Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

YES

Potential Positive Ecological Outcome(s)

Outcome P1: Improve connectivity of seasonally inundated floodplain habitat for juvenile fish (splittail, green and white sturgeon, Chinook salmon and steelhead).

P1a. Fall-run Chinook salmon

Human-built features reduce connectivity to floodplain habitat for salmon (Floodplain Model. Text doesn't specifically state salmon but it cites Ted's paper (Sommer et al. 2005, which does).

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 3-4
Given data on flooding and studies elsewhere.

P1b. Steelhead

Same information for flooding for Chinook salmon. Fish are present (McEwan 2001) at the time (life stage table – Figure 3). Emigrating Jan-August, peak in Jan-May (based on Sacramento River information). Mossdale trawl data (Rosalie provided – FWS 2007) shows more fish occur. Floodplain (page 27) says no information on steelhead use of floodplain. Steelhead model (Figure 2 of steelhead section in salmonid model, page 155) shows floodplain use. Williams (2006), McEwan (2001) and Moyle (2002) support presence.

Page15-16 of salmon model shows estuarine habitat – may show import for lower reach.

Steelhead have been caught on floodplain in Yolo (Sommer, T., B. Harrell, M. Nobriga, R. Brown, P. Moyle, W. Kimmerer, and L. Schemel. 2001. California's Yolo Bypass: evidence that flood control can be compatible with fisheries, wetlands, wildlife, and agriculture. Fisheries 26:6-16.). Some reference in Williams 2006 – chapter 9, page 174.

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 2-3
Non-peer reviewed references.

P1c. Splittail

Splittail model page 12 describes how loss of connectivity has resulted in habitat loss; Floodplain model page 18: human built features such as berms, ditches, etc. reduce connectivity to floodplain habitat.

Magnitude = 3
Given longer life span means it can take advantage of more flashy system.

Certainty = 3-4

P1d. White Sturgeon

Same information for flooding for Chinook salmon. No evidence of juvenile use of floodplains. Adult catch in Yolo are adults (Harrell and Sommer 2003). This mechanism described above is assumed to apply to white sturgeon (Sommer et al 2005 and Floodplain Model).

Magnitude = 1-2

Certainty = 1

P1e. Green Sturgeon

DLO Relationship and General Observations
Same information for flooding for Chinook salmon. No evidence of juvenile use of floodplains. Adult catch in Yolo are adults (Harrell and Sommer 2003). This mechanism described above is assumed to apply to white sturgeon (Sommer et al 2005 and Floodplain Model).

Magnitude = 1

Certainty = 2

Understanding of sturgeon on floodplain is low and needs further study, e.g., could have higher worth if better understood, group had difficulty determining whether to eliminate sturgeon based on understanding of their use of floodplains.

Outcome P2: Create additional spawning habitat (splittail) on floodplain.

P2. Splittail

Floodplain model page 25 and Splittail model pages 9 and 12 describe how additional floodplain habitat supports splittail spawning.

Magnitude = 3
Given longer life span means can take advantage of more flashy system.

Certainty = 3-4

Outcome P3: Create rearing habitat for Chinook salmon, green and white sturgeon, splittail and steelhead. Consider loss to entrainment.

P3a. Fall-run Chinook salmon

Assumption gives duration and frequency. BDCP document shows historic timing is late winter spring. Boundary Condition model (p. 49) shows peaks occur in February period.

Fall-run Chinook salmon juveniles are present in the area during the proposed floodplain inundation period of late winter and spring. San Joaquin fall-run Chinook juveniles enter Delta either as: 1) fry/parr) with high winter flows, typically in January through March (size of 20 to 60 mm fork length, or as 2) smolts after mid March(> 60 mm fork length; (Caswell Annual Report 2007, SJRG 2004, 2005, 2006)

Delta presence of fry confirmed by:

- Presence at Mossdale and Salvage facilities during Jan – March
- San Joaquin River Trawl Dos Reis(RM 51) –Laird(RM 90)
- Salmon < 50mm January through March
- Apparent that much of Tuolumne/Stanislaus River emigrated as fry and pre-smolts with early flood flows in Jan – March…..Early migrants not captured in high numbers at Mossdale/Salvage indicating that juveniles may have remained in the lower San Joaquin above Mossdale…." (SJRG annual report 2006 page 75, 2007 page 66).
- Densities of fry may be underrepresented due to both the trawl and salvage being relatively less effective at capturing fry (Salmon less than 50 mm long). (SJRG 2006 Annual Report page 72)
- Fall run Chinook (Fig 2c) shows juvenile fry/par stage during winter/spring.
- Most Fry enter Delta from tributaries before April (January through March), Smolt enter mid March – June (Based on USFWS/CDFG Mossdale trawl data , SJRG annual reports 2004-2007, Caswell annual report 2007.)

Fall-run Chinook salmon juveniles would use the floodplain to rear. The restored floodplain would create rearing habitat for fry/parr that enter the Delta in the winter, coincident with inundation of the floodplain. These fry would be able to feed and grow in the floodplain, and their larger size would increase the likelihood of survival in the ocean.

- Chinook salmon use the delta inversely proportional to their size (Williams 2006).
- Smolts migrate directly through delta to ocean.
- Fry likely do not migrate out of delta until smolt size. (SJRG annual report 2004 page 76)
- Shallow water habitats including river floodplains and riparian margin provide rearing habitat. Growth rates for juvenile Salmon are higher and emigration rates are slower when in shallow water rearing habitats. (Kjelson 1982, Sommer 2005)
- "during very high flows, fry simply get swept downstream…because the turbulence is too strong for them to resist" (Williams 2006, page76)
- " Fry tend to keep to the margins of large rivers"(Hatton 1940, Healy 1991) meaning fry can move at a slower rate then the river especially if they have access to floodplains where they can find slower moving water.
- Fry that lingered in lower reaches of creek or bypass grew to 70-80mm compared to fry that migrated quickly and averaged 40mm (Ward et all 2003)

Floodplains no longer exist along the lower San Joaquin River, but fall-run Chinook salmon would likely use the restored floodplains, as they have been documented to rear in Yolo Bypass floodplain along the lower Sacramento River.

- CV Chinook salmon may have relied extensively on floodplain in the past as historically much of the central valley was floodplain habitat (Hunter et al 1999)
- Williams (2006 article 2) confirmed fall Chinook emigration if Feb-Mar on San Joaquin. Floodplain model (Fig 7 and assoc text) identifies that floodplains provide habitat for Chinook salmon.
- "Given the temporal and geographic distribution, (Fall-run juvenile) have more opportunities to use floodplain habitats then do other Central Valley runs" (Rosenfield 2007).
- Sommer et al (2005) reported extensive use of Yolo and Sutter bypasses by fall-run.
- Moyle et al (2007) reported use of Cosumnes River floodplain

Limited data on San Joaquin floodplain (none in Floodplain model) No reason to suggest they should behave different from other systems.

Magnitude = 2
Given limited temporal effect in frequency. Availability of floodplain is infrequent, with partial inundation every 7 years. This floodplain would be unavailable for least 2 generations of San Joaquin fall run, of which the majority are 3 year old spawners, with some 2 year old spawners (Myers et al. 1998, p. 61).

Certainty = 3-4
Given data on flooding and studies elsewhere. There is high certainty that juvenile salmon are in the vicinity, and inference juveniles would rear in restored floodplain based on documented rearing in the Yolo Bypass and the restored Cosumnes River floodplain.

P3b. Steelhead

Same information for flooding for Chinook salmon. Fish are present at the time (McEwan 2001 life stage table – Figure 3 - emigrating Jan-August, peak in Jan-May - based on Sacramento River information). Mossdale trawl data (Rosalie provided – FWS 2007) shows more fish occur. Floodplain Model (page 27) says no information on steelhead use of floodplain. Steelhead model (Fig 2 of steelhead section in salmonid model, p155) shows floodplain use. Williams (2006), McEwan (2001) and Moyle (2002) supports presence.

Page15-16 of salmon model shows estuarine habitat – may show import for lower reach.

Steelhead have been caught on floodplain in Yolo (Sommer, T., B. Harrell, M. Nobriga, R. Brown, P. Moyle, W. Kimmerer, and L. Schemel. 2001. California's Yolo Bypass: evidence that flood control can be compatible with fisheries, wetlands, wildlife, and agriculture. Fisheries 26:6-16.). Some reference in Williams 2006 – chapter 9, page 174.

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 2-3
Non–peer reviewed references.

P3c. Splittail

Same information for flooding for Chinook salmon. Table 1 page 3 in Splittail Model indicates juveniles use floodplain Feb-May, distribution shows they are in San Joaquin. based on Baxter sampling (mostly unpublished). Cosumnes publications (Crain et al 2004 conf proc.), Moyle et al 2004. SFEWS. Still not much information from San Joaquin – same inference, no reason to believe they would behave differently.

Magnitude = 3
Longer life span means can take advantage of more flashy system.

Certainty = 3-4
Given data on flooding and studies elsewhere.

P3d. White Sturgeon

Same information for flooding for Chinook salmon. No evidence of juvenile use of floodplains. Adult catch in Yolo are adults (Harrell and Sommer 2003).

This mechanism described above is assumed to apply to white sturgeon (Sommer et al 2005 and Floodplain Model).

Magnitude = 1-2

Certainty = 1
Understanding of sturgeon on floodplain is low and needs further study, e.g., could have higher worth if better understood, group had difficulty determining whether to eliminate sturgeon based on understanding of their use of floodplains.

P3e. Green sturgeon

Same information for flooding for Chinook salmon. No evidence of juvenile use of floodplains. Adult catch in Yolo are adults (Harrell and Sommer 2003).

This mechanism described above is assumed to apply to green sturgeon also (Sommer et al 2005 and Floodplain Model).

Magnitude = 1

Certainty = 2
Understanding of sturgeon on floodplain is low and needs further study, e.g., could have higher worth if better understood, group had difficulty determining whether to eliminate sturgeon based on understanding of their use of floodplains.

Outcome P4: Increase production of food for rearing Chinook salmon, steelhead, green and white sturgeon, and splittail from inundation and riparian vegetation (local).

P4a. Fall-run Chinook salmon

Floodplain Model pages 20-25 - a high level of food production on floodplain provides support for magnitude score. Floodplain Model pages 27 and 29 describe utilization and higher growth rates for Chinook salmon on floodplains. Chinook salmon likely take advantage of small fishes on the floodplain (Splittail Model page 8 and Moyle et al. 2004).

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 3-4
Given data on flooding and studies elsewhere.

P4b. Steelhead

Floodplain Model pages 20-25 - a high level of food production on floodplain provides support for magnitude score.

Nothing really in the literature that describes steelhead feeding on floodplains, however, it can be assumed that they are utilizing the same food sources as juvenile salmon, given their life-history similarities. Moyle 2002 states that stream-dwelling rainbow trout feed mostly on drifting aquatic organisms, terrestrial insects, and bottom dwelling organisms which are in abundance on floodplains.

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 2
Non-peer reviewed.

P4c. Splittail

Floodplain Model pages 20-25 - a high level of food production on floodplain provides support for magnitude score. Floodplain Model pages 25 and 27 describes utilization and higher survival for splittail on floodplains.

Magnitude = 3
Given longer life span means can take advantage of more flashy system.

Certainty = 3-4

P4d. White sturgeon

Floodplain Model pages 20-25 - a high level of food production on floodplain provides support for magnitude score. This mechanism described Chinook salmon is assumed to apply to white sturgeon (Sommer et al 2005 and Floodplain Model).

Magnitude = 1
No evidence of juvenile use of floodplains. Catch in Yolo are adults (Harrell and Sommer 2003).

Certainty = 1
Understanding of sturgeon on floodplain is low and needs further study, e.g., could have higher worth if better understood, group had difficulty determining whether to eliminate sturgeon based on understanding of their use of floodplains.

P4e. Green sturgeon

Floodplain Model pages 20-25 - a high level of food production on floodplain provides support for magnitude score.

This mechanism described for Chinook salmon is assumed to apply to green sturgeon (Sommer et al 2005 and Floodplain Model).

Magnitude = 1
No evidence of juvenile use of floodplains. Catch in Yolo are adults (Harrell and Sommer 2003).

Certainty = 2
Understanding of sturgeon on floodplain is low and needs further study, e.g., could have higher worth if better understood. Group had difficulty determining whether to eliminate sturgeon based on understanding of their use of floodplains.

Outcome P5: Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (off site), longfin smelt, and delta smelt.

P5a. Fall-run Chinook salmon

Floodplain Model pages 20-25 - a high level of food production on floodplain provides support for magnitude score. Floodplain Model pages 27 and 29 describe utilization and higher growth rates for Chinook salmon on floodplains.

Chinook salmon likely take advantage of small fishes on the floodplain (Splittail Model page 8 and Moyle et al. 2004).

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 3-4
Given data on flooding and studies elsewhere.

P5b. Steelhead

Floodplain Model pages 20-25 - a high level of food production on floodplain provides support for magnitude score.

Steelhead feeding on floodplains is not described in the literature. However, it can be assumed that they are utilizing the same food sources as juvenile salmon, given their life-history similarities. Moyle 2002 states that stream-dwelling rainbow trout feed mostly on drifting aquatic organisms, terrestrial insects, and bottom dwelling organisms which are in abundance on floodplains.

Magnitude = 2
Given limited temporal effect in frequency.

Certainty = 2
Non-peer reviewed.

P5c. Splittail

Floodplain Model pages 20-25 - high levels of food production on floodplain provides support for magnitude score. Floodplain Model pages 25 and 27 describes utilization and higher survival for splittail on floodplains.

Magnitude = 3
Longer life span means can take advantage of more flashy system.

Certainty = 3-4

P5d. White sturgeon

Floodplain Model pages 20-25 - high levels of food production on floodplain provides support for magnitude score.

This mechanism described Chinook salmon is assumed to apply to white sturgeon (Sommer et al 2005 and Floodplain Model).

Magnitude = 1
No evidence of juvenile use of floodplains. Catch in Yolo are adults (Harrell and Sommer 2003).

Certainty = 1
Understanding of sturgeon on floodplain is low and needs further study, e.g., could have higher worth if better understood. Group had difficulty determining whether to eliminate sturgeon based on understanding of their use of floodplains.

P5e. Green sturgeon

Floodplain Model pages 20-25 - a high level of food production on floodplain provides support for magnitude score. This mechanism described for Chinook salmon is assumed to apply to green sturgeon (Sommer et al 2005 and Floodplain Model).

Magnitude = 1
No evidence of juvenile use of floodplains. Catch in Yolo are adults (Harrell and Sommer 2003).

Certainty = 2
Understanding of sturgeon on floodplain is low and needs further study, e.g., could have higher worth if better understood, group had difficulty determining whether to eliminate sturgeon based on understanding of their use of floodplains.

P5f. Longfin smelt

Longfin smelt Model page 21 describes the importance of zooplankton.

Magnitude = 2
Given limited temporal effect in frequency; occur under extreme high flow events when food is less likely a constraint.

P5g. Delta smelt

Delta Smelt Model page 12 describes the importance of zooplankton.

Magnitude = 2
Given limited temporal effect in frequency; occur under extreme high flow events when food is less likely a constraint.

Certainty = 3

Outcome P6: Increase establishment of woody riparian vegetation to export LWD.

The following paragraphs are applicable to all covered fish species. Options #`1 and #2 are discussed below.

P6a. Option #1 800 acres.

Assumption for action HRCM3 gives duration and frequency of inundation of the floodplain. Many factors and processes influence natural recruitment of woody riparian vegetation, and are summarized in the DRERIP Riparian Vegetation Model. Figures 5, 6, & 7 of that model demonstrate how levees disrupt the setting of the "physical template" (the surface hydrology and floodplain scouring processes necessary for that template) that is necessary for natural recruitment to occur. Actions in HRCM1 would result in reduction of that stressor (setting back the levee), which would allow for increased establishment of woody riparian vegetation. The altered flow regime of the San Joaquin River system would not be modified by this action, and would therefore remain as a stressor and (in combination with altered channel and floodplain morphology) this would still limit inundation frequency and duration of the site. Thus, while natural riparian vegetation recruitment in the setback area would be possible, infrequent natural flooding may encourage invasive species recruitment (DRERIP Riparian Model, page 20) because surface water and groundwater hydrology drive the recruitment and establishment parameters of vegetation somewhat independently of the physical template. Specifically, this includes recruitment parameters for necessary seedling survival and changes in biotic competition and anoxia that may favor invasive species over native species that are flood-tolerant or require flooding to establish. Infrequent inundation also translates to infrequent LWD export from the area of increased vegetation.

Magnitude = 2
Score is based on effect being local (e.g., 6.5 mile reach) to regional (LWD would move downstream) in scale. However, because new floodplain areas would not be inundated very frequently (and hence the increase in LWD recruitment would be sporadic), the temporal effect is low.

The DRERIP Floodplain Model (pages 5, 6, & 7) describes how flood flows modify the floodplain and interact with riparian vegetation to recruit LWD. The approach to Action HRCM1 will set back levees allowing vegetation recruitment (and flooding) where it is currently precluded; however, the action will not modify the floodplain morphology or increase flood hydrology in terms of frequency or duration. Thus, while riparian vegetation may be increased by the action, because of the morphology of the site and other stressors (specifically, impaired flood hydrology), the inundation frequency—and hence the LWD export—is likely to be infrequent (e.g., every 7 years for half the new floodplain; every 20 years for the entire floodplain). Therefore, because most of this 6-mile reach already includes some water's edge riparian vegetation (DRERIP-BDCP maps & Google Earth satellite imagery), the only additional LWD input would come from the new floodplain areas (which would be flooded relatively infrequently). While this outcome is positive, the actual increase in LWD export is likely to be relatively infrequent and thus of low magnitude.

Certainty = 3
Certainty score is based on dependence of outcome on variable ecosystem processes (i.e., flooding needed to cause LWD input is highly variable—e.g., every 7 to 20 years based on modeling).

P6b. Option #2 1,600 acres. Not evaluated by species.

Assumption for action HRCM3 gives duration and frequency of inundation of the floodplain. Many factors and processes influence natural recruitment of woody riparian vegetation, and are summarized in the DRERIP Riparian Vegetation Model. Figures 5, 6, & 7 of that model demonstrate how levees disrupt the setting of the "physical template" (the surface hydrology and floodplain scouring processes necessary for that template) that is necessary for natural recruitment to occur. Actions in HRCM1 would result in reduction of that stressor (setting back the levee), which would allow for increased establishment of woody riparian vegetation. The altered flow regime of the San Joaquin River system would not be modified by this action, and would therefore remain as a stressor and (in combination with altered channel and floodplain morphology) this would still limit inundation frequency and duration of the site. Thus, while natural riparian vegetation recruitment in the setback area would be possible, infrequent natural flooding may encourage invasive species recruitment (DRERIP Riparian Model, page 20) because surface water and groundwater hydrology drive the recruitment and establishment parameters of vegetation somewhat independently of the physical template. Specifically, this includes recruitment parameters for necessary seedling survival and changes in biotic competition and anoxia that may favor invasive species over native species that are flood-tolerant or require flooding to establish. Infrequent inundation also translates to infrequent LWD export from the area of increased vegetation.

Magnitude = 3
Score is based on effect being local (e.g., 13-mile reach) to regional (LWD would move downstream) in scale. Inundation and LWD export have the same frequencies as the 6.5-mile/downstream version of the action; however, the upper 6-mile reach of the action area includes very little (if any) existing water's edge riparian vegetation (DRERIP-BDCP maps & Google Earth satellite imagery). Thus, under existing conditions, there is little if any LWD input from this upper end of the reach. Though the new floodplain area would be flooded relatively infrequently, water's edge riparian would increase. Flood flows that may not inundate the floodplain may still be capable of eroding banks and recruiting LWD. This represents an increased magnitude from the 6.5-mile/downstream reach version of this action, and results in a slightly higher magnitude.

Certainty = 3
Certainty score is based on dependence of outcome on variable ecosystem processes (i.e., flooding needed to cause LWD input is highly variable—e.g., every 7 to 20 years based on modeling).

Outcome P7: Increase establishment of woody riparian vegetation to provide shaded channel habitat.

P7a. Option #1 800acres

The DRERIP Riparian Model (interactions with floodplains as shown in Figure 5, and specifically the Riparian Vegetation Sub-model; green box in Figure 5) produces a conceptual framework for illustrating the creation of the physical "shaded riverine aquatic habitat" that would be provided by action HRCM1. Removing levees or eliminating vegetation clearing at the river's edge would allow for increased establishment of woody riparian vegetation.

Based on assumptions and approach to HRCM1, "modifications" to the channel will be made to benefit splittail spawning and provide splittail and salmonid rearing habitat. Ostensibly, this would include addition of instream LWD, but because riparian vegetation is assumed to come from "natural recruitment", any increase in woody riparian vegetation establishment (and hence increased shade) along the banks would be expected to occur only in areas where current levees (without vegetation) are located immediately adjacent to the river, or vegetation along the river is cleared all the way up to the edge of the river.

Benefit to covered species would be dependant on water temperature effects. Shade would reduce the amount of shortwave radiation striking the water (see Figure 1, DRERIP Temperature model); however, at this fine habitat-level scale, while shading is important, its influence is difficult to prescribe quantitatively (DRERIP Temperature model, page 6). Predicting the magnitude of the shading effect is beyond the level of the conceptual models.

Magnitude = 2
Currently, compared to the upstream reach (the other 6.5-mile section that completes the 13-mile action area); there is a relatively-substantial amount of riparian vegetation on the levees immediately adjacent to the river channel (Google Earth satellite imagery; DRERIP-BDCP maps). Thus the opportunity for levee setback to increase woody riparian vegetation (and hence shade the channel) immediately adjacent to the channel is lower relative to that in the upstream 6.5 miles. SUMMARY: Compared to upstream 6.5 miles, potential magnitude of increase is lower for this segment of the action area (i.e., relatively-less bank would gain shade).

Certainty = 3
Certainty score is based on dependence on external factors and the lack of predictability in the outcome directly supporting covered species.

P7b. Option #2 1600 acres

The DRERIP Riparian Model (interactions with floodplains as shown in Figure 5, and specifically the Riparian Vegetation Sub-model; green box in Figure 5) produces a conceptual framework for illustrating the creation of the physical "shaded riverine aquatic habitat" that would be provided by action HRCM1. Removing levees or eliminating vegetation clearing at the river's edge would allow for increased establishment of woody riparian vegetation.

Based on assumptions and approach to HRCM1, "modifications" to the channel will be made to benefit splittail spawning and provide splittail and salmonid rearing habitat. Ostensibly, this would include addition of instream LWD, but because riparian vegetation is assumed to come from "natural recruitment", any increase in woody riparian vegetation establishment (and hence increased shade) along the banks would be expected to occur only in areas where current levees (without vegetation) are located immediately adjacent to the river, or vegetation along the river is cleared all the way up to the edge of the river.

Benefit to covered species would be dependant on water temperature effects. Shade would reduce the amount of shortwave radiation striking the water (see Figure 1, DRERIP Temperature model); however, at this fine habitat-level scale, while shading is important, its influence is difficult to prescribe quantitatively (DRERIP Temperature model, page 6). Predicting the magnitude of the shading effect is beyond the level of the conceptual models.

Magnitude = 2
This reach currently has little if any riparian along the water's edge (Google Earth satellite imagery; DRERIP-BDCP maps). Thus the relative increase is greater for this version of the action.

Certainty = 3
Certainty score is based on dependence on external factors and the lack of predictability in the outcome directly supporting covered species.

Outcome P8: Increased downstream turbidity improves habitat quality for delta smelt and longfin smelt.

P8a. Delta smelt

Positive link between delta smelt and turbidity throughout life-history is well documented in both lab and field studies. Longfin smelt abundance appears to be positively linked with turbidity, although less research is available.

Action assumes relatively infrequent inundation events. Inundation will suspend and mobilize sediment from the restored floodplain, increasing turbidity in the water column downstream. Floodplain model: Sediment on floodplains can be resuspended by flows or turbulence such as wind-generated waves (page. 18). Sediment model: The Yolo Bypass floodplain, when inundated, can be a large source of sediment to the Sacramento River (page. 9). A restored floodplain on the San Joaquin River could be a source for suspended sediment downstream, assuming it functions similarly to the Yolo Bypass. Delta smelt model: Turbidity increases larval feeding success (page. 4-5); turbidity conceals juvenile delta smelt from predation (page. 7); and juveniles are most abundant in areas with low water transparency (page. 11). Longfin smelt model: Longfin smelt occurring in turbid water have reduced exposure to predation (pages. 7, 8, 13). Although less information is available for longfin, they likely benefit from higher levels of turbidity in similar ways to delta smelt.

Channel migration and bank erosion could be considered as an intermediate outcome.

Magnitude = 2
Limited temporal and population level effect due to low frequency of inundation (given in assumptions).

Certainty = 3-4
Positive link between delta smelt and turbidity throughout life-history is well documented in both lab and field studies. Longfin smelt abundance appears to be positively linked with turbidity, although less research is available.

P8b. Longfin smelt

The text provided above in Outcome P8a is also applicable here.

Magnitude = 2
Limited temporal and population level effect due to low frequency of inundation (given in assumptions).

Certainty = 3
Positive link between delta smelt and turbidity throughout life-history is well documented in both lab and field studies. Longfin smelt abundance appears to be positively linked with turbidity, although less research is available.

Potential Negative Ecological Outcome(s)

Outcome N1: Increased MeHg and impact on covered species (direct or indirect).

N1. Same for all species

An initial spike in MeHg would be expected when the newly created floodplain habitat in areas where levees are being set back is inundated for the first time (Hg model, page 15, 18). Although concentrations may attenuate from the initial spike over time, MeHg production would likely remain relatively high compared to other types of habitats. Habitats with the highest levels of MeHg production, concentration, and exposure to biota are those with periodic flooding events separated by sufficient time to allow complete drying, such as the seasonal floodplains that would be created in this project (Hg model, page 15). Covered fish species using the restored habitat would be exposed to MeHg through their food chain, and MeHg would be exported downstream along with organic matter and organisms. The effects on fish, if any, would be minimal in most years due to the infrequency of inundation (inundated >30 days once every 7 to 20 years).

The linkage of seasonal flooding to MeHg production and subsequent bioaccumulation of MeHg in fish and their prey is well documented. Effects of this bioaccumulation on covered fish species are more uncertain, due to lack of studies of toxicological effects of MeHg on covered species, uncertainty about sensitivity of covered species relative to species that have been studied, and the subtle nature of the behavioral effects (e.g., impaired predator avoidance and feeding efficiency) that are among the most sensitive endpoints for MeHg toxicity and are difficult to detect.

Magnitude = 1

Certainty = 3
Based on level understanding of affects on fish species.

Outcome N2: Increased resuspension/mobilization and export of toxic compounds w/impact on covered species (consider time course of effect).

N2a. Same for all species:

The habitat is being enhanced to facilitate spawning by splittail and rearing by splittail and other species. Current land uses on and adjacent to the project area are agricultural crops that receive pesticide applications, including pyrethroids. Pyrethroids can be toxic to fish, especially to early life stages (Pyrethroids model, page 16). Pyrethroid concentrations would be expected to peak during the winter/spring storm season and after peak agricultural application in the summer and fall (Pyrethroids model, page 2). Late-winter and spring are also the times splittail would use the enhanced floodplain habitat to spawn (Splittail model, page 1). Effects of pesticides, if any, would be greatest in the early years of the project as pesticides that have accumulated in agricultural soils are mobilized. Potential for pesticide effects would decrease over time in the restored areas where farming will be discontinued. This elimination of farming between the setback levees may actually result in an improvement above baseline with regards to risks of pesticides to fish.

There are critical data gaps on pyrethroids and other pesticides that make it difficult to evaluate risk to covered fish (Pyrethroids model, page 32; Chemical stressors model, page 25). In general, little is known about the toxic effects of contaminants known to be present in the Delta on resident Delta species, and even less is known about the sublethal effects of contaminants (Chemical stressors model, page 25). However, elimination of farming and associated pesticide use between the setback levees would almost certainly minimize the magnitude and duration of potential effects of pesticides on covered fish.

Magnitude = 1
Not much sediment to mobilize.

Certainty = 4

Outcome N3: Decreased downstream turbidity decreases habitat quality for delta smelt and longfin smelt.

N3a. Same for delta and longfin smelt

Water moving out on the floodplain and settling out of sediment. Sediment Model: has a section on floodplain but does not specifically say it traps sediment. Figure 8 in sediment model makes link. Floodplain Model: no information found in model. We expect it would increase turbidity with export of phyto/zooplankton. May be a seasonality issue again – less phytoplankton in winter. Delta Smelt Model: Page 2, 10, and 11 talk about turbidity as important habitat factor. Longfin Smelt Model: link to turbidity is poor (page 7), they tend to hang out in turbid water.

(For potential addition to existing rationale) Floodplain model: Reduced water velocities on floodplains, due to topography and vegetation, results in the deposition of sediment, potentially decreasing turbidity (page. 18).

Channel migration and bank erosion may be considered as an intermediate outcome.

Magnitude = 1

Certainty = 4

Outcome N4: Increased habitat for non-native predators/competitors to native fishes (Chinook salmon, steelhead, green and white sturgeon, and splittail).

Delta and longfin smelt, all life stages are typically not present in this part of the Delta (Delta smelt model and longfin smelt model); therefore no competition or predation would be expected.

N4a. Chinook salmon

The floodplain model does not address non native predation or competition on the floodplain. Evidence from Yolo and Cosumnes about non-natives taking advantage of floodplain (ref Sommer et al 2004, Moyle et al 2006). Floodplain Model: Page 10 talks about sources of invasive species. Foodweb Model is focused on estuarine systems.

The Chinook salmon and steelhead model indicates Non-native predation and competition with invasive species and hatchery produced salmonids is of medium importance in rearing and emigration estuarine habitats, including floodplain (Figure 2a). There is limited data on Chinook salmon and steelhead use of San Joaquin floodplain (no mention in Rosenfield 2007) but the evaluation team thought there is no reason why they would not utilize this habitat in the same way they utilize similar Delta systems (Yolo Bypass).

Magnitude = 2
Based on perennial inundated benches, but not floodplains; benches may support more non-native predators.

Certainty = 4
Based on understanding high concentrations of non-natives in perennially shallow water areas of the San Joaquin (Grimaldo et al. 2003, Feyrer 2003).

N4b. Steelhead

The floodplain model does not address non native predation or competition on the floodplain. Evidence from Yolo and Cosumnes about non-natives taking advantage of floodplain (ref Sommer et al 2004, Moyle et al 2006). Floodplain Model: Page 10 talks about sources of invasive species. Foodweb Model is focused on estuarine systems.

The Chinook salmon and steelhead model indicates Non-native predation and competition with invasive species and hatchery produced salmonids is of medium importance in rearing and emigration estuarine habitats, including floodplain (Figure 2a). There is limited data on Chinook salmon and steelhead use of San Joaquin floodplain (no mention in Rosenfield 2007) but the evaluation team thought there is no reason why they would not utilize this habitat in the same way they utilize similar Delta systems (Yolo Bypass).

Magnitude = 2
Based on perennial inundated benches, but not floodplains; benches may support more non-native predators.

Certainty = 4

Based on understanding high concentrations of non-natives in perennially shallow water areas of the San Joaquin (Grimaldo et al. 2003, Feyrer 2003).

N4c. Green and white sturgeon

The floodplain model does not address non native predation or competition on the floodplain. Evidence from Yolo and Cosumnes about non-natives taking advantage of floodplain (ref Sommer et al 2004, Moyle et al 2006). Floodplain Model: Page 10 talks about sources of invasive species. Foodweb Model is focused on estuarine systems.

White sturgeon – model indicate probable distribution in this reach (Figure 7), green sturgeon model indicates uncertain distribution in this reach (Figure 2). Due to the benthic nature of green and white sturgeon and the timing of floodplain inundation they are not expected to be found on the floodplain (personal communication with Josh Israel 2009).

Magnitude = 1

Certainty = 2
Sturgeon have a lower risk because they are uncommon in this area.

N4d. Splittail

The floodplain model does not address non native predation or competition on the floodplain. Evidence from Yolo and Cosumnes about non-natives taking advantage of floodplain (ref Sommer et al 2004, Moyle et al 2006). Floodplain Model: Page 10 talks about sources of invasive species. Foodweb Model is focused on estuarine systems.

Splittail model - Predation by non native fish is characterized as low with high understanding for juveniles and as medium with medium understanding for adults (Figures 5, 6 and 7.) Bird predation appears limited until water recedes and floodplains begin to isolate from main channels at which point fish are exposed to wading birds. [Moyle 2004].

Magnitude = 2

Certainty = 4

Outcome N5: Increased exposure risk to contaminants (incl. Se) due to longer residence time in this area.

The following text and scores are applicable to all covered fish species (i.e. species were not evaluated separately). Selenium (Se) loading of the Bay-Delta ecosystem is driven mainly by loads entering the Delta from the San Joaquin River (SJR), which in turn receives most of its Se input from agricultural drainwater entering the river through Mud Slough (Se model, Fig. 1). The location of this project along Old River is in the South Delta in proximity to Se inputs from the SJR. Despite this location, the magnitude of potential effects of Se on covered fish species from this project relative to baseline is minimal.

The proposed action involves habitat modification that creates more extensive floodplain and low velocity, shallow water habitats. These types of habitats create a better environment for Se partitioning in food chains than would occur in bed sediment of the river channel. Exposure of covered fish to Se might increase due to higher bioaccumulation of Se in invertebrate prey and longer residence time of the fish in the restored habitat. The effect would be minimal due to the infrequency of inundation (inundated >30 days once every 7 to 20 years).

Salmonids are relatively sensitive to Se compared to other fish species (Se model, page 19). Beckon (2008 abstract from CALFED science conference; manuscript in prep) evaluated Se data from the SJR and concluded that, although discharges of Se to the SJR have been reduced over the last 15 years, Se will pose a substantial risk to salmon that are reintroduced to restored middle reaches of the river unless Se loads are further reduced and/or sufficient dilution flows are provided. The magnitude of potential effects of Se from this project may be lower than would occur at projects along the middle reaches of the SJR (i.e., sites in the vicinity of Mud Slough) because this project occurs in the South Delta, downstream of dilution sources from the Merced, Tuolumne and Stanislaus Rivers. However, this spatial difference does not provide strong protection because Se bioaccumulates in food chains, is recycled in the ecosystem, and can have significant lag times between when loading occurs and when effects are seen.

The seasonal use of the habitat may also reduce the potential magnitude of Se impacts to covered fish species, especially juvenile salmonids. Seasonal use of the Delta by juvenile salmonids occurs mainly during high flow periods (January-June) (salmon model, page 11); whereas highest concentrations of Se occur during low flow periods (Se model, page 6). However, this seasonal difference does not provide strong protection because Se bioaccumulates in food chains, is recycled in the ecosystem, and can have significant lag times between when loading occurs and when effects are seen.

The invertebrate prey of juvenile salmonids are water-column-feeding or detritus-feeding species that are relatively less contaminated than certain suspension or deposit-feeding bivalves (Se model, Table 5 and Fig. 1). Adult splittail and sturgeon feed on bivalves and would be expected to have greater exposure to Se in their diet than salmonids. This project is intended to provide rearing habitat for juvenile sturgeon and splittail rather than habitat for adults, but may also result in increased residence time by spawning and foraging adults. However, the bivalve species present at this freshwater location would be Corbicula fluminea rather than Corbula amurensis (Corbula and Corbicula models). C. fluminea is less efficient at bioaccumulating Se than C. amurensis (Se model, page 14).

Se dynamics in the Bay-Delta system are fairly well understood, but there is uncertainty about how changes in management of SJR flows, water exports, and potential future actions to solve the drainage problem on the west side of the San Joaquin Valley could affect Se loading and cycling in the Delta (Se model, pp 3 and 4). A quantitative analysis of the increased risk of Se toxicity resulting from this project would require estimates of the increase in the amount of time covered fish spend at this location relative to the baseline condition, as well as estimates of future river flows, water exports, and Se loads. Such an analysis is beyond the scope of this worksheet exercise, but should be considered if the project is recommended for evaluation in the NEPA process.

Magnitude = 1

Certainty = 3

Important Gaps in Information and/or Understanding

Data Needs

- Transition from intertidal to riparian vegetation poorly understood. No examples left in the system to allow determination of critical flooding regimes.
- The amount of existing habitat along Old River (e.g., floodplain, riparian, etc.) was not quantified for this evaluation team. Proximity of floodplain habitat to existing riparian habitat would also be useful information.
- What is the likelihood of entrainment of Old River juveniles via Middle River conveyance?

Research Needs

- The turbidity linkage for longfin smelt is not as well documented in the research as it is for delta smelt. Further studies positively linking turbidity and longfin smelt would be helpful.
- The basis of the assumption for the flooding frequency could be refined (Table 2, BDCP doc).
- Rearing habitat for steelhead? Rearing habitat for juvenile sturgeon?
- Hg accumulation in fish has been documented, but does not indicate effect on fish.
- Degree of contaminants affects on POD.
- Degree of sediment settling on floodplains.
- Degree of predation/competition within floodplains on native covered fish species by non-native fish species.
- Better diet information is needed for floodplain use of SH, green and white sturgeon.
- More information is needed about relative importance of food to population level effects for all of the species.
- Transport studies are needed to evaluate the footprint of food transport from floodplains.
- Timing duration of rearing for SH, green and white sturgeon.

Assess Reversibility and Opportunity for Learning

Reversibility

No/Hard. Low reversibility with high resources associated with structural investments in setback levees.

Comments:
Implementation of this action would not provide a suitable opportunity to address critical unknowns or uncertainties. An increase of habitat would not create monitoring ops that we would not be gained form other areas. Score would be higher if inundation was more frequent. Monitoring juvenile use of San Joaquin floodplains would advance understanding of juvenile Chinook in the San Joaquin basin. However we cannot conduct research on area that floods so infrequently. The 30 day inundation period (as written) is a high standard to meet.

Opportunity for Learning

Low, given uncertainty of entrainment risk via Middle River conveyance and diversion operations.

Comments

Opportunity for learning associated with habitat improvements for San Joaquin Basin Chinook juveniles is scored low based on infrequency of inundation .An increase of habitat would not create monitoring ops that we would not be gained form other areas. Score would be higher if inundation was more frequent. Monitoring juvenile use of San Joaquin floodplains would advance understanding of juvenile Chinook in the San Joaquin basin. However we cannot conduct research on area that floods so infrequently. The 30 day inundation period (as written) is a high standard to meet.

Action

Restore between 5,000 and 11,000 acres to tidal action and vegetated tidal marsh and shallow sub tidal habitat in the Yolo Bypass/Cache Slough Complex ROA (in addition to Liberty Island and Little Holland Tract). *(Evaluate both 5,000 and 11,000 acres)*.

Evaluation Team

Dave Harlow (Chair), Stuart Siegel (Coach), Jon Rosenfield, Wim Kimmerer, Chris Enright, Dan Kratville, Charlie Alpers, and Amy Richey.

Date of Last Revision: June 11, 2009

Action Description and Clarifying Assumptions

The evaluation team was asked to consider two restoration scenarios as follows:

5,000-Acre Option Extent

Haas Slough A & B; Shag Slough; and Egbert A & B.

11,000-Acre Option Extent

Areas suitable for restoration include, but are not limited to: Haas Slough (A & B); Hastings Cut; Lindsey and Barker Sloughs and Calhoun Cut (Egbert A & B); Liberty Island, Little Holland, Westland's property, Shag Slough, Little Egbert Tract, and Prospect Island.

Restoration would include a combination of: (1) vegetated marsh plain; (2) tidal channel networks with depths that are shallow to medium subtidal; and (3) shallow subtidal open water in the deeper portions of the restoration sites. Achieving the 5,000 or 11,000 acre restoration target would involve restoring *some* but not all of the sites noted above.

Figure 1 and Table 1 depict the different habitat types that would be expected to result from tidal reintroduction in the Yolo/Cache ROA based on existing elevations. Elevations are reported in the current federal geodetic datum (land surface elevation) of the North American Vertical Datum of 1988 (NAVD88). Elevations are grouped relative to *existing* local tide heights as reported by the National Ocean Service for the Rio Vista station (NOS 941-5316). BDCP modeling has shown that tide ranges will be reduced with implementing tidal reintroduction projects but we have not attempted to integrate those modeling findings at this time. It should also be noted that existing intertidal areas for Liberty, Little Holland and Westlands' property are combined. Sea level rise is indicated by the abbreviation (SLR).

A brief description of each elevation category depicted in Table 1 is provided below the table. Descriptions of the plant community composition associated with the elevation categories listed in Table 1 come from the DRERIP Tidal Marsh Conceptual Model (Kneib et al 2008), findings of the CALFED Integrated Regional Wetland Monitoring Pilot Project (www.irwm.org), and the DRERIP Aquatic Vegetation Conceptual Model (Anderson 2008).

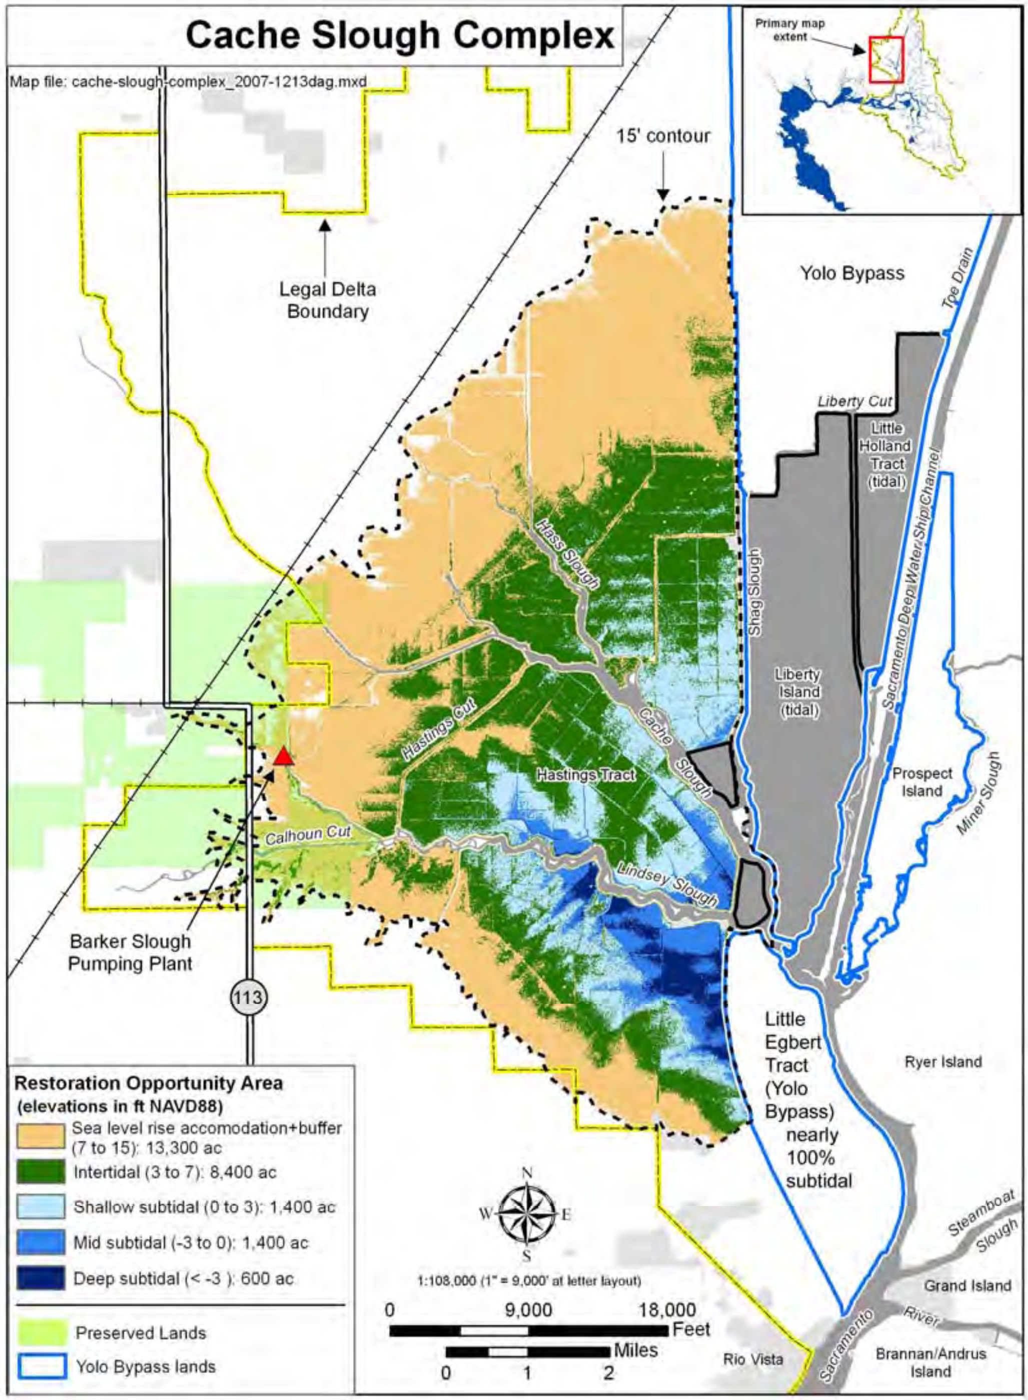

Figure 1. Topography of proposed restoration areas.
Lands shown in green (intertidal) and blue (sub tidal) plus Little Egbert Tract and Prospect Island (both mostly sub tidal) comprise the larger, 11,000-acre option. *Source: Stuart Siegel 2008.*

Table 1.

Total Area Available at BDCP Sites Considered, by Elevation Group

Site (5K option only)	Total (ac)	Area (ac) by Elevation Group (ft NAVD88)			Subtidal			
		> SLR (>12')	SLR (7-12')	Tidal (3-7')	Shallow (0-3')	Medium (-3-0')	Deeper (-6--3')	Deep (<-6')
Egbert A	4,644	3,323	1,034	276	2	3	3	4
Egbert B	7,107	1,496	1,455	1,687	1,541	779	51	97

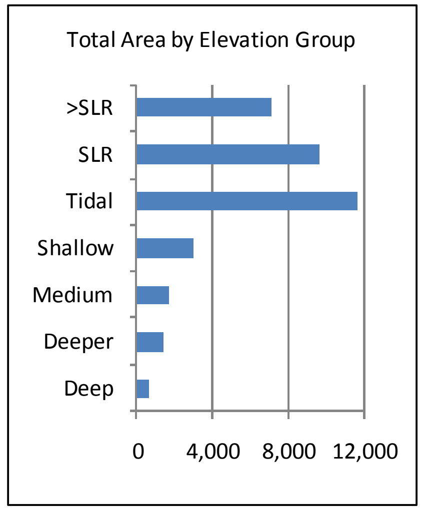
% of tidal, subtidal				63%	16%	10%	7%	4%



* Data provided by SAIC 2/2/09 with corrected Little Egbert data 2/6/09

1) **Above SLR** (sea level rise): elevations above the currently projected upper end of sea level rise. These areas would be expected to remain as uplands over the long term after tidal reintroduction. These areas could support seasonal wetlands and upland habitats utilized by species that also use the marsh (e.g., birds, small mammals, reptiles, amphibians).

2) **SLR**: elevations that are within the currently projected upper end of sea level rise and thus would be expected to become inundated over time after tidal reintroduction as sea level rises. These areas could support a mix of seasonal wetlands, uplands, upland-wetland transition, infrequently inundated tidal marsh at the lowest elevations, and in the future increased extent of tidal marsh as sea level rises.

3) **Tidal**: elevations that are within the current local tide range of mean lower low water (MLLW) (3 ft NAVD88) to mean higher high water (MHHW) (7 feet NAVD88). This elevation category would be dominated over time by a diverse suite of emergent marsh plants showing some zonation patterns relative to elevation and thus inundation regime.

4) **Shallow Subtidal**: elevations that are between MLLW and 3 feet below local MLLW (0 to 3 ft NAVD88). This elevation category would be dominated by open water with tule vegetation extending into its shallowest regions; also subject to colonization by submerged aquatic vegetation in low-energy areas with suitable substrate.

5) **Medium Subtidal**: elevations that are 3 to 6 feet below local MLLW (-3 to 0 ft NAVD88). This elevation category would be open water and subject to colonization by submerged aquatic vegetation in low-energy areas with suitable substrate; SAV would have a greater probability of occurrence at shallower depths with more light penetration.

6) **Deeper Subtidal**: elevations that are 6 to 9 feet below local MLLW (-6 to -3 ft NAVD88). This elevation category would be open water and subject to colonization by submerged aquatic vegetation in low-energy areas with suitable substrate only in areas with high light penetration.

7) **Deep Subtidal**: elevations that are more than 9 feet below local MLLW (below -6 ft NAVD88). This elevation category would be open water and subject to colonization by submerged aquatic vegetation in low-energy areas with suitable substrate only in areas with extremely high light penetration.

Approach

1. Breach levees to provide for tidal exchange with lands being restored; breaches will be of sufficient length not to limit water motion into and out of restored habitat.
2. Modify ditches and cuts to encourage the development of a dendritic system of tidal channels based on local hydrology, sized appropriately for the tidal prism being conveyed.
3. Restore stream functions of erosion and sedimentation (e.g., Ulatis Flood Control channel) to improve spawning conditions for Delta smelt and other fish and macro invertebrates.
4. On subsided lands (e.g., Little Egbert Tract), plant tules before breaching levees to raise ground surface to elevations suitable for tidal marsh restoration.

Intended Outcomes as Stated in Conservation Measure

1. Increase rearing habitat area for Chinook salmon, Sacramento splittail, and possibly steelhead.
2. Increase the production of food for rearing salmonids, splittail, and other covered species.
3. Increase the availability and production of food in the Delta downstream of Rio Vista by exporting organic material from the marsh plain and phytoplankton, zooplankton, and other organisms produced in intertidal channels into the Delta.
4. Locally provide areas of cool water refugia for Delta smelt.

Conceptual Model Information Regarding Intended Outcomes

The Outcomes tables document the following linkages between tidal marsh restoration efforts generally in the Delta and the specific cause-effect relationships implied in the Action:

1. Rearing habitat is a stated outcome for habitat quantity and quality (specifically, water quality). It is a driver for Delta smelt, longfin smelt, splittail, and white and green sturgeon. The higher turbidity levels of Cache Slough region compared to other Delta locations (see Schoellhamer et. al., 2007) improves habitat suitability for Delta smelt.
2. Exported production is a stated outcome. It is a driver for Delta smelt, steelhead, and white and green sturgeon.
3. Cool water refugia is not integrated into the Outcomes table. To the extent that "water quality" implies temperature (it usually implies salinity unless otherwise stated) then it is captured.

Assumptions

Provided in BDCP Conservation Measure

1. Barker Slough Pumping Plant is relocated such that it does not adversely affect benefits of restoration.

Added by Evaluation Team

1. Barker Slough Pumping Plant relocation also eliminates potential conflicts between drinking water supplies and increased organic carbon in the water column.
2. Other large agricultural intakes in the area will be relocated such that they do not adversely affect benefits of restoration.
3. Levee breaches will be large enough not to cause muted tides within a restoration site.
4. Levee breaches will be large enough to avoid steep velocity gradients (eddies) that promote fish predation.
5. Approach #2 includes the excavation of subtidal dendritic channel networks, recognizing that down cutting through prior agricultural fields is unlikely.
6. The time frame for realizing restoration benefits depends upon the approaches used. Reversal of subsidence on restored areas can take several years to a decade or more depending on starting elevations. The accretion rate depends on sediment supply and biomass accretion which depends on site-specific conditions. Sediment supply in the Delta is generally very low. Cache Slough and Suisun Marsh generally have higher concentrations of sediment than other Delta locations (Schoellhamer et. al., 2007).
7. Efforts to reverse subsidence before active restoration would be focused on the more deeply subsided portions of these landscapes, i.e., lands more than 6 feet below low tide. To speed up the subsidence reversal process, an alternative method would be to separate low-lying areas with new levees and reconnect those areas after subsidence reversal is accomplished.
8. Prior to implementation, a complete Phase I Environmental Assessment with on-site sampling to assess legacy and other soil contaminants (i.e. mercury and pesticides) would be conducted.
9. The frequency, magnitude, and duration of Yolo Bypass flooding would be the same as current existing conditions.

Problem(s) with Action as Written:

1. The conservation measure would benefit from an explicit recognition that restoration of tidal marsh functions on subsided landscapes, especially those subsided below emergent vegetation elevations, will take many years to many decades. In the interim, the region will function as a shallow intertidal habitat.
2. The evaluation should consider alternative approaches for shallowly subsided lands. Approach #4 indicates one approach – pre-breach tule planting on the subsided areas. The approach should also consider leaving some part of the restored area as shallow sub tidal habitat, as the Action itself states "tidal marsh and shallow sub tidal habitat". Each approach leads to a different outcome on different time scales. See assumption #8 above.
3. It is unlikely that intertidal mudflats will develop in the Delta because dominant intertidal emergent vegetation species in the Delta can grow throughout the tidal

range and just into shallow sub-tidal elevations (Brown 2003, Simenstad et al 2000 as cited in Schoellhamer et. al., 2007, page 26).

4. Because rearing habitat for juvenile fish by necessity includes local availability of food, the evaluation team merged the first two Intended Outcomes (rearing habitat and local food) into one outcome.
5. As currently written, approach #3 (stream functions) is not clear. The Evaluation Team doubts this watershed is large enough to provide significant sedimentation. Therefore, this approach is not included in this evaluation.

Scale of Action:

Large for both acreage options.

Rationale:
This is a large scale restoration action due to its spatial extent. As listed in Table1 below, the Delta currently has approximately 21,600 acres of tidal marsh habitat (baseline). Additionally 67,000 acres of diked and other lands have been identified as potentially restorable to tidal marsh (neglecting effects of restoration on reducing tidal range). The proposed 5,000 and 11,000 acre restoration options would increase marsh acreage 23% and 51% (respectively) above current conditions. Significant amounts of the 67,000 acres of identified restorable lands are highly constrained such that they could not be restored in the near term (South Delta and Netherlands alone account for 31,000 acres of the 67,000 acres). Therefore, this action also represents an important part of the potentially restorable tidal marsh lands.

Table 2. Summary of Tidal Marsh Acreages

Area	**Acreage**	**Source**
Delta (entire Delta proper)	738,000	DWR, 2009
Historic tidal marsh/wetlands in Delta	525,000	TBI, 2002
Current extent of tidal marsh/wetlands in Delta.	21,600	TBI, 2002
Restorable intertidal lands within Delta.	67,000	CA DVSP, 2008, Table 1, p.77.
Proposed Cache Slough tidal marsh restoration (this action)	5,000 or 11,000	BDCP, 2009

Evaluation Summary Tables

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

Outcomes with Direction of Change Uncertain

The outcomes listed below could be either positive or negative (the direction of change is not certain).

- P/N1. Slough turbidity changes as it affects Delta smelt food locating capacity. This outcome was not evaluated. The team believes there is a relationship but lack of data precludes evaluation (we don't know whether the sign would be positive or negative).
- P/N2. Increased velocities in larger sloughs may alter the energetics of covered fish species. Velocities will increase in some parts of the Delta and decrease in other parts. The direction of change is not known.

Outcomes with Zero Magnitude

- OP1: Increase rearing habitat and local food production for Eastside and San Joaquin Chinook salmon, fall run.
- OP2a: Locally provide areas of cool water refugia for winter-run salmon.
- OP2b: Locally provide areas of cool water refugia for late fall-run salmon.

Other Potential Positive Outcomes Identified, Not Evaluated

When BDCP originally crafted this action, they identified the four potential positive outcomes listed below. The Evaluation Team was instructed to focus evaluation efforts on covered fish species. Since the four outcomes consider species other than covered fish, the team did not evaluate these outcomes.

- OP1. Increase giant garter snake habitat
- OP2. Increase Mason's lilaeopsis habitat
- OP3. Increase habitats for resident native fish (blackfish, Sacramento perch, tule perch)
- OP4. Increase habitats for birds
- OP5: Reduce low velocity-associated salmonid predation pressure in Sutter and Steamboat sloughs (see details in Appendix C)

Other Potential Negative Outcomes Identified, Not Evaluated

During the course of this evaluation, the team identified one potential negative outcome that it did not evaluate due to lack of time. It is recommended that this potential outcome be evaluated at some point in the future when additional time is available.

- ON1. Pesticide use for mosquito control. Tidal marsh provide habitat for mosquito larvae and adults. Since this restoration action will increase tidal marsh habitat, it will also increase the availability of habitat for mosquitoes. County environmental health departments are authorized to utilize pesticides to the extent necessary to manage mosquitoes in order to protect public health and prevent west nile and other viruses. Sacramento, San Joaquin, and other Delta counties have active mosquito management programs that include the application of pesticides on marsh habitats. The effect such pesticide use may have on the flora and fauna in the restored marsh and connected areas have not been evaluated in this worksheet.

Relation to Existing Conditions

Significant changes to hydrodynamics due to Cache Slough restoration have been simulated by the BDCP modeling team (BDCP 2009. and John DeGeorge, pers. comm.). The one-dimensional model results combine Cache Slough restoration with other core elements including modification of the Fremont Weir and new North Delta diversion. The two-dimensional modeling simulated multiple restoration areas at one time in some cases. For this particular evaluation, only altered hydrodynamics in response to Cache Slough restoration are considered. In this section, the evaluation team primarily considers the Cache Slough restoration on its own merits. However, some comments on the integration of Cache Slough restoration and Yolo bypass flow augmentation are also provided.

In general, opening hydraulic connections to formerly diked lands will dissipate tidal energy on a regional (in this case, nominally northwest Delta) scale. Reductions in tidal range and redistribution of tidal flows and associated tidal velocity may also be observed.

While the modeling of Cache Slough restoration includes the north Delta diversion and intermittent Fremont Weir flow, the influence of these elements on tidal range is thought to be minimal (BDCP 2009).

Cache Slough restoration decreases regional tidal range, with generally more reduction near, and less reduction far from the project. The magnitude and aerial extent of decrease is also a function of project acreage, hydraulic connection attributes, the restoration volume or accommodation space, and the roughness characteristics of the site.

Tidal stage range in Cache Slough and the Liberty Island area is estimated to decrease by up to 0.75 feet from its current range of about 4 feet. Simulated changes in Sacramento River stage range downstream of Cache Slough (near Rio Vista) are similar. Upstream, Sacramento River stage range is estimated to be reduced by approximately 0.5 ft. More of the tidal range reduction will on the high tides than the low tides. Sutter, Steamboat, and Georgiana Slough stage changes are anticipated to be similar to that at Freeport.

The magnitude and duration of tidal inundation on newly restored sites is a function of the particular configuration of the project. It is expected that the site will evolve geomorphically over time. Project evolution will be characterized by sediment and vegetation accretions that will reduce accommodation space. This may have the effect of increasing regional tidal range once again. However, along the trajectory of change over time, the balance of forces may yet reduce tidal range further while the site still has most of its initial accommodation space, but also becomes highly frictional as emergent vegetation begins to dominate the tidal fringes. The evolving balance between the tidal prism and the frictional characteristics of the site ultimately determines how regional stage and tidal flow will be affected over time (Friedrichs et al. 2001, Culberson et al. 2003).

Tidal restoration in Cache Slough ROA differentially influences regional tidal flow and velocity depending on channel proximity to the restoration area. In general, tidal flow and velocity increases in Cache Slough as much as 30,000 cfs, because it conveys flow to the increased accommodation space created by the restoration. Tidal flow increases despite the reduced tidal range because there is now slightly less asymmetry between stage and velocity phasing (peak flood and ebb flows occur ~1 hour later). Tidal flow at Rio Vista increases from approximately +/- 100,000 cfs to approximately +/- 130,000 cfs. Modeling suggests that peak tidal velocity will increase 30-40% to accommodate the added flow. This will likely be a transient effect until the channel scours to a new dynamic equilibrium between bed shear stress and sediment cohesion properties.

Tidal flow variability is dramatically decreased upstream of Cache Slough in concert with diminished tidal range. While net flow remains the same, variability of tidal flow at Freeport is decreased from approximately 4,000-15,000 cfs to +6,000-14,000 cfs (simulated spring tide, mid June 2002) (BDCP, 2009). Closer to Cache Slough, Sutter Slough flow range diminishes from +/-2,000-5,500 cfs to +1,000-4,500 cfs. Sutter Slough and Steamboat Slough also no longer exhibits bi-directional flow at their heads, and diminished bi-directional flow downstream. This is important because it reduces or stops the ability of salinity (or other scalars) to disperse upstream.

The hydrodynamic changes described above can be broadly used to describe changes under either the 5,000 or 11,000 acres restoration scenarios, with the magnitude of change corresponding to the acreage restored. Tidal dampening and/or conveyance restrictions appear to increase as more acres are restored, limiting the extent of inundation; further hydrodynamic modeling would be needed to confirm or reject and quantify this effect.

Overview of Productivity Import-Export

The purpose of this section is to discuss the general concepts around productivity in the restored tidal marshes and shallow open water and availability of primary productivity to the aquatic food web within and outside of restoration sites. Available productivity is one of the main intended positive outcomes of this conservation measure. Factors that influence biological productivity include resource availability (e.g., light, nutrients), import-export dynamics (biological and physical), invasive species, and predator-prey relationships As restoration sites evolve over time, the nature and relative magnitude of these factors may change. Climate change and sea level rise will introduce additional dynamics (Callaway et al, 2007).

Freshwater tidal marshes are among the most productive ecosystems globally. The efficiency with which organic material produced at the base of the food web will reach covered fish species has a large influence on the potential positive benefits of tidal marsh restoration. The DRERIP tidal marsh model (Kneib et. al., 2008) hypothesizes that the most prevalent form of carbon bioavailable to the aquatic food web is exported from tidal marshes in the form of small fish, a concept referred to as the “trophic relay”. In addition, the Conservation Measure includes restoration of emergent vegetated tidal marsh, shallow sub tidal channel networks within the restored tidal marshes, and adjacent shallow sub tidal open water areas. See Figure 3 below for a schematic representation of a generic tidal marsh.

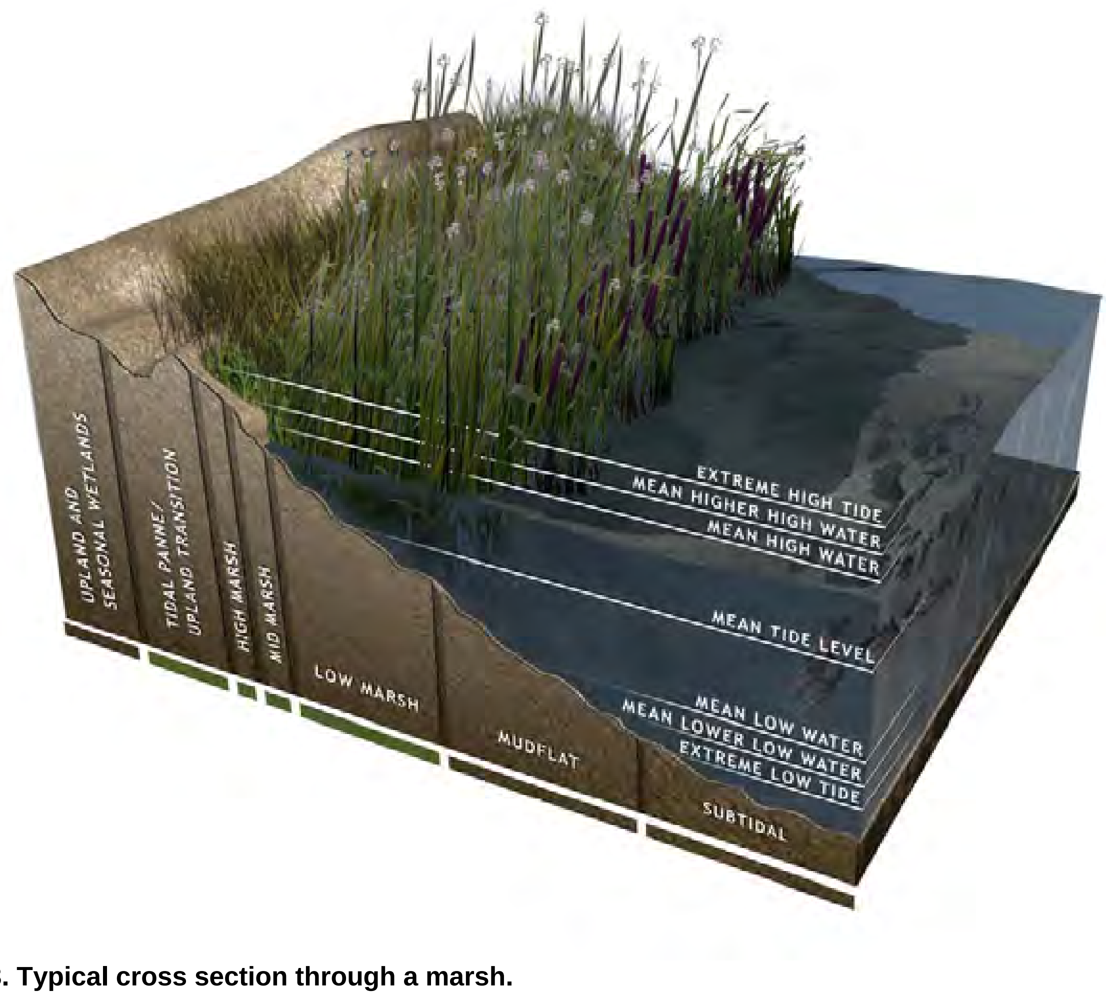


Figure 3. Typical cross section through a marsh.

Tidal marshes generally are net producers of organic matter because of high primary production by marsh plants, epiphytes, submerged and floating vegetation, and phytoplankton. This material is available to support local foodwebs and provide food energy for invertebrates, fish, and other animals. Tidal marshes can both import and export organic carbon in dissolved or particulate, living and nonliving, and bioavailable or refractory forms. However, much of the organic matter exported is in the dissolved form which provides less direct benefit to the estuarine foodweb because the organic matter is not very bioavailable and the microbial foodweb that can use this material is inefficient (Sobczak et al. 2005). Newly created or restored marshes, or marshes that are mainly subtidal, may accrete organic soil and thereby bury organic matter (Kneib et. al., 2008).

An intended outcome is the export of organic matter, based on the assumption that marsh restoration will increase production of phytoplankton and other bioavailable forms. Experiments to stimulate phytoplankton production in natural water bodies have been conducted to investigate nutrient limitation and to explore the possibility of stimulating production of fish. These studies include lake fertilization experiments (Schindler 1977, Carpenter et al. 1995) and iron addition experiments in the ocean (Chisholm et al. 2001). The general conclusion of such studies is that natural ecosystems are complex and that consequences of any change in forcing, whether from nutrient enrichment or alteration of trophic structure, can be difficult to predict (Carpenter et al., Chisholm et al. 2001). This suggests that forecasts of gains in export of productivity from the restored marshes should be made cautiously.

When net flow rates are low, the movement of individual foodweb components depends on tidal exchange and the concentration gradient, affected in turn by source and loss rates in and outside the marsh, and the swimming of organisms. For example, marshes produce particulate detritus that is then available for export, but marshes can also import detritus through particle trapping by marsh plants. Data shows that net phytoplankton production is highest in shallow water because phytoplankton production requires light (Thompson 2000). Although this implies the potential for export there is little quantitative information to support this, and the degree of export depends critically on shallow-deep system connectivity (Cloern 2007 and Monsen et al 2007) and the local phytoplankton growth-loss balance (Lucas et.al. 2009). For example, establishment of invasive clams or mussels in the shallow subtidal regions or marsh channels (Outcome N1B) may increase local phytoplankton loss rates and thus convert restored areas into food sinks instead of sources. Similarly, planktivorous fish in marshes may consume zooplankton at a higher rate than occurs outside the marsh, resulting in a concentration gradient favoring net import of zooplankton. Thus, the restored marsh may or may not export phytoplankton, zooplankton, or other organic matter to the broader foodweb.

Role of Restoration Stage, Sedimentation, and Biomass Accumulation, and Sea Level Rise: Inundation regime (depth, frequency, and duration of flooding) and salinity are the two most dominant controls of tidal marsh ecology (Callaway et al, 2007). Inundation regime is controlled mainly by marsh elevations relative to the tides, with the Delta having a relatively significant seasonal riverine influence. Restored marshes will increase in elevation over time through sediment accretion and biomass accumulation. Accretion rates are not well documented in the Delta but what little information exists suggests generally low rates with high variability (data from BREACH and Integrated Regional Wetland Monitoring Pilot Project), though the Yolo Bypass provides somewhat more sediment (see Schoellhamer et. al., 2007, Simenstad 2000 and Reed 2002) that should benefit restoration in the Cache-Yolo area compared to other Delta locations.

Role of *Corbicula* in Affecting Exported Production: The outcome in terms of organic carbon production depends critically on whether freshwater clams (*Corbicula*) become established in the vicinity of the restored area (Lopez et al. 2007). If they become established and abundant either within marsh channels or in river channels in the vicinity of the marsh or in shallow sub tidal restored areas, they may consume most of the phytoplankton carbon produced there and remove it from the pelagic food web. See Outcome N1c below.

Role of Residence Time in Affecting Productivity Levels: Residence time refers to the time that a particle of water or some constituent of water remains in a water body. This concept is applied here more as a broad concept than a specifically measured quantity (see Monsen et al. 2002 for a discussion of residence time). When the movement of water in the Delta slows either because of lower net flow or reduced tidal velocities, residence time increases (see Kimmerer and Nobriga 2008). With the decrease in inflow to the Delta due to the export of water from the Sacramento River, and the decrease in north-to-south flow of water toward the south Delta export pumps, residence time generally will increase.

The speed of exchange between the Cache Slough restoration area and the rest of the Delta would be influenced by the tidal range, freshwater flow, the physical configuration of the breaches, and how that configuration changed over time. Hydrodynamic modeling results suggest that waters in the Cache Slough area after restoration would have relatively long residence times due to limited mixing in the tidal marsh areas, despite increased exchange of tidal flows in the main connecting channels. When the Yolo Bypass floods, mixing might increase and residence time would be inversely related to the flow rate. The amount of food produced in an area and the fate of this food depends on residence time as well as the local growth-loss balance (Lucas et. al. 2009). When residence time is long, food production can be high but little is exported. When residence time is very short, little production results. Intermediate residence times can maximize the production and export of foodweb organisms, but the magnitude of that export is unknown.

Potential Positive Ecological Outcome(s)

Outcome P1: Increase rearing habitat and local food production

As indicated at the beginning of this worksheet under the section entitled "Problems with Action", the team decided to merge two Intended Outcomes (rearing habitat and local food) into one outcome, P1, as shown below because rearing habitat for juvenile fish by necessity includes local availability of food. This outcome includes food (both primary and secondary production) produced within the vegetated marsh, within marsh channels, and within the subtidal areas adjacent to the vegetated marsh.

P1a. Delta smelt

General Observations: The aquatic food web supporting Delta smelt production is a primary component of habitat suitability that affects Delta smelt growth rates, health, fecundity, and mortality (page 21 in Nobriga and Herbold, 2008). The food web supporting Delta smelt is based on the production of pelagic zooplankton.

Historically, Delta smelt had a larger spawning range as compared with their spawning range in recent years. In some recent years, the Cache Slough area appears to have supported a substantial portion of spawning and rearing Delta smelt (page 11 in Nobriga and Herbold, 2008). Maintenance of suitable habitat conditions in the Cache Slough region is very important to conservation of this species and it is possible (though not at all certain) that habitat conditions for Delta smelt in this area can be improved; however, without restoration of spawning/rearing conditions in other locations (maintenance of spatial distribution and diversity), Delta smelt will remain in great peril of extinction.

Delta smelt are believed to be food limited for at least some life stages (Herbold and Nobriga 2008, page 9). In summary, food resources for Delta smelt would be produced within the restored marsh habitat, and the combination of physical space and food production would constitute habitat for Delta smelt.

Food generated on this site might be lost to invasive clams. This phenomenon is described in detail in Negative Outcome N1b. Predation (especially if it is facilitated by colonization of SAV) may also eliminate any beneficial effect of this action.

Magnitude = 3 - Medium: If implemented, this action is expected to produce a sustained minor population level effect on Delta smelt. The benefit of the action is expected to vary over time depending on the Delta smelt population distribution. When Delta smelt are distributed in many areas of the Delta, the overall population will derive a relatively minor benefit from this localized action. However, if the population is constrained to the Cache Slough area, the relative benefit from this action may increase.

One of the major concerns for Delta smelt relates to their narrow geographic distribution. The maximum suspected spawning range for Delta smelt (i.e. all localities where gravid or early larval fish have been detected) is small enough that this species is at risk of extinction due to localized catastrophic or demographic events (see Rosenfield 2002); this risk is exacerbated by their short life span and semleparous life history. In fact, the geographic range of Delta smelt appears to have decreased in recent years and, during

low outflow years, may be limited to just a few sites (this year, in the Northern Delta, Montezuma and west Delta), totaling just a few square kilometers. Increasing the Delta smelt population without increasing their geographic range (meaning available spawning and rearing habitat within the Delta) addresses only a portion of the threats to Delta smelt.

An additional factor contributing to the medium magnitude score for this outcome is that under circumstances described in the conceptual model (which may no longer hold, as discussed above) the production of habitat here would affect only a portion of the life cycle and the outcome will only benefit a fraction of the population.

Certainty = 2 - Low: The value of food produced on site is related to how much of that food makes it into the adjacent channels and to the suitability of the adjacent open-water regions to continue supporting Delta smelt. Both of these are uncertain. The food available to Delta smelt in directly adjacent channel and open-water habitats depends on how much of the zooplankton produced in the region is consumed by fish that actually forage there. The ability of Delta smelt to compete for available zooplankton is influenced by how well the habitat meets its physiological and behavioral needs.

Corbicula establishment could reduce the productivity benefits of the restoration to Delta smelt. See Negative Outcome N1b. If SAV starts to become established in a restoration site, there also may be an increase in the rate of predation on Delta smelt by several predators during the period SAV begins to establish. If SAV becomes well established, Delta smelt will not occupy the site with much frequency. Thus, poorly designed restoration could dissuade Delta smelt from using the north Delta as extensively as they do currently.

P1b. Longfin smelt

General Observations: Rearing longfin smelt larvae and juveniles are infrequently found in this area at low abundances according to Rosenfield, 2008 and data from the 20mm survey (http://www.delta.dfg.ca.gov/data/20mm/CPUE_Map.asp) and the tow-net survey (http://www.delta.dfg.ca.gov/data/townet/CPUE_Map.asp).

Magnitude = 1 - Minimal: The effect of this action on longfin smelt is expected to be negligible. Tidal marsh is not considered "rearing habitat" for longfin smelt. Although larvae are generally found near the water column surface (Rosenfield, 2008 p.5), where

they might access shallow habitats, juveniles can adjust their position in the water column (Rosenfield, 2008, p.6) and tend to concentrate in deepwater environments (Rosenfield and Baxter 2007). Only a very small proportion of late-stage longfin smelt larvae would be expected to occur in shallow tidal environments.

In addition, longfin smelt are rarely detected above Rio Vista on the Sacramento River (Wang 1991; R. Baxter, CDFG, unpublished data). Recent survey data (in years 2008 and 2009) have shown longfin smelt larvae to be more common in this area (e.g. Smelt Survey; http://www.delta.dfg.ca.gov/data/sls/CPUE_Map.asp; and 20mm survey, http://www.delta.dfg.ca.gov/data/20mm/CPUE_Map.asp). It is possible that the very small proportion of larvae-transitioning-to-juvenile longfin smelt rearing in this area may benefit from food items produced locally.

Certainty = 2 - Low: The scientific certainty about achieving any benefit is low. Sampling rarely detects longfin smelt in the Cache Slough complex and, when they are detected (generally larvae or very small juveniles), abundances are extremely low. In addition, establishment of *Corbicula*, SAV and/or predators on the restoration site could eliminate any net benefits to covered fish species. See Negative Outcome N1b.

P1c. Chinook salmon and steelhead

General considerations that apply to all the salmonids are described below followed by run-specific magnitude and certainty evaluations. The DRERIP Salmonid conceptual model indicates the value of estuarine rearing varies across runs (see Williams and Rosenfield, In preparation page 15).

General Seasonality of Delta Use: Juveniles of most runs migrate during winter through spring.

Role of Outmigrant Size in Duration of Delta Use: Larger outmigrants generally rear for shorter periods in the lower estuary before moving to the ocean. Life histories that include rearing upstream (including in-rivers and on floodplains) produce large outmigrants that are believed to derive less benefit from restoration of rearing habitat in the Delta.

Temperature: Salmonids are sensitive to warm water. Average daily water temperatures from May to September in the vicinity of this restoration (as indicated by those at IEP monitoring station RSAC 101) regularly exceed 20-21 degrees C, beyond which sublethal effects accumulate (Myrick and Cech 2004; Richter and Kolmes 2005). With warming that may occur under climate change, these temperatures are expected to occur in this area with some frequency during April and October as well. Steelhead, fall run Chinook salmon, and spring run Chinook salmon are typically present in the Delta

during some of these months and value of Cache/Yolo tidal marsh restoration to these runs would be reduced because of the warmer water.

Role of Delta in Overall Life-History of Salmonids: Delta rearing is one relatively short period in the overall life of salmonids and is not believed to be a key limiting factor for spring run, winter run, late-fall run or steelhead. Other factors such as upstream spawning and rearing habitats and water diversion structures and operations are more important in the overall life history for these salmonids (Williams and Rosenfield, In preparation).

Food Productivity to Support Rearing: Factors affecting food productivity described in this worksheet indicate that salmonids would find food resources in the Cache Slough area. The benefits of this productivity would accrue more to smaller migrants and when water temperatures support growth and smoltification (Williams and Rosenfield, In preparation).

Predator Exposure: Estuarine habitats that support salmonid rearing potentially also support predator populations, including (in particular) introduced Centrarchids that prefer shallow slow-moving freshwater environments. Increasing the residence time of salmonids in the Delta (by increasing rearing habitat) may also increase exposure to predator populations – the number of predatory fish in the Delta is much higher now than it was historically because of the introduction of Centrarchid and other non-native predators and maintenance of conditions that support those predators.

P1c1. Chinook salmon, Sacramento, winter run

General Observations: Winter-run juveniles move through the northern Delta from late-summer through winter. Winter-run life history strategy is unique. Because they may rear for several months in upstream environments, they are not expected to utilize the estuary extensively for rearing. Winter-run will consume the types of zooplankton produced in this restoration (under the assumed condition). Most winter-run migrate through this area when temperatures are cool enough to support rearing.

Magnitude = 2 - Low: The Salmonid life history conceptual model (Williams and Rosenfield, In preparation, page 16) states that "Spring Chinook, or at least the Butte Creek population, pass quickly through the Delta, so habitat restoration there seems unlikely to do much for them. The same is probably true for late fall Chinook and for steelhead. The presumed benefit of this conservation measure is the provision of food resources for outmigrating smolts. The benefits provided by proposed restoration action for winter run are equivocal.

The magnitude of this benefit for winter-run Chinook is low because of their comparatively large size when they migrate through the Estuary and because it is unlikely that they are limited by the extent of rearing habitat. Winter run are believed to grow little in the Delta. The Salmonid model suggests a moderate impact of this kind of habitat on competition, which may have a moderate impact on growth. However, both of these impacts are highly speculative. Winter-run have the smallest population of any Chinook salmon run in this system and they have access to the same estuarine habitats as the other runs. Also, their migratory season overlaps little with the more populous spring and fall run migrations. Thus, growth limitation due to inter- or intra-population competition for habitat in the Estuary is least likely for this run among all the Central Valley Chinook populations.

Food limitation is not considered a major limitation on survival in this life stage. Limitations on spawning and rearing habitat upstream are far more important to winter-run Chinook salmon conservation than putative habitat limitations in the Delta.

Certainty = 1 - Minimal: No direct studies of this run's habitat use in estuarine habitats have been published. Establishment of *Corbicula*, SAV, or predatory fish populations could limit, if not eliminate the productivity benefits of the restoration to Chinook salmon. See Negative Outcome N1b. Predation by invasive predators (especially if it is facilitated by colonization of SAV) may also eliminate any beneficial effect of this action.

P1c2. Chinook salmon, Sacramento, spring run

General Observations: Spring-run juveniles move through the northern Delta from winter through spring.

Magnitude = 2 - Low: The DRERIP Salmonid conceptual model (Williams and Rosenfield, In preparation, page 16, states that "Spring Chinook, or at least the Butte Creek population, pass quickly through the Delta, so habitat restoration there seems unlikely to do much for them. The same is probably true for late fall Chinook, and for steelhead".

The salmonid model's evaluation focused on one spring run population (Butte Creek). In fact, many juveniles from other populations migrate at a smaller size than Butte Creek juveniles. They migrate at about the same time as fall-run and thus may experience competition with fall run. So, this restoration may alleviate competition for a segment of the population. Williams and Rosenfield (In preparation) indicates moderate benefits of increasing rearing habitat.

Benefits are limited to those emigrants rearing in this habitat in the early-mid spring, before temperatures in this region increase above optimal rearing threshold (12-16 degrees C, Marine and Cech 2004).

Certainty = 2 - Low: There are no direct studies of spring-run Chinook salmon habitat use in this ecosystem. Driver-Linkage-Outcome (i.e. conceptual model) indicates variability (inter-population and inter-annual) in the relationship between habitat volume-density-competition and growth.

Given the temperature limitations and differences in life history among spring-run populations, the Evaluation Team can be moderately certain that the maximum positive magnitude of this impact from this action is low; however, there is relatively low certainty that there will be any beneficial impact at all. Establishment of *Corbicula*, could limit if not eliminate the productivity benefits of the restoration to Chinook salmon. See Negative Outcome N1b. Predation by invasive predators (especially if it is facilitated by colonization of SAV) may also eliminate any beneficial effect of this action.

P1c3. Sacramento Chinook salmon, fall run

Magnitude = 3 – Medium: The conceptual model (Williams and Rosenfield, In preparation, page16), states that "Fall Chinook […] could benefit strongly from tidal marsh restoration". Fall Chinook enter estuarine habitats at a small size and the text anticipates benefits from additional rearing/growth opportunities. Fall-run will consume the types of zooplankton produced in this restoration (under the assumed condition). However, the benefits that may accrue to fall run Chinook are uncertain because it is possible that the "ocean type" life history strategy of this run minimizes Delta residency in favor of rapid migration to the ocean (NMFS 2009, p12 Citing MacFarlane and Norton 2001).

Fall-run juveniles move through the northern Delta from winter through spring. Fall run rearing in this proposed restoration site during late spring will probably be impacted by high temperatures.

This outcome will benefit only the Sacramento portion of the fall-run population. Please note that the eastside Chinook salmon run is discussed in Appendix C.

Certainty = 2 - Low: Sacramento fall run Chinook use of fresh water tidal and sub-tidal environments is documented in other systems but is not well studied in this system – possibly because this kind of habitat is limiting in this system.

The effect of global climate change on water temperatures in this area during Sacramento River fall run migration period also decrease the window of time during each year when restoration will produce benefits. The temperatures experienced in this area during late spring and summer indicate that only a portion of the Sacramento River fall-run population will benefit from this action.

Other factors create uncertainty as to the benefits of this measure for this population. *Corbicula* establishment could limit if not eliminate the productivity benefits of the restoration to Chinook salmon. See Negative Outcome N1b. Similarly, establishment of predators or SAV that supports predation could eliminate most or all of the benefits created by this measure.

P1c4. Chinook salmon, Sacramento, late fall run

General Observations: Late-fall run juveniles move through the northern Delta from early fall through spring. The fisheries biology community is currently debating whether late fall run Chinook exhibit separate reproduction from fall run. As that debate has not yet been settled, this evaluation presents late fall run as a distinct run.

Magnitude = 1 - Minimal: Late fall-run will consume the types of zooplankton produced in this restoration (under the assumed condition). Most late-fall run migrate through this area when temperatures are cool enough to support rearing. The discussion of drivers and outcomes in the figures of Williams and Rosenfield, (In preparation) indicates that tidal marsh has a low impact on competition and competition in this area has a low impact on growth.

Certainty = 1 - Minimal: The importance of growth in estuarine environments is unstudied for this run. Text concerning drivers, linkages, and outcomes in the conceptual model indicates low certainty of impact.

Establishment of *Corbicula* could limit, if not eliminate the productivity benefits of the restoration to Chinook salmon. See Negative Outcome N1b. Predation by invasive predators (especially if it is facilitated by colonization of SAV) may also eliminate any beneficial effect of this action.

P1c5. Steelhead

Magnitude = 1 - Minimal: Steelhead juveniles migrate through the Delta during a six month period from January to June. However, most migration occurs in a two-month window, “mainly in April and May” (Williams and Rosenfield, In preparation, page 34). Steelhead rearing in this proposed restoration site during and after May will probably be impacted by high temperatures and negative impacts could become more common with global warming.

The Salmonid conceptual model regarding estuarine – growth, shows a low impact of this kind of habitat on competition – competition may have a moderate impact on growth. The restoration of tidal marsh habitat will impact only steelhead from Sacramento Basin.

Certainty = 1 - Minimal: There is no direct research on the use of shallow estuarine habitat by steelhead in the Delta system. Any effect will be limited to the Sacramento population and to those times of year when temperatures are not too high in the target area.

Establishment of *Corbicula*, could limit, if not eliminate, the productivity benefits of the restoration to Chinook salmon. See Negative Outcome N1a, b, and c. Predation by invasive predators (especially if it is facilitated by colonization of SAV) may also eliminate any beneficial effect of this action.

P1d. Splittail

Magnitude = 3 - Medium: Additional tidal marsh acreage in the Cache Slough region would be expected to help rearing of juvenile splittail, particularly due to the restoration site’s proximity to the Yolo Bypass, a major spawning location for Sacramento splittail. Post-spawners coming off the Yolo Bypass might benefit. The marsh may also provide dry period spawning habitat when the bypass is flooded less frequently (Kratville 2008). Splittail are benthic fish which forage during the day. Adult splittail typically consume detritus (60-79%), mysid shrimp (2-24%), Corbula (6%), salmon eggs, worms, and invertebrates. Larval and juvenile splittail are typically found on the floodplain and while there they consume small rotifers, cladocerans, chironomid larvae, zooplankton, and copepods (Kratville 2008). To the extent that tidal marsh supports the production of these types of food resources and to the extent that these food resources are available at a time and location that is accessible to splittail, the proposed restoration may offer some food benefits during the limited time window when the fish would be in Cache Slough and moving towards the more brackish areas of Suisun Marsh.

Certainty = 2 - low: The ultimate effect this action will have on splittail population abundance is uncertain because while this restoration will increase opportunities for rearing juveniles, rearing habitat does not appear to be a limiting factor in splittail abundance compared to floodplain inundation (Kratville 2008). The bulk of the adult splittail population resides in brackish areas of Suisun Marsh (Kratville 2008). The freshwater Cache Slough marsh will only provide habitat for juvenile fish migrating into

Suisun Marsh. It might not provide a new population center or increase the number of fish making it to Suisun Marsh.

Outcome P2: Increase food production for local consumption by green and white sturgeon

Magnitude = 2 -Low: Information on juvenile sturgeon diets and physical habitat needs in the Delta is limited. Juvenile sturgeons of other species located in other systems do feed on drifting insects. This area of the Delta will not provide extensive intertidal-mud bottoms as found in lower portions of the estuary. Since the former farm fields on this proposed shallow sub tidal restoration site will remain comparatively hard for many years (such as at Liberty Island and Little Holland Tract), it could take considerable time for conditions that support the growth of soft bottom benthos (organisms) to develop. These soft bottom benthos are a food resource for the sturgeon. Most habitat limitations for sturgeon appear to occur outside of the restoration area (i.e. upstream and downstream), as described on pages 4, 8, 9 in Israel and Klimley, 2008 and pages 19-21 of Israel et. al., 2009.

Certainty = 1 - Minimal: Most of the available information on sturgeon diets and predator/prey relationships is based upon other species of sturgeon, located outside of this system. It is unknown to what extent adult sturgeon historically used fresh water tidal marsh for foraging. The impact to individual sturgeon may be low but the loss of fresh water tidal marsh in the Delta may have lowered the carrying capacity of the entire system for sturgeon. See pages 4, 8, 9 in Israel and Klimley, 2008 and pages 19-21 Israel et. al., 2009 for more detail.

Outcome P3: Food resources produced on the restored marsh will be exported and contribute to food availability downstream of Rio Vista.

General Observations: Outcome P1 above addresses the potential for restoration to produce increased food resources locally within the restoration area (both in the marsh and in adjacent open water). Outcome P3 described below deals explicitly with the potential for food resources (phytoplankton, zooplankton, insects, and small fish) to be exported out of the restoration area and become available to covered species downstream of Rio Vista.

The Tidal Marsh and Foodweb models [Kneib et. al., 2008, page 9 and Durand, 2008, section 2.16)] provide a general indication that there may be a linkage between tidal marsh habitat as a driver and increases in availability and production of food resources as an outcome, but that the mechanism for this linkage may be movement by fish. The tidal marsh conceptual model also states that freshwater tidal marshes are net exporters of high-quality organic production (page 2 in Kneib et. al., 2008). See also Dame et al. 1986, Kimmerer and McKinnon 1989, Kneib 1997, Lucas et al. 2009.

There was disagreement within the evaluation team regarding the magnitude and certainty of expected benefits of tidal reintroductions with regard to the export of food (phytoplankton, zooplankton, insects, and small fish) to areas downstream of Rio Vista and the likely benefits to covered fish species. In the spirit of presenting the scientific discourse, both points of view are captured below.

Two key questions discussed were: (1) can we predict the sign of the flux of productivity (i.e. will the restoration area be a source or a sink for primary and secondary productivity); and (2) will there be adequate advection to move material out of the restoration area and downstream to Rio Vista (assuming the restoration area is a source of productivity, as opposed to a sink). Additional information and analyses is needed to better answer these key questions. To develop this additional information, the team recommends future development of a Tropho-dynamic model as described in the section on page 40 entitled “Research Needs”.

Viewpoint #1

Estuaries are open systems that comprise interconnected yet spatially heterogeneous habitat. Connectivity of these functionally variable habitats is a key design consideration for sustaining biological diversity on degraded landscapes (Cloern, 2007, Friedrichs et al. 2001). Channel habitats downstream of Rio Vista are deeper, light limited, heterotrophic pelagic habitats. In contrast, the proposed Yolo/Cache Slough restoration is shallow intertidal/subtidal, and not nutrient limited. It is likely to comprise autotrophic habitat from which excess productivity could enhance regional pelagic carrying capacity if phytoplankton and a range of secondary production types is exported downstream (Lopez et al. 2006). The export, or water connectivity rate, is key. Regional ecosystem production efficiencies occur when the water connectivity rate between shallow and deep habitats is similar to autotrophic habitat phytoplankton growth rates (Cloern 2007).

Without flow augmentation, the Yolo/Cache area would exhibit variable seasonal water connectivity with channels downstream of Rio Vista. When the Bypass is strongly flowing, complete water exchanges occur on short timescales. In contrast, when the Bypass is dry, water connectivity depends on tidal dispersion that may be minimal due to distances (Cache Slough to Rio Vista) greater than tidal excursion length. On the tail end of hydrographs when the Bypass is draining (usually in Spring), hydraulic connectivity could be near optimal for extended periods. These periods overlap well with native fish usage of deep channels downstream of Rio Vista (see conceptual models for Delta smelt, longfin smelt, and salmonids).

With flow augmentation (e.g. a Fremont Weir notch), water connectivity between Yolo/Cache and Rio Vista could be tuned to provide near optimal connectivity for much longer periods and across a greater number of years (from roughly 1 in 4 years at present to 1 in 2 years as proposed). In this case, the rate of water connectivity would be exactly known since transport to Rio Vista would be advective. The magnitude of the productivity subsidy will keenly depend on how flow augmentation is routed through the restoration area. For maximum subsidy, Yolo/Cache water inputs would be routed in ways that tend to spatially equalize phytoplankton and zooplankton concentration gradients. Adaptive management experiments would elucidate transport strategies that maximize regional ecosystem efficiencies.

The single greatest impediment to realizing these exported productivity benefits would be the colonization by invasive clams that, if established in large numbers, could divert much of the phytoplankton and zooplankton productivity. Clams would exert a greater detrimental effect during tidal dispersion periods (no Yolo outflow and long local residence times) and a lesser detrimental effect during advective transport periods (with Yolo outflow and short local residence times).

Magnitude = 3-4 – Moderate to High: Without advective connection, restoration will still have significant productivity benefits to covered fish species and to many other species due to providing large areas of highly functional habitat in conjunction with restoration elsewhere that collectively provide fish species a range of options that spread risk through exploiting available resources when they are present. Refer to Ted Sommers, IEP Esutarine Ecology Team or CAERS poster. In addition, these areas would export that productivity through the "trophic relay" concept described in the tidal marsh conceptual model (fish export the productivity).

With advective connectivity driven by current and proposed Yolo Bypass flows, productivity will be exported strongly during periods of Yolo flow, generally in the February to May time period. These time periods are identified as very crucial to many covered species. Under current conditions, Yolo floods roughly 1 in 4 years. The Yolo Conservation Measure proposes to increase this frequency to 1 in 2 years. Under either condition, advective-driven transport of Cache Slough productivity will provide important and very substantial productivity contributions to larger geographic regions of the northwestern Delta.

Certainty = 3 – Moderate: Certainty is reduced by the potential for establishment of invasive clams that could consume substantial portions of phytoplankton and hinder zooplankton productivity. These effects would be greater during time periods without Yolo flows through the Cache Slough complex.

Viewpoint #2

Net primary production is highest in shallow water (given the excellent light resources and plentiful nutrients). However, the additional primary production that results from this restoration may be limited due to short residence time. The positive impact of food production also atenuates with distance. Export off the restored marsh will be non-existent when Yolo Bypass is not flowing. When Yolo Bypass is flowing, the additional small quantity of organic matter may (uncertain probability) be exported downstream. However, there is little quantitative information to support the idea that this phytoplankton will be exported downstream. The degree of phytoplankton export is critically dependent on whether clams become established in the shallow subtidal regions or marsh channels, climate change, and other factors (Callaway et al 2007). Dissolved organic carbon, by far the largest component of the organic pool, is very likely exported from marshes. However, for the most part, DOC supports bacterial production and relatively little of the bacteria supports the open-water foodweb of which pelagic fish participate. Established tidal marshes can both import and export organic carbon in dissolved or particulate (living and nonliving) form. The overall net flux of organic carbon must be out of the marsh to the extent that high plant productivity within the marsh exceeds local burial. The direction of the flux of a given constituent across the marsh-channel interface depends on the net flow (i.e., through freshwater runoff through the marsh), the concentration gradient, affected in turn by source and loss rates in and outside the marsh, and the swimming of organisms. For example, marshes produce organic detritus that is then available for export. However, marshes can also import detritus through particle trapping by marsh plants. Zooplankton may be zooplankton sinks because of consumption in the marsh by planktivorous fish (Dean et al. 2005). In some marshes, fish may be important carriers of organic carbon from the marsh to open waters.

Please note that potential modifications to weirs and other water management structures in Cache Slough could alter hydrologic patterns and thereby change residence time and other factors that affect food productivity (i.e. the scores presented below would need to be updated accordingly).

Magnitude = 1 to 2 – Minimal to Low: The implied relationship is that restoring 5,000 to 11,000 acres of tidal marsh will export nonliving and living organic matter including plankton and fish, thereby supporting foodwebs of the upper estuary. An implicit assumption is that any increase in the area of shallow habitat would result in enhanced plant productivity some of which would be exported.

When the Yolo Bypass is flowing, the Cache Slough area may export organic matter, but the additional productivity due to the marsh restoration will be limited because of the short residence time. At other times, relatively little of the production from within the Cache Slough area is likely to be exported.

Certainty = 1 -Minimal: The sign of the signal is difficult to determine, except for total organic carbon, most of which is dissolved. Although dissolved organic carbon (DOC) will likely flow out of the marsh, fluxes of other components may be in or out (Kneib et. al., 2008, page 9).

Outcome P4: Provide local cool water refugia for Delta smelt and rearing salmonids

Temperature in a water body is determined by the balance between gains and losses of heat. Heat is gained from solar radiation and from conduction and convection between water and air, and lost through conduction, convection, evaporation, and infrared radiation. Heat is also gained or lost during mixing of water bodies. All of these processes depend on physical drivers such as current and wind speeds and tidal fluctuations, and on the physical configuration of the water body and landforms.

The fundamental physics of heat transfer is well understood (Malamud-Roam 2000, Stacey and Monismith 2008, Enright 2008), and the large-scale temperature fluctuations in a water body can be predicted to some degree. However, small-scale fluctuations depend critically on local conditions and can be somewhat more difficult to predict.

The temperature of a shallow water body will roughly track air temperature. However, very shallow bodies of water are susceptible to rapid changes in temperature because of small thermal mass and relatively large radiative gains and losses of heat. Thus, the water on a marsh plain at midday will be much warmer than that in an adjacent channel, whereas water on the same plain at night will be cooler.

In Suisun Marsh, the higher-high tide occurs near midnight, resulting in substantial cooling by radiation, conduction, and evaporation (Enright 2008). The result was substantial spatial and temporal variation in water temperature in the marsh channels. It is reasonable to suppose that fish under thermal stress would seek out and remain in cooler water in an area of spatially heterogeneous temperature. This cooling may occur in any mature marsh exposed to a similar tidal regime. The extent to which it will occur, and the extent to which Delta smelt and salmon will actually take advantage of it, are unknown.

.

P4a. Delta smelt

Magnitude = 2 - Low: Thermal stresses for Delta smelt in this location occur typically in May and June, so some potential for a benefit exists. Most Delta smelt are not in the Cache Slough area during summer.

Certainty = 1 - Minimal: The basis for our understanding is a single unpublished study in Suisun Marsh. The extent to which this effect may transfer to the restoration site, and to which Delta smelt and salmon will take advantage of it, cannot be predicted.

P4b. Chinook Salmon

The following describes expected benefits to Spring run, Fall run, and Steelheed. Winter run and late-fall run are discussed in Appendix B.

P4b1: Spring run salmon

Magnitude = 2- Low.
Beneficial effect occurs for only a portion of the salmonid population passing through this region during a particular and narrow window of time. This outcome modifies Outcome P1 (creation of habitat). In evaluating that outcome, benefits of this action were interpreted in the light of unfavorable temperature conditions that occur in the area during late-spring and summer. To the extent that the tidal flooding/cooling phenomenon occurs on this restoration site (a function of geography and restoration design and site elevations) during the period of potential thermal stress (May through end of summer), it may provide some relief from the effects of thermal stress *for those salmon runs that migrate through this region at this time (fall and spring run and steelhead).* That benefit impacts only the proportion of the population that migrates at this time and only the proportion of the population that migrates through this area (i.e. not all fall run or all steelhead). Although the team suggests a magnitude score of 2, for this outcome there is some debate within team as to whether this action's cool water refugia will offer any benefit at all. Chinook salmon using this area during late spring are probably on their way out of the estuary, and if it is too warm they will probably move on. The existence of thermal refugia (if it occurs in the area) may not make much difference to the salmon.

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

P4b2: Fall run salmon

Magnitude = 2- Low.
Beneficial effect occurs for only a portion of the salmonid population passing through this region during a particular and narrow window of time. This outcome modifies Outcome P1 (creation of habitat). In evaluating that outcome, benefits of this action were

interpreted in the light of unfavorable temperature conditions that occur in the area during late-spring and summer. To the extent that the tidal flooding/cooling phenomenon occurs on this restoration site (a function of geography and restoration design and site elevations) during the period of potential thermal stress (May through end of summer), it may provide some relief from the effects of thermal stress *for those salmon runs that migrate through this region at this time (fall and spring run and steelhead).* That benefit impacts only the proportion of the population that migrates at this time and only the proportion of the population that migrates through this area (i.e. not all fall run or all steelhead). Although the team suggests a magnitude score of 2, for this outcome there is some debate within team as to whether this action's cool water refugia will offer any benefit at all. Chinook salmon using this area during late spring are probably on their way out of the estuary, and if it is too warm they will probably move on. The existence of thermal refugia (if it occurs in the area) may not make much difference to salmon.

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

P4b3: Steelhead

Magnitude = 2- Low.
Beneficial effect occurs for only a portion of the salmonid population passing through this region during a particular and narrow window of time. This outcome modifies Outcome P1 (creation of habitat). In evaluating that outcome, benefits of this action were interpreted in the light of unfavorable temperature conditions that occur in the area during late-spring and summer. To the extent that the tidal flooding/cooling phenomenon occurs on this restoration site (a function of geography and restoration design and site elevations) during the period of potential thermal stress (May through end of summer), it may provide some relief from the effects of thermal stress *for those salmon runs that migrate through this region at this time (fall and spring run and steelhead).* That benefit impacts only the proportion of the population that migrates at this time and only the proportion of the population that migrates through this area (i.e. not all fall run or all steelhead).

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

Potential Negative Ecological Outcome(s)

Outcome N1: Establishment of harmful invasive species

Harmful invasive species have the potential to cause two types of adverse effects. First is to worsen conditions relative to the existing baseline; i.e., creating an attractive nuisance. Second is to detract from achieving the positive benefits the action could provide. The magnitude and certainty scores below are based upon an assessment relative to the potential for conditions to become worse than the existing baseline.

N1a. Submerged Aquatic Vegetation (SAV)

General Observation: As described in the conceptual model, the establishment of SAV is controlled by local flow conditions and substrates (Anderson, In Preparation). Many aspects of SAV physiology are influenced by local flow conditions including turbidity and to some extent flow velocity which if too high can scour suitable substrate precluding SAV establishment. In nearby Liberty Island where turbidities are generally higher due to wind wave action and the substrate is a compacted old farm field, SAV is restricted to shallow near shore areas and narrow shallow sloughs (Ustin et al. 2008). If turbidities are high in the restoration area then SAV establishment and growth may be reduced to levels similar to those at Liberty Island. If not, there is the potential for SAV amounts similar to those at overgrown regions of the central and southern Delta. The substrates in the Cache Slough area would be restored farm field hardpan bottoms, which may not be conducive to establishment of SAV. The initial establishment of SAV is an intermediate outcome and the development of a large sustainable SAV population is the final outcome.

Please note that establishment of SAV reduces the certainty that the positive outcome, P1 will occur. This has been noted in the scoring for P1.

Magnitude = 3 - Medium: For this outcome, the baseline condition is that much of the existing 21,600 acres of Delta tidal marsh is infested with submerged aquatic vegetation (Ustin, 2008). The risk of a restored a tidal marsh becoming infested with SAV is significant. Large, sustainable populations of SAV will produce significant changes in water quality (turbidity, pH, DO and temperature), or water flow characteristics (velocity and direction), which in turn can affect the quantity and quality of sediments (Anderson, In Preparation). Eventually, the clarity of water at the site will increase by lowering velocities and allowing particulates to settle out of the water column. This increased water clarity could increase predation of fish entering the site from outside areas (i.e. predators now have greater visual range). One type of predator, Centrarchid fish, is strongly associated with SAV and increased Centrachid populations may create a population sink for native fish at this location, as discussed in N1b, below. In summary, this action may worsen conditions beyond that of baseline conditions and small to moderate fractions of all the covered fish species may experience highly significant but localized effects due to SAV. Given the rarity of Delta smelt, the impact of SAV establishment could be particularly significant on this species if conditions similar to the South Delta are created here.

Certainty = 2 - Low: The initial colonization and ultimate patch distribution of SAV on the substrate is uncertain. As the substrate softens over time, it may be more conducive to SAV establishment and growth (i.e. bed characteristics are described as a driver in the conceptual model – see Anderson, In Preparation). It is well documented that the physical structure of SAV facilitates slower water velocities which allows sediment particles to settle, thereby reducing turbidity, locally and creating a positive feedback loop for more SAV establishment (Anderson, In Preparation). The effect of specific restoration site substrate, how those substrates may change over time after restoration, and the role of flow velocity at these locations is not well understood.

N1b. Centrarchids

General Observations: Centrarchid fish, as an assemblage, cover a range of ecological niches in the Delta. They are competitors for resources as well as predators on native fish. The magnitude of this effect is dependent on the assemblage of centrarchids that invade and the size of the populations. This is in turn partially dependent on the amount of SAV invasion into the restored system.

Please note that establishment of centrachids reduces the certainty that the positive outcome, P1 will occur. This has been noted in the scoring for P1.

Magnitude = 3 - Medium: For this outcome, the baseline condition is that much of the existing 21,600 acres of tidal marsh are excellent habitat for Centrarchid fish where they are associated with adjacent deeper water. This is illustrated by the large number of Bass Tournaments that occur in the Delta. The Delta is a stop on the national professional bass fishing circuit with $100,000 prizes. This action could worsen conditions beyond that of baseline. Centrachids are a concern because they prey upon and compete for food and other resources with native covered fish. Establishment of centrarchids in conjunction with SAV is well documented in the Delta (Brown and Michniuk 2007; Grimaldo et al. 2004; Nobriga and Feyrer 2007; Nobriga et al. 2005). Centrarchid fish would likely become established in this area as they have in other areas of the Delta where flows are more tidal than riverine (Brown and Michniuk 2007). The magnitude score reflects the possible impact that these fish could have given evidence from the southern Delta. Delta smelt are believed to spawn in the Cache Slough area and an increase in populations of Centrarchids could have impacts on nearly every life stage of Delta smelt and other native fishes. Given the rarity of Delta smelt, the impact of Centrachids could be particularly significant.

Certainty = 2 -Low: The spatial extent of a Centrarchid population(s) after initial colonization and the subsequent impacts to local native fish use once established are not well understood. Their abundance and presumed impact on native fish is greatest in areas of large, dense patches of SAV (Brown and Michniuk 2007).

N1c. *Corbicula*

Consequences of *Corbicula* establishment. If established, *Corbicula* would likely have a significant effect on food web dynamics because it consumes phytoplankton in shallow areas (Lopez et al. 2007). *Corbicula*'s consumption of primary productivity represents a significant limiting factor throughout the Delta that could greatly reduce productivity benefits of restoration efforts (Thompson et al., In revision, page 12). No local studies have been undertaken to indicate whether *Corbicula* feeding has reduced zooplankton populations either through competition or direct predation (Thompson et al., In revision, page 11).

Probability and extent of potential establishment. *Corbicula* are prolific reproducers and colonizers of newly available habitats in salinities below 2 ppt. Source populations can come from elsewhere within the Delta or from upstream tributary populations. *Corbicula* can establish on soft and hard substrates and on vegetation and they can colonize intertidal zones as well as deeper water. (*Corbicula* model). Based upon the biology of the species and the physical setting of the restoration site, the probability of *Corbicula* establishment in the Cache Slough restoration areas appears to be high, but ultimately cannot be predicted, partially due high variability in environmental conditions.

Recent very limited *Corbicula* monitoring data from Liberty Island shows that they are present at Liberty Island, with greater abundance in areas with coarser substrate (sand-cobble), small abundance in hard clay substrate, and minimal abundance in soft sediment substrates (Errin Kramer-Wilt, pers. comm. 2009). These data are preliminary and not yet peer reviewed and a part of an ongoing study so findings may change.

Potential Control Options. There are no stressors identified that can limit the success of *Corbicula*. However, salinity can limit the spatial distribution of this species and food limitation is a source of stress (Thompson et. al., In revision, pages 8 and 13). The *Corbicula* conceptual model indicates that the only meaningful method to control their presence or abundance is salinity. This control method would require salinity intrusions into the Cache Slough area of sufficient duration and at the appropriate times of year to have a meaningful effect. The conceptual model does not specify the duration and timing which might be most effective during recruitment. Water temperatures may influence the effectiveness of both recruitment and control measures.

Please note that establishment of *Corbicula* reduces the certainty that the positive outcome, P1 will occur. Establishment of *Corbicula* would consume much of the positive benefits that were previously discussed above under positive outcomes. This has been noted in the scoring for P1.

Magnitude = 1 – Minimal
For this outcome, the baseline condition is that much of the Delta is infested with *Corbicula*. The restoration of tidal marsh that eventually becomes infested with *Corbicula* would not represent a significant change above baseline conditions. This restoration will introduction of *Corbicula* (and its associated phytoplankton cababilities) to a geographic location where it is not currently located. This action may add 5,000 or 11,000 acres of potential *Corbicula* habitat. See also text above.

Certainty = 2 - Low. See text above.

N1d. Inland Silversides Effects on Delta and Longfin Smelt

General Observations: Inland silversides (*Menidia beryllina*) are highly tolerant of warm water and variable salinity and are trophic generalists compared to Delta smelt (Moyle 2002). Inland silversides are the most numerous fish in shallow Delta habitats (Nobriga et al. 2005, Brown and May 2006). Page 3 of Nobriga and Herbold 2008 includes intraguild competition with inland silversides as one of the top five in-Delta stressors to Delta smelt. Inland silversides are thought to be a major predator of Delta smelt eggs (Bennett and Moyle 1996 and Bennett 2005 in Nobriga and Herbold 2008 page 12). In the laboratory, inland silversides reduce Delta smelt size relative to controls when they are reared together (Bennett 2005).

Inland silversides are also treated in the longfin smelt model. Moyle (2002, in Rosenfield 2008) suggested that based on timing of arrival in the Estuary and subsequent longfin population response, inland silverside might have had a major impact on longfin population dynamics. However, the model states that inland silverside prefer shallow water habitats where juvenile and sub-adult longfin are rare, thus, their impact as predators of juvenile and sub-adult longfin is probably slight (Rosenfield 2008, pg. 17). Spawning locations for longfin are unknown, so it is not known whether competition from inland silverside for spawning territory is a factor in their decline.

However, Delta smelt evolved with other intraguild competitors, including longfin smelt, and have survived with striped bass (introduced in 1879). Interaction between silversides and Delta smelt in the wild may be limited because Delta smelt typically inhabit offshore environments, while inland silversides typically inhabit shoreline habitats. Increased shoreline habitat would presumably increase the carrying capacity for inland silversides. However, predator-prey interaction between Delta smelt and inland silversides in the wild is speculative. Silversides may eat Delta smelt eggs or larvae if the eggs and larvae occur on the shorelines. It has not been shown that inland silversides reduce calanoid copepods (Nobriga and Herbold 2008, page 32), so they may not effectively compete with Delta smelt for prey.

Magnitude = 2 - Low: Inland silversides are the most abundant fish in shallow-water habitats in many areas of the Delta and may currently contribute to local depletions of zooplankton otherwise available to native fishes within these areas. Additionally, they may prey on embryos of species who lay eggs in these shallow areas (Moyle 2002). The crash of Delta smelt populations coincided with invasions of inland silversides into the estuary (Bennett and Moyle 1996). This action may change conditions relative to baseline by attracting (via restored marsh) a nuisance (inland silversides). This conservation measure will increase the local inland silverside population by providing additional shoreline breeding habitat. Because of the high existing abundance of inland silversides, the incremental increase in breeding habitat and thus population size above current conditions is considered small and the magnitude of this effect is considered to be low relative to baseline. Further, differential habitat selection (offshore environments for inland silverside) is expected to reduce the interspecific competition effects.

Certainty = 2 - Low: Understanding of interaction between Inland silversides and Delta smelt in the wild is low, particularly in regards to egg predation by inland silversides. Spatial interactions with longfin smelt are also uncertain.

Outcome N2: Local contaminant effects

General Observations, methyl mercury: Although current methylmercury levels on Liberty Island (analogue for future state of areas to be restored) are relatively low (Slotton et al. 2002, Alpers et al., 2008, figure 5), there is potential for enhanced production of methylmercury in areas of high marsh that will be inundated infrequently (only during highest tides). The process of drying out between wetting events tends to oxidize species of sulfur, iron, carbon, and mercury, leading to higher potential to form methylmercury upon rewetting. Once formed, methylmercury biomagnifies in the aquatic food web and ecological effects may occur in some sensitive species. Thus, the specific geomorphology of restoration sites and in particular the degree to which shallow depressions and poorly drained areas of high marsh are part of the restoration projects directly influences the degree of mercury methylization.

General Observations, other contaminants: Past land use determines risk of other contaminants: lead risk in areas with significant hunting, e.g., pheasant farms or duck clubs. There is risk of residual pesticides (e.g., pyrethroids) in areas used for agriculture in past 2 years, which suggests that if these pesticides were used, allowing for a 2 year lag period between application and tidal restoration would be a prudent mitigation measure. Selenium contamination from the San Joaquin Valley isn't an issue in the Cache Slough area.

N2a1. Methyl mercury, covered fish species

General Observations: Alpers et al., 2008 (Table 2 and associated text) describes the relevant issues.

Magnitude = 1 - Minimal: No toxicological studies have been conducted with any of the covered species regarding acute toxicity. Mercury concentrations in covered fish species are compared here against concentrations producing mortality in other fish species. Mercury concentrations in ppm-wet weight for white sturgeon, Chinook salmon and steelhead collected during 2006 were 0.165-0.279, 0.094-0.396 and 0.06-0.13, respectively (Melwani et al. 2007). No tissue data for either longfin or Delta smelt were found. Assume both species will have tissue concentrations similar to other fish taxa living one year and feeding primarily on zooplankton. Mercury concentrations in juvenile threadfin shad and juvenile largemouth bass in the Delta are 0.012-0.076 and 0.035-0.230, respectively (Slotton et al., 2006). In comparison, death in rainbow trout (steelhead) in laboratory studies occurred at 4-ppm wet weight and the NOAEC for death in brook trout at 2.7 ppm (Wiener and Spry, 1996). Conclusion: about a 10X safety factor exists between fish tissue concentrations measured in the Delta and values reported to cause mortality in lab studies.

Regarding chronic toxicity, again no toxicological studies exist with any of the target species. Therefore, we have compared reported tissue concentration for individual species against known laboratory effects in other taxa. Decreased feeding efficiency and some hormones response changes have been observed at 0.25-0.27 ppm wet weight (page 30 of Alpers et al., 2008). Decreases in growth have occurred in fathead minnows at 0.6-0.7 ppm (Hammerschmidt et al., 2002) and in juvenile walleye at 2.4 ppm (Friedmann et al., 1996). In conclusion, some up/down regulation of genes and alterations in feeding behavior are possible in the most contaminated individuals.

Certainty = 2 - Low: Limited tissue data available for most target species but large safety factor regarding acute toxicity. Limited toxicological data available for most of the important sub-lethal processes and none of this has been collected on species of interest.

N2a2. Methyl mercury, non-covered species

Magnitude = 2 - Low: Fifty-eight percent of Forster's terns in San Francisco Bay are at risk of reproductive impairment from consuming fish with elevated mercury levels (Ackerman et al., 2008). Although no Forster's terns nest in Delta, mercury levels in small fish consumed by terns are higher in parts of the Delta such as the Yolo Bypass (Davis et al. 2007) than in the San Francisco Bay (Ackerman et al., 2007). This suggests other bird species filling the Forster's tern niche in the Delta may be at risk.

In laboratory studies, mink have reproductive failure and die when fed fish diets of 0.5 and 1-ppm mercury, respectively (Dansereau et al., 1999). For comparison, mercury concentrations in 64% of largemouth bass, 23% of white catfish, and 35% of channel catfish caught in the Bay-Delta watershed have between 0.23 and 0.93 ppm mercury (Davis et al., 2008). Although the geometry of the high marsh area is poorly understood, evidence suggests a sustained minor population effect.

Most of the studies were conducted in the South San Francisco Bay and Petaluma River marshes with a focus on species native to that area, specifically Clapper and Black rail (endangered and threatened, respectively) (see also Grenier et al., 2002). These studies have shown that rails seem particularly susceptible to methyl mercury. Although neither of these species occurs in the Delta, the related Virginia rail (not a listed species) is present.

Biogeochemical processes create varying conditions and a subset of these conditions promotes mercury methylation and this is the key factor used in evaluating the magnitude of this actions effect. Mercury methylation in tidal wetlands is driven in large part by geomorphology and the resulting inundation regime. Methyl mercury production needs approximately one to four weeks of dryness to re-set the biogeochemical conditions necessary for mercury methylation (specific time frame not determined; table 2 in Alpers et al., 2008). Available restoration lands in the Cache Slough complex all have a relatively uniform and very gradual slope from the uplands to the tidal waterways, suggesting relatively little potential for providing the geomorphic setting needed for extensive high marsh plain that is most susceptible to methyl mercury production. However, available topographic data have not been analyzed to the level necessary to describe the setting more precisely.

Certainty = 2-3 Low - Medium: Scientific understanding of methylmercury effects on some bird and mammal species is high, based on peer-reviewed studies conducted in the San Francisco Bay and elsewhere. However, methylmercury effects on other bird, reptile, and mammal species are unknown. The nature of this outcome is also greatly dependent on highly variable ecosystem processes.

N2a3. Methyl mercury, human health

General Observations: This action could increase mercury content of sport fish.

Magnitude = 2 - Low: Fish consumption advisories for the Delta recommend that children under the age of 17 and women of child bearing age consume no largemouth bass or smallmouth bass, spotted bass or Sacramento pikeminnow, and others should limit their consumption of these species to one meal a month (Gassel et al. 2007, 2008). Between 10,000 and 20,000 fishermen in the Delta are presently eating fish with more than 10X the recommended methylmercury reference dose (RfD) (Klasing and Brodberg, 2008) and could experience some sublethal mercury poisoning (personal communication, Dr. Fraser Shilling). Action could increase mercury content of sport fish.

The probability of increased methylmercury production and export into the food web is the same as that described above for covered fish species and non-covered species.

Certainty = 3 - Medium: There is uncertainty regarding the magnitude and direction of change in mercury content of sport fish, although levels are more likely to increase than decrease. For a given increase in mercury content of sport fish, risk to human health is quantified based on peer-reviewed studies (Gassel et al. 2007, 2008). It is unknown how many anglers would access the project area and what fish they would catch and consume.

The role of restoration projects under this Conservation Measure in contributing to mercury levels in fish species consumed by humans needs to be explored in relation to other mercury sources for those fish species.

N2b1. Residual pesticides and herbicides, covered fish species

General Observations: Pesticide use for calendar year 2007 (DPR, 2008) indicates that 104 pounds of total pyrethroids and pyrethrins were used during 2007 in the Cache Slough area. Possible presence of legacy pesticides from 1960s (e.g. DDT) is unknown. More recent (illicit) use of DDT is likely given the presence of non-degraded forms of DDT in sediment (http://www.bdat.gov, accessed 2008 by P. Green, UC Davis). Pyrethroids are 20x more toxic compared to some other pesticides (organochlorides). They persist in the sediment and degrade in one or two years. Pyrethoids represent several individual pesticides out of about 300 pesticides used during 2007 (DPR, 2008).

Magnitude = 1-2: Mminimal- Low: To the extent that pyrethroids or pyrethrins were used in the area to be flooded, significant toxicity could occur within 1-2 years of application. After ~2 years, near-total degradation should occur. DDT and metabolites could cause reduction of insect populations and bioaccumulation in target fish species (and some non-target bird species).

Certainty = 1 - Minimal: The toxicity of various pesticides is not completely understood. Although some peer-reviewed studies for selected life stages of certain fish exist, there is not much data for covered fish species. The nature of this outcome is highly dependent on highly variable ecosystem processes affecting the fate (degradation) and transport of pesticides.

N2b2. Residual pesticides and herbicides, non-covered wildlife species

General Observations: Pesticide use for calendar year 2007 (DPR, 2008) indicates that 104 pounds of total pyrethroids and pyrethrins were used during 2007 in the Cache Slough area. More recent (illicit) use of DDT is likely given the presence of non-degraded forms of DDT in sediment (http://www.bdat.gov, accessed 2008 by P. Green, UC Davis). Pyrethroids are 20x more toxic compared to some other pesticides (organochlorides). They persist in the sediment and degrade in one or two years. Pyrethoids represent several individual pesticides out of about 300 pesticides used during 2007 (DPR, 2008).

Magnitude = 1-2 Minimal to low: To the extent that pyrethroids or pyrethrins were used in the area to be flooded, significant toxicity could occur within 1-2 years of application. After approximately two years, near-total degradation should occur. DDT and metabolites could cause reduction of insect populations and bioaccumulation in covered fish species (and some non-covered bird species).

Certainty = 1 - Low: The toxicity of various pesticides is not well understood. A limited number of peer-reviewed studies for certain life stages of selected fish species exist. However, there is not much data for covered fish species available (Werner et. al., 2008). The effect that tidal marsh restoration will have on the availability of residual pesticides is greatly dependent on highly variable ecosystem processes affecting the fate (degradation) and transport of pesticides. Additionally, legacy pesticides from 1960s (e.g. DDT) may be present on the restoration site and more recent (illicit) use is unknown.

Outcome N3: Contaminant resuspension

Analysis of resuspension affects considers two separate physical settings: the restoration marsh sites and the adjacent tidal sloughs. The restored marsh sites are not likely to experience much scour, since the adjacent tidal channels would be excavated as part of construction and the hard farm fields are not expected to scour easily. Adjacent tidal sloughs, which are typically comprised of more erodible substrate, may experience more scour both the bed and banks.

N3a. Mercury, methyl mercury

General Observations: The relationship between tidal marsh restoration as a driver of potential contaminant resuspenion is supported by facts outlined in the DRERIP Mercury model (Figures 4, 7, and 8 and associated text in Alpers et. al., 2008).

Magnitude = 1 - Minima: The degree of scouring manifested on pre-project soils depends on hydrodynamics and this could be a short-term phenomenon as channels reach geomorphic equilibrium. Concentrations of total mercury and methylmercury in sediment is relatively low pre-project on the Cache / Prospect Slough areas, compared with other parts of Delta (Heim et al. 2007). Methylmercury concentrations have the potential to increase on high-elevation portions of the marsh (infrequently wetted zone) and this mercury has the potential for export to downstream environments.

Certainty = 2 - Low: The certainty of this outcome is low due to the dependence on highly variable ecosystem processes affecting the fate (e.g. photo degradation) and transport of methylmercury.

N3b. Residual pesticides and herbicides

General Observations: Werner and Oram, 2008, Figure 1, indicates that tidal marsh restoration is a driver for the resuspension of residual pesticides and herbicides.

Magnitude = 1 -Minimal: The degree of scouring occurring on pre-project soils depends on hydrodynamics and it could be a short-term phenomenon as channels reach geomorphic equilibrium. Acute and chronic toxicity effects of some recently used pesticides (e.g. pyrethroids) and legacy pesticides (e.g. DDT) have been documented for some covered fish species and some non-covered species (fish, invertebrates, mammals, humans) (Werner et. al., 2008, pages 16-25).

Certainty = 1 - Minimal: There is a minimal degree of certainty about this outcome because concentrations of recently used pesticides (e.g. pyrethroids) and legacy pesticides (e.g. DDT) are largely unknown on the soils of proposed project area.

Outcome N4: Scour of spawning habitat for Delta smelt and other covered species

General Observations: Breaching levees for tidal restoration affects the hydraulic geometry of adjacent channels, both landward and seaward of the site (Hood 2004). In particular, levee breaching for tidal restoration can be expected to increase the tidal prism through distributary channels downstream of restoration areas. Downstream distributary channels will therefore exhibit transient increases in tidal velocity that, in turn, increase bed shear stress and bed erosion. Preliminary modeling of Cache Slough restoration indicates that the cross-section average tidal velocity in downstream channels will increase to greater than ~3ft/s (Munevar 2009). Depending on the materials, sandy silt material would likely be eroded rather rapidly toward a new (deeper) dynamic equilibrium that balances the increased tidal prism. In-channel island marsh fragments and fringing marsh along the channel edge may also erode; though likely more slowly. Erosion will selectively remove finer sediment from the bed. In summary, the proposed levee breach(es) will change the geomorphic/hydrological configuration of the site. This change in configuration will alter tidal currents, increasing them in some places and decreasing them elsewhere. This could erode or redistribute sediments used during spawning of Delta and longfin smelt (Dinehart, 2002). Since scientists do not actually know where native fish spawn or on what, it is very difficult to ascertain the importance of this effect.

N4a: Delta smelt

Magnitude = 4 - High: Tidal forcing energy is a zero sum game in the Delta. Tidal restorations will cause regional shifts of tidal range, prism, and velocity. Downstream distributary channels from new restoration areas may experience increased tidal prism with transient increase in tidal velocity and bed shear stress. In situ sediment will be eroded until the hydraulic geometry achieves dynamic equilibrium with the new tidal prism. The eroded sediment will be transported to lower energy channels that will become transient sediment sinks until their hydraulic geometry adjusts to the new lower tidal energy. The re-organization of sediment sources and sinks for Yolo-Cache Slough restorations may be confined to the northwest Delta.

During water year types with poor conditions for Delta smelt, Cache Slough appears to be a seriously important habitat area for this species. It is possible that Cache Slough currently represents one of the few areas where substrate availability, suitable hydrodynamics, and fish productivity overlap. Alteration of the hydrodynamics and substrate positioning in this region has the potential for catastrophic effects to Delta smelt (see Rosenfield, J.A. 2002).

Certainty = 1 - Minimal: Little is known about native delta resident fish spawning, especially with respect to the detail of egg placement and attachment to vegetation or sediment substrate. No one has even seen an emplaced Delta smelt egg. Some evidence suggests Delta smelt may use sandy sediment. Within an annual cycle, most of the sediment redistribution will have occurred and a new dynamic equilibrium reached. Progeny spawned in one reach of the lower Sacramento River may find that section deepened and the sediment characteristics changed with a year. It is not possible to predict whether sediment redistribution will occur at a location that is suitable as Delta smelt habitat (i.e. salinity or turbidity conditions etc).

Sediment transport processes are qualitatively understood but difficult to quantify. Erosion is more difficult to quantify than deposition.

N4b: Longfin Smelt

Magnitude = 2 – 3: Low to Medium: Rationale is similar to the information provided above in N4a Delta smelt.

Certainty = 1 - Minimal: Rationale is similar to the information provided above in N4a Delta smelt.

Important Gaps in Information and/or Understanding

Data needed to more fully evaluate tidal marsh restoration actions:

- A study of predator-prey-habitat interactions for Centrarchid fish.
- Striped bass model is needed to compile and synthesize life history information. This should also include a research study of predator-prey-habitat interactions.
- Expected retention time on restored tidal areas to understand likely productivity and food export potential to local sloughs.
- Predation rates in Cache slough vicinity to understand baseline predation pressure in this region.
- More spatially comprehensive hydrodynamics to understand whether changed flow patterns will reduce or simply redistribute predator pressure.
- Hydrologic and sediment information about turbidity levels, duration, and consequences on species as related to the following: Increased ability for Delta smelt to locate food due to increased turbidity from increased velocities in larger channels.
- *Corbicula* monitoring data from previous restoration sites in the Delta, such as Liberty Island or Little Holland Tract, would provide greater information about the probability of colonization on this Cache Slough site.
- Data on mercury bioaccumulation in waterbirds in the Delta would allow an assessment of transfer of methylmercury to higher trophic level wildlife and an assessment of ecotoxicological risk to reproduction.
- Better data on where and when Delta smelt lay their eggs would better allow us to assess the potential impact of inland silverside predation.
- Analysis of factors contributing the success or failure of other past tidal marsh restoration actions in the Delta.
- Liberty Island is often referred to as a model of a successful restoration project. Monitoring data and new bathymetric data from Liberty Island should be fully analyzed to determine the features that makes it successful and to consider how to apply those features to other restoration projects in the Delta. Specifically, the bathymetric data could be turned into a Digital Elevation Model (DEM) and combined with the habitat type mapping (i.e. vegetation and open water) to illustrate how the restoration provides habitat for covered and other species. This would include documenting the quality of existing LiDAR data for the vegetation mapping.
-

To fully evaluate Outcome P5, additional information listed below is needed:

- Data collection and analysis of the relative predation rate of salmon migrating through Cache slough compared with other areas of the Estuary (e.g. can it be estimated in even a qualitative sense?).
- Data collection and analysis of whether relevant predatory species would be displaced by the expected changes in hydrodynamics in these sloughs.
- Modeling of a situation in which predators are displaced from the sloughs, and analysis of whether this would result in a reduced predator population in this region, or whether predators would simply relocate to another part of the migration corridor where hydrodynamics are more suitable (i.e. what is the new distribution of low velocity/tidally influenced habitat that could be suitable to predators?).

- Data collection and analysis of whether other predatory species (i.e. pikeminnow and striped bass, which prefer riverine habitats) benefit from the altered hydrodynamics and occupy Sutter and Steamboat sloughs.

Research Needs

Run (and life-history) specific studies of Central Valley Chinook salmon and studies of steelhead use of tidal marsh habitats would be extremely valuable to defining magnitude of impacts to these populations and increasing certainty. Various tools (including genetic markers and otolith signatures of population origin) could be used to asses both growth and survival of salmonids in tidal marsh habitats as well as changes in life history characteristics (survival and fecundity) over the course of the life cycle that arise from residence in tidal marsh habitats. Currently, all of the evidence for benefits of tidal marsh on salmonids comes from steelhead and fall run populations located well to the north (where high temperatures and invasive predators are not as problematic). Translating these results to all Central Valley salmonid populations is unwarranted and could lead to disastrous "restoration" projects.

In addition, data on nutrient flow from the marsh plain to juvenile fish rearing in the adjacent channels is essential to determining the value of restored marshes as a food source for pelagic fish larvae (i.e. longfin and Delta smelt).

Greater understanding and more research is needed about the availability and production of food in tidal marshes. Export of organic material from the marsh plain and phytoplankton, zooplankton, and other organisms produced in intertidal channels into the Delta has not been studied.

Potential negative effects of methylmercury exposure on covered fish species remain largely unknown. Based on published studies involving other (non-covered fish species, there is reason for concern regarding possible chronic effects caused by methylmercury exposure, including: endocrine disruption, reduced reproductive success, reduced predator avoidance, and reduced feeding efficiency. (See Mercury Conceptual Model, Alpers et al. 2008, Table 4, page 30). Research is especially needed to determine possible effects caused by exposure during early life stages.

A better understanding is needed regarding the relationship of mercury methylation to the duration of wetting and drying events in areas that are intermittently inundated (i.e. tidal marsh and floodplain). Laboratory and field studies of mercury cycling and bioaccumulation involving sediments in tidal marsh and floodplain environments should quantify the duration of drying time and the extent of dryness necessary to change the oxidation-reduction character of iron, sulfur, carbon, and mercury in sediments such that microbial activity associated with mercury methylation is enhanced.

A better understanding is needed of mercury cycling, bioaccumulation and ecological effects on waterbirds in tidal marsh habitats.

Tropho-dynamic model of ecological interactions linking primary production to the food web structure and production flows into, through, and out of the tidal marsh system.

Landscape-level models that address the effects of variation in structural features of the tidal marsh environment (e.g., tidal channel complexity, channel width, channel length, edge: area ratios, etc.) on the population or production dynamics of specific plants and animals.

Reversibility

No/Hard: The following on-the-ground actions would be needed to reverse this action:
1) levees would need to be reconstructed
2) newly created tidal sloughs would have to be regraded
3) sites would have to be dewatered
4) wetland vegetation would have to be removed
5) monitoring pre, during, and post construction

Although this reconstruction is technically possible, there would be significant financial and regulatory costs. Prior to action reversal, the following planning activities would be needed:
1) geotechnical evaluations for levee reconstruction
2) engineering design
3) evaluate land use options for areas subject to subsidence reversal actions
4) environmental permitting and associated agency ESA consultation,
5) mitigation planning

Levee repair costs are estimated to range between $1,000 and $9,000 per linear foot (Snow 2006).

Opportunity for Learning

High: Implementation of this project can be designed such that different engineering designs can be compared. Numerous physical and biological components can be monitored and ideally, the monitoring data would be used to assess and refine modeling simulations of the restoration. Monitoring questions/data collection could address: marsh function, use of marsh by plant and animal species, abundance/influence of non-native species in restored areas, evolution of marsh habitat including patterns of change, and affect on MeHg levels. It is assumed that monitoring and learning would be part of a comprehensive adaptive management program.

Appendix A Summary Tables Organized by Outcome

Table A1. Positive Outcomes

Outcome	Magnitude	Certainty
P1. Increase rearing habitat and local food production		
a. Delta smelt	3	2
b. Longfin smelt	1	2
c1. Chinook, Sac, winter run	2	1
c2. Chinook, Sac, spring run	2	2
c3. Chinook, fall run		
1. Sacramento River	3	2
c4.Chinook, Sac, late fall run	1	1
c5.Steelhead	1	1
d.Splittail	3	2
P2. Increase food production for:		
a. Green sturgeon	2	1
b. White sturgeon	2	1
P3. Increase availability and production of food downstream of Rio Vista	Viewpoint 1: 3-4	Viewpoint 1: 3
	Viewpoint 2: 1	Viewpoint 2: 1
P4. Provide local cool water refugia.		
a: Delta smelt	2	1
b1: Spring-run,	2	1
b2. Fall-run Salmon	2	1
b3. Steelhead.	2	1

Table A2. Negative Outcomes

Outcome	Magnitude	Certainty
N1. Establishment of harmful invasive species		
a. SAV	3	2
b. Clams	2-3	2
c. Centrarchids	3	2
d. Inland silversides	2	2
N2. Local contaminant effects		
a. Methyl mercury		
1. Covered fish species	1	2
2. Non-covered species	2	2-3
3. Human health	2	3
b. Residual pesticides, herbicides		
1. Covered fish species	1-2	1
2. Non-covered species	1-2	1
N3. Contaminant resuspension and export		
a. Mercury, methyl mercury	1	2
b. Residual pesticides, herbicides	1	1
N4. Scour of spawning habitat for Delta smelt or other covered species.	4	1

Appendix B: Other Potential Positive Outcomes Identified, Not Evaluated

Outcome OP5: Reduce low velocity-associated salmonid predation pressure in Sutter and Steamboat sloughs

Preliminary hydrodynamic modeling indicates that tidal velocities will be damped in Sutter and Steamboat Sloughs with the restoration of tidal action to 5,000 -11,000 acres of habitat in the Cache Slough region (Munevar, pers. comm.). This change in hydrodynamics may make Sutter and Steamboat Sloughs less hospitable to certain predators of salmonids (i.e. those that prefer low velocity and/ or tidal environments). Also, the altered hydrodynamics may reduce the encounter rate with predators that remain, once riverine conditions become established. Predation of salmonid juveniles moving through these two sloughs may be high, however, the studies needed to reach a definitive conclusion have not been conducted. This hypothetical outcome cannot be vetted without additional information about relative predation rates, potential for predators to be displaced, and potential benefits predators may reap from the altered hydrodynamic conditions. These information needs are detailed in the “Important Gaps in Information and/or Understanding” section located in this worksheet.

Appendix C - Outcomes With Zero Magnitude

Outcome OP1a: Increase rearing habitat and local food production for Eastside and San Joaquin Chinook salmon, fall run.

Magnitude = 0 for East Side and San Joaquin River

Fall-run juveniles move through the northern Delta from winter through spring. Fall run rearing in this proposed restoration site during late spring will probably be impacted by high temperatures.

This outcome will benefit only the Sacramento portion of the fall-run population.

Certainty = 2 - Low: Fall run Chinook use of fresh water tidal and sub-tidal environments is documented in other systems but is not well studied in this system – possibly because this kind of habitat is limiting in this system.

The effect of global climate change on water temperatures in this area during Sacramento River fall run migration period also decrease the window of time during each year when restoration will produce benefits. The temperatures experienced in this area indicate that only a portion of the Sacramento River fall-run population will benefit from this action.

Other factors create uncertainty as to the benefits of this measure for this population. *Corbicula* establishment could limit if not eliminate the productivity benefits of the restoration to Chinook salmon. See Negative Outcome N1b. Similarly, establishment of predators or SAV that supports predation could eliminate most or all of the benefits created by this measure.

OP2a: Locally provide areas of cool water refugia for winter-run salmon.

Magnitude = 0- Zero.
There will be no benefits of this restoration to winter-run salmon because this run passes through the region during a window of time when temperatures are not believed to be highly stressful to salmonids.

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

OP2b: Locally provide areas of cool water refugia for late fall-run salmon.

Magnitude = 0- Zero.
There will be no benefits of this restoration to late fall-run salmon because this run passes through the region during a window of time when temperatures are not believed to be highly stressful to salmonids

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

Appendix D: Background information on Hydrologic Processes

About Hydrologic Connectivity: Exchange of materials (i.e. import-export balance) between the Cache Slough area and the western Delta is controlled by a number of factors including the following:

- Site hydrologic connection including size, location, and number of levee breaches; levee lowering; emergent vegetation; channel network geometry
- seasonal variation in tidal versus riverine characteristics at the lower end of the Yolo Bypass,
- enlargement of local sloughs through scour,
- other restoration projects locally and elsewhere in the Delta, and
- water exports.

Individual components of the organic matter flux may go into or out of the marsh and the region depending on the net flow, flow velocities, concentration gradients, trapping by vegetation, and the swimming of organisms relative to currents.

About Scour and its potential affect on Delta native fish: Estuary channel geometry reflects the dynamic interaction between channel morphology and physical forcings including wind, waves, tidal currents, and river discharge. The fundamental geomorphic function of estuaries is to attenuate the energy of physical forcings (Orr et al. 2003). One way this is accomplished is by transporting sediment from high to low energy areas in ways that tend to distribute and attenuate wave energy (Pethick 1996).

Sediment on the bed is characterized by particle size, density, and organic content (Schoellhamer et al. 2008). Higher energy channels like the lower Sacramento River where Delta smelt may spawn, tend to have sandy sediment and contain moving bed forms (Dinehart, 2002).

Given this understanding, a potential negative consequence of tidal restoration is loss or relocation of spawning habitat for Delta smelt or other covered species. Since there is a finite amount of tidal energy in the Delta, newly created restoration areas that increase downstream distributary channel energy will also cause reduction in tidal energy elsewhere. Near region reduction of tidal range and tidal velocity can be expected to vary as a function of distance from the site. Eroded sediments from the immediate downstream distributary channel may therefore be deposited relatively nearby, and perhaps even on the newly restored land.

Little is known about native delta resident fish spawning, especially with respect to the detail of egg placement and attachment to vegetation or sediment substrate. Some evidence suggests Delta smelt may use sandy sediment. Since the time from egg laying to spawn is about a fortnight, the transient erosion of bed sediment may not affect a particular spawn. However, within an annual cycle, most of the sediment redistribution will have occurred and a new dynamic equilibrium reached. Progeny spawned in one reach of the lower Sacramento River may find that section deepened, and the sediment characteristics changed with a year. However, it is not possible to predict whether the sediment will be redistributed to a location that is also suitable as Delta smelt habitat. If sandy substrates were to be moved to locations that do not have suitable Delta smelt habitat (i.e. salinity or turbidity is not quite right) then this could pose a serious obstacle to smelt reproduction and livelihood.

Appendix D: Description of McCormick Williamson Tract 40

Action Description

Restore 1,150 acres of vegetated tidal marsh and 300 acres of shallow subtidal habitat within the Cosumnes/Mokelumne ROA (see map presented in Figure 1 below and appendix C).

Evaluation Team

Dave Harlow (Chair), Stuart Siegel (Coach), Jon Rosenfield, Wim Kimmerer, Chris Enright, Dan Kratville, Charlie Alpers, and Amy Richey.

Date of Last Revision: May 18, 2009

Note about this "Incomplete Working Draft": this document is not completed. The Tidal Restoration Evaluation Team had limited time for this evaluation. Much information has been replicated from the Cache evaluation and has not been revised throughout to reflect the specific restoration sites and geographies of this ROA.

Approach

1. Breach levees to reintroduce tidal exchange to currently leveed lands in portions of McCormick-Williamson Tract, New Hope Tract, and Snodgrass Slough. Levee breaches will be of sufficient length to not limit water motion into and out of restored habitat.
2. Construct new levees to isolate deeply subsided lands and protect private property.
3. Plant tules or place fill material to raise elevations of shallowly subsided lands.
4. Modify existing channels to encourage formation of dendritic channels

Intended Outcomes as Stated in Conservation Measure

1. Increase rearing habitat area for Sacramento splittail and Cosumnes and Mokelumne River fall-run Chinook salmon and possibly steelhead.
2. Increase the production of food for rearing salmonids, splittail, and other covered species migrating to and from the Cosumnes and Mokelumne Rivers.
3. Increase the availability and production of food in the east and central Delta by exporting organic material from the marsh plain and phytoplankton, zooplankton, and other organisms produced in intertidal channels into the Delta.
4. Locally provide areas of cool water refugia for Delta smelt.

Conceptual Model Information Regarding Intended Outcomes

The basic drivers and outcomes are described in the following DRERIP conceptual models: Salmon, Delta smelt, Longfin smelt, Temperature, Foodweb, Tidal marsh, Corbicula, Sediment, and Mercury.

Assumptions

Provided in BDCP Conservation Measure

1. Restoration would be located in portions of Snodgrass Slough, McCormick Williamson Tract, and New Hope Tract.

Added by Evaluation Team

1. Restoring tidal marsh habitat on different sub-areas will have varying levels of both positive and negative effects. For example, some sub-areas may be more efficient at the methylization of mercury and so may have a higher magnitude score for an associated negative outcome. Differences in hydrology, topography, soils, and land-use history will also manifest as distinctions in success of this action among sub-areas. BDCP's background information for this ROA is presented in Appendix C. Background information from other sources is presented in Appendix D.

2. The time frame for realizing restoration benefits depends upon the approaches used. Reversal of subsidence on restored areas can take several years to a decade or more depending on starting elevations. The accretion rate depends on sediment supply and biomass accretion which depends on site-specific conditions. Sediment supply in the Delta is generally very low (Schoellhamer et. al., 2007).

3. Efforts to reverse subsidence before active restoration would be focused on the more deeply subsided portions of these landscapes, i.e., lands more than 6 feet below low tide. There is a hypothesis that shallow open water regions located contiguous to emergent tidal marsh provide enhanced ecosystem complexity and functions compared to those tidal marsh habitats located directly adjacent to deeper sloughs. Although this hypothesis has not been tested, preliminary information on current conditions at Liberty Island and Little Holland Tract suggest support. However, the details of these sites are not readily available to the broad research community at this time and so the information is anecdotal. This assumption also includes a time limit to allow for subsidence reversal so that restoration of an entire parcel is not delayed indefinitely. To speed up the subsidence reversal process, an alternative method would be to separate low-lying areas with new levees and reconnect those areas after subsidence reversal is accomplished.

4. Source of fill material will be identified and use of all material, including dredge spoils, will be approved by the RWQCB.

5. Water output from the site, post-restoration, will meet water quality standards.

6. Flood and ownership issues associated with McCormick Williamson Tract and other restoration areas will be resolved (See Florsheim et al 2008).

7. Prior to implementation, a Phase I Environmental Assessment with on-site sampling to assess legacy and other soil contaminants (i.e. mercury and pesticides) would be completed.

Problem(s) with Action as written:

1. Since rearing habitat for juvenile fish by necessity includes local availability of food, the evaluation team merged the Intended Outcomes 1 and 2 (tidal marsh, rearing habitat, and local food) into one outcome.

2. Loading of fill material on top of a shallow island may compress the underlying soils. This approach may not yield the intended result. A close study of existing soil conditions including analysis of the local soil map is needed to further evaluate this issue.

3. The conservation measure would benefit from an explicit recognition that restoration of tidal marsh functions on subsided landscapes, especially those subsided below emergent vegetation elevations, will take many years to many decades. In the interim, restoration sites below vegetation elevations will function as shallow subtidal habitat.

4. It is unlikely that intertidal mudflats will develop in the Delta because dominant intertidal emergent vegetation species in the Delta can grow throughout the tidal range and just into shallow sub tidal elevations (Brown 2003, Simenstad et al 2000 as cited in Schoellhamer et. al., 2007, p.26).

5. The action should state clearly in Approach #1 and #2 that set-back levees will be required to provide tidal flood protection to lands within the islands not restored to tidal action.

Scale of Action:

Small

Rationale:

This is a small scale restoration action due to its limited spatial extent. As listed in Table1 below, the Delta currently has approximately 21,600 acres of tidal marsh habitat (baseline). Additionally, 67,000 acres of diked and other lands have been identified as potentially restorable to tidal marsh (neglecting effects of restoration on reducing tidal range). The proposed 1,150 of tidal marsh plus 300 acres of shallow sub-tidal restoration options would increase marsh acreage 5% above current conditions. Significant amounts of the 67,000 acres of identified restorable lands are highly constrained such that they could not be restored in the near term (South Delta and Netherlands alone account for 31,000 acres of the 67,000 acres). Therefore, this action also represents an important part of the potentially restorable tidal marsh lands.

Table 1. Summary of Tidal Marsh Acreages

Area	Acreage	Source
Delta (entire Delta proper)	738,000	DWR, 2009
Historic tidal marsh/wetlands in Delta	525,000	TBI, 2002
Current extent of tidal marsh/wetlands in Delta.	21,600	TBI, 2002
Restorable intertidal lands within Delta.	67,000	CA DVSP, 2008, Table 1, p.77.
Proposed Cosumnes – Molkemne tidal restoration (this action)	1,150 tidal marsh 300 sub-tidal	BDCP, 2009

Figure 1: Cosumnes/Mokelumne Restoration Opportunity Areas

Evaluation Summary

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

Outcomes with Zero Magnitude

- OP1: Increase rearing habitat area (including physical and biotic attributes) for longfin smelt: No life stage of longfin smelt occurs in this area. There is no impact of this action on this species. Since longfin smelt do not occur with any regularity or abundance in this region, magnitude is scored as a "0" (zero) and certainty as a "4"- High.
- OP2a: Locally provide areas of cool water refugia for winter-run salmon.
- OP2b: Locally provide areas of cool water refugia for late fall-run salmon.

Other Negative Outcomes Identified, Not Evaluated

During the course of this evaluation, the team identified one potential negative outcome that it did not evaluate due to lack of time. It is recommended that this potential outcome be evaluated at some point in the future when additional time is available.

- ON1. Flooding on adjacent properties
- ON2. Mosquito production
- ON3. Pesticide use for mosquito control
- ON4: Increase in the availability of selenium
- ON5: Resuspension and export of contaminants to downstream areas effects on non-covered wildlife species.

Relation to Existing Conditions:

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

No

Nature of Change:

This small scale action to restore 1, 450 acres of tidal marsh and shallow subtidal habitat may change the environment on a local scale but not to such an extent that our current understanding of boundary conditions (Harrell et al 2008), hydrodynamics and ecological processes in the Delta would change.

Overview of Productivity Import-Export

The Cache Slough evaluation (HRCM4) worksheet provides a complete discussion of productivity levels, import and export. Here we describe how conditions may differ from Cache Slough in order to provide the Conservation Measure evaluation appropriate specificity.

The primary difference between this Cosumnes/Mokelumne ROA and the Cache Slough ROA is that the primary sites (McCormick Williamson, New Hope Tracts A&B, and Snodgrass Slough):

- Some restorations sites are located along lower energy waterways, while other areas are further removed. Has similar tidal exchange (to move marsh exports) compared to Cache, due to its geographic location (downstream of the Cosumnes and Molkemne river channels etc).
- May experience increased primary production compared to other restoration sites because its easterly location offers warmer spring and summer temperatures. However, the scale of the action is small in size and it is highly uncertain whether any of this production will be exported or will benefit covered fish species.
- The residence time may be relatively similar to that Cache Slough.

Potential Positive Ecological Outcome(s)

Outcome P1: Increase rearing habitat area (including physical and biotic attributes) for covered fish species.

As indicated at the beginning of this worksheet under the section entitled "Problems with Action", the team decided to merge two Intended Outcomes (rearing habitat and local food) into one outcome, P1, as shown below because rearing habitat for juvenile fish by necessity includes local availability of food. This outcome includes food (both primary and secondary production) produced within the vegetated marsh, within marsh channels, and within the subtidal areas adjacent to the vegetated marsh. General information that applies to salmon runs is provided in the worksheet for HRCM 4 – Cache Slough, Outcome P1c on page 15. Please note that green and white sturgeon are not known to utilize the Cosumnes and Molkemne River systems and so these species are not listed in the analysis below.

P1a. Delta smelt:

General Observations: Delta smelt formerly (1963-1964) occurred in this area (Norbriga and Herbold, 2008, page 43). Although they are uncommon in this area today (2005).

Magnitude = 1 - Minimal
Historically, Delta smelt spawned and reared as larval fish in the vicinity of these east Delta marshes (Norbriga and Herbold, page 11). They eat food produced on tidal marshes; but do not forage in shallow environments (Norbriga and Herbold, 2008 page 27 and pers. comm. with B. Herbold, US EPA). So, the food Delta smelt consume *in the shallow tidal areas* is likely to be nil.

Delta smelt spawning in, and use of, this area was rare historically. Restoration of an area this size might improve rearing habitat for a small numbers of Delta smelt during a limited number of years (Herbold, pers. comm.; Nobriga, pers. comm.).

Consumption of prey resources located in directly adjacent channels or deepwater habitats is dependent upon the quantity of zooplankton produced in shallow areas and competition from other fish species. The benefit of food produced and consumed in the direct vicinity of this project will be confined to a limited fraction of the Delta smelt through only a portion of their life cycle (the larval stage).

This outcome assumes that Delta smelt are limited by food production in this region. Delta smelt rearing in open water habitats may have, in the past, relied on export of food from a vast network of tidal marshes (Norbriga and Herbold, page 12). Water temperatures in this region are not measured? However temperatures >20^{o}C could impede smelt rearing in some years during May and June.

Certainty = 1 - Minimal
Scientific understanding is medium and the nature of this outcome is greatly dependent on highly variable ecosystem processes or other external factors. The Delta smelt conceptual model (Nobriga and Herbold 2008) does not indicate what may cause the

apparent absence of spawning activity in this region. There is no indication that current food production near the Mokelumne/Cosumnes confluence with the Delta limits the spawning productivity of this species in the Delta. The quantity of prey items consumed in channels located directly adjacent to the restored marsh is dependent upon on how much of the zooplankton produced in the restored shallow areas is consumed by fish that actually forage in shallow environments where the food is produced. Water temperatures in this region are unknown and high temperatures could impede smelt rearing in some years during May and June.

Additionally, establishment of *Corbicula*, could limit, if not eliminate the productivity benefits of the restoration to Delta smelt. See Negative Outcome N1b. Similarly, colonization by invasive predators could result in added mortality that would counteract any benefits of restoration (especially if SAV invasion facilitates predation success).

Worth = Low

P1b. Steelhead

General Observations: Steelhead juveniles are produced by a hatchery on the Mokelumne and may exist in the Cosumnes as well, though the conceptual model provides no evidence of this (Williams and Rosenfield, In preparation). The worksheet for HRCM4-Cache Slough provides more detailed information about tidal restoration in relation to salmon and steelhead populations.

Magnitude = 1 - Minimal
This outcome assumes that "rearing habitat area" (quantity) and/or food is limiting. "Spring Chinook, or at least the Butte Creek population, pass quickly through the Delta, so habitat restoration there seems unlikely to do much for them. <u>The same is probably true for late fall Chinook, and for steelhead</u>" (Williams and Rosenfield, In preparation page 16).

In other systems, steelhead utilize this kind of habitat. However, the conceptual model indicates the steelhead which smolt in this system are larger compared to other systems. Therefore research conducted in other systems is not likely to apply here. Steelhead will eat the types of food produced in this habitat. Steelhead migrate through this area "mainly in April and May" (Williams and Rosenfield page 34). Average daily water temperatures in the vicinity were not made available to the evaluation team. However, at sites throughout the lower Sacramento and lower San Joaquin, temperatures regularly exceed 20^{o}C (beyond which sublethal effects accumulate; Reese and Harvey 2002 *and*

see Richter and Kolmes 2005) from May-September. With warming that may occur under climate change, these temperatures will occur in this area with some frequency during April and October as well. Thus, steelhead rearing in this proposed restoration site during May, June, and July will probably be impacted by high temperatures and negative impacts could become more common with global warming. The DRERIP conceptual model for salmon (Williams and Rosenfield In preparation, Estuarine – growth section) shows a low impact of this kind of habitat on competition. Competition may moderately impact growth of steelhead. Restoration will benefit only steelhead from

Mokelumne and Cosumnes Basin and these beneficiaries will largely be hatchery-reared, not wild, fish.

Certainty = 2-Low
Since there is no direct research on use of shallow estuarine habitat by steelhead in this system a low certainty score is warranted. Any effect will be limited to the east side population and to those times of year when temperatures are not too high in the target area.

Establishment of *Corbicula*, could limit, if not eliminate the productivity benefits of the restoration to steelhead. See Negative Outcome N1b. Similarly, colonization by invasive predators could result in added mortality that would counteract any benefits of restoration (especially if SAV invasion facilitates predation success). There is low certainty that this outcome will offer minimal benefits to the steelhead population as a whole.

P1c. Cosumnes and Mokelumne River Fall-run Chinook salmon

General Observations: Fall run juveniles are produced by a hatchery on the Mokelumne and appear to spawn in the Cosumnes as well (Williams and Rosenfield in preparation, page 32).

Magnitude = 1 - Minimal
This outcome assumes that "rearing habitat area" (quantity) and/or food is limiting. "Fall Chinook […] could benefit strongly from tidal marsh restoration"(Williams and Rosenfield, in preparation, page 16). Fall Chinook enter estuarine habitats at a small size and does typically benefit from additional rearing/growth opportunities.

Fall-run will consume the types of zooplankton produced in this restoration (under the assumed condition). Average daily water temperatures in the vicinity were not available to the evaluation team. However, at sites throughout the lower Sacramento and lower San Joaquin, temperatures regularly exceed 20^{o}C (beyond which sublethal effects accumulate (Myrick and Cech 2004; Richter and Kolmes 2005) from May-September. With warming that may occur under climate change, these temperatures will occur in this area with some frequency during April and October as well. Thus, fall run rearing in this proposed restoration site during May, June, and July are likely to be impacted by high temperatures.

Many fall run salmon from east side tributaries migrate later in the year than do the Sacramento River counterparts (Williams and Rosenfield, in preparation, Figure 3), thus their "rearing" time in the Delta is relatively short and occurs when temperatures in this area may be too high to support growth and emigration.

Certainty = 2-Low
Fall run Chinook use of fresh water tidal and sub-tidal environments is documented in other systems but is not well studied in this system – possibly because this kind of habitat is limiting in this system. Effect of global climate change on water temperatures in this area during fall run migration period also decrease the window of time during each

year when restoration will produce benefits. Certainty that the hoped for benefits will be realized is low due to the temperatures likely experienced in this area and the small fraction of the fall run population that will benefit. .

Establishment of *Corbicula*, could limit, if not eliminate the productivity benefits of the restoration to Chinook salmon. See Negative Outcome N1b. Similarly, colonization by invasive predators could result in added mortality that would counteract any benefits of restoration (especially if SAV invasion facilitates predation success).

Worth = Low

P1d. Splittail.

General Observations: Drivers, linkages, and outcomes are described in pages 1h, 12, 13, 14, 15 of the DRERIP Splittail conceptual model (Kratville, 2008).

Magnitude = 3 - Medium
While more tidal marsh will help rearing of juvenile splittail, the expect population benefit is medium. The Cosumnes floodplain system provides important alternate spawning locations for splittail in all years and especially in years when there may be flooding here and not in the Yolo Bypass. This may provide increased population resilience if juvenile fish spawned on the Cosumnes floodplain gain improved passage to Suisun Marsh. For Sacramento splittail, the limiting factor for population abundance is floodplain inundation

that provides spawning habitat. When large scale inundation occurs, splittail population abundance is high for several years following an event. Long periods without floodplain inundation reduce splittail population abundance. Splittail do not appear to be habitat limited at other life history stages.

Certainty = 3 - Medium
The uncertainty lies in whether this new rearing areas will increase splittail population abundance. This area will increase the opportunity for rearing juveniles; however this does not appear to be a limiting factor in splittail abundance compared to floodplain inundation. The bulk of the adult splittail population resides in brackish areas of Suisun Marsh. The Cosumnes/Mokelumne marsh is expected to be freshwater and so will only provide habitat for juvenile fish migrating into Suisun Marsh. This restoration might not provide habitat that supports a new population center or increases the numbers of fish successfully making it to Suisun Marsh.

Establishment of *Corbicula*, could limit, if not eliminate the productivity benefits of the restoration to splittail. See Negative Outcome N1b. Similarly, colonization by invasive predators could result in added mortality that would counteract any benefits of restoration (especially if SAV invasion facilitates predation success).

Outcome P2: Food resources (i.e. organic material from the marsh plain and organic carbon, phytoplankton, zooplankton, and other organisms from intertidal channels) produced on the restored marsh will be exported, via tidal flow, and contribute to food availability downstream in the central and east Delta.

P2a. All covered fish species

General Observations: The Tidal Marsh and Foodweb models [Kneib et. al., 2008, page 9 and Durand, 2008, section 2.16)] provide a general indication that there may be a linkage between tidal marsh habitat as a driver and increases in availability and production of food resources as an outcome, but that the mechanism for this linkage may be movement by fish. The tidal marsh conceptual model also states that freshwater tidal marshes are net exporters of high-quality organic production (page 2 in Kneib et. al., 2008). See also Dame et al. 1986, Kimmerer and McKinnon 1989, Kneib 1997, Lucas et al. 2009. Please see the evaluation worksheet for action # HRCM4-

Cache/Yolo, Outcome P3, for more details about **Tidal Marsh Contributions to Exported Production.**

There was disagreement within the evaluation team regarding the magnitude and certainty of expected benefits of tidal reintroductions with regard to the export of food (phytoplankton, zooplankton, insects, and small fish) to areas downstream of Rio Vista and the likely benefits to covered fish species. In the spirit of presenting the scientific discourse, both points of view are captured below.

Two key questions discussed were: (1) can we predict the sign of the flux of productivity (i.e. will the restoration area be a source or a sink for primary and secondary productivity); and (2) will there be adequate advection to move material out of the restoration area and downstream to Rio Vista (assuming the restoration area is a source of productivity, as opposed to a sink). Additional information and analyses is needed to better answer these key questions. To develop this additional information, the team recommends future development of a Tropho-dynamic model as described in the section on page 41 entitled “Research Needs”.

Viewpoint #1

Please see the text of Outcome P3 in worksheet HRCM4 – Cache Slough for additional background information about Viewpoint #1.

Magnitude = 3-4 – Moderate to High
Without advective connection, restoration will still have significant productivity benefits to covered fish species and to many other species due to providing areas of highly functional habitat in conjunction with restoration elsewhere that collectively provide fish species a range of options that spread risk through exploiting available resources when they are present. Refer to Ted Sommers, IEP Estuarine Ecology Team or CAERS poster. In addition, these areas would export that productivity

through the "trophic relay" concept described in the tidal marsh conceptual model (fish export the productivity).

Certainty = 3 – Moderate
Certainty is reduced by the potential for establishment of invasive clams that could consume substantial portions of phytoplankton and hinder zooplankton productivity.

Viewpoint #2

Please see the text of Outcome P3 in worksheet HRCM4 – Cache Slough for additional background information about Viewpoint #2.

Magnitude = 1-2 - Minimal to Low
The implied relationship is that restored tidal marsh will export nonliving and living organic matter including plankton and fish, thereby supporting foodwebs of the upper estuary. An implicit assumption is that any increase in the area of shallow habitat would result in enhanced plant productivity some of which would be exported.

Certainty = 1 - Minimal
The sign of the signal is difficult to determine, except for total organic carbon, most of which is dissolved. Although dissolved organic carbon (DOC) will likely flow out of the marsh, fluxes of other components may be in or out (Kneib et. al., 2008, page 9). Colonization by invasive clam species can wipe out the food web production effect entirely. We have no certainty at all that they will not colonize. In addition, colonization of the site by vertebrate consumers (e.g, inland silverside) can also significantly reduce the amount of food available for export beyond the site boundaries (Moyle 2002). There is evidence from within this system (Dean et al. 2005) that restored marshes can act as sinks for certain zooplankters; in this case, the sign of the signal would be negative.

Outcome P3: Provide local areas of cool water refugia (Feb-Jun) for Delta smelt and salmon.

The cause and effect relationship associated with this outcome is described in Stacey and Monismith 2008, Malamud-Roam 2000, and Enright 2008. Considering the local scale (small) of the action, the relationship between tides, physiography, and water temperature could be moderate. The relationship between drivers (wind, insolation, fetch, tides, currents) and linkages (long-wave, short wave, latent, and sensible heat flux) is complex and may produce both warmer and cooler water on a variety of time and space scales. Larger spatial gradients of water temperature will likely occur. The frequency of threshold temperatures for various species is uncertain. See Stacey and Monismith (2008), Malamud-Roam (2000), Enright (2008).

For more details, please see the introductory text in the HRCM 4- Cache Slough action worksheet and the Suisun Marsh Tidal Marsh Restoration Worksheet, specifically, Outcome P4.

P3a. Delta smelt

Magnitude = 2- Low
The spatial extent of cool water refugia could be relatively limited. However, in some cases a large effect could be felt across relatively large area across the range. Please refer to the discussion located in HCRM4 – Cache Slough Restoration Action, Outcome P4, page 25 for more details.

Certainty = 1 - Minimal
The basis for our understanding is a single unpublished study in Suisun Marsh. The extent to which this effect may transfer to the restoration site, and to which Delta smelt and salmon will take advantage of it, cannot be predicted. Please refer to the discussion located in HCRM4 – Cache Slough Restoration Action, Outcome P4, page 26 for more details.

