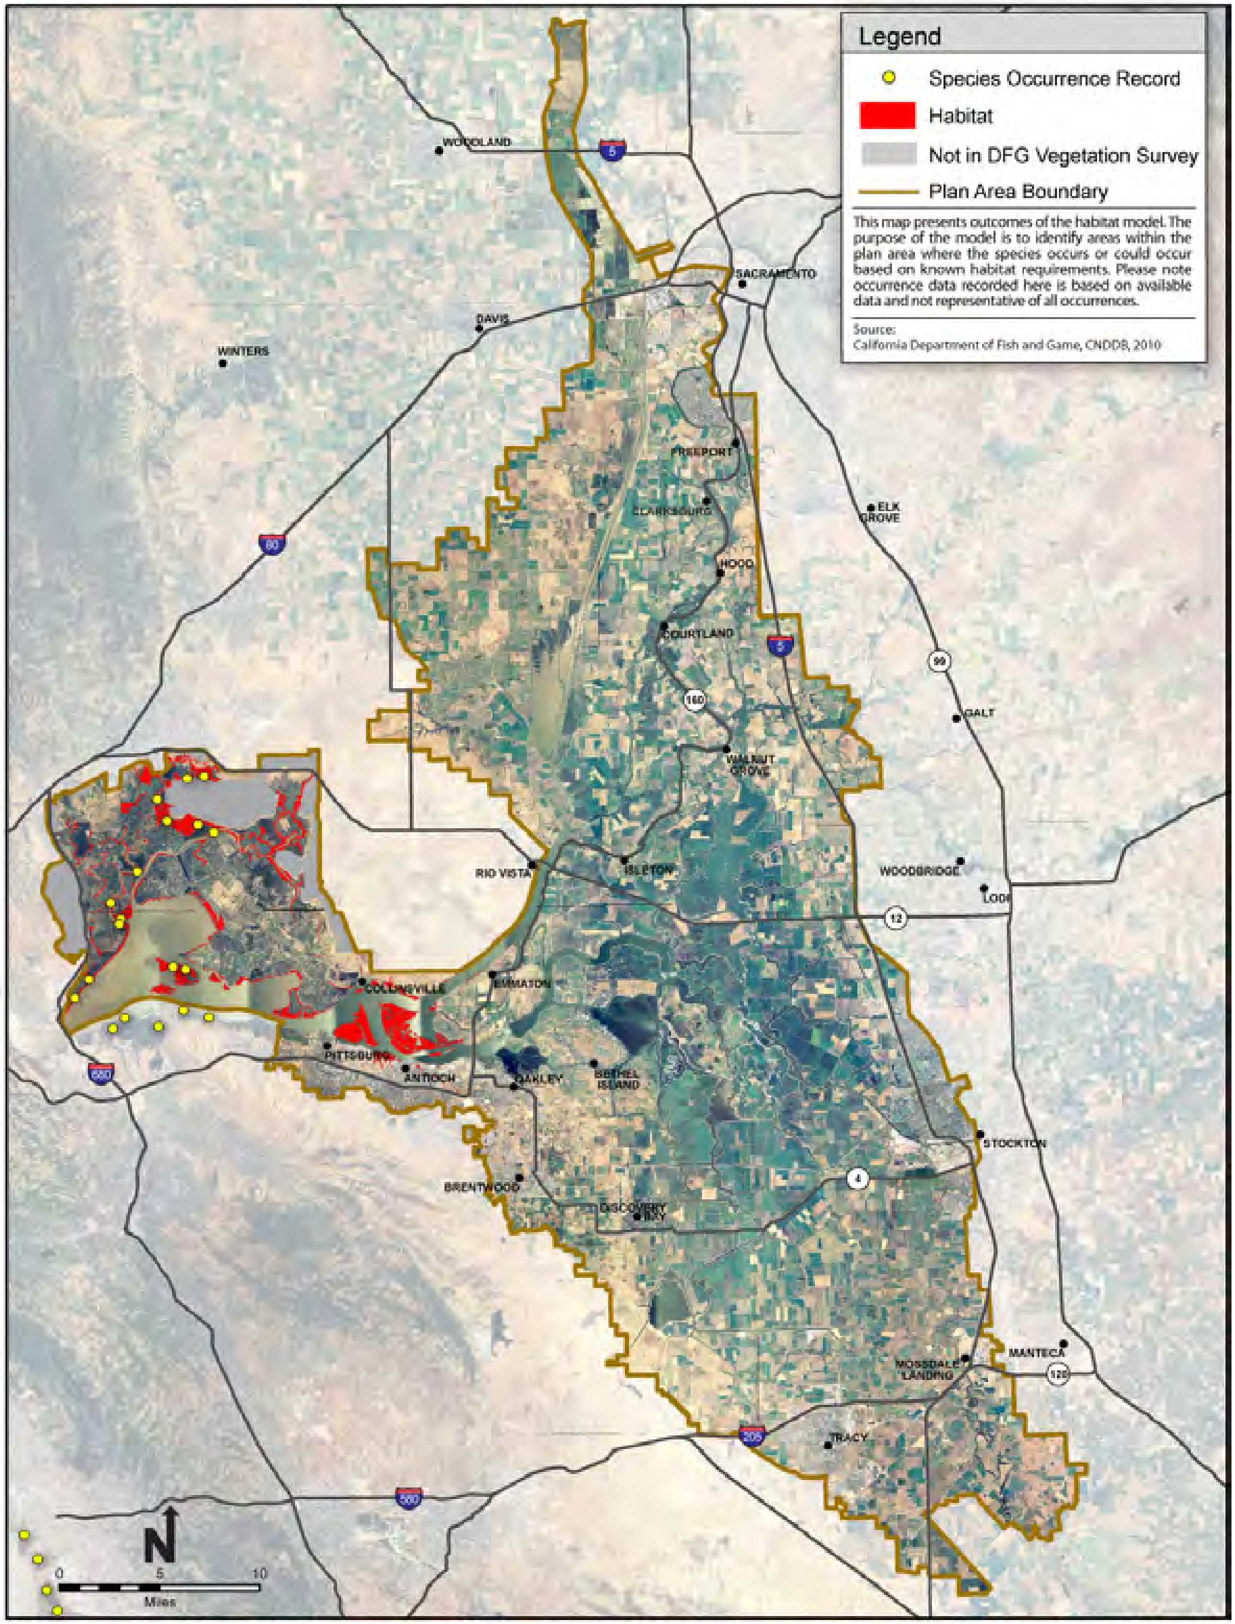

Figure A-27b. California Clapper Rail Habitat Model and Recorded Occurrences

1

In the North Bay (Petaluma Marsh, Napa-Sonoma Marshes, Suisun Marsh), clapper rails also live in tidal brackish marshes that vary significantly in vegetation structure and composition. Use of brackish marshes by clapper rails is largely restricted to major sloughs and rivers of San Pablo Bay and Suisun Marsh, and along Coyote Creek in South San Francisco Bay. Clapper rails have rarely been recorded in nontidal marsh areas (USFWS 1998).

Population density is higher in habitats that exceed 100 hectares (247 acres) in size. Other factors that affect density include proximity of suitable marsh habitats to each other, buffer areas between marsh and upland areas, marsh elevation, and hydrology (LSA 2007). Rail densities have shown to be lower in more brackish habitats resulting from freshwater outflows, possibly due to the resulting change in vegetation (Collins et al. 1994).

Nesting. In saline emergent wetlands, California clapper rails nest mostly in lower zones near tidal sloughs and where cordgrass (*Spartina foliosa*) is abundant (Harvey 1980, Zembal and Massey 1983, Eddleman and Conway 1998). Clapper rails build a platform concealed by a canopy of woven cordgrass stems or pickleweed and gumweed (Harvey 1980). Nests are constructed only as high as necessary to prevent inundation while preserving a natural cover of vegetation. Clapper rail nests are described as a mass or heap of vegetation, deeply cupped and securely woven to the surrounding vegetation that allows for flotation during extreme tidal events. Zucca (1954) discovered that although the nests are somewhat buoyant, they do not remain intact through a series of high tides. Clapper rails also use dead drift vegetation as a platform (Harvey 1990). The vegetation used to construct clapper rail nests is partly determined by the time of the nesting and the tidal influence (Zucca 1954). In fresh or brackish water, clapper rails construct nests in dense cattail or bulrush (Harvey 1980, LSA 2007).

Foraging. California clapper rails forage in higher marsh vegetation, along the vegetation and mudflat interface, and along tidal creeks.

A27.4 LIFE HISTORY

Description. The clapper rail is a coot-sized bird that is generally gray-brown above and buff-cinnamon below with brownish-gray cheeks and black-and-white barred flanks. It has a short neck, slightly down-curved bill, and a short tail cocked upward, revealing a white patch. Overall length ranges from 33 to 48 centimeters (cm) (13 to 19 inches), and bill length is greater than 5 cm (2 inches) (Lewis and Garrison 1983). The sexes differ only in size with males slightly larger than females. Juveniles have a paler bill and darker plumage, with a gray body, black flanks and sides, and indistinct light streaking on flanks and undertail coverts. California clapper rail is larger and of grayer plumage than light-footed clapper rail and Yuma clapper rail. Clapper rails are secretive, elusive, and difficult to observe in dense vegetation. Census data are usually taken by listening for vocal responses to recorded calls. When evading discovery, they typically freeze, hide in small sloughs or under overhangs, or run rapidly through vegetation or along slough bottoms. They prefer to walk or run over land rather than fly, and generally walk upright.

When flushed, they normally fly only a short distance before landing. They can swim well, although swimming is only used to cross sloughs or escape immediate threats at high tide (USFWS 1998, LSA 2007).

Seasonal Patterns. The California clapper rail is apparently non-migratory; however, some seasonal movements occur probably in response to seasonal hydrological changes and their effect on habitat availability and quality (Rozengurt et al. 1987, Collins et al. 1994). Post-breeding dispersal has also been recorded in late fall and early winter (Orr 1939, Wilbur and Tomlinson 1976, Harvey unpubl. data as cited in LSA 2007). In general, these findings indicate that while clapper rails tend to be more dispersed within the marsh following the nesting season, in general they appear to move very little between seasons and between nesting or core-use territories (Albertson 1995 as cited in LSA 2007).

Reproduction. The nesting season for California clapper rails begins mid-March and extends into August with peaks observed in early May and late June (Gill 1973, Harvey 1980). Clutch range is 6 to 10 eggs (Wilbur and Tomlinson 1976). Both the male and female incubate the eggs for approximately 18 to 29 days. Harvey (1980) reports hatching success of approximately 38 percent in the San Francisco Bay area.

Foraging Behavior and Diet. Clapper rails are most active in early morning and late evening, when they forage in marsh vegetation in and along creeks and mudflat edges. Most feeding is surface-gleaning and probing (Zembal and Fancher 1988), which occurs by walking a few steps, thrusting their beaks into the mud up to eye level, then walking a few more steps, then repeating the probing (Wilbur and Tomlinson 1976). Less frequent foraging behaviors include surface gleaning, fishing, and scavenging.

Moffitt (1941) examined the diet of California clapper rail by volumetric content of rail stomachs with the following results: ribbed horse mussels (56.5 percent), spiders (Lycosidae, 15 percent), seeds and hulls of cordgrass (14.6 percent), little macoma clam (*Macoma balthica*, 7.6 percent), mud crabs (3.2 percent), worn-out nassa (*Ilyanassa obsoletus*, 2 percent), insects, clam worms (*Nereis* spp.), and carrion (1.1 percent) (Eddleman and Conway 1998). Overall, the content included over 85 percent animal matter and 14.6 percent vegetable matter.

A27.5 THREATS AND STRESSORS

Habitat Degradation. Degradation of tidal marsh habitats continues to be the most significant threat to California clapper rail. Tidal marshes have been reduced by 84 percent since historical times (Dedrick 1989). While the loss of tidal marsh habitat through filling and diking has largely been curtailed, other current factors associated with declining populations include the conversion of salt marshes to brackish marshes due to freshwater discharges from sewage treatment plants, a progressive rise in sea level, invasion of runoff, industrial discharges, and sewage effluent (Williams 1985, Ohlendorf and Fleming 1988, Ohlendorf et al. 1989, Harvey 1990, Lonzarich et al. 1990, Foerster and Takekawa 1991, Leipsic-Baron 1992, DFG 2000 as cited in LSA 2007).

The suitability of many marshes for clapper rails is further limited, and in some cases precluded, by their small size, fragmentation, and lack of tidal channel systems and other micro-habitat features. These limitations render much of the remaining tidal marsh acreage unsuitable or of low value for the species. In addition, tidal amplitudes are much greater in South San Francisco Bay than in San Pablo or Suisun bays (Atwater et al. 1979). Consequently, many tidal marshes are completely submerged during high tides and lack sufficient escape habitat, likely resulting in nesting failures and high rates of predation. The reductions in carrying capacity in existing marshes necessitate the restoration of larger tracts of habitat throughout the current range of the species to maintain stable populations.

Predation. California clapper rails are subject to heavy predation from nonnative species such as red fox (*Vulpes vulpes*), feral cat (*Felis domesticus*) and Norway rat (*Rattus norvegicus*) as well as various native mammals and raptors (Foerster et al. 1990, Albertson 1995 as cited in LSA 2007, USFWS 1998, DFG 2000). The fragmentation of habitat through the construction of dikes and levees has increased and facilitated predation of clapper rails because terrestrial predators use these features as corridors to access clapper rail habitat (Foerster et al. 1990, Burkett and Lewis 1992). Urban development adjacent to marshland habitat has also increased predation by native predators such as raccoons, which thrive in urban areas, and raptors, which use electric power transmission lines as hunting perches (USFWS 1998). Red foxes, the predator that may pose the most serious threat to California clapper rails, have not yet been detected in the Suisun Marsh; however, river otters (*Lutra canadensis*) are common in the Suisun Marsh area and could also prey on eggs of clapper rails (Albertson and Evens 2000, LSA 2007).

Mercury Contamination. Mercury contamination has been detected in eggs and embryos in the South San Francisco Bay (Schwarzbach et al. 2006). Mortality and embryonic developmental issues associated with mercury contamination could potentially have long-term effects on reproduction and recruitment.

A27.6 RELEVANT CONSERVATION EFFORTS

The Suisun Marsh has been the subject of various conservation efforts for many years, particularly with respect to development and water quality-related issues within its boundaries. The following from the California Department of Water Resources Suisun Marsh Program (http://www.iep.water.ca.gov/suisun/program/index.html) summarizes the major agreements, management plans, and legislation that have directed management of the Suisun Marsh since the mid-1970s. These efforts focus on the preservation and restoration of tidal marsh habitats.

The Nejedly-Bagley-Z'Berg Suisun Marsh Preservation Act (1974). The California Legislature enacted the Suisun Marsh Preservation Act that protects the marsh from urban development. It required the San Francisco Bay Conservation and Development Commission (BCDC) to develop a plan for the marsh and provides for various restrictions on development within marsh boundaries.

Suisun Marsh Protection Plan (1976). This plan was developed by the BCDC and defines and limits development within primary and secondary management areas for the "future of the wildlife values of the area as threatened by potential residential, commercial and industrial development." It recommends that the State purchase 1,800 acres, and maintain water quality. While the focus of the plan is on maintaining waterfowl habitat, it also addresses the importance of tidal wetlands and recommends restoring historical marsh areas to wetland status (managed or tidal).

The Suisun Marsh Protection Act (1977). This bill adopts and calls for implementation of the Suisun Marsh Protection Plan. AB 1717 designates the BCDC as the state agency with regulatory jurisdiction of the marsh and calls for the Suisun Resource Conservation District to have responsibility for water management in the marsh. The bill identifies (and focuses on) actions for the preservation of waterfowl needs along with the retention of the diversity of wildlife. It states that land within the Suisun Marsh should be acquired for public use or resource management if it is suitable for restoration to tidal or managed marsh, but that such restoration cannot be required as a condition of private development.

State Water Resources Control Board (SWRCB) Water Rights Decision 1485 (1978). SWRCB adopted the Water Quality Control Plan for the Sacramento-San Joaquin Delta and issued Water Rights Decision 1485. The Decision includes: channel water salinity standards from October to May and preserves the area as brackish water tidal marsh. It set water quality standards in the Marsh as a condition of export pumping. These come from DFG's recommendations, which were based on (1) the relative value of marsh plants as duck food; (2) the influence of soil salinity and other factors on distribution and growth of marsh plants; and (3) the relationships between channel water salinity and soil salinity. DFG concluded that improved management practices, improved drainage, water control facilities, and adequate quality of water were needed to achieve desired soil salinity conditions for waterfowl food plants.

Plan of Protection for the Suisun Marsh (1984). DWR and the U.S. Bureau of Reclamation (USBR) developed and began implementing the Plan of Protection (POP) in accordance with D-1485. The POP implementation strategy was to construct large facilities and distribution systems to meet salinity standards (lower channel water salinity), in lieu of significant Central Valley Project/State Water Project (CVP/SWP) storage releases estimated as high as 2 million acre-feet in dry/critical water years. The six-phase POP was the programmatic blue print (required by the SWRCB and embodied in the original Suisun Marsh Preservation Agreement). Two of the six phases were completed including the Initial Facilities and the Suisun Marsh Salinity Control Gates.

1. **Suisun Marsh Preservation Agreement (1987)**. This contractual agreement between DWR, United States Bureau of Reclamation (USBR), DFG and Suisun Resource Conservation District (SRCD) contains provisions for DWR and USBR to mitigate the effects on Suisun Marsh channel water salinity from the SWP and CVP operations and

other upstream diversions. The Suisun Marsh Preservation Agreement requires DWR and USBR to meet salinity standards, sets a timeline for implementing the POP, and delineates monitoring and mitigation requirements. The Suisun Marsh Monitoring Agreement and the Suisun Marsh Mitigation Agreement were also signed at this time. The Suisun Marsh Mitigation Agreement defined habitat requirements to mitigate effects of facilities and operations and the Suisun Marsh Monitoring Agreement defines requirements for monitoring salinity and species in the Suisun Marsh.

Bay-Delta Accord (1994). On December 15, 1994, state and federal agencies, working with agricultural, environmental and urban stakeholders, reached agreement on water quality standards and related provisions that would remain in effect for three years. This agreement, known as the Bay-Delta Accord, was based on a proposal developed by the stakeholders. Elements of the agreement include:

- Springtime export limits expressed as a percentage of Delta inflow.
- Regulation of the salinity gradient in the estuary so that a salt concentration of two parts per thousand (X_2) is positioned where it may be more beneficial to aquatic life.
- Specified springtime flows on the lower San Joaquin River to benefit Chinook salmon.
- Intermittent closure of the Delta Cross Channel gates to reduce entrainment of fish into the Delta.

SWRCB Water Quality Control Plan (1995-1998). In 1994, wildlife and fishery agencies and urban water users expressed concerns about the appropriateness of western Suisun Marsh channel water salinity standards. The SWRCB, in the Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary, May 1995, modified the Suisun Marsh salinity objectives. Modeling analysis by the Suisun Marsh Planning Program showed that Suisun Marsh standards would be met most of the time at all Suisun Marsh compliance stations. Some standard exceedances would be expected in the western Suisun Marsh that participants to the Suisun Marsh Preservation Agreement (SMPA) agreed could be mitigated by more active water control by landowners.

SWRCB Water Rights Decision 1641 (1999). The SWRCB issued Decision 1641 in December 1999, which updated salinity standards for Suisun Marsh. Increased outflow and salinity requirements for the Bay-Delta provided indirect benefits to the Suisun Marsh. DWR proposed that the SWRCB adopt the Amendment Three actions for Suisun Marsh in this Decision. The SWRCB was unable to adopt Amendment Three actions because the Section 7 consultation with the USFWS had not concluded. However, the SWRCB did relieve USBR and DWR of its responsibility in meeting salinity objectives at S-35 and S-97 in the western Suisun Marsh.

Suisun Marsh Charter Implementation Plan (2001). The Suisun Marsh Charter was completed in 2001 and commenced development of an Implementation Plan. Charter participants collaborated on a joint presentation to the State of the Estuary Conference on the principles of the Charter Plan including coordinated water quality, endangered species, and heritage value protection in the Suisun Marsh.

Habitat Management, Preservation, and Restoration Plan (2003). The expansion of the Charter process to include additional federal and state agencies to develop a Suisun Marsh Plan that will balance the goals and objectives of the Bay-Delta Program, SMPA, and other management and restoration programs within the Suisun Marsh in a manner that is responsive to the concerns of all stakeholders and is based upon voluntary participation by private landowners.

In addition, several facilities have been constructed in the Suisun Marsh to protect and improve water quality and protect and enhance wildlife habitat including:

- Roaring River Distribution System (1979-80);
- Morrow Island Distribution System (1979-80);
- Goodyear Slough Outfall (1979-80);
- Suisun Marsh Salinity Control Gates (1988); and
- Cygnus and Lower Joyce Facilities (1991).

Several tidal marsh restoration projects are also planned or being implemented within the range of the California clapper rail. These projects, implemented through the direction or support of the San Francisco Bay National Wildlife Refuge (NWR), National Biological Service, East Bay Regional Park District, Regional Water Quality Control Board, DFG, and the City of San Jose include the following:

- Restoration of the 1,500-acre Napa Marsh Unit in the Napa River in the north bay;
- Restoration of the Knapp Property, a 452-acre former salt pond in the Alviso area, on the edge of the bay, between Alviso and Guadalupe Sloughs.
- Enhancement of the 325-acre Oro Loma Marsh, an area of diked salt marsh and adjacent uplands located along the shore of Hayward. The area will be restored to tidal marsh and seasonal wetland habitat.
- Restoration of the Baumberg Tract, an 835-acre inactive salt evaporator in Hayward to tidal marsh and seasonal wetlands.
- Restoration of the Moseley Tract located just north of the west approach to the Dumbarton Bridge from the Port of Oakland.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for California clapper rail is "Contribute to Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its

control and within its scope that are necessary to contribute to the recovery of the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

California clapper rail is also proposed for coverage under the Solano County Multi-species Habitat Conservation Plan.

A27.7 Species Habitat Suitability Model

Model Approach. Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf 2007. Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers, connectivity between habitat types, and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The California clapper rail model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), USDA 2005 aerial photography, and DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable California clapper rail habitat in the Plan Area. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Habitat. California clapper rail habitat includes all *Sarcornia*-dominated natural seasonal wetlands and *Schoenoplectus*[2]*/Tyhpa*-dominated tidal freshwater emergent wetlands located west of State Highway 160 on Sherman Island. Vegetation types designated as species habitat in this model correspond to the mapped vegetation associations in the BDCP GIS vegetation data layer.

California clapper rail habitat in the Delta includes the following types from the BDCP composite vegetation layer:

- Tidal freshwater emergent wetland and tidal brackish emergent wetland
    - Mixed *Scirpus*[3] mapping unit;
    - Mixed *Scirpus*/floating aquatics complex;
    - Mixed *Scirpus*/submerged aquatics complex;
    - Hard-stem bulrush (*Scirpus acutus*);
    - *Scirpus acutus* pure;
    - *Scirpus acutus – Typha angustifolia;*
    - *Scirpus acutus – Typha latifolia;*
    - *Scirpus acutus – (Typha latifolia) – Phragmites australis;*
    - California bulrush (*Scirpus californicus*);

[2] Formerly known as *Scirpus*.
[3] Currently known as *Schoenoplectus*.

  - *Scirpus californicus – Eichhornia crassipes;*
  - *Scirpus californicus – Scirpus acutus;*
  - American bulrush (*Scirpus americanus*);
  - Narrow-leaf cattail (*Typha angustifolia*); and
  - *Typha angustifolia – Distichlis spicata.*

California clapper rail habitat in the Suisun Marsh includes the following tidal brackish emergent wetland and tidal perennial aquatic types from the BDCP composite vegetation layer:

- *Scirpus (californicus* or *acutus)/Rosa;*
- *Scirpus (californicus* or *acutus*)/wetland herb;
- *Scirpus (californicus* or *acutus)-Typha* spp.;
- *Scirpus americanus* (generic);
- *Scirpus americanus/Lepidium;*
- *Scirpus americanus/Potentilla;*
- *Scirpus californicus/S. acutus;*
- *Scirpus maritimus;*
- *Scirpus maritimus/Salicornia*[4]*;*
- *Typha angustifolia/Distichlis;*
- *Typha angustifolia/S. americanus;*
- *Typha* species (generic);
- Bulrush - cattail freshwater marsh NFD super alliance;
- *Scirpus americanus/S. Californicus-S. acutus;*
- *Scirpus maritimus/Sesuvium;*
- *Typha angustifolia;*
- *Typha angustifolia/Phragmites;*
- *Typha angustifolia/Polygonum-Xanthium-Echino;*
- *Typha angustifolia/S. americanus;*
- *Distichlis/Salicornia;*
- *Salicornia* (generic);
- *Salicornia virginica;*

[4] Currently known as *Sarcocornia*.

- *Salicornia/Atriplex;*
- *Salicornia/Cotula;*
- *Salicornia*/annual grasses;
- *Salicornia/Crypsis;*
- *Salicornia/Polygonum-Xanthium-Echinochloa;* and
- *Salicornia/Sesuvium.*

Assumptions. Historical and current records of this species indicate that its known distribution extends eastward in the Suisun Marsh (Figure A-27b). Patches of suitable habitat extend into the Plan Area in the vicinity of Collinsville and Antioch, though no occurrences have been recorded there. For purposes of this model, the potential range of the California clapper rail occurs in suitable habitats west of the western edge of Sherman Island. California clapper rails are found within a range of salt and brackish marshes. Typical habitat consists of dense pickleweed (*Salicornia*) and cordgrass (*Spartina foliosa*)-dominated saline tidal marshes (Zucca 1954, Harvey 1980). There is also reported use of *Schoenoplectus/Typha*-dominated brackish marshes in the North Bay (Petaluma Marsh, Napa-Sonoma Marshes, Suisun Marsh) (USFWS 1998). Suitability of habitat may also be dependent on other factors, such as patch size, tidal connectivity (diked marshes), and proximity to other land uses. However, there is insufficient data on these issues relative to their effects on potential occupancy particularly with respect to determining minimum requirements, and thus potential habitat for the California clapper rail is not further restricted in this model on the basis of these factors. As a result, this model likely overestimates the extent of suitable habitat for California clapper rail in the Plan Area.

A27.8 Recovery Goals

The Salt Marsh Harvest Mouse and California Clapper Rail Recovery Plan was finalized in 1984. It is considered outdated and is under revision by the USFWS. Both species will be covered under the Tidal Marsh Ecosystem Recovery Plan.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designates the California clapper rail as "Contribute to Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its control and within its scope that are necessary to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

APPENDIX A28. SWAINSON'S HAWK (*BUTEO SWAINSONI*)

A28.1 LEGAL STATUS

The Swainson's hawk (*Buteo swainsoni*) is listed as a threatened species under the California Endangered Species Act (Fish and Game Code, Sections 2050 et seq.). The species was listed by the California Fish and Game Commission in 1983.

The Swainson's hawk has no federal regulatory status. However, the species is included on the U.S. Fish and Wildlife Service (USFWS) list of Birds of Conservation Concern (BCC) for Region 1. BCC species are those that the USFWS considers potential candidates for federal listing.

A28.2 SPECIES DISTRIBUTION AND STATUS

A28.2.1 Range and Status

Swainson's hawks nest in the grassland plains and agricultural regions of western North America from southern Canada (and possibly in the northern provinces and territories, and Alaska) to northern Mexico. Other than a few documented small wintering populations in the United States (Herzog 1996, England et al. 1997), the majority of the species winters primarily in the Pampas region of Argentina. The Central Valley population winters mainly between Mexico and central South America (Bradbury et al. in preparation).

Early accounts described Swainson's hawk as one of the most common raptors in California, occurring throughout much of lowland California (Figure A-28a) including the Central Valley, coastal valleys, southern California deserts, and Great Basin deserts east of the Sierra Nevada (Sharp 1902). Since the mid-1800s, native grassland foraging habitats and woodland nesting habitats that supported the species have undergone a gradual conversion to agricultural uses and urban uses. Today, native grassland habitats are virtually nonexistent in the state, and only remnants of the once vast riparian forests and oak woodlands still exist (Katibah 1983). While the species has successfully adapted to certain agricultural landscapes, this habitat loss has caused a substantial reduction in the breeding range and in the size of the breeding population in California (Bloom 1980, England et al. 1997). Current breeding populations occur primarily in the Central Valley, but also in the Klamath Basin, the northeastern plateau, Owen's Valley, and rarely in the Antelope Valley (Grinnell and Miller 1944, Bloom 1980, Garrett and Dunn 1981, Anderson et al. 2007).

Swainson's hawk populations have declined in California, Utah, Nevada, and Oregon (England et al. 1997). Populations in other western states are considered stable. Bloom (1980) reported a statewide estimate of 375 breeding pairs.

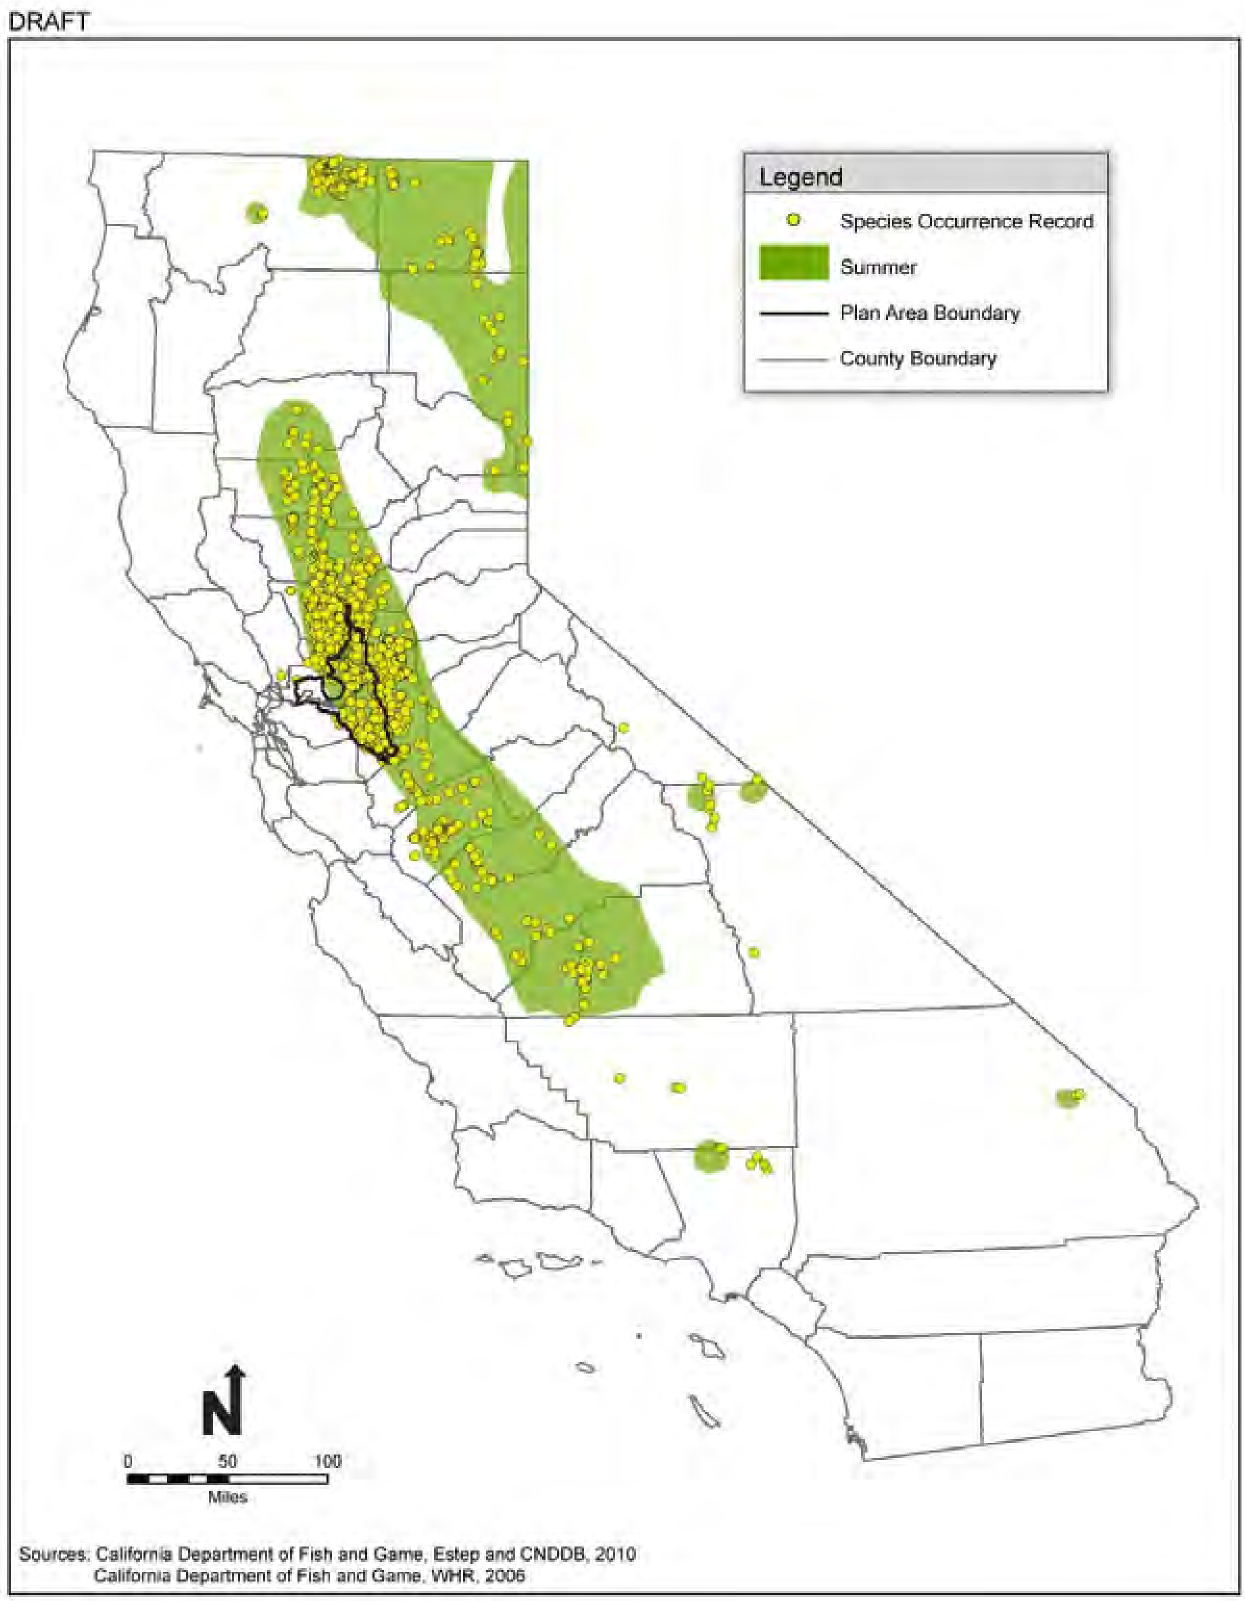

Figure A-28a. Swainson's Hawk Statewide Range and Recorded Occurrences

This was followed by estimates of 550 (DFG 1988) in the late 1980s, and 800 to 1,000 breeding pairs in the late 1990s (Swainson's Hawk Technical Advisory Committee). However, none of these estimates were generated using a statistically-based statewide survey effort and would be considered less credible than the results of a more statistically valid approach. The most recent statewide population estimate for California is 2,081 breeding pairs (Anderson et al. 2007) and is based on a statistically valid statewide survey effort conducted in 2005 and 2006. While this estimate is higher than the original statewide estimate that led to the state listing of the species (Bloom 1980) and subsequent estimates through the 1980s and 1990s, it cannot be reliably used to measure trends. It does, however, represent a substantial decline (50 to 90 percent) of the historical statewide breeding population in California (Bloom 1980).

Nearly 94 percent of nesting Swainson's hawks in California are found in the Central Valley (an estimated 1,948 nesting pairs) (Anderson et al. 2007) from Tehama County south to Kern County. The majority of these are found in the middle section of the Central Valley between approximately Butte County in the north to Merced County in the south, where foraging and nesting habitat conditions are optimized. Over 60 percent of the statewide population occurs within Yolo, Sacramento, Solano, and San Joaquin counties (Anderson et al. 2007). While intensively farmed for over 100 years, much of this area retains a relative abundance of nesting habitat – narrow riparian corridors along rivers and streams, remnant oak groves and trees, roadside trees – and an agricultural pattern that is conducive to Swainson's hawk foraging (Estep 2007, 2008, Anderson et al. 2007).

A28.2.2 Distribution and Status in the Plan Area

Figure A-28b illustrates the nesting distribution of Swainson's hawk in the Plan Area. These data are from recent survey efforts conducted in the Yolo and Sacramento County portions of the Plan Area (Estep 2007, 2008) and the most recent information from the CNDDB (2009). A total of 314 nesting sites are identified on Figure A-28b from within the Plan Area. While the majority of these represent independent nesting territories, a few of the CNDDB locations may represent the same nesting territory in subsequent years. There is, however, a fairly dense nesting population occurring in the northern (north of State Route 12 [SR-12]) and southern (south of SR-4) portions of the Plan Area. These are areas that support a relative abundance of potential nesting habitat and an agricultural landscape that is suitable for Swainson's hawk foraging.

In the northern portion of the Plan Area, nest sites are distributed mainly east of the Deep Water Ship Channel and along the western edge of the Plan Area. These are areas that support mainly annually-rotated irrigated agricultural, hayfield, and irrigated pasturelands, and an abundance of potential nesting habitat, including riparian woodlands, roadside trees, tree rows, and isolated trees.

DRAFT

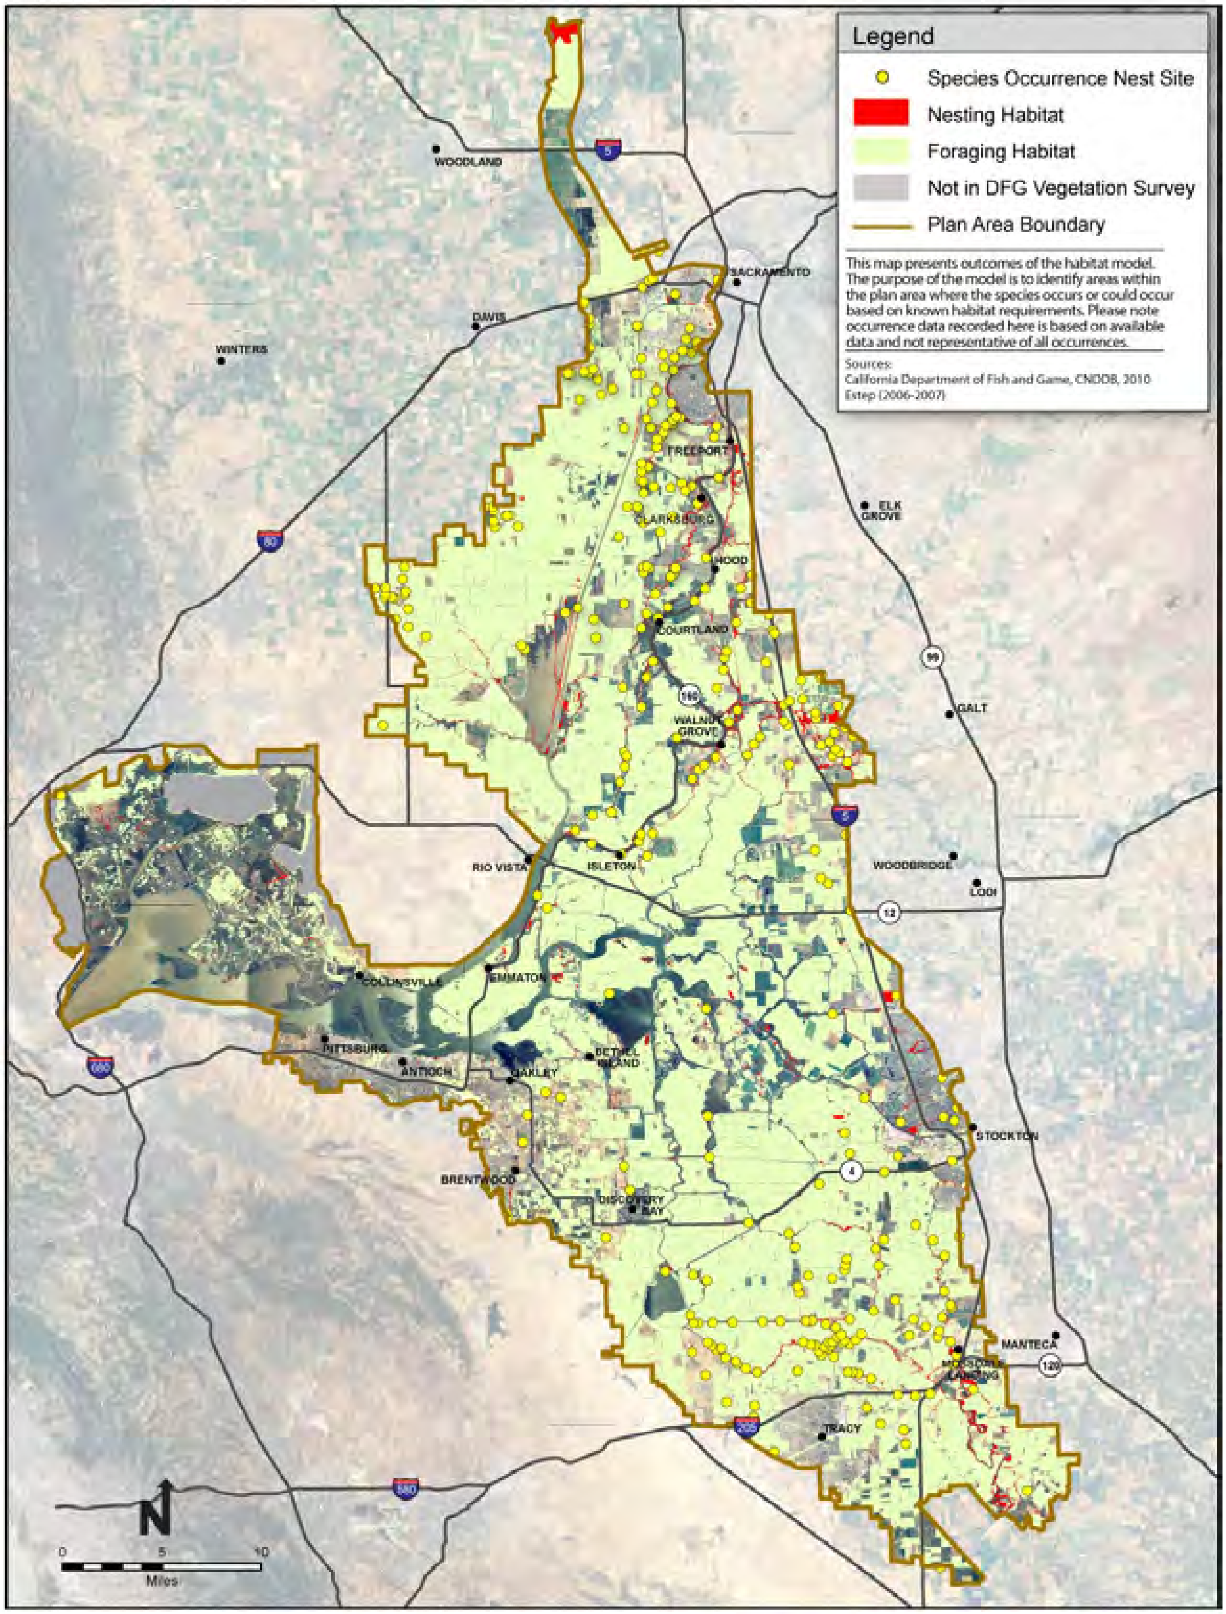

Figure A-28b. Swainson's Hawk Habitat Model and Recorded Occurrences

The area immediately west of the Deep Water Ship Channel (with the exception of the northern Yolo Bypass Wildlife Refuge) and the area immediately north of SR-12 support few potential nest trees and thus fewer known nest sites. However, a very dense nesting population occurs immediately west of the Plan Area boundary in Yolo and Solano counties. These birds likely forage throughout much of the northern Plan Area.

Similarly, the area south of SR-4 also supports a dense nesting population. The agricultural landscape in this area includes an abundance of alfalfa hay and annually rotated irrigated cropland and many potential nest trees, mostly along riparian corridors and roadside tree rows. Areas that lack nest sites, particularly the southernmost portion of the Plan Area south of Interstate 205, also lack sufficient nest trees to support many nesting pairs.

The central Delta, the region between SR-12 and SR-4, supports fewer Swainson's hawk nests compared with the northern and southern regions (Figure A-28b). The agricultural landscape in the central Delta provides generally suitable foraging habitat for Swainson's hawks, although probably less high value cover types; but the lack of nest sites is likely primarily associated with the lack of suitable nest trees in this area. However, it should also be noted that the survey effort in the central Delta has not been as extensive as elsewhere in the Plan Area, and this may contribute in part to the lack of reported nesting territories in that area. DWR 2009 survey data adds numerous additional active nest sites, primarily in the eastern and southern Plan Area, but also several within the central Delta.

A28.3 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

Nesting. Throughout much of its range, both in North and South America, the Swainson's hawk inhabits grasslands, prairies, shrub-steppes, and agricultural landscapes—including dry and irrigated row crops, alfalfa and hay fields, pastures, and rangelands. They nest in trees most often in riparian woodlands and farm shelterbelts (England et al. 1997), as well as in urban/suburban areas with large trees adjacent to suitable foraging habitat (James 1992, England et al. 1995). Suitable nest trees are usually deciduous and tall (up to 100 feet [30 meters]); however, in suburban/urban areas, most nest trees are conifers (England et al. 1995, 1997). Nests are built of sticks and are sometimes several feet in diameter. They are generally placed in the uppermost and outermost branches that will support the nest, often in mistletoe clumps (England et al. 1997).

In the Central Valley, Swainson's hawks usually nest in large native trees such as valley oak (*Quercus lobata*), cottonwood (*Populus fremontia*), walnut (*Juglans hindsii*), and willow (*Salix* spp.), and occasionally in nonnative trees, such as eucalyptus (*Eucalyptus* spp.). Nests occur in riparian woodlands, roadside trees, trees along field borders, isolated trees, small groves, and on the edges of remnant oak woodlands. Stringers of remnant riparian forest along drainages contain the majority of known nests in the Central Valley (Estep 1984, Schlorff and Bloom 1984, England et al. 1997). However, this appears to be a function of nest tree availability rather than dependence on riparian forest. Nests are usually constructed as high as possible in the tree, providing protection to the nest as well as better visibility from it.

Nesting pairs are highly traditional in their use of nesting territories and nesting trees. Many nest sites in the Central Valley are known to have been occupied annually since 1979 and banding studies conducted since 1986 confirm a high degree of nest and mate fidelity (Estep in preparation).

Nesting habitat results from the 2006 and 2007 baseline surveys of South Sacramento County and Yolo County (Estep 2007, 2008) indicate that riparian habitat was the most frequently used nesting habitat type. Isolated trees, roadside trees, tree rows, farmyard trees, and rural residential trees were also frequently used. Valley oak and Fremont cottonwood were the most frequently used nest trees, followed by walnut, willow, and eucalyptus trees.

Foraging. Swainson's hawks are essentially plains or open-country hunters, requiring large areas of open landscape for foraging. Historically, the species used the grasslands of the Central Valley and other inland valleys. With substantial conversion of these grasslands to farming operations, Swainson's hawks have shifted their nesting and foraging into those agricultural lands that provide low, open vegetation for hunting and high rodent prey populations.

Foraging habitat value is a function of: (1) patch size (i.e., Swainson's hawks are sensitive to fragmented landscapes; use will decline as suitable patch size decreases); (2) prey accessibility (i.e., the ability of hawks to access prey depending on vegetation structure and management activities); and (3) prey availability (i.e., the abundance of prey populations in a field). Data on minimum foraging patch size are largely anecdotal, but are generally thought to be between 2 and 10 hectares (5 and 25 acres) (Estep and Teresa 1992, DFG 1994). In the Central Valley, agricultural land use or specific crop type determine the foraging value of a field at any given time. Cover types were evaluated by Estep (1989) and ranked based on these factors. However, suitability ranking is based on a variety of site-specific issues and at a landscape level should be characterized only on a general basis. On a site-specific level—important for land management purposes to maximize foraging value—individual cover types can be assessed based on site-specific and management conditions.

Important land cover or agricultural crops for foraging are alfalfa and other hay, grain and row crops, bare fallow fields, dryland pasture, and annual grasslands. The matrix of these cover types across a large area creates a dynamic foraging landscape as temporal changes in vegetation results in changing foraging patterns and foraging ranges.

Hay crops, particularly alfalfa, provide the highest value because of the low vegetation structure (high prey accessibility), relatively large prey populations (high prey availability), and because farming operations (e.g., weekly irrigation and monthly mowing during the growing season) enhances prey accessibility. Most row and grain crops are planted in winter or spring and have foraging value while the vegetation remains low, but become less suitable as vegetation cover and density increases. During harvest, vegetation cover is eliminated while prey populations are highest, significantly enhancing their suitability during this period. Some crop types, such as rice, orchards, and vineyards, provide little to no value because of reduced accessibility and relatively low prey populations.

A28.4 LIFE HISTORY

Description. Swainson's hawk is a long-winged, medium-sized (19- to 22-inch [48- to 56-centimeter {cm}] and 1.5- to 3- pound [0.7- to 1.4-kilogram]) soaring raptor that nests and roosts in large trees in flat, open grassland or agricultural landscapes. Females, on average, are larger than males, but there are no distinguishing plumage characteristics for separating the sexes.

Swainson's hawk is characterized by its long, narrow, and tapered wings held in flight in a slight dihedral shape. The body size is somewhat smaller, thinner, and less robust than other buteos (broad-winged soaring hawks), although the wings are at least as long as other buteos. This body and wing shape allows for efficient soaring flight and aerial maneuverability. This is important for foraging, which Swainson's hawks do primarily from the wing, and during courtship and inter-specific territorial interactions.

There are three definitive plumage morphs: light, rufous, and dark. However, there are numerous intermediate variations between these plumage morphs. The two most distinguishing plumage characteristics are a dark breast band and the contrasting darker flight feathers and lighter wing lings on the underwings giving most individuals a distinctive bicolored underwing pattern. These characteristics are most pronounced in lighter morph birds and become less so as the plumage darkens, and are indistinguishable in the definitive dark morph, which is completely melanistic. All three definitive plumage morphs are present in the Central Valley with a relatively large proportion of the population categorized as intermediate morph, with varying amounts of streaking or coloration in the belly and wing linings.

Seasonal Patterns. Swainson's hawks arrive on their breeding grounds in the Central Valley from early March to early April. The breeding season extends through mid-to-late August, when most young have fledged and breeding territories are no longer defended. By late August pre-migratory groups begin to form. The fall migration begins early- to mid-September. By early October, most Swainson's hawks have migrated out of the Central Valley. Central Valley Swainson's hawks winter primarily in Central Mexico and, to a lesser extent, throughout portions of Central and South America (Bradbury et al. in preparation). This differs from what is known about the migratory pattern and wintering grounds of Swainson's hawk populations outside of the Central Valley, most of which take a different migratory route and winter entirely in southern South America, with the largest wintering populations known to occur in northern Argentina (England et al. 1997).

Reproduction. Swainson's hawks exhibit a high degree of nest site fidelity, using the same nests, nest trees, or nesting stands for many years (England et al. 1997). Pairs are monogamous and may maintain bonds for many years (England et al. 1997). Immediately upon arrival onto breeding territories, breeding pairs begin constructing new nests or repairing old ones. One to four eggs are laid in mid- to late-April followed by a 30- to 34-day incubation period. Nestlings begin to hatch by mid-May followed by an approximately 20-day brooding period. The young remain in the nest until they fledge in 38 to 42 days after hatching (England et al. 1997). Studies conducted in the Sacramento Valley indicate that one or two—and occasionally three—young typically fledge from successful nests (Estep in preparation). The rate of young fledged per nest in the Central Valley is among the lowest recorded in the entire species range. This geographic difference in reproductive success may be related to the reliance on small voles that may not meet the high energetic demands of breeding adults and developing young compared to the diets that include a higher proportion of gophers, rabbits, ground squirrels, and other larger mammals consumed in other locations. It may also be due to the energetic demands of foraging in a dynamic agricultural landscape that causes birds to travel long distances to forage during times when vegetation growth in agricultural fields reduces available foraging habitat near the nest. In Yolo County, fledging rates ranged from 1.15 to 1.96 young per successful nest from 1988 to 2000 (Estep in prep.).

After fledging, young remain near the nest and are dependent on the adults for about 4 weeks, after which they permanently leave the breeding territory (Anderson et al. in preparation).

Home Range/Territory Size. Home ranges are highly variable depending on cover type, and fluctuate seasonally and annually with changes in vegetation structure (e.g., growth and harvest) (Estep 1989, Woodbridge 1991, Babcock 1995). Smaller home ranges consist of high percentages of alfalfa, fallow fields, and dry pastures (Estep 1989, Woodbridge 1991, Babcock 1995). Larger home ranges were associated with higher proportions of cover types with reduced prey accessibility, such as orchards and vineyards, or reduced prey abundance, such as flooded rice fields. Swainson's hawks regularly forage across a very large landscape compared with most raptor species. Data from Estep (1989) and England et al. (1995) indicate that it remains energetically feasible for Swainson's hawks to successfully reproduce when food resources are limited around the nest and large foraging ranges are required. Radio-telemetry studies indicate that breeding adults in the Central Valley routinely forage as far as 18.6 miles from the nest (Estep 1989, Babcock 1995).

Home ranges (calculated as minimum convex polygons) for 12 Swainson's hawks in the Central Valley averaged 10.7 square miles (mi^2) (range: 1.3 to 33.7 mi^2) (27.7 kilometers [km^2] [range: 3.4 to 87.3 km^2]) (Estep 1989). Using similar methods, four Swainson's hawks in West Sacramento averaged 15.6 mi^2 (range: 2.8 to 29.6 mi^2) (40.4 km^2 [range: 7.3 to 76.7 km^2]), and included fields planted in grain, alfalfa, tomatoes, and safflower, as well as fallow fields (Babcock 1995).

Swainson's hawks in the central region of the Central Valley had the shortest distances between nests of those reported in England et al. (1997); on average, nests were 0.7 miles (1.1 km) apart

(Estep 1989). Results from a 2006 baseline survey of South Sacramento County indicate a nesting density of 37 pairs/100 mi^2 (259 km^2); and from a 2007 baseline survey of nesting Swainson's hawks in Yolo County, a nesting density within the survey area of 38 pairs/100 mi^2, the highest nesting density reported for this species (Estep 2008). This high nest density was attributed to widely available, uniformly distributed optimal foraging habitat and relatively abundant nesting sites along narrow riparian corridors, farm shelterbelts, roadside trees, remnant groves, and isolated trees.

Foraging Behavior and Diet. Swainson's hawks hunt primarily from the wing, searching for prey from a low altitude soaring flight, 98 to 295 feet (30 to 90 meters) above the ground and attack prey by stooping toward the ground (Estep 1989). This species is also highly responsive to farming and seasonal wetland management activities that expose and concentrate prey, such as cultivating, harvesting, and disking. During these activities, particularly late in the season, Swainson's hawks will hunt behind tractors searching for exposed prey. Other activities, such as flood irrigation and burning, also expose prey and attract foraging Swainson's hawks.

In the Central Valley, Swainson's hawks feed primarily on small rodents, usually in large fields that support low vegetation cover (to provide access to the ground) and high densities of prey (Bechard 1982, Estep 1989). These habitats include hay fields, grain crops, certain row crops, and lightly grazed pasturelands. Fields lacking adequate prey populations (e.g., flooded rice fields) or those that are inaccessible to foraging birds (e.g., vineyards and orchards) are rarely used (Estep 1989, Babcock 1995, Swolgaard 2003).

Meadow vole (*Microtus californicus*) is the principal prey item taken by Swainson's Hawks in the Central Valley (Estep 1989). Pocket gopher (*Thomomys bottae*) is also an important prey item. Other small rodents, including deer mouse (*Peromyscus californicus*) and house mouse (*Mus musculus*), are also taken along with a variety of small birds, reptiles, and insects.

A28.5 Threats and Stressors

Swainson's hawks face different threats in different portions of their range. In California, causes of population decline are thought to be loss of nesting habitat (Schlorff and Bloom 1984) and loss of foraging habitat to urban development and to conversion to unsuitable agriculture, such as orchards and vineyards (England et al. 1995, 1997).

Conversion of agricultural lands to urban uses continues at a high rate throughout the range of the Swainson's hawk. Urbanization results in permanent loss of habitat and fragmentation of landscapes, which both result in a reduction of available foraging habitat for the Swainson's hawk.

Conversion from compatible to incompatible crop patterns also reduces available foraging habitat and influences the distribution of nesting Swainson's hawks. Large regions of the Central Valley that have been converted to rice, vineyards, orchards, cotton, and other incompatible crop types support few nesting Swainson's hawks. The continued conversion of suitable agricultural landscapes (e.g., annually rotated irrigated cropland, hayfields, and pasturelands) to vineyards and other unsuitable cover types continues to reduce available foraging habitat on a local and regional basis. Spring and summer inundation of agricultural lands or seasonal wetland habitats also reduces available foraging habitat.

Loss of riparian and other nesting habitat continues throughout the Central Valley from levee projects, agricultural practices, and local development along watercourses. A related issue is the loss and lack of regeneration of valley oak and other native trees. This is an ongoing problem in areas that have continued to support remnant valley oaks and oak groves. Nesting habitat continues to decline as these trees and small groves die off or are removed and are not replaced through natural regeneration or replanting.

Nestlings are vulnerable to starvation and fratricide (i.e., the larger nestling killing the smaller nestling in times of food-stress), and predation from crows, ravens, and other raptors. Natural population cycles of voles in central California may be a major factor in reproductive success where vole population crashes suppress Swainson's hawk reproduction or lead to increased starvation rates of nestlings. In addition, insecticides and rodenticides may contribute to food scarcity by reducing prey abundance. There is little evidence that adult Swainson's hawks are killed by natural predators, but collisions with moving vehicles and illegal shooting and trapping have been identified as sources of mortality (England et al. 1997).

Well documented mass poisoning of hundreds or thousands of Swainson's hawks wintering in Argentina (Woodbridge et al. 1995, Goldstein et al. 1996) have led to that country's ban of an insecticide (organophosphate monocrotophos) used on alfalfa and sunflower fields to control grasshopper populations. Levels of dichlorodiphenyldichloroethylene (DDE) (a toxic degradation product of DDT [dichlorodiphenyltrichloroethane], a pesticide used extensively until 1972 when it was banned in the U.S.) in Swainson's Hawks from the Central Valley may have been high enough to negatively affect reproductive success during the decades when DDT was used extensively in the United States. However, levels of DDE measured in eggs collected in 1982–1983 were not considered high enough to indicate a health threat (Risebrough et al. 1989).

A28.6 Relevant Conservation Efforts

Conservation efforts have focused on the development and implementation of habitat conservation plans/natural community conservation plans. These regional conservation approaches can be an effective tool to managing and sustaining Swainson's hawk populations if sufficient suitable landscape is preserved (Estep and Teresa 1992). Much of the Plan Area overlaps with or is near other conservation planning efforts that are either currently being implemented or are in development. Swainson's hawk is a covered species under the approved San Joaquin County Multi-species Habitat Conservation and Open Space Plan, the East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan, and the

Natomas Basin Habitat Conservation Plan. It is also proposed for coverage under the South Sacramento County Habitat Conservation Plan, the Solano County Multi-species Habitat Conservation Plan, the Yolo County Natural Heritage Program Plan, and the Butte Regional Habitat Conservation Plan and Natural Community Conservation Plan.

DFG is currently finalizing a management strategy for the Swainson's hawk that is designed to coordinate conservation planning efforts to facilitate a comprehensive and consistent approach to managing landscapes to sustain Swainson's hawk populations in the Central Valley (DFG in preparation).

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designates the Swainson's hawk as "Contribute to Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its control and within its scope that are necessary in order to contribute to the recovery of the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

A28.7 SPECIES HABITAT SUITABILITY MODEL

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf 2007. Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers, connectivity between habitat types, and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The Swainson's hawk model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), U.S. Department of Agriculture (USDA) 2005 aerial photography, and DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable Swainson's hawk habitat in the Plan Area according to the species' two primary life requisite parameters, nesting habitat and foraging habitat. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Nesting Habitat. Nesting habitat in the Delta includes the following types using the BDCP composite vegetation layer:

- Valley/foothill riparian
    - White alder (*Alnus rhombifolia*);
    - *Alnus rhombifolia/Salix exigua;*
    - *Alnus rhombifolia/Cornus sericea;*
    - Oregon ash (*Fraxinus latifolia*);
    - Box elder (*Acer negundo*);
    - *Acer negundo-Salix gooddingii;*

- Hinds walnut (*Juglans hindsii*);
- Fremont cottonwood (*Populus fremontii*);
- Black willow (*Salix gooddingii*);
- *Salix gooddingii*/wetland herbs;
- *Salix gooddingii-Populus fremontii* (*Quercus lobata-Salix exigua-Rubus discolor*);
- *Quercus lobata-Salix exigua-Rubus discolor;*
- *Salix goodingii – Quercus lobata*/wetland herbs;
- *Salix gooddingii/Rubus discolor;*
- Coast live oak (*Quercus agrifolia*);
- Valley oak (*Quercus lobata*);
- *Quercus lobata/Rosa californica;*
- *Quercus lobata – Acer negundo;*
- *Quercus lobata – Alnus rhombifolia;*
- *Quercus lobata – Fraxinus latifolia;*
- Black willow (*Salix gooddingii*)-valley oak (*Quercus lobata*) restoration;
- Valley oak (*Quercus lobata*) restoration; and
- White alder (*Alnus rhombifolia*) arroyo willow (*Salix lasiolepis*) restoration.

Nesting habitat in the Suisun Marsh and Yolo Basin includes the following types using the BDCP composite vegetation layer:

- Eucalyptus;
- *Eucalyptus globules;*
- *Fraxinus latifolia;*
- Fremont cottonwood-valley oak-willow riparian forest ;
- Landscape trees;
- Mixed Fremont cottonwood – willow;
- Mixed willow super alliance;
- Oaks;
- *Quercus agrifolia;*
- *Salix lasiolepis/Quercus agrifolia;*

- Valley oak alliance – riparian; and
- Willow trees.

While valley oak and/or cottonwood-dominated riparian forests are considered optimal nesting habitat for this species, the model does not distinguish habitat quality according to overstory composition, tree density, structure, or patch size. For purposes of this model, all overstory riparian and other mature trees are considered potential Swainson's hawk nesting habitat. Natural vegetation types designated as species habitat in this model correspond to the mapped vegetation associations in the BDCP composite vegetation data layer.

Assumptions. In the Central Valley, Swainson's hawks typically nest in large native trees such as cottonwood, valley oak, walnut, and black willow (Figure A-28b). These trees (and thus most nest sites) are most often found along stringers of valley riparian forest (Estep 1984, Schlorff and Bloom 1984, England et al. 1997). Because the age or structure of the overstory trees is not considered here, this model may overestimate the extent of suitable riparian nesting habitat. However, Swainson's hawks also nest in a variety of other native (e.g., Oregon ash, box elder, white alder) and nonnative trees (e.g., eucalyptus) and habitats such as roadside trees, windbreaks, oak groves, isolated trees, and trees around rural residences. These nesting habitat types are not sufficiently captured by this model primarily due to the small mapping units that would be required, and thus potential non-riparian nesting habitat is underestimated here (Figure A-28b). While the model focuses on riparian habitats, to address this issue, impact assessments will include all potential nesting habitat types where they occur in association with suitable foraging habitat.

Foraging Habitat. Foraging habitat in the Delta includes the following types from the BDCP composite vegetation layer using a 5-acre minimum patch size:

- Grasslands
  - Ruderal herbaceous grasses and forbs;
  - California annual grasslands;
  - *Bromus diandrus-Bromus hordeaceus;*
  - Italian rye-grass (*Lolium multiflorum*);
  - *Lolium multiflorum-Convolvulus arvensis;*
  - Degraded vernal pool complex – California annual grasslands;
  - Degraded vernal pool complex – Ruderal herbaceous grasses and forbs; and
  - Degraded vernal pool complex – Italian rye-grass (*Lolium multiflorum*).
- Managed Wetlands
  - Temporarily flooded grasslands;

    - Rabbitsfoot grass (*Polypogon monspeliensis*);
    - Intermittently flooded perennial forbs;
    - Managed annual wetland vegetation (non-specific grasses and forbs);
    - Shallow-flooding with minimal vegetation;
    - Seasonally flooded undifferentiated annual grasses and forbs;
    - Managed alkali wetland (*Crypsis*); and
    - Intermittently or temporarily flooded undifferentiated annual grasses and forbs.
- Alkali seasonal wetland complex and other natural seasonal wetlands
    - *Distichlis spicata* – Annual grasses;
    - Seasonally-flooded grasslands;
    - Vernal pools;
    - Degraded vernal pool complex-vernal pools;
    - Temporarily flooded perennial forbs;
    - Alkaline vegetation mapping unit;
    - *Allenrolfea occidentalis* mapping unit;
    - *Suaeda moquinii* mapping unit; and
    - Salt scalds and associated sparse vegetation.
- Vernal pool complex
    - *Allenrolfea occidentalis* mapping unit;
    - Annual grasses generic;
    - Annual grasses/weeds;
    - California annual grasslands;
    - *Distichlis*/annual grasses;
    - *Distichlis spicata* – Annual grasses;
    - Italian rye-grass (*Lolium multiflorum*);
    - Ruderal herbaceous grasses and forbs;
    - Salt scalds and associated sparse vegetation;
    - Seasonally-flooded grasslands;
    - *Suaeda moquinii* mapping unit; and

  - Vernal pools.

Foraging habitat in the Suisun Marsh and Yolo Basin includes the following types from the BDCP composite vegetation layer:

- Annual grasses generic;
- Annual grasses/weeds;
- *Baccharis*/annual grasses;
- *Bromus* spp./*Hordeum;*
- *Crypsis schoenoides;*
- *Crypsis* spp. – Wetland grasses – Wetland forbs;
- Cultivated annual graminoid;
- *Cynodon dactylon;*
- *Distichlis*/annual grasses;
- Fallow disced field;
- Field crops;
- *Hordeum/Lolium;*
- *Lolium* (generic);
- *Lolium/Rumex;*
- *Lotus corniculatus;*
- Medium upland herbs;
- Medium wetland graminoids;
- Medium wetland herbs;
- Pasture;
- Perennial grass;
- Short upland graminoids;
- Short wetland graminoids;
- Tall wetland graminoids;
- Truck/nursery/berry crops;
- Upland annual grasslands and forbs formation;
- Upland herbs; and

- Agriculture.

The following DWR 2007 Land Use survey types are included as suitable agricultural foraging habitats for Swainson's hawk. These types represent the typical agricultural cover types in the Plan Area that are included in the DWR 2007 land use survey. Rotational crop types that are not common to the Plan Area are not included here. Pasture types are mostly perennial; alfalfa is semi-perennial (3 to 7 years); and all other types are annually or seasonally rotated irrigated crops, only some of which provide suitable foraging habitat for Swainson's hawk.

- Grain and hay crops
  - Barley;
  - Wheat;
  - Oats; and
  - Miscellaneous and mixed grain and hay.
- Field crops
  - Safflower;
  - Sugar beets;
  - Corn;
  - Grain sorghum;
  - Sudan;
  - Beans;
  - Miscellaneous field; and
  - Sunflowers.
- Pasture
  - Alfalfa and alfalfa mixtures;
  - Clover;
  - Mixed pasture;
  - Native pasture;
  - Induced high water table native pasture; and
  - Miscellaneous grasses.
- Truck, nursery and berry crops
  - Asparagus;
  - Beans;
  - Onions and garlic;

  - o Tomatoes; and
  - o Peppers.
- Idle
  - o Land not cropped the current or previous crop season, but cropped within the past three years; and
  - o New lands being prepped for crop production.

The model includes all grassland types, many managed and natural seasonal wetland types, all irrigated pastures and hays, and all seasonally rotated croplands. The model excludes suitable habitat fragments less than 40 acres in size if they are fragmented by urbanization. Suitable habitat fragmented by unsuitable agricultural crop types is not excluded. Agricultural crop types designated as species habitat correspond to DWR 2007 land use database categories.

Assumptions. In the Central Valley, foraging habitat consists primarily of irrigated croplands and pasturelands. Swainson's hawk also forage in annual grasslands and during the summer will use non-inundated seasonal wetlands. Swainson's hawks feed primarily on small rodents, usually in large fields that support low vegetation cover (to provide access to the ground) and high densities of prey (Bechard 1982, Estep 1989). These habitats include hay fields, grain crops, certain row crops, and lightly grazed pasturelands. Fields lacking adequate prey populations (e.g., flooded rice fields) or those that are inaccessible to foraging birds (e.g., vineyards and orchards) are rarely used (Estep 1989, Babcock 1995, Swolgaard 2003) and are excluded here. Because foraging Swainson's hawks must have access to the ground, vegetation structure influences foraging use, which varies according to the crop type and seasonal planting and harvesting regime (Estep 2009). However, because the Grain and Hay, Field, and Truck, Nursery and Berry Crop types listed above are seasonally rotated, the value of individual fields changes each year. Therefore, these crop types are not differentiated based on their seasonal value and are instead combined into a category of seasonally rotated croplands. As a result, this model overestimates the extent of available agricultural foraging habitat in any given year. Foraging use is also a function of patch size. Foraging use generally decreases as suitable foraging patch size decreases below approximately 40 acres. However, this is usually based on fragmentation of foraging habitat due to urbanization, and not necessarily by unsuitable crop types. To maintain consistency with DFG guidance, a minimum foraging patch size of 5 acres is used.

Habitat Units. As described, the Swainson's hawk is closely associated with agricultural lands. Most of the Plan Area consists of agricultural land and most is considered to have some value as foraging habitat for Swainson's hawks. However, the value of crop types differ widely due to their growth and structure, which influences accessibility by foraging hawks, and in prey abundance, which influences the availability of prey to foraging hawks. Because of the dynamic nature of the agricultural landscape and the variability of crop patterns and conditions seasonally and annually, only a proportion of the agricultural landscape is suitable or available for foraging in any given season or year. To account for this variability and to more accurately represent the value of Plan Area-wide foraging habitat, acres of Swainson's hawk foraging habitat can be converted to habitat units.

Sufficient information is available on the growth and structure of different agricultural crops (Estep 1989, 2009) and the prey abundance and use of different crop types to generally categorize crops based on their value as foraging habitat. By placing different crop types and other foraging habitats that traditionally occur in the Plan Area into crop value classes and assigning relative values to those classes (e.g., 0.1, 0.25, 0.5, 0.75, and 1.0), the habitat acres can be converted to habitat units. Habitat units, rather than acres, can then used to describe and calculate impacts to Swainson's hawk foraging habitat using this index of habitat value. Table A-28a provides the rationale for assigning crop types and other agricultural land uses to habitat value categories. Figure A-28c displays the distribution of foraging habitat and the assigned habitat values within the Plan Area.

Table A-28a. Swainson's Hawk Agricultural Foraging Habitat Value Classes

Foraging Habitat Value Class	*Assigned Agricultural Crops/Habitats*	*Rationale for Assignment of Agricultural Crop Class*	*Information Sources[1]*
1.0-Very High	Alfalfa	Alfalfa has the highest value because it is semi-perennial (up to 5 years before rotation), which increases prey abundance; has a relatively low profile such that prey are accessible season-long; and has a management regime (mowing and irrigation) which further increases prey accessibility.	J. Estep, pers. comm., T. Beedy, pers. comm., Estep 1989, Estep 2009, Swolgaard et al. 2008.
.75-High	Native Pasture, Undifferentiated Pasture, Mixed Pasture, Clover, Miscellaneous Grasses (grown for seed)	These pasture types provide a relatively consistent vegetation structure and rodent prey populations. There is less seasonal variability with respect to prey abundance and accessibility compared with grain and vegetable crops, but they lack the management practices that enhance prey accessibility found in alfalfa.	J. Estep, pers. comm., T. Beedy, pers. comm., Estep 1989, Estep 2009, Swolgaard et al. 2008.
.5-Medium	Sugar Beets, Tomatoes, Grain and Hay, annual grasslands, vernal pool grasslands, alkali grasslands	Certain row crops, such as beets and tomatoes also have relatively high value because they support large rodent prey populations, are accessible season-long because of their relatively low vegetation profile, and they are harvested prior to migration, when an abundance of prey becomes available. Most grain crops (primarily wheat in Yolo County) provide value during and following harvesting, when prey become accessible. Grasslands are generally available season-long but provide lower prey abundance compared with higher value agricultural habitats, don't provide a peak period of high value abundance and accessibility like some agricultural crops (e.g., tomatoes), and in some cases grass height reduces prey accessibility during a portion of the breeding season.	J. Estep, pers. comm., T. Beedy, pers. comm., Estep 1989, Estep 2009, Swolgaard et al. 2008.
.25-Low	Broccoli, Sudan, Dry Beans, Undifferentiated Field Crops, Asparagus, Green Beans, Cole Crops, Carrots, Melons/Squash/Cucumbers,	The truck and berry/field crop agriculture types are suitable for a portion of the breeding season depending on their structure and planting/harvesting regime. But in general, they produce less prey abundance and less prey	J. Estep, pers. comm., T. Beedy, pers. comm., Estep 1989, Estep 2008, Swolgaard et al.

	Onions/Garlic, Peppers, Cabbage, Undifferentiated Truck and Berry Crops, Artichokes, Lettuce (all types), Spinach, Mixed Truck and Berry	availability than the other agriculture types listed above.	2008.
.10-Marginal	Safflower, corn, grain sorghum, sunflower	These types are available for a brief time during the breeding season and have particularly low prey accessibility.	J. Estep, pers. comm., T. Beedy, pers. comm., Estep 1989, Estep 2009, Swolgaard et al. 2008.

A28.8 Recovery Goals

A USFWS recovery plan has not been prepared for this species and no recovery goals have been established; however, the CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy (MSCS) designates the Swainson's hawk as "Contribute to Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its control and within its scope that are necessary in order to contribute to the recovery of the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

APPENDIX A29. WHITE-TAILED KITE (*ELANUS LEUCURUS*)

A29.1 LEGAL STATUS

The white-tailed kite is designated as a state Fully Protected species pursuant to California Department of Fish and Game Code Section 3511. Nests are protected in California under Fish and Game Code Sections 3503.5.

White-tailed kite has no federal regulatory status; however, the species is protected under the federal Migratory Bird Treaty Act.

A29.2 SPECIES DISTRIBUTION AND STATUS

A29.2.1 Range and Status

The white-tailed kite was threatened with extinction in North America during the early twentieth century (Eisenmann 1971). Until the 1960s, the species was considered declining throughout its North American range, but since then has recovered in some areas. Currently, the distribution of the species includes the east coast and southeast United States, the southwest United States from Texas to California, and north to Washington State, and from Mexico to South America (Dunk 1995). Relatively stable resident populations occur in California, portions of coastal Oregon and Washington, southern Florida, southern Texas, and portions of northern Mexico. The species is considered rare in remaining portions of its North American range. Range expansion has also been noted in some Central American locales (Eisenmann 1971).

California populations were also thought to be seriously declining prior to the 1960s likely due to habitat loss, shooting, and possible egg collecting (Pickwell 1930, Waian and Stendell 1970). From the 1940s to the 1970s, populations and distribution increased (Fry 1966, Waian and Stendall 1970, Eisenmann 1971), due to protection from shooting and possibly due to increasing agricultural development, which may have increased rodent habitat and expanded the foraging range of white-tailed kite (Eisenmann 1971, Small 1994). In the Sacramento Valley, the kite has increased predominantly in irrigated agricultural areas where meadow vole (*Microtus californicus*) populations are found (Warner and Rudd 1975).

California is currently considered the breeding range stronghold for white-tailed kite in North America (Figure A-29a), with nearly all areas up to the western Sierra Nevada foothills and southeastern deserts occupied (Small 1994, Dunk 1995). It is common to uncommon and a year-round resident in the Central Valley, other lowland valleys, and along the entire length of the coast (Dunk 1995).

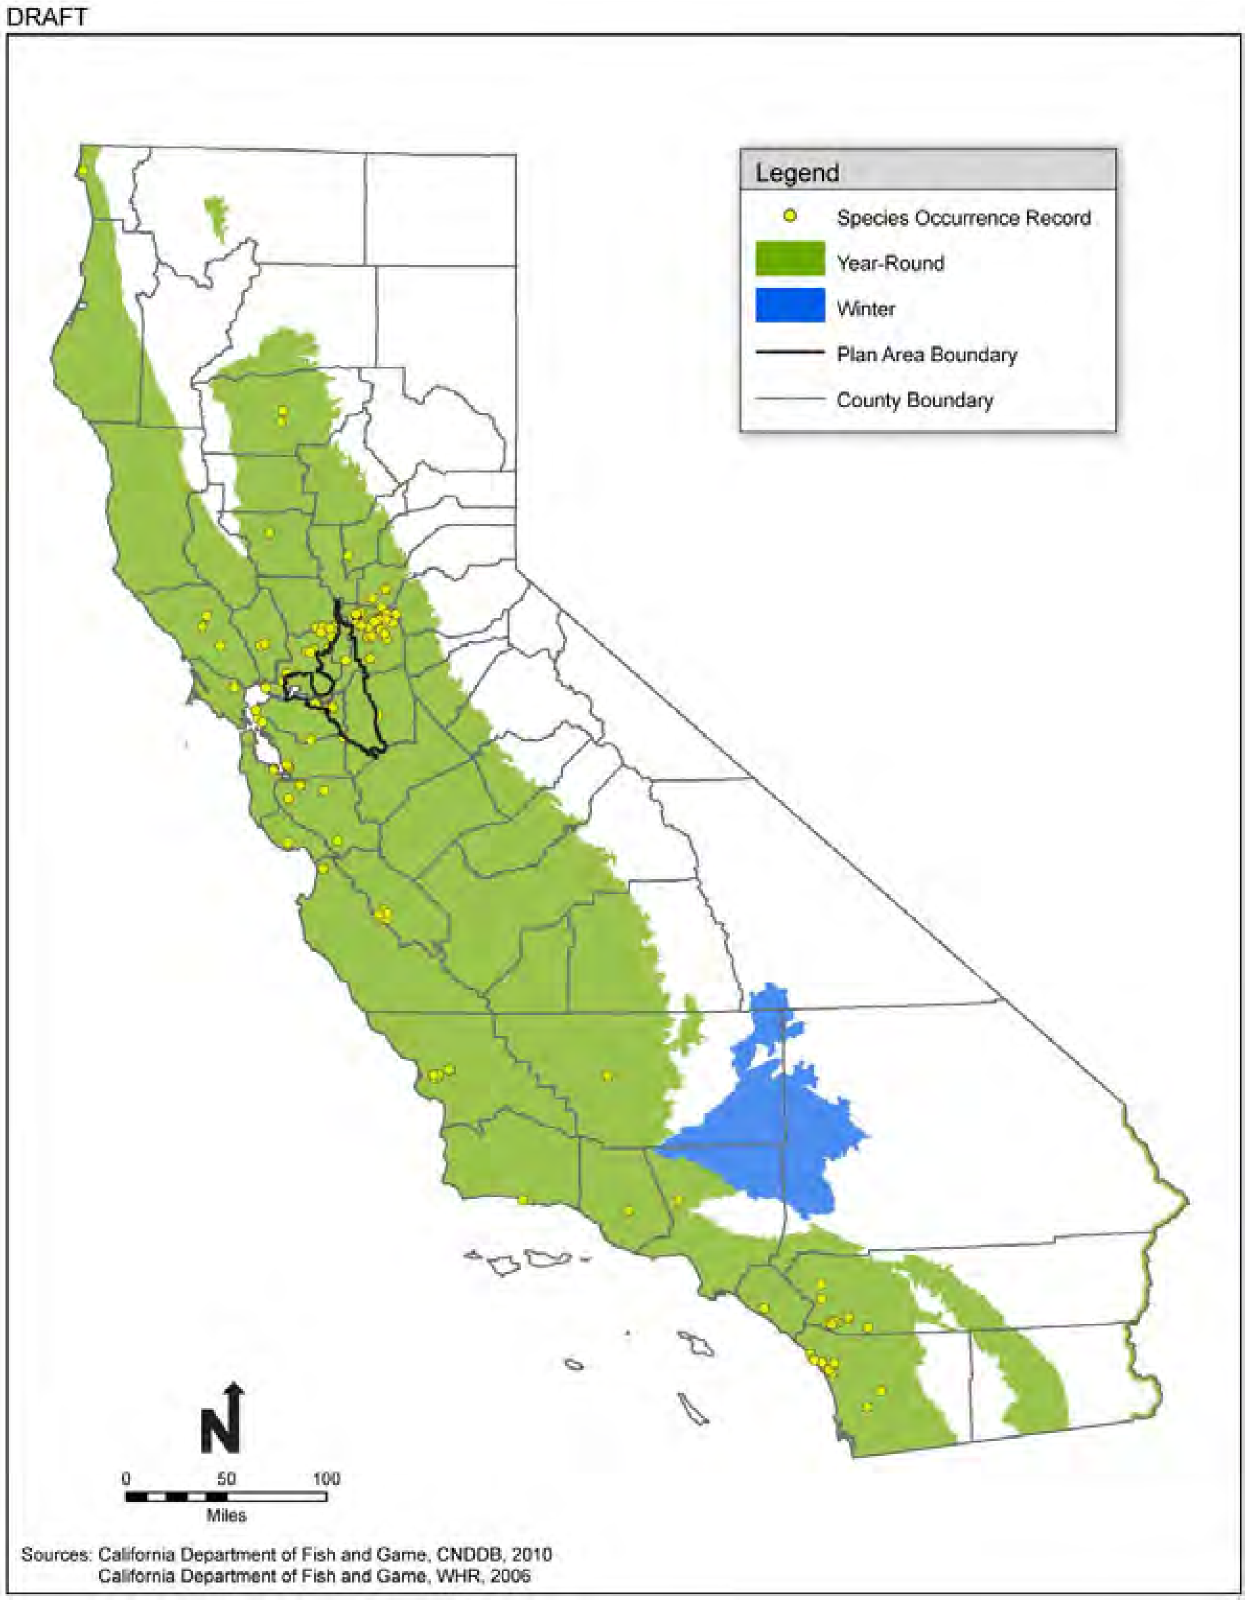

Figure A-29a. White-Tailed Kite Statewide Range and Recorded Occurrences

Although white-tailed kite is probably resident through most of its breeding range, dispersal occurs during the non-breeding season, leading to a winter range expansion that includes most of California (Small 1994, Dunk 1995).

A29.2.2 Distribution and Status in the Plan Area

White-tailed kite is distributed throughout the Plan Area during the breeding and wintering seasons (Figure A-29b), although relatively few nesting locations have been documented. The species is underrepresented in the California Natural Diversity Database (CNDDB), which reports only five locations within the Plan Area (CNDDB 2009). Recent surveys in the Yolo and Sacramento County portions of the Plan Area have documented active nests sites in riparian habitats in the Yolo Bypass and along Steamboat and Georgiana sloughs, and the Sacramento River (Estep 2007, 2008). Additional incidental observations are regularly noted in Audubon field notes, environmental documents, and management plans in the Delta. The California Department of Fish and Game (DFG) also maintains nesting and winter roosting records of white-tailed kites from the Yolo Bypass Wildlife Area. Most nesting habitat for kites in the Plan Area consists of riparian woodlands and scrub along large and small drainages. Nesting distribution is limited by the dearth of suitable trees in much of the central Delta, and nesting density in that area is likely significantly lower than that found in the northern and southern portions of the Plan Area. However, overall the species is likely under-represented by reported occurrences throughout the Plan Area. Most of the Plan Area, including grassland, seasonal wetland, and agricultural cover types, is potential foraging habitat for kites. Thus, the species potentially occurs throughout the entire Plan Area during winter and in the vicinity of suitable nesting habitat during the breeding season.

A29.3 Habitat Requirements and Special Conditions

The white-tailed kite inhabits low elevation, open grasslands, savannah-like habitats, agricultural areas, wetlands, and oak woodlands (Dunk 1995). They nest in trees – usually with a dense canopy, but nest trees can vary from single, isolated trees to trees within large woodlands. Habitat elements that influence nest site selection and nesting distribution include habitat structure (usually a dense canopy) and prey abundance and availability (primarily the association with meadow vole), while the association with specific vegetation types (e.g., riparian, oak woodland, etc.) appears less important (Dunk 1995, Erichsen 1995).

Nesting. White-tailed kite nests have been documented in a variety of tree species, including valley oak (*Quercus lobata*), Fremont cottonwood (*Populus fremontii*), willow (*Salix* spp.), live oak (*Quercus wislizenii*), boxelder (*Acer negundo*), ornamental trees including olive and pine trees, and occasionally in tall shrubs (Dixon et al. 1957, Dunk 1995, Erichsen 1995, Estep 2007, 2008). As noted above, nest trees appear to be selected on the basis of structure and security, and thus typically have a dense canopy or are within a dense group of trees, such as riparian forest or oak woodland. Kites will occasionally use isolated trees, but this is relatively rare.

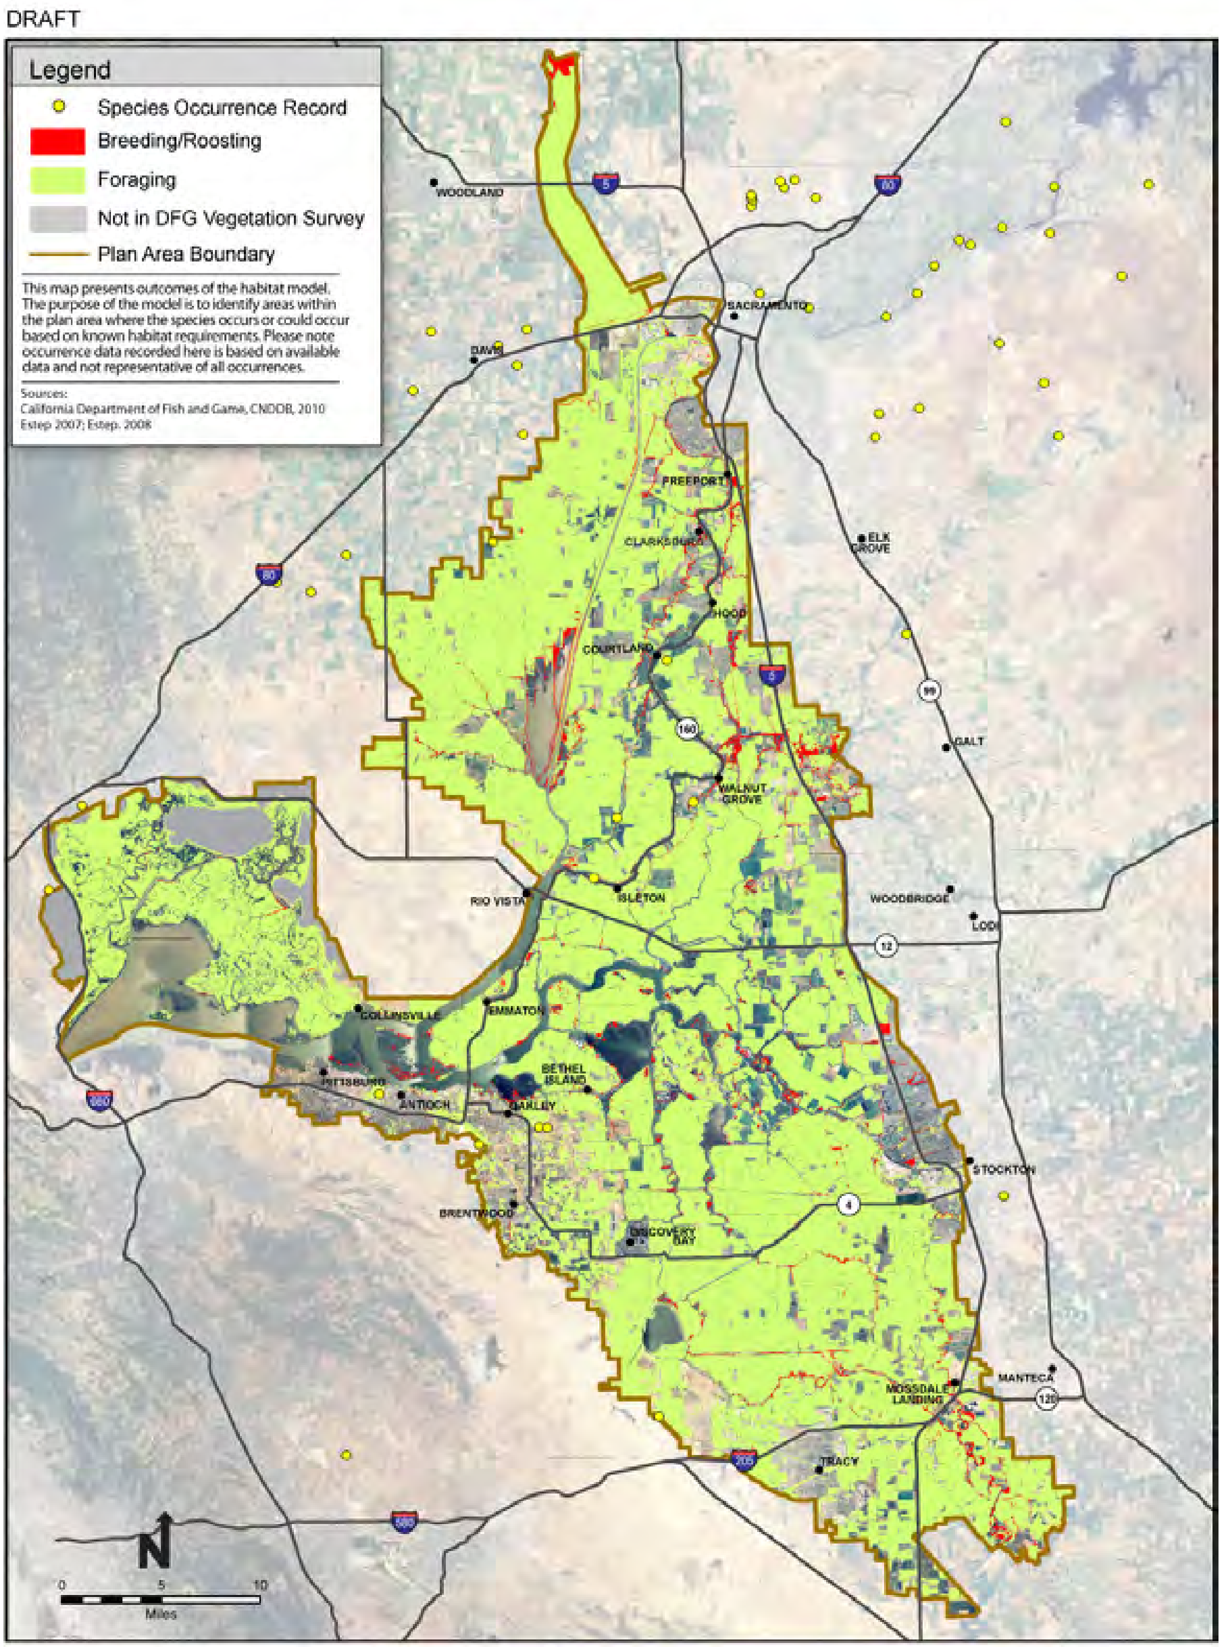

Figure A-29b. White-Tailed Kite Habitat Model and Recorded Occurrences

Most nests in the Sacramento Valley are found in oak/cottonwood riparian forests, valley oak woodlands, or other groups of trees and are usually associated with compatible agricultural foraging habitat, such as pasture and hay crops, compatible row and grain crops, or natural vegetation such as seasonal wetlands and annual grasslands (Erichsen 1995).

Kites often nest in close association with other nesting kites and with several other raptors – including Swainson's hawk (*Buteo swainsoni*), red-tailed hawk (*Buteo jamaicensis*), and red-shouldered hawk (*Buteo lineatus*) – particularly in riparian habitats of the Sacramento Valley (Erichsen 1995, Estep 2007, 2008).

Foraging. A variety of foraging habitat types are used, but those that support larger and more accessible prey populations are more suitable. The presence and abundance of white-tailed kites is strongly correlated with the presence of meadow voles (Stendell 1972). As a result, population cycles of meadow voles can also influence nesting and wintering abundance of white-tailed kites. For example, those portions of the Plan Area that are subject to seasonal flooding experience fluctuating prey numbers, which impacts the occurrence of white-tailed kites until prey populations recover. Cover types that appear to be preferred include alfalfa and other hay crops, irrigated pastures, and some cultivated habitats, particularly sugar beets and tomatoes, both of which can support relatively large populations of voles (Estep 1989) and which have been highly correlated with kite nest site densities (Erichsen et al. 1994). Kites also forage in dry pastures, annual grasslands, rice stubble fields, and occasionally in orchards (Erichsen 1995).

Winter foraging habitat is similar to breeding season foraging habitat – particularly the association with agricultural habitats and vole populations; however, there is less association with riparian forests and woodlands.

Winter Roosts. White-tailed kites roost communally during the winter months, sometimes in great concentrations of hundreds of birds. This roosting behavior usually occurs in large trees, but sometimes occurs in other upland habitats. Significant winter communal roosts have been reported in the Yolo Bypass on the Yolo Bypass Wildlife Area (Feliz pers. comm.)

A29.4 LIFE HISTORY

Description. White-tailed kites are medium-sized hawks (total length 32-38 centimeters (cm) [12.6-15 inches]) with a long white tail and large, black shoulder patches, and red eyes. In adults, these features contrast with the gray back and white underparts. The sexes are similar in size, but females tend to have darker backs than males. Juveniles have yellow eyes, buff streaks on the breast and head, and gray and white-tipped feathers on the back. White-tailed kites are also readily recognized by their foraging behavior, frequently hovering (kiting) in the air while hunting for prey.

Seasonal Patterns. Although apparently a resident bird throughout most of its breeding range, dispersal occurs during the nonbreeding season resulting in some range expansion during the winter. Stendell (1972) believed it to be resident, becoming nomadic during periods of low prey abundance. While population changes and local and regional movements appear to be somewhat predictable based on vole and other rodent cycles, it remains unknown whether in northern California this constitutes a migration movement or nomadic response to changes in the prey populations (Dunk and Cooper 1994).

Reproduction. The breeding season, from pair-bonding to juvenile dependence, occurs from approximately January to October with peak activity occurring from May through August (Dunk 1995). Nests are constructed of loosely piled sticks and twigs that are lined with grass, straw, or rootlets. The nest is placed near the top of a dense oak, willow, or other tree; usually 6 to 20 meters (20-65 feet) above ground in trees that vary from 3 to 50 meters (10-164 feet) in height (Dixon et al. 1957). Females typically lay a clutch of 4 eggs, with a range of 3 to 6. The female incubates exclusively and performs most brooding while the male provisions the female and nestlings. Eggs are incubated for about 28 days. Young fledge in 35 – 40 days following hatching, with the peak fledging period occurring in June (Erichsen 1995).

Home Range/Territory Size. Territory size is variable and regulated primarily by prey abundance and vegetation structure (i.e., accessibility of prey); however, this species also responds to the abundance of interspecific and intraspecific competitors (Dunk 1995, Erichsen 1995). Reported average territory sizes include 1.6 – 21.5 hectares (3.95 – 53.13 acres) (Dunk and Cooper 1994), 19 - 52 hectares (46.95 – 128.49 acres) with a mean of 29 hectares (71.66 acres) (Waian 1973), and 17 - 120 hectares (42.01 – 296.53 acres) (Henry 1983). As with other raptors species, particularly those occurring in agricultural habitats, home ranges may overlap and foraging may be limited to a small portion of the total area possibly a result of competition or fluctuating prey accessibility due to changes in vegetation structure (Henry 1983). Communal roosts are used during the non-breeding season (Waian and Stendell 1970). Home ranges for non-breeders is more difficult to determine since communal roosts may be tens of kilometers away (Dunk 1995).

Foraging Behavior and Diet. White-tailed kites generally hunt from a central perch over areas as large as 3 square kilometers (sq km) (1.16 square miles [sq m]) (Warner and Rudd 1975), but foraging usually occurs within 0.8 km (0.5 m) from the nesting site during the breeding season (Hawbecker 1942). Kites are not particularly territorial. The nest site and immediately surrounding area are defended against crows and other raptors (Pickwell 1930, Dixon et al. 1957), and small defended wintering territories of about 0.10 sq km (0.04 sq m) have been documented (Bammann 1975).

The white-tailed kite preys mostly on voles, but also takes other small, diurnal mammals, and occasionally birds, insects, reptiles, and amphibians. Small mammal prey comprises 95 percent of the kite diet (Dunk 1995). It forages in undisturbed, open grasslands, meadows, farmlands and emergent wetlands, ungrazed grasslands, fence rows and irrigation ditches adjacent to grazed lands (Dunk 1995). It soars, glides, and hovers less than 30 meters (98 feet) above the ground in search of prey. It hunts almost exclusively by hovering from 5 to 25 meters (16-82 feet) in height, with hovering bouts lasting up to 60 seconds. During this time, kites scan the ground searching for prey and watching for potential competitors or predators. The hovering bout ends in a dive to the ground for prey; flight to another location; soaring or interacting with another bird; or flight to the perch (Warner and Rudd 1975).

A29.5 Threats and Stressors

Urbanization/Habitat Fragmentation. Urbanization, including residential and commercial development and infrastructure development (roads and oil, water, gas, and electrical conveyance facilities) is one of the principal causes of continuing habitat loss for white-tailed kite and is a continuing threat to remaining populations, particularly in rapidly urbanizing areas in the Sacramento Valley. Urbanization permanently removes habitat and results in permanent abandonment of nesting territories. Proximity to urban areas also influences kite occurrence. While there are examples of kites nesting and roosting in urban areas, in general, the species is intolerant of noise and human activities and will abandon nesting areas that are subject to increasing levels of human disturbances. Kites are also sensitive to habitat fragmentation. Low density urbanization or isolation of habitats – even if relatively large patches remain undisturbed – also leads to territory abandonment.

Agricultural Crop Conversion. As noted above, white-tailed kite populations are closely associated with rodent abundance and accessibility, which can be influenced by crop patterns. Kite populations have recovered to some extent in California due in part to the expansion of compatible agricultural types. The conversion to crop patterns that do not support sufficient rodent prey, or that restrict accessibility to prey, can result in the abandonment of traditionally active territories.

A29.6 Relevant Conservation Efforts

Few conservation efforts have been undertaken to conserve white-tailed kite populations. The lack of state or federal listing limits the extent of regulatory influence. There remain several significant data gaps regarding population status and trends, migration, dispersal from nesting sites, and other aspects of annual movements.

Protection typically occurs at the local project level pursuant to the California Environmental Quality Act (CEQA). While project level mitigation may address protection of active sites and avoidance of take of this fully protected species, they do not address conservation or protection at a regional level.

Regional conservation efforts have focused on the development and implementation of habitat conservation plans/natural community conservation plans. These regional conservation approaches can be an effective tool to manage and sustain white-tailed kite populations if they protect sufficient suitable and occupied habitat. Much of the Plan Area overlaps with or is near other conservation planning efforts that are either currently being implemented or are in development. These plans include the San Joaquin County Multi-species Habitat Conservation and Open Space Plan, the South Sacramento County Habitat Conservation Plan, the Yolo County Natural Heritage Program Plan, and the Butte Regional Conservation Plan. If effectively coordinated, these efforts can be a valuable tool in managing white-tailed kite populations in the region. However, to date there has been limited coordination between these otherwise complimentary conservation planning efforts with respect to managing covered species.

A29.7 Species Habitat Suitability Model

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, and cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf 2007. Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers, connectivity between habitat types, and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The white-tailed kite model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), USDA 2005 aerial photography, and DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable white-tailed kite habitat in the Plan Area according to the species' two primary life requisites, nesting habitat and foraging habitat. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Breeding/Roosting Habitat. Nesting habitat in the Delta includes the following types from the BDCP composite vegetation layer:

- Agricultural land
    - Eucalyptus.
- Valley/foothill riparian
    - White alder (*Alnus rhombifolia*);
    - *Alnus rhombifolia/Salix exigua;*
    - *Alnus rhombifolia/Cornus sericea;*
    - Oregon ash (*Fraxinus latifolia*);
    - Box elder (*Acer negundo*);
    - *Acer negundo-Salix gooddingii;*
    - Hinds walnut (*Juglans hindsii*);
    - Fremont cottonwood (*Populus fremontii*);
    - Black willow (*Salix gooddingii*);
    - *Salix gooddingii*/wetland herbs;

  - *Salix gooddingii-Populus fremontii (Quercus lobata-Salix exigua-Rubus discolor*);
  - *Salix goodingii – Quercus lobata*/wetland herbs;
  - *Salix gooddingii/Rubus discolor;*
  - Coast live oak (*Quercus agrifolia*);
  - Valley oak (*Quercus lobata*);
  - *Quercus lobata/Rosa californica;*
  - *Quercus lobata – Acer negundo;*
  - *Quercus lobata – Alnus rhombifolia;*
  - *Quercus lobata – Fraxinus latifolia;*
  - Arroyo Willow (*Salix lasiolepis*);
  - *Salix lasiolepis* – Mixed brambles;
  - *Salix lasiolepis – Cornus sericea*/*Scirpus*[1] spp. – complex unit;
  - Shining willow (*Salix lucida*);
  - *Salix Exigua – (Salix lasiolepis – Rubus discolor – Rosa californica*);
  - Black willow (*Salix gooddingii*)-Valley oak (*Quercus lobata*) restoration;
  - Valley oak (*Quercus lobata*) restoration; and
  - White alder (*Alnus rhombifolia*) Arroyo willow (*Salix lasiolepis*) restoration.

Nesting/roosting habitat in the Suisun Marsh and Yolo Basin includes the following types from the BDCP composite vegetation layer:

- Eucalyptus;
- *Eucalyptus globules;*
- *Fraxinus latifolia;*
- Fremont cottonwood-Valley oak-Willow riparian forest;
- Landscape trees;
- Mixed Fremont cottonwood – Willow;
- Mixed willow super alliance;
- Oaks;

[1] Currently known as *Schoenoplectus*.

- *Quercus agrifolia;*
- *Salix lasiolepis/Quercus agrifolia;*
- Valley oak alliance – Riparian; and
- Willow trees.

Breeding habitat for white-tailed kite includes all valley riparian types that support an overstory component. The model does not distinguish habitat quality according to overstory composition, tree density, structure, or patch size. Natural vegetation types designated as species habitat in this model correspond to the mapped vegetation associations in the BDCP composite vegetation data layer. Breeding habitats may also function as winter roosting sites.

Assumptions. White-tailed kites nest in a variety of woodland habitat types (Dunk 1995, Erichsen 1995). Primary nesting habitat on the valley floor includes all riparian forest and some willow scrub habitats regardless of width or density. On the valley floor, kites also nest in isolated trees along irrigation canals, wind breaks and other tree rows, roadside trees, and in trees around rural residences (Erichsen 1995). Because these habitats are often below the minimum mapping unit, kite breeding habitat may be underrepresented here. Kites also roost in these habitats during winter. Large kite roosts have been reported in the Yolo Bypass on DFG's Yolo Bypass Wildlife Area (Feliz pers. comm.).

Foraging Habitat. Foraging habitat in the Delta includes the following types from the BDCP composite vegetation layer:

- Grasslands
  - Ruderal herbaceous grasses and forbs;
  - California annual grasslands;
  - *Bromus diandrus-Bromus hordeaceus;*
  - Italian rye-grass (*Lolium multiflorum*);
  - *Lolium multiflorum-Convolvulus arvensis;*
  - Degraded vernal pool complex – California annual grasslands;
  - Degraded vernal pool complex – Ruderal herbaceous grasses and forbs; and
  - Degraded vernal pool complex – Italian rye-grass (*Lolium multiflorum*).
- Managed wetlands
  - Temporarily flooded grasslands;
  - Rabbitsfoot grass (*Polypogon monspeliensis*);
  - Poison hemlock (*Coniumm maculatum*);

   - Intermittently flooded perennial forbs;
   - Managed annual wetland vegetation (non-specific grasses and forbs);
   - Shallow-flooding with minimal vegetation;
   - Seasonally flooded undifferentiated annual grasses and forbs;
   - Managed alkali wetland (*Crypsis*); and
   - Intermittently or temporarily flooded undifferentiated annual grasses and forbs.
- Alkali seasonal wetland complex and other natural seasonal wetlands
   - *Distichlis spicata* – Annual grasses;
   - Saltgrass (*Distichlis spicata*);
   - Seasonally-flooded grasslands;
   - Vernal pools;
   - Degraded vernal pool complex-vernal pools;
   - *Juncus balticus* – Meadow vegetation;
   - Temporarily flooded perennial forbs;
   - Alkaline vegetation mapping unit;
   - *Allenrolfea occidentalis* mapping unit;
   - *Suaeda moquinii* mapping unit; and
   - Salt scalds and associated sparse vegetation.
- Vernal pool complex
   - *Allenrolfea occidentalis* mapping unit;
   - Annual grasses generic;
   - Annual grasses/weeds;
   - California annual grasslands;
   - *Distichlis spicata;*
   - *Distichlis*/annual grasses;
   - *Distichlis spicata* – Annual grasses;
   - *Distichlis/S. maritimus;*
   - *Distichlis* (generic);
   - Italian rye-grass (*Lolium multiflorum*);
   - Ruderal herbaceous grasses and forbs;

- Salt scalds and associated sparse vegetation;
- Seasonally-flooded grasslands;
- *Suaeda moquinii* mapping unit; and
- Vernal pools.

Foraging habitat in the Suisun Marsh and Yolo Basin includes the following types from the BDCP composite vegetation layer:

- *Agrosits avenacea;*
- Annual grasses generic;
- Annual grasses/weeds;
- *Atriplex lentiformis* (generic);
- *Atriplex triangularis;*
- *Atriplex/*annual grasses;
- *Atriplex/Distichlis;*
- *Atriplex/S. maritimus;*
- *Atriplex/Sesuvium;*
- *Baccharis/*annual grasses;
- *Brassica nigra* (generic);
- *Bromus* spp.*(Hordeum);*
- *Crypsis schoenoides;*
- *Crypsis* spp. – Wetland grasses – Wetland forbs;
- Cultivated annual graminoid;
- *Distichlis* (generic);
- *Distichlis spicata;*
- *Distichlis-Juncus-Triglochin-Glaux;*
- *Distichlis/*annual grasses;
- *Distchilis cotula;*
- *Distichlis/Juncus;*
- *Distichlis/Lotus;*
- *Distichlis/S. americanus;*
- *Distichlis/S. maritimus;*

- *Distichlis/Salicornia*[2]*;*
- *Agrostis avenacea;*
- Annual grasses generic;
- Annual grasses/weeds;
- *Atriplex lentiformis* (generic);
- *Atriplex triangularis;*
- *Atriplex triangularis* (generic);
- *Atriplex/*annual grasses;
- *Atriplex/Distichlis;*
- *Atriplex/S. maritimus;*
- *Atriplex/Sesuvium;*
- *Baccharis/*annual grasses;
- Fallow disced field;
- Field crops;
- Flooded managed wetland;
- *Frankenia/Agrostis;*
- *Frankenia/Distichlis;*
- *Hordeum/Lolium;*
- Intermittently flooded to saturated deciduous shrubland;
- *Juncus balticus;*
- *Juncus balticus/Conium;*
- *Juncus balticus/Lepidium;*
- *Juncus balticus/Potentilla;*
- *Lepidium* (generic);
- *Lepidium/Distichlis;*
- *Leymus* (generic);
- *Lolium* (generic*);*
- *Lolium/Lepidium;*

[2] Currently known as *Sarcocornia*.

- *Lolium/Rumex;*
- *Lotus corniculatus;*
- Medium upland herbs;
- Medium upland shrubs;
- Medium wetland graminoids;
- Medium wetland herbs;
- Flooded managed wetland;
- Pasture;
- Perennial grass;
- *Phalaris aquatica;*
- *Polygonum-xanthium-echinochloa;*
- *Polypogon monspeliensis* (generic);
- Rice;
- *Rumex* (generic);
- *Salicornia* (generic);
- *Salicornia virginica*[3]*;*
- *Salicornia/*annual grasses;
- *Salicornia/Atriplex;*
- *Salicornia/Cotula;*
- *Salicornia/Crypsis;*
- *Salicornia/Polygonum-Xanthium-Echinochloa;*
- *Salicornia/Sesuvium;*
- *Sesuvium verrucosum;*
- *Sesuvium/Distichlis;*
- *Sesuvium/Lolium;*
- Short upland graminoids;
- Short wetland graminoids;
- Short wetland herbs

[3] Currrently known as *Sarcocornia pacifica*.

- Tall wetland graminoids;
- Tall wetland herbs;
- Truck/nursery/berry crops;
- Upland annual grassland and forbs formation;
- Upland herbs; and
- Wetland herbs.

Agriculture. The following DWR 2007 Land Use survey types are included as suitable agricultural foraging habitats for white-tailed kite. These types represent the typical agricultural cover types in the Plan Area that are included in the DWR 2007 land use survey. Rotational crop types that are not common to the Plan Area are not included here. Pasture types are mostly perennial; alfalfa is semi-perennial (3 to 7 years); and all other types are annually or seasonally rotated irrigated crops, only some of which provide suitable foraging habitat for white-tailed kites.

- Grain and hay crops
  - Barley;
  - Wheat;
  - Oats; and
  - Miscellaneous and mixed grain and hay.
- Rice
- Field crops
  - Safflower;
  - Sugar beets;
  - Corn;
  - Grain sorghum;
  - Sudan;
  - Beans;
  - Miscellaneous field; and
  - Sunflowers.
- Pasture
  - Alfalfa and alfalfa mixtures;
  - Clover;
  - Mixed pasture;

  - Native pasture;
  - Induced high water table native pasture; and
  - Miscellaneous grasses.
- Truck, nursery and berry crops
  - Asparagus;
  - Beans;
  - Onions and garlic;
  - Tomatoes; and
  - Peppers.
- Idle
  - Land not cropped the current or previous crop season, but cropped within the past three years; and
  - New lands being prepped for crop production.

Assumptions. Foraging habitat types noted above are considered available year-round; however, flooded seasonal wetlands receive less use during periods of inundation. During the breeding season, kites generally restrict their foraging territories to an approximately 1 square mile area around the nest (Warner and Rudd 1975). During the non-breeding season, kites are not confined to the limits of breeding territories and can be found throughout the Plan Area. Breeding and wintering season foraging habitat was not differentiated in this model.

A variety of foraging habitat types are used, but those that support larger and more accessible prey populations, particularly meadow voles, are more suitable (Stendell 1972). Grassland and seasonal wetland cover types generally provide more stable food resources over the long term; however, irrigated croplands and pasturelands are also widely used. Agricultural cover types that appear to be preferred include alfalfa and other hay crops, irrigated pastures, and some cultivated habitats, particularly sugar beets and tomatoes, both of which can support relatively large populations of voles and which have been highly correlated with kite nest site densities (Erichsen et al. 1994). Kites also forage in pastures, rice stubble fields, and occasionally in orchards (Erichsen 1995).

Winter foraging habitat is similar to breeding season foraging habitat – particularly the association with agricultural habitats and vole populations; however, there is less association with riparian forests and woodlands.

Kites generally forage in agricultural fields based on prey abundance and accessibility, which is highly variable among the crop types listed above. Some crop types provide higher value during the growing season than others due primarily to vegetation structure. However, because the Grain and Hay, Field, and Truck, nursery and berry crop types listed above are seasonally rotated, the value of individual fields changes each year. Therefore, these crop types are not differentiated based on their seasonal value and are instead combined into a category of seasonally rotated croplands. As a result, this model overestimates the extent of available agricultural foraging habitat in any given year.

Habitat Units. As described, the white tailed kite is closely associated with agricultural lands in the Plan Area. Most of the Plan Area consists of agricultural land and most is considered to have some value as foraging habitat for white-tailed kites. However, the value of crop types differ widely due to their growth and structure, which influences accessibility by foraging kites, and in prey abundance, which influences the availability of prey to foraging kites. Because of the dynamic nature of the agricultural landscape and the variability of crop patterns and conditions seasonally and annually, only a portion of the agricultural landscape is suitable or available for foraging in any given season or year. To account for this variability and to more accurately represent the value of Plan Area-wide foraging habitat, acres of white-tailed kite foraging habitat can be converted to habitat units.

Sufficient information is available on the growth and structure of different agricultural crops (Estep 2009) and the prey abundance and white-tailed kite use of different crop types to generally categorize crops based on their value as foraging habitat. By placing different crop types and other foraging habitats that traditionally occur in the Plan Area into crop value classes and assigning relative values to those classes (e.g., 0.1, 0.25, 0.5, 0.75, and 1.0), the habitat acres can be converted to habitat units. Habitat units, rather than acres, can then be used to describe and calculate impacts to white-tailed kite foraging habitat using this index of habitat value. Table A-29a provides the rationale for assigning crop types and other agricultural land uses to habitat value categories. Figure A-29c displays the distribution of foraging habitat and the assigned habitat values within the Plan Area.

Table A-29a. White-tailed Kite Agricultural Foraging Habitat Value Classes

Foraging Habitat Value Class	*Assigned Agricultural Crops/ Habitats*	*Rationale for Assignment of Agricultural Crop Class*	*Information Sources*[1]
1.0-Very High	Alfalfa	Alfalfa has the highest value because it is semi-perennial (up to 5 years before rotation), which increases prey abundance; has a relatively low profile such that prey are accessible season-long; and has a management regime (mowing and irrigation) which further increases prey accessibility.	Erichsen 1995, J. Estep, pers. comm., T. Beedy, pers. comm., Estep 1989, Estep 2009, Swolgaard et al. 2008.
.75-High	Native Pasture, Undifferentiated Pasture, Mixed Pasture, Clover, Miscellaneous Grasses (grown for seed)	These pasture types provide a relatively consistent vegetation structure and rodent prey populations. There is less seasonal variability with respect to prey abundance and accessibility compared with grain and vegetable crops, but they lack the management practices that enhance prey accessibility found in alfalfa.	Erichsen 1995, J. Estep, pers. comm., T. Beedy, pers. comm., Estep 1989, Estep 2009, Swolgaard et al. 2008.

Foraging Habitat Value Class	*Assigned Agricultural Crops/ Habitats*	*Rationale for Assignment of Agricultural Crop Class*	*Information Sources*[1]
.5-Medium	Sugar Beets, Tomatoes, Grain and Hay	Certain row crops, such as beets and tomatoes also have relatively high value because they support large rodent prey populations, are accessible season-long because of their relatively low vegetation profile, and they are harvested prior to migration, when an abundance of prey becomes available. Most grain crops (primarily wheat in Yolo County) provide value during and following harvesting, when prey become accessible.	Erichsen 1995, J. Estep, pers. comm., T. Beedy, pers. comm., Estep 1989, Estep 2009, Swolgaard et al. 2008.
.25-Low	Rice stubble, orchards	Kites occasionally use rice fields following harvest and during idle periods and have occasionally been observed to use orchards for foraging.	Erichsen 1995
.10-Marginal	Broccoli, safflower,corn, grain sorghum, sunflower, Sudan, Dry Beans, Undifferentiated Field Crops, Asparagus, Green Beans, Cole Crops, Carrots, Melons/Squash/Cucumbers, Onions/Garlic, Peppers, Cabbage, Undifferentiated Truck and Berry Crops, Artichokes, Lettuce (all types), Spinach, Mixed Truck and Berry	The truck and berry/field crop agriculture types are suitable for a portion of the breeding season depending on their structure and planting/harvesting regime. But in general, they produce less prey abundance and less prey availability than the other agriculture types listed above.	J. Estep, pers. comm., T. Beedy, pers. comm., Estep 1989, Estep 2009, Swolgaard et al. 2008.

APPENDIX A30. GIANT GARTER SNAKE (*THAMNOPHIS GIGAS*)

A30.1 LEGAL STATUS

The giant garter snake (*Thamnophis gigas*) is a state and federally threatened species. The State of California listed the giant garter snake as threatened on June 27, 1971 (DFG 2008). The U.S. Fish and Wildlife Service (USFWS) listed the species as federally threatened on October 20, 1993 (58 FR 54053). The Draft Recovery Plan for the Giant Garter Snake (*Thamnopsis gigas*) was completed in 1999 (USFWS 1999). Critical habitat has not been designated for this species.

A30.2 SPECIES DISTRIBUTION AND STATUS

A30.2.1 Range and Status

The giant garter snake is endemic to wetlands in the Sacramento and San Joaquin valleys and was historically distributed throughout the San Joaquin Valley (Hansen and Brode 1980). The current distribution extends from near Chico in Butte County south to the Mendota Wildlife Area in Fresno County (Figure A-30a). No occurrences of giant garter snakes are known from the northern portion of the San Joaquin Valley north to the eastern fringe of the Sacramento-San Joaquin River Delta, where the floodplain of the San Joaquin River is limited to a relatively narrow trough (Hansen and Brode 1980, 58 FR 54053). The resulting gap of approximately 100 kilometers (62.3 miles) separates the southern and northern populations, with no giant garter snakes known from the lowland regions of Stanislaus County (Hansen and Brode 1980, CNDDB 2009).

Occurrence records indicate that garter snakes are currently distributed in 13 unique population clusters coinciding with historical flood basins, marshes, wetlands, and tributary streams of the Central Valley (Hansen and Brode 1980, Brode and Hansen 1992, USFWS 1999). These populations are isolated, without protected dispersal corridors to other adjacent populations, and are threatened by land use practices and other human activities, including development of wetland and suitable agricultural habitats. The USFWS recognizes these 13 extant populations (58 FR 54053), including Butte Basin, Colusa Basin, Sutter Basin, American Basin, Yolo Basin-Willow Slough, Yolo Basin-Liberty Farms, Sacramento Basin, Badger Creek-Willow Creek, Coldani Marsh, East Stockton Diverting Canal and Duck Creek, North and South Grassland, Mendota, and Burrel-Lanare. These populations extend from Fresno north to Chico and encompass 11 counties: Butte, Colusa, Glenn, Fresno, Merced, Sacramento, San Joaquin, Solano, Stanislaus, Sutter, and Yolo.

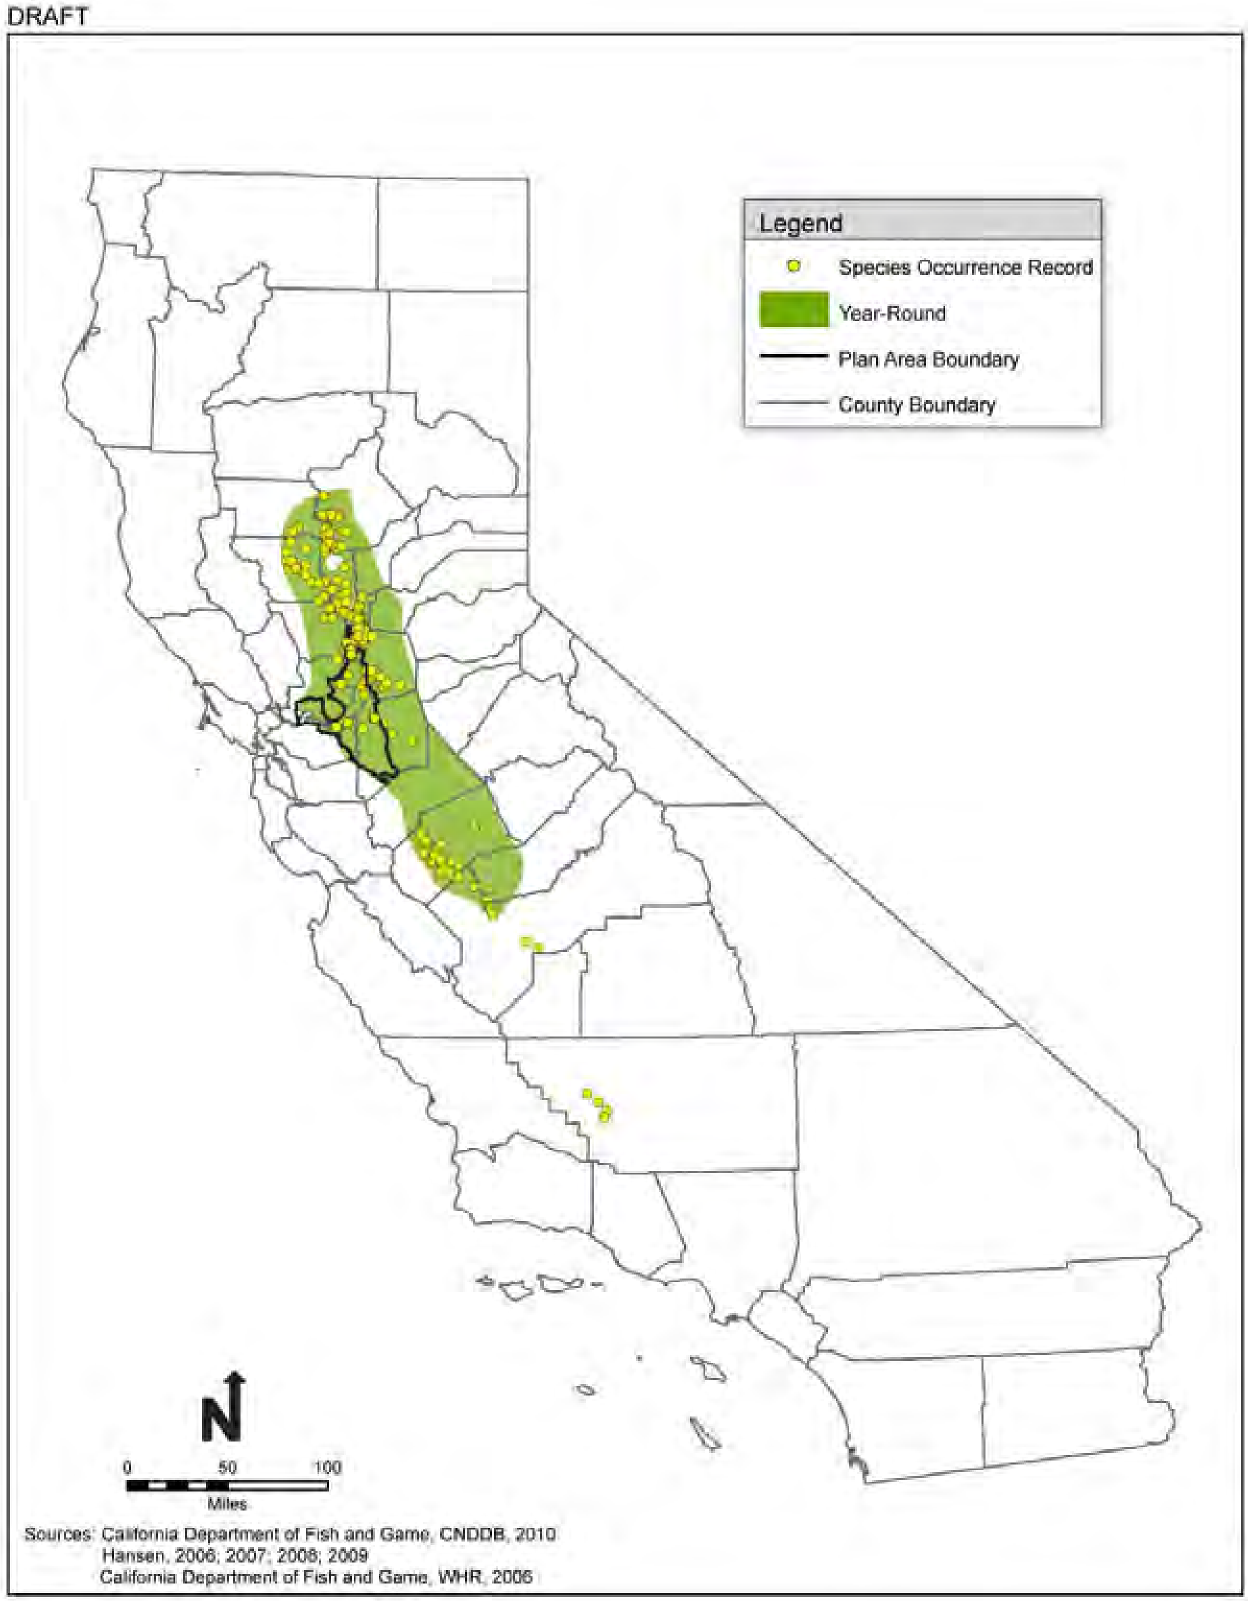

Figure A-30a. Giant Garter Snake Statewide Range and Recorded Occurrences

A30.3 DISTRIBUTION AND STATUS IN THE PLAN AREA

The Bay Delta Conservation Plan [BDCP] Plan Area is within the Mid-Valley Recovery Unit identified in the Draft Recovery Plan, and three of the thirteen giant garter snake populations identified by the USFWS occur within the Plan Area, including Yolo Basin – Willow Slough, Yolo Basin – Liberty Farms, and Coldani Marsh – White Slough populations (USFWS 1999).

Recent survey efforts suggest that extant giant garter snake populations continue to persist mainly in the periphery of the Plan Area in two locations north of the San Joaquin River, including the Yolo Bypass from the Yolo Basin Wildlife Area north to Willow Slough area and Coldani Marsh-White Slough area in the eastern Delta. The few isolated records occurring within most of the Sacramento-San Joaquin River Delta suggest the lack of other extant populations; and that while giant garter snakes may have occupied this region at one time, longstanding reclamation of wetlands for intense agricultural applications has eliminated most suitable habitat (Hansen 1986) and prohibited the reestablishment of viable giant garter snake breeding populations.

CNDDB (2009) reports 15 giant garter snake occurrences sparsely distributed north of State Route 4 (SR-4) in the central and northern Delta portions of the Plan Area (Figure A-30b). Four are west of the Sacramento Deep Water Ship Channel in the wetlands and pasturelands of the Yolo Basin; five are from the cultivated and remnant grassland areas east of the Sacramento River north of Walnut Grove; three are from the vicinity of White Slough south of SR-12 and west of Interstate 5 (I-5); and four are in the central Delta, including two reported from the vicinity of Sherman Island. With the exception of recent detections made from the Yolo Basin, most of these CNDDB records are from the mid-1980s (CNDDB 2009). There are no records from the area west of the Sacramento and Mokelumne Rivers and east of the Deep Water Ship Channel north of SR-12. There are only two records south of the San Joaquin River and none south of SR-4. Recent findings demonstrate that giant garter snake appears extant in portions of the Yolo Basin (Wylie et al. 2003, 2004, Wylie and Amarello 2006, Hansen 2007, E. Hansen pers. comm., CNDDB 2009), and at Coldani Marsh/White Slough (E. Hansen pers. comm.) (Figure A-30b).

Historically, giant garter snakes occurred in both the south and north Delta regions (Hansen and Brode 1980, Hansen 1988, CNDDB 2009). Individuals have been observed in the north Delta region east of the Sacramento River at North Stone Lake, Beach Lake, and near Locke (CNDDB 2009). The species also was recorded on Sherman Island near the Antioch Bridge north of the City of Oakley (Hansen personal observation). Other documented occurrences are distributed around the periphery of the north and east Delta. The extent to which these historically occupied areas represent viable breeding populations is unclear, given agricultural conversion of much of the Delta. Nonetheless, survey efforts since the mid-1980s suggest that much of the Delta is unoccupied or supports few giant garter snakes (see below).

DRAFT

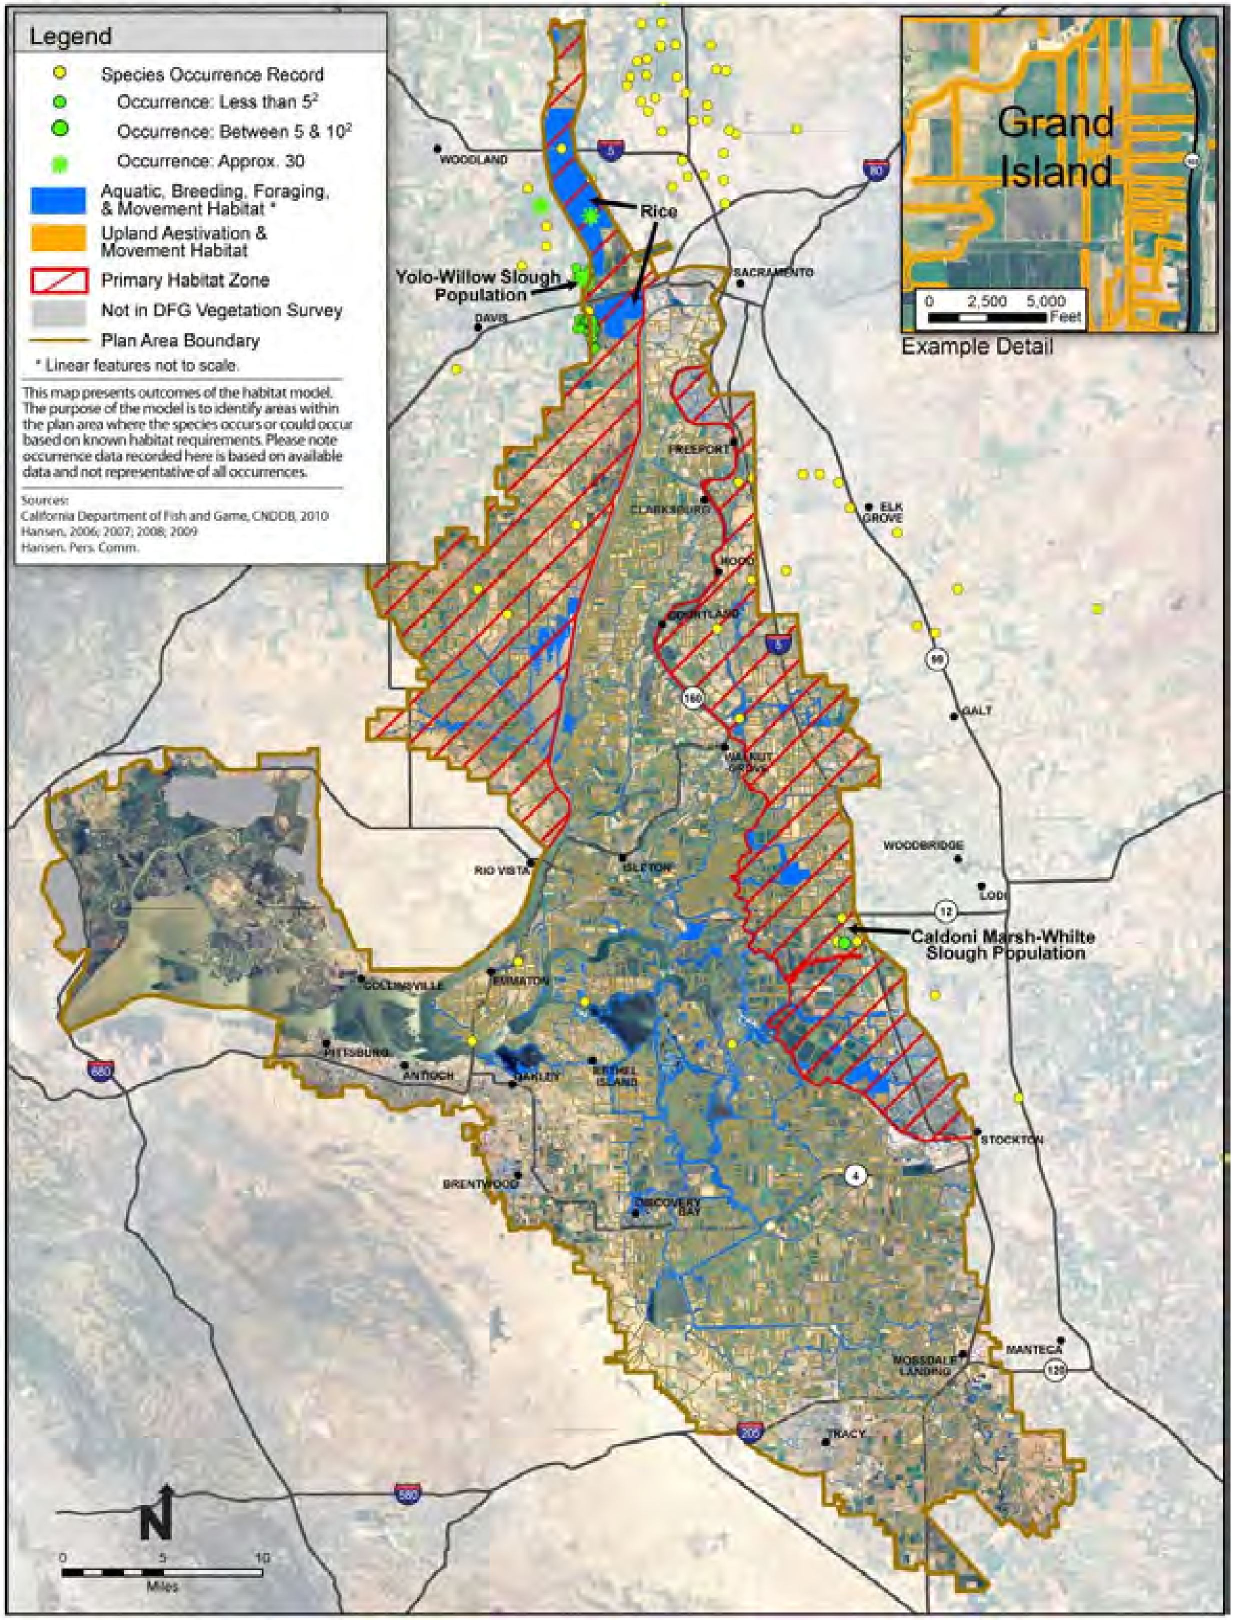

Figure A-30b. Giant Garter Snake Habitat Model and Recorded Occurrences

Still, Hansen (1988) reported that although the major permanent waterways of the Delta are apparently unsuitable for giant garter snake, small backwater sloughs and toe drains support suitable habitat for, and thus could potentially support, small numbers of giant garter snake.

The following describes the historical and current survey work and occurrence information within the Plan Area.

A30.3.1 South Delta

During 1987 and 1988, live trapping and visual surveys were conducted at various locations within the California Department of Water Resource's South Delta Water Management Project area including Trapper Slough, Salmon Slough, and along the irrigation canal at Highway 4 near the Clifton Court Forebay expansion area. No giant garter snakes were observed during either year, although virtually all islands and channels contained some suitable habitat (ECOS 1990).

In 1994, surveys were conducted to determine the status of giant garter snake within DWR's Interim South Delta Project (ISDP) area. The purpose of this study was to focus on particular areas of the ISDP containing the most suitable habitat and to conduct live-trapping as well as additional ground surveys. Ground surveys for giant garter snakes were undertaken during previous work in the south Delta region in 1987, 1988, and 1993. Although no giant garter snakes were observed during any of these surveys, suitable habitat for the snake was present in some of the more remote sloughs and waterways in the ISDP area (e.g., Tom Paine Slough, Salmon Slough, and Paradise Cut). Based on the presence of apparently suitable habitat, the potential for isolated populations of giant garter snake was not ruled out (Miriam Green Associates 1995).

There are only two isolated records of giant garter snake on the south side of the San Joaquin River in the northern aspect of the species' range. Although the historical and current distribution of giant garter snake in the Delta is poorly understood, the south bank of the San Joaquin River lies within the apparent gap between the northern and southern populations (CNDDB 2009). The isolated record on Sherman Island represents the northern population's known southern terminus. The nearest locality record to the south lies more than 50 air miles distant in Madera County; no giant garter snakes are documented in Stanislaus County between the documented extremes of the Sacramento Valley and San Joaquin Valley populations.

A30.3.2 North Delta

Surveys were also conducted to determine the status of giant garter snakes within DWR's Interim North Delta Program (INDP) area (Miriam Green Associates 1996). The species was observed at scattered locations within the INDP area during 1994 surveys, but were not encountered within the major waterways of the North Delta. The species was observed in marsh and canal habitats along the Upland Canal from the confluence of Sycamore Slough and the Upland Canal south to the vicinity of White Slough on the Terminous and Shin Kee tracts. Giant garter snakes also occur in the Upland Canal and the Coldani Marsh, north and east of Shin Kee Tract, respectively (Miriam Green Associates 1996).

A30.3.3 White Slough/Coldani Marsh and Eastern Delta Fringe

Between 1974 and 1978, 13 rectangular borrow pits were excavated from one to five miles west of I-5 to provide fill for freeway construction (DWR 1995). The pits are fed by groundwater and periodic runoff from precipitation, irrigation, and high canal flows, creating a series of ponds characterized by vegetated sloping or vertical banks and open water with adjacent uplands and high ground. White Slough Wildlife Area encompasses ponds 7-13 along a roughly 14-mile (22.5-kilometer) stretch between Thornton and Stockton.

The White Slough Wildlife Area supports one of 13 extant giant garter snake populations recognized by the USFWS (Coldani Marsh/White Slough population) (USFWS 1999). First identified on site in 1974 (CNDDB 2009), giant garter snakes were observed at the White Slough Wildlife Area by George Hansen from the time he began formally surveying for them in 1976 until the mid-1990's (Hansen and Brode 1980, Hansen 1988, 1996). Among two giant garter snake populations recognized in San Joaquin County, the White Slough population is perhaps the only locality still supporting a viable snake population.

Most giant garter snake observations at White Slough Wildlife Area are concentrated at Pond 9, but surveys conducted by George Hansen in 1994 yielded additional sightings at Pond 7, Pond 11, and a site between Ponds 6 and 7 (DWR 1995, CNDDB 2009). Although channels and drainages including Telephone Cut, Sycamore Slough, Hog Slough, and Beaver Slough were surveyed, observations were made only at the ponds (M. Green pers. comm.). Each of the ponds where snakes were observed are characterized by slow moving water with mud banks and bottoms, vegetation cover, and access to high ground (DWR 1995).

In 2009, under a grant provided by the Central Valley Project (CVP) Habitat Restoration Program, Eric Hansen began rigorous trap and visual encounter sampling at Ponds 7-13 of the White Slough Wildlife Area to determine the current status and distribution of giant garter snake. Though the project is not yet complete, giant garter snakes have only been confirmed within the emergent wetlands west of Pond 9 along the Upland Canal, east of Guard Road and south of Highway 12 (E. Hansen pers. comm.). Ten snakes have been captured to date (6 males and 4 females); all are sexually mature adults.

Surveys conducted within and in the vicinity of Lost Slough in 1996 and 2004 failed to detect giant garter snakes east of I-5 (Hansen 2004a, G. Wylie pers. comm.).

A30.3.4 Antioch/Oakley and West Delta

Recent, intensive trapping surveys conducted within Contra Costa County independently by Eric Hansen and by Swaim Biological, Inc. (SBI) have failed to detect giant garter snake. Likewise, SBI intensively trapped in regions northeast of Oakley in 2003 and 2005, including Marsh Creek, Big Break, and Contra Costa Canal, without success (Swaim 2004, Swaim 2005a-f, Swaim 2006). With few exceptions, these surveys spanned three to five months of the species' active period. SBI also rigorously investigated bullfrog stomach contents to see if undetected giant garter snakes had been consumed; none were detected. While all of these surveys produced captures of common snake species, giant garter snakes were not detected, and, in all cases, it was determined that self-sustaining populations were unlikely to occur. Each report cited marginal habitat quality as probable explanations for the species' absence. While the final disposition of SBI's results and recommendations are unknown, the Service concurred with Eric Hansen's findings that the species was unlikely to occur within the areas sampled.

A30.3.5 Central Delta

In support of DWR's Delta Wetlands Project, Eric Hansen intensively trapped for giant garter snakes on Webb Tract and on Bacon Island in 2003 and 2004 without success (Patterson and Hansen 2004, Patterson 2005). Ongoing 2009 surveys in the central Delta conducted by DWR have resulted in no giant garter snake occurrences (L. Patterson pers. comm.).

A30.3.6 Yolo County/Yolo Bypass

Giant garter snakes are documented in two distinct concentrations along the eastern edge of Yolo County (Hansen 2006, 2007, 2008, Wylie and Amarello 2006, CNDDB 2009). The first concentration lies north of the Yolo Basin in the northeastern portion of Yolo County, northwest of Knights Landing and in the southern end of the Colusa Basin near Sycamore Slough and the Colusa Basin Drainage Canal. Wylie and Amarello (2006) report a population density in the Colusa Basin Drainage Canal of 20±3 snakes per kilometer (0.6 mile) during 2006, falling within 2003 and 2004 confidence intervals; noting, however, that local distribution appears to have shifted away from areas formerly in rice production that have either been fallowed or converted to other crop types.

The second concentration lies in the east-central portion of Yolo County and corresponds with the USFWS' Yolo Basin – Willow Slough population (USFWS 1999). Recent records are from the Yolo Bypass east of Conaway Ranch near the Tule Canal; the Willow Slough/Willow Slough Bypass from Conaway Ranch south to the Yolo Wildlife Area; the Davis Wetlands complex south of Conaway Ranch between the Willow Slough Bypass and the Yolo Bypass; the Yolo Wildlife Area along the east edge of the Yolo Bypass west levee; and the adjacent ricelands west of the Yolo Wildlife Area (Hansen 2006, 2007, 2008) (Figure A-30b).

Surveys conducted in 2005, 2006, and 2007 resulted in captures of 34, 9, and 1 unique individual(s), respectively, in the Yolo Wildlife Area; 8, 18, and 8 unique individuals, respectively, in the adjacent ricelands; and 36 unique individuals (2007 only) in the Davis Wetlands complex (Hansen 2006, 2007, 2008). Hansen (2006, 2007, 2008) reports an even distribution within size classes, estimating local populations ranging from approximately 8 to 57 in the Yolo Bypass at the Yolo Wildlife Area; approximately 5 to 17 in the adjacent ricelands; and from approximately 26 to 67 within the Davis Wetlands Complex (Hansen 2006, 2007, 2008), which lies along the western Yolo Bypass levee north of I-80.

In 2009, Eric Hansen trapped in all portions of Conaway Ranch, north of I-80 in the Yolo Bypass, capturing 64 giant garter snakes in a period of roughly twelve weeks (E. Hansen pers. comm.). Of the 64 individuals, 29 were captured within ricelands in the interior of the Yolo Bypass and 35 were captured in the land side ricelands beyond the Yolo Bypass west levee.

USGS conducted surveys for giant garter snake in 2004 and 2005 in the southern portion of the Yolo Basin in the vicinity of Cache Slough between Liberty Island and Lower Ulatis Creek in Solano County (Wylie and Martin 2005). Surveys were conducted in areas that supported habitat similar to known occupied sites and in areas where several historical occurrences were apparently reported. No giant garter snakes were found during these surveys (Wylie and Martin 2005).

While suitable habitat continues to persist along natural streams and artificial channels throughout much of the Delta, historical and recent occurrence records based on substantial survey effort suggests two primary geographic areas that retain extant populations and probably a greater likelihood of potential occurrence and reestablishment of populations. These include the Yolo Bypass and vicinity west of the Deep Water Ship Channel and the eastern Delta fringe from approximately the Stone Lakes area south to Stockton and generally east of the Mokelumne River. These areas are referred to on Figure A-30b as the Primary Habitat Zone.

A30.4 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

The giant garter snake resides in marshes, ponds, sloughs, small lakes, low gradient streams, and other waterways, and in agricultural wetlands, including irrigation and drainage canals, rice fields, and the adjacent uplands (58 FR 54053). Habitat requirements include: (1) adequate water during the snake's active season (early-spring through mid-fall) to provide food and cover; (2) emergent, herbaceous wetland vegetation, such as cattails (*Typha* spp.) and bulrushes (*Schoenoplectus*[1]), accompanied by vegetated banks for escape cover and foraging habitat during the active season; (3) basking habitat of grassy banks and openings in waterside vegetation; and (4) higher elevation uplands for cover and refuge from flood waters during the snake's dormant season in the winter (Hansen and Brode 1980, Hansen 1998, USFWS 2006a). In some rice-growing areas, giant garter snakes have adapted well to vegetated, artificial waterways and associated rice fields (Hansen and Brode 1993). The giant garter snake resides in small mammal burrows and soil crevices located above prevailing flood elevations throughout its winter dormancy period (USFWS 2006a). Burrows are typically located in sunny exposures along south and west facing slopes.

---

[1] Formerly known as *Scirpus*.

Due to lack of habitat and emergent vegetation cover, giant garter snakes generally are not present in larger rivers and wetlands with sand, gravel, or rock substrates. In addition, the major rivers have been highly channelized, removing oxbows and backwater areas that probably at one time provided suitable habitat. Riparian woodlands can provide suitable habitat, but it is not likely because most have excessive shade, lack of basking sites, and absence of prey populations. Giant garter snake is also usually absent from most permanent waters that support established populations of predatory game fishes and from sites that undergo routine dredging, mechanical or chemical weed control, or compaction of bank soils (Hansen and Brode 1980, Rossman and Stewart 1987, Brode 1988, USFWS 1999, 2006a).

Changing agricultural regimes, development, and other shifts in land use create an ever-changing mosaic of available habitat. Giant garter snakes move around in response to these changes in order to find suitable sources of food, cover, and prey. Connectivity between regions is therefore extremely important for providing access to available habitat and for genetic interchange. In an agricultural setting, giant garter snakes rely largely upon the interconnected network of canals and ditches that provide irrigation and drainage to provide this connectivity.

In the Central Valley, rice fields have become important habitat for giant garter snakes. Irrigation water typically enters the ricelands during April along canals and ditches. Giant garter snakes use these canals and their banks as permanent habitat for both spring and summer active behavior and winter hibernation. Where these canals are not regularly maintained, lush aquatic, emergent, and streamside vegetation develops prior to the spring emergence of giant garter snakes. This vegetation, in combination with cracks and holes in the soil, provides much needed shelter and cover during spring emergence and throughout the remainder of the summer active period.

Rice is planted during spring, after the winter fallow fields have been cultivated and flooded with several inches of standing water. In some cases, giant garter snakes move from the canals and ditches into these rice fields soon after the rice plants emerge above the water’s surface, and they continue to use the fields until the water is drained during late summer or fall (Hansen and Brode 1993). It appears that the majority of giant garter snakes move back into the canals and ditches as the rice fields are drained; although a few may overwinter in the fallow fields, where they hibernate within burrows in the small berms separating the rice checks (low dikes) (Hansen 1998).

While within the rice fields, the snakes forage in the shallow warm water for small fish and the tadpoles of bullfrogs and treefrogs. For shelter and basking sites, giant garter snakes utilize the rice plants, vegetated berms dividing the rice checks, and vegetated field margins. Gravid (pregnant) females may be observed within the rice fields during summer, and at least some giant garter snakes are born there (Hansen and Brode 1993, Hansen 1998).

Water is drained from the fields during late summer or fall by a network of drainage ditches. These ditches are sometimes routed alongside irrigation canals and are often separated from the irrigation canals by narrow vegetated berms that may provide additional shelter. Remnants of old sloughs also may remain within rice-growing regions, where they serve as drains or irrigation canals. Giant garter snakes may use vegetated portions along any of these waterways as permanent habitat. Studies indicate that despite the presence of ditches or drains, giant garter snakes will generally abandon aquatic habitat that is not accompanied by adjacent shallow-water wetlands (Wylie and Amarello 2006, Hansen 2007, Jones and Stokes 2008), underscoring the important role that this crop plays in this species' life history.

A30.5 LIFE HISTORY

Description. Giant garter snakes are one of the largest snakes in the genus *Thamnophis*. A sexually dimorphic species, females can reach sizes in excess of 5.3 feet and 1.87 pounds (lbs) (1.6 meters and 0.8 kilograms [kg]), while proportionally smaller males seldom exceed 0.55 lb (0.25 kg). Giant garter snakes possess a dark brown or olive background color separated by light-colored longitudinal stripes. For this species, coloration is geographically and individually variable. Snakes from the San Joaquin Valley region may exhibit a black-checkered pattern along the back and sides, and often lack a distinct dorsal stripe; while snakes from the Sacramento Valley region are typically darker, with a complete dorsal stripe that varies from bright yellow to orange or dull brown.

Activity. Spending cool winter months in dormancy or periods of reduced activity, giant garter snakes typically emerge from late March to early April and remain active through October; the timing of annual activity is subject to varying seasonal weather conditions. Daily activity consists of emerging from burrows after sunrise, basking to warm bodies to active temperatures, and foraging or courting for the remainder of the day (Hansen and Brode 1993). Activity generally peaks during spring emergence and courtship occurs from April into June, whereupon observations of giant garter snakes diminish significantly until a second peak is observed after females give birth during late July into August (Hansen and Brode 1993, Wylie et al. 1997, USFWS 1999, Hansen 2004b). Giant garter snakes then remain actively foraging and occasionally courting until the onset of cooler fall temperatures.

Giant garter snakes are strongly associated with aquatic habitats, typically overwintering in burrows and crevices near active season foraging habitat (Hansen 2004b). Individuals have been noted using burrows as far as 164 feet (50 meters) from marsh edges during the active season, and retreating as far as 820 feet (250 meters) from the edge of wetland habitats while overwintering, presumably to reach hibernacula above the annual high watermark (Hansen 1986, Wylie et al. 1997, USFWS 1999).

Reproduction. Upon emerging from overwintering sites, male giant garter snakes immediately disperse in search of mates and continue breeding from March into early May. Female giant garter snakes brood young internally, giving birth to live young from late July through early September (Hansen and Hansen 1990). Brood size ranges from 10 to 46 young, with a mean of

23.1 (n = 19) (Hansen and Hansen 1990). Young immediately disperse and seek shelter to absorb their yolk sacs, after which they molt and begin feeding on their own. Averaging 0.11 to 0.18 ounces (3 to 5 grams) with a snout-to-vent length of approximately 8.1 inches (20.6 centimeters [cm]), young giant garter snakes will double their size within their first year (Hansen and Hansen 1990, USFWS 1999). Sexual maturity probably averages 3 years in males and 5 years in females (USFWS 1999).

Home Range. Data based on radiotelemetry studies show that home range varies by location, with median home range estimates varying between 23 acres (range [10.3 to 203 acres], n = 8) (9 hectares, range = 4.2 to 82 hectares) in a semi-native perennial marsh system and 131 acres (range [3.2 to 2,792 acres], n = 29) (53 hectares, range = 1.3 to 1130 hectares) in a managed refuge (USFWS 1999).

Foraging Behavior and Diet. Giant garter snakes feed on small fishes, tadpoles, and small frogs (USFWS 1999), specializing in ambushing prey underwater (Brode 1988). Historically, giant garter snakes preyed on native species such as the thick-tailed chub (*Gila crassicauda*) and California red-legged frog (*Rana aurora draytonii*) (which have been extirpated from the giant garter snake's current range), as well as the pacific treefrog (*Pseudacris regilla*) and Sacramento blackfish (*Orthodox microlepidus*) (Cunningham 1959, Rossman et al. 1996, USFWS 1999). Giant garter snakes now utilize introduced species, such as small bullfrogs (*Rana catesbeiana*) and their larvae, carp (*Cyprinus carpio),* and mosquitofish (*Gambusia affinis*). While juveniles probably consume insects and other small invertebrates, giant garter snakes are not known to consume larger terrestrial prey such as small mammals or birds.

A30.6 Threats and Stressors

Habitat loss and fragmentation, flood control activities, changes in agricultural and land management practices, predation from introduced species, parasites, and water pollution are the main causes for the decline of this species.

Habitat Loss and Fragmentation. Continued loss of wetland or other suitable habitat resulting from agricultural and urban development constitutes the greatest threat to this species' survival. Conversion of Central Valley wetlands for agriculture and urban uses has resulted in the loss of as much as 95 percent of historical habitat for the giant garter snake (Wylie et al. 1997). In areas where the giant garter snake has adapted to agriculture, maintenance activities such as vegetation and rodent control, bankside grading or dredging, and discharge of contaminates, threaten their survival (Hansen and Brode 1980, Hansen and Brode 1993, USFWS 1999, Wylie et al. 2004). In developed areas, threats of vehicular mortality also are increased. Paved roads likely have a higher rate of mortalities than dirt or gravel roads due to increased traffic and traveling speeds, and as many as 31 giant garter snake traffic mortalities have been reported during a 4-year period in the Natomas Basin (Hansen and Brode 1993).

The loss of wetland habitat is compounded by elimination or compaction of adjacent upland and associated bankside vegetation cover, as well as water fouling; these conditions are often associated with cattle grazing (Thelander 1994). While irrigated pastures may provide the summer water that giant garter snakes require, high stocking rates may degrade habitat by removing protective plant cover and underground and aquatic retreats such as rodent and crayfish burrows (Hansen 1986, USFWS 1999). Studies of wandering garter snakes (*Thamnophis elegans vagrans*) in northern California have shown population numbers to be much higher in areas where grazing was excluded (Szaro et al. 1985). Radiotelemetry studies in perennial wetlands where grazing was differentially excluded show that giant garter snakes avoid areas where grazing is frequent (Hansen 2002). However, cattle grazing may provide an important function in controlling invasive vegetation that can compromise the overall value of wetland habitat (Hansen 2002).

Predation. Giant garter snakes are also threatened by the introduction of exotic species. Examinations of gut contents confirm that introduced bullfrogs (*Rana catesbeiana*) prey on juvenile giant garter snakes throughout their range (Treanor 1983, Dickert 2003, Wylie et al. 2003). While the extent of this predation and its effect on population recruitment is poorly understood, estimates based on preliminary data from a study conducted at Colusa National Wildlife Refuge suggests that 22 percent of neonate (newborn) giant garter snakes succumb to bullfrog predation (Wylie et al. 2003). Other studies of bullfrog predation on snakes have documented bullfrogs ingesting other species of garter snakes up to 31.5 inches (80 cm) long, resulting in a depletion of this age-class within the population (Bury and Wheelan 1984).

Large vertebrates, including raccoons (*Procyon lotor*), striped skunks (*Mephitis mephitis*), red foxes (*Vulpes vulpes*), gray foxes (*Urocyon cinereoargentius*), river otters (*Lutra canadensis*), opossums (*Didelphis virginiana*), northern harriers (*Circus cyaneus*), hawks (*Buteo* spp.), herons (*Ardea herodius, Nycticorax nyctycorax*), egrets (*Ardea alba*, *Egretta thula*), and American bitterns (*Botaurus lentiginosus*) also prey on giant garter snakes (USFWS 1999). In areas near urban development, giant garter snakes may also fall prey to domestic or feral house cats. In permanent waterways, introduced predatory game fishes, such as bass (*Micropterus* spp.), sunfish (*Lepomis* spp.), and channel catfish (*Ictalurus* spp.), prey on giant garter snakes and compete with them for smaller prey (58 FR 54053, Hansen 1998).

Water Pollution. Selenium contamination and impaired water quality have been identified as a threat to giant garter snakes, particularly in the southern portion of their range (USFWS 1999). While little data are available regarding the effects of specific contaminants, the bioaccumulative properties of selenium in the food web has been well documented in the Kesterson National Wildlife Refuge area (Ohlendorf et al. 1988, Saiki and May 1988, Saiki et al. 1991, USFWS 1999).

A30.7 RELEVANT CONSERVATION EFFORTS

Conservation efforts for the giant garter snake have included restoration efforts on wildlife refuges and through mitigation banking. With the continued loss of habitat within the range of the species, the snake has become increasingly dependent on ten refuges and wildlife management areas in the Central Valley (Czech 2006).

Hundreds of acres in the California refuge system are known to be occupied by the snake, however thousands of acres of apparently suitable habitat in the refuge system are currently unoccupied (Czech 2006). This suggests that factors such as winter flooding and predation (especially by nonnative species such as bullfrogs) may be limiting in some areas. The giant garter snake prefers summer flooding and winter drying, and Central Valley refuges system properties are likely managed intensively for wintering waterfowl with a reversed water regime, resulting in habitat features that are problematic for giant garter snake conservation. These opposing requirements suggest that separate conservation areas for the snake are necessary. In 1995, the Colusa National Wildlife Refuge acquired 449 acres (182 ha) of fallow rice fields, and efforts to restore the ecological integrity of the land have proven beneficial to the snake (Czech 2006).

Some mitigation banks are also designed specifically for giant garter snake habitat preservation and restoration, including the 565-acre (229-hectare) Gilsizer Slough South Giant Garter Snake Conservation Bank in Sutter County, and the 424-acre (172-hectare) Sutter Basin Conservation Bank. Giant garter snake mitigation banks in the Plan Area include the 379-acre (153-hectare) Pope Ranch in Yolo County and the 129-acre (52-hectare) South Stone Lakes Giant Garter Snake Preserve in Sacramento County.

Other wetland conservation efforts, under appropriate management regimes, can also benefit giant garter snakes. Central Valley wetland conservation occurs through a combination of both public and privately managed refuges, mitigation banks, and duck clubs, creating a large network of wetland preserves throughout the historical range of the giant garter snake. A large percentage of these wetland conservation efforts, however, are geared toward waterfowl management, often placing greater emphasis on winter water rather than the summer water upon which giant garter snakes depend (USFWS 1999). With proper consideration given to design, location, and management, these efforts might also significantly benefit the giant garter snake and other wetland-dependent species (USFWS 1999).

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designates the giant garter snake as "Contribute to Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its control and within its scope that are necessary to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts. The ERP has funded several projects designed to supplement current knowledge of giant garter snake populations and habitat use. Two projects were recently funded that contain actions to benefit giant garter snake through ongoing monitoring of semi-permanent wetlands, rice-cover crop rotation fields, and waterways adjacent to agricultural lands. Another project will evaluate the effects of fallowing agricultural habitat on giant garter snake by monitoring habitat use under normal rice growing conditions and comparing results with analogous data from those same fields and adjacent irrigation ditches after fallowing. This project will also monitor habitat use on wetland restoration sites and assess population demographics and viability of the giant garter snake. Study areas for all three projects include Barker Slough and Hastings Cut in Yolo County, Gilsizer Slough in Sutter County, areas within Richvale Water District in Butte County, and various other rice fields and managed wetlands in Butte County. These coordinated ERP projects began work in 2007 and are in the initial stages of data collection. They are designed to provide information that will help guide future restoration and conservation activities as they pertain to managing rice farms and surrounding natural habitats for the giant garter snake. Continuing project activities include ongoing telemetry of radio-marked snakes to evaluate habitat use and behavior, and trapping of snakes to develop mark/recapture estimates. Results from these projects will support filling in some of the research data gaps for the giant garter snake including determination of optimal habitat, effects of cropping patterns and specific agricultural practices on movement patterns and viability, value of restored habitats, and species status and distribution. Additionally, results from these research projects will directly facilitate future revisions of the conservation measures within this strategy.

In addition, the ERP implementing agencies have facilitated the development and preparation of the draft Sacramento Valley Giant Garter Snake Conservation Strategy. Giant garter snake is also a covered species under the Natomas Basin Habitat Conservation Plan, the San Joaquin County Multi-Species Habitat Conservation and Open Space Plan, and the East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan; and it is proposed for coverage in the Solano County Multispecies Habitat Conservation Plan, the South Sacramento County Habitat Conservation Plan, the Yolo Natural Heritage Program Plan currently under development, and the Butte Regional Conservation Plan.

A30.8 Species Habitat Suitability Model

Model Approach. BDCP Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information systems (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, and cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf 2007. Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers, connectivity between habitat types, and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The giant garter snake model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), USDA 2005 aerial photography, DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3, major hydrology 1:24,000 (USBR 2003), and the USGS-National Hydrography Dataset, 1:24,000 (USGS 1999). Using these data sets, the model maps the distribution of suitable giant garter snake habitat in the Plan Area. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

A30.8.1 Aquatic Breeding, Foraging, and Movement Habitat

Breeding, foraging, and movement habitat for the giant garter snake includes the following land cover types throughout the Plan Area and Yolo Bypass north to Fremont Weir.

- All natural perennial streams and canals with the exception of Sacramento and San Joaquin rivers. The National Hydrography Dataset hydrology dataset was used to characterize smaller hydro features such as canals, ditches, and perennial streams. The United States Bureau of Reclamation (USBR) major hydrology dataset was used to characterize the shorelines of larger hydro features such as Liberty Island.
- The following types in the Delta from the BDCP composite vegetation layer:
    - Tidal freshwater emergent wetland
        - Mixed *Scirpus*[2] mapping unit;
        - Mixed *Scirpus*/floating aquatics complex;

- The following agricultural types from the DWR 2007 Land Use Survey:
  - Rice

Aquatic breeding, foraging, and movement habitat is also differentiated into two broad suitability categories, primary and secondary. This distinction is made on the basis of the known distribution of giant garter snakes from past and current survey results as described above. Primary habitat includes lands within the Yolo Bypass west of the Sacramento Deep Water Ship Channel north to Fremont Weir and south to its confluence with the Sacramento River; and lands in the east and northeast Delta (east of, but not including, the Sacramento River south of Stonecrest Avenue to its confluence with the Mokelumne River, east of the South Fork Mokelumne River south to White Slough, east of and including White Slough south to its confluence with the San Joaquin River, and east of the San Joaquin River to Rough and Ready Island) (Figure A-30b). These are areas that include known extant populations and suitable habitat that is similar and contiguous with known population centers based on historical and recent surveys. Secondary habitat includes all lands not within the primary habitat zone. This includes the central Delta, south Delta, and the portion of the north Delta that lies between the

[3] Currently known as *Sarcocornia*.

Deep Water Ship Channel and the Sacramento River. These are areas that appear to be unoccupied or that do not include viable extant breeding populations based on historical and recent survey efforts, but do include areas that generally meet habitat suitability requirements for giant garter snake.

A30.8.2 Upland Aestivation and Movement Habitat

Upland aestivation and movement habitat for giant garter snakes includes the following land cover types immediately adjacent to and within 200 feet (61 meters) of the aquatic habitat types listed above:

- The following types in the Delta from the BDCP composite vegetation layer:
  - Agricultural land – all types
  - Grassland – all types
  - Alkali seasonal wetlands, vernal pool complex, and other natural seasonal wetlands
    - Seasonally flooded grasslands;
    - Temporarily-flooded perennial forbs;
    - *Distichlis spicata* – annual grasses;
    - vernal pools; and
    - Degraded vernal pool complex-vernal pools.
  - Managed wetlands
    - Rabbitsfoot grass (*Polypogon monspeliensis*);
    - Poison hemlock (*Conium maculatum*);
    - Intermittently flooded perennial forbs;
    - Managed annual wetland vegetation (non-specific grasses and forbs);
    - Seasonally-flooded undifferentiated annual grasses and forbs;
    - Managed alkali wetland (*Crypsis*);
    - Intermittently or temporarily flooded undifferentiated annual grasses and forbs;
    - *Scirpus* spp. in managed wetlands;
    - Smartweed – *Polygonum* spp. – mixed forbs;
    - *Polygonum amphibium;* and
    - *Perennial pepperweed (Lepidium latifolium).*
- The following types in the Yolo Bypass from the BDCP composite vegetation layer:

- o Annual grasses generic;
- o Annual grasses/weeds;
- o *Baccharis*/annual grasses;
- o *Bromus* spp./*Hordeum;*
- o Cultivated annual graminoid;
- o *Cynodon dactylon;*
- o *Distichlis*/annual grasses;
- o Fallow disced field;
- o Field crops;
- o *Hordeum/Lolium;*
- o *Lolium* (generic);
- o *Lolium/Rumex;*
- o *Lotus corniculatus;*
- o Medium upland herbs;
- o Pasture;
- o Perennial grass;
- o Short upland graminoids;
- o Truck/nursery/berry crops;
- o Upland annual grasslands and forbs formation; and
- o Upland herbs.

- The following types from the DWR 2007 Survey layer:
  - o All agricultural class types.

Assumptions. Giant garter snakes inhabit marshes, ponds, sloughs, small lakes, low gradient streams, and other waterways, and agricultural wetlands, including irrigation and drainage canals, rice fields, and the adjacent uplands (USFWS 2006b). In the Sacramento Valley, their habitat requirements include: (1) adequate water during the snake's active season (early-spring through mid-fall) to provide food and cover; (2) emergent herbaceous wetland vegetation for escape cover and foraging habitat during the active season; (3) basking habitat of grassy banks and openings in waterside vegetation; and (4) higher elevation uplands for cover and refuge from flood waters during the snake's dormant season in the winter (USFWS 2006b).

For purposes of this model, it is assumed that giant garter snakes could potentially use any watercourse (except the Sacramento and San Joaquin rivers), perennial marsh, or flooded rice field in the Plan Area and Yolo Basin that is consistently inundated during the snake's active season for purposes of breeding, foraging, or movement.

Due to lack of habitat and emergent vegetation cover, giant garter snakes generally are not present in larger rivers with sand, rock, and gravel substrates (e.g., the Sacramento and San Joaquin rivers). Riparian woodlands are unlikely to provide suitable habitat due to excessive shade, lack of basking sites, and absence of prey populations (USFWS 2006b). However, it is assumed that because of the relatively low overstory structure and intermittent occurrence, giant garter snakes could potentially occur along watercourses with *Salix*-dominated riparian or riparian scrub habitats; and that all watercourses with the exception of the Sacramento and San Joaquin rivers can be used as movement corridors.

Giant garter snakes use grassy stream banks and upland habitats adjacent to perennial watercourses or wetlands as aestivation and movement habitat. For purposes of this model and for consistency with USFWS guidance, upland aestivation habitats include all grasslands, seasonal wetlands, and all irrigated croplands within 200 feet (61 meters) of potentially occupied aquatic habitat. Note, however, that it is generally accepted that actively cultivated fields do not support suitable aestivation habitat due to regular ground disturbance. But because fields can be fallowed or converted to more suitable perennial cover types (e.g., alfalfa), and because it is not possible to predict the condition of fields in the future, all agricultural cover types are included as potentially occupied upland aestivation habitat. Thus, the model overestimates the extent of upland aestivation habitat.

In addition, periodic inundation such as that which occurs in the Yolo Bypass, influences use as aestivation habitat; and depending on the frequency of inundation, could act as a biological sink as snakes reestablish aestivation patterns during periods of non-inundation and then are displaced from or killed at aestivation sites during an inundation event. Because there is little research on this topic, the Yolo Bypass is included as potential aestivation habitat for giant garter snake; however, it is likely that either the bypass is not used for this purpose because of the periodic inundation or that it represents a site where snakes are periodically displaced during the inactive season.

Most historical and recent occurrences of the giant garter snake in the Plan Area have been reported from outside of the central Delta, including portions of the Yolo Basin and at Coldani Marsh – White Slough along the eastern edge of the Plan Area (CNDDB 2009, Hansen 2006, 2007, 2008, Wylie and Amarello 2006, E. Hansen pers. comm.). These areas are also consistent with the USFWS' description of extant populations within the Plan Area and Yolo Basin (USFWS 1999). Additional relatively recent occurrences extend north of White Slough to Stone Lakes, east of the Mokelumne and Sacramento rivers. Areas that are known to support extant populations, or where records suggest a greater likelihood of extant populations as described above, are included within the Primary Habitat Zone.

Scattered records within the central Delta suggest that giant garter snakes may have occupied this region at one time, but longstanding reclamation of wetlands for intense agricultural applications has eliminated most suitable habitat (Hansen 1986). Historical and recent surveys conducted within the Sacramento-San Joaquin Delta have failed to identify any extant population clusters in the region (Hansen 1986, Patterson 2003, 2005, Patterson and Hansen 2004), including 2009 surveys conducted by DWR. There is also some speculation that recent occurrences in the central Delta (e.g., Sherman Island) could be of snakes that occasionally move into the central Delta by 'washing-down' from known populations, such as Coldani Marsh, and that these occurrences do not represent local breeding populations (E. Hansen pers. comm.). There are also only two known isolated occurrences south of the San Joaquin River and none south of SR-4. This area is within the approximately 50 air-mile gap that separates the northern and southern populations (Hansen and Brode 1980, 58 FR 54053). Nonetheless, because suitable habitat has been documented and potential occupancy could not be entirely ruled out (ECOS 1990, Miriam Green Associates 1995), areas that support suitable habitat (as defined here) that are not included within the Primary Habitat Zone are considered potentially occupied by giant garter snake. The western end of Sherman Island represents the western extent of potentially occupied habitat, and consistent with the permitted East Contra Costa Habitat Conservation Plan/Natural Communities Conservation Plan, SR-160 approximately represents the westernmost extent south of the San Joaquin River near Antioch.

A30.9 Recovery Goals

The Draft Recovery Plan for the Giant Garter Snake was prepared in 1999 by the USFWS. The overall objective of this recovery plan is to delist the giant garter snake. The goals of the draft plan include: (1) stabilizing and protecting existing populations, and (2) conducting research necessary to further refine recovery criteria.

The plan lists the following conservation actions: (1) Protect existing populations and habitat, (2) Restore populations to former habitat, (3) Survey to determine species distributions, (4) Monitor populations, (5) Conduct necessary research, including studies on demographics, population genetics, and habitat use, and (6) Develop and implement incentive programs, and an outreach and education plan.

The recovery plan divided the Central Valley into four recovery units to aid in the recovery process. These units are (1) the Sacramento Valley Unit, extending from the vicinity of Red Bluff south to the confluence of the Sacramento and Feather rivers; (2) the Mid-Valley Unit, extending from the American and Yolo basins south to Duck Slough near the City of Stockton; (3) the San Joaquin Valley Unit, extending south of Duck Slough to the Kings River; and (4) the South Valley Unit, extending south of the Kings River to the Kern River Basin.

Populations within the Plan Area are included in the Mid-Valley Unit. Recovery criteria for this unit are as follows:

- Monitoring shows that in 17 out of 20 years, 90 percent of the subpopulations in the recovery unit (with the exception of the East Stockton – Diverting Canal and Duck Creek population) contain both adults and young.

- The six existing populations within the recovery unit are protected from threats that limit populations.
- Supporting habitat within the recovery unit is adaptively managed and monitored.
- Subpopulations are well-connected by corridors of suitable habitat.
- Repatriation has been successful at all suitable sites that had recently (within the last 10 years) extirpated populations.

In addition, the CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designates the giant garter snake as "Contribute to Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its control and within its scope that are necessary to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

APPENDIX A31. WESTERN POND TURTLE (*ACTINEMYS MARMORATA*)

A31.1 LEGAL STATUS

The western pond turtle previously included two subspecies, the western pond turtle (*Actinemys marmorata mormorata*) and the southwestern pond turtle (*Actinemys marmorata pallida*). Both subspecies were petitioned for federal listing as endangered or threatened on January 29, 1992. In 1993, the United States Fish and Wildlife Service (USFWS) determined that there was insufficient information to propose listing of the species. Recent phylogenetic research combines the two subspecies into a single species (*A. marmorata*) (Bury and Germano 2008, Spinks and Shaffer 2005). The western pond turtle is a California Species of Special Concern.

A31.2 SPECIES DISTRIBUTION AND STATUS

A31.2.1 Range and Status

The western pond turtle occurs in the Pacific states of North America from Baja California Norte, north through Washington, and possibly into southernmost British Columbia, Canada (Bury and Germano 2008). Elevation range for the species extends from near sea level to 4,690 feet (1,430 meters) (Jennings and Hayes 1994).

Outside California, occurrences east of the Cascade-Sierra crest include the Truckee, Carson, and East Walker Rivers in Nevada; Drews Creek and Canyon Creek in Lake County, Oregon; and introduced occurrences along the Deschutes River at Bend in Deschutes County, Oregon (Jennings and Hayes 1994, Stebbins 2003).

In California, this species historically occurred in most Pacific slope drainages between the Oregon and Mexican borders and in only two drainages on the desert slope: the Mojave River (San Bernardino County) and Andreas Canyon (Riverside County) (Jennings and Hayes 1994). Occurrences east of the crest of the Sierra Nevada Mountain Range include Susanville in Lassen County (Stebbins 2003) (Figure A-31a).

From their phylogenetic analysis, Spinks and Shaffer (2005) divide the current range into four geographically coherent clades: a northern clade extending from Washington State to San Luis Obispo County; a San Joaquin Valley clade; a Santa Barbara clade in Santa Barbara and Ventura counties; and a southern clade south of the Tehachapi Mountains and west of the Transverse Range south to Baja California.

DRAFT

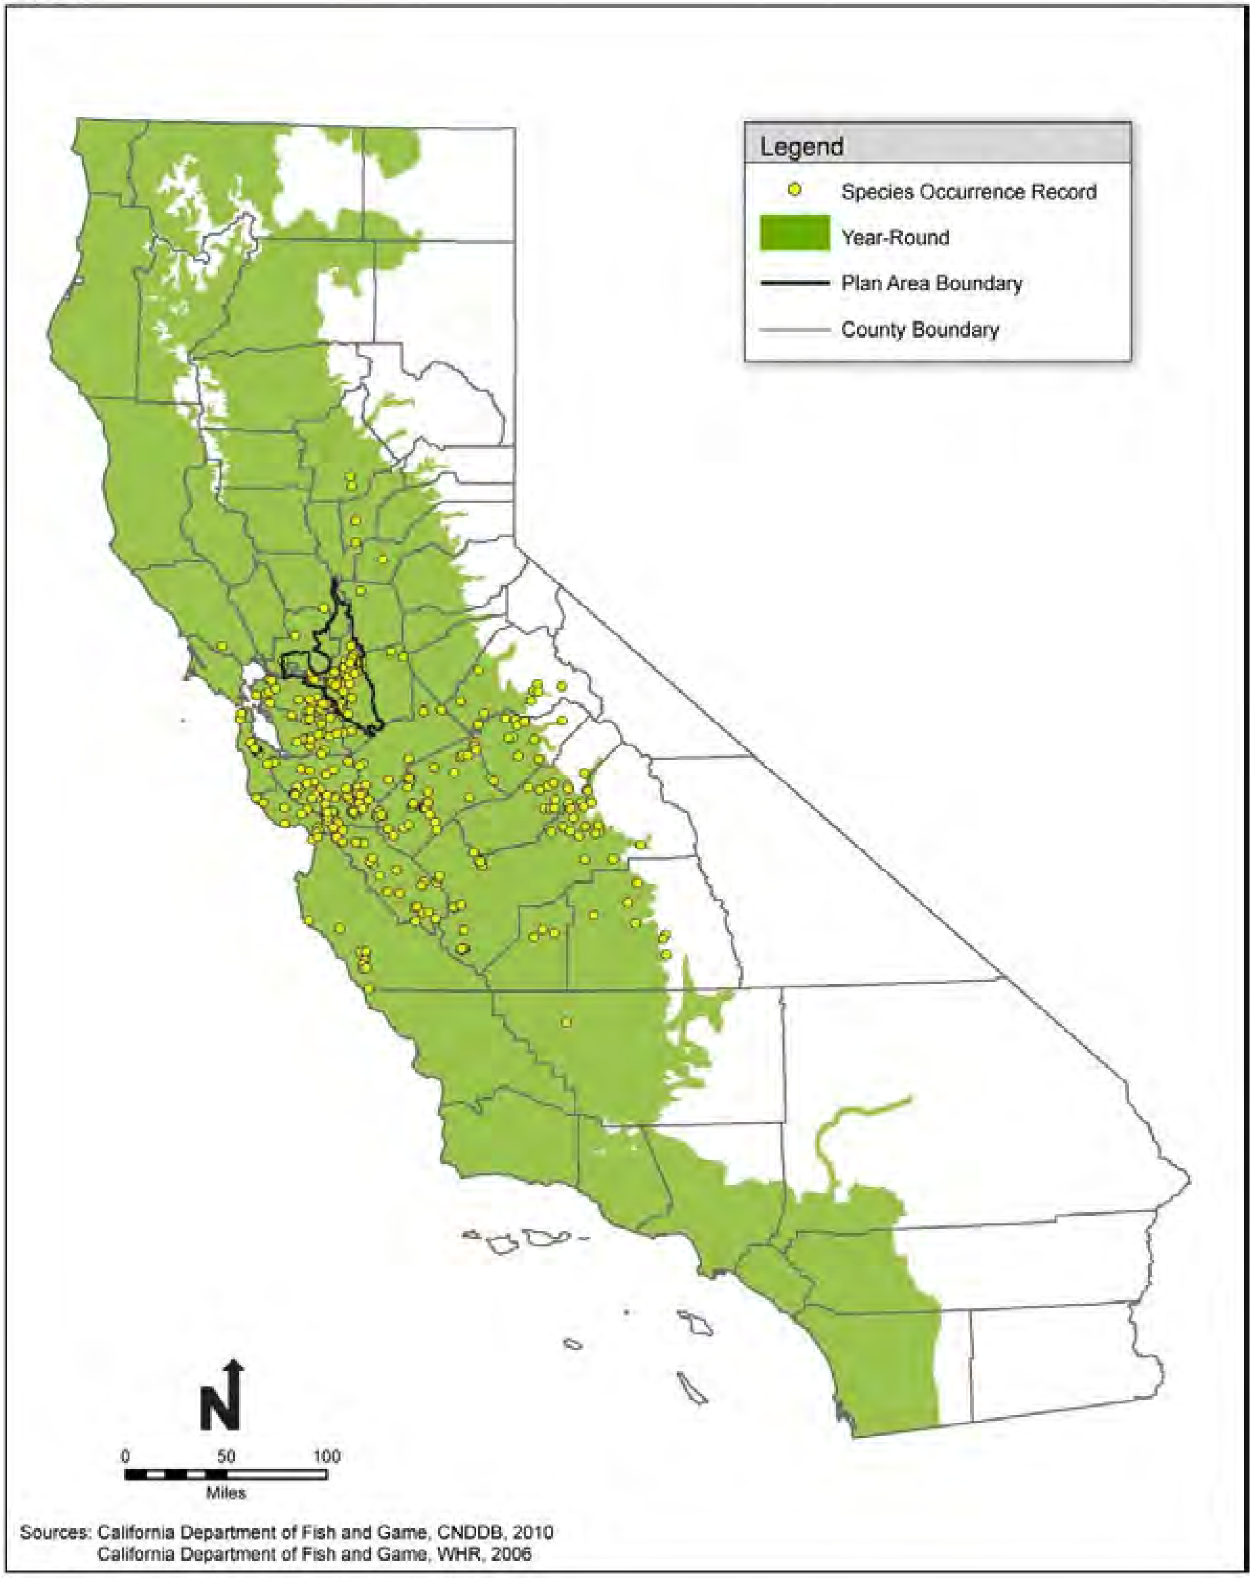

Figure A-31a. Western Pond Turtle Statewide Range and Recorded Occurrences

Population Trends. Most populations throughout the range have exhibited some declines. Bury and Germano (2008) report continued declines in the northern and southernmost portions of the range, but not in the core of the range from central California to southern Oregon. Hays et al. (1999) also report stable populations in southern Oregon while northern Oregon populations have suffered severe declines. Most populations in the state of Washington have been extirpated; however, there has been some progress through implementation of the Western Pond Turtle Recovery Plan (Hays et al. 1999).

In California, Jennings and Hayes (1994) consider the western pond turtle as endangered from the Mokelumne River south and threatened elsewhere within the state. Loss of habitat is the most significant factor in western pond turtle declines. Over 90 percent of the historical wetlands in California have been drained, filled, or diked to support agricultural and urban development (Frayer et al. 1989). In the Central Valley, pond turtles were exploited for food from the 1890s to the 1920s, which is believed to have played an important role in the declines in the San Francisco area and Central Valley populations (Storer 1930, Hays et al. 1999, Yolo Natural Heritage Program 2009). Nonetheless, despite significant population declines, populations in the Central Valley continue to persist in many areas and appear to have sufficient recruitment to maintain numbers (Germano and Bury 2001).

A31.2.2 Distribution and Status in the Plan Area

There are relatively few occurrence records from the Plan Area (Figure A-31b). The California Natural Diversity Database (CNDDB) reports several occurrences spread throughout the Plan Area in Sacramento, San Joaquin, and Contra Costa counties (CNDDB 2009); however, it is likely that this species is underreported and underrepresented in CNDDB. Jennings and Hayes' (1994) distribution map also shows three extant occurrences from the Sacramento River Basin along the southeastern boundary of Yolo County. Western pond turtles are common in the Suisun Marsh, which may be a key area for the species in the Bay-Delta system (Feliz pers. comm.). The species has potential to occur along most of the slower-moving sloughs and other natural watercourses and in artificial channels and other water bodies in the Plan Area where essential habitat elements (streamside cover, logs and other debris for basking, and adjacent upland habitats) are present.

Systematic boat surveys of sensitive species habitat have been conducted by the California Department of Water Resources (DWR) and the California Department of Fish and Game (DFG) staff throughout Suisun Marsh since 1991. These surveys have focused on the detection of sensitive plant and bird species. The presence or absence of western pond turtles has been incidental to these specialized surveys, but observations of pond turtles have been recorded (DWR 1994). Western pond turtles are present throughout Suisun Marsh. Pond turtles bask along the channel banks of tidal sloughs adjacent to emergent tidal marshes. Pond turtles bask on the banks with sunlight exposure at low tide.

DRAFT

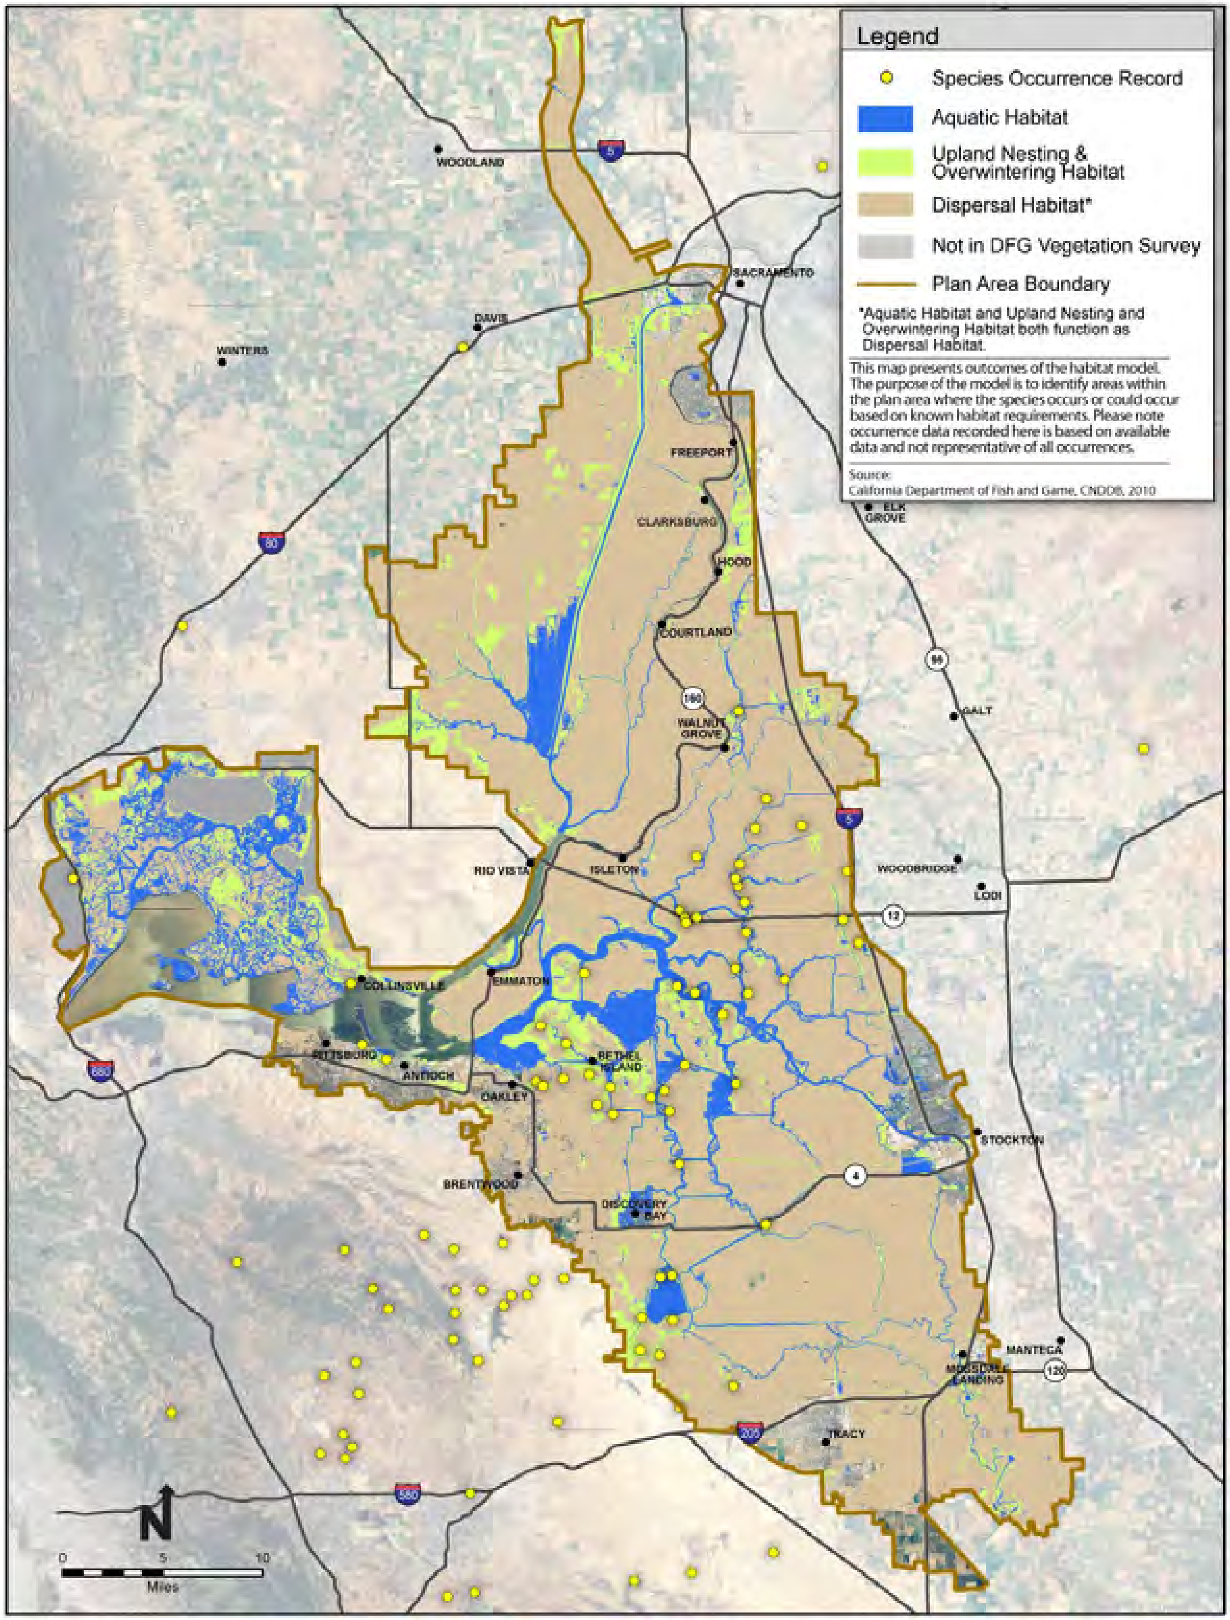

Figure A-31b. Western Pond Turtle Habitat Model and Recorded Occurrences

They have been observed basking on mud banks adjacent to the emergent wetlands of eastern Hill Slough, Nurse Slough, Cutoff Slough, First Mallard Branch, Second Mallard Branch, Boynton Slough, Peytonia Slough, Frank Horan Slough, and Cordelia Slough. Systematic surveys for pond turtles have not been conducted in diked, managed marshes. However, pond turtles have been observed from public roadways along internal water distribution systems which are cut off from natural tidal hydrology. The turtles have been observed along Roaring River, Grizzly Ditch, and Steve's Ditch of Grizzly Island. They have also been observed along Joice Island ponds, distribution ditches, and the Volanti Slough reservoir. It is assumed that western pond turtles are present at other pond and ditch systems within Suisun Marsh.

A31.3 Habitat Requirements and Special Conditions

The western pond turtle, although primarily found in natural aquatic habitats, also inhabits impoundments, irrigation ditches, and other artificial and natural water bodies (Ernst et al. 1994). The species is usually found in stagnant or slow-moving freshwater habitats, but brackish habitats are also utilized (Ernst et al. 1994). This species is uncommon in high gradient streams, most likely due to low water temperatures, high current velocity, and low food resources, which may limit their local distribution (Jennings and Hayes 1994).

The aquatic habitat may be comprised of either mud or rocky substrates and usually contains some vegetation (Ernst et al. 1994). Habitat quality often seems to be positively correlated with the number of available basking sites (Jennings and Hayes 1994). Turtles seem to avoid areas lacking in significant refugia (Holland 1994). Basking sites may be rocks, logs, vegetation, terrestrial islands within the aquatic habitat, and human-made debris (Holland 1994). Hatchlings forage in shallow water areas with dense submergent or short emergent vegetation, where small aquatic organisms are likely to be in abundance. Western pond turtles also inhabit the irrigation within agricultural areas, including ditches servicing rice agriculture (E. Hansen pers. comm.). While rice fields probably confer little advantage for adult western pond turtles, mature rice probably provides valuable cover and foraging habitat for hatchlings.

Upland habitats are also important to western pond turtles for nesting, overwintering, and overland dispersal (Holland 1994). Nesting sites may be as far as 400 meters (1,312 feet) or more from the aquatic habitat, although usually the distance is much less and generally around 100 meters (328 feet) (Jennings and Hayes 1994, Slavens 1995). Nesting sites typically have a southern or western aspect, with slopes of 0-46 percent and compact, dry soils (Holland 1994, Bury et al. 2001). When turtles choose to overwinter in upland habitats, individuals typically leave the aquatic habitat in late fall, moving as much as 500 meters (1,640 feet) from the aquatic habitat (Holland 1994). Turtles typically burrow into duff (leaf litter) and/or soil, where they remain during the winter months (Holland 1994). For reasons not entirely clear, western pond turtles may move into upland habitats for variable intervals at other times of the year, during which times they may be found burrowed into duff or under shrubs (Rathbun et al. 1993, Yolo Natural Heritage Program 2009).

A31.4 LIFE HISTORY

Description. The western pond turtle (Holman and Fritz 2001, Obst 2003, McCord and Joseph Ouni 2006) is a medium-sized aquatic turtle. Previously assigned to the genus *Clemmys,* Feldman and Parham (2002) has also proposed taxonomic realignments that would place *A. marmorata* within the genus *Emys*; current literature may refer to this taxon under either generic name. The carapace (upper portion of shell) color ranges from brown to black (Holland 1994). The carapace may be unmarked or covered with small, fine dark spots or lines (Holland 1994, Stebbins 2003). Adult size ranges from 8.9-21.6 centimeters (cm) (3.5-8.5 inches) straight-line carapace length (Stebbins 2003) and as large as 24.1 cm (9.5 inches) (Lubcke and Wilson 2007). The plastron (lower portion of shell) contains six pairs of yellowish shields, usually with dark blotches (Stebbins 2003). The head usually contains spots or a network of black coloring (Stebbins 2003). Adult females have a more domed, taller carapace, as compared to males, which have a more flattened, lower profile carapace (Holland 1994). Males also have larger, thicker tails than females (Holland 1994). Juveniles have a uniformly brown or olive carapace, with yellow markings along the edge of the marginals (the ring of shields encircling the carapace) and a tail nearly as long as the carapace (Stebbins 2003, Yolo Natural Heritage Program 2009).