P3b. Salmonids

High temperatures are currently rare during May (as indicated by IEP gauges rsac075 and rsac054; Enright *pers. comm.*). Temperatures exceeding 20-21^{o}C (beyond which sublethal effects accumulate; Reese and Harvey 2002 *and see* Richter and Kolmes 2005) are more common and widespread in June, July, and August (as indicated by IEP gauges rsac075 and rsac054; Enright pers. comm.). With warming that may occur under climate change projections, high temperatures may become more frequent and extreme. Thus, Chinook salmon (spring-run and fall-run) and steelhead rearing in this proposed restoration site during June and July will probably be impacted by high temperatures. Forces that reduce those temperatures may improve survival, growth and smoltification success.

Benefits are limited to those emigrants rearing in this habitat after May, when temperatures in this region increase above optimal rearing threshold of 12-16^{o}C (Marine and Cech 2004). These benefits are expected to be transient (on annual and decadal

time scales) and will never effect more than a small fraction of populations for any of the covered species (unless there is a cumulative impact from numerous restoration that produce the same cooling effect. Also, as mentioned in the description, this phenomenon is transient over time as the timing of tidal cycle shifts. Complexity of thermodynamics in conjunction with local geomorphology and long-term climate change and sea level rise introduce considerable uncertainty.

In addition to the runs listed below, please see Appendix B for winter-run etc.

P3b1: Spring run salmon

Magnitude = 2- Low.
This outcome modifies Outcome P1 (creation of habitat). In evaluating that outcome, benefits of this action were interpreted in the light of unfavorable temperature conditions that occur in the area during late-spring and summer. To the extent that the tidal flooding/cooling phenomenon occurs on this restoration site (a function of geography

and restoration design and site elevations) during the period of potential thermal stress (May through end of summer), it may provide some relief from the effects of thermal stress *for those salmon runs that migrate through this region at this time (fall and spring run and steelhead).* That benefit impacts only the proportion of the population that migrates at this time and only the proportion of the population that migrates through this area.

Certainty = 1-Minimal

Certainty is minimal for reasons similar to that described in P3a, above. This outcome is highly dependent upon highly variable ecosystem processes. Although scientists have a reasonable understanding at the general level, the range of data needed to evaluate at the action scale is lacking.

P3b2: Fall run salmon

Magnitude = 2- Low.
As noted above, the beneficial effect occurs for only a portion of the salmonid population passing through this region during a particular and narrow window of time.

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

P3b3: Steelhead

Magnitude = 2- Low.
Beneficial effect occurs for only a portion of the salmonid population passing through this region during a particular and narrow window of time.

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

Potential Negative Ecological Outcome(s)

Outcome N1: Establishment of harmful invasive species .

Harmful invasive species have the potential to cause two types of adverse effects. First is to worsen conditions relative to the existing baseline; i.e., creating an attractive nuisance. Second is to detract from achieving the positive benefits the action could provide. The magnitude and certainty scores below are based upon an assessment relative to baseline conditions. The scores below for N1a to N1d do not represent the potential to distract detract from the positive benefits of the action because these deductions were considered i by reducing the certainty scores for positive outcome # P1. Where appropriate, the impacts associated with the establishment of harmful invasive species on the restored marsh are discussed below.

N1a: Submerged Aquatic Vegetation (SAV) (including Egeria)

General Observations: As described in the conceptual model, the establishment of SAV is controlled by local flow conditions and substrates (Anderson, In Preparation). Many aspects of SAV physiology are influenced by local flow conditions including turbidity and to some extent flow velocity which if too high can scour suitable substrate precluding SAV establishment. The initial establishment of SAV is an intermediate outcome and the development of a large sustainable SAV population is the final outcome. .

Please note that establishment of SAV reduces the certainty that the positive outcome, P1 will occur. This has been noted in the scoring for P1.

Magnitude: 3 - Medium

The establishment of SAV in general is controlled by local flow conditions and substrates. Local flow conditions control many aspects of SAV physiology, most importantly in this area turbidity. In nearby Liberty Island where turbidities are generally higher due to wind wave action SAV is restricted to shallow near shore areas (Ustin et al. 2008). If turbidities are high in the restoration area then SAV establishment and growth may be reduced to levels similar to Liberty Island. If not there is the potential for SAV amounts similar to Franks Tract. The substrates in this area would be expected to support establishment of SAV (Anderson, In preparation). Small to moderate fractions of all the covered fish species may experience highly significant but localized effects due to SAV and therefore the net effect is medium.

For this outcome, the baseline condition is that much of the existing 21,600 acres of Delta tidal marsh is infested with submerged aquatic vegetation (Ustin, 2008). The restoration of a tidal marsh that eventually becomes infested with SAV is significant. Large, sustainable populations of SAV will produce significant changes in water quality (turbidity, pH, DO and temperature), or water flow characteristics (velocity and direction), which in turn can affect the quantity and quality of sediments (Anderson, In Preparation).

Eventually, the clarity of water entering the site from upstream will increase by lowering velocities and allowing particulates to settle out of the water column. This increased water clarity could increase predation of fish entering the site from outside areas (i.e. predators now have greater visual range). One type of predator, Centrarchid fish, is strongly associated with SAV and increased Centrachid populations may create a population sink for native fish at this location, as discussed in N1b, below. In summary, this action will worsen conditions beyond that of baseline conditions and small to moderate fractions of all the covered fish species may experience highly significant but localized effects due to SAV. Given the rarity of Delta smelt, the impact of SAV establishment could be particularly significant on this species.

Certainty: 2- Low
There is high uncertainty about the initial colonization and ultimate patch distribution of SAV on the substrate. As the substrate softens over time, it may be more conducive to SAV establishment and growth (i.e. bed characteristics are described as a driver in the conceptual model). It is well documented that the physical structure of SAV facilities slower water velocities which allows sediment particles to settle, thereby reducing turbidity, locally and creating a positive feedback loop for more SAV establishment (Anderson, In Preparation). The effect of specific restoration site substrate, how those substrates may change over time after restoration, and the role of flow velocity at these locations is not well understood (Anderson, In Preparation).

N1b: Non-native Centrarchids

General Observations: Centrarchid fish, as an assemblage, cover a range of ecological niches in the Delta. They are competitors for resources as well as predators on native fish. The magnitude of this effect is dependent on the assemblage of centrarchids that invade and the size of the populations. This is in turn partially dependent on the amount of SAV invasion into the restored system.

Please note that establishment of centrachids reduces the certainty that the positive outcome, P1 will occur. This has been noted in the scoring for P1. The relationship among drivers and outcomes is described by Brown and Minchniuk 2007, Grimaldo et al 2004, Nobriga and Feyrer 2007, and Nobriga et al 2005.

Magnitude: 4 - High

For this outcome, the baseline condition is that much of the existing 21,600 acres of tidal marsh are excellent habitat for Centrarchid fish where they are associated with adjacent deeper water. This is illustrated by the large number of Bass Tournaments that occur in the Delta. The Delta is a stop on the national professional bass fishing circuit with $100,000 prizes. This action could worsen conditions beyond that of baseline. Centrachids are a concern because they prey upon and compete for food and other resources with native covered fish.

The establishment of Centrarchids in conjunction with SAV is well documented in the Delta (Brown and Michniuk 2007; Grimaldo et al. 2004; Nobriga and Feyrer 2007; Nobriga et al. 2005). Centrarchid fish, as an assemblage, cover a range of ecological niches in the Delta. They are competitors for resources as well as predators on native fish. The magnitude of this effect is dependent on the assemblage of Centrarchids that invade and the size of the populations. This is in turn partially dependent on the amount of SAV invasion into suitable habitat areas of the restored system. The extent of their impact on the native ecology of the restored marsh is partially dependent on the extent of SAV establishment and patch size. Centrarchid fish will become established in this area as they have everywhere else in the Delta. If the eastern Delta becomes brackish to the extant that Suisun Marsh is today, this may change.

Certainty: 2 - Low
The uncertainty is not whether or not Centrarchid fish will become established at the restoration site, but the extent of their populations and impacts on local native fish use once established. In areas with low SAV patch size the numbers of Centrarchid fish and their presumed impact on native fish are lower then where the opposite is true (Brown and Michniuk 2007). If the western Delta becomes brackish to the extant that Suisun Marsh is today, this may change.

N1c: *Corbicula*

General Observations: The relationship between drivers and outcomes is described in the DRERIP Corbicula Conceptual Model (Thompson et. al., In revision).

Consequences of *Corbicula* establishment. If established, *Corbicula* would likely have a significant effect on food web dynamics because it consumes phytoplankton in shallow areas and/or consumes the productivity of shallow areas exported to channels to such a high extent that it exhibits top-down trophic control. *Corbicula*'s consumption of primary productivity represents a significant limiting factor throughout the Delta that could greatly reduce productivity benefits of restoration efforts (Thompson et. al., In revision). According to the *Corbicula* model (Thompson et. al., In revision page 11), no local studies have been

undertaken to indicate whether *Corbicula* feeding has reduced zooplankton populations either through competition or direct predation. In this case, the baseline condition is that much of the Delta is infested with *Corbicula*. The restoration of tidal marsh which may also become infested with *Corbicula* at some future time would not represent a significant change above baseline conditions. Establishment of *Corbicula* would however, consume much of the positive benefits that were previously discussed above under positive outcomes.

Potential Control Options. There are no stressors identified that can limit the success of Corbicula in a significant manner. However, salinity can limit the spatial distribution of this species and food limitation is a source of stress. (Thompson et. al., In revision, pages 8 and 13). The *Corbicula* conceptual model indicates that the only meaningful method to control their presence/abundance is salinity. This control method would require salinity intrusions into the restoration area of sufficient duration and at the appropriate times of year to have a meaningful effect. The conceptual model does not specify the duration and timing which might be most effective during recruitment. Water temperatures may influence the effectiveness of both recruitment and control measures.

Magnitude: 1- Minimal
Corbicula can control phytoplankton biomass development in shallow areas, or consume the productivity of shallow areas exported to channels. Corbicula is a significant limiting

factor throughout Delta (Thompson et. al., In revision). For this outcome, the baseline condition is that much of the Delta is infested with *Corbicula*. The restoration of tidal marsh that eventually becomes infested with *Corbicula* would not represent a significant change above baseline conditions.

Certainty: 2 - Low
The timing and extent of colonization by Corbicula cannot be predicted because of a lack of data.

Corbicula are prolific reproducers and colonizers of newly available habitats in salinities below 2 ppt. Source populations can come from elsewhere within the Delta or from upstream tributary populations. *Corbicula* can establish on soft and hard substrates and on vegetation and they can colonize intertidal zones as well as deeper water. (*Corbicula* model). Based upon the biology of the species and the physical setting of the restoration site, the probability of *Corbicula* establishment in the West Delta restoration areas appears to be high, but ultimately cannot be predicted, partially due high variability in environmental conditions. The low certainty score considers the probability and extent of potential establishment.

Corbicula monitoring data from previous restoration sites in the Delta, such as Liberty Island or Little Holland Tract, would provide greater information about the probability of colonization on these eastern Delta sites. More information would improve the certainty rating. However, such data and analysis was not made available to the evaluation team.

N1d: Inland Silversides Effects on Delta and Longfin Smelt

General Observations: Inland silversides (*Menidia beryllina*) are highly tolerant of warm water, salinity variability and are trophic generalists compared to Delta smelt (Moyle 2002). Inland silversides are the most numerous fish in Suisun Marsh shoreline habitats (Matern et al. 2002), and the most numerous fish in shallow Delta habitats (Nobriga et al. 2005, Brown and May 2006). The Delta smelt model (page 3) includes intraguild competition with inland silversides as one of the top five in-Delta stressors to Delta smelt. Inland silversides are thought to be a major predator of Delta smelt eggs (Bennett and Moyle 1996 and Bennett 2005 in the Delta smelt conceptual model pg 12). In the laboratory, inland silversides reduce Delta smelt size relative to controls when they are reared together (Bennett 2005).

Inland silversides are also treated in the longfin smelt model. Moyle (2002, in Rosenfield, 2008) suggested that based on timing of arrival in the Estuary and subsequent longfin population response, inland silverside might have had a major impact on longfin population dynamics. However, the model states that inland silverside prefer shallow water habitats where juvenile and sub-adult longfin are rare, thus, their impact as predators of juvenile and sub-adult longfin is probably slight (Rosenfield, 2008, pg. 17). Spawning locations for longfin are unknown, so it is not known whether competition from inland silverside for spawning territory is a factor in their decline.

However, Delta smelt evolved with other intraguild competitors, including longfin smelt, and have survived with striped bass (introduced in 1879). Interaction between silversides and Delta smelt in the wild may be limited because Delta smelt typically inhabit offshore environments, while inland silversides typically inhabit shoreline habitats. Increased shoreline habitat would presumably increase the carrying capacity for Inland silversides. However, predator-prey interaction between Delta smelt and inland silversides in the wild is speculative. Silversides may eat Delta smelt eggs or larvae if the eggs and larvae occur on the shorelines. It has not been shown that inland silversides reduce calanoid copepods (Norbriga and Herbold, 2008, page 32), so they may not effectively compete with Delta smelt for prey.

Williams and Rosenfield, In preparation; Israel and Klimley, 2008; Kratville**,** 2008; and Israel et. al., 2009 do not mention inland silversides so this evaluation assumes no adverse effects and focuses its evaluation on Delta smelt and longfin smelt.

Magnitude = 2 - Low

Inland silversides are the most abundant fish in shallow-water habitats in many areas of the Delta and may currently contribute to local depletions of zooplankton otherwise available to native fishes within these areas. Additionally, they may prey on embryos of species who lay eggs in these shallow areas (Moyle 2002). The crash of Delta smelt populations coincided with invasions of inland

silversides into the estuary (Bennett and Moyle 1996). This action may change conditions relative to baseline by attracting (via restored marsh) a nuisance (inland silversides). This conservation measure will increase the local inland silverside population by providing additional shoreline breeding habitat. Because of the high existing abundance of inland silversides, the incremental increase in breeding habitat and thus population size above current conditions is considered small and the magnitude of this effect is considered to be low relative to baseline. Further, differential habitat selection (offshore environments for inland silverside) is expected to reduce the interspecific competition effects. .

Certainty = 2 - Low

Understanding of interaction between Inland silversides and Delta smelt in the wild is low, particularly in regards to egg predation by inland silversides. Spatial interactions with longfin smelt are also uncertain.

Outcome N2: Potential for mercury methylation and local bioaccumulation to affect wildlife: N2-A – Covered fish species, N2-B, Non-covered wildlife species, N2-C, Human health.

N2a: Covered fish species

General Observations - methyl mercury: The relationship between drivers and outcomes is supported by (Alpers et. al., 2008, Table 2 and associated text). Although current methylmercury levels on Liberty Island (analogue for future state of areas to be restored) are relatively low (Slotton et al. 2002, (Alpers et. al., 2008, figure 5), there is potential for enhanced production of methylmercury in areas of high marsh that will be inundated infrequently (only during highest tides).

The process of drying out between wetting events tends to oxidize species of sulfur, iron, carbon, and mercury, leading to higher potential to form methylmercury upon rewetting. Once formed, methylmercury biomagnifies in the aquatic food web and ecological effects may occur in some sensitive species. Thus, the specific geomorphology of restoration sites and in particular the degree

to which shallow depressions and poorly drained areas of high marsh are part of the restoration projects directly influences the degree of mercury methylization.

General Observations, other contaminants
Past land use determines risk of other contaminants: lead risk in areas with significant hunting. Risk of residual pesticides (e.g., pyrethroids) in areas used for agriculture in past 2 years, which suggests that if these pesticides were used, allowing for a 2 year lag period between application and tidal restoration would be a prudent mitigation measure. Selenium contamination from the San Joaquin Valley and other sources is also a concern, however it was not evaluated in this worksheet..

Magnitude: 1 - Minimal
No toxicological studies have been conducted with any of the target species regarding acute toxicity. Mercury concentrations in target fish are compared here against concentrations producing mortality in other fish species. Mercury concentrations in covered fish species are compared here against concentrations producing mortality in other fish species. Mercury concentrations in ppm-wet weight for white sturgeon, Chinook salmon and Steelhead collected during 2006 were 0.165-0.279, 0.094-0.396 and 0.06-0.13, respectively (Melwani et al. 2007). No tissue data for either longfin or Delta smelt was found. It is assumed that both species will have tissue concentrations similar to other fish taxa living one year and feeding primarily on zooplankton. Mercury concentrations in juvenile threadfin shad and juvenile largemouth bass in delta are 0.012-0.076 and 0.035-0.230, respectively (Slotton et al., 2006). In comparison death in rainbow trout in laboratory studies occurred at 4-ppm wet weight and the NOAEC for death in Brook trout at 2.7 ppm (in Wiener and Spry, 1996). In conclusion, there exists about a 10X safety factor between fish tissue concentrations in the Delta and values reported to cause mortality in lab studies.

Regarding chronic toxicity, again, there are no toxicological studies with any of target species. Therefore, have compared reported tissue concentration for individual species against known laboratory effects in other taxa. Decreased feeding efficiency and some hormones response changes observed at 0.25-0.27 ppm wet weight (page 30 of (Alpers et. al., 2008). Decreases in growth occurred in fathead minnows at 0.6-0.7 ppm Hammerschmidt et al., 2002) and in juvenile walleye at 2.4 ppm (Friedmann et al., 1996). In conclusion, some up/down regulation of genes and alterations in feeding behavior are possible in the most contaminated individuals.

Certainty: 2 - Low
Scientists have a low certainty that the magnitude of this outcome is minimal (i.e. magnitude may be higher). The uncertainty is due to the limited amount of tissue data that is currently available for most target species (large safety factor regarding acute toxicity) which makes it impossible to determine the proportion of population potentially at risk. Additionally, only limited toxicological data is available for most of the important sub-lethal processes and none of this has been collected on species of interest.

N2b: Methyl mercury, non covered species

General Observations: The relationship between drivers and outcomes is described in the DRERIP Mercury Conceptual model (Alpers et. al., 2008, Table 2 and associated text).

Magnitude: 3 - Medium
Fifty-eight percent of Forster's terns in San Francisco Bay are at risk of reproductive impairment from consuming fish with elevated mercury levels (Ackerman *et al*., 2008). No Forster's Terns nest in the Delta. However, mercury levels in small fish consumed by terns are higher in parts of the Delta such as the Yolo Bypass than in San Francisco Bay suggesting that other bird species filling the Forster's tern niche in the Delta may be at risk. Mercury may result in a possible sustained, minor population effect on a large area.

In laboratory studies, mink have reproductive failure and die when fed fish diets of 0.5 and 1-ppm mercury, respectively (Dansereau *et al*., 1999). For comparison, mercury concentrations in 64% of largemouth bass, 23% of white catfish, and 35% of channel catfish caught in the Bay-Delta watershed have between 0.23 and 0.93 ppm mercury (Davis et al., 2006). Expected sustained minor population effect or effect on large area.

Additional studies on rails and other species are described in the evaluation worksheet for Cache Slough #HRCM 4, page 36.

Certainty: 2-3 Low-Medium
Scientific understanding of methylmercury effects on some bird and mammal species is high, based on peer-reviewed studies in the San Francisco Bay area and elsewhere. However, methylmercury effects on other bird, reptile, and mammal species are unknown. The nature of this outcome is greatly dependent on highly variable ecosystem processes.

N2c: Methyl mercury, human health

General Observations: See also results from water quality team.

Magnitude: 2 - Low
Fish consumption advisories for the Delta recommend that children under the age of 17 and women of child bearing age consume no largemouth bass or smallmouth bass, spotted bass or Sacramento pikeminnow, and others should limit their consumption of these species to one meal a month (OEHHA, 2006, 2008a,b). Between 10,000 and 20,000 fishermen in the Delta are presently eating fish with more than 10X the recommended methylmercury RfD and could experience some sublethal mercury poisoning (personal communication, Dr Fraser Shilling). Action could increase mercury content of sport fish.

The probability of increased methyl mercury production and export into the food web is the same as that described above for covered and non-covered species.

Certainty: 3 - Medium
Uncertain magnitude and direction of change in mercury content of sport fish, although levels are more likely to increase than decrease. For a given increase in mercury content of sport fish, risk to human health is quantified based on peer-reviewed studies (OEHHA, 2008a,b). Unknown how many anglers would access the project area and what fish they would catch and consume.

The role of restoration projects under this Conservation Measure in contributing to mercury levels in fish species consumed by humans needs to be explored in relation to other mercury sources for those fish species.

Outcome N3: Local effects of contaminants including toxicity from residual pesticides and herbicides: e.g. pyrethroids.

N3a: Covered fish species

General Observations: Possible presence of legacy pesticides from 1960s (e.g. DDT) is unknown. More recent (illicit) use of DDT is possible. Pyrethroids are 20x more toxic compared to some other pesticides (organochlorides). They persist in the sediment and degrade in one or two years (DPR, 2008). The relationship between drivers and outcomes is described by the DRERIP Pyrethroids conceptual model (Werner and Oram, 2008, Figure 1).

Magnitude: 1-2 – Minimal - Low
To the extent that pyrethroids or pyrethrins were used in the area to be flooded, significant toxicity could occur within 1-2 years of application. After ~2 years, near-total degradation should occur. DDT and metabolites could cause reduction of insect populations and bioaccumulation in target fish species (and some non-target bird species). Possible presence of legacy pesticides from 1960s (e.g. DDT) is unknown.

Certainty: 1 - Minimal
The toxicity of various pesticides is not completely understood. Although some peer-reviewed studies for selected life stages of certain fish exist, there is not much data for covered fish species. The nature of this outcome is highly dependent on highly variable ecosystem processes affecting the fate (degradation) and transport of pesticides.

N3b: Non covered wildlife species

General Observations: The relationship between drivers and outcomes is described in Werner and Oram, 2008, Figure 1.

Magnitude: 1-2 Minimal - Low
To the extent that pyrethroids or pyrethrins were used in the area to be flooded, significant toxicity could occur within 1-2 years of application. After ~2 years, near-total degradation should occur. DDT and metabolites could cause reduction of insect

populations and bioaccumulation in target fish species (and some non-target bird species).

Certainty: 1 - Minimal
The toxicity of various pesticides is not well understood. A limited number of peer-reviewed studies for certain life stages of selected fish species exist. However, there is not much data for covered fish species available (Werner et. al., 2008). The effect that tidal marsh restoration will have on the availability of residual pesticides is greatly dependent on highly variable ecosystem processes affecting the fate (degradation) and transport of pesticides. Additionally, legacy pesticides from 1960s (e.g. DDT) may be present on the restoration site and more recent (illicit) use is unknown.

Outcome N4: Resuspension and export of contaminants to downstream areas (A) mercury and methylmercury, (B) pesticides and herbicides (e.g. pyrethroids)

N4a: Covered fish species

Analysis of resuspension affects considers two separate physical settings: the restoration marsh sites and the adjacent tidal sloughs. The restored marsh sites are not likely experience much scour, since the adjacent tidal channels would be excavated as part of construction and the hard farm fields are not expected to scour easily. Adjacent tidal sloughs, which are typically comprised of more erodible substrate, may experience more scour both the bed and banks.

General Observations: The relationship between drivers and outcomes is described in Alpers et. al., 2008 (Figures 4, 7, and 8 and associated text) and Werner and Oram, 2008, Figure 1.

Magnitude: 1 - Minimal
The degree of scouring of pre-project soils depends on hydrodynamics. Scour could be a short-term phenomenon as channels reach geomorphic equilibrium. There is potential for increasing methylmercury concentrations in high-elevation marsh (infrequently wetted zone) and possible export of this to downstream environments.

Certainty: 2 - Low
Nature of this outcome is greatly dependent on highly variable ecosystem processes affecting fate (e.g.photodegradation of methylmercury) and transport.

Important Gaps in Information and/or Understanding

Data needed to more fully evaluate tidal marsh restoration actions

- Residence times (average and spatial variance in that value) are necessary to determine how much and what kind of food would be produced on site and exported from the site. Residence time projections also affect temperature and dissolved oxygen conditions and these are important attributes of physical habitat. Finally, residence times for particles of water could inform assessment of “residence” times for fish. There is a non-linear relationship between fish “residence time” and the benefit of the rearing habitat as, at high “residence times” new habitat may serve to delay important migratory activities whereas at very low residence times, the new habitat will have reduced benefit because fish (or at least those that behave like particles) will experience the habitat for only a short period.
- Additional data and analysis of water temperature at the confluence of the Cosumnes and the Delta and the Molkeumne and the Delta is needed to better evaluate Outcome P1a.
- Centrarchid models to understand predator-prey-habitat interactions.
- Striped bass model to understand predator-prey-habitat interactions.
- Expected retention time on restored tidal areas to understand likely productivity and food export potential to local sloughs.
- More spatially comprehensive hydrodynamics to understand whether changed flow patterns will reduce or simply redistribute predator pressure.
- Hydrologic and sediment information about turbidity levels, duration, and consequences on species as related to the following: Increased ability for felta smelt to locate food due to increased turbidity from increased velocities in larger channels.
- *Corbicula* monitoring data from previous restoration sites in the Delta, such as Liberty Island or Little Holland Tract, would provide greater information about the probability of colonization on this Cache Slough site.
- Better data on where and when Delta smelt lay their eggs would better allow assessment of the potential impact of inland silverside predation.
- Analysis of factors contributing the success or failure of other past tidal marsh restoration actions in the Delta.
- Liberty Island is often referred to as a model of a successful restoration project. Monitoring data and new bathymetric data from Liberty Island should be fully analyzed to determine the features that makes it successful and to consider how to apply those features to other restoration projects in the Delta. Specifically, the bathymetric data could be turned into a Digital Elevation Model (DEM) and combined with the habitat type mapping (i.e. vegetation and open water) to illustrate how the restoration provides habitat for covered and other species. This would include documenting the quality of existing LiDAR data for the vegetation mapping.

Research Needs

- Restoration techniques that will prevent colonization by invasive species.
- Management practices that can control invasive vegetation, clams, and predators (centrarchids and inland silversides) and limit colonization of these sites.

- Run (and life-history) specific studies of Central Valley Chinook salmon and studies of steelhead use of tidal marsh habitats would be extremely valuable to defining magnitude of impacts to these populations and increasing certainty. Various tools (including genetic markers and otolith signatures of population origin) could be used to asses both growth and survival of salmonids in these habitats as well as changes in life history characteristics (survival and fecundity) over the course of the life cycle that arise from residence in tidal marsh habitats. Currently, all of the evidence for benefits of tidal marsh on salmonids comes from steelhead and fall run populations well to the North (where high temperatures and invasive predators are not as problematic). Translating these results to all CV salmonid populations is unwarranted and could lead to disastrous "restoration" projects.
- Future research should generate simulations of generic “applications” of the DRERIP Conceptual Models. For example, the temperature model could be “applied” to generic landscape characteristics, such as a restoration site with specific shapes (bowl or gradation), to consider how temperature dynamics are affected on various spatial and temporal scales. This exercise would help managers understand where further detail is needed by taking the conceptual models to the next level by conducting simulations to apply the concepts to a landscape.
- Data on nutrient flow from the marsh plain to juvenile fish rearing in the adjacent channels is essential to determining the value of restored marshes as a food source for larvae of pelagic fish (like longfin and Delta smelt).
- Evaluate the effectiveness of water management strategies on managed wetlands to reduce the production of low dissolved oxygen events associated with managed wetlands operations and transfer what is learned into best management practices for the broader managed wetlands community in this region. In addition, it is likely the reduction of low DO events will result in conditions less favorable for MeHg production and thus reduce MeHg loading to the surrounding aquatic environment. This hypothesis needs testing.
- Greater understanding and more research is needed about the availability and production of food in tidal marshes. Export of organic material from the marsh plain and phytoplankton, zooplankton, and other organisms produced in intertidal channels into the Delta has not been studied.
- Potential negative effects of methylmercury exposure on covered fish species remain largely unknown. Based on published studies involving other (non-targeted) fish species, there is reason for concern regarding possible chronic effects caused by methylmercury exposure, including: endocrine disruption, reduced reproductive success, reduced predator avoidance, and reduced feeding efficiency. (See Mercury Conceptual Model, Alpers et al. 2008, Table 4, page 30). Research is especially needed to determine possible effects caused by exposure during early life stages.
- A better understanding is needed regarding the relationship of mercury methylation to the duration of wetting and drying events in areas that are intermittently inundated (i.e. tidal marsh and floodplain). Laboratory and field studies of mercury cycling involving sediments in tidal marsh and floodplain environments should quantify the duration of drying time and the extent of dryness necessary to change the oxidation-reduction character of iron, sulfur, carbon, and mercury in sediments such that microbial activity associated with mercury methylation is enhanced.
- Tropho-dynamic model of ecological interactions linking primary production to the food web structure and production flows into, through, and out of the tidal marsh system.

- Landscape-level models that address the effects of variation in structural features of the tidal marsh environment (e.g., tidal channel complexity, channel width, channel length, edge: area ratios, etc.) on the population or production dynamics of specific plants and animals.

Assess Reversibility and Opportunity for Learning

Reversibility

No/Hard. The following on-the-ground actions would be needed to reverse this action:

1) levees would need to be reconstructed
2) newly created tidal sloughs would have to be regarded
3) sites would have to be dewatered
4) wetland vegetation would have to be removed
5) newly installed levees would need to be removed as necessary
6) monitoring pre, during, and post construction

Although this reconstruction is technically possible, there would be significant financial and regulatory costs. Prior to action reversal, the following planning activities would be needed:

1. geotechnical evaluations for levee reconstruction
2. engineering design
3. evaluate land use options for areas subject to subsidence reversal actions
4. environmental permitting and associated agency ESA consultation
5. mitigation planning

Opportunity for Learning

High:

Implementation of this project can be designed such that different engineering designs can be compared. Numerous physical and biological components can be monitored and ideally, the monitoring data would be used to assess and refine modeling simulations of the restoration. Monitoring questions/data collection could address: marsh function, use of marsh by plant and animal species, abundance/influence of non-native species in restored areas, evolution of marsh habitat including patterns of change, and affect on MeHg levels. It is assumed that monitoring and learning would be part of a comprehensive adaptive management program.

See text in the Evaluation Worksheet for HRCM 4 –Cache Slough Tidal Marsh Restoration for details.

Appendices

Appendix A: Summary Tables Organized by Outcome

Table 3: Positive Outcomes

Outcome	Magnitude	Certainty
P1. Increase rearing habitat area (including physical and biotic attributes) for covered fish species.		
a. Delta smelt	1	1
b. Steelhead	1	2
c. Cosumnes and Mokelumne Chinook, fall run	1	2
d. Splittail	3	3
P2. Increase the availability and production of food in the east and central Delta by exporting organic material from the marsh plain and phytoplankton, zooplankton, and other organisms produced in intertidal channels into the Delta. • All covered fish species		
a. Viewpoint #1	3-4	3
b. Viewpoint #2	1-2	1
P3. **Locally provide areas of cool water refugia** (Feb-Jun) for Delta smelt.		
a. Delta smelt	2	1
b1. Chinook salmon spring run	2	1
b2. Chinook salmon fall run	2	1
b3. steelhead	2	1
OVERALL WORTH RATING		

Table 4. Negative Outcomes

Outcome	Magnitude	Certainty
N1. Establishment of undesirable species that may prey, compete, or alter habitat conditions for covered fish.		
a. SAV and Egeria	3	2
b. Non-native Centrarchids	4	2
c. Corbula	4	2
d. Inland silversides	2	2
N2. Local effects of contaminants: Potential for mercury methylation and local bioaccumulation to affect wildlife: N2-A - Target species, N2-B, Non-target wildlife species, N2-C, Human health.		
a. Covered fish species	1	2

b. Other species (not covered.)	3	2-3
c. Humans	2	3
N3. Local effects of contaminants, *including l*ocal toxicity from residual pesticides and herbicides: e.g. pyrethroids.		
a. Covered species	1-2	1
b. Other species (not covered.)	1-2	1
N4: Resuspension and export of contaminants to downstream areas (A) mercury and methylmercury, (B) pesticides and herbicides (e.g. pyrethroids)		
a. Covered species	1	2
OVERALL RISK RATING		

Appendix B - Outcomes with Zero Magnitude

OP2a: Locally provide areas of cool water refugia for winter-run salmon.

Magnitude = 0- Zero.
There will be no benefits of this restoration to winter-run salmon because this run passes through the region during a window of time when temperatures are not believed to be highly stressful to salmonids.

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

OP2b: Locally provide areas of cool water refugia for late fall-run salmon.

Magnitude = 0- Zero.
There will be no benefits of this restoration to late fall-run salmon because this run passes through the region during a window of time when temperatures are not believed to be highly stressful to salmonids

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

Appendix D: Description of McCormick Williamson Tract

McCormack-Williamson (Bean Ranch)
Owner: The Nature Conservancy

Acquisition Date: 1999 Property Acreage: 1,713.4
USGS Quad: Bruceville and Thorton

Property Description

The location and boundaries of this property are shown in Figure 7.8. This property is located west of I-5 and north of Staten Island. It has four linear miles of frontage along the Mokelumne River and is within the 100-year FEMA flood zone. This site is enrolled in a Williamson Act contract with the County. Soils are classified as Prime and Unique.

Land Cover Summary

As shown in Figure 7.9, land cover for the McCormack Williamson property is as follows:

Land Cover Type	*Acreage*
Agricultural Infrastructure	2.9
Crops - Annual or Truck & Berry	1,231.0
Developed	1.1
Grain and Hay Crop	264.2
Grasslands	130.8
Riparian Vegetation	56.5
Water	26.9

Conservation Targets

The McCormick Williamson Tract currently supports two conservation targets: riparian forest and salmon. The Mokelumne River passes through this site and allows salmon passage. An Environmental Impact Report prepared by the Department of Water Resources for the North Delta project will address future management of this site and anticipate restoration efforts within the 2008–2018 timeframe. Future management actions are anticipated to restore freshwater wetlands and riparian scrub habitat on this site. An existing small marsh supports a small stand of willow trees. Giant garter snake has not been documented although suitable habitat may exist for this species. The riparian scrub habitat on this property supports elderberry shrubs and exit holes of the valley elderberry longhorn beetle have been found in some of the elderberry shrubs. The levees ringing this island are being re-sloped in order to accommodate future flooding of the island and restoration to marsh habitat. Native species are being restored on the re-sloped levees.

Land Management Notes

- Routine maintenance of on-site water lines.
- Levee present on-site.
- Agriculture managed via lease to private farmer.
- Invasive plants, fig and locust present on site.
- TV tower lease.

Action:

Restore 3,900 acres of vegetated tidal marsh and 900 acres of shallow subtidal habitat in the West Delta ROA (see map presented in Figure 1 below).

Evaluation Team: Tidal Marsh Workgroup

Dave Harlow (chair); Stuart Siegel (coach); Dan Kratville; Jon Rosenfield; Chris Enright; Armin Munevar; Wim Kimmerer; Amy Richey; Charlie Alpers; Kateri Harrison (note taker).

Date of Last Revision: May 19, 2009

Note about this "Incomplete Working Draft": this document is not completed. The Tidal Restoration Evaluation Team had limited time for this evaluation. Much information has been replicated from the Cache evaluation and has not been revised throughout to reflect the specific restoration sites and geographies of this ROA.

Approach

1. Place fill material on shallowly subsided restoration sites to raise land surfaces to elevations suitable for restoration of intertidal marsh.
2. Plant tules, or other techniques, to raise ground surface elevations suitable for intertidal marsh restoration on shallowly subsided portions of islands and breach levees when target elevations are achieved.
3. Breach and set back levees to provide for tidal exchange with restored habitats. Levee breaches will be of sufficient length to not limit water motion into and out of restored habitat.
4. Excavate channels and/or create berms to encourage the development of dendritic channel networks within restored areas.

Intended Outcomes as Stated in Conservation Measure

1. Provide a continuous corridor of habitat and food productivity linking current and future restored habitat in the Cache Slough Complex with habitat in Suisun Marsh and Bay.
2. Provide intertidal marsh habitat within the anticipated future eastward position of the low salinity zone with sea level rise.
3. Increase rearing habitat area for Chinook salmon, Sacramento splittail, and possibly steelhead.
4. Improve future habitat areas for Delta smelt and longfin smelt within the anticipated eastward movement of the low salinity zone with sea level rise.
5. Increase the production of food for rearing salmonids, splittail, and other covered species.
6. Increase the availability and production of food in the western Delta and Suisun Bay by exporting organic material via tidal flow from the marsh plain and organic carbon,

phytoplankton, zooplankton, and other organisms produced in intertidal channels into the Delta.

7. Locally provide areas of cool water refugia for Delta smelt.

Conceptual Model Information Regarding Intended Outcomes

The basic drivers and outcomes are described in the following DRERIP conceptual models: Salmon, Delta smelt, Longfin smelt, Temperature, Foodweb, Tidal marsh, Corbicula, Sediment, and Mercury.

Assumptions

Provided in BDCP Conservation Measure

1. Restoration would occur on all suitable areas identified within the Restoration Opportunity Area (ROA).

Added by Evaluation Team

1. This West Delta restoration action is expected to occur within many sub-areas which the Evaluation Team has defined as follows: (1) Decker Island, (2) Sherman Island (north end), (3) Bradford Island (west side), (4) Twitchell Island – A (adjacent to Three Mile Slough), (5) Twitchell Island – B (adjacent to Seven Mile Slough), (6) Twitchell Island C (adjacent to Seven Mile Slough), (7) Brannan Island – A (north shore, across Sacramento River from Grand Island), (8) Brannan Island – B (west shoreline), (9) Brannan Island – C (between Three Mile Slough and Sacramento River), (10) West Bank of Sacramento River (across from Brannan Island and Decker Island), (11) Grand Island (southwestern tip). Restoring tidal marsh habitat on these different sub-areas will have varying levels of both positive and negative effects. For example, some of these sub-areas may be more efficient at the methylization of mercury and so may have a higher magnitude score for an associated negative outcome. Differences in hydrology, topography, soils, and land-use history will also manifest as distinctions in success of this action among sub-areas. General information about sub-area size and previous restoration activity is described in Appendix D. BDCP's estimated extent of restoration types based upon elevation for each sub-area is presented in Appendix E. Although the Evaluation Team presents a general analysis of the entire West Delta ROA in this worksheet, BDCP is encouraged to study the issues at a finer spatial resolution (i.e. the sub-area scale) due to the previously noted important differences among sub-areas.

2. The time frame for realizing restoration benefits depends upon the approaches used. Reversal of subsidence on restored areas can take several years to a decade or more depending on starting elevations. The accretion rate depends on sediment supply and biomass accretion which depends on site-specific conditions. Sediment supply in the Delta is generally very low with the West Delta area having slightly higher levels than much of the Delta but not as high as Cache Slough and North Delta (Schoellhamer et. al., 2007).

3. Efforts to reverse subsidence before active restoration would be focused on the more deeply subsided portions of these landscapes, i.e., lands more than 6 feet below low tide. There is a hypothesis that shallow open water regions located contiguous to emergent tidal marsh provide enhanced ecosystem complexity and functions compared to those tidal marsh habitats located directly adjacent to deeper sloughs.

Although this hypothesis has not been tested, preliminary information on current conditions at Liberty Island and Little Holland Tract suggest support. However, the details of these sites are not readily available to the broad research community at this time and so the information is anecdotal. This assumption also includes a time limit to allow for subsidence reversal so that restoration of an entire parcel is not delayed indefinitely. To speed up the subsidence reversal process, an alternative method would be to separate low-lying areas with new levees and reconnect those areas after subsidence reversal is accomplished.

4. Source of fill material will be identified and use of all material, including dredge spoils, will be approved by the RWQCB.

5. Water output from the site, post-restoration, will meet water quality standards.

6. Prior to implementation, a Phase I Environmental Assessment with on-site sampling to assess legacy and other soil contaminants (i.e. mercury and pesticides) would be completed.

Problem(s) with Action as Written:

1. Since rearing habitat for juvenile fish by necessity includes local availability of food, the evaluation team merged the Intended Outcomes 2 through 5 (tidal marsh, rearing habitat, and local food) into one outcome.

2. Loading of fill material on top of a shallow island may compress the underlying soils. This approach may not yield the intended result. A close study of existing soil conditions including analysis of the local soil map is needed to further evaluate this issue.

3. Intended Outcome #1 states "Provide a continuous corridor of habitat and food productivity linking current and future restored habitat in the Cache Slough Complex with habitat in Suisun Marsh and Bay". The choice to use the term "corridor" within this context is a misapplication of a principle from terrestrial conservation biology. The "corridor" concept is more applicable to terrestrial migratory species, where a corridor links separate habitat patches. But for the pelagic fish this concept does not apply as the West Delta is instead a reach of pelagic habitat rather a path between two patches. Pelagic fish may need to travel between low or high salinity zones. Connectivity of habitat can be improved or increased by removing engineered structures (i.e. rip rap) and restoring habitat edges along channels. Thus, Intended Outcome #1 should modified and simplified to something like "provide a continuous reach of tidal marsh and aquatic habitats and associated food productivity between current and future restored habitats in the Cache Slough Complex and Suisun Marsh and Bay."

4. The conservation measure would benefit from an explicit recognition that restoration of tidal marsh functions on subsided landscapes, especially those subsided below emergent vegetation elevations, will take many years to many decades. In the interim, restoration sites below vegetation elevations will function as shallow subtidal habitat.

5. It is unlikely that intertidal mudflats will develop in the Delta because dominant intertidal emergent vegetation species in the Delta can grow throughout the tidal range and just

into shallow sub tidal elevations (Brown 2003, Simenstad et al 2000 as cited in Schoellhamer et. al., 2007, p.26).

6. The action should state clearly in Approach #3 that significant set-back levees will be required to provide tidal flood protection to lands within the islands not restored to tidal action.

Scale of Action:

Medium

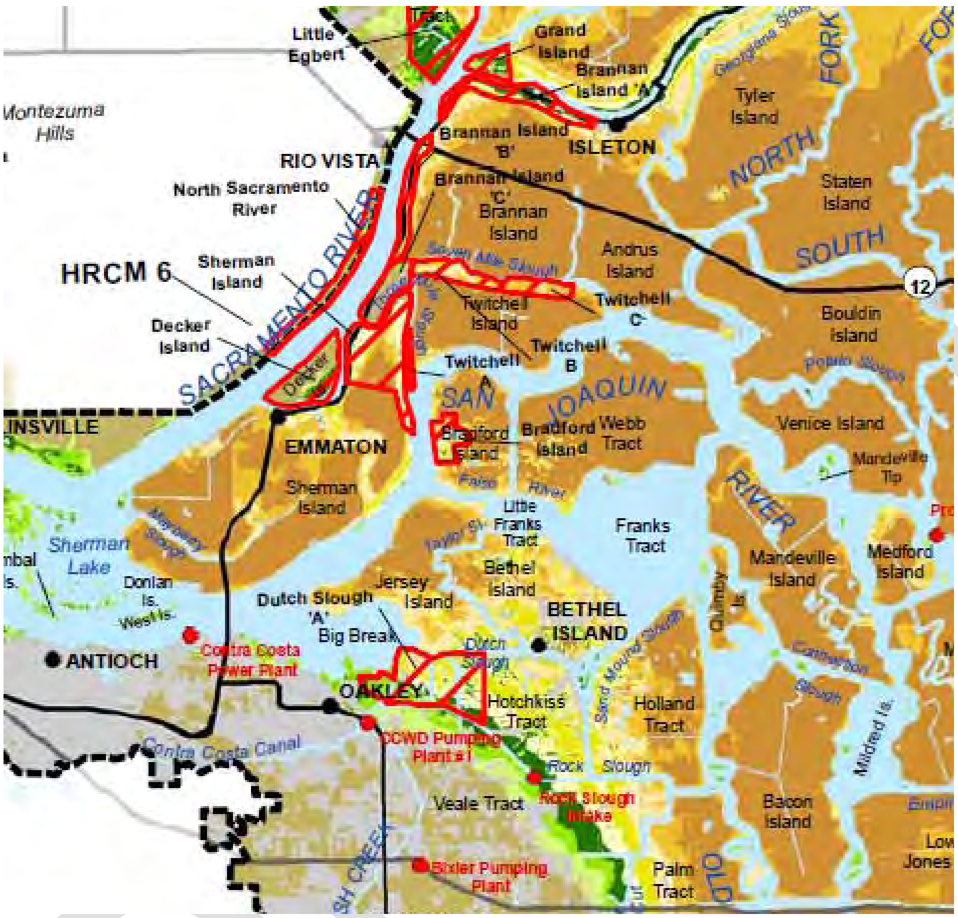
Rationale:

This is a medium scale restoration action due to its moderate spatial extent. As listed in Table1 below, the Delta currently has approximately 21,600 acres of tidal marsh habitat (baseline). Additionally 67,000 acres of diked and other lands have been identified as potentially restorable to tidal marsh (neglecting effects of restoration on reducing tidal range) (Delta Vision Strategic Plan, October 2008, Table 1, p.77). The action proposes restoring 3,900 acres of vegetated tidal marsh and 900 of shallow intertidal habitat. This represents an increase of 18% above the current tidal marsh acreage. Significant amounts of the 67,000 acres of identified restorable lands are highly constrained such that they could not be restored in the near term (South Delta and Netherlands alone account for 31,000 acres of the 67,000 acres). The West Delta restoration action relates to a regional scale.

Table 2. Summary of Tidal Marsh Acreages

Area	**Acreage**	**Source**
Delta (entire Delta proper)	738,000	DWR, 2009
Historic tidal marsh/wetlands in Delta	525,000	TBI, 2002
Current extent of tidal marsh/wetlands in Delta.	21,600	TBI, 2002
Restorable intertidal lands within Delta.	67,000	CA DVSP, 2008, Table 1, p.77.
Proposed West Delta tidal marsh restoration (this action)	4,800 acres total (includes 3,900 acres of vegetated tidal marsh and 900 acres of shallow intertidal habitat.)	BDCP, 2009

Figure 1. West Delta Restoration Opportunity Areas



Evaluation Summary

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

Other Positive Outcomes Identified, Not Separately Evaluated

Several outcomes were identified by BDCP early in the process. Other outcomes were identified by the Evaluation Team. The list below represents those outcomes that were identified, but not listed in the worksheet, because they were merged with another outcome for full evaluation.

OP1. Provide intertidal marsh habitat within the anticipated future eastward position of the low salinity zone with sea level rise.
This outcome was merged with Outcome P1 and fully evaluated in the worksheet below. The benefits of providing intertidal marsh habitat within the anticipated future eastward position of the low salinity zone is a matter of the geographic placement of restoration sites. The benefits will accrue to those species that utilize the restoration site as described in Outcome P1.

OP2. Improve future habitat areas for Delta smelt and longfin smelt within the anticipated eastward movement of the low salinity zone with sea level rise.
This outcome was merged with Outcome P1 and fully evaluated in the worksheet below. The benefits of providing intertidal marsh habitat within the anticipated future eastward position of the low salinity zone is a matter of the geographic placement of restoration sites. The benefits will accrue to those species that utilize the restoration site as described in Outcome P1.

Outcomes with Zero Magnitude

During the Evaluation process, several of the outcomes identified by BDCP early in the process, were found to have a zero magnitude. These outcomes are listed below and their evaluation is provided in Appendix B.

- OP3a: Increase rearing habitat (physical and biotic attributes) area – Steelhead.
- OP3b: Increase rearing habitat (physical and biotic attributes) area. - Winter-run Salmon
- OP3c: Increase rearing habitat (physical and biotic attributes) area. - Late Fall-run Salmon
- OP4. Provide a continuous corridor of habitat and food productivity linking current and future restored habitat in the Cache Slough Complex with habitat in Suisun Marsh and Bay – Salmonids.
- OP5a: Locally provide areas of cool water refugia for winter-run salmon.
- OP5b: Locally provide areas of cool water refugia for late fall-run salmon.

Other Potential Negative Outcomes Identified, Not Evaluated

During the course of this evaluation, the team identified one potential negative outcome that it did not evaluate due to lack of time. It is recommended that this potential outcome be evaluated at some point in the future when additional time is available.

- ON1. Pesticides for mosquito control.
- ON2: Increase in the availability of selenium

Relation to Existing Conditions:

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

No

Nature of Change:

This moderate scale action to restore 3,900 acres of tidal marsh and 900 acres of shallow subtidal habitat may change the environment on a regional scale but not to such an extent that our current understanding of boundary conditions (Harrell et al 2008), hydrodynamics, and ecological processes in the Delta would change.

Overview of Productivity Import-Export

See the Cache Slough evaluation (HRCM4) for complete discussion of productivity levels, import and export. Here we describe how conditions may differ from Cache Slough in order to provide the Conservation Measure evaluation appropriate specificity.

The primary difference with Cache Slough is that most of the eleven sites with the West Delta ROA are located along and directly connected to the margins of very high energy waterways – the lower Sacramento and San Joaquin rivers. Twitchell Island A and B and Dutch Slough area along lower energy waterways but not too far removed from the larger rivers. The result is that water in these restoration areas will exchange much more rapidly with the adjacent water bodies and that those adjacent water bodies will move marsh exports relatively great distances. Thus, the restored areas will have generally lower residence times than those of Cache Slough and exported productivity will reach farther afield.

Potential Positive Ecological Outcome(s)

Outcome P1: Increase rearing habitat (physical and biotic attributes) area for covered fish species.

As indicated at the beginning of this worksheet under the section entitled "Problems with Action", the team decided to merge two Intended Outcomes (rearing habitat and local food) into one outcome, P1, as shown below because rearing habitat for juvenile fish by necessity includes local availability of food. This outcome includes food (both primary and secondary production) produced within the vegetated marsh, within marsh channels, and within the subtidal areas adjacent to the vegetated marsh. General information that applies to salmon runs is provided in the worksheet for HRCM 4 – Cache Slough, Outcome P1c on page 15.

P1a. Spring Run Chinook Salmon

General Observations: Spring-run juveniles move through the Delta in the winter and spring (Williams and Rosenfield, In preparation, figure 3). The DRERIP Conceptual model (Williams and Rosenfield, In preparation, page15) indicates value of estuarine rearing varies across runs. The scoring below assumes that this restoration action only occurs when/if other tidal marsh projects in the Sacramento "corridor" are "restored" as well.

Magnitude = 2 - Low

The salmon model (Williams and Rosenfield, In preparation, page16), states that "Spring Chinook, or at least the Butte Creek population, pass quickly through the Delta, so habitat restoration there seems unlikely to do much for them. The same is probably true for late fall Chinook, and for steelhead". This particular outcome assumes that "rearing habitat area" (quantity) and/or food is limiting. Spring-run will consume the types of fish and zooplankton produced in this restoration (under the assumed condition). Although the information presented in the DRERIP salmon model seems focused on one spring run population (Butte Creek), many juveniles from other populations migrate at a smaller size than Butte Creek juveniles (Williams 2006). They migrate at about the same time as fall-run and thus may experience competition with fall run (Figure 3, in Williams and Rosenfield, In preparation – estuarine growth). So, this restoration may alleviate competition for a segment of the population. The model indicates moderate benefits of increasing rearing habitat.

Spring run may migrate past this restoration site from winter through spring. Average daily water temperatures in the vicinity of this restoration (as indicated by those at IEP monitoring station RSAC 101) regularly exceed 20-21 degrees C, beyond which sublethal effects accumulate (Marine and Cech 2004; Myrick and Cech 2004; Richter and Kolmes 2005) from May-September. With warming that may occur under climate change, these temperatures will occur in this area with some frequency during April and October as well. Thus, spring-run rearing in this proposed restoration site during May, June, and July will probably be impacted by high temperatures.

Benefits are limited to those emigrants rearing in this habitat in the early-mid spring, before temperatures in this region increase above optimal rearing threshold (12-16 degrees C, Marine and Cech 2004).

Upstream habitats are more likely to be important to the productivity of this run. Stressors in the Estuary may be related to competition with hatchery and wild production of fall run Chinook salmon (Williams and Rosenfield, In preparation).

Juvenile spring-run from two of important watersheds (Deer and Mill Creek) appear to migrate at a small size and these fish may benefit from rearing habitat restoration at lower elevations. Spring-run that migrate at small body size must compete with more abundant fall run Chinook salmon migrants. Thus, creation of suitable rearing habitat may alleviate an important bottleneck for this species. Given the moderate size of this restoration and the implicit assumption that it is implemented along with other, larger tidal marsh restorations, the marginal impact of this restoration is low.

Certainty = 1 - Minimal

There are no direct studies of spring-run Chinook salmon habitat use in this ecosystem. There is variability (inter-population and inter-annual) in the relationship between habitat volume-density-competition-and growth (Williams and Rosenfield, In preparation). Given the temperature limitations and differences in life history among spring-run populations, the Evaluation Team has low certainty that the magnitude of this impact from this action is low. Also, some of this restoration (e.g. Dutch slough) is proposed out of the most likely migration corridor for spring run, therefore the magnitude of this impact is less certain.

Establishment of *Corbicula*, could limit, if not eliminate the productivity benefits of the restoration to Chinook salmon. See Negative Outcome N1b. Similarly, colonization by invasive predators could result in added mortality that would counteract any benefits of restoration (especially if SAV invasion facilitates predation success).

P1b. Fall run Chinook salmon

General Observations: Fall-run juveniles move through the Delta in the winter and spring (Williams and Rosenfield, In preparation, figure 3). The salmonid model indicates value of estuarine rearing varies across runs: (page 15). The scoring presented below assumes that this restoration action only occurs when/if other tidal marsh projects in the Sacramento "corridor" are "restored" as well.

Magnitude = 2 - Low

Fall run Chinook salmon are the most abundant Chinook salmon in this Estuary. They are produced in hatcheries and they migrate at the same time as spring-run Chinook salmon. They also migrate during times when potential rearing habitats may be inaccessible due to high temperatures or reduced inundation of habitat. Thus, they are more likely to be exposed to competition for habitat than some other salmonid populations in this Estuary. This particular outcome assumes that "rearing habitat area" (quantity) and/or food is limiting. "Fall Chinook […] could benefit strongly from tidal marsh restoration" (Williams and Rosenfield, In preparation, page 16). Fall Chinook enter estuarine habitats at a small size and the model anticipates benefits from additional rearing/growth opportunities. Fall-run Chinook from the San Joaquin River basin may utilize some of the restored habitat (e.g. Dutch Slough). Most fall-run Chinook migrate as fry and these fish may benefit from restoration of rearing habitat at lower elevations. The creation of suitable rearing habitat may alleviate a bottleneck for this species. The magnitude of the impact will not be more than "low" because fall run Chinook face serious challenges in their upstream spawning and rearing habitat.

Fall-run salmon will consume the types of zooplankton produced in this restoration (under the assumed condition). Average daily water temperatures in the vicinity of this restoration (as indicated by those at IEP monitoring station RSAC 101) regularly exceed 20-21 degrees C, beyond which sublethal effects accumulate (Marine and Cech 2004; Myrick and Cech 2004; Richter and Kolmes 2005) from May-September. With warming that may occur under climate change, these temperatures will occur in this area with some frequency during April and October as well. Thus, fall run rearing in this proposed restoration site during May, June, and July will probably be impacted by high temperatures.

Fall run are impacted by severe stressors and limitation in their upstream spawning and rearing habitats (water temperatures, spawning gravel availability). Given these other stressors, the moderate size of this restoration, and the implicit assumption that it is implemented along with other, larger tidal marsh restorations, the marginal impact of this restoration is very likely to be low.

Certainty = 2-Low
Fall run Chinook use of fresh water tidal and sub-tidal environments is documented in other systems but is not well studied in this system – possibly because this kind of habitat is limiting in this system. The effect of global climate change on water temperatures in this area during the time period of fall run migration also decreases the window of time during each year when restoration will produce benefits.

Establishment of *Corbicula*, could limit, if not eliminate the productivity benefits of the restoration to Chinook salmon. See Negative Outcome N1b. Similarly, colonization by invasive predators could result in added mortality that would counteract any benefits of restoration (especially if SAV invasion facilitates predation success).

Outcome P2: Provide a continuous corridor of habitat and food productivity linking current and future restored habitat in the Cache Slough Complex with habitat in Suisun Marsh and Bay.

P2a. Splittail

General Observations: The relationship between the drivers and outcomes is described in Kratville, 2008 on pages P1h Pg 12, 13, 14, 15.

Magnitude = 3 - Medium
While more tidal marsh will help rearing of <u>juvenile</u> splittail, the expected benefit to the population as a whole (including all life stages) is medium. For Sacramento splittail, the limiting factor for population abundance is floodplain inundation that provides spawning

habitat. When large scale inundation occurs, splittail populations increase to high abundance numbers for several years following an event. Long periods without floodplain inundation reduce splittail population abundance. Splittail do not appear to be habitat limited at other life history stages.

Certainty = 3 - Medium
The uncertainty lies in whether these new rearing areas will increase the abundance of splittail populations. The West Delta ROA will increase opportunities to find sufficient rearing habitat for juveniles; however this does not appear to be a limiting factor in splittail abundance compared to floodplain inundation. The bulk of the adult splittail population resides in brackish areas of Suisun Marsh. If the western Delta becomes brackish to the extant that Suisun Marsh is today, this may change.

P2b. Green sturgeon

General Observations: The basic relationship between drivers and outcomes is described in Israel and Klimley, 2008, pages 1i, 4, 8, and 9.

Magnitude = 2 - Low
Information on juvenile sturgeon diets and physical habitat needs in the Delta is limited. Juvenile sturgeon of other species located in other systems do feed on drifting insects (Radtke 1967 and McCabe, G et al. 1993). This area of the Delta will not provide extensive intertidal-mud bottoms as found in lower portions of the estuary. Soft bottom benthos are a food resource for the sturgeon. Most habitat limitations for sturgeon appear to occur outside of the restoration area (i.e. upstream and downstream), as described on pages 4, 8, 9 in Israel and Klimley, 2008 and pages 19-21 of Israel et. al., 2009. It is unknown to what extent adult sturgeon used fresh water tidal marsh for foraging. The impact to individual sturgeon may be low but the extreme loss of fresh water tidal marsh in the Delta may have lowered the carrying capacity of the entire system for sturgeon. See pages 4, 8, 9 in Israel and Klimley, 2008 and pages 19-21 Israel et. al., 2009 for more detail.

Certainty = 1- Minimal
There is minimal certainty about whether this proposed restoration will benefit sturgeon as described in this outcome. The minimal certainty is due to the lack of research on this aspect of sturgeon biology/ecology in the Delta. Most of the available information on sturgeon diets and predator/prey relationships is based upon other species of sturgeon, located outside of this system.

P2c. White sturgeon

General Observations: The basic relationship linking drivers to outcomes is described in pages 1j, 19, 20, and 21 in (Israel et. al., 2009, the DRERIP White sturgeon model).

Magnitude = 2 - Low
Information on white sturgeon diets and physical habitat needs as juveniles in the Delta is limited. Other species of sturgeon in other systems do feed on drifting insects as juveniles. This area of the Delta will not provide extensive mud bottoms as found in lower portions of the estuary and so benthic food items are expected to be limited in this

restoration (Siegel, personal communication, Feb. 2009). Habitat limitations for white sturgeon appear to occur upstream and downstream of the restoration area (i.e. outside this ROA).

Certainty = 1 - Minimal
There is minimal certainty about whether this proposed restoration will benefit sturgeon as described in this outcome. The minimal certainty is due to the lack of research on this aspect of sturgeon biology/ecology in the Delta. Most of the available information on sturgeon diets and predator/prey relationships is based upon other species of sturgeon, located outside of this system.

Outcome P3: Food resources (i.e. organic material from the marsh plain and organic carbon, phytoplankton, zooplankton, and other organisms from intertidal channels) produced on the restored marsh will be exported, via tidal flow, and contribute to food availability downstream in the western Delta and Suisun Bay.

P3a. All covered fish species

General Observations: The Tidal Marsh and Foodweb models [Kneib et. al., 2008, page 9 and Durand, 2008, section 2.16)] provide a general indication that there may be a linkage between tidal marsh habitat as a driver and increases in availability and production of food resources as an outcome, but that the mechanism for this linkage may be movement by fish. The tidal marsh conceptual model also states that freshwater tidal marshes are net exporters of high-quality organic production (page 2 in Kneib et. al., 2008). See also Dame et al. 1986, Kimmerer and McKinnon 1989, Kneib 1997, Lucas et al. 2009. Please see the evaluation worksheet for action # HRCM4-Cache/Yolo for more details about **Tidal Marsh Contributions to Exported Production.**

There was disagreement within the evaluation team regarding the magnitude and certainty of expected benefits of tidal reintroductions with regard to the export of food (phytoplankton, zooplankton, insects, and small fish) to areas downstream of Rio Vista and the likely benefits to covered fish species. In the spirit of presenting the scientific discourse, both points of view are captured below.
Two key questions discussed were: (1) can we predict the sign of the flux of productivity (i.e. will the restoration area be a source or a sink for primary and secondary productivity); and (2) will there be adequate advection to move material out of the restoration area and downstream to Rio Vista (assuming the restoration area is a source of productivity, as opposed to a sink). Additional information and analyses is needed to better answer these key questions. To develop this additional information, the team recommends future development of a Tropho-dynamic model as described in the section on page 41 entitled "Research Needs".

Viewpoint #1

Please see the text of Outcome P3 in worksheet HRCM4 – Cache Slough for additional background information about Viewpoint #1.

Magnitude = 3-4 – Moderate to High
Without advective connection, restoration will still have significant productivity benefits to covered fish species and to many other species due to providing areas of highly functional habitat in conjunction with restoration elsewhere that collectively provide fish species a range of options that spread risk through exploiting available resources when they are present. Refer to Ted Sommers, IEP Estuarine Ecology Team or CAERS poster. In addition, these areas would export that productivity through the "trophic relay" concept described in the tidal marsh conceptual model (fish export the productivity).

Certainty = 3 – Moderate
Certainty is reduced by the potential for establishment of invasive clams that could consume substantial portions of phytoplankton and hinder zooplankton productivity.

Viewpoint #2

Please see the text of Outcome P3 in worksheet HRCM4 – Cache Slough for additional background information about Viewpoint #2.

Magnitude = 1-2 (Minimal to Low)
The implied relationship is that restored tidal marsh will export nonliving and living organic matter including plankton and fish, thereby supporting foodwebs of the upper estuary. An implicit assumption is that any increase in the area of shallow habitat would result in enhanced plant productivity some of which would be exported.

Certainty = 1 - Minimal
The sign of the signal is difficult to determine, except for total organic carbon, most of which is dissolved. Although dissolved organic carbon (DOC) will likely flow out of the marsh, fluxes of other components may be in or out (Kneib et. al., 2008, page 9). Colonization by invasive clam species can wipe out the food web production effect entirely. We have no certainty at all that they will not colonize. In addition, colonization of the site by vertebrate consumers (e.g, inland silverside) can also significantly reduce the amount of food available for export beyond the site boundaries (Moyle 2002). There is evidence from within this system (Dean et al. 2005) that restored marshes can act as sinks for certain zooplankters; in this case, the sign of the signal would be negative

Outcome P4: Provide local areas of cool water refugia for Delta smelt and salmonids.

The cause and effect relationship associated with this outcome is described in Stacey and Monismith 2008, Malamud-Roam 2000, and Enright 2008. Considering the landscape scale (medium) of the action, the relationship between tides, physiography, and water temperature could be moderate. The relationship between drivers (wind, insolation, fetch, tides, currents) and linkages (long-wave, short wave, latent, and sensible heat flux) is complex and may produce both warmer and cooler water on a variety of time and space scales. Larger spatial gradients of water temperature will likely occur. The frequency of threshold temperatures for various species is uncertain. See Stacey and Monismith (2008), Malamud-Roam (2000), Enright (2008).

For more details, please see the introductory text in the HRCM 4- Cache Slough action worksheet and the Suisun Marsh Tidal Marsh Restoration Worksheet, specifically, Outcome P4.

P4a. Delta smelt

Magnitude = 2- Low
The spatial extent of cool water refugia could be relatively limited. However, in some cases a large effect could be felt across relatively large area across the range. Please refer to the discussion located in HCRM4 – Cache Slough Restoration Action, Outcome P4, page 25 for more details.

Certainty = 1 - Minimal
The basis for our understanding is a single unpublished study in Suisun Marsh. The extent to which this effect may transfer to the restoration site, and to which Delta smelt and salmon will take advantage of it, cannot be predicted. Please refer to the discussion located in HCRM4 – Cache Slough Restoration Action, Outcome P4, page 26 for more details.

P4b. Salmonids

High temperatures are currently rare during May (as indicated by IEP gauges rsac075 and rsac054; Enright *pers. comm.*). Temperatures exceeding 20-21^{o}C (beyond which sublethal effects accumulate; Reese and Harvey 2002 *and see* Richter and Kolmes 2005) are more common and widespread in June, July, and August (as indicated by IEP gauges rsac075 and rsac054; Enright pers. comm.). With warming that may occur under climate change projections, high temperatures may become more frequent and extreme. Thus, Chinook salmon (spring-run and fall-run) and steelhead rearing in this proposed restoration site during June and July will probably be impacted by high temperatures. Forces that reduce those temperatures may improve survival, growth and smoltification success.

Benefits are limited to those emigrants rearing in this habitat after May, when temperatures in this region increase above optimal rearing threshold of 12-16^{o}C (Marine and Cech 2004). These benefits are expected to be transient (on annual and decadal time scales) and will never effect more than a small fraction of populations for any of the covered species (unless there is a cumulative impact from numerous restorations that produce the same cooling effect. Also, as mentioned in the description, this phenomenon is transient over time as the timing of tidal cycle shifts. Complexity of thermodynamics in conjunction with local geomorphology and long-term climate change and sea level rise introduce considerable uncertainty.

In addition to the runs listed below, please see Appendix B for winter-run etc.

P4b1: Spring run salmon

Magnitude = 2- Low.

This outcome modifies Outcome P1 (creation of habitat). In evaluating that outcome, benefits of this action were interpreted in the light of unfavorable temperature conditions that occur in the area during late-spring and Summer. To the extent that the tidal flooding/cooling phenomenon occurs on this restoration site (a function of geography and restoration design and site elevations) during the period of potential thermal stress (May through end of summer), it may provide some relief from the effects of thermal stress *for those salmon runs that migrate through this region at this time (fall and spring run and steelhead).* That benefit impacts only the proportion of the population that migrates at this time and only the proportion of the population that migrates through this area.

Certainty = 1-Minimal

Certainty is minimal for reasons similar to that described in P3a, above. This outcome is highly dependent upon highly variable ecosystem processes. Although scientists have a reasonable understanding at the general level, the range of data needed to evaluate at the action scale is lacking.

P4b2: Fall run salmon

Magnitude = 2- Low.
As noted above, the beneficial effect occurs for only a portion of the salmonid population passing through this region during a particular and narrow window of time.

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

P4b3: Steelhead

Magnitude = 2- Low.
Beneficial effect occurs for only a portion of the salmonid population passing through this region during a particular and narrow window of time.

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

Potential Negative Ecological Outcome(s)

Outcome N1: Establishment of harmful invasive species that will prey or compete or alter habitat conditions for covered fish.

Harmful invasive species have the potential to cause two types of adverse effects. First is to worsen conditions relative to the existing baseline; i.e., creating an attractive nuisance. Second is to detract from achieving the positive benefits the action could provide. The magnitude and certainty scores below are based upon an assessment relative to baseline conditions. The scores below for N1a to N1d do not represent the potential to distract detract from the positive benefits of the action because these deductions were considered by reducing the certainty scores for positive outcome # P1. Where appropriate, the impacts associated with the establishment of harmful invasive species on the restored marsh are discussed below.

N1a: Submerged Aquatic Vegetation (SAV) (including *Egeria*)

General Observations: As described in the conceptual model, the establishment of SAV is controlled by local flow conditions and substrates (Anderson, In Preparation). Many aspects of SAV physiology are influenced by local flow conditions including turbidity and to some extent flow velocity which if too high can scour suitable substrate precluding SAV establishment. The initial establishment of SAV is an intermediate outcome and the development of a large sustainable SAV population is the final outcome. The basic relationship between drivers and outcomes is described in the DRERIP aquatic vegetation conceptual model on pages 8, 9 10 and Figure 2 (Anderson, In preparation). Please note that establishment of SAV reduces the certainty that the positive outcome, P1 will occur. This has been noted in the scoring for P1.

Magnitude: 3 - Medium
The establishment of SAV in general is controlled by local flow conditions and substrates. Local flow conditions control many aspects of SAV physiology, most importantly in this location, turbidity. In nearby Liberty Island where turbidities are generally higher due to wind wave action SAV is restricted to shallow near shore areas (Ustin et al. 2008). If turbidities are high in the restoration area then SAV establishment and growth may be reduced to levels similar to Liberty Island. If not, there is the potential for SAV amounts similar to Franks Tract. The substrates in this area would be expected to support establishment of SAV (Anderson, In preparation). If the western Delta becomes brackish to the extant that Suisun Marsh is today, this may change. Small to moderate fractions of all the covered fish species may experience highly significant but localized effects due to SAV and therefore the net effect is medium.

For this outcome, the baseline condition is that much of the existing 21,600 acres of Delta tidal marsh is infested with submerged aquatic vegetation (Ustin, 2008). The restoration of a tidal marsh that eventually becomes infested with SAV is significant. Large, sustainable populations of SAV will produce significant changes in water quality (turbidity, pH, DO and temperature), or water flow characteristics (velocity and direction), which in turn can affect the quantity and quality of sediments (Anderson, In Preparation).

Eventually, the clarity of water entering the site from upstream will increase by lowering velocities and allowing particulates to settle out of the water column. This increased water clarity could increase predation of fish entering the site from outside areas (i.e. predators now have greater visual range). One type of predator, Centrarchid fish, is strongly associated with SAV and increased Centrachid populations may create a population sink for native fish at this location, as discussed in N1b, below. In summary, this action will worsen conditions beyond that of baseline conditions and small to moderate fractions of all the covered fish species may experience highly significant but localized effects due to SAV.

Certainty: 2- Low
There is high uncertainty about the initial colonization and ultimate patch distribution of SAV on the substrate. As the substrate softens over time, it may be more conducive to SAV establishment and growth (i.e. bed characteristics are described as a driver in the conceptual model). It is well documented that the physical structure of SAV facilities slower water velocities which allows sediment particles to settle, thereby reducing turbidity, locally and creating a positive feedback loop for more SAV establishment (Anderson, In Preparation). The effect of specific restoration site substrate, how those substrates may change over time after restoration, and the role of flow velocity at these locations is not well understood. The uncertainty of this outcome is largely dependent on how the final marsh system functions (Anderson 2007). If the western Delta becomes brackish to the extant that Suisun Marsh is today, this may change.

N1b: Non-native Centrarchids

General Observations: Centrarchid fish, as an assemblage, cover a range of ecological niches in the Delta. They are competitors for resources as well as predators on native fish. The magnitude of this effect is dependent on the assemblage of centrarchids that invade and the size of the populations. This is in turn partially dependent on the amount of SAV invasion into the restored system.

Please note that establishment of centrachids reduces the certainty that the positive outcome, P1 will occur. This has been noted in the scoring for P1. The relationship among drivers and outcomes is described by Brown and Minchniuk 2007, Grimaldo et al 2004, Nobriga and Feyrer 2007, and Nobriga et al 2005.

Magnitude: 4 - High
For this outcome, the baseline condition is that much of the existing 21,600 acres of tidal marsh are excellent habitat for Centrarchid fish where they are associated with adjacent deeper water. This is illustrated by the large number of Bass Tournaments that occur in the Delta. The Delta is a stop on the national professional bass fishing circuit with $100,000 prizes. This action could worsen conditions beyond that of baseline. Centrachids are a concern because they prey upon and compete for food and other resources with native covered fish.

The establishment of Centrarchids in conjunction with SAV is well documented in the Delta (Brown and Michniuk 2007; Grimaldo et al. 2004; Nobriga and Feyrer 2007; Nobriga et al. 2005). Centrarchid fish, as an assemblage, cover a range of ecological niches in the Delta. They are competitors for resources as well as predators on native fish. The magnitude of this effect is dependent on the assemblage of Centrarchids that invade and the size of the populations. This is in turn partially dependent on the amount of SAV invasion into suitable habitat areas of the restored system. The extent of their impact on the native ecology of the restored marsh is partially dependent on the extent of SAV establishment and patch size. Centrarchid fish will become established in this area as they have everywhere else in the Delta. If the western Delta becomes brackish to the extant that Suisun Marsh is today, this may change.

Certainty: 2 - Low
It is highly probable that Centrarchid fish will become established on this restoration site. However, once established, the ultimate size of the centrachid population and their impacts to local native fish are less certain. In areas with low SAV patch size the numbers of Centrarchid fish and their presumed impact on native fish are lower then where the opposite is true (Brown and Michniuk 2007). If the western Delta becomes brackish to the extant that Suisun Marsh is today, this may change.

N1c: *Corbicula*

General Observations: The relationship between drivers and outcomes is described in the DRERIP *Corbicula* Conceptual Model (Thompson et. al., In revision).

Consequences of *Corbicula* establishment. If established, *Corbicula* would likely have a significant effect on food web dynamics because it consumes phytoplankton in shallow areas and/or consumes the productivity of shallow areas exported to channels to such a high extent that it exhibits top-down trophic control. *Corbicula*'s consumption of primary productivity represents a significant limiting factor throughout the Delta that could greatly reduce productivity benefits of restoration efforts (Thompson et. al., In revision). According to the *Corbicula* model (Thompson et. al., In revision page 11), no local studies have been undertaken to indicate whether *Corbicula* feeding has reduced zooplankton populations either through competition or direct predation. In this case, the baseline condition is that much of the Delta is infested with *Corbicula*. The restoration of tidal marsh which may also become infested with *Corbicula* at some future time would not represent a significant change above baseline conditions. Establishment of *Corbicula* would however, consume much of the positive benefits that were previously discussed above under positive outcomes.

Potential Control Options. There are no stressors identified that can limit the success of Corbicula in a significant manner. However, salinity can limit the spatial distribution of this species and food limitation is a source of stress. (Thompson et. al., In revision, pages 8 and 13). The *Corbicula* conceptual model indicates that the only meaningful method to control their presence/abundance is salinity. This control method would require salinity intrusions into the restoration area of sufficient duration and at the appropriate times of year to have a meaningful effect. The conceptual model does not specify the duration and timing which might be most effective during recruitment. Water temperatures may influence the effectiveness of both recruitment and control measures.

Magnitude: 1- Minimal
Corbicula can control phytoplankton biomass development in shallow areas, or consume the productivity of shallow areas exported to channels. Corbicula is a significant limiting factor throughout Delta (Thompson et. al., In revision).

Certainty: 2 - Low
The timing and extent of colonization by *Corbicula* cannot be predicted for specific restoration sites due to lack of data.

Corbicula are prolific reproducers and colonizers of newly available habitats in salinities below 2 ppt. Source populations can come from elsewhere within the Delta or from upstream tributary populations. *Corbicula* can establish on soft and hard substrates and on vegetation and they can colonize intertidal zones as well as deeper water. (*Corbicula* model). Based upon the biology of the species and the physical setting of the restoration site, the probability of *Corbicula* establishment in the West Delta restoration areas appears to be high, but ultimately cannot be predicted, partially due high variability in environmental conditions. The low certainty score considers the probability and extent of potential establishment.

Corbicula monitoring data from previous restoration sites in the Delta, such as Liberty Island or Little Holland Tract, would provide greater information about the probability of colonization on these west Delta sites. More information would improve the certainty rating. However, such data and analysis was not made available to the evaluation team.

N1d: Inland Silversides

General Observations

Inland silversides (*Menidia beryllina*) are highly tolerant of warm water, salinity variability and are trophic generalists compared to Delta smelt (Moyle 2002). Inland silversides are the most numerous fish in Suisun Marsh shoreline habitats (Matern et al. 2002), and the most numerous fish in shallow Delta habitats (Nobriga et al. 2005, Brown and May 2006). The Delta smelt model (Nobriga and Herbold, page 3) includes intraguild competition with inland silversides as one of the top five in-Delta stressors to Delta smelt. Inland silversides are thought to be a major predator of Delta smelt eggs (Bennett and Moyle 1996 and Bennett 2005 in the Delta smelt Conceptual Model pg 12). In the laboratory, inland silversides reduce Delta smelt size relative to controls when they are reared together (Bennett 2005).

Inland silversides are also treated in the longfin smelt model. Moyle (2002, in Rosenfield, 2008) suggested that based on timing of arrival in the Estuary and subsequent longfin population response, inland silverside might have had a major impact on longfin population dynamics. However, the model states that inland silverside prefer shallow water habitats where juvenile and sub-adult longfin are rare, thus, their impact as predators of juvenile and sub-adult longfin is probably slight (Rosenfield, 2008, pg. 17). Spawning locations for longfin are unknown, so it is not known whether competition from inland silverside for spawning territory is a factor in their decline.

However, Delta smelt evolved with other intraguild competitors, including longfin smelt, and have survived with striped bass (introduced in 1879). Interaction between silversides and Delta smelt in the wild may be limited because Delta smelt typically inhabit offshore environments, while inland silversides typically inhabit shoreline habitats. Increased shoreline habitat would presumably increase the carrying capacity for inland silversides. However, predator-prey interaction between Delta smelt and inland silversides in the wild is speculative. Silversides may eat Delta smelt eggs or larvae if the eggs and larvae occur on the shorelines. It has not been shown that inland silversides reduce calanoid copepods (Norbriga and Herbold, 2008, page 32), so they may not effectively compete with Delta smelt for prey.

Williams and Rosenfield, In preparation; Israel and Klimley, 2008; Kratville**,** 2008); and Israel et. al., 2009 do not mention inland silversides so this evaluation assumes no adverse effects and focuses its evaluation on Delta smelt and longfin smelt.

Magnitude = 2 -Low
Inland silversides are the most abundant fish in shallow-water habitats in many areas of the Delta and may currently contribute to local depletions of zooplankton otherwise available to native fishes within these areas. Additionally, they may prey on embryos of species that lay eggs in these shallow areas (Moyle 2002). The crash of Delta smelt populations coincided with invasions of inland silversides into the estuary (Bennett and Moyle 1996). This action may change conditions relative to baseline by attracting (via restored marsh) a nuisance (inland silversides). This conservation measure will increase the local inland silverside population by providing additional shoreline breeding habitat. Because of the high existing abundance of inland silversides, the incremental increase in breeding habitat and thus population size above current conditions is considered small and the magnitude of this effect is considered to be low relative to baseline. Further, differential habitat selection (offshore environments for inland silverside) is expected to reduce the interspecific competition effects.

Certainty = 2 – Low
Understanding of interaction between inland silversides and Delta smelt in the wild is low, particularly in regards to egg predation by inland silversides. Better data on where and when Delta smelt lay their eggs would better allow us to assess the potential impact of inland silverside predation. Spatial interactions with longfin smelt are also uncertain.

Outcome N2: Potential for mercury methylation and local bioaccumulation to affect wildlife: N2-A – Covered fish species, N2-B, Non-covered wildlife species, N2-C, Human health.

N2a: Covered fish species

General Observations: methyl mercury: The relationship between drivers and outcomes is supported by (Alpers et. al., 2008, Table 2 and associated text). Although current methylmercury levels on Liberty Island (analogue for future state of areas to be restored) are relatively low (Slotton et al. 2002, (Alpers et. al., 2008, figure 5), there is potential for enhanced production of methylmercury in areas of high marsh that will be inundated infrequently (only during highest tides). The process of drying out between wetting events tends to oxidize species of sulfur, iron, carbon, and mercury, leading to higher potential to form methylmercury upon rewetting. Once formed, methylmercury biomagnifies in the aquatic food web, and ecological effects may occur in some sensitive species. Thus, the specific geomorphology of restoration sites and in particular the degree to which shallow depressions and poorly drained areas of high marsh are part of the restoration projects directly influences the degree of mercury methylization.

General Observations, other contaminants

Past land use determines risk of other contaminants: lead risk in areas with significant hunting, e.g., pheasant farms or duck clubs. Risk of residual pesticides (e.g., pyrethroids) in areas used for agriculture in past 2 years, which suggests that if these pesticides were used, allowing for a 2 year lag period between application and tidal restoration would be a prudent mitigation measure. Selenium contamination from the San Joaquin Valley and other sources is also a concern, however it was not evaluated in this worksheet.

Magnitude: 1 - Minimal

No toxicological studies have been conducted with any of the covered species regarding acute toxicity. Mercury concentrations in target fish are compared here against concentrations producing mortality in other fish species. Mercury concentrations in covered fish species are compared here against concentrations producing mortality in other fish species. Mercury concentrations in ppm-wet weight for white sturgeon, Chinook salmon and Steelhead collected during 2006 were 0.165-0.279, 0.094-0.396 and 0.06-0.13, respectively (Melwani et al. 2007). No tissue data for either longfin or Delta smelt was found. It is assumed that both species will have tissue concentrations similar to other fish taxa living one year and feeding primarily on zooplankton. Mercury concentrations in juvenile threadfin shad and juvenile largemouth bass in the Delta are 0.012-0.076 and 0.035-0.230, respectively (Slotton et al., 2006). In comparison death in rainbow trout in laboratory studies occurred at 4-ppm wet weight and the NOAEC for death in Brook trout at 2.7 ppm (in Wiener and Spry, 1996). In conclusion, there exists about a 10X safety factor between fish tissue concentrations in the Delta and values reported to cause mortality in lab studies.

Regarding chronic toxicity, again no toxicological studies with any of target species. Therefore, have compared reported tissue concentration for individual species against known laboratory effects in other taxa. Decreased feeding efficiency and some hormones response changes observed at 0.25-0.27 ppm wet weight (page 30 of (Alpers et. al., 2008). Decreases in growth occurred in fathead minnows at 0.6-0.7 ppm Hammerschmidt et al., 2002) and in juvenile walleye at 2.4 ppm (Friedmann et al., 1996). In conclusion, some up/down regulation of genes and alterations in feeding behavior are possible in the most contaminated individuals.

Certainty: 2 - Low

Scientists have a low certainty that the magnitude of this outcome is minimal (i.e. magnitude may be higher). The uncertainty is due to the limited amount of tissue data that is currently available for most target species (large safety factor regarding acute toxicity), which makes it impossible to determine the proportion of population potentially at risk. Additionally, only limited toxicological data is available for most of the important sub-lethal processes and none of this has been collected on species of interest.

N2b: Methyl mercury, non-covered species

General Observations: The relationship between drivers and outcomes is described in the DRERIP Mercury Conceptual model (Alpers et. al., 2008, Table 2 and associated text).

Magnitude: 3 - Medium
Fifty-eight percent of Forster's terns in San Francisco Bay are at risk of reproductive impairment from consuming fish with elevated mercury levels (Ackerman *et al*., 2008). No Forster's Terns nest in the Delta. However, mercury levels in small fish consumed by terns are higher in parts of the Delta such as the Yolo Bypass than in San Francisco Bay suggesting that other bird species filling the Forster's tern niche in the Delta may be at risk. Mercury contamination may result in a possible sustained, minor population effect on a large area.

In laboratory studies, mink have reproductive failure and die when fed fish diets of 0.5 and 1-ppm mercury, respectively (Dansereau *et al*., 1999). For comparison, mercury concentrations in 64% of largemouth bass, 23% of white catfish, and 35% of channel catfish caught in the Bay-Delta watershed have between 0.23 and 0.93 ppm mercury (Davis et al., 2006). Expected sustained minor population effect or effect on large area.

Additional studies on rails and other species are described in the evaluation worksheet for Cache Slough #HRCM 4, page 36.

Certainty: 2-3 Low-Medium
Scientific understanding of methylmercury effects on some bird and mammal species is high, based on peer-reviewed studies in the San Francisco Bay Area and elsewhere. However, methylmercury effects on other bird, reptile, and mammal species is unknown. The nature of this outcome is greatly dependent on highly variable ecosystem processes.

N2c: Methyl mercury, Human Health

General Observation: See also results from water quality team.

Magnitude: 2 - Low
Fish consumption advisories for the Delta recommend that children under the age of 17 and women of child bearing age consume no largemouth bass or smallmouth bass, spotted bass or Sacramento pikeminnow, and others should limit their consumption of these species to one meal a month (OEHHA, 2006, 2008a,b). Between 10,000 and 20,000 fishermen in the Delta are presently eating fish with more than 10X the recommended methylmercury and could experience some sublethal mercury poisoning (personal communication, Dr Fraser Shilling). Action could increase mercury content of sport fish.

The probability of increased methyl mercury production and export into the food web is the same as that described above for target and non-target species.

Certainty: 3 - Medium
Uncertain magnitude and direction of change in mercury content of sport fish, although levels are more likely to increase than decrease. For a given increase in mercury content of sport fish, risk to human health is quantified based on peer-reviewed studies (OEHHA, 2008a,b). The number of anglers that would access the project area and what fish they would consume is unknown.

The role of restoration projects under this Conservation Measure in contributing to mercury levels in fish species consumed by humans needs to be explored in relation to other mercury sources for those fish species.

Outcome N3: Local effects of contaminants including toxicity from residual pesticides and herbicides: e.g. pyrethroids.

N3a: Covered fish species

General Observation: The relationship between drivers and outcomes is described by the DRERIP Pyrethroids conceptual model (Werner and Oram, 2008, Figure 1).

Magnitude: 1-2 – Minimal - Low

To the extent that pyrethroids or pyrethrins were used in the area to be flooded, significant toxicity could occur within 1-2 years of application. After ~2 years, near-total degradation should occur. DDT and metabolites could cause reduction of insect populations and bioaccumulation in target fish species (and some non-target bird species). Possible presence of legacy pesticides from 1960s (e.g. DDT) is unknown.

Certainty: 1 - Minimal

The toxicity of various pesticides is not completely understood. Although some peer-reviewed studies for selected life stages of certain fish exist, there is not much data for covered fish species. The nature of this outcome is highly dependent on highly variable ecosystem processes affecting the fate (degradation) and transport of pesticides.

N3b: Non covered wildlife species

General Observation: The relationship between drivers and outcomes is described in Werner and Oram, 2008, Figure 1.

Magnitude: 1-2 Minimal - Low
To the extent that pyrethroids or pyrethrins were used in the area to be flooded, significant toxicity could occur within 1-2 years of application. After ~2 years, near-total degradation should occur. DDT and metabolites could cause reduction of insect populations and bioaccumulation in target fish species (and some non-target bird species).

Certainty: 1 - Minimal

The toxicity of various pesticides is not well understood. A limited number of peer-reviewed studies for certain life stages of selected fish species exist. However, there is not much data for covered fish species available (Werner et. al., 2008). The effect that tidal marsh restoration will have on the availability of residual pesticides is greatly dependent on highly variable ecosystem processes affecting the fate (degradation) and transport of pesticides. Additionally, legacy pesticides from 1960s (e.g. DDT) may be present on the restoration site and more recent (illicit) use is unknown.

Outcome N4: Resuspension and export of contaminants to downstream areas (A) mercury and methylmercury, (B) pesticides and herbicides (e.g. pyrethroids

N4a: Covered fish species

Analysis of resuspension affects considers two separate physical settings: the restoration marsh sites and the adjacent tidal sloughs. The restored marsh sites are not likely experience much scour, since the adjacent tidal channels would be excavated as part of construction and the hard farm fields are not expected to scour easily. Adjacent tidal sloughs, which are typically comprised of more erodible substrate, may experience more scour both the bed and banks.

General Observations: The relationship between drivers and outcomes is described in Alpers et. al., 2008 (Figures 4, 7, and 8 and associated text) and Werner and Oram, 2008, Figure 1.

Magnitude: 1 - Minimal

The degree of scouring of pre-project soils depends on hydrodynamics. Scour could be a short-term phenomenon as channels reach geomorphic equilibrium. There is potential for increasing methylmercury concentrations in high-elevation marsh (infrequently wetted zone) and possible export of this to downstream environments.

Certainty: 2 - Low

The nature of this outcome is greatly dependent on highly variable ecosystem processes affecting fate (e.g.photodegradation of methylmercury) and transport.

Outcome N5: Movement of fish and food resources to areas in central Delta with high predation.

N5. All covered Species

General Observations: Current water operations move fish into the central Delta (not just the pumps) and this indicates this West Delta ROA could become a population sink resulting in the movement of fish and food resources to areas with high predation. A logical train of thought links the DLO relationship here. This issue is beyond the scope of the current DRERIP conceptual models.

Magnitude = 2 to 3; Low - Medium

Salmon fry do enter the central Delta through the Delta Cross Channel and Georgiana Slough and salmon smolt survival in the Central Delta is lower than in the mainstem of the Sacramento River (Brandes and McLain 2001). Currently, juvenile Chinook salmon that enter the central Delta show lower survival rates than juveniles that stay in the main stem of the Sacramento River (Brandes and Mclain 2001). The exact reasons for this are unknown: however local conditions (e.g. changed hydrology, predatory fish) are the most likely causes. Vogel (ERP 2004) showed that predation rates on Chinook salmon in Georgiana Slough were 82.1% verses the lower Sacramento main stem at 25%. Increased temperature in the Central Delta where flows are low may also be a contributing factor in lowered survival of both salmon and Delta smelt during certain times of the year. How this will change under proposed operations is unclear. If predation remains the same or worse under post-restoration conditions, if altered hydrological conditions continue, and if covered fish are attracted to this area, than lower populations of covered fish may result (as opposed to the hoped for higher populations of covered fish).

Certainty = 1 - Minimal

Certainty is minimal because it is difficult to predict in advance future predation levels in this ROA, future hydrological conditions, and behavioral patterns of covered fish.

Important Gaps in Information and/or Understanding

Data needed to more fully evaluate tidal marsh restoration actions

- Residence times (average and spatial variance in that value) are necessary to determine how much and what kind of food would be produced on site and exported from the site. Residence time projections also affect temperature and dissolved oxygen conditions and these are important attributes of physical habitat. Finally, residence times for particles of water could inform assessment of "residence" times for fish. There is a non-linear relationship between fish "residence time" and the benefit of the rearing habitat as, at high "residence times" new habitat may serve to delay important migratory activities whereas at very low residence times, the new habitat will have reduced benefit because fish (or at least those that behave like particles) will experience the habitat for only a short period.
- Centrarchid models to understand predator-prey-habitat interactions.
- Striped bass model to understand predator-prey-habitat interactions.
- Expected retention time on restored tidal areas to understand likely productivity and food export potential to local sloughs.
- More spatially comprehensive hydrodynamics to understand whether changed flow patterns will reduce or simply redistribute predator pressure.
- Hydrologic and sediment information about turbidity levels, duration, and consequences on species as related to the following: Increased ability for Delta smelt to locate food due to increased turbidity from increased velocities in larger channels.
- *Corbicula* monitoring data from previous restoration sites in the Delta, such as Liberty Island or Little Holland Tract, would provide greater information about the probability of colonization on this site.
- Better data on where and when Delta smelt lay their eggs would better allow assessment of the potential impact of inland silverside predation.
- Analysis of factors contributing the success or failure of other past tidal marsh restoration actions in the Delta.
- Liberty Island is often referred to as a model of a successful restoration project. Monitoring data and new bathymetric data from Liberty Island should be fully analyzed to determine the features that makes it successful and to consider how to apply those features to other restoration projects in the Delta. Specifically, the bathymetric data could be turned into a Digital Elevation Model (DEM) and combined with the habitat type mapping (i.e. vegetation and open water) to illustrate how the restoration provides habitat for covered and other species. This would include documenting the quality of existing LiDAR data for the vegetation mapping.

Research Needs

- Restoration techniques that will prevent colonization by invasive species.
- Management practices that can control invasive vegetation, clams, and predators (centrarchids and inland silversides) and limit colonization of these sites.
- Run (and life-history) specific studies of Central Valley Chinook salmon and studies of steelhead use of tidal marsh habitats would be extremely valuable to defining magnitude of impacts to these populations and increasing certainty. Various tools (including genetic markers and otolith signatures of population origin) could be used to asses both growth and survival of salmonids in these habitats as well as changes in life history

characteristics (survival and fecundity) over the course of the life cycle that arise from residence in tidal marsh habitats. Currently, all of the evidence for benefits of tidal marsh on salmonids comes from steelhead and fall run populations well to the North (where high temperatures and invasive predators are not as problematic). Translating these results to all CV salmonid populations is unwarranted and could lead to disastrous "restoration" projects. In addition, data on nutrient flow from the marsh plain to juvenile fish rearing in the adjacent channels, is essential to determining the value of restored marshes as a food source for larvae of pelagic fish (like longfin and Delta smelt).

- Future research should generate simulations of generic "applications" of the DRERIP Conceptual Models. For example, the temperature model could be "applied" to generic landscape characteristics, such as a restoration site with specific shapes (bowl or gradation), to consider how temperature dynamics are affected on various spatial and temporal scales. This exercise would help managers understand where further detail is needed by taking the conceptual models to the next level by conducting simulations to apply the concepts to a landscape.
- Data on nutrient flow from the marsh plain to juvenile fish rearing in the adjacent channels, is essential to determining the value of restored marshes as a food source for pelagic fish larvae (i.e. longfin and Delta smelt).
- Evaluate the effectiveness of water management strategies on managed wetlands to reduce the production of low dissolved oxygen events associated with managed wetlands operations and transfer what is learned into best management practices for the broader managed wetlands community in this region. In addition, it is likely the reduction of low DO events will result in conditions less favorable for MeHg production and thus reduce MeHg loading to the surrounding aquatic environment. This hypothesis needs testing.
- Greater understanding and more research is needed about the availability and production of food in tidal marshes. Export of organic material from the marsh plain and phytoplankton, zooplankton, and other organisms produced in intertidal channels into the Delta has not been studied.
- Potential negative effects of methylmercury exposure on covered fish species remain largely unknown. Based on published studies involving other (non-targeted) fish species, there is reason for concern regarding possible chronic effects caused by methylmercury exposure, including: endocrine disruption, reduced reproductive success, reduced predator avoidance, and reduced feeding efficiency. (See Mercury Conceptual Model, Alpers et al. 2008, Table 4, page 30). Research is especially needed to determine possible effects caused by exposure during early life stages.
- A better understanding is needed regarding the relationship of mercury methylation to the duration of wetting and drying events in areas that are intermittently inundated (i.e. tidal marsh and floodplain). Laboratory and field studies of mercury cycling involving sediments in tidal marsh and floodplain environments should quantify the duration of drying time and the extent of dryness necessary to change the oxidation-reduction character of iron, sulfur, carbon, and mercury in sediments such that microbial activity associated with mercury methylation is enhanced.
- Tropho-dynamic model of ecological interactions linking primary production to the food web structure and production flows into, through, and out of the tidal marsh system.
- Landscape-level models that address the effects of variation in structural features of the tidal marsh environment (e.g., tidal channel complexity, channel width, channel length, edge: area ratios, etc.) on the population or production dynamics of specific plants and animals.

Assess Reversibility and Opportunity for Learning

Reversibility

No/Hard. The following on-the-ground actions would be needed to reverse this action:
1) levees would need to be reconstructed
2) newly created tidal sloughs would have to be regraded
3) sites would have to be dewatered
4) wetland vegetation would have to be removed
5) newly installed levees would need to be removed as necessary
6) monitoring pre, during, and post construction

Although this reconstruction is technically possible, there would be significant financial and regulatory costs. Prior to action reversal, the following planning activities would be needed:
1) geotechnical evaluations for levee reconstruction
2) engineering design
3) evaluate land use options for areas subject to subsidence reversal actions
4) environmental permitting and associated agency ESA consultation
5) Mitigation planning

Opportunity for Learning

High: Implementation of this project can be designed such that different engineering designs can be compared. Numerous physical and biological components can be monitored and ideally, the monitoring data would be used to assess and refine modeling simulations of the restoration as a part of a comprehensive adaptive management program.

See text in the Evaluation Worksheet for HRCM 4 –Cache Slough Tidal Marsh Restoration for details.

Appendices

Appendix A: Summary Tables Organized by Outcome

Table 3. Positive Outcomes

Outcome	Magnitude	Certainty
P1a. Increase rearing habitat (physical and biotic attributes) area – spring run	2	1
P1b. Increase rearing habitat (physical and biotic attributes) area. – Fall run salmon.	2	2
P2a: Provide a continuous corridor of habitat and food productivity… Splittail	3	3
P2b: Provide a continuous corridor of habitat and food productivity … Green Sturgeon.	2	1
P2c: Provide a continuous corridor of habitat and food productivity … White sturgeon.	2	1
P3: Increase the availability and production of food in the western Delta and Suisun Bay by exporting, via tidal flow, organic material from the marsh plain and organic carbon, phytoplankton, zooplankton, and other organisms from intertidal channels into the Delta.	Viewpoint 1: 3-4 Viewpoint 2: 1-2	Viewpoint 1: 1-2 Viewpoint 2: 1
P4a: Locally provide areas of cool water refugia for Delta smelt.	2	1
P4b1: Provide local cool water refugia for Spring-run (Feb-Jun).	2	1
P4b2: Provide local cool water refugia for fall-run (Feb-Jun).	2	1
P4b3: Provide local cool water refugia for steelhead.	2	1

Table 4. Negative Outcomes

Outcome	Magnitude	Certainty
N1a: Establishment of undesirable species …. Egeria and SAV	3	2
N1b: Establishment of undesirable species …….. Non-native Centrarchids.	4	2
N1c: Establishment of undesirable species …….. Corbicula	4	2
N1d: Establishment of harmful Inland silversides	2	2
N2a: Potential for mercury methylation and local bioaccumulation … Covered fish species.	1	2
N2b: Potential for mercury methylation and local bioaccumulation Other species (not covered).	3	2 to 3
N2c: Potential for mercury methylation and local bioaccumulation … Human health.	2	3
N3a: Local effects of contaminants including toxicity from residual pesticides and herbicides …. Covered fish species	1 to 2	1
N3b: Local effects of contaminants including toxicity from residual pesticides and herbicides … Other species (not covered).	1 to 2	1
N4a: Resuspension and export of contaminants to downstream areas … covered fish species.	1	2
N5: Movement of fish and food resources to areas in central Delta with high predation creating a population sink.	2 to 3	1

Appendix B - Outcomes With Zero Magnitude

OP3a: Increase rearing habitat (physical and biotic attributes) area – Steelhead.

General Observations:
Steelhead juveniles move through Delta from Jan-Jun, but mostly from late March-June. Salmonid model Fig 27. Steelhead Conceptual model figure. The salmonid model indicates value of estuarine rearing varies across populations: (p15).

Magnitude = 0 (zero).
Outcome assumes that "rearing habitat area" (quantity) and/or food is limiting. Model txt (p16)"Spring Chinook, or at least the Butte Creek population, pass quickly through the Delta, so habitat restoration there seems unlikely to do much for them. The same is probably true for late fall Chinook, and for steelhead." In other systems, steelhead use this kind of habitat but, the text notes, steelhead smolt in this system are large compared to other systems so research there is not likely to apply here.

Steelhead will eat the types of food produced in this habitat. Conceptual model (Estuarine – growth) shows a low impact of this kind of habitat on competition – competition may have a moderate impact on growth.

Steelhead migrate through this area "mainly in April and May" (Salmonid model P 34.) Average daily water temperatures in the vicinity of this restoration (as indicated by those at IEP monitoring station RSAC 101) regularly exceed 20-21oC (beyond which sublethal effects accumulate; Reese and Harvey 2002 *and see* Richter and Kolmes 2005) from May-September. With warming that may occur under climate change, these temperatures will occur in this area with some frequency during April and October as well. Thus, steelhead rearing in this proposed restoration site during May, June, and July will probably be impacted by high temperatures and negative impacts could become more common with global warming. Restoration will impact only steelhead from Sacramento Basin.

Certainty = 3 - Medium
No direct research on use of shallow estuarine habitat by steelhead in this system. Any effect will be limited to the Sacramento population and to those times of year when temperatures are not too high in the target area. This is relatively small restoration and presupposed the restoration of larger habitats nearby (as in the habitat "corridor" concept identified in the initial outcomes) – thus, it's marginal value as habitat for emigrating steelhead is likely nil. We can be moderately certain that this outcome will have a negligible or zero impact on the steelhead population as a whole.

In summary, steelhead in this system are not believed to be limited by availability of estuarine rearing habitat, except for the impact of high temperatures, which this restoration will do nothing to alleviate.

OP3b: Increase rearing habitat (physical and biotic attributes) area - Winter-run Salmon

General Observations:
Winter-run juveniles move through the Delta in the winter and early spring (figure 3). The salmonid model indicates value of estuarine rearing varies across runs: (p15). The scoring presented below assumes that this restoration action only occurs when/if other tidal marsh projects in the Sacramento "corridor" are "restored" as well.

Magnitude = 0.
Outcome assumes that "rearing habitat area" (quantity) and/or food is limiting. Model txt (p16)"Spring Chinook, or at least the Butte Creek population, pass quickly through the Delta, so habitat restoration there seems unlikely to do much for them. The same is probably true for late fall Chinook, and for steelhead. The case for winter Chinook seems equivocal.".
Winter-run will consume the types of zooplankton produced in this restoration (under the assumed condition). All winter-run migrate through this area when temperatures are cool enough to support rearing.

The DRERIP Conceptual model shows a moderate impact of this kind of habitat on competition – competition may have a moderate impact on growth – but both of these impacts are speculative. Food limitation is not considered a major limitation on survival in this part of the life cycle. Winter-run have the smallest population of any Chinook salmon run in this system. They have access to the same estuarine habitats as the other runs. Thus, competition and growth limitation due to habitat limitation in the Estuary is least likely for this run among all the Central Valley Chinook populations. In addition, this run rears upstream and probably enters the Estuary at a size where rearing in the Estuary is less important (p. 12, Figure 9).
Finally, the figure depicting relative impact of stressors across habitats indicates that upstream impacts are more likely to be important and that stressors in the Estuary are related to stressors other than limitation of habitat. Given the limited size of this restoration and the implicit assumption that it is implemented along with other, larger tidal marsh restorations, the marginal impact of this restoration is probably neglible or zero.

Certainty = 3 - Medium
Winter run represent a unique life history strategy for the species as a whole. No direct studies of this run's habitat use in estuarine habitats has been published meaning that their use and benefit from tidal marsh habitats is uncertain. However, unless access to additional spawning/rearing habitats (with adequate cold water and spawning gravel) is created upstream, rearing habitats in the Delta will be of little value to this species. Given this CM's small size and assumed (by the Proponents) positioning among other CM habitats and the lack of evidence of food limitation in this part of the life cycle, we are moderately certain that the magnitude of the outcome for this run will be negligible.

In summary, the most important actions necessary to conserve and restore winter run lie outside of the Delta. The small scale of this restoration combined with the lack of evidence that this run is limited by habitat in the estuary mean it is not likely to have a measureable impact on the short, medium, or long-term prospects for this species.

OP3c: Increase rearing habitat (physical and biotic attributes) area. - Late Fall-run Salmon

General Observations:
Late-fall-run juveniles move through the Delta in the fall and winter (figure 3). The salmonid model indicates value of estuarine rearing varies across runs: (p15). The scores presented below assumes that this restoration action only occurs when/if other tidal marsh projects in the Sacramento “corridor” are “restored” as well.

Magnitude = –0.
Outcome assumes that “rearing habitat area” (quantity) and/or food is limiting. Model txt (p16)”Spring Chinook, or at least the Butte Creek population, pass quickly through the Delta, so habitat restoration there seems unlikely to do much for them. The same is probably true for late fall Chinook, and for steelhead”.

Late fall-run will consume the types of zooplankton produced in this restoration (under the assumed condition). Most late-fall run migrate through this area when temperatures are cool enough to support rearing. {See Salmon Model Williams and Rosenfield version dated November 2008 Figure 2d entitled “Sacramento Late-fall run life history – Late Fall Run located on page 108 of the pdf file. See also graph called “Late-fall run growth and emigration rate -- estuarine habitats” on page 115 of pdf file. Graph formerly called (General Model figure 3) of Rosenfield 2007.}

Conceptual model indicates that estuarine growth shows a low impact of this kind of habitat on competition and of competition on growth. This is because the late fall run migrates at larger size than many other runs, its migration coincides with winter run (See Salmon model graphs described above), and temperatures and flows during this period increase accessibility to potential rearing habitat meaning these fish do not need to compete (e.g. with the much more populous fall run) for rearing habitat in the estuary.

The figure depicting relative impact of stressors across habitats indicates that upstream impacts (e.g. access to spawning habitats) are more likely to be important and that stressors in the Estuary are uncertain.

Certainty = 3 - Medium
The importance of growth in estuarine environments is unstudied for this run but is likely to be small. Conceptual model indicates low certainty of impact. Given the limited size of this restoration and the implicit assumption that it is implemented along with other, larger tidal marsh restorations, the marginal impact of this restoration is probably negligible or zero.

In summary, the most important actions necessary to conserve and restore late-fall run lie outside of the Delta. The small scale of this restoration combined with the lack of evidence that this run is limited by habitat in the estuary mean it is not likely to have a measurable impact on the short, medium, or long-term prospects for this population.

Salmonids migrate through the Sacramento River corridor on their way to and from marine environments (Salmonid conceptual model).

OP4. Provide a continuous corridor of habitat and food productivity linking current and future restored habitat in the Cache Slough Complex with habitat in Suisun Marsh and Bay. - Salmonids

Salmonids migrate through the Sacramento River corridor on their way to and from marine environments (Salmonid conceptual model).

There is no mention of (or a conceptual model to support) the benefit of a "corridor" or rearing habitat. Rearing habitat has benefit but the benefits of providing a "continuous corridor" of productive rearing habitat are unsupported in the conceptual model or the literature. The concept of a corridor (which implies habitat beneficial for the movement of organisms between valuable habitats) is misapplied here because the idea is to provide "rearing habitat" not to facilitate movement between habitats. Therefore, this proposed outcome cannot be vetted for salmonids– the anticipated magnitude of the "corridor" or rearing habitat is zero.

Emigrating salmon are trying to achieve two goals – growth and migration. Growth is valuable only up to a certain point, then migration rate is of paramount importance because salmon reach a size where they will have more productive growth in the ocean than in freshwater. A conceptual model of growth: migration trade-offs of this type is supported by evidence on growth of salmon in this estuary (Macfarlane and Norton 2002 – which found a relatively consistent size of salmon smolt entering the ocean over the time period of sampling) and other sources on growth-migration tradeoffs in salmon LH (e.g. Williams 2006 and Quinn 2005). Under this conceptual model, salmon would be expected to grow as rapidly as possible until a size or time threshold (whichever came first) prompted them to migrate. Salmon do not require continuous rearing habitat throughout the migration process – indeed, presence of this habitat may impede migration rates. It is only beneficial to find a rearing habitat, rear in it until the time or growth threshold is reached, and then migrate as rapidly as possible to the more productive marine environment.

In summary, even if the continuity of rearing habitats provides benefits, such continuity would be at the margin of priority (compared to the potential value of the habitat itself and other needs of these species). No future studies or research is recommended for this issue.

OP5a: Locally provide areas of cool water refugia for winter-run salmon.

Magnitude = 0- Zero.
There will be no benefits of this restoration to winter-run salmon because this run passes through the region during a window of time when temperatures are not believed to be highly stressful to salmonids.

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

OP5b: Locally provide areas of cool water refugia for late fall-run salmon.

Magnitude = 0- Zero.
There will be no benefits of this restoration to late fall-run salmon because this run passes through the region during a window of time when temperatures are not believed to be highly stressful to salmonids

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

Appendix C - General Information about the West Delta Sub-Areas

Sub-Area Name	***Total size of Island***	***Location and Existing Conditions***	***Previous Restoration Nearby***
1. Decker Island	470 acres	Island is surrounded by the Sacramento River to the northwest and Horseshoe Bend, a former meander of the Sacramento River, to the east, south, and west. Decker Island is the only high-elevation island in the Delta, as it was built by sediment dredged to straighten the Sacramento River at this location.	Yes. For more details see: http://www.water.ca.gov/floodmgmt/dsmo/ecb/maep/deckerisland/ Has exhibited some of the most undesirable restoration outcomes – large channels with minimal tidal floodplain area resulting in very low velocities which support thick SAV beds and their associated problems.
2) Sherman Island (north end)	1,000 + acres. DWR has plans to acquire most of the property on this island.	Northern end of Sherman Island, bordered by Horseshoe Bend on the west, Three Mile Slough on the north and east, and remainder of Sherman Island to the south. The northern extent of Sherman Island is subsided in the interior portions away from the levees by up to roughly 20 feet, with the levee interior slopes being much higher and more gradually sloping down to the deep interior than at many Delta islands.	Yes. (1) DFG owns the tidal western 3,115 acres at the confluence of the Sacramento and San Joaquin Rivers that breached in the 1920s. (2) DWR funded 4,500 feet of levee setback via RD 341 and restored intertidal channel margin and wetland, Mason's lilaeopsis, and augment existing riparian vegetation. For more details see: http://www.water.ca.gov/floodmgmt/dsmo/ecb/maep/shermanisland.cfm. See also: http://www.water.ca.gov/floodmgmt/dsmo/ecb/maep/mayberry.cfm
3) Bradford Island (west side		Bradford Island lies about 10 miles east of the confluence of the Sacramento and San Joaquin rivers. Bradford Island has 7.4 miles of levees. Located South of Twitchell Island. Fisherman's Cut splits Bradford Island from Webb Tract.	Tract 19 was previously restored by reclamation district as riparian floodplain on subsided lands behind a levee. For more details see: http://www.water.ca.gov/floodmgmt/dsmo/ecb/maep/bradfordisland.cfm and see:

		The restoration site has a mix of higher and lower elevation lands down to about -20 ft and includes what appears to be older mineral deposits from riverine conditions extending in fingers quite a distance to the east onto Webb Tract.	http://www.stillwatersci.com/case_studies.php?cid=44 Aerial Photo at: http://www.water.ca.gov/floodmgmt/dsmo/ecb/maep/bradford.cfm and at: http://www.sacbee.com/1276/gallery/1462198.html?mi_rss=Delta%20Galleries Photos available at: http://www.water.ca.gov/floodmgmt/dsmo/docs/Apx_F-1_Bradford_photo_log.pdf
4, 5, and 6) Twitchell Island	300-400 acres of the island; about 85% owned by DWR.	Located on the San Joaquin River just east of Sherman Island. Three Mile Slough borders to west. Seven Mile Slough border north and east. ROA focuses on the least subsided bench along the levee interior, where elevations are in the medium subtidal to lower intertidal range.	Yes. . For more details see: http://www.water.ca.gov/floodmgmt/dsmo/ecb/maep/twitchellisland.cfm See also: http://www.geiconsultants.com/content505.html See Aerial Photo at: http://www.water.ca.gov/floodmgmt/dsmo/ecb/maep/twitchell.cfm
7, 8, and 9) Brannan Island – A (north shore, across Sacramento River from Grand Island) and Brannan Island – B (west shoreline), Brannan Island – C (between Three Mile Slough and		Located on the southern bank of Sacramento River where it meets Cache Slough and extends south to Three Mile Slough. As above, ROA focuses in strip of levee interior bench that is less subsided than levee interior. Brannan C is the Brannan Island State Recreation Area with campgrounds and boat	? Part of Island is a state recreation area. For more details see: http://www.parks.ca.gov/?page_id=487

Sacramento River.		launch ramp, not a likely restoration candidate.	
10) West Bank of Sacramento River (across from Brannan Island and Decker Island	~200 acres	South of Rio Vista and extending southwest across almost from the western confluence of Sacramento River and Horseshoe Bend. Lands are diked historic margins of the lower Sacramento River. Long, narrow strips of landscape. Elevation data not readily available.	
11) Grand Island (southwestern tip	~150 acres	Located at the confluence of Steamboat Slough and Sacramento River near Rio Vista. Lands appear to be out of agricultural production and coarse elevation on ROA map (Figure 1) indicates in or near to intertidal elevation ranges. Grand Island Road forms natural eastern boundary and location for setback levee (road may already be raised).	
12) Dutch Slough	1,100 acres	Along southern bank of Dutch Slough between Big Break to the West and Jersey Island Road to the east, in Oakley. Site topography ranges from upland, intertidal, shallow subtidal, and some medium subtidal.	The Dutch Slough Tidal Wetland Restoration Project has been in the planning phase for several years. CALFED funds purchased the property in the early 2000s. Draft EIR for restoration project released December 2008. Planned to be an adaptive management restoration experimental site, applying designs to test selected restoration approaches of value for other Delta restoration efforts. May go to construction in 2010.

Excerpt from BDCP Steering Committee Meeting October 31, 2008. Handout #3: Third Draft Habitat Restoration Conservation Measures

Bay Delta Conservation Plan
Steering Committee Meeting
October 31, 2008

Handout #3

Third Draft
Habitat Restoration Conservation Measures

Note to Steering Committee: *This handout presents the third draft of habitat restoration conservation measures. A summary list of proposed habitat restoration conservation measures is presented in Table 1. This draft includes revisions proposed by SAIC—no comments were received from the Steering Committee to the second draft habitat restoration conservation measures presented to the Steering Committee on October 17, 2008. All new text added to this draft from the second draft is displayed in underlined red text; text in black is the same as delivered in the second draft. These draft conservation measures will be discussed at the October 31, 2008 Steering Committee meeting.*

Table 1. List of Proposed Habitat Restoration Conservation Measures

Conservation Measure FIMA1.3: Restore a mosaic of __ to __ acres of intertidal marsh and shallow subtidal aquatic habitat within the West Delta Restoration Opportunity Area. Restored freshwater intertidal marsh and shallow subtidal aquatic habitats would be designed to support the physical and biological attributes described in Attachment A. The mosaic of habitats would include at least __ acres of freshwater intertidal marsh habitat. Areas suitable for restoration include Decker Island, portions of Sherman Island, Jersey Island, Bradford Island, Twitchell Island, and Brannon Island, and along portions of the north bank of the Sacramento River where elevations and substrates are suitable. The purpose of restoring intertidal marsh in the west Delta is to provide a continuous corridor of habitat and food productivity linking current and future restored habitat in the Cache Slough Complex with habitat in Suisun Marsh and Bay and to provide intertidal marsh habitat within the anticipated future eastward position of the low salinity zone with sea level rise.

Design elements of this conservation measure are anticipated to include:

- placing fill material on shallowly subsided restoration sites to raise land surfaces to elevations suitable for restoration of intertidal marsh[3];
- planting tules, or other techniques, to raise ground surface elevations suitable for intertidal marsh restoration on shallowly subsided portions of islands and breaching levees when target elevations are achieved;
- breaching and setting back levees to provide for tidal exchange with restored habitats; and
- excavating channels and/or creating berms to encourage the development of dendritic channel networks within restored marshes.

Rationale: Restoring freshwater intertidal marsh and shallow subtidal aquatic habitats is expected to reduce the adverse effects of stressors related to food and habitat availability for the covered species by:

- increasing rearing habitat area for Chinook salmon, Sacramento splittail, and possibly steelhead (Healey 2001, Brown 2003);
- improving future habitat areas for delta smelt and longfin smelt within the anticipated eastward movement of the low salinity zone with sea level rise;
- increasing the production of food for rearing salmonids, splittail, and other covered species (Kjelson et al. 1982; Siegel 2007);
- increasing the availability and production of food in the western Delta and Suisun Bay by exporting organic material via tidal flow from the marsh plain and organic carbon, phytoplankton, zooplankton, and other organisms produced in intertidal channels into the Delta (Siegel 2007);
- locally providing areas of cool water refugia for delta smelt (C. Enright pers. comm.);
- increasing the extent of habitat available for colonization by Mason's lilaeopsis; and
- increasing the extent of habitat for California black rail and tricolored blackbird.

Lands within the West Delta ROA (see Figure 1) represent the only location to implement intertidal marsh restorations within the anticipated future location of the low salinity zone with sea level rise. A substantial proportion of the suitable restoration sites in this area are in public ownership.

Recommended Implementation Timeframe: This conservation measure could be initiated in the BDCP near-term implementation period and continue to be implemented over the term of the BDCP as restoration opportunities are identified.

---

[3] Sources of fill material could include dredge material from ongoing dredging operations and dredge spoils and sand deposits on Decker Island, Brannon Island, and other nearby suitable sites.

Implementation Considerations: Implementation considerations include:

- the availability of suitable fill material and feasibility for subsidence reversal;
- consideration for the effects of restoration-induced dampening of the tidal range on subsequent marsh restoration designs and local tidal hydrodynamics;
- the need to design levees and provide elevations suitable to accommodate future sea level rise;
- locating and designing levee breaches to maximize the development of intertidal marsh and minimize hydrodynamic conditions that favor non-native predatory fish;
- coordination with Delta levee programs to ensure that restored habitats are protected from adverse effects that could be associated with future levee failures;
- determining the appropriate allowable land uses and management activities on transitional grasslands conserved to accommodate future sea level rise;
- the need to incorporate design features and management strategies to preclude or minimize the establishment and abundance of undesirable non-native species;
- potential for increasing mercury methylation and resuspension of contaminants;
- the need to incorporate design features that will promote the natural establishment of marsh-associated covered plant species; and
- the likelihood for removal of food produced from restored intertidal marshes by non-native clams.

Resiliency to future changes: The resiliency of this conservation measure to accommodate future sea level rise is limited because of the extent of subsidence in the west Delta. It is expected, however, that, to the extent practicable, restoration designs would incorporate elements that would provide land surface elevations sufficient to accommodate the upslope establishment of marsh over time as sea level rises.

Uncertainties/risks: Restoration of subtidal aquatic habitats could result in establishment of *Egeria* and other non-native plants that reduce the ecological benefits for restored subtidal aquatic habitats to covered species. The abundance of non-native predators and competitor abundance could increase and the ability to control these species is uncertain. Methylation of mercury may occur in intertidal zones, making methylmercury bioavailable to plants, fish, and wildlife in and downstream of restored marshes (Alpers et al. 2006). Large scale levee failures, in the central Delta could reduce species and ecosystem benefits associated with restored marshes in the west Delta depending on the effects of changed hydrodynamic conditions on tidal range and salinity gradients in the west Delta. There could be a short-term risk associated with mobilizing pesticides, herbicides, and other contaminants into the Delta following initial introduction of tidal flow onto agricultural lands.

Monitoring and adaptive management considerations: *[Note to reviewers: this section is a general summary; more detail will be provided in future iterations.]* Opportunities for adaptive management are related to assessing the effectiveness of restored marshes to develop as functional covered species habitats and to produce food and organic carbon in support of food web processes. Results of monitoring the development of early marsh restoration projects would help inform improvements in the design and management of subsequent marsh restorations. Results of monitoring early restorations could also be used to develop cost effective management techniques, if needed, to control the establishment of non-native species in restored marshes. Some of the monitoring considerations include:

- type and extent of use by covered fishes;
- extent of phytoplankton, zooplankton, and macroinvertebrate production in marsh channels;
- load of phytoplankton, zooplankton, and macroinvertebrates exported into the Delta and Suisun Bay;
- extent of food produced from restored habitats that are consumed by non-native clams;
- extent of native vegetation relative to non-native vegetation in the restored marsh;
- extent of native relative to non-native submerged aquatic vegetation;
- change in abundance of non-native predatory fish species;
- effects of habitat restoration on salinity gradients in the west Delta;
- levels of mercury methylation and biological uptake;
- organic carbon production in restored marshes and export to the Delta and Suisun Bay; and
- growth and survival of rearing Sacramento splittail and Chinook salmon in shallow subtidal aquatic habitats.

Reversibility: This conservation measure would be difficult to reverse because reversing the measure would require construction of new levees to re-isolate restored habitat areas from tidal flow.

			Viewpoint 1		Viewpoint 2

APPENDIX C: BDCP INFO FOR SOUTH DELTA ROA 46

Action Description

HRCM7: South Delta ROA Tidal Marsh & Shallow Subtidal Restoration

Restore 3,650 acres of vegetated tidal marsh and 950 acres of shallow subtidal habitats on portions of Union, Upper Roberts, and Middle Roberts Islands in the South Delta ROA (see map).

Evaluation Team

Dave Harlow (Chair), Stuart Siegel (Coach), Jon Rosenfield, Wim Kimmerer, Chris Enright, Dan Kratville, Charlie Alpers, Amy Richey and Kateri Harrison (note taker).

Date of Last Revision: May 20, 2009

Approach

1. Plant tules or other techniques to raise currently subsided ground surface elevations suitable for intertidal marsh restoration on shallowly subsided portions of islands and breaching levees when target elevations are achieved.
2. Scalp higher elevation portions of islands to provide fill for placement on subsided portions of islands to raise surface elevations.
3. Breach and set back levees to provide for tidal exchange with restored habitats.
4. Construct cross levees where appropriate to protect property and preclude inundation of deeply subsided portions of islands.
5. Locate and design levee breaches to maximize the development of intertidal marsh and minimize hydrodynamic conditions that favor non-native predatory fish. Levee breaches will be of sufficient length to not limit water motion into and out of restored habitat.
6. Excavate channels to initiate development of dendritic channel networks within restored marshes.

Intended Outcomes as Stated in Conservation Measure

1. Increase rearing habitat area for Sacramento splittail, Chinook salmon produced in the San Joaquin River and other eastside tributaries, and possibly steelhead.
2. Increase the production of food for rearing salmonids, splittail, and other covered species.
3. Increase the availability and production of food in the Delta and Suisun Bay by export from the south Delta of organic material via tidal flow from the new marsh plain and organic carbon, phytoplankton, zooplankton, and other organisms produced in new intertidal channels.
4. Locally provide areas of cool water refugia for Delta smelt.
5. In conjunction with dual conveyance operations, marsh restoration in the south Delta could expand the current distribution of Delta smelt into formerly occupied habitat areas.

Conceptual Model Information Regarding Intended Outcomes

The basic drivers and outcomes discussed in this worksheet are described in the following DRERIP conceptual models Delta smelt, Salmonids, Temperature, Foodweb, Tidal marsh, Corbicula, Sediment, and Mercury.

Assumptions

Provided in BDCP Conservation Measure

1. Restoration would occur on portions of Union and Upper and Middle Roberts Islands
2. Dual conveyance

Added by Evaluation Team

1. Water output from the site, post-restoration, will meet water quality standards.

2. Restoring tidal marsh habitat on the different tracts of the South Delta ROA will have varying levels of both positive and negative effects. For example, some of tracts may be more efficient at the methylization of mercury and so may have a higher magnitude score for an associated negative outcome. Differences in hydrology, topography, soils, and land-use history will also manifest as distinctions in success of this action among the tracts. BDCP's estimated extent of restoration types based upon elevation for each sub-area is presented in Appendix C.

3. The time frame for realizing restoration benefits depends upon the approaches used. Reversal of subsidence on restored areas can take several years to a decade or more depending on starting elevations. The accretion rate depends on sediment supply and biomass accretion which depends on site-specific conditions. Sediment supply in the Delta is generally very low (Schoellhamer et. al., 2007).

4. Efforts to reverse subsidence before active restoration would be focused on the more deeply subsided portions of these landscapes, i.e., lands more than 6 feet below low tide. There is a hypothesis that shallow open water regions located contiguous to emergent tidal marsh provide enhanced ecosystem complexity and functions compared to those tidal marsh habitats located directly adjacent to deeper sloughs. Although this hypothesis has not been tested, preliminary information on current conditions at Liberty Island and Little Holland Tract suggest support. However, the details of these sites are not readily available to the broad research community at this time and so the information is anecdotal. This assumption also includes a time limit to allow for subsidence reversal so that restoration of an entire parcel is not delayed indefinitely. To speed up the subsidence reversal process, an alternative method would be to separate low-lying areas with new levees and reconnect those areas after subsidence reversal is accomplished.

5. Water output from the site, post-restoration, will meet water quality standards.

6. Source of fill material will be identified and use of all material, including dredge spoils, will be approved by the RWQCB.

7. Prior to implementation, a Phase I Environmental Assessment with on-site sampling to assess legacy and other soil contaminants (i.e. mercury and pesticides) will be completed.

Problem(s) with Action as Written:

1. Exporting primary production produced on this restored marsh to the Suisun Bay is not a realistic outcome, given the long distance between the two areas. If successful, this restoration site may export fish.
2. Approach #5 has some ambiguity.
3. The action does not describe how selenium issues will be addressed. Selenium is a concern on this restoration site.
4. Since rearing habitat for juvenile fish by necessity includes local availability of food, the evaluation team merged the Intended Outcomes 1 and 2 (tidal marsh, rearing habitat, and local food) into one outcome.
5. Loading of fill material on top of a shallow island may compress the underlying soils. This approach may not yield the intended result. A close study of existing soil conditions including analysis of the local soil map is needed to further evaluate this issue.
6. The conservation measure would benefit from an explicit recognition that restoration of tidal marsh functions on subsided landscapes, especially those subsided below emergent vegetation elevations, will take many years to many decades. In the interim, restoration sites below vegetation elevations will function as shallow subtidal habitat.
7. It is unlikely that intertidal mudflats will develop in the Delta because dominant intertidal emergent vegetation species in the Delta can grow throughout the tidal range and just into shallow sub tidal elevations (Brown 2003, Simenstad et. al., 2000 as cited in Schoellhamer et. al., 2007, p.26).

Scale of Action:

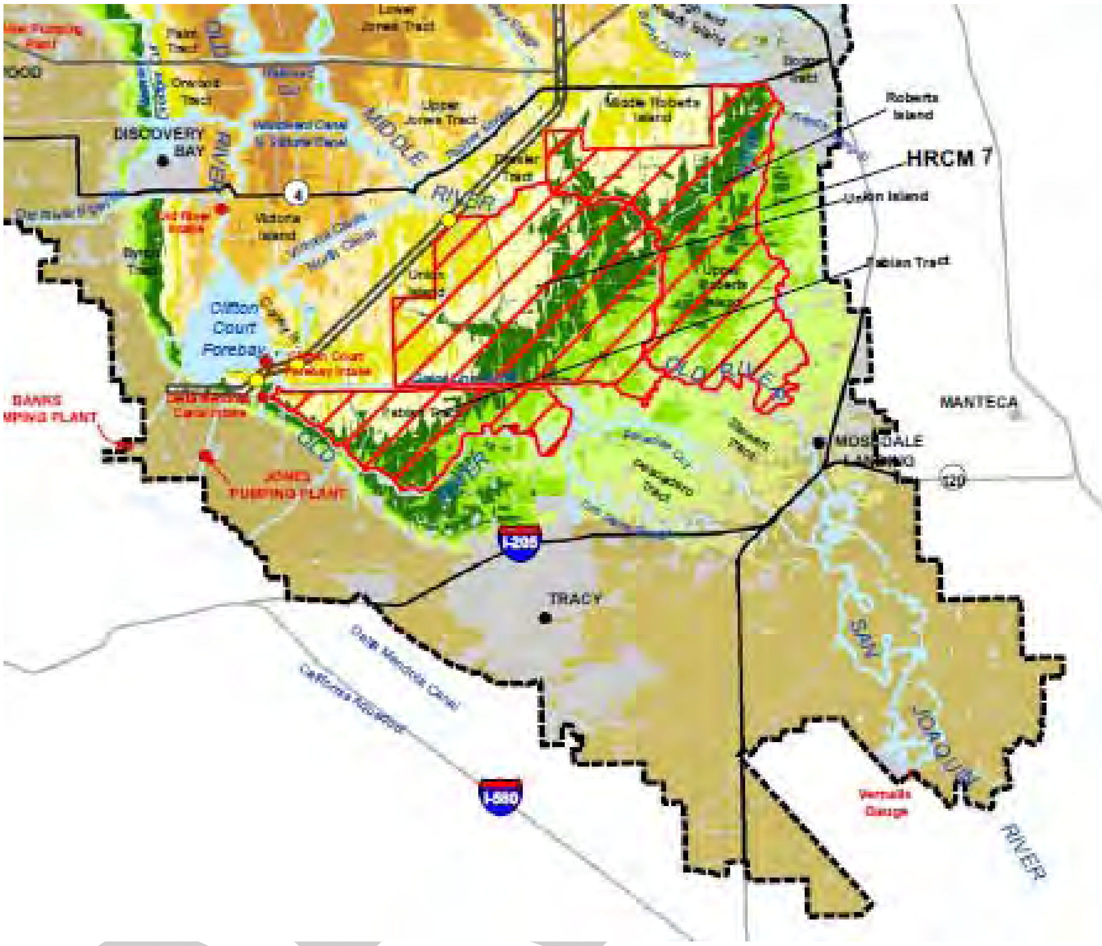
Medium

Rationale:
This is a medium scale restoration action due to its spatial extent. As listed in Table1 below, the Delta currently has approximately 21,600 acres of tidal marsh habitat (baseline). Additionally, 67,000 acres of diked and other lands have been identified as potentially restorable to tidal marsh (neglecting effects of restoration on reducing tidal range). The proposed 3,650 of tidal marsh plus 950 acres of shallow sub-tidal restoration options would increase marsh acreage 16% above current conditions. Significant amounts of the 67,000 acres of identified restorable lands are highly constrained such that they could not be restored in the near term (South Delta and Netherlands alone account for 31,000 acres of the 67,000 acres). Therefore, this action also represents an important part of the potentially restorable tidal marsh lands.

Table 1. Summary of Tidal Marsh Acreages

Area	Acreage	Source
Delta (entire Delta proper)	738,000	DWR, 2009
Historic tidal marsh/wetlands in Delta	525,000	TBI, 2002
Current extent of tidal marsh/wetlands in Delta.	21,600	TBI, 2002
Restorable intertidal lands within Delta.	67,000	CA DVSP, 2008, Table 1, p.77.
Proposed South Delta tidal marsh restoration (this action)	3,650 tidal marsh 950 sub-tidal	BDCP, 2009

Figure 1: South Delta Restoration Areas



Evaluation Summary

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

Note: Negative outcomes are scored relative to baseline conditions. These negative mechanisms may also decrease the certainty that positive effects of site restoration will be realized. Appendix "A" contains the above information in summary tables that are organized by the numerical order of the outcomes, rather than species.

Outcomes with Direction of Change Uncertain

The outcomes listed below could be either positive or negative (the direction of change is not certain).

- Organic carbon levels are increased and may affect drinking water supplies. This outcome was not evaluated. The Evaluation Team believes there is a relationship but lack of data precludes evaluation at this time.

Outcomes with Zero Magnitude

During the Evaluation process, several of the outcomes identified by BDCP early in the process, were found to have a zero magnitude. These outcomes are listed below and their evaluation is provided in Appendix B.

- OP1a: Increase rearing habitat area (including physical and biotic attributes) for longfin smelt.
- OP1b: Increase rearing habitat area (including physical and biotic attributes) for steelhead.
- OP2a: Locally provide areas of cool water refugia for winter-run salmon.
- OP2b: Locally provide areas of cool water refugia for late fall-run salmon.
- OP2c: Locally provide areas of cool water refugia for late spring-run salmon

Other Potential Positive Outcomes Identified, Not Evaluated

When BDCP originally crafted this action, they identified the potential positive outcomes listed below. The Evaluation Team ran out of time and funding before it could fully evaluate this outcome. Although this outcome likely has merit, the team was not able to evaluate this outcome.

- OP3: In conjunction with dual conveyance operations, marsh restoration in the south Delta could expand the current distribution of Delta smelt into formerly occupied habitat areas.

Other Potential Negative Outcomes Identified, Not Evaluated

During the course of this evaluation, the team identified one potential negative outcome that it did not evaluate due to lack of time. It is recommended that this potential outcome be evaluated at some point in the future when additional time is available.

- ON1. Pesticide use for mosquito control. Tidal marsh provide habitat for mosquito larvae and adults. Since this restoration action will increase tidal marsh habitat, it will also increase the availability of habitat for mosquitoes. County environmental health departments are authorized to utilize pesticides to the extent necessary to manage mosquitoes in order to protect public health and prevent west Nile and other viruses. Sacramento, San Joaquin, and other Delta counties have active mosquito management programs that include the application of pesticides on marsh habitats. The effect such pesticide use may have on the flora and fauna in the restored marsh and connected areas have not been evaluated in this worksheet.

- ON2: Increase in the availability of selenium. This negative outcome may affect all covered fish species. This restoration site is located close to the selenium source and in proximity to the pumps.

Relation to Existing Conditions:

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

No

Nature of Change:

This moderate scale action to restore 3,650 acres of tidal marsh and 950 acres of shallow subtidal habitat may change the environment on a regional scale but not to such an extent that our current understanding of boundary conditions (Harrell et al 2008), hydrodynamics, and ecological processes in the Delta would change.

Overview of Productivity Import-Export

The Cache Slough evaluation worksheet (HRCM4) provides a complete discussion of productivity levels, import and export. Here we describe how conditions may differ from Cache Slough in order to provide the Conservation Measure evaluation appropriate specificity.

The South Delta ROA has less tidal exchange and may have lower residence time compared to Cache, due to its geographic location (farther away from a river channel etc).

Although the scale of the action is moderate in size, its southerly location offers warmer temperatures which will increase primary production compared to other restoration sites. However, it is highly uncertain whether any of this production will be exported or will benefit covered fish species.

Potential Positive Ecological Outcome(s)

Outcome P1: ***Increase rearing habitat area (including physical and biotic attributes) for covered fish species.***

As indicated at the beginning of this worksheet under the section entitled "Problems with Action", the team decided to merge two Intended Outcomes (rearing habitat and local food) into one outcome, P1, as shown below because rearing habitat for juvenile fish by necessity includes local availability of food. This outcome includes food (both primary and secondary production) produced within the vegetated marsh, within marsh channels, and within the subtidal areas adjacent to the vegetated marsh. General information that applies to salmon runs is provided in the worksheet for HRCM 4 – Cache Slough, Outcome P1c on page 15. Please note that green and white sturgeon are not known to utilize the Cosumnes and Molkemne River systems and so these species are not listed in the analysis below.

P1a. Delta smelt:

General Observations: The aquatic food web supporting Delta smelt production is a primary component of habitat suitability that affects Delta smelt growth rates, health, fecundity, and mortality (page 21 in Nobriga and Herbold, 2008). The food web supporting Delta smelt is based on the production of pelagic zooplankton.

Delta smelt historically spawned in the South Delta (Nobriga and Herbold, 2008, p. 11).

Delta smelt are believed to be food limited for at least some life stages (Herbold and Nobriga 2008, page 9). In summary, food resources for Delta smelt would be produced within the restored marsh habitat, and the combination of physical space and food production would constitute habitat for Delta smelt.

Food generated on this site might be lost to invasive clams. This phenomenon is described in detail in Negative Outcome N1b. Predation (especially if it is facilitated by colonization of SAV) may also eliminate any beneficial effect of this action.

Magnitude = 1 - Minimal
Delta smelt were historically found in the South Delta (Bennett 2005, Figure 1) but they are infrequent or absent from this area in recent years (Nobriga and Herbold, 2008 Figure 3). Delta smelt eat food produced on tidal marshes; but, the smelt model (p. 27 and elsewhere, and pers. comm. with B. Herbold, US EPA) indicates that Delta smelt do not forage ***in*** shallow environments. Delta smelt will not benefit from the physical habitat structure to be created on shallow parts of this restored landscape. Food consumed in the shallow tidal areas is likely to be nil.

The food consumed in directly adjacent pelagic habitats depends entirely on how much of the zooplankton produced in the shallow areas is consumed by fish that actually forage in shallow environments where the food is produced.

This outcome assumes that Delta smelt are limited by food production in this area. The Model indicates that Delta smelt rearing in open water habitats may have, in the past, relied on export of food from a vast network of tidal marshes (p12). However, today, it is more likely that water quality, flow conditions, and non-native species in this area limit native fish productivity than that productivity is limited by lack of tidal marsh habitat. (e.g., Jassby and Van Nieuwenhuyse, Brown and May 2006, Presser et. al., in revision and Werner and Oram, 2008).

Certainty = 2 - Low
The value of food produced on site is related to how much of that food makes it into the adjacent channels and bays and to the nature and extent of food limitation in this region currently. Both of these factors are uncertain. The magnitude of food production depends on physical aspects of the restoration (e.g. those that contribute to retention time) and biological outcomes (e.g. the amount of food consumed in shallow areas that is then not exported to adjacent deep habitats).

Corbicula establishment could limit, if not eliminate, the productivity benefits of the restoration to Delta smelt. See Negative Outcome N1b. Similarly, establishment of SAV and centrarchid (or other) predators could lead to predation rates on the site that eliminate any net benefits at a population level.

P1b. Fall-run Chinook salmon - San Joaquin or eastside tributaries.

General Observations: Fall-run juveniles move through the Delta from in the winter and spring (Williams and Rosenfield, In preparation, figure 3 and see also page 15 that shows the value of estuarine rearing varies across runs).

Magnitude = 2 - Low
Outcome assumes that "rearing habitat area" (quantity) and/or food is limiting. Page 16 of Williams and Rosenfield, In preparation, states that : "<u>Fall Chinook […] could benefit strongly from tidal marsh restoration</u>". Fall Chinook generally enter estuarine habitats at a small size and the text anticipates benefits from additional rearing/growth opportunities. Fall run will eat the types of food produced in this habitat. San Joaquin River and eastside fall-run migrate through this area from January and into June, with a pulse in May (Williams and Rosenfield, Figure 3).

High temperatures are common in this area during May (as indicated by an IEP gauge, rsan058, in the vicinity). Average daily temperatures exceed 20-21^{o}C (beyond which sublethal effects accumulate; Reese and Harvey 2002 *and see* Richter and Kolmes 2005) during May in approximately 1/3 of years. In June, average daily temperatures exceed this critical threshold in almost every year. With warming that may occur under climate change projections, high temperatures may become more frequent and more extreme, even during April. Fall-run rearing in this proposed restoration site during May will probably be impacted by high temperatures and negative impacts could become more common, and occur earlier in the year, with global warming.

This region has been highly altered by anthropogenic chemical inputs, channel modification, and invasive species (Brown and May 2006). Water quality in this area is notoriously poor: lethally low DO conditions occur throughout the year (including, occasionally, during the fall-run juvenile emigration period; http://www.sjrdotmdl.org/concept_model/bio-effects_model/lifestage.htm). In addition, the area is dominated by SAV and associated Centrarchid predators. Without action to correct water quality and flow problems in this area, construction of tidal marsh habitat is not likely to be successful in restoring native fish. This action will not benefit Sacramento River fall run and will not benefit fall-run that migrate into the lower San Joaquin River after mid-April.

Certainty = 2 - Low
Restoration of Chinook salmon to the San Joaquin River drainage will probably require restoration of flows to the lower San Joaquin River (to create passage for adults and juveniles and to dilute and disperse contaminants). Restoration of these flows will impact the value of "rearing" habitat in the Southern Delta.

P1c. Splittail

General Observations: The relationship between the drivers and outcomes is described in Kratville, 2008 on pages P1h Pg 12, 13, 14, 15.

Magnitude = 2 - Low
While more tidal marsh will help rearing of juvenile splittail, the expect population benefit is medium. Sacramento splittail population abundance is limited the lack of floodplain inundation to provide spawning habitat (Kratville 2008). When large scale inundation occurs splittail population abundance is high for several years following an event. Long periods without floodplain inundation reduce splittail population abundance. Splittail do not appear to be habitat limited at other life history stages. Tidal Marsh in this area may provide similar benefits as the Cosumnes tidal marsh areas in terms of adding resiliency to the population. Future floodplain restoration on the San Joaquin River at a major scale may increase the value of this proposed tidal marsh.

Splittail are benthic fish which forage during the day. Adult splittail typically consume detritus (60-79%), mysid shrimp (2-24%), Corbula (6%), salmon eggs, worms, and invertebrates. Larval and juvenile splittail are typically found on the floodplain and while there they consume small rotifers, cladocerans, chironomid larvae, zooplankton, and copepods (Kratville 2008). To the extent that tidal marsh supports the production of these types of food resources and to the extent that these food resources are available at a time and location that is accessible to splittail, the proposed restoration may offer some food benefits during a limited time window.

Certainty = 3 - Medium

Whether the proposed restored rearing habitats will result in increased splittail population abundance is not certain. Although the restored habitat will increase the opportunity for rearing juveniles to feed during their downstream migration, tidal marsh does not appear to be a limiting factor in splittail abundance compared to floodplain inundation (Kratville 2008). .The bulk of the adult splittail population resides in the brackish areas of Suisun Marsh (Kratville 2008). It is anticipated that most of the restored marsh in this ROA will be freshwater and so will only provide habitat for juvenile fish migrating into Suisun Marsh. This restoration may not provide a new population center or increase the numbers making it to Suisun Marsh. The restoration site is not located directly downstream of a floodplain and so its use by out-migrating fish may be limited.

P1d. Green Sturgeon

General Observations: The basic relationship between drivers and outcomes is described in Israel and Klimley, 2008, pages P1i Pg 4, 8, and 9.

Magnitude = 2 - Low
Information on green sturgeon diets and physical habitat needs as juveniles in the Delta is limited. Other species of juvenile sturgeon located in other systems do feed on drifting insects (Radtke 1967 and McCabe, G et al. 1993). This area of the Delta will not provide extensive mud bottoms as found in lower portions of the estuary. Soft bottom benthos are a food resource for the sturgeon. Most habitat limitations for green sturgeon appear to occur outside of the restoration area (i.e. upstream and downstream), as described on pages 4, 8, 9 in Israel and Klimley, 2008 and pages 19-21 of Israel et. al., 2009. It is unknown to what extent adult sturgeon used freshwater tidal marsh for foraging. The impact to individual sturgeon may be low but the extreme loss of freshwater tidal marsh in the Delta may have lowered the carrying capacity of the entire system for sturgeon. See pages 4, 8, 9 in Israel and Klimley, 2008 and pages 19-21 Israel et. al., 2009 for more detail.

Certainty = 2 - Low
There is minimal certainty about whether this proposed restoration will benefit sturgeon as described in this outcome. The minimal certainty is due to the lack of research on this aspect of sturgeon biology/ecology in the Delta. Most of the available information on sturgeon diets and predator/prey relationships is based upon other species of sturgeon, located outside of this system.

P1e. White Sturgeon

General Observations: The basic relationship linking drivers to outcomes is described in pages 1j, 19, 20, and 21 in the DRERIP White sturgeon model (Israel et. al., 2009).

Magnitude = 2 - Low
Information on white sturgeon diets and physical habitat needs as juveniles in the Delta is limited. Other species of juvenile sturgeon (located in other systems) do feed on drifting insects. . This area of the Delta will not provide extensive mud bottoms as found in lower portions of the estuary so benthic food items are expected to be limited in this restoration (Siegel, personal communication, Feb. 2009). Habitat limitations for white sturgeon appear to occur upstream and downstream of the restoration area (i.e. outside the ROA).

Certainty = 1 -Minimal
There is minimal certainty about whether this proposed restoration will benefit sturgeon as described in this outcome. The minimal certainty is due to the lack of research on this aspect of sturgeon biology/ecology in the Delta. Most of the available information on sturgeon diets and predator/prey relationships is based upon other species of sturgeon, located outside of this system.

Outcome P2: Food resources (i.e. organic material from the marsh plain and organic carbon, phytoplankton, zooplankton, and other organisms from intertidal channels) produced on the restored marsh will be exported, via tidal flow, and contribute to food availability downstream in the Delta and Suisun Marsh.

P2a: All Covered Fish species

General Observations: The Tidal Marsh and Foodweb models [Kneib et. al., 2008, page 9 and Durand, 2008, section 2.16)] provide a general indication that there may be a linkage between tidal marsh habitat as a driver and increases in availability and production of food resources as an outcome, but that the mechanism for this linkage may be movement by fish. The tidal marsh conceptual model also states that freshwater tidal marshes are net exporters of high-quality organic production (page 2 in Kneib et. al., 2008). See also Dame et al. 1986, Kimmerer and McKinnon 1989, Kneib 1997, Lucas et al. 2009.

Under this Conservation Measure, restoration would include vegetated marsh plain, tidal channel networks with depths that are shallow to medium subtidal, and shallow subtidal open water in the deeper portions of the restoration sites. Production and export of food resources from these distinct geomorphic features is a multi-step process that begins with primary production. The nature of the primary production will be different between these three geomorphic features, with the marsh plain being dominated by vascular plants with some epiphytic algae and the marsh channels and shallow subtidal open water being dominated by phytoplankton with contributions from FAV, SAV, and perhaps some epibenthic algae. This primary production is consumed by a range of secondary producers the nature of which again will vary across the three geomorphic elements, with the marsh plain supporting mainly detrital-based microbial communities and epiphytic, epibenthic, and aerial invertebrate grazers and the marsh channels and shallow open water supporting a mix of zooplankton and benthic and epibenthic invertebrates. Fish of varying size will also forage throughout the marsh channels and shallow open water and during higher tide stages on the marsh plain when it is inundated.

Please see the evaluation worksheet for action # HRCM4-Cache/Yolo, Outcome P3, for more details about **Tidal Marsh Contributions to Exported Production.**

There was disagreement within the evaluation team regarding the magnitude and certainty of expected benefits of tidal reintroductions with regard to the export of food (phytoplankton, zooplankton, insects, and small fish) to areas downstream of Rio Vista and the likely benefits to covered fish species. In the spirit of presenting the scientific discourse, both points of view are captured below.

Two key questions discussed were: (1) can we predict the sign of the flux of productivity (i.e. will the restoration area be a source or a sink for primary and secondary productivity); and (2) will there be adequate advection to move material out of the restoration area and downstream to Rio Vista (assuming the restoration area is a source of productivity, as opposed to a sink). Additional information and analyses is needed to better answer these key questions. To develop this additional information, the team recommends future development of a Tropho-dynamic model as described in the section on page 41 entitled “Research Needs”.

Viewpoint #1

Please see the text of Outcome P3 in worksheet HRCM4 – Cache Slough for additional background information about Viewpoint #1.

Magnitude = 3-4 – Moderate to High
Without advective connection, restoration will still have significant productivity benefits to covered fish species and to many other species due to providing areas of highly functional habitat in conjunction with restoration elsewhere that collectively provide fish species a range of options that spread risk through exploiting available resources when they are present. Refer to Ted Sommers, IEP Estuarine Ecology Team or CAERS poster. In addition, these areas would export that productivity through the “trophic relay” concept described in the tidal marsh conceptual model (fish export the productivity).

Certainty = 3 – Moderate
Certainty is reduced by the potential for establishment of invasive clams that could consume substantial portions of phytoplankton and hinder zooplankton productivity.

Viewpoint #2

Please see the text of Outcome P3 in worksheet HRCM4 – Cache Slough for additional background information about Viewpoint #2.

Magnitude = 1-2 - Minimal to Low
The implied relationship is that restored tidal marsh will export nonliving and living organic matter including plankton and fish, thereby supporting foodwebs of the upper estuary. An implicit assumption is that any increase in the area of shallow habitat would result in enhanced plant productivity some of which would be exported.

Certainty = = 1 -Minimal
The sign of the signal is difficult to determine, except for total organic carbon, most of which is dissolved. Although dissolved organic carbon (DOC) will likely flow out of the marsh, fluxes of other components may be in or out (Kneib et. al., 2008, page 9). Colonization by invasive clam species can wipe out the food web production effect entirely. We have no certainty at all that they will not colonize. In addition, colonization of the site by vertebrate consumers (e.g, inland silverside) can also significantly reduce the amount of food available for export beyond the site boundaries (Moyle 2002). There is evidence from within this system (Dean et al. 2005) that restored marshes can act as sinks for certain zooplankters; in this case, the sign of the signal would be negative.

Outcome P3: Provide local areas of cool water refugia (Feb-Jun) for Delta smelt and salmon.

The cause and effect relationship associated with this outcome is described in Stacey and Monismith 2008, Malamud-Roam 2000, and Enright 2008. Considering the local scale (small) of the action, the relationship between tides, physiography, and water temperature could be moderate. The relationship between drivers (wind, insolation, fetch, tides, currents) and linkages (long-wave, short wave, latent, and sensible heat flux) is complex and may produce both warmer and cooler water on a variety of time and space scales. Larger spatial gradients of water temperature will likely occur. The frequency of threshold temperatures for various species is uncertain. See Stacey and Monismith (2008), Malamud-Roam (2000), Enright (2008). Please see the detailed discussion of temperature in the Cache Slough HRCM4 worksheet, under Outcome P4.

P3a: Delta smelt

Magnitude: 2 - Low

Please refer to text in outcome P4 of HCM4 – Cache/Yolo Restoration Action. Delta smelt do experience thermal stress during late spring and summer. The spatial and temporal extent of the cool water refugia may be relatively limited. However, in some cases a large effect could be felt across relatively large area across the range. Drivers and outcomes are described in Stacey and Monismith 2008, Malamud-Roam 2000, and Enright 2008. Please refer to the discussion located in HCRM4 – Cache Slough Restoration Action, Outcome P4, page 25 for more details.

Certainty: 1 - Minimal
The basis for our understanding is a single unpublished study in Suisun Marsh. The extent to which this effect may transfer to the restoration site, and to which Delta smelt and salmon will take advantage of it, cannot be predicted. Please refer to text in outcome P4 of HCM4 – Cache/Yolo Restoration Action Outcome P4, page 26 for more details.

P3b. Chinook Salmon

P3b1: Fall run salmon

Magnitude = 2- Low.
Beneficial effect occurs for only a portion of the salmonid population passing through this region during a particular and narrow window of time. This outcome modifies Outcome P1 (creation of habitat). In evaluating that outcome, benefits of this action were interpreted in the light of unfavorable temperature conditions that occur in the area during late-spring and summer. To the extent that the tidal flooding/cooling phenomenon occurs on this restoration site (a function of geography and restoration design and site elevations) during the period of potential thermal stress (May through end of summer), it may provide some relief from the effects of thermal stress *for those*

salmon runs that migrate through this region at this time (fall and spring run and steelhead). That benefit impacts only the proportion of the population that migrates at this time and only the proportion of the population that migrates through this area (i.e. not all fall run or all steelhead). Although the team suggests a magnitude score of 2, for this outcome there is some debate within team as to whether this action's cool water refugia will offer any benefit at all. Chinook salmon using this area during late spring are probably on their way out of the estuary, and if it is too warm they will probably move on. The existence of thermal refugia (if it occurs in the area) may not make much difference to the salmon, and should not be considered a positive outcome pending further information.

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

P3b2: Steelhead

Magnitude = 2- Low.
Beneficial effect occurs for only a portion of the salmonid population passing through this region during a particular and narrow window of time. This outcome modifies Outcome P1 (creation of habitat). In evaluating that outcome, benefits of this action were interpreted in the light of unfavorable temperature conditions that occur in the area during late-spring and summer. To the extent that the tidal flooding/cooling phenomenon occurs on this restoration site (a function of geography and restoration design and site elevations) during the period of potential thermal stress (May through end of summer), it may provide some relief from the effects of thermal stress *for those salmon runs that migrate through this region at this time (fall and spring run and steelhead).* That benefit impacts only the proportion of the population that migrates at this time and only the proportion of the population that migrates through this area (i.e. not all fall run or all steelhead).

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

**Note: Winter run, late-fall run, and spring do not occur in this area, will not derive benefits from this action, and are further discussed in Appendix B.

Potential Negative Ecological Outcome(s)

Outcome N1: Establishment of harmful invasive species.

Harmful invasive species have the potential to cause two types of adverse effects. First is to worsen conditions relative to the existing baseline; i.e., creating an attractive nuisance. Second is to detract from achieving the positive benefits the action could provide. The magnitude and certainty scores below are based upon an assessment relative to baseline conditions. The scores below for N1a to N1d do not represent the potential to distract detract from the positive benefits of the action because these deductions were considered by reducing the certainty scores for positive outcome # P1. Where appropriate, the impacts associated with the establishment of harmful invasive species on the restored marsh are discussed below.

N1a: Submerged Aquatic Vegetation (SAV)

General Observations: As described in the conceptual model, the establishment of SAV is controlled by local flow conditions and substrates (Anderson, In Preparation). Many aspects of SAV physiology are influenced by local flow conditions including turbidity and to some extent flow velocity which if too high can scour suitable substrate precluding SAV establishment. The initial establishment of SAV is an intermediate outcome and the development of a large sustainable SAV population is the final outcome.

Please note that establishment of SAV reduces the certainty that the positive outcome, P1 will occur. This has been noted in the scoring for P1.

Magnitude = 3 - Medium
The establishment of SAV in general is controlled by local flow conditions and substrates. Local flow conditions control many aspects of SAV physiology, most importantly in this area turbidity. In nearby Liberty Island where turbidities are generally higher due to wind wave action SAV is restricted to shallow near shore areas (UC Davis Egeria Report). . If turbidities are high in the restoration area then SAV establishment and growth may be reduced to levels similar to Liberty Island. If not there is the potential for SAV amounts similar to Franks Tract. The substrates in this area would be expected to support establishment of SAV (Anderson, In Preparation).

For this outcome, the baseline condition is that much of the existing 21,600 acres of Delta tidal marsh is infested with submerged aquatic vegetation (Ustin, 2008). . The restoration of a tidal marsh that eventually becomes infested with SAV is significant. Large, sustainable populations of SAV will produce significant changes in water quality (turbidity, pH, DO and temperature), or water flow characteristics (velocity and direction), which in turn can affect the quantity and quality of sediments (Anderson, In Preparation). Eventually, the clarity of water entering the site from upstream will increase by lowering velocities and allowing particulates to settle out of the water column. This increased water clarity could increase predation of fish entering the site from outside areas (i.e. predators now have greater visual range). One type of predator, Centrarchid fish, is strongly associated with SAV and increased Centrachid populations may create a population sink for native fish at this location, as discussed in N1b, below. In summary, this action will worsen conditions beyond that of baseline conditions and small to moderate fractions of all the covered fish species may experience highly significant but localized effects due to SAV. Given the rarity of Delta smelt, the impact of SAV establishment could be particularly significant on this species.

Certainty = 2 - Low
The initial colonization and ultimate patch distribution of SAV on the substrate is uncertain. As the substrate softens over time, it may be more conducive to SAV establishment and growth (i.e. bed characteristics are described as a driver in the conceptual model). It is well documented that the physical structure of SAV facilities slower water velocities which allows sediment particles to settle, thereby reducing turbidity, locally and creating a positive feedback loop for more SAV establishment (Anderson, In Preparation). The effect of specific restoration site substrate, how those substrates may change over time after restoration, and the role of flow velocity at these locations is not well understood (Anderson, In Preparation).

N1b: Non-native Centrarchids

General Observations: Drivers and outcomes are described in Brown and Michnuik, 2007; Grimaldo et al 2004; Nobriga and Feyrer 2007; and Nobriga et al. 2005. Centrarchid fish, as an assemblage, cover a range of ecological niches in the Delta. They are competitors for resources as well as predators on native fish. The magnitude of this effect is dependent on the assemblage of centrarchids that invade and the size of the populations. This is in turn partially dependent on the amount of SAV invasion into suitable habitat areas of the restored system.

Please note that establishment of Centrachids reduces the certainty that the positive outcome, P1 will occur. This has been noted in the scoring for P1.

Magnitude = 4 - High
For this outcome, the baseline condition is that much of the existing 21,600 acres of tidal marsh are excellent habitat for Centrarchid fish where they are associated with adjacent deeper water. This is illustrated by the large number of Bass Tournaments that occur in the Delta. The Delta is a stop on the national professional bass fishing circuit with $100,000 prizes. infested with centrarchids (citation needed). This action could worsen conditions beyond that of baseline. Centrachids are a concern because they prey upon and compete for food and other resources with native covered fish.

The establishment of Centrarchids in conjunction with SAV is well documented, especially in this portion of the Delta (Brown and Michniuk 2007; Grimaldo et al. 2004; Nobriga and Feyrer 2007; Nobriga et al. 2005). Centrarchid fish will become established in this area as they have in other South Delta locations where flows are more tidal than riverine (Brown and Michniuk 2007). The magnitude score given reflects the possible impact that these fish could have given evidence from the southern Delta. An increase in populations of this assemblage of centrarchids could have impacts on nearly every life stage of Delta smelt and other native fishes. Given the rarity of Delta smelt, the impact of Centrachids could be particularly significant.

Certainty = 2 - Low
The uncertainty is not whether or not Centrarchid fish will become established at the restoration site, but the extent of their populations and impacts on local native fish use once established. In areas with low SAV patch size the numbers of Centrarchid fish and their presumed impact on native fish are lower then where the opposite is true (Brown and Michniuk 2007). If the south Delta becomes brackish to the extant that Suisun Marsh is today, this may change.

N1c: *Corbicula*

The relationship between drivers and outcomes is described in the DRERIP Corbicula Conceptual Model (Thompson et. al., In revision).

Consequences of *Corbicula* establishment. If established, *Corbicula* would likely have a significant effect on food web dynamics because it consumes phytoplankton in shallow areas (Lopez et al. 2007). *Corbicula*'s consumption of primary productivity represents a significant limiting factor throughout the Delta that could greatly reduce productivity benefits of restoration efforts (Thompson et. al., In revision). No local studies have been undertaken to indicate whether *Corbicula* feeding has reduced zooplankton populations either through competition or direct predation (Thompson et. al., In revision page 11). Establishment of *Corbicula* would consume much of the positive benefits that were previously discussed above under positive outcomes.

Potential Control Options. There are no stressors identified that can limit the success of Corbicula in a significant manner. However, salinity can limit the spatial distribution of this species and food limitation is a source of stress (Thompson et. al., In revision, pages 8 and 13). The *Corbicula* conceptual model indicates that the only meaningful method to control their presence/abundance is salinity. This control method would require salinity intrusions into the restoration area of sufficient duration and at the appropriate times of year to have a meaningful effect. The conceptual model does not specify the duration and timing which might be most effective during recruitment. Water temperatures may influence the effectiveness of both recruitment and control measures.

Please note that establishment of *Corbicula* reduces the certainty that the positive outcome, P1 will occur. Establishment of *Corbicula* would consume much of the positive benefits that were previously discussed above under positive outcomes. This has been noted in the scoring for P1.

Magnitude: 1- Minimal
Corbicula can control phytoplankton biomass development in shallow areas, or consume the productivity of shallow areas exported to channels (Thompson et. al., In revision). This is a significant limiting factor throughout the Delta. However, the effect of the restoration on the establishment of Corbicula, and whether that constitutes a net positive or negative effect, is unknown and would be difficult to predict. For this outcome, the baseline condition is that much of the Delta is infested with *Corbicula*. The restoration of tidal marsh that eventually becomes infested with *Corbicula* would not represent a significant change above baseline conditions.

Certainty: 2 - Low

Specifically for restoration sites, the timing and extent of colonization by Corbicula cannot be predicted because of a lack of data from such locations. *Corbicula* are prolific reproducers and colonizers of newly available habitats in salinities below 2 ppt. Source populations can come from elsewhere within the Delta or from upstream tributary populations. *Corbicula* can establish on soft and hard substrates and on vegetation and they can colonize intertidal zones as well as deeper water. (*Corbicula* model). Based upon the biology of the species and the physical setting of the restoration site, the probability of *Corbicula* establishment in the West Delta restoration areas appears to be high, but ultimately cannot be predicted, partially due high variability in environmental conditions. The low certainty score considers the probability and extent of potential establishment.

Corbicula monitoring data from previous restoration sites in the Delta, such as Liberty Island or Little Holland Tract, would provide greater information about the probability of colonization on these eastern Delta sites. More information would improve the certainty rating. However, such data and analysis was not made available to the evaluation team.

N1d: Inland Silversides Effects on Delta and Longfin Smelt

General Observations: Inland silversides (*Menidia beryllina*) are highly tolerant of warm water, and variable salinity variability and are trophic generalists compared to Delta smelt (Moyle 2002). Inland silversides are the most numerous fish in shallow Delta habitats (Nobriga et al. 2005, Brown and May 2006). Page 3 of Nobriga and Herbold 2008 includes intraguild competition with inland silversides as one of the top five in-Delta stressors to Delta smelt. Inland silversides are thought to be a major predator of Delta smelt eggs (Bennett and Moyle 1996 and Bennett 2005 in Nobriga and Herbold 2008 page 12). In the laboratory, inland silversides reduce Delta smelt size relative to controls when they are reared together (Bennett 2005).

Inland silversides are also treated in the longfin smelt model. Moyle (2002, in Rosenfield 2008) suggested that based on timing of arrival in the Estuary and subsequent longfin population response, inland silverside might have had a major impact on longfin population dynamics. However, the model states that inland silverside prefer shallow water habitats where juvenile and sub-adult longfin are rare, thus, their impact as predators of juvenile and sub-adult longfin is probably slight (Rosenfield 2008, pg. 17). Spawning locations for longfin are unknown, so it is not known whether competition from inland silverside for spawning territory is a factor in their decline.

However, Delta smelt evolved with other intraguild competitors, including longfin smelt, and have survived with striped bass (introduced in 1879). Interaction between silversides and Delta smelt in the wild may be limited because Delta smelt typically inhabit offshore environments, while inland silversides typically inhabit shoreline habitats. Increased shoreline habitat would presumably increase the carrying capacity for inland silversides. However, predator-prey interaction between Delta smelt and inland silversides in the wild is speculative. Silversides may eat Delta smelt eggs or larvae if the eggs and larvae occur on the shorelines. It has not been shown that inland silversides reduce calanoid copepods (Nobriga and Herbold 2008, page 32), so they may not effectively compete with Delta smelt for prey.

Magnitude = 2 – Low: Inland silversides are the most abundant fish in shallow-water habitats in many areas of the Delta and may currently contribute to local depletions of zooplankton otherwise available to native fishes within these areas. Additionally, they may prey on embryos of species that lay eggs in these shallow areas (Moyle 2002). The crash of Delta smelt populations coincided with invasions of inland silversides into the estuary (Bennett and Moyle 1996). This action may change conditions relative to baseline by attracting (via restored marsh) a nuisance (inland silversides). This conservation measure will increase the local inland silverside population by providing additional shoreline breeding habitat. Because of the high existing abundance of inland silversides, the incremental increase in breeding habitat and thus population size above current conditions is considered small and the magnitude of this effect is considered to be low relative to baseline. Further, differential habitat selection (offshore environments for inland silverside) is expected to reduce the interspecific competition effects.

Certainty = 2 - Low: Understanding of interaction between Inland silversides and Delta smelt in the wild is low, particularly in regards to egg predation by inland silversides. Spatial interactions with longfin smelt are also uncertain.

Outcome N2: Potential for mercury methylation and local bioaccumulation to affect wildlife: N2-A – Covered fish species, N2-B, Non-covered wildlife species, N2-C, Human health.

General Observations, methyl mercury: Although current methylmercury levels on Liberty Island (analogue for future state of areas to be restored) are relatively low (Slotton et al. 2002, Alpers et. al., 2008, figure 5), there is potential for enhanced production of methylmercury in areas of high marsh that will be inundated infrequently (only during highest tides). The process of drying out between wetting events tends to oxidize species of sulfur, iron, carbon, and mercury, leading to higher potential to form methylmercury upon rewetting. Once formed, methylmercury biomagnifies in the aquatic food web, and ecological effects may occur in some sensitive species. Thus, the specific geomorphology of restoration sites and in particular the degree to which shallow depressions and poorly drained areas of high marsh are part of the restoration projects directly influences the degree of mercury methylization.

General Observations, other contaminants: Past land use determines risk of other contaminants: lead risk in areas with significant hunting, e.g., pheasant farms or duck clubs. Risk of residual pesticides (e.g., pyrethroids) in areas used for agriculture in past 2 years, which suggests that if these pesticides were used, allowing for a 2 year lag period between application and tidal restoration would be a prudent mitigation measure. Selenium contamination from the San Joaquin Valley is a concern.

N2a: Covered fish species

General Observations: Alpers et. al., 2008 (Table 2 and associated text) describes the relevant issues.

Magnitude: 1 – Minimal: No toxicological studies have been conducted with any of the target species regarding acute toxicity. Mercury concentrations in target fish are compared here against concentrations producing mortality in other fish species. Mercury concentrations in covered fish species are compared here against concentrations producing mortality in other fish species. Mercury concentrations in ppm-wet weight for white sturgeon, Chinook salmon and Steelhead collected during 2006 were 0.165-0.279, 0.094-0.396 and 0.06-0.13, respectively (Melwani et al. 2007). No tissue data for either longfin or Delta smelt was found. It is assumed that both species will have tissue concentrations similar to other fish taxa living one year and feeding primarily on zooplankton. Mercury concentrations in juvenile threadfin shad and juvenile largemouth bass in delta are 0.012-0.076 and 0.035-0.230, respectively (Slotton et al., 2006). In comparison death in rainbow trout in laboratory studies occurred at 4-ppm wet weight and the NOAEC for death in Brook trout at 2.7 ppm (in Wiener and Spry, 1996). In conclusion, there exists about a 10X safety factor between fish tissue concentrations in Delta and values reported to cause mortality in lab studies.

Regarding chronic toxicity, again no toxicological studies with any of target species. Therefore, have compared reported tissue concentration for individual species against known laboratory effects in other taxa. Decreased feeding efficiency and some hormones response changes observed at 0.25-0.27 ppm wet weight (page 30 of Alpers et al, 2008) have been noted. Decreases in growth occurred in fathead minnows at 0.6-0.7 ppm Hammerschmidt et al., 2002) and in juvenile walleye at 2.4 ppm (Friedmann et al., 1996). In conclusion, some up/down regulation of genes and alterations in feeding behavior are possible in the most contaminated individuals.

Certainty: 2 - Low
Scientists have a low certainty that the magnitude of this outcome is minimal (i.e. magnitude may be higher). Limited tissue data available for most covered species but large safety factor regarding acute toxicity, which makes it impossible to determine the proportion of population potentially at risk. Additionally, only limited toxicological data available for most of the important sub-lethal processes and none of this has been collected on species of interest.

N2b: Methyl mercury, non covered species

Magnitude: 3 - Medium
Fifty-eight percent of Forster's terns in San Francisco Bay are at risk of reproductive impairment from consuming fish with elevated mercury levels (Ackerman *et al*., 2008). No Forster's Terns nest in Delta. However, mercury levels in small fish consumed by terns are higher in parts of the Delta such as the Yolo Bypass than in San Francisco Bay suggesting that other bird species filling the Forster's tern niche in the delta may be at risk. Mercury may result in a possible sustained, minor population effect on large area.

In laboratory studies, mink have reproductive failure and die when fed fish diets of 0.5 and 1-ppm mercury, respectively (Dansereau *et al*., 1999). For comparison, mercury concentrations in 64% of largemouth bass, 23% of white catfish, and 35% of channel catfish caught in the Bay-Delta watershed have between 0.23 and 0.93 ppm mercury (Davis et al., 2006). Expected sustained minor population effect or effect on large area.

Additional studies on rails and other species are described in the evaluation worksheet for Cache Slough #HRCM 4,. Outcome N2a2, page 36 for additional details.

Certainty: 2-3 Low-Medium
Scientific understanding of methylmercury effects on some bird and mammal species is high, based on peer-reviewed studies conducted in the San Francisco Bay and elsewhere. However, methylmercury effects on other bird, reptile, and mammal species are unknown. The nature of this outcome is also greatly dependent on highly variable ecosystem processes.

N2c: Methyl Mercury, Human Health

General Observations: See also results from water quality team.

Magnitude: 2 – Low: Fish consumption advisories for the Delta recommend that children under the age of 17 and women of child bearing age consume no largemouth bass or smallmouth bass, spotted bass or Sacramento pikeminnow, and others should limit their consumption of these species to one meal a month (OEHHA, 2006, 2008a,b). Between 10,000 and 20,000 fishermen in the Delta are presently eating fish with more than 10X the recommended methylmercury RfD and could experience some sublethal mercury poisoning (personal communication, Dr Fraser Shilling). Action could increase mercury content of sport fish.

The probability of increased methyl mercury production and export into the food web is the same as that described above for covered and non-covered species.

Certainty: 3 - Medium
Uncertain magnitude and direction of change in mercury content of sport fish, although levels are more likely to increase than decrease. For a given increase in mercury content of sport fish, risk to human health is quantified based on peer-reviewed studies (OEHHA, 2008a,b). Unknown how many anglers would access the project area and what fish they would catch and consume.

The role of restoration projects under this Conservation Measure in contributing to mercury levels in fish species consumed by humans needs to be explored in relation to other mercury sources for those fish species.

Outcome N3: Local effects of contaminants including toxicity from residual pesticides and herbicides: e.g. pyrethroids.

N3a: Covered fish species

General Observations: Possible presence of legacy pesticides from 1960s (e.g. DDT) is unknown. More recent (illicit) use of DDT is possible. Pyrethroids are 20x more toxic compared to some other pesticides (organochlorides). They persist in the sediment and degrade in one or two years (DPR, 2008). The relationship between drivers and outcomes is described by the DRERIP Pyrethroids conceptual model (Werner and Oram, 2008, Figure 1).

Magnitude: 1-2 – Minimal - Low
To the extent that pyrethroids or pyrethrins were used in the area to be flooded, significant toxicity could occur within 1-2 years of application. After ~2 years, near-total degradation should occur. DDT and metabolites could cause reduction of insect populations and bioaccumulation in target fish species (and some non-target bird species). Possible presence of legacy pesticides from 1960s (e.g. DDT) is unknown.

Certainty: 1 - Minimal
The toxicity of various pesticides is not completely understood. Although some peer-reviewed studies for selected life stages of certain fish exist, there is not much data for covered fish species. The nature of outcome greatly dependent on highly variable ecosystem processes affecting fate (degradation) and transport of pesticides.

N3b: Non Covered Wildlife Species

General Observations: The relationship between drivers and outcomes is described in Werner and Oram, 2008, (Figure 1).

Magnitude: 1-2 Minimal - Low
To the extent that pyrethroids or pyrethrins were used in the area to be flooded, significant toxicity could occur within 1-2 years of application. After ~2 years, near-total degradation should occur. DDT and metabolites could cause reduction of insect populations and bioaccumulation in target fish species (and some non-target bird species).

Certainty:1 - Minimal
The toxicity of various pesticides is not well understood. A limited number of peer-reviewed studies for certain life stages of selected fish species exist. However, there is not much data for covered fish species available (Werner et. al., 2008). The effect that tidal marsh restoration will have on the availability of residual pesticides is greatly dependent on highly variable ecosystem processes affecting fate (degradation) and transport of pesticides. Additionally, legacy pesticides from 1960s (e.g. DDT) may be present on the restoration site and more recent (illicit) use is unknown.

Outcome N4: Resuspension and export of contaminants to downstream areas (A) mercury and methylmercury, (B) pesticides and herbicides (e.g. pyrethroids.

N4a: Covered fish species

Analysis of resuspension affects considers two separate physical settings: the restoration marsh sites and the adjacent tidal sloughs. The restored marsh sites are not likely experience much scour, since the adjacent tidal channels would be excavated as part of construction and the hard farm fields are not expected to scour easily. Adjacent tidal sloughs, which are typically comprised of more erodible substrate, may experience more scour both the bed and banks. The relationship between drivers and outcomes is described in Alpers et. al., 2008 (Figures 4, 7, and 8 and associated text) and Werner and Oram, 2008, Figure 1.

Magnitude: 1 - Minimal
The degree of scouring of pre-project soils depends on hydrodynamics. Scour could be a short-term phenomenon as channels reach geomorphic equilibrium. There is potential for increasing methylmercury concentrations in high-elevation marsh (infrequently wetted zone) and possible export of this to downstream environments.

Certainty: 2 - Low
Nature of this outcome is greatly dependent on highly variable ecosystem processes affecting fate (e.g.photodegradation of methylmercury) and transport.

Outcome N5: Creation of a population sink due to longer residence times with associated increased exposure to predators and entrainment.

N5a. All covered fish species

The logical argument is the possibility of large amounts of SAV and non-native fish species inhabiting this location and consequent high rates of predation on Delta smelt. In China Camp Marsh there is a net sink for mysid shrimp presumably due to large amounts of predation (Dean et al. 2005). Longer residence times mean more exposure to predators.

Magnitude = 2-Low
Rearing and migration rate are somewhat (not completely) at odds. Implicit in tidal restoration proposals is that fish will find "habitat" with food and stay to rear to a larger size. This implies that they are not migrating as fast as they might otherwise. Longer residence time means greater exposure to sources of mortality that come with the new "habitat" (Williams and Rosenfield, In preparation 2009). If a large percentage of the Delta smelt population spawned here and this outcome occurred here the magnitude could be higher. If not the magnitude could be lower.

Certainty = 4 - High
Lack of published studies in this system contributes to high uncertainty.

Outcome N6: Production of organic matter that will contribute to low dissolved oxygen (DO) conditions.

N6a. All covered fish species

General Observations: The relevant drivers and outcomes are described in Nobriga and Herbold 2008 (p. 25). Low dissolved oxygen concentrations occur during late spring through autumn in the San Joaquin River near Stockton (Jassby and Van Nieuwenhuyse 2006). It is also supported by the Stockton DW ship channel low DO conceptual model, at: http://www.sjrdotmdl.org/concept_model/about.htm
This restoration will produce organic matter that will contribute to low DO conditions. Organic carbon could be transported out of this restored marsh and the flow patterns would take this to problematic locations. (Note other problems may be caused by water treatment plants). (See the water quality group discussion).

Magnitude = 3 - Medium
Importing BOD to the Stockton DWSC will likely exacerbate low dissolved oxygen conditions in this area. This outcome may include increases in the frequency and magnitude of low DO incidents. LOW DO incidents reduce habitat available to fish species in the lower San Joaquin River; low DO conditions also inhibit use of the lower San Joaquin River as a migration corridor for anadromous fish species including Chinook salmon, steelhead, splittail, and (potentially) sturgeon (Stockton DWSC conceptual model: http://www.sjrdotmdl.org/concept_model/bio-effects_model/adverse.htm)

"The available information suggests that BOD concentrations contributed from [immediately upstream of the DWSC] are the primary factor affecting DO concentrations in [the ship channel] (Lehman 2003 and Stockton DWSC conceptual model: http://www.sjrdotmdl.org/concept_model/bio-effects_model/adverse.htm).

"Direct sources of BOD to [the DWSC] include the San Joaquin River and local sources from Smith Canal, the Calaveras River, Fourteen Mile Slough, and the Turning Basin. The San Joaquin River where it enters the DWSC at Channel Point is the greatest source of BOD to the DWSC (Lehman and Ralston 2001). One author found that at least 60% of the NBOD and CBOD in the DWSC at Light 43 (near Rough and Ready Island) were derived from the San Joaquin River (Lehman and Ralston 2001). The San Joaquin River also contributed 65% of the organic carbon, at least 70% of the ammonia load, and 40–60% of the VSS at Light 43 (Lehman and Ralston 2001).

Nitrogenous (ammonia and organic nitrogen) inputs from the Stockton Waste Treatment Plant are a major factor affecting BOD variations in the DWSC (Lehman 2003) and DO concentrations in the DWSC. Carbenaceous sources may account for 30% of BOD and "the phytoplankton biomass load from upstream primarily produced the carbonaceous oxygen demand" Lehman et al. 2004: 405).

Certainty = 2 - Low
The magnitude and timing of BOD exports from restored marshes into the Stockton DWSC are uncertain. Modeling exercises would be needed to understand this effect.

Important Gaps in Information and/or Understanding

Data needed to more fully evaluate tidal marsh restoration actions

- Residence times (average and spatial variance in that value) are necessary to determine how much and what kind of food would be produced on site and exported from the site. Residence time projections also affect temperature and dissolved oxygen conditions and these are important attributes of physical habitat. Finally, residence times for particles of water could inform assessment of "residence" times for fish. There is a non-linear relationship between fish "residence time" and the benefit of the rearing habitat as, at high "residence times" new habitat may serve to delay important migratory activities whereas at very low residence times, the new habitat will have reduced benefit because fish (or at least those that behave like particles) will experience the habitat for only a short period.
- A study of predator-prey-habitat interactions for Centrarchid fish.
- Striped bass model is needed to compile and synthesize life history information. This should also include a research study of predator-prey-habitat interactions.
- Expected retention time on restored tidal areas to understand likely productivity and food export potential to local sloughs.
- More spatially comprehensive hydrodynamics to understand whether changed flow patterns will reduce or simply redistribute predator pressure.
- Hydrologic and sediment information about turbidity levels, duration, and consequences on species as related to the following: Increased ability for Delta smelt to locate food due to increased turbidity from increased velocities in larger channels.
- *Corbicula* monitoring data from previous restoration sites in the Delta, such as Liberty Island or Little Holland Tract, would provide greater information about the probability of colonization on this Cache Slough site.
- Better data on where and when Delta smelt lay their eggs would better allow us to assess the potential impact of inland silverside predation.
- Data collection and analysis of whether relevant predatory species would be displaced by the expected changes in hydrodynamics in these sloughs.
- Modeling of a situation in which predators are displaced from the sloughs, and analysis of whether this would result in a reduced predator population in this region, or whether predators would simply relocate to another part of the migration corridor where hydrodynamics are more suitable (i.e. what is the new distribution of low velocity/tidally influenced habitat that could be suitable to predators?).
- Data collection and analysis of whether other predatory species (i.e. pikeminnow and striped bass, which prefer riverine habitats) benefit from the altered hydrodynamics.
- Liberty Island is often referred to as a model of a successful restoration project. Monitoring data and new bathymetric data should be fully analyzed to determine the features that makes Liberty Island successful and to consider how to apply those features to other restoration projects in the Delta. Specifically, the bathymetric data could be turned into a Digital Elevation Model (DEM) and combined with the habitat type mapping (i.e. vegetation and open water) to illustrate how the restoration provides habitat for covered and other species. This would include documenting the quality of existing LiDAR data for the vegetation mapping.

Research Needs

- Restoration techniques that will prevent colonization by invasive species.
- Management practices that can control invasive vegetation, clams, and predators (centrarchids and inland silversides) and limit colonization of these sites.
- Run (and life-history) specific studies of Central Valley Chinook salmon and studies of steelhead use of tidal marsh habitats would be extremely valuable to defining magnitude of impacts to these populations and increasing certainty. Various tools (including genetic markers and otolith signatures of population origin) could be used to asses both growth and survival of salmonids in tidal marsh habitats as well as changes in life history characteristics (survival and fecundity) over the course of the life cycle that arise from residence in tidal marsh habitats. Currently, all of the evidence for benefits of tidal marsh on salmonids comes from steelhead and fall run populations located well to the North (where high temperatures and invasive predators are not as problematic). Translating these results to all Central Valley salmonid populations is unwarranted and could lead to disastrous "restoration" projects.
- In addition, data on nutrient flow from the marsh plain to juvenile fish rearing in the adjacent channels is essential to determining the value of restored marshes as a food source for pelagic fish larvae (i.e. longfin and Delta smelt).
- Greater understanding and more research is needed about the availability and production of food in tidal marshes. Export of organic material from the marsh plain and phytoplankton, zooplankton, and other organisms produced in intertidal channels into the Delta has not been studied.
- Potential negative effects of methylmercury exposure on covered fish species remain largely unknown. Based on published studies involving other (non-targeted) fish species, there is reason for concern regarding possible chronic effects caused by methylmercury exposure, including: endocrine disruption, reduced reproductive success, reduced predator avoidance, and reduced feeding efficiency. (See Mercury Conceptual Model, Alpers et al. 2008, Table 4, page 30). Research is especially needed to determine possible effects caused by exposure during early life stages.
- A better understanding is needed regarding the relationship of mercury methylation to the duration of wetting and drying events in areas that are intermittently inundated (i.e. tidal marsh and floodplain). Laboratory and field studies of mercury cycling involving sediments in tidal marsh and floodplain environments should quantify the duration of drying time and the extent of dryness necessary to change the oxidation-reduction character of iron, sulfur, carbon, and mercury in sediments such that microbial activity associated with mercury methylation is enhanced.
- Tropho-dynamic model of ecological interactions linking primary production to the food web structure and production flows into, through, and out of the tidal marsh system.
- Landscape-level models that address the effects of variation in structural features of the tidal marsh environment (e.g., tidal channel complexity, channel width, channel length, edge: area ratios, etc.) on the population or production dynamics of specific plants and animals
- Future research could generate simulations of generic “applications” of the DRERIP Conceptual Models. For example, the temperature model could be “applied” to generic landscape characteristics, such as a restoration site with specific shapes (bowl or gradation), to consider how temperature dynamics are affected on various spatial and temporal scales. This exercise would help managers understand where further detail is needed by taking the conceptual models to the next level by conducting simulations to apply the concepts to a landscape.

Assess Reversibility and Opportunity for Learning

Reversibility

No/Hard. The following on-the-ground actions would be needed to reverse this action:

1) levees would need to be reconstructed
2) newly created tidal sloughs would have to be regarded
3) sites would have to be dewatered
4) wetland vegetation would have to be removed
5) newly installed levees would need to be removed as necessary
6) monitoring pre, during, and post construction

Although this reconstruction is technically possible, there would be significant financial and regulatory costs. Prior to action reversal, the following planning activities would be needed:

1) geotechnical evaluations for levee reconstruction
2) engineering design
3) evaluate land options for areas subject to subsidence reversal actions
4) environmental permitting and associated agency ESA consultation, Mitigation planning

Opportunity for Learning

High

Comments (refer to specific sources of information that support the above determination and identify high priority research questions and testable hypotheses).

High: Implementation of this project can be designed such that different engineering designs can be compared. Numerous physical and biological components can be monitored and ideally, the monitoring data would be used to assess and refine modeling simulations of the restoration as a part of a comprehensive adaptive management program. Please see text in the worksheet for Cache Slough, HRCM 4, for details.

Appendix A Summary Tables Organized by Outcome

Table A1. Positive Outcomes

Outcome	Magnitude	Certainty
P1a: Increase rearing habitat area for Delta smelt.	1	2
P1b: Increase rearing habitat area for Fall-run Chinook salmon	2	2
P1c: Increase rearing habitat area for Splittail	2	3
P1d Increase rearing habitat area for Green sturgeon	2	2
P1e: Increase rearing habitat area for White sturgeon.	2	1
P2: Increase the availability and production of food in the Delta and Suisun Bay. All covered fish.	View #1: 3-4 View #2: 1-2	View #1: 3 View #2: 1
P3a: Locally provide areas of cool water refugia (Feb-Jun) for Delta smelt.	2	1
P3b1: Locally provide areas of cool water refugia (Feb-Jun) for spring-run salmon.	2	1
P3b2: Locally provide areas of cool water refugia (Feb-Jun) for fall run salmon	2	1
P3b3: Locally provide areas of cool water refugia (Feb-Jun) for steelhead.	2	1

Table A2. Negative Outcomes

Outcome	Magnitude	Certainty
N1a: Establishment of undesirable species such as SAV and Egeria	3	2
N1b: Establishment of undesirable species such as Non-native Centrarchids	4	2
N1c: Establishment of undesirable species …….. Corbicula	1	2
N1d: Establishment of undesirable species …….. Inland Silversides.	2	2
N2a: Potential for mercury methylation and local bioaccumulation … Covered fish species.	1	2
N2b: Potential for mercury methylation and local bioaccumulation Other species (not covered).	3	2 to 3
N2c: Potential for mercury methylation and local bioaccumulation … Human health.	2	3

N3a: Local effects of contaminants including toxicity from residual pesticides and herbicides …. Covered fish species.	1 to 2	1
N3b: Local effects of contaminants including toxicity from residual pesticides and herbicides ….. Other species (not covered).	1 to 2	1
N4a: Resuspension and export of contaminants to downstream areas … covered fish species.	1	2
N5a: Creation of a population sink due to longer residence times with associated increased exposure to predators and entrainment.	2	4
N6a: Production of organic matter that will contribute to low dissolved oxygen (DO) conditions.	3	2

Appendix B - Outcomes With Zero Magnitude

OP1a: Increase rearing habitat area (including physical and biotic attributes) for longfin smelt.

Longfin smelt do not occur frequently in this region. These fish do not appear to use tidal marsh habitats. The magnitude of this outcome is zero for this species.

OP1b: Increase rearing habitat area (including physical and biotic attributes) for steelhead.

Steelhead juveniles move through Delta from Jan-Jun, but mostly from late March-June. Salmonid model Fig 27. Steelhead conceptual model figure. The salmonid model indicates value of estuarine rearing varies across populations: (p15).

Magnitude = zero.
Outcome assumes that “rearing habitat area” (quantity) and/or food is limiting in this area. Model txt (p16)”Spring Chinook, or at least the Butte Creek population, pass quickly through the Delta, so habitat restoration there seems unlikely to do much for them. The same is probably true for late fall Chinook, and for steelhead.”

In other systems, steelhead use this kind of habitat but, the text notes, steelhead smolt in this system are large compared to other systems so research there is not likely to apply here. Steelhead will eat the types of food produced in this habitat. The DLO figure (Estuarine – growth) shows a low impact of this kind of habitat on competition – competition may have a moderate impact on growth.

Steelhead migrate through this area “mainly in April and May” (Salmonid model P 34.) High temperatures are common in this area during May (as indicated by an IEP gauge, rsan058, in the vicinity). Average daily temperatures exceed 20-21oC (beyond which sublethal effects accumulate; Reese and Harvey 2002 *and see* Richter and Kolmes 2005) during May in approximately 1/3 of years. In June, average daily temperatures exceed this critical threshold in almost every year. With warming that may occur under climate change projections, high temperatures may become more frequent and more extreme, even during April. Steelhead rearing in this proposed restoration site during May and June will probably be impacted by high temperatures and negative impacts could become more common with global warming.

Small benefits to some rearing steelhead may be largely offset by negative temperature effects to later rearing steelhead. This region has been highly altered by anthropogenic chemical inputs, channel modification, and invasive species (e.g., Brown and May 2006). Water quality in this area is notoriously poor: lethally low DO conditions occur throughout the year in the nearby Stockton Deepwater Ship Channel (including, occasionally, during the fall-run juvenile emigration period; http://www.sjrdotmdl.org/concept_model/bio-effects_model/lifestage.htm). In addition, the area is dominated by SAV and associated Centrarchid predators. Without action to correct water quality and flow problems in this area, construction of tidal marsh habitat is not likely to be successful in restoring native fish.

Certainty = 3 - Medium
No direct research on use of shallow estuarine habitat by steelhead in this system. Any effect will be limited to the San Joaquin population and to those times of year when temperatures are not too high in the target area.

In summary, estuarine habitat is not likely to be the limiting factor for steelhead from the San Joaquin River system.

OP2a: Locally provide areas of cool water refugia for winter-run salmon.

Magnitude = 0- Zero.
There will be no benefits of this restoration to winter-run salmon because this run passes through the region during a window of time when temperatures are not believed to be highly stressful to salmonids.

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

OP2b: Locally provide areas of cool water refugia for late fall-run salmon.

Magnitude = 0- Zero.
There will be no benefits of this restoration to late fall-run salmon because this run passes through the region during a window of time when temperatures are not believed to be highly stressful to salmonids

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

OP2c: Locally provide areas of cool water refugia for spring-run salmon.

Magnitude = 0- Zero
Spring run do not occur in this south Delta area and so cannot receive the benefits of this restoration.

Action:

HRCM8: East Delta ROA Tidal Marsh & Shallow Subtidal Restoration

Restore 1,300 acres to tidal action and vegetated tidal marsh and 300 acres of shallow subtidal habitats on portions of Canal Tract, Terminus Tract, and Bract Tract in the East Delta ROA (see Figure 1, below).

Evaluation Team: Tidal Marsh Workgroup

Dave Harlow (chair); Stuart Siegel (coach); Dan Kratville; Jon Rosenfield; Chris Enright; Armin Munevar; Wim Kimmerer; Amy Richey; Charlie Alpers; Kateri Harrison (note taker).

Date of Last Revision: May 21, 2009

Approach

1. Construct levees to isolate deeply subsided lands and protect property.
2. Plant tules or place fill material to raise elevations of shallowly subsided lands.
3. Create channels and/or berms to encourage the development of dendritic tidal channels.
4. Breach levees to reintroduce tidal exchange to leveed lands.
5. The canal levees of the eastern alignment of an around-Delta conveyance facility may be incorporated into the design of intertidal emergent wetland restoration. For example, in locations where the conveyance canal is located at elevations at or below elevations suitable for restoration of intertidal marsh, marsh may be restored to the east of canal levee, with the canal levee forming the western boundary of the restored marsh.

Intended Outcomes as Stated in Conservation Measure

1. Increase rearing habitat area for Sacramento splittail and San Joaquin Chinook salmon and possibly steelhead.
2. Increase the production of food for rearing salmonids, splittail, and other covered species.
3. Increase the availability and production of food in the east and central Delta by exporting organic material from the marsh plain and phytoplankton, zooplankton, and other organisms produced in intertidal channels into the Delta.
4. Locally provide areas of cool water refugia for Delta smelt.

Conceptual Model Information Regarding Intended Outcomes

The drivers and outcomes discussed in this worksheet are described in the following DRERIP conceptual models: Temperature, Delta smelt, Foodweb, Tidal marsh, Corbicula, Sediment, and Mercury. The references listed at the end of this document provide additional information.

Assumptions

Provided in BDCP Conservation Measure

1. Restoration would occur on Terminus Tract, Bract Tract, and Canal Tract.

Added by Evaluation Team

1. Restoring tidal marsh habitat on the different tracts of the East Delta ROA will have varying levels of both positive and negative effects. For example, some of tracts may be more efficient at the methylization of mercury and so may have a higher magnitude score for an associated negative outcome. Differences in hydrology, topography, soils, and land-use history will also manifest as distinctions in success of this action among the tracts. BDCP's estimated extent of restoration types based upon elevation for each sub-area is presented in Appendices C and D.

2. The time frame for realizing restoration benefits depends upon the approaches used. Reversal of subsidence on restored areas can take several years to a decade or more depending on starting elevations. The accretion rate depends on sediment supply and biomass accretion which depends on site-specific conditions. Sediment supply in the Delta is generally very low (Schoellhamer et. al., 2007).

3. Efforts to reverse subsidence before active restoration would be focused on the more deeply subsided portions of these landscapes, i.e., lands more than 6 feet below low tide. There is a hypothesis that shallow open water regions located contiguous to emergent tidal marsh provide enhanced ecosystem complexity and functions compared to those tidal marsh habitats located directly adjacent to deeper sloughs. Although this hypothesis has not been tested, preliminary information on current conditions at Liberty Island and Little Holland Tract suggest support. However, the details of these sites are not readily available to the broad research community at this time and so the information is anecdotal. This assumption also includes a time limit to allow for subsidence reversal so that restoration of an entire parcel is not delayed indefinitely. To speed up the subsidence reversal process, an alternative method would be to separate low-lying areas with new levees and reconnect those areas after subsidence reversal is accomplished.

4. Source of fill material will be identified and use of all material, including dredge spoils, will be approved by the RWQCB.

5. Tidal water would travel through Sycamore Slough.

6. Water output from the site, post-restoration, will meet water quality standards.

7. Prior to implementation, a Phase I Environmental Assessment with on-site sampling to assess legacy and other soil contaminants (i.e. mercury and pesticides) would be completed.

Problem(s) with Action as Written:

1. Since rearing habitat for juvenile fish by necessity includes local availability of food, the evaluation team merged the Intended Outcomes 1 and 2 (tidal marsh, rearing habitat, and local food) into one outcome.
2. Existing sloughs in the East Delta ROA are currently infested with aquatic weeds and function as a "biological desert". Remediation of this existing situation is not described in this action.
3. Fish will need to traverse the lower reaches of barren Hog and Sycamore sloughs.
4. This area's very poor exchange rates with the broader Delta will likely offer little benefit for exported production.
5. Loading of fill material on top of a shallow island may compress the underlying soils. This approach may not yield the intended result. A close study of existing soil conditions including analysis of the local soil map is needed to further evaluate this issue.
6. The conservation measure would benefit from an explicit recognition that restoration of tidal marsh functions on subsided landscapes, especially those subsided below emergent vegetation elevations, will take many years to many decades. In the interim, restoration sites below vegetation elevations will function as shallow subtidal habitat.
7. It is unlikely that intertidal mudflats will develop in the Delta because dominant intertidal emergent vegetation species in the Delta can grow throughout the tidal range and just into shallow sub tidal elevations (Brown 2003, Simenstad et. al., 2000 as cited in Schoellhamer et. al., 2007, p.26).

Scale of Action:

Small

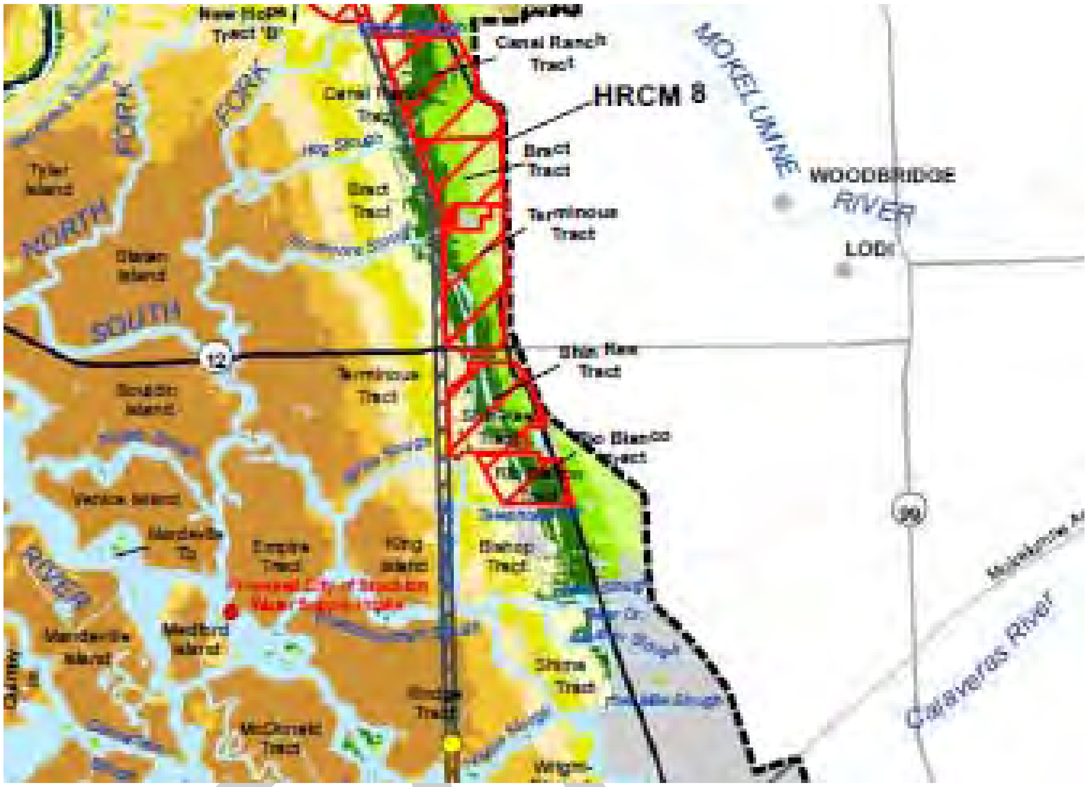
Rationale:

This is a small scale restoration action due to its limited spatial extent. As listed in Table1 below, the Delta currently has approximately 21,600 acres of tidal marsh habitat (baseline). Additionally, 67,000 acres of diked and other lands have been identified as potentially restorable to tidal marsh (neglecting effects of restoration on reducing tidal range). The proposed 1,300 of tidal marsh plus 300 acres of shallow sub-tidal restoration options would increase marsh acreage 6% above current conditions. Significant amounts of the 67,000 acres of identified restorable lands are highly constrained such that they could not be restored in the near term (South Delta and Netherlands alone account for 31,000 acres of the 67,000 acres). Therefore, this action also represents an important part of the potentially restorable tidal marsh lands.

Table 1. Summary of Tidal Marsh Acreages

Area	**Acreage**	**Source**
Delta (entire Delta proper)	738,000	DWR, 2009
Historic tidal marsh/wetlands in Delta	525,000	TBI, 2002
Current extent of tidal marsh/wetlands in Delta.	21,600	TBI, 2002
Restorable intertidal lands within Delta.	67,000	CA DVSP, 2008, Table 1, p.77.
Proposed East Delta tidal restoration (this action)	1,300 tidal marsh 300 sub-tidal	BDCP, 2009

Figure 1. East Delta Restoration Opportunity Areas



Evaluation Summary

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

Note: Negative outcomes are scored relative to baseline conditions. These negative mechanisms may also decrease the certainty that positive effects of site restoration will be realized. Appendix "A" contains the above information in summary tables that are organized by the numerical order of the outcomes, rather than species.

Outcomes with Zero Magnitude

During the Evaluation process, several of the outcomes identified by BDCP early in the process, were found to have a zero magnitude. These outcomes are listed below and their evaluation is provided in Appendix B.

- OP1. Increase rearing habitat area (including physical and biotic attributes) for longfin smelt
- OP2. Increase rearing habitat area (including physical and biotic attributes) for Delta smelt
- OP3. Increase rearing habitat area (including physical and biotic attributes) for steelhead.
- OP4a: Locally provide areas of cool water refugia for winter-run salmon.
- OP4b: Locally provide areas of cool water refugia for late fall-run salmon.

Other Potential Negative Outcomes Identified, Not Evaluated

During the course of this evaluation, the tidal marsh team identified one potential negative outcome that it did not evaluate due to lack of time. It is recommended that this potential outcome be evaluated at some point in the future when additional time is available.

- ON1. Pesticides for mosquito control.
- ON2: Increase in the availability of selenium
- ON3: Resuspension and export of contaminants to downstream areas effects on non-covered wildlife species

Relation to Existing Conditions:

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

No

Nature of Change:

This small scale action to restore 1,300 acres of tidal marsh and 300 acres of shallow subtidal habitat may change the environment on a local scale but not to such an extent that our current understanding of boundary conditions (Harrell et al 2008), hydrodynamics, and ecological processes in the Delta would change.

Overview of Productivity Import-Export

The Cache Slough evaluation worksheet (HRCM4) provides a complete discussion of productivity levels, import and export. Here we describe how conditions may differ from Cache Slough in order to provide the Conservation Measure evaluation appropriate specificity.

- East Delta has less tidal exchange (compared to Cache) due to geographic location (farther away from a river channel etc).
- The small area to be restored in East Delta ROA may result in less primary production (compared to Cache).
- May experience increased primary production compared to other restoration sites because its easterly location offers warmer spring and summer temperatures. However, the scale of the action is small in size and it is highly uncertain whether any of this production will be exported or will benefit covered fish species.

Potential Positive Ecological Outcome(s)

Outcome P1: Increase rearing habitat area (including physical and biotic attributes) for covered fish species.

As indicated at the beginning of this worksheet under the section entitled "Problems with Action", the team decided to merge two Intended Outcomes (rearing habitat and local food) into one outcome, P1, as shown below because rearing habitat for juvenile fish by necessity includes local availability of food. This outcome includes food (both primary and secondary production) produced within the vegetated marsh, within marsh channels, and within the subtidal areas adjacent to the vegetated marsh. General information that applies to salmon runs is provided in the worksheet for HRCM 4 – Cache Slough, Outcome P1c on page 15. Please note that green and white sturgeon are not known to utilize the Cosumnes and Molkemne River systems and so these species are not listed in the analysis below.

P1a. San Joaquin River/eastside Fall-run Chinook salmon & steelhead

General Observations: Fall-run juveniles move through the Delta from in the winter and spring (Williams and Rosenfield, In preparation, figure 3 and see also page 15 that shows the value of estuarine rearing varies across runs). Tidal exchange in some of these marshes will be hard to accomplish and residence times in the channels leading to the Marsh will be high. This will expose emigrating salmon and steelhead to poor habitat conditions for extended periods and delay successful emigration.

Magnitude = 2 - Low
Outcome assumes that "rearing habitat area" (quantity) and/or food is limiting. Page 16 of Williams and Rosenfield, In preparation, states that "Fall Chinook […] could benefit strongly from tidal marsh restoration". Fall Chinook generally enter estuarine habitats at a small size and the text anticipates benefits from additional rearing/growth opportunities. Fall run will eat the types of food produced in this habitat.

San Joaquin River and eastside fall-run migrate through this area from January and into June, with a pulse in May ((Williams and Rosenfield, In preparation) Figure 3). High temperatures are probably common in this area during May (as indicated by IEP gauges in the lower San Joaquin River, rsan 007 and rsan058). Average daily temperatures exceed 20-21^{o}C (beyond which sublethal effects accumulate; Reese and Harvey 2002 and see Richter and Kolmes 2005) during May in many years. In June, average daily temperatures probably exceed this critical threshold in almost every year. With warming that may occur under climate change projections, high temperatures may become more frequent and more extreme, even during April. Steelhead rearing in this proposed restoration site during May and June will probably be impacted by high temperatures and negative impacts could become more common with global warming.

The limited scale of this restoration proposal, the small number of fall-run likely to rear in this area, and the relative isolation of the proposed restoration sites from migratory corridors make the likely magnitude of this outcome undetectable. Benefits to some rearing Chinook salmon may be largely offset by negative temperature effects to later rearing steelhead.

Certainty = 2-Low
Because of the small scale of this project, its relative isolation from salmon migratory corridors, the high temperatures that are likely to persist through a large portion of the rearing season and the many other factors limiting fall run production in the San Joaquin River, it is moderately certain that the positive magnitude of this action will be minimal at best.

Establishment of *Corbicula*, could limit, if not eliminate the productivity benefits of the restoration to Chinook salmon. See Negative Outcome N1b. Similarly, colonization by invasive predators could result in added mortality that would counteract any benefits of restoration (especially if SAV invasion facilitates predation success).

P1b. Splittail

General Observations: The relationship between the drivers and outcomes is described in Kratville, 2008 on pages P1h Pg 12, 13, 14, 15.

Magnitude = 2 Low
While more tidal marsh will help rearing of juvenile splittail, the expected benefit to the overall population is medium. Sacramento splittail population abundance is limited by the lack of floodplain inundation to provide spawning habitat. When large scale inundation occurs, splittail population abundance is high for several years following the inundation event. Long periods without floodplain inundation results in reduced splittail population abundance. Splittail do not appear to be habitat limited at other life history stages.

Certainty = 3 - Medium
Whether the proposed restored rearing habitats will result in increased splittail population abundance is not certain. Although the restored habitat will increase the opportunity for rearing juveniles to feed during their downstream migration, tidal marsh does not appear to be a limiting factor in splittail abundance compared to floodplain inundation. The bulk of the adult splittail population resides in the brackish areas of Suisun Marsh. It is anticipated that most of the restored marsh in this ROA will be freshwater and so will only provide habitat for juvenile fish migrating into Suisun Marsh. This restoration may not provide a new population center or increase the numbers making it to Suisun Marsh. The restoration site is not located directly downstream of a floodplain and so its use by out-migrating fish may be limited.

Establishment of *Corbicula*, could limit, if not eliminate the productivity benefits of the restoration to splittail. See Negative Outcome N1b. Similarly, colonization by invasive predators could result in added mortality that would counteract any benefits of restoration (especially if SAV invasion facilitates predation success).

P1c. Green Sturgeon

General Observations: The basic relationship between drivers and outcomes is described in Israel and Klimley, 2008, pages P1i Pg 4, 8, and 9.

Magnitude = 2 - Low
Information on green sturgeon diets and physical habitat needs as juveniles in the Delta is limited. Other species of juvenile sturgeon located in other systems do feed on drifting insects (Radtke 1967 and McCabe, G et al. 1993). This area of the Delta will not provide extensive mud bottoms as found in lower portions of the estuary. Soft bottom benthos are a food resource for the sturgeon. Most habitat limitations for green sturgeon appear to occur outside of the restoration area (i.e. upstream and downstream), as described on pages 4, 8, 9 in Israel and Klimley, 2008 and pages 19-21 of Israel et. al., 2009. It is unknown to what extent adult sturgeon used freshwater tidal marsh for foraging. The impact to individual sturgeon may be low but the extreme loss of freshwater tidal marsh in the Delta may have lowered the carrying capacity of the entire system for sturgeon. See pages 4, 8, 9 in Israel and Klimley, 2008 and pages 19-21 Israel et. al., 2009 for more detail.

Certainty = 2- Low
There is minimal certainty about whether this proposed restoration will benefit sturgeon as described in this outcome. The minimal certainty is due to the lack of research on this aspect of sturgeon biology/ecology in the Delta. Most of the available information on sturgeon diets and predator/prey relationships is based upon other species of sturgeon, located outside of this system.

P1d. White Sturgeon

General Observations: The basic relationship linking drivers to outcomes is described in pages 1j, 19, 20, and 21 in the DRERIP White sturgeon model (Israel et. al., 2009).

Magnitude = 2 -Low
Information on white sturgeon diets and physical habitat needs as juveniles in the Delta is limited. Other species of juvenile sturgeon (located in other systems) do feed on drifting insects. . This area of the Delta will not provide extensive mud bottoms as found in lower portions of the estuary so benthic food items are expected to be limited in this restoration (Siegel, personal communication, Feb. 2009). Habitat limitations for white sturgeon appear to occur upstream and downstream of the restoration area (i.e. outside the ROA).

Certainty = 1 - Minimal
There is minimal certainty about whether this proposed restoration will benefit sturgeon as described in this outcome. The minimal certainty is due to the lack of research on this aspect of sturgeon biology/ecology in the Delta. Most of the available information on sturgeon diets and predator/prey relationships is based upon other species of sturgeon, located outside of this system.

Outcome P2: Food resources (i.e. organic material from the marsh plain and organic carbon, phytoplankton, zooplankton, and other organisms from intertidal channels) produced on the restored marsh will be exported, via tidal flow, and contribute to food availability downstream in the eastern and central Delta.

P2a. All covered fish species

General Observations: The Tidal Marsh and Foodweb models [Kneib et. al., 2008, page 9 and Durand, 2008, section 2.16)] provide a general indication that there may be a linkage between tidal marsh habitat as a driver and increases in availability and production of food resources as an outcome, but that the mechanism for this linkage may be movement by fish. The tidal marsh conceptual model also states that freshwater tidal marshes are net exporters of high-quality organic production (page 2 in Kneib et. al., 2008). See also Dame et al. 1986, Kimmerer and McKinnon 1989, Kneib 1997, Lucas et al. 2009. Please see the evaluation worksheet for action # HRCM4-Cache/Yolo, Outcome P3, for more details about **Tidal Marsh Contributions to Exported Production.**

There was disagreement within the evaluation team regarding the magnitude and certainty of expected benefits of tidal reintroductions with regard to the export of food (phytoplankton, zooplankton, insects, and small fish) to areas downstream of Rio Vista and the likely benefits to covered fish species. In the spirit of presenting the scientific discourse, both points of view are captured below.

Two key questions discussed were: (1) can we predict the sign of the flux of productivity (i.e. will the restoration area be a source or a sink for primary and secondary productivity); and (2) will there be adequate advection to move material out of the restoration area and downstream to Rio Vista (assuming the restoration area is a source of productivity, as opposed to a sink). Additional information and analyses is needed to better answer these key questions. To develop this additional information, the team recommends future development of a Tropho-dynamic model as described in the section on page 41 entitled "Research Needs".

Viewpoint #1

Please see the text of Outcome P3 in worksheet HRCM4 – Cache Slough for additional background information about Viewpoint #1.

Magnitude = 3-4 – Moderate to High
Without advective connection, restoration will still have significant productivity benefits to covered fish species and to many other species due to providing areas of highly functional habitat in conjunction with restoration elsewhere that collectively provide fish species a range of options that spread risk through exploiting available resources when they are present. Refer to Ted Sommers, IEP Estuarine Ecology

Team or CAERS poster. In addition, these areas would export that productivity through the "trophic relay" concept described in the tidal marsh conceptual model (fish export the productivity).

Certainty = 3 – Moderate
Certainty is reduced by the potential for establishment of invasive clams that could consume substantial portions of phytoplankton and hinder zooplankton productivity.

Viewpoint #2

Please see the text of Outcome P3 in worksheet HRCM4 – Cache Slough for additional background information about Viewpoint #2.

Magnitude = 1-2 Minimal to Low
The implied relationship is that restored tidal marsh will export nonliving and living organic matter including plankton and fish, thereby supporting foodwebs of the upper estuary. An implicit assumption is that any increase in the area of shallow habitat would result in enhanced plant productivity some of which would be exported.

Certainty = 1 - Minimal
The sign of the signal is difficult to determine, except for total organic carbon, most of which is dissolved. Although dissolved organic carbon (DOC) will likely flow out of the marsh, fluxes of other components may be in or out (Kneib et. al., 2008, page 9). Colonization by invasive clam species can wipe out the food web

production effect entirely. We have no certainty at all that they will not colonize. In addition, colonization of the site by vertebrate consumers (e.g, inland silverside) can also significantly reduce the amount of food available for export beyond the site boundaries (Moyle 2002). There is evidence from within this system (Dean et al. 2005) that restored marshes can act as sinks for certain zooplankters; in this case, the sign of the signal would be negative.

Outcome P3: Provide local areas of cool water refugia for Delta smelt and salmonids

The cause and effect relationship associated with this outcome is described in Stacey and Monismith 2008, Malamud-Roam 2000, and Enright 2008. Considering the landscape scale (medium) of the action, the relationship between tides, physiography, and water temperature could be moderate. The relationship between drivers (wind, insolation, fetch, tides, currents) and linkages (long-wave, short wave, latent, and sensible heat flux) is complex and may produce both warmer and cooler water on a variety of time and space scales. Larger spatial gradients of water temperature will likely occur. The frequency of threshold temperatures for various species is uncertain. See Stacey and Monismith (2008), Malamud-Roam (2000), Enright (2008).

For more details, please see the introductory text in the HRCM 4- Cache Slough action worksheet and the Suisun Marsh Tidal Marsh Restoration Worksheet, specifically, Outcome P4.

P3a: Delta smelt

Magnitude: 2 - Low
The spatial extent of cool water refugia could be relatively limited. However, in some cases a large effect could be felt across relatively large area across the range. Please refer to the discussion located in HCRM4 – Cache Slough Restoration Action, Outcome P4, page 25 for more details.

Certainty: 1 - Minimal
The basis for our understanding is a single unpublished study in Suisun Marsh. The extent to which this effect may transfer to the restoration site, and to which Delta smelt and salmon will take advantage of it, cannot be predicted.. Please refer to text in outcome P4 of HCM4 – Cache/Yolo Restoration Action Outcome P4, page 27 for more details.

P3b. Salmonids

High temperatures are currently rare during May (as indicated by IEP gauges rsac075 and rsac054; Enright *pers. comm.*). Temperatures exceeding 20-21°C (beyond which sublethal effects accumulate; Reese and Harvey 2002 *and see* Richter and Kolmes 2005) are more common and widespread in June, July, and August (as indicated by IEP gauges rsac075 and rsac054; Enright pers. comm.). With warming that may occur under climate change projections, high temperatures may become more frequent and extreme. Thus, Chinook salmon (spring-run and fall-run) and steelhead rearing in this proposed restoration site during June and July will probably be impacted by high temperatures. Forces that reduce those temperatures may improve survival, growth and smoltification success.

Benefits are limited to those emigrants rearing in this habitat after May, when temperatures in this region increase above optimal rearing threshold of 12-16°C (Marine and Cech 2004). These benefits are expected to be transient (on annual and decadal time scales) and will never effect more than a small fraction of populations for any of the covered species (unless there is a cumulative impact from numerous restoration that produce the same cooling effect. Also, as mentioned in the description, this phenomenon is transient over time as the timing of tidal cycle shifts. Complexity of thermodynamics in conjunction with local geomorphology and long-term climate change and sea level rise introduce considerable uncertainty.

In addition to the runs listed below, please see Appendix B for winter-run etc.

P3b1: Spring run salmon

Magnitude = 2- Low.
This outcome modifies Outcome P1 (creation of habitat). In evaluating that outcome, benefits of this action were interpreted in the light of unfavorable temperature conditions that occur in the area during late-spring and summer. To the extent that the tidal flooding/cooling phenomenon occurs on this restoration site (a function of geography and restoration design and site elevations) during the period of potential thermal stress (May through end of summer), it may provide some relief from the effects of thermal stress *for those salmon runs that migrate through this region at this time (fall and spring run and steelhead).* That benefit impacts only the proportion of the population that migrates at this time and only the proportion of the population that migrates through this area.

Certainty = 1-Minimal

Certainty is minimal for reasons similar to that described in P3a, above. This outcome is highly dependent upon highly variable ecosystem processes. Although scientists have a reasonable understanding at the general level, the range of data needed to evaluate at the action scale is lacking.

P3b2: Fall run salmon

Magnitude = 2- Low
Beneficial effect occurs for only a portion of the salmonid population passing through this region during a particular and narrow window of time.

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

P3b3: Steelhead

Magnitude = 2- Low.
Beneficial effect occurs for only a portion of the salmonid population passing through this region during a particular and narrow window of time.

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

Potential Negative Ecological Outcome(s)

Outcome N1: Establishment of undesirable species (such as Egeria) that will prey or compete or alter habitat conditions for covered fish.

Harmful invasive species have the potential to cause two types of adverse effects. First is to worsen conditions relative to the existing baseline; i.e., creating an attractive nuisance. Second is to detract from achieving the positive benefits the action could provide. The magnitude and certainty scores below are based upon an assessment relative to baseline conditions. The scores below for N1a to N1d do not represent the potential to distract detract from the positive benefits of the action because these deductions were considered i by reducing the certainty scores for positive outcome # P1. Where appropriate, the impacts associated with the establishment of harmful invasive species on the restored marsh are discussed below.

N1a: Submerged Aquatic Vegetation (SAV) (including *Egeria*)

General Observations: As described in the conceptual model, the establishment of SAV is controlled by local flow conditions and substrates (Anderson, In Preparation). Many aspects of SAV physiology are influenced by local flow conditions including turbidity and to some extent flow velocity which if too high can scour suitable substrate precluding SAV establishment. The initial establishment of SAV is an intermediate outcome and the development of a large sustainable SAV population is the final outcome.

The basic relationship between drivers and outcomes is described in the DRERIP aquatic vegetation conceptual model on pages 8, 9 10 and Figure 2 (Anderson, In preparation). Please note that establishment of SAV reduces the certainty that the positive outcome, P1 will occur. This has been noted in the scoring for P1.

Magnitude = 3 - Medium
The establishment of SAV in general is controlled by local flow conditions and substrates. Local flow conditions control many aspects of SAV physiology, most importantly in this area turbidity. In nearby Liberty Island where turbidities are generally higher due to wind wave action, SAV is restricted to shallow near shore areas (Ustin et al. 2008). If turbidities are high in the restoration area, then SAV establishment and growth may be reduced to levels similar to Liberty Island. If not, there is the potential for SAV amounts similar to Franks Tract. The substrates in this area would be expected to support establishment of SAV (Anderson, In preparation). Small to moderate fractions of all the covered fish species may experience highly significant but localized effects due to SAV and therefore the net effect is medium.

For this outcome, the baseline condition is that much of the existing 21,600 acres of Delta tidal marsh is infested with submerged aquatic vegetation (Ustin, 2008). The restoration of a tidal marsh that eventually becomes infested with SAV is significant. Large, sustainable populations of SAV will produce significant changes in water quality (turbidity, pH, DO and temperature), or water flow characteristics (velocity and direction), which in turn can affect the quantity and quality of sediments (Anderson, In Preparation).

Eventually, the clarity of water entering the site from upstream will increase by lowering velocities and allowing particulates to settle out of the water column. This increased water clarity could increase predation of fish entering the site from outside areas (i.e. predators now have greater visual range). One type of predator, Centrarchid fish, is strongly associated with SAV and increased Centrachid populations may create a population sink for native fish at this location, as discussed in N1b, below. In summary, this action will worsen conditions beyond that of baseline conditions and small to moderate fractions of all the covered fish species may experience highly significant but localized effects due to SAV. Given the rarity of Delta smelt, the impact of SAV establishment could be particularly significant on this species.

Certainty = 2 - Low
There is high uncertainty about the initial colonization and ultimate patch distribution of SAV on the substrate. As the substrate softens over time, it may be more conducive to SAV establishment and growth (i.e. bed characteristics are described as a driver in the conceptual model). It is well documented that the physical structure of SAV facilities slower water velocities which allows sediment particles to settle, thereby reducing turbidity, locally and creating a positive feedback loop for more SAV establishment (Anderson, In Preparation). The effect of specific restoration site substrate, how those substrates may change over time after restoration, and the role of flow velocity at these locations is not well understood (Anderson, In Preparation).. The uncertainty of this outcome is largely dependent on how the final marsh system functions (Anderson 2007). Future changes to water salinity in the eastern Delta may affect the certainty score related to this outcome.

N1b: Non-native Centrarchids

General Observations: Centrarchid fish, as an assemblage, cover a range of ecological niches in the Delta. They are competitors for resources as well as predators on native fish. The magnitude of this effect is dependent on the assemblage of centrarchids that invade and the size of the populations. This is in turn partially dependent on the amount of SAV invasion into the restored system.

Please note that establishment of centrachids reduces the certainty that the positive outcome, P1 will occur. This has been noted in the scoring for P1. The relationship among drivers and outcomes is described in Brown and Michniuk 2007; Grimaldo et al. 2004; Nobriga and Feyrer 2007; Nobriga et al. 2005).

Magnitude = 4 - High
For this outcome, the baseline condition is that much of the existing 21,600 acres of tidal marsh are excellent habitat for Centrarchid fish where they are associated with adjacent deeper water. This is illustrated by the large number of Bass Tournaments that occur in the Delta. The Delta is a stop on the national professional bass fishing circuit with $100,000 prizes. This action could worsen conditions beyond that of baseline. Centrachids are a concern because they prey upon and compete for food and other resources with native covered fish.

The establishment of Centrarchids in conjunction with SAV is well documented, especially in this portion of the Delta (Brown and Michniuk 2007; Grimaldo et al. 2004; Nobriga and Feyrer 2007; Nobriga et al. 2005). Centrarchid fish, as an assemblage, cover a range of ecological niches in the Delta. They are competitors for resources as well as predators on native fish. The magnitude of this effect is dependent on the assemblage of Centrarchids that invade and the size of the populations. This is in turn partially dependent on the amount of SAV invasion into suitable habitat areas of the restored system. The extent of their impact on the native ecology of the restored marsh is partially dependent on the extent of SAV establishment and patch size. It is highly probable that Centrarchid fish will become established in this area as they have everywhere else in the Delta.

Certainty = 3 - Medium
It is highly probable that Centrarchid fish will become established on this restoration site. However, once established, the ultimate size of the centrachid population and their impacts to local native fish are less certain. In areas with low SAV patch size, the numbers of Centrarchid fish and their presumed impact on native fish are lower then where the opposite is true (Brown and Michniuk 2007).

N1c: *Corbicula*

The relationship between drivers and outcomes is described in the DRERIP Corbicula Conceptual Model (Thompson et. al., In revision).

Consequences of *Corbicula* establishment. If established, *Corbicula* would likely have a significant effect on food web dynamics because it consumes phytoplankton in shallow areas and/or consumes the productivity of shallow areas exported to channels to such a high extent that it exhibits top-down trophic control. *Corbicula*'s consumption of primary productivity represents a significant limiting factor throughout the Delta that could greatly reduce productivity benefits of restoration efforts (Thompson et. al., In revision). According to the *Corbicula* model (Thompson et. al., In revision page 11), no local studies have been undertaken to indicate whether *Corbicula* feeding has reduced zooplankton populations either through competition or direct predation. In this case, the baseline condition is that much of the Delta is infested with *Corbicula*. The restoration of tidal marsh which may also become infested with *Corbicula* at some future time would not represent a significant change above baseline conditions. Establishment of *Corbicula* would however, consume much of the positive benefits that were previously discussed above under positive outcomes.

Potential Control Options. There are no stressors identified that can limit the success of Corbicula in a significant manner. However, salinity can limit the spatial distribution of this species and food limitation is a source of stress (Thompson et. al., In revision, pages 8 and 13). The *Corbicula* conceptual model indicates that the only meaningful method to control their presence/abundance is salinity. This control method would require salinity intrusions into the restoration area of sufficient duration and at the appropriate times of year to have a meaningful effect. The conceptual model does not specify the duration and timing which might be most effective during recruitment. Water temperatures may influence the effectiveness of both recruitment and control measures.

Magnitude: 1- Minimal
Corbicula can control phytoplankton biomass development in shallow areas, or consume the productivity of shallow areas exported to channels. Corbicula is a significant limiting factor throughout Delta (Thompson et. al., In revision). For this outcome, the baseline condition is that much of the Delta is infested with *Corbicula*. The restoration of tidal marsh that eventually becomes infested with *Corbicula* would not represent a significant change above baseline conditions.

Certainty: 2 - Low

The timing and extent of colonization by *Corbicula* cannot be predicted for specific restoration sites due to lack of data.

Corbicula are prolific reproducers and colonizers of newly available habitats in salinities below 2 ppt. Source populations can come from elsewhere within the Delta or from upstream tributary populations. *Corbicula* can establish on soft and hard substrates and on vegetation and they can colonize intertidal zones as well as deeper water. (*Corbicula* model). Based upon the biology of the species and the physical setting of the restoration site, the probability of *Corbicula* establishment in the east Delta restoration areas appears to be high, but ultimately cannot be predicted, partially due high variability in environmental conditions. The low certainty score considers the probability and extent of potential establishment.

Corbicula monitoring data from previous restoration sites in the Delta, such as Liberty Island or Little Holland Tract, would provide greater information about the probability of colonization on these east Delta sites. More information would improve the certainty rating. However, such data and analysis was not made available to the evaluation team.

N1d: Inland Silversides Effects on Delta and Longfin Smelt

General Observations

Inland silversides (*Menidia beryllina*) are highly tolerant of warm water, salinity variability and are trophic generalists compared to Delta smelt (Moyle 2002). Inland silversides are the most numerous fish in Suisun Marsh shoreline habitats (Matern et al. 2002), and the most numerous fish in shallow Delta habitats (Nobriga et al. 2005, Brown and May 2006). The Delta smelt model (page 3) includes intraguild competition with inland silversides as one of the top five in-Delta stressors to Delta smelt. Inland silversides are thought to be a major predator of Delta smelt eggs (Bennett and Moyle 1996 and Bennett 2005 in the Delta smelt conceptual model pg 12). In the laboratory, inland silversides reduce Delta smelt size relative to controls when they are reared together (Bennett 2005).

Inland silversides are also treated in the longfin smelt model. Moyle (2002, in Rosenfield, 2008) suggested that based on timing of arrival in the Estuary and subsequent longfin population response, inland silverside might have had a major impact on longfin population dynamics. However, the model states that inland silverside prefer shallow water habitats where juvenile and sub-adult longfin are rare, thus, their impact as predators of juvenile and sub-adult longfin is probably slight (Rosenfield, 2008, pg. 17). Spawning locations for longfin are unknown, so it is not known whether competition from inland silverside for spawning territory is a factor in their decline.

However, Delta smelt evolved with other intraguild competitors, including longfin smelt, and have survived with Striped bass (introduced in 1879). Interaction between silversides and Delta smelt in the wild may be limited because Delta smelt typically inhabit offshore environments, while inland silversides typically inhabit shoreline habitats. Increased shoreline habitat would presumably increase the carrying capacity for Inland silversides. However, predator-prey interaction between Delta smelt and Inland silversides in the wild is speculative. Silversides may eat Delta smelt eggs or larvae if the eggs and larvae occur on the shorelines. It has not been shown that Inland silversides reduce calanoid copepods (Norbriga and Herbold, 2008, page 32), so they may not effectively compete with Delta smelt for prey.

Williams and Rosenfield, In preparation; Israel and Klimley, 2008; Kratville**,** 2008); and Israel et. al., 2009 do not mention inland silversides so this evaluation assumes no adverse effects and focuses its evaluation on Delta smelt and longfin smelt.

Magnitude = 2 (low)
Inland silversides are the most abundant fish in shallow-water habitats in many areas of the Delta and may currently contribute to local depletions of zooplankton otherwise available to native fishes within these areas. Additionally, they may prey on embryos of species who lay eggs in these shallow areas (Moyle 2002). The crash of Delta smelt populations coincided with invasions of inland silversides into the estuary (Bennett and Moyle 1996). This action may change conditions relative to baseline by attracting (via restored marsh) a nuisance (inland silversides). This conservation measure will increase the local inland silverside population by providing additional shoreline breeding

habitat. Because of the high existing abundance of inland silversides, the incremental increase in breeding habitat and thus population size above current conditions is considered small and the magnitude of this effect is considered to be low relative to baseline. Further, differential habitat selection (offshore environments for inland silverside) is expected to reduce the interspecific competition effects.

Certainty = 2 - Low
Understanding of interaction between inland silversides and Delta smelt in the wild is low, particularly in regards to egg predation by Inland silversides. Better data on where and when Delta smelt lay their eggs would better allow us to assess the potential impact of Inland silverside predation. Spatial interactions with longfin smelt are also uncertain.

Outcome N2: Potential for mercury methylation and local bioaccumulation to affect wildlife: N2-A – covered fish species, N2-B, Non-covered wildlife species, N2-C, Human health.

N2a: Covered fish species

General Observations: methyl mercury: The relationship between drivers and outcomes is supported by (Alpers et. al., 2008, Table 2 and associated text). Although current methylmercury levels on Liberty Island (analogue for future state of areas to be restored) are relatively low (Slotton et al. 2002, (Alpers et. al., 2008, figure 5), there is potential for enhanced production of methylmercury in areas of high marsh that will be inundated infrequently (only during highest tides). The process of drying out between wetting events tends to oxidize species of sulfur, iron, carbon, and mercury, leading to higher potential to form methylmercury upon rewetting. Once formed, methylmercury biomagnifies in the aquatic food web and ecological effects may occur in some sensitive species. Thus, the specific geomorphology of restoration sites and in particular, the degree to which shallow depressions and poorly drained areas of high marsh are part of the restoration projects directly influences the degree of mercury methylization.

General Observations, other contaminants
Past land use determines risk of other contaminants: lead risk in areas with significant hunting (e.g., pheasant farms or duck clubs). Risk of residual pesticides (e.g., pyrethroids) in areas used for agriculture in past two years, which suggests that if these pesticides were used, allowing for a two year lag period between application and tidal restoration would be a prudent mitigation measure. Selenium contamination from the San Joaquin Valley and other sources is also a concern, however it was not evaluated in this worksheet..

Magnitude: 1 - Minimal
No toxicological studies have been conducted with any of the covered species regarding acute toxicity. Mercury concentrations in covered fish are compared against concentrations producing mortality in other fish species. Mercury concentrations in covered fish species are compared here against concentrations producing mortality in other fish species. Mercury concentrations in ppm-wet weight for white sturgeon, Chinook salmon and Steelhead collected during 2006 were 0.165-0.279, 0.094-0.396 and 0.06-0.13, respectively (Melwani et al. 2007). Tissue data for longfin and Delta smelt was not found. This analysis assumes that both species will have tissue concentrations similar to that of other fish taxa living one year and feeding primarily on zooplankton. Mercury concentrations in juvenile threadfin shad and juvenile largemouth bass in the Delta are 0.012-0.076 and 0.035-0.230, respectively (Slotton et al., 2006). In comparison death in rainbow trout in laboratory studies occurred at 4-ppm wet weight and the NOAEC for death in Brook trout at 2.7 ppm (in Wiener and Spry, 1996). From these facts, one can conclude that, about a 10X safety factor between fish tissue concentrations in the Delta and the values reported to cause mortality in lab studies.

Regarding chronic toxicity, again there are no toxicological studies with any of covered species. Therefore, this analysis compares the reported tissue concentration for individual species against known laboratory effects in other taxa. Decreased feeding efficiency and some hormone response changes are observed at 0.25-0.27 ppm wet weight (Alpers et. al., 2008, page 30). Decreases in growth occurred in fathead minnows at 0.6-0.7 ppm (Hammerschmidt et al., 2002) and in juvenile walleye at 2.4 ppm (Friedmann et al., 1996). In conclusion, some up/down regulation of genes and alterations in feeding behavior are possible in the most contaminated individuals.

Certainty: 2 - Low
Limited tissue data is available for most covered species and there is a large safety factor regarding acute toxicity.

Limited toxicological data is available for most of the important sub-lethal processes and none of this data has been collected for the species of interest. A very limited tissue data set is available for most of the covered species and this makes it impossible to determine the proportion of population potentially at risk.

N2b: Methyl mercury, non covered species

General Observations: The relationship between drivers and outcomes is described in the DRERIP Mercury Conceptual model (Alpers et. al., 2008, Table 2 and associated text).

Magnitude: 3 - Medium
Fifty-eight percent of Forster's terns in San Francisco Bay are at risk of reproductive impairment from consuming fish with elevated mercury levels (Ackerman *et al*., 2008). No Forster's Terns nest in Delta. However, mercury levels in small fish consumed by terns are higher in parts of the Delta, such as the Yolo Bypass, than in San Francisco Bay. This suggests that other bird species filling the Forster's tern niche in the Delta may be at risk. Mercury contamination may result in possible sustained, minor population effect on large area.

In laboratory studies, mink have reproductive failure and die when fed fish diets of 0.5 and 1-ppm mercury, respectively (Dansereau *et al*., 1999). For comparison, mercury concentrations in 64% of largemouth bass, 23% of white catfish, and 35% of channel catfish caught in the Bay-Delta watershed have between 0.23 and 0.93 ppm mercury (Davis et al., 2006). Expected sustained minor population effect or effect on large area.

Certainty: 2-3 Low-Med
Scientific understanding of methylmercury effects on some bird and mammal species is high and this is based on peer-reviewed studies from the San Francisco Bay Area and elsewhere outside of the system. However, methylmercury effects on other bird, reptile, and mammal species is unknown. The nature of this outcome is greatly dependent on highly variable ecosystem processes.

N2c: Methyl mercury, Human Health

General Observations: See also results from water quality team.

Magnitude: 2 - Low
Fish consumption advisories for the Delta recommend that children under the age of 17 and women of child bearing age consume no largemouth bass or smallmouth bass, spotted bass or Sacramento pikeminnow, and others should limit their consumption of these species to one meal a month (OEHHA, 2006, 2008a,b). Between 10,000 and 20,000 fishermen in the Delta are presently eating fish with more than 10X the recommended methylmercury RfD and could experience some sublethal mercury poisoning (personal communication, Dr Fraser Shilling). The proposed restoration action could increase mercury content of sport fish.

The probability of increased methyl mercury production and export into the food web is the same as that described above for covered and non-covered species.

Certainty: 3 - Medium
Uncertain magnitude and direction of change in mercury content of sport fish; although levels are more likely to increase than decrease. For a given increase in mercury content of sport fish, risk to human health is quantified based on peer-reviewed studies (OEHHA, 2008a,b). It is not known how many anglers would access the project area and what fish they would catch and consume.

Outcome N3: Local effects of contaminants including toxicity from residual pesticides and herbicides: e.g. pyrethroids.

N3a: Covered fish species

General Observations: Possible presence of legacy pesticides from 1960s (e.g. DDT) is unknown. More recent (illicit) use of DDT is possible. Pyrethroids are 20x more toxic compared to some other pesticides (organochlorides). They persist in the sediment and degrade in one or two years (DPR, 2008). The relationship between drivers and outcomes is described by the DRERIP Pyrethroids conceptual model (Werner and Oram, 2008, Figure 1).

Magnitude: 1-2 – Minimal - Low
To the extent that pyrethroids or pyrethrins were used in the area to be flooded, significant toxicity could occur within 1-2 years of application. After ~2 years, near-total degradation should occur. DDT and metabolites could cause reduction of insect populations and bioaccumulation in target fish species (and some non-target bird species). Possible presence of legacy pesticides from 1960s (e.g. DDT) is unknown.

Certainty: 1 - Minimal
The toxicity of various pesticides is not completely understood. Although some peer-reviewed studies for selected life stages of certain fish exist, there is not much data for covered fish species. The nature of outcome greatly dependent on highly variable ecosystem processes affecting fate (degradation) and transport of pesticides.

N3b: Non covered wildlife species

General Observations: The relationship between drivers and outcomes is described in Werner and Oram, 2008, (Figure 1).

Magnitude: 1-2 Minimal - Low
To the extent that pyrethroids or pyrethrins were used in the area to be flooded, significant toxicity could occur within 1-2 years of application. After ~2 years, near-total degradation should occur. DDT and metabolites could cause reduction of insect populations and bioaccumulation in target fish species (and some non-target bird species).

Certainty: 1 - Minimal
The toxicity of various pesticides is not well understood. A limited number of peer-reviewed studies for certain life stages of selected fish species exist. However, there is not much data for covered fish species available (Werner et. al., 2008). The effect that tidal marsh restoration will have on the availability of residual pesticides is greatly dependent on highly variable ecosystem processes affecting fate (degradation) and transport of pesticides. Additionally, legacy pesticides from 1960s (e.g. DDT) may be present on the restoration site and more recent (illicit) use is unknown.

Outcome N4: Resuspension and export of contaminants to downstream areas (A) mercury and methylmercury, (B) pesticides and herbicides (e.g. pyrethroids).

N4a: Covered fish species

Analysis of resuspension affects considers two separate physical settings: the restoration marsh sites and the adjacent tidal sloughs. The restored marsh sites are not likely experience much scour, since the adjacent tidal channels would be excavated as part of construction and the hard farm fields are not expected to scour easily. Adjacent tidal sloughs, which are typically comprised of more erodible substrate, may experience more scour both the bed and banks.

General Observations: The relationship between drivers and outcomes is described in Alpers et. al., 2008 (Figures 4, 7, and 8 and associated text) and Werner and Oram, 2008, Figure 1.

Magnitude: 1 - Minimal
The degree of scouring of pre-project soils depends on hydrodynamics. Scour could be a short-term phenomenon as channels reach geomorphic equilibrium.. Potential for increasing methylmercury concentrations in high-elevation marsh (infrequently wetted zone) and possible export of this to downstream environments.

Certainty: 2 - Low
The nature of this outcome is greatly dependent on highly variable ecosystem processes affecting fate (e.g. photodegradation of methylmercury) and transport.

Outcome N5: Restoration site creates a population sink for covered fish species (Provides rearing habitat that becomes a one-way trip.)

N5a. San Joaquin Chinook:

General Observations:
The relationship linking drivers and outcomes discussed in this analysis is described by Brown 2003 (and sources cited therein). Rearing and migration are two activities that

juvenile salmonids (and other migratory species) must accomplish to complete their life cycle. These two activities are in a dynamic tension as migration rate and rearing time are somewhat inversely proportional (when juveniles are "rearing" in a habitat, they are not migrating). If migrating salmonid juveniles begin to rear in a habitat that then becomes inhospitable (due to changing temperatures, the appearance of predators, or radically altered hydrodynamics cause by export pumping), the "rearing habitat" may instead become an area of high mortality. Similarly, if migrating juveniles have difficulty exiting habitat to continue their migrations, rearing habitat may delay important transitions from one habitat to the next.

Magnitude = 1 - Minimal.
The geographic location of the proposed restoration site is disconnected from probable migration corridors for San Joaquin River salmon. Salmon may migrate upstream into waterways other than their natal stream (Williams 2006) and so it is possible that emigrating Chinook will move into these "restored" areas. However, temperatures will likely become stressful in these areas towards the end of the migratory period. As a result, in the days and weeks after Chinook salmon migrate into the sloughs and restored wetlands, it is possible that the habitat will degrade (due to rising temperature and declining dissolved oxygen) and that Chinook salmon in these backwater wetlands will find them hard to escape.

Certainty = 3 - Medium
The number of Chinook salmon entering these restoration sites (and the frequency with which this occurs) is difficult to project but is likely to be low (making the certainty of a minimal magnitude moderately certain).

N5b. Steelhead:

General Observations:
The relationship linking the drivers to outcomes discussed in this worksheet are described by Brown 2003 (and sources cited therein).

Magnitude = 1 - Minimal
The geographic location of the restoration site is disconnected from probable migration corridors for steelhead. Steelhead may migrate upstream into waterways other than their natal stream (Williams 2006) and so it is possible that emigrating steelhead will move into these "restored" areas. However, temperatures will likely become stressful in these areas towards the end of the migratory period. As a result, in the days and weeks after steelhead migrate into the sloughs and restored wetlands, it is possible that the habitat will degrade (due to rising temperature and declining DO) and that steelhead juveniles in these backwater wetlands will find them hard to escape.

Certainty = 3 - Medium
The number of steelhead entering these restoration sites (and the frequency with which this occurs) is difficult to project but is likely to be low.

N5c. Delta smelt:

General Observations:
The relationship linking drivers to the outcomes discussed in this worksheet are described by Brown 2003 (and sources cited therein).

Magnitude = 2 - Low
The geographic location of the restoration sites occur on the edge of the Delta smelt's historic range. Still, larval Delta smelt may be dispersed into these marshes and the sloughs that surround them. Temperature and other water quality conditions (see above) are likely to deteriorate towards the end of the spring. Delta smelt may be trapped in these areas – unable to escape deteriorating conditions. Because Delta smelt are expected to occur here only in low numbers and with low frequencies, the ultimate impact of this effect is expected to be small.
.

Certainty = 3 - Medium
The low number and frequency of Delta smelt occurrence in this area make it moderately likely that the magnitude of this impact will be low. Under current conditions in the southeast Delta, Delta smelt larvae that enter restored marsh habitats in this area will suffer high mortality rates. This action does not represent a significant change from that baseline condition.

Important Gaps in Information and/or Understanding

Data needed to more fully evaluate tidal marsh restoration actions

- Residence times (average and spatial variance in that value) are necessary to determine how much and what kind of food would be produced on site and exported from the site. Residence time projections also affect temperature and dissolved oxygen conditions and these are important attributes of physical habitat. Finally, residence times for particles of water could inform assessment of “residence” times for fish. There is a non-linear relationship between fish “residence time” and the benefit of the rearing habitat as, at high “residence times” new habitat may serve to delay important migratory activities whereas at very low residence times, the new habitat will have reduced benefit because fish (or at least those that behave like particles) will experience the habitat for only a short period.
- Centrarchid models are needed to understand predator-prey-habitat interactions.
- Striped bass model is needed to understand predator-prey-habitat interactions.
- Expected retention time on restored tidal areas to understand likely productivity and food export potential to local sloughs.
- Baseline predation pressure in this region should be better understood.
- More spatially comprehensive hydrodynamics to understand whether changed flow patterns will reduce or simply redistribute predator pressure.
- Hydrologic and sediment information about turbidity levels, duration, and consequences on species as related to the following: Increased ability for Delta smelt to locate food due to increased turbidity from increased velocities in larger channels.
- Prior to implementation, conduct a complete Phase I Environmental Assessment with on-site sampling to assess legacy and other soil contaminants (i.e. mercury and pesticides).
- *Corbicula* monitoring data from previous restoration sites in the Delta, such as Liberty Island or Little Holland Tract, would provide greater information about the probability of colonization on this site.
- Better data on where and when Delta smelt lay their eggs would better allow assessment of the potential impact of inland silverside predation.
- Analysis of factors contributing the success or failure of other past tidal marsh restoration actions in the Delta.
- Liberty Island is often referred to as a model of a successful restoration project. Monitoring data and new bathymetric data from Liberty Island should be fully analyzed to determine the features that makes it successful and to consider how to apply those features to other restoration projects in the Delta. Specifically, the bathymetric data could be turned into a Digital Elevation Model (DEM) and combined with the habitat type mapping (i.e. vegetation and open water) to illustrate how the restoration provides habitat for covered and other species. This would include documenting the quality of existing LiDAR data for the vegetation mapping.

Research Needs

- Restoration techniques that will prevent colonization by invasive species.
- Management practices that can control invasive vegetation, clams, and predators (centrarchids and inland silversides) and limit colonization of these sites.
- Run (and life-history) specific studies of Central Valley Chinook salmon and studies of steelhead use of tidal marsh habitats would be extremely valuable to defining magnitude of impacts to these populations and increasing certainty. Various tools (including genetic markers and otolith signatures of population origin) could be used to asses both growth and survival of salmonids in these habitats as well as <u>changes in life history characteristics (survival and fecundity) over the course of the life cycle</u> that arise from residence in tidal marsh habitats. Currently, all of the evidence for benefits of tidal marsh on salmonids comes from steelhead and fall run populations well to the North (where high temperatures and invasive predators are not as problematic). Translating these results to all Central Valley salmonid populations is unwarranted and could lead to disastrous "restoration" projects. In addition, data on nutrient flow from the marsh plain to juvenile fish rearing in the adjacent channels is essential to determining the value of restored marshes as a food source for larvae of pelagic fish (like longfin and Delta smelt).
- Future research should generate simulations of generic “applications” of the DRERIP Conceptual Models. For example, the temperature model could be “applied” to generic landscape characteristics, such as a restoration site with specific shapes (bowl or gradation), to consider how temperature dynamics are affected on various spatial and temporal scales. This exercise would help managers understand where further detail is needed by taking the conceptual models to the next level by conducting simulations to apply the concepts to a landscape.
- Data on nutrient flow from the marsh plain to juvenile fish rearing in the adjacent channels is essential to determining the value of restored marshes as a food source for pelagic fish larvae (i.e. longfin and Delta smelt).
- It would be helpful if future research could generate simulations of generic “applications” of the DRERIP Conceptual Models. For example, the temperature model could be “applied” to generic landscape characteristics, such as a restoration site with specific shapes (bowl or gradation), to consider how temperature dynamics are affected on various spatial and temporal scales. This exercise would help managers understand where further detail is needed by taking the conceptual models to the next level by conducting simulations to apply the concepts to a landscape.
- Greater understanding and more research is needed about the availability and production of food in tidal marshes. Export of organic material from the marsh plain and phytoplankton, zooplankton, and other organisms produced in intertidal channels into the Delta has not been studied.
- Evaluate the effectiveness of water management strategies on managed wetlands to reduce the production of low dissolved oxygen events associated with managed wetlands operations and transfer what is learned into best management practices for the broader managed wetlands community in this region. In addition, it is likely the reduction of low DO events will result in

- conditions less favorable for MeHg production and thus reduce MeHg loading to the surrounding aquatic environment. This hypothesis needs testing.
- Potential negative effects of methylmercury exposure on covered fish species remain largely unknown. Based on published studies involving other (non-targeted) fish species, there is reason for concern regarding possible chronic effects caused by methylmercury exposure, including: endocrine disruption, reduced reproductive success, reduced predator avoidance, and reduced feeding efficiency. (See Mercury Conceptual Model, Alpers et al. 2008, Table 4, page 30). Research is especially needed to determine possible effects caused by exposure during early life stages.
- A better understanding is needed regarding the relationship of mercury methylation to the duration of wetting and drying events in areas that are intermittently inundated (i.e. tidal marsh and floodplain). Laboratory and field studies of mercury cycling involving sediments in tidal marsh and floodplain environments should quantify the duration of drying time and the extent of dryness necessary to change the oxidation-reduction character of iron, sulfur, carbon, and mercury in sediments such that microbial activity associated with mercury methylation is enhanced.
- Tropho-dynamic model of ecological interactions linking primary production to the food web structure and production flows into, through, and out of the tidal marsh system.
- Landscape-level models that address the effects of variation in structural features of the tidal marsh environment (e.g., tidal channel complexity, channel width, channel length, edge: area ratios, etc.) on the population or production dynamics of specific plants and animals.

Assess Reversibility and Opportunity for Learning

Reversibility

No/Hard. The following on-the-ground actions would be needed to reverse this action:

1) levees would need to be reconstructed
2) newly created tidal sloughs would have to be regarded
3) sites would have to be dewatered
4) wetland vegetation would have to be removed
5) newly installed levees would need to be removed as necessary
6) monitoring pre, during, and post construction

Although this reconstruction is technically possible, there would be significant financial and regulatory costs. Prior to action reversal, the following planning activities would be needed:

1) geotechnical evaluations for levee reconstruction
2) engineering design
3) evaluate land options for areas subject to subsidence reversal actions
4) environmental permitting and associated agency ESA consultation,
5) Mitigation planning

Opportunity for Learning

High: Implementation of this project can be designed such that different engineering designs can be compared. Numerous physical and biological components can be monitored and ideally, the monitoring data would be used to assess and refine modeling simulations of the restoration as a part of a comprehensive adaptive management program. See text in the Cache Slough (HRCM 4) worksheet for details.

Appendices

Appendix A: Summary Tables Organized by Outcome

Table 3. Positive Outcomes

Outcome	Magnitude	Certainty
P1: Increase rearing habitat area (including physical and biotic attributes) for covered fish species.		
a: San Joaquin River/eastside Fall-run Chinook salmon and steelhead.	2	2
b. Splittail	2	3
c. Green Sturgeon	2	2
d. White sturgeon	2	1
P2: Food resources (i.e. organic material from the marsh plain and organic carbon, phytoplankton, zooplankton, and other organisms from intertidal channels) produced on the restored marsh will be exported, via tidal flow, and contribute to food availability downstream in the eastern and central Delta. (all covered fish species)		
a. Viewpoint #1	3-4	3
b. Viewpoint #2	1-2	1
P3. Locally provide areas of cool water refugia for Delta smelt and salmonids.		
a: Delta smelt.	2	1
b1. Spring-run.	2	1
b2: Fall-run.	2	1
b3: steelhead.	2	1

Table 4. Negative Outcomes

Outcome	Magnitude	Certainty
N1: Establishment of undesirable species (such as Egeria) that will prey or compete or alter habitat conditions for covered fish.		
a. SAV.	3	2
b. Non-native Centrarchids	4	3
c. Corbicula.	4	3
d. Inland silversides.	2	2
N2: Potential for mercury methylation and local bioaccumulation to affect wildlife.		
a. Covered fish species	1	2
b. Other species (not covered).	3	2 to 3
c. Human health.	2	3
N3: Local effects of contaminants including toxicity from residual pesticides and herbicides: e.g. pyrethroids		
a. Covered fish species.	1 to 2	1
b. Other species (not covered).	1 to 2	1
N4: Resuspension and export of contaminants to downstream areas (A) mercury and methylmercury, (B) pesticides and herbicides (e.g. pyrethroids).		
a. covered fish species.	1	2
N5: Restoration site creates a population sink for covered fish species (Provides rearing habitat that becomes a one-way trip.)		
a: San Joaquin Chinook	1	3
b. Steelhead.	1	3
c. Delta smelt	2	3

Appendix B - Outcomes With Zero Magnitude

OP1. Increase rearing habitat area (including physical and biotic attributes) for longfin smelt.

General Observations: Longfin smelt do not occur in this area with any frequency. These fish do not use tidal marsh habitats. The magnitude of this outcome is zero for this species with a certainty of "4".

Longfin smelt do not occur with any regularity or abundance in this region. Longfin smelt model text indicates: LFS are rarely detected above Rio Vista on the Sacramento River (Wang 1991; and R. Baxter, CDFG, unpublished data). Furthermore, model indicates that, soon after they become free-swimming fish, longfin smelt concentrate in deepwater environments – marsh is not considered "rearing habitat" for longfin smelt.

OP2. Increase rearing habitat area (including physical and biotic attributes) for Delta smelt.

General Observations: Drivers, linkages, and outcomes are described by the DRERIP Delta smelt conceptual model (Norbriga and Herbold, 2008) which states that the food web supporting Delta smelt production is a primary component of habitat suitability that affects Delta smelt growth rates, health, fecundity, and mortality. The food web supporting Delta smelt is based on the production of pelagic zooplankton (see page 21 of model). Delta smelt historically spawned in the east Delta in some years (Norbriga and Herbold, 2008, page. 11).

Magnitude: The magnitude is scored as a **zero** because Delta smelt were periodically found in the east Delta historically (Bennett 2005, Figure 1) but they are infrequent or absent from this area in recent years (Norbriga and Herbold, 2008, Figure 3). Delta smelt eat food produced on tidal marshes; but, Delta smelt do not forage in shallow environments (Norbriga and Herbold, 2008, page. 27 and elsewhere, and pers. comm. with B. Herbold, US EPA). Delta smelt will not benefit from the physical habitat structure to be created on shallow parts of this restored landscape. Food consumed *in the shallow tidal areas* is likely to be nil. This outcome assumes that Delta smelt are limited by food production in this area. The food consumed in directly adjacent pelagic habitats depends entirely on how much of the zooplankton produced in the shallow areas is consumed by fish that actually forage in shallow environments where the food is produced. Delta smelt rearing in open water habitats may have, in the past, relied on export of food from a vast network of tidal marshes (Norbriga and Herbold, 2008, page 12). The limited scale of this restoration proposal, the infrequent occurrence of Delta smelt in this area, and the relative isolation of the proposed restoration sites from pelagic habitats and migratory corridors used by later life history stages of Delta smelt make the likely magnitude of this outcome undetectable.

Certainty: Certainty is moderate and is scored as a **3.** The magnitude of outcome is dependent on highly variable ecosystem processes or other external factors. The impact of food produced on site is related to how much of that food makes it into the adjacent channels and bays and to the nature and extent of food limitation in this region currently. These factors are somewhat uncertain. The magnitude of food production depends on physical aspects of the restoration (e.g. those that contribute to retention time) and biological outcomes (e.g. the amount of food consumed in shallow areas that is then not exported to adjacent deep habitats).

OP3. Increase rearing habitat area (including physical and biotic attributes) for Steelhead.

General Observations: Drivers, linkages, and outcomes are described by the DRERIP Salmonid model which indicates that steelhead juveniles move through Delta from Jan-Jun, but mostly from late March-June (Williams and Rosenfield, In preparation, Fig 27 and DLO figure. See also the value of estuarine rearing varies across populations on page 15). Tidal exchange in some of these marshes will be hard to accomplish and residence times in the channels leading to the Marsh will be high. This will expose emigrating salmon and steelhead to poor habitat conditions for extended periods and delay successful emigration.

Magnitude: The magnitude of this action will not be detectable and is scored as a zero. This outcome assumes that "rearing habitat area" (quantity) and/or food is limiting in this area. Page 16 of Williams and Rosenfield, In preparation states "Spring Chinook, or at least the Butte Creek population, pass quickly through the Delta, so habitat restoration there seems unlikely to do much for them. The same is probably true for late fall Chinook, <u>and for steelhead</u>." This conceptual model (Estuarine – growth) shows a low impact of this kind of habitat on competition – competition may have a moderate impact on growth. In other systems, steelhead use tidal marsh habitat but, the text notes, steelhead smolt in this system are large compared to other systems so research there is not likely to apply here. Steelhead will eat the types of food produced in this habitat. Steelhead migrate past this area "mainly in April and May" (Salmonid model P 34.) High temperatures are probably common in this area during May (as indicated by IEP gauges in the lower San Joaquin River, rsan 007 and rsan058). Average daily temperatures exceed 20-21oC (beyond which sublethal effects accumulate; Reese and Harvey 2002 and see Richter and Kolmes 2005) during May in many years. In June, average daily temperatures probably exceed this critical threshold in almost every year. With warming that may occur under climate change projections, high temperatures may become more frequent and more extreme, even during April. Steelhead rearing in this proposed restoration site during May and June will probably be impacted by high temperatures and negative impacts could become more common with global warming.

The limited scale of this restoration proposal, the infrequent occurrence of steelhead in this area, and the relative isolation of the proposed restoration sites from migratory corridors make the likely magnitude of this outcome undetectable. Benefits to some rearing steelhead may be largely offset by negative temperature effects to later rearing steelhead.

Certainty: Certainty is moderate and scored as a 3. There is no direct research on use of shallow estuarine habitat by steelhead in this system. Any effect will be limited to the San Joaquin population and to those times of year when temperatures are not too high in the target area.

OP4a: Locally provide areas of cool water refugia for winter-run salmon.

Magnitude = 0- Zero.
There will be no benefits of this restoration to winter-run salmon because this run passes through the region during a window of time when temperatures are not believed to be highly stressful to salmonids.

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

OP4b: Locally provide areas of cool water refugia for late fall-run salmon.

Magnitude = 0- Zero.
There will be no benefits of this restoration to late fall-run salmon because this run passes through the region during a window of time when temperatures are not believed to be highly stressful to salmonids

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

HANDOUT HABITAT #2

PRELIMINARY DRAFT—FOR DISCUSSION ONLY
Estimated Extent of Lands within Restoration Opportunity Areas that may be Suitable for Tidal Marsh Restoration Area by Elevation Class

Note: The acreage values presented in this table that may be suitable for tidal marsh restoration are likely somewhat less than shown because the footprint of roads and other features that might not be removed to accommodate tidal marsh restoration are included in the table. Acreage values shown for the South Delta ROA do not include lands that may also be suitable for floodplain restoration.

Restoration Opportunity Area (ROA)	Area by Elevation Class (acres)										Total
	Upland (>+15 feet)[1]	Transitional Upland 2 (>+3-15 feet)[2]	Transitional Upland 1 (>+3-6 feet)[2]	Sea level Rise Accommoda-tion (>0-+3 feet)[2,3]	Tidal Marsh[4]	Subtidal 1 (<0-3 feet)[4]	Subtidal 2 (>-3-6 feet)[4]	Subtidal 3 (>-6-9 feet)[4]	Subtidal 4 (>9-12 feet)[4]	Subtidal 5 (>-12 feet)[4]

Viewpoint 1 Advective-driven transport of Cache Slough productivity will provide important and very substantial productivity contributions to larger regions of the northwestern Delta.

Viewpoint 2 Export from the restored marsh will be non-existent when Yolo Bypass is not flowing therby limiting productivity contributions beyond the restoration area.

HRCM 9:
Suisun Marsh ROA Tidal Marsh & Shallow Subtidal Restoration

Scientific Evaluation Worksheet

Note about this "Incomplete Working Draft": this document is not completed. The Tidal Restoration Evaluation Team had limited time for this evaluation. Much information has been replicated from the Cache HRCM 4 evaluation and has not been revised throughout to reflect the specific restoration sites and geographies of this ROA. Information relative to Outcome P4 was updated in August 2009 to reflect individual species evaluations.

Action

HRCM9: Suisun Marsh ROA Tidal Marsh & Shallow Subtidal Restoration

Evaluation Team

Dave Harlow (chair); Stuart Siegel (coach); Dan Kratville; Jon Rosenfield; Chris Enright; Armin Munevar; Wim Kimmerer ; Amy Richey; Charlie Alpers; Kateri Harrison (note taker).

Date of Last Revision: September 17, 2009

Action Description and Clarifying Assumptions

Re-establish 9,000 acres of brackish intertidal marsh and shallow subtidal aquatic within the Suisun Marsh.

Approach

1. Reconnect 10 miles of disconnected remnant sloughs to Suisun Bay and remove remnant slough dikes to reintroduce tidal connectivity to slough watersheds to restore tidal marsh.
2. Breach dikes to reintroduce tidal exchange to diked lands at locations west of Suisun Slough. Including 500 to 2,250 acres in Region 1 (west), and 460 to 2070 acres in Region 2 (central), 180 to 810 acres in Region 3 (north), and 860 to 3,870 acres on Region 4 (south). (See Figure 1 below)
3. Protect transitional grassland contiguous with restored intertidal marsh habitat within the Suisun Marsh.
4. Plant tules or other techniques to raise elevations of shallowly subsided lands.

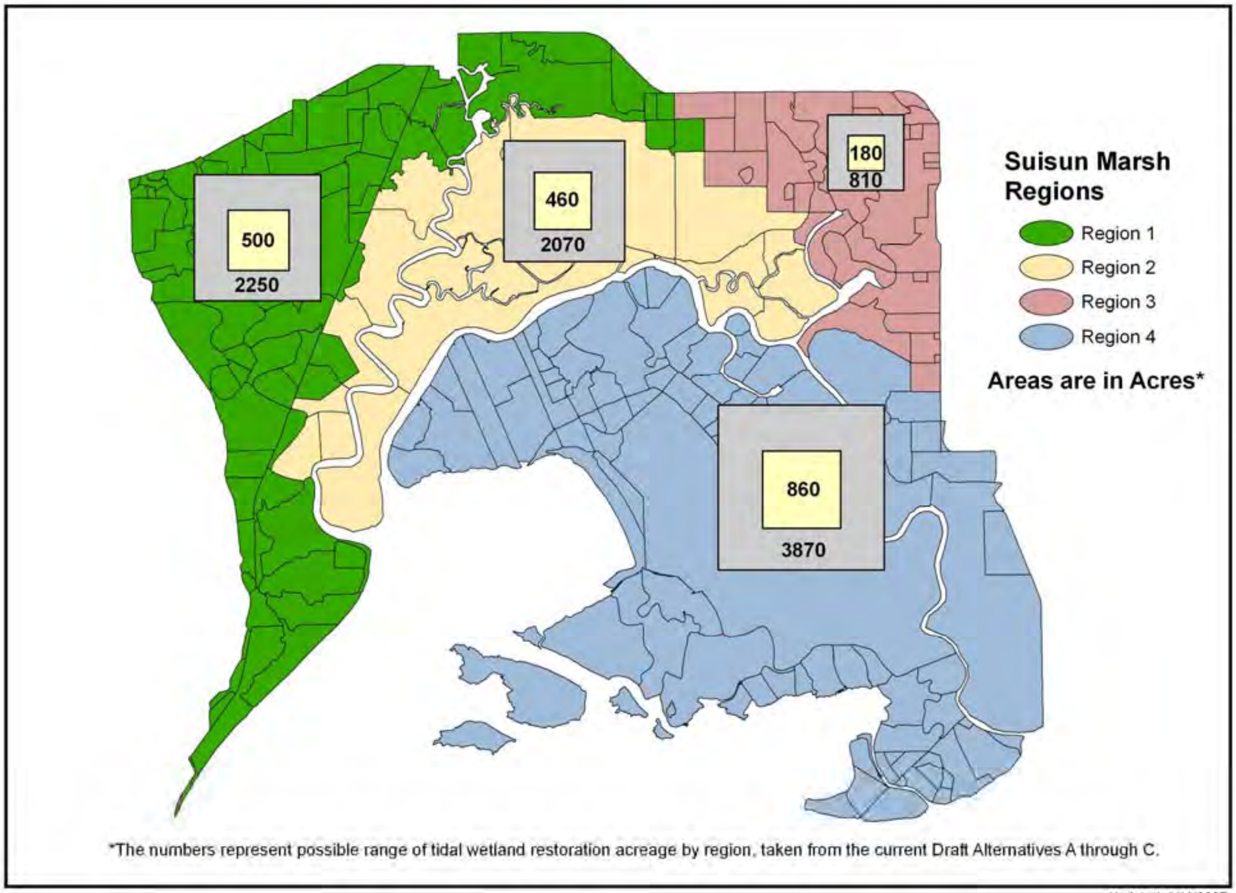

Figure 1. Suisun Marsh Plan Tidal Marsh Restoration Target Ranges by Subregions.
Ranges reflect different alternatives in SMP. *Source: CDFG et. al., In Preparation*

Intended Outcomes as Stated in Conservation Measure

1. Increase rearing habitat area for Chinook salmon, Sacramento splittail, and possibly steelhead.
2. Increase the production of food for rearing salmonids, splittail, and other covered species.
3. Increase the availability and production of food in Suisun Bay by exporting organic material via tidal flow from the marsh plain and phytoplankton, zooplankton, and other organisms produced in intertidal channels into the Bay; locally providing areas of cool water refugia for Delta smelt.
4. Reduce periodic low dissolved oxygen events associated with the discharge of waters from lands managed as seasonal freshwater wetlands that would be restored as brackish intertidal marsh.

Conceptual Model Information Regarding Intended Outcomes

Relationships among drivers, linkages, and outcome is described in the following DRERIP conceptual models: salmonid, Delta smelt, and longfin smelt; and by the following studies as listed "References Cited" located at the end of this document:

- Hobbs, Bennett, and Burton.
- Williams, 2006.
- Enright (Temperature data via pers. comm.).
- IEP Temperature data (as processed by Kimmerer, pers. Comm.)

Assumptions

Provided in BDCP Conservation Measure:

1. Restoration would equally in north and south Suisun Marsh. (See re-write below)

Added by Evaluation Team:

1. The Evaluation Team re-wrote the assumption provided by BDCP to now read as follows: Restoration would <u>occur</u> equally in north and south Suisun Marsh <u>following the regional targets set by the Suisun Marsh Plan (see Figure 1 above) (</u>CDFG et. al., In Preparation).
2. Levee breaches will not mute tides and will be large enough to avoid steep velocity gradients (eddies) that promote fish predation.
3. Subtidal dendritic channel networks will be excavated where necessary, recognizing that downcutting through managed wetland substrate could be slow. It is expected that managed wetland pond bottoms will be less consolidated than Delta agricultural fields.
4. The time frame for providing restoration benefits derives directly from the restoration design and specific approaches utilized. Pre-breach subsidence reversal can take several years to a decade or more depending on starting elevations. The sediment accretion rate, once land is open to the tides, depends on sediment supply and biomass accretion which may be faster or slower depending on site-specific conditions. The southern portion of Suisun Marsh which faces the shallow open bays has higher sediment loads compared to the northern Suisun Marsh. Northern Suisun Marsh has higher baseline land surface elevations compared to southern Suisun, requiring less subsidence reversal. In many cases northern sites are at elevations

5. where emergent vegetation can colonize upon restoring tidal action (see Figure 2 below).
6. The extent of active pre-restoration subsidence reversal efforts would be focused on the more deeply subsided portions of this landscapes in higher energy settings such as where wind fetch large and where sediment supplies low. See existing marsh elevations in Figure 2, below.
7. Water output from the site, post-restoration, will meet water quality standards.
8. Prior to implementation, a Phase I Environmental Assessment with on-site sampling to assess legacy and other soil contaminants (i.e. mercury and pesticides) would be completed.

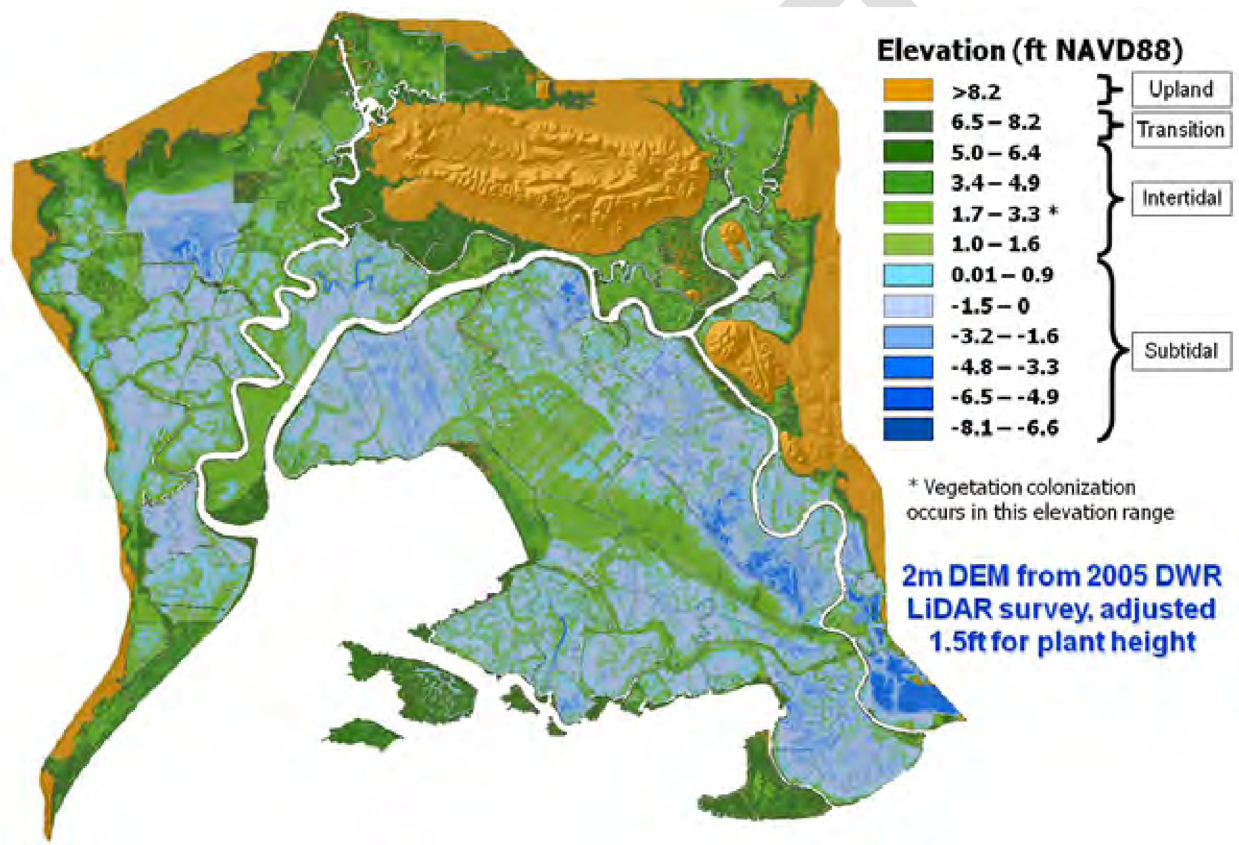

Figure 2. Suisun Marsh approximate existing elevations.
Emergent vegetation interferes with LiDAR detection of actual ground surface; this figure reflects DWR's uniform 1.5-foot uniform lowering of LiDAR elevations within wetland interiors to account for this interference, recognizing the over-simplification of this adjustment. Very little field data exist to calibrate this adjustment. *Source: DWR*

Problem(s) with Action as Written:

1. The conservation measure would benefit from an explicit recognition that restoration of tidal marsh functions on subsided landscapes will take many years to many decades. In the interim, the region will function as a shallow intertidal habitat.

2. The evaluation needs to consider alternate approaches for shallowly subsided lands. Approach #4 indicates one approach – pre-breach tule planting on the subsided areas. Another approach would be to leave some subsided lands as shallow subtidal habitat, since the Action itself is to restore "tidal marsh and shallow subtidal habitat". Each approach leads to a different outcome on different time scales.

3. Because rearing habitat by necessity includes local availability of food, the evaluation team merged the first two Intended Outcomes (rearing habitat and local food) into one outcome.

4. There is generally no functional difference between Approach #1 (reconnecting 10 miles of disconnected remnant sloughs) and Approach #2 (breach dikes to restore tidal exchange) and thus for the purposes of this evaluation, we are considering the approach to be only as stated in #2. Approach #2 provides for restoration acreage targets within the four subregions established in the Suisun Marsh Plan (CDFG et. al., In Preparation). Aiming to restore large clusters will lead to large channels conveying the necessary tidal prism. If the intent is to create large sloughs, then the action should be rewritten to specify large sloughs. The approach should be to either restore large clusters or to restore wetlands that include the few remnant diked large sloughs.

5. The action should articulate whether the intent is restoration of many separate sites or fewer, larger clusters of sites. The pattern of property ownership in Suisun Marsh is hundreds of individually-owned duck clubs and ownership size is typically a few hundred acres (polygons within Figure 1 depict land ownership boundaries). To the extent that the action has a specific goal to restore large tidal sloughs (approach #1 but not reflected distinctly in intended outcomes), restoration should be focused on multiple clubs that border the extant large sloughs currently functioning as water supply distributary canals.

Scale of Action

Large.

Rationale:

This is a large scale restoration action due to its large spatial extent. As listed in Table1 below, the Delta currently has approximately 21,600 acres of tidal marsh habitat (baseline). Additionally, 67,000 acres of diked and other lands have been identified as potentially restorable to tidal marsh (neglecting effects of restoration on reducing tidal range). The proposed 9,000 acres of tidal marsh and shallow sub-tidal restoration options would significantly increase marsh acreage above current conditions. Significant amounts of the 67,000 acres of identified restorable lands are highly constrained such that they could not be restored in the near term (South Delta and Netherlands alone account for 31,000 acres of the 67,000 acres). Therefore, this action also represents an important part of the potentially restorable tidal marsh lands.

Table 1. Summary of Tidal Marsh Acreages

Area	Acreage	Source
Delta (entire Delta proper)	738,000	DWR, 2009
Historic tidal marsh/wetlands in Delta	525,000	TBI, 2002
Current extent of tidal marsh/wetlands in Delta.	21,600	TBI, 2002
Restorable intertidal lands within Delta.	67,000	CA DVSP, 2008, Table 1, p.77.
Proposed Cosumnes/Moklemne tidal restoration (this action)	9,000 tidal marsh and sub-tidal	BDCP, 2009

Evaluation Summary

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

> *Note: Asterisk (*) indicates that this negative outcome is measured relative to baseline conditions. These negative mechanisms also decrease the certainty that positive effects of site restoration will be realized*. Appendix "A" contains the above information in summary tables that are organized by the numerical order of the outcomes, rather than species. This alternative format may be helpful to some readers. Please refer to Appendix A for details.

Other Negative Outcomes Identified, Not Evaluated

During the course of this evaluation, the team identified two potential negative outcome that it did not evaluate due to lack of time. It is recommended that this potential outcome be evaluated at some point in the future when additional time is available.

- ON1. Pesticide use for mosquito control
- ON2: Increase in the availability of selenium

Positive Outcomes Identified, Not Evaluated

During the course of this evaluation, the team identified one potential positive outcome that it did not evaluate due to lack of time.

- Reduce methyl mercury by changing land use.

Outcomes with Zero Magnitude

During the Evaluation process, several of the outcomes identified by BDCP early in the process, were found to have a zero magnitude. These outcomes are listed below and their evaluation is provided in Appendix B.

- OP1: Locally provide areas of cool water refugia for winter-run salmonids.
- OP2: Locally provide areas of cool water refugia for late fall-run salmonids.

Relation to Existing Conditions

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

Yes

Nature of Change:

This action would result in three large changes to baseline conditions:

1. **Conversion of diked managed wetlands to tidal perennial wetlands.** Most of the Suisun Marsh diked wetlands are managed as seasonal wetlands to promote waterfowl utilization during the winter migratory period, in support of hunting activities. Some of the diked wetlands are managed as perennial wetlands, and others are managed to provide habitats for the endangered salt marsh harvest mouse. The most significant change of this conservation measure is conversion of these "duck clubs" from diked seasonal wetlands to perennial tidal marsh which would have corresponding effects on habitat suitability for waterfowl. Although tidal marsh restoration sites provide some waterfowl support functions, especially in early stages of evolution, the final restoration condition/stage will reduce waterfowl habitats relative to existing conditions.

2. **Reduce tidal range in portions of Suisun Marsh.** The Suisun Marsh Plan (SMP) conducted two-dimensional numerical modeling (RMA model) to examine restoration effects on tide range within Suisun Marsh (CDFG et. al., In Preparation). The modeling compared restoration scenarios of differing configurations within the spatial distribution of restoration activities shown in Figure 1. One scenario focused on mostly northern marsh restoration and another scenario focused mainly on southern marsh restoration. In general, the modeling found significant reductions in tidal range, ranging from elimination of tides at the upper reaches of the smaller tidal sloughs to well under one foot in Grizzly Bay in the south. The model predicts effects would be strongly localized to the amount of restoration along any particular reach of tidal slough, to the size of the restoration site, and to the baseline elevation of the restoration site. The lower the starting elevation of the restoration site, the greater the tidal dampening effect.

3. **Altered tidal flows in major sloughs.** The SMP RMA modeling also showed altered tidal flows in the major sloughs with restoration, concurrent with reductions in tidal range (CDFG et. al., In Preparation). Model results for the west end of Montezuma Slough showed flow increases ranging from 6,000 to 12,000 cfs over baseline values

of 17,000-32,000 cfs depending on time of year and spring-neap tide conditions. Suisun Slough tidal flow changes were highly dependent on the scenario modeled. Focusing restoration in the north increased flows 2,000-3,000 cfs over a baseline of 4,000-7,000 cfs (again, varies with time of year and spring-neap tide conditions). In contrast, focusing restoration in the south reduced flows 2,000-4,000 cfs and in particular reduced the variability in flows between spring and neap tide conditions considerably.

4. **Altered west Delta salinity conditions.** The hydrodynamic connectivity between Suisun Marsh and the Delta and the resulting effects on salinity levels exhibits sensitivity to location of restoration in Suisun Marsh and to Delta outflow conditions. Focusing restoration in northern Suisun Marsh tends to reduce salinities in the west Delta under low Delta outflow conditions by up to 10-20%. In contrast, focusing restoration in southern Suisun Marsh tends to increase salinities in the west Delta under low Delta outflow conditions by up to 5-15%. It is important to note that the baseline salinity values being altered are in the range of 0.5-1.5 mS/cm. These percent changes are relatively small in absolute salinity values.

Salinity Management in Suisun Marsh

Water management in Suisun Marsh has focused on salinity control since the 1970's. The State and federal water projects built several salinity control structures in the Marsh between 1970 and 1990, including the Roaring River Distribution System, Morrow Island Distribution System, Goodyear Slough Outfall, Lower Joice Island Unit, Cygnus Unit, and the Suisun Marsh Salinity Control Gate (SMSCG). The SMSCG is the largest and most effective salinity control structure within Suisun Marsh. It is located at the east end of Montezuma Slough near its confluence with the Sacramento River. When operational (October-January), the salinity gate is opened on ebb tide to allow low salinity Sacramento River water into the Marsh and closed on flood tide to prevent ocean water incursion into the western end of Montezuma Slough. When the gate is operating, net flow in Montezuma Slough is more than 70 cubic meters per second (cms) (2,500 cubic feet per second [cfs]) (east to west) compared to nearly zero when not operating. By comparison, the discharge in the Sacramento River measured at Freeport (near Sacramento) during the typical period of gate operation is on the order of 200-500 cms (7,000-18,000 cfs). When not operational, the gate is left in the fully open position, allowing full tidal exchange between Montezuma Slough and the lower Sacramento River. (Enright 2009, in preparation).

Gate operations are effective at controlling salinity levels at most locations in the Marsh. The magnitude, timing, and duration of salinity reduction in response to the SMSCG operation vary with proximity, with greater salinity reductions observed in the eastern part of Suisun Marsh, less reductions in the western Marsh, and no reductions observed in the northwestern part of the Marsh. Water quality stations are located throughout Suisun Marsh. A drop in salinity due to gate operations is seen immediately at monitoring station S-64 (National Steel) and about one day or so later at S-49 (Montezuma Slough at Beldon's Landing) because both are located close to the gates. However, it takes about two to three days before a salinity drop can be observed at S-42 (Suisun Slough and Volanti) and S-21 (Chadborne Slough at Sunrise Club), because both are located in the north-central part of the marsh. Salinity levels at C-2 (Sacramento River at Collinsville) tend to increase slightly from gate operations because the interactions between tidal exchange, outflow, and gate operations result in a more erratic salinity pattern. At S-35 (Goodyear Slough) in the far western Suisun Marsh, gate operations are effective in controlling salinity, but to a lesser magnitude and with a longer time lag due to the distance of the station from the gates. At S-97 (Ibis), gate operations are not effective in controlling salinity because of its location in the far northwest portion of the marsh (Enright 2009, in preparation).

Existing Topography of Suisun Marsh Managed Wetlands

Although DWR LiDAR data from 2005 and 2007 is utilized for planning and analytical purposes, this data has uncertainty in its measurement of existing topography of managed wetlands in the range of 1-3 feet depending on location. The extensive vegetative cover of the managed wetlands combined with the large height variability across plant species present in the marsh and LiDAR's inability to penetrate dense vegetation effectively causes these large uncertainties. Only three wetland-scale ground-based topographic surveys exist for validating LiDAR data (Blacklock surveyed by DWR and clubs 112 and 123 surveyed by the Low DO/MeHg BMP project) and they show difference from 2005 LiDAR ranging from about 0.5 ft with short, lower density vegetation to more than 2 feet with tall, dense vegetation. These three sites are not adequate to evaluate the full LiDAR data but provide some sense of the range of measurement uncertainty. LiDAR cannot penetrate water and therefore ponded areas do not yield accurate LiDAR measurements of elevations. Levees, which are mostly unvegetated, present fairly reliable LiDAR-derived elevations. Figure 2 above shows the 2005 LiDAR topographic data set, with an applied 1.5-foot uniform lowering within managed wetland interiors to account for vegetation interference.

Overview of Productivity Import-Export

The worksheet for HRCM4-Cache Slough contains a detailed discussion of the general concepts around productivity in restored tidal marshes and shallow open water habitat, including the availability of primary productivity to the aquatic food web within and outside of restoration sites. Related discussion items include:

- role of restoration stage, sedimentation, and biomass accumulation, and sea level rise
- role of hydrology and hydrologic connectivity
- role of *Corbicula* in affecting exported production
- role of residence time in affecting productivity levels.

Please see the Cache Slough worksheet for details about this topic.

Potential Positive Ecological Outcome(s)

Outcome P1: Increase rearing habitat area (including physical and biotic attributes) for covered fish species.

As indicated at the beginning of this worksheet under the section entitled "Problems with Action", the team decided to merge two Intended Outcomes (rearing habitat and local food) into one outcome, P1, as shown below because rearing habitat for juvenile fish by necessity includes local availability of food. This outcome includes food (both primary and secondary production) produced within the vegetated marsh, within marsh channels, and within the subtidal areas adjacent to the vegetated marsh. General information that applies to salmon runs is provided in the worksheet for HRCM 4 – Cache Slough, Outcome P1c on page 15. Please note that green and white sturgeon are not known to utilize the Cosumnes and Molkemne River systems and so these species are not listed in the analysis below.

P1a. Delta smelt

The food web supporting Delta smelt production is a primary component of habitat suitability that affects Delta smelt growth rates, health, fecundity, and mortality (Norbriga and Herbold, 2008, page 21). The food web supporting Delta smelt is based on the production of pelagic zooplankton. Delta smelt are believed to be food limited for at least some life stages. Delta smelt are found in the large sloughs of Suisun Marsh (Norbriga and Herbold, 2008, p. 11).

Magnitude = 3 - Medium.
Delta smelt sub-adults rear in Suisun Bay (Norbriga and Herbold, 2008, p 11). Although they consume food produced on tidal marshes, the DRERIP Delta smelt conceptual model (p. 27 and elsewhere, and pers. comm. with B. Herbold, US EPA) indicates that Delta smelt do not forage in shallow environments. Delta smelt will not benefit from the physical habitat structure to be created on shallow parts of this restored landscape. Food consumed *in the shallow tidal areas* is likely to be nil.

The food consumed in directly adjacent pelagic habitats depends entirely on how much of the zooplankton produced in the shallow areas is consumed by fish that actually forage in shallow environments where the food is produced. Historically, a significant component of the Delta smelt population would have access to food produced in the direct vicinity of this project (i.e. they have been found rearing in this area to an extent that depended on hydrologic conditions. (See Norbriga and Herbold, 2008). This outcome assumes that Delta smelt are limited by food production. The Conceptual Model indicates that Delta smelt rearing in open water habitats may have, in the past, relied on export of food from a vast network of tidal marshes (Norbriga and Herbold, 2008, p12).

Certainty = 1-Minimal
The magnitude of outcome is dependent on highly variable ecosystem processes or other external factors. The impact of food produced on site is related to how much of that food makes it into the adjacent channels and bays and to the nature and extent of food limitation in this region currently. These factors are somewhat uncertain. The magnitude of food production depends on physical aspects of the restoration (e.g. those that contribute to retention time) and biological outcomes (e.g. the amount of food

consumed in shallow areas that is then not exported to adjacent deep habitats). This is a significant amount of restored habitat in the center of the Delta smelt geographic range. *Corbicula* establishment could limit, if not eliminate, the productivity benefits of the restoration to Delta smelt. See Negative Outcome N1b. Similarly, establishment of SAV and centrarchid (or other) predators could lead to predation rates on the site that eliminate any net benefits at a population level.

Comments and/or Assumptions used in scoring: Residence times in the restored sections are such that they optimize production and transport of zooplankton species consumed by this fish. This analysis assumes salinities in Suisun Bay are maintained at levels that provide habitat for rearing Delta smelt. If water management in the restored areas includes managed tidal marshes, these are assumed to be managed so as to prevent releases of water with high biological oxygen demand (BOD) into Delta smelt habitat. The team also assumed the area would be managed so as not to entrain Delta smelt.

P1b. Longfin smelt:

Longfin smelt larvae, juveniles, and sub-adults rear in Suisun Bay and other pelagic parts of the estuary, (Rosenfield, 2008). Larvae are commonly found in large sloughs of Suisun Marsh (Suisun Marsh Survey, Moyle pers. comm.), probably because they are forced there by hydrodynamic dispersion. Sub-adults and adults are much less common in Suisun Marsh.

Magnitude = 1 - Minimal
Longfin are widespread in the San Francisco Estuary and are detected each year in the western Delta, Suisun Bay, and Suisun Marsh (Baxter 1999; Fig 6 and Rosenfield 2008, page 5). Although larvae are frequently found in marsh environments, it is likely that they are simply dispersed there by local hydrodynamics (Baxter 1999). It is not likely that they depend on these habitats for survival (Moyle pers. comm.) as larval longfin smelt are found throughout the Estuary (Rosenfield, 2008). Furthermore, the DRERIP Conceptual Model indicates that, soon after they become free-swimming fish, longfin smelt concentrate in deepwater environments (i.e. marsh is not considered “rearing habitat” for longfin smelt). Post-larval longfin are only rarely found in marsh environments.

This outcome assumes that longfin smelt are food-limited in this locality. Indeed, Hobbs et al. 2006 found that longfin in the northern part of Suisun Bay were in better condition than longfin in southern Suisun Bay. Thus, the water bodies influenced by this restoration action may not be food-limiting to longfin smelt.

Certainty = 1- Minimal
Sampling of longfin smelt detects larvae in Suisun Marsh and Suisun Bay. However, only a small fraction of larval longfin is detected in Marsh environments. The lifetime success rate of larval longfin smelt that occur in marsh environments is not known.

P1c. Chinook and Steelhead

A number of considerations apply to all the salmonids for this conservation measure and these are described here, followed by run-specific magnitude and certainty evaluations. The value of estuarine rearing varies across runs (see Williams and Rosenfield, In preparation page 15).

General Seasonality of Delta Use. Juveniles of most runs migrate during winter through spring.

Role of Outmigrant Size in Duration of Delta Use. Larger outmigrants generally rear for shorter periods in the lower estuary before moving to the ocean. Life histories that include rearing upstream (including in-rivers and on floodplains) produce large outmigrants that are believed to derive less benefit from restoration of rearing habitat in the Delta.

Temperature. Salmonids are sensitive to warm water. With warming that may occur under climate change, water temperatures are expected to occur in this area with some frequency during April and October as well. Steelhead, fall run Chinook salmon, and spring run Chinook salmon are typically present in the Delta during some of these months and value of tidal marsh restoration to these runs would be reduced because of the warmer water.

Role of Delta in Overall Life-History of Salmonids. Delta rearing is but one relatively short period in the overall life of salmonids and is not believed to be a key limiting factor for spring run, winter run, late-fall run or steelhead. Other limiting factors such as upstream spawning and rearing habitats and water operations (including Delta exports) are more important in the overall life history for these salmonids.

Food Productivity to Support Rearing. Factors affecting food productivity described in this worksheet indicate that salmonids would find food resources in the Cache Slough area. The benefits of this productivity would accrue more to smaller migrants and when water temperatures support growth and smoltification.

Predator Exposure. Estuarine habitats that support salmonid rearing potentially also support predator populations, including (in particular) introduced Centrarchids that prefer shallow slow-moving freshwater environments. Increasing the residence time of

salmonids in the Delta (by increasing rearing habitat) may also increase exposure to predator populations – the number of predator species in the Delta is much higher now than it was historically because of the introduction of Centrarchid and other non-native predators and maintenance of conditions that support those predators.

P1c1. Winter-run Chinook salmon

Winter-run juveniles move through the Delta from fall through winter.

Magnitude = 1 - Minimal

This outcome assumes that "rearing habitat area" (quantity) and/or food is limiting. The Conceptual Model, page 16, states, "Spring Chinook, or at least the Butte Creek population, pass quickly through the Delta, so habitat restoration there seems unlikely to do much for them. The same is probably true for late fall Chinook, and for steelhead. The case for winter Chinook seems equivocal." Winter-run will consume the types of zooplankton produced in this restoration (under the assumed condition). Most winter-run migrate through this area when temperatures are cool enough to support rearing (Williams and Rosenfield, In preparation, Figure 3).

The conceptual model (Williams and Rosenfield, In preparation) shows a moderate impact of this kind of habitat on competition – competition may have a moderate impact on growth – but both of these impacts are highly speculative. Food limitation is not considered a major limitation on survival in this part of the life stage. Winter-run have the smallest population of any Chinook salmon run in this system. They have access to the same estuarine habitats as the other runs (and probably more access than fall or spring run fry that migrate later in the year when temperatures are higher). Thus, competition and growth limitation due to habitat limitation in the Estuary is least likely for this run among all the Central Valley Chinook populations. In addition, this run rears upstream and probably enters the Estuary at a size where rearing in the Estuary is less important.

The relative impact of stressors across habitats and upstream impacts are more likely to be important. Stressors in the Estuary are related to stressors other than limitation of habitat (Williams and Rosenfield, In preparation). The major impacts to winter-run Chinook salmon occur well-upstream of Suisun Marsh (e.g. they have only one spawning location with limited access to cold water or quality spawning and incubation habitat). Juveniles appear to migrate during the winter when water temperatures and flows allow them access to the maximum amount of presently-available rearing habitat. Also, because they migrate at a different time of year than the more populous fall-run, competition for "habitat" in the Delta is probably not a big stressor to this population. Finally, these fish migrate at a size where estuarine habitat is not believed to be a big benefit to them. For these reasons, the magnitude of impact to this run is expected to be "minimal", at best.

Certainty = 1-Minimal
Winter run represent a unique life history strategy for the species as a whole. No direct studies of this run's habitat use in estuarine habitats have been published. However,

unless access to additional spawning/rearing habitats (with adequate cold water and spawning gravel) is created upstream, rearing habitats in the Delta will be of little value to this species.

P1c2.Spring-Run Chinook Salmon

Spring-run juveniles move through the Delta from winter through spring.

Magnitude = 3 - Medium.
This outcome assumes that "rearing habitat area" (quantity) and/or food is limiting. The conceptual model, page16, states,"Spring Chinook, or at least the Butte Creek population, pass quickly through the Delta, so habitat restoration there seems unlikely to do much for them. The same is probably true for late fall Chinook, and for steelhead". The model's evaluation seems focused on one spring run population (Butte Creek). In fact, many juveniles from other populations migrate at a smaller size than Butte Creek

juveniles (Williams 2006). They migrate at about the same time as fall-run and thus may experience competition with fall run. So, this restoration may alleviate competition for a segment of the population. The conceptual model indicates moderate benefits of increasing rearing habitat.

Spring-run salmon will consume the types of fish and zooplankton produced in this restoration (under the assumed condition). High temperatures are currently rare during May (as indicated by IEP gauges rsac075 and rsac054; Enright *pers. comm.*). Temperatures exceeding 20-21^{o}C (beyond which sub-lethal effects accumulate; Reese and Harvey 2002 *and see* Richter and Kolmes 2005) are more common and widespread in June, July, and August (as indicated by IEP gauges rsac075 and rsac054; Enright *pers. comm.*). With warming that may occur under climate change projections, high temperatures may become more frequent and extreme. Thus, spring-run rearing in this proposed restoration site during June, and July will probably be impacted by high temperatures. Only the component of the population that migrate as fry, early in the year, will experience much benefit from tidal marsh restoration.

Whereas upstream habitats are more likely to be important to productivity of this run, stressors in the Estuary may be related to competition with hatchery and wild production of fall run Chinook salmon (Williams and Rosenfield, In preparation).

In summary, whereas spring-run Chinook are commonly believed to migrate at a large size, juveniles from two of important watersheds (Deer and Mill Creek) appear to migrate at a small size and these fish may benefit from rearing habitat restoration at lower elevations. Spring-run that migrate at small body size must compete with more abundant fall run Chinook salmon migrants. Thus, creation of suitable rearing habitat may alleviate an important bottleneck for this species. However, it is important to note that only a fraction of the spring-run population will benefit from rearing habitat restoration; the fraction includes (a) those fish that migrate at a size where rearing in low elevation habitats is important, (b) those fish that migrate early enough in the year to capitalize on beneficial temperatures in restored habitats (e.g. before May), and (c) those fish that have not already benefited from growth on rearing habitat on floodplains. For all of these reasons, the “medium” magnitude score is probably a generous assessment of likely benefits.

Certainty = 1 - Minimal
There are no direct studies of spring-run Chinook salmon habitat use in this ecosystem. Variability (inter-population and inter-annual) in the relationship between habitat volume-density-competition-and growth contribute to uncertainties (Williams and Rosenfield, In preparation).

Given the temperature limitations and differences in life history among spring-run populations, the Evaluation Team can be moderately certain that the maximum positive magnitude of this impact from this action is medium; however, there is relatively low certainty that there will be any beneficial impact at all. Establishment of *Corbicula*, SAV, or predatory fish populations could limit if not eliminate the productivity benefits of the restoration to Chinook salmon. See Negative Outcome N1a, b, and c.

P1c3. Fall-run Chinook Salmon

Fall-run juveniles move through the Delta from winter through spring.

Magnitude = 3

This outcome assumes that "rearing habitat area" (quantity) and/or food is limiting. The conceptual model, page 16, states "Fall Chinook […] could benefit strongly from tidal marsh restoration". Fall Chinook enter estuarine habitats at a small size and the text anticipates benefits from additional rearing/growth opportunities.

Fall-run will consume the types of zooplankton produced in this restoration (under the assumed condition). High temperatures are currently rare during May (as indicated by IEP gauges rsac075 and rsac054; Enright *pers. comm.*). Temperatures exceeding 20-21^{o}C (beyond which sublethal effects accumulate; Reese and Harvey 2002 *and see* Richter and Kolmes 2005) are more common in June, July, and August (as indicated by IEP gauges rsac075 and rsac054; Enright *pers. comm.)*. With warming that may occur under climate change projections, high temperatures may become more frequent. Thus, fall run rearing in this proposed restoration site during June, and July will probably be impacted by high temperatures.

This outcome will likely benefit the Sacramento portion of the fall-run population as it tends to migrate earlier than the San Joaquin and East side fall run populations (salmonid model Figure 3). Later migrants from the Sacramento or San Joaquin are not likely to benefit from this restoration (and may actually be negatively impacted if they inhabit sloughs when high temperatures prevail).

Stressors in the Estuary are relatively important to fall run Chinook salmon (Williams and Rosenfield, In preparation).

In summary, most fall-run Chinook migrate as fry and these fish may benefit from rearing habitat restoration at lower elevations. Fall run Chinook salmon are the most abundant Chinook salmon in this Estuary. They are produced in hatcheries and they migrate at the same time as spring-run Chinook salmon. They also migrate at times when potential rearing habitats may be inaccessible due to high temperatures or reduced inundation of habitat. Thus, they are more likely to be exposed to competition for habitat than some other salmonid populations in this Estuary. Creation of suitable rearing habitat may alleviate an important bottleneck for this species. A relatively large fraction of the fall-run population may benefit from this habitat restoration; the fraction includes (a) those fish that migrate early enough in the year to capitalize on beneficial temperatures in restored habitats (e.g. before May), and (b) those fish that have not already benefited from growth on rearing habitat on floodplains.

Certainty = 1 - Minimal

Fall run Chinook use of fresh water tidal and sub-tidal environments is well-documented in other systems but is not well studied in this system (Williams and Rosenfield, In preparation p. 24) possibly because this kind of habitat is limited in this ecosystem (Williams and Rosenfield, In preparation p.10). The effect of global climate change on water temperatures in this area during fall run migration period also decreases the window of time during each year when restoration will produce benefits.

Other factors create uncertainty as to the benefits of this measure for this population. *Corbula* establishment could limit if not eliminate the productivity benefits of the restoration to Chinook salmon. Similarly, establishment of predators or SAV that supports predation could eliminate most or all of the benefits created by this measure. See Negative Outcome N1a, b, c, and d.

Assumptions/Comments: Benefits of this restoration for emigrating Chinook salmon from the Sacramento River will be reduced as accessibility to and use of floodplain habitats increases. Juveniles are not likely to spend significant time rearing in downstream habitats if they have already reared on floodplain habitats. Once they reach a threshold size/condition, they are likely to migrate to the ocean.

P1c4. Late Fall-run Chinook salmon

Late-fall run juveniles move through the Delta from fall through winter. The fisheries biology community is currently debating whether late fall run Chinook exhibit separate reproduction from fall run. As that debate has not yet been settled, this evaluation presents late fall run as a distinct run.

Magnitude = 1 - Minimal
This outcome assumes that "rearing habitat area" (quantity) and/or food is limiting. The conceptual model, page 16, states, "Spring Chinook, or at least the Butte Creek population, pass quickly through the Delta, so habitat restoration there seems unlikely to do much for them. The same is probably true for late fall Chinook, and for steelhead" (Williams and Rosenfield, In preparation).

Late fall-run will consume the types of zooplankton produced in this restoration (under the assumed condition). Most late-fall run migrate through this area when temperatures are cool enough to support rearing. Conceptual models suggest a low impact of this kind of habitat on competition and of competition on growth (Williams and Rosenfield, In preparation). Late-fall run are a relatively small population, they emigrate earlier than fall and spring runs (see Figures 3 and 4 of Williams and Rosenfield, In preparation) and therefore are not expected to experience competition for estuarine habitat with these more populous runs (i.e. they are less likely to be "habitat" limited in the estuary than the other runs).

Upstream impacts (e.g. access to spawning habitats) are more likely to be important and that stressors in the Estuary are uncertain (Williams and Rosenfield, In preparation). Tidal marsh has a low impact on competition and competition in this area has a low impact on growth (Williams and Rosenfield, In preparation).

In summary, the major impacts to late fall-run Chinook salmon occur well-upstream of Suisun Marsh (e.g. they have only one spawning location with limited access to cold water or quality spawning and incubation habitat). Juveniles appear to migrate during the winter when water temperatures and flows allow them access to the maximum amount of presently-available rearing habitat. Also, because they migrate at a different time of year than the more populous fall-run, competition for "habitat" in the Delta is probably not a big stressor to this population. Finally, these fish migrate at a size where estuarine habitat is not believed to be a big benefit to them. For these reasons, the magnitude of impact to this run is expected to be "minimal", at best.

Certainty = 1- Minimal
The importance of growth in estuarine environments is unstudied for this run and there is a low certainty of impact (Williams and Rosenfield, In preparation).

The Evaluation Team is moderately certain that this action will have no more than a minimal impact on late-fall run productivity. There is considerably less certainty that there will be any benefit to late-fall Chinook from this restoration. Establishment of *Corbicula*, SAV, or predatory fish populations could limit, if not eliminate the productivity benefits of the restoration to Chinook salmon. See Negative Outcome N1a, b, c, and d.

P1d. Splittail

The relationship of drivers, linkages and outcomes are described in pages 12, 13, 14, and 15 of the Splittail Conceptual model (Kratville, 2008).

Magnitude = 3 - Medium
Suisun Marsh is the dominant population center for Sacramento splittail. Restoring 9,000 acres of tidal marsh to this area may have significant population level effects. This newly restored area will only be used by increased numbers of splittail if adequate floodplain spawning is provided. Splittail populations are largely controlled by floodplain inundation that allows for large scale spawning events. Following a spawning event, if large accessible amounts of new habitat for juvenile and adult splittail become available, the population may increase.

Certainty = 2- Low
The uncertainty lies in whether this new rearing area will increase splittail populations. This restoration will increase the opportunity for rearing juveniles; however this does not appear to be a limiting factor in splittail abundance compared to floodplain inundation. This level of spawning only occurs in years with large scale floodplain inundation. This outcome is dependent on splittail being able to spawn in numbers great enough to need access to this new habitat.

Establishment of *Corbicula*, could limit, if not eliminate the productivity benefits of the restoration to splittail. See Negative Outcome N1b. Similarly, colonization by invasive predators could result in added mortality that would counteract any benefits of restoration (especially if SAV invasion facilitates predation success).

P1e. Green Sturgeon

The relationship of drivers, linkages, and outcomes is described in pages 4, 8, and 9 of the Green Sturgeon Conceptual model (Israel and Klimley, 2008).

Magnitude = 2 - Low
Information on green sturgeon diets and physical habitat needs as juveniles in the Delta is limited. Other species of sturgeon in other systems do feed on drifting insects as juveniles. Tidal marsh restoration in this area may be associated with large mud flats which sturgeon are known to access for food (Israel and Klimley, 2008, pages 10 and16). If this occurs, green sturgeon juveniles and adults may benefit from this increased habitat. This may not translate into improved population numbers.

Certainty = 2 - Low
The key limiting factors are thought to be upstream in spawning locations. There is low certainty about whether this proposed restoration will benefit sturgeon as described in this outcome. The low certainty is due to the lack of research on this aspect of sturgeon biology/ecology in the Delta.

P1f. White Sturgeon

The relationship of drivers, linkages, and outcomes is described in pages 19, 20, 21 of the white sturgeon model (Israel et. al., 2009).

Magnitude = 2 - Low
Information on white sturgeon diets and physical habitat needs as juveniles in the Delta is limited. Other species of sturgeon in other systems do feed on drifting insects as juveniles. Tidal marsh restoration in this area may be associated with large mud flats where sturgeon are known to access for food (Israel et. al., 2009, pages 9, 16, and 17).

If this occurs, white sturgeon juveniles and adults may benefit from this increased habitat. This may not translate into improved population numbers.

Certainty = 2 - Low
The key limiting factors are thought to be upstream in spawning locations. There is low certainty about whether this proposed restoration will benefit sturgeon as described in this outcome. The low certainty is due to the lack of research on this aspect of sturgeon biology/ecology in the Delta.

Outcome P2: Increase the availability and production of food in Suisun Bay by exporting organic material via tidal flow from the marsh plain and phytoplankton, zooplankton, and other organisms produced in intertidal channels into the Bay.

P2a. All covered fish species

General Observations: The Tidal Marsh and Foodweb models [Kneib et. al., 2008, page 9 and Durand, 2008, section 2.16)] provide a general indication that there may be a linkage between tidal marsh habitat as a driver and increases in availability and production of food resources as an outcome, but that the mechanism for this linkage may be movement by fish. The tidal marsh conceptual model also states that freshwater tidal marshes are net exporters of high-quality organic production (page 2 in Kneib et. al., 2008). See also Dame et al. 1986, Kimmerer and McKinnon 1989, Kneib 1997, Lucas et al. 2009. Please see the evaluation worksheet for action # HRCM4-Cache/Yolo, Outcome P3, for more details about **Tidal Marsh Contributions to Exported Production.**

There was disagreement within the evaluation team regarding the magnitude and certainty of expected benefits of tidal reintroductions with regard to the export of food (phytoplankton, zooplankton, insects, and small fish) to areas downstream of Rio Vista and the likely benefits to covered fish species. In the spirit of presenting the scientific discourse, both points of view are captured below.

Two key questions discussed were: (1) can we predict the sign of the flux of productivity (i.e. will the restoration area be a source or a sink for primary and secondary productivity); and (2) will there be adequate advection to move material out of the restoration area and downstream to Rio Vista (assuming the restoration area is a source of productivity, as opposed to a sink). Additional information and analyses is needed to better answer these key questions. To develop this additional information, the team recommends future development of a Tropho-dynamic model as described in the section on page 41 entitled "Research Needs".

Viewpoint #1

Please see the text of Outcome P3 in worksheet HRCM4 – Cache Slough for additional background information about Viewpoint #1.

Magnitude = 3-4 – Moderate to High
Without advective connection, restoration will still have significant productivity benefits to covered fish species and to many other species due to providing areas of highly functional habitat in conjunction with restoration elsewhere that collectively provide fish species a range of options that spread risk through exploiting available resources when they are present. Refer to Ted Sommers, IEP Estuarine Ecology Team or CAERS poster. In addition, these areas would export that productivity through the "trophic relay" concept described in the tidal marsh conceptual model (fish export the productivity).

Certainty = 3 – Moderate
Certainty is reduced by the potential for establishment of invasive clams that could consume substantial portions of phytoplankton and hinder zooplankton productivity.

Viewpoint #2

Please see the text of Outcome P3 in worksheet HRCM4 – Cache Slough for additional background information about Viewpoint #2.

Magnitude = 1 (Minimal) to 2 (Low)
The implied relationship is that restoring 5,000 to 11,000 acres of tidal marsh will export nonliving and living organic matter including plankton and fish, thereby supporting foodwebs of the upper estuary. An implicit assumption is that any increase in the area of shallow habitat would result in enhanced plant productivity some of which would be exported.

Certainty = 1 -Minimal
.The sign of the signal is difficult to determine, except for total organic carbon, most of which is dissolved. Although dissolved organic carbon (DOC) will likely flow out of the marsh, fluxes of other components may be in or out (Kneib et. al., 2008, page 9). Colonization by invasive clam species can wipe out the food web production effect entirely. We have no certainty at all that they will not colonize. In addition, colonization of the site by vertebrate consumers (e.g, inland

silverside) can also significantly reduce the amount of food available for export beyond the site boundaries (Moyle 2002). There is evidence from within this system (Dean et al. 2005) that restored marshes can act as sinks for certain zooplankters; in this case, the sign of the signal would be negative.

Outcome P3: Provide local areas of cool water refugia for Delta smelt and salmonids.

The cause and effect relationship associated with this outcome is described in Stacey and Monismith 2008, Malamud-Roam 2000, and Enright 2008. Considering the landscape scale (Large) of the action, the relationship between tides, physiography, and water temperature could be very large. The relationship between drivers (wind, insolation, fetch, tides, currents) and linkages (long-wave, short wave, latent, and sensible heat flux) is complex and may produce both warmer and cooler water on a variety of time and space scales. Larger spatial gradients of water temperature will likely occur. The frequency of threshold temperatures for various species is uncertain. See Stacey and Monismith (2008), Malamud-Roam (2000), Enright (2008).

Geomorphic complexity in natural marshes filter physical drivers and generate water temperature variability at tidal, spring-neap, and seasonal timescales. These processes may create cool water refugia for Delta smelt as a positive outcome of the proposed conservation measure. Sea level rise and marsh evolution by sedimentation and bioaccumulation will change the nature of the land-water interface over time.

The quantitative dynamics of heat flux by various mechanisms or "linkages" are well understood (Temperature CM; Stacey and Monismith In revision). Heat flux dynamics can be written as advection-diffusion equations with the heat flux linkages explicitly accounted for. Predictability and cause and effect relationships between action-approach-outcome are uncertain because parameterization of each heat flux linkage is data intensive and location specific. Predictable outcomes depend on detailed local understanding of drivers including wind dynamics, wind fetch, shading, humidity, landscape physiography, and tides. These details can be worked out for a given site with sufficient monitoring and assessment. However, in the abstract, local temperature may exhibit net increases or decreases depending on the relationship between drivers and linkages.

Enright (2008) measured large temperature responses to particular combinations of tidal and seasonal tide phase and time of day on a natural marsh. A 335-year tidal precession currently brings the high-high spring tide to the Suisun Marsh region near midnight during the summer. Natural tidal marshes orient their marsh plain elevation to approximately mean higher-high water. Extreme tides overtop the low natural channel levees and inundate the marsh plane shallowly. Water is rapidly cooled by long-wave, latent and sensible heat flux (Stacey and Monismith In revision) before it is returned to the tidal channel on the ensuing ebb tide to low-low water. Measured station temperature decreases up to 5 degrees C have been observed within approximately 6 hours. This process is a direct product of the landscape morphology. There is reasonable certainty that this is a real phenomenon in mature tidal marshes and can generate significant cooling that may have regional effect. The magnitude of the effect depends on acreage within the elevation band, depth of inundation, air temperature, humidity, timing of tides, and the water exchange dynamics between tidal channels and marsh plain.

Where tidal action results in frequent shallow inundation, short-wave, long-wave, latent, and sensible heat transfer will significantly affect the heat content of water. At seasonal, spring-neap, and tidal timescales, episodes of both cool water refugia and warm water are likely to occur depending primarily on the superposition of tidal and diel phasing. Considering the shallow slope of the landscape (hopefully in the absence of ditches), there will be linear elevation bands that will differentially warm and cool water. The Delta smelt spawning months are Feb-May when cool water refugia would be helpful. Currently, high-high spring tides in April-May occur in the early morning hours (~3-5AM), which may facilitate regional cooling; high tides during these months are not at the annual maxima associated with the summer and winter solstices but instead are closer to the annual minima associated with spring and fall equinoxes. The timing of the high-high tide processes ~1.5 hours per decade. Therefore, in 50 years, the May high-high tide may occur in the late morning and general regional warming could occur. This process would be occurring Delta wide. Sea-level rise may deepen northern reach channels.

P3a: Delta smelt

Magnitude: 2 - Low
As noted above, the spatial extent of this outcome could be limited. However, in some cases the effect could occur across a relatively large area. Thermal stresses for Delta smelt in this location occur typically in May and June, so some potential for a benefit exists. Please refer to the discussion located in HCRM4 – Cache Slough Restoration Action, Outcome P4, page 25 for more details.

Certainty: 1 - Minimal
The basis for our understanding is a single unpublished study in Suisun Marsh. The extent to which this effect may transfer to the restoration site, and to which Delta smelt and salmon will take advantage of it, cannot be predicted. Please refer to the discussion located in HCRM4 – Cache Slough Restoration Action, Outcome P4, page 26 for more details.

P3b. Salmonids

High temperatures are currently rare during May (as indicated by IEP gauges rsac075 and rsac054; Enright *pers. comm.*). Temperatures exceeding 20-21^{o}C (beyond which sublethal effects accumulate; Reese and Harvey 2002 *and see* Richter and Kolmes 2005) are more common and widespread in June, July, and August (as indicated by IEP gauges rsac075 and rsac054; Enright pers. comm.). With warming that may occur under climate change projections, high temperatures may become more frequent and extreme. Thus, Chinook salmon (spring-run and fall-run) and steelhead rearing in this proposed restoration site during June and July will probably be impacted by high temperatures. Forces that reduce those temperatures may improve survival, growth and smoltification success.

Benefits are limited to those emigrants rearing in this habitat after May, when temperatures in this region increase above optimal rearing threshold of 12-16^{o}C (Marine and Cech 2004). Benefits of this effect will be transient (temperatures will not be reduced below critical for all days during months when the effect occurs at all). Also, as mentioned in the description, this phenomenon is transient over time as the timing of tidal cycle shifts.

P3b1: Spring run salmon

Magnitude = 2- Low.
Beneficial effect occurs for only a portion of the salmonid population passing through this region during a particular and narrow window of time. This outcome modifies Outcome P1 (creation of habitat). In evaluating that outcome, benefits of this action were interpreted in the light of unfavorable temperature conditions that occur in the area during late-spring and summer. To the extent that the tidal flooding/cooling phenomenon occurs on this restoration site (a function of geography and restoration design and site elevations) during the period of potential thermal stress (May through end of summer), it may provide some relief from the effects of thermal stress *for those salmon runs that migrate through this region at this time (fall and spring run and steelhead).* That benefit impacts only the proportion of the population that migrates at this time and only the proportion of the population that migrates through this area (i.e. not all fall run or all steelhead).

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

P3b2: Fall run salmon

Magnitude = 2- Low.
Beneficial effect occurs for only a portion of the salmonid population passing through this region during a particular and narrow window of time. This outcome modifies Outcome

P1 (creation of habitat). In evaluating that outcome, benefits of this action were interpreted in the light of unfavorable temperature conditions that occur in the area during late-spring and summer. To the extent that the tidal flooding/cooling phenomenon occurs on this restoration site (a function of geography and restoration design and site elevations) during the period of potential thermal stress (May through end of summer), it may provide some relief from the effects of thermal stress *for those salmon runs that migrate through this region at this time (fall and spring run and steelhead).* That benefit impacts only the proportion of the population that migrates at this time and only the proportion of the population that migrates through this area (i.e. not all fall run or all steelhead).

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

P3b3: Steelhead

Magnitude = 2- Low.
Beneficial effect occurs for only a portion of the salmonid population passing through this region during a particular and narrow window of time. This outcome modifies Outcome P1 (creation of habitat). In evaluating that outcome, benefits of this action were interpreted in the light of unfavorable temperature conditions that occur in the area during late-spring and summer. To the extent that the tidal flooding/cooling phenomenon occurs on this restoration site (a function of geography and restoration design and site elevations) during the period of potential thermal stress (May through end of summer), it may provide some relief from the effects of thermal stress *for those salmon runs that migrate through this region at this time (fall and spring run and steelhead).* That benefit impacts only the proportion of the population that migrates at this time and only the proportion of the population that migrates through this area (i.e. not all fall run or all steelhead).

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

Outcome P4: Reduce periodic low dissolved oxygen events and associated mercury methylation events associated with the discharge of waters from lands managed as seasonal freshwater wetlands that would be restored as brackish intertidal marsh.

This outcome includes methylmercury and dissolved oxygen (DO) together because MeHg dynamics are interrelated with dissolved oxygen (DO) dynamics.

P4a. All covered fish species

Interactions between environmental conditions and wetland management practices in Suisun Marsh can lead to localized and periodic episodes of severely low dissolved oxygen (DO) events in adjoining water bodies. These low DO plumes impact the neighboring aquatic ecosystem, impairing primary and secondary production in this area (and its contribution to the larger food web of the Marsh and Estuary) and even causing acute mortality in at-risk fish species. Past research has observed that such DO sags coincide in both time and space with initial fall flood-up and discharge activities of adjacent managed wetlands (Schroeter and Moyle, *pers. comm*.). Low DO levels are also known to occur during June in Peytonia and Boynton sloughs (Schroeter *unpublished*) and these may also be related to management of tidal marshes for waterfowl production. The wetlands in question are dry-managed during the summer and early fall months. The wetlands are then prepared for waterfowl habitat and hunting with a series of flood-drain-flood cycles. Dissolved oxygen sags associated with these events most commonly occur in November (Schroeter *unpublished.*); they can be persistent, lasting from weeks to even months. During large events, the effects from a local discharge may be transported several kilometers through tidal action to sloughs with little or no pond drainage activities. Peytonia, Boynton, and Suisun Sloughs in the northwest Marsh have exhibited the most significant low DO problems. (Schroeter and Moyle, *pers. comm*.).

The indirect effects (e.g. impacts to the local substrate biota and regional food web) of this phenomenon are difficult to assess. Unlike low DO problems elsewhere (e.g. the Stockton Deepwater Ship Channel), low DO plumes in Suisun Marsh do not create a barrier to fish migration to mainstem river habitats; however, the potential for local creeks to support fall-run Chinook or steelhead spawning should be evaluated (Schroeter *pers. comm*.). Because these low DO events are localized and usually occur during a time of the year when many covered species are present in the Marsh only in low numbers, if at all, the impact of low DO events on total population size (or recovery potential) for any particular species is low.

Co-occurring with these low DO events are elevated methyl mercury (MeHg) conditions. MeHg is a neurotoxin endemic to the Delta that bioaccumulates in the food web, adversely affecting fish and wildlife species and posing a health risk to humans. MeHg is thought to be produced in association with bacterial sulfate reduction, a process favorable in low DO environments, in the presence of a labile form of inorganic mercury (Alpers 2008). The amount of MeHg released from managed ponds is currently unknown; preliminary data indicate pond releases have elevated MeHg concentrations that may range up to an order of magnitude over accepted limits (Stephenson pers comm.).

Magnitude of Physical Outcome
The processes that produce low DO and high MeHg events occur across all of Suisun Marsh. The problems may be amplified in some regions, especially the north and northwest Marsh, due to proximity to regional wastewater treatment plant outflows (and associated nutrients), and lower mixing and dilution rates with the larger estuary. If the bulk of the planned 9,000 acres of restoration was concentrated in this region, a significant reduction in seasonal low DO and mercury methylation events could be realized because the processes that create them would be eliminated. [Depending on hydroperiod, elevation, and soil circumstances, restored wetlands may exhibit organic matter decomposition processes, on a far less episodic basis. Organic matter decomposition on natural wetlands do not generally exceed the carrying capacity of adjacent tidal sloughs.]

Certainty of Physical Outcome
Certainty of wetland restoration for improving low DO/MeHg events has several components including variable soil conditions, allochthonous inputs (nutrient loading), and water residence time. Further, restoration of tidal actions on subsided landscape will produce different DO/MeHg characteristics compared to a projected mature tidal marsh of the future. However, the correlation between seasonal managed wetland water operations and spikes of biological oxygen demand (BOD) and methylmercury is well known (Seigel et al. 2008, Schroeter et al 2005, Stephenson et al. 2008). Restoration of tidal action eliminates episodic low DO events that overwhelm the regional aquatic environment's ability to process the organic matter (OM) without consuming the in situ oxygen.

Magnitudes of Biological Outcomes
Reducing periodic low dissolved oxygen events in Suisun Marsh will reduce the fish and invertebrate kills associated with this problem. Addressing this problem is expected to have somewhat beneficial effects on regional food web productivity and to reduce MeHg

contamination. The magnitude of impacts to individual covered species will be proportional to the proportion of the species' population that uses the relevant habitats when periodic low DO events occur. Populations of all covered species are naturally very low in the Marsh during June, when low DO events have been documented. Use of the Marsh in November, when low DO events occur due to managed tidal marsh operations, is described below.

<u>Fall run Chinook</u>
Magnitude = 1 - Minimal
Certainty = 2 – Low
When low DO events result from the management of tidal wetlands in Suisun Marsh, it is unlikely that Fall-run Chinook salmon juveniles are in the area. Fall run Chinook salmon kills have occurred in the marsh coincident with low DO events in Suisun Slough (R. Schroeter, *pers. comm.*). Impacts to adults that are migrating to maintstem rivers are unlikely to be substantial; however, the seasonal biological oxygen demand in the fall would prevent migration of fall run salmon into local creeks. This is not a significant impact to the overall population of the Central Valley, but may represent a local risk to any successful spawning in the small and vulnerable urban creeks (R. Schroeter, *pers. comm.*).

<u>Spring-run Chinook</u>
Magnitude = 0 -Zero
Certainty = 4 – High
When low DO events result from the management of tidal wetlands in Suisun Marsh, it is unlikely that spring-run Chinook salmon juveniles are in the area. Significant numbers of adult spring run are also not expected to be in the area when low DO events occur.

<u>Winter-run Chinook</u>
Magnitude = 1 -Minimal
Certainty = 2 – Low
When low DO events result from the management of tidal wetlands in Suisun Marsh, early migrating winter-run Chinook salmon juveniles could possibly be in the area. It is not certain that these fish are in the area and, if they are, they would represent a small fraction of the total population.

<u>Late-fall run Chinook</u>
Magnitude = 1 -Minimal
Certainty = 2 – Low
When low DO events result from the management of tidal wetlands in Suisun Marsh, late-fall run Chinook salmon juveniles may be in the area. It is not certain that these fish are in the area and, if they are, how many what fraction of the total population is affected by direct mortality from low DO events. Impacts to migrating adults are not likely to be substantial.

<u>Steelhead</u>
Magnitude = 2 -Low
Certainty = 2 – Low
When low DO events result from the management of tidal wetlands in Suisun Marsh, it is unlikely that steelhead juveniles are in the area. Impacts to adults migrating to mainstem rivers are unlikely to be substantial; however low DO plumes could block access to spawning adults migrating to local creeks to spawn (R. Schroeter *pers.*

comm.). The frequency and abundance of steelhead spawning in these local creeks is uncertain.

Longfin smelt
Magnitude = 2-Low
Certainty = 2-Low
In years when longfin smelt adults are in Suisun Marsh, they are most abundant during November (Rosenfield and Baxter 2007). However, the numbers of longfin smelt in Suisun Marsh are, at most in any year, a small fraction of the total adult population. Post-larval LFS may also be affected in June if biological oxygen demand is high in Goodyear Slough when post-larval LFS are present, but this is an infrequent occurrence (R. Schroeter *pers. comm.*) and would not impact a large fraction of the LFS population in any case.

Delta smelt
Magnitude = 1 – Minimal
Certainty = 2 - Low
It is unlikely that sizeable numbers of Delta smelt would be impacted by any but the largest low Dissolved Oxygen plumes from managed wetlands in Suisun Marsh – these events are quite rare (Moyle *pers. comm.*). The degree of impact (numbers of fish affected) is uncertain.

Sacramento splittail
Magnitude = 2 – Low
Certainty = 3 – Medium
Sacramento splittail are relatively abundant in Suisun Marsh and, in particular, in the small sloughs that are most commonly impacted by low DO releases from managed tidal wetlands. Still, these are localized events and the number of fish impacted in any given event is probably not a substantial fraction of the splittail population.

Green sturgeon
Magnitude = 2 – Low
Certainty = 1 – Minimal
Green sturgeon are probably highly susceptible to low DO mortality and sub-lethal effects (*for review, see* http://www.sjrdotmdl.org/concept_model/bio-effects_model/tolerate.htm#wsturgeon). Few sturgeon are ever detected in surveys of Suisun Marsh (B. Herbold, *pers. comm.*) but they are generally rare, so the impact to even a few fish might represent a measureable impact on the population at times.

White sturgeon
Magnitude = 3 – Medium
Certainty = 1 – Minimal
White sturgeon are probably highly susceptible to low DO mortality and sub-lethal effects (*for review, see* http://www.sjrdotmdl.org/concept_model/bio-effects_model/tolerate.htm#wsturgeon). White sturgeon are detected at low levels in surveys of Suisun Marsh (R. Schroeter *pers. comm*.); they are generally rare, so impact to even a few fish might produce a measureable impact on the population.

Potential Negative Ecological Outcome(s)

Outcome N1: Establishment of undesirable species (such as Egeria) that will prey or compete or alter habitat conditions for covered fish.

Harmful invasive species have the potential to cause two types of adverse effects. First is to worsen conditions relative to the existing baseline; i.e., creating an attractive nuisance. Second is to detract from achieving the positive benefits the action could provide. The magnitude and certainty scores below are based upon an assessment relative to baseline conditions. They do not represent the potential to distract from the positive benefits of the action. These deductions are factored into the certainty scores for positive outcome # P1. Where appropriate, the impacts are discussed below.

N1a: Submerged Aquatic Vegetation (SAV)

General Observations: The potential for undesirable species such as *Egeria* to alter habitat condition for covered fish is described in the Aquatic Vegetation Conceptual Model (see Anderson, In preparation pages 8, 9, 10 and Figure 2).

Magnitude = 1 - Low
Salinity conditions in Suisun Marsh are too high to allow for establishment of most species of SAV that occur in the Delta currently. citation needed

Certainty = 4 - High
Global warming is expected to increase salinities in this area of the Delta so future changes should reduce the likelihood of invasion by this group of fresh water SAV (citation needed).

N1b: Non-native Centrarchids

General Observations: The potential for non-native Centrarchids to establish in the Delta is described by Brown and Michniuk 2007; Grimaldo et al. 2004; Nobriga and Feyrer 2007; Nobriga et al. 2005.

Magnitude = 1 - Minimal
Establishment of centrarchids in conjunction with SAV is well documented in the Delta (Brown and Michniuk 2007; Grimaldo et al. 2004; Nobriga and Feyrer 2007; Nobriga et al. 2005). Since salinity levels in this area are currently too high to allow for establishment of submerged aquatic vegetation, the levels are also too high to allow establishment of Centrachids that occur in the Delta. Centrarchid invasion of newly restored Suisun Marsh habitats is very unlikely.

Certainty = 4 - High
Centrarchids do not currently exit in the Suisun Marsh and climate change is expected to increase salinities in this area in the future.

N1c: *Corbicula*

Consequences of *Corbicula* establishment. If established, *Corbicula* would likely have a significant effect on food web dynamics because it consumes phytoplankton in shallow areas and/or consumes the productivity of shallow areas exported to channels to such a high extent that it exhibits top-down trophic control. *Corbicula*'s consumption of primary productivity represents a significant limiting factor throughout the Delta that could greatly reduce productivity benefits of restoration efforts (Thompson et. al., In revision). According to the *Corbicula* model (Thompson et. al., In revision page 11), no local studies have been undertaken to indicate whether *Corbicula* feeding has reduced zooplankton populations either through competition or direct predation. In this case, the baseline condition is that much of the Delta is infested with *Corbicula*. The restoration of tidal marsh which may also become infested with *Corbicula* at some future time would not represent a significant change above baseline conditions. Establishment of *Corbicula* would however, consume much of the positive benefits that were previously discussed above under positive outcomes.

Potential Control Options. There are no stressors identified that can limit the success of Corbicula in a significant manner. However, salinity can limit the spatial distribution of this species and food limitation is a source of stress. (Thompson et. al., In revision, pages 8 and 13). The *Corbicula* conceptual model indicates that the only meaningful method to control their presence/abundance is salinity. This control method would require salinity intrusions into the Suisun Marsh of sufficient duration and at the appropriate times of year to have a meaningful effect. The conceptual model does not specify the duration and timing which might be most effective during recruitment. Water temperatures may influence the effectiveness of both recruitment and control measures.

Magnitude = 1-Minimal
Corbicula can control phytoplankton biomass development in shallow areas, or consume the productivity of shallow areas exported to channels. This is a significant limiting factor throughout Delta. For this outcome, the baseline condition is that much of the Delta is infested with *Corbicula*. The restoration of tidal marsh that eventually becomes infested with *Corbicula* would not represent a significant change above baseline conditions.

Certainty = 2 -Low

The timing and extent of colonization by *Corbicula* cannot be predicted for specific restoration sites due to lack of data.

> *Corbicula* are prolific reproducers and colonizers of newly available habitats in salinities below 2 ppt. Source populations can come from elsewhere within the Delta or from upstream tributary populations. *Corbicula* can establish on soft and hard substrates and on vegetation and they can colonize intertidal zones as well as deeper water. (*Corbicula* model). Based upon the biology of the species and the physical setting of the restoration site, the probability of *Corbicula* establishment in the Suisun Slough restoration areas appears to be high, but ultimately cannot be predicted, partially due high variability in environmental

conditions. The low certainty score considers the probability and extent of potential establishment.

Corbicula monitoring data from previous restoration sites in the Delta, such as Liberty Island or Little Holland Tract, would provide greater information about the probability of colonization on this Suisun site. More information would improve the certainty rating. However, such data and analysis was not made available to the evaluation team.

N1d: Inland Silversides

General Observations: Inland silversides (*Menidia beryllina*) are highly tolerant of warm water, salinity variability and are trophic generalists compared to Delta smelt (Moyle 2002). Inland silversides are the most numerous fish in Suisun Marsh shoreline habitats (Matern et al. 2002), and the most numerous fish in shallow Delta habitats (Nobriga et al. 2005, Brown and May 2006). The Delta smelt model (page 3) includes intraguild competition with inland silversides as one of the top five in-Delta stressors to Delta smelt. Inland silversides are thought to be a major predator of Delta smelt eggs (Bennett and Moyle 1996 and Bennett 2005 in the Delta smelt conceptual model pg 12). In the laboratory, inland silversides reduce Delta smelt size relative to controls when they are reared together (Bennett 2005).

Inland silversides are also treated in the longfin smelt model. Moyle (2002, in Rosenfield, 2008) suggested that based on timing of arrival in the Estuary and subsequent longfin population response, inland silverside might have had a major impact on longfin population dynamics. However, the model states that inland silverside prefer shallow water habitats where juvenile and sub-adult longfin are rare, thus, their impact as predators of juvenile and sub-adult longfin is probably slight (Rosenfield, 2008, pg. 17). Spawning locations for longfin are unknown, so it is not known whether competition from inland silverside for spawning territory is a factor in their decline.