Reproduction. Field observations have reported copulation in May, June, and late August (Holland 1988). Oviposition (egg-laying) may occur as early as late April in central California (Rathbun et al. 1993) to late July, with most occurring in June and July (Holland 1994). Western pond turtles may also double-clutch, potentially resulting in an extended breeding season (Scott et al. 2008). A gravid (pregnant) female approaches the nesting site, empties the contents of her bladder onto the soil, excavates a 90- to 125-millimeter (3.5- to 4.9-inch) deep nest chamber, and deposits 1 to 13 hard-shelled eggs (Holland 1994, Jennings and Hayes 1994). Incubation time ranges from 80 to more than 100 days in California (Holland 1994). In northern California, hatchling western pond turtles (which are about the size of a quarter) overwinter inside the nest chamber and emerge the following spring (Holland 1994). The terrestrial movements of post-emergent hatchlings are poorly understood (Holland 1994), although it is known that at least some move quickly to aquatic habitats (Yolo Natural Heritage Program 2009).

Basking. Western pond turtles spend considerable time basking in order to thermoregulate, preferring body temperatures between 24 and 32° C (75 and 90° F). Turtles seem to avoid body temperatures above 34° C (93° F) and usually cease basking at body temperatures well below their critical thermal maximum of 40° C (104° F). Individuals often bask above the water level on emergent logs, rocks, rocks, vegetation, or other objects. Turtles may sometimes bask at the surface, however, and sometimes within vegetation—where water temperatures may be 10 to 15° C (18 to 27° F) warmer than the water immediately below (Holland 1994). This type of basking may be utilized when air temperatures become too high for aerial basking. Western pond turtles also spend considerable time foraging, which occurs during the day or night (Holland 1994). Intraspecific (within-species) aggressive interactions, in the form of open-mouth gestures and shoving or bumping to secure positions on basking sites, are also common among western pond turtles (Holland 1994, Yolo Natural Heritage Program 2009).

Movements and Home Ranges. Adults sometimes engage in extended overland movements, which may be in response to drought or normal movements to aquatic habitats within a home range (Holland 1994). In one study, a turtle was observed making an overland movement of 5 kilometers (km) (3.1 miles), although in all other cases, overland movements were less than 3 km (1.9 miles) (Holland 1994). Such overland movements may be responses to an environmental stress such as drought or may be part of an individual's normal movements within a home range, which may consist of a series of ponds (Holland 1994). In lotic (stream) habitats, individuals move along the watercourse from pool to pool. During the course of one summer, Bury (1972) found average male, female, and juvenile linear movements were 354, 169, and 142 meters (1,161, 554, and 466 feet), respectively. In that study, adult males had the largest home ranges (0.98 hectares [2.42 acres]), followed by juveniles (0.36 hectares [0.89 acres]) and adult females (0.25 hectares [0.62 acres]) (Yolo Natural Heritage Program 2009).

Foraging Behavior and Diet. Western pond turtles are generalist feeders, with most food being obtained by opportunistic foraging or scavenging (Ernst et al. 1994). Known food items include algae, various plants, crustaceans, various types of insects, spiders, fish, frogs, tadpoles, and birds (Pope 1939 in Ernst et al. 1994, Evenden 1948 in Ernst et al. 1994, Carr 1952, Holland 1985, Bury 1986). Scavenging carrion of various vertebrate species may be a locally and/or seasonally important part of the diet (Holland 1994). Neustophagia, (a form of filter feeding) may be utilized to obtain abundant small invertebrate prey such as *Daphnia* (Ernst et al. 1994, Holland 1994, Yolo Natural Heritage Program 2009).

A31.5 THREATS AND STRESSORS

Habitat Loss and Fragmentation. Habitat loss and fragmentation produce small populations that are increasingly isolated and limited in space. This reduces movement of individuals and genetic exchange between populations. Small, isolated populations are highly susceptible to extinction caused by catastrophic or stochastic events. Isolation limits the ability of the population to recolonize areas with suitable habitat where western pond turtles may have been present in the past.

Agricultural practices such as disking and intensive livestock grazing and trampling have degraded many remaining vernal pools and wetland habitats, as have off-road vehicle use and contaminated runoff.

Roads can create a barrier to dispersal movements of western pond turtle and can isolate populations. Contaminants from road materials, leaks, and spills could further degrade aquatic habitats used by this species.

Corridors from aquatic habitat to historical and long-term nesting sites can be blocked by roads and development. Movement of adult females to and from the nesting locations and the movement of hatchlings from the nest to the aquatic site can be impeded and impacted (Jennings and Hayes 1994, Yolo Natural Heritage Program 2009).

Exotic Species. Nonnative invasive species are a threat to western pond turtles. Bullfrogs and exotic large predatory fish (e.g., largemouth bass) compete for invertebrate prey with western pond turtles and are known to eat hatchlings and small juveniles. Carp alter or eliminate emergent vegetation required as microhabitat by hatchlings (Holland 1994). Exotic turtles, including painted turtles, snapping turtles, and sliders, may compete with pond turtles for food and basking sites. These exotic turtles also may harbor and transmit diseases, such as upper respiratory diseases, to pond turtles (Holland 1994). Cattle trample and eat aquatic vegetation that serves as habitat for hatchlings and may crush nests. Domestic dogs sometimes kill or injure turtles (Yolo Natural Heritage Program 2009).

Flooding and Irrigation. Turtle nests may be inundated during floods and during irrigation of agricultural fields. The egg shells absorb water and can crack or explode from internal pressure (Feldman 1982). Therefore, nest success and recruitment may be reduced in flood-prone or active agricultural areas.

Predation. Predation is a major mortality factor for western pond turtles. Hatchlings and turtle eggs are particularly vulnerable (Holland 1994). Raccoons (*Procyon lotor*), bullfrogs (*Rana catesbeiana*), largemouth bass (*Micropterus salmoides*), gray fox (*Urocyon cineroargenteus*), coyote (*Canis latrans*), and feral and domestic dogs (*Canis familiaris*) are known to be major predators of western pond turtles (Holland 1994). Holland (1994) indicates that other known predators include osprey (*Pandion haliaetus*), bald eagle (*Haliaetus leucocephalus*), river otter (*Lutra canadensis*) (Manning 1990 in Holland 1994), and mink (*Mustela vison*). Numerous other fish, amphibian, bird, and mammal species are suspected to prey on the species (Holland 1994). Raccoons, in particular, are known to depredate nests, sometimes destroying all nests in an entire communal nesting area (Yolo Natural Heritage Program 2009). In urban areas, litter and pet food can increase the presence of some predators, potentially leading to increased predation on turtles.

A31.6 RELEVANT CONSERVATION EFFORTS

Conservation efforts for the western pond turtle are largely limited to those proposed under habitat conservation planning efforts, including those that overlap with the Plan Area. These include preservation of occupied and potentially-occupied habitats, management of watercourses and water bodies to protect existing populations and encourage reestablishment of populations, and restoration or enhancement of channel, riparian, and adjacent upland habitats to benefit pond turtles. The western pond turtle is a covered species under several permitted plans including the Natomas Basin Habitat Conservation Plan, the East Contra Costa County Habitat Conservation

Plan/Natural Community Conservation Plan, and the San Joaquin County Multi-Species Habitat Conservation and Open Space Plan; and is proposed for coverage under the South Sacramento County Habitat Conservation Plan, Yolo County Natural Heritage Program Plan, Solano County Multispecies Habitat Conservation Plan, and Butte Regional Habitat Conservation Plan and Natural Community Conservation Plan.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designates the western pond turtle as "Maintain" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions to maintain the species by avoiding, minimizing, and compensating for any adverse effects to the species created by ERP restoration actions. To the extent practicable, the ERP will improve species habitat conditions.

DFG recently commissioned the U.S. Forest Service's Redwood Sciences Lab to prepare a conservation strategy for the western pond turtle in California.

A31.7 Species Habitat Suitability Model

Model Approach. Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, and cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf 2007. Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers, connectivity between habitat types, and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The western pond turtle model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), USDA 2005 aerial photography, DWR Central Valley Levees 2001, and DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable western pond turtle habitat in the Plan Area according to three life requisite parameters: aquatic habitat, upland nesting and overwintering habitat, and dispersal habitat. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Aquatic Habitat. Aquatic habitat for the western pond turtle includes the following land cover types and conditions:

- Perennial streams, excluding the Sacramento River
- Large water delivery and irrigation channels
- Aquatic habitat in the Delta includes the following types from the BDCP composite vegetation layer:
    - Tidal freshwater emergent wetland – all types;
    - Tidal perennial aquatic types – all types;
    - Nontidal perennial aquatic types – all types;
    - Nontidal freshwater perennial emergent wetland;
        - American bulrush (*Scirpus americanus*);
        - Common reed (*Phragmites australis*);

        - Flooded managed wetland;
        - Hard-stem bulrush (*Scirpus acutus*);
        - Mixed *Scirpus*/floating aquatics (*Hydrocotyle – Eichhornia*) complex;
        - Mixed *Scirpus*/submerged aquatics (*Egeria-Cabomba-Myriophyllum* spp.) complex;
        - Mixed *Scirpus* mapping unit;
        - Narrow-leaf cattail (*Typha angustifolia*);
        - Perennial pepperweed (*Lepidium latifolium*);
        - *Scirpus acutus* (*Typha latifolia*) – *Phragmites australis*;
        - *Scirpus acutus – Typha angustifolia*;
        - *Scirpus acutus* pure; and
        - *Scirpus acutus – Typha latifolia*.
- Aquatic habitat in the Yolo Basin and Suisun Marsh from the BDCP composite vegetation layer (includes vegetation types from portions of tidal brackish emergent wetland, managed wetlands, alkali seasonal wetlands, vernal pool complex, tidal perennial aquatic, grassland and agricultural communities):
    - Freshwater drainage;
    - Slough;
    - Ditch;
    - *Scirpus*[1] *(californicus* or *acutus)/Rosa;*
    - *Scirpus (californicus* or *acutus*)/wetland herb;
    - *Scirpus (californicus* or *acutus)-Typha* spp.;
    - *Scirpus americanus* (generic);
    - *Scirpus americanus/Lepidium;*
    - *Scirpus americanus/Potentilla;*
    - *Scirpus californicus/S. acutus;*
    - *Scirpus maritimus;*
    - *Scirpus maritimus/Salicornia*[2]*;*
    - *Typha angustifolia/Distichlis;*

---

[1] Currently known as *Schoenoplectus*.
[2] Currently known as *Sarcocornia*.

  - *Typha angustifolia/S. americanus;*
  - *Typha* species (generic);
  - Bulrush - cattail fresh water marsh NFD super alliance;
  - *Scirpus americanus/S. Californicus-S. acutus;*
  - *Scirpus maritimus/Sesuvium;*
  - *Typha angustifolia;*
  - *Typha angustifolia/Phragmites;*
  - *Typha angustifolia/Polygonum-Xanthium-Echino*; and
  - *Typha angustifolia/S. americanus.*

Assumptions. Western pond turtles reside in stagnant or slow-moving water in aquatic habitats (Ernst et al. 1994). The Sacramento River and the associated open water bays west of Sherman Island and west of the State Route (SR) 160 bridge along the San Joaquin River are excluded from the model because, with perhaps the exception of low velocity backwater areas, flow velocities are considered to be too high to provide habitat. Aquatic habitat on islands within the bay (e.g., Kimble Island, Brown Island, and Winters Island) are also excluded. Perennial stock ponds and other open water habitats also provide aquatic habitat when located near suitable upland areas. Western pond turtles are also associated with freshwater emergent and perennial aquatic types that are associated with open water habitats where they find cover and food resources. Juvenile western pond turtles may also find food and cover in seasonal wetlands and ricelands during periods of extended inundation (Hansen pers. comm.). However, for purposes of this model, these types are included as dispersal habitat.

While stock ponds and other small water impoundments may provide aquatic habitat for western pond turtle, these features could not be effectively mapped using the model data sources and are thus not included here. It is assumed that stock ponds and other small water impoundments occur within the grassland landscape identified below as potential upland nesting and overwintering habitat that provide additional potential breeding habitat for western pond turtle. It is also assumed that sufficient upland nesting and overwintering habitat has been identified based on proximity to mapped aquatic features to include all potential western pond turtle breeding habitat within the Plan Area.

Upland Nesting and Overwintering Habitat. Nesting and overwintering habitat in the Delta for the western pond turtle includes the following types from the BDCP composite vegetation layer within 500 meters (1,640 ft) of and contiguous with aquatic habitat:

- Grassland – all types (including levees)
- Valley/foothill riparian – all types
- Vernal pool complex

  - Annual grasses generic;
  - Annual grasses/weeds;
  - California annual grasslands;
  - Distichlis (generic);
  - *Distichlis spicata;*
  - *Distichlis spicata* – annual grasses;
  - Districhlis/annual grasses;
  - Distichlis/ *S. maritimus;*
  - Ruderal herbaceous grasses and forbs;
  - Italian rye-grass (*Lolium multiflorum*);
  - *Salicornia virginica*; and
  - *Salicornia*/annual grasses.

Nesting and overwintering habitat in the Yolo Basin and Suisun Marsh from the BDCP composite vegetation layer:

- Valley oak alliance – riparian;
- Fremont cottonwood-valley oak-willow (ash-sycamore) riparian forest NFD association;
- Valley oak alliance – riparian;
- *Salix laevigata/S. lasiolepis;*
- *Salix lasiolepis/Quercus agrifolia;*
- *Fraxinus latifolia;*
- Mixed willow super alliance;
- Annual grasses generic;
- Annual grasses/weeds;
- Perennial grass;
- Pasture;
- Upland annual grasslands and forbs formation;
- *Lolium* (generic);
- *Lolium/Rumex;*
- *Hordeum/Lolium;*
- Medium upland graminoids; and

- Short upland graminoids.

Assumptions. The western pond turtle is primarily aquatic and leaves the water only to reproduce, aestivate, and overwinter (Jennings and Hayes 1994). Females leave the aquatic habitat to find an upland location to nest. Proximity of nesting site to aquatic habitat is dependent on availability, and the nest site is generally within 200 meters (656 feet) from the aquatic habitat, but can be up to 400 meters (1,312 feet) away (Storer 1930, Jennings and Hayes 1994). Holland (1994) reported overwintering sites up to 500 meters (1,640 feet) from the aquatic habitat. Thus, a distance of 500 meters from and contiguous with aquatic habitat was selected to ensure that all likely habitats used for feeding, reproduction, and overwintering was encompassed in the model. Agricultural, urban, disturbed, orchard, and vineyard land cover types are not considered to support nesting or overwintering habitat because they are subject to regular disturbances that could destroy nests or overwintering sites.

Dispersal Habitat. Dispersal habitat includes all types listed under Aquatic Habitat and Upland Nesting and Overwintering Habitat within 3 km (1.86 miles) of aquatic habitat and the following:

Dispersal habitat within 3 km of and contiguous with aquatic habitat in the Delta from the BDCP composite vegetation layer includes:

- Agriculture – all types;
- Grassland – all types;
- Riparian – all types;
- Managed wetland – all types;
- Other natural seasonal wetland – all types;
- Vernal pool complex – all types and;
- Alkali seasonal wetland complex – all types.

Dispersal habitat within 3 km of and contiguous with aquatic habitat in the Yolo Basin and Suisun Marsh from the BDCP composite vegetation layer includes the following vegetation units:

- *Conium maculatum;*
- *Distichlis* (generic);
- *Distichlis spicata;*
- *Distichlis*/annual grasses;
- *Distichlis/Cotula;*

- *Distichlis/Juncus;*
- *Distichlis/Lotus;*
- *Distichlis/S. americanus;*
- *Distichlis/S. maritimus;*
- *Distichlis/Salicornia;*
- *Distichlis-Juncus-Triglochin-Glaux;*
- Flooded managed wetland;
- *Lepidium* (generic);
- *Lepidium/Distichlis;*
- Medium wetland graminoids;
- Medium wetland herbs;
- *Polygonum-Xanthium-Echinochloa;*
- *Polypogon monspeliensis* (generic);
- *Salix laevigata/S. lasiolepis;*
- Short wetland herbs;
- Tall wetland graminoids;
- *Juncus balticus;*
- *Juncus balticus/Conium;*
- *Juncus balticus/Lepidium;*
- *Juncus balticus/Potentilla;*
- Medium upland graminoids;
- Pasture;
- *Phragmites australis;*
- *Phragmites/Scirpus;*
- *Phragmites/Xanthium;*
- Rice;
- Short upland graminoids;
- Short wetland graminoids;
- Tall wetland herbs;
- Upland annual grasslands and forbs formation; and
- Wetland herbs.

Assumptions. Adults sometimes engage in extended overland movements, which may be in response to drought or normal movements to aquatic habitats within a home range (Holland 1994). In one study, a turtle was observed making an overland movement of 5 km (3.1 miles), although in all other cases, overland movements were less than 3 km (1.9 miles) (Holland 1994). Such overland movements may be responses to an environmental stress such as drought or may be part of an individual's normal movements within a home range, which may consist of a series of ponds (Holland 1994). Some of the seasonal wetland types and rice noted above may also be used as aquatic habitat during periods of inundation, particularly by juvenile pond turtles (Hansen pers. comm.). However, because of the shallow water depth and seasonal inundation, adults are more likely to use these habitats for dispersal purposes, and thus they are included here as dispersal habitat.

A31.8 Recovery Goals

A USFWS recovery plan has not been prepared for this species and no recovery goals have been established.

APPENDIX A32. CALIFORNIA RED-LEGGED FROG (*RANA DRAYTONII*)

A32.1 LEGAL STATUS

The California red-legged frog (*Rana draytonii*) was federally listed as threatened pursuant to the federal Endangered Species Act in 1996 (61 FR 25813); and is designated as a species of special concern in California (Jennings and Hayes 1994). A recovery plan was prepared for this species by the U.S. Fish and Wildlife Service (USFWS) in 2002 (USFWS 2002).

Critical habitat was initially designated for this species in 2001, which was subject to legal challenges and resulted in substantial modifications and a final ruling in 2006 (71 FR 19244). Further subsequent challenges resulted in additional modifications and a new proposed rule (73 FR 53492). Critical Habitat Units ALA-1A and CCS-1B border the western edge of the Plan Area.

A32.2 SPECIES DISTRIBUTION AND STATUS

A32.2.1 Range and Status

The historical range of the California red-legged frog is generally characterized as extending south along the coast from the vicinity of Point Reyes National Seashore, Marin County, California, and inland from the vicinity of Redding, Shasta County, California, southward along the interior Coast Ranges and Sierra Nevada foothills to northwestern Baja California, Mexico (USFWS 2007) (Figure A-32a). While there are a few historical records from several Central Valley locales (Jennings and Hayes 1994), Fellers (2005) considers persistent occupancy in the lowlands of the Central Valley unlikely due to extensive annual flooding.

The current range is generally characterized based on the current known distribution. The USFWS (2007) notes that while the California red-legged frog is still locally abundant within portions of the San Francisco Bay area and the central coast, only isolated populations have been documented elsewhere within the species' historical range, including the Sierra Nevada, northern Coast Ranges, and northern Transverse Ranges.

The USFWS (2002) estimates that the species has lost approximately 70 percent of its former range, with severe declines occurring primarily in the Central Valley and southern California (Jennings and Hayes 1994). Prior to recent discoveries at isolated locations in the Sierra Nevada (Placer, Nevada, Yuba, and El Dorado counties) and two populations in the southern Transverse and Peninsular Ranges, the subspecies was considered extirpated from the Sierra Nevada and southern Transverse and Peninsular Ranges.

DRAFT

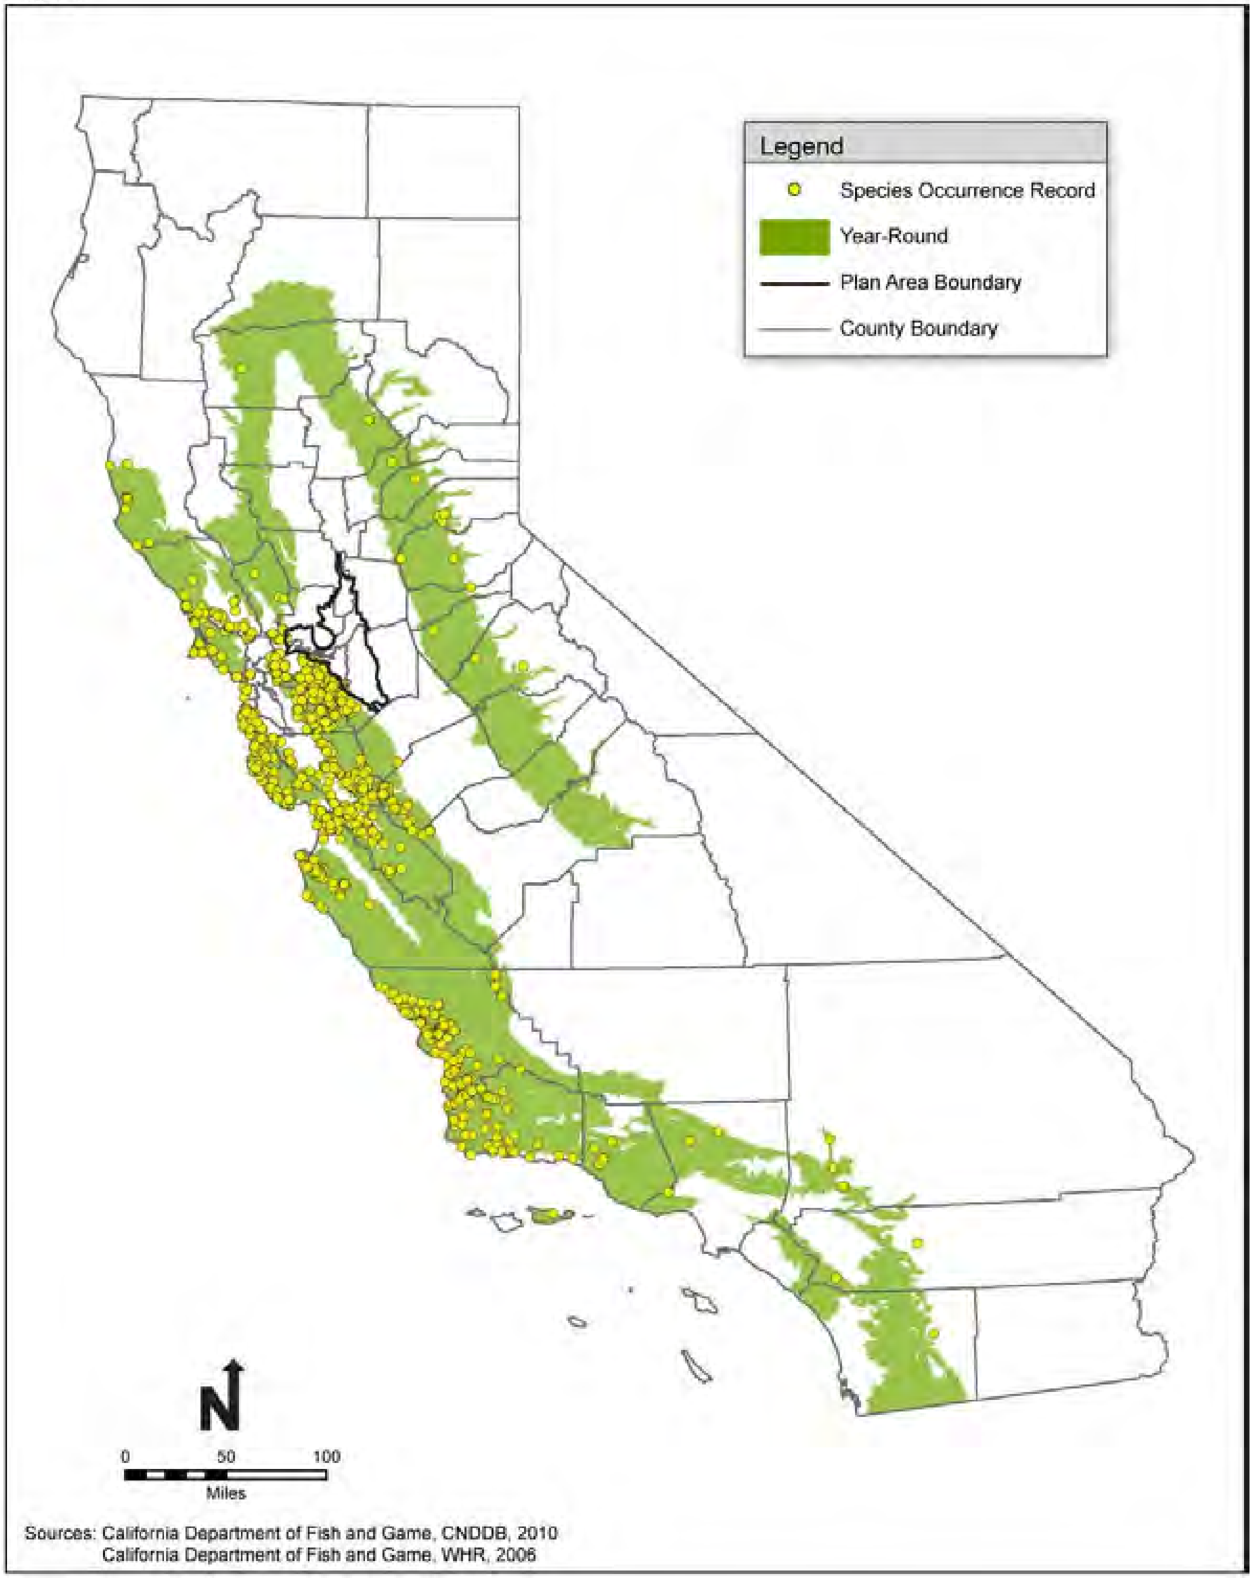

Figure A-32a. California Red-Legged Frog Statewide Range and Recorded Occurrences

Sizable populations continue to exist only in coastal drainages and associated pond habitats between Point Reyes and Santa Barbara (Jennings and Hayes 1994).

The principal factors contributing to the decline of the California red-legged frog are loss of habitat due to urban development, conversion of native habitats to agricultural lands, introduction of nonnative predators, and pesticide use (Fisher and Shaffer 1996, Hobbs and Mooney 1998, Davidson et al. 2002). Habitat loss and fragmentation result in small, isolated populations, which reduce individual movements and genetic exchange between populations.

A32.2.2 Distribution and Status in the Plan Area

Within the Plan Area, the California red-legged frog has been detected only in aquatic habitats within the grassland landscape west and southwest of Clifton Court Forebay and in the vicinity of Brentwood and Marsh Creek along the west-central edge of the Plan Area, and in some upland sites in the vicinity of Suisun Marsh (Figure A-32b). These areas represent the easternmost edge of the current range of California red-legged frog within the Coast Ranges. While there are several recent detections of the species in the Sierra Nevada foothills, California red-legged frog is not known to occur in the agricultural habitats of the Central Valley. The California Natural Diversity Database (CNDDB) reports several extant occurrences from approximately Marsh Creek and Clifton Court Forebay and the western edge of the Suisun Marsh (CNDDB 2009). Surveys conducted by the California Department of Water Resources (DWR) in 2009 confirmed occupancy at sites in the vicinity of Clifton Court Forebay. Occupied habitats are characterized by grassland foothills with stock ponds and slow-moving perennial drainages. The species is not known to occur, nor is it expected to occur, elsewhere in the Plan Area.

A32.3 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

Storer (1925) and Hayes and Jennings (1988) describe aquatic breeding habitat requirements for California red-legged frog as cold water pond habitats (including stream pools) with emergent and submergent vegetation, providing suitable cover for young and adults and ensuring successful reproduction. Optimal habitats are described as deep-water ponds or pools at least 2.3 feet (0.7 meters) deep along low gradient streams with dense stands of overhanging willows and a fringe of cattails between the willow roots and overhanging willow limbs. Note, however, that the lack of wetland or other shallow streamside vegetation does not necessarily preclude the presence of California red-legged frog. Hayes and Jennings (1988) also note that there may be a current preference for pools along intermittent streams rather than backwater pools along perennial streams possibly due to predator avoidance, particularly bullfrogs (*Rana catesbeiana*). The California red-legged frog uses a variety of aquatic habitats that meet these requirements, including permanent and ephemeral ponds, perennial and intermittent streams, seasonal wetlands, springs, seeps, marshes, dune ponds, lagoons, and human-made aquatic features (USFWS 2007).

DRAFT

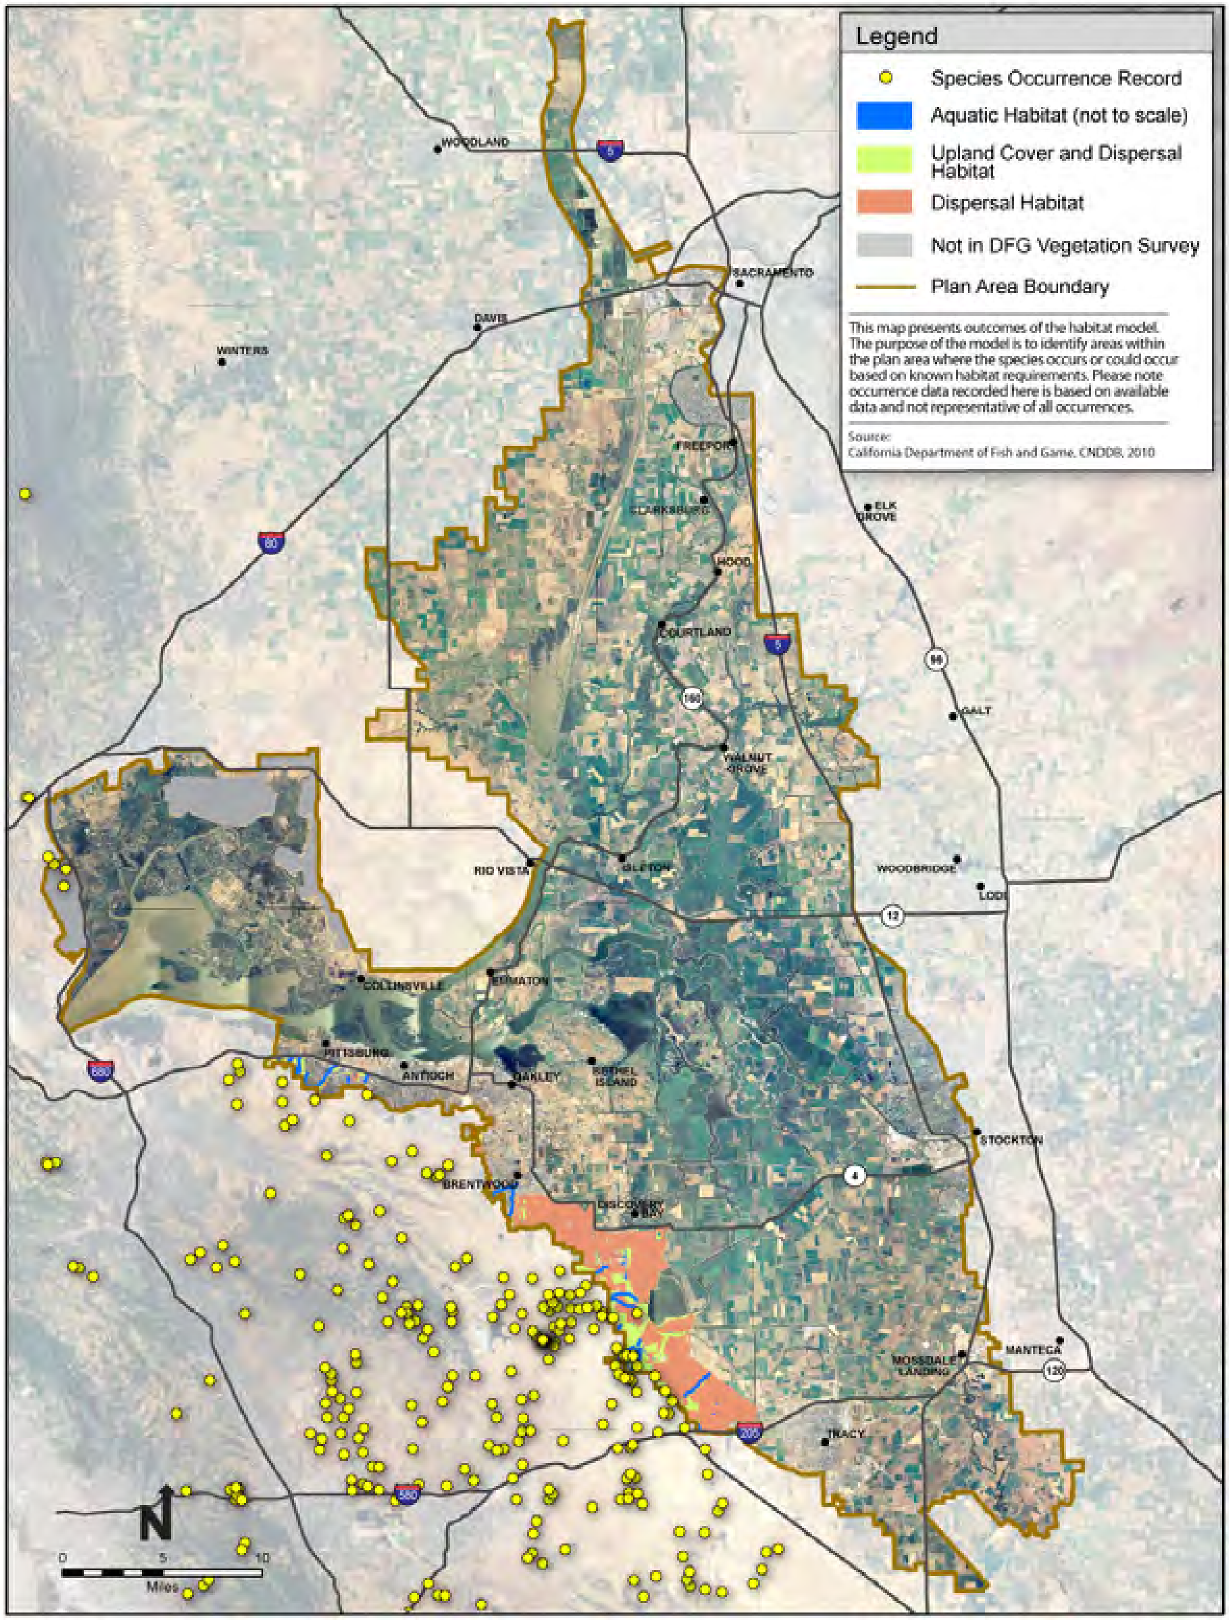

Figure A-32b. California Red-Legged Frog Habitat Model and Recorded Occurrences

In addition to aquatic breeding habitat, the California red-legged frog also requires upland non-breeding habitat used for cover, aestivation, and migration and other movements. Non-breeding cover habitat may include nearly any areas within 1-2 miles (1.6-3.2 kilometers [km]) of a breeding site that stays moist and cool through the summer, and can include vegetated areas with coyote bush (*Baccharis pilularis*), California blackberry thickets (*Rubus ursinus*), and root masses associated with willow (*Salix* spp.) and California bay trees (*Umbellularis californica*) (Fellers and Kleeman 2007). Potential cover habitat includes all aquatic, riparian, and upland areas that provide cover, such as animal burrows, boulders or rocks, organic debris such as downed trees or logs, and industrial debris; agricultural features such as drains, watering troughs, spring boxes, abandoned sheds, or hay stacks may also be used (61 FR 25813). Incised stream channels with portions narrower and depths greater than 18 inches (46 centimeters) also may provide important summer sheltering habitat (61 FR 25813). Accessibility to cover habitat is essential for the survival of red-legged frogs within a watershed and can be a factor limiting frog populations. Movement corridors may include annual grasslands, riparian corridors, woodlands, and sometimes active agricultural lands (Fellers and Kleeman 2007).

A32.4 LIFE HISTORY

Description. California red-legged frogs are brown to reddish brown with prominent dorsolateral folds (Jennings and Hayes 1994, Stebbins 2003). Adult size ranges from 85 to 138 millimeters (3.4-5.4 inches) in length from the snout to urostyle (frog homologue to pelvic bone) (Jennings and Hayes 1994). The dorsal surface is distributed with dark spots, occasionally with light centers (Storer 1925). The amount of red coloration present is variable; some individuals have no such coloration, and others may have red pigment distributed all over the dorsal and ventral surfaces of the body (Jennings and Hayes 1994). A dark mask bordered by a whitish jaw stripe is also usually present (Stebbins 2003).

Activity. Juvenile frogs are active diurnally and nocturnally, while adult frogs are primarily nocturnal (Hayes and Tenant 1985). Local climate influences the red-legged frog's seasonal activity period (Storer 1925). In coastal areas with mild climates, individuals are rarely inactive; however, at inland sites with colder winters individuals may become inactive for longer intervals (Yolo Natural Heritage Program 2009).

Seasonal Movements. California red-legged frogs are most likely to make overland movements through upland habitats at night during wet weather (USFWS 2002, Bulger et al. 2003, Fellers and Kleeman 2007). During the course of a wet season, movements up to 1.6 km (1 mile) are possible (USFWS 2002). During dry weather, the subspecies tends to remain very close to a water source and are typically within 60 meters (m) (~200 feet [ft]) of water (UFSWS 2002, Bulger et al. 2003, Fellers and Kleeman 2007). However, overland dispersal of the California red-legged frogs sometimes occurs in response to receding water during the dry season potentially necessitating greater dispersal distances (USFWS 2002). California red-legged frogs have been known to disperse distances up to 2.9 km (1.8 miles) from the breeding site to sites within the stream system (USFWS 2002, Fellers and Kleeman 2007). Note, however, that Jennings and Hayes (1994) suggest that, in general, adult California red-legged frogs do not appear to move large distances from their aquatic habitat. This is consistent with recent results from Tatarian (2008) who reported average terrestrial movement in Contra Costa County of 24.4 +/- 20.7 m (range: 1-71 m) (80 +/- 68 ft [range: 3.3 - 233 ft]) and average aquatic movement of 107.2 +/- 152.1 m (Range 11 – 661.4 m) (352 +/- 499 ft [range: 36 – 2,170 ft]).

Reproduction. Breeding occurs between late November and late April (Jennings and Hayes 1994) and most frogs lay their eggs in March (USFWS 2002). Males move to breeding sites 2 to 4 weeks before female arrival (Storer 1925). A pair moves into amplexus (breeding position), and the female moves the pair to the oviposition (egg-laying) site, where she deposits 2,000 to 6,000 eggs to an emergent vegetation brace (Storer 1925, Jennings and Hayes 1994). Hatching occurs in 20-22 days, depending on water temperature (USFWS 2002). Thereafter, tadpoles require 11 to 20 weeks to complete metamorphosis (Storer 1925).

Diet. Invertebrates comprise most prey taken by California red-legged frogs, although vertebrates such as pacific tree frogs (*Hyla regilla*) and California mice (*Peromyscus californicus*) comprise over half the prey consumed by larger frogs (USFWS 2002).

Predators. California red-legged frogs are subject to predation by a number of native and nonnative species. Some of the native predators include raccoon (*Procyon lotor*), garter snakes (*Thamnophis* spp.), great blue herons (*Ardea alba*), American bitterns (*Botaurus lentiginosus*), red-shouldered hawks (*Buteo lineatus*), and black-crowned night herons (*Nycticoras nycticoras*) (USFWS 2002, Fellers and Kleeman 2007). Nonnative predators include crayfish, bullfrogs (*Rana catesbeiana*) and various fish species (USFWS 2002).

A32.5 THREATS AND STRESSORS

Urbanization/Habitat Fragmentation. Habitat loss, degradation, and fragmentation are significant factors in declining populations of California red-legged frogs. Conversion of lands to agricultural and urban uses, overgrazing, mining, recreation, and timber harvesting have all contributed to habitat losses and disturbances. Urbanization often fragments habitat and creates barriers to dispersal (USFWS 2002). Road densities generally increase as a consequence of urbanization. Roads can create significant barriers to frog dispersal (Reh and Seitz 1990) and reduce population densities due to mortality caused by automobile strikes (Fahrig et al. 1995, Yolo Natural Heritage Program 2009).

Agricultural Crop Conversion. The conversion of natural lands to agricultural uses, such as stands of monotypic row crops, can alter habitats to the extent that they become uninhabitable for California red-legged frogs (USFWS 2002). Fisher and Shaffer (1996) suggest that intense farming within the San Joaquin Valley has resulted in drastic declines in California red-legged frog populations, resulting from little suitable habitat. Pesticides, herbicides, and other agrochemicals are known to be toxic to various life stages of ranid frogs (Hayes and Jennings

1986). Pesticide drift has also been suggested as a potential cause of declining populations of four species of ranids in California, including California red-legged frogs (Davidson et al. 2002, Yolo Natural Heritage Program 2009).

Exotic Species. Exotic predatory fish and bullfrogs also pose significant threats to California red-legged frogs. Hayes and Jennings (1986) noted that locations in which exotic fish were present contained few California red-legged frogs. Bullfrogs have been implicated in the decline of the subspecies in several studies (Fisher and Shaffer 1996, Kiesecker and Blaustein 1998, Lawler et al. 1999), and Moyle (1973) indicated that bullfrogs might have been the most important factor in the extirpation of California red-legged frogs from the Central Valley floor. Bullfrogs depredate and out-compete California red-legged frogs due to their larger size, more varied diet, and longer breeding season (Hayes and Jennings 1986, Yolo Natural Heritage Program 2009).

Water Diversions and Impoundments. Water diversions and impoundments have altered habitats and made them less suitable for many ranid species (Jennings 1996). The creation of reservoirs through dam construction in the Central Valley and southern California has directly eliminated, fragmented, or isolated populations of California red-legged frogs (USFWS 2002). Smaller impoundments and water diversions can also preclude or inhibit dispersal (USFWS 2002) and reduce high flows required to maintain deep holes in streams (Rathbun in litt. 1998 in USFWS 2002). The stock ponds and small reservoirs formed by smaller impoundments and water diversions often contain exotic fishes and bullfrogs that prey on red-legged frogs (G. Rathbun. and M. Jennings in litt. 1993 in USFWS 2002, Yolo Natural Heritage Program 2009).

Grazing. In some locales, California red-legged frogs appear to thrive in areas with managed grazing, and grazing may actually improve habitat conditions at sites where stock ponds have been constructed (USFWS 2002). However, unmanaged cattle trample and eat emergent riparian vegetation, resulting in severe habitat disturbances (Gunderson 1968 in USFWS 2002, Duff 1979 in USFWS 2002), causing increases in water temperatures (Van Velson 1979 in USFWS 2002). These effects diminish habitat quality for red-legged frogs and improve conditions for bullfrogs and exotic predatory fish (USFWS 2002). Grazing in riparian areas can result in the loss of willows, which are associated with the greatest densities of California red-legged frogs (Jennings 1988). High stocking rates can also result in increased erosion in the watershed (Lusby 1970 in USFWS 2002, Winegar 1977 in USFWS 2002) and sedimentation in the stream (Gunderson 1968 in USFWS 2002), which in turn can alter primary productivity and fill interstitial spaces of the streambed substrate with fine alluvium. This fill impedes water flow, reduces dissolved oxygen levels, and restricts waste removal (Chapman 1988 in USFWS 2002, Yolo Natural Heritage Program 2009).

A32.6 Relevant Conservation Efforts

Since the listing of the California red-legged frog, numerous conservation efforts have been undertaken by various federal, state, and local and private organizations to minimize impacts and establish preserves and protective policies to ensure the viability of this species (USFWS 2002). These include the establishment of federal guidelines to assess habitat and determine presence/absence of the species (USFWS 2005), the designation of critical habitat, and various protections of occupied habitat on public and private lands. The Recovery Plan (USFWS 2002) outlines a series of guidelines that recommend specific actions designed to protect California red-legged frogs and their habitat.

The California red-legged frog is a covered species in the East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan and the San Joaquin County Multi-Species Habitat Conservation and Open Space Plan; and it is proposed as a covered species in the Solano County Multispecies Habitat Conservation Plan, the Yolo County Natural Heritage Program Plan, and the Butte Regional Conservation Plan.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for the California red-legged frog is "Maintain" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions to maintain the species by avoiding, minimizing, and compensating for any adverse effects to the species created by ERP restoration actions. To the extent practicable, the ERP will improve species habitat conditions.

A32.7 Species Habitat Suitability Model

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, and cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf 2007. Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers, connectivity between habitat types, and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The California red-legged frog model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), U.S. Department of Agriculture (USDA) 2005 aerial photography, and DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable California red-legged frog habitat in the Plan Area according to the species' two primary life requisites, aquatic breeding habitat and upland cover and dispersal habitat. Vegetation types were assigned to a suitability category based on the species requirements as described above and the assumptions described below. The model also restricts the distribution of suitable habitat based on the known range of the species.

Aquatic Habitat. Aquatic habitat for the California red-legged frog includes the following land cover types and conditions within the area south and west of Highway 4 from Antioch (Bypass Road to Balfour Road to Brentwood Boulevard) to Old River; then south along Old River to

Clifton Court Forebay; along the west and south sides of Clifton Court Forebay to Old River; then south along the county line to Byron Highway; then west of Byron Highway to I-205, north of I-205 to I-580, and west of I-580. Aquatic habitat also includes the following land cover types along the western edge of the Suisun Marsh, west of I-680.

- Perennial and intermittent streams
- Aquatic habitat types from the BDCP composite vegetation layer including:
  - Managed wetland
    - *Scirpus*[1] spp. in managed wetlands; and
    - *Polygonum amphibium.*
  - Nontidal freshwater perennial emergent
    - Broad-leaf cattail (*Typha latifolia*);
    - American bulrush (*Scirpus americanus*);
    - Mixed *Scirpus* mapping unit;
    - *Scirpus acutus* pure; and
    - *Scirpus acutus* (*Typha latifolia*) – *Phragmites australis.*
  - Tidal freshwater emergent wetland
    - Mixed *Scirpus* mapping unit;
    - Mixed *Scirpus*/floating aquatics complex;
    - Mixed *Scirpus*/submerged aquatics complex;
    - Hard-stem bulrush (*Scirpus acutus*);
    - *Scirpus acutus* pure;
    - *Scirpus acutus – Typha angustifolia;*
    - *Scirpus acutus – Typha latifolia;*
    - *Scirpus acutus – (Typha latifolia) – Phragmites australis;*
    - California bulrush (*Scirpus californicus*);
    - *Scirpus californicus – Eichhornia crassipes;*
    - *Scirpus californicus – Scirpus acutus;*
    - American bulrush (*Scirpus americanus*);
    - Narrow-leaf cattail (*Typha angustifolia*); and
    - *Typha angustifolia – Distichlis spicata.*

[1] Currently known as *Schoenoplectus*.

- Perennial aquatic
  - Floating primrose (*Ludwigia poploides*);
  - *Ludwigia peploides;*
  - Generic floating aquatics;
  - Water hyacinth (*Eichhornia crassipes*);
  - Pondweed (*Potamogeton* spp.);
  - Milfoil – Waterweed (generic submerged aquatics) ;
  - Brazilian waterweed (*Egeria – Myriophyllum*) submerged;
  - *Hydrocotyle ranunculoides;*
  - Algae; and
  - Water.

Assumptions. Within the Plan Area, the California red-legged frog has been detected only in aquatic habitats within the grassland landscape west of Clifton Court Forebay, in the vicinity of Brentwood and Marsh Creek along the west-central edge of the Plan Area, and along the western edge of Suisun Marsh, west of I-680. Habitat occurring within the California Aqueduct and the Delta Mendota Canal were removed. These areas represent the easternmost edge of the current range of California red-legged frog within the Coast Ranges. The species is not known to occur, nor is it expected to occur, elsewhere in the Plan Area.

Storer (1925) and Hayes and Jennings (1988) describe aquatic breeding habitat requirements for California red-legged frog as cold water pond habitats (including stream pools and stock ponds) with emergent and submergent vegetation, providing suitable cover for young and adults and ensuring successful reproduction. Optimal habitats are described as deep-water ponds or pools along low gradient streams with dense stands of overhanging willows and a fringe of cattails between the willow roots and overhanging willow limbs. Hayes and Jennings (1988) also note that the lack of wetland or other shallow streamside vegetation does not necessarily preclude the presence of California red-legged frog and that there may be a current preference for pools along intermittent streams rather than backwater pools along perennial streams possibly due to predator avoidance. California red-legged frog uses a variety of aquatic habitats that meet these requirements, including permanent and ephemeral ponds including stock ponds, perennial and intermittent streams, seasonal wetlands, springs, seeps, marshes, dune ponds, lagoons, and human-made aquatic features (USFWS 2007).

While stock ponds and other small water impoundments provide important aquatic habitat for California red-legged frog, these features could not be effectively mapped using the model data sources and are thus not included here. It is assumed that stock ponds and other small water impoundments occur within the grassland landscape identified below as potential upland cover and dispersal habitat that provide additional potential breeding habitat for California red-legged frog. It is also assumed that sufficient upland and dispersal habitat has been identified based on proximity to mapped aquatic features to include all potential California red-legged frog breeding habitat within the Plan Area.

Upland Cover and Dispersal Habitat. Upland cover and dispersal habitat includes grassland and riparian habitats within the area described above and within 2 miles of aquatic habitat as described above.

Upland cover and dispersal habitat from the BDCP composite vegetation layer includes:

- Grassland – all types
- Valley/foothill riparian – all types
- Vernal pool complex
    - Annual grasses generic;
    - Annual grasses/weeds;
    - California annual grasslands;
    - *Distichlis* (generic);
    - *Distichlis spicata;*
    - *Distichlis spicata* – annual grasses;
    - *Districhlis*/annual grasses;
    - *Distichlis*/ *S. maritimus;*
    - Ruderal herbaceous grasses and forbs;
    - Italian rye-grass (*Lolium multiflorum*);
    - *Salicornia virginica*; and
    - *Salicornia*/annual grasses.

Dispersal Habitat. Upland dispersal habitat also includes agricultural lands within the area described above and within 2 miles (3.2 km) of the aquatic habitat as described above.

Upland Dispersal Habitat from the BDCP composite vegetation layer includes:

- Agricultural land – all types

Assumptions. The California red-legged frog also requires upland non-breeding habitat used for cover, aestivation, and migration and other movements. Non-breeding cover habitat may include nearly any areas within 1-2 miles (1.6-3.2 km) of a breeding site that stays moist and cool through the summer (Fellers and Kleeman 2007). Potential cover habitat includes all aquatic, riparian, and upland areas that provide cover, such as animal burrows, boulders or rocks, organic debris such as downed trees or logs, and industrial debris; agricultural features such as drains, watering troughs, spring boxes, abandoned sheds, or hay stacks may also be used (61 FR 25813). Movement corridors may include annual grasslands, riparian corridors, woodlands, and sometimes active agricultural lands (Fellers and Kleeman 2007).

A32.8 Recovery Goals

The Recovery Plan for the California red-legged frog (USFWS 2002) identifies five recovery criteria:

1. Protection of suitable habitat, in perpetuity, within each of the defined core areas. Protection of habitat would include impacts upstream that could make habitat unsuitable.
2. Documentation that existing populations are stable through a 15-year monitoring program. This program should include representative precipitation cycles.
3. Distribution of existing populations, allowing stable metapopulations despite fluctuations in local populations.
4. Reestablishment of frogs in at least one area of historical occurrence for each core area.
5. Additional habitat needed for connectivity of existing and reestablished populations, reestablishment, and dispersal has been determined and is protected and managed for red-legged frogs.

APPENDIX A33. WESTERN SPADEFOOT TOAD (*SPEA HAMMONDII*)

A33.1 LEGAL STATUS

The western spadefoot toad (*Spea hammondii*) is designated as a state Species of Special Concern (Jennings and Hayes 1994). This species currently does not have any federal listing status. However, because it is associated with vernal pool habitats, it is addressed in the Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon (USFWS 2005).

A33.2 SPECIES DISTRIBUTION AND STATUS

A33.2.1 Range and Status

In North America, the range of the western spadefoot toad includes portions of California, extending south to Mesa de San Carlos in Baja California Norte, Mexico (Stebbins 1985, Jennings and Hayes 1994, California Academy of Sciences 2008, Museum of Vertebrate Zoology 2008). In California, the current range of the western spadefoot toad includes portions of the Central Valley and bordering foothills, and the Coast Range south of Monterey Bay (Figure A-33a) (Stebbins 2003). The western spadefoot toad has been extirpated throughout most of the lowlands of southern California (Stebbins 1985) and from many historical locations within the Central Valley (Jennings and Hayes 1994, Fisher and Shaffer 1996). Fisher and Shaffer (1996) state that the western spadefoot toad populations have declined severely in the Sacramento Valley, and their density has been reduced in eastern San Joaquin Valley. The numbers in the Coast Range have declined more modestly than in the valleys. The population status and trends of the western spadefoot toad outside of California (i.e., Baja California Norte, Mexico) are not well known.

This species occurs mostly below 3,000 feet (914 meters) in elevation (Stebbins 1985). The average elevation of sites where the species still occurs is significantly higher than the average elevation for historical sites, further suggesting that declines have been more pronounced in lowlands (USFWS 2005).

The principal factors contributing to the decline of the western spadefoot are loss of habitat due to urban development, conversion of native habitats to agricultural lands, introduction of nonnative predators, and pesticide use (Fisher and Shaffer 1996, Hobbs and Mooney 1998, Davidson et al. 2002). Habitat loss and fragmentation result in small, isolated populations, which reduce individual movements and genetic exchange between populations.

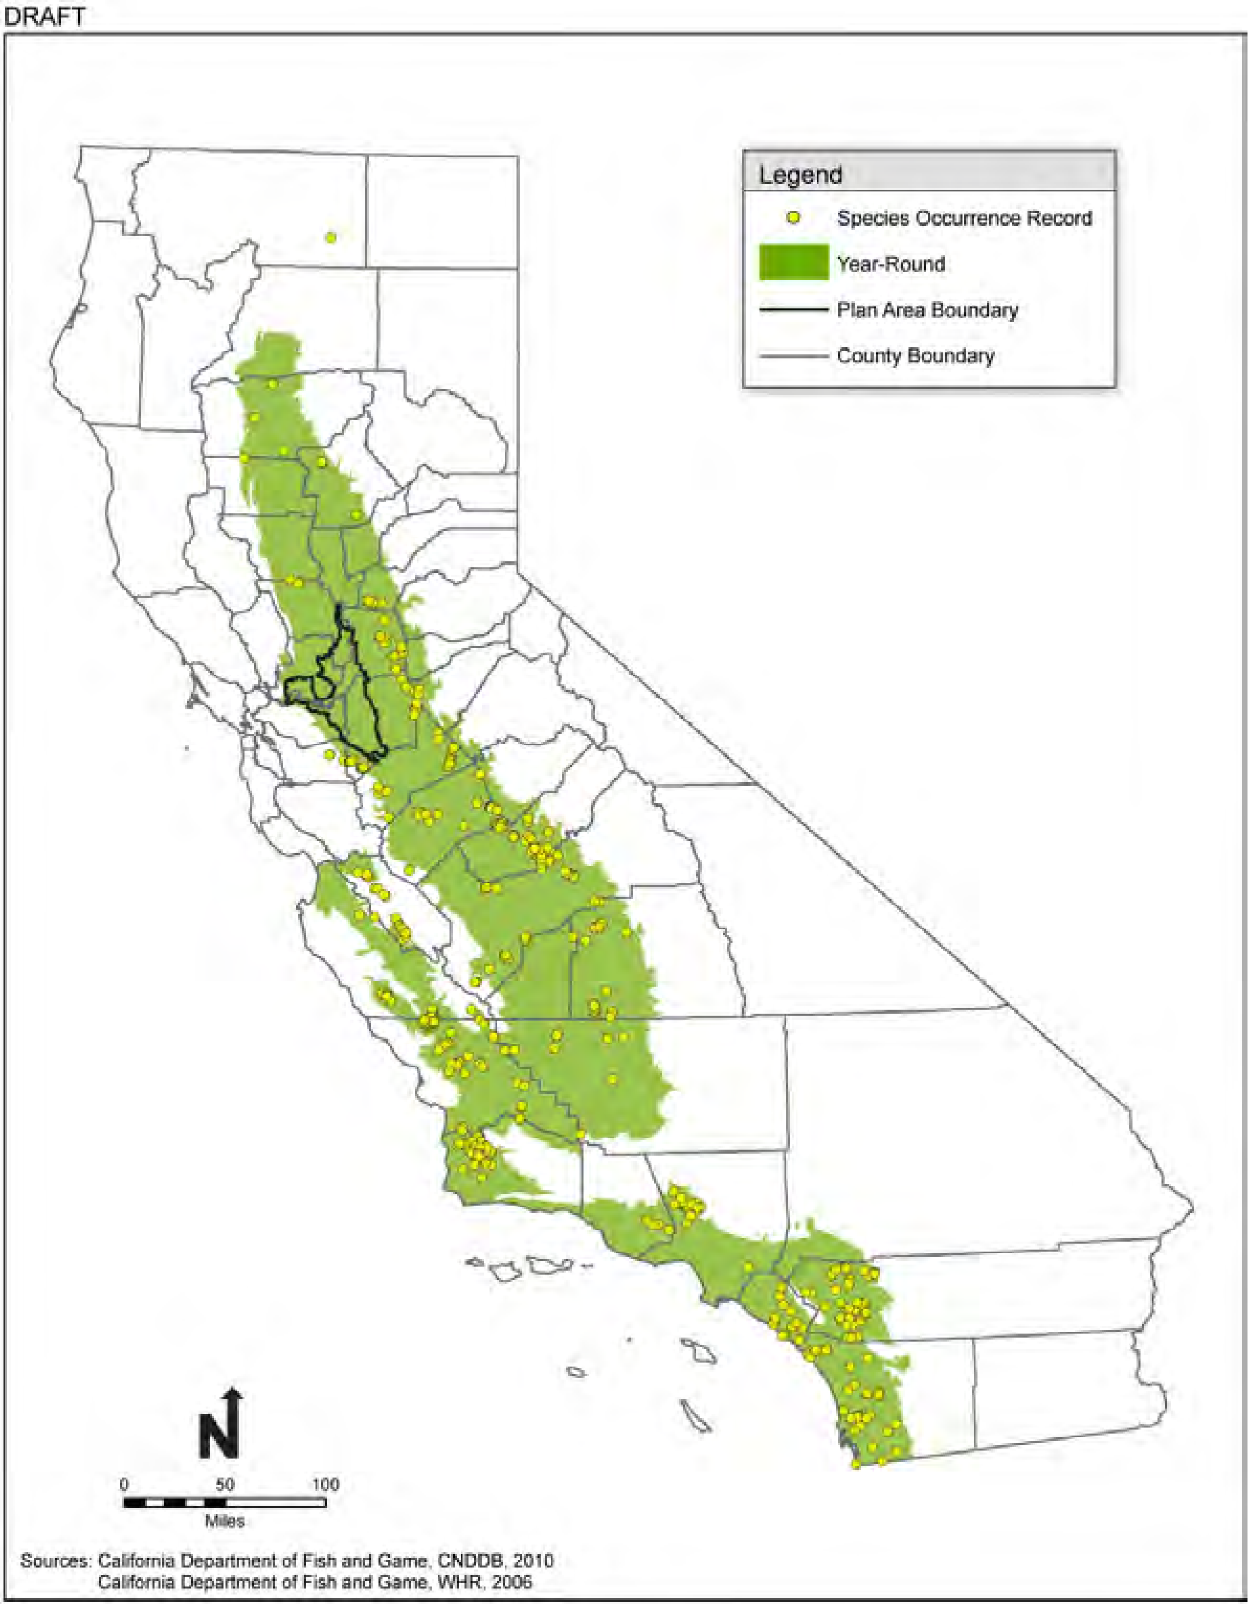

Figure A-33a. Western Spadefoot Toad Statewide Range and Recorded Occurrences

Reduction in gene flow may result in inbreeding depression and a subsequent reduction in population fitness. Furthermore, many remaining vernal pool and other wetland habitats are subject to continuing habitat degradation by disking, intensive livestock grazing, off-road vehicle use, and contaminant run-off (Fisher and Shaffer 1996, Hobbs and Mooney 1998, Davidson et al. 2002).

A33.2.2 Distribution and Status in the Plan Area

Although the expected range extends through the Plan Area (Figure A-33b), no records for western spadefoot toad occur (CNDDB 2009). Potentially suitable habitats occur in remaining uncultivated grasslands near Stone Lakes, east of Interstate 5 (I-5) in the vicinity of the Cosumnes River Preserve, along the southwestern edge of the Plan Area from approximately Brentwood to Tracy, in the southern Montezuma Hills near Collinsville, and in eastern Solano County including Jepson Prairie. While the species has not been documented, portions of the Yolo Basin, particularly the California Department of Fish and Game's (DFG) Yolo Bypass Wildlife Area Tule Ranch Unit may also support suitable habitat for western spadefoot toad.

A33.3 Habitat Requirements and Special Conditions

Western spadefoot toads typically inhabit lowland habitats such as washes, floodplains of rivers, alluvial fans, playas, and alkali flats (Stebbins 1985), extending into foothills and mountains to an elevation of 1,360 meters (4,462 feet) (Jennings and Hayes 1994). Western spadefoot toads select areas with sandy or gravelly soil with open vegetation and short grasses. Vegetation communities where this species may occur include valley and foothill grasslands, open chaparral, and pine-oak woodlands (USFWS 2005).

Western spadefoot toads require two distinct habitat components to complete their life cycle, and these habitats may need to be in close proximity (USFWS 2005). These components are presence of an aquatic habitat for breeding and a terrestrial habitat for feeding and aestivation. Western spadefoot toads are mostly terrestrial, using upland habitats to feed and burrow in for their long dry-season dormancy. Further research is needed to determine the distance this species may travel from aquatic habitats to upland habitats for dispersal and aestivation. Current research on amphibian conservation suggests that average terrestrial habitat use is within 368 meters (1,207 feet) of aquatic habitats (Semlitsch and Brodie 2003).

Western spadefoot toads lay their eggs in a variety of permanent and temporary wetlands including rivers, creeks, pools in intermittent streams, vernal pools, and temporary rain pools (CNDDB 2009) as well as stock ponds. This species reproduces in water when temperatures are between 48 °F and 86 °F, and water must be present for more than three weeks for metamorphosis to be completed (Jennings and Hayes 1994).

DRAFT

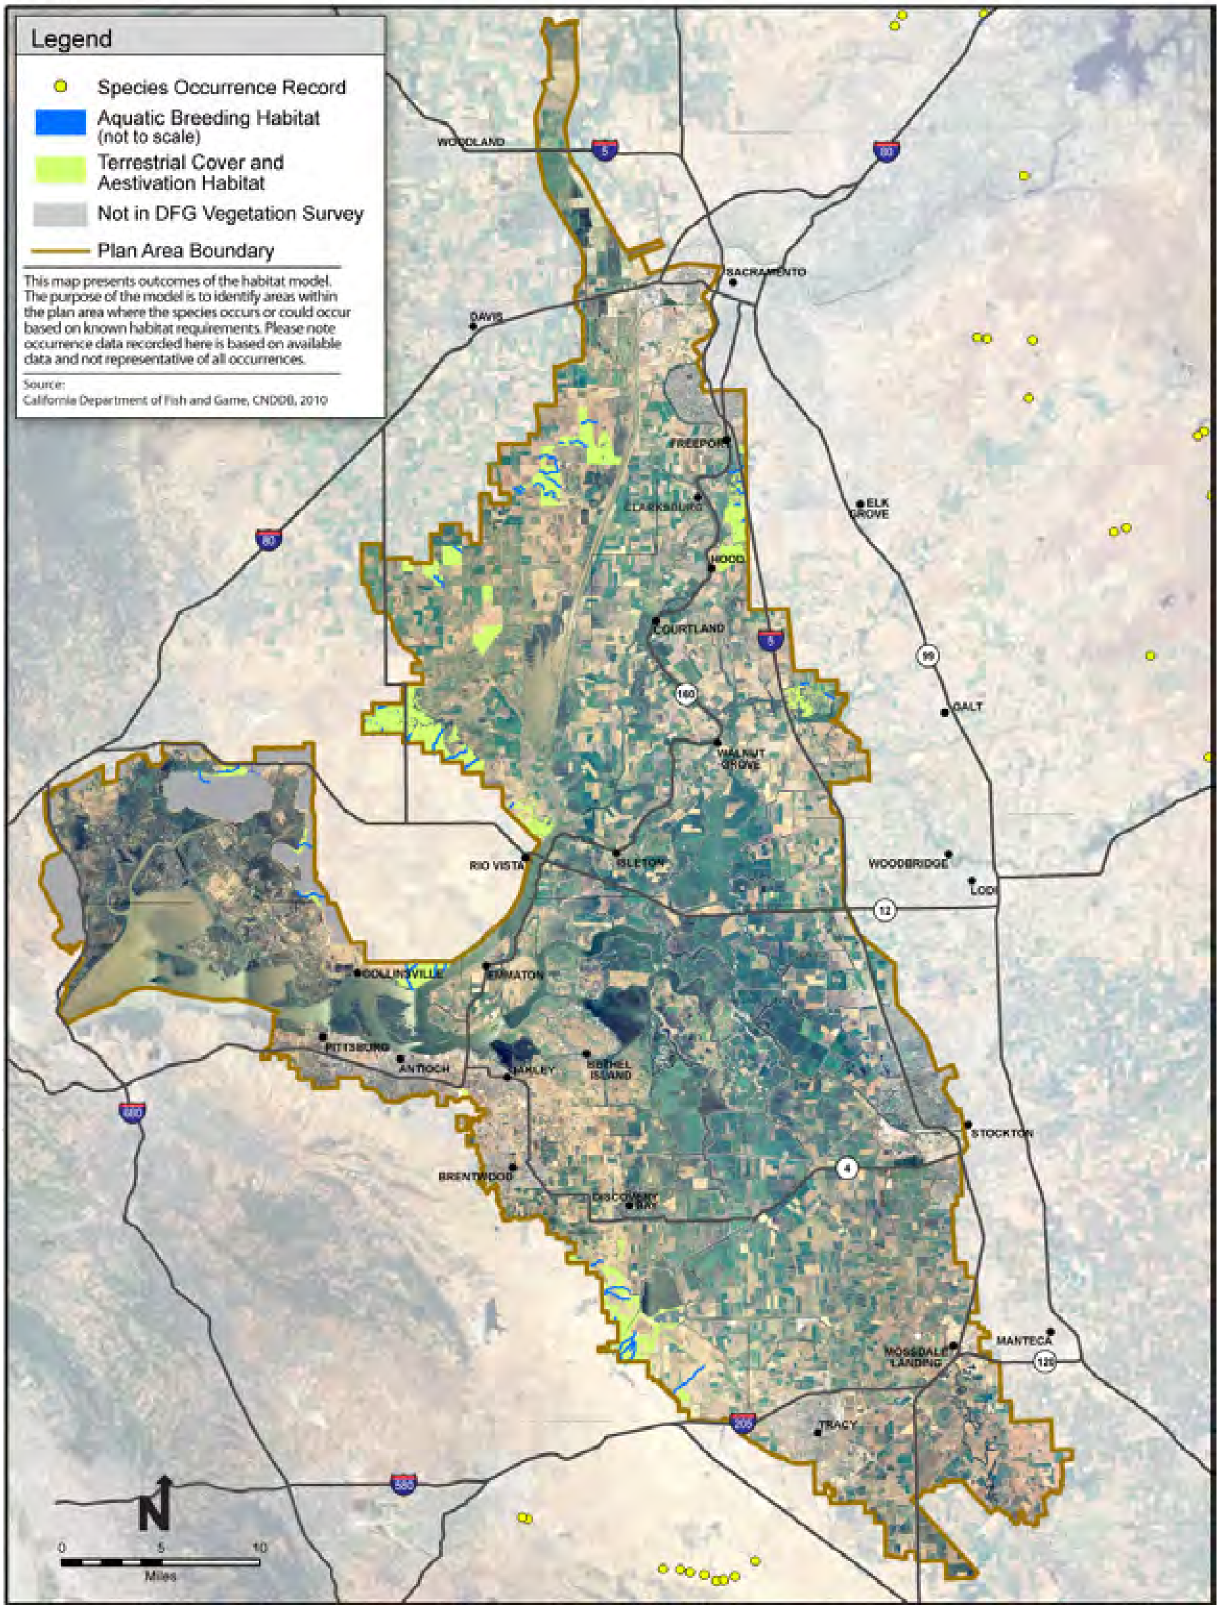

Figure A-33b. Western Spadefoot Toad Habitat Model and Recorded Occurrences

Optimal habitat in vernal pools and other temporary wetlands used for reproduction is free of native and nonnative predators, including fishes, bullfrogs, and crayfishes. Western spadefoot toads may be unable to recruit successfully in the presence of these predators (Jennings and Hayes 1994).

During dry periods, individuals typically excavate burrows into the ground at depths up to 3 feet, but they may also occupy burrows constructed by small mammals; whether these are used as short-term refugia during periods of surface activity is unknown (Jennings and Hayes 1994). Adult western spadefoot toads can consume roughly 11 percent of their body mass at a single feeding (Dimmitt and Ruibal 1980b), and can probably acquire the resources needed for aestivation in just a few weeks (Jennings and Hayes 1994). This aestivation period may continue for nine months at a time (Jennings and Hayes 1994). The skin of western spadefoots is very permeable, enabling them to absorb moisture from the surrounding soil. Spadefoots may also be able to retain urea, increasing their internal osmotic pressure, thereby preventing water loss and facilitating water absorption from soils with relatively high moisture tensions (Ruibal et al. 1969, Shoemaker et al. 1969).

Natural predators of larval and post-metamorphic western spadefoot toads include raccoons (*Procyon lotor*), garter snakes (*Thamnophis* spp.), great blue herons (*Ardea alba*), and California tiger salamanders (*Ambystoma californiense*) (Childs 1953). There are indications that the presence of introduced predators in breeding pools, such as mosquitofish (*Gambusia affinis*), crayfish (order Decapoda), and bullfrogs (*Rana catesbeiana*) may prevent recruitment (Jennings and Hayes 1994).

Although the degree to which predation affects the population dynamics of western spadefoot toads is poorly understood, their extended period of aestivation reduces exposure to predators. Spadefoot toads also produce toxic dermal secretions that deter predation (Duellman and Trueb 1986). Feaver (1971) noted that California tiger salamander larvae preyed on western spadefoot toad larvae whenever the two species co-occurred, and California tiger salamander larvae metamorphosed first. However, Anderson (1968) found that if larvae of the two species are the same size, predation may not occur.

A33.4 LIFE HISTORY

Description. The western spadefoot toad is a smooth-skinned, grayish-green toad with gold-colored eyes. The belly is white, and often the back will have orange or red spots. It is usually 1.5 to 2.5 inches long with a characteristic wedge-shaped spade on its rear feet.

Seasonal Patterns. Movement patterns and colonization abilities of the adult western spadefoot toad are not fully understood (Jennings and Hayes 1994). The western spadefoot toad is primarily a terrestrial amphibian and enters the water mainly for reproduction. They typically emerge at night during periods of warm rainfall to forage (Stebbins 1972). Emerging from burrows constructed in loose soil at least three feet deep (Stebbins 1972), they move toward breeding sites in late winter to spring, in response to favorable temperatures and rainfall (Morey and Guinn 1992). The breeding season is brief (Stebbins 2003), sometimes lasting no more than one to two weeks. Following breeding, individuals return to upland habitats, where they spend most of the year aestivating (in a dormant state) in burrows. The western spadefoot toad may breed in the same ponds as California tiger salamanders in areas where the two species are sympatric (CNDDB 2009).

Reproduction. Western spadefoot toads breed from January to May. Breeding aggregations can form with over 1,000 individuals, but the aggregations are usually much smaller. These groups are highly vocal, and breeding calls can be heard at great distances. These calls help individuals find each other to form breeding aggregations and suitable breeding sites (Stebbins 1985). Oviposition (egg-laying) will not occur until water temperatures reach the critical thermal minimum of 9 °C (48 °F), usually between late February and late May (Jennings and Hayes 1994). Females deposit their eggs in many small irregularly cylindrical clusters of 10 to 42 eggs with an average of 24 (Storer 1925) on stems or pieces of detritus in temporary rain pools, or sometimes in pools of ephemeral stream courses (Storer 1925, Stebbins 1985).

Depending on temperature and availability of food, eggs will hatch within 0.6 to 6 days after oviposition; and larvae can complete development in 3 to 11 weeks (Jennings and Hayes 1994). If the water temperature is too high, above 21 °C (70 °F), hatching success of the eggs may decrease by half possibly due to more favorable temperatures for destructive fungus (Storer 1925).

Metamorphosing larvae may leave the water before their tails fully disappear, and sometimes have tails longer than 0.4 inches (Storer 1925). Larvae benefit from longer periods of development with persisting water and adequate temperatures that allow juveniles to reach larger sizes with greater fat reserves at metamorphosis (Morey 1998). After the juveniles emerge from the water, they take refuge in the surrounding area and may remain nearby for several days before dispersing to adjacent upland habitat. These individuals will then construct subterranean burrows and remain dormant for the following eight to nine months during the warmer summer months to avoid desiccation. Individuals may require at least two years to reach sexual maturity (Jennings and Hayes 1994).

Diet. Adult western spadefoot toads feed on a variety of insects, worms, and other invertebrates, including grasshoppers, true bugs, moths, ground beetles, predaceous diving beetles, ladybird beetles, click beetles, flies, ants, and earthworms (Morey and Guinn 1992, USFWS 2005). Tadpoles forage on planktonic organisms, algae, small invertebrates (Bragg 1964), and dead aquatic larvae of amphibians, even their own species.

A33.5 Threats and Stressors

The main factors contributing to the decline of the western spadefoot toad population include loss of habitat from urban development and conversion of native habitats to agricultural lands, the increase of introduced nonnative predators, and stochastic events that particularly impact small, isolated populations (USFWS 2006).

Habitat Loss and Fragmentation. The loss of vernal pool or other seasonal pool habitats due to land conversion is likely the greatest threat to the western spadefoot toad. More than 80 percent of occupied habitat in southern California and more than 30 percent in northern California have been lost to development or other incompatible land uses (Jennings and Hayes 1994).

Habitat fragmentation resulting from urban development, agricultural conversion, and road construction also threatens western spadefoot toad populations. The relationship between habitat fragmentation and the metapopulation structure of the western spadefoot toad is not entirely understood (Jennings and Hayes 1994); however, ongoing land conversion is undoubtedly resulting in smaller, isolated populations. Habitat loss and fragmentation produces small populations that are increasingly isolated and limited in space. This reduces the movement of individuals and genetic exchange between populations. Small, isolated populations are highly susceptible to extinction caused by catastrophic or stochastic events. Isolation limits the ability of the population to recolonize areas with suitable habitat where western spadefoot toads may have been present in the past.

Agricultural practices such as disking and intensive livestock grazing and trampling have degraded many remaining vernal pools and wetland habitats, along with off-road vehicle use and contaminated runoff. Roads can create a barrier to dispersal movements of western spadefoot toads and isolate populations. Contaminants from road materials, leaks, and spills could further degrade aquatic habitats used by this species. Direct mortality of toads may occur when toads burrow in actively tilled fields, or are hit by vehicles when dispersing across roads.

Noise and Vibration. Low frequency noise and vibration in or near habitat for western spadefoot toads may be harmful, even fatal, to this species. Spadefoot toads are extremely sensitive to such stimuli, and it causes them to break dormancy and emerge from their burrows (Dimmitt and Ruibal 1980a). This could result in mortality or reduced productivity if it causes western spadefoot toads to emerge at inappropriate times (USFWS 2005).

Potential anthropogenic sources of such low-frequency noises and vibrations include seismic exploration for natural gas, land grading, or other motorized vehicles or machinery. Artificial irrigation can induce spadefoot toads to emerge and begin vocalizing in any month (Zeiner et al. 1988).

Nonnative Predators. Nonnative invasive species are also a threat to the western spadefoot toad. The predation of spadefoot toad eggs and larvae by mosquitofish introduced into vernal pools through mosquito abatement programs may threaten some populations (Jennings and Hayes 1994). Bullfrogs, which have been reported to emigrate to some western spadefoot toad breeding pools, may threaten those populations through predation of spadefoot toad eggs and larvae. Exotic predators such as mosquitofish may also compete with western spadefoot toad larvae for limited food resources.

A33.6 Relevant Conservation Efforts

Understanding the life history and important habitat requirements of the western spadefoot toad is essential for conservation of the species (Jennings and Hayes 1994). Jennings and Hayes (1994) state that the most significant data gap related to understanding western spadefoot toad populations is the relationship between habitat fragmentation and metapopulation structure. Movement patterns and colonization abilities of adult western spadefoot toads are also not fully understood. While habitat protection remains the primary strategy for conserving the western spadefoot toad, more research is required to better understand the species' habitat requirements with respect to patch sizes, movement corridors, and other elements of conservation design strategies.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designates the western spadefoot toad as "Maintain" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions to maintain the species by avoiding, minimizing, and compensating for any adverse effects to the species created by ERP restoration actions. To the extent practicable, the ERP will improve species habitat conditions.

Western spadefoot toad is a covered species under the approved San Joaquin County Multi-Species Habitat Conservation and Open Space Plan, and the Natomas Basin Habitat Conservation Plan. Western spadefoot toad is proposed for coverage under the South Sacramento County Habitat Conservation Plan, the Yolo County Natural Heritage Program Plan, and the Butte Regional Conservation Plan.

A33.7 Species Habitat Suitability Model

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information systems (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf 2007. Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers, connectivity between habitat types, and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The western spadefoot toad model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), USDA 2005 aerial photography, and DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable western spadefoot toad habitat in the Plan Area according to the species' two primary life requisites: aquatic breeding habitat and terrestrial feeding and aestivation habitat. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Terrestrial Cover and Aestivation Habitat. Terrestrial habitat is defined as all grassland types with a minimum patch size of 100 acres (40.5 hectares) located west of the Deep Water Ship

Channel; east of the Sacramento River between Freeport and Hood-Franklin Road; east of I-5 between Twin Cities Road and the Mokelumne River; and within the area south and west of Highway 4 from Antioch (Bypass Road to Balfour Road to Brentwood Boulevard) to Old River; then south along Old River to Clifton Court Forebay; along the west and south sides of Clifton Court Forebay to Old River; then south along the county line to Byron Highway; then west of Byron Highway to I-205, north of I-205 to I-580, and west of I-580. Grasslands associated with the Montezuma Hills and Potrero Hills were also included. Grassland strips solely occurring atop levees and not adjacent to grassland areas were excluded. Patches of grassland that were below the 100-acre minimum patch size but were contiguous with grasslands outside of the Plan Area boundary were included.

Terrestrial feeding and aestivation habitat includes the following grassland and alkali seasonal wetland complex types from the BDCP composite vegetation layer:

- Grassland
  - Ruderal herbaceous grasses and forbs;
  - California annual grasslands;
  - *Bromus diandrus-Bromus hordeaceus;*
  - Italian rye-grass (*Lolium multiflorum*);
  - *Lolium mulitflorum – Convolvulus arvensis;*
  - Degraded vernal pool complex – California annual grasslands;
  - Degraded vernal pool complex – ruderal herbaceous grasses and forbs;
  - Degraded vernal pool complex – Italian rye-grass (Lolium multiflorum);
  - Annual grasses generic;
  - Annual grasses/weeds;
  - *Bromus* spp./*Hordeum;*
  - *Hordeum/Lolium;*
  - *Lolium* (generic);
  - *Lotus corniculatus;*
  - Medium upland graminoids;
  - Medium upland herbs;
  - Perennial grass;
  - Short upland graminoids;
  - Upland annual grasslands and forbs formation; and

- Upland herbs.
- Alkali seasonal wetland complex
  - *Distichlis spicata* – annual grasses.

Assumptions. There are no reported occurrences of western spadefoot toad from the Plan Area. The nearest reported occurrences are in the foothill grasslands west of I-505 and south of I-205 southwest of the Plan Area.

Habitat for western spadefoot toad includes vernal pools and seasonal and perennial ponds, and seasonal streams within a grassland landscape (Jennings and Hayes 1994, USFWS 2005). Because the mapping of aquatic breeding habitats within the Plan Area is incomplete, this element cannot be effectively used to model the extent of suitable habitat for this species. Thus, grasslands are used to more generally describe the extent of suitable habitat.

Western spadefoot toad requires relatively large grassland landscapes and is unlikely to occur in fragmented or isolated patches of otherwise suitable habitat. A 100-acre minimum was selected to exclude very small and isolated patches. This generally corresponds to data from Semlitsch and Brodie (2003), who calculated a minimum patch size of 134 acres (54 hectares) to meet the ecological requirements of the species. Grasslands located along the narrow eastern edge of the Suisun Marsh that were contiguous with the larger grassland/agricultural landscape of the Montezuma Hills were reviewed and removed from the terrestrial cover and aestivation habitat component of the model because most appeared transitional to the tidal marsh wetlands that are not suitable for western spadefoot toad.

Cultivated habitats do not provide terrestrial habitat for western spadefoot toads because cultivation disrupts aestivation.

The model is further constrained geographically by eliminating grasslands that are not within seasonal pool or pond/grassland landscapes, such as the central Delta. While periodic flooding may preclude spadefoot toad from occurring in the Yolo Bypass, the vernal pool landscape on the DFG's Tule Ranch Unit and other similar areas on the DFG Yolo Bypass Wildlife Area could potentially support this species in some years. These areas are mapped as Alkali Seasonal Wetland Complex (*Distichlis spicata*-annual grasses); however, they have a substantial grassland component. The model overestimates suitable habitat by assuming there are sufficient aquatic breeding habitats within the grassland landscape as defined.

Aquatic Breeding Habitat. Aquatic habitats include a variety of permanent and temporary wetlands including pools in streams, ponds (including stock ponds), and vernal pools. Aquatic breeding habitat includes the following land cover types and conditions that are within the grassland landscape as defined above:

- Perennial and intermittent streams

- Aquatic breeding habitat includes the following other natural seasonal wetland types from the BDCP composite vegetation layer:
    - Vernal pools; and
    - Degraded vernal pool complex-vernal pools.
- Aquatic breeding habitat includes the following vernal pool complex types from the BDCP composite vegetation layer:
    - *Allenrolfea occidentalis* mapping unit;
    - Annual grasses generic;
    - Annual grasses/weeds;
    - California annual grasslands-herbaceous;
    - *Distichlis* (generic);
    - *Distichlis*/annual grasses;
    - *Distichlis*/*S. maritimus;*
    - *Distichlis spicata;*
    - *Distichlis spicata* – annual grasses;
    - Italian rye-grass (*Lolium multiflorum*);
    - Mix *Scirpus* mapping unit;
    - Ruderal herbaceous grasses and forbes;
    - *Salicornia virginica;*
    - *Salicornia*/annual grasses;
    - Salt scalds and associated sparse vegetation;
    - Saltgrass (*Distichlis spicata*);
    - Seasonally flooded grasslands;
    - *Suadeda moquinii* – (*Lasthenia californica*) mapping unit; and
    - Vernal pools.

Aquatic habitat types in the Suisun Marsh and Yolo Basin from the BDCP composite vegetation layer include:

- Freshwater drainage; and
- Slough.

Assumptions. Aquatic breeding habitats are mapped to the extent data are available, but not used as a model attribute. The data are insufficient to effectively model western spadefoot toad habitat on the basis of aquatic breeding habitat.

Proximity of aquatic breeding habitat and terrestrial habitat is an important element of spadefoot toad life history (current research suggests that average terrestrial habitat use is within 368 meters [1,207 feet] of aquatic habitat [Semlitsch and Brodie 2003]); however, due to the insufficient mapping of the vernal pools, stock ponds, and other small aquatic habitats in the Plan Area, this was not used as a factor in the model. Furthermore, the vernal pool complex natural community was used to represent aquatic breeding habitat, which is comprised of a combination of aquatic and upland habitat that is considered suitable for western spadefoot toad. Potential habitat included within the vernal complex natural community not having concave surfaces or land uses that are incompatible with the species' habitat requirements were removed from the aquatic breeding habitat component of the model.

A33.8 RECOVERY GOALS

While not federally listed, the western spadefoot toad was included in the "Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon" (USFWS 2005). The USFWS's stated goals for the western spadefoot toad and 12 other species of special concern covered under the Recovery Plan are to achieve and protect in perpetuity self-sustaining populations of each species and ensure the species' long-term conservation. The primary focus of the Recovery Plan is protection of vernal pool habitat—in the largest blocks possible—from loss, fragmentation, degradation, and incompatible uses (USFWS 2005). For the western spadefoot toad, the Recovery Plan calls for:

- Conducting research on juvenile and adult dispersal to and from breeding locations,
- Conducting research on the effects of habitat management practices on the western spadefoot toad and their habitat in order to determine the limiting factors with respect to determining minimum reserve sizes,
- Studying the impacts of low-frequency noises and vibrations, and
- Determining the influence of nonnative aquatic vertebrate predators (e.g., bullfrogs and mosquitofish) on population dynamics.

The overall goals of the Vernal Pool Recovery Plan, are to "achieve and protect in perpetuity self-sustaining populations throughout the full ecological, geographical, and genetic range of each listed species by ameliorating or eliminating the threats that caused the species to be listed" (USFWS 2005). Specifically for western spadefoot toad, the goal is to ensure long-term conservation. The Vernal Pool Recovery Plan concluded that:

"Based on calculations from upland habitat use data analyzed by Semlitsch and Brodie (2003), a minimum conservation area to preserve the ecological processes required for the conservation of amphibians may fall within a distance of approximately 368 meters (1,207 feet) from suitable breeding wetlands. Given a square preserve surrounding a single breeding pond, this estimate would suggest a minimum preserve size of approximately 54.2 hectares (134 acres). In any given western spadefoot toad metapopulation, we expect that some subpopulations will disappear, but the habitat they occupied will eventually be recolonized if it remains acceptable. To enable natural recolonization of unoccupied habitat, and to allow for gene flow that is vital for preventing inbreeding, opportunities for dispersal and interbreeding among subpopulations of the western spadefoot toad must be maintained. Where possible, habitat corridors between breeding sites should be protected and maintained."

APPENDIX A34. CALIFORNIA TIGER SALAMANDER (*AMBYSTOMA CALIFORNIENSE*)

A34.1 LEGAL STATUS

The California tiger salamander (*Ambystoma californiense*) is federally listed range-wide as a threatened species (69 FR 47212) and in Sonoma and Santa Barbara counties as endangered (65 FR 57242, 68 FR 13498). The species is also designated as a species of special concern by the California Department of Fish and Game (DFG) (Jennings and Hayes 1994) and as of February 2009 is a candidate for state listing. DFG is currently conducting a status review.

On September 22, 2005, the United States Fish and Wildlife Service (USFWS) designated approximately 199,109 acres (80,576 hectares) of critical habitat for the Central California population. The critical habitat is located within 19 California counties (70 FR 49380). In a December 2005 Final Rule, the USFWS designated but excluded approximately 17,418 acres (7,049 hectares) of critical habitat for the Sonoma County population, stating that interim conservation strategies and measures being implemented by local governing agencies with land use authority over the area, along with economic exclusions authorized under section 4(b)(2) of the federal Endangered Species Act, would be greater than would be achieved through critical habitat (70 FR 74138). On May 6, 2009, the USFWS announced settlement of a lawsuit that challenged its 2005 final decision on proposed critical habitat for the Sonoma County population. In the settlement, the Service agreed to re-propose as critical habitat the same 74,223 acres (30,037 hectares) of the Santa Rosa Plain that it had originally proposed in August 2005 as critical habitat.

A34.2 SPECIES DISTRIBUTION AND STATUS

A34.2.1 Range and Status

The California tiger salamander is endemic to California (Barry and Shaffer 1994, Loredo et al. 1996). Historically, the species occurred throughout the grassland and woodland areas of the Sacramento and San Joaquin River valleys and surrounding foothills, and in the lower elevations of the central Coast Ranges (Barry and Shaffer 1994) (Figure A-34a). The species is found in a relatively xeric landscape where its range is limited by its aestivation and winter breeding habitat requirements, which is generally defined as open grassland landscapes with ephemeral pools and with burrowing squirrels and pocket gophers (Barry and Shaffer 1994).

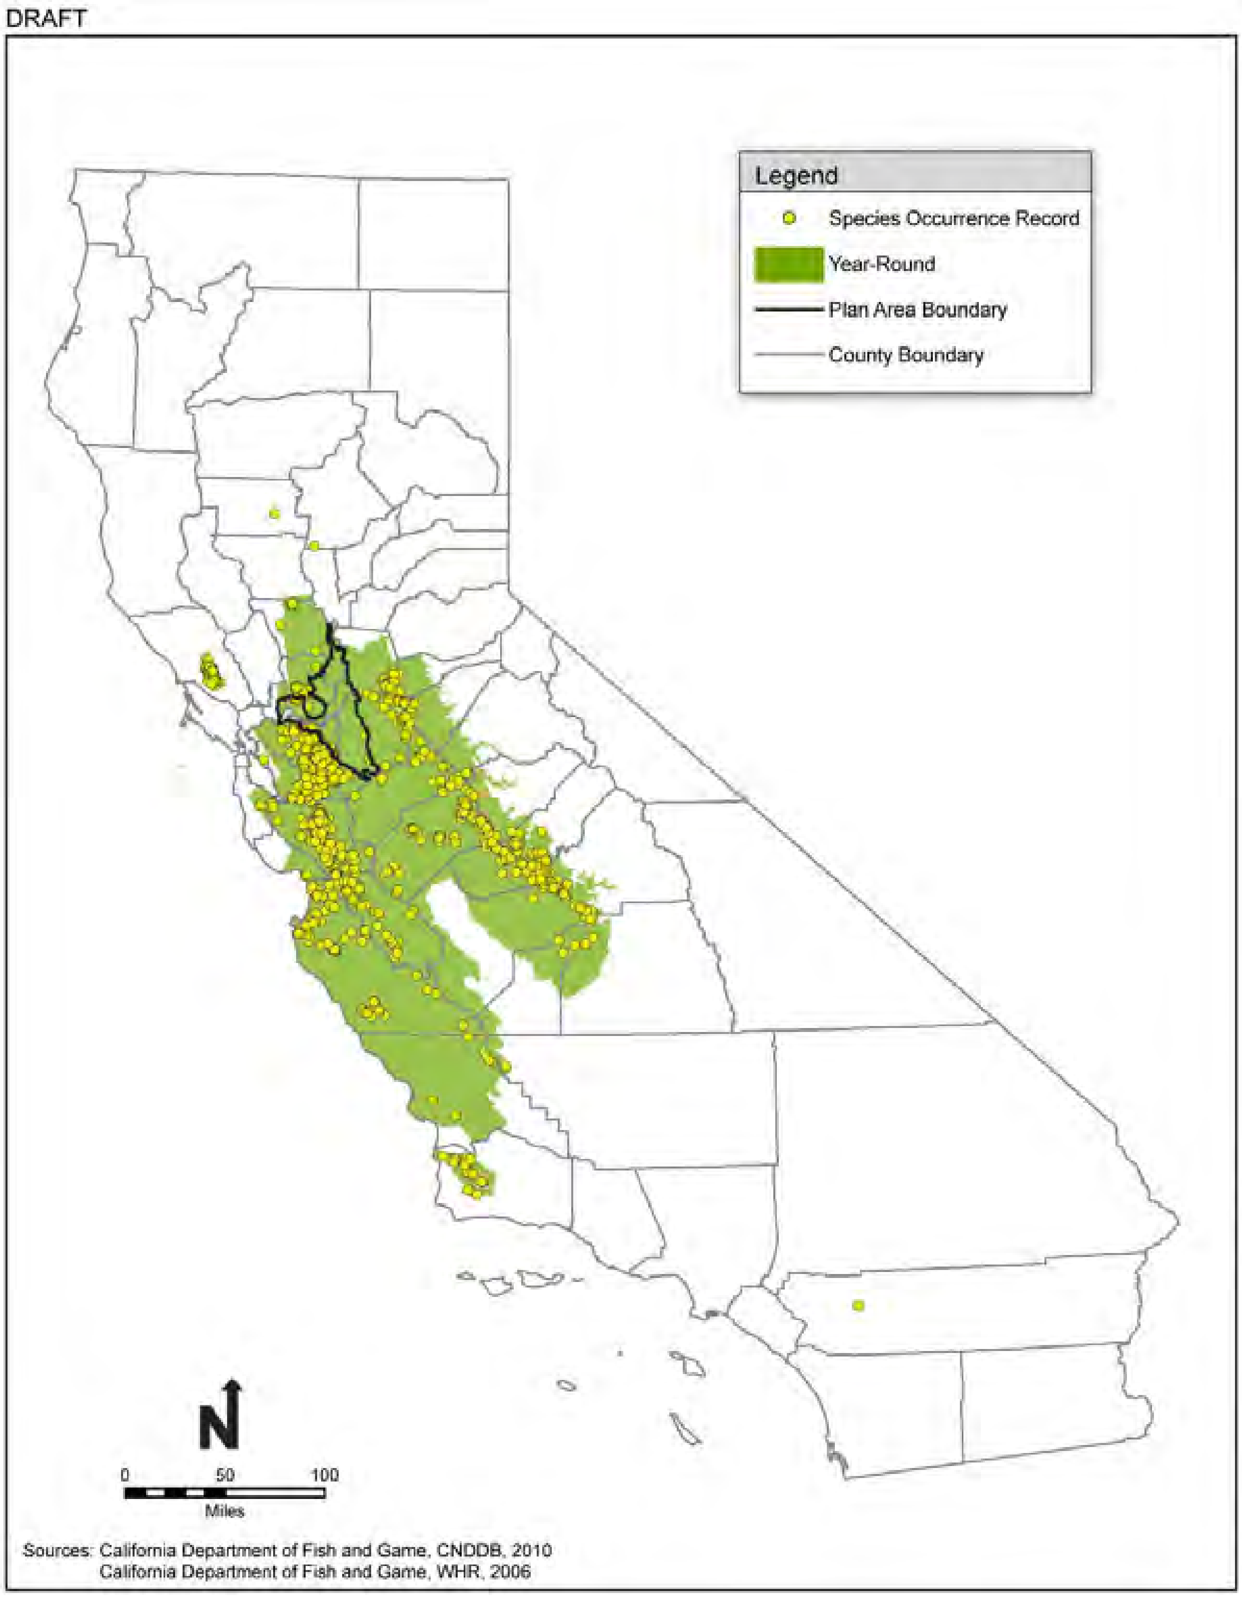

Figure A-34a. California Tiger Salamander Statewide Range and Recorded Occurrences

Within the coastal range, the species currently occurs from southern San Mateo County south to San Luis Obispo County, with isolated populations in Sonoma and northwestern Santa Barbara counties (CNDDB 2009). In the Central Valley and surrounding Sierra Nevada foothills, the species occurs from northern Yolo County southward to northwestern Kern County and northern Tulare and Kings counties (CNDDB 2009).

California tiger salamanders still occur throughout much of their historical range (Trenham et al. 2000) and can be common at localities where it still occurs. Total adult population size is unknown, but populations are thought to be declining due to habitat loss. An estimated 80 percent of the species' historical natural aquatic (i.e., vernal pool) habitat has been lost (Holland 1998) and the species has been eliminated from 55 to 58 percent of historical breeding sites (Barry and Shaffer 1994). Shaffer et al. (1993) also estimated that as much as 75 percent of the historical grassland habitat in the Central Valley used by California tiger salamander has been lost.

A34.2.2 Distribution and Status in the Plan Area

CNDDB (2009) reports several occurrences within the Plan Area immediately west of Clifton Court Forebay (Figure A-34b). There are numerous additional occurrences in vernal pool and pond habitats in the grassland foothills immediately west of the Plan Area between Corral Hollow and south of Antioch. Potential habitat exists in vernal pool habitats in Yolo and Solano counties west of Liberty Island and in the vicinity of Stone Lakes in Sacramento County.

A34.3 Habitat Requirements and Special Conditions

The California Tiger Salamander is found in annual grasslands and open woodland communities in lowland and foothill regions of central California where aquatic sites are available for breeding (USFWS 2003). The species is typically found at elevations below 460 meters (1,509 feet) (68 FR 13498), although the known elevational range extends up to 1,053 meters (3,455 feet) (Jennings and Hayes 1994). Ecological characteristics of this area include dry soils, needlegrass grasslands, valley oaks, coast live oaks and ephemerally flooded claypan vernal pools (USFWS 2003).

Vernal pools and other seasonal rain pools are the primary breeding habitat of California tiger salamanders (Barry and Shaffer 1994, 68 FR 13498). However, because the species requires at least 10 weeks of pool inundation in order to complete metamorphosis of larvae (Anderson 1968a, Feaver 1971), California tiger salamanders are usually only found in the largest vernal pools (Laabs et al. 2001). The species is also known to successfully reproduce in ponds, including artificial stock ponds (Barry and Shaffer 1994, 69 FR 47212). In the East Bay Regional Park District in Contra Costa and Alameda counties, California tiger salamanders breed almost exclusively in seasonal and perennial stock ponds (Bobzien and DiDonato 2007).

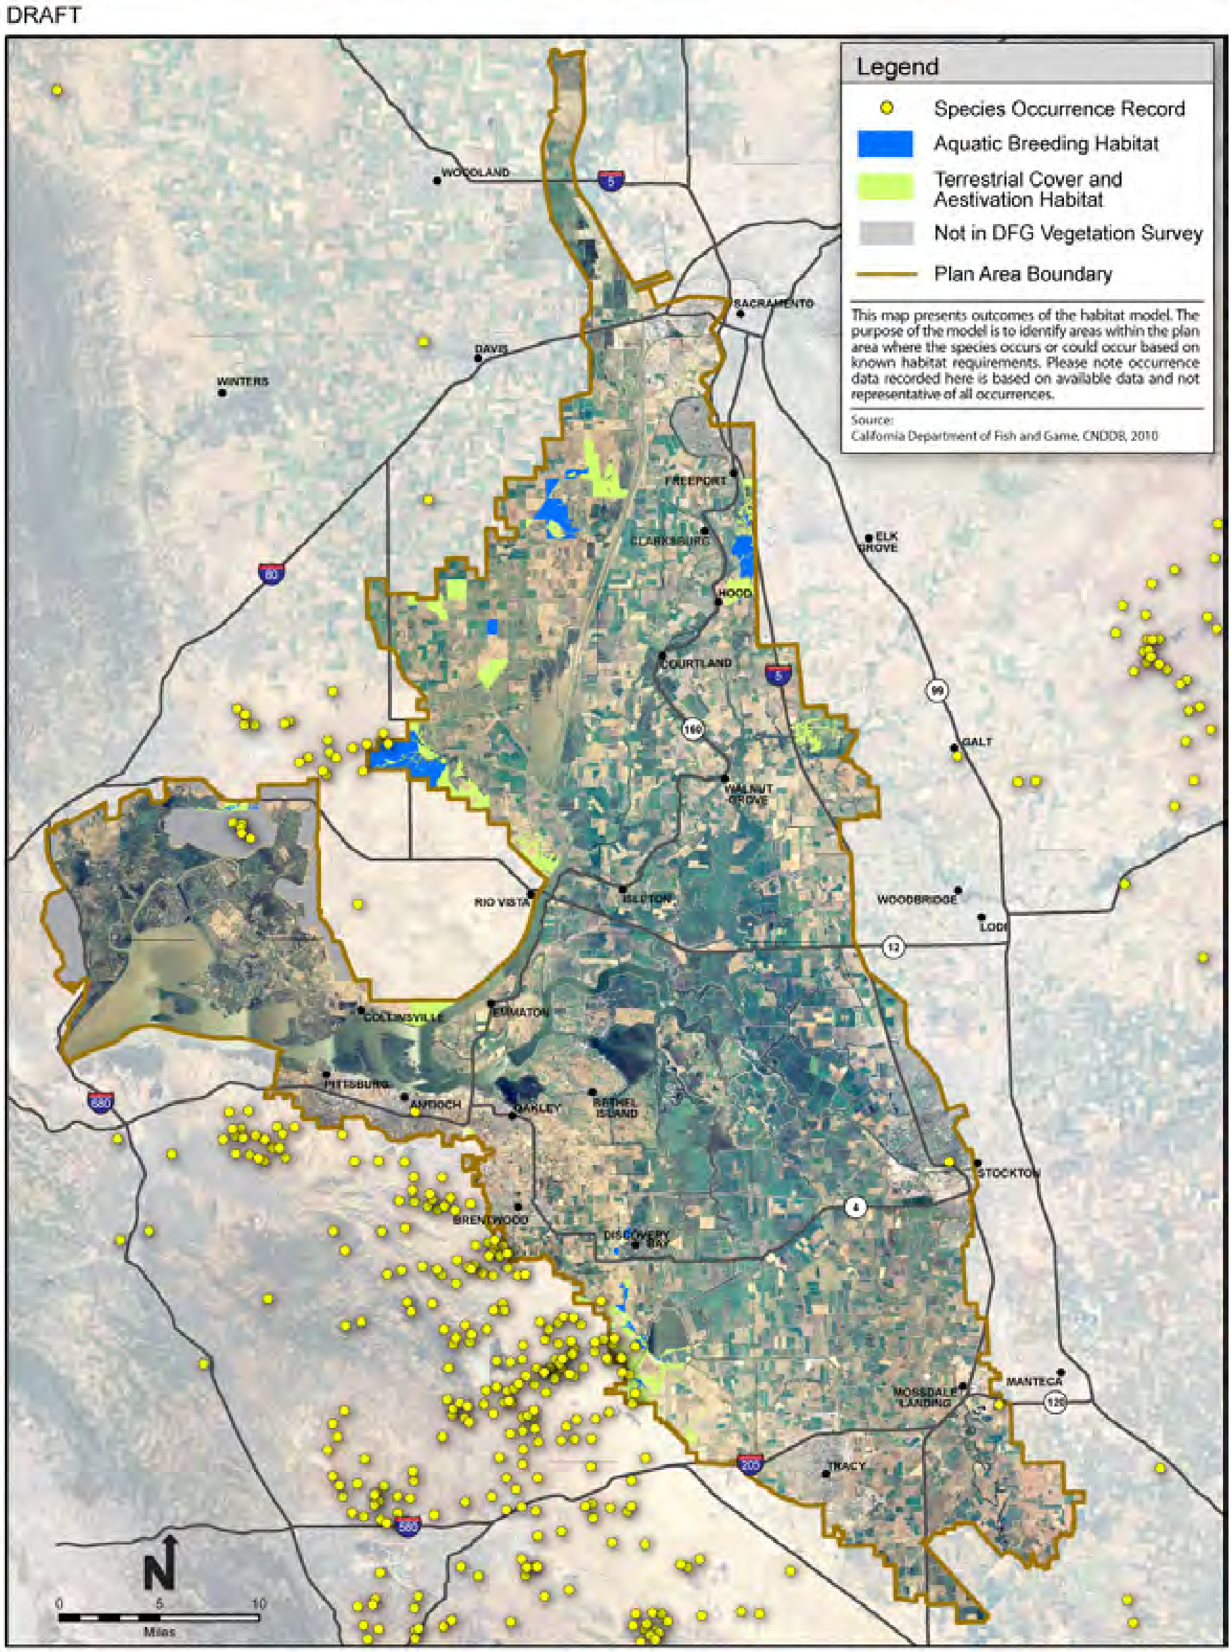

Figure A-34b. California Tiger Salamander Habitat Model and Recorded Occurrences

However, the presence of predatory fish and bullfrogs (*Rana catesbeiana*) can affect the suitability of perennial ponds (Holomuzki 1986, Fitzpatrick and Shaffer 2004). Barry and Shaffer (1994) note that stock ponds can be productive breeding sites as long as they are drained annually, which can prevent predatory species from establishing.

Adult California tiger salamanders are terrestrial and occur most of the year (six to nine months) in grassland and open woodland habitats where they find cover and aestivation sites in the underground burrows of small mammals, such as California ground squirrels (*Spermophilus beecheyi*) and Botta's pocket gopher (*Thomomys bottae*) (Storer 1925, Loredo and Van Vuren 1996, Petranka 1998, Trenham 1998a). Active rodent burrow systems are considered an important component of California tiger salamander upland habitat (Seymour and Westphal 1994, Loredo et al. 1996). Loredo et al. (1996) indicate that active ground-burrowing rodent populations are probably necessary to sustain California tiger salamander populations because inactive burrow systems begin to deteriorate and collapse over time. In a two-year radiotelemetry project in Monterey County (Hastings), Trenham (2001) found that salamanders preferentially used open grassland and isolated oaks; salamanders present in continuous woody vegetation were never more than 3 meters (10 feet) from open grassland, potentially because ground squirrels prefer to construct burrows in open habitats (Jameson and Peeters 1988 in Trenham 2001).

A34.4 LIFE HISTORY

Description. The California tiger salamander is large and thickset, with a wide, rounded snout (69 FR 47212). Average total length of males is 20.3 centimeters (cm) (8 inches) and average total length of females is 17.3 cm (6.8 inches) (69 FR 47212). Dorsal coloration consists of a black background on the back and sides, interspersed with white or pale yellow spots or bars (69 FR 47212). Ventral coloration ranges from almost uniform white or pale yellow to a variegated pattern of white, pale yellow, and black (Jennings and Hayes 1994). The salamander's small eyes have black irises and protrude from their heads (Jennings and Hayes 1994). During the breeding season, the cloacal region of males becomes enlarged (Petranka 1998) and is a useful means of distinguishing sexes. Males also have larger tails with more developed fins.

Activity Patterns. Adults emerge from upland sites on rainy nights during fall and winter rains to feed and migrate to breeding ponds (Stebbins 1989, 2003, Shaffer et al. 1993). Adults generally use the same traditional migratory routes between breeding pools and upland burrows each year (Loredo et al. 1996, Petranka 1998). Metamorphosed juveniles leave the breeding sites in late spring or early summer and migrate to small mammal burrows (Zeiner et al. 1988, Shaffer et al. 1993, Loredo et al. 1996). Like adults, juveniles may emerge from burrows to feed during nights of high relative humidity (Storer 1925, Shaffer et al. 1993) before settling in their selected upland sites for the summer months. California tiger salamanders are also active in and feed while in burrows (van Hattem 2004). While most California tiger salamanders rely on rodent burrows for shelter, some individuals may utilize soil crevices as temporary shelter during upland migrations (Loredo et al. 1996).

Reproduction. California tiger salamanders breed and lay eggs in vernal pools and ponds following relatively warm rains between November and February (Shaffer and Fisher 1991). Adults engage in mass migration (however, only a portion of the adult population emerges from underground burrows to breed in any give year) during a few rainy nights and leave the breeding ponds shortly after breeding. Males usually migrate to the breeding pond before females (Twitty 1941, Shaffer et al. 1993, Loredo and Van Vuren 1996, Trenham 1998b) and remain in the ponds for an average of 6 to 8 weeks, while females stay for approximately 1 to 2 weeks (69 FR 47212). Breeding activity occurs in pulses depending on rainfall patterns and wetland inundation. In drought years, insufficient water in the breeding pools may prevent breeding (Barry and Shaffer 1994). Late rains may also affect breeding opportunities and reproductive success (Trenham et al. 2000). Barry and Shaffer (1994) suggest that while local California tiger salamander populations may not breed during drought years when ephemeral pools do not fill, the longevity of adults is probably sufficient to ensure population persistence through all but the longest of droughts.

After mating, females lay eggs in the water and attach them singly or in small groups to underwater vegetation including twigs, grass stems, or other debris (Storer 1925, Twitty 1941, Jennings and Hayes 1994). Following breeding, adults leave the pool and return to the upland habitat, emerging at night to feed during the breeding season (Shaffer et al. 1993, Loredo et al. 1996, Trenham 1998a). Eggs hatch into aquatic larvae in two to four weeks (Petranka 1998). Larvae metamorphose during the summer and migrate from the ponds at night during dry weather. The larval stage usually lasts 3 to 6 months (Petranka 1998), but individuals may remain in their breeding sites over the summer if breeding pools remain inundated (Shaffer and Trenham 2005). The longer the inundation period, the larger the larvae and metamorphosed juveniles are able to grow, and the more likely they are to survive and reproduce (Semlitsch et al. 1988, Pechmann et al. 1989, Morey 1998, Trenham 1998b).

Movements and Spatial Considerations. The distance between occupied upland habitat and breeding sites depends on local topography and vegetation, and the distribution of California ground squirrel or other rodent burrows (Stebbins 1989). While juvenile California tiger salamanders have been observed to disperse up to 2.59 kilometers (km) (1.6 miles) from breeding pools to upland areas (Austin and Shaffer 1992) and adults have been observed up to 2 km (1.2 miles) from breeding ponds, most movements are closer to the breeding pond. Trenham et al. (2001) observed California tiger salamanders moving up to 670 meters (0.42 miles) between breeding ponds in Monterey County. Similarly, Shaffer and Trenham (2005) found that 95 percent of California tiger salamanders resided within 640 meters (0.4 miles) of their breeding pond at Jepson Prairie in Solano County.

Interconnectivity of breeding sites may be an important factor in long-term conservation of this species in order to sustain the species' metapopulation structure, where local extinction and recolonization by migrants of other subpopulations are probably common (69 FR 47212). Thus, providing movement corridors between potential breeding sites and avoiding isolation of these sites may be important to counterbalance the effects of normal ecological processes (e.g., drought) that may result in local extinctions by allowing for movements to new sites and facilitating recolonization (Semlitsch et al. 1996).

Diet. Adults probably feed mainly on a variety of invertebrates, including earthworms, snails, and insects, as well as fish and small mammals (Stebbins 1972, Lindquist and Bachmann 1980). Aquatic larvae feed on littoral, benthic, and planktonic arthropods (Anderson 1968b).

A34.5 Threats and Stressors

Urbanization/Habitat Fragmentation. Conversion of land to residential, commercial, and agricultural activities is considered the most significant threat to California tiger salamanders. These activities result in destruction and fragmentation of upland and/or aquatic breeding habitat, and killing of individual California tiger salamanders (Twitty 1941, Hansen and Tremper 1993, Shaffer et al. 1993, Jennings and Hayes 1994, Fisher and Shaffer 1996, Launer and Fee 1996, Loredo et al. 1996, Davidson et al. 2002).

Roads can fragment breeding and dispersal migratory routes in areas where they traverse occupied habitat. Features of road construction, such as solid road dividers, can further impede migration, as can other potential barriers such as berms, pipelines, and fences.

Nonnative Predators. Exotic species, such as bullfrog, mosquitofish (*Gambusia affinis*), sunfish species (e.g., largemouth bass [*Micropterus salmoides*] and bluegill [*Lepomis macrochirus*]), catfish (*Ictalurus* spp.), and fathead minnows (*Pimephales promelas*), that live in perennial ponds—such as stock ponds—are considered to have negatively affected California tiger salamander populations by preying on larval salamanders (Anderson 1968a, Morey and Guinn 1992, Graf and Allen-Diaz 1993, Shaffer et al. 1993, Seymour and Westphal 1994, Fisher and Shaffer 1996, Lawler et al. 1999, Laabs et al. 2001, Leyse 2005).

Fisher and Shaffer (1996) suggest that elevation may be a factor in local extirpations due to exotic predators. They suggest that introduced exotics are more common in low elevation aquatic habitats (below 200 meters [656 feet]) and that habitat modification and low levels of topographic relief may facilitate invasion by increasing opportunities for dispersal through interconnected watersheds or suitable terrestrial habitats, or through deposition by floodwaters (Fisher and Shaffer 1996).

Hybridization. Riley et al. (2003) examined hybridization between California tiger salamanders and an introduced congener, the tiger salamander (*Ambystoma tigrinum*). The tiger salamander had been deliberately introduced as fish bait in California and is thought to have contaminated the genome of California tiger salamanders through interbreeding (Riley et al. 2003). The sale and use of *A. trigrinum* as bait is now illegal in California. In the Salinas Valley, Riley et al. (2003) sampled salamanders from four artificial ponds and two natural vernal pools. Based on mitochondrial DNA and two nuclear loci, Riley et al. (2003) found that hybrids were present in all six ponds, and that these hybrids were viable and fertile. Hybridization with the barred tiger salamander (*Ambystoma tigrinum mavortium*) has been occurring since fishermen and bait shop owners began introducing the species 50-60 years ago, resulting in 15-30 generations of genetic mixing (Fitzpatrick and Shaffer 2004). Fitzpatrick and Shaffer (2004) report more nonnative alleles in large perennial ponds despite the proximity of ephemeral ponds, perhaps attributable to the presence of open water refugia providing an extended breeding season or facilitating a paedomorphic life history strategy in which adult nonnative salamanders retain larval characteristics. Fitzpatrick and Shaffer (2007) report evidence of hybrid vigor or increased fitness of hybrids based on early-larval survival (Yolo Natural Heritage Program 2009).

Pesticides. Pesticides, hydrocarbons, and other pollutants are all thought to negatively affect breeding habitat, while rodenticides and gases used in burrowing mammal control (e.g., chlorophacinone, diphacinone, strychnine, aluminum phosphide, carbon monoxide, and methyl bromide) are considered toxic to adult salamanders (Salmon and Schmidt 1984). California ground squirrel and pocket gopher control operations may have the indirect effect of reducing the availability of upland burrows for use by California tiger salamanders (Loredo-Prendeville et al. 1994).

A34.6 RELEVANT CONSERVATION EFFORTS

Critical habitat has been designated within 19 counties in central California (70 FR 49380). However, there are no critical habitat units within the Plan Area. A critical habitat unit initially planned for East Contra Costa County was rejected because the East Contra Costa County Habitat Conservation Plan/Natural Communities Conservation Plan (under which the California tiger salamander is a covered species) was permitted and operable and is expected to sufficiently address conservation of the species within that area. Occupied sites within the Plan Area are within the East Contra Costa County Habitat Conservation Plan/Natural Communities Conservation Plan Area.

A conservation strategy for the Santa Rosa Plains population of California tiger salamander and other sensitive species has been finalized (USFWS 2005); however, the local implementing agencies have to date been unsuccessful in adopting implementing ordinances or acquiring funding. The plan establishes conservation areas throughout the plan area and guidance regarding preserve acquisition and management, habitat enhancement, and mitigation.

Several other habitat conservation plans that address California tiger salamander are either in progress or are operational. Plans that overlap or are near the Plan Area and include the California tiger salamander as a covered species are the East Contra Costa County Habitat

Conservation Plan/Natural Community Conservation Plan, the San Joaquin County Multi-Species Habitat Conservation and Open Space Plan, the Natomas Basin Habitat Conservation Plan, the Yolo Natural Heritage Program Plan, the South Sacramento County Habitat Conservation Plan, the Solano County Multispecies Habitat Conservation Plan, and the Butte Regional Habitat Conservation Plan and Natural Community Conservation Plan. Each does or will include conservation measures to protect and restore populations and habitat for this species.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for the California tiger salamander is "Maintain" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions to maintain the species by avoiding, minimizing, and compensating for any adverse effects to the species created by ERP restoration actions. To the extent practicable, the ERP will improve species habitat conditions.

East Bay Regional Parks has established protections of California tiger salamander and California red-legged frogs on lands in the vicinity of the Los Vaqueros watershed, west of the Plan Area in Contra Costa and Alameda counties. Actions focus on protection of breeding sites, maintaining an intact landscape and protecting movement corridors, and managing grazing regimes.

In June 2009, East Bay Municipal Utility District and the USFWS finalized the largest environmental safe harbor agreement awarded to a single landowner. The 30-year agreement covers 28,000 acres of San Joaquin, Amador and Calaveras counties (USFWS 2009).

A34.7 Species Habitat Suitability Model

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, and cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf 2007. Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers, connectivity between habitat types, and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The California tiger salamander model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), USDA 2005 aerial photography, and DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable California tiger salamander habitat in the Plan Area according to the species' two primary life requisite parameters: aquatic breeding and terrestrial cover, and aestivation habitat. Vegetation types were assigned based on the species' requirements as described above and the assumptions described below.

Terrestrial Cover and Aestivation Habitat. Terrestrial habitat is defined as all grassland types with a minimum patch size of 100 acres (40.5 hectares) located west of the Yolo Basin but including the Tule Ranch Unit of DFG's Yolo Basin Wildlife Area; east of the Sacramento River between Freeport and Hood-Franklin Road; east of Interstate 5 (I-5) between Twin Cities Road and the Mokelumne River; and within the area south and west of Highway 4 from Antioch (Bypass Road to Balfour Road to Brentwood Boulevard) to Old River; then south along Old

River to Clifton Court Forebay; along the west and south sides of Clifton Court Forebay to Old River; then south along the county line to Byron Highway; then west of Byron Highway to I-205, north of I-205 to I-580, and west of I-580. Grasslands associated with the south Montezuma Hills and Petrero Hills were also included. Grassland strips solely occurring atop levees and not adjacent to grassland areas were excluded. Patches of grassland that were below the 100-acre minimum patch size but were contiguous with grasslands outside of the Plan Area boundary were included.

Terrestrial habitat includes the following types from the BDCP composite vegetation layer:

- Grassland
  - Ruderal herbaceous grasses and forbs;
  - California annual grasslands;
  - *Bromus diandrus-Bromus hordeaceus;*
  - Italian rye-grass (*Lolium multiflorum*);
  - *Lolium mulitflorum – Convolvulus arvensis;*
  - Degraded vernal pool complex – California annual grasslands;
  - Degraded vernal pool complex – ruderal herbaceous grasses and forbs;
  - Degraded vernal pool complex – Italian rye-grass (Lolium multiflorum);
  - Annual grasses generic;
  - Annual grasses/weeds;
  - *Bromus* spp./*Hordeum;*
  - *Hordeum/Lolium;*
  - *Lolium* (generic);
  - *Lotus corniculatus;*
  - Medium upland graminoids;
  - Medium upland herbs;
  - Perennial grass;
  - Short upland graminoids;
  - Upland annual grasslands and forbs formation; and
  - Upland herbs.
- Alkali seasonal wetland complex
  - *Distichlis spicata* – annual grasses.

Assumptions. Habitat for California tiger salamander includes vernal pools and seasonal and perennial ponds including artificial stock ponds within a grassland landscape (Barry and Shaffer 1994, 69 FR 47212, Bobzien and DiDonato 2007). Because the mapping of aquatic breeding habitats within the Plan Area is incomplete, this element cannot be effectively used to model the extent of suitable habitat for this species. Thus, grasslands are used to more generally describe the extent of suitable habitat. Minimum patch size is 100 acres, which corresponds with the minimum conservation patch size identified by Trenham (2009). Grasslands located along the narrow eastern edge of the Suisun Marsh that were contiguous with the larger grassland/agricultural landscape of the Montezuma Hills were reviewed and removed from the terrestrial cover and aestivation habitat component of the model because most appeared transitional to the tidal marsh wetlands that are not suitable for California tiger salamander. The model is further constrained geographically by eliminating grasslands that are not within seasonal pool or pond/grassland landscapes, such as the central Delta. While periodic flooding may preclude California tiger salamander from occurring in the Yolo Bypass, the vernal pool landscape on the DFG's Tule Ranch Unit and other similar areas on the DFG Yolo Bypass Wildlife Area could potentially support this species in some years. These areas are mapped as Alkali Seasonal Wetland Complex (*Distichlis spicata*-annual grasses); however, they have a substantial grassland component. The model overestimates suitable habitat by assuming there are sufficient aquatic breeding habitats within the grassland landscape as defined.

Aquatic Breeding Habitat. Aquatic breeding habitat for California tiger salamander includes vernal pools and seasonal and perennial ponds. Aquatic breeding habitat includes the following land cover types and conditions that are within the grassland landscape as defined above:

- Aquatic breeding habitat includes the following other natural seasonal wetland types from the BDCP composite vegetation layer:
    - Vernal pools;
    - Degraded vernal pool complex- vernal pools
- Vernal pool complex breeding habitat includes the following vernal pool complex types from the BDCP composite vegetation layer:
    - *Allenrolfea occidentalis* mapping unit;
    - Annual grasses generic;
    - Annual grasses/weeds;
    - California annual grasslands-herbaceous;
    - *Distichlis* (generic);
    - *Distichlis*/annual grasses;
    - *Distichlis*/*S. maritimus;*
    - *Distichlis spicata;*

- *Distichlis spicata* – annual grasses;
- Italian rye-grass (*Lolium multiflorum*);
- Mix *Scirpus* mapping unit;
- Ruderal herbaceous grasses and forbs;
- *Salicornia virginica;*
- *Salicornia*/annual grasses;
- Salt scalds and associated sparse vegetation;
- Saltgrass (*Distichlis spicata*);
- Seasonally flooded grasslands;
- *Suadeda moquinii* – (*Lasthenia californica*) mapping unit; and
- Vernal pools.

Assumptions. Aquatic breeding habitats are mapped to the extent data are available, but not used as a model attribute. The data for vernal pools and other seasonal wetlands and stock ponds are insufficient to effectively model California tiger salamander habitat on the basis of aquatic breeding habitat. Vernal pools and other seasonal rain pools are the primary breeding habitat of California tiger salamanders (Barry and Shaffer 1994, 68 FR 13498). While deeper and larger pools are more likely to be occupied (Anderson 1968a, Feaver 1971, Laabs et al. 2001), all vernal pools are considered here as potential habitat for this species. California tiger salamander is also known to successfully reproduce in ponds, including artificial stock ponds (Barry and Shaffer 1994, 69 FR 47212). Stock pond habitats are used almost exclusively at occupied sites on the western edge of the Plan Area and in the hills immediately west of the Plan Area (Bobzien and DiDonato 2007). Mapping of vernal pools and other isolated seasonal wetlands and stock ponds is incomplete. In lieu of this, the vernal pool complex natural community was used to represent aquatic breeding habitat, which is comprised of a combination of aquatic and upland habitat that is considered suitable for California tiger salamander. Potential habitat included within the vernal complex natural community not having concave surfaces or land uses that are incompatible with the species' habitat requirements were removed from the vernal pool complex breeding habitat component of the model. For example, polygons falling on lands that did not have characteristic vernal pool/swale signatures that would demonstrate seasonal inundation did not qualify for this habitat type. This element of the model overestimates the extent of potential breeding habitat.

A34.8 RECOVERY GOALS

A USFWS recovery plan has not yet been prepared for the California tiger salamander, although the USFWS (69 FR 47212) has stated its intention to do so. There are currently no recovery goals established for this species.

APPENDIX A35. LANGE'S METALMARK BUTTERFLY (*APODEMIA MORMO LANGEI*)

A35.1 LEGAL STATUS

Lange's metalmark butterfly (*Apodemia mormo langei*) is listed as endangered under the Federal Endangered Species Act (June 1976) (41 FR 22041) but is not listed under the California Endangered Species Act. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G5T1/S1.1 which means that globally (G) the species is demonstrably secure to ineradicable due to being commonly found in the world, but the subspecies or variety (T) is has less than 6 viable element occurrences, less than 1,000 individuals, or less than 2,000 acres (809 hectares); and within the state (S) the threat level rank is "very threatened."

A35.2 SPECIES DISTRIBUTION AND STATUS

A35.2.1 Range and Status

The historical range of Lange's metalmark butterfly is uncertain as it has been collected from the Antioch Dune, near Brannan Island, and near the town of Oakley (Opler and Powell 1961, Arnold 1983, 2005). The collections from Brannan Island Oakley may have been vagrant individuals (hundreds of individuals per day) that had moved with the persistent upriver winds from the much larger populations that existed at the Antioch dune prior to the 1960s (Powell, pers. comm.). A reported genetic blending area along the inner southern Coast Range where there are colonies that are morphologically similar to Lange's metalmark butterfly (Opler and Powell 1961) has been recently shown to be genetically distinct (Powell, pers. comm.). Currently, Lange's metalmark is thought to be restricted to approximately 4 acres (1.6 hectares) of the 20-acre (8.1-hectare) remnant (plus an unknown amount of two Pacific Gas & Electric (PG&E) parcels that total 12 acres [4.9 hectares]) of a former 190-acre (77-hectare) dune near the city of Antioch, California (Arnold 1983, USFWS (1984, 2001, 2008, 2010) (Figure A-35a). It is one of 15 subspecies of *Apodemia mormo* in the state of California. There is a small red-orange central patch on the upper hind wing that separates this subspecies and the individuals of the genetic blending area mentioned above from the other subspecies (Opler and Powell 1961). Lange's metalmark is protected on the USFWS Antioch Dunes National Wildlife Refuge (NWR) and on the two small adjacent parcels owned by Pacific Gas & Electric which manages the property in cooperation with USFWS (USFWS 1984, 2001, 2008, 2010). Historical population estimates using peak count data have ranged up to approximately 2,300 individuals in 1999 but a steeply declining trend since 1999, with a peak flight count of only 45 individuals in 2006, triggered management actions including habitat restoration and a captive breeding and release program (Johnson et al. 2007, USFWS 2008, 2010).

Figure A-35a. Lange's Metalmark Butterfly Statewide Recorded Occurrences

1

A35.2.2 Distribution and Status in the Plan Area

The recognized current distribution of Lange's metalmark is entirely within the Plan Area on the Antioch Dunes NWR and PG&E properties as described above (Figure A-35b). However, there apparently have been no recent searches for Lange's metalmark near Oakley or on Delta islands with deposits of Oakley sand soil (A. Shapiro in litt.) and colonies may have persisted in some of those areas if its host plant (discussed below) is present.

A35.3 HABITAT REQUIREMENTS AND SPECIAL CONSIDERATIONS

Lange's metalmark is entirely dependent on a particular white-flowered, sand-associated, ecotype of nakedstem buckwheat (*Eriogonum nudum* ssp. *auriculatum*) as its larval host plant and as its primary adult nectar plant. This particular ecotype has a later and longer blooming season than ecotypes growing on rocky areas nearby on Mt. Diablo. The dependence of Lange's metalmark on the plant extends to the leaf litter that accumulates near the base of large plants growing in large clumps (Arnold 1983). This ecotype of nakedstem buckwheat is currently only known from the former Antioch dune (Arnold 1983). For the buckwheat to function as habitat for Lange's metalmark it is critical that the individuals of nakedstem buckwheat be relatively large and robust, be more than three years old, be concentrated in fairly dense clumps, and that their leaf litter be undisturbed (Arnold 1983). The sandy soil of the former dune and the area near Oakley has been mapped as Oakley sand (Carpenter and Cosby 1939) and more recently as Delhi sand, 2 to 9 percent slopes (NRCS 2010). This soil is infertile with very uniform-textured fine sand and very little clay content. While the dune is localized immediately along the bank of the San Joaquin River, Oakley sand is also distributed from the dune to the southwest as a 5.5-mile (8.9-kilometer [km]) long by 2-mile (3.2-km) wide oblong patch (Carpenter and Cosby 1939).

Historically, based on early maps, charts, and a postcard dating from the early 1900s, the vegetation of the Antioch dune contained widely scattered large valley oaks, live oaks, various shrub species, and numerous herbaceous species (Howard and Arnold 1980, SFEI 2010). Very similar vegetation occurred 1.5 miles (2.4 km) southeast of the dune as a 3 mile (4.8 km) long by 1.5 mile (2.4 km) wide 3,000-acre (1214-acre) oblong patch on the Oakley sand soil southwest of Oakley (SFEI 2010). That area of chaparral/scrub, which was originally described as nearly impenetrable, was cleared for grain production in the 1800s, later planted as almond orchards and vineyards, and now is almost entirely developed (SFEI 2010). While there was one collection of Lange's metalmark from that area, there are no herbarium collections of the sand-associated ecotype of nakedstem buckwheat from that area.

Because of its relatively poor flight ability, Lange's metalmark appears to require perches in areas protected from the high velocity winds that are a common to the Antioch area. Most of the observed dispersal among the existing colonies, including one dispersal event of 2,025 feet (617 meters), was with the prevailing wind from east to west (Arnold 1983).

DRAFT

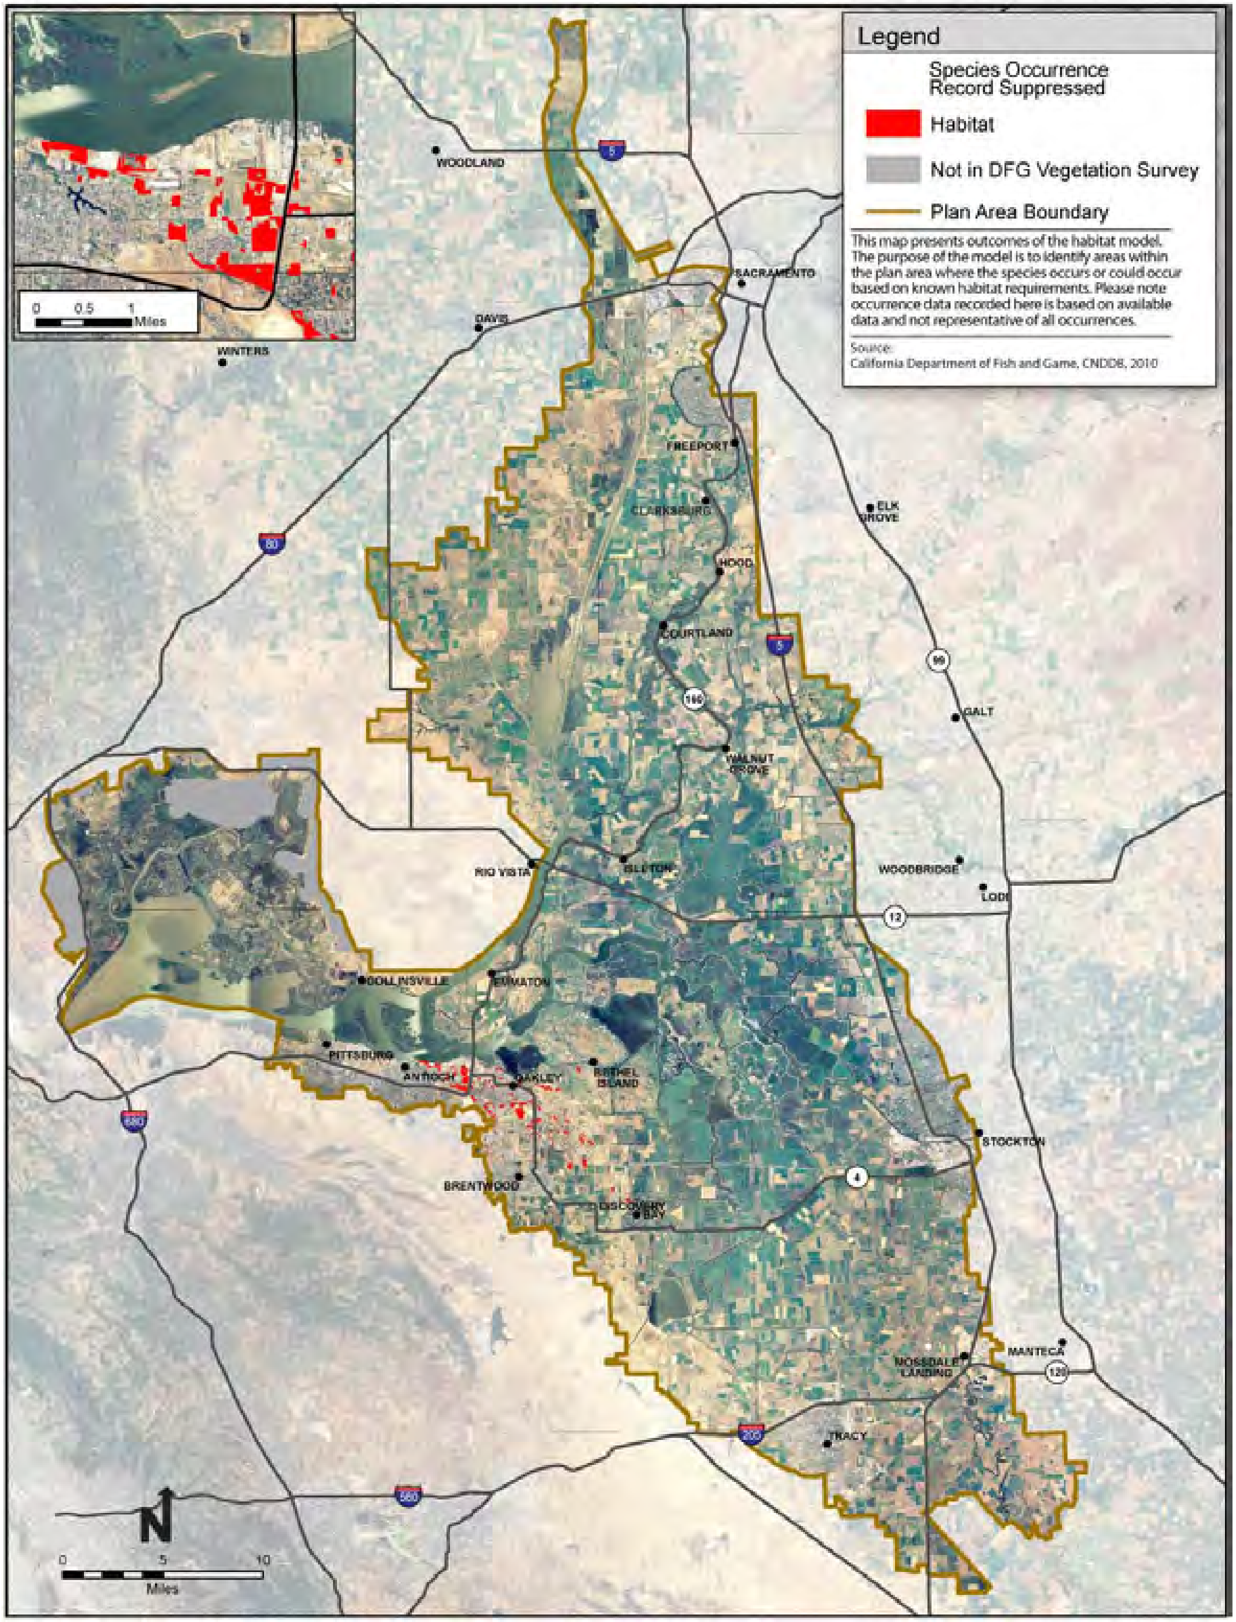

Figure A-35b. Lange's Metalmark Butterfly Habitat Model and Recorded Occurrences

These biological and environmental factors suggest that it may be a back-dune species that lived in the wind shadow of the south side of the 120-foot (37-meter) high dune, within the former dense patch of chaparral near Oakley, and possibly also in small patches of similar chaparral/soil combinations on Delta islands.

A35.4 Life History

Lange's metalmark is a fragile, brightly colored butterfly in the Riodinidae (metalmark) family. Adult wingspan varies from 1 to 1.5 inch (2.5 to 3.8 centimeter). Dorsal wing surfaces are largely black with white spots. Red-orange coloration extends through the inner forward half of the forewing, the hindwing bases, and a small central patch subtended by black. Below, the wings have a more muted pattern of gray, white, black, and orange. As described above, Lange's metalmark is a specialist on the sand ecotype of nakedstem buckwheat, which is its larval food plant, its primary nectar plant, and its primary perch site for males seeking females and for mating (Arnold 1983).

Adults, which live an average of about 13 days, begin to emerge in late July or early August. Continued emergence sustains the flight of adults, which continues for 30-40 days (Arnold 1983). The highest number of individuals in the flight generally occurs 10-15 days after emergence has begun and generally coincides with the peak blooming period of the sand ecotype of nakedstem buckwheat. Eggs are deposited throughout the flight in protected locations on senescing foliage in the lower portion of the buckwheat plant in clusters of about 2-4 eggs or less (Arnold 1983).

Larvae hatch from the eggs in late fall or early winter prior to leaf fall and enter diapause in the leaf litter at the base of the plants. Apparently, sufficient leaf litter for larval protection only accumulates under large plants growing in dense clusters (Arnold 1983). Termination of diapause occurs in late winter, when larvae begin feeding on basal foliage. Late instar[1] larvae climb the flowering stalks in June and July where they feed at night and retreat to the base of the plants for concealment during the day. Pupation occurs in the leaf litter around the base of the plants.

A35.5 Threats and Stressors

Invasive plants are one of the primary threats to Lange's metalmark because of their negative effects on its buckwheat host plant and also because they alter the microclimate around the base of host plants, which reduces the habitat quality for Lange's metalmark (Arnold 1983, USFWS 2008, 2010). The most common invasive nonnative grasses and forbs found at the Antioch Dunes NWR include ripgut brome (*Bromus diandrus*), winter vetch, (*Vicia villosa*) and star thistle (*Centaurea solstitialis*). Wildfires started by trespassers on the Antioch Dunes NWR

[1] Stage in the lifecycle of arthropods, between molts.

threaten the Lange's metalmark butterfly by reducing the plant size and density of its buckwheat host plant (Arnold 1983, USFWS 2008, 2010).

A35.6 Relevant Conservation Efforts

Because Lange's metalmark was declining significantly at Antioch Dunes NWR and appeared to be headed towards extinction, a captive breeding and release program was begun in 2006 (Johnson et al. 2007, USFWS 2008).

Neither the remnant dune environment nor the captive breeding program conditions replicate the conditions of its historical habitat. Instead, it will act as artificial selective agents likely to produce a new partially domesticated genotype that is distinct from Lange's metalmark as it existed prior to the destruction of the dune, development of the surrounding land, and recent recovery efforts. Genetic changes have occurred since the discovery of Lange's metalmark that include a decrease in the flight period by about 4 weeks, a 10-15 percent decrease in wing size, and decreased egg production (Arnold 1986).

The current management plan for the Antioch Dunes NWR provides for invasive nonnative plant species control efforts which are being implemented by hand pulling individual invasive plants through the efforts of volunteers, targeted herbicide application, the restoration of some dune-like topography, and planting of nursery-grown nakedstem buckwheat (USFWS 2001, 2008). Controlled burns have been discontinued as a management tool (L.Terrazas in litt.).

A35.7 Species Habitat Suitability Model

Model Approach. Bay Delta Conservation Plan (BDCP) species habitat suitability models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nevertheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lower probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf 2007. Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers, connectivity between habitat types, and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life history requirements. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The Lange's metalmark butterfly habitat suitability model is based on an iterative analysis of the following datasets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], USDA 2005 aerial photography, DWR 2007 LiDAR elevation data, and United States Department of Agriculture (USDA) Soils Survey (Carpenter and Cosby, 1939). Using these data sets, the model maps the distribution of suitable Lange's metalmark butterfly habitat in the Plan Area.

Habitat. The modeled habitat for Lange's metalmark consisted of areas of Oakley sand soils that appear to support shrubby vegetation when viewed with aerial imagery.

Vegetation Units. The following vegetation subunits were selected from the California Department of Fish and Game (DFG) vegetation units (Hickson and Keeler-Wolf 2007):

- *Lupinus albifrons* Antioch Dunes Association;
- *Lotus scoparius* Antioch Dunes Association;
- Sparsely or unvegetated areas;
- Abandoned orchards; and

- California annual grasslands herbaceous.

Soils Units. Using the USDA Soils Survey (Carpenter and Cosby 1939) the Oakley sand soil was considered suitable for this species when co-occurring with the identified vegetation units.

Elevation Constraints. The DWR 2007 LiDAR was used to identify areas located above the intertidal range. The upper limit of the intertidal marsh elevation range within the south-west delta has been estimated to be 6 feet (NAVD88) (Siegel 2007). Land areas having an elevation greater than 6 feet were determined to be suitable. Because the Oakley sand soil deposits in the Delta are older than the peat (Howard and Arnold 1980) they would have established on a solid substrate and would not have subsided due to anthropomorphic changes to the Delta. Therefore, they were intertidal historically and were not habitat.

A spatial intersection of the vegetation types, soils, and topography were used to identify potential suitable habitat. The potential habitat was then overlaid on Google Earth aerial imagery to assess physical characteristics and use conditions (Google 2009). Potentially suitable habitat located land uses that are incompatible with the species' habitat requirements, for example, potential habitat polygons falling on developed lands were removed from the model.

Assumptions. The habitat suitability model for Lange's metalmark assumes that habitat suitable for its host plant is also suitable for the butterfly. This assumption will overestimate the potential habitat for Lange's metalmark as it is not a strong flier and it would likely be blown off of small patches of habitat in the Delta due to strong and constant local wind conditions and the lack of substantial wind shadows.

A35.8 Recovery Goals

A USFWS revised Recovery Plan for Lange's metalmark was approved in 1984 but the recent 5-year species review (USFWS 2008) found that there are no recovery criteria listed in the Recovery Plan. Additionally, the CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for Lange's metalmark is "Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP has established a goal to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

APPENDIX A36. VALLEY ELDERBERRY LONGHORN BEETLE (*DESMOCERUS CALIFORNICUS DIMORPHUS*)

A36.1 LEGAL STATUS

The valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*) is listed as threatened under the federal Endangered Species Act (45 FR 52803). On October 2, 2006, the United States Fish and Wildlife Service (USFWS) announced a recommendation for this species to be removed from the endangered species list (USFWS 2006). Critical habitat was designated for this species in the initial listing of the species (45 FR 52803); however, neither of the two sites designated as critical habitat occur within the Plan Area. The valley elderberry longhorn beetle has no state regulatory status.

A36.2 SPECIES DISTRIBUTION AND STATUS

A36.2.1 Range and Status

Valley elderberry longhorn beetle is one of three species of *Desmocerus* in North America and one of two subspecies of *D. californicus*. The valley elderberry longhorn beetle subspecies is a narrowly defined, endemic taxon, limited to portions of the Central Valley below 900 meters (2,953 feet) in elevation (Figure A-36a) (USFWS 1999, 2006).

Historically, valley elderberry longhorn beetle presumably occurred throughout the Central Valley of California. Little is known about the historical abundance of valley elderberry longhorn beetle. The extensive destruction of its habitat, however, suggests that the beetle's range has been largely reduced and fragmented (USFWS 1984).

Studies to assess the distribution and extent of the valley subspecies began in the late 1970s (Eya 1976), and the USFWS proposed the species for listing in 1978. Since valley elderberry longhorn beetle was listed in 1980 (45 FR 52803), numerous distributional studies have been conducted (summarized in Talley et al. 2006).

Subsequent to various surveys throughout the Central Valley (Linsley and Chemsak 1972, Eya 1976, Jones & Stokes 1985, 1986, 1987a, 1987b, Barr 1991, Collinge et al. 2001), the USFWS (1999) prepared a map of the presumed range of valley elderberry longhorn beetle. This map encompasses the entire California Central Valley and the Sacramento River Delta below 900 meters (2,953 feet) elevation.

DRAFT

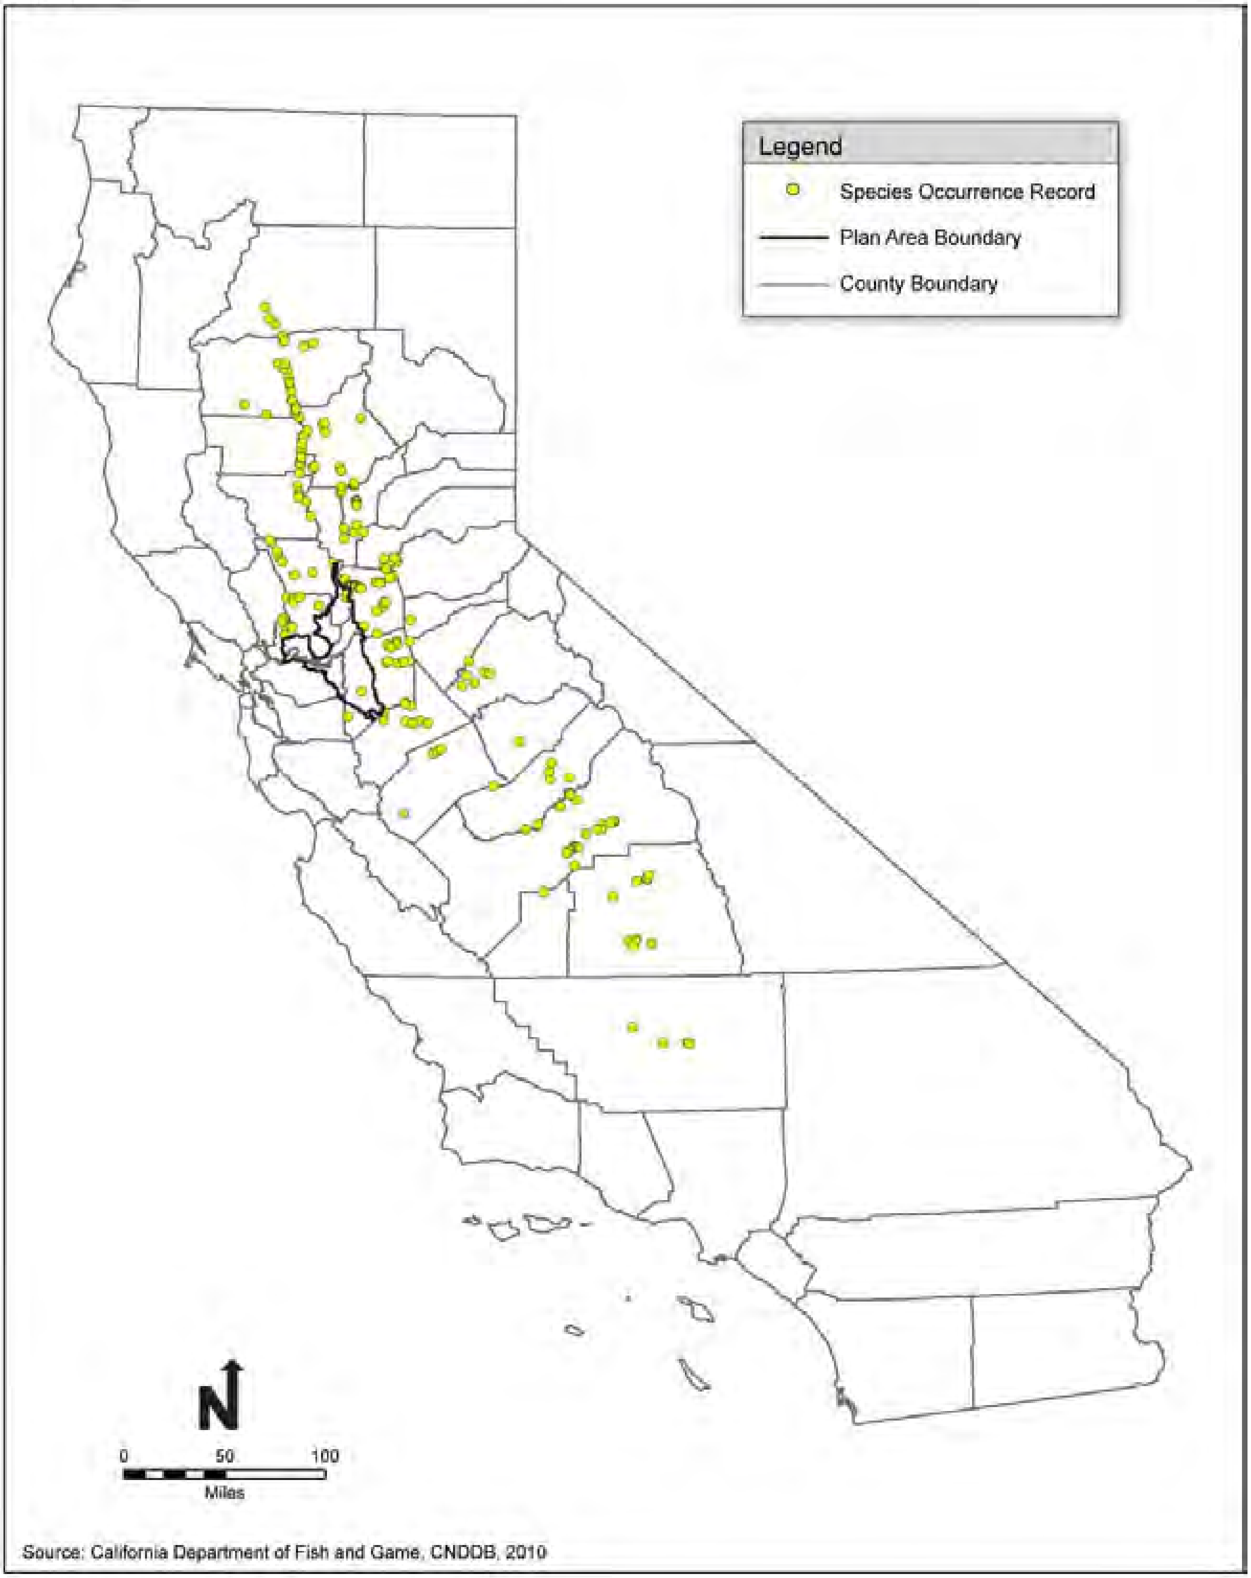

Figure A-36a. Valley Elderberry Longhorn Beetle Statewide Recorded Occurrences

Habitat occupied by valley elderberry longhorn beetle tends to form and exist in riparian corridors and on the level open ground of periodically flooded river and stream terraces and floodplains. This geomorphic setting historically has been desirable for agricultural, urban, or industrial development. As a result, much of this habitat type has been converted through dams and levees for use as developable land. Although it has been estimated that 90 percent of California riparian habitat has been lost over the last century and a half (Smith 1980, Barr 1991, Naiman et al. 1993, Naiman and Décamps 1997), these losses are difficult to accurately quantify in terms of direct valley elderberry longhorn beetle habitat losses (Talley et al. 2006). Therefore, an unknown amount of riparian forest and elderberry savannah habitat has been lost and an unknown number of valley elderberry longhorn beetle populations as well (Collinge et al. 2001). Due to current pressures from increasing human populations in California, more valley elderberry longhorn beetle habitat is being encroached upon and affected throughout the species' range (TAIC 2008).

A36.2.2 Distribution and Status in the Plan Area

There are only three reported occurrences of valley elderberry longhorn beetle from the Plan Area, including one along Old River north of Tracy and two recent occurrences along small drainages between the Sacramento River and the Sacramento Deep Water Ship Channel in the vicinity of West Sacramento (Figure A-36b) (CNDDB 2008). There are additional historical occurrences from along the Sacramento River corridor and Putah Creek in Yolo County (Eya 1976, Jones & Stokes 1985, 1986, 1987a, 1987b, USFWS 1984, Barr 1991, Collinge et al. 2001). Comprehensive surveys for the species or its host plant, elderberry, have not been conducted and thus the population size and location of the species within the Plan Area is unknown. Distribution is typically based on the occurrence of elderberry shrubs, which are known to occur along riparian corridors throughout the Plan Area, including the Sacramento River, Stanislaus River, San Joaquin River, and along smaller natural and channelized drainages, as well as in upland habitats. The valley elderberry longhorn beetle is considered to potentially occur in all mature elderberry shrubs in the Plan Area.

A36.3 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

Valley elderberry longhorn beetle is endemic to moist valley oak riparian corridors in the lower Sacramento and lower San Joaquin valleys (USFWS 1984). Valley elderberry longhorn beetle is closely associated with a few species of elderberry (*Sambucus* spp.). These plants are an obligate host plant for larvae and are necessary for the completion of the life cycle (Linsley and Chemsak 1972, 1997, Eng 1984, Barr 1991, Collinge et al. 2001). The two main species of elderberry utilized by this species are the blue elderberry (*S. mexicana*) and red elderberry (*S. racemosa*). This shrub is a component of riparian forests throughout the Central Valley. Although this shrub occasionally occurs outside riparian areas, shrubs supporting the greatest beetle densities are located in areas where the shrubs are abundant and interspersed among dense riparian forest.

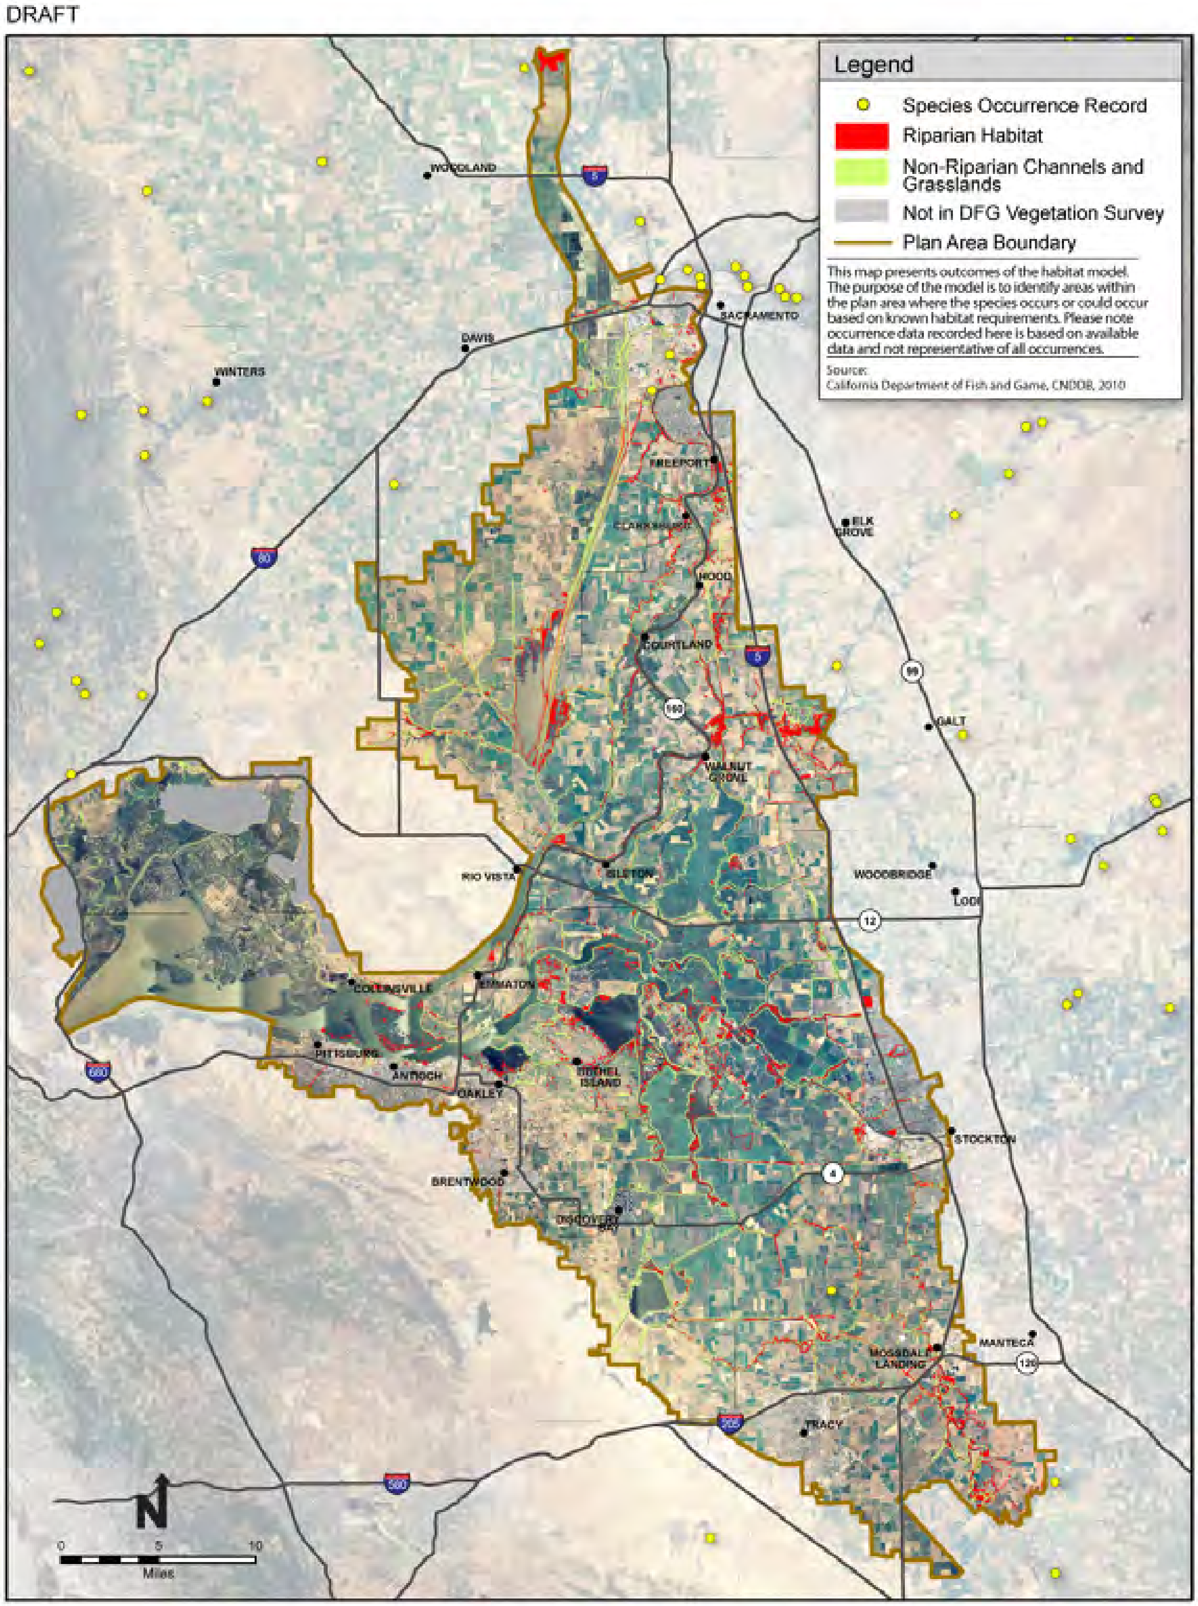

Figure A-36b. Valley Elderberry Longhorn Beetle Habitat Model and Recorded Occurrences

The existing remnants of riparian woodlands and forests within the distribution of valley elderberry longhorn beetle are a collection of various canopy layers and dominant species. Ideally, the riparian ecosystem consists of several canopy layers with dense understory. Fremont cottonwood (*Populus fremontii*), California walnut (*Juglans californica*), California sycamore (*Platanus racemosa*), willow (*Salix* spp.), and valley oak (*Quercus lobata*) commonly compose the upper canopy of the woodland (USFWS 1984). Common species contributing to the intermediate canopy include box elder (*Acer negundo* var. *californicum*), Oregon ash (*Fraxinus latifolia*), elderberries, and several willows. The understory can be widely diverse and may include wild grape (*Vitis californica*), California hibiscus (*Hibiscus californica*), and poison oak (*Toxicodendron diversilobum*), as well as many nonnative species (USFWS 1984, 1999, Barr 1991, Collinge et al. 2001). In some areas, the margins of riparian woodlands and forests are lined with elderberry savanna with *S. mexicana* as the dominant species (Holland 1986). Isolated elderberry shrubs separated from contiguous habitat by extensive development are not typically considered to provide viable habitat for the valley elderberry longhorn beetle (USFWS 1998, Collinge et al. 2001).

Elderberry savannah was a habitat type that was previously more extensive in the California Central Valley, but now is limited to the confluence area of the American River, which is outside the Plan Area (USFWS 1984, 1999, Jones & Stokes 1985, 1986, 1987a, 1987b, Barr 1991), and the valley elderberry longhorn beetle was probably a component of this habitat. Therefore, potential valley elderberry longhorn beetle habitat is defined as stands of elderberry shrubs that are adjacent to, or contiguous with, riparian forest, floodplains, or relict elderberry savannah (TAIC 2008).

A36.4 LIFE HISTORY

Description. The valley elderberry longhorn beetle is an atypical lepturine (the Lepturinae is a subfamily of the Cerambycidae, longhorn beetle family). Elderberry beetles are separated from all other lepturines by the form of the mandibles, which are broad and short, without internal pubescence (Linsley and Chemsak 1972). Originally described by Horn (1881), the valley elderberry longhorn beetle is black in color, with red to orange margins on the elytra (wing covers), which fades to yellow after death. The pronotum (plate behind the head) is smooth, with confluent punctuations. The elytra are densely punctate or rugose. Adult beetles range from 14 to 25 millimeters (mm) (0.5-1.0 inch) in length (Linsley and Chemsak 1972).

The valley elderberry longhorn beetle was described as a separate species by Fisher (1921) and was reduced to subspecific status by Doane et al. (1936). The majority of male valley elderberry longhorn beetles can be separated from other subspecies by the short, suberect, pale setae (bristle or hair-like structures) on the antennae (as opposed to dark setae) and the black markings on each forewing (Linsley and Chemsak 1972). The female valley elderberry longhorn beetle cannot be separated morphologically from other subspecies.

Life Cycle. Little research has been conducted on the life cycle of the valley elderberry longhorn beetle; therefore, current knowledge has been gathered from individual field observations and assumed similarities with closely related taxa. The following account of the life cycle chronicles the one reported in the USFWS Recovery Plan (USFWS 1984).

The beetle can be found from mid-March through early-June and is most active from late-April to mid-May. The adult beetles feed on the elderberry foliage and possibly its flowers. During this time of activity, the beetles mate, and the female lays between 8 and 20 eggs on the living elderberry plant host. The eggs are placed individually or in small clusters within crevices in the bark or junctions of the stem and trunk or leaf petiole and stem. The egg is attached to the shrub by a thin secretion, and the larva encloses within 30 to 40 days (Burke 1921). The eggs most likely hatch after a short time and the newly emerged larvae bore into the wood of the host plant (Linsley and Chemsak 1972, Barr 1991). Burke (1921) and Eya (1976) reported that the larvae take 2 years to mature; however, Halstead (1991) believes that 1 year is the norm. The larva typically bores into the central pith of stems and feeds there; however, on large trunks, the larvae feed on the wood (Burke 1921). The larvae create an elongated, longitudinal gallery through the heart of the stems, filling it with debris and shredded wood (Barr 1991). When the larva is ready to pupate, it chews a circular to slightly oval exit hole (7-10 mm in diameter [0.3-0.4 inch]) to the outside, which it plugs with frass (fecal material produced by insects). The exit holes are distinctive and typically are the only sign of the beetle's presence. Then the larva backs up into the gallery and constructs a pupal chamber out of shredded wood and frass (Barr 1991). Jones & Stokes (1985, 1986, 1987a, 1987b) and Halstead (1991) reported that 70 percent of exit holes are within 3.9 feet (1.2 meters) of the ground in stems greater than 13 mm (0.5 inch) in diameter; however, holes may be as high as 10 feet (3 meters) above the ground (Barr 1991). Pupae can be found between January and April, and the pupal stage lasts about one month (Burke 1921).

After pupation, the adult remains in the pupal cell for several weeks prior to emergence (Burke 1921). The adult eventually emerges from the pupal chamber, through the exit hole (Barr 1991). The adults readily fly from shrub to shrub. The valley elderberry longhorn beetle is most often seen on, in, or immediately under the host plant's flowers. However, copulation occurs on the lower parts of the stems (Barr 1991). The adults feed on the leaves (Linsley and Chemsak 1972, Barr 1991, Talley et al. 2006) and are active from March to early June.

A36.5 THREATS AND STRESSORS

The greatest historical threat to the valley elderberry longhorn beetle has been the elimination, loss, or modification of its habitat by urban, agricultural, or industrial development and other activities that reduce or eliminate its host plants (Talley et al. 2006). While mitigation and restoration actions do not come close to restoring the enormous amount of habitat lost in the more remote past they appear to be adequate for current levels of impact (Talley et al. 2006). However Talley et al. (2006) observed that the quality and persistence of mitigation and restoration efforts are uncertain and that there have been declines in the total number of valley elderberry longhorn beetle-occupied sites and in the number of riparian sites. Talley et al. (2006) also noted that the information included in reports is often unusable, making assessments of mitigation and restoration success difficult.

The greatest current threat to the valley elderberry longhorn beetle is from the invasive nonnative Argentine ant (*Linepithema humile*) and European earwig (*Forficula auricularia*) (Talley et al. 2006). The nonnative invasive Argentine ant has been observed attacking and killing valley elderberry longhorn beetle larvae. The ants enter the exit hole that the beetle makes prior to pupation and remove the larva (Huxel 2000, Huxel et al. 2003). Given that the invasion of riparian systems by Argentine ant in the Central Valley is continuing to spread, it is unclear how the invasion will impact the valley elderberry longhorn beetle, but it appears that the Argentine ant may have caused the disappearance of some populations (Talley et al. 2006). Field bait and trapping experiments have determined that the Argentine ant has been introduced widely through mitigation plantings and irrigation (Klasson et al. 2005). Irrigation plays a major role in the Argentine ant's rate and distance of dispersal in other ecosystems (Menke and Holway 2006). Those data also suggest that there may be a threshold of Argentine ant density above which valley elderberry longhorn beetle is extirpated from a site (Klasson et al. 2005). If confirmed, this would be a serious threat to the valley elderberry longhorn beetle's recovery because once the valley elderberry longhorn beetle is extirpated from a site recolonization is unlikely (Talley et al. 2006). The nonnative invasive European earwig is also considered to be a threat to the valley elderberry longhorn beetle through direct predation or by supporting higher populations of predators of insects (Talley et al. 2006), and earwig populations are also significantly larger in mitigation plantings and irrigated areas (Klasson et al. 2005).

Nonnative invasive plant species such as black locust (*Robinia pseudoacacia*), giant reed (*Arundo donax*), red sesbania (*Sesbania punicea*), Himalaya blackberry (*Rubus armeniacus*), tree of heaven (*Ailanthus altissima*), Spanish broom (*Spartium junceum*), Russian olive (*Eleagnus angustifolia*), edible fig (*Ficus carica*), and Chinese tallowtree (*Sapium sebiferum*), may have significant indirect impacts on the valley elderberry longhorn beetle by impacting elderberry shrub vigor and recruitment (Talley et al. 2006). It is also predicted that ripgut brome (*Bromus diandrus*), foxtail barley (*Hordeum murinum*), Italian ryegrass (*Lolium multiflorum*), and yellow starthistle (*Centaurea solstitialis*) may increase seedling mortality through competition for light and water or through increased fire return intervals (Talley et al. 2006).

Long-term data regarding site persistence, population size and dynamics, extirpation, and recolonization are also lacking as are estimates regarding the minimum self-sustaining population size, riparian forest corridor size, or habitat complex size for the valley elderberry longhorn beetle or other riparian forest organisms.

A36.6 Relevant Conservation Efforts

Conservation Guidelines for the Valley Elderberry Longhorn Beetle were established by the USFWS in 1999 (USFWS 1999). The guidelines were designed mainly to mitigate development-related impacts on valley elderberry longhorn beetle habitat. Using a formula based on stem sizes, habitat association, and presence of emergence holes, the guidelines require losses of elderberry shrubs that meet the minimum standard for potential occupancy to be mitigated through a program that: 1) identifies and secures suitable and approved mitigation land, and 2) includes transplanting of mature elderberry shrubs to the mitigation site, and replacement compensation using a standardized stem replacement formula. In response to the increasing need for valley elderberry longhorn beetle mitigation, numerous private valley elderberry longhorn beetle mitigation banks have become established throughout the Sacramento region. While the USFWS valley elderberry longhorn beetle mitigation compensates for the loss of elderberry shrubs (USFWS 1999), there is no evidence that it has been successful at either mitigating direct impacts on valley elderberry longhorn beetle or has successfully compensated for the loss of occupied valley elderberry longhorn beetle habitat.

Valley elderberry longhorn beetle conservation has also been addressed in several regional conservation plans. It is a covered species under the approved San Joaquin County Multi-Species Habitat Conservation and Open Space Plan and the Natomas Basin Habitat Conservation Plan. It is proposed for coverage under the South Sacramento Habitat Conservation Plan, the Solano County Multispecies Habitat Conservation Plan, the Yolo County Natural Heritage Program Plan, and the Butte Regional Conservation Plan.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for the valley elderberry longhorn beetle is "Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP has established a goal to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

A36.7 Species Habitat Suitability Model

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf 2007. Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers, connectivity between habitat types, and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The valley elderberry longhorn beetle model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin], USDA 2005 aerial photography, and DWR 2007 land use survey of the Delta and Suisun Marsh area-version 3. Using these data sets, the model maps the distribution of suitable valley elderberry longhorn habitat in the Plan Area. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Habitat. Habitat in the Delta includes the following types from the BDCP composite vegetation layer:

- Valley riparian – all types
- Grassland – all types within 200 feet of streams
- Vernal pool complex types within 200 feet of streams
    - Annual grasses generic;
    - Annual grasses/weeds;
    - California annual grasslands;
    - *Distichlis* (generic);
    - *Distichlis spicata;*
    - *Distichlis spicata* – annual grasses;
    - *Districhlis*/annual grasses;
    - *Distichlis/ s. maritimus*;
    - Ruderal herbaceous grasses and forbs;
    - Italian rye-grass (*Lolium multiflorum*);
    - *Salicornia virginica*; and
    - *Salicornia*/annual grasses.

Habitat in the Suisun Marsh and Yolo Basin includes the following riparian types from the BDCP composite vegetation layer:

- *Fraxinus latifolia;*
- Fremont cottonwood-valley oak – willow riparian forest;
- Mixed Fremont cottonwood – willow;
- Mixed willow super alliance;
- *Quercus agrifolia;*
- *Salix lasiolepis/Quercus agrifolia*; and
- Valley oak alliance – riparian.

Habitat in the Suisun Marsh and Yolo Basin also includes following grassland types within 200 feet of streams:

- Annual grasses generic;
- Annual grasses/weeds;
- *Bromus* spp./*Hordeum;*
- *Hordeum/Lolium;*

- *Lolium* (generic);
- *Lotus corniculatus;*
- Medium upland graminoids;
- Medium upland herbs;
- Perennial grass;
- Short upland graminoids;
- Upland annual grasslands and forbs formation; and
- Upland herbs.

Assumptions. The valley elderberry longhorn beetle is endemic to moist riparian corridors in the Sacramento and San Joaquin valleys (USFWS 1984). The species is completely dependent on its host plant, the elderberry (*Sambucus* spp.) (Collinge et al. 2001). This model identifies habitat for the valley elderberry longhorn beetle as locations where the elderberry shrub is expected to be found in the Plan Area. Elderberry is a common component of the remaining riparian forests and woodlands of the Central Valley (USFWS 1984). In these forests and woodlands, a variety of tree species compose the upper canopy, including Fremont cottonwood, valley oak, willow, walnut, alder, and Oregon ash. However, low abundances of valley elderberry longhorn beetle also occur in some non-riparian scrub and grassland habitats adjacent to waterways (Talley et al. 2007, Talley et al. 2006). Elderberry shrubs also occur in upland areas, mainly in grasslands adjacent to riparian forests and woodlands (Barr 1991). Therefore, this model designates additional habitat as grasslands within 200 feet of streams. Note, however, that elderberry shrubs are unevenly distributed along riparian corridors and adjacent upland habitats and in some areas may be lacking entirely. Thus, the model overestimates the extent of suitable habitat for valley elderberry longhorn beetle. Elderberry shrubs also occur incidentally along fence rows and in a variety of other disturbed conditions, particularly where birds may congregate and deposit seeds. This model does not include these incidental habitat areas, and thus in this respect may underestimate the distribution of potential habitat (i.e., elderberry shrubs) for the valley elderberry longhorn beetle in the Plan Area.

A36.8 RECOVERY GOALS

The USFWS Recovery Plan for valley elderberry longhorn beetle was established in 1984 (USFWS 1984). Due to limited knowledge of the species' requirements, recovery objectives were restricted to the following: 1) preserve and protect known habitat sites to provide adequate conditions for the beetle; 2) survey riparian vegetation along certain Central Valley rivers for remaining colonies and habitat; 3) determine ecological requirements and management needs; 4) preserve and protect newly discovered habitat to provide suitable conditions for the species; 5) reestablish the species at rehabilitated habitat sites within the presumed historical range; 6) increase public awareness of the species through education and information programs; and 7) enforce laws and regulations to protect the species.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for the valley elderberry longhorn beetle is "Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP has established a goal to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

APPENDIX A37. VERNAL POOL TADPOLE SHRIMP (*LEPIDURUS PACKARDI*)

A37.1 LEGAL STATUS

Vernal pool tadpole shrimp (*Lepidurus packardi*) was listed as endangered throughout its range under the federal Endangered Species Act on September 19, 1994 (59 FR 48136). In September, 2007, USFWS published a 5-year review recommending that the species remain listed as endangered. Revised critical habitat was designated on February 10, 2006 (71 FR 7118). This species is covered by the December 15, 2005, Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon. None of the critical habitat units are within the Plan Area; however, one unit (Unit 11 A-D) is just west of the Plan Area in Solano County. Vernal pool tadpole shrimp has no state regulatory status.

A37.2 SPECIES DISTRIBUTION AND STATUS

A37.2.1 Range and Status

Vernal pool tadpole shrimp is distributed across the Central Valley of California and in the San Francisco Bay area (Figure A-37a). Populations are found at 18 vernal pool complexes in the Sacramento Valley from east of Redding in Shasta County south through the Central Valley to the San Luis National Wildlife Refuge in Merced County. It also occurs in a single vernal pool complex located on the San Francisco Bay National Wildlife Refuge in the City of Fremont, Alameda County. The easternmost known location is around 3,500 feet (1,067 meters) in elevation in the central Sierra Nevada foothills (Merced County) and the westernmost known location is in the San Francisco Bay Area (Alameda County). The Bay Area location is the only known population of vernal pool tadpole shrimp outside of the Central Valley (USFWS 2005, 2007). The largest concentration of vernal pool tadpole shrimp occurrences is found in the Southeastern Sacramento Vernal Pool Region, where the species occurs on a number of public and private lands in Sacramento County (USFWS 2005, 2007).

A37.2.2 Distribution and Status in the Plan Area

Vernal pool tadpole shrimp has been reported from several locations within the Plan Area (Figure A-37b) (USFWS 2005, 2007, CNDDB 2010). In general, within the Plan Area, vernal pools that may support the species occur on alkaline soils from the DFG Tule Ranch Unit of the Yolo Bypass Wildlife Area southwest to the Montezuma Wetlands Mitigation Projects and from the Byron Airport to Discovery Bay. Other potential vernal pool habitat occurs along the eastern boundary of the Plan Area near Stone Lakes (Figure A-37b). Six additional occurrences were discovered in the Stone Lakes area during 2009 surveys conducted by the California Department of Water Resources (DWR). A comprehensive survey of vernal pools or habitat for vernal pool tadpole shrimp has not been conducted in the Plan Area.

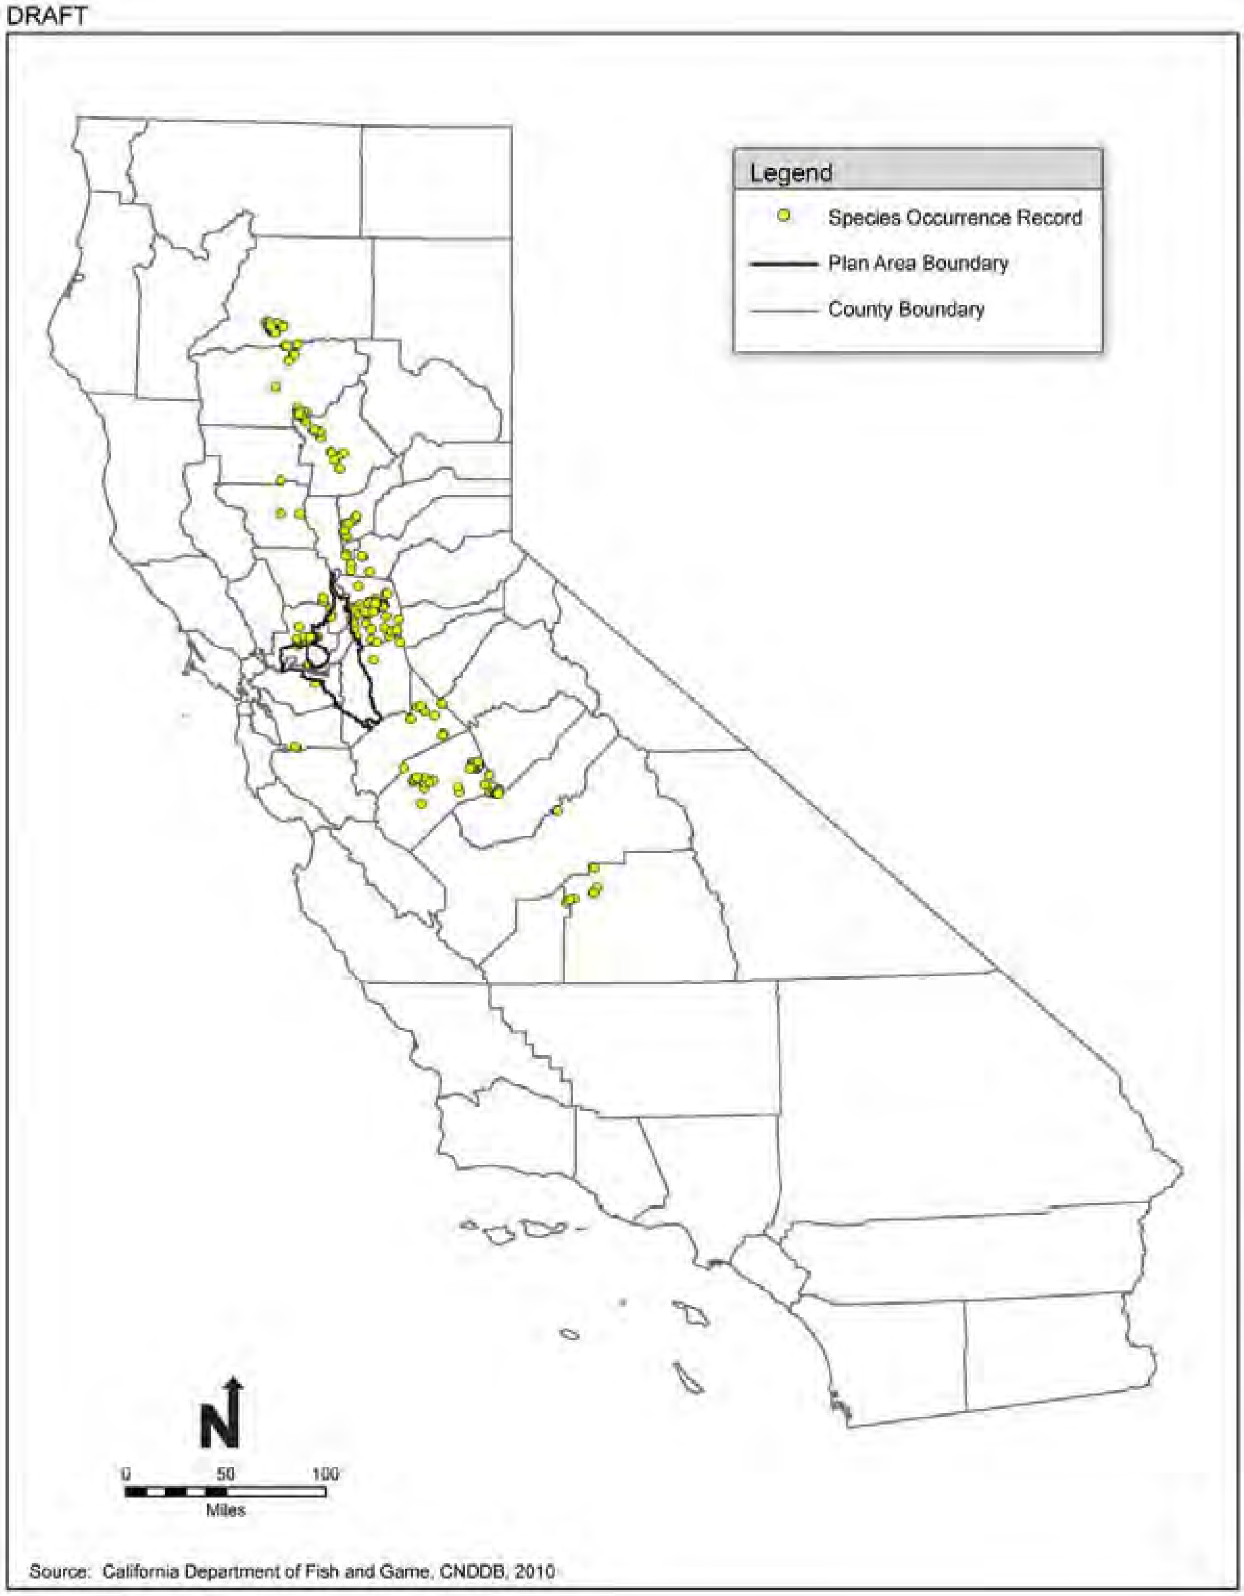

Figure A-37a. Vernal Pool Tadpole Shrimp Statewide Recorded Occurrences

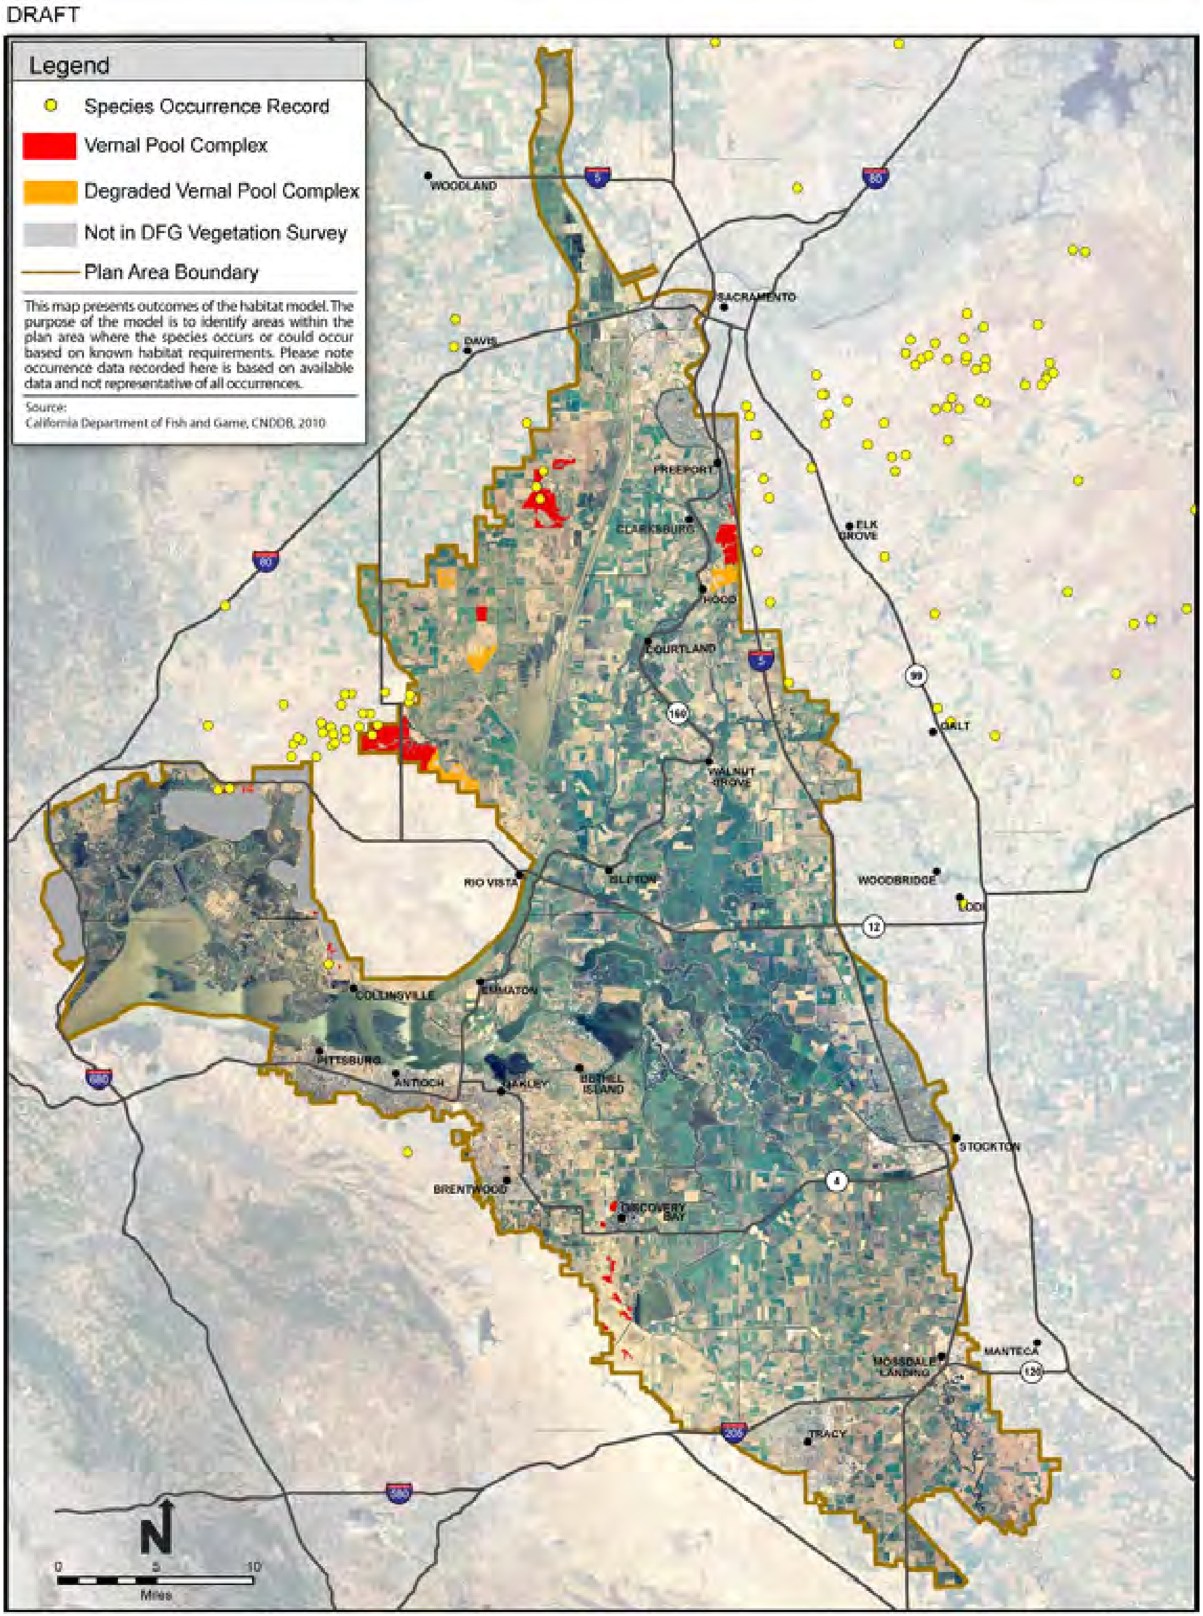

Figure A-37b. Vernal Pool Tadpole Shrimp Habitat Model and Recorded Occurrences

A37.3 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

This species is entirely dependent on the aquatic environment provided by the temporary waters of natural vernal pool and playa pool ecosystems as well as the artificial environments of ditches and tire ruts (King et al. 1996, Helm 1998, Eriksen and Belk 1999). The temporary waters in which vernal pool tadpole shrimp inhabits fill in the fall and winter during the beginning of the wet season and dry in late-spring at the beginning of the dry season and remain desiccated throughout the summer (Helm 1998, Eriksen and Belk 1999). The temporary waters fill directly from precipitation as well as from runoff from their watersheds (Williamson et al. 2005, Rains et al. 2006, 2008, O'Geen et al. 2008). The watershed extent that is necessary for maintaining the hydrological functions of the temporary waters depends on a number of complex factors including the hydrologic conductivity of the surface soil horizons, the continuity and extent of hard-pans and clay-pans underlying non-clay soils, the existence of a perched aquifer overlying the pans, slope, effects of vegetation on evapotranspiration rates, compaction of surface soils by grazing animals, and other factors (Marty 2004, Pyke and Marty 2005, Williamson et al. 2005, Rains et al. 2006, 2008, O'Geen et al. 2008).

The temporary waters that are habitat for vernal pool tadpole shrimp are extremely variable and range from clear sandstone pools with little alkalinity to turbid vernal pools on clay soils with moderate alkalinity (King et al. 1996, Eriksen and Belk 1999). Common wetland plant species that co-occur with vernal pool tadpole shrimp include toad rush (*Juncus bufonius*), coyote thistle (*Eryringium* spp.), downingia (*Downingia ornatissma* or *D. bicornuta*), goldfields (*Lasthenia* spp.), woolly marbles (*Psilocarphus* spp.), and hair grass (*Deschampsia* spp.) (King et al. 1996, Alexander and Schlising 1997, 1998, Helm 1998, Plattencamp 1998, Eriksen and Belk 1999, Alexander 2007).

Vernal pool tadpole shrimp commonly co-occur with the fairy shrimp (*Linderiella occidentalis*, *Branchinecta conservatio*, *B. lindahli*, *B. coloradensis*) and vernal pool fairy shrimp (*B. lynchi*). The midvalley shrimp (*B. mesovallensis*) and *B. longiantenna* both occur within the range of vernal pool tadpole shrimp but are typically found in different habitats (USFWS 2005, 2007).

A37.4 LIFE HISTORY

Description. Vernal pool tadpole shrimp is characterized by a smooth protective concave shell or carapace that protects its head and thorax. A pair of eyes is centered at the anterior end of its shell. Its segmented abdomen is visible (posterior), and the last segment produces a caudal lamina (tail plate), which is diagnostic for the genus, and a pair of whip-like appendages called cercopods. At full maturity, vernal pool tadpole shrimp has 30-35 pairs of appendages called phyllopods (leaf-feet) that propel it through the water and through which it exchanges oxygen (Rogers 2001). Vernal pool tadpole shrimp may vary in coloration, depending on habitat, although it is most commonly green. In highly turbid water, this species may be nearly translucent to buff-colored with brown mottles. In slightly turbid to clear water, vernal pool tadpole shrimp shows greater variety; coloration may be light green, dark green, dark green mottled with brown, chocolate brown, brown with green mottles, and black.

Reproduction and Growth. Vernal pool tadpole shrimp are adapted to the environmental conditions of their ephemeral habitats. One adaptation is the ability of vernal pool tadpole shrimp eggs, or cysts, to remain dormant in the soil when their vernal pool habitats are dry. The cysts survive the hot, dry summers and cold, wet winters that follow until the vernal pools and swales fill with rainwater and conditions are right for hatching. When the pools refill in the same or subsequent seasons some, but not all, of the eggs may hatch. The egg bank in the soil may comprise eggs from several years of breeding (USFWS 2005, 2007). Beyond inundation of the habitat, the specific cues for hatching are unknown, although temperature and conductivity (solute concentration) are believed to play a large role (Helm 1998, Eriksen and Belk 1999).

In a study using large plastic pools to simulate natural vernal pools, Helm found no difference in the time to reproduce among California linderiella, Conservancy fairy shrimp, longhorn fairy shrimp, vernal pool fairy shrimp, midvalley fairy shrimp, and vernal pool tadpole shrimp (46 days) (Helm 1998). However, that experiment supplemented by field data (Gallagher 1996, Alexander 2007) suggests that the average time to reproduce for California linderiella, Conservancy fairy shrimp, longhorn fairy shrimp, and vernal pool fairy shrimp is approximately 8 weeks, while that for midvalley fairy shrimp is approximately 2 weeks. No data were reported regarding pool fertility or the impacts of predation on the time to reproduce. These reproduction periods may be shortened or lengthened by warmer or colder water temperatures (Helm 1998).

Vernal pool tadpole shrimp have relatively high reproductive rates and may be hermaphroditic. Sex ratios can vary, perhaps in response to changes in water temperature (Ahl 1991). Genetic variation among vernal pool tadpole shrimp was studied in populations at 20 different sites in the Central Valley (King 1996). The results found that 96 percent of the genetic variation measured was due to differences between sites. This result corresponds with the findings of other researchers that vernal pool crustaceans have low rates of gene flow between separated sites. The low rate of exchange between vernal pool tadpole shrimp populations is probably a result of the spatial isolation of their habitats and their reliance on passive dispersal mechanisms. However, the studies also found that gene flow between pools within the same vernal pool complex is much higher. This indicates that vernal pool tadpole shrimp populations, like most vernal pool crustacean populations, are defined by vernal pool complexes and not by individual vernal pools (USFWS 2005).

Feeding. Vernal pool tadpole shrimp are omnivorous, with a strong preference for animal matter, and will capture and consume live invertebrates including fairy shrimp and other vernal pool tadpole shrimp, amphibian larvae, or carrion, and they also filter detritus for micrometazoa (USFWS 2005, 2007).