However, Delta smelt evolved with other intraguild competitors, including longfin smelt, and have survived with Striped bass (introduced in 1879). Interaction between silversides and Delta smelt in the wild may be limited because Delta smelt typically inhabit offshore environments, while Inland silversides typically inhabit shoreline habitats. Increased shoreline habitat would presumably increase the carrying capacity for Inland silversides. However, predator-prey interaction between Delta smelt and Inland silversides in the wild is speculative. Silversides may eat Delta smelt eggs or larvae if the eggs and larvae occur on the shorelines. It has not been shown that inland silversides reduce calanoid copepods (Norbriga and Herbold, 2008, page 32), so they may not effectively compete with Delta smelt for prey.

Williams and Rosenfield, In preparation; Israel and Klimley, 2008; Kratville**,** 2008); and Israel et. al., 2009 do not mention inland silversides so this evaluation assumes no adverse effects and focuses its evaluation on Delta smelt and longfin smelt.

Magnitude: 2 - Low

Inland silversides are the most abundant fish in shallow-water habitats in many areas of the Delta and may currently contribute to local depletions of zooplankton otherwise available to native fishes within these areas. Additionally, they may prey on embryos of species that lay eggs in these shallow areas (Moyle 2002). The crash of Delta smelt populations coincided with invasions of inland silversides into the estuary (Bennett and Moyle 1996). This action may change conditions relative to baseline by attracting (via restored marsh) a nuisance (inland silversides). This conservation measure will increase the local inland silverside population by providing additional shoreline breeding habitat. Because of the high existing abundance of inland silversides, the incremental increase in breeding habitat and thus population size above current conditions is considered small and the magnitude of this effect is considered to be low relative to baseline. Further, differential habitat selection (offshore environments for inland silverside) is expected to reduce the interspecific competition effects.

Certainty: 2 - Low
Understanding of interaction between Inland silversides and Delta smelt in the wild is low, particularly in regards to egg predation by inland silversides. Better data on where and when Delta smelt lay their eggs would better allow us to assess the potential impact of inland silverside predation. Spatial interactions with longfin smelt are also uncertain.

Outcome N2: Potential for mercury methylation and local bioaccumulation: N2-A – Covered fish species, N2-B, Non-covered wildlife species, N2-C, Human health.

N2a: Covered fish species

General Observations: The potential for mercury methylation and local bioaccumulation to affect fish and wildlife is described in the Mercury Conceptual Model (see Table 2 and associated text). Although current methylmercury levels on Liberty Island (analogue for future state of areas to be restored) are relatively low (Slotton et al. 2002, Alpers et al., 2008, figure 5), there is potential for enhanced production of methylmercury in areas of high marsh that will be inundated infrequently (only during highest tides). The process of drying out between wetting events tends to oxidize species of sulfur, iron, carbon, and mercury, leading to higher potential to form methylmercury upon rewetting. Once formed, methylmercury biomagnifies in the aquatic food web and ecological effects may occur in some sensitive species. Thus, the specific geomorphology of restoration sites and in particular the degree to which shallow depressions and poorly drained areas of high marsh are part of the restoration projects directly influences the degree of mercury methylation.

Magnitude: 1 - Minimal
No toxicological studies have been conducted with any of the covered species regarding acute toxicity. So mercury concentrations in covered fish species are compared here against concentrations producing mortality in other fish species. Mercury concentrations in ppm-wet weight for white sturgeon, Chinook salmon and steelhead collected during 2006 were 0.165-0.279, 0.094-0.396 and 0.06-0.13, respectively (Melwani et al. 2007). No tissue data for either longfin or Delta smelt were found. It is assumed both species will have tissue concentrations similar to other fish taxa living one year and feeding primarily on zooplankton. Mercury concentrations in juvenile threadfin shad and juvenile

largemouth bass in the Delta are 0.012-0.076 and 0.035-0.230, respectively (Slotton et al., 2006). In comparison death in rainbow trout (steelhead) in laboratory studies occurred at 4-ppm wet weight and the NOAEC for death in brook trout at 2.7 ppm (in Wiener and Spry, 1996). In conclusion there exists about a 10X safety factor exists between fish tissue concentrations measured in the Delta and values reported to cause mortality in lab studies.

Regarding chronic toxicity, again no toxicological studies exist with any of the covered fish species. Therefore, have compared reported tissue concentration for individual species against known laboratory effects in other taxa. Decreased feeding efficiency and some hormones response changes observed at 0.25-0.27 ppm wet weight (page 30 of Alpers et al., 2008). Decreases in growth occurred in fathead minnows at 0.6-0.7 ppm Hammerschmidt et al., 2002) and in juvenile walleye at 2.4 ppm (Friedmann et al., 1996). In conclusion, some up/down regulation of genes and alterations in feeding behavior are possible in the most contaminated individuals.

Certainty: 2 - Low
Scientists have a low certainty that the magnitude of this outcome is minimal (i.e. magnitude may be higher). The uncertainty is due to the limited tissue data are available for most covered fish species. However, review of data on other similar taxa suggests there is a large safety factor regarding acute toxicity.

There are limited toxicological data available for most of the important sub-lethal processes and none of this has been collected for covered species. The limited tissue data set makes it difficult to determine the proportion of population potentially at risk.

N2b: Methyl mercury, non-covered species

General Observations: The potential for mercury methylation and local bioaccumulation to affect fish and wildlife is described in Alpers et al., 2008 (see Table 2 and associated text).

Magnitude: 3 - Medium
Fifty-eight percent of Forster's terns in San Francisco Bay are at risk of reproductive impairment from consuming fish with elevated mercury levels (Ackerman et al., 2008). Although it is unknown whether Forster's terns nest in Siusun Marsh, they have been observed in the area and are likely to forage there. Mercury levels in small fish consumed by terns are of similar magnitude in parts of Suisun Marsh (Davis et al. 2007) compared with those in South San Francisco Bay (Ackerman et al., 2007). Other bird species filling the Forster's tern niche such as egrets, herons, and grebes may be at risk in Siusun Marsh from increased methylmercury exposure. Mercury could cause a sustained, minor population effect on a large area.

In laboratory studies, mink have reproductive failure and die when fed fish diets of 0.5 and 1-ppm mercury, respectively (Dansereau et al., 1999). For comparison, mercury concentrations in 64% of largemouth bass, 23% of white catfish, and 35% of channel catfish caught in the Bay-Delta watershed have between 0.23 and 0.93 ppm mercury (Davis et al., 2008).

Most of the studies were conducted in the South San Francisco Bay and Petaluma River marshes with a focus on species native to that area, specifically Clapper and Black rail (endangered and threatened, respectively). These studies have shown that rails seem particularly susceptible to methyl mercury. Although neither of these species occurs in Siusun Marsh, the related Virginia rail (not a listed species) is present.

Biogeochemical processes create varying conditions and a subset of these conditions promotes mercury methylation and this is the key factor used in evaluating the magnitude of this actions effect. Mercury methylation in tidal wetlands is driven in large part by geomorphology and the resulting inundation regime. Methyl mercury production needs approximately one to four weeks of dryness to re-set the biogeochemical conditions necessary for mercury methylation (specific time frame not determined; table 2 in Alpers et al., 2008). Available topographic data have not been analyzed to the level necessary to describe the setting more precisely.

Certainty: 2-3 Low-Med
Scientific understanding of methylmercury effects on some bird and mammal species is high, based on peer-reviewed studies from the San Francisco Bay Area and elsewhere. However methylmercury effects on other bird, reptile, and mammal species are unknown. The nature of the outcome is greatly dependent on highly variable ecosystem processes.

N2c: Methyl mercury, Human Health

General Observations: This action could increase mercury content of sport fish.

Magnitude: 2 - Low
Fish consumption advisories for the Delta recommend that children under the age of 17 and women of child bearing age consume no largemouth bass, smallmouth bass, spotted bass or Sacramento pikeminnow. Others are warned to limit their consumption of these species to one meal a month (OEHHA, 2006, 2008a,b). Between 10,000 and 20,000 fishermen in the Delta are presently eating fish with more than 10X the recommended methylmercury reference dose (RfD) (Klasing and Brodberg, 2008) and could experience some sublethal mercury poisoning (personal communication, Dr. Fraser Shilling).

The probability of increased methylmercury production and export into the food web is the same as that described above for covered fish species and non-covered species.

Certainty: 3 - Medium
There is uncertainty regarding the magnitude and direction of change in mercury content of sport fish, although levels are more likely to increase than decrease. For a given increase in mercury content of sport fish, risk to human health is quantified based on peer-reviewed studies (Gassel et al. 2007, 2008). It is unknown how many anglers would access the project area and what fish they would catch and consume.

The role of restoration projects under this Conservation Measure in contributing to mercury levels in fish species consumed by humans needs to be explored in relation to other mercury sources for those fish species.

Important Gaps in Information and/or Understanding

Data needed to more fully evaluate tidal marsh restoration actions

- Residence times (average and spatial variance in that value) are necessary to determine how much and what kind of food would be produced on site and exported from the site. Residence time projections also affect temperature and dissolved oxygen conditions and these are important attributes of physical habitat. Finally, residence times for particles of water could inform assessment of "residence" times for fish. There is a non-linear relationship between fish "residence time" and the benefit of the rearing habitat as, at high "residence times" new habitat may serve to delay important migratory activities whereas at very low residence times, the new habitat will have reduced benefit because fish (or at least those that behave like particles) will experience the habitat for only a short period.
- Current and projected daily/weekly temperature projections specific to each restoration site.
- Centrarchid models to understand predator-prey-habitat interactions.
- Striped bass model to understand predator-prey-habitat interactions.
- Expected retention time on restored tidal areas to understand likely productivity and food export potential to local sloughs.
- Predation rates in Suisun Marsh vicinity to understand baseline predation pressure in this region.
- More spatially comprehensive hydrodynamics to understand whether changed flow patterns will reduce or simply redistribute predator pressure.
- Hydrologic and sediment information about turbidity levels, duration, and consequences on species as related to the following: Increased ability for Delta smelt to locate food due to increased turbidity from increased velocities in larger channels.
- Prior to implementation, conduct a complete Phase I Environmental Assessment with on-site sampling to assess legacy and other soil contaminants (i.e. mercury and pesticides).
- *Corbicula* monitoring data from previous restoration sites in the Delta, such as Liberty Island or Little Holland Tract, would provide greater information about the probability of colonization on this Cache Slough site.
- Data on mercury bioaccumulation in waterbirds in the Delta would allow an assessment of transfer of methylmercury to higher trophic level wildlife and an assessment of ecotoxicological risk to reproduction.
- Better data on where and when Delta smelt lay their eggs would better allow us to assess the potential impact of inland silverside predation.

Research Needs

- Restoration techniques that will prevent colonization by invasive species.
- Management practices that can control invasive vegetation, clams, and predators (centrarchids and inland silversides) and limit colonization of these sites.

- Run (and life-history) specific studies of Central Valley Chinook salmon and studies of steelhead use of tidal marsh habitats would be extremely valuable to defining magnitude of impacts to these populations and increasing certainty. Various tools (including genetic markers and otolith signatures of population origin) could be used to assess both growth and survival of salmonids in these habitats as well as changes in life history characteristics (survival and fecundity) over the course of the life cycle that arise from residence in tidal marsh habitats. Currently, all of the evidence for benefits of tidal marsh on salmonids comes from steelhead and fall run populations well to the North (where high temperatures and invasive predators are not as problematic). Translating these results to all CV salmonid populations is unwarranted and could lead to disastrous "restoration" projects.
- Data on nutrient flow from the marsh plain to juvenile fish rearing in the adjacent channels is essential to determining the value of restored marshes as a food source for larvae of pelagic fish (like longfin and Delta smelt).
- Evaluate the effectiveness of water management strategies on managed wetlands to reduce the production of low dissolved oxygen events associated with managed wetlands operations and transfer what is learned into best management practices for the broader managed wetlands community in Suisun Marsh. In addition, it is likely the reduction of low DO events will result in conditions less favorable for MeHg production and thus reduce MeHg loading to the surrounding aquatic environment. This hypothesis needs testing.
- Greater understanding and more research is needed about the availability and production of food in tidal marshes. Export of organic material from the marsh plain and phytoplankton, zooplankton, and other organisms produced in intertidal channels into the Delta has not been studied.
- Potential negative effects of methylmercury exposure on covered fish species remain largely unknown. Based on published studies involving other (non-covered) fish species, there is reason for concern regarding possible chronic effects caused by methylmercury exposure, including: endocrine disruption, reduced reproductive success, reduced predator avoidance, and reduced feeding efficiency. (See Mercury Conceptual Model, Alpers et al. 2008, Table 4, page 30). Research is especially needed to determine possible effects caused by exposure during early life stages.
- A better understanding is needed regarding the relationship of mercury methylation and bioaccumulation to the duration of wetting and drying events in areas that are intermittently inundated (i.e. tidal marsh and floodplain). Laboratory and field studies of mercury cycling involving sediments in tidal marsh and floodplain environments should quantify the duration of drying time and the extent of dryness necessary to change the oxidation-reduction character of iron, sulfur, carbon, and mercury in sediments such that microbial activity associated with mercury methylation is enhanced.
- A better understanding is needed of mercury cycling, bioaccumulation and ecological effects on waterbirds in tidal marsh habitats.
- Tropho-dynamic model of ecological interactions linking primary production to the food web structure and production flows into, through, and out of the tidal marsh system.
- Landscape-level models that address the effects of variation in structural features of the tidal marsh environment (e.g., tidal channel complexity, channel width, channel length, edge: area ratios, etc.) on the population or production dynamics of specific plants and animals.

Assess Reversibility and Opportunity for Learning

Reversibility

No/Hard: The following on-the-ground actions would be needed to reverse this action:

1) levees would need to be reconstructed
2) newly created tidal sloughs would have to be regraded
3) sites would have to be dewatered
4) wetland vegetation would have to be removed
5) monitoring pre, during, and post construction

Although this reconstruction is technically possible, there would be significant financial and regulatory costs. Prior to action reversal, the following planning activities would be needed:

1) geotechnical evaluations for levee reconstruction
2) engineering design
3) evaluate land use options for areas subject to subsidence reversal actions
4) environmental permitting and associated agency ESA consultation,
5) mitigation planning

Levee repair costs are estimated to range between $1,000 and $9,000 per linear foot (Snow 2006).

Opportunity for Learning

High:

Suisun Marsh is divided into over 150 public and private properties. Therefore, opportunities for research leading to significant advances in the knowledge base are available if experimental treatments take advantage of adjacent properties with otherwise similar hydrology and water quality. The in-progress study by Seigel et al. (2008) is a small scale attempt along these lines to test alternative water and vegetation management options on adjacent ownerships. Across potentially 9,000 acres of restoration opportunity, several research questions and testable hypotheses are available including:

1. What is the water quality supplied to and discharged from managed and tidal wetlands?
2. What is the amount of available mercury in the soils?
3. What is the amount of available organic matter in the soils for contributing to oxygen demand?
4. What is relationship between dissolved oxygen sags, site vegetation, and MeHg production?
5. What mixing characteristics are required to adequately disperse low DO water? There are also approximately 6000 acres of remnant tidal marshes that exhibit unknown DO and MeHg dynamics. There are key questions about the tradeoff between managed wetland water operations and natural tidal marsh land-water interface dynamics, especially regarding MeHg production.

Implementation of this project could be designed such that different engineering designs could be compared. Numerous physical and biological components could be monitored and ideally the monitoring data would be used to assess and refine modeling simulations of the restoration as a part of a comprehensive adaptive management program. See text in HRCM 4 for details.

Appendices

Appendix A: Summary Tables Organized by Outcome

Table A1. Positive Outcomes

Outcome	Magnitude	Certainty
P1: Increase rearing habitat area (including physical and biotic attributes) for covered fish species.		
a. Delta smelt	3	1
b. Longfin smelt.	1	2
c1: Winter-run	1	1
c2: Spring-run Chinook Salmon.	3	1
c3: Fall-run Chinook salmon.	3	1
c4: Late Fall-run	1	1
d: Sacramento splittail.	3	2
e: Green Sturgeon	2	2
f: White Sturgeon	2	2
P2: Increase the availability and production of food in Suisun Bay by exporting organic material via tidal flow from the marsh plain and phytoplankton, zooplankton, and other organisms produced in intertidal channels into the Bay		
a. Viewpoint #1	3-4	3
b. Viewpoint #2	1-2	1
P3: Locally provide areas of cool water refugia (Feb-Jun)		
a: Delta smelt	2	1
b1: Spring-run,	2	1
b2. Fall-run Salmon	2	1
b3. Steelhead.	2	1
P4: Reduce periodic low dissolved oxygen events		
a. Fall-run Chinook Salmon.	1	2
b. Spring-run Chinook Salmon.	0	4
c: Winter-run Chinook Salmon	1	2
d: Late Fall-run Chinook Salmon	1	2
e: Steelhead	2	2
f: Longfin smelt	2	2
g: Delta smelt	1	2
h: Sacramento splittail.	2	3
i: Green Sturgeon	2	1
j: White Sturgeon	3	1

Table A2. Negative Outcomes

Outcome	Magnitude	Certainty
N1: Establishment of undesirable species (such as Egeria) that will prey or compete or alter habitat conditions for covered fish.		
A: Submerged Aquatic Vegetation	1	4
b: Non-native Centrarchids	1	4
c: Corbicula	4	2
d: Inland Silversides	2	2
N2: Potential for mercury methylation and local bioaccumulation.		
a: Covered fish species	1	2
b: Other species (not covered).	3	2 to 3
c: Human health.	2	3

Appendix B - Outcomes with Zero Magnitude

OP1: Locally provide areas of cool water refugia for winter-run salmon.

Magnitude = 0- Zero.
There will be no benefits of this restoration to winter-run salmon because this run passes through the region during a window of time when temperatures are not believed to be highly stressful to salmonids.

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

OP2: Locally provide areas of cool water refugia for late fall-run salmon.

Magnitude = 0- Zero.
There will be no benefits of this restoration to late fall-run salmon because this run passes through the region during a window of time when temperatures are not believed to be highly stressful to salmonids

Certainty = 1-Minimal
As noted above, certainty is reduced due to a great dependence on highly variable ecosystem processes. While a reasonable understanding at the general level is prevalent, the range of data needed to evaluate at the action scale is lacking.

Action: HRCM 11 - Riparian and emergent vegetation establishment along existing levees.

Evaluation Team: Floodplains Workgroup
Campbell Ingram (chair), Denise Reed (coach), Carie Battistone (notetaker), Eric Ginney, Ted Sommers, Rosalie Del Rosario, Dennis McEwan, Bill Harrell, Dan Welsh, Yvette Redler, and Vance Russell.

Date of Last Revision: March 1, 2009

Action Description and Clarifying Assumptions

Establish native riparian woody vegetation and emergent vegetation along a 5 mile segment of levee constructed along the Sacramento River in the West Delta (somewhere between Isleton and Ryde), and along a 5 mile segment of levee along Old River near Bacon Island.

Assumptions

1. The language regarding BDCP constructed levees was determined to be irrelevant and was removed from the action description.
2. LWD installed "at low elevation surfaces of the levee (e.g., levee benches)" will be anchored with cable because it will be in a narrow, navigable waterway and integrated within a project levee.

Approach

1. Plant riparian vegetation along the levee to increase overhead cover and instream shaded riparian aquatic habitat
2. Provide for the establishment of tidal emergent vegetation along low elevation surfaces of the levee (e.g., levee benches).
3. Install large woody debris at low elevation surfaces of the levee (e.g., levee benches)

Intended Outcomes as Stated in Conservation Measure

1. Provide (rearing?) habitat for salmonids, splittail, and other covered fish species
2. Provide cover for covered fish species from predators.
3. Provide organic carbon input into adjacent channels in support of food web processes that would provide food to covered fish species.

Positive

P1. Increased establishment of instream structure through export of LWD to benefit covered species.
P2. Increase splittail spawning habitat on narrow floodplain margin.
P3. Increase rearing habitat for splittail, green and white sturgeon, Chinook salmon and steelhead (consider loss to entrainment for Old River).
P4. Increased production and export of terrestrial invertebrates into the aquatic ecosystem for rearing splittail, green and white sturgeon, Chinook salmon and steelhead.
P5. Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (offsite), longfin smelt, and delta smelt (consider loss to entrainment on Bacon option).

Negative

N1. Increased habitat for non-native predators/competitors to Chinook salmon, steelhead, green and white sturgeon, and splittail, if flows through sloughs are not sufficient to prevent colonization by non natives.

N2. Increased exposure risk to contaminants (including Selenium) due to longer residence time in this area (for Bacon option only).

Conceptual Model Information Regarding Intended Outcomes

The basic drivers and outcomes are described in the DRERIP conceptual models, as listed below:

Models used:
Corbicula and Corbula
Delta smelt
Fish Habitat Linkages
Floodplain
Longfin smelt
Salmon Model (Rosenfield 2007)
Selenium
Splittail
Sturgeon
Steelhead
Tidal Marsh

Assumptions

Provided in BDCP Conservation Measure
None provided.

Added by Evaluation Team
None provided.

Problem(s) with Action as Written:

None provided.

Scale of Action:

Small

Rationale:
Small extent (5 miles along each Old River and West Delta), reversibility high. Existing conditions along these segments include sporadic riparian habitat.

Evaluation Summary Tables

Summary tables listing magnitude and certainty scores for each outcome, by species, are provided in Appendix A. Details regarding each of the listed scores, and the rationales for the scores, are provided in the discussion of positive and negative outcomes on the following pages.

Positive Outcomes Identified, Not Separately Evaluated

Below is an outcome that was identified, but not listed in the worksheet, because it was merged with another outcome for full evaluation.

- OP1: Increased establishment of woody riparian and emergent vegetation to provide high quality rearing habitat for covered species. This outcome was merged with P2 and P3.

Relation to Existing Conditions:

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?
YES

Nature of Change: Not provided

Potential Positive Ecological Outcome(s)

Outcome P1: Increased establishment of instream structure through export of LWD to benefit covered species.

This outcome is divided into two suboutcomes, one for green sturgeon and one for white sturgeon.

P1. All covered fish species

The approach and assumptions for HRCM11 do not indicate that the channel will be allowed to evolve, and the levees are not being set back. No changes to the currently impaired flood hydrology are included in the action. Thus, the ability for natural channel processes (DRERIP Floodplain Model, Figure 2) to erode banks and recruit & export the increased riparian vegetation as LWD will be minimal.

The action will actively place LWD "…at low elevation surfaces of the levee (e.g., levee benches)." This will increase spawning and rearing habitat for covered species (page 34, DRERIP Salmon model; DRERIP Splittail model pages 2-6; and perhaps delta smelt: DERIP Delta Smelt model page 2-5); however, this local habitat will not be available for export to other areas because of its fixed nature.

Magnitude = 1
Based on the approach and assumptions for HRCM11, it is very unlikely that these static, local habitat improvements will increase LWD export to downstream areas (DRERIP Floodplain Model Figure 2).

Certainty = 1
Nature of outcome (export of cabled wood) would be very dependent on flooding of a magnitude that is rare.

Outcome P2: Increase splittail spawning habitat on narrow floodplain margin.

P2. Splittail

Floodplain model page 25 and Splittail model pages 9 and 12 describe how additional floodplain habitat supports splittail spawning. Assume that there will be floodplain habitat available, but action as described does not indicate that there will be seasonally-inundated FP habitat. Splittail will spawn on flooded vegetation (Moyle et al. 2004) if floodplain is not accessible.

Increased establishment of woody riparian and emergent vegetation to provide high quality rearing habitat for covered species is an intermediate outcome.

Magnitude = 2
Area is limited.

Certainty = 3-4

Outcome P3: Increase rearing habitat for splittail, green and white sturgeon, Chinook salmon and steelhead (consider loss to entrainment on Old River).

P3a. Splittail

Floodplain model page 25 and Splittail model pages 9 and 12 describe how additional floodplain habitat supports splittail spawning. Assume that there will be floodplain habitat available, but action as described does not indicate that there will be seasonally-inundated FP habitat. Splittail will spawn on flooded vegetation (Moyle et al. 2004) if FP is not accessible.

Increased establishment of woody riparian and emergent vegetation to provide high quality rearing habitat for covered species is an intermediate outcome.

Magnitude = 2
Greatest importance is in dry years when floodplains aren't available.

Certainty = 3-4
Sommer et al. 2002, 2007 shows Splittail prefer shallow flooded habitat.

P3b. Green Sturgeon

Juvenile sturgeon are benthic feeders so creation of additional benthic habitat would be beneficial (Sturgeon model page 8), Channelization of the estuary has reduced foraging habitat for green sturgeon (Green Sturgeon model page 20). Juveniles use intertidal habitats along the Sacramento River and many areas in the Delta (Green Sturgeon Model page 4.

Magnitude = 2
Small spatial extent.

Certainty = 1
Limited data on rearing preferences.

P3c. White Sturgeon

Juvenile sturgeon are benthic feeders so creation of additional benthic habitat would be beneficial (Sturgeon model page 8). Although it is unknown whether white sturgeon will utilize habitats this shallow. They were never captured in YOLO Bypass studies (Sommer and Harrell Unpub data). Although it's not mentioned in the White Sturgeon model, it is likely that White Sturgeon will utilize the same habitats for foraging as described below for Green Sturgeon. Shallow water habitats and low tidal areas are likely nursery habitat (White Sturgeon Model page 15).

Magnitude = 2
Small spatial extent

Certainty = 1
Limited data on rearing preferences

P3d. Steelhead

Tidal marshes can provide rearing habitat and foraging opportunities to fishes that enter marsh channels (Fish Habitat Linkages Model). The primary food organisms of juvenile salmonids are drifting aquatic insects and the larval stages of terrestrial insects (Quinn 2005).

Riparian vegetation is important to salmonids (inc steelhead) by contributing terrestrial insects into the stream and logs and branches that shape channel morphology, retaining organic matter, providing essential cover, stabilizing banks, maintaining undercut banks, and modifying water temperatures through shading (Murphy and Meehan 1991).

Allochthonous inputs from streamside vegetation are important to salmonids because they provide food for the aquatic invertebrate food base (Murphy and Meehan 1991). Given their similarities in life history, it can be assumed that they are utilizing the same habitats as juvenile salmon, and many of the references below for Chinook salmon would apply to steelhead as well.

Magnitude = 3
Rearing habitat in the delta is so reduced, this could have a sustained minor population effect.

Certainty = 2
Not much in the literature regarding steelhead use of estuaries for rearing.

P3e. Chinook Salmon

Juvenile salmon use emergent vegetation in large channels like Sacramento. 1) fry/parr use emergent vegetation to rear; 2) smolts may also use emergent vegetation.

Several studies suggest that emigrating salmon derive great benefit from connection with vegetated riparian areas…it provides a variety of benefits including shading, terrestrial food web inputs and habitat structure (Opperman and Merenlender 2004, Quinones and Mulligan 2005).

Environments that offer habitat structure, such as emergent vegetation or dead woody debris, allow juvenile salmon to escape predators and avoid high flows. Chinook salmon prefer habitat with dead and living plant matter over habitats that offer relatively simple bank and bottom surfaces (Opperman and Merenlender 2004, Quinones and Mulligan 2005).

As juvenile Chinook salmon grow, they move into deeper water with higher velocities, but still seek shelter & refugia to minimize energy expenditure. (Healy 1991). Re: Sacramento River juveniles in West Sacramento. Smaller sized fry along margins, larger juvenile in main channel (USFWS 1997).

Juvenile Chinook within pools in the American River were associated with instream cover such as rootwads, logs or submerged vegetation, or with overhead cover, and were also associated with eddies or other areas with steep velocity gradients. Such positions allow fish to hold in slower water but make forays into faster water to capture drifting insects (Jackson 1992).

Magnitude = 2-3
For Sacramento River only; Old River contingent on conveyance and operational scenario. Sustained minor population effect spatially on habitat but addresses a key limiting factor (suitable rearing habitat); 5 miles on mainstem Sacramento is small spatial scale, compared to the > 60 mile migratory corridor along Sacramento River within the legal Delta, or within >250 river miles to the Upper Sacramento spawning habitats.

Certainty = 2-3
For Sacramento River only; Old River contingent on conveyance and operational scenario. Studies in the Delta and Central Valley have shown the connection between channel and riparian habitats are important for juvenile rearing. Numerous studies have indicated that shallow riparian habitat benefits fry Chinook (Sommer 2005, Quinones 2005, Kjelson 1982). Loss of this habitat has been indicated as a major source of decline in CV Chinook.(NMFS 1997, CDFG 2004). Shallow water habitats including river floodplains and riparian margin provide rearing habitat. Growth rates for juvenile salmon are higher and emigration rates are slower when in shallow water rearing habitats (Kjelson 1982, Sommer et al 2005).

Outcome P4: Increased production and export of terrestrial invertebrates into the aquatic ecosystem for rearing splittail, green and white sturgeon, Chinook salmon and steelhead.

P4a. Splittail

Adult consumption of earthworms is common (Moyle et al. 2004). Consumption of other invertebrates is common in all life stages (Feyrer et al. 2003).

Magnitude = 3

Certainty = 3

P4b. Green/white Sturgeon

Invertebrates are common food items for small sturgeon, but it’s unclear how much they use terrestrial prey (White Sturgeon Model page 8)

Magnitude = 1

Certainty = 2
Sturgeon are benthic feeders and it’s unknown how much they will feed on surface drift. More than 1 because there is diet data for sturgeon.

P4c. Steelhead

Moyle et al. 2004, page 277 states that stream-dwelling O. mykiss feed mostly on drifting aquatic organisms and terrestrial insects.

Magnitude = 2
Given that existing rearing habitat in the Delta is very limited, this restoration action could have a sustained minor population effect for this species.

Certainty = 3
Steelhead use of estuaries for rearing is not well described in the literature.

P4d. Chinook Salmon

Consumption of terrestrial invertebrates in drift is very common (Sommer et al. 2001). Diet has a large effect on growth and survival.

Magnitude = 2
Spatial extent is low.

Certainty =3-4

Outcome P5: Increase availability and production of food (POM, phytoplankton, zooplankton, small fish, etc) for Chinook salmon, steelhead, green and white sturgeon, splittail (offsite), longfin smelt, and delta smelt (consider loss to entrainment on Bacon Island option).

The text and scores provided here are applicable to all covered fish species. Tidal Marsh subsidizes the broader estuarine ecosystem. This includes benthic and terrestrial invertebrates and zooplankton (Tidal Marsh Model page 9)

Magnitude = 1
Spatial extent is low.

Certainty = 3

Potential Negative Ecological Outcome(s)

Outcome N1: Increased habitat for non-native predators/competitors to Chinook salmon, steelhead, green and white sturgeon, and splittail, if flows through sloughs are not sufficient to prevent colonization by non natives.

The floodplain model does not address non native predation or competition on the floodplain. Evidence from Yolo and Cosumnes about non-natives taking advantage of floodplain (ref Sommer et al 2004, Moyle et al 2006). Floodplain Model: Page 10 talks about sources of invasive species. Foodweb Model is focused on estuarine systems.

N1a. Delta Smelt

Delta smelt model: fish are adapted to sustain high mortality during the adult stage (Winemiller and Rose 1992). Predation is one of two primary factors for population dynamics (Figure 7). The most likely ancestral delta smelt predators would have been piscivorous birds, salmonid fishes, and, secondarily, longfin smelt as a larval predator and predatory freshwater fishes like Sacramento pikeminnow, Sacramento perch, and striped bass (Moyle 2002). All of the above listed species could be expected to inhabit the enhanced channel margin habitat.

Magnitude = 2

Certainty = 3

N1b. Longfin Smelt

Longfin model - Predation is a source of direct mortality to eggs and larvae. Some fish species (e.g., suckers, splittail and sturgeon) may feed on LFS eggs. Larval LFS are not strong swimmers (Wang 1986) and are thus highly vulnerable to predation. Striped bass and inland silverside are probably major predators on LFS larvae. Terns, gulls, and cormorants may also prey on this life stage. There appears to be a correlation between high flows and the abundance and distribution of LFS; high flows also decrease the success of LFS predators by increasing turbidity (Page 8.) There is little information in the model specific to competition with non-natives, competition for food resources is expected to have decreased with the recent decline in LFS (Page 14.), competition for spawning sites is unknown (Page 10.). Predation and competition are characterized as medium importance and medium understanding (Figure 5.); floodplain predation and competition are not specifically addressed.

Magnitude = 3

Certainty = 2

N1c. Splittail

Splittail model - Predation by non native fish is characterized as low with high understanding for juveniles and as medium with medium understanding for adults (Figures 5, 6 and 7.) Bird predation appears limited until water recedes and floodplains begin to isolate from main channels at which point fish are exposed to wading birds. [Moyle 2004].

Magnitude = 2

Certainty = 3

N1d. Green/white Sturgeon

White sturgeon – model indicates probable distribution in this reach (Figure 7), green sturgeon model indicates probable distribution in this reach (Figure 2). Need to view model again for competition and predation information.

Magnitude = 1

Certainty = 2

N1e. Steelhead/Chinook Salmon

Chinook salmon and steelhead. The CS and steelhead model indicates Non-native predation and competition with invasive species and hatchery produced salmonids is of medium importance in rearing and emigration estuarine habitats, including floodplain (Figure 2a).

Magnitude = 2-3

Certainty = 2

Outcome N2: Increased exposure risk to contaminants (including Selenium) due to longer residence time in this area (for Bacon Island option only).

The text and scores provided here are applicable to all covered fish species. Selenium (Se) loading of the Bay-Delta ecosystem is driven mainly by loads entering the Delta from the San Joaquin River (SJR), which in turn receives most of its Se input from agricultural drainwater entering the river through Mud Slough (Se model, Fig. 1). The location of the Bacon Island component of this project is in the South Delta in proximity to Se inputs from the SJR. Despite this location, the magnitude of potential effects of Se on covered fish species from this project relative to baseline is minimal.

The proposed action is limited in its spatial scale and does not involve habitat modification other than planting trees along existing levees, creating levee benches, and installing large woody debris. These actions would not increase Se loading or bioavailability. However, exposure of covered fish to Se might increase due to longer residence time of the fish in the enhanced habitat.

Salmonids are relatively sensitive to Se compared to other fish species (Se model, page 19). Beckon (2008 abstract from CALFED science conference; manuscript in prep) evaluated Se data from the SJR and concluded that, although discharges of Se to the SJR have been reduced over the last 15 years, Se will pose a substantial risk to salmon that are reintroduced to restored middle reaches of the river unless Se loads are further reduced and/or sufficient dilution flows are provided. The magnitude of potential effects of Se from this project at Bacon Island may be lower than would occur at projects along the middle reaches of the SJR (i.e., sites in the vicinity of Mud Slough) because this project occurs in the South Delta, downstream of dilution sources from the Merced, Tuolumne and Stanislaus Rivers. However, this spatial difference does not provide strong protection because Se bioaccumulates in food chains is recycled in the ecosystem, and can have significant lag times between when loading occurs and when effects are seen.

The seasonal use of the habitat may also reduce the potential magnitude of Se impacts to covered fish species, especially juvenile salmonids. Seasonal use of the Delta by juvenile salmonids occurs mainly during high flow periods (January-June)(salmon model, page 11); whereas highest concentrations of Se occur during low flow periods (Se model, page 6). However, this seasonal difference does not provide strong protection because Se bioaccumulates in food chains, is recycled in the ecosystem, and can have significant lag times between when loading occurs and when effects are seen.

The invertebrate prey of juvenile salmonids are water-column-feeding or detritus-feeding species that are relatively less contaminated than certain suspension or deposit-feeding bivalves (Se model, Table 5 and Fig. 1). Adult splittail and sturgeon feed on bivalves and would be expected to have greater exposure to Se in their diet than salmonids. This project is intended to provide rearing habitat for juvenile sturgeon and splittail rather than habitat for adults, but may also result in increased residence time by spawning and foraging adults. However, the bivalve species present at this freshwater location would be Corbicula fluminea rather than Corbula amurensis (Corbula and Corbicula models). C. fluminea is less efficient at bioaccumulating Se than C. amurensis (Se model, page 14).

Se dynamics in the Bay-Delta system are fairly well understood, but there is uncertainty about how changes in management of SJR flows, water exports, and potential future actions to solve the drainage problem on the west side of the San Joaquin Valley could affect Se loading and cycling in the Delta (Se model, pp 3 and 4). A quantitative analysis of the increased risk of Se toxicity resulting from this project would require estimates of the increase in the amount of time covered fish spend at this location relative to the baseline condition, as well as estimates of future river flows, water exports, and Se loads. Such an analysis is beyond the scope of this worksheet exercise, but should be considered if the project is recommended for evaluation in the NEPA process.

Magnitude = 1

Certainty = 3

Important Gaps in Information and/or Understanding

Research Needs

- Major gaps – rearing habitat for steelhead? Rearing habitat for juvenile sturgeon?
- Better diet information is needed for riparian and channel margin habitat use of SH, green and white sturgeon;
- More information is needed about relative importance of food to population level effects for all of the species.
- Transport studies are needed to evaluate the footprint of food transport.
  Timing duration of rearing for SH, green and white sturgeon.

Assess Reversibility and Opportunity for Learning

Reversibility

Yes/Easy.

Comments: This action is easily reversible.

Opportunity for Learning

Low

Comments LWD placements on levee repair projects exist in many other locations, thus, the action does not provide a unique research opportunity.

Action: HRCM12: Channel margin habitat in Sutter and Steamboat Sloughs.

Evaluation Team: Floodplain Workgroup

Campbell Ingram (chair), Denise Reed (coach), Carie Battistone (notetaker), Eric Ginney, Ted Sommers, Rosalie Del Rosario, Dennis McEwan, Bill Harrell, Dan Welsh, Yvette Redler, and Vance Russell.

Date of Last Revision: March 1, 2009

Action Description and Clarifying Assumptions

Enhance channel margin habitats along between 12 and 36 miles of Steamboat and Sutter Sloughs to improve habitat conditions for covered fish species.

Option #1: 12 miles = 6 miles of channel, each side

Option #2: 36 miles = 18 miles of channel, each side

Approach

1. Modify channel geometry in Steamboat and Sutter Sloughs to improve hydrodynamic and structural complexity.
2. Allow for establishment of native emergent vegetation in intertidal elevations.
3. Establish woody riparian vegetation along banks that do not already support woody riparian vegetation.

Intended Outcomes as Stated in Conservation Measure

1. Increase the extent of shaded riverine aquatic cover and increasing instream structural complexity through contributions of instream large woody material.
2. Provide inputs of organic material (e.g., leave and twig drop) in support of aquatic foodweb processes.
3. Increase production and export of terrestrial invertebrates into the aquatic ecosystem.
4. Improve connectivity with upstream habitat areas, including existing and future restored habitats.
5. Reduce the risk for predation on covered fish species by non-native fish predators.
6. Reduce the risk for entrainment of juvenile salmonids by providing a migration corridor that bypasses the intakes of a new north Delta diversion point, the Delta Cross Channel, and Georgiana Slough.

Positive

P1. Increased establishment of instream structure through export of LWD to benefit covered species.

P2. Additional splittail spawning habitat on narrow floodplain margin.

P3. Additional rearing habitat for splittail, green and white sturgeon, Chinook salmon and steelhead (consider loss to entrainment).

P4. Increased production and export of terrestrial invertebrates into the aquatic ecosystem for rearing splittail, green and white sturgeon, Chinook salmon and steelhead

Negative

N1. Increased habitat for non-native predators/competitors to Chinook salmon, steelhead, green and white sturgeon, and splittail, if flows through sloughs are not sufficient to prevent colonization by non natives (by creating more predator habitat)

N2. Increased mortality of covered species due to increased exposure risk to contaminants due to longer residence time in this area

Conceptual Model Information Regarding Intended Outcomes

The basic drivers and outcomes are described in the DRERIP conceptual models, specifically, the salmonid model.

Assumptions

Problem(s) with Action as Written:

Not provided.

Scale of Action:

Large

Rationale: Not provided.

Evaluation Summary Tables

Summary tables listing magnitude and certainty scores for each outcome, by species, are provided in Appendix A. Details regarding each of the listed scores and the rationales for the scores are provided in the discussion of positive and negative outcomes on the following pages.

Positive Outcomes Identified, Not Separately Evaluated

Below is an outcome that was identified, but not listed in the worksheet, because it was merged with another outcome for full evaluation.

- OP1: Increased establishment of woody riparian and emergent vegetation to provide high quality rearing habitat for covered species. This outcome was merged with P2 and P3.

Relation to Existing Conditions:

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

YES

Nature of Change:

Not provided.

Potential Positive Ecological Outcome(s)

Outcome P1: Increased establishment of instream structure through export of LWD to benefit covered species.

The text and scores provided here are applicable to all covered fish species (i.e. species were not evaluated separately). The approach and assumptions for HRCM12 indicates that the channel will be reconfigured to increase HD and structural complexity; however, it does not include any levee setbacks and will not allow for the channel to evolve. No changes to the currently impaired flood hydrology are included in the action. Thus, the ability for natural channel processes (DRERIP Floodplain Model, Figure 2) to erode banks and recruit & export the increased riparian vegetation as LWD will be minimal. Note: score for salmonids maybe splittail. Good evidence that woody debris is important for upstream areas, less for Delta.

Magnitude = 3
Based on the approach and assumptions for HRCM12, there will be an increase in riparian vegetation on the channel margin. While flood hydrology will not be changed by HRCM12, the channel morphology will be changed, ostensibly such that high water events will be able to recruit LWD and export it to downstream areas (DRERIP Floodplain Model Figure 2). This will result in an effect on a large area/multiple patches.

Certainty = 2
Understanding is high, but nature of outcome would be dependent on the uncertain timing of flooding events.

Outcome P2: Additional splittail spawning habitat on narrow floodplain margin.

P2a1: Splittail 12 mile

DLO Relationship and General Observations:
Floodplain model page 25 and Splittail model pages 9 and 12 describe how additional floodplain habitat supports splittail spawning; Assume that there will be floodplain habitat available, but action as described does not indicate that there will be seasonally-inundated FP habitat. Splittail will spawn on flooded vegetation (Moyle et al. 2004) if FP is not accessible.

Increased establishment of woody riparian and emergent vegetation to provide high quality rearing habitat for covered species is an intermediate outcome.

Magnitude = 2
See general observations above.

Certainty = 3
See general observations above.

P2a2: Splittail - 36 mile

Floodplain model page 25 and Splittail model pages 9 and 12 describe how additional floodplain habitat supports splittail spawning; Assume that there will be floodplain habitat available, but action as described does not indicate that there will be seasonally-inundated FP habitat. Splittail will spawn on flooded vegetation (Moyle et al. 2004) if FP is not accessible.

Increased establishment of woody riparian and emergent vegetation to provide high quality rearing habitat for covered species is an intermediate outcome.

Magnitude = 3
See general observations above.

Certainty = 3
See general observations above.

Outcome P3: Additional rearing habitat for splittail, green and white sturgeon, Chinook salmon and steelhead (consider loss to entrainment).

P3a1: Splittail - 12 mile

Greatest importance is in dry years when floodplains are not available.

Increased establishment of woody riparian and emergent vegetation to provide high quality rearing habitat for covered species is an intermediate outcome.

Magnitude = 2
See general observations above.

Certainty = 3
See general observations above.

P3a2: Splittail - 36 mile

Greatest importance is in dry years when floodplains are not available.

Magnitude = 3
See general observations above.

Certainty = 3
See general observations above.

P3b. Green Sturgeon (12 and 36 mile the same)

Juvenile sturgeon are benthic feeders so creation of additional benthic habitat would be beneficial (Sturgeon model page 8). Channelization of the estuary has reduced foraging habitat for Green Sturgeon (Green Sturgeon Model page 20). Juveniles use intertidal habitats along the Sacramento River and many areas in the Delta (Green Sturgeon Model page 4).

Magnitude = 2
Small spatial extent

Certainty = 1
Limited data on rearing preferences

P3c. White Sturgeon (12 and 36 mile the same)

Juvenile sturgeon are benthic feeders so creation of additional benthic habitat would be beneficial (Sturgeon model page 8). Although it is unknown whether white sturgeon will utilize habitats this shallow. They were never captured in Yolo Bypass studies (Sommer and Harrell, unpublished data). Although it's not mentioned in the White Sturgeon model, it is likely that white sturgeon will utilize the same habitats for foraging as described for green sturgeon. Shallow water habitats and low tidal areas are likely nursery habitat (White Sturgeon Model page 15).

Magnitude = 2
Small spatial extent

Certainty = 1
Limited data on rearing preferences

P3d. Steelhead (12 and 36 mile the same)

Tidal marshes can provide rearing habitat and foraging opportunities to fishes that enter marsh channels (Fish Habitat Linkages Model). The primary food organisms of juvenile salmonids are drifting aquatic insects and the larval stages of terrestrial insects (Quinn 2005).

Riparian vegetation is important to salmonids (inc steelhead) by contributing terrestrial insects into the stream and logs and branches that shape channel morphology, retaining organic matter, providing essential cover, stabilizing banks, maintaining undercut banks, and modifying water temperatures through shading (Murphy and Meehan 1991). .

Allochthonous inputs from streamside vegetation are important to salmonids because they provide food for the aquatic invertebrate food base (Murphy and Meehan 1991). Given their similarities in life history, it can be assumed that they are utilizing the same habitats as juvenile salmon, and many of the references below for Chinook salmon would apply to steelhead as well.

Magnitude = 2
Rearing habitat in the delta is reduced. This could have a sustained minor population effect.

Certainty = 2
Not much in the literature regarding steelhead use of estuaries for rearing.

P3e. Chinook Salmon (12 and 36 mile the same)

Greatest importance is in dry years when floodplains are not available.

Magnitude = 3
Sutter and Steamboat are one of several emigration routes juvenile salmon can choose, and are among the few that provide rearing habitat. Habitat improvements would improve rearing success in these corridors. Limited spatial or temporal habitat effects.

Certainty = 3
Numerous studies have indicated that shallow riparian habitat benefits fry Chinook (Sommer 2005, Quinones 2005, Kjelson 1982). Loss of this habitat has been indicated as a major source of decline in CV Chinook.(NMFS 1997, CDFG 2004). Shallow water habitats including river floodplains and riparian margin provide rearing habitat. Growth rates for juvenile Salmon are higher and emigration rates are slower when in shallow water rearing habitats (Kjelson 1982, Sommer et al 2005).

Outcome P4: Increased production and export of terrestrial invertebrates into the aquatic ecosystem for rearing splittail, green and white sturgeon, Chinook salmon and steelhead.

P4a1: Splittail - 12 mile

Adult consumption of earthworms is common (Moyle et al. 2004). Consumption of other invertebrates is common in all life stages (Feyrer et al. 2003).

Magnitude = 2
See general observations.

Certainty = 3
See general observations.

P4a2: Splittail - 36 mile

Adult consumption of earthworms is common (Moyle et al. 2004). Consumption of other invertebrates is common in all life stages (Feyrer et al. 2003).

Magnitude = 3
See general observations.

Certainty = 3
See general observations.

P4b. Green Sturgeon (12 and 36 mile the same)

Invertebrates are common food items for small sturgeon, but it's unclear how much they use terrestrial prey (White Sturgeon Model page 8).

Magnitude = 1
See general observations.

Certainty = 2
Sturgeon are benthic feeders and it is unknown how much they will feed on surface drift. More than 1 because there is diet data for sturgeon

P4c. White Sturgeon (12 and 36 mile the same)

DLO Relationship and General Observations:
Invertebrates are common food items for small sturgeon, but it's unclear how much they use terrestrial prey (White Sturgeon Model page 8).

Magnitude = 1
See general observations.

Certainty = 2
Sturgeon are benthic feeders and it is unknown how much they will feed on surface drift. More than 1 because there is diet data for sturgeon.

P4d. Steelhead

Moyle et al. 2004, page 277 states that stream-dwelling O. mykiss feed mostly on drifting aquatic organisms and terrestrial insects.

Magnitude = 2
See general observations.

Certainty = 2
See general observations.

P4e.1 Chinook Salmon 12 Mile

Consumption of terrestrial invertebrates in drift is very common (Sommer et al. 2001). Diet has a large effect on growth and survival.

Magnitude = 2
See general observations.

Certainty = 3-4
See general observations.

P4e2: Chinook Salmon - 36 Mile

Consumption of terrestrial invertebrates in drift is very common (Sommer et al. 2001). Diet has a large effect on growth and survival.

Magnitude = 3
See general observations.

Certainty = 3-4
See general observations.

Potential Negative Ecological Outcome(s)

Outcome N1: Increased habitat for non-native predators/competitors to Chinook salmon, steelhead, green and white sturgeon, and splittail, if flows through sloughs are not sufficient to prevent colonization by non natives (by creating more predator habitat).

Note: Scored under current operations/flows. If flows were to increase then predator risk would decrease. Longfin are unlikely to be in this area so magnitude was scored lower. Predation could have negative affect, but not certain what balance is between non-native/native abundance shifts. Many migration studies in this area are assuming predation is the cause of mortality. Concern is that we are increasing predation rate in these areas by routing fish (up to 50% of the population) in an area that predators exist in. However, we do not know if this will be a population level affect.

N1a. Longfin Smelt

Longfin model - Predation is a source of direct mortality to eggs and larvae. Some fish species (e.g., suckers, splittail, sturgeon) may feed on LFS eggs. Larval LFS are not strong swimmers (Wang 1986) and are thus highly vulnerable to predation. Striped bass and inland silverside are probably major predators on LFS larvae. Terns, gulls, and cormorants may also prey on this life stage. There appears to be a correlation between high flows and the abundance and distribution of LFS; high flows also decrease the success of LFS predators by increasing turbidity (Page 8.) There is little information in the model specific to competition with non-natives, competition for food resources is expected to have decreased with the recent decline in LFS (Page 14.), competition for spawning sites is unknown (Page 10.). Predation and competition are characterized as medium importance and medium understanding (Figure 5.); floodplain predation and competition are not specifically addressed.

Magnitude = 2

Certainty = 2

N1b. Splittail

The floodplain model does not address non native predation or competition on the floodplain. Evidence from Yolo and Cosumnes about non-natives taking advantage of floodplain (ref Sommer et al 2004, Moyle et al 2006). Floodplain Model: Page 10 talks about sources of invasive species. Foodweb Model is focused on estuarine systems.

Splittail model—Predation by non native fish is characterized as low with high understanding for juveniles and as medium with medium understanding for adults (Figures 5, 6 and 7.) Bird predation appears limited until water recedes and floodplains begin to isolate from main channels at which point fish are exposed to wading birds (Moyle 2004).

Magnitude = 2

Certainty = 3

N1c. Green/White Sturgeon

Models indicate probable distribution in the mainstem Sacramento River adjacent to these sloughs (Figure 7, white sturgeon model, Figure 2, green sturgeon model). There is no direct evidence of utilization of these sloughs by green sturgeon or white sturgeon.

Magnitude = 1

Certainty = 2

N1d. Steelhead/Chinook Salmon

The Chinook salmon and steelhead model indicates Non-native predation and competition with invasive species and hatchery produced salmonids is of medium importance in rearing and emigration estuarine habitats, including floodplain (Figure 2a).

Magnitude = 2-3

Certainty = 2

Outcome N2: Increased mortality of covered species due to increased exposure risk to contaminants due to longer residence time in this area.

The text and scores provided here are applicable to all covered fish species. The primary risk of this type of project at these locations is increased exposure to pesticides due to increased fish use and residence time in the enhanced habitat. The proposed habitat enhancements would not themselves result in significant changes in contaminant cycling or exposure. The habitat is being enhanced to facilitate spawning by splittail and rearing by splittail and other species. Surrounding lands are agricultural, including orchards and other crops. Pyrethroids, a class of pesticides used as dormant sprays on orchards, can be toxic to fish, especially to early life stages (Pyrethroids model, page 16). Pyrethroid concentrations would be expected to peak during the winter/spring storm season and after peak agricultural application in the summer and fall (Pyrethroids model, page 2). Late-winter and spring are also the times splittail would use the enhanced floodplain habitat to spawn (Splittail model, page 1).

There are critical data gaps on pyrethroids and other pesticides that make it difficult to evaluate risk to covered fish (Pyrethroids model, page 32; Chemical stressors model, page 25). In general, little is known about the toxic effects of contaminants known to be present in the Delta on resident Delta species, and even less is known about the sublethal effects of contaminants (Chemical stressors model, page 25).

Magnitude = 1
See general observations.

Certainty = 3
See general observations.

Important Gaps in Information and/or Understanding

Research Needs

- Major gaps – rearing habitat for steelhead? Rearing habitat for juvenile sturgeon?
- Better diet information is needed for riparian and channel margin habitat use of SH, green and white sturgeon.
- More information is needed about relative importance of food to population level effects for all of the species.
- Transport studies are needed to evaluate the footprint of food transport.
- Timing duration of rearing for SH, green and white sturgeon.
- Better understanding of rearing habitat restoration while minimizing predatory fish abundance.

Assess Reversibility and Opportunity for Learning

Reversibility

Action: HRCM13: Channel margin habitat between Vernalis and Mossdale

Evaluation Team: Floodplain Workgroup

Campbell Ingram (chair), Denise Reed (coach), Carie Battistone (notetaker), Eric Ginney, Ted Sommers, Rosalie Del Rosario, Dennis McEwan, Bill Harrell, Dan Welsh, Yvette Redler, and Vance Russell.

Date of Last Revision: March 1, 2009

Action Description and Clarifying Assumptions

Enhance channel margin habitats along between 14 and 28 miles of the San Joaquin River in the San Joaquin River ROA to improve habitat conditions for covered fish species.

1. 14 miles = 7 miles of channel, each side
2. 28 miles = 14 miles of channel, each side
3. Area between Vernalis to Mossdale that includes 1,800 acres of existing floodplain
4. 7 to 14 miles are linear measures (river miles, no setbacks, no area)
5. All South Delta work will be contingent on significant reduction in south Delta entrainment (need to evaluate some negative outcomes with 1) Old River isolated and 2) current configuration and reduced pumping (i.e., dual conveyance)).
6. No setbacks. Assume 50% of area improved in patches.
   - Backwaters within existing small floodplain areas
   - Low velocity areas within channel
   - Shallow low velocity benches
   - LWD for in-stream structural cover
   - Shade trees adjacent to channel margin
7. There are not institutional barriers preventing implementation

Approach

1. Modify channel geometry to improve hydrodynamic and structural complexity and to create low velocity habitat areas designed to provide spawning habitat for splittail and rearing habitat for splittail and salmonids; and
2. Establishing woody riparian vegetation along banks that do not support woody riparian vegetation to provide shaded riverine aquatic and instream cover for covered fish species.

Intended Outcomes as Stated in Conservation Measure

Positive

P1: Increase availability of high quality rearing habitat for Chinook salmon, steelhead, splittail, green and white sturgeon (includes instream cover, shade, food; consider loss to entrainment).

P2: Increase availability of spawning habitat for splittail.

P3: Improved resting habitat for migrating adult Chinook salmon (upstream), steelhead (up and downstream), and green and white sturgeon.

P4. Increased food production and availability (fall of OM, terrestrial invertebrates) for Chinook salmon, steelhead, splittail and green and white sturgeon (consider loss to entrainment).

Negative

N1: Increased exposure risk to contaminants (including Selenium) to longer residence time in this area.

N2: Increased frequency and magnitude of low dissolved oxygen in SDWSC due to increased POM and impact on salmon, steelhead, and green and white sturgeon passage.

N3: Increased habitat for non-native predators/competitors to Chinook salmon, steelhead, green and white sturgeon, and splittail.

Conceptual Model Information Regarding Intended Outcomes

The basic drivers and outcomes are described in the DRERIP conceptual models, specifically, the salmonid model. Numerous studies have indicated that shallow riparian habitat benefits fry Chinook (Sommer 2005, Quinones 2005, Kjelson 1982). Loss of this habitat has been indicated as a major source of decline in Central Valley Chinook (NMFS 1997, CDFG 2004).

Assumptions

Provided in BDCP Conservation Measure

Not provided.

Added by Evaluation Team

Not provided.

Problem(s) with Action as Written:

Modification may depend on width of channel – benches may not be feasible if setbacks are not constructed.

Scale of Action:

7 mile reach – (50% extent = 7 miles of bank) Medium
14 mile reach - (50% extent = 14 miles of bank) Medium

Rationale:

Some reasonable conditions seem to exist in this area at the moment (floodplain, evidence of meandering on maps, presence of riparian habitat), increment over current condition.

Evaluation Summary Tables

Summary tables listing magnitude and certainty scores for each outcome, by species, are provided in Appendix A. Details regarding each of the listed scores, and the rationales for the scores, are provided in the discussion of positive and negative outcomes on the following pages.

Relation to Existing Conditions:

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

YES

Nature of Change:

Conditions have been studied.

Potential Positive Ecological Outcome(s)

Outcome P1: Increased establishment of woody riparian and emergent vegetation to provide high quality rearing habitat for covered species.

P1a1: Splittail - 14 mile

Sommer et al. 2002, 2007 shows Splittail prefer shallow habitat, however there was no evidence of preferences for distinct vegetation types.

Magnitude = 1
Depending on extent of action; not changing the inundation frequency and pattern.

Certainty = 3-4

P1a2: Splittail - 28 mile

Sommer et al. 2002, 2007 shows Splittail prefer shallow habitat, however there was no evidence of preferences for distinct vegetation types.

Magnitude = 2
Depending on extent of action; not changing the inundation frequency and pattern

Certainty = 3-4

P1b. Green Sturgeon (Same for 14 or 28 mi scenario)

In the San Joaquin, the green sturgeon appears to be extirpated (green sturgeon Model page 3).

Magnitude = 2
Depending on extent of action; not changing the inundation frequency and pattern

Certainty = 1
Limited data on rearing preferences

P1c. White Sturgeon (Same for 14 or 28 mi scenario)

Juvenile sturgeon are benthic feeders so creation of additional benthic habitat would be beneficial (Sturgeon model page 8). Although it is unknown whether white sturgeon will utilize habitats this shallow. They were never captured in Yolo Bypass studies (Sommer and Harrell unpublished data). Although it's not mentioned in the White Sturgeon Model, it is likely that white sturgeon will utilize the same habitats for foraging as described below for green sturgeon.

Shallow water habitats and low tidal areas are likely nursery habitat (White Sturgeon Model page 15). Most sturgeon spawning is focused on the Sacramento, (page 9 of

White Sturgeon Model) therefore restoration benefits in the San Joaquin would not be as great.

Magnitude = 2
Depending on extent of action; not changing the inundation frequency and pattern.

Certainty = 1
Limited data on rearing preferences

P1d. Steelhead (Same for 14 or 28 mi scenario)

Tidal marshes can provide rearing habitat and foraging opportunities to fishes that enter marsh channels (Fish Habitat Linkages Model). The primary food organisms of juvenile salmonids are drifting aquatic insects and the larval stages of terrestrial insects (Quinn 2005).

Riparian vegetation is important to salmonids (inc steelhead) by contributing terrestrial insects into the stream and logs and branches that shape channel morphology, retaining organic matter, providing essential cover, stabilizing banks, maintaining undercut banks, and modifying water temperatures through shading (Murphy and Meehan 1991). .

Allochthonous inputs from streamside vegetation are important to salmonids because they provide food for the aquatic invertebrate food base (Murphy and Meehan 1991). Given their similarities in life history, it can be assumed that they are utilizing the same habitats as juvenile salmon, and many of the references below for Chinook salmon would apply to steelhead as well.

Magnitude = 3
Given that existing rearing habitat in the Delta is so limited, this action could have a sustained minor population effect on this species.

Certainty = 2
Steelhead use of estuaries for rearing is not well described in the literature.

P1e. Chinook Salmon (Same for 14 or 28 mi scenario)

Chinook Salmon fry inhabited marginal areas of the river, particularly back eddies, behind fallen trees, undercut tree roots, or other areas of bank cover. As they grew larger, they move away from the shore into midstream and higher velocity areas (Lister and Genoe 1970). San Joaquin Technical Annual reports suggest fall-run fry are rearing in the Delta because they are documented leaving San Joaquin tributaries, are later found in Mossdale (Caswell Annual Report 2007, SJRG 2004, 2005, 2006). Peak seasonal catches of fry at Stanislaus in 2005 and Tuolumne River in 2006 during January and March were not picked up at Mossdale in great numbers. Mossdale peaks occurred in April and May of smolt sized fish (SJRG annual reports 2005, 2006).

Fall-run Chinook salmon juveniles are present in the area. San Joaquin fall-run Chinook juveniles enter Delta either as: 1) fry/parr) with high winter flows, typically in January through March (size of 20 to 60 mm fork length, or as 2) smolts after mid March(> 60 mm fork length; (Caswell Annual Report 2007, SJRG 2004, 2005, 2006).

Juvenile Chinook within pools in the American River, were associated with instream cover such as rootwads, logs or submerged vegetation, or with overhead cover, and were also associated with eddies or other areas with steep velocity gradients. Such positions allow fish to hold in slower water but make forays into faster water to capture drifting insects (Jackson 1992). Among the wide variety of suitable substrates and habitat types for rearing, young salmon appear to seek out low velocity areas (Sommer 2005).

Fall-run Chinook salmon juveniles would use the channel margin habitats to rear. Chinook salmon use the delta inversely proportional to their size (Williams 2006). The restored channel margin habitat would create rearing habitat for fry/parr that enter the Delta in the winter. These fry would be able to feed and grow in the channel margins, and their larger size would increase the likelihood of survival in the ocean.

Several studies suggest that emigrating salmon derive great benefit from connection with vegetated riparian areas--it provides a variety of benefits including shading, terrestrial food web inputs and habitat structure. (Opperman and Merenlender 2004, Quinones and Mulligan 2005).

Fall-run Chinook fry (<70mm) rear primarily in the upper fresh-water Delta…peak fry rearing is (Feb-March) young fry appear to be most abundant in shallow water/shoreline habitat, rearing occurs for two months or more. (Kjelson et al 1982). Levee development in the central valley…disrupts the natural processes of the river. These changes generally reduce the range of habitat conditions typically found along natural shorelines, especially by eliminating the shallow, slow-velocity river margins used by juvenile fish as refuge and to escape from fast currents, deep water, and predators (Stillwater Sciences 2006). Growth rates for juvenile Salmon are higher and emigration rates are slower when in shallow water rearing habitats (Kjelson 1982, Sommer et al 2005).

Note: Citations regarding channel margin habitat are from riverine systems and not the Delta. Therefore importing woody debris not as important.

Magnitude = 2-3
Temporally significant, expected sustained minor population effect.

Certainty = 2-3
Steelhead use of estuaries for rearing is not well described in the literature.

Outcome P2: Increase availability of spawning habitat for splittail.

P2. Splittail (Same for 14 or 28 mi scenario)

Floodplain model page 25 and Splittail model pages 9 and 12 describe how additional floodplain habitat supports splittail spawning. Good evidence that woody debris is important for upstream areas, less for Delta.

Magnitude = 3

Certainty = 3-4

Outcome P3: Improved resting habitat for migrating adults (Chinook Salmon upstream, steelhead up and downstream, Green/White sturgeon).

The text and scores provided here are applicable to all covered fish species. Shelter from predators may come in the form of deep pools, cut banks, and submerged dead and living woody material. Riparian vegetation may shade “holding” habitat and ameliorate temperature gain in this habitat. Streamside vegetation also provides woody material salmon may use for cover from predators or high flows.(Rosenfield draft salmon model page 67).

Adult salmonids migrating upstream are assumed to make greater use of pool and mid-channel habitat than channel margins (Stillwater Sciences 2004), particularly larger salmon such as Chinook salmon, as described by Hughes (2004).(NMFS Draft OCAP page 36). This statement contradicts need for channel margin habitat for adults.

Adult migration corridors should provide satisfactory water quality, water quantity, water temperature, water velocity, cover/shelter and safe passage conditions in order for adults to reach spawning areas (NMFS 2008).

Magnitude = 1-3

Certainty = 1-2
Lack of information in literature regarding resting habitat needs of migrating adult salmon.

Outcome P4: Increased food production and availability (fall of OM, terrestrial invertebrates) for Chinook salmon, steelhead, splittail, green/white sturgeon. Consider loss to entrainment.

P4a. Splittail (Same for 14 or 28 mi scenario)

Floodplain Model pages 20-25 describe floodplain food production. Floodplain Model pages 25 and 27 describe utilization and higher survival for splittail on floodplains.

Magnitude = 1
Given limited temporal effect in frequency and no change in hydrology. Action represents a change in vegetation type only.

Certainty = 3

P4b. Green Sturgeon (Same for 14 or 28 mi scenario)

Floodplain Model pages 20-25 describe floodplain food production. No evidence of juvenile use of floodplains. Catch in Yolo are adults (Harrell and Sommer unpublished). This mechanism described for Chinook salmon is assumed to apply to green sturgeon

(Sommer et al 2005 and Floodplain Model). In the San Joaquin, the green sturgeon appears to be extirpated (Green Sturgeon Model page 3).

Note: Citations regarding channel margin habitat are from riverine systems not Delta and therefore importing woody debris not as important.

Magnitude = 1

Certainty = 3)

P4c. White Sturgeon (Same for 14 or 28 mi scenario)

Floodplain Model pages 20-25 describe floodplain food production. No evidence of juvenile use of floodplains. Catch in Yolo are adults (Harrell and Sommer unpublished). This mechanism described for Chinook salmon is assumed to apply to green sturgeon (Sommer et al 2005 and Floodplain Model).

Magnitude = 1

Certainty = 1

P4d. Steelhead (Same for 14 or 28 mi scenario)

Floodplain Model pages 20-25 describe floodplain food production. Nothing in the literature that describes steelhead feeding on floodplains, however, it can be assumed that they are utilizing the same food sources as juvenile salmon, given their life-history similarities. Moyle et a. 2004 states that stream-dwelling RT feed mostly on drifting aquatic organisms, terrestrial insects, and bottom dwelling organisms which are in abundance on floodplains.

Magnitude = 1
Given limited temporal effect in frequency and no change in hydrology). Action represents a change in vegetation type only.

Certainty = 2
Non peer reviewed

P4e. Chinook Salmon (Same for 14 or 28 mi scenario)

Floodplain Model pages 20-25 describe floodplain food production. Floodplain Model pages 27 and 29 describe utilization and higher growth rates for Chinook salmon on floodplains. Chinook salmon likely take advantage of small fishes on the FP (Splittail Model page 8 and Moyle et al. 2004).

Magnitude = 1
Given limited temporal effect in frequency and no change in hydrology. Action represents a change in vegetation type only.

Certainty = 3
Given data on flooding and studies elsewhere.

Potential Negative Ecological Outcome(s)

Outcome N1: Increased exposure risk to contaminants (including Se) due to longer residence time in this area.

Although the text and scores provided here are applicable to all covered fish species, it should be noted that Salmonids more sensitive to selenium. Selenium (Se) loading of the Bay-Delta ecosystem is driven mainly by loads entering the Delta from the San Joaquin River (SJR), which in turn receives most of its Se input from agricultural drainwater entering the river through Mud Slough (Se model, Fig. 1). This project is along the mainstem SJR downstream of these Se inputs.

The proposed action involves habitat modification that enhances floodplains and creates more low velocity, shallow water habitats. These types of habitats create a better environment for Se partitioning in food chains than would occur in bed sediment of the river channel. Exposure of covered fish to Se might increase due to higher bioaccumulation of Se in invertebrate prey and longer residence time of the fish in the enhanced habitat.

Salmonids are relatively sensitive to Se compared to other fish (Se model, page 19). Beckon (2008 abstract from CALFED science conference; manuscript in prep) evaluated Se data from the SJR and concluded that, although discharges of Se to the SJR have been reduced over the last 15 years, Se will pose a substantial risk to salmon that are reintroduced to restored middle reaches of the river unless Se loads are further reduced and/or sufficient dilution flows are provided. The magnitude of potential effects of Se from this project between Vernalis and Mossdale may be lower than would occur at projects along the middle reaches of the SJR mainstem (i.e., sites in the vicinity of Mud Slough) because this project occurs downstream of dilution sources from the Merced, Tuolumne and Stanislaus Rivers. However, this spatial difference does not provide strong protection because Se bioaccumulates in food chains, is recycled in the ecosystem, and can have significant lag times between when loading occurs and when effects are seen.

The seasonal use of the habitat may also reduce the potential magnitude of Se impacts to covered fish species, especially juvenile salmonids. Seasonal use of the Delta by juvenile salmonids occurs mainly during high flow periods (January-June)(salmon model, page 11); whereas highest concentrations of Se occur during low flow periods (Se model, page 6). However, this seasonal difference does not provide strong protection because Se bioaccumulates in food chains, is recycled in the ecosystem, and can have significant lag times between when loading occurs and when effects are seen.

The invertebrate prey of juvenile salmonids are water-column-feeding or detritus-feeding species that are less contaminated than certain suspension or deposit-feeding bivalves (Se model, Table 5 and Fig. 1). Adult splittail and sturgeon feed on bivalves and would be expected to have greater exposure to Se in their diet than salmonids. This project is intended to provide rearing habitat for juvenile sturgeon and splittail rather than habitat for adults, but may also result in increased residence time by spawning and foraging adults. However, the bivalve species present at this freshwater location would be *Corbicula fluminea* rather than *Corbula amurensis* (*Corbula* and *Corbicula* models). *C. fluminea* is less efficient at bioaccumulating Se than *C. amurensis* (Se model, page 14).

Se dynamics in the Bay-Delta system are fairly well understood, but there is uncertainty about how changes in management of SJR flows, water exports, and potential future actions to solve the drainage problem on the west side of the San Joaquin Valley could affect Se loading and cycling in the Delta (Se model, pp. 3 and 4). A quantitative analysis of the increased risk of Se toxicity resulting from this project would require estimates of the increase in the amount of time covered fish spend at this location relative to the baseline condition, as well as estimates of future river flows, water exports, and Se loads. Such an analysis is beyond the scope of this worksheet exercise, but should be considered if the project is recommended for evaluation in the NEPA process.

Magnitude = 2

Certainty = 3

Outcome N2: Increased exposure risk to contaminants (including Selenium) to longer residence time in this area.

The text and scores provided here are applicable to all covered fish species. Presence of fish species needs to be considered. Page 33 salmon model talks about DO as migration barrier and timing issue (juveniles not migrating when DO is an issue) Also see page 60 re adults. More of issues for adult and juvenile salmon.

Magnitude = 1

Certainty = 4
Would not cause affects on species based on seasonality (more of a late summer fall issue).

Outcome N3: Increased habitat for non-native predators/competitors to native fishes (longfin smelt, splittail, green/white sturgeon, steelhead, Chinook salmon).

Note 1 The floodplain model does not address non native predation or competition on the floodplain. Evidence from Yolo and Cosumnes about non-natives taking advantage of floodplain (ref Sommer et al 2004, Moyle et al 2006). Floodplain Model: Page 10 talks about sources of invasive species. Foodweb Model is focused on estuarine systems.

Note 2 Scored under current operations/flows. If flows were to increase then predator risk would decrease. Longfin are unlikely to be in this area so magnitude was scored lower. Predation could have negative affect, but not certain what balance is between non-native/native abundance shifts. Many migration studies in this area are assuming predation is the cause of mortality. Concern is that we are increasing predation rate in these areas by routing fish (up to 50% of the population) in an area that predators exist in. However, we do not know if this will be a population level affect.

N3a. Longfin Smelt

Longfin model—predation is a source of direct mortality to eggs and larvae. Some fish species (e.g. suckers, splittail, sturgeon) may feed on LFS eggs. Larval LFS are not strong swimmers (Wang 1986) and are thus highly vulnerable to predation. Striped bass and inland silverside are probably major predators on LFS larvae. Terns, gulls, and cormorants may also prey on this life stage. There appears to be a correlation between high flows and the abundance and distribution of LFS; high flows also decrease the success of LFS predators by increasing turbidity (Page 8.) There is little information in the model specific to competition with non-natives, competition for food resources is expected to have decreased with the recent decline in LFS (Page 14.), competition for spawning sites is unknown (Page 10.). Predation and competition are characterized as medium importance and medium understanding (Figure 5.); floodplain predation and competition are not specifically addressed.

Magnitude = 2

Certainty = 2

N3b. Splittail

Splittail model - Predation by non native fish is characterized as low with high understanding for juveniles and as medium with medium understanding for adults (Figures 5, 6 and 7.) Bird predation appears limited until water recedes and floodplains begin to isolate from main channels at which point fish are exposed to wading birds (Moyle 2004).

Magnitude = 3

Certainty = 2

N3c. Green/white Sturgeon (scored the same)

Green and white sturgeon – models indicate probable distribution in the mainstem Sacramento River adjacent to these sloughs (Figure 7, white sturgeon model, Figure 2, green sturgeon model). There is no direct evidence of utilization of these sloughs by green sturgeon or white sturgeon.

Magnitude = 1

Certainty = 2

N3d. Steelhead/Chinook salmon (scored the same)

Chinook salmon and steelhead. The DRERIP salmonid model indicates non-native predation and competition with invasive species and hatchery produced salmonids is of medium importance in rearing and emigration estuarine habitats, including floodplain (Figure 2a).

Magnitude = 2-3

Certainty = 2

Important Gaps in Information and/or Understanding

Data Needs

Lack of information on migrating adults through the Delta and the use of habitat as they journey through to spawning grounds.

Research Needs

- The basis of the assumption for the flooding frequency could be refined (Table 2, BDCP doc).
- Major gaps – rearing habitat for steelhead? Rearing habitat for juvenile sturgeon?
- Hg accumulation in fish has been documented, but does not indicate effect on fish.
- Degree of contaminants affects on POD.
- Degree of sediment settling on floodplains.
- Degree of predation/competition within floodplains on native covered fish species by non-native fish species.
- Better diet information is needed for floodplain use of SH, green and white sturgeon;
- More information is needed about relative importance of food to population level effects for all of the species.
- Transport studies are needed to evaluate the footprint of food transport from floodplains.
- Timing duration of rearing for SH, green and white sturgeon.
- Acoustic tagging studies that target adults as they enter estuary/Delta.

Action: Reduce Ammonia Discharges

Evaluation Team: Water Quality & Invasives Workgroup

James Haas - Chair , Bruce Herbold – Coach, Chris Foe, Charles Alpers; Inge Werner, Frances Brewster, Karen Larsen, Chrisinte Joab, David Fullerton, Holly Gellerman, Ron Smith, Jan Thompson, Lori Clammurro (note taker)

Date of Last Revision: February 23, 2009

Action Description and Clarifying Assumptions

Implement advanced treatment processes at Sac Regional County Sanitation District (SRCSD) Wastewater Treatment Plant to reduce the concentrations and load of ammonia in effluent discharged into the Sacramento River to levels that do not directly or indirectly harm covered fish species.

Approach

Implement advanced treatment processes at the SRCSD WWTP to remove ammonia from effluent before discharging into the Sacramento River

Intended Outcomes as Stated in Conservation Measure

1. Increased food abundance for delta and longfin smelt by increasing the abundance of diatoms. *Note: the group re-worded this outcome to: Reductions of ammonia in the Sacramento River will increase diatom production and abundance (Outcome P1)*
2. Reduced direct mortality by ammonia of delta and longfin smelt, white and green sturgeon, salmonids (all races), and splittail *Note: the group re-worded this outcome to: Reduction in direct toxic effects on fish species (Outcome P6)*

Conceptual Model Information Regarding Intended Outcomes

1. Food Web conceptual model (Durand, 2008) – Section 1.32 and Section 4.13
2. Delta smelt model – pages 8, 29-30

Assumptions

Provided in BDCP Conservation Measure

1. *Implied: with* SRCSD *as the largest identified source of ammonia loads into the Delta, controlling only this source would result in increased food abundance and reduced direct mortality on covered fish species.*

Added by Evaluation Team

1. Assumed that increased diatom abundance increases zooplankton production and abundance.
2. Assumed that increased zooplankton abundance increases smelt abundance.
3. There is an assumption from data linkages and correlations that ammonia levels at Hood drive ammonia levels in Suisun Bay (Fullerton correlations). There is not consensus among scientists on this point.

Problem(s) with Action as Written:

1. Despite evidence that SCRSD is the largest single source of ammonia discharge to the Delta, discharging 10-times more ammonia than all other Delta wastewater treatment plants (WWTPs) combined (Jassby 2008), this action should be expanded to include other WWTPs, as well as other potential ammonia sources (e.g. refineries in Suisun and Grizzly Bays, smaller discharges). There may be other sources of significant magnitude that wouldn't show up in the correlations prepared by Fullerton.
2. The action, as written, does not account for the primary drivers of phytoplankton production, including light/turbidity, residence time/transport, salinity, and invasive clams.
3. The action needs to account for how the primary drivers of phytoplankton production vary in specific geographic regions of the estuary. Consequently, the action should be separated into at least two, and most likely three, distinct geographic areas: 1) the freshwater portion of the estuary, including the Sacramento River; 2) the low-salinity zone portion of the estuary, ranging from ~Big Break (River Kilometer 81) and Three Mile Slough to Chipps Island; and 3) areas west of Chipps Island, including Suisun and Grizzly Bays. Corbula/clam grazing is the prominent limitation to food production in areas west of Chipps Island (Kimmerer pers. comm.. and Alpine and Cloern 1992), but the role of clams is less well understood in upstream portions of the estuary. It is therefore believed that ammonia/um has the potential to play a much greater role in the upper estuary than in the lower estuary.
4. "Advanced treatment processes" is not defined (i.e., would the WWTP effluent undergo a full denitrification process?). There could be implications for food web productivity from a potential lack of nutrients resulting from denitrification.
5. *Based on three years of monitoring, the Lower Sacramento River has the highest ammonia/ium levels, followed by Carquinez Strait, then Old River. Nowhere else in the Delta has significantly elevated ammonia/ium concentrations (concentration range [highest of 0.5-0.6 mg/L total ammonia/ium]). With salinity intrusion, ammonia/ium levels are also elevated in the Bay as compared to Suisun.*
6. *Ammonia effects on submerged and floating aquatic vegetation (SAV & FAV) could be leading to potential impacts on covered species from predation.*

Scale of Action:

Large

Rationale:

The action is of significant duration and frequency (continuous), and spatial extent (under the assumption that the source of ammonia from SCRSD extends to Suisun & Grizzly Bay, in accordance with correlations Dave Fullerton has found between ammonia levels at Hood and in Suisun Bay) – this action could provide a major reversal over existing conditions, but only as it relates to the concentrations and loads of ammonia in the Sacramento River.

Evaluation Summary Tables

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

Relation to Existing Conditions:

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

NO

Nature of Change:

Primary production is still controlled primarily by turbidity (Cloern et al 1985, Cloern 2001, 1996) and transport times in the deep water and a combination of those factors, plus grazing by the benthos for most of the year (Thompson 2005) – but species composition of primary production may change. The action is not expected to change any of these physical drivers of primary production.

However, the action could provide a significant improvement over existing conditions in terms of ammonia loads (and possibly nitrate, depending on treatment level) discharged into the Sacramento River.

Potential Positive Ecological Outcome(s)

Outcome P1: Reductions in total ammonia in the Sacramento River will increase Delta smelt and longfin smelt abundance by increasing diatom production and abundance in the freshwater portion of the estuary (Lower Sacramento River)

Evaluation of the action was split into three distinct geographic regions of the estuary to better describe the potential role of ammonium (as opposed to other primary drivers such as light/turbidity, clam grazing, and residence time) in limiting phytoplankton production. The evaluation was also divided into each level of the food web to better describe the different levels of uncertainty as the effect of ammonium moves up the food web from diatom production, to zooplankton production, to fish abundance within the geographic regions. Magnitude and certainty for the diatom and zooplankton effects are provided in the discussion to help explain the magnitude and certainty scores assigned to the covered species within the geographic area. The species scores only are rolled up into Table 1. Although this action was written to address the two smelt species, positive outcomes are possible for juvenile salmonids as well.

The three geographic regions used for the purposes of this analysis are:

1) The freshwater portion of the estuary, including the Sacramento River(hereafter identified as Outcome P1);
2) The low-salinity zone portion of the estuary, ranging from ~Big Break (River Kilometer 81) and Rio Vista to Chipps Island (hereafter identified as Outcome P2); and
3) Areas west of Chipps Island, including Suisun and Grizzly Bays (hereafter identified as Outcome P3).

The relationship between ammonium and productivity are supported by the Delta Food Web conceptual model, Dugdale et al 2007, Wilkerson et al 2006, and correlations between ammonium and chlorophyll a prepared by David Fullerton (unpublished data).

Dugdale and Wilkerson have observed that ammonium above 4 micromole/L suppresses diatom blooms in Suisun, San Pablo and Central Bays by inhibiting diatom uptake of nitrate.

Per discussion with Wim Kimmerer, light limitation has been the primary driver of phytoplankton production throughout the system. Post-1987, diatom production went down as the result of clam grazing; now, as a result, there is much more nano- and micro-plankton as opposed to larger cells, decreasing the efficiency of the food web. Effects of Corbula grazing can extend at least as far upstream as Rio Vista in some years. In the low-salinity zone, production is happening in shallow areas. In the freshwater/river influenced portions of the estuary, where clam grazing is less of a driver, it's possible that ammonium is a limiting factor in the production of phytoplankton. However, the shorter residence time in this part of the estuary throughout much of the year is no doubt a large factor in the low phytoplankton growth rate.

Clams eat diatoms not out of preference, but as a function of diatoms' settling rate. Because they settle to the bed of the water body, there is a lot less effort for clams to "catch" this food source. Upstream of Chipps Island, however, not as much is known about what controls the growth of phytoplankton, partly because the hydrology is so complicated. Corbula may affect phytoplankton production through tidal influence as far upstream as Decker Island and possibly as far as Rio Vista in most years. However, there are stations along the Sacramento River, outside of the influence of Corbula, where chlorophyll a levels have also gone down. In addition, corbula biomass is not high enough in every year, or in every spring to influence phytoplankton levels upstream to Rio Vista. The grazing rate of the freshwater clam, Corbicula fluminea, may also influence primary production but its importance as a phytoplankton consumer in the river channel is not well defined.

Dave Fullerton presented data showing relationships between ammonium and chlorophyll a, pre- and post-1987 (the approximate year of introduction of Corbula). For San Pablo Bay, the relationships were the same pre-and post-1987; chlorophyll a production was higher when ammonium concentrations were below 4 micromoles/L. For the lower Sacramento River, it appeared chlorophyll a production improved when ammonium dropped down to 2-3 micromoles/L. In Suisun Bay pre-1987, it appeared that chlorophyll a production peaked when ammonium was less than 2 micromoles/L, but the y-intercept decreases post-1987, indicating that clam grazing may have “muted” the response of chlorophyll a production to reduced ammonium levels. Despite a demonstrated impact from clam grazing in Suisun Bay, Fullerton’s correlations suggest that reducing ammonium below 4 micromoles/L may provide the opportunity for more chlorophyll a production, even with the clams in place; however, there was not consensus amongst the scientists on this point.

Chris Foe noted that Alex Parker’s sampling of ammonium along transects of the Sacramento River, show a decrease in ammonium as you move downstream to Suisun/Grizzly Bay, and an increase in concentration downstream of Suisun/Grizzly Bay, suggesting a potential “mid-Suisun” source.

P1a. Effect of reducing ammonium on diatom production:

Magnitude = 3
Certainty = 1

The Sacramento Regional County Sanitation District is the major source of ammonium in this area (Jassby 2008). SRCSD ammonium reaches to the lower Sacramento River, Cache Slough, and the lower San Joaquin River (SJR). There is less confidence that SRCSD ammonium reaches Suisun and Grizzly Bay. SRCSD appears to be the largest single source of total ammonia in the Delta (90% of Sacramento River load, per Jassby 2008).

In the freshwater/river influenced portions of the estuary, where clam grazing is less of a driver, ammonium has a greater potential to be a limiting factor in the production of phytoplankton year round. It’s possible that ammonium might be a limiting factor in portions of the Delta that have longer residence time and are relatively clear (low turbidity), but it’s not well known how much and which areas in the Delta have these characteristics. Turbidity in this part of the estuary has been declining (Jassby 2008); however, the short residence time in the deep river channels is still likely a critical factor in determining where and if phytoplankton growth occurs. The importance of Corbicula’s grazing on primary producers in shallow areas is also not well known.

Ammonium is a control factor of phytoplankton productivity in Suisun, San Pablo and Central Bays (Wilkerson et al 2006, Dugdale et al 2007); however, it is not known if ammonium exerts the same control on phytoplankton production further upstream in the Sacramento River. Preliminary analyses by the Dugdale-Wilkerson Lab indicate that the phytoplankton near the treatment plant are able to grow sufficiently well with high concentrations of ammonium present, but that does not appear to be the case at Rio Vista. It is not yet known how far up the Sacramento River from Suisun Bay ammonium may be an important factor in inhibiting phytoplankton production. Phytoplankton community composition may be important in this fresher part of the estuary. Quantitatively, researchers have not figured out where ammonium comes into play.

Herbicides and metals may also play a role, (e.g. diuron, rice herbicides, copper). Widespread phytoplankton toxicity to the green algae, *Selenastrum capricornutum,* was found at Delta sites monitored by the Irrigated Lands Program. No information is available on differential toxicity to diatoms and microcystis.

Jassby contends, "In the past, flows into Suisun Bay generally diluted the higher phytoplankton concentrations within the bay; now they bring in higher phytoplankton concentrations from upstream" (Jassby 2008). If Jassby's assertion is correct, then increasing phytoplankton production in the Lower Sacramento River, away from the influence of corbula, may have a larger magnitude effect on the low salinity zone foodweb than was historically the case.

While there is greater certainty on the source of ammonium in this part of the estuary, there is great uncertainty regarding the magnitude of the potential role of ammonium in the upper estuary, due to the complicated hydrology of this area (characterized by deep, fast-moving water). This short residence time limits the time that a parcel of water may produce phytoplankton before it enters a new light, nutrient, and grazer environment. Given the nature of the primary drivers of primary production in this area (light/turbidity, residence time, and nutrients – only one of which would change with this action), significant questions remain as to whether controlling ammonia/ium discharges would really address the problem of low primary productivity in the Delta.

P1b. Effect of increasing diatom production on zooplankton abundance:

Magnitude = 2
Certainty = 2

The decline in diatoms in Suisun Bay (c) apparently caused a decline in abundance of at least some zooplankton (Kimmerer and Orsi 1996). At present the zooplankton populations appear to be severely food-limited, at least in the Low-Salinity Zone (b) (Kimmerer 2006, unpublished). However, the change in species composition of the zooplankton since Corbula arrived means that the system may not go back to its previous state. Furthermore, since gains in phytoplankton biomass (as opposed to specific growth rate) are likely to be modest because of continued clam grazing, the response of the zooplankton will likely be small. This is a suitable area for research but nobody should expect a large boost to the foodweb without further information.

The importance of Corbicula's grazing on primary producers in shallow areas is also not well known (Thompson pers. comm.). We don't know if Corbicula are widely distributed in Cache slough. Corbicula babies are found up the Sacramento River as far as we sampled; however, they don't grow in most of this part of the river. Based on Chris Foe's dissertation, it seems likely that they are food limited in the Sacramento River. Whether increasing food will increase clam or zooplankton populations is unknown as part of the issue is transport of food to the clams on the bottom which has to be done at an appropriate time scale relative to the concentration of food.

P1c. Effect of increasing zooplankton abundance on fish abundance:

Delta smelt:

Magnitude = 3
Certainty = 1

There is evidence that Delta smelt are food-limited based on analyses of their liver glycogen levels (Bennett et al 2008). In addition, spring zooplankton abundance is decreasing just as temperatures are starting to rise, and Delta smelts' bioenergetic needs are increasing. According to Herbold (pers. comm..) April/May and August may be a particularly important bottleneck for Delta smelt. Delta smelt often occur in this part of the estuary in April and May. Given their currently very low population level, increasing the base of their foodweb has the potential to have a sustained minor population effect. This action also has the potential to increase productivity in multiple patches of habitat (lower Sacramento River directly, and confluence and Suisun Bay through transport of productivity). There is minimal certainty because understanding is not widely accepted and outcome is dependent on variable ecosystem processes such as residence time and water clarity.

Longfin smelt:

Magnitude = 2
Certainty = 2

Kimmerer (2002b) found evidence of bottom-up trophic limitations on longfin smelt productivity in this Estuary (see p. 26 Longfin smelt conceptual model, Rosenfield, 2008). The potential magnitude of effect on longfin in the lower Sacramento River would be smaller than for Delta smelt because longfin do not generally occur in this part of the estuary. However, increased productivity in the lower Sacramento River has the potential to flow into Suisun Bay and the confluence area where longfin smelt do occur. Magnitude is low because action addresses productivity in a minor way with limited spatial habitat effects. Since they don't occur in this area, there is greater certainty that the magnitude of effect is low.

Salmon spp.

Magnitude = 2
Certainty = 1

Juvenile salmonids consume a significant amount of crustaceans in their diet, but Information is limited regarding their dependence on the specific zooplankton species preferred by Delta smelt.

Steelhead

Magnitude = 2
Certainty = 1

Juvenile steelhead consume a significant amount of crustaceans in their diet, but information is limited regarding their dependence on the specific zooplankton species preferred by Delta smelt.

Splittail and Sturgeon spp

Magnitude = 1
Certainty = 4

Splittail are both benthic and pelagic feeders. If the pelagic foodweb is limited they are able to take advantage of the benthic foodweb; therefore this action is not likely to increase splittail abundance. Sturgeon are primarily benthic feeders; therefore it is quite certain that they are unlikely to benefit from increases in the pelagic foodweb.

Outcome P2: Reductions in total ammonia in the Sacramento River will increase Delta smelt and longfin smelt abundance by increasing diatom production and abundance in low-salinity portion of the estuary (confluence).

P2a. Effect of reducing ammonium on diatom production:

Magnitude = 3
Certainty = 1

The source of ammonium to this area is still likely largely from the Sacramento Regional County Sanitation District, but other treatment plant discharges in Suisun may also be important.

Phytoplankton can be produced in this section of the estuary or transported into the reach from the river upstream, the bay downstream, or the western delta. In this part of the system the major controls on diatom abundance and production are turbidity/light, residence time, and benthic grazing. The effect of clam grazing on phytoplankton in Suisun and Grizzly Bays often extends into this confluence area due to tidal mixing. Benthic grazing is important in many years; however, this area potentially has a longer window in the spring when benthic biomass and grazing rates may be low enough to allow a spring bloom if light, residence time and ammonium levels are favorable. A similar phenomena seems to occur in the western Delta where *Corbicula fluminea* limit the biomass of phytoplankton in Franks Tract where we might expect the shallow water and residence time would be favorable for phytoplankton growth (Lucas et al. 2002). *C. fluminea* grazing may also play a role in limiting phytoplankton biomass in this area. Decreasing sediment load and turbidity may make ammonium more important as light becomes less limited.

This area likely has the largest opportunity for ammonium to be a significant limiting factor when light conditions and grazing pressures are relaxed in the spring. In lab grow out experiments, the algal community in this area appears to respond to ammonium in a similar fashion to the diatoms on Suisun Bay. Unlike near the treatment plant discharge itself, preliminary analyses by the Dugdale-Wilkerson Laboratory indicate that ammonium may be inhibiting phytoplankton production in this area.

Herbicides and metals may also play a role, (e.g. diuron, rice herbicides, copper). Widespread phytoplankton toxicity to the green algae, *Selenastrum capricornutum,* was found at Delta sites monitored by the Irrigated Lands Program. No information is available on differential toxicity to diatoms and microcystis.

P2b. Effect of increasing diatom production on zooplankton abundance:

Magnitude = 2
Certainty = 2

The decline in diatoms in Suisun Bay apparently caused a decline in abundance of at least some zooplankton (Kimmerer and Orsi 1996). At present the zooplankton populations appear to be severely food-limited, at least in the Low-Salinity Zone (b) (Kimmerer 2006, unpublished). However, the change in species composition of the zooplankton since Corbula arrived means that the system may not go back to its previous state. Furthermore, since gains in phytoplankton biomass (as opposed to specific growth rate) are likely to be modest because of continued clam grazing, the response of the zooplankton will likely be small. This is a suitable area for research but nobody should expect a large boost to the foodweb without further information.

P2c. Effect of increasing zooplankton abundance on fish abundance:

Delta smelt:

Magnitude = 3
Certainty = 1

There is evidence that Delta smelt are food-limited based on analyses of their liver glycogen levels (Bennett et al 2008). In addition, spring zooplankton abundance is decreasing just as temperatures are starting to rise, and Delta smelts' bioenergetic needs are increasing. According to Herbold (pers. comm.), April/May and August may be a particularly important bottleneck for Delta smelt. Delta smelt often occur in this part of the estuary in April, May and August. Benthic biomass and grazing rates may be low enough to allow a bloom only in April and maybe May if light, residence time and ammonium levels are favorable. Increasing the base of their foodweb has the potential to have a sustained minor population effect, but the effect would be limited to short but critical periods in April and May of some years. There is minimal certainty because understanding is not widely accepted and outcome is dependent on variable ecosystem processes such as residence time and water clarity.

Longfin smelt:

Magnitude = 2
Certainty = 1

Kimmerer (2002b) found evidence of bottom-up trophic limitations on longfin smelt productivity in this Estuary (p. 26 Longfin smelt conceptual model). The potential magnitude of effect on longfin in the confluence area would be greater than for outcome P1c because longfin occur this area for a longer portion of their life cycle. Benthic biomass and grazing rates may be low enough to allow a bloom only in April and maybe May if light, residence time and ammonium levels are favorable. The critical time period of food limitation for longfin smelt is not known. Increasing the base of their foodweb has the potential to have a sustained minor population effect if food limitation in April and May is a critical bottleneck in longfin survival. There is minimal certainty because understanding is not widely accepted and outcome is dependent on variable ecosystem processes such as residence time and water clarity.

Salmon spp.

Magnitude = 2
Certainty = 1

Juvenile salmonids consume a significant amount of crustaceans in their diet, but Information is limited regarding their dependence on the specific zooplankton species preferred by Delta smelt.

Steelhead

Magnitude = 2
Certainty = 1

Juvenile steelhead consume a significant amount of crustaceans in their diet, but information is limited regarding their dependence on the specific zooplankton species preferred by Delta smelt.

Splittail and Sturgeon spp.

Magnitude = 1
Certainty = 4

Splittail are both benthic and pelagic feeders. If the pelagic foodweb is limited they are able to take advantage of the benthic foodweb; therefore this action is not likely to increase splittail abundance. Sturgeon are primarily benthic feeders; therefore it is quite certain that they are unlikely to benefit from increases in the pelagic foodweb.

Outcome P3: Reductions in total ammonia in the Sacramento River will increase Delta smelt and longfin smelt abundance by increasing diatom production and abundance in the brackish portion of the estuary (Suisun and Grizzly Bays).

P3a. Effect of reducing ammonium on diatom production:

Magnitude = 2
Certainty = 2

Suisun & Grizzly Bay phytoplankton are heavily grazed by clams. Except for a short period in spring when clam biomass and grazing rates are lower, it may be irrelevant whether phytoplankton are growing on nitrate or ammonium, because any production occurring here will be consumed by clams before it would yield food web benefits to covered species. If clam grazing rates are reduced in spring, the magnitude score for this region could be increased.

There is uncertainty as to how much of the ammonium in this part of the system is from Sacramento Regional County Sanitation District versus from other discharges within Suisun Bay such as Central Contra Costa Sanitary District. If other sources of ammonia are included in this action, the "certainty" score for this region could be revisited.

P3b. Effect of increasing diatom production on zooplankton abundance:

Magnitude = 2
Certainty = 2

The decline in diatoms in Suisun Bay apparently caused a decline in abundance of at least some zooplankton (Kimmerer and Orsi 1996). At present the zooplankton populations appear to be severely food-limited, at least in the Low-Salinity Zone (Kimmerer 2006, unpublished). However, the change in species composition of the zooplankton since Corbula arrived means that the system may not go back to its previous state. Furthermore, since gains in phytoplankton biomass (as opposed to specific growth rate) are likely to be modest because of continued clam grazing, the response of the zooplankton will likely be small. This is a suitable area for research but nobody should expect a large boost to the food web without further information.

P3c. Effect of increasing zooplankton abundance on fish abundance:

Delta smelt:

Magnitude = 2
Certainty = 2

There is evidence that Delta smelt are food-limited based on analyses of their liver glycogen levels (Bennett et al 2008). In addition, spring zooplankton abundance is decreasing just as temperatures are starting to rise, and Delta smelts' bioenergetic needs are increasing. According to Herbold (pers. comm.), April/May and August may be a particularly important bottleneck for Delta smelt. Delta smelt often occur in this part of the estuary in April, May and August. Benthic biomass and grazing rates may be low enough to allow a bloom only in April and maybe May if light, residence time and ammonium levels are favorable. It is highly unlikely that phytoplankton biomass would increase in August in response to lower ammonium levels because grazing pressure is too high at this time. Increasing the base of the Delta smelt's foodweb has the potential to have a sustained minor population effect, but the effect would be limited to short but critical periods in April and May of some years. There is minimal certainty because understanding is not widely accepted and outcome is dependent on variable ecosystem processes such as residence time and water clarity. If the clam grazing pressure were reduced, reductions in ammonium may have a larger effect.

Longfin smelt:

Magnitude = 3
Certainty = 1

Kimmerer (2002b) found evidence of bottom-up trophic limitations on longfin smelt productivity in this Estuary (see p. 26 Longfin smelt conceptual model). The potential magnitude of effect on longfin in Suisun and Grizzly Bays would be greater than for outcome P2c because longfin occur this area for a significant part of their life cycle. Benthic biomass and grazing rates may be low enough to allow a bloom only in April and maybe May if light, residence time and ammonium levels are favorable. The critical time period of food limitation for longfin smelt is not known. Increasing the base of their foodweb has the potential to have a sustained minor population effect if food limitation in April and May is a critical bottleneck in longfin survival. There is minimal certainty because understanding is not widely accepted and outcome is dependent on variable ecosystem processes such as residence time and water clarity.

Salmon spp.

Magnitude = 2
Certainty = 1

Juvenile salmonids consume a significant amount of crustaceans in their diet, but Information is limited regarding their dependence on the specific zooplankton species preferred by Delta smelt.

Steelhead

Magnitude = 2
Certainty = 1

Juvenile steelhead consume a significant amount of crustaceans in their diet, but information is limited regarding their dependence on the specific zooplankton species preferred by Delta smelt.

Splittail and Sturgeon spp.

Magnitude = 1
Certainty = 4

Splittail are both benthic and pelagic feeders. If the pelagic foodweb is limited they are able to take advantage of the benthic foodweb; therefore this action is not likely to increase splittail abundance. Sturgeon are primarily benthic feeders; therefore it is quite certain that they are unlikely to benefit from increases in the pelagic foodweb.

Outcome P4: Reduction in ammonia would decrease blooms of nuisance species such as microcystis or non-native zooplankton***

In some systems, nuisance/toxic algae blooms are linked to high concentrations of inorganic nutrients including ammonium (in addition to availability of sunlight & elevated water temp.) with strong correlation between total N and microcystin concentration between 1.5 and 4.0 mg TN/L (Camargo & Alonso 2006, Lehman, pers comm., Takamura et al 1987)

P4a. Microcystis

All Covered Fish Species
Potential benefits of this action do not apply if all Sacramento WWTP discharge were to be diverted into an new North Delta diversion facility. However, it depends on how much of the Sacramento River ends up in the diversion; could change with high flows in Yolo Bypass.

Magnitude = 2
Limited spatial or temporal effects
Lehman et al 2008: Nutrients secondary factor in development of microcystis

Certainty = 3
Relatively high certainty that magnitude of effect is low, from published literature (Lehman et al 2008)

P4b. Non-Native Zooplankton

All Covered Fish Species

Potential benefits of this action do not apply if all Sacramento WWTP discharge were to be diverted into an new North Delta diversion facility. However, it depends on how much of the Sac R ends up in the diversion; could change with high flows in Yolo Bypass.

Magnitude = 2
Limnoithona doesn't appear to have correlation with ammonia, unlike eurytemora and pseudodiaptomus (Fullerton, field data); however, Thompson considers the strong spatial gradient associated with distribution of eurytemora and pseudodiaptomus to confound interpretation of the ammonia relationship.

Certainty = 1
No info or data to substantiate

Outcome P5: Reduction in direct toxic effects on zooplankton species

Information regarding this outcome includes:
EPA 1999 Ammonia criteria
Werner et al., Final Report, 2008 found that growth of H. azteca was correlated with ammonia/ium at some Delta stations.
Johnson, Fullerton ambient data

Buhl 2002: Synergistic effects of ammonia mixing with other toxicants could increase the risk for aquatic invertebrates.

Prenter et al., 2004: Simultaneous or pre-exposure to other stressors such as pathogens can increase ammonia/ium toxicity

P5a. Pelagic Foraging Fish (Smelt and salmonid species)

Magnitude = 2
Could affect large geographic area. Other invertebrates such as hyalella azteca are highly sensitive to ammonia in chronic exposures (USEPA 1999). Effects on hyalella growth have been detected and related to ammonia in the Delta (Werner et al 2008).

Certainty = 3
Information for specific zooplankton species and life cycle exposures is minimal; however, effects on invertebrates (such as Hyalella) in the delta have been documented.

P5b. Benthic Foraging Fish (Splittail and Sturgeon spp.)

Magnitude = 1
No indication that benthic invertebrates are impacted by ammonia

Certainty = 2
Information for benthic species and life cycle exposures is minimal.

Outcome P6: Reduction in direct toxic effects on fish species

Information regarding this outcome includes:
EPA 1999 ammonia criteria
Werner et al. Draft Final Report, 2009: Sacramento WWTP effluent did not cause acute effects on larval Delta smelt survival at environmentally relevant concentrations, and effect concentrations (LC50, LOEC) of ammonia/ium are above concentrations measured in the lower Sacramento River (Werner et al., POD Progress Report, September 2008).

Average ambient ammonia/um and unionized ammonia concentrations in the Sacramento River below SRWTP are within a safety factor of approximately 10 based on acute effect concentrations reported for 50-d old Delta smelt larvae and other sensitive fish species (Werner et al. 2008, 2009).

No information is currently available for chronic effect concentrations.
Delta smelt model – p. 29

Passell et al 2007 concluded that NH3 toxicity must be considered seriously for its potential ecological impacts on the Rio Grande and as a mechanism contributing to the decline of the Rio Grande fish community in general and the Rio Grande silvery minnow specifically.

Buhl 2002: Synergistic effects of ammonia mixing with other toxicants could increase the risk for aquatic species.

Prenter et al., 2004: Simultaneous or pre-exposure to other stressors such as pathogens can increase ammonia/ium toxicity.

Reported unionized ammonia concentrations in the Sacramento River immediately below the SRWTP are 0.0085±0.005 and could exceed chronic safe values for Delta smelt. During January-June 2008, maximum unionized ammonia concentrations measured at Hood and Grand Island (POD site 711) were 0.019 mg/L and 0.021 mg/L, respectively (Werner I., UCD-ATL, unpublished data).

The chronic criterion for the Tittabawasee River in Michigan for fathead minnow embryos and larvae was established at 0.095 mg/L unionized ammonia (Passell et al. and references therein. Fathead minnows are approximately 5 times less sensitive to ammonia/um than Delta smelt (50 d old).

Dodds and Welch (2000) suggest that chronic effects of unionized ammonia on fish may occur at concentrations as low as 0.005 mg/L, which is below average concentrations in the Sacramento River below the WWTP.

The USEPA (1999) reports that some data have indicated that unionized ammonia can have adverse effects on aquatic life at concentrations as low as 0.001–0.006 mg/L.

Chronic effects: For fish, the US EPA (1999) reports mean acute-to-chronic ammonia/ium ratios for warm water fish that range between 2.7 (channel catfish, *Ictalurus punctatus*) and 10.9 (fathead minnow, *P. promelas*). Cold water species such as rainbow trout, with acute ammonia/ium sensitivity similar to Delta smelt, have a ratio between 14.6 and 23.5, respectively (US EPA, 1999; Passell et al., 2007). If a safety factor of 23.5 were applied to acute ammonia effect concentrations for Delta smelt larvae (unionized ammonia 96-h LC_{50}: 0.15 mg/L) then the resulting threshold concentration would be 0.0064 mg/L unionized ammonia.

Thurston and Russo (1983) demonstrated that large rainbow trout were measurably more sensitive than other life stages.

P6a. Delta smelt

Magnitude = 3
Delta smelt larvae at 50 dph are >5-fold more sensitive to ammonia/ium than larval fathead minnow (UCD-ATL, unpublished data), and about as sensitive as salmonid species, which are considered the most sensitive fish species with species mean acute values of 11.23, 17.34 and 20.26 mg/L total ammonia/ium (pH 8.0) for rainbow trout

(*Oncorhynchus mykiss*), Chinook salmon (*O. tshawytscha*) and Coho salmon (*O. kisutch*) (US EPA, 1999).

High probability for Delta smelt exposure. Salmon and smelt are the most sensitive fish species, and ammonia/ium levels in the delta are at least as high as that reported in other systems.

Certainty = 2
Information for fish species life cycle exposure is minimal.

P6.b Longfin Smelt

Magnitude = 1
longfin limited in spatial and temporal overlap with Sacramento Regional ammonia.

Certainty = 3
Reasonable certainty there are minimal impacts on longfin smelt Sac Regional's ammonia.

P6c. Salmonids

Magnitude = 2
Salmon and smelt most sensitive (salmon data from other systems – should revisit the literature). But levels in the Delta are at least as high as that reported in other systems.

Certainty = 3
No info or data from inside the delta to substantiate effects to salmon, but their sensitivity has been demonstrated to be comparable to that of Delta smelt.

P6d. Green & White Sturgeon

Magnitude = 1

Certainty = 3
Reasonable certainty that there are minimal impacts on GS/WS from Sac Regional's ammonia.

P6e. Splittail

Magnitude = 1
Splittail due to small percentage of population being directly exposed.

Certainty = 3
Reasobable certainty that there are minimal impacts on splittail from Sac Regional's ammonia.

Potential Negative Ecological Outcome(s)

Outcome N1: Removal of valuable nutrients as a function of WWTP outputs

All Covered Fish Species
See Delta smelt model, p. 30 (cites Van Nieuwenheyse 2007, with regard to positive influence of nutrients)

Both Outcome N1 and N2 are dependent on treatment. N1) are you doing nitrification or denitrification? If nitrification, magnitude is still minimal. System is not Nitrogen limited.

Magnitude = 1
Likely low magnitude if Sacramento River is not nutrient limited above the WWTP (Dalgren data)
Depends on treatment process chosen; more nutrients possible.

Certainty = 4
Dalgren data (unpublished – down to Freeport)
High certainty that there are high Nitrogen levels in the Sacramento River entering the system from upstream of the Sac Regional discharge.

Outcome N2: Nitrification will reduce ammonia, but increased nitrate could result in growth of undesirable algal blooms and macrophytes

All Covered Fish Species
Both Outcome N1 and N2 are dependent on treatment. Nutrients are an important factor supporting the growth on invasive macrophytes. Treatment that removes ammonia but increase nitrates could support macrophyte growth. Microcystis blooms can be attributed in part to increased nutrient inputs, and can cause fish mortality due to toxin production and reduced dissolved oxygen as a bloom decays.

Magnitude = 2
Limited spatial or temporal habitat effects based on current distribution of microcystis and invasive macrophytes.

Certainty = 2
Dalgren data (unpublished – down to Freeport) shows high nutrient loading to the delta; Sac Regional discharges nutrients to the delta, but how that contribution affects overall productivity relative to other nitrogen sources is not known.

Outcome N3: Increased phytoplankton productivity will increase clam biomass and uptake of selenium, impairing reproduction in benthic foraging fish species.

Splittail, Green Sturgeon, White Sturgeon

See:
Corbula model, p.13.
Corbicula Model, p. 12.
Selenium Model, p.14.
Splittail Model, p. 7.
Green Sturgeon Model, p. 9.
White Sturgeon Model, p. 9.

Magnitude = 3
Elevevated selenium concentrations in splittail and sturgeon suggest the possibility that reproductive impairment might be occurring; the population-levels effects of such exposure have not been evaluated

Certainty = 4
Greater contaminant uptake by clams, shifts in diets of splittail and sturgeon to clams, and elevated selenium in these benthic foraging species have been document within the delta system.

Important Gaps in Information and/or Understanding

Data Needs

- Other sources of ammonia are currently not included in the action; there could be others besides SRCSD that are important sources, (e.g. agriculture, dairies) in addition to SRCSD. The relative importance of all sources of ammonia should be evaluated.
- Ammonia model (Stuart Siegel's draft model for ammonia was circulated to the group)
- Analysis of data correlating ammonia, salinity, flow, temperature, and light penetration (numerical modeling to manipulate variables to ascertain importance of ammonia)
- Question of whether ammonia levels at Hood actually affect ammonia levels in Suisun Bay.
- Chronic effects of ammonia on fish species and zooplankton (in progress with Mike Johnson).

Research Needs

Integrated research should be undertaken to develop a numerical model of ammonia affects on the delta food web and covered species so that the multiple factors influencing production can be manipulated/isolated from other factors, and the respective roles of each factor can be determined for the different portions of the estuary. The model should address:

(a) Ammonia effects on food web production and species within the phytoplankton and zooplankton communities;
(b) Relative importance of ammonium versus nitrate;
(c) Sources, transport, and fate of ammonia through the Delta (into SF Bay), including the extent to which ammonium levels at Hood translate to effects in Suisun bay;
(d) Overall contribution of in-delta versus out-of-delta nutrient loading;
(e) Relationships of covered fish species to specific zooplankton;
(f) The adverse effects of clams on phytoplankton and diatom productivity and subsequent effects on zooplankton;
(g) Relationship between nitrate loading, macrophytes, and microcystis.

Approaches to consider include mesocosm studies and/or tracer studies using radio-labeled or stable isotopes.

Action: Reduce the Load of Endocrine Disrupting Compounds

Evaluation Team: Water Quality and Invasives Workgroup

James Haas - Chair , Bruce Herbold – Coach, Chris Foe, Charles Alpers; Inge Werner, Frances Brewster, Karen Larsen, Chrisinte Joab, David Fullerton, Holly Gellerman, Ron Smith, Jan Thompson, Lori Clammurro (note taker)

Date of Last Revision: February 19, 2009

Action Description and Clarifying Assumptions

Implement advanced treatment processes at wastewater treatment plants in the Delta to reduce the loads of endocrine disrupting compounds (EDCs) discharged into the Delta to levels that do not harm covered fish species.

Approach

Implement advanced treatment processes at the wastewater treatment plants.

Intended Outcomes as Stated in Conservation Measure

1. Increased reproductive success of covered fish species.
2. Reduced endocrine issues (transgender, reproductive, etc.) caused by endocrine disruptors in delta and longfin smelt, white and green sturgeon, salmonids (all races), and splittail.

Outcomes added by evaluation team:

3. Reduced effects of endocrine disrupting chemicals to food web organisms/invertebrates.
4. Ancillary benefits – if you're removing EDCs you're also removing other harmful chemicals (e.g. methylmercury, personal care products, ammonia, antibacterial, flame retardants, pharmaceuticals, etc.) depending on the treatment process selected. (See also OSCM1 (ammonia), OSCM3 (MeHg), OSCM4 (pesticides and herbicides), and OSCM5 (urban runoff) actions.) – *Potentially a large ancillary benefit, but is treatment specific and will be difficult to analyze impacts to species. Group suggested keeping this outcome as an important consideration, but chose not to assign scoring to it*

General Conceptual Model Support for Intended Outcomes

Werner I, Anderson S, Larsen K, and Oram J. 2008. Chemical stressors conceptual model. Sacramento (CA): Delta Regional Ecosystem Restoration Implementation Plan.

- page 6, "Effluents from municipal wastewater treatment plants are significant sources of ammonium as well as complex mixtures of contaminants that affect reproductive endocrine function (Kidd et al., 2007; Huang and Sedlak, 2001 and references therein)."
- Page 6, "Exposure of fish populations to low concentrations of such compounds can have dramatic effects. In a multi-year field study, Kidd et al (2007) showed that chronic exposure of fathead minnow to 5-6 ng/L 17alphaethynylestradiol (EE2, a synthetic estrogen used in birth-control pills) led to near extinction of this species from the experimental lake. Huang and Sedlak (2001) measured concentrations of up to 4.05 ng/L 17beta-estradiol (E2, the natural estrogen) and 2.45 ng/L EE2 in treatment plant effluent after secondary treatment/chlorination, while concentrations were mostly below 1 ng/L in effluents treated with more sophisticated methods."
- Page 22, "One of the more potent synthetic estrogens found in surface waters is 17 alpha-ethynylestradiol (EE2), a biologically persistent analogue of estradiol that is widely used in oral contraceptives, which is not completely removed by sewage treatment plants (Newman and Unger, 2003)."

Werner I, and Oram J. 2008. Pyrethroid insecticides conceptual model. Sacramento (CA): Delta Regional Ecosystem Restoration Implementation Plan.

- Page 30, "*Reproductive toxicity and endocrine disruption:* Moore and Waring (2001) demonstrated that the pyrethroid cypermethrin reduced the fertilization success in Atlantic salmon after a 5-day exposure to 0.1 ppb. In a study on bluegill sunfish, Tanner and Knuth (1996) found delayed spawning and reduced larval survival after two applications of 1 ppb esfenvalerate. Results of a study performed by Werner et al. (2002b) suggest that dietary uptake of esfenvalerate (148 ppm) may lead to a decrease in fecundity in adult medaka (*Oryzias latipes),* and a decrease in the percentage of viable larvae."
- Page 30, "Day (1989) showed that concentrations of <0.01 ppb permethrin and other pyrethroids reduced reproduction and rates of filtration of food by daphnids. A concentration of 0.05 ppb esfenvalerate led to a significant decrease in reproductive success (number of neonates) of *Daphnia carinata* (Barry et al., 1995). Reynaldi and Liess (2005) demonstrated that fenvalerate delayed the age at first reproduction in *Daphnia magna*, and reduced fecundity at a LOEC of 0.1 ppb (complete mortality occurred at 1 ppb). Population growth rate was inhibited at 0.6 ppb (24 h), and recovery occurred after 21 d. Results of chronic toxicity studies in mysid shrimp show that exposure to cypermethrin had adverse effects on reproductive parameters. For decreased number of young, a chronic NOEC value of 1.5 pptrillion (ng/L) was reported in two studies (USEPA, 2005)."

Unassigned. 2008. Semi-Final Species Life History Conceptual Model: Delta smelt (*Hypomesus transpacificus).*

- Page 25, "Endocrine-disrupting chemicals present in treated wastewater can interfere with fish maturation and reproduction (Jobling et al. 1998). A recent study in a Canadian lake showed that very low concentrations of EDCs caused rapid population failure of fathead minnow *Pimephales promelas* (Kidd et al. 2007). One of the biomarkers of EDCs is intersex fish – fish with both male and female reproductive organs. A recent histopathologic evaluation of Delta smelt for the pelagic organism decline study found 9 of 144 maturing Delta smelt (6%) collected in the fall were intersex males (Baxter et al.

2008). This is evidence that Delta smelt are being exposed to EDCs. However, there are no long-term data to compare this data point to, so its significance is unknown."

Unassigned 2007. Draft Species Life History Conceptual Model: Longfin Smelt (*Spirinchus thaleichthys).*

- Page 34, Stressor Table for San Francisco Estuary Longfin Smelt Population, EDC Importance: 3, understanding: 3, certainty of importance: 2, life stages affected: all, geographic extent: Delta and lower estuary, season: all. "Toxicity thresholds remain to be determined. Duration and magnitude of exposure remain to be determined."

Unassigned, 2008. Administrative Draft Species Life History Conceptual Model: Chinook salmon and Steelhead *Oncorhynchus tshawytscha* and *Oncorhynchus mykiss*.

- Page 81, Stressor Table for Sacramento winter-run Chinook salmon, EDC Importance: 3, understanding: 3, certainty of importance: 2-3, life stages affected: fry, juvenile, geographic extent: Throughout river systems and Delta/Suisun, season: fall and winter. "Toxicity thresholds remain to be determined. Duration and magnitude of exposure remain to be determined."
- Page 103, Stressor Table for Sacramento fall-run Chinook salmon, EDC Importance: 3, understanding: 3, certainty of importance: 2-3, life stages affected: fry, juvenile, geographic extent: Throughout river systems and Delta/Suisun, season: fall and late-spring "Toxicity thresholds remain to be determined. Duration and magnitude of exposure remain to be determined."
- Page 126, Stressor Table for Sacramento late-fall run Chinook salmon, EDC Importance: 3, understanding: 3, certainty of importance: 2-3, life stages affected: fry, juvenile, geographic extent: Throughout river systems and Delta/Suisun, season: summer-winter. "Toxicity thresholds remain to be determined. Duration and magnitude of exposure remain to be determined."
- Page 129, Stressor Table for Sacramento spring-run Chinook salmon, EDC Importance: 3, understanding: 3, certainty of importance: 2-3, life stages affected: fry, juvenile, geographic extent: Throughout river systems and Delta/Suisun, season: all. "Toxicity thresholds remain to be determined. Duration and magnitude of exposure remain to be determined."

"Toxicity thresholds remain to be determined. Duration and magnitude of exposure remain to be determined."

Unassigned. 2008. Semi-Final Species Life History Conceptual Model: Sacramento Splittail *Pogonichthys macrolepidotus)*.

+ Page 24, Table 3: Stressor Understanding Matrix. Endocrine Disruptors: Importance:3, understanding: 1, predictability: 1

Unassigned. 2008. Semi-Final Species Life History Conceptual Model: North American Green Sturgeon *Acipenser medirostris*

+ Page 22, "Intersexual changes characterized by the formation of ovaries in males have been observed in shovelnose sturgeon and have been potentially linked to endocrine-disrupting organochlorine chemicals (Harshbarger et al. 2000)."

Assumptions

Provided in BDCP Conservation Measure
Implied: wastewater treatment plants are largest sources of EDCs.

Added by Evaluation Team
Plant specific information is needed to fully assess the magnitude and certainty of this action for each plant. For the purpose of this evaluation, the reviewers assessed the potential effect if this action was targeted to the Sacramento Regional Wastewater Treatment Plant since it is the largest discharger in the Delta and information on its treatment process was available to the reviewers at the time of this review

Problem(s) with Action as Written:

1. Advanced treatment is a general term used to describe several different possible treatment processes, each of which will reduce different types and quantities of endocrine disrupting compounds from the wastewater influent. Every treatment plant has unique influent characteristics and even plants utilizing identical treatment processes can have different effluent characteristics. Plant specific information is needed to fully assess the magnitude and certainty of this action for each plant.
2. Consider including other potential sources of EDCs (other than wastewater treatment plants) as part of this action. For example, pesticides and other contaminants in urban and agricultural runoff have been shown to cause endocrine disruption in aquatic organisms.

Scale of Action:

Medium-large, depending on the number of treatment plants upgraded.

Rationale:
Reduction in endocrine disrupting chemicals would be year-round, but extent would depend on number of treatment plants requiring upgrades, extent of EDC reductions achieved with the upgrades, and relative contribution of wastewater treatment plants to the total load of EDCs in the Delta.

Evaluation Summary Tables

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

Relation to Existing Conditions:

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

NO

Nature of Change:

Unless additional treatment increased the use of recycled water (e.g. decreased the amount of wastewater discharged to the Delta), the action would not change inflows, hydrodynamic conditions or salinity regimes.

Potential Positive Ecological Outcome(s)

Outcome P1: Increased reproductive success of covered fish species

General Observations:

+ Kidd et al. 2007 linked endocrine disruption to reproductive success in fathead minnows in a whole lake exposure.
+ Lavado et al 2009 found estrogenic activity in water from Lower Napa River, Lower Sacramento River and Carquinez Strait nr. Benicia.
+ Brander et al 2008 observed choriogenin induction in male silversides from Suisun Marsh.
+ Delta smelt species model, Page 25, "Endocrine-disrupting chemicals present in treated wastewater can interfere with fish maturation and reproduction (Jobling et al. 1998). A recent study in a Canadian lake showed that very low concentrations of EDCs caused rapid population failure of fathead minnow *Pimephales promelas* (Kidd et al. 2007). One of the biomarkers of EDCs is intersex fish – fish with both male and female reproductive organs. A recent histopathologic evaluation of Delta smelt for the pelagic organism decline study found 9 of 144 maturing Delta smelt (6%) collected in the fall were intersex males (Baxter et al. 2008). This may be evidence that Delta smelt are being exposed to EDCs. However, there are no long-term data to compare this data point to, so its significance is unknown."
+ An et al., 2008 reference numerous studies that link secondary effluents to reproductive effects in wild fish.
+ Riordan (Calfed Science Conference 2008) reported endocrine disruption in male fathead minnows following in-situ exposures below the Sacramento WTP.
+ Huang et al., 2001 measured 0.08 ng/L ethinylestradiol in Delta water samples.
+ Johnson (pers. comm.) reported vitellogenin induction in 100% of male splittail from Suisun Bay.

Goodbred, Xie, Hemming, Dwyer
NOAA review paper (2002)

Refute or fail to support

+ Martinovic et al., 2007 observed reduced reproductive success in estrogen exposed male fathead minnows, but at estrogen levels significantly higher than those typically measured in WWTP effluent or ambient samples.
+ Williams et al., 2009 report that the treatment level may not be as important to intersex fish risk as the dilution capacity of the receiving water; however, their modeling study assigned the same removal efficiencies to secondary treatment with activated sludge as to all advanced treatment processes.

Magnitude = 2

+ Exposure to estrogen levels similar to those found downstream of wastewater treatment plants caused a population level collapse in fathead minnows (Kidd et al., 2007).
+ Data on EDC concentrations in Delta waterways are limited; however, Kolpin et al. (2002) detected organic wastewater contaminants in 80% of streams sampled in 30 states. 75% of streams had multiple detections with a median of 7 and maximum of 38

contaminants per sample. Cholesterol and 3 detergent metabolites accounted for more than 60% of the higher concentrations detected.

+ Several studies link endocrine disrupting chemical exposure to spawning competency in fathead minnows in laboratory exposures, but it is unclear whether those effects would translate to impacts on species reproductive success in the wild (Bistodeau et al., 2006)
+ deVlaming et al., 2007 state that population level effects of increased liver vitellogenin mRNA in juvenile rainbow trout is largely unknown.

Certainty = 2

+ Analysis of effluent from secondary treatment plants has detected concentrations of estrogenic hormones at levels that can cause vitellogenesis in fish (Huang et al., 2001). Huang et al (2001) also found that the concentration of estrogenic hormones in wastewater treatment effluent was generally related to the sophistication of the treatment system; biological nutrient removal, sand filtration, microfiltration, reverse osmosis and engineered wetlands all reduced estrogen levels more than secondary treatment alone. Servos et al. (2005), and numerous references, within report similar findings.
+ Numerous studies report endocrine disrupting compounds in surface waters (Batt et al., 2008; deVlaming et al., 2007; Dussault et al., 2008; Kolpin et al., 2002).
+ The literature is full of studies from outside the system that observe endocrine effects in fish downstream of treatment plant discharges (An et al., 2008; Douxfils et al., 2007; Williams et al., 2009; Matthiessen 2003), four are Delta specific (Riordan et al 2008, Brander et al 2008, Johnson pers. comm., and Lavado et al 2009).
+ Barber et al., 2007 report that reproductive response of male fathead minnows to wastewater treatment plant effluent indicates both beneficial and detrimental effects.

Summary Conclusions

Outcome P1:			
Ratings:	**Magnitude = 2**	**Certainty = 2**	
Explanation:	Magnitude score is influenced by the large geographic and temporal extent of potential positive outcomes. There is some information available for Delta smelt, splittail, and salmon (data from upstream areas); not as much information available for green or white sturgeon. This outcome is focused on reproductive success in terms of population-level effects. There is not as much literature for reproductive effects as there is for other endocrine-disrupting effects. The level of concern over intersex individuals, coupled with the large geographic extent, factored into the magnitude score. There is relatively high certainty that WWTP effluent is a major source of endocrine disruption in fish where endocrine disruption is observed. There is also relatively high certainty that advanced treatment processes more efficiently remove many EDCs than does secondary treatment alone. However, there is limited data on how extensive endocrine disruption is in wild fish populations, limited observations of actual effects within the Delta, and limited studies that link observed endocrine effects to population level impacts		

Outcome P2: Reduced endocrine issues (transgender, reproductive, etc.) caused by endocrine disruptors in delta and longfin smelt, white and green sturgeon, salmonids (all races), and splittail

General Observations:
[See P1, above]
+ An et al., 2008, vitellogenin induction increased with exposure time.
+ Matthiessen 2003 states that the adrenal system is vital to stress response, thyroid hormones influence neural development, metabolism, osmoregulation and smoltification. He cites a study that found intersex Chinook salmon on the Columbia River.
+ Ward et al., 2008 reported that exposure to 1.0 ug/L of 4-nonylphenol for only 1-hour disrupted the shoaling behavior of juvenile killifish. The response was restored after exposure ended. Ward also cites studies that detected 4-nonylphenol at concentrations from 0.5-343 ug/L near sewage outfalls.
+ Werner et al 2008, and references therein, report that pyrethroids were shown to have steroid receptor-binding activity *in vitro* (*14*). Their effects on the endocrine system are not uniform. While Fenpropathrin and permethrin act as weak estrogen agonists, allethrin and cypermethrin have antiestrogenic as well as antiandrogenic activity. Cyfluthrin and fenvalerate showed very weak antiestrogenic activity, but several metabolites and products of environmental degradation of permethrin and cypermethrin had up to more than 100-fold greater potencies than the parent compound (*13, 14, 44*). In mammals, pyrethroids affect sperm concentration, motility and morphology (*10*).

  In fish, Moore and Waring (*35*) demonstrated that the pyrethroid cypermethrin reduced the fertilization success in Atlantic salmon after a 5-day exposure to concentrations of 0.1 µg/L. In a study on bluegill sunfish, Tanner and Knuth (*45*) found delayed spawning and reduced larval survival after two applications of 1 µg/L esfenvalerate.

+ Webb et al. (2006) reported reduced concentrations of plasma androgens associated with muscle mercury concentrations > 0.187 ppm (wet weight) in Columbia River white sturgeon. This concentration is within the range discussed for this species in the delta (See OSCM3).

Refute or fail to support DLO
+ deVlaming et al., 2007 collected 113 ambient water samples from 66 sites in California, 26 of which represented some WWTP effluent contribution. Only 6 samples caused significant, though weak, endocrine response in juvenile trout and only 1 of those represented WWTP effluent. However, these fish were only exposed for 4-days.

Magnitude = 2-3
+ Bennett et al., 2008 report 6% of pre-adult Delta smelt analyzed in 2005 had ovatestis.
+ Johnson (pers. comm.) observed vitellogenin induction in 100% of male splittail from Suisun Bay.
+ Population level effects of transgender fish are not well understood.

+ The literature is full of studies that observe endocrine effects in fish downstream of treatment plant discharges.

Certainty = 3

The literature is full of studies (from outside of the system) that observe endocrine effects in fish downstream of treatment plant discharges.

Geographically, covers the same area as under Outcome P1; also, impacts limited to small fraction of the population (so question that there's a population-level effect)

Summary Conclusions

Outcome P2:			
Ratings:	**Magnitude = 2-3**	**Certainty = 3**	
Explanation:	Magnitude score is slightly more than in P1. P2 encompasses all endocrine effects, regardless of reproductive success [P1]. It looks at biomarker-type responses that may not have population-level or reproductive success issues; evidence suggests these are widespread, but it is unclear whether there is a population-level effect. Potential impacts are greater (than in P1) because more than reproductive success is being considered		

Outcome P3: Reduce effects of endocrine disrupting compounds to food web organisms/invertebrates

General Observations:

+ Oetken et al. (2004) reviewed the evidence for endocrine disruption in invertebrates. Some mollusk species were highly sensitive to the tributyl tin at extremely low concentrations (ng/L). In addition, TBT and insect growth regulators had effects on crustacean species at concentrations in the low ug/L in laboratory exposures. Whether these laboratory exposure conditions are met in the delta is unknown.
+ Canesi et al., 2007, reported effects of synthetic estrogen on muscle digestive gland.
+ Dussault et al., 2008 measured response in midge and amphipod and calculated hazard quotients based on exposure values from the literature for 4 compounds. They conclude that there is a potential risk to benthic invertebrates exposed to triclosan and carbamazepine, but not for atorvastatin or ethinylestradiol.
+ Adams et al., 2008 report that secondary treated wastewater effluent was not acutely toxic but did cause chronic toxicity to microalgae, macroalgae and scallop larval development. However, there was no evidence presented that the observed chronic effects were from endocrine disrupting compounds within the waste stream.
+ Werner et al 2008 cite numerous studies: Day (*46*) showed that concentrations of <0.01 µg/L permethrin and other pyrethroids reduced reproduction and rates of filtration of food by daphnids. A concentration of 0.05 µg/L esfenvalerate also led to a significant decrease in reproductive success (number of neonates) of *Daphnia carinata* (*47*). Reynaldi and Liess (*48*) demonstrated that fenvalerate delayed the age at first reproduction in *Daphnia magna*, and reduced fecundity at a LOEC (lowest observed effect concentration) of 0.1 µg/L (complete mortality occurred at 1 µg/L). Population growth rate was inhibited at 0.6 µg/L (24 h), and recovery occurred after

21 d. Results of chronic toxicity studies in mysid shrimp show that exposure to cypermethrin had adverse effects on reproductive parameters: For a decrease in the number of young, a chronic NOEC value of 1.5 ng/L was reported in two studies (*39*).

Refute or fail to support

+ Kidd et al., 2007 did not find major changes in the lower trophic levels and the food web following whole lake exposure to a synthetic estrogen at concentrations found downstream of WWTPs.

Magnitude = 2

+ Invertebrates are generally resilient to intermittent exposure to low concentrations of pesticides; amphipods (Hyallela azteca) showed the greatest sensitivity in mesocosm studies. Most species tested showed no effect or quick recovery following exposure to cypermethrin and/or esfenvalerate (Giddings et al. 2001). Oetken etal. (2004) noted: "With the exception of TBT effects on mollusks, which have been associated with a locally severe impact on community levels, and IGRs in terrestrial insects, there are only a few field examples of endocrine disruption in invertebrates."
+ Results of chronic toxicity studies in mysid shrimp show that exposure to cypermethrin had adverse effects on reproductive parameters: For a decrease in the number of young, a chronic NOEC value of 1.5 ng/L was reported in two studies (*Werner and Moran, 2008*).
+ Since hormones regulate the main events in the crustacean life cycle, chemicals that interfere with their biosynthetic and/or biotransformation pathways would consequently have impact on individual and population growth. Regardless of this, the understanding of basic crustacean endocrine systems and pathways is scarce and may vary considerably (Dahl et al 2008).

Certainty = 1

+ Dussault et al., 2008 state that considerable uncertainty exists regarding potential impacts to benthic invertebrates of chronic exposure to mixtures of biologically active contaminants

Summary Conclusions

Outcome P3a:			
Ratings:	**Magnitude = 2**	**Certainty = 1**	
Explanation:	Magnitude score is influenced by the large geographic and temporal extent of potential positive outcomes. There is some information available on effects on invertebrates outside the system, but limited data within the system. There is not as much literature for effects on invertebrates as there is for effects on fish.		

Outcome P4: Ancillary benefits – if you're removing EDCs you're also removing other harmful chemicals (e.g. methylmercury, personal care products, ammonia, antibacterial, pharmaceuticals, pesticides)

Because these "ancillary benefits" incorporate analyses under other water quality conservation measures (OSCMs1, 3, 4 and 5), the group opted not to assign a score for this outcome, but rather to refer the reader to those other worksheets.

Potential Negative Ecological Outcome(s)

The group did not identify any potential negative ecological outcomes for this action.

Important Gaps in Information and/or Understanding

Data Needs

There is limited data on the presence and concentrations of EDCs in Delta waterways and in Delta wastewater treatment plant effluent. It is unknown whether EDCs occur in the Delta at levels that pose concerns for covered species. And, it if they do occur at levels of concern, the relative contribution from each source is unknown.

- Bruce Herbold provided references for two studies showing intersex in Central Valley salmon (Sacramento River).

USFWS is finding EDCs in increasing levels and numbers of fish in the Delta, but there is not much information on population-level consequences of any of the endocrine disruptions in this estuary (our knowledge of levels of compounds isn't sufficient in this estuary), but see Kidd et al 2007.

Research Needs

There is a need to learn more about endocrine disrupting effects (other than estrogenic) in the covered species, such as androgenic and thyroid effects. Much more is currently known about estrogenic effects than other endocrine disrupting effects.

Information is needed on the linkages of monitoring endpoints such as vitellogenin or alteration of thyroid function and higher level effects such as reproductive success and ecological fitness in covered species or appropriate surrogate species.

EDC monitoring based on biological responses is needed to identify hotspots and sources as well as temporal and special distribution of EDCs.

Finally, there is acknowledgement that when EDCs are detected, it is very difficult to determine where they came from. It is expected that wastewater treatment plants contribute to the problem, but EDCs can also come from pyrethroids and other agricultural runoff, particularly dairies, which represent large potential untreated loadings. There is therefore a need to determine the relative contributions of wastewater treatment plants to other potential EDC sources such as hatcheries, pesticide sources, and dairies. However, while reducing wastewater treatment plant loads may not fix the problem in and of itself, addressing even small amounts of EDCs could be helpful because species effects occur at such low concentrations (low ng/L).

Research should be conducted to determine whether temperature is a confounding factor for EDC effects in salmonids in the Delta. Temperature affects the potential for intersex effects in salmonids (separate from contaminant effects), as documented in studies from outside of the system.

Assess Reversibility and Opportunity for Learning

Reversibility

NO – hard.

> ***Comments:*** Implementing advanced treatment at wastewater treatment plants to remove EDCs would be very costly, and is irreversible

Opportunity for Learning

Medium.

> **Comments**: It is difficult to observe cause and effect relationships in wild fish populations, especially for sublethal and chronic effects such as those likely to be caused by EDCs

Action: Reduce the Load of Methylmercury

Evaluation Team: Water Quality & Invasives Workgroup

James Haas - Chair , Bruce Herbold – Coach, Chris Foe, Charles Alpers; Inge Werner, , Frances Brewster, Karen Larsen, Chrisinte Joab, David Fullerton, Holly Gellerman, Ron Smith, Jan Thompson, Lori Clammurro (note taker)

Date of Last Revision: February 17, 2009

Action Description and Clarifying Assumptions

Implement measures to reduce the load of methylmercury entering the Delta from upstream and in-Delta sources by 50 percent.

Approach

1. Modify the Cache Creek settling basin to improve mercury and sediment trapping efficiency.
2. Remediate mercury sources upstream of the Delta, including mercury-contaminated sediment hot spots in stream channels and mercury and gold mines.
3. Avoid or minimize methylation and transport of mercury in floodplain and intertidal marsh habitats that are restored through BDCP actions.
4. Work with the CVRWQCB to identify best management practices for other sources of methylmercury.

Intended Outcomes as Stated in Conservation Measure

1. Reduced direct mortality due to consumption of mercury by splittail, Delta and longfin smelt, green and white sturgeon, steelhead, and Chinook salmon.
2. Reduced sublethal effects (genetic, tissue/organ damage, development, reproductive, growth, and immune) of mercury on splittail, Delta and longfin smelt, green and white sturgeon, steelhead, and Chinook salmon.
3. *(Added by the group): Reduced toxic concentrations of methyl mercury in forage and sportfish to protect wildlife and humans from chronic sublethal toxicity.*

General Conceptual Model Support for Intended Outcomes

1. No information available for the covered fish species within this system. Mercury concentrations in covered fish species are assumed from concentrations documented to produce mortality in other fish species.
2. Little or no information available for the covered fish species within this system. Mercury concentrations in covered fish species are assumed from concentrations documented to produce sub-lethal effects in other fish species. Some decreases in feeding efficiency and some hormonal responses are possible in the most contaminated individuals (*need a citation here?*).

3. *OEHHA fish consumption advisories for humans; potential effects on birds as documented by Ackerman et al. 2008, and Burgess and Meyer 2008.*

Assumptions

Added by Evaluation Team

1. The action has several underlying assumptions. First, that the inorganic mercury content of sediment is an important factor in creation of methyl mercury by sulfate reducing bacteria. This assumption is supported by submodel #1 of the mercury conceptual model and by positive correlations between inorganic and methyl mercury concentrations in sediment in the Delta (Heim et al. 2007), by amendment of increasing concentrations of inorganic mercury to intact sediment cores in the laboratory and the measurement of increasing concentrations of methyl mercury in the overlying water column (Rudd et al., 1983; Bloom et al., 2003) and, finally, by about 10 papers in the peer reviewed literature where decreases in methyl mercury concentrations in fish were observed after the load of incoming inorganic mercury was reduced (reviewed in Wood et al., 2008).
2. The second assumption of the action is that methyl mercury production is not the same in all habitats. Seasonally flooded habitats like some wetlands, most floodplains and newly created reservoirs are disproportionately important methylation sites. These sites must also have hydrologic connectivity to the Delta. This assumption is supported by submodel # 1 of the mercury model (Alpers et al., 2008, pages 15 and 16) and work by Foe et al., 2008; Slotton et al. 2007.
3. The third critical assumption is that methyl mercury bioaccumulation is a food web dietary process. Methyl mercury concentrations in water (attached to phytoplankton) determine biomagnification further up the food chain including concentrations in sport and forage fish. This assumption is supported by submodel #2 (Alpers et al., 2008, pages 17 and 19) and by positive correlations between unfiltered methyl mercury concentrations in water and in standard sized largemouth bass in the Delta (Wood et al. 2008).

Problem(s) with Action as Written:

1. Methyl mercury production, transport, fate and bioaccumulation are not completely understood. There are likely to be other important factors controlling fish tissue concentrations that have not yet been identified. For example, longer water residence times in the Delta appear to be associated with lower aquatic methyl mercury levels, which may be related to photodegradation of methyl mercury (Foe et al. 2008). Therefore, changes in hydrology from operation of a peripheral canal or a dual conveyance system may produce unexpected changes in baseline conditions.
2. The action of a 50% reduction in methyl mercury is arbitrary. There is a gradient in both methyl mercury concentrations in water and fish across the Delta. Highest levels are in rivers and in areas of Delta immediately downstream of rivers and lower levels are at water export sites (State and Federal pumping facilities at Tracy and at Chipps Island, the main channel to Suisun and San Francisco Bay). Some areas of Delta may need more methyl mercury reduction than others.

3. A program of reducing methyl mercury by a defined amount requires an accurate assessment of baseline conditions. At present there are only 4 years of water and fish tissue data for the Delta. It is unknown whether the present limited data set has captured all the natural variability in baseline concentrations.

4. The fourth approach listed is to "*Work with the CVRWQCB to identify best management practices*…" is problematical. First, it is unclear whether best management approaches can be identified that will be successful. Of course, we will not know unless we try. Second, identifying best management practices without a way to implement them will never reduce methyl mercury. Recommend that the approach be modified to say, "*identify and implement most promising best management practices*…"

Scale of Action:

Large

Rationale:
This action is of a large spatial and temporal scale. Spatially the action is likely to have impacts across much of the Delta and into Suisun and Grizzly Bays. Temporally, reductions in total mercury loads into the Delta are also likely to have measurable impacts for decades and possibly even centuries to come.

Evaluation Summary Tables

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

Relation to Existing Conditions:

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?
NO

Nature of Change: Insert short sentence here.
If successful the action is likely to reduce methyl mercury levels in water and fish but should not produce any fundamental changes to other key physical or biotic properties of the Delta.

Potential Positive Ecological Outcome(s)

Outcome P1: Reduced direct mortality due to consumption of mercury by splittail, Delta and longfin smelt, green and white sturgeon, steelhead, and Chinook salmon.

P1. *All covered fish species*

No toxicological studies have been conducted with any of the target species. So, mercury concentrations in target fish are compared here against concentrations documented to produce mortality in other fish species. For toxicological comparison, death in rainbow trout in laboratory studies occurred at 4-ppm wet weight and the NOAEC for death in Brook trout was 2.7 ppm (in Wiener and Spry, 1996). Conclusion, about a 10X safety factor exists between tissue concentrations in the target fish species in Delta and values reported in the literature to cause mortality.

There was a question of whether this outcome should be separated into short- vs. longer-lived fish species, grouped by the data information and assumed value assignments (for similar fish taxa). It was agreed that fundamentally MeHg is not a fish problem; it's more of a problem for humans and birds – thus, separating the covered fish into short- vs. longer-lived fish for analysis would not add any value to this evaluation, and would not change the magnitude or certainty scores.

For these reasons, the magnitude and certainty scores are the same for all of the covered fish species.

Fall-run Chinook salmon: Mercury concentrations (ppm-wet weight) for Chinook salmon are 0.094-0.396 (Davis et al., 2002; SFEI, 2006).

Steelhead: Mercury concentrations (ppm-wet weight) for steelhead are .05 -.3 (Davis et al., 2002; SFEI, 2006).

Splittail: No information available.

White Sturgeon: Mercury concentrations (ppm-wet weight) for white sturgeon are 0.165 - .279 (Davis et al., 2002; SFEI, 2006).

Green Sturgeon: Green sturgeon is assumed to have a similar tissue concentration as white sturgeon. Mercury concentrations (ppm-wet weight) for white sturgeon are 0.165 - .279 (Davis et al., 2002; SFEI, 2006).

Delta smelt: No tissue data for Delta smelt was found. Assume Delta smelt will have similar tissue concentrations as other fish taxa living one year and feeding primarily on zooplankton. Mercury concentrations in juvenile threadfin shad and juvenile largemouth bass in Delta are assumed to have similar mercury burdens as Delta smelt and are 0.012-0.076 and 0.035-0.230, respectively (Slotton et al., 2006).

Longfin smelt: No tissue data for longfin smelt was found. Assume longfin smelt will have similar tissue concentrations as other fish taxa living one year and feeding primarily on zooplankton. Mercury concentrations in juvenile threadfin shad and juvenile largemouth bass in Delta are assumed to have similar mercury burdens as longfin smelt and are 0.012-0.076 and 0.035-0.230, respectively (Slotton et al., 2006).

Magnitude = 1

Few toxicological studies have been conducted with any of the target species, with the exception of rainbow trout. So, mercury concentrations in target fish are compared here against concentrations documented to produce mortality in other fish species. Mercury concentrations (ppm-wet weight) for white sturgeon, Chinook salmon and steelhead are 0.165-0.279, 0.094-0.396 and 0.05-0.3, respectively (Davis et al., 2002; SFEI, 2006). Bennett et al. (2001) reported Hg concentrations in Delta smelt ranging from 0.10-0.23 ppm (wet weight) No tissue data for either longfin or green sturgeon were found. Assume longfin smelt will have similar tissue concentrations as other fish taxa living one year and feeding primarily on zooplankton. Mercury concentrations in juvenile threadfin shad and juvenile largemouth bass in Delta are assumed to have similar mercury burdens as longfin smelt and are 0.012-0.076 and 0.035-0.230, respectively (Slotton et al., 2006). Green sturgeon is assumed to have a similar tissue concentration as white sturgeon.

For toxicological comparison, death in rainbow trout in laboratory studies occurred at 4-ppm wet weight and the NOAEC for death in Brook trout was 2.7 ppm (in Wiener and Spry, 1996). Conclusion, about a 10X safety factor exists between tissue concentrations in the target fish species in Delta and values reported in the literature to cause mortality.

Certainty = 2

Limited tissue data available for some species and none for others but an apparent large safety factor seems to exist been predicted fish tissue concentrations in Delta and values reported to be acutely toxic in the peer reviewed literature.

Summary Conclusions

Outcome P1:			
Ratings:	**Magnitude = 1**	**Certainty = 2**	
Explanation:	Limited tissue data available for some species and none for others, but an apparent 10x safety factor seems to exist been predicted fish tissue concentrations in the Delta and values reported to be acutely toxic in the peer reviewed literature.		

Outcome P2: Reduced sublethal effects (genetic, tissue/organ damage, development, reproductive, growth, and immune) of mercury on splittail, Delta and longfin smelt, green and white sturgeon, steelhead, and Chinook salmon.

Few relevant toxicological studies have been conducted with any of the target species. So, mercury concentrations in target fish are compared here against concentrations documented to produce sublethal effects in other fish species. See Outcome P1 above for mercury tissue concentration ranges.

Magnitude = 2

Again, few relevant toxicological studies have been conducted with any of the target species. Therefore, have compared reported tissue concentration for individual species against documented sublethal effects in other fish taxa. See Outcome P1 above for mercury tissue concentration ranges. An exception is white sturgeon. Webb et al. (2006) reported reduced concentrations of plasma androgens associated with muscle mercury concentrations > 0.187 ppm (wet weight) in Columbia River white sturgeon. This concentration is within the range discussed for this species in the Delta. Decreased feeding efficiency and some hormones response changes were observed at 0.25-0.27 ppm wet weight (page 30 of mercury model). Decreases in spawning success and increases in time to first spawn occurred in fathead minnows at 1.96-4.26 ppm (Hammerschmidt et al., 2002) and decreases in tissue growth in juvenile male walleye at 2.4 ppm (Friedmann et al., 1996). In conclusion, some up/down regulation of genes and alterations in feeding behavior are possible in the most contaminated individuals in Delta but questionable whether these changes could have measurable population level effects.

Certainty = 2

Limited toxicological data available in literature for many important sublethal processes and none of this research has been collected on any of the species of interest. Moreover, there is only a very limited tissue data set for most of target species making it impossible to determine the proportion of population potentially at risk.

Summary Conclusions

Outcome P2:			
Ratings:	**Magnitude = 2**	**Certainty = 2**	
Explanation:	Some up/down regulation of genes and alterations in feeding behavior are possible in the most contaminated individuals in the Delta, but it is questionable whether these changes could have measurable population level effects. There is limited toxicological data available in literature for many important sublethal processes. Although a number of papers use rainbow trout as the test organism in laboratory exposures to evaluate chronic endpoints (e.g. see: Wobeser 1975; Rogers and Beamish 1982; Niimi and Kissoon 1994), little of this research has been collected on any of the other covered fish species. Moreover, there is only a very limited tissue data set for most of the species making it impossible to determine the proportion of population potentially at risk.		

Outcome P3: Reduce toxic concentrations of methyl mercury in forage and sportfish to protect wildlife and humans from chronic sublethal toxicity

Fundamentally, a high concentration of methyl mercury in fish tissue is not a problem for the fish itself; it's a problem for the humans and birds that eat them. Because these analyses are being conducted primarily for the covered fish species, this particular outcome is an important "other" consideration for decision makers, which must be weighed against the evaluation of impacts to the covered fish species (outcomes P1 and P2).

Magnitude = 3
Fish consumption advisories for the Delta recommend that children under the age of 17 and women of child bearing age consume no largemouth or smallmouth bass, spotted bass or Sacramento pikeminnow , others should limit their consumption of these species to one meal a month (OEHHA, 2006, 2008a,b). Between 10,000 and 20,000 fishermen in the Delta are presently eating fish at more than 10X the recommended methylmercury RfD and should, therefore, experience some sublethal mercury poisoning (personal communication, Dr Fraser Shilling).

A significant portion (>50%) of Forster's terns breeding in S Francisco Bay are at risk of reproductive impairment from consuming fish with elevated mercury levels (Ackerman *et al*., 2008). No Forster's terns nest in Delta, however, mercury levels in small fish consumed by Terns are higher in parts of the Delta, such as the Yolo Bypass, than in S. Francisco Bay suggesting that other bird species feeding in a similar ecological niche as Forster's terns may be at risk in the Delta.

Burgess and Meyer (2008) estimate that the production of young common loons (*Gavia immer*) is reduced by 50% if methylmercury concentrations in prey fish are 0.210-ppm wet weight. Again, I do not think that loons nest in the Delta but methyl mercury levels may be at levels posing risks to other fish eating birds.

Certainty = 3
Need human epidemiological studies in Delta to refine estimate of number of people consuming methylmercury above the RfD, determine whether actual poisons can be documented, and the severity of the incidents. Similarly, need more toxicological research in the Delta on impacts to obligate fish eating avian species.

Summary Conclusions

Outcome P3:			
Ratings:	**Magnitude = 3**	**Certainty = 3**	**Worth = H**
Explanation:	Fish consumption advisories for the Delta recommend that children under the age of 17 and women of child bearing age consume no largemouth or smallmouth bass, spotted bass or Sacramento pikeminnow, others should limit their consumption of these species to one meal a month (OEHHA, 2006, 2008a,b). Between 10,000 and		

	20,000 fishermen in the Delta are presently eating fish at more than 10X the recommended methylmercury RfD and should, therefore, experience some sublethal mercury poisoning (personal communication, Dr Fraser Shilling). A significant portion (>50%) of Forster's terns breeding in S Francisco Bay are at risk of reproductive impairment from consuming fish with elevated mercury levels (Ackerman *et al*., 2008). Mercury levels in small fish consumed by terns are higher in parts of the Delta, such as the Yolo Bypass, than in S. Francisco Bay, suggesting that other bird species feeding in a similar ecological niche as Forster's terns may be at risk in the Delta. Burgess and Meyer (2008) estimate that the production of young common loons (*Gavia immer*) is reduced by 50% if methylmercury concentrations in prey fish are 0.210-ppm wet weight. Methyl mercury levels in Delta fish may be at levels that pose risks to similar fish-eating birds.

Potential Negative Ecological Outcome(s)

The group did not identify any potential negative ecological outcomes for this action.

Important Gaps in Information and/or Understanding

Data Needs

Need to collect data on splittail, to determine whether there are possible sublethal effects (e.g. feeding efficiency, growth, or spawning success)

Research Needs

Need continued monitoring of methyl mercury concentrations in water and fish as more seasonal wetland are created in the Yolo Bypass and elsewhere and the hydrology of the Delta is changed with construction of a peripheral canal or dual conveyance system.

Need a numerical methyl mercury transport and fate model with a food web component. The model should combine source information, water transport and residence times, photodemethylation and particle settling to predict methyl mercury concentrations in water, sediment, and biota at various locations in the Delta under different hydrologic conditions.

Need species-specific studies on sublethal population-level effects of methylmercury in target fish species.

Need better estimates of the number of people at risk for mercury toxicity, the range of likely impairments and how to educate them to reduce the risk

Assess Reversibility and Opportunity for Learning

Reversibility

No/Hard.

> ***Comments:*** It depends on the specific approach. For example, if one approach to this action is to modify Cache Creek Settling Basin, this is a very costly action that cannot be reversed once it is completed. If the approach is to identify and implement BMPs in cooperation with the State & Regional Water Quality Control Board programs, funding for implementation of said BMPs could stop if it is determined that it is not effectively addressing the problem.

Opportunity for Learning

High.

Comments (refer to specific sources of information that support the above determination and identify high priority research questions and testable hypotheses).
Continued monitoring of methylmercury concentrations in water and fish will enable a better understanding of methylmercury in the system, and its impacts on the biota, as more seasonal wetlands are created and the Delta's hydrology changes with a new conveyance system.

A numerical methylmercury transport and fate model, with a food web component, may help predict methylmercury concentrations in water, sediment, and biota at various locations in the Delta under different hydrologic conditions.

More species-specific studies on sublethal and population-level effects of methylmercury are necessary to conclusively determine whether covered fish species are or are not experiencing sub-lethal effects.

Better estimates of the number of people at risk for mercury toxicity, and the range of likely impairments, can help educate at-risk populations as well as decision makers.

Action: Reduce the Load of Pesticides and Herbicides

Evaluation Team: Water Quality & Invasives Workgroup

James Haas - Chair , Bruce Herbold – Coach, Chris Foe, Charles Alpers; Inge Werner, Frances Brewster, Karen Larsen, Chrisinte Joab, David Fullerton, Holly Gellerman, Ron Smith, Jan Thompson, Lori Clammurro (note taker)

Date of Last Revision: February 19, 2009

Action Description and Clarifying Assumptions

Implement measures to reduce loads of pesticides and herbicides entering Delta waterways to levels that are not toxic to covered fish species

Approach

1. Support efforts by the CVRWQCB under its Irrigated Lands Regulatory Program to reduce inputs of toxics from agricultural return flows into the Delta and tributaries to levels at which they are not toxic to covered fish species.
2. Work with farmers, reclamation districts, and irrigation/drainage districts to develop voluntary agricultural chemical management plans to reduce the amounts of pesticides and herbicides reaching Delta waterways. Plans could include funding conservation easements, cost-sharing programs, and working with farmers and irrigation districts to:
    - Change pesticides and herbicides used to compounds less toxic to aquatic species and provide education on proper use;
    - Reduce amounts of pesticides and herbicides used through more direct application methods or implementation of integrated pest management techniques;
    - Reduce concentrations of pesticides and herbicides in return flows to Delta waterways through specific management practices;
    - Reduce return flows from agricultural fields to the Delta by using water-efficient technologies (e.g., drip irrigation); and
    - Reduce wind drift of pesticides and herbicides into Delta waterways

Intended Outcomes as Stated in Conservation Measure

1. Reduced direct mortality of splittail, Delta and longfin smelt, green and white sturgeon, steelhead, and Chinook salmon (all races) from pesticides
2. Reduced sublethal effects (behavior, tissue/organ damage, reproduction, growth, and immune) of pesticides on splittail, Delta and longfin smelt, green and white sturgeon, steelhead, and Chinook salmon (all races).
3. Increased food abundance for splittail, Delta and longfin smelt, green and white sturgeon, steelhead, and Chinook salmon (all races) from reduced food web disruption.

General Conceptual Model Support for Intended Outcomes

1. Both the Chemical Stressors and the Pyrethroids DRERIP models indicate that contaminants may exert acutely toxic effects leading to mortality in individuals (p. 20 and p. 19, respectively).
2. Both the Chemical Stressors and the Pyrethroids DRERIP models indicate that contaminants may exert sublethal effects, with potential consequences for fitness, reproductive success, and survival of individuals (p. 20 and p. 19, respectively).
3. Both the Chemical Stressors and the Pyrethroids DRERIP models indicate that contaminants may exert effects on food web structure and dynamics; food web organisms are highly susceptible to pyrethroids in particular (p. 24 and p. 30, respectively).

Assumptions

Added by Evaluation Team

1. Safe levels for sensitive invertebrates can be generally assumed to be safe for the covered fish species with respect to acute toxicity.
2. Species for which larval stages occur outside the Delta towards the ocean are at less risk of pesticide exposure due to in-Delta sources.
3. Larvae and young juveniles are at greater risk than older juveniles or adult fish.
4. Pesticides of greatest concern do not biomagnify in the foodweb;
5. Effects of aquatic vegetation control are addressed in the evaluation of OSCM 13.

Problem(s) with Action as Written:

1. Need to include indirect effects (e.g. effects on food web organisms). Indirect effects via food organisms might have severe effects on covered species. Food limitation can lead to reduced survival and fitness at all life stages in their life-cycle.
2. BMPs are still under development, and their efficacy is not always known. Uncertainties and their resolution should be addressed.
3. The action should also incorporate programs to control submerged aquatic macrophytes.
4. *Very little information exists on exposure levels and impacts to most covered fish species.*
5. *The analysis needs to be site- and season-specific looking at existing data of what pesticides are being used where, and what covered species are present in these areas, would reduce uncertainty in real-world application.*

Scale of Action:

Large

Rationale:
This action is of a large spatial and temporal scale since much of the land use in the Delta and surrounding areas is agricultural. Spatially, the action is therefore likely to have impacts across much of the Delta and into Suisun and Grizzly Bays. Temporally, reductions in pesticide loads into the Delta are likely to have measurable impacts for decades and beyond.

Evaluation Summary Tables

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

Relation to Existing Conditions:

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

NO

Nature of Change:
If successful, the action will reduce pesticide levels in water. This will likely affect the phytoplankton and aquatic animal community composition; however food web dynamics should not change in a significant way. It is currently not known if macrophyte abundance and distribution would be affected. The action should not produce any fundamental changes to other key physical or biotic properties of the Delta.

.

Potential Positive Ecological Outcome(s)

Outcome P1: Reduced direct mortality of splittail, Delta and longfin smelt, green and white sturgeon, steelhead, and Chinook salmon (all races) from pesticides

P1a. Delta Smelt

General Observations

General Contaminants Model Page11, "early life stages of many Delta fish species are in the system during late winter and spring, a time when stormwater runoff from agricultural and urban areas can transport contaminants such as dormant spray pesticides and PAHs/metals into the Delta" and "Such early life stages are generally far more sensitive to contaminants than adults."

Pyrethroids Model Pages 3-4, Pages 6-7, Sediments in general are considered to be a "sink" for pyrethroids due to their hydrophobic properties, and the presence of aquatic macrophytes, phytoplankton and detritus can lead to adsorption of pyrethroids to plant surfaces. However, pyrethroids may remain in solution for hours to days before they sequester to suspended particles.
Page 17, chemical mixtures may pose a much bigger threat than individual compounds
Page 18, pyrethroids may be acting synergistically with pathogens to compromise survivorship of fish populations through immunologic or physiologic disruption.
P. 19-25, fish highly susceptible to pyrethroids.

Delta Smelt species Model, page 23

Other References:
Laetz et al. 2008
Kuivila et al. 2004, demonstrates overlap of rice pesticides with presence of Delta smelt larvae.
Fox and Archibald, 1997

Also data from Irrigated Lands Program (CVRWQCB), SWAMP, Sacramento Watershed Program.

Magnitude = 3.

The occurrence of relatively high concentrations of insecticides and herbicides in the Delta has been documented since the 1990s and earlier. In addition, metals such as copper are widely used as pesticides, and have been applied directly to Delta waters in the past (and possibly present). The potential positive outcome of this action is likely to affect a large area, and could have a sustained positive effect on larval survival of covered fish.

Certainty = 3

There is little toxicological information for Delta smelt; however, existing data indicates that Delta smelt are more sensitive to some chemical pollutants than standard toxicity test species such as fathead minnows.

No direct evidence exists for acute effects of pesticides in the Delta such as “fish kills” after approximately 1988 (Fox and Archibald, 1997). This could be due to the fact that it is difficult to detect dead fish unless there is a massive die off in areas where people regularly go. Similarly, it is unlikely that mortality of larval stages could be detected and quantified, so we simply don’t know if this is occurring.

Single chemical effect thresholds and available data on pesticides in the system suggest that direct lethal effects on covered fish species are relatively unlikely, but this is only true when individual chemicals are considered. The effects of chemical mixtures, which have been shown to be present in the Delta, are likely to be additive or synergistic. (See: Laetz et al. 2008.) Additive or synergistic effects are likely to be species-specific, In addition, multiple stressor effects (e.g. pathogens, temperature stress) are likely.

P1b. Longfin Smelt

General Observations

General Contaminants Model Page11, “early life stages of many Delta fish species are in the system during late winter and spring, a time when stormwater runoff from agricultural and urban areas can transport contaminants such as dormant spray pesticides and PAHs/metals into the Delta” and “Such early life stages are generally far more sensitive to contaminants than adults.”

Longfin Smelt Species Model, pages 9 and 16.

Magnitude = 2

See discussion P1a. Since longfin smelt typically occur further west in the Delta system, the potential exposure to pesticides is less than for Delta smelt.

Certainty = 2

See discussion P1a. There is no or little toxicological information on the covered fish species for all of the species of concern; however, data exists for salmonids, white sturgeon and Delta smelt, all of which indicates that these species are more sensitive to chemical pollutants than standard toxicity test species. Sensitivity of longfin smelt to pesticides is likely comparable to that of tested species.

P1c. Splittail

General Observations

See discussion P1a. Splittail spawn in the Yolo Bypass, potentially exposing more sensitive early life stages to agricultural pesticides, including such legacy pesticides as DDT.

Splittail CM Page 15

Magnitude = 3

Concentrations of pesticides in the Yolo Bypass are considered below the concentrations associated with acute or chronic toxicity in fish; however, early life stages of splittail in the Yolo Bypass could be more sensitive than adults or juveniles. .

Smalling et al. 2007, Occurrence of pesticides in Yolo bypass.

Certainty = 2
Peer-reviewed studies document the occurrence of pesticides in the Delta and Yolo Bypass; specific studies have not been conducted on Splittail responses under the documented conditions. The synergistic effects of these compounds on listed species are unknown but potentially significant.

P1d. Green Sturgeon

General Observations
See discussion P1a. Sturgeon species in general have been found to be at least as sensitive as salmonids to chemical contamination (Dwyer et al. 2005), and more sensitive in some cases (Little and Calfee 2008a, b); however, green sturgeon have not been used as a test species in laboratory studies. Their sensitivity is assumed to be similar to white sturgeon. More sensitive life stages occur outside the Delta.. Sediment-associated contaminants may play a bigger role due to feeding on benthic organisms.

Green Sturgeon Species Model, page 37

Magnitude = 2
Assuming sensitivity similar to white sturgeon suggests potential effects due to herbicides used for aquatic vegetation control (Little and Calfee, 2008 a, b) (See OSCM13).

Certainty = 2
Species-specific toxicity studies on green sturgeon are lacking; assuming sensitivity similar to white sturgeon suggests potential sensitivity

P1e. White Sturgeon

General Observations
See discussion P1a and P1d. Columbia River white sturgeon have been evaluated for exposure to methylmercury (see OSCM3) and aquatic vegetation control herbicides (see OSCM13).

Magnitude = 3
The greater sensitivity of white sturgeon to compounds evaluated with standard laboratory species suggests the possibility of effects to sensitive life stages in some locations.(Dwyer et al. 2005; Little and Calfee, 2008 a, b)

Certainty = 3
Peer-reviewed studies have been reported for this species in the Columbia River.

P1f. Steelhead

DLO Relationship and General Observations
See discussion P1a. The most sensitive stages of steelhead occur outside the Delta.

Salmonid Species Model, page 14
NOAA Biological Opinion!

Magnitude = 2
Direct mortality, if any, would be highly localized; synergy of multiple compounds cannot be discounted (Laetz et al. 2008).

Certainty = 3
Rainbow trout are a commonly used species in laboratory toxicity tests, resulting in an extensive body of peer-reviewed literature, and water quality criteria are often established to be protective of salmonid species; effects, particularly synergistic effects of steelhead life stages in the Delta have not been evaluated.

P1g. Chinook Salmon, Sac. Winter run

General Observations
See discussion P1a and P1f. More sensitive life-stages occur outside the Delta.

Salmonid Species Model, page 12

Magnitude = 2
See discussion P1f.

Certainty = 3
Coho salmon are a commonly used test species with a body of peer reviewed literature available (for examples see Laetz et al 2009); sensitivity of Chinook salmon is probably similar to rainbow trout and coho salmon (Teather and Parrott 2006); limited information is available for juvenile Chinook salmon and effects of insecticides and copper. Information is available on mixture and multiple stressor effects (Clifford et al., 2005; Eder et al. 2007, other).

NOAA Technical Memorandum NMFS-NWFSC-8, Contaminant Exposure and Associated Biological Effects in Juvenile Chinook Salmon (*Oncorhynchus tshawytscha*) from Urban and Nonurban Estuaries of Puget Sound

P1h. Chinook Salmon, Sac. Spring run

General Observations
See discussion P1a, P1f, and P1g.

Salmonid Species Model, page 12

Magnitude = 2
See discussion P1f.

Certainty = 3
See discussion P1g.

P1i. Chinook Salmon, fall and late fall run

DLO Relationship and General Observations
See discussion P1a, P1f, and P1g.

Salmonid Species Model, page 12

Magnitude = 2
See discussion P1f.

Certainty = 3
See discussion P1g.

Outcome P2: Reduced sublethal effects (behavior, tissue/organ damage, reproduction, growth, and immune) of pesticides on splittail, Delta and longfin smelt, green and white sturgeon, steelhead, and Chinook salmon (all races)

P2a. Delta Smelt

General Observations:

Sublethal effects of pesticide exposure in fish can be expected at concentrations well below those associated with acute or chronic mortality. The population-level effects of such exposures are difficult to estimate without specific studies of the species and chemicals involved, both individually and in combination (Laetz et al. 2008).

General Contaminants Model Page11, "early life stages of many Delta fish species are in the system during late winter and spring, a time when stormwater runoff from agricultural and urban areas can transport contaminants such as dormant spray pesticides and PAHs/metals into the Delta" and "Such early life stages are generally far more sensitive to contaminants than adults.

General Contaminants Model Page 24, "Pesticides including pyrethroids (Werner and Oram, 2008), metals, in particular copper, and polychlorinated biphenyls (PCBs) are among those identified to cause immunosuppressive effects in fish (Anderson and Zeeman 1995; Banerjee 1999; Austin 1999). Zelikoff et al. (1998) found reduced disease resistance in fish exposed to the pyrethroid permethrin. The susceptibility of juvenile Chinook salmon and rainbow trout to infectious hematopoietic necrosis virus (IHNV) was dramatically increased in juvenile fish exposed to sublethal concentrations of esfenvalerate (Clifford et al. 2005) and copper (Hetrick et al. 1979)."

Werner et al. 2008 (POD final report) contains information on the effects of a pyrethroid and copper in Delta smelt.

Werner et al. 2009 (POD Progress report, Feb 2009, contains effect concentrations of various contaminants on Delta smelt, and a draft manuscript of Connon et al. on sublethal effects of esfenvalerate in Delta smelt.

Pyrethroids Model
P. 26-29 Sublethal Effects

Delta Smelt Species Model Page 23.

Magnitude = 4.

The potential positive outcome of this action is likely to affect a large area, but mostly smaller waterways and sloughs of the Delta. It could have a sustained positive effect on fitness of covered fish species. Delta smelt primarily spawn in one area (Sacramento Ship Channel/Cache Slough), where elevated levels of pesticides and invertebrate toxicity have been detected in recent years. The magnitude of this action for Delta smelt could therefore be large.

Certainty = 3
Sublethal effects of pesticides on salmonids, Delta smelt, and white sturgeon have been documented in laboratory studies at extremely low concentrations that are environmentally relevant in the Delta (OP and pyrethroid insecticides and copper). In addition, synergistic or additive effects have been documented between pesticides that occur in the Delta (OP, pyrethroids and carbamates). Chemical mixture and multiple stressor effects are likely. However, the nature of the outcome is constrained by the variability in the system.

Salmonid Species Model Page 14

Magnitude = 3.
Deleterious effects on the olfactory system and escape response of salmonids have been demonstrated at copper concentrations that are common in the Delta, thus salmonids could be affected as well. No toxicological information exists on such effects in other anadromous fish species. Hecht, S.A., D.H. Baldwin, C.A. Mebane, T. Hawkes, S.J. Gross, and N.L. Scholz. 2007. An overview of sensory effects on juvenile salmonids exposed to dissolved copper:
Applying a benchmark concentration approach to evaluate sublethal neurobehavioral toxicity. U.S. Dept. Commer., NOAA Tech. Memo. NMFS-NWFSC-83, 39 p. "To estimate toxicological effect thresholds for dCu in surface waters, benchmark concentrations (BMCs) were calculated. BMCs for juvenile salmonid olfactory function ranged 0.18–2.1 ìg/L, corresponding to reductions in predator avoidance behavior of approximately 8–57%. The BMC examples represent the dCu concentration (above background) expected to affect the ability of juvenile salmonids to avoid predators in freshwater. These concentration thresholds for juvenile salmonid sensory and behavioral responses fall within the range of other sublethal endpoints affected by dCu such as behavior, growth, and primary production, which is 0.75–2.5 ìg/L."
Also see NOAA Biological Opinion (2008) for effects of OP insecticides on salmonids.

Outcome P3: Increased food abundance and quality for splittail, Delta and longfin smelt, green and white sturgeon, steelhead, and Chinook salmon (all races) from reduced food web disruption

P3a. All Covered Species

DLO Relationship and General Observations:
Food web model (contaminants is a driver in the models; referenced in 2.19 and linked to the Chemical Stressors Model)

Monitoring results from the Irrigated Lands Program shows frequent toxicity to phytoplankton and zooplankton in Delta water samples (CVRWQCB, Johnson Report (pending submission to CVRWQCB)).

General Contaminants Model
Page 3: Organophosphates (e.g. chlorpyrifos, diazinon) have been shown to be present at acutely toxic concentrations in tributaries and the Delta (Kuivila and Foe, 1995; Werner et al.,2000; California Regional Water Quality Control Board Agricultural Waiver Program, 2007).

"Many contaminants, in particular pesticides and heavy metals, are more likely to directly affect lower trophic levels, with potential negative effects on species composition and food web dynamics."

Pyrethroids Model
P. 19-31

Amweg, Erin L., Donald P. Weston, and Nicole Ureda. 2005. Use and toxicity of pyrethroid pesticides in the Central Valley, California, USA. Environmental Toxicology and Chemistry, 24(4):966-972 with erratum in 24(5). *Determined that pyrethroid levels at or near most laboratory detection levels can have lethal and sublethal effect on* Hyalella azteca*.Toxic levels are found in many ag-dominated water bodies in Central Valley*

Bergamaschi, B.A., K.M.Kuivila, and M.S.Fram. 1999. Pesticides associated with suspended sediments in the San Francisco Bay during the first flush, December 1995. Published in USGS Toxic Substances Hydrology Program-Proceedings of the Technical Meeting, Charleston, South Carolina, March 8-12, 1999, v.2 Contamination of Hydrologic Systems and Related Ecosystems, 1999. USGS Water-Resources Investigations Report 99-4018 B. They analyzed suspended sediment samples from Mallard Island during slack current for 19 compounds and found an average of 10. Total suspended sediment pesticide concentrations ranged from 9.8 to 43.8 ng/g with no apparent temporal pattern.

Mesocosm studies typically show rapid recovery of aquatic organisms from pesticide applications (Giddings et al.2001;Hanson et al. 2007).

Magnitude = 3

Invertebrates are typically more sensitive than fish to chemicals at a given concentration, so that levels protective of fish still cause adverse effects in invertebrates. Although recovery of invertebrate populations following a pesticide-induced depletion can be rapid, short-term depletion of food resources could be locally/seasonally important to listed species, particularly those that forage in the water column. The potential positive outcome of this action is likely to affect a large area, but mostly smaller waterways and sloughs of the Delta. It could have a positive effect on food supply for, and fitness of covered fish species.

Certainty = 2

Although information on toxic thresholds is available for only a few invertebrate species resident in the Delta, there is sufficient data showing that crustaceans such as cladocerans, amphipods and copepods are more sensitive to insecticides than fish. Bivalves tend to be less sensitive.

There is abundant evidence that water in smaller waterways of the Delta is at times acutely toxic to zooplankton and benthic crustaceans. In addition, data from the Irrigated Lands Program demonstrated frequent phytoplankton toxicity in the Delta. It is therefore likely that lower trophic levels are negatively affected by pesticides in the system. However, there is significant uncertainty with regard to population level effects of pesticides, the consequences of herbicides on phytoplankton community composition (and thus food quality for invertebrates). In addition, the relative importance of pesticide effects, versus other stressors such as clam filtration, on phytoplankton primary production and subsequent effects on zooplankton abundance and diversity is not known.

Potential Negative Ecological Outcome(s)

Outcome N1: Possible drying up of smaller creeks

All Covered Species

General Observations:
Tailwater recovery systems are the most commonly used BMP for controlling contaminated runoff, and tend to dry up smaller creeks

Magnitude = 3
Predictable water supplies and riparian habitat are scarce in the Central Valley for terrestrial wildlife. Agriculturally dominated small creeks and sloughs provide valuable scarce habitat. Drying them up through a tailwater recovery system, which is the most common BMP, could be real rough for wildlife that are not very mobile.

Second, small ag dominated creeks and sloughs are primary nursery areas for algae and zooplankton. If you remove that habitat or decrease the size of that habitat then you have less nursery areas to feed into the large, deep, cold moving rivers. (Chris Foe, pers.comm. No direct evidence to cite or reference for comment)..

Certainty = 1
Understanding is lacking.

Important Gaps in Information and/or Understanding

Data Needs

- Very little information exists on exposure levels and impacts to most covered fish species, particularly the effects of multiple chemicals, and pesticides in combination with other stressors such as pathogens and temperature..
- The analysis needs to be site- and season-specific looking at existing data of what pesticides are being used where, and what covered species are present in these areas, would reduce uncertainty in real-world application.

Assess Reversibility and Opportunity for Learning

Reversibility - Yes

Comments: If the primary reductions in pesticides are from BMPs with little investment in infrastructure or equipment, they could be easily reversed**.**

Opportunity for Learning - High

Comments: A monitoring program could evaluate species/site/product-specific reductions using before and after data; collection could be designed to evaluate other stressors such as water quality parameters concurrently with pesticide reductions. Direct and indirect (e.g. food web) effects could be evaluated.

Action: Reduce the Loads of Toxic Contaminants in Stormwater and Urban Runoff

Evaluation Team: Water Quality & Invasives Workgroup

James Haas - Chair , Bruce Herbold – Coach, Chris Foe, Charles Alpers; Inge Werner, Frances Brewster, Karen Larsen, Chrisinte Joab, David Fullerton, Holly Gellerman, Ron Smith, Jan Thompson, Lori Clammurro (note taker)

Date of Last Revision: March 22, 2009

Action Description and Clarifying Assumptions

Develop and implement stormwater management plans and additional measures to reduce loads of toxic contaminants in stormwater and urban runoff entering Delta waterways to levels below which they are toxic to covered fish species

Approach

Develop and implement stormwater management plans and additional measures.

Intended Outcomes as Stated in Conservation Measure

1. Reduced direct mortality of splittail, Delta and longfin smelt, green and white sturgeon, steelhead, and Chinook salmon (all races) from contaminants
2. Reduced sublethal effects (behavior, tissue/organ damage, reproduction, growth, and immune) of contaminants on splittail, Delta and longfin smelt, green and white sturgeon, steelhead, and Chinook salmon (all races)
3. Increased food abundance for splittail, Delta and longfin smelt, green and white sturgeon, steelhead, and Chinook salmon (all races) from reduced food web disruption
4. Increased food quality and abundance for important invertebrate species.

General Conceptual Model Support for Intended Outcomes

1. Both the Chemical Stressors and the Pyrethroids DRERIP models indicate that contaminants may exert acutely toxic effects leading to mortality in individuals (p. 20 and p. 19, respectively).
2. Both the Chemical Stressors and the Pyrethroids DRERIP models indicate that contaminants may exert sublethal effects, with potential consequences for fitness, reproductive success, and survival of individuals (p. 20 and p. 19, respectively).
3. Both the Chemical Stressors and the Pyrethroids DRERIP models indicate that contaminants may exert effects on food web structure and dynamics; food web organisms are highly susceptible to pyrethroids in particular (p. 24 and p. 30, respectively).

Assumptions

Provided in BDCP Conservation Measure

1. Stormwater runoff is the leading source of water pollution in the United States and is believed to be a large contributor to toxics in the Delta.
2. Stormwater runoff from urban residential areas is a larger source of pyrethroid pesticides than agricultural runoff.

Problem(s) with Action as Written:

1. It is difficult to evaluate approach no. 1 as no specific information is given with regard to stormwater management plans. The team therefore assumes that methods included in such plans will reduce the load of toxic contaminants entering waterways via stormwater runoff.
2. It is important to also reduce indirect effects of runoff-associated toxicants (e.g. on prey organisms of covered species)
3. “Additional measures” – what are these specifically?

4. Suggestion for re-writing: Make actions more specific (what exactly will be done?) and provide available information on the efficiency of these measures in reducing contaminant input into waterways.

Scale of Action:

Medium

Rationale:
This action is of a medium spatial and temporal scale since it is focused on storm and irrigation water outfalls in urban areas. Spatially, the action is therefore likely to have impacts in the vicinity of Stockton, Sacramento, and in the more developed areas adjacent to Carquinez Strait and Suisun Bay. Where urban runoff is directed into the sewer system, as is the case in Sacramento, stable contaminants also enter the Delta via treated wastewater treatment effluent. Temporally, reductions in urban runoff associated contaminant loads into the Delta are likely to have measurable impacts for decades and beyond.

Evaluation Summary Tables

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

Relation to Existing Conditions

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

NO

Nature of Change:

If successful, the action will reduce contaminant levels in water and sediments. This will likely affect the phytoplankton and aquatic animal community composition in some areas of the Delta, however food web dynamics should not change in a significant way. The action should not produce any fundamental changes to other key physical or biotic properties of the Delta.

Potential Positive Ecological Outcome(s)

Outcome P1: Reduced direct mortality of splittail, Delta and longfin smelt, green and white sturgeon, steelhead, and Chinook salmon (all races) from contaminants.

P1. All Covered Fish spp.

General Observations

Chemical Stressors Model

Lack of occurrence and exposure Page 6, "Stormwater runoff from urban and industrialized areas, and inflow from tributaries (including the Delta) are the major sources of polycyclic aromatic hydrocarbons (PAHs) in San Francisco Bay (Oros et al., 2007). Oros et al (2007) report relatively low PAH concentrations in the Sacramento/San Joaquin Rivers and the Delta during the 1993-2001 monitoring period."

Pyrethroid Model

Page 4: Urban area uses of pyrethroids make up nearly half of the total amount of pyrethroids used in the Central Valley, thus making storm and irrigation runoff from urban areas an important potential source of pyrethroids.

Page 7, Sediments in general are considered to be a "sink" for pyrethroids due to their hydrophobic properties, and the presence of aquatic macrophytes, phytoplankton and detritus can lead to adsorption of pyrethroids to plant surfaces. However, pyrethroids may remain in solution for hours to days before they sequester to suspended particles.

Page 8, Urban use of pyrethroid insecticides and subsequent transport into surface waters

may be a significant contributor to the contamination of rivers with pyrethroids. A study on sediments in urban creeks in Sacramento (Weston, 2007) showed that all 28 sediment

samples taken had measurable concentrations of pyrethroids.

Page 17, chemical mixtures may pose a much bigger threat than individual compounds

Page 18, pyrethroids may be acting synergistically with pathogens to compromise survivorship of fish populations through immunologic or physiologic disruption.

P. 19-25, fish are highly susceptible to pyrethroids.

TDC Environmental. 2008. Pesticides in urban surface water: urban pesticides use trends annual report April 2008. Prepared for San Francisco Estuary Project.: Report cites another TDC report that concludes "use of pyrethroid insecticides in California urban areas is causing adverse effects in aquatic ecosystems receiving urban runoff."(page1).

McCarthy et al. 2008. Pre-spawn die-offs of salmonids in Seattle urban creeks due to urban stormwater runoff.

Fish kills (threadfin shad) have been recorded by Fish and Game in the San Joaquin River west of Stockton following the first major rainstorm of the season.

Magnitude = 2

Limited to areas that receive urban runoff, Sacramento, Stockton, Suisun Bay, Carquinez Strait, but also part of wastewater treatment effluent if stormwater is directed into sewer system (Sacramento) or directly into major sloughs and rivers (for example, Stockton). Could be of high importance if covered species use urban creeks or lower San Joaquin River. Chemicals of highest concern: copper, pyrethroids and unknown mixture effects.

Certainty = 2
Information exists for direct toxicity to invertebrates in urban streams in the area, but the direct effects on fish effects as these streams feed into the larger ecosystem are not known. Fish kills following storm runoff events have been recorded in recent years in the San Joaquin River.

Overall, little evidence exists for acute effects of stormwater runoff in the Delta such as "fish kills. This could be due to the fact that it is difficult to detect dead fish unless there is a massive die off in areas where people regularly go. Similarly, it is unlikely that mortality of larval stages could be detected and quantified, so we simply don't know if this is occurring.

Outcome P2: Reduced sublethal effects (behavior, tissue/organ damage, reproduction, growth, and immune) of contaminants on splittail, Delta and longfin smelt, green and white sturgeon, steelhead, and Chinook salmon (all races)

P2a. Delta Smelt

General Observations:
General Contaminants Model
Page 24, "Pesticides including pyrethroids (Werner and Oram, 2008), metals, in particular copper, and polychlorinated biphenyls (PCBs) are among those identified to cause immunosuppressive effects in fish (Anderson and Zeeman 1995; Banerjee 1999; Austin 1999). Zelikoff et al. (1998) found reduced disease resistance in fish exposed to the pyrethroid permethrin. The susceptibility of juvenile Chinook salmon and rainbow trout to infectious hematopoietic necrosis virus (IHNV) was dramatically increased in juvenile fish exposed to sublethal concentrations of esfenvalerate (Clifford et al. 2005) and copper (Hetrick et al. 1979)."

Pyrethroids Model
See notes under P1.
P. 26-29 Sublethal Effects

NOAA Technical Memorandum NMFS-NWFSC-83; An Overview of Sensory Effects on Juvenile Salmonids Exposed to Dissolved Copper.

Sandahl, J.F., Baldwin, D.H., Jenkins, J.J., and Scholz, N.L. 2007. A sensory system at the interface between urban stormwater runoff and salmon survival. Environmental Science and Technology, 41:2998-3004. Olfactory response in juvenile coho salmon exposed to 2 ug/l dissolved copper for 3-hours was reduced by 40%. This loss in olfactory sensitivity led to a failure to initiate predatory avoidance behaviors in response to chemical alarm cues. Sandahl et al. cite recent monitoring in northern California following a storm event that detected copper at a mean concentration of 15.8 ug/l, ranging from 3.4 - 64.5 ug/l. They also cite two recent studies that indicate that dissolved copper also impacts fish lateral line neurons that provide cues for shoaling, prey capture and predator evasion.

TDC Environmental. 2008. Pesticides in urban surface water: urban pesticides use trends annual report April 2008. Prepared for San Francisco Estuary Project.: Report cites another TDC report that concludes "use of pyrethroid insecticides in California urban areas is causing adverse effects in aquatic ecosystems receiving urban runoff."(page1).

Irrigation runoff from urban areas could be of importance to Delta smelt in Suisun Marsh.

Mixture effects may be far worse than those of individual toxicants (Laetz et al. 2009).

.

Magnitude = 2
Limited to areas that receive urban runoff, Sacramento, Stockton, Suisun Bay, Carquinez Strait, but also part of wastewater treatment effluent if stormwater is directed into sewer system like in Sacramento. Could be of high importance if covered species use urban creeks (like in Seattle), but these are likely to be small subgroups.

More important for species that spend extended periods of time near urban areas or directly downstream from urban areas (Lower San Joaquin River, Suisun Marsh, Lower Sacramento River, Western Delta, Suisun Bay, Napa River) Chemicals of highest concern: copper, pyrethroids and unknown mixture effects..

Certainty = 2
See OSCM4; much of the same information is relevant, except the potential sources, distribution, and concentrations might differ.

Although there are some uncertainties regarding the magnitude of the evaluated outcomes based on specific in-Delta studies, the sensitivity of fish to pyrethroid pesticides and copper in water and the wide-spread occurrence in these compounds in urban runoff suggest that benefits to the species of concern would accrue from a reduction of contaminants flowing to the Delta in urban runoff.

P2b. Longfin Smelt

General Observations:
See discussion P2a.

Magnitude = 2
See discussion P2a.

Certainty = 2
See discussion P2a.

P2c. Splittail

General Observations:
See discussion P2a.

Magnitude = 2
See discussion P2a.

Certainty = 2
See discussion P2a.

P2d. Green Sturgeon

General Observations:
See discussion P2a.

Magnitude = 2
See discussion P2a.

Certainty = 2
See discussion P2a.

P2e. White Sturgeon

General Observations:
See discussion P2a.

Magnitude = 2
See discussion P2a.

Certainty = 2
See discussion P2a.

P2f. Steelhead

General Observations:
See discussion P2a.

Magnitude = 3
Typical Cu concentrations originating from road runoff from a California study were 3.4–64.5 µg/L, with a mean of 15.8 µg/L (Tiefenthaler et al. 2008). Taken together, the information reviewed and presented herein indicates that impairment of sensory functions important to survival of juvenile salmonids is likely to be widespread in many freshwater aquatic habitats. Impairment of these essential behaviors may manifest within minutes and continue for hours to days depending on concentration and exposure duration. Therefore, Cu has the potential to limit the productivity and intrinsic growth potential of wild salmon populations by reducing the survival and lifetime reproductive success of individual salmonids (Hecht et al. 2007;Sandahl et al. 2007).

Certainty = 3
See pesticide evaluation; much of the same information is relevant, except the potential sources, distribution, and concentrations might differ; sensitivity of salmonids to olfactory effects of copper at sub-lethal concentrations is well-document in laboratory exposures (Hansen et al. 1999).

P2g. Chinook Salmon, Sac, winter run

General Observations:
See discussion P2a.

Magnitude = 3
See discussion P2f.

Certainty = 3
See discussion P2f.

P2h. Chinook Salmon, Sac, spring run

General Observations:
See discussion P2a.

Magnitude = 3
See discussion P2f.

Certainty = 3
See discussion P2f.

P2i. Chinook Salmon, fall run

General Observations:
See discussion P2a.

Magnitude = 3
See discussion P2f.

Certainty = 3
See discussion P2f.

Outcome P3: Increased food abundance for splittail, Delta and longfin smelt, green and white sturgeon, steelhead, and Chinook salmon (all races) from reduced food web disruption and increased food quality and abundance for important invertebrate species.

P3a. All Covered species

General Observations:
Chemical Stressors Model Page 3: Organophosphates (e.g. chlorpyrifos, diazinon) have been shown to be present at acutely toxic concentrations in tributaries and the Delta (Kuivila and Foe, 1995; Werner et al.,2000; California Regional Water Quality Control Board Agricultural Waiver Program, 2007). "Many contaminants, in particular pesticides and heavy metals, are more likely to directly affect lower trophic levels, with potential negative effects on species composition and food web dynamics."

Occurrence and exposure and in support of P1: page 4, "In recent years, pyrethroids at toxic concentrations [*to invertebrates*] have been detected in the majority of sediment samples collected from urban creeks in the Bay/Delta region (Amweg et al., 2006; Woudneh and Oros, 2006a & b).

Pyrethroids Model

See notes under P1 and P2.

P. 19-31

Occurrence data and in support of P3: Weston, D.P., R.W. Holmes, J. You, and M.J. Lydy. 2005. Aquatic toxicity due to residential use of pyrethroid insecticides. Environmental Science and Technology, 39(24):9778-9784. *Sediment from 9 of 21 urban creek sites caused >90% mortality to H. azteca. Bifenthrin in the secondary tributaries reached levels 15 times greater than found in samples draining agricultural areas. Results suggest minimal transport of contaminated sediments downstream of outfalls, but "given the numerous outfalls scattered throughout the system, the result is a patchwork of highly contaminated reaches."*

Amweg, Erin L., Donald P. Weston, Jing You, and Michael J. Lydy. 2006. *Pyrethroid insecticides and sediment toxicity in urban creeks from California and Tennessee.* Environmental Science and Technology, 40(5):1700-1706. *Sampled 15 urban creeks in and around Sacramento and the East Bay and tested for toxicity to Hyalella azteca in a 10-d sediment exposure. In the Sacramento area 22 of the 33 samples were toxic and 7 of the 8 creeks had toxic samples on at least one occasion. Pyrethroid concentrations were sufficient to explain the toxicity in 21 of the 22 toxic samples.*

Giddings et al. 2000. ECT 20:660 conducted mesocosm studies of pyrethroids on invertebrates and fish. The results for cypermethrin and esfenvalerate were remarkably consistent. They revealed a trend in sensitivity from amphipods, isopods, midges, mayflies, copepods, and cladocerans (most sensitive) to fish, snails, oligochaetes, and rotifers (least sensitive). With few exceptions, populations affected by pyrethroids in the mesocosms recovered to normal levels before the end of the year of exposure; most populations recovered within weeks. Factors presumed responsible for population recovery included internal refuges (areas of low exposure), resistant life stages, rapid generation times, and egg deposition by adults from outside the treated systems. Indirect effects on fish (which have been hypothesized to occur when invertebrate food sources are reduced) were not observed.

Lawler et al. (2008) reported that survival of Daphnia and mayflies in mesocosms treated with pyrethrin and PBO in amounts used for mosquito control were not different from survival in control mesocosms.

Komjarova I., Blust J. 2008. Mixture effects of trace metals on zooplankton. Copper and lead increase each others uptake.

Tiefenthaler et al 2008 ETC 27:277 evaluated metals concentration in urban runoff in southern California. They reported mean flux at land use sites ranged from 24 to 1,238, 0.1 to 1,272, and 6 to 33,189 g/km2 for total copper, total lead, and total zinc, respectively. Storm water runoff from industrial land use sites contained higher EMCs and generated greater flux of trace metals than other land use types. For all storms sampled, the highest metal concentrations occurred during the early phases of storm water runoff, with peak concentrations usually preceding peak flow. Early season storms produced significantly higher metal flux compared with late season storms at both mass emission and land use sites.

Effects of copper have been shown on fish eggs and larvae (Adema-Hannes, R. and J. Shenker. 2008), algae growth (Stoiber et al. 2008), and leaf litter decomposition rates (Roussel et al. 2008) at concentrations found in urban runoff.

Magnitude = 2-3
Effects, if any, are likely localized.

Certainty = 2-3

Acute toxic effects on invertebrates have been shown in sediments and water column of urban creeks; mesocosm studies suggest lower level effects in receiving waters. Copper at concentrations associated with urban runoff show adverse effects on algal growth and leaf litter decomposition rates, suggesting possible effects on primary production and detritivores/shredders. How these effects translate to effects in receiving waters and beneficial effects on covered species is not known.

Although there are some uncertainties regarding the magnitude of the evaluated outcomes based on specific in-Delta studies, the sensitivity of invertebrates to pyrethroid pesticides and copper in water and the wide-spread occurrence in these compounds in urban runoff suggest that benefits to the species of concern would accrue from a reduction of contaminants flowing to the Delta in urban runoff.

Potential Negative Ecological Outcome(s)

Outcome N1: Ponded or contained stormwater could exacerbate mosquito control problems and associated human health issues.

N1a. Humans.

Magnitude = 1
Spatial extent is likely to be small.

Certainty = 3
Mosquito occurrence should be monitored, but if the stormwater management systems are well designed, they should be able to accommodate large rain events without standing water present for more than 48-72 hours

Outcome N2: Ponded or contained stormwater could transfer contaminants to groundwater by infiltration.

N2a. Humans.

Magnitude = 1
Spatial extent is likely to be small.

Certainty = 3
Enhanced infiltration of urban runoff will increase adsorption and degradation of most contaminants. The use of highly mobile and persistent contaminants should be restricted or other management actions chosen if upper levels of groundwater are used as a drinking water source.

Important Gaps in Information and/or Understanding

Data Needs

See research needs.

Research Needs

Evaluation of mixture effects of multiple contaminants on fish, invertebrates and phytoplankton.

Monitor how and when small subgroups of the covered species and their zooplankton prey use urban creeks.

Evaluate how contaminants in urban runoff translate into effects in receiving waters.

Assess Reversibility and Opportunity for Learning

Reversibility

No

Comments: Once communities invest in technologies to reduce and manage urban runoff, it might be difficult to return to the status quo if monitoring indicates they are ineffective.

Opportunity for Learning

High

Comments: Implementation of urban runoff technologies would provide the opportunity to evaluate before and after conditions, with reference to the research needs, to determine whether management objectives are met, and which technologies are most effective at reducing both the volume and contaminant load of urban runoff.

OSCM7:
Improve Dissolved Oxygen Conditions in the Stockton Deep Water Ship Channel (SDWSC)

Scientific Evaluation Worksheet

Evaluation Team: Water Quality and Invasives Workgroup

James Haas - Chair , Bruce Herbold – Coach, Chris Foe, Charles Alpers; Inge Werner, Frances Brewster, Karen Larsen, Chrisinte Joab, David Fullerton, Holly Gellerman, Ron Smith, Jan Thompson, Lori Clammurro (note taker)

Date of Last Revision: 30 January 2009

Action: Improve dissolved oxygen conditions in the Stockton Deep Water Ship Channel (SDWSC) to meet the Basin water quality objectives (6.0 mg/l in the San Joaquin River [between Turner Cut and Stockton, 1 September through 30 November] and 5.0 mg/l the remainder of the year).

Problem(s) with Action as written: The action itself can be evaluated but the approaches used to address the action need to be rewritten and the outcomes based on the revised approaches may need to be refined or clarified.

Approach: The current approaches are:

1. Fund the Port of Stockton and other cooperators to evaluate the causes of dissolved oxygen in the Stockton Deep Water Ship Channel.
2. Implement measures to solve the problem.

The approaches listed above need to be rewritten. Justification for the rewriting of the approaches and outcomes is provided below.

Approach 1: Studies to determine and evaluate the causes of the low dissolved oxygen in the Stockton Deep Water Ship Channel (DWSC) have already been done. These studies, however, did not involve funding the Port of Stockton or other cooperators (not sure what is meant by "other cooperators"). Between 1999 and 2003, CALFED funded around $3M for studies to determine the causes of low dissolved oxygen in the Stockton Deep Water Ship Channel. From these studies, three factors were identified as causing the low dissolved oxygen conditions in the Stockton DWSC (see references at the end). These three factors are:

- Geometry (cross-sectional area) of the DWSC, which is controlled and manipulated by the US Army Corps of Engineers and the Port of Stockton through deepening projects and maintenance dredging.
- Reduced flow through the DWSC, which is controlled and manipulated by the US Bureau of Reclamation, Department of Water Resources, and the Water Rights Division of the State Water Resources Control Board (SWRCB) through various projects such as the CVP and SWP pumping at Tracy, diversions and dams along the upstream tributaries that feed flow into the San Joaquin River, and various water users along the San Joaquin River and its upstream tributaries.
- Loads of oxygen depleting substances from upstream sources such as the Stockton Regional Waste Control Facility, non-point sources such as irrigated lands, and unknown sources/new sources that have a reasonable potential to impact dissolved oxygen.

In 2000, Proposition 13, Article 3 Bay-Delta Multi-Purpose Water Management Programs (Water Code Sections 79196.5[b] and [e]) was approved by California voters to allocate $40M in bond funds for the purpose of implementing the CALFED Ecosystem Restoration Program (ERP), of which the dissolved oxygen impairment in the Stockton Deep Water Ship Channel is an ERP Directed Action Proposal.

Funded by Proposition 13, one study titled *Monitoring and Investigations of the San Joaquin River and Tributaries Related to Dissolved Oxygen* was completed in June 2008 and numerous aeration studies were completed along with a Demonstration Aeration Facility constructed in 2006 at Rough & Ready Island in the Stockton Deep Water Ship Channel.

A second study titled *Characterizing the Impact of Upstream San Joaquin River Algae Loads on Dissolved Oxygen Conditions in the Stockton Deep Water Ship Channel* was approved by the Ecosystem Restoration Program Implementing Agency Managers in August 2008 and is currently making its way through the contracts process for funding through Proposition 13. This second study was to begin in early 2009 and be completed in 2011. However, the State budget crisis has pushed this project into the FY 2009/2010 funding cycle.

These two studies were designed to address the remaining issues of source and linkages to the dissolved oxygen impairment. These studies were requirements specified in the Central Valley Regional Water Board's June 2005 adopted Basin Plan Amendment (BPA) - The Control Program for Factors Contributing to the Dissolved Oxygen Impairment in the Stockton Deep Water Ship Channel. This Total Maximum Daily Load (TMDL) BPA required entities responsible for point and non-point sources of oxygen demanding substances within the TMDL source area to conduct studies that would identify and quantify three remaining unknowns:

- Identify the sources of oxygen demanding substances and their precursors in the dissolved oxygen TMDL source area;
- Growth or degradation mechanisms of these oxygen demanding substances in transit through the source area to the DWSC; and
- Impact of these oxygen demanding substances on DO concentrations in the DWSC under a range of environmental conditions considering the effects of chemical, biological, and physical mechanisms that add or remove DO from the water column in the DWSC.

If the approach listed above is to be retained, then all of the studies completed-to-date should be fully evaluated and synthesized to determine what remaining issues need to be studied, and then list the remaining unknowns as the studies to be funded. Studies that are truly lacking are control projects that could be constructed to improve dissolved oxygen, and studies to evaluate the effectiveness of certain control projects and or mitigation projects that have been or could be constructed to improve dissolved oxygen in the Stockton DWSC. One measure with the potential to improve dissolved oxygen is the use of an aeration device. Currently, there are three different types of aeration systems operating in the DWSC:

- The Demonstration Aeration Facility, which was constructed using Proposition 13 bond funds is operated and maintained by the Department of Water Resources (DWR) during its two-year demonstration phase (2009 is the last year of the demonstration phase);
- The Port of Stockton aerator, which was originally constructed by the US Army Corps of Engineers for mitigation of the prior deepening of the Stockton DWSC, and was then handed over to the Port of Stockton for their control and maintenance ; and,

- The City of Stockton, which operates 8 lateral line aerators in the DWSC east of the Turning Basin, were installed to alleviate the algae and odor issues in that section of the DWSC. The City of Stockton aerators do not have any direct affect on the DO concentration downstream in the DWSC west of the I-5 bridge.

Approach 2: The second approach listed above is too broad and nebulous. Recommended implementation measures, if known, should be specified, and should focus on the three causative factors along with the entities responsible for them. The Regional Water Board is developing Phase II of the Stockton DO TMDL, and the BDCP conservation measure and associated approaches relating to the low dissolved oxygen in the Stockton DWSC should be developed in coordination with their efforts. Implementation measures, aside from what the Regional Board has direct control, need to be directed to agencies that are responsible for the geometry of the ship channel (US Army Corps) and flow through the ship channel (US Bureau of Reclamation, DWR, and SWRCB Div. of Water Rights). Implementation measures (approaches) focused on these contributing factors will assist the Regional Water Board in developing the final TMDL, and improving the dissolved oxygen in the Stockton DWSC.

Outcome(s): Some outcomes require a minor revision or rewrite. See notes below.

Outcome P(1): Reduce impediments to upstream migration of adult San Joaquin River fall-run Chinook salmon, steelhead, and white sturgeon during summer and fall.

Since the action is focused on dissolved oxygen as an impediment to migrating fish in the Stockton DWSC, it may be better to clarify the statement to specifically identify the impediment. For example, "Reduce the dissolved oxygen impediment…".

Outcome P(2): Reduced mortality associated with low dissolved oxygen in white sturgeon, steelhead, fall-run Chinook salmon (San Joaquin populations), and splittail.

If data is available that quantifies the level of mortality directly related to low dissolved oxygen in the Stockton DWSC, then the outcome statement is fine. If data is not available to measure the success of the associated approach, then the outcome statement should be more general such as "Reduced risk of mortality associated with low dissolved oxygen…"

Outcome P(3): Reduced sublethal effects associated with low dissolved oxygen in white sturgeon, steelhead, fall-run Chinook salmon (San Joaquin populations), and splittail.

This appears to be a very logical intended outcome. Although sublethal effects may warrant a description or definition in order to clearly identify which sublethal effects the action is intended to improve.

Outcome P(4): Increase food availability nearby and downstream of the SDWC to delta and longfin smelt, green and white sturgeon, and fry and juvenile steelhead and Chinook salmon.

Although oxygen is the focus of this action and approach, there are other factors within the Stockton DWSC that can affect the lower trophic food webs. Slow moving, neutrally buoyant organisms (phytoplankton and zooplankton) can be negatively affected by depth and residence time (low flows and high flows) in the DWSC, especially if the approach taken does not address depth and flow as a method to improve dissolved oxygen.

Outcome N(1): Potential for oxygen toxicity or free radical formation to fish.

This negative outcome seems out of place considering there was no mention of aeration as an approach. If aeration is included as an approach, this negative outcome should be retained.

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Positive Outcomes				
P4	delta and longfin smelt, green and white sturgeon, and fry and juvenile steelhead and Chinook salmon.	Increase food availability nearby and downstream of the SDWC to delta and longfin smelt, green and white sturgeon, and fry and juvenile steelhead and Chinook salmon.		
P3	white sturgeon, steelhead, fall-run Chinook salmon (San Joaquin populations), and splittail.	Reduced sublethal effects associated with low dissolved oxygen in white sturgeon, steelhead, fall-run Chinook salmon (San Joaquin populations), and splittail.		
P2	white sturgeon, steelhead, fall-run Chinook salmon (San Joaquin populations), and splittail.	Reduced mortality associated with low dissolved oxygen in white sturgeon, steelhead, fall-run Chinook salmon (San Joaquin populations), and splittail.		
P1	Chinook salmon, steelhead, and white sturgeon	Reduce impediments to upstream migration of adult San Joaquin River fall-run Chinook salmon, steelhead, and white sturgeon during summer and fall.		
Negative Outcomes				
N1	All	Potential for oxygen toxicity or free radical formation to fish.		

OSCM12
Reduce Risk of Establishment of Zebra and Quagga Mussels

Scientific Evaluation Worksheet

Evaluation Team: Water Quality and Invasives Workgroup

James Haas - Chair , Bruce Herbold – Coach, Chris Foe, Charles Alpers; Inge Werner, Frances Brewster, Karen Larsen, Chrisinte Joab, David Fullerton, Holly Gellerman, Ron Smith, Jan Thompson, Lori Clammurro (note taker)

Date of Last Revision: 15 January 2009

Action: Utilize chemical treatment of isolated populations to reduce risk of establishment of zebra and quagga mussels in Delta waterways.

Problem(s) with Action as written:

This action needs to be rewritten as one specific approach. Chemical treatment cannot be used in the Delta and there is no reasonable way to isolate a specific area within the Delta.
This action should be rewritten under consultation and in cooperation with the Quagga/Zebra Mussel Task Force. Susan Ellis, who is the Aquatic Invasives Department Head for the State of CA, will be making the final decisions within this program (Task Force).

The listed approaches do not reflect the current state of science in regards to the eradication and control of zebra and quagga mussels. For example, rock barriers would not be a reasonable or functional approach in a river channel and would not have consensus (approval) from USACE and, ultimately, would not work. No current monitoring program is in place to tell us if the quagga and zebra mussels are present, and there is currently no program in place to isolate and treat a specific area. By the time these mussels are found in the system, the populations are already too well established.

Current monitoring programs include an early detection monitoring with plankton tows and PCR (DNA analysis) done on high priority waterways. If PCR analysis is positive and veligers are found (test positive), then a team goes into the system and tries to find the mussels. Currently, there is no definitive early detection program which can find non-established populations.

Outcomes: The intended outcomes are applicable for the action but they cannot implement the outcomes given the action and approach outlined.

Potential negative outcome: If chemical treatment proceeded, then you would end up killing all native clams and other mollusks.

OSCM 13:
Remove Non-Native SAV and FAV

Action: OSCM13: Remove Non-Native Submerged Aquatic Vegetation (SAV) and Floating Aquatic Vegetation (FAV)

Evaluation Team: **Water Quality & Invasives Workgroup**

James Haas - Chair , Bruce Herbold – Coach, Chris Foe, Charles Alpers; Inge Werner, Frances Brewster, Karen Larsen, Chrisinte Joab, David Fullerton, Holly Gellerman, Ron Smith, Jan Thompson, Lori Clammurro (note taker)

Date of Last Revision: March 25, 2009

Action Description and Clarifying Assumptions

Remove water hyacinth (*Eichornia crassipes*) and Brazilian waterweed (*Egeria densa*) from 1,000 water acres of ecologically important Delta waterways each year

Approach

Augment the Department of Boating and Waterways' existing vegetation control program of mechanical and chemical removal of water hyacinth and chemical removal of Brazilian waterweed.

Intended Outcomes as Stated in Conservation Measure

1. Increase food consumption by delta smelt and longfin smelt larvae and juveniles due to higher turbidity
2. Reduce predation mortality of delta smelt as a result of higher turbidity
3. Improve the extent of delta and longfin smelt rearing habitat by reducing local water temperatures
4. Reduce predation on juvenile salmon, steelhead, and splittail by reducing habitat for non-native predatory fish
5. Increase rearing habitat for juvenile salmon (all races), steelhead, and splittail
6. Increased extent of spawning habitat for delta smelt and longfin smelt
7. Increased food availability for delta and longfin smelt near removal locations by increasing light levels below vegetation. *Note: The group opted to remove this outcome from consideration. One wouldn't expect to see an increase in productivity due to more light – as Egeria dies, production is occurring in the water, so it's not likely there would be a large difference. In addition, Egeria is not a habitat delta smelt are believed to occur in.*

Conceptual Model Information Regarding Intended Outcomes

1. The Delta Smelt conceptual model (p. 5, 8) indicates that delta smelt larvae and juveniles' ability to see prey organisms in the water is enhanced by turbidity. Potential implications regarding l*ongfin smelt* are less clear.
2. The Delta Smelt conceptual model (p. 7) indicates that delta smelt may use turbidity to conceal themselves from predators.
3. The Delta Smelt and Longfin Smelt conceptual models indicate the importance of water temperatures for these species. The *Aquatic Vegatation conceptual model indicates that SAV/FAV may increase water temps by slowing water velocities, but shading of the water column due to SAV/FAVcould decrease water temperatures.*

4. *It is well-documented that juvenile Chinook experience predation by sunfish lurking in SAV.*
5. *Reduced predation due to reduced SAV/FAV could provide for more rearing habitat .*
6. There is a question as to whether delta and longfin smelt occur in the areas targeted by this action.
7. The Delta Food Web conceptual model (Durand, 2008) identifies turbidity levels in the Delta as having an inhibitory effect on primary production due to reduced photic zone depth. Removal of SAV/FAV is expected to increase photic zone depth, thereby increasing the potential for phytoplankton blooms. *Note: The group opted to remove this outcome from consideration. One wouldn't expect to see an increase in productivity due to more light – as Egeria dies, production is occurring in the water, so it's not likely there would be a large difference. In addition, Egeria is not a habitat delta smelt are believed to occur in.*

Assumptions

Provided in BDCP Conservation Measure

1. "Ecologically important Delta waterways" include Sutter and Steamboat Sloughs, Middle, Old, and San Joaquin Rivers, the mainsteam Sacramento River, Georgiana Slough, and the North and South forks of the Mokelumne River.
2. Removal would be in addition to that conducted by the Department of Boating and Waterways (projected to be 3000-5000 acres per year for 2007-2011)

Problem(s) with Action as Written:

1. There is a question of whether delta and longfin smelt actually occur in SAV/FAV areas in the Delta, and therefore whether the action would yield the expected benefits to those species. The overlap (or possible lack of overlap) between Egeria and Eichornia extent, and the presence of delta and longfin smelt should be examined.

Scale of Action:

Small – increase of 20% but just 1,000 acres Delta-wide.

Rationale:

If it is assumed that the listed waterways are the only ecologically important waterways, and these totaled 1,000 acres, then this action would be of a larger scale. It doesn't appear that the listed waterways are the only ecologically important waterways, so the group assumed this was a small action. Also, spring (April-May) is believed to be the most important period for delta and longfin smelts' food organisms to grow, but the SAV/FAV in this action experience their peak growth in summer.

Evaluation Summary Tables

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

Relation to Existing Conditions:

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

NO

Nature of Change: Insert short sentence here.

In light of the information contained in several conceptual models and the group's understanding of how the system physically works, this action is not expected to yield substantial changes in system dynamics, possibly with some exception of very small, localized changes where the vegetation has been removed.

Potential Positive Ecological Outcome(s)

Outcome P1: Increase food consumption by delta and longfin smelt due to higher turbidity.

P1a. Delta smelt

The Delta smelt conceptual model (Nobriga and Herbold, 2008) notes the following: "Delta smelt larvae require turbidity to initiate feeding (Baskerville-Bridges et al. 2004); though the distribution of delta smelt near the end of their larval stage is not strongly influenced by turbidity (indexed as Secchi disk depths) ".

Delta smelt larvae do not feed in water that is too clear – we do not know if turbidity associated with SAV is sufficient to have this benefit to delta smelt because it is a spatial range effect.

Turbidity effects on habitat seem to manifest later in the year; earlier turbidity plays a role in initiating upmigration because higher flows of winter/spring raise turbidity.

Magnitude = 1
Inappropriate life stage and season for effect postulated; delta smelt model identifies temperature as primary larval determinate and turbidity as major juvenile/ summer distribution determinate (Bruce Herbold, pers comm.)

There is not believed to be any overlap between SAV treatment areas and delta smelt food areas (Bruce Herbold, pers comm.)

The ecological area of the waterways identified in this action represent a very small percentage of those areas thought to be important for delta smelt.

Certainty = 4
There are published local studies. There is also documentation on the distribution of smelt over many years.

P1b. Longfin smelt

Longfin smelt retain yolk sac long into larval life so that hatched larvae start feeding far downstream of their emergence site (Randy Baxter DFG, pers. comm.). The role and importance of turbidity for longfin smelt feeding efficiency is not as well-known as it is for delta smelt.

As is the case with delta smelt, we do not know if turbidity associated with SAV is sufficient to benefit longfin smelt, even if the importance of turbidity for longfin smelt is demonstrated,.

Turbidity effects on habitat seem to manifest later in the year; earlier turbidity plays a role in initiating upmigration because higher flows of winter/spring raise turbidity.
The magnitude and certainty scores below for long-fin smelt are largely based on what we know about delta smelt, but the certainty score is lower because we generally know less about long-fin smelt behavior and potential relationships to turbidity.

Magnitude = 1
Not believed to be overlap between SAV treatment areas and longfin smelt food areas (Bruce Herbold, pers comm.)

The ecological area of the waterways identified in this action represent a very small percentage of those areas thought to be important for longfin smelt.

Certainty = 3
There is documentation of the distribution of longfin smelt over many years suggesting that they do not overlap with those areas targeted by this action.

Outcome P2: Reduce predation of delta smelt as a result of reduced turbidity

P2. Delta smelt

The Delta smelt model (Nobriga and Herbold, 2008) notes that "Turbidity in the Delta is lower than it was 30-40 years ago (Jassby et al. 2002). Decreasing turbidity in the Delta has constrained the distribution of juveniles (Feyrer et al. 2007; Nobriga et al. 2008) and possibly spawning delta smelt. The most likely explanation is that delta smelt use turbidity to conceal themselves from predators. This is a hypothesis based on studies of small pelagic fishes in other river systems (e.g., Gregory and Levings 1998; Quist et al. 2004)." Thus, smelt probably avoid overly clear water and thereby reduce risk of predation, but it may be that smelt in too clear water are eaten.

As noted under Outcome P1 above, SAV/FAV treatment areas may not be important for delta smelt, as it is believed delta smelt don't occur in these areas. Any benefits of increased turbidity from the removal of SAV/FAV would depend on the spatial range of the effect.

Magnitude = 3
Predation by the visual predator, inland silversides, has been postulated as a likely mortality on emerging smelt. (Bruce Herbold, pers. comm..)

There is not believed to be any overlap between SAV treatment areas and delta smelt distribution (Bruce Herbold, pers comm.), but the predation question is different than feeding (Outcome P1). Delta smelt are concentrated in an area for part of the year, so magnitude would be slightly higher than for Outcome P1

The ecological area of the waterways identified in this action represent a very small percentage of those areas thought to be important for delta smelt.

Certainty = 2
Unclear that turbidity changes would manifest in the appropriate season to provide protection. Much studied elsewhere.

Delta smelt eggs have never been found in the field (Bruce Herbold, pers. comm.)

Outcome P3: Improve the extent of delta and longfin smelt rearing habitat by reducing local water temperatures

P3a. Delta smelt

The rationale for this outcome is that Egeria reduces flow velocities, increasing residence times and water temperatures. There is a question as to whether enhancing light penetration into more turbid water (from Egeria removal) would increase water temperatures..

It is dubious that the action and this potential outcome would overlap in time or space; i.e. reduced Egeria in spring, when fish are present, may be limited; and rearing habitat is limited in the targeted waterways. There are questions regarding the spatial extent of the potential temperature benefits from this action.

Magnitude = 1
Egeria restricts flow and therefore increases water temperatures, but delta smelt are not in these areas at the time of year that Egeria would have an effect. Spring temperatures might be an issue, when delta smelt have a small window for spawning, but it's a stretch (Bruce Herbold, pers comm)

Certainty = 2
Data / study findings not yet published.

P3b. Longfin smelt

This outcome is expected to be the same for longfin smelt as delta smelt (see discussion above).

Magnitude = 1
Egeria restricts flow and therefore increases water temperatures, but longfin smelt are not in these areas at the time of year that Egeria would have an effect. Spring temperatures might be an issue.

Certainty = 2
Data / study findings not yet published.

Outcome P4: Reduce predation on juvenile salmon, steelhead, and splittail by reducing habitat for non-native predatory fish

P4. Salmon, steelhead, and splittail

Predation on juvenile salmon, steelhead, and splittail in the migration corridor can be significant (see Nobriga and Feyrer, 2007; Brown and Michniuk, 2007; and Greenberg et al., 1995. Non-native SAV/FAV may be replaced by other plants, with similar resulting impacts to fish.

Magnitude = 2
There is likely a measurable effect, but the magnitude is small due to the small scale of the action.

Certainty = 2
Certainty is low due to the potential establishment of other non-native vegetation, which would continue to serve as habitat for non-native predators.

Outcome P5: Increase rearing habitat for juvenile salmon (all races), steelhead, and splittail

P5a. Chinook Salmon

The potential role this area plays as rearing habitat is unclear, particularly relative to total rearing habitat.

Magnitude = 3
There is likely a measurable effect; scale of action slightly larger than for other fish species due to salmonids' use of "ecologically important waterways" as defined by this action.

Certainty = 3
Certainty somewhat higher because salmonids expected to rear in areas treated for Egeria, as defined by this action.

P5b. Steelhead

The effect of this action on steelhead rearing is expected to be similar to that on Chinook salmon.

Magnitude = 3
There is likely a measurable effect; scale of action slightly larger than for other fish species due to salmonids' use of "ecologically important waterways" as defined by this action. Also, steelhead juveniles stay in the system longer than juvenile salmon.

Certainty = 3
Certainty somewhat higher because salmonids expected to rear in areas treated by Egeria, as defined by this action.

P5c. Splittail

Smaller scale action than for salmonids; splittail rear over a larger geographic area.

Magnitude = 2
There is likely a measurable effect, but the magnitude is smaller than for salmonids due to the smaller scale of the action.

Certainty = 3
Certainty somewhat high that impact on splittail rearing is less than that for salmonids, because ecological area of those waterways is a smaller portion of splittail rearing habitat.

Outcome P6: Increase extent of spawning habitat for delta smelt and longfin smelt

P6a. Delta smelt

The Delta smelt conceptual model, spawning habitat section notes that "suitable spawning microhabitats likely exist throughout the upper estuary when the overlying water is fresh enough (Hobbs et al. 2007)."

Magnitude = 2
There is no indication that the delta smelt population is affected by limitations of spawning habitat area, since they spawn throughout the Delta in different years, although larval distribution suggests smaller spawning areas in drier years (Bruce Herbold, pers. comm.)

Also, the ecological area of the waterways affected by the action is a very small percentage of the total area important for delta smelt.

Certainty = 2
Preferred spawning habitat in lab does not match habitats in delta, but larvae documented from wide areas of delta suggesting widespread successful spawning in some years (Bruce Herbold, pers. comm..)

P6b. Longfin smelt

Magnitude = 1
Longfin don't have as wide a distribution in the eastern Delta as delta smelt; mostly limited to western Delta and bays.

Certainty = 2
Longfin smelt are not believed to spawn in the geographic areas covered by this action.

Potential Negative Ecological Outcome(s)

Outcome N1: Reduction in zooplankton from effects of herbicide

N1. All covered fish species

Possible impacts from 2,4-D & Glyphosate (both w/ adjuvant Agridex) used on Hyacinth, Fluridone used for Egeria.

Magnitude = 2
Function of herbicide and transport and overt toxicity. Magnitude of the effect may be lower for species that spend only short periods in the Delta.

Certainty = 2
Significant uncertainty with regard to population-level effects of herbicides on zooplankton.

Outcome N2: Reduction in phytoplankton quantity or quality from effects of herbicide

N2. All covered fish species

There is some evidence of reduced green algae production from herbicides (Lürling and Roessink, 2006).

Studies in lakes suggest that filter feeding zooplankton remove phytoplankton while using submerged macrophytes as a refuge from predation (Stansfield et al. 1997).

Submerged macrophytes as refuges for grazing Cladocera against fish predation: observations on seasonal changes in relation to macrophyte cover and predation pressure. (Stansfield et al. 1997).

Recent work in this system using stable isotopes shows that trophic pathways within *E. densa* beds are largely distinct from those in offshore habitats, particularly for juvenile fishes (Grimaldo et al. 2004).

Magnitude = 3
Function of herbicide and transport and overt toxicity.

Certainty = 1
Significant uncertainty with regard to population-level effects of herbicides on phytoplankton, especially in light of other possible stressors (e.g. residence time). Removal of Egeria might enhance feeding success of Corbicula – possible “double-whammy” effect from toxicity of phytoplankton (from herbicides), and resultant increase in phytoplankton consumption by Corbicula who may colonize the former Egeria areas.

Outcome N3: Increase in detritus POC – temporally and spatially limited

SAV is noted in the Dissolved Oxygen (DO) conceptual model in a variety of places – as a source of DO during phytosynthesis (ranked as medium on all DLO); as a source of increased oxygen demand in the sediment (DLO was uniformly low) and as a potential source of reduced velocity and turbulence resulting in less oxygen being mixed into the water from the atmosphere.

N3. All covered fish species

Removal of SAV and FAV will result in localized collections of particulate organic carbon (POC) at the sediment surface, in the water column and as bedload material. The Dissolved Oxygen conceptual model rates the impact of POC derived from SAV/FAV as low in importance, understanding and predictability. However, the DO model does not consider the importance of recently killed plant material. The DO model also shows that an increase in POC in the water column will increase the water column oxygen demand with a rating of high importance and medium understanding and predictability. The ratings shown below are a mixture of these levels of importance and our limited knowledge about the transport or retention of recently killed plants in a treated area.

Magnitude = 2

The magnitude of the effect is likely to be localized and since the critical fish do not live in the SAV beds it seems unlikely they would be directly affected.

Certainty = 2

There is no published data that tells us how long the plant material would reside in the water column or on the bottom. If it rafts up into isolated embayments we might see localized effects that last longer than we might expect. Once the plant leaves start to decompose the plants will be harder to move and are likely to become part of the sediment.

Outcome N4: Increased blooms of microcystis due to a reduction in competition for nutrients

N4. All covered fish species

Two documented effects / possible causal mechanisms. First, microcystis is resistant to glyphosate (Lopez-Rodas et al. 2007). Second, since green algae are not resistant to glyphosate, more nutrients are available to microcystis from reduced competition with green algae (Lürling and Roessink, 2006). Rapid selection for glysophate-resistant plants increases the occurrence of microcystis.

There appears to be considerable anecdotal evidence that microcystis and SAV coexist with little mention of competition for nutrients (Lehman, pers. comm). The best reference is probably: Mazzeo, N., L. Rodriguez-Gallego, C. Kruk, M. Meerhoff, J. Gorga, G. Lacerot, F. Quintans, M. Loureiro, D. Larrea, and F. Garcia-Rodriguez. 2003. Effects of *Egeria densa* plant beds on a shallow lake without piscivourous fish. Hydrobiologia 506-509:591-602.

Magnitude = 2

Based on what we've seen so far, the geographic extent of effects is small, when comparing the area of beds as a food source relative to other food source areas. The discrete areas where Egeria would be treated, as this action is written, translates into a low magnitude score.

Response to herbicides would favor microcystis due to reduced competition for nutrients and because microcystis develops more resistance to herbicides than phytoplankton does.

Certainty = 3
Have peer-reviewed information from outside the system, plus the work of the Department of Boating and Waterways inside the system. There are two peer-reviewed papers for this system, as well.

Outcome N5: Possible toxic effects to juvenile white and green sturgeon from Fluridone and 2,4-D used at approved application rates.

N5. Green and white sturgeon

Documented greater sensitivity of white sturgeon to weed control chemicals (Little and Calfee 2008); green sturgeon included due to relationship (Dwyer et al. 2005), but the extent to which they would use these areas is unclear.

Magnitude = 2
White sturgeon don't spawn in the targeted areas, but juveniles rear in shallow, low-tidal areas (the same conditions in which Egerial colonizes). However the overall magnitude is expected to be small due to the relatively small scale of action.

Certainty = 3
Peer-reviewed studies from outside of the system; ongoing studies within the system.

Outcome N6: Possible endocrine disruption in fish by 2,4-D.

N6. All covered fish species.

LOAEC 164 ug/L (Xie et al. 2005)

Magnitude = 2
Concentrations used to treat Egeria are several orders of magnitude lower than levels of concern from toxicity tests.

Peer-reviewed study: production of vitaligennin (rainbow trout) – concentrations much lower than LC-50 concentrations.

Certainty = 2
Peer-reviewed literature from outside the system; limited range of endocrine disruption effects; also, temporal considerations.

Important Gaps in Information and/or Understanding

Data Needs

It would be helpful to define "ecologically important waterways" for this action, then see how these areas overlap with existing data on the distribution of SAV in the Delta.

Would like to know what percentage of productivity is supplied by Egeria. Two of the amphipods that live in Egeria beds are important food items for native fish. Surface area of Egeria contains algae; could be important for low-productivity system.

Research Needs

Need to research reduction in zooplankton and phytoplankton from herbicides.

When areas are treated for certain SAV, what plant species come in to replace them? Good opportunity for experimental design and monitoring.

Should have follow-up studies to document how species respond to the removal of the SAV/FAV – is the benefit really occurring, does it last, and what's the long-term ecosystem benefit?

Assess Reversibility and Opportunity for Learning

Reversibility

Yes/Easy

> ***Comments:*** If unsuccessful, funding could be de-obligated and spraying for SAV/FAV could stop at any time.

Opportunity for Learning

High

> **Comments** Would be beneficial to ascertain food web effects of aquatic weed spraying activities and of absence of the SAV/FAV communities inhabited by invertebrates, and to see whether other plant species colonize areas formerly occupied by non-native veg.

Action: Increase Sport Fishing Harvest of Non-native Predatory Fish

Evaluation Team: Hatcheries and Harvest Workgroup

Brad Cavallo - Chair, Dave Zezulak – Coach/participant, Jim Smith, Jason Kindopp, Shirley Witalis, Alison Willy, Josh Israel, Larry Wise (note taker).

Date of Last Revision: February 18, 2009

Action Description and Clarifying Assumptions

Modify sport fishing regulations to reduce the abundance, size, and, therefore, reproductive capacity of black bass (largemouth, smallmouth, and spotted bass) and striped bass in the Sacramento-San Joaquin Delta (the Delta).

Approach

1. Remove all size and bag limits for sport fishing take of black bass and striped bass in the Delta.

Intended Outcomes as Stated in Conservation Measure

Note: Striped bass and black bass use habitat differently, occur in different areas, and therefore affect the covered species differently. As such, they are treated separately in this evaluation.

Striped bass

1a. Reduced predation mortality of Chinook salmon (all races) by striped bass.
1b. Reduced predation mortality of steelhead by striped bass.
1c. Reduced predation mortality of Delta smelt by striped bass.
1d. Reduced predation mortality of longfin smelt by striped bass.
1e. Reduced predation mortality of splittail by striped bass.
1f. Reduced predation mortality of green sturgeon by striped bass.
1g. Reduced predation mortality of white sturgeon by striped bass.
2. Reduced competition for food with delta and longfin smelt by juvenile striped bass.

Black bass

3a. Reduced predation mortality of Chinook salmon (all races).
3b. Reduced predation mortality of steelhead by black bass.
3c. Reduced predation mortality of Delta smelt by black bass.
3d. Reduced predation mortality of longfin smelt by black bass.
3e. Reduced predation mortality of splittail by black bass.
3f. Reduced predation mortality of green sturgeon by black bass.
3g. Reduced predation mortality of white sturgeon by black bass.

Both bass species

4. Increased knowledge about the efficacy of using sport fishing regulations to modify bass population size.

Additional outcomes:

- Increased bycatch of non-target species during fishing efforts targeted at striped and black bass.
- Release other predator populations from predation pressure currently imposed by striped and black bass.
- Release other competitor populations from predation pressure currently imposed by striped and black bass.
- Unintended changes to the striped and black bass populations. e.g., decrease abundance but increase average size.

General Conceptual Model Support for Intended Outcomes

1a. Reduced Chinook mortality (striped bass): Yes, implied in Chinook, Salmonid model pages 41 and 46, Chinook Stressors tables.
1b. Reduced steelhead mortality (striped bass): Yes, implied in Salmonid model Stressor Table for Central Valley Steelhead, predation by bass is an important stressor.
1c. Reduced Delta smelt mortality (striped bass): Yes, implied in Delta smelt model pages 12, 13, 27.
1d. Reduced longfin smelt mortality (striped bass): Yes, implied and stated in Longfin smelt model pages 8, 14, 19, 26, 34.
1e. Reduced splittail mortality (striped bass): Yes, implied in Splittail model page 8.
1f. Reduced green sturgeon mortality (striped bass): Yes, implied in Green sturgeon model p. 7.
1g. Reduced white sturgeon mortality (striped bass): No model support.
2. Reduced competition for food: Yes, implied and stated in Longfin smelt model pages 8 and 25.
3a. Reduced Chinook mortality (black bass): Yes, implied in Salmonid model on page 46 and in Stressor Tables for Chinook salmon.
3b. Reduced steelhead mortality (black bass): Yes, implied in Salmonid model Stressor Table for Central Valley Steelhead.
3c. Reduced Delta smelt mortality (black bass): No model support.
3d. Reduced longfin smelt mortality (black bass): Yes, implied in longfin smelt model Stressor table (p. 34).
3e. Reduced splittail mortality (black bass): No model support. See supporting reference in Attachment A.
3f. Reduced sturgeon mortality (black bass): No model support.
3g. Reduced white sturgeon mortality (black bass): No model support.
4. Increased knowledge: No model support. Supported by simple logic.

Assumptions

Provided in BDCP Conservation Measure
None.

Added by Evaluation Team
None

Problem(s) with Action as Written

1. The action assumes that removing size and bag limits will increase harvest and reduce population sizes of black bass and striped bass. However, the action may simply change the age structure of these populations without changing their total abundance or biomass.
2. Additionally, social pressure to establish a trophy striped bass fishery may exist and the cultural shift required to implement the action has not been evaluated.

Scale of Action

Large

Rationale:
The action has a large spatial extent, a significant duration, and represents a major reversal compared to existing conditions.

Evaluation Summary Tables

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

Relation to Existing Conditions

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

The action is not expected to change any of the boundary conditions (physical background and inputs within and outside the Delta) described in the DRERIP Boundary Conditions paper.

Potential Positive Ecological Outcome(s)

Outcome P1: Reduced predation mortality by striped bass

P1a. Chinook salmon (all races)

General Observations

See Attachment A for detailed information regarding the following references:
- Salmonid model pages 41 and 46, Chinook Stressors tables
- Nobriga & Feyrer (2007) Table 1 (page 6) and page 9
- Nobriga & Feyrer (2008) Table 2
- ODFW 1998 pages 5, 14, 15

Magnitude = 2

As this predator is a generalist, predation pressure on a single prey species may not be high. Thus the magnitude of the prey species' response to reduced predator population size is difficult to predict. Predation rates may be higher than steelhead, but not enough to result in increased magnitude.

Certainty = 3

Empirical evidence for this outcome is limited to a few references.

P1b. Steelhead

General Observations

See Attachment A for detailed information regarding the following references:
- Salmonid model Stressor Table for Central Valley Steelhead
- ODFW 1998 pages 5, 14, 15

Magnitude = 2

As this predator is a generalist, predation pressure on a single prey species may not be high. Thus the magnitude of the prey species' response to reduced predator population size is difficult to predict. Steelhead are larger when moving through the delta making them less susceptible to predation than Chinook salmon.

Certainty = 2

Empirical evidence for this outcome is limited to a few references.

P1c. Delta smelt

General Observations

See Attachment A for detailed information regarding the following references:
- Delta smelt model pages 12, 13, 27
- Nobriga & Feyrer (2008) Table 2

Magnitude = 2

As this predator is a generalist, predation pressure on a single prey species may not be high. Thus the magnitude of the prey species' response to reduced predator population size is difficult to predict.

Certainty = 2

Empirical evidence for this outcome is limited to a few references.

P1d. Longfin smelt

General Observations

See Attachment A for detailed information regarding the following references:

- Longfin smelt model pages 8, 14, 19, 26, 34

Magnitude = 2

As this predator is a generalist, predation pressure on a single prey species may not be high. Thus the magnitude of the prey species' response to reduced predator population size is difficult to predict.

Certainty = 2

Empirical evidence for this outcome is limited to a few references.

P1e. Splittail

General Observations

See Attachment A for detailed information regarding the following references:

- Splittail model page 8
- Nobriga & Feyrer (2008) Table 2

Magnitude = 2

As this predator is a generalist, predation pressure on a single prey species may not be high. Thus the magnitude of the prey species' response to reduced predator population size is difficult to predict. Splittail abundances are driven more by hydrology than predation, and so predation may not be an important population driver.

Certainty = 2

Empirical evidence for this outcome is limited to a few references.

P1f. Green sturgeon

General Observations

See Attachment A for detailed information regarding the following reference:

- Green sturgeon model page 7

Magnitude = 1

As this predator is a generalist, predation pressure on a single prey species may not be high. Thus the magnitude of the prey species' response to reduced predator population size is difficult to predict. Green sturgeon are a benthic species and as such may be less susceptible to pelagic predation.

Certainty = 2

Empirical evidence for this outcome is limited to a few references.

P1g. White sturgeon

Magnitude = 1

As this predator is a generalist, predation pressure on a single prey species may not be high. Thus the magnitude of the prey species' response to reduced predator population size is difficult to predict. White sturgeon are a benthic species and as such may be less susceptible to pelagic predation.

Certainty = 2

Empirical evidence for this outcome is limited to a few references.

Outcome P2: Reduced competition for food with delta and longfin smelt by juvenile striped bass

General Observations

See Attachment A for detailed information regarding the following references:
- Longfin smelt model page 8, 25

Magnitude = 3

These species all feed on copepods at some point in their life.

Certainty = 2

Empirical evidence for this outcome is limited to a few references. Window of dietary overlap may be limited, but striped bass juvenile populations would be substantially reduced.

Outcome P3: Reduced predation mortality by black bass

P3a. Chinook salmon (all races)

General Observations

See Attachment A for detailed information regarding the following references:
- Salmonid model p. 46 and Stressor Tables for Chinook salmon
- Nobriga & Feyrer (2007) Table 1
- ODFW (1998) pages 5, 11

Magnitude = 2

As this predator is a generalist, predation pressure on a single prey species may not be high. Thus the magnitude of the prey species' response to reduced predator population size is difficult to predict.

Certainty = 3

There are a number of studies indicating predation of salmon by black bass, but magnitude of this predation is unknown.

P3b. Steelhead

General Observations

See Attachment A for detailed information regarding the following references:
- Salmonid model Stressor Table for Central Valley Steelhead
- ODFW (1998) pages 5, 11

Magnitude = 2

As this predator is a generalist, predation pressure on a single prey species may not be high. Thus the magnitude of the prey species' response to reduced predator population size is difficult to predict.

Certainty = 2

Empirical evidence for this outcome is limited to a few references. Steelhead are larger when migrating through Delta and so may not be as susceptible to predation.

P3c. Delta smelt

General Observations

See Attachment A for detailed information regarding the following reference:
- Eisermann (2006) page 33

Magnitude = 2

As this predator is a generalist, predation pressure on a single prey species may not be high. Thus the magnitude of the prey species' response to reduced predator population size is difficult to predict.

Certainty = 2

Empirical evidence for this outcome is limited to a few references.

P3d. Longfin smelt

General Observations

See Attachment A for detailed information regarding the following references:
- Longfin smelt model p. 19, stressor table (p. 34)
- Eisermann (2006) page 33

Magnitude = 2

As this predator is a generalist, predation pressure on a single prey species may not be high. Thus the magnitude of the prey species' response to reduced predator population size is difficult to predict.

Certainty = 2

Empirical evidence for this outcome is limited to a few references.

P3e. Splittail

General Observations

See Attachment A for detailed information regarding the following reference:
- Nobriga & Feyrer (2007) Table 1
- Eisermann (2006) page 33

Magnitude = 1

As this predator is a generalist, predation pressure on a single prey species may not be high. Thus the magnitude of the prey species' response to reduced predator population size is difficult to predict. Populations driven by hydrology, not predation.

Certainty = 2

Empirical evidence for this outcome is limited to a few references.

P3f. Green sturgeon

Magnitude = 1

As this predator is a generalist, predation pressure on a single prey species may not be high. Thus the magnitude of the prey species' response to reduced predator population size is difficult to predict.

Certainty = 2

Empirical evidence for this outcome is limited to a few references.

P3g. White sturgeon

Magnitude = 1

As this predator is a generalist, predation pressure on a single prey species may not be high. Thus the magnitude of the prey species' response to reduced predator population size is difficult to predict.

Certainty = 2

Empirical evidence for this outcome is limited to a few references.

Outcome P4: Increased knowledge about the efficacy of using fishing regulations to modify bass population size

Magnitude = 2

Certainty = 2

Support for this outcome is based on reasoning rather than empirical evidence.

Potential Negative Ecological Outcome(s)

Outcome N1: Increased bycatch of non-target species

General Observations

Not believed to be large risk.

Magnitude = 1

Certainty = 2

We have found no empirical evidence for this outcome.

Outcome N2: Release of other predator populations from predation pressure

General Observations

See Attachment A for detailed information regarding the following reference:
- Nobriga & Feyrer (2008) Table 2
- Swingle (1946)
- Missouri Dept. of Conservation Student Guide (2006)
- Shroyer et al. (2003)

Magnitude = 2

Largemouth bass are shown to prefer sunfish species (e.g., bluegill) over other forage fish, and often keep sunfish populations at or below carrying capacity (see Swingle 1946, Missouri Dept of Conservation 2006, Shroyer et al. 2003 – observed only a weak negative relationship between bass density and bluegill recruitment)

Certainty = 2

Empirical evidence for this outcome is limited to a few references.

Outcome N3: Release of other competitor populations from predation pressure

General Observations

See Attachment A for detailed information regarding the following references:
- Dettmers et al. (1998)
- Gleason & Bengston (1996)
- Bennett (2005) pages 49-50
- Nobriga & Feyrer (2008) Table 2
- Begon et al. (1996) pp. 325-326

Magnitude = 3

Numerous competitors to these species in Delta, who are also preyed upon by striped bass and black bass

Certainty = 3

Outcome N4: Unintended changes to the striped and black bass populations (e.g., decrease abundance but increase average size)

General Observations

See Attachment A for detailed information regarding the following references:
- Hartman (2003)
- Mayo et al. (1998)

Magnitude = 2

Might shift the population to smaller fish that are less desirable to anglers, which may consume more smelt.

Certainty = 2

Important Gaps in Information and/or Understanding

Data Needs

- Additional data are needed to address whether the action could release other delta and longfin smelt predators or competitor populations from predation pressure currently imposed by striped and black bass.
- Additional data are needed to address the potential response of target populations.
- Understanding of how fishermen would respond to changes in harvest regulations.
- Potential for other cascading effects. For example, Maezono & Miyashita (2004) found removal of bass resulted in increased crayfish populations, which then reduced macrophyte densities because they are consumed by crayfish. This type of effect could affect habitat structure.

Assess Reversibility and Opportunity for Learning

Reversibility

Yes/easy

Opportunity for Learning

High – with regard to managing predator populations through sport harvest regulations

DRERIP Evaluation Workshop – Attachment A: References arranged by Outcome, with notes

OUTCOME P1: Reduced predation mortality by striped bass

P1a. Chinook salmon (all races)

1. Salmonid Conceptual Model
    - Striped bass consume Chinook salmon in the Delta, although the effect is likely small (pages 41 and 46).
    - Predation by bass is an important stressor (Chinook Stressors Tables).
2. Nobriga & Feyrer (2007)
    - Striped bass consume Chinook salmon in the Delta (Table 1).
    - Striped bass may be significant predators of Chinook in the Delta (page 9).
3. Nobriga & Feyrer (2008)
    - Prey items for striped bass in the Delta include Chinook salmon (Table 2).
    - However, striped bass appear to consume a wide variety of prey species and this diversity in prey items may mean that striped bass will not exert strong control over any one prey species (Table 2).
3. ODFW (1998)
    - Evidence of relief from predation via increased exploitation on non-native fishes is mixed (p. 5)
    - Periods of high striped bass abundance have correlated with periods of high coho salmon abundance, indicating that striped bass do not exert a lot of control over coho populations evaluated in Oregon. Evidence that striped bass cause declines in coho is mixed, although they are shown to eat salmonids in this region (p. 15).
    - Removal of the two bass per 24-hr period/30” limit would substantially increase harvest of smaller striped bass and cause reductions in those populations (p. 15).

P1b. Steelhead

1. Salmonid Conceptual Model
    - Predation by bass is an important stressor (Central Valley Steelhead Stressors Table).
2. ODFW (1998)
    - See information under Chinook salmon (P1a).

P1c. Delta smelt

1. Delta smelt Conceptual Model
    - Striped bass consume Delta smelt (pages 12, 13, 27).
2. Nobriga & Feyrer (2008)
    - Prey items for striped bass include Delta smelt (Table 2).
    - However, striped bass appear to consume a wide variety of prey species and this diversity in prey items may mean that striped bass will not exert strong control over any one prey species (Table 2).

P1d. Longfin smelt

1. Longfin Smelt Conceptual Model
    - Striped bass in the Delta consume longfin smelt (pages 8, 14, 19, 26, 34).

P1e. Splittail

1. Splittail Conceptual Model
    - Striped bass consume splittail in the Delta (page 8).
2. Nobriga & Feyrer (2008)
    - Prey items for striped bass in the Delta include splittail (Table 2).
    - However, striped bass appear to consume a wide variety of prey species and this diversity in prey items may mean that striped bass will not exert strong control over any one prey species (Table 2).

P1f. Green sturgeon

1. Green Sturgeon Conceptual Model
   - Anecdotally, striped bass may consume green sturgeon in the Sacramento River (page 7).

P1g. White sturgeon

OUTCOME P2: Reduced competition for food with delta and longfin smelt by juvenile striped bass

1. Longfin Smelt Conceptual Model
   - Juvenile striped bass compete for prey with longfin smelt (page 8, 25).
2. **See Stevens et al. (1985), Musick et al. (2000), & Bay-Delta Oversight Council (1995) below indicating that increased harvest would reduce striped bass populations.**

OUTCOME P3: Reduced predation mortality by black bass

P3a. Chinook salmon (all races)

1. Salmonid Conceptual Model
   - Predation by bass is an important stressor (p. 46 and Chinook Stressors Tables).
2. Nobriga & Feyrer (2007)
   - Black bass consume Chinook salmon in the Delta (Table 1).
3. ODFW (1998)
   - Evidence of relief from predation via increased exploitation on non-native fishes is mixed (p. 5)
   - The harvest rate for bass is generally low because they are difficult to catch, and catch-and-release is practiced by the most effective bass anglers (p. 11).
   - Modeling results for Tenmile Lakes in Oregon (area where largemouth bass angling is higher than in most other largemouth bass fisheries) indicate that removal of harvest regulations for largemouth would increase the harvest rate from 8-18%, reducing the bass population by 16%. Unlikely that reductions of this magnitude would have a measurable effect on native salmonid populations (p. 11).

P3b. Steelhead

1. Salmonid Conceptual Model
   - Predation by bass is an important stressor (Central Valley Steelhead Stressors Table).
2. ODFW (1998)
   - See information under Chinook salmon (P3a).

P3c. Delta smelt

1. Eisermann (2006)
   - Introduction of largemouth bass resulted in extinction of bird species (Atitlan grebe) in Guatemala because bass reduced abundance of grebe's food resources (p. 33). Removal of bass should results in increased abundance of forage fish for waterbirds.

P3d. Longfin smelt

1. Longfin Smelt Conceptual Model
   - Predation by bass is an important stressor (Stressors Table).
   - Predation is likely an important source of mortality for eggs and larvae (page 19).
2. Eisermann (2006)
   - See information under Delta smelt (P3c).

P3e. Splittail

1. Nobriga & Feyrer (2007)
   - Black bass consume splittail in the Delta (Table 1).
2. Eisermann (2006)
   - See information under Delta smelt (P3c).

P3f. Green sturgeon

P3g. White sturgeon

OUTCOME P4: Increased knowledge about the efficacy of using sport fishing regulations to modify bass population size

- No external references – this outcome is sufficiently supported by simple logic.

OUTCOME N2: Release other predator populations from predation pressure currently imposed by striped and black bass

1. Nobriga & Feyrer (2008)
   - Striped bass prey on other piscivorous Delta fishes (Table 2).
2. Swingle (1946)
   - Largemouth bass preferred bluegill over other forage fish (golden shiners, gizzard shad, *Gambusia*) stocked in experimental ponds (Abstract).
3. Missouri Department of Conservation (2006)
   - Largemouth bass prey on sunfish. Reduced bass populations could cause sunfish to exceed their carrying capacity and to consume large numbers of their prey (pp. 19, 20).
4. Shroyer et al. (2003)
   - Several authors have reported overharvest of largemouth bass leading to bluegill overpopulation and poorer fishing (see references within Shroyer et al.)
   - Shroyer et al. documented a significant increase in largemouth bass density with prohibition of bass harvest, but only a weak negative correlation between bass density and bluegill recruitment.
5. Maezono & Miyashita (2004)
   - Black bass removal from farm ponds in Japan resulted in increased populations of invasive crayfish, which reduced abundance of macrophytes. Macrophytes are important for spawning and shelter for native species.

OUTCOME N3: Release other competitor populations from predation pressure currently imposed by striped and black bass

1. Dettmers et al. (1998)
   - Striped bass can directly regulate shad populations in a closed system
2. Gleason & Bengston (1996)
   - Striped bass can directly regulate silverside populations in a closed system
3. Bennett (2005)
   - Delta smelt and inland silversides compete for prey (pages 49-50).
4. Nobriga & Feyrer (2008)
   - Striped bass prey on inland silversides in the Delta (Table 2), which compete with Delta smelt (see above).
5. Begon et al. (1996)
   - Increased predation may result in reduced competition among remaining prey for limiting resources (pp. 325-326). Thus, reduced predation would be expected to increase competition.

OUTCOME N4: Unintended changes to the striped and black bass populations (e.g., decrease abundance but increase average size)

1. Hartman (2003)
   - Management actions to change the effect of striped bass predation on prey species can be difficult due to the complexity of the interactions between populations.
2. Mayo et al. (1998)
   - Striped bass may not act as direct top-down control in open system with many predator and prey species interacting
   - Management actions to change the effect of predation on prey species can be difficult due to the complexity of the interactions between populations.

----

1. Stevens et al. (1985)

   - Removal of bag and size limits will likely decrease population and reproductive effort of basses. Twice during the last century, angling regulations were made more stringent to protect the striped bass population in the Sacramento-San Joaquin Estuary. Reductions in both the daily bag limit and the minimum total length were implemented. The striped bass population stabilized after the 1956 change in angling regulations but destabilized after 1976 (from A. Willy).

2. Musick et al. (2000)

   - Marine overfishing is a well-known phenomenon and the references are too numerous to site. See Musick 2000 for an illustrative list of citations. If angling regulations that protect both numbers and age-classes of striped bass can be used to stabilize the population, as has been done in the past, then relief from angling regulations is likely to destabilize the population (from A. Willy).

3. Bay-Delta Oversight Council (1995), Stevens et al. (1985)

   - Angling regulations implemented in 1982 (Stevens et al 1985) apparently had less of a population response than earlier regulations, even though a hatchery program was concurrently implemented (Bay-Delta Oversight Council 1995). It should be noted that, by 1995, CDFG biologists looked at striped bass declines after 1976 and stated that “other factors are to blame and existing angling regulates are appropriate.” In addition, catch of “sub-legal” striped bass has consistently exceeded legal harvest indicating that there is ongoing harvest pressure on striped bass (Bay-Delta Oversight Council 1995; from A. Willy).

Action: Enhance Delta Enforcement

Evaluation Team: Hatcheries and Harvest Workgroup

Brad Cavallo - Chair, Jim Smith, Jason Kindopp, Shirley Witalis, Alison Willy, Josh Israel, Dave Zezulak – Coach, Larry Wise (note taker)

Date of Last Revision: February 17, 2009

Action Description and Clarifying Assumptions

Increase enforcement of existing fishing regulations to reduce illegal harvest of catchable covered salmonids and sturgeon in the Delta and tributary rivers, including summer holding habitat for spring-run and sturgeon.

Approach

1. Fund increased enforcement of fishing regulations by the California Department of Fish and Game through the term of the BDCP.

Intended Outcomes as Stated in Conservation Measure

1. Increased population sizes of green sturgeon.
2. Increased population sizes of white sturgeon.
3. Increased population sizes of Chinook salmon (all races).
4. Increased population sizes of steelhead.

Note: This may not result in a larger population size, but will reduce mortality. Enforcement is only part of the process. Penalties should also be addressed.

NOTE: The degree of importance of this action varies inversely with the size of the population.

See Attachment A for detailed information regarding the following references:
- Bay-Delta Oversight Council (1995) p. 17
- Moyle et al. (2008) p. 69 (Fisheries section)
- Futuyma (1998) p. 304
- Begon et al. (1996) pp. 385-386

General Conceptual Model Support for Intended Outcomes

1. Green sturgeon population: yes, implied in life stage stressor matrix pp. 27,30; population section pp. 18-19, poaching is likely, but limited understanding of impact on population.
2. White sturgeon population: yes, implied on pp. 10,17,20, poaching is serious and increasing problem.
3. Chinook population: yes, implied in stressor tables for winter- fall- and spring-run Chinook, poaching during holding period for spring-run.
4. Steelhead population: no, implied in stressor table for steelhead, intentional illegal poaching is probably rare. By-catch mortality is unavoidable so long as sportfishing is legal.

Assumptions

Provided in BDCP Conservation Measure

1. Funds will support the addition of 17 field wardens and 5 supervisory and support staff as part of the Delta-Bay Enhanced Enforcement Program (DBEEP). The program currently employs 9 field wardens and 1 supervisor
2. Field wardens' efforts will focus on enforcement of regulations for covered fish species only.

Added by Evaluation Team

1. List here.

Problem(s) with Action as Written:

1. Numerous other factors affect population sizes. Therefore, this action may not result in a detectable change in populations.

Scale of Action:

Medium

Rationale:
Will substantially increase size of enforcement group, regional basis.

Evaluation Summary Tables

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

Relation to Existing Conditions

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

NO. It is not affecting habitat or biological processes. This may influence population dynamics of species/runs with small adult abundances.

Potential Positive Ecological Outcome(s)

Outcome P1: Increased population sizes of green sturgeon

General Observations

See Attachment A for detailed information regarding the following references:
- Green sturgeon conceptual model life stage stressor matrix pp. 27,30; population section pp. 18-19
- Beamesderfer et al. (2007)
- CDFG (unpublished)
- Boreman (1997)
- D. Tanner, NMFS Enforcement Officer (pers. comm., 2009)
- DBEEP (2007)

Magnitude = 3

Small decrease in mortality may result in a large change in population. Don't know if adult population size is a key limiting factor for green sturgeon.

Certainty = 2

Limiting factors not well understood, production highly variable and influenced by environmental factors.

Outcome P2: Increased population sizes of white sturgeon

General Observations

See Attachment A for detailed information regarding the following references:
- White sturgeon conceptual model pp. 10,17,20
- Beamesderfer et al. (2007)
- Bay-Delta Oversight Council (1995) p. 34
- CDFG (unpublished)
- Boreman (1997)
- DFG Sturgeon Report Card (2007)
- DBEEP (2007)

Magnitude = 3

Small decrease in mortality may result in a large change in population.

Certainty = 2

Poaching well documented in bay. Effect of poaching on population size is not well understood.

Outcome P3: Increased population sizes of Chinook salmon

General Observations

DRERIP (salmon stressor tables) indicates spring run is more susceptible to poaching due to over summer holding and ease of locating them. The mark selective program will necessitate additional enforcement.

See Attachment A for detailed information regarding the following references:
- Salmonid conceptual model stressor tables for winter- fall- and spring-run Chinook
- Williams (2006) p. 248
- Bay-Delta Oversight Council (1995) p. 17

Magnitude = 2-3

Spring-run populations are more susceptible than other runs because they are found consistently in summer holding pools, where they are easy to poach (CV Salmon model).

Small populations are more vulnerable to the effects of poaching than larger populations.

Certainty = 2

Effect of poaching on population size is not well understood.

Outcome P4: Increased population sizes of steelhead

General Observations

See Attachment A for detailed information regarding the following references:
- Salmonid conceptual model stressor table for steelhead
- Moyle et al. (2008) p. 69 (Fisheries section)
- DFG Creel Survey Annual Performance Report, July 2007-June 2008
- DBEEP (2007)
- DFG Steelhead Report Card (2007)

Magnitude = 2

All hatchery steelhead are marked, so distinguishing from hatchery fish from wild fish is possible for legal fisherman. Fishery is closed to wild fish.

Magnitude score of 2 for outcome P4 is partially informed by DBEEP (2007). DBEEP (2007) briefly discusses poaching of sturgeon and striped bass as significant enforcement issues with no mention of steelhead. Although the report is limited in its discussion of poaching activities, the fact that steelhead are not mentioned demonstrates the relative lack of concern on the part of the DBEEP staff.

Certainty = 2

Steelhead biology and harvest is poorly understood. Production is highly variable depending on environmental conditions (McEwan & Jackson 1996).

Potential Negative Ecological Outcome(s)

Outcome N1: Information gap about where poaching is most important may result in effort being directed at less important areas and may shift poaching to areas with greater importance to the population

General Observations

See Attachment A for detailed information regarding the following references:
- Moeltner (2006) pp. 18-21
- Gentner (2004) pp. 8,10

Magnitude = 1

Potential for impact for this happening is small and dependent on faulty implementation.

Certainty = 2

Important Gaps in Information and/or Understanding

Data Needs

- Information gap about where poaching is most important.
- Importance of poaching on individual runs.

Research Needs

Assess Reversibility and Opportunity for Learning

Reversibility

YES

Opportunity for Learning

Low

Comments: Potential to better understand importance of poaching in population dynamics.

DRERIP Evaluation Workshop – Attachment A

Enhanced Delta Enforcement

OUTCOME P1: INCREASED POPULATION SIZES OF GREEN STURGEON

1. Green sturgeon conceptual model

   - "*Poaching for sturgeon seems to be a threat in the Sacramento River, and green sturgeon may be illegally harvested in these operations.* Manager's understanding for the effect of fishing-associated mortality on green sturgeon is low and the predictability of this stressor is little" (Population section, pp. 18-19).

   - Life stage stressor matrix (p. 27): Harvest causes direct mortality in the Delta and river.

   - Life stage stressor matrix including importance, understanding and predictability scores (p. 30): Harvest will have moderate impacts on coastal migrants (Delta), spawning adults (river), and mature adults (ocean/Delta/river) with an importance score of 3 for each. An importance score of 2 was assigned to spawning adults in Delta/bay habitat and post-spawners in river/Delta habitat. There is a limited understanding (score of 2) for all sturgeon except mature adults in ocean/Delta/bay habitat (score of 3). Predictability scores were 3 across the board.

2. Beamesderfer et al. (2007)

   - Models indicate that an increase in harvest of 2-3% reduces egg production levels indicating stocks are susceptible to reduced population sizes.

3. CDFG (unpublished)

   - Green sturgeon fishing mortality estimated at 0%.

4. Boreman (1997)

   - "Restricting fishing mortality may be the only tool available to managers for restoring depleted populations. At a minimum, reducing fishing pressure on long-lived species allows managers time to detect and correct the true causes of population decline."

5. NMFS Enforcement Officer Don Tanner (Personal Communication 2009)

   - "I know CDFG has a 'task force' geared towards stopping the poaching of green sturgeon for roe. They consider the cases important and large in scope due to its nexus to organized crime. . ."
   - Don also explained that poaching is considered significant because of makeshift factories where workers jar (with fake labels) the illegally harvested roe for sale and consumption—therefore it is an on-going operation.
   - NMFS Enforcement will actively partner with CDFG Enforcement on green sturgeon issues once the proposed 4(d) rule and designated critical habitat is finalized for green sturgeon, expected to occur in the Spring of 2009 (a few months).

6. DBEEP (2007)

   - Poaching of sturgeon is a significant enforcement issue.

OUTCOME P2: INCREASED POPULATION SIZES OF WHITE STURGEON

1. White sturgeon conceptual model

    - "*Poaching and the illegal commercialization of the sturgeon fishery to supply the black market with caviar and sturgeon flesh is a serious and increasing problem (Gingras, CDFG, pers. comm.), and the resultant mortality rates from this industry are unquantifiable but may be quite high. For example, the unusually low annual survival rates (~ 60-82%) during the 1990s (Schaffter and Kohlhorst 1999) may have been due in part to poaching.* In sum, the total annual mortality attributable to humans may be sufficient to limit completion of the life cycle for a significant proportion of the white sturgeon population via reduction in overall population size and size-selective harvest for large, fecund individuals" (Key limiting factors section, p. 10).

    - "Flows are diverted back to the main channel from the bypasses when water levels subside, and the bypasses dry up. *When these bypasses are closed, white sturgeon on their way to the spawning grounds are often stranded, leaving them vulnerable to poaching*, desiccation, scavenging, and death unless they are rescued (Zoltan Matica, DWR, pers. comm.)" (Poaching of fish stranded in dry bypass areas, p. 17).

    - "White sturgeon are a popular sport fish and *the object of a lucrative illegal fishery of unknown size.* The eggs alone from a ripe 72" female fish (which was legally harvestable until March 1, 2007) are reported to fetch $3,000 on the black market, therefore a *tremendous financial incentive exists for poachers to exploit this population. Indeed, several poaching rings have been exposed and prosecuted since 2000"* (Critical factors affecting the species, p. 20).

      "Harvest rates by legal anglers have been within reasonable limits (< 5%) since 1990. However, total mortality, which includes mortality due to all other unknown causes (including natural mortality and poaching) was extremely high during the 1990s. Annual mortality was between 20% and 35% for four of the five years in the 1990s for which we have data (Schaffter and Kohlhorst 1999, CDFG unpublished data). This is exceedingly high for a species with a life history like white sturgeon (e.g., slow growing, late to mature, infrequent successful reproduction, etc). *Poaching could have possibly been responsible for a significant portion of this additional mortality."*

2. Beamesderfer et al. (2007)

    - Models indicate that an increase in harvest of 2-3% reduces egg production levels indicating stocks are susceptible to reduced population sizes.

3. Bay-Delta Oversight Council (1995)

    - With more utilizing the resource, and improved catch success, illegal harvest likely increasing (p. 34).

4. CDFG (unpublished)

    - Fishing mortality during 12 more or less random years between 1968-1998 estimated at 1.4-11.5%.

5. Boreman (1997)

    - "Restricting fishing mortality may be the only tool available to managers for restoring depleted populations. At a minimum, reducing fishing pressure on long-lived species allows managers time to detect and correct the true causes of population decline."

6. DFG Sturgeon Report Card (2007)

    - White sturgeon are harvested outside of legal size limit.

- Harvest in 2007/2008 was reported as 23% (report card), which differs from creel data (48%).

7. DBEEP (2007)

   - Poaching of sturgeon is a significant enforcement issue.

OUTCOMES P3 & P4: INCREASED POPULATION SIZES OF CHINOOK SALMON & STEELHEAD

1. Chinook salmon and steelhead Conceptual Model

   - Stressor table for winter- fall- and spring-run Chinook: Importance level of 3 indicating incidental/accidental catch is likely. *"Poaching during the holding period may be important"* for spring-run.

   - Stressor table for CV steelhead: "*Intentional illegal poaching is probably rare. By-catch mortality is unavoidable so long as sportfishing is legal*." Importance level of 3 indicating incidental/accidental catch is likely.

2. Williams (2006)

   - "Inland harvest is significant and variable source of mortality that is not well-monitored. *Poaching is hard to quantify, but there are indications that it can be significant. Spring-run are particularly vulnerable while adults hold in pools through the summer"* (Inland harvest section, p. 248).

3. Bay-Delta Oversight Council (1995)

   - Estimated loss of spawning stock and smolts. Poaching/bycatch expected to increase proportionally with population size and CPUE (p. 17).

4. Moyle et al. (2008)

   - Mortality via incidental catch is likely occurring. This could be deleterious as wild fish numbers continue to decline and a greater percentage of the fish are caught and released (Fisheries section, p. 69).

5. DFG Creel Survey Annual Performance Report, July 2007-June 2008

   - Creel data shows the majority of steelhead angling effort (82.1%) takes place on the Feather and American Rivers, making illegal harvest of steelhead in the delta and bay an unlikely occurrence.

   - Creel data (DFG 2008?) indicates a 4.3% harvest rate.

6. DBEEP (2007)

   - DBEEP reports briefly discuss poaching of sturgeon and striped bass as significant enforcement issues with no mention of steelhead. Although the report is limited in its discussion of poaching activities, the fact that steelhead are not mentioned demonstrates the relative lack of concern on the part of the DBEEP staff.

7. DFG Steelhead Report Card (2007)

   - Based on volunteered reporting – 5% of wild fish are harvested in legal fishery.

*IMPORTANCE OF THIS ACTION WILL VARY INVERSELY WITH SIZE OF POPULATION.

- Bay-Delta Oversight Council (1995): Poaching/bycatch will increase with population size and CPUE (p. 17).
- Moyle et al. (2008): Greater proportion of small population affected by poaching.
- Futuyma (1998): Population bottlenecks will result in reduced genetic diversity; if population remains small, genetic drift will continue to erode genetic variation rapidly; if population grows in size, heterozygosity will be restored.
- Begon et al. (1996): Allee effects would also make this action more important for small populations (i.e., difficult to find mates when population is small, pp. 385-386).

OUTCOME N1: FISHING EFFORT SHIFTS TO OTHER SPECIES OR AREAS

1. Moeltner (2006)
   - 55-65% of respondents indicated that implementation of a catch and release rule would not affect their license purchase or trip decisions; 10-15% would compensate for the segment closures primarily with additional trips to sites not affected by catch and release rule (pp. 18-21).
2. Gentner (2004)
   - Anglers are substituting away from one fishery into another when fishing regulations are tightened (pp. 8, 10).

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Positive Outcomes				
P3	Chinook Salmon	Increased population sizes of Chinook salmon	2-3	2
P1	Green Sturgeon	Increased population sizes of green sturgeon	3	2
P4	Steelhead	Increased population sizes of steelhead	2	2
P2	White Sturgeon	Increased population sizes of white sturgeon	3	2
Negative Outcomes				
N1	Chinook salmon & Green & White Sturgeon	Information gap about where poaching is most important may result in effort being directed at less important areas and may shift poaching to areas with greater importance to the population	1	2

Action: Modify Splittail Harvest Regulations

Evaluation Team: Hatcheries and Harvest Workgroup

Brad Cavallo - Chair, Jim Smith, Jason Kindopp, Shirley Witalis, Alison Willy, Josh Israel, Dave Zezulak – Coach, Larry Wise (note taker)

Date of Last Revision: February 17, 2009

Action Description and Clarifying Assumptions

Modify fishing regulations to reduce the effects of harvest on Sacramento splittail.

Approach

1. Establish regulations on size and daily bag limits for splittail enforced by the California Department of Fish and Game.

Intended Outcomes as Stated in Conservation Measure

1. Increase population abundance of splittail.

Additional Outcomes:

- Establishing as a sport fishery would eliminate commercial fishery for restaurant trade
- Improved foodweb energy transfer in wet years
- Would improve ability to gather information about species
- Increased predation on Corbula

General Conceptual Model Support for Intended Outcomes

1. Increased abundance: yes, implied on p. 16, Tables 2&3 (pp. 19-20), considerable but poorly documented fishery, may significantly reduce egg supply.

Assumptions

Provided in BDCP Conservation Measure

1. Size limit: Size at which an adult has had one year to spawn.
2. Daily Bag limit: 10 fish.

Added by Evaluation Team

No new assumptions added.

Problem(s) with Action as Written:

1. Allows take of most productive fish, consider targeting fishery on smaller, rather than larger, fish.

Scale of Action:

Large

Rationale:

Change from unregulated to regulated fishery, broad spatial extent, long-term action.

Evaluation Summary

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

Relation to Existing Conditions:

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

YES

Nature of Change: Foodweb energy transfer.

May affect foodweb energy transfer in wet years if number of females are low already (Splittail model – pg 7).

Potential Positive Ecological Outcome(s)

Outcome P1: Increase population abundance of splittail

General Observations

See Attachment A for detailed information regarding the following references:
- Splittail conceptual model p. 16, Tables 2&3 (pp. 19-20).
- DFG Creel Data (2007, 2008) indicates that harvest is similar to salvage at TFCF (USBR 2008 TFCF website).

Magnitude = 3

See Splittail model.

Certainty = 2

Current fishery is poorly documented. Splittail populations may not be driven as much by harvest as by hydrology and floodplain inundation.

Outcome P3: Improved foodweb energy transfer in wet years

General Observations

See Attachment A for detailed information regarding the following references:
- Splittail conceptual model p. 7

Magnitude = 3

See Foodweb model (pg 128).

Certainty = 2

This transfer may be highly variable from year to year, depending on population size.

Outcome P4: Would improve ability to gather information about species

General Observations

Information on this species would be collected during routine creel census surveys if the species were regulated.

Magnitude = 2

Information on harvest poorly documented.

Certainty = 3

Info would be gathered during creel surveys.

Outcome P5: Increased predation on Corbula

General Observations

See Attachment A for detailed information regarding the following references:
- Splittail model pp. 7, 15.
- Foodweb model p. 129.

Magnitude = 2

See Splittail model pg 7, Foodweb model pg 129. Corbula represent about 6% of splittail diet. This impact may not be great.

Certainty = 2

Effect is dependent on a number of external factors unaffected by the action that may affect the populations of both splittail and *Corbula*.

Potential Negative Ecological Outcome(s)

Outcome N1: Potential for redirection of fishing effort to other sensitive species

General Observations

See Attachment A for detailed information regarding the following references:
- Gentner (2004) pp. 8,10

Magnitude = 2

Size of current fishery not well known.

Certainty = 2

Response of fishing community is unknown.

Important Gaps in Information and/or Understanding

Data Needs

- Need better information on amount of harvest currently occurring.
- Need to understand what other species might be targeted if splittail are regulated.

Research Needs

Assess Reversibility and Opportunity for Learning

Reversibility

Yes/easy

Opportunity for Learning

High

Comments: Would allow us to better understand effects of harvest on splittail populations.

DRERIP Evaluation Workshop – Attachment A

Splittail Harvest Regulations

OUTCOME P1: INCREASED POPULATION ABUNDANCE

1. Splittail conceptual model

   - "One of the least appreciated aspects of the splittail migration is that they are subject to a *considerable but poorly documented legal fishery from November through May*. Anglers catch splittail using earthworms and cut bait. Most fish caught are kept because they are prized as food fish in Asian cuisine. Incidental data collected during creel surveys for striped bass and salmon (K. Murphy, unpublished data) suggest that *at times hundreds of adult fish may be caught on a daily basis. It is possible the fishery could significantly reduce egg supply available for spawning by reducing the number of large females.* However, most of the fish caught are relatively small (15-25 cm TL) so may be mostly males (J. Hileman, pers. comm.)" (Stressors by life history stage, p. 16).

   - Tables 2 & 3 (pp. 19-20): Harvest is moderately important stressor to juveniles and adults (pre-spawning, spawners, post-spawning adults). Low understanding of impact (score of 2).

2. DFG Creel Data (2007, 2008)

   - There is considerable information in the DFG creel (2007,2008) surveys for 2006-2008. This subsistence fishery (92-97% of catch harvested; 2006-07- est. 2,442 harvested; 2007-08- est. 11,191 harvested) is focused on the Sac River between Rio Vista and Colusa. Fishing also occurs on the lower Feather from Verona to Shanghai Bend. These fisheries occur principally from Jan-March.

3. TFCF website

   - Salvage of splittail at the TFCF was est. to be 23,200/annually between 2000-03.

OUTCOME P2: Establishing as a sport fishery would eliminate commercial fishery for restaurant trade

1. DFG (2009)

   - Fish and Game Code Section 7121: "Unlawful sale, purchase, or possession of fish or amphibian 7121. Except as otherwise provided by this code or by regulation, it is unlawful to sell or purchase any fish or amphibia taken in, or brought into, the waters of the state, or brought ashore at any point in the state. It is unlawful to buy, sell, or possess in any place of business where fish are bought, sold, or processed, any fish or amphibia taken on any boat, barge, or vessel which carries sport fishermen, except those fish may be possessed in such a place only for the purposes of canning or smoking under regulations adopted by the commission."

2. Fish and Game Commission (2009)

   - 5.95. Other Species. "Other species of fish may be taken in any number and at any time of the year by angling, except for closures and restrictions listed under district special regulations."

   - Splittail are included in the "Other Species" category.

OUTCOME P3: Improved foodweb energy transfer in wet years

1. Splittail conceptual model

   - "It is likely that splittail are responsible for large transfers of energy from upstream floodplains into Suisun Marsh and Bay areas. These large migrations, both upstream adults and downstream juveniles are probably important in the seasonal transfer of energy within the estuary's foodweb (Feyrer et al. 2007). While this is unquantified, *the sheer numbers of juvenile splittail that are found following large inundation events would indicate a significant positive impact to the downstream foodweb*" (Ecology section, p. 7).

OUTCOME P5: INCREASED PREDATION ON CORBULA

1. Splittail conceptual model

   - "In Suisun Marsh adult splittail gut contents are predominantly detritus (60-79%), however, a shift has occurred since the invasion of *Corbula amurensis* in 1986 (Feyrer et al. 2003). After the invasion and establishment of the clam, mysid shrimp (*Neomysis mercedis*) populations collapsed (Kimmerer and Orsi 1996). Mysid shrimp which originally made up to 24% (average dietary importance) of splittail gut contents was reduced to 2% in the post clam period (Feyrer et al. 2003). The amount of detritus remained similar at 70% with the difference being made up with other invertebrates and *Corbula* (6%) itself (Feyrer et al. 2003)." (p. 7)

   - Adult splittail feed on the overbite clam (*Corbula amurensis*), which accumulates and transfers Selenium at high concentrations. With the decline of native mysid shrimp in the estuary, splittail have turned more to benthic foods such as bivalves (Feyrer et al. 2003)." (p. 15)

2. Foodweb model

   - *"Corbula amurensis* has been found in the guts of white sturgeon, suggesting that demersal fish are able to utilize these clams as a prey item." (p. 129)

OUTCOME N1: POTENTIAL FOR REDIRECTION OF FISHING EFFORT TO OTHER SENSITIVE SPECIES

1. Gentner (2004)

   - Anglers are substituting away from one fishery into another when fishing regulations are tightened (pp. 8, 10) (from E. Floyd).

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Positive Outcomes

Action: Implement a Mark-Select program to reduce the harvest of wild Chinook salmon

Evaluation Team: Hatcheries & Harvest Workgroup

Brad Cavallo - Chair, Dave Zezulak – Coach/participant, Jim Smith, Jason Kindopp, Shirley Witalis, Alison Willy, Josh Israel, Larry Wise (note taker).

Date of Last Revision: February 16, 2009

Action Description and Clarifying Assumptions

Mark all Central Valley Chinook salmon produced in hatcheries with a visible mark (e.g., adipose fin clip), and limit all commercial and recreational harvest of Chinook salmon to those with visible marks.

Approach

1. Mark all Central Valley Chinook salmon produced in hatcheries with a visible mark (e.g., adipose fin clip).
2. Limit all commercial and recreational harvest of Chinook salmon to those with visible marks.

Intended Outcomes as Stated in Conservation Measure

1. Increased population size of wild Chinook salmon.
2. Increased knowledge base regarding Central Valley Chinook salmon (population sizes, harvest rates, success of restoration programs, and other key biological parameters) for improved management.

Additional Outcomes Added by Group

1. Increased harvest of hatchery fish.

General Conceptual Model Support for Intended Outcomes

1. Increased population size: yes, implied because hatchery fish may play a role in recent Chinook population declines (Salmonid CM p. 28), hatchery fish compete with wild fish, may attract predators, and divert attention from condition ("mask" the true status) of wild stocks (Salmonid CM pp. 45-46).
2. Increased knowledge base: yes, implied because hatchery fish may conceal or divert attention from the condition of wild or naturally reproducing fish. This is particularly the case when few hatchery fish are marked (Salmonid CM pp. 45-46).
3. Reduce competition and introgression: yes, hatchery fish compete with wild Chinook (Salmonid CM p. 45).
4. Improved broodstock management: Not discussed in conceptual model. See references discussed in following Positive Outcomes section.

Assumptions

Provided in BDCP Conservation Measure

1. None

Added by Evaluation Team

1. All hatchery fish intended for harvest, regardless of run, will be marked. (*note, the team already discussed the necessity of handling hatchery conservation fish differently).
2. Our evaluation assumes that the requisite changes in harvest and hatchery management and monitoring programs would be developed to support this action.
3. Assumes adequate manpower/funding to implement the program.
4. Assumes most or all hatchery fish escapement will be harvested.

Notes:

- To obtain the anticipated resource benefit, this action will require coordinated efforts across agencies and various levels of government. "Need science, management, legislation and politics to implement a successful program." (Richards and Rago 1999). Changes to hatchery and harvest management would be profound and far reaching.
- The action lacks the specific hatchery and harvest management actions that would be necessary to obtain the desired objective of reducing catch of protected species and the adverse impacts that production hatcheries can have on wild stocks.
- Action may benefit some conservation stocks more than others depending on intermixing of stocks and level of protections currently afforded some stocks (Excerpt F, Attachment A).
- A mark-select program would allow a better forecast of the potential fishery harvest. It would also allow the development of better index to the number of wild fish harvested, which is currently estimated based on harvest of hatchery fish.
- Tagging fish, in addition to Mark Select would increase the amount of knowledge obtained through monitoring. (Note: tagging is crucial for management actions leading to the recovery of listed species and providing a knowledge base for management actions.)

Problem(s) with Action as Written:

1. Effectiveness of program largely dependent on implementation and especially monitoring
2. It would be difficult, if not impossible, to limit all commercial and recreational harvest to marked fish (Excerpt F, Attachment A). Different stocks mix in the ocean, so you can't target a specific stock. These mixed stock fisheries encompass multiple watersheds and states.
3. NMFS is not convinced that this approach will address the issue of take of protected species adequately (Mohr 2009, PSC-SFEC 2003, 2005, 2008a,b).

Existing M-S fisheries in WA and OR have met with mixed success (Lindsay et al. 2004).

Scale of Action:

Large

Rationale:
Action will affect all hatcheries. Will affect both ocean and inland harvest, population, ecosystem. Action would be continuous over the long term. Action has never been implemented in California.

Evaluation Summary

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

Relation to Existing Conditions:

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

YES

Nature of Change: Major change in ecosystem and population dynamics.

This action would cause a major change in ecosystem and population dynamics through its effects on harvest/hatchery management.

Note: There is an existing mass marking program in CA for inland steelhead, which demonstrates that such a program can be implemented. The IEP is using this mass marking program to develop and implement monitoring programs to develop scientific and management information for these stocks.

Potential Positive Ecological Outcome(s)

Outcome P1: Increased population size of Central Valley Chinook salmon (all races)

General Observations

See Attachment A for detailed information regarding the following references:

Info in Support:
- Population Modeling Papers (Cramer in press)
- Salmonid conceptual model Population trends (p. 28), Hatchery fish (p. 45-46).
- Hankin (1982) Introduction (p. 286)
- ISAB (2003) Executive summary (supplementation risks & Findings 1&2; pp. iv-vi), Modeling results (p. viii, point #5).
- Lindsay et al. (2004)
- Mohr (2009)

Info in Conflict:
- PSC-SFEC (2003, 2005, 2008a,b), Mohr (2009)

Magnitude = 4 (high)

The effects of this action would be large scale, major population level effect. A mark select fishery does not guarantee that the populations of conservations stocks would increase as other stressors may exert an overriding influence on population levels.

Certainty = 3 (medium)

Supported by ecological theory. Supported by modeling studies (Cramer et al. 2008)

See Richards and Rago 1999, Lindsay et al 2004, Wertheimer 1988, Cox-Rogers et al. 1999, Grover et al. 2002, Excerpt D (J. Kindopp)

Outcome P2: Increased knowledge base regarding Central Valley Chinook salmon (population sizes, harvest rates, success of restoration programs, and other key biological parameters) for improved management

General Observations

See Attachment A for detailed information regarding the following references:
- Salmonid conceptual model Stressors: Hatchery fish (p. 45).
- JHRC (2001) p. 12
- AFS Position Paper (2009)
- ISAB (2003) Supplementation uncertainties (p. v), Finding 4 (p. xi), Primary Recommendation 3 (p. xii).
- Hankin (1982) Abstract
- Mohr (2009)
- PSC-SFEC (2005) p. 4
- PSC-SFEC (2008a) p. vii

Magnitude = 3

Knowledge base would be increased (but knowledge would be increased even more through tagging).
Assumes monitoring component.
Would be able to obtain a High certainty for population size and harvest rate as you can distinquish wild and hatchery fish.
Much better than under existing conditions.
Medium increase in knowledge for restoration success because will not allow us to distinguish among different runs/stocks/hatcheries.

Certainty = 3

Monitoring is a key element, and history indicates there is little reliability to monitoring programs. (Note: this action cannot be evaluated without monitoring and expected outcomes would not be validated; monitoring efforts are increasing with improved methodology and creative problem-solving to meet challenges in the field).

Outcome P3: Reduce competition and introgression from hatchery fish with natural fish on spawning grounds

General Observations

These benefits would occur mainly on spawning grounds and would only result if the proportion of hatchery fish to natural fish spawning were reduced. This may require some active management of which fish are allowed to reach the spawning grounds or relies on the assumption that this would be obtained through higher harvest of returning hatchery fish downstream of the spawning grounds.

See Attachment A for detailed information regarding the following references:
- AFS Position Paper 2009
- HSRG assembled info
- Goodman (2005) Abstract & Introduction (p. 374).
- Hankin (1982) Introduction (p. 286)
- Weber & Fausch (2005) Abstract
- Araki et al. (2006) Abstract
- Flagg et al. (2000) Competition (pp. 36-40).
- Mohr (2009)

Magnitude = 4

Will affect number of hatchery fish returning to spawn (HSRG 2008, Cramer et al. 2008, Kostow 2008).

Certainty = 3

Reduction in hatchery fish variable and uncertain depending on external factors (e.g. harvest management, Cramer et al. 2008).

Outcome P4: Can improve broodstock management at hatcheries (with tagging, much improved)

General Observations

Knowing which fish are natural fish and which are hatchery fish could improve harvest efficiency and broodstock management. If implemented in coordination with sorting weirs, this could reduce competition and genetic effects relating to hatchery fish reaching the spawning grounds. It could also improve broodstock management as hatchery managers would be able to better manage the proportion of wild fish that they spawn in the hatchery. However this measure could also interfere with the data collection methods used by conservation hatcheries, requiring them to use alternative and more expensive techniques to assess their success.

See Attachment A for detailed information regarding the following references:
- AFS Postion Paper (2009)
- Araki refs (NEED SPECIFIC INFO)
- HSRG assembled info (www.lltk.org)
- ISAB (2003) Supplementation uncertainties (p. v).

Magnitude = 4

Would provide ability to control input of wild broodstock.

Certainty = 4

Would provide ability to identify wild broodstock. Would not affect ability to detect strays from other hatcheries.

Potential Negative Ecological Outcome(s)

Outcome N1: Complicates management and data acquisition for conservation hatcheries (e.g., Livingston-Stone) and associated agency sampling programs

General Observations

See Attachment A for detailed information regarding the following references:
- Excerpt A, Attachment A (J. Smith)
- Excerpt B, Attachment A (J. Smith)
- Excerpt C, Attachment A (J. Smith)
- PSC-SFEC (2003) pp. 6,7,9,10, 15, Figs 1&2
- PSC-SFEC (2005) pp. 10, 11
- PSC-SFEC (2008a) pp. 6, 22
- PSC-SFEC (2008b)
- Alexandersdottir (2007)

This outcome assumes conservation hatcheries will mark with same technique and these fish will be indistinguishable from production fish. Problem could be partially mitigated if conservation fish are marked differently from production fish.

Magnitude = 4

Conservation fish will be harvested at a different rate than non-conservation fish and thus the use of non-conservation fish as surrogates for conservation fish management objectives could be adversely affected.

Certainty = 4

This impact would occur under current monitoring program for conservation hatcheries. Marking at conservation hatcheries would need to be modified to accommodate this. These modifications could be expensive. This would not alleviate the problem of no longer being able to use production fish as surrogates for conservation hatchery fish in making management decisions.

Outcome N2: Action may lead to increased harvest of hatchery fish, which may result in higher bycatch of covered salmonids

General Observations

Outcome N2 relates to bycatch mortality. If there is increased incidence of bycatch for conservation species, this could result in higher mortality for conservation stocks. However, this is a management issue. Currently, there is no information on bycatch of conservation stocks, as fish are not marked and every fish caught is kept.

This action would allow for the clear distinction of hatchery fish from naturally produced fish, if carried out universally. This would allow more directed take of hatchery fish in the fishery. However, there would be societal pressure to maximize this take. Currently, conservation stocks are taken in the creel, so there is high mortality in the fishery. Under the M-S fishery these fish would continue to be caught, but they would be released. If maximizing the take of hatchery fish results in increased bycatch of naturally produced fish, naturally produced stocks may be impacted through increased catch and release or drop-off mortality associated with more frequent encounters with fishing gear (this mortality is estimated to range from 14 to 42 percent, depending on fishing technique). This type of effect might be avoided by implementing closures based on bycatch rates, supported by a reporting system that would facilitate such "real-time" management decisions.

See Attachment A for detailed information regarding the following references:
- Excerpt D, Attachment A (J. Kindopp)
- Excerpt E, Attachment A (B. Cavallo)
- Hankin (1982) Introduction (p. 286)
- Kostow (2008) p. 5 ("Large releases of hatchery fish" section, 2nd paragraph)

Magnitude = 2

See Excerpt D and E.

Certainty = 2

Outcome N3: Action may lead to sociological pressure for increased hatchery production

Not evaluated.

Important Gaps in Information and/or Understanding

Data Needs

- Non-catch mortality is not well-documented in the literature.
- Anecdotal information from the Feather River indicates that non-catch mortality appears significant (Jason, Brad).
- Approaches to management of conservation stocks that do not utilize surrogate production fish as an indicator of conservation fish need to be developed.

Assess Reversibility and Opportunity for Learning

Reversibility

Yes, easy.

Comments: This program would be easy to terminate once implemented.

Opportunity for Learning

Medium

Comments: This action will provide an opportunity for learning. This opportunity would be increased through a tagging program. This action may also increase the difficulty and expense of some programs to assess the success of conservation hatchery programs. Implementation of this action may require coordination among other regional marking and monitoring programs in the state of California.

DRERIP Evaluation Workshop – Attachment A

Mark-select Program

OUTCOME P1: INCREASED POPULATION SIZE FOR WILD CHINOOK

1. Salmonid conceptual model

   - Sharp declines for fall-run in recent years. Increasing influence of hatchery fish may be involved, but particular mechanism is unknown. Recent haphazard sample of 100 fish from the party-boat fishery was 90% hatchery fish (Population trends section, p. 28).

   - Hatchery Chinook compete with naturally produced salmon in the Delta. Large numbers of hatchery fish may attract predators that reduce survival of naturally produced fish. Hatchery fish may also conceal or divert attention from the condition of wild or naturally reproducing fish. This is particularly the case when few hatchery fish are marked (Stressors: Hatchery fish, p. 45).

2. Hankin (1982)

   - Hatchery stocks may withstand higher harvest rates (due to higher egg to smolt survival and greater numbers of returning adults per spawning female). “Increasing reliance on hatchery returns may promote and sustain fishery harvest rates exceeding those that wild stocks may withstand” (Introduction, p. 286). (from A. Willy)

3. ISAB (2003)

   - Executive Summary (supplementation risks & Findings 1&2; pp. iv-vi).
   - Modeling results (p. viii, point #5):

“*Supplementation can result in decreased fitness of the target population*. Whether it does so, and to what extent, depends on the particular magnitudes of the pertinent parameters, e.g., the initial hatchery and natural spawning replacement rates, the broodstock mining rates, *the harvest selectivity*, as well as the degree of the negative correlation between natural spawning and hatchery spawning fitness.” (from E. Floyd)

4. Goodman (2005)

   - Negative effects of hatchery fish include competition, predation, overharvest of wild fish, inbreeding depression. Document potential for substantial erosion of natural spawning fitness (Abstract & Introduction, p. 374) (from E. Floyd).

5. Weber and Fausch (2005)

   - Evidence of negative effect of hatchery fish on wild fish growth (Abstract, p. 44) (from E. Floyd).

6. Flagg et al. (2000)

   - Competition (pp. 36-40), Predation (pp. 46-49), Fish Health (pp. 54-55), Migratory Behavior (p. 56) (from E. Floyd).

7. Lindsay et al. (2004)

   - Demonstrated that a selective sport fishery in the lower Willamette River, OR could be used to reduce harvest mortality on Wild Chinook Salmon while maintaining fishing opportunities for hatchery Chinook. Harvest of wild Chinook was estimated to be 12.2% (from J. Kindopp).

8. Mohr (2009)

   - Fishery mortality rates for unmarked fish may increase or decrease. This will depend on marked/unmarked rations in ocean, allowable fishing effort and marked fish mortality rates, hook and release mortality, and the number of repeat encounters.

   - Constant fractional marking (CFM) allows for estimating of percentage of strays, but does not allow for control over individuals as 100% marking would (from E. Floyd).

Info from NMFS (Watalis):

1. Arguments for Mass Marking/ Mark Selective Fisheries:

Mass marking (MM) and Mark Selective Fisheries (MSF) would allow for greater control of hatchery versus natural fish in spawning areas. In some years, MM and MSF may reduce the number of hatchery strays due to greater harvest rates, and increase the information on marked fish. There could also be a possible increase in California commercial fishery opportunity and harvest, dependent on the mark-ratio and other factors.

2. Arguments against Mass Marking/ Mark Select Fishery

MM and MSF will not restore listed Evolutionarily Significant Units (ESUs) because there will be pressure to increase harvest rates on marked-fish to maximum levels possible (subject to ESA constraints) without a net reduction in fishery impacts on listed stocks. MM and MSF will not ensure recovery of listed fish; recovery is really contingent on all Viable Salmonid Population (VSP) parameters (abundance, productivity, diversity and spatial structure) of fish populations and ESUs.

Supplemental monitoring in the form of Genetic Stock Identification would be required to determine the impact of MSF on listed stocks, and its prohibitive cost for tissue sampling and typing makes this impractical. Therefore, no data would be generated on commercial harvest impacts to listed stocks.

More research needs to be conducted on the all consequences of MSF. The current work on MM and MSF: 1) does not consider that Northern CA fisheries are largely constrained from expansion because of coho incidental impacts, and 2) incorrectly models Klamath River fall Chinook harvest allocation agreements, stock dynamics, and stock distribution.

Other considerations:

- costs and consistent implementation for all CA production programs
- change in management of listed hatchery conservation fish
- new fishery assessment, forecast and management models would need to be developed
- the CA recreational fishery harvest from Fort Bragg to Mexico would decrease
- there would be no change in season length (set by limits to coho incidental mortality)

- harvest would be reduced because of release of nonmarked fish (not popular)
- fisheries will still be closed in poor years for maximum escapement to maintain hatchery runs

OUTCOME P2: INCREASED KNOWLEDGE BASE FOR IMPROVED MANAGEMENT

1. Salmonid conceptual model

   - Hatchery fish may conceal or divert attention from the condition of wild or naturally reproducing fish. This is particularly the case when few hatchery fish are marked (Stressors: Hatchery fish section, p. 45).

2. JHRC (2001)

   - "There is no solid data base at present upon which to project the natural escapement of any race of Central Valley Chinook for the coming year (p. 12)."

   - "…the management hazards posed by the masking effect are worrisome because masking is definitely occurring, and the odds of making management mistakes because of this are high. The masking problem could be solved with constant fractional marking of all hatchery production (Hankin 1982, Hankin and Newman 1999), and careful genetic and behavioral studies of naturally-spawning fish (p. 12)."

3. AFS Position Paper (2009)

   - "In order to enhance opportunity for improved salmon management, and minimize genetic and ecological impacts of hatchery programs, the Cal-Neva Chapter of the American Fisheries Society proposes and supports 100% marking (by adipose fin clip) all fall run Chinook salmon produced at Central Valley (CV) and Klamath anadromous fish hatcheries."

4. ISAB (2003)

   - "…supplementation (with unmarked hatchery fish) can introduce uncertainty through masking the numbers of natural-origin fish, making a determination of reproductive success difficult (for both natural-origin and hatchery-origin fish)" (Supplementation uncertainties section, p. v).

   - Current monitoring and evaluation efforts are inadequate to estimate either benefit or harm from ongoing supplementation projects. The correct parameters are not being consistently measured (Finding 4, p. xi).

   - To reduce uncertainty and to contain the risk of long-term impacts, all supplementation programs should be conducted within an explicit experimental design that is accepted by all affected parties (Primary Recommendation 3, p. xii) (from E. Floyd).

5. Hankin (1982)

Accurate discrimination between river returns of wild and hatchery anadromous Pacific salmon (*Oncorhynchus* spp.) is necessary if the status of the two stocks is to be monitored and if the success of hatchery mitigation programs is to be assessed. Usual hatchery management practices, including release of large numbers of unmarked fish and variable fractional marking of releases, prevent such discrimination. Many Pacific-coast salmon hatcheries presently release some fish with an adipose fin clip and a binary-coded wire tag inserted in the nasal region (AD–CWT). If a constant fraction of remaining releases carried a distinctive identifying mark, then the proportion of hatchery fish in subsequent spawning runs could be estimated. Should the majority of hatchery fish in the spawning [illegible]

- "The variance in an estimated proportion of hatchery fish in the run depends strongly on the fraction of releases marked in excess of AD-CWT releases. The variance declines substantially as this fraction increases from 0.05 to 0.25, but marking fractions above 0.5 give little further statistical improvement" (Abstract). Indicates that marking all fish may not be necessary.

- Sample sizes needed to estimate the hatchery fish proportion decline as the number of hatchery fish marked increases (Abstract).

- Variance in escapement estimators increases when a high proportion of hatchery fish stray (should not release hatchery fish away from the hatchery rearing site to avoid this problem) (from A. Willy).

6. Mohr (2009)

   - Increased information on marked fish.

   - Greater control of hatchery vs. natural spawning interactions possible.

   - Need universal implementation for program to be effective (consistency among all CA production hatcheries). May not be possible due to economic and logistic constraints (100% CWT is expensive and physically difficult to accomplish).

   - Would be unable to assess impacts of fisheries on listed stocks (from E. Floyd).

7. SFEC (2005), SFEC (2008a)

   - Mass marking and CWT sampling programs are no longer synchronized among agencies. U.S. mass marking initiatives are in conflict with sampling programs in California, Alaska and Canada. The differences in sampling and tagging methodologies will impact efficacy of evaluation programs and management (SFEC 2005, p. 4; SFEC 2008a, p. vii) (from S. Witalis).

OUTCOME P3: REDUCE COMPETITION AND INTROGRESSION FROM HATCHERY FISH

1. AFS Position Paper (2009)

   - "Accumulating data indicate that hatchery-origin fish have lower fitness in natural environments than their wild counterparts (see Araki et al. 2008 for review) and that hatchery origin fish compete with natural origin fish for spawning habitat (Hatchery Scientific Review Group 2008)(p.1)".

2. Goodman (2005)

   - Negative effects of hatchery fish include competition, predation, overharvest of wild fish, inbreeding depression. Document potential for substantial erosion of natural spawning fitness (Abstract & Introduction, p. 374).

3. Hankin (1982)

   - Interbreeding of wild and hatchery fish might reduce genetic fitness of subsequent generations (Introduction, p. 286).

4. Weber and Fausch (2005)

   - Evidence of negative effect of hatchery fish on wild fish growth (Abstract).
   -

5. Araki et al. (2006)

   - Evidence of reduced fitness in fish from traditional hatchery breeding in river relative to wild fish (Abstract) (from E. Floyd).

8. Flagg et al. (2000)

   - Evidence that wild and hatchery fish utilize same habitat and eat same food resources in some cases (Competition section, pp. 36-40).

9. Mohr (2009)

   - Decreased number of hatchery strays in some years due to greater harvest rates.

OUTCOME P4: CAN IMPROVE BROODSTOCK MANAGEMENT PRACTICES

1. AFS Position Paper (2009)

   - "Allows biologists to manage hatchery broodstock and natural spawning escapement such that the natural environment (rather than the hatchery) drives adaptation and fitness.
     - Hatcheries could improve genetic fitness of hatchery broodstock by including known natural origin fish
     - Broodstock segregation weirs could be operated on some rivers to limit hatchery origin fish spawning naturally
     - Better genetic diversity and fitness among natural origin Chinook stocks will improve resilience to changing environments such as poor ocean conditions observed in 2005 (p. 2)."

2. ISAB (2003)

   - "…supplementation (with unmarked hatchery fish) can introduce uncertainty through masking the numbers of natural-origin fish, making a determination of reproductive success difficult (for both natural-origin and hatchery-origin fish)" (Supplementation uncertainties section, p. v).

OUTCOME N1: COMPLICATES MANAGEMENT AND DATA FOR CONSERVATION HATCHERIES

1. SFEC (2003), SFEC (2005), SFEC (2008a), SFEC (2008b), Alexandersdottir (2007)

   - Conversion to ETD (necessitated by implementation of MM and MSFs) results in numerous impacts to agency sampling programs: increased equipment costs, complexity of sampling process, need for more data collection, greater dependence on proper sampling technique, slower sampling process, physically demanding sampling process (SFEC 2003, p. 6; SFEC 2008a, p. 6).

   - Data analysts will have to understand and interpret a more complex data set; potential for misinterpretation of recovery data with implementation of MSFs (SFEC 2003, p. 7).

   - Because there are no direct methods of measuring incidental unmarked mortality, estimations must be made based on more assumptions and inference, adding uncertainty to estimates of total fishery-related mortality (SFEC 2003, p. 9). "The impact on assessments of exploitation rates of wild stocks may be more substantial" (SFEC 2003, p. 10).

   - Modeling could be used to assess negative impacts of MSFs (SFEC 2003, p. 15).

- SFEC (2003) Fig 1. Quality criteria for evaluating MSF effects on viability of the CWT system; Fig

2. Examples of proposal evaluations (from S. Witalis).

- Implementation of mass marking programs can have impacts on CWT data integrity (SFEC 2005, p.11). Under a mark-select fishery, tagged and untagged do not have same exploitation rate, and

  cannot extrapolate unmarked (wild) exploitation rate from recovery of marked fish (Alexandersdottir 2007, from E. Floyd). Must use a DIT approach, combined with ETD, for this to work, but ETD is very expensive on a large scale (SFEC 2005, p.11) (from S. Witalis).

- Mass marking will result in increased encounters with marked, untagged fish by visual sampling programs. Processing these untagged fish may impact agency sampling programs, potentially increasing the sampling effort and financial burden on these agencies, and reducing CWT recovery rates (SFEC 2005, p. 10; SFEC 2008a, p. 6) (from S. Witalis).

- Some concern over whether there is adequate DIT coverage considering the expanded mass marking of Chinook (SFEC 2008a, p. 22).

OUTCOME N2: ACTION MAY LEAD TO INCREASED HARVEST, RESULTING IN INCREASED MORTALITY OF COVERED SALMONIDS

1. Hankin (1982)

   - Hatchery stocks may withstand higher harvest rates (due to higher egg to smolt survival and greater numbers of returning adults per spawning female). “Increasing reliance on hatchery returns may promote and sustain fishery harvest rates exceeding those that wild stocks may withstand” (Introduction, p. 286).

2. Kostow (2008)

   - Large releases produced tens of thousands of adult hatchery fish that supported high harvest rates (p. 5, “Large releases of hatchery fish” section, 2nd paragraph).

Issues Pertaining to Mass Marking and Mark-Selective Fisheries

Differential fishery impacts on natural fish and their hatchery indicators

Because marked hatchery fish and unmarked natural fish are no longer subject to the same patterns of exploitation under mark-selective fisheries, CWTs on hatchery indicator stocks can no longer serve as suitable surrogates to evaluate and monitor fishery impacts on natural stocks. In the presence of mass marking and mark-selective fisheries, impacts on natural stocks cannot be inferred from direct sampling because unmarked fish must be released. In addition, analytical results increasingly rely upon new assumptions on fishery impacts that are difficult to validate (e.g., assumed values for release and drop off mortality rates, plus mark retention and unmarked recognition error).

A concept termed Double Index Tagging (DIT) has been proposed as a means to provide data to help evaluate the impact of mark-selective fisheries on natural stocks. With DIT, two groups of fish with CWTs are released, identical in every respect except that: (a) the groups carry different CWT codes; and (b) only one of the groups is mass marked. When these fish are subjected to mark-selective fishing, fish from the unmark DIT pair are released while fish from the marked DIT pair are retained. In mark-selective fisheries, only CWTs from the marked DIT pair can be recovered while in non-mass-selective fisheries, CWTs from both marked and unmarked DIT releases could be collected.

With DIT, CWT recovery programs for fisheries and spawning escapements now must sample both marked and unmarked fish, must be provisions for recovering CWTs in both mark-selective and non-mark selective fisheries on the same stock. In theory, differences in recovery patterns between the DIT pairs would be used to assess the effect of mark-selective fishing.

DIT effectively doubles tagging costs for indicator stocks because now two groups of fish would need to be tagged. The number of fish in each group could not be reduced because of increased uncertainty surrounding recovery statistics.

Report of the Expert Panel on the Future of the Coded Wire Tag Recovery Program for Pacific Salmon, Pacific Salmon Commission Technical Report No. 18, Nov 2005,
Page 29.
http://www.psc.org/pubs/psctr18.pdf

Respond to Mass Marking and Mark-Selective Fisheries
Implement enhancements to the basic CWT system and introduce new analytical methods that are consistent with the anticipated scope of MSFs. Implementation of MSFs will ultimately depend on value judgments that must somehow balance many competing factors: a) the benefits of wild stock conservation as compared to enhanced fishing opportunities; b) the financial costs of selective fishery implementation as compared to the fishery benefits; c) the degree of uncertainty in natural stock assessments that proves politically acceptable for fishery management; and d) the theoretical viability and costs of alternative management strategies that might meet policy objectives. If MSFs are extensively implemented, our Panel has identified analytical methods and short-term enhancements to the current CWT system that could provide improved stock assessment capabilities for the CTC and CoTC. The enhancements considered should depend on the scope of MSF, including the species targeted, the geographic location of the fisheries, and the intensity of fishery exploitation.

Existing and Future Technologies that Might Complement or Replace the CWT System

Expert Panel members were provided with published reports, oral presentations, and email correspondence concerning currently available technologies and proposed future technologies that might somehow complement or replace the existing CWT system. Below we present our findings concerning two existing technologies and two emerging technologies that may have promise. The two existing technologies are otolith thermal marking and microsatellite-based genetic stock identification (GSI) methods. The emerging technologies are genetic - use of SNPs (single nucleotide polymorphisms) for stock or release group identification - and electronic – use of radio frequency identification (RFID) tags (electronic technology). We emphasize that even if these new technologies were introduced and supplemented or replaced the CWT system, the serious problems that we have identified for estimation of non-landed fishing mortalities, made more serious by mark-selective fisheries, would not be eliminated. These problems would remain.

Excerpt D (J. Kindopp) – Catch release mortality studies in ocean

There are many papers available on this topic but one paper did a very good job of summarizing most of the current work. The following is derived mostly from this review…A review of hooking mortality rates for marine recreational Coho and Chinook Salmon Fisheries in British Columbia (Cox-Rogers et al., 1999)

Catch and release mortality rates vary greatly depending on the type of fishery (mooching v. trolling), the type of bait/lure, hook size and type, depth of capture, aggressiveness of the fish, food availability, stage of maturity, age at capture, temperature of water and skill of the angler in playing and releasing the fish. Furthermore, study results vary greatly from Alaska to California depending upon the type study conducted. For example, in California, one study (Grover, 1995a) of recreational fishing mortality conducted from 1993-1995 estimated mortality as low as 11% for Chinook caught trolling to 73% for Chinook caught by mooching with anchovies. One NRC study (NRC 1998 in Cox-Rogers et al.) conducted in Oregon from 1996-1997 found hooking mortality for Chinook from 0 to 15%, depending upon the type of gear treatment used. These types of results are fairly typical up and down the Pacific Northwest. The huge range of results from these studies is mostly a byproduct of the different types of studies performed along with all of the aforementioned factors. In general, hooking mortality has been documented to be much higher in California than in Oregon, Washington or British Columbia, regardless of gear type used. It is unknown whether this is a real phenomenon or if the study designs are so different that it precludes a fair comparison (See Cox-Rogers, 1999 for a review of recent studies). It is clear that more work of this type needs to be done in California to determine the most accurate rates of hooking mortality.

Other work: Wertheimer, 1988 (23.5% mortality for legal and sublegal Chinook in commercial troll fishing in southeastern Alaska).
Lindsay et al. (2004) demonstrated that a selective sport fishery in the lower Willamette River, OR could be used to reduce harvest mortality on Wild Chinook Salmon while maintaining fishing opportunities for hatchery Chinook. Harvest of wild Chinook was estimated to be 12.2%.

Bendock and Alexandersdottir (1993) demonstrated that a hook-and-release fishery can effectively reduce sport fishing mortality and help achieve escapement goals in the Kenai River, Alaska.

Excerpt E (B. Cavallo) – Catch/Release and Non-Catch Mortality Review

Commercial and recreational fishing in the Pacific Ocean south of Cape Falcon, Oregon, are conducted by trolling, and a technique known as “mooching” has also become popular among recreational fishermen, by which a baited hook is slowly jigged from a drifting vessel (Boydstun 2001). Both harvest methods lead to fish being either released voluntarily, due to size regulations (catch and release), or hooked but not landed (drop-off). A portion of those fish die as a result of capture or attempted capture.

Catch-and-release mortality (CRM) rates vary between methods of capture for commercial and sport fisheries (PFMC 2008b). CRM in commercial troll fisheries is assumed to be 26% by the PFMC. Fish caught while mooching are more likely to swallow bait and hook than during trolling, and extraction of swallowed hooks results in higher CRM rates than for fish hooked in the mouth (Grover et al. 2002). PFMC’s Salmon Technical Team estimated CRM due to mooching at 42.2%, and recreational trolling at 14% (PFMC 2008b). Based on the expected proportion of fish caught using mooching versus trolling, the aggregate catch and release mortality for recreational fisheries south of Point Arena was estimated to be 16% (PFMC 2008b). As part of a retrospective analysis to examine the potential fishery benefits of mark-selective fisheries in California, Cramer (2008) further aggregated CRM for fall Chinook caught in recreational and commercial fisheries in the Pacific Ocean using a weighted average CRM of 24% (assuming 75% of harvest occurred in the commercial fisheries).

In addition to CRM mortality, fish that are hooked but not landed may incur increased mortality rates, deemed drop-off mortality. Drop-off mortality may be caused by gear remaining embedded in escaped fish, or increased predation rates due to restricted movements caused by the fishing line (Lawson and Sampson 1996). Unfortunately, it is not feasible to estimate drop-off mortality rates experimentally because the process is unobserved. However, for a given fishery it is reasonable to expect the drop-off mortality rate to be lower than, but related to, the corresponding CRM rate (Lawson and Sampson 1996). Cramer (2008) and Pacific Fishery Management Council (2008a) arbitrarily assume a drop off mortality rate of 5% for fall Chinook in the Pacific Ocean.

After initial release or drop-off, additional mortality may occur because some fish will be hooked and released more than once (Lawson and Sampson 1996; Cramer 2008). Therefore, mortality rates likely increase with repeated gear encounters. However, once hooked, a fish is possibly less likely to be hooked again. Studies with rainbow trout caught in catch and release fisheries, indicate that surviving fish learn to avoid being caught again (Askey et al. 2006). No similar experiments have been conducted with Chinook or coho salmon, but it is possible their catchability would likewise drop with each capture (Cramer 2008).

Excerpt F (S. Witalis) – Get and review NMFS BiOp for ocean harvest. How many covered fish are allowed to be harvested now?

Background

NMFS manages ocean salmon fisheries in the 3-200 mile exclusive economic zone (EEZ) off the U.S. coasts. Annual fishery management recommendations are developed by the Pacific Fisheries Management Council (PFMC) in accordance with the Pacific Coast Salmon Fisheries Management Plan (FMP) for the EEZ off the states of Washington, Oregon and California. PMFC provides its recommendations to the Secretary of Commerce, who implements the measures if found to be consistent with the Magnuson-Stevens Fishery Conservation and Management Act (MSA) and other applicable laws, including the Endangered Species Act (ESA).

In California, ESA Section 7 consultations analyze the effects of FMP and recommendations on endangered Sacramento River (SR) winter-run Chinook salmon, threatened Central Valley (CV) spring-run Chinook salmon, threatened California Coastal (CC) Chinook salmon, threatened Southern Oregon-Northern California Coastal Coho (SONCC), and endangered Central California Coastal (CCC) Coho. NMFS collaborates with affected states and PFMC to ensure ocean salmon fisheries are monitored and sampled for stock composition, including the collection of CWTs and other biological information for post season analysis of fishery impacts on listed species.

The biological opinion on the FMP for SR winter-run will be reinitiated by NMFS in 2009 in order to be in place at the start of the 2010 fishing season. NMFS will also consider if reinitiation of the other FMP biological opinions (i.e., for the other listed Chinook and Coho) at this time is warranted.

Harvest Limitations in Place

The MSA requires all Federal fisheries to be managed to prevent overfishing, which could lead to an overfished state, and to rebuild any stock determined to be overfished. Ocean salmon fisheries off California target Sacramento River fall Chinook and Klamath River fall Chinook. Because salmon stocks intermingle in the ocean and are caught together, the fishery is a mixed stock fishery and is managed to prevent overfishing on the weakest stock and to be consistent with ESA jeopardy

standards for listed salmon species affected by the fisheries. There is also prohibition on retention of California Coastal Chinook and all California coho.

Chinook: California Central Valley (CA CV) Complex

The CA CV complex in the FMP includes all fall, late-fall, winter, and spring stocks of the Sacramento and San Joaquin Rivers and their tributaries. Management of this complex is based primarily on Sacramento River fall Chinook, which includes a large hatchery component, and natural Sacramento River winter Chinook, which are listed as endangered.

Sacramento Fall-run Chinook (Not ESA listed)

The Salmon FMP sets the escapement goal for Sacramento River fall Chinook as a range from 122,000 to 180,000 adults. This stock comprises approximately 80-90 percent of the escapement of all Chinook stocks that return to Central Valley streams and hatcheries. The Central Valley Index (CVI), which provides an annual index of abundance for the combined Central Valley Chinook stocks, is the sum of ocean fishery Chinook harvests in the area south of Point Arena plus the Central Valley adult Chinook spawning escapement. The CVI harvest index is the ocean harvest landed south of Point Arena divided by the CVI. Since 1991, the Council's Salmon Technical Team (made up of scientists from NMFS, USFWS, and state fisheries agencies from OR, WA, and CA) has used a linear regression of the CVI on the previous year's Central Valley age-2 return to forecast the CVI. A new model is being developed that focuses on the Sacramento run.

Sacramento River Winter-run Chinook (ESA listed – Endangered)

PFMC is required to reduce ocean harvest sufficiently to increase the adult spawning escapement by 31% relative to a base period (1989-1993). Since 1992, the commercial troll effort off California has been largely limited to San Francisco and Monterey areas. Fishing seasons are severely restricted in areas north of Pt. Arena to allow longer seasons south of Pt. Arena and permit access to CV fall Chinook. In addition, commercial and recreational salmon fisheries between Pt. Arena and Pigeon Pt./Pigeon Pt. and Mexico border are restricted by time and fish length limits, from April/May through early October/November. Based on 1969 and 1970 cohort reconstruction of marked winter Chinook, it was ascertained that 80% of all recoveries occurred in the recreational fishery and 28% of all recoveries occurred in the February and March recreational fisheries. Over 95% of the landings occurred south of Pt. Arena, CA and 74% of all landings occurred in the recreational fish south of Pt. Arena. Analysis of CWT allows for analysis of effectiveness of current fishing regulations.

Central Valley Spring-run Chinook salmon (ESA listed – Threatened)

There are no FMP objectives in place specifically regulating the harvest of spring-run except that the FMP will manage ocean fisheries consistent with NMFS ESA consultation standards. The current FMP harvest constraints on winter-run serve as proxy for CV spring-run. Feather River Hatchery spring-run provides indices of harvest of natural spring-run. Maturing age-3 and age-4 spring Chinook are vulnerable to the early portion of the recreational and commercial season, whereas fall Chinook are exposed to an entire harvest season. Inferences drawn from coded-wire tag recoveries indicate that 44% of the spring-run are taken prior to May 1, the start of the commercial fishing season.

Northern California Coast Chinook Complex

The Northern CA Coast Chinook complex in the FMP includes all fall and spring stocks of California streams north of the entrance to San Francisco Bay. Management of this complex is based primarily on meeting spawning escapements for natural fall Chinook.

Klamath River Fall Chinook (KRFC) (Not ESA listed)

The Council's FMP conservation objective for Klamath River fall Chinook permits a natural spawner reduction rate via fisheries of no more than 0.67, with a minimum escapement of 35,000 natural spawning adults and an age-4 ocean harvest rate of 16.0 percent to meet the NMFS ESA consultation standard for protection of California coastal Chinook. NMFS uses the Klamath Ocean Harvest Model (developed from historical catch and spawning populations of KR fall Chinook) to predict the age-specific harvests rates on Klamath River fall Chinook resulting from proposed management measures. The harvest rate of age-4 KR fall Chinook is an indicator of the percentage reduction in adult (age 3, 4 and 5) spawning abundance due to harvest. The harvest rate of 0.16 is the maximum rate observed since 1996, the year in which additional ESA requirements to protect winter-run Chinook were put in place. The decrease in commercial fishing effort off northern and central California is in part due to the KR fall Chinook harvest allocation to in-river tribal fisheries (50% of fall-run escapement back to the Klamath River).

California Coastal (CC) Chinook (ESA listed – Threatened)

There are no PFMC goals or FMP objectives currently in place for CC Chinook. PFMC will manage ocean fisheries consistent with NMFS' ESA consultation standards. California coastal Chinook management relies on the indirect measure of the preseason prediction of the Klamath Ocean Harvest Model. Fishing mortality on CC Chinook is almost entirely limited to ocean harvest and is similar to ocean harvest rates on KRFC to the extent that ocean distribution of the stocks are the same. The California Fish and Game Commission has prohibited retention of Chinook salmon in all streams within the CC Chinook ESU.

Oregon Production Index Area Coho Complex

This FMP complex includes all WA, OR, and CA natural and hatchery coho stocks from streams south of Leadbetter Pt. Those found in CA are described below.

Southern Oregon/Northern California Coast (SONCC) Coho (ESA listed – Threatened) The SONCC coho ESU includes all naturally spawned populations of coho salmon in coastal streams from the Elk River, Oregon, through the Mattole River, California. It also includes three artificial propagation programs: Cole River Hatchery in the Rogue River Basin, Trinity River and Iron Gate Hatcheries in the Klamath-Trinity River Basin. Coho south of Cape Blanco have a southerly recovery pattern primarily in California (65-92% recovery). Exploitation rates on SONCC CA coho are expected to be similar to exploitation rates estimated by the PFMC for the Klamath/Rogue hatchery coho stocks (5% to 12%) to the extent of shared distribution pattern. PFMC recommendations have resulted in the prohibition of coho retention south of Cape Falcon since 1994, although coho are still impacted by hook-and-release mortality in Chinook-directed fisheries.

Protection for CA populations is the limitation on harvest rates and management of all listed stocks consistent with ESA consultation standards. Management measures developed under the FMP must be designed to achieve an ocean exploitation rate on Rogue/Klamath hatchery stocks of no greater than 13%, the lowest exploitation rates specified under Amendment 13 for OCN subaggretages.

Reinitiation of consultation is contingent on the development of monitoring programs that can permit a better assessment of population trends.

Central California Coastal (CCC) Coho (ESA listed – Endangered)

The CCC ESU consists of all coho reproducing in streams between Punta Gorda and the San Lorenzo River, including the Warm Springs Hatchery, and the Kingfisher Flat Hatchery coho stocks and associated captive broodstock at the SWFSC. Incidental exploitation rates on CCC coho are expected to be similar to exploitation rates (5 – 12%) estimated by the PFMC for the Klamath/Rogue hatchery coho stocks to the extent that ocean distributions of CCC coho and SONCC are similar. Reduced fishing effort off California and a continued prohibition on coho fisheries and coho retention in Chinook fisheries insures that incidental mortality of CCC coho remains low (encounters have been reduced by 25%); incidental take of CCC coho associated with ocean salmon fisheries authorized under the FMP cannot be assessed at this time. This also ensures that mortality rates on California coho stocks associated with the fishery do not increase until adequate assessment of parent spawner recruitment rates can be carried out.

Outcome Code	Covered Spp.	Description	Magnitude	Certainty
Positive Outcomes				
P1	Chinook Salmon	Increased population size of Central Valley Chinook salmon (all races)	4	3
P2	Chinook Salmon	Increased knowledge base regarding Central Valley Chinook salmon (population sizes, harvest rates, success of restoration programs, and other key biological parameters) for improved management	3	3
P3	Chinook Salmon	Reduce competition and introgression from hatchery fish with natural fish on spawning grounds	4	3
P4	Chinook Salmon	Can improve broodstock management at hatcheries (with tagging, much improved)	4	4
Negative Outcomes				
N1	Chinook Salmon	Complicates management and data acquisition for conservation hatcheries (e.g., Livingston-Stone) and associated agency sampling programs	4	4
N2	Chinook Salmon	Action may lead to increased harvest of hatchery fish, which may result in higher bycatch of covered salmonids	2	2
N3	Chinook Salmon	Action may lead to sociological pressure for increased hatchery production	?	?

Action Description and Clarifying Assumptions

Establish artificial propagation programs for delta smelt and longfin smelt.

Approach

1. Fund a conservation hatchery program to restore Delta smelt and longfin smelt to self-sustaining levels in the wild. A new facility would:
   a. House genetically-managed refuge population sufficiently to minimize loss of genetic diversity,
   b. Provide fish stocks to augment existing populations and provide fish stocks for reintroduction where necessary.
2. Fund efforts by the UC Davis Fish Conservation and Culture Laboratory (FCCL) to expand the refugial population of Delta smelt and establish a refugial population of longfin smelt. The goal of the FCCL's refuge program is to preserve populations and genetic diversity of smelt. The laboratory also provides Delta smelt for multiple research efforts that will further our understanding of the threats to and management options for this species.

Intended Outcomes as Stated in Conservation Measure

1. Increased population sizes of Delta smelt and longfin smelt to self-sustaining levels in the wild.
2. Preserve genetic diversity of delta and longfin smelt.
3. Improved knowledge base about threats to and management of the species stemming from ability to study the effects of various stressors on these species using hatchery reared specimens.

General Conceptual Model Support for Intended Outcomes

1a. Increased population sizes of Delta smelt: Yes, implied in Delta smelt model p. 17, via prevention of Allee effects.

1b. Increased population sizes of longfin smelt: Uncertain, see Longfin smelt model pp. 7,8,29, uncertainty regarding life history, ecology (including breeding system), biogeography, and population viability. Increased research in these areas would improve ability to manage.

2a. Preserve genetic diversity of Delta smelt: Yes, implied in Delta smelt model p. 17, small population sizes can result in genetic problems (genetic drift, inbreeding).

2b. Preserve genetic diversity of longfin smelt: Uncertain, see Longfin smelt model pp. 8, 29, uncertainty regarding genetic independence of population, breeding system not well-studied.

3. Improved knowledge base: No conceptual model support. See support in Attachment

Assumptions

Provided in BDCP Conservation Measure

1. Genetic diversity and integrity necessary for wild survival of hatchery reared smelt will be maintained.
2. The action will produce fish that are able to survive and reproduce in the wild.

Added by Evaluation Team

1. Spawning cues may be related to total abundance (based on European smelt). Current population may be at or below this level.
   Note: Concept is that there need to be a threshold number of spawners to obtain good spawning success, and that natural populations may be below this level. Robert Clarke says that they are more concerned about swamping the natural population with hatchery releases.

2. Wild populations are not functionally extinct, however if the become so, the hatchery population may serve as a refugial population for future restoration.

Problem(s) with Action as Written:

1. Action does not discuss how fish would be returned to the environment, i.e., as fry or adults. Bob Clarke TBD by the Recovery Plan.
2. Action does not specify how fish would be collected for broodstock (see Excerpt B, Attachment A, J. Smith). For our evaluation, we have assumed adults would be collected. May be difficult to use juveniles, because they are so fragile and thus have high mortality when captured.
3. Assumptions provided with the action are not supported by experience with existing conservation hatcheries, which all report problems in maintaining genetic diversity (Turner et al. 2007)
4. Fish produced in hatcheries currently are maladapted to conditions in the natural environment and have reduced fitness relative to wild fish. These fish also have been shown to negatively affect wild populations through a variety of mechanisms. However, see Raney 1942 regarding alternate rearing techniques for silvery minnow.
5. Conservation hatcheries are generally experimental in nature and need to be managed adaptively to meet objectives. There is only one example of conservation hatcheries for group spawners (silvery minnow).
6. There is nothing in this action that would prevent it from destabilizing the population, through removal of broodstock, or through exacerbating Allee effects, which are already a problem for this species.
7. Goals of the hatchery need to be explicitly stated. This will govern hatchery procedures.

Scale of Action:

Medium to large

Rationale:

If the natural population becomes functionally extinct then it would contribute substantially and the effect would be large.

If it is used to supplement the natural population (e.g., 10% of natural population) then effect would be medium.

Evaluation Summary

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

Relation to Existing Conditions:

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

NO. This will not affect ecosystem dynamics, small biomass going into system

Potential Positive Ecological Outcome(s)

Outcome P1: Increased population sizes to self-sustaining levels in the wild

P1a. Delta smelt

General Observations

See Attachment A for detailed information regarding the following references:
- Info from other conservation hatcheries
- Flagg et al. (2000) Conservation Hatchery Protocols (pp. 29-36).
- Delta smelt conceptual model p. 17
- Carolsfeld 1997, Kowalski et al 2006, Sorensen 1998, and Sveinsson and Hara 1995 (references from A. Willy)
- USFWS (2003) pp. 31-37 (History of Conservation Measures, pp. 37-42 (Strategy for Recovery and Recovery Analysis)
- USFWS (1998) p. iv (Exec. Summary), pp. 3-7 (distribution info), pp. 14-15 (conservation measures), pp. 16-19 (recovery plan), pp. 20-40 (tasks for recovery)
- Richards et al. (2004)
- Nobriga (2008), Excerpt D (Nobriga)
- Excerpt A, Attachment A (A. Willy)

Magnitude = 3

Sustained minor population effect if supplemental. Potential large effect if wild population goes functionally extinct.

Certainty = 2

Many factors control populations in the wild that would not be affected by this action. There is considerable uncertainty regarding the fitness of any hatchery produced fish to conditions in the wild.

P1b. Longfin smelt

General Observations

See Attachment A for detailed information regarding the following references:
- Info from other conservation hatcheries
- Flagg et al. (2000) Conservation Hatchery Protocols (pp. 29-36).
- Carolsfeld 1997, Kowalski et al 2006, Sorensen 1998, and Sveinsson and Hara 1995 (references from A. Willy)
- USFWS (2003) pp. 31-37 (History of Conservation Measures, pp. 37-42 (Strategy for Recovery and Recovery Analysis)
- USFWS (1998) p. iv (Exec. Summary), pp. 3-7 (distribution info), pp. 14-15 (conservation measures), pp. 16-19 (recovery plan), pp. 20-40 (tasks for recovery)
- Richards et al. (2004)
- Nobriga (2008), Excerpt D (Nobriga)

Magnitude = 3

Sustained minor population effect if supplemental. Potential large effect if wild population goes functionally extinct.

Certainty = 1

Propagation techniques have not been established for longfin smelt.

Outcome P2: Preserve genetic diversity

P2a. Delta smelt

General Observations

See Attachment A for detailed information regarding the following references:
- Hatchery management protocols for group spawners
- Carolsfeld 1997, Kowalski et al 2006, Sorensen 1998, and Sveinsson and Hara 1995 (references from A. Willy)
- Turner & Osborne (2008) CALFED Workshop presentation.
- Delta smelt conceptual model p. 17
- USFWS (2003) pp. 31-37 (History of Conservation Measures, pp. 37-42 (Strategy for Recovery and Recovery Analysis)
- USFWS (1998) p. iv (Exec. Summary), pp. 3-7 (distribution info), pp. 12-13 (genetic considerations), pp. 14-15 (conservation measures), pp. 16-19 (recovery plan), pp. 20-40 (tasks for recovery)
- Hedgecock et al. (2000) Abstract
- Hedrick et al. (1995)
- Nobriga (2008), Excerpt D (Nobriga)
- Clarke, pers comm. to A. Willy
- Turner et al. 2007. Example of determining effective population size for a group spawner.

Magnitude = 3

Controlled breeding can increase effective population size, especially with supplementation from wild stocks.

Certainty = 2

Existing conservation hatcheries generally have reduced diversity. However, Hedrick 2004 succeeded in increasing effective population size in winter-run Chinook salmon.

P2b. Longfin smelt

General Observations

See Attachment A for detailed information regarding the following references:
- Hatchery management protocols for group spawners
- Carolsfeld 1997, Kowalski et al 2006, Sorensen 1998, and Sveinsson and Hara 1995 (references from A. Willy)
- Turner & Osborne (2008) CALFED Workshop presentation.
- USFWS (2003) pp. 31-37 (History of Conservation Measures, pp. 37-42 (Strategy for Recovery and Recovery Analysis)
- USFWS (1998) p. iv (Exec. Summary), pp. 3-7 (distribution info), pp. 12-13 (genetic considerations), pp. 14-15 (conservation measures), pp. 16-19 (recovery plan), pp. 20-40 (tasks for recovery)
- Hedgecock et al. (2000) Abstract
- Hedrick et al. (1995)
- Nobriga (2008), Excerpt D (Nobriga)

- Turner et al. 2007. Example of determining effective population size for a group spawner.

Magnitude = 3

Controlled breeding can increase effective population size, especially with supplementation from wild stocks.

Certainty = 1

Existing conservation hatcheries generally have reduced diversity. However, Hedrick 2004 succeeded in increasing effective population size in winter-run Chinook salmon. Greater uncertainty for longfin smelt because propagation techniques have not been established for this species.

Outcome P3: Improved knowledge base about threats to and management of the species stemming from ability to study the effects of various stressors on these species using hatchery reared specimens

General Observations

Research is being conducted by multiple UC Davis researchers and others into Delta smelt stressors (e.g., Inge Werner's work).

Magnitude = 4

Demonstrated through studies conducted by Werner and others.

Certainty = 4

Demonstrated through studies conducted by Werner and others.

Potential Negative Ecological Outcome(s)

Outcome N1: Genetic consequences for hatchery and wild populations

N1a. Delta smelt

General Observations

See Attachment A for detailed information regarding the following references:
- Robert Clarke, pers. comm.
- Komen et al. (2006) Abstract
- Kostow (2008) Abstract & Intro
- Fraser (2008) Abstract
- Excerpt A, Attachment A (A. Willy)

Magnitude = 3

Existing conservation hatcheries for similar species have reduced diversity (Alo and Turner 2005). Fraser 2008. Meta-analysis of Captive Breeding Programs. in Evolutionary Applications.

Certainty = 2

Fraser 2008 suggests that conservation breeding programs are highly variable in their success in preserving genetic integrity and fitness.

N1b. Longfin smelt

General Observations

See Attachment A for detailed information regarding the following references:
- Robert Clarke, pers. comm.
- Komen et al. (2006) Abstract
- Kostow (2008) Abstract & Intro
- Fraser (2008) Abstract
- Excerpt A, Attachment A (A. Willy)

Magnitude = 3

Existing conservation hatcheries for similar species have reduced diversity (Alo and Turner 2005). Fraser 2008. Meta-analysis of Captive Breeding Programs. in Evolutionary Applications.

Certainty = 1

Fraser 2008 suggests that conservation breeding programs are highly variable in their success in preserving genetic integrity and fitness. Greater uncertainly for longfin smelt because propagation techniques have not been established for this species.

Outcome N2: Negative ecological interactions with wild fish (competition, displacement)

The following applies to both delta and longfin smelt.

General Observations

See Attachment A for detailed information regarding the following references:
- Robert Clarke, pers. comm.
- Kostow (2008) Abstract & Intro
- Nobriga & Feyrer (2007)
- Nobriga & Feyrer (2008)
- Nobriga et al. (2008)
- Bennett et al. (2008) p. 4 (Figure 1), Discussion (p. 24-26)
- Miller (2005) p. 1
- Excerpt A, Attachment A (A. Willy)

Magnitude = 3

Documented depression of food resources for Delta smelt in the late summer and fall (Nobriga and Feyrer 2007, 2008; Bennett et al. 2008; Miller 2005). Increasing populations would increase competition for these food resources. Less is known about longfin smelt.

Certainty = 2

Competition would certainly occur, but impact would be variable because of the effects of external factors on food production.

Outcome N3: Mining of wild population to support broodstock needs

The following applies to both delta and longfin smelt.

General Observations

Information from the Hatchery Scientific Review Group .

Magnitude = 3

Small natural populations. May be more of a problem for longfin smelt.

Certainty = 3

We have a good understanding of catch mortality (Swanson et al. 1996) and a general understanding of the population and the location of the existing population. This allows this catch to be managed appropriately to minimize impacts to wild populations. Because longfin smelt are larger, they will likely be less sensitive to handling stress and physical injury than Delta smelt.

Outcome N4: Mortality associated with catching broodstock (genetic material lost)

N4a. Delta smelt

General Observations

Currently using Lampara nets which results in low mortality; consider collecting fish from areas where they would already be lost to entrainment.

See Attachment A for detailed information regarding the following references:
- Swanson et al. (1996) - paper on Delta smelt handling effects, pp. 326-328.
- See Excerpt B, Attachment A (J. Smith) for information about type of net used.

Magnitude = 2

Existing brood stock collection program has very low mortality (Swanson et al. 1996, Bob Clarke pers. comm. to J. Smith).

Certainty = 3

Existing studies (Swanson et al. 1996) indicate that using current techniques there is relatively low mortality associated with collection of brood stock.