Predation and Dispersal. Planktonic Crustacea are important in the food web, as they represent a high-fat, high-protein resource for migratory waterfowl. Mallard (*Anas platyrhynchos*), green-winged teal (*A. crecca*), bufflehead (*Bucephala albeola*), greater yellowlegs (*Tringa melanoleuca*), and killdeer (*Charadrius vociferus*) all forage actively in Central Valley vernal pools on the invertebrate and amphibian fauna during the winter months (Silveira 1996, Bogiatto and Karnegis 2006).

Predator consumption of tadpole shrimp cysts aids in distributing populations of tadpole shrimp. Predators (e.g., birds and amphibians) expel viable cysts in their excrement, often at locations other than where they were consumed. If conditions are suitable, these transported cysts may hatch at the new location and potentially establish a new population. Cysts are also transported by wind and in mud carried on the feet of animals, including livestock that may wade through vernal pool tadpole shrimp habitat. This type of dispersal aids ephemeral pool crustaceans in exploiting a wide variety of ephemeral habitats (Erickson and Belk 1999).

A37.5 THREATS AND STRESSORS

Threats to vernal pool habitat and species in general, including vernal pool tadpole shrimp, were identified in the Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon (USFWS 2005). In addition, the Recovery Plan identified several threats specific to vernal pool tadpole shrimp.

Habitat Loss and Fragmentation. Habitat loss and fragmentation were identified as the largest threats to the survival and recovery of vernal pool species. Habitat loss generally is a result of agricultural conversion from rangelands to intensive farming, urbanization, aggregate mining, infrastructure projects (such as roads and utility projects), and recreational activities (such as off-highway vehicles and hiking) (USFWS 2005, 2007). Habitat fragmentation occurs when vernal pool complexes are broken into smaller groups or individual vernal pools and become isolated from each other as a result of activities such as road development and other infrastructure projects (USFWS 2005, 2007).

Agricultural Conversion. Conversion of land use, such as from grasslands or pastures, to more intensive agricultural uses (e.g., croplands) or from one crop type to another, has contributed and continues to contribute to the decline of vernal pools in general (USFWS 2005, 2007).

Invasive Species. The invasions of vernal pools by waxy mannagrass (*Glyceria declinata*), an invasive aquatic grass (Gerlach et al. 2009), greatly increases the amount of decomposing biomass in vernal pools and may result in higher respiratory oxygen consumption relative to photosynthetic oxygen generation (Rogers 1998). Also, upland biomass of invasive species such as medusahead (*Taeniatherum caput-medusae*) can produce dense vegetation and thatch, shortening the ponding duration of some vernal pools (Marty 2004, Pyke and Marty 2005). Italian ryegrass (*Lolium multiflorum*) has rapidly become a dominant invasive species of the uppermost zone of vernal pools and appears to have undergone rapid adaptation to alkaline clay soils (Dawson et al. 2007).

Altered Hydrology. Human disturbances can alter the hydrology of temporary waters and result in a change in the timing, frequency, or duration of inundation in vernal pools, which can create conditions that render existing vernal pools unsuitable for vernal pool species (USFWS 2005, 2007).

A37.6 Relevant Conservation Efforts

Vernal pool tadpole shrimp is protected as a threatened species under the Endangered Species Act, and critical habitat has been designated as noted above. Critical habitat unit 11D includes the Potrero Hills and adjacent areas, some of which is within the Plan Area. In the Solano-Colusa Vernal Pool Region, vernal pool tadpole shrimp are protected at the Burke Ranch mitigation bank and on the Jepson Prairie Preserve which is owned by the Solano County Open Space and Farmland Conservancy (USFWS 2005, 2008).

Although conservation efforts have been undertaken for vernal pool ecosystems in general, very few actions have been taken specifically to benefit vernal pool tadpole shrimp. An example of one of these actions is a grazing program at the Stone Corral Ecological Reserve for the benefit of vernal pool crustaceans that is being monitored by California Department of Fish and Game staff (USFWS 2005).

Vernal pool tadpole shrimp is covered under the Natomas Basin Habitat Conservation Plan, the San Joaquin County Multi-species Habitat Conservation and Open Space Plan, and the East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan. In addition, the species is proposed for coverage in the Solano County Multispecies Habitat Conservation Plan, the South Sacramento County Habitat Conservation Plan, the Yolo Natural Heritage Program Plan currently under development, and the Butte Regional Habitat Conservation Plan and Natural Community Conservation Plan.

A37.7 Species Habitat Suitability Model

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing GIS data sources (described below and in Section 2.3.1, *Data Sources and Natural Community Classification*). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as vernal pools, individual trees, or small groups of trees. It is also possible, as with some vernal pool invertebrates that are restricted to seasonally ponded habitats, to underestimate potentially-occupied habitat due to the lack of information on small, degraded or artificially-created seasonal wetland habitats.

Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The vernal pool tadpole shrimp model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), DWR 2007 LiDAR elevation data, Google Earth 2009 aerial imagery and USDA 2005 aerial photography. Using these data sets, the model maps the distribution of suitable vernal pool tadpole shrimp habitat in the Plan Area according to the species' two habitat types, vernal pool complex and degraded vernal pool complex habitat. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Vernal Pool Complex Habitat: High quality permanent habitat that consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly impacted by agricultural or development practices. Vernal pool complex habitat for vernal pool tadpole shrimp includes the following vegetation subunits that were selected from the BDCP vernal pool complex natural community:

- Vernal pool complex – all vegetation types

Degraded Vernal Pool Complex Habitat: Low quality ephemeral habitat that ranges from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, disking, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. The aquatic features in this habitat are more clearly classified as temporary waters *sensu lato* (Williams 2006) than intact and fully functional vernal pools. Because these features are inundated during the wet season and may have historically been located in or near areas with natural vernal pool complex, they may support individuals or small populations of species that are found in vernal pools and swales. However, they do not possess the full complement of ecosystem and community characteristics of natural vernal pools, swales and their associated uplands and they are generally ephemeral features that are eliminated during the course of normal agricultural practices. Degraded vernal pool complex habitat for vernal pool tadpole shrimp includes the following vegetation subunits that were selected from the BDCP other natural seasonal wetlands and grasslands communities:

- Grasslands
  - Degraded vernal pool complex – California annual grasslands;
  - Degraded vernal pool complex – Ruderal herbaceous grasses and forbs;
  - Degraded vernal pool complex – Italian rye-grass (*Lolium multiflorum*); and
  - Degraded vernal pool complex – Rabbitsfoot grass (*Polygpogon maritimus*).
- Other natural seasonal wetlands
  - Degraded vernal pool complex - vernal pools.

Potential habitat without concave surfaces was removed from the model. LiDAR elevation data was then visually inspected in four general areas to further assess specific locations that had been identified by the habitat selection process. These areas were selected based both on *a priori* knowledge of the region and because they were identified by the intersection of the selected vegetation types and soils. The analysis of the LiDAR data further refined the habitat model and provided a more accurate demarcation of suitable habitat. The GIS habitat model was then compared against field data from surveys conducted by the California Department of Water Resources in 2009. Land uses that are incompatible with the species' habitat requirements, for example, potential habitat polygons falling on leveled or developed lands were removed from the model.

Assumptions. Historical and current records of this species in the Plan Area indicate that it occurs in appropriate habitat along the perimeter of the Plan Area (Figure A-37b) (Witham 2002, 2003, 2006, ESA 2005, Barona et al. 2007, CNDDB 2010). The vegetation cover of the alkaline soils is typically a combination of vernal pool adapted species and annual ryegrass (Witham 2002, 2003, 2006, CNDDB 2010).

A37.8 RECOVERY GOALS

A general statement for recovery of vernal pool tadpole shrimp is presented in the USFWS (2005) Recovery Plan: to ensure protection of the full geographic, genetic, and ecological extent of this species and to improve the circumstances that caused it to be listed in the first place. Interim goals are to (1) stabilize and protect populations, (2) conduct research to refine reclassification and recovery criteria, and (3) downlist endangered species to threatened. Vernal pool habitats used by the species, as well as historical and potential habitats, need to be protected; and habitat management plans for these habitats need to be developed and implemented. Recovery criteria have been established in the Recovery Plan (USFWS 2005).

The criteria to downlist the species are to protect 80 percent of this species' existing occurrences and 85 to 95 percent of this species' suitable habitat within 13 Core Areas, including: Chico, Oroville and Vina Plains, Grasslands Ecological Area, Davis Communications Annex, Jepson Prairie, Collinsville, Sacramento National Wildlife Refuge (NWR), Cosumnes/Rancho Seco, Mather, Madera, Merced, and Table Mountain. A total of 85 percent of suitable habitat is to be protected within 11 Core Areas, including: SE San Francisco Bay, Dales, Doe Mill, Red Bluff, Redding, Cross Creek, Dolan, Beale, Western Placer County, Cottonwood Creek, and Turlock. The criteria to delist the species are: protect 100 percent of newly discovered/reintroduced populations and reintroduce the species into vernal pool regions and soil types from which surveys indicate that it has been extirpated (USFWS 2005).

APPENDIX A38. CONSERVANCY FAIRY SHRIMP (*BRANCHINECTA CONSERVATIO*)

A38.1 LEGAL STATUS

Conservancy fairy shrimp (*Branchinecta conservatio*) was listed as endangered throughout its range under the federal Endangered Species Act on September 19, 1994 (59 FR 48136). In September 2007, U.S. Fish and Wildlife Services (USFWS) published a 5-year review recommending that the species remain listed as endangered. Revised critical habitat was designated on February 10, 2006 (71 FR 7118), although none of the critical habitat units are within the Plan Area. This species is covered by the December 15, 2005, Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon. Conservancy fairy shrimp has no state regulatory status.

A38.2 SPECIES DISTRIBUTION AND STATUS

A38.2.1 Range and Status

The historical distribution of Conservancy fairy shrimp is not known, but the distribution of vernal pool habitats in the areas where the species is now known to occur was once more continuous and larger in area than today (USFWS 2005). The species is currently found in disjunct and fragmented habitats across the Central Valley of California from Tehama County to Merced County and at two southern California locations on the Los Padres National Forest in Ventura County (Figure A-38a) (USFWS 2005, 2007, CNDDB 2010).

A38.2.2 Distribution and Status in the BDCP Plan Area

Conservancy fairy shrimp is known to occur at three locations within the Plan Area (Figure A-38b) (USFWS 2007). In general, within the Plan Area, turbid-water playas and vernal pools that may support the species occur on alkaline soils from the Department of Fish and Game (DFG) Tule Ranch Unit of the Yolo Bypass Wildlife Area southwest to the Montezuma Wetlands Mitigation Projects and from the Byron Airport to Discovery Bay.

A38.3 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

As with other vernal pool crustacean species, Conservancy fairy shrimp is sporadic in its distribution, often inhabiting only one or a few vernal pools in otherwise more widespread pool complexes. Pools within a complex typically are separated by distances on the order of five or more feet (1.5 meters) and may form dense mosaics of small pools or a sparser scattering of larger pools (USFWS 2005). Conservancy fairy shrimp have been found in vernal pools ranging

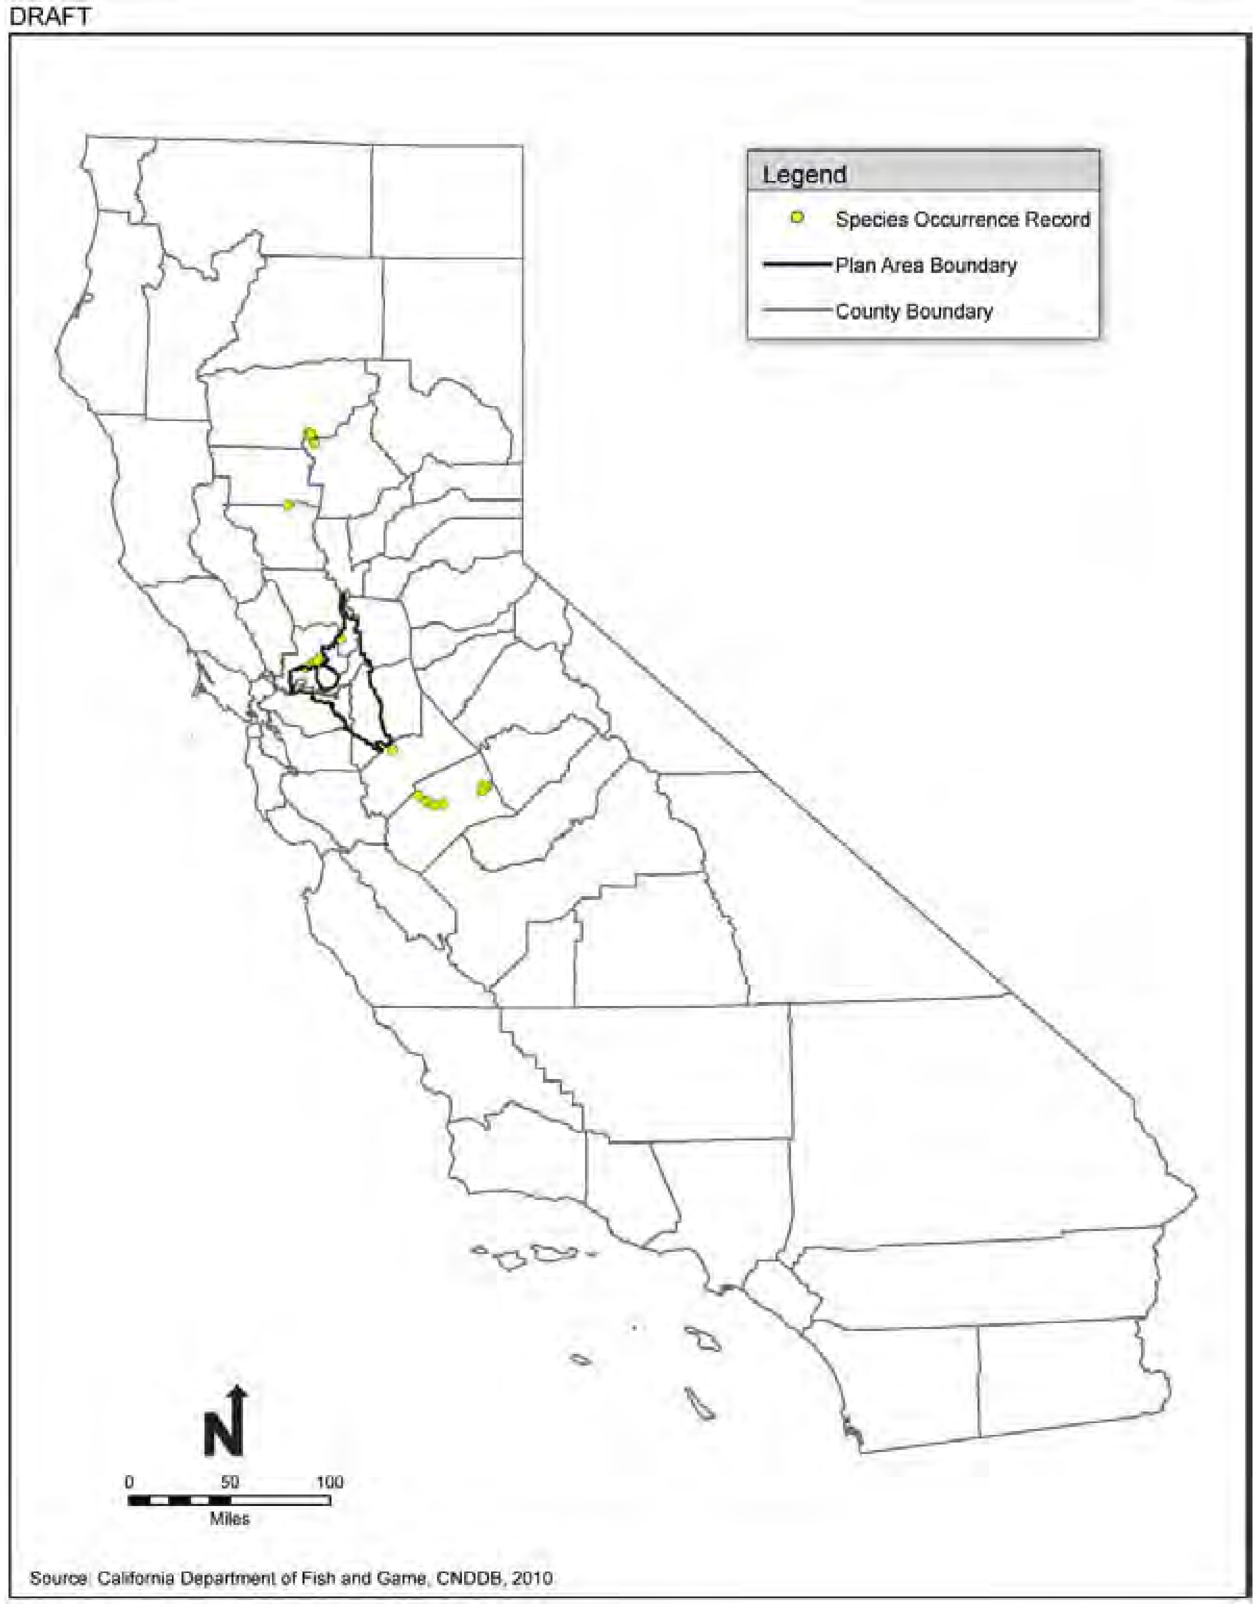

Figure A-38a. Conservancy Fairy Shrimp Statewide Recorded Occurrences

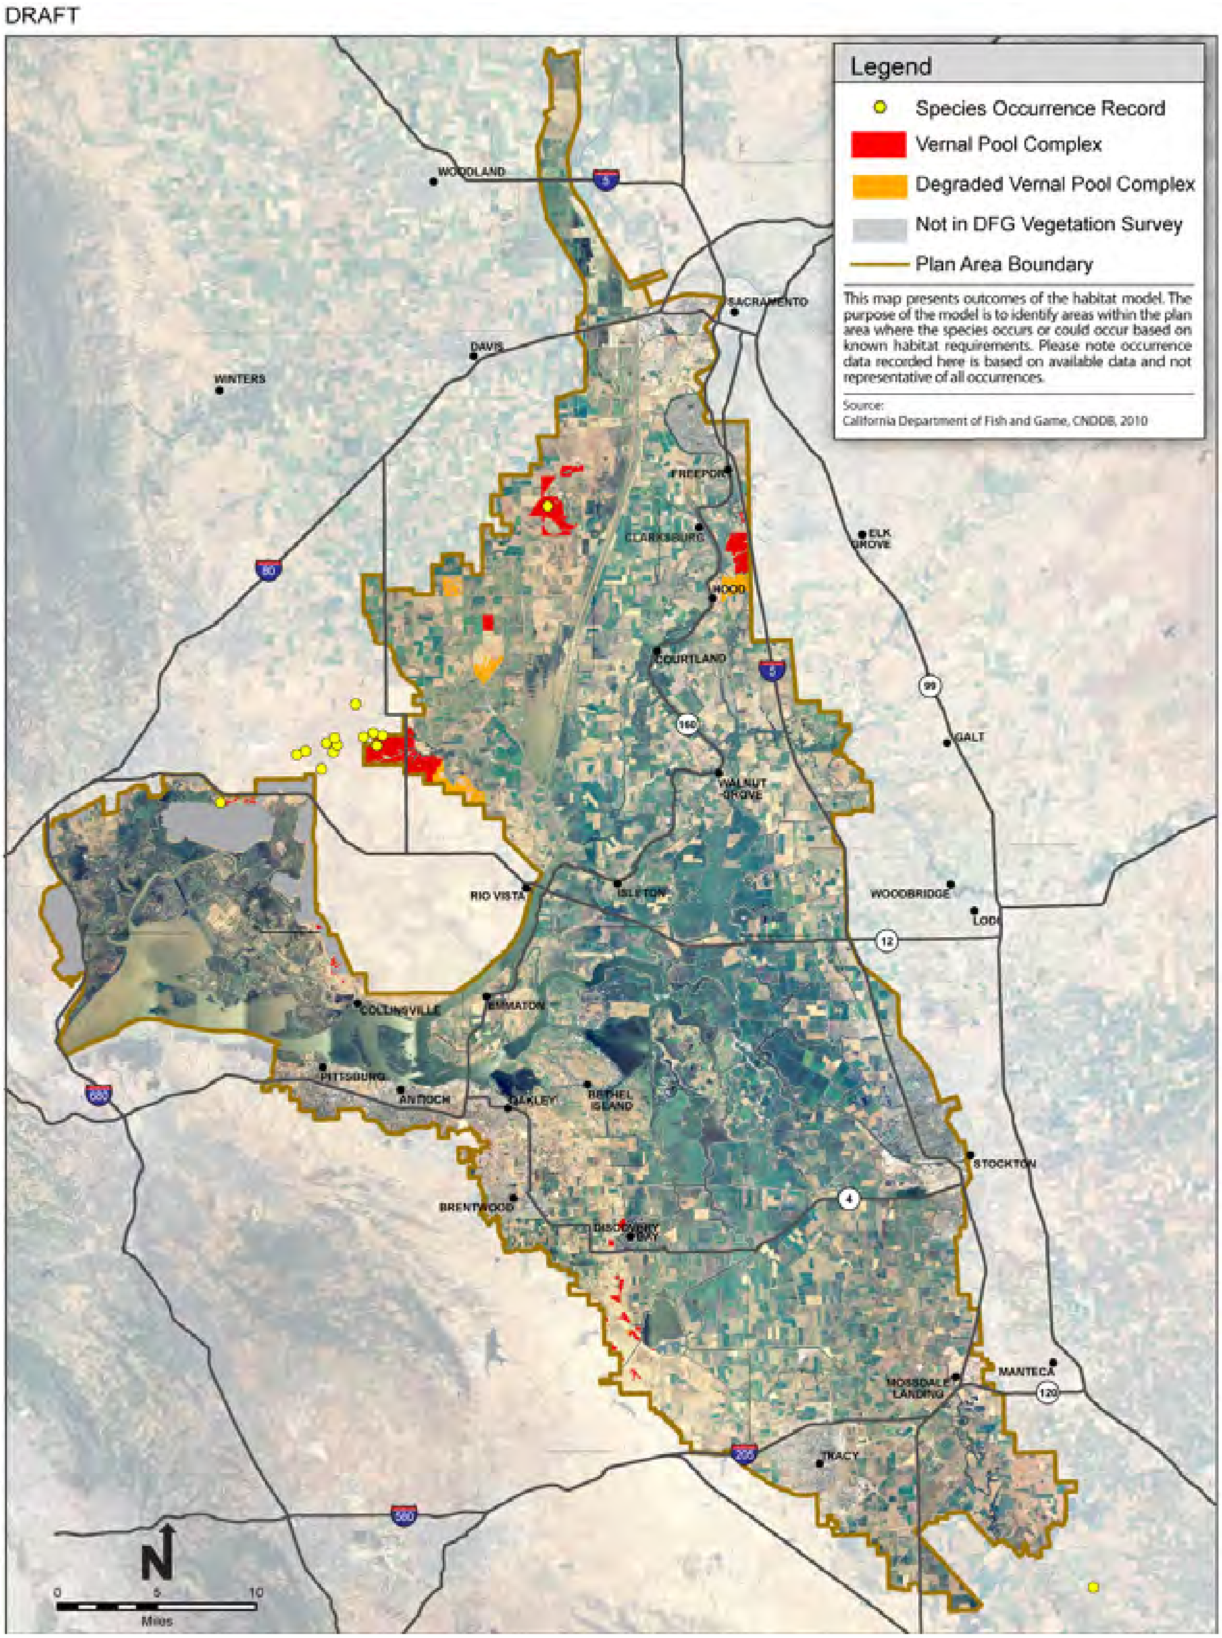

Figure A-38b. Conservancy Fairy Shrimp Habitat Model and Recorded Occurrences

in size from 323 square feet to 88 acres (30 m^2 to 35.6 hectares) at elevations ranging from 16 to 5,577 feet (5 to 1,700 meters) (USFWS 2005, 2007).

This species is entirely dependent on the aquatic environment provided by the temporary waters of natural vernal pool and playa pool ecosystems as well as the artificial environments of ditches and tire ruts (King et al. 1996, Helm 1998, Eriksen and Belk 1999). The temporary waters in which Conservancy fairy shrimp inhabits fill in the fall and winter during the beginning of the wet season and dry in late-spring at the beginning of the dry season and remain desiccated throughout the summer (Helm 1998, Eriksen and Belk 1999). The temporary waters fill directly from precipitation as well as from runoff from their watersheds (Williamson et al. 2005, Rains et al. 2006, 2008, O'Geen et al. 2008). The watershed extent that is necessary for maintaining the hydrological functions of the temporary waters depends on a number of complex factors including the hydrologic conductivity of the surface soil horizons, the continuity and extent of hard-pans and clay-pans underlying non-clay soils, the existence of a perched aquifer overlying the pans, slope, effects of vegetation on evapotranspiration rates, compaction of surface soils by grazing animals, and other factors (Marty 2004, Pyke and Marty 2005, Williamson et al. 2005, Rains et al. 2006, 2008, O'Geen et al. 2008).

Typical turbid-water habitats for Conservancy fairy shrimp in California are large, playa-type vernal pools or long inundation smaller vernal pools (Eng et al. 1990, USFWS 2007). Common wetland plant species that co-occur with Conservancy fairy shrimp include toad rush (*Juncus bufonius*), coyote thistle (*Eryringium* spp.), downingia (*Downingia ornatissma* or *D. bicornuta*), goldfields (*Lasthenia* spp.), woolly marbles (*Psilocarphus* spp.), and hair grass (*Deschampsia* spp.) (King et al. 1996, Alexander and Schlising 1997, 1998, Helm 1998, Plattencamp 1998, Eriksen and Belk 1999, Alexander 2007).

A38.4 Life History

Description. Conservancy fairy shrimp is a typical Branchinectid anostracan. They are typically off-white to grey, although the brood patch may be green or yellow. Depending on the rapidity of development, mature animals may vary in length from 3 to 38 millimeters (0.12 to 1.50 inches). Like other fairy shrimp, they are entirely aquatic with delicate elongate bodies, large stalked compound eyes, no carapaces, and eleven pairs of swimming legs. Males and females are generally differentiated on the basis of antennae development, thoracic projections, and brood pouch development.

Reproduction and Growth. Conservancy fairy shrimp is adapted to the environmental conditions of their ephemeral habitats. One adaptation is the ability of Conservancy fairy shrimp eggs, or cysts, to remain dormant in the soil when their vernal pool habitats are dry. The cysts survive the hot, dry summers and cold, wet winters that follow until the vernal pools and swales fill with rainwater and conditions are right for hatching. When the pools refill in the same or subsequent seasons some, but not all, of the eggs may hatch. The egg bank in the soil may comprise eggs from several years of breeding (USFWS 2005, 2007).

In a study using large plastic pools to simulate natural vernal pools, Helm found no difference in the time to reproduce among California linderiella, Conservancy fairy shrimp, longhorn fairy shrimp, vernal pool fairy shrimp, midvalley fairy shrimp, and vernal pool tadpole shrimp (46 days) (Helm 1998). However, that experiment supplemented by field data (Gallagher 1996, Alexander 2007) suggests that the average time to reproduce for California linderiella, Conservancy fairy shrimp, longhorn fairy shrimp, and vernal pool fairy shrimp is approximately 8 weeks, while that for midvalley fairy shrimp is approximately 2 weeks. No data were reported regarding pool fertility or the impacts of predation on the time to reproduce. These reproduction periods may be shortened or lengthened by warmer or colder water temperatures (Helm 1998).

Feeding. Conservancy fairy shrimp is an omnivorous filter-feeder. In general, all fairy shrimp species indiscriminately filter particles that include bacteria, unicellular algae, and micrometazoa (Eriksen and Belk 1999). The precise size of items these fairy shrimp are capable of filtering is currently unknown. However, fairy shrimp species will attempt to consume whatever material they can fit into their feeding groove and do not discriminate based upon taste, as do other crustacean groups (Eriksen and Belk 1999).

Predation and Dispersal. Planktonic Crustacea are important in the food web, as they represent a high-fat, high-protein resource for migratory waterfowl. Mallard (*Anas platyrhynchos*), green-winged teal (*A. crecca*), bufflehead (*Bucephala albeola*), greater yellowlegs (*Tringa melanoleuca*), and killdeer (*Charadrius vociferus*) all forage actively in Central Valley vernal pools on the invertebrate and amphibian fauna during the winter months (Silveira 1996, Bogiatto and Karnegis 2006).

Predator consumption of fairy shrimp cysts aids in distributing populations of fairy shrimp. Predators (e.g., birds and amphibians) expel viable cysts in their excrement, often at locations other than where they were consumed. If conditions are suitable, these transported cysts may hatch at the new location and potentially establish a new population. Cysts are also transported by wind and in mud carried on the feet of animals, including livestock that may wade through fairy shrimp habitat. This type of dispersal aids ephemeral pool crustaceans in exploiting a wide variety of ephemeral habitats (Erickson and Belk 1999).

A38.5 Threats and Stressors

Threats to vernal pool habitat and species in general, including Conservancy fairy shrimp, were identified in the Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon (USFWS 2005). In addition, the Recovery Plan identified several threats specific to the Conservancy fairy shrimp.

Habitat Loss and Fragmentation. Habitat loss and fragmentation were identified as the largest threats to the survival and recovery of vernal pool species. Habitat loss generally is a result of agricultural conversion from rangelands to intensive farming, urbanization, aggregate mining, infrastructure projects (such as roads and utility projects), and recreational activities (such as off-highway vehicles and hiking) (USFWS 2005, 2007). Habitat fragmentation occurs when vernal pool complexes are broken into smaller groups or individual vernal pools and become isolated from each other as a result of activities such as road development and other infrastructure projects (USFWS 2005, 2007).

Agricultural Conversion. Conversion of land use, such as from grasslands or pastures to more intensive agricultural uses (e.g., croplands) or from one crop type to another, has contributed and continues to contribute to the decline of vernal pools in general (USFWS 2005, 2007).

Invasive Species. The invasions of vernal pools by waxy mannagrass (*Glyceria declinata*), an invasive aquatic grass (Gerlach et al. 2009), greatly increases the amount of decomposing biomass in vernal pools and may result in higher respiratory oxygen consumption relative to photosynthetic oxygen generation (Rogers 1998). Also, upland biomass of invasive species such as medusahead (*Taeniatherum caput-medusae*) can produce dense vegetation and thatch, shortening the ponding duration of some vernal pools (Marty 2004, Pyke and Marty 2005). Italian ryegrass (*Lolium multiflorum*) has rapidly become a dominant invasive species of the uppermost zone of vernal pools and appears to have undergone rapid adaptation to alkaline clay soils (Dawson et al. 2007).

Altered Hydrology. Human disturbances can alter the hydrology of temporary waters and result in a change in the timing, frequency, or duration of inundation in vernal pools, which can create conditions that render existing vernal pools unsuitable for vernal pool species (USFWS 2005, 2007).

A38.6 RELEVANT CONSERVATION EFFORTS

Conservancy fairy shrimp was listed as endangered and critical habitat was designated as noted above. Critical habitat unit 3 includes an area north of the Potrero Hills that is within the Plan Area. Throughout the range of the species, vernal pool habitats supporting populations of Conservancy fairy shrimp have been protected through a variety of other means, including preserves, refuges, and protections on private lands. Within the Solano-Colusa Vernal Pool Region, Conservancy fairy shrimp is protected on the DFG Tule Ranch Reserve, the proposed Burke Ranch mitigation bank, in the Jepson Prairie Preserve system, and in the Montezuma Wetlands Mitigation site (Witham 2003, 2006, USFWS 2007).

Conservancy fairy shrimp is covered under the approved San Joaquin County Multi-species Habitat Conservation and Open Space Plan, and is proposed for coverage under the Solano County Multispecies Habitat Conservation Plan, the Yolo County Natural Heritage Program Plan, and the Butte Regional Conservation Plan.

A38.7 SPECIES HABITAT SUITABILITY MODEL

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below and in Section 2.3.1, *Data Sources and Natural Community Classification*). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as vernal pools, individual trees, or small groups of trees. It is also possible, as with some vernal pool invertebrates that are restricted to seasonally ponded habitats, to underestimate potentially-occupied habitat due to the lack of information on small, degraded or artificially-created seasonal wetland habitats.

Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The Conservancy fairy shrimp model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), DWR 2007 LiDAR elevation data, Google Earth 2009 aerial imagery and United States Department of Agriculture (USDA) 2005 aerial photography. Using these data sets, the model maps the distribution of suitable Conservancy fairy shrimp habitat in the Plan Area according to the species' two habitat types, vernal pool complex and degraded vernal pool complex habitat. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Vernal Pool Complex Habitat: High quality permanent habitat that consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly impacted by agricultural or development practices. Vernal pool complex habitat for Conservancy fairy shrimp includes the following vegetation subunits that were selected from the BDCP vernal pool complex natural community:

- Vernal pool complex – all vegetation types

Degraded Vernal Pool Complex Habitat: Low quality ephemeral habitat that ranges from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, disking, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. The aquatic features in this habitat are more clearly classified as temporary waters *sensu lato* (Williams 2006) than intact and fully functional vernal pools. Because these features are inundated during the wet season and may have historically been located in or near areas with natural vernal pool complex, they may support individuals or small populations of species that are found in vernal pools and swales. However, they do not possess the full complement of ecosystem and community characteristics of natural vernal pools, swales and their associated uplands and they are generally ephemeral features that are eliminated during the course of normal agricultural practices. Degraded vernal pool complex habitat for Conservancy fairy shrimp includes the following vegetation subunits that were selected from the BDCP other natural seasonal wetlands and grasslands communities:

- Grasslands
    - Degraded vernal pool complex – California annual grasslands;
    - Degraded vernal pool complex – Ruderal herbaceous grasses and forbs;
    - Degraded vernal pool complex – Italian rye-grass (*Lolium multiflorum*); and
    - Degraded vernal pool complex – Rabbitsfoot grass (*Polygpogon maritimus*).
- Other natural seasonal wetlands
    - Degraded vernal pool complex – Vernal pools.

Potential habitat without concave surfaces was removed from the model. LiDAR elevation data was then visually inspected in four general areas to further assess specific locations that had been identified by the habitat selection process. These areas were selected based both on *a priori* knowledge of the region and because they were identified by the intersection of the selected vegetation types and soils. The analysis of the LiDAR data further refined the habitat model and provided a more accurate demarcation of suitable habitat. The GIS habitat model was then compared against field data from surveys conducted by the California Department of Water Resources in 2009. Land uses that are incompatible with the species' habitat requirements, for example, potential habitat polygons falling on leveled or developed lands were removed from the model.

Assumptions. Historical and current records of this species in the Plan Area indicate that its current distribution is limited to the northwestern perimeter of the Plan Area (Figure A-38b) (Witham 2002, 2003, 2006, CNDDB 2010). However, because the Plan Area has not been completely surveyed, its potential distribution was increased to the southwestern and eastern perimeter of the Plan Area as well. The vegetation cover of the alkaline soils is typically a combination of vernal pool adapted species and annual ryegrass (Witham 2002, 2003, 2006, CNDDB 2010).

A38.8 Recovery Goals

The recovery goal of Conservancy fairy shrimp is to delist the species and ensure its long-term conservation (USFWS 2005). Interim goals are to: (1) stabilize and protect populations, (2) conduct research to refine reclassification and recovery criteria, and (3) downlist endangered species to threatened. Vernal pool habitats used by the species as well as historical and potential habitats need to be protected, and habitat management plans for these habitats need to be developed and implemented. Recovery criteria have been established in the Recovery Plan (USFWS 2005). The criteria to downlist the species are: protect 100 percent of the present occurrences and protect 95 percent of its suitable habitat in the Vina Plains, Caswell, Grassland Ecological Area, Ventura County, Jepson Prairie, Sacramento National Wildlife Refuge (NWR), Collinsville, and Madera Core Areas. The criteria to delist the species are: protect 100 percent of newly discovered/reintroduced populations and regions and soil types from which surveys indicate the species has been extirpated and reintroduce the species into vernal pool regions and soil types from which surveys indicate that it has been extirpated (USFWS 2005).

APPENDIX A39. LONGHORN FAIRY SHRIMP (*BRANCHINECTA LONGIANTENNA*)

A39.1 LEGAL STATUS

The longhorn fairy shrimp (*Branchinecta longiantenna*) was federally listed as endangered by the U.S. Fish and Wildlife Service (USFWS) on September 19, 1994 (59 FR 48136). On October 9, 2007, the USFWS published a 5-year review recommending that the species remain listed as endangered (USFWS 2007). Revised critical habitat was designated on February 10, 2006 (71 FR 7118) and critical habitat unit designations were published for Contra Costa, Alameda, Merced, and San Luis Obispo counties on February 10, 2006 (71 FR 7118). This species is covered by the December 15, 2005, Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon (USFWS 2005). The longhorn fairy shrimp has no state regulatory status.

A39.2 SPECIES DISTRIBUTION AND STATUS

A39.2.1 Range and Status

The historical distribution of the longhorn fairy shrimp is not known, but probably did not extend into the northern portion of the Central Valley or into southern California (USFWS 2005, 2007). Currently, populations are known from Concord in Contra Costa County in the north to Soda Lake in San Luis Obispo County in the south (Figure A-39a), including populations in Alameda and Merced counties (USFWS 2007). The Contra Costa and Alameda County populations are located within the Livermore Vernal Pool Region, while known populations in Merced County are at the Kesterson National Wildlife Refuge and in a roadside ditch just north of Los Banos in the San Joaquin Vernal Pool Region (USFWS 2005, 2007). Those in San Luis Obispo County are adjacent to Soda Lake in the Carrizo Vernal Pool Region (both immediately outside and within the Carrizo Plain National Monument). Occurrences are rare and highly disjunct with specific pool characteristics largely unknown (USFWS 2005, 2007). The Altamont Pass subunits of the species (Contra Costa and Alameda counties) occur within clear-water depression pools in sandstone outcrops (Eng et al. 1990, Eriksen and Belk 1999, CNDDB 2010).

A39.2.2 Distribution and Status in the Plan Area

The species is not known to occur in the Plan Area (Figure A-39b) (CNDDB 2010). The closest populations are in Contra Costa County (Vasco Caves Preserve) and Alameda County (Brushy Peak Preserve) just southwest of the Plan Area. These occurrences are in seasonal pools within sandstone depressions in rocky outcrops which are not present anywhere within the Plan Area.

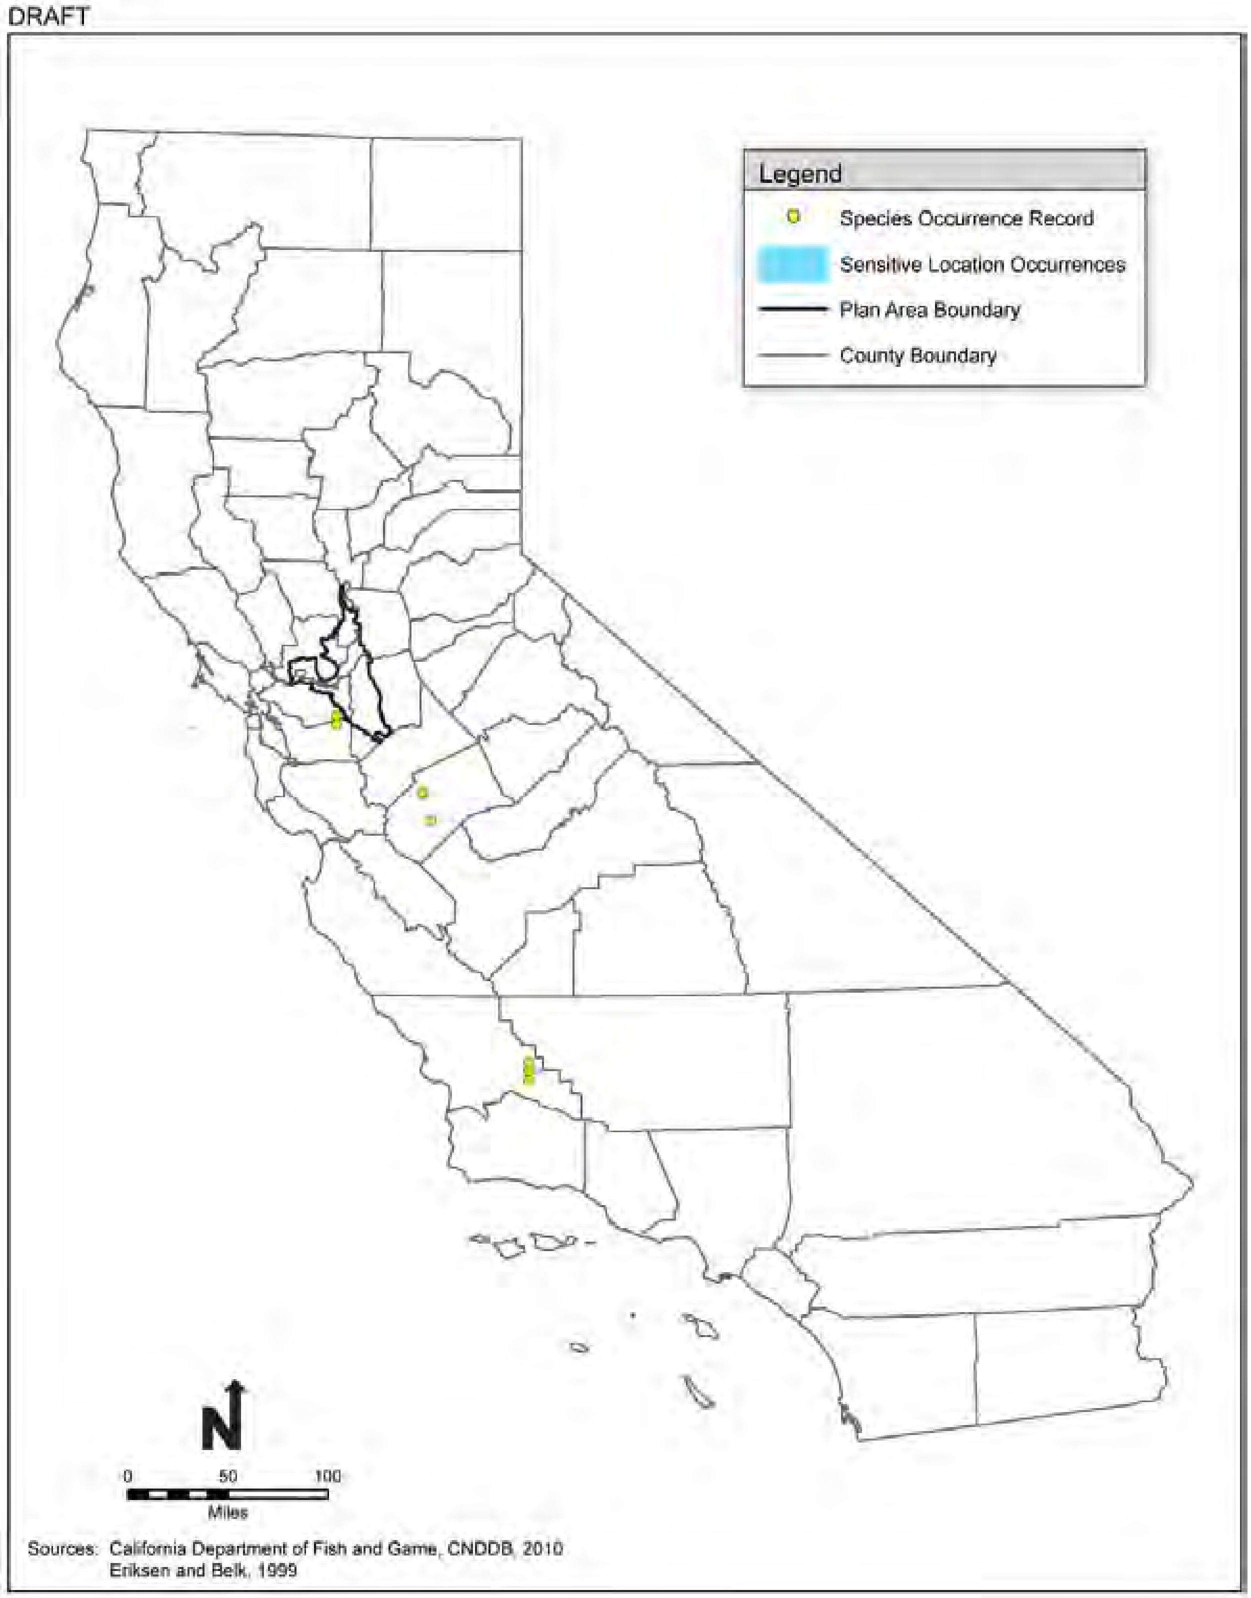

Figure A-39a. Longhorn Fairy Shrimp Statewide Recorded Occurrences

DRAFT

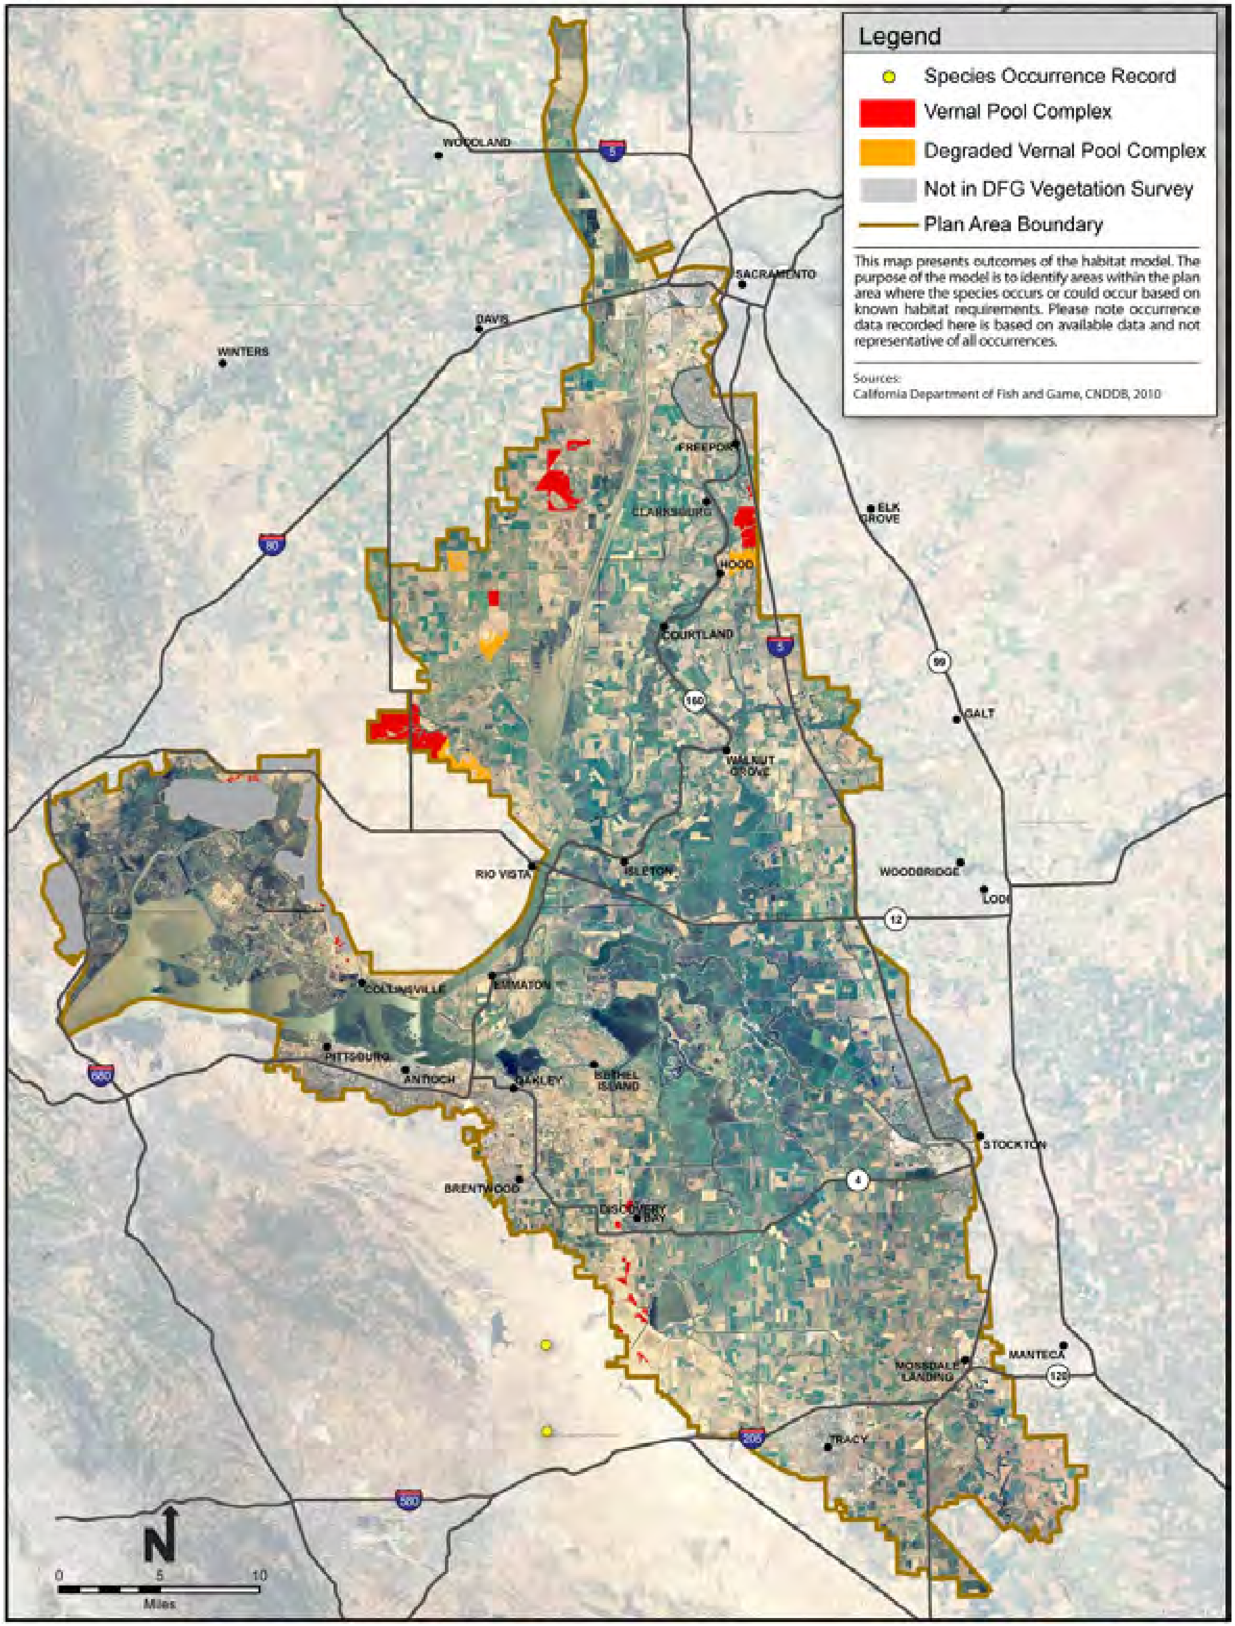

Figure A-39b. Longhorn Fairy Shrimp Habitat Model and Recorded Occurrences

This species also occurs in pools within alkali sink vegetation in other parts of its known range (USFWS 2005, 2007, CNDDB 2010), but it has not been detected in similar pools in the Plan Area despite at least 14 years of extensive vernal pool surveys (USFWS 2005, 2007). While it has not been detected in the Plan Area, vernal pools that may support the species occur on alkaline soils from the Tule Ranch Unit of the California Department of Fish and Game (DFG) Yolo Bypass Wildlife Area southwest to the Montezuma Wetlands Mitigation Projects and from the Byron Airport to Discovery Bay.

A39.3 Habitat Requirements and Special Conditions

Longhorn fairy shrimp in Contra Costa and Alameda counties are primarily reported from small (less than one meter diameter) water-filled sandstone depressions while those in the San Joaquin Valley and Carrizo Plain are found in shallow vernal pools within alkali sink vegetation in water with neutral potential of hydrogen (pH) (7.2) and a low chloride concentration (Helm 1998, USFWS 2005, 2007, CNDDB 2010). These vernal pool habitats are subject to seasonal variations including duration of ponding. This species has likely evolved adaptations to these variations (59 FR 48136). The longhorn fairy shrimp is capable of living in vernal pools of relatively short duration (ponding six to seven weeks in winter and three weeks in spring) (Eriksen and Belk 1999).

A39.4 Life History

Description. Longhorn fairy shrimp are generally similar to other fairy shrimp species with delicate elongate bodies, large stalked compound eyes, no carapaces, and eleven pairs of swimming legs. Longhorn fairy shrimp is distinguished from other species by its elongated second antennae, which is twice the length, relative to its body, of that of other Branchinecta species. Size ranges from approximately 12 to 21 millimeters (0.5 to 0.8 inches). Males and females are differentiated primarily on the basis of the length of the second antennae, but also by thoracic projections and brood pouch development.

Reproduction and Growth. Longhorn fairy shrimp is a component of the planktonic crustacea within seasonal temporary pools, but nothing is known about its role in foodwebs. Beyond inundation, the specific cues for cyst hatching are unknown (Eriksen and Belk 1999), although temperature is believed to play a large role. When reared in plastic pools, with their bottoms lined with soil excavated from vernal pools and without supplemental food, some individuals of this species completed their lifecycle in 23 days but the average time was 43 days (Helm 1998). Longhorn fairy shrimp have been reported to co-occur in the same general area with the vernal pool fairy shrimp (*Branchinecta lynchi*), but the species did not occupy the same vernal pools (Eng et al. 1990).

Feeding. Longhorn fairy shrimp is an omnivouous filter-feeder. In general, all fairy shrimp species indiscriminately filter particles that include bacteria, unicellular algae, and micrometazoa

(Eriksen and Belk 1999). The precise size of items these fairy shrimp are capable of filtering is currently unknown. However, fairy shrimp species will attempt to consume whatever material they can fit into their feeding groove and do not discriminate based upon taste, as do some other crustacean groups (Eriksen and Belk 1999).

Predation and Dispersal. Planktonic Crustacea are important in the food web, as they represent a high-fat, high-protein resource for migratory waterfowl. Mallard (*Anas platyrhynchos*), green-winged teal (*A. crecca*), bufflehead (*Bucephala albeola*), greater yellowlegs (*Tringa melanoleuca*), and killdeer (*Charadrius vociferus*) all forage actively in Central Valley vernal pools on the invertebrate and amphibian fauna during the winter months (Silveira 1996, Bogiatto and Karnegis 2006).

Predator consumption of fairy shrimp cysts aids in distributing populations of fairy shrimp. Predators (e.g., birds and amphibians) expel viable cysts in their excrement, often at locations other than where they were consumed. If conditions are suitable, these transported cysts may hatch at the new location and potentially establish a new population. Cysts are also transported by wind and in mud carried on the feet of animals, including livestock that may wade through fairy shrimp habitat. This type of dispersal aids ephemeral pool crustaceans in exploiting a wide variety of ephemeral habitats (Erickson and Belk 1999).

A39.5 THREATS AND STRESSORS

The primary disturbance to longhorn fairy shrimp occurring in the vicinity of the Plan Area (i.e., Altamont Pass area) is from habitat disturbances caused by the construction and operation of wind energy equipment and related activities (USFWS 2007). Within this area, habitat loss or disturbance from urbanization and agricultural development and impacts related to these activities are of less concern compared with other vernal pool types in locations more vulnerable to these activities.

A39.6 RELEVANT CONSERVATION EFFORTS

The species was listed as endangered and critical habitat was designated as noted above. Vernal pool habitat on the Carrizo Plain has been partially protected in the Carrizo National Monument (USFWS 2007). Habitats in the San Joaquin Vernal Pool region are protected at the Kesterson National Wildlife Refuge (USFWS 2005, 2007). Known occurrences in sandstone depression pools in the Altamont area are protected in the Brushy Peak and Vasco Caves preserves which are on property owned and managed by the East Bay Regional Parks District (USFWS 2007).

The longhorn fairy shrimp is covered under the approved San Joaquin County Multi-species Habitat Conservation and Open Space Plan and East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan.

A39.7 SPECIES HABITAT SUITABILITY MODEL

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below and in Section 2.3.1, *Data Sources and Natural Community Classification*). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as vernal pools, individual trees, or small groups of trees. It is also possible, as with some vernal pool invertebrates that are restricted to seasonally ponded habitats, to underestimate potentially-occupied habitat due to the lack of information on small, degraded or artificially-created seasonal wetland habitats.

Still, for most species the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The longhorn fairy shrimp model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), DWR 2007 LiDAR elevation data, Google Earth 2009 aerial imagery and United States

Department of Agriculture (USDA) 2005 aerial photography. Using these data sets, the model maps the distribution of suitable longhorn fairy shrimp habitat in the Plan Area according to the species' two habitat types, vernal pool complex and degraded vernal pool complex habitat. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Vernal Pool Complex Habitat: High quality permanent habitat that consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly impacted by agricultural or development practices. Vernal pool complex habitat for longhorn fairy shrimp includes the following vegetation subunits that were selected from the BDCP vernal pool complex natural community:

- Vernal pool complex – all vegetation types

Degraded Vernal Pool Complex Habitat: Low quality ephemeral habitat that ranges from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, disking, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. The aquatic features in this habitat are more clearly classified as temporary waters *sensu lato* (Williams 2006) than intact and fully functional vernal pools. Because these features are inundated during the wet season and may have historically been located in or near areas with natural vernal pool complex, they may support individuals or small populations of species that are found in vernal pools and swales. However, they do not possess the full complement of ecosystem and community characteristics of natural vernal pools, swales and their associated uplands and they are generally ephemeral features that are eliminated during the course of normal agricultural practices. Degraded vernal pool complex habitat for longhorn fairy shrimp includes the following vegetation subunits that were selected from other natural seasonal wetlands and grasslands communities:

- Grasslands
    - Degraded vernal pool complex – California annual grasslands;
    - Degraded vernal pool complex – Ruderal herbaceous grasses and forbs;
    - Degraded vernal pool complex – Italian rye-grass (*Lolium multiflorum);* and
    - Degraded vernal pool complex – Rabbitsfoot grass (*Polygpogon maritimus*).
- Other natural seasonal wetlands
    - Degraded vernal pool complex – Vernal pools.

Potential habitat without concave surfaces was removed from the model. LiDAR elevation data was then visually inspected in four general areas to further assess specific locations that had been identified by the habitat selection process. These areas were selected based both on *a priori* knowledge of the region and because they were identified by the intersection of the selected vegetation types and soils. The analysis of the LiDAR data further refined the habitat model and provided a more accurate demarcation of suitable habitat. The GIS habitat model was then compared against field data from surveys conducted by the California Department of Water Resources in 2009. Land uses that are incompatible with the species' habitat requirements, for example, potential habitat polygons falling on leveled or developed lands were removed from the model.

Assumptions. Longhorn fairy shrimp is not known to occur in the Plan Area. The Plan Area does not support rock outcrops with seasonal pools, which is the primary habitat type this species is known to use in the region. However, because this species is known to occur in vernal pools in alkali sink vegetation in San Joaquin County and the Carrizo Plain, identifying potential habitat for this species was conducted similarly to other covered vernal pool invertebrates. Potential habitat is limited to alkaline soil areas with vernal pool and swale microtopography within the Plan Area (Figure A-39b) (Witham 2002, 2003, 2006, CNDDB 2010). The vegetation cover of the alkaline soils is typically a combination of vernal pool adapted species and annual ryegrass (Witham 2002, 2003, 2006, CNDDB 2010).

A39.8 Recovery Goals

The Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon was finalized by the USFWS in 2005. With an overall recovery goal to delist the species and ensure its long-term conservation, interim goals include: (1) stabilize and protect populations, (2) conduct research to refine reclassification and recovery criteria, and (3) downlist endangered species to threatened. Vernal pool habitats used by the species as well as historical and potential habitats need to be protected, and habitat management plans for these habitats need to be developed and implemented. Recovery criteria have been established in the Recovery Plan. The criteria to downlist the species are: protect 100 percent of the present occurrences and protect 95 percent of its suitable habitat in the North Carrizo Plain, South Carrizo Plain, Altamont Hills, and Grassland Ecological Area Core Areas. The criteria to delist the species are: protect 100 percent of newly discovered/reintroduced populations, reintroduce the species into vernal pool regions and soil types from which surveys indicate the species has been extirpated, and discover or establish additional populations (USFWS 2005).

APPENDIX A40. VERNAL POOL FAIRY SHRIMP (*BRANCHINECTA LYNCHI*)

A40.1 LEGAL STATUS

Vernal pool fairy shrimp (*Branchinecta lynchi*) is listed as threatened under the federal Endangered Species Act throughout its range (59 FR 48136). In September 2007, the U.S. Fish and Wildlife Service (USFWS) published a 5-year review recommending that the species remain listed as threatened. Revised critical habitat was designated on February 10, 2006 (71 FR 7118). This species is covered by the December 15, 2005, Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon (USFWS 2005). Only one unit, 19B, is partially within the Plan Area boundary. Vernal pool fairy shrimp has no state regulatory status.

A40.2 SPECIES DISTRIBUTION AND STATUS

A40.2.1 Range and Status

Vernal pool fairy shrimp was identified in 1990 (Eng et al. 1990) and there is little information on the historical range of the species. It has the largest geographical range of listed fairy shrimp in California, but is seldom abundant (Eng et al. 1990). The species is currently found in disjunct and fragmented habitats across the Central Valley of California from Shasta County to Tulare County and the central and southern Coast Ranges from northern Solano County to Ventura County, California (Figure A-40a) (USFWS 2005, 2007, CNDDB 2010). Additional disjunct occurrences have been identified in southern California and in Jackson County, Oregon. In California, it occurs in a wide range of vernal pools, and in the Altamont Pass area (Contra Costa and Alameda counties) it occurs in clear-water depression pools in sandstone outcrops (Eng et al 1990, Eriksen and Belk 1999, CNDDB 2010).

A40.2.2 Distribution and Status in the Plan Area

Vernal pool fairy shrimp has been reported from several locations within the Plan Area (Figure A-40b) (USFWS 2005, 2007, CNDDB 2010). In general, within the Plan Area, vernal pools that may support the species occur on alkaline soils from the California Department of Fish and Game (DFG) Tule Ranch Reserve southwest to the Montezuma Wetlands Mitigation Projects and from the Byron Airport to Discovery Bay. Other potential vernal pool habitat occurs along the eastern boundary of the Plan Area near Stone Lakes (Figure A-40b). Seven additional occurrences were discovered in the south Stone Lakes area during 2009 surveys conducted by the California Department of Water Resources (DWR). A comprehensive survey of vernal pools or habitat for vernal pool fairy shrimp has not been conducted in the Plan Area.

Figure A-40b. Vernal Pool Fairy Shrimp Habitat Model and Recorded Occurrences

1

A40.3 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

This species is entirely dependent on the aquatic environment provided by the temporary waters of natural vernal pool and playa pool ecosystems as well as the artificial environments of ditches and tire ruts (King et al. 1996, Helm 1998, Eriksen and Belk 1999). The temporary waters in which vernal pool tadpole shrimp inhabits fill in the fall and winter during the beginning of the wet season and dry in late-spring at the beginning of the dry season and remain desiccated throughout the summer (Helm 1998, Eriksen and Belk 1999). The temporary waters fill directly from precipitation as well as from runoff from their watersheds (Williamson et al. 2005, Rains et al. 2006, 2008, O'Geen et al. 2008). The watershed extent that is necessary for maintaining the hydrological functions of the temporary waters depends on a number of complex factors including the hydrologic conductivity of the surface soil horizons, the continuity and extent of hard-pans and clay-pans underlying non-clay soils, the existence of a perched aquifer overlying the pans, slope, effects of vegetation on evapotranspiration rates, compaction of surface soils by grazing animals, and other factors (Marty 2004, Pyke and Marty 2005, Williamson et al. 2005, Rains et al. 2006, 2008, O'Geen et al. 2008).

The temporary waters that are habitat for vernal pool fairy shrimp are extremely variable and range from clear sandstone pools with little alkalinity to turbid vernal pools on clay soils with moderate alkalinity (King et al. 1996, Eriksen and Belk 1999). Common wetland plant species that co-occur with vernal pool fairy shrimp include toad rush (*Juncus bufonius*), coyote thistle (*Eryringium* spp.), downingia (*Downingia ornatissma* or *D. bicornuta*), goldfields (*Lasthenia* spp.), woolly marbles (*Psilocarphus* spp.), and hair grass (*Deschampsia* spp.) (King et al. 1996, Alexander and Schlising 1997, 1998, Helm 1998, Plattencamp 1998, Eriksen and Belk 1999, Alexander 2007). Vernal pool fairy shrimp have also occasionally been found in degraded vernal pool habitats and artificially-created seasonal pools (Helm 1998). Vernal pool fairy shrimp commonly co-occur with the fairy shrimp (*Linderiella occidentalis*, *Branchinecta conservatio*, *B. lindahli*, *B. coloradensis*) and vernal pool tadpole shrimp (*Lepidurus packardi*). The midvalley shrimp (*B. mesovallensis*) and *B. longiantenna* both occur within the range of vernal pool tadpole shrimp but are typically found in different habitats (USFWS 2005, 2007).

A40.4 LIFE HISTORY

Description. Vernal pool fairy shrimp is a typical Branchinectid anostracan. They are typically off-white to grey. Depending on the rapidity of development, mature animals may vary in length from 3 to 38 millimeters (0.12 to 1.50 inch). Like other fairy shrimp, they are entirely aquatic with delicate elongate bodies, large stalked compound eyes, no carapaces, and eleven pairs of swimming legs. Males and females are generally differentiated on the basis of antennae development, thoracic projections, and brood pouch development.

Reproduction and Growth. Vernal pool fairy shrimp are adapted to the environmental conditions of their ephemeral habitats. One adaptation is the ability of vernal pool fairy shrimp eggs, or cysts, to remain dormant in the soil when their vernal pool habitats are dry. The cysts survive the hot, dry summers and cold, wet winters that follow until vernal pools and swales fill with rainwater and conditions are right for hatching. When the pools refill in the same or subsequent seasons some, but not all, of the eggs may hatch. The egg bank in the soil may comprise eggs from several years of breeding (USFWS 2005, 2007). Beyond inundation of the habitat, the specific cues for hatching are unknown, although temperature and conductivity (solute concentration) are believed to play a large role (Helm 1998, Eriksen and Belk 1999).

In a study using large plastic pools to simulate natural vernal pools, Helm found no difference in the time to reproduce among California linderiella, Conservancy fairy shrimp, longhorn fairy shrimp, vernal pool fairy shrimp, midvalley fairy shrimp, and vernal pool tadpole shrimp (46 days) (Helm 1998). However, that experiment supplemented by field data (Gallagher 1996, Alexander 2007) suggests that the average time to reproduce for California linderiella, Conservancy fairy shrimp, longhorn fairy shrimp, and vernal pool fairy shrimp is approximately 8 weeks, while that for midvalley fairy shrimp is approximately 2 weeks. No data were reported regarding pool fertility or the impacts of predation on the time to reproduce. These reproduction periods may be shortened or lengthened by warmer or colder water temperatures (Helm 1998).

Feeding. Vernal pool fairy shrimp is an omnivorous filter-feeder. In general, all fairy shrimp species indiscriminately filter particles that include bacteria, unicellular algae, and micrometazoa (Eriksen and Belk 1999). The precise size of items these fairy shrimp are capable of filtering is currently unknown. However, fairy shrimp species will attempt to consume whatever material they can fit into their feeding groove and do not discriminate based upon taste, as do some other crustacean groups (Eriksen and Belk 1999).

Predation and Dispersal. Planktonic Crustacea are important in the food web, as they represent a high-fat, high-protein resource for migratory waterfowl. Mallard (*Anas platyrhynchos*), green-winged teal (*A. crecca*), bufflehead (*Bucephala albeola*), greater yellowlegs (*Tringa melanoleuca*), and killdeer (*Charadrius vociferus*) all forage actively in Central Valley vernal pools on the invertebrate and amphibian fauna during the winter months (Silveira 1996, Bogiatto and Karnegis 2006).

Predator consumption of fairy shrimp cysts aids in distributing populations of fairy shrimp. Predators (e.g., birds and amphibians) expel viable cysts in their excrement, often at locations other than where they were consumed. If conditions are suitable, these transported cysts may hatch at the new location and potentially establish a new population. Cysts are also transported by wind and in mud carried on the feet of animals, including livestock that may wade through fairy shrimp habitat. This type of dispersal aids ephemeral pool crustaceans in exploiting a wide variety of ephemeral habitats (Erickson and Belk 1999).

A40.5 THREATS AND STRESSORS

Threats to vernal pool habitat and species in general, including vernal pool fairy shrimp, were identified in the Recovery Plan (USFWS 2005, 2007). In addition, the Recovery Plan identified several threats specific to vernal pool fairy shrimp. Within the entire range of the species, more than half of the known populations of vernal pool fairy shrimp are threatened by development or agricultural conversion. Several populations are found on military bases, and although not an immediate threat, military activities can result in alteration of pool characteristics, including introduction of non-native plant species (USFWS 2005, 2007).

Habitat Loss and Fragmentation. Habitat loss and fragmentation were identified as the largest threats to the survival and recovery of vernal pool species. Habitat loss generally is a result of agricultural conversion from rangelands to intensive farming, urbanization, aggregate mining, infrastructure projects (such as roads and utility projects), and recreational activities (such as off-highway vehicles and hiking) (USFWS 2005, 2007). Habitat fragmentation occurs when vernal pool complexes are broken into smaller groups or individual vernal pools and become isolated from each other as a result of activities such as road development and other infrastructure projects (USFWS 2005, 2007).

Agricultural Conversion. Conversion of land use, such as from grasslands or pastures to more intensive agricultural uses (e.g., croplands) or from one crop type to another has contributed and continues to contribute to the decline of vernal pools in general (USFWS 2005, 2007).

Invasive Species. The invasions of vernal pools by waxy mannagrass (*Glyceria declinata*), an invasive aquatic grass (Gerlach et al. 2009), greatly increases the amount of decomposing biomass in vernal pools and may result in higher respiratory oxygen consumption relative to photosynthetic oxygen generation (Rogers 1998). Also, upland biomass of invasive species such as medusahead (*Taeniatherum caput-medusae*) can produce dense vegetation and thatch, shortening the ponding duration of some vernal pools (Marty 2004, Pyke and Marty 2005). Italian ryegrass (*Lolium multiflorum*) has rapidly become a dominant invasive species of the uppermost zone of vernal pools and appears to have undergone rapid adaptation to alkaline clay soils (Dawson et al. 2007).

Altered Hydrology. Human disturbances can alter the hydrology of temporary waters and result in a change in the timing, frequency, or duration of inundation in vernal pools, which can create conditions that render existing vernal pools unsuitable for vernal pool species (USFWS 2005, 2007).

Habitat alteration may also occur due to large-scale climate and environmental changes, such as global climate change, which lead to changes in precipitation patterns and atmospheric conditions. Most of the populations of vernal pool fairy shrimp are isolated from other populations and are distributed in discontinuous vernal pool systems. Small, isolated populations are vulnerable, which could result in extirpation from a particular area (USFWS 2005, 2007).

A40.6 RELEVANT CONSERVATION EFFORTS

A total of 597,821 acres, occupying 30 units, has been designated as critical habitat within the state of California (71 FR 7118). Critical habitat unit 16A, which is immediately north of the Potrero Hills, and units 19A and 19B in east Contra Costa County are partially within the Plan Area. In addition, approximately 13,000 acres of vernal pool habitats, including mitigation banks, have been set aside for vernal pool fairy shrimp specifically as terms and conditions of Section 7 consultations. These areas are scattered throughout the Central Valley and represent important building blocks toward recovery of vernal pool fairy shrimp. Throughout the range of the species, vernal pool habitats supporting populations of vernal pool fairy shrimp have been protected through a variety of other means, including preserves, refuges, and protections on private lands. In the Solano-Colusa Vernal Pool Region, vernal pool fairy shrimp are protected in the Jepson Prairie Ecosystem, including the Tule Ranch unit of the DFG Yolo Bypass Wildlife Area (Tule Ranch, DFG Calhoun Cut Ecological Reserve, Burke Ranch, Jepson Prairie Preserve, and Montezuma Wetlands Mitigation owned by the Solano County Open Space and Farmland Conservancy (USFWS 2005, 2007). Known occurrences in sandstone depression pools in the Altamont area are protected in the Brushy Peak and Vasco Caves preserves that are on property owned and managed by the East Bay Regional Parks District (USFWS 2007).

Vernal pool fairy shrimp is covered under the approved San Joaquin County Multi-species Habitat Conservation and Open Space Plan, Natomas Basin Habitat Conservation Plan, and East Contra Costa Habitat Conservation Plan/Natural Community Conservation Plan. In addition, the species is proposed for coverage under the Solano County Multispecies Habitat Conservation Plan, South Sacramento County Habitat Conservation Plan, the Yolo County Natural Heritage Program Plan that are under development, and the Butte Regional Conservation Plan.

A40.7 SPECIES HABITAT SUITABILITY MODEL

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing GIS data sources (described below and in Section 2.3.1, *Data Sources and Natural Community Classification*). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as vernal pools, individual trees, or small groups of trees. It is also possible, as with vernal pool fairy shrimp, to underestimate potentially-occupied habitat due to the lack of information on small, degraded or artificially-created seasonal wetland habitats.

Still, for most species the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

For each model, the mapping data sets and each vegetation type or association is identified. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. Vernal pool fairy shrimp model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), DWR 2007 LiDAR elevation data, Google Earth 2009 aerial imagery and USDA 2005 aerial photography. Using these data sets, the model maps the distribution of suitable vernal pool fairy shrimp habitat in the Plan Area according to the species' two habitat types, vernal pool complex and degraded vernal pool complex habitat. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Vernal Pool Complex Habitat: High quality permanent habitat that consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly impacted by agricultural or development practices. Vernal pool complex habitat for vernal pool fairy shrimp includes the following vegetation subunits that were selected from the BDCP vernal pool complex natural community:

- Vernal pool complex – all vegetation types

Degraded Vernal Pool Complex Habitat: Low quality ephemeral habitat that ranges from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, disking, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. The aquatic features in this habitat are more clearly classified as temporary waters sensu lato (Williams 2006) than intact and fully functional vernal pools. Because these features are inundated during the wet season and may have historically been located in or near areas with natural vernal pool complex, they may support individuals or small populations of species that are found in vernal pools and swales. However, they do not posses the full complement of ecosystem and community characteristics of natural vernal pools, swales and their associated uplands and they are generally ephemeral features that are eliminated during the course of normal agricultural practices. Degraded vernal pool complex habitat for vernal pool fairy shrimp includes the following vegetation subunits that were selected from the BDCP other natural seasonal wetlands and grasslands communities:

- Grasslands
    - Degraded vernal pool complex – California annual grasslands;
    - Degraded vernal pool complex – Ruderal herbaceous grasses and forbs;
    - Degraded vernal pool complex – Italian rye-grass (*Lolium multiflorum*); and
    - Degraded vernal pool complex – Rabbitsfoot grass (*Polygpogon maritimus*).
- Other natural seasonal wetlands
    - Degraded vernal pool complex- Vernal pools.

Potential habitat without concave surfaces was removed from the model. LiDAR elevation data was then visually inspected in four general areas to further assess specific locations that had been identified by the habitat selection process. These areas were selected based both on *a priori* knowledge of the region and because they were identified by the intersection of the selected vegetation types and soils. The analysis of the LiDAR data further refined the habitat model and provided a more accurate demarcation of suitable habitat. The GIS habitat model was then compared against field data from surveys conducted by the DWR in 2009. Land uses that are incompatible with the species' habitat requirements, for example, potential habitat polygons falling on leveled or developed lands were removed from the model.

Assumptions. Historical and current records of this species in the Plan Area indicate that it occurs in appropriate habitat along the perimeter of the Plan Area (Figure A-40b) (Witham 2002, 2003, 2006, ESA 2005, Barona et al. 2007, CNDDB 2010).

A40.8 RECOVERY GOALS

A general statement for recovery of vernal pool fairy shrimp is presented in the USFWS (2005) Recovery Plan: to ensure protection of the full geographic, genetic, and ecological extent of this species and to improve the circumstances that caused it to be listed in the first place. Accomplishment of this goal would be achieved by protecting 80 percent of species occurrences throughout its range, including 85 percent of its suitable habitat in 38 core areas. In addition, the species would be reintroduced into vernal pool regions and soil types from which surveys indicate that it has been eradicated.

APPENDIX A 41. MIDVALLEY FAIRY SHRIMP (*BRANCHINECTA MESOVALLENSIS*)

A41.1 LEGAL STATUS

Midvalley fairy shrimp (*Branchinecta mesovallensis*) currently has no legal status under either the state or federal endangered species acts. It was petitioned for listing under the federal Endangered Species Act in 2001. In 2003, the U.S. Fish and Wildlife Service (USFWS) published a finding (68 FR 22724) that the petition provided substantial evidence to indicate that listing may be warranted. However, in 2004 the USFWS determined, following a review of available scientific and commercial information, that listing was not warranted (69 FR 3592).

A41.2 SPECIES DISTRIBUTION AND STATUS

A41.2.1 Range and Status

Distribution. Midvalley fairy shrimp is endemic to California Central Valley grassland vernal pools (Belk and Fugate 2000). All known occurrences are between central Sacramento County and northern Fresno County (Figure A-41a). Reported occurrences include scattered occurrences from the Mather Field area of Sacramento, south through Galt from Sacramento County; two locations in the Yolo Bypass southwest of Saxon in Yolo County; Jepson Prairie, Travis Air Force Base, and Vacaville areas in Solano County; from Lodi, north to the county border in San Joaquin County; the Byron Airport in Contra Costa County; the Virginia Smith Trust (Haystack Mountain), and Arena Plains National Wildlife Reserve (NWR) in Merced County; one location in central Madera County; and one in northern Fresno County (Eriksen and Belk 1999, Belk and Fugate 2000).

Population Trends. There is no reliable information on population trends for this species due to its recent description (Belk and Fugate 2000), lack of information on its historical distribution, and the extent of loss of vernal pool habitats in the Central Valley.

An unknown amount of vernal pool habitat and midvalley fairy shrimp occurrences have been lost. Attempts have been made to calculate lost vernal pool acreages (Holland 1978, 1988, 1998, Bauder and McMillan 1998). Due to increasing pressures of human populations in California and Oregon, more vernal pool habitat is being encroached upon and affected throughout the species' range.

Adequate determination of remaining midvalley fairy shrimp occurrences throughout the animal's range, as well as population trends, remains largely incomplete. Eriksen and Belk (1999) present a map of localities for the midvalley fairy shrimp with less than 30 localities represented; the greatest density of occurrences is in southern Sacramento County.

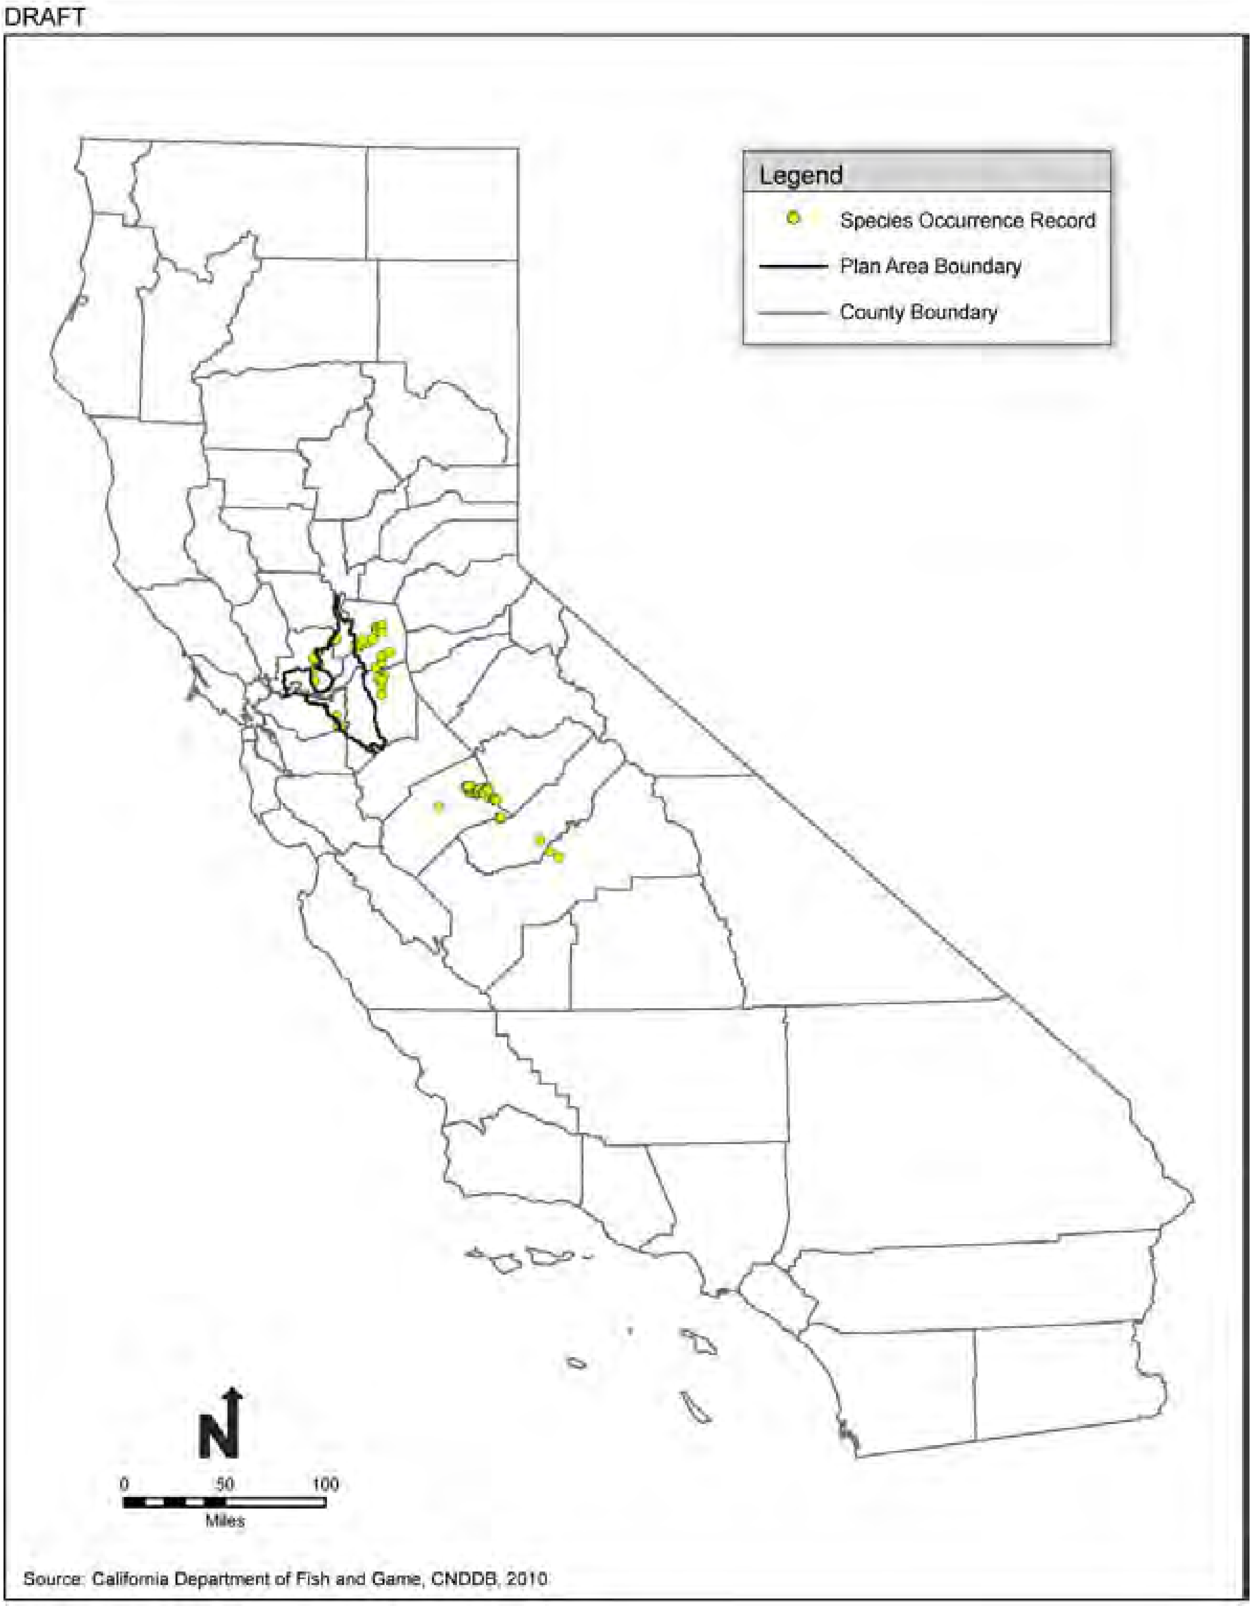

Figure A-41a. Midvalley Fairy Shrimp Statewide Recorded Occurrences

This generally corresponds with the current distribution as derived from California Natural Diversity Database (CNDDB) occurrences (CNDDB 2010). A further complication may be that midvalley fairy shrimp possibly escape early detection particularly during dry years or during the dry season because they inhabit swales and short-lived pools to a greater extent relative to other species (Helm 1998, Belk and Fugate 2000).

A41.2.2 Distribution and Status in the Plan Area

Distribution and status in the Plan Area is largely unknown and based primarily on CNDDB records, which provide an incomplete and inconsistent record of occurrence for this species. Recorded locations from the Plan Area include several occurrences in the vicinity of the Cosumnes River Preserve and two locations in the Yolo Bypass, both in small vernal pools southwest of Saxon (CNDDB 2010) (Figure A-41b). Based on existing knowledge of the species' requirements, the species could potentially occur in shallow grassland vernal pools and similar seasonal wetlands wherever they occur in the Plan Area. More complete systematic surveys would be required to more accurately determine the distribution of this species in the Plan Area.

A41.3 Habitat Requirements and Special Conditions

This species is entirely dependent on the aquatic environment provided by the temporary waters of natural vernal pool and playa pool ecosystems as well as the artificial environments of ditches and tire ruts (King et al. 1996, Helm 1998, Eriksen and Belk 1999). The temporary waters in which vernal pool tadpole shrimp inhabits fill in the fall and winter during the beginning of the wet season and dry in late-spring at the beginning of the dry season and remain desiccated throughout the summer (Helm 1998, Eriksen and Belk 1999). The temporary waters fill directly from precipitation as well as from runoff from their watersheds (Williamson et al. 2005, Rains et al. 2006, 2008, O'Geen et al. 2008). The watershed extent that is necessary for maintaining the hydrological functions of the temporary waters depends on a number of complex factors including the hydrologic conductivity of the surface soil horizons, the continuity and extent of hard-pans and clay-pans underlying non-clay soils, the existence of a perched aquifer overlying the pans, slope, effects of vegetation on evapotranspiration rates, compaction of surface soils by grazing animals, and other factors (Marty 2004, Pyke and Marty 2005, Williamson et al. 2005, Rains et al. 2006, 2008, O'Geen et al. 2008).

The temporary waters that are habitat for midvalley fairy shrimp are extremely variable and range from clear sandstone pools with little alkalinity to turbid vernal pools on clay soils with moderate alkalinity (King et al. 1996, Eriksen and Belk 1999).

DRAFT

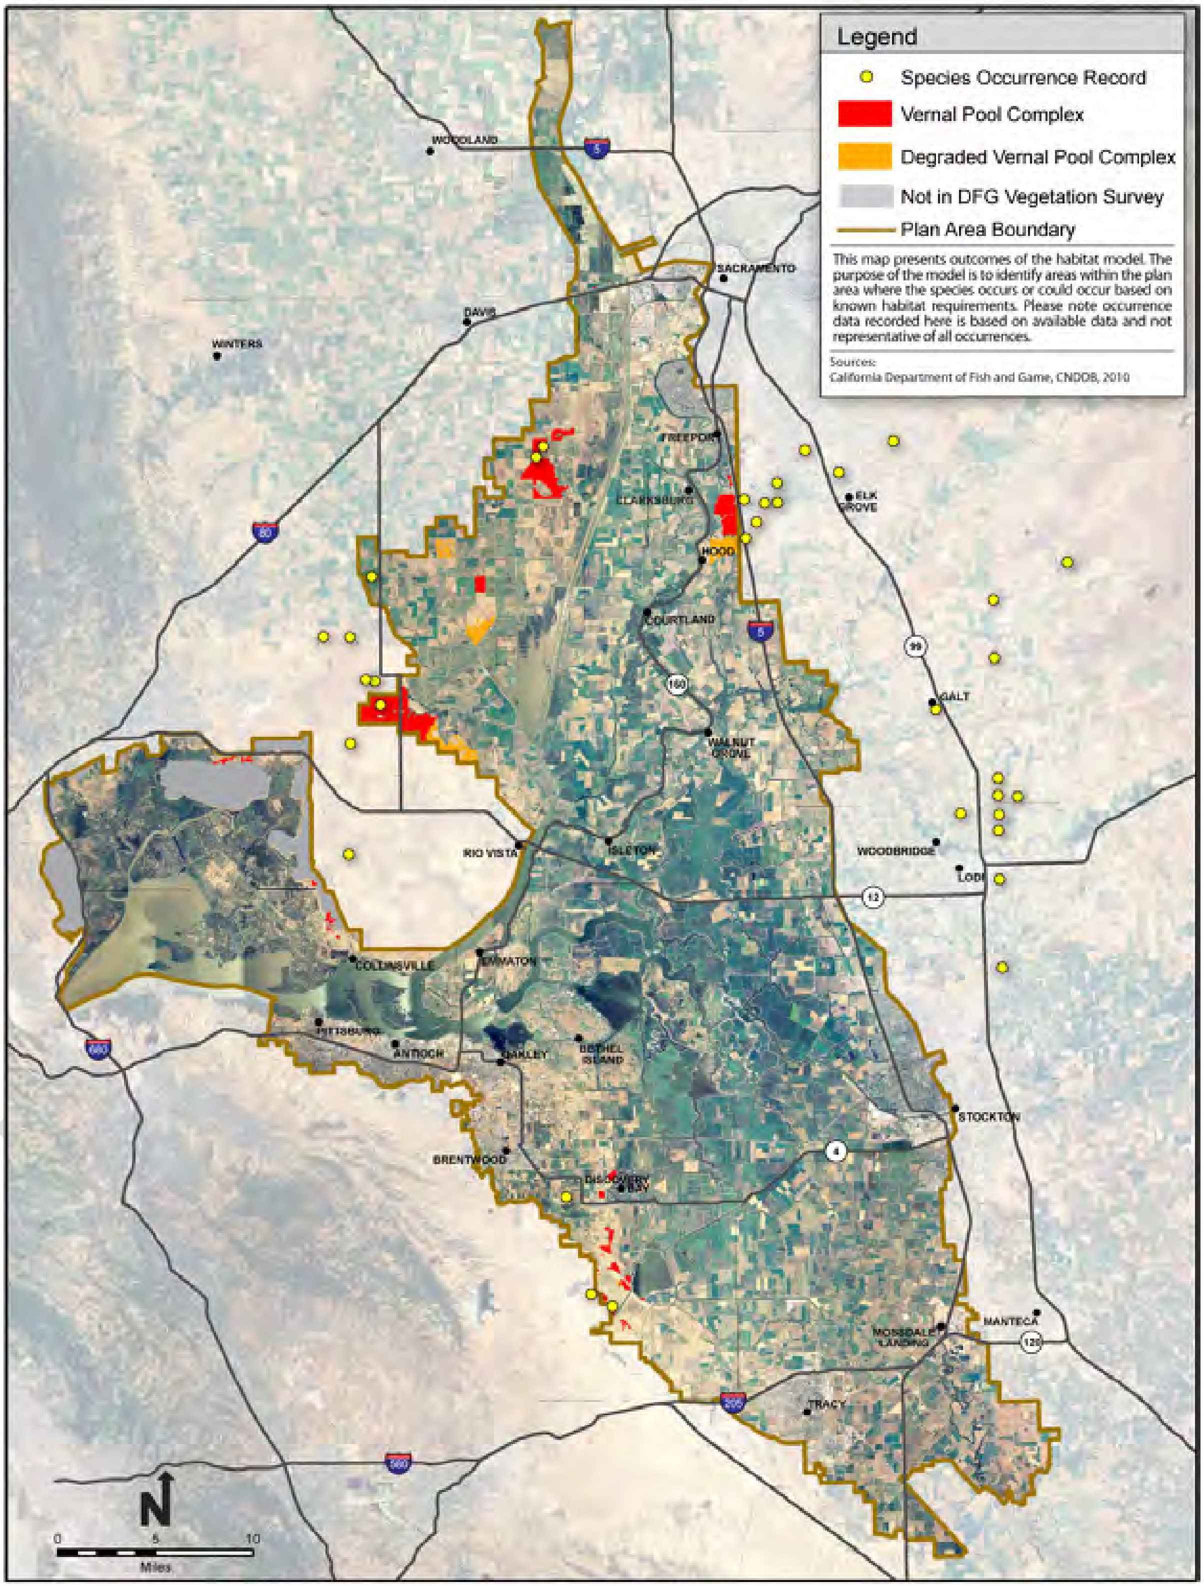

Figure A-41b. Midvalley Fairy Shrimp Habitat Model and Recorded Occurrences

Common wetland plant species that co-occur with midvalley shrimp include toad rush (*Juncus bufonius*), coyote thistle (*Eryringium* spp.), downingia (*Downingia ornatissma* or *D. bicornuta*), goldfields (*Lasthenia* spp.), woolly marbles (*Psilocarphus* spp.), and hair grass (*Deschampsia* spp.) (King et al. 1996, Alexander and Schlising 1997, 1998, Helm 1998, Plattencamp 1998, Eriksen and Belk 1999, Alexander 2007).

Vernal pools that support these fairy shrimp are often grass or mud-bottomed, with clear to tea-colored water, and are often in basalt flow depression pools in grasslands (Eriksen and Belk 1999). Midvalley fairy shrimp have been found in habitats ranging from 0.0004 to 0.2 hectares (0.001 to 0.5 acre) and typically are found in smaller, short-lived pools and other seasonal wetlands compared with other species within the same genus (Eriksen and Belk 1999).

Midvalley fairy shrimp commonly co-occur with California fairy shrimp (*Linderiella occidentalis*) (Eriksen and Belk 1999, Rogers in review). This species has also been reported co-occurring with the vernal pool fairy shrimp (*Branchinecta lynchi*) (Eng et al. 1990) on three occasions, where midvalley fairy shrimp was probably washed into the vernal pool fairy shrimp habitat by abnormally high rainfall (Eriksen and Belk 1999).

A41.4 LIFE HISTORY

Description. Midvalley fairy shrimp is a typical branchinectid anostracan. Live animals are typically off-white to grey, although the brood pouch may be green or yellow. Depending upon the rapidity of development, mature animals may vary in length from 3 to 38 millimeters (0.12 to 1.5 inch). Like other fairy shrimp, they are entirely aquatic with delicate elongate bodies, large stalked compound eyes, no carapaces, and eleven pairs of swimming legs. Males and females are generally differentiated on the basis of antennae development, thoracic projections, and brood pouch development.

Reproduction and Growth. During the dry phase of their habitat, the anostracans survive as diapausing cysts (resting eggs) in and on the substrate (Sars 1896, 1898, Eriksen and Belk 1999, Rogers and Fugate 2001). When the habitat inundates from seasonal rainfall, some of the cysts hatch, and the nauplii (early larval form of anostraca) swim into the upper water column (Eriksen and Belk 1999). The cysts lie dormant in the substrate until the pool dries and re-inundates during the subsequent rains. Beyond inundation of the habitat, the specific cues for hatching are unknown, although temperature and conductivity (solute concentration) are believed to play a large role (Helm 1998, Eriksen and Belk 1999).

In a study using large plastic pools to simulate natural vernal pools, Helm found no difference in the time to reproduce among California linderiella, Conservancy fairy shrimp, longhorn fairy shrimp, vernal pool fairy shrimp, midvalley fairy shrimp, and vernal pool tadpole shrimp (46 days) (Helm 1998). However, that experiment supplemented by field data (Gallagher 1996, Alexander 2007) suggests that the average time to reproduce for California linderiella, Conservancy fairy shrimp, longhorn fairy shrimp, and vernal pool fairy shrimp is approximately

8 weeks, while that for midvalley fairy shrimp is approximately 2 weeks. No data were reported regarding pool fertility or the impacts of predation on the time to reproduce. These reproduction periods may be shortened or lengthened by warmer or colder water temperatures (Helm 1998).

Predation and Dispersal. Planktonic Crustacea are important in the food web, as they represent a high-fat, high-protein resource for migratory waterfowl. Mallard (*Anas platyrhynchos*), green-winged teal (*A. crecca*), bufflehead (*Bucephala albeola*), greater yellowlegs (*Tringa melanoleuca*), and killdeer (*Charadrius vociferus*) all forage actively in Central Valley vernal pools on the invertebrate and amphibian fauna during the winter months (Silveira 1996, Bogiatto and Karnegis 2006).

Predator consumption of fairy shrimp cysts aids in distributing populations of fairy shrimp. Predators (e.g., birds and amphibians) expel viable cysts in their excrement, often at locations other than where they were consumed. If conditions are suitable, these transported cysts may hatch at the new location and potentially establish a new population. Cysts are also transported by wind and in mud carried on the feet of animals, including livestock that may wade through fairy shrimp habitat. This type of dispersal aids ephemeral pool crustaceans in exploiting a wide variety of ephemeral habitats (Erickson and Belk 1999).

A41.5 Threats and Stressors

Threats to vernal pool habitat and species in general, including midvalley fairy shrimp, were identified in the Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon (USFWS 2005). In addition, the Recovery Plan identified several threats specific to midvalley fairy shrimp.

Habitat Loss and Fragmentation. Habitat loss and fragmentation were identified as the largest threats to the survival and recovery of vernal pool species. Habitat loss generally is a result of agricultural conversion from rangelands to intensive farming, urbanization, aggregate mining, infrastructure projects (such as roads and utility projects), and recreational activities (such as off-highway vehicles and hiking) (USFWS 2005). Habitat fragmentation occurs when vernal pool complexes are broken into smaller groups or individual vernal pools and become isolated from each other as a result of activities such as road development and other infrastructure projects (USFWS 2005).

Agricultural Conversion. Conversion of land use, such as from grasslands or pastures, to more intensive agricultural uses (e.g., croplands) or from one crop type to another, has contributed and continues to contribute to the decline of vernal pools in general (USFWS 2005).

Competition from Invasive Species. Vernal pool plant species have declined due to the introduction of invasive non-native plant and animal species. Changes in hydrology and poor grazing management has contributed to increasing dominance by invasive plants, which affects habitat suitability for midvalley fairy shrimp (Marty 2004).

Invasive Species. The invasions of vernal pools by waxy mannagrass (*Glyceria declinata*), an invasive aquatic grass (Gerlach et al. 2009), greatly increases the amount of decomposing biomass in vernal pools and may result in higher respiratory oxygen consumption relative to photosynthetic oxygen generation (Rogers 1998). Also, upland biomass of invasive species such as medusahead (*Taeniatherum caput-medusae*) can produce dense vegetation and thatch, shortening the ponding duration of some vernal pools (Marty 2004, Pyke and Marty 2005). Italian ryegrass (*Lolium multiflorum*) has rapidly become a dominant invasive species of the uppermost zone of vernal pools and appears to have undergone rapid adaptation to alkaline clay soils (Dawson et al. 2007).

Altered Hydrology. Human disturbances can alter the hydrology of temporary waters and result in a change in the timing, frequency, or duration of inundation in vernal pools, which can create conditions that render existing vernal pools unsuitable for vernal pool species (USFWS 2005).

A41.6 Relevant Conservation Efforts

Midvalley fairy shrimp is not listed; however, it may be protected through conservation efforts for vernal pool ecosystems in general. USFWS (2005) reports that of 53 midvalley fairy shrimp locations (as of 2003) 22 (41.5 percent) are on protected lands, including two National Wildlife Refuges (NWRs), several vernal pool mitigation banks, a DFG Ecological Reserve, and several Nature Conservancy conservation easements.

Midvalley fairy shrimp is covered under the approved Natomas Basin Habitat Conservation Plan, San Joaquin County Multi-species Habitat Conservation and Open Space Plan, and East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan. Further, the species is proposed for coverage under the Solano County Multispecies Habitat Conservation Plan, Yolo County Natural Heritage Program Plan, and South Sacramento County Habitat Conservation Plan.

A41.7 Species Habitat Suitability Model

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below and in section 2.3.1, *Data Sources and Natural Community Classification*). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as individual trees or small groups of trees. It is also possible, as with some vernal pool invertebrates that are restricted to seasonally ponded habitats, to underestimate potentially-occupied habitat due to the lack of information on small, degraded or artificially-created seasonal wetland habitats.

Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. Midvalley fairy shrimp model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), California Department of Water Resources (DWR) 2007 LiDAR elevation data, Google Earth 2009 aerial imagery and United States Department of Agriculture (USDA) 2005 aerial photography. Using these data sets, the model maps the distribution of suitable midvalley fairy shrimp habitat in the Plan Area according to the species' two habitat types, vernal pool complex and degraded vernal pool complex habitat. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Vernal Pool Complex Habitat: High quality permanent habitat that consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly impacted by agricultural or development practices. Vernal pool complex habitat for midvalley fairy shrimp includes the following vegetation subunits that were selected from the BDCP vernal pool complex natural community:

- Vernal pool complex – all vegetation types

Degraded Vernal Pool Complex Habitat: Low quality ephemeral habitat that ranges from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, disking, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. The aquatic features in this habitat are more clearly classified as temporary waters *sensu lato* (Williams 2006) than intact and fully functional vernal pools. Because these features are inundated during the wet season and may have historically been located in or near areas with natural vernal pool complex, they may support individuals or small populations of species that are found in vernal pools and swales. However, they do not possess the full complement of ecosystem and community characteristics of natural vernal pools, swales and their associated uplands and they are generally ephemeral features that are eliminated during the course of normal agricultural practices. Degraded vernal pool complex habitat for midvalley fairy shrimp includes the following vegetation subunits that were selected from the BDCP's other natural seasonal wetlands and grasslands communities:

- Grasslands
  - Degraded vernal pool complex – California annual grasslands;
  - Degraded vernal pool complex – Ruderal herbaceous grasses and forbs;
  - Degraded vernal pool complex – Italian rye-grass (*Lolium multiflorum*); and
  - Degraded vernal pool complex – Rabbitsfoot grass (*Polygpogon maritimus*).
- Other natural seasonal wetlands
  - Degraded vernal pool complex-vernal pools.

Potential habitat without concave surfaces was removed from the model. LiDAR elevation data was then visually inspected in four general areas to further assess specific locations that had been identified by the habitat selection process. These areas were selected based both on *a priori* knowledge of the region and because they were identified by the intersection of the selected vegetation types and soils. The analysis of the LiDAR data further refined the habitat model and provided a more accurate demarcation of suitable habitat. The GIS habitat model was then compared against field data from surveys conducted by the DWR in 2009. Land uses that are incompatible with the species' habitat requirements, for example, potential habitat polygons falling on leveled or developed lands were removed from the model.

Assumptions. Historical and current records of this species in the Plan Area indicate that it occurs in appropriate habitat along the perimeter of the Plan Area (Figure A-41b) (Witham 2002, 2003, 2006, CNDDB 2010). The vegetation cover of the alkaline soils is typically a combination of vernal pool adapted species and annual ryegrass (Witham 2002, 2003, 2006, CNDDB 2010).

A41.8 RECOVERY GOALS

A general statement for recovery of midvalley fairy shrimp is presented in the USFWS (2005) Recovery Plan: to achieve and protect, in perpetuity, self-sustaining populations throughout the full ecological, geographic, and genetic range of the species and to ameliorate or eliminate threats to the species. Interim goals are to stabilize and protect populations and conduct research to refine reclassification and recovery criteria. Vernal pool habitats used by the species as well as historical and potential habitats need to be protected, and habitat management plans for these habitats need to be developed and implemented. Recovery criteria have been established in the Recovery Plan (USFWS 2005).

APPENDIX A42. CALIFORNIA LINDERIELLA *(LINDERIELLA OCCIDENTALIS)*

A42.1 LEGAL STATUS

California linderiella (*Linderiella occidentalis*) has no state or federal regulatory status. This species was addressed as a species of concern by the U.S. Fish and Wildlife Service (USFWS) in the December 15, 2005, Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon (USFWS 2005).

A42.2 SPECIES DISTRIBUTION AND STATUS

A42.2.1 Range and Status

California linderiella is the most common fairy shrimp in California and is endemic to the state (Eriksen and Belk 1999). It has been reported in the Central Valley from Shasta County south to Fresno County and in the Coast and Transverse ranges from Mendocino County south to Ventura County (Figure A-42a) (Eriksen and Belk 1999, CNDDB 2010) and has been collected at elevations from near sea level to 1,159 meters (3,800 feet) (Eriksen and Belk 1999).

California linderiella co-occurs with 19 other large branchiopods including conservancy fairy shrimp (*Branchinecta conservatio*), longhorn fairy shrimp (*B. longiantenna*), vernal pool fairy shrimp (*B. lynchi*), mid-valley fairy shrimp (*B. mesovallensis*), and vernal pool tadpole shrimp (*Lepidurus packardi*) (Helm 1998, Eriksen and Belk 1999). It most often co-occurs in pools also inhabited by vernal pool fairy shrimp, in which case California linderiella is generally more numerous (Eriksen and Belk 1999).

A42.2.2 Distribution and Status in the Plan Area

California linderiella has been reported from several locations within the Plan Area (Figure A-42b) (USFWS 2005, CNDDB 2010). In general, within the Plan Area, vernal pools that may support the species occur on alkaline clay soils from the California Department of Fish and Game (DFG) Tule Ranch Reserve southwest to the Montezuma Wetlands Mitigation Projects and from the Byron Airport to Discovery Bay. Other potential vernal pool habitat occurs on clay-pan soils along the eastern boundary of the Plan Area near Stone Lakes. California linderiella was not found during 2009 surveys conducted by the California Department of Water Resources (DWR) in the Stone Lakes and Clifton Court Forebay areas.

Figure A-42b. California Linderiella Habitat Model and Recorded Occurrences

A42.3 HABITAT REQUIREMENTS AND SPECIAL CONDITIONS

This species is entirely dependent on the aquatic environment provided by the temporary waters of natural vernal pool and playa pool ecosystems as well as the artificial environments of ditches and tire ruts (King et al. 1996, Helm 1998, Eriksen and Belk 1999). The temporary waters in which California linderiella inhabits fill in the fall and winter during the beginning of the wet season and dry in late spring at the beginning of the dry season and remain desiccated throughout the summer (Eriksen and Belk 1999). The temporary waters fill directly from precipitation as well as from runoff from their watersheds (Williamson et al. 2005, Rains et al. 2006, 2008, O'Geen et al. 2008). The watershed extent that is necessary for maintaining the hydrological functions of the temporary waters depends on a number of complex factors including the hydrologic conductivity of the surface soil horizons, the continuity and extent of hard-pans and clay-pans underlying non-clay soils, the existence of a perched aquifer overlying the pans, slope, effects of vegetation on evapotranspiration rates, compaction of surface soils by grazing animals, and other factors (Marty 2004, Pyke and Marty 2005, Williamson et al. 2005, Rains et al. 2006, 2008, O'Geen et al. 2008).

The temporary waters that are habitat for California linderiella are extremely variable and range from clear sandstone pools with little alkalinity to turbid vernal pools on clay soils with moderate alkalinity (King et al. 1996, Eriksen and Belk 1999, CNDDB 2010). Common wetland plant species that co-occur with California linderiella include toad rush (*Juncus bufonius*), coyote thistle (*Eryringium* spp.), downingia (*Downingia ornatissma* or *D. bicornuta*), goldfields (*Lasthenia* spp.), woolly marbles (*Psilocarphus* spp.), and hair grass (*Deschampsia* spp.) (King et al. 1996, Alexander and Schlising 1997, 1998, Helm 1998, Plattencamp 1998, Eriksen and Belk 1999, Alexander 2007).

California linderiella is a component of a larger invertebrate community (King et al. 1996, Rogers 1998, Eriksen and Belk 1999). This invertebrate community includes mostly planktonic Crustacea dependent on temporary waters, including copepods, cladocerans, and ostracodes—as well as flatworms and a suite of insect species, including vernal pool haliplid beetle (*Apterliplus parvulus*), scimitar backswimmers (*Buenoa scimitra*), Ricksecker's hydrochara (*Hydrochara rickseckeri*), and many others (Rogers 1998). These habitats are usually low in opportunistic species that include mosquitoes and chironomid midges in the genus *Chironomus* (Rogers 1998).

A42.4 LIFE HISTORY

Description. Like other fairy shrimp, California linderiella is entirely aquatic with delicate elongate bodies, large stalked compound eyes, no carapaces, and eleven pairs of swimming legs. Males and females are generally differentiated on the basis of antennae development, thoracic projections, and brood pouch development. Live animals are off-white to grayish in color and are translucent, but unlike similar fairy shrimp in the genus Branchinecta, California linderiella tend to be slightly smaller and have distinctive red eyes (Eriksen and Belk 1999).

Reproduction and Growth. Like other fairy shrimp species, California linderiella are adapted to the environmental conditions of their ephemeral habitats. One adaptation is the ability of the eggs, or cysts, to remain dormant in the soil when their vernal pool habitats are dry. The cysts survive the hot, dry summers and cool, wet winters that follow until the vernal pools and swales fill with rainwater and conditions are right for hatching. When the pools refill in the same or subsequent seasons some, but not all, of the eggs may hatch. The egg bank in the soil may include eggs from several years of breeding (USFWS 2005).

Beyond inundation of the habitat, the specific cues for hatching are unknown, although temperature and conductivity (solute concentration) are believed to play a large role (Helm 1998, Eriksen and Belk 1999).

In a study using large plastic pools to simulate natural vernal pools, Helm found no difference in the time to reproduce among California linderiella, conservancy fairy shrimp, longhorn fairy shrimp, vernal pool fairy shrimp, mid-valley fairy shrimp, and vernal pool tadpole shrimp (Helm 1998). However, that experiment supplemented by field data (Gallagher 1996, Alexander 2007) suggests that the average time to reproduce for California linderiella, conservancy fairy shrimp, longhorn fairy shrimp, vernal pool fairy shrimp is approximately 8 weeks, while that for mid-valley fairy shrimp is approximately 2 weeks. No data were reported regarding pool fertility or the impacts of predation on the time to reproduce. These reproduction periods may be shortened or lengthened by warmer or colder water temperatures as the minimum time to reproduce for California linderiella is in the range of 2-4 weeks (Helm 1998).

Feeding. California linderiella is an omnivorous filter-feeder. In general, all fairy shrimp species indiscriminately filter particles that include bacteria, unicellular algae, and micrometazoa (Eriksen and Belk 1999). The precise size of items these fairy shrimp are capable of filtering is currently unknown. However, fairy shrimp species will attempt to consume whatever material they can fit into their feeding groove and apparently do not discriminate based upon taste, as do some other crustacean groups (Eriksen and Belk 1999).

Predation and Dispersal. Planktonic Crustacea are important in the food web, as they represent a high-fat, high-protein resource for migratory waterfowl. Mallard (*Anas platyrhynchos*), green-winged teal (*A. crecca*), bufflehead (*Bucephala albeola*), greater yellowlegs (*Tringa melanoleuca*), and killdeer (*Charadrius vociferus*) all forage actively in Central Valley vernal pools on the invertebrate and amphibian fauna during the winter months (Silveira 1996, Bogiatto and Karnegis 2006).

Predator consumption of fairy shrimp cysts aids in distributing populations of fairy shrimp. Predators (e.g., birds and amphibians) expel viable cysts in their excrement, often at locations other than where they were consumed. If conditions are suitable, these transported cysts may hatch at the new location and potentially establish a new population. Cysts are also transported by wind and in mud carried on the feet of animals, including livestock that may wade through fairy shrimp habitat. This type of dispersal aids ephemeral pool crustaceans in exploiting a wide variety of ephemeral habitats (Erickson and Belk 1999).

A42.5 THREATS AND STRESSORS

Threats to vernal pool habitat and California linderiella were identified in the Recovery Plan (USFWS 2005). These threats include the following:

Habitat Loss and Fragmentation. Habitat loss and fragmentation were identified as the largest threats to the survival and recovery of vernal pool species. Habitat loss generally is a result of agricultural conversion from rangelands to intensive farming, urbanization, aggregate mining, infrastructure projects (such as roads and utility projects), and recreational activities (such as off-highway vehicles and hiking) (USFWS 2005). Habitat fragmentation occurs when vernal pool complexes are broken into smaller groups or individual vernal pools and become isolated from each other as a result of activities such as road development and other infrastructure projects (USFWS 2005).

Agricultural Conversion. Conversion of land use, such as from grazed grasslands to more intensive agricultural uses (e.g., rice, vineyards, and orchards) has contributed and continues to contribute to the decline of vernal pools in general (USFWS 2005).

Invasive Species. The invasions of vernal pools by waxy mannagrass (*Glyceria declinata*), a non-native invasive aquatic grass (Gerlach et al. 2009), greatly increases the amount of decomposing biomass in vernal pools and may result in higher respiratory oxygen consumption relative to photosynthetic oxygen generation (Rogers 1998). Also, upland biomass of non-native invasive species such as medusahead (*Taeniatherum caput-medusae*) can produce dense vegetation and thatch, shortening the ponding duration of some vernal pools (Marty 2004, Pyke and Marty 2005). Italian ryegrass (*Lolium multiflorum*) has rapidly become a dominant non-native invasive species of the uppermost zone of vernal pools and appears to have undergone rapid adaptation to alkaline clay soils (Dawson et al. 2007).

Altered Hydrology. Human disturbances can alter the hydrology of temporary waters and result in a change in the timing, frequency, or duration of inundation in vernal pools, which can create conditions that render existing vernal pools unsuitable for vernal pool species (USFWS 2005).

Mosquito Control. Experiments have shown that mosquito fish (*Gambusia affinis*) that are sometimes introduced into ponds for mosquito control can have a negative impact on California linderiella (Leyse et al. 2004).

A42.6 RELEVANT CONSERVATION EFFORTS

California linderiella is proposed for coverage under the Solano County Multispecies Habitat Conservation Plan and the Yolo County Natural Heritage Program Plan.

A42.7 SPECIES HABITAT SUITABILITY MODEL

Model Approach. BDCP Species Habitat Suitability Models are formulated primarily using vegetation data from existing GIS data sources (described below and in Section 2.3.1, *Data Sources and Natural Community Classification*). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as vernal pools, individual trees, or small groups of trees. It is also possible, as with the California linderiella, to underestimate potentially-occupied habitat due to the lack of information on small, degraded or artificially-created seasonal wetland habitats.

Still, for most species the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lower probability of species occurrence compared with areas identified as suitable habitat.

For each model, the mapping data sets and each vegetation type or association is identified. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the BDCP Plan Area.

GIS Model Data Sources. The California linderiella model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), DWR 2007 LiDAR elevation data, Google Earth 2009 aerial imagery and United States Department of Agriculture (USDA) 2005 aerial photography. Using these data sets, the model maps the distribution of suitable California linderiella habitat in the Plan Area according to the species' two habitat types, vernal pool complex and degraded vernal pool complex habitat.

Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Vernal Pool Complex Habitat. High quality permanent habitat that consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly impacted by agricultural or development practices. Vernal pool complex habitat for California linderiella includes the following vegetation subunits that were selected from the BDCP vernal pool complex natural community:

- Vernal pool complex – all vegetation types

Degraded Vernal Pool Complex Habitat: Low quality ephemeral habitat that ranges from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, disking, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. The aquatic features in this habitat are more clearly classified as temporary waters *sensu lato* (Williams 2006) than intact and fully functional vernal pools. Because these features are inundated during the wet season and may have historically been located in or near areas with natural vernal pool complex, they may support individuals or small populations of species that are found in vernal pools and swales. However, they do not possess the full complement of ecosystem and community characteristics of natural vernal pools, swales and their associated uplands and they are generally ephemeral features that are eliminated during the course of normal agricultural practices. Degraded vernal pool complex habitat for California linderiella includes the following vegetation subunits that were selected from the BDCP other natural seasonal wetlands and grasslands communities:

- Grasslands
    - Degraded vernal pool complex – California annual grasslands;
    - Degraded vernal pool complex – Ruderal herbaceous grasses and forbs;
    - Degraded vernal pool complex – Italian rye-grass (*Lolium multiflorum*); and
    - Degraded vernal pool complex – Rabbitsfoot grass (*Polygpogon maritimus*).
- Other natural seasonal wetlands
    - Degraded vernal pool complex – Vernal pools.

Potential habitat without concave surfaces was removed from the model. LiDAR elevation data was then visually inspected in four general areas to further assess specific locations that had been identified by the habitat selection process. These areas were selected based both on *a priori* knowledge of the region and because they were identified by the intersection of the selected vegetation types and soils. The analysis of the LiDAR data further refined the habitat model and provided a more accurate demarcation of suitable habitat. The GIS habitat model was then compared against field data from surveys conducted by the California Department of Water Resources in 2009. Land uses that are incompatible with the species' habitat requirements, for example, potential habitat polygons falling on leveled or developed lands were removed from the model.

Assumptions. Historical and current records of this species in the Plan Area indicate that it occurs in appropriate habitat along the perimeter of the Plan Area (Figure A-42b) (Witham 2002, 2003, 2006, ESA 2005, CNDDB 2010).

A42.8 RECOVERY GOALS

A general statement for recovery of California linderiella is presented in the USFWS (2005) Recovery Plan: to achieve and protect, in perpetuity, self-sustaining populations throughout the full ecological, geographic, and genetic range of the species and to ameliorate or eliminate threats to the species. Interim goals are to stabilize and protect populations and conduct research to refine reclassification and recovery criteria. Vernal pool habitats used by the species as well as historical and potential habitats need to be protected, and habitat management plans for these habitats need to be developed and implemented. Species-specific recovery criteria are to conserve 80 percent of its occurrences and 95 percent of suitable vernal pool habitat in the Jepson Prairie and Cosumnes-Rancho Seco recovery core areas.

APPENDIX A43. ALKALI MILK-VETCH (*ASTRAGALUS TENER* VAR. *TENER*)

A43.1 LEGAL STATUS

Alkali milk-vetch (*Astragalus tener* var. *tener*) is not listed under either federal or California Endangered Species Acts. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G1T1/S1.1 which means that globally (G) and within the state (S) both the species and variety have either less than six viable element occurrences, less than 1,000 individuals, or less than 2,000 acres (809 hectares) of occupied habitat. Its state threat level rank is "very threatened."

The California Native Plant Society (CNPS) List ranking of 1B.2 for alkali milk-vetch indicates that it is rare, threatened, or endangered in California and elsewhere, and is considered by CNPS to be fairly endangered in California with between 20 to 80 percent of occurrences threatened. Plants with a CNPS List rank of 1B are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

A43.2 SPECIES DISTRIBUTION AND STATUS

A43.2.1 Range and Status

The range of alkali milk-vetch extends from Sonoma, Napa, Solano, and Yolo counties in the north, to Monterey and San Benito counties in the south, to San Francisco, Contra Costa, Alameda, and Santa Clara counties in the west, and San Joaquin, Stanislaus, and Merced counties in the east (Figure A-43a). Alkali milk-vetch was widely distributed around the San Francisco Bay region and in the Sacramento and northern San Joaquin valleys 100 years ago (Barneby 1964), but by 1989 only a few populations remained (Liston 1992). A 2002 survey concluded that 25 of the 65 known occurrences should be considered extirpated (Witham 2002). Sixteen of the known extant occurrences are in the Solano-Colusa Vernal Pool Region of Solano County (Keeler-Wolf et al. 1998), and another five are located in an area between Newman, Merced, and Los Banos in the San Joaquin Vernal Pool Region of Merced County (Silveira 1996 as cited in USFWS 2005, CNDDB 2008). In Yolo County, Crampton (1979) noted the presence of this species near the City of Woodland on the Maupin property. A 1990 survey of historical collection sites in Yolo and Solano counties found six plants at the City of Woodland Preserve and six small populations at the Jepson Prairie Preserve (Witham 1990).

DRAFT

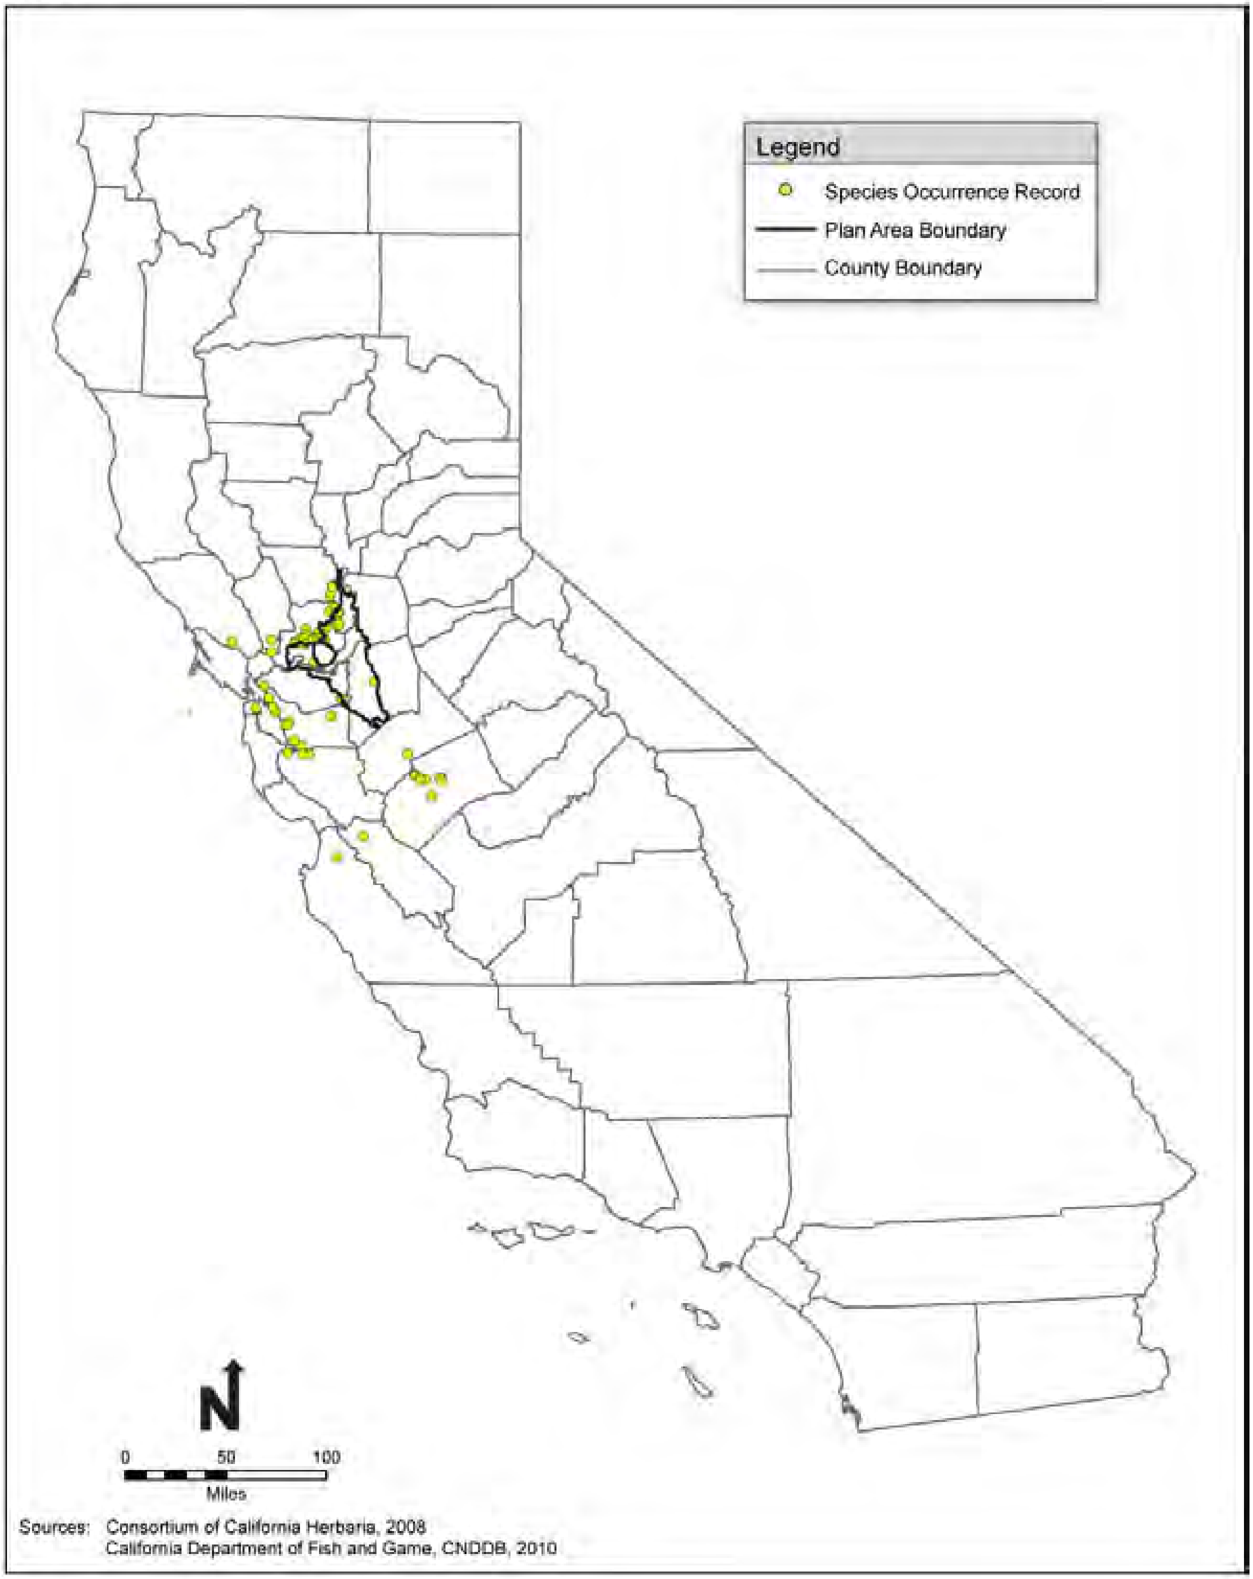

Figure A-43a. Alkali Milk-Vetch Statewide Recorded Occurrences

Currently, the Yolo County distribution of adult plants of this species includes the City of Woodland Preserve, the Woodland Regional Park, the Brauner and Maupin (near the Road 25 and 103 intersection) properties, the Yolo Grasslands Park, the Tule Ranch unit of the California Department of Fish and Game (DFG) Yolo Bypass Wildlife Area (Tule Ranch), and the Willow Slough Bypass (Showers 1996, EIP Associates 1998, Foothill Associates 2002, Witham 2003, University of California Davis Herbarium 2004, ESA 2005, A. Shapiro pers. comm. 2005).

A43.2.2 Distribution and Status in the Plan Area

Within the Plan Area are several reported occurrences (Figure A-43b). Small groups of up to 20 plants are found on suitable habitat on the Tule Ranch (Witham 2003). It has been observed 1/4 mile south of Saxon Station on the western edge of the Yolo Bypass on the Yolo Bypass Wildlife Area. To the west, it was reported as observed growing in clay soils west of Bunker Station. To the south, multiple sightings have been observed in vernally wet grassland in the Jepson Prairie Preserve. Further south in the Suisun Marsh area, it was observed in an alkaline vernal pool in the Montezuma Wetlands Restoration Project. On the southwest edge of the Plan Area, it has been observed in alkaline grassland vegetation northwest of the junction of Byron Hot Springs Road and Armstrong Road (CNDDB 2008). A previous instance observed in the Stockton area near Smith Canal is believed to be extirpated (CNDDB 2008).

A43.3 HABITAT REQUIREMENTS AND SPECIAL CONSIDERATIONS

Little is known about the ecology of alkali milk-vetch. In the Central Valley, it appears to be restricted to alkaline soils in areas that are, or were historically subject to flooding and overland flows (Silveira 2000, Witham 2003, ESA 2005). At the McClellan Air Force Base Davis Communications Facility site in Yolo County, it is found growing on the annual ryegrass (*Lolium multiflorum*) dominated floodplains above the upper margins of vernal pools and swales that contain Solano grass (*Tuctoria mucronata*) and Colusa grass (*Neostapfia colusiana*) (ESA 2005). All individuals at that site were found in areas that had been subjected to a prescribed burn and which subsequently flooded briefly in February (ESA 2005). In two subsequent years, the same area burned due to arson-caused fires and also flooded during the winter, but only a few individuals were detected during the following springs in contrast to the large population that established after the prescribed burn (J. Gerlach unpubl. data). At the Tule Ranch site in the Yolo Bypass, it is found in vernally mesic grasslands dominated by annual ryegrass and associated with alkaline vernal pools (Witham 2003). It is also found near the City of Woodland and along the Willow Slough Bypass in Yolo County in areas that were once alkali sink vegetation, but which were converted to rice fields and then fallowed for many years or which were converted into a levee system (Andrews 1970, Crampton 1979, Showers 1988, 1996, EIP Associates 1998, Foothill Associates 2002). There were historical occurrences along the railroad tracks north of the City of Davis and on the Hunt and Wesson tomato canning plant property (CNDDB 2008), but no individuals were located during surveys of those areas in 2006 (J. Gerlach unpubl. data).

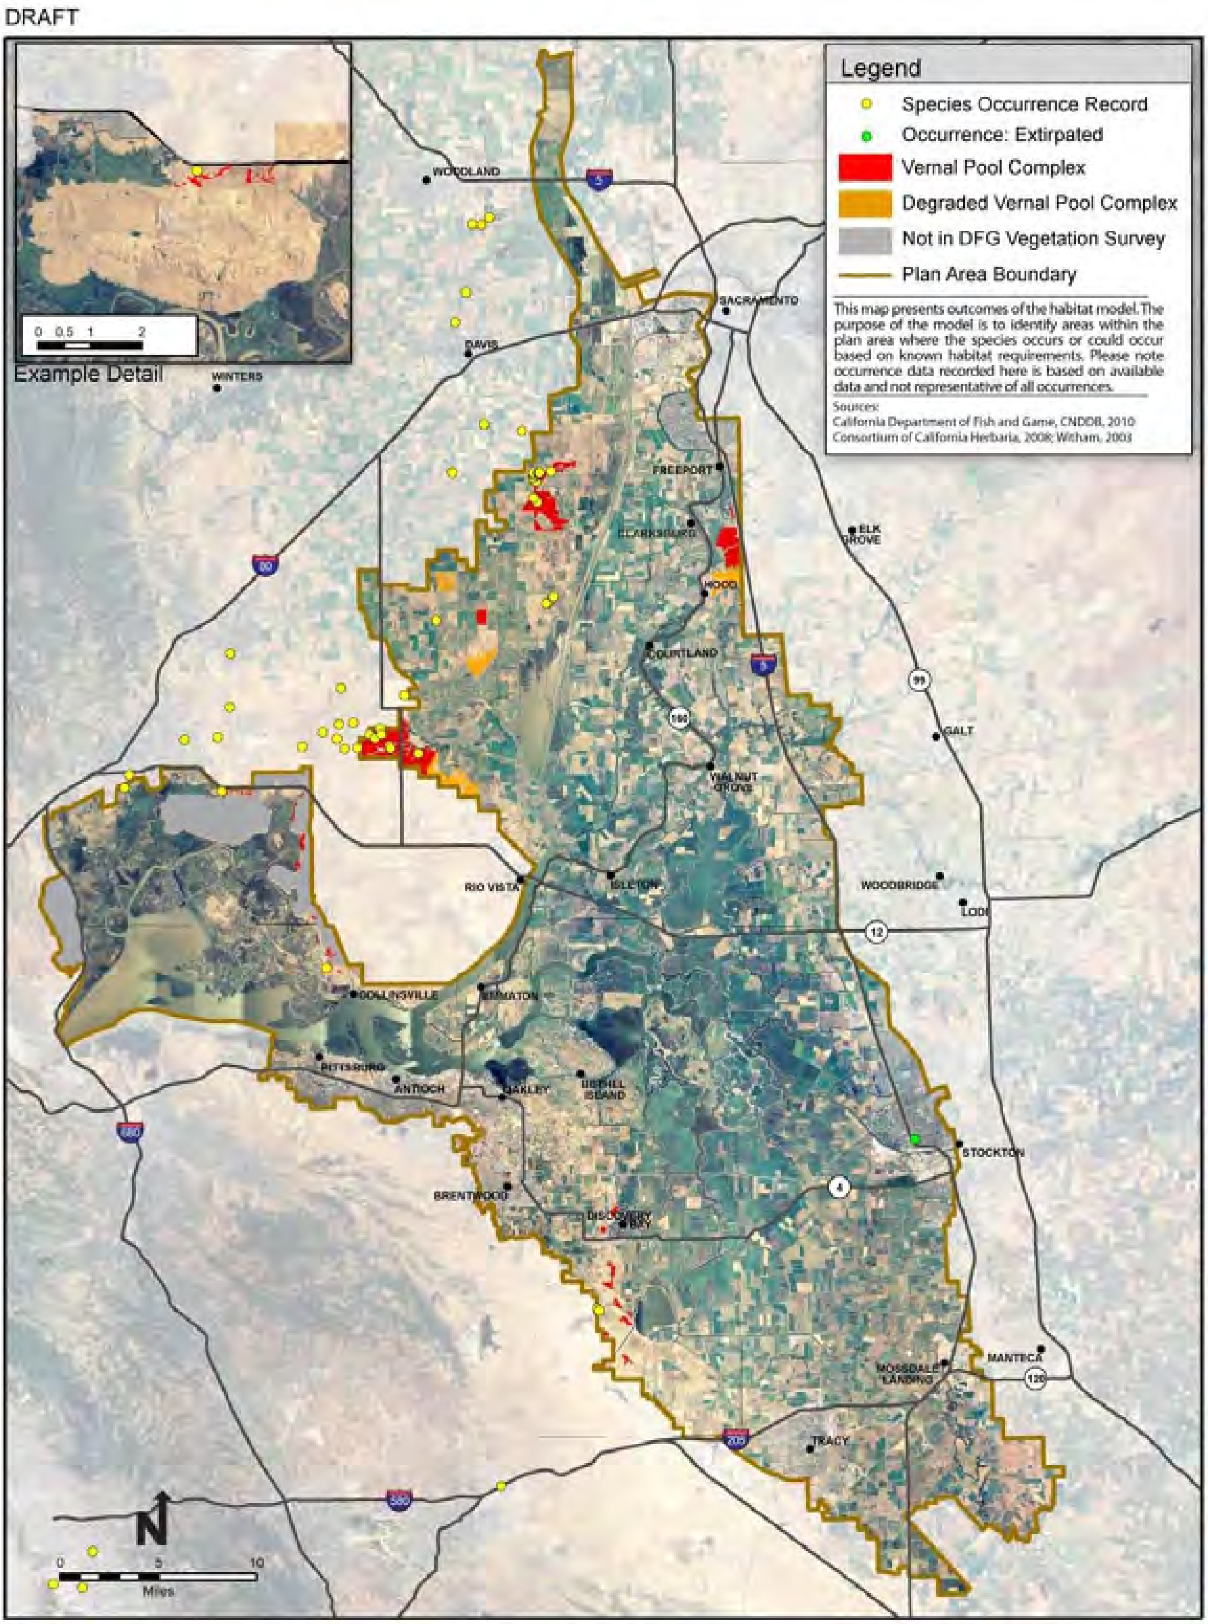

Figure A-43b. Alkali Milk-Vetch Habitat Model and Recorded Occurrences

The canning plant has been closed for several years and the alkaline soil areas are no longer farmed and are now densely vegetated with annual ryegrass (J. Gerlach unpubl. data). In the greater Jepson Prairie area it grows in vernal pool grassland that is dominated by annual ryegrass (Witham 2006).

The populations southeast of the City of Woodland and north of the City of Davis are in a heavily human-impacted area of what historically was alkaline sink vegetation lying along both sides of the north channel of Putah Creek and Willow Slough and above the Yolo Basin (U. S. Bureau of Soils 1909a, 1909b, Mann et al. 1911). The hydrology, salts, and clay soils that created and maintained the alkaline sink vegetation were deposited when floodwaters from Putah Creek flowed northward from the area near the City of Davis and emptied into Willow Slough. That flow was also supplemented when the combined floodwaters of Putah Creek, Cache Creek, and all of the drainages of the Blue Ridge filled the Cache/Putah Basin, drained eastward through a gap in the Plainfield Ridge, and flowed into the Yolo Basin through Willow Slough (Graymer et al. 2002). This area has also been heavily invaded by annual ryegrass (Dawson et al. 2007).

Laguna Callé, as Willow Slough was previously known, was a unique perennial stream (Eliason 1850, Anonymous 1870) that during the dry season originated from a series of pond-like springs approximately 9 miles (14.5 kilometers [km]) southwest of Woodland on the eastern edge of the Plainfield Ridge. As the slough approached the area of Merritt, south of the City of Woodland, it transformed into a 2.5-mile (4 km) long, gravel-bottomed, linear lake, with an average width of 150 feet (46 meters) and a maximum depth of 75 feet (23 meters). Approximately 1 mile (1.6 km) east of County Road 103, the stream flowing from the lake branched as it dropped over the edge of the alluvial deposits into the Yolo Basin, where it flowed another 2.5 miles northeastward until it emptied into a tule marsh. Large floods from Cache Creek and Putah Creek have flowed through Willow Slough as recently as 1942, but gravel mining in Cache Creek, dam building on both Cache and Putah creeks, and the construction of the Willow Slough Bypass have drastically altered the hydrology, salt budgets, and clay deposition patterns in the area of the alkali sink vegetation. Aerial photographs show that all of the alkaline sink vegetation was converted into various kinds of agricultural fields, ditched for drainage (USDA 1952), or subsequently developed as the cities expanded. Given the intensity and extent of the agricultural impacts to the entire alkali sink area and the irreversible changes in hydrology, those areas do not currently support alkali sink vegetation, and it would be very difficult to replicate the natural hydrological regimes that would allow that type of vegetation to be successfully restored in the area.

There are few data documenting the population trends of alkali milk-vetch. Because most of the recent observations of individuals have been at sites where it was considered extirpated, it appears that those individuals have established from pre-existing long-lived seed banks. Witham's observation that recruitment increased in a population near the Jepson Prairie Preserve after pipeline construction (CNDDB 2008) appears to confirm the importance of the seed bank. More recently, a large multi-year survey of California's vernal pool vegetation found that alkali milk-vetch was the most variable rare taxon and only occurred once during the 5-year study at a very low cover value (1 percent) (Buck 2004, Barbour et al. 2007).

A43.4 LIFE HISTORY

Alkali milk-vetch is a 2- to 16-inch (4- to 40-centimeter [cm]) tall herbaceous annual plant in the pea family (Fabaceae) (Hickman 1993) that has been differentiated from Ferris' milk-vetch (*Astragalus tener* var. *ferrisiae*) based on the morphology of its fruits (Liston 1990, 1992). Alkali milk-vetch has short, stout, strongly curved pods (Witham 2003). The leaves of alkali milk-vetch are 1 to 3 inches (2 to 9 cm) long, with 7 to 17 pinnately compound, well-separated leaflets. Three to 12 pink-purple, pea-like flowers comprise a dense inflorescence.

A protein electrophoresis analysis of two populations, one from Jepson Prairie in Solano County and the other from northern Merced County, found very little genetic differentiation between the populations and high levels of genetic diversity within each population (Liston 1992). This technique uses allozymes or slight alterations in plant proteins as indicators or markers. Because small mutations in the genetic code results in markers that are generally invisible to the forces of natural selection, these allozyme markers are classified as neutral markers. Therefore, because the neutral markers used in the study have not been shown to be correlated with any traits that might provide an adaptive advantage, Liston's results provide no information concerning the extent of local adaptation or other measures of the "genetic health" of the populations and no information regarding the amount of variation for adaptive traits (McKay et al. 2001, Latta and McKay 2002, McKay and Latta 2002, Wayne and Morin 2004).

Based on a crossing study by Liston (1992), the species was found to be self-compatible, and the inbreeding coefficients for the two populations were not significantly different from the expected value for a randomly mating population. Therefore, Liston concluded that insect pollinators are responsible for maintaining high levels of outcrossing within the populations. Liston also concluded that the recent dramatic range and population reductions experienced by alkali milk-vetch might explain the lack of neutral marker differentiation between the two populations and that the lack of inter-population neutral marker differentiation might also be attributed to a seed bank, as milk-vetch species are known to produce long-lived seed banks. Liston indicated that the unique morphology of the plant's flower suggested that alkali milk-vetch is pollinated by butterflies, which is rare for a species in the pea family (Liston 1992).

It is not known when or under which environmental conditions germination of alkali milk-vetch seeds occurs (USFWS 2005). Skinner and Pavlik (1994) indicate the flowering period to be March through June. Witham observed that recruitment increased in a population near the Jepson Prairie Preserve after pipeline construction (Witham 1990). Alkali milk-vetch was also observed in an artificially constructed vernal pool near Albrae at a site where no observations had been recorded since 1923 (USFWS 2005). These observations indicate the importance of a long-lived soil seed bank and suggest that viable seed may exist in the soil seed bank in areas where mature plants have not been observed for many years. This importance of a long-lived seed bank is also supported by studies that have found that this species persists across multiple seasons despite the absence of reproductive plants (Buck 2004, Barbour et al. 2007).

A43.5 Threats and Stressors

Development, intensive agriculture, and exotic plant species (especially annual ryegrass) are considered the primary threats to alkali milk-vetch (Showers 1996, Witham 2003, ESA 2005, Dawson et al. 2007).

A43.6 Relevant Conservation Efforts

Alkali milk-vetch is included in the Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon (USFWS 2005). Alkali milk-vetch is a covered species under the permitted San Joaquin County Multi-species Habitat Conservation and Open Space Plan and is proposed for coverage under the Solano County Multi-species Habitat Conservation Plan and the Yolo County Natural Heritage Program Plan.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for alkali milk-vetch is "Contribute to Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its control and within its scope that are necessary to contribute to the recovery of the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

A43.7 Species Habitat Suitability Model

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below and in Section 2.3.1, *Data Sources and Natural Community Classification*). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as vernal pools, individual trees, or small groups of trees. It is also possible, as with some vernal pool invertebrates that are restricted to seasonally ponded habitats, to underestimate potentially-occupied habitat due to the lack of information on small, degraded or artificially-created seasonal wetland habitats.

Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The alkali milk-vetch model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), DWR 2007 LiDAR elevation data, Google Earth 2009 aerial imagery and USDA 2005 aerial photography. Using these data sets, the model maps the distribution of suitable alkali milk-vetch habitat in the Plan Area according to the species' two habitat types, vernal pool complex and degraded vernal pool complex habitat. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Vernal Pool Complex Habitat: High quality permanent habitat that consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly impacted by agricultural or development practices. Vernal pool complex habitat for alkali milk-vetch includes the following vegetation subunits that were selected from the BDCP vernal pool complex natural community:

- Vernal pool complex – all vegetation types

Degraded Vernal Pool Complex Habitat: Low quality ephemeral habitat that ranges from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, disking, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. The aquatic features in this habitat are more clearly classified as temporary waters sensu lato (Williams 2006) than intact and fully functional vernal pools. Because these features are inundated during the wet season and may have historically been located in or near areas with natural vernal pool complex, they may support individuals or small populations of species that are found in vernal pools and swales. However, they do not posses the full complement of ecosystem and community characteristics of natural vernal pools, swales and their associated uplands and they are generally ephemeral features that are eliminated during the course of normal agricultural practices. Degraded vernal pool complex habitat for alkali milk-vetch includes the following vegetation subunits that were selected from the BDCP other natural seasonal wetlands and grasslands communities:

- Grasslands
  - Degraded vernal pool complex – California annual grasslands;
  - Degraded vernal pool complex – Ruderal herbaceous grasses and forbs;
  - Degraded vernal pool complex – Italian rye-grass (*Lolium multiflorum*); and
  - Degraded vernal pool complex – Rabbitsfoot grass (*Polygpogon maritimus*).
- Other natural seasonal wetlands
  - Degraded vernal pool complex-vernal pools.

Potential habitat without concave surfaces (except for seeps along Suisun Marsh) was removed from the model. LiDAR elevation data was then visually inspected in four general areas to further assess specific locations that had been identified by the habitat selection process. These areas were selected based both on *a priori* knowledge of the region and because they were identified by the intersection of the selected vegetation types and soils. The analysis of the LiDAR data further refined the habitat model and provided a more accurate demarcation of suitable habitat. The GIS habitat model was then compared against field data from surveys conducted by the California Department of Water Resources/Delta Habitat Conservation and Conveyance Program (DWR/DHCCP) for the Bay Delta Conservation Plan (BDCP) in 2009. Land uses that are incompatible with the species' habitat requirements (for example, potential habitat polygons falling on leveled or developed lands) were removed from the model.

Assumptions. Historical and current records of this species in the Plan Area indicate that its current distribution is limited to alkaline soil areas with vernal pool and swale microtopography along the western border of the Plan Area (Figure A-43b) (Witham 2002, 2003, 2006, ESA 2005, Barona et al. 2007, CNDDB 2010). The vegetation cover of the alkaline soils is typically a combination of vernal pool adapted species and annual ryegrass (Witham 2002, 2003, 2006, CNDDB 2010). Because alkali milk-vetch also frequently occurs in the same habitats as Heckard's peppergrass (Witham 2002, 2003, 2006, CNDDB 2010) and Heckard's peppergrass was discovered in the Stone Lakes area by DWR/DHCCP field survey teams, its habitat range was extended into areas with vernal pool and swale microtopography along the eastern border of the Plan Area.

A43.8 Recovery Goals

Although alkali milk-vetch is not a federally listed taxon, it is included in the Draft Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon (USFWS 2005). The Recovery Plan explicitly states that its goal is to ensure the long-term conservation of this variety and 32 other taxa by using an ecosystem level strategy that is based on: current knowledge of the existing conditions of vernal pool communities, the distribution and status of the populations of each of the species, and current and anticipated process that impact vernal pool ecosystems. Because the goal of the Recovery Plan is primarily directed at habitat preservation, its implementation program specifically addresses factors that relate to habitat acquisition and management: (1) habitat protection; (2) adaptive habitat management and monitoring; (3) status surveys; (4) research; and (5) public participation.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designates the alkali milk-vetch as "Contribute to Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its control and within its scope that are necessary to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

A43.9.2 Personal Communication

A. Shapiro. Professor, University of California, Davis. Meeting with John Gerlach, 2005.

APPENDIX A44. HEARTSCALE (*ATRIPLEX CORDULATA*)

A44.1 LEGAL STATUS

Heartscale (*Atriplex cordulata*) is not listed under either federal or California endangered species acts. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G2?/S2.2? which means that globally (G) and within the state (S) there are either between six to 20 viable element occurrences of this species, 1,000 to 3,000 individuals of this species, or 2,000 to 10,000 acres (809 to 4,047 hectares) where this species occurs; and the state threat level rank is "threatened." The "?" portion of the rank indicates that there is uncertainty about the rank.

The California Native Plant Society (CNPS) List ranking of 1B.2 for heartscale indicates that it is rare, threatened, or endangered. It is endemic to California and is considered by CNPS to be fairly endangered with between 20 to 80 percent of occurrences threatened. Plants with a CNPS List rank of 1B are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

A44.2 SPECIES DISTRIBUTION AND STATUS

A44.2.1 Range and Status

Heartscale is endemic to California, and its reported range extends through the Central Valley from Glenn County in the north to Kern County in the south, and in valleys of the inner Coast Range in Alameda and San Luis Obispo counties (Figure A-44a) (CNPS 2009). Many of the reported occurrences are 70 years old or older and in areas that are now under more intensive agriculture (CNDDB 2009).

A44.2.2 Distribution and Status in the Plan Area

Heartscale is found in meadows, seeps, riparian wetlands, chenopod scrub, and valley and foothill grasslands in a variety of soils that are either saline or alkaline (CNDDB 2009, CNPS 2009) (Figure A-44b). The populations in the Plan Area are generally small and often subjected to prolonged grazing by sheep (CNDDB 2009) which may have both positive and negative impacts on this species.

DRAFT

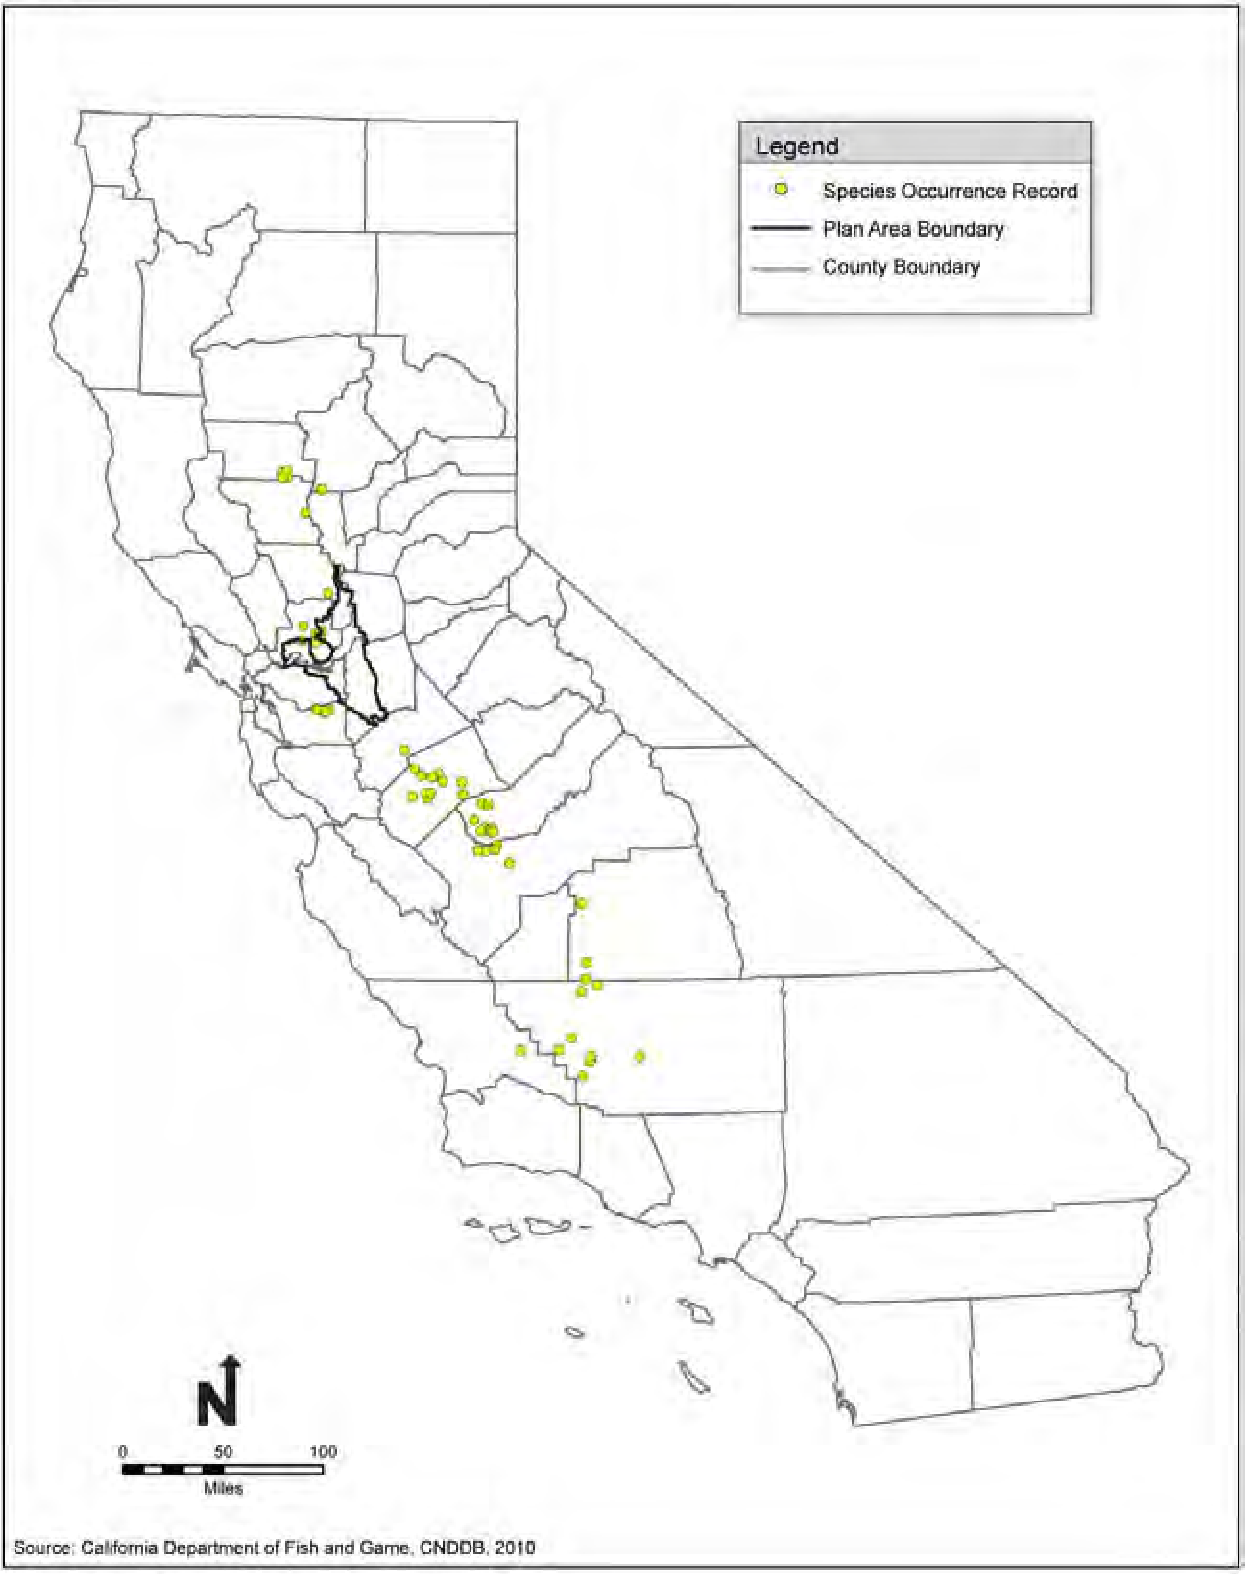

Figure A-44a. Heartscale Statewide Recorded Occurrences

DRAFT

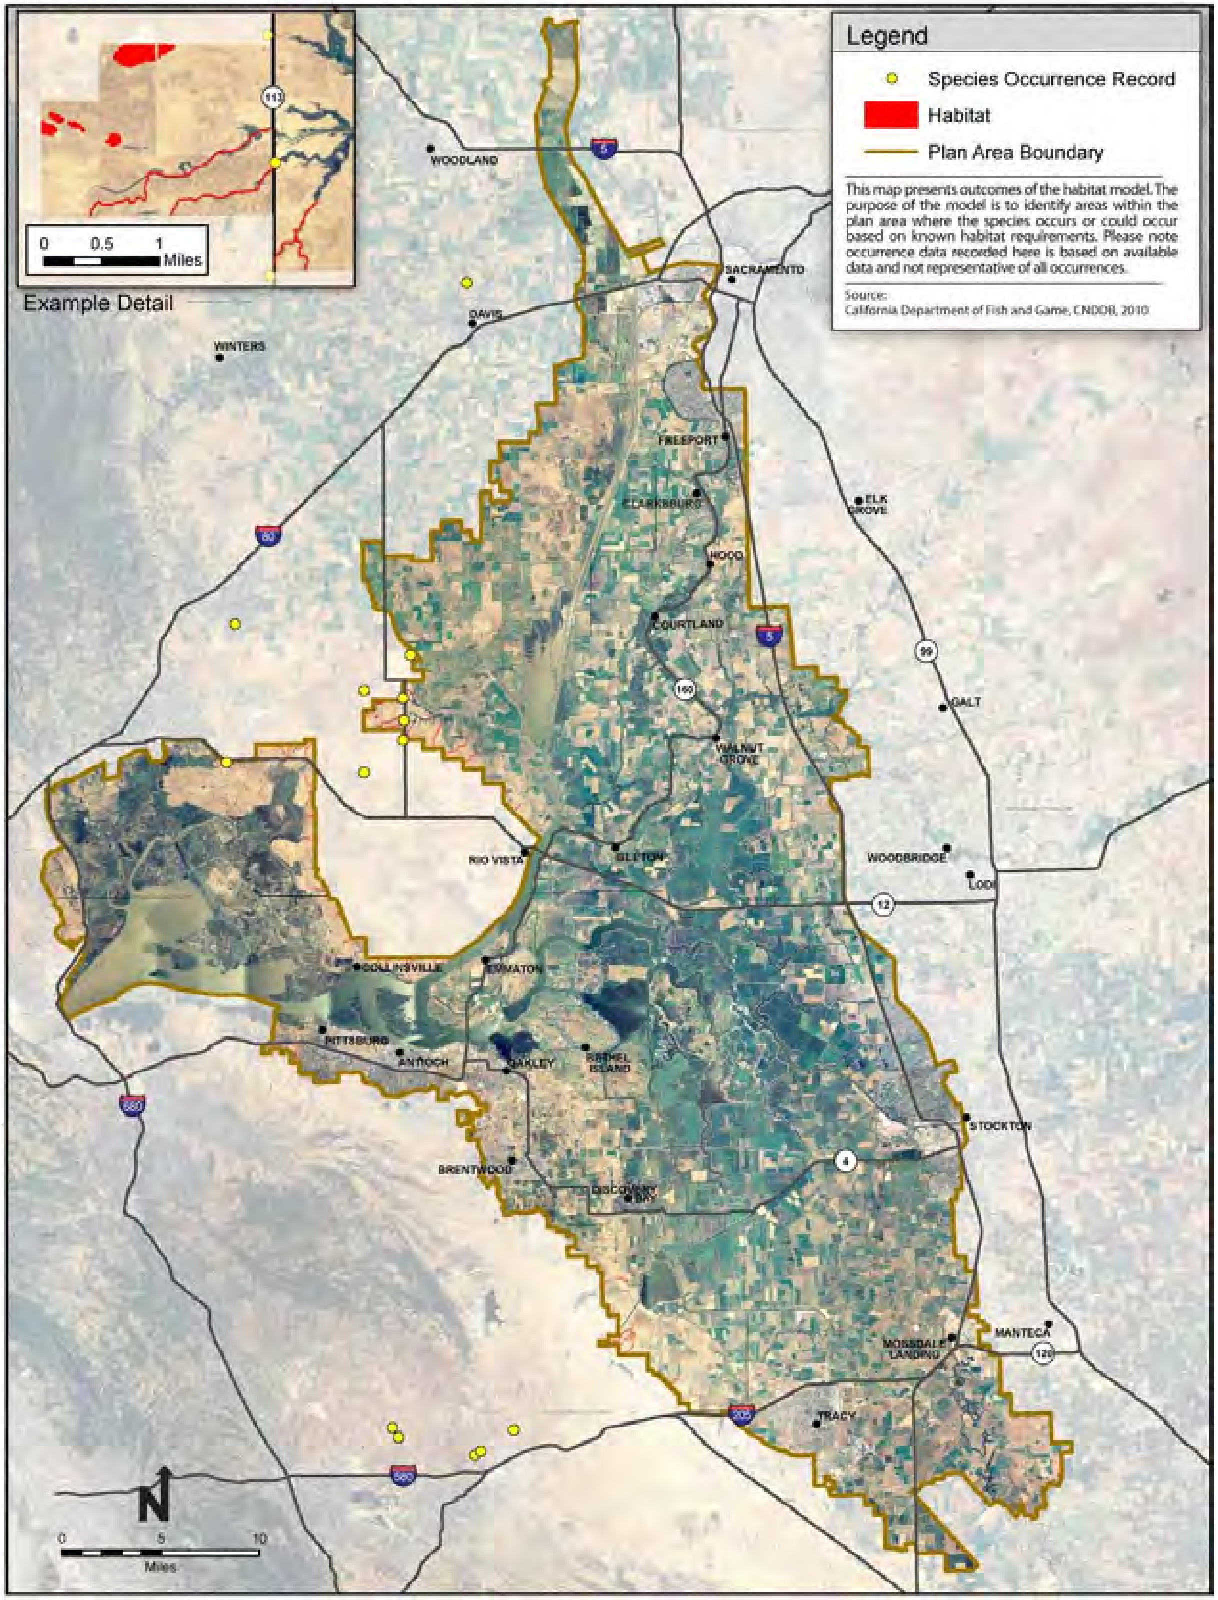

Figure A-44b. Heartscale Habitat Model and Recorded Occurrences

A44.3 Habitat Requirements and Special Considerations

In the Plan Area, heartscale is found in meadows, seeps, drainage corridors, and vernal pools, underlain by alkaline clay soils (CNPS 2009). Species associated with heartscale can include common spikeweed (*Centromadia pungens*), saltgrass (*Distichlis spicata*), alkali heath (*Frankenia salina*), low barley (*Hordeum depressum*), bush seepweed (*Suaeda moquinii*), brittlescale (*Atriplex depressa*), and San Joaquin spearscale (*Atriplex joaquiniana*) (CNDDB 2009, CNPS 2009). The reported CNDDB occurrences in Solano and east Contra Costa counties are in close proximity to hydrological features such as stream corridors and playas pools. It is not known whether this association with hydrological features is a strict habitat requirement or a legacy of land management practices, such as extensive dry-farmed grain and other intensive agriculture that avoid planting and cultivation of hydrological features, continuing to the present (John Gerlach, personal observation on May 30, 2009).

A44.4 Life History

Heartscale is a small to medium-sized 4- to 20-inch (10- to 50-centimeter [cm]) tall annual herb of the goosefoot family (Chenopodiaceae) that blooms from April to October (Hickman 1993, CNPS 2009). It produces one or more erect stems with branches ascending to scaly gray tips with woolly fibers. The leaves are grayish-green, scaly, egg-shaped, and from 0.25-0.5 inch (0.6 to 1.5 cm) in length. Lower leaf bases are heart-shaped while upper leaf bases are rounded. Plant inflorescences are small dense clusters of flowers, and seeds are reddish brown and about 0.1 inch (2 millimeters) wide (Hickman 1993). Heartscale can be found at elevations of 3.3 to 1,230 feet (1 to 375 meters) (CNPS 2009).

A44.5 Threats and Stressors

Reported threats to heartscale include agriculture intensification, development, nonnative plants, overgrazing, and trampling (CNDDB 2009, CNPS 2009).

A44.6 Relevant Conservation Efforts

Heartscale is a covered species under the San Joaquin County Multi-species Habitat Conservation and Open Space Plan and is proposed for coverage under the Solano County Multispecies Habitat Conservation Plan. In the Plan Area, occurrences are generally protected on the Greater Jepson Prairie Ecosystem Management Plan (Witham 2006) while many of the other occurrences are located on wildlife refuges (CNDDB 2009).

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for heartscale is "Maintain" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions to maintain the species by avoiding, minimizing, and compensating for any adverse effects to the species created by ERP restoration actions. To the extent practicable, the ERP will improve species habitat conditions.

A44.7 Species Habitat Suitability Model

Heartscale occurrences in the Plan Area are all in close proximity to hydrological features such as stream corridors and playa pools which are located on either alluvium associated with the Montezuma Block along the western boundary of the Plan Area (Band 1998, Graymer et al. 2002), or on alluvium associated with tertiary formations located along the southwest boundary of the Plan Area (Schruben et al. 1998).

Stream corridors (intermittent and perennial) that intersected these geologic units were selected and truncated at the point at which they encountered the upper elevation of intertidal marsh (Siegel 2007). The corridors were buffered 50 feet (15.2 meters) on either side of their centerlines to capture the estimated maximum extent of alluvium deposits in close proximity to the streams. Field reconnaissance on the Montezuma Block area on May 30, 2009, found that this buffering width is liberal and tends to overpredict potential habitat (J. Gerlach, pers. obs.).

The identified potential habitat was then overlaid on National Agricultural Imagery Program (NAIP) aerial imagery (USDA 2005) to visually assess whether estimated habitat agreed with current land use practices (i.e., to ensure that habitat was not currently impacted by urban or agricultural uses). Predicted habitat that was impacted by urban or intensive agricultural uses was removed from the model.

A44.8 Recovery Goals

A USFWS recovery plan has not been prepared for this species and no recovery goals have been established.

APPENDIX A45. BRITTLESCALE (*ATRIPLEX DEPRESSA*)

A45.1 LEGAL STATUS

Brittlescale (*Atriplex depressa*) is not listed under either federal or California endangered species acts. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G2Q/S2.2 which means that globally (G) and within the state (S) there are either between six to 20 viable element occurrences of this species, 1,000 to 3,000 individuals of this species, or 2,000 to 10,000 acres (809 to 4,047 hectares) where this species occurs; and the state threat level rank is "threatened." The "Q" portion of the rank indicates that unresolved taxonomic questions remain for this rare species (CNDDB Special Vascular Plants, Bryophytes, and Lichens List).

The California Native Plant Society (CNPS) List ranking of 1B.2 for brittlescale indicates that it is rare, threatened, or endangered. It is endemic to California and is considered by CNPS to be fairly endangered with between 20 to 80 percent of occurrences threatened. Plants with a CNPS List rank of 1B are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

A45.2 SPECIES DISTRIBUTION AND STATUS

A45.2.1 Range and Status

Brittlescale is endemic to California, and its distribution is based on 58 observations (Figure A-45a). There has been confusion in identifying this species correctly and some of the occurrences are lesser saltscale (*Atriplex minuscula*) (Preston 2003). There is also disagreement regarding the morphological characteristics that separate these species (Preston 2009, pers. comm.). The range of brittlescale extends from Colusa and Glenn counties in the north, to Fresno, Merced, Stanislaus, and Tulare counties in the south and east, to Alameda, Contra Costa, Solano, and Yolo counties in the west (CNDDB 2009, CNPS 2009). It is found on a range of alkaline or saline soils in the Sacramento Valley and in the inner North Coast Ranges (CNDDB 2009).

A45.2.2 Distribution and Status in the Plan Area

Brittlescale has been reported from Solano County: at Olcott Lake on Jepson Prairie; between Bird's Landing and Montezuma Slough; south of Cement Road; along Creed Road; in the mitigation area for the access to Potrero Hills Landfill; and the Elsie Gridley Mitigation Bank (AMEC&FA 2001, CNDDB 2009) (Figure A-45b). Population sizes are reported for two of them: the Bird's Landing population had approximately 300 plants in 1991; and the Potrero Hills population had 213 plants in 1996 (CNDDB 2009). It is also found in and along drainages and alkaline seeps in eastern Contra Costa County and near alkaline seeps (CNDDB 2009).

DRAFT

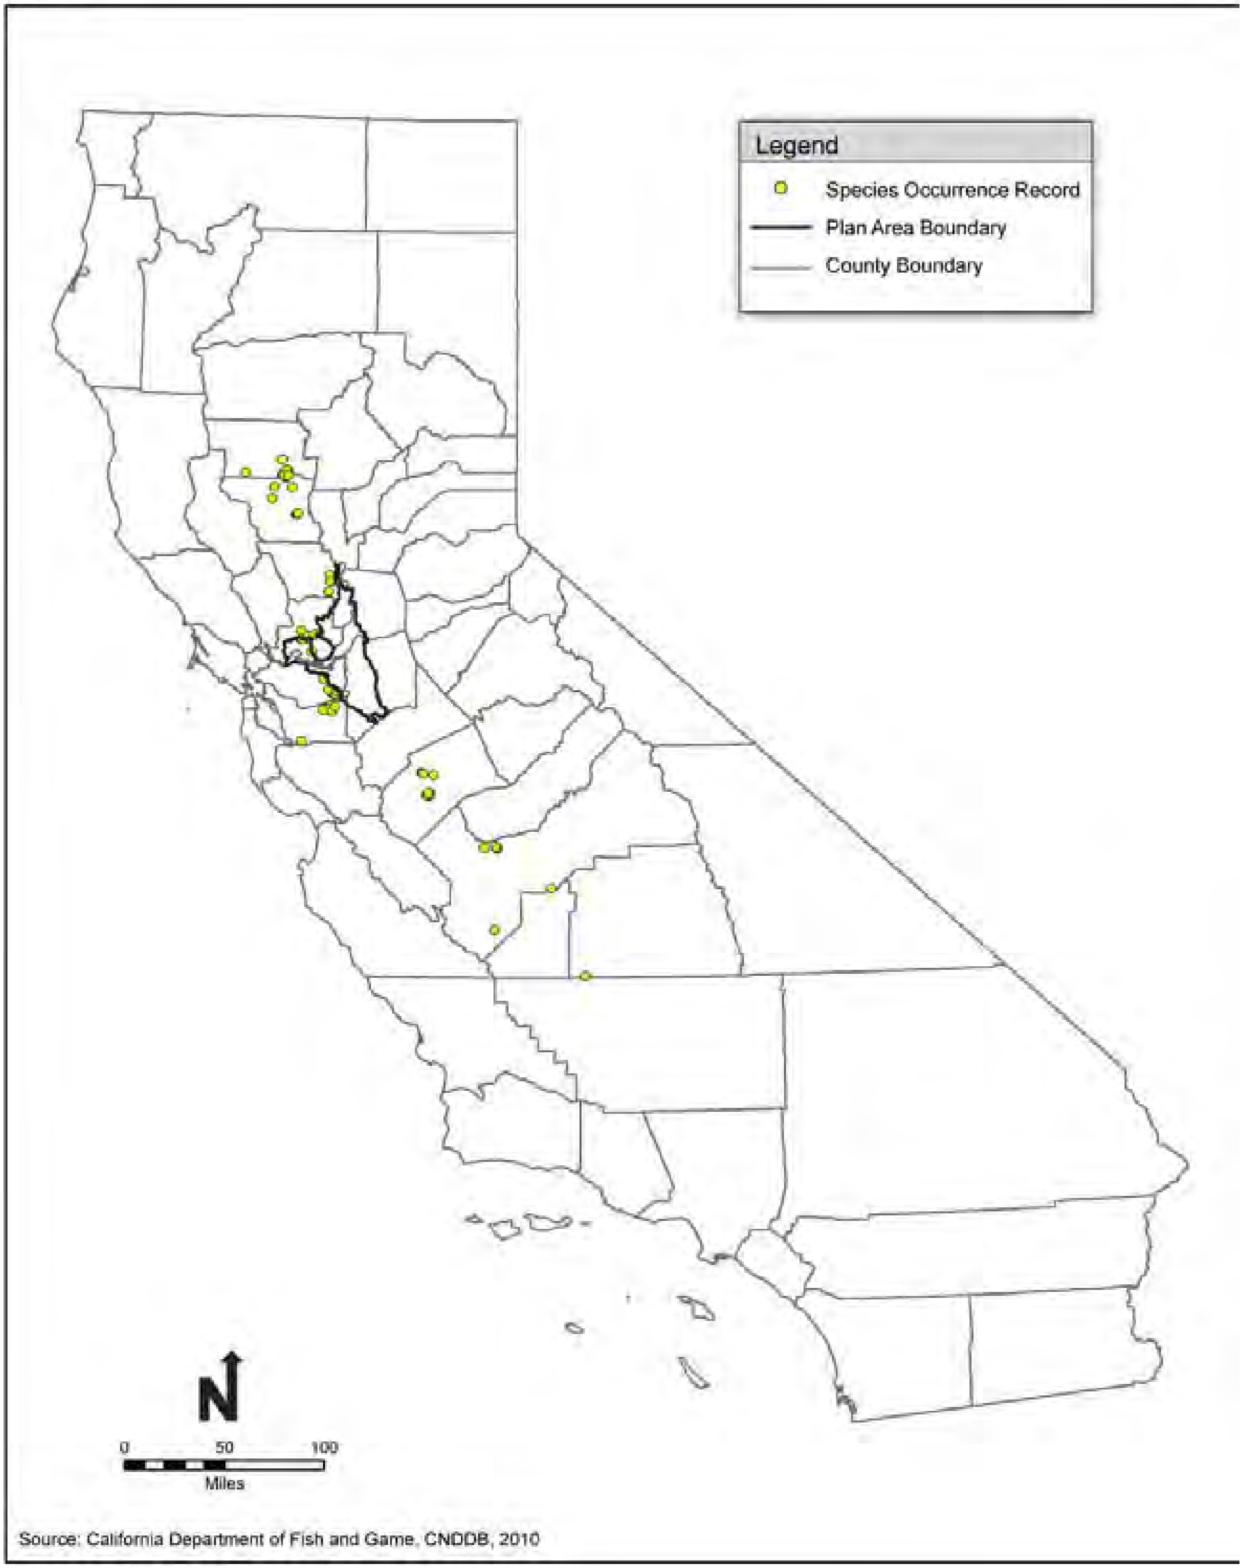

Figure A-45a. Brittlescale Statewide Recorded Occurrences

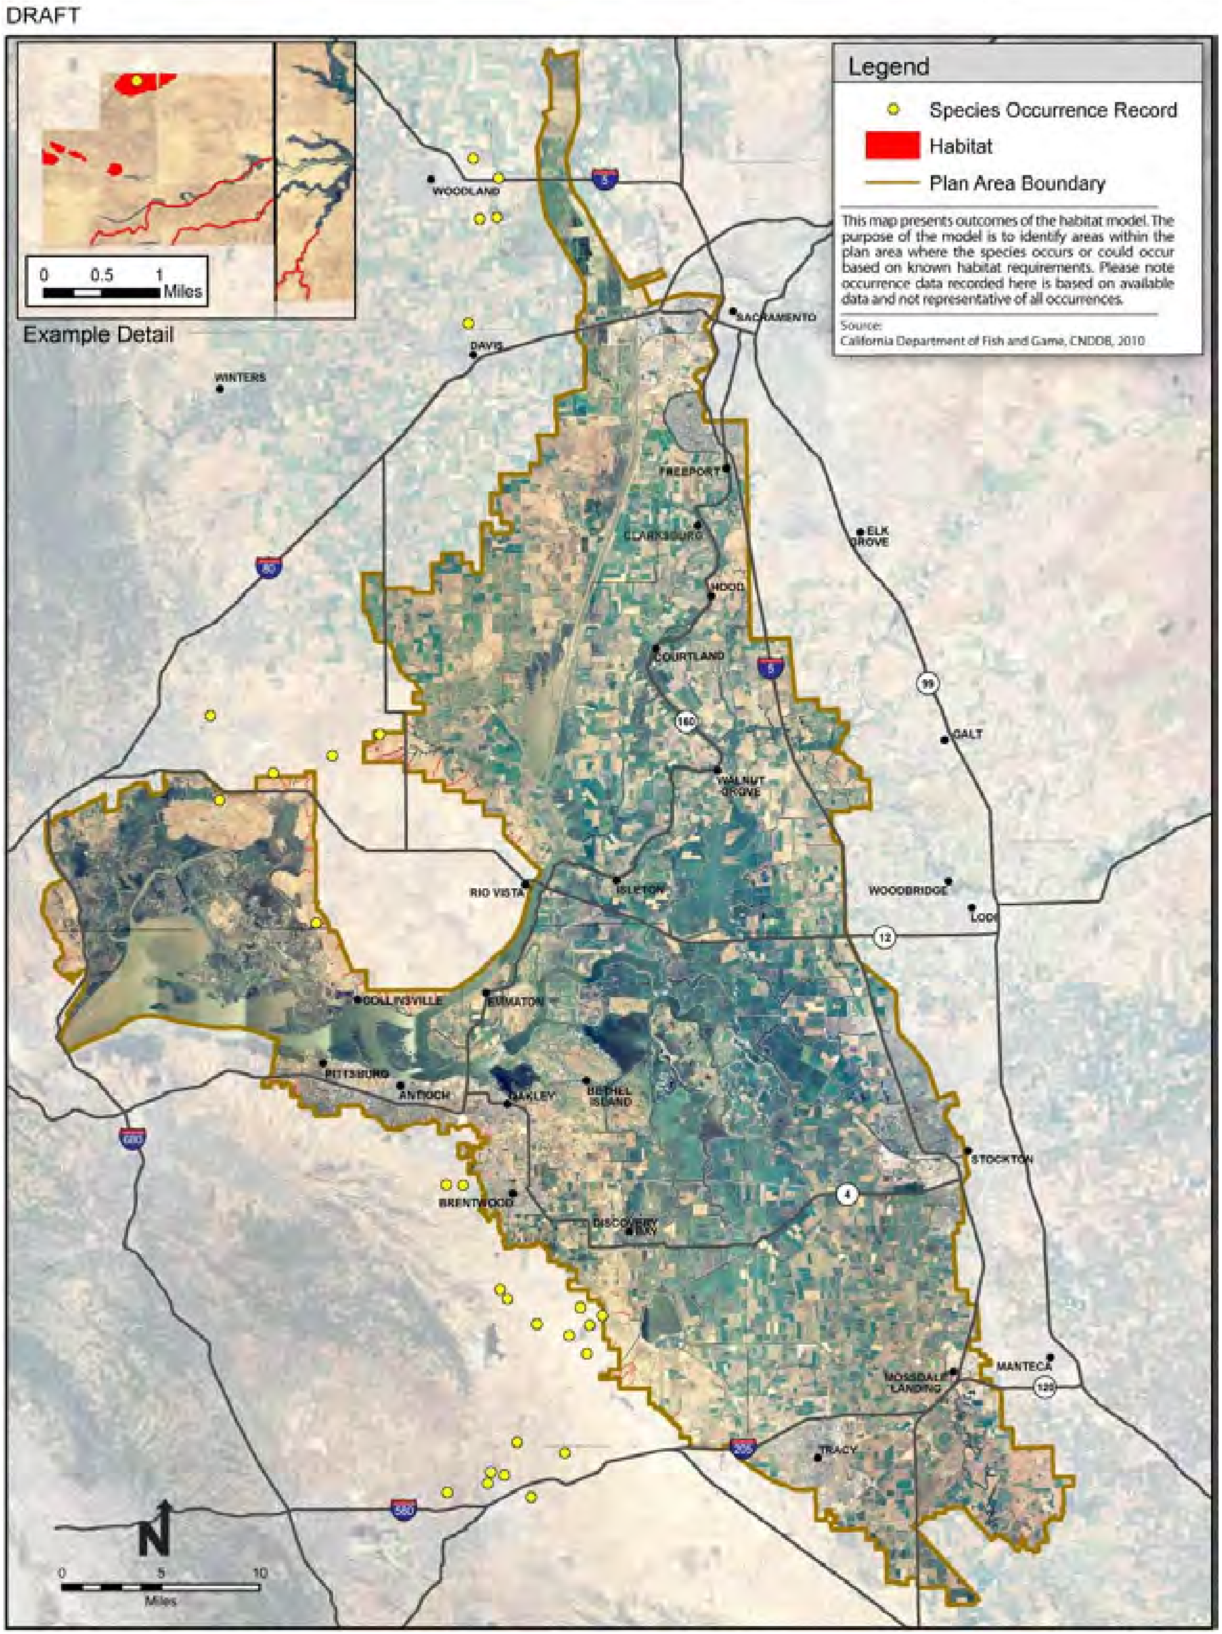

Figure A-45b. Brittlescale Habitat Model and Recorded Occurrences

1

A45.3 Habitat Requirements and Special Considerations

Brittlescale is found in meadows, seeps, and vernal pools, with alkaline clay soils (CNPS 2009). Species associated with brittlescale can include common spikeweed (*Centromadia pungens*), saltgrass (*Distichlis spicata*), alkali heath (*Frankenia salina*), low barley (*Hordeum depressum*), Mediterranean barley (*Hordeum marinum* ssp. *gussoneanum*), western niterwort (*Nitrophila occidentalis*), Parish's pickleweed (*Salicornia subterminalis*[1]), bush seepweed (*Suaeda moquinii*), heartscale (*Atriplex cordulata*), and San Joaquin spearscale (*Atriplex joaquiniana*) (CNDDB 2009, CNPS 2009). The reported CNDDB occurrences in Solano and east Contra Costa counties are in close proximity to hydrological features such as stream corridors and playa pools. It is not known whether this association with hydrological features is a strict habitat requirement or a legacy of land management practices such as extensive dry-farmed grain and other intensive agriculture that avoid planting and cultivation of hydrological features, continuing to the present (John Gerlach, personal observation on May 30, 2009).

A45.4 Life History

Brittlescale is a small (< 20-centimeter [cm] [8-inch]) annual herb of the goosefoot family (Chenopodiaceae) that blooms from April to October (Hickman 1993, CNPS 2009). Its stems grow flat along the ground and turn upwards near their tips and are white, scaly and brittle (Hickman 1993). Leaf blades are small (0.2-0.3 inch [4-8 millimeters {mm}]), egg-shaped to heart-shaped, with entire margins, are generally densely white-scaly, and can be opposite unlike many other *Atriplex* species (Hickman 1993). Brittlescale can be found at elevations of 3 to 1,050 feet (1 to 320 meters) (CNPS 2009). It is closely related to *Atriplex minuscula* (lesser saltscale) and *Atriplex parishii* (Parish's brittlescale) and has, in the past, been described as a synonym for *Atriplex parishii* (Parish's brittlescale) (CNPS 2009). Its reddish seeds are 0.04 to 0.06 inch (1 to 1.5 mm) long (Hickman 1993).

A45.5 Threats and Stressors

The primary threat to brittlescale is the loss of suitable habitat within the range of the species (CNDDB 2009). Other threats include invasive species and the creation of waterfowl habitat (Showers 1996).

A45.6 Relevant Conservation Efforts

Brittlescale is a covered species in the San Joaquin County Multi-species Habitat Conservation and Open Space Plan and the East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan; and it is proposed for coverage under the Yolo County Natural

---

[1] Currently known as *Arthrocnemum subterminale.*

Heritage Program Plan and the Solano County Multi-species Habitat Conservation Plan. In the Plan Area, occurrences are generally protected on the Greater Jepson Prairie Ecosystem Management Plan (Witham 2006) while many of the other occurrences are located on wildlife refuges (CNDDB 2009).

A45.7 Species Habitat Suitability Model

Brittlescale occurrences in and near the Plan Area are all in close proximity to hydrological features such as stream corridors and playa pools which are located on either alluvium associated with the Montezuma Block along the western boundary of the Plan Area (Band 1998, Graymer et al. 2002) or on alluvium associated with tertiary formations located along the southwest boundary of the Plan Area (Schruben et al. 1998).

Stream corridors (intermittent and perennial) that intersected these geologic units were selected and truncated at the point at which they encountered the upper elevation of intertidal marsh (Siegel 2007). The corridors were buffered 50 feet (15.2 meters) on either side of their centerlines to capture the estimated maximum extent of alluvium deposits in close proximity to the streams. Field reconnaissance on the Montezuma Block area on May 30, 2009, found that this buffering width is liberal and tends to overpredict potential habitat (J. Gerlach, pers. obs.).

The identified potential habitat was then overlaid on National Agricultural Imagery Program (NAIP) aerial imagery (USDA 2005) to visually assess whether estimated habitat agreed with current land use practices (i.e. to ensure that habitat was not currently impacted by urban or agricultural uses). Predicted habitat that was impacted by urban or intensive agricultural uses was removed from the model.

A45.8 Recovery Goals

A United States Fish and Wildlife (USFWS) recovery plan has not been prepared for this species and no recovery goals have been established.

APPENDIX A46. SAN JOAQUIN SPEARSCALE (*ATRIPLEX JOAQUINIANA*)

A46.1 LEGAL STATUS

San Joaquin spearscale (*Atriplex joaquiniana*) is not listed under either federal or California endangered species acts. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G2/S2.1 which means that globally (G) and within the state (S) there are either between six to 20 viable element occurrences of this species, 1,000 to 3,000 individuals of this species, or 2,000 to 10,000 acres (809 to 4,047 hectares) where this species occurs. Its state threat level rank is "very threatened."

The California Native Plant Society (CNPS) List ranking of 1B.2 indicates that it is rare, threatened, or endangered in California and elsewhere, and is considered by CNPS to be fairly endangered in California with between 20 to 80 percent of occurrences threatened. Plants with a CNPS List rank of 1B are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

A46.2 SPECIES DISTRIBUTION AND STATUS

A46.2.1 Range and Status

The range of San Joaquin spearscale includes Glenn, Colusa and Yolo counties to the north, Contra Costa, Santa Clara, San Benito, Napa, Solano, and Alameda counties to the west, Sacramento, Fresno, Merced, and San Joaquin counties to the south (Figure A-46a). Population trends of San Joaquin spearscale have not been documented. According to the CNPS (2008), occurrences of San Joaquin spearscale in California are limited and at risk throughout its range, although it may have been more abundant historically.

Endemic to California, San Joaquin spearscale historically has been collected in the Central Valley from Glenn County south to Merced County (Silveira 2000, CNDDB 2008). Specimens have also been collected in the inner North Coast Ranges in Glenn County and in the ranges of Alameda, Contra Costa and San Benito counties (Silveira 2000, CNDDB 2008). It has been collected in, or adjacent to, salt marshes in Napa, Sacramento, San Luis Obispo, and Solano counties and on the shore of a small lake in Solano County (CNDDB 2008). Populations remain extant at many of the collection sites. Of 94 observations of the distribution of San Joaquin spearscale in California, seven occurred in Yolo County (CalFlora 2000, CNDDB 2008).

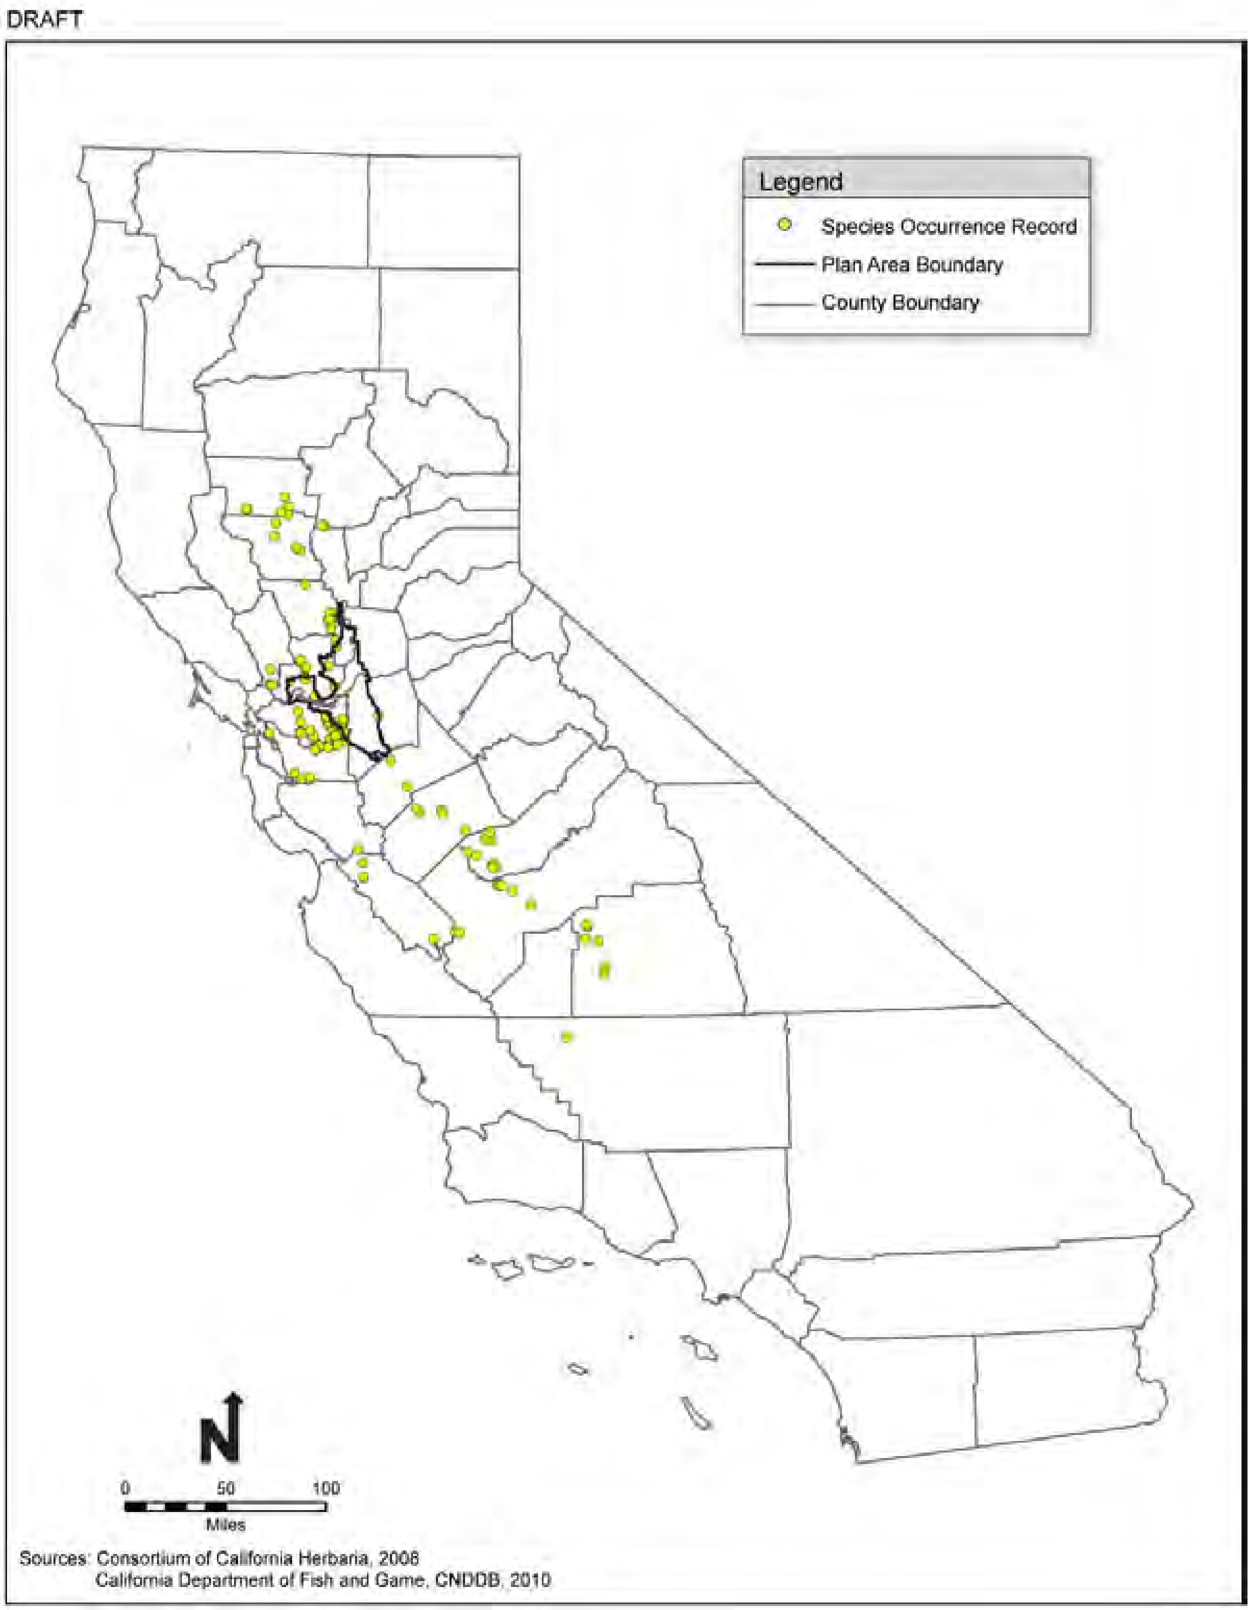

Figure A-46a. San Joaquin Spearscale Statewide Recorded Occurrences

1

In Yolo County, San Joaquin spearscale has been collected on, and adjacent to, alkaline soils north of Davis, east of the City of Woodland, the McClellan Air Force Base Davis Communications Facility site, the California Department of Fish and Game (DFG) Tule Ranch Preserve, which is within the Plan Area, and near Dunnigan (Showers 1996, EDAW 2004, ESA 2005, Dean 2007, CNDDB 2008).