N4b. Longfin smelt

General Observations

Catch mortality is expected to be lower for longfin smelt than for Delta smelt. See Attachment A for catch mortality information from Swanson et al. 1996.

Magnitude = 2

Existing studies (Swanson et al. 1996) indicate that using current techniques for Delta smelt, there is relatively low mortality associated with collection of brood stock. This suggests that mortality associated with collecting longfin smelt would also be relatively low because longfin are larger and presumably less sensitive to handling stress and physical.

Certainty = 2

Although current techniques for catching broodstock for Delta smelt are associated with relatively low mortality, brood stock collection and artificial propagation have not been conducted for longfin smelt to date.

Important Gaps in Information and/or Understanding

Data Needs

- Don't know at what lifestage stock would be collected or released.
- Little is known about spawning and rearing longfin smelt under hatchery conditions.
- If numbers produced were sufficient to supplement and encourage spawning when released into the wild, then this would be beneficial. However, the number of fish needed to boost spawning is unknown. Number needed for hatchery 60,000 to 6 million per Bob Clarke.
- Information on genetics of wild populations vs. captive populations. Is fitness of hatchery fish comparable to wild fish? All conservation hatcheries, except winter run Chinook, have reduced genetic diversity (see Excerpt A, Attachment A, A. Willy). So far there has been little success in maintaining genetic diversity in hatchery programs for group spawners. The winter run hatchery has been successful, but this is not a group spawner.
- Very little is known about longfin smelt genetics and hatchery propagation.
- Adaptive characteristics of fish are unknown.

Research Needs

- Initiate research into captive breeding of longfin smelt, perhaps using specimens from other populations in Washington or elsewhere.
- Need to discover ways to capture larval and juvenile smelt so they will survive to be brought to the hatcheries.
- Look at methods to implement hatcheries using larval or juvenile smelt as a mechanism to increase genetic diversity and reduce take of adult smelt needed to support wild populations.
- Compare genetic diversity of wild larval vs. adults smelt to reduce the risk of bottlenecks and allee effects associated with adult broodstock.
- Development of adaptive management plan with an emphasis on spreading risk and continually modifying the program to maximize genetic input to the program and minimize impacts to wild populations.
- This action should be implemented as a targeted research program to determine the best way to manage the risks inherent in such a program, before being implemented at full scale.

Assess Reversibility and Opportunity for Learning

Reversibility

Yes/easy

Opportunity for Learning

High

Comments: Current research being done on factors affecting Delta smelt by UC Davis and others using hatchery produced fish.

DRERIP Evaluation Workshop – Attachment A

Artificial Propagation of Smelt

OUTCOME P1: INCREASED POPULATION SIZES TO SELF-SUSTAINING LEVELS IN THE WILD

P1a. Delta smelt

1. Flagg et al. (2000)

    - Conservation Hatchery Protocols: Discusses potential ways in which conservation hatchery practices can enhance wild populations and gives specific examples from literature (pp. 29-36) (from E. Floyd).

2. Delta smelt conceptual model

    - “Allee effects occur when reproductive output per fish declines at low population levels (Allee 1931, Berec et al. 2006). Below a certain threshold the individuals in a population can no longer reproduce rapidly enough to replace themselves and the population spirals to extinction. For Delta smelt, possible mechanisms for Allee effects include mechanisms directly related to reproduction such as difficulty finding enough males to maximize egg fertilization during spawning (e.g., Purchase et al. 2007) or depensatory egg predation (e.g., DeBlois and Leggett 1991)” (Ecology section, p. 17). Supplementing populations via a conservation hatchery should prevent Allee effects.

3. Carolsfeld 1997, Kowalski et al 2006, Sorensen 1998, and Sveinsson and Hara 1995 (references from A. Willy)

    - As seen in other pelagic, group-spawning species, the number of males in the spawning run affects the spawning cue, milt production, and semen viability. It is unknown how many male Delta smelt are needed to cue and increase spawning when abiotic conditions are favorable for spawning.

4. USFWS (2003)

    - Provides history of conservation measures and their success and strategy for recovery used (pp. 31-42).

5. USFWS (1998)

    - Provides review of successful and unsuccessful conservation measures and methods for reintroduction and recovery (pp. iv, 3-7, 12-40).

6. Richards et al. (2004)

    - “We found that stocked and wild lake trout both contributed to restoring self-sustaining stocks in Lake Superior, which was the primary objective of all fishery management agencies involved with lake trout rehabilitation in the Great Lakes.” (from J. Smith)

7. Nobriga (2008) (from J. Isreal)

- Turner: Rio Grande Silvery Minnow

  - Trying environmentally induced communal spawning (turbidity): variable success relative to hormonally induced.
  - Will not be self-sustaining until improve river habitat.
  - AP is insurance vs. catastrophe, not a long-term solution.

- Waples:

  - Many risks are tightly inversely linked (e.g., inbreeding vs. catastrophic loss or swamping wild populations).
  - PacNW hatcheries cannot demonstrate success of ultimate goals of self-sustaining natural populations.
  - Supplemented salmonid populations not increasing relative to unsupplemented.
  - Supplementation might buffer very low abundance.

- See panel discussion (Excerpt D, Nobriga) for summary of pros and cons of artificial propagation.

P1b. Longfin smelt

*See references above for Delta smelt, excluding information from the Delta smelt conceptual model.

OUTCOME P2: PRESERVE GENETIC DIVERSITY

P2a. Delta smelt

1. Carolsfeld 1997, Kowalski et al 2006, Sorensen 1998, and Sveinsson and Hara 1995 (references from A. Willy)

   - It is unknown whether hatchery fish can be used to assist in enhancing spawning without genetically suppressing the wild population.

2. Turner and Osborne (2008)

   - Presentation discussing successful conservation hatchery practices for the Rio Grande silvery minnow, a group spawner. In-stream propagation, such as that used for Rio Grande silvery minnow captive propagation, may assist in maximizing genetic variability and studying optimal release sizes (from E. Floyd).

3. Robert Clarke, pers. comm.

   - Inbreeding depression is likely. A captive population is likely to have more of a genetic bottleneck than a wild population (from A. Willy).

4. Delta smelt conceptual model

   - Genetic problems like inbreeding and genetic drift result from small population sizes. Supplementing populations via a conservation hatchery should reduce these problems to some degree (Ecology section, p. 17).

5. USFWS (2003)

   - Provides history of conservation measures and their success and strategy for recovery used (pp. 31-42) (from J. Smith).

8. USFWS (1998)

- Provides review of successful and unsuccessful conservation measures and methods for reintroduction and recovery (pp. iv, 3-7, 12-40) (from J. Smith).

9. Hedgecock et al. (2000)

- Findings provide optimistic outlook for success of supplementation program for winter-run Chinook, suggesting that overall effective population size has not been greatly reduced. Returning spawners represented a broad sample of parents and not fish from only a few families in this study (Abstract) (from E. Floyd).

10. Hedrick et al. (1995)

- “It does not appear that the hatchery program has reduced the overall effective population size” (Abstract, from J. Smith).

11. Nobriga (2008) (from J. Isreal)

- Hedrick: Summary: small populations, inbreeding, adapt to captivity; Recommendations: large population size, minimize kin breeding, replicate populations, bring in wild genes, keep captive generations minimal, captive environment like natural environment.

- Turner: Rio Grande Silvery Minnow

    - o Low genetic diversity despite high population numbers at times, but still have significant genetic differences among populations in the river.
    - o Temporary population structure from reproductive schooling; not same groups year after year.
    - o 0.5M reproductively capable adults needed in captive broodstock, multiple facilities needed.
    - o Catching eggs and repatriating as adults is working well for maintaining genetic diversity.
    - o Augmentation increased gene diversity, but not variance in the EPS.

- Clarke: UCD and Livingston Stone, neither facility is large enough to maintain subpopulations.

- Bridges: Don’t wait; start refugial population now so do not risk loss of genetic diversity.

- Fisch: Need to know both wild fish genetics and MGD genetics to develop a good plan.

- See panel discussion notes (Excerpt D, Nobriga) for summary of pros and cons of artificial propagation.

P2b. Longfin smelt

*See references above for Delta smelt, excluding information from the Delta smelt conceptual model.

OUTCOME P3: IMPROVED KNOWLEDGE BASE ABOUT THREATS TO AND MANAGEMENT OF THE SPECIES

1. Current research being conducted by UC Davis and others into Delta smelt stressors

- e.g., Dr. Inge Werner (Aquatic Toxicology Lab, UC Davis), effects of chemical contaminants on survival, behavior.

OUTCOME N1: GENETIC CONSEQUENCES FOR WILD AND HATCHERY POPULATIONS

N1a. Delta smelt

1. Robert Clarke, pers. comm.

   - FWS policy is that reintroduction of species happens when a captive population can help support a wild population (negative genetic consequences would have to be negligible for supplementation to occur). It may be difficult to assess genetic consequences for wild fish.

   - Plan to introduce 10% of the effective breeding population size; "enough to work, but not so much as to swamp the population." Uncertainty on how many to introduce (estimate between 60,000 and 6 million fish).

   - Plan to model breeding protocols after Rio Grand silvery minnow (i.e., cultivated in channels, where flow and water quality are controlled, and many generations are kept concurrently. This will allow for group spawning.). Mating structure is not known when group spawning takes place, and this may result in increased rates of inbreeding (see Komen et al. 2006) (from E. Floyd).

2. Kostow (2008)

   - Review paper outlining potential negative effects of hatchery fish on wild populations, and ways to mitigate these impacts (Abstract & Intro provide good overview) (from J. Isreal).

3. Fraser (2008)

   - Suggests that conservation breeding programs are highly variable in their success in preserving genetic integrity and fitness (Abstract) (from J. Isreal).

N1b. Longfin smelt

*See references above for Delta smelt.

OUTCOME N2: NEGATIVE ECOLOGICAL INTERACTIONS WITH WILD FISH (COMPETITION, DISPLACEMENT)

1. Robert Clarke, pers. comm.

   - FWS policy is that reintroduction of species happens when a captive population can help support a wild population (negative ecological consequences would have to be negligible for supplementation to occur). It may be difficult to assess negative ecological consequences for wild fish.

   - Plan to introduce 10% of the effective breeding population size; "enough to work, but not so much as to swamp the population." Uncertainty on how many to introduce (estimate between 60,000 and 6 million fish).

2. Kostow (2008)

   - Review paper outlining potential negative effects of hatchery fish on wild populations, and ways to mitigate these impacts (Abstract & Intro provide good overview) (from J. Isreal).

3. Nobriga & Feyrer (2007, 2008), Nobriga et al. (2008)

   - The release of hatchery fish during the summer and fall, when food productivity and availability is low, is likely to stress wild fish that are attempting to survive with limited food resources (i.e., increased competition for food resources with release of hatchery fish, from A. Willy).

4. Bennett et al. (2008)

   - Reduced food availability late summer through fall (p. 4, Figure 1); evidence of selection for slow growing larvae and poor body condition under food limited conditions (i.e., otolith data for growth, most individuals showed signs of reduced glycogen content; Discussion, p. 24-25).

   - Results suggest selective mortality (for slow growers) and poor body condition were intensified by extreme environmental conditions (Discussion, p. 24-25).

   - Patterns are consistent with widespread decline of calanoid copepods in Delta (Discussion, p. 26) (from A. Willy).

5. Miller (2005)

   - Strong correlation between Delta smelt abundance and the availability of *Pseudodiaptomus* (i.e., low Delta smelt fall midwater trawl abundance index associated with extremely low level of prey (the zooplankton *Pseudodiaptomus forbesi*, p. 1).

OUTCOME N3: MINING OF WILD POPULATION TO SUPPORT BROODSTOCK NEEDS

*See information from Swanson et al. (1996) below (N4). Good understanding of catching associated mortality will allow catch to be managed appropriately.

OUTCOME N4: MORTALITY ASSOCIATED WITH CATCHING BROODSTOCK (GENETIC MATERIAL LOST)

N4a. Delta smelt

1. Swanson et al. (1996)

   - Delta smelt are extremely sensitive to handling. Initial attempts to collect transport and handle smelt were hampered by mortality rates over 90% (Intro, p. 326).

   - Use of polyethylene bags instead of rectangular coolers increased 4-h survival from 40.7 to 83.6%; 72-h survival increased from 6.9 to 27.9% (Results, p. 327).

   - With addition of NovAqua to transport water, 72-h survival increased to 54.4% (Results, p. 327).

   - Survival increased as season progressed (survival of fish collected in November was significantly higher than fish collected two months prior at 74.3%), likely due to seasonal changes in fish size and estuary conditions (i.e., temperature, salinity; Results & Discussion, pp. 327-328)

   - Existing brood stock collection program has very low mortality (from R. Wilder).

N4b. Longfin smelt

*See information from Swanson et al. (1996) under N4a.

Excerpt A (Willy) – Conservation hatchery information from Bob Clarke

How many adult (?) Delta smelt will be planted by hatchery? Will this number be a large or small component of likely current population? Is it enough? Age and timing of release?

The number of Delta smelt propagated in the hatchery will be dependent on the size of the facility, but the range would be between 60,000 and 6,000,000 fish. The final determination of size will probably support approximately 500,000 Delta smelt and represent about 10 percent of the wild population (Robert Clarke *pers comm.*). The hatchery is initially intended to hold a genetic refuge population. The Fish and Wildlife Service will be able to consider supplementation or reintroduction if those become recovery needs identified in a recovery plan. The point would be to "try and nurse along a wild population...[and] we need enough to work, but not so much as to swamp the population" (Robert Clarke *pers comm.*). It is unknown whether this will be enough. Age, timing, and location of release are yet to be determined.

As seen in other pelagic, group-spawning species, the number of males in the spawning run affects the spawning cue, milt production, and semen viability (Carolsfeld 1997, Kowalski et al 2006, Sorensen 1998, and Sveinsson and Hara 1995). It is unknown how many male Delta smelt are needed to cue and increase spawning when abiotic conditions are favorable for spawning. It is also unknown whether hatchery fish can be used to assist in enhancing spawning without genetically suppressing the wild population. In-stream propagation, such as that used for Rio Grande silvery minnow captive propagation, may assist in maximizing genetic variability and studying optimal release sizes.

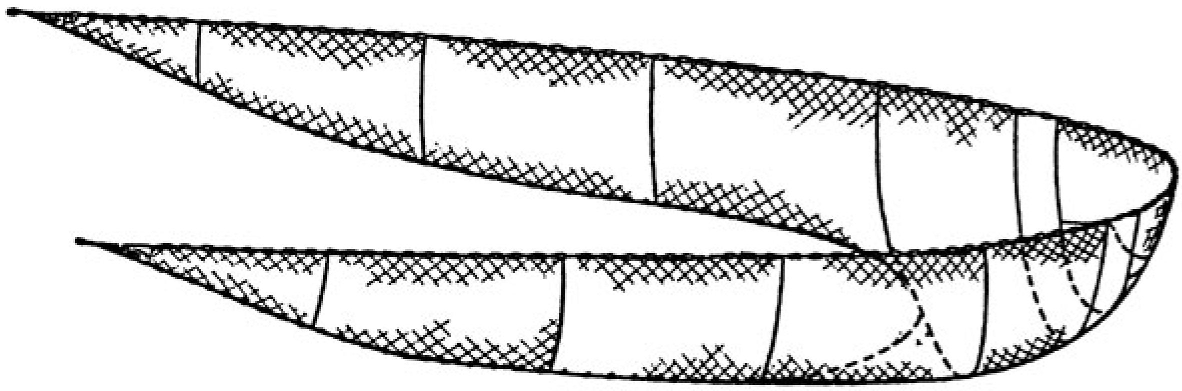
Find literature on how species similar to Delta smelt may adapt to hatchery environment such that natural fitness may be reduced. Rainbow smelt? Annual, group spawner (silvery minnow).

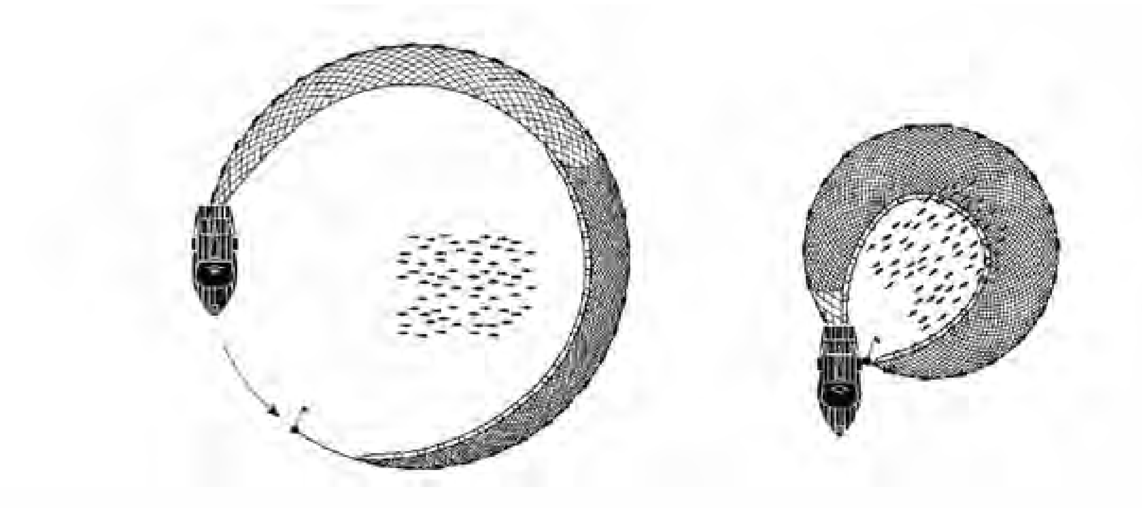
Inbreeding depression is likely. Ongoing work on the Rio Grande silvery minnow (Osborne et al 2006) may inform our future decisions. A captive population is likely to have more of a genetic bottleneck than a wild population (Robert Clarke *pers comm.*).

Excerpt B (Smith) – How will DS and LFS be collected for broodstock?

Delta smelt broodstock are collected by UC Davis Fish. Conservation and Culture Lab folks who go out with USBR. They use a lampara net (kind of like a purse seine) and collected about 70. I have not been out with them, but they tell me the boat is pretty small, so my guess is the net is handled by hand, not winches. - Bob Clarke

Lampara net
The lampara net is similar to a purse seine, but it has tapered panels to give a characteristic scoop shape rather than being flat. The lampara net is set around a school of fish and when both ends are retrieved the vessel tows the net forward, closing the bottom and then top of the net. This type of net is used to catch pilchards and anchovy in inshore waters.





Excerpt C (Smith) – Get examples of conservation hatcheries and how they've worked from Bob Clarke - FWS

List of Conservation hatcheries reviewed
Apache trout
Gila trout
Gila topminnow
Greenback trout
Barren's topminnow
Lake trout (Lake Superior)
Stripped bass - East Coast
Robust redhorse
Chinook salmon - Winter-run
Lahontan cutthroat trout
Kootenai River sturgeon
Lake Sturgeon – Menominee Res
Paddlefish
Razorback sucker
Bonytail chub Colorado pikeminnow

Gila trout

1975 – Only 4 populations remain
1989 – Stocking begins
Increased from 4 to 14 populations – 7 as a direct result of hatcheries
Natural reproduction occurring in all populations

Lake trout (Lake Superior)

1830 to 1960 – Stocks decimated
1950s – Stocking programs begin
2000 – Self-sustaining pops restored to MI waters of Superior
2007 – Natural reproduction widespread, most stocking discontinued

Chinook salmon - Winter-run

1994 – Approximately 200 fish return
1998 – Livingston Stone NFH begins operations
2006 – 17,000 fish return
Hatchery operations increased returns
Loss of genetic diversity unlikely
Little phenotypic variation

Still need to gather up reference on above programs.

Excerpt D (Nobriga) - CALFED AP Workshop 7/24/2008

Dahm:

1. Please attend Science Conference!
2. Speaker overviews
3. Discussion questions:
    a. Pros and cons
    b. Circumstances

c. When to say no
d. What kinds of fishes more or less successful
e. Alternatives?

Hedrick

1. Lower Colorado – very few large river fishes left 0-a few thousand
2. Long-term EPS; originally ca. 100,000+ effective population size
3. current census oom lower than evolutionary EPS
4. Bonytail brood stock 5-10 30 yr old fish; no successful reintro; substantial bottleneck
5. humpback range extended above Chute Falls and that worked; marked fish have been seen traversing falls now that fish are there
6. razorbacks repat'd for 20 yr or so, but need to be 350 mm to be successful; ~ 2500 repats in Havasu; but have released 100,000's; stripers are taking razorbacks even more than 350 mm
7. Genetic variation: adaptive, neutral, detrimental
8. Most adaptive variants are quickly fixed by selection; rarely polymorphic
9. Winter-run
10. Disease is a huge problem for rare spp (wolves, tasman devil, etc.)
11. exposure from common spp and new pathogens w/ inbreeding or other reduced genetic variation
12. WR MHC heteros vs homos; inbred vs. outbred; virus, bacteria, parasite Arkush etal 2002 CJFAS; if natural condition stressful; incidence higher?
13. Neutral var used for ID and genetic rate estimation; microsats, snps, mtDNA
14. Humans have estim 7m SNPs, so large pool of potential info
15. Gila/Yaqui topminnow; morpho identical, 99% mtDNA and microsats so different that diverged ~ 1m years ago; typical massive decline; genetic var all over; definitely blinking out, but ASU has captive broodstock
16. WR supplementation gain in production vs. decline in natural EPS
17. careful genetic monitoring showed returns weren't all coming from 1 parent; survival from supp parents were more or less random
18. Pallid sturgeon n= 45-136; little to no recruitment; starting captive broodstock, but releases have low survival; effective size in captivity approaching 80
19. Genetic rescue worked for mex wolves, FL panther – bringing genes from elsewhere; mex wolf has low fitness, but hunting still taking 'em out
20. Summary: small pops, inbreeding, adapt to capt
21. Recs: large pop size, minimize kin breedin', replicate pops, bring in wild genes, keep captive generations minimal, captive environ like natural one

Turner

1. Rio Grande silvery minnow is annual; pelagic eggs and larvae; then larvae go lateral
2. captive breeding, bringing wild larvae into cap, refugial pops in mg'd habitat
3. Spawning cued to flow pulses
4. Dams are passable in downstream direction, but not upstream
5. rgsms are dominant fish in their habitat and rebounded when SW drought ended in 2004-2005
6. genetic monitoring for 10 yr EPS/Pop ab.
7. low genetic diversity despite high pop #s at times; but still signif genetic diffs among little pops wi the river! Temporary pop structure from repro schooling; not same groups year after year
8. Effective pop size is on order of 100-500 fish, but 10,000s to 100,000s in census; how?

9. distance of spawning from a diversion dam; some schools get lucky; before dams were built, EPS/TPS was much higher than current; eggs drift in genetically cohesive groups; Bill's "spreading the risk" multiple cohorts; Pecos River minnows have unfrag'd habitat and higher EPS/TPS
10. Argue 0.5M repro capable adults needed in capt broodstock; multiple facilities
11. Catching eggs and repat'ing as adults is working well for maint. Genetic div.
12. Trying env induced communal spawning – turbidity; much variability compared to hormonal treatments, which ensure fish good to go
13. Hormonal communal spawn is looking like best econ and success option
14. Gene diversity was plummeting until captive broodstock repat'd fish started being added because reintroduced a lost rare haplotype
15. However, until river habitat is improved; no self-sustaining possible
16. Augmentation increased gene diversity but not variance EPS
17. AP seen as insurance against catastrophe; not long-term solution

Clarke

1. UCD + Livingston Stone; neither facility large enough esp. if subpops need to be maintained; little room for supplementation/reintro program; no ability to address other spp – FWS wants to remedy these
2. Goal; Estab a cons hatchery to help restore Delta smelt to self-sust levels in the wild
3. Model on Dexter NFH; $15-20M for smelt + 2 additional spp
4. Hatchery success list; reintros
5. work when in conjunction w/ habitat fixes

Qs for Bob

1. McEwan: will facilities have an end point? Yes – recovery plan would establish when supp would cease
2. Planning and Conservation League: when is supp appropriate (wild pop + habitat) FWS policy – recovery plan and looks at data; pro judgment; good insurance policy; annual fish forward planning
3. Kolborn Assembly parks committee: WR no genetic diversity loss – generally applicable? Didn't check; picked clearest examples to show its possible Facility cost is construction? How to pay for it? Maintenance cost? Yes; annual cost $1-2M; funding source undecided – multigroup contribution?
4. Hedrick: WR 17,000 spawners? 17,000 total return; unknown hatchery contribution; see FWS compendium report
5. Turner CFSciences: hatchery + hab restoration – what is that hab fix that is needed here? No comment but Victoria chimed in…plan will fall out of developing threats assessment
6. Maissonueve DWR: decision yes or no is part of recovery plan; now, 2 yrs from now – dunno; Do we know if wild gene pool is sufficient; Katie's talk

Bridges

1. Don't wait – risks loss of gene diversity – started a refugial pop
2. no actual supp plan for now
3. New site in Byron is where CHTR studies were done; adult system is not finished/larvae-juv is
4. > 500 broodstock incl 2 yr olds from Dec 2006
5. Livingston Stone is backup

6. Cuz facility not big enough used single pair crosses; historically did multimale; keeping fish alive as long as they are willing!
7. Age-2 massive more fecund
8. Needed min 50 SPCs to minimize inbreeding
9. Each SPC is kept alone throughout life cycle
10. 2nd clutch fecundity was same as 1st; even got 3rd and 4th time spawners (rare and lower batch fecundity) temps kept low
11. Peaks between 1st and 2nd spawns ~ 3 mos?
12. breeding plan needs to be updated – how many MFGs actually surviving? How many are needed? If only SPCs lots o' tanks! Establish a pedigree; verify parent DNA at spawning; wild supps are unlikely, so gonna go mostly on fully captive broods; hope to add a few wilds in (probably recommended); artif selection does occur
13. Refuge phase 1 nearly complete; phase 2 plan for expansion – uncertain how large they need to be – waiting on genetic data

Qs for Bradd

1. Turner: multiple spawns in the wild? DFG has found KT evidence; how many 2 yr olds? < 5%; gene variation for spawn success? Unknown but will eventually be able to tell
2. Berm PCLeague: mock release? Gonzalo's study; PIT tagging? 30% efficiency at trashrack thru salvage(not sure); also doing calcein marking and checking w/ light; adult studies in Jan-Feb
3. Waples: historic pop structure? Katie's talk
4. Hedrick: Allee effects? Katie – says not discussing

Fisch

1. Trying to develop pedigree on indiv fish to develop mating schemes
2. Pop structure, hybridization, spawning strategies (a la Turner presentation)
3. Captive fish had high allelic richness; high heterozygosity; in HW equilibrium; good markers for analysis; currently no evidence of multiple pops but input data not up to task
4. Markers can pull out individual fams from MFGs; wild fish comparatively unrelated
5. Need to know both wild fish genetics and mgd genetics to develop a good plan

Qs for Katie

1. Waples: Need power analysis to conclude HW equilibrium; so may not have pop structure evidence – or no major diffs
2. Hedrick: archives? Yes back to 40s and many from 1990s on
3. Kolborn: what's timing on additional work to develop breeding plan toward reintro? Natural genetic var part is guideline for reintro; 1 yr-ish
4. Clarke: make sure everybody knows we aren't saying FWS will supplement; only that they want to develop the tool to do it
5. Brim PCLeague: if you see differential survival; offspring do well in capt – will you favor offspring doing well? No – that's why monitored – to make sure you maintain equal representation
6. Turner: are there bad crosses that never work? Bradd – occasionally; this year more, but changed protocols (e.g. 1:1 spawn ratio)
7. Brim: question to Tom: hormonally induced multifish worked best; hormone cues so every fish rep'd
8. Hedrick: Allee effect related to mating ability? Artificial mating can exacerbate an already occurring Allee effect? Bradd: everybody crossed this year AMAP; if left to own devices likely would have been lower, so minimzing opps for worsening Allee fx

Waples:

1. Risk-Benefit; empirical results; Columbia meta-analysis; Repro success in Columbia salmon
2. Reasons not to rely on hatcheries only: long-term sustainability unproven; don't promote natural ecosystems
3. Risks and benefits eval'd on multiple levels, but science can only deal with risks/bennies to natural pops
4. Empirical evidence that sometimes AP can reduce short-term extinct risk and reseed vacate habs; uncertain can speed recovery
5. risks are genetic and ecological fx
6. Ryman-Laikre is dark side of production "success"
7. Fitness declines rapidly with every generation in the hatchery
8. Many risks are tightly inversely linked e.g., inbreeding vs. catastrophic loss or swamping wild pop; sample part of run = low contam, but low gene var vs sample whole run = contam with other runs
9. Expect the (bad) unexpected
10. It has proven impossible to stop hatchery programs once started – consider that before starting
11. PacNW hatcheries cannot demonstrate success of ultimate goals of self-sustaining natural pops
12. Supplemented salmonid pops are not increasing relative to unsupp'd pops
13. Supp might help buffer very low abundance
14. Size and spawning distribution affect repro success
15. questions answered in slide show

Qs for Robin
Berm: why diff response to ocean conditions? Slide was wild fish ocean survival; interp'd as hatchery fish compete w/ wilds in low productivity yrs, but not better yrs; hatchery fish aren't better just swamping the system

Israel
1. Biocoupling – a critter in tune w/ the modified system it gets placed in
2. Recovery opps if not relying on "nature" in a highly modified environ
3. Can AP increase survival of representing a "desired" outcome?
4. Many hatcheries doing their thing w/o considering impacts on other listed fish they aren't propagating
5. Molecular markers as tags for hatchery management: e.g., are fish adapting to the local environment?
6. Know baseline genetics and pop repro demographics before translocation to know what you're shooting for
7. Do you want the strays when trying to repat? Will keeping them promote more straying?
8. More hatchery fish proportionately = more natural selective force
9. Essential studies for repat'ing: source eval (breedng/stocking), pedigree studies, domestication studies; recognize repat is an experiment

Qs for Josh
Hedrick: origin of %'s about wild/hatchery? Based on theory in Mike Ford paper; ratio seems low? Robin said originally Ford model, maybe tweeked by someone else; many folks don't realize numbers aren't independent; nobody has eval'd as dependent

Panel Discussion

1. What are the pros and cons of AP?

Pros
- a. maintain gene pool
- b. reseed vacant habs
- c. meet some societal goals (public edu, meeting harvest goals)
- d. provide a safe-haven stave extinction; not all eggs in one broodstock
- e. captive source to undo extirpation
- f. supplement low spawner density/Allee fx? One circumstance is that Allee low equilibrium; empirical examples lacking

Cons
- a. long-term bennies not demonstrated
- b. expect reductions in fitness
- c. expect reductions in gene diversity
- d. expect unanticipated complications
- e. when are pros cons? False appearances with high hatchery production

Does AP have a role in helping fish thru 7 drivers of change?
- a. how long can fish go w/o going into a low equilibrium? If need to pull an annual thru 10 yr of drought – maybe can; long-term solution, probably not
- b. preserving gene var in AP provides template for adaptation; too much hatchery might generate a fish that's "stuck in the past"
- c. If things change, diff habs might become exploitable; AP provides fish to reseed
- d. THE role for AP; big change = big need for insurance policy; buy time until system improves for smelt, salmon

2. Under what circumstances can (might) AP be effective? Short-term stop gap

Pros
- a. high short-term extinction risk
- b. serious concern for IBD
- c. suitable hab unseeded – moving individs might be better than AP (when possible)
- d. bennies outweigh risks (demonstrated)
- e. in conjunction w/ comprehensive recovery actions; does not work w/o solutions to underlying problems – concern that Delta smelt AP will be panacea to not fixing problems

Is AP in the SJ spring strategy? Program is considering several alts incl AP, could be repast, planning risk-benefit analysis

Density-dependent situation [missed this]
Did Gila trout restoration occur from AP or translocation? Both
Some pops were more amenable to AP

3. When should AP not be used?

a. impression there aren't enough fish is undemonstrated or known not to be high extinction risk
b. natural colonization can do the job
c. logistic challenges prevent risk-averse implementation
d. when risks outweigh bennies; does this involve things w/I culture facility or greater scope?
e. Neg fx on non-target spp
f. Bullets might need to be modified in context of other societal goals

How do you assess that there's vacant habitat that can be colonized?

1. connected or historically connected waterways
2. is genetic diversity consistent with previous connections among waterways
3. historical meta-population dynamics vs. contempo short-term hybridization problems
4. When there are better or easier solutions – cui ui – blocked spawning access to Truckee – easy to fix

Cases where AP shouldn't be used because no viable habitat left (Australia)?

1. Mex wolf your last broodstock will be hunted
2. flip side – old dams will be removed in pac NW? Do you let natural repat or AP assist? Experimental benefit of understanding natural recolonization

What happened with Mt St Helens streams?
Pretty rapid recoveries
Ditto w/ receding glaciers in AK; need nearby robust pops w/ propagules

3. What spp are best suited to AP?

a. freshwater
b. anadromous w/ brief life history phase
c. spp w/ weak pop gen structure (panmictic)
d. crowding tolerant spp
e. long-lived spp like sturgeon – lots of chances to get things right
f. but more chance for catastrophe?

Which local fishes would be most amenable to AP?

a. which are most suitable to have AP for long-term recovery
b. Is Delta smelt suitable?
c. Fw vs. anadromous; sockeye/kokanee more diverged than rtrout/steelhead; kokanee transplant well, sockeye do not; more opp for local adaptation in anadromous fish; not adaptation to fw for part of year; cod showing very discreet pops with local adaptations

Are there alts to AP that should be used for endangered fish conservation?

a. abundant good qual hab
b. fxing natural systems
c. fix the causes of decline
d. fixes can take decades, so AP provides time to fix

e. translocate when possible

Natural flow regime – amount, timing, frequency?
Being implemented in highly mg'd rivers
RGSM partly due to divdam re-op toward more natural hydrograph; ESA motivated, but ecosystem fx are more broadly applicable e.g., into riparian areas
Lower Colorado – semi-nat breeding to get past predation bottleneck, so this type of supplementation is not AP and superior to it
Can supplementation help Delta smelt?
Can't find eggs
Uncertain bottlenecks

Public comment
Barbara BermPCL
CA leg bill on smelt hatcheries; full take authorization in exchange for funding for hatchery; comments? Where do existing conservation hatcheries get their funding and tie into bigger pic restoration?

No general rule; some are FWS funded; others by action agencies as mitigation; Dexter may get Congressional funding

Fed mandates eg Columbia hydropower system; usually state/tribal funded; not originally conservation-oriented; had to demonstrate net benefit to listed ESU; rough times, but substantial changes in ops due to ESA

Action Description and Clarifying Assumptions

Modify or eliminate non-project diversions in the Delta to reduce the entrainment of covered fish species.

Approach

For non-project diversions that are >50 cfs do one of the following:

1. Screen the diversion with a screen that is 99% efficient at screening particles,
2. Remove the diversion,
3. Relocate the diversion to a channel in which its effect would be reduced,
4. Relocate the diversion within a channel to reduce the effect on covered fish species,
5. Consolidate multiple diversions in a single location into one screened diversion, or
6. Alter timing of operation of the diversion (e.g., diel operations) to reduce the effect on covered fish species.

Intended Outcomes as Stated in Conservation Measure

1. Reduce entrainment mortality by non-project diversions of larval and juvenile delta and longfin smelt, juvenile green and white sturgeon, juvenile splittail, and fry and juvenile Chinook salmon (all races) and steelhead.
2. Increase food availability to delta and longfin smelt, green and white sturgeon, splittail, and Chinook salmon (all races) and steelhead.

General Conceptual Model Support for Intended Outcomes

1a. Reduced mortality of larval and juvenile Delta smelt: Unlikely to reduce mortality significantly; Delta smelt Conceptual Model, section 5.1.5.f, page 21

1b. Reduced mortality of larval and juvenile longfin smelt: Implied in Longfin Smelt Conceptual Model, section 5-Diversions, page 22; mortality at diversions may be significant in some years.

1c. Reduced mortality of juvenile green sturgeon: Yes, possibly; Green sturgeon Conceptual Model, section 5, page 13.

1d. Reduced mortality of juvenile white sturgeon: Yes, possibly; Green sturgeon Conceptual Model, page 21.

1e. Reduced mortality of juvenile splittail: Yes, possibly; Splittail model p. 18; power plants have ability to entrain large numbers of fish, YOY have Ucrit near velocities at large pumps and are entrained at the CVP and SWP.

1f. Reduced mortality of fry and juvenile Chinook: Yes, possibly; Salmonid Conceptual Model, page 21.

1g. Reduced mortality of fry and juvenile steelhead: Yes, possibly; Salmonid Conceptual Model, page 21.
2a. Increased food for Delta smelt: Yes, probably; Delta smelt model pp. 27, 32; water diversions constrain copepod standing stocks, could increase food availability via improved water quality management.
2b. Increased food for longfin smelt: Yes, probably; Delta smelt model pp. 27, 32: water diversions constrain copepod standing stocks, could increase food availability via improved water quality management; Longfin smelt model p. 22: water diversions may impact abundance and distribution of longfin smelt prey.
2c. Increased food for green sturgeon: Possibly; Green sturgeon model p. 9, diet of green sturgeon is unknown, but other sturgeons are known to consume drifting invertebrates.
2d. Increased food for white sturgeon: Possibly; White sturgeon model p. 8, diet of larval white may include zooplankton.
2e. Increased food for Chinook: Possibly; Salmonid model p. 47 (stressors table), indirect mortality caused by diversions.
2f. Increased food for steelhead: Possibly; Salmonid model p. 47 (stressors table), indirect mortality caused by diversions.

Assumptions

Provided in BDCP Conservation Measure

1. Willing diverters for this action will be found.
2. Priority on which diversions to focus will be based on criteria developed by DFG and USFWS.

Problem(s) with Action as Written:

1. The approach mentions using screens for particles. Shouldn't fish screens be used? Note: As the screening criteria is based upon particle size, this may increase the amount of screen clogging and require a high-maintenance cleaning regime to maintain intake flows. Farmers may advocate for more than one diversion so that they could alternate the use and cleaning of screens (one in water, one being cleaned).

   Use of screens may results in bio-clogging: "Although invasive, substrate-colonizing mussels (Zebra and Quagga mussels) have not been reported in the Delta, should they appear, it would be necessary to dry out the intakes periodically to kill off any mussel spat which have settled on the screens. To minimize bio-clogging, the intake structure should be kept out of water until needed (again, this might result in having two pumps which could alternate diversion---one drying out, one being used). Also, there is a critical velocity threshold of flow at 1.5 m/sec (Claudi & Macki 1994) that prevents the settling of spat; however, within the diversion pipe, there is a gradation of laminar flow which may still allow spat to colonize within or around the edge of the diversion." (Martha Volkoff, Staff Environmental Scientist, CDFG Invasive Species Program, Quagga-Zebra Mussel Division, pers. comm. to Shirley Witalis).

2. How was the cutoff of >50 cfs determined?

3. Relative to the >50 cfs cutoff, does this refer to the maximum capacity of the diversion? If so, this should be stated.

Scale of Action:

Medium

Rationale:

Information from CDFG indicates that there are 69 unscreened diversions with a capacity greater than 50 cfs in the Delta. Excluding Banks and Jones pumping plants, the combined capacity of these diversions exceeds 7,000 cfs

The entrainment of larvae and juveniles of covered fish species by non-project diversions >50 cfs is poorly documented. The only empirical studies of this potential impact found low rates of entrainment for listed fish (Nobriga et al. 2004, Cook and Buffaloe 1998). These studies evaluated few diversions and suffered from a lack of staffing, funding and coordination with the diverters. Most of the fish entrained were non-native fish, benthic oriented fish, observed in high numbers. These authors, however, do hypothesize that the cumulative effect of these diversions could be large. This is corroborated in a literature review by Moyle and White (2002). Impacts to any of the other covered species are likely to be even smaller than what has been estimated for Delta smelt. Results of the PTM modeling completed for the BDCP suggests that DICU entrainment is low, ranging from 3% under high flow conditions, to about 20% under low flow conditions (BDCP 2009).

Note: with a north Delta diversion these numbers increased to 20 to 50%.

Evaluation Summary

Summary tables listing magnitude and certainty scores for each outcome, by species are provided in the Outcome Summary Table Appendix at the end of this worksheet. Details regarding each of the listed scores, and the rationales for the scores are provided in the discussion of positive and negative outcomes herein.

Relation to Existing Conditions:

Would the action result in a change to system dynamics (either within the Delta or as inputs to the Delta) such that the current understanding of how the system works may no longer hold?

NO. The scale of this action is medium.

Potential Positive Ecological Outcome(s)

Outcome P1: Reduce entrainment mortality by non-project diversions

P1a. Larval and juvenile Delta smelt

Magnitude = 2

Empirical study (Nobriga et al. 2004) indicates low entrainment of Delta smelt by non-project Delta diversions. Low entrainment of listed species (Cook and Buffaloe 1998)

Certainty = 2

Two empirical studies (Nobriga et al. 2004, Cook and Buffaloe 1998). Nobriga et al. (2004) found that the presence of screens significantly reduced entrainment of unlisted species, even when the individual fish present in the surrounding environment were small enough to pass through the screens.

P1b. Larval and juvenile longfin smelt

Magnitude = 1

No empirical studies for this species, but given the low entrainment found for another Delta fish (Delta smelt; Nobriga et al. 2004) this outcome is likely to have little or no effect at the population level. Many of the diversions would also be located outside of the geographic range for this species.

Certainty = 1

No empirical studies for this species.

P1c. Juvenile green sturgeon

Magnitude = 1

Empirical studies do not report entrainment for this species (Nobriga et al. 2004, Cook and Buffaloe 1998). Other benthic fish (i.e. catfish, sculpin) have been observed to be entrained (Cook and Buffaloe 1998), establishing that entrainment is possible, but would be low and this outcome is likely to have little or no effect at the population level.

Certainty = 1

No empirical studies for this species.

P1d. Juvenile white sturgeon

General Observations

Magnitude = 1

Empirical studies do not report entrainment for this species (Nobriga et al. 2004, Cook and Buffaloe 1998). Other benthic fish (i.e. catfish, sculpin) have been observed to be entrained (Cook and Buffaloe 1998), establishing that entrainment is possible, but would be low and this outcome is likely to have little or no effect at the population level.

Certainty = 1

No empirical studies for this species.

P1e. Juvenile splittail

Magnitude = 1

Empirical studies report low entrainment for this species (Nobriga et al. 2004, Cook and Buffaloe 1998). Other benthic fish (i.e. catfish, sculpin) have been observed to be entrained (Cook and Buffaloe 1998), establishing that entrainment is possible, but would be low and this outcome is likely to have little or no effect at the population level.

Certainty = 1

No empirical studies for this species.

P1f. Fry and juvenile Chinook salmon (all races)

Magnitude = 1

Little empirical studies for this species, but given the low entrainment found by Cook and Buffaloe (1998) and for another Delta fish (Delta smelt; Nobriga et al. 2004) this outcome is likely to have little or no effect at the population level.

Certainty = 1

No empirical studies for this species.

P1g. Fry and juvenile steelhead

Magnitude = 1

Little empirical studies for this species, but given the low entrainment found by Cook and Buffaloe (1998) and for another Delta fish (Delta smelt; Nobriga et al. 2004) this outcome is likely to have little or no effect at the population level.

Certainty = 1

No empirical studies for this species.

Outcome P2: Increase food availability

P2a. Delta smelt

Magnitude = 1

Supported by conceptual model (Delta smelt model pp. 27, 32; water diversions constrain copepod standing stocks. No empirical studies for this species. Volume is more than 7,000 cfs. Results of the PTM modeling completed for the BDCP suggests that DICU entrainment is low, ranging from 3% under high flow conditions, to about 20% under low flow conditions (BDCP 2009).

Certainty = 1

No empirical studies for this species.

P2b. Longfin smelt

Magnitude = 1

Same as Delta smelt.

Certainty = 1

No empirical studies for this species.

P2c. Green sturgeon

Magnitude = 1

Likely little impact on food resources for this species, which is mainly a benthic feeder.

Certainty = 1

No empirical studies for this species.

P2d. White sturgeon

Magnitude = 1

Same as green sturgeon

Certainty = 1

No empirical studies for this species.

P2e. Splittail

Magnitude = 1

Mainly a benthic feeder

Certainty = 1

No empirical studies for this species.

P2f. Chinook salmon (all races)

Magnitude = 1

Possibly; Salmonid model p. 47 (stressors table), indirect mortality caused by diversions.

Certainty = 1

No empirical studies for this species.

P2g. Steelhead

Magnitude = 1

Possibly; Salmonid model p. 47 (stressors table), indirect mortality caused by diversions.

Certainty = 1

No empirical studies for this species.

Important Gaps in Information and/or Understanding

Data Needs

- Evaluation of entrainment risks due to non-project diversions in a quantitative fashion that can be linked to population levels.
- Evaluation of entrainment risks due to non-project diversions that focuses on the geography – namely, the location of diversions relative to the location of covered fish species and the timing of diversions relative to fish distributions.
- Evaluation of entrainment risks due to non-project diversions that focuses on temporal overlap between diversion pumping and proximity of covered fish species to the diversions.

Research Needs

- GIS analysis of geographical questions mentioned above.
- Investigation of the pumping schedules associated with non-project diversions in different locations and of different sizes and types.

Assess Reversibility and Opportunity for Learning

Reversibility

Yes/easy

Comments: Screened diversions could be reversed simply by removing the installed screens. Reversing the action would simply require removal of screens. The cost of this reversal would likely be much lower than the original cost of installing screens. For diversions that were eliminated or moved, the cost of reversal would likely be equivalent to the original action.

Opportunity for Learning

Low

Comments Without long-term, rigorous monitoring programs for all of the non-project diversions that receive screens, determining the impact of this action would be difficult.

Acknowledgements

The Advisors acknowledge the support of many individuals and agencies during their deliberations and reporting. Several colleagues provided unpublished materials for use by the Advisors as they prepared for the workshop. The Department of Fish and Game and the Bureau of Reclamation provided transportation for field trips during the Advisors' workshop. The support of Steering Committee members in attending parts of the workshop is appreciated. The Lead Scientist and the Facilitation Team thank the Science Liaison Committee and the Management Team for their assistance in preparing for the workshop and subsequent briefings. Members of the Steering Committee also provided useful comments of the draft report. Karen Biastre and Jon Petrillo of The Essex Partnership assisted with the preparation of this report.

EXECUTIVE SUMMARY

A group of nine scientists were convened in September 2007 to provide independent advice to the Bay Delta Conservation Plan (BDCP) Steering Committee. These scientists provided advice on the use of science in developing an effective Conservation Plan for the Sacramento-San Joaquin Delta in accordance with California's Natural Community Conservation Planning Act (NCCPA) and the BDCP Planning Agreement. Consistent with the requirements of the NCCPA, the Science Advisors' report includes a listing of principles for conservation planning, design, and management. The Report also includes a series of more specific recommendations regarding application of the existing knowledge base and the use of data and analyses for informing the BDCP. The following briefly summarizes key foundational principles and recommendations from the Report. These principles and recommendations should be considered as the overall conservation strategy and potential conservation measures are developed for the BDCP.

Principles for Conservation Planning

The Advisors developed sixteen principles that address overarching issues, fundamental aspects, of Delta ecosystem dynamics, and conservation approaches and analyses. These points should be considered during the development and implementation of the BDCP.

Overarching Principles

A. Changes in the estuarine ecosystem may be irreversible.

B. Future states of the Delta ecosystem depend on both foreseeable changes (e.g., climate change and associated sea-level rise) and unforeseen or rare events (e.g., the consequences of new species invasions).

C. The Delta is part of a larger river-estuarine system that is affected by both rivers and tides. The Delta is also influenced by long-distance connections, extending from the headwaters of the Sacramento and San Joaquin Rivers into the Pacific Ocean.

Delta Ecosystem Dynamics

D. The Delta is characterized by substantial spatial and temporal variability, including disturbances and extreme events that are fundamental characteristics of ecosystem dynamics. The Delta cannot be managed as a homogeneous system.

E. Species that use the Delta have evolved life history strategies in response to variable environmental processes. Species have limited ability to adapt to rapid changes caused by human activities.
F. Achieving desired ecosystem outcomes will require more than manipulation of Delta flow patterns alone.
G. Habitat should be defined from the perspective of a given species and is not synonymous with vegetation type, land (water) cover type, or land (water) use type.
H. Changes in water quality have important direct and indirect effects throughout the estuarine ecosystem.
I. Land use is a key determinant of the spatial distribution and temporal dynamics of flow and contaminants which, in turn, can affect habitat quality.
J. Changes in one part of the Delta may have far-reaching effects in space and time.

Conservation Approaches and Analysis

K. Prevention of undesirable ecological responses is more effective than attempting to reverse undesirable responses after they have occurred.
L. Adaptive management is essential to successful conservation.
M. Conservation measures to benefit one species may have negative effects on other species.
N. Data sources, analyses, and models should be documented and transparent so they can be understood and repeated.
O. Ecosystem responses, especially to changes in system configuration, can be predicted using a combination of statistical and process models. Statistical models document status, trends, and relationships between responses and environmental variables, whereas process-based models are useful in understanding system responses and for forecasting responses to new conditions.
P. There are many sources of uncertainty in understanding a complex system and predicting its responses to interventions and change.

Plan Scope

The Advisors agree that the BDCP Planning Agreement has correctly identified the aquatic species to be covered assuming the current list of Covered Activities. However, the extent of the available information for each species varies considerably, suggesting that each species should be evaluated individually. The Advisors specifically caution against using guilds, communities of species, or other "groupings of convenience" for planning and analysis. Rather, the Advisors recommend an approach to planning that embraces the spatial and temporal environmental gradients that occur within the Delta and the influence of these gradients on Covered Species. The Advisors developed six recommendations regarding Plan Scope:

1. Seek further advice on the appropriate geographic scope as the nature of the Covered Activities and conservation strategies becomes more defined.
2. Consider the San Joaquin fall-run Chinook salmon as a Covered Species distinct from other Central Valley fall-run Chinook salmon.
3. Revisit the inclusion of Swainson's hawk, giant garter snake, bank swallow, and other listed taxa as Covered Species once the Covered Activities, including conservation strategies, are more fully identified.
4. Use planning species such as threadfin shad, striped bass, largemouth bass, Brazilian waterweed, overbite clam, and freshwater clam to assess effects of conservation strategies on a wider range of ecosystem components and dynamics than the Covered Species represent.
5. Examine how individual species respond to gradients in environmental conditions (and changes in those gradients) to inform assessment of the effects of conservation strategies, rather than using guilds, species communities, or other groupings of convenience.
6. Assess the sensitivity of conservation outcomes to anticipated changes in environmental gradients that will likely arise from sea-level rise, subsidence, climate-change induced alteration in the timing of runoff, human activities, and other processes over the time frame of the Plan and beyond.

Delta Ecosystem Dynamics

The Delta is a highly complex system of interacting physical, geomorphic, biological, and chemical processes, all of which are influenced by human activities both inside and outside the Delta. The Advisors consider several of these interactions particularly important for anticipating the response of the Covered Species to changes in environmental conditions, the Covered Activities, and other human influences. The report includes a set of tables that identify the most important processes influencing covered species, assess the current state of knowledge regarding those processes, outline key uncertainties, and assess the ability to predict how these processes operate within the system. The Advisors developed four recommendations concerning information needs, recognizing that a wide array of studies will be needed to support successful Plan implementation:

7. Routinely collect high resolution airborne imagery over the Delta, including lidar, hyperspectral or multispectral, and thermal, to detect and quantify spatial changes in miocrotopography, surface water temperature, surface turbidity, algal blooms, aquatic wetland and riparian plant species composition, and fractional cover.
8. Maintain current monitoring programs within the Delta and institute a comprehensive, long-term, Delta-wide monitoring program to provide data on contaminants in sediments, water, and aquatic organisms, including in-Delta diversions and return flows.
9. Refine and expand existing monitoring programs as Covered Activities and conservation actions are specified, and critical data needs can be identified.
10. Develop an integrated database of monitoring data (e.g., salinity, temperature, nutrients, contaminants) and relevant spatial data layers (e.g., topography, distributions of submerged, emergent, and floating aquatic plant species).

The report discusses population dynamics and process interactions at higher trophic levels. Understanding and forecasting population dynamics requires considering influences of key environmental variables on all life stages. In the case of the Covered Activities, understanding and forecasting population dynamics may also require considering the effects of environmental conditions outside the range of conditions that the species currently experience. The Advisors developed four recommendations for incorporating understanding of population dynamics into conservation planning:

11. Consider relationships between environmental conditions and the Covered Species in a life cycle context.
12. Pursue efforts to quantify the contribution of entrainment and other factors to stage-specific mortality rates of Covered Species in order to assess the population-level benefits of offsetting such losses.
13. Identify how anticipated changes in environmental conditions, including those associated with Covered Activities and climate change, propagate through populations of Covered Species, and consider how uncertainties regarding future environmental conditions potentially influence population response to Covered Activities.
14. Examine possible bottlenecks at other life stages, including those that occur outside the planning area, rather than only those at the life stage immediately affected by Covered

Activities or within the Delta. Bottlenecks at other life stages can modulate the population response to changes in environmental conditions within the Delta.

Methods of Analysis

Detailed consideration of analytical tools was beyond the Advisors' scope of work. However, the Advisors offered twelve recommendations concerning approaches for analyzing Delta hydrodynamics and species populations. The intent is not to provide a comprehensive evaluation of all available tools and models, but to provide recommendation on how analytical tools can be used to address conservation issues.

15. When potential conservation measures have been developed, convene a group of science advisors with experience in systems analysis, ecosystem restoration, population and food web dynamics, and other relevant disciplines to identify appropriate analytical tools and assessment techniques to support conservation planning and implementation in the Delta.
16. Use a hydrodynamic model that is based on fundamental physics and that accurately reproduces tidal flows in the system for analysis of Delta transport and dispersion, particularly for predictions of proposed management scenarios on hydrodynamics.
17. Use data that span as broad a range of hydrologic and operational conditions as possible to evaluate a model's performance and increase the probability that the model will have sufficient accuracy and precision for evaluating management scenarios.
18. Use models with appropriate dimensionality for the target of the analysis:
    a. Use a two-dimensional, depth-averaged analysis to predict transport of passive dissolved substances.
    b. Use a three-dimensional hydrodynamic model to account for both tidal dispersion processes and gravitational circulation associated with salinity intrusion into the Delta, or parameterize gravitational circulation based on local density forcing.
19. To allow integration of particle or organism behavior into Delta transport models:
    a. Develop a highly resolved three-dimensional hydrodynamic model to produce accurate projections of vertical and lateral variability in channels and junctions.
    b. Conduct drifter-tracking studies, especially around channel junctions, to evaluate model ability to predict particle trajectories.
20. Apply an array of tools to improve prediction of water temperature at various spatial and temporal scales:

a. Develop a correlative analysis of atmospheric conditions and water temperatures to assess large-scale variations in temperature,
b. Analyze river inputs and tidal dispersion to predict temperature at finer spatial and temporal resolution.
c. If prediction of fine-scale temperature variation between adjacent environments is desired, pursue observational and modeling studies into the effects of shallow, vegetated environments on local temperature dynamics, including the effects of shading along perimeter water.

21. Evaluate future sediment supply to the Delta from the watershed, and document sediment resuspension characteristics in the Delta, to support the development of an integrated hydrodynamic-sediment transport model to predict sediment concentrations and their variability
22. Develop spatially-explicit models of plankton dynamics, and institute monitoring to provide necessary input to these models, to improve prediction of Covered Species response to changing environmental conditions.
23. Develop statistical models that relate a) spatial and temporal distributions of environmental factors to life history stages of the Covered Species, b) fish movement to environmental factors that cue migration, c) net and tidal flows to migration, and d) abundances of the Covered Species at different life stages to relevant environmental variables.
24. When sufficient information is available and the questions to be addressed are tractable to model, develop and apply process models for covered species that are built upon the conceptual and statistical models. These process models can be used for predicting short-term, life stage-specific responses, and for predicting long-term responses of population dynamics.
25. Use hydrodynamic models of the Delta built on fundamental processes to analyze the potential consequences of different climate change scenarios (e.g., sea-level rise, timing and amount of runoff) on net and tidal flow patterns.
26. Develop and apply statistical and process models to examine the potential effects of increasing variability in salinity and water temperatures on ecosystem processes and Covered Species in the Delta.

Adaptive Management and Monitoring

Adaptive management is a systematic process for continually improving management policies and practices by learning formally from their outcomes. The Advisors think that adaptive management is perfectly suited to the BDCP, but implementing it will require a sincere, ongoing commitment to the principle and the process, and a decision-making process specifically designed to accommodate adaptive management. The Advisors developed three recommendations concerning adaptive management and monitoring:

27. Design a conservation plan based on adaptive management.
28. Identify and implement as soon as possible an administrative mechanism for the Plan to be modified in response to rapidly evolving information, data, and analyses.
29. Convene a group of science advisors to work with consultants, PREs, and implementing agencies to develop an appropriate adaptive management and monitoring strategy to support implementation of the BDCP.

1.0 INTRODUCTION

This report presents early advice and recommendations regarding the use of science in the development of the Bay Delta Conservation Plan (BDCP or Plan). The report was prepared by a multidisciplinary group of independent science advisors[1] (Science Advisors or Advisors) convened by the BDCP Steering Committee (Steering Committee) in accordance with the state of California's Natural Community Conservation Planning Act (NCCPA) and the BDCP Planning Agreement[2] (Agreement).

The advice and recommendations provided herein are based on current knowledge of the Bay Delta ecosystem and the current state of the BDCP planning process. Both the knowledge base and the planning process are evolving rapidly. Because it is early in the BDCP planning process, many of the details regarding the specific actions that the Plan will cover are undefined, as are the potential conservation measures that may be included in the Plan. Science and scientists will be able to inform management options more directly as more details emerge regarding the overall conservation strategy, including information on potential water management and conveyance actions. Additional scientific information from ongoing studies and analyses (e.g., those under the auspices of the Interagency Ecological Program, the Pelagic Organism Decline (POD) Management Team and the CALFED Science Program) should also be incorporated into the BDCP process as it becomes available. The Advisors strongly suggest establishing a mechanism for continued scientific engagement throughout the BDCP process.

1.1 Independent Scientific Input

The BDCP Planning Agreement calls for the use of the best available scientific information, including advice from well-qualified independent scientists, in preparation of the BDCP. In accordance with NCCPA requirements, the Agreement specifically seeks independent scientific advice on:

[1] Science Advisors: Jim Anderson, Univ. Washington; Erica Fleishman, UC Santa Barbara; David Freyberg, Stanford Univ.; Wim Kimmerer, San Francisco State Univ.; Denise Reed, Univ. New Orleans; Kenneth Rose, Louisiana State Univ.; Mark Stacey, UC Berkeley; Susan Ustin, UC Davis; Inge Werner, UC Davis

[2] see http://resources.ca.gov/bdcp/docs/BDCP_Planning_Agreement_revised_9.13.2007.pdf

- Scientifically sound conservation strategies for species and natural communities proposed to be covered by the BDCP;
- Conservation actions that would address the needs of species, ecosystems, and ecological processes in the Planning Area proposed to be addressed by the BDCP;
- Management principles and conservation goals that can be used in developing a framework for the monitoring and adaptive management component of the BDCP; and
- Data gaps and uncertainties.

The Planning Agreement also notes that independent scientists may be asked to provide additional feedback, including reports, on key scientific issues during preparation of the BDCP.

A Facilitation Team was retained by the Steering Committee to assist in convening independent Science Advisors and establishing an overall process for engaging scientific input. In June 2007 the Facilitation Team developed a workplan for facilitating independent scientific input for the BDCP (Appendix A). The workplan recommends a series of topically based workshops designed to provide focused, timely advice.

In consultation with the Steering Committee, the Facilitation Team identified and convened a group of independent Science Advisors for an initial workshop focused on addressing the broad requirements of the NCCPA as reflected in the Planning Agreement (see above). The workshop was held September 12-14, 2007. The workshop was designed specifically to:

- Identify principles to inform regional conservation planning under the NCCPA;
- Assess the knowledge base available for planning (what is known and not known);
- Comment on the scope of the ecological and conservation goals and objectives of the BDCP;
- Identify critical ecological processes and scales of variability that the Plan should embrace.

To help focus the Science Advisors' input and to highlight the range of scientific issues that might be relevant to development of the BDCP, a list of topics and questions was developed with input from the Steering Committee (Appendix B). Specific questions were also submitted individually by Steering Committee members (Appendix C).

The Advisors were asked not to review or comment on the specific Conservation Strategy Options being considered by the Steering Committee at the time of the September 2007 Advisors' workshop. The Conservation Strategy Options Evaluation Report prepared by the Plan consultants was not completed until after the Science Advisors' workshop.

1.2 Report Scope and Organization

The contents of this report reflect the Advisors' review of existing information, results of the three-day Advisors' workshop, and subsequent discussions amongst the Advisors. The report addresses key requirements of the NCCPA, as noted in Section 1.1. However, due to the complexity of the scientific issues involved and the early state of the planning process, some topics are addressed in more detail than others. For example, the report provides a clear set of conservation planning principles to help guide Plan development. The report also addresses principles for adaptive management and monitoring, but at this early stage of planning it is not possible to provide detailed recommendations on these topics.

Following this introduction, the remainder of the report is organized to provide scientific input, advice, and recommendations on specific topics as follows:

- Section 2 – Principles for Conservation Planning in the Delta;
- Section 3 - Plan Scope;
- Section 4 – Delta Ecosystem Dynamics;
- Section 5 – Methods of Analyses; and
- Section 6 – Adaptive Management and Monitoring

Specific recommendations are imbedded within each of the respective report sections. To the extent possible, the Advisors provided concrete recommendations that address how specific principles and analytical approaches can be applied to conservation planning. The Advisors also comment on information needs given the scope of the Plan as currently understood.

The recommendations contained in this report are intended to apply broadly to conservation planning in the Delta, both in terms of approaches that could be employed to inform decision-making (e.g. methods of analysis) and in terms of more specific implementation actions (e.g. monitoring). In crafting these recommendations, the Advisors have not focused on legal issues related to who would be responsible for implementation. In some cases, the recommendations may go beyond the specific responsibilities of the BDCP and the Potentially Regulated Entities (PREs). For example, development of a comprehensive monitoring program for contaminants in the Delta (Recommendation R8) would involve regulatory issues and entities beyond the BDCP. Similarly, there are significant ongoing monitoring programs such as those under the purview of the Interagency Ecological Program (IEP). These will likely continue regardless of the BDCP and are beyond the direct scope of the Plan, but could be enhanced or augmented by the Plan. The Advisors do not intend to imply that all recommendations contained in the report should be pursued solely by the PREs as part of the BDCP. Instead, the recommendations represent actions that could support conservation of species and their habitats in the Delta.

The Advisors have not attempted to prioritize the recommendations contained in this report. The relative importance of various recommendations and appropriate sequencing depends on the specific goals and objectives of the Plan and nature of the Plan actions, both of which are still under development. Once the Plan objectives and proposed actions are more clearly defined and if requested by the Steering Committee, the Advisors can provide further guidance on prioritization of the recommendations.

2.0 PRINCIPLES FOR CONSERVATION PLANNING IN THE DELTA

The following principles reflect broad, fundamental concepts that the Science Advisors think are important to acknowledge and understand in developing an HCP/NCCP for the Delta. Although the principles are framed in the context of the BDCP, most if not all are relevant to any comprehensive management plan. As the overall conservation strategy and potential conservation actions are developed for the BDCP, they should be reviewed and evaluated in light of the principles outlined below. The principles are further referenced throughout the report to complement additional observations and recommendations regarding the scope of the Plan and the knowledge base for planning.

A. ***Changes in the estuarine ecosystem may be irreversible.*** Relatively permanent changes in structure or processes (e.g., species introductions, extinctions, and succession, changing climate, or human infrastructure) within the ecosystem may prevent the ecosystem from reverting to a former state when temporary influences (e.g., toxicants, diversions) are removed. Similarly, some ecosystem processes within the Delta result in progressive change and cannot be reversed. Therefore, the future state of the ecosystem is difficult, if not impossible, to predict. Accordingly, goals and objectives that target restoration to historic conditions may not be realistic. Indeed, it may not even be possible to quantify historic or baseline conditions. Because predictions of the outcome or success of management interventions are highly uncertain, a strategy of adaptive management[3] may increase the probability that conservation goals will be achieved (see Principle L).

B. ***Future states of the Delta ecosystem depend on both foreseeable changes (e.g., climate change and associated sea-level rise) and unforeseen or rare events (e.g., the consequences of new species invasions).*** Conservation strategies should take into account the probability of particular system responses to both foreseeable changes and inevitable rare and unpredictable events. Evaluation of mitigation or adaptive management strategies for Covered Species should include consideration of potential alternative future states (e.g., salinity intrusion further into the Delta or large numbers of deeply flooded islands) and incorporate management flexibility (both operational and institutional) that can account for and respond to changing conditions.

[3] For more on adaptive management see Busch, D.E. and J.C. Trexler, editors. 2003.

C. ***The Delta is part of a larger river-estuarine system that is affected by both rivers and tides. The Delta is also influenced by long-distance connections, extending from the headwaters of the Sacramento and San Joaquin Rivers into the Pacific Ocean.*** For example, high inter-annual variability in precipitation and river flows are, in part, due to climate patterns that span the entire Pacific Ocean. In addition, many animals that use the Delta do so for only part of their life cycles, spending other parts upstream in the rivers or as far away as northern Canada. Effective conservation strategies will require a system-wide approach that considers the Delta in its larger environmental context. Such strategies may consider implementing actions outside the planning area that would benefit species within the planning area.

D. ***The Delta is characterized by substantial spatial and temporal variability, including disturbances and extreme events that are fundamental characteristics of ecosystem dynamics. The Delta cannot be managed as a homogeneous system***. Gradients in salinity, temperature, and turbidity establish a range of environments with boundaries that vary seasonally and among years. Variations in channel depth, vegetation density, and water velocity interact to create additional spatial and temporal variability. Potential spatial and temporal variation in the system response should be explicitly considered in development of potential conservation measures.

E. ***Species that use the Delta have evolved life history strategies in response to variable environmental processes. Species have limited ability to adapt to rapid changes caused by human activities.*** Changes in geomorphology, tidal and freshwater flow, and chemical composition of the water may fundamentally alter the processes that maintain populations of animals and plants. Examples include cues for migration, feeding, and avoiding predation, all of which affect rates of survival. Conservation strategies that seek to reestablish or maintain conditions within known tolerances of the species and that acknowledge the inherent natural variability in these conditions will likely be more successful.

F. ***Achieving desired ecosystem outcomes will require more than manipulation of Delta flow patterns alone.*** Many important drivers of ecosystem dynamics are highly variable, unpredictable, and difficult to manipulate (for example, humans cannot convert a dry year into a wet year). Furthermore, a number of key ecosystem drivers are independent of freshwater flow patterns (e.g., species introductions). Achieving conservation goals will require that managers directly address drivers that are difficult to manipulate and not related to flow.

G. ***Habitat should be defined from the perspective of a given species and is not synonymous with vegetation type, land (water) cover type, or land (water) use type.*** The term 'habitat' refers to the space and time within which an organism lives and the abiotic and biotic resources in that space and time. Thus, habitat location and quality are dynamic in space and time. At any given time, a given species may be absent from high-quality habitat because of various external constraints that restrict its populations to locations of lower-quality habitat.

H. ***Changes in water quality have important direct and indirect effects throughout the estuarine ecosystem.*** Water quality, including salinity, temperature, turbidity and contaminants, is influenced by inputs of substances from rivers, downstream sources, and local sources, estuarine physics and geomorphology, and water operations. The distribution of salinity determines the distribution of geochemical conditions and affects all estuarine species. Temperature and turbidity influence growth and reproductive rates, and contaminants can have a variety of negative effects. Water quality may affect Covered Species directly or indirectly through water quality effects on the estuarine food web that supports the Covered Species.

I. ***Land use is a key determinant of the spatial distribution and temporal dynamics of flow and contaminants which, in turn, can affect habitat quality.*** Chemicals enter the Delta from many land-use-related sources along many pathways, including atmospheric drift, rain, river flow, storm runoff during winter, return flow from irrigation during summer and fall and from seepage year round, point sources including municipal and industrial effluents, and direct application to surface waters (e.g., control of non-native aquatic plants). These patterns in distribution and timing of contaminants can influence habitat quality for species.Other effects of land use include significant alteration of high flow behavior from flood-damage mitigation, and alteration of local water inflow volumes and timing. Consequently, conservation planning must consider the role of current and future land use within and outside the Delta.

J. ***Changes in one part of the Delta may have far-reaching effects in space and time.*** Although specific actions may affect the entire Delta, the effects are not uniform in magnitude throughout the Delta. For example, changes in the physical structure of one part of the Delta, such as a levee failure or new barriers, can alter flow patterns that may affect how organisms migrate and therefore where they are abundant in or outside the Delta. Similarly, changes in flow and sediment transport determine how chemicals are partitioned among sediments, plants, and water, and where those chemicals will accumulate.

K. ***Prevention of undesirable ecological responses is more effective than attempting to reverse undesirable responses after they have occurred***. Potential negative ecological impacts of management actions should be considered and designs should attempt to minimize these impacts before projects are implemented, rather than assuming that mitigation will be effective. For example, it is better to take actions that reduce take of fish at the pumps then to rely on salvage of entrained fish to minimize pumping effects. While habitat enhancement or restoration can theoretically benefit populations, these effects are difficult to quantify compared to direct mortality. Consequently, the measurable impact of habitat improvement on fish populations may be small, and the scale of restoration needed to achieve conservation goals through mitigation is likely very large. Moreover, the potential for success of large-scale restoration efforts is often uncertain.

L. ***Adaptive management is essential to successful conservation***. Uncertainty about the likely outcomes of conservation actions arises from a variety of causes that may be inherent in the system, due to substantial changes within the system, or related to incomplete monitoring or understanding. Therefore, conservation actions should be implemented in an adaptive management context. For the BDCP, like any other conservation plan, adaptive management involves the development of quantitative conservation objectives and quantitative triggers for changes in management. The objectives also should be achievable within a specified period of time, given the scope and constraints of the Plan.

Conservation actions should be based on well-supported hypotheses about their outcomes, given the potential irreversibility of changes to the state of the ecosystem. Information from monitoring of projects and system response must feed back to system models used to inform managers and those overseeing implementation[4].

M. Conservation measures to benefit one species may have negative effects on other species. Actions necessary to achieve objectives for different conservation targets may conflict (i.e., a given action simultaneously may benefit some species or ecological processes of conservation concern and have a negative influence on other species or processes) (Margoluis and Salafsky 1998). Conservation plans must recognize these potential conflicts, evaluate tradeoffs among conservation targets, and, to the extent possible, minimize negative effects.

N. Data sources, analyses, and models should be documented and transparent so they can be understood and repeated. Important environmental decisions may be informed by statistical analysis and modeling, both of which have multiple sources of uncertainty. Analysts can obtain different results by using different data or models. Comparison among alternative methods of analyses is an effective way to explore uncertainties. These comparisons require sufficient clarity about the differences among analyses. Clear documentation of data and analyses enables comparison of results derived from alternative methods. Documentation also helps to identify what is known and not known, and the major sources of uncertainty.

O. Ecosystem responses, especially to changes in system configuration, can be predicted using a combination of statistical and process models. Statistical models document status, trends, and relationships between responses and environmental variables, whereas process-based models are useful in understanding system responses and for forecasting responses to new conditions. Statistical models may allow us to characterize empirically how a system works. However, statistical models may not allow us to predict system responses, because they apply only within the range of conditions over which data have been collected. Process models rooted in underlying mechanisms provide a much stronger basis for predicting system responses to environmental change (i.e., extrapolating beyond

[4] For more on adaptive management see Busch, D.E. and J.C. Trexler, editors. 2003.

available data), although model calibration and validation of process models are more challenging than for statistical models.

P. ***There are many sources of uncertainty in understanding a complex system and predicting its responses to interventions and change.*** Some of these uncertainties are reducible, often through additional data collection and scientific study, which can be important components of adaptive management. Other uncertainties are not reducible because they are rooted in inherent system variability. Uncertainty is unavoidable and methods for addressing uncertainty should be incorporated explicitly into decision-making.

3.0 PLAN SCOPE

The scope of an NCCP/HCP is defined by its geographic area and time horizon, and the actions, species, and communities to be covered. This report provides some preliminary observations and advice regarding each of these items based on available information. The Advisors recommend that the Steering Committee seek additional scientific input regarding the plan scope as new information becomes available, particularly as more specifics concerning the nature of the actions to be covered by the BDCP are developed.

3.1 Geographic Area

The Advisors emphasize that the Delta is embedded within a larger environmental context and cannot be managed as an isolated system (Principle C). The current boundary, as defined in the Planning Agreement, is the Statutory Delta[5]. Species and communities in the Planning Area are affected by actions and processes outside the Planning Area (e.g., upstream water diversions, spawning habitat for anadromous fish, contaminant inputs, precipitation patterns in the Sierra Nevada, sea level rise, and other aspects of climate change). Also, depending on the selected conservation strategies, some Covered Activities may occur outside the Statutory Delta. Some Covered Activities also may affect species and communities outside the Planning Area (e.g., by changing the quality of Delta outflow or increasing salinity in Suisun Bay).

The Advisors think it is premature to make firm recommendations regarding changes to the Planning Area (Recommendation R1). However, the Advisors note that alterations to the Planning Area may be necessary as planning progresses to reduce regulatory uncertainties and undesired consequences of Covered Activities..

> ***R1. Seek further advice on the appropriate geographic scope as the nature of the Covered Activities and conservation measures becomes more defined.***

[5] As defined by section 12220 of the California Water Code.

3.2 Time Horizon

For the purposes of this report, the Advisors assumed that the duration of the permit, and the time available to plan and implement Covered Activities, would be 50 years. Some actions to be permitted under the Plan will likely take many years to implement. The distribution of species and the distribution and quality of their habitat will change during that time (e.g., due to species introductions and climate change). Therefore, the Advisors recommend building contingencies into the Plan via an adaptive management program (see Section 6.0) that anticipates and can adjust to such changes to the degree feasible (Principles A and L).

3.3 Covered Species

The Advisors agree that the Planning Agreement has correctly identified the aquatic species to be covered assuming the current list of Covered Activities[6]. These species are Central Valley steelhead (*Oncorhynchus mykiss*), Central Valley Chinook salmon *(Oncorhynchus tshawytscha)* (spring run, winter run, and fall/late-fall runs), Delta smelt *(Hypomesus transpacificus),* green sturgeon *(Acipenser medirostris),* white sturgeon (*Acipenser transmontanus),* splittail (*Pogonichthys macrolepidotus)* and longfin smelt (*Spirinchus thaleichthys)*. However, the Advisors suggest that the San Joaquin River fall-run Chinook salmon deserves consideration as a Covered Species, distinct from other Central Valley Chinook salmon, because the two taxa are exposed to significantly different environmental conditions in and upstream of the Delta (Recommendation R2).

> ***R2. Consider the San Joaquin fall-run Chinook salmon as a Covered Species distinct from other Central Valley fall-run Chinook salmon.***

The Planning Agreement also identified four additional species to consider for coverage (Recommendation R3). The Advisors agree that it is premature to make firm recommendations about coverage for these species until Covered Activities and conservation strategies, are specified. However, the Advisors offer the following preliminary thoughts about including these species.

[6] The Covered Activities are those described at the 3/23/07 BDCP Steering Committee meeting. See http://resources.ca.gov/bdcp/docs/03_23_2007__handout_Covered_Activities_List.pdf

R3. Revisit the inclusion of Swainson's hawk, giant garter snake, bank swallow, and other listed taxa as Covered Species once the Covered Activities and conservation strategies, are more fully identified.

- Swainson's hawk (*Buteo swainsonii*) – This species is listed as threatened under the California ESA. It nests within the Planning Area where large trees for nesting occur near extensive agricultural fields over which the species can forage (Woodbridge 1998). The Delta is also an important wintering area for the species (Herzog 1996). Swainson's hawk typically does not travel far to forage and is likely to nest only near foraging habitat. Nesting habitat probably will not be affected directly by the currently listed Covered Activities. However, coverage for the species should be considered more thoroughly if Covered Activities are likely to include flooding of islands or major changes in agricultural practices. Such activities could reduce the amount of foraging habitat for Swainson's hawk and result in abandonment of nesting territories within the Planning Area.
- Giant garter snake (*Thamnophis gigas*) – This aquatic snake is listed as threatened under the California and federal ESA. It is found in the northern and eastern Delta (with one recent record from the western Delta in the vicinity of Decker and Sherman Islands), associated with agricultural wetlands, irrigation canals, sloughs, ponds, low gradient streams, and other aquatic land use and land cover types with emergent vegetation (USFWS 1999); http://www.californiaherps.com/snakes/maps/tgigasmap.jpg). Covered Activities could potentially affect giant garter snakes, positively or negatively, via construction in occupied areas, changes in agricultural practices, or flooding of habitat.
- Bank swallow (*Riparia riparia*) – This species is listed as threatened under the California ESA. It is not known to nest within the Statutory Delta (Garrison 1998). It nests on vertical banks with soft soil or in cliffs, usually after flood waters recede and low water levels expose cut banks. If BDCP conveyance approaches or conservation measures cause direct or indirect changes to the structure of channel banks outside the current planning area, this species may be affected and coverage should be considered.
- Valley Elderberry longhorn beetle (*Desmocerus californicus dimorphus*) – This species has been recommended for delisting by the U.S. Fish and Wildlife Service due to positive effects of ongoing conservation actions and evidence of the existence of many more populations, over a much broader geographic range, than was known at the time of listing (USFWS 2006). Therefore, the Advisors suggest that the subspecies not be covered under the NCCP/HCP.

Given that regulatory assurance is a priority for the Potentially Regulated Entities (PREs), it is prudent to examine the potential effects of Covered Activities on the full range of species that are listed under federal and state endangered species acts, or are likely to be listed during the permit period. For example, plant and animal species associated with tidal marsh and riparian vegetation may be candidates for coverage by the Plan depending on the final array of Covered Activities.

3.4 Planning Species

In addition to species to be covered by incidental take authorizations, it may be useful for the Plan to consider other species as "planning species". Although planning species may not be listed and therefore do not require incidental take permits, considering the effects of the Plan on these species may assist in meeting ecosystem goals. Planning species might include species that have strong effects (positive or negative) on Covered Species or ecological processes. For example, a planning species might play a key role in food webs that include Covered Species. Participants in other NCCPs (e.g., San Diego Multiple Species Conservation Plan, Yuba-Sutter HCP/NCCP, and Santa Clara Valley HCP/NCCP) have identified non-listed species that they think should be considered as planning species.

The Advisors discussed whether to recommend planning species for the BDCP. In general, the Advisors do not advise designating species as planning species solely for economic, recreational, or aesthetic reasons. However, some non-listed species that may be affected by Covered Activities and conservation measures exert strong influences on the Bay-Delta ecosystem and on populations of Covered Species. Specifically, the Advisors have identified two groups of species as potentially useful planning species given the current list of Covered Activities: two non-native species of pelagic fish shown to be in decline (i.e., POD species, see Sommer et al. 2007) that are not included in the list of covered aquatic species, and four non-native invasive species that have altered the structure, composition, and function of the Delta ecosystem (Recommendation R4). These two categories are addressed further below.

POD Species

- Striped bass (*Morone saxatilis).* Striped bass is not native to the Delta, although its introduction was intentional. Its decline is of concern because it contributes to the total biomass of pelagic fishes in the ecosystem, and abundance indices for 2002-2005 included record lows for young striped bass (Sommer et al. 2007). The reason for this decline is unknown, although it is not due to low adult abundance (Sommer et al. 2007). The POD Management Team and collaborating scientists are analyzing trends and associations between abundance and environmental covariates.

- Threadfin shad (*Dorosoma petenense).* Like striped bass, threadfin shad is not native to the Delta and is of interest as a planning species primarily because of its previously high abundance (in some years it has been the most abundant fish in the Delta (Sommer et al. 2007)) and sharp drop in abundance in 2001, concurrent with the declines of other POD species.

Life histories of striped bass and threadfin shad are different from those of Delta smelt and longfin smelt (two other declining pelagic species covered by BDCP). This implies that their abundance and population dynamics may be responding to different drivers. Furthermore, adult striped bass consume other fish and may cause substantial mortality to young winter-run Chinook salmon (Lindley and Mohr 2003) and possibly other pelagic species. Considering striped bass and threadfin shad as planning species and exploring their potential response to conservation strategies may provide insight into the effect of conservation measures on diverse components of the ecosystem. Their inclusion as planning species does not imply that conservation actions should be developed to increase their abundance. Rather, considering how these species may respond to actions that are designed to benefit the Covered Species may provide information on the potential effects of plan implementation on a more diverse set of components of the Delta ecosystem.

Non-native species with ecosystem-level impacts

- Largemouth bass (*Micropterus salmoides).* Abundance of this species has increased in the Delta over the past few decades concurrently with the increase in submerged vegetation (Brown and Michniuk 2007). Largemouth bass have a much more limited distribution in the estuary than striped bass, but a higher per capita impact on small fishes in near-shore waters (Nobriga and Feyrer 2007). The effects of consumption of Covered Species by largemouth bass are unknown.
- Brazilian water weed (*Egeria densa*). This species increases water clarity by trapping fine sediments, and increases vegetation structure in littoral areas. This shifts the Delta waterways from turbid, pelagic conditions that favor native species of fish to clear, vegetated littoral conditions that favor introduced species such as largemouth bass (Brown and Michniuk 2007). Remote sensing studies from 2003 to 2006 showed that the range of Brazilian water weed has fluctuated from year to year and that previously occupied areas are

frequently recolonized, even where control methods have been applied. Submerged non-native vegetation covers about 10-12% of the waterways in the Delta. Approximately 80% of the submerged vegetation is Brazilian water weed (S. Ustin, unpublished).

- Overbite clam (*Corbula amurensis*). This species was introduced in 1986. Grazing by overbite clam is thought to have resulted in a substantial decline in phytoplankton and calanoid copepods, the primary prey of early life stages of pelagic fishes, in brackish waters of the Delta and Suisun Bay (Kimmerer 2002b).
- Freshwater clam (*Corbicula fluminea).* This species was introduced to the Delta in 1945, but understanding its effect on the ecosystem is hampered by the lack of ecological studies preceding its invasion. However, the introduction of freshwater clam has caused substantial changes to other estuarine ecosystems, including shifts from a phytoplankton base toward submerged aquatic vegetation (Phelps 1994). Freshwater clams are food limited in the Delta (Foe 1986) and they can control phytoplankton biomass in at least some locations in the Delta (Lucas et al. 2002, Jassby et al. 2002), which likely reduces the energy supply to some Covered Species.

The identification of these non-natives as planning species does not mean that conservation actions need to be developed for their benefit. Rather, because these species have caused substantial changes in ecosystem processes, assessing how the species respond to conservation actions designed to benefit the Covered Species may provide information on the potential effects of plan implementation on a more diverse set of components of the Delta ecosystem.

R4. Use planning species such as threadfin shad, striped bass, largemouth bass, Brazilian waterweed, overbite clam, and freshwater clam to assess effects of conservation measures on a wider range of ecosystem components and dynamics than the Covered Species represent.

3.5 Covered Communities

The Advisors caution against using guilds, communities of species, or other groupings of convenience for planning and analysis. Although species interact to form ecological communities, we often lack knowledge about the effects of a given species on the distribution or probability of persistence of another species. In addition, although sets of species often use some resources in common, each species has distinct resource requirements that should be accounted for individually. Although the Advisors acknowledge that the statutory language of the NCCPA focuses on communities, they do not think communities are defined clearly enough to be particularly useful for conservation planning within the Delta.

It will be more scientifically robust and effective to consider the presence of Covered Species relative to characteristic sets of ecological conditions than to correlate the presence of Covered Species with easily observed vegetation or substrate types (Recommendation R5). These sets of ecological conditions are defined by the way in which key environmental gradients interact across the Delta. Two of the most influential gradients within the Delta are (1) distance from the ocean which influences tidal exchange and salinity, and (2) elevation which influences inundation (Figure 1).

The interaction of tidal exchange and salinity produces four zones from ocean to rivers: (1) high salinity with tidal exchange, (2) fluctuating salinity with tidal exchange, (3) freshwater with tidal exchange, and (4) freshwater with no tidal exchange. The borders of these zones are dynamic and depend on Delta inflows, the range of oceanic tides (mainly spring vs. neap), and regional weather.

The elevation gradient produces four zones: (1) constantly inundated, (2) inundated and exposed on tidal time scales, (3) seasonally inundated, and (4) infrequently inundated. Although the elevations are fixed, at least on short time scales, the zones of inundation vary according to water levels, which depend on the interaction of river flows and the tide as well as atmospheric pressure and winds. Structures such as levees, barriers, and tidal gates modify gradual gradients of tidal exchange and salinity, creating abrupt shifts in environmental conditions (e.g., in elevation or salinity), and subsidence increases the degree of inundation during floods. These alterations can disrupt the transport and exchange of chemical and biological materials along these gradients.

R5. Examine how individual species respond to gradients in environmental conditions (and changes in those gradients) to inform assessment of the effects of conservation strategies, rather than using guilds, species communities, or other groupings of convenience.

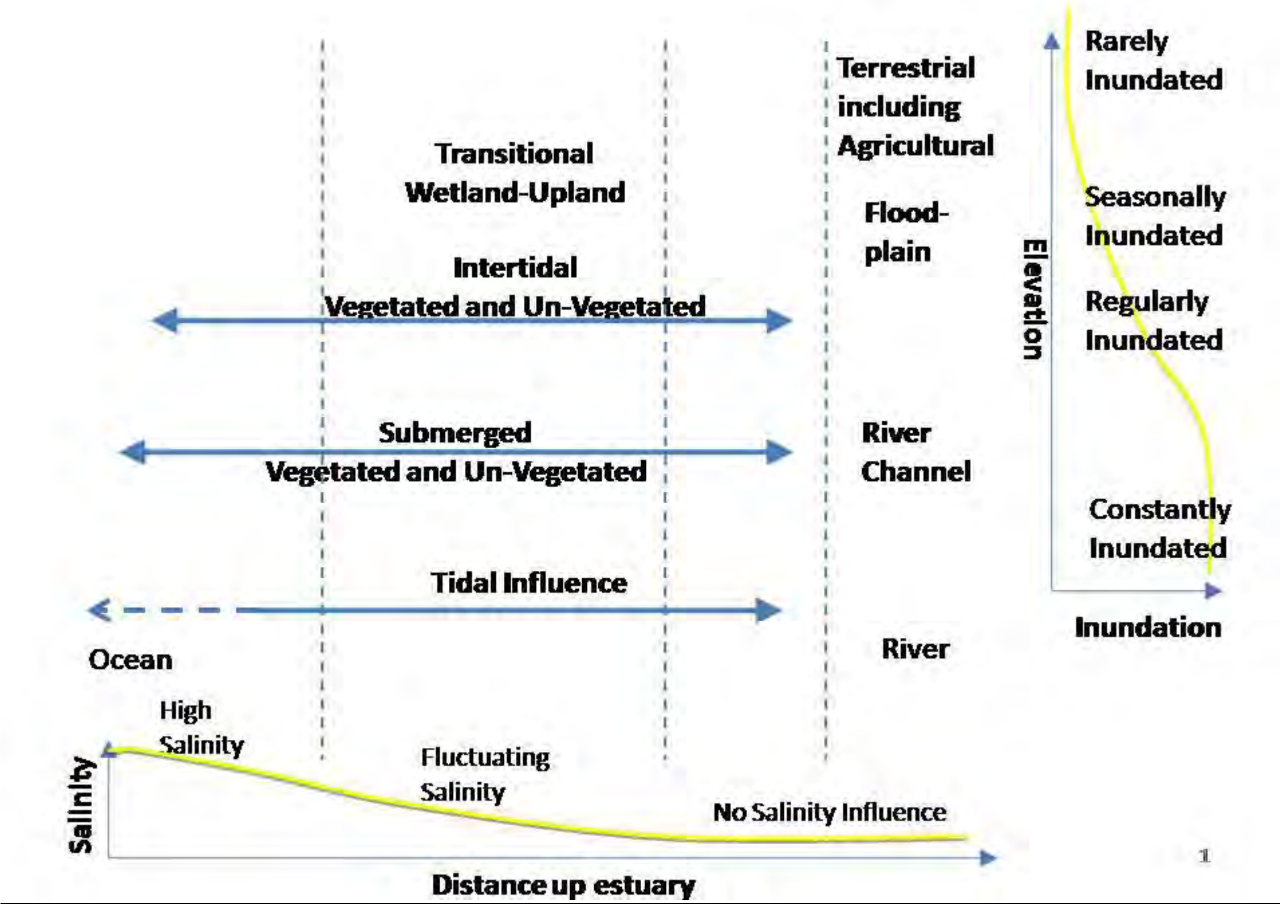

Figure 1. Horizontal and vertical gradients that control environmental conditions in the Delta.

Species disperse and are distributed across gradients of tidal exchange and salinity according to intraspecific and interspecific competition (especially in lower-stress environments) and the species' ability to exploit the range of environmental conditions (Byrd and Kelly 2006). As a result, different combinations of species occur in different areas at different times (Principle G). For example, inundation and salinity gradients affect the species richness, distributions, abundance, and biomass of tidal wetland plants (Mahall and Park 1976b, Atwater 1979).

Tidal exchange and salinity are interdependent. For example, soil salinity increases as wetland elevation increases to mean high high tide (MHHT), and then decreases further inland (Mahall and Park 1976b). Thus, spatial zonation in wetlands reflects a combination of biotic factors and physical and chemical factors, such as tidal regime, soil topographic features, and soil properties (Silvestri et. al. 2003, Belluco 2006, Mahall and Park 1976a, b, c).

Incorporating an understanding of environmental gradients in the Delta into conservation planning allows for consideration of changes to the drivers of those gradients. For example, sea-level rise will shift tidal gradients within the Delta and alter salinity penetration. Current estimates of global sea-level rise range from 9 cm[7] to more than 1 m[8] by 2100. Some scientists suggest conservation planning in the Delta should use sea-level rise estimates of 50-140 cm for the 21st century[9]. Similarly, increased temperature associated with climate change has already begun to alter runoff patterns in the system through a shift to an earlier peak in snowmelt (Knowles and Cayan 2002), which will influence environmental gradients within the estuary. Subsidence in the Delta and associated salinity penetration in the event of a levee failure have been identified as a potentially substantial influence on long-term salinity patterns (Mount and Twiss, 2005). Considering the influence of these anticipated changes on conservation measures is an essential element of planning (Recommendation R6).

Changes in the human environment should also be considered. This will likely take the form of increased urbanization around and within the Delta, and a shift in the pattern of demand for water from agriculture to municipal use. Increases in demand are expected to have at least as great an effect on water supplies globally as reductions in supply due to climate change (Vörösmarty et al. 2000). The same may be true at a regional level for water supplies in the Delta.

R6. Assess the sensitivity of conservation outcomes to anticipated changes in environmental gradients that will likely arise from sea-level rise, subsidence, climate-change induced alteration in the timing of runoff, human activities, and other processes over the time frame of the Plan and beyond.

---

[9] Memo from CALFED Independent Science Board to Lead Scientist, 6 September 2007. Located at http://www.calwater.ca.gov/science/isb/isb_archive_07.html August28-29, 2007 meeting.

4.0 DELTA ECOSYSTEM DYNAMICS

The Delta is a highly complex system of interacting physical, geomorphic, biological, and chemical processes, all of which are influenced by human activities both inside and outside the Delta. The Advisors consider certain of these interactions particularly important for anticipating the response of the Covered Species to future changes in environmental conditions, the Covered Activities, and other aspects of human use of the Delta. External influences (e.g., river inflows, diversions, tides) interact with the underlying physical structure of the system to influence physical, geomorphic, food web, and chemical processes. The interaction of these processes influences species population dynamics in a variety of ways (Figure 2). A process-based approach provides a basic framework for understanding system dynamics and for developing and evaluating conservation strategies (Principle O). Physical processes drive many aspects of the ecosystem both directly and indirectly (Principle F), (Figure 2).

This section is not intended to provide a detailed description of the all the physical, geomorphic, biotic, and chemical processes within the Delta. Rather, this section aims to

1. Identify the most important processes influencing Covered Species;
2. Assess the current state of knowledge regarding those processes;
3. Outline key uncertainties, and;
4. Assess the ability to predict how these processes operate within the system.

Understanding these processes, and acknowledging the limits of our understanding, is critical to the formulation of a conservation strategy. It is important to keep in mind that the system is neither static nor homogeneous (Principle D) so our understanding changes with time and new data.

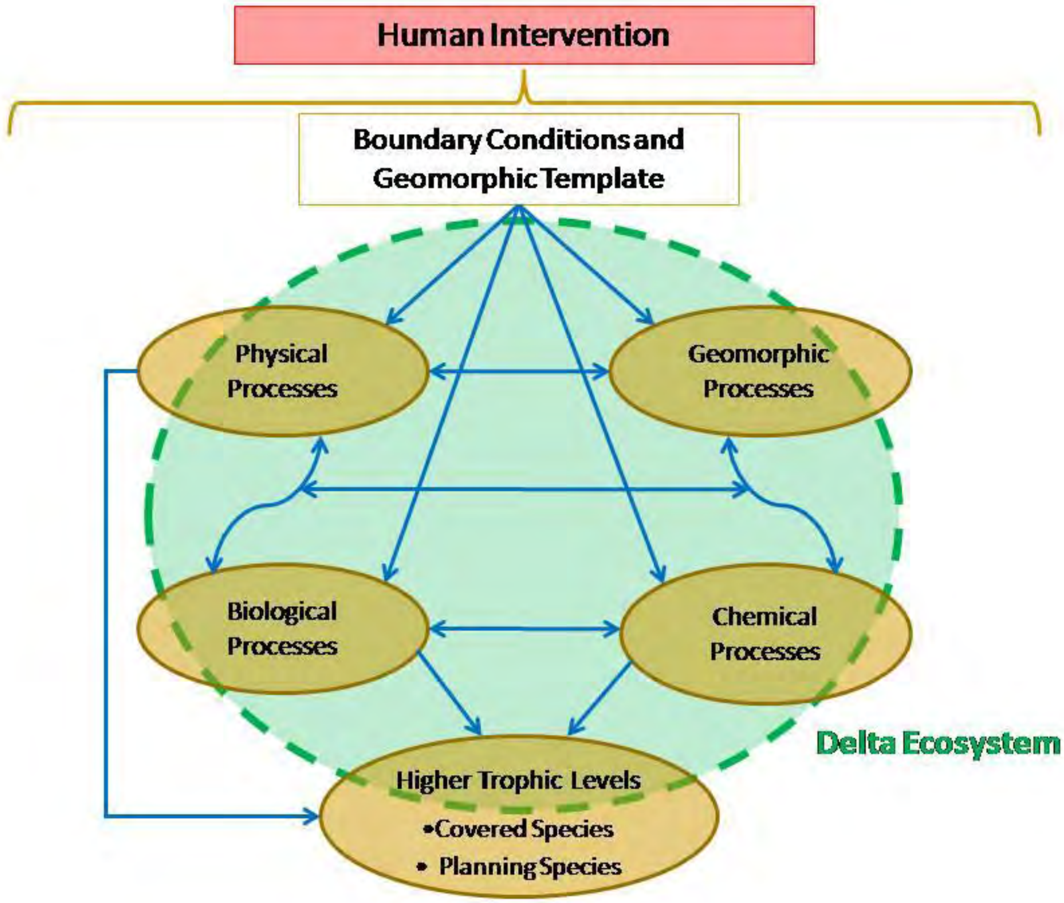

Figure 2 – Conceptual diagram of interactions among environmental processes that influence responses of higher trophic levels, including Covered Species, to changing conditions.

4.1 Process Interactions in the Delta

To understand the Delta ecosystem it is essential to consider the factors both internal and external to the Delta that drive the ecosystem (Principle C). At least 11 external processes or factors fundamentally influence the Delta ecosystem (Table 1). In addition to physical processes that are driven by external factors, some biological and chemical processes in the Delta are directly influenced from outside the Delta (e.g., harvest of salmon in the ocean, chemical applications) (Figure 2).

The Advisors have identified a number of critical processes that influence higher trophic levels, including the Covered Species (Tables 2-5). The roles of these processes in influencing different life stages of Covered Species are addressed in section 4.3 below. Interactions among these processes are frequently more important than any one process alone. Many interactions among processes are mediated by changes in dissolved constituents, (Principle H), including salts and nutrients. Inputs from upstream and from within the Delta alter the amount of these constituents, but their dynamics are often controlled by tidal dispersion (Table 5 and Principle I).

Water quality in the Delta influences higher trophic levels directly and indirectly via changing environmental conditions (Figure 1) and toxicity, and as a control on primary production and energy inputs to the food web (Table 4). Other important process interactions occur at a local scale. The Delta's aquatic food web is driven by phytoplankton and, to some extent, bacteria rather than by detrital organic matter (Table 4). However, aquatic plants, which are often the primary source of detritus, can influence turbidity through flow attenuation (Tables 1 and 2), which potentially increases phytoplankton growth. Aquatic plants may also absorb contaminants such as pyrethroid insecticides (Table 5).

Anticipating the ecosystem response to Covered Activities requires an understanding of these and other complex interactions among abiotic and biotic processes. The use of models to predict population dynamics of Covered Species is addressed in Section 4.4.3. However, forecasting changes in the process interactions described here and in Figure 2 is important for understanding the system level implications of Covered Activities. Many of these interactions are driven by physical processes. Because our ability to predict the physical dynamics of the system is effectively limited to the current system configuration (Table 2 and Section 4.4.2); predictions of how these process interactions will change in the future are highly uncertain.

4.2 Information Needs

Although monitoring programs have been implemented for some aspects of the Bay Delta system (e.g., hydrodynamics, salinity, fish densities and distribution), the ability to predict the response of any system component to the Covered Activities is limited in many instances by available data (Tables 1-5). To address the needs outlined in Tables 1-5, additional data that could be collected include detailed topography and bathymetry, wind stress and solar insolation, bed sediment character, and distribution and rates of clam grazing. This list is not intended to be comprehensive but serves to illustrate the range of data needs currently limiting conservation planning. The Advisors acknowledge efforts of groups such as CMARP (Comprehensive Monitoring and Research Program) in identifying a broader array of monitoring needs. It may be possible to monitor some parameters using recently developed techniques for the acquisition of detailed spatial data (e.g., remote sensing, towed samplers) and the Advisors encourage the evaluation and, if appropriate, implementation of these approaches (Recommendation R7). The influence of contaminants on the dynamics of plants and animals in the Delta is unclear. With the exception of mercury, which has been relatively well studied in the Delta and surrounding watersheds, and selenium, for which data are available upstream but not in the Delta, predictive ability related to effects of contaminants is fundamentally constrained by a lack of information (Recommendation R8).

Existing monitoring programs should be maintained (Recommendation R8), but as conservation options become more fully developed it is likely that additional data will need to be collected to support analysis of options; these analyses include model development and validation (Section 4.4). Development of detailed recommendations on monitoring to inform BDCP conservation actions requires more information on the nature of Covered Activities and more explicit conservation goals (Recommendation R9 and section 6.0). The effective and transparent use of existing and newly acquired data in conservation planning requires a database that can incorporate data collected over space and time (Recommendation R10). Such a database will be an important tool in Plan development. The database could inform the design of future research and monitoring activities, and assist in developing both hypotheses about relationships among ecosystem components and statistical and process models.

R7. Routinely collect high resolution airborne imagery over the Delta, including lidar, hyperspectral or multispectral, and thermal, to detect and quantify spatial changes in miocrotopography, surface water temperature, surface turbidity, algal blooms, and aquatic, wetland, and riparian plant species composition and fractional cover.

R8. Maintain current monitoring programs within the Delta and institute a comprehensive, long-term, Delta-wide monitoring program to provide data on contaminants in sediments, water, and aquatic organisms, including in-Delta diversions and return flows.

R9. Refine and expand existing monitoring programs as Covered Activities and Conservation Actions are specified and critical data needs can be identified.

R10. Develop an integrated database of monitoring data (e.g., salinity, temperature, nutrients, contaminants) and relevant spatial data layers (e.g., topography, distributions of submerged, emergent, and floating aquatic plant species).

Scientific studies will be necessary to explore the effects of Conservation Actions and other environmental changes on Covered Species. These studies will need to examine the fundamental interactions between physical, chemical, biogeomorphic and food web processes that influence the Covered Species. Targeted research can facilitate development of more successful statistical and process models, including models that support predictions of ecosystem response to changing Delta configurations and boundary conditions. More information on the Covered Activities and conservation strategies is essential before the Advisors can offer guidance on the array of scientific input that will be needed to support BDCP planning and implementation.

4.3 Population Dynamics and Process Interactions at Higher Trophic Levels

The discussion below focuses on fish because of their dominance on the list of Covered Species, but similar issues and recommendations would apply to any other covered and planning species. Organisms at higher trophic levels in the Delta are influenced by interactions among physical, chemical, biogeomorphic and food web processes (Figure 2).

Of relevance for evaluating alternative management and conservation actions is how the factors shown in Tables 1-5 affect the growth, mortality, reproduction, and movement of individual members of the Covered Species. The cumulative responses of individuals over life stages, space, and time influence the dynamics of populations. Population dynamics encompasses seasonal and interannual fluctuations in distribution and abundance, long-term trends in distribution and abundance, likelihood of persistence and recovery, and other phenomena. Understanding and forecasting population dynamics requires consideration of the dependence of all life stages on key environmental variables. Understanding and forecasting population changes due to Covered Activities may also require understanding how Covered Species respond to environmental conditions outside the range of conditions they currently experience

4.3.1 Life Cycles

To identify how environmental changes in the Delta may affect the Covered Species, first it is necessary to consider which portions of each species' life cycle occur within the Delta. For anadromous species such as salmon and steelhead the Delta serves as a migratory corridor for juveniles and adults, and a rearing area for some juveniles (Williams 2006). By contrast, one or more of the life stages of resident species of fishes occur within the Delta, Delta smelt spawn in the central and northern Delta. The juveniles move downstream into the brackish waters of the western Delta and Suisun Bay, and adults migrate back into the Delta to spawn (Bennett 2005, Moyle et al. 1992). Longfin smelt are thought to spawn in the Delta, while juveniles and sub-adults are found throughout the saline parts of the estuary, and adults may enter the near-shore areas of the ocean (Moyle 2002). Splittail spawn on floodplains in the Yolo and Sutter bypasses and along the Cosumnes River. Juvenile and adult splittail inhabit tidal freshwater and brackish water in the Delta (Moyle et al. 2004). Sturgeon, like salmon, are anadromous, but sturgeon tend to spend a greater proportion of their adult life stage throughout the estuary than do salmon (Moyle 2002). Thus, each Covered Species uses the Delta in a different way.

The Advisors suggest viewing each species' use of the Delta through a life cycle triangle that depicts the species' life cycle from birth to death as a closed migration path (Harden-Jones 1968) (Figure 3 and Recommendation R11). The path begins in the spawning habitat where adults produce offspring. The larval fish disperse to the juvenile habitat and eventually move to the adult habitat. The path is completed when the adults migrate back to the spawning habitat to reproduce. The population dynamics of a species are determined by the survival of fish over the migration path, the number of offspring produced by adults in the spawning habitat, and the number of times adults cycle between the adult and spawning habitats during their lifetime. The critical life history processes, or vital rates, include growth of individuals, mortality in each habitat, movement among habitats, and reproduction in the spawning habitat. These vital rates control the population dynamics of the species in the Delta. The set of vital rates across life stages dictates the rate at which an individual moves through its life cycle. Specific sets of vital rates, which have proven successful over evolutionary time, define the life history strategy of the species (Winemiller and Rose 1992).

R11. Consider relationships between environmental conditions and the Covered Species in a life cycle context.

4.3.2 Population Responses to Environmental Conditions

A major challenge for assessing how populations respond to environmental changes and management actions is to determine how the vital rates at different life stages may respond to the altered environmental conditions. Quantifying the effects of conservation measures on abundances at different life stages is difficult. Determining whether these effects are sufficient to offset uncertain management-induced mortality rates is even more difficult (Principle K). It is necessary to examine how hydrodynamics, salinity, temperature, food availability, contaminants, and other environmental variables directly and indirectly affect the rates of growth, reproduction, mortality, and movement. Of these processes, growth is usually the easiest to study in the field and in the laboratory. Reproduction is also generally quantifiable under current environmental conditions. Mortality is difficult to quantify and the sources and locations of mortality are notoriously difficult to identify (Recommendation R12). Even mortality at the south Delta export pumps, which are intensively monitored for fish entrainment, has some major unknowns such as mortality in the channels leading to the pumps (Kimmerer in press). Some of the unknowns related to entrainment mortality could be reduced through a program of research that might include studies of radio-tagged fish, predator removal studies, bioenergetic analysis of predators, sampling fish behind the louvers at the fish facilities, and studies of predator aggregation at release points[10]. Such a program should be built around a modeling component so results of individual studies could be compared and placed in a population context.

[10] See also the Summary of the June 22 -23, 2005 CALFED Science Program Predation Workshop at http://www.calwater.ca.gov/science/events/workshops/workshop_predation.html

R12. Pursue efforts to quantify the contribution of entrainment and other factors to stage-specific mortality rates of Covered Species to in order to assess the population-level benefits of offsetting such losses.

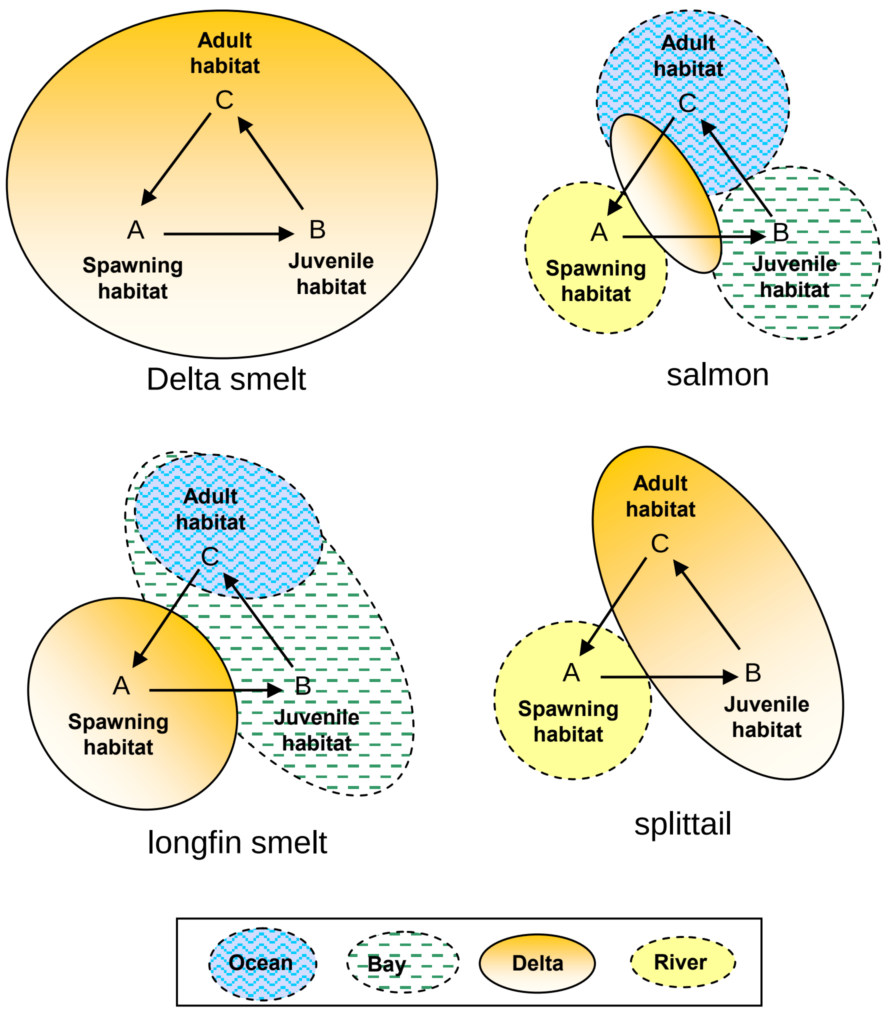

Figure 3. General pattern of use of the Delta by Covered Species over their life cycle. Arrows indicate migration among habitat types.

Determining how changes in environmental conditions may affect movement of the Covered Species is particularly important and challenging. Aquatic organisms in the Delta use various cues to move among habitats. Thus, effects of tidal and net flows on fish movement must be explicitly considered in analyses. Movement is important because vital rates, especially growth and mortality, depend on the timing and routes of movement through the Delta. For example, the central Delta is probably poorer habitat for salmon than the migration pathway along the Sacramento River (Brandes and McLain 2001). The vulnerability of many species to detrimental effects of the Delta pumps depends on their location within the Delta. Additionally, understanding how water operations and management actions affect fish exposure to salinity, temperature, and food is critical to understanding growth, movement, and mortality. Yet relatively little is known about how environmental cues affect fish behavior and movement. Even less is known about how alteration of these cues by management actions might affect movement, which, in turn, would affect the vital rates and population dynamics of species that use the Delta (Principle E).

Tables 1 through 5 describe factors that affect the vital rates at each life stage (Figure 3). These factors can influence habitat quantity and quality differently for each species by modifying the connections among habitats, pathways of movement, and the growth, survival, and reproduction of individuals as they move through their habitats.

- Table 1 describes the fundamental drivers of the Delta ecosystem, many of which can affect the vital rates of fish at different life stages, and most of which can be altered by human activities. The boundaries of the environment are defined by bathymetry, shorelines, and topography, which together determine the geographic extent of habitats for each species and the physical connections among habitats.
- Table 2 describes relevant physical processes and factors in the Delta, such as transport and mixing of water and dissolved and particulate constituents (including salts, sediments, and biota) and water temperature. These processes are particularly important because they affect both the physical transport of species and the temporal and spatial cues that the species use to navigate between specific habitats (Figure 3). For example, the hydraulic characteristics of the Delta Cross Channel determine the fraction of migrating juvenile salmon moving into the interior Delta. Throughout their life cycle, resident species rely on cues that initiate and direct their migrations. It is plausible that a species' ability to use the Delta may be the result of behavioral responses to hydraulic and chemical cues that have evolved over long time periods through natural selection. Individuals that moved in certain ways in response to specific cues had higher survival and reproductive success. For example, to avoid being flushed out of the estuary by the net river flow, many small organisms, including some larval fish, have evolved

behaviors that move them into water with higher velocities during the flood tide and lower velocities on the ebb tide. These behaviors may produce a net upstream movement to counteract losses due to the net river outflow (Bennett et al. 2002, Kimmerer et al. 2002). Changes in these cues due to management actions, or the ability to respond to such cues due to other environmental changes (e.g., contaminants - Little and Finger 1990, Sandahl et al. 2004), may alter movement patterns in ways that disrupt a how a species progresses through its life cycle (Figure 3).

- Table 3 identifies important biogeomorphic processes that determine the quality of the habitats for the different life stages of each species. For example, splittail attach their fertilized eggs to submerged aquatic vegetation on floodplains (Sommer et al. 1997). Therefore, the extent, structure, and composition of floodplain vegetation and the frequency and extent of flooding influence spawning success. Further, processes such as flow, wave energy, marsh accretion, and subsidence of Delta islands can indirectly affect spawning success through their effects on vegetation structure.
- Table 4 identifies critical processes in lower trophic levels of the food web that structure the habitat quality for fish, in particular through the effects of these processes on the growth rates of Covered Species within each of their habitat types. Growth rate, in turn, affects survival and reproduction because body size is a major determinant of the vulnerability of fish to predation and because maturity and fecundity are size-dependent (Rose et al. 2001). Critical processes that affect food web dynamics include the energy inputs in terms of primary organic material, the structuring of predator-prey communities, and the effects of non-native invasive species on the food web dynamics. For example, the western Delta and Suisun Bay, which provide habitat for juvenile to adult Delta smelt, contain invasive clams that consume Delta smelt prey and therefore can affect Delta smelt growth and survival. Food web processes can also affect the Covered Species by affecting their predators.
- Table 5 identifies contaminants that have the potential to affect the growth, survival, and reproduction of the Covered Species as they develop through their life cycle. The table considers current-use and legacy pesticides; mercury, selenium and other metals; polychlorinated biphenyls, and polyaromatic hydrocarbons. The table notes pathways by which the chemicals move through the habitats of Covered Species, their indirect effects on Covered Species via the food webs, and some direct effects on the Covered Species.

Together, Tables 1 through 5 describe the environment in which the Covered Species complete the portion of their life cycle that occurs within the Delta. Understanding how environmental factors affect the population dynamics of Covered Species is central to predicting how Covered Activities and conservation strategies may influence those species. Uncertainties regarding future changes in these environmental factors, and how cumulative uncertainties influence predictions of species response, must be considered in conservation planning (Recommendation R13).

R13. Identify how anticipated changes in environmental conditions, including those associated with Covered Activities and climate change, propagate through populations of Covered Species, and consider how uncertainties regarding future environmental conditions potentially influence population response to Covered Activities.

The complex life cycles (e.g., use of multiple habitats by different life stages) and the diversity of life history strategies (i.e., different collections of vital rates) of the Covered Species will complicate evaluation of management and conservation actions. There will likely be trade-offs among the species of concern (Principle M). The effects of management and conservation actions on population dynamics of Covered Species will be constrained by unknown bottlenecks (i.e., constraints on life stage survival and reproduction from environmental and other factors) within and outside of the Delta (Recommendation R14).

More-detailed descriptions of how to consider limiting stages or bottlenecks in a population's life history can be found in McElhany et al. (2000) and the OCAP review (Technical Review Panel 2005). These two papers addressed the concept of viable salmonid populations. The papers described four parameters that are central in evaluating population status, and ultimately, population viability: abundance, population growth rate, population spatial structure, and diversity (life history and genetic). For anadromous fish species that use the Delta as a migration corridor, improvement in water quality or other environmental conditions in the Delta may not have proportional responses at the population level. In general, anadromous fish in the San Joaquin River appear to be more sensitive to conditions in the Delta during migration than fish in the Sacramento River (Technical Review Panel 2005). Under the best passage conditions, the Delta will have limited negative impacts on survival and reproduction of anadromous fish. However, if physical and hydraulic configurations act to block migration, divert fish into the pumps, or extend migration time, then the effects of management actions in the Delta could be negative and significant. In neither case is it obvious how the populations will respond to within-Delta actions because of the potentially large effects of conditions outside of the Delta.

R14. Examine possible bottlenecks at other life stages, including those that occur outside the planning area, rather than only those at the life stage immediately affected by Covered Activities or within the Delta. Bottlenecks at other life stages can modulate the population response to changes in environmental conditions within the Delta.

Table 1 Assessment of Knowledge Base, Uncertainty and Predictive Ability for Important Drivers of the Delta Ecosystem

Critical Process/ Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability
Riverine inflows	Riverine inflows are a key driver of the hydrodynamics of flow and transport (scalar, biotic) in the Delta channel system. Characteristics include daily flows and concentrations of dissolved constituents such as organic matter, nutrients, and contaminants, as well as particulate organic matter, sediment, and biota. Time scales range from minutes (flood flows) to seasons to decades and longer. Periodic and aperiodic variability is strongly coupled to climate and weather. Trends are strongly driven by climate change and human alteration of the catchment, including systems that affect upstream water resources (e.g., dams and reservoirs, diversions, return flows, levees).	Inputs of constituents from the watershed are strongly dependent on riverine inflows at all times. Current understanding at the level of fundamental processes is high. Data are available only for a few specific locations.	Understanding of variability (including extreme events) and the influence of climate is moderate.	Variability is very high, limiting predictability. Modeling tools exist, but application at relevant scales is limited by computing capacity, and especially by limited availability of characterization data. Hydrologic models are calibrated to existing conditions, which constrains applicability under changed conditions. Confounded by non-physical elements of upstream operations, e.g., operating rules and emergency actions

Table 1 Assessment of Knowledge Base, Uncertainty and Predictive Ability for Important Drivers of the Delta Ecosystem

Critical Process/ Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability
Tides	Mixing in the Delta is largely driven by tidal flows (Burau *in press*). Net flows in western Delta channels are modest relative to tidal flows, except during flood periods (Burau *in press*).	Tides in the San Francisco Estuary have principal periods at ~12.4 and 25 hours and 2 weeks, but many other tidal periods are present, and tides are modified by non-periodic oscillations in water level in the ocean due to wind set-up and atmospheric pressure fluctuations. Existing network of tide gages at the Golden Gate and around the estuary provides high-frequency traces of water-surface elevation.		High predictive ability for the astronomical tides through tide tables. Moderate predictive ability for non-periodic modifications because the controlling processes are not predictable over time scales longer than hours to days. Tides may be modestly affected by sea level rise, which is moderately predictable.
Sea level	Mean sea level defines the base level of the seaward boundary of the estuary and thus is a critical driver for tidal processes in the estuary including the Delta. Sea level is predicted to rise over the time scales of an NCCP/HCP. Some recommend planning for a rise of 50-140 cm by 2100[9]. A rise of this magnitude will cause inundation in some low-lying areas and can alter thermal and salinity regimes, pumping heads, wave regimes.	Mechanisms leading to changes in mean sea level and non-periodic modification of the periodic tide are well understood. Substantial, long-term historic data are available at a number of locations near and within the Bay-Delta system.	Prediction of rates and extents of change.	Sea level rise is a near certainty and has been observed. The rate of sea level rise is only moderately predictable over the period of the NCCP/HCP because of inherent stochasticity in climate, incomplete data, and dependence on future human behavior and policy decisions.

Table 1 Assessment of Knowledge Base, Uncertainty and Predictive Ability for Important Drivers of the Delta Ecosystem				
Critical Process/ Factor	**Description and Importance**	**Current State of Knowledge**	**Key Uncertainties**	**Predictive Ability**
Water exports	Large volumes of water are diverted from the freshwater Delta by large state and federal pumps in the southern Delta. This water supplies farms and cities throughout central and southern California, some in the San Joaquin basin and some outside. Fish facilities associated with the pumping plants extract fish from the water and return them to the estuary, but these facilities are not very efficient, and there is considerable concern over the number of fish killed and the potential population-level consequences[11] .	Export flows are set by operators, and water is released from reservoirs in the Sacramento basin to meet export needs and salinity or other standards in the estuary. The quantity exported is well known, but the impacts to fish are only beginning to be quantified.		High for flow.
In-Delta Diversions	Substantial volumes of water are diverted from channels and ground water within the Delta. Diversions influence in-Delta flows[12] and may remove substances and organisms from the Delta.	The nature of most surface-water diversions is well-understood. The quantity and timing of diversion flows is estimated from cropping patterns and weather, which is a crude estimate. Estimates are unavailable for actual diversion volumes. Coupling between surface water and ground water is well understood, but has received relatively little attention in the specific context of the Delta.	Ground water diversions and their impacts on surface waters.	Moderate predictive ability on time scales of months, since magnitude and timing are dependent on weather, water law, population growth, land use, etc.

[11] Brown et al. 1996, Kimmerer in press.
[12] Kimmerer and Nobriga in press

Table 1 Assessment of Knowledge Base, Uncertainty and Predictive Ability for Important Drivers of the Delta Ecosystem

Critical Process/ Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability
Return flows	Some of the water extracted and used within the Delta may return to the Delta (e.g., wastewater treatment plant (WWTP) discharges, island drainage, ground water seepage to channels)	High level of understanding for the underlying physical processes, although return flows have received relatively little study. Data are available for WWTP discharges. Few data are available for return flows via ground water seepage or island pumping.	Quantity of return flows. Ground water seepage or island pumping.	Moderate predictive ability for large-scale exports and point return flows (e.g., WWTPs) due to unpredictability of future patterns of weather, climate, population growth, land-use change, etc. Moderate predictive ability for distributed return flows in a bulk, temporal sense, (e.g., as a fraction of diversions), but low for specific return flows due to variability in subsurface properties, vegetation patterns, etc.
Weather	Solar radiation, air temperature, relative humidity, wind speed and direction drive a number of important processes and conditions e.g. water temperature, precipitation, snowmelt, evaporation/transpiration, water waves and set-up, and demands for water diversion and export (especially for irrigation).	High level of understanding of basic processes at local spatial scales. Moderate for variability (including extreme events) and climate drivers, and for conditions over large spatial extents at shorter time scales. Data are limited to specific measurement locations; but improved remote sensing instruments show promise.	Connections between climate change and local weather changes.	Low to moderate predictive ability. Weather forecasting remains constrained by stochasticity (limits predictability over long time scales).

Table 1 Assessment of Knowledge Base, Uncertainty and Predictive Ability for Important Drivers of the Delta Ecosystem

Critical Process/ Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability
Land use	Land use plays a significant role in determining the magnitude, rates, and trends in many other Delta system drivers. Especially critical are land use changes that can alter the hydrologic response of catchments to precipitation, demand for water, return flows, and constituents in inflows and return flows.	Moderate level of understanding for the mechanisms connecting land use changes to changes in hydrologic response. Aggregated data sets of land use are available across a wide range of relevant scales. Substantial local land use data are available, but dispersed and inconsistent, making aggregation difficult. Remote sensing and GIS tools are increasing in use and improving in capacity and ease of use.		Low to moderate predictive ability due to dependence on population growth, policy decisions, etc.
Levees/barriers/ gates	Barriers within the Delta can significantly affect flow, transport, and mixing. Levees influence channel flow geometry, friction, and channel-island exchange. Levee failure causes a rapid change in physical configuration of the Delta and a short-term intrusion of saline water into the Delta .	Physical processes are well-understood but friction parameters are not well known. Moderate knowledge of levee geometry and local data on structures. Data on the condition of levees are limited but growing		Moderate predictive ability. Non-catastrophic performance predictable with available tools. Prediction of catastrophic performance limited by lack of detailed spatial data and dependence on the stochasticity of weather, climate, and earthquakes.

Table 1 Assessment of Knowledge Base, Uncertainty and Predictive Ability for Important Drivers of the Delta Ecosystem

Critical Process/ Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability
Bathymetry	Water depth and distribution is a fundamental influence on hydrodynamics. Complex bathymetry at channel junctions and bends is an important influence on tidal dispersion. Shallow water limits the height of wind waves and water depth determines their interaction with the bottom, which can stir up sediment.	The positions of most Delta channels are fixed but cross- sections and bed forms are dynamic. USGS recently compiled a 10 m grid of depth from 9 km inland of Mare Island and 10 km from Sacramento south to Mossdale[13]. Many surveys used to provide bathymetric data are decades old.	Detail around junctions and bends. Bed forms and their movement[14]. Inconsistent survey-to-survey accuracy limits accuracy of USGS grid. Major change possible with levee failure.	Small changes in bathymetry are influenced by sediment inflows. Bedload is a small fraction of total sediment inputs from the Sacramento River but poorly documented. Levee failure is the most significant likely future change (unless new dredging of navigation channels occurs).
Shorelines	Slope, sediment characteristics, and exposure to wave action influence colonization by plants and use by aquatic animals. Fetch, or the distance over which wind waves are produced, determines wave height for a given wind speed and thus is an important influence on erosion of shorelines.	General typology of bank forms and characteristics are well established (few natural shorelines remain). Limited studies of bank erosion by boat wakes[15].	Detailed mapping of shoreline type and characteristics	Most Delta shorelines are managed. Major changes associated with levee failure and responses.

[15] Bauer et al. 2002

Table 1 Assessment of Knowledge Base, Uncertainty and Predictive Ability for Important Drivers of the Delta Ecosystem

Critical Process/ Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability
Topography	Fundamental control on inundation regimes (see Section 3.5).	Recent Light Detection and Ranging (LIDAR) surveys will provide the best synoptic data. Subsidence rates of up to 4 cm/yr have been documented in peat soils[16]. Peat has been eliminated in some parts of delta; subsidence continues in the central, western and northern Delta. Peat strata are thickest in the western Delta.	Effect of alterations in land use on subsidence. Consequences of levee failure.	Low predictive ability for land use effects.

[16] Rojstaczer and Deverel 1995

Table 2 Assessment of Knowledge Base, Uncertainty, Predictive Ability and Role of External Factors for Important Physical Processes

Critical Process or Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability	Human Intervention/External Factors
Hydrodynamics	Hydrodynamics in the Delta are driven by tides, freshwater flows, water exports and local diversions, and atmospheric forcing.	The geometry of the Delta is highly altered from its historical structure of dendritic sloughs. Today, the Delta consists of a network of interconnected channels that extend around Delta Island, leading to circular flow paths that are distinctively different from the branching structure of the historical Delta. Hydrodynamics in the Delta are governed by a combination of tidal motions and net, river-derived flow. Net flow transports water and its dissolved and particulate constituents, and tidal exchange mixes and transports water and constituents. Tidal exchange becomes increasingly important moving from east to west, and as river flow decreases. The complex phasing of tidal flows at the intersections of channels can determine transport. A critical parameter is the ratio of tidal excursion to channel length: where this parameter is large, the flow environment will be highly dispersive and the hydrodynamics of the junctions will be control transport. Where this parameter is small, as in the eastern Delta which is more under the influence of river flow, transport is largely driven by the net flow. When salt penetrates into the western Delta, stratification and density-driven net flows (e.g., gravitational circulation) may have important effects on salt transport and mixing.	Temporal and spatial details become progressively more difficult to predict at smaller scales.	Variable predictive ability. In general, the ability to predict physical characteristics in the Delta, including hydrodynamics and transport of constituents (salinity, temperature, turbidity and particles), increases with increasing spatial and temporal scale.	Exports, reservoir releases, configuration, barriers, dredging in channels (see Table 1).

Table 2 Assessment of Knowledge Base, Uncertainty, Predictive Ability and Role of External Factors for Important Physical Processes

Critical Process or Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability	Human Intervention/External Factors
Transport of dissolved constituents (Eulerian transport)	The transport and dispersion of water constituents (salinity, temperature, suspended sediment and contaminants) are dominated by the interaction of tidal hydrodynamics with the complex geometry of the Delta	Much of the Delta is strongly tidally dispersive, but becomes increasingly advective towards its northern, eastern, and southern boundaries. Increases and decreases in freshwater flows and exports shift the boundaries between “advective” and “dispersive” environments. Large-scale dispersion in the Delta is largely determined by flow interactions with a number of local features. Most common of these are channel junctions, which split the flow and separate water parcels rapidly and broadly. Open tracts of water (Franks Tract, e.g.) alter the transport pathways through the Delta, and their influence may vary seasonally.	A quantitative measure of Delta-scale dispersion is not readily available. The vertical variation of flows, particularly in junctions, is not well resolved.	Dispersion in the Delta can be well modeled with a highly resolved two-dimensional model as long as the hydrodynamics are accurately represented. Most hydrodynamic models of the Delta are well-calibrated to current conditions (geometry, range of flows, etc.); their performance under scenarios of large-scale change would be uncertain.	

Table 2 Assessment of Knowledge Base, Uncertainty, Predictive Ability and Role of External Factors for Important Physical Processes

Critical Process or Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability	Human Intervention/External Factors
Transport of particles (Lagrangian transport)	Lagrangian transport applies to any constituent for which history is important. Examples would include the dynamics of reacting contaminants or individual-based modeling of biota.	Particle transport in the Delta is governed by the same hydrodynamics as for dissolved constituents, but the resolution required is much finer (i.e., the scale of the particle under consideration). If the velocity distribution and turbulent coefficients were known exactly, transport of particles could be easily calculated. In channels, the lateral and vertical velocity structures are reasonably well understood, with possible limitations in the cases of strong curvature or large bedforms (e.g., sand waves). Particle transport is very complex in junctions between channels of different tidal phase, depth, and density of water, and can be very difficult to resolve.	There is a severe lack of Lagrangian data in the Delta so that it is nearly impossible to even assess our ability to accurately predict transport. Some data have been collected at Sherman Lake and the DCC (both drifter studies) and Mildred Island (dye releases). The lack of detailed descriptions of transport and mixing in channel junctions is probably the most substantial limitation in the scientific understanding of transport in the Delta.	Predictability requires a highly-resolved three-dimensional model of water velocities, mixing coefficients, and particle characteristics. This is especially true for junctions where flows are particularly complex.	
Salinity	Salinity transport is largely governed by tidal dispersion and gravitational flow, which in turn occurs due to salinity variations.	Down-estuary the response of salinity to Delta outflows is well-established (X2 relationships.[17]) Within the Delta itself, the importance of tidal dispersion processes means that X2-type relationships are unlikely to hold. Movement of the salinity field into the Delta creates new dispersion mechanisms due to density forcing in the complex channel network.	Quantitative measures of tidal dispersion in the Delta are limited. In the case of a large event like a levee failure, prediction of salinity intrusion into the Delta becomes more difficult and would likely require a three-dimensional approach.	The prediction of salinity movement into the Delta is difficult because of uncertainties associated with Delta dispersion, and because density stratification and gravitational circulation are themselves difficult to predict

Table 2 Assessment of Knowledge Base, Uncertainty, Predictive Ability and Role of External Factors for Important Physical Processes

Critical Process or Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability	Human Intervention/External Factors
Temperature	Temperature variation is dominated by exchanges with the atmosphere through heating and cooling by solar insolation and surface heat fluxes. Tidal dispersion mixes oceanic temperatures and river temperatures.	Temperature in the Delta is governed locally by a heat balance between inputs from solar radiation and convection, and losses to convection and evaporation. This balance is influenced by the temperature of water flowing in from the rivers, and by exchange with the ocean. Therefore, the statistical relationships between water temperature and air temperature vary spatially throughout the Delta. Although much of the variability in water temperature in the Delta can be explained by variability in air temperature [18], the influences of flow, exchange, and temperatures in the rivers and down-estuary are also important. For example, recent analysis [19] of historical water and air temperature records indicate that at stations near temporary barriers in the South Delta, the correlation between water temperature and air temperature changes when the barriers are in place.	Local variations in forcing due to, for example, shading, sheltering from wind, and channel morphology, will create local variations in temperature. Data to drive analysis at these small scales are not available.	Predictability depends on scale, but data requirements for atmospheric forcing (e.g., insolation, convection, evaporation) could be large. A three-dimensional modeling approach may be required due to the vertical structure created by heating/cooling at the air-water interface

Table 2 Assessment of Knowledge Base, Uncertainty, Predictive Ability and Role of External Factors for Important Physical Processes

Critical Process or Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability	Human Intervention/External Factors
Turbidity	Sediment dynamics are strongly governed by hydrodynamics, but complicated by the supply of sediment and the interaction of the particles with the bed through deposition and resuspension.	Sediment supply from the rivers depends strongly on river flow, but may be lower than historical values because of trapping behind dams. While in suspension, sediment is subjected to transport by the tidal currents in the same way as dissolved constituents. Particles move into or drop out of suspension depending on the bed stresses created by the tidal flows (in the channels) and wind waves (in the shallows). The size distribution and composition of the particles can also change due to flocculation in low-salinity water and the aggregation of particles due to 'sticky' biological films. The interaction of flows with the bed are strongly modulated by the presence of submerged vegetation (notably the Brazilian waterweed, see below). The reduction in turbulence due to vegetation allows particles to drop out of suspension, clarifying the water in areas of extensive vegetation.	Threshold for resuspension uncertain due to two factors: 1) Determining the hydrodynamic bed stress, and; 2) Determining threshold values of the bed stress for resuspension and deposition.	Prediction of bed stresses is difficult due to: 1) Importance of wind waves in shallows; 2) Bed forms; 3) Bed movement, and; 4) Effects of vegetation on bed stresses.	

Table 3 Assessment of Knowledge Base, Uncertainty, Predictive Ability and Role of External Factors for Important Biogeomorphic Processes

Critical Processes/Factors	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability	Human Intervention/External Factors
Attenuation of flow and waves by vegetation	The presence of emergent and submerged vegetation impedes flow and reduces wave energy, resulting in decreased turbidity, reduced bed stress, and sediment deposition. Tidal pumping in the Delta is influenced by extensive SAV[20].	Direct effects of vegetation on flow and waves have been studied in a few cases[21] and only recently in the Delta[22] . The drag created by submerged vegetation directs the primary flow paths over the top of the vegetation. Vertical exchange across the top of the canopy by turbulence produced in the resulting shear layer dominates the exchange between the open water and vegetated regions of the Delta. Field and laboratory studies show the importance of turbulence and drag around stems and through foliage are important[23]. Studies of wave attenuations how non-linearities associated with depth of inundation and length scale of vegetation[24].	Characterization of buoyancy and flexibility of the vegetation in response to inundation and flow. Small-scale vegetation-flow interactions and how they produce turbulence.	Application of analytical theory is limited by the lack of detailed knowledge of vegetation characteristics[25]	Control measures for Brazilian water weed limit its influence but must be repeated continually.

[20] SAV (submerged aquatic vegetation).
[21] For example, Leonard and Reed 2002; Howe et al. 2005; Chrstiansen et al. 2000; Tsihrintzis 2002.
[22] Sereno *unpublished*
[23] For summary see Tsihrintzis 2002.
[24] For example Koch et al. 2006; Mazda et al. 2006
[25] Analytical theory has been well developed by Nepf and co-workers among others (e.g., Nepf 2004) and has been field tested with relatively rigid vegetation (Lightbody and Nepf 2006). However, this has not yet been fully applied to flexible and buoyant SAV like Brazilian water weed.

Table 3 Assessment of Knowledge Base, Uncertainty, Predictive Ability and Role of External Factors for Important Biogeomorphic Processes

Critical Processes/Factors	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability	Human Intervention/External Factors
Marsh vertical accretion	The vertical accretion of tidal marshes in the Delta allows them to keep pace with sea-level rise.	Accretion is controlled by mineral sediment deposition and soil organic matter accumulation. Limited studies within the Delta of contemporary accretion dynamics show sediment supply is greatest close to the Sacramento River, and organic accumulation is relatively constant across the Delta[26]. The response of vegetation to salinity changes associated with sea-level rise is driven by complex interactions between soil salinity and inundation[27]. Studies in Suisun Marsh show low sediment input to high marshes and accretion dominated by organic accumulation[28].	Rates of net belowground production (production less decomposition) in tidal fresh and low-salinity brackish marshes in the Delta and its sensitivity to changes in inundation and salinity. The response of vegetation, especially in more brackish areas, to changes in timing of freshwater inflows[29].	Available models for vertical accretion[30] require local data on soil characteristics, which themselves are highly variable, so models have not yet been applied in the Delta. Most models of vegetation response to changes in salinity and inundation are empirical[31] and cannot be applied in the Delta.	Changes in salinity and nutrient inputs influence vegetative growth and organic accumulation. Influence of increased atmospheric CO_2 on plant productivity.

[26] Reed, 2002

[27] Few plant species tolerate salinities approaching 0.5 seawater strength, although even higher salinities and hypersaline conditions occur seasonally on the marsh plain due to salts in tidal waters and evapotranspiration concentrating salts in the root zone. Strong seasonal variation in salinity is important for controlling the distribution of some brackish marsh species, with low winter and early spring salinity promoting the canopy development stage and tolerance of higher salinities in late summer when annual expansive growth is complete.

[28] Culberson et a l. 2004

[29] Vegetative growth of most salt marsh species, with the exception of the hypersaline *Salicornia virginica*, generally begins with mild late winter temperatures in February and March and peaks in late spring when salinities begin to rise (Ustin et al. 1982; Pearcy and Ustin 1984).

[31] For example Reyes et al. 2000

Table 3 Assessment of Knowledge Base, Uncertainty, Predictive Ability and Role of External Factors for Important Biogeomorphic Processes

Critical Processes/Factors	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability	Human Intervention/External Factors
Subsidence reversal	High rates of subsidence on Delta islands used for agriculture are of concern due to the increasing potential for levee failure. Subsidence reversal by converting land use to permanent shallow flooding has been proposed to limit oxidation of existing peat and promote the accumulation of new organic material.	An experimental study has been underway at Twitchell Island since 1997. Unpublished results show average vertical elevation change of approximately 4cm/yr in managed tule/cattail stands. Field studies of tidal marshes show lower rates of accumulation. Preliminary findings from Twitchell Island experiment show variations in vertical change with hydrology.	'Optimal' hydrology not yet determined. Effect on wildlife of large-scale change from agriculture to tule/cattail stands.	Predictions of the effectiveness of subsidence reversal techniques will require mechanistic understanding of the processes.	Requires continued intervention.

Table 4 Assessment of Knowledge Base, Uncertainty, Predictive Ability and Role of External Factors for Important Food web Processes

Critical Process or Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability	Human Intervention/External Factors
Energy Inputs (unvegetated open water)	Inputs of energy (as organic matter or sunlight) provide the basis for all biological activity in an estuarine ecosystem. Declines in the production of organic matter in the Delta and Suisun Bay are likely responsible for declines in some aquatic organisms, including some covered species.	Principal source of organic matter available to Delta open-water food web is phytoplankton (microscopic algae) [32], but in brackish water the foodweb depends largely on bacteria, implying a subsidy of phytoplankton-derived organic matter from freshwater or marine water. Phytoplankton growth is limited by light, which greatly reduces the probability of eutrophication (excessive growth of phytoplankton)[33] Phytoplankton abundance and production in the Delta have declined substantially in recent decades.[34] The decline in brackish water is probably due to grazing by the overbite clam, but the cause of an earlier decline in freshwater has not been identified. Accumulation of phytoplankton depends on conditions for growth and losses to clam grazing and to transport in the water, so areas of sluggish circulation with few clams (e.g., southern Delta) have high phytoplankton biomass. Water exports remove about 18% of annual phytoplankton production in the Delta, but this loss was a relatively small component of the mass balance of phytoplankton.[35]. Studies in Suisun Bay show phytoplankton growth can be suppressed by high concentrations of ammonium at high light levels.[36] The blue-green alga *Microcystis* has formed blooms in recent years that may be causing problems in the food web.	Spatial distribution and abundance of clams. Resolution of the role of ammonium. Importance of *Microcystis* blooms in producing toxins and disrupting foraging by animals	Moderate	Human control over phytoplankton of the Delta is extremely limited. Ammonium inputs from sewage treatment plants could have some negative influence. Changes in hydrodynamics (especially residence time) could be important. These changes could be overwhelmed by the effect of clam grazing.

Table 4 Assessment of Knowledge Base, Uncertainty, Predictive Ability and Role of External Factors for Important Food web Processes

Critical Process or Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability	Human Intervention/External Factors
Foodweb Dynamics (unvegetated open water)	Declines in estuarine fish may be linked to changes in the abundance of their prey (mostly zooplankton).	There is a fundamental difference in how planktonic and benthic (bottom-dwelling) animals respond to changes in salinity. Plankton do not experience rapid changes in salinity because they move with the water. Benthic organisms are more subject to variable salinity since they stay in place on the bottom. Zooplankton include small forms (rotifers and the larvae of copepods) and larger zooplankton, mainly cladocerans in the freshwater Delta and copepods in brackish water [37]. Mysid shrimp are less abundant than in the past – many fish species now feed more on introduced amphipods (some associated with waterweed beds) than on mysids [38]. Zooplankton feed mainly on phytoplankton in freshwater and on ciliates in brackish water; the ciliates are part of a microbial foodweb based on both phytoplankton and bacteria.[39] Species composition of zooplankton has changed especially since the invasion of the overbite clam. Plankton populations have responded to changes in abundance of major predators (e.g., decline in northern anchovy) and new invasions (e.g., *Limnoithona tetraspina* in 1993). Zooplankton, freshwater clams, and juvenile Delta smelt experience food limitation.	There is no monitoring program for ciliates, bacteria, and other microbes. Abundance of clams (especially the freshwater clam) is not adequately monitored because of their great spatial variability in abundance. Extent of consumption of zooplankton by freshwater clams is unknown. Salinity response of clams is unknown. Importance of hydrodynamic connections including losses to export pumping and local diversions, and changing hydrology and salinity distributions.	Low	There are few opportunities to manipulate or control food web dynamics. It might be possible to control clam distributions by manipulating salinity, but this must be thoroughly investigated before it is attempted in the Delta.

[37] Orsi and Mecum. 1986.
[38] Feyrer et al. 2003; Nobriga 2007
[39] Zooplankton in the freshwater Delta consume mainly phytoplankton (Müller-Solger et al. 2002). However, in brackish regions they feed mostly on single-celled ciliates (Bouley and Kimmerer 2006). Gifford et al. *in press*; Hollibaugh and Wong (1996); Sobczak et al. (2005); Sobczak et al. (2002) suggest a subsidy of phytoplankton-derived organic matter to the Low-Salinity Zone, possibly from the freshwater Delta, and a foodweb based on bacteria more than phytoplankton.

Table 4 Assessment of Knowledge Base, Uncertainty, Predictive Ability and Role of External Factors for Important Food web Processes

Critical Process or Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability	Human Intervention/External Factors
Foodweb Dynamics (vegetated water bodies)	The foodwebs associated with submerged vegetation (mainly Brazilian waterweed) support some species of fish, although these may be fishes that prey upon covered species.	Fishes of vegetated margins are supported by a different foodweb from fishes in the open water [40]. This little studied foodweb is based mainly on algae that live on the vegetation rather than the vegetation itself. Fishes primarily prey on amphipods (crustaceans).	Degree of interaction with open-water foodwebs. Energy balance and overall productivity	Moderate; presumably these foodwebs occur wherever there is submerged vegetation.	Removal of waterweeds would also remove the associated food webs but the impact on open-water food webs is unknown.
Species introductions	Introduced species believed to have had an important impact on the Delta ecosystem include many fish species, Brazilian waterweed and water hyacinth, and the freshwater and overbite clams. The only invasion event whose effect was observed through monitoring and analysis was that of the overbite clam.	Species introduction s can cause rapid changes in the ecosystem such as the decline in phytoplankton and some zooplankton resulting from the introduction of the overbite clam. These changes are not generally predictable because of the multiple foodweb relationships that change when a non-native species becomes established, and because only some non-native species have such profound effects on the ecosystem	Nature of future invasions.	Future introductions are likely to produce large, and largely unpredictable, changes to the estuarine ecosystem.	Changes resulting from invasions could counteract the benefits of restoration or other management actions meant to support covered species.

Table 5 Assessment of Knowledge Base, Uncertainty, Predictive Ability and Role of External Factors for Important Chemical Processes and Contaminants

Critical Process/Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability	Human Intervention/External Factors
Pesticides in current use	Winter storm runoff and irrigation return water can contain fertilizer, current-use pesticides, and other chemicals. Organophosphate insecticides are gradually being replaced by pyrethroid insecticides. Large amounts of herbicides are being applied.	Insecticides, in particular organophosphates (e.g. chlorpyrifos, diazinon), have been present at acutely toxic concentrations in tributaries and the Delta[41] Pyrethroids at toxic concentrations have been found in sediment samples from water bodies draining agricultural areas in the Central Valley[42] Dissolved pyrethroid concentrations toxic to aquatic life have been found in water samples from Central Valley agricultural drains and creeks[43] Aquatic plants have been shown to absorb pyrethroids, and microbial assemblages living on the plants may enhance pyrethroid degradation[44].	Geographic and temporal distribution of contaminants within the Delta. Effects of structural changes (wetlands, floodplains) on contaminant dynamics. Contaminant effects on Delta species in the context of their habitats – direct and indirect, lethal and sub-lethal (e.g., on behavior, growth, reproduction). Effects of multiple stressors, e.g. contaminants, high temperature, food limitation, or disease[45]	Low due to lack of information on environmental concentrations and toxic effects, especially chronic effects.	Input could be controlled by changes in use and pesticide control methods. Half-lives are relatively short, so existing contaminants would degrade within months-years.

Table 5 Assessment of Knowledge Base, Uncertainty, Predictive Ability and Role of External Factors for Important Chemical Processes and Contaminants

Critical Process/Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability	Human Intervention/External Factors
Legacy pesticides	Residues of legacy pesticides, primarily organochlorine (OC) pesticides including DDTs, chlordanes, and dieldrin, remain high	In San Francisco Bay, pesticides and their breakdown products occur at concentrations high enough to contribute to advisories against the consumption of sport fish from the Bay[46] Legacy pesticides continue to enter the Bay from the Central Valley, from dredging and disposal, and other sources. DDT and other OC pesticides have been detected in agricultural irrigation ditches and drainage canals of the Delta region[47].	Geographic and temporal distribution of contaminants within the Delta. Effects of structural changes (wetlands, floodplains) on contaminant dynamics. Information on bioaccumulation of contaminants in wildlife and the extent and effects of maternal transfer to offspring. Understanding of the toxic effects of legacy pesticides, singly and in combination, on Delta species.	Low due to lack of information on environmental concentrations and toxic effects, especially chronic effects.	Legacy contaminants are persistent and difficult to remove. Other than mechanically removing contaminated sediments, human control is extremely limited. May contribute to advisories against consumption of fish due to high bioaccumulation potential.
Mercury	The Delta, and many of its tributaries, are on the State Water Quality Control Board's 303 (d) list of impaired water bodies because of mercury contamination.	Measured at potentially toxic concentrations, and associated with detrimental effects in some waterbirds in the Bay area[48] . Methylmercury is the most bioavailable and toxic form of mercury. Methylation occurs in wetlands, but rates of production vary widely, and some wetlands even appear to reduce methylmercury concentrations.[49]	Geographic and temporal distribution of mercury within the Delta. Effects of structural changes (wetlands, floodplains) on mercury dynamics. Information on bioaccumulation of mercury in wildlife and the extent and effects of maternal transfer to offspring. Understanding of the toxic effects of mercury, alone or in combination with other contaminants, on Delta species.	Possibly the best understood contaminant in the system[29]. Understanding of the effect of wetlands on biochemical fate of mercury is important for predictability.	Mercury sources are difficult to control. May contribute to advisories against consumption of fish due to high bioaccumulation potential.

Table 5 Assessment of Knowledge Base, Uncertainty, Predictive Ability and Role of External Factors for Important Chemical Processes and Contaminants

Critical Process/Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability	Human Intervention/External Factors
Selenium	Selenium is a reproductive toxicant. Selenium in agricultural drainages in the western San Joaquin Valley remains a threat because drainage problems are unresolved. Other sources are refineries (reduced after 1995) and wastewater treatment plants (minor source).	Loading through the San Luis Drain was reported to have caused massive bird deformities and local extirpation of most fish species at the Kesterson Refuge[50]. Loading of selenium to the San Joaquin River from approximately 100,000 acres of the western San Joaquin Valley was authorized in 1995.[51] Selenate, the form of selenium is most common in agricultural drainage, and can be converted to selenite in oxygen-poor environments, such as wetlands and organic-rich, stagnant waters. Selenite is bioaccumulated much more readily than selenate.[52].	Monitoring of the San Joaquin River near Vernalis is minimal and therefore effects of selenium in the Delta are extrapolated with some uncertainty. No monitoring of selenium downstream of Vernalis takes place in the Delta. Selenium inputs in drains, sloughs, and rivers are variable because of biological removal. [53] Information on bioaccumulation of contaminants in wildlife and the extent and effects of maternal transfer to offspring. Understanding of the toxic effects of Se, alone or in combination with other contaminants, on Delta species.	Low	Source control methods to reduce selenium concentration in irrigation return flows are under development.

[50] Presser and Luoma 2006
[51] Presser et al. 2007
[52] In the San Francisco Bay-Delta, Se concentrations in white sturgeon are just above the monitoring threshold of 5.9 µg/g. While these concentrations are below the current USEPA standard of 7.9 µg/g, there is substantial scientific evidence indicating that this standard is not protective enough and more stringent standards for the Bay-Delta are being considered.

Critical Process/Factor	**Description and Importance**	**Current State of Knowledge**	**Key Uncertainties**	**Predictive Ability**	**Human Intervention/External Factors**
Polychlorinated biphenyls (PCBs)	PCBs are industrial legacy contaminants, very persistent, and bioaccumulation potential in aquatic organisms is high.	PCB concentrations in some San Francisco Bay sport fish today are more than ten times higher than the threshold of concern for human health[55]. PCB contamination is generally associated with industrial areas along shorelines and urban runoff in local watersheds. PCB concentrations in the estuary may be high enough to adversely affect wildlife.	Although reports[56] suggest that significant PCB loads enter San Francisco Bay through Delta outflow, no monitoring data are available for the Delta. Understanding of the toxic effects of PCBs, singly and in mixture, on Delta species. Information on bioaccumulation of contaminants in wildlife and the extent and effects of maternal transfer to offspring.	Low due to lack of information on environmental concentrations and toxic effects, especially chronic effects.	Legacy contaminants are persistent and difficult to remove. Other than mechanically removing contaminated sediments, human control is extremely limited. May contribute to advisories against eating fish due to high bioaccumulation potential.

Table 5 Assessment of Knowledge Base, Uncertainty, Predictive Ability and Role of External Factors for Important Chemical Processes and Contaminants

Critical Process/Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability	Human Intervention/External Factors
Polycyclic aromatic hydrocarbons (PAHs)	Polycyclic aromatic hydrocarbons (PAHs) are generated by the incomplete combustion of organic matter and enter the aquatic environment through atmospheric deposition or stormwater runoff from roads, urban areas, and industrial areas. Another potential source is creosote, which has been used to impregnate wood products such as pier pilings.	Stormwater runoff from urban and industrialized areas and inflow from tributaries (including the Delta) are the major sources of PAHs in San Francisco Bay. Relatively low PAH concentrations were observed in the Sacramento/San Joaquin Rivers and the Delta during the 1993-2001 monitoring period[57].	Geographic and temporal distribution of contaminants within the Delta. Understanding of other toxic effects of these contaminants, singly and cumulative, on Delta species.	Low due to lack of information on environmental concentrations and toxic effects, especially chronic effects.	Could be controlled in part by reducing the input of stormwater runoff.

[57] Oros et al. 2007

Table 5 Assessment of Knowledge Base, Uncertainty, Predictive Ability and Role of External Factors for Important Chemical Processes and Contaminants

Critical Process/Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability	Human Intervention/External Factors
Emerging Pollutants	A growing number of organic compounds, including flame retardants, pesticides, plasticizers, water repellents, fragrances, pharmaceuticals, and personal care product ingredients can mimic the actions of natural hormones. Endocrine disrupting chemicals (EDCs) can interfere with the hormonal systems in humans and wildlife, and act at extremely low concentrations resulting in negative effects on reproduction and development. Exposure of fish populations to low concentrations of such compounds can have dramatic effects.	High concentrations of flame retardants (polybrominated diphenyl ethers, PBDE) have been found in freshwater clam tissue from the Sacramento and San Joaquin River[58] . Tissue concentrations of PBDE in striped bass and halibut significantly increased in 1997 and 2003. PBDE was also found in least tern (*Sternula antillarum*) and California clapper rail (*Rallus longirostris obsoletus*) eggs.	Distribution and effects of endocrine disruptors on reproduction of Delta species.	Low due to lack of information on environmental concentrations and toxic effects, especially chronic effects.	Better wastewater treatment methodology (enhanced treatment) will potentially lead to breakdown or elimination of these compounds from WWTP effluents, but some chemicals may become more toxic due to chlorination.

[58] Hoenicke et al. 2007

Table 5 Assessment of Knowledge Base, Uncertainty, Predictive Ability and Role of External Factors for Important Chemical Processes and Contaminants

Critical Process/Factor	Description and Importance	Current State of Knowledge	Key Uncertainties	Predictive Ability	Human Intervention/External Factors
Nutrients	Un-ionized ammonia (NH_3) can be toxic to fish[59]. Ammonia contributes to the depletion of oxygen in the Stockton Deep Water Ship Channel[60] and creates a barrier to fish passage.	NH_3 has reached concentrations that could be toxic to sensitive fish species such as salmon[61].	Information on sensitivity of Delta fish species to ammonia.	Moderate. Ammonia concentrations have been monitored for decades at some sites in the Delta.	Better wastewater treatment methodology (enhanced treatment) will reduce ammonia load released into Delta

[59] Note that this is a different chemical form from ammonium (the ionized form), discussed under foodweb assessment, above. The two forms are in equilibrium and the relative proportion of ammonia increases as pH and temperature increase.

5.0 ANALYTICAL METHODS

Predicting the effects of Covered Activities and conservation strategies on Covered Species and communities is one of the most important tasks for most HCP/NCCPs. At a minimum, the BDCP should analyze individual and cumulative effects of the Covered Activities on populations of Covered Species. This requires assessing effects of the Covered Activities on the various physical, chemical, and biotic processes and gradients influencing population dynamics (Section 4.3). The Plan should also explicitly disclose and address uncertainties about these predictions and should address how foreseeable changes in the system (e.g., sea-level rise and other consequences of climate change, changing salinities) are likely to affect species and ecosystem processes over at least the 50-year permit duration. The scale of the area influencing the Delta (Principle C), the inherent variability in ecosystem processes (Principle D), and the need to address both conservation measures and other foreseen changes in the system (Principle B) means that analyses in support of BDCP planning and implementation must embrace a wide range of processes and uncertainties (Tables 1-5).

Detailed consideration of uncertainties requires more information on Covered Activities and conservation strategies than is currently available. In addition, detailed consideration of analytical tools was beyond the scope this group of advisors was convened to address. In this section, the Advisors offer some initial recommendations concerning appropriate approaches to analyze Delta hydrodynamics and population dynamics of Covered Species. The intent here is not to provide a comprehensive evaluation of all available tools and models. The Advisors recognize the urgent need for in-depth consideration of analytical tools and assessment techniques, beyond that provided here, to support BDCP planning and implementation (Recommendation R15).

R15. When potential Covered Activities and conservation strategies have been developed, convene a group of science advisors with experience in systems analysis, ecosystem restoration, modeling, population and food web dynamics, and other relevant disciplines to identify appropriate analytical tools and assessment techniques to support conservation planning and implementation in the Delta.

5.1 Hydrodynamic Analyses

The Sacramento-San Joaquin Delta is an unusual hydrodynamic environment due to strong tidally driven flows in a channel network. The interaction of tidal flows with this geometry creates a highly dispersive environment, in which the phasing of flows in intersecting channels strongly determines dispersion throughout the system. While the net flows affect transport over large spatial and temporal scales, the dispersion of salt, temperature, phytoplankton, and other constituents is much more strongly influenced by tidal-timescale flows. As a result, any hydrodynamic model that is used to predict transport and dispersion in the Delta must accurately predict the tidal flows, including the phasing of flows in intersecting channels (Recommendation R16). Transport models may be based on fundamental physics, or may use empirically determined dispersion coefficients. Because these coefficients are not based on fundamental processes, they will have limited utility in forecasting future conditions, especially changes involving large-scale alterations in the configuration of the Delta (Recommendation R17).

R16. Use a hydrodynamic model that is based on fundamental physics and that accurately reproduces tidal flows in the system for analysis of Delta transport and dispersion, and particularly for prediction of the effects of proposed management scenarios on hydrodynamics.

R17. Use data that span as broad a range of hydrologic and operational conditions as possible to evaluate a model's performance and increase the probability that the model will have sufficient accuracy and precision for evaluating management scenarios.

The appropriate dimensionality of a model will depend on the target of the analysis. For many dissolved substances, a depth-averaged (two-dimensional) tidal model that can accurately reproduce the tidal flows, including the phasing in junctions, is likely to be sufficiently accurate (Recommendation R18). This is because much of the Delta is relatively shallow and unstratified, resulting in limited vertical variability in the concentrations of dissolved substances. To examine the distribution of dissolved substances, it is not critical to resolve the vertical structure of the flows. Instead, computational effort would be better focused on quantifying temporal variability on the tidal time scale and the horizontal variability of flows in intersecting channels and junctions.

Resolving vertical structure of flows is more relevant for constituents that produce density stratification (salinity and temperature), settle through the water column (sediment), or have their own behavior (fish). In each of these cases, a higher dimensional model may be required. For example, one would expect the initial dispersion of salt into the Delta from Suisun Bay resulting from a levee failure to be dominated by tidal dispersion processes (the phasing and interaction of tidal flows). This aspect of the salt intrusion would be well represented by a depth-averaged tidal model. Once the salt field enters the Delta, however, the density gradients that are created lead to further intrusion. The resulting gravitational circulation brings saline waters upstream in the deep portions of the Delta (e.g., San Joaquin and Sacramento channels) and moves relatively fresh water downstream at the surface. This exchange flow will not be well represented in a depth-averaged model (Recommendation R18). One alternative is simply to pursue a three-dimensional model, which would require significant computational effort. Another alternative is to parameterize the effects of exchange flow through a supplemental along-channel dispersion coefficient (Chatwin 1976) that includes a threshold based on the local salinity gradient (Stacey et al. 2001).

R18. Use models with appropriate dimensionality for the target of the analysis:

- ***a. Use a two-dimensional, depth-averaged analysis to predict transport of passive dissolved substances.***
- ***b. Use a three-dimensional hydrodynamic model to account for both tidal dispersion processes and gravitational circulation associated with salinity intrusion into the Delta, or parameterize gravitational circulation based on local density forcing.***

The integration of particle (or organism) behavior into transport analysis requires refinement of hydrodynamic models of the Delta. As with the other transport analyses, the tidally driven flows, including the phasing of flows in intersecting channels and the resulting flow structures that arise in channel junctions, must be accurately predicted. At the same time, many species have limited ability to swim relative to tidal currents, but they are capable of vertical and lateral migrations that allow them to selectively sample tidal streamlines (see Section 4.3). As a result, a hydrodynamic model must accurately resolve the vertical and lateral structure of both the mean flows and the turbulent motions (Recommendation R19). Developing such a model will require additional data collection and hydrodynamic analysis to establish the lateral and vertical structure of flows in channel junctions. Lagrangian particle trajectories should also be studied in the field (Recommendation R19) and used to evaluate the model's ability to project particle paths, particularly flow paths through junctions.

R19 . To allow integration of particle or organism behavior into Delta transport models

a. Develop a highly resolved three-dimensional hydrodynamic model to produce accurate projections of vertical and lateral variability in channels and junctions.

b. Conduct drifter-tracking studies, especially around channel junctions, to evaluate model ability to predict particle trajectories.

Water temperature affects all vital rates of aquatic organisms, and in some cases (Delta smelt, salmon) adverse effects of high temperature have been demonstrated (Bennett, 2005; Brandies and McLean, 2001). Nevertheless, there is no model of temperature in the Delta that could be used to analyze the effects on biota. Whereas salinity in the Delta is a result of intrusion from the Bay, temperature variation in the Delta is largely forced at a local level by atmospheric heating and cooling (Kimmerer 2004). The influence local atmospheric forcing, however, varies across the Delta because of river inflows and mixing with the lower estuary. The mixing of these adjacent waters alters the correlation between atmospheric conditions and Delta water temperatures. Depending on the spatial and temporal scales of interest, a correlative analysis of atmospheric conditions and water temperatures may be sufficient for predictions of water temperature. However, refining the spatial and temporal details of water temperatures within the Delta requires inclusion of tidal dispersion processes in the analysis (Recommendation R20). At a smaller scale, temperature gradients will develop between Delta channels and shallow environments and between open and vegetated regions. Current understanding of these finer scale variations is limited by uncertainties in how shallow vegetated environments affect temperature and the exchange between shallow vegetated locations and adjacent regions. If the analysis requires data on fine-scale temperature variation between adjacent environments, observational and modeling studies of the effects of shallow, vegetated environments on the local temperature dynamics, including the effects of shading along perimeter waters, will be needed (Recommendations R9 and R20).

R20. Apply an array of tools to improve prediction of water temperature at various spatial and temporal scales:

a. Develop a correlative analysis of atmospheric conditions and water temperatures to assess large-scale variations in temperature.

b. Analyze river inputs and tidal dispersion to predict temperature at finer spatial and temporal resolution.

c. If prediction of fine-scale temperature variation between adjacent environments is desired, pursue observational and modeling studies into the effects of shallow, vegetated environments on local temperature dynamics, including the effects of shading along perimeter water.

Suspended sediments have a variety of important effects on biota, and concentrations of sediments are changing (Table 2). Sediment movement must be modeled at the tidal time scale because particles are deposited and resuspended at short time scales. Tidal dispersion redistributes sediments that enter the estuary from the watershed. To predict future concentrations of suspended sediments, future sediment supply must first be evaluated through an analysis of land use in the watersheds, hydrologic forcing, and reservoir operations. Additionally, short time-scale bed stresses (due to tidal flows and wind waves) and the effects of these bed stresses on sediment resuspension define the key uncertainties in predictive modeling of dynamics of suspended sediment (Recommendation R21). Studies of sediment particle characteristics in the Delta and associated resuspension characteristics are needed to reduce these uncertainties. Once such studies are complete, an integrated hydrodynamic-sediment transport model of the Delta can be developed to predict sediment concentrations and their variability.