A46.2.2 Distribution and Status in the Plan Area

Within the Plan Area, San Joaquin spearscale generally occurs along the west side of the Sacramento Valley and adjacent to the San Joaquin River. It has been observed near Hass Slough, Orwood Tract, Byron Tract, Clifton Court Forebay, and northwest of Collinsville in the Suisun Marsh area (CNDDB 2008) (Figure A-46b).

A46.3 Habitat Requirements and Special Considerations

San Joaquin spearscale occurs in chenopod scrub and in meadows, playas, valley grassland, and foothill grassland vegetation growing on alkaline soils. In the Central Valley of California, it appears to be restricted to alkaline soils along the rims of alkaline basins and the edges of clay bottom vernal pools (CNDDB 2008). It is also found in alkaline and saline soils near creeks and seeps of the eastern flank of the inner North Coast Ranges (Taylor and Wilken 1993, CNDDB 2008). Similar soils occur in the alluvial fans of Brushy, Kellogg, and Marsh creeks along the northeastern edge of the San Joaquin Valley. In many instances the species occurs with or is found near populations of brittlescale (*Atriplex depressa*), a BDCP covered species, and palmate-bracted bird's-beak (*Cordylanthus palmatus*) (CNDDB 2008).

A46.4 Life History

San Joaquin spearscale was first described in 1904 by A. Nelson (Nelson 1904). It is a 4- to 39-inch (10- to 100-centimeter) tall herbaceous annual plant in the goosefoot family (Chenopodiaceae) (Taylor and Wilken 1993). The species is also known as San Joaquin saltbush and San Joaquin orache (Taylor and Wilken 1993, CalFlora 2000). It has erect stems, with many branches, which spread out as the plant ascends. The twigs are dense and finely scaled, becoming glabrous (hairless and smooth). The ovate to triangular-shaped leaves measure 0.4 to 2.8 inches (1 to 7 cm) (Taylor and Wilken 1993). The leaves are finely gray-scaled and may be green above. They are also generally irregularly wavy-toothed, with the base truncated and tapered in form (Taylor and Wilken 1993). The staminate inflorescence is spike- or panicle-like, which refers to branched clusters of flowers in which the branches are racemes. They are congested on the ends of the main stem and branches, resembling little "sausages." Species of *Atriplex* are most easily identified after flowering, based on fruiting bracts enclosing the seed (Hickman 1993). San Joaquin spearscale blooms from April through October, depending upon environmental conditions (CNPS 2008). The seeds are approximately 1 to 1.5 millimeters (0.04 to 0.06 inch) in length and are dark brown (Taylor and Wilken 1993).

DRAFT

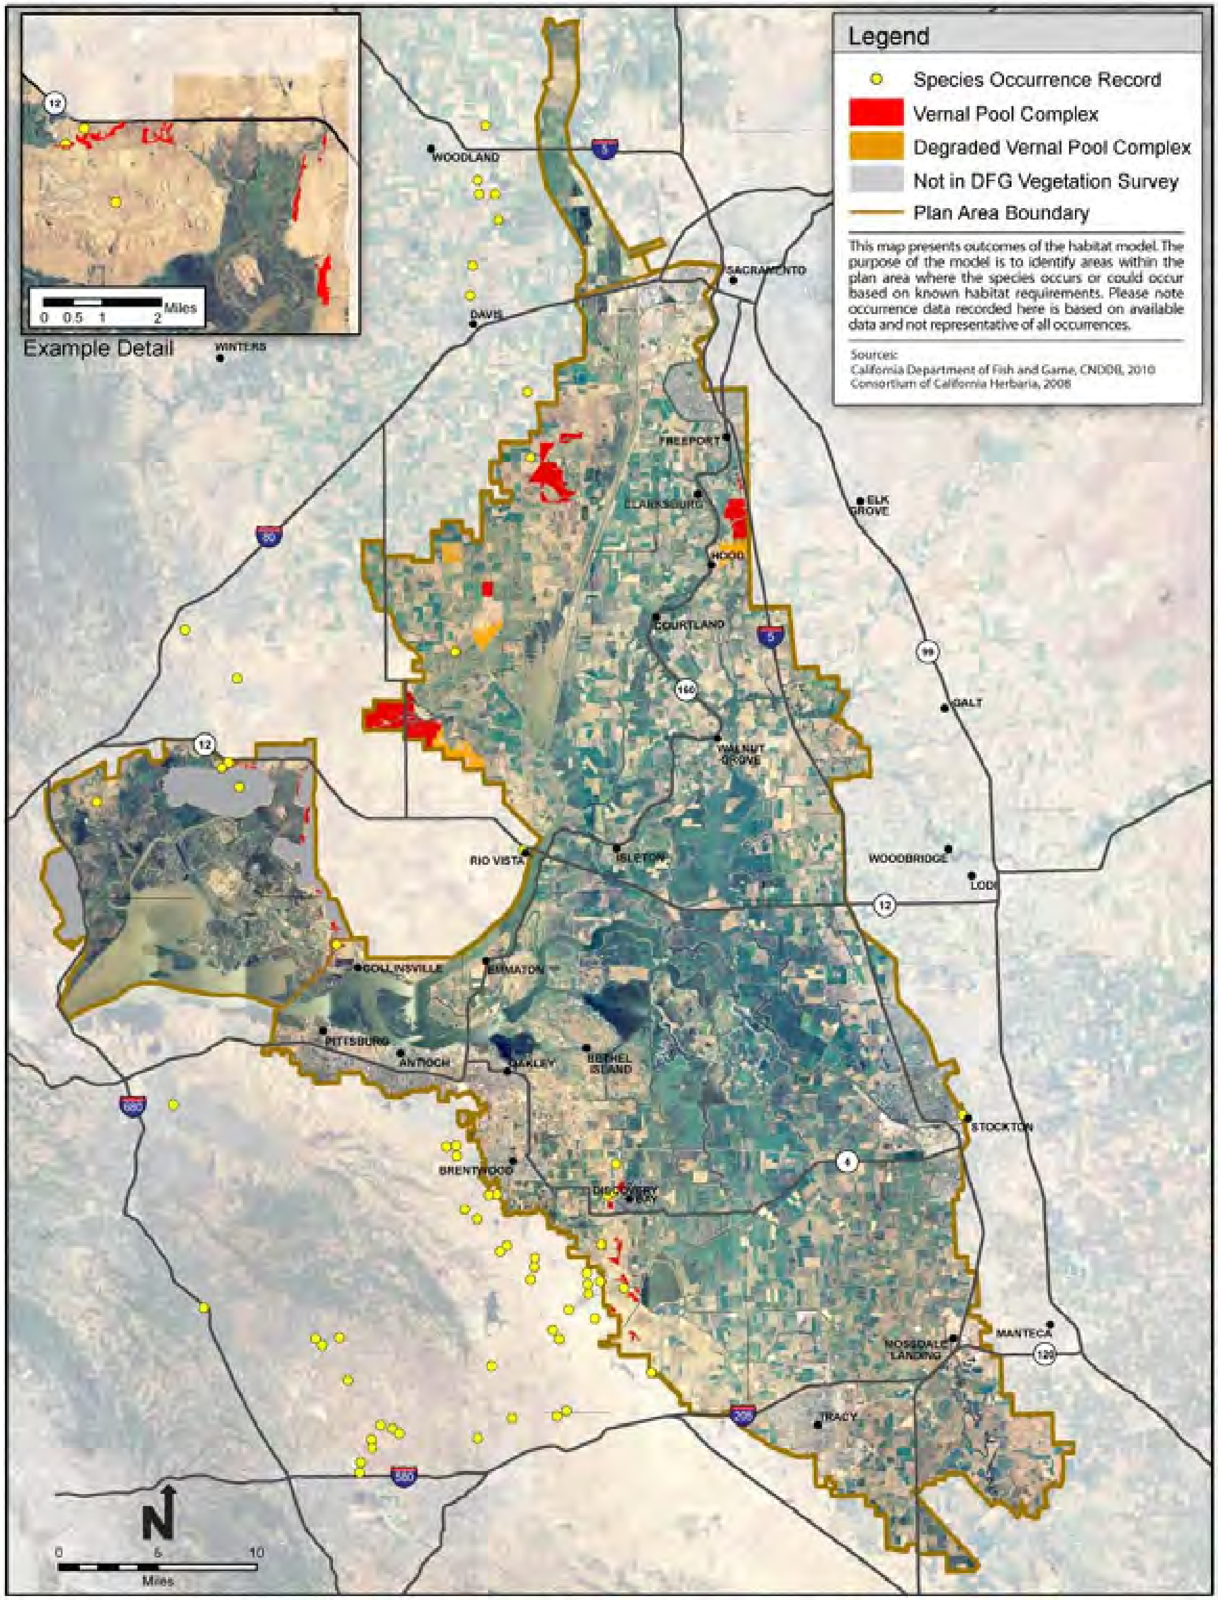

Figure A-46b. San Joaquin Spearscale Habitat Model and Recorded Occurrences

1

Very little is known about the biology and germination patterns of the species; however, spearscale is known to produce a long-lived seed bank that germinates in response to soil disturbances and can persist in weedy grasslands dominated by exotic species (EDAW 2004).

A46.5 Threats and Stressors

Development, intensive agriculture, waterfowl management, and exotic plant species are considered to be the primary threats to the species (Showers 1996, EDAW 2004, CNDDB 2008). All of these impacts lead to loss of habitat and degradation of the specific soils the plant requires to survive. Research should be directed towards invasive species control methods and techniques for establishing the appropriate hydrological regime to maintain the saline and alkaline soils.

A46.6 Relevant Conservation Efforts

San Joaquin spearscale is a covered species under the East Contra Costa County Habitat Conservation Plan/Natural Community Conservation Plan which includes measures to protect populations and habitat. San Joaquin spearscale is proposed for coverage under the Solano County Multispecies Habitat Conservation Plan and the Yolo County Natural Heritage Program Plan.

A46.7 Species Habitat Suitability Model

Model Approach. BDCP Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below and in Section 2.3.1, *Data Sources and Natural Community Classification*). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as vernal pools, individual trees, or small groups of trees. It is also possible, as with some vernal pool invertebrates that are restricted to seasonally ponded habitats, to underestimate potentially-occupied habitat due to the lack of information on small, degraded or artificially-created seasonal wetland habitats.

Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The San Joaquin spearscale model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and

pool complex and degraded vernal pool complex habitat. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Vernal Pool Complex Habitat: High quality permanent habitat that consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly impacted by agricultural or development practices. Vernal pool complex habitat for San Joaquin spearscale includes the following vegetation subunits that were selected from the vernal pool complex natural community:

- Vernal pool complex – all vegetation types

Degraded Vernal Pool Complex Habitat: Low quality ephemeral habitat that ranges from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, disking, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. The aquatic features in this habitat are more clearly classified as temporary waters sensu lato (Williams 2006) than intact and fully functional vernal pools. Because these features are inundated during the wet season and may have historically been located in or near areas with natural vernal pool complex, they may support individuals or small populations of species that are found in vernal pools and swales. However, they do not possess the full complement of ecosystem and community characteristics of natural vernal pools, swales and their associated uplands and they are generally ephemeral features that are eliminated during the course of normal agricultural practices. Degraded vernal pool complex habitat for San Joaquin spearscale includes the following vegetation subunits that were selected from the BDCP other natural seasonal wetlands and grasslands communities:

- Grasslands
  - Degraded vernal pool complex – California annual grasslands;
  - Degraded vernal pool complex – ruderal herbaceous grasses and forbs;
  - Degraded vernal pool complex – Italian rye-grass (*Lolium multiflorum*); and
  - Degraded vernal pool complex – rabbitsfoot grass (*Polygpogon maritimus*).
- Other natural seasonal wetlands
  - Degraded vernal pool complex - vernal pools.

Potential habitat without concave surfaces (except for seeps along Suisun Marsh) was removed from the model. LiDAR elevation data was then visually inspected in four general areas to further assess specific locations that had been identified by the habitat selection process. These areas were selected based both on *a priori* knowledge of the region and because they were identified by the intersection of the selected vegetation types and soils. The analysis of the LiDAR data further refined the habitat model and provided a more accurate demarcation of suitable habitat. The GIS habitat model was then compared against field data from surveys conducted by the California Department of Water Resources/Delta Habitat Conservation and Conveyance Program (DWR/DHCCP) for the Bay Delta Conservation Plan (BDCP) in 2009. Land uses that are incompatible with the species' habitat requirements, for example potential habitat polygons falling on leveled or developed lands, were removed from the model.

Assumptions. Historical and current records of this species in the Plan Area indicate that its current distribution is limited to alkaline soil areas with vernal pool and swale microtopography along the western border (Figure A-46b) (CNDDB 2010). The vegetation cover of the alkaline soils is typically a combination of vernal pool adapted species, alkaline soil adapted species, and annual ryegrass (CNDDB 2010).

A46.8 RECOVERY GOALS

A United States Fish and Wildlife (USFWS) recovery plan has not been prepared for this species and no recovery goals have been established.

APPENDIX A47. SLOUGH THISTLE (*CIRSIUM CRASSICAULE*)

A47.1 LEGAL STATUS

Slough thistle (*Cirsium crassicaule*) is not listed under either federal or California endangered species acts. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G2/S2.2 which means that globally (G) and within the state (S) there are either between six to 20 viable element occurrences of this species, 1,000 to 3,000 individuals of this species, or 2,000 to 10,000 acres (809 to 4,047 hectares) where this species occurs; and the state threat level rank is "threatened."

The California Native Plant Society (CNPS) List ranking of 1B.1 for slough thistle indicates that it is rare, threatened, or endangered. It is endemic to California and is considered by CNPS to be seriously endangered with more than 80 percent of occurrences threatened. Plants with a CNPS List rank of 1B are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

A47.2 SPECIES DISTRIBUTION AND STATUS

A47.2.1 Range and Status

Slough thistle is endemic to the San Joaquin Valley and has been reported from San Joaquin County in the north and in Kings and Kern counties in the south (CNPS 2009) (Figure A-47a). The few individuals who have direct experience with this species believe that its populations are declining throughout the San Joaquin Valley (T. Griggs pers. comm. 2009, R. Hansen pers. comm. 2009). A cluster of occurrences (CNDDB 2009) have been reported from the Hacienda Spillway which is a former flood channel of the Kern River at the southern end of Tulare Lake that is maintained as a flood conveyance and floodwater storage area (Hacienda Reservoir). Long term casual monitoring indicates that this species has declined to zero plants at one Hacienda Spillway occurrence (R. Hansen pers. comm. 2009) while the CNDDB record indicates that another occurrence was extirpated by the construction of storage ponds.

A47.2.2 Distribution and Status in the Plan Area

Slough thistle occurs in the southern end of the Plan Area in the San Joaquin River (Figure A-47b). There are seven records from near Lathrop and Vernalis; all but two of which have been extirpated by agriculture or urbanization (CNDDB 2009).

DRAFT

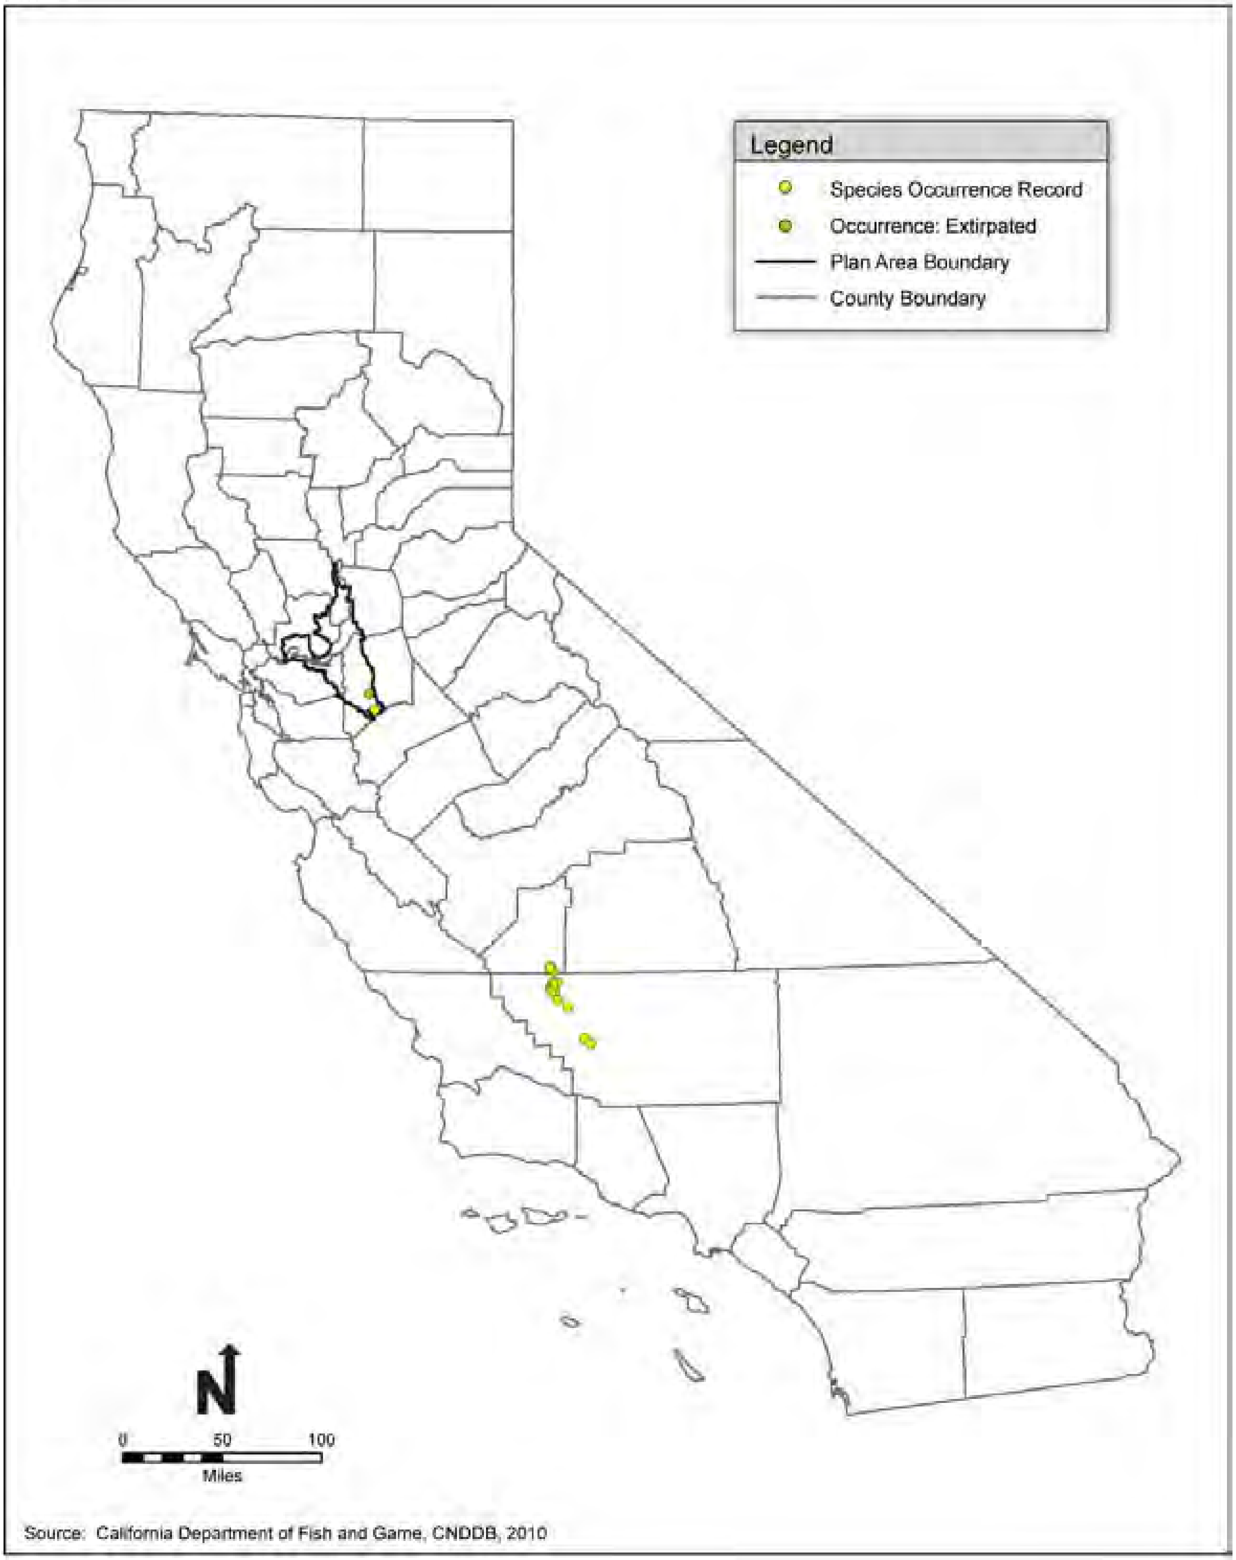

Figure A-47a. Slough Thistle Statewide Recorded Occurrences

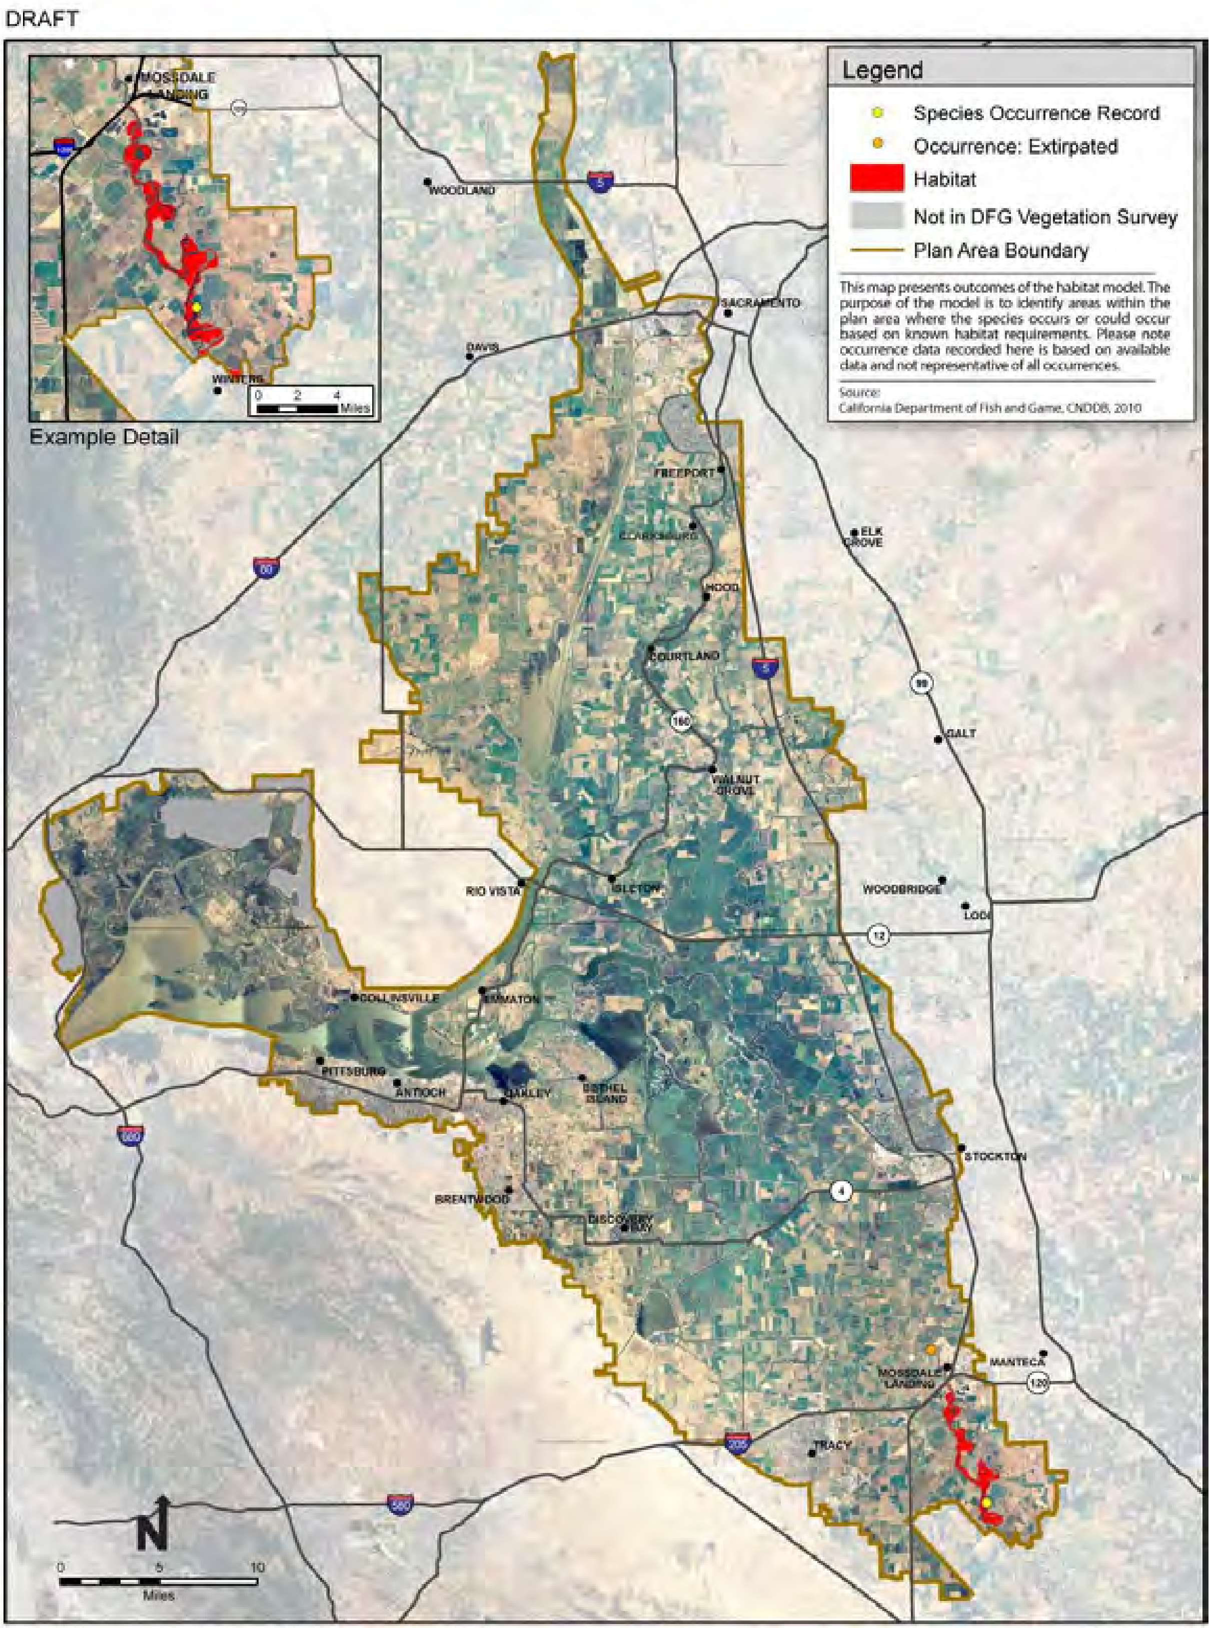

Figure A-47b. Slough Thistle Habitat Model and Recorded Occurrences

1

A47.3 HABITAT REQUIREMENTS AND SPECIAL CONSIDERATIONS

Slough thistle has been reported from freshwater marshes and swamps, and in chenopod scrub and riparian scrub habitats (CNPS 2009). Under natural conditions, it almost always occurs in wetlands (Calflora 2009). Population sizes widely fluctuate (CNPS 2009). The locations reported in the southern San Joaquin Valley are all along or adjacent to high flood flow areas (CNDDB 2009) such as the Hacienda Spillway where high flows from the Kern River broke through the Sand Ridge and flowed into Tulare Lake (R. Hansen pers. comm. 2009). Because these high flow areas have been preserved, albeit in a modified condition, for floodwater conveyance, some habitat has been preserved in what is now an area of intensive agricultural production. Historically slough thistle was likely present throughout the Tulare Basin in lesser flow channels as well. It is generally found within the portions of channels that flood at high water and on the banks of flood water conveyance canals and drains (T. Griggs pers. comm. 2009, R. Hansen pers. comm. 2009).

A47.4 LIFE HISTORY

Slough thistle is a large (3.3- to 9.8-feet [1- to 3-meter]) tall annual to biennial herb of the sunflower family (Asteraceae) that blooms from May to August (Hickman 1993, CNPS 2009). It is found at elevations of 9.8 to 328 feet (3 to 100 meters) above sea level (CNPS 2009). Unless grazed, it generally has one stem that is hollow and openly branched near the top of the plant (Hickman 1993, T. Griggs pers. comm. 2009). Its leaves are thinly covered with cobwebby-tomentose hairs on top and gray-tomentose hairs below. Lower leaf lengths range from 6 to 27 inches (15.2 to 69 centimeters [cm]); middle and upper leaves are smaller, narrower, and sessile (Hickman 1993). Slough thistle flowers are pale rose-purple or sometimes white in color, 0.75 to 1.0 inch (1.0 to 5.1 cm) long, and are grouped into spiny heads one half to one inch wide which are in turn grouped into loose to crowded clusters called cymes in which the central flowers open before the surrounding flowers (Hickman 1993).

A47.5 THREATS AND STRESSORS

Conversions of suitable habitat to agricultural land uses and competition from nonnative plants have been reported as the primary threats to slough thistle (CNPS 2009). In the southern San Joaquin Valley, other threats include vegetation clearing on the banks of drains and canals, and weed control efforts (T. Griggs pers. comm. 2009, R. Hansen pers. comm. 2009).

A47.6 RELEVANT CONSERVATION EFFORTS

Slough thistle is a covered species in the San Joaquin County Multi-species Habitat Conservation and Open Space Plan, the Metro Bakersfield Habitat Conservation Plan, and the Kern Valley Floor Habitat Conservation Plan. It is also covered under the Kern and Pixley National Wildlife Refuges Comprehensive Conservation Plan (USFWS 2005).

A47.7 Species Habitat Suitability Model

Habitat. Slough thistle habitat was identified as all areas between the levees from the Mossdale Bridge to Vernalis. A historical occurrence from 1933 was located just north of the Mossdale Bridge but aerial imagery indicates that the occurrence has likely been extirpated due to intensive agriculture.

Assumptions. Historical and current records of this species indicate that its distribution within the Plan Area is limited to the flood plain of the San Joaquin River (Figure A-47b). Based on its distribution in the southern San Joaquin Valley, its habitat is likely to be areas along the river that have been disturbed by flood events and are being colonized by willow scrub vegetation.

A47.8 Recovery Goals

A USFWS recovery plan has not been prepared for this species and no recovery goals have been established.

APPENDIX A48. SUISUN THISTLE (*CIRSIUM HYDROPHILUM* VAR. *HYDROPHILUM*)

A48.1 LEGAL STATUS

Suisun thistle (*Cirsium hydrophilum* var. *hydrophilum*) is listed as endangered under the federal Endangered Species Act (November 1997) (62 FR 61916). It is not listed under the California Endangered Species Act. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G1T1/S1.1 which means that globally (G) and within the state (S) both the species and variety have either less than 6 viable element occurrences, less than 1,000 individuals, or less than 2,000 acres (809 hectares) of occupied habitat; and the state threat level rank is "very threatened."

The California Native Plant Society (CNPS) List ranking of 1B.1 for Suisun thistle indicates that it is rare, threatened, or endangered. It is endemic to California and is considered by CNPS to be seriously endangered with more than 80 percent of occurrences threatened. Plants with a CNPS List rank of 1B are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

The United States Fish and Wildlife Service (USFWS) recently designated critical habitat that specifies the protection of Suisun thistle habitat in three areas of Suisun Marsh (72 FR 18517). Unit One contains no Suisun thistle (Hill Slough Marsh), but it has all the necessary habitat features. Units Two and Three contain or did contain Suisun thistle populations at the time of the listing (Peytonia Slough Ecological Reserve and Rush Ranch/Grizzly Island Wildlife Area).

A48.2 SPECIES DISTRIBUTION AND STATUS

A48.2.1 Range and Status

Suisun thistle has a very small range as it is endemic to a few areas in the northern portion of the Suisun Marsh in Solano County, California (62 FR 61916, USFWS 2009) (Figure A-48a). It is protected on public lands, and on non-governmental organization conservation lands in the Suisun Marsh, but its current primary habitat is along mosquito control ditches that may degrade through time (USFWS 2009). The Peytonia Slough Ecological Reserve population may have been extirpated through arson (USFWS 2009).

A48.2.2 Distribution and Status in the Plan Area

In 1975, Suisun thistle was presumed to be extinct because it had not been observed for 15 years (62 FR 61916, USFWS 2003, 2009); however, extensive surveys conducted at Suisun Marsh in 1989 rediscovered this species at two locations (62 FR 61916, USFWS 2003, 2009) (Figure A-48b).

Figure A-48a. Suisun Thistle Statewide Recorded Occurrences

DRAFT

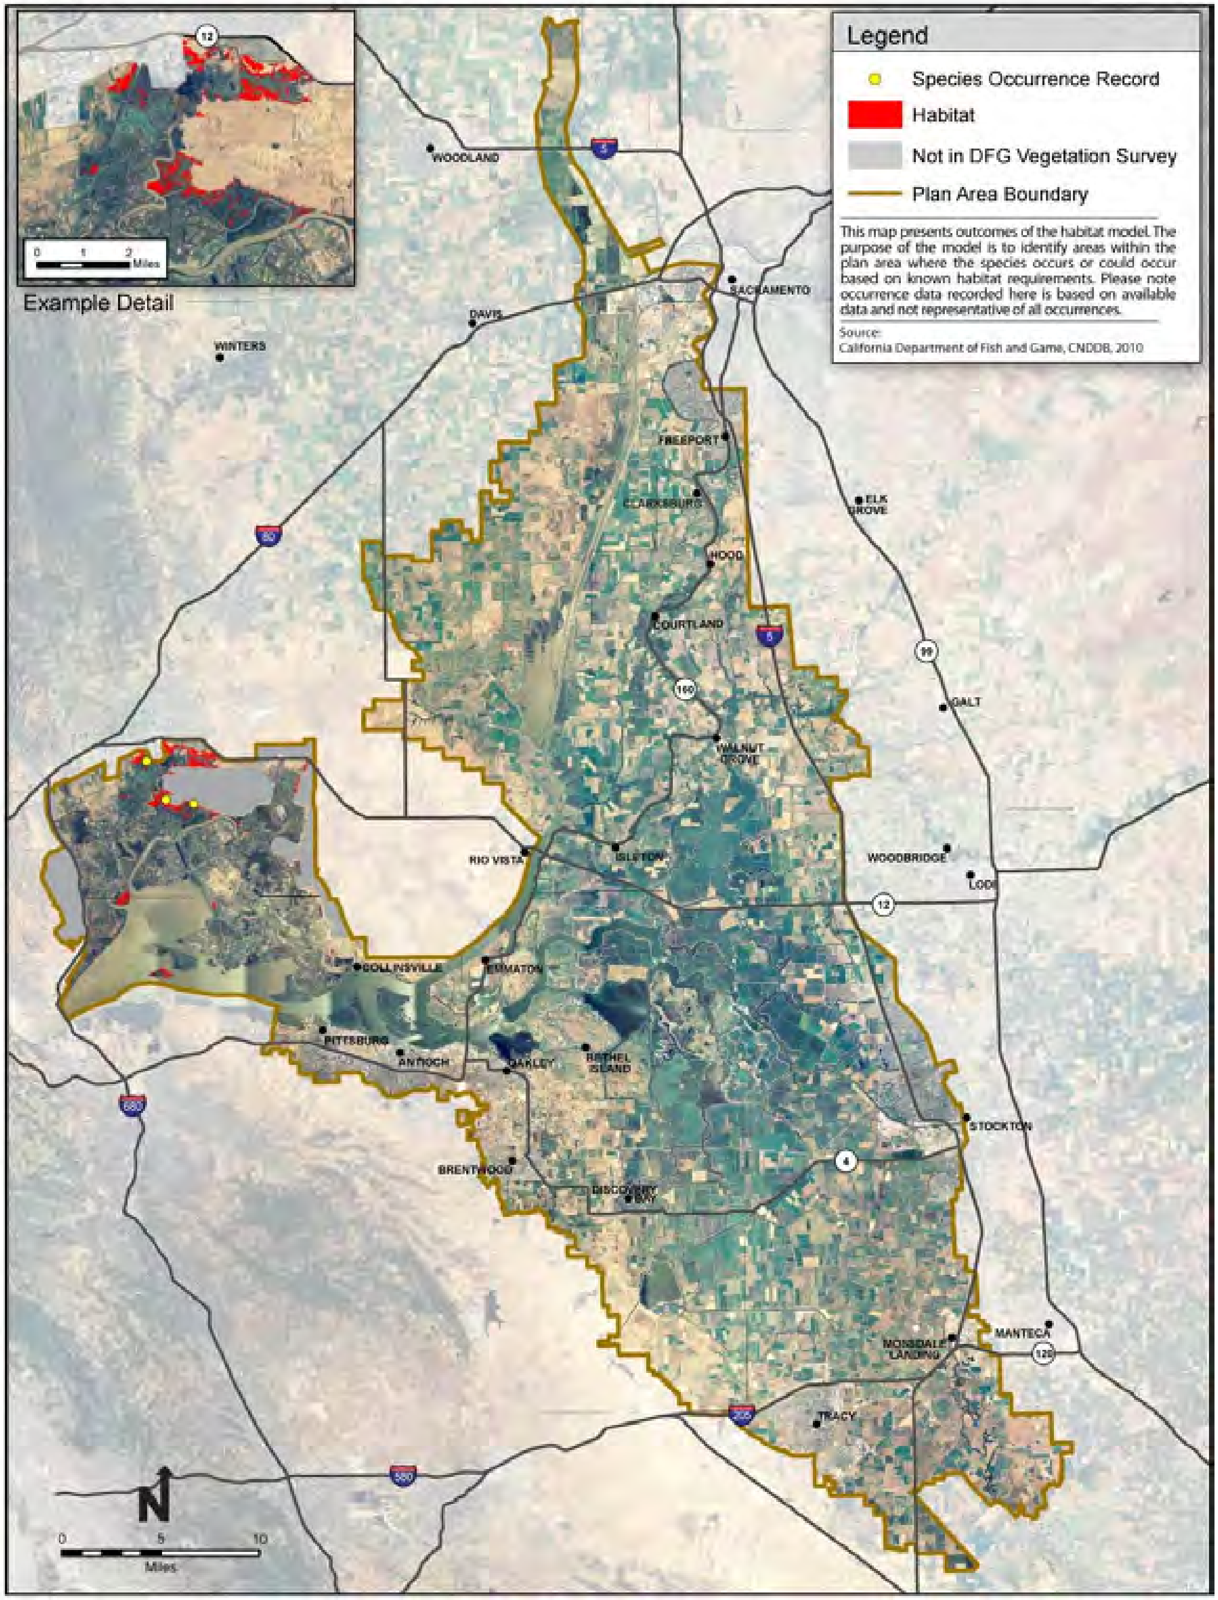

Figure A-48b. Suisun Thistle Habitat Model and Recorded Occurrences

1

Recent surveys have found Suisun thistle within relict undiked high tidal marshes at Rush Ranch, the Joice Island portion of the Grizzly Island Wildlife Area, and the Peytonia Slough Ecological Reserve (USFWS 2003, Fiedler et al. 2007). Thousands of plants were observed at Rush Ranch, much smaller numbers were observed at Grizzly Island Wildlife Area, and the population at the Peytonia Slough Ecological Reserve had declined to a single plant in 1996 (USFWS 2003, 2009).

A48.3 Habitat Requirements and Special Considerations

Suisun thistle is restricted to the brackish tidal marshes of Suisun Marsh (62 FR 61916, USFWS 2009) and is almost always found adjacent to first-order channels or mosquito control ditches that link to first-order channels (Fiedler et al. 2007, USFWS 2009). This habitat restriction is likely due to its low tolerance to soil salinity and possibly a preference for soils with less organic matter content. The Rush Ranch area of Suisun Marsh has been studied recently to determine how biological and physical factors interact in marshes around the Mean High Water (MHW) elevation (Culberson 2001, Culberson et al. 2004). A pattern emerged in this study such that the marsh could be analyzed spatially as channel (within 3.28 feet [1 meter] of a first-order channel), transitional (out to 82 feet [25 meters] from the channel), or marsh plain (beyond 82 feet [25 meters] from the channel). The study found that proximity to a channel, and not marsh elevation, was strongly correlated with the plant species composition and cover of the vegetation. The primary factor driving this correlation was found to be soil pore water salinity. The salinity of the water in the channel water and streamside soil pore water was generally 2-5 parts per thousand (ppt) with a non-linear increase with distance from the channel to approximately 15 ppt in the plain 131 feet (40 meters) from the channel. The study also found that below ground accumulation of organic carbon was the likely cause of the gradual increase in elevation (30 centimeters [cm]) from streamside to 230 feet (70 meters) out in the plain. Two other factors relevant to the ecology of Suisun thistle are the invasion of the streamside and transition zone by perennial pepperweed (*Lepidium latifolium*) which as of 2003 had invaded 85 percent of the Suisun thistle populations (Fiedler et al. 2007), and the extensive soil disturbance and plant damage caused by feral pigs (Culberson 2001, Fiedler et al. 2007, USFWS 2009).

A48.4 Life History

Suisun thistle is a large (3- to 4.5-feet [1- to 1.5-meter]) perennial herb of the sunflower family (Asteraceae) that blooms from June to September (62 FR 61916, CNPS 2009). It is found at sea level (< 3.28 feet [1 meter]) (Hickman 1993, Fiedler et al. 2007, USFWS 2009). Its stems are erect, slender, and branched above the middle (Hickman 1993, USFWS 2003). Suisun thistle leaves are spiny and deeply lobed; lower leaves have ear-like basal lobes, and upper leaves are reduced to narrow strips with strongly spine-toothed margins (62 FR 61916, USFWS 2003). The inflorescences are pale lavender-rose in color, about 1 inch (2.5-3 cm) in length, and grow singly or in loose groups (Hickman 1993, USFWS 2003). Flower head bracts have a distinct green, glutinous ridge on the back that distinguishes Suisun thistle from other *Cirsium* species in the area (62 FR 61916).

A48.5 Threats and Stressors

Historically, the marsh habitat suitable for Suisun thistle has been lost mostly through development, dredge disposal, agricultural conversion, and diking. Diked marshes generally lack rare tidal marsh species. It is believed that the conditions brought about by dikes favor robust generalist species that can better tolerate the long inundation periods in diked managed wetlands (Goals Project 2000).

Current threats to Suisun thistle include: the nonnative and highly invasive perennial pepperweed, feral pigs, and fire during sensitive periods of the species' lifecycle (Fiedler et al. 2007, USFWS 2009). Other potential but unquantified threats include hybridization with bull thistle (*Cirsium vulgare*) and seed predation by the introduced biocontrol thistle weevil (*Rhinocyllus conicus*) (Fiedler et al. 2007, USFWS 2009).

A48.6 Relevant Conservation Efforts

The California Department of Fish and Game provides some protection for Suisun thistle populations at Grizzly Island Wildlife Area and Peytonia Slough Ecological Reserve (CNPS 2009). The Suisun Marsh Habitat Management, Preservation and Restoration Plan is currently under development and should provide further conservation efforts for Suisun thistle.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for Suisun thistle is "Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP has established a goal to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

Suisun thistle is proposed for coverage under the Solano County Multispecies Habitat Conservation Plan.

A48.7 Species Habitat Suitability Model

Habitat. The modeled habitat for Suisun thistle in and near Suisun Marsh consists of all tidal brackish emergent wetland polygons with the appropriate vegetation (SFEI 2005, Boul and Keeler-Wolf 2008).

Vegetation Units. The following vegetation subunits were selected from the tidal brackish emergent wetland natural community:

- *Atriplex triangularis;*
- *Atriplex triangularis* (generic);
- *Atriplex*/annual grasses;
- *Atriplex*/*Distichlis;*
- *Distichlis* (generic);
- *Distichlis spicata;*
- *Distichlis spicata* - annual grasses;
- *Distichlis spicata - Salicornia virginica*[1]*;*
- *Distichlis-Juncus-Triglochin-Glaux;*
- *Distichlis*/annual grasses;
- *Distichlis*/*Cotula;*
- *Distichlis*/*Juncus;*
- *Distichlis*/*Lotus;*
- *Distichlis*/*S. americanus;*
- *Distichlis*/*S. maritimus;*
- *Distichlis*/*Salicornia*[2]*;*
- *Lepidium* (generic);
- *Lepidium*/*Distichlis;*
- Pickleweed (*Salicornia virginica*);
- *Salicornia* (generic);
- *Salicornia virginica;*
- *Salicornia virginica* - *Cotula coronopifolia;*
- *Salicornia virginica* - *Distichlis spicata;*
- *Salicornia*/annual grasses; and
- *Salicornia*/*Atriplex.*

Assumptions. Suisun thistle is endemic to Suisun Marsh and is found primarily away

[1] Currently known as *Sarcocornia pacifica.*
[2] Currently known as *Sarcocornia.*

from the main channels that are dominated by large emergent wetland species.

A48.8 Recovery Goals

A United States Fish and Wildlife Service (USFWS) approved Recovery Plan has not been prepared for this species but the recent 5-year species review (USFWS 2009) recommended that a recovery plan be prepared. However, this species is included in the Draft Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California which specifies the preservation of individuals and habitat, the control of invasive species, and the restoration of tidal flows as recovery criteria goals (USFWS 2010). Additionally, the CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for Suisun thistle is "Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP has established a goal to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

APPENDIX A49. SOFT BIRD'S-BEAK (*CORDYLANTHUS MOLLIS* SSP. *MOLLIS*)

A49.1 LEGAL STATUS

Soft bird's-beak (*Cordylanthus mollis* ssp. *mollis*) is listed as endangered under the federal Endangered Species Act (November 1997) and listed as rare under the California Native Plant Protection Act (July 1979). Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G2T1/S1.1, which means that globally (G) this species has either between six to 20 viable element occurrences, 1,000 to 3,000 individuals, or 2,000 to 10,000 acres (809 to 4,047 hectares) of occupied habitat. In contrast, this particular subspecies has been ranked as threatened globally and within the state (S) as it has either less than six viable element occurrences, less than 1,000 individuals, or less than 2,000 acres (809 hectares) of occupied habitat. Its state threat level rank is "threatened."

The California Native Plant Society (CNPS) List ranking of 1B.2 for soft bird's-beak indicates that it is rare, threatened, or endangered in California and elsewhere, and is considered by CNPS to be fairly endangered in California with between 20 to 80 percent of occurrences threatened. Plants with a CNPS List rank of 1B are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

USFWS recently designated critical habitat that specifies the protection of soft bird's-beak populations in the four areas that contain the largest and most intact populations and habitat (72 FR 18517). Additionally, in its 5-year review of this species the United States Fish and Wildlife (USFWS) recommended the continuation of its endangered status and the development of a recovery plan (USFWS 2009).

A49.2 SPECIES DISTRIBUTION AND STATUS

A49.2.1 Range and Status

Historically, the range of soft bird's-beak extended from tidal marshes of Napa and Solano counties in the north, Contra Costa County in the south, Sonoma and Marin counties in the west, and Sacramento and San Joaquin counties in the east (Figure A-49a). It is now believed to be extirpated from Marin, San Joaquin, and Sonoma counties, and extant in Napa, Solano, Contra Costa, and Sacramento counties (CNDDB 2008). The largest extant occurrences are on California Department of Fish and Game (DFG) reserves and wildlife areas, a California Department of Parks and Recreation park, a county park, and a property held for conservation purposes by a land trust.

DRAFT

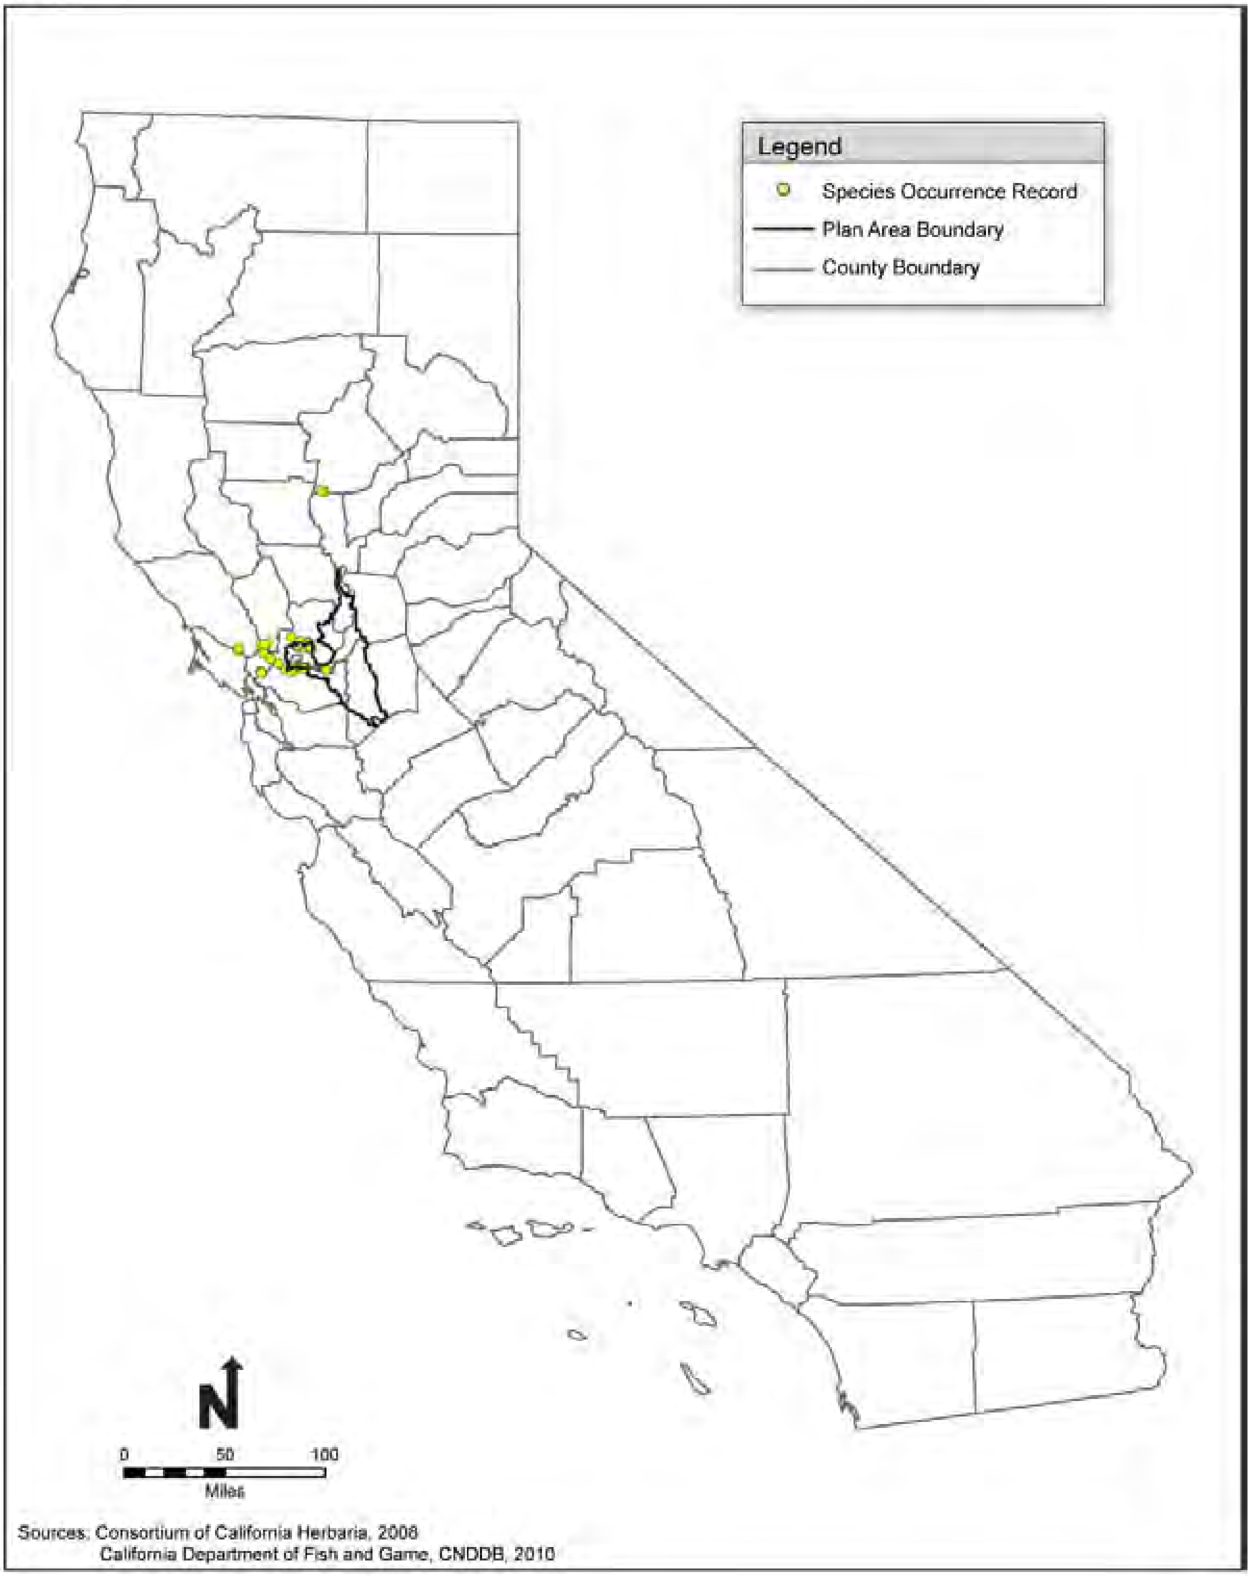

Figure A-49a. Soft Bird's-Beak Statewide Recorded Occurrences

1

A49.2.2 Distribution and Status in the Plan Area

The majority of the occurrences in the Plan Area are in and around Suisun Marsh and Suisun Bay (USFWS 2009). A single occurrence has been reported in in Sacramento County along the north bank of the San Joaquin River immediately west of the Antioch Bridge (CNDDB 2008) (Figure A-49b). This occurrence was last observed in 1972 and may have been extirpated, but there are no additional data describing the site which aerial photographs now show to be a rip-rapped shoreline. No voucher specimen for this occurrence is on record at any California herbarium (Consortium of California Herbaria 2008).

A49.3 Habitat Requirements and Special Considerations

Soft bird's-beak grows at the lower margin of tidal brackish high marshes in the San Francisco Estuary (Baye et al. 2000, Grewell 2005, Grewell et al. 2007). Where the topography is relatively uniform, soft bird's-beak is distributed in bands at the lower margin of the brackish high marsh. In Suisun Marsh these bands are not correlated with elevation, but with soil pore water salinity during the dry season which is determined by distance to channel and varies from season to season depending on freshwater flows from creeks draining into the marsh (Culberson 2001). Where the topography is more complex, such as areas with ridges or mounds and on levee banks, soft bird's-beak can be found in a variety of patch shapes (Baye et al. 2000, Grewell 2005, Grewell et al. 2007). The distribution of these patches and the distribution of individual plants within the patches is controlled by a number of factors including the existence of a persistent seed bank, the dispersal and germination dynamics of its floating seed, the extent of bare soil where seedlings can establish, the presence of appropriate long-lived annual or perennial host species, and the absence of dense populations of large, perennial, nonnative plant species (Baye et al. 2000, Grewell et al. 2003, Grewell 2005, Grewell et al. 2007). The presence of a natural tidal inundation pattern is important and the more muted the tidal influence is, such as tidal creeks with salt water exclusion gates or marshes with extensive levee systems, the less valuable the habitat is for soft bird's-beak (Grewell et al. 2003, Grewell 2005, Grewell et al. 2007). A number of hypotheses have been suggested to explain the effects of the muted tidal influence including increased rates of seed predation and herbivory by native insects, high densities of inappropriate host species such as nonnative annual plants, and invasion and space preemption by large nonnative plant species such as perennial pepperweed (*Lepidium latifolium*) (Grewell 2005).

Dominant plant associates include pickleweed (*Sarcocornia pacifica*[1]), saltgrass (*Distichlis spicata*), salt marsh dodder (*Cuscuta salina*), and spearscale (*Atriplex triangularis*) (Baye et al. 2000, Grewell 2005, Grewell et al. 2007).

[1] Formerly known as *Salicornia virginica.*

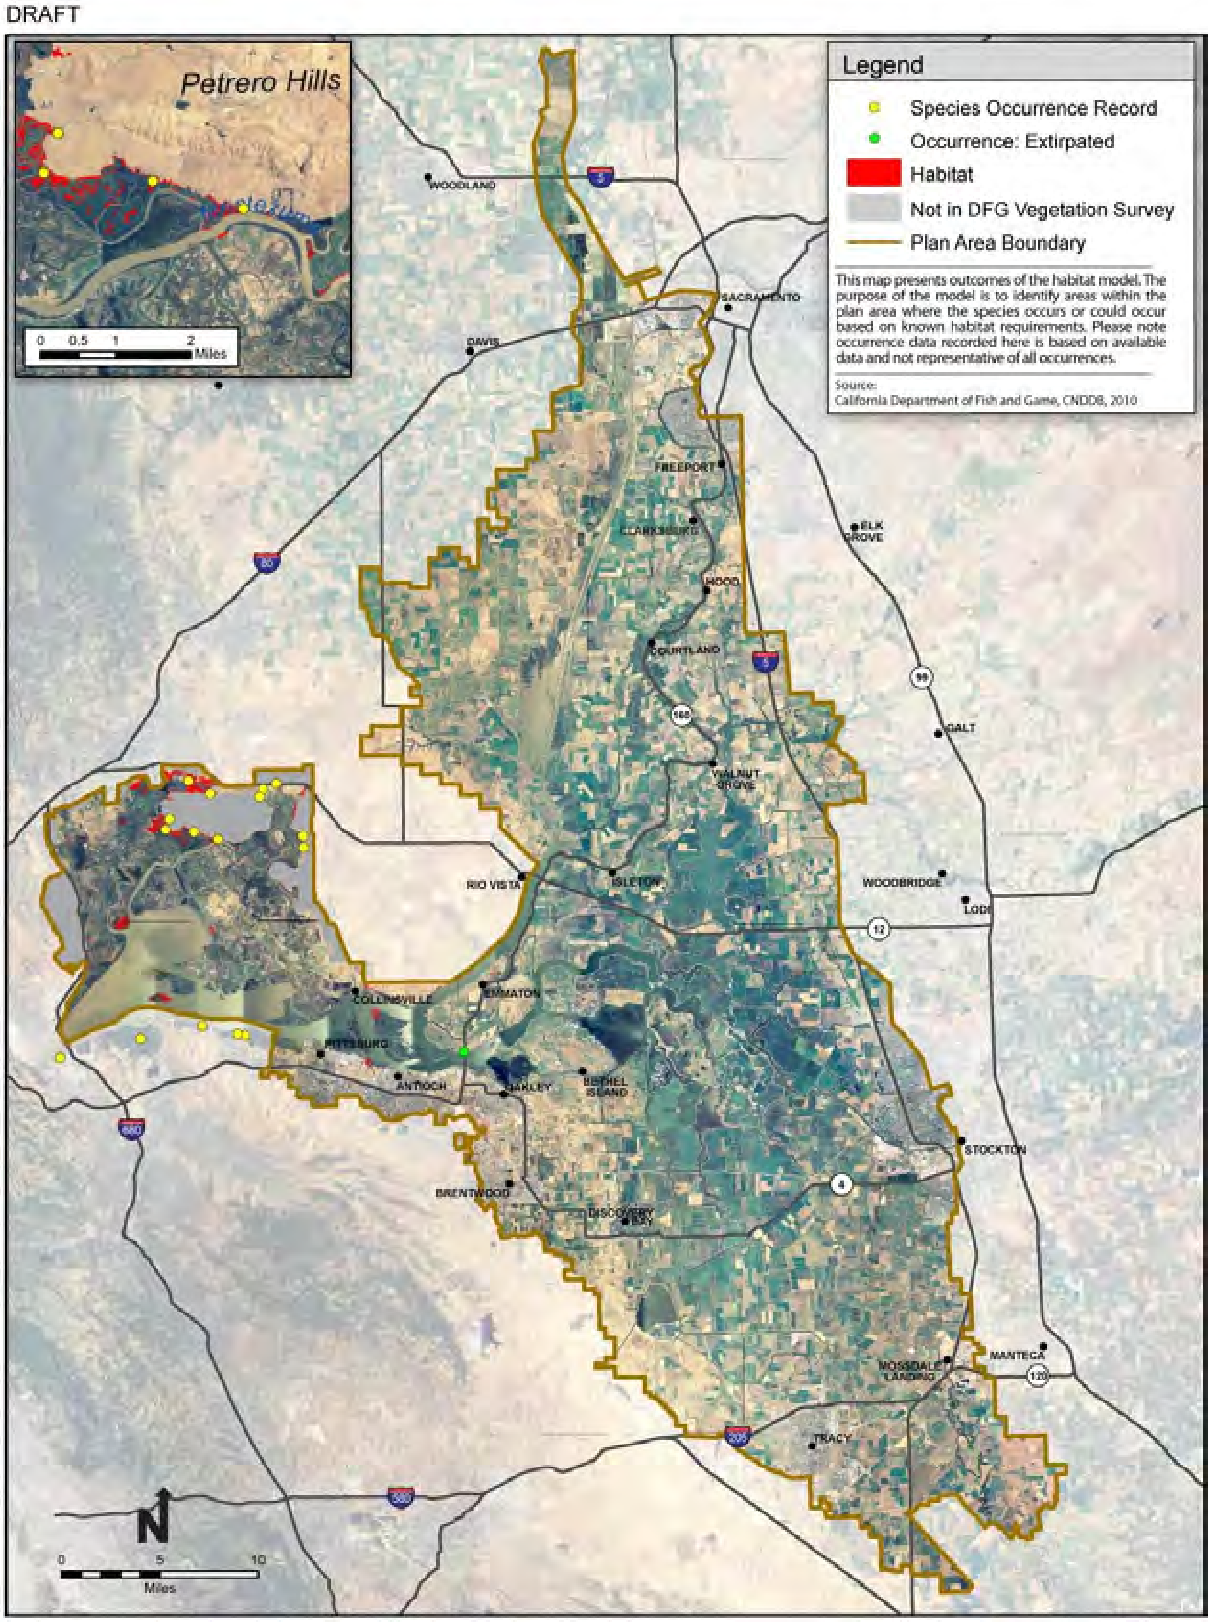

Figure A-49b. Soft Bird's-Beak Habitat Model and Recorded Occurrences

1

Recent research in an analogous plant community has documented complex positive and negative ecological relationships between the related Point Reyes bird's-beak (*Cordylanthus maritimus* ssp. *palustris*), salt marsh dodder, and other species including pickleweed (Grewell 2008), but these findings have not been extended to soft bird's-beak.

A49.4 Life History

Soft bird's-beak is a 4- to 12-inch (10- to 30-centimeter) tall annual herb that parasitizes and draws nutrients from other plants through their roots systems (Hickman 1993, Grewell 2005). It may require pollinators such as bumblebees (*Bombus* spp.) or other insects to pollinate its flowers and produce viable seed but is apparently capable of producing seed without the movement of pollen by insects (Grewell et al. 2003, Grewell 2005). It appears to have a persistent seed bank and specific seed germination cues. Complex interactions between its seed germination characteristics, which respond to variable environmental factors, the lack or presence of bare soil for seedling establishment, and the presence or absence of appropriate host species can result in large annual changes in population sizes (Grewell 2005). Its seeds float and are dispersed by water, which is likely to aid its spread and reestablishment (Grewell 2005).

A49.5 Threats and Stressors

Threats to the species include the destruction of habitat, the elimination or muting of tidal regimes, overgrazing and trampling by livestock, rooting by feral pigs, invasion of habitat by nonnative annual plants that are inappropriate hosts, and invasion of its habitat by perennial pepperweed (Grewell et al. 2003, Grewell 2005, Fiedler et al 2007, CNDDB 2008, USFWS 2009).

A49.6 Relevant Conservation Efforts

Soft bird's-beak occurs on a number of government lands where is it protected from development, but sometimes impacted by lawful site use and management activities (Grewell 2005, 72 FR 18517, USFWS 2009). At the Rush Ranch site in Suisun Marsh, which is owned by the Solano Land Trust and protected by a conservation easement, marsh restoration was coupled with the reintroduction of soft bird's-beak through a high density seeding in 2000 (Grewell et al. 2003, Grewell 2005). It is unclear if this reintroduction has been successful as the 2004 census reported a substantial increase in the number of plants in the population but each plant was significantly smaller than a nearby natural population and the number of seeds produced by each plant had declined from 2000 per plant to near zero (Grewell 2005).

A United States Fish and Wildlife Service (USFWS) approved Recovery Plan has not been prepared for this species but the very recent 5-year species review (USFWS 2009) recommended that a recovery plan be prepared. However, this species is included in the Draft Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California which specifies the preservation of individuals and habitat, the control of invasive species, and the restoration of tidal flows as recovery criteria goals (USFWS 2010). Additionally, the CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for soft bird's-beak is "Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP has established a goal to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

Soft bird's-beak is proposed for coverage under the Solano County Multispecies Habitat Conservation Plan.

A49.7 SPECIES HABITAT SUITABILITY MODEL

Habitat. The modeled habitat for soft bird's-beak consisted of pickleweed and saltgrass dominated vegetation located west of the Antioch Bridge. To isolate habitat in and near Suisun Marsh the model used all Tidal Brackish Emergent Wetland polygons from the San Francisco Estuary Institute (SFEI) (2005) that was limited by specific DFG vegetation units of Boul and Keeler-Wolf (2008) that are known to be closely associated with soft bird's-beak habitat.

Vegetation Units. The following vegetation subunits were selected from the BDCP vegetation dataset:

- *Atriplex triangularis;*
- *Atriplex triangularis* (generic);
- *Atriplex*/annual grasses;
- *Atriplex*/*Distichlis;*
- *Distichlis* (generic);
- *Distichlis spicata;*
- *Distichlis spicata* - Annual grasses;
- *Distichlis spicata - Salicornia virginica*[2]*;*
- *Distichlis-Juncus-Triglochin-Glaux;*
- *Distichlis*/annual grasses;
- *Distichlis*/*Cotula;*
- *Distichlis*/*Juncus;*
- *Distichlis*/*Lotus;*

---

[2] Currently known as *Sarcocornia pacifica*.

- *Distichlis/S. americanus;*
- *Distichlis/S. maritimus;*
- *Distichlis/Salicornia*[3]*;*
- *Lepidium* (generic);
- *Lepidium/Distichlis;*
- Pickleweed (*Salicornia virginica*);
- *Salicornia* (generic);
- *Salicornia virginica;*
- *Salicornia virginica - Cotula coronopifolia;*
- *Salicornia virginica - Distichlis spicata;*
- *Salicornia*/annual grasses; and
- *Salicornia/Atriplex.*

Assumptions. Historical and current records of this species indicate that its distribution is limited to parts of the Plan Area and other conservation areas that are west of the Antioch Bridge (Figure A-49b) (CNDDB 2008). Soft bird's-beak grows at the lower margin of tidal brackish high marshes in the San Francisco Estuary (Baye et al. 2000, Grewell 2005, Grewell et al. 2007). Where the topography is relatively uniform, soft bird's-beak is generally distributed in bands in the Transition zone into the Marsh Plain zone. Where the topography is more complex, such as along tidal creeks, areas with some relief such as ridges or mounds, and on levees, soft bird's-beak can be found in a variety of patch shapes (Baye et al. 2000, Grewell 2005, Grewell et al. 2007). Dominant plant associates include pickleweed, saltgrass, salt marsh dodder (*Cuscuta salina*), and spearscale (Baye et al. 2000, Grewell 2005, Grewell et al. 2007).

A49.8 RECOVERY GOALS

Soft bird's-beak is federally listed as endangered, but a USFWS recovery plan has not yet been developed; however, the CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for soft bird's-beak is "Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP has established a goal to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

APPENDIX A50. DWARF DOWNINGIA (*DOWNINGIA PUSILLA*)

A50.1 LEGAL STATUS

Dwarf downingia (*Downingia pusilla*) is not listed under either the federal or California Endangered Species Act. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G3/S2.2 which means that globally (G) and within the state (S) there are either between 21 to 100 viable element occurrences of this species, 3,000 to 10,000 individuals of this species, or 10,000 to 50,000 acres (4,047 to 20,234 hectares) where this species occurs. Its state threat level rank is "threatened."

The California Native Plant Society (CNPS) List ranking of 2.2 for dwarf downingia indicates that it is rare, threatened, or endangered in California but more common elsewhere. Plants with a CNPS List rank of 2 are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

A50.2 SPECIES DISTRIBUTION AND STATUS

A50.2.1 Range and Status

In California, dwarf downingia's range extends from southern Tehama County to Fresno County and from Sonoma County to Placer County (Figure A-50a); and it is also found in Chile. It is found on alluvial terraces and floodplains in the Sacramento Valley, with its distribution at the south end of the Sacramento Valley bifurcated by the Delta (CNDDB 2010). It has been reported from the northeastern part of the San Joaquin Valley, but not near the border of the Plan Area and is also found on valley floors and margins in Sonoma and Napa counties (CNDDB 2010).

A50.2.2 Distribution and Status in the Plan Area

Dwarf downingia has been reported in the Plan Area from vernal pools, vernal swales, alkaline seasonal wetlands, tire ruts, and hydrologically altered sloughs in the greater Jepson Prairie area (Figure A-50b) (Witham 2006, Barbour et al. 2007, Lazar 2007, CNDDB 2010). During the spring 2009 California Department of Water Resources /Delta Habitat Conservation and Conveyance Program (DWR/DHCCP) field surveys conducted for the Bay Delta Conservation Plan (BDCP), dwarf downingia was found in vernal pools on the North Stone Lakes Unit of the Stone Lakes National Wildlife Refuge (NWR) area.

DRAFT

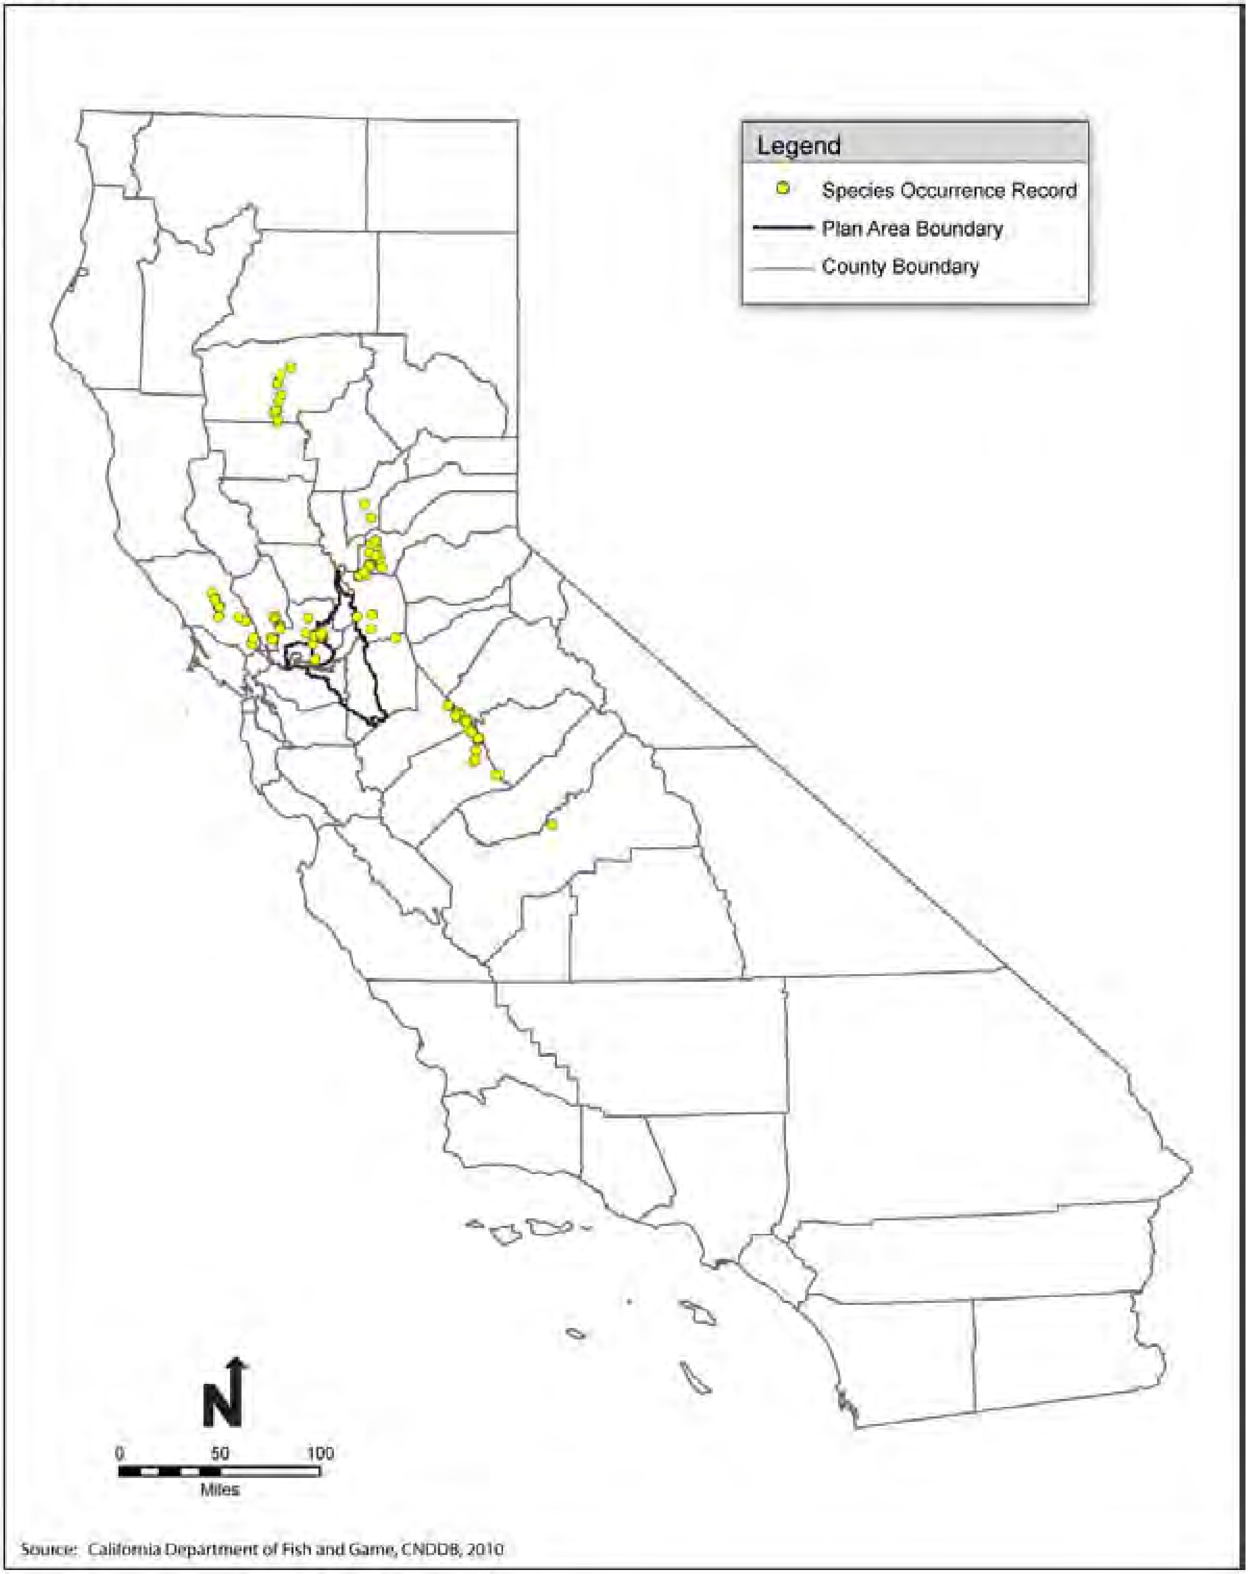

Figure A-50a. Dwarf Downingia Statewide Recorded Occurrences

DRAFT

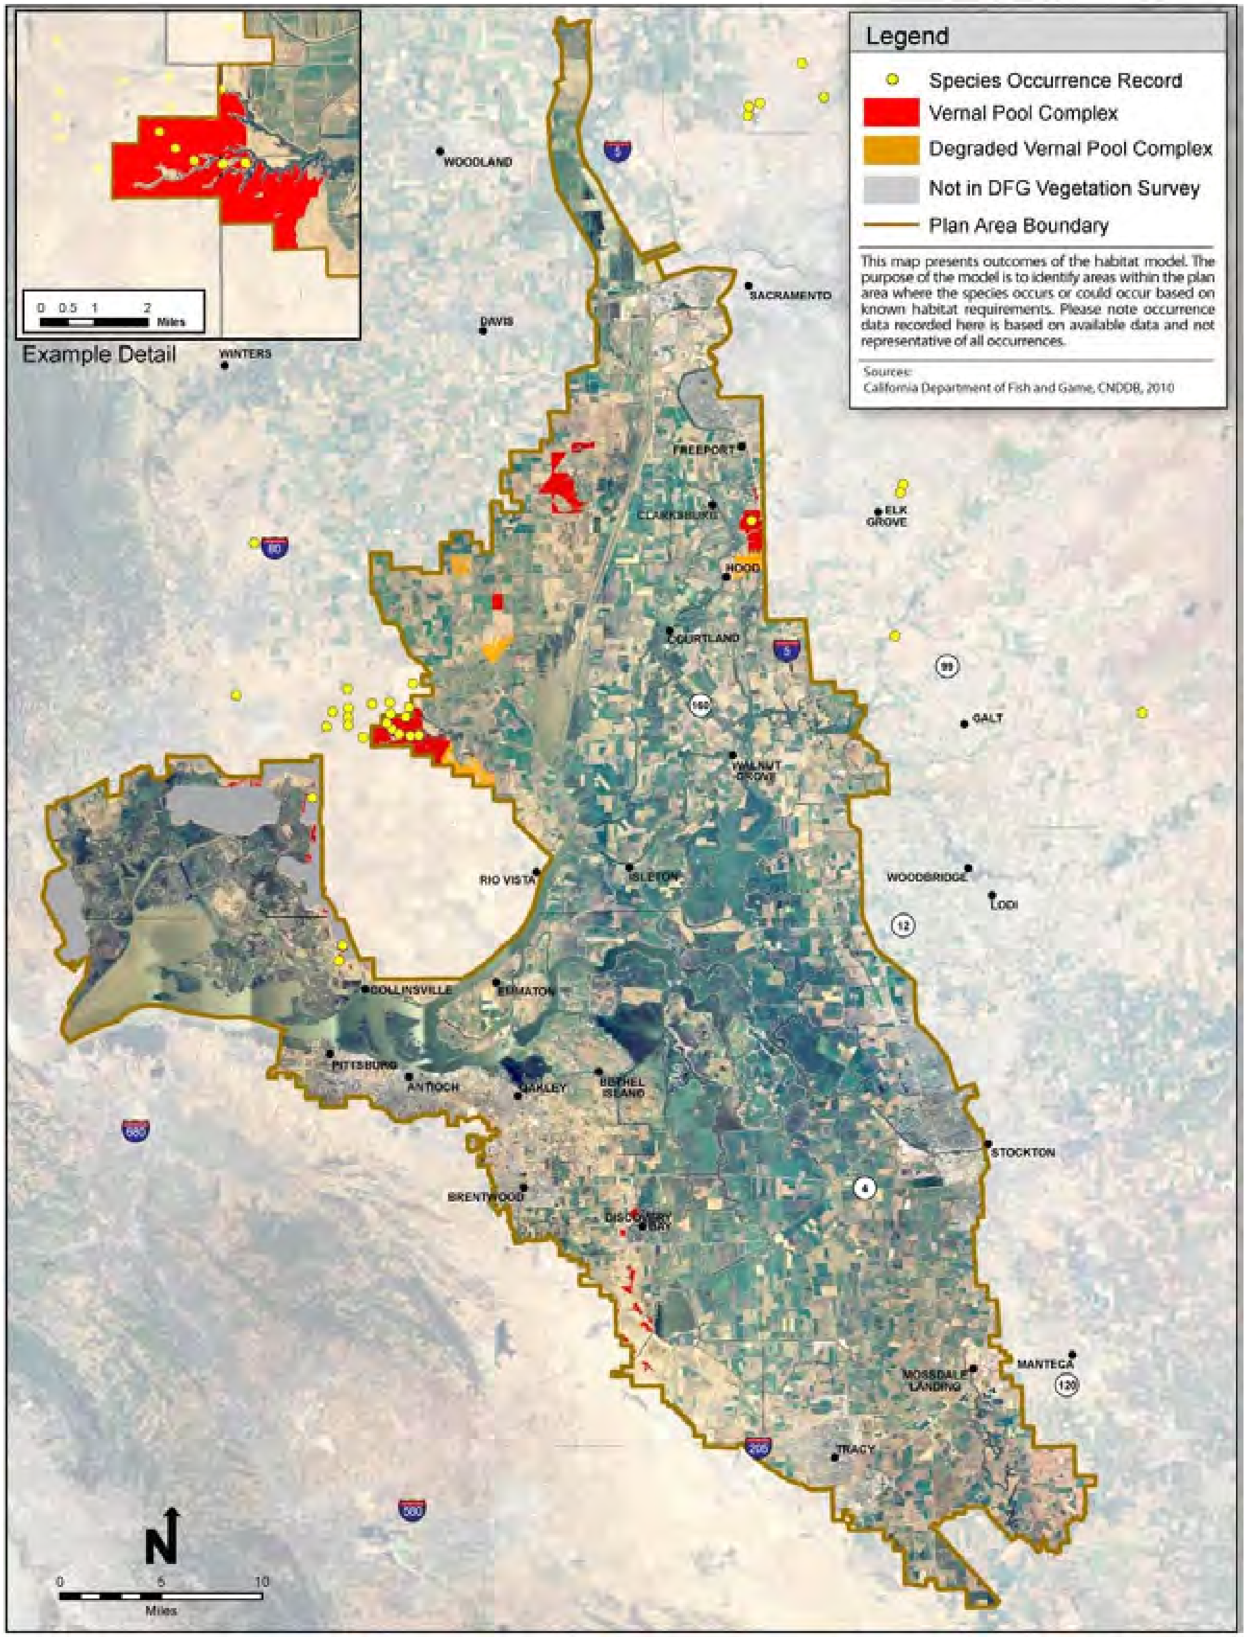

Figure A-50b. Dwarf Downingia Habitat Model and Recorded Occurrences

A50.3 Habitat Requirements and Special Considerations

Throughout its distribution, dwarf downingia occurs in vernal pools, vernal swales, pools in seasonal streambeds, vernal marshes, tire ruts, hydrologically altered sloughs, and irrigation ponds (CNDDB 2010). Some occurrence records state that it is found with long inundation indicator species such as pale spikerush (*Eleocharis macrostachya*), but on the clay soils of the greater Jepson Prairie area it is found in a range of microtopographic positions in vernal pools within grassland vegetation that typically has a high cover of the nonnative annual grass *Lolium multiflorum* (Witham 2006, Barbour et al. 2007, Lazar 2007). In the Stone Lakes areas, it is associated with vernal pools that form in the former headwaters of natural drainages propagating upslope from the Delta. When present in a vernal pool, its population persistence has been found to be relatively constant when compared to other rare vernal pool species (Buck 2004, Barbour et al. 2007).

A50.4 Life History

Dwarf downingia is a small submerged to emergent aquatic annual herbaceous plant during the wet season, when habitat is ponded, that becomes a small 4-12 inch (10-30 centimeter) terrestrial plant at the end of the wet season as the habitat dries. It has small, 0.02-0.25 inch (0.5-2 millimeters) wide, awl-like leaves and very small light blue flowers (Hickman 1993). Dwarf downingia seed dispersal is apparently aided by waterfowl, as it appeared spontaneously in vernal pools constructed as part of the Montezuma Wetlands Restoration Project (SFEI 2006). Nothing is known about its pollination biology, seed germination characteristics, or many other important biological and ecological characteristics.

A50.5 Threats and Stressors

Development, intensive agriculture, and exotic plant species (especially *Lolium multiflorum*) are considered to be the primary threats to alkaline vernal pools (Showers 1988, Showers 1996, Dawson et al. 2007) which are habitat for dwarf downingia. Additionally, waxy mannagrass (*Glyceria declinata*) may pose a threat to this species and many other vernal pool species (Gerlach et al. 2009).

A50.6 Relevant Conservation Efforts

The known occurrences in the Plan Area are protected from development or intensified agriculture under conservation easements or under ownership by a governmental agency (Witham 2006, Barbour et al. 2007, Lazar 2007, USFWS 2007, CNDDB 2010). Dwarf downingia is proposed for coverage under the Solano County Multi-species Habitat Conservation Plan and the South Sacramento County Habitat Conservation Plan.

A50.7 SPECIES HABITAT SUITABILITY MODEL

Model Approach. BDCP Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below and in Section 2.3.1, *Data Sources and Natural Community Classification*). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as vernal pools, individual trees, or small groups of trees. It is also possible, as with some vernal pool invertebrates that are restricted to seasonally ponded habitats, to underestimate potentially-occupied habitat due to the lack of information on small, degraded or artificially-created seasonal wetland habitats.

Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The dwarf downingia model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), DWR 2007 LiDAR elevation data, Google Earth 2009 aerial imagery and USDA 2005 aerial photography. Using these data sets, the model maps the distribution of suitable dwarf downingia habitat in the Plan Area according to the species' two habitat types, vernal pool complex and degraded vernal pool complex habitat. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Vernal Pool Complex Habitat: High quality permanent habitat that consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly impacted by agricultural or development practices. Vernal pool complex habitat for dwarf downingia includes the following vegetation subunits that were selected from the BDCP vernal pool complex natural community:

- Vernal pool complex – All vegetation types

Degraded Vernal Pool Complex Habitat: Low quality ephemeral habitat that ranges from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, disking, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. The aquatic features in this habitat are more clearly classified as temporary waters sensu lato (Williams 2006) than intact and fully functional vernal pools. Because these features are inundated during the wet season and may have historically been located in or near areas with natural vernal pool complex, they may support individuals or small populations of species that are found in vernal pools and swales. However, they do not possess the full complement of ecosystem and community characteristics of natural vernal pools, swales and their associated uplands and they are generally ephemeral features that are eliminated during the course of normal agricultural practices. Degraded vernal pool complex habitat for dwarf downingia includes the following vegetation subunits that were selected from the BDCP other natural seasonal wetlands and grasslands communities:

- Grasslands
    - Degraded vernal pool complex – California annual grasslands;
    - Degraded vernal pool complex – Ruderal herbaceous grasses and forbs;
    - Degraded vernal pool complex – Italian rye-grass (*Lolium multiflorum*); and
    - Degraded vernal pool complex – Rabbitsfoot grass (*Polygpogon maritimus*).
- Other natural seasonal wetlands
    - Degraded vernal pool complex-Vernal pools.

Potential habitat without concave surfaces (except for seeps along Suisun Marsh) was removed from the model. LiDAR elevation data was then visually inspected in four general areas to further assess specific locations that had been identified by the habitat selection process. These areas were selected based both on *a priori* knowledge of the region and because they were identified by the intersection of the selected vegetation types and soils. The analysis of the LiDAR data further refined the habitat model and provided a more accurate demarcation of suitable habitat. The GIS habitat model was then compared against field data from surveys conducted by DWR/DHCCP for the BDCP in 2009. Land uses that are incompatible with the species' habitat requirements, for example potential habitat polygons falling on leveled or developed lands, were removed from the model.

Assumptions. Historical and current records of this species in the Plan Area indicate that its current distribution is limited to alkaline soil areas with vernal pool and swale microtopography along the western border of the Plan Area (Figure A-50b) (Witham 2006, CNDDB 2010) and areas with swales and vernal pools along the eastern boundary of the Plan Area (CNDDB 2010). The vegetation cover is typically a combination of vernal pool adapted species and annual ryegrass (Witham 2006, CNDDB 2010).

A50.8 Recovery Goals

A USFWS recovery plan has not been prepared for this species and no recovery goals have been established.

APPENDIX A51. DELTA BUTTON-CELERY (*ERYNGIUM RACEMOSUM*)

A51.1 Legal Status

Delta button-celery (*Eryngium racemosum*) is listed as endangered under the California Endangered Species Act (August 1981). It is not listed under the federal Endangered Species Act. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G2Q/S2.1, which indicates that globally (G) and within the state (S) there are either between six to 20 viable element occurrences of this species, 1,000 to 3,000 individuals of this species, or 2,000 to 10,000 acres (809 to 4,047 hectares) where this species occurs. Its state threat level rank is "very threatened." The "Q" portion of the rank indicates that unresolved taxonomic questions remain for this rare species (NatureServe 2008).

The California Native Plant Society (CNPS) List ranking of 1B.1 for Delta button-celery indicates that it is rare, threatened, or endangered in California and elsewhere, and is considered by CNPS to be seriously endangered in California with more than 80 percent of occurrences threatened. Plants with a CNPS List rank of 1B are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

A51.2 Species Distribution and Status

A51.2.1 Range and Status

The range of Delta button-celery extends from San Joaquin County in the north, to Stanislaus and Merced counties in the south, to Contra Costa County in the west, and Calaveras County in the east (Figure A-51a).

Delta button-celery is endemic to the San Joaquin Valley, south of Brentwood, California (NatureServe 2008). All 26 reported occurrences are from Contra Costa, San Joaquin, Calaveras, Stanislaus, and Merced counties with the greatest number in Merced County. All reported localities are between 15 and 100 feet (4.6 and 30.5 meters) in elevation, except one location at 240 feet (73 meters) in Stanislaus County and one at 1,100 feet (335 meters) in Calaveras County. However, the herbarium voucher specimens for the two occurrences in the Sierra Nevada Foothills, Salt Spring Reservoir in Calaveras County and Turlock Lake in Stanislaus County have recently been examined and were determined to have been erroneously identified (R. Preston pers. comm.). Six of the recorded occurrences have been extirpated by agricultural expansion and disturbance (NatureServe 2008).

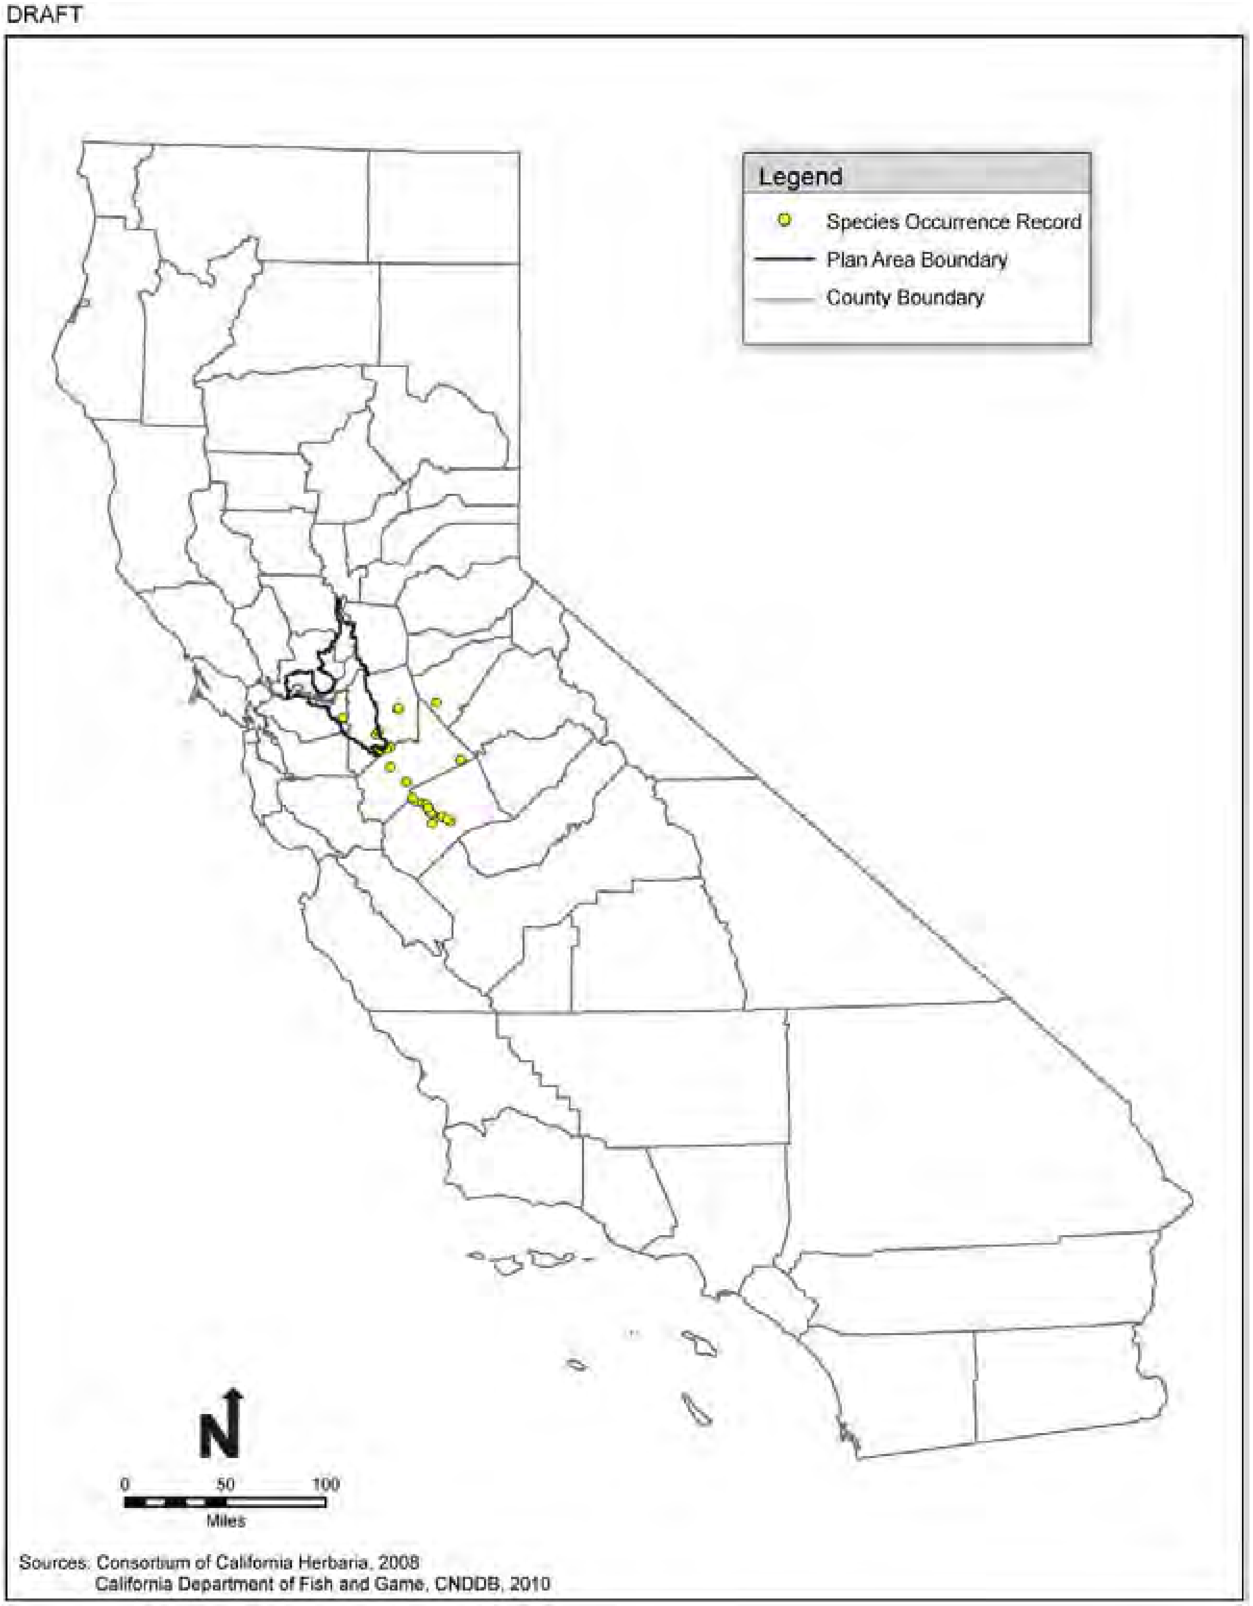

Figure A-51a. Delta Button-Celery Statewide Recorded Occurrences

Extant occurrences are on private land, and on land owned by California Department of Fish and Game (DFG), U.S. Fish and Wildlife Service (USFWS), and other public agencies. Occurrences on state and federally owned land are within designated wildlife areas and wildlife refuges.

A51.2.2 Distribution and Status in the Plan Area

Delta button-celery is known to occur in two locations in the Plan Area, one on the alluvial plain of Kellogg and Marsh creeks immediately west of Discovery Bay, and one along the San Joaquin River northeast of Tracy (Figure A-51b). The population near Discovery Bay was last observed in 1998 in a small area with about 1,500 individuals in alkali sink habitat with iodine bush (*Allenrolfea occidentalis*), alkali heath (*Frankenia salina*), and saltgrass (*Distichlis spicata*) (NatureServe 2008). The other occurrence in the Plan Area, located about 3 miles south of Lathrop, was first observed in 1984 and is believed to have been subsequently extirpated due to development of a walnut orchard.

Two occurrences have been recorded near the edge of the Plan Area. Both of these occurrences may have been extirpated. One was about 2.5 miles (4 kilometers) northeast of Vernalis, and the other was at the northeast end of Caswell Memorial State Park. Both sites were last visited in 1985, and the habitat was deemed unsuitable at that time.

A51.3 Habitat Requirements and Special Considerations

Based on its current and historical distributions, Delta button-celery occurs in two habitat types. One habitat type is seasonally scoured and inundated swales, depressions, and clay flats in the floodplain of the San Joaquin River (D. Woolington pers. comm.). The specific location of occurrences may shift depending on the disturbance and flooding regime. As a disturbance follower, there is no strong fidelity to a particular soil or vegetation type, but occurrences are primarily reported on alkaline clays deposited within bands of coarser textured soils and willow scrub vegetation. The associated species in this habitat type are characteristic of frequently disturbed riparian bottom lands and include turkey tangle fogfruit (*Phyla nodiflora*), spike rush (*Eleocharis* spp.), American bird’s foot trefoil (*Lotus purshianus*), Goodding’s black willow (*Salix gooddingii*), and common sunflower (*Helianthus annuus*).

The other habitat type is alkaline clay deltas of Coast Range tributaries that are deposited immediately above the flood basin of the San Joaquin River where plant cover is typical alkaline sink vegetation. The associated species in the alkaline sink vegetation include saltgrass, alkali heath, and iodine bush (NatureServe 2008).

A51.4 Life History

Delta button-celery is a prostrate biennial to short-lived perennial herb that germinates following flooding in areas adjacent to rivers and streams in the San Joaquin Valley (Hickman 1993). The sprawling stems are generally 4 to 20 inches (10 to 50 centimeters) in length (Hickman 1993). It is unique as it is California’s only native *Eryngium* species that produces roots and juvenile leaves at its stem nodes, and its spiny flower heads are arranged in an elongated raceme instead of a compact cyme (Hickman 1993).

DRAFT

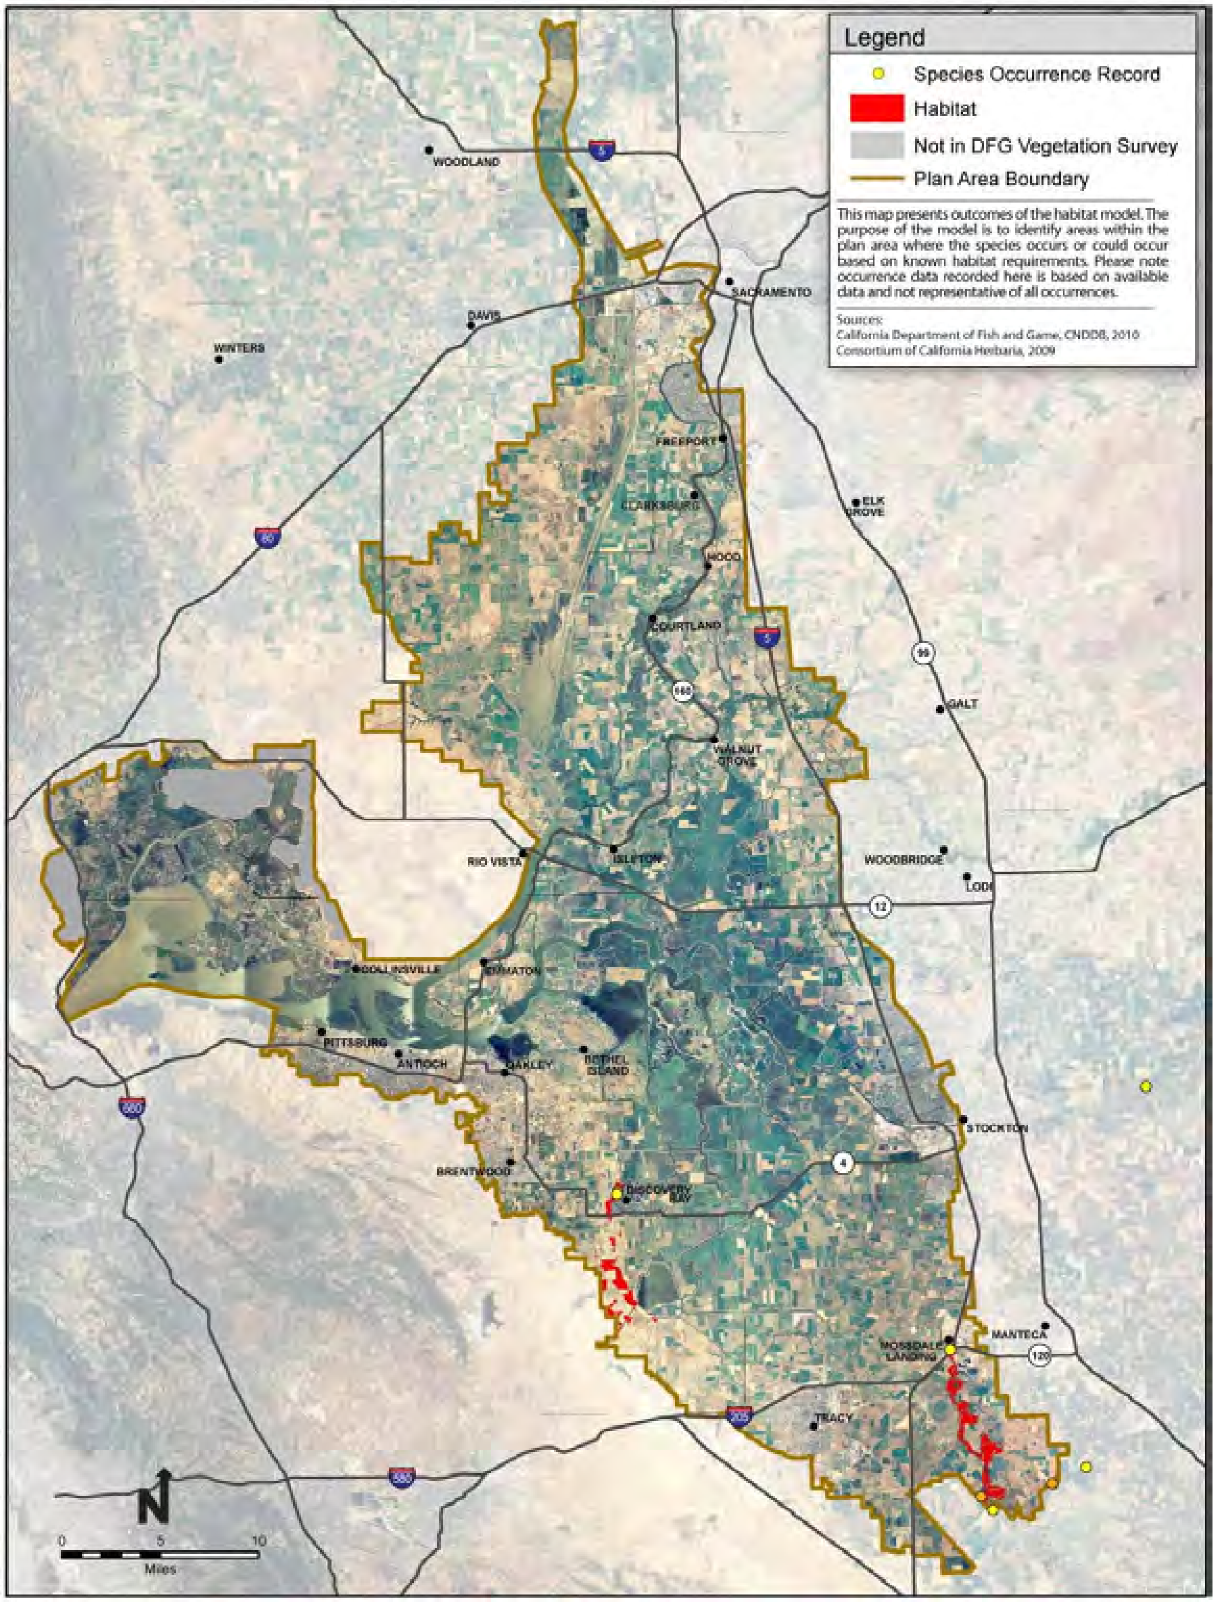

Figure A-51b. Delta Button-Celery Habitat Model and Recorded Occurrences

1

California's *Eryngium* species can be difficult to differentiate based on morphological characteristics because individuals with characteristics that are intermediate between different species are common (Hickman 1993). It flowers from June to September (CNPS 2008).

A51.5 Threats and Stressors

Threats to the species include agricultural habitat conversion, channelization and channel maintenance activities, overgrazing, dredging, and invasion of habitat by nonnative plant species (DFG 2008, NatureServe 2008). Some occurrences have been eliminated by flood control activities and conversion of lowlands to agriculture including all of the occurrences in San Joaquin County and most in Stanislaus County (DFG 2008). Many occurrences along the San Joaquin River in Merced County are threatened due to reduced flooding because of controlled releases from Friant Dam and the construction of an extensive levee system (DFG 2008).

Agriculture. A substantial portion of the suitable habitat for the Delta button-celery is also prime agricultural land. Much of the suitable habitat for this species has been developed in various forms of agriculture, thus removing this species and severely altering that habitat. The known occurrences that have been extirpated have been converted to agriculture (NatureServe 2008).

Channel Maintenance Activities. Past channel maintenance has resulted in changes to the nature of the habitat and severe disturbance of adjacent areas (NatureServe 2008). More importantly, channel maintenance lessens the degree and frequency of flooding, reducing suitable habitat for this species.

Overgrazing. Overgrazing may adversely affect this species, but grazing may benefit the species by keeping the habitat open between floods and by controlling competing species such as Baltic rush (*Juncus balticus*). In addition, heavy grazing at one site did not appear to prevent occurrence of this species (DFG 1986). Additionally, the saltgrass covered bottom lands of the San Joaquin River basin have been heavily grazed by large cattle ranching operation since the 1820s.

Dredging. Dredging of waterways may reduce the extent of floodplain inundation, which appears to be necessary for seed germination, growth, and the maintenance of habitat openings that Delta button-celery may require (NatureServe 2008).

Invasion by Nonnative Plant Species. Nonnative invasive plant species compete with the Delta button-celery for habitat. Since the San Joaquin River floodplain habitat is subject to periodic natural disturbance (scouring), the habitat is ideal for many native and nonnative ruderal species as well. Some of these species include common sunflower (*Helianthus annus*) and cockle bur (*Xanthium* spp.), which may shade out Delta button-celery (NatureServe 2008) as has been noted at two protected sites in San Luis National Wildlife Refuge and Merced National Wildlife Refuge (NatureServe 2008).

A51.6 Relevant Conservation Efforts

The Delta button-celery occurs or formerly occurs at several publicly-owned properties including Caswell State Park, Merced National Wildlife Refuge, San Luis National Wildlife Refuge Complex, and the North Grasslands Wildlife Area. It is also a covered species in the San Joaquin County Multi-species Habitat Conservation and Open Space Plan.

A51.7 Species Habitat Suitability Model

Habitat. Delta button-celery habitat was identified as all areas between the levees from the Mossdale Bridge to Vernalis and as alkali seasonal wetland complex, vernal pool complex and Grassland on Brentwood (Bc), Grangerville (166), Marcuse (Mb), Solano (Sh, Sk), and Vernalis (269) soils within the San Joaquin Basin (i.e., south of the mainstem San Joaquin River). Vegetation types designated as species habitat in this model correspond to the mapped vegetation associations in the Bay Delta Conservation Plan (BDCP) geographic information system (GIS) vegetation data layer. For this species, a misclassification of land cover in the source data occurred north and south of the Discovery Bay area where intensive agriculture was classified as annual grassland, and those parcels were deleted from the area of predicted habitat. Additionally, other areas of potential habitat that have been developed were also deleted.

Assumptions. Historical and current records of this species indicate that its distribution is limited to the San Joaquin River Basin where it occurs in two discrete habitat types (Figure A-51b). In the floodplain of the San Joaquin River, it occurs on seasonally scoured and inundated swales, depressions, and clay flats (D. Woolington pers. comm.). The specific locations of the occurrences may shift depending on the disturbance and flooding regime. As a disturbance follower, there is no strong fidelity to a particular soil or vegetation type, but occurrences are primarily reported on alkaline clays deposited within bands of coarser textured soils and willow scrub vegetation. The other habitat type is alkaline clay deltas of Coast Range tributaries that are deposited immediately above the flood basin of the San Joaquin River where plant cover is typical alkaline sink vegetation or various types of grassland (CNDDB 2008, NatureServe 2008).

A51.8 Recovery Goals

A USFWS recovery plan has not been prepared for this species and no recovery goals have been established.

APPENDIX A52. CONTRA COSTA WALLFLOWER (*ERYSIMUM CAPITATUM* VAR. *ANGUSTATUM*)

A52.1 LEGAL STATUS

Contra Costa wallflower (*Erysimum capitatum* var. *angustatum*) is listed as endangered under both the Federal Endangered Species Act (April 1978) (43 FR 17910) and the California Endangered Species Act. It is endemic to a former dune near the city of Antioch, California. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G5T1/S1.1 which means that globally (G) the species is demonstrably secure to ineradicable due to being commonly found in the world, but the subspecies or variety (T) is has less than 6 viable element occurrences, less than 1,000 individuals, or less than 2,000 acres (809 hectares); and within the state (S) the threat level rank is “very threatened.”

The California Native Plant Society (CNPS) List ranking of 1B.1 for Contra Costa wallflower indicates that it is rare, threatened, or endangered in California (List 1B); the threat ranking (.1) indicates that it is considered by CNPS to be seriously threatened in California (high degree/immediacy of threat). Plants with a CNPS List rank of 1B are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

United States Fish and Wildlife Service (USFWS)-designated critical habitat that specifies the protection of Contra Costa wallflower habitat lies on and adjacent to the USFWS Antioch Dunes National Wildlife Refuge (43 FR 39042). This critical habitat was specifically established for this and two other endangered species. The designated critical habitat is entirely within the Plan Area.

A52.2 SPECIES DISTRIBUTION AND STATUS

A52.2.1 Range and Status

Contra Costa wallflower has an extremely restricted range. It is found only on a 20-acre (8-hectare) remnant of a former 190-acre (77-hectare) dune (plus an unknown amount of two Pacific Gas & Electric [PG&E] parcels that total 12 acres [5 hectares]) near the city of Antioch, California (USFWS 1984, 2001, 2008, 2010) (Figure A-52a). It is protected on the Antioch Dunes National Wildlife Refuge (NWR) and also occurs on two small adjacent parcels owned by PG&E, which manages the property in cooperation with USFWS. The second edition of the *Jepson Manual* treats this taxon as synonymous with the widespread variety *E. capitatum* var. *capitatum* which hybridizes with *E. ammophilum, E. franciscanum,* and *E. suffrutescens* (Rosatti ed. 2010).

DRAFT

Figure A-52a. Contra Costa Wallflower Statewide Recorded Occurrences

A52.2.2 Distribution and Status in the Plan Area

The entire distribution of Contra Costa wallflower is within the Plan Area on the Antioch Dunes NWR and PG&E properties as described above (Figure A-52b).

A52.3 HABITAT REQUIREMENTS AND SPECIAL CONSIDERATIONS

Contra Costa wallflower is restricted to the remnant of former dune near the city of Antioch, California (USFWS 1984, 2001, 2008, 2010). This soil of the dune has been mapped as Oakley sand (Carpenter and Cosby 1939) and Delhi sand, 2 to 9 percent slopes (NRCS 2010) and is an infertile, very uniform textured, fine sand with very little clay content. While experiments at Antioch Dunes NWR found that Contra Costa wallflower will not grow and reproduce on soils with a relatively high clay content (Pavlik and Manning 1993), it does well and even becomes weedy, on gravelly or organic garden soils at the Tilden Regional Park Botanic Gardens in Berkeley, California (USFWS 1984). However, in its native habitat it appears to be restricted to sloping areas or banks with loose sand (USFWS 1984).

A52.4 LIFE HISTORY

Contra Costa wallflower is an erect, coarse-stemmed, biennial or short-lived perennial herb in the mustard family (Brassicaceae) (USFWS 1984, Hickman 1993, Rosatti ed. 2010, USFWS 2010). Plants are subshrubs that grow from a somewhat woody caudex (trunk-like base), which typically elongates into multiple branched stems 8 to 32 inches (20 to 81 centimeters [cm]) tall in mature plants. Lower leaves are lance-like to linear and tapering at the base, up to 6 inches (15 cm) long and about 0.5 inch (1.3 cm) wide, with minute teeth. It produces yellow four-petalled flowers, which bloom from March to July of the second year, laterally on unbranched stems at the top of the plant. The petals have claws (slender stalks) and are about 0.5 to 1 inch (1.3 to 2.5 cm) long. The slender pod-like fruit (silique) is dry when ripe and can be up to 4 inches (10 cm) long.

A52.5 THREATS AND STRESSORS

Invasive plants are one of the primary threats to Contra Costa wallflower because they cause habitat loss and may compete for soil moisture (USFWS 2008, 2010). The most common invasive nonnative grasses and forbs found at the refuge include ripgut brome (*Bromus diandrus*), winter vetch (*Vicia villosa*), and yellow star thistle (*Centaurea solstitialis*). Wildfires started by trespassers on the Antioch Dunes NWR are another serious threat.

DRAFT

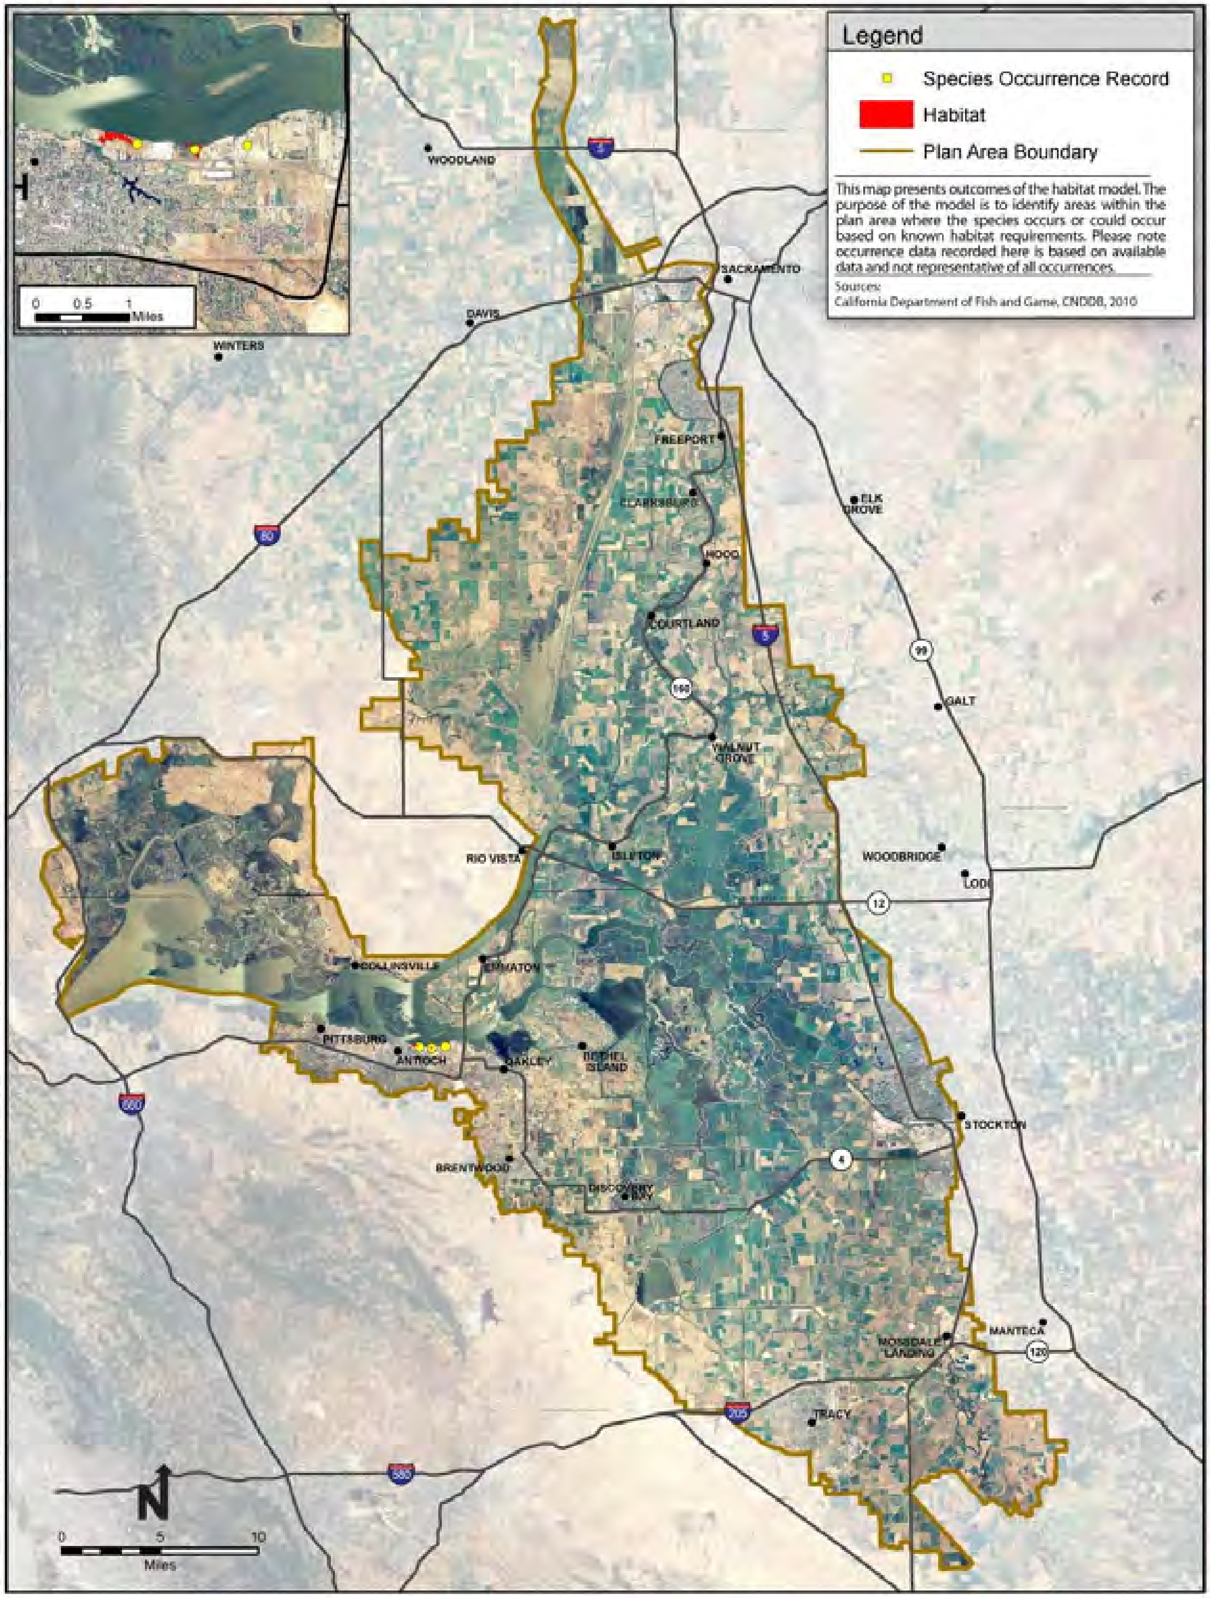

Figure A-52b. Contra Costa Wallflower Habitat Model and Recorded Occurrences

1

A52.6 RELEVANT CONSERVATION EFFORTS

Contra Costa wallflower was declining significantly at Antioch Dunes NWR until an out-planting of nursery grown stock and direct seeding into restored sandy habitat in 2005 and 2006 appears to have stopped the decline. However, the population is not yet considered to be self-sustaining because of invasive species problems (USFWS 2008). The current management plan for the Antioch Dunes NWR provides for invasive nonnative plant species control efforts which are being implemented by hand pulling individual invasive plants through the efforts of volunteers, and targeted herbicide application (USFWS 2001, 2008). Controlled burns have been discontinued as a management tool (L.Terrazas *In Litteris*).

A52.7 SPECIES HABITAT SUITABILITY MODEL

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nevertheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lower probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf 2007. Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers, connectivity between habitat types, and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life history requirements. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The Contra Costa wallflower habitat suitability model is based on the California Department of Fish and Game (DFG) mapping of Delta vegetation (Hickson and Keeler-Wolf 2007).

Habitat. The modeled habitat for Contra Costa wallflower consists of two shrub dominated vegetation associations from the Antioch Dunes NWR (Hickson and Keeler-Wolf 2007).

Vegetation Units. The following vegetation subunits were selected from the DFG vegetation units (Hickson and Keeler-Wolf 2007):

- *Lupinus albifrons* Antioch Dunes Association
- *Lotus scoparius* Antioch Dunes Association

A52.8 Recovery Goals

A USFWS revised recovery plan for Contra Costa wallflower was approved in 1984 but the very recent 5-year species review (USFWS 2008) found that there are no recovery criteria listed in the Recovery Plan. The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for Contra Costa wallflower is "Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP has established a goal to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

APPENDIX A53. BOGGS LAKE HEDGE-HYSSOP (*GRATIOLA HETEROSEPALA*)

A53.1 LEGAL STATUS

Boggs Lake hedge-hyssop (*Gratiola heterosepala*) is listed as endangered under the California Endangered Species Act (November 1978). It is not listed under the federal Endangered Species Act. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G3/S3.1 which means that globally (G) and within the state (S) there are either between 21 to 80 viable element occurrences of this species, 3,000 to 10,000 individuals of this species, or 10,000 to 50,000 acres (4,047 to 20,234 hectares) where this species occurs; and the state threat level rank is "very threatened" (CNDDB Special Vascular Plants, Bryophytes, and Lichens List).

The California Native Plant Society (CNPS) List ranking of 1B.2 for Boggs Lake hedge-hyssop indicates that it is rare, threatened, or endangered in California and elsewhere, and is considered by CNPS to be fairly endangered in California with between 20 to 80 percent of occurrences threatened. Plants with a CNPS List rank of 1B are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

A53.2 SPECIES DISTRIBUTION AND STATUS

A53.2.1 Range and Status

Boggs Lake hedge-hyssop occurs in northeastern California on the Modoc Plateau in Siskiyou, Modoc, Lassen, Shasta, and Tehama counties and then southwards in the Central Valley to Fresno County. There are also records from Bogg's Lake in Lake County (Figure A-53a) (CNDDB 2009, CNPS 2009). It is widely distributed throughout the range of vernal pool habitat (Barbour et al. 2007); and there is one occurrence found in Oregon, where it is state listed as "threatened" (CNPS 2009). Population sizes range from small numbers to thousands of plants (CNDDB 2009, CNPS 2009).

A53.2.2 Distribution and Status in the Plan Area

Within the Plan Area, several populations have been reported to occur sporadically on and in the vicinity of Jepson Prairie Preserve and the Gridley Preserve (Witham 2006, Barbour et al. 2007, CNDDB 2009) (Figure A-53b). There are no reported occurrences in the southwestern portion of the Plan Area, but that area is within the species' range and suitable claypan vernal pool habitat occurs there.

Figure A-53b. Boggs Lake Hedge-Hyssop Habitat Model and Recorded Occurrences

1

A53.3 HABITAT REQUIREMENTS AND SPECIAL CONSIDERATIONS

Boggs Lake hedge-hyssop has been reported from a variety of habitats including the edges of marshes and natural lakes, stock ponds, swales, and vernal pools (Witham 2006, Barbour et al. 2007, CNDDB 2009). It has been observed in several types of vernal pools including basalt flow, hardpan, claypan, and alkaline playa pools. In the Plan Area, the species commonly associated with Boggs Lake hedge-hyssop include toothed downingia (*Downingia cuspitata*), dwarf downingia (*Downingia pusilla*), Fremont's goldfields (*Lasthenia fremontii*), and white-headed navarretia (*Navarretia leucocephala* ssp. *bakeri*) (Barbour et al. 2007, CNDDB 2009).

Grazing has been reported as both a positive and negative factor for this species (CNDDB 2009). A general finding of recent grazing research in the Jepson Prairie area is that the timing and intensity of grazing are important for maintaining native plant diversity and cover in the vernal pools and that seasonal changes in precipitation generally have a larger effect than grazing intensity but less of an effect that the cessation of grazing (Swiecki and Bernhardt 2008). This study found that light and/or sporadic grazing during the period of time when the vernal pools are inundated is the best management option and that the positive effect was largely due to impacts on nonnative annual ryegrass (*Lolium multiflorum*) growing around the margins of the inundated vernal pools. In the 2007 season, the pattern of precipitation was such that the vernal pools were not inundated during the grazing season and grazing had a significant negative effect on native plant species.

A53.4 LIFE HISTORY

Boggs Lake hedge-hyssop is a very small (less than 10-centimeter [cm] [less than 4-inch]), semi-aquatic annual herb of the snapdragon family (Scrophulariaceae) that blooms from April to August (Hickman 1993, CNPS 2009). The lower portions of the brownish-red fleshy stems are glabrous, and the upper portions are glandular-sticky with puberulent hairs (Hickman 1993). Leaves are small less than 2 cm less than 0.8 inch]) and rounded at the tips. The predominantly yellow corolla has five lobes: two are yellow and fused; three are white and separate (Hickman 1993). A related species that is much more common – bractless hedge-hyssop (*Gratiola ebracteata*) – can be distinguished from Boggs Lake hedge-hyssop by its more elongate and pointed sepals and mostly white flowers. Boggs Lake hedge-hyssop seeds can lie dormant in the soil for years, and the number of vegetative plants in a population can vary greatly from year to year (USFWS 2005).

A53.5 THREATS AND STRESSORS

Vernal pool loss through development, damage by intensive grazing, trampling, off-road vehicles, and invasive nonnative species are generally cited as threats (CNDDB 2009, CNPS 2009). As noted above, grazing can have both positive and negative effects on this species.

A53.6 Relevant Conservation Efforts

Boggs Lake hedge-hyssop is protected on a number of government, non-governmental organization, and mitigation bank sites throughout California (USFWS 2005). In the Plan Area, it is generally protected on Solano Land Trust properties in the Jepson Prairie area (Witham 2006). It is a covered species under the Natomas Basin Habitat Conservation Plan and the San Joaquin County Multi-species Habitat Conservation and Open Space Plan; and it is proposed for coverage under the Solano County Multispecies Habitat Conservation Plan and the South Sacramento Habitat Conservation Plan.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for the Boggs Lake hedge-hyssop is "Maintain" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions to maintain the species by avoiding, minimizing, and compensating for any adverse effects to the species created by ERP restoration actions. To the extent practicable, the ERP will improve species habitat conditions.

A53.7 Species Habitat Suitability Model

Model Approach. The Bay Delta Conservation Plan (BDCP) Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below and in Section 2.3.1, *Data Sources and Natural Community Classification*). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as vernal pools, individual trees, or small groups of trees. It is also possible, as with some vernal pool invertebrates that are restricted to seasonally ponded habitats, to underestimate potentially-occupied habitat due to the lack of information on small, degraded or artificially-created seasonal wetland habitats.

Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The Boggs Lake hedge-hyssop model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), DWR 2007 LiDAR elevation data, Google Earth 2009 aerial imagery and USDA 2005 aerial photography. Using these data sets, the model maps the distribution of suitable Boggs Lake hedge-hyssop habitat in the Plan Area according to the species' two habitat types, vernal pool complex and degraded vernal pool complex habitat. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Vernal Pool Complex Habitat: High quality permanent habitat that consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly impacted by agricultural or development practices. Vernal pool complex habitat for Boggs Lake hedge-hyssop includes the following vegetation subunits that were selected from the BDCP vernal pool complex natural community:

- Vernal pool complex – All vegetation types

Degraded Vernal Pool Complex Habitat: Low quality ephemeral habitat that ranges from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, disking, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. The aquatic features in this habitat are more clearly classified as temporary waters sensu lato (Williams 2006) than intact and fully functional vernal pools. Because these features are inundated during the wet season and may have historically been located in or near areas with natural vernal pool complex, they may support individuals or small populations of species that are found in vernal pools and swales. However, they do not possess the full complement of ecosystem and community characteristics of natural vernal pools, swales and their associated uplands and they are generally ephemeral features that are eliminated during the course of normal agricultural practices. Degraded vernal pool complex habitat for Boggs Lake hedge-hyssop includes the following vegetation subunits that were selected from the BDCP other natural seasonal wetlands and grasslands communities:

- Grasslands
  - Degraded vernal pool complex – California annual grasslands;
  - Degraded vernal pool complex – Ruderal herbaceous grasses and forbs;
  - Degraded vernal pool complex – Italian rye-grass (*Lolium multiflorum*); and
  - Degraded vernal pool complex – Rabbitsfoot grass (*Polygpogon maritimus*).
- Other natural seasonal wetlands
  - Degraded vernal pool complex-Vernal pools.

Potential habitat without concave surfaces (except for seeps along Suisun Marsh) was removed from the model. LiDAR elevation data was then visually inspected in four general areas to further assess specific locations that had been identified by the habitat selection process. These areas were selected based both on *a priori* knowledge of the region and because they were identified by the intersection of the selected vegetation types and soils. The analysis of the LiDAR data further refined the habitat model and provided a more accurate demarcation of suitable habitat. The GIS habitat model was then compared against field data from surveys conducted by the California Department of Water Resources/Delta Habitat Conservation and Conveyance Program (DWR/DHCCP) for the Bay Delta Conservation Plan (BDCP) in 2009. Land uses that are incompatible with the species' habitat requirements, for example potential habitat polygons falling on leveled or developed lands, were removed from the model.

Assumptions. Historical and current records of this species in the Plan Area indicate that its current distribution is limited to alkaline soil areas with vernal pool and swale microtopography along the northwestern border of the Plan Area (Figure A-53b) (Witham 2006, CNDDB 2010). The vegetation cover of the alkaline soils is typically a combination of vernal pool adapted species and annual ryegrass (Witham 2006, CNDDB 2010). Similar habitat exists in the central-western and southwestern portions of the Plan Area, and its habitat was extended into those alkaline soil areas as well. Also, because this species occurs in similar habitats with Heckard's peppergrass which was recently discovered in the Stone Lakes area by DWR/DHCCP field survey teams, the habitat range of Boggs Lake hedge-hyssop was extended into areas with vernal pool and swale microtopography along the eastern border of the Plan Area. The vegetation cover of the alkaline soils is typically a combination of vernal pool adapted species and annual ryegrass (Witham 2002, 2003, 2006, CNDDB 2010).

A53.8 Recovery Goals

Although Boggs Lake hedge-hyssop is not a federally listed taxon, it is included in the Draft Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon (USFWS 2005). The Recovery Plan explicitly states that its goal is to ensure the long-term conservation of this species and 32 other taxa by using an ecosystem level strategy that is based on: current knowledge of the existing conditions of vernal pool communities, the distribution and status of the populations of each of the species, and current and anticipated process that impact vernal pool ecosystems. Because the goal of the Recovery Plan is primarily directed at habitat preservation, its implementation program specifically addresses factors that relate to habitat acquisition and management: (1) habitat protection, (2) adaptive habitat management and monitoring, (3) status surveys, (4) research, and (5) public participation.

APPENDIX A54. CARQUINEZ GOLDENBUSH (*ISOCOMA ARGUTA*)

A54.1 Legal Status

Carquinez Goldenbush (*Isocoma arguta*) is not listed under either federal or California endangered species acts. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G1/S1.1 which means that globally (G) and within the state (S) there are less than six viable element occurrences, less than 1,000 individuals, or less than 2,000 acres (809 hectares) of occupied habitat; and the state threat level rank is "very threatened."

The California Native Plant Society (CNPS) List ranking of 1B.1 for Carquinez goldenbush indicates that it is rare, threatened, or endangered. It is endemic to California and is considered by CNPS to be seriously endangered with more than 80 percent of occurrences threatened. Plants with a CNPS List rank of 1B are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

A54.2 Species Distribution and Status

A54.2.1 Range and Status

Carquinez goldenbush is known only from a very limited geographic range in Solano County, California (Nesom 1991, Hickman 1993, CNDDB 2009, CNPS 2009) (Figure A-54a). All of the 13 reported occurrences are on the Montezuma Block geological formation or its western fault line with small populations of plants restricted to ephemeral drainages, within a very narrow elevation band between uplands and Suisun Marsh, or adjacent to a large alkaline playa (Band 1998, Graymer et al. 2002, DWR 2007, CNDDB 2009). Based on the reported occurrences, it appears to be restricted to alluvial soils associated with the Tehama geological formation and the Montezuma Block north and west of the Montezuma Hills in Solano County (Hickman 1993, Graymer et al. 2002, CNPS 2009, NRCS 2009).

A54.2.2 Distribution and Status in the Plan Area

The 13 reported occurrences are scattered in a small populations that are within the potential Impacts Area and in adjacent area immediately outside of the Planning and Impacts Areas. It occurs near Bird's Landing, Denverton, the Montezuma Hills, the Hay Road Landfill, Jepson Prairie, and historically in the Vanden area. Aerial imagery shows that the Vanden occurrence has likely been extirpated by development. Each occurrence generally consists of a few plants and by far the largest number of plants was reported in 1992 from near Bird's Landing and consisted of 760 plants. Two populations in the Jepson Prairie area had 35 and 85 plants in the late 1990's (CNDDB 2009). Nine reported occurrences of Carquinez goldenbush are potentially within the Plan Area (Figure A-54b).

DRAFT

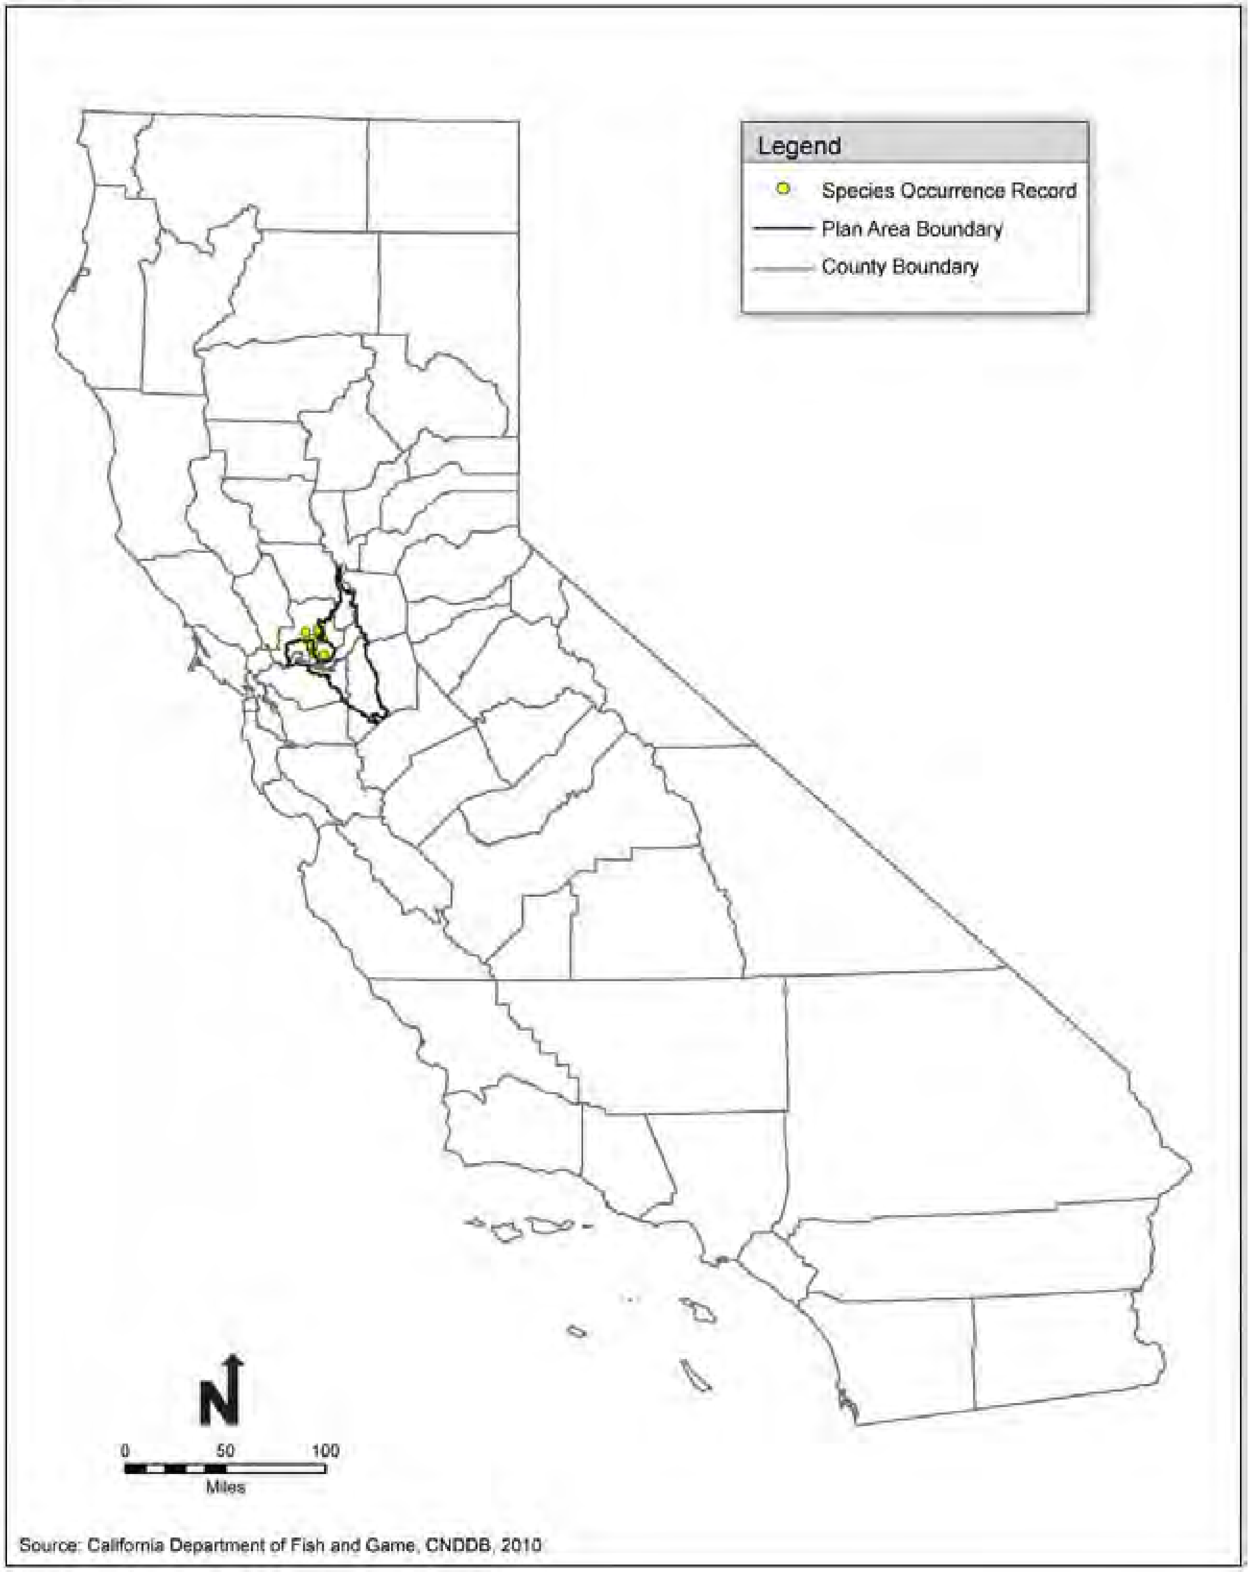

Figure A-54a. Carquinez Goldenbush Statewide Recorded Occurrences

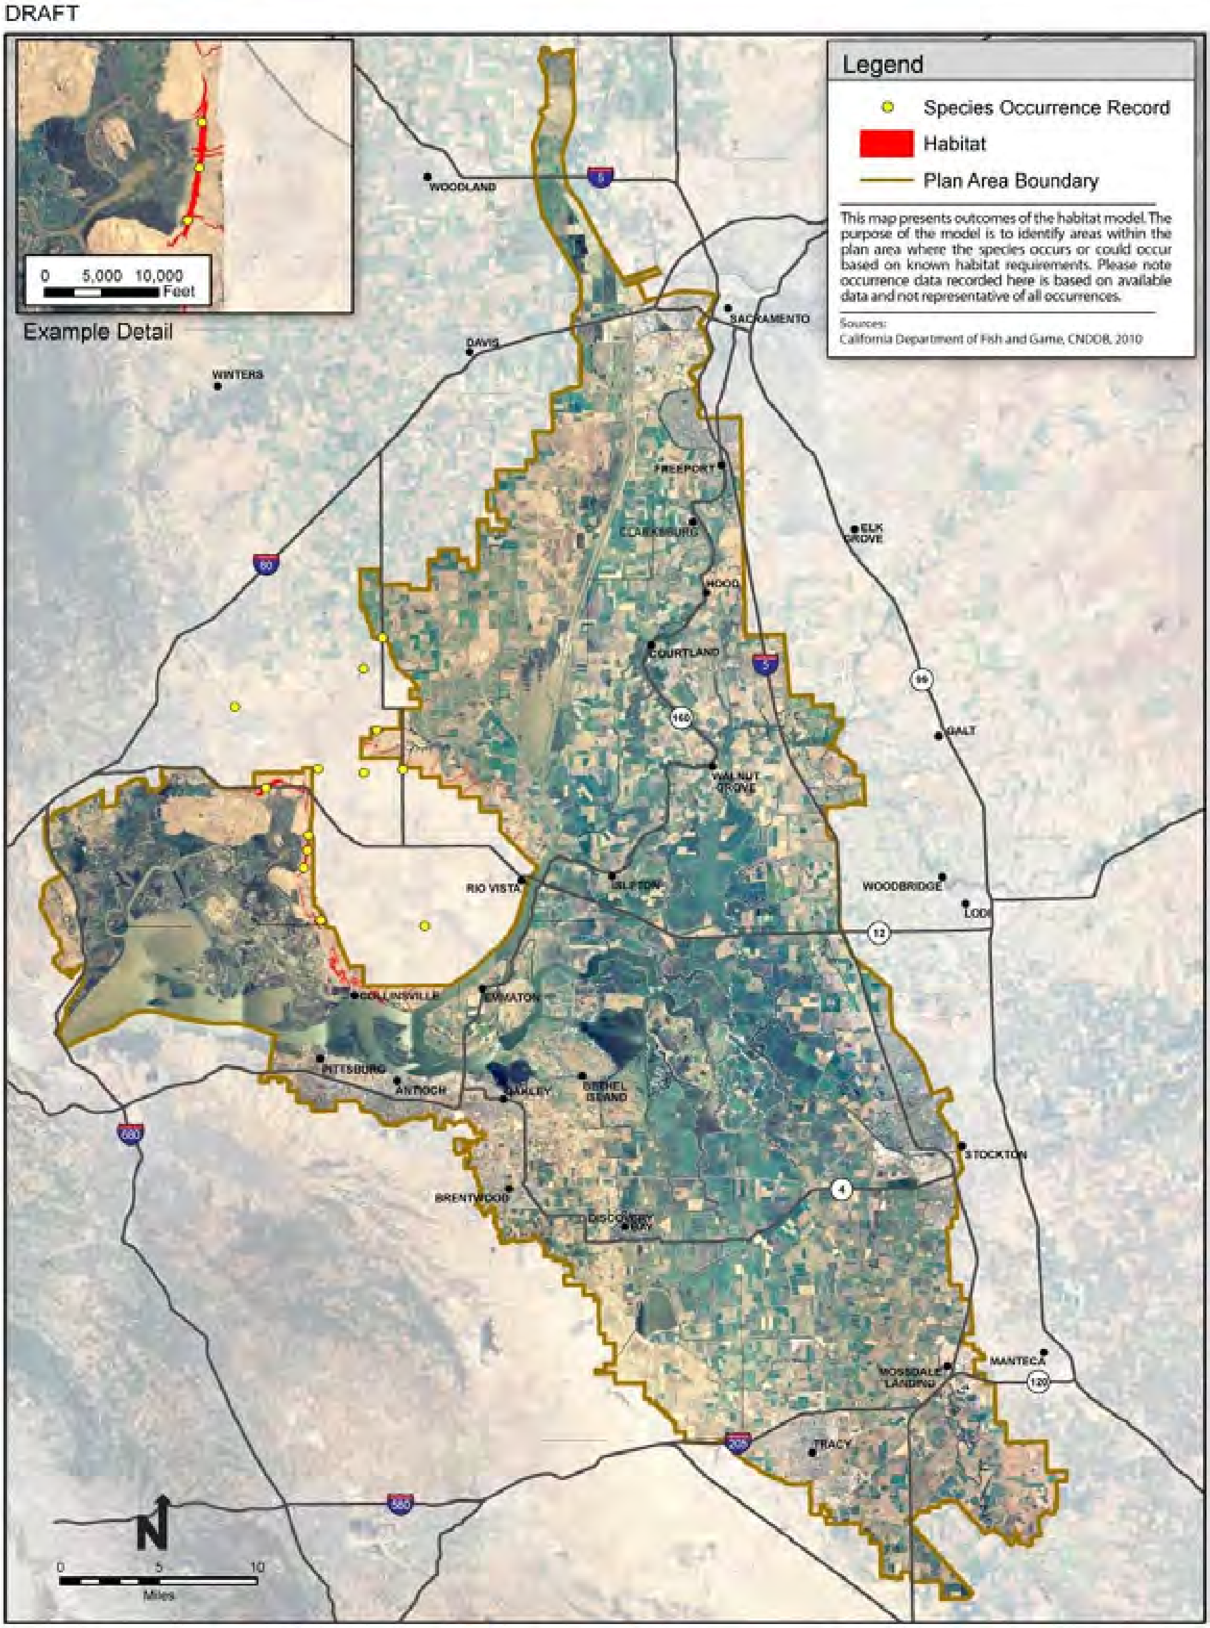

Figure A-54b. Carquinez Goldenbush Habitat Model and Recorded Occurrences

A54.3 Habitat Requirements and Special Considerations

Very little is known about the habitat requirements of Carquinez goldenbush. Based on its reported distribution and collection notes, it is restricted to recent alluvial soils that are derived from the Tehama geological formation and which are located on the Montezuma Block or along the fault that runs along its western margin (Hickman 1993, Band 1998, Graymer et al. 2002, Calflora 2009, CNDDB 2009, CNPS 2009). It grows along seasonal drainages, adjacent to the margins of alkaline playas, and in association with vegetation that is transitional between the brackish marsh and the grasslands within the 3.4-4.3 meter NAVD88 elevation band along the eastern border of Suisun Marsh (Hickman 1993, Band 1998, Graymer et al. 2002, DWR 2007, CNDDB 2009, CNPS 2009, NRCS 2009).

A54.4 Life History

Carquinez goldenbush is a very small shrub in the sunflower family (Asteraceae) with flowering heads that bloom from August to December and contain 10-13 yellow flowers (Hickman 1993, CNPS 2009). Its maximum reported height is 30 centimeters (cm) (< 1 foot) and the woody stems which branch from the base of the plants can be either erect or lie mostly flat on the ground with the branch tips curving upward (Nesom 1991). The leaves are hairless, light gray-green in color, dotted with glands, and less than 2 cm (0.8 inch) long. Unlike the highly variable and closely related species that occur immediately to the south, Carquinez goldenbush has consistent morphological characteristics across its distribution (Nesom 1991).

A54.5 Threats and Stressors

Activities that have been reported to have impacted Carquinez goldenbush include agricultural land conversion, grazing, road widening, and development (CNPS 2009).

A54.6 Relevant Conservation Efforts

Carquinez goldenbush is a covered species under the Solano County Multispecies Habitat Conservation Plan. Some of the reported extant occurrences are generally within protected areas such as the Greater Jepson Prairie Ecosystem Regional Management Plan area (Witham 2006) or within the Suisun Marsh Management Area.

A54.7 Species Habitat Suitability Model

Carquinez goldenbush occurrences in the Plan Area are all in close proximity to hydrological features such as alluvium in stream corridors on the Montezuma Block and along the upper margin of Suisun Marsh. The United States Geological Survey (USGS) geological data (Graymer et al. 2002) was used to select the following alluvium units that were related to the Montezuma Block and along the Suisun Marsh: Qa, Qhb, Qhbm, Qhc, Qhbm, Qhc, Qhdm, Qhf, Qmz Qoa, and Qpf. Stream corridors (intermittent and perennial) that intersected these geologic units were selected and truncated at the point at which they encountered the upper elevation of intertidal marsh (Siegel 2007). The corridors were buffered 50 feet (15 meters) on either side in an effort to capture the estimated maximum extend of alluvium deposits in close proximity to the actual rivers/streams. Field reconnaissance on the Montezuma Block area in May 2009 indicates that this buffering width is liberal and tends to overpredict potential habitat (J. Gerlach, personal observation).

Physical factors such as the tidal waters and high groundwater elevations in the Suisun Marsh may cause a backwater effect on the down gradient moving groundwater of the uplands resulting in localized shallow upland groundwater and resulting changes in vegetation (Rains et al. 2004), or the change in slope combined with finer textured soils at the transition from upland to marsh may cause temporary shallow water tables in the same area (Loheide II et al. 2009). Alternatively, the association of this species with stream corridors and the narrow elevation band along Suisun Marsh may be an artifact of the area's extensive dry-farmed grain cropping where soil disking fallows and seeding commonly occur through smaller drainages and to the wetland borders of larger drainages and Suisun Marsh (J. Gerlach, personal observation). The upper margins of the marsh (11-15 feet LiDAR elevation re-sampled to 10 meters, NAVD88) were used to identify areas that may provide suitable combinations of soil properties and moisture.

A54.8 Recovery Goals

A United States Fish and Wildlife Service (USFWS) recovery plan has not been prepared for this species and no recovery goals have been established.

APPENDIX A55. DELTA TULE PEA (*LATHYRUS JEPSONII* VAR. *JEPSONII*)

A55.1 LEGAL STATUS

Delta tule pea (*Lathyrus jepsonii* var. *jepsonii*) is not listed under either federal or California endangered species acts. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G5T2/S2.2, which means that this species has a population or stand demonstrably secure to ineradicable due to being commonly found in the world. In contrast, this particular variety of the species has been ranked as globally (G) and within the state (S) rarer with either between six to 20 viable element occurrences, 1,000 to 3,000 individuals, or 2,000 to 10,000 acres (809 to 4,047 hectares) of occupied habitat; and the state threat level rank is "threatened."

The California Native Plant Society (CNPS) List ranking of 1B.2 for Delta tule pea indicates that it is rare, threatened, or endangered in California and elsewhere, and is considered by CNPS to be fairly endangered in California with between 20 to 80 percent of occurrences threatened. Plants with a CNPS List rank of 1B are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

A55.2 SPECIES DISTRIBUTION AND STATUS

A55.2.1 Range and Status

The range of Delta tule pea extends from Sacramento and Solano counties in the north, Napa and Sonoma counties in the west, and Contra Costa and San Joaquin counties in the south (Figure A-55a). Delta tule pea is endemic to California, and its distribution is based on 207 observations (Calflora 2007). Historically, it was reported as common in Suisun Marsh in 1894 and 1911, but today it is occasional to rare in Suisun Marsh. It occurs throughout the legal Delta (CNDDB 2008) and along the Napa River (Dutchman Slough) (Goals Project 2000).

A55.2.2 Distribution and Status in the Plan Area

Within the Plan Area, there are occurrences of Delta tule pea at and immediately above the tidal zone in marshes and along rivers and streams (Figure A-55b). It has been observed near Hass Slough, Snodgrass Slough, Lost Slough, on Ryer Island, Staten Island, Andrus Island, Bouldin Island, Rough and Ready Island, Browns Island, Winter Island, on the banks of the Middle River by the Upper and Lower Jones tracts, and near Collinsville and Pittsburgh among other locations throughout the Delta (CNDDB 2008). It also occurs within the tidal zone along Calhoun Cut and Barker Slough (Witham and Kareofelas 1994).

DRAFT

Figure A-55a. Delta Tule Pea Statewide Recorded Occurrences

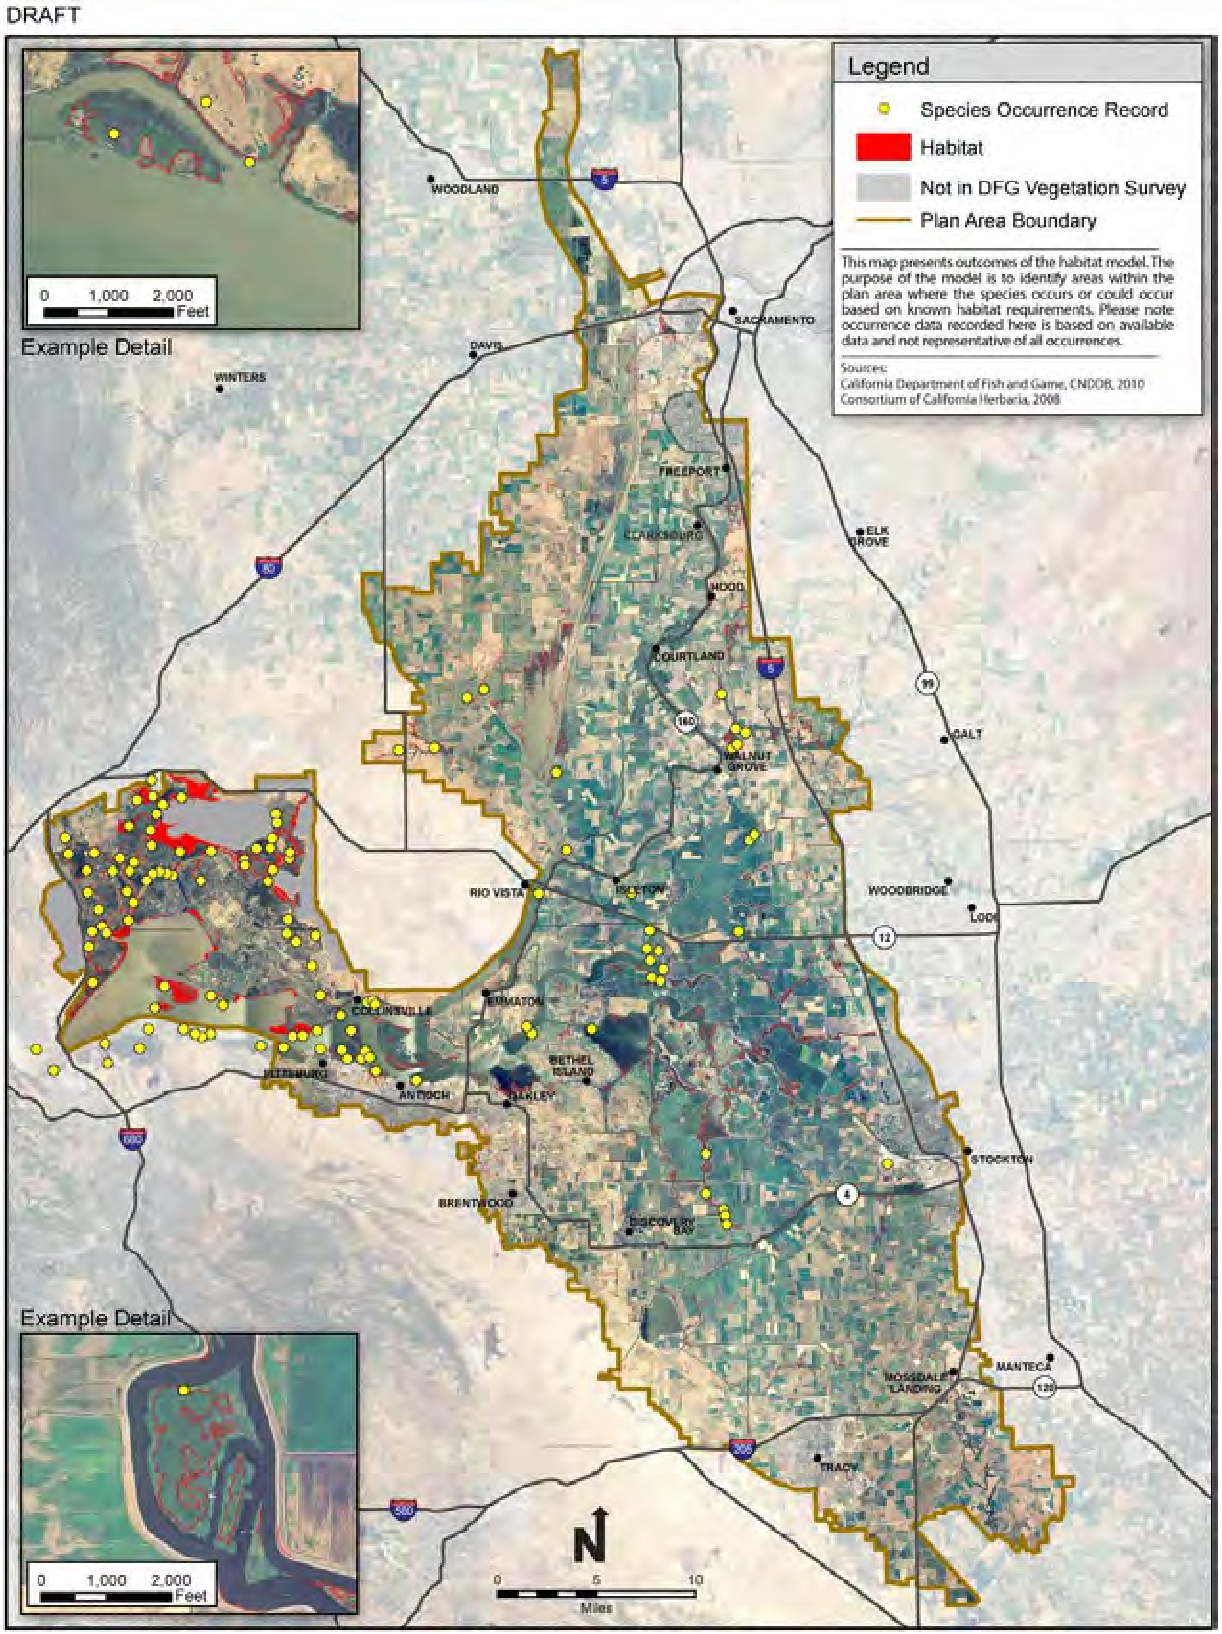

Figure A-55b. Delta Tule Pea Habitat Model and Recorded Occurrences

1

Population trends of Delta tule pea have not been documented. It is unclear whether this species is in decline. According to the CNPS (2008), occurrences of Delta tule pea in California are highly limited, most known occurrences are small, and the species is at risk throughout its range.

A55.3 Habitat Requirements and Special Considerations

Delta tule pea occurs on the borders of fresh and brackish marshes from zero to 13 feet in elevation (Grewell et al. 2007, CNPS 2008). It has been observed to co-occur with or near other BDCP covered plant species, such as soft bird's-beak (*Cordylanthus mollis* ssp. *mollis*), Mason's lilaeopsis (*Lilaeopsis masonii*), Suisun Marsh aster (*Symphyotrichum lentum*), and Delta mudwort (*Limosella subulata*) (CNDDB 2008).

A55.4 Life History

Delta tule pea is a glabrous climbing perennial herb with winged stems and is a member of the pea family (Fabaceae) (Hickman 1993). It is identified by the number of leaflets, its glabrous winged stem, blue-grey leaf color, and pink to pink-purple flowers. Because of its climbing habit, Delta tule pea tends to grow over other vegetation and can have stems up to 2.5 meters (8.2 feet) tall. The leaves have small narrow stipules, 10 to 16 leaflets, and coiled branched tendrils (Hickman 1993). It bears six to 15 pink-purple flowers, 0.6 to 0.8 inches (1.5 to 2 centimeters [cm]) long, in an unbranched inflorescence (raceme) at the end of the stems. The fruits (legumes) are glabrous (without hairs) (Hickman 1993, CNPS 2008). This species blooms from May to September (CNPS 2008).

A55.5 Threats and Stressors

The primary threat to Delta tule pea is the loss of marsh and floodplain habitat within the range of the species. Potential ways this habitat could be eliminated or degraded include agriculture, water diversions, and erosion (CNPS 2008). Fishing and hunting access also pose a threat to this species through trampling impacts (Witham and Kareofelas 1994).

A55.6 Relevant Conservation Efforts

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designates the Delta tule pea as "Contribute to Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its control and within its scope that are necessary to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

Delta tule pea is a covered species under the approved San Joaquin County Multi-species Habitat Conservation and Open Space Plan and the Natomas Basin Habitat Conservation Plan. Delta tule pea is proposed for coverage under the Solano County Multi-species Habitat Conservation Plan and the Yolo County Natural Heritage Program Plan.

A55.7 Species Habitat Suitability Model

Habitat. Habitat was modeled separately based upon the salinity of the water. For freshwater areas, essentially the area within the legal delta, Suisun Marsh aster habitat was identified as the area within 10 feet (3 meters) of the landward side of the landward boundary of tidal freshwater emergent wetland BDCP land cover type exclusively where this land cover type is adjacent to grassland, vernal pool complex, valley/foothill riparian, or agricultural habitats cover types. For brackish water areas in and near Suisun Marsh, the model used all tidal brackish emergent wetland polygons (SFEI 2005, Boul and Keeler-Wolf 2008) which, using the California Department of Water Resources (DWR) LiDAR data set as resampled at 10 meters (DWR 2007), were then intersected with an elevation range of 7 to 10 feet (2 to 3 meters) to capture elevations 1 foot (30 cm) below intertidal to 2 feet (60 cm) above intertidal (i.e. the upper limit of the intertidal range was estimated at 8 feet, NAVD88; Siegel estimated the intertidal range in Suisun to occur between 1 to 8 feet (30 cm to 2.4 meters), NAVD88 (Siegel 2007).

Assumptions. Historical and current records of this species indicate that its distribution extends throughout most of the Plan Area having been observed in tidally influenced waters from Calhoun Cut and in the Sacramento River near Walnut Grove southward and from Tom Pain Slough near the southern boundary of the Plan Area northward (Figure A-55b) (Witham and Kareofelas 1994, CNDDB 2008). While there are no occurrences within the Plan Area north of Calhoun Cut and Walnut Grove, patches of suitable habitat extend into those areas. For purposes of this model, a 10 foot-wide (3 meter) buffer on the landward side of the landward boundaries of the tidal freshwater emergent wetland land and tidal brackish emergent wetland contained within the 7-10 foot (2-3 meter) elevation within Suisun Marsh have been included as the potential extent of habitat that supports Suisun Marsh aster.

A55.8 Recovery Goals

A United States Fish and Wildlife Service (USFWS) approved Recovery Plan has not been prepared for this species; however, this species is included in the Draft Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California which specifies the preservation of individuals and habitat, the control of invasive species, and the restoration of tidal flows as recovery criteria goals (USFWS 2010). Additionally, the CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan’s Multi-Species Conservation Strategy designates the Delta tule pea as “Contribute to Recovery” (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its control and within its scope that are necessary to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

APPENDIX A56. LEGENERE (*LEGENERE LIMOSA*)

A56.1 Legal Status

Legenere (*Legenere limosa*) is not listed under either federal or California endangered species acts. Legenere has been designated as sensitive by the Bureau of Land Management (BLM), which means that the BLM State Director calls for special management consideration of this species on BLM-administered lands. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G2/S2.2 which means that globally (G) and within the state (S) there are either between six to 20 viable element occurrences of this species, 1,000 to 3,000 individuals of this species, or 2,000 to 10,000 acres (809 to 4,047 hectares) where this species occurs. Its state threat level rank is “threatened.”

The California Native Plant Society (CNPS) List ranking of 1B.1 for legenere indicates that it is rare, threatened, or endangered in California and elsewhere, and is considered by CNPS to be seriously endangered in California with more than 80 percent of occurrences threatened. Plants with a CNPS List rank of 1B are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

A56.2 Species Distribution and Status

A56.2.1 Range and Status

Legenere’s range extends from southern Shasta County to southern Santa Clara County (Figure A-56a). It is found on bottom lands and alluvial terraces in the Sacramento Valley with its distribution at the south end of the Sacramento Valley bifurcated by the Delta (CNDDB 2008). It occurs in the extreme northeastern part of the San Joaquin Valley and is also found on valley floors and margins in both the northern end of Southern Coast Range in San Mateo, Alameda, and Santa Clara counties and the southern end of the Northern Coast Range in Sonoma and Napa counties (CNDDB 2008).

A56.2.2 Distribution and Status in the Plan Area

Legenere has been reported in the Plan Area from vernal pools, vernal swales, and alkaline flats in vernal pool grasslands in the greater Jepson Prairie area (Figure A-56b) (Witham 2003, Buck 2004, Witham 2006, Barbour et al. 2007, Lazar 2007, CNDDB 2008). During spring 2009 California Department of Water Resources/Delta Habitat Conservation and Conveyance Program (DWR/DHCCP) field surveys conducted for the Bay Delta Conservation Plan (BDCP), legenere was discovered growing in a roadside ditch in the Stone Lakes area.

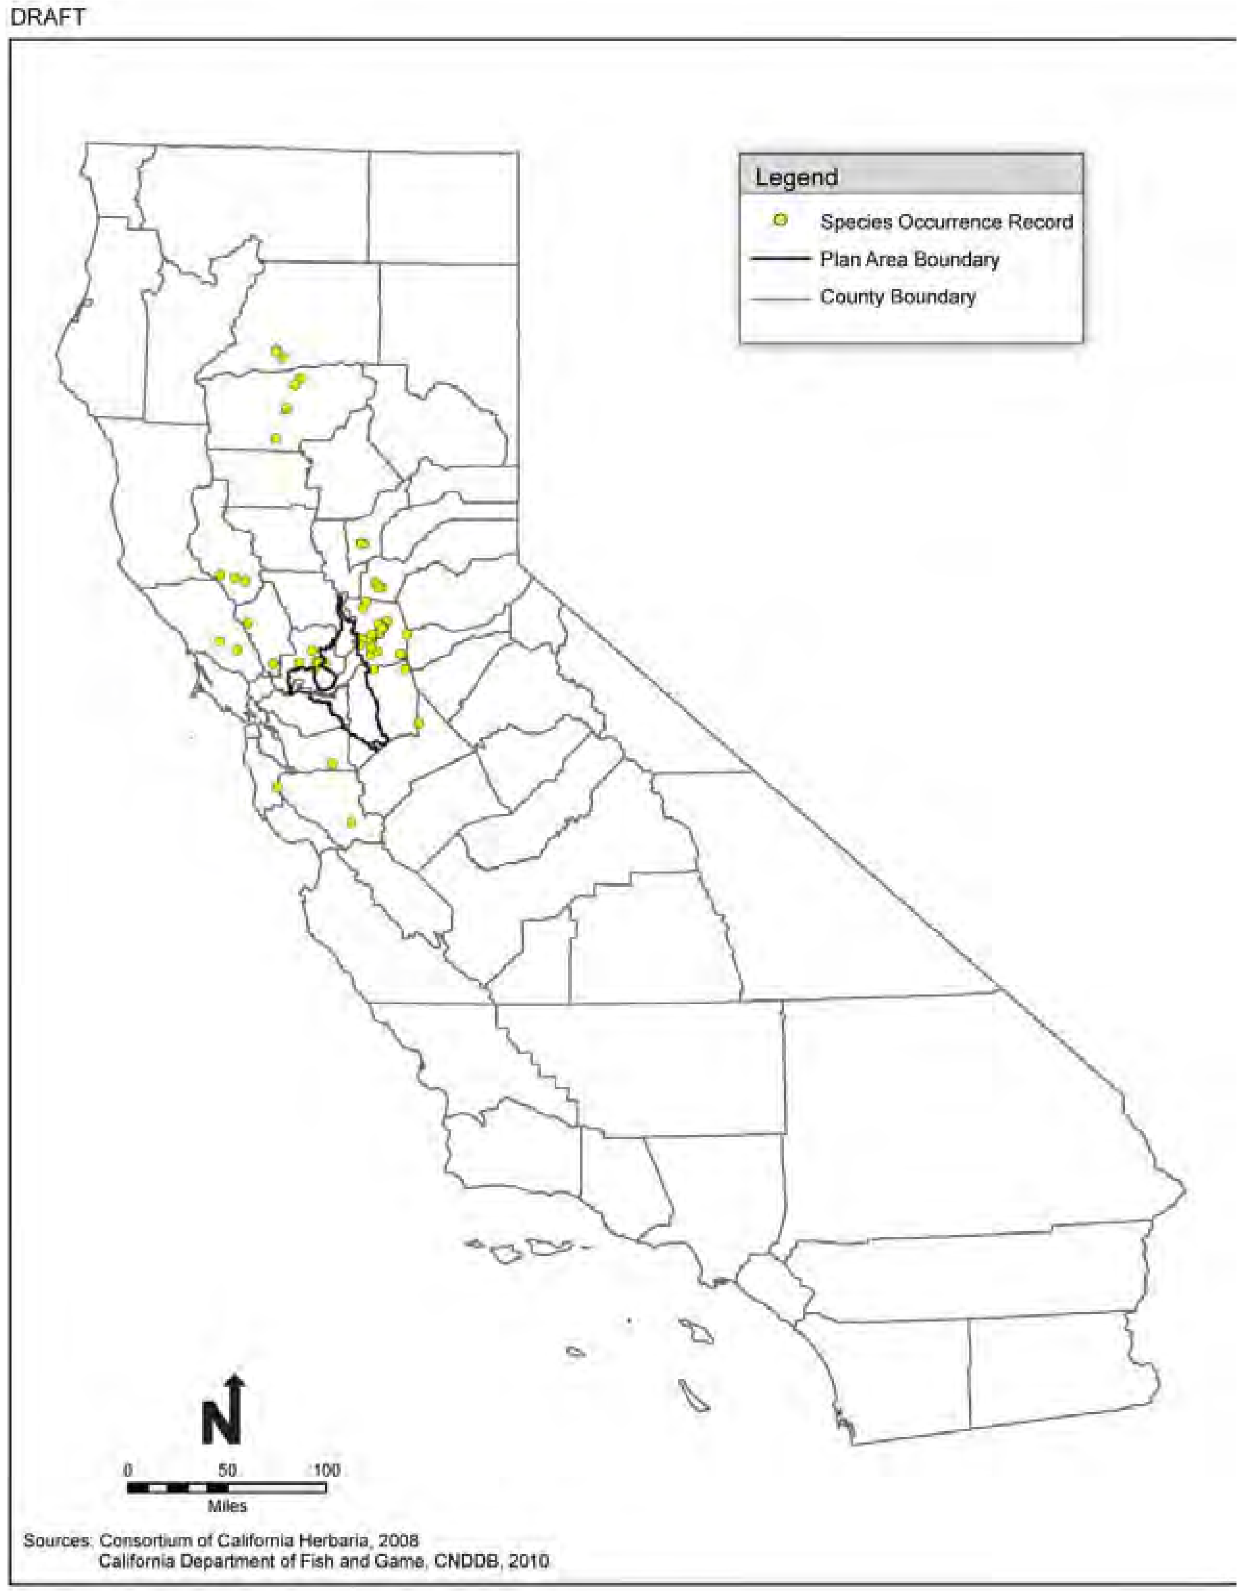

Figure A-56a. Legenere Statewide Recorded Occurrences

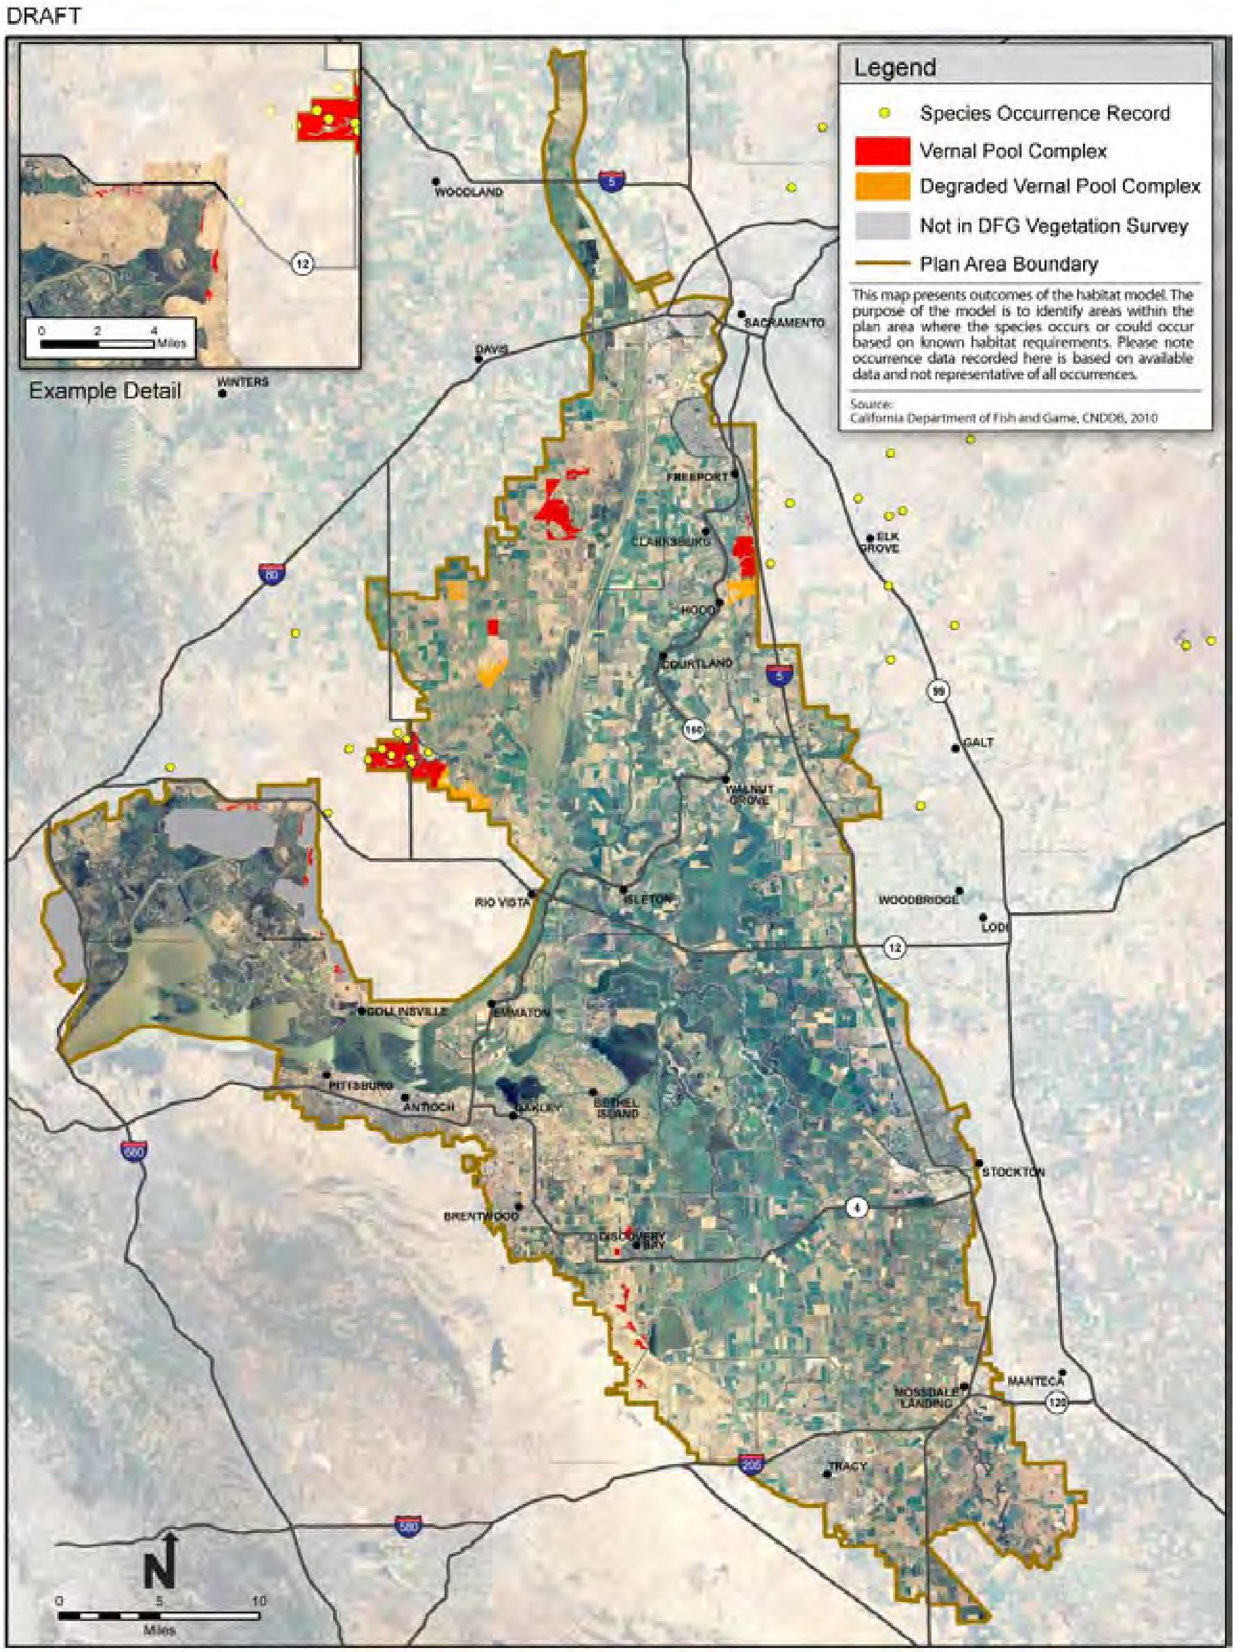

Figure A-56b. Legenere Habitat Model and Recorded Occurrences

Recorded occurrences in western Sacramento and San Joaquin counties are immediately east of the eastern boundary of the Plan Area.

A56.3 Habitat Requirements and Special Considerations

Throughout its distribution, legenere occurs in vernal pools, vernal swales, pools in seasonal streambeds, vernal marshes, and stock ponds (CNDDB 2008). Occurrence records often state that it is found with long inundation indicator species such as pale spikerush (*Eleocharis macrostachya*), but on the clay soils of the greater Jepson Prairie area it is found in a range of microtopographic positions in vernal pool grassland vegetation that typically have a high cover of the nonnative annual grass *Lolium multiflorum* (Witham 2006, Barbour et al. 2007, Lazar 2007, CNDDB 2008).

In a large multiple-year vernal pool study, the occurrence of vegetative plants in particular vernal pools was found to fluctuate dramatically with the species disappearing and reappearing in some years (Buck 2004, Barbour et al. 2007). These fluctuations can occur for decades as one occurrence observed in 1961 was not observed in 1971, 1980, or 1983 but was observed again in 1991 (CNDDB 2008). Legenere species may respond positively to dry season soil disturbances as one occurrence in Sacramento County was reported to support up to 1,000 to 10,000 plants in 1991 despite having been "…disked annually for firebreak," but no plants were observed during a 2007 survey (CNDDB 2008). Legenere is one of few vernal pool endemic species that can be considered an evolutionary relict (remnant of an otherwise extinct flora or fauna in an environment much changed from that in which it originated) (Stone 1990).

A56.4 Life History

Legenere is a small submerged to emergent aquatic annual herbaceous plant during the wet season when habitat is ponded that becomes a 4- to 12-inch (10- to 30-centimeter) long sprawling terrestrial plant at the end of the wet season as the habitat dries. The small, 0.1- to 0.5-inch (2- to 10-millimeter) long, narrow leaves support flowers in the upper axils of the characteristic zigzag appearing stems (Hickman 1993). Because of its small size and inconspicuous white flowers, it is difficult to detect during field surveys and may be frequently overlooked (Anonymous 2008). Nothing is known about its pollination biology, seed germination characteristics, or many other important biological and ecological characteristics.

A56.5 Threats and Stressors

Development, intensive agriculture, and exotic plant species (especially *Lolium multiflorum*) are considered to be the primary threats to legenere (Showers 1988, Showers 1996, Dawson et al. 2007, CNDDB 2008). Additionally, waxy mannagrass (*Glyceria declinata*) may pose a threat to legenere and many other vernal pool species (Gerlach et al. 2009).

A56.6 Relevant Conservation Efforts

The known occurrences in the Plan Area are protected from development or intensified agriculture under conservation easements (Witham 2006, Barbour et al. 2007, Lazar 2007, CNDDB 2008). Legenere is included in the Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon (USFWS 2005). Legenere is a covered species under the permitted San Joaquin County Multi-species Habitat Conservation and Open Space Plan and the Natomas Basin Habitat Conservation Plan; and it is proposed for coverage under the Solano County Multispecies Habitat Conservation Plan and the South Sacramento County Habitat Conservation Plan.

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for legenere is "Maintain" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions to maintain the species by avoiding, minimizing, and compensating for any adverse effects to the species created by ERP restoration actions. To the extent practicable, the ERP will improve species habitat conditions.

A56.7 Species Habitat Suitability Model

Model Approach. Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below and in Section 2.3.1, *Data Sources and Natural Community Classification*). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as vernal pools, individual trees, or small groups of trees. It is also possible, as with some vernal pool invertebrates that are restricted to seasonally ponded habitats, to underestimate potentially-occupied habitat due to the lack of information on small, degraded or artificially-created seasonal wetland habitats.

Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The legenere model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), DWR 2007 LiDAR elevation data, Google Earth 2009 aerial imagery and USDA 2005 aerial photography. Using these data sets, the model maps the distribution of suitable legenere habitat in the Plan Area according to the species' two habitat types, vernal pool complex and degraded vernal pool complex habitat. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Vernal Pool Complex Habitat: High quality permanent habitat that consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly impacted by agricultural or development practices. Vernal pool complex habitat for legenere includes the following vegetation subunits that were selected from the BDCP vernal pool complex natural community:

- Vernal pool complex – all vegetation types

Degraded Vernal Pool Complex Habitat: Low quality ephemeral habitat that ranges from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, disking, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. The aquatic features in this habitat are more clearly classified as temporary waters sensu lato (Williams 2006) than intact and fully functional vernal pools. Because these features are inundated during the wet season and may have historically been located in or near areas with natural vernal pool complex, they may support individuals or small populations of species that are found in vernal pools and swales. However, they do not possess the full complement of ecosystem and community characteristics of natural vernal pools, swales and their associated uplands and they are generally ephemeral features that are eliminated during the course of normal agricultural practices. Degraded vernal pool complex habitat for legenere includes the following vegetation subunits that were selected from the BDCP other natural seasonal wetlands and grasslands communities:

- Grasslands
  - Degraded vernal pool complex – California annual grasslands;
  - Degraded vernal pool complex – Ruderal herbaceous grasses and forbs;
  - Degraded vernal pool complex – Italian rye-grass (*Lolium multiflorum*); and
  - Degraded vernal pool complex – Rabbitsfoot grass (*Polygpogon maritimus*).
- Other natural seasonal wetlands
  - Degraded vernal pool complex-Vernal pools.

Potential habitat without concave surfaces (except for seeps along Suisun Marsh) was removed from the model. LiDAR elevation data was then visually inspected in four general areas to further assess specific locations that had been identified by the habitat selection process. These areas were selected based both on *a priori* knowledge of the region and because they were identified by the intersection of the selected vegetation types and soils. The analysis of the LiDAR data further refined the habitat model and provided a more accurate demarcation of suitable habitat. The GIS habitat model was then compared against field data from DWR/DHCCP surveys conducted in 2009 for the BDCP. Land uses that are incompatible with the species' habitat requirements, for example potential habitat polygons falling on leveled or developed lands, were removed from the model.

Assumptions. Historical and current records of this species in the Plan Area indicate that its current distribution is limited to alkaline soil areas with vernal pool and swale microtopography along the western border of the Plan Area (Figure A-56b) (Witham 2006, CNDDB 2010) and areas with swales and vernal pools along the eastern boundary of the Plan Area (CNDDB 2010). The vegetation cover is typically a combination of vernal pool adapted species and annual ryegrass (Witham 2006, CNDDB 2010).

A56.8 Recovery Goals

Although legenere is not a federally listed species, it is included in the Draft Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon (USFWS 2005). The Recovery Plan explicitly states that its goal is to ensure the long-term conservation of legenere and 32 other taxa by using an ecosystem level strategy that is based on: (1) current knowledge of the existing conditions of vernal pool communities, (2) the distribution and status of the populations of each of the species, and (3) current and anticipated processes that impact vernal pool ecosystems. Because the goal of the Recovery Plan is primarily directed at habitat preservation, its implementation program specifically addresses factors that relate to habitat acquisition and management: (1) habitat protection; (2) adaptive habitat management and monitoring; (3) status surveys; (4) research; and (5) public participation.

APPENDIX A57. HECKARD'S PEPPER-GRASS (*LEPIDIUM LATIPES* VAR. *HECKARDII*)

A57.1 LEGAL STATUS

Heckard's pepper-grass (*Lepidium latipes* var. *heckardii*) is not listed under either federal or California endangered species acts. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G4T1/S1.2 which means that the species as a whole is apparently secure across its overall distribution, but some factors of concern, such as narrow habitat requirements or continuing threats, do exist. In contrast, this particular variety of the species has been ranked as threatened globally (G) and within the state (S) because it has either fewer than six viable occurrences, fewer than 1,000 individuals, or fewer than 2,000 acres (809 hectares) of occupied habitat. Its state threat level rank is "threatened."

The California Native Plant Society (CNPS) List ranking of 1B.2 for Heckard's pepper-grass indicates that it is rare, threatened, or endangered in California and elsewhere, and it is considered by CNPS to be fairly endangered in California with between 20 to 80 percent of occurrences threatened. Plants with a CNPS List rank of 1B are considered by CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

A57.2 SPECIES DISTRIBUTION AND STATUS

A57.2.1 Range and Status

The reported range of Heckard's pepper-grass extends from Glenn and Colusa counties to Merced County (Figure A-57a) (CNDDB 2008, Consortium of California Herbaria 2008, Burmester pers. comm. 2009). The distribution of this species includes the alkaline soil areas to the southeast and south of the City of Woodland and at the California Department of Fish and Game (DFG) Tule Ranch unit of the DFG Yolo Bypass Wildlife Area (Tule Ranch) in Yolo County (Showers 1996, Witham 2003, CNDDB 2008). Populations of Heckard's pepper-grass at the Tule Ranch site are sparse but dispersed throughout the site (Witham 2003). In Solano County, Heckard's pepper-grass has been reported from the East Wilcox and Gridley ranches in the greater Jepson Prairie area (Witham 2006, CNDDB 2008) and along Haas Slough, but that occurrence was last observed by Jepson in 1891 (Consortium of California Herbaria 2008). Aerial imagery indicates that Haas Slough occurrence is likely to have been extirpated by the spread of intensive agriculture along both sides of the slough. Although occurrences have been recently discovered, Heckard's pepper-grass is extremely rare in California (CalFlora 2000, CNPS 2008) and is expected to continue to decline, although data on population trends are lacking.