R21. Evaluate future sediment supply to the Delta from the watershed, and document sediment resuspension characteristics in the Delta, to support the development of an integrated hydrodynamic-sediment transport model to predict sediment concentrations and their variability

5.2 Approaches to Assessing Population-Level Responses

It is challenging to describe the dynamics of species throughout their life cycles with sufficient accuracy and precision to allow for predictions of the effects of alternative managements actions on population dynamics. We recommend that analyses be performed on a population level for pragmatic reasons (e.g., data availability, tractability) but viewed in an ecosystem context (i.e., analyze populations but think ecosystem). The analysis of effects of environmental changes in the Delta on Covered Species depends on the development and application of a variety of predictive models. These models depend on accurate and somewhat mechanistic descriptions of environmental influences (Figure 2). Hydrodynamics strongly affects biological interactions and the distribution of salinity, temperature, turbidity, and vegetative cover that influence Covered

Species both directly and indirectly (Section 5.1). For example, turbidity (Table 2) has a direct influence on at least some of the Covered Species. Delta smelt will not feed in clear water (J. Lindberg, UC Davis, pers. comm.), and the abundances of Delta smelt, threadfin shad, and young striped bass in autumn increase as turbidity increases (Feyrer et al. 2007). Presumably these species can forage more efficiently where turbid water provides some protection from predators. Turbidity also has a direct negative influence on phytoplankton production, so these energy inputs to the food web (Table 4) may increase as the water becomes clearer.

During their juvenile life stages in the Delta, the Covered Species feed mainly on zooplankton, epibenthic crustaceans (e.g., mysids and amphipods), and insects. Analyses of Covered Species currently treat their food sources as a static input. However, the abundance of zooplankton and epibenthic crustaceans is highly dynamic. Models and analyses of Covered Species could be improved, and the range of applicability of the models and analyses increased, by including some dynamic aspects of their food supplies (Recommendation R22).

R22. Develop spatially-explicit models of plankton dynamics, and institute monitoring to provide necessary input to these models, to improve prediction of Covered Species responses to changing environmental and food web conditions.

The Advisors suggest that the evaluation of the potential effects of Covered Activities on populations use a step-wise approach involving both qualitative and quantitative models. While the analyses should be at the population level, the analyses must be set in an ecosystem context. The qualitative models (conceptual models, such as those being developed by POD and DRERIP) provide a common framework for discussion, for evaluating expert opinion, and for general planning and research on Delta processes. Quantitative models, including both statistical (e.g., regression) and process (population dynamics) models, are valuable for exploring the possible effects of current and future management actions.

The Advisors suggest using a stepwise approach based on the life cycles of the Covered Species (Recommendation R11). Evaluations might begin with analyses of how potential changes in environmental conditions caused by management actions (e.g., flow, salinity, temperature, turbidity, vegetation) would affect each of the vital rates of the life stage(s) known or thought to be *directly* affected by those actions. The next step would examine if and how the environmental changes could directly affect the vital rates of *other life stages*. In addition, analyses should examine how direct effects of Covered Activities on one life stage may indirectly affect other life stages. By examining effects of management actions on the vital rates of each life stage of the species of interest, and then iterating through all of the life stages, one obtains information not only on responses of key life stages but also on responses at the population level. Availability of data varies among the Covered Species; for some species, such as winter run Chinook salmon and Delta smelt, data are likely sufficient to estimate population level responses. For the less well studied species, analyses may be limited to the response of the directly affected life stage.

Together, qualitative and quantitative models provide a framework for clearly stating assumptions of analyses and allowing others to easily understand and evaluate the analyses (Principle N). Qualitative (e.g., conceptual) models describe important process-response relationships but do not quantify them. Quantitative models are more valuable for understanding specific interactions between the Covered Species and their environment. Quantitative population models include both statistical and process models. Statistical and process models are distinguished based on how they represent the relationship between populations and environmental variables. Statistical models can quantify correlations between environmental variables and the abundance, vital rates, and spatial distributions of populations at different life stages. Statistical models often have weak predictive power, especially for forecasting the responses of populations to environmental conditions that the species have not experienced during the period of data collection.

Process models relate the rate of change in abundance (rather than abundance itself) to environmental and other explanatory variables via mathematical equations (often differential or difference equations). Process models attempt to represent how growth, mortality, reproduction, and movement (i.e., vital rates) are affected by environmental conditions. Process models can also integrate these vital rates across life stages to predict population-level responses, such as annual biomass, biomass production, long-term abundance, resilience (ability of a population to return to baseline after a perturbation), or persistence. Moreover, because they represent how changes in the environment may affect vital rates, process models can also be used to explore how alternative future states of the Delta might affect the population dynamics of the Covered Species. With such models, it is possible to explore the impacts of climate change scenarios, other major environmental changes, and the increasing demands on the Delta ecosystem and its resources. Process models also provide a platform for evaluation of the responses of populations to simultaneous changes in multiple environmental factors. The combined effects of these factors at the population level are often not obvious from the effects of individual factors on different life stages.

Process models are more difficult to validate than statistical models because process models do not have an evaluation criterion like a significance test. In addition, process models must be used cautiously because they include a large number of parameters, not all of the relevant mechanisms may be represented. Development of a comprehensive conservation and management plan will require the complementary use of statistical models and multiple types of process models.

An important step in linking the factors described in Tables 1-5 to population dynamics of the Covered Species is to correlate the spatial and temporal distributions of the environmental drivers with the life history stages of the species (Recommendation R23). For example, because salmon use the Delta as a migratory corridor, it is important to understand how the Delta affects juvenile migration (Figure 3). Vital rates of resident species such as Delta smelt are affected by movement of the species between the juvenile and adult habitats. Accordingly, statistical models can relate the movement of resident and anadromous fish to the environmental factors that cue migrations and flows at the tidal time scale that affect the migrations.

Statistical modeling should also be used to identify correlations between abundance and vital rates at different life stages and environmental variables (Tables 1-5). Although such correlations do not indicate causation, identifying relationships is valuable for developing the process models and prioritizing further analyses and data collection (Recommendation R24). For example, a relationship between Delta water exports and the survival of juvenile salmon passing through the Delta relative to those passing through the lower Sacramento River implicates water exports as a factor in the survival of a key life stage in the salmon life cycle (Brandes and White 2005). Quantifying how vital rates at each life stage are directly affected by Covered Activities, and applying statistical and process modeling to accumulate these effects over the life cycle, is critical to quantifying how the activities will affect the population dynamics of Covered Species.

An extensive database of monitoring information for the Delta is available, and Plan development should take advantage of the reviews and analyses that were performed for the biological opinions (BO), OCAP, the Environmental Water Account (EWA), and the POD. The OCAP review (Technical Review Panel 2005) dealt with the life cycle approach for salmon. The EWA analyses and panel suggestions are relevant given that EWA also was faced with quantifying how changes in water availability (albeit at a smaller scale than may be anticipated under BDCP) might affect the population dynamics of Delta smelt and other species. The POD effort concentrates on understanding the general decline of four species, which including two of the Covered Species. Note, however, that results of analyses conducted for other programs, while helpful, may not be sufficient for evaluating management and conservation actions proposed for the BDCP. Additional analyses tailored to the specific issues related to the BDCP will likely be needed.

R23. Develop statistical models that relate a) spatial and temporal distributions of environmental factors to life stages of the Covered Species, b) fish movement to environmental factors that cue migration, c) net and tidal flows to migration, and d) abundances of the Covered Species at different life stages to relevant environmental variables.

The Advisors emphasize that there are no shortcuts to understanding and realistically evaluating the effects of management and conservation actions on Delta species. Well-informed conceptual models are the foundation. Conceptual models are strengthened with statistical analyses that identify relationships among the species and biotic and abiotic properties of the species' critical habitats inside the Delta and, when relevant, outside the Delta (Figure 3). Finally, the accumulated conceptual and statistical information provides the basis for developing scientifically-sound process-based models of population dynamics (Recommendation R24). Some of the past efforts at process modeling for species in the Delta have tried to simply link correlative relationships across life stages. This rarely results in a process model with any predictive power, and is not recommended. Process-based population models with a long history of development and use, and based on well-known mathematics (e.g., matrix, projection, individual-based), are available for developing scientifically sound models of population dynamics (Caswell, 2000; Grimm and Railsback, 2005). The process models use the information from the statistical analyses, but are not simply a set of linked statistical relationships.

R24. When sufficient information is available and the questions to be addressed are tractable to model, develop and apply process models for Covered Species that are built upon the conceptual and statistical models. These process models can be used for predicting short-term, life stage-specific responses and, in some cases, for predicting long-term responses of population dynamics.

5.3 Cautionary Notes

Models for higher trophic levels are difficult to parameterize and validate because they require a diverse set of information both for their development and to evaluate the effects of many possible predictor variables over different temporal and spatial scales. Species at higher trophic levels also tend to have relatively complex life cycles and live for multiple years. As a result, models for higher trophic levels that truly address population responses must generate long-term predictions that span multiple generations in order to estimate the full effects of responses to environmental change and management actions. The Advisors suggest, as an initial step, the development of a series of process-based models that focus on separate life stages. This approach differs from statistical modeling, as it requires more extensive decisions about temporal, biological, and spatial scale. Before a model can be developed, for example, analysts must specify the time step and the duration of the simulations, the level of biological detail needed (e.g., total abundance, age-classes, individuals), how each of the vital rates will be represented (e.g., assign growth rates or simulate foraging), and the spatial resolution (size of cells). The extent and resolution of a model should reflect the questions it is being used to address.

It is important to consider the potential influence of density dependence on each of the key vital-rate processes. Density dependence usually is assumed to be compensatory (a negative feedback) because as abundance increases, resources become limiting, resulting in changes in the key processes that act to reduce net population growth rate and reduce population size (Rose et al. 2001). However, depensatory density dependence (or Allee effects) is a positive feedback on abundance and thus destabilizes population size. Depensatory density dependence operates when abundance becomes so low that mortality increases or reproduction decreases, thereby decreasing abundance even further (Liermann and Hilborn 2001). It is not clear whether the Covered Species exhibit depensatory density dependence, but because depensatory density dependence increases the probability of extinction of small populations, the possibility should be considered.

Models of higher trophic levels should be developed with great care and scrutiny to increase the probability that acceptable accuracy is obtained in their forecasts. Confidence intervals around model predictions must be quantified. Models will need to represent the environment of the Covered Species at the temporal and spatial scales that affect the vital rates of those species.

As a final cautionary note, the Advisors emphasize that no model, however carefully developed, will describe a sufficiently complete set of mechanisms to allow accurate and reliable prediction of future system states. This situation arises because of lack of knowledge of some key processes or variables, and because a large number of complex processes must be represented simply. Models are, by definition, simplifications of the real system. For example, models of Delta smelt must represent both their prey and their predators with relatively simple relationships based on available data. However, the population dynamics of prey and predators are neither simple nor well understood. Thus, while some aspects of the smelt population could be quite accurately represented in a model, (weight at age), the factors affecting those dynamics (e.g., salinity) might themselves vary in ways not represented in the model. Therefore, the process of developing a model should be seen as iterative, with scientific investigations applied to resolve uncertainties as the model is refined.

5.4 Exploring Future System States

The Advisors caution that models used to predict system responses must explain a considerable amount of the variation in the data used to construct the model. Further, the data used for calibrating the model must represent a broad range of antecedent conditions, including hydrologic and operational variability, in order to increase the ability of the model to assess future conditions. If predictions encompass new locations or time periods in which values of independent or response variables exceed the values used to build the model, the model forecasts need to be evaluated with great care

While a number of uncertainties currently limit our ability to predict all of the changes in critical processes and factors in the Delta ecosystem (Principle P), sufficient data and adequate tools exist to explore some of the anticipated changes. For example, the consequences of climate change in the Delta include sea level rise and a shift toward earlier peak runoff of precipitation. The Advisors recognize that existing process-based hydrodynamic models are of limited application if the structure of the Delta is altered (e.g., by levee failures or major siphons) or manipulated (e.g., by additional gates and barriers), but these models should be used to provide insight into the potential effects of climate change under the current Delta geometry (Recommendation R25).

R25. Use hydrodynamic models of the Delta built on fundamental processes to analyze the potential consequences of different future climate change scenarios (e.g., sea-level rise, timing and amount of runoff) on net and tidal flow patterns.

A subset of future conditions potentially can be examined with existing models. In some cases, however, the use of existing models in a predictive context may be misleading. For example, the ecological theory that spatial and temporal variability is important for maintaining the species richness of ecosystems has been extended to suggest that native species would benefit from increased variability in the Delta (Lund et al. 2007). Our ability to examine whether this concept indeed applies to the Delta is limited because, among other reasons, most data on the system have been collected during a period of reduced variability compared to historical conditions (Recommendation R26). Importantly, there is no one perfect model for use in conservation planning. Instead, planning can sometimes be better informed by results from several different models that address the same issue. However, in all cases data analyses and models should be fully documented and accessible (Principle N).

R26. Develop and apply statistical and process models to examine the potential effects of increasing variability in salinity and water temperatures on ecosystem processes and Covered Species in the Delta.

6.0 ADAPTIVE MANAGEMENT AND MONITORING

The BDCP must be developed despite great uncertainty about the outcomes of the selected management actions. These uncertainties arise because of lack of knowledge about the current state of the ecosystem, inherent variability, and the likelihood that the future state of the system will differ from the current state as a result of deliberate and unplanned events. Several approaches can be taken in the face of such uncertainty to increase the probability that conservation objectives will be achieved. First, analyses can be conducted to attempt to minimize the uncertainty about a particular course of action,. Exclusive of other measures, such an approach is unlikely to succeed because of the magnitude of the uncertainties discussed above. Second, an initial course of action can be taken with plans to revisit the action in the future and alter it if necessary. This approach is preferable to the first, but it fails to maximize application of the information that can be gained from the response of the system to the actions taken; this approach is essentially static, and passive. An improvement on these approaches is to investigate and learn systematically from the course of action taken using adaptive management, a formal process designed to reduce uncertainties and identify significant negative consequences as they arise (Holling 1978, Walters 1986). An adaptive management approach was formally incorporated into the Strategic Plan for the CALFED Ecosystem Restoration Program (CALFED, 2000) but adaptive management was never fully implemented. The Advisors recommend that conservation planning for the BDCP be founded on adaptive management as described here (Recommendation R27).

R27. Design a conservation plan based on adaptive management.

Adaptive management is a systematic process for continually improving management policies and practices by learning formally from their outcomes. First, conceptual models are developed to describe current understanding of the system and how a given action is expected to affect the system. These conceptual models are then developed into quantitative models that may be used, with some degree of uncertainty, to predict system responses. Management actions are designed to include collection of data needed to detect responses to the actions and to other variables that influence the system. Perhaps most crucially, a feedback loop is established by which monitoring data, model outputs, and other information are periodically assessed, the success of the action is evaluated, and, if appropriate, alternative actions are implemented.

Adaptive management is most powerful when an action can be implemented as a formal experiment with replicates and controls. However, active adaptive management is rarely possible for a large system under severe constraints. Passive adaptive management, in which the response of the system to a manipulative action is observed, is much less powerful because it is difficult to separate the effects of the action from other simultaneous environmental changes. Nevertheless, even passive adaptive management is a great improvement over less rigorous processes that fail to examine the effects of management actions.

Adaptive management has been criticized because of institutional impediments to implementation. One of the most challenging aspects of adaptive management is ensuring that information from monitoring of projects and system response is used to refine system models. Data must flow to managers and others overseeing implementation. The information needs of managers, in turn, must be used to guide collection of data. The process of adaptive management requires institutional mechanisms that provide for revisiting objectives and models over time as more is learned about the species and processes being targeted for conservation (Recommendation R28).

> ***R28. Identify and implement as soon as possible an administrative mechanism for the Plan to be modified in response to rapidly evolving information, data, and analyses.***

The Advisors think that adaptive management is well suited to the BDCP, but implementing adaptive management will require a sincere, ongoing commitment to the principle and the process, and a decision-making process specifically designed to accommodate adaptive management. A formal adaptive management program cannot be designed until conservation measures are more fully defined. However, the Advisors recognize the potential value of implementing the BDCP as an adaptive management program, and reiterate their advice that adaptive management be incorporated as early as possible in planning (Principle L). Accordingly, the Advisors recommend that the Steering Committee seek further input on the development of an adaptive management approach for BDCP planning and implementation (Recommendation R29).

> ***R29. Convene a group of science advisors to work with consultants, PREs, and implementing agencies to develop an adaptive management and monitoring strategy to support implementation of the BDCP.***

APPENDIX A:

Workplan for Facilitating Independent Scientific Input

Science Advisory Process
Bay Delta Conservation Plan

1. Introduction and Purpose

The State of California's Natural Community Conservation Plan (NCCP) Act mandates a process for the inclusion of independent scientific input to ensure that each NCCP is informed with best available science. Regional Habitat Conservation Plans (HCP) developed under the federal Endangered Species Act are often guided by similar input. To meet this mandate for the Bay Delta Conservation Plan (BDCP), a group of independent scientists will be convened to identify and evaluate scientific information and provide objective insight and expert opinion pertaining to species, ecological communities, and habitats addressed by the plan. The role of the Science Advisory Group is to establish science-based conservation and natural resource management principles and standards that will be used to guide BDCP preparation.

This document outlines procedures for engaging independent scientific input for the BDCP, consistent with the requirements of the NCCP Act and guidance developed by the California Department of Fish and Game (August, 2002). Topics addressed include:

1. Communication protocols and ground rules for engaging independent scientific input;
2. A workplan for obtaining meaningful scientific input in a timely fashion;
3. Processes for selecting advisors, framing relevant conservation science questions, and developing work products; and
4. Guidelines for avoiding conflicts of interest.

Bruce DiGennaro (The Essex Partnership) and Dr. Wayne Spencer (Conservation Biology Institute) will collectively serve as the Facilitation Team for the BDCP independent science advisory process. This document is based on the Scope of Work adopted by the BDCP Steering Committee on May 4, 2007, the experience of other NCCP science advisory processes, and the NCCPA and guidance noted above.

2. Ground Rules for Engagement and Communication Protocols

The Facilitation Team will act as a neutral intermediary between the Steering Committee and the Science Advisors. In this capacity, the Facilitation Team will work with both the Steering Committee and the Science Advisors (coordinating closely with the Lead Scientist) to facilitate communications and maintain the integrity and independence of the process.

Communication between the Steering Committee and Science Advisers shall be channeled through the Facilitator. Questions from stakeholder groups or the public will be channeled through the Steering Committee to the Facilitator, who will forward appropriate questions to Science Advisors. The Facilitation Team will recommend which questions or other input are appropriate for the advisors to address. If there is not consensus among Steering Committee members based on the recommendations of the Facilitation Team, the Facilitation Team will make a decision in consultation with the Lead Scientist based on the input received and their collective experience.

The Lead Scientist, other Science Advisors, and the Steering Committee may communicate directly in meetings during the information gathering, field trip, and workshop phases of the science advisory process, and in briefings following submittal of the Science Advisor products to the Steering Committee. Steering Committee members will not contact the Lead Scientist or other Science advisors individually concerning BDCP matters. Similarly, Science Advisors (including the Lead Scientist) will not communicate with the Steering Committee or its representatives during their deliberative process except through the Facilitator.

Science Advisors (including the Lead Scientist) will be free to directly contact other members of the scientific community during the information gathering phase of the process for the purposes of obtaining existing data or other materials needed to inform their deliberations. To encourage informative deliberations, and for allow for transparency and recording of information sources, Science Advisors shall track their contacts with other scientists regarding BDCP matters, explicitly report the use of any such unpublished information in the science advisory reports. and provide the Facilitation Team with a summary of their interactions.

The Facilitation Team will ensure that all Science Advisors understand their roles pursuant to the NCCP Act. Science advisor recommendations are advisory only and not binding on the Steering Committee, member agencies, or consultants involved in NCCP/HCP preparation. Recommendations from the Science Advisors will be made available to the public after distribution to the Steering Committee.

Communications regarding the Science Advisors should be directed to the Steering Committee Chair or her designee or to Bruce DiGennaro (bruce@essexpartnership.com, 401-709-2449) as the designated points of contact for the Steering Committee and Facilitation Team respectively.

3. Workplan

The Facilitation Team proposes a workplan for engaging science advisors in the BDCP process that is tailored to meet the specific needs of the BDCP while providing focused and timely advice consistent with the requirements of the NCCP Act. The proposed workplan is described in Attachment 1 and shown graphically in Figure 1. The workplan includes topically focused interactions with the Steering Committee to facilitate input, as well as discrete deliverables designed to advance the planning process.

4. Process for Selecting Advisors

The Facilitation Team will be responsible for engaging Science Advisors, after appropriate input from the BDCP Steering Committee and Lead Scientist. Key steps in identifying and selecting Science Advisor shall include:

1. Development and review of Areas of Expertise
2. Nomination of potential Science Advisors
3. Selection and contact of Science Advisors

The BDCP Steering Committee, with input from the Facilitation Team and Lead Scientist, will create a "long-list" of science advisor candidates that possess appropriate expertise and qualities and that fit into the identified Areas of Expertise. The Facilitation Team will work with Steering Committee and the Lead Scientist to identify any potential conflicts of interest and to develop a "short list" of candidates based on expertise, experience, proven ability to work well with groups, and ability to contribute useful information on schedule. Using the short list, the Facilitation Team and the Lead Scientist will make initial contact with candidates to determine their interest and availability to serve. Once the Facilitation Team has assessed advisor interest, they will formally invite the science advisors into the process on behalf of the Steering Committee.

To the degree feasible, the Science Advisors will be balanced in terms of the following factors, keeping in mind that adequate coverage of key areas of expertise is the primary criterion:

- local, regional, and national perspectives
- species-specific expertise vs. more holistic ecosystem and conservation planning viewpoints
- previous independent science advisory experience

Final recommendations regarding the selection of advisors shall be made by the Facilitation Team. If there is not consensus among Steering Committee members, the Facilitation Team will make a final decision to ensure that there is no actual or perceived influence by the Steering Committee, consultants, Lead Scientist or other parties concerning the final composition of the group. The Facilitation Team can replace or supplement the initial group of advisors if need arises during the process. The Facilitation Team will establish appropriate agreements and arrangements for honoraria with individual advisors. The timeframe for selecting advisors is outlined in Attachment 1 (Proposed Workplan).

5. Process for Identifying Issues and Developing Questions

To help focus the Science Advisor's input, and to ensure the full range of pertinent scientific issues are addressed, an initial list of science questions will be developed by the Facilitation Team, in consultation with the Lead Scientist and the Steering Committee. The initial list of science questions will be provided to the Steering Committee for review and comment. Advisors may identify additional questions to address during their deliberations.

The Facilitation Team, in consultation with the Lead Scientist, will be responsible for channeling pertinent questions from the Steering Committee to the Science Advisors and communicating answers back to the Steering Committee, or ensuring that they are incorporated into the Science Advisors' work products. Questions to the Science Advisors will be addressed only if they are directly relevant to NCCP/HCP conservation goals and objectives. The Science Advisors will not make value judgments about policies, procedures, laws, economic costs, or societal values. However, it is appropriate for them to objectively address scientific implications of how policy decisions might affect biological resources, such as covered species populations or habitats, as well as how scientific information will be used.

6. Development of Work Products

The Facilitation Team will be responsible for coordinating development of Science Advisor work products. The Facilitation Team will work with the Science Advisors, including the Lead Scientist, to identify writing assignments and track completion of those assignments. The Facilitation Team will work with the Lead Scientist to compile and edit material from the Advisors to ensure that their products are understandable to a broad audience and meet the requirements of the NCCP Act. The Facilitation Team will also ensure that the products reflect the consensus of advisors wherever possible, or to clarify any areas of disagreement or scientific uncertainty that remain.

A draft Guidance Report will be prepared following the science advisor workshops. The draft will be distributed to the Steering Committee for review and comment prior to being finalized for public release. The purpose of this review is to identify any factual errors or portions of the report that may require additional clarification, and not to influence the substance of the report. In no case shall the Facilitation Team allow for the Steering Committee or any other parties to influence the nature of the scientific recommendations in the report, which must substantially reflect the consensus recommendations of the Independent Science Advisors. The Facilitation Team, in consultation with the Lead Scientist, will review comments provided by the Steering Committee and work with Science Advisors to make appropriate adjustments and produce a final Guidance Report.

7. Conflict of Interest

Individuals currently under contract to member agencies of the Steering Committee for work related to the BDCP will be precluded from serving as Science Advisors. At the outset of the process, all selected Science Advisors will be required to disclose for the record any activities they are, or have been, engaged in within the past three years in the Delta, including research projects, as well as any financial affiliations they may have with members of the Steering Committee. Service as a BDCP Science Advisor shall not preclude the pursuit of future grants or research related to the Delta.

ATTACHMENT 1
PROPOSED WORKPLAN FOR INDEPENDENT SCIENCE INPUT

The following outlines a proposed workplan for obtaining independent, timely, focused science input for the BDCP process. The workplan is organized over time as described below and shown graphically in Figure 1.

Initial Planning (by End of June 2007)
Initial planning for science advisor engagement. Specific tasks will include the following:
(a) the selection of advisors;
(b) initial written guidance for the scientific input process and
(c) framing science questions.

Deliverables:

- Guidelines for Scientific Input
- Identification and selection of Science Advisors
- Science Questions

Steering Committee Engagement:

- Meeting #1 – June 1, 2007; Review proposed plan and solicit input on areas of expertise and potential science advisors.
- Meeting #2 – June 15, 2007; Discuss science questions.

<u>Initial Engagement (by September 2007)</u>
The Science Advisors will be convened to participate in topically focused workshops. The exact number and focus of each workshop will be determined based on discussions with the Steering Committee and the Lead Scientist regarding the development of Science Questions (which will be used to frame the advisor discussions). Potential topics may include broad principles for guiding preparation of the Conservation Plan, as required by the NCCP Act. The exact timing of the workshops will be influenced by the availability of the selected Science Advisors.

Deliverables:

- Workshop Summaries
- Draft Guidance Report(s) containing Science Advisor observations and recommendations
- Final Guidance Report(s)

Steering Committee Engagement:

- Meeting #3 – TBD: Review initial workshop observations and recommendations
- Meeting #4 – TBD; Meet with Lead Scientist to discuss Guidance Report(s)

<u>Later Engagement (2008)</u>
Recognizing that additional science input on specific issues such as adaptive management and monitoring may be needed once a conservation strategy has been selected, the Facilitation Team recommends that the Steering Committee commit to a second engagement of Science Advisors in 2008. This additional independent scientific input could be used to advance discussion on specific elements of the selected conservation strategy (e.g., management and monitoring principles) as the well as the design of potential near-term conservation actions while longer-term investment strategies mature. The second engagement would also allow for advice regarding new information that may emerge after the initial engagement.

Deliverables:

- Input on specific issues or plan elements

Steering Committee Engagement:

- Meeting #5 – TBD: Review additional observations and recommendations
- Meeting #6 – TBD; Meet with Lead Scientist to discuss input

APPENDIX B:

Topics and Issues to be Discussed by Independent Science Advisors

BDCP INDEPENDENT SCIENCE ADVISORY WORKSHOP
SEPETEMBER 12-14, 2007
RYDE HOTEL

WORKSHOP TOPICS AND ISSUES TO BE DISCUSSED

The following major topics, and issues listed under each topic, are intended to help frame the advisors' discussions and not to rigidly dictate the scope of the discussions nor form the outline of the advisors' report. There is necessarily broad overlap and intertwining of issues amongst the major topic areas, and we have purposely structured the workshop to allow advisors to circle back to refine their input on particular topics or issues after moving on to other topic areas (in case discussion on a particular topic stimulates new thoughts on a topic already addressed).

Note also that the list of issues under each topic is not necessarily comprehensive. Additional issues are likely to arise before and during advisors' discussions and will be addressed as appropriate. We encourage Steering Committee members to continue submitting additional topics or issues to the Facilitation Team.

Conservation Principles

Charge: Formulate scientific principles for guiding ecosystem restoration and conservation of species and natural communities in the study area.

Issues to Consider:

a. The current, highly altered nature of the system
b. Invasive species
c. Flows and transport pathways
d. Water qualities
e. Future climate regimes
f. Physical and/or biological characteristics
g. Natural processes and self-sustaining outcomes
h. Ecological gradients (e.g., water depths, salinity, temperature regimes, substrate types)

Plan Scope

Charge: Identify natural communities, species, and processes that should be addressed to help achieve the plan's goals.

Issues to Consider:

a. The list of natural communities to be addressed by the plan
b. The list of species intended for coverage under state and federal take permits
c. Additional "planning" species, which may lack special protection status but may serve as useful indicators for other species, communities, or processes of interest
d. Effective ways of grouping species to assist in developing and assessing conservation strategies (e.g., species guilds, resident vs. anadromous species, species sharing limiting factors)

e. Physical and ecological processes to be addressed by the plan
f. The plan's geographic scope and how to address effects that extend beyond geographic boundaries
g. The temporal scope of the plan and how to address short vs. long-term effects

Knowledge Base for Planning

Charge: Review existing information and assess it's adequacy as a scientific foundation for conservation planning.

Issues to Consider:

a. Gaps in existing information that create uncertainties for planning, analyzing, managing, and monitoring
b. Additional data sources or literature that should be considered during planning and analysis
c. Methods for addressing data gaps and dealing with uncertainties
d. Physical or biological process models that might inform development of conservation strategies, (e.g., models of population dynamics, community dynamics, or nutrient or water flows)
e. Sufficiency of available data (including accuracy and precision) for use in models identified above
f. The need to expressly and specifically identify and document the implications of scientific uncertainties on the recommendations of the science advisors

Critical Processes

Charge: Identify critical physical and ecological processes for restoring and conserving species and natural communities, and methods for assessing, conserving, restoring, and monitoring such processes.

Issues to Consider:

a. Historic ecological processes that maintained ecosystem and species viability
b. Current state of those processes
c. Future desired states for those processes
d. Methods for achieving future desired states
e. Examples of processes to address:
    - Nutrient flows
    - Water flows
    - Population dynamics
    - Disturbance cycles
    - Ecological migration
    - Exotic species invasions
    - Harvest
    - Population genetics
    - Climate change

External Factors

Charge: Identify external factors or processes, not under direct influence of BDCP participants, that might affect BDCP covered resources, and how can these externalitices be addressed by BDCP analyses and actions.

Issues to Consider:

a. Climate change (e.g., how might it affect this ecosystem and the target species, and how can these effects be addressed by the plan?)
b. Current and future land uses in the vicinity of the Bay Delta, or beyond plan boundaries, that may directly or indirectly affect the success of BDCP conservation strategies
c. Other existing or ongoing regional conservation plans in the vicinity of the Bay Delta.

The following index table provides a summary of where within the Independent Science Advisors Report specific issues and topics are discussed.

Conservation Principles	
Charge: Identify scientific principles for guiding ecosystem restoration and conservation of covered species and communities in the study area. Response Summary: Sixteen principles were formulated reflecting broad, fundamental concepts deemed important to acknowledge and understand in the process of developing an HCP / NCCP for the Delta.	
Specific Issues:	Report Section Reference
Current altered state of the system	Section 2 (Principles – A, B, & E)
Invasive species	Section 2 (Principles – A, B, F & P)
Flows and transport pathways	Section 2 (Principles – D, C, F, H, I, & J)

Plan Scope	
Charge: Identify natural communities, species, and processes that should be addressed to help achieve the plan's goals. Response Summary: The report provides preliminary observations and advice regarding geographic and temporal scope of the plan, covered species, communities, processes, and conservation strategies based on currently available information. The Advisors recommend seeking further advice on these topics as the Covered Activities become more defined.	
Specific Issues:	Report Section Reference
List natural communities to be addressed by plan	Section 3.5
List species intended for coverage under state and federal permits	Section 3.3
Identify additional "planning species"	Section 3.4
Identify effective ways of grouping species, communities, or processes of interest to assist in developing and assessing conservation strategies	Section 3.5
Identify physical and ecological processes to be addressed by the plan	Section 4.0
Geographic scope of the plan	Section 3.1
Temporal scope of plan	Section 3.2

Knowledge Base for Planning	
Charge: Review existing information and assess its adequacy as a scientific foundation for conservation planning. Response Summary: The Advisors have made observations on the current state of knowledge, its limitations, and made several recommendations for addressing data gaps and refining predictive ability. These observations are generally summarized in Section 4 and its associated tables.	
Issues:	Report Section Reference
Gaps in existing information that create uncertainties	Section 2 (Principles – N & P) Section 4.2 Tables 1-5
Additional data sources of literature that should be considered during planning and analysis	Tables 1-5 Section 4.3 Section 5
Methods for addressing data gaps and dealing with uncertainties	Section 2 (Principles – N, O, & P) Section 4.2 & 4.3 Section 5
Physical or biological process models that might inform development of conservation strategies	Section 2 (Principle - O) Section 5
Sufficiency of available data for use in models	Section 2 (Principles – N, O, & P) Tables 1-5
The need to expressly and specifically identify and document the implications of scientific uncertainties on the recommendations of the advisors	Section 2 (Principles – L, N, & P) Tables 1-5 Section 5

Critical Processes	
Charge: Identify critical physical and ecological processes for restoring and conserving species and natural communities, and methods for assessing, conserving, restoring, and monitoring such processes. Response Summary: The Advisors identified certain process interactions considered to be particularly important for understanding the response of Covered Species to changing conditions. Boundary conditions (e.g. river inflows, diversions, tides) combine with the geomorphic template (the physical structure of the system) to influence physical, geomorphic, foodweb, and chemical processes, which in turn act on each other and influence species population dynamics in a variety of ways.	
Issues:	Report Section Reference

Water flows	Tables 1 & 2
Population dynamics	Section 4.3
Disturbance cycles	Section 2 (Principles – D & E)
Ecological migration	Section 2 (Principles – C, D, E, G, & H) Section 4.3
Exotic species invasions	Section 2 (Principles – A, B, C, D, & G) Section 3.4 Table 4
Harvest[63]	Section 2 (Principle C)
Population genetics	Section 2 (Principles – C & E) Section 4.3
Climate change	Section 2 (Principles – B & P) Section 3.5 Tables 1, 2, &3 Section 5.4

[62] The Advisors did not evaluate specific future Delta conditions or conservation strategies.
[63] The Advisors focused on ways in which harvest can be considered in studies of population dynamics rather than its specific role

External Factors

Charge: Identify external factors or processes, not under direct influence of BDCP participants, that might affect BDCP covered resources, and how these externalities can be addressed by BDCP analyses and actions.

Response Summary: The Delta is part of a larger river-estuarine system that is affected by both rivers and tides as well as by long-distance connections, extending from the headwaters of the Sacramento and San Joaquin rivers into the Pacific Ocean.

[64] The Advisors did not specifically examine other plans. However, they did draw on work from POD, DRERIP and IEP in their deliberations.

APPENDIX C:

Additional Questions Submitted to the Independent Science Advisors from the Steering Committee

The following table lists additional questions provided to the Independent Science Advisors by Steering Committee before the September 2007 Advisors Workshop and provides references for where within the Advisor's report these questions are generally discussed. Because many of these questions are very specific, requiring detailed investigations beyond the scope of the Advisor's initial charge, the Advisors did not attempt to specifically answer each question. However, the questions were used to better understand the interests of the Steering Committee and to help frame the overall discussion of the Advisors. In the course of developing Principles for Conservation Planning and other general guidance, the Advisors did touch upon several of the fundamental issues underlying many of the specific questions posed, as noted in the index table below.

Questions Provided by Non-Governmental Organizations	
Question	Report Section Reference
Understanding that ecosystems are dynamic and past conditions cannot be duplicated, how can information about historical conditions in the Bay-Delta estuary and historical relationships between Bay-Delta habitat conditions and biological resources best be used to guide development of the conservation strategy?	Section 2 (Principles - A & E)
Flows have been the most obvious driver of ecological conditions in the Bay-Delta estuary. Is it possible to protect and restore covered species without significantly improving flow conditions in this system?	Section 2 (Principle F)
The degree to which most previous management actions protect Bay-Delta ecological resources have been implemented has been very small in scale when measured against the degree of human alteration of the Bay-Delta estuary's habitats, hydrology, etc. To what extent should the consideration of the magnitude of potential management changes[65] in habitat, hydrology and other ecological conditions help both in generating meaningful data and in securing significant improvement in estuarine functions?	Section 4.3 Section 5 Section 6
Is there any quantitative basis for concluding that factors other than flow and exports are affecting covered species at the population level?	Section 2 (Principle F) Section 4.3

[65] The Advisors did not consider specific management strategies.

Questions Provided by Potentially Regulated Entities	
Question	Report Section Reference
Do biological evaluation criteria developed to help screen conservation strategy options adequately address the range of issues adversely affecting the covered species?	The Advisors did not examine the criteria.
What are the factors influencing the populations of covered species and their relative importance?	Tables 1-5 Section 4
Can a more variable Delta hydrologic regime (variation between freshwater outflow and saltwater inflow) be detrimental or beneficial to covered species?	Section 2 (Principles – F & M) Section 3.5 Section 4.3 Section 5.4
Has climate change affected the necessary conditions for native species in the Delta that are at the southern most extent of their range? How would climate change affect the covered species in the future under each of the climate change scenarios described in DWR's report, *Progress on Incorporating Climate Change in to Management of California's Water Resources* (July 2006)[66]. Under the projected effects of climate change is there a time in the future when the Delta will no longer be suitable habitat for one or more covered species?	Section 2 (Principles – A, B, E, & P) Section 3.5
Has reduced turbidity affected the necessary conditions for native species in the Delta? Can the effects of reduced turbidity be addressed by the conservation strategy options?	Section 2 (Principles – A & E) Section 5.2 Table 2
Please review the Delta smelt/*eurytemora* co-occurrence analysis by BJ Miller Does food supply (zooplankton density and geographic distribution) appear to be a major determinant of smelt population? How can food supply be considered in the conservation strategy?	Section 4.1 (Table 4)
Would a more variable Delta hydrologic regime be detrimental or beneficial to non-native species such as the zebra or quagga mussels?	Section 2 (Principle D) Section 3.5 Section 5.4
Will replacing riprap-lined levees with riparian vegetation have a substantial positive effect on the population of covered species? Should this be included as part of our conservation strategy options? For which species?	Section 2 (Principle G) Section 3.5 Section 5.1

[66] The Advisors did not consider the implications of specific climate change scenarios

Does increasing shallow water habitat improve populations for covered species?	Section 2 (Principle G) Section 3.5
Is it possible to create refugia for foundational species of the Delta ecosystem such as *eurytemora*?	This specific question was not addressed.
Is it environmentally beneficial to covered species be able to move large Delta water diversion points based on the location of habitat needs of the Delta's native species?	Section 2 (Principle M) Section 4.3
What conclusions are supported by the data on the effect of unscreened in-delta diversions on covered species:	The Advisors did not specifically examine these data.
A. Can screening in-Delta diversions improve conditions for the Delta's native pelagic and anadromous fish?	Section 2 (Principle G) Section 4.3.2
B. How does the #/AF of entrainment due to in-Delta diversions compare to entrainment caused by exports?	Section 4.3.2
Is there sufficient data to determine if toxic events in the north Delta, and municipal and agricultural wastewater discharges throughout the Delta have affected the viability of zooplankton, pelagic, and anadromous species in the Delta? Should toxics and wastewater discharge control program for areas in and immediately adjacent to the Delta be included in the conservation strategy options?	Section 4.1 Table 5
What effects do upstream diversions on the San Joaquin River tributaries have on the covered species?	Section 2 (Principle C) Table 1
Is it possible to achieve recovery of the Delta smelt by addressing only the effects of pumping at the SWP and CVP pumping plants?	Section 2 (Principle F)
Given the uncertainty of some of the science surrounding the covered species and the associated Delta ecosystem what strategies can be incorporated into the conservation plan to address known data gaps? What uncertainties do you feel are most important to consider when developing specific conservation measures or adaptive management protocols?	Section 4.1 Tables 1-5 Section 6

Attachment C – Documents Reviewed by Advisors

1 Introduction

This report summarizes recommendations from a group of independent science advisors (ISA) concerning the treatment of non-aquatic species and communities by the Bay Delta Conservation Plan (BDCP). The intent of the ISA process is to ensure that the plan has access to the best available science. Our recommendations are not binding, and are not intended to either question or promote particular plan goals or policies, but are intended to help inform the planning process. Attachment A provides brief biographies of the advisors.

Contents of this report reflect discussion among the science advisors at a workshop held on September 30, 2008 (Attachment B) and their review of various draft plan documents (Attachment C). A previous ISA workshop and report (Reed et al. 2007) focused on the aquatic species and communities that have been the BDCP's highest priorities. This second workshop and report, by a different set of science advisors, focuses on non-aquatic species and communities that could be affected by plan actions.

2 Covered Species

This section provides information concerning what non-aquatic species may be affected by BDCP implementation, either positively or negatively. The intent is not to recommend which species should or should not be covered by regulatory take authorizations or permits under endangered species regulations. It is up to the potentially regulated entities (PREs) to decide which species they wish to obtain permit coverage for, whether under Endangered Species Act Section 10 and the NCCP Act or under other regulations (e.g., Section 7 of the ESA or Section 2081 of the Fish & Game Code). Moreover, it is up to the fish and wildlife agencies to determine for which species permit coverage is ultimately warranted, under what regulations, and with what terms and conditions. We offer the following scientific information and advice to be considered as BDCP participants make decisions about species coverage and conservation actions.

2.1 Species Selection Process

The advisors generally concur with the evaluation criteria and process that was used to identify potentially covered species by the consulting team (Attachment C, Document #3). However, we have some questions and concerns about how the four evaluation criteria (listing status, occurrence in planning area, potential to be affected, and information sufficiency) were applied, and we suggest reconsidering the evaluation of certain species.

First, the advisors were unclear how the original list of 111 species that SAIC evaluated for coverage was derived, and are concerned that some at-risk species or subspecies that may occur in or near the planning area were not evaluated. For example, several birds that are California Species of Special Concern (SSC) (Shuford and Gardali 2008) are known or potentially occur in the planning area, but were apparently not evaluated, such as the Modesto song sparrow (*Melospiza melodia mailliardi*) and yellow warbler (*Dendrocia petechia*).

Listing Status. For some species, advisors question how the determination was made that they were unlikely to be listed, in light of myriad uncertainties and considering the proposed 50-year permit duration. We believe it is prudent to err on the side of caution in making such determinations, because an unexpected listing can be disruptive to plan implementation[1]. In particular, the advisors note that there is an inherent circularity in the logic to not cover some SSC on grounds they are unlikely to be listed. Inclusion on the California SSC list indicates that a species meets some or all criteria for California Threatened or Endangered status, and that highlighting this at-risk status may help prevent the need to list the species by encouraging conservation and recovery actions for it (Shuford and Gardali 2008). The advisors therefore recommend treating SSC as if they are likely to be listed. If the planning area is important to viability of an SSC, the plan should evaluate whether implementation may adversely affect it and therefore warrant coverage.

Occurrence in Plan Area. The advisors note that survey coverage in the plan area is sparse for many species, and that it is difficult to assume absence on the basis of existing data, such as CNDDB records. This is particularly true for plants and invertebrates. Some species occurring in the vicinity of the Bay Delta have been found outside their known geographic ranges after being listed and could occur in the plan area. We also note that species ranges are dynamic, and that shifts in response to climate change and other factors are being documented for numerous taxa in California and throughout the world (Moritz et al 2008, Parmesan 2006, Root et al. 2003). We therefore recommend carefully considering the potential for species to occur within the plan area over the proposed 50-year permit duration.

We understand that some plan actions may occur outside the planning area (the statutory boundary of the Delta) but that only species occurring inside the boundary were evaluated. We recommend identifying all at-risk species that may be affected by the plan (i.e., listed, SSC, or CNPS list species), whether inside or outside the plan boundary (e.g., by an around-Delta conveyance or by restoration actions in Suisun Marsh). We recognize that permits for BDCP effects on some species may be obtained via other regulatory means than BDCP take authorizations (e.g., project-specific Section 7 or 2081 authorizations), but it seems wise to anticipate the full range of potential effects to inform such decisions as early as possible.

Potential to be Affected by Plan Actions. The advisors also feel it is prudent to err on the side of caution when considering the potential for species to be affected by plan actions, whether positively or negatively, because the nature and extent of the plan's covered actions and conservation measures are not yet fully defined. For example, we understand that the consultants only considered an eastern alignment in determining whether species may be adversely affected by an around-Delta conveyance. It appears from maps and other information we reviewed that additional species could be adversely affected by other alignments, especially a western alignment. Until the conveyance alignments and other plan measures are more fully developed,

---

[1] For example, during development of the San Diego Multiple Species Conservation Plan (MSCP) the Quino checkerspot butterfly (*Euphydryas editha quino*) was considered unlikely to be listed and was not covered. The butterfly was listed as Endangered one year after MSCP approval, triggering project delays and a costly plan amendment.

we recommend keeping an inclusive list of potentially affected species, and winnowing the list as decisions are made and uncertainties resolved.

Advisors question the assumption that siphoning aqueducts under tidal channels, streams, and sloughs can completely avoid impacts on riparian habitat or other floodplain habitats. While the impacts of siphons may be lower than alternative conveyance solutions, based on observations of existing siphons elsewhere in the Central Valley, advisors are uncertain whether all direct and indirect impacts associated with construction and maintenance of siphons can be completely avoided. We recommend not relying on this assumption in considering species for coverage until facility design is sufficiently advanced to remove such uncertainties.

Restoration actions intended to benefit aquatic species may positively or negatively affect habitat for or populations of terrestrial species. For example, restoration of tidal marshes in lowland portions of the plan area could flood habitats currently occupied by covered terrestrial plant and animal species, while increasing habitat potential for marsh species.

Even if plan actions do not directly affect habitats or populations of certain terrestrial species, they have potential to constrain conservation or recovery actions for these species by other plans. For instance the Antioch Dunes represent a rare sand dune habitat that supports a number of rare, endemic plants and animals, such as the federally endangered Contra Costa wallflower (*Erysimum capitatum* ssp. *angustatum*), Antioch Dunes evening primrose (*Oenothera deltoides* ssp. *howelli*), and Lange's metalmark butterfly (*Apodemia mormo langei*). We agree that this community and its endemic species are not likely to be directly affected by BDCP actions. However, due to the extreme rarity and conservation importance of this community, we recommend analyzing whether any covered actions might constrain the possibility of future habitat restoration within this very limited geographic area by other entities, or whether BDCP conservation actions could contribute to recovery of these species.

Sufficiency of Information. The advisors were unclear about how this determination was made for each species, given uncertainties about the distribution of many species in the plan area and the preliminary nature of the covered actions and conservation measures. We assume that the determination focused on whether scientific understanding is sufficient to determine how covered actions and conservation measures might affect each species, provided the species is present in affected areas. We understand the rationale that there must be sufficient scientific understanding about how covered actions and conservation measures may affect a species to determine whether that species should ultimately be covered by take authorizations. However, where there is not sufficient information to make such a determination at this time, we believe it is prudent to keep the species on a comprehensive species list as the plan develops, in case sufficient information becomes available to make the assessment, rather than to remove such "uncertain" species from the list prematurely.

The explanation for this criterion (Attachment C, Document #3, Page 8) states, "A guide for this criterion is if the species is covered or proposed for coverage under other HCPs and NCCPs, which indicates a confidence that sufficient information is available to cover the species." We point out that the nature of BDCP covered actions and conservation measures differs considerably from that of most other HCPs and NCCPs, which usually involve trading off habitat losses due to development, primarily in upland areas, with conservation and management of habitat preserves in other locations. In contrast, BDCP actions will likely result in complex and widespread changes in hydrodynamics, water qualities, etc., as well as potentially widespread habitat restoration projects, especially of wetland communities. Such actions may affect covered species in ways not addressed by other HCPs and NCCPs in the region. Moreover, how these changes may interact with climate change and other factors to influence habitat and populations of covered species is highly uncertain. We believe that where existing scientific information is not currently sufficient to determine plan effects on species, those species should be retained on the list of potentially covered species until sufficient information becomes available to determine that the plan is unlikely to have effects on them (e.g., until covered actions are more fully defined and more comprehensive surveys can be performed). These uncertainties about plan effects on diverse species reemphasize the critical importance of a solid adaptive management and monitoring program for the BDCP.

2.2 Potential Covered Species Additions

Based on the above review of the species selection criteria, we believe the following species should be considered (or reconsidered) for coverage, because they are listed or have potential to be listed as Threatened or Endangered and they could be affected by plan actions. These include some species not addressed in the consultants' evaluation, and others that were evaluated but determined unlikely to require coverage due to one or more of the evaluation criteria. For example, they include several SSC that we believe should be treated as likely to be listed, for reasons explained above. Finally, they include some species about which the consultants were uncertain for one or more of the evaluation criteria.

- **Riparian woodrat** (*Neotoma fuscipes riparia*[2]). The consultants' evaluation was uncertain about this federally endangered species' occurrence in the plan area and likelihood of being affected. Surveys are being performed for the species in appropriate habitats within the BDCP area, and we recommend awaiting results of those surveys before determining whether to pursue coverage. Before 2003 riparian woodrats were thought to survive only at Caswell Memorial State Park and a few other areas along the lower Stanislaus River. However, the species was found in 2003 at the San Joaquin River National Wildlife Refuge, just south of the planning area, and it may be more widely distributed than previously thought. Ongoing riparian habitat restoration efforts at the San Joaquin River NWR and elsewhere will likely lead to population and range expansion. In addition to loss of habitat, riparian woodrats are threatened by fires and floods, as evidenced by population reductions in San Joaquin River NWR following a wildfire there in 2004 and major flooding in 2006. Riparian woodrats are expected to respond favorably to riparian habitat restoration programs.
- **Northern harrier** (*Circus cyaneus*) has been a California Bird SSC since 1978 (Shuford and Gardali 2008). Recent declines throughout the Central valley have been attributed to habitat loss, intensified agricultural practices, and increases in nonnative predators (cats, dogs, and eastern red foxes). Harriers are known to breed regularly at the Cosumnes Reserve and were found in 69 widely scattered blocks in the Sacramento County Breeding Bird Atlas. The

[2] Taxonomic revision will likely result from studies that are presently ongoing by Marjorie Matocq at University of Nevada, Reno (P. Kelly).

nests of this ground-nesting species are highly vulnerable to disturbance from humans, dogs, livestock, and agricultural activities during the breeding season. Conservation measures, such as restoring wetland habitats in what are currently uplands, could adversely affect a small number of harriers. Further information on occupancy, persistence, and ideally nesting success in protected areas is needed.

- **Lesser sandhill crane** (*Grus canadensis canadensis*). This recent addition to the California bird SSC list (Shuford and Gardali 2008) winters in large numbers within the Delta (Christmas Bird Count data). Like the greater sandhill crane (which was included as potentially covered in the consultant's evaluation) the greatest threats to the species are changes in agricultural practices and habitat loss. Management actions, such as promoting late (February) discing of grain crops, managing grasslands with cattle, providing shallow wetlands, and preventing collision with power lines, will benefit both the lesser sandhill crane and the greater sandhill crane.

- **Least Bell's vireo** (*Vireo belli pusillus*) was not evaluated by the consultants, presumably because it has not been found in the plan area since before the species was listed as Endangered in the 1980s. Least Bell's vireo was restricted to a few small populations in southern California at the time of listing, but it has since been increasing in population and expanding northward within its historic range in the Central Valley. In recent years least Bell's vireos have nested as far north as Gilroy (Santa Clara County) and San Joaquin River National Wildlife Refuge (Merced County). Experts consider it likely to re-occupy riparian habitats in the BDCP area in the near future.

- **Yellow warbler** (*Dendroica petechia*) was not evaluated by the consultants. A California SSC since 1978 (Shuford and Gardali 2008) this species has declined significantly as a breeding bird throughout the state and in the Central Valley and may be close to extirpation (Heath 2008). Extensive surveys in the Bay Delta and San Joaquin valley in the late 1900s failed to locate breeding populations. Possible breeding records in Contra Costa County and a new expanding population on the San Joaquin River NWR (Hospital Creek) suggests high potential for this species to return to the delta in healthy numbers. An early seral-stage, riparian-dependent species, restoration programs that restore ecosystem processes (e.g., natural flood events), a mosaic of riparian habitat, and healthy understory will benefit this easily monitored species (Riparian Habitat Joint Venture 2004).

- **Modesto song sparrow** (*Melospiza melodia*, "Modesto" Population) was not evaluated by the consultants. This resident California bird was considered a valid subspecies (*M. m. mailliardi)* until 2001 (Patten 2001), and may be again under additional taxonomic research (Gardali 2008). Regardless of whether the "Modesto population" of the song sparrow is ultimately determined to be a valid subspecies, it is a California SSC that is endemic to the Sacramento Valley (Gardali 2008). The Bay-Delta is one of two areas with the highest population densities. Major loss (> 90%) of its preferred wetland and riparian habitat has led to a significant reduction in range and abundance. While it can be locally abundant along riparian corridors or small wetlands it is rare along irrigation canals, levees, and in mature riparian habitat. The protection and restoration of wetlands and dynamic riparian systems with understory and habitat mosaics will aid in this species' recovery.

- **Western pond turtle** (*Clemmys marmorata*). The western pond turtle is a California state SSC. The turtle's habitat includes freshwater sloughs and marshes in the Delta (Zeiner et al.

1988-1990). Salt-water intrusion brought about by reducing freshwater flows into the Delta could have a negative effect on local populations.

- **California tiger salamander** (*Ambystoma californiense*) is a federally threatened species with recent sightings in the vernal pool habitats on the western edge of the project area. This area is included in designated Critical Habitat for the species (U.S. Fish and Wildlife Service 2004), and actions there, such as construction of a western around-Delta conveyance, have the potential to adversely affect the species. The consultants' evaluation was uncertain about the potential for plan actions to affect the species, presumably because covered actions are not yet fully defined.

- **California red-legged frog** (*Rana aurora draytonii*) is federally Threatened and a California SSC that is known to occur in the plan area. The consultant's evaluation concluded that plan actions were unlikely to affect the species. The advisors are unclear how this determination was made given that locations of covered actions and conservation measures have not yet been fully defined and that surveys sometimes find this species in unexpected locations. Red-legged frog could be adversely affected if covered actions occurred in or near occupied or potential habitat. We recommend including this as a potentially covered species pending further analysis as covered actions and conservation measures are better defined.

- **California black walnut** (*Juglans hindsii*) was considered by the consultants' evaluation to be unlikely to become listed. However, this California endemic is a CNPS list 1B.1 species (seriously endangered in California) and has a Natural Heritage Rank of G1/S1.1. It is known to hybridize with other species of walnuts. Although it has been widely planted and used for root stock, natural occurrences are limited, and only one confirmed natural stand appeared viable as of 2003 (http://cnps.web.aplus.net/cgi-bin/inv/inventory.cgi). We recommend considering covered status for this species if natural populations occur in the plan area that could be positively or negatively affected by covered actions.

- **Bristly sedge** (*Carex comosa*) is found along the margins of marshes, swamps, and in wet meadows. The consultants' evaluation was uncertain about this species' potential to be listed. We share this uncertainty, and believe there is a small potential for it to be listed in the next 50 years. We therefore agree with the consultants "undetermined" finding and suggest keeping this species on the list until uncertainty is reduced.

- **Various plant species** found in vernal pools, swales, or flats that could be adversely affected by plan actions, especially in combination with climate change, or have the potential to benefit from the plan's conservation actions. The consultant's evaluation determined that these species were unlikely to be affected by covered actions, or they were uncertain about the potential for effects. We are also uncertain about potential plan effects on these species, given that plan actions aren't yet fully described, and believe they should be retained until uncertainties are resolved.
    - Bogg's Lake hedge-hyssop (*Gratiola heterosepala*)
    - San Joaquin Valley Orcutt grass (*Orcuttia inaequalis*)
    - Heartscale (*Atriplex cordulata*)
    - Brittlescale (*Atriplex depressa*)
    - Vernal pool smallscale (*Atriplex persistens*)

- o Round-leafed filaree (*Erodium macrophyllum*)
- o Fragrant fritillary (*Fritillaria liliacea*)
- o Lesser saltscale (*Atriplex minuscule*)

We agree with the consultant's evaluation that the following species, which are associated with the extremely rare Antioch Dune community, are unlikely to be directly affected by the covered actions or conservation measures currently under consideration. However, as explained earlier, we recommend evaluating whether BDCP implementation could contribute to the recovery of these species or whether BDCP implementation might indirectly constrain potential conservation and recovery actions for these species by other entities.

- Delta green ground beetle (*Elaphrus viridis*)
- Lange's metalmark butterfly (*Apodemia mormo langei*)
- Antioch Dunes evening primrose (*Oenothera deltoides* ssp. *howelli*)
- Contra Costa wallflower (*Erysimum capitatum* spp. *angustatum)*

2.3 Potential Covered Species Deletions

The consultants' draft evaluation concluded that the following species should be considered for coverage, or stated that this conclusion was "undetermined." The advisors believe that these species are unlikely to require coverage, and they could be deleted from the list.

- **Snowy plover** (*Charadrias alexandrinus,* interior population). Since 1945 there are only three breeding records for this species in the Central Valley (all in Yolo County). Its extremely rare occurrence and preference for agricultural evaporation ponds and alkali playas in the Valley suggest that BDCP is unlikely to affect this species and that the delta is not an area in which to focus conservation efforts for it.
- **Coast horned lizard** (*Phrynosoma coronatum*) does not likely inhabit the plan area (Stebbens 2003) or areas likely to be affected by around-Delta conveyances.
- **Caper-fruited tropidocarpum** (*Tropidocarpum capparideum).* This species was believed to be extinct for several decades, but was rediscovered in Monterey County at Fort Hunter Liggett in 2000-2001. It primarily occupied valley grasslands, with some documented locations within the plan area. However, it has not been re-located in the plan area in recent years and is presumed extirpated.

2.4 Planning Species

The advisors are concerned that the plan focuses so strongly on species for which regulatory coverage is being sought (e.g., listed threatened and endangered species) that it might not adequately account for ecological processes and community interactions that are essential to all species in the area, including covered species. Some conservation plans identify additional "planning species" for which regulatory coverage may not be necessary, but that can serve as indicators of ecological conditions or processes in covered communities. Indicator species can be effective monitoring tools in adaptive management plans, especially where intensive monitoring of covered species is infeasible. We recommend considering whether some additional planning species should be evaluated in the plan and included in the monitoring program to help meet BDCP goals.

One approach for identifying useful planning species is to identify groups of species whose vulnerability can be attributed to a common threat or stressor, such as loss of habitat area or alteration of a natural disturbance regime. For each group, one or more species are selected that are both highly sensitive to the threat category and relatively easy to monitor. Such species can thus serve as indicators for that group. We recommend that the plan identify what threat categories are most appropriate for non-aquatic communities in the BDCP area, systematically evaluate whether the proposed list of covered species already has sufficient indicator species for each threat category and each community type, and then supplement the covered species list as necessary to fill any gaps in this matrix with additional planning species.

One example system for identifying threat categories that has been applied in previous conservation plans is based on Lambeck (1997) who identified four groups of species. We suggest adjusting this general approach to the BDCP issues and area to identify planning species that may help attain plan goals and objectives. The following groups could be modified or supplemented with others, as appropriate for this purpose.

- *Area-limited species* have large home ranges, occur at low densities, or otherwise require large areas to maintain viable populations. Examples include large mammals (especially carnivores) and large raptors, such as northern harrier. Although this category has proved useful in design of large-scale, terrestrial reserve systems, the advisors do not necessarily recommend selecting large, wide-ranging terrestrial species as good planning species for BDCP. However, it may be useful to identify species that require relatively large habitat patches or habitat mosaics as indicators of successful habitat restoration efforts, if covered species do not already meet this need for all communities.
- *Dispersal-limited species* are limited in their dispersal capacity, sensitive to particular movement barriers such as highways or canals, or are vulnerable to mortality when trying to move through a human-dominated landscape. Examples include salamanders, turtles, large snakes, flightless insects, and large-seeded herbaceous plants. The advisors believe that some of the potentially covered species may adequately cover this category for most communities (e.g., California tiger salamander, Valley elderberry longhorn beetle).
- *Resource-limited species* require specific resources or habitats that are very rare or at least occasionally in short supply. Classic examples include nectarivores, cavity-nesting birds, cliff-nesting birds, vernal pool species, or burrow-dwelling animals. The advisors recommend considering whether there are resource specialists in the planning area that could serve as useful indicators for rare ecological communities or resources that may not be adequately addressed by covered species. For example, tree swallows and possibly spotted sandpipers are good indicators of healthy floodplain environments, diverse aquatic insect communities, and fish breeding habitat (gravel bars).
- *Process-limited species* are sensitive to details of the disturbance regime (e.g., the frequency, severity, or seasonality of floods or fires) or other manifestations of natural processes, such as hydroperiod, salinity gradients, or fire-return intervals. Examples include riparian plants like sycamore and elderberry that establish following floods, or vernal pool species which

require seasonal flooding, such as Contra Costa goldfields (*Lasthenia conjugens*). Early seral species such as song sparrows and yellow warblers are good indicators of ecosystem processes such as periodic flooding (Chase and Geupel 2005).

To this list of four categories, we suggest adding one for invasive species that serve as indicators of where management intervention is required. For example, wetland margins are often highly invaded by non-native species like Lepidium; and black rats (*Rattus rattus)* seem ubiquitous in riparian habitat in the Central Valley. Rats are nest predators of birds, including the Modesto song sparrow (Hammond 2008), and unpublished data from the Endangered Species Recovery Program suggests that woodrat reproductive success is lower in areas with high *Rattus* densities (P. Kelly).

3 Covered Communities

Due to the BDCP's focus on conserving imperiled fish species, the plan currently includes three "covered communities" and seven "other communities." [3] We recommend considering whether the plan should add more covered communities, in recognition of the interdependences among ecological communities within a broader ecosystem context. We point out that (1) many of the potentially covered species are found in the "other communities" rather than in the covered communities; (2) some of the rarest communities in the plan area are disproportionately vital to imperiled species, such as inland dune scrub and seasonal wetlands; and (3) community types are interdependent in complex ways and should not be treated in isolation of one another. For instance, changes in water level, flooding period, or nutrient deposition from flooding in certain habitats will likely impact adjacent habitats and associated covered species. Moreover, many covered species require resources from multiple community types (e.g., amphibians that require wetlands and uplands). Even if all communities in the plan area are not treated as "covered communities," the advisors at least recommend describing and assessing all communities within the plan area with a comparable level of detail and care, and describing community interdependencies in an ecosystem context. We expand on this in our review of the Existing Ecological Conditions chapter in Section 4.1.

We further recommend that analysis and documentation of plan effects recognize the finer vegetation types or habitat conditions that exist within these broadly defined natural community types[4]. The plan documents we reviewed (e.g., Attachment C, Document #2) appropriately recognize these finer distinctions by providing cross-walk tables of the various plant associations and alliances (Hickson and Keeler-Wolf 2007, Sawyer and Keeler-Wolf 1995) within each natural community type. We recommend continuing to recognize these finer distinctions, especially where they are important to assessing plan effects on covered species. For example, the category "natural seasonal wetlands" includes diverse types of seasonal wetlands, from vernal pools to alkali flats, which differ tremendously in ecological conditions and in the suite of covered species each supports.

---

[3] BDCP Planning Agreement: Attachment C, Document #1.
[4] Community types were defined based on the CALFED Bay-Delta Program Ecosystem Restoration Program Volume 1 and Multiple Species Conservation Strategy (CALFED 2000), which defined 18 "broad" natural communities, while recognizing that there are finer habitat types and vegetation communities within each of these.

The Antioch Dunes represents a unique ecosystem of critical conservation concern that lies entirely within the project area. The dunes once extended along a two-mile reach of the southern shore of the San Joaquin River immediately east of the town of Antioch (Powell 1983) and totaled approximately 190 acres. This unique, isolated ecological community supports a diversity of rare and endemic species of plants and insects. For example, the Antioch Dunes are the type locality for 27 insect species, including eight that are endemic to the Dunes, and four that are considered extinct (Bettleheim 2005). Today, only 55 acres of remnant aeolian dunes are protected within the Antioch Dunes National Wildlife Refuge, although an additional 12 acres of dunes are found on the adjacent Pacific Gas & Electric property. A comprehensive conservation plan was issued by the U.S. Fish & Wildlife Service in 2002, but few if any of the management needs have been fully addressed. The Antioch Dunes National Wildlife Refuge was identified as a potential area for habitat restoration under the Ecological Restoration Program of CALFED (1999).

As discussed earlier, we recognize that the Antioch Dunes community is unlikely to be directly impacted by BDCP covered actions, but in light of the extreme rarity of this community and its associated species, we recommend assessing whether BDCP actions may in any way constrain restoration and recovery actions within this community, or whether BDCP conservation actions could contribute to recovery actions (e.g., by including restored dune habitats as a possible component of BDCP restoration plans in appropriate locations).

Communities need to be considered not just in isolation but as interdependent communities of species that affect one another within mosaics and across gradients. This is important in assessing effects of covered activities and designing conservation measures (e.g., locating restoration areas). The goal should be to recreate and maintain natural transitions between communities along gradients (such as elevation, salinity, and moisture gradients) rather than creating isolated habitat types with “hard edges.” For example, the unnaturally abrupt transitions from marsh vegetation to uplands that are created by dikes around marshlands provide no safe haven for rails and other species during flood events, subjecting them to high predation rates. Naturally connected and transitioning communities along elevation and moisture gradients will (1) benefit the covered fish species, (2) provide more natural habitat mosaics to support terrestrial and wetland species, and (3) create more sustainable conditions during climate change and sea-level rise.

Each community type has a characteristic set of species (of all kinds, not just plants). The advisors urge more consideration of the sets of species in each community and how they interact. As discussed in Section 2.4, it would be valuable to identify species that are indicators of particular communities. It may also be useful to identify common species associations or guilds typical of particular habitat types, plant assemblages, or limiting resources. Such species groups can provide useful indicators of biological integrity within ecological communities, which can be useful in adaptive management and monitoring.

4 Draft Plan Documents

In general, the advisors were impressed with the quality of documents and maps we reviewed. The following general comments are intended to improve what already appear to be thoroughly researched and thoughtfully prepared information products.

4.1 Existing Ecological Conditions

We recommend that the existing ecological conditions chapter begin with a broader treatment of the Bay-Delta ecosystem, natural communities, and processes, including those important to non-aquatic species. All communities in the study area should be described to a similar level of detail as the three covered communities. Currently, the three covered communities are treated fully, with detailed depictions of physical conditions, vegetation, fish and wildlife, non-native species, ecosystem processes, environmental gradients, and future conditions under a changing climate. However, the seven "other communities" have briefer descriptions of only the physical conditions, vegetation, fish, and wildlife, and these are more cursory than those for covered communities.

Section 2.3.2 on existing ecosystem processes does a good job of describing the broad suite of physical, chemical, and biological processes occurring within the project area. Likewise section 2.3.3 describes well the physical processes, and 2.3.4 describes the covered communities. What is missing is an integration of community types to describe how they are arranged or interconnected in spatial mosaics, and how these mosaics work to provide ecosystem services and support covered species. For example, it would be useful to characterize patterns of adjacency and intergradation among different community types and whether the boundaries between communities are (1) natural vs. artificial (e.g., separated by dikes, roads, or ditches), or (2) gradual vs. abrupt (e.g., transitioning along natural gradients or having sharp, discrete edges). How different habitat types interact both physically and through the movement of organisms across habitat boundaries or gradients is important to understanding likely affects of plan actions and other changes on covered species. Physical interaction is likely through the interdependence of water levels in adjacent (undiked) habitats and fluxes of sediments and nutrients. In the absence of additional species-specific information, the adjacency of habitats is expected to provide a measure of the flux of organisms across habitat boundaries, and barriers of various kinds (dikes, roads, railroads, etc.) may hinder the movement of certain species. Conservation measures should strive to create habitat mosaics with natural transitions between adjacent communities along gradients. Such mosaics will be more robust in the face of changes in hydrology and sea-level rise by allowing species, communities, and processes to adjust gradually over space and time. We expand on these concepts in Section 5.

4.2 Species Accounts

The draft species accounts that we reviewed were generally well researched, organized, and accurate. We recommend producing similar accounts for all potentially covered species, with perhaps shorter accounts for those species that were considered but not retained on the potentially covered list.

Below is a sampling of minor improvements that the advisors recommend for particular species. In Section 4.4 we provide additional information sources that should be consulted and referenced in the species accounts.

- Valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*). It is important to note that, although this species has been proposed for delisting by the U.S Fish & Wildlife Service, it is still officially listed and should continue being treated as such. The delisting process is not yet final, and even once it is finalized, there will still be a required monitoring period of 5 years.
- The riparian brush rabbit account should be updated with the latest information developed by the Endangered Species Recovery Program (ESRP) at California State University – Stanislaus[5]. Note that the accounts currently available on the ESRP website are not particularly current, as results of recent and ongoing research are not yet incorporated. Surveys are being conducted within the BDCP plan area, the results of which should be used to update the account.
- An account should be prepared for the riparian woodrat using the latest information from ongoing surveys and research by ESRP[4]. As with the riparian brush rabbit, please note that the species account on the ESRP website is not particularly current. For example, recent unpublished data suggest that woodrat reproductive success is lower in areas with high black rat densities than in areas where black rats are systematically removed (P. Kelly). Riparian woodrats were first captured by ESRP in the San Joaquin River National Wildlife Refuge on March 26, 2003. Although they are captured periodically there, they are not abundant, especially since a wildfire in 2004 and major flooding in 2006. Woodrats usually build stick houses (also called nests, dens, or middens) on the ground, making them susceptible to flooding. However, they can also den arboreally in stick nests and cavities, which makes them somewhat less vulnerable to flooding than riparian brush rabbit populations. Fires may therefore be a more serious threat to riparian woodrats than flooding. As with the riparian brush rabbit, surveys are being conducted within the BDCP plan area over the next two years, the results of which should be used to update species information.

4.3 Species Habitat Models

We reviewed preliminary draft maps prepared by the consultants for a selection of covered species, to assess the general modeling approach they are using to predict habitat distribution for covered species. The approach has been to use available GIS layers (especially land cover types) and known or assumed habitat associations to depict the potential distribution of each species in the plan area.[6] This approach is fine when the relationships between species occurrence and mapped land-cover types (or other discretely mapped GIS polygons) are well established and reliable. However, errors of omission and commission are common, and their extent or frequency is difficult to assess. Overlaying available occurrence records onto these maps offers some additional information and a rough indication of model accuracy. However, when

[5] Please contact Pat Kelly at pkelly@esrp.csustan.edu for more information.
[6] The term "models" is somewhat misleading because the maps are more like compilations of information and expert opinion rather than being based on any graphical or mathematical algorithm.

occurrence records are sparse or spatially biased, for instance when based on ad-hoc reporting of occurrences to CNDDB, they are not in themselves reliable indicators of model accuracy.

A more thorough approach to habitat modeling would be to use niche models to statistically quantify the relationship between occurrence (or abundance) and habitat conditions (e.g., Guisan and Thuiller 2005, Elith et al. 2006), although we recognize that species occurrence records are too sparse for most covered species to build reliable statistical models. Regardless of the method used, all distribution maps must be applied and interpreted with great caution due to uncertainties.

Furthermore there is a need to consider more fully the likely distribution of habitat 50 years into the future based on climate change predictions. Habitat models can be coupled with climate envelope models to forecast changes in species ranges under different climate change models (e.g., Loarie et al. 2008).

4.4 Information Sources

We recommend considering the following information sources to bolster the scientific foundations of the plan and plan documents.

- California Riparian Habitat Restoration Handbook (Griggs 2008). This recent publication is based on years of experience designing, implementing, and monitoring riparian and riverine habitats in California, and serves as a practical "how-to" guide for planners and practitioners.
- California Bird Species of Special Concern (Shuford and Gardali 2008).
- California Mammal Species of Special Concern.[7]
- Contra Costa County Breeding Bird Atlas (http://www.flyingemu.com/ccosta/).
- State Wildlife Action Plan (Bunn et al. 2005).
- Antioch Dunes National Wildlife Refuge Comprehensive Conservation Plan (USFWS 2002).
- The most recent publications and model results concerning climate change effects on species ranges and phenologies that pertain to the study area and species. For example, Loarie et al. (2008) assessed likely effects of climate change on California's flora, and predicted that about 2/3 of our endemic plant species will experience >80% range contractions over the next century, with major disassociation of current plant communities likely. Hijmans and Graham (2006) discuss the accuracy of predictions from widely used climate-envelope models, and Green et al. (2008) showed that such models are able to retroactively predict range shifts for bird species.
- ClimateWizard is a climate change modeling and analysis "toolbox" that should be ready for public use in the near future. It may be useful for investigating how climate change may

[7] Unfortunately, the most current version of this document has been under review for several years now and is not yet available. We recommend checking on the status with the California Department of Fish and Game. See also: http://www.dfg.ca.gov/wildlife/species/ssc/mammals.html

affect covered species and communities in the BDCP area. See http://faculty.washington.edu/girvetz/ClimateWizard/index.html for more information.

- PRBO Conservation Sciences has created predictive models of species distribution for 19 different bird species using a machine-learning algorithm called Maxent (Phillips et al. 2006, http://www.cs.princeton.edu/~schapire/maxent/). The models predict distributions based on species occurrence locations and GIS-based environmental data layers. This approach can significantly improve predictive ability over simple habitat suitability index (HSI) or wildlife habitat relationship (WHR) models, which are often based on broad-scale habitat associations that are not necessarily applicable throughout a species' range. CADC (http://www.prbo.org/cadc/) provides links to maps for 19 species of land birds the Central Valley that includes the delta region, including California Bird SSC and California Partners in Fight (http://www.prbo.org/cms/258) focal species. For more information on modeling methods: see http://data.prbo.org/cadc/tools/lip/background.php.

5 Conservation Measures

Based on our review of information provided by the consultants, the advisors offer some recommendations about how conservation measures under consideration to benefit aquatic communities and species may affect terrestrial communities and species, along with some additional recommendations for conservation actions specific to the terrestrial resources. Our discussions focused primarily on the following pragmatic questions:

- What potential positive or negative effects might the proposed conservation measures (Attachment 3, Documents 4-8) have on non-aquatic species and communities? How can potential negative effects be avoided, minimized, or mitigated, and how can potential positive effects be enhanced?
- How can restoration of floodplain, intertidal marsh, channel margin, and riparian vegetation designed to benefit covered fish species be implemented or refined to also benefit non-aquatic species?
- Is establishing appropriate hydrologic conditions sufficient to provide for the natural establishment of native woody riparian vegetation ("passive restoration") or is more active restoration, such as planting trees and shrubs, necessary?
- Will native species and communities naturally shift ranges in response to changes in hydrological regimes (e.g., upslope shifting of intertidal plants) or colonize restored habitats, or is more active intervention necessary (e.g., transplantation or reintroduction)?
- What additional conservation actions should be considered to benefit covered non-aquatic species, beyond those conservation measures already being considered to benefit aquatic species?
- Are there specific locations in the planning area that are essential to sustaining populations of covered terrestrial species, or "hotspots" where numerous species coexist, and that therefore should be focal areas or avoidance areas for conservation measures?

Based on these discussions, we have organized recommendations for BDCP conservation measures into the following sections on conservation design principles, recommended analyses, locations of conservation concern, restoration recommendations, and species-specific conservation actions.

5.1 Conservation Design Principles

We recommend the following general principles be considered during the selection, design, and implementation of conservation measures:

- Plan conservation measures hierarchically, working from ecosystem to community to species-level considerations. Do not plan conservation measures for specific covered species or communities in isolation, without considering their relationships with other species and communities in the broader ecosystem.
- Design reserve or management areas to achieve mosaics of community types within areas large enough to support the most area-dependent covered (or planning) species and desired ecological services, and to accommodate future shifts due to climate change (e.g., sea-level rise, changing runoff patterns, shifting climate "envelopes").
- Strive for representation of all community types in habitat mosaics well distributed across the Delta, but considering site-specific conditions. Where possible, maintain or create "soft edges" or natural transitions along environmental gradients, as opposed to abrupt transitions or "hard edges" between community types.
- Bigger is better for habitat conservation and restoration sites, but don't ignore small areas that support rare communities or species. For example, small areas of seasonal wetlands, inland dunes, or alkali flats support disproportionate numbers of imperiled species.
- Seek to preserve and enhance natural heterogeneity in elevation, water depth, flooding frequency, nutrient conditions, vegetation types, and adjacency of different habitat types within and among the conserved, restored, or maintained habitat mosaics.[8]
- Enhance and preserve habitat connectivity where possible to maximize potential for natural range shifts, population expansions, escape from disturbance events (fires, floods), and maintenance of ecological processes, and to avoid isolating small populations of those species having limited dispersal abilities.
- Strive to create self-sustaining systems, but recognize that some communities and species may need active or perpetual management. For example, some invasive, nonnative species may require prolonged control efforts to sustain covered species or communities that they adversely affect.

5.2 Recommended Analyses

We recommend the following analyses be performed prior to finalizing the plan's conservation design, to assess likely effects of proposed covered activities and conservation measures on non-aquatic resources, and to inform how best to design and locate covered activities and conservation measures.

[8] A variety of observational studies demonstrate that species diversity is higher in heterogeneous habitats than in homogeneous habitats (Harman 1972; Abele 1974; Pollock et al. 1998; Williams et al. 2002).

- Do an overlay analysis for covered actions (e.g., facilities, conveyance alignments) and conservation measures (e.g., potential wetland restoration sites) with known and potential locations of covered species and communities. This should include an assessment of how changing hydrological regimes (water depth, flows, flooding, etc.) overlay onto existing ecological communities and species. Assess how the combination of changes will affect the conservation design principles discussed in section 5.1 (e.g., community representation, habitat patch size, environmental heterogeneity, natural gradients, maintenance of rare communities, and adjacency and connectivity of existing community types within mosaics). Pay particular attention to the potential for rare communities, such as seasonal wetlands and inland dune scrub, to be impacted. This should include consideration both of direct effects (e.g., flooding of rare upland habitats for wetland restoration) as well as potential indirect effects (e.g., constraining options for restoration efforts that could be carried out by other entities or under other plans).
- Assess for each covered species whether natural range shifts or colonization into restored habitat is likely to occur with changing conditions (e.g., hydrological and sea-level changes, restoration actions), or whether translocation/transplantation is required. For species not likely to shift naturally, prioritize avoidance of occupied areas and consider translocation/transplantation plans as part of the adaptive management program.
- Assess the distribution of “hard” vs. “soft” edges and determine where restoration actions can be used to soften edges. For example, determine where covered wetland or transitional plants are located at unnaturally sharp transitions to other physical conditions or habitat types that may constrain their ability to shift range over time in response to climate change and rising water levels. This analysis can inform where restoration actions could be prioritized to sustain ecological shifts due to water-level changes (including grading to create gradual elevation gradients and revegetation to create wetland-upland vegetation gradients).
- Use climate envelope models coupled with habitat models (Loarie et al. 2008, Hijmans and Graham 2006, Green et al. 2008) to identify potential effects on covered species over a 50-year horizon. This could inform where offsite conservation actions may be more effective in hedging against climate change for some covered species.

5.3 Locations of Special Concern

The advisors discussed whether there are certain geographic locations in the BDCP plan area that are of particular importance to at-risk species or communities, or to maintaining critical ecological processes. The following are a few key locations where impacts should be avoided or where additional conservation, restoration, and management may be beneficial. We realize that these locations and their importance are likely already well known to BDCP participants, but felt their importance was worthy of emphasis.

- **Staten Island** is a critical wintering area for sandhill cranes and other birds, due in large part to wildlife-friendly agricultural practices.
- **Franks Tract State Recreation Area**. In addition to its importance to aquatic resources, the marshes of Frank’s Tract are a hotspot of bird diversity and support a variety of rare and imperiled species, including California black rail, yellow warbler, yellow-breasted chat, and song sparrow.

- Occupied areas for riparian brush rabbits, including **Stewart Tract**, and near Lathrop. Occupied areas should be better defined by surveys currently underway by ESRP.
- **Antioch Dunes** represent a small remnant of a very rare ecological community that supports numerous endemic and imperiled species (see Sections 2 and 3). Remaining dunes have become isolated by urban development, limiting potential for restoring or expanding habitat.

5.4 Restoration Recommendations

- Recognize that restoration is a process, not a one-time action. We recommend following the restoration process designed by River Partners (Griggs 2008) for riparian and riverine restoration projects.
- Passive riparian restoration (just restoring semi-natural flooding regimes) is unlikely to be effective due to invasive weeds and insufficient colonization by dispersal-limited species. Some planting of woody vegetation, including both understory and overstory plants is recommended (Riparian Habitat Joint Venture 2004). Also, follow-up management to control invasives may be needed for up to 10 years post restoration to ensure success, and translocation may be necessary for some species.
- Given that water level changes will occur (due to conveyance changes, restoration efforts, and climate change), design and engineer plan facilities and structures in a manner that allows for control of water flows and depths to maintain diverse ecological conditions and particular species' needs. We recommend assigning a BDCP Work Group or Technical Team to evaluate the range of conditions desired to support the diverse requirements of covered species, communities, and processes in the plan area (terrestrial as well as aquatic). Recognize that optimizing how these metrics can best be manipulated to sustain covered species should be a focus of the systematic adaptive management and monitoring program.
- All else being equal, locate habitat restoration areas near existing habitat areas to expand or connect similar habitats, and to facilitate population expansions for covered species. For example, consult The Nature Conservancy's Cosumnes Watershed Plan and prioritize adjacent or nearby restoration sites. On the other hand, distributing restoration sites across the plan area will capture broader gradients in ecological conditions and may help spread the risk of restoration failures, maximize habitat diversity, and deal with uncertainties due to climate change and other dynamics.
- For floodplain restoration, consider leaving breached levees at least partially in place to provide physical habitat diversity and serve as refugia for species during floods ("bunny mounds"). Such physical features provide for habitat heterogeneity and increased bird diversity (Riparian Habitat Joint Venture 2004). However, it is important that old levees or other elevated areas be vegetated or revegetated with natural, local, plant palettes to provide escape cover during flood events as well as year-round habitat for diverse covered species.
- Also for floodplain and marsh restoration, meandering and dendritic channels are better than straight, undivided, and unbraided channels. Where floodplain areas are to be graded to create proper depths and drainage, consider leaving some permanent aquatic habitat (slightly deeper ponds or channels) to provide habitat for giant garter snakes, so long as these are configured to prevent fish stranding.

- Strive to create natural combinations of habitat types in mosaics that transition along physical gradients, rather than restoring single community types in isolation. For example, where tidal emergent marsh restoration is planned, also restore adjacent transitional and upland vegetation communities moving up the elevation gradient. This establishes the natural mosaic of habitat conditions required by many species, increases biological diversity and foodweb complexity for covered species (including fish), and will help accommodate ecological shifts due to changing climate and water levels.
- Use restoration to increase the rarest habitat types, if feasible. Seasonal wetlands (vernal pools) stand out as a rare habitat type that may be affected by project actions. Although vernal pool creation is controversial as a mitigation action, there may be opportunities for enhancing or restoring existing or former vernal pool areas in appropriate locations. If adverse impacts to vernal pools and associated species are unavoidable, offsite conservation of intact vernal pool systems may be preferable to attempting to create or restore vernal pools within the plan area. Inland dune scrub is also extremely rare. Although we do not anticipate direct negative plan effects on inland dune communities, BDCP actions have potential to create opportunities for restoring dune communities in some locations, perhaps to be implemented by other entities or plans.
- Use restoration to create "soft edges" between habitat types along ecological gradients. For example, many populations of potentially covered plant species occupy narrow bands of conditions along the elevation-tidal gradient, and many are currently up against "hard edges" (i.e., sharp transitions to other physical conditions or habitat types) due to dikes, levees, or other artificial features. This provides little or no opportunity for these populations to shift ranges with changing water levels or hydrological regimes. Where possible, restoration should be used to soften such edges via grading and/or revegetation to create opportunities for gradual range shifts and other adjustments to changing conditions.

5.5 Species-specific Conservation Actions

The advisors do not recommend relying on species-specific mitigation actions or structures (e.g., artificial burrows, nest boxes, nesting islands, "bunny mounds," created pools) as *primary* conservation tools. Conservation, maintenance, and restoration of intact habitat mosaics and ecological communities must be primary. However, the following specific mitigation actions should be considered as supplements to conservation and management of diverse habitats to enhance habitat value, particularly where covered species face specific life-requisite shortcomings despite habitat conservation and restoration:

- **Artificial burrows** are sometimes used by nesting burrowing owls, but have not been shown to increase owl populations in the long term. It is better to maintain natural burrow conditions and healthy prey populations (e.g., no ground squirrel control programs or insecticide use). Artificial burrows may be beneficial in certain situations where natural burrows are limiting as a supplemental mitigation measure.
- "**Bunny mounds**," or areas of ground elevated above the highest expected flood levels, are important in floodplain habitats to allow for escape by riparian brush rabbits and other species. These can be expensive to create from scratch, especially if fill has to be transported from other sites, but high mounds that are vegetated with brushy cover can contribute significantly to sustaining individuals and populations during floods, and create habitat

heterogeneity that also benefits diverse communities of birds and other taxa. Look for opportunities to get "free bunny mounds" such as, by leaving portions of the old levee as elevated ground when breaching levees for floodplain restoration. These should be revegetated with appropriate trees and shrubs, if necessary.

- **Nesting islands.** Creating or leaving some higher ground within subtidal and intertidal restoration areas can provide nesting islands for some shorebirds as part of an overall heterogeneity strategy.
- **Brown-headed cowbird trapping** (following guidelines of the North American Cowbird Advisory Council http://cowbird.lscf.ucsb.edu/) can benefit populations of songbirds that are adversely affected by nest parasitism by this species, such as least Bell's vireo and yellow warbler.
- **Contaminant control**, including control of herbicides, rodenticides, and light pollution may be an important management measure in conservation areas.
- **Vegetation management** on levees. We do not recommend burning, mowing, or herbicide use to control vegetation on levees.
- **Feral cat control** may be necessary in conservation areas or other areas important to covered species. Restrictions on maintaining feral or free-roaming cat populations should be enforced throughout the plan area.

Attachment A – Advisor Biographies

Dr. Peggy L. Fiedler, Senior Botanist & Co-Director, Ecosystem Science and Natural Resources Management Services, WSP Environment & Energy, LLC. Dr. Fiedler has 30 years of experience in field research and teaching in conservation biology, ecology and evolutionary biology, and waters/wetlands ecosystem restoration. Her current interests are focused on designing plant community types in mega-diverse floras for ecosystem restoration, applying population viability models and metapopulation theory to the reintroduction of rare plant species, understanding demographic patterns of rare plants (including hybrid taxa) and improving monitoring protocol in waters/wetland ecosystem restoration.

Geoffrey R. Geupel, Director, Terrestrial Ecology Division, PRBO Conservation Science, Petaluma, CA. Geoff has over 28 years of experience in ornithological monitoring and conservation research in California. Recent publications and presentations have helped define bird monitoring protocols now used throughout North America. He has taught numerous technical workshops on bird monitoring and currently oversees more than 20 projects that use bird data to evaluate conservation actions. Current areas of interest include breeding and population biology, demographic monitoring, bird response to habitat restoration and management, and developing measurable populations metrics for conservation planning. He is currently Co-chair of California Partners in Flight and is formally involved with five of the six habitat joint ventures in the state.

Dr. Marcel Holyoak, Professor, Environmental Science and Policy, University of California at Davis. Dr. Holyoak is broadly trained as a population and community ecologist, with interests in conservation, biostatistics, and theoretical ecology. Much of his recent work addresses the responses of individual species and ecological communities to habitat fragmentation. His research group has conducted most of the work on the federally threatened Valley Elderberry Longhorn Beetle that has been performed in the last decade. He has a PhD. from the University of London (Imperial College) in ecology and biostatistics from 1992, and a BSc. in biology from the same university in 1989. He is acting Editor-in-Chief of a top-ranked ecology journal, *Ecology Letters*, and will become the new editor for this journal in January 2009.

Dr. Patrick A. Kelly, **Coordinator and Director of Endangered Species Recovery Program (ESRP) and Professor of Zoology, California State University, Stanislaus**. Dr. Kelly's main research interests are in mammalian ecology and conservation, and his current research focuses on the conservation and recovery of endangered mammals in California, including the riparian brush rabbit and riparian woodrat. He joined ESRP as Assistant Director in July 1993 and became Director in January 1996. Pat received a B.Sc. from University College Galway, Ireland, in 1981, and a Ph.D. from the University of California, Berkeley, in 1990.

Dr. Wayne Spencer, Senior Conservation Biologist, Conservation Biology Institute, San Diego, CA. Dr. Spencer is a conservation biologist and wildlife ecologist with expertise in conservation planning and endangered species recovery. He has worked on various regional NCCPs and HCPs in California as a consulting biologist, science advisor, and science facilitator. His research focuses primarily on rare and endangered mammal species, including the Pacific fisher, Stephens' kangaroo rat, and Pacific pocket mouse. He is also a Research Associate with the San Diego Natural History Museum. He served as the Facilitator for this BDCP Non-aquatic resources workshop and report.

Dr. Glenn Wylie, **Research Wildlife Biologist, USGS Western Ecological Research Center, Dixon, CA**. Dr. Wylie is a wildlife biologist specializing in wetland ecology as is concerns migratory birds and listed species in California. In the last 10 years he has been researching the distribution, abundance, and ecological requirements of giant garter snakes. Dr. Wylie was a science advisor for the Recovery Team for giant garter snakes and has advised habitat conservation planning for the city of Sacramento. He is currently advising Solano County in developing a habitat recovery plan as well as participating in the Yuba/Sutter and Yolo County efforts in habitat conservation planning.

Bay-Delta Conservation Plan
Independent Science Advisors' Workshop
Concerning Non-aquatic Resources

30 September 2008

Hawthorn Suites Hotel, Crocker Room
321 Bercut Road, Sacramento. 916-441-1200
(Exit Richards Blvd East off of I-5, take first left at Bercut)

0900 – 1030 Orientation Session (Science Advisors and Consultant Team)

0900 – 0915	Welcome, introductions, and logistics
0915 – 0930	Overview of science advisory process and workshop goals (Wayne Spencer)
0930 – 1000	Overview of BDCP conservation approach and issues (Pete Rawlings, John Gerlach, and Jim Estep)
1000 – 1030	Q & A session and open discussion
1030 – 1045	Break

1045 – 1600 Advisors Only Session

1045 – 1130	Review of proposed covered species list and process
1130 – 1200	Review of existing conditions documents (Existing Ecological Conditions, stressors summaries, species accounts, distribution maps, habitat measures)
1200 – 1300	Working lunch (provided) – continued discussion of existing conditions documents and maps
1300 – 1400	Principles for addressing data gaps and uncertainties
1400 – 1500	Principles for conservation, restoration, and management of species, communities, and ecological processes
1500 – 1515	Break
1515 – 1600	Outline report and writing assignments
1600	Adjourn

Attachment C – Documents Reviewed By Advisors

Advisors reviewed the following documents in preparing this report. All documents (accept Document 1, BDCP Planning Agreement) are unpublished Draft reports, memoranda, chapters, or handouts prepared by SAIC.

1. October 6, 2006. Planning Agreement regarding the Bay Delta Conservation Plan.
2. March 7, 2008. Draft existing ecological conditions chapter and covered species accounts (on CD).
3. May 22, 2008. Proposed covered species selection process and potential species for coverage under BDCP.
4. September 5, 2008. Steering Committee Handout 1. Summary table: Other Stressors Working Group recommended conservation measures for consideration by the BDCP Steering Committee.
5. September 5, 2008. Steering Committee Handout 2. Other Stressors Working Group recommended conservation measures for consideration by the BDCP Steering Committee.
6. September 5, 2008. Steering Committee Handout 3. Summary table: Draft other stressors conservation measures by working biological objectives.
7. September 19, 2008. Steering Committee Handout 1. Restoration Program Technical Team recommended conservation measures for consideration by the BDCP Steering Committee.
8. September 19, 2008. Steering Committee Handout 2. Summary table: Draft habitat restoration conservation measures by working biological objective.
9. September 19, 2008. Draft plant species accounts and associated distribution maps for the following species:
    - Alkali milk-vetch
    - Delta button celery
    - Delta mudwort
    - Delta tule pea
    - Heckard’s peppergrass
    - Legenere
    - Mason’s lilaeopsis
    - San Joaquin spearscale
    - Soft bird’s beak
    - Suisun Marsh aster
10. September 19, 2008 Draft animal species accounts and associated distribution maps for the following species:
    - California black rail
    - California clapper rail
    - Conservancy fairy shrimp
    - Giant garter snake
    - Greater sandhill crane

- Longhorn fairy shrimp
- Riparian brush rabbit
- Salt marsh harvest mouse
- Suisun shrew
- Swainson's hawk
- Tri-colored blackbird
- Valley elderberry longhorn beetle
- Vernal pool fairy shrimp
- Vernal pool tadpole shrimp
- Western burrowing owl
- Western spadefoot toad
- Yellow-breasted chat

11. September 30, 2008. Poster-sized maps and PDFs of the following plan maps:

- BDCP natural communities
- Elevation-based restoration suitability categories
- Aerial imagery of the planning area
- DWR agricultural classes
- BDCP conveyance route options

Appendix D --Examples of Recommended Adaptive Management Framework Applied to Two Proposed Conservation Measures

Executive Summary

This report summarizes recommendations from a group of independent scientists (Advisors; Appendix A) convened in December 2008 (Appendix B) concerning incorporation of adaptive management into the Bay Delta Conservation Plan (BDCP). The report includes a general review of pertinent BDCP documents and a recommended framework for incorporating adaptive management into the planning, design, and implementation of the BDCP.

Comments on BDCP Documents

It is clear from documents reviewed by Advisors (Appendix C) that efforts to develop an Adaptive Management Program (AMP) for BDCP are in their early stages. The documents show progress toward defining the elements of an AMP but lack several elements essential to effective adaptive management. The incomplete state of the documents made it difficult to evaluate the plan's scientific foundations, and many statements in the documents suggest a need to more fully assimilate and apply existing knowledge about the Delta to the development of conservation measures and the AMP.

The Advisors offer the following general comments and recommendations:

Existing Knowledge and Peer Review - Far more is known about the Bay-Delta ecosystem than is suggested by the BDCP documents we reviewed. The extensive knowledge base about the Delta should be fully exploited in selecting and designing BDCP actions. The omission of critical knowledge about the functioning of the Bay-Delta ecosystem also indicates the need for more development of the conservation plan itself. **We strongly recommend that technical documents that form the basis of the BDCP be reviewed by independent technical experts to ensure the credibility of the program and a sound foundation for conservation actions.**

Goals and Objectives - We agree that goals and objectives should be placed within a hierarchy of ecosystems, communities, and species. However, most objectives stated in the documents, and the conservation measures meant to address them, apply only to the species level. **We recommend developing explicit community and ecosystem objectives to reflect the hierarchical approach described in BDCP documents.**

Modeling - Models are extremely valuable for formalizing the link between objectives and proposed conservation measures to clarify how and why each conservation measure is expected to contribute to objectives. This key element of adaptive management is largely missing from BDCP documents we reviewed. **We recommend more extensive and explicit use of models to formalize knowledge about the system and to select, design, and predict outcomes of conservation measures to be implemented and monitored.**

Feedback – Formal processes for devising actions to maximize learning, and for assimilating new knowledge to provide the feedback that is key to adaptive management, were not discussed in the documents. **We recommend that greater attention be given to the learning value of actions, and to establishing a formal process by which new knowledge is used to alter actions or revise goals or objectives.**

Integration - The documents reviewed by the Advisors did not link the various conservation measures together as a package, and there was little sense of synergy or potential conflict among these clearly related actions. **We recommend the development of models to show clearly how various actions relate and how interactions will be integrated across multiple conservation measures and the entire adaptive management process.**

Guidance for a Robust Adaptive Management Program

Effective adaptive management includes several key steps, some of which are not included in the documents we reviewed. Adaptive management does far more than simply adjust actions as new information becomes available (which is merely common sense). It is a more comprehensive process of deciding how to choose initial actions in the face of uncertainty and systematically learning and evaluating how the manipulated system responds to those activities so that changes can be made as events unfold. Key missing elements of adaptive management in BDCP documents include (1) the formal setting of goals *based on problems to be addressed*, (2) the establishment of objectives (as distinct from goals), and (3) the use of conceptual or simulation models to bring the knowledge base to bear on the problems to be solved and predict outcomes of conservation actions. In addition, (4) monitoring must be more clearly and formally designed to establish criteria to evaluate effectiveness, and (5) monitoring results must be analyzed and assimilated to provide the information necessary for the feedback critical to adaptive management. Most critical are the succeeding steps (6) of capturing and interpreting information from monitoring and other sources to evaluate how the actions are working, what they are accomplishing, and how the knowledge base is changing. These critical steps require substantial investment in time, people, and resources.

We suggest that particular attention be paid to the following:

The Adaptive Management Approach - The form of adaptive management to apply (active vs. passive)[1] to a given conservation measure depends on the scope of the measure and its degree of reversibility. In the design phase, it is important to recognize where an adaptive management strategy resides on the active-to-passive spectrum.

Knowledge Base - The knowledge base comprises the scientific understanding of a system; it should be used to identify likely influences of conservation measures on the ecosystem and the degree of confidence in those influences. It provides the context for establishing goals and objectives, the information base for models, and the foundation for selecting, designing, and monitoring conservation measures.

Assessment and Synthesis - Assessment is critical to making monitoring useful. In the adaptive management framework, monitoring provides a quantitative basis for analysis, synthesis, and evaluation of knowledge to support management decisions.

[1] Active adaptive management is experimental, involving manipulations intended to achieve conservation goals but also to improve knowledge. Passive adaptive management is not experimental, but is nevertheless approached from a scientific perspective to improve knowledge and adapt strategies during project implementation.

Continual Assimilation of Knowledge and Decision Making - The weakest aspect of most adaptive management plans is in the sequence of steps required to link the knowledge gained from implementation and other sources to decisions about whether to continue, modify, or stop actions, refine objectives, or alter monitoring. This step must be much more fully developed than was evident in the BDCP documents we reviewed. Responsibility for this step should be assigned to a highly skilled agent (person, team, office) having the right mix of policy and technical expertise. This investment is critical to making adaptive management effectively support the BDCP.

1 Introduction

This report presents recommendations from a multidisciplinary group of independent science advisors concerning the use of adaptive management in the development and implementation of the Bay Delta Conservation Plan (BDCP). The advice and recommendations are intended not to question or promote particular plan goals or policies, but to provide guidance for incorporating adaptive management into the BDCP.

The group of nine advisors (Appendix A) was convened by the BDCP Steering Committee at a facilitated workshop held on December 17-19, 2008 (Appendix B). Prior to the workshop, advisors were provided with several draft BDCP documents for review (Appendix C). Comments in this report are based on the documents we reviewed and brief discussions with representatives of the BDCP planning team, who presented overviews of the emerging plan and important unresolved issues during two open sessions at the workshop.

Because the draft documents provided to us were in an early stage of development and did not describe a comprehensive Adaptive Management Program (AMP), we did not evaluate them in detail as a finished plan. Rather, we focused our effort on providing guidance for structuring an AMP for the BDCP that would support effective application of existing and evolving scientific understanding to BDCP decisions both before and during its implementation.

Section 2 articulates eight principles that we suggest be used as a foundation for the BDCP AMP. Section 3 incorporates these fundamental principles into an adaptive management framework tailored specifically to the BDCP and describes key elements of that framework. Appendix D provides two detailed examples of how draft BDCP conservation measures could be revised to better reflect the suggested framework.

2 Principles for Adaptive Management

The following principles for effective adaptive management emerged from our deliberations and are integral to our proposed adaptive management framework (see Section 3):

1. The scope and degree of reversibility of each proposed action (i.e., conservation measure) determines the form of adaptive management that can be applied (e.g., “active” or experimental adaptive management versus “passive” adaptive management).
2. The knowledge base about the ecosystem is key to decisions about what to do and what to monitor, and includes all relevant information, not just that derived from monitoring and analysis within the context of BDCP.
3. Program goals should relate directly to the problems being addressed and provide the intent behind the conservation measures; objectives should correspond to measurable, predicted outcomes.

4. Models should be used to formalize the knowledge base, develop expectations of future conditions and conservation outcomes that can be tested by monitoring and analysis, assess the likelihood of various outcomes, and identify tradeoffs among conservation measures.
5. Monitoring should be targeted at specific mechanisms thought to underlie the conservation measures, and must be integrated with an explicitly funded program for assessing the resulting data.
6. Prioritization and sequencing of conservation measures should be assessed at multiple steps in the adaptive management cycle.
7. Specifically targeted institutional arrangements are required to establish effective feedback mechanisms to inform decisions about whether to retain, modify, or replace conservation measures.
8. A dedicated, highly skilled agent (person, team, office) is essential to assimilate knowledge from monitoring and technical studies and make recommendations to senior decision makers regarding programmatic changes.

In the following section we expand on these principles and provide details of the proposed adaptive management framework.

3 Framework for Adaptive Management

Figure 1 presents a framework for incorporating adaptive management into the planning, design, and implementation of the BDCP. The framework is based on previously developed adaptive management frameworks, but has been refined to make key aspects of the process more explicit and to tailor the approach to the needs of the BDCP. The framework is specifically intended to improve the approach described in the draft BDCP documents and to avoid shortcomings of many previous AMPs. **We recommend adopting this refined framework to guide BDCP planning and implementation.**

In the following sections we detail elements of this adaptive management framework, while expanding on the principles presented in Section 2. Appendix D provides two detailed examples of how elements of the proposed BDCP Conservation Measures might correspond to the elements of the diagram and be guided by the proposed framework and principles.

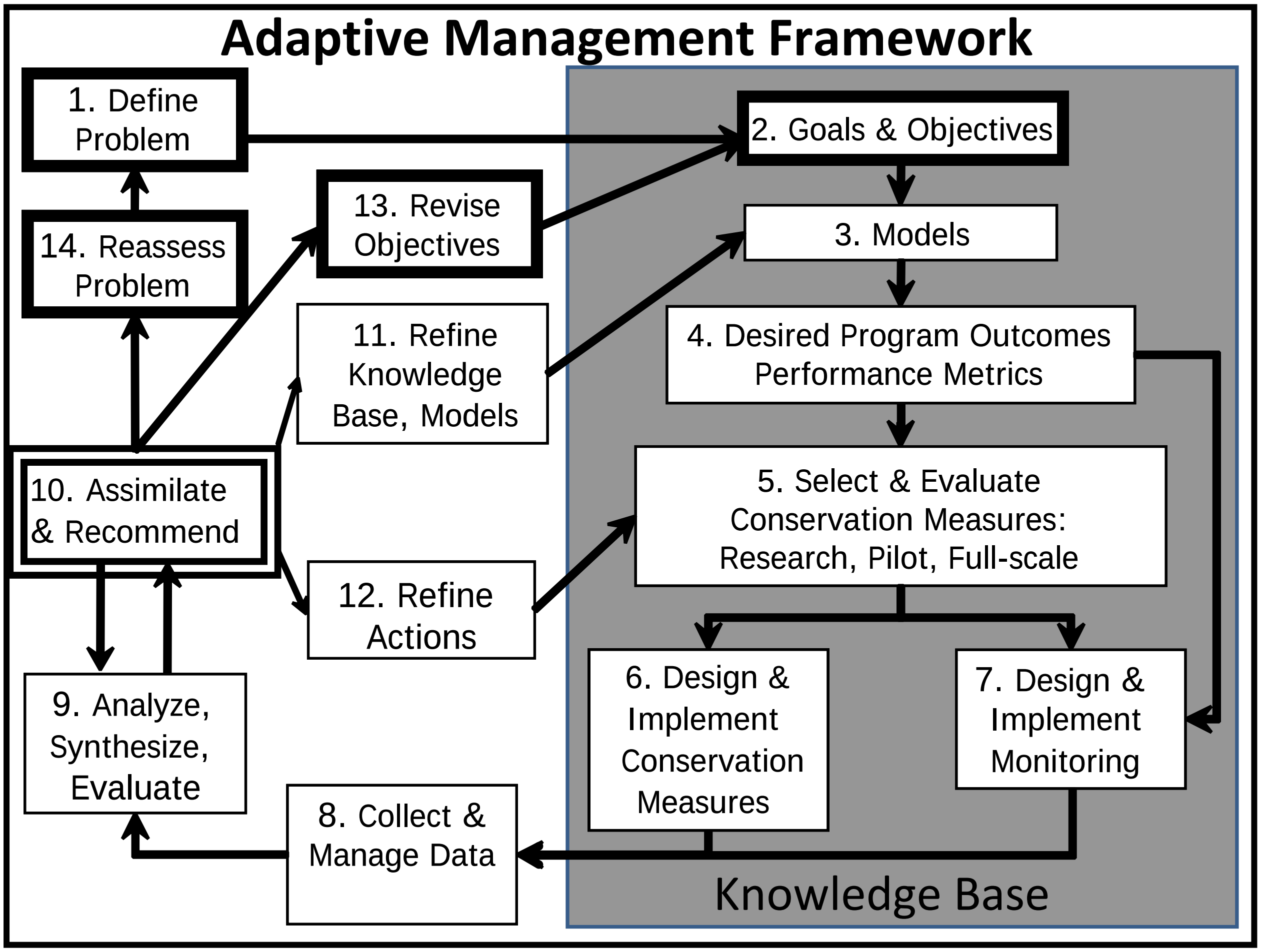

Figure 1. *A recommended AMP framework for BDCP showing the flow of information and responsibilities of different entities.* The large shaded box underlying the right side of the figure represents the knowledge base for defining goals and objectives, designing predictive models, predicting outcomes, identifying performance metrics, and designing and implementing conservation measures and monitoring actions. Boxes framed with thin lines represent tasks performed by technical staff, such as scientists, land and water managers, and other analysts. Boxes framed with bold lines represent tasks performed by senior decision makers (i.e. policy makers and program managers who control program objectives and funding). The box framed with double lines (Box 10) represents a key step that is missing from most AMPs: Assimilate and Recommend. This task requires a body of skillful "polymaths" who understand both the technical and policy implications of the information passed along by technical staff (who analyze, synthesize, and evaluate monitoring and other data; Boxes 8 and 9). The task represented by Box 10 is to assimilate this diverse information, understand its consequences, and formulate recommendations to both the senior decision makers and the technical staff, such as revising plan objectives or conservation measures.

3.1 Form of Adaptive Management (Principle 1)

The literature on adaptive management defines two broad categories: active and passive. Active adaptive management is experimental, involving manipulations intended to achieve conservation goals but also to improve knowledge. Passive adaptive management refers to actions that are not experimental, but that are nevertheless approached from a scientific perspective in order to improve knowledge and adapt strategies during project implementation.

The form of adaptive management applied to a given conservation measure depends on the scope of the measure and its degree of reversibility. At one extreme, there is only one Delta, ruling out simultaneous replication of actions that broadly affect the system. In addition, some conservation measures, such as major investment in an around-Delta conveyance, are unlikely to be reversed, so temporal replication is also impossible. In such circumstances, monitoring of processes and of system responses to natural and managed events form the basis for learning, as is the case in various non-experimental sciences. At the other extreme, there are many opportunities for experimental manipulation to achieve goals while simultaneously learning. For example, gates on Delta tidal channels could be operated on a schedule intended to produce contrasts with predictable and testable consequences. It is crucial to recognize that passive adaptive management differs from active only in the use of experimental manipulations and the consequently greater power to detect the influence of the manipulations. Otherwise, these two forms of adaptive management proceed according to identical principles and processes, as outlined in Figure 1. Note also that research aimed at particular sources of uncertainty can be part of an adaptive management program (Box 5 in Figure 1).

3.2 Applying the Knowledge Base (Principle 2)

The knowledge base (large gray box in Figure 1) is key to decisions about what conservation measures might be implemented and what responses to monitor. It forms the foundation for all steps from formulation of goals and objectives (Box 2) to the selection, design, and implementation of conservation measures and monitoring (Boxes 6 and 7). The knowledge base comprises the scientific understanding of the system and is used to identify likely influences of conservation measures on the ecosystem. It also includes knowledge of the feasibility, costs, and probable external implications of projects for the broader society and economy of the region. The knowledge base provides the context for establishing goals and objectives, the source of information for models used to project conservation outcomes, and the basis for believing that an action will have a certain outcome. The knowledge base is continually updated as new information becomes available and as adaptive management proceeds.

Far more is known about the Bay-Delta ecosystem than is suggested by BDCP documents we reviewed, which strongly emphasized (1) uncertainties about the system, (2) a central role for hypothesis testing, and (3) the role of monitoring data in reducing uncertainties. We certainly do not discount the importance of these issues, but point out that the extensive knowledge base about the Delta and the planning context should be fully exploited in selecting and designing BDCP actions. Enough is known about the Bay-Delta ecosystem, or can be inferred from studies of other systems, to conclude that:

1. Certain outcomes can be predicted with confidence[2].
2. Most scientific knowledge about the Delta has been derived by approaches other than hypothesis testing (e.g., analysis of monitoring data, modeling, and parameter estimation).
3. Not all pertinent knowledge comes from regular monitoring; knowledge may also stem from short, targeted field campaigns and observations in single natural events that cannot be replicated.
4. Monitoring adds no knowledge without a dedicated process for data management and analysis.

A thorough understanding of the knowledge base is essential for modeling, monitoring, and other actions to be efficiently focused on reducing key uncertainties.

For this plan to incorporate "best available scientific information" requires that the components of the overall knowledge base used for each step in the process be synthesized and referenced. The information in the knowledge base should be used according to a hierarchy that emphasizes peer-reviewed science and other formal evaluations. Published papers should be given the greatest weight (especially highly influential or often-cited, and therefore highly scrutinized and replicated papers), followed by unpublished papers, technical reports, newsletter articles, and presentations or personal communications from experts. Review or summary articles can be used in lieu of extensive lists of publications. Personal communications should be cited with the name and affiliation of the person and the date of the communication. Local knowledge of experts or stakeholders is also an important component of the knowledge base, even if not published, but such knowledge should be recorded explicitly so that it can be reviewed.

Although peer review is the gold standard of scientific publication, it may not always provide assurances as to the quality of the data or the accuracy of statistical analyses, since reviewers rarely have time to replicate reported analyses or examine raw data. Therefore studies used as a basis for significant decisions should be thoroughly checked and analyses replicated if possible.

Data used in analyses must have undergone a quality assurance check. Generally this is done routinely for widely-used data, such as daily flows, salinity, and fish abundance indices. Documents using the knowledge base should promote transparency by explaining clearly what we know and how we know it, with full citations to the sources of information (e.g., papers, data sets, websites, personal communications with affiliation) and ensuring that these are readily available (e.g., posting technical reports on websites).

The incomplete state of the draft BDCP documents we reviewed made evaluation of scientific content of the plan difficult. However, many statements in these documents suggest an incomplete knowledge of the Delta among the project team. For example:

- Literature citations were sometimes inaccurate (e.g., Handout #5 lines 41-45: "highly productive" and similar statements are not true and not stated in the reference).

---

[2] For example, field studies in the California Bay-Delta and elsewhere indicate that restoring intertidal marsh will increase carbon input to estuarine food webs for well-understood biogeochemical reasons, although monitoring and research would be essential to show the magnitude of this input and its long-term fate.

- Inappropriate citations were used (e.g., the use of Kimmerer 2004 to support a statement about tidal marshes and sea-level rise on page 2-43 of the March 2008 Draft Existing Ecological Conditions Chapter and Covered Species Accounts).
- Often the most recent published findings were not used (e.g., Feyrer et al., 2007).
- Unpublished data and presentations appear to be given equal weight to published findings (e.g., Handout #5 page 28 line 33).
- Several statements fail to reflect the current state of knowledge or provide little substantive foundation, for example, in handout #4 page 14:
  - Lines 41-42: "These zooplankton can reduce phytoplankton to very low concentrations, resulting in a clear water state" is poorly supported by the citations provided. In fact, published work indicates that phytoplankton biomass in the Delta is rarely if ever limited by zooplankton (Kimmerer 2004).
  - Line 35: "Additionally, the statistical analyses used in this paper may be questionable" should be amplified and supported by reference to specific work.

Note that these and several other examples in Appendix D are presented only to illustrate a broad and pervasive problem identified by the Advisors in the documents that were provided. **We recommend that the technical documents that form the basis of the BDCP plan and conservation actions be reviewed by independent technical experts to ensure the credibility of the program and a sound foundation for conservation actions.**

3.3 Problem Statement Leads to Goals and Objectives (Principle 3)

A clear problem statement should link directly to program goals, which in turn are linked to specific objectives. The BDCP documents we reviewed generally failed to distinguish among these elements. The CALFED Ecosystem Restoration Program (ERP) Strategic Plan defines goals and objectives for ecosystem restoration, which BDCP planners might find helpful.

The problem statement specifies the issue or concern that proposed conservation measures are intended to solve or mitigate. If the problem is not stated clearly, the linkages to everything else in the adaptive management framework will be weak or inconsistent, compromising the entire approach.

Goals are broad, general intentions or visions for some aspect of the system. Goals propose broad solutions and encapsulate desired future conditions. For example, a central problem statement for BDCP is that some native fishes are in danger of extinction. One goal therefore is to restore the abundance of those species (ERP Goal 1). However, declines in each species may be linked to broader, systemic problems. Therefore, additional goals call for rehabilitation of natural processes (Goal 2) and habitats (Goal 4), and reductions in the rate of introduction of new species (Goal 5) and in contaminant effects (Goal 6). The last two goals are included regardless of whether a quantitative link can be made to the abundance of a particular species, because it is widely believed that accomplishing these goals is highly likely to favor several species and other societal preferences.

Objectives are specific, often quantitative, statements of outcomes that reflect the goals that the program is expected to achieve. Some objectives can be stated as quantitative targets for species or locations in a hierarchical arrangement (see Figure 4-2 of the CALFED ERP Strategic Plan). However, given uncertainties, it is not yet possible to develop quantitative conservation objectives for many species, communities, or processes, so many objectives must be stated in qualitative form. Nevertheless, as information accumulates, objectives can be refined and made progressively more quantitative. This step need not always await monitoring data, because predictive models applied within the context of the knowledge base can also assist in developing quantitative objectives (Box 3 in Figure 1).

Note that objectives for different species or communities may conflict or require tradeoffs (for example, altering flows to benefit one species may harm another). Such conflicts should not preclude development of objectives for each species or community. Rather, it would be beneficial to explicitly articulate such competing objectives and thereby highlight tradeoffs implicit in planning and management decisions.

We strongly recommend that the problem, goals and objectives, and the linkages among them, be clearly articulated steps in the process. The Advisors agreed with the approach of placing goals and objectives within the hierarchical scaling framework of ecosystems, communities, and species that was included in the draft BDCP Goals and Objectives documents. Careful consideration of program objectives within this context may help identify possible undesirable interactions and minimize conflicts among objectives that might occur if developed independently at the species level. In fact, most examples of objectives in the draft BDCP documents address individual species, with less attention to community and ecosystem level objectives. Thus, they fail to address the array of potential conflicts among objectives. Although the advisors encourage the continued inclusion of these species-specific objectives in the plan, **we recommend development of explicit community and ecosystem objectives to reflect the hierarchical approach described in the BDCP documents.**

3.4 Use of Models (Principle 4)

Models (Box 3) are used to formalize and apply the knowledge base, develop expectations, assess the likelihood of success, and identify tradeoffs. In particular, models should be used to formalize the link between objectives and proposed conservation measures to make clear how and why each conservation measure is expected to contribute to objectives. This key element of adaptive management is missing from the BDCP documents we reviewed, except for mention of hydrodynamic and particle tracking models. The use of models would make more explicit the relative potential benefits of different conservation measures and how they may interact (conflicts, tradeoffs, or synergies). Our impression on reviewing the BDCP documents is that this formal analytical step was skipped in jumping directly from objectives to potential conservation measures.

The types of models used in adaptive management should include at least conceptual, statistical, and process models. Conceptual models are used to make clear the expected links between actions and outcomes, the roles of other factors, the degree of confidence in the outcomes, and potential tradeoffs (e.g., among species or alternative conservation measures). The roles of conceptual models are described in Chapter 3 and Appendix B of the ERP Strategic Plan and the uses of conceptual diagrams (as components of conceptual models) are explained at http://ian.umces.edu/pdfs/stc_2008_conceptualdiagrams.pdf. A formalized approach to the development of conceptual models has been developed under the auspices of the Delta Regional Ecosystem Restoration Implementation Plan (DRERIP) and should be used to guide the development of any additional conceptual models needed for the BDCP. Statistical models may allow us to characterize empirically how a system works. However, statistical models may not allow us to predict all system responses, because they apply only within the range of conditions over which data have been collected.

Process models rooted in underlying mechanisms provide a much stronger basis for predicting system responses to environmental change (i.e., extrapolating beyond available data), although model calibration and validation of process models are more challenging than for statistical models[3]. Process models should be used increasingly as the knowledge base becomes more diversified and complex. Process models (e.g., population models, particle tracking models) express the mechanisms responsible for the relationships in conceptual models as mathematical equations and can incorporate uncertainty and system variability. Process models are especially useful in analyzing complex actions and developing plans for irreversible changes to the system (e.g., an around-delta conveyance). Given the expense and potential for unforeseen consequences of large-scale permanent changes to the system, process model simulations offer a relatively inexpensive way of anticipating problems and developing operational criteria or other design elements to minimize problems.

Process models also provide a powerful tool for refining reversible actions. For example, BDCP action FLOO1.1 (Yolo Bypass) includes a reference to varying operations to "adaptively manage" floodplain conditions and extensive monitoring to track changes. Such post-hoc monitoring will likely have low power to detect effects given background variability. Enough is known about this system to develop process models to forecast the magnitude of effects of these manipulations and maximize the value of the manipulation and the monitoring. Modeling will allow calculations of the monitoring effort needed to detect effects and comparisons between expectations and observations during the manipulations.

3.5 Desired Program Outcomes and Performance Metrics (Principle 5)

A key component of our proposed adaptive management framework is definition of measurable outcomes and associated performance metrics (Box 4 in Figure 1) that are directly related to the programmatic objectives via models (Box 3 and Section 3.4). These measurable outcomes and performance metrics are critical for several reasons. First, they document desires and expectations about how the system could function in the future following implementation of conservation measures. Second, they are used to track progress toward meeting the objectives. Third, they help define the monitoring essential to the evaluation of any chosen conservation measure. Measurable outcomes can be predicted using models (see Section 3.4). Each outcome should have at least one associated performance metric, a target for successful achievement of

[3] See BDCP Independent Science Advisors Report, November 2007 for a more detailed description of the potential application of statistical and process models to BDCP issues.

that outcome, a monitoring program designed to identify progress toward that target, and decision points for amending actions if acceptable progress is not being made.

3.6 Select and Evaluate Conservation Measures (Principles 2 and 4)

The specific actions to be taken as part of an adaptive management program (i.e., conservation measures) should be selected and evaluated based on a comprehensive and formal application of the knowledge base and models, with full consideration of possible interactions among the actions. At this step in the process (Box 5) critical decisions are made about which conservation measures to implement, as well as whether each measure is to be implemented as a full-scale action, as a pilot study, or as a research program. This decision regarding the nature or level of each action depends on each action's physical and temporal scale, the degree of confidence in its benefits, and the consequences of being wrong:

- A full-scale action is taken to solve a large-scale problem when (1) the action is considered highly likely to achieve or contribute to one or more key objectives, (2) the benefits are believed to outweigh potential detriments, and (3) there is little additional benefit to performing pilot studies or research before implementing the action.
- A pilot action is taken if there is good reason to think that the action will have an effect, but there are uncertainties that can be resolved only through manipulation of the ecosystem.
- Research is considered a conservation measure if it is directed at resolving specific issues key to implementation of the Plan.

The DRERIP scientific evaluation process initiated by the ERP Science Board includes an approach for evaluating conservation measures using conceptual models. Where available, process models may be more suitable for this task.

It is also important to consider the interactions among various conservation measures. The documents reviewed by the Advisors did not clearly link the various conservation measures together as a package, and there was little sense of synergy or potential conflict among the actions. Yet, many of the actions are clearly linked or represent different aspects of the same manipulation. For example, design of an around-Delta conveyance would perforce include operational requirements on inflows and outflows, cross-channel gate operations, south Delta flows, X2, and other flow-related aspects of the system. Thus, most if not all of the conservation measures would be influenced by, or result from, the new operational criteria. Likewise, changes in outflow (WAOP9) are acknowledged as the principal cause of changes in salinity in Suisun Bay and the western Delta (WAOP10), yet they are presented as if they were separate. It is confusing and inaccurate to present these conservation measures as independent actions. This also results in excessive repetition and impedes comprehension of the documents.

3.7 Prioritization and Sequencing of Conservation Measures (Principle 6)

As part of developing goals, objectives, and outcomes, attention should be given to determining the priority and sequencing of conservation measures. *Priority* indicates the relative importance or urgency of a conservation measure, while *sequencing* indicates the order in which the measures are implemented. It is unlikely that funds and other resources necessary for implementing all conservation measures will be immediately available when the plan is finalized and implementation begins. Even though priority and sequencing may be determined by financial or political considerations, the decision-makers should be provided with an assessment of the consequences of their choices that has been developed using the knowledge base.

Prioritization should involve the allocation of conservation measures to categories (e.g., High, Medium, or Low Priority) rather than ranking all measures relative to one another. This categorization should be based on consensus criteria that consider the scale and breadth of the expected outcomes relative to the objectives. For example, measures contributing to more than one objective should generally receive a higher priority ranking than those contributing to only one. In addition, measures *essential* to achieving an objective should receive a higher priority than measures that may further an objective but are not essential.

Sequencing criteria could include (1) ease of implementation, (2) interdependence of measures, (3) feasibility of near-term implementation, (4) availability of funding, (5) uncertainty of measure implementation and outcomes, and (6) the potential for synergies among measures.

3.8 Design and Implement Conservation Measures and Monitoring (Principles 5 and 6)

Once conservation measures have been evaluated and selected (Box 5) they must be designed, analyzed, implemented, and constructed (Box 6). By "design" we mean to clearly describe the actions to be undertaken, including exactly what will be done, where, on what schedule, how, by whom, with what anticipated results, and with what accompanying monitoring actions. In cases where the measure is being implemented as part of an adaptive management experiment, the design need not adhere to formalisms of strict experimental design. It should focus on achieving the desired conservation outcomes but should also consider how monitoring will be conducted and how data will be managed and analyzed to assess the relative performance of the experimental units. The design should carefully consider the pertinent knowledge base, including results of any relevant research, pilot studies, or full-scale studies performed in the previous step (Box 5).

The monitoring plan for a conservation measure is designed and implemented in parallel with the conservation measure itself (Boxes 6 and 7) to generate data useful in comparing system performance to expected outcomes. The National Research Council (1990) defines three classes or purposes of monitoring: *compliance, model verification,* and *trend*. Building on this concept, the Advisors identified four types of monitoring that seem appropriate within our proposed adaptive management framework:

1. *Compliance* monitoring is built into permit requirements and focuses on whether the conservation measures are being implemented as planned.
2. *Performance* monitoring identifies whether individual conservation measures are achieving their expected outcomes or targets.
3. *Mechanistic* monitoring demonstrates whether the mechanisms thought to link conservation measures to desired outcomes are working as predicted.

4. *System-level* monitoring is used to identify the degree of success of the entire program (i.e., the cumulative effects of numerous conservation measures) relative to ultimate desired outcomes as described in the BDCP documents. This requires a sustained, long-term commitment to monitoring of critical features of the whole system, rather than the response of a single measure in the vicinity of a single locality.

Current monitoring practice is usually limited to compliance and system-level monitoring, with some performance monitoring. However, the outcomes of most conservation measures are likely to be influenced by external factors that are uncontrolled or unobserved. Mechanistic monitoring is therefore essential to understand whether changes at the system level are a result of one or more conservation measures or are due to external factors beyond the control of BDCP. Thus, mechanistic monitoring is crucial to adaptive management because it allows effects of the conservation measures, acting through the proposed mechanisms, to be distinguished from other effects.

Table 3X[4] lists a series of hypotheses associated with each conservation measure and monitoring target. Framing the monitoring targets as hypotheses makes clear the links to mechanistic monitoring. In order to be useful, however, scientific hypotheses should be stated in ways that allow them to be tested. For example, the first hypothesis in the table, "Increase production of organic carbon in support of food production within the Delta" is not stated as a hypothesis, and contains two concepts that should be separate if they are to be tested. This could be restated as: (1) The production of labile organic carbon will increase during the additional periods of flooding; and (2) The production of zooplankton (i.e., food for fish) in the estuarine foodweb will increase during periods of flooding. Note that some hypotheses lend themselves to formal tests, whereas others are more suited to parameter estimates (e.g., in the above example, the quantitative increases in carbon production and zooplankton production). Also note that hypotheses may not apply to all monitoring targets, particularly compliance and system-level monitoring.

Much of the trend monitoring and some of the other types of monitoring for aquatic species are already being conducted by the Interagency Ecological Program (IEP) and other agencies. BDCP should capitalize on these ongoing efforts to the fullest extent possible. However, these other monitoring programs may be altered or discontinued by the controlling agency; therefore, BDCP should coordinate with those agencies to ensure continuity of monitoring required specifically for evaluating the performance of the BDCP.

3.9 Collect, Manage, Analyze, Synthesize, and Evaluate Data (Principle 7)

Assessment is crucial to making monitoring useful. Much of the current monitoring in the Bay-Delta produces data that are under-analyzed and therefore under-used. The purpose of monitoring in the adaptive management framework is to provide a quantitative basis for analysis, synthesis, and evaluation. These activities are essential steps in the feedback to management decisions that are hallmarks of adaptive management.

[4] This was a draft summary table titled “Conservation Measure Effectiveness Monitoring and Potential Adaptive Management Responses” provided to advisors in December 2008.

Monitoring data must be made readily available online as soon as quality-control analyses have been completed. This has not always been the case with Bay-Delta monitoring programs, but it is essential for ease of access and transparency. Data management is also critical to allow analyses, synthesis, and evaluation. Data management must include the metadata required to identify how the data were collected, the methods used, any calculations employed, time and date, and site locations and characteristics. Effective data management is designed before data collection begins and is integral in the budgeting of successful monitoring frameworks.

Figure 1 highlights the expectation that the consequences of any conservation measure will be monitored and assessed to improve understanding of whether and how the measure is having the desired effects. No data should be collected under BDCP without a specific plan for analysis and synthesis by a particular person or group, with an adequate budget expressly allocated for data analysis and synthesis. This budget should be at least 10% of the cost of the monitoring, based on the Advisors' collective experience. The synthesis should provide answers to the questions implicit in the design of performance metrics: how have things changed, have they changed in expected ways, and what might have caused deviations from the expected trajectory? Note that expectations, generated by conceptual or simulation models, are essential to this effort. Although expectations often will not be met, they provide a basis for evaluating the data and trends. The results of these analyses should be published in technical, peer-reviewed reports to ensure both a degree of external review and easy access.

3.10 Translating Information into Action (Principles 7 & 8)

The weakest aspect of most adaptive management plans is in the sequence of steps required to link the knowledge gained from the implementation of conservation and monitoring actions (Boxes 3 through 9) to the governance actions of sustaining, refining, or replacing program goals and objectives or judging an action to be complete and successful (bold boxes in Figure 1). However, adaptive management plans rarely define the process and the responsibility for assimilating this information into the governance of the conservation plan. In the absence of this step, the adaptive management plan cannot really be adaptive. Information from technical reports is often captured and transmitted to decision-makers in irregularly scheduled exercises, such as ad hoc white papers and through conferences to brief managers or policy-makers. Such processes are inefficient and ineffective as a means of informing decision-makers, and lack the transparency needed in adaptive management.

To assimilate information and formulate recommendations (Box 10) requires both policy and technical expertise. This step is fundamental to the successful integration of accumulating knowledge and information into plan policies, such as revising goals and objectives, refining analytical models, or allocating funding. This step also is a key responsibility that is generally lacking from AMPs, a flaw that undermines successful implementation of adaptive management. The link between the technical step of "Analyze, Synthesize, Evaluate" and the decision-making step of "Assimilate and Recommend" requires regular interaction and exchange of information between technical staff and decision makers.

Box 10 in Figure 1 therefore highlights the need for some highly skilled agent (person, team, office) to be assigned the responsibility for continually assimilating scientific information generated by investigations *both within and external to the adaptive management program* and transforming it into knowledge of the kind required for management actions. Boxes 11 through 14 indicate that such actions may include (1) refining a particular conservation measure, (2) refining the knowledge base and models of system behavior that are extracted from the knowledge base, (3) revising objectives of an entire conservation measure, and (4) reassessing whether the original target problem is solved, transformed, or still a problem. This last action may also be affected by external events such as changing societal preferences, newly recognized environmental threats, or other changed or unforeseen circumstances.

The actions of the agent represented by Box 10 need to be carried out continually but on a range of time scales. For example, individual components of the knowledge base might be refined gradually and annually, whereas particular conservation measures might be refined only after a few years of project implementation. The entire problem might be re-assessed or re-visited once in a decade. The key principle, however, is that *the process of transferring and transforming the results of technical analyses into knowledge to support decisions cannot be taken for granted in the hope that it will occur in the absence of a body specifically charged with making it happen*. This function requires remarkably skillful people, who are truly inter-disciplinary ("polymaths"). Whatever their training, these individuals (or team of individuals) need to be comfortable with a wide range of technical information, as well as understand the functioning of government, law, economics, and the management of large projects.

Although this component of the adaptive management process is not well-developed in the field of environmental and resource management, examples of it are widespread in other, well-capitalized areas of human affairs. For example, the medical and biotechnology industries support highly trained personnel to monitor the myriad scientific results relevant to that field and to convey that information into forms that support the goal of the industry to deliver products and make a profit. This is the foundation of evidence-based medicine (Elstein 2004). Military Departments support links to the scientific community (e.g., Army Research Office, Office of Naval Research, Strategic Environmental Research and Development Program) to assimilate their useful results and recommend support for relevant studies. In government, the Congressional Budget Office, Government Accountability Office, and the Office of Science and Technology Policy all employ people who can assimilate disparate technical information into forms required for government decision-making.

Investment in some entity with the specific role of assimilating knowledge from the technical studies and making recommendation for changes is an essential component of large, complex environmental management projects. **We strongly recommend that BDCP put considerable thought and investment into institutionalizing an entity that is specifically tasked with assimilating knowledge and recommending adaptive changes to goals, objectives, models, conservation measures, and monitoring, as illustrated in Box 10 of Figure 1.** We consider this investment critical to the success of BDCP and to making adaptive management an integral part of the plan.

Appendix A – Advisor Biographies

Cliff Dahm, Ph.D., Lead Scientist, CALFED Science Program, Sacramento, and Professor, Department of Biology, University of New Mexico. Dr. Dahm is an ecosystem ecologist with expertise in restoration ecology, biogeochemistry, microbial ecology, hydrology, climatology and aquatic ecology. He is presently on loan to the US Geological Survey to serve as lead scientist for the CALFED Science Program from the University of New Mexico (UNM), where he is a professor in the Department of Biology. He emphasizes interdisciplinary approaches required for understanding aquatic ecosystems. He has served as interim director for the Sevilleta Long-Term Ecological Research (LTER) Program at the Sevilleta National Wildlife Refuge in central New Mexico, director for the Freshwater Sciences Interdisciplinary Doctoral Program at UNM and is currently a member of the Science Steering Group for the Global Water Budget Program of the U.S. Global Change Research Program. He has served as a program director for the Division of Environmental Biology of the National Science Foundation and was awarded the NSF's Director's Award for Program Management Excellence. He has worked on adaptive management protocols in Florida and Queensland, Australia. Dr. Dahm received a B.S. in Chemistry from Boise State University, an M.A. in Chemical Oceanography from Oregon State University, and a Ph.D. in aquatic ecology and oceanography from Oregon State University.

Tom Dunne, Ph.D., Professor of Environmental Science & Management and of Earth Sciences, University of California Santa Barbara. Dr. Dunne conducts field and theoretical research in fluvial geomorphology and in the application of hydrology, sediment transport, and geomorphology to landscape management and hazard analysis. He has worked on hydrology and geomorphology in many parts of the world, including New England, Northern Canada, Kenya, the Pacific Northwest, and the Andean and lowland parts of the Amazon River Basin. His current work concentrates on sediment transport and river channel evolution in gravel-bed rivers of the Sacramento and San Joaquin basins, including the relationship between physical and biological processes in a restored reach of the Merced River. He has served on many National Research Council Committees, the CALFED Ecosystem Restoration Program, the CALFED Independent Science Board, as well as the Adaptive Management Forum of the US Fish and Wildlife Service. Dr. Dunne received his Ph.D. in Geography from The Johns Hopkins University.

Wim Kimmerer, Ph.D., Research Professor of Biology, Romberg Tiburon Center for Environmental Studies, San Francisco State University. Dr. Kimmerer's research focuses on the San Francisco Estuary, emphasizing effects of human activities on the estuarine ecosystem. Research topics include zooplankton ecology, effects of introduced species and variable freshwater flow, population dynamics of fish such as salmon, striped bass, and the threatened delta smelt, simulation modeling of populations, and analysis of the extensive monitoring database from the estuary. Dr. Kimmerer is chair of the Interagency Ecological Program's Estuarine Ecology Team, and has assisted the IEP with long-range planning and design of monitoring programs. He was a member of the CALFED Ecosystem Restoration Program Core Team, developing a strategic plan for the program, and the Ecosystem Restoration Program Science Board, providing guidance on the application of adaptive management in the program. He is also serving as a science advisor to the CALFED Science Program, and has participated on numerous review panels on key issues in the Delta. Dr. Kimmerer received his Ph.D. in biological oceanography from the University of Hawaii.

Denise Reed, Ph.D., Professor, Department of Earth and Environmental Sciences, and Interim Director, Pontchartrain Institute for Environmental Sciences, University of New Orleans. Dr. Reed's research interests include coastal marsh response to sea-level rise, the contributions of fine sediments and organic material to marsh soil development, and how these are affected by human alterations to marsh hydrology. She has worked on coastal issues on the Atlantic, Pacific, and Gulf coasts of the US, as well as other parts of the world, and has published the results in numerous papers and reports. She is involved in restoration planning both in Louisiana and in California, and in scientifically evaluating the results of restoration projects. Dr. Reed has served on numerous boards and panels concerning the effects of human alterations on coastal environments and the role of science in guiding ecosystem restoration, including the Chief of Engineers Environmental Advisory Board, a number of National Research Council Committees, and the Ecosystems Sciences and Management Working Group of the NOAA Science Advisory Board. She received her B.A. and Ph.D. from the University of Cambridge in England and has worked in coastal Louisiana for over 20 years.

Elizabeth Soderstrom, PhD., Senior Director of Conservation for American Rivers. Previously, Dr. Soderstrom was the Senior Director for Sierra and International Rivers at the Natural Heritage Institute, during which time; she managed the Sharing Water Project on the Okavango River in Southern Africa, launched the Mountain Meadows Initiative, and applied adaptive management principles to river restoration as a Switzer Leadership Fellow. She also assisted both the CALFED Science Program and the Sierra Nevada Conservancy in developing and using performance measures. Dr. Soderstrom has also served as an International Engineering and Diplomacy Fellow with the American Association for the Advancement of Science at USAID's Center for the Environment in Washington, DC, and at USAID's Regional Center for Southern Africa based in Gaborone, Botswana. In these positions, she implemented the International Coral Reef Initiative, was an advisor and representative to the Ramsar Convention on Wetlands of International Importance, and the Convention on Biodiversity, and researched and designed a role for United States assistance in the management of international rivers in southern Africa. Dr. Soderstrom received a B.A. in English Literature, and a B.S. and M.S. in Biological Sciences from Stanford University, and a Ph.D. from the University of California, Berkeley.

Wayne Spencer, Ph.D., Senior Conservation Biologist, Conservation Biology Institute, San Diego. Dr. Spencer is a conservation biologist and wildlife ecologist with expertise in conservation planning and endangered species recovery. He has worked on various regional NCCPs and HCPs in California as a consulting biologist, science advisor, and science facilitator. His research focuses on rare and endangered mammal species, including the endangered Stephens' kangaroo rat, Pacific pocket mouse, and Pacific fisher. He has also worked extensively on approaches to designing landscape-level reserve systems and maintaining ecological connectivity. He is a Research Associate with the San Diego Natural History Museum and a science advisor to numerous conservation NGOs. He received his B.S. in Biology and Wildlife Management at the University of Wisconsin, Stevens Point, his M.S. in

Wildland Resource Science at UC Berkeley, and his Ph.D. in Ecology and Evolutionary Biology at the University of Arizona.

Inge Werner, Ph.D., Associate Adjunct Professor and Director of the Aquatic Toxicology Laboratory, University of California at Davis, School of Veterinary Medicine. Dr. Werner's research focuses on the molecular, biochemical and physiological responses of fish and aquatic invertebrates to anthropogenic environmental stressors, and interpreting these in an ecological context. Her work includes aquatic monitoring programs to assess pollutant impacts in California's Sacramento-San Joaquin watershed and delta, studies on the impact and efficacy of alternative pest control methods in orchard and field agriculture, and the effects of elevated temperature, pesticides and heavy metals on aquatic organisms. She has worked on various zooplankton, amphipod and clam species, as well as native fishes including Chinook salmon, steelhead trout, delta smelt, and green sturgeon. Dr. Werner has an M.S. in Limnology from the University of Freiburg, Germany, and a Ph.D. in Zoology with specialization in aquatic toxicology from the University of Mainz, Germany.

Susan Ustin, Ph.D., Professor of Environmental Resource Science, Department of Land, Air, and Water Resources, University of California Davis. Dr. Ustin is an ecosystem ecologist with 25 years experience in environmental applications of remote sensing. Her current research involves working at a variety of scales from leaf level radiative transfer modeling to quantify landscape biogeochemistry to global mapping of wildfire occurrence. She has extensive experience in developing methods of analysis for hyperspectral imaging data, focusing on detection of environmental stresses and degradation. She has worked on many projects in the San Francisco estuary and delta, starting with her dissertation research and most recently mapping invasive aquatic plants in the delta region. She received a B.S. and M.S. in Biological Sciences from California State University Hayward and a Ph.D. in Botany from the University of California Davis in 1983 in the area of plant physiological ecology with work on physiological responses to salinity and drought stress in wetland plant species in the California Delta.

John Wiens, Ph.D., Chief Conservation Science Officer, PRBO Conservation Science, Petaluma. John Wiens grew up in Oklahoma as an avid birdwatcher. Following degrees from the University of Oklahoma and the University of Wisconsin-Madison (M.S., Ph.D.), he joined the faculty of Oregon State University and, subsequently, the University of New Mexico and Colorado State University, where he was a Professor of Ecology and University Distinguished Professor. His work has emphasized landscape ecology and the ecology of birds, leading to over 200 scientific papers and 7 books. John left academia in 2002 to join The Nature Conservancy as Lead Scientist, with the challenge of putting years of classroom teaching and research into conservation practice in the real world. In 2008, he joined PRBO Conservation Science as Chief Conservation Science Officer. His aim is to build on the long-standing work of PRBO on bird populations to address conservation in a rapidly changing world – "conservation futures." Climate change is affecting species distributions, economic globalization is altering land uses, and demands for the goods and services provided by nature are changing how people relate to nature. John is working with PRBO staff and partners to develop guidance for assessing the impacts of these changes and how management practices can help natural systems adapt.

Appendix B – Workshop Agenda

DECEMBER 17-19, 2008

<u>Wednesday - December 17, 2008</u>

1. **<u>CLOSED SESSION</u> - Embassy Suites Sacramento – Steamboat Rm.** **12:00 – 1:30**
   (Advisors Only)
   - *Advisors meet to review charge*

– **2:00 – 4:00**

3. **<u>CLOSED SESSION</u> - Embassy Suites Sacramento – Steamboat Rm.** **4:00 – 5:00**
   (Advisors Only)
   - *Organize Review*
   - *Homework assignments*

<u>Thursday - December 18, 2008</u>

1. **<u>CLOSED SESSION</u> - Embassy Suites Sacramento – John Sutter Rm.** **8:00 – 12:00**
   (Advisors Only)
   - *Discuss program strengths and weaknesses*
   - *Discuss successful elements from other programs*
   - *Craft initial recommendations*

Lunch **12:00 – 1:30**

2:00 – 3:30

3. **<u>CLOSED SESSION</u> – Resources Building – Rm. 1131** **3:30 – 5:00**
   (Advisors Only)
   - *Refine recommendations*
   - *Work on findings memorandum.*

<u>Friday - December 19, 2008</u>

<u>CLOSED SESSION</u> - Embassy Suites Sacramento – John Sutter Rm. **8:00 – 12:00**
(Advisors Only)
- *Finalize language for findings memorandum*

Adjourn **12:00**

Appendix D.

Examples of Recommended Adaptive Management Framework Applied to Two Proposed Conservation Measures

The Advisors selected two examples of BDCP proposed conservation measures to illustrate how our proposed Adaptive Management Framework would apply to them and to developing additional conservation measures. These examples illustrate the need for goals and objectives to be articulated clearly and that the existing knowledge base must be integrated into models (conceptual or otherwise) to identify expected outcomes. This will connect goals and objectives, expected outcomes, performance metrics, and monitoring in a logical manner. We also point out inaccuracies or gaps in how these examples are presented in the draft BDCP documents. We recommend that these examples be used to improve the development, analysis, and presentation of conservation measures for the BDCP.

Other Stressors Example

Conservation measure TOC01 is to "Reduce the Load of Ammonia in Effluent Discharged from the Sacramento Regional County Sanitation District into the Sacramento River…If Warranted Based on Research." [5]

Knowledge Base

The knowledge base is currently provided in the form of a rationale in draft BDCP documents. Although information from a few key scientific publications is cited, the rationale does not provide a satisfactory summary of the knowledge base with respect to ammonia/ammonium and effects on different trophic levels of the Delta, as well as secondary effects due to trophic interactions. The information provided is also not well substantiated. Ammonia and ammonium are some of the best-characterized contaminants in this system, and information on concentrations producing toxic effects for fish and other species is relatively abundant. The BDCP documents should explain in a more specific manner why ammonia and ammonium are of concern in the Lower Sacramento River. Examples of available information that should be included are data on total ammonia/ammonium concentrations collected by Sacramento Regional County Sanitation District (SRCSD), California Department of Water Resources, and the Interagency Ecological Program toxicity information reviewed in US EPA (1999), as well as many scientific papers in the peer-reviewed literature. Results from Teh et al. (2008) are misquoted, as no conclusive evidence was found to support the statement that ammonium caused the observed reduction in survival of prey species (copepods) for delta smelt and longfin smelt.

---

[5] This goal is inaccurately worded, and this inaccuracy is perpetuated throughout BDCP documents. The terms ammonia and ammonium refer to two chemical species that are in equilibrium in water (un-ionized ammonia and ionized ammonium). Chemical tests usually measure both ammonia and ammonium (NH_3, NH_4^+), while the toxicity is primarily, but not completely, attributable to the un-ionized form. Ammonia concentration is not directly measured but can be calculated if temperature and pH are known.

Goals and Objectives

This conservation measure is essentially a research and monitoring program, but no clear goals or objectives are provided, and the title of the conservation measure is inconsistent with the performance measure or measures of success, which are focused on adverse effects on fish (see below). For example, a clear goal statement would be:

Minimize or eliminate direct and indirect toxic effects of ammonia and ammonium from Sacramento Regional County Sanitation District (SRCSD) effluent on covered species.

Objective statements could then be:

1. Reduce the load of ammonia and ammonium in SRCSD effluent to levels which will not cause adverse indirect or direct effects to covered species in the Lower Sacramento River.
2. Reduce the load of ammonia and ammonium in SRCSD effluent to ….mg/L (quantitative threshold).
3. Reduce the load of ammonia and ammonium in SRCSD effluent to minimize or eliminate risk of indirect and direct ammonia/ammonium toxicity to covered species in the Lower Sacramento River.

This would lead directly to specifications of performance metrics and potential research goals, such as monitoring total ammonia/ammonium concentrations as well as pH and water temperature downstream of the outfall in areas where fish habitat and elevated concentrations coincide (Objective 2; relatively easy), reducing ammonia/ammonium to “safe” concentrations of ammonia/ammonium for covered fish species and their prey (Objectives 1 and 3) and identifying performance metrics for monitoring adverse effects on Delta species at different trophic levels (more difficult).

This conservation measure is stated as contingent upon ongoing or planned research. The BDCP documents should explain specifically what the goals of this research are, and what outcomes will warrant the implementation of the full-scale conservation measure.

Tradeoffs are not explicitly addressed, but should be. For example, it is possible that a reduction in nutrient input due to an increased level of treatment could affect primary productivity or phytoplankton community composition downstream of the treatment plant. It is important to discuss different levels of wastewater treatment (nitrification or coupled nitrification and denitrification to achieve removal as nitrogen gas) and their expected outcomes. This should be discussed in the context of studies by Dugdale et al. (e.g., 2007; ammonium inhibition of diatom growth), Jassby et al. (2002; 2008; nutrient loading and dynamics), and Lehman et al. (2005, 2008; *Microcystis aeruginosa*), as well as related publications and ongoing studies referred to in the “Rationale.”

Models

Models should capture and formalize the knowledge base. A conceptual model could provide the framework for the conservation measure and inform selection of performance metrics, but sufficient data already exist to create a more quantitative model. For example, information on the oxidation of ammonia and ammonium in municipal wastewater treatment effluent after upgrading to tertiary treatment (nitrification only) is readily available from the Stockton Wastewater Treatment Plant, which recently switched from secondary to tertiary treatment. Information on total ammonia/ammonium concentrations in the Lower Sacramento River is also available (DWR, SRCSD, Interagency Ecological Program (IEP) Pelagic Organism Decline (POD)). There also is a relatively large body of information on the acute and chronic toxic effects of ammonia and ammonium on fish and some aquatic invertebrates, and US EPA water quality criteria exist (US EPA, 1999).

Desired Program Outcomes and Performance Metrics

Contingent upon the goals and objectives, it is important to clearly state the desired outcomes of the conservation measure: While it is relatively easy to define desired outcomes and performance metrics if the goal is to "reduce the load of effluent-related ammonia and ammonium…," it is more difficult to define these if the goal is to "reduce adverse direct or indirect effects on covered fish species." The latter requires information on acute, chronic, and sublethal effects of ammonia and ammonium on covered fish species and their prey under current conditions and conditions projected under reduced loading. It also requires seasonal assessment of ammonia and ammonium loads under variable pH and temperature and the hydrodynamic transport and fate of the ammonia and ammonium downstream in the Sacramento River and within the Delta.

Select and Evaluate Conservation Measures

The choice about whether to implement a conservation measure as a full-scale action, as a pilot study, or as a research program depends on its physical and temporal scale, the degree of confidence in its benefits, and the consequences of being wrong (see Section 3.6). A full-scale action is taken to solve a problem when the action is considered highly likely to achieve or contribute to one or more key objectives, and there is little additional benefit to performing pilot studies or research before implementing the full-scale action. Clearly, this is not the case here. At present, the actual conservation measure TOC01 provided in the BDCP document consists of a research program to "evaluate the need and, if demonstrated to be necessary to protect covered fish species, reduce the levels of SRCSD effluent-derived ammonia and ammonium entering the Delta." The "need" is defined by the goal "to protect covered fish species." The full-scale action would be to improve the SRCSD wastewater treatment process to reduce ammonia and ammonium in the effluent. To realize this measure, the plan calls for monitoring total ammonia/ammonium concentrations in the river, and for performing studies to provide conclusive evidence of whether or not the discharge of ammonia and ammonium in effluent from the SRCSD Wastewater Treatment Plant has substantial adverse direct or indirect effects on covered fish species.

It would facilitate evaluation and future adaptive management decisions if the development of this conservation measure was described in detail, provided clear information on goals and objectives, specified research objectives, and detailed why presently available data are insufficient to implement a full-scale action.

Design and Implement Conservation Measures

As stated above and in Section 3.6, the actions to be undertaken under this conservation measure should be described in greater detail. What are the specific research goals and hypotheses, and what is monitoring expected to show? How is risk to covered species defined? Provide details of the design to be used in determining what levels of ammonium and ammonia have adverse direct or indirect effects on covered fish species, and how often these levels are exceeded. Specific information gaps that lead to uncertainties should be addressed clearly. What actions will be taken to reduce uncertainties? Text in Lines 16-18 of the draft plan describes neither uncertainties nor risks. Identify alternative strategies if identified partner entities choose not to collaborate on the conservation measure.

Collect, Manage, Synthesize, and Evaluate Data

Performance metrics should provide useful information to evaluate the success of the conservation measure and should be directly related to the objectives. For example, data collection and management planning should address the questions of how and where will monitoring be conducted, what sorts of inputs may be required to model the system, and how will results be analyzed? As an important example, monitoring of total ammonia/ammonium should involve simultaneous pH and temperature measurements so levels of un-ionized ammonia can be calculated. The spatial and temporal scope of data collection also needs to be considered as impacts to foodwebs and covered species are evaluated. A well designed data collection and management plan will facilitate effective synthesis and evaluation of the resulting data as the BDCP is implemented.

Remaining Components of the Adaptive Management Framework

The full-scale action to reduce the ammonia/ammonium load in the Lower Sacramento River by improving treatment technology at SRCSD would be costly and largely irreversible. This conservation measure makes the full-scale action contingent upon the significant risk of direct or indirect toxic effects on covered fish species due to effluent-derived ammonia/ammonium. Establishing the "need" for the full-scale action, or refining the conservation measure to achieve this goal, requires in-depth scientific knowledge of ecotoxicological principles and risk assessment strategies. Highly skilled individuals are needed to successfully include results provided by research in adaptive management decisions.

Riparian Restoration Example

The stated conservation measure is to "restore between XX and XX acres of riparian forest and scrub communities as a component of restored floodplain, freshwater intertidal marsh, and channel margin habitats."[6]

Knowledge Base

The benefits to covered species of restoring riparian forest and scrub are presumably supported by previous science and applied management, but little of this background knowledge is apparent in the plan documentation. Only two citations are provided to support elements of the rationale for the conservation measure.

While it is not necessary to provide complete documentation of all of the knowledge that underlies development of the plan, the knowledge base should be developed sufficiently to provide a clear and transparent foundation and justification for the proposed plan.

Goals and Objectives

Goal NACO1 is to "Protect, enhance, and restore tidal perennial aquatic, tidal freshwater emergent, brackish freshwater emergent, floodplain, and valley riparian communities to provide habitat and ecosystem functions to increase the natural production (reproduction, growth, and survival), abundance, and distribution of covered species."

This goal is too broad and includes implicit assumptions that may not be warranted. The first part is about plant communities, the second about unspecified habitat, the third about functions of unspecified parts of the ecosystem, and the fourth is about population processes of unspecified species. Moreover, this goal includes five habitat types and production, abundance, and distribution characteristics for each habitat type. This makes it impossible to define clear metrics for each of these important Delta habitats. This goal should be broken into parts that logically hang together. Again, the ERP Strategic Plan provides guidance on this. More carefully stated, this might read as four goals, each having a discussion of why these goals have been selected:

1. Protect, enhance, and restore tidal perennial aquatic, tidal freshwater emergent, brackish freshwater emergent, floodplain, and valley riparian plant communities.
2. Protect or restore functional habitat types.
3. Restore and enhance ecosystem functions such as….
4. Increase the natural production, abundance, and distribution of covered species.

Objective NACO1.5 is to "Restore at least XX acres of riparian forest and scrub within the Delta to provide habitat and ecological functions in support of covered species."

This is a clearly stated and measurable objective, although it is not clear what variables or processes qualify as "ecological functions." The objective should lead to specific outcomes that

[6] The documents we reviewed did not supply acreages, but explained these would be determined in the future.

can be evaluated to determine whether the goal (as expressed in this objective) is being achieved. What does "support" mean operationally?

Models

There is no indication in the documentation we received that modeling of any sort has been used to assemble and synthesize the knowledge base about the dynamics and controlling factors of riparian forest and scrub communities and their linkages to various habitats in the Delta. Such models might be used, for example, to determine *how* restoration of riparian forest and scrub will actually provide habitat and "ecological functions" to covered species. Is XX acres a sufficient amount of forest or scrub to provide habitat to which covered species (species differ in the amount of habitat needed to support functioning populations)? One might use existing information on breeding birds in riparian habitats, for example, to model how restoration at different levels might affect reproduction, growth, or survival of different species. Spatial optimization models might be employed to assess the consequences of different spatial arrangements of riparian forest and scrub restoration within different areas of the Delta, and to explore tradeoffs among different approaches to riparian restoration. At a minimum, the Delta Regional Ecosystem Restoration Implementation Plan (DRERIP) conceptual models could be used to be more explicit about the relationships between the covered species and riparian forest and scrub.

Desired Program Outcomes and Performance Metrics

Expected outcomes are scattered through the description of Riparian Habitat Restoration conservation measures. For example:

- "At floodplain restoration sites that function hydrologically as flood bypasses (e.g., the Yolo Bypass), riparian vegetation is expected to establish along margins of existing and created drains and channels and other locations with suitable hydrology."
- "Levees constructed and maintained by other entities that incorporate "green" levee components would also increase the extent of riparian habitat … by allowing for the establishment and growth of riparian vegetation on levee surfaces."
- "Restoring riparian forest and riparian scrub habitats is expected to … increase the extent of valley elderberry longhorn beetle habitat and nesting habitat for Swainson's hawk and yellow-breasted chat; … increase … instream cover … through contributions of instream woody material; … increase production and export of terrestrial invertebrates into the aquatic ecosystem; and … increase cover for rearing juvenile salmonids and Sacramento splittail."

In general, these outcomes are framed in ways that enable conservation measures to be developed and measurements designed to assess progress in meeting the goal and objectives. Thinking about outcomes could be broadened to include other benefits, such as the potential role of riparian vegetation in flood abatement, water retention or in carbon sequestration. In general, outcomes could be more broadly considered in the context of ecosystem services.

Metrics to measure progress toward realizing these outcomes are not provided; this section is still in preparation.

Select and Evaluate Conservation Measures

Presumably the evaluation and selection among several potential conservation measures has already occurred, although this measure is sufficiently broad that it likely includes several alternatives. It would facilitate adaptive management if the conservation measures were developed in greater detail, to indicate how restoration is to be accomplished, where restoration will be targeted, what factors will be considered in determining whether, when, where, and how to undertake restoration, and the like. For example, the approach embraces a "build it and they will come" philosophy – e.g., "riparian habitat would be allowed to naturally establish in floodplain habitat areas that are restored…"[7] A more proactive approach to ensuring that the desired type of riparian habitat becomes established may be more effective. This additional level of detail will be needed before this measure can be evaluated using the DRERIP tools.[8]

The possibilities of conducting preliminary research or pilot studies to evaluate whether the conservation measures are likely to produce the expected outcomes in a cost-effective and timely manner are not considered; this may be an outcome of the recent scientific evaluation using the DRERIP tools. Pilot projects can be invaluable tools for generating public support for restoration actions and for the design of larger-scale projects (e.g., Toth et al. 1998).

Design and Implement Conservation Measures

Details of the design(s) to be used in restoring riparian habitat are not provided; it may not be the intent of this plan to include such details, but they will be needed in order to design effective monitoring programs.

Design and Implement Monitoring

The BDCP documents indicated that monitoring will be conducted to assess the use of restored habitats by covered species, factors that govern the establishment and growth of native riparian vegetation, the need to control non-native invasive species, and the ability of restored habitat to provide unspecified "desired ecosystem and covered species benefits."

Monitoring must be adequate to determine whether the expected and desired outcomes are being met. This requires a monitoring plan be developed that describes what will be monitored, at what spatial and temporal intervals, by what methods, and how the data will be used to assess performance.

Remaining Components of the Adaptive Management Framework

The report mentions using adaptive management to (1) improve the design and management of restored areas to provide for the successful establishment, growth, and benefits of restored riparian habitats, and (2) evaluate the need for control of non-native invasive species or the use of riparian plantings to improve success. These are appropriate adaptive management responses.

[7] Although the report acknowledges that this approach could allow the establishment of non-native invasive species, it does not fully address the implications of this issue.

[8] The BDCP independent science advisory report concerning non-aquatic resources (November 2008) also noted that simply restoring semi-natural hydrological regimes in floodplains won't restore natural riparian conditions, that restoration is a process rather than a one-time action, and that there is a useful knowledge base for guiding restoration actions that should be fully integrated into restoration planning, implementation, and monitoring.

The application of adaptive management to riparian habitat restoration, however, would be enhanced by considering the potential management responses to various outcomes *as part of the conservation plan*. The use of models to explore likely scenarios would help managers anticipate and plan for adaptive management actions as the effects of the conservation measures undertaken become evident through focused monitoring.

BAY-DELTA CONSERVATION PLAN

DELTA SCIENCE PROGRAM PANEL

REVIEW OF THE "LOGIC CHAIN" APPROACH

Prepared for
BDCP Steering Committee

Prepared by
Cliff Dahm, Delta Science Program
Denise Reed, University of New Orleans
Elizabeth Soderstrom, American Rivers
John Wiens, PRBO Conservation Science (Chair)

19 March 2010

Background

The Bay-Delta Conservation Plan (BDCP) is being prepared through collaboration among several government, non-government, and private-sector entities. The goal of BDCP is to identify actions that will contribute to the recovery and protection of endangered and sensitive species and their habitats in the Sacramento-San Joaquin Delta of California while maintaining or improving water supplies to a diversity of users. To this end, a "logic chain" has been proposed as a framework for linking recovery goals for covered fish species with BDCP goals, objectives, conservation measures, monitoring, and adaptive management.

The review panel convened by the Delta Science Program met in Sacramento on March 2-4, 2010, to evaluate this approach. In this review, we drew heavily from the following documents: Logic Chain Status Report, Chapters 3.3 and 3.4 of the draft BDCP, SAIC Draft Effectiveness Monitoring for Conservation Measures document, Summary Report of the DRERIP Evaluations of BDCP Draft Conservation Measures, Independent Science Advisors' Report on Adaptive Management, and examples of logic chains provided by American Rivers and The Bay Institute.

The Charge

The charge to the review team had three elements. The first was to address whether the logic chain framework is a useful tool for refinement of BDCP goals and objectives. The second was an assessment of the logic chain framework with a focus on determining if the internal logic was sound and if there were critical gaps. The third element was to recommend next steps for populating key logic chains and to consider where additional science was needed in the BDCP process. This report addresses these three elements of the charge to the review team.

Recommendations

Adequacy of the logic chain framework

- The general logic-chain approach should continue to be developed and then applied, as it has the potential to clearly articulate and link goals, objectives, actions, and outcomes.
- The logic chain should be first applied to the covered fish species.
- The revisions to the logic chain structure developed by the review panel should be incorporated, as appropriate, to reduce areas of ambiguity and refine the logic chain.

Assessment of the logic chain framework

- BDCP should distinguish between order-of-magnitude approximations of BDCP goals and objectives that are acceptable in the early planning phase and the more detailed descriptions that will be necessary as the plan is finalized and ready for implementation.
- The projected outcomes should be framed as testable hypotheses linked to specific conservation measures and evaluated against actual outcomes. Outcomes must be quantified, with specified and measurable parameters and appropriate metrics. The analytical methodology to be employed should also be specified. It is important to know with clarity whether a conservation measure is working as intended.
- Use metrics to evaluate the success of outcomes that clearly link to biological functions; consider the judicious use of surrogate metrics. For example, accurate quantification of rare and endangered fish species may not be possible but overall community structure that characterizes native and non-native groups could serve as a surrogate measure.
- Constraints to implementation of the conservation measures (e.g., financial, environmental, logistical) should be considered as part of the planning process rather than as factors to be included only when one comes to implementing conservation measures. This will ensure that expectations about implementation are commonly understood. For example, budgetary requirements to make the necessary monitoring measurements and analyze the resulting data should be developed as soon as possible so that this information can be used in the prioritization of conservation measures.
- The potential impacts of system dynamics, variation, and change (especially those associated with climate variability, climate change, and sea-level rise) on the effectiveness of conservation measures should be explicitly addressed in the logic chain. A steady-state equilibrium, in which the system varies around some stable long-term state (i.e., stationarity), cannot be assumed.
- The adaptive management framework should be developed in greater detail, recognizing that analysis is *not* the endpoint of adaptive management. Adaptive management

approaches should be incorporated into the body of the logic chain rather than relegated to something that is done at the end, after measures have been implemented.

Next steps and science needs

- Rather than developing all logic chains at the same pace, logic chains should be developed in detail for 2-3 species and then evaluated as a proof of concept. These logic chains should be for species for which understanding is high (e.g., splittail). A user-friendly version of the logic chain that describes the approach and its uses in readily understandable terms should be developed now.

- The upper section of the logic chain (problem, recovery/species goals, and recovery/species objectives) should be developed and populated by the responsible regulatory and permitting agencies. This needs to be done immediately, because the application of logic chains to BDCP goals and objectives and the evaluation of hypotheses that feed into adaptive management depend on a clear statement of the problem to be addressed and well-defined recovery/species goals and objectives.

- The middle section of the logic chain (BDCP goals and BDCP objectives) should be developed through collaborative efforts. A limited number of experts from the permitting agencies, non-governmental organizations, and the potentially regulated entities should participate in developing this section of the logic chains.

- A science expert workshop should be convened to populate the lower part of the logic chain, focusing on the conservation measures, outcomes, monitoring, metrics, and the form of an adaptive management process once the upper and middle sections of the logic chains have been completed.

- Simulation models and scenario analysis should be used to explore the potential consequences and cost-effectiveness of conservation measures as part of the planning process, before measures are actually implemented.

- The formalisms of other approaches such as cost-benefit analysis, return-on-investment, or ecological risk analysis should be used to help set priorities and evaluate outcomes. Such tools should be used to inform decision making and negotiations, to consider tradeoffs, and to establish priorities among conservation measures.

General Comments

Before dealing with the details of the logic-chain, we offer several general comments as broad guidance for further development of the approach. First, our ability to recover or manage covered species depends on a clear understanding of what factors are limiting or creating stress to populations. These are the factors that must be removed or mitigated by the conservation measures. Such factors may be identified in recovery plans or may require additional information obtained from the scientific literature and/or expert opinion, and should be refined through the adaptive management process.

Second, there is an underlying (but unstated) assumption of stationarity that runs through the logic chain approach, the draft BDCP documents, and recovery plans. This assumption leads to the expectation that there is a stable "baseline" condition for the Bay-Delta ecosystem and the populations it supports. Given the massive changes in this ecosystem over the past century, this is almost certainly not true now. The potential effects of climate change on sea level, tidal fluxes, Sierra snowfall, and the timing of freshwater runoff make it even less likely to hold in the future. The logic chain and BDCP should explicitly incorporate non-stationary dynamics into the framework.

Third, it is important to incorporate study designs, monitoring protocols, and metrics as part of the logic chain. In particular, consideration of the statistical power required for detecting the effects of conservation measures, coupled with a determination of acceptable levels of response of covered species or other targets to conservation measures, may help to determine the feasibility or priority of particular measures.

Fourth, although it is important to have a clear and logical structure for developing hypotheses about the consequences of conservation measures and the efficacy of these measures in addressing BDCP goals and objectives, the framework should not be so highly structured and prescriptive that it constrains thought or resists the exercising of dynamic adaptive management. The Bay-Delta ecosystem is complex. The responses of covered species to conservation measures will always be clouded by uncertainty – did a species respond to a measure or to something else? Dealing with such uncertainties requires flexibility in planning and implementation.

Evaluation of the Logic Chain

In order to understand the logic and function of the logic chain, the review team chose to delve into the logic chain example for the Delta Smelt (Appendix 2). We reviewed and assessed this example from top to bottom; here are our observations and comments, utilizing the terminology of the example provided.

<u>Problem statement, goals and objectives</u>

The problem statement, goals, and objectives need to match or encompass those in the recovery plan(s). Broad statements for the species/populations as a whole are acceptable at this level.

<u>Conceptual models</u>

This part of the logic chain only references *conceptual* models. Various types of models -- conceptual, statistical, process, simulation, etc. – can be used to identify factors that limit the population as a whole, and different models and types of models consider factors such as population dynamics, hydrology, predation, or habitat availability. These models (or perhaps a nested set of increasingly more specific models) can be used to identify what limiting factors or stressors (if any) occur within the planning area and, therefore, would be addressed by BDCP actions. In addition, when these models are used, they relate to what has caused the problem, as articulated in the problem statement.

Hypotheses

The "hypotheses" (which as stated in the logic chain are actually assumptions rather than hypotheses) can better be characterized as specific "BDCP goals" with each goal statement articulating how a limiting factor might be addressed *within the BDCP planning area*. One goal statement for each limiting factor (e.g., increase food in the pelagic zone by 15 percent to improve sub-adult survival) specifying season and location would be necessary.

The limiting factors framed as goals do not need to be directly tested as formal hypotheses. The process relies on the models (above) or the wider knowledge base to identify the limiting factors and assumes that alleviating those factors will in fact address the problem.

Desired change

To link with the goal statements described above, the "desired change" category would be logically called "BDCP objectives." The level of quantification of the objectives depends on whether they will be used to develop prioritizations in the early planning phase (in which case they can be order-of-magnitude approximations) or if they are part of the finalized plan. If the latter, the objectives would need to be the so-called "SMART objectives" that are specific, measurable, achievable, relevant and time-based.

In some cases, the terminology "thresholds of change" has been used instead of "desired change," suggesting that there is a lower threshold of detectability of an effect or an upper threshold beyond which additional changes have no additional beneficial effects. These levels define an envelope of effects or change that is either detectable or relevant. We find the use of this terminology confusing and, in some instances, inaccurate. It needs to be clear whether this is something to be achieved (like a target) or exceeded (like a minimum acceptable achievement).

Conservation Measures

The conservation measures are the BDCP conservation measures or actions. They relate directly to the BDCP goal and objective statements and reduce the limiting factors within the BDCP planning area. Linking proposed conservation measures to BDCP goals and objectives will help to show gaps, such as objectives for which no appropriate measure exists.

Once the conservation measures have been described, a clear prioritization process would be useful, as not all measures will be logistically, financially, or politically feasible. Such prioritization could be based on an evaluation of cost effectiveness of measures relative to their outcomes and the linkages between implementation, analysis, and adaptive management. Negative consequences and the timing of actions (sequencing) would also need to be considered.

Outcomes

The projected outcomes currently are not framed as quantitative, testable hypotheses. It is at this level of the logic chain where such hypothesis testing should occur. Stated as such, these hypotheses would drive the analytical approaches for evaluating the hypotheses and the form and structure of monitoring (i.e., gathering the information to evaluate or test the hypotheses).

The monitoring design (or experimental design) may vary among different conservation measures or be applied in different ways to different places for the same conservation measure (i.e., a real experiment). It will be critical to determine what level of measurement, monitoring, and analysis would be considered not too little (to demonstrate an effect), nor not too much (a huge investment in limited resources), but just right (the Goldilocks approach). Costing of the analytical methods and monitoring would be a consideration in the prioritization of conservation measures mentioned above. The monitoring structure will in turn lead to the selection of appropriate metrics and consideration of such key attributes as spatial and temporal resolution, statistical power, analytical framework to employ, and best representation and visualization of results.

Analysis

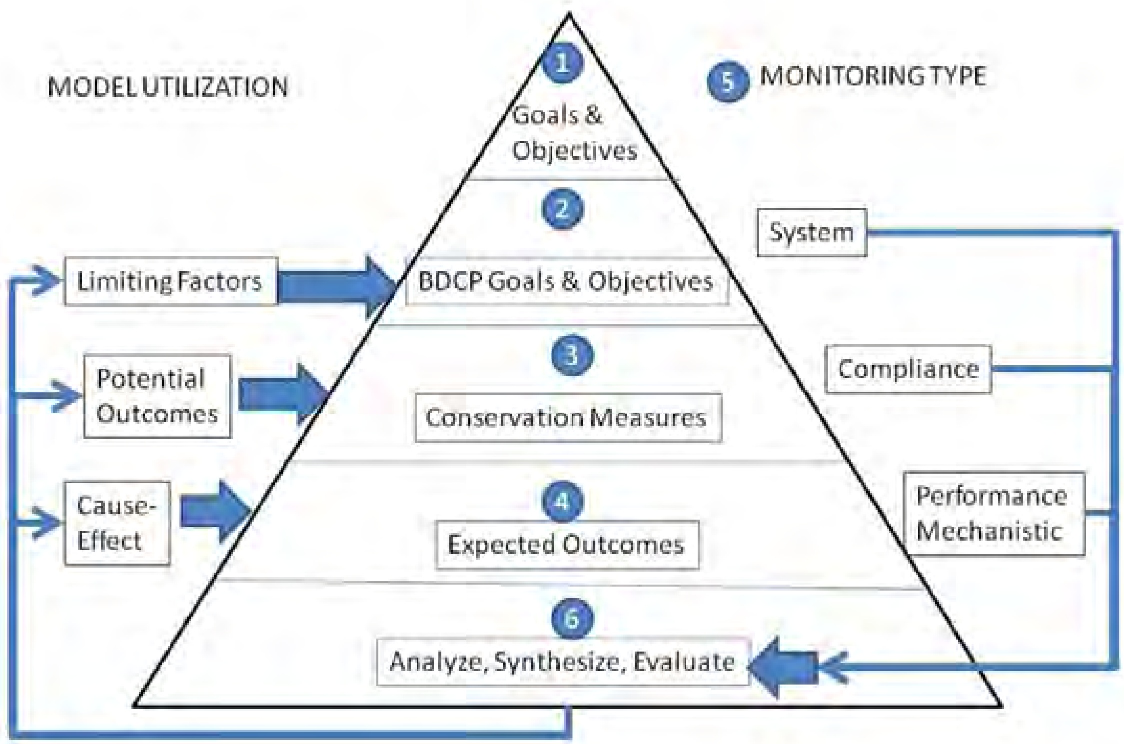
The analysis box in the Delta smelt logic chain provided would benefit from being more detailed and expanded to include the adaptive management loop. Adaptive management is not the same thing as the hypothesis testing that is included as part of the logic chain. Implementation of conservation measures leads to actual outcomes that must be monitored and analyzed. The comparison of projected outcomes (the hypotheses) with the actual outcomes is the focus of analysis. These results then feed into the adaptive management loop and back into other components of the logic chain (see next section). This is also where the system metrics may come in - how do the outcomes relate back not only to the specific objectives (e.g., food supply), but to the broader objectives (e.g., population growth, survival).

The adaptive management phase involves not only the analytical element, but the synthesis/interpretation component – what does analysis comparing projected and actual outcomes mean in terms of the objectives, identification of limiting factors, goals, or problem statement? To be effective, adaptive management needs to be part of the process, not an add-on at the end or a post-facto component once the actions have been taken. The details of adaptive management are missing from the logic chain.

There are two aspects of the hypothesis testing/analysis/interpretation components that must be distinguished: (1) the “virtual,” in which the analysis is conducted as a sophisticated conceptual or analytical modeling exercise, to explore the *anticipated* consequences of a conservation measure and the adaptive management loop; and (2) the “real,” in which the conservation measure has been implemented and we are looking at what *actually* results.

An Alternative Approach

Although there is much of value in the logic-chain approach, our evaluation and comments suggest that there is room for improvement, especially to clarify some of the logical relationships in the logic chain. We offer here an alternative approach that incorporates elements of the logic chain. The following diagram traces the main elements of this approach; the following comments are keyed to the numbered sections in the diagram.



1. At the top of triangle are the recovery/species goals and objectives. Because the BDCP needs to contribute to recovery of the covered species, there must be a clear link to the needs of those species. This is best defined by existing recovery plans for the species. If a recovery plan is not available, the responsible agencies should provide guidance on appropriate goals and objectives for the species as a whole.

2. The contribution to recovery made by BDCP is not predefined. Expert opinion and conceptual models of the species can be used to identify limiting factors/stressors for the species; BDCP should further select those limiting factors/stressors that can be addressed by the potentially regulated entities (PREs) and that occur within the planning area. From this subset of limiting factors, BDCP can then identify more specific goals and objectives that are within its scope and that are scaled by the level of effort envisioned for the Plan.

3. Conservation Measures must be identified that have the capacity to achieve the BDCP goals and objectives. Candidate measures can be screened using simple models (e.g., conceptual, statistical) to assess potential outcomes, both positive and negative. After

screening an initial list of conservation measures, some BDCP goals and objectives may appear unlikely to be addressed; additional conservation measures should then be developed and/or the BDCP goals and objectives should be revisited to ensure that their scale and scope generally match with the level of effort envisioned for the Plan.

4. Once the types and overall scale of the conservation measures have been determined, they can be further developed to the ‘project level’ and more specific expected outcomes identified. At this level of specificity, models of all types can be used to apply cause-effect relationships and find outcomes that achieve BDCP goals and objectives (and identify any potential negative outcomes). Where cause-effect relationships are weak or there is disagreement over the nature or magnitude of outcomes, testable hypotheses can be developed linking the action to the outcome and projects designed to test the hypotheses. The analytical framework for testing these hypotheses (and the necessary mechanistic monitoring) should be developed at this stage, prior to implementation of the projects.

5. Monitoring informs all of these steps. System-level monitoring informs whether goals and objectives for BDCP and the species are being achieved. Compliance monitoring ensures that measures (e.g., actual Old and Middle River (OMR) flows, elevation of grade or fill, water quality standards) are being implemented as expected. Performance monitoring is used to tell whether a conservation measure is achieving the expected outcomes, and mechanistic monitoring provides diagnostic information on why the expected outcomes are or are not being achieved. These types of monitoring are described in the Independent Advisors’ Report on Adaptive Management.

6. Once projects have been implemented and monitoring data are available, the key adaptive management step of Analyze, Synthesize and Evaluate must be conducted to: a) assess performance; b) inform adjustments to implemented projects and future actions; c) incorporate information as part of the knowledge base and; d) utilize information in models for future use in the planning process. This is the essence of adaptive management.

Linking Conservation Measures to Outcomes: Issues of Study Design, Quantification, Metrics, and Monitoring

Specific conservation measures provide the opportunity to develop clear hypotheses that predict outcomes, require rigorous quantification, and lead to well-designed studies with defined metrics and monitoring approaches. Conservation measures exert themselves at a variety of spatial scales. For example, reduction in a specific stressor might produce a response at the scale of the entire Delta while a habitat restoration project will impact a specific location. Study designs must necessarily consider the spatial component of the conservation measures and monitor appropriate response variables to the action. Study designs also must consider appropriate analytical frameworks for comparing responses to the actions. Will evaluation of the conservation measure be compared to a long-term trend, a control site, or a change in trajectory within a specific location? Scientists should be engaged to address the challenges of designing studies that effectively evaluate whether implemented conservation measures are yielding desired outcomes. This is an area where scientific expertise should be focused rather than on identifying overarching goals and objectives.

Well-designed studies linked to specific conservation measures are critical for developing the larger integrated monitoring framework. Finite resources will be available to evaluate the effectiveness of conservation measures agreed upon through BDCP. The sooner that study designs with designated metrics and monitoring locations are developed for each conservation measure to be implemented, the more readily can decisions be made on the best package of metrics to deploy, the locations for these measurements, and the analytical framework for data analyses. These decisions are integral to application of adaptive management, communication of outcomes from specific conservation measures, and informing decision-makers on management actions. These steps must be carried out within the context of the overall planning effort and not left until later.

The Role of Adaptive Management

In a system as complex as the Bay-Delta, involving multiple constituencies and numerous projects that entail huge investments, it is essential to avoid costly mistakes. The focus of the logic-chain approach on defining meaningful goals and objectives for BDCP is an important part of a successful planning process. It is also an essential element of adaptive management, which itself must be a core part of BDCP. Much has been made of adaptive management and its role in effective conservation and management. *Real* adaptive management, however, is rarely undertaken. In particular, the part of the process that involves assessment and synthesis of information gained after actions have been taken is often neglected or short-circuited, and the critical phase of linking that knowledge to decisions about whether to continue, modify, or stop actions, refine objectives, or alter monitoring efforts is usually missing. The report of Independent Science Advisors on Adaptive Management to the BDCP Steering Committee provides detailed guidance that should be incorporated into any logic-chain approach in BDCP.

Several aspects of adaptive management merit particular attention in relation to the logic-chain approach. First, adaptive management must begin with a clear definition of the problem to be addressed and the goals and objectives to be met. The hierarchical structure of logic plans helps to bring clarity to these statements of goals and objectives. Second, models can play a valuable role in adaptive management. Many of the conservation measures being proposed for the Bay-Delta are large and expensive; simulation or scenario models can be used to explore the likely outcomes of these measures before actually implementing the measures, and this information can be used in an adaptive-management framework to adjust goals, objectives, hypotheses, or measures as appropriate. Third, the adaptive-management phases of assessment, synthesis, translation, and communication must be integral parts of either model-based or actual implementations of adaptive management. Little is accomplished by producing model output or monitoring following the implementation of conservation measures if the resulting information does not make its way, in a carefully evaluated and readily comprehensible form, into the decision-making process.

Prioritization and Sequencing

The successful development of quantifiable objectives for BDCP will provide added benefits by allowing the expected outcomes of individual conservation measures to be compared to one another and used with other data to prioritize and sequence implementation. Measures with more significant outcomes and a broader range of species to benefit will be identified. Together with cost information (including the potential for negative outcomes), this information can be used by BDCP to develop a prioritized list of conservation measures, with the order of implementation being dependent upon decision criteria such as risk tolerance, availability of funds, cost relative to expected benefit, water requirements, and ease of implementation. For example, an implementation plan could sequence high-priority projects based on costs and reliability of benefits to seek to achieve early successes at minimal cost. Well-developed decision-support tools, such as ecological risk assessment or return-on-investment analysis, should be incorporated into the prioritization process.

APPENDIX 1

Specific Questions to the Panel and Panel Responses

The charge to the Review Panel included several specific questions. Here are our answers; the main body of the report describes our responses, evaluations, and suggestions in greater detail.

Purpose

- Does the framework reflect the recommendations made in February 2009 by the BDCP Independent Science Advisors' Report on Adaptive Management? *No*
- Can the framework adequately serve as a basis for refining the BDCP goals and objectives and developing an adaptive management plan? *Yes, if developed fully*
- Is the logic framework clearly defined and described? *Only partially*
- Is it internally consistent? *It is not consistent in how hypothesis testing is being employed*
- Is it clear for what purpose and how the framework might be used? *Yes, although greater clarity in linking BDCP goals and objectives to conservation measures and outcomes would be an improvement*

Approach

- Are the linkages between elements of the framework clear? *Yes*
- Is the relationship between recovery plan goals and BDCP goals and objectives clear? *No*
- What level of detail is necessary for the goals and objectives and for the framework in general? *Recovery/species goals and objectives can be stated qualitatively if sufficient detail is not available; BDCP objectives can be stated qualitatively or with order-of-magnitude approximations in the early planning stages, but with greater quantification as the plan is finalized for implementation; expected outcomes to conservation measures should be stated in sufficient quantitative detail to permit measurement, analysis, and testing of hypotheses.*
- Is the current use of conceptual models and hypotheses clear and helpful? *Only partially; currently the hypotheses are in the wrong place in the logic chain.* If not, how might this be changed or refined? *We have offered a refinement of the logic chain approach that improves clarity*
- What are the next steps regarding populating the logic chain? *General goals and objectives should be defined and populated by the appropriate regulatory agencies; it should be an immediate priority to develop clearer, more concise language and to find consensus on goals and objectives within the BDCP steering committee*
- What, if any, future role/need is there for additional scientific input? *The hypotheses linking conservation measures to projected outcomes, the design of studies to assess these linkages, and the framework for implementing adaptive management would benefit from additional scientific input*

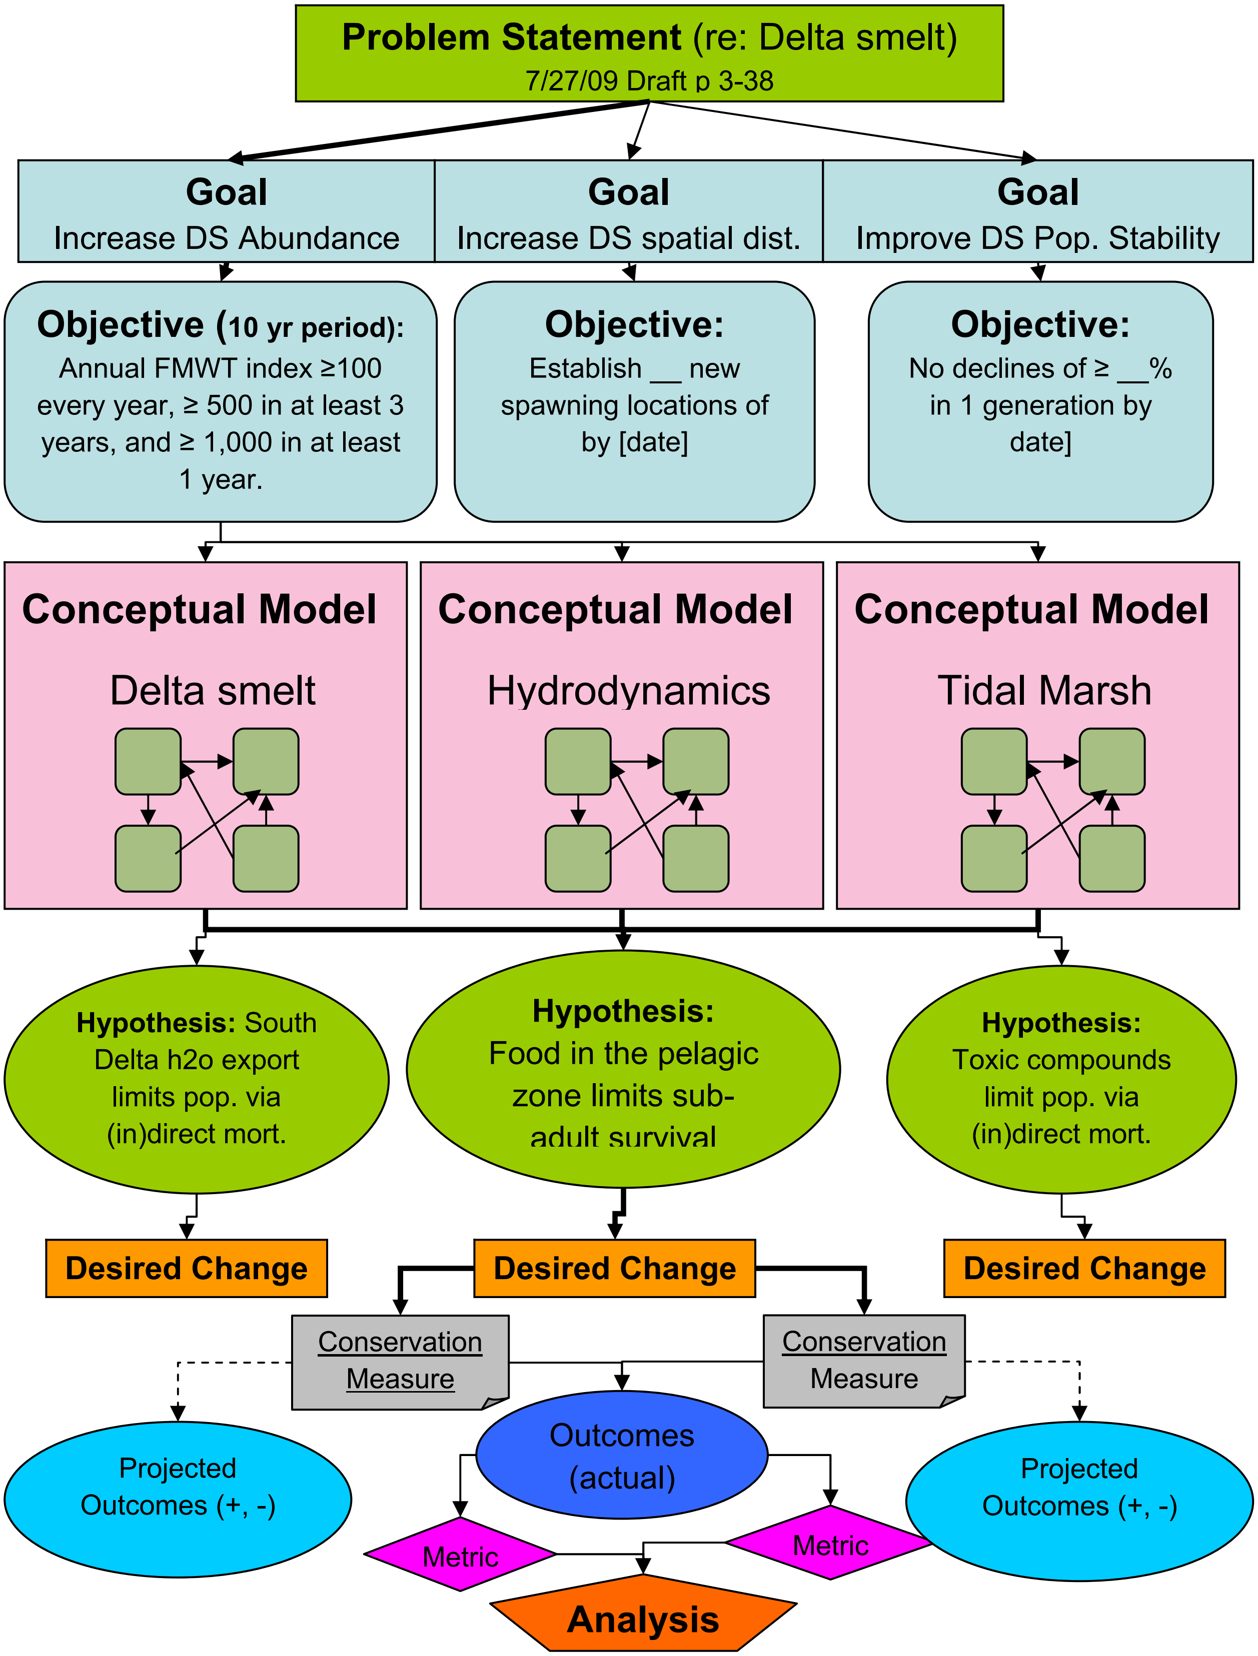
Feasibility

- Is the framework approach feasible to implement? *Yes, if done so in a focused manner*

- If not, what can be done to streamline or phase the approach? *Conduct a complete logic chain assessment for 2-3 species as proof of concept*

APPENDIX 2

The Current Version of the Logic Chain for Delta Smelt
(Appendix B of the Logic Chain provided by American Rivers and The Bay Institute)



Problem Statement (re: Delta smelt)
7/27/09 Draft p 3-38
Goal
Increase DS Abundance
Goal
Increase DS spatial dist.
Goal
Improve DS Pop. Stability
Objective (10 yr period):
Annual FMWT index ≥100 every year, ≥ 500 in at least 3 years, and ≥ 1,000 in at least 1 year.
Objective:
Establish __ new spawning locations of by [date]
Objective:
No declines of ≥ __% in 1 generation by date]
Conceptual Model
Delta smelt
Conceptual Model
Hydrodynamics
Conceptual Model
Tidal Marsh
Hypothesis: South Delta h2o export limits pop. via (in)direct mort.
Hypothesis: Food in the pelagic zone limits sub-adult survival
Hypothesis: Toxic compounds limit pop. via (in)direct mort.

Summary Findings and Recommendations

Panel findings and recommendations are summarized below according to the three primary goals of the logic chain approach.

Develop reasonably achievable BDCP objectives and conservation measures that contribute to broader species recovery goals.

The logic chain structure could be simplified to reduce the number of objective statements and to focus BDCP objectives. Recommended changes to the logic chain structure are shown in Figure 2. Specific findings and recommendations include:

- The identification of "BDCP" goals and objectives, versus global goals and objectives, is very important. The structure of the upper portion of the logic chains needs to be agreed upon for the logic chains to be effective.
- Identify stressors prior to the development of BDCP objectives. BDCP objectives should be linked to specific stressors, and stressors to both BDCP and global goals.
- Explicitly identify stressors that are outside of BDCP's management zone in the logic chains.
- Whenever possible, focus BDCP objectives on measures of individual and population-level performance, such as habitat-specific estimates of growth and survivorship, quantitative estimates of abundance, and quantitative measures of movement and/or distribution.
- Consider developing logic chains for selected key community and ecosystem properties to capture outcomes associated with certain conservation measures that are not obvious from piece-wise presentation among species-specific logic chains.
- Include estimates of magnitude and certainty to facilitate prioritization of conservation measures and to aid in future adaptive management. Estimates of both the magnitude of effects and their associated certainty can be done in narrative form with supporting documentation.
- Retain flexibility to tailor logic chains for each species, recognizing the trade-off between consistency and uniqueness. For example, although the four Viable Salmonid Population (VSP) characteristics should be important in conserving most fish populations, a simpler structure may provide more biologically realistic logic chains for species like delta and longfin smelt.
- Consider a workshop with technical experts for each species, with the goal of preparing a simpler "influence diagram".
- Adjust the format and presentation of the chains to make them more readable.
- Minimize "insider" information and poorly-defined jargon in the logic chains. Terms like "productivity", as used in the logic chains, are generic terms, and not sufficiently specific to ensure clear goals or objectives.

Describe possible metrics designed to monitor and evaluate the effectiveness of implementing the BDCP conservation measures.

- Great care should be used when populating the compliance and performance monitoring boxes in the logic chain. Three levels need to be considered separately: 1) the level that addresses the Global Goal, 2) the “covered activity” level, and 3) compliance monitoring, which measures implementation of the planned conservation measure.
- Although the Panel sees a distinction between annual abundance indices and BDCP performance metrics, the Panel strongly recommends that the BDCP performance metrics be related to fish vital rates (reproduction, growth, mortality).
- Contribute funding to creating and maintaining a repository of data, similar to the National Science Foundation’s Long-Term Ecological Research site network.
- Identify the key unknown biological attributes of covered species, and commit to long-term sampling and focused studies on fundamental biology and ecology of species to be paired with that centered on solving immediate problems related to water management.

Link implementation of conservation measures, through monitoring and evaluation, to the adaptive management program.

- Clearly identify the management goals that can be addressed via adaptive management (sensu Walters 1986) in the draft Plan (i.e., by November), those that can be addressed during the subsequent refinement phase (prior to the formal permit issuance), and those that can only be addressed during implementation.
- A programmatic approach to research should be developed for early adoption, even prior to permitting, and the post-permitting adaptive management approach must be described and finalized as soon as possible, so that conservation measures and post-implementation monitoring can be refined and developed using that research.
- Consider an objective process for developing an implementation plan that acknowledges: (1) the certainty of achieving expected outcomes; (2) that not all measures can be implemented immediately; (3) that not all will achieve their ultimate outcomes immediately, and (4) that some are contingent on the success of others (perhaps using optimization or other approaches as suggested by the first Logic Chain Panel) to provide more realistic expectations of how the system might change as a result of the Plan.
- Consider using a formal decision support system (one that allows for incomplete information, generalized relationships, uncertainties etc.) to identify high priority measures and those for early implementation.
- Develop an adaptive management plan in sufficient detail for the November Draft Plan so it is clear to all participants which procedures will be used to revise BDCP objectives and how additional information, especially reduced uncertainty, will be incorporated into the Plan during implementation (i.e., revisiting the logic chains).
- Comprehensively articulate conservation outcomes based on the logic chains, including their spatial distribution, at decadal intervals to provide a realistic expectation of the changes expected as a result of plan implementation.

1. Background

The Bay Delta Conservation Plan (BDCP) is being prepared through a collaboration of state, federal, and local water agencies, private enterprise, state and federal fish agencies, environmental organizations, and other interested parties to obtain permits under federal and state endangered species acts. The plan will identify a set of conservation measures that will provide for changes in conveyance and operations of the State and federal water projects, operations of Mirant power generation, reductions of other stressors, and habitat restoration actions to contribute to the recovery of endangered and sensitive species and their habitats in California's Sacramento-San Joaquin Delta. The goal of the BDCP is to provide for both species and habitat protection and improved water supplies.

The logic chain approach has been developed by the BDCP Steering Committee to provide a framework and planning tool for:

1. Developing reasonably achievable BDCP objectives and conservation measures that contribute to the broader (global) species recovery goals;
2. Describing possible metrics designed to monitor and evaluate the effectiveness of implementing the BDCP conservation measures; and
3. Linking implementation of conservation measures, through monitoring and evaluation, to the adaptive management program.

An earlier version of the Logic Chain approach was reviewed in March 2010 by a panel convened by the Delta Science Program (Dahm et al., 2010). This second Review Panel was also convened by the Delta Science Program on August 4 and 5, 2010 and was supported by Delta Science Program staff, including Cliff Dahm and Elizabeth Soderstrom, and BDCP support contractors including Bruce DiGennaro of the Essex Partnership, Wayne Spencer of the Conservation Biology Institute and Kateri Harrison of Swale Consulting. The agenda for the second review meeting is included as Attachment 1.

2. The Charge

This Review Panel was charged with focusing on:

1. Assessing populated logic chains to evaluate internal logic, measurability, linkages between plan components, and consistency in approach;
2. Recommending alternative strategies or metrics for identifying progress towards meeting goals and objectives or alternative ways of framing goals and objectives such that they are practicable; and
3. Offering advice on constructing an integrated monitoring and evaluation program linked to the logic chains.

Other topics suggested by the BDCP and included in the charge to the Panel were:

4. Discussion and review of metrics and how they provide a context for design of measureable, practicable BDCP Objectives and Stressor Sub-objectives.
5. Discussion of current and potential future monitoring within this system to create a context for objectives that will be measureable and practicable that will support adaptive management in the future.

The Panel members were asked to review four logic chains: longfin smelt (*Spirinchus thaleichthys*), winter-run Chinook salmon (*Oncorhynchus tshawytscha*), and white and green sturgeon (*Acipenser transmontanus* and *A. medirostris*). The Panel focused their efforts on reviewing the longfin smelt and Chinook salmon logic chains because these were the most complete. Although no members of the Panel currently conducts research specifically on any of these species, several have previous experience working in these environments and with estuarine species, and so represent an experienced group of fish biologists and natural resource scientists. Therefore, the Panel reasoned that the logic chain architecture and presentation should be clear and apparent to them, with minimal additional information required and the comments and recommendations provided in this report are based on that reasoning. This report includes some general observations on progress since the previous logic chain review panel and provides some recommendations on logic chain structure, content and use within the BDCP planning process. Key comments and recommendation are shown in bold italics in the text.

3. Progress to Date

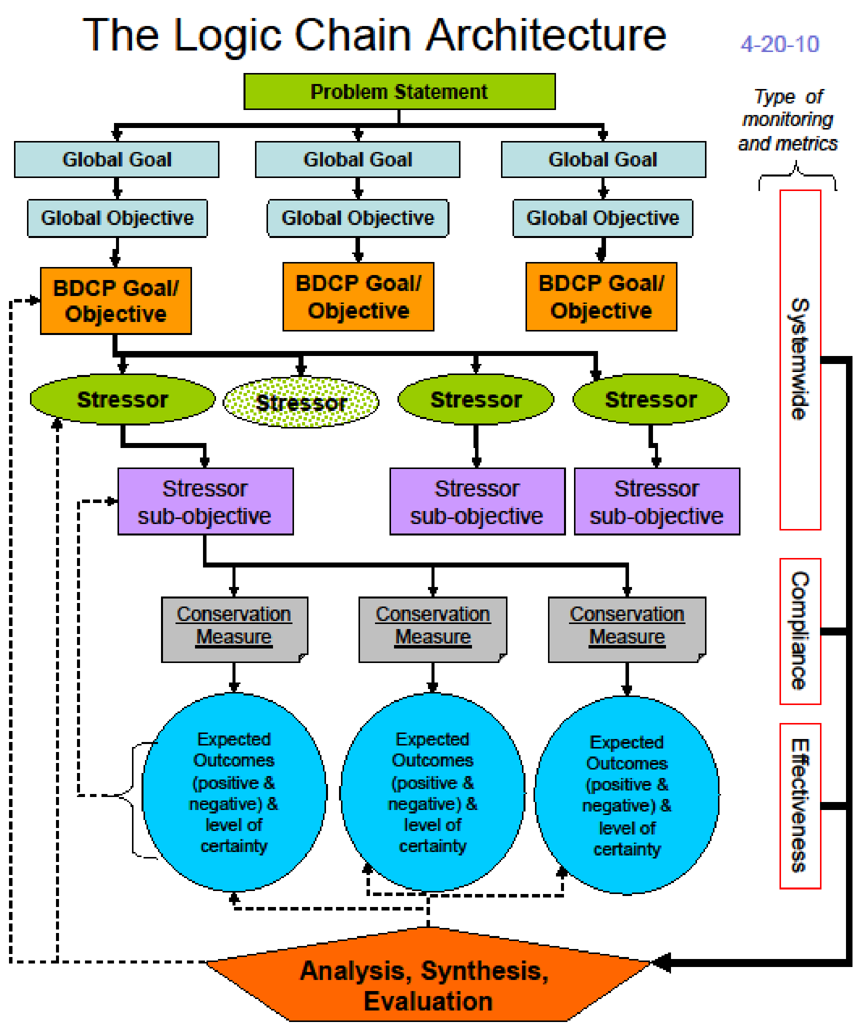
The Panel was impressed with the tremendous amount of work and detail that went into development of the two example logic chains. Conceptually, the logic chain approach will aid in identifying how conservation measures influence the key stressors affecting fish populations in the Delta as well as those affecting the ecosystem as a whole. The Panel appreciated that the logic chain structure enables the chains to capture many of the potential factors affecting the species involved. The two examples reviewed in detail by the Panel (longfin smelt; winter run Chinook salmon) seemed to be relatively complete in terms of accounting for possible stressors, and how conservation measures fit into the overall Bay Delta Conservation Plan. The example logic chains were well thought-out and documented, given the data available.

The Panel also noted that the BDCP team was responsive to the earlier review of the logic chain approach (Dahm et al., 2010). In particular, the two examples and the presentations made by the BDCP team members reflected steps 1-3 proposed in the earlier review. These recommendations were: detailed preparation of logic chains for 2-3 species, development of upper portion of the logic chain (additional comments on this aspect are provided below), and collaborative development of the middle portion of the logic chain. The Panel notes that other comments in the earlier report also were considered, such as the use of metrics that were clearly linked to biological functions for evaluating conservation measures and the inclusion of, and distinction between, compliance and performance monitoring. The use of the conceptual models from the DRERIP evaluation as one of the building blocks for the logic chains, at least at this stage of their development, is endorsed by the Panel.

4. Logic Chain Structure

The Panel recommends several changes to the original logic chain structure (Figure 1) which are described below and in Figure 2. In order to clearly illustrate our suggested revisions, we prepared a hypothetical (and overly simplified) logic chain for longfin smelt (Figure 3) that includes one possible conservation measure.

Figure 1. Logic Chain Structure presented to the Review Panel

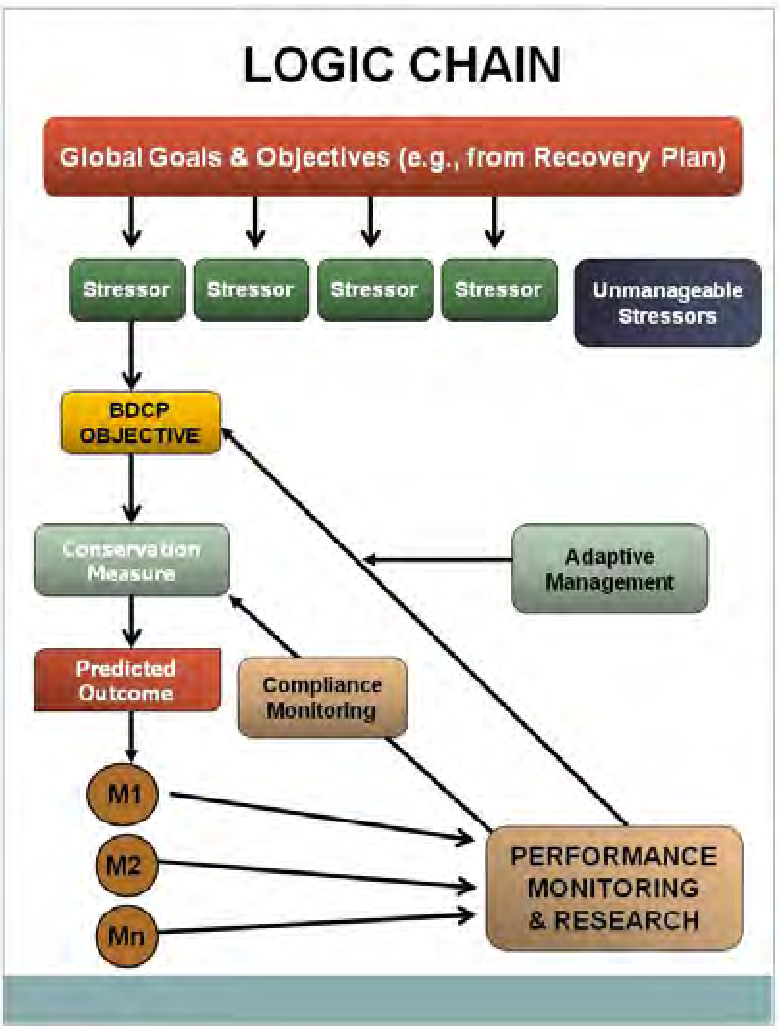


Schematic of the Logic Chain architecture for one species. One stressor (dappled green) is outside of the BDCP purview; thus it has no associated BDCP goal. In this example, stressors and steps below this level refer to one of the BDCP objectives; other BDCP objectives would be developed simultaneously. Similarly, for illustration purposes, only one stressor sub-objective is developed here. Dashed lines refer to different types of evaluations (based on monitoring data) that will be used to adaptively manage within the conservation strategy.

4.1 Goals, Objectives and Stressors

The structure of the upper portion of the logic chains needs to be agreed upon or else the logic chains will be ineffective. The Panel recognizes the importance of all parties agreeing upon a clear statement of goals and objectives and identifying the role of BDCP in achieving them. As presented to the Panel, the logic chains included a problem statement as well as both global goals and objectives and BDCP goals/objectives (Figure 1); this resulted in difficulties in identifying

Figure 2. Proposed Revised Logic Chain Structure. See text for explanation. M1, M2 and Mn refer to an indeterminate number of metrics developed for use in monitoring of the conservation measure and predicted outcomes.



the scale at which conservation measures were to be evaluated (i.e., the global context or a BDCP context). It also appeared to the Panel that the BDCP team was having difficulty resolving some of the wording of the goals and objectives – a very important element of the logic chain approach in that it sets expectations regarding the scope of BDCP 'responsibilities' for meeting the conservation outcomes. The responsibility for species recovery is determined by the ESA, and how recovery is measured is determined by the US Fish and Wildlife Service (USFWS) and NOAA Fisheries. How is the global goal for recovery of endangered species (set by the agencies) linked to the BDCP goals? These links need to be made explicit.

The Panel endorses the recommendation of the previous logic chain review panel (Dahm et al., 2010) concerning the placement of the stressors within the logic chains, and expands on that earlier recommendation here. In the logic chains, BCDP objectives should be linked to specific stressors, and stressors to global goals. For example, for the stressor of "insufficient flow through the Yolo Bypass", the conservation measure would be to increase flows and the BDCP objective(s) could be to increase survival and successful migration of juvenile Chinook salmon, and increase juvenile foraging habitat for sturgeon.

It is important to recognize within the logic chain structure that BDCP will not address all of the stressors identified by the recovery plans. Those not addressed can be grouped together in the logic chain and identified as "unmanageable stressors." It should be clearly stated whether they are unmanageable because BDCP has not identified any appropriate conservation measures, because they are simply not influenced by any management actions under the auspices of BDCP (e.g., they are associated with ocean, or upstream factors), or they are not under management control (e.g., droughts).

To address these issues the Panel recommends the following changes to the upper sections of logic chain structure:

- ***Distinguish between Global goals and objectives set by agencies and "BDCP" goals and objectives.***
- ***Stressors linked to the global goals and objectives should be considered prior to the identification of BDCP objectives.***
- ***Stressors not potentially influenced by BDCP should be explicitly listed in the logic chains.***

The Panel's recommended structure reduces four levels (Problem, Global Goal, Global Objective and BDCP Goal and Objectives) to two levels (Figure 2). The problem in general will be described elsewhere in the Plan and Global Goals and Objectives should be derived from existing recovery plans or provided by resource agencies.

4.2 Monitoring Metrics

The Panel discussed at length compliance and performance metrics for monitoring. It was not clear that the monitoring approach within the logic chains focused on vital demographic rates and population-related parameters that are directly related to rates of population change. The global goals and objectives will relate to the recovery of the species, which the Panel assumes will be assessed by the agencies and that will include some sort of annual abundance index. Compliance and performance metrics would be the responsibility of BDCP. Compliance monitoring is designed to confirm that the conservation measure was achieved, whereas performance monitoring is designed to evaluate how well the expected outcomes of the conservation measure are being achieved[1]. It is critical to utilize performance metrics that reflect the spatial and temporal scales of the specific conservation measure and its expected local biological effect. This not only allows for the success of the conservation measure to be evaluated as part of adaptive management, but also provides information on possible causes of changes in the abundance indices when such changes are detected. However, the Panel does recognize that, in some cases, performance metrics can be based on the annual abundance indices if that is appropriate for evaluation of the effects of a specific conservation measure. Ultimately, local performance measures must be considered in the context of trends in abundance indices to assess the population-level effects of the conservation measure.

Within the revised logic chain structure, multiple monitoring metrics are shown related to each conservation measure and its expected outcome. This performance monitoring can then be used within an adaptive management framework to evaluate BDCP objectives (Figure 2). The revised structure also specifically notes the need for compliance monitoring to determine that conservation measures were implemented as expected. In addition to these clarifications within the logic chain, the Panel recommends that:

- ***Whenever possible, objectives of the chains should focus on measures of individual and population-level performance, such as habitat-specific estimates of growth and survivorship, quantitative estimates of abundance, and quantitative measures of movement and/or distribution.***
- ***The BDCP performance metrics must relate to fish vital demographic rates.***

[1] See Science Advisors Report on Adaptive Management (Dahm et al., 2009) for more on different types of monitoring.

4.3 Explicit Treatment of Uncertainty

The logic chains appeared to take a static approach to ecosystem processes, and did not explicitly consider uncertainty. Yet everyone recognizes that conditions in the Delta are not at equilibrium. The logic chains will likely need to consider variation in physical and biological factors for wet, dry, and “average” years. The concept of tailoring performance metrics to the water year type adjusted for flow variation seems promising. The example logic chains presented to the Panel do not include estimates of either the magnitude or uncertainty associated with a given conservation measure and its expected outcome. Some information on magnitude and uncertainty was presented in the logic chains provided to the Panel as part of the DRERIP evaluations, but it was unclear how this information was to be incorporated into the BDCP logic chains.

The Panel recommends that:

- ***Given the 50-year projected life of the BDCP, issues like climate change and continued invasion by non-native species need to be considered.***
- ***Magnitude and uncertainty estimates should be included to facilitate prioritization of conservation measures and aid in future adaptive management. Estimates of both magnitude of effects and their associated uncertainty can be done in narrative form with supporting documentation.***

4.4 Focus of Logic Chains

The current logic chains are species - based, which is appropriate given that the species involved have different life histories and ecological requirements; however, this separation can only result in successful management when the ecosystem context of the species is explicitly recognized. In addition, there may be both positive and negative effects at the community and ecosystem levels associated with certain conservation measures that are not obvious from piece-wise presentation among species-specific logic chains. This could be achieved by including the community and ecosystem aspects in each species logic chain but broader implications could be lost.
The Panel recommends that:

- ***In addition to covered species, the BDCP Steering Committee should consider developing logic chains that focus on key community or ecosystem properties.***

4.5 Example of Revised Structure

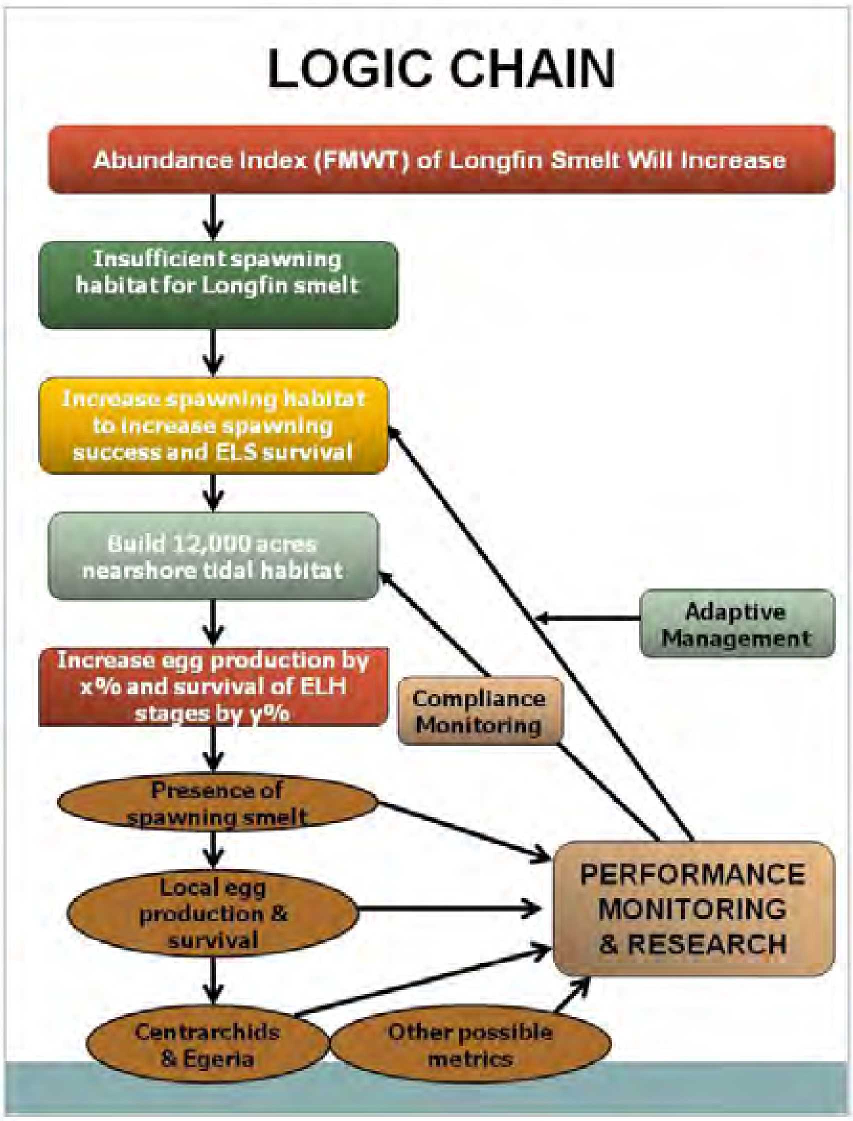
To illustrate the different levels in the revised structure and the linkages among them, the Panel outlined an example application for one line in the chain (i.e., one stressor, one BDCP objectives, one conservation measure for that objective, etc.). This is shown in Figure 3. A completed logic chain would have multiple branches from each stressor, objective, conservation measure and outcome. This example does not include uncertainties as recommended above. These could be identified on the diagram using a color coded key or in supporting narrative.

In our example logic chain (Figure 3), the global goal is to increase the Fall Mid-Water Trawl index and a stressor is insufficient spawning habitat for longfin smelt, and underneath this in the chain is a potential BCPD objective of creating nearshore tidal habitat. The conservation measure deemed to meet that objective was to build 12,000 acres of nearshore tidal habitat to increase spawning, overall egg production and survival of early life stages. Compliance monitoring would involve measuring how many acres were built. Performance monitoring would measure the presence of spawning smelt (i.e., smelt did use the new habitat), quantifying local egg production and survival (i.e., the new habitat is suitable for spawning), and determining whether the new habitat also resulted in increases in invasive competitors and predators such as centrachids and *Egeria* (i.e., were there negative consequences?).

5. Logic Chain Content, Format and Knowledge Base

After evaluating the general structure of the logic chains, the Panel examined the information required to populate (i.e., assign information) and interpret the logic chain. These comments and recommendations pertain to how the information is presented, its sources and how knowledge should be organized to support development and evolution of the logic chains.

Figure 3. Outline Example of Revised Logic Chain Structure for longfin smelt. Refer to text for additional explanation.



5.1 Logic Chain Content

Although the four characteristics that form the basis of the viable salmonid populations (VSP) approach are important in conserving most fish populations, a simpler structure, where some characteristics are combined or down - weighted in importance, would aid in creating more biologically realistic logic chains for species like the two smelts. There may also be other aspects of the logic chains that require a tradeoff between consistency and uniqueness among species. The Panel suggests that greater flexibility be used so that the logic chains can be tailored to each species. The use of the VSP (McElhany et al. 2000) as a framework for the logic chains is good, but may not be ideal for all species. The four parameters highlighted in the VSP are population size, population growth rate, spatial structure, and life history and genetic diversity. The VSP approach is useful because it focuses on the intersection of spatial and temporal scales around which managers make water resource decisions, and over which fish populations and metapopulations carry out their life cycles (e.g., Fausch et al. 2002; Fausch 2010). However, the use of the VSP framework for all species may result in forcing a salmonid-based framework on species for which it is inappropriate. For example, what is known about life-history diversity for Delta smelt, and how important is it?

Terms like "productivity", as used in the Logic Chains, are generic terms, and not sufficiently specific to ensure clear goals or objectives. Clear terms are needed for clear communication. The term productivity allows users to conjure up their own specific meaning. It becomes clear on further reading that the goals really involve vital demographic rates (e.g., reproduction, survival, and growth). The term "production" has a specific meaning in fish population biology. This term refers to the total increase in biomass (fish tissue) within the fish population during a time interval, including that lost through mortality (Chapman 1978). In practical terms, it is the product of the mean biomass in the population times its growth rate, usually measured at rather frequent intervals, especially during the season that fish are growing rapidly. Thus, the units of production are g/m^2/year of tissue produced. Avoid vaguely defined terms and define what is meant.

Great care should be used when populating the compliance and performance monitoring boxes in the logic chain. Three levels needs to be considered separately: 1) the level that addresses the Global Goal, such as measuring adult sturgeon returning to spawning areas or the FMWT index for smelt, 2) the "covered activity" level (e.g., Yolo Bypass), to assess how a specific conservation measure action at a local-to-regional scale affects appropriate abiotic and biotic variables, and 3) compliance monitoring, which measures that the conservation measure was implemented as planned. Dealing with the specifics of the monitoring will have a great influence on the adaptive management and evaluation of the BDCP. The revised logic chain tries to emphasize this by delineating measurements at these three levels. Often, measurements for the first level are used by the USFWS and NOAA-Fisheries to monitor the status of the species. At the second level, although physico-chemical variables can be used as performance metrics, variables that directly relate to fish processes and vital rates must also be included.

In most cases, measuring vital demographic rates as part of performance monitoring is possible, though technically and analytically challenging. For example, for the Yolo Bypass, Chinook salmon smolt output downstream, and adult salmon and sturgeon passage upstream, could be explicitly measured. For smolts, capture-recapture methods (i.e., marking and recapturing individuals) focused explicitly on estimating abundance and survival (where appropriate), and the uncertainty in these parameters (i.e., confidence intervals), have been available for more than two decades (see Burnham et al. 1987; White and Burnham 1999), but application of these methods requires trained field biologists, often large field sampling programs, and biometricians with expertise in analyses of these data (for an example with spotted owl management, see Burnham et al. 1996).

5.2 Logic Chain Format

The logic chain should provide a mechanism by which biologists and decision makers can easily grasp the information, while retaining supporting documents that provide the details about all possible stressors and conservation measures. One solution would be a workshop with technical experts for each species, with the goal of preparing a simpler "influence diagram". In their deliberations, the Panel worked with the example logic chains, and found the extensive and complicated supporting materials challenging to both read and understand. This certainly is a consequence of trying to abstract the critical features from a complex and variable system. Nonetheless, the massive tables of goals, objectives, stressors, conservation measures, and expected outcomes hamper understanding and indentifying key issues for each species, and hence make it difficult for general users to prioritize conservation measures. For example, for winter-run Chinook salmon, restoration of floodplain rearing habitat in the Yolo Bypass is likely a key conservation measure which, if addressed, might have the largest positive effect that could contribute to recovery. Such information needs to be readily identified by logic chain users. This problem could be addressed by the development of a simpler 'influence diagram" (a term borrowed from decision theory, such as use of Bayesian Belief Networks; see Jensen 1996; Marcot et al. 2006) for each chain. The diagram could include: 1) the *key* factors that influence habitat, growth, and survival of the target species at the most important life stages, 2) the *key* stressors that reduce these physical and biological attributes, 3) the options for altering these factors, and 4) how these coalesce to influence the key population performance measures (e.g., persistence of the species or stock). Peterson et al. (2008) provide an example application in a much more circumscribed system.

The Panel suggests adjusting the format of the logic chains themselves to make them more readable. The Logic Chain tables presented to the panel used a vertical format in which the reader attempted to work linearly from top to bottom within a "stressor" column, but soon was faced with Expected Outcomes and Risk Factors that did not seem to belong in the column. For example, in the winter-run Chinook salmon table, Stressor 3 addresses Predators and Invasive/non-native species, with a Sub-objective of reducing predation on juveniles by a given percentage by a certain date from Sacramento to Rio Vista. However, the next item working down the table (an Expected Outcome) states "Removal of old structures was not evaluated by DRERIP", which initially the panel did not understand. Likewise, the metric under the next

Expected Outcome down (OCSM13-P4: Reduce predation) includes two statements "Change in biovolume of *Egeria densa* relative to control areas (#20)," and "Change in areal coverage of water hyacinth relative to control areas (#21)". Overall, it was not clear why old structures, *Egeria densa*, or water hyacinth would influence predation, nor was it very clear that Risk Factors encompassed the idea that various conservation measures might have unanticipated negative effects that would cause problems elsewhere. Although it is possible that some of these things are explained elsewhere in material that the Panel did not read, it would be wise to clarify them more for new users.

The Panel recommends minimizing "insider" information and poorly-defined jargon in the logic chains. If the logic chains are expected to present important information in a way that is accessible to the many parties interested in BDCP, it would seem wise to use simpler and more direct statements that the average biologist or policy maker can understand, rather than codes and terms that are familiar only to BDCP personnel (e.g., OCSM13-P4, or Metric #20). Likewise, one could clearly label Risk Factors as Possible Negative Effects of conservation measures, or something similar. However, it is certainly advisable to hyperlink these simpler statements to documents where codes and details used by BDCP from past analyses and plans are found.

5.3 Knowledge Base for Logic Chain Development

Funds need to be targeted to create and maintain such a repository of data, similar to the National Science Foundation's Long-Term Ecological Research site network. The credibility and usefulness of the logic chains are dependent on the quality of the information used to populate them. There is apparently no centralized repository of data and analysis for species covered by the BDCP, and much is unpublished. This prevents reanalysis of past data, and synthesis of new and past data into useful models. The Panel was struck by the realization that data are often in the hands only of the original investigators, multiple versions of the same dataset exist, and data are susceptible to either physical loss (computer crashes, media deterioration) or retirements (the investigator leaves or dies, and much information and interpretation is lost). Given that these data are all that we have from the expenditure of millions of dollars of research and monitoring over many years, this modest investment in standardizing and protecting that irreplaceable knowledge seems self-evident. Although we acknowledge the need for publication by the primary collectors of the data, a central repository will facilitate subsequent analyses by a variety of scientists that will result in the quickest assessment of the biological processes being described.

The Panel recommends that technical experts identify the key unknown biological attributes of covered species, and a concerted effort be made to provide stable funding to address these knowledge gaps. These studies will require long-term efforts, with adequate funding, but will reap long-term rewards. Availability of information for some species and stressors is limited, and this will ultimately limit the usefulness of the logic chains. The logic chains are only as strong as their weakest link and presently that link is basic life history information for many Delta species. Examination of the example logic chains highlighted how information-limited we are for some species and stressors. The Panel was struck by the lack of key biological information for some of the covered species and life stages. Key information such as movement patterns and residence times in various habitats (river vs. delta, north delta vs. south delta) for key life stages in a species life cycle, population structure, habitat-specific growth and survivorship rates, diets over the life cycle, and identification of spawning habitat, are essential to populate the logic chains, yet also are missing or weakly known. This is a common problem, and requires a commitment to long-term sampling and focused studies on fundamental biology and ecology of species to be paired with that centered on solving immediate problems related to water management (e.g., survival through pumps and screens).

6. Applying the Logic Chains in the BDCP

The Panel recognizes that the logic chains can provide a useful tool for organizing current ideas and formulating a comprehensive restoration plan to address BDCP goals and objectives. The approach provides more than just a better articulation of the existing goals – it links actions to those goals and lays out expected outcomes. However, to be used as a key building block for the Plan, it is important that the narrative is scientifically credible and that both potential positive and negative outcomes are considered.

To effectively use the logic chains to build the plan, it will be essential to clearly lay out linkages among logic chains, effects analysis, implementation plan, monitoring and research components, and adaptive management. It is clear to the Panel, and those who briefed them, that there need to be feedbacks between the logic chains and the effects analysis. The effects analysis will become a new and important set of data for the Plan, and the process of incorporation of those data in the decision processes and logic chains needs to be described explicitly.

The Panel recommends that BDCP clearly identify the issues raised by the logic chains that can be addressed in the draft Plan (i.e., by November), or addressed during the subsequent refinement phase (e.g., the following year as the Plan is finalized and prior to the formal permit application), and that can only be addressed during implementation. A programmatic approach to research should be developed for early adoption, even prior to permitting, and the post-permitting adaptive management approach must be described and finalized as soon as possible, so that conservation measures and post-implementation monitoring can be refined and developed using that research.

The Steering Committee should consider using a formal decision support system (one that allows for incomplete information, generalized relationships, uncertainties etc) to identify high priority measures and those for early implementation. The panel believes that BDCP will be most successful if an objective process for implementation is developed that acknowledges: 1) the uncertainty of achieving expected outcomes, 2) that not all measures can be implemented immediately, 3) that not all measures will achieve their ultimate outcomes immediately, and 4) that some are contingent on the success of others (perhaps using optimization or other approaches as suggested by the first Logic Chain Panel) to provide more realistic expectations of how the system might change as a result of the implementation of the Plan. Conceptually, developing the BDCP calls for optimization of solutions for multiple objectives, subject to various constraints. Formal optimization, or at least the thinking underlying optimization, can be applied to subsets of measures and specific spatial regions. The Panel recognized that, unless the intent is to implement every conservation measure currently under consideration, some means of discriminating among conservation measures, in terms of their expected outcomes and the certainty of achieving those outcomes, is needed. Such a structured decision process could also consider issues such as cost, feasibility of implementation, and effectiveness in alleviating stressors. At present, the procedures for making decisions are, at the least, unclear. Transparency is especially important due to the complexity of the issues being addressed and the short time frames within which the Plan is being developed. Although it is unlikely that a formal decision support system could be applied prior to the issuance of the Draft Plan in November 2010, the Draft Plan should include consideration of how such an approach will be used during plan refinement (i.e., post-November 2010).

An adaptive management plan should be developed in sufficient detail for the November Draft Plan so it is clear to all participants which procedures will be used to revise BDCP objectives and how additional information, especially reduced uncertainty, will be incorporated into the Plan during implementation (i.e., revisiting the logic chains). During the Panel meeting there were frequent references to the adaptive management component of the BDCP effort. The nature of the adaptive management plan being proposed by the Steering Committee and how it would be implemented was not clear to the Panel, based on the materials provided. Formal adaptive management, as outlined in Kendall (2001Walters (1986), Stankey et al. (2005), and Nichols et al. (2009), would require clear agreement on the objective to be optimized, and would require specific expertise in decision analysis to apply. As it stands now, adaptive management comes after the Plan has been developed and during implementation, and the Panel is concerned that 'punting' too many difficult issues that far into the future into an undefined process called adaptive management can undermine the credibility of the Plan. Issues deferred to the adaptive management phase should be those which require specific monitoring data, research, and analyses. The more decisions which are left for adaptive management to address, the more important it is that a robust adaptive management plan, in terms of thinking, coordination and funding, be developed.

The Panel recommends a comprehensive articulation of BDCP conservation outcomes based on the logic chains, including their spatial distribution, at decadal intervals to identify targeted outcomes and provide flexibility for changing environmental conditions. Creating appropriate expectations will be important for BDCP. The success of BDCP relies on good science, effective implementation, rigorous monitoring, strong adaptive management, and transparency, and judging the success of the BDCP will be how the results measure up to expectations. On one hand, it is important to emphasize the importance of the positives of the BDCP process. On the other hand, it is also important to ensure that everyone understands what can realistically be achieved and over what time and space scales.

Attachment 1

Logic Chain Review Panel
August 4-5, 2010
Delta Stewardship Council Office, Bay Room
650 Capitol Mall, 5th Floor
Sacramento, CA 95814
AGENDA

Wednesday August 4th

1. **Advisory Panel meets and reviews charge** (panel only) — **8:00 – 8:30**
2. **Presentation on BDCP logic chains, metrics and monitoring** — **8:30 – 10:30**
    a. Overview and Context (15 min)
    Laura King Moon, Wayne Spencer
    b. Logic Chains (1 hr)
    Dave Harlow (winter run chinook salmon, longfin smelt)
    Josh Israel (green and white sturgeon)
    c. Metrics and Monitoring (15 min)
    Cliff Dahm

    d. Example Monitoring Framework (30 min)
    Ted Sommer (Yolo Bypass)
    Chris Enright (Suisun Marsh)

3. **Questions and Discussion** — **10:30 - 11:30**
    Lunch Break — **11:30 –12:30**
4. **Advisory Panel further reviews materials, begins to draft recommendations, and formulates questions** — **12:30 – 5:30**

Thursday, August 5th

1. **Advisory Panel meets with BDCP Team with further questions** — **8:00 – 10:00**
2. **Advisory Panel refines recommendations** — **10:00 – 12:00**
    Lunch Break — **12:00 – 1:00**
3. **Advisory Panel Reports out to BDCP Team and takes comments** — **1:00 – 4:30**
4. **Advisory Panel discusses next steps and writing assignments** — **4:30 – 5:00**

BDCP Agreements

Appendix H-1

January 2006 Statement of Principles

This page intentionally left blank.

Regulatory Commitments – User Contributions
Statement of Principles

Changes in available CALFED funding and the need to enable water supply, water quality, ecosystem, and levee projects to progress within a stable regulatory framework require a new structure that provides regulatory and funding assurances for the key actions described herein.

This Statement of Principles is the foundation for an agreement among the California Department of Water Resources, California Department of Fish and Game, U.S. Fish and Wildlife Service, NOAA's National Marine Fisheries Service, the U.S. Bureau of Reclamation, and others. This agreement proposes to cause (1) the development of one or more Habitat Conservation Plan/Natural Communities Conservation Plan(s) [HCP/NCCP(s)] for the Delta and its upstream basins and (2) the implementation of key, near-term water supply, water quality, ecosystem, and levee actions, subject to compliance with any applicable environmental review under CEQA and NEPA.

The negotiators intend these HCP/NCCP(s) to:

- *Ensure implementation of actions that will adequately conserve and assist in the recovery of fish and wildlife affected by covered activities as a major part of the overall CALFED Multi-Species Conservation Strategy's effort to recover fish and wildlife, and*

- *Provide long-term assurances related to implementation of and operation of designated water and power related projects and associated activities.*

Development and/or implementation of the water-related projects and protection of and recovery efforts for fish and wildlife resources are critical to the people and economy of California.

A key principle of the CALFED Bay-Delta Program is that the elements of the program (ecosystem, water quality, water supply, and levees) should be implemented in a balanced fashion with appropriate linkages among the elements, costs and benefits. This document acknowledges that a long-term water supply, water quality, ecosystem restoration and levee funding framework and a funding program for these actions needs to be developed in a timely manner including a long-term science program.

A process has begun regarding the development of a 100 year vision for the future of the Delta, consistent with AB 1200. This process could provide input and guidance for the HCP/NCCP(s).

DWR and DFG will continue to work cooperatively with the State Water Contractors and other interested parties in developing a separate NCCP to cover existing operations of the State Water Project and the operable gates.

I. Goal

A. The negotiators pledge their good faith efforts to obtain ratification of this presently non-binding Statement of Principles by each of their appropriate authorized persons and/or governing bodies on or before January 31, 2006.

B. Upon ratification, the undersigned negotiators pledge their good faith efforts to work diligently toward a Memorandum of Understanding (MOU) and final written Planning Agreement (the Agreement) that is consistent with the Principles set forth herein.

C. The negotiators anticipate that these Principles will be incorporated into a binding MOU by April 1, 2006.

II. The MOU and Agreement

A. The MOU shall establish the process for developing an Agreement for integrated or coordinated Habitat Conservation Plans ("HCP") and Natural Community Conservation Plans ("NCCP") covering the areas set forth in Section II.D.

B. The HCP/NCCP(s) are a mechanism voluntarily entered into, meeting the requirements of the Federal Endangered Species Act (FESA), the California Endangered Species Act (CESA) and the California Natural Community Conservation Planning Act (NCCPA). The Parties and Participants shall seek to structure the Agreement and the HCP/NCCP(s) in a manner that meets FESA, CESA, and the NCCPA and also enables the United States Bureau of Reclamation to be a Party. The Agreement shall address the relationship of the HCP/NCCP(s) to other regulatory actions such as Section 401 and 404 of the CWA, FERC relicensing, or other actions as appropriate. Actions proposed under the Agreement may be subject to compliance with any applicable environmental review under CEQA and NEPA.

C. Conservation strategies will be developed to contribute to regulatory compliance strategies, *inter-alia,* under Section 7 of the FESA and the HCP/NCCP(s).

D. Scope

The Agreement and the HCP/NCCP(s) shall identify covered activities and covered species which utilize the Delta, the Sacramento River Basin and the San Joaquin River Basin. The initial list of species to be covered by the HCP/NCCP(s) shall be set forth in an attachment or appendix to the Agreement. It is the intent of the negotiators to limit the Agreement to those fish and wildlife species, particularly state and federally listed delta pelagic and anadromous species that are impacted by covered activities. Covered activities shall include water and power facilities and operations. Other activities may be added subsequently.

The negotiators anticipate the following geographic areas:

1. The statutory Delta as defined in the California Water Code plus the Suisun Marsh and Suisun Bay.

2. All or parts of the Sacramento River and its tributaries.

3. All or parts of the San Joaquin River and its tributaries.

4. All or parts of the three eastside streams, the Mokelumne, Cosumnes, and Calaveras Rivers.

This Statement of Principles creates the broadest possible geographic scope and it is possible that it will be restricted in the future, depending on the Parties and Participants of the HCP/NCCP(s).

E. Parties and Participants

1. The United States Fish and Wildlife Service (FWS), NOAA's National Marine Fisheries Service (NOAA Fisheries), and the California Department of Fish and Game (DFG) shall be Parties to the MOU, Agreement and to the HCP/NCCP(s).

2. Persons or entities whose otherwise lawful activities could cause incidental take of threatened or endangered species may comply with FESA and/or CESA by voluntarily electing to become Parties to the MOU, Agreement and the HCP/NCCP(s) prepared under the Agreement. DWR, USBR, and all or some of their water supply contractors may become Parties to the MOU and the Agreement.

3. The MOU, Agreement and the HCP/NCCP(s) shall include provisions for Participants (e.g., an entity that is not a party but involved in an adaptive management committee) including but not limited to environmental organizations, water user groups, and other interested entities.

F. Science and Adaptive Management

1. The MOU and the Agreement shall recognize and provide that the HCP/NCCP(s) be based on the best available science. The development and implementation of the HCP/NCCP(s) shall include a science process that focuses on providing the best available answers to management questions, including measurable objectives that are needed to develop and implement a comprehensive and balanced HCP/NCCP(s), including a monitoring program. All Parties and Participants shall be involved in this science process.

2. The negotiators understand that provisions for adaptive management, oversight and coordination, and independent scientific input will be developed and implemented as part of the HCP/NCCP(s) process and may result in the need to terminate the HCP/NCCP(s) to provide adequate protection of covered species and proceed under regulatory provisions.

3. The Agreement will establish a broad-based adaptive management team comprised of policy and technical representatives who will provide input to the process of developing and implementing any necessary changes resulting from additional information for the HCP/NCCP(s).

G. Interim Projects:

The Agencies (DWR, DFG, FWS, NOAA Fisheries, and USBR), subject to completion of any required environmental review document and permitting, support implementation of the Projects described in Attachments B (water supply projects), C (water quality projects), D (ecosystem projects), and E (levees and other work in the waterways), during development of the Agreement and the HCP/NCCP(s).[1] The agencies are committed to following legal process and to consider all points of view, including those of conservation groups or other water agencies that have expressed concerns with the implementation of these projects. The development of the Agreement and the HCP/NCCP(s) shall not delay the implementation of those interim projects.

1. In the event for reasons beyond the control of the Agencies any interim project is delayed beyond completion of the HCP/NCCP(s), it is anticipated that the HCP/NCCP(s) will advance progress of the interim projects. Execution of the MOU or the Agreement shall not constitute a waiver by any Party or Participant of any right or remedy they may have nor does it constitute agency pre-approval of any project or preferred project

[1] Some parties may not be supportive of the implementation of these Projects at this point.

alternative or waive or otherwise abridge agency Responsible or Trustee duties required, or discretion authorized, under state and federal law.

2. Inclusion of interim projects on Attachments B, C, D or E does not commit state or federal funding beyond that already approved or budgeted for those projects, nor does it constitute agency pre-approval of any project or preferred project alternative or waive or otherwise abridge agency Responsible or Trustee duties required, or discretion authorized, under state and federal law.

3. The MOU and the Agreement will provide a means to augment the project lists set forth in Attachments B, C, D, and E to add additional covered activities if such projects meet agreed upon criteria, including:

    i. They will not result in stranded investments;
    ii. They will not impede development and implementation of the HCP/NCCP(s) (generally consistent with the HCP/NCCP(s) goals);
    iii. Their implementation and operation shall be based on best available science; and
    iv. They are consistent with HCP/NCCP(s) objectives as they are developed.

H. Process for Amendments and Withdrawal

1. The MOU, Agreement and the HCP/NCCP(s) will include a process for amendments, e.g. to include additional covered activities and associated Parties and Participants. The amendment process will be designed to balance the need to be inclusive, the need to be decisive, and the need to complete the HCP/NCCP(s) on time.

2. The MOU, Agreement and the HCP/NCCP(s) will define the criteria and process for early withdrawal.

3. The MOU, Agreement and HCP/NCCP(s) should provide a definition of the criteria for early withdrawal or termination should for any reason the Parties' objectives, including species recovery, not be achieved.

I. If the state imposes fees or an involuntary financial obligation on any water agency or utility signatory to this Statement of Principles for implementation of any CALFED Programs, including the Ecosystem Restoration Program, the Environmental Water Account, or other activities funded under the Statement of Principles or the MOU, the terms of this Statement of Principles and MOU shall terminate. The negotiators recognize that the State is exploring the adoption of a water resources investment fund through an amendment of the California Constitution, and they commit to work cooperatively to develop a water resources investment fund, the implementation of which their principals/boards of directors would support and which would not affect any rights or obligations under the MOU or Agreement.[2]

J. Negotiators agree to work together to establish a structure that will facilitate the design of a functional planning and implementation process, including, if appropriate, an executive director.

III. Near Term Funding

This Statement of Principles proposes to provide, over the next two years, $60 million in contributions for the HCP/NCCP(s), Species Recovery Capital Fund, Ecosystem Restoration Project, POD Studies, and the 100-Year Vision for the Future of the Delta. This $60 million does not include the value of the commitments made pursuant to Section III.E for the Environmental Water Account.

In order to provide sufficient supplemental funds, which when combined with state, federal and other funding that will enable implementation of priority ecosystem restoration projects for Delta pelagic and anadromous fish through the end of Stage 1 (December 31, 2007), the following near-term funding is proposed:

A. HCP/NCCP(s)

1. For calendar years 2006 and 2007, the Central Valley Project and State Water Project (hereinafter referred to as The Projects) shall contribute an aggregate of $3 million annually for the collective use of DFG, USFWS, and NOAA Fisheries for staff and administrative costs related to the development of the HCP/NCCP(s) and regional conservation strategies. The negotiators anticipate that a more informed budget will be developed prior to the execution of the MOU, and the annual contribution may be adjusted with the mutual consent of DFG, USFWS, NOAA Fisheries, the Projects and their water supply contractors signatory to this Statement of Principles.

---

[2] The non-state and non-federal negotiators are in agreement that any mandatory fee, regardless of its use, imposed by the state should be subject to an open public hearing process in which all interested parties have had the opportunity to present testimony on appropriate payments, whether as a beneficiary or as a responsible party. Such conditions should not be construed in any way as support for any mandatory fee.

2. The Projects and other Applicants who have activities that will be covered by the HCP/NCCP(s) will develop a cost-share agreement as part of the application process for the HCP/NCCP(s), which may provide for reimbursement of the Applicants if new applicants are able to utilize work for which the Applicants paid.
3. DFG, USFWS, and NOAA Fisheries will expend contributions made under this section consistent with a work plan developed in cooperation with contributing Applicants.
4. DFG, USFWS, and NOAA Fisheries shall seek additional contributions for agency costs from other HCP/NCCP participants.
5. DFG, USFWS, and NOAA Fisheries will apply for additional funding through a FESA Section 6 application.
6. If new bond funds become available and are appropriated for this purpose, the contributions by the Projects for agency staff and administrative costs shall be reduced accordingly.

B. Species Recovery Capital Fund

1. The SWP shall contribute a total of $12 million to a Species Recovery Capital Fund through the end of Stage 1 (December 31, 2007) for restoration projects.
2. Money in this fund contributed by the SWP shall only be used to fill funding gaps for identified restoration projects and only if all bond money available for and appropriated for these purposes has been committed.
3. Contributing Parties will be actively engaged in the selection and management of restoration projects funded by the Species Recovery Capital Fund.
4. The $12 million in SWP contributions shall be credited towards future Delta pelagic and anadromous fish restoration obligations identified under HCP/NCCP(s).
5. If the HCP/NCCP(s) are not developed the SWP contributions shall be credited towards environmental obligations of the SWP.

C. Ecosystem Restoration Program

1. The State and Federal agencies agree to continue annual contributions of $15 million from the CVPIA restoration fund and Four Pumps Fish Mitigation Agreement towards the Ecosystem Restoration Program.
2. The Parties anticipate that current contributions under the CVPIA, combined with the Four Pumps, Species Recovery Capital Fund and available bond funds will meet the

requirements of the Conservation Agreement for financing the Ecosystem Restoration Program through the end of Stage 1.

D. POD studies

1. For the calendar years 2006 and 2007, the Projects shall continue to contribute up to an aggregate of $4 million annually or additional amounts as necessary upon mutual agreement, to research into the causes of the Delta Pelagic Organism Decline.
2. These contributions do no offset other obligations of the SWP or the CVP.

E. Environmental Water Account

1. DWR and DFG agree to pursue full public funding from the Legislature as provided in the CALFED ROD and the 2004 MOU that extended Environmental Water Account (EWA) through 2007.
2. Until full public funding is made available for the 2005-2006 state fiscal year, and after exhausting all other Tier II assets and in an attempt to avoid the use of Tier III assets, the SWP will loan EWA up to 80 TAF of water to make up for the current funding shortfall. This loan will be repaid with variable EWA assets or financial assets.
3. Sufficient public resources are identified in the 10-Year Action Plan and, if appropriated, will fully fund the EWA through the 2006-2007 state fiscal year.
4. If public funds are not made available to meet the terms of the 2004 MOU and DFG or DWR require the SWP to provide a non-reimbursable fiscal or water contribution to provide adequate resources for the EWA until December 31, 2007, then the SWP may terminate this Statement of Principles in its entirety.
5. The EWA Agencies agree to conduct a comprehensive review of the EWA by July 1, 2007 to determine if the program should be continued and, if continued, how it will be sized, managed, and funded for the 2007-2008 state fiscal year and beyond.

F. 100 Year Vision for the Future of the Delta

1. The Projects and other water and hydropower project operators will contribute 50% of the cost of the process to develop a long-term vision for the future of the Delta up to a maximum of $2 million annually not to exceed $4 million in total.
2. DWR and DFG will obtain at least an equivalent amount of funding from other private or public sources.

3. If bond funding is available for this purpose, the obligations of The Projects and other water and hydropower project operators under Section III.F.1 and the public under Section III.F.2 will be reduced proportionally.

IV. Interim and Long-term Funding

Interim funding before the HCP/NCCP(s) are complete will be developed though the Agreement that will be signed and take effect prior to January 1, 2008. Negotiators will work diligently and cooperatively so as to expedite developing the framework for the planning stage of the HCP/NCCP(s).

Long-term funding in support of the HCP/NCCP(s) will be developed during the planning stage and will contain a financing plan for the term of the HCP/NCCP(s) that provides for contributions from those that choose to participate.

V. Concurrent Linked Actions

This section describes the need to develop plans for long-term programs for the protection and funding of Delta levees and funding and an improved implementing structure for a Long-term Water Quality Program. If these packages are not developed in a timely manner or as outlined below, the agencies agree to inform the Secretary of the Interior and the Governor and to consider this as a substantial factor in annual review of progress and balance under state and federal law. If imbalance is found then the agencies will take the steps required by law, including those measures prescribed by Section 105 (b)2 of the CALFED Bay-Delta Authorization Act, P.L. 108-361.

A. Delta Levees

The negotiators recognize the need to develop a funding plan for a long-term program for the protection and funding of Delta levees. In addition, as the HCP/NCCP(s) is/are prepared, Parties involved in the levee program that need to comply with CESA and FESA can consider whether they would like to have their activities in the program included as covered activities in the HCP/NCCP(s).

B. Long-Term Water Quality

The negotiators recognize a need to establish funding and an improved implementing structure for a Long-term Water Quality Program by April 2007.

Attachment A – Parties

The negotiators for the Parties below have initialed this document as a means of pledging good faith efforts to obtain ratification of the Statement of Principles by each of their appropriate authorized persons and/or governing bodies on or before January 31, 2006.

Joe Grindstaff
California Bay-Delta Authority

For
Ryan Broddrick
California Department of Fish and Game

For
Lester Snow
California Department of Water Resources

Brent E. Walthall
Kern County Water Agency

Timothy H. Quinn
Metropolitan Water District

for
Rodney R. McInnis
NOAA Fisheries

Daniel G. Nelson
San Luis & Delta-Mendota Water Authority

Walter L. Wadlow
Santa Clara Valley Water District

Laura King Moon
State Water Contractors

Jeanne M. Zolezzi, Esq.
Attorney for Stockton East Water District

Kirk C. Rodgers
U.S. Bureau of Reclamation

Steve Thompson
U.S. Fish and Wildlife Service

Thomas W. Birmingham
Westlands Water District

Dale Myers
Zone 7 Water Agency

Attachment A (1) – Participants

The negotiators for the Participants below appreciate participation in this process and pledge to bring this document to their boards or governing bodies for review and further discussion.

Walter J. Bishop
Contra Costa Water District

Thomas Zuckerman
Central Delta Water Agency

Ronald D. Jacobsma
Friant Water Users Authority

Steve Johnson
The Nature Conservancy

Appendix H-2

MOA of Supplemental Funding/Near-Term Water Supply

Memorandum of Agreement
For Supplemental Funding for Certain Ecosystem Actions and Support for Implementation of Near-Term Water Supply, Water Quality, Ecosystem, and Levee Actions

I. Purpose

Changes in available CALFED funding and the need to enable water supply, water quality, ecosystem, and levee projects to progress within a stable regulatory framework require a new structure that provides regulatory and funding assurances for the actions described herein. The foundation for this framework was established in a Statement of Principles agreed to by the California Department of Water Resources, California Department of Fish and Game, U.S. Fish and Wildlife Service, NOAA's National Marine Fisheries Service, U.S. Bureau of Reclamation, and others. This Memorandum of Agreement (MOA) is intended to further:

1. The development of a conservation plan for the Delta and its upstream basins, hereinafter referred to as the Bay Delta Conservation Plan (BDCP) and to obtain the permits necessary to comply with the California Endangered Species Act and the Federal Endangered Species Act; and

2. The implementation of key interim water supply, water quality, ecosystem, and levee projects, subject to compliance with applicable environmental review under CEQA and NEPA.

II. Interim Projects

The Agencies (DWR, DFG, FWS, NOAA Fisheries, and USBR), subject to completion of any required environmental review document and permitting, support implementation of the interim projects described in Attachments B (water supply projects), C (water quality projects), D (ecosystem projects), E (levees and other work in the waterways), and F (project schedules) during development of the BDCP. The current schedules for these interim projects are included in Attachment F and are displayed for information purposes only. The Agencies are committed to following legal process and to consider all points of view, including those of conservation groups or other water agencies that have expressed concerns with the implementation of these interim projects. The development of the BDCP shall not delay the implementation of those interim projects.

1. In the event for reasons beyond the control of the Agencies any interim project is delayed beyond completion of the BDCP, it is anticipated that the BDCP will advance progress of the interim projects. Execution of the

MOA shall not constitute a waiver by any signatory of any right or remedy they may have.

2. Inclusion of interim projects on Attachments B, C, D, E, or F. does not commit state or federal funding beyond that already approved for those interim projects, nor does it constitute agency pre-approval of any project or preferred project alternative or waive or otherwise abridge agency Responsible or Trustee duties required, or discretion authorized, under state and federal law.

3. The interim project lists set forth in Attachments B, C, D, E, and F may be augmented to add additional covered activities if such projects meet agreed upon criteria, including:

   i. They will not result in stranded investments;
   ii. They will not impede development and implementation of the BDCP (generally consistent with the BDCP goals);
   iii. Their implementation and operation shall be based on best available science; and
   iv. They are consistent with BDCP objectives as they are developed.

III. Near-Term Funding

Subject to Section V, this MOA proposes to provide, over the next two years, $60 million in contributions for the BDCP, Species Recovery Capital Fund, Ecosystem Restoration Program, POD Studies, and the 100-Year Vision for the Future of the Delta. This $60 million does not include the value of the commitments made pursuant to Section III.E for the Environmental Water Account.

In order to provide sufficient supplemental funds, which when combined with state, federal and other funding that will enable implementation of priority ecosystem restoration projects for Delta pelagic and anadromous fish through the end of Stage 1 (December 31, 2007), the following near-term funding is proposed:

A. BDCP

1. For calendar years 2006 and 2007, the USBR and DWR on behalf of the State Water Project (hereinafter referred to as The Projects) shall contribute an aggregate of $3 million annually for the collective use of DFG, USFWS, and NOAA Fisheries for staff and administrative costs related to the development of the BDCP. The budget in Attachment A details how these funds are anticipated to be spent.
2. The Projects and/or other applicants who have activities that will be covered by the BDCP will develop a cost-share agreement as part of the application process for the BDCP, which may provide for reimbursement

of the The Projects and/or other applicants if new parties are able to utilize work for which The Projects and/or other applicants paid.

3 DFG, USFWS, and NOAA Fisheries will expend contributions made under this section consistent Attachment A.
4. DFG, USFWS, and NOAA Fisheries shall seek additional contributions for agency costs from other BDCP participants.
5. DFG, USFWS, and NOAA Fisheries will apply for additional funding through a Federal Endangered Species Act (FESA) Section 6 application.
6. If new bond funds become available and are appropriated for this purpose, the contributions by The Projects for agency staff and administrative costs shall be reduced accordingly.

B. Species Recovery Capital Fund

1. DWR on behalf of the SWP shall contribute a total of $12 million to a Species Recovery Capital Fund through the end of Stage 1 (December 31, 2007) for restoration projects.
2. Money in this fund contributed by DWR on behalf of the SWP shall only be used to fill funding gaps for identified restoration projects and only if all bond money available for and appropriated for these purposes has been committed.
3. DWR and their contractors will be actively engaged in the selection and management of restoration projects funded by the Species Recovery Capital Fund.
4. The $12 million contributions on behalf of the SWP shall be credited towards future Delta pelagic and anadromous fish restoration obligations identified under the BDCP.
5. If the BDCP is not completed, or permits are not issued, the SWP contributions shall be credited towards environmental obligations of the SWP.

C. Ecosystem Restoration Program

1. The state and federal agencies agree to continue annual contributions of $15 million from the CVPIA restoration fund, and Four Pumps Fish Mitigation Agreement towards the Ecosystem Restoration Program.
2. The signatories to this MOA anticipate that current contributions under the CVPIA, combined with the Four Pumps Mitigation Agreement, Species Recovery Capital Fund and available bond funds will meet the requirements of the CALFED Conservation Agreement Regarding Multi-Species Conservation Strategy for financing the Ecosystem Restoration Program through the end of Stage 1.

D. POD Studies

1. For the calendar years 2006 and 2007, The Projects shall continue to contribute up to an aggregate of $4 million annually or additional amounts as necessary upon mutual agreement, to research into the causes of the Delta Pelagic Organism Decline.
2. These contributions do not offset other obligations of the SWP or the federal government.

E. Environmental Water Account

1. DWR and DFG agree to pursue full public funding from the Legislature as provided in the CALFED ROD and the 2004 MOU that extended Environmental Water Account (EWA) through 2007.
2. Until full public funding is made available for the 2005-2006 state fiscal year, and after exhausting all other Tier II assets and in an attempt to avoid the use of Tier III assets, the SWP will loan EWA up to 80 TAF of water to make up for the current funding shortfall. This loan will be repaid with variable EWA assets or financial assets.
3. Sufficient public resources are identified in the 10-Year Action Plan and, if appropriated, will fully fund the EWA through the 2006-2007 state fiscal year.
4. If public funds are not made available to meet the terms of the 2004 MOU and DFG or DWR require the SWP to provide a non-reimbursable fiscal or water contribution to provide adequate resources for the EWA until December 31, 2007, then DWR on behalf of the SWP may terminate this MOA in its entirety.
5. The EWA Agencies agree to conduct a comprehensive review of the EWA by July 1, 2007, to determine if the program should be continued and, if continued, how it will be sized, managed, and funded for the 2007-2008 state fiscal year and beyond.

F. 100-Year Vision for the Future of the Delta

1. The Projects and other water and hydropower project operators will contribute 50% of the cost of the process to develop a long-term vision for the future of the Delta up to a maximum of $2 million annually not to exceed $4 million in total.
2. DWR and DFG will obtain at least an equivalent amount of funding from other private or public sources.
3. If bond funding is available for this purpose, the obligations under Section III.F.1 and Section III.F.2 will be reduced proportionally.

IV. Contingent on Appropriation of Funds and Future Actions

The expenditure or advance of any money, or the performance of any obligation of the United States or the State of California under this MOA, will be contingent upon appropriation or allotment of funds, and, for the United States, is in accordance with 31 United States Code section 1341 (Anti-Deficiency Act). No liability will accrue to the United States or the State of California for failure to perform any obligation under this MOA in the event that funds are not appropriated or allotted.

V. Preserves Rights and Authorities

All provisions of this MOA are intended and will be interpreted to be consistent with all applicable provisions of state and federal law. The undersigned recognize that public agency signatories to this MOA have specific statutory and regulatory authority and responsibilities, and that actions of these public agencies must be consistent with applicable procedural and substantive requirements. Nothing in this MOA is intended to, nor will have the effect of, constraining or limiting any public entity in carrying out its statutory responsibilities. Nothing in this MOA constitutes an admission by any party as to the proper interpretation of any provision of law, nor is anything in this MOA intended to, nor will it have the effect of, waiving or limiting any public entity's rights and remedies under any applicable law.

This MOA does not delegate from or to any person or entity any existing ability to:

1. make a final decision on a project;
2. modify or halt a project; or
3. pursue a project according to individual legal authority.

Execution of this MOA does not constitute a waiver by any signatory of any right or remedy it may have nor does execution constitute pre-approval of any project or preferred project alternative or waive or otherwise abridge responsible or trustee duties required, or discretion authorized, under state and federal law.

VI. Non-Discriminatory

The program or activities contemplated under this MOA when and if conducted or funded by any federal agency will be in compliance with the nondiscrimination provisions contained in Titles VI and VII of the Civil Rights Act of 1964, as amended; the Civil Rights Restoration Act of 1987 (Public Law 100-259); and other nondiscrimination statutes: namely, Section 504 of the Rehabilitation Act of 1973, Title IX of the Education Amendments of 1972, the Age Discrimination Act of 1975, and American's With Disabilities Act of 1990. They will also be in accordance with applicable federal regulations, which provide that no person in the United States will on the grounds of race, color, national origin, gender, religion, age, disability, political beliefs, sexual orientation, and marital or family status, be excluded from participation in, be denied the benefits of, or be otherwise subjected to discrimination under any program or activity receiving federal financial assistance.

VII. Termination

1. This MOA will terminate if the State of California imposes fees or an involuntary financial obligation on any water agency or utility signatory to the MOA for implementation of any CALFED Programs, including, but not limited to the Ecosystem Restoration Program, the Environmental Water Account, or other activities funded under this MOA.

2. The signatories to this MOA recognize that the state is exploring the adoption of a water resources investment fund through an amendment of the California Constitution, and they commit to work cooperatively to develop a water resources investment fund, the implementation of which their principals/boards of directors could support and which would not affect any rights or obligations under this MOA.

3. The termination provision provided under section VII(1) does not apply to a water resources investment fund developed consistent with VII(2) the state may adopt through an amendment of the California Constitution.

VIII. Term of the MOA

Upon DWR, DFG, USBR, USFWS, NOAA Fisheries, and four of the SWP contractors and one of the CVP entities that initialed the Statement of Principles signing this MOA, it will be become effective. Unless terminated, this MOA will remain in effect until December 31, 2007.

IX. Signature in Counterparts

This MOA may be executed in counterparts.

Attachment F - Interim Project Schedules

Water Supply Actions	Program Plan (Lead Agency)	ROD Target Date	DIP 8/04 Target Date	Expected Date	Comments
SWP/CVP Integration Plan	Conveyance (USBR/DWR)				
➢ Complete SWP/CVP Operations Criteria and Plan and BO and early consultation			Summer 2004	Completed Fall 2004	
➢ Complete Response Plans required by D-1641 for Joint Point of Diversion			Aug 2004	Completed Aug 2004	JPOD approvals needed each year for those that are not long term approvals
➢ Complete NEPA/CEQA ESA and public review of interim SWP/CVP operations			Early 2005	Schedule under development	
➢ Implement interim SWP/CVP operation actions			2005	Schedule under development	

Water Supply Actions (Cont)	Program Plan (Lead Agency)	ROD Target Date	DIP 8/04 Target Date	Expected Date	Comments
Delta Mendota Canal / California Aqueduct Intertie ➢ Complete envir. Studies	Conveyance (USBR)	July 2004	Summer 2004	Apr 2007	USBR withdrew its FONSI in May 2006 to further consider implications of the project. An EIS is being prepared. CEQA is complete.
➢ Secure construction funding				Completed 2005	
➢ Re-bid construction contracts, initiate construction		Dec 2004	Late 2005	Feb 2008	USBR terminated its construction contract.
➢ Complete construction, begin operations				Mar. 2009	
Expanded Intertie ➢ Conduct federal feasibility study				Schedule under development	Federal feasibility authorization received in CALFED Bay-Delta Act.
➢ Obtain authorization and funding for expanded intertie				Schedule under development	
San Luis Reservoir Low Point Improvement Project ➢ Complete Appraisal Study	Storage (USBR)		Sept 2004	May 2006	Sequence is as follows: 1. Complete an Initial Alternatives Report 2. Complete a Plan Formulation Report 3. Complete Feasibility Studies and Designs4. Complete the Environmental Impact Statement 5. Complete the ROD.
➢ Complete Feasibility / EIS/EIR		Late 2009	May 2005	Spring 2009	
➢ Obtain funding for implementation			June 2006	Schedule under development	

Water Quality Actions	Program Plan (Lead Agency)	ROD Target Date	DIP 8/04 Target Date	Expected Date	Comments
Permanent Operable Gates/8500 cfs	Conveyance (DWR)				
➢ Complete South Delta Improvements (SDIP) EIR/EIS		Dec 2002	Mid 2005	Aug 2006	
Stage 1 Permanent Operable Gates					
➢ Secure permits to construct permanent operable gates, dredge, modify local agriculture diversions		Jul 2003		Nov 2006	Permits for agricultural diversion dredging and extensions are in place.
➢ Obtain funding and authority for gate at Head of Old River			Dec 2006	Sept 2006	Adequate State funding and authority needed by Sept 2006 (NOD date) so that real estate can be certified no later than Mar 2007.
➢ Obtain funding and authority for gates in Middle River, Old River and Grantline Canal			Dec 2007		
➢ Acquire land and begin construction				2007	
➢ Complete dredging/modifications of local agriculture diversions				Nov 2008	
➢ Complete construction of permanent operable gates				Apr 2009	
Stage 2 – 8,500 cfs		2003	Dec 2007		
➢ Supplemental EIS/EIR				Schedule under development	Schedule dependent on information from POD studies and follow-up analysis. A supplemental document compliant with NEPA and CEQA will be prepared prior to Stage 2 decision and implementation.
➢ Notice of Determination for 8,500 cfs operation					
➢ Secure permit for increasing SWP export limit to 8500 cfs					
➢ Fully operate under 8500 cfs			Jan 2008		

Water Quality Actions (Cont)	Program Plan (Lead Agency)	ROD Target Date	DIP 8/04 Target Date	Expected Date	Comments
San Joaquin River Salinity Management Plan	Water Quality (DWR)	Start source control measures by 2003			
➢ Coordinated Drainage Strategy				Ongoing	
➢ Salt Load Management and Reduction			Begin study by summer 2004		SJRIP is being incorporated into the larger Westside Regional Drainage Plan.
- SJRIP				2010	
- EIS for San Luis Drainage Feature				June 2006	
- Drainage management of Managed Wetlands			Initiate studies by fall 2004	Schedule under development	
➢ Recirculation					
- Draft Feasibility Study and EIS/R				Dec 2007	
- Final Feasibility Study and EIS/R				Nov 2008	
➢ Voluntary Water Exchanges and Transfers				Ongoing	
➢ Real Time Monitoring			Initial draft by Oct 2004		
➢ Coordination of East Side Tributary Operations			Initial draft by March 2004	Ongoing	
➢ Westside Groundwater Management				Ongoing 2010	Part of the Westside Regional Drainage Plan. Proponents propose to pump to lower regional groundwater levels, therefore reducing subsurface drainage discharges into SJR. Excess water will be transferred to CVP.

Water Quality Actions (Cont)	Program Plan (Lead Agency)	ROD Target Date	DIP 8/04 Target Date	Expected Date	Comments
Old River and Rock Slough Water Quality Improvement Projects ➢ Complete construction of Veale and Byron tracts drainage improvements ➢ Complete construction of first phase Canal lining project	Water Quality (DWR)	Before permanent operable gates		Completed Jan 2006 Jun 2009	
Franks Tract ➢ Complete feasibility and EIR/EIS Study (pilot project) ➢ Implement pilot project construction and monitoring	Water Quality (DWR)			April 2010 June 2011	Currently CEQA/NEPA process is being initiated. If it is determined (by June 2007) that a Mitigated Negative Declaration is sufficient for the pilot project, then the pilot project implementation will be done by June 2008.
Relocation of M& I Intake ➢ Complete evaluation of water quality improvements	Water Quality (CCWD)			Date to be determined	CCWD is proceeding with scoping and environmental documentation

Delta Levees Actions	Program Plan	ROD Target Date	DIP 8/04 Target Date	Expected Date	Comments
Delta Levees Implement the Levee System Intregrity Multi-Year Program Plan (including Base Level Protection, Special Improvements Projects, Delta Risk Management Strategy, Subsidence Best Management Practices, and Levee Emergency Management and Response).	Levee System Integrity (DWR)			Years 5-8	State and local funding has addressed maintenance and slow incremental levee improvements. The absence of federal funding and reduced local cost share envisioned in the ROD has severely limited the ability of the program to obtain base level protection. Unless legislation is passed to extend the sunset date the ability of the program to achieve results will be further reduced on July 1, 2006. A Delta Risk Management Strategy study is now underway.

Environmental Protection Actions	Program Plan	ROD Target Date	DIP 8/04 Target Date	Expected Date	Comments
Environmental Water Account	Environmental Water Account (DWR)				
➢ Decision on continuing short-term EWA			Sept 2004	Completed Sept. 2004	DWR, USBR, USFWS, NOAA Fisheries and CDFG completed Long-Term EWA EIS/EIR public scoping meetings in March 2005
➢ Draft EIS/EIR on long-term EWA			Jun 2005	Dec 2006	
➢ Final EIS/EIR on long-term EWA			Dec 2005	Dec 2007	
➢ Comprehensive Review of EWA				Dec 2007	Conducted prior to implementation of Long-Term EWA to inform decisions regarding purpose and need

BAY DELTA CONSERVATION PLAN
Planning Agreement

This agreement (Planning Agreement) regarding the planning and preparation of the Bay Delta Conservation Plan (BDCP) is entered into as of the Effective Date by and among the California Resources Agency, the Fishery Agencies, the Potential Regulated Entities, and the Non-Governmental Organizations, as listed in Exhibit A.

1. Definitions

The following terms as used in this Planning Agreement will have the meanings set forth below.

1.1. "BDCP" means the Bay Delta Conservation Plan, a conservation plan prepared to meet the requirements of Federal Endangered Species Act (FESA), California Endangered Species Act (CESA) and/or the Natural Community Conservation Plan Act (NCCPA).

1.2. "Biological Assessment" or "BA" means the information prepared by or under the direction of a Federal Action Agency for the purpose of identifying the potential effects of the agency action within the Planning Area on species which are listed or proposed to be listed and critical habitat which has been designated or proposed, and submitted to the United States Fish and Wildlife Service (USFWS) and/or National Marine Fisheries Service (NMFS) pursuant to section 7(c)(1) of FESA.

1.3. "CEQA" means the California Environmental Quality Act, Public Resources Code, section 21000, *et seq.*

1.4. "CESA" means the California Endangered Species Act, California Fish and Game Code, section 2050, *et seq.*

1.5. "Covered Activities" means those certain activities that will be addressed in the BDCP and for which the Potential Regulated Entities may seek take authorizations pursuant to the California Fish and Game Code (section 2080.1, section 2081, and/or section 2835) and FESA.

1.6. "Covered Species" means those certain species that may be identified in the BDCP, both listed and non-listed, whose conservation and management are provided for in the BDCP, and which may be authorized for take under State and/or federal law once the BDCP is approved.

1.7. "CVP" means the Central Valley Project.

1.8. "Effective Date" means the date on which this Planning Agreement has been executed by the Parties, as listed in Exhibit A.

1.9. "Federal Action Agency" means a federal agency that authorizes, funds, or carries out actions that may require consultation with USFWS and/or NMFS pursuant to FESA section 7(a)(2).

1.10. "FESA" means the federal Endangered Species Act, 16 United States Code section 1530, *et seq.*

1.11. "Fishery Agencies" means Department of Fish and Game (DFG), USFWS and NMFS.

1.12. "Habitat Conservation Plan" or "HCP" means a conservation plan prepared pursuant to section 10(a) (1) (B) of FESA.

1.13. "Implementing Agreement" or "IA" means an agreement that defines the terms for implementing the BDCP.

1.14. "Statutory Delta" means the Sacramento-San Joaquin Delta as defined by section 12220 of the California Water Code.

1.15. "Listed Species" means those species designated as candidate, threatened or endangered pursuant to CESA and/or listed as threatened or endangered under FESA.

1.16. "MOA Projects" means those projects identified in Attachment B (water supply projects), Attachment C (water quality projects), Attachment D (ecosystem projects", Attachment E, (levees and other work in the waterways), and Attachment F (project schedules) to the "Memorandum of Agreement for Supplemental Funding for Certain Ecosystem Actions and Support for Implementation of Near-Term Water Supply, Water Quality, Ecosystem, and Levee Actions."

1.17. "Natural Community Conservation Plan" or "NCCP" means a conservation plan created to meet the requirements of Fish and Game Code, section 2800, *et seq.*

1.18. "Natural Community Conservation Planning Act" or "NCCPA" means Fish and Game Code, section 2800, *et seq.*

1.19. "NEPA" means the National Environmental Policy Act, United States Code section 4321, *et seq.*

1.20. "Non-Governmental Organizations" or "NGOs" means the Non-Governmental Organizations identified in Exhibit A. As of the Effective Date, the Non-Governmental Organizations are American Rivers, Environmental Defense, the Natural Heritage Institute, and The Nature Conservancy. Additional NGOs may be added as Parties in accordance with Section 9.6 of this Planning Agreement.

1.21. "Other Delta Water Users" means the Other Delta Water Users identified in Exhibit A. As of the Effective Date, Mirant Delta is the sole Other Delta Water User. Additional Other Delta Water Users may be added as Parties in accordance with Section 9.6 of this Planning Agreement.

1.22. "Party" means an entity that is a signatory to this Planning Agreement. Such entities may be referred to individually as "Party" or collectively as "Parties." Additional Parties may be added in accordance with Section 9.6 of this Planning Agreement. The Parties are identified on Exhibit A.

1.23. "Planning Area" means the geographic area proposed to be addressed in the BDCP as described in section 5 and Exhibit B.

1.24. "Potential Regulated Entities" means certain federal and non-federal entities that export, divert or otherwise benefit from diversion of water from the Delta and/or its tributaries within the Planning Area, which may seek take authorizations pursuant to the California Fish and Game Code (section 2080.1, section 2081, and/or section 2835) and/or FESA. The Potential Regulated Entities are identified in Exhibit A. As of the Effective Date, Reclamation, Department of Water Resources (DWR), the Water Contractors, and Other Delta Water Users are the Potential Regulated Entities. Additional Potential Regulated Entities (i.e., Water Contractors and Other Delta Water Users) may be added as Parties in accordance with Section 9.6 of this Planning Agreement.

1.25. "Section 7" means 16 United States Code section 1536.

1.26. "Section 10" means 16 United States Code section 1539.

1.27. "Steering Committee" means the committee established in accordance with Section 7.4.1 of this Planning Agreement.

1.28. "SWP" means the State Water Project.

1.29. "Water Contractors" means the Water Contractors identified in Exhibit A. As of the Effective Date, the Water Contractors are Metropolitan Water District (MWD), Kern County Water Agency (KCWA), Santa Clara Valley Water District (SCVWD), Zone 7, San Luis Delta Mendota Water Agency (SLDMWA) and Westlands Water District (WWD). Additional Water Contractors may be added as Parties in accordance with Section 9.6 of this Planning Agreement.

2. Purposes of this Agreement

The purposes of this Planning Agreement are to:

- Define the Parties' goals and commitments with regard to development of the BDCP;
- Define the initial geographic scope of the Planning Area;
- Identify a preliminary list of natural communities and species known or reasonably expected to be found in those communities that are intended to be the initial focus of the BDCP;
- Identify preliminary conservation objectives for the Planning Area;
- Establish a process for the inclusion of independent scientific input into the planning process;
- Ensure coordination among the Fishery Agencies, particularly with respect to FESA;
- Establish a process to review certain interim projects within the Planning Area that will help achieve the preliminary conservation objectives and maintain viable conservation opportunities and alternatives for the BDCP; and
- Ensure public participation and outreach throughout the planning process.

The Potential Regulated Entities have not yet determined whether it would be feasible or practicable to implement the BDCP, if it is developed, to meet the substantive requirements of the NCCPA. However, to enable the BDCP to serve as an NCCP, should that be feasible and practicable, the Parties intend that this Planning Agreement will fulfill the NCCPA's requirements for planning agreements and will establish a mutually agreeable planning process for the BDCP that meets the procedural requirements of the NCCPA, CESA and FESA.

3. Planning Goals

The planning goals for the BDCP include the following:

- Provide for the conservation and management of Covered Species within the Planning Area;
- Preserve, restore and enhance aquatic, riparian and associated terrestrial natural communities and ecosystems that support Covered Species within the Planning Area through conservation partnerships;
- Allow for projects to proceed that restore and protect water supply, water quality, and ecosystem health within a stable regulatory framework;
- Provide a means to implement Covered Activities in a manner that complies with applicable State and federal fish and wildlife protection laws, including CESA and FESA, and other environmental laws, including CEQA and NEPA;
- Provide a basis for permits necessary to lawfully take Covered Species;
- Provide a comprehensive means to coordinate and standardize mitigation and compensation requirements for Covered Activities within the Planning Area;

- Provide a less costly, more efficient project review process which results in greater conservation values than project-by-project, species-by-species review; and
- Provide clear expectations and regulatory assurances regarding Covered Activities occurring within the Planning Area.

These BDCP planning goals are consistent with the objectives of the CALFED Bay-Delta Program as set forth in the CALFED Record of Decision (ROD). (August 28, 2000, ROD, at pp. 9, 10.) While the Parties have developed specific decision-making protocols for the BDCP in section 7.4.1, they anticipate exchanging information and cooperating with participants in other public processes, such as the proposed Delta Vision Process.

The goal of the BDCP to "provide for the conservation and management of Covered Species" means that the plan will ensure the implementation of measures that will contribute to the recovery of Covered Species, taking into consideration the scope of the BDCP Planning Area in relation to the geographic range of the Covered Species, and the effect of Covered Activities on these species in relation to other activities not addressed by the BDCP. The Parties acknowledge that this planning goal is intended to reflect the constraints inherent to the BDCP that may limit its capacity to ensure the recovery of Covered Species.

The Parties further recognize that, until conservation strategies are developed for the Covered Species and their habitats, and conservation partnerships formed, the cost and feasibility of achieving these goals will not be known. During the development of the BDCP, the BDCP goals, preliminary conservation objectives, Covered Species, Covered Activities, and Planning Area may be modified to ensure that implementation of the BDCP will be practicable. The Parties recognize that, regardless of any such modifications, the BDCP must meet applicable State and federal regulatory requirements to support the issuance of permits or authorizations for Covered Activities.

4. Compliance with Federal and State Fish and Wildlife Protection Laws

The Planning Area contains valuable biological resources, including native species of fish and wildlife and their habitats. Among the species within the Planning Area are certain species that are protected, or may be protected in the future, under CESA and/or FESA. The Parties intend for the BDCP to meet the requirements of State and federal fish and wildlife protection laws that apply to Covered Activities and to provide a basis for State and federal authorizations for the take of Covered Species that may be caused by Covered Activities.

Under State law, take of species listed pursuant to CESA may be authorized under Fish and Game Code section 2080.1, section 2081, (both provisions of CESA) or section 2835 (a provision of the NCCPA). The NCCPA provides that after the approval of an NCCP, DFG may permit the taking of any identified species, listed or non-listed, whose conservation and management is provided for in the NCCP. Take of listed species may also be authorized pursuant to CESA. Non-listed species may be included as covered species in a conservation plan prepared pursuant to CESA, but a CESA take authorization would become effective with regard to non-listed species only if and when such species were listed.

The Parties intend for the BDCP to be sufficient to support the issuance of take authorizations for Covered Activities under CESA or the NCCPA. Alternatively, the BDCP may be developed to support the issuance of take authorizations under both CESA and the NCCPA, in which case, at DFG's discretion, take authorizations may be provided under CESA for some Covered Activities and Covered Species and under the NCCPA for those species whose conservation and management are provided for under the BDCP.

The Parties also intend for the BDCP to serve as a Habitat Conservation Plan that meets the requirements of section 10(a)(2)(A) of FESA, and to serve as a Biological Assessment that provides the basis for consultations between Reclamation and the USFWS and/or NMFS under section 7(a)(2) of FESA, to support the issuance of take authorizations for Covered Activities. The Parties acknowledge that the BDCP may be used to address compliance with other applicable federal and State statutes.

FESA provides that after the approval of an HCP, USFWS and/or NMFS may permit the taking of fish and wildlife species covered in the HCP if the HCP and permit application meet the requirements of section 10(a)(2)(A) and (B) of FESA. Take authorization for FESA-listed fish and wildlife species covered in the HCP are generally effective upon approval of the HCP and issuance of an incidental take permit. Take authorization for any non-listed species covered in the HCP becomes effective if and when the species is listed pursuant to FESA.

For actions authorized, funded or carried out by a Federal Action Agency, take of listed species may be authorized under section 7 of FESA based on a biological opinion prepared by the USFWS and/or NMFS. Take of non-listed species cannot be authorized under section 7 of FESA.

4.1. Potential Regulated Entities' Obligation to Implement the BDCP

The Potential Regulated Entities recognize that they will be obligated to implement and/or fund implementation of measures in the BDCP that are required to appropriately minimize and mitigate (including, in certain instances, to avoid destruction or adverse modification of critical habitat pursuant to section 7 of FESA) the impacts of Covered Activities on Covered Species and their habitat within the Planning Area in accordance with applicable federal and State fish and wildlife protection laws. However, the Parties may elect to include in the BDCP additional measures that exceed what is necessary to appropriately minimize or mitigate Covered Activities. For example, the BDCP may include measures that are necessary to provide for the conservation and management of Covered Species, but are not necessary to minimize and mitigate the impacts of Covered Activities. The Parties acknowledge that the Potential Regulated Entities' execution of this Planning Agreement and participation in the BDCP planning process does not reflect a commitment on the part of the Potential Regulated Entities to assume the obligation to implement conservation measures that exceed minimization and mitigation requirements. Rather, the Parties expect that the obligation to fund and/or to implement any such conservation measures would be shared by the Parties and that the Potentially Regulated Entities' share would be roughly proportional to the impact of their Covered Activities on Covered Species and their habitats. The shared obligation would be defined by mutual agreement and set forth in the Implementing Agreement. Nothing in this Planning Agreement obligates the Potentially Regulated Entities to fund or implement measures to minimize and mitigate impacts to Covered Species resulting from the activities of individuals or entities that do not participate in the implementation of the BDCP or to fund and/or implement conservation measures required as a result of such activities.

4.2. Future FESA Section 7 Consultations

To the extent allowed under law, the Parties intend that the measures adopted to meet regulatory standards included in the BDCP, once approved by the USFWS and NMFS and included as a condition of federal incidental take authorizations to any Potential Regulated Entity, will serve as the range of measures to be incorporated into biological opinions associated with future section 7 consultations between the USFWS and/or NMFS and a Federal Action Agency regarding Covered Activities that may adversely affect listed Covered Species and/or that may result in the destruction or adverse modification of critical habitat.

4.3. Other Fish and Wildlife Protection Laws

Based on the BDCP, the Potential Regulated Entities may seek approval or authorization under other State and federal fish and wildlife protection laws, including, but not necessarily limited to, the Magnuson-Stevens Fishery Act, the Migratory Bird Treaty Act, the Bald and Golden Eagle Protection Act, and various provisions of the Water Code and Fish and Game Code. The Parties agree to collaborate to explore the feasibility of developing the BDCP to serve as the means by which Covered Activities may comply with these additional laws.

4.4. Concurrent Planning for Wetlands and Waters of the United States

Based on the BDCP, the Potential Regulated Entities may seek future programmatic permits or other forms of authorization under the Clean Water Act, section 1600 *et seq.* of the Fish and Game Code, and the Rivers and Harbors Act, as necessary for Covered Activities. The Parties agree to work together to explore the feasibility of undertaking concurrent but separate planning regarding these permits. However, such programmatic permits or other forms of authorization are not necessary for approval of the BDCP or for issuances of take permits.

4.5. Regulatory Assurances Under FESA

Upon approval of the BDCP and issuance of incidental take permits for Covered Activities, USFWS and NMFS will provide assurances to those Potential Regulated Entities that receive coverage under FESA Section 10(a) that neither the USFWS nor NMFS will require the commitment of additional land, water, or financial compensation or additional restrictions on the use of land, water, or other natural resources beyond the level otherwise agreed upon for Covered Species, without the consent of the affected Potential Regulated Entities, in accordance with 50 C.F.R. section 17.22(b)(5), section 17.32(b)(5), and section 222.307(g).

4.6. Regulatory Assurances Under the NCCPA

If the BDCP meets the criteria for issuance of NCCP permits under section 2835 of the Fish and Game Code, DFG will approve the BDCP and provide assurances consistent with its statutory authority upon issuance of NCCP permits. Under section 2820(f) of the Fish and Game Code, DFG may provide assurances for the Covered Activities commensurate with the level of long-term conservation and associated implementation measures provided in the BDCP, including the assurance that, if unforeseen circumstances arise during implementation of the BDCP, DFG will not require additional land, water, or financial compensation or additional restrictions on the use of land, water, or other natural resources without the consent of the affected Potential Regulated Entities, as long as the BDCP is being implemented consistent with the terms of the Implementation Agreement and associated take permit.

5. Planning Area

Because the Parties expect that the BDCP's Covered Activities will be situated within the Statutory Delta, the Planning Area for the BDCP will consist of the Statutory Delta. The Parties anticipate, however, that it may be necessary for the BDCP to include conservation actions outside of the Statutory Delta that advance the goals and objectives of the BDCP, including as appropriate, conservation actions in the Suisun Marsh, Suisun Bay, and areas upstream of the Delta. The Parties intend that conservation actions will be implemented pursuant to cooperative agreements or similar mechanisms with local agencies, interested non-governmental organizations, landowners, and others. A map of the Planning Area is attached hereto as Exhibit B.

6. Preliminary Conservation Objectives

The preliminary conservation objectives the Parties intend to achieve through the BDCP are to:

- Provide for the protection of Covered Species and associated natural communities and ecosystems that occur within the Planning Area;
- Preserve the diversity of fish, wildlife, plant and natural communities within the Planning Area;
- Minimize and mitigate, as appropriate, the take of proposed Covered Species;
- Preserve and restore habitat and contribute to the recovery of Covered Species;
- Reduce the need to list additional species;
- Set forth species-specific goals and objectives;
- Set forth specific habitat-based goals and objectives; and
- Implement an adaptive management and monitoring program to respond to changing ecological conditions;

- Avoid actions that are likely to jeopardize the continued existence of Covered Species or result in the destruction or adverse modification of critical habitat.

6.1. Conservation Elements

6.1.1. Ecosystems, Natural Communities, and Covered Species List

The BDCP will employ a strategy that focuses on the conservation of ecosystems, natural communities, and ecological processes in the Planning Area. In addition, the BDCP will establish species-specific minimization, mitigation, conservation and management measures where appropriate.

The BDCP will focus primarily on aquatic ecosystems and natural communities. The BDCP may also cover adjacent riparian and floodplain natural communities, as appropriate, to fully address the impacts of Covered Activities and to provide for the conservation of Covered Species. Natural Communities that are likely to be addressed by the BDCP include: riverine aquatic, lacustrine, tidal sloughs, tidal perennial aquatic, nontidal perennial aquatic, saline emergent wetland, freshwater emergent wetland, and riverine natural communities.

Species that are intended to be the initial focus of the BDCP include aquatic species such as Central Valley steelhead, Central Valley Chinook salmon (spring run and fall/late-fall runs), Sacramento River Chinook salmon (winter run), Delta smelt, green sturgeon, white sturgeon, splittail, and longfin smelt. Other species that will be considered for inclusion in the BDCP include Swainson's hawk, bank swallow, giant garter snake and valley elderberry longhorn beetle.

This list identifies the species that will be evaluated for inclusion in the BDCP as proposed Covered Species and is not necessarily the BDCP's final Covered Species list. The Parties anticipate that species may be added or removed from the list once more is learned about the nature of the Covered Activities and the impact of Covered Activities on native species within the Planning Area. Issuance of State and federal take authorizations for any particular Covered Species will require an individual determination by the applicable Fishery Agency that the BDCP meets applicable State and/or federal permit issuance requirements.

6.1.2. Conservation Areas and Viable Habitat Linkages

The BDCP will protect, enhance, or restore aquatic, and associated riparian and floodplain habitat throughout the Planning Area and provide or enhance habitat linkages, where appropriate within the Planning Area. The BDCP will also identify where linkages between important habitat areas inside and outside the Planning Area should occur. The BDCP conservation strategy will address a range of environmental gradients and ecological functions, and will address appropriate principles of ecosystem management, ecosystem restoration, and population biology.

6.1.3. Project Design

The BDCP will ensure that each Covered Activity is appropriately designed to avoid and/or minimize direct and indirect impacts to Covered Species and their habitats.

7. Preparing the BDCP

The Parties intend that this Planning Agreement will establish a mutually agreeable process for preparing the BDCP that meets the procedural requirements of the NCCPA, CESA and FESA. The process used to develop the BDCP will incorporate independent scientific input and analysis and include extensive public participation with ample opportunity for comment from the general public and from key groups of stakeholders, as described below.

7.1. Best Available Scientific Information

The BDCP will be based on the best available scientific information, including, but not limited to:

- Principles of conservation biology, community ecology, aquatic ecology, individual species' ecology, and other appropriate scientific data and information;
- Thorough information about all natural communities and proposed Covered Species within the Planning Area; and
- Advice from well-qualified, independent scientists.

7.2. Data Collection

The Parties agree that the BDCP will be based on the best available scientific information, and that the Parties will collaborate to ensure that such information is obtained through a range of credible governmental and non-governmental sources. Data collection efforts for preparation of the BDCP will be coordinated with existing efforts, including the CALFED Science Program. Preference should be given to collecting data essential to address the needs of natural communities and proposed Covered Species for purposes of developing conservation measures and strategies for the BDCP. The science advisory process and analysis of existing information may reveal data gaps currently not known that are necessary for the full and accurate development of the BDCP. Data needed for preparation of the BDCP may not be known at this time nor identified herein. Therefore, the Parties anticipate that data collection priorities may be adjusted from time to time during the planning process. All data collected for the preparation and implementation of the BDCP will be made available to the Fishery Agencies in hard and digital formats, as requested.

7.2.1. Types of Data

Data will be gathered to establish baseline conditions, evaluate impacts of Covered Activities on Covered Species, and develop conservation strategies and measures for Covered Species. Data needed to accomplish these tasks may include, but will not necessarily be limited to: species life histories, species occurrence, population abundance and distribution, population trends, population genetics, habitat locations and conditions, hydrologic regime, hydrodynamics, salinity, temperature, flow patterns, water quality, barrier and hazard types and locations, habitat connectivity, ecological threats and stressors, and riverine processes.

7.3. Independent Scientific Input

The Parties intend to include independent scientific input and analysis to assist in the preparation of the BDCP. For that purpose, independent scientists representing a broad range of disciplines, including conservation biology and locally-relevant ecological knowledge, will, at a minimum:

- Recommend scientifically sound conservation strategies for species and natural communities proposed to be covered by the BDCP;
- Recommend a range of conservation actions that would address the needs of species, ecosystems, and ecological processes in the Planning Area proposed to be addressed by the BDCP;
- Recommend management principles and conservation goals that can be used in developing a framework for the monitoring and adaptive management component of the BDCP; and
- Identify data gaps and uncertainties so that risk factors can be evaluated.

The independent scientists may be asked to provide additional feedback on key issues during preparation of the BDCP, and may prepare reports regarding specific scientific issues throughout the process, as deemed necessary by the Parties.

The Parties will design and implement the science advisory process, in consultation with the Steering Committee and the CALFED Science Program, and will ask the CALFED Science Program's Independent Science Board to recommend potential science advisors. The Parties will develop a detailed scope of work for the independent science advisory process and establish funding and payment procedures. The independent science advisory process will include the use of a professional facilitator, input from technical experts, and production of a report by the scientists. The Parties will make the report available to the public during the planning process.

7.4. Public Participation

The Parties will ensure an open and transparent process with an emphasis on obtaining input from a balanced variety of public and private interests. The planning process will provide for thorough public review and comment.

7.4.1. Steering Committee and Interested Observers

To assist in the development of the BDCP, the Parties have formed a Steering Committee. The Steering Committee consists of representatives of the Parties, with the USFWS and NMFS participating as ex officio members. The Parties expect that Steering Committee will be the principal forum within which key policy and strategy issues pertaining to the BDCP will be discussed and considered. The Parties intend that the meaningful exchange of ideas and viewpoints during Steering Committee meetings will help guide the development of the plan.

7.4.1.1. Process

The Steering Committee will convene in regularly scheduled public meetings, and its proceedings will be facilitated by the Secretary's Office of the California Resources Agency. The Steering Committee may elect to form subcommittees and workgroups as it may deem appropriate to analyze issues in greater detail and to report back to the full Steering Committee. Members of the Steering Committee are encouraged to caucus between such meetings. Staff and consultants from the Parties will work with the Steering Committee to provide technical expertise and share information for the development and implementation of the BDCP. Technical documents, draft agreements, and other information or documents will be provided to members of the Steering Committee at a stage early enough to allow for meaningful participation in deliberations.

With respect to those matters that are considered by the Steering Committee, the Parties agree that every reasonable effort should be made to have each such matter approved by a consensus of the members. Consensus is reached when a position reflects the predominant opinion of the Steering Committee members. In the event that a Steering Committee member opposes a proposal that has predominant support, that member will propose for further discussion an alternative that it would support. The Parties will make all reasonable efforts to prevent disputes and resolve matters by consensus in the Steering Committee. However, the Parties acknowledge that if consensus about a given matter is not reached in the Steering Committee, the Potential Regulated Entities, in consultation with the Fishery Agencies, will decide how to address the matter and maintain progress in the development of the BDCP.

7.4.1.2. Reserved Authority

The Parties recognize that decisions made by the Steering Committee in the course of preparing the BDCP are preliminary and are not legally binding. The Parties further recognize that several Parties have statutory or legal responsibilities that cannot be delegated, and that no action of the Steering Committee or provision of this Agreement shall be construed to delegate or abrogate any of those responsibilities.

7.4.1.3 Interested Observers

The Parties recognize the involvement of "Interested Observers," representing other stakeholder interests. Interested Observers will be provided notice of Steering Committee meetings and invited to attend. At each Steering Committee meeting, Interested Observers and other members of the public will have an opportunity to provide comments. A list of Interested Observers will be maintained on the BDCP website.

7.4.2. Outreach

Parties will provide access to information for persons interested in the BDCP, including interested tribes and people of all races, cultures and socio-economic status. The Parties expect and intend that public outreach regarding preparation of the BDCP will be conducted largely by and through the Steering Committee meetings. In addition, Parties will hold public meetings to present key decisions regarding the preparation of the BDCP to allow the public the opportunity to comment on and inquire about the decisions. The Parties may use Bay Delta Public Advisory Committee or its successor as a venue for public meetings. Other outreach efforts will include a BDCP website and informational mass mailings.

7.4.3. Availability of Public Review Drafts

The Parties will designate and make available for public review in a reasonable and timely manner "public review drafts" of pertinent planning documents including, but not limited to, plans, memoranda of understanding, maps, conservation guidelines, and species coverage lists. Such documents will be made available by the Parties at least ten working days prior to any public hearing addressing these documents. In addition, the Parties will make available all reports and formal memoranda prepared by the Steering Committee. Not all documents drafted during preparation of the BDCP will be distributed for public review. However, the Parties will periodically designate various pertinent documents drafted during preparation of the BDCP as "public review drafts", and will make these documents available to the public. The Parties agree the Internet will be the principal means of making documents available for public review, but that more traditional means such as distribution and display of hard copies of such documents will be used where practicable.

7.4.4. Public Hearings

Public hearings regarding development of the BDCP will be planned and conducted in a manner that satisfies the requirements of CEQA, NEPA, and any other applicable State or federal laws.

7.4.5. Public Review and Comment Period Prior to Adoption

The Potential Regulated Entities will make the draft BDCP and Implementing Agreement available for public review and comment a minimum of 60 days before adoption. The draft BDCP and Implementing Agreement will be distributed with the draft environmental impact report prepared for the BDCP pursuant to CEQA and/or the draft environmental impact statement prepared for the BDCP pursuant to NEPA.

7.5. Covered Activities

The BDCP will identify and address the Covered Activities carried out by the Potential Regulated Entities that may result in take of Covered Species within the Planning Area. Covered Activities may include, but are not necessarily limited to, existing or new activities related to:

- Conveyance elements of the State Water Project (SWP) and Central Valley Project (CVP)
- Operational activities, including emergency preparedness, of the SWP and CVP
- Operational activities related to water transfers involving Water Contractors or to serve environmental programs
- Maintenance of the SWP, CVP, and other Potential Regulated Entities' facilities

- Facility improvements of the SWP and CVP
- Ongoing operation of, and recurrent and future projects related to Other Delta Water Users
- Projects designed to improve salinity conditions
- Conservation measures included in the BDCP, including, but not limited to, adaptive habitat management, restoration, enhancement and monitoring activities

The Parties intend that the BDCP will allow Covered Activities in the Planning Area to be carried out in compliance with FESA and applicable provisions of the Fish and Game Code, and potentially with other laws as described in Section 4.

7.6. Interim Project Processing

The Parties recognize that before the Fishery Agencies approve the BDCP, certain projects and activities associated with Potential Regulated Entities may be proposed within the Planning Area. The Parties agree to the following interim project process to: (1) help ensure that new major discretionary projects approved or initiated in the Planning Area before completion of the Plan are consistent with the preliminary conservation objectives (section 6) and do not compromise successful completion and implementation of the Plan; (2) facilitate CEQA, CESA, and FESA compliance for such interim projects that require it; and (3) ensure that processing of such interim projects is not unduly delayed during preparation of the Plan.

The Parties acknowledge and agree that MOA Projects will not require separate or additional review pursuant to the interim project process set forth in this section. The Parties recognize that the MOA Projects will be required to comply with all applicable State and federal wildlife protection laws and environmental review processes. Other projects or activities within the Planning Area that are proposed by the Potential Regulated Entities that require discretionary approvals will be subject to the interim project process. The Parties agree that the development of the BDCP shall not delay the implementation of any of the MOA Projects or interim projects.

7.6.1. Notification Process for Interim Projects

The PRE proposing to undertake or approve an interim project will notify the Fishery Agencies of the project prior to the time, or as soon as possible after, the project description or application is deemed complete. The PRE will notify the particular individuals designated by the Fishery Agencies to be notified of interim projects, and will provide these designated individuals with (1) a depiction of the project location on a United States Geological Survey 7.5 minute quadrangle map with the quadrangle name and section, township, and range identified; (2) copy of the project description or application, including a description of the project along with the land cover types present on the project site using the most current land cover data available to the PRE; and (3) any other biological information available to the PRE about the project area.

7.6.2. Fishery Agency Review of Interim Projects

Information concerning interim projects will be presented to the Fishery Agencies in a complete and timely manner, and the Fishery Agencies will use reasonable efforts to review and provide any comments on the projects to the referring PRE within the legally prescribed comment periods. The Fishery Agencies will recommend mitigation measures or project alternatives that would help achieve the preliminary conservation objectives and will not preclude important conservation planning options or connectivity between areas of high habitat values. Any take of listed or candidate species arising out of an interim project will be authorized in accordance with applicable federal and/or state law. In providing any such authorizations, the Fishery Agencies acknowledge that they may not impose mitigation measures or project alternatives that result in regulatory obligations that exceed the requirements of applicable State and federal wildlife protection laws.

7.6.3. Coordinating Interim Process with BDCP Preparation

The Parties will meet as needed to discuss interim projects and to coordinate with development of the BDCP. Independent scientific input will be considered by the Parties during interim project review.

7.7. Protection of Habitat and Other Resources During Planning Process

7.7.1. Conservation Actions

The Parties may elect to preserve, enhance or restore, either by acquisition or other means, aquatic and associated riparian and floodplain habitat in the Planning Area that support native species of fish, wildlife or natural communities prior to approval of the BDCP. The Parties will confer with the Fishery Agencies regarding potential resources to be protected. The Fishery Agencies agree to credit such resources toward the land and water acquisition or habitat protection, enhancement, and restoration requirements of the BDCP, as appropriate, provided these resources are appropriately conserved, restored or enhanced, and managed and contribute to the BDCP's conservation strategy.

7.7.2. Mitigation

Actions to protect, enhance, or restore habitat that are undertaken solely to mitigate the impacts of specific projects, actions, or activities approved prior to BDCP approval will only be considered as mitigation for those projects, actions or activities. Such measures will be considered during the BDCP analysis, but will not count toward future mitigation obligations of the BDCP.

7.8. Implementing Agreement

An Implementing Agreement that includes specific provisions and procedures for the implementation, monitoring and funding of the BDCP will be developed for the BDCP. A draft of the Implementing Agreement will be made available for public review and comment with the final public review draft of the BDCP. The Implementing Agreement will contain provisions for:

- Conditions of species coverage;

- The long-term protection of any habitat reserves or other measures that provide equivalent conservation;
- Implementation of mitigation and conservation measures;
- Adequate funding to implement the plan;
- Terms for suspension or revocation of the take permit;
- Procedures for amendment of the BDCP, Implementing Agreement, and take authorizations;
- Implementation of monitoring and adaptive management;
- Oversight of BDCP effectiveness and funding; and
- Periodic reporting.

8. Commitment of Resources

8.1. Funding

The Parties agree that they will work together to bring available funding to the planning effort.

8.1.1. Funding of Fishery Agencies' Costs

As set forth in Section III(A) of the "Memorandum of Agreement for Supplemental Funding for Certain Ecosystem Actions and Support for Implementation of Near-Term Water Supply, Water Quality, Ecosystem and Levee Actions," (see Exhibit C) for calendar years 2006 and 2007, Reclamation and DWR on behalf of the SWP shall contribute an aggregate of approximately $3 million annually for the collective use of DFG, USFWS, and NMFS staff and for administrative costs related to the development of the BDCP. The Fishery Agencies shall use the contributed funds to provide technical and scientific information, analyses, and advice to assist in the timely and efficient development of the BDCP. Reclamation and DWR may be reimbursed in whole or in part in the event that Other Delta Water Users become Parties to this Agreement.

8.1.2. DFG and DWR Assistance with Funding

DFG and DWR agree to cooperate with the other Parties in identifying and securing, where appropriate, federal and State funds that may be used to support the development and implementation of the BDCP. DFG and DWR's commitments and obligations under this Planning Agreement are subject to the availability of appropriated funds and the written commitment of funds by an authorized DFG or DWR representative.

8.1.3. USFWS, NMFS, and Reclamation Assistance with Funding

The USFWS, NMFS, and Reclamation agree to cooperate with the other Parties in identifying and securing, where appropriate, federal and State funds earmarked for habitat conservation planning purposes. Potential federal funding sources may include: the USFWS' Cooperative Endangered Species Conservation Fund, Land and Water Conservation Fund, and land acquisition grants or loans through other federal agencies such as the Environmental Protection Agency, the Army Corps of Engineers, or the Departments of Agriculture or Transportation. The commitments of the USFWS, NMFS and Reclamation under this Planning Agreement are subject to the requirements of the federal Anti-Deficiency Act (31 U.S.C. section 1341) and the availability of appropriated funds. The Parties acknowledge that this Planning Agreement does not require any federal agency to expend its appropriated funds unless and until an authorized officer of that agency provides for such expenditures in writing.

9. Miscellaneous Provisions

9.1. Public Officials Not to Benefit

No member of or delegate to Congress will be entitled to any share or part of this Planning Agreement, or to any benefit that may arise from it.

9.2. Statutory Authority

The Planning Agreement is not intended, nor will it be construed, to modify any authority granted by statute, rule or regulation, or to make applicable to the CVP any State law that, in the absence of this Planning Agreement, would not apply to the CVP.

9.3. Multiple Originals

This Planning Agreement may be executed by the Parties in multiple originals, each of which will be deemed to be an official original copy.

9.4. Effective Date

The Effective Date of this Planning Agreement will be the date on which it is fully executed by the Parties.

9.5. Duration

This Planning Agreement will be in effect until the BDCP is approved and permitted by the Fishery Agencies, but shall not be in effect for more than three years following the Effective Date, unless extended by amendment. This Planning Agreement may be terminated pursuant to Section 9.7 below.

9.6. Amendments

This Planning Agreement can be amended only by written agreement of all Parties; provided, however, that without amending this Planning Agreement, new Potential Regulated Entities and other Parties may be added pursuant to the process described in Section 7.4.1.

9.7. Termination and Withdrawal

Subject to the requirement in Section 9.7.1 of the Planning Agreement, any Party may withdraw from this Planning Agreement upon 30 days' written notice to the other Parties, after which time the withdrawing Party shall no longer be a Party. The Planning Agreement will remain in effect as to all non-withdrawing Parties unless the remaining Parties determine that the withdrawal requires termination of the Planning Agreement. This Planning Agreement can be terminated only by written agreement of all non-withdrawing Parties.

9.7.1. Funding

In the event that federal, State or local funds have been provided to assist with BDCP preparation or implementation, any Party withdrawing from this Planning Agreement shall return to the granting agency unspent funds awarded to that Party prior to withdrawal. A withdrawing Party shall also provide the remaining Parties with a complete accounting of the use of any federal, State or local funds it received regardless of whether unspent funds remain at the time of withdrawal. In the event of termination of this Planning Agreement, all Parties who received funds shall return any unspent funds to the grantor prior to termination.

9.8. No Precedence

This Planning Agreement is not intended, and shall not be construed, to modify any existing or subsequently amended law, rule, regulation or other legal authority, or requirements established thereunder.

The Parties' execution of this Planning Agreement and participation in the development of the BDCP is voluntary and does not ensure that any of said Parties will participate in later planning phases of the BDCP or related agreements or actions. As provided in Section 9.7, above, any Party may withdraw from this Planning Agreement. In addition, participation in this Planning Agreement shall not be deemed acquiescence to the development of an NCCP. The Potential Regulated Entities shall decide whether to seek approval of the BDCP under the NCCPA or to apply for a section 2081 permit at or before the time that the BDCP is finalized.

The Parties recognize that participation in this Planning Agreement or in the BDCP planning process does not constitute, expressly or implicitly, an authorization by any of the Fishery Agencies to take any species listed under CESA and/or FESA. The Parties further recognize that such participation does not reflect or represent an acknowledgement by any Party that its activities or projects are not in compliance with any State or federal law or that the BDCP is necessary to comply with any such law.

EXHIBIT A

The Parties to the Planning Agreement are as follows:

The California Resources Agency
The Resources Agency mission statement is to restore, protect and manage the state's natural, historical and cultural resources for current and future generations using creative approaches and solutions based on science, collaboration and respect for all the communities and interests involved. The Resources Agency is home to all California's natural resources policies and programs. It operates on a $4.1 billion budget, employs over 14,500 people in 24 departments, commissions, boards and conservancies on conservation, water, fish and game, forestry, parks, energy, coastal, marine and landscape.

Fishery Agencies

The California Department of Fish and Game
DFG is the agency of the State of California authorized to act as trustee for the fish and wildlife of the State, designated rare and endangered plants, game refuges, ecological reserves, and other areas administered by the Department. DFG also administers and enforces the provisions of the Fish and Game Code and is authorized to enter into agreements with federal and local governments and other entities for the conservation of species and habitats. Take of threatened or endangered species which is incidental to an otherwise lawful activity may be authorized by DFG under CESA. DFG may also permit taking and provide regulatory assurances under the NCCPA for identified species whose conservation and management is provided for in a DFG-approved NCCP.

The United States Fish & Wildlife Service
The USFWS is an agency of the United States Department of the Interior authorized by Congress to administer and enforce FESA with respect to terrestrial wildlife, certain fish species, insects and plants, to enter into agreements with states, local governments, and other entities to conserve threatened, endangered, and other species of concern, to authorize incidental take under FESA, and to provide regulatory assurances in accordance with 50 C.F.R. section 17.22(b)(5) and section 17.32(b)(5).

The National Marine Fisheries Service
NMFS is an agency of the United States Department of Commerce authorized by Congress to administer and enforce FESA with respect to marine mammals and certain fish species (including anadromous fish), to enter into agreements with states, local governments, and other entities to conserve federally threatened, endangered, and other species of concern, to authorize incidental take under FESA, and to provide regulatory assurances in accordance with 50 C.F.R. section 222.307(g).

Potential Regulated Entities

The California Department of Water Resources
DWR operates and maintains the State Water Project, including the California Aqueduct. The Department also provides dam safety and flood control services, assists local water districts in water management and conservation activities, promotes recreational opportunities, and plans for future statewide water needs.

The U.S. Bureau of Reclamation
The mission of the Bureau of Reclamation is to manage, develop, and protect water and related resources in an environmentally and economically sound manner. Originally conceived under the Reclamation Act of 1902 as a means to help settle the West by providing infrastructure for agricultural development, the Reclamation program focused on the construction of dams and facilities to store and convey water. As the potential for additional project purposes was identified by the states and local entities, Congress supplemented the Reclamation Act to add hydropower production, flood control, municipal and industrial water, recreation, and fish and wildlife enhancement to the list of authorized project purposes.

Water Contractors

The Metropolitan Water District of Southern California
MWD is a special water district organized and existing under California Water Code Appendix, Chapter 109. MWD acquires and develops water for delivery to 26 public agencies who in turn deliver water directly to homes and businesses, or to other water agencies who ultimately deliver the water to retail customers. The water acquired and developed by MWD, which includes water from the State Water Project, serves approximately 18 million people in portions of six southern California counties (Ventura, Los Angeles, Orange, San Bernardino, Riverside, and San Diego).

The Kern County Water Agency
KCWA is a special water district organized and existing under California Water Code Appendix, Chapter 99. KCWA is a contractor for water from the State Water Project. The State Water Project water is diverted to 15 member units and is used to irrigate, in whole or in part, more than 500,000 acres of prime farmland and to serve municipal water throughout Kern County, including the City of Bakersfield.

The Santa Clara Valley Water District
SCVWD is a special district organized and existing under California Water Code Appendix, Chapter 60. SCVWD's water supply includes water developed by both the Central Valley Project and the State Water Project. SCVWD's water supply serves approximately 1.7 million people in homes and businesses located throughout Santa Clara County, including the vital high technology industry in the area known as "Silicon Valley." SCVWD is a member agency of the SLDMWA.

Alameda County Flood Control and Water Conservation District, Zone 7
Zone 7 Water Agency is one of the 10 active zones of the Alameda County Flood Control and Water Conservation District. Zone 7 receives up to 75% of its water from the State Water Project. Along with flood protection, Zone 7 manages the local ground water basins and is the wholesale water supplier to all of eastern Alameda County and a population of more than 190,000. Treated water is sold to local retailers,including the cities of Livermore and Pleasanton, the Dublin San Ramon Services District, and the California Water Service Company. Zone 7 also distributes untreated water to local agriculture operations and golf courses.

The San Luis & Delta Mendota Water Authority
The SLDMWA is a joint powers authority formed pursuant to California Government Code section 6500 *et seq.* The SLDMWA consists of 32 member public agencies that contract with Reclamation for water supply from the CVP for distribution and use within areas of San Joaquin, Stanislaus, Merced, Fresno, Kings, San Benito, and Santa Clara Counties, California.

The Westlands Water District
WWD, a member of the SLDMWA, is a California water district formed pursuant to California Water Code section 34000 *et seq.* WWD holds contractual rights to receive water from Reclamation, through the Central Valley Project, for distribution and consumption within the areas of Fresno County and Kings County. WWD provides water for municipal and industrial uses, and for the irrigation of approximately 500,000 acres on the west side of the San Joaquin Valley in Fresno County and Kings County. WWD's farmers produce more than 60 high quality commercial food and fiber crops sold for the fresh, dry, canned and frozen food markets, both domestic and export. More than 50,000 people live and work in the communities, dependant on WWD's agricultural economy

Other Delta Water Users

Mirant Delta
Mirant Corporation owns and operates two natural-gas fired power generation plants on the Delta, one in Pittsburg and one in an unincorporated area of Contra Costa County east of Antioch. Both plants use water from the adjacent Sacramento River for power generation operations.

Non-Governmental Organizations

American Rivers
American Rivers is a national non-profit conservation organization founded in 1973 dedicated to protecting and restoring healthy natural rivers and the variety of life they sustain for people, fish, and wildlife. We deliver innovative solutions to improve river health; raise awareness among decision-makers and the public; serve and mobilize the river conservation movement; and collaborate with our partners to develop the Citizens' Agenda for Rivers which creates a unified vision for improving river health across the country. We have a membership of approximately 40,000. Our national office is located in

Washington, DC and we operate a regional office in the Northwest with locations in Seattle and Portland. In addition, we have six field offices in California, Connecticut, Nebraska, Pennsylvania and South Dakota.

The Bay Institute
The Bay Institute was founded in 1981 by pioneers of a new advocacy approach which viewed the entire Bay-Delta ecosystem as a single, interdependent watershed. They claimed that environmental reform benefiting the Bay must recognize the importance of events in the farthest reaches of the watershed just as urgently as those along the Bay shoreline, and that reduced freshwater flow was the biggest factor in the decline of the estuary's fish and wildlife resources.

Today, this approach is accepted wisdom. Tragically, it is also widely recognized that the water quality of the Bay and its river Delta is unacceptable, and that species and habitats are in danger.

The Bay Institute uses a combination of scientific research, political advocacy, and public education to work toward the environmental restoration of the entire watershed which drains into San Francisco Bay. This watershed includes the Sacramento River and the San Joaquin Rivers as well as their tributaries, Suisan Marsh, San Pablo Bay, and San Francisco Bay. The land area covers 40 percent of California. Nearly half of the surface water in California starts as rain or snow that falls in this area, and about half of that is diverted for use on farms, in homes, and in factories. The remaining water flows downstream through the largest inland delta, the largest brackish water marsh, and the largest estuary on the west coast of the Americas.

The Bay Institute's work encompasses the centers of political and economic power, from Sacramento to Los Angeles to Washington DC., where it fights to place long-term environmental needs on equal footing with other priorities in the formation of the area's environmental and economic policies.

California Farm Bureau Federation
The California Farm Bureau Federation is a non-governmental, non-profit, voluntary membership California corporation whose purpose is to protect and promote agricultural interests throughout the state of California and to find solutions to the problems of the farm, the farm home and the rural community. Farm Bureau is California's largest farm organization, consisting of 53 county Farm Bureaus currently representing approximately 91,000 members in 56 counties.

The Farm Bureau strives to protect and improve the ability of farmers and ranchers engaged in production agriculture to provide a reliable supply of food and fiber through responsible stewardship of California's resources.

Contra Costa Water
The Contra Costa Water District (CCWD) was formed in 1936 to provide water for irrigation and industry and is now one of the largest urban water districts in California and a leader in drinking-water treatment technology and the protection of the Sacramento-San Joaquin Delta (Delta). CCWD provides treated and untreated water to approximately 550,000

people in Central and Eastern Contra Costa County in Northern California. CCWD receives water under contract from the Central Valley Project and under its own water rights. All of CCWD's water supply is delivered through the Delta to the Contra Costa Canal or for storage in Los Vaqueros Reservoir, which is used for water quality control and emergency storage.

Defenders of Wildlife

Defenders of Wildlife is a national non-profit organization, with more than half a million members nationwide, of which more than 125,000 members reside in California. Defenders is dedicated to the protection of all native wild animals and plants in their natural communities. Defenders focuses its programs on addressing the accelerating rate of species extinction, loss of biological diversity, and habitat alteration and destruction. Defenders' California Program office is located in Sacramento, California, with additional offices in Bodega Bay, Monterey, Stockton, and Joshua Tree.

Environmental Defense

Environmental Defense is a national non-profit organization, with over 50,000 members residing in California. The organization seeks to link science, economics and law to create innovative, equitable and cost-effective solutions to today's most important environmental problems. For more than three decades, Environmental Defense has used technical, legal and political expertise to advocate for the protection and restoration of the San Francisco Bay-Delta ecosystem through water policy reform and market-based incentives to encourage efficient and equitable water use.

The Friant Water Authority

FWA is a joint powers authority formed pursuant to California Government Code section 6500 et seq. FWA, consisting of twenty water, irrigation and public utility districts in the southern San Joaquin Valley, operates and maintains the Friant-Kern Canal, which is a conveyance feature of the Friant Division of the Central Valley Project. Friant Division water supplies are made available pursuant to an exchange of San Joaquin River water rights that involves exports from the Delta. The Friant Division service area includes approximately one million acres and 15,000 mostly small family farms on the east side of the southern San Joaquin Valley (Merced, Madera, Fresno, Tulare and Kern Counties). Friant Division water supplies are also relied upon by several cities and towns, including the City of Fresno, as a major portion of their municipal and industrial water supplies. FWA also represents the interests of the four largest Cross Valley Canal contractors.

The Nature Conservancy

The Nature Conservancy is an international nonprofit membership organization, whose mission is to preserve plants, animals, and natural communities by protecting the lands and waters they need to survive. Founded in 1951, The Nature Conservancy and its more than one million embers have safeguarded more than 12 million acres in all 50 states and Canada. The Conservancy has also worked with like-minded partner organizations to preserve more than 100 million acres in Canada, Latin America, the Caribbean, the Pacific, and Asia. In California, The Nature Conservancy has protected more than 1.2 million acres, including over 10,000 acres in the Delta.

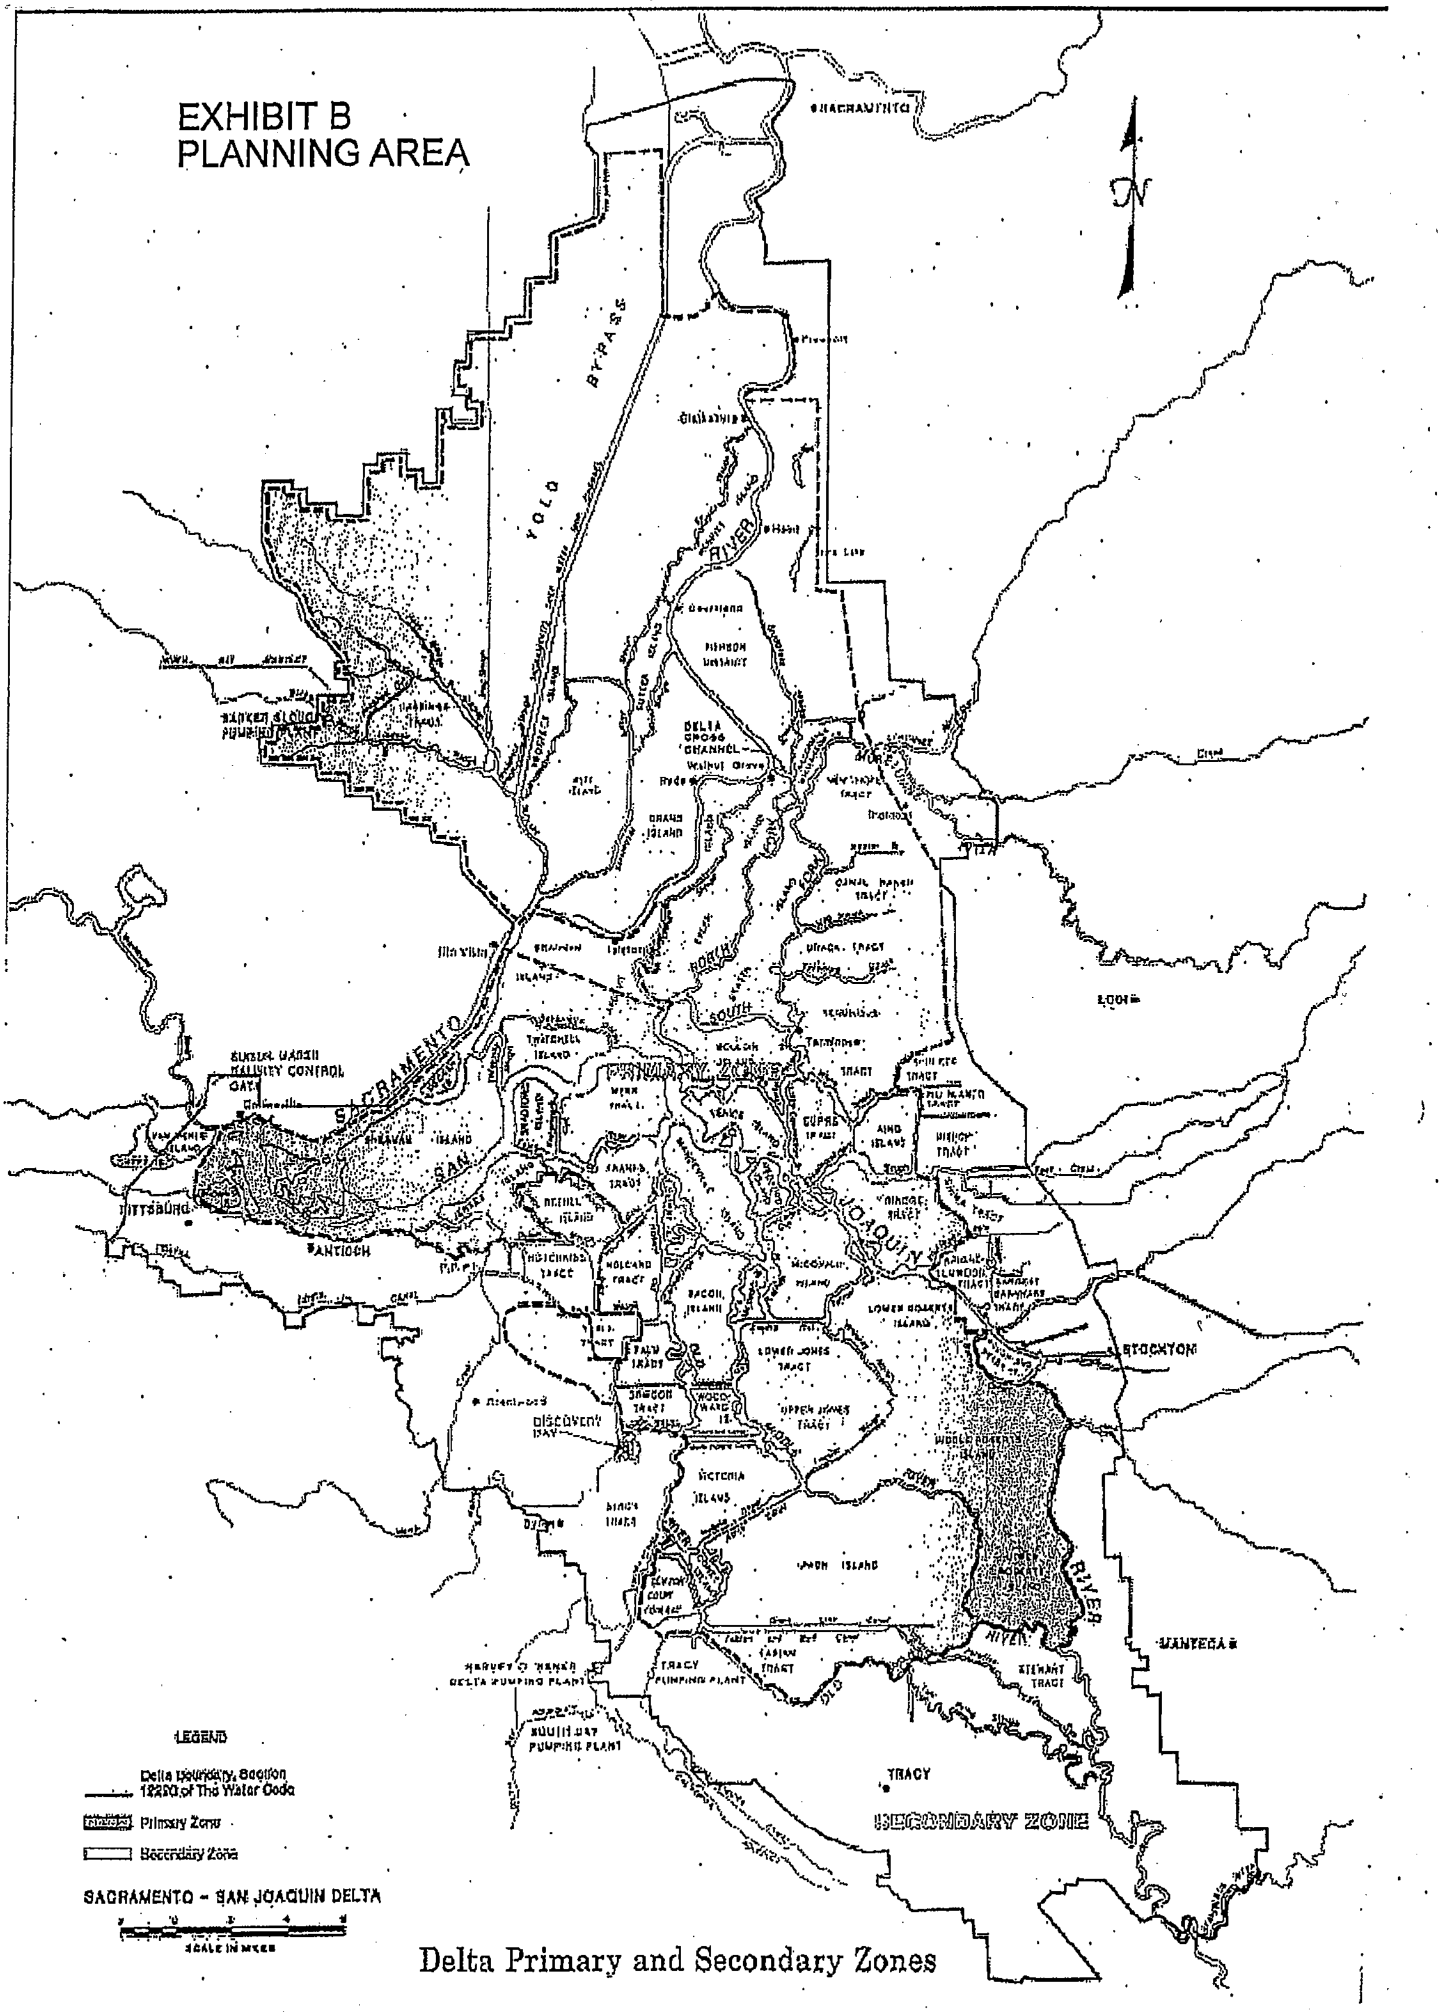
The Natural Heritage Institute

Natural Heritage Institute is a non-profit corporation organized under the laws of the State of California. Natural Heritage Institute's mission is to restore and protect rivers and other aquatic ecosystems in California, other states, and world-wide. It acts in two capacities: as a law firm which represents other conservation organizations and public agencies, and also independently on its own behalf. In these several capacities, since 1989 it has actively participated in regulatory proceedings to establish or modify water rights, water quality standards, and other requirements for the protection and restoration of the Bay-Delta.

North Delta Water Agency

The North Delta Water Agency (NDWA) was formed by a special act of the Legislature in 1973. Its boundaries encompass approximately 277,000 acres, including portions of Sacramento, San Joaquin, Solano, and Yolo counties. The NDWA administers a water rights settlement contract, entered into in 1981, with the Department of Water Resources for the protection of water rights and water quality for farmers and municipal water users in the North Delta. The 1981 Contract is essentially a guarantee by the State of California that, on an ongoing basis, suitable water will be available in the North Delta for agriculture and other beneficial uses. To that end, the Contract requires DWR to operate the State Water Project to meet specific water quality criteria for the Delta channels within NDWA boundaries while guaranteeing the water rights of NDWA water users against any challenge by the State of California. In return, NDWA makes an annual payment to DWR. In addition, the NDWA has assessment authority and collects assessments from property owners in the North Delta to fund the expenses and obligations of the Agency, including its annual payment to DWR. The NDWA is managed by a board of directors consisting of five members, each of whom is elected from one of the five divisions defined in the act forming the Agency.

EXHIBIT B
PLANNING AREA



Delta Primary and Secondary Zones

EXHIBIT C

III. Near-Term Funding

Subject to Section V, this MOA proposes to provide, over the next two years, $60 million in contributions for the BDCP, Species Recovery Capital Fund, Ecosystem Restoration Program, POD Studies, and the 100-Year Vision for the Future of the Delta. This $60 million does not include the value of the commitments made pursuant to Section III.E for the Environmental Water Account.

In order to provide sufficient supplemental funds, which when combined with state, federal and other funding that will enable implementation of priority ecosystem restoration projects for Delta pelagic and anadromous fish through the end of Stage 1 (December 31, 2007), the following near-term funding is proposed:

A. BDCP

1. For calendar years 2006 and 2007, the USBR and DWR on behalf of the State Water Project (hereinafter referred to as The Projects) shall contribute an aggregate of $3 million annually for the collective use of DFG, USFWS, and NOAA Fisheries for staff and administrative costs related to the development of the BDCP. The budget in Attachment A details how these funds are anticipated to be spent.
2. The Projects and/or other applicants who have activities that will be covered by the BDCP will develop a cost-share agreement as part of the application process for the BDCP, which may provide for reimbursement of the The Projects and/or other applicants if new parties are able to utilize work for which The Projects and/or other applicants paid.
3. DFG, USFWS, and NOAA Fisheries will expend contributions made under this section consistent Attachment A.
4. DFG, USFWS, and NOAA Fisheries shall seek additional contributions for agency costs from other BDCP participants.
5. DFG, USFWS, and NOAA Fisheries will apply for additional funding through a Federal Endangered Species Act (FESA) Section 6 application.
6. If new bond funds become available and are appropriated for this purpose, the contributions by The Projects for agency staff and administrative costs shall be reduced accordingly.

FIRST AMENDMENT TO

PLANNING AGREEMENT

BY AND AMONG

THE PARTIES TO THE PLANNING AGREEMENT

REGARDING THE

THE BAY DELTA CONSERVATION PLAN

This First Amendment ("Amendment") to the Planning Agreement regarding the Bay Delta Conservation Plan ("Planning Agreement") is made and entered into by and between the California Natural Resources Agency, California Bay Delta Authority, State Water Resources Control Board, U.S. Army Corps of Engineers, California Department of Water Resources, U.S. Bureau of Reclamation, the Kern County Water Agency, Metropolitan Water District, Mirant Delta, San Luis and Delta-Mendota Water Authority, The Santa Clara Valley Water District, Westlands Water District, Alameda County Flood Control and Water Conservation District Zone 7, American Rivers, Defenders of Wildlife, Environmental Defense Fund, Natural Heritage Institute, the Nature Conservancy , the Bay Institute, California Farm Bureau Federation, Contra Costa Water District, Friant Water Authority, North Delta Water Agency, California Department of Fish and Game, U.S. Fish and Wildlife Service, National Oceanic and Atmospheric Administration. These entities are referred to collectively as "Parties" and each individually as a "Party." This Agreement is made with reference to the following Recitals.

Recitals

A. The Parties have entered into a Planning Agreement, dated October 6, 2006, regarding the Bay Delta Conservation Plan.

B. The terms used in this Amendment will have the meanings set forth in Section 1 of the Planning Agreement.

C. The Effective Date of the Planning Agreement is December 6, 2006. Pursuant to Section 9.5 of the Planning Agreement, the Planning Agreement will automatically terminate three (3) years from the Effective Date, unless extended by an amendment or terminated pursuant to Section 9.7.

D. The Parties agree by this Amendment to extend the Duration of the Planning Agreement by two (2) years.

Terms and Conditions

1. The Duration of the Planning Agreement is hereby extended for two (2) years beyond the original termination date of December 6, 2009. This additional two-year term shall be referred to as the "Extension Period."

2. All other terms and conditions of the Planning Agreement shall remain in full force and effect during the Extension Period.

3. This Amendment will take effect on the date that it is fully executed by the Parties.

4. This Amendment can be amended only by written agreement of all Parties.

IN WITNESS THEREOF, the Parties have executed this Amendment on the dates set forth below.