DRAFT

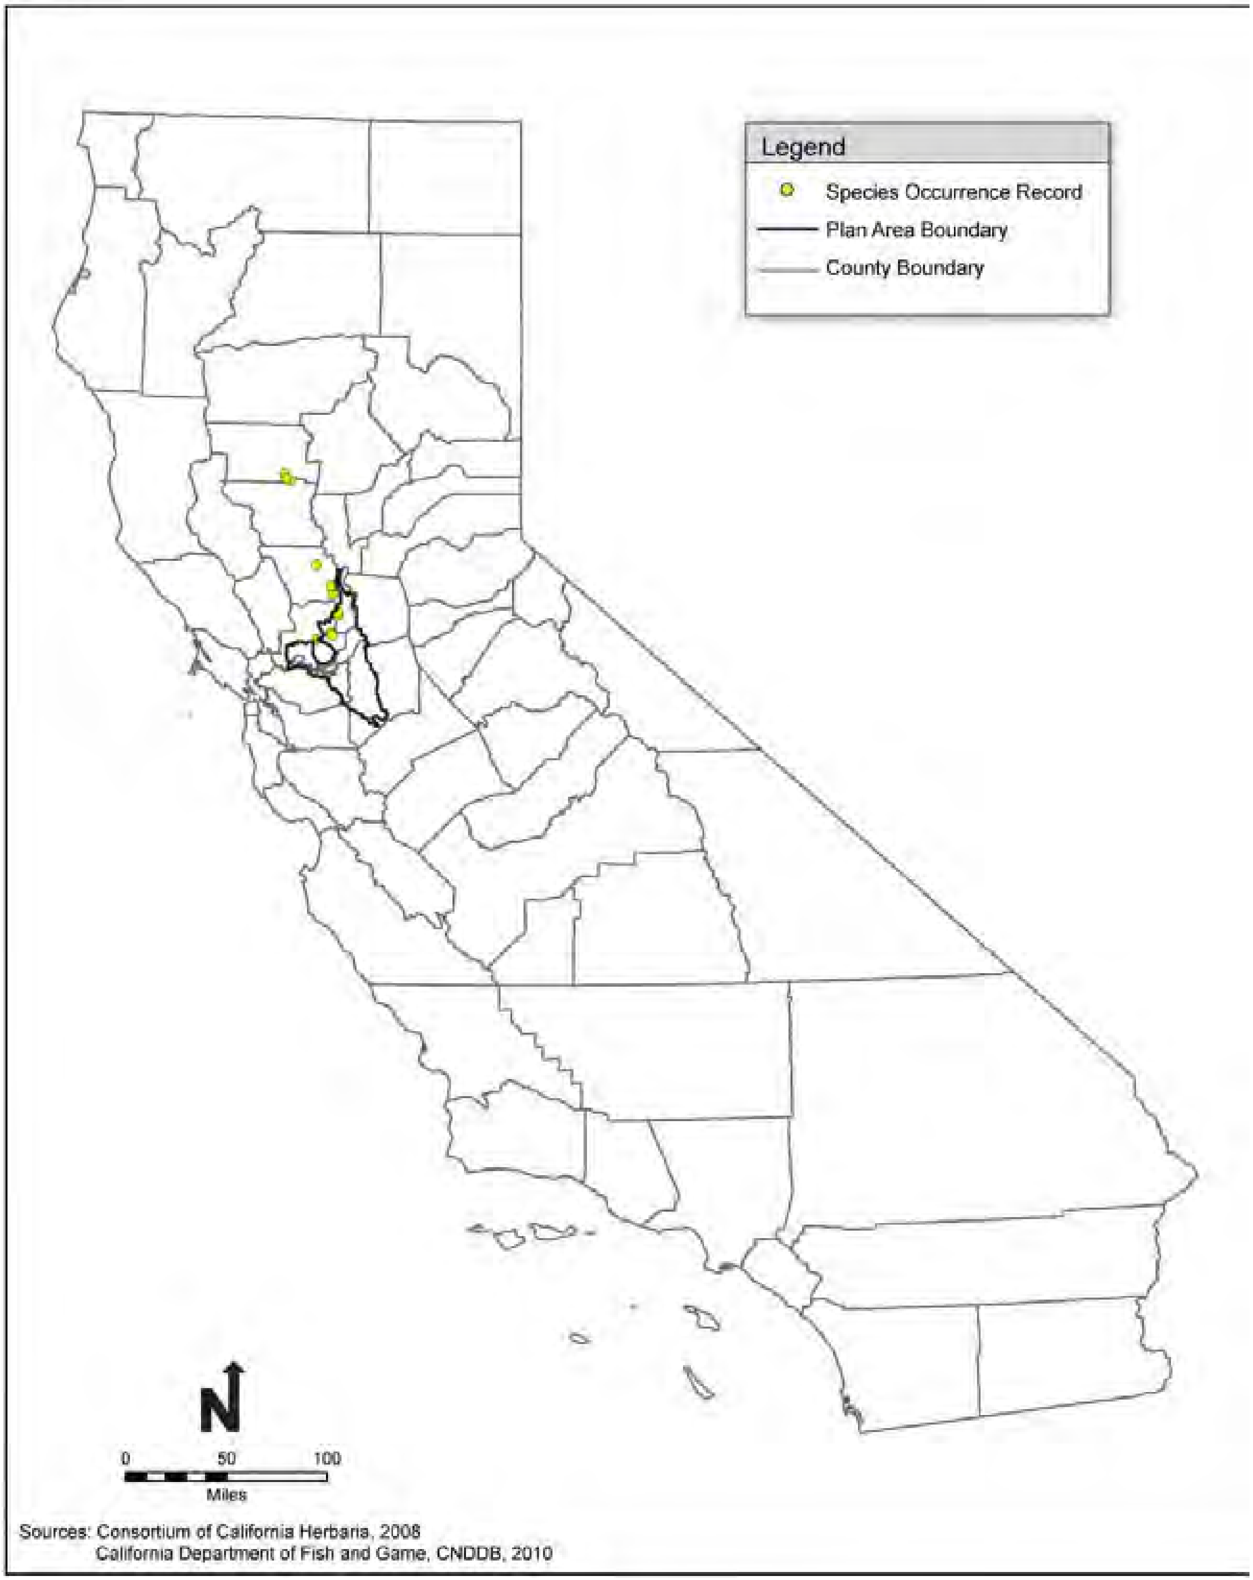

Figure A-57a. Heckard's Pepper-Grass Statewide Recorded Occurrences

A57.2.2 Distribution and Status in the Plan Area

Heckard's pepper-grass has been observed in the Plan Area west of Yolo Bypass in Yolo County in the area of the Tule Ranch (Witham 2003, CNDDB 2008, Consortium of California Herbaria. 2008), and in Solano County on the Wilcox and Gridley ranches of the greater Jepson Prairie area (Figure A-57b) (Witham 2006). The hydrology and vegetation of the Gridley Ranch site is described in Williamson et al. (2005). It has also been detected along agricultural ditches in the Stone Lakes area during 2009 California Department of Water Resources/Delta Habitat Conservation and Conveyance Program (DWR/DHCCP) field surveys conducted for the Bay Delta Conservation Plan (BDCP). The occurrences in natural communities in the Plan Area are within vernal pool complexes on clay-rich alkaline soils that have not been intensively farmed.

A57.3 Habitat Requirements and Special Considerations

Very little is known regarding the ecology of Heckard's pepper-grass. Populations near the city of Woodland occur on alkaline flats and mesic alkaline grasslands that were once contour rice fields on Pescadero silty clay, saline-alkali, Marvin soils, and Willows clay soil types. On the Tule Ranch site in the Yolo Bypass, and on the East Wilcox and Gridley ranches in Solano County it occurs in grazed, slightly alkaline vernal pool grassland in areas that are dominated by annual ryegrass (*Lolium multiflorum*) (Witham 2006, CNDDB 2008), a nonnative that is tolerant of alkaline soils (Dawson et al. 2007). Occurrence records and survey reports suggest that Heckard's pepper-grass is closely associated with Sacramento Valley populations of alkali milk-vetch (*Astragalus tener* var. *tener*) (another BDCP covered species) (CNDDB 2008).

A57.4 Life History

Heckard's pepper-grass is a 1- to 10-inch (3- to 25-centimeter [cm]) tall herbaceous annual plant in the mustard family (Brassicaceae). It is differentiated from dwarf pepper-grass (*L. latipes* var. *latipes*) based on its height, the distance between its leaf nodes, and its lack of a basal rosette (Hickman 1993, Rollins 1993). Heckard's pepper-grass has dense foliage with 2- to 4-inch (5- to 10-cm) long linear leaves. Small, greenish flowers occur in a raceme in fruit that is greater than basal leaves and the flat, oval fruits are deeply notched at their tops (Hickman 1993, Rollins 1993). Heckard's pepper-grass flowers March through May (CNPS 2008). Studies are needed to shed light on basic biological and ecological requirements such as pollination systems, seed dormancy and germination cues, dispersal vectors, and seed predation.

A57.5 Threats and Stressors

Development, waterfowl management, agricultural conversion, urban development, and exotic plant species are considered the primary threats to Heckard's pepper-grass (Showers 1988, Showers 1996, Dawson et al. 2007, CNDDB 2008). All of these threats lead to the loss of habitat or the degradation of conditions the plant requires to survive.

DRAFT

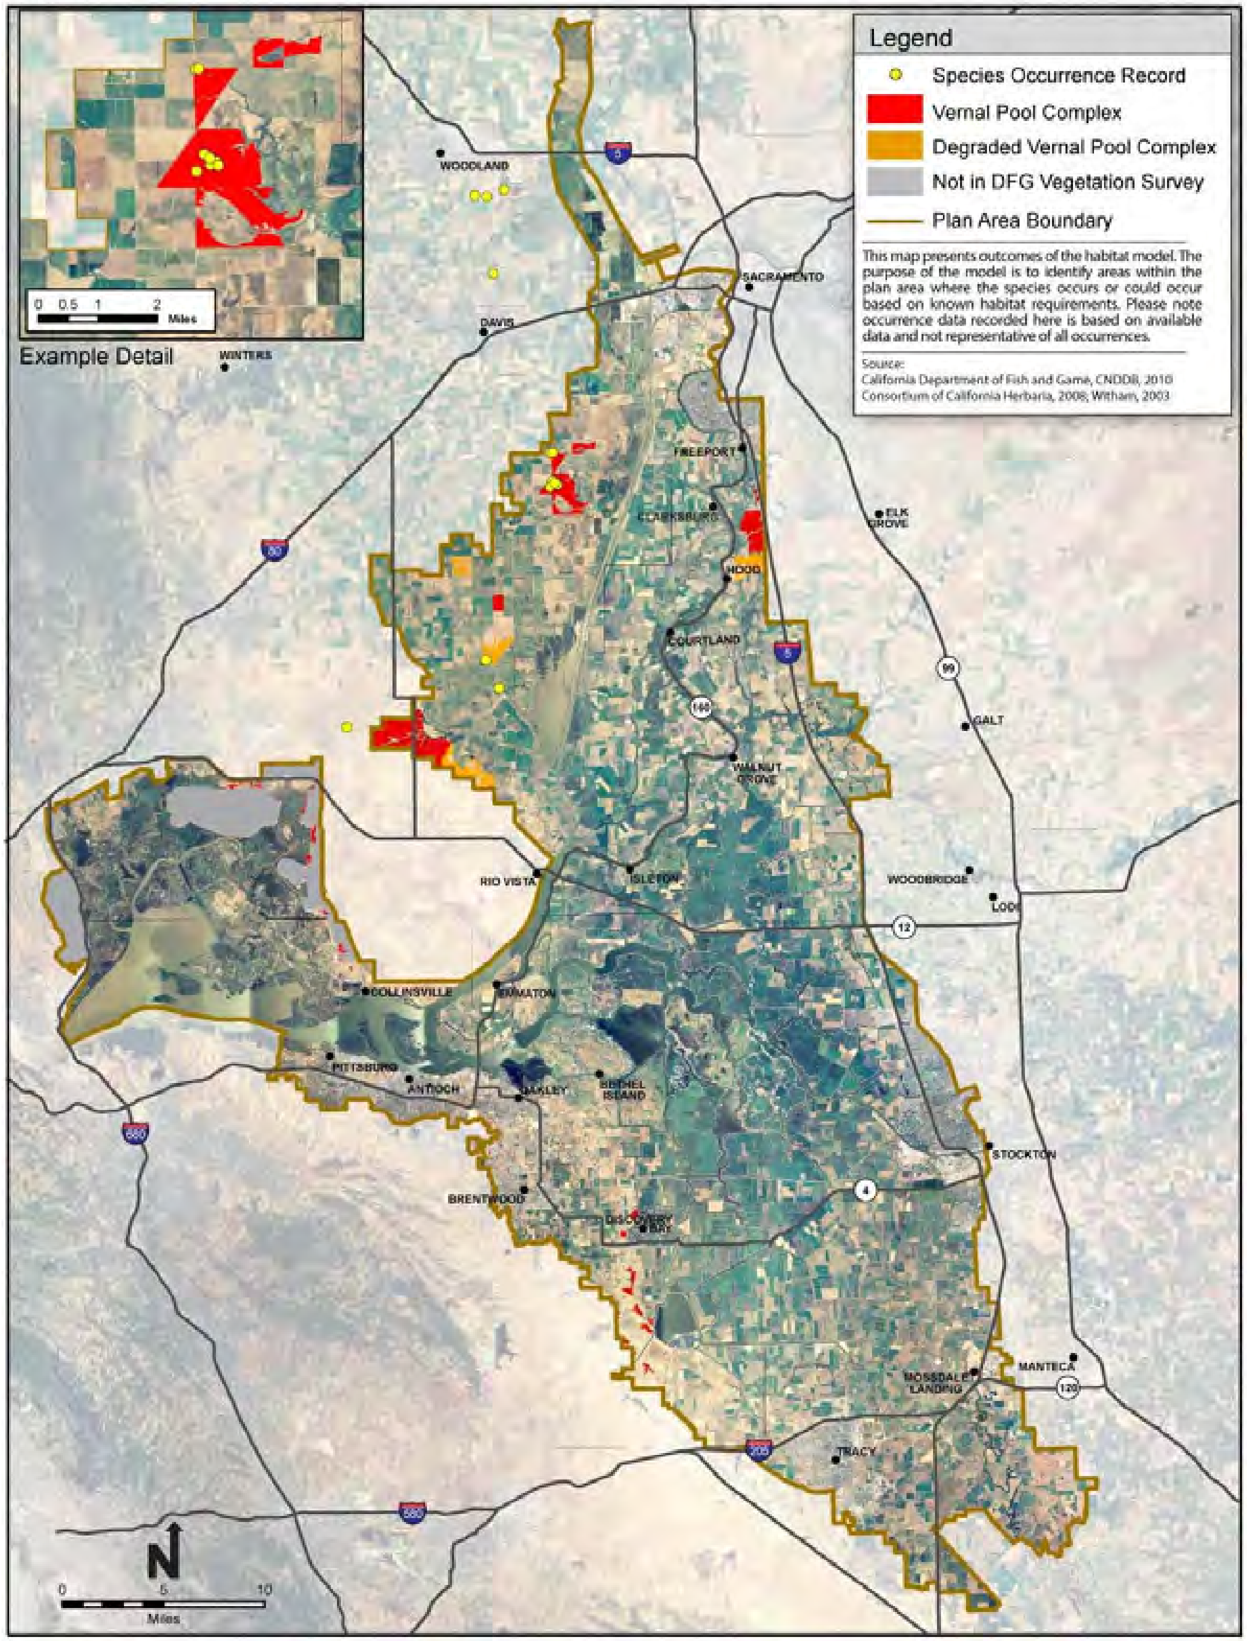

Figure A-57b. Heckard's Pepper-Grass Habitat Model and Recorded Occurrences

A57.6 Relevant Conservation Efforts

The known populations of Heckard's pepper-grass in Solano County are under conservation easements and those in Yolo County are protected on the DFG Tule Ranch Reserve or by a conservation easement in the Spring Lakes area near the city of Woodland. The Tule Ranch and greater Jepson Prairie area populations are currently grazed.

Heckard's pepper-grass is proposed for coverage under the Solano County Multispecies Habitat Conservation Plan and the Yolo County Natural Heritage Program Plan.

A57.7 Species Habitat Suitability Model

Model Approach. BDCP Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below and in Section 2.3.1, *Data Sources and Natural Community Classification*). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as vernal pools, individual trees, or small groups of trees. It is also possible, as with some vernal pool invertebrates that are restricted to seasonally ponded habitats, to underestimate potentially-occupied habitat due to the lack of information on small, degraded or artificially-created seasonal wetland habitats.

Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life requisite association. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The Heckard's pepper-grass model uses vegetation types and associations from the following data sets: BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007 [Delta], Boul and Keeler-Wolf 2008 [Suisun Marsh], TAIC 2008 [Yolo Basin]), DWR 2007 LiDAR elevation data, Google Earth 2009 aerial imagery and USDA 2005 aerial photography. Using these data sets, the model maps the distribution of suitable Heckard's pepper-grass habitat in the Plan Area according to the species' two habitat types, vernal pool complex and degraded vernal pool complex habitat. Vegetation types were assigned based on the species requirements as described above and the assumptions described below.

Vernal Pool Complex Habitat: High quality permanent habitat that consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly impacted by agricultural or development practices. Vernal pool complex habitat for Heckard's pepper-grass includes the following vegetation subunits that were selected from the BDCP vernal pool complex natural community:

- Vernal pool complex – All vegetation types

Degraded Vernal Pool Complex Habitat: Low quality ephemeral habitat that ranges from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, disking, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. The aquatic features in this habitat are more clearly classified as temporary waters sensu lato (Williams 2006) than intact and fully functional vernal pools. Because these features are inundated during the wet season and may have historically been located in or near areas with natural vernal pool complex, they may support individuals or small populations of species that are found in vernal pools and swales. However, they do not possess the full complement of ecosystem and community characteristics of natural vernal pools, swales and their associated uplands and they are generally ephemeral features that are eliminated during the course of normal agricultural practices. Degraded vernal pool complex habitat for Heckard's pepper-grass includes the following vegetation subunits that were selected from the BDCP other natural seasonal wetlands and grasslands communities:

- Grasslands
    - Degraded vernal pool complex – California annual grasslands;
    - Degraded vernal pool complex – Ruderal herbaceous grasses and forbs;
    - Degraded vernal pool complex – Italian rye-grass (*Lolium multiflorum*); and
    - Degraded vernal pool complex – Rabbitsfoot grass (*Polygpogon maritimus*).

- Other natural seasonal wetlands
  - Degraded vernal pool complex-Vernal pools.

Potential habitat without concave surfaces (except for seeps along Suisun Marsh) was removed from the model. LiDAR elevation data was then visually inspected in four general areas to further assess specific locations that had been identified by the habitat selection process. These areas were selected based both on *a priori* knowledge of the region and because they were identified by the intersection of the selected vegetation types and soils. The analysis of the LiDAR data further refined the habitat model and provided a more accurate demarcation of suitable habitat. The GIS habitat model was then compared against DWR/DHCCP field data from surveys conducted for the BDCP in 2009. Land uses that are incompatible with the species' habitat requirements, for example potential habitat polygons falling on leveled or developed lands, were removed from the model.

Assumptions. Historical and current records of this species in the Plan Area indicate that its current distribution is limited to alkaline soil areas with vernal pool and swale microtopography along the northwestern border of the Plan Area (Figure A-57b) (Witham 2002, 2003, 2006, ESA 2005, Barona et al. 2007, Consortium of California Herbaria 2008, CNDDB 2010). The vegetation cover of the alkaline soils is typically a combination of vernal pool adapted species and annual ryegrass (Witham 2002, 2003, 2006, CNDDB 2010). Heckard's pepper-grass was discovered in the Stone Lakes area by DWR/DHCCP field survey teams, and its habitat range was extended into areas with vernal pool and swale microtopography along the northeastern border of the Plan Area. Because Heckard's pepper-grass also frequently occurs in the same habitats as alkali milk-vetch (Witham 2002, 2003, 2006, CNDDB 2010), its habitat range was extended in the central-western and southwestern portions of the Plan Area to match that of alkali milk-vetch. The vegetation cover of the alkaline soils is typically a combination of vernal pool adapted species and annual ryegrass (Witham 2002, 2003, 2006, CNDDB 2010).

A57.8 Recovery Goals

A United States Fish and Wildlife Service (USFWS) recovery plan has not been prepared for this species and no recovery goals have been established.

APPENDIX A58. MASON'S LILAEOPSIS (*LILAEOPSIS MASONII*)

A58.1 Legal Status

Mason's lilaeopsis (*Lilaeopsis masonii*) is state-listed as rare under the California Native Plant Protection Act (November 1979). It is not listed under the federal or California endangered species acts. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G3/S3.1 which means that globally (G) and within the state (S) there are either between 21 to 80 viable element occurrences of this species, 3,000 to 10,000 individuals of this species, or 10,000 to 50,000 acres (4,047 to 20,234 hectares) where this species occurs. Its state threat level rank is "very threatened."

The California Native Plant Society (CNPS) List ranking of 1B.1 for Mason's lilaeopsis indicates that it is rare, threatened, or endangered in California and elsewhere, and is considered by CNPS to be seriously endangered in California with more than 80 percent of occurrences threatened. Plants with a CNPS List rank of 1B are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

A58.2 Species Distribution and Status

A58.2.1 Range and Status

Mason's lilaeopsis is endemic to California and its distribution is based on 298 observations (Figure A-58a) (Calflora 2007). The range of Mason's lilaeopsis extends from Napa and Solano counties in the north, to Contra Costa and Alameda counties in the south, to Marin County in the west, and Sacramento and San Joaquin counties in the east (CNDDB 2008). Contemporary distribution includes occurrences at Napa Marsh, Suisun Marsh area, Tolay Creek, and San Pablo Bay (Goals Project 2000). Currently it is less common in the western Sacramento River area (Goals Project 2000).

Although population trends of Mason's lilaeopsis have not been documented, this species has been determined to be stable to declining (CNDDB 2008). According to the CNPS (2008), occurrences of Mason's lilaeopsis in California are highly limited and the species is at serious risk throughout its range. Surveys in Solano County found that it had declined because its habitat along the margins of small islands within the sloughs had decreased as the islands shrunk in size (Meisler 2002).

There are some data that indicate that Mason's lilaeopsis is indistinguishable from western lilaeopsis (*Lilaeopsis occidentalis*) based on morphological characteristics and a preliminary molecular genetic analysis (Fiedler and Zebell 1993).

DRAFT

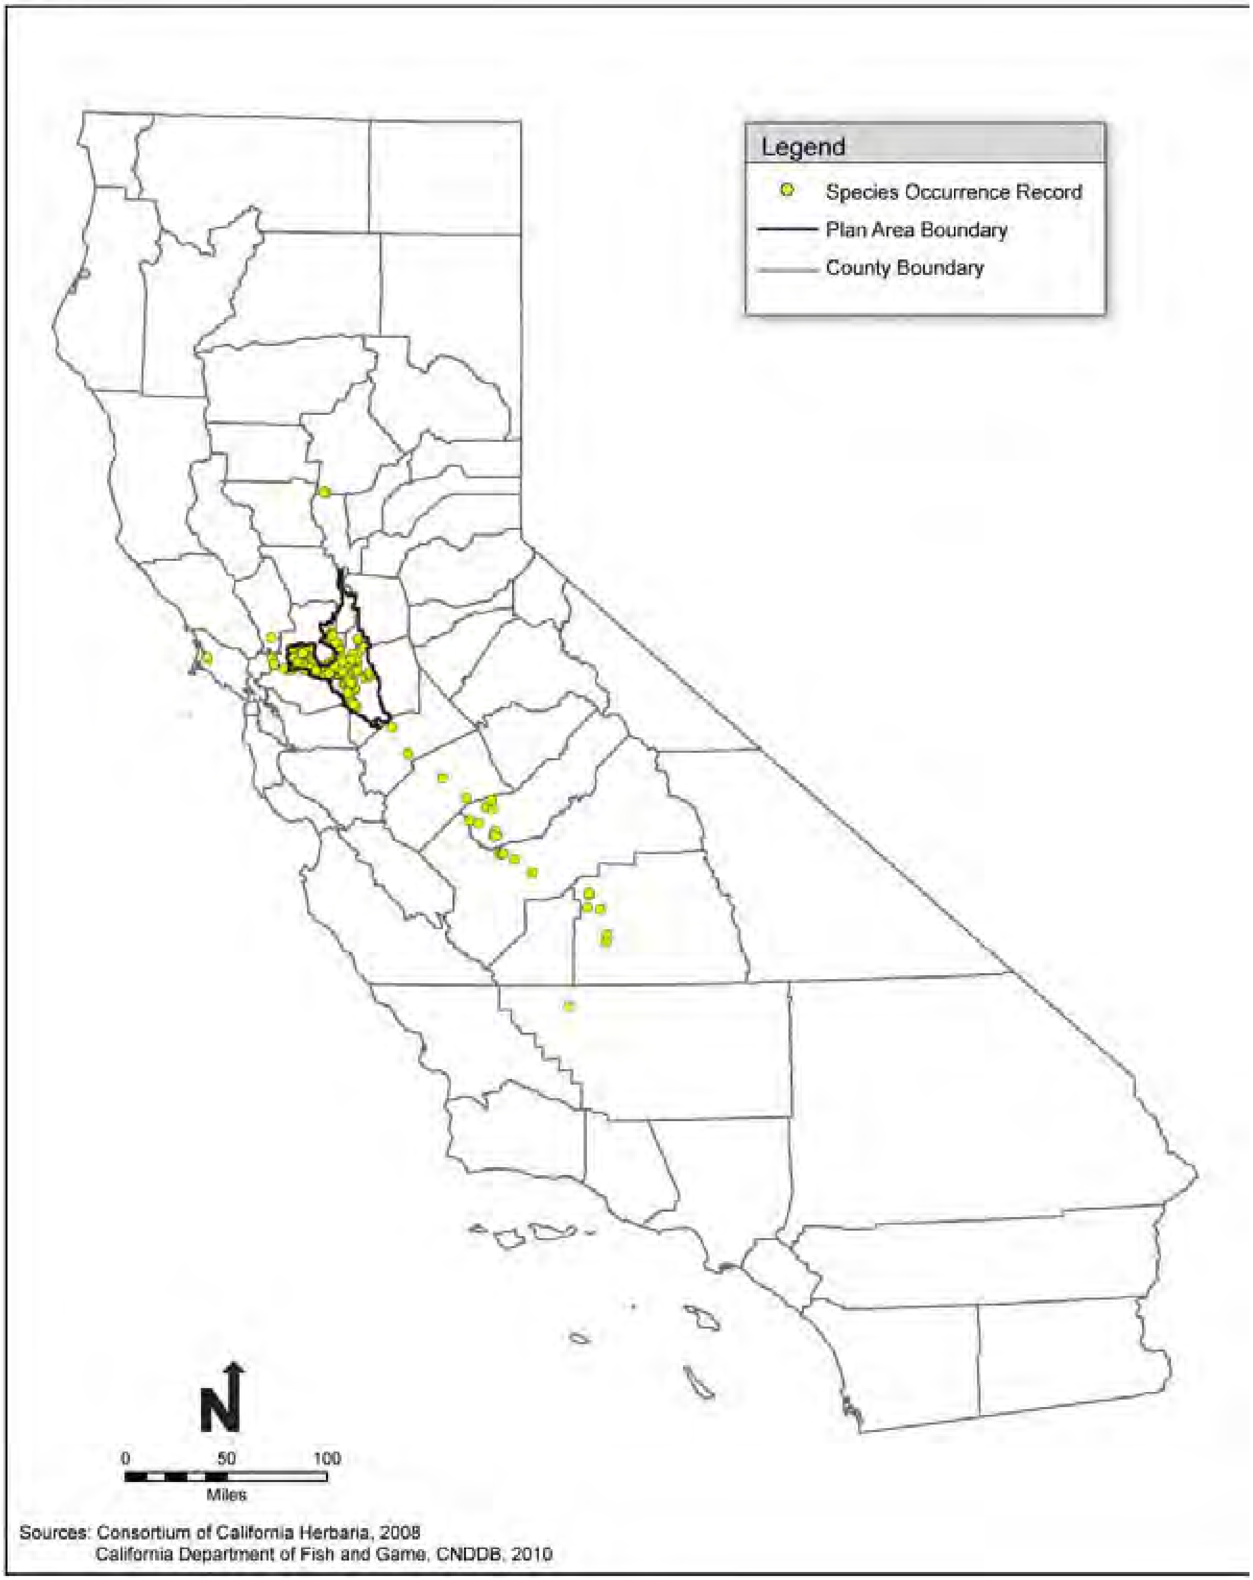

Figure A-58a. Mason's Lilaeopsis Statewide Recorded Occurrences

A58.2.2 Distribution and Status in the Plan Area

Mason's lilaeopsis is found throughout the Delta along rivers and sloughs (Figure A-58b) (CNDDB 2008, Consortium of California Herbaria 2008). Most occurrences are known from the central and west Delta. In the south Delta, occurrences are predominately along Old River and Middle River. In the north Delta, it occurs in the Cache Slough Complex and near Delta Meadows.

A58.3 HABITAT REQUIREMENTS AND SPECIAL CONSIDERATIONS

Mason's lilaeopsis is found in relatively unvegetated areas within brackish or fresh water habitats that are inundated by waves or tides such as estuarine wetlands and immediately below the banks of tidal sloughs, rivers, and creeks (Golden and Fiedler 1991, Fiedler and Zebell 1993, DFG 2000, CNPS 2008). It is a colonizing species that establishes on newly deposited or exposed sediments (CNPS 2008) and has a preference for low tidal flats on clayey or silty soils (Witham and Kareofelas 1994). It is occasionally found distributed among rip-rap lining levees (Golden and Fiedler 1991) and along the edges of tule marshes (Witham and Kareofelas 1994, May & Associates 2005). It has been found in areas with high soil salinity, but those sites might not be optimum habitat (Fiedler and Zebell 1993). Within the Delta, Mason's lilaeopsis is not found upstream of the extent of active tidal fluctuation (B. Grewell, personal observation as cited in Suisun Ecological Workgroup 1997).

Some of the species commonly associated with Mason's lilaeopsis in the Sacramento Delta include California tule (*Scirpus californicus*[1]), whorled marsh pennywort (*Hydrocotyle verticillata*), and annual tule (*Scirpus cernuus*[2]) (Golden and Fiedler 1991). In the sloughs that radiate westward into Solano County at the southern end of the Sacramento River Deep Ship Channel, it grows in a narrow band between the mudflats and mesic terrestrial vegetation (Meisler 2002). In Suisun Marsh and other places, California tule (*Scirpus californicus*), annual tule (*Scirpus cernuus*), and three-ribbed arrowgrass (*Triglochin striata*) are predominantly associated with Mason's lilaeopsis (B. Grewell per. comm. as cited in Suisun Ecological Workgroup 1997, May & Associates 2005, CNDDB 2008). Mason's lilaeopsis does not appear to be substrate-specific as it is found in organic mucks, silty clays, and even pure sand throughout its range (Golden and Fiedler 1991).

[1] Currently known as *Schoenoplectus californicus*.
[2] Currently known as *Isolepis cernua*.

DRAFT

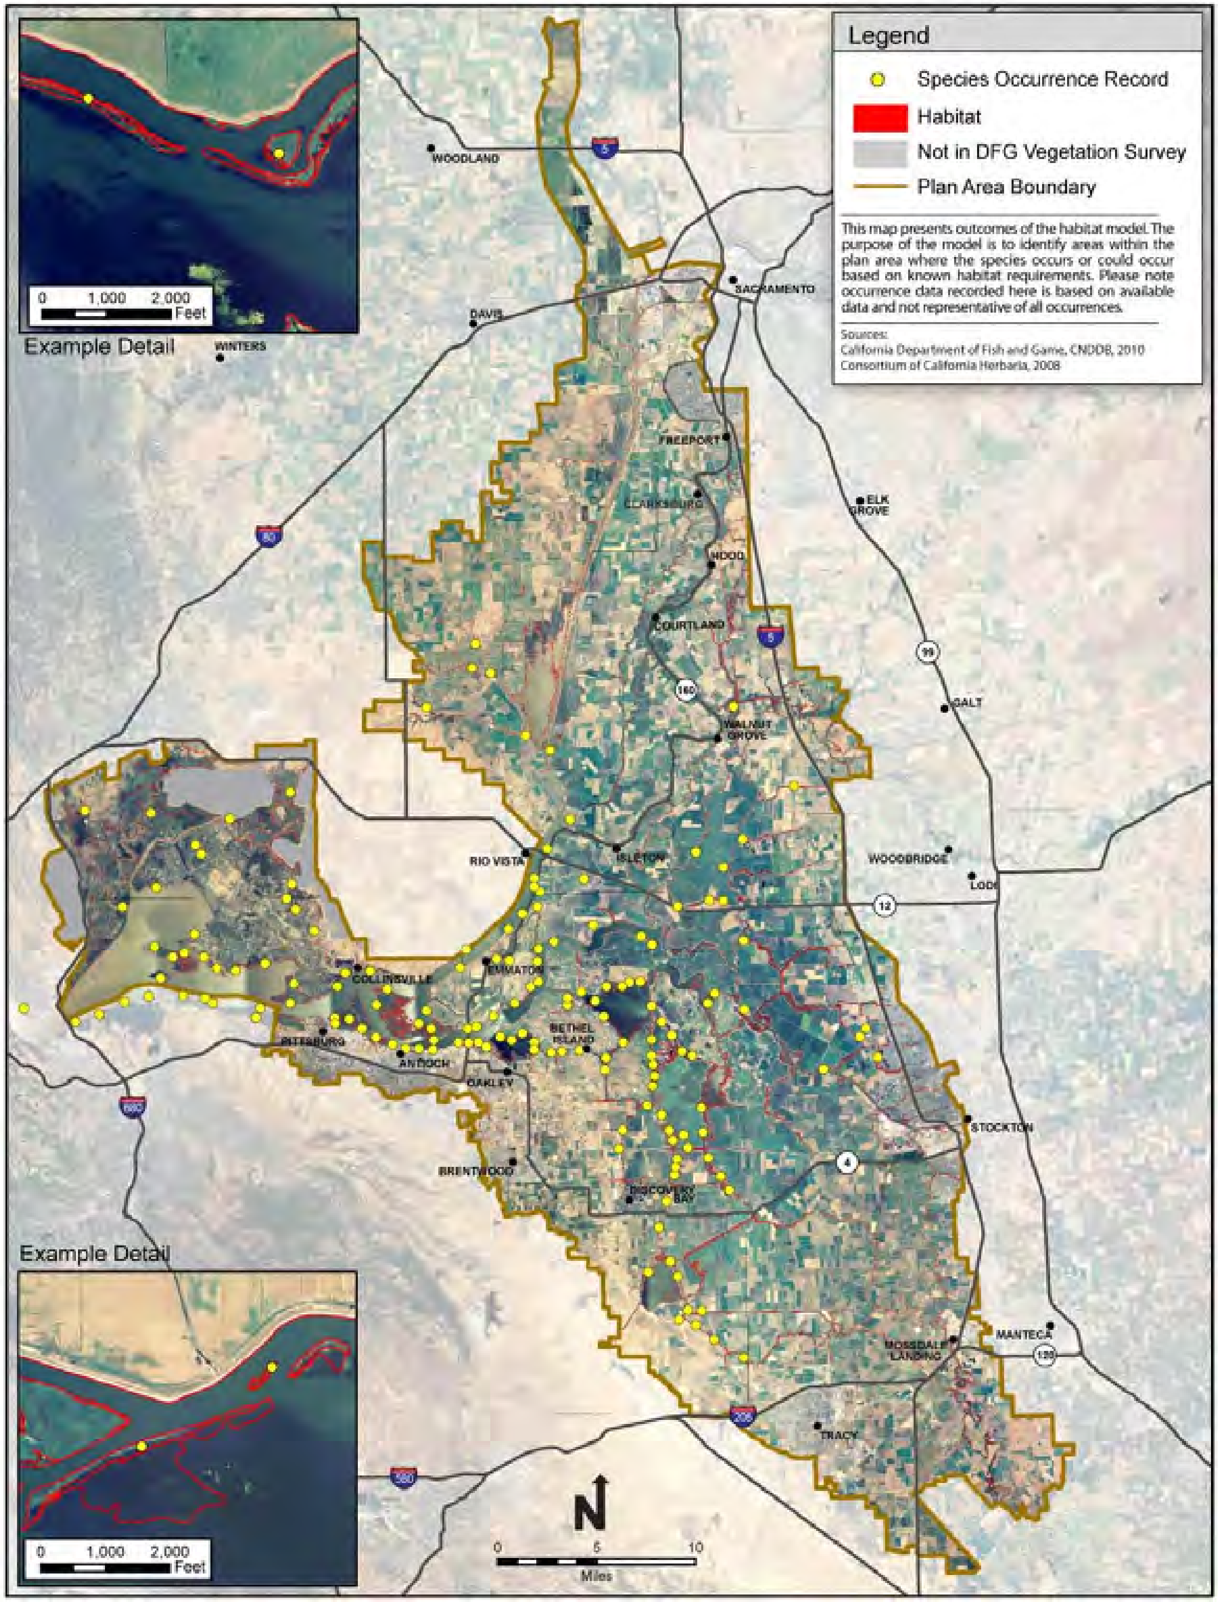

Figure A-58b. Mason's Lilaeopsis Habitat Model and Recorded Occurrences

A58.4 Life History

Mason's lilaeopsis is a small 1.5- to 7.5-centimeter (0.6- to 3-inch) perennial, rhizomatous herb with tufted linear or thread-like jointed leaves and is a member of the carrot family (Apiaceae) (Hickman 1993, DFG 2000). The inflorescences consist of few to several-flowered umbels of tiny white or maroon flowers (Hickman 1993, CNPS 2008), and they bloom from April to November (CNPS 2008). Mason's lilaeopsis primarily reproduces vegetatively by creeping rhizomes or by being dislodged and floating to new sites. Because it is a rhizomatous plant, the number of individuals in a population is difficult to determine. Population size is therefore often expressed as "several colonies" or as an "area." Reported colony sizes range from 16 to 3,000 ft^2 (5 to 700 m^2) (CNDDB 2008).

A58.5 Threats and Stressors

Fishing and hunting access pose a threat to this species due to trampling effects (Witham and Kareofelas 1994).

Reduced habitat. The primary threat to Mason's lilaeopsis is the loss of marsh and floodplain habitat. There are numerous processes and activities that threaten this habitat including erosion, channel stabilization, levee maintenance and construction, flood-control improvements, dredging, dumping spoils, agriculture, recreation, and water quality changes (CNPS 2008, CNDDB 2008). A long-term threat is the stabilization of banks and mudflats due to highly regulated water flow regimes, which can cause floodplain habitat to be less dynamic (Fiedler and Zebell 1993).

Nonnative species. Successional changes in marsh vegetation to denser vegetation types or to types that could grow in the intertidal area could pose an additional threat (CNPS 2008). One example of this type of threat is the invasion of some areas by nonnative water hyacinth (*Eichhornia crassipes*) (Zebell and Fiedler 1996, CNDDB 2008, CNPS 2008). Additionally, diked salt marshes generally lack rare tidal marsh species. It is believed that the conditions brought about by dikes favor robust generalist species that can better tolerate the extremes of inundation and dryness in diked wetlands (Goals Project 2000).

Exposure to toxics. Petroleum product spills could have a significant impact on tidal flat biota, and non-biodegradable litter such as plastics could collect near the tidal drift line, inhibiting plant establishment and growth (Witham and Kareofelas 1994).

A58.6 Relevant Conservation Efforts

Mason's lilaeopsis is found in a range of protected and unprotected sites (Fiedler and Zebell 1993, Witham and Kareofelas 1994, Zebell and Fiedler 1996, CNDDB 2008).

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for Mason's lilaeopsis is "Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP has established a goal to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

Mason's lilaeopsis is a covered species under the approved San Joaquin County Multi-species Habitat Conservation and Open Space Plan. It is also proposed for coverage under the Solano County Multi-species Habitat Conservation Plan and the Yolo County Natural Heritage Program Plan.

A58.7 Species Habitat Suitability Model

Habitat. Mason's lilaeopsis habitat is identified as areas within 10 feet (3 meters) on either side of the landward boundary of tidal perennial aquatic land cover type. Vegetation types designated as species habitat in this model correspond to the mapped vegetation associations in the Bay Delta Conservation Plan (BDCP) geographic information system (GIS) vegetation data layer. Tidal perennial aquatic vegetation type from the Suisun Marsh and Yolo Natural Heritage Program (Boul and Keeler-Wolf 2008, TAIC 2008) classifications was converted to a line shapefile and then buffered 10 ft on either side of each line. For this species, the golf course, artificial lake, and boat docks of Discovery Bay represented a misclassification of land cover in the source data and they were deleted from the GIS vegetation data layer.

Assumptions. Historical and current records of this species indicate that its distribution extends almost throughout the Plan Area, having been observed in tidally influenced waters from Liberty Island southward and from the area of the Clifton Court Forebay northwards (Figure A-58b) (Golden and Fiedler 1991, Fiedler and Zebell 1993, Witham and Kareofelas 1994, Zebell and Fiedler 1996, Suisun Ecological Workgroup 1997, Goals Project 2000, Meisler 2002, May & Associates 2005, CNDDB 2008). While there are no occurrences within the Plan Area north of Liberty Island or significantly south of the Old River channel near the Clifton Court Forebay, patches of suitable habitat extend beyond those areas. For purposes of this model, a 10 foot-wide (3 meter) buffer on each side of the landward edge of the tidal perennial aquatic land cover type (20 foot combined width [6 meter]) is included as the potential extent of tidal mudflat habitat that supports the Mason's lilaeopsis. Within the Plan Area this species' primary habitat is tidally-inundated bare areas of clay or clay loam substrate that is located on the outer margin of wave-cut beaches, or eroding earthen levees, or on the flats immediately below wave-cut beaches and eroding levees (Witham and Kareofelas 1994, Zebell and Fiedler 1996). This substrate-defined habitat has not been mapped separately, but it generally occurs in close association with the tidal perennial aquatic land cover type. Therefore, the habitat model uses the buffered landward boundary of tidal perennial aquatic land cover type as a surrogate for identifying tidal mudflats that support this species' habitat. Mason's lilaeopsis is also found in a range of less suitable habitats that include the spaces between riprap on armored banks and levees which also occur in close association with the tidal perennial aquatic land cover type (Zebell and Fiedler 1996).

A58.8 Recovery Goals

A United States Fish and Wildlife (USFWS) recovery plan has not been prepared for this species and no recovery goals have been established; however, the CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for Mason's lilaeopsis is "Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP has established a goal to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

APPENDIX A59. DELTA MUDWORT *(LIMOSELLA SUBULATA)*

A59.1 LEGAL STATUS

Delta mudwort (*Limosella subulata*) is not listed under either federal or California endangered species acts. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G4?Q/S2.1 which means that the species as a whole is apparently secure across its overall distribution, but some factors of concern, such as narrow habitat or continuing threats, do exist. The "?" portion of the rank indicates that there is uncertainty about the rank. The "Q" portion of the rank indicates that unresolved taxonomic questions remain for this rare species. The state level rank of distribution indicates that in the State of California, there are either between six to 20 viable element occurrences of this species, 1,000 to 3,000 individuals, or 2,000 to 10,000 acres (809 to 4,047 hectares) where this species occurs. Its state threat level rank is "very threatened."

The California Native Plant Society (CNPS) List ranking of 2.1 for Delta mudwort indicates that it is rare, threatened, or endangered in California, but more common elsewhere. It is considered by CNPS to be seriously endangered in California with over 80 percent of occurrences threatened. Without the wider distribution outside of California, plants on CNPS List 2 would be placed on List 1B. Plants with a CNPS List rank of 1B are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

A59.2 SPECIES DISTRIBUTION AND STATUS

A59.2.1 Range and Status

In California, Delta mudwort is found only in the Sacramento-San Joaquin Delta region (Figure A-59a). Its range extends from Solano County in the north, San Joaquin County in the south, Contra Costa County in the west, and Sacramento County in the east. Outside of California, it can be found in British Columbia, on the east coast of North America, and in Europe (Hickman 1993). On the east coast of the United States, it is threatened by habitat destruction (CNPS 2008).

A59.2.2 Distribution and Status in the Plan Area

Within the Plan Area, Delta mudwort occurs in the tidal zones of marshes, rivers, and creeks, predominantly in the central area of the legal Delta (Figure A-59b). It has been observed within the tidal zone along Calhoun Cut and Barker Slough (Witham and Kareofelas 1994), in the Miner Slough Wildlife Area, along Montezuma Slough, near Three Mile Slough, at Brown's Island, and near Collinsville among other locations throughout the Delta (CNDDB 2008).

DRAFT

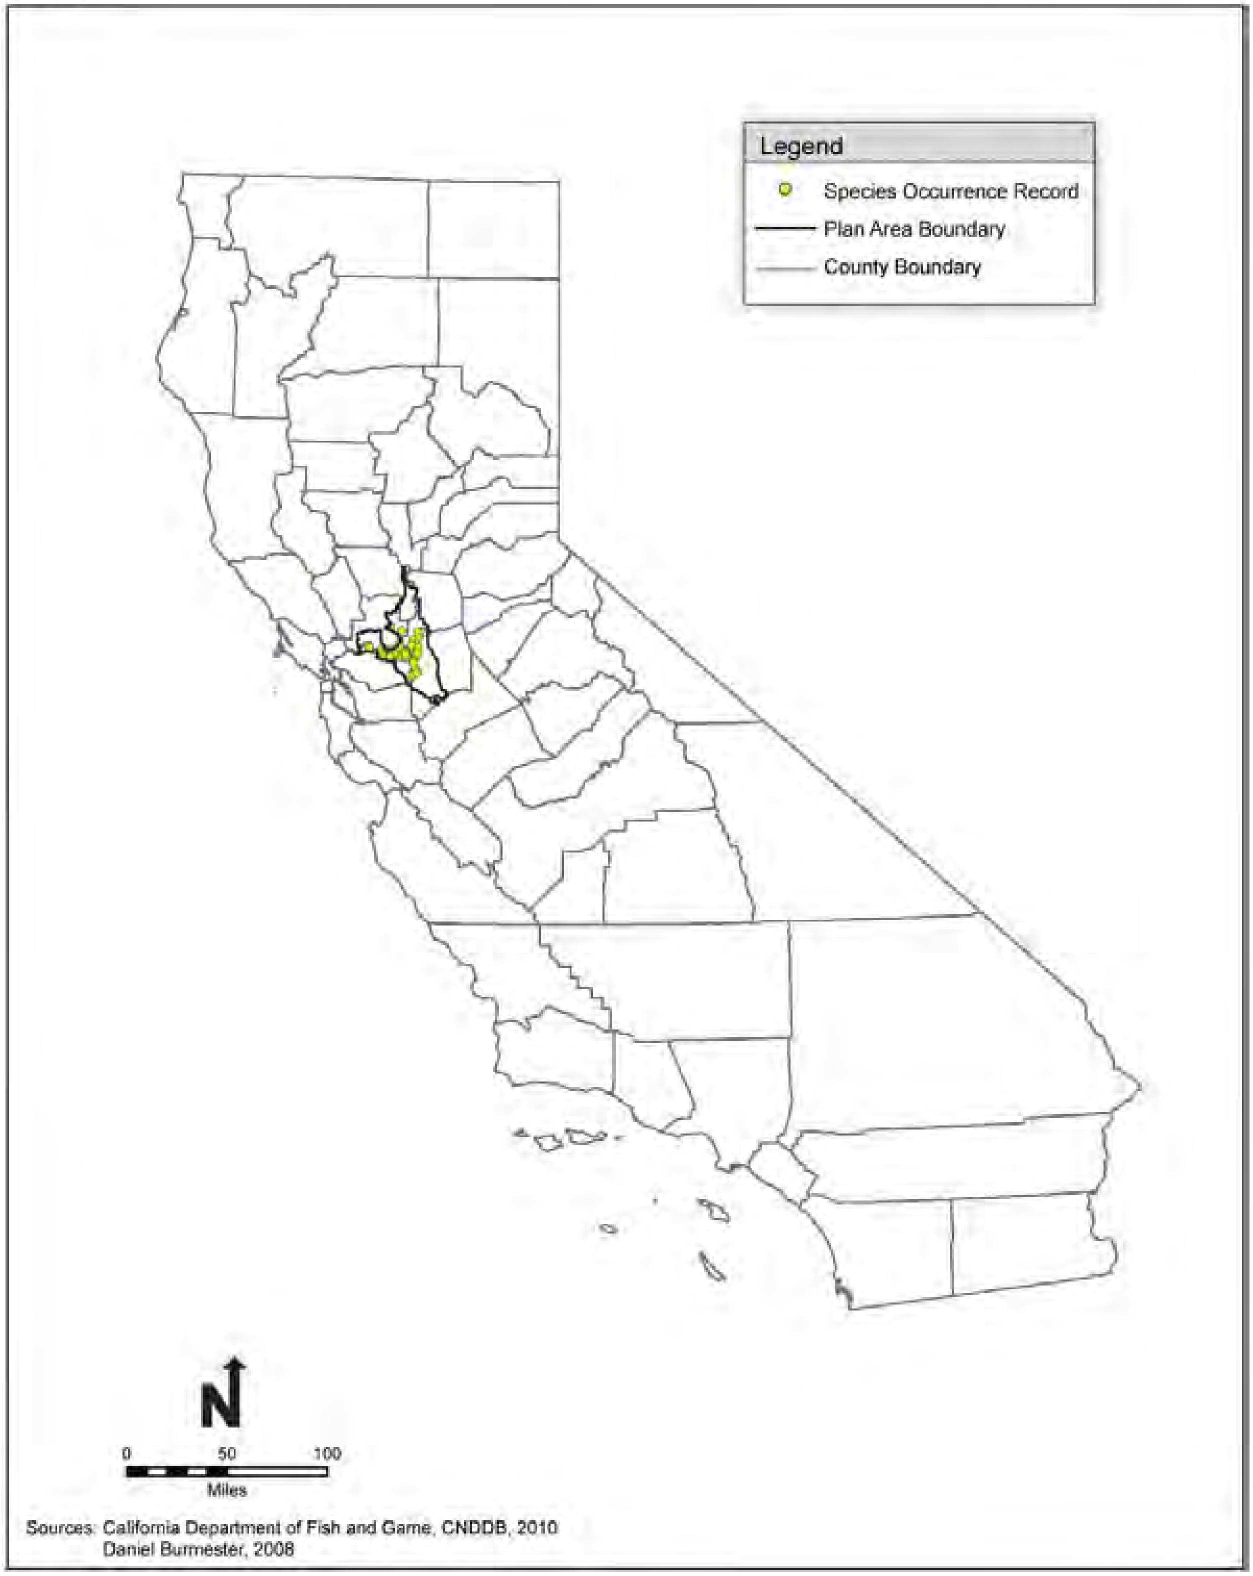

Figure A-59a. Delta Mudwort Statewide Recorded Occurrences

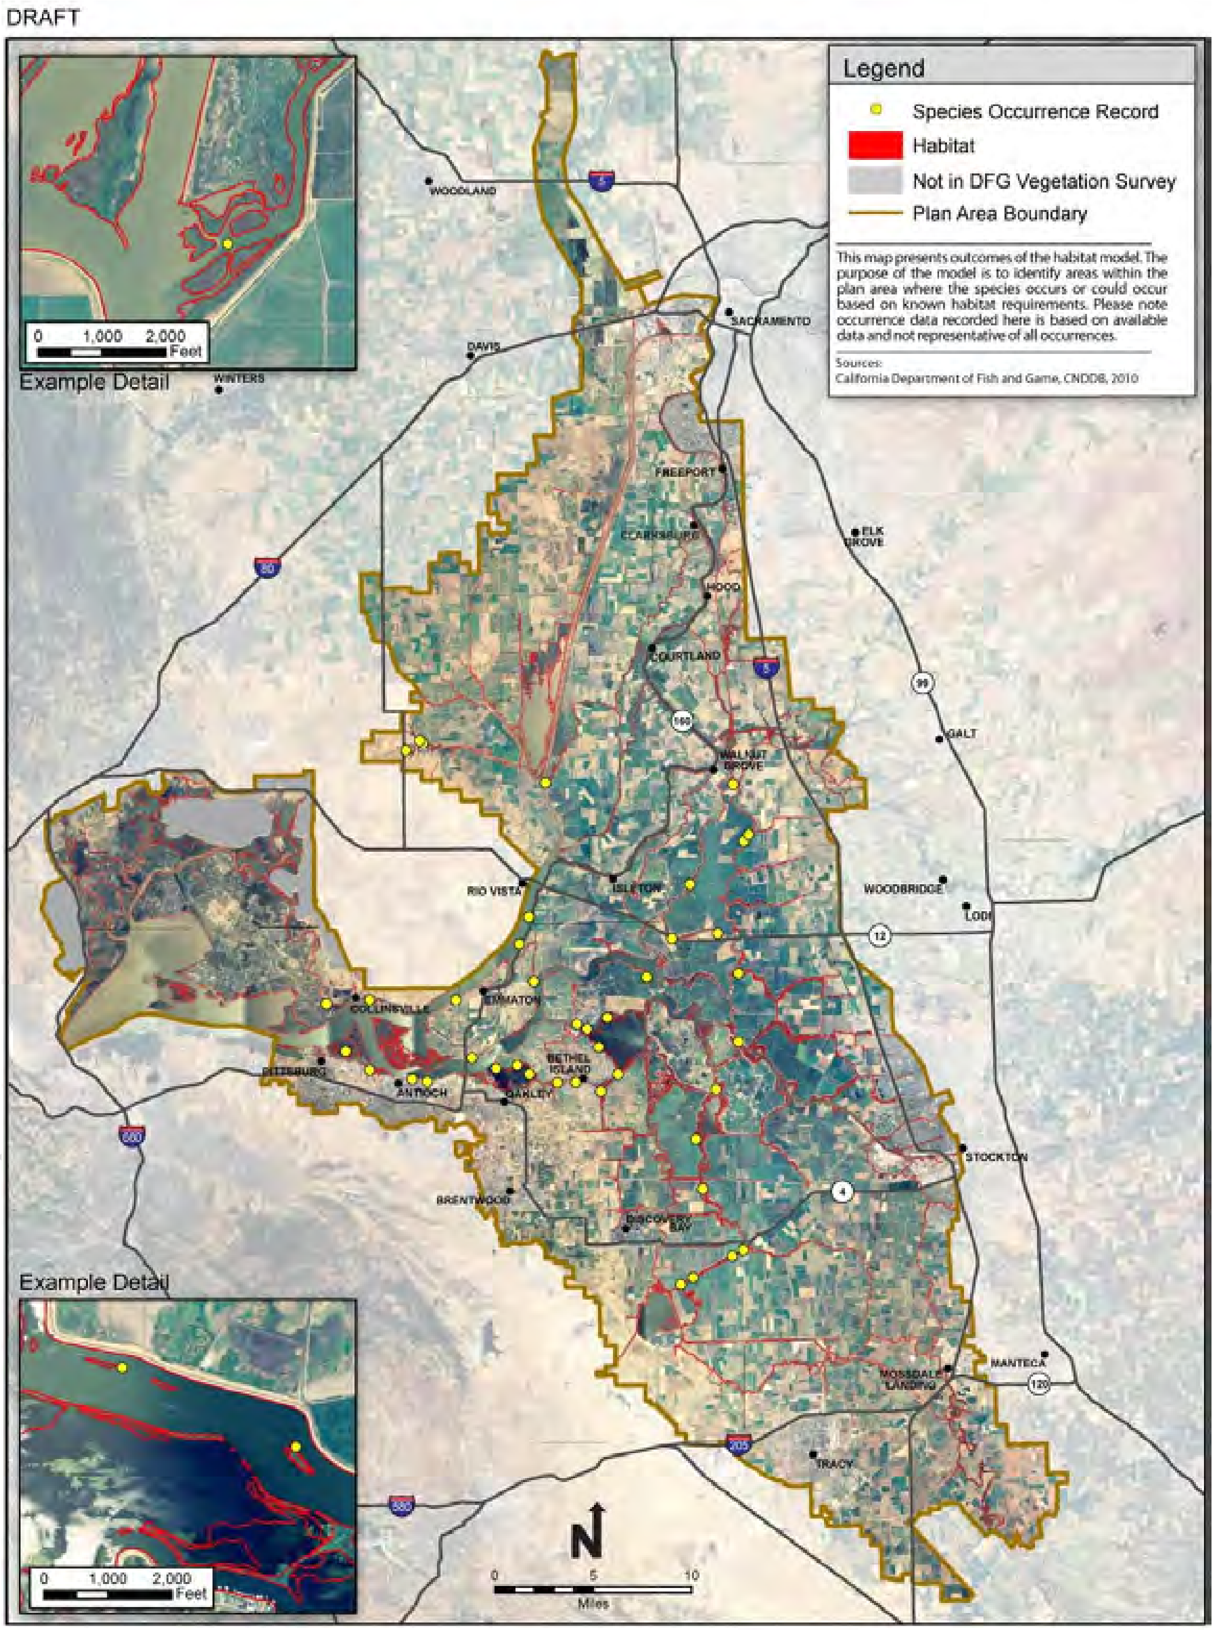

Figure A-59b. Delta Mudwort Habitat Model and Recorded Occurrences

1

It is found in brackish and freshwater tidal marsh plant communities along with Mason's lilaeopsis (*Lilaeopsis masonii*) immediately below the tidal elevation where Delta tule pea (*Lathyrus jepsonii* var. *jepsonii*) and Suisun Marsh aster (*Symphyotrichum lentum*) are commonly found (Witham and Kareofelas 1994).

A59.3 Habitat Requirements and Special Considerations

Delta mudwort grows on intertidal flats and muddy banks of watercourses in estuarine areas, surrounded by brackish or freshwater marsh and riparian scrub vegetation. Occasionally it can be found along the edges of tule marshes (Witham and Kareofelas 1994). It blooms from May to August (Hickman 1993, CNPS 2008) and has been observed associated with or near other Bay Delta Conservation Plan (BDCP) covered species Mason's lilaeopsis, Delta tule pea, and Suisun Marsh aster (Witham and Kareofelas 1994, May & Associates 2005). Although the data are somewhat inconclusive, Delta mudwort appears to be more sensitive to salinity concentrations near or greater than 7 parts per thousand than is Mason's lilaeopsis, with substantially reduced flowering and seed germination rates (Golden and Fiedler 1991, Fiedler and Zebell 1993, Zebell and Fiedler 1996).

A59.4 Life History

Delta mudwort is a stoloniferous, aquatic, perennial herb in the snapdragon family (Scrophulariaceae). The leaves are 1 to 3 centimeters (0.4 to 1.2 inches) long and cylindrical, giving the plant a "grasslike" appearance. The stems bear solitary white to lavender-blue flowers approximately 3 millimeters (0.1 inch) in length (Hickman 1993). Delta mudwort strongly resembles Mason's lilaeopsis when vegetative (before flowering and fruiting). The bell-shaped flowers of Delta mudwort make it easy to distinguish when in bloom. When not blooming, Mason's lilaeopsis can be distinguished by partitions in its cylindrical leaves; while Delta mudwort lacks this feature (Witham and Kareofelas 1994). The California Department of Fish and Game (DFG) considers the Delta mudwort to be native to California (R. Bittman pers. comm.), while *The Jepson Manual* (Hickman 1993) identifies the species as not native to California.

A59.5 Threats and Stressors

Delta mudwort is threatened by habitat destruction, including alteration of hydrology and recreational activities such as boating, which creates wakes that erode banks and shorelines. Fishing and hunting access also pose a threat to this species (Witham and Kareofelas 1994). Petroleum product spills could have a significant impact on tidal flat biota, and non-biodegradable litter such as plastics could collect near the tidal drift line, inhibiting plant establishment and growth (Witham and Kareofelas 1994).

A59.6 RELEVANT CONSERVATION EFFORTS

Populations are preserved on the DFG Calhoun Cut Ecological Preserve and in the Miner Slough Wildlife Area (CNDDB 2008).

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designates the Delta mudwort as "Contribute to Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its control and within its scope that are necessary to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

Delta mudwort is a covered species under the approved San Joaquin County Multi-species Habitat Conservation and Open Space Plan. It is also proposed for coverage under the Solano County Multispecies Habitat Conservation Plan.

A59.7 SPECIES HABITAT SUITABILITY MODEL

Habitat. Vegetation types designated as species habitat in this model correspond to the mapped vegetation associations in the BDCP geographic information system (GIS) vegetation data layer. Tidal perennial aquatic vegetation type from the BDCP GIS vegetation dataset, Suisun Marsh, and Yolo Natural Heritage Program (Boul and Keeler-Wolf 2008, TAIC 2008) classifications was converted to a line shapefile and then buffered 10 feet (3 meters) on either side of each line. For this species, the golf course, artificial lake, and boat docks of Discovery Bay represented a misclassification of land cover in the source data and they were deleted from the GIS vegetation data layer. Delta mudwort habitat is identified as all areas within 10 feet on either side of the landward boundary of tidal perennial aquatic land cover type.

Assumptions. Historical and current records of this species indicate that its distribution extends almost throughout the Plan Area having been observed in tidally influenced waters from Liberty Island southward and from the area of the Clifton Court Forebay northwards (Figure A-59b) (Fiedler and Zebell 1993, Witham and Kareofelas 1994, Zebell and Fiedler 1996, CNDDB 2008). While there are no occurrences within the Plan Area north of Liberty Island or significantly south of the Old River channel near the Clifton Court Forebay, patches of suitable habitat extend beyond those areas. For purposes of this model, a 10-foot wide buffer on each side of the landward edge of the tidal perennial aquatic land cover type (20 foot combined width) is included as the potential extent of tidal mudflat habitat that supports this species. Within the Plan Area this species' primary habitat is tidally inundated bare areas of clay or clay loam substrate on the outer margin of wave-cut beaches, or eroding earthen levees, or on the flats immediately below wave-cut beaches and eroding levees (Witham and Kareofelas 1994, Zebell and Fiedler 1996). This substrate-defined habitat has not been separately mapped, but it generally occurs in close association with the tidal perennial aquatic land cover type. Therefore, the habitat model uses the buffered landward boundary of tidal perennial aquatic land cover type as a surrogate for identifying tidal mudflats that support habitat for Delta mudwort.

A59.8 RECOVERY GOALS

A United States Fish and Wildlife (USFWS) recovery plan has not been prepared for this species and no recovery goals have been established; however, the CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designates the Delta mudwort as "Contribute to Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP will undertake actions under its control and within its scope that are necessary to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

APPENDIX A60. ANTIOCH DUNES EVENING PRIMROSE *(OENOTHERA DELTOIDES SSP. HOWELLII)*

A60.1 LEGAL STATUS

Antioch Dunes evening primrose (*Oenothera deltoides* ssp. *howellii*) is listed as endangered under both the Federal Endangered Species Act (April 1978) (43 FR 17910) and the California Endangered Species Act. It is endemic to a former dune near the city of Antioch, California. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G5T1/S1.1 which means that globally (G) the species is demonstrably secure to ineradicable due to being commonly found in the world, but the subspecies or variety (T) is has less than 6 viable element occurrences, less than 1,000 individuals, or less than 2,000 acres (809 hectares); and within the state (S) the threat level rank is "very threatened."

The California Native Plant Society (CNPS) List ranking of 1B.1 for Antioch Dunes evening primrose indicates that it is rare, threatened, or endangered in California (List 1B); the threat ranking (.1) indicates that it is considered by CNPS to be seriously threatened in California (high degree/immediacy of threat). Plants with a CNPS List rank of 1B are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

United States Fish and Wildlife Service (USFWS)-designated critical habitat that specifies the protection of Antioch Dunes evening primrose habitat lies in and adjacent to the USFWS Antioch Dunes National Wildlife Refuge (NWR) (43 FR 39042). This critical habitat was specifically established for this and two other endangered species. The designated critical habitat is entirely within the Plan Area.

A60.2 SPECIES DISTRIBUTION AND STATUS

A60.2.1 Range and Status

Antioch Dunes evening primrose has an extremely restricted range. It is found only on a 20-acre (8-hectare) remnant of a former 190-acre (77-hectare) dune (plus an unknown amount of two Pacific Gas & Electric [PG&E] parcels that total 12 acres [5 hectares]) near the city of Antioch, California and has been introduced into a sandy area on Brown Island and on sandy dredged material on Brannan Island (USFWS 1984, 2001, 2008, 2010) (Figure A-60a). There are CNDDB records indicating that it occurs just north of the town of Oakley, but according to herbarium records, those collections are apparently *Oenothera deltoides* ssp. *cognata* (CNDDB 2010, Consortium of California Herbaria 2010, USFWS 2010). Recent life history and molecular marker research is consistent with the morphological distinctness of the two taxa (Evans et al. 2005, 2007, 2009).

Figure A-60a. Antioch Dunes Evening-Primrose Statewide Recorded Occurrences

Antioch Dunes evening primrose is protected on the Antioch Dunes NWR, on two small adjacent parcels owned by PG&E, which manages the property in cooperation with USFWS, and on Brannan Island State Recreation Area (BISRA) (USFWS 1984, 2001, 2008, 2010).

A60.2.2 Distribution and Status in the Plan Area

The entire distribution of Antioch Dunes evening primrose is within the Plan Area on the Antioch Dunes NWR, PG&E, and BISRA properties as described above (Figure A-60b).

A60.3 Habitat Requirements and Special Considerations

Antioch Dunes evening primrose is restricted to the former dune near the city of Antioch, California (USFWS 1984, 2001, 2008, 2010). This soil of the dune has been mapped as Oakley sand (Carpenter and Cosby 1939) and Delhi sand, 2 to 9 percent slopes (NRCS 2010) and is an infertile, very uniform textured, fine sand with very little clay content. Experiments at Antioch Dunes NWR have found that Antioch Dunes evening primrose will grow and reproduce on soils with a slightly higher clay content if the soil is disturbed to break up the crust (Pavlik and Manning 1993).

A60.4 Life History

The Antioch Dunes evening-primrose is a short-lived perennial in the evening-primrose family (Onagraceae) (USFWS 2010). It forms large tufts with coarse, drooping, much branched stems from 4 to 40 inches (10 to 101 centimeters [cm]) long. Leaves are lance-like in outline, 1-5 inches (2.5-12.7 cm) long, 0.4-1.2 inches (1-3 cm) wide, with grayish hairs. It has white flowers and blooms from March to September. The petals are about one inch long and the stamens are yellow. Antioch Dunes evening-primrose is considered to be an out-breeding species pollinated by hawk moths at night and a variety of insects during the day and its reproductive ability may currently be reduced either by insufficient pollinators or by an insufficient number of compatible genotypes (Pavlik et al. 1993, Evans et al. 2005, USFWS 2008, Evans et al. 2009).

Invasive plants are one of the primary threats to Antioch Dunes evening primrose because they cause habitat loss and may compete for soil moisture (USFWS 2008, 2010). The most common invasive nonnative grasses and forbs found at the refuge include ripgut brome (*Bromus diandrus*), winter vetch, (*Vicia villosa*) and star thistle (*Centaurea solstitialis*). Wildfires started by trespassers on the Antioch Dunes NWR are another serious threat.

A60.5 Relevant Conservation Efforts

Antioch Dunes evening primrose was declining significantly at Antioch Dunes NWR and appeared to be headed towards extinction until an out-planting of nursery-grown stock and direct seeding into restored sandy habitat in 2005 and 2006 appears to have stopped the decline.

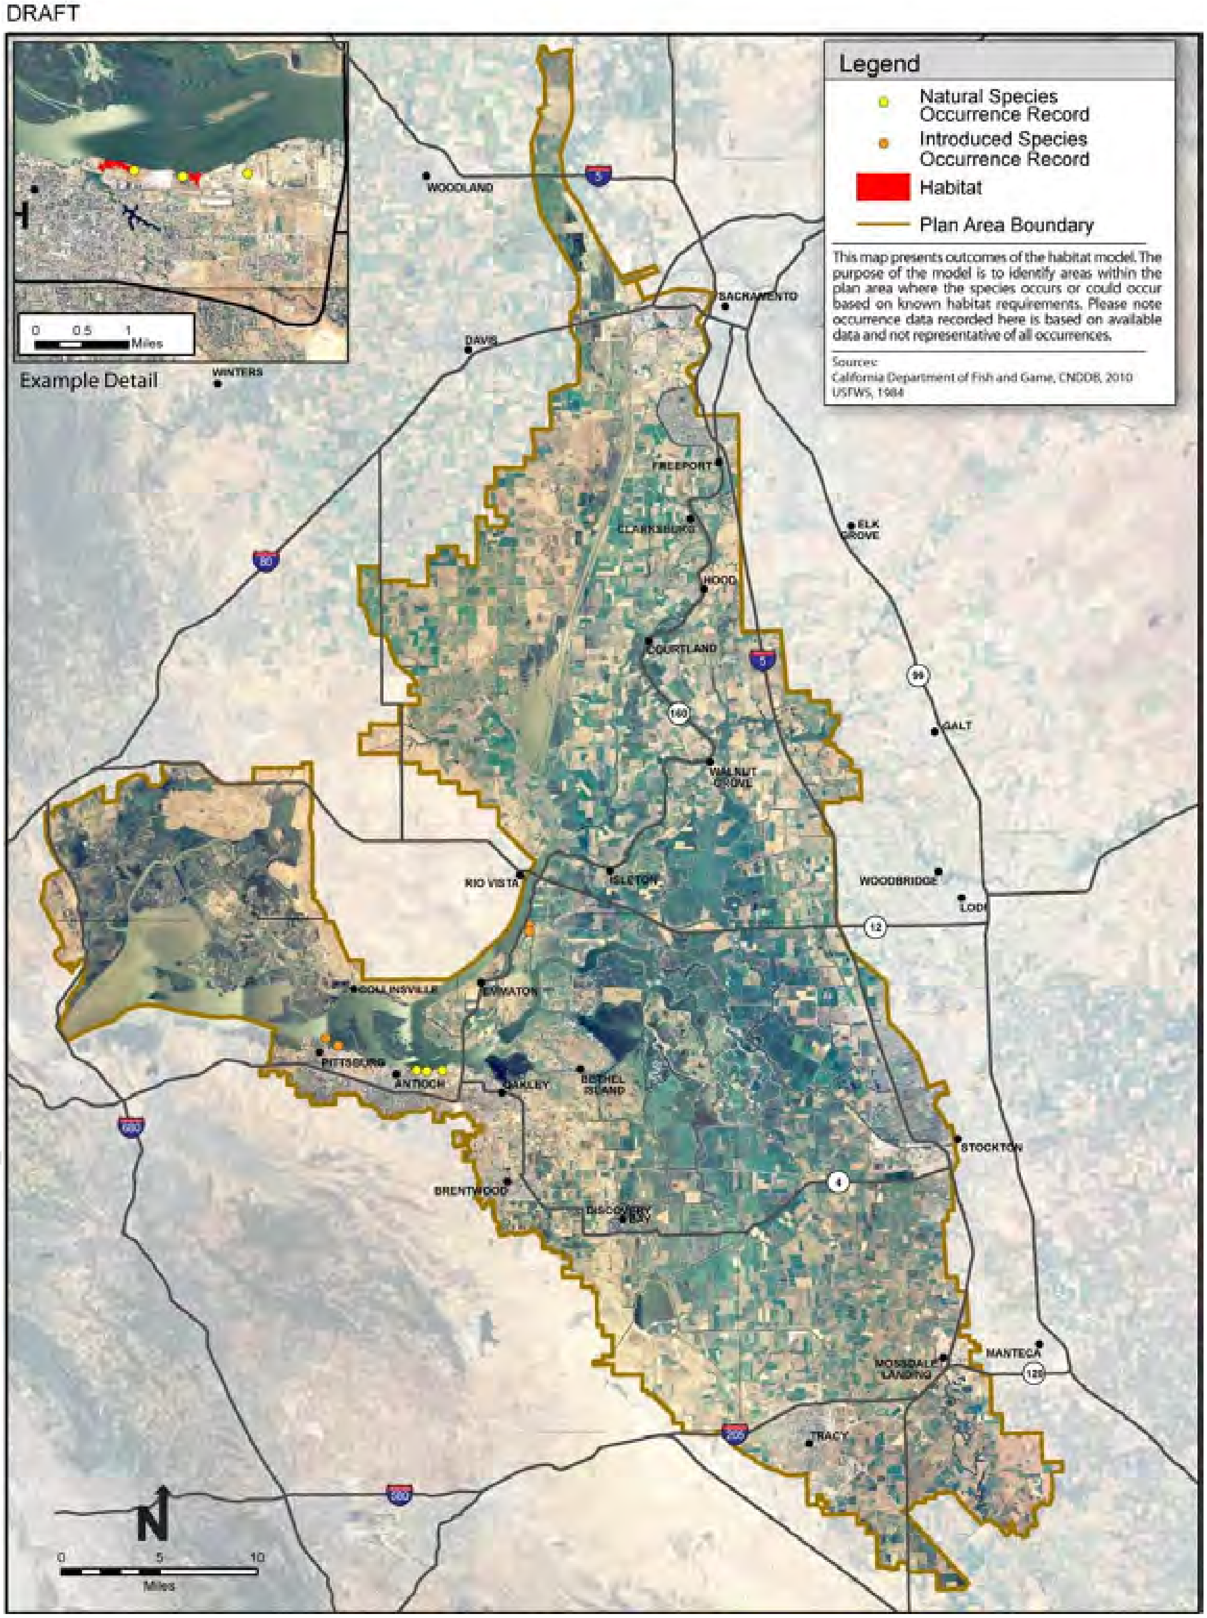

Figure A-60b. Antioch Dunes Evening-Primrose Habitat Model and Recorded Occurrences

Mowing is currently being used to control invasive species at Antioch Dunes NWR, and Antioch Dunes evening primrose appears to have increased in 2009 and 2010 (L.Terrazas in litt.). However, the population is not yet considered to be self-sustaining because of invasive species problems (USFWS 2008).

While the enhancement of the natural population through the out-planting and seeding of nursery grown material may have slowed or stopped its population decline, it is not clear that this management tactic will preserve the genetic uniqueness of this subspecies. First of all, Antioch Dunes evening primrose is considered to be a "microendemic" species that is adapted to a very unique set of environmental characteristics provided by a 120-foot (36.5-meter) high dune in the western Delta (Evans et al. 2005, Evans et al. 2009). Given the general windiness of that portion of the Delta, there would be large differences in temperature, wind velocity, and evapotranspiration rates between the pristine dune and the 30-foot (9-meter) high remnant where Antioch Dunes evening primrose persists through the augmentation program. The conditions acted on the genetic variation present in the ancestral genotype to produce the microendemic taxon that is the Antioch Dunes evening primrose. Neither the remnant dune environment nor the nursery growth conditions replicate the conditions of the pristine dune and will instead act as artificial selective agents to produce a new partially domesticated genotype that is distinct from the Antioch Dunes evening primrose as it existed prior to the destruction of the dune, development of the surrounding land, and recent recovery efforts. Secondly, survey data strongly suggest that Antioch Dunes evening primrose produces a dormant seed bank similar to other evening primrose species (USFWS 1984, 2001, Evans et al. 2005, USFWS 2008, Evans et al. 2009). Seed banks are a unique evolutionary response to unpredictable variation in the environment that represent a decrease in measures of fitness such as seed production in average environments by not germinating and remaining as a seed and increasing fitness over the long-term in exceptional environments (Evans et al. 2007). Again, neither the remnant dune environment nor the nursery growth conditions replicate the environmental conditions of the pristine dune and will instead act as artificial selective agents to produce a new partially domesticated genotype that is distinct from Antioch Dunes evening primrose.

The current management plan for the Antioch Dunes NWR provides for invasive nonnative plant species control efforts which are being implemented by hand pulling individual invasive plants through the efforts of volunteers, and targeted herbicide application (USFWS 2001, 2008). Controlled burns have been discontinued as a management tool (L. Terrazas in litt.).

A60.6 Species Habitat Suitability Model

Model Approach. The Bay Delta Conservation Plan (BDCP) species habitat suitability models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as individual trees or small groups of trees. Still, the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nevertheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lower probability of species occurrence compared with areas identified as suitable habitat.

Where applicable, habitat suitability is also identified according to the life requisite of the species, such as breeding, foraging, or movement/dispersal habitat, and in some cases according to minimum habitat area requirements using home range or territory size data. Where appropriate, habitat suitability is also defined qualitatively (e.g., high, medium, and low value) based on broad suitability categories (e.g., grassland, pastureland, cultivated land) or through a general examination of species associations within vegetation types (e.g., species and range of percent cover of understory shrub layer) such as that provided in Hickson and Keeler-Wolf 2007. Finally, other input variables are used to address specific conditions that are not accounted for in the vegetation databases but that can be generated through GIS analysis. These include incorporating buffers, connectivity between habitat types, and specific land use types, such as levee slopes.

For each model, the mapping data sets are identified and each vegetation type or association is identified along with its life history requirements. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS Model Data Sources. The Antioch Dunes evening primrose habitat suitability model is based on the California Department of Fish and Game (DFG) mapping of Delta vegetation (Hickson and Keeler-Wolf 2007).

Habitat. The modeled habitat for Antioch Dunes evening primrose consists of two shrub dominated vegetation associations from the Antioch Dunes NWR (Hickson and Keeler-Wolf 2007).

Vegetation Units. The following vegetation subunits were selected from the DFG vegetation units (Hickson and Keeler-Wolf 2007):

- *Lupinus albifrons* Antioch Dunes Association
- *Lotus scoparius* Antioch Dunes Association

A60.7 Recovery Goals

A USFWS revised recovery plan for Antioch Dunes evening primrose was approved in 1984 but the very recent 5-year species review (USFWS 2008) found that there are no recovery criteria listed in the Recovery Plan. The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for Antioch Dunes evening primrose is "Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP has established a goal to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

APPENDIX A61. SIDE-FLOWERING SKULLCAP (*SCUTELLARIA LATERIFLORA)*

A61.1 LEGAL STATUS

Side-flowering skullcap (*Scutellaria lateriflora*) is not listed under either federal or California endangered species acts. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G5/S1.2 which means that globally (G) the species population is secure or ineradicable due to being common outside of California, but within California (S) there are either less than six viable element occurrences, less than 1,000 individuals, or less than 2,000 acres (809 hectares) of occupied habitat. Its state threat level rank is “threatened.”

The California Native Plant Society (CNPS) List ranking of 2.2 for side-flowering skullcap indicates that it is rare, threatened, or endangered in California but more common elsewhere, and is considered by CNPS to be fairly endangered in California. Plants with a CNPS List rank of 2 are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

A61.2 SPECIES DISTRIBUTION AND STATUS

A61.2.1 Range and Status

The known range of side-flowering skullcap within California is limited to the Delta where it has been reported from two areas (Figure A-61a). In 1892 it was reported from Bouldin Island but that occurrence has not been relocated (CNDDB 2010). The other areas where it occurs are in the vicinity of Delta Meadows State Park where it was discovered during plant surveys in 1993; and in Sycamore Slough where it was discovered during the California Department of Water Resources/Delta Habitat Conservation and Conveyance Program (DWR/DHCCP) botanical survey of Delta waterways for the Bay Delta Conservation Plan (BDCP) in the summer of 2009 (CNDDB 2010). The DWR/DHCCP survey also found additional occurrences in the Delta Meadows State Park area (CNDDB 2010). At Delta Meadows Park side-flowering skullcap is found at upper tidal ranges growing on stumps and old pilings along tidal channels. It has also been recorded from a crop field on an herb farm in Gilroy in Santa Clara County (Hrusa 1999). A reported occurrence from Saline Valley in Inyo County has been determined to be erroneous (R. Bittman pers. com.) (CNDDB 2010).

DRAFT

Figure A-61a. Side-Flowering Skullcap Statewide Recorded Occurrences

A61.2.2 Distribution and Status in the Plan Area

As noted above, side-flowering skullcap appears to occur in California only within the Plan Area on Bouldin Island in San Joaquin County and in the Delta Meadows State Park area in Sacramento County (Figure A-61b) (CNDDB 2010). The Bouldin Island location was recorded in 1892 and the exact location of the collection is unknown. The Delta Meadows State Park occurrence was recorded in 1993. During botanical surveys of the Plan Area conducted by DWR/DHCCP in the summer of 2009 it was found growing on rotting pilings and stumps in and along the channels of Snodgrass Slough, Lost Slough, and the Mokelumne River. No additional occurrences of this species were discovered during the 2009 surveys conducted along channels in the north, west, south, and central Delta.

A61.3 HABITAT REQUIREMENTS AND SPECIAL CONSIDERATIONS

Side-flowering skullcap is a widespread species of swamps, marshes, and bogs in the central and eastern US, but rarely is it abundant (USDA 2010). It occurs in wet meadows, seeps, marshes and swamps (Holman et al. 2007, CNDDB 2010, CNPS 2010, E-Flora BC 2010, University of Washington Herbarium 2010, USDA 2010). Most relevant to the Plan Area is its occurrence in freshwater tidal swamps along the Pacific Northwest and in the Carolinas that are dominated by a variety of tree species (Holman et al. 2007, E-Flora BC 2010, University of Washington Herbarium 2010). In the freshwater tidal swamps it is found almost exclusively on hummocks formed by stumps and downed wood which place it in the higher regions of the tidal range. This ensures that the plant is well watered but not growing in anaerobic soils.

In the Delta Meadows State Park area it co-occurs with marsh skullcap (*Scutellaria galericulata*), apparently on the same stumps and pilings, which before the DWR/DHCCP surveys was only known from the Delta in the vicinity of Woodward Island despite being common in the northern Sierra Nevada, and with false nettle (*Boehmeria cylindrica*), which is not native to California. All three species frequently co-occur in the Midwest and on the East Coast.

A61.4 LIFE HISTORY

Side-flowering skullcap is a perennial rhizomatous herb 7 to 24 inches (20 to 60 centimeters [cm]) long (Hickman 1993, CNPS 2010). The 0.5 to 1 inch (1.3 to 2.5 cm) opposite leaves crowd down toward the base of the stem and support blue-purple to white flowers of about the same size that are typically produced along the length of side branches that grow from nodes of the main stem. Flowers are grouped in pairs and oriented on one side of the stem. The stem can be erect, branched, or some other type, ranges from light green to pale reddish-green, and may be smooth or sparsely covered with short hairs < 0.02 inch (< 0.5 millimeter) long. It blooms from July to September (CNPS 2010. It can produce small, more or less spherical brown fruit (Hickman 1993). This species is also used as a medicinal herb.

DRAFT

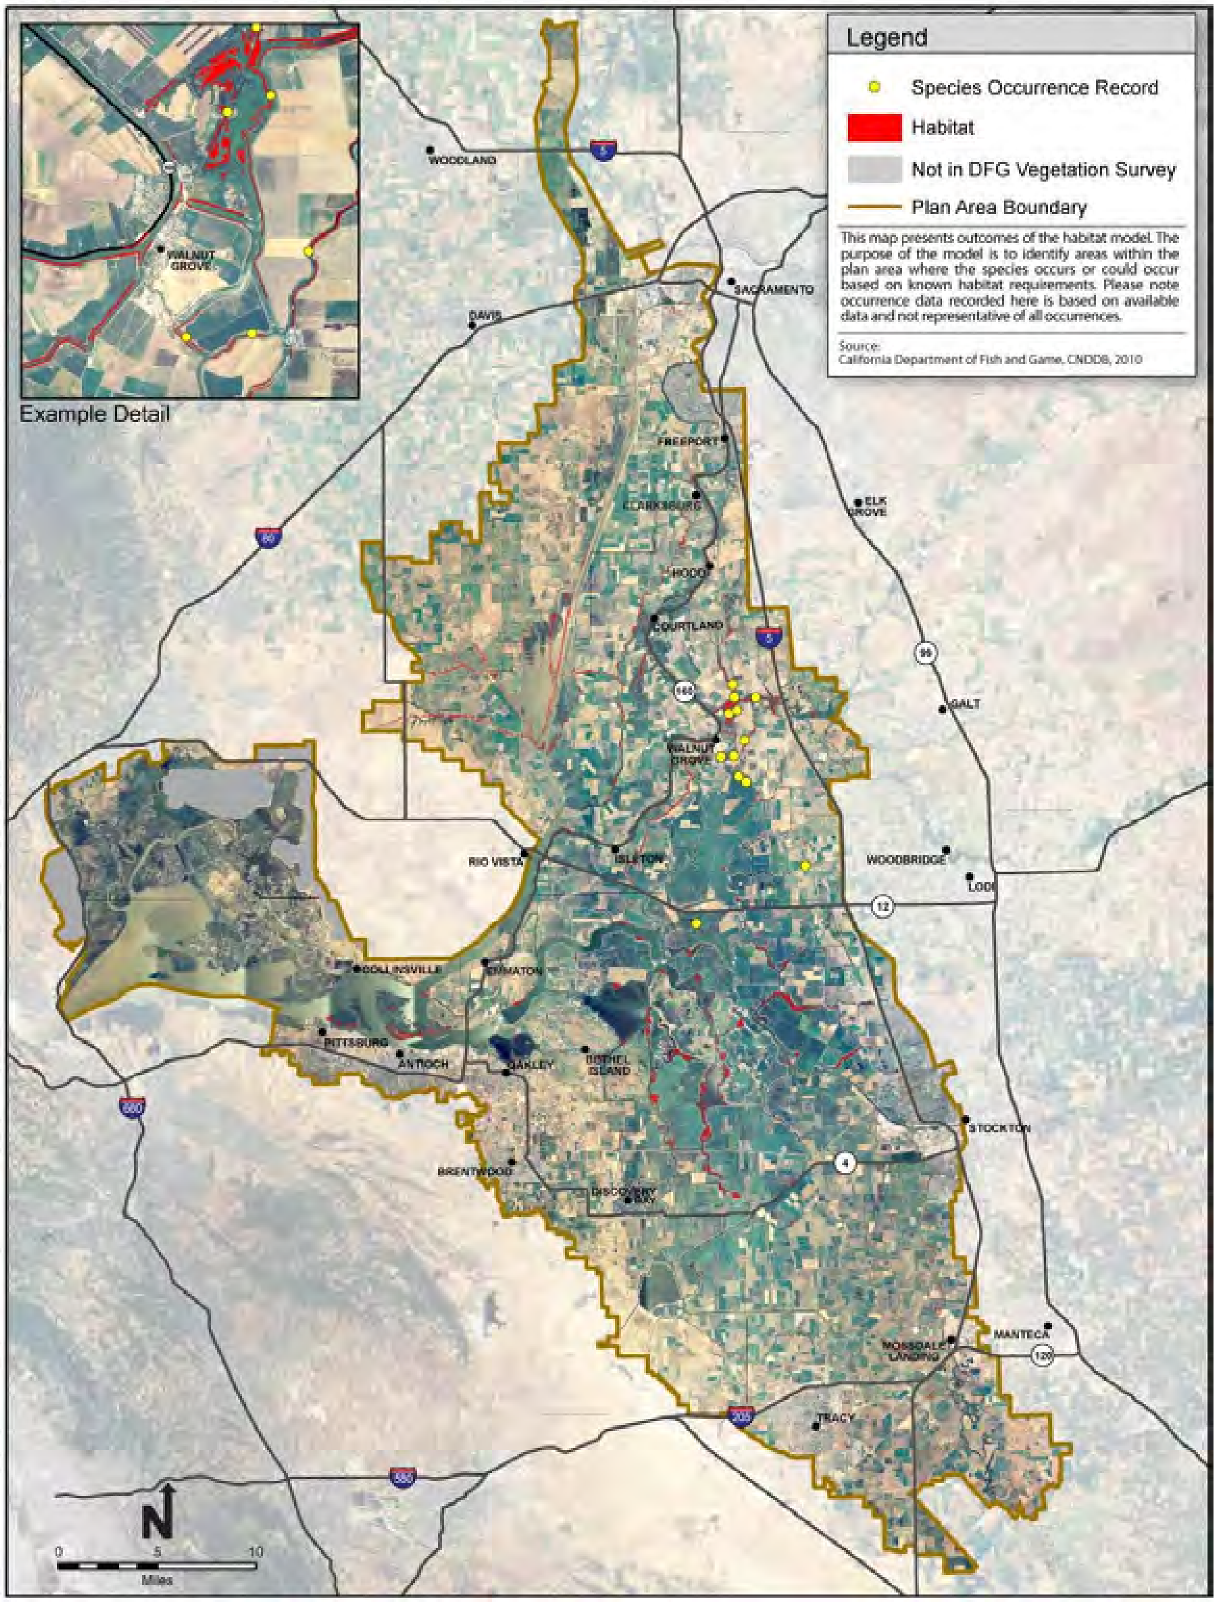

Figure A-61b. Side-Flowering Skullcap Habitat Model and Recorded Occurrences

A61.5 Threats and Stressors

While side-flowering skullcap populations are deemed secure globally (CNDDB 2010), general threats to wetland habitats around the world include development, intensive agriculture, and exotic plant species. Side-flowering skullcap grows on logs, stumps, and other large woody material along shoreline that supports primarily riparian and some marsh vegetation and lack of shoreline coarse woody material may be a limiting factor in parts of the Delta.

A61.6 Relevant Conservation Efforts

Most side-flowering skullcap plants found in the Plan Area are located within or directly adjacent to Delta Meadows State Park, a California State Park that was established to preserve and protect one of the last remaining areas of the northern Sacramento-San Joaquin River Delta that possesses large stands of fairly mature riparian vegetation (California State Parks 2010).

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for side-flowering skullcap is "Maintain" (CALFED Bay-Delta Program 2000). This designation indicates that the ERP will undertake actions to maintain the species by avoiding, minimizing, and compensating for any adverse effects to the species created by ERP restoration actions. It also means that the species' population and habitat are unlikely to be affected by ERP actions.

A61.7 Species Habitat Suitability Model

BDCP Species Habitat Suitability Models are formulated primarily using vegetation data from existing geographic information system (GIS) data sources (described below). Habitat suitability for each species is determined on the basis of whether or not a vegetation type or association is likely to be occupied based on the species' habitat requirements as described in the species account. The models are not formulated on the basis of species occurrence data, which is incomplete for most covered species in the Plan Area. Instead, species occurrence data are used to verify the habitat models and as necessary revise the vegetation input data.

By its nature, this type of model tends to provide conservative results with respect to the extent of suitable habitat. The tendency is to overestimate suitable habitat by attempting to be as inclusive as possible in the absence of site-specific data on vegetation structure, species composition, hydrology, occurrence of or proximity to other habitat elements and other variables that would provide more certainty with respect to habitat quality and the potential for occurrence.

However, due to minimum mapping unit limitations, it is possible to underestimate as well as overestimate the extent of suitable habitat. For example, suitable habitat areas that are below the minimum mapping unit size (1 acre) may not be identified. This may be important for species that can use small isolated habitats, such as vernal pools, individual trees, or small groups of trees. It is also possible, as with the side-flowering skullcap, to underestimate potentially-occupied habitat due to the lack of information on stumps and downed wood substrate on which it is found.

Still, for most species the more likely scenario is that an overestimate occurs as small acreages of unsuitable habitat are absorbed into larger suitable habitat polygons. Nonetheless, it is also important to note that while the models portray a reasonable distribution of habitat suitability for each covered species, they do not necessarily indicate with certainty that covered species would not occur in all areas identified as non-habitat; but instead indicate that non-habitat areas have a much lowered probability of species occurrence compared with areas identified as suitable habitat.

For each model, the mapping data sets and each vegetation type or association is identified. Finally, the assumptions used in the formulation of the model are described and if and how the model is expected to over- or under-estimate the extent of habitat in the Plan Area.

GIS model data sources. The side-flowering skullcap model is based on the following data set: Hickson and Keeler-Wolf 2007.

Vegetation Units. The following DFG vegetation subunits were selected from the BDCP Valley Riparian natural community as mapped by Hickson and Keeler Wolf 2007:

- *Alnus rhombifolia* / *Cornus sericea;*
- *Alnus rhombifolia* / *Salix exigua* (*Rosa californica*);
- California dogwood (*Cornus sericea*);
- *Cornus sericea* - *Salix exigua;*
- *Cornus sericea* - *Salix lasiolepis* / (*Phragmites australis*);
- *Quercus lobata* - *Alnus rhombifolia* (*Salix lasiolepis* - *Populus fremontii* - *Quercus agrifolia*);
- *Salix lasiolepis* - (*Cornus sericea*) / *Scirpus* spp.- (*Phragmites australis* - *Typha* spp.) complex unit;
- White alder (*Alnus rhombifolia*); and
- White alder (*Alnus rhombifolia*) - Arroyo willow (*Salix lasiolepis*) restoration.

Soils. Side-flowering skullcap is found primarily on stumps and downed wood both within the Delta Plan Area and regions that are similar to Delta habitats. Therefore, the presence of stumps and downed wood seems to be more of a determining factor of the presence of side-flowering skullcap than soil type. Moist soils with plenty of organic matter would most closely resemble woody substrate.

Assumptions. *Cornus sericea* is an appropriate species to use for a preliminary side-flowering skullcap species model due to its association with marsh skullcap and side-flowering skullcap and because it can provide the habitat characteristics that side-flowering skullcap seems to require, namely, woody substrate in freshwater tidal areas.

A61.8 Recovery Goals

Side-flowering skullcap is not a federally or state listed species. No recovery goals have been formulated for this species. Possible conservation measures could include avoidance, collection of clones by moving woody substrate with plants to new locations in the appropriate tidal range, and by the restoration of tree dominated vegetation along the uppermost limits of freshwater tidal areas in the Delta.

APPENDIX A62. SUISUN MARSH ASTER *(SYMPHYOTRICHUM LENTUM, FORMERLY ASTER LENTUS)*

A62.1 LEGAL STATUS

Suisun Marsh aster (*Symphyotrichum lentum*, formerly *Aster lentus*) is not listed under either federal or California endangered species acts. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G2/S2.2, which means that globally (G) and within the state (S) there are either between six to 20 viable element occurrences of this species, 1,000 to 3,000 individuals of this species, or 2,000 to 10,000 acres (809 to 4,047 hectares) where this species occurs. The state threat level rank is "threatened."

The California Native Plant Society (CNPS) List rank of 1B.2 for Suisun Marsh aster indicates that it is rare, threatened, or endangered in California and elsewhere, and is considered by CNPS to be fairly endangered in California with between 20 to 80 percent of occurrences threatened. Plants with a CNPS List rank of 1B are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

A62.2 SPECIES DISTRIBUTION AND STATUS

A62.2.1 Range and Status

The range of Suisun Marsh aster extends from Napa and Solano counties in the north, to San Joaquin County in the south, to Contra Costa County in the west, and Sacramento County in the east (Figure A-62a). It is endemic to Suisun Marsh and the Sacramento-San Joaquin Delta (CNDDB 2008, CNPS 2008). Historically, it was known from marshes in the East Bay portion of San Francisco Bay (California State Coastal Conservancy 2003) and the Sonoma and Napa rivers (Goals Project 2000).

A62.2.2 Distribution and Status in the Plan Area

Within the Plan Area, Suisun Marsh aster occurs in tidal areas throughout the west and central Delta and Suisun Marsh with scattered occurrences in the north and south Delta (Figure A-62b). Suisun Marsh aster occurs at the upper margin and immediately above the tidal zones of fresh and brackish marshes and along rivers and creeks. It has been observed on Andrus Island, Terminous Tract, Rindge Tract, Bethel Island, Franks Tract, and near Collinsville and Antioch among other locations in the Plan Area (CNDDB 2008). A large single occurrence was once reported along Baker Slough and Lindsey Slough on the Calhoun Cut Ecological Reserve, but more recently it has been remapped as several smaller polygons (Witham and Kareofelas 1994) and many new occurrences were mapped in that same area in 1994 (Witham and Kareofelas).

DRAFT

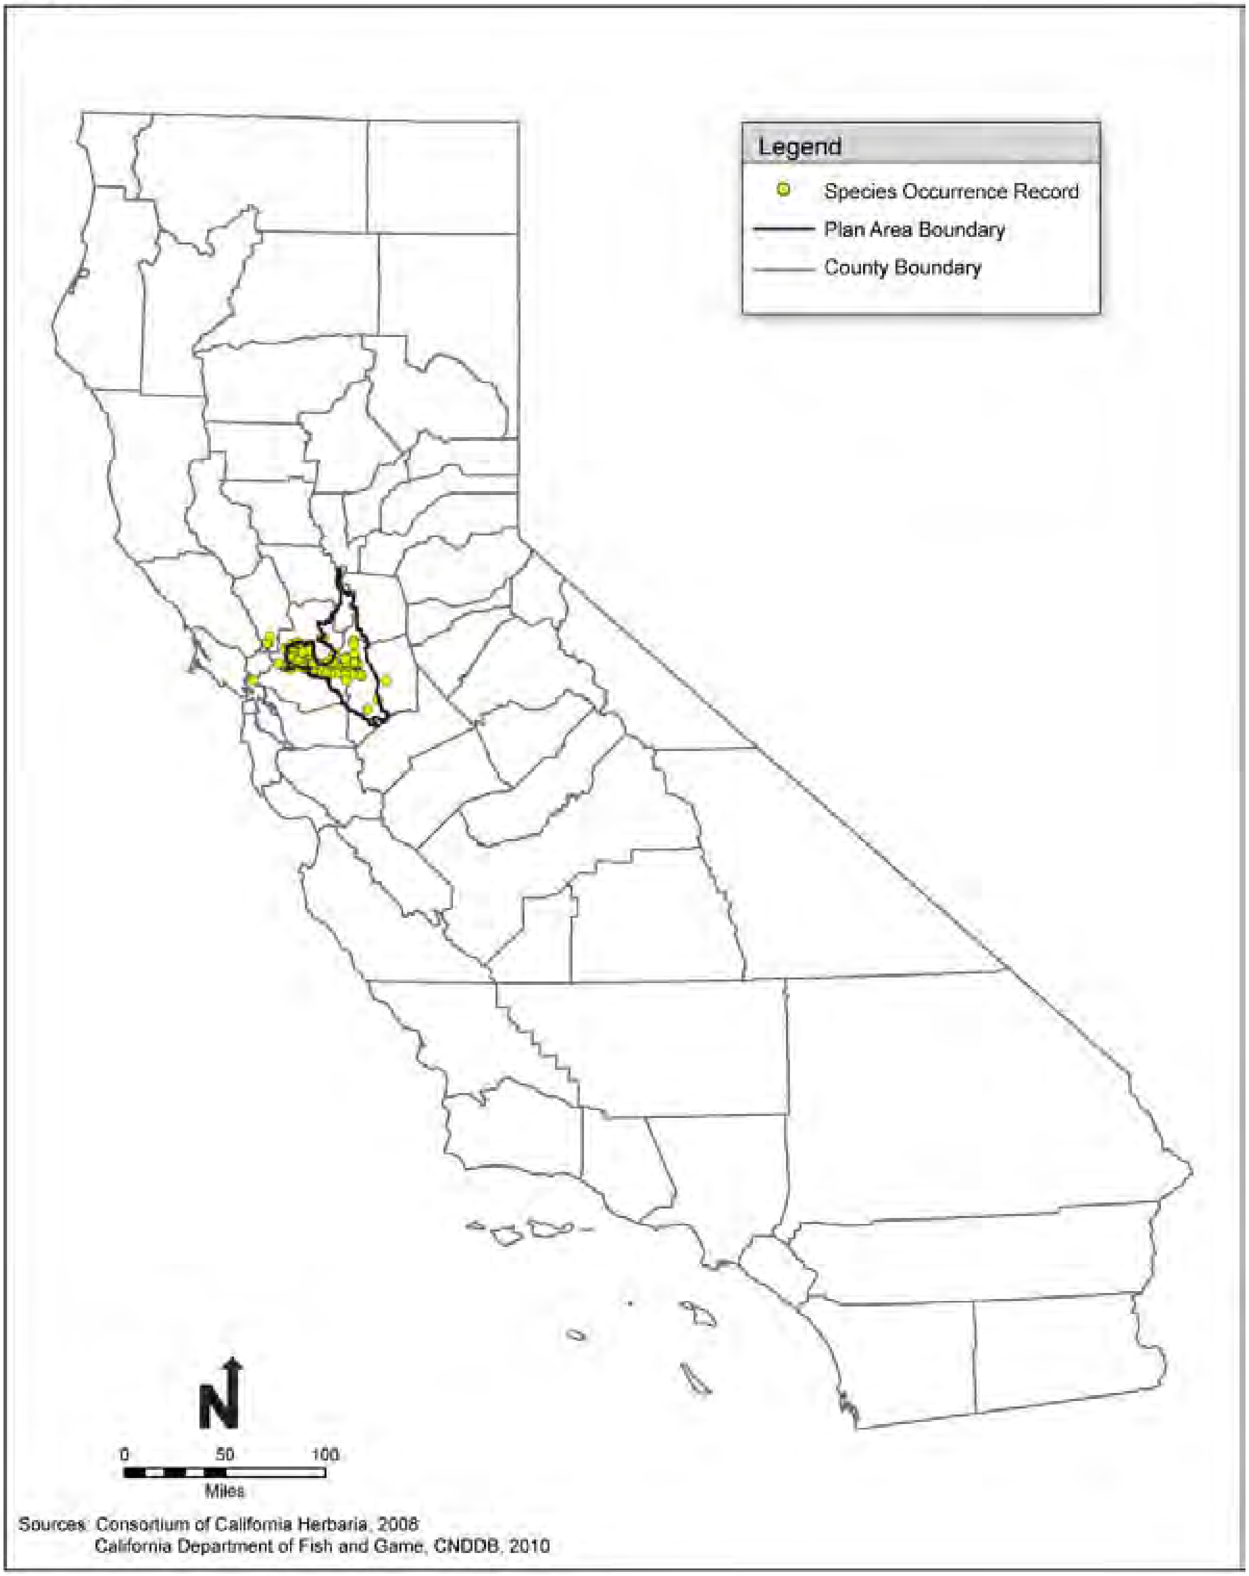

Figure A-62a. Suisun Marsh Aster Statewide Recorded Occurrences

DRAFT

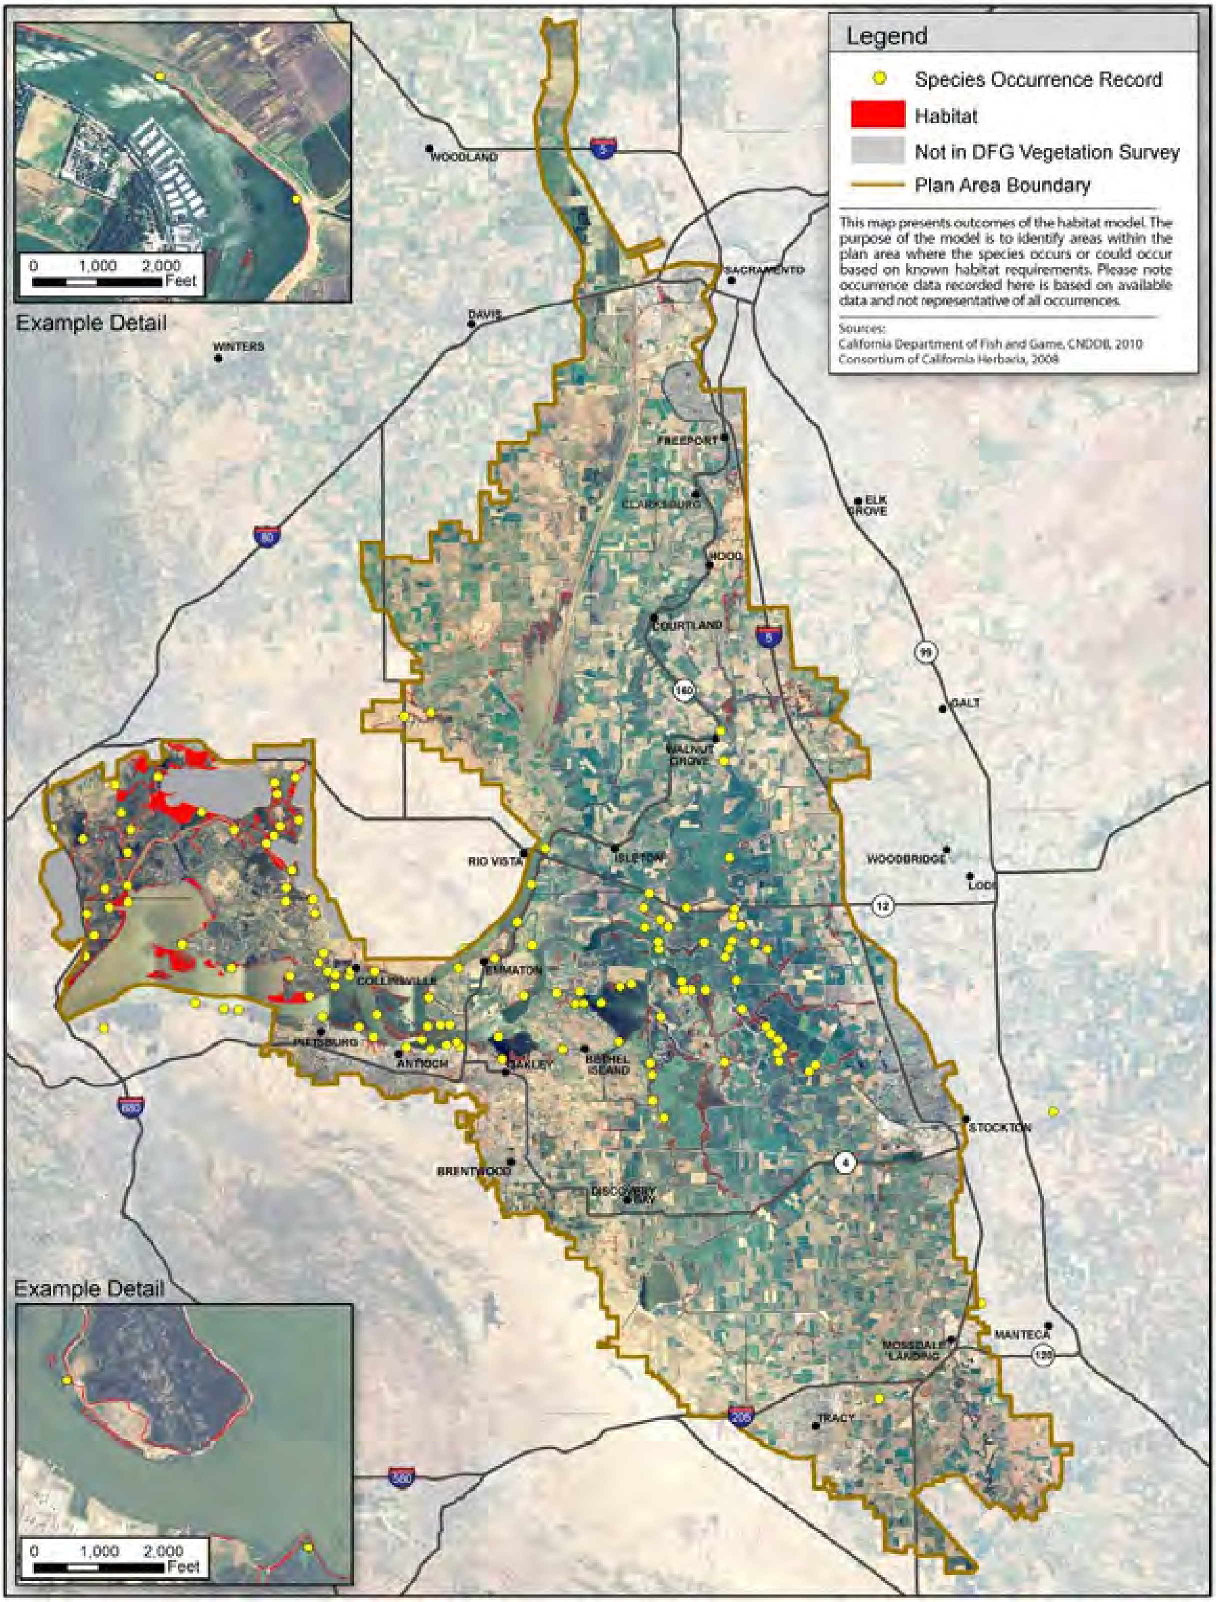

Figure A-62b. Suisun Marsh Aster Habitat Model and Recorded Occurrences

A62.3 Habitat Requirements and Special Considerations

Suisun Marsh aster grows on the upper margins of brackish and freshwater marshes in the ecotone with terrestrial habitats (Goals Project 2000) and above erosional cuts and along the banks of sloughs and watercourses, often occurring with common reed, cattails, bulrushes, and blackberry (Witham and Kareofelas 1994, May & Associates 2005). A 1994 report from the Calhoun Cut Ecological Reserve noted that many occurrences of Suisun Marsh aster were in relatively shaded areas either along north-facing banks or under overhanging trees (Witham and Kareofelas 1994). It has been observed in close proximity to other rare plant species including Mason's lilaeopsis (*Lilaeopsis masonii*), Delta Tule pea (*Lathyrus jepsonii* var. *jepsonii*), Delta mudwort (*Limosella subulata*), and soft bird's-beak (*Cordylanthus mollis* ssp. *mollis*) (Goals Project 2000, CNPS 2008, CNDDB 2008).

A62.4 Life History

Suisun Marsh aster is a perennial, rhizomatous herb in the aster tribe (Astereae) of the sunflower family (Asteraceae) (Hickman 1993). Some occurrences may be single plants with one to several main stems (Witham and Kareofelas 1994). It blooms from May through November, depending on environmental conditions. Suisun Marsh aster stems are 16 to 59 inches (41 to 150 centimeters [cm]) tall and have open inflorescences of several flowerheads with purple ray flowers (outer flowers) and yellow centers (disc flowers). Suisun Marsh aster hybridizes with the common California aster (*Aster chilensis*), but it can be recognized by its larger size and flowerheads without hairs on the involucre (leaflike bracts beneath the flowerhead), and its slightly succulent leaves which are thicker than those of the common California aster (Hickman 1993, CNPS 2008). It also closely resembles western goldentop (*Euthamia occidentalis*), but they are easily distinguished when flowering as western goldentop flowerheads are all-yellow (Baye 2007). Both the Suisun Marsh aster and the common California aster are local host plants for the Field Crescent butterfly (*Phyciodes campestris*) (Witham and Kareofelas 1994).

A62.5 Threats and Stressors

Historically, the marsh habitat suitable for Suisun Marsh aster has been lost mostly through development, dredge disposal, agricultural conversion, and diking. Diked marshes generally lack rare tidal marsh species. It is believed that the conditions brought about by dikes favor robust generalist species that can better tolerate the extremes of inundation and dryness in diked wetlands (Goals Project 2000). Such habitat losses from human activities still occur, but many of the large marshes are now parts of preserves or are in highly restrictive development zones. Current threats to Suisun Marsh aster include invasive plants, erosion, creek channelizing, levee maintenance and construction, and possibly herbicide applications (CNDDB 2008, CNPS 2008).

A62.6 RELEVANT CONSERVATION EFFORTS

The CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for the Suisun Marsh aster is "Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP has established a goal to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

Suisun Marsh aster is a covered species under the approved San Joaquin County Multi-species Habitat Conservation and Open Space Plan. It is proposed for coverage under the Solano County Multispecies Habitat Conservation Plan.

A62.7 SPECIES HABITAT SUITABILITY MODEL

Habitat. Habitat was modeled separately based upon the salinity of the water. For freshwater areas, essentially the area within the legal delta, Suisun Marsh aster habitat was identified as the area within 10 feet (3 meters) of the landward side of the landward boundary of tidal freshwater emergent wetland Bay Delta Conservation Plan (BDCP) land cover type exclusively where this land cover type is adjacent to grassland, vernal pool complex, valley/foothill riparian, or agricultural habitats land cover types. For brackish water areas in and near Suisun Marsh, the model used all tidal brackish emergent wetland polygons (SFEI 2005, Boul and Keeler-Wolf 2008) which, using the California Department of Water Resources (DWR) LiDAR data set as resampled at 10 meters (DWR 2007), were then intersected with an elevation range of 7 to 10 feet (2 to 3 meters) to capture elevations 1 foot (30 cm) below intertidal to 2 feet (60 cm) above intertidal (i.e. the upper limit of the intertidal range was estimated at 8 feet, NAVD88; Siegel estimated the intertidal range in Suisun to occur between 1 to 8 feet (30 cm to 2.4 meters), NAVD88 (Siegel 2007).

Assumptions. Historical and current records of this species indicate that its distribution extends throughout most of the Plan Area, having been observed in tidally influenced waters from Calhoun Cut and in the Sacramento River near Walnut Grove southward and from Tom Pain Slough near the southern boundary of the Plan Area northward (Figure A-62b) (Witham and Kareofelas 1994, CNDDB 2008). While there are no occurrences within the Plan Area north of Calhoun Cut and Walnut Grove, patches of suitable habitat extend into those areas. For purposes of this model, a 10 foot-wide (3 meter) buffer on the landward side of the landward boundaries of the tidal freshwater emergent wetland land and tidal brackish emergent wetland contained within the 7-10 foot elevation within Suisun Marsh have been included as the potential extent of habitat that supports Suisun Marsh aster.

A62.8 Recovery Goals

A USFWS recovery plan has not been prepared for this species and no recovery goals have been established; however, the CALFED Bay-Delta Ecosystem Restoration Program (ERP) Plan's Multi-Species Conservation Strategy designation for the Suisun Marsh aster is "Recovery" (CALFED Bay-Delta Program 2000). This means that the ERP has established a goal to recover the species. Recovery is equivalent to the requirements of delisting a species under federal and state endangered species acts.

APPENDIX A63. CAPER-FRUITED TROPIDOCARPUM (*TROPIDOCARPUM CAPPARIDEUM*)

A63.1 LEGAL STATUS

Caper-fruited tropidocarpum (*Tropidocarpum capparideum*) is not listed under either federal or California endangered species acts. Its Heritage Ranking in the California Natural Diversity Database (CNDDB) is G1/S1.1 which means that globally (G) and within the state (S) there are less than 6 viable element occurrences, less than 1,000 individuals, or less than 2,000 acres (809 hectares) of occupied habitat; and the state threat level rank is “very threatened.”

The California Native Plant Society (CNPS) List ranking of 1B.1 for caper-fruited tropidocarpum indicates that it is rare, threatened, or endangered. It is endemic to California and is considered by CNPS to be seriously endangered with more than 80 percent of occurrences threatened. Plants with a CNPS List rank of 1B are considered by the CNPS to meet the definitions of Section 1901, Chapter 10 (Native Plant Protection Act) or Sections 2062 and 2067 (California Endangered Species Act) of the California Fish and Game Code.

A63.2 SPECIES DISTRIBUTION AND STATUS

A63.2.1 Range and Status

Caper-fruited tropidocarpum is endemic to California and its distribution is based on 19 observations (Figure A-63a). Its range extends from Glenn County in the north, to Monterey, San Luis Obispo, and Fresno counties in the south, to San Joaquin County in the east, and Alameda, Contra Costa, and Santa Clara counties in the west (CNPS 2009).

It was thought to have been extinct since the 1950s; however, it was observed on Fort Hunter Liggett, a United States Army fort in southern Monterey County, in 2000 and 2001 (Hickman 1993, Al-Shehbaz 2003, CNDDB 2009, CNPS 2009).

A63.2.2 Distribution and Status in the Plan Area

Within the Plan Area, caper-fruited tropidocarpum was observed historically at Byron Hot Springs, near the current location of the Clifton Court Forebay, near the City of Tracy, and near Mountain House (CNDDB 2009, Consortium of California Herbaria 2009) (Figure A-63b).

A63.3 HABITAT REQUIREMENTS AND SPECIAL CONSIDERATIONS

Caper-fruited tropidocarpum has been found in valley and foothill grassland habitats in moderately alkaline soils (CNPS 2009) or, on Fort Hunter Liggett, also in foothill oak woodland habitats on slightly alkaline clay soils (CNDDB 2009).

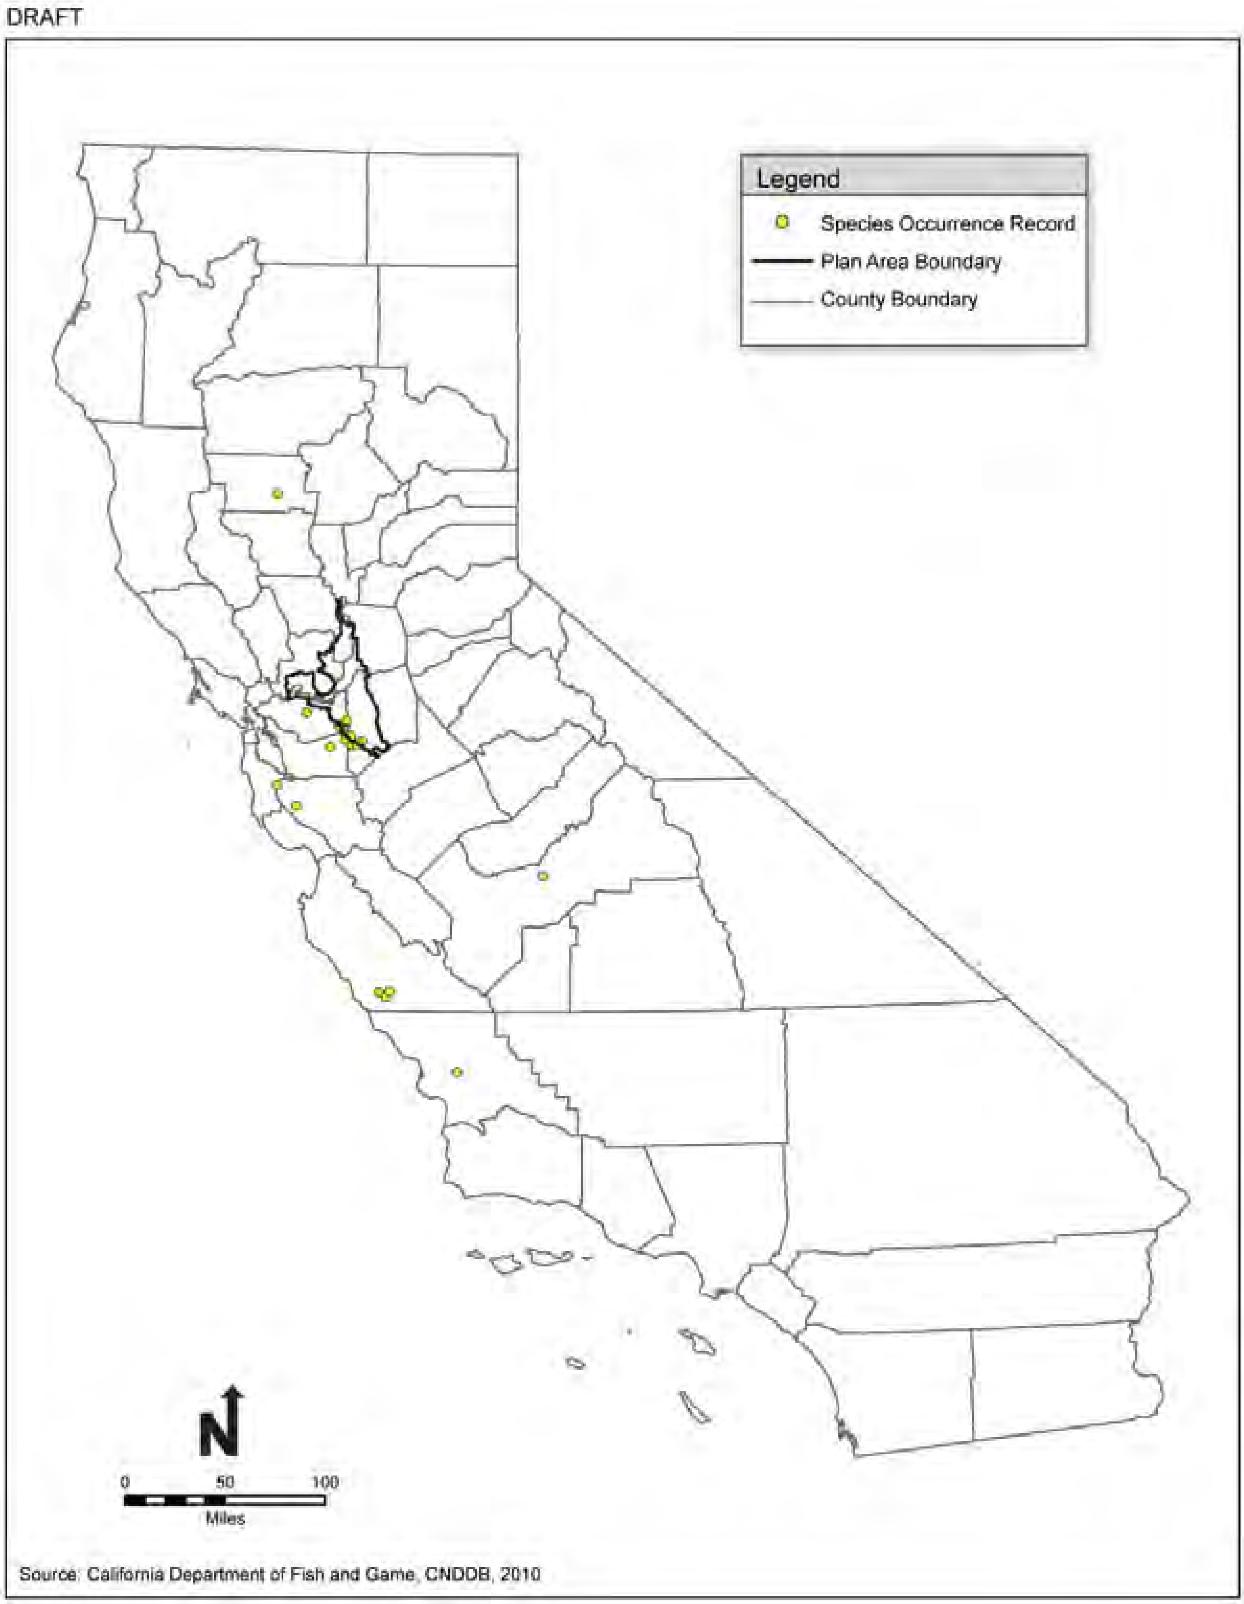

Figure A-63a. Caper-Fruited Tropidocarpum Statewide Recorded Occurrences

DRAFT

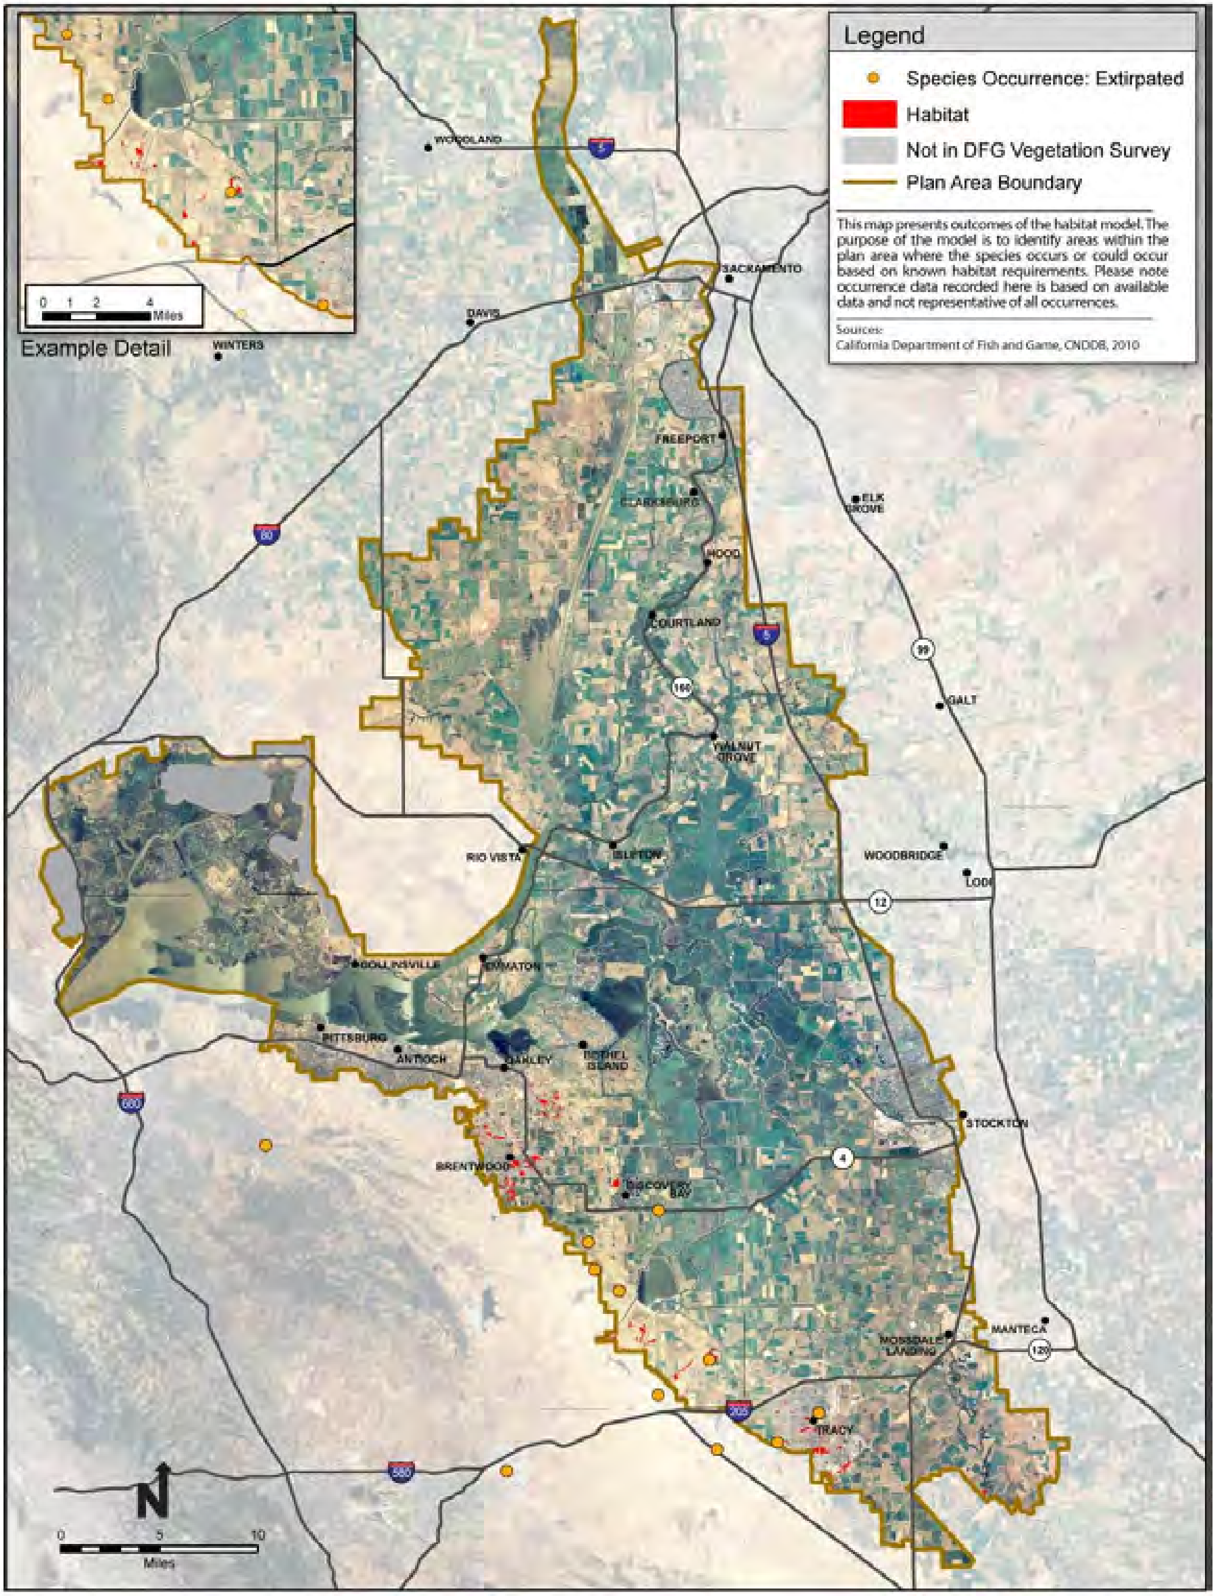

Figure A-63b. Caper-Fruited Tropidocarpum Habitat Model and Recorded Occurrences

The CNDDB locations on Fort Hunter Liggett overlaid on soils maps generally indicate that the species occurs on fine textured soils on gentle slopes in locations that are immediately above small drainages (NRCS 2009).

A63.4 Life History

Caper-fruited tropidocarpum is a small to medium-sized (8-20 inches [20–51 centimeters {cm}]) annual herb of the mustard family (Brassicaceae) that blooms from March to April (Hickman 1993, CNPS 2009). Caper-fruited tropidocarpum can be found at elevations of 3 to 1,500 feet (1 to 455 meters) (CNPS 2009). Its stems stand erect, are few-branched and slightly hairy. Its leaves are 1–2.5 inches (2-5 cm) long and also slightly hairy. The flowers are yellowish and have sparse hairs; and the petals are 0.2–0.3 inch (4-5 millimeters) long and spoon-shaped.

A63.5 Threats and Stressors

Reported threats to caper-fruited tropidocarpum are grazing, military activities, trampling, and nonnative plants (CNPS 2009). Based on its historical distribution in the Plan Area most impacts appear to have occurred through intensive agriculture and urbanization or other development activities.

A63.6 Relevant Conservation Efforts

The caper-fruited tropidocarpum is a covered species in the San Joaquin County Multi-species Habitat Conservation and Open Space Plan.

A63.7 Species Habitat Suitability Model

GIS Model Data Sources. The caper-fruited tropidocarpum model is based on an iterative analysis of the following data sets: SSURGO Soils (NRCS 2009), and BDCP composite vegetation layer (Hickson and Keeler-Wolf 2007).

Vegetation Units. The following vegetation subunits were selected from the BDCP grassland natural community:

- *Bromus diandrus - Bromus hordeaceus;*
- California annual grasslands herbaceous;
- Italian rye-grass (*Lolium multiflorum*);
- *Lolium multiflorum - Convolvulus arvensis;*
- Pasture; and
- Upland annual grasslands and forbs formation.

Soils. Soils having clay content greater than 30 percent were selected in Alameda, Contra Costa, Sacramento, San Joaquin, Solano, and Yolo counties. Soils having a potential of hydrogen (pH) greater than 7 were then selected from those clay soils.

Soil Constraint Characteristics. From the selected soils the following subset of soils were further selected based upon fluvial geomorphic characteristics:

- alluvial fans, stream terraces, valleys;
- alluvial fans, terraces;
- alluvial fans, valleys;
- basin floors, valleys;
- fan terraces, valleys;
- fans, valley floors;
- rims on basin floors, valleys;
- terraces, valleys;
- valley floors; and
- valleys.

A spatial intersection of the vegetation types and soils was then used to identify potential suitable habitat. Locations found unsuitable because of hydrological conditions were removed.

A63.8 Recovery Goals

A United States Fish and Wildlife Service (USFWS) recovery plan has not been prepared for this species and no recovery goals have been established.

Appendix B-1

Species Name by Common Name

This page intentionally left blank.

Type	*Common name*	*Scientific name*
Fish	American shad	*Alosa sapidissima*
Fish	Bigscale logperch	*Percina macrolepida*
Fish	Black bullhead	*Ameiurus melas*
Fish	Black crappie	*Pomoxis nigromaculatus*
Fish	Bluegill sunfish	*Lepomis macrochirus*
Fish	Brown bullhead	*Ameiurus nebulosus*
Fish	California Roach	*Hesperoleucus symmetricus*
Fish	Central Valley fall and late fall-run Chinook salmon	*Oncorhynchus tshawytscha*
Fish	Central Valley spring-run Chinook salmon	*Oncorhynchus tshawytscha*
Fish	Central Valley steelhead	*Oncorhynchus mykiss*
Fish	Chameleon Goby	*Tridentiger trigonocephalus*
Fish	Channel catfish	*Ictalurus punctatus*
Fish	Chinook salmon	*Oncorhynchus tshawytscha*
Fish	Common carp, Carp	*Cyprinus carpio carpio*
Fish	Delta smelt	*Hypomesus transpacificus*
Fish	Fathead minnow	*Pimephales promelas*
Fish	Golden shiner	*Notemigonus crysoleucas*
Fish	Goldfish	*Carassius auratus auratus*
Fish	Green sturgeon	*Acipenser medirostris*
Fish	Green sunfish	*Lepomis cyanellus*
Fish	Hardhead	*Mylopharodon conocephalus*
Fish	Hitch	*Lavinia exilicauda*
Fish	Inland silverside	*Menidia beryllina*
Fish	Largemouth bass	*Micropterus salmoides*
Fish	Longfin smelt	*Spirinchus thaleichthys*
Fish	Northern Anchovy	*Engraulis mordax*
Fish	Northern pike	*Esox lucius*
Fish	Pacific herring	*Clupea pallasii*
Fish	Pacific lamprey	*Entosphenus tridentatus*
Fish	Pacific Staghorn Sculpin	*Leptocottus armatus*
Fish	Prickly sculpin	*Cottus asper*
Fish	Pumpkinseed	*Lepomis gibbosus*
Fish	Rainbow Trout	*Oncorhynchus mykiss*
Fish	Rainwater killifish	*Lucania parva*
Fish	Red shiner	*Cyprinella lutrensis*
Fish	Redear sunfish	*Lepomis microlophus*
Fish	Redeye bass	*Micropterus coosae*
Fish	River lamprey	*Lampetra ayresii*
Fish	Sacramento Blackfish	*Orthodon microlepidotus*
Fish	Sacramento perch	*Archoplites interruptus*
Fish	Sacramento Pikeminnow	*Ptychocheilus grandis*
Fish	Sacramento River winter-run Chinook salmon	*Oncorhynchus tshawytscha*
Fish	Sacramento splittail	*Pogonichthys macrolepidotus*
Fish	Sacramento sucker	*Catostomus occidentalis*
Fish	Shimofuri goby	*Tridentiger bifasciatus*
Fish	Shokihaze goby	*Tridentiger barbatus*
Fish	Smallmouth bass	*Micropterus dolomieu*
Fish	Spotted bass	*Micropterus punctulatus*
Fish	Starry flounder	*Platichthys stellatus*
Fish	Steelhead	*Oncorhynchus mykiss*
Fish	Striped bass	*Morone saxatilis*
Fish	Sturgeon	*Acipenser* spp.

Type	*Common name*	*Scientific name*
Fish	Thicktail chub	*Gila crassicauda*
Fish	Threadfin shad	*Dorosoma petenense*
Fish	Threespine Stickleback	*Gasterosteus aculeatus*
Fish	Topsmelt	*Atherinops affinis*
Fish	Tule perch	*Hysterocarpus traskii*
Fish	Wakasagi	*Hypomesus nipponensis*
Fish	Warmouth	*Lepomis gulosus*
Fish	Western mosquitofish	*Gambusia affinis*
Fish	Whie crappie	*Pomoxis annularis*
Fish	White catfish	*Ameiurus catus*
Fish	White sturgeon	*Acipenser transmontanus*
Fish	Yellowfin goby	*Acanthogobius flavimanus*
Mammals	American badger	*Taxidea taxus*
Mammals	Beaver	*Castor canadensis*
Mammals	Black rat	*Rattus rattus*
Mammals	Black-tailed jackrabbit	*Lepus californicus*
Mammals	Bobcat	*Lynx rufus*
Mammals	California gray fox	*Urocyon cinereoargenteus*
Mammals	California ground squirrel	*Otospermophilus beecheyi*
Mammals	Cottontail	*Sylvilagus* spp.
Mammals	Coyote	*Canis latrans*
Mammals	Feral cat	*Felis domesticus*
Mammals	Feral pig	*Sus scrofa*
Mammals	Grizzly	*Ursus arctos*
Mammals	House mouse	*Mus musculus*
Mammals	Long-tailed weasel	*Mustela frenata*
Mammals	Mountain lion	*Puma concolor*
Mammals	Mule Deer	*Odocoileus hemionus*
Mammals	Muskrat	*Ondatra zibethicus*
Mammals	Nelson’s antelope ground squirrel	*Ammospermophilus nelsoni*
Mammals	Norway rat	*Rattus norvegicus*
Mammals	Pocket gopher	*Thomomys* spp.
Mammals	Pronghorn	*Antilocapra americana*
Mammals	Raccoon	*Procyon lotor*
Mammals	Rat	*Rattus* spp.
Mammals	Red fox	*Vulpes vulpes*
Mammals	Ringtail	*Bassariscus astutus*
Mammals	Riparian brush rabbit	*Sylvilagus bachmani riparius*
Mammals	Riparian woodrat	*Neotoma fuscipes riparia*
Mammals	River otter	*Lontra canadensis*
Mammals	Salt marsh harvest mouse	*Reithrodontomys raviventris*
Mammals	San Joaquin kit fox	*Vulpes macrotis mutica*
Mammals	Suisun shrew	*Sorex ornatus sinuosus*
Mammals	Townsend’s big-eared bat	*Corynorhinus townsendii*
Mammals	Townsend’s mole	*Scapanus townsendii*
Mammals	Tule elk	*Cervus canadensis nannodes*
Mammals	Woodrat	*Neotoma* spp.

Reptiles	Giant garter snake	*Thamnophis gigas*
Reptiles	Glossy snake	*Arizona elegans*
Reptiles	Gopher snake	*Pituophis melanoleucus*
Reptiles	Racer	*Coluber constrictor*
Reptiles	Red-eared slider	*Trachemys scripta elegans*
Reptiles	San Joaquin whipsnake	*Masticophis flagellum ruddocki*
Reptiles	Silvery legless lizard	*Anniella pulchra*
Reptiles	Western fence lizard	*Sceloporus occidentalis*
Reptiles	Western pond turtle	*Actinemys* (formerly *Clemmys* and *Emys*) *marmorata*
Amphibians	Bullfrog	*Rana catesbeiana*
Amphibians	California red-legged frog	*Rana draytonii*
Amphibians	California tiger salamander	*Ambystoma californiense*

Type	*Common name*	*Scientific name*
Amphibians	Western spadefoot toad	*Spea hammondii*
Invertebrates	Acanthomysis	*Acanthomysis bowmani*
Invertebrates	Asian clam	*Corbicula fluminea*
Invertebrates	California linderiella	*Linderiella occidentalis*
Invertebrates	Callippe silverspot	*Speyeria callippe callippe*
Invertebrates	Chinese mitten crab	*Eriocheir sinensis*
Invertebrates	Conservancy fairy shrimp	*Branchinecta conservatio*
Invertebrates	Copepod	*Acanthocyclops vernalis*
Invertebrates	Corophium	*Corophium* spp.
Invertebrates	Crayfish	e.g., *Procambarus clarkii, Astacoidea*
Invertebrates	Daphnia	*Daphnia parvula, Daphnia pulex*
Invertebrates	Diaptomus	*Diaptomus* spp.
Invertebrates	Eurytemora	*Eurytemora affinis*
Invertebrates	Giant flower-loving fly	*Thaphiomydas trochilus*
Invertebrates	Lange's metalmark butterfly	*Apodemia mormo langei*
Invertebrates	Limnocalanus	*Limnocalanus macrurus*
Invertebrates	Limnoithona	*Limnoithona tetraspina*
Invertebrates	Longhorn fairy shrimp	*Branchinecta longiantenna*
Invertebrates	Midvalley fairy shrimp	*Branchinecta mesovallensis*
Invertebrates	Neomysis	*Neomysis mercedis*
Invertebrates	Overbite clam	*Corbula amurensis*
Invertebrates	Pseudodiaptomus	*Pseudodiaptomus forbesi*
Invertebrates	Valley elderberry longhorn beetle	*Desmocerus californicus dimorphus*
Invertebrates	Vernal pool fairy shrimp	*Branchinecta lynchi*
Invertebrates	Vernal pool tadpole shrimp	*Lepidurus packardi*
Plants	Alder	*Alnus* spp.
Plants	Alkali bulrush	*Schoenoplectus* (formerly *Scirpus*) maritimus
Plants	Alkali heath	*Frankenia salina*
Plants	Alkali milk-vetch	*Astragalus tener var. tener*
Plants	Alkali peppergrass	*Lepidium dictyotum var. dictyotum*
Plants	Alkali ryegrass	*Leymus triticoides*
Plants	Annual hairgrass	*Deschampsia danthonioides*
Plants	Annual ryegrass	*Lolium multiflorum*
Plants	Antioch dunes evening-primrose	*Oenothera deltoides* ssp. *howellii*
Plants	Arrowleaf	*Sagittaria* spp.
Plants	Arroyo willow	*Salix lasiolepis*
Plants	Baltic rush	*Juncus balticus*
Plants	Barbgrass	*Hainardia cylindrical*
Plants	barnyard grass	*Echinochloa crus-galli*
Plants	Bermuda grass	*Cynodon dactylon*
Plants	Black locust	*Robinia pseudoacacia*
Plants	Blackberries	*Rubus* spp.
Plants	Blue dicks	*Dichelostemma capitatum*
Plants	Blue elderberry	*Sambucus cerulea*
Plants	Blue wildrye	*Elymus glaucus*
Plants	Blue-green algae	*Anabaena azollae*
Plants	Bluegum eucalyptus	*Eucalyptus globulus*
Plants	Boggs Lake hedge-hyssop	*Gratiola heterosepala*
Plants	Box elder	*Acer negundo*
Plants	Brass buttons	*Cotula coronopifolia*
Plants	Brazilian waterweed	*Egeria densa*

Type	*Common name*	*Scientific name*
Plants	Bristled downingia	*Downingia bicornuta var. bicornuta*
Plants	Brittlescale	*Atriplex depressa*
Plants	Broadleaf filaree	*Erodium botrys*
Plants	Bull thistle	*Cirsium vulgare*
Plants	Bulrush	*Schoenoplectus* (formerly *Scirpus*) spp.
Plants	Burhead	*Echinodorus berteroi*
Plants	Bush seepweed	*Suaeda moquinii*
Plants	Buttonbush	*Cephalanthus occidentalis* var. *californicus*
Plants	California brome	*Bromus carinatus*
Plants	California bulrush	*Schoenoplectus* (formerly *Scirpus*) *californicus*
Plants	California croton	*Croton californicus*
Plants	California hair-grass	*Deschampsia caespitosa*
Plants	California matchweed	*Gutierrezia californica*
Plants	California melic	*Melica californica*
Plants	California poppy	*Eschscholzia californica*
Plants	California sycamore	*Platanus racemosa*
Plants	California wild grape	*Vitis californica*
Plants	California wild rose	*Rosa californica*
Plants	Caper-fruited tropidocarpum	*Tropidocarpum capparideum*
Plants	Carquinez goldenbush	*Isocoma arguta*
Plants	Cattail	*Typha* spp.
Plants	Chinese tallow tree	*Triadica sebifera*
Plants	Coast live oak	*Quercus agrifolia*
Plants	Colusa grass	*Neostapfia colusana*
Plants	Common cattail	*Typha latifolia*
Plants	Common muilla	*Muilla maritima*
Plants	Common reed	*Phragmites australis*
Plants	Common spikerush	*Eleocharis macrostachya*
Plants	Contra Costa wallflower	*Erysimum capitatum* var. *angustatum*
Plants	Cordgrass	*Spartina* spp.
Plants	Cottonwood	*Populus fremontii*
Plants	Coyote thistle	*Eryngium vaseyi*
Plants	Creeping wildrye	*Leymus triticoides*
Plants	Curved sicklegrass	*Parapholis incurva*
Plants	Cyanobacteria	*Microcystis aeruginosa*
Plants	Dallisgrass	*Paspalum dilatatum*
Plants	Deerweed	*Lotus scoparius*
Plants	Delta button-celery	*Eryngium racemosum*
Plants	Delta mudwort	*Limosella subulata*
Plants	Delta tule pea	*Lathyrus jepsonii* var. *jepsonii*
Plants	Devil's-lettuce	*Amsinckia tessellata*
Plants	Downingia	*Downingia* spp.
Plants	Duckweed	*Lemna* spp.
Plants	Dwarf downingia	*Downingia pusilla*
Plants	Eared naked buckwheat	*Eriogonum nudum* var. *auriculatum*
Plants	Eel grass	*Zostera marina*
Plants	Elderberry	*Sambucus* spp.
Plants	Elegant clarkia	*Clarkia unguiculata*
Plants	Eurasian watermilfoil	*Myriophyllum spicatum*
Plants	Fennel	*Foeniculum vulgare*

Type	***Common name***	***Scientific name***
Plants	Fiddleneck	*Amsinckia* spp.
Plants	Fig	*Ficus* spp.
Plants	Filarees	*Erodium* spp.
Plants	Flatsedges	*Cyperus* spp.
Plants	Floating primrose	*Ludwigia peploides*
Plants	Floating water fern	*Azolla filiculoides*
Plants	Foxtail fescue	*Vulpia myuros*
Plants	Fremont's cottonwood	*Populus fremontii*
Plants	Giant reed	*Arundo donax*
Plants	Gold nugget	*Calochortus luteus*
Plants	Goldfields	*Lasthenia fremontii*
Plants	Gooding's black willow	*Salix gooddingii*
Plants	Grain Sorghum	*Sorghum bicolor*
Plants	Grand redstem	*Ammania* spp.
Plants	Greene's tuctoria	*Tuctoria greenei*
Plants	Grindelia	*Grindelia* spp.
Plants	Gum plant	*Grindelia stricta*
Plants	Hairy orcutt grass	*Orcuttia pilosa*
Plants	Hard-stem bulrush	*Schoenoplectus* (formerly *Scirpus*) *acutus* var. *acutus*
Plants	Harvest brodiaea	*Brodiaea coronaria*
Plants	Heartscale	*Atriplex cordulata*
Plants	Heckard's peppergrass	*Lepidium latipes var. heckardii*
Plants	Himalayan blackberry	*Rubus discolor*
Plants	Hinds' walnut	*Juglans californica* var. *hindsii*
Plants	Honeysuckle	*Lonicera* spp.
Plants	Idaho fescue	*Festuca idahoensis*
Plants	Iodine bush	*Allenrolfea occidentalis*
Plants	Italian ryegrass	*Lolium multiflorum*
Plants	Ithuriel's spear	*Triteleia laxa*
Plants	Johnson grass	*Sorghum halepense*
Plants	Legenere	*Legenere limosa*
Plants	Lesser saltscale	*Atriplex minuscula*
Plants	Lessingia	*Lessingia glandulifera*
Plants	Lotus	*Lotus* spp.
Plants	Low mannagrass	*Glyceria declinata*
Plants	Mason's lilaeopsis	*Lilaeopsis masonii*
Plants	Meadow barley	*Hordeum brachyantherum*
Plants	Meadowfoam	*Limnanthes alba*
Plants	Medusahead	*Taeniatherum caput-medusae*
Plants	Mexican elderberry	*Sambucus mexicana*
Plants	Mexican rush	*Juncus mexicanus*
Plant	Microcystis	*Microcystis aeruginosa*
Plants	Mojave seablight	*Suaeda moquinii*
Plants	Monkeyflowers	*Mimulus* spp.
Plants	Mule fat	*Baccharis salicifolia*
Plants	Naked stem buckwheat	*Eriogonum nudum* var. *auriculatum*
Plants	Narrow-leaf cattail	*Typha angustifolia*
Plants	Narrow-leaf willow	*Salix exigua*
Plants	Narrow-leaved soap plant	*Chlorogalum angustifolium*
Plants	Navarretia	*Navarretia leucocephala* ssp. *plieantha*
Plants	Oak	*Quercus* spp.

Type	*Common name*	*Scientific name*
Plants	One-sided bluegrass	*Poa secunda*
Plants	Oregon ash	*Fraxinus latifolia*
Plants	Pacific foxtail	*Alopecurus saccatus*
Plants	Pacific willow	*Salix lucida* ssp. *lasiandra*
Plants	Pampas grass	*Cortaderia selloana*
Plants	Paper onion	*Allium amplectens*
Plants	Perennial pepperweed	*Lepidium latifolium*
Plants	Perennial pepperweed	*Lepidium latifolium*
Plants	Pickleweed	*Sarcocornia pacifica* (formerly *Salicornia virginica*)
Plants	Poison hemlock	*Conium maculatum*
Plants	Poison oak	*Toxicodendron diversilobum*
Plants	Pondweed	*Potamogeton* spp.
Plants	Prostrate pigweed	*Amaranthus blitoides*
Plants	Purple needlegrass	*Nassella pulchra*
Plants	Rabbitsfoot grass	*Polypogon monspeliensis*
Plants	Rayless goldfields	*Lasthenia glaberrima*
Plants	Red alder	*Alnus rubus*
Plants	Red brome	*Bromus madritensis* ssp. *rubens*
Plants	Red elderberry	*Sambucus racemosa*
Plants	Red fescue	*Festuca rubra*
Plants	Red willow	*Salix laevigata*
Plants	Redosier dogwood	*Cornus sericea*
Plants	Redstem filaree	*Erodium cicutarium*
Plants	Ripgut brome	*Bromus diandrus*
Plants	Rush	*Juncus* spp.
Plants	Russian olive	*Elaeagnus angustifolia*
Plants	Russian thistle	*Salsola tragus*
Plants	Sacramento mesamint	*Pogogyne zizyphoroides*
Plants	Sacramento orcutt grass	*Orcuttia viscida*
Plants	Salt marsh dodder	*Cuscuta salina*
Plants	Saltgrass	*Distichlis spicata*
Plants	San Joaquin spearscale	*Atriplex joaquiniana*
Plants	San Joaquin Valley orcutt grass	*Orcuttia inaequalis*
Plants	Santa Barbara sedge	*Carex barbarae*
Plants	Seaside arrowgrass	*Triglochin maritima*
Plants	Sedge	*Carex* spp.
Plants	Shining peppergrass	*Lepidium nitidum var. nitidum*
Plants	Side-flowering skullcap	*Scutellaria lateriflora*
Plants	Slender orcutt grass	*Orcuttia tenuis*
Plants	Sliver bush lupine	*Lupinus albifrons*
Plants	Slough thistle	*Cirsium crassicaule*
Plants	Small stipitate popcorn flowers	*Plagiobothrys stipitatus* var. *micranthus*
Plants	Smartweed	*Polygonum* spp.
Plants	Soft bird's beak	*Cordylanthus mollis* ssp. *mollis*
Plants	Soft chess	*Bromus hordeaceus*
Plants	Solano grass	*Tuctoria mucronata*
Plants	Spearscale	*Atriplex triangularis*
Plants	Stinging nettle	*Urtica dioica*
Plants	Strawberry clover	*Trifolium fragiferum*
Plants	Succulent owl’s clover	*Castilleja campestris* ssp. *succulenta*
Plants	Sudan Grass	*Sorghum vulgare* var. *sudanense*

Type	***Common name***	***Scientific name***
Plants	Suisun marsh aster	*Symphyotrichum lentum*
Plants	Suisun thistle	*Cirsium hydrophilum var. hydrophilum*
Plants	Swamp grass	*Crypsis* spp.
Plants	Swamp timothy	*Crypsis schoenoides*
Plants	Sycamore	*Platanus* spp.
Plants	Tall fescue	*Festuca arundinacea*
Plants	Tamarisk	*Tamarix ramosissima*
Plants	Telegraph weed	*Heterotheca grandiflora*
Plants	Toad rush	*Juncus bufonius*
Plants	Tree-of-heaven	*Ailanthus altissima*
Plants	True clovers	*Trifolium* spp.
Plants	Tufted hairgrass	*Deschampsia cespitosa*
Plants	Tule	*Schoenoplectus* (formerly *Scirpus*) spp.
Plants	Tule bulrush	*Schoenoplectus* (formerly *Scirpus*) *acutus*
Plants	Turkey mullein	*Eremocarpus setigerus*
Plants	Valley oak	*Quercus lobata*
Plants	Vetch	*Vicia* spp.
Plants	Walnut	*Juglans* spp.
Plants	Water hyacinth	*Eichhornia crassipes*
Plants	Water primrose	*Ludwigia peploides* var. *peploides*
Plants	Watercress	*Rorippa nasturtium-aquaticum*
Plants	White alder	*Alnus rhombifolia*
Plants	White clover	*Trifolium repens*
Plants	White hyacinth	*Triteleia hyacinthina*
Plants	Wild barley	*Hordeum spontaneum*
Plants	Wild mustard	*Hirschfeldia incana, Brassica nigra*
Plants	Wild oats	*Avena* spp.
Plants	Wild rose	*Rosa* spp.
Plants	Willow	*Salix* spp.
Plants	Woolly marbles	*Psilocarphus brevissimus*
Plants	Yellow starthistle	*Centaurea solstitialis*

Appendix B-2

B2. Species Name by Scientific Name

This page intentionally left blank.

Fish	Yellowfin goby	*Acanthogobius flavimanus*
Fish	Green sturgeon	*Acipenser medirostris*
Fish	Sturgeon	*Acipenser* spp.
Fish	White sturgeon	*Acipenser transmontanus*
Fish	American shad	*Alosa sapidissima*
Fish	White catfish	*Ameiurus catus*
Fish	Black bullhead	*Ameiurus melas*
Fish	Brown bullhead	*Ameiurus nebulosus*
Fish	Sacramento perch	*Archoplites interruptus*
Fish	Topsmelt	*Atherinops affinis*
Fish	Goldfish	*Carassius auratus auratus*
Fish	Sacramento sucker	*Catostomus occidentalis*
Fish	Pacific herring	*Clupea pallasii*
Fish	Prickly sculpin	*Cottus asper*
Fish	Red shiner	*Cyprinella lutrensis*
Fish	Common carp, Carp	*Cyprinus carpio carpio*
Fish	Threadfin shad	*Dorosoma petenense*
Fish	Northern Anchovy	*Engraulis mordax*
Fish	Northern pike	*Esox lucius*
Fish	Western mosquitofish	*Gambusia affinis*
Fish	Threespine Stickleback	*Gasterosteus aculeatus*
Fish	Thicktail chub	*Gila crassicauda*
Fish	California Roach	*Hesperoleucus symmetricus*
Fish	Wakasagi	*Hypomesus nipponensis*
Fish	Delta smelt	*Hypomesus transpacificus*
Fish	Tule perch	*Hysterocarpus traskii*
Fish	Channel catfish	*Ictalurus punctatus*
Fish	River lamprey	*Lampetra ayresii*
Fish	Pacific lamprey	*Entosphenus tridentatus*
Fish	Hitch	*Lavinia exilicauda*
Fish	Green sunfish	*Lepomis cyanellus*
Fish	Pumpkinseed	*Lepomis gibbosus*
Fish	Warmouth	*Lepomis gulosus*
Fish	Bluegill sunfish	*Lepomis macrochirus*
Fish	Redear sunfish	*Lepomis microlophus*
Fish	Pacific Staghorn Sculpin	*Leptocottus armatus*
Fish	Rainwater killifish	*Lucania parva*
Fish	Inland silverside	*Menidia beryllina*
Fish	Redeye bass	*Micropterus coosae*
Fish	Smallmouth bass	*Micropterus dolomieu*
Fish	Spotted bass	*Micropterus punctulatus*
Fish	Largemouth bass	*Micropterus salmoides*
Fish	Striped bass	*Morone saxatilis*
Fish	Hardhead	*Mylopharodon conocephalus*
Fish	Golden shiner	*Notemigonus crysoleucas*
Fish	Central Valley steelhead	*Oncorhynchus mykiss*
Fish	Rainbow Trout	*Oncorhynchus mykiss*
Fish	Steelhead	*Oncorhynchus mykiss*
Fish	Central Valley fall and late fall-run Chinook salmon	*Oncorhynchus tshawytscha*
Fish	Central Valley spring-run Chinook salmon	*Oncorhynchus tshawytscha*
Fish	Chinook salmon	*Oncorhynchus tshawytscha*
Fish	Sacramento River winter-run Chinook salmon	*Oncorhynchus tshawytscha*

Fish	Sacramento Blackfish	*Orthodon microlepidotus*
Fish	Bigscale logperch	*Percina macrolepida*
Fish	Fathead minnow	*Pimephales promelas*
Fish	Starry flounder	*Platichthys stellatus*
Fish	Sacramento splittail	*Pogonichthys macrolepidotus*
Fish	Whie crappie	*Pomoxis annularis*
Fish	Black crappie	*Pomoxis nigromaculatus*
Fish	Sacramento Pikeminnow	*Ptychocheilus grandis*
Fish	Longfin smelt	*Spirinchus thaleichthys*
Fish	Shokihaze goby	*Tridentiger barbatus*
Fish	Shimofuri goby	*Tridentiger bifasciatus*
Fish	Chameleon Goby	*Tridentiger trigonocephalus*
Mammals	Nelson's antelope ground squirrel	*Ammospermophilus nelsoni*
Mammals	Pronghorn	*Antilocapra americana*
Mammals	Ringtail	*Bassariscus astutus*
Mammals	Coyote	*Canis latrans*
Mammals	Beaver	*Castor canadensis*
Mammals	Tule elk	*Cervus canadensis nannodes*
Mammals	Townsend's big-eared bat	*Corynorhinus townsendii*
Mammals	Feral cat	*Felis domesticus*
Mammals	Black-tailed jackrabbit	*Lepus californicus*
Mammals	River otter	*Lontra canadensis*
Mammals	Bobcat	*Lynx rufus*
Mammals	House mouse	*Mus musculus*
Mammals	Long-tailed weasel	*Mustela frenata*
Mammals	Riparian woodrat	*Neotoma fuscipes riparia*
Mammals	Woodrat	*Neotoma* spp.
Mammals	Mule Deer	*Odocoileus hemionus*
Mammals	Muskrat	*Ondatra zibethicus*
Mammals	California ground squirrel	*Otospermophilus beecheyi*
Mammals	Raccoon	*Procyon lotor*
Mammals	Mountain lion	*Puma concolor*
Mammals	Norway rat	*Rattus norvegicus*
Mammals	Black rat	*Rattus rattus*
Mammals	Rat	*Rattus* spp.
Mammals	Salt marsh harvest mouse	*Reithrodontomys raviventris*
Mammals	Townsend's mole	*Scapanus townsendii*
Mammals	Suisun shrew	*Sorex ornatus sinuosus*
Mammals	Feral pig	*Sus scrofa*
Mammals	Riparian brush rabbit	*Sylvilagus bachmani riparius*
Mammals	Cottontail	*Sylvilagus* spp.
Mammals	American badger	*Taxidea taxus*
Mammals	Pocket gopher	*Thomomys* spp.
Mammals	California gray fox	*Urocyon cinereoargenteus*
Mammals	Grizzly	*Ursus arctos*
Mammals	San Joaquin kit fox	*Vulpes macrotis mutica*
Mammals	Red fox	*Vulpes vulpes*
Birds	Tricolored blackbird	*Agelaius tricolor*
Birds	Mallard	*Anas platyrhynchos*
Birds	Gadwall	*Anas strepera*
Birds	Western burrowing owl	*Athene cunicularia hypugaea*
Birds	Scaup	*Aythya spp.*
Birds	Red-tailed hawk	*Buteo jamaicensis*

Birds	Swainson's hawk	*Buteo swainsoni*
Birds	Sandpiper	*Calidris spp.*
Birds	Willet	*Catoptrophorus semipalmatus*
Birds	Western yellow-billed cuckoo	*Coccyzus americanus occidentalis*
Birds	California yellow warbler	*Dendroica petechia*
Birds	White-tailed kite	*Elanus leucurus*
Birds	American coot	*Fulica americana*
Birds	Loon	*Gavia spp.*
Birds	Common yellowthroat	*Geothlypis trichas*
Birds	Sandhill cranes	*Grus canadensis*
Birds	Greater sandhill crane	*Grus canadensis tabida*
Birds	Bald eagle	*Haliaetus leucocephalus*
Birds	Yellow-breasted chat	*Icteria virens*
Birds	Gull	*Larus spp.*
Birds	California black rail	*Laterallus jamaicensis coturniculus*
Birds	Godwit	*Limosa spp.*
Birds	Surf scoter	*Melanitta perspicillata*
Birds	Suisun song sparrow	*Melospiza melodia maxillaris*
Birds	Brown-headed cowbird	*Molothrus ater*
Birds	Cowbird	*Molothrus ater*
Birds	Osprey	*Pandion haliaetus*
Birds	House sparrow	*Passer domesticus*
Birds	California brown pelican	*Pelecanus occidentalis californicus*
Birds	Pelican	*Pelecanus spp.*
Birds	Cormorant	*Phalacrocorax spp.*
Birds	Ring-necked pheasant	*Phasianus colchicus*
Birds	California clapper rail	*Rallus longirostris obsoletus*
Birds	Bank swallow	*Riparia riparia*
Birds	California least tern	*Sternula antillarum browni*
Birds	European starling	*Sturna vulgaris*
Birds	Least Bell's vireo	*Vireo bellii pusillus*
Birds	Wilson's warbler	*Wilsonia pusilla*
Birds	Mourning dove	*Zenaida macroura*
Reptiles	Western pond turtle	*Actinemys (formerly Clemmys and Emys) marmorata*
Reptiles	California legless lizard	*Anniella pulchra*
Reptiles	Silvery legless lizard	*Anniella pulchra*
Reptiles	Glossy snake	*Arizona elegans*
Reptiles	Racer	*Coluber constrictor*
Reptiles	Blunt-nosed leopard lizard	*Gambelia silus*
Reptiles	San Joaquin whipsnake	*Masticophis flagellum ruddocki*
Reptiles	Alameda whipsnake	*Masticophis lateralis euryxanthus*
Reptiles	Coast horned lizard	*Phrynosoma coronatum*
Reptiles	Gopher snake	*Pituophis melanoleucus*
Reptiles	Western fence lizard	*Sceloporus occidentalis*
Reptiles	Giant garter snake	*Thamnophis gigas*
Reptiles	Red-eared slider	*Trachemys scripta elegans*
Reptiles	Common side-blotched lizard	*Uta stansburiana*
Amphibians	California tiger salamander	*Ambystoma californiense*
Amphibians	Bullfrog	*Rana catesbeiana*
Amphibians	California red-legged frog	*Rana draytonii*
Amphibians	Western spadefoot toad	*Spea hammondii*
Invertebrates	Copepod	*Acanthocyclops vernalis*

Invertebrates	Acanthomysis	*Acanthomysis bowmani*
Invertebrates	Lange's metalmark butterfly	*Apodemia mormo langei*
Invertebrates	Conservancy fairy shrimp	*Branchinecta conservatio*
Invertebrates	Longhorn fairy shrimp	*Branchinecta longiantenna*
Invertebrates	Vernal pool fairy shrimp	*Branchinecta lynchi*
Invertebrates	Midvalley fairy shrimp	*Branchinecta mesovallensis*
Invertebrates	Asian clam	*Corbicula fluminea*
Invertebrates	Overbite clam	*Corbula amurensis*
Invertebrates	Corophium	*Corophium* spp.
Invertebrates	Daphnia	*Daphnia parvula, Daphnia pulex*
Invertebrates	Valley elderberry longhorn beetle	*Desmocerus californicus dimorphus*
Invertebrates	Diaptomus	*Diaptomus* spp.
Invertebrates	Chinese mitten crab	*Eriocheir sinensis*
Invertebrates	Eurytemora	*Eurytemora affinis*
Invertebrates	Vernal pool tadpole shrimp	*Lepidurus packardi*
Invertebrates	Limnocalanus	*Limnocalanus macrurus*
Invertebrates	Limnoithona	*Limnoithona tetraspina*
Invertebrates	California linderiella	*Linderiella occidentalis*
Invertebrates	Neomysis	*Neomysis mercedis*
Invertebrates	Crayfish	e.g., *Procambarus clarkii, Astacoidea*
Invertebrates	Pseudodiaptomus	*Pseudodiaptomus forbesi*
Invertebrates	Callippe silverspot	*Speyeria callippe callippe*
Invertebrates	Giant flower-loving fly	*Thaphiomydas trochilus*
Plants	Cordgrass	*Spartina* spp.
Plants	Box elder	*Acer negundo*
Plants	Tree-of-heaven	*Ailanthus altissima*
Plants	Iodine bush	*Allenrolfea occidentalis*
Plants	Paper onion	*Allium amplectens*
Plants	White alder	*Alnus rhombifolia*
Plants	Red alder	*Alnus rubus*
Plants	Alder	*Alnus* spp.
Plants	Pacific foxtail	*Alopecurus saccatus*
Plants	Prostrate pigweed	*Amaranthus blitoides*
Plants	Grand redstem	*Ammania* spp.
Plants	Fiddleneck	*Amsinckia* spp.
Plants	Devil's-lettuce	*Amsinckia tessellata*
Plants	Blue-green algae	*Anabaena azollae*
Plants	Giant reed	*Arundo donax*
Plants	Alkali milk-vetch	*Astragalus tener var. tener*
Plants	Heartscale	*Atriplex cordulata*
Plants	Brittlescale	*Atriplex depressa*
Plants	San Joaquin spearscale	*Atriplex joaquiniana*
Plants	Lesser saltscale	*Atriplex minuscula*
Plants	Spearscale	*Atriplex triangularis*
Plants	Wild oats	*Avena* spp.
Plants	Floating water fern	*Azolla filiculoides*
Plants	Mule fat	*Baccharis salicifolia*
Plants	Harvest brodiaea	*Brodiaea coronaria*
Plants	California brome	*Bromus carinatus*
Plants	Ripgut brome	*Bromus diandrus*
Plants	Soft chess	*Bromus hordeaceus*
Plants	Red brome	*Bromus madritensis* ssp. *rubens*
Plants	Gold nugget	*Calochortus luteus*

Plants	Santa Barbara sedge	*Carex barbarae*
Plants	Sedge	*Carex* spp.
Plants	Succulent owl’s clover	*Castilleja campestris* ssp. *succulenta*
Plants	Yellow starthistle	*Centaurea solstitialis*
Plants	Buttonbush	*Cephalanthus occidentalis* var. *californicus*
Plants	Narrow-leaved soap plant	*Chlorogalum angustifolium*
Plants	Slough thistle	*Cirsium crassicaule*
Plants	Suisun thistle	*Cirsium hydrophilum var. hydrophilum*
Plants	Bull thistle	*Cirsium vulgare*
Plants	Elegant clarkia	*Clarkia unguiculata*
Plants	Poison hemlock	*Conium maculatum*
Plants	Soft bird's beak	*Cordylanthus mollis* ssp. *mollis*
Plants	Redosier dogwood	*Cornus sericea*
Plants	Pampas grass	*Cortaderia selloana*
Plants	Brass buttons	*Cotula coronopifolia*
Plants	California croton	*Croton californicus*
Plants	Swamp timothy	*Crypsis schoenoides*
Plants	Swamp grass	*Crypsis* spp.
Plants	Salt marsh dodder	*Cuscuta salina*
Plants	Bermuda grass	*Cynodon dactylon*
Plants	Flatsedges	*Cyperus* spp.
Plants	California hair-grass	*Deschampsia caespitosa*
Plants	Tufted hairgrass	*Deschampsia cespitosa*
Plants	Annual hairgrass	*Deschampsia danthonioides*
Plants	Blue dicks	*Dichelostemma capitatum*
Plants	Saltgrass	*Distichlis spicata*
Plants	Bristled downingia	*Downingia bicornuta var. bicornuta*
Plants	Dwarf downingia	*Downingia pusilla*
Plants	Downingia	*Downingia* spp.
Plants	barnyard grass	*Echinochloa crus-galli*
Plants	Burhead	*Echinodorus berteroi*
Plants	Brazilian waterweed	*Egeria densa*
Plants	Water hyacinth	*Eichhornia crassipes*
Plants	Russian olive	*Elaeagnus angustifolia*
Plants	Common spikerush	*Eleocharis macrostachya*
Plants	Blue wildrye	*Elymus glaucus*
Plants	Turkey mullein	*Eremocarpus setigerus*
Plants	Naked stem buckwheat	*Eriogonum nudum* var. *auriculatum*
Plants	Eared naked buckwheat	*Eriogonum nudum* var. *auriculatum*
Plants	Broadleaf filaree	*Erodium botrys*
Plants	Redstem filaree	*Erodium cicutarium*
Plants	Filarees	*Erodium* spp.
Plants	Delta button-celery	*Eryngium racemosum*
Plants	Coyote thistle	*Eryngium vaseyi*
Plants	Contra Costa wallflower	*Erysimum capitatum* var. *angustatum*
Plants	California poppy	*Eschscholzia californica*
Plants	Bluegum eucalyptus	*Eucalyptus globulus*
Plants	Tall fescue	*Festuca arundinacea*
Plants	Idaho fescue	*Festuca idahoensis*
Plants	Red fescue	*Festuca rubra*
Plants	Fig	*Ficus* spp.
Plants	Fennel	*Foeniculum vulgare*
Plants	Alkali heath	*Frankenia salina*

Plants	Oregon ash	*Fraxinus latifolia*
Plants	Low mannagrass	*Glyceria declinata*
Plants	Boggs Lake hedge-hyssop	*Gratiola heterosepala*
Plants	Grindelia	*Grindelia* spp.
Plants	Gum plant	*Grindelia stricta*
Plants	California matchweed	*Gutierrezia californica*
Plants	Barbgrass	*Hainardia cylindrical*
Plants	Telegraph weed	*Heterotheca grandiflora*
Plants	Wild mustard	*Hirschfeldia incana, Brassica nigra*
Plants	Meadow barley	*Hordeum brachyantherum*
Plants	Wild barley	*Hordeum spontaneum*
Plants	Carquinez goldenbush	*Isocoma arguta*
Plants	Hinds' walnut	*Juglans californica* var. *hindsii*
Plants	Walnut	*Juglans* spp.
Plants	Baltic rush	*Juncus balticus*

Plants	Eel grass	*Zostera marina*

Appendix C

Covered Species Evaluation

This page intentionally left blank.

Appendix C. Evaluation of Species Considered for Coverage

The table in this appendix presents results of the BDCP evaluation of 234 special-status species to identify species to be proposed for coverage under the BDCP. Species considered for BDCP coverage were limited to special-status species that are known or believed to occur in the vicinity of the Plan Area and, thus potentially occur within the Plan Area. Special-status species were defined as species that are:

- listed as threatened or endangered under the ESA;
- proposed or candidates for listing under ESA;
- listed as threatened or endangered under the California Endangered Species Act (CESA);
- candidates for listing under CESA;
- California species of special concern;
- California fully protected species;
- U.S. Fish and Wildlife Service (USFWS) birds of conservation concern;
- National Marine Fisheries Service (NMFS) species of concern;
- plants listed as rare under the California Native Plant Protection Act (NPPA); or
- plants included in the California Native Plant Society (CNPS) List 1A, 1B, or 2.

The evaluation process relied primarily on four criteria to determine which special-status species would be included on the list of species proposed for coverage under the BDCP. The selection criteria are as follows:

1. Listing status of the species.
2. Likelihood that the species is present in the Plan Area or other areas within the geographic scope.
3. Potential for the species to be adversely affected by BDCP covered activities, including the implementation of conservation measures.
4. Level of information available to determine potential impacts to species and to identify effective conservation measures.

Those species that meet all four of these criteria are proposed for coverage under the BDCP and these "covered species" are identified with a "Yes" in the column "Consider for Coverage?" in the table below. See Section 1.4.3, *Covered Species*, for a list of just the proposed covered species.

Scientific Name/ Common Name	*Status[A] (Federal/State/ CNPS)*	*Selection Criteria For Coverage[B]*				*Consider for Coverage?*	*Comments*
		Listing Potential	**Occurrence in the Plan Area**	**Potential to Adversely Affect[C]**	**Sufficient Information**		
Fish							
1. Sacramento perch *Archoplites interruptus*	-/-/-	-	-	-	+	No	This species has been extirpated from the Plan Area and, therefore, is not recommended for coverage.
2. Tule perch, Sacramento subspecies *(Hysterocarpus traskii traskii)*	-/SSC/-	-	+	+ (AD, H, ID, O)	+	No	This species is not recommended for coverage under the BDCP. It has no federal or state status and is not likely to be listed. They are very common in large tributaries of the Sacramento River (e.g., American and Feather Rivers) and, in the San Joaquin watershed, have a persisting population in the Stanislaus River. The species appears to be in long-term decline in the San Francisco Estuary.
3. Steelhead, Central Valley DPS *Oncorhynchus mykiss*	T/-/-	+	+	+ (AD, H, ID, O)	+	Yes	Meets all four criteria. Identified as a covered species in the BDCP Planning Agreement.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	Status[A] (Federal/State/ CNPS)	Selection Criteria For Coverage[B]				Consider for Coverage?	Coverage Comments
		Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information		
4. Chinook salmon, Sacramento River winter-run *Oncorhynchus tshawytscha*	E/E/-	+	+	+ (AD, H, ID, O)	+	Yes	Meets all four criteria. Identified as a covered species in the BDCP Planning Agreement.
5. Chinook salmon, Central Valley spring-run *Oncorhynchus tshawytscha*	T/T/-	+	+	+ (AD, H, ID, O)	+	Yes	Meets all four criteria. Identified as a covered species in the BDCP Planning Agreement.
6. Chinook salmon, Central Valley fall-/late fall-run *Oncorhynchus tshawytscha*	NSC /SSC/-	+	+	+ (ID, O)	+	Yes	Meets all four criteria. Identified as a covered species in the BDCP Planning Agreement.
7. Longfin smelt *Spirinchus thaleichthys*	-/T/-	+	+	+ (AD, H, ID, O)	+	Yes	Meets all four criteria. Identified as a covered species in the BDCP Planning Agreement.
8. Pacific smelt *Thaleichthys pacificus*	-[1]/SSC/-	+	U	U	+	No	This species is not recommended as a BDCP covered species. A 2007 petition to list the southern distinct population segment of pacific smelt under ESA[1] documented one source[2] reporting that the species may have been seen in the Sacramento River. However, numerous other available scientific sources[3] state that the species range does not include the Sacramento-San Joaquin River watersheds.
9. Delta smelt *Hypomesus transpacificus*	T/T/-	+	+	+ (AD, H, ID, O)	+	Yes	Meets all four criteria. Identified as a covered species in the BDCP Planning Agreement.
10. Hardhead *Mylopharadon conocephalus*	-/SSC/-	-	+	+ (AD, H, ID, O)	+	No	This species is not recommended for coverage under the BDCP. It has no federal or state status. The species is common throughout the Sacramento-San Joaquin watershed and is not likely to become listed. The species is widely distributed in foothill streams.
11. Sacramento splittail *Pogonichthys macrolepidotus*	-/SSC/-	+	+	+ (AD, H, ID, O)	+	Yes	Meets all four criteria. Identified as a covered species in the BDCP Planning Agreement.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	*Status*[A] *(Federal/State/ CNPS)*	*Selection Criteria For Coverage*[B] Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information	*Consider for Coverage?*	*Coverage Comments*
12. California roach, Sacramento-San Joaquin subspecies *Lavinia symmetricus* ssp. *symmetricus*	-/SSC/-	-	+	+ (AD, H, ID, O)	+	No	This species is not recommended for coverage under the BDCP. It has no federal or state status and is not likely to be listed. The subspecies is abundant in a large number of streams throughout the Sacramento-San Joaquin watershed, although it has been locally extirpated from many streams since 1970.
13. Hitch *Lavinia exilicauda*	-/SSC/-	-	+	+ (AD, H, ID, O)	+	No	This species is not recommended for coverage under the BDCP. It has no federal or state status and is not likely to be listed. The species has scattered populations throughout the Central Valley, from the Tulare Lake basin in the southern San Joaquin River drainage to the Shasta Reservoir in the northern Sacramento River drainage.
14. White sturgeon *Acipenser transmontanus*	-/-e/-		+	+ (AD, H, ID, O)	+	Yes	Meets all four criteria. Identified as a covered species in the BDCP Planning Agreement.
15. Green sturgeon *Acipenser medirostris*	T/SSC/- +	+	+	+ (AD, H, ID, O)	+	Yes	Meets all four criteria. Identified as a covered species in the BDCP Planning Agreement.
16. Pacific lamprey *Entosphenus tridentatus*	-/-/-		+	+ (AD, ID, O)	+	Yes	Meets all four criteria. Although this species has no regulatory or conservation status, it has a similar life history characteristics to those of the river lamprey and populations are in decline. Potential effects could occur through water operations and in-Delta conveyance construction.
17. River lamprey *Lampetra ayresii*	-/SSC/- +	+	+	+ (AD, ID, O)	+	Yes	Meets all four criteria. This species is a state species of concern. It is a covered species under the Butte County HCP.
Mammals							
1. American badger *Taxidea taxus*	-/SSC/-	-	+	+ (AD)	+	No	Although a special-status species that has experienced local declines in some areas of the state, there is no indication that it has experienced declines sufficient to warrant listing over the term of the BDCP. While there are no documented occurrences, this species could potentially occur in grassland habitats on and near the Stone Lakes National Wildlife Refuge and along the western edge of the Plan Area from Yolo County to San Joaquin County.
2. Ringtail *Bassariscus astutus*	-/FP/-	+	-	-	+	No	The ringtail is a state Fully Protected species. It is being considered for coverage under the South Sacramento County HCP and the Yolo HCP/NCCP. While the species is known to occur in dense riparian woodlands, the limited extent of riparian habitat in the Plan Area limits the potential for occurrence and the potential for affect. The possible exception is the Cosumnes River Preserve east of Interstate 5 that would not be affected by covered activities.
3. San Joaquin kit fox *Vulpes macrotis mutica*	E/T/-	+	+	+ (AD)	+	Yes	Meets all four criteria. There is potential for affect if this species is found to occur in the grassland habitats along the western edge of the Plan Area between approximately Brentwood and Clifton Court Forebay.
4. Riparian woodrat *Neotoma fuscipes riparia*	E/SSC, SA/-	+	U	U (ID/AD/H)	+	Yes	Though it does not meet all four criteria, due to this species' rarity and dependence on limited specialized habitat that is found in the Plan Area, it is proposed for coverage under the BDCP. In addition to being a state species of special concern, this species is also considered a Special Animal because it is included on the IUCN Red List as Critically Endangered. This species is also a covered species under the San Joaquin County HCP. This species is restricted to riparian habitats. While occurrence in the Plan Area is unknown, it is known to occur immediately adjacent to the Plan Area and there are patches of suitable habitat that potentially support this species.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	*Status[A] (Federal/State/ CNPS)*	*Selection Criteria For Coverage[B]*				*Consider for Coverage?*	*Coverage Comments*
		Listing Potential	**Occurrence in the Plan Area**	**Potential to Adversely Affect[C]**	**Sufficient Information**		
5. Salt marsh harvest mouse *Reithrodontomys raviventris*	E/E,FP/-	+	+	+ (H)	+	Yes	Meets all four criteria. This species is also being considered as a covered species in the Solano HCP/NCCP. This species is closely associated with tidal marsh habitats. It occurs in the western extreme of the Plan Area where restoration activities could affect occupied habitats.
6. San Joaquin pocket mouse *Perognathus inornatus inornatus*	-/SA/-		+	+ (ID, AD)	+	No	This species is considered a Special Animal by DFG because it is included on the IUCN Red List, under which it is designated as Least Concern. It has no legal or other conservation status. This species is a covered species under the San Joaquin County HCP. However, there is no other indication that this species would be listed during the timeframe of the plan and the potential for affecting this species is minimal. So, while this conflicts with the criteria that includes "…covered under permits by other HCPs in northern California", it is not considered for coverage. This species potentially occurs in grassland habitats on the western edge of the Plan Area where it could be affected by activities associates with conveyance construction.
7. Berkeley kangaroo rat *Dipodomys heermanni berkeleyensis*	- -/SA/-	+	-	-	+	No	This species is considered a Special Animal by DFG because it is included on the IUCN Red List, for which it is designated as Vulnerable. It has no legal or other conservation status. It is a covered species under the San Joaquin HCP. This species has a very limited distribution and is known primarily from short grass prairies west of the Plan Area. It is unlikely to occur in the Plan Area and would therefore not be subject to project impacts.
8. Riparian brush rabbit *Sylvilagus bachmani riparius*	E/E/-	+	+	+ (H, ID, AD)	+	Yes	Meets all four criteria. This species is restricted to riparian habitats that could potentially be affected by conveyance and restoration activities.
Big free-tailed bat *9. Nyctinomops macrotis*	-/SSC/-	+	-	-	+	No	In addition to being a state species of special concern, this species is designated as Moderate-High Priority by the Western Bat Working Group (WBWG). It is also designated as Least Concern on the IUCN Red List. This species has a very restricted distribution in the San Francisco Bay Area. Due to its status and restricted range, it is reasonable to assume that this species could become listed over the term of the BDCP. The range of this species does not extend into or near the Plan Area and thus would not be affected by covered activities.
10. Western mastiff bat *Eumopsperotis californicus*	-/SSC/-	+	+	-	+	No	In addition to being a state species of special concern, this species is also included on the IUCN Red List as Least Concern and is designated as High Priority by WBWG. It is reasonable to conclude that this species could be listed over the term of the BDCP. It is not being considered for coverage under any other overlapping HCP/NCCPs. This colonial species uses caves and rock outcrops for roosting. Thus, while the species could potentially occur in the Plan Area for foraging, because the area lacks suitable roosting habitat, there is no potential to adversely affect this species.
11. Pallid bat *Antrozous pallidus*	-/SSC/-	-	+	+ (ID/AD)	+	No	In addition to being a state species of special concern, this species is also included on the IUCN Red List as Least Concern and is designated as High Priority by WBWG. While declines of this species have been reported, the pallid bat is widespread throughout California. There are insufficient data to indicate that listing of this species would be warranted over the term of the BDCP. This widely distributed species roosts in small colonies in caves, rock crevices, and tree hollows, but will also use bridges and buildings. Potential to adversely affect is based on the potential for removal of occupied trees, buildings, and bridges.
12. Yuma Myotis bat *Myotis yumanensis*	-/SA/-		+	+ (ID/AD)	+	No	This species is considered a Special Animal by DFG because it is included on the IUCN Red List, for which it is designated as Least Concern, and on the WBWG list, for which it is designated as Low-Medium Priority. It has no legal or other conservation status. There is no indication that it would be listed over the term of the BDCPover the term of the BDCP. This species is being considered as a covered species in the South Sacramento HCP. It is widely distributed and so likely occurs in Plan Area, but the limited extent of riparian forests suggests that there are few areas where roosting or maternity colonies are possible. The species more likely occurs during feeding and during migration. Potential to adversely affect based on the limited potential for removing occupied trees.

-

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	*Status[A] (Federal/State/ CNPS)*	*Selection Criteria For Coverage[B]*				*Consider for Coverage?*	*Coverage Comments*
		Listing Potential	**Occurrence in the Plan Area**	**Potential to Adversely Affect[C]**	**Sufficient Information**		
13. Silver-haired bat *Lasionycteris noctivagans*	-/SA/-		+	+ (ID/AD)	+	No	This species is considered a Special Animal by DFG because it is included on the IUCN Red List, for which it is designated as Least Concern, and on the WBWG list, for which it is designated as Medium Priority. It has no legal or other conservation status. There is no indication that it would be listed over the term of the BDCP. It is not a covered species under any of the overlapping permitted or in-process HCPs/NCCPs. Typically a higher elevation forest-dwelling species, it can occur in mature riparian forests in the Central Valley; however, the limited extent of riparian forests in the Plan Area may be insufficient to support this species, at least in abundance. The species more likely occurs during feeding and during migration. Potential to adversely affect is based on the unlikely possibility of removing active roosting or maternity sites in riparian habitat.
14. Western red bat *Lasiurus blossevillii*	- -/SSC/-	-	+	+ (ID/AD)	+	No	In addition to being a state species of special concern, this species is also designated as High Priority by WBWG. It is reasonable to conclude that this species could become listed over the term of the BDCP. It is also being considered as a covered species in the South Sacramento HCP and the Yolo HCP/NCCP. This species roosts in trees and is usually solitary. In the Plan Area, potentially occupied habitat includes mature riparian – usually cottonwood/sycamore riparian woodland. Potential to affect based on the potential for removal of active roost trees. While declines of this species have been reported, the red bat is widespread throughout California. There are insufficient data to indicate that listing of this species would be warranted over the term of the BDCP.
15. Hoary bat *Lasiurus cinereus*	-/SA/-		+	+ (ID/AD)	+	No	This species is considered a Special Animal by DFG because it is included on the IUCN Red List, for which it is designated as Least Concern, and on the WBWG list, for which it is designated as Medium Priority. It has no legal or other conservation status. There is no indication that it would be listed over the term of the BDCP. It is not a covered species under any of the overlapping permitted or in-process HCPs/NCCPs. This is a solitary bat that does not nest or roost colonially. It ranges widely, but populations in the Central Valley are most likely non-reproductive or migratory. Roosts in large trees in mature riparian – usually cottonwood/sycamore, which is limited in study area. Potential to affect based on the potential for removal of active roost trees.
16. Townsend's big-eared bat *Corynorhinus townsendii*	- -/SSC/-	+	+	+ (ID/AD)	+	Yes	Meets all four criteria. In addition to being a state species of special concern, this species is also included on the IUCN Red List as Vulnerable and is designated as High Priority by WBWG. It is reasonable to conclude that this species could be listed over the term of the BDCP. It is also included as a covered species in the East Contra Costa HCP/NCCP and is being considered for coverage under the Yolo HCP/NCCP. This is a highly colonial bat that typically occupies natural caves; however, it is also known to colonize old structures such as barns. It is widely distributed throughout most of California and while there are no known roosts or maternity sites from the Plan Area, there is potential for use of old barns and other structures.
17. Suisun shrew *Sorex ornatus sinuosus*	-/SSC/-	+	+	+ (H)	+	Yes	Meets all four criteria. This species is also being considered as a covered species in the Solano HCP/NCCP. This species is closely associated with tidal marsh habitats and could potentially be listed in the future. It occurs in the western extreme of the Plan Area where restoration activities could affect occupied habitats.
Birds							
1. Yellow-headed blackbird *Xanthocephalus xanthocephalus*	-/SSC/-	-	+	+ (H, AD)	+	No	Priority 3 as a state species of special concern with relatively stable populations since 1980. Not covered or considered for coverage on other overlapping HCP/NCCPs. Potentially affected from removal of occupied breeding habitat associated with conveyance and restoration activities, but not sufficient to adversely affect the species.
2. Tricolored blackbird *Agelaius tricolor*	BCC/SSC/-	+	+	+ (H, AD, ID)	+	Yes	Meets all four criteria. Significant and dramatic population declines and covered or considered for coverage under all overlapping HCP/NCCPs. Potential adverse effects from removal or disturbance to occupied breeding sites associated with conveyance and restoration activities.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	*Status[A] (Federal/State/ CNPS)*	*Selection Criteria For Coverage[B]*				*Consider for Coverage?*	*Coverage Comments*
		Listing Potential	**Occurrence in the Plan Area**	**Potential to Adversely Affect[C]**	**Sufficient Information**		
3. Grasshopper sparrow *Ammodramus savannarum*	-/SSC/-	-	+	+ (AD, ID, H)	+	No	While population declines are reported, the population trend data is unreliable and insufficient to indicate that a listing would be warranted over the term of the BDCP. Also being considered for coverage in the Yolo HCP/NCCP. Breeding has been documented at Cosumnes River and Yolo Bypass. Potential adverse effects from conveyance construction and possibly from restoration activities in the Yolo Basin.
4. Bell's sage sparrow *Amphispiza belli belli*	BCC/SA/-	-	-	-	+	No	This species is a former state species of special concern and currently remains on the DFG Watch List. It is also designated as Least Concern on the IUCN Red List. There is no indication that this species would become listed over the term of the BDCP. This species occurs in chaparral habitats and is not known to occur in the Plan Area. Therefore, covered activities are not expected to adversely affect this species.
5. Song sparrow "Modesto"*Melospiza melodia*	-/SSC/-	-	+	+ (H)	+	No	Because it is a Priority 3 state species of special concern, it is not covered by any other overlapping HCP/NCCPs, and because there is ongoing debate regarding whether this population is a valid subspecies, there is no indication that it would become listed over the term of the BDCP. In addition, while it could be affected – particularly associated with restoration actions – this species may benefit from restoration activities in the long term.
6. Suisun song sparrow *Melospiza melodia maxillaris*	BCC/SSC/-	+	+	+	+	Yes	Meets all four criteria. This species is also being considered as a covered species in the Solano HCP/NCCP. This species is closely associated with tidal marsh habitats and has a restricted distribution within the Delta and Suisun Marsh. It could potentially be listed over the term of the BDCP. It occurs in the western extreme of the Plan Area and Suisun Marsh where restoration activities could affect occupied habitats.
Samuels (San Pablo) *7.* song sparrow *Melospiza melodia samuelis*	BCC/SSC/-	+	-	-	+	No	This species' range does not extend into the Plan Area and thus would not be affected by project actions.
8. California yellow warbler *Dendroica petechia*	-/SCC/-	+	+	-	+	No	Populations of this species continue to trend downward. It is a covered species in the San Joaquin County HCP. It is reasonable to suggest that this species would become listed over the term of the BDCP. The species does not nest within the Plan Area, but can be observed during migration. There is also limited potential for nesting, particularly on portions of the Cosumnes River Preserve, but these areas are not expected to be affected by covered activities.
9. Yellow-breasted chat *Icteria viriens*	-/SSC/-	+	+	+ (H, AD, ID)	+	Yes	Meets all four criteria. Negative population trend since 1980. Also covered under the San Joaquin HCP and considered for coverage under the Solano and Yolo HCP/NCCPs and the South Sacramento County HCP. It is reasonable to suggest that this species would become listed over the term of the BDCP. This species occurs in riparian habitat and could be affected by conveyance and possibly restoration activities.
10. Salt Marsh Common Yellowthroat *Geothlypis trichas sinuosa*	BCC/SSC/-	+	-	-	+	No	This species' range does not extend into the Plan Area and thus would not be affected by project actions.
11. Purple martin *Progne subis*	-/SSC/-	+	+	-	+	No	This species is considered extirpated from the Plan Area, but birds that nest in the Sacramento urban area may occasionally occur in the Plan Area. Due to substantial population declines since the 1960s, it is reasonable to suggest that this species could become listed over the term of the BDCP. It is being considered for coverage under the Yolo HCP/NCCP. Because the species does not nest within the Plan Area with the exception of the Sacramento urban area, and is absent from the Central Valley; and because major riparian corridors would be avoided through tunneling, covered activities are not expected to adversely affect this species.
12. Bank swallow *Riparia riparia*	-/T/-	+	+	-	+	No	Possibility for nesting colonies along the Sacramento River near Fremont Weir. This species is covered in the San Joaquin and Natomas Basin HCPs, and is considered for coverage in the Yolo HCP/NCCP. However, BDCP activities are not expected to disturb potential habitat.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	*Status[A] (Federal/State/ CNPS)*	*Selection Criteria For Coverage[B]* Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information	*Consider for Coverage?*	*Coverage Comments*
13. California horned lark *Eremophila alpestris actia*	-/SA/-	-	+	-	+	No	This species is on the DFG Watch List and is designated as Least Concern on the IUCN Red List. It is not covered under any overlapping HCP/NCCPs. There is no indication that it would become listed over the term of the BDCP. This is a relatively common species and is considered an agricultural pest.
14. Least Bell's vireo *Vireo bellii pusillus*	SE/FE/-	+	+	+	+	Yes	Meets all four criteria. Two individual male least Bell's vireo spent the spring and summer of 2010 within the Plan Area in the Yolo Bypass Wildlife Area singing and attempting to attract mates. This increases the likelihood of individuals returning to the Plan Area in subsequent years and perhaps establishing a breeding pair over the term of the BDCP. The potential for the project to affect this species also increases with these new occurrences.
15. Loggerhead shrike *Lanius ludovicianus*	BCC/SSC/-	-	+	+ (H, AD, ID)	+	No	While somewhat stabilized recently, significant negative population trend since 1968. Also a covered species under the San Joaquin HCP and Natomas Basin HCP and considered for coverage in the South Sacramento County HCP and Yolo County HCP/NCCP. This species potentially occurs throughout the Plan Area and could be affected by conveyance and possibly restoration activities. However, it is unlikely that the species would become listed during the time period that covered activities that could affect the species would be implemented.
16. Lewis's woodpecker *Melanerpes lewis*	BCC/SA/-	-	+	+	+	No	This species is designated as Least Priority on the IUCN Red List. There is no indication that it would become listed over the term of the BDCP.
17. Western burrowing owl *Athene cunicularia hypugaea*	BCC/SSC/-	+	+	+ (AD, ID, H)	+	Yes	Meets all four criteria. This species is a covered species under all overlapping HCP/NCCPs. Burrowing owls could potentially be affected from removal of grassland and pastureland habitats associated with conveyance activities, and possibly restoration activities in the Yolo Basin.
18. Long-eared owl *Asio otus*	-/SSC/-	-	+	+ (H, AD, ID)	+	No	This species has been a state species of special concern since 1978. Its range includes all of California with the exception of much of the Central Valley. There is little recent reliable data on the abundance of this species and insufficient data to indicate that a listing is warranted over the term of the BDCP. Although there are no recently reported occurrences of this species from the plan area, long-eared owl could potentially be affected from removal of riparian woodland and grassland/seasonal wetland habitats associated with conveyance and restoration activities.
19. Short-eared owl *Asio flammeus*	-/SSC/-	-	+	+ (H, AD)	+	No	This species has been a state species of special concern since 1978. While local population declines have been reported, there is insufficient data on statewide populations to indicate that a listing would be warranted over the term of the BDCP.
20. Western yellow-billed cuckoo *Coccyzus americanus occidentalis*	C,BCC /E/-	+	+	-	+	Yes	Though it does not meet all four criteria, due to this species' rarity and dependence on limited specialized habitat that is found in the Plan Area, it is proposed for coverage under the BDCP. This species has been observed within the Plan Area during migration in riparian patches too small to support breeding habitat, but that can still serve as migratory corridors. Potential breeding habitat for cuckoos in the Plan Area is restricted to the Cosumnes River Preserve, which would not be affected by covered activities. Riparian restoration actions under the BDCP could allow the re-establishment of sufficiently large areas of riparian habitat that will permit the re-colonization of the Plan Area by breeding cuckoos.
21. California gull *Larus californicus*	-/SA/-		+	+ (H)	+	No	This species is a former state species of special concern and remains on the DFG Watch List. It is also designated as a Least Concern species on the IUCN Red List. No other overlapping HCP/NCCPs include this species as a covered species. There is no indication that this species would become listed over the term of the BDCP. There are no California gull breeding colonies within the Plan Area with the possible exception of small colonies in the far western end of the Plan Area that could be affected by restoration activities.

-

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	*Status[A] (Federal/State/ CNPS)*	*Selection Criteria For Coverage[B]*				*Consider for Coverage?*	*Coverage Comments*
		Listing Potential	**Occurrence in the Plan Area**	**Potential to Adversely Affect[C]**	**Sufficient Information**		
22. Black tern *Chlidonias niger*	-/SSC/-	-	+	+ (H)	+	No	This species was recently designated a state species of special concern and is a proposed covered species under the yolo County HCP/NCCP. While local population declines have been reported, particularly from the Central Valley, there is no indication that listing of this species would be warranted over the term of the BDCP. This species has been documented in the Yolo Basin, where it is associated with rice fields. The effects of covered activities on this species are expected to be minimal.
23. California least tern *Sterna antillarum browni*	E/E,FP/-	+	+	+ (H)	+	Yes	Meets all four criteria. This species occurs in discrete locations within the Plan Area in small breeding colonies. Habitat restoration actions could attract or affect nesting terns.
24. Long-billed curlew *Numenius americanus*	BCC/SA/-	-	+	+ (H, AD)	+	No	This species is a former state species of special concern and remains on the DFG Watch List. It is also a federal bird of conservation concern. There is no indication that this species would become listed over the term of the BDCP. Curlews only winter in the Plan Area and thus effects would be limited to temporary displacement from winter foraging habitats and possibly loss of winter foraging habitats from conveyance construction and restoration activities.
25. Snowy plover (interior population) *Charadrius alexandrinus*	BCC/SSC/-	+	+	-	+	No	The range of the inland population of the snowy plover includes a small portion of the Plan Area in the Yolo Basin. This population is a state species of special concern and a federal bird of conservation concern. It is reasonable to suggest that this population (along with the coastal population that is currently federally listed) could become listed over the term of the BDCP. There are few breeding records of this species from the Yolo Bypass Wildlife Area, but none from anywhere else in the Plan Area. Potential effects would be limited to restoration activities planned for the Yolo Basin. It is assumed that this site would be protected from impacts resulting from restoration activities, and that the project would be unlikely to adversely affect this species.
26. Snowy plover (coastal population) *Charadrius alexandrinus*	T/-/-	+	-	-	+	No	The coastal population of snowy plover is federally listed but has no state status. This population occurs primarily along the coast and none of the recovery units, which generally define the range of the species, occur within the Plan Area. Thus, this population does not occur in the Plan Area and would not be affected by covered activities.
27. Mountain plover *Charadrius montanu*	BCC/SSC/-	-	+	+ (H, AD)	+	No	In addition to being a state species of special concern and federal bird of conservation concern, the mountain plover is also designated as Vulnerable on the IUCN Red List. The species is being considered as a covered species on the Solano County and Yolo County HCP/NCCPs. There is no indication that the species would become federally listed over the term of the BDCP, and since the species only winters in California, it is unlikely that the species would become state listed. Mountain plovers do not breed in California, but the species has been reported during winter at several sites in Yolo and Solano Counties, including occasional occurrences in the Yolo Basin. However, given that the species only winters in a small portion of the Plan Area, potential impacts are limited to temporary displacement during winter foraging, and thus covered activities are not expected to affect this species.
28. Lesser sandhill crane *Grus canadensis canadensis*	-/SSC/-	-	+	+ (H, AD, ID)	+	No	This species was recently designated a state species of special concern. While there is concern that agricultural conversions could continue to reduce habitat for this species, the range size and population trend have remained fairly stable and there is no indication that the species would become listed over the term of the BDCP. This species does not nest in the Plan Area, but the Plan Area encompasses the majority of the traditional winter range of this species in the Delta. It occurs in seasonal wetland and agricultural habitats where it roosts and forages. Potential effects include displacement of foraging habitats from conveyance and restoration activities.
29. Greater sandhill crane *Grus canadensis tabida*	-/T,FP/-	+	+	+ (H, AD, ID)	+	Yes	Meets all four criteria. This species is also a covered species in the Natomas and San Joaquin HCPs and is being considered for coverage in the South Sacramento HCP. This species does not nest in the Plan Area, but the Plan Area encompasses the majority of the traditional winter range of this species in the Delta. It occurs in seasonal wetland and agricultural habitats where it roosts and forages. Potential effects include displacement and possible removal of roosting and foraging habitats from conveyance and restoration activities.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	Status[A] (Federal/State/ CNPS)	Selection Criteria For Coverage[B]: Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information	Consider for Coverage?	Coverage Comments
30. California black rail *Laterallus jamaicensis coturniculus*	BCC /T,FP/-	+	+	+ (H, ID, AD)	+	Yes	Meets all four criteria. This species is also being considered as a covered species in the Solano HCP/NCCP, and is a covered species in the San Joaquin County HCP. This species is closely associated with tidal marsh habitats. It occurs throughout the Western and Central Delta and could be affected by conveyance and restoration activities.
31. California clapper rail *Rallus longirostris obsoletus*	E/E,FP/-	+	+	+ (H)	+	Yes	Meets all four criteria. This species is also being considered as a covered species in the Solano HCP/NCCP. This species is closely associated with tidal marsh habitats. It occurs in the western extreme of the Plan Area where restoration activities could affect occupied habitats.
32. Merlin *Falco columbarius*	-/SA/-	-	+	-	+	No	The merlin is a former state species of special concern and currently remains on the DFG Watch List. It is also designated as Least Concern on the IUCN Red List. It is being considered for coverage in the South Sacramento HCP; however, the species has no state or federal status and there is no indication that the species would become listed over the term of the BDCP. The merlin does not nest in California. It is observed occasionally during winter in the Plan Area. Potential affects would be limited to temporary displacement from foraging habitat during project construction. It is therefore not expected to be adversely affected by the project.
33. American Peregrine Falcon *Falco peregrinus anatum*	BCC/E,FP/-	+	+	-	+	No	The peregrine falcon was recently delisted by the USFWS. It remains state endangered and fully protected; and is a federal bird of conservation concern. It is a covered species in the Natomas Basin HCP, and is being considered for coverage in the Yolo HCP/NCCP and South Sacramento County HCP. This species does not nest within or near the Plan Area. It is occasionally observed foraging in the Plan Area during the winter. Potential affects are limited to temporary displacement of foraging individuals during winter. Thus, the project is not expected to adversely affect this species.
34. Prairie falcon *Falco mexicanus*	BCC/SA/-	-	+	-	+	No	The prairie falcon is a former state species of special concern and currently remains on the DFG Watch List. It is also a federal Bird of Conservation Concern and is designated Least Concern on the IUCN Red List. It is a covered species in the San Joaquin HCP probably a result of its previous status as a species of special concern. The prairie falcon does not nest in the Plan Area. It is, however, occasionally observed foraging in the Plan Area, mostly during the winter. Potential affects are limited to possible temporary displacement from foraging areas during covered activities. It is therefore not expected to be adversely affected by the project.
35. Bald eagle *Haliaeetus leucocephalus*	-/E,FP/-	+	+	-	+	No	The bald eagle was recently delisted by the USFWS and currently has no federal status. It remains a state endangered species and state fully protected species. The species is being considered for coverage under the South Sacramento County HCP. However, there are several traditional use areas in the south Sacramento County Plan Area (primarily the upper American River) and an important winter use area and one nest location in the Yolo County Plan Area. This species does not nest in the Plan Area. It is occasionally observed foraging in the Plan Area during the winter, but there are no traditionally used bald eagle roosts or winter foraging habitats in the Plan Area, with the possible exception of a portion of the Cosumnes River Preserve that would not be affected by project actions. Thus, covered activities are not expected to adversely affect this species.
36. Northern harrier *Circus cyaneus*	-/SSC/-	-	+	+ (H, ID, AD)	+	No	This is a covered species under the San Joaquin HCP and is being considered for coverage under the Yolo HCP/NCCP, Solano HCP/NCCP, and South Sacramento HCP. This species occurs throughout the Plan Area and could be affected by conveyance and restoration activities. While declines of this species have been documented, it remains widespread throughout California and is unlikely to become listed over the term of the BDCP.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	Status[A] (Federal/State/ CNPS)	Selection Criteria For Coverage[B]				Consider for Coverage?	Coverage Comments
		Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information		
37. Sharp-shinned Hawk *Accipiter striatus*	-/SA/-	-	+	-	+	No	This species was formerly a state species of concern, but was removed from that list and is currently on DFG's Watch List. It is also designated as a Least Concern species on the IUCN Red List. It is a covered species in the San Joaquin County HCP. It is also currently considered for coverage under the South Sacramento HCP and the Solano HCP/NCCP. While it may be a covered species in other HCP/NCCPs that overlap the Plan Area, there is no indication that this species would become listed over the term of the BDCP. This species only winters in the Plan Area and so would not be affected by covered activities.
38. Cooper's Hawk *Accipiter cooperii*	-/SA/-		+	+ (ID, AD)	+	No	This species was formerly a state species of special concern, but was removed from that list and is currently on DFG's Watch List. It is also designated as a Least Concern species on the IUCN Red List. It is a covered species in the San Joaquin County HCP. It is also currently considered for coverage under the South Sacramento HCP and the Solano HCP/NCCP. While it may be a covered species in other HCP/NCCPs that overlap the Plan Area, there is no indication that this species would become listed over the term of the BDCP. This species occurs in riparian and other woodland habitats and could be affected by conveyance or restoration activities.
39. White-tailed kite *Elanus leucurus*	-/FP/-	+	+	+ (H, ID, AD)	+	Yes	Meets all four criteria. The white-tailed kite is a state Fully Protected species. It is also being considered for coverage under the South Sacramento County HCP and the Yolo HCP/NCCP. The kite occurs in riparian and other woodland habitats and could be affected through conveyance or restoration activities that remove trees or disturb active nests.
40. Swainson's hawk *Buteo swainsoni*	BCC /T/-	+	+	+ (H, ID, AD)	+	Yes	Meets all four criteria. Swainson's hawk is a covered species or is being considered for coverage in all overlapping HCPs/NCCPs. Swainson's hawks nest in riparian woodlands, roadside trees, tree rows, isolated trees, woodlots, and trees in farmyards and rural residences. They forage in grasslands and agricultural fields. Nest sites and foraging habitat would be affected by conveyance facilities and possibly by restoration activities.
41. Ferruginous hawk *Buteo regalis*	BCC/SA/-	-	+	-	+	No	The ferruginous hawk is a former state species of special concern and remains on the DFG Watch List. It is also a federal bird species of conservation concern and is designated as Near Threatened on the IUCN Red List. The species does not breed in California and only winters in relatively small numbers in the Plan Area. There is no indication that the species would become listed over the term of the BDCP. It is being considered as a covered species in the South Sacramento HCP, but was initially considered due to its former status as a state species of special concern. Because this species only winters in the Plan Area, it is not expected to be affected by covered activities.
42. Golden eagle *Aquina chrysaetos*	BCC/FP/-	+	+	-	+	No	The golden eagle is a state Fully Protected species. The species was formerly a state species of concern, but was removed from that list and is currently on DFG's Watch List. It is also designated as a Least Concern species on the IUCN Red List and is a federal Bird of Conservation Concern. The East Contra Costa HCP/NCCP and San Joaquin HCP both include the golden eagle as a covered species, and the Solano and Yolo HCP/NCCPs and the Sacramento HCP are considered the species for coverage. However, each of these plans includes Plan Areas that could support nesting golden eagles. Golden eagles do not currently and are not expected to nest within the Plan Area. While they may forage occasionally in the Plan Area, affects would be limited to temporary displacement of foraging birds. Thus, the species is not likely to be adversely affected by covered activities.
43. Osprey *Pandion haliaetus*	-/SA/-	-	+	-	+	No	The osprey is a former state species of special concern and remains on the DFG Watch List. It is also included on the IUCN Red List, for which it is designated as Least Concern. While there are occasional wintering occurrences, the species is not known to nest in the Plan Area. The species is a covered species in the San Joaquin County HCP. Ospreys would typically be found roosting in riparian areas or trees or artificial structures around water bodies. Because it is not expected to nest in the Plan Area, affects are limited to displacement of foraging birds. Thus, covered activities are not expected to adversely affect this species.
44. Cackling (Aleutian Canada) goose *Branta hutchinsii leucopareia*	-/SA/-		+	+ (H)	+	No	This species was delisted by the USFWS. It remains on the DFG Special Animal list but has no status designation. There is no indication that this species would become listed over the term of the BDCP. It is not covered in any other neighboring HCP/NCCP except San Joaquin HCP due to its previous listing. Winters in the Yolo Basin and various locations in the Delta and could potentially be affected by restoration activities.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	Status[A] (Federal/State/ CNPS)	Selection Criteria For Coverage[B]				Consider for Coverage?	Coverage Comments
		Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information		
45. Tule white-fronted goose (wintering) *Anser albifrons elgasi*	-/SSC/-	-	+	+ (H)	+	No	Although this is a species of special concern, it is also a species closely managed by DFG on its wintering grounds. There is no indication that this species would become listed over the term of the BDCP. This species only winters in California where it relies on dense tule-cattail marsh habitat. It has been documented within the Plan Area west of Sherman Island and in various locations in the Suisun Marsh. It could potentially be affected by restoration activities, but because the species occurs only during the winter, impacts can be avoided. Also, in the long term the species would benefit from these activities.
46. Redhead (nesting) *Aythya Americana*	-/SSC/-	-	+	+ (H)	+	No	This species has declined throughout much of its range in California in recent years. Restricted primarily to state and federal refuges, restoration activities in these areas have failed to restore deep water habitats required by redhead. However, this species would likely respond to changes in refuge management and thus there is no indication that it would become listed over the term of the BDCP. It is not covered or being considered for coverage in other overlapping HCPs/NCCPs. This species breeds in the Yolo Bypass. It could be affected by restoration activities occurring in the Yolo Bypass.
47. White-faced Ibis *Plegadis chihi*	-/SA/-		+	+ (H, ID, AD)	+	No	White-faced ibis *rookeries* are considered sensitive colonial breeding sites for this species and are thus included on the DFG Special Animals list. The species is also included on the DFG Watch List and on the IUCN Red List, where it is designated Least Concern. The San Joaquin County HCP and the Natomas Basin HCP include this species as a covered species; and the South Sacramento HCP is considering the species for coverage. However, this species was recently removed from the state bird species of special concern list due to significantly increased populations and there is no indication that this species would be listed over the term of the BDCP. It is therefore not recommended for coverage. White-faced ibis rookeries could occur in emergent marsh habitats and could be affected by conveyance and restoration activities.
48. Snowy Egret *Egretta thula*	-/SA/-		+	+ (H, ID, AD)	+	No	Snowy egret *rookeries* are considered sensitive colonial breeding sites for this species and are thus included on the DFG Special Animals list. They are also included on the DFG Watch List and on the IUCN Red List, where it is designated as Least Concern. The San Joaquin County HCP includes this species as a covered species; however, there is no indication that this species would be listed over the term of the BDCP and so is not recommended for coverage. Snowy egret rookeries could occur in riparian habitat or other woodland habitats or in emergent marsh habitats, and could be affected by conveyance and restoration activities.
49. Least bittern (nesting)*Ixobrychus exilis*	-/SSC/-	-	+	+ (H, ID, AD)	+	No	This species has been documented more regularly in recent years, and while possibly attributed to an increase in observer coverage, information on population trends are unreliable. While this species has declined as a result of loss of freshwater marsh habitats, there is no indication that a listing of this species would be warranted over the term of the BDCP. This species occurs in fresh water marsh habitats in the Yolo Bypass, east of the Sacramento River, and in the western Delta. It could be affected by restoration and conveyance activities.
50. Great egret *Ardea albus* (rookery)	-/SA/-		+	+ (H, ID, AD)	+	No	Great egret *rookeries* are considered sensitive colonial breeding sites for this species and are thus included on the DFG Special Animals list. It is also included on the IUCN Red List, where it is designated as Least Concern. The San Joaquin County HCP includes this species as a covered species; however, there is no indication that this species would be listed over the term of the BDCP and so is not recommended for coverage. Rookeries could occur in riparian habitat or in other woodland habitats, including eucalyptus groves in the Plan Area, and could be affected by conveyance and restoration activities.
51. Black-crowned night heron *Nycticorax nycticoraxs*	-/SA/-		+	+ (H, ID, AD)	+	No	Black-crown night heron *rookeries* are considered sensitive colonial breeding sites for this species and are thus included on the DFG Special Animals list. It is also included on the IUCN Red List, where it is designated as Least Concern. The San Joaquin County HCP includes this species as a covered species; however, there is no indication that this species would be listed over the term of the BDCP and so is not recommended for coverage. Black-crowned night heron rookeries could occur in riparian habitat or other woodland habitats or in emergent marsh habitats, and could be affected by conveyance and restoration activities.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	Status[A] (Federal/State/ CNPS)	Selection Criteria For Coverage[B]				Consider for Coverage?	Coverage Comments
		Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information		
52. Great blue heron *Ardea herodias* (rookery)	-/SA/-		+	+ (H, ID, AD)	+	No	Great blue heron *rookeries* are considered sensitive colonial breeding sites for this species and are thus included on the DFG Special Animals list. It is also included on the IUCN Red List, where it is designated as Least Concern. The San Joaquin County HCP includes this species as a covered species; however, there is no indication that this species would be listed over the term of the BDCP and so is not recommended for coverage. Rookeries could occur in riparian habitat or in other woodland habitats, including eucalyptus groves in the Plan Area, and could be affected by conveyance and restoration activities.
53. Double-crested cormorant *Phalacrocorax auritus*	- -/SA/-		+	+ (H, ID, AD)	+	No	Double-crested cormorant is a former state species of special concern; however, only *rookeries* were considered sensitive. It remains on DFG's Special Animals list as a Watch List species, which includes primarily delisted species or species that do not meet the criteria as a species of special concern. It is also is included on the IUCN Red List, where it is designated as Least Concern. The species has no legal or other conservation status. This is a covered species under the San Joaquin County HCP. There is no indication that this species is likely to be listed over the term of the BDCP. This species potentially nests in small rookeries in riparian habitats or some artificial structures in the Plan Area and could be affected by conveyance and restoration activities.
54. Western grebe *Aechmophorus occidentalis*	- -/-/-		+	+ (ID)	+	No	Western grebe has no legal or conservation status. The San Joaquin County HCP includes it as a covered species and it is on the IUCN Red List designated as a species of Least Concern. While there have been concerns regarding the status of breeding populations, there is no indication that the species would become listed over the term of the BDCP. There is one known breeding location in the Plan Area – within the Bouldin Island quadrangle, which could potentially be affected by the in-Delta conveyance activities; but otherwise it occurs mainly during the winter.
Reptiles							
1. Giant garter snake *Thamnophis gigas*	T/T/-	+	+	+ (H, ID, AD)	+	Yes	Meets all four criteria. This species is covered under all overlapping HCP/NCCPs. Potential affects could occur through disturbance of watercourses and adjacent upland habitats from conveyance and restoration activities.
2. Alameda whipsnake *Masticophis lateralis euryxanthus*	T/T/-	+	-	-	+	No	The East Contra Costa HCP/NCCP is the only overlapping plan to cover this species due to its distribution within the Contra Costa County. This species' range does not extend into the Plan Area and thus covered activities are not expected to adversely affect this species.
3. San Joaquin whipsnake *Masticophis flagellum ruddocki*	-/SSC/-	-	+	-	+	No	The San Joaquin County HCP is the only overlapping plan to cover this species with occurrences from Corral Hollow inSan Joaquin County. While the species may be found along the western edge of the Plan Area, it is unlikely to occur in the vicinity of conveyance or restoration activities and thus is not expected to be adversely affected by the project.
4. Silvery legless lizard *Anniella pulchra pulchra*	-/SSC/-	+	+	-	+	No	The East Contra Costa HCP/NCCP is the only overlapping plan to cover this species. That plan documented occurrences and potential habitat along the western edge of the Plan Area; however, none are in the vicinity of proposed conveyance or restoration activities.
5. Coast horned lizard *Phrynosoma coronatum frontale*	-/SSC/-	-	+	+ (AD)	+	No	This species is covered under the San Joaquin HCP. Documented occurrences in the grasslands on the western edge of the Plan Area in the vicinity of Clifton Court Forebay. Likelihood for impacts are low and the species is unlikely to become listed in the foreseeable future.
6. Western pond turtle *Actinemys marmorata*	-/SSC/-	+	+	+ (H, ID, AD)	+	Yes	Meets all four criteria. In addition to being a state species of special concern, this species is also designated as Vulnerable on the IUCN Red List. It is covered or considered for coverage on all overlapping HCP/NCCPs. It is reasonable to suggest that this species could become listed over the term of the BDCP. This species could potentially be affected by ground disturbances in watercourses and adjacent uplands associated with conveyance and possibly restoration activities.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	Status[A] (Federal/State/ CNPS)	Selection Criteria For Coverage[B]: Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information	Consider for Coverage?	Coverage Comments
Amphibians							
1. California red-legged frog *Rana aurora draytonii*	T/SSC/-	+	+	+ (AD)	+	Yes	Meets all four criteria. This species is covered under the East Contra Costa HCP/NCCP and the San Joaquin County HCP and is considered for coverage under the Yolo and Solano HCP/NCCPs. There are reported occurrences of this species in grassland/pond habitats in the vicinity of Clifton Court Forebay. Potential affects could occur through disturbance of occupied ponds or streams.
2. Foothill yellow-legged Frog *Rana boylii*	-/SSC/-	+	-	-	+	No	This species is covered under the East Contra Costa HCP/NCCP and the San Joaquin County HCP and is considered for coverage under the Yolo and Solano HCP/NCCPs. Each of these Plan Areas include potential habitat for this species. There are no occurrence records and no potential habitat for foothill yellow-legged frog in the Plan Area and thus covered activities are not expected to affect this species.
3. Western spadefoot toad *Spea hammondii*	-/SSC/-	+	+	+ (H, AD)	+	Yes	Meets all four criteria. This species is covered under the San Joaquin HCP and is considered for coverage under the Yolo County HCP/NCCP and the South Sacramento County HCP. Potential effects could occur through disturbance of vernal pools and intermittent streams and adjacent grassland habitats from conveyance and restoration activities.
4. California tiger salamander (Central Valley DPS) *Ambystoma californiense*	T/SSC/-	+	+	+ (H, AD)	+	Yes	Meets all four criteria. This species is covered or is being considered for coverage under all overlapping HCP/NCCPs. Potential affects could occur through disturbance of vernal pools and ponds and adjacent grassland habitats from conveyance and restoration activities. As of February 2009 this species is a candidate for state listing as endangered.
Invertebrates							
1. Blennosperma vernal pool andrenid bee *Andrena blennospermatis*	-/-/-		+	+ (AD)	+	No	This species has no regulatory or conservation status and is not covered or considered for coverage in any overlapping HCP/NCCP. There is no indication that it would become listed over the term of the BDCP.
2. Redheaded sphecid wasp *Eucerceris ruficeps*	-/-/-	-	U	U	-	No	This species has no regulatory or conservation status and is not covered or considered for coverage in any overlapping HCP/NCCP. There is no indication that it would become listed over the term of the BDCP.
3. Antioch multilid wasp *Myrmosula pacifica*	-/-/-	-	+	-	+	No	This species has no regulatory or conservation status and is not covered or considered for coverage in any overlapping HCP/NCCP. There is no indication that it would become listed over the term of the BDCP. It is known from Antioch Dunes and thus is not expected to be affected by covered activities.
4. Antioch adrenid bee *Perdita scitula antiochensis*	-/-/-	-	+	-	+	No	This species has no regulatory or conservation status and is not covered or considered for coverage in any overlapping HCP/NCCP. There is no indication that it would become listed over the term of the BDCP. It is known from Antioch Dunes and thus is not expected to be affected by covered activities.
5. Antioch specid wasp *Philanthus nasalis*	-/-/-	-	+	-	+	No	This species has no regulatory or conservation status and is not covered or considered for coverage in any overlapping HCP/NCCP. There is no indication that it would become listed over the term of the BDCP. It is known from Antioch Dunes and thus is not expected to be affected by covered activities.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	*Status[A] (Federal/State/ CNPS)*	*Selection Criteria For Coverage[B]* Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information	*Consider for Coverage?*	*Coverage Comments*
6. Antioch Dunes halcitid bee *Sphecodogastra antiochensis*	-/-/-	-	+	-	+	No	This species has no regulatory or conservation status and is not covered or considered for coverage in any overlapping HCP/NCCP. There is no indication that it would become listed over the term of the BDCP. It is known from Antioch Dunes and thus is not expected to be affected by covered activities.
7. Lange's metalmark butterfly *Apodemia mormo langei*	E/-/-	+	+	-	+	Yes	Though it does not meet all four criteria, due to this species' rarity and dependence on limited specialized habitat that is found in the Plan Area, it is proposed for coverage under the BDCP. This species is known only from the Antioch Dunes within the Antioch Dunes Wildlife Refuge and is not expected to be affected by covered activities. It is proposed for coverage because it is a listed species associated with the inland dune scrub natural community.
8. San Bruno elfin butterfly *Callophrys mossii bayensis*	E/-/-	+	-	-	+	No	This species' range does not extend into the Plan Area and thus it is not expected to be affected by covered activities.
9. Monarch butterfly *Danaus plexippus*	-/-/-	-	-	-	+	No	This species has no regulatory or conservation status. It is not a covered species in any overlapping HCP/NCCP. There is no indication that it would become listed over the term of the BDCP. There are no records of monarch roosts from within the Plan Area and thus covered activities are unlikely to affect this species.
10. Callippe Silverspot Butterfly *Speyeria callippe callippe*	E/-/-	+	-	-	+	No	Range does not appear to extend into the Plan Area and is thus not expected to be affected by covered activities.
11. Antioch efferian robberfly *Efferia antiochi*	-/-/-	-	+	-	-	No	This species has no regulatory or conservation status and is not covered or considered for coverage in any overlapping HCP/NCCPs. There is no indication that it would become listed over the term of the BDCP. This species is known only from the Antioch area within the Plan Area and is not expected to be affected by covered activities.
12. Hurd's metapogon robberfly *Metapogon hurdi*	-/-/-	-	+	-	-	No	This species has no regulatory or conservation status and is not covered or considered for coverage in any overlapping HCP/NCCPs. There is no indication that it would become listed over the term of the BDCP. This species is known only from the Antioch area within the Plan Area and is not expected to be affected by covered activities.
13. Ciervo aegialian scarab beetle *Aegialia concinna*	-/SA/-	-	+	-	+	No	This species is designated as Vulnerable by the IUCN Red List. It has no regulatory or conservation status. It is a covered species under the San Joaquin County HCP. However, there is no indication that it would become listed over the term of the BDCP. It occurs in loose sands and sand dunes and is unlikely to be affected by covered activities.
14. Antioch Dunes anthicid beetle *Anthicus antiochensis*	-/-/-	-	+	-	-	No	This species has no regularly or conservation status. It is not covered or considered for coverage in any overlapping HCP/NCCP. There is no indication that it could become listed over the term of the BDCP. It occurs in loose sands and sand dunes and is unlikely to be adversely affected by covered activities.
15. Sacramento anthicid beetle *Anthicus sacramento*	-/SA/-	-	+	-	-	No	This species is designated as Endangered on the IUCN Red List. It has no regularly or conservation status and is not covered or considered for coverage in any overlapping HCP/NCCP. There is no indication that it could become listed over the term of the BDCP. It occurs in loose sands and sand dunes and is unlikely to be adversely affected by covered activities.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	Status[A] (Federal/State/ CNPS)	Selection Criteria For Coverage[B]				Consider for Coverage?	Coverage Comments
		Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information		
16. Sacramento Valley tiger beetle *Cicindela hirticollis abrupta*	-/-/-	-	U	U	-	No	USFWS recently denied listing petition due to insufficient information. It has no regulatory or conservation status and is not covered or considered for coverage in any overlapping HCP/NCCP. All known populations are extirpated and recent surveys suggest the species is extinct. There is no indication that this species would be listed over the term of the BDCP.
17. San Joaquin dune beetle *Coelus gracilis*	-/SA/-		+	+ (AD)	-	No	This species is designated as Vulnerable on the IUCN Red List. It has no regularly or conservation status and is not covered or considered for coverage in any overlapping HCP/NCCP. There is no indication that it could become listed over the term of the BDCP. It occurs in loose sands and small sand dunes along the western edge of San Joaquin Valley and could potentially be affected by conveyance facilities.
18. Valley elderberry longhorn beetle *Desmocerus californicus dimorphus*	T/-/-	+	+	+ (H, ID, AD)	+	Yes	Meets all four criteria. Potentially occupied shrubs could be affected by activities associated with conveyance and restoration activities.
19. Delta green ground beetle *Elaphrus viridis*	E/-/-	+	+	-	+	No	This species is being considered for coverage in the Solano County HCP/NCCP. Its restricted distribution may extend into the northwestern portion of the Plan Area. However, it does not occur in the vicinity of conveyance or restoration activities and thus is not expected to be affected by the project.
20. Ricksecker's water Beetle *Hydrochara rickseckeri*	-/-/-		+	+ (AD)	+	No	This species has no regulatory or conservation status and there is no indication that it would become listed over the term of the BDCP. However, it is being considered for coverage in the Solano HCP/NCCP and the South Sacramento County HCP. This is a vernal pool-associated species and could be affected by activities associated with conveyance activities.
21. Curved-foot diving beetle *Hygrotus curvipes*	-/-/-		+	+ (AD)	+	No	This species has no regulatory or conservation status and there is no indication that it would become listed over the term of the BDCP. However, it is a covered species in the San Joaquin HCP. This is a vernal pool/seasonal wetland-associated species and could be affected by activities associated with conveyance activities. .
22. Moestan blister beetle *Lytta moesta*	-/-/-	-	-	-	+	No	This species has no regulatory or conservation status. It is not a covered species in any overlapping HCP/NCCP. There is no indication that it would become listed over the term of the BDCP. Its known range does not extend into the Plan Area and thus covered activities would not affect this species.
23. Molestan blister beetle *Lytta molesta*	-/-/-		+	+ (AD)	+	No	This species has no regulatory or conservation status and is not covered or considered for coverage in any overlapping HCP/NCCPs. There is no indication that it would become listed over the term of the BDCP. This is a vernal pool/seasonal wetland-associated species and could be affected by activities associated with conveyance activities.
24. San Francisco lacewing *Nothochrysa californica*	-/-/-	-	-	-	-	No	This species has no regulatory or conservation status. It is not a covered species in any overlapping HCP/NCCP. There is no indication that it would become listed over the term of the BDCP. Its known range does not extend into the Plan Area and thus covered activities would not affect this species.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	*Status[A] (Federal/State/ CNPS)*	*Selection Criteria For Coverage[B]*				*Consider for Coverage?*	*Coverage Comments*
		Listing Potential	**Occurrence in the Plan Area**	**Potential to Adversely Affect[C]**	**Sufficient Information**		
25. Wilbur Springs shorebug *Saldula usingeri Polhemus*	-/-/-	-	-	-	+	No	This species has no regulatory or conservation status. It is not a covered species in any overlapping HCP/NCCP. There is no indication that it would become listed over the term of the BDCP. Its known range does not extend into the Plan Area and thus covered activities would not affect this species.
26. Middlekauff's shieldback katydid *Idiostatus middlekauffi*	-/SA/-	-	U	U	-	No	This species is designated as Critically Endangered by the IUCN Red List. It has no regulatory or conservation status. There is no indication that it would become listed over the term of the BDCP. It is not covered or considered for coverage in any overlapping HCP/NCCPs.
27. Hairy water flea *Dumontia oregonensis*	-/-/-	-	-	-	+	No	This species has no regulatory or conservation status. It is not a covered species in any overlapping HCP/NCCP. There is no indication that it would become listed over the term of the BDCP. Its known range does not extend into the Plan Area and thus covered activities would not affect this species.
28. Vernal pool tadpole shrimp *Lepidurus packardi*	E/-/-	+	+	+ (H, AD)	+	Yes	Meets all four criteria. This species could be affected through disturbances to vernal pool and other seasonal wetland habitats associated with conveyance and restoration activities.
29. Conservancy fairy shrimp *Branchinecta conservatio*	E/-/-	+	+	+ (H, AD)	+	Yes	Meets all four criteria. This species could be affected through disturbances to vernal pool and other seasonal wetland habitats associated with conveyance and restoration activities.
30. Longhorn fairy shrimp *Branchinecta longiantenna*	E/-/-	+	+	+ (H, AD)	+	Yes	Meets all four criteria. This species could be affected through disturbances to vernal pool and other seasonal wetland habitats associated with conveyance and restoration activities.
31. Vernal pool fairy shrimp *Branchinecta lynchi*	T/-/-	+	+	+ (H, AD)	+	Yes	Meets all four criteria. This species could be affected through disturbances to vernal pool and other seasonal wetland habitats associated with conveyance and restoration activities.
32. Mid Valley Fairy Shrimp *Branchinecta mesovalleyensis*	-/-/-		+	+ (H, AD)	+	Yes	Meets all four criteria. This species is thought to have a very restricted range. A 2001 petition for listing was rejected by the USFWS in 2004 on the basis of insufficient data. However, it is reasonable to assume that this species could become listed over the term of the BDCP. This species is covered in all overlapping HCP/NCCPs. This species could be affected through disturbances to vernal pool and other seasonal wetland habitats associated with conveyance and restoration activities.
33. California linderiella *Linderiella occidentalis*	-/SA/-[+]	+	+	+ (H, AD)	+	Yes	Meets all four criteria. USFWS indicated likelihood of this species becoming listed within the term of the permit. This species is designated as Near Threatened on the IUCN Red List. It has no regulatory or conservation status. It is relatively common throughout its range, but occurs in association with listed vernal pool species that could be affected by covered activities.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

		Selection Criteria For Coverage[B]					
Scientific Name/ Common Name	***Status**[A]* ***(Federal/State/ CNPS)***	**Listing Potential**	**Occurrence in the Plan Area**	**Potential to Adversely Affect**[C]	**Sufficient Information**	***Consider for Coverage?***	***Coverage Comments***
34. Bridges' coast range shoulderband *Helminthoglypta nickliniana bridgesi*	-/SA/-	-	-	-	-	No	This species is designated as Data Deficient on the IUCN Red List. It has no regulatory or conservation status. It is not covered under other overlapping HCP/NCCPs. This species' range does not extend into the Plan Area and thus covered activities are not expected to affect this species.
Plants							
1. Santa Clara thorn-mint *Acanthomintha lanceolata*	-/-/4	-	-	-	+	No	This species is widely distributed on hillsides in the inner Coast Range southwest of the Delta and does not occur within the Plan Area.
2. Purdy's onion *Allium fimbriatum* var. *purdyi*	-/-/4	-	-	-	+	No	This variety is widely distributed in the inner Coast Range north of the Delta and does not occur within the Plan Area.
3. Large-flowered fiddleneck *Amsinckia grandiflora*	E/E/1B	+	-	-	+	No	This species is found in a very few occurrences that are all located in the inner Coast Range southwest of the Delta and does not occur present within the Plan Area.
4. Bent flowered fiddleneck *Amsinckia lunaris*	-/-/1B	-	-	-	+	No	This species is widely distributed in the inner and outer Coast Ranges from Colusa and Lake Counties in the north to Santa Cruz County in the south and does not occur within the Plan Area.
5. California androsace *Androsace elongata* ssp. *Acuta*	-/-/4	-	-	-	+	No	This subspecies is widely distributed in the inner and outer Coast Ranges from Tehama County in the north and southward to the Peninsular Range in San Diego County and does not occur within the Plan Area.
6. Slender silver moss *Anomobryum julaceum*	-/-/2	-	-	-	+	No	This species is widely distributed in forests of the inner and outer Coast Ranges and Sierra Nevada on road cuts and rocks and in seeps and streams and does not occur within the Plan Area.
7. Twig-like snapdragon *Antirrhinum virga*	-/-/4	-	-	-	+	No	This species is widely distributed in the inner Coast Range in Lake, Mendocino, and Sonoma Counties and does not occur within the Plan Area.
8. Coast rock cress *Arabis blepharophylla*	-/-/4	-	-	-	+	No	This species is widely distributed in the inner Coast Range from Marin County south to Monterrey County and does not occur within the Plan Area.
9. Modest rock cress *Arabis modesta*	-/-/4	-	-	-	+	No	This species is widely distributed in the Klamath Range and in the Blue Ridge of Napa and Solano Counties and does not occur within the Plan Area.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	*Status[A] (Federal/State/ CNPS)*	*Selection Criteria For Coverage[B]* Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information	*Consider for Coverage?*	*Coverage Comments*
10. Mt. Diablo manzanita *Arctostaphylos auriculata*	-/-/1B	_	+	-	+	No	This species is distributed in chaparral on the hillsides of Mt. Diablo and does not occur within the Plan Area.
11. Contra Costa manzanita *Arctostaphylos manzanita* ssp. *Laevigata*	-/-/1B	-	-	-	+	No	This subspecies is distributed in chaparral on the hillsides of Mt. Diablo and does not occur within the Plan Area.
12. Serpentine milkweed *Asclepias solanoana*	-/-/4	-	-	-	+	No	This species is found at high elevations elevation in the inner Coast Range from Tehama County south to Solano County and does not occur within the Plan Area.
13. Carlotta Hall's lace fern *Aspidotis carlotta-halliae*	-/-/4	-	-	-	+	No	This species is broadly distributed in the inner and outer Coast Ranges from Marin County south to San Luis Obispo County and does not occur within the Plan Area.
14. Brewer's milk-vetch *Astragalus breweri*	-/-/4	-	-	-	+	No	This species is broadly distributed in the outer Coast Range from Mendocino County south to Marin County and does not occur within the Plan Area.
15. Cleveland's milk-vetch *Astragalus clevelandii*	-/-/4	-	-	-	+	No	This species is broadly distributed along streams, springs, and seeps in the inner Coast Range from Tehama County south to Napa County and does not occur within the Plan Area.
16. Ocean bluff milk-vetch *Astragalus nuttallii* var. *nuttallii*	-/-/4	-	-	-	+	No	This variety is broadly distributed along the coast from Marin County to Santa Barbara County and does not occur within the Plan Area.
17. Jepson's milk-vetch *Astragalus rattanii* var. *jepsonianus*	-/-/1B	-	-	-	+	No	This variety is broadly distributed on serpentine soils in the inner Coast Range from Tehama County to Yolo County and does not occur within the Plan Area.
18. Ferris' milk-vetch *Astragalus tener* var. *ferrisiae*	-/-/1B	+	+	-	+	No	While this variety is present within the Plan Area in large playa pools at the Jepson Prairie Preserve and CDFG Tule Ranch Preserves, those areas will not be impacted.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	Status[A] (Federal/State/ CNPS)	Selection Criteria For Coverage[B]				Consider for Coverage?	Coverage Comments
		Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information		
19. Alkali milk-vetch *Astragalus tener* var. *tener*	-/-/1B	+	+	+ (H, AD)	+	Yes	Meets all four criteria. Alkali milk-vetch is almost always found on alkaline or saline soils occurring in vernally wet playas, flats, fallowed rice fields, and vernal swales in valley/foothill grasslands below 500 ft (Solano HCP, 2007; San Joaquin HCP 2000). It is covered in the Solano and San Joaquin HCPs and proposed for coverage in the Yolo County HCP. Locally, it is found in the Jepson Prairie Area, the CDFG Tule Ranch Preserve, and the Montezuma Wetlands in vernally flooded swales and flood plains of playa pools. There is a single historical occurrence near Stockton but that location has been completely developed. There are other historical collections within impacts areas at the lower margins of uplands in the Cache Slough and Suisun Marsh areas but that habitat has been lost through intensive agriculture. There is the potential for the listing of this species within the plan period due to development impacts in the south San Francisco Bay area and agricultural impacts in the Central Valley.
20. Heartscale *Atriplex cordulata*	-/-/1B	+	+	+ (H, AD)	+	Yes	Meets all four criteria. Heartscale grows in sandy, saline or alkaline flats and scalds, in chenopod scrub, meadows, and valley/foothill grassland (Solano HCP 2007; San Joaquin HCP 2000). It is covered in the Solano and San Joaquin HCPs and the ISA Report recommends that this species be retained for consideration of coverage. It occurs within the Plan Area and potentially at the lower margins of uplands in the Cache Slough area and possibly in the Clifton Court Forebay area that could be affected by covered activities. While heartscale is a widespread species, it may be declining due to loss of habitat through current and future development which may lead to listing during the plan period.
21. Crownscale *Atriplex coronata* var. *coronata*	-/-/4	-	+	-	+	No	This variety is widely distributed in the northern Sacramento Valley and central and southern San Joaquin Valley and is present at scattered alkaline soil areas in the inner Coast Range from Alameda County southward . Subspecies var *vallicola* was found in the Clifton Court Forebay area by DHCCP survey teams in 2009 and 2010.
22. Lost Hills Crownscale *Atriplex coronata var. vallicola*	-/-/1B	-	+	?	+	No	Lost Hills Crownscale is widely distributed in the San Joaquin Valley (alkaline clay soils on the valley bottom and gypsum clay soils on the hills of the Coast Range) and on alkaline clay soils of the Carrizo Plain. It was discovered on BDCP surveys in the vicinity of the Clifton Court Forebay. It is not covered by any HCPs.
23. Brittlescale *Atriplex depressa*	-/-/1B	+	+	+ (H, AD)	+	Yes	Meets all four criteria. Brittlescale grows on alkaline or clay soils occurring in grasslands contained by valleys or foothills, meadows saltbrush, vernal pools, and at the edge of playas (San Joaquin HCP 2000; Solano HCP 2007; ECCC HCP, 2007). It is covered in the Solano and San Joaquin HCPs and the ISA Report recommends that this species be retained for consideration of coverage. It occurs within the Plan Area and potentially at the lower margins of uplands in the Cache Slough area and possibly in the Clifton Court Forebay area that could be affected by covered activities. While brittlescale is a widespread species it may be declining due to loss of habitat through current and future development which may lead to listing during the plan period.
24. San Joaquin spearscale *Atriplex joaquiniana*	-/-/1B	+	+	+ (H, AD)	+	Yes	Meets all four criteria. San Joaquin spearscale grows on alkaline clay soils in alkali grasslands and meadows or on the margins of alkali scrub, (ECCC HCP 2007) and is also found in seasonal alkali wetlands and sinks in chenopod scrub, meadows, playas, and valley/grassland foothills (Solano HCP 2007). It is covered in the Solano and East Contra Costa County HCPs and proposed for coverage in the Yolo County HCP. The ISA Report recommends that this species be retained for consideration of coverage. It occurs within the Plan Area and potentially at the lower margins of uplands in the Cache Slough area that could be affected by covered activities. While San Joaquin spearscale is a widespread species it may be declining due to loss of habitat through current and future development which may lead to listing during the plan period.
25. Lesser saltscale *Atriplex minuscula*	-/-/1B	+	-	-	+	No	Lesser saltscale grows on alkaline or clay soils occurring in grasslands contained by valleys or foothills, meadows saltbrush, vernal pools, and at the edge of playas. Although there are no documented occurrences in the Plan Area, lesser saltscale is assumed to be within the Plan Area because of several herbarium specimens. These specimens have been reannotated as *A. depressa* from *A. minuscula*. Consequently, it is no longer considered as being present in the Plan Area.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	*Status[A] (Federal/State/ CNPS)*	*Selection Criteria For Coverage[B]* Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information	*Consider for Coverage?*	*Coverage Comments*
26. Vernal pool smallscale *Atriplex persistens*	-/-/1B	+	-	-	+	No	This species has been reported from alkaline playas on the Jepson Prairie Preserve immediately outside of the Plan Area but those playas will not be affected by restoration activities.
27. Big-scale balsamroot *Balsamorhiza macrolepis* var. *macrolepis*	-/-/1B	-	-	-	+	No	This variety is widely distributed on hill slope soils derived from serpentinite or basalt in the inner Coast Range from Tehama County south to Kern County and is sporadically distributed on sandy soils along the lower margin of the Sierra foothills but does not occur within the Plan Area.
28. Big tarplant *Blepharizonia plumosa*	-/-/1B	-	+	-	+	No	This species is broadly distributed on hillsides on sites with shrink/swell clay soils, does not appear to be declining, and is not likely to be listed within the period of this plan. Additionally, there are no documented collections within impacts areas with the exception of a single occurrence near Tracy from along railroad tracks west of town.
29. Brewer's calandrinia *Calandrinia breweri*	-/-/4	-	-	-	+	No	This species is widely distributed in the Peninsular Range from San Diego County northward and on serpentine soils in the Coast Range north and south of the San Francisco Bay area but does not occur within the Plan Area.
30. Round-leafed filaree *California macrophyllum*	-/-/2	-	+	-	+	No	This species is broadly distributed throughout California on sites with shrink/swell clay soils, does not appear to be declining, and not likely to be listed within the period of this plan. Additionally, there are no documented occurrences within impacts areas.
31. Mt. Diablo fairy-lantern *Calochortus pulchellus*	-/-/1B	-	-	-	+	No	This species is widely distributed in the Peninsular Range from San Diego County northward and on serpentine soils in the Coast Range north and south of the San Francisco Bay area but does not occur within the Plan Area.
32. Oakland star-tulip *Calochortus umbellatus*	-/-/4	-	-	-	+	No	This species is broadly distributed on Mount Diablo and on adjacent hills but does not occur within the Plan Area.
33. Butte County morning-glory *Calystegia atriplicifolia* ssp. *Buttensis*	-/-/1B	-	-	-	+	No	This subspecies is widely distributed in Butte, Del Norte, and Tehama Counties in foothill coniferous forests but does not occur within the Plan Area.
34. Chaparral harebell *Campanula exigua*	-/-/1B	-	-	-	+	No	This species is broadly distributed on scree and talus slopes in the inner Coast Range from San Benito County northwards to Contra Costa County but does not occur within the Plan Area.
35. Bristly sedge *Carex comosa*	-/-/2	-	+	+ (H, AD, ID, O)	+	No	This species is broadly distributed throughout North America but spotty in California (its seed is eaten and likely dispersed by waterfowl). It does not appear to be declining and is not likely to be listed within the period of this plan.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	*Status[A] (Federal/State/ CNPS)*	*Selection Criteria For Coverage[B]*				*Consider for Coverage?*	*Coverage Comments*
		Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information		
36. Fox sedge *Carex vulpinoidea*	-/-/2	-	+	+ (H, AD, ID, O)	+	No	This species is broadly distributed throughout North America but spotty in California (its seed is eaten and likely dispersed by waterfowl). The Flora of North America indicates that it is weedy along ditches, etc.
37. Succulent owl's clover *Castilleja campestris* ssp. *succulenta*	T/E/1B	+	-	-	+	No	This subspecies is broadly distributed in hardpan vernal pools along the east side of the Central Valley but does not occur within the Plan Area.
38. Lemmon's jewelflower *Caulanthus coulteri* var. *lemmonii*	-/-/1B	-	-	-	+	No	This variety is widely distributed on loose slopes in the Transverse Range in Ventura County northwards and in the inner Coast Range to Alameda County but does not occur within the Plan Area.
39. Congdon's tarplant *Centromadia parryi* spp. *congdonii*	-/-/1B	-	-	-	+	No	This subspecies is broadly distributed throughout central California, does not appear to be declining, and does not occur within the Plan Area.
40. Pappose tarplant *Centromadia parryi ssp. Parryi*	-/-/1B	-	-	+ (H)	+	No	While this subspecies occurs within the Suisun Marsh impacts area, it is broadly distributed throughout central California in brackish marshes, salt springs, hot springs, and other areas, does not appear to be declining, and is not likely to be listed within the period of this plan.
41. Parry's red tarplant *Centromadia parryi* ssp. *Rudis*	-/-/4	-	+	-	+	No	This subspecies is not likely to be listed during the plan period and while it is present on alkali soils in the Sacramento Valley on USFWS and CDFG preserves, it is not expected to be affected by the covered activities.
42. Slough thistle *Cirsium crassicaule*	FSC/-/1B	+	+	+ (H)	+	Yes	Meets all four criteria. Slough thistle is known from two locations in the Legal Delta, one about 5 miles west of Manteca and one about 10 miles southeast of Tracy. It is also present within in the habitat restoration area upstream of the Mossdale Bridge. It is very uncommon across its limited range in the San Joaquin Valley and subjected to numerous negative impacts which may lead to listing during the plan period.
43. Suisun thistle *Cirsium hydrophilum* var. *hydrophilum*	E/-/1B	+	+	+ (H)	+	Yes	Meets all four criteria. Suisun thistle is present within the Suisun Marsh and could be affected by habitat restoration actions.
44. Brewer's clarkia *Clarkia breweri*	-/-/4	-	-	-	+	No	This species is broadly distributed in the inner Coast Range from Monterrey County north to Alameda County but does not occur within the Plan Area.
45. Santa Clara red ribbons *Clarkia concinna* ssp. *automixa*	-/-/4	-	-	-	+	No	This subspecies is broadly distributed in the inner Coast Range from Alameda County north to Trinity County but does not occur within the Plan Area.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	*Status[A] (Federal/State/ CNPS)*	*Selection Criteria For Coverage[B]*				*Consider for Coverage?*	*Coverage Comments*
		Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information		
46. Serpentine collomia *Collomia diversifolia*	-/-/4	-	-	-	+	No	This species is broadly distributed on rocky serpentine hill slopes from Contra Costa County north to Siskiyou County but does not occur within the Plan Area.
47. Small-flowered morning-glory *Convolvulus simulans*	-/-/4	-	-	-	+	No	This species is broadly distributed on hill slopes from San Diego County north to Contra Costa County but does not occur within the Plan Area.
48. Hispid bird's-beak *Cordylanthus mollis* ssp. *hispidus*	-/-/1B	-	-	-	+	No	This subspecies is broadly distributed in alkaline sink habitat in the San Joaquin Valley and Livermore Valley, in alkaline seeps near Rocklin, and along the margins of alkaline seasonal wetlands and vernal pools near Travis Air Force Base in Solano County but does not occur within the Plan Area.
49. Soft bird's-beak *Cordylanthus mollis* ssp. *mollis*	E/R/IB	+	+	+ (H)	+	Yes	Meets all four criteria. This subspecies occurs within Suisun Marsh and could be affected by habitat restoration actions.
50. Mt. Diablo bird's-beak *Cordylanthus nidularius*	-/SR/1B	-	-	-	+	No	This species it is known from a single occurrence on Bald Ridge within the Mt. Diablo park system and does not occur within the Plan Area.
51. Palmate-bracted bird's-beak *Cordylanthus palmatus*	E/E/1B	+	-	-	+	No	This species does not occur within Plan Area. CNDDB records show that the Stockton occurrence was last seen in 1881 and could not be relocated in the 1960's.
52. Hoover's cryptantha *Cryptantha hooveri*	-/-/1A	+	+	-	+	No	While this species occurs within the Plan Area it is limited to sandy areas near Antioch Dunes which are not within an impact area.
53. Livermore tarplant *Deinandra bacigalupi*	-/-/1B	-	-	-	+	No	This species occurs on alkaline soils in the Livermore Valley and does not occur within the Plan Area.
54. Hospital Canyon larkspur *Delphinium californica* ssp.*interius*	-/-/1B	-	-	-	+	No	This subspecies is broadly distributed in seeps and dried creek bottoms in the inner Coast Range from San Benito County north to Contra Costa County but does not occur within the Plan Area.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	*Status*[A] *(Federal/State/ CNPS)*	*Selection Criteria For Coverage*[B] Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information	*Consider for Coverage?*	*Coverage Comments*
55. Gypsum-loving larkspur *Delphinium gypsophilum* ssp. *Gypsophilum*	-/-/4	-	-	-	+	No	This subspecies is broadly distributed in the inner Coast Range from Ventura County north to Stanislaus County but does not occur within the Plan Area.
56. Recurved larkspur *Delphinium recurvatum*	-/-/1B	U	+	-	+	No	While there are occurrences of this species in the Clifton Court Forebay area, those occurrences are to the west of the potential impact areas in relatively undisturbed alkaline vegetation in contrast to the intensive agriculture of the impact areas. Listing potential is uncertain as while this species has a broad historical distribution in the San Joaquin Valley its populations are described as very small, subject to extirpation, and many have not been surveyed for a number of years.
57. Norris' beard moss *Didymodon norrisii*	-/-/2	-	-	-	+	No	This species is widespread on mesic rock outcrops from Tulare County to Humboldt County but does not occur within the Plan Area.
58. Dwarf downingia *Downingia pusilla*	-/-/2	-	+	+ (H)	+	Yes	Meets all four criteria. USFWS indicated likelihood of this species becoming listed within the term of the permit. This species is broadly distributed throughout California in seasonal marshes and vernal pools and is not likely to be listed within the period of this plan. It does occur in areas near Cache Slough and in the Stone Lakes area but those occurrences are not within impact areas.
59. Small spikerush *Eleocharis parvula*	-/-/4	-	-	-	+	No	This species is widely distributed from Orange County in the south to Humboldt and Lassen Counties in the north but does not occur in the Plan Area.
60. Brandegee's eriastrum *Eriastrum brandegeeae*	-/-/1B	-	-	-	+	No	This species occurs on rock outcrops and rocky soils on hill slopes from Santa Clara County to Shasta County but does not occur within the Plan Area.
61. Mt. Diablo buckwheat *Eriogonum truncatum*	-/-/1B	+	-	-	+	No	This species occurs on hill slope outcrops of the Tehama geological formation on the slopes of Mt. Diablo and in the Portrero Hills but does not occur within the Plan Area. The two CNDDB occurrences that were mapped in the Plan Area are best guesses based on very old herbarium collections and the actual collection sites were most likely on nearby hill slopes.
62. Bay buckwheat *Eriogonum umbellatum* var. *bahiiforme*	-/-/4	-	-	-	+	No	This variety occurs on hill slopes from Los Angeles County to Siskiyou County but does not occur within the Plan Area.
63. Jepson's woolly sunflower *Eriophyllum jepsonii*	-/-/4	-	-	-	+	No	This species occurs on hill slopes and in canyons from Ventura County to Contra Costa County but does not occur within the Plan Area.
64. Delta button celery *Eryngium racemosum*	-/E/1B	+	+	+ (H, AD, ID, O)	+	Yes	Meets all four criteria. Delta button celery is found in riparian scrub and subalkaline swales in the San Joaquin River bed (CDFG 2000; SJ HCP 2000). It is also found in chenopod scrub and alkaline grasslands near Discovery Bay. It is covered in the San Joaquin HCP. It has the potential to occur near Clifton Court Forebay and the San Joaquin River upstream of the Mossdale Bridge.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	Status[A] (Federal/State/ CNPS)	Selection Criteria For Coverage[B]: Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information	Consider for Coverage?	Coverage Comments
65. Contra Costa wallflower *Erysimum capitatum* var. *angustatum*	E/E/1B	+	+	-	+	Yes	Though it does not meet all four criteria, due to this species' rarity and dependence on limited specialized habitat that is found in the Plan Area, it is proposed for coverage under the BDCP. This subspecies only occurs in the Antioch Dunes which are within the plan area but does not occur within the impacts area. It is proposed for coverage because it is a listed species associated with the inland dune scrub natural community.
66. Diamond-petaled California poppy *Eschscholzia rhombipetala*	-/-/1B	-	+	- (AD)	+	No	This species is broadly distributed throughout the inner central and southern Coast Range on clay soils and is not likely to be listed within the period of this plan. There is a small probability of it being present in the Clifton Court Forebay area.
67. Stinkbells *Fritillaria agrestis*	-/-/4	-	+	-	+	No	This widespread species occurs on gentle hill slopes of the Transverse Range and northward in the outer and inner Coast Ranges to Monterrey and Yolo Counties. It also occurs in the foothills of the Sierra Nevada from Tulare County to Placer County. Therefore, this species does not occur within the Plan Area.
68. Fragrant fritillary *Fritillaria liliacea*	-/-/1B	-	+	-	+	No	This species is broadly distributed throughout California on sites with clay soils and is not likely to be listed within the period of this plan. Additionally, occurrences in the Plan Area are in upland habitats near vernal pools that will not be impacted and there are no documented occurrences within impacts areas.
69. Adobe-lily *Fritillaria pluriflora*	-/-/1B	-	+	-	+	No	This species is broadly distributed on gently sloping hillsides with clay soils from Yolo County to Glenn County in the inner Coast Range and in clay soils in the uplands surrounding vernal pool complexes in Butte and Tehama Counties. There is a 1910 reported occurrence in Solano County which CNDDB attributes to an incorrect identification. Therefore, this species does not occur within the Plan Area.
70. Purdy's fritillary *Fritillaria purdyi*	-/-/4	-	-	-	+	No	This species is found in the inner and outer Coast Ranges from Napa county north to Humboldt County and possibly in the foothills of the Sierra Nevada in Butte County but it does not occur within the Plan Area.
71. Phlox-leaf serpentine bedstraw *Galium andrewsii* ssp. *gatense*	-/-/4	-	-	-	+	No	This subspecies occurs at high elevations. Most recent occurrences have been recorded in San Benito and Stanislaus counties. Other occurrences have been recorded in Santa Cruz, Contra Costa, Santa Clara, Monterey, San Luis Obispo, Fresno, and San Bernardino counties. It does not occur within the Plan Area.
72. Boggs Lake hedge-hyssop *Gratiola heterosepala*	-/E/1B	+	+	+ (H)	+	Yes	Meets all four criteria. Boggs Lake hedge-hyssop in vernal pools and in marshy area on the margins of reservoirs and lakes; also found in man-made habitats such as borrow pits and cattle ponds (FWS Vernal Pool Recovery Plan 2006; San Joaquin HCP 2000). Covered in the San Joaquin, South Sacramento, and Solano HCPs. Occurs in areas near Cache Slough that are proposed for habitat restoration and, while no occurrences have been reported, may occur in the Stone Lakes area but not in impacted areas. The ISA Report recommends that this species be retained for consideration of coverage.
73. Nodding harmonia *Harmonia nutans*	-/-/4	-	-	-	+	No	This species occurs on hillsides and at high elevations of the North Coast range in Lake, Sonoma, and Napa counties and does not occur within the Plan Area.
74. Diablo helianthella *Helianthella castanea*	-/-/1B	-	-	-	+	No	This species generally occurs on hillsides and at high elevations in San Francisco Bay counties. Most recorded occurrences have been in Contra Costa and Alameda counties. Occurrences have also been recorded in San Francisco, San Mateo, and Marin counties. This species does not occur within the Plan Area.
75. Hogwallow Starfish *Hesperevax caulescens*	-/-/4	-	+	-	+	No	This species is widely distributed throughout California. There are recorded occurrences from Tehama County to San Diego County. It is present within the Plan Area in large playa pools at CDFG Tule Ranch Preserve but that area will not be impacted. Because it is widely distributed throughout California (herbaria specimens) it is unlikely to be listed within the period of this plan.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	Status[A] (Federal/State/ CNPS)	Selection Criteria For Coverage[B]				Consider for Coverage?	Coverage Comments
		Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information		
76. Brewer's western flax *Hesperolinon breweri*	-/-/1B	-	+	-	+	No	Distribution of this species is limited to Napa, Contra Costa, and Solano counties but it does not occur within impacts areas. Additionally, it occurs in the inner Coast Range north and south of the Delta in areas that are not likely to be impacted by development so its listing potential is very low.
77. Rose-mallow *Hibiscus lasiocarpus*	-/-/2	-	+	+ (H, AD, ID, O)	+	No	This species is broadly distributed throughout the Delta and Sacramento Valley in riparian areas, springs, and seeps and is not likely to be listed within the period of this plan.
78. Santa Cruz tarplant *Holocarpha macradenia*	E/T/1B	+	-	-	+	No	The distribution of this species is limited to several coastal counties: Marin, Santa Cruz, Monterey, Alameda, and Contra Costa but it does not occur within the Plan Area.
79. Coast iris *Iris longipetala*	-/-/4	-	-	-	+	No	This species has been observed in the outer Coast Range from Humboldt County to Monterey County, and in the inner Coast Range from Contra Costa County to Santa Clara County but it does not occur within the Plan Area.
80. Carquinez goldenbush *Isocoma arguta*	-/-/1B	+	+	+ (H)	+	Yes	Meets all four criteria. Carquinez goldenbush is present within impact areas of Suisun Marsh and Cache Slough. This shrub species in endemic to the alkaline and saline areas around the Montezuma Hills and sometimes grows along the transition between saline tidal marshes and uplands. Because of its extremely narrow distribution and small population sizes it is likely to be listed within the period of the plan. It is also likely to be impacted by sea level rise.
81. Northern California black walnut *Juglans californica* var. *hindsii*	-/-/1B	-	+	+ (H, AD, ID)	+	No	This variety is widespread in the Central Valley and Delta and is not likely to be listed within the plan period.
82. Ahart's dwarf rush *Juncus leiospermus* var. *ahartii*	-/-/1B	+	-	-	+	No	The distribution of this variety is limited to vernal pools in northern California. It has been recorded from Tehama, Butte, Yuba, Placer, Calaveras, and Sacramento counties but does not occur within the Plan Area.
83. Contra Costa goldfields *Lasthenia conjugens*	E/-/1B	+	+	-	+	No	This species occurs in counties along the California coast from Mendocino County to Santa Barbara County but does not occur within the plan and impacts areas.
84. Ferris' goldfields *Lasthenia ferrisiae*	-/-/4	-	+	+ (AD)	+	No	This species is widely distributed throughout California from Colusa and Butte counties in the north, to San Luis Obispo, Kern and Ventura counties in the south; and from Contra Costa and Alameda counties in the west to Merced, Fresno, and Tulare counties in the east. It does occur within the planning and impacts areas in the Clifton Court Forebay, but it is not likely to be listed during the plan period.
85. Delta tule pea *Lathyrus jepsonii* var. *jepsonii*	-/-/1B	+	+	+ (H, AD, ID, O)	+	Yes	Meets all four criteria. Delta tule pea grows in tidally influenced freshwater and brackish marshes, commonly along slough edges and levees (Solano HCP 2007; San Joaquin HCP 2000). It is covered in the Solano and San Joaquin HCPs. It is found in valley riparian, tidal perennial aquatic, tidal freshwater emergent wetland, and grasslands throughout central Plan Area. There are numerous occurrences throughout the lowland Legal Delta. It will likely be impacted by BDCP actions while possibly benefitting from habitat restoration, and may be listed within the period of this plan.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	*Status[A] (Federal/State/ CNPS)*	Selection Criteria For Coverage[B]				*Consider for Coverage?*	*Coverage Comments*
		Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information		
86. Legenere *Legenere limosa*	-/-/1B	+	+	?	+	Yes	Current covered activity and habitat restoration concepts may avoid impacts. Habitat is usually deep well defined vernal pools within grasslands (Solano HCP 2007; SJ HCP 2000). Covered in the SJ HCP and proposed for coverage in the Solano HCP. Found within Plan Area in grasslands along western border; found east and west outside of Plan Area.
87. Heckard's peppergrass *Lepidium latipes* var. *heckardii*	-/-/1B	+	+	?	+	Yes	Heckard's peppergrass grows on alkaline flats and in alkaline grasslands along the edges of vernal pools (Solano HCP 2007). It is proposed for coverage in the Solano HCP. The historical occurrence along Haas Slough was last observed by Jepson in 1891 (Consortium of California Herbaria 2008). Aerial imagery indicates that the Haas Slough occurrence is likely to have been extirpated by the spread of intensive agriculture along both sides of the slough. Present within the Plan Area in large playa pools at the DFG Tule Ranch Preserve and in vernal pools and swales at Jepson Prairie and Gridley Ranch Preserves, but those areas are in upland habitat that will not be affected. Current covered activity and habitat restoration concepts may affect species.
88. Bristly leptosiphon *Leptosiphon acicularis*	-/-/4	-	-	-	+	No	This species is generally found on hillsides and at high elevations. Most recent occurrences have been recorded in Mendocino, Sonoma, Lake, Napa, and Butte counties. Humboldt and Marin counties have recorded occurrences that pre-date 1950, and Alameda County's most recent recorded occurrence was in 1900. Single occurrences have been recorded in Colusa, Santa Cruz, San Benito, and San Diego counties. This species does not occur within the Plan Area.
89. Serpentine leptosiphon *Leptosiphon ambiguus*	-/-/4	-	-	-	+	No	This species occurs on hillsides and at high elevations. Most recorded occurrences are in central California from Contra Costa, Alameda, San Mateo, and Santa Clara counties in the west to Stanislaus and Merced counties in the east. There are single occurrences recorded for each of the following counties: Fresno, Plumas, Santa Cruz, and Tehama. This species does not occur within the Plan Area.
90. Large-flowered leptosiphon *Leptosiphon grandiflorus*	-/-/4	-	-	-	+	No	Most recent recorded occurrences of this species have been reported from Los Angeles, Marin, and Monterey counties. Other occurrences have been reported from Santa Clara, Santa Barbara, and Madera counties. This species does not occur within the Plan Area.
91. Spring lessingia *Lessingia tenuis*	-/-/4	-	-	-	+	No	This species is generally found at high elevations in central and southern California counties. Recorded occurrences are widely distributed from Alameda and Stanislaus counties south to Santa Barbara and Ventura counties. It does not occur within the Plan Area.
92. Mason's lilaeopsis *Lilaeopsis masonii*	-/R/1B	+	+	+ (H, ID, O)	+	Yes	Meets all four criteria. Mason's lilaeopsis grows in regularly flooded tidal zones, on mud banks and flats, and along eroding creek banks, sloughs, and rivers. It is also found in freshwater marshes, brackish marshes, and riparian scrub vegetation types that are tidally influenced. It is covered in the San Joaquin HCP and proposed for coverage in the Solano HCP. It is broadly distributed throughout the Delta and in the Napa River and will likely benefit from habitat restoration.
93. Delta mudwort *Limosella subulata*	-/-/2	+	+	+ (H, ID, O)	+	Yes	Meets all four criteria. Habitat consists of muddy or sandy intertidal flats in estuarine areas, surrounded by brackish or freshwater marsh or riparian scrub (SJ HCP 2000; Solano HCP 2007). Covered in the San Joaquin HCP and proposed for coverage in the Solano HCP. Generally found throughout the central Plan Area within valley riparian, tidal perennial aquatic, tidal freshwater emergent wetland, and grassland SAIC veg. types. A later assessment found that all of the numerous known occurrences are in the Legal Delta lowland areas.
94. Hoover's lomatium *Lomatium hooveri*	-/-/4	-	-	-	+	No	This species occurs at high elevations in Colusa, Lake, Glenn and Napa counties and does not occur within the Plan Area.
95. Napa lomatium *Lomatium repostum*	-/-/4	-	-	-	+	No	This species is distributed on hillsides and at high elevations in Lake, Napa, Solano and Sonoma counties and does not occur within the Plan Area.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	Status[A] (Federal/State/ CNPS)	Selection Criteria For Coverage[B] Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information	Consider for Coverage?	Coverage Comments
96. Showy madia *Madia radiata*	-/-/1B	+	+	-	+	No	This species occurs on hillsides and at high elevations. Recent recorded occurrences have been in southern central California in the counties of San Benito, Monterey, San Luis Obispo, Fresno, and Kern. There have also been recorded occurrences in Kings, Contra Costa, San Joaquin, and Stanislaus counties but this species does not occur within the plan and impacts areas.
97. Hall's bush-mallow *Malacothamnus hallii*	-/-/1B	-	-	-	+	No	Most of the recent recorded occurrences of this species have been on hillsides in Contra Costa and Santa Clara counties, but occurrences have also been recorded in Stanislaus, Merced, San Mateo, and Mendocino counties. This species does not occur within the Plan Area.
98. Heller's bush-mallow *Malacothamnus helleri*	-/-/4	-	-	-	+	No	This species has been observed on hillsides in Colusa and Napa counties and does not occur within the Plan Area.
99. Sylvan microseris *Microseris sylvatica*	-/-/4	-	-	-	+	No	This species is widely distributed on hillsides throughout California. It has been observed as far north as Tehama County, as far west as Napa County, as far south as Los Angeles County, and as far east as Inyo County. However, it does not occur within the Plan Area.
100. Sierra monardella *Monardella candicans*	-/-/4	-	-	-	+	No	This species is widely distributed - primarily on hillsides of the Sierra Nevada. It has been observed as far north as Placer County and as far south as San Bernardino County. There is also an undated record of this species in St. Helena in Napa County. This species does not occur within the Plan Area.
101. Green monardella *Monardella viridis* ssp. *viridis*	-/-/4	-	-	-	+	No	This subspecies has been observed on hillsides of the North Coast Range in Sonoma, Lake and Napa counties. It has also been recorded as occurring in the San Gabriel Mountains region in San Bernardino County. This species does not occur within the Plan Area.
102. Little mousetail *Myosurus minimus* ssp. *apus*	-/-/3	-	+	+ (H)	+	No	This subspecies is found in southern California with occurrences recorded only in San Diego and Riverside counties.
103. Cotula Navarretia *Navarretia cotulifolia*	-/-/4	-	+	+ (H)	+	No	This species is widely distributed throughout central and northern California. Its range extends from Lake and Glenn counties in the north to Sonoma and Marin counties in the west to San Benito County in the south and Sutter County in the east.
104. Hoary navarretia *Navarretia eriocephala*	-/-/4	-	+	-	+	No	This species occurs throughout central California from Glenn, Lake and Yuba counties in the north to Stanislaus and Tuolumne counties in the south. It does occur in the Plan Area in the Jepson Prairie area, but not within the impacts areas.
105. Jepson's navarretia *Navarretia jepsonii*	-/-/4	-	-	-	+	No	This species has been observed on hillsides in northern and central California counties Tehama, Glenn, Colusa, Lake, Napa, Sonoma, and Placer but it does not occur within the Plan Area.
106. Baker's navarretia *Navarretia leucocephala* ssp. *bakeri*	-/-/1B	+	+	-	+	No	This subspecies has been observed in vernal pool and swales in northern California counties from Mendocino and Tehama in the north to Marin, Napa, and Solano in the south. It is present within the Plan Area in large playa pools at CDFG Tule Ranch Preserve and in vernal pools and swales at Jepson Prairie and Gridley Ranch Preserves, but those areas are in upland habitat that will not be impacted.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	*Status[A] (Federal/State/ CNPS)*	*Selection Criteria For Coverage[B]*				*Consider for Coverage?*	*Coverage Comments*
		Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information		
107. Pincushion navarretia *Navarretia myersii* ssp. *myersii*	-/-/1B	+	-	-	+	No	This subspecies has been observed in vernal pools in Sacramento, Placer, Amador, Calaveras, and Merced counties but it does not occur within the Plan Area.
108. Adobe navarretia *Navarretia nigelliformis* ssp. *nigelliformis*	-/-/4	-	-	-	+	No	This subspecies is widespread throughout central California from Butte County in the north to Kern County in the south, but there have been no recorded occurrences within the counties included in the Plan Area.
109. Prostrate vernal pool navarretia *Navarretia prostrata*	-/-/1B	-	-	-	+	No	This species is broadly distributed in southern and central California. The northernmost counties in which it has been observed are Alameda and Merced. It does not occur within the Plan Area.
110. Colusa grass *Neostapfia colusana*	T/E/1B	+	+	-	+	No	This species is present within the Plan Area in large playa pools at the Jepson Prairie Preserve but that area is upland habitat that will not be impacted.
111. Antioch Dunes evening primrose *Oenothera deltoides* ssp. *howellii*	E/E/1B	+	+	-	+	Yes	Though it does not meet all four criteria, due to this species' rarity and dependence on limited specialized habitat that is found in the Plan Area, it is proposed for coverage under the BDCP. This subspecies only occurs in the Antioch Dunes and does not occur within impacts areas. It is proposed for coverage because it is a listed species associated with the inland dune scrub natural community.
112. San Joaquin Valley Orcutt grass *Orcuttia inaequalis*	T/E/1B	+	-	-	+	No	With the exception of a single population near Travis Air Force Base in Solano County, this species is distributed in large vernal pools on the east side of the San Joaquin Valley and it does not occur within the Plan Area.
113. Hairy Orcutt grass *Orcuttia pilosa*	E/E/1B	+	-	-	+	No	This species occurs in large vernal pools and playas on the eastern margin of the Central Valley north and south of the Delta and does not occur within the Plan Area.
114. Slender Orcutt grass *Orcuttia tenuis*	T/E/1B	+	-	-	+	No	This species occurs in vernal pools and vernally wet areas in Lake County, the eastern side of the Sacramento Valley, and the Modoc Plateau and does not occur within Plan Area.
115. Sacramento Orcutt grass *Orcuttia viscida*	E/E/1B	+	-	-	+	No	This species occurs in hard-pan vernal pools on the eastern edge of Sacramento County and does not occur within the Plan Area.
116. Gairdner's Yampah *Perideridia gairdneri* ssp. *gairdneri*	-/-/4	-	-	-	+	No	This subspecies is widely distributed throughout California. It has been observed as far north as Humboldt and Siskiyou counties and as far south as Kern and Orange counties but it does not occur within the Plan Area.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	Status[A] (Federal/State/ CNPS)	Selection Criteria For Coverage[B]				Consider for Coverage?	Coverage Comments
		Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information		
117. Mt. Diablo phacelia *Phacelia phacelioides*	-/-/1B	-	-	-	+	No	This species occurs at high elevations of the inner Coast Range and does not occur within the Plan Area.
118. Michael's rein orchid *Piperia michaelii*	-/-/4	U	-	-	+	No	This species is widely distributed throughout California. It has been observed in coastal counties from Humboldt to Los Angeles and in inland counties from Butte to Tulare. However, it does not occur within the Plan Area.
119. Hairless popcorn-flower *Plagiobothrys glaber*	-/-/1A	U	-	-	+	No	Herbarium collections of this species are mostly very old and its current status is unknown. The collections are from heavy alkaline clays in the south San Francisco Bay area and from scattered alkaline seeps in the inner Coast Range from the Livermore Valley to San Benito County. Therefore, this species does not occur within the Plan Area.
120. Bearded popcorn-flower *Plagiobothrys hystriculus*	-/-/1B	+	+	-	+	No	This species is present within the Plan Area in vernal pools and swales at Jepson Prairie and Gridley Ranch Preserves, but those areas are in upland habitat that will not be impacted. It is endemic to a small area of Solano County from Gridley Ranch to the Montezuma Hills.
121. Marin knotweed *Polygonum marinense*	-/-/3	-	-	+ (H)	+	No	This species is present in the Suisun Marsh, but it is a widespread species in central California salt marshes in Marin, Sonoma, Napa, and Solano counties.
122. Eel-grass pondweed *Potamogeton zosteriformis*	-/-/2	-	+	+ (H, ID, O)	+	No	This species is not likely to be listed within the plan period as it is widely distributed in northern California (Consortium of California Herbaria 2008).
123. Delta woolly-marbles *Psilocarphus brevissimus* var. *multiflorus*	-/-/4	-	+	-	+	No	This variety is widespread in vernal pools found in central California counties from Butte and Glenn counties in the north to Santa Clara and Stanislaus counties in the south. It is also likely to be present in vernal pools in the Jepson Prairie area, but that upland area will not be impacted.
124. Lobb's Aquatic Buttercup *Ranunculus lobbii*	-/-/4	-	U	U	+	No	This species is widespread in vernal pools found from Mendocino and Lake counties in the north to Monterey County in the south. It is not present in the Jepson Prairie area but may be present at the Tule Ranch Preserve, but that upland area will not be impacted.
125. Victor's gooseberry *Ribes victoris*	-/-/4	-	-	-	+	No	This species is found on hillsides of the Coastal Ranges of northern and central California and it does not occur within the Plan Area.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	Status[A] (Federal/State/ CNPS)	Selection Criteria For Coverage[B]				Consider for Coverage?	Coverage Comments
		Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information		
126. Sanford's arrowhead *Sagittaria sanfordii*	-/-/1B	-	+	+ (H, AD, ID, O)	+	No	This species is broadly distributed in the Central Valley (CNDDB, Consortium of California Herbaria 2008) and is unlikely to be listed during the plan period.
127. Rock sanicle *Sanicula saxatilis*	-/SR/1B	-	-	-	+	No	This species occurs at high elevations of the inner Coast Range does not occur within the Plan Area.
128. Marsh skullcap *Scutellaria galericulata*	-/-/2	-	+	+ (H, AD, ID, O)	+	No	This species is broadly distributed in wet soils in central and northern California from Siskiyou and Modoc counties in the north to Inyo County in the south.
129. Side-flowering skullcap *Scutellaria lateriflora*	-/-/2	U	+	+ (H, AD, ID, O)	U	Yes	Though it does not meet all four criteria, due to this species' rarity and dependence on limited specialized habitat that is found in the Plan Area, it is proposed for coverage under the BDCP. There are only three reported occurrences of this species: one herbarium collection from Santa Clara that was recently determined to be this species; an 1882 collection from Bouldin Island, and; a 1999 collection at Delta Meadows River Park, (Consortium of California Herbaria 2008).
130. Rayless Ragwort *Senecio aphanactis*	-/-/2	-	-	-	+	No	This species is widely distributed on hillsides of California coastal ranges from the inner Coast Ranges in Solano County to the Peninsular Ranges in San Diego County and does not occur within the Plan Area.
131. Most beautiful jewel-flower *Streptanthus albidus* ssp. *peramoenus*	-/-/1B	-	-	-	+	No	This subspecies occurs on rocky serpentine slopes of the coast range from Contra Costa County to San Luis Obispo County, and does not occur within the Plan Area.
132. Mt. Diablo jewel-flower *Streptanthus hispidus*	-/-/1B	-	-	-	+	No	This species is found at high elevations of Mount Diablo in Contra Costa County does not occur within the Plan Area.
133. Suisun Marsh aster *Symphyotrichum lentum*	-/-/1B	+	+	+ (H, AD, ID, O)	+	Yes	Meets all four criteria. Suisun Marsh aster grows in brackish and freshwater marshes and along the banks of sloughs and watercourses. It has been observed growing with common reed, cattails, bulrushes, and blackberry (Solano HCP 2007). It is covered in the Solano and San Joaquin HCPs. It is found in valley riparian, tidal perennial aquatic, tidal freshwater emergent wetland, managed seasonal wetland, grassland, agricultural, and developed. There are numerous occurrences in the Legal Delta, particularly near the Sacramento River, San Joaquin River, and tributaries and in the vicinity of Pittsburg, Antioch, and Big Break going eastward. Broadly distributed throughout the Delta and in the Napa River, will likely benefit from habitat restoration.
134. Wright's trichocoronis *Trichocoronis wrightii*	-/-/2	-	+	+ (H, AD)	+	No	Both the Jepson Manual and the Flora of North America state that this species is not native to California, but is instead native to Texas and Mexico.
135. Showy indian clover *Trifolium amoenum*	E/-/1B	+	-	-	+	No	This species is known from two extant occurrences near Tomales Bay and Bodega Bay and a few historical occurrences near Fairfield. It does not occur within the Plan Area.

Appendix C. Evaluation of Special-Status Fish, Wildlife, and Plants Known or Likely to Occur in the Plan Area for Coverage under the BDCP (continued)

Scientific Name/ Common Name	Status[A] (Federal/State/ CNPS)	Selection Criteria For Coverage[B]				Consider for Coverage?	Coverage Comments
		Listing Potential	Occurrence in the Plan Area	Potential to Adversely Affect[C]	Sufficient Information		
136. Saline Clover *Trifolium depauperatum* var. *hydrophilum*	-/-/1B	-	+	U (H, AD)	+	No	This variety is widely distributed in central California coastal counties, and it is not likely to be listed during the duration of the plan (CNDDB, Consortium of California Herbaria 2008). Known from the Plan Area at CDFG Tule Ranch, could be in the impacts area of the Suisun Marsh and Cache Slough but surveys have not found it in the Jepson Prairie area. Could also be in the vicinity of the Clifton Court Forebay impacts area.
137. Coastal triquitrella *Triquetrella californica*	-/-/1B	-	-	-	+	No	This species is widely distributed from Laguna Mountain in San Diego County to the Coast Range of central California to the North Coast but does not occur within the Plan Area.
138. Dark-mouthed triteleia *Triteleia lugens*	-/-/4	-	-	-	+	No	This species occurs at high elevations. Recent occurrences have been recorded in the Coastal Range from Napa to Monterey. Other occurrences have been recorded in the Sierra Nevada in Plumas, El Dorado, and Mariposa counties; and several occurrences have been recorded Lake, Fresno, and Los Angeles counties. It does not occur within the Plan Area.
139. Caper-fruited tropidocarpum *Tropidocarpum capparideum*	-/-/1B	+	+	+ (AD)	+	Yes	Meets all four criteria. Caper-fruited tropidocarpum grows on alkaline flats and low alkaline hills within valley and foothill grassland (San Joaquin HCP 2000; CNDDB 2008). It is covered in the San Joaquin HCP. Historical occurrences are within Plan Area at the Clifton Court Forebay but no current occurrences are documented from that area. The ISA Report recommends that this species be eliminated from consideration for coverage. However, this species is very rare and appears to have a long-lived seed bank that may be present in the Clifton Court Forebay impacts areas.
140. Greene's tuctoria *Tuctoria greenei*	E/R/1B	+	-	-	+	No	This species occurs in large playa type vernal pools on the east side of the Sacramento Valley. None of these occurrences are within Plan Area.
141. Solano grass *Tuctoria mucronata*	E/E/1B	+	-	-	+	No	This species is not present within Plan Area. The Olcott Lake population has been extirpated and the existing populations in Solano and Yolo Counties are outside of the project and impacts areas.
142. Oval-leaved viburnum *Viburnum ellipticum*	-/-/2	-	-	-	+	No	This species is widely distributed from the North Coast-Klamath Region to the inner Coast Range and Sierra Nevada but does not occur within the Plan Area.

[A] Status Explanations

Federal
- E = listed as endangered under the federal Endangered Species Act (ESA)
- T = listed as threatened under the federal ESA
- C = candidate for listing under the federal ESA
- BCC = U.S. Fish and Wildlife Service bird of conservation concern
- NSC = National Marine Fisheries Service species of concern
- – = no status

State
- E = listed as endangered under the California ESA
- T = listed as threatened
- C = Candidate for listing under CESA
- SSC = California species of special concern
- FP = fully protected under the California Fish and Game Code
- R = listed as rare under the California Native Plant Protection Act
- – = no status

California Native Plant Society (CNPS)
- 1A = presumed extinct in California
- 1B = rare or endangered in California and elsewhere
- 2 = rare and endangered in California, more common elsewhere
- 3 = species lacking sufficient information to determine status
- 4 = limited distribution, low threats at this time
- – = no status

[B] Criteria met or not
- + = Species meets the selection criterion
- – = Species does not meet the selection criterion
- U = Uncertain whether species meets selection criterion. More investigation required.

[C] BDCP Actions (covered activities and conservation measures) potentially adversely affecting the species
- H = habitat restoration actions
- ID = in-Delta conveyance facilities
- AD = around-Delta conveyance facilities
- O = water operations

1. INTRODUCTION

This report describes the application of the Delta Regional Ecosystem Restoration Implementation Plan (DRERIP) Scientific Evaluation Process to evaluate draft conservation measures being considered for inclusion in the Bay Delta Conservation Plan (BDCP). The report summarizes the DRERIP process, how it was applied, who was involved, and the key findings. This application of the DRERIP process to proposed BDCP conservation measures is intended to provide technical input to the BDCP planning process and to provide insights into potential refinement of draft conservation measures.

The DRERIP evaluation process, as described in more detail below, involved evaluating each proposed BDCP conservation measure independently to identify the effectiveness of each on its own merits. Some measures related to water operations such as the Hood Bypass Criteria were provided to the evaluation team as a single measure with a given set of assumptions regarding Delta Cross Channel operations and south Delta diversions, because they are integral components of the dual conveyance strategy being pursued by the BDCP. Ultimately, the BDCP will include an overall Conservation Strategy comprised of a suite of conservation measures, many of which bear on each other (see *An Overview of the Draft Conservation Strategy for the Bay Delta Conservation Plan* dated January 12, 2009). Such a suite of measures may provide benefits greater than the sum of the individual measures. To begin to address this issue, a Synthesis Team was convened following the initial DRERIP evaluations to consider potential synergies and conflicts between various measures and to develop recommendations for possible modifications to the draft conservation measures. Due to time limitations, however, the Synthesis Team did <u>not</u> utilize the DRERIP evaluation procedure to evaluate the outcomes of modified conservation measures or the potential impact of combinations of conservation measures.

All evaluation results presented herein are relative to existing, baseline conditions in the Delta (i.e. will the measure result in a change, either positive or negative, making conditions better or worse than they currently are). The existing regulatory baseline was assumed to be D-1641.

Following this introduction, Section 2 provides general background information on the DRERIP evaluation process. Section 3 provides a summary of how the process was specifically applied to proposed BDCP conservation measures and Section 4 provides a summary of findings from the evaluations of individual conservation measures. Section 5 presents results and recommendations from the Synthesis Team.

2. DRERIP EVALUATION PROCESS

The following sections provide a brief summary of how the DRERIP evaluation process is structured including information on scoring procedures and scoring criteria.

2.1 Background and Purpose

The DRERIP Scientific Evaluation Process was developed to aid planning and decision making for ecosystem restoration projects in the Delta. The process entails engaging teams of experts to work through a structured, step-by-step scientific examination of the potential positive and negative outcomes resulting from proposed restoration actions. Detailed instructions describing each of the steps used in the evaluation process, as well as definitions for key terms, is provided in Appendix A.

The process relies on a series of ecosystem and species' life history conceptual models developed specifically for the Delta. These conceptual models describe the current scientific understanding of how the Delta ecosystem works and are designed to serve as a foundation for the evaluation process. The conceptual models are useful because they summarize existing scientific knowledge in a comprehensive manner for a given species or aspect of the ecosystem. Additional sources of information, for example recent published literature not embraced by the models can also be utilized, resulting in evaluations based on up-to-date information. In a few limited cases, the evaluation team conducted new analyses to assess potential outcomes. In these cases, the analysis is provided as an appendix to the evaluation worksheet. These additional analyses have not been peer reviewed.

The DRERIP process focuses strictly on ecological issues. It is not designed, or intended to address other factors that may ultimately influence decisions, such as cost or socio-economic considerations. The process also does not address issues of feasibility or priority setting. Most of the BDCP conservation measures evaluated were previously screened relative to basic feasibility factors.

The DRERIP process is designed to evaluate restoration actions at any level provided, with the evaluations results being more specific as the action itself is described in more specific terms. It can look at single actions and groups of actions; the more complex the restoration action, the more effort required to conduct the evaluation and potentially less certainty in the findings. DRERIP was not designed to conduct new technical analyses of restoration actions (e.g., numerical hydrodynamic modeling) but instead to draw upon the existing knowledge base as contained in peer-reviewed conceptual models and other information where needed and available.

The scope of evaluations for BDCP were focused on individual BDCP conservation measures (which in many cases are very large in nature) and not on considering multiple conservation measures together. The Synthesis Team examined these possible synergies and provided recommendations to further refine the conservation measures, where appropriate, to improve their overall benefits to covered fish species. Readers should be cautious in attempting to estimate cumulative or synergistic impacts of different actions; the scores are not necessarily additive or multiplicative. Several low magnitude actions may or may not correspond to a "medium" overall outcome. Also, some conservation measures may interact negatively with other conservation measures (e.g. if habitat restoration produces changes in tidal prism or hydrodynamics that are counter to those required for positive outcomes of another conservation measure).

2.2 Magnitude and Certainty Scores

After identifying likely outcomes for each conservation measure, the evaluation team assigned scores to each outcome reflecting the expected magnitude of the outcome (positive and negative) and the level of certainty regarding that magnitude. Magnitude and certainty scores were assigned to both positive and negative outcomes based on current scientific information. Definitions and the criteria used for assigning magnitude and certainty scores are shown in Table 1 and 2 below.

Table 1 - Criteria for Scoring the Magnitude of Ecological Outcomes

Magnitude *–the size or level of the outcome, either positive or negative, in terms of population or habitat effects on a given species. Magnitude is not the same as the scale of the action; however, higher magnitude scores require consideration of scale.*
4 - High: expected sustained major population level effect, e.g., the outcome addresses a key limiting factor, or contributes substantially to a species population's natural productivity, abundance, spatial distribution and/or diversity (both genetic and life history diversity) or has a landscape scale habitat effect, including habitat quality, spatial configuration and/or dynamics. Requires a large-scale Action.
3 - Medium: expected sustained minor population effect or effect on large area (regional) or multiple patches of habitat. Requires at least a medium-scale Action.
2 - Low: expected sustained effect limited to small fraction of population, addresses productivity and diversity in a minor way, or limited spatial (local) or temporal habitat effects.
1 - Minimal: Conceptual model indicates little effect.

Table 2 - Criteria for Scoring Certainty of Ecological Outcomes

Certainty *-– the likelihood that a given Restoration Action will achieve a certain Outcome. Certainty considers both the predictability and understanding of linkages in the pathway from the action to the outcome. Generally, high importance-low predictability linkages drive the scoring; it is important to ensure that certainty is not unduly weighted by a comparatively low-importance, albeit low-predictability linkage.*
4 - High: Understanding is high (based on peer-reviewed studies from within system and scientific reasoning supported by most experts within system) and nature of outcome is largely unconstrained by variability (i.e., predictable) in ecosystem dynamics, other external factors, or is expected to confer benefits under conditions or times when model indicates greatest importance.
3 - Medium: Understanding is high but nature of outcome is dependent on other highly variable ecosystem processes or uncertain external factors or understanding is medium (based on peer-reviewed studies from outside the system and corroborated by non peer-reviewed studies within the system) and nature of outcome is largely unconstrained by variability in ecosystem dynamics or other external factors
2 - Low: Understanding is medium and nature of outcome is greatly dependent on highly variable ecosystem processes or other external factors or understanding is low (based on non peer-reviewed research within system or elsewhere) and nature of outcome is largely unconstrained by variability in ecosystem dynamics or other external factors
1 - Minimal: Understanding is lacking (scientific basis unknown or not widely accepted), or understanding is low and nature of outcome is greatly dependent on highly variable ecosystem processes or other external factors

These definitions indicate how challenging it is for an individual action to achieve a magnitude score of 4 (population level effect) in a complex ecosystem with many stressors. Similarly, because many of the outcomes are influenced by highly variable (and thus unpredictable) ecosystem dynamics, only rarely will an individual action achieve high or even medium certainty scores. A measure with a "low" magnitude score can still be implemented – and the cumulative effects of many such actions may result in a greater level of effect at the population level scale.

For some species, particularly salmonids and sturgeon that spend a relatively short portion of their life history in the Delta, it is rare for Delta-specific actions to have population level effects. The benefits of measures in the Delta can easily be overwhelmed by conditions upstream and/or downstream (i.e., ocean), which may be driving the population in more significant ways. Given this fact, magnitude scores of "3" or "4" are not common for salmonids with Delta restoration alone.

Beyond individual magnitude and certainty scores, it is important to review combinations of magnitude and certainty (i.e., different combinations suggest different things). For example, a medium benefit with low certainty (combined score of "3, 2") means that the team concluded that the outcome would have a minor population level effect and that the certainty that this magnitude would be achieved (as opposed to a lower magnitude) was low.

Both positive and negative outcomes are scored, and it's important to look at the positive scores in combination with the negative scores to provide an overall evaluation of the action. Together, these outcomes could result in a theoretical no-net-gain, or even a net negative effect. Many of these trade-offs are potentially quite complex and very difficult to predict in terms of likely net biological response, the mechanisms underlying those responses, and our ability to mitigate risk factors in design and implementation.

3. EVALUATION OF BDCP CONSERVATION MEASURES

The following sections describe how the DRERIP Scientific Evaluation Process was applied to proposed BDCP measures.

A total of 32 draft BDCP conservation measures were identified for evaluation. These measures were selected by the BDCP planning team from the draft conservation measures described in Handouts #3, 4, and 5 from the October 31, 2008 BDCP Steering Committee meeting. These measures were reviewed and refined in December 2008 for the purposes of conducting the DRERIP evaluations. Refinements included stipulating details such as target restoration acreages and bypass flows. A listing of the measures evaluated as well as descriptions of those measures as provided to the evaluation team are contained in Appendix C. This refinement for the purposes of evaluation occurred prior to the release of the BDCP Overview document entitled *An Overview of the Draft Conservation Strategy for the Bay Delta Conservation Plan* dated January 12, 2009. As a result, there are some minor differences in the descriptions and assumptions between the measures evaluated and those described in the Overview document.

A team of 50 experts was convened to evaluate several draft proposed BDCP conservation measures. Team members were selected based on their expertise relative to the specific ecological issues associated with the draft conservation measures, as well as their familiarity with the Delta, the DRERIP conceptual models, and the DRERIP evaluation process. Team members were trained on how to conduct the evaluations and were tasked with reviewing particular conceptual models prior to the evaluations. The team was further divided into five subteams with each team assigned specific conservation measures on related topics. Each subteam was headed by a Chair familiar with the topic and was assigned a 'coach; familiar with the DRERIP process. A listing of evaluation team members is provided in Appendix D.

A series of workshops were held where team members discussed the draft measures and worked through the pre-established evaluation steps for each action. Workshops were followed by team conference calls and email deliberations over a three-month period from January to April 2009, including review and refinement of findings. The results of each team's evaluations were recorded in standardized worksheets which were reviewed and edited by the teams. Due to the intensity and volume of work, not all evaluations were completed to the same level of detail and not all worksheets were reviewed by all team members.

4. SUMMARY OF FINDINGS

The following presents a brief summary of findings from the evaluation of individual draft proposed BDCP conservation measures. Summary findings are presented for each subteam. All findings are for the specific conservation measures as given to the teams in January 2009 (see Appendix C). Findings regarding interrelationships between conservation measures are discussed in Section 5 of this report.

Completed evaluation worksheets for each measure, including the rationales behind the findings, can be viewed at http://baydeltaconservationplan.com/BDCPPages/BDCPInfoBackgroundDOcsDRERIP.aspx . The detailed worksheets include the specifics regarding individual measures and expected species outcomes. The numerous and complex ecological interactions and trade-offs between the various measures do not lend themselves well to simple summary results. For example, there can be a temptation to gauge a measure's merits by simply reviewing the magnitude scores for positive outcomes. Readers should note that: (1) magnitude scores for positive outcomes represent the highest possible outcome; (2) certainty scores indicate the degree of certainty experts have about attaining an outcome as high as that indicated by the magnitude score; and (3) negative outcomes associated with the conservation measures deserve attention as well. The worksheets prepared by each evaluation subteam describe in detail the potential benefits and pitfalls associated with each conservation measure.

Not all evaluations were completed with equal degrees of analysis due to time and budget constraints. In several instances, general conclusions from one evaluation were applied to other evaluations, with varying levels of measure-specific refinements. Details of measure-specific differences were not always explored fully due to limited information and uncertainties about the population level effects of these differences. Evaluations that fall into this category are noted in their worksheets.

Each evaluation worksheet contains a list of data gaps and future research needs. These lists warrant further consideration by BDCP.

Appendix D provides a series of tables listing the magnitude and certainty scores for each measure and the expected outcomes (positive and negative) by species.

4.1 Floodplain and Riparian Habitat Restoration Measures

Nine specific floodplain and riparian habitat restoration measures were evaluated including restoring former floodplains along the San Joaquin River (HRCM1, 2) and in the South Delta (HRCM3), creating channel margin habitat along Steamboat and Sutter sloughs (HRCM12) and the San Joaquin River (HRCM13), and creating riparian habitat in association with other actions (HRCM11, 14). The Floodplain and Riparian Habitat team also evaluated measures to modify and reoperate the Fremont Weir and Yolo Bypass (Core Element No.1, WOCM2) and to create a new bypass adjacent to the Sacramento River Deep Water Ship Channel (WOCM3). Multiple scenarios were considered for several of the actions involving different restoration acreages and different inundation regimes.

Fremont Weir and Yolo Bypass (Core Element No.1; WOCM2)

- Modifications to the Fremont Weir and reoperation of the Yolo bypass to provide higher frequency and duration of inundation is expected to have high magnitude benefits for several covered species with a high degree of certainty.
- Benefits are attributable to increased spawning and rearing habitat as well as expected reductions in stranding and associated illegal harvest.
- Results suggest that Option 1 (spill discharge of 4,000 cfs for 45 days) would provide greater benefits for covered species than Option 2 (spill discharge of 2,000 cfs for 30 days) due to the greater extent and duration of flooding.
- Potential negative outcomes to covered species were few, and appear to be manageable through more detailed design and effective monitoring. The potential for mercury methylation and associated environmental toxicity is expected to be of low magnitude for covered fish species, but the certainty of that outcome is low because there is very limited data on mercury toxicity to fish in the Delta.
- Results for creation of a new floodplain bypass adjacent to the Sacramento Deep Water Ship channel (WOCM3) were similar to those for reoperation of the Yolo bypass.

San Joaquin River and South Delta (HRCM1, 2, and 3)

- Floodplain restoration measures along the San Joaquin River would be expected to provide minimal to low benefits (with a medium to high degree of certainty) due to infrequent floodplain inundation associated with the current San Joaquin River flow regime, which is a limiting factor.
- Expected benefits of floodplain restoration in the south Delta (along Old River at Fabian Tract) are also minimal to low due to the relatively small scale of the action (800 to 1600 acres). However, there could be minor population level benefits for splittail associated with this measure if the Old River were isolated such that it did not experience the effects of south Delta pumping.

Channel Margin and Riparian Habitat (HRCM 11, 12, 13 and 14)

- Proposed improvements to "channel margin habitat" would be expected to have largely minimal to low benefits for covered species due to the relatively small scale of the actions, the lack of any change in the currently impaired flood hydrology, and the fact that channels would not be allowed to evolve and erode providing limited instream structure such as woody debris.
- The team recommended providing a clearer definition of "channel margin" habitat.

4.2 Tidal Restoration Measures

The effects of reintroducing tidal flows into six Restoration Opportunity Areas (ROA) in the Delta were evaluated, including the Yolo/Cache Slough Complex ROA (Core Element No. 6; HRCM4), the Cosumnes/Mokelumne ROA (HRCM5), the West Delta ROA (Core Element No. 7; HRCM6), the South Delta ROA (HRCM7), the East Delta ROA (HRCM8), and the Suisun Marsh ROA (Core Element No. 8; HRCM9). Restoration of these areas would involve varying degrees of tidal marsh and shallow subtidal restoration as described in more detail in Appendix C. Multiple scenarios were considered for several of the ROAs reflecting different amounts of restored habitat. The evaluation team focused its greatest efforts on HRCM4 (Yolo/Cache) and HRCM9 (Suisun); HRCM6 (West Delta) received the next level of effort; and the remaining measures were evaluated with far less detail.

In general, evaluation results vary considerably depending on the species in question and the geographic location of the restoration. The magnitude of the benefits tend to be greater for delta smelt (which spends its entire life history in the delta preferring cooler, turbid waters) than they are for migratory fish, such as salmon and sturgeon which spend a relatively small portion of their life cycle in the Delta. The likelihood that restored tidal areas would export zooplankton and insects to provide food for covered species in other areas of the Delta is a function of the size of the restoration area, its relative mix of marsh and open water, its connectivity to the estuary, the amount of riverine influence on the area, and the degree to which production is consumed within the ROA. The evaluation team had difficulty evaluating this outcome and in the end presented alternate conclusions. These different viewpoints reflect a core need to gain better understanding, which can be accomplished most effectively through implementing restoration efforts and evaluating their outcomes on this issue.

Negative outcomes of concern include the potential for restored areas to be colonized by *Egeria* providing habitat that increases predation risk, and the potential for methylation of mercury.

Yolo/Cache Slough ROA (Core Element No. 6; HRCM4)

- Many of the benefits of this restoration depend upon relocation of major urban and agricultural water supply diversions within the Cache Slough area, especially the North Bay Aqueduct intake and a handful of the large agricultural intakes.
- Expected medium magnitude benefits (minor population level effect) for delta smelt, splittail, and Sacramento fall-run Chinook salmon, but with low certainty. While the measure would increase the amount of habitat area for delta smelt in the north Delta, it would not expand the range of the species in the Delta, a critical concern for delta smelt conservation.
- Expected minimal to low population benefits for longfin smelt, sturgeon, winter and spring-run Chinook salmon, and steelhead with low certainty. The evaluation recognized that the near total absence of tidal marshes in the Delta and thus the near total absence of local data to understand how these species may use or be affected by restored tidal habitats contribute to the low certainty score.
- The measure has the potential to produce a considerable quantity of organic carbon to support the aquatic food web; uncertainty exists regarding the extent to which the primary production component might be reduced if invasive clams colonize restored areas. Uncertainty also exists about the magnitude of secondary production being transported to locations where covered fish species could gain the most benefit.
- The establishment of *Corbicula* could limit or eliminate the benefits of the action by consuming increases in primary productivity created by the restored marsh and subtidal areas. Uncertainty is high regarding whether this loss of primary production could affect secondary production – zooplankton and insects – that serve as the primary prey items for covered fish species.
- Other invasives, namely *Egeria* and centrarchids, could have a medium magnitude negative effect on covered species, but the certainty of this effect is low.

- The potential for mercury methylation is expected to be of low magnitude with medium certainty; the associated environmental toxicity for covered fish species is expected to be of low magnitude, but the certainty of this toxicity outcome is low because there is very limited data on mercury toxicity to fish.
- The negative outcomes for human health and piscivorous wildlife associated with the potential for habitat restoration to increase MeHg concentrations in fish received low magnitude and medium certainty scores and need to be seriously considered.
- Increased mercury methylation could potentially be a significant issue for birds and humans.
- Linkage to Yolo Bypass improvements identified as raising the benefits of this measure though the magnitudes were not assessed.

Cosumnes/Mokelumne ROA (HRCM5)

- This evaluation was not subject to the full development and review by the evaluation team so its findings are preliminary and subject to revision were further analysis to be conducted.
- Expected medium magnitude benefits (minor population level effect) for splittail with medium certainty.
- Expected minimal to low benefits for delta smelt, longfin smelt, sturgeon, steelhead, and salmonids (all runs) with minimal to low certainty.
- The measure would likely provide low magnitude local increases in productivity, but may not provide a significant net increase in zooplankton or insects to other areas of the Delta. See productivity discussion for HRCM4 above.
- Potential for negative outcomes, including establishment of *Egeria* and centrarchids are similar to that described above for the Yolo/Cache ROA.

West Delta ROA (Core Element No. 7; HRCM6)

- This evaluation was not subject to the full development and review by the evaluation team so its findings are preliminary and subject to revision were further analysis to be conducted.
- Results indicate that the effects of *Egeria* establishment and associated predation are potential medium to high magnitude negative outcomes, but certainty is low. This measure has a greater likelihood for this negative outcome due to its composition of many, relatively small restorations alongside large water bodies vs. the larger restorations of other ROAs.
- The West Delta ROA is particularly limited by the fact that it consists of numerous, small, disconnected parcels.

South Delta ROA (HRCM7)

- This evaluation was not subject to the full development and review by the evaluation team so its findings are preliminary and subject to revision were further analysis to be conducted.
- Expected minimal to low benefits for all covered species with minimal to low certainty.
- Similar to the West Delta ROA, results indicate that the effects of *Egeria* establishment and associated predation are potential medium to high magnitude negative outcomes, but certainty is low.
- The potential for this measure to adversely contribute to low dissolved oxygen (DO) conditions in the Delta was also identified as a concern with a medium magnitude, but low certainty. Increased residence times associated with limited circulation combined with greater biological productivity contributing to increased water column Biological Oxygen Demand (BOD) could lead to low DO conditions.

- Benefits considered minimal at best under current conveyance and export configuration.
- Potential for negative outcomes is similar to that described above for the Yolo/Cache ROA.

<u>East Delta ROA (HRCM8)</u>

- This evaluation was not subject to the full development and review by the evaluation team so its findings are preliminary and subject to revision were further analysis to be conducted.
- Benefits for covered fish species are expected to be low with minimal to low certainty.
- Potential for negative outcomes is similar to that described above for the Yolo/Cache ROA.
- Evaluation noted potential for greater magnitude of negative outcomes due to the relative isolation of this ROA and the poor quality habitats linking it to other suitable habitat areas.

<u>Suisun Marsh ROA (Core Element No. 8; HRCM9)</u>

- Expected medium magnitude benefits (minor population level effect) of providing habitats for splittail, delta smelt, and fall and spring-run Chinook salmon, but certainty is minimal to low.
- Expected medium magnitude benefits for contributing desired productivity contributions, with low to medium certainty; benefits highly dependent on where within Suisun Marsh the restoration efforts are located.
- Expected to reduce periodic low dissolved oxygen conditions that originate with the existing managed wetlands.
- May reduce overall methyl mercury production and exposure that originate with the existing managed wetlands (medium magnitude, low to medium certainty).
- Potential for establishment of *Egeria* is zero, but potential for establishment of *Corbula*, which could constrain the desired productivity benefits, is high with a low certainty. Predator establishment potential is minimal to low, with low certainty.

4.3 Water Operations Measures

The team evaluated two potential water operations conservation measures, a new diversion point in the north Delta with Hood Bypass Criteria and other Measures (Core Elements No. 2, 3, 4, and 5; WOCM1) and new Interim Tidal Gates in the south Delta (Core Element No. 9; WOCM8) - commonly referred to as 2-Gates. Evaluation of the new north Delta diversion and associated other measures included reductions in south Delta pumping (dual conveyance), changes to Delta Cross-channel gate operations, and two alternative Hood bypass flow criteria. Modifications and operational changes to the Yolo Bypass (WOCM2) were evaluated as part of the floodplains evaluation. The Interim Tidal Gates measure included installing operable tidal gates in Old River on the eastern side of Bacon Island, and in Connection Slough on the western side of Bacon Island. The implications of the Interim Tidal Gates measure were only evaluated for delta smelt and longfin smelt.

The evaluation of WOCM1 did <u>not</u> include any assessment of entrainment or impingement related to fish screens on the new North Delta Diversion(s). The team assumed that the fish screens would be 100% efficient.

Results of the evaluation point to complex trade-offs between potential positive outcomes in the south Delta associated with reduced export pumping resulting in modified Old and Middle River (OMR) flows and potential negative outcomes in the north Delta associated with the new diversion. Negative outcomes are also expected in the south Delta related to exacerbation of existing low dissolved oxygen conditions and other water quality impacts, including the potential for greater residence times (i.e., less flushing) and less dilution of San Joaquin River inflows.

<u>New North Delta Diversion with Hood Bypass Criteria and other Measures (Core Elements No. 2, 3, 4, and 5; WOCM1)</u>

- Reduced diversions at the South Delta facilities, and associated reductions in entrainment are expected to result in:
  - medium magnitude benefits with medium certainty for delta smelt adults and juveniles;
  - medium magnitude benefits for longfin smelt juveniles and low magnitude benefits for longfin smelt adults with medium certainty; and
  - low magnitude benefits for splittail, Sacramento River salmon runs, and steelhead with medium certainty.
- The potential benefits of reduced diversions at the South Delta facilities are expected to be minimal for San Joaquin fall-run Chinook salmon (*Stanislaus, Merced, and Tuolumne rivers)* because exports remain high during the period SJR fall run Chinook are migrating through the south Delta and the action does not address SJR flows which are needed to facilitate escapement.
- New diversions on the Sacramento River would have negative effects due to increased predation, both at the diversion facilities themselves and downstream due to modified hydrodynamics and fish travel time. The magnitude of the negative impact due to increased predation ranged from low to high depending of species, and will depend on the design of the diversion structures and associated screens (particularly their location and orientation to the river bank), and the change in flow conditions downstream.
- Potential impacts of large diversions of Sacramento River water on foodweb dynamics are highly uncertain. Removal of organic carbon and organisms from the system could adversely impact productivity downstream. However, increased residence time associated with reduced flows could increase primary productivity (additional conservation measures could also potentially influence productivity downstream, namely Yolo Bypass inundation and tidal marsh restoration). Increased primary productivity may not yield suitable secondary productivity utilized by covered fish species because the primary productivity may be intercepted by other organisms, including invasive clams, or it may be of an undesirable form (e.g., Microcystis).
- Evaluation results indicate that operation of a new North Delta Diversion would have medium to high magnitude negative impacts on covered species due to potential declines in water quality in the South Delta, including increased frequency and duration of low dissolved oxygen events.
- There is a medium to high level of certainty that there would be medium level negative impacts to Mokelumne and Cosumnes fall run Chinook.

<u>Interim Tidal Gates (Core Element No. 9; WOCM8)</u>

- The construction of operable tidal gates in Old River and Connection Slough along the east and west sides of Bacon Island is expected to provide medium to high magnitude benefits for adult delta smelt and low to medium benefits for juvenile delta smelt, with low to medium certainty for both outcomes.

- The potential for negative outcomes for delta and longfin smelt associated with increased predation at the new gate structures and increased entrainment at the pumps are expected to be low, with a low certainty.
- Potential implications of the 2-Gates measure on other covered species, including salmonids were not evaluated.

4.4 Hatcheries and Harvest Measures

Six "Other Stressor" conservation measures related to hatcheries and harvest regulations were evaluated including increased sport harvest of non-native predatory fishes (OSCM14), enhanced enforcement in the Delta (OSCM16), modified splittail harvest regulations (OSCM17), implementing a Mark-Select program to reduce the harvest of wild Chinook salmon (OSCM19), establishing artificial propagation programs for delta smelt and longfin smelt (OSCM20), and modifying or eliminating non-project diversions in the Delta (OSCM21).

Increased Sport Harvest of Non-Native Predatory Fishes (OSCM14)

- Expected medium benefits for delta and longfin smelt, but low certainty. Potential benefits for other covered species are minimal to low with low certainty.
- The likelihood and magnitude of positive effects on covered species are not well-understood due to uncertainty regarding (1) the magnitude and frequency of competition between juvenile striped bass and delta and longfin smelt, (2) how fishermen will respond to changes in sport fishing regulations, and (3) the magnitude of the impact of bass predation on any one species. Research in these areas will increase our understanding of the benefits provided to covered species by this measure.
- Negative outcomes identified for this conservation measure are: (1) increased by-catch of non-target species (minimal magnitude, low certainty), (2) release of other predator populations from predation pressure (low magnitude, low certainty), (3) release of other competitor populations from predation pressure (medium magnitude, medium certainty), and (4) unintended changes to the bass populations (i.e., may shift average size of bass populations) (low magnitude, low certainty).

Enhanced Enforcement in the Delta (OSCM16)

- Expected medium benefits for green and white sturgeon, low to medium benefits for Chinook salmon, and low benefits for steelhead – all with low certainty.
- Uncertainty regarding the impact of poaching on population sizes of covered fishes, relative to other threats, makes it difficult to determine the potential benefits of implementing this measure.
- There is a possibility that lack of information regarding where poaching is most important may result in greater effort to enforce fishing regulations in less important areas and a shift of poaching to areas of greater importance to the population.

Modified Splittail Harvest Regulations (OSCM17)

- Two positive outcomes were identified by the evaluation team: (1) increased population abundance of splittail, and (2) improved foodweb energy transfer in wet years. Both are expected to result in medium benefit with low certainty.

- It is difficult to evaluate the potential benefits of this measure due to uncertainty regarding the size of the current splittail fishery, and magnitude of foodweb energy transfer caused by movement of splittail into and out of inundated floodplains.
- The primary negative outcome identified was the potential for redirection of fishing effort toward other sensitive species as splittail harvest regulations are put in place (low magnitude, medium certainty).

Mark-Select Program for Chinook salmon (OSCM19)

- Based on experiences in other states with mark-select fisheries, the evaluation team stated that the effectiveness of such a program largely depends on implementation and monitoring, and that it would be difficult, if not impossible, to limit all commercial and recreational harvest to marked fish.
- Expected medium magnitude benefits for integrated (natural and hatchery produced) Chinook salmon population with medium certainty. The evaluations found that natural Chinook populations may not necessarily increase abundance as other stressors may exert a greater influence on the population.
- Potential negative outcomes include: (1) complication of management and data for conservation hatcheries and agency sampling programs; and (2) increased bycatch and non-harvest mortality of covered salmonids. These outcomes are based largely on uncertainty regarding the magnitude of non-catch mortality and approaches for managing conservation stocks.

Artificial Propagation of Delta and Longfin Smelt (OSCM20)

- Expected medium magnitude benefits for delta smelt and longfin smelt with minimal to low certainty.
- Negative outcomes include: (1) potential genetic consequences for hatchery and wild populations; (2) negative ecological interactions with wild fish (e.g., competition, displacement); (3) genetic bottlenecks resulting from mining of wild population to support broodstock needs leading to reduced capacity of species to adapt to changing environmental conditions; and (4) mortality associated with catching broodstock.
- The potential for mortality associated with collection of broodstock is considered to be low (with medium certainty) because effective collection techniques have been established for delta smelt. Longfin smelt are expected to be less sensitive to handling stress and physical injury than delta smelt (magnitude low, certainty low).
- It will be difficult to determine how many hatchery fish are needed to boost spawning in the wild. Adaptively managing the numbers of hatchery fish introduced will be necessary. Numbers should be adjusted if reproductive rates do not increase.
- The negative outcome results are based largely on uncertainty regarding the genetic implications of hatchery propagation for wild and hatchery delta and longfin smelt. The genetic diversity of hatchery fish is of concern because these fish are to be introduced into the wild, are expected to interbreed with wild fish, and will undergo domestication without integrating new wild broodstock into the propagation activity. Information is particularly limited for longfin smelt, for which hatchery propagation has not been conducted to date.

<u>Reducing Non-project Diversions (OSCM21)</u>

- The positive outcomes identified include: (1) reduced entrainment mortality by non-project diversions; and (2) increased food availability. Benefits are expected to be of minimal magnitude, with minimal certainty for both outcomes due to uncertainty regarding the entrainment mortality caused by non-project diversions and how these diversions affect planktonic food availability.
- No negative outcomes for covered species were identified for this measure.

4.5 Water Quality and Invasive Species Measures

Six "Other Stressor" conservation measures related to water quality and invasive species were evaluated including, measures to: reduce the concentrations of ammonia discharged into the Sacramento River (OSCM1); reduce the loads of endocrine disrupting compounds (EDCs) (OSCM2); reduce the load of methylmercury (OSCM3); reduce loads of pesticides and herbicides (OSCM4); reduce loads of toxic contaminants in stormwater and urban runoff (OSCM5); and remove water hyacinth (*Eichornia crassipes*) and Brazilian waterweed (*Egeria densa*) from select areas of the Delta (OSCM13).

Results of the evaluation indicate that the majority of the water quality and invasive species measures would be expected to deliver positive benefits to covered species, with the exception of OSMC13 (SAV and FAV), for which significant negative outcomes were identified that could potentially deliver net losses for covered species. Negative outcomes were also identified for OSCM1 (Ammonia), OSCM4 (Pesticides) and OSCM5 (Urban runoff). In general, reducing the amounts of chemicals in Delta waterways are expected to be a good thing for covered fish species, even if the specific benefits are difficult to quantify.

<u>Ammonia Loadings Reductions (OSCM1)</u>

- Expected to have medium magnitude benefits for delta smelt and longfin smelt, but the certainty of these benefits is minimal. Benefits for other species are minimal to low magnitude with a range of certainty depending on the species and the specific outcome (see Appendix D).
- Negative outcomes identified include: (1) possible removal of important nutrients from the system by tertiary treatment of WWTP effluent (magnitude minimal, certainty high); (2) microcystis blooms could result from increased nitrate (from nitrification of ammonium) (magnitude low, certainty low); and (3) enhanced phytoplankton production from reduction of ammonium (by nitrification) could increase clam biomass and uptake of selenium, impairing reproduction in benthic-foraging fishes (magnitude medium, certainty high).
- The negative outcomes anticipated in the evaluation are based largely on uncertainty regarding the need to identify more sources of ammonia and the unsettled state of the science regarding food web relationships of phytoplankton, diatoms, microcystis, zooplankton, and clams, and how they and their relationships are affected by excess ammonium in the system, water residence time, salinity, temperature, and flow.
- Integrated research should be undertaken to develop a numerical model of ammonia/ammonium affects on the Delta food web and covered species so that the multiple factors influencing production can be manipulated/isolated from other factors, and the respective roles of each factor can be determined for the different portions of the estuary.

Endocrine Disrupting Compounds (EDCs) Loadings Reductions (OSCM2)

- Reducing EDCs is expected to result in benefits for all covered fish species. The magnitude of these benefits range from low to medium, while certainty is minimal to medium, depending on the outcome.
- There were no negative outcomes identified by the evaluation team for this conservation measure. However, to effectively target reductions in EDCs, the main sources need to be identified and quantified.
- WWTPs contribute to the EDC problem. However, EDCs can also come from pyrethroids and other agricultural runoff, particularly dairies, which represent potentially large, untreated loadings. Therefore, the relative contributions of wastewater treatment plants to those of other potential EDC sources such as hatcheries, pesticide sources (which include both agricultural and urban use), and dairies need to be determined.
- Secondarily, EDC monitoring based on biological responses is needed to identify hotspots and sources as well as temporal and special distribution of EDCs within the system.

Methyl Mercury Loadings Reductions (OSCM3)

- The expected benefits for covered fish species of reducing methyl mercury loadings and resulting bioavailability are minimal to low, with low certainty. The benefits to wildlife and humans, however, are expected to be of medium magnitude with medium certainty.
- There were no negative outcomes for covered species identified by the evaluation team for this conservation measure.
- As more seasonal wetlands are created in the Delta and as the Delta's hydrology changes due to the dual conveyance system or climate change, monitoring of MeHg concentrations in water and fish becomes more important. Species-specific studies on sub-lethal population-level effects (e.g. feeding efficiency, growth, or spawning success) of MeHg in covered fish species are also necessary.
- Monitoring studies would contribute to the development of a numerical MeHg transport and fate model, with a food web component, that combines source information, water transport and residence times, photodemethylation and particle settling to predict methyl mercury concentrations in water, sediment, and biota at various locations in the Delta under different hydrologic conditions.
- From a sociological perspective, better estimates of the number of people at risk for MeHg toxicity due to recreational or subsistence fishing should be made to refine or expand fish consumption advisories and to develop educational strategies for teaching the affected public how to reduce the risk.

Pesticide and Herbicide Loadings (OSCM4)

- Reducing pesticide and herbicide loadings in Delta waterways would be expected to have benefits (medium to high magnitude, medium certainty) for several covered fish species, including delta smelt, green and white sturgeon, spring-run Chinook salmon, and winter-run Chinook salmon.
- The negative outcome identified for this conservation measure was loss of freshwater input to the system and loss of habitat for freshwater phytoplankton and zooplankton if tailwater recovery systems are used as a BMP to reduce pesticide-contaminated runoff (medium magnitude, minimal certainty). This outcome, if confirmed, could be managed by specifying appropriate BMPs to avoid loss of freshwater input.

- There are currently no data on the use of small creeks by covered species or their phytoplankton and zooplankton prey. Such data could be developed to evaluate: 1) the relative importance of the freshwater input of small creeks to the system; 2) the use of small creeks as nursery areas by ecologically important phytoplankton and zooplankton species; and 3) where to avoid freshwater reductions.

Urban Runoff (OSCM5)

- Reducing urban runoff is expected to have benefits (medium magnitude, low to medium certainty) for several covered fish species, including steelhead, spring-run Chinook salmon, winter-run Chinook salmon, fall-run Chinook salmon, delta smelt, longfin smelt, and green and white sturgeon,.
- Negative outcomes identified include: (1) human health impacts from use of ponded stormwater by breeding mosquitoes; and (2) contamination of groundwater by infiltration of impounded surface water. Both of these outcomes could be managed to reduce the likelihood of occurrence.
- Urban runoff containment and treatment methods (both existing and potential future methods) should be assessed with respect to mosquito control and groundwater infiltration. Monitoring should include collection of data to determine how and when small subgroups of the covered species and their zooplankton prey use urban creeks, and how individual sources of runoff affect receiving waters.

Submerged and Floating Aquatic Vegetation (SAV and FAV) (OSCM13)

- Reducing non-native SAV and FAV in specific areas of the Delta is expected to have positive benefits for Chinook salmon and steelhead rearing in the Delta (magnitude medium, certainty medium).
- Negative outcomes identified include: (1) reduction in zooplankton from herbicide toxicity (magnitude low, certainty low); (2) reduction in phytoplankton from herbicide toxicity (magnitude medium, certainty minimal); (3) increased detritus including particulate organic carbon (POC) (magnitude low, certainty low); (4) increased microcystis blooms due to reduced competition for nutrients from phytoplankton and microcystis resistance to herbicides (magnitude low, certainty medium); (5) toxic effects on juvenile sturgeon from fluridone and 2,4-D used at approved application rates (magnitude low, certainty medium); and (6) endocrine disrupting effects of 2,4-D on fish (magnitude low, certainty low).
- A large part of the uncertainty regarding this conservation measure is due to unknown factors in the relationship between phytoplankton and microcystis and how they are affected by herbicides. In addition, more information is needed on the interactive effects of flow and temperature on microcystis blooms.
- The potential toxic effects on sturgeon are based on studies from outside the system that looked specifically at aquatic herbicides. Sturgeon were more sensitive than salmon to these chemicals in controlled laboratory tests. However, the use of proposed weed control areas in the Delta and actual water concentrations resulting from the CDBW program are unknown.
- Most of the uncertainties could be addressed by controlled, small-scale pilot studies with detailed before-and-after monitoring.

5. SYNTHESIS TEAM RECOMMENDATIONS

Following the individual evaluations, a Synthesis Team was formed to examine potential synergies and conflicts between the various draft conservation measures. The team was comprised of the five DRERIP evaluation subteam chairs and select members of the evaluation subteams. Members of the Synthesis Team (see Table 5.1) were assigned to review the evaluation worksheets and identify potential refinements to the draft conservation measures, including additional information or analyses that would be useful in reducing uncertainties. The Team also looked at areas where measures could work with or against each other and tried to identify refinements that would enhance potential synergies and reduce potential conflicts among actions. The Team did not attempt a comprehensive assessment of cumulative impacts or a scoring of the ultimate net effect of the all the measures combined. Synthesis Team findings, as presented below, were based on a series of meetings and discussions among team members culminating in a two-day workshop where the team developed final recommendations.

Table 5.1 – Synthesis Team

Name	Affiliation	Evaluation Team(s) Role
Dave Harlow	SWC	Tidal reintroduction, chair
Stuart Siegel	Wetland and Water Resources	Tidal reintroduction, coach
Chuck Hanson	Hanson Environmental	Tidal reintroduction
Amy Richey	Mosaic/SLDMWA	Tidal reintroduction
Campbell Ingram	TNC	Floodplains, chair
Denise Reed	UNO	Floodplains, coach
Jim Haas	USFWS	Water quality and invasives, chair
David Fullerton	MWD	Water quality and invasives, member
Brad Cavallo	CFS/SWC	Hatcheries and harvest, chair
John Cain	NHI	Water operations, chair
Joshua Israel	EDF	Water operations, Hatcheries and harvest
Rosalie del Rosario	NMFS	Water operations, Floodplains
Matt Norbriga	DFG	Water operations
Armin Munevar	CH2M Hill	Hydrodynamic modeling results
Carl Wilcox	DFG	NA
Michael Hoover	USFWS	NA

5.1 General Synthesis Team Conclusions

Collectively, the synthesis team concluded that a number of the conservation measures have the potential for additional synergistic effects that can raise or lower the worth of some individual conservation measures when implemented concurrently with other actions. The complexity of various trade-offs between expected positive and negative effects make it difficult to predict the biological responses to multiple measures in combination. The Synthesis Team recommended that refinements could be made to the proposed modification of the Fremont Weir and Yolo Bypass inundation, North Delta diversions with bypass criteria, and Cache slough restoration to optimize ecological benefits and water supply goals. They also identified the need for better information and modeling of the survival and growth of covered species and predators to establish baseline conditions against which benefits can be assessed as these BDCP conservation measures are further developed and implemented. The Synthesis Team further recommends that BDCP proceed with large scale implementation of tidal reintroductions in Cache Slough, Suisun Marsh and Dutch Slough based on the existence of favorable landscape characteristics for restoration in the areas and expected benefits to multiple covered fish species.

The Synthesis Team identified seven general conclusions that apply broadly to the evaluations and that form the foundation for the Team's recommendations.

1. Refinements should be made to add specificity to the proposed modifications to the Fremont Weir and Yolo Bypass inundation (WOCM2), North Delta Diversions with Hood bypass criteria and other measures (WOCM1), and Cache Slough restoration (HRCM4) to reduce potential conflicts between ecosystem and water supply goals, and better optimize ecological benefits.

2. Better information on the survival and growth of covered species and predators using the Yolo Bypass, Cache Slough and Sacramento River (above, within, and below the section where new diversions are proposed) is needed to establish baseline conditions against which covered species benefits resulting from implementing the conservation measures can be determined and documented.

3. Potential benefits to San Joaquin River fish are limited by San Joaquin River flows and source water quality. The potential benefits of proposed BDCP measures, including reduced south Delta pumping and habitat restoration for San Joaquin River fishes, is minimal without concurrently addressing other limiting factors.

4. Tidal restoration measures could be more clearly defined, to clarify the desired future conditions, including the intent to provide tidal marsh and tidally influenced open water habitats with hydrodynamic and water quality characteristics suitable to native fishes and not suitable for extensive growth of *Egeria densa* and with conditions that promote desirable secondary production and its availability to target covered fish species within and beyond the restoration areas. Unpublished research data (Wilcox, pers. comm.) on the ecological characteristics and fish use in the Cache Slough/Liberty Island area suggest it could serve as a model for future tidal restoration.

5. The potential benefits of habitat restoration measures (tidal reintroduction and floodplain restoration) are highly dependent on location, scale, landscape setting, and design that considers site specific characteristics (e.g., elevations, tidal exchange, substrate, sediment supply, turbidity, quality and frequency of available habitat, geomorphology, wind-wave regime, and connectivity to adjacent aquatic and upland environments).

6. The uncertainties surrounding benefits of tidal restoration for habitat and productivity can be reduced primarily through two main strategies: (1) implementation of large-scale pilot projects designed to address these questions and with associated science-based monitoring, and (2) collection of further data from existing restorations to maximize their "lessons learned" value for subsequent project designs.

7. Other stressor measures should be refined and strategically paired with habitat restoration and conveyance conservation measures to enhance benefits for covered species; some also have value as stand-alone measures.

5.2 Specific Observations and Recommendations

Results from the DRERIP evaluations point to complex ecological trade-offs between implementation of multiple conservation measures, particularly measures that influence hydrodynamic conditions in the Delta such as modifying the Fremont Weir, operating new diversions in the north Delta, reintroducing tidal flows to large areas, and reducing pumping in the south Delta. There are likely opportunities to optimize benefits and manage risks for covered species better through more refined modeling analyses and a closer examination of the interrelationships between measures.

The following sections describe specific observations regarding trade-offs, synergies between various draft conservation measures, and recommendations regarding potential adjustments to the draft conservation measures. It should be noted that the DRERIP evaluations were defined by dual conveyance Scenarios 1 and 2, which assumed 2-10% greater export levels over the Reference Scenario (D1641 with existing infrastructure). Neither the Synthesis Team nor the evaluation team were tasked with considering lowered export levels to improve biological outcomes; no such Conservation Measure was provided for evaluation.

Floodplain Inundation Benefits and Predation Losses - Results of the DRERIP evaluations indicate that increased flooding of the Yolo bypass would enhance conditions for splittail and salmon. However, operation of a New North Delta Diversion could have negative population level effects on splittail and salmon due to increased predation (see WOCM1, Outcome N2). Predation losses could off-set the positive benefits of increased Yolo inundation. This may be particularly true in dry years when both the predation effects associated with the new diversion could be higher (as all salmon must pass the new diversion point) and the Yolo Bypass may not be available, or may not flood for a sufficient duration to allow adequate splittail spawning or salmon access to off-set predation losses. Under certain flow conditions, Particle Tracking Model(PTM) results indicate that fewer particles (i.e., representing salmon smolts) exit the Delta.

High uncertainty about salmon survival necessitates better hydrodynamic modeling capabilities (with salmon models of the diversion structures and important junctions). DSM2 modeling to date of reintroducing large tidal flows into the Yolo/Cache Slough area shows a big impact on phase shift, tidal range, net flow, and flow magnitudes of tides which in turn affect conditions at the North Delta Diversions and thus operating scenarios for Fremont Weir. These changes will affect residence times, salmon migration, availability of streambank habitat, and predation losses in the Sacramento River and its distributaries, particularly Georgiana, Steamboat and Sutter sloughs.

Recommendations:

1. Institute pre-implementation acoustic studies to establish baseline survival data and growth for covered species and predators using the Yolo Bypass, Cache Slough, and Sacramento

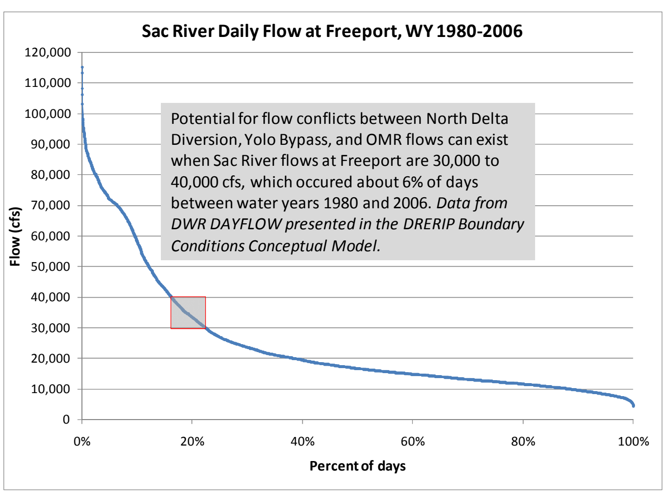
River. Use the Delta Passage Model as a working hypothesis to look at how fish respond to various dual conveyance and habitat restoration scenarios.

- Couple with CALSIM to develop relationships for baseline alternative.
- Review CWT/acoustic study design from past study to inform study design for evaluating alternative combinations of conservation measures. Past study designs are not sufficient to develop a necessary pre-project baseline for BDCP.
- Test sensitive model outputs with refined study design to field validate survival estimates.
- Consider similar studies for San Joaquin River and Cosumnes/Mokelumne.
- Develop explicit Hood Bypass survival data.

2. Develop modeling capability to assess salmon survival, using a diversity of potential diversion designs as necessary with:
   - 3D hydrodynamic model in the diversion reach, including fish behavior;
   - 2D hydrodynamic model at the tributaries influenced by the diversion;
   - Field validations;
   - Comparisons of with and without diversions, and with and without diversion structures;
   - Fish screen effectiveness (i.e., what happens if a screen does not meet its expected efficiencies).

3. Conduct more sophisticated 2D modeling in order to better understand the potential implications of changing hydrodynamics, on factors such as tidal phase, tidal amplitude, net tidal flow, and tidal flow magnitudes, under different scenarios of flooded island inundation on covered species (including the influence of Cache Slough restoration on hydrodynamics in Steamboat and Sutter sloughs). DSM2 was not designed to do this type of modeling.

Yolo Bypass Inundation, Hood bypass criteria, and South Delta Entrainment -Modeling results indicate that when flows at Freeport are between 30,000 to 40,000 cfs (see figure below) there is a potential conflict between inundating Yolo Bypass and Hood bypass flow and OMR flow. This potential conflict was not evaluated by either the DRERIP Water Operations subteam or the DRERIP Floodplains subteam.



Recommendations:

4. Conduct sensitivity analyses using finer scale modeling tools (e.g., daily time step modeling) and refined operational criteria to examine the effects different combinations of Hood bypass flow, Yolo inundation, and south Delta export pumping on OMR flows, residence time, and the fate of SJR waters. Scenarios should include examining the potential benefits of higher Hood bypass flows, as well as modified Yolo inundation regimes (including modified timing and inflow volumes).

5. Better optimize potential ecological benefits of WOCM1 and 2 through modified Hood bypass flow criteria and more refined Yolo Bypass operations (see recommendation below) to reduce negative OMR flows and associated entrainment, particularly for periods when Sacramento River flows are between 30k and 40k cfs. Consider incorporating OMR flow criteria as an explicit element of WOCM1.

6. Develop more specific operational criteria for Yolo inundation based on daily time-step modeling to optimize potential benefits. Take advantage of additional information being developed by DWR (e.g., improved bathymetry data) and utilize BDCP hydrologic modeling of Yolo Bypass to estimate increased production of adult splittail in the Yolo bypass and weigh that against increased predation in dry years.

7. Consider more naturalistic floodplain pulse flows into the Yolo Bypass that could involve an early pulse to achieve inundation and more fish onto the floodplain, followed by occasional inputs of smaller volumes of water to retain depths, and subsequent higher volume pulse flows that would move fish and material downstream. The CM presents the Yolo Bypass more as a higher-flow side channel to the Sacramento River than a pulse-flow floodplain system.

8. Consider flooding the Yolo Bypass only when sufficient flows exist to support a sustained level of inundation (i.e., avoid risk of stranding from attraction flows that cannot be followed by sufficient inundation flows).

<u>North Delta Diversions and South Delta Water Quality</u> - Changes in Delta hydrodynamics resulting from operational modifications (new diversions in the north Delta coupled with modified diversions in the south Delta), particularly in the summer and potentially in combination with proposed south Delta restoration measures, are expected to result in increased South Delta residence times, which, when combined with the influence of greater levels of nitrate- and phytoplankton-rich San Joaquin River water in the south and central Delta, could exacerbate the frequency and severity of low dissolved oxygen conditions. Reduced estuary flows and turbidity combined with the existing high nutrient levels, warming temperatures, greater relative contributions from the San Joaquin River, and constricted tidal flows could produce many "classic" eutrophication symptoms in the Delta. Reduced exports in the south Delta could also result in increased concentrations of Selenium (Se) and other chemical stressors in the Delta.

Recommendations:

9. Develop a comprehensive water quality – biological response modeling capability to inform decisions about flow needs given particular water temperature and nutrient load scenarios. Modeling should include examining nutrient uptake potential for marsh and floodplain vegetation which could increase bioavailability or provide alternate exposure pathways affecting different receptors.

10. Consider in-Delta and upstream source control measures to reduce nutrient and contaminant loading, including the effects of ongoing efforts to reduce Se loading into the San Joaquin River.

11. Refine and articulate Other Stressor conservation measures to target specific issues in the southern and central Delta, so they are coupled strategically with proposed habitat restoration measures. .

Limitations for San Joaquin River Fishes - Results of the DRERIP evaluations indicate that the benefits of reduced south Delta pumping and floodplains habitat restoration along the San Joaquin River (SJR) and in the south Delta are limited by SJR flows through the Delta (i.e., not just inflow but through-flow as well), source water quality, and limited tidal exchange capacity of existing waterways, particularly for San Joaquin fishes. Under current operations, little San Joaquin River water makes it to Chipps Island when juvenile salmon and steelhead are out-migrating, except under rare flood flow conditions. Proposed BDCP conservation measures do not appear to improve these conditions measurably.

12. Run fingerprinting analyses for San Joaquin River water without south Delta exports to determine if conditions for out-migrating juvenile San Joaquin River fishes could be improved by getting more San Joaquin water into the west Delta.

13. Consider the use of a Vernalis to south Delta export ratio as an additional operational criterion.

Adjustments to San Joaquin River Floodplain Restoration, Levee Setbacks, and Channel Margin Habitat Measures - Similar to the limitations for San Joaquin River fishes noted above, the benefits of floodplain restoration measures in the south Delta are limited by San Joaquin River flows and the expected low frequency of inundation. The DRERIP evaluations were based on simplified assumptions regarding levee setbacks (i.e., 500 feet on each side of the river). More specific designs that work with the existing flow regime and seek to incorporate important site specific features such as backwater areas, more habitat diversity, greater channel migration capacity, and more overbank flooding could increase the potential benefits of these measures. The current configuration of largely rip-raped, trapezoidal channels in the Delta provides little habitat for covered species and contributes to a high degree of predation.

Recommendations:

14. Evaluate the likely outcomes of San Joaquin River Floodplain Restoration, Levee Setbacks, and Channel Margin Habitat measures under several scenarios of future increased SJR flows to identify the benefits such restoration could provide if flows were increased under other authorities.

15. Where there are currently narrow corridors, consider levee setbacks for wider floodplain with natural meanders, backwaters, and channel margin habitat.

16. Revise the existing BDCP definition of channel margin habitat (see evaluation worksheets for HRCM 12 and13).

17. Integrate ecological design into future flood control projects. Incorporate modified channel geometry to provide habitat for splittail and other covered species, including allowing for channels to meander providing more microhabitats with emergent vegetation, woody debris, and more structural heterogeneity.

Yolo Bypass Inundation and Cache Slough Productivity

The potential benefits of coupled Yolo Bypass improvements and tidal restoration in Cache Slough, especially desired productivity benefits, are influenced greatly by flows (inputs) and urban and agricultural diversions (losses), or the net flows. First and foremost, relocation of the major diversions (North Bay Aqueduct and the major agricultural intakes) is essential to realize many of these benefits and in particular to allow the advective transport capacity of Yolo Bypass outflows to increase transport and mixing. Second, there is potential to improve the hydrologic connectivity of the southern end of the Yolo Bypass and the Cache Slough area in a manner that takes better advantage of the base flows from Putah and Cache creeks, reported to be on the order of 100-200 cfs, in providing contributions to advective transport. The magnitude of these contributions to advective transport has not been evaluated quantitatively. Through physical modifications at the southern end of the bypass it may be possible to enhance the benefits of increased seasonal flooding of the Yolo Bypass. These adaptations to the conservation measure should be articulated as part of a possible adaptive management program including Cache Slough.

Recommendations:

18. Develop plans for relocating the major water supply intakes away from the Cache Slough area.

19. Identify and articulate specific physical landscape modifications (focused on tributaries at the bottom end of the Yolo Bypass and Cache Slough restoration) to improve distribution of Yolo Bypass base outflow into the Cache Slough area to enhance the movement of insects and zooplankton to the northwest Delta. Descriptions regarding the type, location, and nature of the modifications should be developed based on more specific operational criteria and analysis for Yolo Bypass flooding (see Recommendation #6 above).

Tidal Reintroductions and Restoration Design

While restoration of tidal marsh and open water habitat in the Cache Slough and Suisun Marsh areas are expected to benefit covered species, particularly delta smelt, there is uncertainty and disagreement on the potential population level effects of the proposed measures for rearing juvenile salmonids. Unpublished data (Wilcox, pers. comm.) regarding salmon use of the Cache Slough/Liberty Island area are available, but need to be compiled and summarized.

The value of tidal reintroductions for covered fish species will be strongly influenced by location, landscape setting, and site specific design considerations such as elevation, tidal exchange, substrate, sediment supply, turbidity, geomorphology, wind-wave regime, and connectivity to aquatic and upland environments. Careful siting and design can influence the likelihood of species benefits as well as the potential adverse effects of non-native invasives such as *Egeria* and associated predation risk.

The relationships between geomorphic elements of a tidal reintroduction (vegetated tidal marsh, channels, and open water), tidal flow regimes and connectivity to pelagic environments, and the potential for adverse effects from invasive species establishment affect the benefits that may be achieved for covered fish species. Key uncertainties include relative benefits of vegetated tidal marsh vs. open water (and thus how to address subsided properties), importance of productivity contributions from vegetated tidal marsh directly or indirectly to covered species, conditions that promote vs. discourage *Egeria* establishment (see page 25), extent to which invasive clams may divert considerable quantities of new primary production, magnitude of suitable productivity (zooplankton and insects) exported from restoration areas, and density of channels in Delta historical tidal marshes and ability of natural processes to establish channels in restored marshes.

Recommendations:

20. Compile, analyze, and summarize existing fish utilization data from existing restored and reference sites in the Delta and Suisun Marsh to identify “lessons learned” applicable to proposed restorations.

21. Proceed with large scale tidal reintroduction in Cache Slough, Suisun Marsh and Dutch Slough based on existing information and maximize adaptive management in the design and monitoring in recognition that proto-habitat types and additional research are both needed to address uncertainties and make future decisions.

22. Describe baseline survival and growth of salmon runs so that post-restoration monitoring and analysis can demonstrate to what extent tidal marsh contributes to salmonid survival.

23. Develop a focused suite of restoration design principles for the Delta and Suisun, building on existing work where available, that reflects the variability in landscape context, unique setting of each restoration site, and lessons learned from successful and unsuccessful projects. These principles should not be overly prescriptive nor contain any single “template” so as to avoid over-engineering or over-simplification. They should also direct incorporation of adaptive management design features to address the uncertainties identified here to the extent possible at each site. Principles should specifically address approaches for areas below the elevation of potential colonization by emergent vegetation: e.g. whether to incorporate as open water, grading/sculpting, reverse subsidence by planting before tidal reintroduction, or retain as leveed.

24. Pursue tidal restoration of small parcels in the West Delta ROA only if they are expected to result in net benefits for covered species. Focus on aggregation of smaller parcels so as to create larger, contiguous restoration areas wherever possible.

Egeria Control - *Egeria* changes habitat toward conditions more suitable for largemouth bass and other centrarchids fishes than for native fishes and increases predation success on covered fish species. However, the presence of some Egeria may not eliminate covered fish species benefits, as evidenced at Sherman Lake which has extensive *Egeria* within small tidal channel networks, but does not extend into Delta smelt's pelagic habitat in the open-water like it does in Franks Tract. There are three categories of *Egeria* control methods each with varying efficacy and undesirable consequences:

1) Through various design considerations including tidal flushing, wind fetch and turbidity, competitive exclusion via establishment of other vegetation such as tules in the area of tidal reintroduction. Promoting higher energy open water should reduce *Egeria* but also limits tidal marsh formation.
2) Mechanical removal after establishment. Has practicality limitations given *Egeria*'s ability to reestablish quickly and to reestablish from cut pieces.
3) Chemical treatment after establishment. Though has had reasonable effectiveness where used (e.g., Frank's Tract, Big Break), the chemicals used pose direct and indirect risks to covered species that limit desirability.

Recommendations:

25. Explicitly design tidal, floodplain, and channel margin restoration measures to control the establishment of *Egeria* and to reduce predator success. Existing areas in the Delta should be used as models both successful and unsuccessful: Liberty Island, Little Holland Tract, Frank's Tract, Mildred Island, Big Break, Sherman Lake, and Donlon Island.

26. Focus post-establishment *Egeria* control measures on locations and habitats that are known to be, or could become important for covered fish and where physical design approaches are insufficient.

27. Prioritize tidal reintroduction locations where control through design has the best chances for success.

Managing MeHg Release from Restored Tidal Areas and Floodplains - DRERIP evaluations indicate that there is a potential for Mercury methylation in high marsh and floodplain areas due to ongoing input of mercury and patterns of wetting and drying. While not a direct threat to covered fish species, elevated mercury levels in fish could adversely affect wildlife that prey on fish, as well as humans that harvest them.

28. Monitor MeHg concentrations in water, fish and wildlife as more seasonal wetlands are created in the Yolo Bypass and elsewhere and the hydrology of the Delta is changed with construction of a dual conveyance system

29. Conduct species-specific studies on sub-lethal population-level effects (e.g. feeding efficiency, growth, or spawning success) of MeHg in birds and wildlife species.

30. Develop a numerical MeHg transport and fate model, with a food web component, that combines source information, water transport and residence times, photodemethylation and particle settling to predict methyl mercury concentrations in water, sediment, and biota at various locations in the Delta under different hydrologic conditions.

31. Establish better estimates of the number of people at risk for MeHg toxicity due to hunting and recreational or subsistence fishing to refine or expand fish and wildlife consumption advisories and develop educational strategies for teaching the affected public how to reduce the risk.

32. Focus efforts on controlling ongoing mercury loading into the Delta and Suisun Marsh so as to reduce mercury supply over the long term available for methylation. Plan tidal and floodplain inundations to minimize frequent wetting and drying of areas containing mercury.

Appendix A:
DRERIP Scientific Evaluation Process Instructions

Appendix A
DRERIP Scientific Evaluation Process Instructions

The following instructions were developed for the Delta Regional Ecosystem Restoration Implementation Plan (DRERIP). For the purpose of evaluating draft Bay Delta Conservation Plan (BDCP) conservation measures, evaluation teams were asked to stop after Step 9. Overall worth and risk scores were not developed, and the DRERIP Decision Tree was not applied.

Step 1: Is the action written in such a way that it can be evaluated?

The action should be clearly written and contain basic components (action, approach, and outcome) as outlined in the Guidelines for Writing and Parsing Actions (*7/16/07*). An action can include multiple outcomes, but should list only one approach.

Step 2: Is the cause and effect relationship between the action, approach, and outcome supported by the conceptual models, or other source material?

Review General Outcomes table to identify conceptual models that include the general type of outcome identified in the action. Use these models and any other relevant source materials to assess if the relationship inferred by the action has been documented. If it is determined that the cause and effect relationship is not supported, document why and provide suggestions for how the actions might be re-cast to better achieve the desired outcome based on information in the conceptual models and other available scientific information. These suggestions can be used by action developers to improve the action for the next round of screening.

Step 3: Identify Scale of Action

Identify the scale of the Action 'scope' based on the following criteria. The purpose of establishing Action scale is to assist with determining the magnitude of effect on the ecosystem. Large, medium and small should be considered relative to the Delta and the temporal dynamics of processes being manipulated.

Large: Broad spatial extent, significant duration and/or frequency, and/or major reversal compared to existing conditions. Landscape scale.

Medium: Moderate spatial extent, moderate duration and/or frequency, and/or moderate change compared to existing conditions. Regional scale.

Small: Small acreage, short duration or only occasionally, and/or small change compared to existing conditions. Local scale.

Step 4: Describe Relation to Existing Conditions

Review the Boundary Conditions paper to assess whether or not the action has the potential to change system dynamics (either within the Delta or as inputs to the Delta) beyond the existing range conditions (i.e. change in inflows to the Delta, modified hydrodynamic conditions, or salinity regimes) such that the current understanding of how the system works may no longer hold? Consider how the changes may affect the ability to evaluate the action using existing models and information.

Step 5: Identify Positive and Negative Outcome(s) to be Evaluated

Using the standardized lists of outcomes and stressors from the Outcomes Table, identify as many positive and negative outcomes as possible (including the intended outcome). Outcomes should not be evaluated at this step, just simply listed. Outcomes not captured in models but identified based on other available information should be included, with notes describing the information used to identify the outcomes.

Identify positive and negative outcomes focusing only on covered species, but ensuring that all covered species anticipated to be affected are addressed, i.e., if the action is intended to benefit salmon, still look at effects on smelt.

Step 6: Score Magnitude and Certainty of Potential Positive Ecological Outcome(s)

Using the conceptual models and other relevant source materials, identify and score the expected magnitude and certainty of the identified positive ecological outcomes. Record the magnitude and certainty for each positive outcome. ***Use one table per positive outcome.*** Add additional tables as needed to reflect additional outcomes.

Step 7: Score Magnitude and Certainty of Potential Negative Ecological Outcome(s)

Using the conceptual models and other relevant source materials identify and score the expected magnitude and certainty of each negative ecological outcome. Record the magnitude and certainty in the tables below. ***Use one table per outcome***. Add additional tables as needed to reflect additional outcomes.

Step 8: Identify any Important Gaps in Information and/or Understanding

Using the levels of understanding described in the conceptual models, and/or other additional information sources used, identify important data or research needs, that could enhance future evaluation of this or similar actions.

Step 9: Assess Reversibility and Opportunity for Learning

Assess reversibility and opportunity to learn using the criteria below.

Reversibility

Yes/Easy Outcome could likely be reversed as, or more quickly and cheaply than implementing the action.

No/Hard Reversing outcomes would require more time or more money than implementing the action; outcomes may not be completely reversible.

Opportunity for Learning

High Expect to advance our understanding of critical uncertainties as identified in Conceptual Models in a quantifiable manner

Low Impractical or excessive time or resources likely required to achieve such understanding.

Definitions and Scoring Criteria

The following definitions and criteria are provided to aid the Scientific Evaluation process. Some of the definitions pertain to terms used in the conceptual models, such as understanding and predictability. Other definitions relate directly to completion of the Scientific Evaluation worksheet.

Scientific Evaluation Terms

The terms ***scale, magnitude, and certainty*** are Scientific Evaluation terms used to characterize the cumulate "path" or "chain" found between a Restoration Action being evaluated and each Outcome being considered within Scientific Evaluation. Such a path or chain is not the same as the linkages in the conceptual models that describe the cause-effect relationships between a single driver and a single outcome (see conceptual model terms below).

The terms ***reversibility, and opportunity for learning*** are Scientific Evaluation terms designed to aid in making decisions regarding implementation of proposed actions.

Scale - Scale addresses temporal and spatial considerations, quantity and/or degree of change contained within the Action.

Magnitude – Magnitude assesses the size or level of the outcome, either positive or negative, in terms of population or habitat effects on a given species. Magnitude is not the same as the scale of the action, however, higher magnitude scores require consideration of scale.

Certainty - Certainty describes the likelihood that a given Restoration Action will achieve a certain Outcome. Certainty considers both the predictability and understanding of linkages in the DLO pathway from the action to the outcome. Generally, high importance-low predictability linkages drive the scoring; it is important to ensure that certainty is not unduly weighted by a comparatively low-importance, albeit low-predictability linkage.

Reversibility - The ease and predictability with which the outcome(s) of a Restoration Action or a group of Restoration Actions can be undone and/or reversed. For example, if the Action changes the ecosystem structure, can the original form be re-established? Have such outcomes been un-done in the past? A change to a flow regime is relatively easy to reverse; successful introduction of a new species is relatively difficult to reverse.

Opportunity for learning - Opportunity for learning is the likelihood that a Restoration Action or a group of Restoration Actions will increase the level of understanding with regard to the species, process, condition, region or system that is in question or of concern, assuming that appropriate monitoring and evaluation is conducted.

Conceptual Model Terms

The terms ***importance, predictability, and understanding*** are used in the conceptual models to characterize individual linkages (depicted as arrows in the models) between a driver and an outcome. The terms pertain to specific processes or mechanisms within a given model (e.g. how important is the supply of organic matter to mercury methylation?). The graphical forms of the conceptual models apply line color, thickness, and style to represent these three terms.

> ***Importance*** - The degree to which a linkage controls the outcome *relative to* other drivers and linkages affecting that same outcome. Models are designed to encompass all identifiable drivers, linkages and outcomes but this concept recognizes that some are more important than others in determining how the system works. If a driver is potentially more important under particular environmental conditions, the graphic should display the maximum level of importance of this driver with the narrative describing the range of spatial and temporal conditions associated with this driver.
>
> ***Predictability*** - The degree to which the performance or the nature of the outcome can be predicted from the driver. Predictability seeks to capture the variability in the driver-outcome relationship. Predictability can encompass temporal or spatial variability in conditions of a driver (e.g., suspended sediment concentration or grain size), variability in the processes that link the driver to the outcome (e.g., sediment deposition or erosion rate as influenced by flow velocity), or our level of understanding about the cause-effect relationship (e.g., magnitude of sediment accretion inside vs. outside beds of submerged aquatic vegetation). Any of these forms of variability can lead to difficulty in predicting change in an outcome based on changes in a driver.
>
> ***Understanding* –** A description of the known, established, and/or generally agreed upon scientific understanding of the cause-effect relationship between a single driver and a single outcome. Understanding may be limited due to lack of knowledge and information or due to disagreements in the interpretation of existing data and information; or because the basis for assessing the understanding of a linkage or outcome is based on studies done elsewhere and/or on different organisms, or conflicting results have been reported. Understanding should reflect the degree to which the model that is used to represent the system does, in fact, represent the system.

Scientific Evaluation Scoring Criteria

The following tables should be used to inform ***magnitude and certainty*** scores for Scientific Evaluation. These entail looking holistically at the cumulative value (positive or negative) of an action.

Table 1 - Criteria for Scoring Magnitude of Ecological Outcomes (positive or negative)

4 - High: expected sustained major population level effect, e.g., the outcome addresses a key limiting factor, or contributes substantially to a species population's natural productivity, abundance, spatial distribution and/or diversity (both genetic and life history diversity) or has a landscape scale habitat effect, including habitat quality, spatial configuration and/or dynamics. Requires a large-scale Action.
3 - Medium: expected sustained minor population effect or effect on large area (regional) or multiple patches of habitat. Requires at least a medium-scale Action.
2 - Low: expected sustained effect limited to small fraction of population, addresses productivity and diversity in a minor way, or limited spatial (local) or temporal habitat effects.
1 - Minimal: Conceptual model indicates little effect.

Table 2 - Criteria for Scoring Certainty of Ecological Outcomes (positive or negative)

4 - High: Understanding is high (based on peer-reviewed studies from within system and scientific reasoning supported by most experts within system) and nature of outcome is largely unconstrained by variability (i.e., predictable) in ecosystem dynamics, other external factors, or is expected to confer benefits under conditions or times when model indicates greatest importance.
3 - Medium: Understanding is high but nature of outcome is dependent on other highly variable ecosystem processes or uncertain external factors or understanding is medium (based on peer-reviewed studies from outside the system and corroborated by non peer-reviewed studies within the system) and nature of outcome is largely unconstrained by variability in ecosystem dynamics or other external factors
2 - Low: Understanding is medium and nature of outcome is greatly dependent on highly variable ecosystem processes or other external factors or understanding is low (based on non peer-reviewed research within system or elsewhere) and nature of outcome is largely unconstrained by variability in ecosystem dynamics or other external factors
1 - Minimual: Understanding is lacking (scientific basis unknown or not widely accepted), or understanding is low and nature of outcome is greatly dependent on highly variable ecosystem processes or other external factors

Appendix C:
Conservation Measures Evaluated

Tidal Restoration Conservation Measures

HRCM4: Yolo/Cache Slough Complex ROA Tidal Marsh & Shallow Subtidal Restoration - Restore between 5,000 and 11,000 acres to tidal action and vegetated tidal marsh and shallow sub tidal habitat in the Yolo Bypass/Cache Slough Complex ROA (in addition to Liberty Island and Little Holland Tract). *(Evaluate both 5,000 and 11,000 acres).*

HRCM5: Cosumnes/Mokelumne ROA Tidal Marsh & Shallow Subtidal Restoration
Restore 1,150 acres of vegetated tidal marsh and 300 acres of shallow subtidal habitat within the Cosumnes/Mokelumne ROA.

HRCM6: West Delta ROA Tidal Marsh & Shallow Subtidal Restoration
Restore 3,900 acres of vegetated tidal marsh and 900 acres of shallow subtidal habitat in the West Delta ROA.

HRCM7: South Delta ROA Tidal Marsh & Shallow Subtidal Restoration
Restore 3,650 acres of vegetated tidal marsh and 950 acres of shallow subtidal habitats on portions of Union, Upper Roberts, and Middle Roberts Islands in the South Delta ROA.

HRCM8: East Delta ROA Tidal Marsh & Shallow Subtidal Restoration
Restore 1,300 acres to tidal action and vegetated tidal marsh and 300 acres of shallow subtidal habitats on portions of Canal Tract, Terminus Tract, and Bract Tract in the East Delta ROA.

HRCM9: Suisun Marsh ROA Tidal Marsh & Shallow Subtidal Restoration
Re-establish 9,000 acres of brackish intertidal marsh and shallow subtidal aquatic within the Suisun Marsh.

Floodplains and Riparian Habitat Restoration Measures

HRCM1: San Joaquin ROA Floodplain Restoration (upstream of Mossdale)
Restore floodplain habitat along 7 to 14 miles of the San Joaquin River from Vernalis to Mossdale.

HRCM2: San Joaquin ROA Floodplain Restoration (downstream of Mossdale)
Restore floodplain habitat along 6 to 12 miles of the San Joaquin River from Mossdale to French Camp Slough.

HRCM3: South Delta ROA Floodplain
Restore between 800 and 1,600 acres of floodplain habitat (including aquatic, intertidal marsh, floodplain and riparian features) along Old River at Fabian Tract. (Evaluate both 800 and 1,600 acres).

HRCM11: BDCP-Constructed Levees
Establish native riparian woody vegetation and emergent vegetation along a 5 mile segment of levee constructed along the Sacramento River in the West Delta (somewhere between Isleton and Ryde), and along a 5 mile segment of levee along Old River near Bacon Island.

HRCM12: Channel Margin Habitat in Sutter and Steamboat Sloughs
Enhance channel margin habitats along between 12 and 36 miles of Steamboat and Sutter Sloughs to improve habitat conditions for covered fish species. *(Evaluate both 12 and 36 miles of habitat enhancement).*

HRCM13: Channel Margin Habitat in the San Joaquin River ROA
Enhance channel margin habitats along between 14 and 28 miles of the San Joaquin River in the San Joaquin River ROA to improve habitat conditions for covered fish species.

HRCM14: Riparian/scrub Habitat Restoration as a Component of Other Restoration Actions –

Water Operation Conservation Measures

WOCM1: New North Delta Diversions with Hood Bypass Criteria and other Measures
Construct new diversion facilities in the North Delta along the Sacramento River between Walnut Grove and Freeport with a capacity to divert up to 15,000 cfs. The new diversions would be operated to divert large amounts of water during wet periods and less in dry periods. No diversion would be allowed unless flows downstream of the diversion points exceed minimum flow requirements known as the Hood Bypass Flow Criteria.

WOCM2: Modify And Reoperate The Yolo Bypass And Fremont Weir
Option #1 Period of Potential Operation: December 1-May 15
Desired Duration of Inundation: 45 days
Target Spill Discharge into Bypass: 4000 cfs
Predicted area of inundation: 22,982 acres
Predicted mean depth of inundated area: 2.2 feet
Predicted travel time: 6.5 days
Spill Frequency of Fremont Weir (assuming 4000 cfs and 45 day duration with a spill intermission of no more than 7 days): 48% of years (38 of 79), compared to 6% of years (5 out of 79) at existing weir height.

Option #2 Period of Potential Operation: January 1-April 15
Desired Duration of Inundation: 30 days
Target Spill Discharge into Bypass: 2000 cfs
Predicted area of inundation: 17,421 acres
Predicted mean depth of inundated area: 2.3 feet
Predicted travel time: 9.3 days

Spill Frequency of Fremont Weir (assuming 2000 cfs and 30 day duration with a spill intermission of no more than 7 days): 54% of years (43 of 79), compared to 6% of years (5 out of 79) at existing weir height.

WOCM3: Deep Water Ship Channel Bypass Floodplain
Create a new flood bypass that provides up to 3800 acres (at 3000 cfs) of inundated floodplain habitat adjacent to and east of the Sacramento Deep Water Ship Channel (DWSC) and that inundates in ~50% of years from December 1 to May 15 for 45 consecutive days with a spill intermission of no more than 7 days.

WOCM8: Interim Tidal Gates (2-Gates)
Construct and operate two tidal gates:

1. one installed in Old River on the eastern side of Bacon Island,
2. the second gate would be installed in Connection Slough on the western side of Bacon Island.

Water Quality and Invasives Other Stressor Measures

OSCM1: Reduction Of Ammonia Discharges
Implement advanced treatment processes at Sac Regional County Sanitation District (SRCSD) Wastewater Treatment Plant to reduce the concentrations and load of ammonia in effluent discharged into the Sacramento River to levels that do not directly or indirectly harm covered fish species.

OSCM2: Reduction Of The Load Of Endocrine Disrupting Compounds
Implement advanced treatment processes at wastewater treatment plants in the Delta to reduce the loads of endocrine disrupting compounds (EDCs) discharged into the Delta to levels that do not harm covered fish species.

OSCM3: Reduce The Load Of Methylmercury
Implement measures to reduce the load of methylmercury entering the Delta from upstream and in-Delta sources by 50 percent.

OSCM4: Reduce The Load Of Pesticides And Herbicides
Implement measures to reduce loads of pesticides and herbicides entering Delta waterways to levels that are not toxic to covered fish species.

OSCM5: Reduce The Loads Of Toxic Contaminants In Stormwater And Urban Runoff
Develop and implement stormwater management plans and additional measures to reduce loads of toxic contaminants in stormwater and urban runoff entering Delta waterways to levels below which they are toxic to covered fish species.

OSCM7: Improve Dissolved Oxygen Levels In The Stockton Deep Water Ship Channel

OSCM8: Improve Managed Seasonal Wetlands Discharge

OSCM 12: Reduce The Risk For Establishment Of Zebra Mussel And Quagga Mussel In Delta Waterways –

OSCM 13: Remove Non-Native Sav And Fav
Remove water hyacinth (*Eichornia crassipes*) and Brazilian waterweed (*Egeria densa*) from 1,000 water acres of ecologically important Delta waterways each year.

Harvest and Hatcheries Other Stressor Measures

OSCM 14: Increase Harvest Of Non-Native Predatory Fish
Modify sport fishing regulations to reduce the abundance, size, and, therefore, reproductive capacity of black bass (largemouth, smallmouth, and spotted bass) and striped bass in the Sacramento-San Joaquin Delta (the Delta).

OSCM16: Enhanced Delta Enforcement
Increase enforcement of existing fishing regulations to reduce illegal harvest of catchable covered salmonids and sturgeon in the Delta and tributary rivers, including summer holding habitat for spring-run and sturgeon.

OSCM17: Splittail Harvest Regulations
Modify fishing regulations to reduce the effects of harvest on Sacramento splittail.

OSCM19: Mark-Select Chinook Salmon Fishery
Mark all Central Valley Chinook salmon produced in hatcheries with a visible mark (e.g., adipose fin clip), and limit all commercial and recreational harvest of Chinook salmon to those with visible marks.

OSCM20: Artificial Propagation Of Smelt
Establish artificial propagation programs for delta smelt and longfin smelt.

OSCM21: Non-Project Diversions
Modify or eliminate non-project diversions in the Delta to reduce the entrainment of covered fish species.

Appendix D:
Summary of Evaluation Scores and Tables

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Positive Outcomes				
P6	All	Increased establishment of woody riparian vegetation to export LWD	2	3
P7a/b	Chinook salmon-San Joaquin	Increase establishment of woody riparian vegetation to provide shaded channel habitat	2	3
P8a	Delta smelt	Increased downstream turbidity improves habitat quality for delta smelt and longfin smelt	2	3-4
P5g	Delta smelt	Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (off site), longfin smelt, and delta smelt	2	3
P5a	Fall-run Chinook Salmon	Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (off site), longfin smelt, and delta smelt	2	3-4
P4a	Fall-run Chinook Salmon	Increase production of food for rearing Chinook salmon, steelhead, green/white sturgeon, splittail from inundation and riparian vegetation (local)	2	3-4
P3a	Fall-run Chinook Salmon	Create rearing habitat for Chinook salmon, green/white sturgeon, splittail and steelhead. Consider loss to entrainment.	2	3-4
P1a	Fall-run Chinook Salmon	Improve connectivity of seasonally inundated floodplain habitat for juvenile fish (Splittail, G/W sturgeon, Chinook salmon and steelhead)	2	3-4
P5e	Green Sturgeon	Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (off site), longfin smelt, and delta smelt	1	2
P4e	Green Sturgeon	Increase production of food for rearing Chinook salmon, steelhead, green/white sturgeon, splittail from inundation and riparian vegetation (local)	1	2
P3e	Green Sturgeon	Create rearing habitat for Chinook salmon, green/white sturgeon, splittail and steelhead. Consider loss to entrainment.	1	2
P1e	Green Sturgeon	Improve connectivity of seasonally inundated floodplain habitat for juvenile fish (Splittail, G/W sturgeon, Chinook salmon and steelhead)	1	2
P8b	Longfin smelt	Increased downstream turbidity improves habitat quality for delta smelt and longfin smelt	2	3
P5f	Longfin smelt	Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (off site), longfin smelt, and delta smelt	2	3

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Positive Outcomes (contd.)				
P5c	Splittail	Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (off site), longfin smelt, and delta smelt	3	3-4
P4c	Splittail	Increase production of food for rearing Chinook salmon, steelhead, green/white sturgeon, splittail from inundation and riparian vegetation (local)	3	3-4
P3c	Splittail	Create rearing habitat for Chinook salmon, green/white sturgeon, splittail and steelhead. Consider loss to entrainment.	3	3-4
P2a	Splittail	Create additional splittail spawning habitat on floodplain	3	3-4
P1c	Splittail	Improve connectivity of seasonally inundated floodplain habitat for juvenile fish (Splittail, G/W sturgeon, Chinook salmon and steelhead)	3	3-4
P5b	Steelhead	Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (off site), longfin smelt, and delta smelt	2	2
P4b	Steelhead	Increase production of food for rearing Chinook salmon, steelhead, green/white sturgeon, splittail from inundation and riparian vegetation (local)	2	2
P3b	Steelhead	Create rearing habitat for Chinook salmon, green/white sturgeon, splittail and steelhead. Consider loss to entrainment.	2	2
P1b	Steelhead	Improve connectivity of seasonally inundated floodplain habitat for juvenile fish (Splittail, G/W sturgeon, Chinook salmon and steelhead)	2	2-3
P5d	White Sturgeon	Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (off site), longfin smelt, and delta smelt	1	1
P4d	White Sturgeon	Increase production of food for rearing Chinook salmon, steelhead, green/white sturgeon, splittail from inundation and riparian vegetation (local)	1	1
P3d	White Sturgeon	Create rearing habitat for Chinook salmon, green/white sturgeon, splittail and steelhead. Consider loss to entrainment.	1-2	1
P1d	White Sturgeon	Improve connectivity of seasonally inundated floodplain habitat for juvenile fish (Splittail, G/W sturgeon, Chinook salmon and steelhead)	1-2	1

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Negative Outcomes				
N6a	All	Increased exposure risk to contaminants (including Selinium) due to longer residence time in this area	2	3
N3a	All	Increased frequency and magnitude of low DO in SDWSC due to an increase in algae/POM and impact on Chinook salmon, steelhead, and green and white sturgeon passage.	1	4
N2a	All	Increased resuspension/mobilization and export of toxic compounds with impact on covered species (consider time course of effect)	1	2
N1a	All	Increased MeHg and impact on covered species (direct or indirect)	1	3
N5a	Chinook salmon	Increased habitat for non-native predators/competitors to native fishes (Chinook salmon, steelhead, green and white sturgeon, and splittail)	2	4
N4	Delta smelt & Longfin smelt	Decreased downstream turbidity decreases habitat quality for longfin smelt and delta smelt	1	4
N5c	Green & White Sturgeon	Increased habitat for non-native predators/competitors to native fishes (Chinook salmon, steelhead, green and white sturgeon, and splittail)	1	2
N5d	Splittail	Increased habitat for non-native predators/competitors to native fishes (Chinook salmon, steelhead, green and white sturgeon, and splittail)	2	4
N5b	Steelhead	Increased habitat for non-native predators/competitors to native fishes (Chinook salmon, steelhead, green and white sturgeon, and splittail)	2	4

Outcome Code	Covered Spp.	Description	Scenario 1 Magnitude	Scenario 1 Certainty
Positive Outcomes				
P7	All	Increased establishment of woody riparian vegetation to provide shaded channel habitat	3	2
P6	All	Increased establishment of woody riparian vegetation to export LWD	2	3
P8a	Delta smelt	Increased downstream turbidity to improve habitat quality for longfin smelt and delta smelt	2	3-4
P5g	Delta smelt	Increased availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for splittail, green and white sturgeon, Chinook salmon, steelhead (off site), longfin smelt, and delta smelt	2	3
P5a	Fall-run Chinook Salmon	Increased availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for splittail, green and white sturgeon, Chinook salmon, steelhead (off site), longfin smelt, and delta smelt	2	3-4
P4a	Fall-run Chinook Salmon	Increased production of food for rearing splittail, green and white sturgeon, Chinook salmon and steelhead from inundation and riparian vegetation (local)	2	3-4
P3a	Fall-run Chinook Salmon	Additional rearing habitat for splittail, green and white sturgeon, Chinook salmon and steelhead (consider loss to entrainment)	2	3-4
P1a	Fall-run Chinook Salmon	Improved connectivity of seasonally inundated floodplain habitat for juvenile splittail, green and white sturgeon, Chinook salmon and steelhead	2	3-4
P5e	Green Sturgeon	Increased availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for splittail, green and white sturgeon, Chinook salmon, steelhead (off site), longfin smelt, and delta smelt	1	2
P4e	Green Sturgeon	Increased production of food for rearing splittail, green and white sturgeon, Chinook salmon and steelhead from inundation and riparian vegetation (local)	1	2
P3e	Green Sturgeon	Additional rearing habitat for splittail, green and white sturgeon, Chinook salmon and steelhead (consider loss to entrainment)	1	2
P1e	Green Sturgeon	Improved connectivity of seasonally inundated floodplain habitat for juvenile splittail, green and white sturgeon, Chinook salmon and steelhead	1	2

Outcome Code	Covered Spp.	Description	Scenario 1 Magnitude	Scenario 1 Certainty
Positive Outcomes (contd.)				
P8b	Longfin smelt	Increased downstream turbidity to improve habitat quality for longfin smelt and delta smelt	2	3
P5f	Longfin smelt	Increased availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for splittail, green and white sturgeon, Chinook salmon, steelhead (off site), longfin smelt, and delta smelt	2	3
P5c	Splittail	Increased availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for splittail, green and white sturgeon, Chinook salmon, steelhead (off site), longfin smelt, and delta smelt	3	3-4
P4c	Splittail	Increased production of food for rearing splittail, green and white sturgeon, Chinook salmon and steelhead from inundation and riparian vegetation (local)	3	3-4
P3c	Splittail	Additional rearing habitat for splittail, green and white sturgeon, Chinook salmon and steelhead (consider loss to entrainment)	3	3-4
P2	Splittail	Additional splittail spawning habitat on floodplain	3	3-4
P1c	Splittail	Improved connectivity of seasonally inundated floodplain habitat for juvenile splittail, green and white sturgeon, Chinook salmon and steelhead	3	3-4
P5b	Steelhead	Increased availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for splittail, green and white sturgeon, Chinook salmon, steelhead (off site), longfin smelt, and delta smelt	2	2
P4b	Steelhead	Increased production of food for rearing splittail, green and white sturgeon, Chinook salmon and steelhead from inundation and riparian vegetation (local)	2	2
P3b	Steelhead	Additional rearing habitat for splittail, green and white sturgeon, Chinook salmon and steelhead (consider loss to entrainment)	2	2-3
P1b	Steelhead	Improved connectivity of seasonally inundated floodplain habitat for juvenile splittail, green and white sturgeon, Chinook salmon and steelhead	2	2

Outcome Code	Covered Spp.	Description	Scenario 1 Magnitude	Scenario 1 Certainty
Positive Outcomes (contd.)				
P5d	White Sturgeon	Increased availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for splittail, green and white sturgeon, Chinook salmon, steelhead (off site), longfin smelt, and delta smelt	1	1
P4d	White Sturgeon	Increased production of food for rearing splittail, green and white sturgeon, Chinook salmon and steelhead from inundation and riparian vegetation (local)	1	1
P3d	White Sturgeon	Additional rearing habitat for splittail, green and white sturgeon, Chinook salmon and steelhead (consider loss to entrainment)	1-2	1
P1d	White Sturgeon	Improved connectivity of seasonally inundated floodplain habitat for juvenile splittail, green and white sturgeon, Chinook salmon and steelhead	1-2	1

Outcome Code	Covered Spp.	Description	Scenario 1 Magnitude	Scenario 1 Certainty
Negative Outcomes				
N6	All	Increased exposure risk to contaminants (including Selinium) due to longer residence time in this area	2	3
N2	All	Increased resuspension/mobilization and export of toxic compounds with impact on covered species (consider time course of effect)	1	2
N1	All	Increased MeHg and impact on covered species (direct or indirect)	1	3
N5a	Chinook salmon	Increased habitat for non-native predators/competitors to Chinook salmon, steelhead, green and white sturgeon, and splittail	2	4
N4	Delta smelt & Longfin smelt	Decreased downstream turbidity decreases habitat quality for longfin smelt and delta smelt	1	4
N5c	Green & White Sturgeon	Increased habitat for non-native predators/competitors to Chinook salmon, steelhead, green and white sturgeon, and splittail	1	2
N3	green and white sturgeon, Chinook salmon and steelhead	Increased frequency and magnitude of low DO in SDWSC due to an increase in algae/POM and impact on Chinook salmon, steelhead, and green and white sturgeon passage.	1	4
N5d	Splittail	Increased habitat for non-native predators/competitors to Chinook salmon, steelhead, green and white sturgeon, and splittail	2	4
N5b	Steelhead	Increased habitat for non-native predators/competitors to Chinook salmon, steelhead, green and white sturgeon, and splittail	2	4

			Scenario 1		Scenario 2	
Outcome Code	Covered Spp.	Description	Magnitude	Certainty	Magnitude	Certainty
Positive Outcomes						
P7	All	Increase establishment of woody riparian vegetation to provide shaded channel habitat	2	3	2	3
P6	All	Increase establishment of woody riparian vegetation to export LWD	2	3	3	3
P8a	Delta smelt	Increased downstream turbidity improves habitat quality for delta smelt and longfin smelt	2	3-4		
P5g	Delta smelt	Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (off site), longfin smelt, and delta smelt	2	3		
P5a	Fall-run Chinook Salmon	Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (off site), longfin smelt, and delta smelt	2	3-4		
P4a	Fall-run Chinook Salmon	Increase production of food for rearing Chinook salmon, steelhead, green and white sturgeon, and splittail from inundation and riparian vegetation (local)	2	3-4		
P3a	Fall-run Chinook Salmon	Create rearing habitat for Chinook salmon, green and white sturgeon, splittail and steelhead (consider loss to entrainment)	2	3-4		
P1a	Fall-run Chinook Salmon	Improve connectivity of seasonally inundated floodplain habitat for juvenile fish (splittail, green and white sturgeon, Chinook salmon and steelhead).	2	3-4		

			Scenario 1		Scenario 2

P1c2	Spring-run Chinook Salmon	Increase rearing habitat area for covered fish species.	3	1		
P3b3	Steelhead	Locally provide areas of cool water refugia for Delta smelt and Salmonids	2	1		
P1f	White Sturgeon	Increase rearing habitat area for covered fish species.	2	2		
P1c1	Winter-run Chinook Salmon	Increase rearing habitat area for covered fish species.	1	1		

Outcome Code	Covered Spp.	Description	Magnitude	Certainty	Magnitude	Certainty
Negative Outcomes						
N2a	All	Potential for mercury methylation and local bioaccumulation: N2-A-Covered species, N2-B, Non-covered wildlife species, N2-C, human health.	1	2		
N1b	All	Establishment of undesirable species (such as Centrachids) that will prey or compete or alter habitat conditions for covered fish.	1	4		
N1a	All	Establishment of undesirable species (such as Egeria) that will prey or compete or alter habitat conditions for covered fish.	1	4		
N1c	All	Establishment of undesirable species (such as Corbicula) that will prey or compete or alter habitat conditions for covered fish.	4	2		
N1d	Delta smelt	Establishment of undesirable species (such as Inland Silversides) that will prey or compete or alter habitat conditions for covered fish.	2	2		
N2c	Human health	Potential for mercury methylation and local bioaccumulation: N2-A-Covered species, N2-B, Non-covered wildlife species, N2-C, human health.	2	3		
N2b	Wildlife	Potential for mercury methylation and local bioaccumulation to affect wildlife: N2-A - Target species, N2-B, Non-target wildlife species, N2-C, Human health.	3	2-3		

Viewpoint 1 Advective-driven transport of Cache Slough productivity will provide important and very substantial productivity contributions to larger regions of the northwestern Delta.

Viewpoint 2 Export from the restored marsh will be non-existent when Yolo Bypass is not flowing therby limiting productivity contributions beyond the restoration area.

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Positive Outcomes				
P6	All	Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (offsite), longfin smelt, and delta smelt (consider loss to entrainment on Bacon Island option)	1	3
P2	All	Increased establishment of instream structure through export of LWD to benefit covered species	1	1
P5d	Chinook salmon	Increased production and export of terrestrial invertebrates into the aquatic ecosystem for rearing splittail, green and white sturgeon, Chinook salmon and steelhead	2	3-4
P4e	Chinook salmon	Increase rearing habitat for splittail, green and white sturgeon, Chinook salmon and steelhead (consider loss to entrainment for Old River)	2-3	2-3
P5b	Green & White Sturgeon	Increased production and export of terrestrial invertebrates into the aquatic ecosystem for rearing splittail, green and white sturgeon, Chinook salmon and steelhead	1	2
P4b	Green Sturgeon	Increase rearing habitat for splittail, green and white sturgeon, Chinook salmon and steelhead (consider loss to entrainment for Old River)	2	1
P5a	Splittail	Increased production and export of terrestrial invertebrates into the aquatic ecosystem for rearing splittail, green and white sturgeon, Chinook salmon and steelhead	3	3
P4a	Splittail	Increase rearing habitat for splittail, green and white sturgeon, Chinook salmon and steelhead (consider loss to entrainment for Old River)	2	3-4
P3	splittail	Increase splittail spawning habitat on narrow floodplain margin	2	3-4
P5c	Steelhead	Increased production and export of terrestrial invertebrates into the aquatic ecosystem for rearing splittail, green and white sturgeon, Chinook salmon and steelhead	2	3
P4d	Steelhead	Increase rearing habitat for splittail, green and white sturgeon, Chinook salmon and steelhead (consider loss to entrainment for Old River)	3	2
P4c	White Sturgeon	Increase rearing habitat for splittail, green and white sturgeon, Chinook salmon and steelhead (consider loss to entrainment for Old River)	2	1

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Negative Outcomes				
N2	All	Increased exposure risk to contaminants (including Selinium) due to longer residence time in this area (for Bacon Island option only)	1	3
N1a	Delta smelt	Increased habitat for non-native predators/competitors to Chinook salmon, steelhead, green and white sturgeon, and splittail, if flows through sloughs are not sufficient to prevent colonization by non natives	2	3
N1d	Green & White Sturgeon	Increased habitat for non-native predators/competitors to Chinook salmon, steelhead, green and white sturgeon, and splittail, if flows through sloughs are not sufficient to prevent colonization by non natives	1	2
N1b	Longfin smelt	Increased habitat for non-native predators/competitors to Chinook salmon, steelhead, green and white sturgeon, and splittail, if flows through sloughs are not sufficient to prevent colonization by non natives	3	2
N1c	Splittail	Increased habitat for non-native predators/competitors to Chinook salmon, steelhead, green and white sturgeon, and splittail, if flows through sloughs are not sufficient to prevent colonization by non natives	2	3
N1e	Steelhead & Chinook salmon	Increased habitat for non-native predators/competitors to Chinook salmon, steelhead, green and white sturgeon, and splittail, if flows through sloughs are not sufficient to prevent colonization by non natives	2-3	2

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Negative Outcomes				
N4	All	Unintended changes to the striped and black bass populations (e.g., decrease abundance but increase average size)	2	2
N3	All	Release of other competitor populations from predation pressure	3	3
N2	All	Release of other predator populations from predation pressure	2	2
N1	All	Increased bycatch of non-target species	1	2

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Positive Outcomes				
P3	Chinook Salmon	Increased population sizes of Chinook salmon	2-3	2
P1	Green Sturgeon	Increased population sizes of green sturgeon	3	2
P4	Steelhead	Increased population sizes of steelhead	2	2
P2	White Sturgeon	Increased population sizes of white sturgeon	3	2
Negative Outcomes				
N1	Chinook salmon & Green & White Sturgeon	Information gap about where poaching is most important may result in effort being directed at less important areas and may shift poaching to areas with greater importance to the population	1	2

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Positive Outcomes				
P3	All	Would improve ability to gather information about species	2	3
P4	Splittail	Increased predation on Corbula	2	2
P2	Splittail	Improved foodweb energy transfer in wet years	3	2
P1	splittail	Increase population abundance of splittail	3	2
Negative Outcomes				
N1	Splittail	Potential for redirection of fishing effort to other sensitive species	2	2

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Positive Outcomes				
P1	Chinook Salmon	Increased population size of Central Valley Chinook salmon (all races)	4	3
P2	Chinook Salmon	Increased knowledge base regarding Central Valley Chinook salmon (population sizes, harvest rates, success of restoration programs, and other key biological parameters) for improved management	3	3
P3	Chinook Salmon	Reduce competition and introgression from hatchery fish with natural fish on spawning grounds	4	3
P4	Chinook Salmon	Can improve broodstock management at hatcheries (with tagging, much improved)	4	4
Negative Outcomes				
N1	Chinook Salmon	Complicates management and data acquisition for conservation hatcheries (e.g., Livingston-Stone) and associated agency sampling programs	4	4
N2	Chinook Salmon	Action may lead to increased harvest of hatchery fish, which may result in higher bycatch of covered salmonids	2	2
N3	Chinook Salmon	Action may lead to sociological pressure for increased hatchery production	?	?

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Positive Outcomes				
P2a	Delta smelt	Preserve genetic diversity	3	2
P1a	Delta smelt	Increased population sizes to self-sustaining levels in the wild	3	2
P3	Delta smelt & Longfin smelt	Improved knowledge base about threats to and management of the species stemming from ability to study the effects of various stressors on these species using hatchery reared specimens	4	4
P2b	Longfin smelt	Preserve genetic diversity	3	1
P1b	Longfin smelt	Increased population sizes to self-sustaining levels in the wild	3	1
Negative Outcomes				
N4a	Delta smelt	Mortality associated with catching broodstock (genetic material lost)	2	3
N1a	Delta smelt	Genetic consequences for hatchery and wild populations	3	2
N3	Delta smelt & Longfin smelt	Mining of wild population to support broodstock needs	3	3
N2	Delta smelt & Longfin smelt	Negative ecological interactions with wild fish (competition, displacement)	3	2
N4b	Longfin smelt	Mortality associated with catching broodstock (genetic material lost)	2	2
N1b	Longfin smelt	Genetic consequences for hatchery and wild populations	3	1

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Positive Outcomes				
P2f	Chinook Salmon	Increased Food Availability	1	1
P1f	Chinook salmon-Fry and juvenile	Reduce entrainment mortality by non-project diversions	1	1
P2a	Delta smelt	Increased Food Availability	1	1
P2c	Green Sturgeon	Increased Food Availability	1	1
P1c	Green Sturgeon-juvenile	Reduce entrainment mortality by non-project diversions	1	1
P1a	Larval and juvenile delta smelt	Reduce entrainment mortality by non-project diversions	2	2
P2b	Longfin smelt	Increased Food Availability	1	1
P1b	longfin smelt- Larval and juvenile	Reduce entrainment mortality by non-project diversions	1	1
P2e	Splittail	Increased Food Availability	1	1
P1e	Splittail- Juvenile	Reduce entrainment mortality by non-project diversions	1	1
P2g	Steelhead	Increased Food Availability	1	1
P1g	steelhead-Fry and juvenile	Reduce entrainment mortality by non-project diversions	1	1
P2d	White Sturgeon	Increased Food Availability	1	1
P1d	White Sturgeon-Juvenile	Reduce entrainment mortality by non-project diversions	1	1

Outcome Code	Covered Spp.	Description	Scenario 1 Magnitude	Scenario 1 Certainty	Scenario 2 Magnitude	Scenario 2 Certainty
Positive Outcomes						
P1a	Fall-run Chinook salmon- San Joaquin River	Reduced entrainment and predation mortality of covered species directly associated with South Delta project facilities and operations.	1	4	1	4
P1b	Spring-run Chinook salmon, Sac	Reduced entrainment and predation mortality of covered species directly associated with South Delta project facilities and operations.	2	3	3	3
P1c	Fall-run Chinook salmon, Sac.	Reduced entrainment and predation mortality of covered species directly associated with South Delta project facilities and operations.	2	3	3	3
P1d	Late Fall-run Chinook Salmon	Reduced entrainment and predation mortality of covered species directly associated with South Delta project facilities and operations.	2	3	3	3
P1e	Winter-run Chinook salmon	Reduced entrainment and predation mortality of covered species directly associated with South Delta project facilities and operations.	2	3	3	3
P1f	White Sturgeon	Reduced entrainment and predation mortality of covered species directly associated with South Delta project facilities and operations.	1	3	1	3
P1g	Green Sturgeon	Reduced entrainment and predation mortality of covered species directly associated with South Delta project facilities and operations.	1	3	1	3
P1h	Steelhead, Sacramento	Reduced entrainment and predation mortality of covered species directly associated with South Delta project facilities and operations.	2	3	3	3
P1i	Steelhead, San Joaquin	Reduced entrainment and predation mortality of covered species directly associated with South Delta project facilities and operations.	1	2	1	2

Outcome Code	Covered Spp.	Description	Scenario 1 Magnitude	Scenario 1 Certainty	Scenario 2 Magnitude	Scenario 2 Certainty
Positive Outcomes (contd.)						
P1j	Delta smelt-adult	Reduced entrainment and predation mortality of covered species directly associated with South Delta project facilities and operations.	3	3	3	3
P1k	Delta Smelt – Larval and Juvenile	Reduced entrainment and predation mortality of covered species directly associated with South Delta project facilities and operations.	3	3	3	3
P1L	Longfin Smelt - Adult	Reduced entrainment and predation mortality of covered species directly associated with South Delta project facilities and operations.	2	3	2	3
P1m	Longfin Smelt – Larval-Juvenile	Reduced entrainment and predation mortality of covered species directly associated with South Delta project facilities and operations.	3	3	3	3
P1n	Splittail	Reduced entrainment and predation mortality of covered species directly associated with South Delta project facilities and operations.	2	3	2	3
P2	All	Increased food availability for covered species due to higher productivity at lower trophic levels in the Delta associated with increased residence time	2	3	2	3

Outcome Code	Covered Spp.	Description	Scenario 1 Magnitude	Scenario 1 Certainty	Scenario 2 Magnitude	Scenario 2 Certainty
Negative Outcomes						
N1a	Sac Chinook & Steelhead	Increased predation on juvenile Sacramento salmon, steelhead, and sturgeon associated with local hydraulics at new North Delta water diversion structures	4	2	4	2
N1b	White sturgeon	Increased predation on juvenile Sacramento salmon, steelhead, and sturgeon associated with local hydraulics at new North Delta water diversion structures	2	2	2	2
N1c	Splittail- Juvenile	Increased predation on juvenile Sacramento salmon, steelhead, and sturgeon associated with local hydraulics at new North Delta water diversion structures	4	2	4	2
N3	Delta smelt	Increased mortality of juvenile delta smelt associated with new North Delta facilities and operations	2	3	2	2
N4a,b	Green & White Sturgeon	Increased mortality of covered species due to degradation of water quality which increases a stressor (on fish species of concern)	3	2	3	2
N4c	Chinook salmon- San Joaquin	Increased mortality of covered species due to degradation of water quality which increases a stressor (on fish species of concern)	4	2	4	2
N4d	Steelhead- San Joaquin	Increased mortality of covered species due to degradation of water quality which increases a stressor (on fish species of concern)	4	2	4	2
N4e	Splittail, Sac.	Increased mortality of covered species due to degradation of water quality which increases a stressor (on fish species of concern)	3	3	3	3

Outcome Code	Covered Spp.	Description	Scenario 1 Magnitude	Scenario 1 Certainty	Scenario 2 Magnitude	Scenario 2 Certainty
Negative Outcomes (contd.)						
N5	Delta smelt	Lower quality Delta smelt habitat due to reduced turbidity (i.e. loss of sediment due to fewer pulse flows on the Sacramento River).	2-3	1		
N6a,b	Chinook Salmon & steelhead- San Joaquin	Increased frequency, duration and extent of low DO at Stockton and blockage of salmon/steelhead migration on the San Joaquin River.	4	4		
N9	Chinook Salmon - Mokelumne River	Increased mortality of juvenile Mokelumne River Chinook salmon.	3	3-4		
N6c,d,e	Green & White Sturgeon, & Sacramento splittail	Increased frequency, duration and extent of low DO at Stockton and blockage of salmon/steelhead migration on the San Joaquin River.	1	2		
N7	All	Loss of Sacramento River food material for covered species into the Delta due to diversions of water and reduction in flow to the Delta.	2	1		
N8	All	Increased Microcystis biomass which will affect aquatic food webs and covered fish species due to the new North Delta Diversion.	3	2		
N9	All	Increased predationof juvenile Mokelumne River salmon due to modified Delta Cross Channel operations	3	3		

Scenario 1

Mid-Range Hood Bypass Criteria.

- December 1 through June 30 maintain a Sacramento River bypass flow of not less than 11,000 cfs;
- July 1 through August 30 maintain a Sacramento River bypass flow of not less than 5,000 cfs;
- September 1 through November 30 maintain a Sacramento River bypass flow of not less than 7,000 cfs for fall salmon attraction and migration;
- Require at least 55% of river flows above minimum bypass flows during February-April, 45% during January and May, and 35% during December and June

Scenario 2

Low (5,000 cfs) Hood Bypass Criteria

- Set minimum bypass flow of 5,000 cfs year round except as provided in the bullet below;
- Require at least 55% of river flows above 5,000 cfs during February-April, 45% during January and May, and 35% during December and June (see figure 3) to maintain the shape of the hydrograph.

Outcome Code	Covered Spp.	Description	Scenario 2a Magnitude	Scenario 2a Certainty	Scenario 2b Magnitude	Scenario 2b Certainty
Positive Outcomes						
P8a	Chinook salmon	Increase survival of out migrating juveniles (steelhead and Chinook salmon) by providing migration route with lower predation and entrainment (at North and South Delta diversions) risk	3-4	3	3-4	3
P6c	Chinook salmon	Reduce losses due to stranding, illegal harvest and blocked/delayed passage for Chinook salmon, steelhead, green/white sturgeon	4	3-4	4	3-4
P5f	Chinook Salmon	Increase frequency and magnitude of transport of OC and organisms from Cache Slough/Bypass tidal marshes to support Delta foodweb for delta smelt, longfin smelt, Chinook salmon, splittail, steelhead, and green and white sturgeon	2	2	2	2
P4f1	Chinook Salmon	Increase frequency and magnitude of export of DOM, POM and organisms from seasonal floodplain to provide food in Delta for delta smelt, longfin smelt, Chinook salmon, splittail, steelhead, and green and white sturgeon	2-3	2	2-3	2
P3d1 & 2	Chinook salmon	Increase production of food for rearing of Chinook salmon, green and white sturgeon, splittail, and steelhead, on the seasonal floodplain	4	3	3-4	3
P2d	Chinook salmon	Create additional juvenile rearing habitat for splittail, green and white sturgeon, steelhead and Chinook salmon	4	4	4	4
P7	delta smelt	Increase delivery of readily suspendable sediments to north Delta and improved delta smelt habitats	3	3	3	3
P5a	Delta Smelt	Increase frequency and magnitude of transport of OC and organisms from Cache Slough/Bypass tidal marshes to support Delta foodweb for delta smelt, longfin smelt, Chinook salmon, splittail, steelhead, and green and white sturgeon	3	2	3	2
P4a	Delta Smelt	Increase frequency and magnitude of export of DOM, POM and organisms from seasonal floodplain to provide food in Delta for delta smelt, longfin smelt, Chinook salmon, splittail, steelhead, and green and white sturgeon	3	3	3	3

Outcome Code	Covered Spp.	Description	Scenario 2a Magnitude	Scenario 2a Certainty	Scenario 2b Magnitude	Scenario 2b Certainty
Positive Outcomes (contd.)						
P2b	Green & White Sturgeon	Create additional juvenile rearing habitat for splittail, green and white sturgeon, steelhead and Chinook salmon	1	2	1	2
P6a	Green & White Sturgeon Scenarios 1 & 2	Reduce losses due to stranding, illegal harvest and blocked/delayed passage for Chinook salmon, steelhead, green/white sturgeon	4	4	4	4
P5d	Green & White Sturgeon Scenarios 1 & 2	Increase frequency and magnitude of transport of OC and organisms from Cache Slough/Bypass tidal marshes to support Delta foodweb for delta smelt, longfin smelt, Chinook salmon, splittail, steelhead, and green and white sturgeon	2	2	2	2
P4d	Green & White Sturgeon Scenarios 1 & 2	Increase frequency and magnitude of export of DOM, POM and organisms from seasonal floodplain to provide food in Delta for delta smelt, longfin smelt, Chinook salmon, splittail, steelhead, and green and white sturgeon	2	2	2	2
P3b	Green & White Sturgeon Scenarios 1 & 2	Increase production of food for rearing of Chinook salmon, green and white sturgeon, splittail, and steelhead, on the seasonal floodplain	1	2	1	2
P5b	Longfin Smelt	Increase frequency and magnitude of transport of OC and organisms from Cache Slough/Bypass tidal marshes to support Delta foodweb for delta smelt, longfin smelt, Chinook salmon, splittail, steelhead, and green and white sturgeon	3	2	3	2
P4b	Longfin Smelt	Increase frequency and magnitude of export of DOM, POM and organisms from seasonal floodplain to provide food in Delta for delta smelt, longfin smelt, Chinook salmon, splittail, steelhead, and green and white sturgeon	2-3	2	2-3	2

Scenario 2a

Period of Potential Operation: December 1-May 15
Desired Duration of Inundation: 45 days
Target Spill Discharge into Bypass: 4000 cfs
Predicted area of inundation: 22,982 acres
Predicted mean depth of inundated area: 2.2 feet
Predicted travel time: 6.5 days
Spill Frequency of Fremont Weir (assuming 4000 cfs and 45 day duration with a spill intermission of no more than 7 days): 48% of years (38 of 79), compared to 6% of years (5 out of 79) at existing weir height.

Scenario 2b

Period of Potential Operation: January 1-April 15
Desired Duration of Inundation: 30 days
Target Spill Discharge into Bypass: 2000 cfs
Predicted area of inundation: 17,421 acres
Predicted mean depth of inundated area: 2.3 feet
Predicted travel time: 9.3 days
Spill Frequency of Fremont Weir (assuming 2000 cfs and 30 day duration with a spill intermission of no more than 7 days): 54% of years (43 of 79), compared to 6% of years (5 out of 79) at existing weir height.

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Positive Outcomes				
P4f	Chinook salmon	Increase frequency and magnitude of export of DOM, POM and organisms from seasonal floodplain to provide food in Delta for delta smelt, longfin smelt, Chinook salmon, splittail, steelhead, and green and white sturgeon	2	2
P2d	Chinook salmon	Create additional juvenile rearing habitat for splittail, green and white sturgeon, steelhead and Chinook salmon	3-4	3-4
P8a	Chinook salmon	Increase survival of out migrating juveniles by providing mitigation route with lower predation and entrainment (at North and South Delta diversions) risk.	3-4	3
P7a	Delta smelt	Increase delivery of readily suspendable sediments to Prospect Is and improved DS habitats	3	2
P5a	Delta smelt	Increase transport of OC and organisms from Prospect/Miner Sl tidal marshes to support Delta foodweb for DS, LS, CS, splittail, steelhead, G/W sturgeon	3	2
P4a	Delta smelt	Increase export of DOM, POM and organisms from seasonal floodplain to provide food in Delta for DS, LS, CS, splittail, steelhead, G/W sturgeon	3	3

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Positive Outcomes (contd.)				
P4d	Green & White Sturgeon	Increase frequency and magnitude of export of DOM, POM and organisms from seasonal floodplain to provide food in Delta for delta smelt, longfin smelt, Chinook salmon, splittail, steelhead, and green and white sturgeon	1	2
P2b	Green & White Sturgeon	Create additional juvenile rearing habitat for splittail, green and white sturgeon, steelhead and Chinook salmon	1	2
P4b	Longfin smelt	Increase frequency and magnitude of export of DOM, POM and organisms from seasonal floodplain to provide food in Delta for delta smelt, longfin smelt, Chinook salmon, splittail, steelhead, and green and white sturgeon	2	2
P4c	Splittail	Increase frequency and magnitude of export of DOM, POM and organisms from seasonal floodplain to provide food in Delta for delta smelt, longfin smelt, Chinook salmon, splittail, steelhead, and green and white sturgeon	4	4
P3a	Splittail	Increase production of food for rearing of CS, splittail, steelhead, (onsite = seasonal floodplain only)	4	4
P2a	Splittail	Create new juvenile rearing habitat for CS, splittail, steelhead, G/W sturgeon (esp. for American River CS and steelhead)	4	4

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Positive Outcomes (contd.)				
P1a	Splittail	Create new spawning habitat for Splittail	4	4
P6a	Steelhead	Increase in upstream migration opportunity for CS and steelhead	2	2
P4e	Steelhead	Increase production of food for rearing Chinook salmon, steelhead, green and white sturgeon, and splittail from inundation and riparian vegetation (local)	2	2
P2c	Steelhead	Create additional juvenile rearing habitat for splittail, green and white sturgeon, steelhead and Chinook salmon	3	3

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Negative Outcomes				
N4a	All	Reduced flows in Sacramento River and distributaries to support successful outmigration.	2	3
N2a	All	Increased resuspension/mobilization and export of toxic compounds w/impact on covered species (consider sensitivity to changes in land use - none stated in assumptions)	2	2
N1a	All	Increased MeHg and impact on covered species (on floodplain and downstream)	2	3
N3d1	Chinook salmon-adults	Increased stranding of covered species	1	4
N3d2	Chinook salmon-juvenile	Increased stranding of covered species	2	4

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Negative Outcomes (contd.)				
N5a	Delta smelt	Increased habitat for non-native predators/competitors to covered species	1	3
N6a	Delta smelt & Longfin smelt	Decrease in turbidity downstream of Yolo and reduction in habitat for delta smelt and longfin smelt	1	3
N5d	Green & White Sturgeon	Increased habitat for predators/competitors to covered species	1	2
N3b	Green & White Sturgeon	Increased stranding of covered species	1	4
N5b	Longfin smelt	Increased habitat for predators/competitors to covered species	1	3

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Negative Outcomes (contd.)				
N3a1	Spilttail- Adults	Increased stranding of covered species	1	4
N3a2	Spilttail- Juvenile	Increased stranding of covered species	2	4
N5c	Splittail	Increased habitat for predators/competitors to covered species	1	3
N5e	Steelhead & Chinook salmon	Increased habitat for predators/competitors to covered species	1	3

ACTION DESCRIPTION AND CLARIFYING ASSUMPTIONS 3

APPROACH 5
INTENDED OUTCOMES AS STATED IN CONSERVATION MEASURE 6
INFORMATION REGARDING INTENDED OUTCOMES 6
San Joaquin Chinook Salmon *6*
Sacramento Chinook Salmon Runs *6*
Delta Smelt *8*
PROBLEM(S) WITH ACTION AS WRITTEN: 8
SCALE OF ACTION 10

EVALUATION SUMMARY TABLES 10

OUTCOMES IDENTIFIED BUT NOT EVALUATED 10

RELATION TO EXISTING CONDITIONS 10

POTENTIAL POSITIVE ECOLOGICAL OUTCOME(S) 11

OUTCOME P1: REDUCED ENTRAINMENT AND PREDATION MORTALITY OF COVERED SPECIES DIRECTLY ASSOCIATED WITH SOUTH DELTA PROJECT FACILITIES AND OPERATIONS. 11
P1a. San Joaquin River fall-run Chinook salmon *13*
P1b. Sacramento Spring-run Chinook salmon *16*
P1c. Sacramento fall-run Chinook salmon *18*
P1d. Late-fall-run Chinook salmon *18*
P1e. Winter-run Chinook salmon *19*
P1f. White sturgeon *20*
P1g. Green sturgeon *21*
P1h. Steelhead – Sacramento Run *21*
P1i. Steelhead – San Joaquin Run *22*
P1j. Delta Smelt - Adult *22*
P1k. Delta Smelt – Larval and Juvenile *23*
P1l. Longfin Smelt - Adult *24*
P1m. Longfin Smelt – Larval-Juvenile *24*
P1n. Splittail *25*
OUTCOME P2: INCREASED FOOD AVAILABILITY FOR COVERED SPECIES DUE TO HIGHER PRODUCTIVITY AT LOWER TROPHIC LEVELS IN THE DELTA ASSOCIATED WITH INCREASED RESIDENCE TIME. 26

POTENTIAL NEGATIVE ECOLOGICAL OUTCOME(S) 28

OUTCOME N1: INCREASED PREDATION ON JUVENILE SACRAMENTO SALMON, STEELHEAD, SPLITTAIL AND STURGEON ASSOCIATED WITH LOCAL HYDRAULICS AT NEW NORTH DELTA WATER DIVERSION STRUCTURES. 29
N1a. Sacramento Chinook salmon and Steelhead *31*

N1b. White sturgeon ... *31*
N1c. Splittail - Juvenile ... *32*
OUTCOME N2: INCREASED PREDATION DUE TO ALTERED MIGRATION ROUTES AND MIGRATION RATES OF OUTMIGRATING JUVENILE FISH ... 33
OUTCOME N3: ENTRAINMENT OF LARVAL AND JUVENILE DELTA AND LONGFIN SMELT ASSOCIATED WITH NEW NORTH DELTA FACILITIES AND OPERATIONS. ... 36
OUTCOME N4: INCREASED MORTALITY OF COVERED SPECIES DUE TO DEGRADATION OF WATER QUALITY WHICH INCREASES A STRESSOR (ON FISH SPECIES OF CONCERN) ... 37
N4a, b. White and Green Sturgeon ... *41*
N4c. San Joaquin Salmon ... *41*
N4d. San Joaquin Steelhead ... *42*
N4e. Sacramento Splittail ... *42*
OUTCOME N5: LOWER QUALITY DELTA SMELT HABITAT DUE TO REDUCED TURBIDITY (I.E. LOSS OF SEDIMENT DUE TO FEWER PULSE FLOWS ON THE SACRAMENTO RIVER). ... 42
OUTCOME N6: INCREASED FREQUENCY, DURATION AND EXTENT OF LOW DO AT STOCKTON AND BLOCKAGE OF SALMON/STEELHEAD MIGRATION ON THE SAN JOAQUIN RIVER. ... 44
N6a, b. San Joaquin Salmon and steelhead ... *44*
N6c, d, e. White and Green Sturgeon, and Sacramento splittail ... *45*
OUTCOME N7: LOSS OF SACRAMENTO RIVER FOOD MATERIAL FOR COVERED SPECIES INTO THE DELTA DUE TO DIVERSIONS OF WATER AND REDUCTION IN FLOW TO THE DELTA. ... 45
OUTCOME N8: INCREASED MICROCYSTIS BIOMASS DUE TO THE NEW NORTH DELTA DIVERSION WHICH WILL AFFECT AQUATIC FOOD WEBS AND COVERED FISH SPECIES ... 46
OUTCOME N9: – INCREASED PREDATION OF JUVENILE MOKELUMNE RIVER SALMON DUE TO MODIFIED DELTA CROSS CHANNEL OPERATIONS ... 47

Action

Construct new diversion facilities in the North Delta along the Sacramento River between Walnut Grove and Freeport with a capacity to divert up to 15,000 cfs. The new diversions would be operated to divert large amounts of water during wet periods and less in dry periods. No diversion would be allowed unless flows downstream of the diversion points exceed minimum flow requirements known as the Hood Bypass Flow Criteria. Additional description of this action provided below.

Evaluation Team

Date of Last Revision: June 3, 2009

Action Description and Clarifying Assumptions

For the DRERIP analysis, the following two by-pass flow Scenarios were evaluated:

Scenario 1- Mid-Range Hood Bypass Criteria (See figures 1 and 2).

- December 1 through June 30 maintain a Sacramento River bypass flow of not less than 11,000 cfs;
- July 1 through August 30 maintain a Sacramento River bypass flow of not less than 5,000 cfs;
- September 1 through November 30 maintain a Sacramento River bypass flow of not less than 7,000 cfs for fall salmon attraction and migration;
- Require at least 55% of river flows above minimum bypass flows during February-April, 45% during January and May, and 35% during December and June (see figure 2)[1].

Scenario 2 - Low (5,000 cfs) Hood Bypass Criteria (See figures 1 and 2).

- Set minimum bypass flow of 5,000 cfs year round except as provided in the bullet below;
- Require at least 55% of river flows above 5,000 cfs during February-April, 45% during January and May, and 35% during December and June (see figure 3) to maintain the shape of the hydrograph.

[1] For example, if there is 12,000 cfs inflow above diversion point during February, 450 cfs can be diverted and 11,550 must flow past diversions point as Hood Bypass flow.

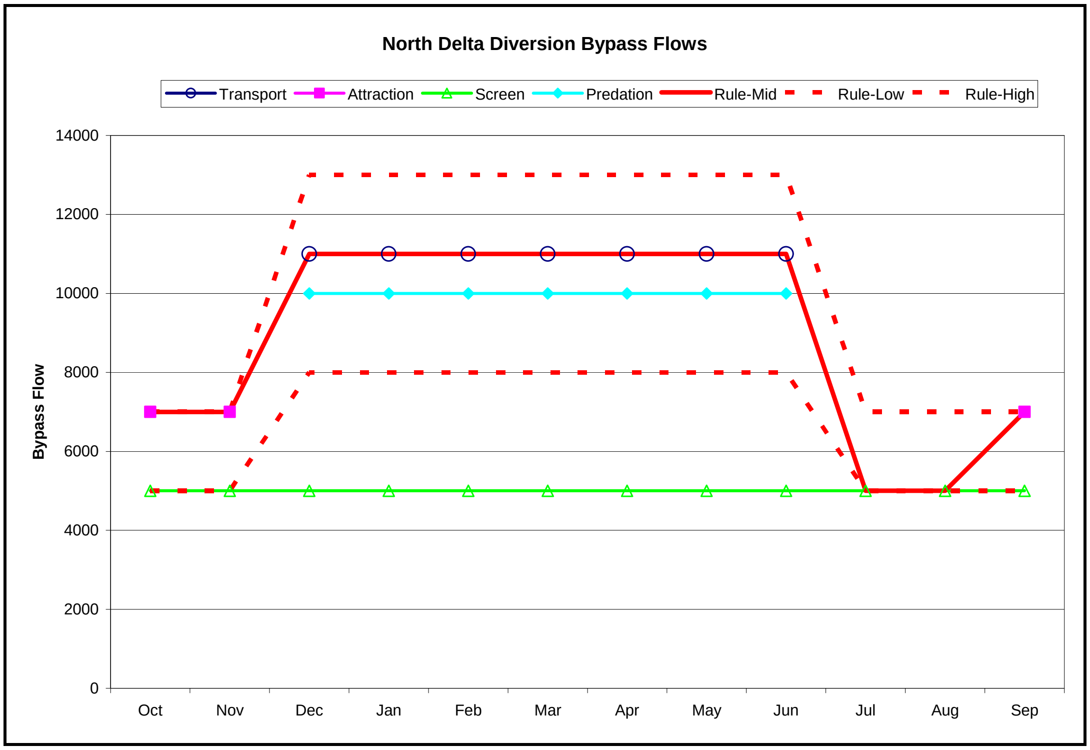

Figure 1. DRAFT Consultant's proposal for minimum Hood bypass flow rules: One rule at "Mid-range" ("Rule-Mid" or 11,000cfs) and second "5,000cfs rule" at minimum flows for fish screen ("screen") function.

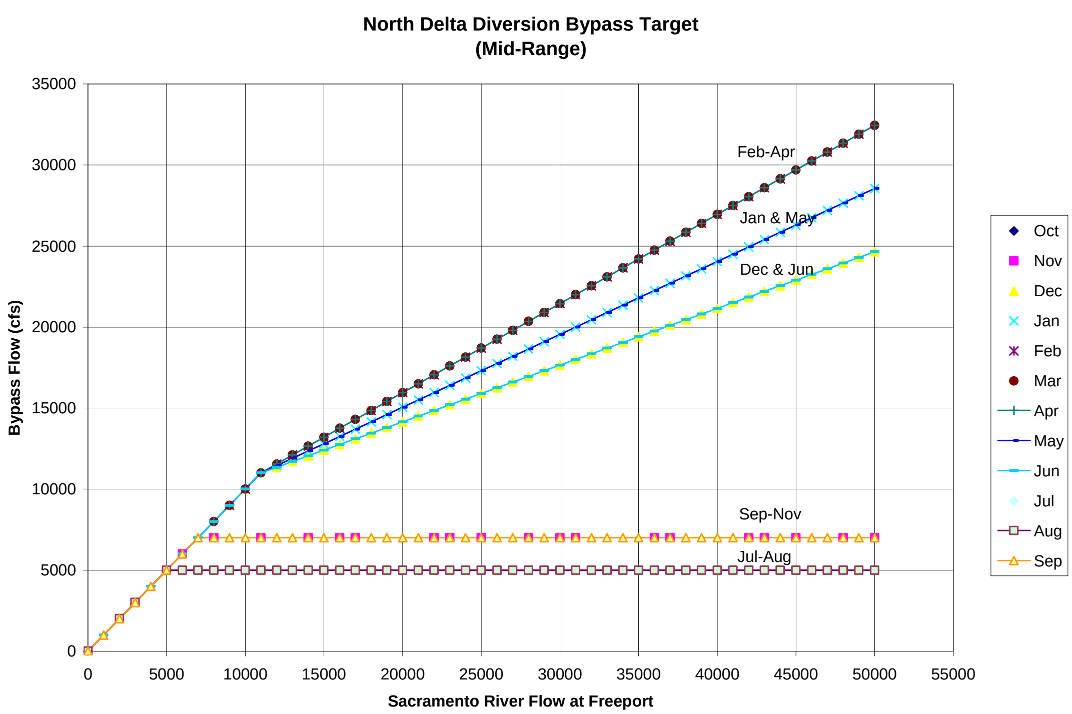

Figure 2. Consultant proposed minimum north Delta diversion bypass flows depicted as a function of Sacramento River flow for the "mid-range rule."

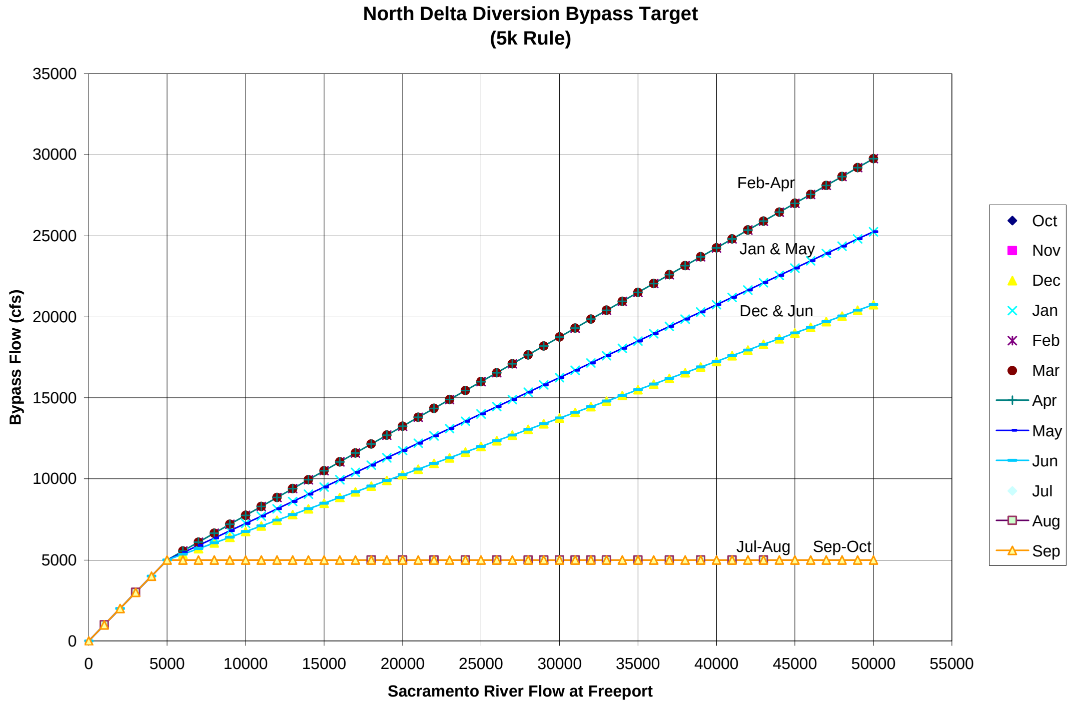

Figure 3. Consultant proposed minimum north Delta diversion bypass flows depicted as a function of Sacramento River flow for the 5,000cfs rule.

Approach

This action will be implemented in combination with several other actions and changes to the Delta environment described in greater detail in "*An Overview of the Draft Conservation Strategy for the Bay Delta Conservation Plan*", dated January 12, 2009. For the DRERIP analysis, the following was assumed:

1. **Total Diversions and Outflow:** Preferentially divert from the North Delta. Assume existing D-1641 outflow requirements, but 2-10% greater diversions than D-1641, depending on the scenaro.
2. **Diversion Infrastructure:** Five or more diversion intakes b/t Freeport and Walnut Grove each with a diversion capacity of 3,000 cfs or less.
   a. State of the art fish screens will prevent entrainment of juvenile fish (salmon, steelhead, sturgeon etc.) and will be operated to minimize entrainment of larval life stages of delta smelt and striped bass.
   b. All relevant screens are operating as designed 100% of the time that water is being diverted and are efficient at proposed operational flows.
   c. Individual diversion structures are sufficiently spaced to allow for recovery in between involuntary encounter with screens.
3. **Delta Cross Channel gate operations:** Closed from November through June and be open during July and August. In September and October, the Delta Cross Channel (DCC) would be open half the time, but actively operated to minimize harm to covered species through strategies such as a diel closure schedule.
4. **Cache Slough Tidal Habitat:** 10,000 acres of tidal marsh restoration will likely reduce tidal excursion up Steamboat and Sutter Sloughs. Development of tidal marsh may take time and may or may not achieve target area.

5. **South Delta Exports:** Preferentially divert from North Delta and only utilize South Delta diversions when diversions from North Delta are not adequate to meet D-1641. Minimum 14-day average OMR flows for July through November set at -5,000 cfs. Minimum 14-day average net OMR flows for December through June set at -3,500 cfs**.**
6. **Evaluation Baseline:** Evaluators considered population level effects relative to existing conditions.

Intended Outcomes as Stated in Conservation Measure

1. Reduced entrainment of juvenile San Joaquin, Mokelumne, Calaveras, and Cosumnes salmon and steelhead (March-June) in the South Delta (some runs were not evaluated).
2. Reduced entrainment in the south Delta of adult delta smelt that move east of Jersey Island (December-January).
3. Reduced entrainment of larval delta smelt (March-May).
4. Expand the potential to restore tidal habitat in the southern Delta.

Information Regarding Intended Outcomes

San Joaquin Chinook Salmon

The action implies that a dual conveyance system, as described in Scenario 1 or 2, would reduce entrainment of juvenile San Joaquin Chinook and steelhead. However, the following information must be considered in evaluating the action:

1. Very little San Joaquin River water makes it to the western Delta (at Jersey Point) except in the wet season of the wetter years (Fig 3-8, BDCP Draft Technical Memorandum, Feb 2009; Kimmerer and Nobriga 2008). Compared to the Reference Scenario (D-1641), this improves somewhat with Scenario 1 in the wetter years but there is no noticeable difference in the drier years.
2. Spring flows in the San Joaquin basin are correlated with adult returns 3 years later (Speed 1993) and survival of outmigrating smolts (SJRGA 2007)
3. South Delta Exports: Vernalis flow ratios are inversely correlated with adult production and juvenile survival. However, this relationship is not as strong as Vernalis flows alone. The action does change the Vernalis flows to south Delta exports ratio, with substantially lower TD:VNS ratios with Scenario 1. However it is not clear this change is sufficient to improve problems associated with low San Joaquin River flows.
4. Reduced negative OMR relative to D-1641 baseline may not be sufficient to ensure better passage of steelhead and Chinook emigrating from the San Joaquin basin.

Sacramento Chinook Salmon Runs

1. The North Delta serves as the primary rearing and migratory corridor for Sacramento anadromous fishes in the Delta.
   a. Juvenile Chinook salmon that rear in the Delta (spring-run, fall-run, and winter run) are assumed to be influenced by changes in critical habitat such as lowered river stages and associated reductions in cover and food availability and accessibility. It is assumed steelhead also rear in the Delta.
   b. Based on previous research, salmon migrating into the Delta as smolts are assumed to be negatively influenced by increased residence time and routing into Central and south Delta channels. Potential for entrainment in the south Delta persists in both of the proposed scenarios, though to a lesser extent.

   c. Upstream migrating adult salmon are assumed to have sufficient attraction flows (via Rio Vista requirements) and unimpeded passage (via Fremont Weir modifications).
   d. Sacramento River green and white sturgeon stage during the late winter and spring in the north Delta before migrating up the Sacramento River as late as May. Sturgeons typically reside close to spawning habitats in the river, and water temperatures appear to be a critical cue for spawning activity.
2. The potential direct impacts of Sacramento River diversions on juvenile anadromous fishes have not yet been assessed. This includes the effects of impingement (multiple and repeated), the efficiency and effectiveness of large fish screens and the degree to which aggregations of predators will reduce survival past the diversions. The fish facilities technical team assumes meeting screening according to DFG/NMFS criteria is sufficiently protective (R. Wantuck, personal communication, January 28, 2009).
3. Of particular importance to Sacramento juvenile anadromous fish habitat are the months of November through May, when juvenile anadromous fishes emigrate in relatively high abundance.

There are several major assumptions in this action

1. Dual conveyance reduces entrainment of juvenile (e.g., spring-run) Chinook salmon at South Delta Facilities assumes:
   a. The primary mechanism for entrainment at South Delta Facilities is reverse flows towards CVP/SWP facilities indexed by OMR.
   b. The likelihood of entrainment is increased when DCC gates are open during migratory period.

2. Dual conveyance affects the probability of juveniles reaching Chipps Island via two mechanisms:
   a. migration route: lower likelihood of Central and South Delta routes due to more positive OMR, increased QWEST, and DCC closure.
   b. Transport time: delayed travel time for outmigrating smolts through the north Delta increases risk of mortality through exposure to predation and rerouting to less favorable routes.

It is not possible to eliminate south Delta entrainment because water – and by extension some component of migratory fish populations – is transported by both tidal dispersion and the advective (net) flow of the rivers (Kimmerer and Nobriga 2008). Since both tides and river flows influence transport, it is possible for small percentages of water (and by extension fish) to be entrained in the south Delta from the Sacramento River even when river flows are high relative to exports (see Figure 5 in Kimmerer and Nobriga 2008). Thus, Sacramento basin juvenile salmon are still subject to South Delta entrainment when OMR is positive or slightly negative. This is even more pronounced for particles (fish) originating in the San Joaquin basin from which even very low export:inflow ratios are associated with high particle entrainment risk (see Figure 6 in Kimmerer and Nobriga 2008, and Appendix B). Although OMR is more positive under both dual conveyance Scenarios, the range of flows still encompasses reverse flows when juveniles are present and the frequency of fish entrainment increases when OMR flows are negative (see Appendix B). Negative OMR flows are correlated with high numbers of fish salvaged. Under Scenario 1, mean OMR flows in April are -1,400 cfs, yet under current conditions, daily salvage of winter-run and spring-run sized fish, occurred when OMR flows were greater than 1,400 cfs in April (see Appendix B). The occurrence of winter-run sized fish in the salvage facilities indicate fish from the Sacramento basin may be entrained via mildly negative OMR flows.

Scenario 1 would provide desirable conditions for outmigrating smolts only during spring. However, both dual conveyance Scenarios would create *undesirable* conditions for outmigrating smolts in fall and winter. This is based on Particle Tracking Modeling[2] (PTM) for the north Delta.

River stage for north Delta migratory corridors under either dual conveyance Scenario is lowered throughout the year, and at times lowered by ~30%. This will translate to reduced rearing habitat along sloughs and the mainstem Sacramento River.

North Delta diversions would decrease discharge in migratory sloughs[3], such that reverse flows in Sutter and Steamboat Sloughs would be more frequent. Reverse flows in migratory corridors during smolt migration increases risks to predation, routing into the Central Delta, and/or injury from more passes by fish screens.

Delta Smelt

The cause and effect relationship is a non-linear relationship between adult delta smelt salvage at the Banks and Jones diversions and OMR flows. A specific threshold for OMR flows above which salvage increases is not provided in Norbriga and Herbold, 2008. The CALSIM/DSM2 model constrains OMR flow for this action to -3500 cfs. Under D-1641, winter OMR was often more negative than -3500 cfs. Given the less negative OMR flows that stemmed from the modeling to support this proposed action, it is possible the action would protect most adult delta smelt and essentially all adult longfin smelt from entrainment at Banks and Jones pumping plants.

Although benefit to longfin smelt is not one of the originally intended outcomes, data from Grimaldo et al. (in press) indicate longfin smelt entrainment is rare when OMR is less negative than -5000 cfs.

Assumptions

Provided in BDCP Conservation Measure

1. See “Approach” and “Information Regarding Intended Outcomes” sections above.

Added by Evaluation Team

For purposes of this evaluation, the Team assumed that:

1. South Delta water export facilities remain in their current configuration (i.e. no modifications).
2. The baseline is equivalent to D1641 (i.e. Pre-Wanger type of operation). The 2008-2009 Biological Opinions are not considered part of the baseline.
3. D1641 includes VAMP with a San Joaquin River pulse flow in April-May.
4. New fish screens will operate at 100% efficiency, 100% of the time.

Problem(s) with Action as Written:

---

[2] PTM end of 45 days; and 50% particles. Median monthly flows are from Calsim II Inputs of Sacramento River at Hood, Reference Conditions.

[3] “Preliminary Modeling Evaluation of Draft Conservation Strategy Core Elements” Update to BDCP Steering Committee, January 30, 2009. Powerpoint presentation, slide 11.

1. **Intended Outcome 1**: The Evaluation Team felt that Sacramento River salmonids should be added to the list of species to be evaluated because they are also entrained at the SWP and CVP facilities. There may be some effect on Mokelumne and Cosumnes river salmonids but this was not evaluated. Sturgeon were also added to the evaluation. The wording of Outcome 1 was changed from "entrainment…in the South Delta" to "mortality directly associated with South Delta project operations" because mortality from a suite of factors related to entrainment into south Delta channels and the pumping facilities seemed to be the relevant issue being addressed in this outcome. The date range (March-June) was removed from the outcome because there is no scientific basis to limit the analysis to only to this period.
2. **Intended Outcome 2**: As in intended Outcome 1, the wording of this outcome was changed from "entrainment" to "mortality directly associated with South Delta project operations". The Evaluation Team decided to add longfin smelt to the evaluation.
3. **Intended Outcome 3**: As in intended Outcome 1, the wording of this outcome was changed from "entrainment" to "mortality directly associated with South Delta project operations". The team also added longfin smelt to the evaluation of this outcome.
4. **Intended Outcome 4**: This outcome was not evaluated. The team concluded that it is not possible to evaluate the ecological value associated with the "potential" for habitat restoration.
5. **Fish Screens:** The assumption that the state of the art fish screens will eliminate entrainment at the intake facilities is untested. No similar set of structures as large as what is proposed exist on which this assumption can be fully evaluated. For the purpose of this evaluation, the team decided to accept the assumption because there are no data to support or refute it.
6. **Tidal Excursion:** The modeling supporting the assumption that tidal reintroduction to restore aquatic habitat in the Cache Slough area will substantially reduce tidal excursion up Sutter and Steamboat sloughs treats the "restored" areas as reservoirs that are filled with water. The analysis does not attempt to evaluate changes in tidal excursion as tidal marsh habitats are established over time.
7. **Modeling Notes:** Conclusions presented in this worksheet are sometimes based upon the modeling output presented by Armin Munevar from CH2MHill during our Team workshop on Jan. 21, 2009. These analyses rely heavily on the output of models, particularly CALSIM II and DSM2. The validation of these models for these analyses has not been peer-reviewed. Further, as in all models, the outputs depend heavily on the assumptions and parameters used as inputs. These include the operating rules, criteria, and limitations set by the proposed actions, as well as those included in the baseline. Changes in these rules as the actions are refined may alter the quantitative outcome of the Team's assessment. The models also use an 82-year historical record of flow as a boundary condition. Future patterns of flow, sea level, and temperature will be different from historical. This may cause the actual outcomes to diverge from the expected outcomes in terms of flow patterns, salinity, and exports. In particular, the shift to an earlier snowmelt peak forecasted by climate analyses has already been observed and rising sea level will increase the influence of tides in the project area. The Team suggests that future iterations of the analysis include sensitivity analysis with variations in operating criteria and precipitation patterns based on climate and sea level forecasts.
8. **Diversion Point Flexibility:** BDCP has proposed an assumption of 2-10% more water diversion than D1641 standards. A dual conveyance system would provide flexibility in switching between north and south Delta diversion points. However, this is not quantitatively demonstrated and this lack of quantitative information is problematic when analyzing potential outcomes in this worksheet. This Team recommends that BDCP

provide probability distributions of exports from the north vs. south Delta Diversion points that clarify the desired export rates.

Scale of Action

Large

Rationale:
This action will change the boundary conditions of the Delta on a landscape scale. It will change hydrodynamics and associated ecology throughout the Delta and Yolo Bypass.

Evaluation Summary Tables

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

Outcomes Identified but Not Evaluated

Because of either marginal effects, limited time and/or the lack of specific information to support an evaluation, the following outcomes were identified by the team but were not evaluated:

- Entrainment of larval fish and eggs that can fit between fish screen mesh.
- Entrainment of juvenile salmon, steelhead, and sturgeon at non-project diversions in the Delta.
- Entrainment and predation mortality of Mokelumne and Cosumnes fall-run Chinook salmon and steelhead directly associated with South Delta project facilities and operations.
- Survival of out-migrating juvenile smelt due to increased travel time. Delta and longfin smelt are highly unlikely to spawn upstream of the North Delta diversions in large numbers. This may need to be re-evaluated if hydrodynamic modeling indicates strong reverse flows up the Sacramento River will frequently occur during smelt spawning migrations.
- Changes in reproductive success of salmon (egg-fry mortality) due to changes in reservoir storage and associated cold water pools.

Relation to Existing Conditions

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold? YES

Nature of Change: Adding additional points of diversion in the North Delta is beyond the scope of the current DRERIP models (including its Boundary Conditions model) and may exceed the conditions for which numerical models have been validated. For example, the conceptual models do not address the possibility of reverse flows on the Sacramento River, due to new diversions. They do not address the timing, magnitude and distribution of changes to Delta inflow that modeling indicates will result from new north Delta diversions. They do not specifically address fish passage at multiple long fish screens. Nor do they specifically address the changes stemming from major changes in Delta source water and water quality. Further, if the Delta's "plumbing" is changed, then ecological operating criteria (E/I ratio, X2) might need to be revisited. Given the dramatic change in the system presented by this proposal, the use of all models (conceptual, statistical and simulation) must be cautious. However, in the absence of any other information they have been used to the extent they can to support this evaluation.

Potential Positive Ecological Outcome(s)

Outcome P1: Reduced entrainment and predation mortality of covered species directly associated with South Delta project facilities and operations.

One of the key factors in evaluating the potential benefits of reduced entrainment and predation mortality associated with modified operations of South Delta project facilities is the presence of various covered fish species in the south Delta relative to the proposed operational modifications. Figures 4 and 5 below show the temporal distribution of salvage data for various Chinook salmon runs. These data provide an indication of when various runs are typically in the south Delta, including peak occurrence. These data are used throughout the evaluation below.

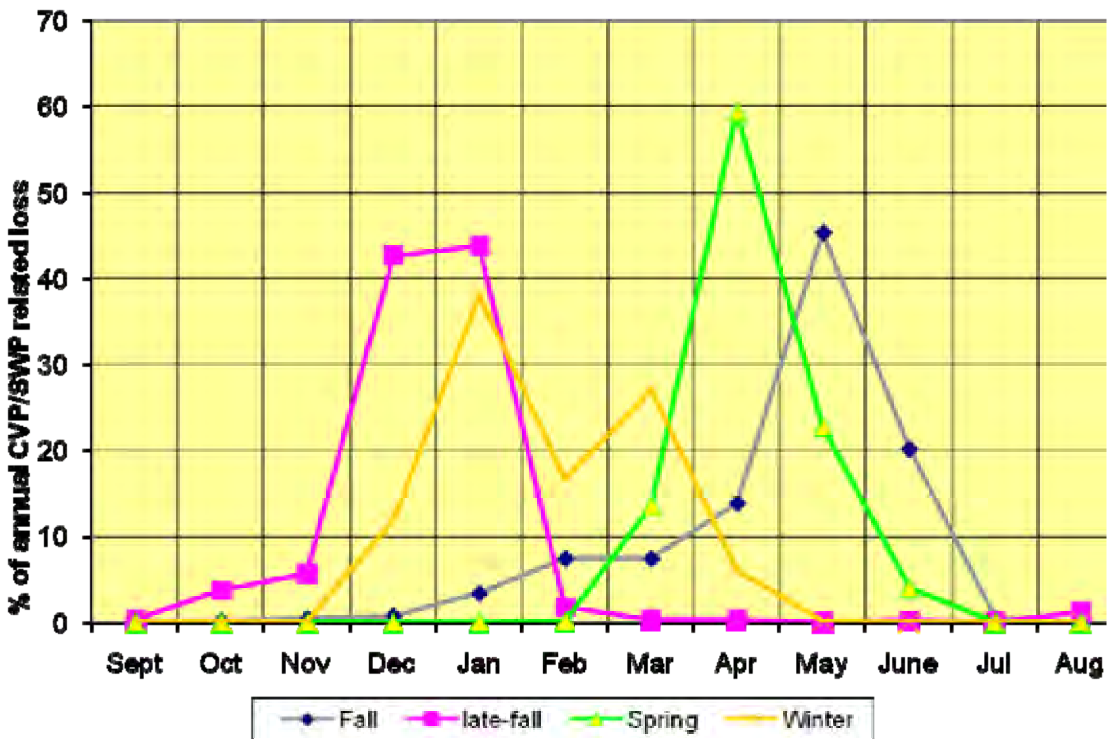

Figure 4. Temporal distribution of annual run-specific loss due to SWP/CVP pumping. Relative, run-specific loss associated with SWP/CVP pumping. Run-identification assignments based on expected size of each of the different runs on the date collected. Source: CDFG's Delta Fish Salvage Monitoring Unit.

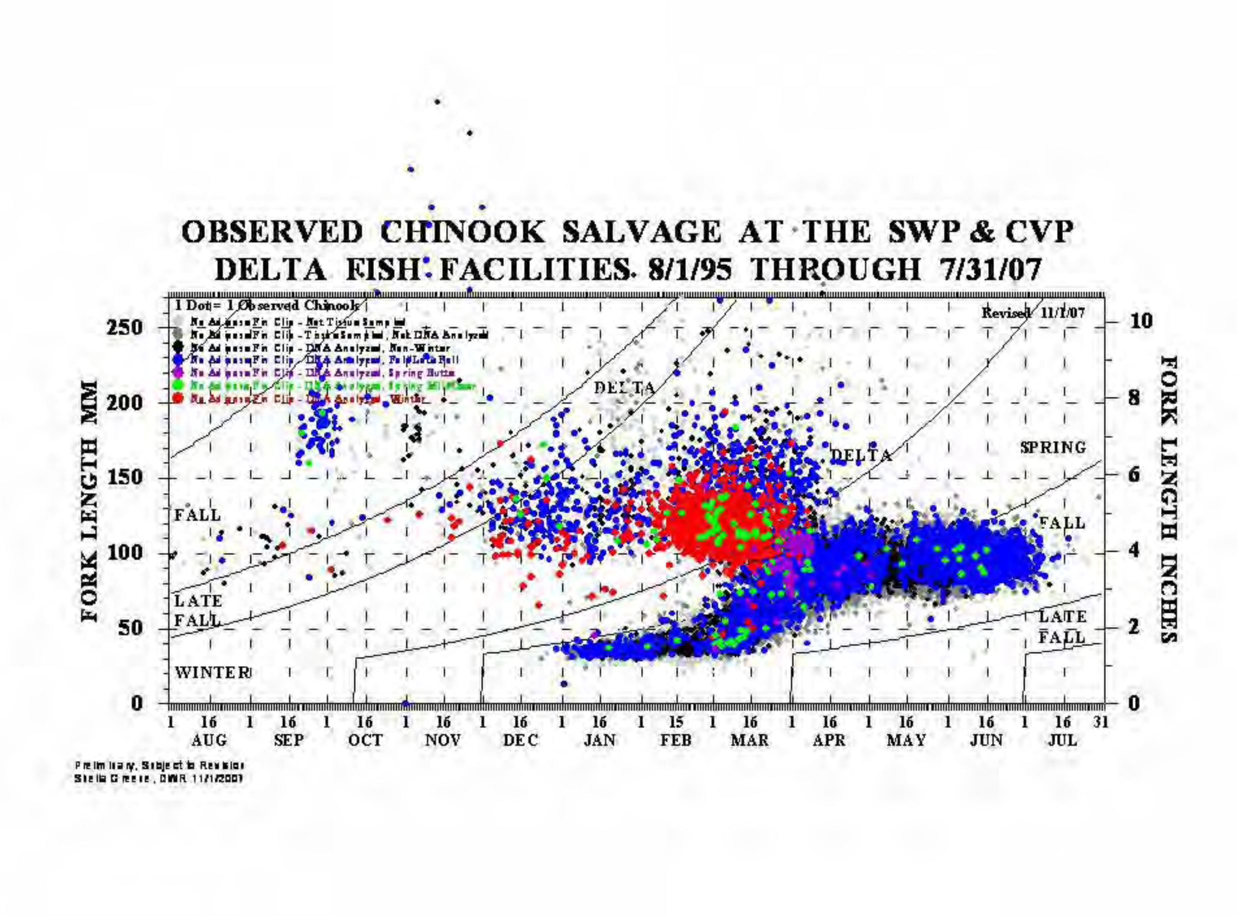

Figure 5. Observed Chinook salvage at SWP and CVP Delta Fish Facilities with DNA analysis. Source: Shiela Green, DWR,

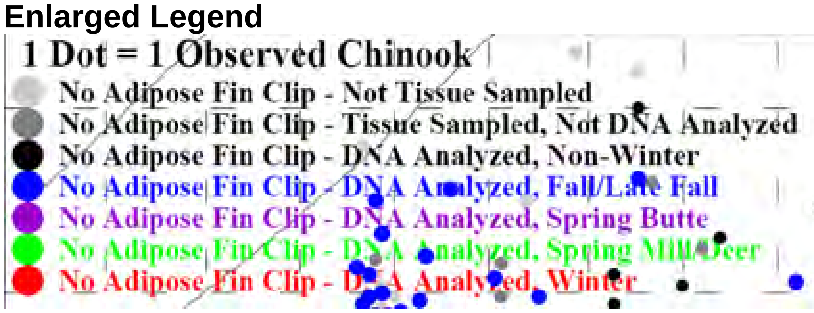
Enlarged Legend



All the following information regarding correlations between survival and various other factors; must be used with a degree of caution in the evaluation of this action as the correlations do not provide information on mechanisms of mortality in the South Delta.

When export pumping is low, there can still be substantial salmon entrainment at the South Delta pumping facilities. However, the mechanisms affecting this entrainment are not well understood. As described in Appendix G, net flows, tidal cycles and salinity gradients all likely influence migratory patterns. Factors such as pumping, agricultural drainage influencing salinity gradients, and operation of barriers and gates (including the DCC) all likely interact to affect with the tidal cycles to influence salmon survival in the south Delta.

P1a. San Joaquin River fall-run Chinook salmon

This evaluation assumes San Joaquin River (SJR) system fall-run are not vulnerable to losses at the Hood facility.

With a North Delta diversion, water would be exported from the south Delta throughout the year, with monthly averages ranging from 1,900 cfs to 4,500 cfs (Scenario 1). Under certain conditions (in Scenario 1) the composition of source water changes at key regions of the Delta when compared to the reference Scenario (Figures 6a-b).

- Water in Old River at Tracy Road is predominantly San Joaquin water, with Sacramento water being drawn during critical years (Fig 3-9, BDCP Draft Technical Memorandum, Feb 2009).
- Very little of the San Joaquin River water makes it to the western Delta (at Jersey Point) except in the wet season of the wetter years (see Appendix H: Water Source Fingerprinting and Kimmerer and Nobriga 2008). Scenario 1 provides some improvements in the wetter years but there is no noticeable difference in the drier years.
- During the Vernalis Adaptive Management Program (VAMP) period, CVP + SWP exports are positively correlated with Vernalis flows (p. 65, Fig 5-16; 2005 SJRGA).

San Joaquin Chinook juveniles are bimodally distributed in the Delta system with a winter peak of small juveniles (<50 mm) entering the Delta in some years with high winter flows between January and March, and in all years a larger spring peak of outmigrating smolts (>70 mm) between April and June (2005 SJRGA).

- Reported numbers of fry and pre-smolt fish are generally underrepresented because salvage and trawls are less effective at capturing fry and pre-smolts (p. 69, 2007 SJRGA).

The San Joaquin River flows at Vernalis in the spring months are correlated with increased numbers of adult Chinook salmon returning to the San Joaquin Basin in subsequent years, as well as increased survival of outmigrating San Joaquin juvenile Chinook to Chipps Island.

- Adult escapement of San Joaquin Chinook salmon is positively correlated with increasing San Joaquin River flow at Vernalis (Fig 5-20, 2005 SJRGA; Marston and Mesick 2006; Dean Marston, DFG, unpublished data). High Vernalis flow to export ratios are also correlated with higher adult escapement in the San Joaquin Basin (Fig 5-21, 2005 SJRGA; Dean Marston, DFG, unpublished data).
- Survival of outmigrating juveniles increases with increased San Joaquin River flows, and in some cases this relationship is statistically significant. (Newman 2008; SJRGA 2007, p. 76; 2004, 2005, 2006 SJRGA). This relationship is more variable without the Head of Old River Barrier in place. Fewer fish are salvaged at CVP/SWP facilities when Vernalis flows are higher (2005 SJRGA).

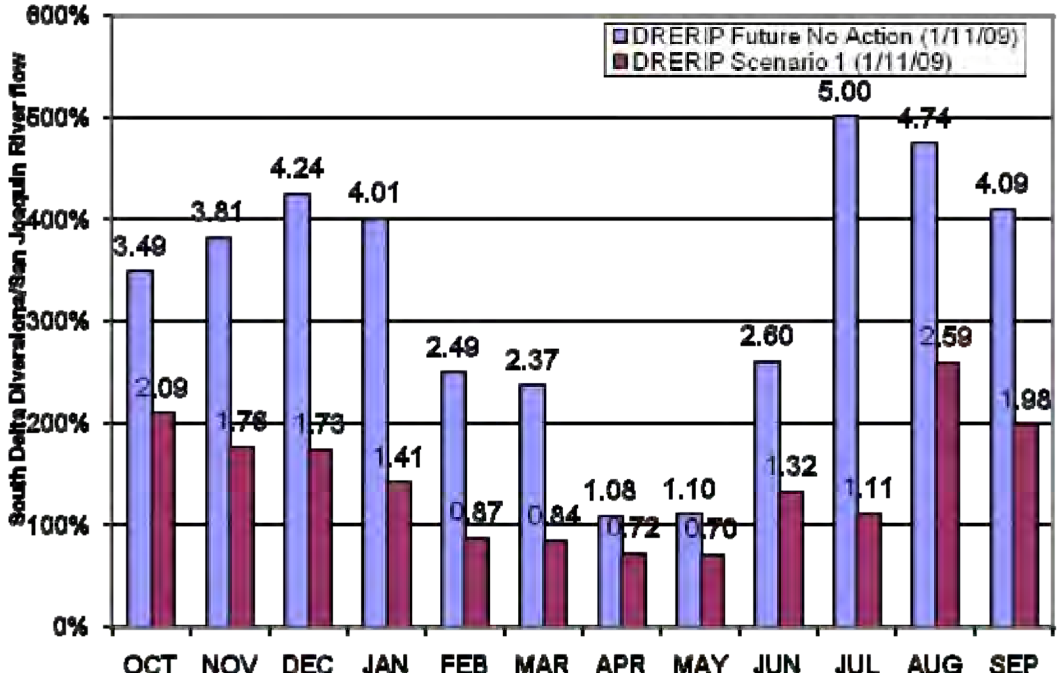


Figure 6a. Project South Delta Exports as Percent of SJR Flow (Scenario 1 & Reference)

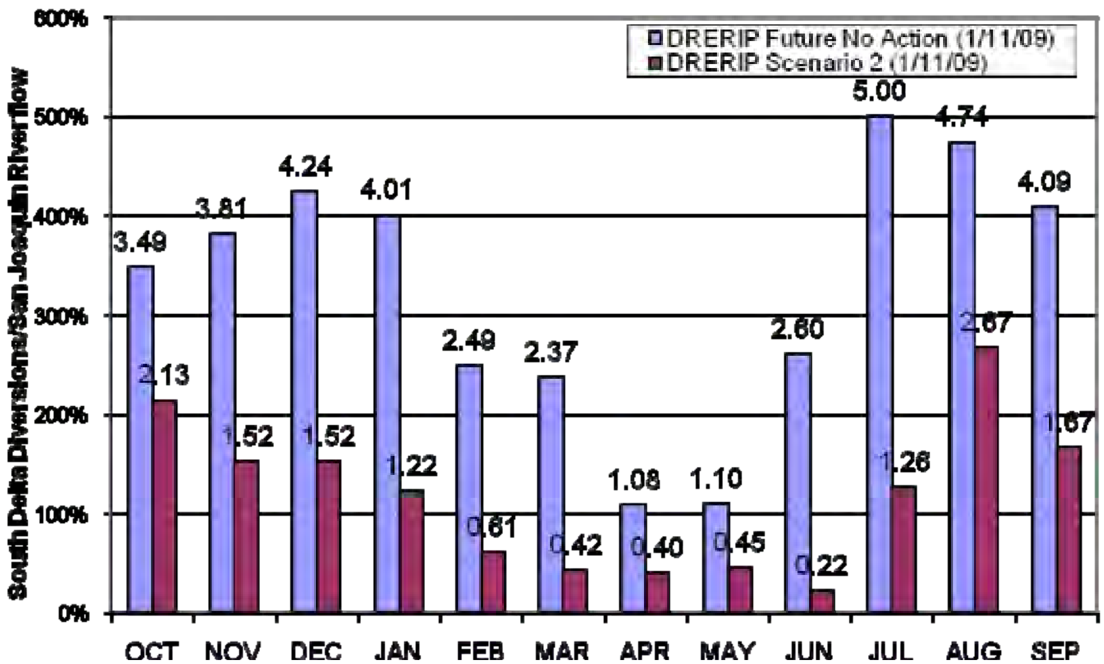

Figure 6b. Project South Delta Exports as Percent of SJR Flow (Scenario 2 & Reference)

The assumption that San Joaquin fish are entrained at pumps can be supported by comparing salvage to the timing, abundance, and size of salmon collected in San Joaquin basin monitoring, such as San Joaquin tributaries, San Joaquin River at Mossdale and salvage facilities (2007 SJRGA, p. 66).

- Timing of salvage rate and fish size can be compared with Mossdale trawl data and CWT recovery data for Merced River Hatchery smolts at the salvage facilities to provide indications as to the origin of the unmarked fish (p. 60, 2007 SJRGA). When marked Chinook juveniles are released in the San Joaquin tributaries some of them are recovered at the CVP/SWP fish facilities (Fig 5-29, 2005 SJRGA).
- During Jan-June, the size distribution of unmarked salmon in the Mossdale trawl overlaps with that of salmon salvaged at the fish facilities (p. 60; figure 5-25, 2007 SJRGA; p. 68 2006 SJRGA).

A high South Delta export to Vernalis flow ratio is positively associated with juvenile Chinook salvage at the CVP/SWP facilities (Figures 5-23 and 5-24 of 2007 SJRGA, p. 77 of 2007 SJRGA). However, the strength of this relationship is limited by the narrow range of exports (1,500-3,000 cfs) during the VAMP period (p. 63, 2005 SJRGA).

- San Joaquin adult escapement (2.5 years later) is higher when Vernalis flow to Export ratios increases (Fig 5-21, p. 69; 2005 SJRGA).
- San Joaquin juvenile survival to Chipps Island is higher when Vernalis flow: Export ratio is high (Figs 5-14, 5-15, 2005 SJRGA).
- Survival of juvenile CWT Chinook during VAMP period was positively correlated with Vernalis flow: Export ratio (p. 65, Fig 5-14; and p. 66 Fig 5-17, 2005 SJRGA).

According to Newman (2008): Flow was positively associated with the probability of surviving from Dos Reis to Jersey Point. San Joaquin fish that avoid Old River by either being released downstream (i.e. at Dos Reis) or due to HORB being in place had higher survival rates. But flows are lower by design when the barrier is in place so flow effect on survival is clouded. For fish entering Old River, there was little evidence for an association between exports and survival. With the HORB in, survival of coded wire tagged San Joaquin fish was positively associated with San Joaquin River flow but was not associated with exports. Newman (personal communication, May 4, 2009), however, explains the evidence for associations between exports and survival is likely swamped by the level of environmental noise in the south Delta, and the observations used in the analyses are limited by the narrow range of observed ratios between export and San Joaquin River flows.

Magnitude = 1 - Minimal

The water fingerprinting model results that show very little SJR water makes it past Jersey Point as shown in Appendix H: Water Source Fingerprinting. VAMP studies show very low survival during all years except when flow in SJR is high. As long as ratio of export to SJR flow is high, correlations indicate that entrainment of SJR fall Chinook will continue, and not be reduced. Figure 6b shows the ratio is reduced in both Scenarios in the January -June timeframe. However, even low negative flows on OMR will not prevent SJR salmon from being entrained to the pumps so this does not alter the score for Scenario 2. These effects could be better identified with examination of the effect of water year status on monthly changes in the flow ratio (e.g., the entire 82 year run as a box plot rather than simply the mean for each Scenario).

Certainty = 4 - High

Published studies indicate that San Joaquin Chinook salmon survival in the south Delta is influenced by multiple factors and is strongly correlated with San Joaquin River flows.

It is highly certain, based on these data that measures to address south Delta pumping alone will have a minimal effect on San Joaquin Chinook salmon populations without simultaneously addressing other factors such as San Joaquin River flows. The central and south Delta are known zones of entrainment under current water management regimes.

P1b. Sacramento Spring-run Chinook salmon

The focus here is on spring-run juveniles though the same rationale can be used, with consideration for changes in temporal distribution, for other runs of Chinook, and steelhead. Figure 4 shows that spring-run occur in the south Delta Feb-June with a peak in April.

The primary mechanism for juvenile entrainment at the South Delta Facilities is reverse flows towards CVP/SWP facilities via OMR. OMR flows are negative year round (Figure 7a) and draw Sacramento basin salmon into the SWP and CVP facilities. Evidence of entrainment of Sacramento fish at the SWP and CVP facilities is documented by genetically analyzed salvaged fish (Figure 5), as well as recovery of Coleman Hatchery late-fall releases at the facilities within weeks and months of release (data from 2004-2008 provided by Sheila Greene, DWR, unpublished data). Juvenile spring-run sized-fish are subject to entrainment when OMR is negative (Figures 7a-c).

Peak salvage of spring-run sized fish occurs in April, followed by March and May. (Source - Appendix B: OMR vs. Salvage Relationship Graphs).

Magnitude
Scenario 1: 2- Low
Scenario 2: 3 - Medium

Figure 7b shows negative OMR flows during spring-run migratory period still occur under Scenario 1. Under Scenario 1, median OMR flows are at least -1,400 cfs during April. During spring-run presence, Scenario 2 median OMR is negative only in May (Figure 6c). Because peak salvage occurs in April, Scenario 2 would be more protective than Scenario 1. Spring-run are salvaged at the pumps between March and June with a peak in April (see Figure 4 on page 11). This suggests a larger benefit based on improved OMR flows in February and March (both Scenario 1 and 2 have relatively good February and March OMR flows). However, as salvage does not peak until April, the importance of February OMR flows is not clear.

Certainty = 3
Species are present in the system when water is conveyed through the Delta. Juveniles are rearing or migrating through the Delta starting in November through May (data from DFG Knights Landing; CVP/SWP salvage; FWS trawl and beach seine). DFG salvage data shows juvenile spring-run are entrained at South Delta facilities.

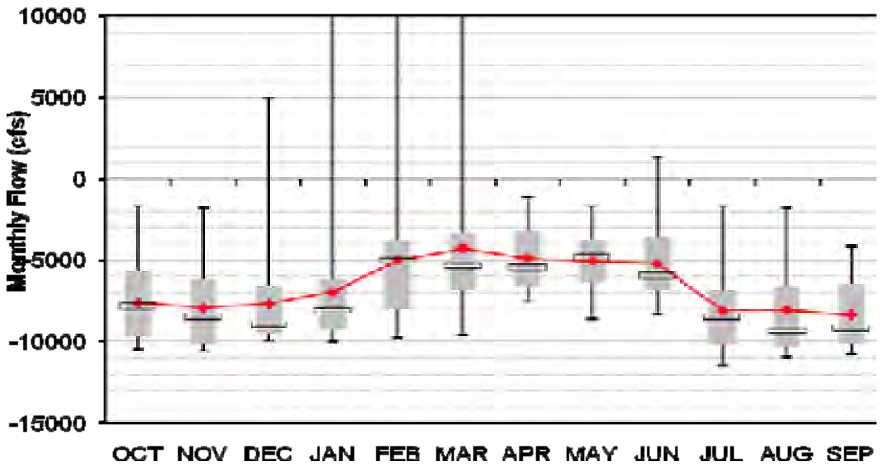

Figure 7a. Combined Old and Middle River Flows (Reference Conditions)

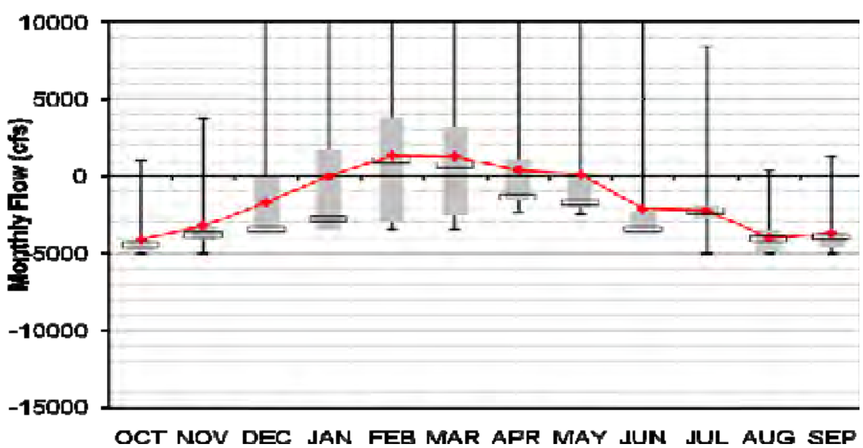

Figure 7b. Combined Old and Middle River Flows (Scenario 1)

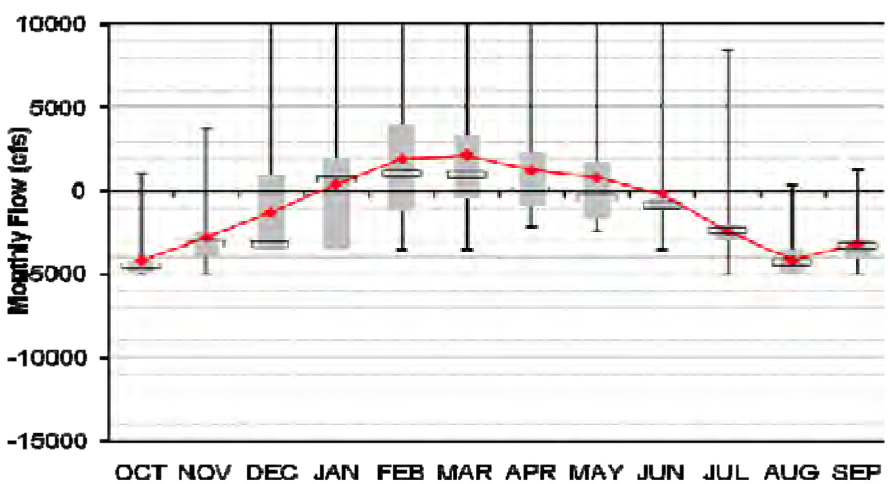

Figure 7c. Combined Old and Middle River Flows (Scenario 2)

P1c. Sacramento fall-run Chinook salmon

Sacramento fall-run Chinook are salvaged between December and June with a peak in May (see Figure 4). USFWS (2000) described the presence of juvenile fall-run Chinook from multiple monitoring sites in the central and south Delta during this period with a peak during February. These data included information on water year type and Chinook present later in the winter (March and April) in this region of the Delta appear to make up a larger proportion of the spring/fall Chinook captured in these locations during above normal and critical years than in wet years, when a larger proportion appears to emigrate earlier in the winter. OMR flows under the two Scenarios are both better than the reference conditions, (Figures 7a-c). It seems operation of south Delta diversions will produce higher fall-run Chinook juvenile mortality under Scenario 1 than under Scenario 2, due to the greater duration and earlier start of negative OMR flows.

One confounding factor is that the origin (hatchery vs. natural) of the fish reported on in USFWS 2000 is unknown.

Magnitude
Scenario 1: 2 - Low
Scenario 1 is similar to the reference condition and will expose fall run Chinook to negative OMR flows (and thus presumably levels of entrainment) closer to the reference condition earlier in the spring. Mortality will likely be reduced, but a significant period of emigration will still be subject to negative OMR flows (Figure 7b).; A negative (-) 2000 ± 500 OMR is associated with increased salmonid entrainment risks during April and May (see Appendix B). It is likely there is limited effect on productivity and diversity of fall Chinook due to this reduced mortality in the south Delta compared to the reference condition.

Scenario 2: 3 - Medium
Scenario 2 is less similar to the reference condition and will expose fall run Chinook to negative OMR flows at the tail of the fall run juvenile emigration period through the Delta (Figure 7c). Given the periodicity of fish and OMR flows, reduced mortality in the south Delta may have a minor population effect on fall run Chinook juvenile mortality.

Certainty = 3 - Medium
Salvage data are available to show entrainment on this run and modeling results show that the improvement in OMR flows occurs in many year types.

P1d. Late-fall-run Chinook salmon

Late fall run Chinook appear to emigrate out of the mainstem earlier than fall-run Chinook salmon, which belong to the same ESU. Late fall run Chinook are salvaged in August to June with a peak in January, and moderate levels of salvage in November, December and February (see Figure 4 and Figure 5 - DNA analyses conducted by USFWS) OMR flows under the two scenarios are both increased (less negative) compared to the reference conditions (Figure 6a-c). OMR flows are likely to be negative in more years under Scenario 1 than Scenario 2 but both represent an improvement over the reference condition.

One confounding factor in this analysis is its basis on length-ESU identification of Chinook. It is not clear length is the best delineator of late fall yearlings, which may be the same size as spring run Chinook yearlings or fall, which may be late emigrating juvenile fall run Chinook.

Magnitude
Scenario 1: 2 – Low
In Scenario1 late fall yearlings should be subject to entrainment similar to reference levels since in most years OMR flows remain at -2000 ± 500 throughout the winter in Scenario 1. Late fall run fry that are at the threshold for emigration into the central and south Delta in April and May will also be subject to negative OMR flows during most years and are then likely to be entrained. .It is likely there is limited effect on productivity and diversity on late fall Chinook due to reduced mortality in the South Delta compared to the reference.

Scenario 2: 3 - Medium
In Scenario 2, late fall yearlings should be subject to entrainment despite the change from the reference since OMR flows remain at >-2000 ± 500 throughout the winter in December and January in most years when these fish are present in the south Delta. Late fall fry Chinook may have reduced mortality in the south Delta during April and May since OMR is positive under Scenario 2 in these months for most years. There is likely limited effect on productivity and diversity of late fall Chinook caused by reduced mortality in the South Delta due to Scenario 2.

The affect of reducing OMR flows for this race should be similar to that of other races.

Certainty = 3 - Medium
The difficulty of specifically identifying late fall run yearlings leads to reduced certainty regarding the effects of this action on this run. The late fall magnitude score is based on the identification and the same data as the other runs (i.e. same as P1 c above).

P1e. Winter-run Chinook salmon

Sacramento winter run are present in the south Delta from December to April with a peak in January-March (Figure 1). While flows are less negative during this period than the reference conditions (Figure 7a) both scenarios still show negative flows in many years of up to -2000 cfs during this period (Figures 7a - b). OMR flows are likely to be negative in more years under Scenario 1 than Scenario 2 but both represent an improvement over the reference condition. The earlier arrival of these fish in the south Delta means they benefit less from reduced pumping than some other runs.

Magnitude
Scenario 1: 2-Low
Scenario 1 is more similar to the reference condition and will expose winter run Chinook to negative OMR flows (and thus presumably levels of entrainment) closer to the reference condition during late winter. Mortality will likely be reduced, but a significant period of emigration will still be subject to negative OMR flows. It is likely there is limited effect on productivity and diversity of winter Chinook due to this reduced mortality in the South Delta compared to the reference.

Scenario 2: 3-Medium
Scenario 2 is less similar to the reference condition and will expose winter run Chinook to negative OMR flows during fewer year (Figure 4c). Given the periodicity of fish and OMR flows, reduced mortality in the south Delta may have a minor population effect on fall run Chinook juvenile mortality.

Certainty = 3-Medium
Salvage data show entrainment of winter-run run (Figure 4 and 5) and modeling results show there is a difference in OMR flows (See Figures 7a-c).

P1f. White sturgeon

White sturgeon entrainment during the reference period was primarily between June and September (DWR and BOR unpublished salvage data) and appears related to successful spawning and recruitment of juvenile sturgeon into the Delta. White sturgeon actively emigrate at night (Israel et. al., 2009 page 4). White sturgeon juveniles have limited capacity to survive in brackish waters and likely enter the south Delta via the DCC when it is open and during reversal of flows in the western delta. OMR median flows in Scenario 1 go negative in April and remain negative into the winter, while OMR median flows in Scenario 2 become negative in May and remain negative into the winter. Operation of south Delta diversions under the two Scenarios likely will not differentially reduce white sturgeon mortality since it will remain negative during the period when white sturgeon are historically present in salvage.

Magnitude = 1 - Minimal
White sturgeon juveniles are entrained from June – September and will be subject to negative OMR flows during most years under Scenario 1 (Figure 7b) and Scenario 2 (Figure 7c). The conceptual model indicates little effect of this action on reducing mortality in the south Delta for white sturgeon.

Certainty = 3 - Medium
There is some evidence of high entrainment, yet some question regarding the data (Israel et al., 2009). These questions include the influence of the DCC on entrainment and the cyclic dynamics of recruitment in the population driving highly variable entrainment, thus population and/or external mechanism may be responsible for our observations. Little is known about the effect of the entrainment mortality on populations – DRERIP model indicates that the understanding of entrainment of juveniles on the population is low (Table 5), though the DCC and cyclic dynamics are recognized as influence entrainment estimates in other species. Please see Appendix F, White Sturgeon Salvage Data, for more details.

P1g. Green sturgeon

Green sturgeon may still be exposed to an open DCC between July and August under this action and enter the central and south Delta through this pathway. Juvenile green sturgeon actively emigrate during the night (Israel and Klimey, 2008; p. 2l). Green sturgeon entrainment between 1993 and 2003 (Fish Salvage Monitoring database, http://www.delta.dfg.ca.gov/Data/Salvage/) occurs every month, was greatest in February, and seems to occur more over the summer and fall than during the spring. OMR median flows in Scenario 1 become negative in April and remain negative into the winter, while OMR median flows in Scenario 2 become negative in May and remain negative into the winter (Figure 7a and 7b).. Operation of south Delta diversions under the two Scenarios likely will not differentially reduce green sturgeon mortality since it will remain negative during the period when green sturgeon are historically most present in salvage (summer and fall), and will not reduce their distribution within the zone of entrainment.

Magnitude = 1 - Minimal
Green sturgeon juveniles reside in the south and central Delta during all months (Israel and Klimey, 2008; pg 4), and will still be subject to negative OMR flows during most of their period of salvage (March – December) (Israel and Klimey, 2008; pg 4).

Certainty = 3 - Medium
The DRERIP conceptual model indicates high understanding of the effects of entrainment at the pumps on juveniles (Israel and Klimey, 2008; Table 5) but there have been no studies of the specific effects of OMR flows on green sturgeon.

P1h. Steelhead – Sacramento Run

Little information is available to support a specific evaluation of this action of steelhead. The Evaluation Team determined that in the absence of any additional information that steelhead should be evaluated similarly to spring-run and winter salmon (as described in P1c).

Magnitude = Scenario 1: 2- Low
Scenario 2: 3 - Medium
Figure 7b shows negative OMR flows during spring-run and winter-run migratory period still occur under Scenario 1. Under Scenario 1, median OMR flows are at least -1,400 cfs during April. During this period, Scenario 2 median OMR is negative only in May (Figure 7c). Because peak salvage occurs in April, Scenario 2 would be more protective than Scenario 1. This suggests a larger benefit based on improved OMR flows in February and March (both Scenario 1 and 2 have relatively good February and March OMR flows).

Certainty = 3 - Medium
Species are present in the system when water is conveyed through the Delta. Juveniles are rearing or migrating through the Delta starting in November through June). Good data to show juvenile steelhead are entrained at South Delta facilities (Nobriga and Cadrett 2001).

P1i. Steelhead – San Joaquin Run

Little information is available to support a specific evaluation of this action of steelhead. The Evaluation Team determined that in the absence of any additional information that steelhead should be evaluated similarly to San Joaquin fall-run Chinook salmon.

Magnitude = 1 – Minimal (for both scenarios)
The rationale for a minimal magnitude score is that in both scenarios, it is still an infrequent occurrence that any significant fraction of water originating in the San Joaquin basin is predicted to leave the Delta. Similar to the San Joaquin fall-run, this continued export of nearly 100% of San Joaquin River water was likely to confuse steelhead migration even though they are large fish that can swim strongly relative to Chinook smolts.

Certainty = 2 - Low (for both scenarios)
The tagging and survival studies that have been conducted for San Joaquin Chinook (e.g., Newman 2008; Vogel 2008) have not been conducted using San Joaquin steelhead. Since less is known about steelhead (in comparison to Chinook salmon) the certainty score is low.

P1j. Delta Smelt - Adult

According to the delta smelt model, “Delta hydrodynamics and resulting entrainment in water diversions are primary components of habitat suitability that affect delta smelt mortality.” (Nobriga and Herbold, 2008 p. 23 & Figures on pp 53-54 of the pdf). Kimmerer (2008) showed that nearly all adult delta smelt entrainment has been associated with negative OMR. Grimaldo et al. (in press) proposed a linear model that associated multi-month OMR and salvage. Other unpublished analyses based on monthly average OMRs have indicated that delta smelt entrainment does not increase substantially until OMR is less than -3500 cfs or so. Turbid water in the south Delta is required in addition to any particular OMR flow to cause adult delta smelt entrainment (Grimaldo et al. in press).

Magnitude = 3 (for both scenarios)
Average OMR flows of -3500 cfs during winter will reduce south Delta entrainment (Grimaldo et al. in press), but not entirely prevent it (Kimmerer 2008).

The magnitude of this action is medium for both Scenario 1 and Scenario 2 because both operate to an OMR ceiling of -3500 cfs during delta smelt's winter migration. Both scenarios predict median OMR very near -3500 cfs in December (Figures 7b and 7c). Scenario 2 (Figure 7c) provides better median OMR conditions in January, but both Scenarios have very similar predictions of average January OMR. Predicted OMR in February are typically sufficient to prevent adult entrainment in both scenarios because both scenarios show positive mean and median OMR in February.

Certainty = 3 - Medium
Factors leading to adult delta smelt salvage are broadly understood (Kimmerer 2008; Grimaldo et al. in press). Certainty is medium because:

- OMR and timing of first flush/sediment runoff events that lead to salvage are not predictable far in advance;
- If north Delta diversions reduce downstream Sacramento basin turbidity pulses, this might change the South Delta turbidity regime, which might reduce entrainment more than current data suggest if high turbidity in the south Delta happens less frequently.

P1k. Delta Smelt – Larval and Juvenile

DRERIP smelt model (pg 23) states that "Delta hydrodynamics and resulting entrainment in water diversions are primary components of habitat suitability that affect delta smelt mortality".

Magnitude = 3 - Medium (for both scenarios).
Delta smelt hatching primarily occurs from March-May and juvenile delta smelt often remain in the south Delta through June. During these months, OMR flows affect larval and juvenile delta smelt entrainment (Kimmerer 2008; Grimaldo et al. in press). Estimated south Delta entrainment loss in recent dry years is up to about 25%; but upper confidence limits are near 40% (Kimmerer 2008; Appendix Y). Appendix D shows that both outflow (or X2), and OMR need to be considered when evaluating larval-juvenile entrainment.

Appendix D shows that -5000 OMR can result in entrainment of up to about 25% of the population depending on concurrent outflow. In contrast, positive OMR is predicted to result in entrainment of less than < 2% of the population. The model results shown in Figure 7a, suggest the baseline operations would yield OMR around -5000 cfs for March-June, whereas both Scenario 1 and Scenario 2 result in positive OMR during March-June. Thus, both are sufficient to produce a roughly equivalent entrainment reduction on average; both could reduce peak entrainment loss from 25% to nearly 0%. In conclusion, the magnitude is medium (3) for both Scenarios.

Certainty = 3 - Medium
The influence of Delta hydrodynamics on young delta smelt distribution (Dege and Brown 2004; Nobriga et al. 2008) and entrainment (Sommer et al. 1997; Kimmerer 2008) is well-described in the literature. High outflows (low X2) shift the delta smelt population west so greater proportions of the individual fish are in Suisun Bay. Low outflows (high

X2) compel greater fractions of fish to rear in the Delta. OMR covaries somewhat with outflow because its range is constrained at high outflow. The more project operations tend toward highly negative OMR during low outflow periods, the greater the risk of entrainment for delta smelt. Appendix D (based on empirical data) summarizes this understanding showing the simultaneous influences of outflow and OMR.

P1l. Longfin Smelt - Adult

According to the longfin smelt model 'Sexually mature longfin smelt may be particularly susceptible to entrainment and mortality at water diversions because these fish tend to swim into freshwater prior to spawning and physiological preparations for spawning may leave them in a weakened state.' (Rosenfield, 2008; pg 19) Also see Figure 11. According to Rosenfield, 2008; pg 12, 'Water export operations of the CVP and SWP are highly likely to entrain larval longfin smelt because; larval LFS are not enumerated at the pumps. The problem is potentially serious during years when Delta outflows are low during the spawning period or following the hatching period for longfin smelt (late-winter and early spring). .Larvae (and spawning adults) may be placed at greater risk of entrainment at the south Delta export pumps by this shift of spawning location to the east.

Magnitude = 2 - Low
Average -3500 cfs during winter will reduce south Delta entrainment (Grimaldo et al. in press), but not entirely prevent it. DRERIP longfin smelt model indicates high population importance of south Delta entrainment (pdf pg 20). However, the Team disagreed strongly with the model. Appendix C shows the south Delta entrainment effect on longfin smelt has almost always been lower than the effect on delta smelt. It likely represents something << delta smelt's 15% median. This new assessment is based on the observation that longfin smelt has typically had higher to much higher fall midwater trawl abundance indices than delta smelt, but longfin smelt salvage has usually been lower than delta smelt. This means the magnitude of this action for longfin smelt is lower than it is for delta smelt. The generally lower importance of adult take is further supported by analyses DFG conducted for the SWP incidental take permit under CESA (http://www.delta.dfg.ca.gov/data/longfinsmelt/documents/LongfinSmeltIncidentalTakePermitNo.2081-2009-001-03.asp).

Certainty = 3 - Medium
Although this evaluation relied on newly generated unpublished data (Appendix C and DFG 2009), the data are derived from standard IEP datasets that have been used extensively in previous research. Participants are familiar with these datasets. Longfin smelt are impacted by south Delta entrainment to a much lesser extent than Delta smelt (i.e. data suggest a high probability that adult longfin are comparatively less impacted by south Delta diversions).

P1m. Longfin Smelt – Larval-Juvenile

According to Rosenfield, 2008; pg 14, 'Entrainment at water export facilities may be a significant source of mortality limiting successful transition of juveniles and sub-adults into sexually mature LFS' It also cites, (Rosenfield, 2008; pg 17), Grimaldo et al. in press as a source linking juvenile/young adult longfin smelt entrainment with OMR. The new DFG Effects Analysis for the SWP take permit (DFG 2009) provides considerable evidence that age-0 longfin smelt entrainment is influenced by outflow (X2) and OMR (see http://www.delta.dfg.ca.gov/data/longfinsmelt/documents/LongfinSmeltIncidentalTakePermitNo.2081-2009-001-03.asp) similar to that described above for delta smelt (Appendix D).

Magnitude = 3 - Medium
The longfin smelt DRERIP model does not provide a solid basis for determining a magnitude. Thus, this assessment is based on DFG (2009; see link above) and modeling of OMR flows (Figures 7a-c).

Peak age-0 delta smelt entrainment estimates averaged about 25% (Kimmerer 2008). Based on DFG (2009) peak larval longfin smelt entrainment is not quite as high – perhaps up to 15% in dry years and much less in wet years. Peak longfin smelt hatching occurs in Jan-Mar, but especially in dry years larvae and juveniles can rear in the Delta throughout the spring. Because longfin smelt entrainment is mainly a concern in dry years, this analysis focused on the lower whisker of the box plots in Figures 7a-c.

Figures 7a shows baseline January-March OMR often approaching -10,000 cfs (lower whisker of box plots). Both Scenario 1 and 2 improve the condition by capping winter OMR at -3500 cfs. The two scenarios have considerably different median OMR in January (about -3000 in Scenario 1 and > 0 cfs in Scenario 2). This could contribute to greater larval survival in Scenario 2, but the lower whisker for January-March is near -3500 in both scenarios. To the degree the lower whiskers reflect dry year pumping patterns, there is likely to be little difference between the scenarios in terms of reducing south Delta entrainment at the times it has the biggest effect. The -3500 cfs OMR is likely to be substantially more protective to longfin smelt larvae than the baseline OMR of -5000 to -10,000 cfs. The PTM analyses in DFG (2009) suggest this level of operational change could reduce larval entrainment by about 10% in dry years – a medium population level effect. Thus, we consider both scenarios to have a magnitude of 3.

Certainty = 3 – Medium
The information relating Delta hydrodynamics to longfin smelt entrainment is newer and unpublished. Further, unlike with delta smelt, the estimates of proportions of larval and juvenile longfin smelt lost to entrainment in the south Delta have only been partly quantified using PTM simulations weighted by dry year larval distributions (DFG, 2009). However, the PTM simulations strongly suggest that outflow pulses and negative OMR limits reduce larval longfin smelt entrainment in a manner analogous to delta smelt. Additionally, the salvage of juvenile longfin smelt, which is the visible fraction of entrainment, is clearly related to X2 and OMR, so there is no reason to believe the same basic hydrodynamic mechanisms could not explain entrainment risk for both smelts.

P1n. Splittail

State and Federal water projects sometimes have high salvage of splittail. The DRERIP splittail model (Kratville, 2008; pg 22) states, 'YOY splittail are typically captured in large numbers at the SWP and CVP fish salvage operations in the south Delta in late May through mid-July'. Splittail spawn in the San Joaquin River (Feyrer et al. 2005) and if corrected for abundance, an OMR effect on salvage might exist, but this has not been determined.

Magnitude = 2 -Low
The DRERIP splittail model (Kratville, 2008; pg 22) states that "The State Water Project and Central Valley Project show high rates of salvage when splittail populations are at high levels…" (See also Sommer et al.1997). Quantitative estimates of the proportion of age-0 splittail entrained in the south Delta do not exist. As for other migratory fishes, relative impacts are probably highest in dry years (Kratville, 2008; pg 27).

Certainty = 3 - Medium
Splittail relative abundance has been indexed using several of the IEP's trawls (Meng and Moyle 1995; Sommer et al. 1997; Kimmerer 2002; Feyrer et al. 2006). Splittail abundance varies with X2 (Kimmerer 2002; 2009). However, this is thought to be a surrogate for the reproductive opportunity provided by floodplain inundation in wet years rather than a reflection of entrainment loss (Sommer et al. 1997; Feyrer et al. 2006).

It is also likely these trawl-based relative abundance estimates are less reliable than estimates based on salvage, which has much higher sample sizes and detects age-0 fish every year. Salvage is both the best estimate of SWP/CVP entrainment loss and the best relative abundance estimate. Therefore, it is not possible to determine the effect of splittail entrainment on the population without using mark-recapture techniques.

The weight of available evidence suggests a small south Delta entrainment effect because loss is high when reproductive output is high and the population has shown resilience through time, and because most reproduction occurs in the Sacramento basin (Sommer et al. 1997; Feyrer et al. 2006; Moyle et al. 2004; Figure 5 in Kratville, 2008).

Outcome P2: Increased food availability for covered species due to higher productivity at lower trophic levels in the Delta associated with increased residence time.

The DRERIP Foodweb model (Durand, 2008; Section 1.12) references a positive relationship between phytoplankton and zooplankton production and residence time (Importance: High, Understanding: High, Predictability: High). However, Cloern (2007) hypothesizes that intermediate residence time maximizes lower trophic productivity. Cloern's view is more in line with studies of lake eutrophication and attempts to manage it via food web interventions; e.g., very high phytoplankton abundance is not necessarily associated with high zooplankton abundance (Drenner et al. 2002).

Magnitude = 2 - Low
Residence time may increase as a result of this action. However, the influence of residence time on the foodweb can be difficult to predict. Primary productivity may not transfer up through the food web to the target species.

Residence time refers to the time that a particle of water or some constituent of water remains in a location. This concept is applied here more as a broad concept than a specifically measured quantity (see Monsen et al. 2002 for a discussion of residence time). When the movement of water in the Delta slows either because of lower net flow or reduced tidal velocities, residence time increases (see Kimmerer and Nobriga 2008). Under the proposed scenarios, the decrease in inflow to the Delta due to the export of water from the Sacramento River, and the decrease in north-to-south flow of water toward the south Delta export pumps will generally increase residence time - particularly during summer.

Certainty = 3 - Medium
The influence of residence time on the foodweb can be difficult to predict. Few estuarine ecologists would claim that in general an increase in residence time due to a decrease in freshwater flow would increase fish productivity. Phytoplankton productivity may be maximized by a mix of residence times allowing time for biomass to develop but also with enough exchange to export some of that production to other areas (Durand, 2008; Section 1.12; Cloern 2007). However, the interaction between residence time and the species composition of phytoplankton that blooms is not well understood, and species matters to the transfer to higher trophic levels. Furthermore, areas of long residence time that have suitable substrate for settlement of Corbicula clams may simply grow more clams (Thompson et al., In Revision; p. 9).

In considering the transfer of productivity to higher trophic levels and ultimately to the target fish, it is helpful to recall that many species in the estuary respond positively to freshwater flow or its covariates, and that these responses may not be linked to changes in food supply (Kimmerer 2002). Although many if not all estuarine species are food limited (Durand, 2008; Thompson et al., In Revision), or have interactions between poor feeding conditions and thermal stress (Norbriga and Herbold, 2008), this does not necessarily imply that more phytoplankton production will produce more fish because habitat conditions have to be suitable for the fish to occupy or the prey need to be transported to habitats where the fish are rearing. In the case of delta smelt, both habitat suitability and prey transport to the low-salinity zone are most likely to be optimized by higher rather than lower freshwater flow.

Experiments to stimulate phytoplankton production in natural water bodies have been conducted to investigate nutrient limitation, and to explore the possibility of stimulating production of fish. These studies include lake fertilization experiments (Schindler 1977, Carpenter et al. 1995) and iron addition experiments in the ocean (Chisholm et al. 2001). The general conclusion of such studies is that natural ecosystems are complex and that consequences of any change in forcing, whether from nutrient enrichment or alteration of trophic structure, can be difficult to predict (Carpenter et al. 1995, Chisholm et al. 2001). For the Delta, we can draw this general lesson, and extend it to the link between stimulated phytoplankton production, and thereby fish production, through alteration of residence time. It is very difficult to predict the direction a natural system will take when phytoplankton production mechanisms are changed. A similar lesson can be taken from the divergence of outcomes in shallow waters with and without large numbers of clams (Lopez et al. 2006) and with and without large quantities of submerged plants (Nobriga et al. 2005).

Potential Negative Ecological Outcome(s)

Nine potential negative outcomes were identified and evaluated by the team:

N1 – Increased predation of juvenile salmon, steelhead, splittail, and sturgeon associated with the presence of new structures in the Sacramento River. This outcome is focused on predation at the new diversion structures themselves.

N2 – Increased predation of juvenile salmon and steelhead associated with new North Delta diversions affecting flows and residence times in the Sacramento River and other distributaries downstream of the new facilities

N3 – Increased mortality of juvenile delta smelt associated with the new North Delta diversion facilities and their operation. This is referring to the potential for entrainment if flows reverse in the Sacramento River.

N4 - Increased mortality of covered species due to potential degradation of water quality, particularly in the central and south Delta.

N5 – Reduced turbidity and associated reductions in delta smelt habitat due to operation of the new diversion facilities and the entrainment of sediment.

N6 – Increased frequency, duration, and extent of low dissolved oxygen conditions at Stockton adversely affecting salmon and steelhead migration on the San Joaquin River.

N7 – Loss of food material due to water diversions at the new North Delta diversion facilities.

N8 – Increased Microcystis biomass due to the new North Delta diversions.

N9 – Increased predation of juvenile Mokelumne River salmon due to modified Delta Cross Channel operations.

Each of these potential outcomes and the results of the evaluation are described below. It should be noted that the potential negative effects of impingement and entrainment at the new North Delta diversions were <u>not</u> evaluated by the team (except for the smelts). These effects could be significant and should be carefully examined prior to any final decision regarding the proposed new North Delta diversion.

One of the keys to understanding the potential effects of new North Delta diversions on different covered fish species is the periodicity and timing of these fishes in the Sacramento River in the vicinity of the proposed diversion structures. Table 1 below summarizes the peak occurrence of species in the North Delta, including the area of the proposed diversions.

Table 1: Relative Temporal Distribution of Juvenile Anadromous Fishes At Knights Landing

PRESENCE			
High	Medium	Low	None /Rare

Species	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep
Winter-run Chinook	Low	Medium	High	Medium	Low	Low	Low					
Spring-run Chinook		Low	High	Medium	Low	High	High	Low				
Fall-run Chinook			Low	High	High	Medium	Medium	Medium	Low			
Late-fall run Chinook		Low	Medium	Low			Medium	High				
Steelhead			Low	Low	Low	High	High	Low				
Green Sturgeon								Medium	Medium	Medium	Medium	Medium
White Sturgeon						Medium	Medium	Medium	Medium			

Data sources for: salmon and steelhead, California Department of Fish and Game rotary screw trap data at Knights Landing, 1996 – 2008; for sturgeon, California Department of Fish and Game Comments to NMFS Regarding Green Sturgeon Listing, 2002; Gaines, P.D. and C.D. Martin. 2002. Abundance and seasonal, spatial and diel distribution patterns of juvenile salmonid passing the Red Bluff Diversion Dam, Sacramento River. Red Bluff Research Pumping Plant Report Series, Volume 14. U.S. Fish and Wildlife Service, Red Bluff, California.

Outcome N1: Increased predation on juvenile Sacramento salmon, steelhead, splittail and sturgeon associated with the presence of new diversion structures in the Sacramento River.

The Evaluation Team assumed that new diversion structures in the Sacramento River would attract predators (mainly striped bass and Sacramento pikeminnow) because predators are attracted to instream structures and feeding opportunity "events" (Gingras 1997) and these two predators are large open-water and stream-associated fishes that have been shown to aggregate around instream structures in the Sacramento River from Red Bluff to the Delta. The team assumed that predation by largemouth and smallmouth bass would be less relevant adjacent to the new structures because these fishes are rare in channelized riverine habitats. New intake structures in the Sacramento River will create local hydraulic discontinuity that will create ambush habitat for striped bass and pikeminnow. Rip rap, concrete, and other material installed near the diversion facilities would reduce habitat suitability and cover opportunities for young covered fishes.

The team recognized that this outcome is highly dependent on the way in which the intake structure(s) is designed, constructed and operated. While some information is available regarding operation of the proposed diversion(s), the physical nature of the intakes and their position relative to the channel has not yet been determined. For the purpose of this evaluation, it was assumed that the intake structure(s) would be situated at or near mid-channel.

The team discussed the possibility that the diversion structures could be designed to create shallow-water habitat where fish could travel along the margins, but the team decided that such a design has not been accomplished elsewhere and thus, they should not assume such a design for this evaluation.

The analysis provided herein is preliminary in nature and is contingent upon the final design of the intake structures.

The following analyses regarding on-site predation are applicable to all Sacramento Chinook and steelhead runs given predators are present year round, independent of Chinook run timing.

Likelihood of Predation

<u>Prey size preferences for predators</u>: Striped bass and Sacramento pikeminnow more than about 12 inches long can efficiently capture salmon smolts that typically range from about 70-125 mm in length. They probably feed less efficiently on steelhead smolts (DFG 1999), which typically emigrate at about twice the size of salmon smolts (Nobriga and Cadrett 2001).

<u>Temperature effects on predation rate</u>: Water temperature affects the metabolic demand of all fishes, so all of the Delta's predators eat more as water temperatures increase from winter through summer. However, research on fish predation in Clifton Court Forebay has found no evidence that salmon, steelhead and striped bass losses are affected by temperature (DFG 1999; Clark et al. 2009). Therefore, we do not expect water temperature to greatly affect listed fish losses adjacent to new north Delta diversions. All of the Delta's predatory fishes eat year-round, though spawning striped bass seem to reduce their feeding frequency (DFG 1999).

Vulnerability

1. Hydraulics around diversion structures can increase predator foraging success because when prey fish become disoriented, predators aggregate.

2. Increased stress due to repeated involuntary contact with screens (impingement) leading to disorientation and an increase in predation downstream of structure could also occur, but fish treadmill experiments suggest that juvenile Chinook recover quickly from impingement and are not stressed (Swanson et al. 2004).

N1a. Sacramento Chinook salmon and Steelhead

Comments and/or Assumptions used in scoring:

Chinook were observed to frequently contact fish screens and contact rates were correlated with flows, light level, and fish size (Swanson et al. 2004). Contact rates increased with increases in sweeping velocity, were higher in the dark, and increased with larger fish size. Screen contacts were not injurious or lethal for juvenile Chinook salmon. At higher sweeping velocities (>60cm/s) juvenile Chinook swam close to their maximum sustained swimming velocity. Juvenile Chinook swam slower during dark conditions (simulated night) compared to light conditions (day).

Magnitude: 4 - High
Predator densities are assumed to be high close to a structure protruding into the channel and lower bypass flows will increase the exposure risk to predators. Because almost all Sacramento salmonids would have to pass these structures when Yolo Bypass is not flooding, the effect under the worst case could be a major population effect.

Certainty: 2 - Low
The certainty of this outcome is low because the data do not exist to estimate the fraction of salmonid fishes that are expected to be lost to predators while migrating past 1-5 water diversions. The lack of details regarding the number and design of the diversions adds to the uncertainty.

N1b. White sturgeon

White sturgeon larvae will be present in proximity to a north Delta diversion facility between March and May. Stevens and Miller (1970) captured most of their white sturgeon larvae between Collinsville and Rio Vista. Juvenile white sturgeon will be present in proximity to a north Delta diversion when water temperature remain >20°C (Table 1 in Israel et. al., 2009). These temperatures appear in this section of river initially in mid-May and become sustained by mid-June (J. Israel, UC Biotelemetry Lab unpublished temperature data).

This periodicity likely exposes white sturgeon larvae and juveniles to potential predation between March and June in the north Delta. Predation by a native predator, prickly sculpin (bottom dwelling ambush predator) of white sturgeon larvae and young-of-year is well documented in the Columbia River (Gadomski and Parsley 1995a) and rates of predation are influenced by level of light, cover, and size of white sturgeon. White sturgeon larvae and young-of-year were also consumed by catfish (Gadomski and Parsley 1995c). Thus, it seems likely that north Delta diversion operations where native and nonnative predators may aggregate to ambush prey would also lead to predation of white sturgeon larvae and juveniles during the months of March through June.

Screening criteria for larval and juvenile white and green sturgeon are not developed. Limited observations of green sturgeon around fish screens suggest they frequently made contact with experimental screens, contact was non-injurious, and survival was uniformly high (UCD Fish treadmill report, 2004).

Magnitude = 2 – Low
Operation of any diversion, where predators are likely to aggregate due to local hydraulics may increase predation upon sturgeon at the diversion location. Sturgeon larvae and juveniles are preyed upon by native and nonnative predators in other systems (Gadomski and Parsley 1995a and 1995c). Depending on operations the diversion (due to turbidity, light conditions) resulting predation at a diversion site may be expected to be on a limited fraction of the population and influence productivity of the population in a minor way. Strangely, if sturgeon voluntarily initiate and repeat contact with screens, an observation of fish screen studies (UCD Fish Treadmill Report, 2004), the frequency of sturgeon visits to fish screens will increase the likelihood of predation mortality and related population level effects.

Certainty = 2 – Low
Certainty of this effect is low due to lack of information on the specific design of the structure.

N1c. Splittail - Juvenile

Although this specific predation issue was beyond the scope of the DRERIP splittail model, the model does consider predation by nonnative fishes to be “important from a population perspective” (Kratville, 2008; pg 23-Table 2). Predators will aggregate around the new diversions (Gingras 1997; USFWS RBDD studies). Predators eat young splittail (DFG 1999, Nobriga and Feyrer 2007). Predators are opportunists and habitat and prey field will support (e.g., Shively et al. 1996).

When floodplain inundation does not occur, the splittail must migrate further upriver to find suitable spawning habitat (Kratville**,** 2008, Figure 1 based on Feyrer et al. 2005). Young splittail will seek shallow margin areas. They travel slowly back towards the estuary, not strongly influenced by net flows. Splittail juveniles use water temperature as a cue (Kratville, 2008; pg 18).

Magnitude = 4 - High
Most splittail reproduction occurs in the Sacramento basin (Sommer et al. 1997; Feyrer et al. 2006). Essentially all Sacramento basin splittail will have to pass the north Delta diversions in dry years because Yolo Bypass will not flood and many will pass during low bypass flow months (population center of distribution is near the upper margin of Delta during June-July; Feyrer et al. 2005). The two different bypass flow scenarios are not very different because these juvenile splittail are not really “going with the flow” and the structures are there in either case. Rather than go with the flow, splittail rear and grow in shallow habitats (Feyrer et al. 2005).

Certainty = 2 – Low
A good scientific understanding of splittail migration and predation is based upon a combination of peer-reviewed papers and non-peer-reviewed information (Kratville, 2008). Ecosystem variability is noted. For instance, the population effect of predation associated with the north Delta diversions will be relevant mainly in years the Yolo Bypass floods less than 3-4 weeks (Sommer et al. 1997; Feyrer et al. 2006).

Part of the resilience of splittail, as described in the model and most papers, is their ability to forego reproduction in dry years and to spawn heavily in appropriate years – much unlike salmon and steelhead and more like sturgeon, which would seem to reduce the population level magnitude of dry-year predation at these diversions. However, some splittail spawn in dry years (Feyrer et al. 2005) and the later and slower emigration of splittail likely means more effect than for salmon. Wet year production definitely drives population dynamics, but viability might be compromised during a 5-10 yr drought if their primary source of successful dry-year reproduction in the Sacramento River is greatly affected.

Splittail are good at avoiding a fish screen and so they will generally avoid impingement (Danley et al. 2002). However, multiple diversions are problematic because they will create a situation where large stretches of river habitat will be altered to engineer optimal conditions for the diversions. Deliberate flooding of Yolo Bypass would only happen in some years and will not generally encompass dry year splittail emigration timing (June-July; Feyrer et al. 2005). The splittail model suggests that under current conditions, predation of splittail near export structures is not a huge problem (Kratville, 2008; pg 34-Fig. 5). However, the proposed action will be under very new conditions, outside the scope of analysis in the conceptual model.

Outcome N2: Increased predation of juvenile salmon and steelhead associated with new North Delta diversions affecting flows and residence times in the Sacramento River and other distributaries downstream of the new facilities

Appendix I provides graphs and tables containing particle fate and travel time. This data informs the analysis of flow conditions, residence time and pathway of fish in the Delta as described in this worksheet.

Data from salmon tagging studies (e.g., Newman 2008; Perry and Skalski unpublished) suggest that predation rates on emigrating salmon vary spatially in the Delta. In theory, predation loss should also be a function of time spent migrating because predation loss accumulates at some rate – number lost per unit time. The concept behind this potential negative outcome is that water diversions at the new North Delta diversion facilities might change the proportions of fish migrating through different routes and/or increase the residence time of fishes that are ocean- or lower estuary-bound and thus, not trying to rear in the Delta.

A third possibility is that less net downstream flow through Sutter and Steamboat sloughs might lower water velocities and as a result, increase the foraging success of predators and/or increase the abundance of largemouth bass, which are not currently thought to be a predator of concern in the north Delta.

<u>Mechanisms contributing to increased predation</u>:

1. Lower net river flows increase travel time of outmigrating juvenile salmon through the system.
2. Flow changes disperse fish through Delta channels differently than occurs presently possibly causing more emigration through Georgiana Slough.

3. Predator habitat suitability increases in Sutter/Steamboat Slough relative to baseline because of lower net river flows.

Downstream migrating salmonids have been observed to migrate passively, dependent on riverine and tidal currents (Folmar and Dickhoff 1980). Physiological changes during smoltification trigger behavioral changes such as passive migration, swimming upwards to 80% slower and increased buoyancy (Folmar and Dickhoff 1980). Travel time is biologically significant because each day of migration depletes energy reserves and exposes individuals to threats, such as predation (Zabel 2002).

Particle Tracking Modeling (PTM) results are an applicable tool for analyzing salmon smolt life stage. PTM based upon monthly average flows indicates that it takes 3 days to pass 50% of particles from Freeport to Three Mile Slough (Appendix I). This represents a significant (perhaps 50-60%) residence time increase over baseline. Thus, this action may reduce the flow pulses that salmonid smolts use to quickly emigrate through the Delta. The entire salmon population could experience a 50% - 60 % increase in predation. Mortality is high, based on existing studies of salmon.

There is a need to understand how many fish survive their Delta emigration as flow changes. Travel time and routes are important. Different routes yield different rates of predation. Data could be extracted from the PTM to consider the differences between Scenario 1 and 2 by changing predation rate vs. time exposed (see Appendix I). The idea of PTM results having application to salmon is relevant for the smolt life stage (Folmar and Dickhoff 1980).

Under either dual conveyance scenario, some particles enter Georgiana Slough. If the predation rate is held constant, regardless of flow, the 1.5 extra days spent in travel time will lower survival, all else being equal.

<u>Movement/migration rate/survival of different runs of salmon</u>:

- Reach specific data on the speed and survival of juvenile Chinook migrating through the Delta are available from three separate acoustic tagging and monitoring studies. Two of these released fish in the Sacramento River (see Burau et al. 2007, Perry and Skalski 2008, Vogel 2008) and the other released fish in the San Joaquin River (see SJRGA 2008). Late-fall fun Chinook from the Coleman National Fish Hatchery were used in the Sacramento River acoustic tagging and monitoring studies (Burau et al. 2007, Vogel 2008). Fall-run Chinook from the Merced River Hatchery were used in the San Joaquin River acoustic tagging and monitoring study (SJRGA 2008).
- In addition to the acoustic tagging studies, migration and relative survival estimates are available for other runs and sizes of salmon from coded-wire-tag (CWT) studies (Brandes and McLain 2001; Newman and Rice 2002; Newman 2003; Newman and Brandes in press). In the Central Valley, CWT studies have been conducted using fall run, late-fall run, spring run, and surrogate winter run Chinook (surrogate winter run fish are late-fall or fall fish released to mimic the migration timing of winter run fish; RMPC 2008). For steelhead, only small acoustic tagging and monitoring studies have been conducted but these data are also available (CVFTC 2008).
- In each of the three acoustic tagging studies mentioned above the primary cause of fish loss is assumed to be predation. Some results provided direct anecdotal evidence of predation, for example aberrant tag movements were detected near one acoustic receiver and most likely represented tagged salmon that were inside of a predator (Vogel 2008). In the San Joaquin River study, researchers used a mobile acoustic receiver to detect tags that became motionless and most likely represented salmon that

had died or tags from eaten salmon that were defecated by a predator (SJRGA 2008). This study also identified predation events when multiple tags began to display identical detailed movement, indicating that a single predator had consumed multiple tagged salmon (SJRGA 2008).

Modeling results on net flow, reverse flows, velocity, and particle travel time:

- **Downstream flows (monthly averaged)** – Minimum flows do not change much, because under new operational scenarios, Hood diversion is not operational at extremely low flows. Flows during the high flow periods (Jan, Feb, and March) reduced (monthly averages down ~25%; monthly median down ~30%). Dec, April, May, and June have somewhat reduced flows (monthly averages and medians) in Scenario 2 vs. Scenario 1.
- **Particle travel time** – Insertions at three places (Freeport, Sutter, Steamboat) for two scenarios and at three different river flows (low, mid, and high).
- DCC operation, diversions at new north Delta facility and Cache Slough restoration affect travel time. Effect of new operations on travel time depends largely on river flow.
  - At low flows, not much change from reference scenario.
  - At mid flows, travel time down the Sacramento River decreases for Scenario 1 and increases for Scenario 2. Travel time down Sutter and Steamboat sloughs increases for Scenario 2.
  - At high flows, travel time down the Sacramento River increases under both scenarios.
- In dry years, modeling indicates that downstream flows would be reduced mainly in the wet time of year (winter peak flows truncated). In wet years, downstream flows reduced most of the year (higher flows allow for diversion year-round).

Williams (2006; SFEWS) states the following “The most detailed information on migration rates comes from fish in the Columbia River that are individually marked with passive integrated transponder (PIT) tags that are detected when fish move through passage facilities on the dams”. Rates for individual Chinook, sockeye, and steelhead between Rock Island and McNary dams were all highly variable (Giorgi et al. 1997). For age 0 Chinook, the average migration rate over four years was 15.5 km d-1, but increased with size from about 5 km d-1 on average at 60 mm to about 30 km d-1 on average at 140 mm. Migration rates varied directly with flow and inversely with temperature and day of the year, but not as strongly as with length. For yearling Chinook, the average migration rate was about 20 km d^{-1}, and was independent of length but increased somewhat with temperature, mean flow, and day of the year. Time of year had a strong effect on the migration rate of naturally produced yearling Chinook from the Snake River (Congleton et al. 2004).”

Spring-run Chinook will experience longer travel time. Chipps Island and Salvage data indicate that April is a peak abundance month (~2/3 of all spring-run) for spring-run Chinook salmon in the Delta. Mean monthly and median flows are ~16,882 cfs in April, mid flows defined by PTM results are ~13,200 cfs. So, flows during April in the mid-range occur ~66% of the time. High flows (defined by PTM of 28,000 cfs) are exceeded 27% of the time. Low flows (defined by PTM results) are not reached at any time during April.

Magnitude: 4 - High
Lower bypass flows will increase the exposure risk to predators due to increased travel time and different migratory pathways. . Because almost all Sacramento salmonids

would be exposed to higher predation the effect under the worst case could be a major population level effect.

Certainty: 2 - Low
The certainty of this outcome is low because the data do not exist to estimate the fraction of salmonid fishes that are expected to be lost to predators due to changing flow conditions. The lack of data on how different bypass flows would affect travel time and flow splits adds to the uncertainty.

Outcome N3: Entrainment of larval and juvenile delta and longfin smelt associated with new North Delta facilities and operations.

The team assumed this outcome was possible because delta and longfin smelt larvae can be drawn in the direction of net river flows (e.g., Kimmerer and Nobriga 2008; Kimmerer 2008). Note that the striped bass egg and larval survey conducted by DFG in the early 1990s collected some larvae identified as delta and longfin smelt from the mainstem Sacramento River in the region the diversions are proposed (Wang 1999). Delta smelt cannot travel past miles of screen without getting impinged (Swanson et al. 2005; White et al. 2007) or entrained so they have a high entrainment/impingement risk if they approach the screens. In addition to fish spawned in the Sacramento River near the diversions, modeling for BDCP indicates that on flood tides or during very low outflow springs, larvae below the Sacramento River – Cache Slough confluence might also be vulnerable to upstream draws. However, net flows in the mainstem of the Sacramento River near the diversions are expected to remain positive due to the combination of tidal prism and bypass flow criteria, so this is expected to occur only rarely.

Magnitude = 2 - Low
Both Scenarios:
The DRERIP smelt models do not address north Delta diversions. DRERIP delta smelt model indicates adult delta smelt are associated with turbidity; migrating adults are included in this generalization (Grimaldo et al. in press). Longfin smelt are also associated with turbid water in the Delta (Kimmerer et al. 2009). During low flows, the mainstem Sacramento River, including sites near the proposed diversions, has high water clarity. It is unlikely that a significant number of delta or longfin smelt would migrate into a low turbidity environment even with negative flow (extension of observations at south Delta diversions. (Grimaldo et al. in press,).

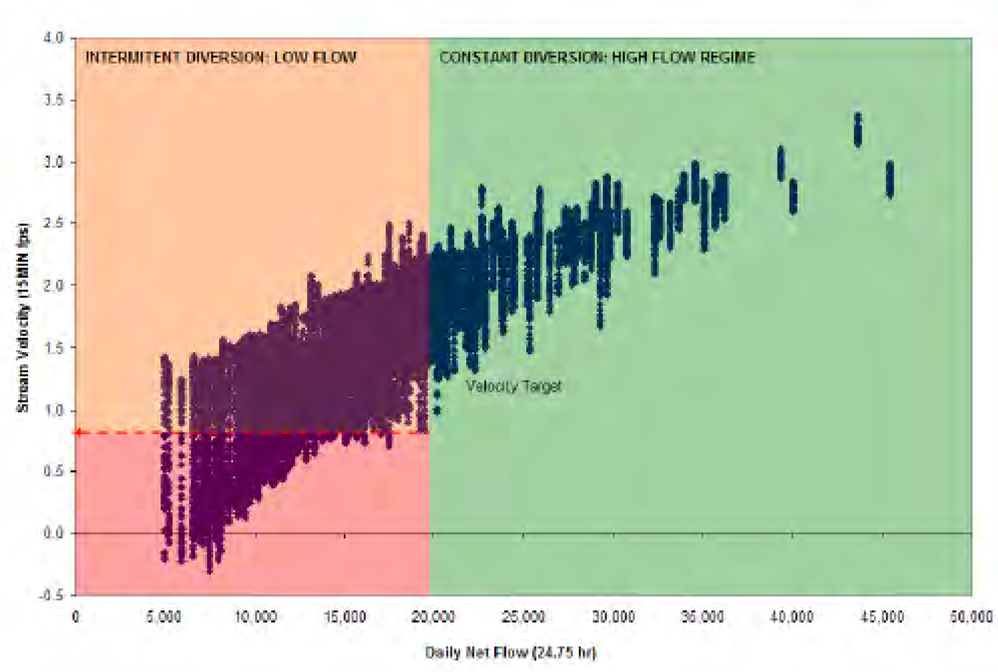
Larvae are not strongly associated with turbidity based on 20mm sampling (Figure 5 in Norbriga and Herbold, 2008), but this is inconsistent with Kimmerer et al. (2009), who reported a fairly strong effect of Secchi depth (turbidity) on delta smelt abundance based on 20 mm sampling. Therefore, larval delta and longfin smelt might be susceptible to reverse flows if spawning occurs nearby (Norbriga and Herbold, 2008, Figure 3). It is not thought that this would affect large fractions of their populations.

Certainty =
Scenario 1 (higher critical period flows): **3 - Medium**
Scenario 2 (lower critical period flows): **2- Low**

Data do not presently exist to evaluate this set of Scenarios objectively, but the scores differ by scenario because the higher the bypass flows, the less likely larvae will wind up near the north Delta diversions. The team recommends a particle tracking model run for low flow conditions, including proposed north Delta tidal marsh restoration and north Delta diversions, to determine the likelihood of particle entrainment toward the north Delta diversions from Cache Slough/lower Sacramento River.

The certainty that the effect would be low is higher for Scenario 1 because the higher Hood bypass flow criteria would reduce the frequency and magnitude of net reverse flows (see Figure 8).

Figure 8 - Diversion Operational Regimes (Tidal) in "Preliminary Modeling Evaluation of Draft Conservation Strategy Core Elements" dated January 30, 2009



Outcome N4: Increased mortality of covered species due to degradation of water quality which increases a stressor (on fish species of concern)

Overview of Water Quality Effects

Changes to hydrodynamics and transport associated with a dual conveyance approach (i.e. new North Delta diversion operated in addition to the existing South Delta pumps) might influence water quality and toxicity to species of concern through three mechanisms:

1) Increases in loading of selenium and agricultural chemicals in south Delta waterways due to increased South of Delta deliveries (D1641+10% for Scenario 2);
2) Changes in contaminant distribution (and possibly, concentrations) through shifting the primary export location north (reduces ammonia/um load, reduces Sacramento River pesticide and Hg loads, increases SJR loads of pesticides, sulfates, Se, etc. - essentially

there would be a shifting to a San Joaquin River (SJR) dominated risk in the South Delta). and;

3) Changes to fish exposure due to lower flushing rates and higher concentrations of contaminants in south Delta waterways.

<u>San Joaquin River loading of [Se], salt, pesticides</u>

Selenium, salt and pesticide loadings from the San Joaquin would likely increase in proportion to additional deliveries (D-1641 + 10% for Scenario 2). The exact increase is unknown, as allocation to specific crops will vary. Pesticide loading will increase, and salt/Se loading will decrease assuming a continued shift to orchards and away from bottomland crops. However, senior water right holders (exchange contractors) in the north San Joaquin Valley will possibly plant both.

For purposes of this analysis, it is assumed that the current regulatory baseline for San Joaquin River TMDL 2010 limit will be extended. Therefore, the contaminant profile predicted by this analysis is:

- Se loads will increase by <10% (influent concentrations the same).
- Pesticide loads will increase by ~10% above the current profile (reflecting continued shift to permanent crops).
- ECD's and pyrethroids etc. from municipal use will increase by >10% (because urban growth will shift water use from agricultural to municipal and industrial uses).

Habitat quality will degrade in the South Delta through elevated contaminant concentrations (see discussion on changes in fish exposure below).

Pesticide tailwater loadings/deliveries in the Delta could change with the new diversion and associated operational scenarios. Modeling included meeting salinity standards. Based on these results we assume no change in South Delta agricultural returns.

Within-Delta herbicide applications could change with altered operations or if other stressor actions try to manage aquatic plants with herbicide treatments. Also, hydrodynamic changes would likely change the effects of contaminants on the food web. These potential outcomes are not evaluated here, but should be further analyzed.

<u>Potential Mechanisms</u>:

- Increased concentration of SJR contaminants in the south and central Delta.
- Change in concentration of contaminants in the north Delta as a result of new diversion facilities.

How do operations influence route and duration of migration?

- Exposure to poor water quality varies with route and duration.

<u>Impact of shifting diversion point on concentration/loads:</u>

Current south Delta exports quickly remove most San Joaquin River water from the Delta most of the time (Kimmerer and Nobriga 2008). This and Sacramento inflows dilute Se and other loading from the San Joaquin River into the estuary. San Joaquin River water quality will become a bigger driver of estuary water quality under both scenarios. Some less stable contaminants may be partitioned or lost with higher residence time in the South Delta. Water quality at the confluence will continue to be dominated by Sacramento flows despite the increased movement of SJR contaminants to the confluence, because the proposed Sacramento River inflows would continue to greatly outweigh the SJR volumes. Source modeling conducted by CH2M Hill corroborates these assumptions.

Timing of source loading might change under the new operational scenarios, but modeling conducted by CH2M Hill suggests this is not likely. Total Delta exports under Scenario 1 (11K hood bypass) would decrease slightly in December to January and August to September, increase slightly in February to March, increase significantly in April to June, and change little in July, and October-November. Under Scenario 2 (5000 hood bypass), October to November are unchanged, January to March have slight increase, December and June have more moderate increase, April and May have a significant increase, and July though September have a slight decrease.

<u>South Delta residence time will increase during all months:</u>
The longer residence times of water may cause the Delta to shift towards an even more benthic-driven ecosystem with increased source loading from the SJR and decreased exports of contaminants. Decreased export of contaminants through South Delta pumping is expected to generally increase selenium and agricultural chemical exposure risk in the estuary, and particularly the south Delta. Bioaccumulation and biotransformation are expected to increase for contaminants in which this phenomenon is relevant (e.g., Se, Hg, breakdown or metabolite products from organics), which will change their environmental fate and increase both exposure and toxicity. The potential for net increased loads and contamination downstream, including the potential for more bioavailable forms (methyl-mercury or selenite/organic selenides) should be further analyzed quantitatively. This would require quantitative mass balance modeling. Possible changes in foodweb composition and dynamics will have an impact on bioconcentration factors (Presser et. al., in revision). This is an important factor that is hard to predict.

<u>Species occurrence matrix</u>: The interface and timing of species within their habitat determines exposure and therefore risk (see Table 1 for a temporal distribution of fish within the Delta).

<u>General analytical strategy</u>: North Delta diversions are expected to extract approximately 25% of Sacramento River flow based on CH2MHill modeling. Sacramento River flows would decrease reducing rates of fish transport and possibly increasing exposure time. Results from particle tracking models indicate that residence times will increase increasing exposure times.

<u>Methyl-Mercury</u>: Based on data from TMDL reports, most loading is from the Sacramento River. We presume this will be diverted resulting in reduced loadings to the Delta, but biomethylation potential may go up with additional tidal marsh and sulfate loads from the San Joaquin River.

<u>Selenium</u>: There will likely be a higher risk from increased loads from the San Joaquin River and increased residence time and bioconcentration potential. For organics, exposure time for delta smelt larvae (or other juveniles using passive dispersion) may increase (potentially in both the North and South Delta). Selenium in the food chain may increase, with greater impacts on splittail and sturgeon (possibly juvenile salmonids associated with other core elements—e.g. tidal marsh and riparian restoration). Benthic foragers could be affected through increased Se in Corbicula that serve as food for sturgeon, splittail and other fishes (Stewart et al. 2004, Teh et al. 2004).

Agricultural chemicals: Higher residence times may increase exposure and mortality. Larval smelt may be detrimentally impacted.

N4a, b. White and Green Sturgeon

Juvenile white and green sturgeon are year round residents of the Delta. The movements of these fish are primarily for foraging, with white sturgeon migrating downstream to cooler brackish or marine water during the summer and back to fresher water in the winter (Israel et. al. 2009). Once green sturgeon start their marine migrations, their behavior changes and they spend summer in estuaries and rivers, and winters migrating in the ocean (Israel and Klimey, 2008). Lastly, both species of sturgeon are able to tolerate hypoxic conditions (Israel et. al. 2009 and Israel and Klimey, 2008 – Ecology Sections) and likely are able to actively move away from these conditions when they become too severe. While sturgeons are bioaccumulators of contaminants and toxicants, the acute effect of contaminants on mortality or sub-lethal effects does not seem large (Israel et. al. 2009 and Israel and Klimey, 2008 - Stressor Sections) although levels are rising to where they maybe of concern (Stewart 2004). Thus, any increase in Se bioavailability to sturgeon might be significant in terms of reproductive success.

Magnitude = 3 - Medium
White and green sturgeon mortality is likely not closely linked to water-quality problems, though maternal effects and sub-lethal effects are likely. Little of the white sturgeon population passes through the south Delta. Very little of the green sturgeon population passes through the south Delta since spawning is restricted to the Sacramento side. However, selenium loads are already high and increased benthic bioaccumulation of selenium may amplify the risk to those fish feeding in the south Delta. Stewart et al. (2004) have concluded that sturgeon are on the cusp of reproductive impairment already.

Certainty = 2 - Low
These types of exposure to contaminants are likely long-term and cumulative, and not likely to change much due to changes in north or south Delta water operations.

N4c. San Joaquin Salmon

All adult and young San Joaquin salmon must pass through the south Delta. Operations models show salinity increasing in the south Delta, probably due to salt loading from the San Joaquin. This probably is a good estimate of the increase in concentrations of other contaminants coming from agricultural runoff. Rapid urbanization in the south Delta will also increase local loadings of contaminants from urban sources.
Together these suggest greatly increased likelihood of exposure of fish to diverse concentrations of contaminants at various points along their migration.

Magnitude = 4 - High
The entire San Joaquin salmon population is at risk to many chemicals that have been found to be toxic to fish.

Certainty = 2 - Low
Very little data exist to show an impact. Many contaminants known to be toxic or damaging to salmonids are known to be present in the SJR and their presence in the Delta is likely to increase in both concentration and duration. Few are directly

monitored, but bioassays show frequent toxicity to invertebrates. Thus, the magnitude is very high, but certainty is low for impacts on fish.

N4d. San Joaquin Steelhead

All adult and young San Joaquin steelhead must pass through the south Delta. Operations models show salinity increasing in the south Delta, probably due to salt loading from the San Joaquin. This probably is a good estimate of the increase in concentrations of other contaminants coming from agricultural runoff. Rapid urbanization in the south Delta area will also increase local loadings of contaminants from urban sources. Together these suggest greatly increased likelihood of exposure of fish to diverse concentrations of contaminants at various points along their migration.

Magnitude = 4 - High
The entire steelhead population is at risk to many chemicals that have been found to be toxic to fish.

Certainty = 2 - Low
Very little data exist to show an impact. Many contaminants known to be toxic or damaging to salmonids are known to be present in the SJR and their presence in the Delta is likely to increase in both concentration and duration. Few are directly monitored, but bioassays show frequent toxicity to invertebrates. Thus, the magnitude is very high, but certainty is low for impacts on fish.

N4e. Sacramento Splittail

Because they are predators of overbite clams (Feyrer 1999), splittail show comparatively high Se body burdens (Stewart 2004). The current bioaccumulation of Se by splittail is right at the margin of what is expected to cause some reproductive impairment. Thus, any increase in Se bioavailability to splittail might be significant in terms of population-level reproductive success.

Magnitude = 3 - Medium
The benthic feeding of splittail puts them more at risk of accumulating sediment bound contaminants and contaminants accumulated by bivalves. Stewart et al. (2004) have concluded that splittail are on the cusp of reproductive impairment already.

Certainty = 3 - Medium
Feeding behavior of splittail makes them likely to be exposed to benthic animals and sediments.

Outcome N5: Lower quality delta smelt habitat due to reduced turbidity (i.e. loss of sediment due to fewer pulse flows on the Sacramento River).

"Suspended sediment is the primary attenuator of sunlight in the water column of the Delta" (Schoellhamer et. al., 2007, pg 5 of 39 in the pdf copy). A key component of delta smelt habitat suitability is water transparency (Feyrer et al. 2007; Nobriga et al. 2008, which is cited several times throughout the DRERIP delta smelt model).

"Most sediment is supplied by rivers to the Delta only a few days per year during large floods. This episodic nature is driven largely by pulses from the Sacramento River that deposit in the Delta and move into San Francisco Bay (Fig. 1, Wright and Schoellhamer 2005). During water years 1999-2002, 82% of the sediment was delivered during the wet period (31% of the time)" (Schoellhamer et. al., 2007, pg 6 of 39 in the pdf copy). Most of the sediment enters the Delta as suspended sediment rather than bedload (Schoellhamer et. al., 2007, pg 8 of 39 in the pdf copy).

Water transparency is a result of sediment in the water column per above references from the sedimentation model. Because the action proposes to divert Sacramento River water during flood events that bring most of the sediment into the Delta, it is possible the diversions might exacerbate increasing water transparency downstream that has already increased in part due to dams and armored levees in the watershed (DRERIP sedimentation model).

Magnitude = 2 - 3, Low - Medium

There is some conflicting evidence regarding the magnitude of the diversion effect on sediment. Schoellhamer et. al., 2007 (p. 10) states that, "…human activities that alter watershed sediment supply are likely to have a greater effect on river supply to the Delta than those that modify the flow regime". This statement implies that the magnitude of the diversion effect on sediment will be small relative to the impact of dams and channel-floodplain disconnection in the watershed.

There is also evidence that the magnitude of the diversion effect on sediment will not be small (Schoellhamer et. al., 2007, Figure 4): current south Delta diversions take ~ 20% of sediment passing Stockton and coming from east side tributaries.

The Sacramento River loads most of the estuary's sediment and loads most of it during floods when north Delta diversion rates are assumed to be high in this evaluation. If north Delta diversions removed 20% of Sacramento sediment load, the sediment loss to exports would be 10 times higher than current levels.

Certainty = 1 - Minimal

Given that there is no known quantitative study of the potential effects of north Delta diversions on turbidity in the Delta, the level of certainty is minimal. It is made more uncertain by the time scale of any effect. For instance, Sacramento River sediment supply has declined by 50% over 50 years (Wright and Schoellhamer 2004), which implies the annual effect is very small. A conceptual understanding of the average annual sediment budget is provided in Schoellhamer et. al., 2007. A more refined understanding of sediment dynamics will be needed to inform operational protocols of the diversion.

Note that both the magnitude and the certainty in this evaluation apply to both Hood bypass Scenarios because most of the sediment transport will occur during high flows that greatly exceed either bypass flow criterion. Thus, in both Scenarios it could be expected that north Delta diversions would be at maximum pumping capacity during major sediment transport flows.

Assumptions used in Scoring:
Turbidity is a key component of Delta smelt habitat (Feyrer et al. 2007; Nobriga et al. 2008 as cited in Norbriga and Herbold, 2008). The estuary has been losing sediment supply for years (Schoellhamer et. al., 2007). This is an issue of large spatial scale and long time scale change in the Sacramento River sediment budget. Currently, sediment comes into the Delta on river flow pulses (Schoellhamer et. al., 2007). Suisun/San Pablo Bay experiences this pulse in sediment. To better predict the effect of north Delta diversions on the estuary's sediment budget, proponents should consider the rating curve of sediment vs. flow for the mainstem Sacramento River, and include sediment supply for Yolo Bypass then compare the results to a reduced supply of sediment scenario due to north Delta diversions. When flow is high enough to inundate the Yolo Bypass, then there is a sediment pulse to the estuary that is not susceptible to north Delta diversions, but this averages ~ 30% of Sacramento River sediment inputs on average.

Outcome N6: Increased frequency, duration and extent of low DO at Stockton and blockage of salmon/steelhead migration on the San Joaquin River.

The effects of low DO on species of interest center on the migration of San Joaquin populations of fall-run salmon and steelhead. Other effects can be expected on the distribution of fish that reside in the Delta, especially benthic foragers like sturgeon and splittail.

Dissolved oxygen in the Stockton Deep Water Ship Channel is controlled by inflow from the San Joaquin River, BOD loads of inflowing water, and BOD loads generated in the local area. Flow modeling suggests that the area of Stockton will receive a much higher fraction of San Joaquin River water for much of the year, in many years, under both scenarios. Thus, this will deliver water with higher nutrient concentrations which will promote the growth of phytoplankton. Death and decomposition of this phytoplankton in the deeper waters of the ship channel can be expected to increase the severity, duration, and frequency of periods of low dissolved oxygen ("eutrophication").

<u>Potential Mechanisms</u>:

- Lower pumping from south Delta will result in more of the south Delta being filled with San Joaquin River water and lead to longer residence times of water in south Delta channels. Together these changes can be expected to worsen DO problems known to occur in the South Delta. Proposed tidal marsh restoration in the south Delta could improve or worsen DO problems in the region depending on design.

N6a, b. San Joaquin Salmon and steelhead

Magnitude = 4 - High
All adult and young San Joaquin salmon must pass through the south Delta. Operations models suggest conditions that represent worsening of drivers known to control DO levels. This suggests greatly increased likelihood of delaying or blocking upstream migration of salmonids.

Certainty = 4 - High
The entire population is at risk of worsened conditions due to a problem already known to be important.

N6c, d, e. White and Green Sturgeon, and Sacramento splittail

Magnitude = 1 - Minimal
These species are widely distributed and spawning primarily occurs in the Sacramento Basin. Thus, a small part of the population is at risk.

Certainty = 2 - Low
These species are comparatively tolerant of low DO (Joe Cech references). They can likely avoid entering areas where DO would be lethal by avoiding areas of low, but non-lethal DO levels. Operations models suggest conditions that represent worsening of drivers known to control DO levels. Thus, the magnitude is low but certainty is high.

Outcome N7: Loss of Sacramento River food material for covered species into the Delta due to diversions of water and reduction in flow to the Delta.

Food resources (phytoplankton, zooplankton and other organic matter) may be diverted along with the water as a result of this project and downstream areas, particularly the north Delta, will be deprived of this input. However, the river is a minor source of phytoplankton and probably zooplankton to the Delta so this effect is likely to be small.

Magnitude = 2 – Low (for both scenarios)
The foodweb model does not address loading of organic matter (from the rivers) to the estuary. The concentration of "food material" (living phytoplankton, microbes, and zooplankton, labile organic matter) in the river depends on what is in the reservoirs and on the travel time from the reservoirs to the Delta. This source of variability is unknown. For a given river flow, these concentrations will not change with increasing diversions, although the loading to the Delta will decrease as diversion flows increase.

River flow provides the largest source of total organic matter to the Delta, which helps fuel the food web (Jassby & Cloern 2000) and contributes to the Delta's overall net heterotrophy (Sobczak et al 2002). Nevertheless, most of the food consumed by the Delta foodweb is either phytoplankton or derived from phytoplankton. Phytoplankton production within the Delta greatly exceeds river inputs according to the mass balance developed by Jassby et al. (2002). Furthermore, accumulation of phytoplankton biomass in the Delta is directly related to residence time (Jassby et al. 2002), and therefore inversely to flow, implying that the higher loading of material during high-flow periods is less important than how long the water stays in the Delta. The same is probably true for zooplankton although a mass balance has not been calculated.

Certainty = 1 – Minimal
Although it is a tautology that loading of organic matter to the Delta will decrease as more water is diverted from the Sacramento River, this does not allow us to predict how that will affect foodwebs in the Delta. Several additional factors are important in determining the influence of reduced Sacramento River flow on the Delta foodweb. Reduced flow corresponds with reduced turbidity, reduced loading of ammonium (Dugdale et al. 2007), increased temperature, increased residence time in the Delta, and increased contribution of the productive San Joaquin River. Together with continued high nutrient concentrations, these factors are generally associated with increased phytoplankton growth and biomass accumulation in the Delta.

We cannot predict whether this will result in blooms of phytoplankton that support the foodweb, or in blooms of nuisance species such as *Microcystis* (see next outcome). The combination of factors due to reduced flow, together with rising temperature, could cause eutrophication, possibly resulting in depressions in dissolved oxygen and fish kills. These have been largely prevented so far because of the “filtering” provided by turbidity, grazing, & hydrodynamics in this estuary (Cloern 2001). This filtering effect would be reduced, particularly during the summer, if a significant proportion of Sacramento River water were diverted.

Outcome N8: Increased Microcystis biomass due to the new North Delta Diversion which will affect aquatic food webs and covered fish species

Lower Sacramento River flows may reduce summertime turbidity and will reduce summertime Delta inflows, which may create a higher potential for more intense *Microcystis* blooms than have occurred previously.

Magnitude = 3 - Medium
Laboratory experiments showed that *Microcystis* is a poor food source for the copepods *Eurytemora affinis* and *Pseudodiaptomus forbesi* (Ger 2008). Whether the strains used were toxic or not, results indicate the higher the abundance of *Microcystis* relative to palatable phytoplankton, the lower the survival of the copepods. Thus, the effects of *Microcystis* on the foodweb depend not only on the concentration of *Microcystis*, but also on the availability of other phytoplankton that are suitable as food.

Phytoplankton biomass in the Delta has declined over the last several decades (Jassby et al. 2002). Meanwhile, blooms of Microcystis have increased. Localized blooms were initially observed in the late 1990’s, though the species was recorded previously in non-bloom forming quantities (Lehman et al 2008). In the last decade, annual blooms have extended over wide regions of the Delta, in salinities of 0.1-18, beginning in June and reaching their peak between September and October (Lehman et al 2008). The geographic range of the blooms has been expanding (POD Management Team 2007). Although *Microcystis* was previously most abundant in low-flow waters of the Central Delta (Old River), the most recent monitoring from 2007 suggests that its abundance in

Antioch has become comparable to that in the Central Delta (POD Management Team 2007).

The two calanoid copepod species *E. affinis* and *P. forbesi* comprise much of the diet of delta smelt and of young longfin smelt and other fishes. Both of these species have declined recently, although those declines have not been linked to *Microcystis* or any other cause. Nevertheless, a reduction in food quality in the Delta will affect these species and thereby reduce food availability to covered fish species.

By extension, if the north Delta diversions worsened *Microcystis* blooms in the Delta, then there might be less food available to some fishes including delta smelt. There is reason to believe that the reduction in Sacramento River flow would exacerbate blooms. Although nutrient concentrations and ratios have been implicated in formation of blooms elsewhere, these seem of less importance in the Delta (Lehman et al. 2008). Rather, bloom formation seems to depend on low freshwater flow, stratification, high water clarity, and high water temperature (Lehman et al. 2005, 2008), all factors that indicate more potential for bloom formation with low Sacramento River flow. In addition, increasing water clarity during the last several decades (Kimmerer 2004, Nobriga et al. 2008) may be a long-term contributing factor and would likely be exacerbated by low flow.

Microcystis is a freshwater phytoplankton with limited tolerance for high salinity. This does not imply that higher salinity in the Delta, a likely consequence of reduced flow, would reduce *Microcystis* bloom formation. Since *Microcystis* and other plankton (including larval fish) move with the water, the blooms would simply shift in extent with the landward movement of the salt field. Lehman et al. (2005) have also hypothesized that bloom toxicity may be elevated where salinity causes the Microcystis cells to lyse (burst open).

Certainty = 2 - Low
All of the evidence points to increased frequency of *Microcystis* blooms with lower Sacramento River flow. However, there are some missing pieces that preclude a higher certainty rating. First, we do not now have a model that allows reliable prediction of bloom formation, and therefore cannot quantify the effect of the change in flow. Second, the basis for assuming that *Microcystis* is having a substantial effect on the estuarine foodweb is predominantly from laboratory studies (Ger 2008) and field measurement of toxin concentration in foodweb organisms (Lehman et al. 2008). So far the only indications of population-level effects in the field are anecdotal (die-offs of copepods during times of high *Microcystis* abundance, Kimmerer unpublished). Third, the link to covered species will remain speculative until we have better evidence on these population-level effects, and on the degree to which summer food limitation drives covered species population dynamics.

Outcome N9: – Increased predation of juvenile Mokelumne River salmon due to modified Delta Cross Channel operations

Reduced flows into the interior Delta resulting from Hood diversions and expanded Delta Cross Channel (DCC) closures have the potential to adversely impact Mokelumne River juvenile emigrant salmonids by decreasing flows through the Delta forks of the Mokelumne River. The proposed operation includes the following expanded DCC closures:

- DCC will be closed continuously from November through January, where it is currently open up to 45 days during this period.
- DCC will be closed continuously from May 21 through June 15, where it is currently open up to 14 days during this period.
- DCC will be closed continuously from June 15 through June 30, where it is currently open continuously during this period.
- DCC will be closed half the time from September through October, where it is currently open continuously during this period.

The timing of extended DCC closures in relation to Mokelumne River fry, sub-yearling smolts, and yearling smolt emigration is depicted in Table 1. Comparing the timing and relative abundance for each species-life stage indicates that proposed DCC operations will impact an additional 15% of fry, 37% of sub-yearling smolts, and 27% of yearling fall run Chinoook salmon smolts. For steelhead proposed DCC operations will impact approximately an additional 36% of fry, 49% sub-yearling smolts, and 33% of yearling smolts. Furthermore, some emigrating steelhead smolts are known to outmigrate through the DCC and down the Sacramento River. Extended DCC closures would also reduce potential use and increase mortality for this migratory pathway.

Magnitude = 3

Certainty = 3

Important Gaps in Information and/or Understanding

Data Needs

- Specific analysis of tradeoffs associated with potential benefits and impacts of proposed new operation of the Delta Cross Channel.
- Acoustical studies

Appendices

Appendix A: Further Information on Route Selection and Travel Time

- In Winter (Jan-Mar), dual conveyance Scenarios 1 & 2 would create *undesirable* conditions for outmigrating smolts. Dual conveyance Scenarios would increase particle residence time (i.e., vulnerability to predation, rerouting to interior Delta) AND reduce particle likelihood of exiting western Delta (i.e., fewer individuals would complete outmigration to Chipps Island).
    - These conditions would affect all salmonids (Greene 2006), except late-fall.

- In Spring and Fall (Apr-Jun, Nov & Dec), conditions are improved under Scenario 1, which allows for faster travel time through Sacramento River as well as more particles exiting Delta. However, Scenario 2 would create undesirable conditions for outmigrating smolts, with increased residence time and fewer particles exiting western Delta.
    - These conditions would affect all salmonids.

"High flow conditions" (mean = 28,000 cfs; characterize median flows from Jan-Mar; affects winter, spring, fall runs, steelhead)

- Both Scenarios 1 & 2 result in *slower particle travel time* through Sacramento River (from Freeport to 3 mile Slough) and *fewer Sacramento particles reaching western Delta*. These particles are going to Delta Island Channel Use and in channels.
- **Longer residence time and lower success in exiting Delta are not favorable conditions for outmigrating smolts.**
    - Sacramento River particles took longer traveling from Freeport to Three mile Slough under Scenario 1 (152% longer than Reference) and Scenario 2 (165% longer than Reference). For outmigrating smolts, increased residence time increases vulnerability to predation and rerouting to Central Delta.
    - More particles under Scenario 1 (78% of reference) make it to Sherman Lake compared to Scenario 2 (73% of reference).

"Mid flow conditions" (mean = 13,200 cfs; characterize median flows from Apr-Jun; Nov & Dec) affects winter, spring, fall, late-fall runs, steelhead

- Scenario 1 results in *faster particle travel time* through Sacramento and *more particles making it to western Delta* compared to reference conditions.
    - Under Scenario 1, Sacramento River particles were 13% faster traveling from Freeport to Three mile Slough relative to Reference Scenario.
    - More particles under Scenario 1 (+40% of reference) make it to Sherman Lake relative to Reference Condition.
    - **Shorter residence time and higher success in exiting Delta are favorable conditions for outmigrating smolts.**
- Scenario 2 results in *slower particle travel time* through Sacramento River (from Freeport to 3 mile Slough) and *fewer Sacramento particles reaching western Delta* compared to reference conditions.
    1. Under Scenario 2, Sacramento River particles took 150% longer relative to Reference Scenario.
    2. Fewer particles under Scenario 2 (91% of reference) make it to Sherman Lake.

Longer residence time and lower success in exiting Delta are not favorable conditions for outmigrating smolts.

Appendix C: Analytical results for BDCP ops study

Wim Kimmerer
January 23, 2009

The results presented here are to support the analysis of BDCP actions involving operations, specifically focused on changing flows in Old and Middle Rivers. These analyses have not been peer reviewed.

Summary

Question 1: Is the impact of export losses likely to be substantial for longfin smelt? The analysis I did suggests not: the ratio of salvage to abundance for longfin smelt is much smaller than that for delta smelt in most years. In dry years it is comparable or even higher.

Question 2: Can we estimate the impact of export losses on longfin as for delta smelt? I did a curtailed version of the analyses in Kimmerer (2008) for longfin smelt, essentially trying to calculate daily losses based on abundance in the south Delta, abundance overall, and Old and Middle River flows. The mean annual loss, compounded over 60 days, was 0.3% of the population. Longfin smelt apparently move out of the Delta rather soon after hatching, though, so the 60-day figure may be too long. In contrast, delta smelt remain in freshwater until ~July, resulting in longer exposure to export losses.

Question 3: Can we estimate the impact of export losses on splittail? No.

Question 4. How is salvage of adult delta smelt likely to change with changing Old and Middle River flows? This is still in progress. I have a model to relate salvage to OMR flow, but there are a couple of problems with it. I will work on this some more. I also need the flow Scenarios.

Question 1: Is the impact of export losses likely to be substantial for longfin smelt?
Approach: Generally, I compared the ratio of salvage to population size between delta and longfin smelt. Salvage is a poor proxy for export mortality, but probably scales the number of fish that are entrained in the southward-flowing water and thereby toward the pumps. A similar analysis to that of Kimmerer (2008) for delta smelt does not appear feasible, since that analysis relied on the 20mm survey which begins each year well after the spawning peak of longfin smelt.

I calculated total monthly salvage from 1980 through 1995 for each species. I then calculated the total by natal year: for delta smelt all salvage before May was assumed to be from the previous year's cohort, and for longfin smelt I assumed salvage before February was from the previous year (I ignored age of the fish so some 2-year-olds may have been in there). Note that salvage of both species is highest in spring. I took mean catch per trawl from the fall midwater trawl survey and calculated (approximate) population size assuming a volume sampled of 7000 m^3 and a habitat volume of 1.5×10^9 m^3 (these numbers don't really matter for the final result). I then took ratios of total annual salvage to total population size for each year and species. I combined that with estimated export mortality of juvenile delta smelt at the south Delta export facilities from Kimmerer (2008; SFEWS).

Results: Pumping mortality was ~ 1/3 of the salvage:abundance ratio of delta smelt but the two were uncorrelated. The ratio for longfin smelt was always lower than that for delta smelt except during 1989-1991 (Figure 1), which was a drought period when longfin smelt abundance was low. The salvage:abundance ratio for longfin was about 4% of that for delta smelt (median). The salvage:abundance ratio for delta smelt was not a good proxy for the estimate of export mortality; the two were uncorrelated, and the export mortality on average was about 1/3 of the salvage:abundance ratio.

Conclusion: These results show that the magnitude of the export losses to longfin smelt depend on the flow regime. Generally proportional salvage is much lower than that for delta smelt, and usually very near zero. However, during extended periods of low flow, the combination of low abundance and moderate export losses results in rather high ratio of salvage to abundance, so presumably mortality during those periods can be high.

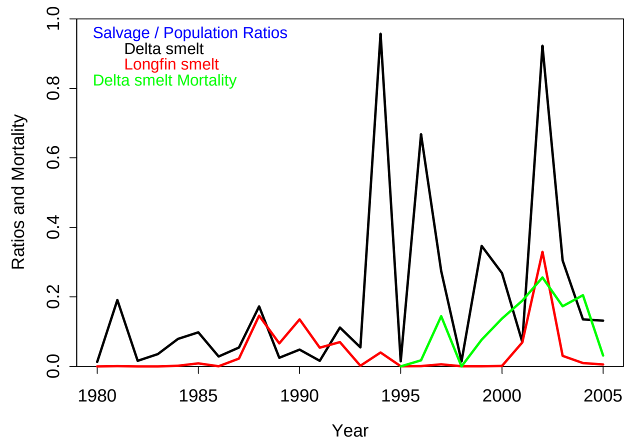

Figure 1. Time course of ratios of annual salvage to population size for delta and longfin smelt, and export-related mortality of delta smelt from Kimmerer (2008)

Question 2: Can we estimate the impact of export losses on longfin as for delta smelt?
Approach: I developed image plots of length by date for longfin smelt from both the 20mm survey and salvage data. The time course of the 20mm survey does not include the entire larval period of longfin smelt, which spawn earlier than delta smelt. The salvage data cover the whole period but do not include fish smaller than 20mm.

I used a similar approach to that applied to determine daily percent mortality of Age-0 delta smelt due to export pumping in Kimmerer (2008). See that paper for assumptions. No correction was made for efficiency of the 20mm net, since similar sizes were assumed to occur in the south Delta and other parts of the system. Mortality was calculated for each 20mm survey from 1995 through 2006. In contrast to the analysis for delta smelt I included stations in San Pablo Bay since longfin smelt are common there, and included the volume of that region (0.9×10^9 m^3, Kimmerer 2004) in the calculation of population size.

Results: The image plot from salvage (Figure 2) shows a peak around julian days 90-150 (April – May) in small fish, and a much lower peak earlier in the year of fish that are from previous year classes. Fish below the line in Figure 2 were assumed to be Age-0. The catch in the 20mm survey roughly corroborates the timing of the peak in salvage (Figure 3), although the start of the peak is earlier since the 20mm survey catches smaller fish.

Export mortality was much lower than that for delta smelt (see Kimmerer 2008 Figure 15; daily mortality based on the 20mm survey was as high as 6% d^{-1}). The highest value was a single, somewhat anomalous value of 0.12% d^{-1} in 1996 (Figure 5). The highest mean value was 0.02% d^{-1} in 2002. If this were compounded over a 60-day period of vulnerability, the result would be a loss of 1% of the population. The mean compounded loss was 0.3%. Note that the calculation for delta smelt was much more involved than this, which should be considered only an estimate for range-finding.

Even that estimate may be high. Delta smelt remain in the Delta until around July, possibly to avoid high temperature. Longfin smelt are larger in samples taken further from the pumps (Figure 6), indicating that they are probably leaving the area within some period after hatching. Therefore individual longfin smelt do not remain vulnerable to pumping for as long a period as delta smelt.

Conclusion: Longfin smelt are much less vulnerable to export pumping than delta smelt, although the 20mm survey is somewhat less suitable for making the calculation for longfin than delta smelt. The reasons for the difference are the lower fraction of the longfin smelt population that occurs in the southern Delta, and the earlier movement of longfin smelt to brackish waters out of reach of the pumps.

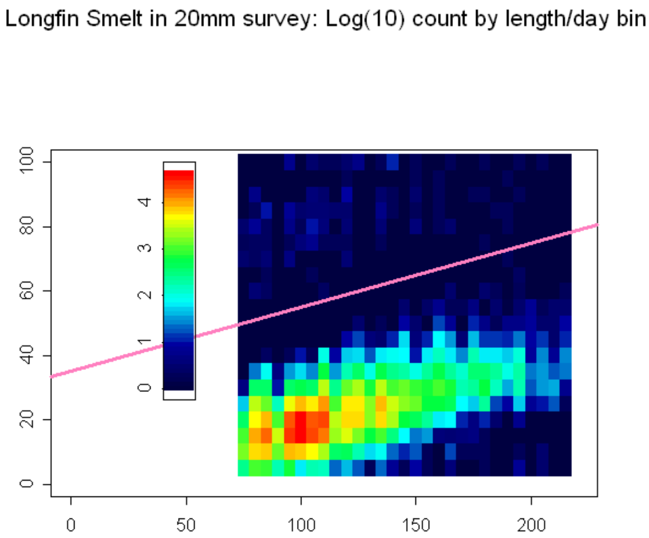

Figure 3. As in Figure 2 for the 20mm survey.

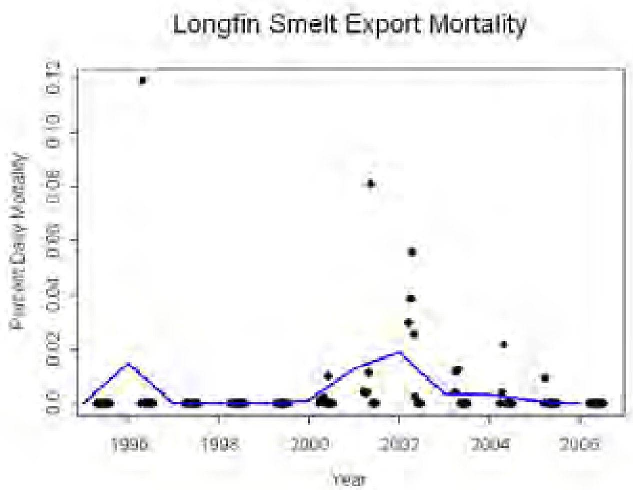

Figure 4. Daily percent mortality due to export pumping and annual mean. Each point represents data from one survey.

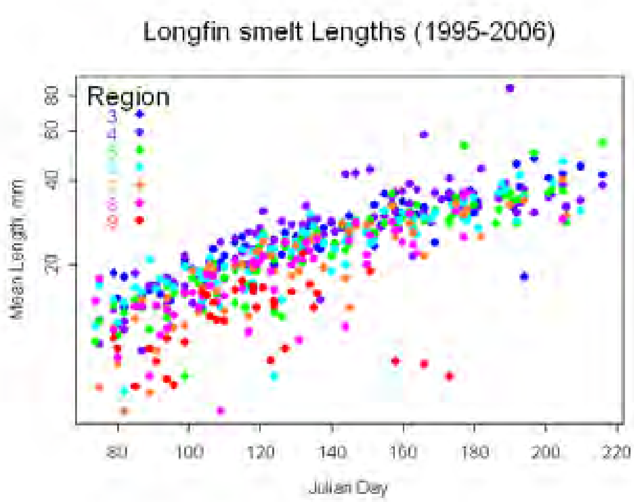

Figure 5. Mean length of longfin smelt from 20mm survey by day and region. The region is the first digit in the station number, and increases generally from San Pablo Bay (3) to the south Delta (9).

Question 3: Can we estimate the impact of export losses on splittail?

Approach: As for delta and longfin smelt except that I did not have the catch per trawl for this species. I therefore used the abundance index from the fall midwater trawl survey, and divided it by 500 (the mean ratio of index to mean catch per trawl for the 4 POD species ranges from 400 to 600). Otherwise the approach was the same.

Results: Salvage was generally higher, sometimes much higher than population size estimated from the MWT (Figure 6)

Conclusion: We can't estimate the impact of export losses on splittail. There is no other sampling program with the right combination of quantitative sampling and seasonal suitability to do this.

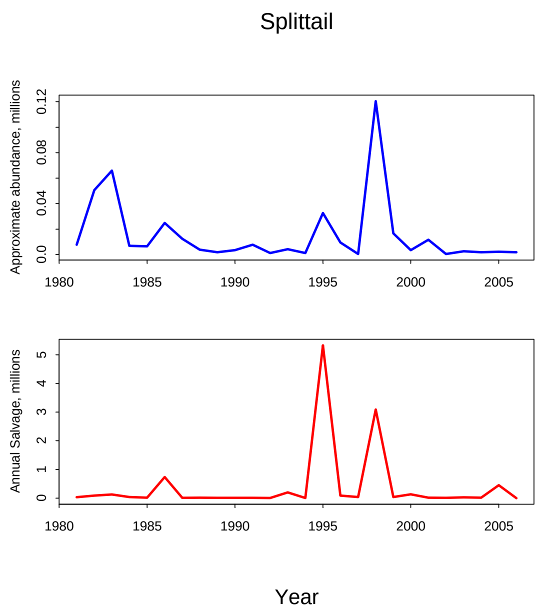

Figure 6. Approximate abundance and annual salvage of Sacramento splittail (millions).

Question 4. How is salvage of adult delta smelt likely to change with changing Old and Middle River flows?

Approach: The basic problem is that the salvage of delta smelt is sometimes high when OMR flows are strongly negative, and sometimes zero. Salvage is usually low when the flows are positive (but not necessarily zero). The question, then, is what benefit accrues from restricting OMR flows in winter.

The general approach was to find a suitable model of the effect of flow on salvage, and then use forecast changes in OMR flow from the 82-year set of Scenarios to estimate the change in salvage. If salvage is proportional to export-related mortality, then this should represent the proportional decrease in mortality.

Salvage data from December 12 through March were used in the analysis. A total of 5413 data points were available from 1981 through 2006: 2653 from the state facility and 2760 from the federal facility. The expansion factor to convert counts in the salvage facility to salvage was determined as the ratio of reported salvage to counts for delta smelt, or if that was zero, for all fish. Two cases had zero counts and one had a missing salvage value; these were eliminated. Thirteen cases (February 2006 in the state facility) had missing values for salvage of delta smelt; these were calculated using the expansion factor for all fish. Note that these expansion factors are approximate, in that the actual calculation is done for each of several time periods over the course of a day and summed over the day; however, the expansion factors for delta smelt and all fish were reasonably close so using daily values seemed a useful simplification to avoid having to work with massive amounts of uninformative data.

A suitable model of these relationships must be nonlinear, and allow zero salvage but not negative values; therefore a linear model is unsuitable. However, since the salvage data are based on counts of fish in the two salvage facilities, we can use a model with a Poisson error distribution in which the raw count data are modeled directly. The model is specified separately for the state and federal facilities, since they may have different relationships. The model is specified in steps:

$$\text{Salvage density} = e^{(a + b * \text{OMR})}$$

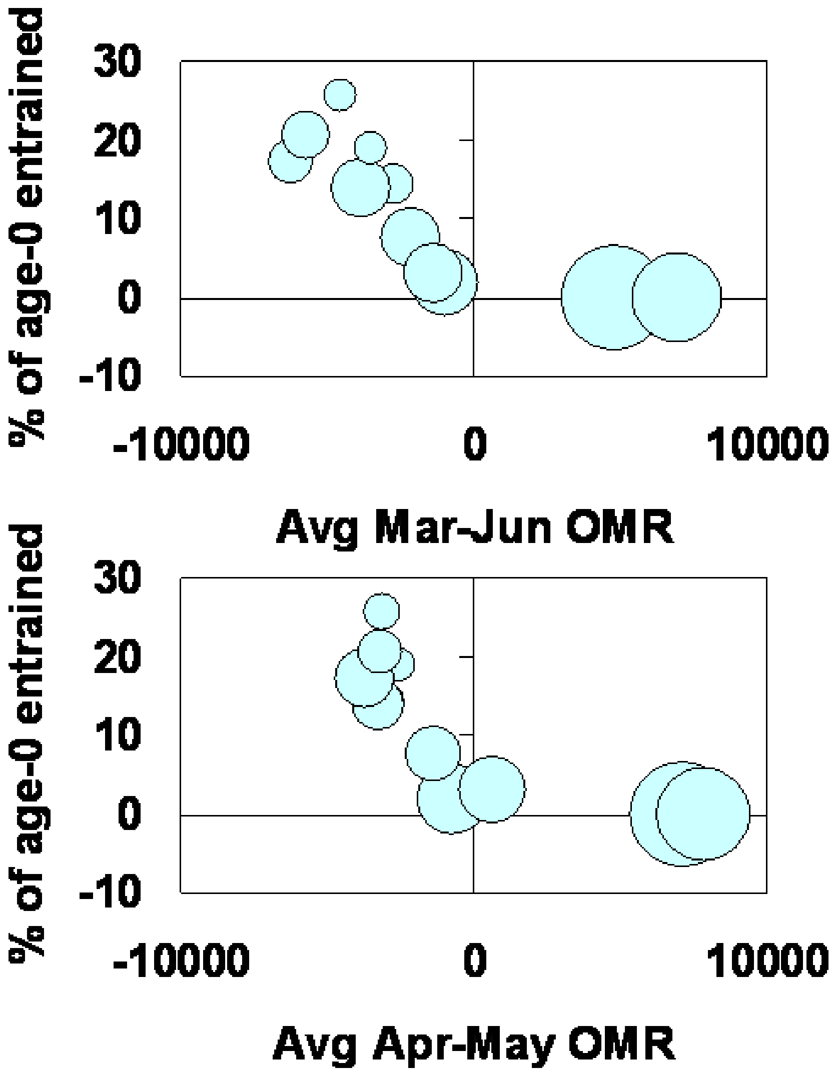
```
Expected Salvage = Salvage density * export flow
Expected count    = Expected salvage / Expansion factor
Observed count ~ Poisson (Expected count)
```

Where a and b are the coefficients to be estimated. Salvage density is the number of fish per unit volume of exported water. This is modeled as a function of OMR flow, since salvage would vary with export flow but salvage density would presumably vary only with OMR flow. Then the expected count is used as the mean of a Poisson distribution, and the raw count data were fit using a Poisson error distribution.

For practical reasons model was fit in a Bayesian analysis using WinBUGS. Uninformative priors for a and b were used, which has the effect that the analysis is similar to a likelihood analysis but is provides more information about the parameters. The prior distributions of the parameters were log normal for **a** (since it can't be less than zero), and normal for **b**, both with means of zero and variances of 10^6. Parameters were estimated from 10,000 iterations after a burn-in of 10,000 iterations to remove the effects of the assumed starting points.

Appendix D: Scatterplot of Average Flow In Old and Middle Rivers

Effects Figure 7



Upper panel is March – June. Lower panel is April – May. The percentage of the larval and juvenile delta smelt population entrained in the SWP and CVP export pumps. The entrainment estimates were taken from Kimmerer (2008). The bubble sizes are scaled to the average Delta outflow for the same averaging periods as the OMR flows.

Appendix E: Comparative Analysis of the Two Scenarios

This action proposes two Scenarios:

- Scenario 1 is the Mid-Range Hood Bypass Criteria where December 1 through June 30 maintain a Sacramento River bypass flow of not less than 11,000 cfs; and July 1 through August 30 maintain a Sacramento River bypass flow of not less than 5,000 cfs.
- Scenario 2 is the Low (5,000 cfs) Hood Bypass Criteria.

The Team evaluated modeling Scenario results for each of the two Scenarios. The modeling output was displayed in graphs that included the following variables:

- Monthly averages of combined OMR flows
- OMR in comparison to both the high bypass flow Scenario and to D1641 baseline.
- OMR in comparison to the low Bypass flow Scenario (#2) and to D1641 baseline
- average OMR flows (above) and dry year OMR flows
- frequency of different flows during the Delta Smelt season

Based upon this analysis, the Team concluded that the positive and negative outcomes for each Scenario and the magnitude and certainty scores for each outcome would be similar under both Scenarios, unless otherwise noted in the individual outcome scores in the main body of this worksheet.

Appendix G: Flow, Salinity and Migration of Salmon

By, Greg Gartrell[4] and Bruce Herbold[5]
April 2009

This is a brief discussion of how flow and salinity likely affect salmon outmigration. The first section discusses the difference between average flow and tidal flow, and how the “net flow model” leads to incorrect conclusions. The second section applies a tidal view to salinity gradients to provide an alternative explanation of observations.

1) Net flow models versus a tidal view of the Delta

Net flow (whether QWEST or OMR net flow or any other net flow) in channels influenced by tides is a mathematical construct, not a physical factor felt by fish. QWEST was first used in an old “Carriage Water model” that attempted to describe how the outflow required to meet a given salinity level in the Delta increased with increasing exports. That model failed miserably: the hydrodynamics were wrong, the outflow levels the model predicted were wrong and the shape of the curve relating exports and outflow was backwards (predicting a monotonically increasing curve when the actual curve has a minimum value before increasing).

Net flows are averages of flows measured at a point (an Eulerian view), effectively the view of water movement from the river bank. This is not something that fish experience. This mathematical construct simplifies a complex flow field, and in the case of fish movement, confuses the picture just as the old Carriage Water Model confused the understanding of salinity in the Delta. Fish experience local velocity[6] as they move around (the fish-eye or Lagrangian view). Of course, to the extent that fish move with the flow, they experience no change in velocities any more than we sense the movement of the Earth through space, except that they feel accelerations due to factors like turbulence, fish body motion or changes in channel shape. However, the movement of water and fish with flow is very different when viewed without the averaging needed to calculate net flows. To give an idea of how badly a model based on average flows (Eulerian or Lagrangian average) in a tidal environment can be, consider the following:

a) Tagged salmon released north of Rio Vista have been caught after just a few days at Chipps Island where tidal flows are very high but net flows are very small. If the fish moved with the average flow, it would take them one to two months to arrive.
b) A salmon could start the day in Old River, travel with the instantaneous local flow down the river on the flood tide towards the export pumps, move across Woodward Cut and travel up Middle River on the ebb tide. The daily average flow (in this case Lagrangian average) would be pointing from Old River to Middle River, leading to the false conclusion that the salmon walked across the island. All information about the intermediate movement of the salmon is lost in the averaging. On the other hand, using the (Eulerian) average of the measured water velocity at one location in the channel (the USGS velocity meter for example) could give an average velocity of a

---
[4] Contra Costa Water District
[5] U.S. Environmental Protection Agency
[6] Flow in a channel is the average velocity times the cross-section. The velocity in a channel varies across the width and depth of the channel. Fish will experience the local velocity (in space and time), not the cross-sectionally averaged velocity, nor the overall flow in the channel.

few millimeters per second (or about 300 meters per day), an equally false conclusion.

Two problems with net flows prevent them from reflecting conditions that directly affect fish: they throw out important information in the process of averaging and they are derived variables (not independent variables) both mathematically and physically.

The following graphs illustrate these problems. The graphs show instantaneous flows.

Figure 1 shows Delta flows with the ebb and flood flows generally of the same magnitude in opposite directions. The average net flow is much smaller than any flow affecting the fish at a given moment.

Figure 1. Flow with flood and ebb nearly balanced, 1 = 10,000 cubic feet per second

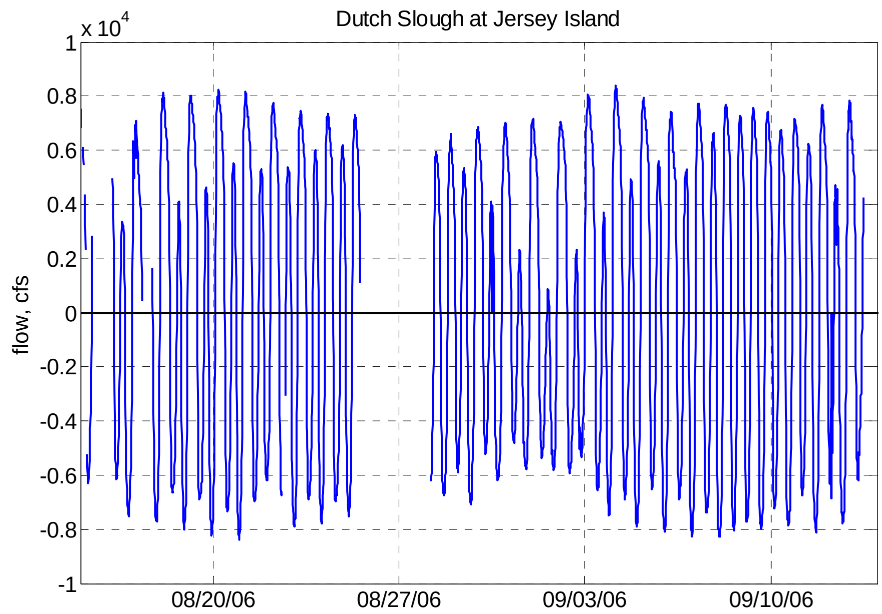

Figure 2 shows tidal flows with a stronger flood than ebb. While the direction of the average is obvious, the magnitude of the average is not. A fish experiencing this still has a chance to move in the opposite direction from the average if it uses the tides correctly (i.e., if it gets into the high velocity part of the channel on the ebb, and stays near the channel sides on the flood). Salmon clearly have the ability to pick the right tide based on cues, or they could not get from north of Rio Vista to Chipps Island in a few days.

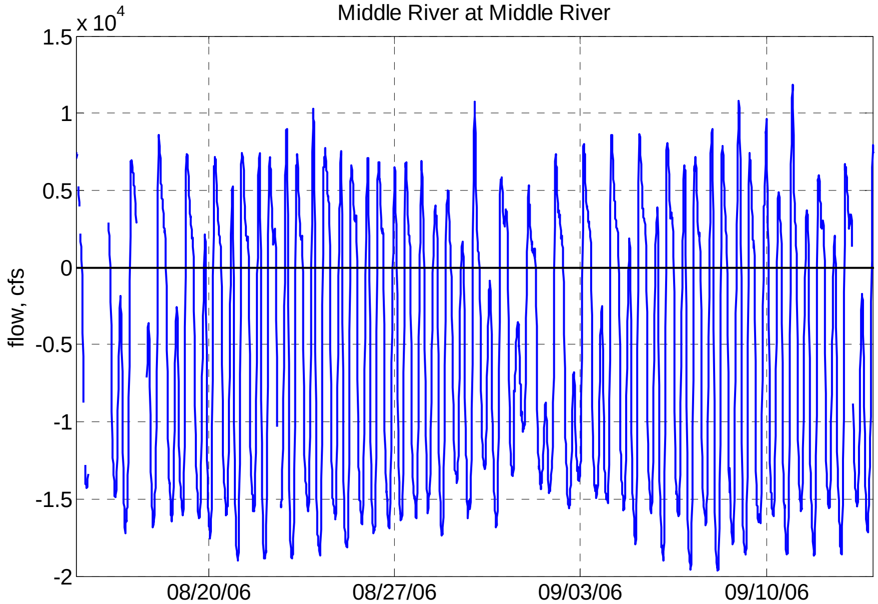
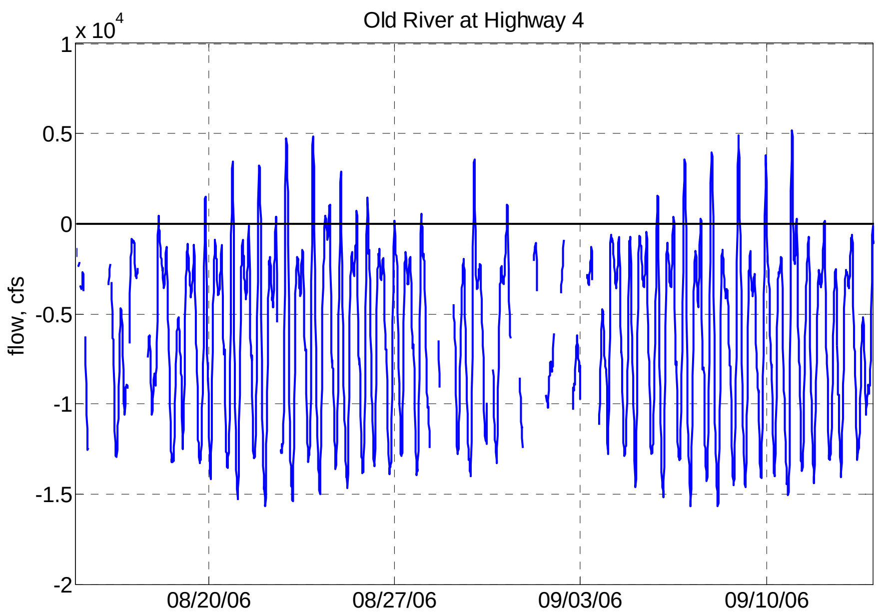
Figure 2. Flow with strong flood tide compared to ebb, 1 = 10,000 cubic feet per second



Finally, Figure 3 shows a tidal flow where, at times, the ebb and flood are both less than zero. In this case, a salmon trying to surf the ebb will have a rough time of it. In fact, one can find no ebb tide at all for days at a time. This is a not a good situation if, in one flood tide, the salmon can end up in Clifton Court Forebay.

Figure 3. Flow in Old River at Highway 4, 1 = 10,000 cubic feet per second



Clearly, the situation in Figure 3 is going to result in high entrainment of fish: the export flows are so big that the ebb tide is lost and it is a one-way trip south, with tidal excursions double the normal 4 or 5 miles. When does this situation occur? It starts when exports are 5000 cfs to

7000 cfs. The Bay Institute argued in the OCAP lawsuit that high entrainment of salmon occurs when exports are over 7000 cfs: that is when the ebb tide is lost. That level of exports is also when delta smelt entrainment is high in January and February.[7] An examination of Figures 1 through 3 tells the story very quickly: this is about tides and export levels, not net flows. It is not the “net flow”; it’s the “no ebb flow”.

What about entrainment that occurs when net flows are small (or even positive)? The net flow view of the world fails completely (just like the old Carriage Water model) in this situation. When viewed with the tides in mind, the picture becomes clear, as the examples in the next section illustrate.

2) Salmon movement in a tidal environment

Consider salmon moving down the Sacramento River into the Delta. Some will make it to Chipps Island and beyond, but some will end up in the Lower San Joaquin River, via Georgiana Slough, through Three-Mile Slough or around Sherman Island. In this central delta area their advective (i.e. non-swimming) movement would be governed by tidal flows. Some will, even when export pumping is low and net flows are positive, go through False River into Franks Tract, where they (the survivors, anyway) have a good chance of being discharged out into Old River. Others can get sloshed into Middle River. This is their starting point for the Scenarios that are described below.

For San Joaquin Salmon, the starting point for the Scenarios below will be the San Joaquin River at the Head of Old River.

Scenario 1: High exports, typical San Joaquin River flow and salinity (i.e., low flow, high salinity).
In this case, exports are high and the ebb tide is very small or non-existent. It is a short trip down the river (the salmon simply cannot swim against 1 to 2 fps currents for long) to the export pumps for Sacramento salmon. San Joaquin salmon have two likely fates: those entering Old River have a quick trip to the export pumps; those moving down the San Joaquin River get to the Lower San Joaquin River and then some will make it to Chipps Island and some will move into Old and Middle Rivers and thence to the export pumps. In all cases salmon entrainment will be high.

Scenario 2: Low exports, typical San Joaquin River flow and salinity (i.e., low flow, high salinity). Sacramento salmon coming from the north experience substantial ebb and flood tides. However, one thing is peculiar in the central and south Delta compared to what should be found in an estuary: San Joaquin River salinity (generally as much as 1 mS/cm, with chloride levels over 150 mg/l) is much higher than Sacramento River salinity (about 0.15 mS/cm with chloride levels around 10 mg/l).[8] An obvious cue in a tidal system for the ocean is salinity (electrical conductivity or specific ions; two obvious ions would be sodium and chloride). What salmon in the central and south Delta see is a reverse salinity gradient because of high San Joaquin

[7] Pete Smith used OMR net flow to show this, but OMR net flow is a dependent, not independent variable. Exports and San Joaquin inflow are independent variables, and the correlation between delta smelt entrainment and exports/San Joaquin flows is better than the correlation between entrainment and OMR flows for the same time period.
[8] As an example, with flows increasing during the VAMP period, SJR salinity is currently about 0.4 mS/cm today (April 20, 2009). That level is also found near Collinsville today, but in between it is as low as 0.2 mS/cm (Jersey Point area).

salinity and saline discharges (ag and urban) within the Delta. Salmon attempting to follow the salinity gradient to the ocean would jump into the high velocity zone on the flood, rather than ebb. That takes them the wrong way, and exposes them to entrainment at the export pumps. (Even if export rates are very low, there is a good chance to get into the pumps).

The situation for San Joaquin salmon is probably very much worse: arriving in a low flow with high salinity and entering a reverse salinity gradient, the chances of a bad ending would lead one to wonder how any salmon at all find their way out. This is consistent with the extremely low survival rates reported by USFWS under all but flood conditions in the Delta.

In this case it is neither the "net reverse flow", nor the "no ebb tide"; it is the "reverse salinity gradient".

Scenario 3: Low exports, typical San Joaquin River flow and salinity (i.e., low flow, high salinity) with an Isolated Facility.
This case is little different from Scenario 2, except that the exports are liable to be less and the water quality situation could easily be worse. With apologies to our friends who authored the PPIC reports, it is likely to create an "Arkansas cesspool" from the "Arkansas Lake". With drainage (from the San Joaquin River and in-Delta agriculture) and urban discharges ringing the area (clockwise: Sacramento Regional, Stockton, Tracy, Discovery Bay, Ironhouse SD, Delta Diablo SD, Central Contra Costa SD), and little inflow, the central and south Delta are likely to become (with apologies to Thomas Friedman) "Hot (warm SJR water), Flat (gradients) and Crowded (with non-natives)". Entrainment, in the absence of screens will be high at both export pumps and agricultural intakes (you only have to see the vortex spinning above a siphon to realize just how fast the velocity is in the siphon), and confusion will be high. The number of fish orienting correctly to the ocean would be very small and even for them the very long transit time would probably subject them to extremely high mortality rates within the delta.

Scenario 4: Good flows and high quality on the San Joaquin River. Salinity gradients are not reversed and fish orient correctly to the tidal salinity gradient and tidal flows. This is totally different from Scenario 1, 2 or 3. The key is improved San Joaquin River flow and salinity.

Scenario 1

Mid-Range Hood Bypass Criteria.
- December 1 through June 30 maintain a Sacramento River bypass flow of not less than 11,000 cfs;
- July 1 through August 30 maintain a Sacramento River bypass flow of not less than 5,000 cfs;
- September 1 through November 30 maintain a Sacramento River bypass flow of not less than 7,000 cfs for fall salmon attraction and migration;
- Require at least 55% of river flows above minimum bypass flows during February-April, 45% during January and May, and 35% during December and June

Scenario 2

Low (5,000 cfs) Hood Bypass Criteria
- Set minimum bypass flow of 5,000 cfs year round except as provided in the bullet below;
- Require at least 55% of river flows above 5,000 cfs during February-April, 45% during January and May, and 35% during December and June (see figure 3) to maintain the shape of the hydrograph.

APPENDIX A 32

Action Description and Clarifying Assumptions

Option #1 Period of Potential Operation: December 1-May 15

Desired Duration of Inundation: 45 days
Target Spill Discharge into Bypass: 4000 cfs
Predicted area of inundation: 22,982 acres
Predicted mean depth of inundated area: 2.2 feet
Predicted travel time: 6.5 days
Spill Frequency of Fremont Weir (assuming 4000 cfs and 45 day duration with a spill intermission of no more than 7 days): 48% of years (38 of 79), compared to 6% of years (5 out of 79) at existing weir height.

Option #2 Period of Potential Operation: January 1-April 15

Desired Duration of Inundation: 30 days
Target Spill Discharge into Bypass: 2000 cfs
Predicted area of inundation: 17,421 acres
Predicted mean depth of inundated area: 2.3 feet
Predicted travel time: 9.3 days
Spill Frequency of Fremont Weir (assuming 2000 cfs and 30 day duration with a spill intermission of no more than 7 days): 54% of years (43 of 79), compared to 6% of years (5 out of 79) at existing weir height.

Approach

1. Fremont Weir would be notched to an elevation of 17.5 feet (NAVD88) approximately 225 feet wide and fitted with an operable gate(s) that, when operated, would allow Sacramento River water to flow into the Yolo Bypass when Sacramento River stage at the weir exceeds 17.5 feet. Channel dimensions would avoid channel velocities of >3 ft/s.
2. A trapezoidal canal (225' width, side slopes 2:1) would be excavated to convey water past the higher elevation natural levee of the Sacramento River upstream of the new gate at the Fremont Weir and 10,000 feet past accumulated sediment below the new gate in the Bypass to the Tule Canal.
3. The existing Fremont Weir fish ladder would be removed and replaced with a new fish passage facility designed to effectively allow for the passage of adult salmonids and sturgeon from the Yolo Bypass past the weir into the Sacramento River.
4. To the extent necessary, the Bypass would be graded, existing berms or levees would be removed, and berms or levees would be constructed to improve the distribution and hydrodynamic characteristics of water moving through the Bypass, prevent stranding of covered fish species, and protect property.
5. If needed, a structure would be constructed in the Sacramento River in the vicinity of the new weir gate to encourage the passage of juvenile salmonids migrating down the Sacramento River into the bypass.

Note: At flood stage (>33.5 feet) the weir would overtop as under current conditions.

Intended Outcomes as Stated in Conservation Measure

Positive Outcomes:

P1 (intended): Create additional spawning habitat for splittail

P2 (intended): Create additional juvenile rearing habitat for Chinook salmon, splittail, steelhead, and green and white sturgeon

P3 (intended): Increase production of food for rearing of Chinook salmon, splittail, steelhead, (onsite = seasonal floodplain only)

P4 (intended): Increase frequency and magnitude of export of DOM, POM and organisms from seasonal floodplain to provide food in Delta for Delta smelt, longfin smelt, Chinook salmon, splittail, steelhead, and green and white sturgeon

P5 (intended): Increase frequency and magnitude of transport of organic carbon and organisms from Cache Slough/Bypass tidal marshes to support Delta foodweb for Delta smelt, longfin smelt, Chinook salmon, splittail, steelhead, and green and white sturgeon

P6 (intended): Reduce losses due to stranding and illegal harvest Chinook salmon, steelhead, and green and white sturgeon

P7: Increase delivery of readily suspendable sediments to north Delta and improved Delta smelt habitats

P8 (intended): Increase survival of out migrating juvenile salmonids by providing migration route with lower predation and entrainment (at North and South Delta diversions) risk.

Negative Outcomes:

N1: Increased MeHg and impact on covered species (on floodplain and downstream)

N2: Increased resuspension/mobilization and export of toxic compounds w/impact on covered species

N3: Increased stranding of covered species (consider grading proposed in the approach)

N4: Reduced flows in Sacramento River and distributaries to support successful outmigration.

N5: Increased habitat for non-native predators/competitors to covered species

Conceptual Model Information Regarding Intended Outcomes

Additional spawning habitat for splittail is supported by the Floodplain Model (Opperman, 2008) which notes that splittail population dynamics are strongly associated with annual patterns of flow and floodplain inundation (Moyle et al., 2004), and the importance of flooding of the Yolo Bypass in particular as a factor influencing the strength of the splittail year class (Sommer et al., 1997). Adult splittail move into inundated areas in late February or early March and spawning occurs in March and April. Recent research from the Yolo Bypass suggests that spawning is most likely to occur near the vernal equinox (late March) (Feyrer et al. 2006). Opperman, 2008 also notes the use of floodplain habitats, including the Yolo Bypass, by juvenile Chinook salmon but notes that little is known regarding steelhead. The Floodplain model makes no mention of green or white sturgeon, but the sturgeon models (as noted in the Outcomes Table) document loss of habitat as a stressor. Both sturgeon models note that Freemont Weir is a barrier for sturgeon. The Outcomes Table identified food production and increased food availability as outcomes in the Floodplain model and as drivers in the Delta smelt and longfin smelt models. Opperman, 2008 notes that salmon emigrate from floodplains as long as drainage connectivity is available and that certain features, such as pits, can lead to stranding.

Assumptions

Provided in BDCP Conservation Measure
The Toe drain would be graded where appropriate

Added by Evaluation Team
The evaluation team recognized that there may be future changes in land use but since predictions were not available only current land use was considered relative to the availability of toxic compounds for resuspension (Outcome N2).

Problem(s) with Action as Written

None identified

Scale of Action

Large

Rationale:
This represents an order of magnitude increase in frequency of inundation of existing floodplain habitat in the Delta.

Evaluation Summary Tables

Summary tables listing magnitude and certainty scores for each outcome, by species, are provided in Appendix A. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes following this section.

Relation to Existing Conditions

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

No. While this action represents a huge increase in the area of frequently inundated floodplain within the Delta it is expected that the area will function similarly to existing floodplains and the understanding generated from studies of Yolo Bypass and the Cosumnes River, as well as other areas, will be applicable to understanding the consequences of this action.

Potential Positive Ecological Outcome(s)

Outcome P1: Create additional spawning habitat for Splittail

P1a.1 Splittail Scenario 1

The Splittail Model (Kratville, 2009 - pages 9 and 12) describes how floodplain habitat supports splittail spawning:

- "Splittail are considered to be obligate flood plain spawners (Moyle 2002)."
- "Large scale spawning occurs only in years with significant inundation of flood plains in the Sacramento-San Joaquin watershed."
- "Splittail need water levels and inundation duration in ranges that were historically present (30 - 90 days)…The minimum length of inundation is required to achieve strong year classes when associated with large scale flood plain inundation as occurs on the Yolo Bypass. Longer inundation periods allow for extended and multiple spawning events as well as other food web associated benefits."

On page 14 of Splittail Model (Kratville, 2009), modification and loss of floodplain habitats is identified as a key limiting factor:

- **"**The substantial loss of floodplain from conversion to agriculture and urban areas and loss of river edge spawning habitat is probably the key limiting factor for splittail populations (Moyle et al. 2004)."

Magnitude = 4
The action is expected to have a landscape scale effect based on the increased frequency of flooding and extent of additional floodplain habitat.

Certainty = 4
The importance of floodplains for splittail spawning is well established by published papers based on evidence from this system.

P1a.2 Splittail Scenario 2

The rationale for the important of floodplain habitat to splittail spawning is same as for P1a.1 above.

Magnitude = 3
The lesser extent and decreased duration of flooding (30 days) compared to P1a.1 makes this scenario a regional scale habitat effect.

Certainty = 4
The importance of floodplains for splittail spawning is well established by published papers based on evidence from this system.

Outcome P2: Create additional juvenile rearing habitat for splittail, green and white sturgeon, steelhead and Chinook salmon

P2a.1 Splittail Scenario 1

Table 1 page 3 in Splittail Model (Kratville, 2009) indicates larvae use floodplains February through May and juveniles use floodplain February through July. Page 8 states "must have seasonally flooded lands on which to spawn for early rearing of larval and juvenile fish". Page 12 notes "Although some are swept off floodplains and downstream by flood currents (Baxter et al. 1996), many splittail larvae and juveniles remain in riparian or annual vegetation along shallow edges on floodplains as long as water temperatures remain cool" (Sommer et al. 2002, Moyle et al. 2004). This outcome is supported by peer reviewed publications from the Cosumnes River and Yolo Bypass (Crain et al. 2004, Moyle et al. 2004, Sommer et al. 1997, 2001, 2007, Feyrer 2006, 2007).

Magnitude = 4
Splittail rely on shallow water habitat which is extremely limited without floodplain inundation (Sommer et al. 2008)

Certainty = 4
Supported by publications based on the Yolo Bypass in peer reviewed journals.

P2a.2 Splittail Scenario 2

The rationale for the importance of floodplain habitat to splittail rearing is same as for P2a.1 above.

Magnitude = 3
The lesser extent and decreased duration of flooding (30 days) compared to P2a.1 makes this scenario a regional scale habitat effect.

Certainty = 4
Supported by publications based on the Yolo Bypass in peer reviewed journals.

P2b. Green/white sturgeon Scenario 1 and 2

There is no evidence of juvenile sturgeon use of floodplains. Sturgeon caught in Yolo Bypass studies are adults (Harrell and Sommer 2003).

Magnitude = 1
There is little evidence of floodplain use by sturgeon.

Certainty = 2
Some data available but only for adults.

P2c. Steelhead Scenarios 1 and 2

Steelhead are present in the area at the time of flooding (McEwan 2001, Figure 3). According to Mossdale trawl data from the Sacramento River steelhead are emigrating January through August, with the peak in January through May. The Floodplain Model (Opperman, 2008, pg 27) indicated little information is available on steelhead use of floodplain habitats. However, the steelhead model (Williams and Rosenfield, in preparation, page 155, Figure 2) shows floodplain use. Juvenile steelhead have been caught on the floodplain in Yolo (Sommer et al. 2001). There is some reference to additional observations in Williams 2006 (Chapter 9, page 174). McEwan (2001) and Moyle (2002) also support the presence of steelhead on floodplains.

Magnitude = 4
There is sufficient evidence of the use of floodplains by steelhead; Action includes major increase in habitat availability.

Certainty = 2
Few direct observations of steelhead benefiting from floodplain habitat.

P2d. Chinook salmon Scenario 1 and 2

Chinook salmon juveniles are present in the area during the proposed floodplain inundation period of late winter and spring.

- Knights Landing data indicates:
  Winter Run Juvenile peaks Nov –Feb
  Fall run peaks Jan – Feb then Apr -May
  Late Fall run peaks on Dec and April
  Spring Run peaks are Dec-Jan and March – April (CDFG rotary screw trap)

Chinook salmon juveniles use the floodplain for rearing. The restored floodplain would create rearing habitat for fry/parr that enter the Delta in the winter, coincident with inundation of the floodplain. These fry would be able to feed and grow in the floodplain, and their larger size would increase the likelihood of survival in the ocean.

- "Recent work shows that the bypasses do indeed provide habitat for juvenile Chinook, that they grow well there, and that most avoid stranding". (Williams 2006)
- Juvenile salmon collected from the inundated Yolo Bypass were substantially larger and grew more rapidly then juveniles collected from Sacramento River (Sommer et al. 2001).

Fall-run Chinook fry (<70mm) rear primarily in the upper freshwater delta. Peak fry rearing is February through March and young fry appear to be most abundant in shallow water and shoreline habitat. Rearing occurs for two months or more (Kjelson et al. 1982).

- Central Valley Chinook salmon may have relied extensively on floodplain in the past; historically much of the Central Valley was floodplain habitat (Hunter et al. 1999)
- Sommer et al. (2005) reported extensive use of Yolo and Sutter bypasses by fall-run Chinook salmon.
- Moyle et al. (2007) reported use of Cosumnes River floodplain by Chinook salmon.

Magnitude = 4
Compared to current conditions, the frequency and extent of inundated floodplain habitat for Chinook salmon will be significantly increased representing a landscape scale habitat effect.

Certainty = 4
There is high certainty that juvenile salmon are in the vicinity (based on data), and juveniles rear in restored floodplain based on documented rearing in the Yolo Bypass and the restored Cosumnes River floodplain (various published papers).

Outcome P3: Increase production of food for rearing of Chinook salmon, green and white sturgeon, splittail, and steelhead, on the seasonal floodplain

P3a. Splittail Scenario 1 and 2

The use of floodplains for rearing is established (P2a above). The Splittail Model (Kratville, 2009) notes, "After yolk sac absorption the larvae begin feeding on small rotifers (Bailey 1994). Prey composition shifts as they increase in size to cladocerans and chironomid larvae (Kurth and Nobriga 2001). Larval splittail to 15mm feed heavily on zooplankton, primarily made up of cladocerans. Chironomid larvae begin to dominate after 15mm in length has been achieved (Feyrer et al. 2007)." The model also notes that flooding of the Yolo bypass is associated with "a large hatch of an endemic chironomid, *Hydrobaenus saetheri*" (Cranston et al. 2007, Benigno and Sommer 2008). Floodplain Model (Opperman, 2008 - pgs 20-25 and Figure 5) describes floodplain food production and notes a positive relationship between temperature and zooplankton and the influence of floodplain flow velocity on macroinvertebrates,

Magnitude = 4
Splittail are floodplain dependent (Moyle et al. 2004; Sommer et al. 2007) and food resources are large on the floodplain.

Certainty = 4
There are substantial data and publications on splittail use of seasonal floodplain.

P3b. Green and white sturgeon Scenarios 1 and 2

The draft White Sturgeon Model (Israel et. al., 2009 - page 8) indicates "White sturgeons are unique in that their digestive systems are nearly fully formed both physically and physiologically at the larval stage (Gawlicka et al. 1995). Nothing is known about the diets of white sturgeon larvae in the wild, although laboratory studies suggested that they consist of benthos, periphyton, and possibly pelagic fry and zooplankton (Brannon et al. 1984, Buddington and Christofferson 1985)." Juvenile white sturgeon also may consume tube dwelling amphipods, mysids (*Neomysis spp*), isopods, benthic invertebrates, and fish eggs or fry, including those of other sturgeon (Brannon et al. 1987, PSMFC 1992). The draft Green Sturgeon Model (Israel and Klimley, 2008 - page 9) indicates that no studies have been undertaken of food resources for larval green sturgeon. However, there is no evidence of juvenile sturgeon use of floodplains. Sturgeon caught in Yolo Bypass have been adults (Harrell and Sommer 2003).

Magnitude = 1
There is no evidence of juvenile sturgeon use of floodplains. Sturgeon caught in Yolo Bypass have been adults.

Certainty = 2
Historical sampling in Yolo Bypass has not been well-designed to capture young sturgeon, thereby reducing certainty about this issue.

P3c.1 Steelhead Scenario 1

We know of no observations in the literature that support steelhead feeding on floodplains; however, it can be assumed that they are utilizing the same food sources as juvenile salmon (see P3d), given their life-history similarities. Moyle et al. 2004 states that stream-dwelling rainbow trout feed mostly on drifting aquatic organisms, terrestrial insects, and bottom dwelling organisms which are in abundance on floodplains.

Magnitude = 3
Effect demonstrated for species with similar life histories.

Certainty = 3
There have been some studies on similar species within the system.

P3c.2 Steelhead Scenario 2

We Know of no observations in the literature that support steelhead feeding on floodplains, however, it can be assumed that they are utilizing the same food sources as juvenile salmon (see P3d), given their life-history similarities. Moyle et al. 2004 states that stream-dwelling rainbow trout feed mostly on drifting aquatic organisms, terrestrial insects, and bottom dwelling organisms which are in abundance on floodplains.

Magnitude = 2
Magnitude is lower than scenario 1 because inundation frequency and duration is lower

Certainty = 3
See P3c.1

P3d.1 Chinook Salmon Scenario 1

Juvenile Chinook salmon use of floodplain habitats is well established (Sommer et al. 2001b, Whitener and Kennedy 1999). Opperman, 2008 (page 29) notes that the higher growth rates of juvenile Chinook on Central Valley floodplains, relative to river habitats, has largely been attributed to the greater availability of prey items within floodplain habitats (Jeffres et al. 2007, Sommer et al. 2001b). This includes Dipterans (Sommer et al., 2001) and zooplankton (Grosholz and Gallo 2006). Chinook salmon likely take advantage of small fishes on the floodplain (Williams and Rosenfield, In preparation pg 8) and (Moyle et al. 2004).

Magnitude =4
Extensive floodplain area inundated and high likelihood of appropriate food production.

Certainty = 3
Juvenile Chinook salmon use of floodplain habitats is well established.

P3d.2 Chinook Salmon Scenario 2

Rationale is similar to P3d.1. Differences in scores reflect reduction in scale of floodplain inundation.

Magnitude = 3-4
Reduced scale and duration of floodplain inundation compared to P3d.1

Certainty = 3
Juvenile Chinook use of floodplain habitats is well established.

Outcome P4: Increase frequency and magnitude of export of DOM, POM and organisms from seasonal floodplain to provide food in Delta for Delta smelt, longfin smelt, Chinook salmon, splittail, steelhead, and green and white sturgeon

P4a. Delta smelt Scenarios 1 and 2

Delta smelt Model (Norbriga and Herbold, 2008 - pg 12) describes the importance of zooplankton to Delta smelt. Opperman, 2008 notes that the most important variables influencing zooplankton production on floodplain are hydraulic residence time and the availability of food resources (e.g., phytoplankton and periphyton). Grosholz and Gallo (2006) also found that zooplankton densities peaked about 2-3 weeks after disconnection between river and floodplain (draining phase). The Foodweb Model (Durand, 2008) notes that DOC reaches the estuarine foodweb via bacteria and notes this is well understood in this estuary. The model also notes recent studies by Sobczak et al. (2005) that indicates that some zooplankton tend not to use phytoplankton exclusively, supplementing their diets substantially with particulate organic matter or ciliates: According to the fall midwater and Kodiak trawl data and Sommer et al. (in prep), Delta smelt rear in areas immediately downstream of Yolo Bypass.

Magnitude = 3
Delta smelt rear immediately downstream from Yolo Bypass where exported food would be readily available.

Certainty = 3
Delta smelt Model (Norbriga and Herbold, 2008 - pg 12) describes the importance of zooplankton to Delta smelt. Opperman, 2008 notes that the most important variables influencing zooplankton production on floodplains are hydraulic residence time and the availability of food resources (e.g., phytoplankton and periphyton) - see above paragraph.

P4b. Longfin Smelt Scenarios 1 and 2

The Longfin Smelt Model (Rosenfield, 2008 - pg 15) notes that early stage longfin smelt juveniles probably rely on *Eurytemora affinis* as a prey item during April and May with other copepods becoming important later in the year. Food limitation is considered a stressor on juveniles and sub adults. Opperman, 2008 notes that the most important variables influencing zooplankton production on floodplains are hydraulic residence time and the availability of food resources (e.g., phytoplankton and periphyton). Grosholz and Gallo (2006) also found that zooplankton densities peaked about 2-3 weeks after disconnection between river and floodplain (draining phase). The Foodweb Model (Durand, 2008) notes that dissolved organic carbon (DOC) reaches the estuarine foodweb via bacteria and that this is well understood in this estuary. The model also notes recent studies by Sobczak et al. (2005) that indicates that some zooplankton tend not to use phytoplankton exclusively, supplementing their diets substantially with particulate organic matter or ciliates.

Magnitude = Between 2 and 3
The shift in the longfin smelt-X2 relationships after the introduction of *Corbula* suggest longfin smelt are sensitive to food availability (Kimmerer 2002). Young longfin smelt occur close to Yolo Bypass but the benefit to longfin smelt further downstream may be limited due to the role of *Corbula*.

Certainty = 2
The relative importance of exported floodplain carbon to longfin smelt is unclear, particularly given high densities of the grazer *Corbula* between floodplain and main brackish habitat of longfin smelt.

P4c. Splittail Scenarios 1 and 2

Opperman, 2008 (pg 20) describes the importance of exporting food to downstream foodwebs and the links between carbon produced on floodplains and the downstream foodweb (Sobczak et al. 2005). The use and importance of these food resources has been described for splittail in outcome P3a.

Magnitude = 3
Splittail use Yolo bypass, but the benefit to splittail further downstream may be limited due to role of *Corbula.*

Certainty = 2
The relative importance of exported floodplain carbon to splittail is unclear, particularly given high densities of the grazer *Corbula* between floodplain and downstream habitat of splittail.

P4d. Green/white sturgeon Scenarios 1 and 2

Opperman, 2008 (pg 20) describes the importance of export of food to downstream food webs and the links between carbon produced on floodplains and the downstream foodweb (Sobczak et al. 2005). The use and importance of these food resources has been described for green and white surgeon in outcome P3b.

Magnitude =2
The White Sturgeon Model (Israel et. al., 2009 - pg 11) notes feeding on highly-abundant suspension-feeding bivalves such as *Corbula amurensis.* The Green Sturgeon Model (Israel and Klimley, 2008) notes that invasive *Corbula* has replaced native mollusks and shrimp as food for green sturgeon in recent years. Sturgeon may indirectly benefit from the export of food through the *Corbula* foodweb linkage.

Certainty = 2
Importance of food exported from floodplains for sturgeon directly or indirectly is unclear. Little evidence available.

P4e.1 Steelhead Scenarios 1 and 2

Opperman, 2008 (pg 20) describes the importance of exporting food to downstream foodwebs and the links between carbon produced on floodplains and the downstream foodweb (Sobczak et al. 2005). The use and importance of these food resources has been described for steelhead in outcome P3c.

Magnitude = 2-3
Floodplains produce aquatic insects. Increased flows will export these resources downstream. Steelhead feed mostly on drifting aquatic organisms, terrestrial insects, and bottom dwelling organisms (Moyle et al. 2004).

Certainty = 2
It can be assumed that steelhead are utilizing similar food sources as juvenile salmon given their life-history similarities (see P3d), however there is little documentation.

P4f.1 Chinook Salmon Scenario 1 and 2

Opperman, 2008 (pg 20) describes the importance of exporting food to downstream food webs and the links between carbon produced on floodplains and the downstream foodweb (Sobczak et al. 2005). The availability of these food resources has been described for Chinook salmon in outcome P3d, However the importance of these food resources in downstream habitats is not as well documented.

Magnitude = 2-3
Floodplains produce aquatic insects. Increased flows will export these resources downstream. Steelhead feed mostly on drifting aquatic organisms, terrestrial insects, and bottom dwelling organisms (Moyle et al. 2004).

Certainty = 2
The importance of these food resources in downstream habitats is not as well documented.

Outcome P5: Increase frequency and magnitude of transport of OC and organisms from Cache Slough/Bypass tidal marshes to support Delta foodweb for Delta smelt, longfin smelt, Chinook salmon, splittail, steelhead, and green and white sturgeon

P5a. Delta smelt Scenarios 1 and 2

Marsh production of phytoplankton is high in Liberty Island (Lehman et al. 2007); Phytoplankton supports the delta food web (Sobzack et al. 2002; Mueller-Solger et al. 2002). Production from lower Yolo Bypass including. Liberty and Cache slough marshes stays relatively intact as it moves down the estuary (Monsen 2003). Delta smelt diets are largely comprised of zooplankton (Delta smelt model p. 5), especially larval stages of specific copepods. Food is potentially an important limiting factor for Delta smelt but its effect cannot be readily separated from water temperature (Norbriga and Herbold, 2008 pg. 8).

Magnitude = 3
Magnitude is higher than other species because Delta smelt are planktivorous.

Certainty = 2
It is uncertain whether the increased production associated with the action will be reduced by *Corbicula.*

P5b. Longfin Smelt Scenarios 1 and 2

Marsh production of phytoplankton is high in Liberty Island (Lehman et al. 2007); Phytoplankton supports the delta food web (Sobzack et al. 2002; Mueller-Solger et al. 2002). Production from lower Yolo Bypass, including Liberty and Cache slough marshes, stays relatively intact as it moves down the estuary (Monsen 2003). Longfin Smelt Model (Rosenfield, 2008 - pg 15) notes that early stage longfin smelt juveniles probably rely on *Eurytemora affinis* as a prey item during April and May with other copepods becoming important later in the year. Food limitation is considered a stressor on juveniles and sub adults (Rosenfield, 2008 Figure 4).

Magnitude = 3
Magnitude is higher than other species because longfin smelt are planktivorous.

Certainty = 2
It is uncertain whether the increased production associated with the action will be reduced by *Corbicula.*

P5c. Splittail Scenarios 1 and 2

Marsh production of phytoplankton is high in Liberty Island (Lehman et al. 2007); Phytoplankton supports the delta food web (Sobzack et al. 2002; Mueller-Solger et al. 2002). Production from lower Yolo Bypass, including Liberty and Cache slough marshes, stays relatively intact as it moves down the estuary (Monsen 2003). According to the Splittail Model (Kratville, 2008), larval splittail up to 15mm feed heavily on zooplankton, primarily made up of cladocerans. Chironomid larvae begin to dominate the diet after 15mm in length has been achieved (Feyrer et al. 2007). Moyle et al. (2004)

notes that growth rates, especially in the first year or two of life, may be strongly dependent on availability of high quality food, as suggested by changes in growth rate following the invasion of the overbite clam in the 1980s and by the collapse of *Neomysis* populations upon which splittail historically specialized (Feyrer et al. 2003).

Magnitude = 2
Food availability is not identified as key stressor in the Splittail Model.

Certainty = 2
It is uncertain whether the increased production associated with the action will be reduced by *Corbicula.*

P5d. Green and White Sturgeon Scenario 1 and 2

Marsh production of phytoplankton is high in Liberty Island (Lehman et al. 2007); Phytoplankton supports the delta food web (Sobzack et al. 2002; Mueller-Solger et al. 2002). Production from lower Yolo Bypass, including Liberty and Cache slough marshes, stays relatively intact as it moves down the estuary (Monsen 2003). The Draft White Sturgeon Model (Israel et. al., 2009) indicates nothing is known about the diets of white sturgeon larvae in the wild, although laboratory studies suggested that they consist of benthos, periphyton, and possibly pelagic fry and zooplankton (Brannon et al. 1984, Buddington and Christofferson 1985). Juvenile white sturgeon also may consume tube dwelling amphipods, mysids (*Neomysis spp*), isopods, benthic invertebrates, and fish eggs or fry, including those of other sturgeon (Brannon et al. 1987, PSMFC 1992). The Draft Green Sturgeon Model (Israel and Klimley, 2008 - page 9) indicates that no studies have been undertaken of food resources for larval green sturgeon.

Magnitude =2
There is limited evidence that sturgeon will benefit from this additional food resource.

Certainty = 2
Few studies have been conducted to support juvenile sturgeon feeding. It is uncertain whether the increased production associated with the action will be reduced by *Corbicula.*

P5e. Steelhead Scenario 1 and 2

Marsh production of phytoplankton is high in Liberty Island (Lehman et al. 2007); Phytoplankton supports the delta food web (Sobzack et al. 2002; Mueller-Solger et al. 2002). Production from lower Yolo bypass, including Liberty and Cache slough marshes, stays relatively intact as it moves down the estuary (Monsen 2003). Steelhead feeding strategies and dietary preferences are similar to those of Chinook salmon (Williams and Rosenfield, In preparation p.38). Fish in the wild are expected to be food-limited (Moyle and Cech 2004). Marshes produce aquatic insects; increased flows will export these resources downstream. Steelhead feed mostly on drifting aquatic organisms, terrestrial insects, and bottom dwelling organisms (Moyle et al. 2004).

Magnitude = 2
Marshes produce aquatic insects; increased flows will export these resources downstream. Steelhead feed mostly on drifting aquatic organisms, terrestrial insects, and bottom dwelling organisms.

Certainty = 2
It is uncertain whether the increased production will be consumed by *Cobicula* and thus be unavailable to sturgeon downstream of Yolo.

P5f. Chinook Salmon Scenario 1 and 2

Marsh production of phytoplankton is high in Liberty Island (Lehman et al. 2007); Phytoplankton supports the delta food web (Sobzack et al. 2002; Mueller-Solger et al. 2002). Production from lower Yolo bypass, including Liberty and Cache slough marshes, stays relatively intact as it moves down the estuary (Monsen 2003). Chinook salmon in the wild are expected to be food-limited (Moyle and Cech 2004).

Magnitude = 2
See above

Certainty = 2
It is uncertain whether the increased production will be consumed by *Cobicula* and thus be unavailable to salmon downstream of Yolo.

Outcome P6: Reduce losses due to stranding, illegal harvest and blocked/delayed passage for Chinook salmon, steelhead, green/white sturgeon

P6a. Green and White Sturgeon Scenario 1 and 2

Adult passage of white and green sturgeon is likely constrained in the Yolo Bypass (Harrell and Sommer 2003). Current configuration of Fremont and Sacramento weirs create stranding and poaching problems for white and green sturgeon (Sommer et al. 2005, (Israel et. al., 2009 pg 20), (Israel and Klimley, 2008 page 18); hence efforts to improve passage and redesign weirs will reduce poaching and stranding.

Magnitude = 4
Blocked passage (and resulting legal and illegal harvest) is substantial; loss of spawners is particularly harmful to the populations. Frequent poaching has been well-documented by the Department of Fish and Game.

Certainty = 4
Studies within Yolo have identified the problem (DFG Unpublished Data, Harrell and Sommer 2003; Harrell et al. in prep).

P6b. Steelhead Scenarios 1 and 2

Adult passage of salmon (and steelhead) is likely constrained in the Yolo Bypass (Harrell and Sommer 2003). Current Fremont and Sacramento weirs create stranding problems for salmon (Sommer et al. 2005); hence efforts to improve passage and redesign weirs will reduce poaching and stranding.

Magnitude = 4
Blocked passage is more of a problem than stranding.

Certainty = 3
Studies within Yolo have identified the stranding problem (DFG Unpublished Data, Harrell and Sommer 2003; Harrell et al. in prep). But it is less well documented for steelhead due to relatively low catch of adults.

P6c. All Races Chinook Salmon Scenarios 1 and 2

Adult passage of salmon is likely constrained in the Yolo Bypass (Harrell and Sommer 2003). Current Fremont and Sacramento weirs create stranding problems for salmon (Sommer et al. 2005); hence efforts to improve passage and redesign weirs will reduce poaching and stranding. Williams (2006) indicates that water flowing through the Yolo Bypass attracts migrating adult salmon into this seasonally flooded wetland; however, the Fremont Weir, at the top of the Bypass does not allow salmon passage. This barrier represents either a serious delay to spawning; or a literal "dead end" (Williams and Rosenfield, In preparation page 55).

Magnitude = 4
A serious delay in salmon spawning has been documented. Blocked passage involved an extensive (~100 mile) increase in passage.

Certainty = 3 to 4
Studies within Yolo have identified the problem (DFG Unpublished Data, Harrell and Sommer 2003; Harrell et al. in prep). The certainty is lower for spring and winter-run salmon because of lower numbers and lower catch rates in sampling.

Outcome P7: Increase delivery of readily suspendable sediments to north Delta and improved Delta smelt habitats

<u>Scenario 1:</u>
Sedimentation Model (Schoellhamer et. al., 2007 - page 9) describes Yolo Bypass as the second largest source of sediment for the Delta. Lehman et al. (2008) also found that the concentration of suspended solids were higher in the Yolo Bypass than in the Sacramento River.

The Delta smelt Model (Norbriga and Herbold, 2008 – pages 4-5 and 11) shows that Delta smelt spawn in the Cache Slough region of the northern Delta and that larval Delta smelt have an improved ability to see prey in water with enhanced turbidity. There is an additional hypothesis that Delta smelt use turbidity to conceal themselves from predators (Norbriga and Herbold, 2008 - page 7).

<u>Scenario 2:</u>
Sedimentation Model (Schoellhamer et. al., 2007 - pages 6 and 10) shows that sediment transport is flow dependant, also Floodplain Model (Opperman, 2008 - page 10) states

that floodplain benefits are proportional to the spatial extent of floodplains; however, given the relatively small difference in flow and inundation area between the two scenarios, it seems likely the benefits of enhanced turbidity provided under scenario 1 would be similar to scenario 2.

Magnitude = 3
Increase in quality and quantity of larval/juvenile Delta smelt habitat based on substantial increase in frequency and duration of inundation and sediment delivery over current conditions.

Certainty = 3
There is a high understanding but with many variables.

Outcome P8: Increase survival of out migrating juveniles (steelhead and Chinook salmon) by providing migration route with lower predation and entrainment (at North and South Delta diversions) risk.

Passage through the bypass and reentering the Sacramento River near Rio Vista avoids possible migratory routes into the central delta. As floodwaters recede from the Yolo Bypass, the juveniles exit to the south, ultimately into the toe drain which provides the only means of passage into the delta (Sommer et al. 2001, 2005). Thus Yolo Bypass when inundated during winter/spring months will provide additional migratory paths for emigrating Chinook salmon and steelhead juveniles above the location of the proposed peripheral canal. This would also mitigate entrainment exposure at this new facility

Newman (2008) showed that survival rates were 66% higher for juvenile salmon released in the lower mainstem of Sacramento River (near Ryde) than for those released in central delta (Georgiana Slough). Vogel (2008) conducted an acoustical tag study in 2006 and 2007 which showed there were reach specific characteristics for loss rates on juvenile salmon released in Sacramento River near Old Town. Preliminary results showed that loss in Delta Cross Channel and Georgiana Slough was at least 2 times greater then on main stem or Sutter and Steamboat Slough. This effect is likely similar for steelhead although few specific data are available.

Note: Evaluation assumes that new North Delta facilities would increase predation risks.

Magnitude = 3-4
This action provides an additional migratory route that currently exists but increases the frequency and duration of its availability. The action will benefit upper Sacramento migrating juveniles when functioning properly on a biennial basis. Fish will be able to avoid predators that will likely congregate in the vicinity of the North Deltas diversion as well as being able to benefit from the food resources/habitat provided by the bypass.

Certainty = 3 for Chinook salmon, 2 for Steelhead
Migratory routes for salmon in the north delta have been shown through several studies to have higher survival rates then those in the central Delta (Vogel 2008, Newman 2008) Little data available for steelhead – reduced certainty is based on the assumption that they respond the same as Chinook salmon.

Potential Negative Ecological Outcome(s)

Outcome N1: Increased MeHg and impact on covered species (on floodplain and downstream)

Proximity to mining-related mercury loading sources is an important factor affecting methyl mercury (MeHg) exposure and bioaccumulation in fish in the Bay-Delta (Alpers et al. 2008, page 23). The Yolo Bypass is downstream of mining-related mercury sources in the Cache Creek and Putah Creek watersheds.

Inundation frequency is another important factor affecting MeHg production. Habitats with the highest levels of MeHg production, concentration and exposure to biota are those with periodic flooding events separated by sufficient time to allow complete drying, such as the seasonal floodplains that would be enhanced in this project (Alpers et al. 2008, pages 15 and 17), also cites Marvin-DiPasquale et al. (2007).

The project would result in inundation of larger areas of floodplain, for longer periods of time, and in more years than the baseline weir height condition. These changes from baseline may result in higher MeHg concentrations in the Yolo Bypass aquatic food chain as conditions are improved for development of the phytoplankton and zooplankton communities. The single largest concentration jump in food web MeHg bioaccumulation occurs between aqueous MeHg and algal cells or phytoplankton (Alpers et. al., 2008, page 19). The frequency and magnitude of export of MeHg downstream would increase over baseline, resulting in increased exposure to covered fish species downstream in the Delta.

The linkage of seasonal flooding to MeHg production and subsequent bioaccumulation of MeHg in fish and their prey is well documented. Fish tend to accumulate greater burdens and concentrations of MeHg over time, so older individuals typically have higher body burdens and higher absolute concentrations of MeHg than younger ones (Wiener and Spry 1996). Effects of this bioaccumulation on covered fish species are more uncertain, due to lack of studies of toxicological effects of MeHg on covered species, uncertainty about sensitivity of covered species relative to species that have been studied, and the subtle nature of the behavioral effects that are among the most sensitive endpoints for MeHg toxicity and are difficult to detect. Some of the sub-lethal effects related to Hg in fish include: altered hormone expression, reduced spawning success, reduced reproductive output, reduced gonadosomatic indices and testicular atrophy, liver necrosis, and altered predator avoidance behavior (Alpers et. al., 2008, pg 31).

The Mercury Model (Alpers et. al., 2008, pg 31) indicates that an Hg concentration of 0.20 ppm, (wet-wt) in fish tissue is a threshold for the onset of adverse effects in fish (Beckvar et al. 2005). Concentrations of Hg in some fish from some parts of the Yolo Bypass may currently exceed this effect concentration. For example, Ackerman et al. (2008) found average Hg concentrations of 1.76 ppm, dry-wt (approximately 0.35 ppm wet-wt, assuming wet-weight concentrations are approximately 20% of dry-weight concentrations) in caged mosquitofish placed at the outlets of white rice fields and exposed for 60 days in the Yolo Bypass. Similarly, Hg concentrations in wild mosquitofish and wild silverside were 1.09 ppm, dry-weight (approximately 0.218 ppm, wet-weight) and 1.25 ppm, dry-weight (approximately 0.25 ppm, wet-weight), respectively, at white rice outlets. Mercury concentrations were lower in fish sampled at the inlets to rice fields and in permanent wetlands in the Yolo Bypass (Ackerman et al. 2008). Previous studies focused on canals and permanent ponds in the Yolo Bypass found Hg concentrations in small fish were below effects concentrations (Slotton et al. 2002, Davis et al. 2007). A recent, unpublished study of MeHg bioaccumulation in juvenile Chinook salmon found that the rate of MeHg bioaccumulation was higher in the Yolo Bypass than the mainstream Sacramento River, but the concentrations of MeHg in the juvenile salmon remained below the threshold for toxic effects (Henery et al., in review).

Magnitude = 1-2
The proposed action could result in increases in MeHg production and bioaccumulation that would cause fish tissue Hg concentrations to exceed effects levels for sub-lethal impacts to fish health. The magnitude of this negative outcome would vary depending on species and life-stage due to differences in exposure (a function of distribution and diet) and sensitivity. Acute toxicity (i.e., death from mercury poisoning) would be very unlikely to occur in any covered fish species. Chronic toxicity manifested as adverse behavioral or physiological effects may occur in some individual fish of covered species that spawn in the Yolo Bypass (e.g., splittail), rear in the Bypass (e.g., splittail, salmon and steelhead) or rear immediately downstream in the Cache Slough area (Delta smelt). The risk of chronic toxicity from Hg methylation and bioaccumulation in the Yolo Bypass would be minimal in species that do not use the Yolo Bypass or Cache Slough area for spawning or rearing (e.g., sturgeon and longfin smelt).

Certainty = 2
The linkage of seasonal flooding to MeHg production and subsequent bioaccumulation of MeHg in fish and their prey is well documented. However, potential effects of this bioaccumulation on covered fish species are less clear because of lack of information on the sensitivity of these species to MeHg and uncertainty in predicting the degree to which MeHg concentrations in fish would increase as a result of the action. Two of the most relevant studies of MeHg bioaccumulation in fish in the Yolo Bypass are recent studies that have not yet been published.

Outcome N2: Increased resuspension/mobilization and export of toxic compounds w/impact on covered species

A wide variety of crops are grown in the Yolo Bypass and surrounding areas, and many different pesticides are used on these crops (Smalling et al. 2007) including, but not limited to, pyrethroids (Werner et al. 2008, pg 3). Pesticides were detected in water samples collected in the inflows to the Yolo Bypass and within the Bypass in 2004 (Smalling et al. 2007). Pesticides detected in water samples included herbicides, especially hexazinone and simazine, and insecticides, especially diazinon (Smalling et al. 2007). The concentrations of dissolved pesticides were below levels known to cause acute or chronic toxicity to fish; however, some of the herbicide concentrations (e.g., hexazinone) were high enough to potentially adversely affect primary productivity (Smalling et al. 2007).

Sediments and soils from the Bypass and its inflows contained other pesticides, such as pyrethroids and DDTs (Smalling et al. 2007). The concentrations of pesticides associated with sediments were below levels known to cause acute toxicity to fish; however, the concentration of at least one pyrethroid (lambda-cyhalothrin) in suspended sediment was high enough to adversely affect benthic macroinvertebrates that fish rely on for food (Smalling et al. 2007).

Increased seasonal flooding of agricultural lands may mobilize pyrethroids and other pesticides from soils and increase exposure to covered fish species in the Yolo Bypass and downstream. One of the goals of the project is to facilitate spawning by splittail and rearing by splittail and other species. Pyrethroids can be toxic to fish, especially to early life stages (Werner et al. 2008, pg 16). Teh et al. (2005) showed sub-lethal effects and delayed mortality to larval splittail exposed to orchard storm water runoff that contained a pyrethroid (esfenvalerate) and an organophosphate (diazinon). These fish showed higher mortality rates and slowed growth even after a three month recovery period. Combinations of low concentration toxic chemicals (Pyrethroids, Organophosphates, Organochlorines, etc.) which may have low effects on fish directly can have significant negative impacts on Chironomids (Lydy and Austin 2004), and other invertebrates (Hunt et al. 1999, Hunt et al. 2003, Amweg et al. 2005, Weston et al. 2008). Pyrethroid concentrations would be expected to peak during the winter/spring storm season and after peak agricultural application in the summer and fall (Werner et al. 2008, pg 2). Late-winter and spring are also the times splittail would use the enhanced floodplain habitat to spawn (Kratville**,** 2008, pg 1).

There are critical data gaps on pyrethroids and other pesticides that make it difficult to evaluate risk to covered fish (Werner et al. 2008, pg 32; Werner et. al., 2008, pg 25). In general, little is known about the toxic effects of contaminants known to be present in the Delta on resident Delta species, and even less is known about the sub lethal effects of contaminants (Werner et. al., 2008, pg 25). The potential effects of complex mixtures of low level pesticides, such as those detected in the Yolo Bypass by Smalling et al. (2007) are also poorly understood. Due to additive and synergistic effects, mixtures of pesticides that have been commonly reported in salmon habitats may pose a more important challenge for species recovery than previously anticipated (Laetz et al. 2009).

Magnitude = 1-2
The highest concentrations of dissolved pesticides enter the Bypass as a pulse during the first high-flow event following winter pesticide application (Smalling et al. 2007). Late-winter and spring are also the times splittail would use the enhanced floodplain habitat to spawn (Splittail model, pg 1). The magnitude of potential adverse effects to splittail and other covered fish would vary depending on species and life-stage due to differences in distribution and sensitivity. Species that spawn in the Yolo Bypass (e.g., splittail) or rear in the Bypass (e.g., splittail, salmon and steelhead) or immediately downstream in the Cache Slough area (Delta smelt) would be at greater risk of toxicity than species that do not use these areas for spawning or rearing (e.g., sturgeon and long-fin smelt).

Certainty = 2
There are critical data gaps on pyrethroids and other pesticides that make it difficult to evaluate risk to covered fish (Werner and Oram, 2008 pg 32; Werner et. al., 2008, pg 25). The potential effects of complex mixtures of low level pesticides, such as those detected in the Yolo Bypass by Smalling et al. (2007) are also poorly understood.

Outcome N3: Increased stranding of covered species

N3a.1 & N3a.2 Splittail adult and juvenile Scenarios 1 and 2

Connectivity problems can strand splittail (Opperman, 2008 pg 27 citing Sommer et al. 2005). The approach specified for this action includes grading which may reduce this risk, however the specifics are not known.

Magnitude = 1
Densities of splittail are low in isolated ponds in the Yolo Bypass (DWR unpublished data; Feyrer et al. 2004)

Certainty = 4
Sommer et al (2005) showed that there is relatively little ponded area following floodplain inundation. Low level of ponding reduces stranding.

N3b. Green/white Sturgeon adult/juvenile Scenarios 1 and 2

Current Fremont and Sacramento weirs create stranding and passage problems for white sturgeon and green sturgeon, (Sommer et al. 2005; Harrell and Sommer 2003). Observations indicate substantial legal/illegal harvest resulting from blocked passage.

Poaching may be a major issue for white sturgeon (White Sturgeon model pg 20)

Magnitude = 1
Blocked passage will be minimal behind the modified weir as it will be designed to improve passage, and grading will limit stranding on the floodplain for adults

Certainty = 4
The assumption is that the problem of blocked passage will be resolved by the modifications to the weir.

N3c. Steelhead Scenarios 1 and 2

Adult passage of white sturgeon, green sturgeon, splittail, steelhead and salmon is likely constrained in the Yolo Bypass (Harrell and Sommer 2003). Current Fremont and Sacramento weirs create stranding problems for white sturgeon and green sturgeon (Sommer et al. 2005); hence efforts to improve passage and redesign weirs will reduce stranding (Harrell and Sommer 2003).

Magnitude = 1 (adults), 2 (juveniles)
Blocked passage will be minimal behind the modified weir as it will be designed to improve passage, and grading will limit stranding on the floodplain for adults. Juveniles are more susceptible to stranding thus the effect is greater.

Certainty = 4
Evidence is good that efficient drainage results in low stranding (Sommer et al. 2005); hence additional grading should prevent stranding.

N3d. Chinook Salmon Scenarios 1 and 2

Most juvenile Chinook salmon can exit the existing floodplain configuration (Sommer et al. 2005). Adult passage of salmon is likely constrained in the Yolo Bypass (Harrell and Sommer 2003). Current Fremont and Sacramento weirs create stranding problems for salmonids (Sommer et al. 2005); hence efforts to improve passage and redesign weirs will reduce stranding. (Harrell and Sommer 2003)

Assumption is that is operable gates/ladders would be operable at all times to allow for year-round passage.

Magnitude = 1 (adults), 2 (juveniles)
Stranding is minimal on the Yolo Bypass now. This project will further reduce stranding behind the weir because the new weir design will improve passage and the floodplain will be graded. There is some possibility of reduced passage if migrating salmon encounter the modified structure when it is closed or there is insufficient flow to allow passage.

Certainty = 4
Evidence is good that efficient drainage results in low stranding (Sommer et al. 2005) hence additional grading should prevent stranding.

Outcome N4: Reduced flows in Sacramento River and distributaries to support successful outmigration (Scenarios 1 and 2).

Juvenile salmon survival is dependent on sufficient river flow and water quality (NMFS 2008). Diversions for habitat restoration reduce flow in the mainstem Sacramento River in the same way as diversions for water use. As much as 60 percent of the natural historical inflow to Central Valley watersheds and the Delta have been diverted. Depleted flows have contributed to higher temperatures, lower DO levels, and decreased recruitment of gravel and large woody debris (LWD). More uniform flows year round have resulted in diminished natural channel formation, altered food web processes, and slower regeneration of riparian vegetation (NMFS 2008)

Direct relationships exist between water temperature, water flow, and juvenile salmonid survival (Brandes and McLain 2001).

Elevated water temperatures in the Sacramento River have limited the survival of young salmon in those waters. Juvenile fall-run Chinook salmon survival in the Sacramento River is also directly related to June streamflow and June and July Delta outflow (Dettman et al. 1987).

Magnitude = 2
The effect of this action is limited to the diversion of 2000-4000 cfs at a time when the river flow is approximately 30,000 cfs. It is difficult to evaluate the net negative effect of this action via this outcome as water diverted through the bypass is presumably going to remain in the system to support another migratory route. The action will only affect the Sacramento River between the Fremont Weir and it’s confluence with Cache slough. There is no spawning habitat in this reach and rearing habitat is limited – hence its

primary benefit for emigrating salmonids is as a migration corridor. Since the river is constrained in a well-defined channel by levees, reduction in flow should not affect its' ability to pass fish downstream to any great degree.

Certainty = 3
The relationship between river flow and salmon survival has been well documented (Newman and Rice 2002, Brandes and McLain 2001).

Outcome N5: Increased habitat for predators/competitors to covered species.

N5a. Delta smelt

Evidence from Yolo and Cosumnes of non-natives taking advantage of floodplain (ref Sommer et al 2004, Moyle et al 2006). Opperman (2008 page 10) discusses sources of invasive species.

Delta smelt model (semi final with note – do not cite) – notes that DS are adapted to sustain high mortality during the adult stage (Winemiller and Rose 1992). Predation is one of two primary factors for population dynamics (Figure 7). The most likely ancestral Delta smelt predators would have been piscivorous birds, salmonid fishes, and, secondarily, longfin smelt as a larval predator and predatory freshwater fishes like Sacramento pikeminnow, Sacramento perch, (Moyle 2002). All of the above species could be expected to inhabit the proposed inundated floodplain habitat. Though predation on the floodplain is not specifically addressed in the Delta smelt model, the evaluation team thought predation of Delta smelt on the lower portion of the bypass was significant. Wetlands that flood only in spring and winter (as does the Yolo Bypass) provide substantial benefits for larval and juvenile native fishes, but only limited benefits (as compared to perennially flooded habitats) for non-native larval fish that were spawned later in the year (Grimaldo et al. 2004).

Magnitude = 2
Adaptation to high mortality and the occurrence of many native predators implies that an increased predation rate is not substantial.

Certainty = 3
It is likely the introduction of striped bass (*Morone saxatilis*) in the 1870s greatly increased predation pressure on Delta smelt by placing a resident low-salinity zone predator where there was not one historically (Moyle 2002). Striped bass are likely to inhabit the area downstream of the bypass increasing the certainty of this predation effect.

N5b. Longfin smelt

Predation is a source of direct mortality to eggs and larvae (Rosenfield, 2008). Some fish species (e.g. suckers, splittail, and sturgeon) may feed on longfin smelt eggs. Larval longfin smelt are not strong swimmers and are thus highly vulnerable to predation (Wang 1986). Striped bass and inland silverside are probably major predators on longfin smelt larvae. Terns, gulls, and cormorants may also prey on this life stage. Predation and competition are characterized as medium importance and medium understanding

(Rosenfield, 2008, Figure 5), but floodplain predation and competition are not specifically addressed.

Magnitude = 2
Predation and competition are characterized as medium importance and medium understanding.

Certainty = 3
There is good evidence that predation is an important stressor for juvenile longfin smelt.

N5c. Splittail

Splittail model - Bird predation appears limited until water recedes and floodplains begin to isolate from main channels at which point fish are exposed to wading birds (Moyle 2004). Predation by non native predators in floodplain habitats is characterized as medium with high understanding (Figure 5 and Table 3).

Magnitude = 2
The action will increase the availability of floodplain habitat to splittail but will not influence the presence of the avian predators

Certainty = 4
Good evidence of this predation impact from within the system.

N5d. Green and white sturgeon

The White Sturgeon Model (Israel et. al., 2009, Figure 7) and Green Sturgeon Model (Israel et. al., 2009, Figure 2) both indicate probable distribution of sturgeon in this reach. Due to the benthic nature of green and white sturgeon and the timing of floodplain inundation they are not expected to be found on the floodplain (Josh Israel pers comm.). Juvenile sturgeon are subject to greater predation effects, however, there is no evidence of juvenile sturgeon use of floodplains. Sturgeon caught in Yolo Bypass are adults (Harrell and Sommer 2003).

Magnitude = 1
Juvenile sturgeon are subject to greater predation effects, however, there is no evidence of juvenile sturgeon use of floodplains.

Certainty = 3
Little documentation of effect on juveniles.

N5e. Steelhead and Chinook salmon

The Chinook Salmon Model (Williams and Rosenfield, In preparation) and Steelhead Model (Williams and Rosenfield, In preparation) both indicate non-native predation and competition with invasive species and hatchery produced salmonids is of medium importance in rearing and emigration estuarine habitats, including floodplain (Opperman, 2008, Figure 2a).

Magnitude = 2 (see text above)

Certainty = 4 (see text above)

Important Gaps in Information and/or Understanding

Data Needs

The number of salmonids and sturgeon attracted into the Yolo Bypass and their ultimate fate (death, loss of spawning opportunity, eventual return to the Sacramento River).

Research Needs

- Major gaps – rearing habitat for steelhead? Rearing habitat for juvenile sturgeon?
- Hg accumulation in fish has been documented, but does not indicate there is an effect on fish.
- Degree of contaminants affects on POD.
- Degree of sediment settling on floodplains.
- Degree of predation/competition within floodplains on native covered fish species by non-native fish species.
- Better diet information is needed for floodplain use of steelhead, green and white sturgeon;
- More info is needed about relative importance of food to population level effects for all of the species.
- Transport studies are needed to evaluate the footprint of food transport from floodplains.
- Timing duration of rearing for steelhead, green and white sturgeon.
- Additional information is needed to help quantify the contribution of suspended sediment that Yolo Bypass provides to the north Delta region. Understanding the duration of the suspended sediment benefit would be helpful. Is the increased sediment load only part of a first flush? Can the flows and inundation areas described in scenario 1 and 2 result in the anticipated turbidity benefit?
- Telemetry study of salmonid and sturgeon to study movement of these species in the Yolo Bypass
- Assess Reversibility and Opportunity for Learning
- Better understanding of physiological toxicity affects of in situ native fish

Reversibility

Yes/Easy: As the action includes operable gates the action would not necessarily have to be implemented on the proposed schedule or at all if adverse consequences made its reversal necessary. Grading aspects of the action could theoretically be reversed but this would be more challenging and is less likely to occur.

Opportunity for Learning

High: The operable gates would allow the flooding timing and duration of the bypass to be experimentally manipulated allowing the exploration of specific relationships between floodplain inundation and covered species.

APPENDIX A....23

Action: WOCM 3a/3b: Create new flood bypass east of SDWSC.

Evaluation Team: Floodplain Workgroup

Campbell Ingram (chair), Denise Reed (coach), Carie Battistone (notetaker), Eric Ginney, Ted Sommers, Rosalie Del Rosario, Dennis McEwan, Bill Harrell, Dan Welsh, Yvette Redler, and Vance Russell.

Date of Last Revision: February 21, 2009

Action Description and Clarifying Assumptions

Create a new flood bypass that provides up to 3800 acres (at 3000 cfs) of inundated floodplain habitat adjacent to and east of the Sacramento Deep Water Ship Channel (DWSC) and that inundates in ~50% of years from December 1 to May 15 for 45 consecutive days with a spill intermission of no more than 7 days.

Assume:

1. New bypass empties into Prospect Island with connectivity into Miner's Slough to provide tidal connectivity.
2. Operation is independent of Yolo.
3. Water depth ~1m (possibly though channelization/contouring), low velocity.

Approach

1. Lower 500 linear feet of the west levee on the Sacramento River located upstream of Freeport near the Pocket area (see Attachment) to an elevation of 9 feet (NAVD88).
2. Install an operable bypass diversion structure where the levee was lowered. The new diversion structure would include a fish passage facility designed to effectively allow for the passage of adult salmonids and sturgeon.
3. Construct a new levee adjacent to and east of the DWSC floodplain to confine bypass flows between the DWSC and the new levee. The resulting floodplain would be approximately 2000' wide along the distance of the floodplain.
4. Modify landform to prevent stranding of covered fish species.
5. Remove levees between Miner Slough and Prospect Island to provide for tidal connectivity at the south end of the floodplain.

Intended Outcomes as Stated in Conservation Measure

Positive Outcomes:

P1 (intended): Create new spawning habitat for splittail

P2: Create new juvenile rearing habitat for CS, splittail, steelhead, G/W sturgeon (esp. for American River CS and steelhead)

P3: Increase production of food for rearing of CS, splittail, steelhead, (onsite = seasonal floodplain only)

P4: Increase export of DOM, POM and organisms from seasonal floodplain to provide food in Delta for DS, LS, CS, splittail, steelhead, G/W sturgeon

P5: Increase transport of OC and organisms from Prospect/Miner Slough tidal marshes to support Delta foodweb for DS, LS, CS, splittail, steelhead, G/W sturgeon

P6. Increase in upstream migration opportunity for CS and steelhead

P7: Increase delivery of readily suspendable sediments to Prospect Is and improved DS habitats
P8: Increase survival of out migrating juveniles by providing mitigation route with lower predation and entrainment (at North and South Delta diversions) risk.

Negative Outcomes:
N1: Increased MeHg and impact on covered species (on floodplain and downstream)
N2: Increased resuspension/mobilization and export of toxic compounds w/impact on covered species (consider sensitivity to changes in land use - none stated in assumptions)
N3: Increased stranding of covered species (consider grading proposed in the approach)
N4: Reduced flows in Sacramento River and distributaries to support successful outmigration.
N5: Increased habitat for non-native predators/competitors to covered species
N6: Decrease in turbidity downstream of Yolo and reduction in habitat for Delta smelt and longfin smelt

Conceptual Model Information Regarding Intended Outcomes

The basic drivers and outcomes are described in the DRERIP conceptual models.

Assumptions

Provided in BDCP Conservation Measure
Not provided

Added by Evaluation Team
None identified

Problem(s) with Action as Written:

Needs a map

Scale of Action:

Large

Rationale:
Extent of inundated habitat (3800 acres).

Evaluation Summary

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in Appendix A. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes following this section.

Relation to Existing Conditions:

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

YES - Yolo Bypass information is useful.

Nature of Change: None provided.

Potential Positive Ecological Outcome(s)

Outcome P1: Create new spawning habitat for splittail

P1a. Splittail

Floodplain model page 25 and splittail model pages 9 and 12 describe how additional floodplain habitat supports splittail spawning.

Magnitude = 4

Certainty = 4

Outcome P2: Create new juvenile rearing habitat for splittail, green/white sturgeon steelhead and Chinook salmon

P2a Splittail

Same information for flooding for Chinook salmon. Table 1 page 3 in Splittail model indicates juveniles use floodplain Feb-May. Cosumnes publications (Crain et al 2004 conf proc.). Moyle et al 2004. SFEWS. Sommer et al. 1997, 2001, 2007. Moyle et. al. 2004. Feyrer 2006, 2007.

Magnitude = 4

Certainty = 4

P2b. Green/white sturgeon

Same information for flooding for CS. No evidence of juvenile use of floodplains. Adult catch in Yolo are adults (Harrell and Sommer 2003). Mechanism described for Chinook salmon is assumed to apply to White sturgeon (Sommer et al 2005 and Floodplain Model).

Mechanism described for green sturgeon is assumed to apply to white sturgeon (Sommer et al 2005 and Floodplain Model).

Magnitude = 1

Certainty = 2

P2c. Steelhead

Same info for flooding for Chinook salmon. They are there at the time (McEwan 2001) (life stage table – Figure 3). Emigrating Jan-August, peak in Jan-May. Based on Sacramento River information. Mossdale trawl data (Rosalie provided – FWS 2007) shows more fish occur. Floodplain (page 27) says no information on steelhead use of floodplain. Steelhead model (Fig 2 of steelhead section in salmonid model, p155) shows floodplain use. Williams (2006), McEwan (2001) and Moyle (2002) support presence.

Page15-16 of salmon model shows estuarine habitat – may show import for lower reach. Steelhead have been caught on floodplain in Yolo. Some reference in Williams 2006 – chapter 9, page 174. Check Cosumnes.

Magnitude = 3

Certainty = 3

P2d. Chinook salmon

1. Chinook salmon juveniles are present in the area during the proposed floodplain inundation period of late winter and spring.

- Knights Landing data indicates:
  Winter Run Juvenile peaks Nov –Feb
  Fall run peaks Jan – Feb then Apr -May
  Late Fall run peaks on Dec and April
  Spring Run peaks are Dec-Jan and March – April (CDFG rotary screw trap)

2. Chinook salmon juveniles would use the floodplain to rear. The restored floodplain would create rearing habitat for fry/parr that enter the Delta in the winter, coincident with inundation of the floodplain. These fry would be able to feed and grow in the floodplain, and their larger size would increase the likelihood of survival in the ocean.

- "Recent work shows that the bypasses do indeed provide habitat for juvenile Chinook, that they grow well there, and that most avoid stranding". (Williams 2006)
- Juvenile salmon collected from the inundated Yolo Bypass were substantially larger and grew more rapidly than juveniles collected from Sac River (Sommer et al. 2001).

Fall-run Chinook fry (<70mm) rear primarily in the upper fresh-water delta…peak fry rearing is (Feb-March) young fry appear to be most abundant in shallow water/shoreline habitat…rearing occurs for two months or more. (Kjelson et al 1982)

1. Floodplains no longer exist along the lower San Joaquin River, but fall-run Chinook salmon would likely use the restored floodplains, as they have been documented to rear in Yolo Bypass floodplain along the lower Sacramento River.

    - CV Chinook salmon may have relied extensively on floodplain in the past as historically much of the central valley was floodplain habitat (Hunter et al 1999)
    - Williams (2006 article 2) confirmed fall Chinook emigration if Feb-Mar on SJ. Floodplain model (Fig 7 and assoc text) identifies that floodplains provide habitat for CS.
    - Sommer et al (2005) reported extensive use of Yolo and Sutter bypasses by fall-run.
    - Moyle et al (2007) reported use of Cosumnes River floodplain

    Limited data on San Joaquin floodplain (none in Floodplain model). No reason to suggest they should behave different from other systems.

    Magnitude = 3-4
    Creates floodplain habitat and migratory route that is not currently available in this area. Would be accessible once every two years to Sacramento and American river salmon.

    Certainty = 3-4
    There is high certainty that juvenile salmon are in the vicinity, and inference juveniles would rear in restored floodplain based on documented rearing in the Yolo Bypass and the restored Cosumnes River floodplain.

Outcome P3: Increase production of food for rearing of Chinook salmon, green/white sturgeon, splittail, steelhead, (onsite = seasonal floodplain only).

P3a. Splittail

Floodplain Model pages 20-25 describe floodplain food production. Floodplain Model pages 25 and 27 describe utilization and higher survival for splittail on floodplains.

Magnitude = 4
Species is floodplain dependent (Moyle et al. 2004; Sommer et al. 2007)

Certainty = 4

P3b. Green/white sturgeon

Floodplain Model pages 20-25 - a high level of food production on floodplain provides support for magnitude score. No evidence of juvenile use of floodplains. Catch in Yolo are adults (Harrell and Sommer 2003). The mechanism describing CS is assumed to apply to white sturgeon (Sommer et al 2005 and Floodplain Model).

Magnitude = 1

Certainty = 2

P3c. Steelhead

Floodplain Model pages 20-25 - a high level of food production on floodplain provides support for magnitude score. Nothing really in the literature that describes steelhead feeding on floodplains, however, it can be assumed that they are utilizing the same food sources as juvenile salmon, given their life-history similarities. Moyle et al. 2004 states that stream-dwelling RT feed mostly on drifting aquatic organism, terrestrial insects, and bottom dwelling organism which are in abundance on floodplains.

Magnitude =3

Certainty = 2-3

P3d. Chinook Salmon

Floodplain Model pages 20-25 - a high level of food production on floodplain provides support for magnitude score. Floodplain Model pages 27 and 29 describe utilization and higher growth rates for Chinook salmon on floodplains. Chinook salmon likely take advantage of small fishes on the FP (Splittail Model page 8 and Moyle et al. 2004).

Magnitude =3-4

Certainty = -3-4

Outcome P4: Increase export of DOM, POM and organisms from seasonal floodplain to provide food in Delta for Delta smelt, longfin smelt, Chinook salmon, splittail, steelhead, green/white sturgeon.

Floodplain Model page 20 describes the importance of export of food to downstream food webs. All other information under P3 applies to CS, SH, G/W Sturgeon and splittail.

P4a. Delta smelt

DLO Relationship and General Observations:
DS Model page 12 describes the importance of zooplankton; recent studies by Sobzak (2002) indicates that organic carbon can support estuarine food webs: DS rear in area immediately downstream of Yolo Bypass (Sommer et al. in prep – see www.dfg.ca.gov – fall midwater and Kodiak trawl data).

Magnitude = 3
Rear just downstream from Yolo

Certainty = 3

P4b. Longfin Smelt

LF Model page 21 describes the importance of zooplankton: recent studies by Sobzak et al. (2002) indicates that organic carbon can support estuarine food webs.

Magnitude =2
Present in flooding period- but mostly far downstream.

Certainty = -2

P4c. Splittail

Floodplain Model page 20 describes the importance of export of food to downstream food webs. All other information under P3 applies to Chinook salmon, steelhead, green/white sturgeon and splittail.

For CS, SH, G/W Sturgeon and splittail, magnitude and certainty are the same as for P3.

Magnitude =4

Certainty = -4

P4d. Green/white sturgeon

Floodplain Model page 20 describes the importance of export of food to downstream food webs. All other information under P3 applies to Chinook salmon, steelhead, green/white sturgeon and splittail.

For Chinook salmon, steelhead, Green/white sturgeon and splittail, magnitude and certainty are the same as for P3.

Magnitude =1

Certainty = -2

P4e. Steelhead

Floodplain Model page 20 describes the importance of export of food to downstream food webs. All other information under P3 applies to Chinook salmon, steelhead, green/white sturgeon and splittail.

For CS, SH, G/W Sturgeon and splittail, magnitude and certainty are the same as for P3.

Magnitude =2

Certainty = -2

P4f. Chinook salmon

Floodplain Model page 20 describes the importance of export of food to downstream food webs. All other information under P3 applies to Chinook salmon, steelhead, green/white sturgeon and splittail.

For CS, SH, G/W Sturgeon and splittail, magnitude and certainty are the same as for P3.

Magnitude =2

Certainty = -2

Outcome P5: Increase frequency and magnitude of transport of OC and organisms from Cache Slough/Bypass tidal marshes to support Delta foodweb for DS, LS, CS, splittail, steelhead, G/W sturgeon

P5a. Delta smelt

Marsh production of phytoplankton is high in Liberty Island (Lehman et al. 2007); Phytoplankton supports the food web Sobzack et al. 2002; Mueller-Solger et al. 2002). Production from lower Yolo bypass inc. Liberty and Cache slough marshes stays relatively intact as it moves down the estuary (Monsen 2003? PhD thesis, Stanford University). Food is an important limiting factor for all of these species (DS model page 5 and 8;

Magnitude = 3
Higher than others because they are planktivorous

Certainty = 2
Unsure whether the increased production will be eaten by clams**.**

P5b. Longfin Smelt

Marsh production of phytoplankton is high in Liberty Island (Lehman et al. 2007); Phytoplankton supports the food web Sobzack et al. 2002; Mueller-Solger et al. 2002). Production from lower Yolo bypass inc. Liberty and Cache slough marshes stays relatively intact as it moves down the estuary (Monsen 2003? PhD thesis, Stanford University). Food is an important limiting factor for all of these species (DS model page 5 and 8.

Magnitude = 3
Higher than others because they are planktivorous

Certainty = 2
Unsure whether the increased production will be eaten by clams

P5c. Splittail

DLO Relationship and General Observations:
Marsh production of phytoplankton is high in Liberty Island (Lehman et al. 2007); Phytoplankton supports the food web Sobzack et al. 2002; Mueller-Solger et al. 2002). Production from lower Yolo bypass inc. Liberty and Cache slough marshes stays relatively intact as it moves down the estuary (Monsen 2003? PhD thesis, Stanford

University). Food is an important limiting factor for all of these species (Delta Smelt model pages 5 and 8.

Magnitude = 2
Higher than others because they are planktivorous

Certainty = 2
Unsure whether the increased production will be eaten by clams

P5d. Green/white Sturgeon

Marsh production of phytoplankton is high in Liberty Island (Lehman et al. 2007); Phytoplankton supports the food web Sobzack et al. 2002; Mueller-Solger et al. 2002). Production from lower Yolo bypass inc. Liberty and Cache slough marshes stays relatively intact as it moves down the estuary (Monsen 2003? PhD thesis, Stanford University). Food is an important limiting factor for all of these species (DS model page 5 and 8.

Magnitude = 1

Certainty = 2
Unsure whether the increased production will be eaten by clams

P5e. Steelhead

Marsh production of phytoplankton is high in Liberty Island (Lehman et al. 2007); Phytoplankton supports the food web Sobzack et al. 2002; Mueller-Solger et al. 2002). Production from lower Yolo bypass inc. Liberty and Cache slough marshes stays relatively intact as it moves down the estuary (Monsen 2003? PhD thesis, Stanford University). Food is an important limiting factor for all of these species (DS model page 5 and 8.

Magnitude = 2

Certainty = 2
Unsure whether the increased production will be eaten by clams.

P5f. Chinook Salmon

Marsh production of phytoplankton is high in Liberty Island (Lehman et al. 2007); Phytoplankton supports the food web Sobzack et al. 2002; Mueller-Solger et al. 2002). Production from lower Yolo bypass inc. Liberty and Cache slough marshes stays relatively intact as it moves down the estuary (Monsen 2003? PhD thesis, Stanford University). Food is an important limiting factor for all of these species (DS model page 5 and 8.

Magnitude = 2

Certainty = 2
Unsure whether the increased production will be eaten by clams.

Outcome P6: Increase in upstream migration opportunity for CS and steelhead

P6a. Steelhead

Magnitude = 2

Certainty = 2

P6b. Chinook Salmon

Adult Chinook salmon have been observed using the Yolo Bypass as an upstream migration corridor (Harrell and Sommer 2003). However, two passage issues currently exist in Yolo Bypass that make it a risky migratory path for adults:

1. Passage barriers and impediments caused by existing structures that limits access to Sacramento River.
2. False attraction into bypass by tributary

A more natural floodplain environment that coincides with winter flood pulses would benefit the native fish, particularly those with winter and spring spawning and rearing periods. The bypass would provide floodplain-dependent species with an important migration corridor. Seasonal inundation is less important for exotic fishes, which generally use the deeper perennial waters of the bypass and spawn in late spring or summer after the floodplain has drained. (Moyle 2002, Harrell and Sommer 2002).

Magnitude = 2
Blocked passage is more of a problem than stranding

Certainty = 2

Outcome P7: Increase delivery of readily suspendable sediments to north Delta and improved Delta smelt habitats.

Sedimentation model (p. 6 and 10) shows that sediment transport is flow dependant; also Floodplain model (p. 10) states that floodplain benefits are proportional to the spatial extent of floodplains. P. Lehman et al, 2008 also found that the concentration of suspended solids were higher in the Yolo Bypass than in the Sacramento River. Sedimentation model p. 9 describes Yolo Bypass as second largest source of sediment for the Delta. It is logical to assume this bypass would have similar sediment functions as shown in the Yolo Bypass.

The Delta smelt model shows that Delta smelt spawn in the Cache Slough region of the northern Delta (p. 11) and that larval Delta smelt have an improved ability see their prey in water with enhanced turbidity (p. 4 and 5). There is an additional hypothesis that Delta smelt use turbidity to conceal themselves from predators (p. 7 Delta smelt model).

Magnitude = 3
Increase in quality and quantity of larval/juvenile Delta smelt habitat based on substantial increase in inundation over current conditions.

Certainty = 2
High understanding but with many variables.

Outcome P8: Increase survival of out migrating juveniles by providing mitigation route with lower predation and entrainment (at North and South Delta diversions) risk.

This drainage into Prospect by the lower Sacramento River avoids possible migratory routes into the central delta. Newman 2008 showed that Survival rates were 66% higher for salmon juvenile released in the lower mainstem of Sacramento river (Ryde YEAR) then for those released in central delta (Georgiana slough). Will provide additional migratory paths for emigrating Chinook juveniles above the location of proposed peripheral canal, this would mitigate entrainment exposure at this new facility. Vogel 2008 conducted an acoustical tag study in 2006 and 2007 which showed there were reach specific characteristics for loss rates on juvenile salmon released in Sacramento River near Old Town. Preliminary results showed that loss in DCC and Georgiana Slough was at least 2 times greater than on main stem or Sutter and Steamboat Slough. Will provide additional migratory route for American River salmonids that cannot access Yolo Bypass geographically.

Magnitude = 3-4

Certainty = 3
This drainage into Prospect by the lower Sacramento River avoids possible migratory routes into the central delta and proposed intake facility of proposed canal at Hood.

Potential Negative Ecological Outcome(s)

Outcome N1: Increased MeHg and impact on covered species (on floodplain and downstream).

The text and scores provided here are applicable to all covered fish species. Conceptual models: Mercury. An initial spike in MeHg would be expected when the newly created floodplain habitat is inundated for the first time (Hg model, page 15, 18). Although concentrations may attenuate from the initial spike over time, MeHg production would likely remain relatively high compared to other types of habitats. Habitats with the highest levels of MeHg production, concentration, and exposure to biota are those with periodic flooding events separated by sufficient time to allow complete drying, such as the seasonal floodplains that would be created in this project (Hg model, page 15). Covered fish species using the restored habitat would be exposed to MeHg through their food chain, and MeHg would be exported downstream along with organic matter and organisms.

The linkage of seasonal flooding to MeHg production and subsequent bioaccumulation of MeHg in fish and their prey is well documented. Effects of this bioaccumulation on covered fish species are more uncertain, due to lack of studies of toxicological effects of MeHg on covered species, uncertainty about sensitivity of covered species relative to species that have been studied, and the subtle nature of the behavioral effects (e.g., impaired predator avoidance and feeding efficiency) that are among the most sensitive endpoints for MeHg toxicity and are difficult to detect.

Magnitude = 2

Certainty = 3

Outcome N2: Increased resuspension/mobilization and export of toxic compounds w/impact on covered species (consider sensitivity to changes in land use - none stated in assumptions).

The text and scores provided here are applicable to all covered fish species. Drivers and outcomes are generally described in the following DRERIP Conceptual Models: Chemical Stressors, Pyrethroids, and Splittail.

The habitat is being enhanced to facilitate spawning by splittail and rearing by splittail and other species. Current land uses on and adjacent to the project area are agricultural, including orchards and other crops that receive pesticide applications. Pyrethroids, a class of pesticides used as dormant sprays on orchards, can be toxic to fish, especially to early life stages (Pyrethroids model, page 16). Pyrethroid concentrations would be expected to peak during the winter/spring storm season and after peak agricultural application in the summer and fall (Pyrethroids model, page 2). Late-winter and spring are also the times splittail would use the enhanced floodplain habitat to spawn (Splittail model, page 1). Effects of pesticides, if any, would be greatest in the early years of the project and would attenuate over time if the restored habitat is no longer used for farming.

There are critical data gaps on pyrethroids and other pesticides that make it difficult to evaluate risk to covered fish (Pyrethroids model, page 32; Chemical stressors model, page 25). In general, little is known about the toxic effects of contaminants known to be present in the Delta on resident Delta species, and even less is known about the sublethal effects of contaminants (Chemical stressors model, page 25). Clarification is needed on whether the restored floodplain areas would be farmed when they are not inundated, as the amount and type of ongoing farming and pesticide use would affect the magnitude and duration of potential effects of pesticides on covered fish.

External reference: Smalling, K.L., J. Orlando, and K. Kuivila. 2007. Occurrence of pesticides in water, sediment, and soil from the Yolo Bypass, California. San Francisco Estuary and Watershed Science. Vol. 5, Issue 1 (February 2007, Article 2) http://repositories.cdlib.org/jmie/sfews/vol5/iss1/art2

Magnitude = 2
A wide variety of crops are grown in the Yolo Bypass and surrounding areas, and many different pesticides are used on these crops (Smalling et al. 2007). Pesticides were detected in water samples collected in the inflows to the Yolo Bypass and within the Bypass in 2004 (Smalling et al. 2007). Pesticides detected in water samples included herbicides, especially hexazinone and simazine, and insecticides, especially diazinon (Smalling et al. 2007). The concentrations of dissolved pesticides were below levels known to cause acute or chronic toxicity to fish; however, some of the herbicide concentrations (e.g., hexazinone) were high enough to potentially adversely affect primary productivity (Smalling et al. 2007).

Sediments and soils from the Bypass and its inflows contained other pesticides, such as pyrethroids and DDTs (Smalling et al. 2007). The concentrations of pesticides associated with sediments were below levels known to cause acute toxicity to fish; however, the concentration of at least one pyrethroid (lambda-cyhalothrin) in suspended sediment was high enough to adversely affect benthic macroinvertebrates that fish rely on for food (Smalling et al. 2007).

This project involves habitat enhancement to facilitate spawning by splittail and rearing by splittail and other species. The highest concentrations of dissolved pesticides enter the Bypass as a pulse during the first high-flow event following winter pesticide application (Smalling et al. 2007). Late-winter and spring are also the times splittail would use the enhanced floodplain habitat to spawn (Splittail model, page 1).

Certainty = 2
There are critical data gaps on pyrethroids and other pesticides that make it difficult to evaluate risk to covered fish (Pyrethroids model, page 32; Chemical stressors model, page 25). In general, little is known about the toxic effects of contaminants known to be present in the Delta on resident Delta species, and even less is known about the sublethal effects of contaminants (Chemical stressors model, page 25). The potential effects of complex mixtures of low level pesticides, such as those detected in the Yolo Bypass by Smalling et al. (2007) are also poorly understood.

Outcome N3: Increased stranding of covered species (consider grading proposed in the approach)

N3a1: Splittail adults

Connectivity problems can strand splittail (FP model page 27).

Magnitude = 1

Certainty = 4

N3a2: Splittail juveniles

Connectivity problems can strand splittail (Floodplains Model page 27).

Magnitude = 2
Stranding is minimal now.

Certainty = 4

N3b. Green/white Sturgeon adult/juvenile

Adult passage of white sturgeon, green sturgeon, splittail and salmon is likely constrained in the Yolo Bypass (Harrell and Sommer 2003); Current Fremont and Sacramento weirs create stranding problems for white sturgeon, green sturgeon, splittail and salmon (Sommer et al. 2005); hence efforts to improve passage and redesign weirs will reduce poaching and stranding.

Poaching may be a major issue for white sturgeon (white sturgeon model page 20. hence efforts to improve passage and redesign weirs will reduce poaching and stranding.

Magnitude = 1

Certainty = 4

N3c. Steelhead

Adult passage of white sturgeon, green sturgeon, splittail and salmon is likely constrained in the Yolo Bypass (Harrell and Sommer 2003); Current Fremont and Sacramento weirs create stranding problems for white sturgeon, green sturgeon, splittail and salmon (Sommer et al. 2005); hence efforts to improve passage and redesign weirs will reduce poaching and stranding. Efforts to improve passage and redesign weirs will reduce poaching and stranding.

Magnitude = 1 (adults) 2 (juveniles)
Stranding is minimal now.

Certainty = 4

N3d. Chinook Salmon

Most juvenile CS can exit the existing FP configuration (Sommer et al. 2005). Adult passage of white sturgeon, green sturgeon, splittail and salmon is likely constrained in the Yolo Bypass (Harrell and Sommer 2003); Current Fremont and Sacramento weirs create stranding problems for adult white sturgeon, green sturgeon, splittail and salmon (Sommer et al. 2005); hence efforts to improve passage and redesign weirs will reduce poaching and stranding.

Magnitude = 1 (adults) 2 (juveniles)
Stranding is minimal now.

Certainty = 4

Outcome N4: Reduced flows in Sacramento River and distributaries to support successful outmigration.

The text and scores provided here are applicable to all covered fish species. Juvenile salmon survival is dependent on sufficient water flow and quality. Diversions for habitat restoration can have the same impact that diversions for other purposes do. Restoration efforts have to keep a proper balance on water diversions so as to enable the best possible outcome for the system as a whole.

As much as 60 percent of the natural historical inflow to Central Valley watersheds and the Delta have been diverted. Depleted flows have contributed to higher temperatures, lower DO levels, and decreased recruitment of gravel and large woody debris (LWD). More uniform flows year round have resulted in diminished natural channel formation, altered food web processes, and slower regeneration of riparian vegetation (NMFS 2008)

Water withdrawals have reduced river flows and increased temperatures during the critical summer months, and in some cases, have been of a sufficient magnitude to result in reverse flows in the lower San Joaquin River (Reynolds *et al*. 1993). Direct relationships exist between water temperature, water flow, and juvenile salmonid survival (Brands and McLain 2001).

Elevated water temperatures in the Sacramento River have limited the survival of young salmon in those waters. Juvenile fall-run Chinook salmon survival in the Sacramento River is also directly related to June stream flow and June and July Delta outflow (Dustman *et al*. 1987).

Magnitude = 2

Preliminary information indicates a low magnitude. However, this needs more analysis before a more definitive determination can be made. The water diverted is presumably going to remain in the system to support another migratory route.

Certainty = 3

Outcome N5: Increased habitat for non-native predators/competitors to covered species.

The floodplain model does not address non native predation or competition on the floodplain.

N5a. Delta smelt

Evidence from Yolo and Cosumnes about non-natives taking advantage of floodplain (ref Sommer et al 2004, Moyle et al 2006). Floodplain Model: Page 10 talks about sources of invasive species. Foodweb Model is focused on estuarine systems.

Delta smelt model (semi final with note – do not cite) - adapted to sustain high mortality during the adult stage (Winemiller and Rose 1992). Predation is one of two primary factors for population dynamics (Figure 7). The most likely ancestral Delta smelt predators would have been piscivorous birds, salmonid fishes, and, secondarily, longfin smelt as a larval predator and predatory freshwater fishes like Sacramento pikeminnow, Sacramento perch, and striped bass (Moyle 2002). All of the above listed species could be expected to inhabit the proposed inundated floodplain habitat. Though predation on the floodplain is not specifically address in the model the evaluation team thought predation of DS on the lower portion of the bypass was significant.

Magnitude = 1

Certainty = 3

N5b. Longfin smelt

Longfin model - Predation is a source of direct mortality to eggs and larvae. Some fish species (e.g. suckers, splittail, and sturgeon) may feed on LFS eggs. Larval LFS are not strong swimmers (Wang 1986) and are thus highly vulnerable to predation. Striped bass and inland silverside are probably major predators on LFS larvae. Terns, gulls, and cormorants may also prey on this life stage. Predation and competition are characterized as medium importance and medium understanding (Figure 5.) but floodplain predation and competition are not specifically addressed.

Magnitude = 1

Certainty = 3

N5c. Splittail

Splittail model - Bird predation appears limited until water recedes and floodplains begin to isolate from main channels at which point fish are exposed to wading birds (Moyle 2004). Predation by non native predators is characterized as medium with high understanding (Figure 5 and Table 3).

Magnitude = 1

Certainty = 3

N5d. Green and white sturgeon

White sturgeon model indicate probable distribution in this reach (Figure 7), green sturgeon model indicates probable distribution in this reach (Figure 2). Due to the benthic nature of green and white sturgeon and the timing of floodplain inundation they are not expected to be found on the floodplain (personal communication with Josh Israel 2009).

Magnitude = 1

Certainty = 2

N5e. Steelhead and Chinook salmon

The Chinook salmon and steelhead model indicates Non-native predation and competition with invasive species and hatchery produced salmonids is of medium importance in rearing and emigration estuarine habitats, including floodplain (Figure 2a).

Magnitude = 1

Certainty = 3

Outcome N6: Decrease in turbidity downstream of Yolo and reduction in habitat for Delta smelt and longfin smelt.

N6a. Delta and longfin smelt

Sedimentation model (p. 7 and 16) portray floodplains as sediment sinks. Floodplain model (p. 18) states: “Sediment deposition therefore is common at locations where flow velocities decline such as just interior of flooding locations, where internal topography and vegetation reduce velocities, and when spilling onto the floodplain from internal sloughs and channels.” The above statement would seem to be applicable to the Yolo Bypass downstream of the Fremont Weir where heavy bed sediments (sands) may accumulate.

The Delta smelt model shows that Delta smelt spawn in the Cache Slough region of the northern Delta (page 11). Larval Delta smelt have an improved ability see their prey in water with enhanced turbidity (p. 4 and 5) and use turbidity to conceal themselves from predators (page 7).

Longfin smelt model (page 8) shows that increased turbidity helps LS avoid predators but model further states (page 5) that LS are rarely detected above Rio Vista.

Magnitude = 1
Negative outcome could affect a portion of delta smelt habitat if this bypass acts as a 'sink' for suspended sediments in addition to bed sediments.

Certainty = 3
No documentation that Yolo Bypass floodplain is depositional.

Important Gaps in Information and/or Understanding

Research Needs

- Major gaps – rearing habitat for steelhead? Rearing habitat for juvenile sturgeon?
- Hg accumulation in fish has been documented, but does not indicate there is an effect on fish.
- Degree of contaminants affects on POD.
- Degree of sediment settling on floodplains.
- Degree of predation/competition within floodplains on native covered fish species by non-native fish species.
- Better diet information is needed for floodplain use of SH, G/W Sturgeon;
- More information is needed about relative importance of food to population level effects for all of the species.
- Transport studies are needed to evaluate the footprint of food transport from floodplains.
- Timing duration of rearing for SH, green and white sturgeon.
- Additional information is needed to help quantify the contribution of suspended sediment that Yolo Bypass provides to the north Delta region. Understanding the duration of the suspended sediment benefit would be helpful. Is the increased sediment load only part of a first flush? Can the flows and inundation areas described in scenario 1 and 2 result in the anticipated turbidity benefit?

Reversibility

Yes/Easy

Action

Construct and operate two tidal gates:

1. one installed in Old River on the eastern side of Bacon Island,
2. the second gate would be installed in Connection Slough on the western side of Bacon Island.

Evaluation Team

Water Operations Workgroup – Smelt Team **-** Matt Nobriga, Bruce Herbold, Wim Kimmerer, Steve Detwiler, David Fullerton, John Burke, Kateri Harrison (note-taker), and John Cain (Chair)

Date of Last Revision: May 12, 2009

Action Description and Clarifying Assumptions

Construct and operate two tidal gates – one gate would be installed in Old River on the eastern side of Bacon Island, and the second gate would be installed in Connection Slough on the western side of Bacon Island.

The evaluation team was asked to consider two baseline conditions (D-1640 and OCAP smelt Biological Opinion) and two operational scenarios as follows:

Scenario #1

- Early in the season (December-February) gates would be tidally operated (closed on flood, open on ebb) for 14 days in response to an initial storm event to minimize the movement of preferred smelt habitat (turbidity and salinity) in the south Delta entrainment zone. The gates would be operated December to January to reduce adult delta smelt entrainment risk.

Scenario #2

- Later in the season (March to June), the gates would be closed on flood tides and opened on ebb tides each day to eliminate or reduce movement of larval-juvenile delta smelt towards the pumps (to reduce entrainment) while continuing to allow passage of emigrating salmonids.

The evaluation team considered both operational scenarios together as they are not mutually exclusive. Potential outcomes were only evaluated for delta and longfin smelt.

Approach

Gates would be designed to be easily removed or re-operated, in the event that monitoring results indicate that they are not accomplishing their intended purpose.

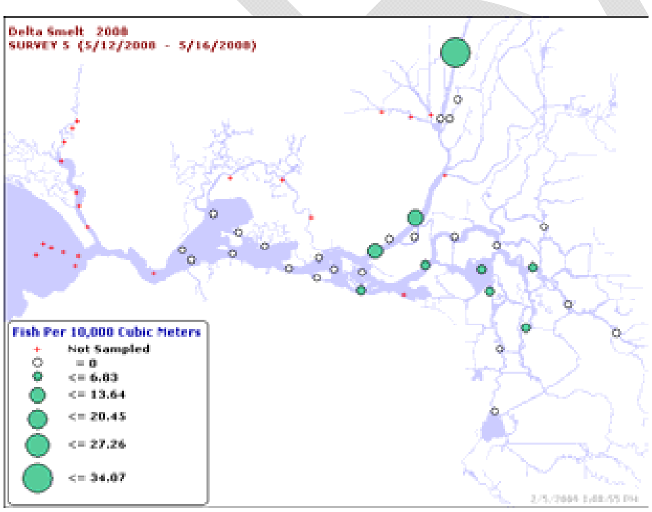
Intended Outcomes as Stated in Conservation Measure

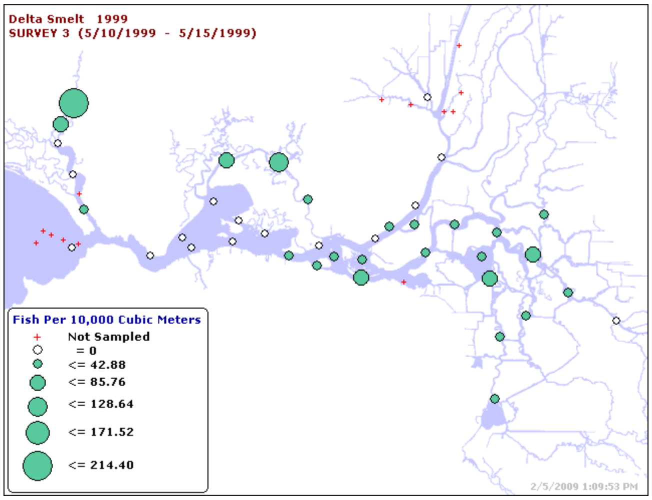
- Reduce entrainment-induced mortality of adult delta smelt from the western Delta.
- Reduce entrainment-induced mortality of adult longfin smelt from the western Delta
- Reduce entrainment-induced mortality of larval delta smelt from the western Delta.
- Reduce entrainment-induced mortality of larval longfin smelt from the western Delta.

General Conceptual Model Support for Intended Outcomes

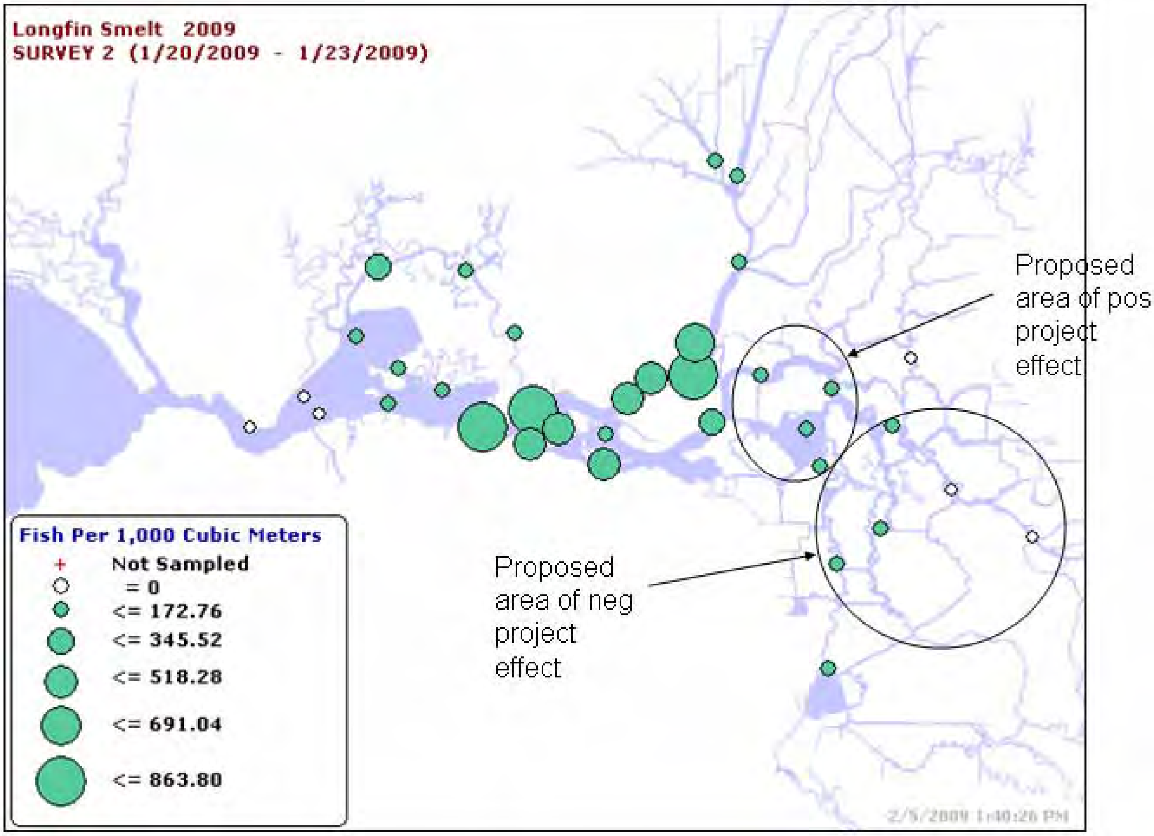
The DRERIP delta smelt and longfin smelt models suggest the cause-effect relationship might apply to the adult migration action because adult smelt would start their migrations from west of the project area. As written, the action is unclear about whether the 14-day operation would potentially occur more than once in a season. This might be necessary to fully ensure a benefit to both species – particularly if the action is used simultaneously to increase exports during winter precipitation events. This is also relevant to larval longfin smelt (see below) because of their earlier spawn timing.

The DRERIP delta smelt model does not provide strong support for the larval cause-effect (e.g., the section on habitat connectivity on pg 14 of the pdf). Further, 20mm data for low outflow springs clearly show delta smelt larvae regularly occur in parts of the central and south Delta where this project would increase their entrainment risk (see attached examples). Any firm decisions about net gains or losses to the population would require quantitative rather than conceptual (qualitative) modeling of larval entrainment risk (a la Kimmerer 2008). Note the OCAP BO intended for OMR restrictions to increase spawning opportunities in the San Joaquin River, not lessen opportunities which this project proposes to do. Therefore, this project proposes to attempt to keep delta smelt out of a portion of the Delta that they have used historically and in the recent past.





The DRERIP longfin smelt model provides qualitative support for the larval cause-effect (e.g., the section of diversions, pgs 12-13 of the pdf), but the timing of the action isn't optimal for longfin larvae (see attached Figure for January 2009 from the smelt larvae survey). Because longfin larvae are already in the water by January, 14 days of operation may make no difference to them given the protracted spawning season described in the DRERIP model. Note also, these surveys provide distribution snapshots. There is no way to determine whether the longfin larvae observed in the central and south Delta were a small fraction that were spawned there, in which case two gates would not improve their fate or a snapshot of the flux rate of the main part of the population into the central and south Delta from the lower Sacramento and confluence regions, which the Interim Tide Gate measure might reduce.



The above is based upon the information contained within the DRERIP: delta smelt and longfin smelt conceptual models. In addition, data and modeling information were obtained from DFG survey data (www.delta.dfg.ca.gov) and CALSIM/DSM2.

Assumptions

Provided in BDCP Conservation Measure

- D1641 is the baseline

Provided by Metropolitan Water District

- OCAP Biological Opinion is the Baseline.

Comments on Action as Written:

1. It is unclear if the early December tidal operations would be done more than once per season if needed.

2. From March to June, DFG would track the distribution of smelt via 20 mm surveys and gate operators would try to keep the fish westward from region of control. Gate closing in conjunction with OMR flow is expected to keep the smelt out of the region. Difficulties arise because the sampling surveys are less reliable at low fish density, and the survey

was not designed for this purpose. It has a two-week sampling interval, but gate ops are proposed daily.

3. In dry years when the gates are needed most to protect water supply, delta smelt also occur in the region where the gates do not provide any hydrodynamic protection. When gates are closed the fish would be stuck between the gates and the pumps, so this increases the risk of entrainment. Operating the gates tidally creates a bit more circulation through the central Delta. Gates would be closed on the flood tide and open on the ebb, tidally pumping water out of Old River. This is balanced by an increased flow towards the pumps from Middle River. Any fish that starts its journey east of Old River has a higher risk of entrainment. Old River carries more flow compared to Middle River (i.e. the flow balance for Old to Middle Rivers may be 60:40).

4. Although a net positive effect on delta smelt is assumed by the project proponents, during the March to June timeframe, there is a trade-off in conditions for smelt vs. salmonids, particularly SJR salmonids.

5. PTM model shows tidally pumping out Old River. If a smelt were located to the north- or southeast of the “control region”, they would see increased entrainment. The fish can get up through the San Joaquin River.

6. Effects on Sacramento salmonids via the Molkulmne River are dependent on what channel the fish enter the SJ River from. Fish come to the pumps from Georgiana Slough. More Sacramento fish could potentially travel to the export pumps.

7. Flows in the model are distributed so that 60% goes to Old River and 40% go to Middle river. If gate operations change such that flow is now directed 100% down Middle River, then a particle located between Old and Middle River or the San Joaquin mainstem east of Old River confluence near Franks Tract would NOT see any benefit.

8. Positive Qwest would likely be maintained. However, assuming an OCAP BO baseline, any incremental benefit of these gates seems more like a tradeoff. The gates prevent entrainment in one direction, but all fish in the other direction will have a higher risk of entrainment. The gates allow exports at the higher end of their approved range (based on new OCAP criteria of -5000 to -1250 cfs). OCAP is designed to achieve a “zero” level of entrainment of adult delta smelt and very low entrainment of larval-juvenile delta smelt. Thus, the benefit of this action at this baseline would be minimal for fisheries. This proposal is an alternative way of implementing OCAP that would deliver more water south of Delta. It is an interim action (near-term) that would be operated before alternative conveyance is complete.

Scale of Action:

Small - Medium

Rationale:

Limited area of proposed project influence; relevance varies with outflow; limited applicability to longfin smelt (as written).

Evaluation Summary Tables

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

Relation to Existing Conditions

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

NO. It would not affect boundary conditions. It would affect hydrodynamics in the south and eastern Delta, but not to the point that our current understanding of the system wouldn't hold.

Potential Positive Ecological Outcome(s)

Outcome P1: Reduce entrainment induced mortality of covered fish species from the western Delta.

P1a - X. Delta Smelt – adult (*OCAP BO Baseline*)

General Observations:
Particle-tracking modeling in support of the proposed project purportedly indicates it would limit adult delta smelt's encroachment into the south Delta.

Magnitude = 2 - Low
The OCAP BO has actions intended to greatly limit adult delta smelt entrainment. Thus, the ability of this project to affect greater benefits seems very limited.

Certainty = 3 - Medium
The OCAP actions were developed in response to increased scientific understanding of adult delta smelt entrainment (Kimmerer 2008; Grimaldo et al. in press) that is also reviewed in the delta smelt DRERIP model. The factors that lead to entrainment events are weather-dependent, so they are subject to "variable ecosystem processes" that increase their uncertainty.

P1a - Y. Delta Smelt – adult (D-1641 baseline)

General Observations:
Particle-tracking modeling in support of the proposed project purportedly indicates it would limit adult delta smelt's encroachment into the south Delta.

Magnitude = 3 -4 Medium - High
delta smelt adult entrainment was a median 15% during the D-1641 era (Kimmerer 2008); overall a "sustained minor population effect" though if gates were operated as planned, they could have had a high magnitude effect in a couple of years

Certainty = 2- 3 Low - Medium
Dynamics of adult delta smelt entrainment are conceptually well-understood (Kimmerer 2008; Grimaldo et al. in press) as reviewed in the DRERIP delta smelt model (pg 24 of the pdf)

P1b – X. Delta Smelt - Larval (OCAP BO Baseline)

General Observations
The MWD presentation in support of the project shows a spatial trade-off; possibility for a net positive outcome in some years, no net effect in others, possible net negative effect in others.

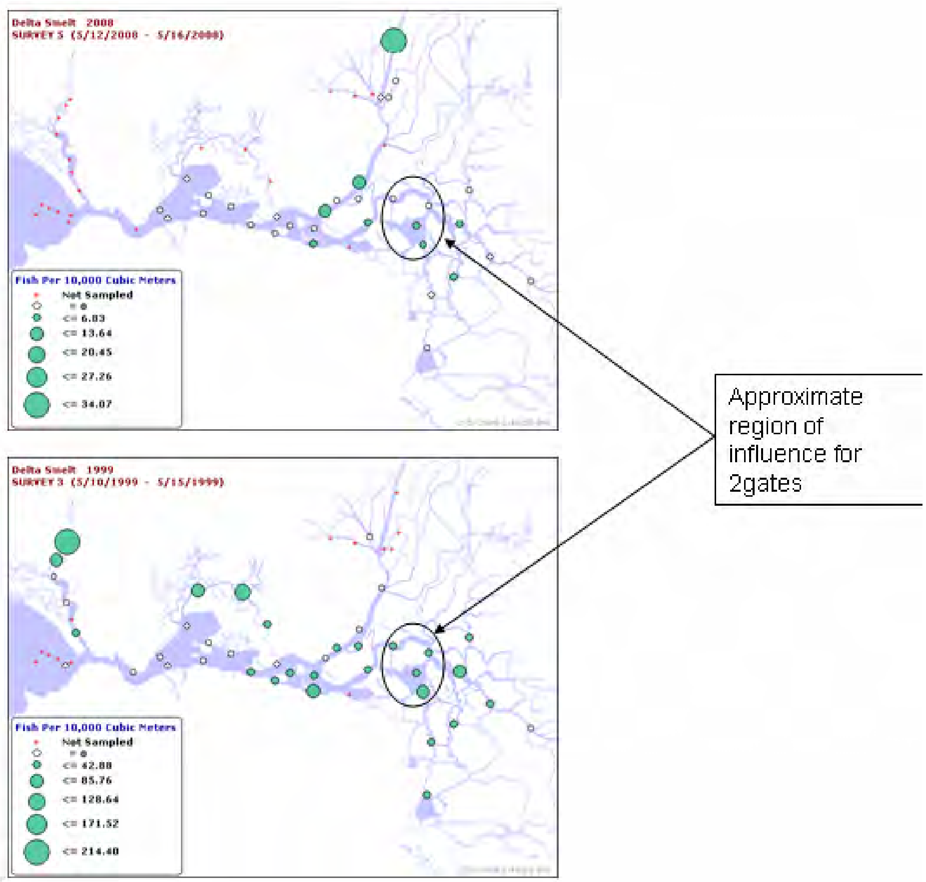
Magnitude = 2 - Low

The OCAP actions were designed to minimize larval-juvenile entrainment; any benefit from this action is therefore minor relative to an OCAP baseline

Certainty = 1 - Minimal

It is not known if OCAP actions will change spawner distributions to more frequently include SJ River, but they are intended to. The 2 gates presentation suggested operations of this project might bisect the fraction of delta smelt larvae rearing in the central Delta in some years – improving survival of some, but decreasing survival of others (see attached figures). The DRERIP delta smelt model does not provide a quantitative breakdown of where larvae have been found. A quantitative assessment of hatch distributions across water year types is needed to fairly evaluate this project.

Assumptions used in Scoring:



P1b – Y: Delta Smelt - Larval *(D-1641 Baseline)*

General Observations

The MWD presentation in support of the project shows a spatial trade-off; possibility for a net positive outcome in some years, no net effect in others, possible net negative effect in others.

Magnitude = 2 - 3 Low - Medium

OMR was often more negative in the D-1641 era than it likely would be under OCAP, so there might be more opportunity for the proposed project to prevent delta smelt entrainment relative to the D-1641 baseline

Certainty = 2 - Low

Uncertainty is high for the utility of this action. The 2 gates presentation suggested operations of this project might bisect the fraction of delta smelt larvae rearing in the central Delta in some years – improving survival of some, but decreasing survival of others (see attached figures). The DRERIP delta smelt model does not provide a quantitative breakdown of where larvae have been found. A quantitative assessment of hatch distributions across water year types is needed to fairly evaluate this project. The utility of the action also depends on outflow: (delta smelt DRERIP model pg 24 of the pdf, which adds weather-related uncertainty.

P1c - X. Longfin Smelt – Adult (*OCAP BO Baseline*)

General Observations:

Particle-tracking modeling in support of the proposed project purportedly indicates it would limit adult delta smelt's encroachment into the south Delta.

Magnitude = 1 - Minimal

The analysis by Kimmerer (shown in Appendix X) for the operation evaluations shows adult longfin entrainment effects are usually less than delta smelt, but the underlying mechanism of adult longfin entrainment is similar to delta smelt (Grimaldo et al. in press).

Certainty = 3 - Medium

There is less certainty about what drives adult longfin smelt entrainment, but it might be similar to delta smelt (Grimaldo et al. in press). Higher certainty that the magnitude of the effect is low because few adult longfin are entrained.

P1c Y. Longfin Smelt – Adult (D-1641 baseline)

General Observations:

Particle-tracking modeling in support of the proposed project purportedly indicates it would limit adult delta smelt's encroachment into the south Delta

Magnitude = 2-3 Low - Medium

longfin smelt entrainment relative to population is usually lower than delta smelt (WK analysis for this evaluation)

Certainty = 2 - Low
There is less certainty about what drives adult longfin smelt entrainment. Higher certainty that the magnitude of the effect is low because few adult longfin are entrained.

P1d - X. Longfin Smelt – Larval (*OCAP BO Baseline*)

General Observations:
The MWD presentation in support of the project shows a spatial trade-off; possibility for a net positive outcome in some years, no net effect in others, possibly net negative effect in others.

Magnitude = 1 – 3 Minimal - Medium
The OCAP Biological Opinion does not provide “full-time” regulation of OMR during peak longfin smelt hatching periods in Jan-Feb. The 2Gates project description (aka write-up) is unclear whether it would either, but it might if the gates were operated consistently Jan-Mar. The 14-d operation that is proposed would be a low magnitude effect. Greater frequency of operation might increase the magnitude of the effect, particularly since larval longfin smelt tend to be located seaward of most delta smelt larvae (Dege and Brown 2004).

The comparatively seaward distribution of longfin smelt might mean the gates could keep distributions out of the south Delta better than for delta smelt larvae.

Certainty = 2 - Low
The spawning distributions of longfin smelt are not well understood; the longfin smelt DRERIP model suggests they might be in or near the LSZ, rather than predominantly in fresh water like delta smelt; larval distributions also depend on X2, so the effect of the project will vary with flow.

P1d - Y. Longfin Smelt – Larval (D-1641 *Baseline*)

General Observations:
The MWD presentation in support of the project shows a spatial trade-off; possibility for a net positive outcome in some years, no net effect in others, possibly net negative effect in others.

Magnitude = 1 – 3 Minimal - Medium
The OCAP does not provide “full-time” regulation of OMR during peak longfin smelt hatching periods in Jan-Feb. The 2Gates project description (write-up) is unclear whether it would either, but it might if the gates were operated consistently Jan-Mar. The 14-d operation that is proposed would be a low magnitude effect. Greater frequency of operation might increase the magnitude of the effect – particularly since larval longfin smelt tend to occur seaward of most delta smelt larvae (Dege and Brown 2004).

The comparatively seaward distribution of longfin smelt might mean the gates could keep distributions out of the south Delta better than for delta smelt larvae.

Certainty = 2 - Low

The spawning distributions of longfin smelt are not well understood; the longfin smelt DRERIP model suggests they might be in or near the LSZ, rather than predominantly in fresh water like delta smelt; larval distributions also depend on X2, so the effect of the project will vary with flow.

Potential Negative Ecological Outcome(s)

Outcome N1: When closed, the gates may block the movement (increase risk of entrainment) of other important fish, including out migrating San Joaquin and Sacramento salmonids and sturgeon.

Outcome identified, but not evaluated.

Outcome N2: When closed, the gates could increase entrainment and mortality of delta smelt in the central and southern Delta.

N2a. Delta Smelt:

General Observations:
20 mm data suggest this will happen in some years (see attached figures).

Magnitude = 2 - Low
These gates will likely bisect larval delta smelt distribution to some degree trapping some fraction of the smelt in the central and south Delta (see attached figures). However, this has historically been a small fraction of the population most of the time. Note this rationale applies to larval longfin smelt too.

Certainty = 2 - Low
There are two kinds of uncertainty regarding this effect. It is uncertain how OCAP OMR flows may influence delta smelt spawning in the SJ River. Additionally, the magnitude of effect depends on the weather and project operations which affect X2.

N2b. Longfin Smelt:

General Observations:
20 mm data suggest this will happen in some years (see attached figures).

Magnitude = 2 - Low
These gates will likely bisect larval longfin smelt distribution to some degree trapping some fraction of the smelt in the central and south Delta (see attached figures). However, this has historically been a small fraction of the population most of the time

Certainty = = 2 - Low
There are two kinds of uncertainty regarding this effect. It is uncertain how OCAP OMR flows may influence longfin smelt spawning in the SJ River. Additionally, the magnitude of effect depends on the weather and project operations which affect X2.

Outcome N3: The gate structure may be conducive to higher predator presence and therefore the risk of predation on covered fish species may increase.

N3a. Delta Smelt

General Observations:
More delta smelt might migrate to the structure than longfin smelt, so there might be some increased loss to predators. However, the DRERIP model notes that delta smelt do not associate strongly with structures in the water (pg 7 of the pdf), so exposure time would likely be limited.

Magnitude = 2 - Low
Kimmerer (2008) estimated adult delta smelt entrainment had a median value of 15% in the past decade. Thus, that fraction of the population might conceivably pass the gate structure and be exposed to hovering predators.

Certainty = 2 - Low
It is known that predators will aggregate around this structure like they do other structures in the Delta. The exposure times and prey fields that the smelts would have, and be part of near the structure are completely unknown.

N3c. Longfin Smelt

General Observations:
The DRERIP longfin model says few longfin smelt migrate past Twitchell Island. That is consistent with the WK analysis for longfin from this eval and suggests this outcome is probably too minor to bother with a full evaluation (for longfin smelt; salmonid folks may conclude differently).
Magnitude = 1 -Minimal
The preliminary analyses for longfin smelt done by Kimmerer for this evaluation (shown in Appendix ___) suggest the effect on longfin smelt would be much lower (as compared to delta smelt above).

Certainty = 2 - Low
It is known that predators will aggregate around this structure like they do other structures in the Delta. The exposure times and prey fields that the smelts would have, and be part of near the structure are completely unknown.

Important Gaps in Information and/or Understanding

Data Needs

1. Smelt spawning micro habitats, (southward flux versus spawn location issue described above for both smelts).
2. Exposure times and prey fields near the gate structures
3. Effects of OCAP Biological Opinion OMR restrictions on smelt spawner distributions
4. Quantitative data to determine particle fates from various locations

January 23, 2009

The results presented here are to support the analysis of BDCP actions involving operations, specifically focused on changing flows in Old and Middle Rivers. These analyses have not been peer reviewed.

Summary

Question 1: Is the impact of export losses likely to be substantial for longfin smelt? The analysis I did suggests not: the ratio of salvage to abundance for longfin smelt is much smaller than that for delta smelt in most years. In dry years it is comparable or even higher.

Question 2: Can we estimate the impact of export losses on longfin as for delta smelt? I did a curtailed version of the analyses in Kimmerer (2008) for longfin smelt, essentially trying to calculated daily losses based on abundance in the south Delta, abundance overall, and Old and Middle River flows. The mean annual loss, compounded over 60 days, was 0.3% of the population. longfin smelt apparently move out of the Delta rather soon after hatching, though, so the 60-day figure may be too long. In contrast, delta smelt remain in freshwater until ~July, resulting in longer exposure to export losses.

Question 3: Can we estimate the impact of export losses on splittail? No.

Question 4. How is salvage of adult delta smelt likely to change with changing Old and Middle River flows? This is still in progress. I have a model to relate salvage to OMR flow, but there are a couple of problems with it. I will work on this some more. I also need the flow scenarios.

Question 1: Is the impact of export losses likely to be substantial for longfin smelt?
Approach: Generally, I compared the ratio of salvage to population size between delta and longfin smelt. Salvage is a poor proxy for export mortality, but probably scales the number of fish that are entrained in the southward-flowing water and thereby toward the pumps. A similar analysis to that of Kimmerer (2008) for delta smelt does not appear feasible, since that analysis relied on the 20mm survey which begins each year well after the spawning peak of longfin smelt.

I calculated total monthly salvage from 1980 through 1995 for each species. I then calculated the total by natal year: for delta smelt all salvage before May was assumed to be from the previous year's cohort, and for longfin smelt I assumed salvage before February was from the previous year (I ignored age of the fish so some 2-year-olds may have been in there). Note that salvage of both species is highest in spring. I took mean catch per trawl from the fall midwater trawl survey and calculated (approximate) population size assuming a volume sampled of 7000 m^3 and a habitat volume of 1.5×10^9 m^3 (these numbers don't really matter for the final result). I then took ratios of total annual salvage to total population size for each year and species. I combined that with estimated export mortality of juvenile delta smelt at the south Delta export facilities from Kimmerer (2008; SFEWS).

Results: Pumping mortality was ~ 1/3 of the salvage:abundance ratio of delta smelt but the two were uncorrelated. The ratio for longfin smelt was always lower than that for delta smelt except during 1989-1991 (Figure 1), which was a drought period when longfin smelt abundance was low. The salvage:abundance ratio for longfin was about 4% of that for delta smelt (median). The salvage:abundance ratio for delta smelt was not a good proxy for the estimate of export mortality; the two were uncorrelated, and the export mortality on average was about 1/3 of the salvage:abundance ratio.

Conclusion: These results show that the magnitude of the export losses to longfin smelt depend on the flow regime. Generally proportional salvage is much lower than that for delta smelt, and usually very near zero. However, during extended periods of low flow, the combination of low abundance and moderate export losses results in rather high ratio of salvage to abundance, so presumably mortality during those periods can be high.

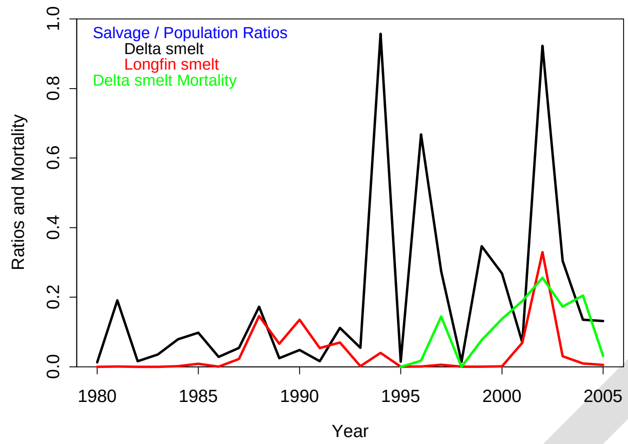

Figure 1. Time course of ratios of annual salvage to population size for delta and longfin smelt, and export-related mortality of delta smelt from Kimmerer (2008)

Question 2: Can we estimate the impact of export losses on longfin as for delta smelt?
Approach: I developed image plots of length by date for longfin smelt from both the 20mm survey and salvage data. The time course of the 20mm survey does not include the entire larval period of longfin smelt, which spawn earlier than delta smelt. The salvage data cover the whole period but do not include fish smaller than 20mm.

I used a similar approach to that applied to determine daily percent mortality of Age-0 delta smelt due to export pumping in Kimmerer (2008). See that paper for assumptions. No correction was made for efficiency of the 20mm net, since similar sizes were assumed to occur in the south Delta and other parts of the system. Mortality was calculated for each 20mm survey from 1995 through 2006. In contrast to the analysis for delta smelt I included stations in San Pablo Bay since longfin smelt are common there, and included the volume of that region (0.9 X 10^9 m^3, Kimmerer 2004) in the calculation of population size.

Results: The image plot from salvage (Figure 2) shows a peak around julian days 90-150 (April – May) in small fish, and a much lower peak earlier in the year of fish that are from previous year classes. Fish below the line in Figure 2 were assumed to be Age-0. The catch in the 20mm survey roughly corroborates the timing of the peak in salvage (Figure 3), although the start of the peak is earlier since the 20mm survey catches smaller fish.

Export mortality was much lower than that for delta smelt (see Kimmerer 2008 Figure 15; daily mortality based on the 20mm survey was as high as 6% d^{-1}). The highest value was a single, somewhat anomalous value of 0.12% d^{-1} in 1996 (Figure 5). The highest mean value was 0.02% d^{-1} in 2002. If this were compounded over a 60-day period of vulnerability, the result would be a loss of 1% of the population. The mean compounded loss was 0.3%. Note that the calculation for delta smelt was much more involved than this, which should be considered only an estimate for range-finding.

Even that estimate may be high. delta smelt remain in the Delta until around July, possibly to avoid high temperature. longfin smelt are larger in samples taken further from the pumps (Figure 6), indicating that they are probably leaving the area within some period after hatching. Therefore individual longfin smelt do not remain vulnerable to pumping for as long a period as delta smelt.

Conclusion: longfin smelt are much less vulnerable to export pumping than delta smelt, although the 20mm survey is somewhat less suitable for making the calculation for longfin than delta smelt. The reasons for the difference are the lower fraction of the longfin smelt population that occurs in the southern Delta, and the earlier movement of longfin smelt to brackish waters out of reach of the pumps.

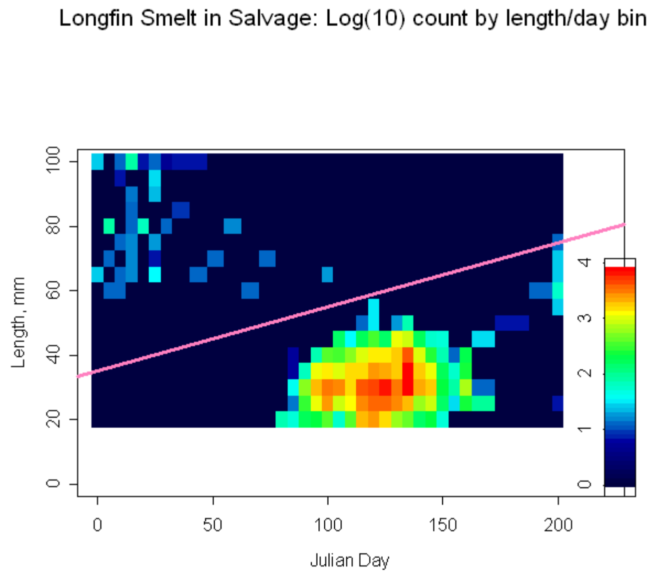

Figure 2. Image plot of catch (log scale) in the salvage facilities by length and day, 1995 – 2006.

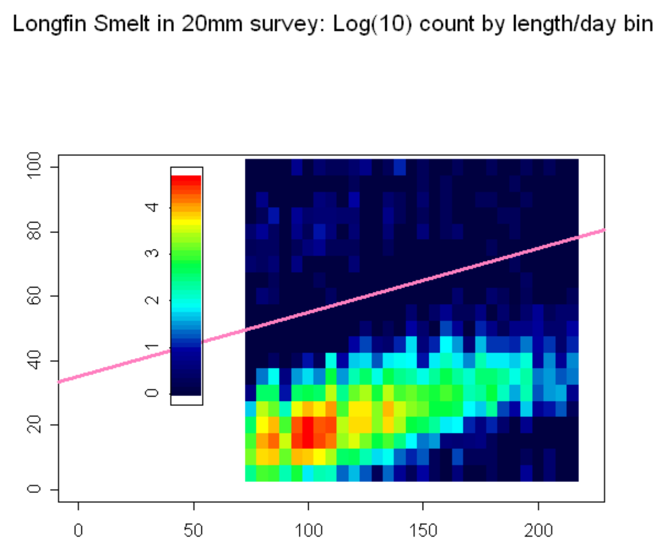

Figure 3. As in Figure 2 for the 20mm survey.

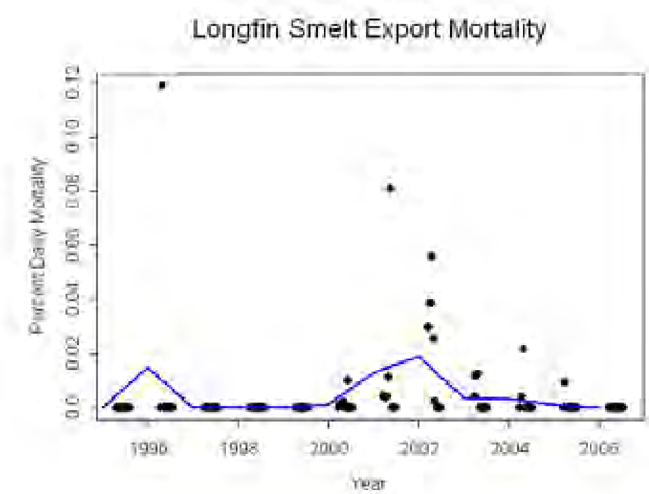

Figure 4. Daily percent mortality due to export pumping and annual mean. Each point represents data from one survey.

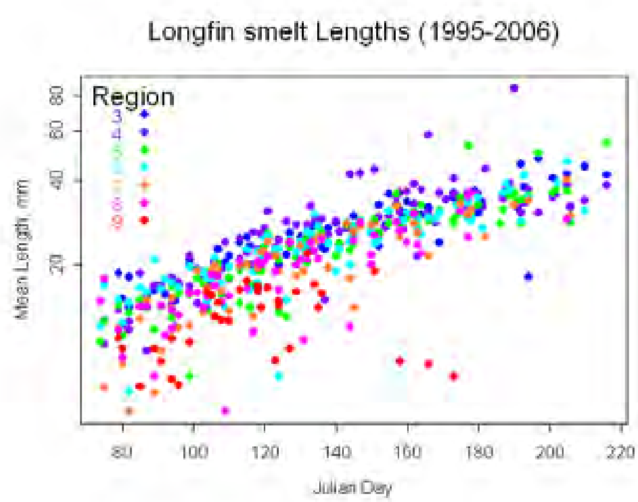

Figure 5. Mean length of longfin smelt from 20mm survey by day and region. The region is the first digit in the station number, and increases generally from San Pablo Bay (3) to the south Delta (9).

Question 3: Can we estimate the impact of export losses on splittail?

Approach: As for delta and longfin smelt except that I did not have the catch per trawl for this species. I therefore used the abundance index from the fall midwater trawl survey, and divided it by 500 (the mean ratio of index to mean catch per trawl for the 4 POD species ranges from 400 to 600). Otherwise the approach was the same.

Results: Salvage was generally higher, sometimes much higher than population size estimated from the MWT (Figure 6)

Conclusion: We can't estimate the impact of export losses on splittail. There is no other sampling program with the right combination of quantitative sampling and seasonal suitability to do this.

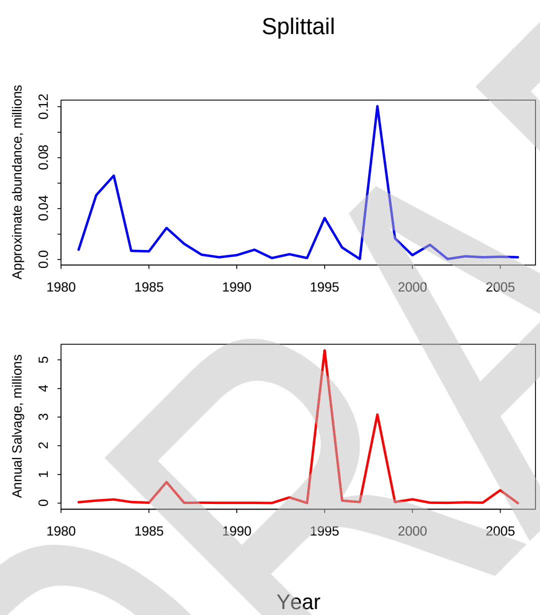

Figure 6. Approximate abundance and annual salvage of Sacramento splittail (millions).

Question 4. How is salvage of adult delta smelt likely to change with changing Old and Middle River flows?

Approach: The basic problem is that the salvage of delta smelt is sometimes high when OMR flows are strongly negative, and sometimes zero. Salvage is usually low when the flows are positive (but not necessarily zero). The question, then, is what benefit accrues from restricting OMR flows in winter.

The general approach was to find a suitable model of the effect of flow on salvage, and then use forecast changes in OMR flow from the 82-year set of scenarios to estimate the change in salvage. If salvage is proportional to export-related mortality, then this should represent the proportional decrease in mortality.

Salvage data from December 12 through March were used in the analysis. A total of 5413 data points were available from 1981 through 2006: 2653 from the state facility and 2760 from the federal facility. The expansion factor to convert counts in the salvage facility to salvage was determined as the ratio of reported salvage to counts for delta smelt, or if that was zero, for all fish. Two cases had zero counts and one had a missing salvage value; these were eliminated. Thirteen cases (February 2006 in the state facility) had missing values for salvage of delta smelt; these were calculated using the expansion factor for all fish. Note that these expansion factors are approximate, in that the actual calculation is done for each of several time periods over the course of a day and summed over the day; however, the expansion factors for delta smelt and all fish were reasonably close so using daily values seemed a useful simplification to avoid having to work with massive amounts of uninformative data.

A suitable model of these relationships must be nonlinear, and allow zero salvage but not negative values; therefore a linear model is unsuitable. However, since the salvage data are based on counts of fish in the two salvage facilities, we can use a model with a Poisson error distribution in which the raw count data are modeled directly. The model is specified separately for the state and federal facilities, since they may have different relationships. The model is specified in steps:

```
 Salvage density  = e^(a + b * OMR)
 Expected Salvage = Salvage density * export flow
Expected count    = Expected salvage / Expansion factor
Observed count ~ Poisson (Expected count)
```

Where a and b are the coefficients to be estimated. Salvage density is the number of fish per unit volume of exported water. This is modeled as a function of OMR flow, since salvage would vary with export flow but salvage density would presumably vary only with OMR flow. Then the expected count is used as the mean of a Poisson distribution, and the raw count data were fit using a Poisson error distribution.

For practical reasons model was fit in a Bayesian analysis using WinBUGS. Uninformative priors for a and b were used, which has the effect that the analysis is similar to a likelihood analysis but is provides more information about the parameters. The prior distributions of the parameters were log normal for **a** (since it can't be less than zero), and normal for **b**, both with means of zero and variances of 10^6. Parameters were estimated from 10,000 iterations after a burn-in of 10,000 iterations to remove the effects of the assumed starting points.

Outcome Code	Covered Spp.	Description	Scenario 1 Magnitude	Scenario 1 Certainty	Scenario 2 Magnitude	Scenario 2 Certainty
Positive Outcomes						
P1a	Delta smelt – adult	Reduce entrainment induced mortality of covered fish species from the western Delta.	2	3	3-4	2-3
P1b	Delta smelt - Larval	Reduce entrainment induced mortality of covered fish species from the western Delta.	2	1	2-3	2
P1c	Longfin smelt – Adult	Reduce entrainment induced mortality of covered fish species from the western Delta.	1	3	2-3	2
P1d	Longfin smelt – Larval	Reduce entrainment induced mortality of covered fish species from the western Delta.	1-3	2	1-3	2
Negative Outcomes						
N3a	Delta smelt	The gate structure may be conducive to higher predator presence and therefore the risk of predation on covered fish species may increase	2	2		
N2a	Delta smelt	When closed, the gates could increase entrainment and mortality of Delta smelt in the central and southern Delta.	2	2		
N3c	Longfin smelt	The gate structure may be conducive to higher predator presence and therefore the risk of predation on covered fish species may increase	1	2		
N2b	Longfin smelt	When closed, the gates could increase entrainment and mortality of Delta smelt in the central and southern Delta.	2	2

Action: San Joaquin ROA Floodplain Restoration (upstream of Mossdale)

Evaluation Team: Floodplain and Riparian Workgroup

Campbell Ingram (chair), Denise Reed (coach), Carie Battistone (notetaker), Eric Ginney, Ted Sommers, Rosalie Del Rosario, Dennis McEwan, Bill Harrell, Dan Welsh, Yvette Redler, Vance Russell

Date of Last Revision: February 23, 2009

Action Description and Clarifying Assumptions

Restore floodplain habitat along 7 to 14 miles of the San Joaquin River from Vernalis to Mossdale.

Option #1: 850 acres (7 miles)

Option #2: 1,700 acres (14 miles)

Approach

1. Set back levees along both sides of the channel and remove all or large sections of the existing levees.
2. Contour floodplain area as needed to reduce and avoid the potential for stranding of juvenile and adult fish following inundation events.
3. Modify channel where practicable within the restored floodplain reach to create low velocity habitat areas designed to provide spawning habitat for splittail and rearing habitat for splittail and salmonids.
4. Discontinue farming within setback levee where width will not support floodplain characteristics and farming practices.
5. Allow riparian vegetation to naturally establish.
6. Allow channel to meander between the new levees through the natural processes of erosion and sedimentation.

Intended Outcomes as Stated in Conservation Measure

1. Expand the floodplain to allow flood waters to attenuate, improving access of juvenile fish, such as Chinook salmon and steelhead, to seasonally inundated floodplain habitat.
2. Create additional spawning habitat for Sacramento splittail by expanding floodplain habitat area and providing in-channel spawning habitat by creating backwaters.
3. Create additional rearing habitat for San Joaquin Basin runs of Chinook salmon, Sacramento splittail, and possibly steelhead.
4. Increase the production of food for rearing salmonids, splittail, and other covered species.
5. Increase the availability and production of food in Delta channels downstream of restored floodplain habitat for delta smelt, longfin smelt, and other covered species by exporting organic material and phytoplankton, zooplankton, and other organisms produced from the inundated floodplain into Delta channels.
6. Increase habitat complexity by allowing the natural establishment and growth of woody riparian vegetation that will provide inputs of large woody debris into the river channel and provide overhead cover.

Positive
P1. Improved connectivity of seasonally inundated floodplain habitat for juvenile splittail, green and white sturgeon, Chinook salmon and steelhead
P2. Additional splittail spawning habitat on floodplain
P3. Additional rearing habitat for splittail, green and white sturgeon, Chinook salmon and steelhead (consider loss to entrainment)
P4. Increased production of food for rearing splittail, green and white sturgeon, Chinook salmon and steelhead from inundation and riparian vegetation (local)
P5. Increased availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for splittail, green and white sturgeon, Chinook salmon, steelhead (off site), longfin smelt, and delta smelt
P6. Increased establishment of woody riparian vegetation to export LWD
P7. Increased establishment of woody riparian vegetation to provide shaded channel habitat
P8. Increased downstream turbidity to improve habitat quality for longfin smelt and delta smelt

Negative
N1. Increased MeHg and impact on covered species (direct or indirect)
N2. Increased resuspension/mobilization and export of toxic compounds with impact on covered species (consider time course of effect)
N3. Increased frequency and magnitude of low DO in SDWSC due to an increase in algae/POM and impact on Chinook salmon, steelhead, and green and white sturgeon passage.
N4. Decreased downstream turbidity decreases habitat quality for longfin smelt and delta smelt
N5. Increased habitat for non-native predators/competitors to Chinook salmon, steelhead, green and white sturgeon, and splittail
N6. Increased exposure risk to contaminants (including Selenium) due to longer residence time in this area

General Conceptual Model Support for Intended Outcomes

DRERIP models were referenced in evaluations, along with several outside sources.

Assumptions

Provided in BDCP Conservation Measure

1. 500 foot setback on each side.
2. 850 acres for 7 mile option.
3. 1,700 acres for 14 mile option.
4. Approximately half of the acreage would flood for at least 30 days every 7 years; all of the acreage would flood for at least 30 days approximately every 20 years.

Added by Evaluation Team

1. Assumes choke point at Mossdale on river distinguishes between tidal and non-tidal.
2. Assumes no lowering of floodplain to increase inundation
3. Assume all South Delta work will be contingent on significant reduction in south Delta entrainment (need to evaluate some negative outcomes with both 1) Old River isolated and 2) current configuration and reduced pumping (i.e., dual conveyance)).

Problem(s) with Action as Written:

1. Natural recruitment of desirable, native riparian vegetation seems unreasonable given the infrequent inundation of the site (the entire site only floods for a significant duration every 20 years).
2. Took out "(including aquatic, floodplain, and riparian features)" from the original stated action.
3. Contouring needs further explanation – focused on stranding not on connections.
4. Approach 3 and 6 are incompatible.
5. The floodplain inundation target of "half of the acreage would flood for at least 30 days every 7 years; all of the acreage would flood for at least 30 days approximately every 20 years" will likely be hard to reach. Ultimately this assumption affects overall scoring.

Scale of Action:

Option #1 – LARGE SCALE (50% increase in habitat area)
Option #2 – LARGE SCALE (100% increase in habitat area)

Rationale:
Relative magnitude depends on system-wide condition. During flood events you have a large increase in area inundated.

Evaluation Summary Tables

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in Appendix A. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes on the following pages.

Relation to Existing Conditions

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

YES

Nature of Change: Insert short sentence here.

Levees appear to be wide in areas: Mossdale to French Camp is more channelized. Levees are not continuous. This action will create an increased level of inundation/flow. Modeling has been sparse in this area – had to make broad assumptions.

Existing Acreages: 1,866 acres (Vernalis to Mossdale)
Existing Acreages: 233 acres (Mossdale to French Camp)

The effects associated with levee setbacks can be considered within our current understanding of the system.

Note: Would help to describe the relation to historical conditions to help us understand the level of habitat to restore.

Potential Positive Ecological Outcome(s)

Outcome P1: Improve connectivity of seasonally inundated floodplain habitat for juvenile fish (Splittail, G/W sturgeon, Chinook salmon and steelhead).

P1a. Fall-run Chinook salmon

Human-built features reduce connectivity to floodplain habitat for salmon (Floodplain Model - text doesn't specifically state salmon but it cites Ted's paper (Sommer et al. 2005)

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 3-4
Given data on flooding and studies elsewhere.

P1b. Steelhead

Same info for flooding for Chinook Salmon. They are there (McEwan 2001) at the time (life stage table – Figure 3). Emigrating Jan-August, peak in Jan-May based on Sacramento River info. Mossdale trawl data (Rosalie provided – FWS 2007) shows more fish occur. Floodplain (page 27) says no info on steelhead use of floodplain. Steelhead model (Fig 2 of steelhead section in salmonid model, p155) shows floodplain use. Williams (2006), McEwan (2001) and Moyle (2002) support presence. Page15-16 of salmon model shows estuarine habitat – may show import for lower reach.

Steelhead have been caught on floodplain in Yolo (Sommer, T., B. Harrell, M. Nobriga, R. Brown, P. Moyle, W. Kimmerer, and L. Schemel. 2001. California's Yolo Bypass: evidence that flood control can be compatible with fisheries, wetlands, wildlife, and agriculture. Fisheries 26:6-16.). Some reference in Williams 2006 – chapter 9, page 174.

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 2-3
Non-peer reviewed references.

P1c. Splittail

Splittail model, pg 12, describes how loss of connectivity has resulted in habitat loss; Floodplain model pg 18: human-built features such as berms and ditches reduce connectivity to floodplain habitat.

Magnitude = 3
Given longer life span means it can take advantage of more flashy system.

Certainty = 3-4

P1d. White Sturgeon

Same info for flooding for CS. No evidence of juvenile use of floodplains. Adult catch in Yolo are adults (Harrell and Sommer 2003). This mechanism described above is assumed to apply to WS (Sommer et al 2005 and Floodplain Model).

Magnitude = 1-2

Certainty = 1

P1e. Green Sturgeon

Same info for flooding for CS. No evidence of juvenile use of floodplains. Adult catch in Yolo are adults (Harrell and Sommer 2003). This mechanism described above is assumed to apply to WS (Sommer et al 2005 and Floodplain Model).

Magnitude = 1

Certainty = 2

Outcome P2: Create additional splittail spawning habitat on floodplain

P2a. Splittail

Floodplain model pg 25 and Splittail model pgs 9 and 12 describe how additional floodplain habitat supports splittail spawning.

Magnitude = 3
Given longer life span means can take advantage of more flashy system.

Certainty = 3-4

Outcome P3: Create rearing habitat for Chinook salmon, green/white sturgeon, splittail and steelhead. Consider loss to entrainment.

P3a. Fall-run Chinook salmon

Assumption gives duration and frequency. BDCP document shows historic timing is late winter spring. Boundary Condition model (p. 49) shows peaks occur in February period.

Fall-run Chinook salmon juveniles are present in the area during the proposed floodplain inundation period of late winter and spring. San Joaquin fall-run Chinook juveniles enter Delta either as: 1) fry/parr) with high winter flows, typically in January through March (size of 20 to 60 mm fork length, or as 2) smolts after mid March(> 60 mm fork length; (Caswell Annual Report 2007, SJRG 2004, 2005, 2006)

Delta presence of fry confirmed by:

- Presence at Mossdale and Salvage facilities during Jan – March
- San Joaquin River Trawl Dos Reis(RM 51) –Laird(RM 90)
- Salmon < 50mm January through March

- Apparent that much of Tuolumne/Stanislaus River emigrated as fry and pre-smolts with early flood flows in Jan – March…..Early migrants not captured in high numbers at Mossdale/Salvage indicating that juveniles may have remained in the lower San Joaquin above Mossdale….” (SJRG annual report 2006 pg 75, 2007 pg 66).
- Densities of fry may be underrepresented due to both the trawl and salvage being relatively less effective at capturing fry (Salmon less than 50 mm long). (SJRG 2006 Annual Report pg 72)
- Fall run Chinook (Fig 2c) shows juvenile fry/par stage during winter/spring.
- Most Fry enter Delta from tributaries before April (January through March), Smolt enter mid March – June (Based on USFWS/CDFG Mossdale trawl data , SJRG annual reports 2004-2007, Caswell annual report 2007.)

Fall-run Chinook salmon juveniles would use the floodplain to rear. The restored floodplain would create rearing habitat for fry/parr that enter the Delta in the winter, coincident with inundation of the floodplain. These fry would be able to feed and grow in the floodplain, and their larger size would increase the likelihood of survival in the ocean.

- Chinook salmon use the delta inversely proportional to their size (Williams 2006).
- Smolts migrate directly through delta to ocean.
- Fry likely do not migrate out of delta until smolt size. (SJRG annual report 2004 pg 76)
- Shallow water habitats including river floodplains and riparian margin provide rearing habitat. Growth rates for juvenile Salmon are higher and emigration rates are slower when in shallow water rearing habitats. (Kjelson 1982, Sommer 2005)
- “during very high flows, fry simply get swept downstream…because the turbulence is too strong for them to resist” (Williams 2006, pg76)
- “ Fry tend to keep to the margins of large rivers”(Hatton 1940, Healy 1991) meaning fry can move at a slower rate then the river especially if they have access to floodplains where they can find slower moving water.
- Fry that lingered in lower reaches of creek or bypass grew to 70-80mm compared to fry that migrated quickly and averaged 40mm (Ward et all 2003)

Floodplains no longer exist along the lower San Joaquin River, but fall-run Chinook salmon would likely use the restored floodplains, as they have been documented to rear in Yolo Bypass floodplain along the lower Sacramento River.

- CV Chinook salmon may have relied extensively on floodplain in the past as historically much of the central valley was floodplain habitat (Hunter et al 1999)
- Williams (2006 article 2) confirmed fall Chinook emigration if Feb-Mar on SJ. Floodplain model (Fig 7 and assoc text) identifies that floodplains provide habitat for CS.
- “Given the temporal and geographic distribution, (Fall-run juvenile) have more opportunities to use floodplain habitats than do other Central Valley runs” (Rosenfield 2007).
- Sommer et al (2005) reported extensive use of Yolo and Sutter bypasses by fall-run.
- Moyle et al (2007) reported use of Cosumnes River floodplain

Limited data on SJ floodplain (none in Floodplain model) No reason to suggest they should behave different from other systems.

Magnitude = 2
Given limited temporal effect in frequency. Availability of floodplain is infrequent, with partial inundation every 7 years. This floodplain would be unavailable for at least 2 generations of San Joaquin fall run, of which the majority are 3 year old spawners, with some 2 year old spawners (Myers et al. 1998, p. 61). There is high certainty that juvenile salmon are in the vicinity, and inference juveniles would rear in restored floodplain based on documented rearing in the Yolo Bypass and the restored Cosumnes River floodplain.

Certainty = 3-4
Given data on flooding and studies elsewhere.

P3b. Steelhead

Same info for flooding for Chinook salmon. They are there at the time (McEwan 2001 life stage table – Figure 3 - emigrating Jan-August, peak in Jan-May -based on Sacramento River info). Mossdale trawl data (Rosalie provided – FWS 2007) shows more fish occur. Floodplain Model (page 27) says no info on steelhead use of floodplain. Steelhead model (Fig 2 of steelhead section in salmonid model, p155) shows floodplain use. Williams (2006), McEwan (2001) and Moyle (2002) supports presence.

Page15-16 of salmon model shows estuarine habitat – may show import for lower reach.

Steelhead have been caught on floodplain in Yolo (Sommer, T., B. Harrell, M. Nobriga, R. Brown, P. Moyle, W. Kimmerer, and L. Schemel. 2001. California's Yolo Bypass: evidence that flood control can be compatible with fisheries, wetlands, wildlife, and agriculture. Fisheries 26:6-16.). Some reference in Williams 2006 – chapter 9, page 174.

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 2
Non–peer reviewed references.

P3c. Splittail

DLO Relationship and General Observations:
Same info for flooding for CS. Table 1 page 3 in Splittail model indicates juveniles use floodplain Feb-May, distribution shows they are in SJ. based on Baxter sampling (mostly unpublished). Cosumnes publications (Crain et al 2004 conf proc.), Moyle et al 2004. SFEWS. Still not much info from SJ – same inference, no reason to believe they would behave differently.

Magnitude = 3
Given longer life span means can take advantage of more flashy system.

Certainty = 3-4
Given data on flooding and studies elsewhere.

P3d. White Sturgeon

DLO Relationship and General Observations:
Same info for flooding for Chinook salmon. No evidence of juvenile use of floodplains. Adult catch in Yolo are adults (Harrell and Sommer 2003). This mechanism described above is assumed to apply to WS (Sommer et al 2005 and Floodplain Model).

Magnitude = 1-2

Certainty = 1

P3e. Green sturgeon

DLO Relationship and General Observations:
Same info for flooding for Chinook salmon. No evidence of juvenile use of floodplains. Adult catch in Yolo are adults (Harrell and Sommer 2003). This mechanism described above is assumed to apply to WS (Sommer et al 2005 and Floodplain Model).

Magnitude = 1

Certainty = 2

Outcome P4: Increase production of food for rearing Chinook salmon, steelhead, green/white sturgeon, splittail from inundation and riparian vegetation (local).

P4a. Fall-run Chinook salmon

Floodplain Model pgs 20-25 - high levels of food production on floodplain provides support for magnitude score. Floodplain Model pgs 27 and 29 describe utilization and higher growth rates for Chinook salmon on floodplains. Chinook salmon likely take advantage of small fishes on the floodplain (Splittail Model pg 8 and Moyle et al. 2004).

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 3-4
Given data on flooding and studies elsewhere.

P4b. Steelhead

Floodplain Model pgs 20-25 - high levels of food production on floodplain provides support for magnitude score. Nothing in the literature that describes steelhead feeding on floodplains, however, it can be assumed that they are utilizing the same food sources as juvenile salmon, given their life-history similarities. Moyle 2002 states that stream-dwelling rainbow trout feed mostly on drifting aquatic orgs, terrestrial insects, and bottom dwelling orgs which are in abundance on floodplains.

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 2
Non-peer reviewed.

P4c. Splittail

Floodplain Model pgs 20-25 - high levels of food production on floodplain provides support for magnitude score. Floodplain Model pgs 25 and 27 describes utilization and higher survival for splittail on floodplains.

Magnitude = 3
Given longer life span means can take advantage of more flashy system.

Certainty = 3-4

P4d. White sturgeon

Floodplain Model pgs 20-25 - high levels of food production on floodplain provides support for magnitude score. This mechanism described Chinook salmon is assumed to apply to WS (Sommer et al 2005 and Floodplain Model).

Magnitude = 1
No evidence of juvenile use of floodplains. Catch in Yolo are adults (Harrell and Sommer 2003).

Certainty = 1
Understanding of sturgeon on floodplain is low and needs further study, e.g., could have higher worth if better understood, group had difficulty determining whether to eliminate sturgeon based on understanding of their use of floodplains.

P4e. Green sturgeon

DLO Relationship and General Observations:
Floodplain Model pgs 20-25 - high levels of food production on floodplain provides support for magnitude score. This mechanism described for Chinook salmon is assumed to apply to GS (Sommer et al 2005 and Floodplain Model).

Magnitude = 1
No evidence of juvenile use of floodplains. Catch in Yolo are adults (Harrell and Sommer 2003).

Certainty = 2
Understanding of sturgeon on floodplain is low and needs further study, e.g., could have higher worth if better understood, group had difficulty determining whether to eliminate sturgeon based on understanding of their use of floodplains.

Outcome P5: Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (off site), longfin smelt, and delta smelt.

P5a. Fall-run Chinook salmon

Floodplain Model pgs 20-25 - high levels of food production on floodplain provides support for magnitude score. Floodplain Model pgs 27 and 29 describe utilization and higher growth rates for Chinook salmon on floodplains.

Chinook salmon likely take advantage of small fishes on the floodplain (Splittail Model pg 8 and Moyle et al. 2004).

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 3-4
Given data on flooding and studies elsewhere.

P5b. Steelhead

Floodplain Model pgs 20-25 - high levels of food production on floodplain provides support for magnitude score.

Nothing really in the literature that describes steelhead feeding on floodplains, however, it can be assumed that they are utilizing the same food sources as juvenile salmon, given their life-history similarities. Moyle 2002 states that stream-dwelling rainbow trout feed mostly on drifting aquatic orgs, terrestrial insects, and bottom dwelling orgs which are in abundance on floodplains.

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 2
Non-peer reviewed.

P5c. Splittail

Floodplain Model pgs 20-25 - high levels of food production on floodplain provides support for magnitude score. Floodplain Model pgs 25 and 27 describes utilization and higher survival for splittail on floodplains.

Magnitude = 3
Given longer life span means can take advantage of more flashy system.

Certainty = 3-4

P5d. White sturgeon

Floodplain Model pgs 20-25 - high levels of food production on floodplain provides support for magnitude score.

This mechanism described Chinook salmon is assumed to apply to WS (Sommer et al 2005 and Floodplain Model).

Magnitude = 1
No evidence of juvenile use of floodplains. Catch in Yolo are adults (Harrell and Sommer 2003).

Certainty = 1
Understanding of sturgeon on floodplain is low and needs further study, e.g., could have higher worth if better understood, group had difficulty determining whether to eliminate sturgeon based on understanding of their use of floodplains.

P5e. Green sturgeon

Floodplain Model pgs 20-25 - high levels of food production on floodplain provides support for magnitude score.

This mechanism described for Chinook salmon is assumed to apply to GS (Sommer et al 2005 and Floodplain Model).

Magnitude = 1
No evidence of juvenile use of floodplains. Catch in Yolo are adults (Harrell and Sommer 2003).

Certainty = 2
Understanding of sturgeon on floodplain is low and needs further study, e.g., could have higher worth if better understood, group had difficulty determining whether to eliminate sturgeon based on understanding of their use of floodplains.

P5f. Longfin smelt

Longfin smelt Model pg 21 describes the importance of zooplankton.

Magnitude = 2
Given limited temporal effect in frequency; occur under extreme high flow events when food is less likely a constraint.

Certainty = 3

P5g. Delta smelt

Delta smelt Model pg 12 describes the importance of zooplankton.

Magnitude = 2
Given limited temporal effect in frequency; occur under extreme high flow events when food is less likely a constraint.

Certainty = 3

Outcome P6: Increase establishment of woody riparian veg to export LWD.

P6. Not evaluated by species

Assumption for action HRCM1 gives duration and frequency of inundation of the floodplain. Note that highway and railroad bridges, existing developments and homes will make it difficult to actually implement this action in many areas of the action area.

Many factors and processes influence natural recruitment of woody riparian vegetation, and are summarized in the DRERIP Riparian Vegetation Model. Figures 5, 6, & 7 of that model demonstrate how levees disrupt the setting of the “physical template” (the surface hydrology and floodplain scouring processes necessary for that template) that is necessary for natural recruitment to occur. Actions in HRCM1 would result in reduction of that stressor (setting back the levee), which would allow for increased establishment of woody riparian vegetation. The altered flow regime of the San Joaquin River system would not be modified by this action, and would therefore remain as a stressor and (in combination with altered channel and floodplain morphology) this would still limit inundation frequency and duration of the site.

While natural riparian vegetation recruitment in the setback area would be possible, infrequent natural flooding may encourage invasive species recruitment (DRERIP Riparian Model, page 20) because surface water and groundwater hydrology drive the recruitment and establishment parameters of vegetation somewhat independently of the physical template. Specifically, this includes recruitment parameters for necessary seedling survival and changes in biotic competition and anoxia that may favor invasive species over native species that are flood-tolerant or require flooding to establish. Infrequent inundation also translates to infrequent LWD export from the area of increased vegetation.

Chinook salmon likely take advantage of small fishes on the floodplain (Splittail Model pg 8 and Moyle et al. 2004).

Magnitude = 2
Magnitude score is based on effect being local (e.g., 7 or 14 mile reach) to regional (LWD would move downstream) in scale. However, because new floodplain areas would not be inundated very frequently (and hence the increase in LWD recruitment would be sporadic), the temporal effect is low. The DRERIP Floodplain Model (pages 5, 6, & 7) describes how flood flows modify the floodplain and interact with riparian vegetation to recruit LWD. The approach to Action HRCM1 will set back levees allowing vegetation recruitment (and flooding) where it is currently precluded; however, the action will not modify the floodplain morphology or increase flood hydrology in terms of frequency or duration. Thus, while riparian vegetation may be increased by the action, because of the morphology of the site and other stressors (specifically, impaired flood hydrology), the inundation frequency—and hence the LWD export—is likely to be infrequent (e.g., every 7 years for half the new floodplain; every 20 years for the entire floodplain). Therefore, while this outcome is positive, the actual increase in LWD export is likely to be relatively infrequent and thus of low magnitude.

Certainty = 3
Certainty score is based on dependence of outcome on variable ecosystem processes (i.e., flooding needed to cause LWD input is highly variable—e.g., every 7 to 20 years based on modeling).

Outcome P7: Increase establishment of woody riparian vegetation to provide shaded channel habitat.

P7a. 7-mile reach option

The DRERIP Riparian Model (interactions with floodplains as shown in Figure 5, and specifically the Riparian Vegetation Sub-model; green box in Figure 5) produces a conceptual framework for illustrating the creation of the physical “shaded riverine aquatic habitat” that would be provided by action HRCM1. Removing levees or eliminating vegetation clearing at the river’s edge would allow for increased establishment of woody riparian vegetation.

Based on assumptions and approach to HRCM1, “modifications” to the channel will be made to benefit splittail spawning and provide splittail and salmonid rearing habitat. Ostensibly, this would include addition of instream LWD, but because riparian vegetation is assumed to come from "natural recruitment", any increase in woody riparian vegetation establishment (and hence increased shade) along the banks would be expected to occur only in areas where current levees (without vegetation) are located immediately adjacent to the river, or vegetation along the river is cleared all the way up to the edge of the river.

Benefit to covered species would be dependant on water temperature effects. Shade would reduce the amount of shortwave radiation striking the water (see Figure 1, DRERIP Temperature model); however, at this fine habitat-level scale, while shading is important, its influence is difficult to prescribe quantitatively (DRERIP Temperature model, page 6). Predicting the magnitude of the shading effect is beyond the level of the conceptual models.

Magnitude = 2
Currently, compared to the upstream reach (the other 7 mile section that comprises the 14-mile action area), more levee is adjacent to the river channel, and hence the opportunity for levee setback to increase woody riparian vegetation (and hence shade the channel) immediately adjacent to the channel is greater relative to that in the upstream 7 miles (Google Earth satellite imagery; DRERIP-BDCP maps). Only about 1 mile of floodplain along the river is cleared right up to the river's edge. However, highway and railroad bridges, existing developments and homes in the downstream portion of this reach will make it difficult to actually implement this action at the scale and extent assumed for this area. SUMMARY: Compared to upstream 7 miles, potential magnitude of increase is larger for this segment of the action area (more sections of bank would gain shade); however, the likelihood of actual implementation is lower than upstream because of constraints.

Certainty = 3
Certainty score is based on dependence on external factors and the lack of predictability in the outcome directly supporting covered species.

P7b. 14-mile reach option

The DRERIP Riparian Model (interactions with floodplains as shown in Figure 5, and specifically the Riparian Vegetation Sub-model; green box in Figure 5) produces a conceptual framework for illustrating the creation of the physical "shaded riverine aquatic habitat" that would be provided by action HRCM1. Removing levees or eliminating vegetation clearing at the river's edge would allow for increased establishment of woody riparian vegetation.

Based on assumptions and approach to HRCM1, "modifications" to the channel will be made to benefit splittail spawning and provide splittail and salmonid rearing habitat. Ostensibly, this would include addition of instream LWD, but because riparian vegetation is assumed to come from "natural recruitment", any increase in woody riparian vegetation establishment (and hence increased shade) along the banks would be expected to occur only in areas where current levees (without vegetation) are located immediately adjacent to the river, or vegetation along the river is cleared all the way up to the edge of the river.

Benefit to covered species would be dependant on water temperature effects. Shade would reduce the amount of shortwave radiation striking the water (see Figure 1, DRERIP Temperature model); however, at this fine habitat-level scale, while shading is important, its influence is difficult to prescribe quantitatively (DRERIP Temperature model, page 6). Predicting the magnitude of the shading effect is beyond the level of the conceptual models.

Magnitude = 3
This version of the action would include another 7 miles located upstream. Currently, compared to the downstream reach (the lower 7 mile section that comprises the 14-mile action area), the levees are relatively far back from the channel (Google Earth satellite imagery; DRERIP-BDCP maps) and vegetation exists along most of the river channel. Hence, the relative opportunity for levee setback to increase woody riparian vegetation (and hence shade the channel) immediately adjacent to the channel is lower than in the downstream 7 miles. However, existing developments and homes in this reach are located in areas with relatively large areas between them and the river, so the opportunity to actually implement this action at the scale and extent assumed for this upstream reach is greater than in the downstream. SUMMARY: Compared to downstream 7 miles, potential magnitude of increase is less for this segment of the action area (because existing conditions are currently better), but likelihood of actual implementation is higher than downstream. Would affect multiple patches of habitat.

Certainty = 3
Certainty score is based on dependence on external factors and the lack of predictability in the outcome directly supporting covered species.

Outcome P8: Increased downstream turbidity improves habitat quality for delta smelt and longfin smelt.

P8a. Delta smelt

Positive link between delta smelt and turbidity throughout life-history is well documented in both lab and field studies. Longfin smelt abundance appears to be positively linked with turbidity, although less research is available.

Action assumes relatively infrequent inundation events. Inundation will suspend and mobilize sediment from the restored floodplain, increasing turbidity in the water column downstream. Floodplain model: Sediment on floodplains can be resuspended by flows or turbulence such as wind-generated waves (pg. 18). Sediment model: The Yolo Bypass floodplain, when inundated, can be a large source of sediment to the Sacramento River (pg. 9). A restored floodplain on the San Joaquin River could be a source for suspended sediment downstream, assuming it functions similarly to the Yolo Bypass. Delta smelt model: Turbidity increases larval feeding success (pg. 4-5); turbidity conceals juvenile delta smelt from predation (pg. 7); and juveniles are most abundant in areas with low water transparency (pg. 11). Longfin smelt model: Longfin smelt occurring in turbid water have reduced exposure to predation (pgs. 7, 8, 13). Although less information is available for longfin, they likely benefit from higher levels of turbidity in similar ways to delta smelt.
Magnitude = 2
Limited temporal and population level effect due to low frequency of inundation (given in assumptions).

Certainty = 3-4

P8b. Longfin smelt

Same as delta smelt above.

Magnitude = 2
Limited temporal and population level effect due to low frequency of inundation (given in assumptions).

Certainty = 3

Potential Negative Ecological Outcome(s)

Outcome N1: Increased MeHg and impact on covered species (direct or indirect).

N1a. Same for all species

Figure 2 in Hg model – shows seasonally flooded links. Page 10 – Hg formation relation to habitat (episodic wetting/drying). Hg is less of a factor in SJR system compared to northern Delta (Yolo). Seasonal affects on fish in different locations (Fig 6) – with existing system. No major of minor population affects (regional or local). Isn't very much info showing an affect, especially in Delta. Refer to Henery and Sommer (in press). Certainty of methylation high, affects on covered species low (unknown but likely). Species models do not address Hg directly (little known) but need to check. Floodplain Model: Figure 4 links to Hg model – no other references found Daryl Slotten paper: Hg accumulation in fish, but does not indicate affect on fish. Sites that are inundated less frequently have higher methyl rates then those that inundate more frequently – apply differently based on tidal influence in areas.

Magnitude = 1
Details described here.

Certainty = 3
Based on level understanding of affects on fish species.

Outcome N2: Increased resuspension/mobilization and export of toxic compounds w/impact on covered species (consider time course of effect).

N2a. Same for all species:

Time scale considerations: depends on the specific chemical (some compounds are short lived in the system, some stay longer). Outcome worded very generally. Look at worse case scenario and what is most likely. Chemical Stressors Models: generally speaks to transport (more transport with more inundation) and supports as negative outcomes. Sedimentation model: Figure 2 – river mobilizes toxics from hydraulic mining (pg 6). Temperature model: may affect some of the processes related to toxics. Not applicable here – more applies to WQ. Pyrethroids Model: general - more runoff during rainy season. Is there an ammonia or nitrogen model? How do they relate? May not be applicable here, more from wastewater point sources.

Magnitude = 1
Not much sediment to mobilize.

Certainty = 2

Outcome N3: Increased freq. and magnitude of Low DO in SDWSC due to inc in algae/POM and impact on salmon/steelhead/G&W sturgeon passage.

N3a. Same for all species

Plus presence of fish species needs to be considered. Page 33 salmon model talks about DO as migration barrier and timing issue (juvenile not migrating when DO is an issue) Also see page 60 re adults. More of an issue for adult and juvenile salmon.

Magnitude = 1

Certainty = 4
Would not cause affects on species based on seasonality (more of a late summer fall issue

Outcome N4: Decreased downstream turbidity decreases habitat quality for delta smelt and longfin smelt.

N4. Same for delta and longfin smelt

Water moving out on the floodplain and settling out of sediment. Sediment Model: has a section on floodplain but does not specifically say it traps sediment. Figure 8 in sediment model makes link. Floodplain Model: no information found in model. We expect it would increase turbidity with export of phyto/zooplankton. May be a seasonality issue again – less phytoplankton in winter. Delta Smelt Model: Pg 2, 10, and 11 talk about turbidity as important habitat factor. Longfin Smelt Model: link to turbidity is poor (pg 7), they tend to hang out in turbid water.

(For potential addition to existing rationale) Floodplain model: Reduced water velocities on floodplains, due to topography and vegetation, results in the deposition of sediment, potentially decreasing turbidity (pg. 18).

Magnitude = 1

Certainty = 4

Outcome N5: Increased habitat for non-native predators/competitors to native fishes (Chinook salmon, steelhead, green and white sturgeon, and splittail).

N5a. Chinook salmon

Evidence from Yolo and Cosumnes about non-natives taking advantage of floodplain (ref Sommer et al 2004, Moyle et al 2006). Floodplain Model: Page 10 talks about sources of invasive species. Foodweb Model is focused on estuarine systems.

Chinook salmon and steelhead. The CS and steelhead model indicates Non-native predation and competition with invasive species and hatchery produced salmonids is of medium importance in rearing and emigration estuarine habitats, including floodplain (Figure 2a). There is limited data on CS and steelhead use of SJ floodplain (no mention in Rosenfield 2007) but the evaluation team thought there is no reason why they would not utilize this habitat in the same way they utilize similar Delta systems (Yolo Bypass).

Magnitude = 2
Based on perennial inundated benches, but not floodplains; benches may support more non-native predators.

Certainty = 4
Based on understanding high concentrations of non-natives in perennially shallow water areas of the San Joaquin (Grimaldo et al. 2003, Feyrer 2003).

N5b. Steelhead

Evidence from Yolo and Cosumnes about non-natives taking advantage of floodplain (ref Sommer et al 2004, Moyle et al 2006). Floodplain Model: Page 10 talks about sources of invasive species. Foodweb Model is focused on estuarine systems.

Chinook salmon and steelhead. The CS and steelhead model indicates Non-native predation and competition with invasive species and hatchery produced salmonids is of medium importance in rearing and emigration estuarine habitats, including floodplain (Figure 2a). There is limited data on CS and steelhead use of SJ floodplain (no mention in Rosenfield 2007) but the evaluation team thought there is no reason why they would not utilize this habitat in the same way they utilize similar Delta systems (Yolo Bypass).

Magnitude = 2
Based on perennial inundated benches, but not floodplains; benches may support more non-native predators.

Certainty = 4
Based on understanding high concentrations of non-natives in perennially shallow water areas of the San Joaquin (Grimaldo et al. 2003, Feyrer 2003).

N5c. Green and white sturgeon

DLO Relationship and General Observations:
Evidence from Yolo and Cosumnes about non-natives taking advantage of floodplain (ref Sommer et al 2004, Moyle et al 2006). Floodplain Model: Page 10 talks about sources of invasive species. Foodweb Model is focused on estuarine systems.

White sturgeon – model indicate probable distribution in this reach (Figure 7), green sturgeon model indicates uncertain distribution in this reach (Figure 2). Due to the benthic nature of green and white sturgeon and the timing of floodplain inundation they are not expected to be found on the floodplain (personal communication with Josh Israel 2009).

Magnitude = 1

Certainty = 2

N5d. Splittail

Evidence from Yolo and Cosumnes about non-natives taking advantage of floodplain (ref Sommer et al 2004, Moyle et al 2006). Floodplain Model: Page 10 talks about sources of invasive species. Foodweb Model is focused on estuarine systems.

Splittail model - Predation by non native fish is characterized as low with high understanding for juveniles and as medium with medium understanding for adults (Figures 5, 6 and 7.) Bird predation appears limited until water recedes and floodplains begin to isolate from main channels at which point fish are exposed to wading birds. [Moyle 2004].

Magnitude = 2

Certainty = 4

Outcome N6: Increased exposure risk to contaminants (including Selenium) due to longer residence time in this area.

N6a. Not evaluated by species.

Selenium (Se) loading of the Bay-Delta ecosystem is driven mainly by loads entering the Delta from the San Joaquin River (SJR), which in turn receives most of its Se input from agricultural drainwater entering the river through Mud Slough (Se model, Fig. 1). This project is along the mainstem SJR downstream of these Se inputs.

The proposed action involves habitat modification that creates more extensive floodplain and low velocity, shallow water habitats. These types of habitats create a better environment for Se partitioning in food chains than would occur in bed sediment of the river channel. Exposure of covered fish to Se might increase due to higher bioaccumulation of Se in invertebrate prey and longer residence time of the fish in the enhanced habitat.

Salmonids are relatively sensitive to Se compared to other fish (Se model, pg 19). Beckon (2008 abstract from CALFED science conference; manuscript in prep) evaluated Se data from the SJR and concluded that, although discharges of Se to the SJR have been reduced over the last 15 years, Se will pose a substantial risk to salmon that are reintroduced to restored middle reaches of the river unless Se loads are further reduced and/or sufficient dilution flows are provided. The magnitude of potential effects of Se from this project between Vernalis and Mossdale may be lower than would occur at projects along the middle reaches of the SJR mainstem (i.e., sites in the vicinity of Mud Slough) because this project occurs downstream of dilution sources from the Merced, Tuolumne and Stanislaus Rivers. However, this spatial difference does not provide strong protection because Se bioaccumulates in food chains, is recycled in the ecosystem, and can have significant lag times between when loading occurs and when effects are seen.

The seasonal use of the habitat may also reduce the potential magnitude of Se impacts to covered fish species, especially juvenile salmonids. Seasonal use of the Delta by juvenile salmonids occurs mainly during high flow periods (January-June)(salmon model, pg 11); whereas highest concentrations of Se occur during low flow periods (Se model, pg 6). However, this seasonal difference does not provide strong protection because Se bioaccumulates in food chains, is recycled in the ecosystem, and can have significant lag times between when loading occurs and when effects are seen.

The invertebrate prey of juvenile salmonids are water-column-feeding or detritus-feeding species that are less contaminated than certain suspension or deposit-feeding bivalves

(Se model, Table 5 and Fig. 1). Adult splittail and sturgeon feed on bivalves and would be expected to have greater exposure to Se in their diet than salmonids. This project is intended to provide rearing habitat for juvenile sturgeon and splittail rather than habitat for adults, but may also result in increased residence time by spawning and foraging adults. However, the bivalve species present at this freshwater location would be Corbicula fluminea rather than Corbula amurensis (Corbula and Corbicula models). C. fluminea is less efficient at bioaccumulating Se than C. amurensis (Se model, pg. 14).

Se dynamics in the Bay-Delta system are fairly well understood, but there is uncertainty about how changes in management of SJR flows, water exports, and potential future actions to solve the drainage problem on the west side of the San Joaquin Valley could affect Se loading and cycling in the Delta (Se model, pp. 3 and 4). A quantitative analysis of the increased risk of Se toxicity resulting from this project would require estimates of the increase in the amount of time covered fish spend at this location relative to the baseline condition, as well as estimates of future river flows, water exports, and Se loads. Such an analysis is beyond the scope of this worksheet exercise, but should be considered if the project is recommended for evaluation in the NEPA process.

Magnitude = 2

Certainty = 3

Important Gaps in Information and/or Understanding

Research Needs

- The basis of the assumption for the flooding frequency could be refined (Table 2, BDCP doc).
- Major gaps – rearing habitat for steelhead? Rearing habitat for juvenile sturgeon?
- Hg accumulation in fish has been documented, but does not indicate affect on fish.
- Degree of contaminants affects on POD.
- Degree of sediment settling on floodplains.
- Degree of predation/competition within floodplains on native covered fish species by non-native fish species.
- Better diet information is needed for floodplain use of SH, G/W Sturgeon;
- More info is needed about relative importance of food to population level effects for all of the species.
- Transport studies are needed to evaluate the footprint of food transport from floodplains.
- Timing duration of rearing for SH, G/W Sturgeon.
- The turbidity linkage for longfin smelt is not as well documented in the research as it is for delta smelt. Further studies positively linking turbidity and longfin smelt would be helpful.

Assess Reversibility and Opportunity for Learning

Reversibility

No/Hard

Comments:

- Would be monumental effort/cost to reconstruct levees
- Low reversibility with high resources associated with structural investments in setback levees. Land acquisition and jurisdiction also constraints.
- Implementation of this action would not provide a suitable opportunity to address critical unknowns or uncertainties. If action were implemented at a larger scale and with more-frequent inundation, this score may change.
- The change from existing conditions to as-built conditions is not strong for this action. Existing vegetation and channel shade already exist in many parts of the action area.

Opportunity for Learning

Low

Comments

Opportunity for learning associated with habitat improvements for San Joaquin Basin Chinook juveniles is scored low based on infrequency of inundation .An increase of habitat would not create monitoring ops that we would not be gained form other areas. Score would be higher if inundation was more frequent. Monitoring juvenile use of San Joaquin floodplains would advance understanding of juvenile Chinook in the San Joaquin basin. However we cannot conduct research on area that floods so infrequently. The 30 day inundation period (as written) is a high standard to meet.

P3e	Green Sturgeon	Create rearing habitat for Chinook salmon, green/white sturgeon, splittail and steelhead. Consider loss to entrainment.	1	2
P1e	Green Sturgeon	Improve connectivity of seasonally inundated floodplain habitat for juvenile fish (Splittail, G/W sturgeon, Chinook salmon and steelhead)	1	2
P8b	Longfin smelt	Increased downstream turbidity improves habitat quality for delta smelt and longfin smelt	2	3
P5f	Longfin smelt	Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (off site), longfin smelt, and delta smelt	2	3

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Positive Outcomes (contd.)				
P5c	Splittail	Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (off site), longfin smelt, and delta smelt	3	3-4
P4c	Splittail	Increase production of food for rearing Chinook salmon, steelhead, green/white sturgeon, splittail from inundation and riparian vegetation (local)	3	3-4
P3c	Splittail	Create rearing habitat for Chinook salmon, green/white sturgeon, splittail and steelhead. Consider loss to entrainment.	3	3-4
P2a	Splittail	Create additional splittail spawning habitat on floodplain	3	3-4
P1c	Splittail	Improve connectivity of seasonally inundated floodplain habitat for juvenile fish (Splittail, G/W sturgeon, Chinook salmon and steelhead)	3	3-4
P5b	Steelhead	Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (off site), longfin smelt, and delta smelt	2	2
P4b	Steelhead	Increase production of food for rearing Chinook salmon, steelhead, green/white sturgeon, splittail from inundation and riparian vegetation (local)	2	2
P3b	Steelhead	Create rearing habitat for Chinook salmon, green/white sturgeon, splittail and steelhead. Consider loss to entrainment.	2	2
P1b	Steelhead	Improve connectivity of seasonally inundated floodplain habitat for juvenile fish (Splittail, G/W sturgeon, Chinook salmon and steelhead)	2	2-3
P5d	White Sturgeon	Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (off site), longfin smelt, and delta smelt	1	1
P4d	White Sturgeon	Increase production of food for rearing Chinook salmon, steelhead, green/white sturgeon, splittail from inundation and riparian vegetation (local)	1	1
P3d	White Sturgeon	Create rearing habitat for Chinook salmon, green/white sturgeon, splittail and steelhead. Consider loss to entrainment.	1-2	1
P1d	White Sturgeon	Improve connectivity of seasonally inundated floodplain habitat for juvenile fish (Splittail, G/W sturgeon, Chinook salmon and steelhead)	1-2	1

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Negative Outcomes				
N6a	All	Increased exposure risk to contaminants (including Selinium) due to longer residence time in this area	2	3
N3a	All	Increased frequency and magnitude of low DO in SDWSC due to an increase in algae/POM and impact on Chinook salmon, steelhead, and green and white sturgeon passage.	1	4
N2a	All	Increased resuspension/mobilization and export of toxic compounds with impact on covered species (consider time course of effect)	1	2
N1a	All	Increased MeHg and impact on covered species (direct or indirect)	1	3
N5a	Chinook salmon	Increased habitat for non-native predators/competitors to native fishes (Chinook salmon, steelhead, green and white sturgeon, and splittail)	2	4
N4	Delta smelt & Longfin smelt	Decreased downstream turbidity decreases habitat quality for longfin smelt and delta smelt	1	4
N5c	Green & White Sturgeon	Increased habitat for non-native predators/competitors to native fishes (Chinook salmon, steelhead, green and white sturgeon, and splittail)	1	2
N5d	Splittail	Increased habitat for non-native predators/competitors to native fishes (Chinook salmon, steelhead, green and white sturgeon, and splittail)	2	4
N5b	Steelhead	Increased habitat for non-native predators/competitors to native fishes (Chinook salmon, steelhead, green and white sturgeon, and splittail)	2	4

Action: San Joaquin ROA Floodplain Restoration (downstream of Mossdale)

Evaluation Team: Floodplain and Riparian Workgroup
Campbell Ingram (chair), Denise Reed (coach), Carie Battistone (notetaker), Eric Ginney, Ted Sommers, Rosalie Del Rosario, Dennis McEwan, Bill Harrell, Dan Welsh, Yvette Redler, and Vance Russell.

Date of Last Revision: February 23, 2009

Action Description and Clarifying Assumptions

HRCM 2: Restore floodplain habitat along 6 to 12 miles of the San Joaquin River from Mossdale to French Camp Slough.

- **Option #1:** 363 acres (6 miles)
- **Option #2:** 725 acres (12 miles)

Approach

1. Set back levees along one side of the channel and remove all or large sections of the existing levees.
2. Contour floodplain area as needed to reduce and avoid the potential for stranding of juvenile and adult fish following inundation events.
3. Contour surface elevations along tidal reaches to allow natural establishment of tidal freshwater wetland and riparian habitat.
4. Modify channel where practicable within the restored floodplain reach to create low velocity habitat areas designed to provide spawning habitat for splittail and rearing habitat for splittail and salmonids.
5. Discontinue farming within setback levee where width will not support floodplain characteristics and farming practices.
6. Allow riparian vegetation to naturally establish
7. Allow channel to meander between the new levees through the natural processes of erosion and sedimentation.

Intended Outcomes as Stated in Conservation Measure

1. Expand the floodplain to allow flood waters to attenuate, improving access of juvenile fish, such as Chinook salmon and steelhead, to seasonally inundated floodplain habitat, and reducing flood risk to properties upstream and downstream.
2. Create additional spawning habitat for Sacramento splittail by expanding floodplain habitat area and providing in-channel spawning habitat by creating backwaters.
3. Create additional rearing habitat for San Joaquin Basin runs of Chinook salmon, Sacramento splittail, and possibly steelhead.
4. Increase the production of food for rearing salmonids, splittail, and other covered species.
5. Increase the availability and production of food in Delta channels downstream of restored floodplain habitat for delta smelt, longfin smelt, and other covered species by exporting organic material and phytoplankton, zooplankton, and other organisms produced from the inundated floodplain into Delta channels.

6. Increase habitat complexity by allowing the natural establishment and growth of woody riparian vegetation that will provide inputs of large woody debris into the river channel and provide overhead cover.

Positive

P1. Improved connectivity of seasonally inundated floodplain habitat for juvenile splittail, green and white sturgeon, Chinook salmon and steelhead.
P2. Additional splittail spawning habitat on floodplain.
P3. Additional rearing habitat for splittail, green and white sturgeon, Chinook salmon and steelhead (consider loss to entrainment).
P4. Increased production of food for rearing splittail, green and white sturgeon, Chinook salmon and steelhead from inundation and riparian vegetation (local).
P5. Increased availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for splittail, green and white sturgeon, Chinook salmon, steelhead (off site), longfin smelt, and delta smelt.
P6. Increased establishment of woody riparian vegetation to export LWD.
P7. Increased establishment of woody riparian vegetation to provide shaded channel habitat.
P8. Increased downstream turbidity to improve habitat quality for longfin smelt and delta smelt.

Negative

N1. Increased MeHg and impact on covered species (direct or indirect).
N2. Increased resuspension/mobilization and export of toxic compounds with impact on covered species (consider time course of effect).
N3. Increased frequency and magnitude of low DO in SDWSC due to an increase in algae/POM and impact on Chinook salmon, steelhead, and green and white sturgeon passage.
N4. Decreased downstream turbidity decreases habitat quality for longfin smelt and delta smelt.
N5. Increased habitat for non-native predators/competitors to Chinook salmon, steelhead, green and white sturgeon, and splittail.
N6. Increased exposure risk to contaminants (including Selenium) due to longer residence time in this area.

General Conceptual Model Support for Intended Outcomes

DRERIP models were referenced in evaluations, along with several outside sources.

Models used:
Salmon (Williams/Rosenfield 2007)
Splittail
Floodplain
Riparian
Longfin Smelt
Delta Smelt
Boundary Condition
Mercury
Selenium
Sedimentation
Temperature
Chemical Stressors/Pyrethroids
Dissolved Oxygen
Foodweb
Fish Habitat Linkages

Assumptions

Provided in BDCP Conservation Measure

1. 500 foot setback on one side.
2. 363 acres for 6 mile option.
3. 725 acres for 12 mile option.
4. Approximately half of the acreage would flood for at least 30 days every 7 years; all of the acreage would flood for at least 30 days approximately every 20 years.

Added by Evaluation Team

1. Assumes choke point at Mossdale on river distinguishes between tidal and non-tidal.
2. Assumes no lowering of floodplain to increase inundation
3. Assume all South Delta work will be contingent on significant reduction in south Delta entrainment (need to evaluate some negative outcomes with both 1) Old River isolated and 2) current configuration and reduced pumping (i.e., dual conveyance)).

Problem(s) with Action as Written:

1. Natural recruitment of desirable, native riparian vegetation seems unreasonable given the infrequent inundation of the site (the entire site only floods for a significant duration every 20 years).
2. Took out "(including aquatic, floodplain, intertidal marsh, and riparian features)" from the original stated action.
3. Contouring needs further explanation – focused on stranding not on connections.
4. The floodplain inundation target of "half of the acreage would flood for at least 30 days every 7 years; all of the acreage would flood for at least 30 days approximately every 20 years" will likely be hard to reach. Ultimately this assumption affects overall scoring.

Scale of Action:

Option #1 – LARGE SCALE (50% increase in habitat area)
Option #2 – LARGE SCALE (100% increase in habitat area)

Rationale:
Relative magnitude depends on system-wide condition. During flood events you have a large increase in area inundated.

Evaluation Summary Tables

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in Appendix A. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes on the following pages.

Relation to Existing Conditions:

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

YES

Nature of Change:

Levees appear to be more channelized. Levees are not continuous. The level of inundation/flow this action will create increases. Modeling has been sparse in this area – had to make broad assumptions.

Existing Acreages: 233 acres (Moss-French)

The effects associated with levee setbacks can be considered within our current understanding of the system.

Note: Would help to describe the relation to historical conditions to help us understand the level of habitat to restore.

Potential Positive Ecological Outcome(s)

Outcome P1: Improve connectivity of seasonally inundated floodplain habitat for juvenile fish (splittail, green and white sturgeon, Chinook salmon and steelhead).

P1a. Fall-run Chinook salmon

Human-built features reduce connectivity to floodplain habitat for salmon (Floodplain Model. Text doesn't specifically state salmon but it cites Ted's paper (Sommer et al. 2005, which does).

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 3-4
Given data on flooding and studies elsewhere

P1b. Steelhead

Same information for flooding for Chinook Salmon. They are there (McEwan 2001) at the time (life stage table – Figure 3). Emigrating Jan-August, peak in Jan-May (based on Sacramento River information). Mossdale trawl data (Rosalie provided – FWS 2007) shows more fish occur. Floodplain (page 27) says no information on steelhead use of floodplain. Steelhead model (Fig 2 of steelhead section in salmonid model, p155) shows floodplain use. Williams (2006), McEwan (2001) and Moyle (2002) support presence.

Page15-16 of salmon model shows estuarine habitat – may show import for lower reach.

Steelhead have been caught on floodplain in Yolo (Sommer, T., B. Harrell, M. Nobriga, R. Brown, P. Moyle, W. Kimmerer, and L. Schemel. 2001. California's Yolo Bypass: evidence that flood control can be compatible with fisheries, wetlands, wildlife, and agriculture. Fisheries 26:6-16.). Some reference in Williams 2006 – chapter 9, page 174.

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 2
Non-peer reviewed references.

P1c. Splittail

Splittail model page 12 describes how loss of connectivity has resulted in habitat loss; Floodplain model page 18: human-built features such as berms, ditches, etc. reduce connectivity to floodplain habitat.

Magnitude = 3
Given longer life span means it can take advantage of more flashy system.

Certainty = 3-4

P1d. White Sturgeon

Same information for flooding for Chinook salmon. No evidence of juvenile use of floodplains. Adult catch in Yolo are adults (Harrell and Sommer 2003). This mechanism described above is assumed to apply to white sturgeon (Sommer et al 2005 and Floodplain Model).

Magnitude = 1-2

Certainty = 1
Understanding of sturgeon on floodplain is low and needs further study, e.g., could have higher worth if better understood. It is difficult to determine whether to eliminate sturgeon based on understanding of their use of floodplains.

P1e. Green Sturgeon

Same information for flooding for Chinook salmon. No evidence of juvenile use of floodplains. Adult catch in Yolo are adults (Harrell and Sommer 2003). This mechanism described above is assumed to apply to WS (Sommer et al 2005 and Floodplain Model).

Magnitude = 1

Certainty = 2
Understanding of sturgeon on floodplain is low and needs further study, e.g., could have higher worth if better understood. It is difficult to determine whether to eliminate sturgeon based on understanding of their use of floodplains.

Outcome P2: Create additional spawning habitat (splittail) on floodplain.

P2. Splittail

Floodplain model page 25 and Splittail model pages 9 and 12 describe how additional floodplain habitat supports splittail spawning.

Magnitude = 3
Given longer life span means can take advantage of more flashy system.

Certainty = 3-4

Outcome P3: Create rearing habitat for Chinook salmon, green and white sturgeon, splittail and steelhead. Consider loss to entrainment.

P3a. Fall-run Chinook salmon

Assumption gives duration and frequency. BDCP document shows historic timing is late winter spring. Boundary Condition model (p. 49) shows peaks occur in February period.

Fall-run Chinook salmon juveniles are present in the area during the proposed floodplain inundation period of late winter and spring. San Joaquin fall-run Chinook juveniles enter Delta either as: 1) fry/parr) with high winter flows, typically in January through March (size of 20 to 60 mm fork length, or as 2) smolts after mid March(> 60 mm fork length; (Caswell Annual Report 2007, SJRG 2004, 2005, 2006)

Delta presence of fry confirmed by:

- Presence at Mossdale and Salvage facilities during Jan – March
- San Joaquin River Trawl Dos Reis(RM 51) –Laird(RM 90)
- Salmon < 50mm January through March
- Apparent that much of Tuolumne/Stanislaus River emigrated as fry and pre-smolts with early flood flows in Jan – March…..Early migrants not captured in high numbers at Mossdale/Salvage indicating that juveniles may have remained in the lower San Joaquin above Mossdale….” (SJRG annual report 2006 page 75, 2007 page 66).
- Densities of fry may be underrepresented due to both the trawl and salvage being relatively less effective at capturing fry (Salmon less than 50 mm long). (SJRG 2006 Annual Report page 72)
- Fall run Chinook (Fig 2c) shows juvenile fry/par stage during winter/spring.
- Most Fry enter Delta from tributaries before April (January through March), Smolt enter mid March – June (Based on USFWS/CDFG Mossdale trawl data , SJRG annual reports 2004-2007, Caswell annual report 2007.)

Fall-run Chinook salmon juveniles would use the floodplain to rear. The restored floodplain would create rearing habitat for fry/parr that enter the Delta in the winter, coincident with inundation of the floodplain. These fry would be able to feed and grow in the floodplain, and their larger size would increase the likelihood of survival in the ocean.

- Chinook salmon use the delta inversely proportional to their size (Williams 2006).
- Smolts migrate directly through delta to ocean.
- Fry likely do not migrate out of delta until smolt size. (SJRG annual report 2004 page 76)
- Shallow water habitats including river floodplains and riparian margin provide rearing habitat. Growth rates for juvenile Salmon are higher and emigration rates are slower when in shallow water rearing habitats. (Kjelson 1982, Sommer 2005)
- “during very high flows, fry simply get swept downstream…because the turbulence is too strong for them to resist” (Williams 2006, page76)
- “ Fry tend to keep to the margins of large rivers”(Hatton 1940, Healy 1991) meaning fry can move at a slower rate then the river especially if they have access to floodplains where they can find slower moving water.
- Fry that lingered in lower reaches of creek or bypass grew to 70-80mm compared to fry that migrated quickly and averaged 40mm (Ward et all 2003)

Floodplains no longer exist along the lower San Joaquin River, but fall-run Chinook salmon would likely use the restored floodplains, as they have been documented to rear in Yolo Bypass floodplain along the lower Sacramento River.

- CV Chinook salmon may have relied extensively on floodplain in the past as historically much of the central valley was floodplain habitat (Hunter et al 1999)
- Williams (2006 article 2) confirmed fall Chinook emigration if Feb-Mar on SJ. Floodplain model (Fig 7 and assoc text) identifies that floodplains provide habitat for CS.
- "Given the temporal and geographic distribution, (Fall-run juvenile) have more opportunities to use floodplain habitats then do other Central Valley runs" (Rosenfield 2007).
- Sommer et al (2005) reported extensive use of Yolo and Sutter bypasses by fall-run.
- Moyle et al (2007) reported use of Cosumnes River floodplain

Limited data on SJ floodplain (none in Floodplain model) No reason to suggest they should behave different from other systems.

Magnitude = 2
Given limited temporal effect in frequency. Availability of floodplain is infrequent, with partial inundation every 7 years. This floodplain would be unavailable for least 2 generations of San Joaquin fall run, of which the majority are 3 year old spawners, with some 2 year old spawners (Myers et al. 1998, p. 61).

Certainty = 3-4
Given data on flooding and studies elsewhere. There is high certainty that juvenile salmon are in the vicinity, and inference juveniles would rear in restored floodplain based on documented rearing in the Yolo Bypass and the restored Cosumnes River floodplain.

P3b. Steelhead

Same information for flooding for Chinook salmon. They are there at the time (McEwan 2001 life stage table – Figure 3 - emigrating Jan-August, peak in Jan-May -based on Sacramento River information). Mossdale trawl data (Rosalie provided – FWS 2007) shows more fish occur. Floodplain Model (page 27) says no information on steelhead use of floodplain. Steelhead model (Fig 2 of steelhead section in salmonid model, p155) shows floodplain use. Williams (2006), McEwan (2001) and Moyle (2002) supports presence.

Page15-16 of salmon model shows estuarine habitat – may show import for lower reach.

Steelhead have been caught on floodplain in Yolo (Sommer, T., B. Harrell, M. Nobriga, R. Brown, P. Moyle, W. Kimmerer, and L. Schemel. 2001. California's Yolo Bypass: evidence that flood control can be compatible with fisheries, wetlands, wildlife, and agriculture. Fisheries 26:6-16.). Some reference in Williams 2006 – chapter 9, page 174.

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 2-3
Non–peer reviewed references.

P3c. Splittail

Same information for flooding for Chinook salmon. Table 1 page 3 in Splittail Model indicates juveniles use floodplain Feb-May, distribution shows they are in SJ. based on Baxter sampling (mostly unpublished). Cosumnes publications (Crain et al 2004 conf proc.), Moyle et al 2004. SFEWS. Still not much information from SJ – same inference, no reason to believe they would behave differently.

Magnitude = 3
Given longer life span means can take advantage of more flashy system.

Certainty = 3-4
Given data on flooding and studies elsewhere.

P3d. White Sturgeon

Same information for flooding for Chinook salmon. No evidence of juvenile use of floodplains. Adult catch in Yolo are adults (Harrell and Sommer 2003).

This mechanism described above is assumed to apply to WS (Sommer et al 2005 and Floodplain Model).

Magnitude = 1-2

Certainty = 1
Understanding of sturgeon on floodplain is low and needs further study, e.g., could have higher worth if better understood. It is difficult to determine whether to eliminate sturgeon based on understanding of their use of floodplains.

P3e. Green sturgeon

Same information for flooding for Chinook salmon. No evidence of juvenile use of floodplains. Adult catch in Yolo are adults (Harrell and Sommer 2003).

This mechanism described above is assumed to apply to WS (Sommer et al 2005 and Floodplain Model).

Magnitude = 1

Certainty = 2
Understanding of sturgeon on floodplain is low and needs further study, e.g., could have higher worth if better understood. It is difficult to determine whether to eliminate sturgeon based on understanding of their use of floodplains.

Outcome P4: Increase production of food for rearing Chinook salmon, steelhead, green and white sturgeon, and splittail from inundation and riparian vegetation (local).

P4a. Fall-run Chinook salmon

Floodplain Model pages 20-25 - high levels of food production on floodplain provides support for magnitude score. Floodplain Model pages 27 and 29 describe utilization and higher growth rates for Chinook salmon on floodplains. Chinook salmon likely take advantage of small fishes on the floodplain (Splittail Model page 8 and Moyle et al. 2004).

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 3-4
Given data on flooding and studies elsewhere.

P4b. Steelhead

Floodplain Model pages 20-25 - high levels of food production on floodplain provides support for magnitude score. Steelhead feeding on floodplains is not described in the literature. However, it can be assumed that they are utilizing the same food sources as juvenile salmon, given their life-history similarities. Moyle 2002 states that stream-dwelling rainbow trout feed mostly on drifting aquatic orgs, terrestrial insects, and bottom dwelling orgs which are in abundance on floodplains.

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 2
Non-peer reviewed.

P4c. Splittail

Floodplain Model pages 20-25 - high levels of food production on floodplain provides support for magnitude score. Floodplain Model pages 25 and 27 describes utilization and higher survival for splittail on floodplains.

Magnitude = 3
Given longer life span means can take advantage of more flashy system.

Certainty = 3-4

P4d. White sturgeon

Floodplain Model pages 20-25 - high levels of food production on floodplain provides support for magnitude score.

This mechanism described Chinook salmon is assumed to apply to white sturgeon (Sommer et al 2005 and Floodplain Model).

Magnitude = 1
No evidence of juvenile use of floodplains. Catch in Yolo are adults (Harrell and Sommer 2003).

Certainty = 1
Understanding of sturgeon on floodplain is low and needs further study, e.g., could have higher worth if better understood, group had difficulty determining whether to eliminate sturgeon based on understanding of their use of floodplains.

P4e. Green sturgeon

Floodplain Model pages 20-25 - high levels of food production on floodplain provides support for magnitude score. This mechanism described for Chinook salmon is assumed to apply to green sturgeon (Sommer et al 2005 and Floodplain Model).

Magnitude = 1
No evidence of juvenile use of floodplains. Catch in Yolo are adults (Harrell and Sommer 2003).

Certainty = 2
Understanding of sturgeon on floodplain is low and needs further study, e.g., could have higher worth if better understood, group had difficulty determining whether to eliminate sturgeon based on understanding of their use of floodplains.

Outcome P5: Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (off site), longfin smelt, and delta smelt.

P5a. Fall-run Chinook salmon

Floodplain Model pages 20-25 - high levels of food production on floodplain provides support for magnitude score. Floodplain Model pages 27 and 29 describe utilization and higher growth rates for Chinook salmon on floodplains. Chinook salmon likely take advantage of small fishes on the floodplain (Splittail Model page 8 and Moyle et al. 2004).

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 3-4
Given data on flooding and studies elsewhere.

P5b. Steelhead

Floodplain Model pages 20-25 - high levels of food production on floodplain provides support for magnitude score.

Steelhead feeding on floodplains is not described in the literature. However, it can be assumed that they are utilizing the same food sources as juvenile salmon, given their life-history similarities. Moyle 2002 states that stream-dwelling rainbow trout feed mostly on drifting aquatic orgs, terrestrial insects, and bottom dwelling organisms which are in abundance on floodplains.

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 2
Non-peer reviewed.

P5c. Splittail

Floodplain Model pages 20-25 - high levels of food production on floodplain provides support for magnitude score. Floodplain Model pages 25 and 27 describes utilization and higher survival for splittail on floodplains.

Magnitude = 3
Given longer life span means can take advantage of more flashy system.

Certainty = 3-4

P5d. White sturgeon

Floodplain Model pages 20-25 - high levels of food production on floodplain provides support for magnitude score. This mechanism described Chinook salmon is assumed to apply to white sturgeon (Sommer et al 2005 and Floodplain Model).

Magnitude = 1
No evidence of juvenile use of floodplains. Catch in Yolo are adults (Harrell and Sommer 2003).

Certainty = 1
Understanding of sturgeon on floodplain is low and needs further study, e.g., could have higher worth if better understood, group had difficulty determining whether to eliminate sturgeon based on understanding of their use of floodplains.

P5e. Green sturgeon

Floodplain Model pages 20-25 - high levels of food production on floodplain provides support for magnitude score. This mechanism described for Chinook salmon is assumed to apply to green sturgeon (Sommer et al 2005 and Floodplain Model).

Magnitude = 1

No evidence of juvenile use of floodplains. Catch in Yolo are adults (Harrell and Sommer 2003).

Certainty = 2
Understanding of sturgeon on floodplain is low and needs further study, e.g., could have higher worth if better understood, group had difficulty determining whether to eliminate sturgeon based on understanding of their use of floodplains.

P5f. Longfin smelt

Longfin smelt Model page 21 describes the importance of zooplankton.

Magnitude = 2
Given limited temporal effect in frequency; occur under extreme high flow events when food is less likely a constraint.

Certainty = 3

P5g. Delta smelt

Delta smelt Model page 12 describes the importance of zooplankton.

Magnitude = 2
Given limited temporal effect in frequency; occur under extreme high flow events when food is less likely a constraint.

Certainty = 3

Outcome P6: Increase establishment of woody riparian vegetation to export LWD.

This evaluation applies to all covered species (i.e. species were not evaluated individually. Scores apply to both options. Assumption for action HRCM2 gives duration and frequency of inundation of the floodplain.

Many factors and processes influence natural recruitment of woody riparian vegetation, and are summarized in the DRERIP Riparian Vegetation Model. Figures 5, 6, & 7 of that model demonstrate how levees disrupt the setting of the "physical template" (the surface hydrology and floodplain scouring processes necessary for that template) that is necessary for natural recruitment to occur. Actions in HRCM1 would result in reduction of that stressor (setting back the levee), which would allow for increased establishment of woody riparian vegetation. The altered flow regime of the San Joaquin River system would not be modified by this action, and would therefore remain as a stressor and (in combination with altered channel and floodplain morphology) this would still limit inundation frequency and duration of the site. Thus, while natural riparian vegetation recruitment in the setback area would be possible, infrequent natural flooding may encourage invasive species recruitment (DRERIP Riparian Model, page 20) because surface water and groundwater hydrology drive the recruitment and establishment parameters of vegetation somewhat independently of the physical template. Specifically, this includes recruitment parameters for necessary seedling survival and changes in biotic competition and anoxia that may favor invasive species over native species that are flood-tolerant or require flooding to establish. Infrequent inundation also translates to infrequent LWD export from the area of increased vegetation.

Chinook salmon likely take advantage of small fishes on the floodplain (Splittail Model page 8 and Moyle et al. 2004).

Magnitude = 2
Magnitude score is based on effect being local (e.g., 7 or 14 mile reach) to regional (LWD would move downstream) in scale. However, because new floodplain areas would not be inundated very frequently (and hence the increase in LWD recruitment would be sporadic), the temporal effect is low. The DRERIP Floodplain Model (pages 5, 6, & 7) describes how flood flows modify the floodplain and interact with riparian vegetation to recruit LWD. The approach to Action HRCM1 will set back levees allowing vegetation recruitment (and flooding) where it is currently precluded; however, the action will not modify the floodplain morphology or increase flood hydrology in terms of frequency or duration. Thus, while riparian vegetation may be increased by the action, because of the morphology of the site and other stressors (specifically, impaired flood hydrology), the inundation frequency—and hence the LWD export—is likely to be infrequent (e.g., every 7 years for half the new floodplain; every 20 years for the entire floodplain). Therefore, while this outcome is positive, the actual increase in LWD export is likely to be relatively infrequent and thus of low magnitude.

Certainty = 3
Certainty score is based on dependence of outcome on variable ecosystem processes (i.e., flooding needed to cause LWD input is highly variable—e.g., every 7 to 20 years based on modeling).

Outcome P7: Increase establishment of woody riparian vegetation to provide shaded channel habitat.

P7a. 6-mile reach option

The DRERIP Riparian Model (interactions with floodplains as shown in Figure 5, and specifically the Riparian Vegetation Sub-model; green box in Figure 5) produces a conceptual framework for illustrating the creation of the physical “shaded riverine aquatic habitat” that would be provided by action HRCM1. Removing levees or eliminating vegetation clearing at the river’s edge would allow for increased establishment of woody riparian vegetation.

Based on assumptions and approach to HRCM1, “modifications” to the channel will be made to benefit splittail spawning and provide splittail and salmonid rearing habitat. Ostensibly, this would include addition of instream LWD, but because riparian vegetation is assumed to come from “natural recruitment”, any increase in woody riparian vegetation establishment (and hence increased shade) along the banks would be expected to occur only in areas where current levees (without vegetation) are located immediately adjacent to the river, or vegetation along the river is cleared all the way up to the edge of the river.

Benefit to covered species would be dependant on water temperature effects. Shade would reduce the amount of shortwave radiation striking the water (see Figure 1, DRERIP Temperature model); however, at this fine habitat-level scale, while shading is important, its influence is difficult to prescribe quantitatively (DRERIP Temperature model, page 6). Predicting the magnitude of the shading effect is beyond the level of the conceptual models.

Magnitude = 3
Currently, in the action area for both 6 & 12 mile versions of the action, the levees along the river are immediately adjacent to the channel for the vast majority of the reach (Google Earth satellite imagery; DRERIP-BDCP maps). The levees in this reach are almost entirely devoid of woody riparian vegetation. The action would allow for a substantial change in vegetation and shading within the local reach. Compared to the HRCM1 action [7 or 14 mile versions] the relative opportunity for levee setback, even on only one bank, as in HRCM2, to increase woody riparian vegetation, and hence shade the channel, immediately adjacent to the channel is higher.

Certainty = 2
Certainty score is based on dependence on external factors and the lack of predictability in the outcome directly supporting covered species.

P7b. 12-mile reach option

The DRERIP Riparian Model (interactions with floodplains as shown in Figure 5, and specifically the Riparian Vegetation Sub-model; green box in Figure 5) produces a conceptual framework for illustrating the creation of the physical "shaded riverine aquatic habitat" that would be provided by action HRCM1. Removing levees or eliminating vegetation clearing at the river's edge would allow for increased establishment of woody riparian vegetation.

Based on assumptions and approach to HRCM1, "modifications" to the channel will be made to benefit splittail spawning and provide splittail and salmonid rearing habitat. Ostensibly, this would include addition of instream LWD, but because riparian vegetation is assumed to come from "natural recruitment", any increase in woody riparian vegetation establishment (and hence increased shade) along the banks would be expected to occur only in areas where current levees (without vegetation) are located immediately adjacent to the river, or vegetation along the river is cleared all the way up to the edge of the river.

Benefit to covered species would be dependant on water temperature effects. Shade would reduce the amount of shortwave radiation striking the water (see Figure 1, DRERIP Temperature model); however, at this fine habitat-level scale, while shading is important, its influence is difficult to prescribe quantitatively (DRERIP Temperature model, page 6). Predicting the magnitude of the shading effect is beyond the level of the conceptual models.

Magnitude = 3
Currently, in the action area for both 6 & 12 mile versions of the action, the levees along the river are immediately adjacent to the channel for the vast majority of the reach (Google Earth satellite imagery; DRERIP-BDCP maps). The levees in this reach are

almost entirely devoid of woody riparian vegetation. The action would allow for a substantial change in vegetation and shading within the local reach. Compared to the HRCM1 action [7 or 14 mile versions] the relative opportunity for levee setback, even on only one bank, as in HRCM2, to increase woody riparian vegetation, and hence shade the channel, immediately adjacent to the channel is higher.

Certainty = 2
Certainty score is based on dependence on external factors and the lack of predictability in the outcome directly supporting covered species.

Outcome P8: Increased downstream turbidity improves habitat quality for delta smelt and longfin smelt.

P8a. Delta smelt

Positive link between delta smelt and turbidity throughout life-history is well documented in both lab and field studies. Longfin smelt abundance appears to be positively linked with turbidity, although less research is available.

Action assumes relatively infrequent inundation events. Inundation will suspend and mobilize sediment from the restored floodplain, increasing turbidity in the water column downstream. Floodplain model: Sediment on floodplains can be resuspended by flows or turbulence such as wind-generated waves (page. 18). Sediment model: The Yolo Bypass floodplain, when inundated, can be a large source of sediment to the Sacramento River (page. 9). A restored floodplain on the San Joaquin River could be a source for suspended sediment downstream, assuming it functions similarly to the Yolo Bypass. Delta smelt model: Turbidity increases larval feeding success (page. 4-5); turbidity conceals juvenile delta smelt from predation (page. 7); and juveniles are most abundant in areas with low water transparency (page. 11). Longfin smelt model: Longfin smelt occurring in turbid water have reduced exposure to predation (pages. 7, 8, 13). Although less information is available for longfin, they likely benefit from higher levels of turbidity in similar ways to delta smelt.

Channel migration and bank erosion could be considered as an intermediate outcome.

Magnitude = 2
Limited temporal and population level effect due to low frequency of inundation (given in assumptions).

Certainty = 3-4

P8b. Longfin smelt

The discussion provided for delta smelt in the above paragraphs is also applicable here.

Magnitude = 2
Limited temporal and population level effect due to low frequency of inundation (given in assumptions).

Certainty = 3

Potential Negative Ecological Outcome(s)

Outcome N1: Increased MeHg and impact on covered species (direct or indirect).

N1a. Same for all species

An initial spike in MeHg would be expected when the newly created floodplain habitat in areas where levees are being set back is inundated for the first time (Hg model, page 15, 18). Although concentrations may attenuate from the initial spike over time, MeHg production would likely remain relatively high compared to other types of habitats. Habitats with the highest levels of MeHg production, concentration, and exposure to biota are those with periodic flooding events separated by sufficient time to allow complete drying, such as the seasonal floodplains that would be created in this project (Hg model, page 15). Covered fish species using the restored habitat would be exposed to MeHg through their food chain, and MeHg would be exported downstream along with organic matter and organisms. The effects on fish, if any, would be minimal in most years due to the infrequency of inundation (inundated >30 days once every 7 to 20 years).

The linkage of seasonal flooding to MeHg production and subsequent bioaccumulation of MeHg in fish and their prey is well documented. Effects of this bioaccumulation on covered fish species are more uncertain, due to lack of studies of toxicological effects of MeHg on covered species, uncertainty about sensitivity of covered species relative to species that have been studied, and the subtle nature of the behavioral effects (e.g., impaired predator avoidance and feeding efficiency) that are among the most sensitive endpoints for MeHg toxicity and are difficult to detect.

Magnitude = 1

Certainty = 3
Based on level understanding of affects on fish species.

Outcome N2: Increased resuspension/mobilization and export of toxic compounds w/impact on covered species (consider time course of effect).

The information provided here (including scores) is applicable to all covered fish species. The habitat is being enhanced to facilitate spawning by splittail and rearing by splittail and other species. Current land uses on and adjacent to the project area are agricultural, including orchards and other crops that receive pesticide applications. Pyrethroids, a class of pesticides used as dormant sprays on orchards, can be toxic to fish, especially to early life stages (Pyrethroids model, page 16). Pyrethroid concentrations would be expected to peak during the winter/spring storm season and after peak agricultural application in the summer and fall (Pyrethroids model, page 2). Late-winter and spring are also the times splittail would use the enhanced floodplain habitat to spawn (Splittail model, page 1). Effects of pesticides, if any, would be greatest in the early years of the project as pesticides that have accumulated in agricultural soils are mobilized. Potential for pesticide effects would decrease over time in the restored areas where farming will be discontinued, but may continue in areas that continue to be farmed or are affected by runoff from adjacent agricultural areas.

There are critical data gaps on pyrethroids and other pesticides that make it difficult to evaluate risk to covered fish (Pyrethroids model, page 32; Chemical stressors model, page 25). In general, little is known about the toxic effects of contaminants known to be present in the Delta on resident Delta species, and even less is known about the sublethal effects of contaminants (Chemical stressors model, page 25). Clarification is needed on how much of the restored floodplain areas would be farmed when they are not inundated, as the amount and type of ongoing farming and pesticide use would affect the magnitude and duration of potential effects of pesticides on covered fish.

Magnitude = 1
Not much sediment to mobilize.

Certainty = 2

Outcome N3: Increased frequency and magnitude of low DO in SDWSC due to increase in algae/POM and impact on salmon, steelhead, and green and white sturgeon passage.

The information provided here (including scores) is applicable to all covered fish species. Plus presence of fish species needs to be considered. Page 33 salmon model talks about DO as migration barrier and timing issue (juvenile not migrating when DO is an issue). Also see page 60 regarding adults. More of an issue for adult and juvenile salmon.

Magnitude = 1

Certainty = 4
Would not cause affects on species based on seasonality (more of a late summer fall issue

Outcome N4: Decreased downstream turbidity decreases habitat quality for delta smelt and longfin smelt.

The information provided here (including scores) is applicable to all covered fish species. Water moving out on the floodplain and settling out of sediment. Sediment Model: has a section on floodplain but does not specifically say it traps sediment. Figure 8 in sediment model makes link. Floodplain Model: no information found in model. We expect it would increase turbidity with export of phyto/zooplankton. May be a seasonality issue again – less phytoplankton in winter. Delta Smelt Model: pages 2, 10, and 11 talk about turbidity as important habitat factor. Longfin Smelt Model: link to turbidity is poor (page 7), they tend to hang out in turbid water.

Floodplain model: Reduced water velocities on floodplains, due to topography and vegetation, results in the deposition of sediment, potentially decreasing turbidity (page. 18).

Channel migration and bank erosion may be considered as an intermediate outcome.

Magnitude = 1

Certainty = 4

Outcome N5: Increased habitat for non-native predators/competitors to native fishes (Chinook salmon, steelhead, green and white sturgeon, and splittail).

Delta and longfin smelt, all life stages are typically not present in this part of the Delta (Delta smelt model and longfin smelt model), therefore no competition or predation would be expected.

N5a. Chinook salmon

The floodplain model does not address non native predation or competition on the floodplain. Evidence from Yolo and Cosumnes about non-natives taking advantage of floodplain (ref Sommer et al 2004, Moyle et al 2006). Floodplain Model: Page 10 talks about sources of invasive species. Foodweb Model is focused on estuarine systems.

The Chinook salmon and steelhead model indicates Non-native predation and competition with invasive species and hatchery produced salmonids is of medium importance in rearing and emigration estuarine habitats, including floodplain (Figure 2a). There is limited data on CS and steelhead use of SJ floodplain (no mention in Rosenfield 2007) but the evaluation team thought there is no reason why they would not utilize this habitat in the same way they utilize similar Delta systems (Yolo Bypass).

Magnitude = 2
Based on perennial inundated benches, but not floodplains; benches may support more non-native predators.

Certainty = 4
Based on understanding high concentrations of non-natives in perennially shallow water areas of the San Joaquin (Grimaldo et al. 2003, Feyrer 2003).

Risk = Low

N5b. Steelhead

The floodplain model does not address non native predation or competition on the floodplain. Evidence from Yolo and Cosumnes about non-natives taking advantage of floodplain (ref Sommer et al 2004, Moyle et al 2006). Floodplain Model: Page 10 talks about sources of invasive species. Foodweb Model is focused on estuarine systems.

The Chinook salmon and steelhead model indicates Non-native predation and competition with invasive species and hatchery produced salmonids is of medium importance in rearing and emigration estuarine habitats, including floodplain (Figure 2a). There is limited data on CS and steelhead use of SJ floodplain (no mention in Rosenfield

2007) but the evaluation team thought there is no reason why they would not utilize this habitat in the same way they utilize similar Delta systems (Yolo Bypass).

Magnitude = 2
Based on perennial inundated benches, but not floodplains; benches may support more non-native predators.

Certainty = 4
Based on understanding high concentrations of non-natives in perennially shallow water areas of the San Joaquin (Grimaldo et al. 2003, Feyrer 2003).

N5c. Green and white sturgeon

The floodplain model does not address non native predation or competition on the floodplain. Evidence from Yolo and Cosumnes about non-natives taking advantage of floodplain (ref Sommer et al 2004, Moyle et al 2006). Floodplain Model: Page 10 talks about sources of invasive species. Foodweb Model is focused on estuarine systems.

White sturgeon – model indicate probable distribution in this reach (Figure 7), green sturgeon model indicates uncertain distribution in this reach (Figure 2). Due to the benthic nature of green and white sturgeon and the timing of floodplain inundation they are not expected to be found on the floodplain (personal communication with Josh Israel 2009).

Magnitude = 1

Certainty = 2

N5d. Splittail

The floodplain model does not address non native predation or competition on the floodplain. Evidence from Yolo and Cosumnes about non-natives taking advantage of floodplain (ref Sommer et al 2004, Moyle et al 2006). Floodplain Model: Page 10 talks about sources of invasive species. Foodweb Model is focused on estuarine systems.

Splittail model - Predation by non native fish is characterized as low with high understanding for juveniles and as medium with medium understanding for adults (Figures 5, 6 and 7.) Bird predation appears limited until water recedes and floodplains begin to isolate from main channels at which point fish are exposed to wading birds. [Moyle 2004].

Magnitude = 2

Certainty = 4

Outcome N6: Increased exposure risk to contaminants (including Selenium) due to longer residence time in this area.

The information presented here (including scores) is applicable to all covered fish species. Selenium (Se) loading of the Bay-Delta ecosystem is driven mainly by loads entering the Delta from the San Joaquin River (SJR), which in turn receives most of its Se input from agricultural drainwater entering the river through Mud Slough (Se model, Fig. 1). This project is along the mainstem SJR downstream of these Se inputs.

The proposed action involves habitat modification that creates more extensive floodplain and low velocity, shallow water habitats. These types of habitats create a better environment for Se partitioning in food chains than would occur in bed sediment of the river channel. Exposure of covered fish to Se might increase due to higher bioaccumulation of Se in invertebrate prey and longer residence time of the fish in the restored habitat. The effect would be minimal due to the infrequency of inundation (inundated >30 days once every 7 to 20 years).

Se dynamics in the Bay-Delta system are fairly well understood, but there is uncertainty about how changes in management of SJR flows, water exports, and potential future actions to solve the drainage problem on the west side of the San Joaquin Valley could affect Se loading and cycling in the Delta (Se model, pp 3 and 4). A quantitative analysis of the increased risk of Se toxicity resulting from this project would require estimates of the increase in the amount of time covered fish spend at this location relative to the baseline condition, as well as estimates of future river flows, water exports, and Se loads. Such an analysis is beyond the scope of this worksheet exercise, but should be considered if the project is recommended for evaluation in the NEPA process.

Magnitude = 2

Certainty = 3

Important Gaps in Information and/or Understanding

Research Needs

- The basis of the assumption for the flooding frequency could be refined (Table 2, BDCP doc).
- Major gaps – rearing habitat for steelhead? Rearing habitat for juvenile sturgeon?
- Hg accumulation in fish has been documented, but does not indicate affect on fish.
- Degree of contaminants affects on POD.
- Degree of sediment settling on floodplains.
- Degree of predation/competition within floodplains on native covered fish species by non-native fish species.
- Better diet information is needed for floodplain use of SH, green sturgeon and white sturgeon.
- More information is needed about relative importance of food to population level effects for all of the species.
- Transport studies are needed to evaluate the footprint of food transport from floodplains.
- Timing duration of rearing for SH, green sturgeon and white sturgeon.
- The turbidity linkage for longfin smelt is not as well documented in the research as it is for delta smelt. Further studies positively linking turbidity and longfin smelt would be helpful.

Assess Reversibility and Opportunity for Learning

Reversibility

No/Hard

Comments:

- Would be monumental effort/cost to reconstruct levees
- Low reversibility with high resources associated with structural investments in setback levees.
- Land acquisition and jurisdiction also constraints.
- Implementation of this action would not provide a suitable opportunity to address critical unknowns or uncertainties. If action were implemented at a larger scale and with more-frequent inundation, this score may change.

Opportunity for Learning

Low

Comments

Opportunity for learning associated with habitat improvements for San Joaquin Basin Chinook juveniles is scored low based on infrequency of inundation .An increase of habitat would not create monitoring ops that we would not be gained form other areas. Score would be higher if inundation was more frequent. Monitoring juvenile use of San Joaquin floodplains would advance understanding of juvenile Chinook in the San Joaquin basin. However we cannot conduct research on area that floods so infrequently. The 30 day inundation period (as written) is a high standard to meet.

Action: HRCM 3 - South Delta ROA Floodplain Restoration

Evaluation Team: Floodplain and Riparian Workgroup
Campbell Ingram (chair), Denise Reed (coach), Carie Battistone (notetaker), Eric Ginney, Ted Sommers, Rosalie Del Rosario, Dennis McEwan, Bill Harrell, Dan Welsh, Yvette Redler, and Vance Russell.

Date of Last Revision: February 23, 2009

Action Description and Clarifying Assumptions

Restore between 800 and 1,600 acres of floodplain habitat (including aquatic, intertidal marsh, floodplain and riparian features) along Old River at Fabian Tract

Option #1: 800 acres (6.5 miles with 500 foot setback on each side)

Option #2: 1,600 acres (13.2 miles with 500 foot setback on each side)

Approach

1. Set back levees along both sides of the channel and remove all or large sections of the existing levees
2. Discontinue farming within the setback levees and allowing riparian vegetation to naturally establish on the floodplain.
3. Re-contour the restored floodplain surface, if needed, to avoid potential for stranding of juvenile and adult fish following inundation events.
4. Contour surface elevations along tidal reaches to allow natural establishment of tidal freshwater wetland and riparian habitat.
5. Allow riparian vegetation to naturally establish.
6. Allow channel to meander between the new levees through the natural processes of erosion and sedimentation.

Intended Outcomes as Stated in Conservation Measure

1. Expand the floodplain to allow flood waters to attenuate, improving access of juvenile fish, such as Chinook salmon and steelhead, to seasonally inundated floodplain habitat, and reducing flood risk to properties upstream and downstream.
2. Create additional spawning habitat for Sacramento splittail by expanding floodplain habitat area.
3. Create additional rearing habitat for Sacramento splittail, runs of Chinook salmon from the San Joaquin River and other eastside tributaries, and possibly steelhead.
4. Increase the production of food for rearing salmonids, splittail, and other covered species.
5. Increase the availability and production of food in the Delta downstream of restored floodplain habitat for delta smelt, longfin smelt, and other covered species by exporting organic material and phytoplankton, zooplankton, and other organisms produced from the inundated floodplain into the Delta.
6. Increase the load of organic carbon, phytoplankton, zooplankton, and macroinvertebrates exported into aquatic habitat in the Delta.
7. Increase the hydrodynamic and structural complexity within the channel by allowing the natural establishment and growth of woody riparian vegetation that would provide inputs of large woody debris into the river channel and provide overhead cover.

8. Improve in-channel habitat complexity along the Old River corridor would be expected to reduce the predation risk to covered fish species.
9. Improve connectivity between San Joaquin River habitats and Delta habitats for passage of juvenile salmonids outmigrating from the San Joaquin River and eastside tributaries.
10. Increase habitat complexity by allowing the natural establishment and growth of woody riparian vegetation that will provide inputs of large woody debris into the river channel and provide overhead cover.

Positive

P1: Improve connectivity of seasonally inundated floodplain habitat for juvenile splittail, green and white sturgeon, Chinook salmon and steelhead.
P2: Create additional spawning habitat for splittail on floodplain.
P3: Create rearing habitat for Chinook salmon, green and white sturgeon, splittail and steelhead (consider loss to entrainment).
P4: Increase production of food for rearing Chinook salmon, steelhead, green and white sturgeon, and splittail from inundation and riparian vegetation (local).
P5: Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (offsite), longfin smelt, and delta smelt (consider loss to entrainment).
P6: Increase establishment of woody riparian vegetation to export LWD.
P7: Increase establishment of woody riparian vegetation to provide shaded channel habitat.
P8: Increased downstream turbidity improves habitat quality for delta smelt and longfin smelt.

Negative

N1: Increased MeHg and impact on covered species (direct or indirect)
N2: Increased resuspension/mobilization and export of toxic compounds with impact on covered species (consider time course of effect).
N3: Decreased downstream turbidity decreases habitat quality for delta smelt and longfin smelt.
N4: Increased habitat for non-native predators/competitors to Chinook salmon, steelhead, green and white sturgeon, and splittail.
N5: Increased exposure risk to contaminants (inc. Se) due to longer residence time in this area.

General Conceptual Model Support for Intended Outcomes

DRERIP models were referenced in evaluations, along with several outside sources.

Models used:
Salmon model (Williams/Rosenfield 2007)
Steelhead
Splittail
Green and white sturgeon
Longfin smelt
Delta smelt
Floodplain
Boundary conditions
Riparian vegetation
Temperature
Mercury
Pyrethroids
Chemical stressors
Selenium

Assumptions

Provided in BDCP Conservation Measure

1. Restoration would be focused on Old River corridor, with Middle River serving as a water conveyance channel.
2. 800 acres = 6.5 miles with 500 foot setback on each side.
3. 1,600 acres = 13.2 miles with 500 foot setback on each side.
4. Approximately half of the acreage would flood for at least 30 days every 7 years; all of the acreage would flood for at least 30 days approximately every 20 years.

Added by Evaluation Team

1. All South Delta work will be contingent on significant reduction in south Delta entrainment (need to evaluate some negative outcomes with both 1) Old River isolated and 2) current configuration and reduced pumping (i.e., dual conveyance).
2. The improvements occur west of the confluence between Old and San Joaquin Rivers and east of the point of intertidal elevation.
3. Reduced entrainment risk considering alternate conveyance.
4. Flooding based on existing hydrology (Feb/March).
5. There is a 1 meter depth in floodplain.

Problem(s) with Action as Written:

1. Natural recruitment of desirable, native riparian vegetation seems unreasonable given the infrequent inundation of the site (the entire site only floods for a significant duration every 20 years).
2. Took out language in action specifying sub-habitats within floodplain habitat – "including aquatic, intertidal marsh, floodplain and riparian features".
3. Contouring needs further explanation – focused on stranding not on connections.
4. The floodplain inundation target of "half of the acreage would flood for at least 30 days every 7 years; all of the acreage would flood for at least 30 days approximately every 20 years" will likely be hard to reach. Ultimately this assumption affects overall scoring.
5. Possible limited production of phytoplankton and zooplankton during floods (intended outcome #5).
6. Some question about steelhead (outcomes #1 and #3). Does rearing habitat and food matter during steelhead migration?

Scale of Action:

Option #1 – SMALL SCALE
Option #2 – SMALL SCALE

Rationale:
Frequency of inundation is low for both, some floodplain habitat already (may need to modify if data available).

Evaluation Summary Tables

Summary tables listing magnitude and certainty scores for each outcome, by species, are provided in Appendix A. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes on the following pages.

Relation to Existing Conditions:
