KRRC will conduct surveys in accordance with the Guidelines for Conducting Field Archaeology in Oregon, published by the Oregon State Historic Preservation Office (SHPO 2007), and, in California, by the guidelines provided by the California Department of Historic Preservation. KRRC will complete all inventory efforts on federal lands under the supervision of field supervisors authorized under agency-specific cultural resources permits. All inventory methods will follow those prescribed by United States Forest Service (USFS) and Bureau of Land Management (BLM) protocols, dependent upon the lands being surveyed, and will be conducted by field supervisors and archaeological technicians that fully meet qualifications and standards dependent upon appropriate land management agency permitting requirements

KRRC expects that two categories of cultural resources will be identified: archaeological sites and isolated finds. An archaeological site in Oregon is defined as 10 or more artifacts (including lithic debitage) or a feature likely to have been generated by patterned cultural activity within a surface area reasonable to that activity (a form of density measure). An isolated find in Oregon is defined as one (1) to nine (9) artifacts discovered in a location that appears to reflect a single event, loci, or activity. The presence of any feature advances the find into a site status. KRRC will follow similar guidelines in California, where a strict written policy is not provided. Alternatively, on lands managed by federal agencies, KRRC will follow the policies of those agencies.

Previously recorded sites present within the areas to be inventoried will be relocated, if possible, and re-recorded, as necessary. KRRC will give newly identified sites a temporary field number and plot them onto a USGS field map; UTM coordinates will be recorded using a GPS instrument. KRRC will not permanently flag identified resources or otherwise mark them in the field, unless requested by land management agencies.

All above-ground resources, such as buildings, within or adjacent to (within 100 feet of) the survey areas that are 50 years of age or older, or of indeterminate age, will be noted, and their location and information provided to the Built Environment study team for documentation on an appropriate site record. KRRC will consider visual effects to above-ground resources beyond the pedestrian survey area in a separate study.

Built Environment Inventory

Fieldwork methodology will consist of two phases of identification and evaluation, and will focus on two distinct resource categories – hydroelectric (Phase I) and non-hydroelectric (Phase II) facilities. A reconnaissance level effort will make a preliminary evaluation of all historic-era resources and determine whether they meet the NRHP criteria for evaluation, retain integrity, whether they were constructed over 45 years ago (before 1973), and if they meet any NRHP criteria considerations. KRRC chose the 45-year criterion to take into account that effects that could be present during the full course of project activities.

KRRC will typically conduct fieldwork with teams of two architectural historians, who will drive publicly accessible rights-of-way and record resources in a systematic manner. For those resources that would clearly not have views of the Project due to vegetation, landform, or surrounding development, KRRC will collect only location information, as the resource will be considered outside the APE. For those resources inventoried in the APE, KRRC will collect specific information, at least two or more photographs taken, and each resource noted on a field map with recorded by GPS. For those properties that clearly lack historic integrity, or that is a type of resource that is not indicative of broad patterns of history or related to historical events (Criterion A), not associated with significant person or people (Criterion B), and/or is of a common type, style, or method of construction that does not exhibit high artistic values or represent a significant and distinguishable entity whose components may lack individual distinction (Criterion C), no additional information will be collected and a "not eligible" recommendation will be made. In order to apply the criteria, KRRC will use information collected during fieldwork to revise the historic context for the APE and provide an initial basis from which to evaluate the relative importance of identified resources. KRRC will also conduct additional secondary and archival research on common resource types so that a more comprehensive historic context of these resources within the APE can be developed and used for a comparative analysis and an assessment of significance. This assessment will consider whether the resource retains significance at the local, state, or national levels. Further, the analysis will take into account the relative rarity of a resource type and likewise adjust considerations related to that resource's historical integrity. For those resources that retain integrity, are 45 years old or older, and may be eligible under any of the NRHP criteria for evaluation, the resource will be listed as "unevaluated" and subject to Phase II analysis. This analysis will include detailed recordation and full evaluation.

In addition to field recordation, KRRC will undertake research to better understand the resource's history. This will include SHPO/USFS/BLM files, historic maps (such as GLO, Metsker's, and Sanborn, newspapers, and other applicable resources such as census records, genealogical records, biographical encyclopedias, city directories, and family histories. After taking into account the overall integrity and historical significance of the resource, KRRC will make a final recommendation concerning a resource's NRHP eligibility.

Built Environment HABS/HAER/HALS Recordation

KRRC anticipates that mitigation for impacts on the hydroelectric facility buildings and structures will involve some level of Historic American Building Survey (HABS) and Historic American Engineering Record (HAER), documentation. HABS/HAER recordation has been previously determined to be an important mitigation measure in compliance with NHPA Section 106 provisions.

Chapter 7: Resource Evaluation

This page intentionally left blank.

7. RESOURCE EVALUATION

7.1 Archaeological Evaluation

To date, the evaluation of cultural resources identified within the limits of work (and subject to potential direct effects) has occurred based on survey-level data or from subsurface testing work (Phase II investigations) conducted by other parties (not KRRC). The 2004 PacifiCorp report identified three levels of NRHP eligibility for identified sites: eligible, potentially eligible, and not eligible. Eligible sites include those resources that were designated as historic properties on the basis of sufficient existing information about them to draw that conclusion. Potentially eligible sites include those that require more intensive, subsurface investigations to obtain information necessary to determine if they are or are not eligible for the NRHP under Criterion D. Those sites identified as not eligible lack attributes necessary for their inclusion in the NRHP. Neither the California nor Oregon SHPOs has concurred with the NRHP evaluations offered in the previous Klamath River cultural resources reports (Cardno ENTRIX 2012; PacifiCorp 2004). KRRC, working through the CRWG, is facilitating SHPO review of the previous eligibility recommendations to reach NRHP eligibility determinations under the Section 106 process. Once eligibility concurrence is reached, the list of potentially eligible and any yet unevaluated properties will be screened against areas of direct impacts to develop an inventory of affected sites that require evaluation through Phase II testing. Because most individual sites have not yet been identified for evaluation, site-specific methods will be developed later.

The TCPs identified in the tribal ethnographic reports (Section 6.1.4 above) may or may not have archaeological components with information potential and have been evaluated as NHRP-eligible based on other cultural values including associations under Criterion A. Section 106 consultation performed by the FERC, as supported by KRRC, will assist in verifying the NRHP eligibility of TCPs and how TCPs will be integrated into project planning and compliance.

TCRs identified by Tribes as a part of the AB52 consultation process may be disclosed to the SWRBC. If this information is shared with the KRRC, the KRRC will coordinate the evaluation of TCRs for the NRHP with the CRWG and FERC as a part of the Section 106 consultation process.

7.2 Evaluation of Historic Built Environment Resources

The evaluation of historic built environment resources will include an update to the Klamath Hydroelectric Project Request for Determination of Eligibility to include Iron Gate Dam as a historic property and to identify contributing elements to the Klamath Hydroelectric Historic District (KHHD). In addition, an estimated 50 non-hydroelectric historic structures (including buildings, bridges, and other built environment facilities) identified during inventory efforts will require evaluation for eligibility to the NRHP. KRRC will perform built environment evaluation studies to Oregon and California standards. Two historical resources reports for both hydroelectric and non-hydroelectric resources, will be prepared that include information on the resources located in the respective states. The reports will identify the APE, apply the NRHP Criteria for Evaluation, assess project effects, and make recommendations to avoid and minimize effects and mitigate adverse effects. This task will also include a reassessment of those built environment resources that were not 50 years old at time of previous evaluation; and a complete analysis of cultural resources within 100-year flood plain below Iron Gate Dam to Humbug Creek.

Chapter 8: Management Plans and Agreement Documents

This page intentionally left blank.

8. MANAGEMENT PLANS AND AGREEMENT DOCUMENTS

KRRC will produce a number of management plans and agreements to support the Project's Section 106, CEQA, and AB 52's compliance efforts. The documents currently planned include a HPMP, Programmatic Agreement, Inadvertent Discovery Plan, Plan of Action for the treatment of human remains, and a Cultural Resources Monitoring Plan. KRRC may add other plans based on recommendations made by the CRWG and Tribes.

8.1 Historic Properties Management Plan and Programmatic Agreement

FERC, with the assistance of KRRC, will prepare and implement a PA for the Project. KRRC will prepare HPMP to assure compliance with the federal and state laws and regulations that govern historic, cultural, and tribal resources. In preparing the PA and HPMP, KRRC will consult, as appropriate, with FERC and the CRWG. KRRC will continue to consult with FERC and the CRWG as appropriate through the Project's implementation until the expiration of the PA.

On the federal level, the relevant statutes include: (1) Section 106 of the NHPA; (2) National Environmental Policy Act (NEPA); and (3) the Native American Graves Protection and Repatriation Act (NAGPRA). Section 106 requires federal agencies to take into account the effects of their undertakings on historic properties, engage consulting parties, and to provide the ACHP with reasonable opportunity to comment. A "historic property" is "any prehistoric or historic district, site, building, structure, or object included in, or eligible for inclusion in the NRHP. This term includes artifacts, records, and remains that are related to and located within such properties" (36 CFR § 800.16(l)). The term also includes "properties of traditional religious and cultural importance to an Indian tribe . . . and that meet the National Register criteria" (Ibid). Section 106 also requires consultation with relevant SHPOs, THPOs, Indian Tribes, representatives of local governments, individuals and organizations with a demonstrated interest in the Project, and the public (36 CFR § 800.2(c)).

NEPA requires federal agencies to determine whether an action may "significantly affect the quality of the human environment." Among other things, agencies must consider the "unique characteristics of the geographic area such as proximity to historic or cultural resources (40 CFR § 1508.27(b)(8)." NEPA also encourages agencies to the fullest extent possible, prepare environmental documents concurrently with and integrated with environmental impact analyses and related surveys and studies required by the NHPA (40 CFR § 1502.25(a)).

NAGPRA establishes the ownership of cultural items excavated or discovered on federal or tribal land lies with the lineal descendants and culturally affiliated Indian tribes and Native Hawaiian organizations and, among other things, establishes procedures for the inadvertent discovery or planned excavation of Native American cultural items on federal or tribal lands.

As discussed above, KRRC and PacifiCorp have initiated informal Section 106 consultation consistent with FERC's direction and convened a CRWG that includes FERC, other federal agencies, SHPOs, THPOs, Indian Tribes, as well as other consulting parties that will consider the identification and evaluation of cultural resources as well as the avoidance, minimization, and resolution of adverse effects to historic properties. This informal consultation will establish the groundwork for a PA that KRRC will submit for FERC's approval. The PA and HPMP will be completed prior to FERC's Surrender Order. The HPMP will be appended to the PA, once the agreement is finalized. The PA will be effective for the duration of FERC's jurisdictional authority (i.e. the effective duration of FERC's License Surrender Order) which, if so ordered, is currently estimated to end in 2025.

KRRC will also work with FERC, as well as other federal agencies, SHPOs, Tribes, and consulting parties (which include state-recognized tribes who engage in the State Water Board's AB 52 consultation process) to develop and integrate effect avoidance, minimization, and mitigation measures into the HPMP. KRRC will also implement avoidance, minimization, and mitigation measures developed in the ongoing AB 52 consultation led by the SWRCB. Since these measures are tailored to compliance with California laws and regulations, KRRC may develop comparable measures consistent with Oregon's laws and regulations that govern cultural resources, if applicable. KRRC will work with FERC, other federal agencies, SWRCB, tribes, SHPOs, THPOs, and consulting parties to consider and incorporate these measures into the HPMP and PA as appropriate.

8.2 Programmatic Agreement

As the designated non-federal representative, KRRC will prepare a PA for FERC's consideration that is designed to assist with compliance of Section 106 of the NHPA consistent with 36 CFR § 800.14. The PA will consist of a signed, formal agreement between KRRC, lead and cooperating federal and/or state agencies, the California and Oregon SHPOs, THPOs, Indian Tribes, and consulting parties, and will outline all measures necessary for full compliance with NHPA. These will include but will not be limited to protocols for the identification and evaluation of historic properties, permitting requirements, treatment of historic properties, monitoring requirements, inadvertent discovery protocols, curation, and treatment of human remains. KRRC, in consultation with the federal agencies, SHPOs, THPOs, Indian tribes, and consulting parties will draft a PA suitable for review and consideration by FERC. KRRC will assist with revising the PA following consultation and review by the CRWG and incorporate any necessary revisions to the HPMP (discussed in greater detail in Section 8.2). Finalization of the PA, which includes obtaining necessary signatures for acceptance of the PA, will be the responsibility of FERC. The PA will be effective for the duration of FERC's jurisdiction over the Project.

8.3 Historic Properties Management Plan

KRRC will prepare an HPMP to identify mitigation measures and other protective measures to be implemented before and during drawdown and dam removal activities to protect historic, cultural, and tribal resources during the Project's implementation. KRRC will ask FERC and other applicable federal agencies to approve the HPMP before the commencement of any ground disturbance or reservoir draw down activities. At a minimum, the HPMP will incorporate protocols to address the following: (1) identification and evaluation of historic properties; (2) the avoidance, minimization, and mitigation measures to be implemented;(3) the inadvertent discovery of historic, cultural, and tribal resources; (4) the inadvertent discovery human remains and associated grave artifacts; and (5) the monitoring of cultural resources during KRRC's implementation of the Project. The process to amend the HPMP in the event that additional information is obtained during the Project's implementation will be provided in the PA. Other protocols developed during the Section 106 consultation process will be implemented in the HPMP.

8.3.1 Identification and Evaluation of Historic Properties

The HPMP will address historic properties identified to date within the APE, as well as those historic properties potentially identified during project implementation. The HPMP will include the protocols for the phased identification of (1) resources encountered following dewatering activities; (2) resources on properties (if any) where access is not granted until after permitting, (3) resources (including human remains) found as inadvertent discoveries, and/or (4) resources found during cultural resource monitoring. The HPMP will guide treatment measures to avoid, minimize, and mitigate adverse effects to historic properties through the course of the Project. The HPMP will also identify classes of historic properties, relevant research, and potential data gaps in research for classes of properties present in the APE. The HPMP may include other historic property identification and evaluation considerations developed over the course of the Section 106 consultation process.

8.3.2 Effect Avoidance, Minimization, and Mitigation Measures

KRRC will develop the HPMP, which will include a discussion of measures to avoid, minimize, and/or mitigate adverse effects to historic properties. KRRC will implement feasible mitigation recommendations developed during the SWRCB's AB 52 process. Additional avoidance, minimization, and mitigation measures will be identified through the Section 106 consultation process. These additional measures may include but are not limited to mitigation and monitoring, to address reasonably foreseeable direct, indirect and/or cumulative adverse effects that may result from drawdown and dam removal. Wherever feasible, avoidance and preservation in place will be the preferred treatment for historic properties located within the APE. Avoidance may include design changes and/or use of fencing or barricades to limit access to identified historic properties during dam removal and restoration activities.

In cases where avoidance and minimization are not feasible, resource-specific treatment protocols will be drafted as necessary to resolve adverse effects to historic properties adversely affected by the Project. The process for the development of treatment protocols will be outlined in the HPMP and will be consistent with the Secretary of the Interior's Standards for Archaeological Documentation, Historical Documentation, and Architectural and Engineering Documentation; the ACHP Section 106 Archaeology Guidance; and other guidance from the appropriate SHPOs and/or THPOs, as applicable. Additional standards and guidelines may be identified by FERC and/or the CRWG during the Section 106 process. For effects to archaeological sites that will be mitigated through data recovery, mitigation protocols will include but not be limited to a research design that articulates research questions; data needed to address research questions; methods to be employed to collect data; laboratory methods employed to examine collected materials; and proposed disposition and curation of collected materials and records.

Mitigation protocols for direct effects to historic properties eligible for listing in the NRHP under criteria other than or in addition to criterion D will articulate the context for assessing the properties significance, an assessment of the character-defining features that make the property eligible for listing in the NRHP, and an assessment of how the proposed mitigation measures will resolve the effects to the property. Additional mitigation protocols may be developed during the Section 106 consultation process.

8.4 Inadvertent Discovery Program

KRRC will develop a plan for resolving post-review discoveries. Drawdown of the reservoirs proposed as part of the Project could potentially expose previously recorded and unidentified cultural resources, including archaeological resources and human remains. KRRC will prepare an Inadvertent Discovery Plan that will address the inadvertent discovery of resources protected under federal and state law. KRRC will develop the Inadvertent Discovery Plan during agency and tribal consultations and incorporate feedback from the tribes engaged in such consultations as feasible.

The Inadvertent Discovery Plan will include measures that will be implemented in and downstream of the reservoirs if archaeological materials, human remains, or other cultural resources are discovered during drawdown activities. The Inadvertent Discovery Plan will comply with applicable federal and state laws and regulations regarding cultural resources and human remains. The Inadvertent Discovery Plan will address such situations occurring once reservoir drawdown has commenced and throughout the dam removal and restoration process. The discussion below provides a basis and framework for KRRC's Inadvertent Discovery Plan for the Project and may be adjusted and/or supplemented during the Section 106 consultation process.

8.4.1 Inadvertent Discovery of Cultural Resources

KRRC will develop and implement procedures for its personnel and contractors if historic properties are discovered or unanticipated effects on historic properties occur in conjunction with the drawdown of the reservoirs. KRRC will develop these procedures prior to the initiation of dam removal in accordance with 36 CFR § 800.13(a)(2)(b) (Post-review Discoveries).

As noted above, KRRC will provide instruction to environmental monitors regarding the historic, cultural, and tribal resources that could be discovered during project activities. In addition, all KRRC personnel involved in project field activities will be instructed on site discovery, avoidance, and protection measures that will be triggered in the event of an inadvertent discovery, including information on the federal and state statutes and regulations protecting cultural and tribal resources.

KRRC will develop and implement procedures that address situations where unanticipated cultural resources are encountered on private, non-federal public, or federal lands. The procedures will also include the appropriate agency and tribal contacts and consultations in the event of an inadvertent discovery. Applicable federal, tribal, and state laws may govern the procedures.

If previously unidentified cultural resources are discovered during the implementation of the Project, KRRC will immediately implement the Inadvertent Discovery Plan.

8.4.2 Inadvertent Discovery of Human Remains

KRRC will prepare written protocols that will be incorporated into the Inadvertent Discovery Plan specifically for the discovery of human remains in coordination with the CRWG and with Native American tribes (both the tribes engaged in the Section 106 process and the tribes that engaged in the State Water Board's AB 52 consultation process). The protocol will require signature by FERC as the Federal agency official for purposes of Section 106, and a copy of the protocol will be provided to the consulting tribes.

The protocol for the treatment of human remains will include: (1) planned treatment, care, and handling of human remains, funerary objects, sacred objects, and objects of cultural patrimony; (2) information on the kinds of objects that are considered to be funerary objects, sacred objects, and objects of cultural patrimony; (3) specific information used to determine custody/ownership of the remains; (4) the methods to be used for archaeological recording, analysis, and reporting of human remains, funerary objects, sacred objects, and objects of cultural patrimony; (5) the steps to be followed to contact relevant Native American tribal officials at the time of excavation or inadvertent discovery of human remains, funerary objects, sacred objects, and objects of cultural patrimony; (6) the kind of traditional treatment, if any, to be used for human remains, funerary objects, sacred objects, objects of cultural patrimony; and (7) the planned disposition of human remains, funerary objects, sacred objects, and objects of cultural patrimony.

KRRC will utilize the following as a basis and framework to develop the protocol:

- Human remains and associated grave goods may be discovered during various phases of project's planning and implementation. In all cases, human remains encountered during project activities will be treated in a respectful manner and in accordance with the protocol.
- If human remains and/or associated grave goods are discovered as a result of project activities, project activities near the find will cease to the extent feasible. Project activities will be not be allowed within 200 feet of the discovery until authorization is provided through implementation of the approved treatment protocols unless such a restriction is not feasible (e.g., the infeasibility of

halting reservoir drawdown). One exception to this general principle is the conduct of controlled archaeological investigations, which will be subject to specific requirements outlined in the protocol.

- Human remains and/or associated grave goods will be secured and protected to the extent feasible until appropriate disposition has been determined, in accordance with the protocol and applicable federal, state, and local statutes and regulations. Specific procedures to be followed in the event of a discovery will depend on the ownership status of the lands where the human remains and associated grave goods are discovered.
- The provisions of the NAGPRA will govern inadvertent discoveries of Native American human remains on federal or tribal lands. The federal land management agency, in consultation with FERC, as the lead agency, will be responsible for compliance with the NAGPRA and its implementing regulations for all NAGPRA-related inadvertent discoveries and discovery situations on federal or tribal lands. FERC and any relevant land management agency (e.g., BLM) will consult with the relevant Native American tribe(s) or other ethnic groups related to the human remains identified to determine the treatment and disposition measures consistent with the applicable federal laws, regulations, and policies.
- If human remains are encountered on state or private lands, the appropriate County Coroner will be contacted. All human remains will be treated according to the provisions of the applicable federal, state laws, regulations, or policies, as determined through consultation with the appropriate SHPO, federally- or state-recognized Native American tribe, or other ethnic groups related to the human remains.
- In California, treatment of human burials found on State or private lands are covered under the Public Resources Code, Division 5, Parks and Monuments (Division 5 added by Stats. 1939, Ch. 94.), Chapter 1.75. Native American Historical, Cultural, and Sacred Sites, and the California Native American Graves Protection and Repatriation Act of 2001 (Chapter 5 of Part 2 of Division 7 of the Health and Safety Code).
- In Oregon, treatment of human burials found on State or private lands are covered under Oregon Revised Statute (ORS) 97.745. If human remains are encountered, the state police, Oregon SHPO, the Commission on Indian Services, and the appropriate Native American tribe(s) (which are determined by the Commission on Indian Services) need to be immediately contacted.

8.5 Cultural Resources Monitoring Plan

KRRC will develop a Cultural Resources Monitoring Plan as part of the HPMP for implementation during drawdown and dam removal efforts proposed as part of the Project. The Cultural Resource Monitoring Plan will establish general protocols for monitoring when ground disturbing work is occurring in close proximity to historic properties or where work is occurring in areas where there is a high probability of encountering cultural resources. The Cultural Resources Monitoring Plan may include other areas that will benefit from monitoring, including known archaeological sites and those areas determined to show a high probability for buried cultural deposits. Monitoring will, as appropriate, include field inspection by personnel under the direct supervision of a person meeting the Secretary of the Interior's Professional Qualifications standards and will consult with federally- and state-recognized tribes for tribal monitors, as appropriate. The Cultural Resources Monitoring Plan will address the management and protection of historic properties in the APE to avoid Project-related effects from drawdown, dam removal, and restoration activities. Cultural resources, human remains, or funerary objects discovered during the monitoring of project activities will be treated in accordance with the protocols described in the Inadvertent Discovery Plan.

8.6 Looting and Vandalism Prevention Plan

KRRC will develop a Looting and Vandalism Prevention Plan to reduce the risk of looting or vandalism during the implementation of the Project to the extent that the Project's implementation creates additional risk of looting or vandalism. If looting and vandalism occur to sites in California, KRRC will consult with federal agencies, SHPOs, THPOs, tribes engaged in the Section 106 process and tribes participating in the AB 52 consultation with SWRCB.

The Looting and Vandalism Prevention Plan will include training of KRRC monitors and personnel about looting and vandalism of tribal, cultural, and historic resources. It will also include an established communications protocol and reporting process to law enforcement and other relevant federal, state, and local agencies upon discovery of evidence that looting or vandalism is or has occurred. Public access to the reservoirs will be restricted during drawdown for safety reasons, as well as protecting against the potential looting and vandalism of protected tribal, cultural, or historic resources.

KRRC will also include in the Looting and Vandalism Plan other protective measures, including appropriate restrictions to public access to known or inadvertently discovered historic, tribal, or cultural resources as appropriate and feasible on a case by case basis. Specific measures that will be considered include fencing, posting of signs, strategic plantings, strategic routing of roads, boating access points and trails, or other means that are feasible and necessary to protect unauthorized looting or vandalism of resources protected under federal and state law. Additional measures may be identified during the Section 106 consultation process with FERC and the CRWG.

Chapter 1: Introduction

This page intentionally left blank.

1. INTRODUCTION

This Water Quality Monitoring Plan (WQ Plan) describes the proposed water quality monitoring activities prior to, during, and following completion of the Project. In general, the monitoring plan covers the following elements:

- Assessment of Klamath River water quality parameters (e.g. dissolved oxygen, temperature, turbidity, conductivity, suspended sediment, nutrients) collected prior to, during, and following dam removal.
- Sampling and analysis for the presence of blue-green algae related toxins (microcystin) during and following dam removal.
- Toxicity assessment of residual reservoir sediments, and sediments deposited downstream of the project reservoirs in the Klamath River and estuary following dam decommissioning.

This WQ Plan presents a general overview of the water quality monitoring that is presently being conducted in the Klamath River through Interim Measure 15 - Water Quality Monitoring (IM-15), the KRRC's approach to augment this monitoring before, during, and after dam decommissioning, and the KRRC's approach to sampling and analyzing the river and estuary waters and sediments.

KRRC will revise this draft document to be consistent with the water quality monitoring requirements in the final Clean Water Act Section 401 Water Quality Certifications from California and Oregon. Draft 401 Water Quality Certifications from both states are currently under public review and public comments are expected through mid-July 2018. The information collected under this WQ Plan will assist the KRRC in making adaptive management decisions during and following dam decommissioning to lessen impacts to aquatic resources by implementing aspects of the KRRC's Aquatic Resource Measures (Section 7.2 of the Definite Plan).

Chapter 2: Background

This page intentionally left blank.

2. BACKGROUND

2.1 Klamath Interim Measure 15 Water Quality Monitoring

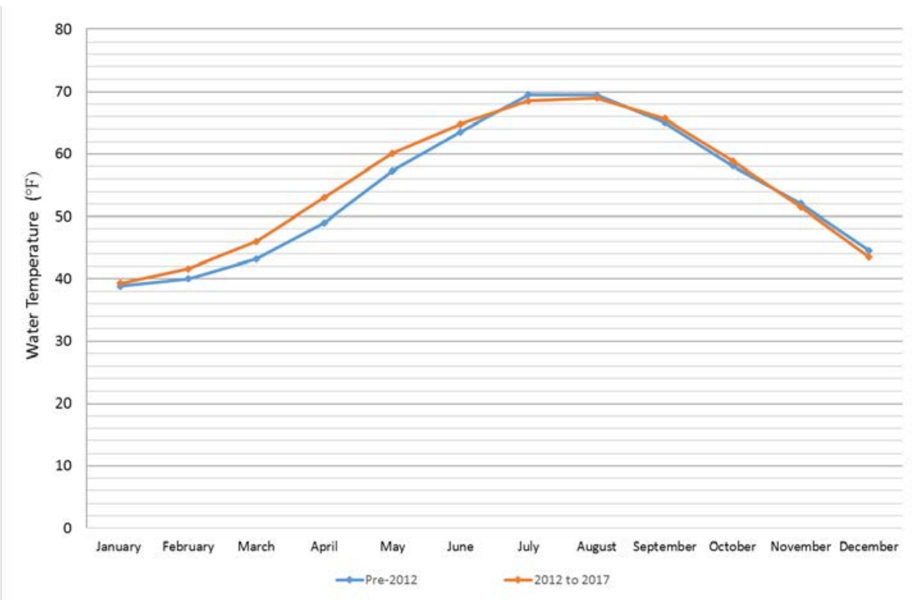
The amended KHSA includes provisions for the interim operation of the Lower Klamath Project (FERC Project 14803) by PacifiCorp prior to decommissioning and included several Interim Measures (IMs) to mitigate conditions created by the dams and to collect baseline information prior to the beginning of dam removal drawdown Activities. The KHSA includes IM-15 that requires PacifiCorp to fund water quality monitoring from Upper Klamath Lake to the Klamath River estuary at the Pacific Ocean. The water quality monitoring under IM-15 entered its tenth year in 2018 and PacifiCorp has an obligation to continue IM-15 monitoring until the dam decommissioning phase of the Project begins. IM-15 contains the following water quality monitoring elements:

- Cyanobacteria and cyanotoxin grab sampling for public health protection at 18 locations from Upper Klamath Lake to the estuary, including nine locations downstream of Iron Gate Dam in the Klamath River.
- Water quality monitoring at 18 sites on the Klamath River from Link River Dam to the estuary. Additional water quality monitoring is conducted at the mouth of the four major Klamath River tributaries (Shasta, Scott, Salmon, and Trinity).
- Hourly sonde data collection at six locations between Iron Gate Dam and the community of Klamath for temperature, dissolved oxygen, pH, and electrical conductivity.
- Seasonal (May-October), monthly, and bimonthly) discrete grab sampling conducted for nutrients, including total nitrogen and phosphorus, nitrate and nitrite, ammonia, particulate and organic phosphorus and dissolved carbon.

The above monitoring is conducted by the U.S. Bureau of Reclamation (USBR), PacifiCorp, and the Yurok and Karuk tribes and is funded by PacifiCorp. The Klamath Basin Monitoring Program (KBMP), a consortium of in-basin regulatory and resource agencies and interested stakeholders, maintains the water quality monitoring data collected under IM-15. KBMP's Klamath River monitoring data and location maps can be found at http://www.kbmp.net. KRRC intends to utilize the existing KBMP data set, augmented by new data collected before, during, and after dam decommissioning, as the WQ Plan data set.

2.1.1 Water Quality Trends

Water quality monitoring in the Klamath Basin has continued since the publication of the Klamath Facilities Removal Environmental Impact Statement/Environmental Impact Report, 2012 (2012 EIS/R). Data compiled from real-time continuous monitoring of parameters such as water temperature, dissolved oxygen (DO), pH, conductivity, and turbidity at a point on the Klamath River just below Iron Gate Dam was analyzed for trends, some of which is presented below. This location provides an overview of water quality in the river as it exits the last dam of the Lower Klamath Project. Water quality in the area generally continues to follow the trends evaluated in the 2012 EIS/R. Figure 2-1 shows the average monthly water temperature in the Klamath River below Iron Gate Dam from 2006 to 2011 and 2012 to 2017, where data was available. In general, water temperature below Iron Gate Dam is warmer in spring months (March through May) than it was in the past, differing by up to 4 percent in April. Figure 2-2 presents the average DO recorded from 2006 to 2017 for the months of June through October, when available. Typically, during the summer and early fall, water temperature in the river is higher and issues with DO occur. During these months, DO was recorded higher in June, July, and October, but lower in August and September compared to previous years. The average monthly pH from 2012 onward was recorded at higher values than those between 2006 and 2011; though similar from May to October, see Figure 2-3. This information suggests that there would be no changes to the conclusion made in the 2012 EIS/R.



Source: Karuk Tribe 2017

Figure 2-2 Average Percent DO in the Klamath River below Iron Gate Dam between June and October

Source: Karuk Tribe 2017

Figure 2-3 Monthly pH in the Klamath River below Iron Gate Dam

2.1.2 Contaminants in Sediment

In 2011, an evaluation of the sediments from each reservoir was completed to assess the risk of contamination in biota and humans from the release of reservoir sediments. Results of this evaluation were compared to the 2009 U.S. Army Corps of Engineers (USACE) Sediment Evaluation Framework (SEF) for the Pacific Northwest and U.S. Environmental Protection Agency (EPA) screening levels (SLs). Freshwater contaminant screening levels were updated and finalized in the 2016 SEF and are typically less protective than standards set forth by EPA SLs and Oregon Department of Environmental Quality (ODEQ) Bioaccumulation Screening Level Values (SLVs) for fish consumption. The marine SLs are relatively unmodified from the 2009 SEF. KRRC reviewed the results from the 2011 evaluation under the 2016 SEF SLs and compliance with a level 2B evaluation (see Section 4.7.5 of the Definite Plan for a full discussion). This reevaluation confirmed the conclusions presented in the 2012 EIS/R that the reservoir sediments in each reservoir are suitable for unconfined, aquatic disposal and that contamination risks from reservoir sediment are unlikely and/or are either lower than with the dams still in place and/or lower than background levels.

2.1.3 Algae in the Klamath Hydroelectric Reach

There are two dominant algal communities within the Hydroelectric Reach in the Klamath Basin, phytoplankton and periphyton. Blue-green algae and cyanobacteria are the predominant phytoplankton in Copco 1 and Iron Gate reservoirs and frequently reach nuisance levels in the summer and fall, often producing toxins (i.e. microcystin) at levels that are potentially harmful to humans and animals. Phytoplankton accumulation from the reservoirs occurs in portions of the Klamath River below Iron Gate Dam and can contribute to nuisance levels of blue-green algae, under certain conditions. Cyanobacteria and green algae are the dominate periphyton (i.e., attached algae) in the riverine portions of the Klamath River. The growth and prevalence of nuisance algal blooms of blue-green algae and other species are generally determined by the nutrient concentration, primarily nitrogen and phosphorus, and water temperature within the river. Continued monitoring of nutrients, algae, and algal toxins show the continuation of trends observed and presented in the 2012 EIS/R. A study published in 2015 (Otten et al. 2015) used a variety of genetic approaches to track the source of toxic algae found in the Klamath River below Iron Gate Dam, in addition to 15 other sampling locations throughout the Klamath River. The study concluded that microcystin producing algal populations originate within Copco 1 and Iron Gate reservoirs rather than imported from upstream sources (e.g. Upper Klamath Lake). The relative significance of contributions of the reservoirs and upstream sources is complex and disputed. The KRRC does not state a position on the relationship or relative significance of such sources. To the extent that these reservoirs are a source, the Project will remove the source.

In 2016, the Oregon Heath Authority released the updated Public Health Advisory Guidelines for Harmful Algae Blooms in Freshwater Bodies. This updated the criteria for issuing and lifting a public health advisory. Criteria for issuing a public health advisory is dependent on visible scum (photos and water testing), cell counts (greater than or equal to 100,000 cells per milliliter [cells/mL] for combined species or 40,000 cells/mL for microcystin), and/or toxicity levels (greater than or equal to 10 micrograms per liter for microcystin). Public health advisories can be lifted only after the initial cell count or toxin results are reported below the threshold. The Yurok Tribe also updated their advisory threshold guidelines after the 2012 EIS/R. These updated Level 1 thresholds are equal to those issued by the Oregon Health Advisory for combined species (100,000 cells/mL) but are much lower for microcystin cell count (1,000 cells/mL) and microcystin toxin concentrations (0.8 micrograms per liter). Despite the changes to the guidelines for posting public health advisories for toxic algae blooms, the most recent monitoring data shows that health advisory postings remain common place at Copco 1 and Iron Gate reservoirs and on the Klamath River below Iron Gate Dam.

This page intentionally left blank.

Chapter 3: Water Quality Monitoring Plan

This page intentionally left blank.

3. WATER QUALITY MONITORING PLAN

3.1 Rationale for Water Quality Monitoring Plan

KRRC anticipates impacts from the Project on aquatic resources in the lower Klamath River through the release of reservoir sediment. The 2012 EIS/R for dam removal anticipated that the reservoir sediments, composed largely of organic silt and clay size particles would exhibit high chemical oxygen demand (COD) and high suspended sediment concentrations (SSC) downstream of Iron Gate Dam. The highly turbid water and low dissolved oxygen caused by sediment release will result in stress and mortality to fish and other aquatic organisms in the mainstem Klamath River during reservoir drawdown. KRRC plans to conduct pre-, concurrent, and post-dam removal water quality monitoring (one year before and three years following dam removal) to assess the impacts of dam removal on the aquatic environment from J.C. Boyle Dam to the estuary. The KRRC will also collect water quality samples at Keno Dam upstream from the Project to assess baseline river conditions.

3.2 Monitoring Locations

Table 3-1 and Figure 3-1 present the locations and characteristics of the project water quality monitoring stations that will operate 12 months of the year at least one year prior to dam removal and up to three years following dam removal. Each monitoring location is also an existing IM-15 monitoring site, thus enabling KRRC to augment previously collected data. KRRC will collect water quality and discharge data at each site, as discussed in the next section.

KRRC was informed by the IM-15 monitoring entities that all locations require strengthening of the sonde holding mechanism to withstand winter conditions (currently, IM-15 data collection activities are ceased from approximately November through April). KRRC is working with the Karuk tribe, Yurok tribe and US Geological Services (USGS) to complete the necessary improvements prior to the beginning of pre-drawdown monitoring activities. KRRC will augment the IM-15 monitoring during the pre-drawdown monitoring period by upgrading and operating the stations during the winter months. Once drawdown is initiated, KRRC will operate the monitoring stations year-round and IM-15 monitoring will cease.

KRRC removed the Walker Bridge site along the Klamath River at River Mile 156.3 from the list due to access approval issues. If access issues are resolved, KRRC may add the site back into the list of monitoring sites.

The Klamath River site above Shovel Creek is located approximately 3 river miles downstream from the California/Oregon stateline and KRRC is considering it as a possible location for a stateline monitoring station. The site is currently monitored under IM-15. The final location of the stateline monitoring location may change including moving this monitoring to the JC Boyle Powerplant location at RM 219.7. The stateline monitoring location, specifics and duration of operation will be defined in consultation with will ODEQ and California SWRCB.

Table 3-1 Monitoring Locations

Location	River Mile	Current Monitoring Entity	Existing Sonde	USGS Gage Station
Klamath River below Keno Dam	233.4	USBR and PacifiCorp	n	y
Klamath River below J.C. Boyle Powerplant	219.7	PacifiCorp	n	y
Klamath River above Shovel Creek (near Stateline)*	206.42	PacifiCorp	n	n
Klamath River below Iron Gate Dam	189.7	PacifiCorp	y	y
Klamath River below Seiad	128.5	Karuk Tribe	y	y
Klamath River at Orleans (USGS)	59.1	Karuk Tribe	y	y
Klamath River near Klamath	6.0	Yurok Tribe	y	y

3.3 Water Quality Monitoring Parameters and Frequency

Table 3-2 lists the water quality parameters KRRC will monitor at each of the monitoring locations. KRRC will collect time-series water quality and stream discharge data, in accordance with the Water Quality Certifications, to assess water quality impacts of the Project. Discrete water quality samples will also be collected to support the suspended sediment load quantification, characterize constituent concentrations that cannot be measured using sondes, and to validate the sonde time-series data.

Table 3-2 Water Quality Monitoring Parameters

Constituent	Frequency	Type of Data
Temperature	Hourly, 12 months per year	Time-Series
Dissolved Oxygen	Hourly, 12 months per year	Time-Series
pH	Hourly, 12 months per year	Time-Series
Conductivity	Hourly, 12 months per year	Time-Series
Turbidity	Hourly, 12 months per year	Time-Series
SSC	Up to 24 samples pre-drawdown; weekly during drawdown, monthly following drawdown for 36 months or until TSS equals background at Keno	Discrete (Auto-Sampler)

Constituent	Frequency	Type of Data
SSC	4 storm events pre-drawdown; every two weeks during and after drawdown or until TSS equals background at Keno	Depth-width integrated sample
Chemical Oxygen Demand	Monthly, daily during drawdown	Discrete
Total Nitrogen	Monthly	Discrete
Total Phosphorous	Monthly	Discrete
Microcystin Cell Count	Monthly	Discrete

KRRC will collect sonde turbidity data as Nephelometric Turbidity Units (NTUs). However, impacts to aquatic resources from reservoir sediments have been quantified in milligrams per liter (mg/L) of SSC. The KRRC collected reservoir sediment samples in 2017 and plans to have the USGS conduct a series of laboratory tests to develop a SSC versus turbidity relationship for the reservoir sediments. This relationship will assist in making adaptive management decisions during and following dam removal and in understanding the impacts to aquatic resources. KRRC will develop a laboratory protocol for the SSC/turbidity relationship analysis that identifies the accuracy and reliability of this relationship along with any uncertainties and specific field verification testing during dam decommissioning.

KRRC will characterize chemical Oxygen Demand and nutrient concentrations to assess the impacts of reservoir sediment decomposition, and other biological activities, on the dissolved oxygen concentrations in the river.

KRRC will quantify cell counts of microcystin producing blue-green algae to determine attainment of existing heath related water quality standards.

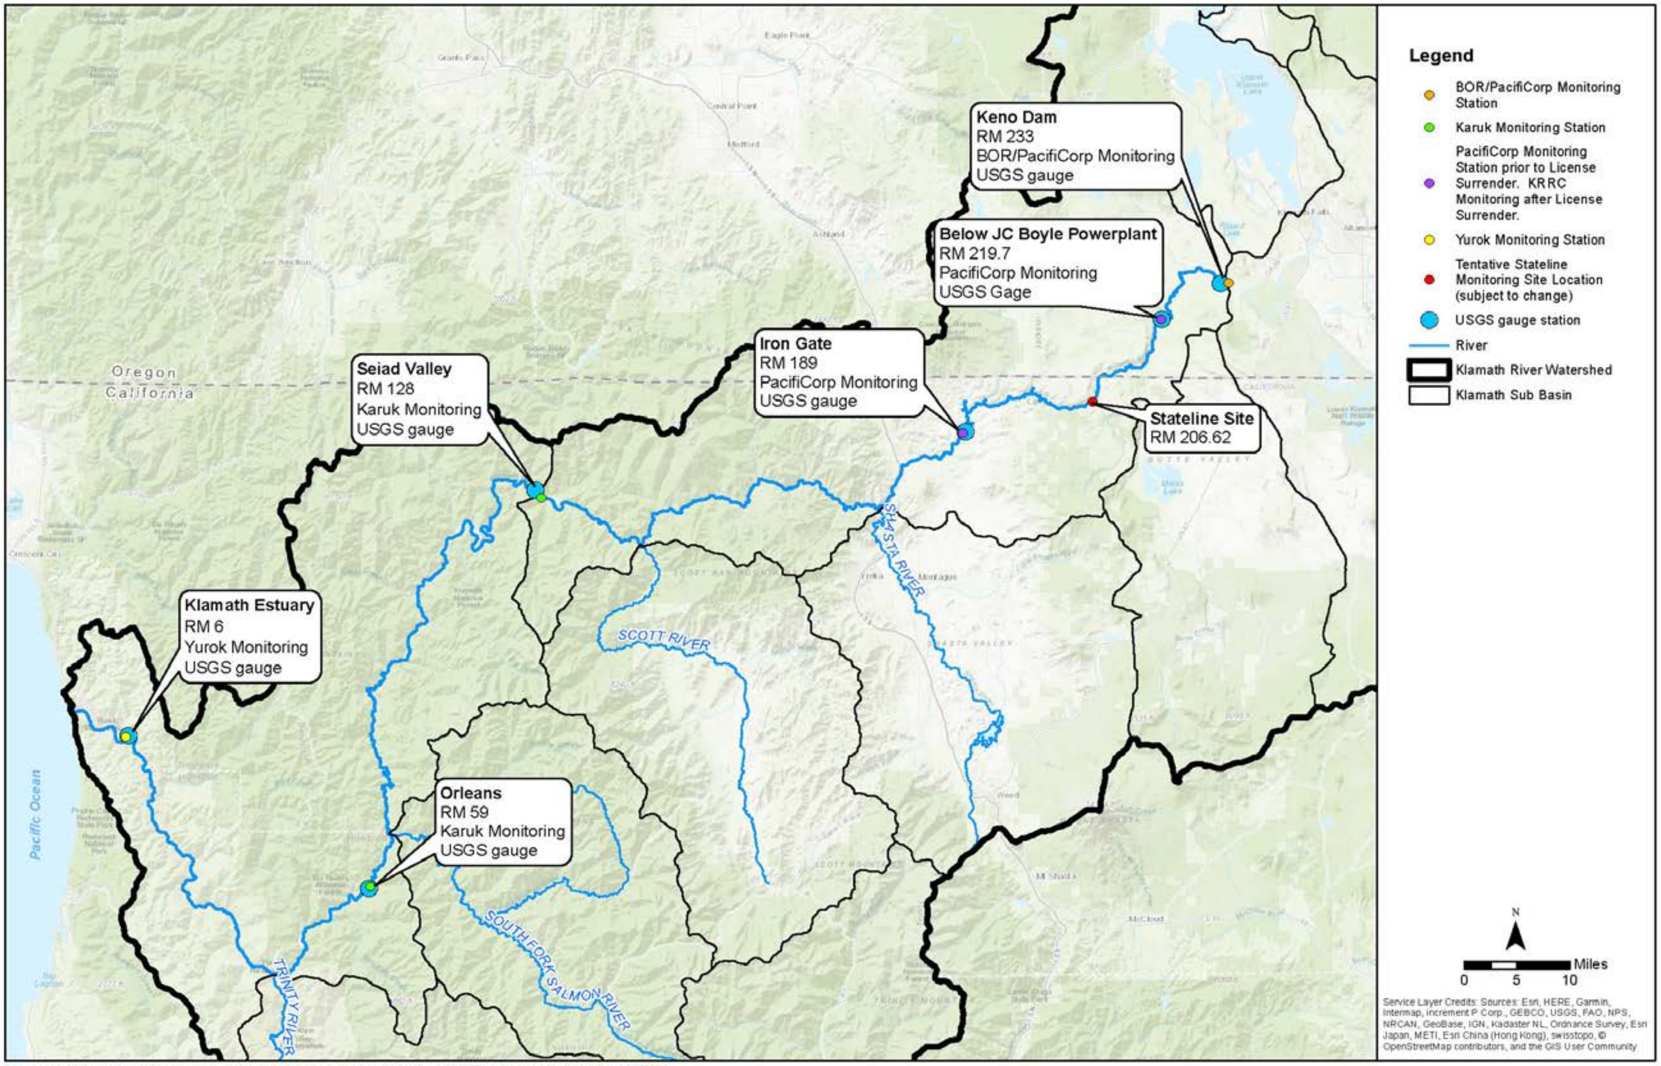

Figure 3-1 Water Quality Monitoring Locations

3.4 Riverbed Sediment Sampling and Analysis

During the Secretarial Determination process, USBR collected 75 five sediment cores in 2009 from the three reservoirs that will be removed as part of the Project and analyzed sediments for 501 anthropogenic and naturally occurring chemicals and compounds. USBR assessed whether significant risk existed for humans or aquatic biota via five contaminate exposure pathways. The data analysis was done in collaboration with the states of Oregon and California, as well as the EPA. The USBR concluded that no chemicals or compounds were detected in reservoir sediments at concentrations exceeding human health screening levels, and no other preclusions to releasing the reservoir sediments during dam decommissioning to the freshwater or marine environment were identified for human or aquatic biota exposure (USBR 2012d).

The above finding aside, the draft California Section 401 Water Quality Certification requires characterization of sediment quality in reservoir and riverbed sediments upstream and downstream of the project reservoirs, and in the Klamath estuary. KRRC will develop a sediment characterization plan in consultation with Oregon and California regulatory agencies to satisfy the requirements of the Section 401 Water Quality Certifications for both states with consistent sampling and testing protocols and procedures.

All sampling, analysis, and evaluation of sediments for the presence of toxic compounds will follow the procedures and protocols defined in the USACE Sediment Evaluation Framework for the Pacific Northwest, July 2016 (RSET 2016).

3.5 Plan Implementation and Schedule

The KRRC will implement this Plan in accordance with the sampling schedules and frequencies defined herein and for up to three years following dam removal. Monitoring activities will continue until the State Water agencies are satisfied that attainment of Basin Plan water quality standards occurs, or after the specified time period (3 years) expires for post-construction monitoring stated within the California and Oregon 401 Water Quality Certifications, whichever occurs first.

KRRC will implement the WQ Plan in accordance with the State Water Resources Control Board's Surface Water Ambient Monitoring Program (SWAMP). KRRC will develop a project-specific Quality Assurance Project Plan (QAPP) to describe the monitoring protocols and will include detailed mapping and figures depicting site locations, characteristics and equipment configurations. The QAPP will define:

- Monitoring entities (i.e. Yurok and Karuk tribes, USGS, USBR) and their specific roles and responsibilities
- Monitoring program design details and data collection protocols
- Data management activities and data storage
- Data quality objectives and quality assurance/quality control (QA/QC)
- Regulatory, stakeholder, and public reporting of the collected data.

Chapter 1: Introduction and Purpose

This page intentionally left blank.

1. INTRODUCTION

The Project may impact groundwater levels in the immediate vicinity of the reservoirs. The United States Bureau of Reclamation (USBR) performed a desktop review of wells located within a 2.5-mile radius of the three main reservoirs (Iron Gate, Copco, and J.C. Boyle) of the Project and reported these well locations in the 2012 Final Environmental Impact Statement/Environmental Impact Report for dam decommissioning (USBR and CDFW 2012). The USBR concluded that additional monitoring work would be required before, during, and following dam decommissioning to better understand reservoir removal effects on the surrounding groundwater wells.

This Groundwater Well Management Plan identifies groundwater wells that the Project may adversely impact. If the Project adversely impacts groundwater wells, KRRC will take steps (e.g., well deepening) to return the production rate of any affected domestic or irrigation groundwater supply well to conditions prior to dam decommissioning. There are five steps in this plan:

1. Database Search and Agency Coordination
2. Outreach to land owners and residents
3. Installation of groundwater monitoring wells
4. Groundwater monitoring
5. Post-Dam removal outreach/notification of findings
6. Proposed actions to improve production rate

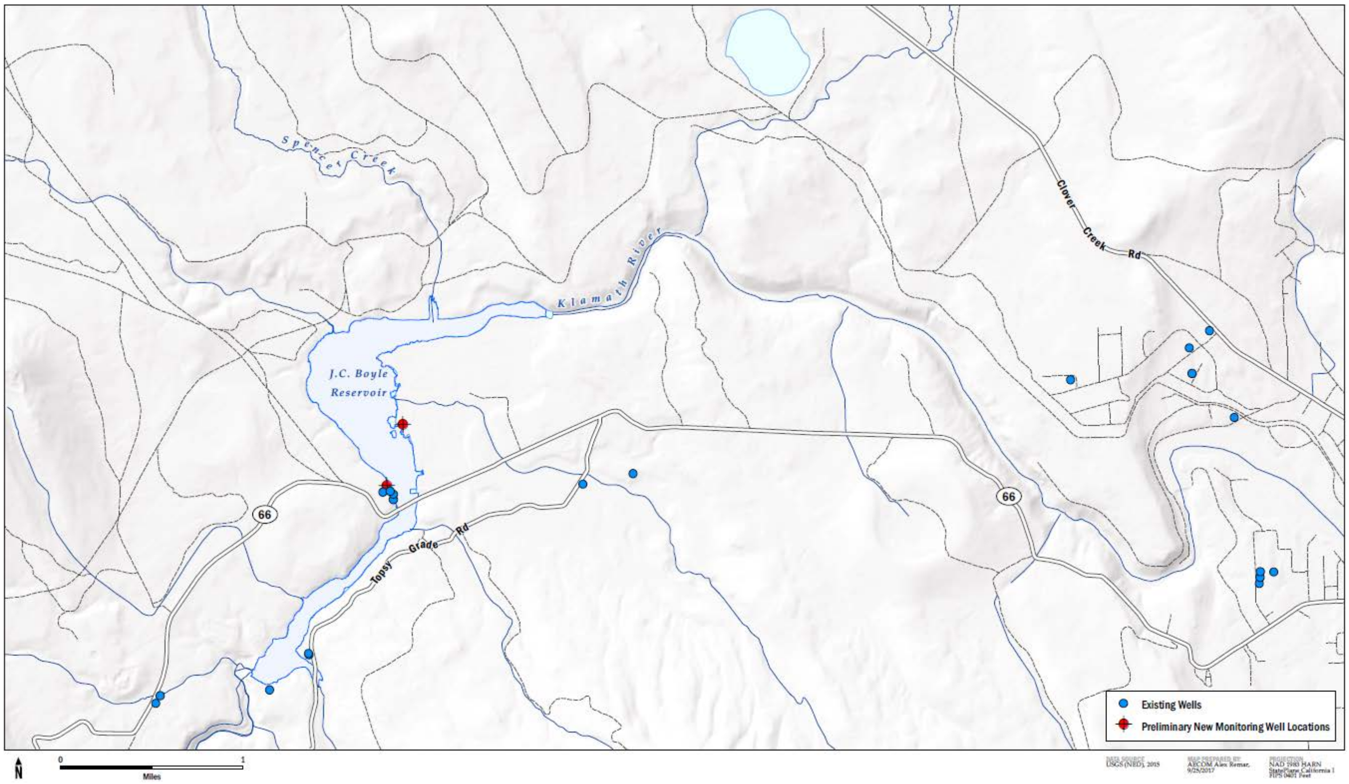

Figure 1 Identified Groundwater Wells within 2.5 Miles of J.C. Boyle Reservoir

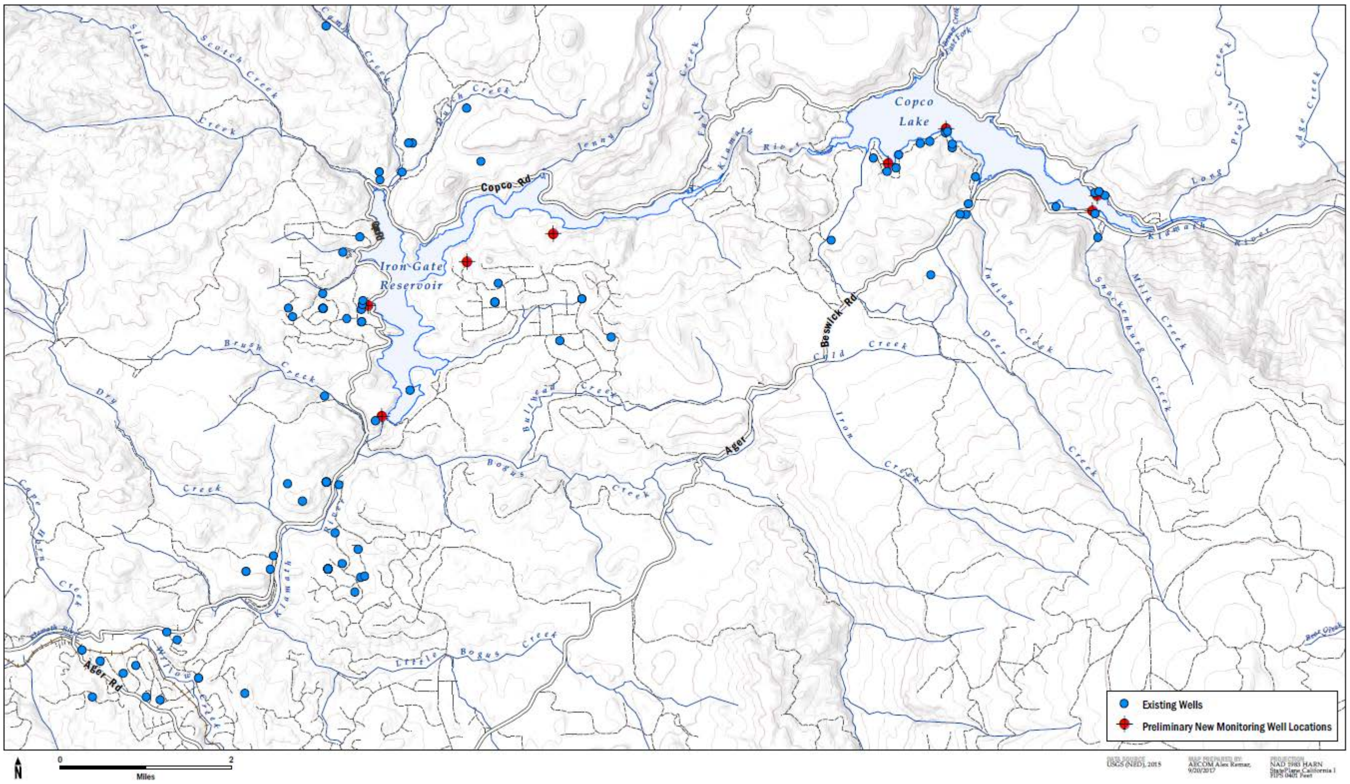

Figure 2 Identified Groundwater Wells within 2.5 Miles of Copco Lake and Iron Gate Reservoir

This page intentionally left blank.

Chapter 2: Management Plan

This page intentionally left blank.

2. MANAGEMENT PLAN

The following sections summarize the five steps in this plan:

1. Database Search and Agency Coordination
2. Outreach to land owners and residents
3. Installation of groundwater monitoring wells
4. Groundwater monitoring
5. Post-Dam removal outreach/notification of findings
6. Proposed actions to improve production rate

2.1 Database Search and Agency Coordination

The KRRC reviewed USBR's database that identifies 124 existing wells located within a 2.5-mile radius of the project reservoirs. The KRRC attempted to verify the location of these wells and identified any new wells within this radius installed since 2012. The KRRC contacted Siskiyou County, the California Department of Water Resources (DWR), and Oregon Water Resources Department (OWRD) about the accessibility of their groundwater well data bases.

Siskiyou County did not provide any specific information on well locations or ownership due to insufficient staff resources. County staff stated that there are no shared water systems at the California reservoirs[1], so KRRC assumed that all reservoir residents utilize groundwater for domestic use. (Rick Dean, personal communication, July 27, 2017). Siskiyou County recommended that the KRRC contact DWR to verify previously recorded well locations and to identify any potential new well records.

The KRRC contacted DWR and was told that DWR's policy does not allow the sharing of well ownership information (Benjamin Brezing, personal communication, August 8, 2017). .

The KRRC contacted OWRD and was directed to use their public database to download well logs for those surrounding J.C. Boyle (Mary Grainey, personal communication, August 23, 2017). Of the 17 well logs that KRRC identified and downloaded using the OWRD database search, only one provided a specific location..

Given the gaps in information discernable from these data bases,, the KRRC has proposed a broad land owner outreach program as described below.

[1] KRRC has since learned from residents that there is a shared spring water supply near Copco Lake that supplies a portion of the residences there.

2.2 Outreach to Land Owners and Residents

KRRC retained the locations reported by USBR in 2012 for further analysis. To fully understand and update this information, the KRRC will undertake an outreach effort in 2018-2019 to all residents and landowners within 2.5 miles of the project reservoirs to inquire about their groundwater wells.

The KRRC will develop and send an information and questionnaire mailer to property owners, residents, and businesses within 2.5 miles of each project reservoir in 2018. The mailer will include a request to monitor the well for water level prior to, during, and following dam decommissioning. The KRRC will also use its planned public meetings and meetings targeted at reservoir land owners to "spread-the-word" about the proposal to identify wells for monitoring within 2.5 miles of the reservoirs. The KRRC will identify as many well owners as possible that are willing to participate in the monitoring program. Initial information requested by the questionnaire will include:

- Description of the well monitoring program
- Request to participate in the well monitoring program
- Specific information requests:
  - Property address and well location
  - Current depth to groundwater
  - Physical parameters of the well (casing size, well depth, screen interval, pump size)
  - Historical groundwater well problems (quantity and quality)

2.3 Installation of Groundwater Monitoring Wells

The KRRC will identify a sufficient number of residential wells within the proximity of each reservoir to monitor the effects of reservoir drawdown on the groundwater aquifer (sentinel wells). Wells near the reservoirs (less than ¼ mile) are preferred, as the groundwater recharge effect from the reservoir decreases with distance from the reservoir. If an insufficient number of well owners agree to participate in the groundwater monitoring activity, the KRRC will install a minimum of 10 sentinel monitoring wells around the three reservoirs. KRRC will install the monitoring wells between residents and the reservoirs on PacifiCorp land. KRRC proposes to install up to four monitoring wells each at Iron Gate Reservoir and Copco Lake and two wells at J.C. Boyle Reservoir. Figures 1 and 2 show proposed monitoring well locations.

2.4 Groundwater Monitoring

KRRC will monitor sentinel wells belonging to participating landowners including any monitoring wells installed by the KRRC pre- and post-dam decommissioning to identify seasonal fluctuations in groundwater levels and any groundwater level changes that may be attributable to reservoir removal. KRRC will also monitor sentinel wells for general water quality parameters including pH, conductivity, and major anions and cations. To establish baseline conditions, the KRRC plans to monitor sentinel wells monthly for a minimum of one year prior to dam decommissioning. Following dam decommissioning, KRRC will conduct groundwater monitoring monthly for up to one year or until such time that post-project groundwater levels and general water quality parameters have been determined (no discernable water level declines or changes in quality over a four-month period) or they mirror baseline conditions.

During the drawdown period, KRRC will install data loggers in the sentinel wells to continuously record groundwater levels and pH and conductivity. If KRRC identifies changes attributable to reservoir removal to water levels or quality that might indicate potential supply problems, the KRRC proposes to take the actions described in Section 2.6 to restore temporary and/or long-term water supplies.

2.5 Post-Dam Removal Outreach/ Notification of Findings

The KRRC will compile and summarize in writing the groundwater data collected prior to, during, and following dam decommissioning. KRRC will use these data to identify any trends or changes in groundwater water levels and quality that may be attributable to reservoir removal. The KRRC will prepare a report of findings and identify any areas where groundwater wells are determined to be vulnerable to groundwater levels or water quality declines resulting from reservoir removal. The KRRC will make the report available to all well owners in the study area. Well owners will have the opportunity to request an evaluation of their well to determine if there are changes in groundwater water levels and quality attributable to reservoir removal.

2.6 Proposed Actions

If the data collected during or following dam decommissioning indicates a loss of supply or adverse water quality to any potable or irrigation well, and that these circumstances are attributable to reservoir removal, then the KRRC will provide temporary water supplies until long-term measures such as motor replacement, well deepening, or full well replacement are identified and implemented as needed to return the production rate of any affected domestic or irrigation groundwater supply well to conditions prior to dam decommissioning .

Chapter 1: Need for Fire Management

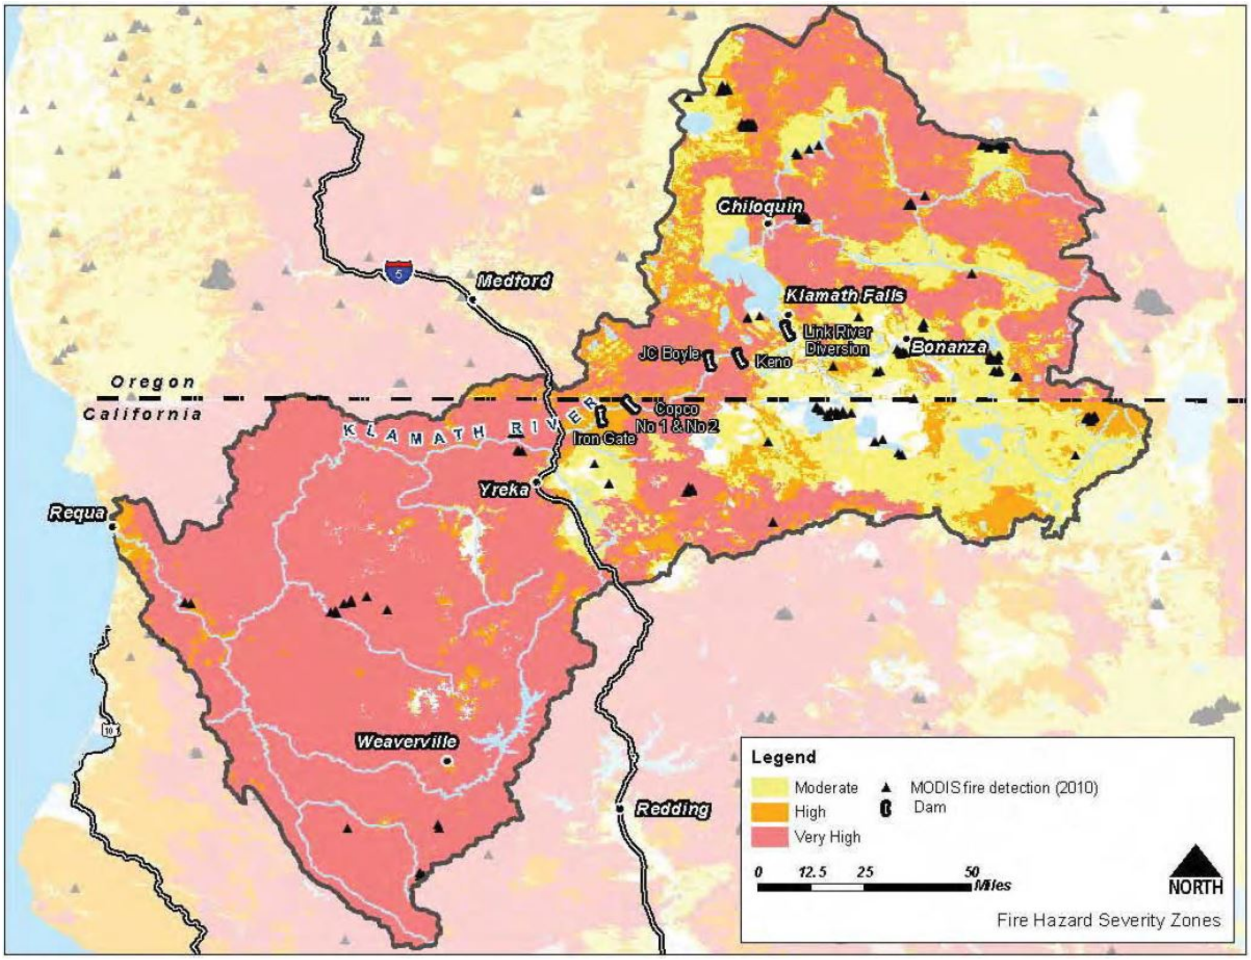
This page intentionally left blank.

1. NEED FOR FIRE MANAGEMENT

KRRC developed this Fire Management Plan (FMP) to address fire prevention and response methods including fire precaution, pre-suppression, and suppression measures to support implementation of the Definite Plan for the Lower Klamath Project (Definite Plan) proposed by the Klamath River Renewal Corporation (KRRC) for physical removal of four dam developments (Iron Gate, Copco No. 1, Copco No. 2, and J.C. Boyle), hereinafter the Project. The FMP requires that areas of construction and deconstruction work involving activities that could result in open sparks or flame be cleared of dried vegetation or wetted-down to prevent wildfires. The FMP also requires fire suppression equipment be on-site at all times and emergency contact numbers be posted, in case of a fire. With the removal of the reservoirs as a source of water for fighting wildfires, the Fire Management Plan also provides measures for potential alternative sources of water for firefighting.

The areas surrounding the four Klamath River dams are at risk of wildfires particularly during the dry season, and the risk of triggering a fire associated with construction and demolition activities necessitates the development and implementation of a fire management plan such as this FMP to prevent and respond to fires. California Department of Forestry and Fire Protection (Cal Fire) categorizes the fire threat in the region as high to very high (Cal Fire, 2007). Fire hazard mapping using the MODerate-resolution Imaging Spectroradiometers by the US Forest Service Remote Sensing Application Center (USFS 2010) shows the distribution of fire threats in the Klamath basin (Figure 1-1), and Klamath County has identified Wildland Urban Interfaces (WUI), where fire damage hazards are high (Wildland Fire Technologies, 2016). There is a ranking system associated with WUIs and J.C. Boyle Dam, which is partially located in the Keno WUI Community, has a WUI rating of High, the highest value in Klamath County.

Construction and dam removal activities potentially increase the risk of fire if not properly managed. Activities of concern include accidental spills of flammable material, spark generation in vegetated open space, use of equipment and machinery that generates heat such as welding, grinding, and use of generators. Agencies dealing with fire prevention and suppression in the region have developed regulations and management methods to combat the increased risk of fire associated with construction activities. KRRC developed the FMP in accordance with the standards of, and in consultation with the local, state, and federal fire suppression agencies. The following sections describe the relevant agencies, their jurisdictions and regulatory requirements, and the FMP components to ensure the safe execution of the Project.



Source: USBR 2012

Figure 1-1 Map of fire hazard in the Klamath River basin generated using the MODerate-resolution Imaging Spectroradiometers by the USFS.

Chapter 2: Fire Suppression Agencies

This page intentionally left blank.

2. FIRE SUPPRESSION AGENCIES

The FMP requires coordination with multiple city, county, state, and federal fire suppression agencies including USDA Forest Service (USFS), Bureau of Land Management (BLM), the Oregon Department of Forestry (ODF) Klamath-Lake District (KLD), Cal Fire - Siskiyou Unit (Cal Fire SU), local districts of Klamath and Jackson Counties in Oregon and Siskiyou County in California, and local city and volunteer fire stations (Table 2-1). Fire safety and suppression resources are available from the various agencies in the event of a fire.

Table 2-1 Fire protection agencies in the project vicinity

Agency	Type	Jurisdiction
USDA Forest Service	Federal	National Forests, federally managed land
Bureau of Land Management	Federal	BLM lands, federally managed land
Cal Fire	State of California	State Resource Lands, California
Oregon Department of Forestry	State of Oregon	State Resource Lands, Oregon, BLM land in Klamath River Canyon
Klamath County Fire District	Local, County of Klamath	Unincorporated County Lands and the City of Klamath Falls
Colestin Rural Fire District	Local, County of Jackson	County Fire District in Jackson County, Oregon
Siskiyou County Fire Protection Districts: Copco Lake, Hornbrook, Montague, South Yreka, Tulelake, Etna, Ft. Jones, Weed	Local, County	Unincorporated County Lands throughout Siskiyou County, California
Mount Shasta Fire Department	Local, City of Mount Shasta	Mt. Shasta Municipal Boundaries
Yreka Fire Department	Local, City of Yreka	City of Yreka Municipal Boundaries

Source: USBR and CDFW 2012

The USFS and BLM are the two federal agencies responsible for fire support and suppression in the Project vicinity. Both agencies provide wildfire protection primarily on land under their direct ownership and management but will provide support and assistance to other agencies when requested. Federal land near the Project limit of work is primarily limited to several BLM parcels along the Klamath River downstream of J.C. Boyle Dam and along Iron Gate and Copco reservoirs (Figure 2-1). BLM land near the Project limit of work in Oregon, including the Klamath River Canyon, is managed for fire by ODF KLD.

The Oregon and California State forestry and fire prevention agencies (ODF and Cal Fire) are the primary fire protection providers in the unincorporated areas in the Project limit of work. ODF and Cal Fire enforce their respective state laws and regulations and coordinate fire support with the local agencies. Cal Fire operates and works with local city, county, and volunteer fire departments. Fire management in Siskiyou County is operated as the Cal Fire SU. The Iron Gate and Copco developments are located within the Siskiyou County Unit Shasta Valley Battalion 2 area, and the Klamath River flows through Battalion 3. Cal Fire stations in the project vicinity include the City of Yreka and Hornbrook, which is located 10 miles west of Iron Gate Dam. The J.C. Boyle development in Oregon is under the jurisdiction of ODF KLD. The ODF KLD is a member of the South Central Oregon Fire Management Partnership (SCOFMP), which is a cooperative group of agencies including USFS, BLM, US Fish and Wildlife, and Crater Lake National Park. The SCOFMP shares resources to manage fire in the region, which primarily comprises Klamath and Lake Counties. Dispatch responsibilities for the SCOFMP are with the Lakeview Interagency Fire Center (LIFC).

The city-operated fire stations in the region include the Yreka and Mount Shasta Fire Departments in California. Many county fire stations are present throughout the project vicinity, and are associated with Klamath and Jackson counties in Oregon and Siskiyou County in California (Table 2-1).

Chapter 3: Regulations and Requirements

This page intentionally left blank.

3. REGULATIONS AND REQUIREMENTS

KRRC developed this FMP to meet the regulations and requirements set forth by the fire suppression agencies in the Project vicinity (Figure 2-1). Most of the dam deconstruction and reservoir management will take place on private land. ODF and Cal Fire handle state regulations for fire management with regard to various construction related activities. BLM and USFS manage their respective lands, and those regulations only need to be met for construction taking place on federal land. There are several BLM parcels along the Klamath River adjacent to and in the Project limits of work. In Oregon, ODF KLD manages the BLM lands east of the Cascades crest and west of Hwy 97 and regulates them for fire according to ODF rules. This area includes the Klamath Canyon project area. In California, a few BLM parcels are located near the Copco project footprint. In these locations, BLM generally defers to restrictions corresponding to the Predicted (or Designated) Activity Levels (PALs) set by the USFS Klamath National Forest and relies on Cal Fire for direct protection responsibilities (Brodhead, L., personal communication 2017.08.29). For logging operations on BLM land in California, contractual fire prevention and suppression measures vary between projects but must typically conform to general Cal Fire and USFS regulations and the input from a BLM Authorized Agent assigned to the contract (Brodhead, L., personal communication 2017.08.29). The USFS owns land that is near Copco reservoir but outside of the project footprint. Therefore, the FMP does not address specific USFS fire prevention and suppression requirements outlined in the Code of Federal Regulations (CFR).

3.1 Oregon Department of Forestry – Klamath Lake Unit

Oregon law prescribes regulations and minimum requirements for fire prevention and suppression that are applicable in each ODF Fire Protection District during fire season. In Oregon, fire season is declared by each ODF district and is typically between early June and mid- to late-October. Table 3-1 lists the laws and requirements for all ODF districts.

ODF districts west of the Cascades crest have industrial operations requirements and restrictions that correspond to four adjective classes Industrial Fire Precautionary Levels (IFPL). A different system is in place for ODF districts east of the Cascades crest, such as the ODF KLD. Construction operations must follow the regulations in Table 3-1 for all levels of fire danger during fire season. Additional restrictions are enforced when fire hazard is classified as “extreme.” ODF does not have general restrictions or requirements when work is performed outside of the fire season.

If required by Oregon law ORS 477.625, KRRC’s contractor will obtain a permit for Power-Driven Machinery (PDM) from the ODF state forester for construction activities that involve heavy machinery. Fire prevention requirements under the PDM permit are dependent on the Fire Danger Level (FDL) and requirements for fire prevention and suppression preparedness relate to the type of machinery and fire hazard. The PDM permit requirements are more restrictive during "Extreme" adjective class FDL and include the suspension of the operation of tracked machinery between the hours of 1 pm and 8 pm ((ORS 477.625(1a), OAR 629-043-0026(5)). The Project will use tracked equipment and, if a PDM permit is required, such use will be subject to these restrictions during extreme fire danger. ODF typically informs PDM permit holders of changes in fire hazard and operation requirements. PDM permits expire at each new calendar year and KRRC's contractor will renew a PDM as necessary.

The ODF forester can grant waivers from the fire prevention and suppression requirements, including the PDM permit, in some instances. Waivers may be granted for favorable weather conditions, topographic setting, and/or alternate methods and equipment proposed by the operator that provide equal or better fire prevention and suppression.

Table 3-1 2017 ODF fire season minimum requirements

Category	Reference	Requirement
No Smoking	ORS 477.510	No smoking while working or traveling in an operation area
Hand Tools	ORS 477.655, OAR 629-043-0025	Supply hand tools for each operation site - 1 tool per person with a mix of pulaskis, axes, shovels, hazel hoes. Store all hand tools for fire in a sturdy tool box clearly identified as containing firefighting tools. Supply at least one box for each operation area. Crews of 4 or less are not required to have a fire tools box as long as each person has a shovel, suitable for fire-fighting and available for immediate use while working on the operation.
Fire Extinguishers	ORS 477.655, OAR 629-43-0025	Each internal combustion engine used in an operation, except power saws, shall be equipped with a chemical fire extinguisher rated as not less than 2A:10BC (5 pound).
Power Saws	ORS 477.640, OAR 629-043-0036	Power saws must meet Spark Arrester Guide specifications - a stock exhaust system and screen with < .023 inch holes. The following shall be immediately available for prevention and suppression of fire: • One gallon of water or pressurized container of fire suppressant of at least eight ounce capacity • One round pointed shovel at least 8 inches wide with a handle at least 26 inches long • The power saw must be moved at least 20' from the place of fueling before it is started.
Fire Tools, Extinguishers for Trucks	ORS 477.655, OAR 629-043-0025	Equip each truck driven in forest areas for industrial purposes with: • One round pointed shovel at least 8 inches wide, with a handle at least 26 inches long • One axe or Pulaski with 26 inch handle or longer • One fire extinguisher rated not less than 2A:10BC (5 pound).

Category	Reference	Requirement
Spark Arresters and Mufflers	ORS 477.645, OAR 629-043-0015	All non-turbo charged engines must meet Spark Arrester Guide specifications except: • Fully turbo charged engines. • Engines in motor vehicles operating on improved roads equipped with an adequate muffler and exhaust system. • Engines in light trucks (26,000 GVW or less) that are equipped with an adequate muffler and an exhaust system. • Engines in heavy trucks (greater than 26,000 GVW) that are equipped with an adequate muffler and exhaust system. • If a truck engine is not fully turbo-charged, then the exhaust must extend above the cab and discharge upward or to the rear, or to the end of the truck frame. • Water pumping equipment used exclusively for fighting fire. • Engines of 50 cubic inch displacement or less, except ATV's and motorcycles, shall be equipped with an adequate muffler and an exhaust system. • Engines in ATV's and motorcycles must be equipped with an adequate muffler and exhaust system or an approved screen, which completely encloses exhaust system. • Power saws. (See power saw requirements)
Pump, Hose, and Water Supply	ORS 477.650, 477.625, OAR 629-043-0026, 629-43-0020	Supply a pump, hose and water supply for equipment used on an operation. • Pump must be maintained ready to operate and capable to provide a discharge of not less than 20 gallons per minute at 115 psi at pump level. Note: Volume pumps will not produce the necessary pressure to effectively attack a fire start. Pressure pumps are recommended. • Water supply shall be a minimum of 300 gallons if a self-propelled engine. Water supply shall be a minimum of 500 gallons if not self-propelled (pond, stream, tank, sump, etc.) • One water supply is adequate as long as the operator can deliver water to the fire within 10 minutes • Provide enough hose (500 feet minimum) not less than 3/4" inside diameter to reach areas where power driven machinery has worked. Note: Should a fire occur, the operator must be able to position the water supply in a location where enough hose is available to reach the area worked by power driven machinery. This includes mobile equipment as well as motorized carriages and their moving lines. Moving lines are defined as main lines and haul back lines. This can be achieved in many ways, including the practice of having a water tank and hose attached to a piece of equipment, like a skidgen or skidder, that can get the water to the fire. • Water supply, pump, and at least 250' of hose with nozzle must be maintained as a connected, operating unit ready for immediate use.

Category	Reference	Requirement
Fire Watch Service	ORS 477.665, OAR 629-043-0030	Each operation area is to have a fire watch. Fire watch shall be on duty during any breaks (up to 3 hours) and for three hours after all power-driven machinery used by the operator has been shut down for the day. The ODF KLD has specific fire watch duration prescriptions based on Fire Danger Level adjective class. • Low = 1 hr fire watch • Moderate = 2 hrs • High to Extreme = 3 hrs Fire watch shall: • Be physically capable and experienced to operate firefighting equipment. • Have facilities for transportation and communications to summon assistance. • Observe all portions of the operation on which activity occurred during the day. Upon discovery of a fire, Fire watch personnel must: First report the fire, summon any necessary firefighting assistance, describe intended fire suppression activities and agree on a checking system; then, after determining a safety zone and an escape route that will not be cut off if the fire increases or changes direction, immediately proceed to control and extinguish the fire, consistent with firefighting training and safety.
Operation Area Fire Prevention	ORS 477.625, OAR 629-043-0026	• Keep all power driven machinery free on excess flammable material which may create a risk of fire. • Avoid line-rub on rock or woody material, which may result in sparks or sufficient heat to cause ignition of a fire. • Disconnect main batteries from powered components (other than what may be necessary to retain computer memory) through a shut-off switch or other means or leave equipment on ground cleared of flammable material.

Source: ODF 2010, 2017

3.2 Cal Fire – Siskiyou Unit

California law prescribes regulations and minimum requirements for fire prevention and suppression that are applicable during fire season in all lands within the Cal Fire jurisdiction. The California Public Resources Code (PRC) requires preventative fire measures (Table 3-2) that are imposed during the time where a Burn Permit is required under PRC-4423. For Zone B, which includes northern California counties, this period usually begins May 1 and persists until proclamation of the termination of fire season by the fire director. Cal Fire does not require a permit for the use of equipment and heavy machinery on a construction site. State forest and fire laws may be enforced by USFS, BLM, NPS, and certain county fire departments in addition to Cal Fire personnel. The California Code of Regulations (CCR) has specific and generally applicable regulations that pertain to fire prevention and suppression, e.g., requirements for smoking during fire season, but no associated permits are required. The CCR, PRC, and FRC regulations pertaining to construction sites and logging operations in California and the associated best management practices are described in detail in the Cal Fire Industrial Operations Fire Prevention Field Guide (1999).

Table 3-2 California Public Resources Code Fire precautionary measures*

Category	Reference	Requirement
Fire Causing Equipment	PRC-4427	No person shall use or operate any motor, engine, boiler, stationary equipment, welding equipment, cutting torches, tarpots, or grinding devices from which a spark, fire, or flame may originate, which is located on or near any forest-covered land, brush-covered land, or grass-covered land, without doing both of the following: a. First clearing away all flammable material, including snags, from the area around such operation for a distance of 10 feet. b. Maintain one serviceable round point shovel with an overall length of not less than 46 inches and one backpack pump water-type fire extinguisher fully equipped and ready for use at the immediate area during the operation. This section does not apply to portable powersaws and other portable tools powered by a gasoline-fueled internal combustion engine.
Use of Internal Combustion Engines	PRC-4428	No person shall use or operate any vehicle, machine, tool or equipment powered by an internal combustion engine operated on hydrocarbon fuels, in any industrial operation located on or near any forest, brush, or grass-covered land between April 1 and December 1 of any year, or at any other time when ground litter and vegetation will sustain combustion permitting the spread of fire, without providing and maintaining, for firefighting purposes only, suitable and serviceable tools. a. A sealed box of tools shall be located, within the operating area, at a point accessible in the event of fire. This fire toolbox shall contain: one backpack pump-type fire extinguisher filled with water, two axes, two McLeod fire tools, and a sufficient number of shovels so that each employee at the operation can be equipped to fight fire. b. One or more serviceable chainsaws of three and one-half or more horsepower with a cutting bar 20 inches in length or longer shall be immediately available within the operating area, or, in the alternative, a full set of timber-felling tools shall be located in the fire toolbox, including one crosscut falling saw six feet in length, one double-bit ax with a 36-inch handle, one sledge hammer or maul with a head weight of six, or more, pounds and handle length of 32 inches, or more, and not less than two falling wedges. c. Each rail speeder and passenger vehicle shall be equipped with one shovel and one ax, and any other vehicle used on the operation shall be equipped with one shovel. Each tractor used in such operation shall be equipped with one shovel.

Category	Reference	Requirement
Fire Fighting Tools	PRC-4429	In an area of any industrial or other operations on or near any forest-covered land or brush-covered land, there shall be provided and maintained at all times, in a specific location, for firefighting purposes only, a sufficient supply of serviceable tools to equip 50% of the able-bodied personnel for fighting fires. • Tools shall be included shovels, axes, saws, backpack pumps, and scraping tools. • One serviceable headlight adaptable for attachment to at least one-half of the tractor-bulldozers used on the operation. • A sufficient number of canteens and flashlights to equip a third of the able-bodied personnel.
Water Pumps	PRC-4430	The use or operation of any steam-operated engine or machine equipment, located on or near forest-covered land or brush-covered land, requires • One adequate force pump or water under pressure equivalent to a pump, and not less than 200 feet of hose not less than one inch in diameter for each steam-operated engine or equipment. • The pump or water pressure shall be capable of applying a minimum of 40 pounds pressure at the nozzle on 200 feet of hose, such nozzle to be 0.25 inch or larger in diameter. • If two steam-operated engines or steam equipment are customarily operated within 100 feet of each other, only one engine or piece of equipment need be equipped with pump and hose.
Gas Powered Saws	PRC-4431	No person shall use or operate or cause to be operated any portable saw, auger, drill, tamper, or other portable tool powered by a gasoline-fueled internal combustion engine on or near any forest-covered land, brush-covered land, or grass-covered land, within 25 feet of any flammable material, without providing and maintaining at the immediate locations of use or operation of the saw or tool, for firefighting purposes one serviceable round point shovel, with an overall length of not less than 46 inches, or one serviceable fire extinguisher. The type and size of fire extinguisher necessary to provide at least minimum assurance of controlling fire caused by use of portable power tools under various climatic and fuel conditions shall be specified in regulations issued by the Director of Forestry and Fire Protection. The required fire tools shall at no time be farther from the point of operation of the power saw or tool than 25 feet with unrestricted access for the operator from the point of operation.

Category	Reference	Requirement
Spark Arresters	PRC-4442	a. No person shall use, operate, or allow to be used or operated, any internal combustion engine which uses hydrocarbon fuels on any forest-covered land, brush-covered land, or grass-covered land unless the engine is equipped with a spark arrester maintained in effective working order or the engine is constructed, equipped, and maintained for the prevention of fire. b. Spark arresters affixed to the exhaust system of engines or vehicles shall not be placed or mounted in such a manner as to allow flames or heat from the exhaust system to ignite any flammable material. c. A spark arrester is a device constructed of nonflammable materials specifically for the purpose of removing and retaining carbon and other flammable particles over 0.0232 of an inch in size from the exhaust flow of an internal combustion engine that uses hydrocarbon fuels or which is qualified and rated by the United States Forest Service. d. Engines used to provide motor power for trucks, truck tractors, buses, and passenger vehicles, except motorcycles, are not subject to this section if the exhaust system is equipped with a muffler. e. Turbocharged engines are not subject to this section if all exhaust gases pass through the rotating turbine wheel, there is no exhaust bypass to the atmosphere, and the turbocharger is in effective mechanical condition.
Exclusion of Outdated, Handheld Internal Combustion Equipment	PRC-4443	No person shall use, operate, or cause to be operated on any forest-covered land, brush-covered land, or grass-covered land any handheld portable, multi-position, internal-combustion engine manufactured after June 30, 1978, which is operated on hydrocarbon fuels, unless it is constructed and equipped and maintained for the prevention of fire.

** Measures are applicable during any times of the year when burning permits are required unless otherwise stated.*

This page intentionally left blank.

Chapter 4: Contacts

This page intentionally left blank.

4. CONTACTS

KRRC's contractor will be in frequent contact with the pertinent fire suppression agencies during construction to discuss fire hazards, prevention, suppression, and contingency plans. KRRC's contractor and a designated Safety Officer will identify the nearest local fire stations to the current operation areas and ensure the emergency contact information for each agency is posted at the project site and available to fire watch personnel and on-site workers.

In Oregon, the primary contact agency is ODF KLD. KRRC's contractor will contact the ODF KLD Unit Forester and Stewardship Forester during development of detailed, site-specific fire management plans to identify fire management resources in the Project vicinity. ODF KLD will be the first agency contacted in the event of a fire on the Oregon portion of the Project.

In California, the primary contact agency is Cal Fire SU. KRRC's contractor will contact the Cal Fire SU Prevention Specialist during development of detailed, site-specific fire management plans to identify resources in the Project vicinity. Cal Fire SU will be the first agency contacted in the event of a fire on the California portion of the Project.

This page intentionally left blank.

Chapter 5: Fire Management Plan

This page intentionally left blank.

5. FIRE MANAGEMENT PLAN

5.1 Responsibilities

KRRC's contractor will designate an individual as "Safety Officer" to be available and on-call 24 hours a day, 7 days a week in the event of a fire at the project site. The Safety Officer will be the primary on-site communication linkage to ODF and Cal Fire foresters and will be responsible for managing all on-site fire prevention and suppression documentation, including the contact information for local emergency services, such as local fire departments and hospitals. The Safety Officer will be responsible for instructing other workers in the required fire prevention and suppression measures, including the use of fire suppression equipment and the protocols in the event of a fire, and for communicating current fire hazards and any changes in prevention and suppression methods on a daily basis. KRRC's contractor will clearly post a table of emergency contact agencies, their jurisdictions, and phone numbers at each project site. The Safety Officer will ensure that all fire suppression equipment is well-maintained and located in proper position within the construction site.

In the event of a fire, the Safety Officer will immediately contact LIFC dispatch and ODF KLD in Oregon or Cal Fire SU in California and subsequently any other pertinent fire suppression agencies and the Federal Energy Regulatory Commission local office as appropriate. The Safety Officer will then initiate fire suppression protocols and command fire control activities on the site until relieved by fire suppression professionals. The goal is to immediately and aggressively extinguish any fire that occurs during the Project without sacrificing the safety of workers. If the Safety Officer judges equipment on-site incapable of suppressing the fire, the Safety Officer will initiate an evacuation of the project site.

KRRC's contractor and Safety Officer will work with ODF KLD and Cal Fire SU foresters to develop broad scale contingency plans for fire containment within their respective jurisdictions in the Project areas. KRRC's contractor will meet regularly with ODF KLD and Cal Fire SU foresters to discuss Project progress and updates as they pertain to fire prevention and suppression. The Safety Officer will continuously evaluate the location, condition, and importance of existing fuel breaks and will alert the relevant fire suppression agencies if fuel breaks need to be modified. KRRC's contractor and Safety Officer will identify the location of water resources for fire suppression, and KRRC's contractor will inform the ODF KLD and Cal Fire SU foresters of any modifications to existing water resources due to dam removal activities, e.g., the drawdown of the reservoirs.

5.2 Fire Prevention and Suppression Measures and Equipment

This FMP includes fire prevention and response methods that are consistent with the policies and standards of the various local, county, state, and federal jurisdictions. KRRC's contractor will take precautionary, pre-suppression, and suppression measures to ensure public safety in the Project vicinity and comply with the fire season regulations and requirements set forth by ODF (Table 3-1) and Cal Fire (Table 3-2). KRRC's contractor will work closely with the ODF KLD Unit Forester and Stewardship Forester and the Cal Fire SU Forester to develop effective communication links, evolving plans for fire prevention and suppression, and suppression actions in the event of a fire. ODF KLD will likely assign a Stewardship Forester to the Project for the duration of the Project.

If required by ORS 477.625, KRRC's contractor will obtain an ODF PDM permit. Operation hours of tracked machinery are limited by the PDM permit during extreme fire danger, and KRRC's contractor will suspend operation of these machines between the hours of 1 pm to 8 pm when required. KRRC's contractor will take additional measures to keep machinery and the work area clear of excess flammable material. If acquired, KRRC's contractor will renew the PDM permit annually, if needed, until Project completion. California does not have restrictions on the hours of operation of equipment and machinery.

A fire watch will take place on work breaks and following the completion of each work day to monitor the Project limit of work for fire. The Safety Officer will train the fire watchman in the appropriate responses in the event of a fire. ODF KLD prescribes fire watch duration based on FDL. Low fire danger requires a 1-hour fire watch, medium requires 2 hours, and high and extreme require 3 hours. ODF alerts all PDM permit holders of upcoming changes in FDL.

A primary feature of this FMP is preparedness for fire prevention and response in compliance with Oregon and California state regulations (Table 3-1 and Table 3-2, respectively). All construction vehicles and crews will be outfitted with the appropriate type and number of fire suppression tools, including but not limited to shovels, axes, and fire extinguishers. All vehicles and machinery will be equipped with functional spark arresters and/or mufflers, where applicable, and KRRC's contractor will routinely clean spark arrester ports. Gas powered saws, if operated at the Project, will maintain the fire suppression equipment prescribed by Oregon and California. Water pumping systems conforming to the Oregon and California requirements for water volume, hose dimensions, and pumping rates will be located on-site to suppress fires. The Safety Officer will develop best management practices for smoking in accordance with ORS and CCR regulations.

KRRC's contractor and Safety Officer will conduct work using best management practices in addition to compliance with all federal, state, and local laws. KRRC's contractor will establish communication lines to the various fire suppression agencies, particularly ODF KLD and Cal Fire SU. KRRC's contractor will maintain all equipment to the working standards of the manufacturer and keep them clean of flammable material and debris. This includes ensuring that the batteries and hydraulic and fuel lines are in good condition. Equipment will be stored overnight in locations cleared of flammable material. KRRC's contractor will clear work areas of dried vegetation to reduce risk of fire.

5.3 Additional Areas of Concern

Local and regional weather patterns and antecedent moisture conditions can significantly impact fire hazards and fire behavior. Lightning is a leading cause of wildfire in Siskiyou County, and most of the larger fires are categorized as wind-driven fires (Siskiyou County, 2016). Current and antecedent temperature and precipitation conditions directly influence the amount and condition of fuels. KRRC's contractor will consult with ODF KLD and Cal Fire SU foresters about anticipated weather conditions that may increase fire hazards and frequently update operations and fire response plans to changing environmental conditions. It is possible for favorable weather conditions to result in ODF KLD foresters granting waivers of certain fire prevention and suppression requirements.

KRRC's contractor will consult local and state fire management plans where available and communicate with local and state fire suppression agencies to identify existing resources and infrastructure in the Project areas that are at risk in the event of a fire.

Table 5-1 Fire services in the project vicinity

County	Fire Protection Services
Siskiyou County, CA	Fire protection is provided by 9 incorporated cities fire protection districts: Yreka, Fort Jones, Etna, Weed, Mt. Shasta, Dorris, Dunsmuir, Montague, and Tulelake. Other nearby fire protection districts and stations in Siskiyou County include Copco Lake Fire Protection District, Hornbrook Fire Protection District, Butte Valley Fire Protection District, Mayten Fire Protection District, and Grenada Fire Protection District. (Siskiyou County, 2016)
City of Yreka, CA	Fire services are provided by the Yreka Fire Volunteer Department (City of Yreka 2010d; City of Yreka 2010e).
Klamath County, OR	Klamath County is served by 17 fire districts including Klamath County Numbers 1 through 5, Keno, Chiloquin, Central Cascades, Crescent, Oregon Outback, Chemult, Bonanza, Bly, Malin, and Merrill (Klamath County, 2016).
Jackson County, OR	Fire protection services provided by Jackson County include Ashland and Medford Fire and Rescue Stations and Jackson County Fire District Stations. Nearby services are provided by Colestin Rural Fire Protection District and Greensprings Rural Fire District.

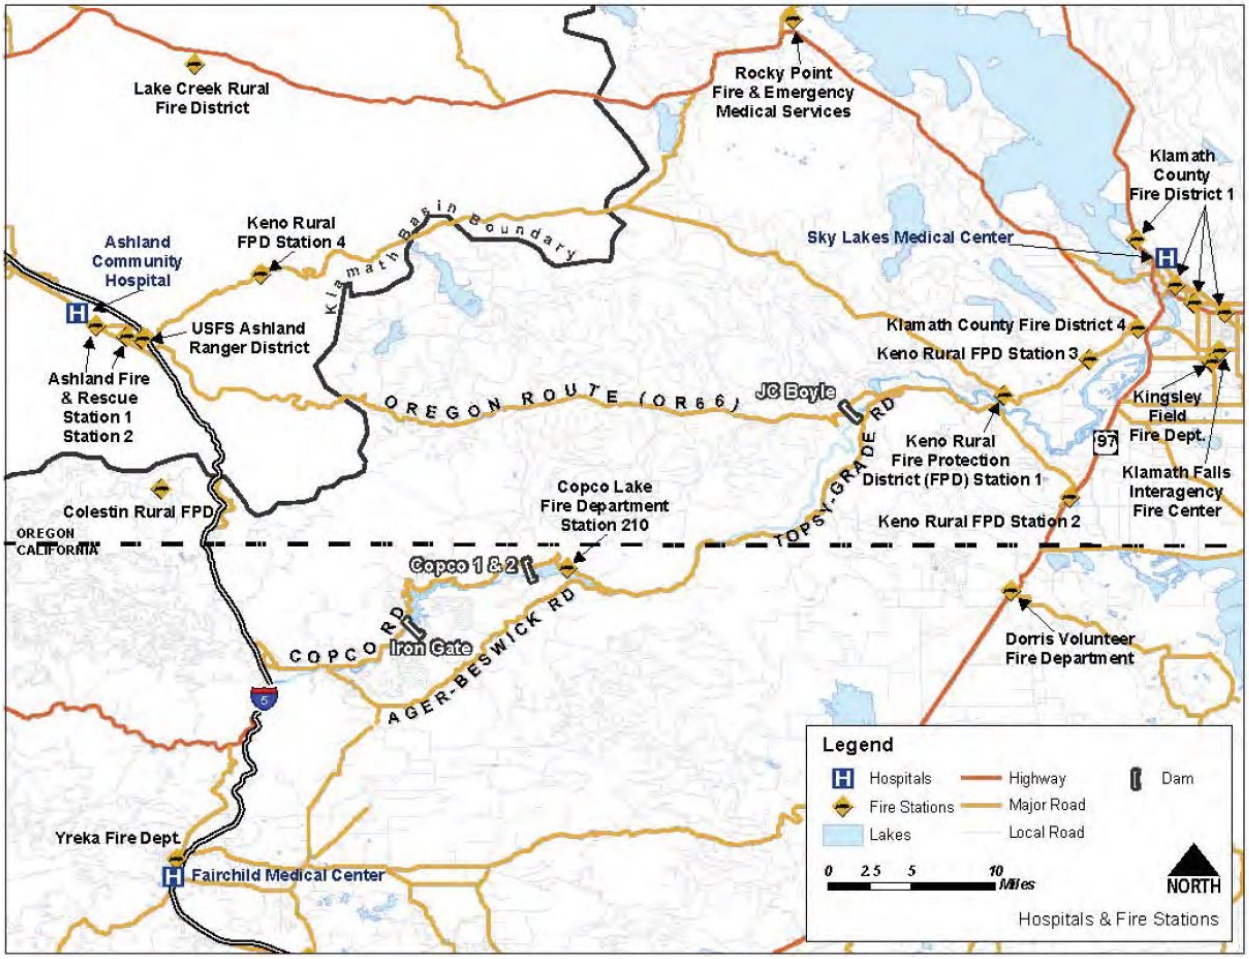
5.4 Fire Suppression Resources

KRRC's contractor will work with local and state fire agencies to locate necessary fire suppression infrastructure and emergency resources. Several of the fire suppression agencies have fire management and suppression plans that identify resources at risk and resources for fire suppression within their respective jurisdictions and outline protocols that would be initiated in the event of a fire. SCOFMP has developed a plan and set of operation protocols for fire support in the area (South Central Oregon Fire Management Partnership, 2015). Klamath County has a Community Wildfire Protection Plan document and companion database to support wildfire prevention and suppression planning efforts in the county (Wildland Fire Technologies, 2016). Cal Fire SU has a Unit Strategic Fire Plan that describes fire prevention goals and resources and guides fire management and fire suppression tactics (Siskiyou County, 2016).

KRRC's contractor and Safety Officer will provide the location of nearby fire stations, hospitals, access roads, evacuation routes, and water sources (Figure 5-1) to all employees. Due to the rural nature and the low concentration of roads in the area, most roads are used as evacuation routes in the event of fire or other emergencies. The Safety Officer will ensure that water tanks intended for fire suppression are full during operation hours and the fire watch period at the end of each work day. KRRC's contractor will identify the location of and access to the closest water sources in the event fire suppression tanks need to be refilled during fire suppression. The Safety Officer will communicate with local fire suppression agencies to identify water sources (e.g., fire hydrants, reservoirs, rivers) and access points proximal to the operation areas, and supplement scarce water resources with water storage tanks as needed.

In the California Project vicinity, Cal Fire SU provides fire suppression resources and coordinates with additional local fires suppression entities (Table 5-1). It has a Cal Fire- and USFS-staffed Emergency Command Center located at the Siskiyou Unit Headquarters in Yreka that handles dispatching services for Cal Fire, USFS, 30 local government departments, and 5 ambulance companies (Siskiyou County, 2016). The Cal Fire SU is divided into 4 battalions, and the Project limit of work is in Battalion 2 (Shasta Valley), which has Cal Fire stations in Yreka and Hornbook. For the Copco and Iron Gate dams, the closest fire stations in the area are the Copco Lake Fire Department Station 210, which services the area surrounding the Copco 1 reservoir, and the Yreka Fire Department. Jackson County, Oregon, has several nearby fire districts, including Ashland and Jackson County Fire Districts and Colestin Rural Fire District that can provide additional fire suppression resources.

In the Oregon Project vicinity, ODF KDL is primarily responsible for organizing fire prevention and suppression; and stations and districts that service Oregon are in Table 5-1. ODF KLD operates within the SCOFMP and shares resources and responsibilities with the other agencies therein. LIFC handles dispatch responsibilities for SCOFMP. Klamath County has 17 fire districts and 30 fire stations. Jackson County has several nearby fire districts also capable of providing fire suppression resources, including Greensprings Rural Fire District, Jackson County Fire Districts, and Ashland fire stations. For J.C. Boyle Dam, the closest station is the Keno Rural Fire Protection District (FPD) Station 1.



Source: USBR 2012

Figure 5-1 Map of hospitals, fire stations, and major fire routes near the Klamath Dams

This page intentionally left blank.

Chapter 6: Water Supply Assessment Post-Dam Removal

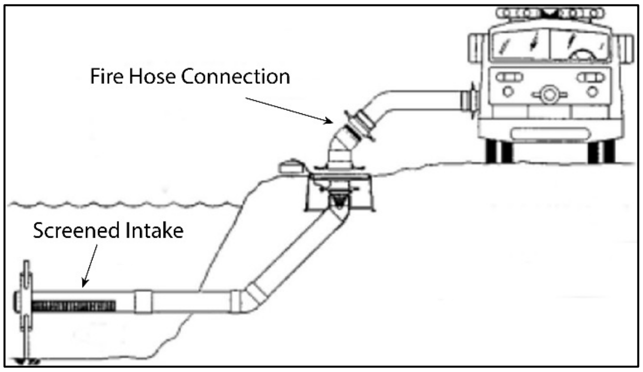
This page intentionally left blank.

6. WATER SUPPLY ASSESSMENT POST-DAM REMOVAL

The reservoirs provide a source of water for helicopter fire suppression crews fighting fires in the Project vicinity, and this resource will be reduced following removal of the dams and drawdown of the reservoirs. Following removal, helicopter crews will be able to extract water from the Klamath River (both the current channel and the channel reaches to be exposed in the current reservoirs following drawdown), Ewauna Lake, and Upper Klamath Lake (USBR and CDFW 2012). However, most helicopter water tanks require 3 feet of water depth to be filled, so helicopters will be able to use only certain portions of the Klamath River. Response and travel times between water tank fills for helicopter crews are expected to increase following reservoir drawdown (USBR and CDFW 2012). Fire suppression efforts near J.C. Boyle will not experience significant increases in travel time given that Ewauna and Upper Klamath Lakes are located approximately 13 miles away. With typical fire-fighting helicopter speeds between 90 and 140 mph (Jarrell, J., personal communication 2017.09.25), increases in round-trip travel time will be a maximum of 15 minutes after removal of J.C. Boyle. Analysis of aerial photos shows the presence of deep pools with suitable conditions for helicopter filling in the currently free-flowing reaches of the Klamath River around three reservoirs, particularly in the reaches between Copco and J.C. Boyle reservoirs and downstream of Iron Gate Dam. Maximum travel time increases to utilize the Klamath River for refilling are also expected to be on the order of 15 minutes, and potentially even less if pools are present in the former reservoirs post-removal.

To compensate for the loss of reservoir water supply, KRRC will develop additional water supplies and access points for fire suppression following the removal of the dams. Flows in the Klamath River and tributaries will not change post-removal, so firefighting crews can still use the river as a water supply. The potential of pool features for helicopter water filling will be evaluated in the field and used to generate a map of resources that can be used by air-based firefighting crews. To assist ground-based firefighting efforts, this FMP proposes the development of sites for installation of permanent dry hydrants from which water trucks and fire engines could draw directly from the Klamath River and larger tributaries. Dry hydrants are passive, unpressurized systems with a screened intake placed in the channel above the channel bed in a location of satisfactory depth (during dry conditions), flow rate, and channel stability and an above-ground fire hose connection to which truck-mounted pumps can be connected (Figure 6-1). Dry hydrants are commonly used as water supply for fighting fires in rural areas. Typical dry hydrants and fire truck pumps can supply over 1,500 gallons per minute, which is sufficient for rapid filling of typical water tankers and firefighting apparatus.

Potential sites for the dry hydrants were selected that leverage existing, permanent infrastructure (e.g., fire stations, bridges, roads, boat launches), offer proximity and ease of access to current or anticipated post-removal Klamath River or tributary channels, and are within PacifiCorp or state-owned property boundaries. Bridges and crossings are desirable given the increased certainty of access to water post-removal and the ability to utilize the structure for mounting the dry hydrant rather than excavating earthen material for pump installation.



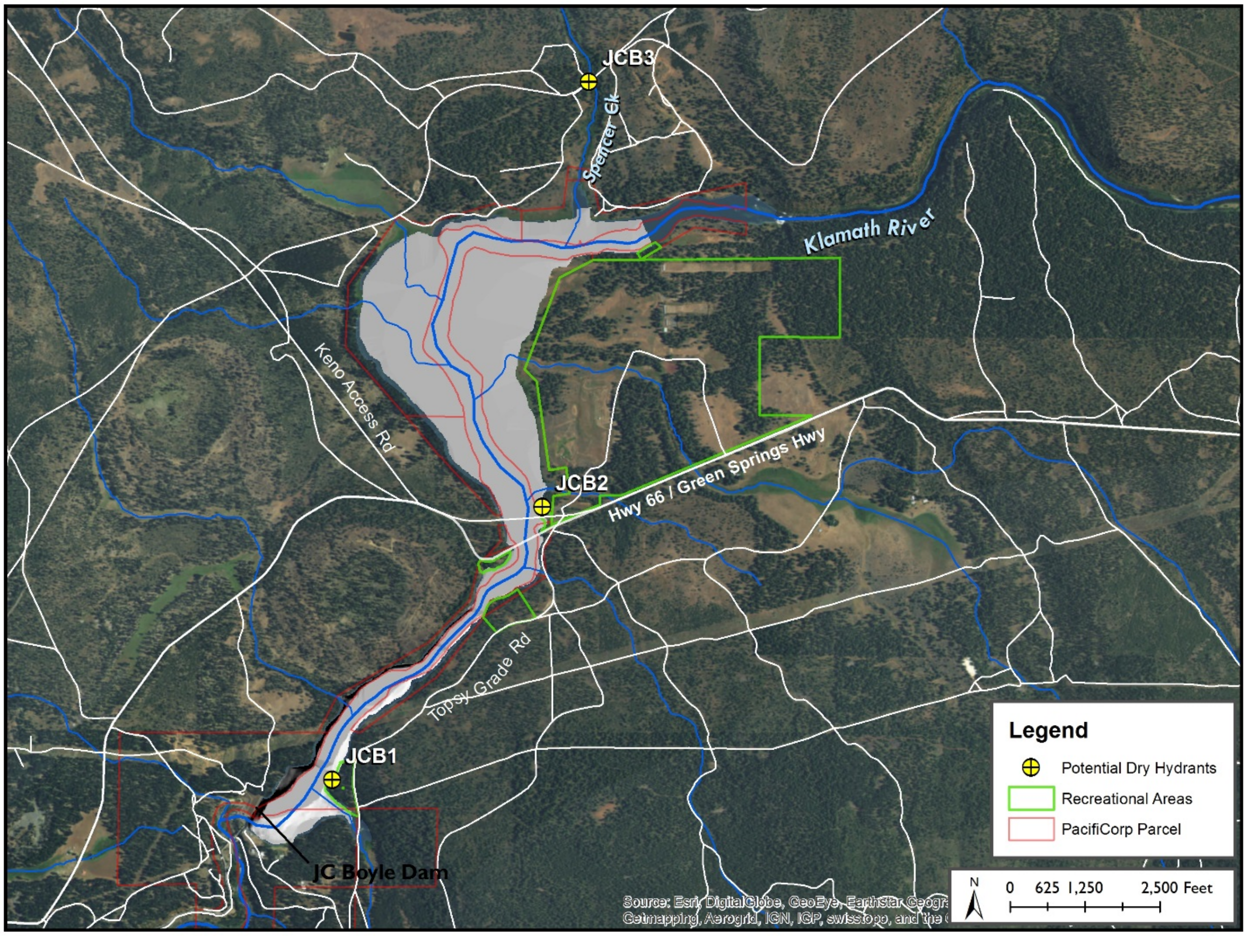
Adapted from ettfire.com

Figure 6-1 Diagram of dry hydrant system

At J.C. Boyle, three potential dry hydrant locations were identified (Figure 6-2). JCB1 is sited at Topsy Campground along Topsy Grade Road, where the valley is wider and more accessible. JCB2 is located on Highway 66 and could utilize the bridge for dry hydrant placement. JCB3 is located at a bridge over Spencer Creek, which maintains sufficient flow rate in the summers for dry hydrant pumping.

At Copco and the reach of the Klamath River upstream of Copco Lake, eight potential dry hydrant sites were identified (Figure 6-3). Access to the mainstem Klamath River upstream of Copco No. 1 after removal will be limited if the channel reoccupies the historical alignment as predicted. The historical Klamath River had a sinuous planform, and the mainstem will likely be either far from existing roads or difficult to access because of steep, high relief bluffs particularly near the Copco No. 1 Dam site.

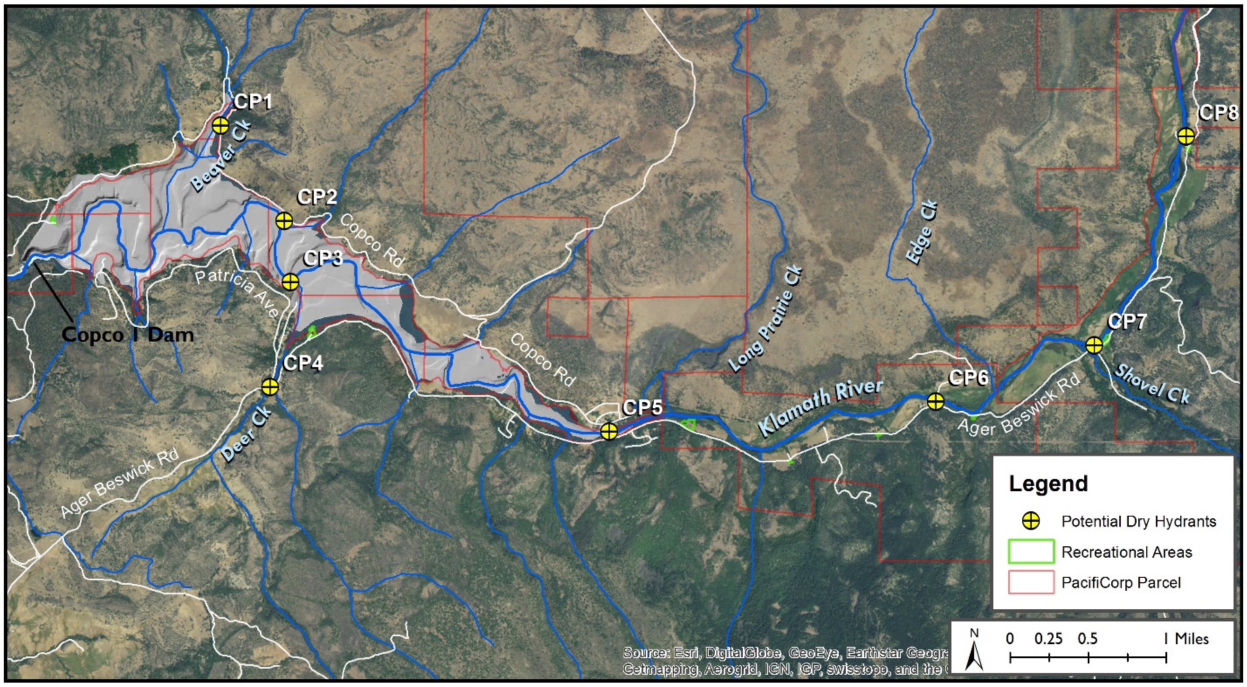
CP1 is located along Copco Road adjacent to where Beaver Creek is expected to run post-removal, but, if flow is sufficient, could be moved to where Copco Road crosses Beaver Creek upstream of the confluence with East Beaver Creek. CP2 is along the historical Klamath River and Copco Road downstream of Raymond Gulch at a location where the valley topography is locally expected to be less steep. CP3 is located near the historical confluence of the Klamath River and Deer Creek off Patricia Avenue, where historic topography is locally less steep and a Copco Lake Fire Station is nearby. CP4 is sited where Ager Beswick Road crosses Deer Creek. CP5 is at the Copco Road bridge over the Klamath River at the eastern margin of the reservoir and is situated adjacent to the Copco Lake Fire Department Station A. CP6 is located on a bridge over the Klamath River upstream of the current influence of the dam that is accessible off Ager Beswick Road. CP7 is located on a small bridge over the Klamath River off Ager Beswick Road and immediately upstream of the Shovel Creek confluence. CP8 is located at a fishing access area off Ager Beswick Road where a rapid holds grade to maintain a deeper pool for water extraction.



Historical topographic surface beneath the reservoir and historic Klamath River centerline are shown for reference.

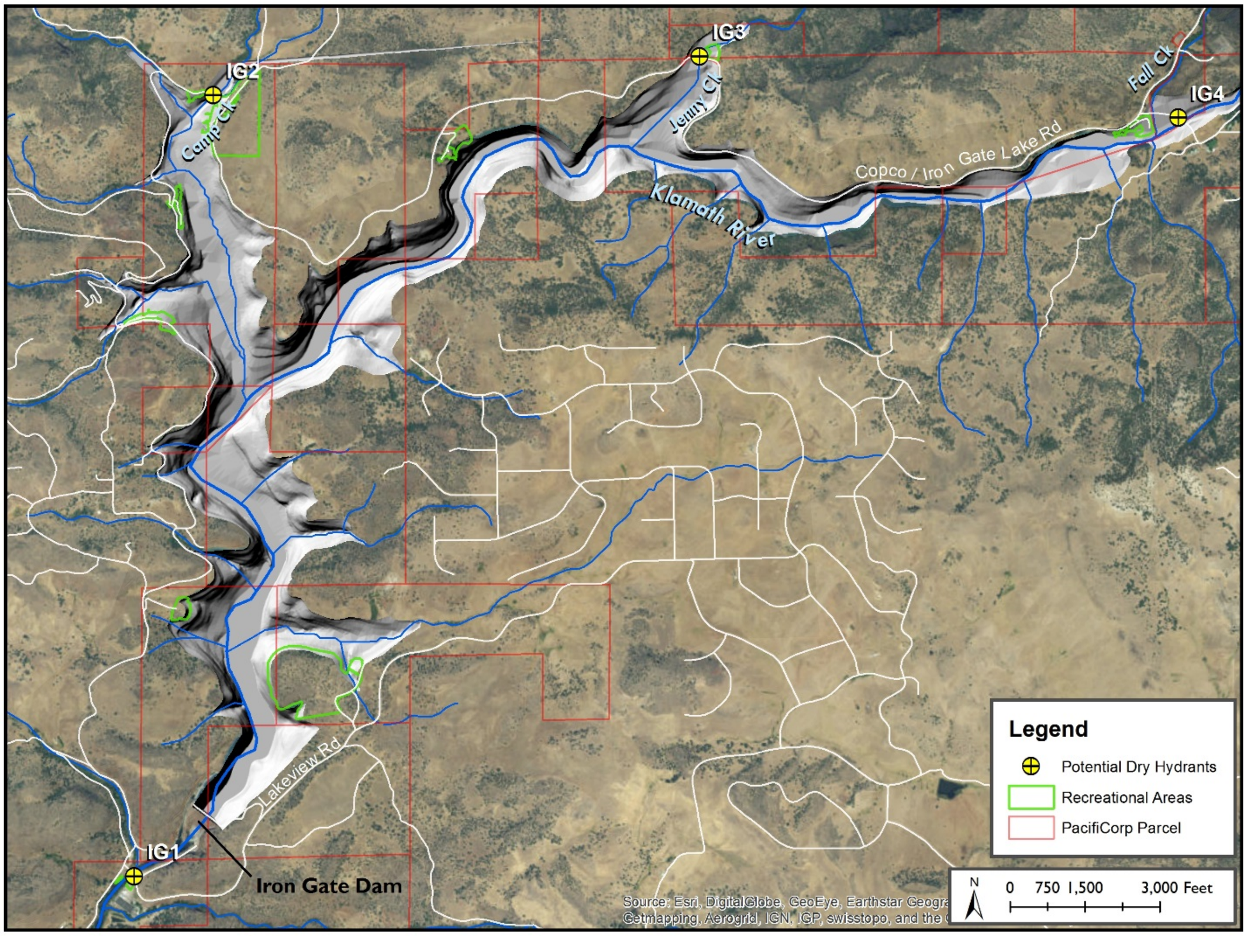
Figure 6-2 Locations of potential dry hydrants for J.C. Boyle Reservoir

At Iron Gate, four potential dry hydrant locations were identified (Figure 6-4). IG1 is sited at the Lakeview Rd bridge crossing over the Klamath River, downstream of Iron Gate dam and adjacent to the Iron Gate hatchery. IG2 is located in the vicinity of the Camp Creek campground where Copco Road crosses Camp Creek. IG3 is located at the bridge where Copco Road crosses Jenny Creek. IG4 is sited at the Daggett Road bridge crosses the Klamath River, which is adjacent to the Fall Creek confluence and Copco Road.



Historical topographic surface beneath the reservoir and historic Klamath River centerline are shown for reference.

Figure 6-3 Locations of potential dry hydrants for Copco Lake



Historical topographic surface beneath the reservoir and historic Klamath River centerline are shown for reference.

Figure 6-4 Locations of potential dry hydrants for Iron Gate Reservoir

Chapter 1: Need for Traffic Management Plan

This page intentionally left blank.

1. NEED FOR TRAFFIC MANAGEMENT PLAN

KRRC prepared this Traffic Management Plan (TMP) for the implementation of the Definite Plan for the Lower Klamath Project (Definite Plan) proposed by the Klamath River Renewal Corporation (KRRC) for physical removal of the four dam developments (Iron Gate, Copco No. 1. Copco No. 2, and J.C. Boyle) (the Project). The TMP is a specialized program tailored to minimize impacts by applying a variety of techniques such as *Public Information, Motorist Information, Incident Management and Construction Strategies.* The major objectives of the TMP are to maintain efficient and safe movement of vehicles through the construction zone covered by activities in the Definite Plan and to provide public awareness of potential impacts to traffic on both haul routes and access roads to the four dam developments.

Construction activities can create additional traffic delays and safety concerns on the affected highways and roadways. Planning work activities and balancing traffic demand with highway capacity is more critical during construction or maintenance. To prevent unreasonable traffic delays resulting from planned work during implementation of the Definite Plan, KRRC developed this TMP, and KRRC's contractor will implement it, to maintain acceptable levels of service, traffic circulation and safety on the state and county highway and roadway system.

This TMP outlines the structure and key requirements that will be incorporated by the KRRC's contractor into a final traffic management plan. The final traffic management plan will be informed by KRRC's contractor's specific means and methods for construction, which could refine the approach to access and traffic management. The final traffic management plan will meet applicable regulatory permit requirements, as well as applicable state and local ordinances, as appropriate. In developing the final traffic management plan, the Contractor will coordinate with the following agencies:

- Oregon Department of Transportation (ODOT)
- California Department of Transportation (Caltrans)
- Klamath and Siskiyou Counties
- Oregon State Police
- California Highway Patrol (CHP)

1.1 Access Summary

Throughout the construction and demolition contemplated in the Definite Plan, various roads in the vicinity of the four developments will experience some changes to traffic conditions, with the potential to impact other road users. The KRRC anticipates changes to traffic conditions could result from the following activities:

- Delivery of construction equipment
- Short haul of deconstructed dam materials (concrete and soil) for near-site disposal
- Long haul of deconstructed dam, hydropower and other materials for off-site disposal
- Delivery of rehabilitation materials
- Road, bridge and culvert improvements
- Worker access
- Fish hauling, as applicable

The proposed haul routes for each development are summarized in Table 1.1-1, and generally shown in Definite Plan Figure 1.2-2(C). Definite Plan Section 5 (Dam Removal Approach) and Section 7.4 (Road Improvements) provide additional details concerning access and associated road improvements.

Table 1.1-1 Primary Access Route Summary

Development	Interstate Access	Regional Access	Local Access
J.C. Boyle	Interstate 5 (in Oregon) and US97	Oregon Route (OR) 66	Topsy Grade Road, Keno Worden Road
Copco No.1 and Copco No. 2	Interstate 5 (in California)	Copco Road	Ager-Beswick Road, Patricia Ave.
Iron Gate	Interstate 5 (in California)	Copco Road	Lakeview Road, Daggett Road

1.2 Management Strategies

This section describes strategies KRRC proposes to minimize construction-related traffic delays and maintain safe movement of vehicles during implementation of the Definite Plan. These strategies are of a general nature and are intended to reduce the overall level of congestion. KRRC's contractor will include more detailed techniques for management of potential traffic impacts in the final traffic management plan. The proposed management strategies are grouped into the following four broad categories: (1) public information; (2) motorist information; (3) incident management; and (4) construction strategies. The numbered list below summarizes each category of management strategy and associated details.

1. **Public Information:** KRRC's contractor will adopt various methods to ensure the public have easy access to information regarding any current or upcoming interruptions to the local or state road network. Proposed methods, at a minimum, will include the use of telephone hotlines, a Traveler Information System via the Project website, local community outreach (meetings, newsletters, etc.), press release(s), and local news media, as appropriate.
2. **Motorist Information:** KRRC's contractor will develop a motorist information system to provide advance notice to motorists of potential traffic delays throughout the project sites and associated access routes. Proposed methods will include portable changeable message signs, stationary mounted signs, and highway advisory radio.

3. **Incident Management:** KRRC's contractor will devise an incident management procedure to outline traffic procedures to be adopted in the case of an incident on a road or highway. The procedure will be developed in collaboration with local and state agencies (listed above), and in accordance with local and state requirements.
4. **Construction Strategies:** KRRC's contractor will incorporate the following construction strategies into the final traffic management plan:

   a) **Roadway Closures**: During construction, some longer-term (more than a day) road closures will occur, though only on minor dam access roads where no public interruption would occur. Some short duration road closures will occur on more frequented roads, to enable bridge, culvert and road upgrades or replacements. KRRC's contractor will consider road users when these closures are scheduled and appropriate public and motorist information regarding detours will be issued in due course.
   b) **Traffic Handling and Stage Construction**: During construction, KRRC's contractor will provide signage and traffic control where Project generated traffic will impact road users. KRRC's contractor will determine the extent of signage and traffic control through consideration of the changes to road conditions caused by the activities and the amount of public traffic using the roads. KRRC's contractor will develop more detailed signage and traffic control plans as part of the final traffic management plan.
   c) **Construction Access to Work Zones**: KRRC's contractor will locate informational signs along the roads directly adjacent or leading to construction work zones, to direct construction traffic and notify other motorists of their presence. Where possible, KRRC's contractor will plan trip schedules to minimize impacts, i.e. avoiding peak traffic times. KRRC's contractor will control ingress and egress of construction trucks when exiting and entering the work areas to and from the respective highways.
   d) **Haulage**: Various waste materials will originate from the deconstruction of the four developments. The majority of waste volume, the embankment dam fill and concrete, will be disposed of onsite, requiring minimal haulage. KRRC's contractor will haul some materials such as reinforcing steel, mechanical and electrical equipment and other building waste to local recycling facilities or dump sites. KRRC's contractor will schedule haul trips to minimize interruption on the road network, such as by avoiding peak hour times. In addition, KRRC's contractor will use signage to give other motorists notice of truck haulage activities.
   e) **Emergency Detour Plan**: KRRC's contractor will identify emergency service routes within the project area, as appropriate, during detailed design, in coordination with state and local jurisdictions. These emergency detour routes will likely serve hospitals, fire/police stations, emergency shelters, command centers, and other facilities that provide essential services in times of emergencies. The KRRC does not anticipate material impacts on emergency serviced routes, though the potential for minor impacts due to increased traffic will nevertheless be considered.
   f) **Traffic Safety Effects**: The KRRC has identified potential traffic safety hazards from truck hauling, including, the use of blind or sharp corners and turnouts, slow vehicles conflicting with roadway speed limits, and visibility reduction due to dust. KRRC's contractor will manage these by adopting appropriate best practice signage, traffic management systems and dust control

measures. KRRC's contractor will perform a risk assessment of all intersections and roadways as part of the final traffic management plan.

g) **Pedestrians and Bicycles**: KRRC's contractor will identify areas where pedestrians and cyclists could potentially share roads with construction vehicles. KRRC's contractor will install appropriate signage to notify both construction vehicle drivers and non-motorized users of each other's potential presence on the roads. If an unacceptable level of risk to non-motorized users is deemed to persist, KRRC's contractor will arrange appropriate detours to allow continued movement for such users.

Chapter 1: Hazardous Materials Management Plan

This page intentionally left blank.

1. HAZARDOUS MATERIALS MANAGEMENT PLAN

This Hazardous Materials Management Plan (HMMP) was developed to address the management of hazardous materials during implementation of the Definite Plan proposed by the Klamath River Renewal Corporation (KRRC) for physical removal of four developments (Iron Gate, Copco No. 1, Copco No. 2, and J.C. Boyle), hereinafter, the Project. PacifiCorp, EDR, or local agencies provided all data KRRC used to develop this HMMP. KRRC will update the HMMP, as appropriate, following the planned Phase I-Environmental Site Assessment (ESA) visits and interviews and the Phase II Site Investigation, if needed after the Phase I ESA.

The following structures have been reported at each of the four developments.

- J.C. Boyle Dam and Powerhouse: This facility consists of a reservoir, combination embankment and concrete dam, gated spillway, diversion culvert, water conveyance system, and powerhouse, completed in 1958. Current structures at the site include an office building (known as the Red Barn), a maintenance shop, a fire protection building, a communications building, two (2) occupied residences near the dam, and a large warehouse near the powerhouse.
- Copco No. 1 Dam and Powerhouse: This facility consists of a reservoir, concrete dam, gated spillway, diversion tunnel, intake structure, and powerhouse constructed between 1911 and 1922. Current structures at the site include an occupied residence with small garage, a vacant house, and a maintenance building.
- Copco No. 2 Dam and Powerhouse: This facility consists of a reservoir, concrete diversion dam, embankment section, gated spillway, water conveyance system, and powerhouse completed in 1925. Current structures at the site include a control center building, a maintenance building, and an oil and gas storage building.
- Iron Gate Dam and Powerhouse: This facility consists of a reservoir, embankment dam, ungated side-channel spillway, diversion tunnel, intake structures, and powerhouse completed in 1962. Current structures at the site include a communications building, restroom building, and two (2) occupied residences.

Asbestos Containing Material (ACM), lead based paint (LBP), and polychlorinated biphenyls (PCBs) may be present in building materials based on the years construction activity occurred at each of the four developments. Prior to removal, KRRC or KRRC's contractor will sample and test for ACM, LBP, and PCBs at all structures that are to be removed. KRRC's contractor will handle and dispose of any abated material with asbestos, lead, and or PCBs which exceed hazardous waste criteria levels as hazardous waste at approved hazardous waste facilities in accordance with applicable federal and state regulations. KRRC's contractor will dispose of remaining materials as non-hazardous construction debris.

KRRC's contractor will manage all hazardous materials removed from the developments (i.e., paints, oils, and welding gases) by returning to the vendor, recycling, or managing and disposing of such materials as hazardous waste at an approved hazardous waste facility in accordance with applicable federal and state regulations. If not data exists, KRRC's contractor will test transformer oils for PCBs. Prior to disposal, KRRC's contractor will decontaminate any tanks which contained hazardous materials.

KRRC's contractor will handle universal hazardous waste (i.e., lighting ballasts, mercury switches, and batteries) in accordance with applicable federal and state universal waste regulations.

Table 1 shows the types of hazardous materials that may be present at each development.

Table 1 Anticipated Types of Hazardous Waste

Type of Waste	J.C. Boyle	Copco No. 1	Copco No. 2	Iron Gate
Asbestos	X	X	X	X
Batteries	X	X	X	X
Bearing and hydraulic control system oils	X	X	X	X
Treated wood	X	X	X	X
Coatings containing heavy metals	X	X	X	X
Contaminated soils	?	?	?	?
PCBs	?	?	?	?
Oil and fuel tanks	X	X	X	X
Hazardous materials storage	X		X	
Septic system	X		X	X
Gas cylinders	X			
Mercury containing fixtures		?	?	
Creosote treated wood			X	

KRRC's contractor will include any additional hazardous materials identified during the Phase I site visits and Phase II investigations, if any, in an updated hazardous materials management plan.

1.1 J.C. Boyle

According to the Detailed Plan (USBR 2012), potential hazardous materials at the J.C. Boyle Dam and Powerhouse include asbestos, batteries, bearing and hydraulic control system oils, treated wood, and coatings containing heavy metals in the powerhouse and on the exterior surfaces of the steel penstock pipes, surge tank, bulkhead gate, generator gantry crane, and other painted equipment, which will require specialized abatement and disposal. Contaminated soils may exist at the locations of painted exterior equipment and would require remediation. Asbestos may be found in ceiling and floor tiles, roofing materials, and electrical wiring insulation. Although all transformers have tested negative for PCBs, some residual PCBs may exist in closed systems such as transformer bushings. Equipment containing over 37,500 gallons of various types of oils and fuels has been identified at the site. The Red Barn administration complex includes a hazardous materials building for the storage of materials regulated by the Environmental Protection Agency (EPA), and a fueling facility containing above-ground gasoline (1,000 gallon) and diesel (500 gallon) tanks which meet state and federal requirements. Underground septic systems in use within the Red Barn complex of office and maintenance buildings and two residences will be removed. KRRC's contractor will follow applicable federal, state, and local regulations, including those for spill prevention and containment, in the transportation and disposal of all waste materials. Table 2 lists the reported material and quantities for J.C Boyle from the Hazardous Materials Inventories provided by PacifiCorp.

Table 2 Hazardous Materials Inventory – J.C. Boyle

Hazardous Class	Common Name	Quantities (Average daily)	Storage Container
Flammable and Combustible Liquids	Gasoline	500 gallons	AST
Flammable and Combustible Liquids	Diesel Fuel No. 2	300 gallons	AST
Flammable Gases	Acetylene	200 cubic feet	Cylinder
Nonflammable Gases	Argon, Liquid	200 cubic feet	Cylinder
Flammable and Combustible Liquids	Gear Oil	20 gallons	Plastic Drum
Flammable and Combustible Liquids	Hydraulic oil	30 gallons	Plastic Drum
Corrosives (Liquids and Solids)	Lead Acid Batteries	10,840 pounds	Glass bottle or Jug
Flammable and Combustible Liquids	Used Oil	20 gallons	Steel Drum
Flammable and Combustible Liquids	Paint	15 gallons	Cans
Nonflammable Gases	Nitrogen	1,200 cubic feet	Cylinder
Flammable Gas	Propane	300 gallon	AST

1.2 Copco No. 1

According to the Detailed Plan, potential hazardous materials at Copco No. 1 Dam and Powerhouse include asbestos, batteries, bearing and hydraulic control system oils, treated wood, and coatings containing heavy metals in the powerhouse and on the exterior surfaces of the steel penstock and air vent pipes, as well as on other painted equipment, which will require specialized abatement and disposal. Contaminated soils may exist at the locations of painted exterior equipment and would require remediation. Asbestos may be found in electrical wiring insulation and possibly in other building materials. Mercury may exist in older light switches. Although all transformers have tested negative for PCBs, some residual PCBs may exist in closed systems such as transformer bushings. Equipment containing nearly 12,000 gallons of various types of oils has been identified at the Copco No. 1 site. KRRC's contractor will follow applicable federal, state, and local regulations, including those for spill prevention and containment for the transportation and disposal of all waste materials. Table 3 lists the reported material and quantities for Copco No. 1 from the Hazardous Materials Inventories provided by PacifiCorp.

Table 3 Hazardous Materials Inventory – Copco No. 1

Hazardous Class	Common Name	Quantities	Storage Container
Flammable Gas	Liquefied Petroleum Gas	171 gallons	AST - Cylinder
Flammable and Combustible Liquids	Governor Oil (hydraulic oil)	1,500 gallons	Tank inside building
Flammable and Combustible Liquids	Transformer Oil	11,000 gallons	Tank inside building
Corrosives (Liquids and Solids)	Lead Acid Batteries	66 gallons	Glass bottle or Jug
Nonflammable Gases	Nitrogen	150 cubic feet	Cylinder
Flammable Gases	Liquefied Petroleum Gas	499 gallons	Cylinder

1.3 Copco No. 2

According to the Detailed Plan, potential hazardous materials at Copco No. 2 Dam and Powerhouse include creosote-treated wood-stave (redwood) penstock and treated wood, asbestos, batteries, bearing and hydraulic control system oils, and coatings containing heavy metals in the powerhouse and on the exterior surfaces of the steel penstock and air vent pipes, which will require specialized abatement and disposal. Contaminated soils may exist at the locations of painted exterior equipment and would require remediation. Asbestos may be found in electrical wiring insulation and possibly in other building materials. Mercury may exist in older light switches. Although all transformers have tested negative for PCBs, some residual PCBs may exist in closed systems such as transformer bushings. Equipment containing over 18,000 gallons of various types of oils and fuels has been identified at the site. The administration and control center includes a building for the storage of EPA-regulated materials, and a fueling facility containing above-ground gasoline (1,000 gallon) and diesel (500 gallon) tanks which meet state and federal requirements. Underground septic systems in use for seven residences near the powerhouse will be removed. KRRC's contractor will follow applicable federal, state, and local regulations, including those for spill prevention and containment for transportation and disposal of all waste materials. Table 4 lists the reported material and quantities for Copco No. 2 from the Hazardous Materials Inventories provided by PacifiCorp.

Table 4 Hazardous Materials Inventory – Copco No. 2

Hazardous Class	Common Name	Quantities	Storage Container
Flammable and Combustible Liquids	Diesel Fuel No. 2	375 gallons	AST
Flammable Gas	Liquefied Petroleum Gas	250 gallons	AST - Cylinder
Flammable and Combustible Liquids	Transformer Oil	12,778 gallons	AST
Flammable and Combustible Liquids	Gasoline	500	AST
Nonflammable Gases	Oxygen	500 cubic feet	Cylinder
Flammable and Combustible Liquids	Governor and Bearing Oil (hydraulic oil)	3,600 gallons	Steel drum, Plastic/Non-metallic drum
Flammable Gases	Acetylene	300 cubic feet	Cylinder
Nonflammable Gases	Nitrogen	750 cubic feet	Cylinder
Nonflammable Gases	Argon, Liquid	700 cubic feet	Cylinder
Flammable and Combustible Liquids	Oil base paint	50 gallons	Cans
Corrosives (Liquids and Solids)	Lead Acid Batteries	64 gallons	Glass bottle or Jug

1.4 Iron Gate

According to the Detailed Plan, potential hazardous materials at Iron Gate Dam and Powerhouse include asbestos, batteries, bearing and hydraulic control system oils, treated wood, and coatings containing heavy metals in the powerhouse and on the exterior surfaces of the steel penstock and air vent pipes, and other painted equipment, which will require specialized abatement and disposal. Contaminated soils may exist at the locations of painted exterior equipment and would require remediation. Asbestos may be found in electrical wiring insulation and possibly in other building materials. Although all transformers have tested negative for PCBs, some residual PCBs may exist in closed systems such as transformer bushings. Equipment containing nearly 5,000 gallons of various types of oils has been identified at the site. Underground septic systems in use for the restroom and two residences near the dam will be removed. KRRC's contractor will follow applicable federal, state, and local regulations, including those for spill prevention and containment, for transportation and disposal of all waste materials. Table 5 lists the reported material and quantities for Iron Gate from the Hazardous Materials Inventories provided by PacifiCorp.

Table 5 Hazardous Materials Inventory – Iron Gate

Hazardous Class	Common Name	Quantities	Storage Container
Nonflammable Gases	Nitrogen	1,850 cubic feet	Cylinder
Flammable and Combustible Liquids	Governor and Bearing Oil (hydraulic oil)	1,400 gallons	Tank Inside Building
Flammable and Combustible Liquids	Transformer Oil	3,500 gallons	Other
Corrosives (Liquids and Solids)	Lead Acid Batteries	102 gallons	Other

Chapter 1: Emergency Response Plan

This page intentionally left blank.

1. EMERGENCY RESPONSE PLAN

This Emergency Response Plan (ERP) was developed to support implementation of the Definite Plan for the Lower Klamath Project (Definite Plan) proposed by the Klamath River Renewal Corporation (KRRC) for physical removal of the four developments (Iron Gate, Copco No. 1, Copco No. 2, and J.C. Boyle), hereinafter the Project. The Detailed Plan (USBR 2012) had proposed mitigation measure H-1 to develop and implement an Emergency Response Plan to provide adequate notification to agencies and the public of the potential changes in timing and magnitude of flooding below Iron Gate; the KRRC is instead proposing this ERP as part of the Definite Plan.

KRRC's contractor will develop written procedures to help prevent incidents, to assure preparedness in the event incidents occur, and to provide a systematic and orderly response to emergencies. KRRC's contractor will closely coordinate this ERP with the Contractor's Health and Safety Plan, Spill Prevention and Response Plan, Fire Management Plan, and PacifiCorp's Emergency Action Plan for each development.

This ERP applies to all personnel working on the project site. Prior to commencing construction activities, the Contractor's Health and Safety lead will review emergency response procedures with all personnel assigned to the project site, as appropriate.

Applicable emergency scenarios include, but are not limited to, the following:

- Medical, including injury or illness
- Fire
- Traffic incident
- Hazardous material spill
- Downstream hydraulic change planning
- Dam or tunnel failure
- Catastrophic emergency (e.g. earthquake, high wind event, etc.)
- Security threat

The sections below discuss each type of emergency scenario and its associated response plan.

1.1 General Requirements

This ERP includes the following list of general emergency requirements.

1. KRRC's contractor will post emergency service cards in all offices within the project limit of work and in all construction vehicles. KRRC's contractor will post maps to clinics and hospitals by all land-line phones. Emergency service cards will list emergency phone numbers for the local fire department,

ambulance services, life flight medical helicopters, local police department, local medical clinic, nearest hospital, and KRRC contractor's construction manager, onsite supervisor, and Safety Officer.

2. This ERP, as well as the steps to take in an emergency, will be posted and readily accessible at each of the developments within the project limit of work.
3. An adequate number of site personnel (minimum of one per dam site) will have current certification cards in First Aid and CPR.
4. Each development on the project site will be equipped with a First Aid cabinet, trauma kit, AED, and stretcher basket.
5. In the event of an emergency, all personnel will clear the radio for "Emergency Use Only" by calling "May-Day, May-Day, please clear the radio for emergency use."
6. Should an offsite emergency response team be required, the Contractor's on-site supervisor or the KRRC construction manager will designate an on-site employee to meet and escort the response team to the injury or emergency location.
7. Medical personnel/facilities on the project site: This will be specifically determined before the start of construction.
8. Emergency response plan procedures and documentation are subject to annual KRRC audits and shall be reviewed and/or updated annually.

1.2 Medical Emergency

In the event of an onsite medical emergency, KRRC contractor's onsite supervisor and the KRRC construction manager shall be notified immediately with details concerning the location, name of injured person(s) and a brief description of the situation. First aid action will be initiated immediately, as necessary, through the use of trained onsite first aid providers. The injured shall not be left unless absolutely necessary to quickly notify the jobsite office and then return. Injured person(s) shall not be moved unless they are in immediate danger of further injury. KRRC's contractor will develop written procedures for medical emergencies that include standard reporting forms to document the emergency.

The following hospitals are located within the project vicinity:

1. Sky Lakes Medical Center
   2865 Daggett Ave, Klamath Falls, OR 97601
   (541) 882-6311
2. Fairchild Medical Center
   444 Bruce St, Yreka, CA 96097
   (530) 842-4121
3. Asante Ashland Community Hospital
   280 Maple St, Ashland, OR 97520
   (541) 201-4000

1.3 Fire Management

Refer to the Fire Management Plan in Appendix O1 - Fire Management Plan for procedures and contacts related to managing fire emergencies.

1.4 Traffic Incident or Emergency

In the event of a traffic incident or emergency onsite, or along construction access routes currently in use by KRRC's contractor, the onsite supervisor and the KRRC construction manager shall be notified immediately with details concerning the location, name of injured person(s), if any, and a brief description of the situation. An incident management procedure will be devised to outline traffic procedures to be adopted in the event of an incident on a road or highway. If medical attention is required, protocols outlined above in 1.2 for "Medical Emergencies" shall be followed. KRRC's contractor onsite supervisor will notify the local authorities of a traffic incident or emergency, as appropriate.

1.5 Hazardous Material Spill Management

The Contractor shall develop a separate Spill Prevention and Response Plan, which shall comply with all governmental approvals and applicable local, state and federal laws and regulations. In the event of an onsite hazardous material spill, KRRC contractor's onsite supervisor and the KRRC construction manager shall be notified immediately with details concerning the location, type of material and a brief description of the situation. The Spill Prevention and Response Plan shall include detailed procedures and documentation forms to prevent and respond to spills. Topics or requirements to be provided in the final plan include, but are not limited to, the following:

1. Identification and location of staging and material stockpiles in areas that will prevent spills from entering the river channel
2. All hazardous materials shall be stored in a clearly identified and protected area, and all hazardous materials brought onsite will have a Material Safety Data Sheet (MSDS), which will be provided to the Contractor's Health and Safety lead.
3. Vehicles or equipment operated adjacent to a lake, river, stream or other water body shall be checked and maintained daily to prevent leaks of materials. If a leak is discovered, the leak will be stopped and the equipment will be removed from the project site for repair.
4. Required equipment/vehicle maintenance, refueling and lubrication will be performed at a pre-determined, protected location. If this is not possible, the activity will be completed at least 100 feet from any water body.
5. All aboveground storage tanks containing fuel or oil stored onsite in excess of 1,320 gallons will require a site-specific Spill Prevention Control and Countermeasures (SPCC) Plan.
6. All workers will receive training on the Project Spill Response and Reporting Procedures

In the event of a hazardous materials spill, the MSDS will be referenced to identify safe handling and cleanup procedures. Attempts to handle a hazardous materials spill will only be undertaken if doing so presents no exposure or risk of danger or contamination to personnel. Cleanup of all hazardous material spills will commence as soon as is safely possible following any spill. If a spill requires a hazardous waste cleanup operation and specially trained crew, the Contractor's Health and Safety lead will ensure properly trained personnel conduct the cleanup and remediation. This is not anticipated for cleanup of spills of common construction materials.

1.6 Downstream Hydraulic Change Planning

Prior to dam removal, the KRRC or KRRC's contractor will inform the National Weather Service River Forecast Center of any planned major hydraulic change (removal of one or more of the dams) to the Klamath River that could potentially affect the timing and magnitude of flooding below Iron Gate. The River Forecast Center is the federal agency that provides official public warning of floods. As needed, the River Forecast Center would update their hydrologic model of the Klamath River to incorporate these hydraulic changes so that changes to the timing and magnitude of flood peaks would be included in their forecasts. As currently occurs, flood forecasts and flood warnings would be publicly posted by the River Forecast Center for use by federal, state, county, tribal, and local agencies, as well as the public, so timely decisions regarding evacuation or emergency response could be made.

Contact Information for the California Nevada River Forecast Center:

US Dept. of Commerce
National Oceanic and Atmospheric Administration
National Weather Service
California Nevada River Forecast Center
3310 El Camino Avenue, Room 227
Sacramento, CA 95821-6373
916-979-3056
Webmaster Email: cnrfc.webmaster@noaa.gov

During the detailed design phase, the KRRC or KRRC's contractor will submit a conditional letter of map revision (CLOMR) report to FEMA of a planned major hydraulic change to the Klamath River that could affect the 100-year flood plain. Subsequently, the KRRC or KRRC's contractor will submit a letter of map revision (LOMR) to FEMA, to provide recent hydrologic/hydraulic modeling and updates to the land elevation mapping. This information will be provided to FEMA so they can update their 100-year flood plain maps downstream of Iron Gate Dam (as needed), so flood risks (real-time and long-term) can be evaluated and responded to by agencies, the private sector, and the public.

1.7 Dam or Tunnel Failure

In the event of a tunnel failure during construction activities or drawdown, the immediate area shall be evacuated and the KRRC contractor's onsite supervisor and the KRRC construction manager shall be notified immediately. In the event tunnel failure results in partial or full blockage of flow, KRRC or KRRC's contractor will notify the Federal Energy Regulatory Commission (FERC) and other regulatory agencies, as required,, and the KRRC or KRRC's contractor will develop a plan to mitigate any associated impacts. The plan will be developed within five (5) calendar days of the tunnel failure, and will be sent to the FERC for review and approval and to other regulatory agencies, as required.

In the event of a dam failure, or an imminent dam failure, during construction activities or drawdown, the immediate area shall be evacuated and KRRC contractor's onsite supervisor and the KRRC construction manager shall be notified immediately. KRRC's contractor onsite supervisor shall contact 911, local law enforcement, local fire departments, the Klamath and Siskiyou County emergency services, the FERC local Office of Dam Safety, and the California Division of Safety of Dams (DSOD) immediately.

County Emergency Services, FERC's local Office of Dam Safety and DSOD contact information is provided below:

1. Siskiyou County Office of Emergency Services
   806 South Main Street
   Yreka, CA 96097
   530-841-2155
2. Klamath County Emergency Management
   2543 Shasta Way
   Klamath Falls, OR 97601
   541-851-3741
3. FERC Local Office of Dam Safety
   805 SW Broadway
   Fox Tower - Suite 550
   Portland, OR 97205
   503-552-2715
4. DSOD: Specific contact and phone numbers for working and non-working hours shall be coordinated with DSOD prior to finalization of the Emergency Action Plan by the contractor. The current project contact at DSOD is Nekane Hollister at 916-227-4627.

Klamath County, Oregon, has an Emergency Operations Plan that outlines procedures to ensure protection of life and property during a dam failure. The government and private agencies involved as well as their roles and responsibilities in response to a dam failure are defined therein. Flood inundation maps are available in the office of the Klamath County Emergency Manager. KRRC's contractor will review this document during preparation of the final ERP.

During preparation of the written procedures to implement this ERP, KRRC's contractor shall review PacifiCorp's Emergency Action Plans for each development. These plans will contain useful information on emergency contacts and protocol.

1.8 Catastrophic emergency (e.g., earthquake, extreme weather event, etc.)

In the event of a catastrophic emergency, KRRC contractor's onsite supervisor and the KRRC construction manager shall be notified immediately with details concerning the location, name of any injured person(s) and a brief description of the situation at any damaged structure or facility. It is imperative that each employee is accounted for. The designated supervisor will perform a physical headcount of all on-site personnel as soon as possible.

When evacuation is determined necessary, the following procedures shall be followed:

1. Employees will leave any buildings and the site area or as advised and report to the designated emergency staging area. The emergency staging area for the various project sites will be clearly identified in KRRC contractor's written emergency response procedures. When evacuating, employees should walk, remain quiet, and follow all other emergency instructions.
2. When evacuating work areas, employees should close doors behind them, but not lock doors unless otherwise instructed.
3. Employees working with electrically operated machines or equipment should switch the equipment off or unplug it prior to leaving the work area.
4. After evacuation is completed, the KRRC expects the police and other emergency personnel will prevent entrance to the effected site area.
5. When the catastrophic emergency is over, KRRC contractor's project manager or KRRC construction manager, in conjunction with the Safety Officer, will advise employees when it is safe to return to the site.

1.9 Security Threat

Security threats to any facility within the project site will be immediately communicated to KRRC contractor's onsite supervisor and the KRRC construction manager. Based on the information or type of threat received, a response will be initiated by KRRC contractor's onsite supervisor that may include any of the following:

1. Cessation of all work activity and mustering of site personnel
2. Notification of local law enforcement agencies
3. Notification of the Federal Bureau of Investigation

Chapter 1: Noise and Vibration Control Plan

This page intentionally left blank.

1. NOISE AND VIBRATION CONTROL PLAN

The purpose of this Noise and Vibration Control Plan (NVCP) is to address and reduce increases in day and night time noise levels resulting from construction activities during implementation of the Definite Plan for the Lower Klamath Project (Definite Plan) proposed by the Klamath River Renewal Corporation (KRRC) for physical removal of the four dam developments (Iron Gate, Copco No. 1, Copco No. 2, and J.C. Boyle), hereinafter the Project. KRRC's contractor will develop a final NVCP to document the KRRC's noise and vibration objectives based on regulatory and industry guidelines as relevant to specific activities to be completed under the Definite Plan. The final NVCP will address KRRC's contractor staff roles and responsibilities for noise and vibration control, define noise intensive activities and timing, identify sensitive receptors, evaluate construction noise levels, and outline a monitoring program for noise and vibration.

KRRC's contractor will incorporate the following measures into the final NVCP to reduce effects to sensitive receptors associated with noise and vibration. Measures include, but are not limited to, the following:

- KRRC's contractor shall maintain equipment in compliance with federal, state and local noise standards (e.g., exhaust mufflers, acoustically attenuating shields, shrouds, or enclosures)
- KRRC's contractor shall schedule truck loading, unloading, and hauling operations to reduce daytime and nighttime noise impacts to the extent feasible
- Construction activities will be conducted or phased so that noise generated during construction will not exceed thresholds or durations identified by the appropriate regulatory authorities
- KRRC's contractor shall employ appropriate blasting techniques to minimize noise and vibration to the extent feasible
- Equipment and trucks used for the Project shall employ the best available noise control techniques to the extent feasible
- Stationary sources shall be located as far from adjacent noise-sensitive receptors as reasonably possible and shall be enclosed if feasible
- Where feasible, temporary portable sound barriers will be deployed where construction noise would cause noise levels at sensitive receptor locations to exceed an applicable criteria threshold
- KRRC or KRRC's contractor shall notify nearby residents of hours and duration of construction activities
- At least two weeks prior to the anticipated start of construction at a particular location, KRRC or KRRC's contractor will notify all property owners within 1,000 feet of that location that construction activities are about to commence
- KRRC's contractor shall have a complaint hotline for local residents, and shall promptly address noise and vibration complaints

1. FRESHWATER MUSSELS

The objective of the freshwater mussels measure is to address reservoir drawdown and project effects on freshwater mussels located in the Klamath River in the Hydroelectric Reach and downstream from Iron Gate Dam (RM 193.1). The 2012 EIS/R AR-7 focused conducting a freshwater mussel relocation pilot study followed by the salvage and relocation of freshwater mussels prior to reservoir drawdown. Salvaged mussels were to be held in a temporary location for later placement following reservoir drawdown, and placed in locations that will not be affected by the reservoir drawdown. Based on a review of the information discussed in greater detail below, KRRC and the ATWG concluded that a moderate scale freshwater mussel relocation effort is warranted. The proposed measure includes a freshwater mussel reconnaissance in 2019 followed by a limited freshwater mussel salvage prior to reservoir drawdown. Specifically, KRRC will salvage freshwater mussels from the 8-mile long Iron Gate Dam (RM 193.1) to Cottonwood Creek (RM 185.1) reach and translocate these mussels to one or more appropriate locations in the Klamath River, downstream from the Trinity River confluence (RM 43.4), and between J.C. Boyle Dam (RM 230.6) and Copco Reservoir (RM 209.0). The translocation sites will be determined following the 2019 reconnaissance and discussion with the ATWG.

Deleted: between the upstream extent of J.C. Boyle Reservoir (RM 234.1) and Keno Dam (RM 239.2

Deleted:)

1.1 Proposed Measure

Based on a review of the 2012 EIS/R AR-7 presented in Section 9.2 below, input from the ATWG, and current freshwater mussels literature, the KRRC concluded that revisions to AR-7 are necessary to offset the anticipated short-term effects of the Project on freshwater mussels. The proposed measure includes a reconnaissance, salvage, and relocation of freshwater mussels from the 8-mile reach between Iron Gate Dam and the Cottonwood Creek confluence with the Klamath River. The monitoring and adaptive management plan has two specific actions.

- **Action 1:** KRRC will complete a reconnaissance in 2019 to assess the distribution and density of freshwater mussels in the 8-mile long bedload deposition reach from Iron Gate Dam (RM 193.1) downstream to the Cottonwood Creek confluence (RM 185.1). The reconnaissance effort will determine if the mussel beds identified in the 2007-2010 surveys are still present, and estimate abundance of a subset of the mussel beds in the reach.

- **Action 2**: Based on the reconnaissance and discussions with ATWG, KRRC will salvage and relocate a portion of the freshwater mussels located between Iron Gate Dam and Cottonwood Creek prior to drawdown to reduce project effects to the mussel community. Up to 20,000 mussels are planned for translocation to appropriate habitats in the Klamath River, downstream from the Trinity River confluence (RM 43.4), and between J.C. Boyle Dam (RM 230.6) and Copco Reservoir (RM 209.0). Translocation sites will be located in areas that are anticipated by KRRC to experience minimal changes in channel bed elevation due to sediment deposition associated with the Project.

Deleted: between the upstream extent of J.C. Boyle Reservoir (RM 234.1) and Keno Dam (RM 239.2)

The proposed measure is intended to reduce project effects on freshwater mussels located downstream from Iron Gate Dam. The following sections provide additional detail on the proposed measure actions.

1.1.1 Action 1: Freshwater Mussel Reconnaissance

The KRRC will prepare a reconnaissance plan to assess freshwater mussels in the Iron Gate Dam to Cottonwood Creek reach in 2018. Habitat conditions will also be evaluated downstream from the Trinity River confluence, and between J.C. Boyle Dam and Copco Reservoir to determine the habitat capacity for translocated mussels. An existing freshwater mussel data set (base data for Davis et al. 2013), compiled by the Karuk Tribe, USFWS, and other collaborators from 2007 to 2010 for the Klamath River downstream from Iron Gate Dam, will be reviewed and used to plan the reconnaissance. The reconnaissance will confirm mussel beds identified in the 2007-2010 surveys and estimate abundance at a subset of the mussel beds locations. Habitat metrics in the potential translocation reach will be evaluated to maximize translocation success. The freshwater mussel reconnaissance and translocation reach habitat assessment are anticipated to take 5 days.

Deleted: from

Deleted: the upstream extent of J.C. Boyle Reservoir (RM 234.1) upstream to Keno Dam (RM 239.2)

1.1.2 Action 2: Freshwater Mussel Salvage and Relocation

The KRRC will coordinate and implement a freshwater mussel salvage plan with freshwater mussel specialists. Based on the reconnaissance, a portion of the freshwater mussels located between Iron Gate Dam and Cottonwood Creek will be salvaged and relocated to reduce project effects to the freshwater mussel community. The freshwater mussel salvage and translocation effort is anticipated to require 10 days. The percentage of the existing mussel beds that will be salvaged and translocated is predicated on the available habitat in the Klamath River downstream from the Trinity River confluence, and between J.C. Boyle Dam and Copco Reservoir, and the abundance of mussels between Iron Gate Dam and Cottonwood Creek. Approximately 15,000 to 20,000 mussels are planned for translocation. During the course of these actions, it is not anticipated that the entire population of mussels residing below Iron Gate Dam will be recovered.

Deleted: from the upstream extent of J.C. Boyle Reservoir to Keno

Deleted: Dam,

1.2 Summary of the Affected Species, Anticipated Project Benefits and Effects, Recent Literature, 2012 EIS/R AR-7, and Proposed Measure

The following sections review the components of the 2012 EIS/R AR-7, anticipated project effects and long-term benefits on freshwater mussels, and current freshwater mussel literature.

1.2.1 Affected Species

Species intended to be addressed in the 2012 EIS/R AR-7 include:

- Oregon floater *(Anodonta oregonensis)*
- California floater *(A. californiensis)*
- Western ridged mussel *(Gonidea angulata)*
- Western pearlshell mussel *(Margaritifera falcata)*

1.2.2 Anticipated Project Effects on Measure Species

Short-term effects of the Project (prolonged exposure to high suspended sediment levels and bedload movement) are predicted to be deleterious to freshwater mussels in the Hydroelectric Reach and in the lower Klamath River downstream from Iron Gate Dam (Reclamation and CDFG 2012). Substantial freshwater mussel population reductions are expected due to sediment effects and possibly low dissolved oxygen levels. The change in hydrological properties following project implementation may also disrupt the current distribution of freshwater mussels downstream from Iron Gate Dam (Davis et al. 2013). Table 9-1 includes the likely and worst-case effects on freshwater mussel species in the Klamath River.

Table 9-1 2012 EIS/R anticipated effects summary for freshwater mussels

Species	Life Stage	Likely Effects	Worst Effects
California Floater Oregon Floater Western Ridged Western Pearlshell	All	Substantial reduction in populations	Substantial reduction in populations

Source: USBR and CDFG 2012

The following sections include descriptions of anticipated effects to freshwater mussels based on information 2012 EIS/R (Reclamation and CDFG 2012; Vol. 1, pp. 3.3-173 to 3.3-175) as well as additional information from additional freshwater mussel studies, some of which were completed after the publication of the 2012 EIS/EIR.

Freshwater Mussels

Available studies have evaluated Klamath River Basin freshwater mussel age structure, growth rates, and size distribution (*G. angulata*; Tennant 2010); population distribution and habitat use (Krall 2010; Davis et al. 2013; May and Pryor 2015); and habitat associations (Westover 2010; Davis et al. 2013). Klamath River mussels are long lived (from 10 to more than 100 years, depending on species) and may not reach sexual maturity until 4 years of age or more. *Anodonta* species are found primarily downstream from Iron Gate Dam, and likely benefit from the stable hydrology and fine sediment deposits attributed to hydroregulation below the dam (Davis et al. 2013). *G. angulata* is the most abundant freshwater mussel in the Klamath River and the species is widely distributed between Iron Gate Dam and the Trinity River (Westover 2010;

Davis et al. 2013). *M. falcata* is the least abundant freshwater mussel found in the Klamath River and seems to be mostly found downstream from the confluence of the Salmon River (Westover 2010; Davis et al. 2013).

Freshwater mussel tolerance of high suspended sediment, low dissolved oxygen, and bedload deposition are not well understood. Vannote and Minshall (1982) evaluated freshwater mussels in an aggrading river system in Idaho and concluded that *G. angulata* appear to be better adapted for aggrading rivers based on siphon positions, shell morphology, and foot placement in the underlying substrate. *M. falcata* seemed to be less adapted for aggrading rivers due to a less developed siphon for filtering water. *M. falcata* also rarely burrow into substrate more than 25-40 percent of the valve length which may increase the mussel's susceptibility to scour (Vannote and Minshall 1982). *G. angulata* migrate vertically in the channel bed and are capable of maintaining position near the channel bed surface (Vannote and Minshall 1982). *M. falcata* are not known to migrate and are therefore more susceptible to sediment burial. *Anodonta* species are likewise susceptible to sediment scour and burial due to their thinner shells. Mussels that are dislodged from their normal vertical position and fall onto their sides may not regain the normal position and may perish (Vannote and Minshall 1982).

Mussels play important roles in aquatic ecosystems. Mussels influence water quality, nutrient cycling, and habitat and are also known as "ecosystem engineers" that actively modify their environment (Xerces Society 2009; Lopes-Lima et al. 2016; Lummer et al. 2016). They filter fine sediment and organic particles, create byproducts that are food items for macroinvertebrates, and comprise the greatest proportion of animal biomass in some waterbodies (Xerces Society 2009). In the Klamath River Basin, freshwater mussels filter and sequester toxins including toxigenic algae microsystins (Kann et al. 2010) and mercury (Bettaso and Goodman 2010). Filtration of waterborne toxins may result in bioaccumulation in freshwater mussels leading to human consumption risks (Bettaso and Goodman 2010; Kann et al. 2010).

The Project is anticipated to result in high suspended sediment levels and bedload deposition in the 8 miles of the Klamath River between Iron Gate Dam and Cottonwood Creek. Extremely poor water quality due to high suspended sediment concentrations is expected in the first 2 miles of the Klamath River downstream from Iron Gate Dam (Reclamation and CDFG 2012). Fine sediment effects on freshwater mussels include gill clogging, possible growth reduction, and impairment to mussel larval stages (Lummer et al. 2016). Due to both the anticipated deleterious high suspended sediment concentrations and low dissolved oxygen levels, freshwater mussels downstream from Iron Gate Dam may experience substantial mortality with the most significant impacts anticipated to mussels located immediately downstream from Iron Gate Dam.

Over the long-term, freshwater mussels are expected to benefit from the Project through the conversion of Hydroelectric Reach reservoirs to gravel bed rivers which will restore freshwater mussel habitat, reduce water quality and water temperature impairments related to the reservoirs, and restore access for anadromous and resident host fish species that will distribute freshwater mussel larvae throughout the Klamath River upstream from Iron Gate Dam. However, due to the long time freshwater mussels take to reach sexual maturity, the recolonization and/or growth of existing freshwater mussel populations upstream of Iron Gate Dam may be slow and may not be readily noticeable for some time.

1.2.3 2012 EIS/R AR-7

The 2012 EIS/R AR-1 (Vol. I, pp. 3.3-248 to 3.3-249) directed the salvage of freshwater mussels from the Hydroelectric Reach and downstream from Iron Gate Dam. Salvaged mussels were to be relocated to suitable instream habitat unaffected by high suspended sediment concentrations, or could be placed in temporary facilities and returned to the Klamath River following the Project. A salvage and relocation pilot study was also suggested to assess salvage feasibility and relocated mussel survival. Based on the pilot study results, a detailed salvage and relocation plan was to be developed.

1.2.4 KRRC's and the ATWG's Review of AR-7 for Feasibility and Appropriateness

The KRRC assessed the feasibility and appropriateness of AR-7 through multiple planning meetings held with the ATWG between May and August 2017. During these meetings, current information on Klamath River fisheries was presented and information on other dam removal projects conducted in the western United States was reviewed to understand how the aquatic ecosystem might respond, as discussed above. The ATWG's concerns regarding the 2012 AR-7 included:

- Unfamiliarity with successful freshwater mussel relocation efforts.
- Disease transmission concerns.

The following sections provide additional information regarding AR-7 feasibility and appropriateness, based on fisheries literature and ATWG input.

Unfamiliarity with Successful Freshwater Mussel Relocation Efforts

The ATWG was unfamiliar with successful freshwater mussel translocation efforts. Anecdotal information discussed during the ATWG planning meeting (Yreka, CA, May 23, 2017) alluded to low translocation success for the Elwha Dam Removal Project and highway construction projects. Additional information was acquired by the KRRC on the Elwha Dam Removal Project freshwater mussel (*M. falcata*) translocation. For that project, freshwater mussels were translocated to two sites and remained in one site prior to the dam removal project (P. Crain, U.S. Park Service, personal communication, 2017). The relocated freshwater mussels had high survival following the translocation and prior to the dam removals. Subsequent events that impacted the translocated mussels resulted in high mussel mortality. The events included raccoon predation due to shallow habitat at the first translocation site, and excessive sediment deposition at a side channel translocation site. The third monitored site was an artificial outfall channel from the water treatment facility that went dry due to inadvertent project operations. Mussels that remained in the Elwha River downstream from Elwha Dam are suspected to have experienced high mortality due to excessive sediment deposition following dam removal, followed by channel scour during the post-dam sediment sorting process.

Freshwater mussel translocation project monitoring results are not well represented in the fisheries literature. Unpublished freshwater mussel translocation monitoring manuscripts were reviewed to better understand the range of potential translocation success. Fernandez (2013) described the translocation success of 265 individual *M. falcata* in coastal southwest Washington. Between 55 percent and 95 percent of the transplanted *M. falcata* were accounted for in the translocation sites between one and three years following the translocation.

A review of translocation projects found mean mortality of relocated mussels was 49 percent based on an average recovery rate of 43 percent (Cope and Waller 1995). Cope and Waller (1995) found that survival of relocated mussels was generally poor and the factors influencing the survival of relocated mussels were poorly understood. For mussel relocation to be successful, more consideration must be given to habitat characterization at both the source and translocation sites. Olden et al. (2010) and Germano et al. (2015) offer considerations for successful freshwater organism and wildlife translocation efforts, respectively Luzier and Miller (2009) offer suggestions and considerations for freshwater mussel translocations.

Disease Transmission Concerns

The role of freshwater mussels in freshwater disease transmission is not well understood. Freshwater mussels are known to provide habitat for polychaete worms, one of the hosts in the life *C. shasta*. Polychaetes have been infrequently collected from freshwater mussel shells in the Hydroelectric Reach of the Klamath River (PacifiCorp 2004). Mussels may serve as a vector for other fish pathogens like *Flavobacterium columnare* and *Ichthyophthirius multifiliis* that are endemic to the Klamath River Basin (K. Kwak, CDFW, personal communication 2017).

Freshwater mussels inhabit the Klamath River upstream from Iron Gate Dam (Byron and Tupen 2017) and in tributaries upstream (Byron and Tupen 2017) and downstream from Iron Gate Dam (Davis et al. 2013; Howard et al. 2015; May and Pryor 2015), disease transmission may be less of a concern.

1.3 Summary

The Project is anticipated to have significant short-term effects, but long-term benefits for freshwater mussels. The 2012 EIS/R AR-7 included a freshwater mussel salvage and relocation pilot study followed by an informed salvage and relocation plan prior to the Project. The proposed measure includes completing a reconnaissance of existing freshwater mussels from Iron Gate Dam to Cottonwood Creek and potential translocation habitat on the Klamath River downstream from the Trinity River confluence, and between J.C. Boyle Dam and Copco Reservoir. KRRC will salvage and relocate freshwater mussels prior to the reservoir drawdown. It is not anticipated that the entire population of mussels residing below Iron Gate Dam will be recovered.

Chapter 1: Introduction

This page intentionally left blank.

1. INTRODUCTION

This report documents the estimated project cost for the Lower Klamath Project (Project), which in addition to construction cost, includes costs for management, administration and legal support, environmental compliance and permitting, engineering design, procurement, mitigation and monitoring before, during and following construction, as well as construction management. The estimated project cost is based on the preliminary design presented in the Definite Plan for the Lower Klamath Project (KRRC 2018) (the Definite Plan), in addition to ongoing coordination and consultation with Project stakeholders and regulatory agencies.

1.1 Report Objectives

Section 7.2 of the Klamath Hydroelectric Settlement Agreement, as amended (KHSA) sets forth required elements of the Definite Plan, which include:

- A detailed estimate of the actual or foreseeable costs associated with: the physical performance of Facilities Removal[1] consistent with the Detailed Plan; each of the tasks associated with the performance of the [Klamath River Renewal Corporation (KRRC)]'s obligations as stated in Section 7.1; seeking and securing permits and other authorizations; and insurance, performance bond, or similar measures, as set forth in Appendix L to this Settlement;
- The [KRRC]'s analysis demonstrating that the total cost of Facilities Removal is likely to be less than the State Cost Cap, which is the total of Customer Contribution and California Bond Funding as specified in Section 4[2]; and
- A detailed statement of the estimated costs of Facilities Removal.

This report addresses these elements of the KHSA and documents both the engineer's opinion of construction cost, based on the project design elements and construction plan summary provided in the Definite Plan, and the total estimated project implementation cost. In addition to reporting the estimated project costs, Most Probable Low (MPL) and Most Probable High (MPH) estimates were prepared using a Monte Carlo analysis to account for uncertainties associated with the estimated project costs and identified project risks. The MPL and MPH estimates represent more optimistic and more conservative opinions of project costs, respectively.

[1] "Facilities Removal" is defined in the KHSA as the "physical removal of all or part of each of the Facilities to achieve at a minimum a free-flowing condition and volitional fish passage, site remediation and restoration, including previously inundated lands, measures to avoid or minimize adverse downstream impacts, and all associated permitting for such actions."
[2] The State Cost cap is $450,000.000.

1.2 Project Scope

The proposed Project (also referred to as the Full Removal alternative) is described in Sections 1, 4, 5, 6 and 7 of the Definite Plan. The Project involves the physical removal of each of the four dam developments (Iron Gate, Copco No. 1 and No. 2, and J.C. Boyle) to achieve at a minimum a free-flowing condition and volitional fish passage, site remediation and restoration, including previously inundated lands, measures to avoid or minimize adverse downstream impacts, and all associated permitting for such actions. Table 1-1 provides an overview of the four dam developments. The Project is located on the Klamath River approximately 200 miles from the Pacific Ocean in the states of Oregon and California (see Figure 1-1). The Definite Plan also describes a "Partial Removal" alternative which is presented for purposes of environmental review. Under the Partial Removal alternative, the objectives of free-flowing river conditions and volitional fish passage will be achieved, but portions of each dam will remain in place, along with ancillary buildings and structures such as powerhouses, foundations, tunnels, and pipes. Section 5 of the Definite Plan discusses the details of infrastructure to remain under this alternative.

Prior to removal of the dams and hydropower facilities, KRRC's contractor will draw down the water surface elevation in each reservoir as low as possible to facilitate accumulated sediment evacuation and to create a dry work area for development removal activities. A number of infrastructure modifications will be necessary to facilitate drawdown. In general, drawdown will begin on January 1 of the drawdown year, and will extend through mid-March of the same year.

Table 1-1 Existing Dam Development Overview

Dam (Sate)	Description	Year Built	Capacity/ Average Annual Production	Max. Surface Area of Reservoir (acres)	Reservoir Storage Capacity (acre-feet)	Dam Type	Dam Height/Length (feet)
J.C. Boyle (OR)	Reservoir, dam, fish ladder, power canal, two turbines and powerhouse	1958	98 MW/ 329,000 MWh	420	3,495 (total) 1,724 (active)	Earthfill	68/ 693
Copco No. 1 (CA)	Reservoir, dam, two turbines and powerhouse	1918	20 MW/ 106,000 MWh	1,000	46,900 (total) 6,235(active)	Concrete	126/ 415
Copco No. 2 (CA)	Division dam, small impoundment, two turbines and powerhouse	1925	27 MW/ 135,000 MWh	40	73 (total) negligible (active)	Concrete	33/ 278
Iron Gate (CA)	Reservoir, dam, one turbine, powerhouse and fish hatchery	1962	18 MW/ 116,000 MWh	944	58,800 (total) 3,790 (active)	Earthfill	173/ 740

After drawdown is accomplished, remaining reservoir sediments will be stabilized to the extent feasible and dam and hydropower facility removal will begin. Full reservoir area restoration will begin after drawdown, extend throughout the year, and possibly extend into the subsequent year. Vegetation establishment could extend several years.

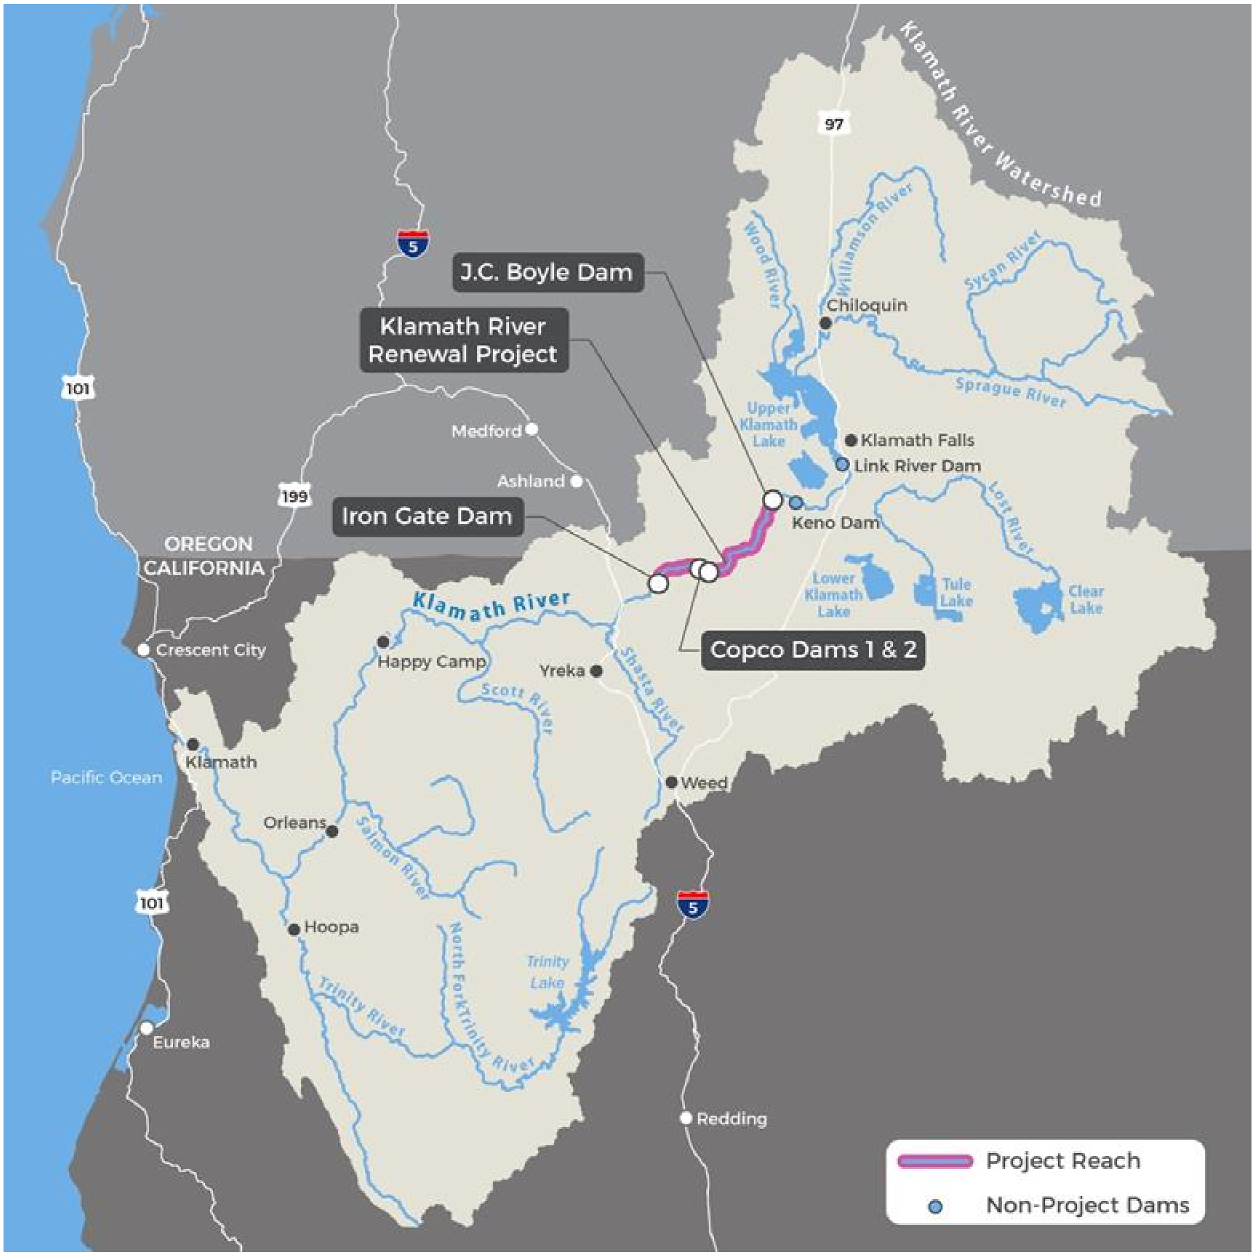

Figure 1-1 Klamath River Watershed and Facilities Locations

Other key project components include measures to reduce Project-related effects to aquatic and terrestrial resources, road and bridge improvements, relocation of the City of Yreka's pipeline across Iron Gate Reservoir and associated diversion facility improvements, as well as demolition of various recreation facilities adjacent to the reservoirs. This estimate does not include costs associated with design and construction of any hatchery improvements associated with the Project (as described in the Definite Plan), and as per the KHSA, these will be funded separately by PacifiCorp.3

1.3 Limitations

The opinion of estimated project costs presented in this report is based on information in the Definite Plan, ongoing coordination and consultation with project stakeholders and regulatory agencies, and market conditions at the time of preparation of the estimate. The construction cost was estimated with the use of a combination of built-up unit prices and statistical unit prices from published and internally developed and maintained historical databases factored for location, contractor markups, and other project-specific criteria. Logic, methods, and procedures for developing costs are typical for the construction industry.

Various limitations need to be considered in the use of both built-up and statistical unit prices. These limitations include the potential for changes in technology, methods, and construction applications; the impact of short-term economic cycles; and the time-lag of reporting databases. Any estimate of unit prices is not intended to predict the outcome of hard dollar results from open and competitive bidding.

AECOM represents that the services were conducted in a manner consistent with the standard of care ordinarily applied as the state of practice in the profession, given the amount of design information available at the time of estimate preparation. No other warranties, either expressed or implied, are included or intended.

Other implementation costs presented in this report, outside of the preliminary design and construction activities, should be considered preliminary, due to the fact that:

- Permitting coordination is currently ongoing. The understanding of anticipated mitigation, monitoring and reporting requirements should be considered preliminary until feedback is received from the agencies on the draft permit applications. KRRC will obtain additional clarity on mitigation, monitoring and reporting once the California Environmental Quality Act (CEQA) and National Environmental Policy Act (NEPA) processes are complete.
- KRRC has not yet selected a Progressive Design-Builder (PDB) to finalize the dam removal designs and subsequently complete the associated construction. The current understanding and effort associated with PDB field studies and final design should be considered preliminary until that selection process is complete.

KRRC is undertaking additional due diligence on construction costs, measures to lower construction costs, and measures to manage construction risk. These measures include risk management, selection of a PDB to perform the work, and negotiation of a PDB contract with a guaranteed maximum price for construction. Many risks considered in the Monte Carlo analysis that deal with design and regulatory compliance will be managed or better understood when this process is completed, likely lowering the MPH. These results of these inquiries will be further informed by the review and recommendations of a FERC approved

[3] See Section 7.6.6 of the KHSA.

independent Board of Consultants (BOC) for the Lower Klamath Project. Among other inquires, the BOC will be convened to review and provide recommendations regarding the adequacy of available funding and reasonableness of updated cost estimates for the most probable cost and maximum cost for the Full Removal alternative, and the assumptions made to calculate those estimates. KRRC will incorporate the recommendations of the BOC into a revised Definite Plan.

1.4 Results Summary

Tables 1-2 and 1-3 below summarize the estimate of project costs, for both Full Removal and Partial Removal of the four dams.

Similar to previous project estimates, the results show probabilistic MPL and MPH costs based on the results of Monte Carlo simulations. The right-hand column indicates the estimated project costs, whereas the forecast range from MPL to MPH indicate the range of probabilistic outcomes. The MPL is P10 (likely final project cost in 10% of all scenarios) and the MPH is P90 (likely final project cost in 90% of all scenarios). Details on these methods are described further in Section 2.7 (Monte Carlo Analysis) of this report.

Table 1-2 Results Summary - Full Removal

Cost Category	Forecast Range		Estimated Project Cost
	MPL (P10)	MPH (P90)	
Project Oversight			$29,581,000
Environmental Compliance & Permitting			$8,637,000
Engineering & Procurement			$15,632,000
Construction Management			$10,617,000
Construction	$202,108,000	$268,560,000	$227,980,000
Anticipated Mitigation Measures			$18,407,000
Monitoring & Reporting			$18,405,000
Design & Construction Contingency			$68,394,000
TOTAL	**$346,500,000**	**$507,100,000**	**$397,700,000**

Table 1-3 Results Summary - Partial Removal

Cost Category	Forecast Range		Estimated Project Cost
	MPL (P10)	MPH (P90)	
Project Oversight			$29,581,000
Environmental Compliance & Permitting			$8,637,000
Engineering & Procurement			$15,632,000
Construction Management			$10,617,000
Construction	$169,140,000	$229,250,000	$193,030,000
Anticipated Mitigation Measures			$18,407,000
Monitoring & Reporting			$18,405,000
Design & Construction Contingency			$57,909,000
TOTAL	**$313,500,000**	**$467,800,000**	**$352,200,000**

Chapter 2: Basis of Estimate

This page intentionally left blank.

2. BASIS OF ESTIMATE

2.1 Cost Categories

For organizational purposes, the project costs have been summarized using the following cost categories:

- **Project Oversight:** Support services providing administration, project management and controls, contract management, Board of Consultants (BOC), outreach, insurance and legal support.
- **Environmental Compliance and Permitting**: Environmental compliance support and permitting.
- **Engineering and Procurement:** Field studies, engineering design, and construction procurement for the various project work packages. Design and procurement estimates assume a PDB, performance security, construction delivery method for the large dam removal work package.
- **Construction Management:** Full construction management services for implementation of all project components.
- **Construction:**
    - Dam removals: Sequential removal of all four dams, including dam modifications, reservoir drawdown and removal of all associated dam infrastructure (including spillways, fish ladders, intake structures, penstocks, turbine units, electrical installations, buildings)
    - Reservoir area improvements: Removal, grading and shaping of portions of reservoir sediment, bank stability measures
    - Reservoir area restoration: Seeding, planting, weeding, monitoring and maintenance. Hydroseeding methods include by barge along the reservoir bank, by helicopter along steep slopes, by airplane along uneven large areas and by trailer mounted blower for areas easily accessible by truck
    - Yreka water supply improvements: Improvements to the City of Yreka's water supply intake and relocation of their water supply pipeline.
    - Transportation infrastructure: Improvements to, or replacement of, bridges, culverts and road resurfacing to mitigate any project or construction related impact
    - Recreation demolition: Demolition of existing recreation infrastructure and restoration of disturbed area to native vegetation
    - Recreation improvements: New recreation infrastructure (e,g, water access, day-use areas, etc.) to avoid or minimize project impacts
    - Downstream flood improvements: Improvements to existing structures and facilities to avoid or minimize adverse downstream flood-related impacts.

- **Anticipated Mitigation Measures**: Anticipated cultural resource measures, groundwater improvements, and water supply improvements that may be required by regulatory agencies to mitigate Project-related impacts.
- **Monitoring and Reporting:** Proposed aquatic resource, terrestrial resource, water quality, and sediment monitoring and reporting.

2.2 Construction Procurement Approach

KRRC based estimates for the various cost categories on a PDB construction procurement of the large dam removal work package, which includes construction access road and bridge accommodations, dam modifications, dam and hydropower facility removal, recreation demolition and reservoir and other restoration. KRRC will use a qualifications-based selection approach and hire a PDB contractor in late 2018/early 2019, followed by the PDB's completion of the final design in 2019.

There is a possibility that smaller work packages, including downstream flood control improvements, City of Yreka water supply improvements and proposed recreation facilities, may be procured separately using a design-bid-build, or similar, procurement strategy. For these packages, final design will proceed in 2018 and 2019, with request for construction proposals being issued in mid- to late-2019.

2.3 Construction Pricing

The construction estimates summarized herein are intended to capture the most current pricing for materials, wages and salaries, equipment, accepted productivity standards, and typical construction practices, procurement methods, current construction economic conditions, and site conditions for the current level of design. Detailed construction cost breakdowns for both Full Removal and Partial Removal alternatives are provided in Attachment A. Pay item cost detail worksheets, describing the calculation of individual cost estimate line items rates and prices are provided in Attachment B.

Construction cost estimates were prepared based on less than complete designs, and have inherent levels of risk and uncertainties (as discussed in Section 2.7). The following sections discuss the various aspects and assumptions associated with construction pricing for the Project.

2.3.1 Construction Pricing - Direct Costs

Experienced construction cost estimators developed direct cost construction pricing using logic, methods, and procedures for pricing that are typical for the construction industry. Unit rates were established using input from RS Means database, Equipment Watch database and Davis Bacon Wage Determination database. Overall prices were established by taking location, access and construction operation into consideration.

KRRC used the latest Davis Bacon Wage Determination for labor rates and fringes. The area used is based on Siskiyou County, California. The Project is located in a remote location which will require per diem for all employees. This consideration is included within the Contractor's overhead cost and associated percentage

KRRC based equipment costs on the latest understanding of the equipment required to complete the work. Unit prices include equivalent/similar pieces of equipment with present day rates from Equipment Watch Blue Book, and include equipment mobilization. In selecting the rates, Redding, California was used as the nearest available location. Equipment hourly rates include fuel, which is a factored rate of $3.00/gallon based on average retail prices from nearby gas stations. KRRC estimated equipment and material sales tax at 7.75% based on recent sales tax data in Siskiyou County.

The major features and/or items in the estimate, such as the dam modifications, dam removal, and reservoir restoration are fairly well defined. KRRC estimated costs for these items using crew and equipment work-item analysis to develop unit costs, and then multiplying these by the quantity measurement to arrive at work item subtotals. Crew and equipment work-item analysis spreadsheets are presented in Attachment B.

KRRC used vendor quotes for materials such as gates for drawdown, pipelines, instrumentation, and hydroseeding. KRRC based costs for some of the smaller items of work within the estimate on the experience and judgment of the estimator using historical data from similar types of construction, factored for location, size, and other Project-specific criteria.

2.3.2 Construction General Requirements

As discussed in more detail below, the following markups were applied into the contractor's direct costs to account for general requirements:

- PDB Contractor's overhead at 15%
- PDB Contractor's profit and risk at 8%
- PDB Contractor's markup on subcontractors at 10%
- PDB Contractor's insurance at 1%
- PDB Contractor's bond at 1%

Contractor Overhead

KRRC calculated construction overhead for this Project using a slightly higher percentage than normal due to the remoteness of the Project, including establishing and maintaining workers' accommodation facilities, travel compensation, per diem payments and labor rate market conditions caused by the size of the Project in the remote location.

Construction overhead includes salaried payroll costs (salary, insurance, taxes, and fringe benefits) for management, supervisory, administrative, and safety employees. These employees include the Contractor's jobsite project management, documentation control, submittal preparation, surveying, field engineering, and quality assurance costs. Recurring jobsite overhead expenses such as office rentals, utility bills, and maintenance expenses for jobsite facilities are also included in the general requirements, as are non-recurring expenses such as the bonds and insurance, purchase of office, engineering, and safety equipment, and outside engineering and surveying expenses.

The Contractor overhead percentage (15% percentage of direct construction cost) amounts to approximately $30M over the construction duration. This is approximately equivalent to the following from the estimate of project costs (Full Removal):

- PDB Contractor's project management 2019 $3M
- PDB Contractor's project management 2020-2021 $10M
- Establish and maintain workers accommodations $6M
- Offices & facilities for PDB Contractor $4M
- Offices & facilities for contract manager $4M
- Temporary facilities $3M

Contractor Profit and Risk Markups

KRRC derived a profit and risk markup on direct construction costs of 8% by using the United States Army Corps of Engineers (USACE) Profited Weight Guidelines following the steps listed below. Figure 2-1 shows the calculation summary using the reference guidelines. The resulting amount included in the estimated project cost for Contractor's profit and risk compensation is approx. $17M.

- Risk: Where the work involves no risk or the degree of risk is very small, the weighting is 0.03; as the degree of risk increases, the weighting increase up to a maximum of 0.12. Lump sum items will have, generally, a higher weighted value than unit price items for which quantities are provided. Considerations include the portion of work to be done by subcontractors, nature of work, where work is to be performed, reasonableness of negotiated costs, amount of labor included in costs, whether negotiation is before or after performance of work, etc.
- Difficulty: If the work is most difficult and complex, the weighting is 0.12 and is proportionately reduced to .03 on the simplest jobs. This factor is tied in to some extent with the degree of risk. Considerations include the nature of the work, schedule, by whom it is done, where it is done, etc.
- Size of Job: Jobs not in excess of $100,000 are weighted at 0.12. Jobs estimated between $100,000 and $5,000,000 are proportionally weighted from 0.12 to .05. Jobs from $5,000,000 to $10,000,000 are weighted at 0.04 and work in excess of $10,000,000 at 0.03.
- Duration: Jobs in excess of 24 months are weighted at 0.12. Jobs of lesser duration are proportionately weighted to a minimum of .03 for jobs not to exceed 30 days. The period applies to only the change -- not the contract duration.
- Investment: Weighted from 0.03 to 0.12 on the basis of below average, average, and above average. Considerations include the amount of subcontracting, mobilization payment item, Government-furnished property, method of making progress payments, etc.

- Government Assistance: Weighted from 0.12 to 0.03 on the basis of average to above average. Considerations include use of Government-owned property, equipment and facilities, expediting assistance, etc.
- Subcontracting: Weighted inversely proportional to the amount of subcontracting. Where 80% or more of the work is to be subcontracted, the weighting is to be 0.03 and such weighting proportionally increased to 0.12 where all the work is performed by the Contractor's own forces.

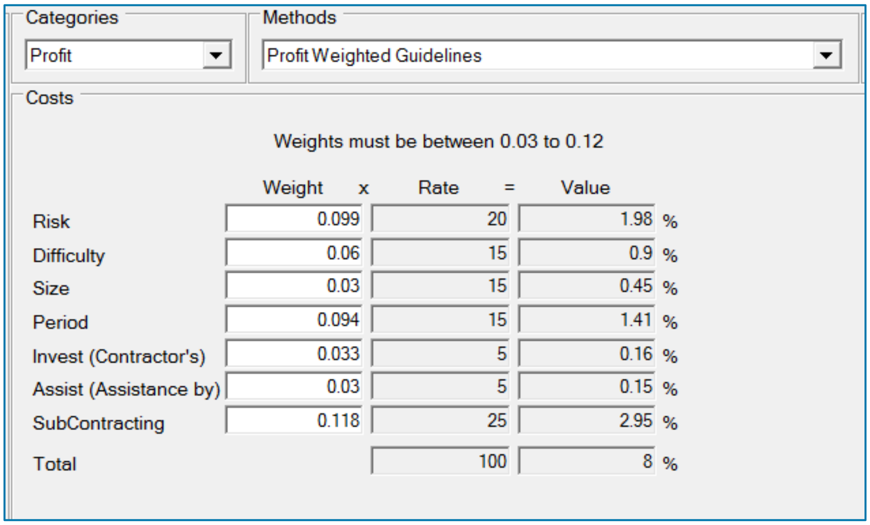

Figure 2-1 Contractor Profit and Risk Calculation Summary

Risks identified on the risk register as transferred to the PDB Contractor are assumed to be covered within this amount. No allowance for risks categorized as transferred to the PDB Contractor are included in other project contingencies.

Subcontractor Markups

KRRC selected a subcontractor markup of 10% as derived by using industry standard construction subcontract requirements on similar projects.

Insurance Markups

KRRC selected an insurance markup of 1% of direct construction cost as derived by using industry standard insurance requirements on similar projects. Insurance markup can vary to account for work complexity, procurement lead time, etc. However, since the project scope is primarily demolition, KRRC considers a 1% insurance markup appropriate.

Bond Markups

KRRC selected a bonding markup of 1% of direct construction cost as derived by using industry standard bond requirements on similar projects.

2.3.3 Quantities

Detailed quantity takeoffs made for the earthworks items (excavation, fill and erosion protection) were computer-generated (and independently checked) using the surfaces presented in the drawings, and represent neat-line quantities. Earthwork volumes (cut, fill, balance) and other quantities are provided in Section 5 and associated figures of the Definite Plan.

2.3.4 Construction Schedule

KRRC based the estimate on the construction schedule and the construction plan described in the Definite Plan. As discussed in the plan, the schedule is predicated on the following:

- Construction of City of Yreka water supply improvements will be completed in 2020 (prior to drawdown) and may be under a separate contract from the PDB Contract for the dam removal work
- Construction of downstream flood control improvements will be completed in 2020 prior to drawdown) and may be under a separate contract from the PDB Contract for the dam removal work
- Construction of the access road improvements will be completed in 2020 (prior to drawdown)
- An effective Date of Agreement (guaranteed maximum price) for the dam removal PDB on or before February 15, 2020
- Lineal and concurrent activities
- Equipment application and production
- The ability to drawdown J.C. Boyle, Copco No. 1 and Iron Gate reservoirs at the beginning of 2021
- Major earthworks and removal activities are assumed to be performed using two 10-hour shifts, six days per week
- In-stream construction window in Oregon is assumed to be from July 1 through September 30
- In-stream construction window in California is assumed to be from June 15 through October 15

The duration of many of the schedule activities are determined from the labor and equipment productivity associated with the estimate pay item sheets.

The access road, dam modification, water supply, and downstream flood control construction will be completed during an estimated 6- to 8-month period in 2020, since these activities require completion prior to drawdown and facility removal. Subsequent dam removal and associated construction will occur during 8 months of work in 2021, with restoration related construction activities likely extending through 2022. Monitoring and reporting will extend for 5 years after construction completion.

2.4 Consulting Services Pricing

Outside of construction costs, other implementation activities such as project oversight, field studies, design, permitting, mitigation measures and monitoring generally involve labor and associated other direct costs (ODCs). ODCs can include office space, travel, meals, postage, specialty reproduction, and vendor quotes for materials, supplies or services. For each of the implementation activities referenced above, KRRC developed independent estimates using standard labor rates and ODC values based on the latest understanding of the scope or work for the life of the Project. Details for each cost category are provided in Section 3. KRRC used a standard labor rate sheet for an environmental/engineering consulting firm, as shown below in Table 2-1, to develop the majority of the other implementation costs listed above. In some cases, KRRC used specialty rates to develop estimates for specialty activities such as project oversight and legal support.

Table 2-1 Environmental/Engineering Labor Rate Sheet

Labor Classification	Hourly Rate	Labor Classification	Hourly Rate
Senior Technical Advisor	$285.00	Field Technician	$75.00
Principal	$285.00	Junior Field Technician	$55.00
Project Manager	$230.00	Certified Industrial Hygienist	$165.00
Principal Engineer	$200.00	Senior Data Management	$130.00
Senior Engineer	$180.00	Data Management	$85.00
Engineer	$145.00	Senior GIS/CADD/Graphics	$120.00
Junior Engineer	$100.00	GIS/CADD/Graphics	$90.00
Principal Scientist/Planner	$180.00	Technical Editor	$105.00
Senior Scientist/Planner	$160.00	Community Relations Specialist	$110.00
Scientist/Planner	$120.00	Project Controls/Procurement	$95.00
Junior Scientist/Planner	$95.00	Administrative Assistant	$75.00
Senior Field	$110.00	Clerical/Support	$65.00

The hourly rates set forth in this schedule of fees and charges is valid from January 1, 2017 through December 31, 2017. The Hourly Rates are adjusted annually on January 1 of each subsequent year. The new Schedule of Fees and Charges will apply to existing and new assignments. For work extends beyond December 31, 2017 a 3% annual escalation on hourly rates will apply.

2.5 Escalation

KRRC based estimates on contemporary market information at the time of estimate preparation. As such it is necessary to include escalation to account for cost increases over the duration of the Project, particularly as this Project spans multiple years. KRRC escalated each line item in the cost estimate based on scheduled construction and other implementation activities.

KRRC used an escalation rate of 4% per year. This is based on cost index references and current cost trends observed in the industry. As shown in the below Engineering News Record (ENR) Historic Cost Index (Table 2-2), the last few years have seen a consistent uptrend in escalation, including the beginning of 2018. Considering this trend, along with other published historical data and professional judgment, it is reasonable to expect escalation to average out at around 4% per year over the duration of the Project.

Table 2-2 ENR Historic Cost Index

	JAN	FEB	MAR	APR	MAY	JUN	JUL	AUG	SEP	OCT	NOV	DEC	ANNUAL AVG	AVERAGE ANNUAL INCREASE
1990	4680	4685	4691	4693	4707	4732	4734	4752	4774	4771	4787	4777	4732

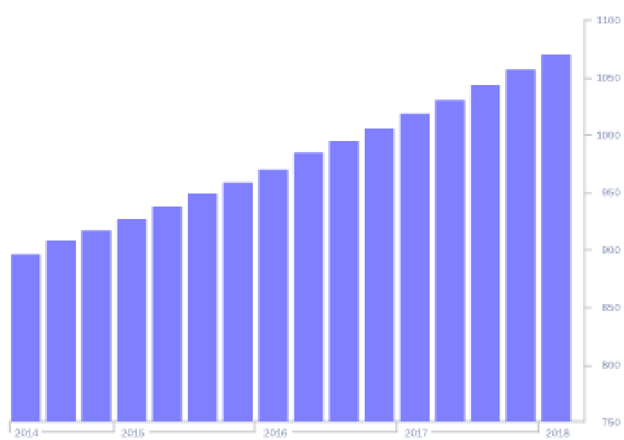
Table 2-3 Turner Construction Building Cost Index

Turner Building Cost Index

2018 First Quarter Forecast

"In a construction market that continues to show high levels of activity, the first quarter saw modest growth in raw material prices. Additionally, we are seeing a surge in steel driven by rising demand and limited offshore supply."

Attilio Rivetti
Vice President



Quarter	Index	Δ%
1st Quarter 2018	**1071**	**1.23**
4th Quarter 2017	1058	1.34
3rd Quarter 2017	1044	1.26
2nd Quarter 2017	1031	1.18

Year	Average Index	Δ%
2017	1038	5.0
2016	989	4.7
2015	943	4.5
2014	902	4.4
2013	864	4.1
2012	830	2.1
2011	812	1.6
2010	799	-4.0
2009	832	-8.4
2008	908	6.3
2007	854	7.7
2006	793	10.6
2005	717	9.5

The Turner Building Cost Index is determined by the following factors considered on a nationwide basis: labor rates and productivity, material prices and the competitive condition of the marketplace.

2.6 Design & Construction Contingency

Design contingencies are intended to account for three types of uncertainties which directly affect the estimated cost of a project as it advances from the planning stage through final design. These include: (1) unlisted items, (2) design and scope changes, and (3) cost estimating refinements. Based upon the apparent completeness of the listed items for the dam removal estimates, the design contingency was set at ±10 percent of the construction cost, which is a typical value for a the level of design presented in the Definite Plan, particularly given the fact that a large percentage of the demolition work is means and methods driven, as opposed to detailed design

This estimate of project costs includes a percentage allowance for construction contingencies to cover differences in actual and estimated quantities, unforeseeable difficulties at the site, changed site conditions, possible changes in plans, and other uncertainties during the construction period. The allowance is based on engineering judgment of the major pay items in the estimate, reliability of the data, adequacy of the estimated quantities, and general knowledge of the site conditions. KRRC used a value of ±20 percent of the construction cost for construction contingencies for the dam removal estimates, which is a typical value for this stage of project development.

KRRC applied the design and construction contingencies (total of 30%) discussed above as a percentage of the total construction cost, and added to the total estimate of project costs.

2.7 Monte Carlo Analysis

KRRC completed a Monte Carlo analysis to analyze uncertainties and risk, to be used as the basis for development of the MPL and MPH estimates.

The probabilistic range of costs for each estimate line item was determined with the use of '@Risk' Monte Carlo analysis software. The Monte Carlo analysis involves determining the impact and likelihood of occurrence of identified and quantified uncertainties and risks by running simulations to identify the range of possible outcomes for a number of scenarios - 10,000 scenarios in the case of this Project. A random sampling is performed in the simulation by using uncertain risk variable inputs to generate the range of outcomes with a confidence measure for each outcome.

Levels of probability are described from P1 to P100, where the number following the 'P' represents the percentage of most probable outcomes. For example, the P1 estimate amount will only cover the lowest 1% of the possible cost outcomes, whereas P100 will cover the maximum estimate amount determined from running the 10,000 scenarios. A P80 estimate covers the most likely final project cost in 80% of all scenarios, and is often used by the construction industry (Barreras 2011), including the USACE ("Per regulation and guidance, the P80 confidence level is the normal and accepted cost confidence level"), to calculate the amount of risk contingency to carry on a project.

Due to the unique nature of this Project and the KRRC, KRRC selected a conservative P90 to represent the MPH for the Project. The P90 estimate covers the most likely final project cost in 90% of all scenarios. KRRC selected a P10 to represent the MPL.

2.8 Ongoing Due Diligence

2.8.1 General

KRRC is undertaking additional due diligence on construction costs, measures to lower construction costs, and measures to manage construction risk. KRRC will complete additional engineering, select a design-build contractor, negotiate a construction agreement with the Contractor, establish a guaranteed maximum price for the work to be performed, implement its insurance programs, and establish the requirements for all bid bonds, payment bonds, and the performance bond. Many risks considered in the Monte Carlo analysis that deal with design and regulatory compliance will be mitigated or better understood when this process is completed, likely lowering the MPH significantly.

2.8.2 Independent Board of Consultants (BOC)

The FERC approved the BOC for the Lower Klamath Project on May 22, 2018. Among other things, FERC's letter of approval included a plan and schedule to obtain BOC review of the estimate of project costs and MPH estimates for the Full Removal alternative, adequacy of available funds for facilities removal, adequacy of the proposed contingency reserve, and adequacy of the proposed insurance and bonding arrangements. The five-member BOC includes Dan Hertel, PE (Engineering Solutions, LLC), James Borg, PE (D&H Concepts, LLC), Craig Findlay, PhD, PE, GE (Findlay Engineering, Inc.), Mary Louise Keefe, PhD (R2 Resource Consultants, Inc.), Ted Chant, PE (Chant Limited) and Robert Muncil, ARM (Cool Insurance Agency, Inc.). KRRC plans to convene the BOC on or before August 1, 2018.

The Definite Plan will be further informed by the review and recommendations of the BOC. KRRC will incorporate the recommendations of the BOC into a revised Definite Plan and this Appendix P will be updated accordingly.

Chapter 3: Cost Category Summaries

This page intentionally left blank.

3. COST CATEGORY SUMMARIES

The following sections provide detailed summaries of methods, assumptions and results of the estimate development for the various cost categories and subcategories.

3.1 Project Oversight

Project oversight and administration costs generally include costs associated with KRRC set-up and corporate insurance, management labor and travel, accounting and administrative support, project controls, contract management, BOC participation and facilitation, legal support, and outreach. Oversight costs exclude technical services, engineering, mitigation measures, construction contracting and land survey contracting. Table 3-1 summarizes estimated project costs for project oversight across the various project phases. Project oversight costs are the same for the Full and Partial Removal alternatives.

KRRC developed labor estimates for each activity using the latest understanding of management requirements in any given year, and applicable industry labor rates. KRRC developed ODCs using an understanding of actuals spent to date and requirements to continue management efforts into the future. ODCs include office space, travel, meals, postage, specialty reproduction, and vendor quotes for materials, supplies or services.

Table 3-1 Project Oversight Estimate Per Phase

Project Oversight	July 2016 - Jun 2017 (1 year)	July 2017 - Dec 2019 (2.5 years)	Jan 2020 - Jun 2022 (2.5 years)	Jul 2022 - Jun 2027 (5 years)	Total
Management Labor, ODCs & Insurance	$ 722,000	$ 3,653,000	$ 4,469,000	$ 832,000	$ 9,676,000
Accounting and Administation	$ 1,139,000	$ 2,777,000	$ 3,189,000	$ 811,000	$ 7,916,000
Contract Management and Controls	$ 1,110,000	$ 1,738,000	$ 373,000	$ 86,000	$ 3,307,000
Board of Consultants Process	$ -	$ 906,000	$ 494,000	$ -	$ 1,400,000
Legal Support	$ -	$ 3,052,000	$ 1,294,000	$ 241,000	$ 4,587,000
Outreach	$ 460,000	$ 1,102,000	$ 1,051,000	$ 75,000	$ 2,688,000
					$ 29,580,000

Note: Numbers based on 2018 dollars and exclude escalation

Table 3-2 summarizes average Full Time Equivalent (FTE) staffing for the various activities and line items. FTE numbers give a general understanding of how many full time staff may be working on each activity throughout each year or phase. KRRC calculated FTEs by dividing annual labor costs by the total working hours per year/phase and the average labor rate for each activity. FTE values for the BOC were calculated using working hours for a quarter of any given year, since BOC members are not full-time employees.

Project oversight FTEs are generally highest from 2019 through 2021, as the KRRC will be managing numerous contracts for engineering and construction of the various project components.

Table 3-2 Project Oversight Average FTEs Per Phase

Project Oversight	July 2016 - Jun 2017 (1 year)	July 2017 - Dec 2019 (2.5 years)	Jan 2020 - Jun 2022 (2.5 years)	Jul 2022 - Jun 2027 (5 years)
Management Labor, ODCs & Insurance	1.1	2.4	2.9	0.2
Accounting and Administation	3.4	3.3	3.8	0.5
Contract Management and Controls	4.4	2.8	0.6	0.0
Board of Consultants Process	-	2.3	1.2	-
Legal Support	-	1.7	0.7	0.1
Outreach	1.0	1.0	0.9	0.0

3.2 Environmental Compliance and Permitting

KRRC's plan for compliance with applicable laws and regulations is provided at Section 1.3 of the Definite Plan. Cost estimates reflected in this Appendix P are based upon implementation of that plan, and further assume that the license surrender order to be issued by the FERC will authorize implementation of the Definite Plan (as proposed) and will not impose any conditions that conflict with or are materially inconsistent with the Definite Plan. In additional to FERC 's surrender order (which will incorporate any conditions or requirements of the National Environmental Policy Act, California § 401 Clean Water Act Water Quality Certification, Oregon § 401 Clean Water Act Water Quality Certification, the Endangered Species Act, the Magnuson-Stevens Fishery Conservation and Management Act and the National Historic Preservation Act), the California § 401 Clean Water Act Water Quality Certification to be issued by the California State Water Resources Control Board will include and address any measures needed to comply with the CEQA. This report also assumes that implementation of the Definite Plan will require a Section 404 individual permit from the USACE, coverage under an National Pollutant Discharge Elimination System (NPDES) Construction Stormwater General Permits for construction-related stormwater discharges to surface waters in California and Oregon, and various other state and local permits required by applicable law. Table 3-3 summarizes estimated environmental compliance and permitting costs across the applicable project years. Environmental compliance and permitting costs are the same for the Full and Partial Removal alternatives.

KRRC developed labor estimates for each activity using the latest understanding of management requirements in any given year, and applicable industry labor rates. KRRC developed ODCs using an understanding of actuals spent to date and requirements to continue permitting and associated field efforts into the future. ODCs include travel, meals, and vendor quotes for materials, supplies or services.

Table 3-4 summarizes average FTE staffing for the various activities and line items. FTE numbers give a general understanding of how many full time staff may be working on each activity throughout each year or phase. KRRC calculated FTEs by dividing annual labor costs by the total working hours per year and the average labor rate for each activity.

Environmental compliance and permitting FTEs are generally highest in 2018 while numerous biological surveys are being completed along with development of materials to support FERC.

Table 3-3 Environmental Compliance Estimate Per Year

Permitting Activity	2017	2018	2019	2020	2021	2022	Subtotal
Permitting Approach	$ 90,000	$ 50,000	$ -	$ -	$ -	$ -	$ 140,000
Biological Surveys	$ 50,000	$ 960,000	$ 800,000	$ -	$ -	$ -	$ 1,810,000
Federal Permitting	$ 468,000	$ 1,335,000	$ 643,000	$ 427,000	$ 427,000	$ 214,000	$ 3,514,000
State Permitting	$ 115,000	$ 573,000	$ 28,000	$ -	$ -	$ -	$ 716,000
Local Permitting	$ 66,000	$ 445,000	$ 28,000	$ -	$ -	$ -	$ 539,000
TOTAL	**$ 789,000**	**$ 3,363,000**	**$ 1,499,000**	**$ 427,000**	**$ 427,000**	**$ 214,000**	**$ 6,719,000**

Note: Numbers based on 2018 dollars and exclude escalation

Table 3-4 Environmental Compliance Average FTEs Per Year

Permitting Activity	2017	2018	2019	2020	2021	2022
Permitting Approach	0.3	0.1	-	-	-	-
Biological Surveys	0.0	3.7	3.0	-	-	-
Federal Permitting	1.4	4.0	1.9	1.3	1.3	0.6
State Permitting	0.3	1.7	0.1	-	-	-
Local Permitting	0.2	1.3	0.1	-	-	-

3.3 Engineering and Procurement

Engineering and procurement includes all activities required to complete the final project engineering designs and procure construction contractors to complete the construction. Section 2.2 describes the construction procurement approach for the Project, and is a basis for the procurement estimates provided herein.

The first step in the design process is to complete the necessary field work to obtain design data to support the design analyses and drawings. The following activities fall into this category:

- Topographic/Bathymetric Surveys: Obtain updated data of topographic and reservoir bathymetric conditions at the Project
- Geotechnical Investigations: Obtain geologic information to evaluate reservoir rim stability and other geologic conditions to support design components
- Hazardous Material Investigation: Complete phase 1 hazardous material assessments for existing hydropower and other pertinent project features
- Biological Reconnaissance: Obtain initial understanding of existing biological conditions that may affect proposed design layout
- Engineering Reconnaissance: Obtain understanding of existing site facilities and infrastructure to inform design and demolition activities
- Groundwater Monitoring: Obtain groundwater well data adjacent to reservoirs to assess potential impacts associated with reservoir drawdown

The next step in the design process is to refine the preliminary designs based on the latest field data and input from regulatory and other stakeholders. This refined design will serve as the basis for environmental and regulatory reviews. Primary project components are listed below, and described in detail in the Definite Plan.

- Dam & hydropower demolition
- Reservoir restoration
- Road and bridge improvements
- Relocation of the City of Yreka's pipeline across Iron Gate Reservoir and associated diversion facility improvements
- Demolition [and replacement] of various recreation facilities adjacent to the reservoirs
- Recreation improvements
- Downstream flood control improvements
- Groundwater system improvements
- Fish hatchery modification and improvements (not included in estimate since funded separately by PacifiCorp)
- Cultural resource measures (to protect identified historic, cultural, and tribal resources)
- Groundwater improvements (well improvements adjacent to the reservoirs, if needed)

After preliminary design, the final engineering plans and specifications are developed. As described in Section 2.2, the PDB will complete final design of the large dam removal work package (access road improvements, dam modifications, access road improvements, dam and hydropower removal, and reservoir restoration), while final design of other components may be completed by a separate engineering entity.

The final activity for the engineering team(s) will be to provide engineering support during construction for quality control purposes.

Table 3-5 summarizes estimated engineering and procurement costs across the applicable project years. Engineering and procurement costs are the same for the Full and Partial Removal alternatives.

KRRC developed labor estimates for each activity using the latest understanding of engineering and procurement requirements in any given year, and applicable industry labor rates. KRRC developed ODCs using an understanding of actuals spent to date and requirements to continue engineering and procurement efforts into the future. ODCs include travel, meals, and vendor quotes for materials, supplies or services.

Table 3-5 Engineering & Procurement Estimate Per Year

Engineering & Procurement Activity	2017	2018	2019	2020	2021	2022	Subtotal
Design Data	$ 537,000	$ 1,455,000	$ -	$ -	$ -	$ -	$ 1,992,000
Preliminary Design	$ 1,909,000	$ 1,796,000	$ 125,000	$ 25,000	$ 25,000	$ -	$ 3,880,000
Final Design & Eng. Construction Support	$ -	$ 100,000	$ 6,120,000	$ 1,256,000	$ 1,094,000	$ 178,000	$ 8,748,000
Procurement	$ 37,000	$ 524,000	$ 348,000	$ 103,000	$ -	$ -	$ 1,012,000
TOTAL	**$ 2,483,000**	**$ 3,875,000**	**$ 6,593,000**	**$ 1,384,000**	**$ 1,119,000**	**$ 178,000**	**$ 15,632,000**

Note: Numbers based on 2018 dollars and exclude escalation

Table 3-6 summarizes average FTE staffing for the various activities and line items. FTE numbers give a general understanding of how many full time staff may be working on each activity throughout each year or phase. KRRC calculated FTEs by dividing annual labor costs by the total working hours per year and the average labor rate for each activity.

FTEs are highest for engineering design in 2019, when multiple engineering design teams will be developing final design packages for the various project components.

Table 3-6 Engineering & Procurement FTEs Per Year

Permitting Activity	2017	2018	2019	2020	2021	2022
Design Data	1.6	4.4	-	-	-	-
Preliminary Design	5.6	5.3	0.3	-	-	-
Final Design & Eng. Construction Support	0.0	0.3	18.3	3.8	3.3	0.5
Procurement	0.1	1.3	1.3	-	-	-

3.4 Construction Management

The estimate and proposed construction management (CM) approach for the Project is based on the information available at the time of the development of this analysis and on the assumption that the dam removal construction will be performed under a PDB contract and that other project components may be constructed through the implementation of conventional contracting methods (e.g. design-bid-build (DBB)).

KRRC estimated construction management to support all construction commencing mobilization in early 2020, dam modifications and commencement of work on construction of other components such as access road and bridge work, waterline relocation and downstream flood control improvements. Support continues through reservoir drawdowns into 2021 and ramps-up in the second year of construction for the parallel demolition of dams, and reservoir restoration.

The proposed CM approach is based on the assumption that two construction management offices located at the Iron Gate and Copco areas will be established for 2020, with a third office established in 2021 for the J.C. Boyle area. The estimate also reflects the traveling constraints between each of the sites under the prospective contracts.

The principal construction management office will be located near the existing Iron Gate dam, where the Senior Construction Manager is located. There will be one Project Control Manager, one Scheduler and one Field Contract Administrator to support the construction, who will likely be located in the Iron Gate dam offices. KRRC considers establishing the principal office at this location advantageous as the excavation work at Iron Gate is one of the more labor-intensive critical path aspects to the construction. Secondary construction management offices will each be headed up by a separate Construction Manager. Costs for these facilities are included in the construction Contractor's general conditions.

Third-party inspection oversight on the PDB is an important factor in construction management of a sensitive high-visibility project such as this. Inspectors will provide oversight of Contractors' safety, quality, environmental, cultural and scope compliance. They will also make timely observations of construction progress and conditions, to support identification of potential productivity issues, and support avoidance and evaluation of potential change work.

KRRC assumed that some construction work may occur outside normal working hours, and is likely required for excavation of Iron Gate dam and demolition of Copco No. 1 dam. A second shift Dam Removal Inspector has been included for 7 months to allow for this likelihood.

A Safety Manager and Quality Manager are included at 40 hours/month each to provide audits of contractor and construction management practices against established procedures and standards.

KRRC calculated labor costs based on applicable industry contract rates where available and escalated them at 3% annually. KRRC based all labor costs on a 40 hour work week, except for inspector labor costs which are based on a 50 hour work week. An allowance of 20% on labor has been included to cover ODCs including travel, lodging and other remuneration associated with the remote sites.

The estimated project cost assumes that cultural resources and environmental monitoring will be required. These costs are not captured in the CM section, but are included elsewhere in this estimate.

Table 3-7 summarizes estimated construction management costs on a per-year basis, per labor category and shows ODCs included in the estimate. Construction management costs are the same for the Full and Partial Removal alternatives.

Table 3-8 show staff included in this estimate, where 1.00 = one FTE for one month.

Table 3-7 Construction Management Estimate Per Year

Construction Management Staff	Hrs/ week	2020	2021	2022	Total
Sr. Construction Manager (1 person)	40	$ 441,852	$ 508,019	$ 43,605	$ 993,477
Construction Manager (2 people)	40	$ 410,262	$ 916,948	$ 80,378	$ 1,407,588
Administrative Assistant (3 people at peak)	40	$ 277,025	$ 482,882	$ 45,214	$ 805,121
Field Contract Administration (1 person)	40	$ 283,162	$ 327,748	$ 28,132	$ 639,042
Lead Dam Removal Inspector (3 people at peak)	50	$ -	$ 1,090,055	$ -	$ 1,090,055
Second Shift Dam Removal Inspector (1 person)	50	$ -	$ 305,215	$ -	$ 305,215
Yreka Water Supply Inspector (0.5 person)	50	$ 148,163	$ -	$ -	$ 148,163
Rec Improvements Inspector (0.5 person)	50	$ 148,163	$ 174,409	$ -	$ 322,572
Flood Improvements Inspector (0.5 person)	50	$ 148,163	$ 174,409	$ -	$ 322,572
Bridges and Roads Inspector (1 person)	50	$ 370,407	$ 436,022	$ 37,425	$ 843,854
Specialty Inspectors (1 person)	50	$ -	$ 339,128	$ -	$ 339,128
Scheduler (1 person)	40	$ 282,846	$ 327,748	$ 28,132	$ 638,726
Project Control Engineer (1 person)	40	$ 282,846	$ 327,748	$ 28,132	$ 638,726
Safety Manager (0.25 person)	40	$ 79,485	$ 89,312	$ 7,666	$ 176,463
Quality Manager (0.25 person)	40	$ 79,485	$ 89,312	$ 7,666	$ 176,463
ODCs at 20%	-	$ 590,372	$ 1,117,791	$ 61,270	$ 1,769,433
TOTAL		$ 3,542,231	$ 6,706,749	$ 367,620	$ 10,616,599

Note: Numbers based on 2018 dollars and exclude escalation

3.5 Construction

3.5.1 Dam Removal

The dam removal scope for Full and Partial Dam Removal alternatives is defined in Section 5 of the Definite Plan and was used as the basis for this estimate. Estimates were developed using the methods and schedule constraints summarized in Section 2.3 of this report. Escalation was applied per Section 2.5.

Pertinent assumptions from the Definite Plan are as follows:

- KRRC confirmed or updated quantities where new information was available, and as described in Section 5 of the Definite Plan.
- Estimate and schedule assumes that a second shift will be required for Copco No. 1 and Iron Gate demolition. KRRC assumed two 10-hour shifts, 5 days a week.
- Estimate and schedule assumes that work days are 8 hours per day, 6 days a week for Copco No. 2 and J.C. Boyle demolition.
- All concrete demolition debris will be hauled to onsite disposal area as described in more detail in Section 5 of the Definite Plan for Decommissioning (KRRC 2018).
- All earth work material from excavation activities will be hauled to onsite disposal area as described in more detail in Section 5 of the Definite Plan for Decommissioning (KRRC 2018).
- All concrete and earthwork demolition material will be processed during demolition activity and there is no process equipment (crusher, screener, and stacker) operated at disposal areas.
- One general PDB will be used to manage the entire design build process, but subcontractors will be used for certain specialized activities.

3.5.2 Reservoir Earthwork & Engineered Structures

This estimate assumes that a small percentage of sediment that remains in the reservoirs after drawdown will be mechanically excavated and placed elsewhere in the proposed floodplain area. Earthwork excavation volumes within the reservoir are based on surface models from historical site surveys compared to recently collected bathymetric data. KRRC developed labor rates, equipment rates, and materials costs from a combination of actual costs from past similar projects and RS Means Heavy Civil publication.

This estimate assumes the following:

- Earth excavation and subsequent fill (or disposal) will happen at the same time so that material is handled only once and placed on-site in the final location with minor grading and compaction. KRRC based volume estimates on neat line quantities using digital surface models.
- All excavated material is suitable for in-water disposal and will be disposed of on-site.

- Estimates include equipment and road access into site, assuming 3,000 linear feet (LF) on center (OC) or 0.56 miles per site (6 sites).

KRRC proposes elements for bank stability and channel fringe complexity, and will include a process-based restoration and velocity variations along bank line by adding large wood complexity for resting zone, feeding seams, cover and velocity refugia. KRRC based restoration areas and treatments on expected conditions after drawdown and may change based on actual conditions.

Areas identified for reservoir earthwork activities and engineered stability elements are described and shown in plan in Appendix H, Restoration Plan of the Definite Plan.

3.5.3 Restoration

Restoration activities can be broken into three primary categories: (1) Earthwork/engineered improvements (Section 3.5.2), (2) pre-drawdown activities, and (3) post drawdown activities. The following text summarizes key assumptions that are pertinent to the estimate development for the second two categories. A full description of these components can be found in Appendix H, Restoration Plan of the Definite Plan.

Pre-drawdown activities include seed collection, seed propagation and weed eradication, as further summarized below. In addition to the work described below, KRRC assumes completion of an RFP process to select a contractor or vendor for each activity.

1. **Seed Collection:** The main component of the revegetation process will be locally eco-typic seed of native plants for four different planting zones (bank wetland, bank riparian, floodplain riparian, and upland) based on hydrology. The seed will preserve the genetic integrity of the site and provide species and genetics best suited for this specific landscape. Collection of locally eco-typic seed subsequently grown by commercial growers to produce large amounts of seed or plant material will require advanced planning and will be implemented during the pre-dam removal period. To produce 50,000 lbs of pure live seed (PLS) in each of the four growing years before the 2022 fall season (totaling 200,000 lbs.), it is assumed that 3-7 lbs. of PLS/acre of wild collected seed will produce 2,000 LBS PLS/ acre. KRRC based this estimate upon propagation rate quotes obtained from BFI Native seed and Pacific Coast Seed. Conservatively, the higher seeding rate of 7 lbs PLS/acre is assumed to be planted on 25 acres at the seed propagation farm totaling the 175 lbs PLS of seed needed each year and resulting in the expected 50,000 lbs PLS if 2,000 lbs PLS is produced per acre on 25 acres. The cost of collecting 1 pound of wild seed ranges from low $1,000 to high $1,800. The seed must then be cleaned, stored in climate control warehouses and in some cases pre-treated. Seed pre-treatment may include scarification, stratification, imbibition, and others. Wild collected seed will be substantially more expensive than propagated seed due to additional cleaning costs.
2. **Seed Propagation:** In order reach the goal of 200,000 lbs. of PLS over 4 years, 25 acres of land will need to be rented to propagate collected seed (with an assumed minimal yield of 2,000 lbs PLS/acre) to produce 50,000 lbs per year. KRRC based the yield and other unit cost estimates on

information received from BFI, J Herbert Stone nursery, Pacific Coast Seed and the local forest service office.

3. **Weed Eradication:** The objective will be to implement a combination of weed control techniques that minimize the extent of environmental degradation and reduce the impact of chemical inputs on humans and non-target organisms. To identify the populations of existing invasive species, a field survey will be conducted at the site, geo-locating all invasive species. Assuming 100% of the project area outside of the existing reservoirs needs to be surveyed, it will take approximately 900 hours to survey the area. For a Scientist and Principal Scientist, the estimated cost is $135,000 plus approximately $2,247 for gas & mileage and $21,000 for per diems and accommodations. In the years before drawdown, KRRC assumed that 30% of the site above the water line of the reservoir (85- acres) will require invasive species eradication. KRRC based this percentage on estimates from surveys performed in the fall of 2017. Once drawdown occurs, the acreage of the site with vegetation will increase along with the need for invasive species control. For two years after drawdown, KRRC assumed 300 acres to potentially require weed eradication treatment.

Post-drawdown activities include pioneer seeding, pole cutting and salvaged plant collection, revegetation in each planting zone, followed by establishment period and long-term maintenance. Each activity is further summarized below:

1. **Pioneer Seeding:** Establishing a pioneer crop on the site, soon after drawdown of the reservoirs, is essential to preventing erosion, planting inhospitable moist substrate, preventing invasive species from establishing at the site and building up soil biota and structure. The pioneer seed mix is intended to take advantage of less expensive native seed. The seed generated in large amounts during propagation (overstock), and sterile non-native seed (sterile wheat and Regreen) that can readily establish in the sediment and will be less of a risk if it is washed out due to spring flooding or if it freezes in the early months of the year. Once river and soil conditions have stabilized, a fall broadcast seeding will be applied including locally ecotypic, native and diverse seed stock for each planting zone. Broadcast aerial seeding will be performed from helicopter(s), and is a very cost-efficient method of application. KRRC based pricing on an estimate from Ben Timberland (Timberland Helicopters, Inc, Ashland, OR) on the hourly rate of $950/hr. at the rate at which the operator can distribute the seed. KRRC assumed that the seed weighs on average 14 lbs/cubic foot, with a seed bucket that holds 27 cubic feet of seed, 12 minutes is assumed for each bucket. For distributing 100 lbs. PLS per acre, KRRC estimated to be 140 hours totaling 133,000 for a medium cost. The cost of seed per pound is based on cost for readily available seed from nurseries we anticipate working within the Project (i.e., California brome = $8-9 per PLS).
2. **Pole Cuttings and Salvaged Plants:** The establishment of habitat will greatly accelerate with the installation of pole cuttings, as well as transplantation of salvaged plants. These plants will also help prevent erosion and add species diversity to the site. KRRC's contractor will collect pole cuttings and potentially store them, short-term, prior to installation. 'Salvaged plants' will be transplanted on site; therefore their costs are not associated with contract growing and nursery care. KRRC assumed that the contractor will absorb the cost of an expected 30% mortality rate of the pole cuttings. KRRC's contractor will collect pole cuttings from areas surrounding the site. In order to increase the number of pole cuttings available, in the year prior to drawdown, contractors will selectively cut back pole

cutting species marked for plant salvage. This will promote an ample supply of young growth that can be harvested as needed the following year. It is assumed that the harvest and installation will be simultaneous, limiting the need for storage off-site. The number of pole cuttings allotted will vary by zone. Each 100 square foot area, for both the bank riparian and bank wetland zones, will include five pole cuttings. For the floodplain riparian zone, each 100 square foot area will contain one pole cutting.

3. **Revegetation**

   a) Emergent Wetland Planting Zone: Revegetation for emergent wetlands will be installed instream along the river's edge. This vegetation will consist of 100% salvaged plants, taken from the rim of the reservoirs. During the first year, KRRC assumes salvaged plants at 20 LF OC along the edges of the river. The following spring, once the plants have established, KRRC's contractor will harvest propagules from installed salvaged plants and will then be planted at 10 LF OC between the plants from the prior year. KRRC based cost estimates for plant layout per acre on estimates from Caltrans and RS Means.

   b) Bank Wetland Planting Zone: Bank wetland zones will be delineated as areas suitable for plant growth approximately between the base flow and 2-year flood event water surface elevations (Q2) of the Klamath River. These areas will consist of salvaged plants and pole cuttings. KRRC expects 50 percent of this area to be restored. KRRC's contractor will transplant salvaged plants to this zone from the existing reservoir edge. KRRC based cost estimates for this work on RS Means and Caltrans data for the operation of a backhoe with a bucket and the plantings for pole cuttings. KRRC's contractor will install pole cuttings in this initial stage of planting in the spring after drawdown. KRRC's contractor will perform plant layout for all plants by the Contractor's crews marking each planting spot with a pinflag for an overall review by a restoration ecologist. KRRC's contractor will aerial seed the pioneer crop in all zones early in the drawdown year creating fast-growing erosion control before the river stabilizes. Once the pioneer crop has grown, KRRC's contractor will either roll or mow it to help open the soil to sunlight and create a habitat for the fall broadcasting of ecotypic native seed. In the early spring of the following year, KRRC's contractor will layout and install one pole cutting per 100 square foot (SF).

   c) Bank Riparian Planting Zone: The Bank Riparian Zone will extend approximately from the 2-year (Q2) to the 25-year (Q25) flood water surface elevations (Q-lines) of the Klamath River. KRRC expects 50 percent of this area to be available for restoration. It will be the most critical zone for rapid re-establishment of riparian habitat, short-term stability of the channel and banks, and for long-term establishment of an important transitional area between the riverine features and floodplain habitat areas. Planting densities within the riparian-bank areas will be variable, however, the substantial density of initial planting will be important to prevent invasion by reed canary grass (*Phalaris arundinacea*), a highly invasive non-native hybrid that is widespread around the reservoirs. The Bank Riparian zone will have a similar treatment to the Bank Wetland; with the same plant material and spacing. After drawdown, KRRC's contractor will transplant the plants from the rim of the reservoir to the river's edge. In the pioneer seeding process, KRRC's contractor will mainly apply mycorrhiza, with the seed in this area. In the fall, the area will be broadcast seeded with ecotypic zone selected seed. KRRC's contractor will install an additional pole cutting in the following spring. Selected areas will be fenced off to deter deer predation and to serve as a seed bank to areas without fencing. Costs for fencing and installation and based on Caltrans data.

d) Floodplain Riparian Planting Zone: Floodplain riparian zones will be delineated as those areas suitable for revegetation that occur approximately between the 25-year (Q25) and 100-year (Q100) flood water surface elevations of the Klamath River. The Riparian Floodplain Planting Zone will be planted similarly to the Bank Riparian Planting Zone; however, the plant densities will decrease, producing a decrease in plant layout costs for this zone. For each 100 SF area, there will be one pole cutting and one seed plant installation in the second year. The cost of Construction/Installation maintenance decreases slightly from Bank Riparian area; it will have an18-month duration, until Plant Establishment. This section also includes emergency overhead irrigation in the high price estimate. KRRC based unit prices for this on a quote from Rain for Rent for the entire site. Costs include $60k for setup and design, $40k/month rent and $30k to disassemble the irrigation system, and a 5-month rental ($320K) and an uncertainty factor of 2 for 1,790 acres (costs pro-rated from the estimate for the Project). KRRC based costs for this on a quote from Rain for Rent that includes design and rental of all equipment.

e) Uplands below Rocky Wake Zone: The area between the upper edge of the Riparian Floodplain Planting Zone and the lower edge of the Rocky Wake Planting Zone constitutes the Uplands below the Rocky Wake Planting Zone. This area is the only formerly submerged area where upland vegetation will grow on sedimentary substrate. KRRC expects 50 percent of this area to be restored. The restoration process will be the same as for the planting zones below; mycorrhizal inoculant will be in the pioneer seed mix in the spring, broadcast seeding of the native ecotypic seed will be conducted in the fall 2021, and a spring 2022 with deer fence, emergency irrigation, and construction/installation maintenance. However, plantings in this zone will consist of four woody plants per 100 SF. Species will include acorns, juniper berries, pine nuts fir and various shrubs. KRRC's contractor will install these plants with cocoon irrigation planters that will irrigate the plants and slowly deteriorate as the plant becomes self-sustainable. KRRC's contractor will use an auger to create a planting pit approximately 2 feet in diameter and 1 foot deep. KRRC based installation costs upon Saylor's installation cost.

f) Rocky Wake Planting Zone: The Rocky Wake Planting Zone is the area of wake and wave action erosion around the edge of the existing reservoirs. Fluctuations of water level and wave action in the reservoir has eroded soil in a band or 'bathtub ring' leaving exposed rocky substrate, bedrock, areas that lack in vegetation. KRRC assumed that only 20% of this area is feasible to restore. Soil amendments consisting of mycorrhizal inoculant will be added at the time of seeding. After the pioneer crop is broadcast seeded in the spring, the grown vegetation will be mowed or rolled in preparation for the fall broadcast seeding of the ecotypic seed. The plant selection and densities will be the same as the uplands below rocky wake zone. KRRC's contractor will place deer fence in selected areas within the zone to create areas free of deer predation. These areas will serve as seed banks for the rest of the site if predation becomes severe. Additionally, overhead irrigation is included in the high estimation cost.

g) Disturbed Uplands Planting Zone: The Disturbed Uplands Planting Zone will consist of the existing developed areas proposed for demolition and recreational areas that will be removed after drawdown occurs. The revegetation schedule remains the same. However, the initial soil preparation may vary. These areas will most likely have highly compacted areas due to the existence of concrete or vehicular traffic on gravel areas. In these areas, it is assumed that 75% of the recreation area will need de-compaction. KRRC's contractor will cross rip compacted areas (before fall seeding) to a depth of 24 inches to loosen the soil and prepare it for seeding and planting. After de-compaction, KRRC expects this area to have healthy viable soils, so it is assumed that 90% of the area will be restored.

h) Upland Stockpiles Planting Zone: Upland Stockpiles Planting Zones include areas where materials from the dam removal will be deposited. The topsoil in these areas will be heavily compacted. The revegetation process for these areas will be the same as for the Disturbed Uplands Planting Zone, however, 100% of this zone will have to be de-compacted, slightly increasing it's per acre cost. KRRC based estimates for this treatment on RS Means data for $110 to rip soil with a bulldozer.

i) Undisturbed Uplands Planting Zone: The Undisturbed Uplands Planting Zone will consist of areas above the Rocky Wake Zone that may be only minimally disturbed by the eradication of invasive exotic species. These areas will go through active weed removal for at least 3 years before drawdown. KRRC's contractor will reseed potential bare and disturbed patches resulting from invasive species eradication with a native upland seed mix via broadcasting. The majority of these areas will have existing native vegetation and only 30% is expected to need restoration.

4. **Establishment Period Maintenance**: KRRC assumes that the Project will be monitored and maintained for 5 consecutive years. Maintenance and monitoring, during the first plant establishment year is crucial to achieving revegetation performance criteria established in the revegetation plan and agreed to with regulatory agencies. The quality of establishment maintenance and monitoring will determine whether the project area will be taken over by invasive exotics or by heathy native plants. KRRC's contractor will perform monthly establishment maintenance and monitoring from November 1 through April 1 and bi-weekly the rest of the year, totaling approximately 20 visits during this critical first year. During each visit, botanists will be surveying the project area for a number of performance criteria related objectives. Plant species diversity and cover, the growth and health of woody vegetation, acres of wetlands, and noxious weed coverage may be monitored. The location of individual species or areas of species will be geo-located. Other monitoring items may include the minimum coverage of woody shrubs and trees in key restoration areas. KRRC based the labor rate for monitoring on the mean hourly rate of a Scientist and Principal Scientist, resulting in a probable cost of $139,884 for each visit, equaling about 932 hours of monitoring surveys at a rate of 2.5 acre/hour. Maintenance will follow monitoring, and may include re-seeding/re-planting of native vegetation (as necessary), invasive plant management, herbivore control, irrigation maintenance and other activities as situations arise (e.g., implementation of erosion repairs). KRRC based rates for these items roughly on quoted rates for invasive species removal in the area ($3,000/acre).
5. **Long-term Maintenance:** After Establishment Period Maintenance and Monitoring, long-term monitoring will continue for 4 years. For monitoring, the cost per visit and the rate of surveying is consistent throughout at 2.5 acres/hour (assuming the mean hourly rate of a Scientist and Principal Scientist). Tasks outlined in the Establishment Maintenance activity will also continue throughout this period. However, KRRC anticipates both the number of visits and maintenance needs (i.e. hourly

cost) to decrease. In Year Two (2024), there are bi-monthly surveys from November through April and monthly surveys the rest of the year, totaling 10 visits. In the second year, the number of acres in need of treatment is 80% of the total acreage, and cost of maintenance is 80% of the establishment monitoring. In Year Three (2025) there are 5 visits, one visit between November and April and bi-monthly the rest of the year. The number of acres and the cost of maintenance are 60% of the total acreage and cost of the establishment maintenance. In Year Four (2026) there are 4 visits and the acres and cost decrease to 40%. And in Year Five (2027), the final year, visits are down to twice a year and the percentage of land in need of maintenance and the rate cost is down to 20%. At this point the site should be close to natural conditions and meet the performance criteria for the upland, riparian floodplain, riparian bank, and wetland zones, as well as for invasive exotic plant presence.

3.5.4 Yreka Water Line Replacement

KRRC assumed for development of this estimate that an underground pipeline will be constructed to relocate the City of Yreka's water supply line currently crossing Iron Gate reservoir. This relocation option is discussed in detail in Section 7.5 of the Definite Plan.

The scope for replacing the Yreka Water Line will involve installation of two micro-tunneling pits on either side of the Klamath River. Once these pits are fully excavated and shored, micro tunneling equipment will install a 36" steel casing below the river bed. Once the casing is installed, a new 24-inch waterline will be installed to take the place of the river crossing section of the existing water line. On either side of the Klamath River, the new pipe will be installed using an open cut excavation method. Once the waterline is completely installed, tested and active, the micro tunneling pits and the open excavation are to be backfilled with existing material. Once the backfill operation is complete, the existing waterline will be removed and recycled.

The cost estimate for the Yreka Water Line Replacement was developed using the RS Means database with a city cost index adjustment of Redding, California. Crew output for each operation was adjusted to account for access, location, and construction operation. KRRC assumed that a pile and lagging wall will be used to shore micro tunneling pits and it will be installed simultaneously with the excavation operation.

3.5.5 Transportation Improvements

This section describes the proposed road improvements and maintenance activities that are the basis for the estimate of project costs. It is based on design information provided in Sections 5 and 7.4 of the Definite Plan. Several road, intersection, structure and culvert improvements are proposed as part of the Project to:

- Facilitate access for project-related vehicles and equipment associated with dam removal
- Provide safety measures for both public and project roads used during the dam removals
- Return roads used by project-related vehicles to the respective owners and users in an acceptable state, restoring any reduction in function attributed to the Project

The improvements will be implemented at various phases throughout the Project. Some will require completion prior to the dam removals (related to construction access), and others will be contingent on a future assessment of road elements once reservoir drawdown or hauling activities are complete (maintenance activities). There will also be some ongoing activities throughout the Project to maintain roads heavily trafficked by project construction vehicles.

Table 3-9 provides a summary of all pertinent road segments, bridges, and culverts and the associated improvements or maintenance. Table 3-10 summarizes maintenance and rehabilitation cost assumptions associated with roads being used for construction access. Section references within the table are to the sections within the Definite Plan.

Table 3-9 Transportation Improvements

Location	Improvements (Section References to Definite Plan (KRRC 2018))	Purpose		
		Construction Access	Drawdown Related	Maintenance/ Rehabilitation
J.C. Boyle				
The Dalles California Highway (US97)	• Pavement rehabilitation unlikely during or post-Project (Section 5.2.2)			X
Green Springs Highway (OR66)	• Pavement rehabilitation unlikely during or post-Project (Section 5.2.2)			X
Keno Worden Road	• Pavement rehabilitation unlikely during or post-Project (Section 5.2.2)			X
Topsy Grade Road	• Potential pavement rehabilitation during or post-Project (Section 5.2.2)			X
Culvert at Unnamed Creek	• Potential sediment removal and downstream erosion protection (Section 7.4.3)		X	
J.C. Boyle Dam Access Road from OR66	• Re-grading uneven or rutted areas (Section 5.2.2)	X		
Junction of OR66 and J.C. Boyle Dam Access Road	• Intersection widening (Section 5.2.2) • Tree removal (Section 5.2.2) • Signage (Section 5.2.2)	X		
Timber Bridge	• Remove (Section 5.2.2)	X		
Power Canal Access Road	• Periodic roadway maintenance grading during construction (Section 5.2.2)	X		
J.C. Boyle Disposal Access Road	• Re-grading (Section 5.2.2) • Minor widening (Section 5.2.2)	X		
Copco and Iron Gate				
Copco Road (I-5 to Ager Road)	• Potential pavement rehabilitation during or post-Project (Section 5.2.2)			X
Copco Road (Ager Road to Lakeview Road)	• Potential pavement rehabilitation during or post-Project (Section 5.2.2)			X
Dry Creek Bridge	• Temporary bridge for construction access during Project (Section 5.2.2)	X		

Location	Improvements (Section References to Definite Plan (KRRC 2018))	Purpose		
		Construction Access	Drawdown Related	Maintenance/ Rehabilitation
Copco Road (Lakeview Road to Daggett Road)	• Roadway maintenance during construction (Section 5.2.2) • Potential pavement rehabilitation during or post-Project (Section 5.2.2)	X		X
Unnamed Culverts between Brush Creek and Scotch Creek	• Potential rehabilitation or replacement post-construction (Section 7.4.3)			X
Scotch Creek Culvert	• Replace (Section 7.4.3)		X	
Camp Creek Culvert	• Replace with bridge (Section 7.4.3)		X	
Jenny Creek Bridge	• Replace (Section 7.4.3)		X	
Copco Road (Daggett Road to Copco Access Road)	• Potential road surface maintenance during or post-Project (Section 5.2.2)			X
Fall Creek Bridge	• Replace (Section 5.2.2)	X		
Copco Road (Copco Access Road to Copco Road Bridge)	• Potential road surface maintenance during or post-Project (Section 5.2.2)			X
Beaver Creek and E.F. Beaver Creek Culverts	• Potential erosion protection (Section 7.4.3)		X	
Raymond Gulch Culvert	• Potential erosion protection (Section 7.4.3)		X	
Copco Road Bridge	• Potential abutment erosion protection (Section 7.4.3)		X	
Copco Access Road	• Clear, grub and regrade (Section 5.2.2) • Minor widening into hillside if possible (Section 5.2.2) • Remove after construction is complete and restore area to native vegetation	X		
Copco Cove Access	• Minor works to enable barge mobilization (Section 5.2.2)	X		
Culverts at Unnamed Creeks (Copco Lake)	• Potential erosion protection (Section 7.4.3)		X	

Location	Improvements (Section References to Definite Plan (KRRC 2018))	Purpose		
		Construction Access	Drawdown Related	Maintenance/ Rehabilitation
Ager Beswick Road	• None (Section 5.2.2)			
Mallard Cove Boat Ramp Access	• Minor works to enable barge mobilization (Section 5.2.2)	X		
Daggett Road	• Minor grading improvements (Section 5.2.2) • Potential road surface maintenance during and post-Project (Section 5.2.2)	X		X
Daggett Road Bridge	• Replace (Section 5.2.2)	X		
Lakeview Road (Copco Road to Iron Gate disposal site)	• Potential road surface maintenance during and post-Project (Section 5.2.2)			X
Lakeview Road Bridge	• Replace (Section 5.2.2)	X		
Iron Gate Powerhouse Access Road	• Signage • Potential road surface maintenance during construction (Section 5.2.2) • Remove after construction is complete and restore area to native vegetation (Section 5.2.2)	X		X
Iron Gate Left Abutment Access Road	• Remove after construction is complete and restore area to native vegetation (Section 5.2.2)	X		
Iron Gate Upstream Left Abutment Access Road	• Remove after construction is complete and restore area to native vegetation (Section 5.2.2)	X		
Other Locations	•			
Pedestrian Bridge #1	• Will likely need to be removed by KRRC (Section 7.2). Cost estimate includes demolition only.			X
Pedestrian Bridge #2	• Evaluation will be performed by KRRC to determine whether removal or replacement will be required (Section 7.2). Cost estimate includes demolition only.			X

Table 3-10 Road Maintenance Assumptions

Location	Maintenance/Rehabilitation Assumptions
J.C. Boyle	
The Dalles California Highway (US97)	• None
Green Springs Highway (OR66)	• None
Keno Worden Road	• None
Topsy Grade Road	• Pre and post-construction 0.9 miles of 9-inch aggregate base section repair
J.C. Boyle Dam Access Road from OR66	• Pre-construction improvements include minor cut/fill, 0.25 miles of new 9-inch aggregate base section and 0.7 miles of 9-inch aggregate base section repair; Post-construction improvements include 0.6 miles of 9-inch aggregate base section repair
Power Canal Access Road	• Pre and post-construction 1.5 miles of 9-inch aggregate base section repair
Powerhouse Access Road	• None
J.C. Boyle Disposal Access Road	• Minor regrading & widening
Copco and Iron Gate	
Copco Road (I-5 to Ager Road)	• Post-construction 1 mile new asphalt overlay
Copco Road (Ager Road to Lakeview Road)	• Pre-construction improvements include 0.5 miles of crack sealer, and 0.75 miles of new asphalt section; Post-construction improvements include 1.0 miles of new asphalt overlay
Copco Road (Lakeview Road to Daggett Road)	• Pre-construction improvements include 1.0 mile of crack sealer, and 1.5 miles of new asphalt section; Post-construction improvements include 2.0 miles of new asphalt overlay
Copco Road (Daggett Road to Copco Access Road)	• Pre and post-construction 1.5 miles of 9-inch aggregate base section repair
Copco Road (Copco Access Road to Copco Road Bridge)	• Pre and post-construction 1.5 miles of 9-inch aggregate base section repair • Post-construction 0.25 mile overlay and minor riprap
Copco Access Road	• Pre-construction 2,500 CY cut/fill and 0.9 miles 9-inch aggregate base overlay • Remove after construction is complete and restore area to native vegetation
Ager Beswick Road	• None
Mallard Cove Boat Ramp Access	• Minor works to enable barge mobilization
Daggett Road	• None
Lakeview Road (Copco Road to Iron Gate disposal site)	• Post-construction improvements include 0.7 miles 6-inch aggregate base overlay
Iron Gate Powerhouse Access Road	• Remove after construction is complete and restore area to native vegetation

Location	Maintenance/Rehabilitation Assumptions
Iron Gate Left Abutment Access Road	• Remove after construction is complete and restore area to native vegetation
Iron Gate Upstream Left Abutment Access Road	• Remove after construction is complete and restore area to native vegetation

3.5.6 Recreation Plan

Costs associated with demolition of existing recreation facilities are included in the dam removal cost category. This section summarizes assumptions associated with construction of any new recreation facilities connected with the Project. Although the final recommendation for proposed recreation facilities has not been made, a list of possible improvements have been scoped for inclusion in this cost estimate.

Recreation costs were derived from itemized estimates for the various recreation facilities listed in Table 3-11. Rates and prices are derived from a combination of historical contracting information including Lake Berryessa Recreation Area Renovation project, and RS Means. Estimated project costs assume operation and maintenance support at each facility for up to 5 years.

Table 3-11 Assumptions For New or Improved Recreation Facilities

Dam (Sate)	Description
Campgrounds	
Jenny Creek Campground Expansion	Expand campground and upgrade facilities including new restroom, 5 picnic tables, 2 fire grates, 5 trash bins and minimal earthwork
Topsy Campground Upgrade	Replace or redesign boat ramp for river access
New Campground	New 20-site campground in TBD location (includes picnic tables, fire grates, trash bins and restroom)
Day-use Areas	
Fall Creek Day-use Area Upgrade	Upgrade facilities and reconstruct trail leading to Fall Creek waterfall
Iron Gate Hatchery Day-use Area Upgrade	Reconstruct day use site to provide additional facilities and a boat ramp
New Day-use Areas	Provide up to two day-use sites with river access at TBD defined locations. Includes new picnic table, fire grate, and trash bins. One of the sites may be located at the J.C. Boyle powerhouse and substation
River Access	
Fishing River Access Points	Up to two river access points at TBD locations. Sites include signage, portable toilets and trash receptacles
Boating River Access Ramps	Up to two river boating access points at TBD locations. Sites include access and boat ramps
Trails	
J.C. Boyle to Iron Gate walking trail	Up to 20 miles of non-motorized trail from J.C. Boyle to Iron Gate. Includes up to two viewing areas and/or interpretive signage

Dam (Sate)	Description
Walking Trails for River Access	Non-motorized side trails off main trail for access river

3.5.7 Downstream Flood Control Improvements

This section summarizes the assumptions used to develop costs associated with any required downstream flood control improvements. The analysis that led to the selection of improvements is discussed in Section 7.7 of the Definite Plan.

The cost estimate includes elevating 36 habitable homes and other structures. The rate used assumes that it will take five days to raise each house, with subcontractor costs based on the average cost of raising a building in California. Additional cost was included to add two sets of stairs per house, and supporting labor team for ancillary work associated with flood proofing.

3.5.8 Public Health and Safety Measures

The estimate includes costs for cattle exclusion fencing at reservoir sites where the former reservoirs will no longer be able to serve as a natural barrier to livestock, and for the protection of revegetation efforts against damage. Fencing will likely be four-wire fence with metal T-posts at 12 LF intervals.

Fencing quantities have been determined from a detailed analysis of fencing lengths in GIS, focused on fencing the reservoir restoration areas while avoiding fencing along portions of the perimeter with steep topography above the reservoir, forest and housing. As the scope is developed further, additional definition may be obtained by considering where fences might need to tie into property boundary fences (if they exist) or where steep topography just below the reservoir surface might act as a barrier.

3.6 Anticipated Mitigation Measures

The following sections summarize cost assumptions associated with anticipated regulatory mitigation measures for groundwater wells, downstream water intakes and cultural resources.

3.6.1 Groundwater Improvements

Groundwater well improvements adjacent to the reservoirs may be necessary if reservoir drawdown has a negative impact on existing well water levels. A groundwater well management plan is contained in Appendix N of the Definite Plan and is the basis for the estimate.

The current estimates assume public outreach will be completed with relevant property owners, and subsequent installation and monitoring of up to five (5) new 60-foot deep, 3-inch diameter monitoring wells will be completed. Well drilling costs assume PVC casing and hard rock geology. Wells will be monitored monthly for water level and water quality constituents over a 3-year period.

The estimate assumes up to 20 wells will ultimately require replacement. Costs include drilling of new wells and abandonment of existing wells. The estimate also assumes temporary water will be provided for up to 30 days during well installation.

3.6.2 Downstream Water Supply

Sediment buildup during reservoir drawdown may affect some downstream water supply intakes as needed, the KRRC will excavate affected intakes to clear them of aggraded sediment materials, and provide temporary settling basins or groundwater wells if potable water supply is impacted. Jetting and vacuum technologies such as those used for cleaning storm drains and sewers will be used to remove sediment at intakes. Temporary settling basins may also be used to remove silt and sediment prior to the primary treatment performed by the water right holder.

There are approximately 50 water diversions off the Klamath River that could be affected. The USBR believed between 7 and 18 intakes would require maintenance. As some intakes have been added after the 2012 EIS/R, this estimate is based on the higher end of the range as the most probable number of intakes that could require maintenance actions.

In some cases, where diversions are used primarily for irrigation, the KRRC may need to pay for lost or damaged crops. Water rights holders reported alfalfa and pasture as the majority crop types irrigated with the diverted water during the drawdown period. In 2012, the average return for alfalfa produced in Siskiyou County was approximately $1,200 per acre, where the average yield was approximately 6 tons per acre (UCCE 2012). Assuming all 129 acres will be affected, the cost will be approximately $154,800.

Supplying livestock with water requires providing a stock water tank and water. A 500 gallon stock water tank is estimated.

Table 3-12 Assumptions For Downstream Water Supply

Cost Level	Elements Included in Cost Estimate
MPE	Intake excavation for 18 intakes Water supply for domestic use for 8 water rights (claimed or registered rights with reported diversions) Temporary settling basins at 18 intakes Temporary groundwater wells at 18 intakes
Direct Crop Loss Mitigation	Payment for lost hay crops on 129 acres of irrigated lands.
Stock watering	Provide 500 gallon water tank and 1,500 gallons of water per month.

3.6.3 Cultural Resources

Cultural resources mitigation and protective measures may be required during drawdown, throughout the dam removal and reservoir restoration durations, and post-construction. Activities will likely involve short- and long-term cultural site monitoring, inadvertent discovery of cultural resources, among others. Additional information about the potential scope of activities is available in Appendix L of the Definite Plan.

Site monitoring and resolution of inadvertent discoveries of cultural resources and human remains will follow protocols established during agency and tribal consultations, as documented in the Historic, Cultural, and Tribal Resources Management Plan discussed in Appendix L, as well as actions developed and approved during consultations under Section 106 and agreed to during consultations with California-recognized tribes.

The cultural resource mitigation and protective measures estimate is based on the following assumptions associated with agency and tribal outreach, drawdown and post-drawdown surveys/inspections, curation fees, discovery contingencies and associated protection and mitigation measures.

Agency and Tribal Outreach

During the two-year construction period starting with reservoir drawdown, management of cultural resources and associated mitigation will require ongoing agency and tribal outreach, consultation, and meeting attendance.

Post-construction, long-term cultural resources management and monitoring activities are estimated for a 3-year period, and based on the Historic, Cultural, and Tribal Resources Management Plan.

Drawdown Surveys

Archaeological and cultural inventories are planned for the J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate reservoir zones during (1) the course of drawdown activities, and (2) post-drawdown reservoir areas as soon as surface conditions permit. Cost assumptions associated with each are listed below:

- Drawdown Shoreline Survey: To the extent possible, and in consideration of safety factors, periodic pedestrian archaeological inventory will be conducted along the reservoir shorelines as drawdown occurs. The principal goal of this shoreline survey is to identify and reduce looting and disturbances of known and currently unknown cultural resources. Inventory methods for this shoreline survey are still under development, but may include low-elevation aerial surveys (e.g., drones, helicopter) or barge surveys, if feasible, that target areas subject to slumping or those that are not sufficiently dried to allow safe access via foot-traffic and survey vehicles. A team of one archaeologist and one tribal monitor will conduct the shoreline inventory at each reservoir, for three teams (J.C. Boyle, Copco No.1 and 2, and Iron Gate). The estimate allows for weekly reconnaissance for six people for a 2-month period before the post-drawdown pedestrian inventory of the reservoir areas can begin.

- Post-drawdown Reservoir Survey: Archaeological inventory will be conducted of the post-drawdown reservoir areas after water has receded and soils have sufficiently dried to allow for pedestrian survey. Based on current estimates, the former reservoir footprints encompass a total of 2,275 acres. Archaeological pedestrian inventory will focus on reservoir areas covered by 0-4 feet of sediment, where water-induced erosion has the greatest potential to reveal buried archaeological deposits. The 0-4 foot sediment area is estimated as encompassing about 1,500 acres. Selected deep probing may be used in areas of high archaeological sensitivity that exceed sediment depth of 4 feet. Using a standard rate of 25 acres per person per day, 1,500-acre survey will require approximately 60 person/days to complete. Assuming an average of one site per every 50 acres inventoried, 30 archaeological sites would require recordation, which in turn will require an additional 60 person/days of effort.

Construction Surveys

Construction cultural resource monitoring is associated with implementation of the reservoir restoration plan during 2021 and 2022. The restoration plan involves removal of some portion of the remaining reservoir sediments to re-expose some high value pre-inundation river terraces. The Klamath River corridor and its associated terraces are areas of high archaeological and tribal resource sensitivity, and any subsurface disturbances associated with exposing the pre-inundation landscape (within approx. 5 vertical feet) will minimally require cultural resources monitoring.

Two teams comprised of archaeologists and tribal monitors, will participate during the course of any reservoir restoration actions. The estimate allows for monitoring for four people for a period of one year (FY 2021-2022). If cultural resources are inadvertently discovered during the restoration area monitoring activity, their recordation and evaluation will continue under Discovery Contingencies (see below).

Post-Construction Surveys

Post-construction cultural resources management and monitoring reflects compliance with mitigation of tribal cultural impacts, will be developed in the Historic, Cultural and Tribal Resources Management Plan, will require ongoing consultation with affected tribes, including meetings to identify site-specific mitigation as new sites are exposed or discovered; needs for additional survey; development and implementation of a Looting and Vandalism Protection Program (LVPP), including long-term monitoring and site documentation; tribal issue facilitation; and long-term assistance with implementation of the Programmatic Agreement. These requirements are expected to include efforts beyond those covered under more routine agency and tribal consultation.

The LVPP provisions for archaeological and tribal monitoring is estimated to occur for a maximum of 3 years following completion of ground disturbance activities. Monitoring frequency is currently estimated at quarterly. The estimate for LVPP monitoring allows for two, 2-person crews, comprised of one archaeologist and one tribal monitor, for a 2-week period every quarter, for a total of 12 quarters. Additional non-field related costs are included for ongoing agency and tribal consultation and meetings.

Curation Fees

Curation fees have been included in the estimate for artifacts recovered during phase II and phase III fieldwork. As currently estimated, archaeological investigations involve excavation of 120m³ for phase II efforts and 200m3 for phase III efforts, for a total of 320m³. The estimate allows for permanent curation of archaeological materials recovered during the phase II and phase III programs as 1 archive box per 2m³ of excavated sediment, for a 160 archive boxes. An additional 250 boxes may be required for discovery contingencies, for an estimated project total of 410 boxes. At an average of $500/ft³ (2018 price quote from Oregon Museum of Natural and Cultural History), the curation of 410 archive boxes of cultural materials is estimated at $205,000 excluding escalation. Curation support labor for final artifact and paperwork preparation is estimated at an average of 4 hours per archive box.

Inadvertent Discovery Contingencies

Two types of inadvertent discovery contingencies are anticipated during project implementation, including unanticipated exposure of archaeological resources and human remains. For purposes of this cost estimate, it is assumed that up to 160 discoveries (60 archaeological materials and 100 human remains) may occur in both short-term and long-term contexts. Additional information is provided below:

- Archaeological Resources: It is anticipated that up to 30 new archaeological resources may be discovered during inventory of the former reservoir areas. Stabilization and/or recovery work (excavation) may be required at the anticipated sites to reduce project-related effects, particularly those related to erosion. In addition, ground disturbances associated with the reservoir restoration actions may expose archaeological components when reservoir sediments are removed and the pre-inundation landscape is exposed. The estimate allows for discovery, stabilization, and/or recovery work of up to an additional 30 new archaeological resources associated with restoration actions. The estimate allows a per unit rate of $30,000 per resource for stabilization and/or recovery work for each of the 60 newly identified archaeological resources, to include recordation, archaeological excavation, analysis, and reporting.
- Human Remains: Drawdown, dam removal, and post-dam removal activities have the potential to expose human burials within the former reservoir areas, as well as in downriver contexts where elevated water levels and subsequent bank erosion may occur. The estimate allows a per resource rate of $15,000 for recovery of 100 human remain locations. Discovery, removal, and/or relocation of human remains will require investigation and recovery by a 4-person team, comprised of one field supervisor (archaeologist or physical anthropologist), two archaeological technicians, and one tribal monitor for a period of two days in the field. Archaeological materials recovered from discovery situations will require reporting, analysis and curation.

TCP Reserve Fund

Current agency and tribal consultation efforts have not yet addressed issues related to mitigation of impacts to TCPs. Therefore, a conservative reserve fund of $1,000,000 has been estimated for this possibility.

3.7 Monitoring & Reporting

3.7.1 Aquatic Resource Measures

Measures to benefit aquatic resources (AR) have been developed through coordination with state and federal regulatory agencies, and have been incorporated into the Project. Aquatic resource activities will take place prior to, during, and after dam removal and are based on Appendix I of the Definite Plan. The following provides a summary of cost assumptions associated with AR measures:

- Monitoring of tributary confluence areas for connectivity will occur for 2 years post-dam removal and will include 9 key tributaries within the reservoir and downstream depositional reach (Iron Gate Dam to Cottonwood Creek).
- Tributary confluence connectivity maintenance will occur for 2 years and will require hand crews for 3 weeks per year for downstream tributaries, and 4 weeks of equipment removal per year for reservoir reach tributaries.
- Water quality monitoring and fish rescue/relocation will occur at 13 key tributaries and only during the year of drawdown.
- Juvenile fish rescue and relocation efforts will only take place if temperature and sediment thresholds are exceeded and will take no more than 3 weeks to complete during year of drawdown.
- Cost includes approximately $4 million in gravel augmentation for full mitigation of spawning habitat. The actual amount necessary is likely less and will be based on surveys completed after drawdown.
- Sucker rescue and relocation effort will occur on all three reservoirs and take no more than 2 weeks to complete.
- Freshwater mussels will be relocated to the hydroelectric reach between Keno Dam and the head of J.C. Boyle Reservoir. The relocation effort will take no more than 2 weeks.

3.7.2 Terrestrial Resource Measures

Measures to benefit terrestrial resources (TER) have been developed through coordination with state and federal regulatory agencies, and have been incorporated into the Project. Terrestrial resource activities will take place prior to, during, and after dam removal and are based on Appendix J of the Definite Plan. The following provides a summary of cost assumptions associated with TER measures:

- Habitat Restoration: Includes monitoring and reporting for 3 years following vegetation installation.
- Nesting Bird Surveys: Includes osprey and cliff swallow nest exclusion; monitoring; reporting; pre-clearing nest surveys; work zone monitoring and rescue. Likelihood of northern spotted owl nesting during construction period is low and is excluded from the estimate.

- Bald and Golden Eagles: Likelihood of existence and discovery of nesting bald or golden eagles during construction period is low and is excluded from the estimate.
- Special Status Plants: Likelihood of existence and discovery of special status plants during the construction period is low and is excluded from the estimate.
- Permanent Loss of Wetlands: Includes monitoring and reporting for 5 years, post-construction.
- Roosts for Special Status Bats: Estimate includes a combination of retained/modified structures and new artificial roost structures.

3.7.3 Water Quality Monitoring

Water quality monitoring was estimated to include monitoring at up to ten main stem stations along the Klamath River. Eight of these are existing USGS stations, while two will be new stations. Existing stations will be upgraded with equipment to meet the project objectives.

All sites will be equipped with a multi-parameter sonde to measure temperature, pH, dissolved oxygen, specific conductance and turbidity. In addition, all sites except Keno will be equipped with a high-range turbidity sensor and side-looking acoustic profiler (for acoustic attenuation and backscatter measurements). A TSS and NTU laboratory relationship study will be conducted using sediment samples collected from the reservoirs.

Analysis and reporting of data will be according to United States Geological Survey (USGS) guidelines. The primary final products of the monitoring network will be 15-minute time series of stage, discharge, temperature, pH, dissolved oxygen, specific conductance, turbidity, acoustic attenuation, acoustic backscatter, and suspended-sediment concentration (SSC, potentially discriminating between silt/clay and sand), and suspended-sediment flux.

Rates and prices are based on a USGS proposal submitted in March 2018, and account for monitoring for 3 years following dam removal.

Additional sediment, reservoir and estuary monitoring were assumed during the 5 year period after removal of the dams. The estimate assumes the following:

- High definition aerial photos and LiDAR will be flown together in a single aircraft mobilization each year in the spring of years 2-5. Year 1 includes only high definition aerial photos.
- Volitional fish passage monitoring includes 2 weeks of fieldwork to monitor fish passage through hydroelectric reach, and additional amounts for reporting.
- Monitoring work for all three reservoir areas will be performed at the same time.
- Corrective actions are not included in costs, if they are needed based on monitoring results.
- Estuary and river sampling for toxins before and after dam removal using four separate sampling events.

4. RESULTS

The following sections provide a summary of the results of the cost analyses described above. Detailed construction cost breakdowns for both Full Removal and Partial Removal alternatives are provided in Attachment A. Pay item cost detail worksheets, describing the calculation of individual cost estimate line items rates and prices are provided in Attachment B.

In addition to the estimated project cost results, a full range of results from the Monte Carlo analysis are provided in Section 4.2, and a comparison to the USBR 2012 estimate is provided in Section 4.3.

4.1 Total Cost Summary

Tables 4-1 and 4-2 provide a summary of the estimate of project costs for Full and Partial Removal alternatives, respectively. As described in Section 2.6, a combined design and construction contingency (30% of construction cost) has been included in the estimates. As the detailed design advances toward final construction drawings and specifications, the design contingency will decrease to near zero. While the construction contingency may decrease as more field data and information becomes available, some level of construction contingency will persist throughout the construction phase.

In addition to the estimate of project costs, the summary tables show probabilistic MPL and MPH costs based on the results of Monte Carlo simulations. The right-hand column indicates the estimated project costs, whereas the forecast range from MPL to MPH indicate the range of probabilistic outcomes.

As discussed in more detail in Section 2.7, while it is typical for large water infrastructure projects to select P80 to represent the upper range of project planning contingency (MPH), due to the unique nature of this Project and the KRRC, a more conservative P90 was selected to represent the MPH for the Project. The P90 estimate will cover the most likely final project cost in 90% of all risk scenarios. A P10 was selected to represent the MPL.

Table 4-1 Results Summary - Full Removal

Line Item/Cost Category		Forecast Range		Estimated Project Cost
		MPL (P10)	MPH (P90)	
Project Oversight		$29,466,000	$29,778,000	$29,581,000

4.2 Monte Carlo Results

The probabilistic range of costs for each estimate line item was determined with the use of '@Risk' Monte Carlo analysis software. The Monte Carlo analysis involves determining the impact and likelihood of occurrence of identified and quantified uncertainties and risks by running simulations to identify the range of possible outcomes for a number of scenarios - 10,000 scenarios in the case of this Project. A random sampling is performed in the simulation by using uncertain risk variable inputs to generate the range of outcomes with a confidence measure for each outcome. For each uncertain variable in a simulation, the possible values are defined using probability distributions. The type of distribution selected depends on the factors surrounding the variable. Selected distributions are included in Attachment C.

Tables 4-3 and 4-4 summarize the results of the Monte Carlo analysis for the Full Removal and Partial Removal alternatives, respectively. Levels of probability are described from P1 to P100, where the number following the 'P' represents the percentage of most probable outcomes. For example, the P1 estimate amount will only cover the lowest 1% of the possible cost outcomes, whereas P100 will cover the maximum estimate amount determined from running the 10,000 scenarios.

4.3 Comparison with Previous Estimates

A previous estimate was developed by the USBR in 2012 and is documented in the Detailed Plan for Dam Removal – Klamath River Dams (USBR 2012). Table 4-5 below compares the new estimate of project cost for Full Removal to the 2012 estimate amounts. It is important to note that previous USBR estimate were organized using different cost categories, in addition to separating escalation out as a stand-alone line item. For comparison purposes, the 2012 estimate has been reorganized into the new cost categories, and escalation has been incorporated into applicable line items.

Based on the analyses summarized herein, the projected project cost estimate for Full Removal increased from approximately $292M to $398K. The MPH estimate for Full Removal increased from $493M to $507M. The MPL estimate for Full Removal increased from $238M to $347M.

Based on the analyses summarized herein, the projected project cost estimate for Partial Removal increased from approximately $235M to $352K. The MPH estimate for Partial Removal increased from $404M to $468M. The MPL estimate for Full Removal increased from $185M to $314M.

There are several categories where the new estimate shows notable increases from the previous USBR estimate. A brief discussion of these increases is provided below:

- Escalation: The current project construction schedule includes construction beginning in 2020, which is one year later than what was assumed in the 2012 USBR estimate. This results in an increase in project funds that are reserved to account for escalation.
- Project Oversight: The previous USBR estimate did not account for costs attributable to KRRC project oversight and associated costs currently required for KRRC management, accounting, controls, etc. Accounting for these project oversight costs increases the overall project cost by approximately $30M.
- Transportation Costs: As new field data and associated engineering assessments have been completed, the costs associated with anticipated improvements and maintenance activities to accommodate construction access and traffic have increased significantly. It is anticipated that these costs may decrease through value engineering and future PDB input.
- Restoration Costs: Through close coordination with resource agency representatives and other stakeholders, the approach to reservoir restoration has evolved from the approach and assumptions that were utilized by USBR in 2012. The revised approach is detailed in Appendix H of the Definite Plan and represents both current resource agency expectations, as well as the latest science on restoration techniques to increase the probability of successful plant and habitat establishment. The revised approach includes accommodation of some level of floodplain earthwork, as well as more proactive revegetation efforts within the riparian zone, both of which have increased cost.

Table 4-5 Comparison to Previous Estimate

PAY ITEM INFORMATION

PAY ITEM NUMBER :	1.001	Project :	JC Boyle			
Description :	Removal of Diversion Conduit Bulkheads					
Quantity :	14.00 CY					
Daily Production :	7.00 CY per 8 hour shift	Project # :	1			
Work Days :	2.0 Days	Estimator :	Eric Jones	CY per	Total Cost	Unit Price Per CY
Unit Price :	$1,323.00 per CY	Probable Low Cost Parameter		7.35	$17,596	$1,256.85
Total Cost :	$18,522	Probable High Cost Parameter		6.65	$19,448	$1,389.15

					TOTAL COST for pay item	**$693,263**

Additional Pay Item Notes :

The work is done by two 6-men crew (foreman, 4 laborers, and 1 equipment operator). Concrete hauling to scour hole is also included - based on the current production rate, only 5 trips a day would be necessary. Demolition is done using hydraulic chipping hammers and excavator mounted claw. Allowance for saw cutting sub is included at one mobilization a week. Blasting method is not found to be feasible for this work. A check using RS Means was used: reference 03055110 ($224/CY, excludes hauling, sawing, and dumping) - Selective concrete demolition, reinforcing more than 2% cross-sectional area.

Additional Pay Item Notes :

Used RS Means : Assumed " Pipe, metal pipe, to 1-1/2" diam., selective demolition", 2390 LF of 1 1/2" oil pipes at 2.72 Lbs/LF. Used 1 Forman, 1 Steelworkers to cut the pipes and 1 Laborers to load the pipes in the truck. The cooling and lubrication systems for the Hydroelectric Barge turbine, speed increaser and generator will be a combination of water and oil. These systems will be isolated from the water passages so that no contamination of passing water will occur. The following is a list of hazardous materials, substances, chemicals, and wastes normally found at a hydropower facility that may require disposal actions if not recycled or reused for their intended purpose:

1. Polychlorinated Biphenyls (PCBs)
2. Asbestos
3. Paint/abrasive blast grit (red lead paint)
4. **Oil**
5. Mercury
6. Antifreeze
7. Halogenated and non-halogenated solvents
8. Greases
9. Pesticides (includes herbicides, insecticides, and wood preservatives)
10. Petroleum contaminated
11. Chlorinated fluorocarbons (CFCs) Freon/Halon
12. Gasoline/diesel (includes product and sludge in tanks)
13. Batteries (includes acid)
14. Water treatment sludge (septic tanks/wastewater treatment). Assumed hazardous waste 100% of the total lbs

Additional Pay Item Notes :

Working with a crew formed of 1 El. Foreman 2 Electrician starting to disconnect power and take care of the temporary electrical power they need at the site. The crew of 10 Ironworker / Millwright. open the engine side panels, and remove the nacelle access panels. Disconnect the engine thermocouple leads at the terminal board. Before disconnecting any lines all fuel, oil, and hydraulic fluid valves are closed. Plug all lines as they are disconnected to prevent entrance of foreign material. Remove the clamps securing the bleed-air ducts at the firewall. Then, disconnect the electrical connector plugs, engine breather and vent lines, and fuel, oil, and hydraulic lines. Disconnect the engine power lever and propeller control rods or cables. Remove the covers from the lift points, attach the sling, and remove slack from the cables using a suitable hoist. The sling must be adjusted to position. Remove the engine mount bolts. The engine ready to be removed. Move the engine forward, out of the nacelle structure, until it clears the aircraft. Lower the into position on the stand, and secure it prior to removing the engine sling. The crew of 4 Welder are going to cut in pieces the big parts of the turbine to be able to load them in the truck using a loader and dispose.

Additional Pay Item Notes :

Used RS Means : Pipe, metal pipe, to 1-1/2" diam., selective demolition, 2390 LF of 1 1/2" fire protection pipes at 2.72 Lbs. Used 1 Forman, 2 Steelworkers to cut the pipes and 3 Laborers to load the pipes in the truck. Calculated 58.6 miles from JC Boyle to Yreka Transfer Recycling. Each hydropower facility has at least 150,000 gallons to 250,000 gallon of oil currently in use. This oil would have to be properly disposed of in the event of decommissioning. Oil removed from the turbines and other equipment, including transformer oil, would be either a waste oil or used oil, depending on prior use and contaminants found in the oil. Containerized oil containing contaminants such as solvents are commonly encountered at hydropower facilities. Oil sludge are common in tanks. Oil disposal would likely be costly due to the large volumes found at hydropower facilities and the ease of contamination with other regulated hazardous wastes.

Additional Pay Item Notes :

Used 3 Crews (2 sections each) formed of 1 Forman, 3 Electrician, 2 laborer to haul with the crane in the truck. Assumed containing hazardous waste that will be disposed at 85.6 miles away from the construction site. In normal circumstances, decontaminated residual components could be accepted at landfill sites but Polychlorinated biphenyl, otherwise known as PCB, is a synthetic chemical that is widely used for industrial and commercial use as dielectric fluid in transformers and capacitors because of its high resistance to decomposition, low electrical conductivity, low flammability and high heat capacity. Transformer repair, reconditioning and retro-filling facilities are the major industry sectors that contributes to the spread of PCB contamination. Types of PCB Wastes:
PCB wastes are discarded materials that contain PCB or have been contaminated with PCBs and that are without any commercial, industrial, or economic use. For the purpose of this Code of Practice, PCBs wastes are classified as follows: Liquid PCB wastes
o PCB-based dielectric fluids removed from transformers and other equipment
o PCB-based heat transfer and hydraulic fluids Metallic solid wastes
o PCB equipment such as capacitors, transformers, switchgears, circuit breakers, heat transfer systems, etc.
o Contaminated components removed from electrical equipment such as windings; PCB-contaminated containers and equipment such as metal drums, tanks, pumps, metal filters, etc. Calculated 85.6 miles fromJC Boyle to Yreka Transfer Recycling

Additional Pay Item Notes :

When a transmission line is decommissioned and is not converted to another use, the decommissioning typically includes the removal of all infrastructure if it is no longer required, or has reached end-of-life conditions. Removed parts will be re-used, recycled or disposed. Production is based off of RSMs using Crew B-1C and B-3 (1 Forman, 2 laborer, 1 Excavator & 1 crane for lift, position and load in the truck, 1 Hydraulic rock-splitting/rock-drilling equipment to break equipment foundations and concrete for demo :2 Electrician,, 1 utility truck to access poles, string conductor, modify structure arms, provide guard structures, etc. Crews may be working simultaneously along the project alignment and substations, hydro plant and switchyard. Transmission line poles or structures are commonly between 60 and 140 feet tall. There are several different kinds of transmission structures. Transmission structures can be constructed of metal or wood. They can be single-poled or multi-poled. They can be single-circuited, carrying one set of transmission lines or double-circuited with two sets of lines. Assumed based on RSMs we have "Communications transmission tower, radio towers self-supporting, wind load 70 mph basic wind speed, 120' high" (33811310). Pole height and load capacity limitations determine the distance between poles (span length) either on the basis of ground clearance or ability to support heavy wind and ice loads. Assumed average span between structures to be 275 feet so for 1.66 miles of overhead transmission we will have approximately 31 structures. In areas where single-pole structures are preferred, weak or wet soils may require concrete foundations for support. Where a transmission line must cross a street or slightly change direction, larger angle structures or guy wires may be required. Poles with guy wires impact a much larger area. Angle structures are usually more than double the diameter of other steel poles. They are made of steel, usually five to six feet in diameter, and have a large concrete base. The base may be buried ten or more feet below the ground surface. The diameter of the pole and the depth the base is buried depends on the condition of the soils and the voltage of the line. Assumed the structures are disposed to Yreka recycling, 85.6 miles away. This estimate is made as the best AECOM assumption, as actual pricing would occur during the detailed engineering and construction bid process.

					TOTAL COST for pay item	**$471,675**

Additional Pay Item Notes :

The work is done by one 6-men crew (foreman, 4 laborers, and 2 equipment operators). Concrete hauling to scour hole is also included - based on the current production rate only 3 trips a day would be necessary. Demolition is done using hydraulic chipping hammers and excavator mounted claw. This productivity is considerably slower than flume demolition due to access. Allowance for saw cutting sub is included at one mobilization a week. Blasting method is not found to be feasible for this work. A check using RS Means was used: reference 03055110 ($224/CY, excludes hauling, sawing, and dumping) - Selective concrete demolition, reinforcing more than 2% cross-sectional area.

Additional Pay Item Notes :

Duration accounts for mobilization and demobilization, crane is to be used for flying material out of the demolition area as the excavator tears building down building, some of the building will need to be taken down by hand with crane support due to excavator not be able to reach certain sections. 1 excavator will be used to load trucks, 1 FE loader will be used half of the time to maintain hauling area. due to the building being near water limiting access the production has been reduced when compared to other buildings being demolished.

					TOTAL COST for pay item	**$316,752**

Additional Pay Item Notes :

The work is done by FOUR 7-men crew (foreman, 4 laborers, and 2 equipment operators). Concrete hauling to scour hole is also included - based on the current production rate only 3 trips a day would be necessary. Demolition is done using hydraulic chipping hammers and excavator mounted claw. This productivity is considerably slower than flume demolition due to access. Allowance for saw cutting sub is included at one mobilization a week. Blasting method is not found to be feasible for this work. A check using RS Means was used: reference 03055110 ($224/CY, excludes hauling, sawing, and dumping) - Selective concrete demolition, reinforcing more than 2% cross-sectional area.

Contingency @	0.0%			on	$746,951.16	$0
					TOTAL COST for pay item	**$746,951**

Additional Pay Item Notes :

The work is done by FOUR 7-men crew (foreman, 4 laborers, and 2 equipment operators). Concrete hauling to scour hole is also included - based on the current production rate only 3 trips a day would be necessary. Demolition is done using hydraulic chipping hammers and excavator mounted claw. This productivity is considerably slower than flume demolition due to access. Allowance for saw cutting sub is included at one mobilization a week. Blasting method is not found to be feasible for this work. A check using RS Means was used: reference 03055110 ($224/CY, excludes hauling, sawing, and dumping) - Selective concrete demolition, reinforcing more than 2% cross-sectional area.

Additional Pay Item Notes :

The process of removing stop logs is not manual, but done with hydraulic stop log lifters and hoists done by one 12-men crew (5 steelworkers, 1 laborer, 1 electrician, 1 welder and 4 equipment operators). Based on the current production rate and 1 truck per day. The gate side guides and invert assumed having a minimum weight of 4 lbs./ft. for wall mounted and 3 lbs./ft. for embedded in concrete. The gate invert should contain a removable neoprene seal. Including stop log grooves, lifter, guide - weight around 136,000 lbs.

Additional Pay Item Notes :

Assumed the process of removing 108" butterfly valves is done in around 6 days by 2 crew formed of 1 foreman, 2 journeymen, 2 steelworkers ;We dispose cradles with 1 trucks per day for each crew. Assumed contains paint with heavy metals 50% of the total lbs, 85.6 miles from Copco lake to Yreka transfer recycling. Based on the current production rate, only 1 trips a day would be necessary. Demolition is done using one crawler crane, excavator and welding machine.

Additional Pay Item Notes :

Petroleum-based products, ranging from fuel oil and hydraulic fluid to lubricating greases and oils, are found throughout every type of power generating plant or system. Lubrication supports bearings and moving parts in all sorts of equipment: pumps, conveyors, feeders, scrubbers, cranes, turbines, and more. A good oil/water separation system will result in a flow of concentrated waste oil to a collection area and a flow of oil-free water ready for secondary processing or discharge. Once an oil layer has been separated from free water, it must be removed for recycling or disposal. Many plants use one or more of these oil removal methods, but each has costly limitations:

1. Absorbent materials. Absorbent mats or materials are frequently used to dam up and absorb excess oils and greases resulting from accidents or the routine operation of machinery. These materials are very effective for preventing the spread of a source leak and very efficient in terms of oil pickup. Yet, their use on large volumes of waste oil results in multiple, recurring costs that can make them impractical as an everyday solution:

- the costs of the materials themselves
- the labor costs for ordering, stocking, application, and removal
- the costs of used-media collection, disposal, or re-processing/recycling.

2. Manually operated "slotted pipes." Many separators feature a "slotted pipe," a pipe located near the top of the vessel that has a horizontal opening. Oil is removed by turning the horizontal opening downward until it meets the floating oil layer, which drains through the pipe to a collection receptacle. These pipes work well on thick layers of oil, but cannot drain off a sheen of oil without draining off a large amount of water as well.

AECOM assumed the best is Vacuum truck removal method .Used a crew formed of 1 Forman, 5 Laborers to takeout the petroleum waste, 1 Electrician to unplug the power and to assure the temporary power at the construction site. Vacuum-equipped tank trucks are used to remove waste oil from collection points at plants so that it can be transported to recycling or disposal locations. If the waste oil has been thoroughly separated, highly concentrated, and stored in an appropriate receptacle, this service can be used very efficiently. However, vacuum disposal units are often used to pump oil layers directly off of water. This results in the intake of a significant amount free water along with the waste oil – and a significantly higher cost.

					TOTAL COST for pay item	**$63,762**

Additional Pay Item Notes :

Production is based off of a total of 2150 total tons of material, each truck can haul 18 tons per load. Roughly 119 loads of stone hauled with 4 trucks would be 30 loads per truck. Operation lasting 5 days would mean each of the 4 trucks would have to deliver 6 loads a day or 430 tons. 1 dozer will be used to place the initial material as it is dumped from the truck, 1 dozer will be used to fine grade in sequence with the compaction roller that is stabilizing the surface coarse. Loader will be assisting operation by scooping up loose material as needed and placing it back in to the surface foot print.

					TOTAL COST for pay item	**$4,313,417**

Additional Pay Item Notes :

Each dump truck will be able to haul 10 CY per load which will be 5590 loads of material. 8 trucks will be hauling 5 loads a day or 500 CY per day. Production is lower than usual due to placing material in a critical area that will need extra safety observation. A crane will need to be mobilized to fly excavators to bottom of scour hole and to fly them out once filled. 1 excavators and 1 dozer will be placed up top to manage the delivery of the material and 2 excavators will be placed at the bottom managing material placement. Laborers will directing truck traffic and spotting in critical areas at the top and the bottom.

					TOTAL COST for pay item	$1,201,333

Additional Pay Item Notes :

Above production is based on having two crews working simultaneously. 1 excavator will be loading material in to dump trucks, two excavators with breakers/ shears will be demolishing concrete, Laborers and Carpenters will support truck and equipment operations, 2 foremans with trucks will oversee operation. Crane will be used half of the time to support demolition as needed, Figuring the use of 2 dump trucks due to the access restrictions from the haul road size, This would mean that each dump truck will have to get 3 loads a day and with the dump site being a short distance this should be achieveable.

Additional Pay Item Notes :

The process of removing toplogs is not manual, but done with hydraulic stop log lifters and hoists and is done by one 11-men crew (6 steelworkers, 4 journeymen and 4 equipment operators). Based on the current production rate and the fact that we dispose big pieces of material we use 2 trucks per day. The gate side guides and invert shall have a minimum weight of 4 lbs./ft. for wall mounted and 3 lbs./ft. for embedded in concrete that we assume we have The gate invert should contain a removable neoprene seal. Including stop log grooves, lifter, 13 set of guides - weight around 18000 lbs.

Additional Pay Item Notes :

Used RS Means : Pipe, metal pipe, to 1-1/2" diam., selective demolition, 4040 LF of 1 1/2" oil pipes at 2.72 Lbs. Used 1 Forman, 2 Steelworkers to cut the pipes and 3 Laborers to load the pipes in the truck.The cooling and lubrication systems for the Hydroelectric Barge turbine, speed increaser and generator will be a combination of water and oil. These systems will be isolated from the water passages so that no contamination of passing water will occur.The following is a list of hazardous materials, substances, chemicals, and wastes normally found at a hydropower facility that may require disposal actions if not recycled or reused for their intended purpose:

1. Polychlorinated Biphenyls (PCBs)
2. Asbestos
3. Paint/abrasive blast grit (red lead paint)
4. Oil
5. Mercury
6. Antifreeze
7. Halogenated and non-halogenated solvents
8. Greases
9. Pesticides (includes herbicides, insecticides, and wood preservatives)
10. Petroleum contaminated
11. Chlorinated fluorocarbons (CFCs) Freon/Halon
12. Gasoline/diesel (includes product and sludge in tanks)
13. Batteries (includes acid)
14. Water treatment sludge (septic tanks/wastewater treatment) Based on the hazardous materials above assumed hazardous waste 100% of the total lbs

Additional Pay Item Notes :

Working with a crew formed of 1 El.Forman 2 Electrician starting to disconnect power and take care of the temporay electrical power they need at the site. The crew of 5 Ironworker and 5 Millwright open the engine side panels, and remove the nacelle access panels. Disconnect the engine thermocouple leads at the terminal board. Before disconnecting any lines all fuel, oil, and hydraulic fluid valves are closed. Plug all lines as they are disconnected to prevent entrance of foreign material.Remove the clamps securing the bleed-air ducts at the firewall. Then, disconnect the electrical connector plugs, engine breather and vent lines, and fuel, oil, and hydraulic lines.Disconnect the engine power lever and propeller control rods or cables. Remove the covers from the lift points, attach the sling, and remove slack from the cables using a suitable hoist. The sling must be adjusted to position. Remove the engine mount bolts. The engine ready to be removed. Move the engine forward, out of the nacelle structure, until it clears the aircraft. Lower the into position on the stand, and secure it prior to removing the engine sling. The crew of 4 Welder are going to cut in pieces the big parts of the turbine to be able to load them in the truck using a loader and dispose.

Additional Pay Item Notes :

Based on RS Means : Pipe, metal pipe, to 1-1/2" diam., selective demolition. 1985 LF of 1 1/2" fire protection pipes at 2.72 Lbs. Used 1 Forman and 1 Laborers to load in drums and put them in the truck.Calculated 34 miles from Copco 1 to Yreka Transfer Recycling. Each hydropower facility has at least 150,000 gallons to 250,000 gallon of oil currently in use. This oil would have to be properly disposed of in the event of decommissioning. Oil removed from the turbines and other equipment, including transformer oil, would be either a waste oil or used oil, depending on prior use and contaminants found in the oil. Containerized oil containing contaminants such as solvents are commonly encountered at hydropower facilities. Oil sludges are common in tanks. Oil disposal would likely be costly due to the large volumes found at hydropower facilities and the ease of contamination with other regulated hazardous wastes.

Additional Pay Item Notes :

Petroleum-based products, ranging from fuel oil and hydraulic fluid to lubricating greases and oils, are found throughout every type of power generating plant or system. Lubrication supports bearings and moving parts in all sorts of equipment: pumps, conveyors, feeders, scrubbers, cranes, turbines, and more A good oil/water separation system will result in a flow of concentrated waste oil to a collection area and a flow of oil free water ready for secondary processing or discharge. Once an oil layer has been separated from free water, it must be removed for recycling or disposal. Many plants use one or more of these oil removal methods, but each has costly limitations:

1. Absorbent materials. Absorbent mats or materials are frequently used to dam up and absorb excess oils and greases resulting from accidents or the routine operation of machinery. These materials are very effective for preventing the spread of a source leak and very efficient in terms of oil pickup. Yet, their use on large volumes of waste oil results in multiple, recurring costs that can make them impractical as an everyday solution:

- the costs of the materials themselves
- the labor costs for ordering, stocking, application, and removal
- the costs of used-media collection, disposal, or re-processing/recycling

2. Manually operated "slotted pipes." Many separators feature a "slotted pipe," a pipe located near the top of the vessel that has a horizontal opening. Oil is removed by turning the horizontal opening downward until it meets the floating oil layer, which drains through the pipe to a collection receptacle. These pipes work well on thick layers of oil, but cannot drain off a sheen of oil without draining off a large amount of water as well.

AECOM assumed the best is Vacuum truck removal method to remove petroleum fromturbines, generator, oil sumps, tanks, etc. Used a crew formed of 1 Forman, 2 Laborers and 2 journemen to takeout the petroleum waste, Vacuum-equipped tank trucks are used to remove waste oil from collection points (assumed existing drums or tanks) so that it can be transported to recycling or disposal locations. If the waste oil has been thoroughly separated, highly concentrated, and stored in an appropriate receptacle, this service can be used very efficiently. However, vacuum disposal units are often used to pump oil layers directly off of water. This results in the intake of a significant amount free water along with the waste oil – and a significantly higher cost.

Additional Pay Item Notes :

Used 3 Crews (2 sections each weight around 800 LBS per crew) formed of 1 Forman, 3 Electrician, 2 laborer to haul with the crane in the truck. Assumed containing hazardous waste that will be disposed at 34 miles away from the construction site to Yreka Transfer Recycling . In normal circumstances, decontaminated residual components could be accepted at landfill sites but Polychlorinated biphenyl, otherwise known as PCB, is a synthetic chemical that is widely used for industrial and commercial use as dielectric fluid in transformers and capacitors because of its high resistance to decomposition, low electrical conductivity, low flammability and high heat capacity.Transformer repair, reconditioning and retro-filling facilities are the major industry sectors that contributes to the spread of PCB contamination.Types of PCB Wastes:
PCB wastes are discarded materials that contain PCB or have been contaminated with PCBs and that are without any commercial, industrial, or economic use. For the purpose of this Code of Practice, PCBs wastes are classified as follows:Liquid PCB wastes
o PCB-based dielectric fluids removed from transformers and other equipment
o PCB-based heat transfer and hydraulic fluidsMetallic solid wastes
o PCB equipment such as capacitors, transformers, **switchgears**, circuit breakers, heat transfer systems, etc.
o Contaminated components removed from electrical equipment such as windings; o PCB contaminated containers and equipment such as metal drums, tanks, pumps, metal filters, etc.

Additional Pay Item Notes :

Weight and dimensions of the transformers have particular importance so transport vehicles must be adequate. A considerable proportion of the weight is due to the oil, so the direct consequence is that the big transformers have to be transported empty. During transport the transformers are filled either by dry air or nitrogen. Because of transportation, the auxiliaries have to be removed . For this reason the collaboration with all the people involved in the project is essential. AECOM best assumption for a 5000 kVA, 2300/72000 volt transformer removal- - 3 crew R3 formed of 1 Formen, 1 Electricians, 1 Utility man-backet truck, 1 crane for disposal of each transformer in the truck and 2 laboreres to remove the auxiliaries and the pad (1 excavator).

Additional Pay Item Notes :

Weight and dimensions of the transformers have particular importance so transport vehicles must be adequate. A considerable proportion of the weight is due to the oil, so the direct consequence is that the big transformers have to be transported empty. During transport the transformers are filled either by dry air or nitrogen. Because of transportation, the auxiliaries have to be removed . For this reason the collaboration with all the people involved in the project is essential. AECOM best assumption for a 4165 kVA, 2300/72000 volt transformer removal- 3 crew R3 formed of 1 Formen, 1 Electricians, 1 Utility man-backet truck, 1 crane for disposal of each transformer in the truck and 2 laboreres to remove the auxiliaries and the pad (1 excavator).

Additional Pay Item Notes :

Petroleum-based products, ranging from fuel oil and hydraulic fluid to lubricating greases and oils, are found throughout every type of power generating plant or system. Lubrication supports bearings and moving parts in all sorts of equipment: pumps, conveyors, feeders, scrubbers, cranes, turbines, and more.A good oil/water separation system will result in a flow of concentrated waste oil to a collection area and a flow of oil-free water ready for secondary processing or discharge. Once an oil layer has been separated from free water, it must be removed for recycling or disposal. Many plants use one or more of these oil removal methods, but each has costly limitations:

1. Absorbent materials. Absorbent mats or materials are frequently used to dam up and absorb excess oils and greases resulting from accidents or the routine operation of machinery. These materials are very effective for preventing the spread of a source leak and very efficient in terms of oil pickup. Yet, their use on large volumes of waste oil results in multiple, recurring costs that can make them impractical as an everyday solution:
- the costs of the materials themselves
- the labor costs for ordering, stocking, application, and removal
- the costs of used-media collection, disposal, or re-processing/recycling.

2. Manually operated "slotted pipes." Many separators feature a "slotted pipe," a pipe located near the top of the vessel that has a horizontal opening. Oil is removed by turning the horizontal opening downward until it meets the floating oil layer, which drains through the pipe to a collection receptacle. These pipes work well on thick layers of oil, but cannot drain off a sheen of oil without draining off a large amount of water as well.

AECOM assumed the best is Vacuum truck removal method .Used a crew formed of 1 Forman, 5 Laborers to takeout the petroleum waste, 1 Electrician to unplug the power and to assure the temporaty power at the contruction site. Vacuum-equipped tank trucks are used to remove waste oil from collection points at plants so that it can be transported to recycling or disposal locations. If the waste oil has been thoroughly separated, highly concentrated, and stored in an appropriate receptacle, this service can be used very efficiently. However, vacuum disposal units are often used to pump oil layers directly off of water. This results in the intake of a significant amount free water along with the waste oil – and a significantly higher cost.

Additional Pay Item Notes :

When a transmission line is decommissioned and is not converted to another use, the decommissioning typically includes the removal of all infrastructure if it is no longer required, or has reached end-of-life conditions. Removed parts will be re-used, recycled or disposed. Production is based off of RSMs using Crew B-1C and B-3 (1 Forman, 2 laborer, 1 Excavator & 1 crane for lift, position and load in the truck, 1 Hydraulic rock-splitting/rock-drilling equipment to break equipment foundations and concrete for demo :2 Electrician,, 1 utility truck to access poles, string conductor, modify structure arms, provide guard structures, etc. Crews may be working simultaneously along the project alignment and substations, hydro plant and switchyard. Transmission line poles or structures are 60 feet tall. There are several different kinds of transmission structures. Transmission structures are constructed of wood. They can be single-poled or multi-poled. They can be single-circuited, carrying one set of transmission lines or double-circuited with two sets of lines. Pole height and load capacity limitations determine the distance between poles (span length) either on the basis of ground clearance or ability to support heavy wind and ice loads. Assumed average span between structures to be 275 feet so for 1.66 miles of overhead transmission we will have aproximately 31 structures. In areas where single-pole structures are preferred, weak or wet soils may require concrete foundations for support. Where a transmission line must cross a street or slightly change direction, larger angle structures or guy wires may be required. Poles with guy wires impact a much larger area. Angle structures are usually more than double the diameter of other steel poles. They are made of steel, usually five to six feet in diameter, and have a large concrete base. The base may be buried ten or more feet below the ground surface. The diameter of the pole and the depth the base is buried depends on the condition of the soils and the voltage of the line. Assumed the structures are disposed to Yreka recycling, 36 miles away.This estimate is made as the best AECOM assumption, as actual pricing would occur during the detailed engineering and construction bid process.

					TOTAL COST for pay item	**$315,398**

Additional Pay Item Notes :

The work is done by two 6-men crew (foreman, 4 laborers, and 1 equipment operator). Concrete hauling to disposable site - based on the current production rate, only 5 trips a day would be necessary. Demolition is done using hydraulic chipping hammers and excavator mounted claw. Allowance for saw cutting sub is included at one mobilization a week. Blasting method is not found to be feasible for this work. A check using RS Means was used: reference 03055110 ($224/CY, excludes hauling, sawing, and dumping) - Selective concrete demolition, reinforcing more than 2% cross-sectional area.

Additional Pay Item Notes :

The work is done by one 6-men crew (foreman, 4 laborers, and 2 equipment operators). Concrete hauling to disposal site is also included - based on the current production rate only 3 trips a day would be necessary. Demolition is done using hydraulic chipping hammers and excavator mounted claw. Allowance for saw cutting sub is included at one mobilization a week. Blasting method is not found to be feasible for this work. A check using RS Means was used: reference 03055110 ($224/CY, excludes hauling, sawing, and dumping) - Selective concrete demolition, reinforcing more than 2% cross-sectional area.

PAY ITEM INFORMATION

PAY ITEM NUMBER	:	3.015	Project	: Copco 2			
Description	:	Remove concrete equipment slab from top of embankment wing dam on right abutment					
Quantity	:	5.00 CY					
Daily Production	:	15.00 CY per 8 hour shift	Project #	: 3			
Work Days	:	0.3 Days	Estimator	: Eric Jones	CY per	Total Cost	Unit Price Per CY
Unit Price	:	$353.89 per CY	Probable Low Cost Parameter		16.5	$1,593	$318.50
Total Cost	:	$1,769	Probable High Cost Parameter		13.5	$1,946	$389.28

					TOTAL COST for pay item	$570,702

Additional Pay Item Notes :

There will be 2 excavators managing material and loading trucks, 1 excavator with shear attachment to cut reinforcement, 1 excavator with breaker attachment breaking concrete, 4 trucks will be used to haul material to scour site, each truck will have to make roughly 2 loads per day for the duration of the operation, due to the distance to the dump site location 4 trucks will be the minimum used. Production of the concrete demolition will be reduced due to the amount of items that will need to be demolished.

Additional Pay Item Notes :

Used RS Means : Pipe, metal pipe, to 1-1/2" diam., selective demolition,4890 LF of 1 1/2" oil pipes at 2.72 Lbs. Used 1 Forman, 2 Steelworkers to cut the pipes and 3 Laborers to load the pipes in the truck. The cooling and lubrication systems for the Hydroelectric Barge turbine, speed increaser and generator will be a combination of water and oil. These systems will be isolated from the water passages so that no contamination of passing water will occur. The following is a list of hazardous materials, substances, chemicals, and wastes normally found at a hydropower facility that may require disposal actions if not recycled or reused for their intended purpose:

1. Polychlorinated Biphenyls (PCBs)
2. Asbestos
3. Paint/abrasive blast grit (red lead paint)
4. Oil
5. Mercury
6. Antifreeze
7. Halogenated and non-halogenated solvents
8. Greases
9. Pesticides (includes herbicides, insecticides, and wood preservatives)
10. Petroleum contaminated
11. Chlorinated fluorocarbons (CFCs) Freon/Halon
12. Gasoline/diesel (includes product and sludge in tanks)
13. Batteries (includes acid)
14. Water treatment sludge (septic tanks/wastewater treatment).

Based on the hazardous materials above assumed hazardous waste 100% of the total lbs

PAY ITEM COST DETAIL WORKSHEET

3.035 Remove & Dispose - Oil / Water separator tank and piping

PAY ITEM INFORMATION

PAY ITEM NUMBER	:	3.035		Project	: COPCO 2		
Description	:	Remove & Dispose - Oil / Water separator tank and piping					
Quantity	:	2,700.00 LBS					
Daily Production	:	15,000.00 LBS per 8 hour shift		Project #	: Klamath Dams Removal		
Work Days	:	0.2 Days		Estimator	: Mihaela Tomulescu	LBS per	Total Cost	Unit Price Per LBS
Unit Price	:	$0.93 per LBS		Probable Low Cost Parameter		16500	$2,268	$0.84
Total Cost	:	$2,520		Probable High Cost Parameter		12000	$3,024	$1.12

Additional Pay Item Notes :

Working with a crew formed of 1 El. Foreman 2 Electrician starting to disconnect power and take care of the temporary electrical power they need at the site. The crew of 5 Ironworker and 5 Millwright. open the engine side panels, and remove the nacelle access panels. Disconnect the engine thermocouple leads at the terminal board. Before disconnecting any lines all fuel, oil, and hydraulic fluid valves are closed. Plug all lines as they are disconnected to prevent entrance of foreign material. Remove the clamps securing the bleed-air ducts at the firewall. Then, disconnect the electrical connector plugs, engine breather and vent lines, and fuel, oil, and hydraulic lines. Disconnect the engine power lever and propeller control rods or cables. Remove the covers from the lift points, attach the sling, and remove slack from the cables using a suitable hoist. The sling must be adjusted to position. Remove the engine mount bolts. The engine ready to be removed. Move the engine forward, out of the nacelle structure, until it clears the aircraft. Lower the into position on the stand, and secure it prior to removing the engine sling. The crew of 4 Welder are going to cut in pieces the big parts of the turbine to be able to load them in the truck using a loader and dispose. .Assumed contains paint with heavy metals 10% of the total lbs, 36 miles from Copco2 to Yreka transfer recycling.

					TOTAL COST for pay item	$5,633

Additional Pay Item Notes :

Based on RS Means : Pipe, metal pipe, to 1-1/2" diam., selective demolition, 2390 LF of 1 1/2" fire protection pipes at 2.72 Lbs. Used 1 Forman and 1 Laborers to load in drums and put them in the truck. Calculated 36 miles from Copco 1 to Yreka Transfer Recycling. Each hydropower facility has at least 150,000 gallons to 250,000 gallon of oil currently in use. This oil would have to be properly disposed of in the event of decommissioning. Oil removed from the turbines and other equipment, including transformer oil, would be either a waste oil or used oil, depending on prior use and contaminants found in the oil. Containerized oil containing contaminants such as solvents are commonly encountered at hydropower facilities. Oil sludges are common in tanks. Oil disposal would likely be costly due to the large volumes found at hydropower facilities and the ease of contamination with other regulated hazardous wastes.

Additional Pay Item Notes :

Petroleum-based products, ranging from fuel oil and hydraulic fluid to lubricating greases and oils, are found throughout every type of power generating plant or system. Lubrication supports bearings and moving parts in all sorts of equipment: pumps, conveyors, feeders, scrubbers, cranes, turbines, and more.A good oil/water separation system will result in a flow of concentrated waste oil to a collection area and a flow of oil-free water ready for secondary processing or discharge. Once an oil layer has been separated from free water, it must be removed for recycling or disposal. Many plants use one or more of these oil removal methods, but each has costly limitations:

1. Absorbent materials. Absorbent mats or materials are frequently used to dam up and absorb excess oils and greases resulting from accidents or the routine operation of machinery. These materials are very effective for preventing the spread of a source leak and very efficient in terms of oil pickup. Yet, their use on large volumes of waste oil results in multiple, recurring costs that can make them impractical as an everyday solution:

- the costs of the materials themselves
- the labor costs for ordering, stocking, application, and removal
- the costs of used-media collection, disposal, or re-processing/recycling.

2. Manually operated “slotted pipes.” Many separators feature a “slotted pipe,” a pipe located near the top of the vessel that has a horizontal opening. Oil is removed by turning the horizontal opening downward until it meets the floating oil layer, which drains through the pipe to a collection receptacle. These pipes work well on thick layers of oil, but cannot drain off a sheen of oil without draining off a large amount of water as well.

AECOM assumed the best is Vacuum truck removal method .Used a crew formed of 1 Forman, 2 Laborers and 2 journemen to takeout the petroleum waste, Vacuum-equipped tank trucks are used to remove waste oil from collection points (assumed existing drums or tanks) so that it can be transported to recycling or disposal locations. If the waste oil has been thoroughly separated, highly concentrated, and stored in an appropriate receptacle, this service can be used very efficiently. However, vacuum disposal units are often used to pump oil layers directly off of water. This results in the intake of a significant amount free water along with the waste oil – and a significantly higher cost.

Additional Pay Item Notes :

Used 2 Crews (2 sections each weight around 2400 LBS per crew) formed of 1 Forman, 3 Electrician, 2 laborer to haul with the crane in the truck. Assumed containing hazardous waste that will be disposed at 36 miles away from the construction site to Yreka Transfer Recycling . In normal circumstances, decontaminated residual components could be accepted at landfill sites but Polychlorinated biphenyl, otherwise known as PCB, is a synthetic chemical that is widely used for industrial and commercial use as dielectric fluid in transformers and capacitors because of its high resistance to decomposition, low electrical conductivity, low flammability and high heat capacity. Transformer repair, reconditioning and retro-filling facilities are the major industry sectors that contributes to the spread of PCB contamination. Types of PCB Wastes:
PCB wastes are discarded materials that contain PCB or have been contaminated with PCBs and that are without any commercial, industrial, or economic use. For the purpose of this Code of Practice, PCBs wastes are classified as follows: Liquid PCB wastes
o PCB-based dielectric fluids removed from transformers and other equipment
o PCB-based heat transfer and hydraulic fluids Metallic solid wastes
o PCB equipment such as capacitors, transformers, **switchgears**, circuit breakers, heat transfer systems, etc.
o Contaminated components removed from electrical equipment such as windings;
o PCB-contaminated containers and equipment such as metal drums, tanks, pumps, metal filters, etc.

					TOTAL COST for pay item	$494,479

Additional Pay Item Notes :

The work is done by two 6-men crew (foreman, 4 laborers, and 1 equipment operator). Concrete hauling to disposable site - based on the current production rate, only 5 trips a day would be necessary. Demolition is done using hydraulic chipping hammers and excavator mounted claw. Allowance for saw cutting sub is included at one mobilization a week. Blasting method is not found to be feasible for this work. A check using RS Means was used: reference 03055110 ($224/CY, excludes hauling, sawing, and dumping) - Selective concrete demolition, reinforcing more than 2% cross-sectional area.

						TOTAL COST for pay item	$392,197

Additional Pay Item Notes :

The work is done by two 6-men crew (foreman, 4 laborers, and 1 equipment operator). Concrete hauling to disposable site - based on the current production rate, only 5 trips a day would be necessary. Demolition is done using hydraulic chipping hammers and excavator mounted claw. Allowance for saw cutting sub is included at one mobilization a week. Blasting method is not found to be feasible for this work. A check using RS Means was used: reference 03055110 ($224/CY, excludes hauling, sawing, and dumping) - Selective concrete demolition, reinforcing more than 2% cross-sectional area.

Additional Pay Item Notes :

The removal of gate, frame and hoist is done by one 9-men crew (1 foreman, 6 steelworkers, 1 welder, 1 electrician and 2 equipment operators). Based on the current production rate and the fact that we dispose big pieces of steel we use 2 trucks per day. Assumed hazardous waste cleanup 100% disposal because of the engine Oil and Transmission Oil used for cranes .

Additional Pay Item Notes :

The process of removing top logs is not manual, but done with hydraulic stop log lifters and hoists is done by one 11-men crew (6 steelworkers, 4 journeymen and 4 equipment operators). Based on the current production rate and the fact that we dispose big pieces of material we use 2 trucks per day. The gate side guides and invert shall have a minimum weight of 4 lbs./ft. for wall mounted and 3 lbs./ft. for embedded in concrete that we assume we have. The gate invert should contain a removable neoprene seal. Including stop log grooves, lifter, guide - weight around 220,000 lbs.

Additional Pay Item Notes :

Assumed the process of removing pipes, expansion joints and support rings encased in concrete is done in around 20 days by 3 crew formed of 1 foreman, 4 journeymen, 4 steelworkers ;6 equipment operators 1 for each excavator, crane and loader. We dispose pipes with 1 trucks per day for each crew. Assumed contains paint with heavy metals 10% of the total lbs, 36 miles from Copco lake to Yreka transfer recycling. Based on the current production rate, only 1 trips a day would be necessary. Demolition is done using one crawler crane, excavator and welding machine.

						TOTAL COST for pay item	**$15,773**

Additional Pay Item Notes :

The work is done by two 6-men crew (foreman, 4 laborers, and 1 equipment operator). Concrete hauling to disposable site - based on the current production rate, only 5 trips a day would be necessary. Demolition is done using hydraulic chipping hammers and excavator mounted claw. Allowance for saw cutting sub is included at one mobilization a week. Blasting method is not found to be feasible for this work. A check using RS Means was used: reference 03055110 ($224/CY, excludes hauling, sawing, and dumping) - Selective concrete demolition, reinforcing more than 2% cross-sectional area.

Additional Pay Item Notes :

Turning of the actuating bolts and nuts - accomplished by steelworker / weder crew using only standard hand tools - spreads the yoke halves until they are fully separated, allowing the head to be swung open on its hinge. Contact surfaces of the clamping yokes, head and hub are tapered and when the head is closed and the yoke bolts are tightened, the head and hub are wedged together, compressing the 0-ring and effecting a leakproof seal. Removing flanges is cumbersome and time consuming because of the tunnel work and the rusted fasteners. There is need to tug or hammer at bulky flanges or to struggle with bulky lugs and threads. Using loader, crane to load the flange and associated metal work in the truck. Included 5' of pipe spool.

Additional Pay Item Notes :

Remove sluice and diversion gates from shaft by divers, based on RSMeans we used a crew of 4 divers for demolition in 10 days. Hauling to disposable site - based on the current production rate, only 1 trips a day would be necessary. Demolition is done using one crawler crane, a welding machine and barge.

Additional Pay Item Notes :

The work is done by two 6-men crew (foreman, 4 laborers, and 1 equipment operator). Concrete hauling to disposal site - based on the current production rate, only 5 trips a day would be necessary. Demolition is done using hydraulic chipping hammers and excavator mounted claw. Allowance for saw cutting sub is included at one mobilization a week. Blasting method is not found to be feasible for this work. A check using RS Means was used: reference 03055110 ($224/CY, excludes hauling, sawing, and dumping) - Selective concrete demolition, reinforcing more than 2% cross-sectional area.

Additional Pay Item Notes :

Production is based on using 20CY trucks, Material will be used for temporary coffer dams and hauled to disposal area. Excavators will load material into 20CY trucks that we aniticipate will be able to haul 18CY per load. This will be roughly 14 loads per truck per day.Dozers will be used to push material in to piles for load out. Laborers will direct truck traffic and laborer foreman will oversee operation. During Dam construction the rip rap was placed on the upstream slope at a thickness of 10'.

Additional Pay Item Notes :

Price is based on hauling material to spillway using both dozers and haul trucks. Figured 1/4 of the material will be placed using Dozer and excavators only and the other half of the material will need haul trucks to move material to spillway from opposite side of dam. Figuring 10 trucks moving 14 loads a day.

Additional Pay Item Notes :

The work is done by two 6-men crew (foreman, 4 laborers, and 1 equipment operator). Concrete hauling to disposal site - based on the current production rate, only 5 trips a day would be necessary. Demolition is done using hydraulic chipping hammers and excavator mounted claw. Allowance for saw cutting sub is included at one mobilization a week. Blasting method is not found to be feasible for this work. A check using RS Means was used: reference 03055110 ($224/CY, excludes hauling, sawing, and dumping) - Selective concrete demolition, reinforcing more than 2% cross-sectional area.

Additional Pay Item Notes :

Working with a crew formed of 1 El. Forman 2 Electrician starting to disconnect power and take care of the temporary electrical power they need at the site. The crew of 5 Ironworker and 5 Millwright. open the engine side panels, and remove the nacelle access panels. Disconnect the engine thermocouple leads at the terminal board. Before disconnecting any lines all fuel, oil, and hydraulic fluid valves are closed. Plug all lines as they are disconnected to prevent entrance of foreign material. Remove the clamps securing the bleed-air ducts at the firewall. Then, disconnect the electrical connector plugs, engine breather and vent lines, and fuel, oil, and hydraulic lines. Disconnect the engine power lever and propeller control rods or cables. Remove the covers from the lift points, attach the sling, and remove slack from the cables using a suitable hoist. The sling must be adjusted to position. Remove the engine mount bolts. The engine ready to be removed. Move the engine forward, out of the nacelle structure, until it clears the aircraft. Lower the into position on the stand, and secure it prior to removing the engine sling. The crew of 4 Welder are going to cut in pieces the big parts of the runner, turbine, scroll case to be able to load them in the truck using a loader and dispose.

Additional Pay Item Notes :

Used RS Means : Pipe, metal pipe, to 1-1/2" diam., selective demolition, 3375 LF of 1 1/2" oil pipes at 2.72 Lbs. Used 1 Forman, 2 Steelworkers to cut the pipes and 3 Laborers to load the pipes in the truck.
The cooling and lubrication systems for the Hydroelectric Barge turbine, speed increaser and generator will be a combination of water and oil. These systems will be isolated from the water passages so that no contamination of passing water will occur. The following is a list of hazardous materials, substances, chemicals, and wastes normally found at a hydropower facility that may require disposal actions if not recycled or reused for their intended purpose:

1. Polychlorinated Biphenyls (PCBs)
2. Asbestos
3. Paint/abrasive blast grit (red lead paint)
4. Oil
5. Mercury
6. Antifreeze
7. Halogenated and non-halogenated solvents
8. Greases
9. Pesticides (includes herbicides, insecticides, and wood preservatives)
10. Petroleum contaminated
11. Chlorinated fluorocarbons (CFCs) Freon/Halon
12. Gasoline/diesel (includes product and sludge in tanks)
13. Batteries (includes acid)
14. Water treatment sludge (septic tanks/wastewater treatment)

Additional Pay Item Notes :

Used RS Means : Pipe, metal pipe, to 1-1/2" diam., selective demolition, 3375 LF of 1 1/2" fire protection pipes at 2.72 Lbs. Used 1 Forman, 2 Steelworkers to cut the pipes and 3 Laborers to load the pipes in the truck. Used a pump for the oil disposal. Each hydropower facility has at least 150,000 gallons to 250,000 gallon of oil currently in use. This oil would have to be properly disposed of in the event of decommissioning. Oil removed from the turbines and other equipment, including transformer oil, would be either a waste oil or used oil, depending on prior use and contaminants found in the oil. Containerized oil containing contaminants such as solvents are commonly encountered at hydropower facilities. Oil sludges are common in tanks. Oil disposal would likely be costly due to the large volumes found at hydropower facilities and the ease of contamination with other regulated hazardous wastes. Calculated 28 miles from Iron Gate Dam to Yreka Transfer Recycling.

Additional Pay Item Notes :

Petroleum-based products, ranging from fuel oil and hydraulic fluid to lubricating greases and oils, are found throughout every type of power generating plant or system. Lubrication supports bearings and moving parts in all sorts of equipment: pumps, conveyors, feeders, scrubbers, cranes, turbines, and more. A good oil/water separation system will result in a flow of concentrated waste oil to a collection area and a flow of oil-free water ready for secondary processing or discharge. Once an oil layer has been separated from free water, it must be removed for recycling or disposal. Many plants use one or more of these oil removal methods, but each has costly limitations:

1. Absorbent materials. Absorbent mats or materials are frequently used to dam up and absorb excess oils and greases resulting from accidents or the routine operation of machinery. These materials are very effective for preventing the spread of a source leak and very efficient in terms of oil pickup. Yet, their use on large volumes of waste oil results in multiple, recurring costs that can make them impractical as an everyday solution:

- the costs of the materials themselves
- the labor costs for ordering, stocking, application, and removal
- the costs of used-media collection, disposal, or re-processing/recycling.

2. Manually operated "slotted pipes." Many separators feature a "slotted pipe," a pipe located near the top of the vessel that has a horizontal opening. Oil is removed by turning the horizontal opening downward until it meets the floating oil layer, which drains through the pipe to a collection receptacle. These pipes work well on thick layers of oil, but cannot drain off a sheen of oil without draining off a large amount of water as well.

AECOM assumed the best is Vacuum truck removal method .Used a crew formed of 1 Forman, 5 Laborers to takeout the petroleum waste, 1 Electrician to unplug the power and to assure the temporary power at the construction site. Vacuum-equipped tank trucks are used to remove waste oil from collection points at plants so that it can be transported to recycling or disposal locations. If the waste oil has been thoroughly separated, highly concentrated, and stored in an appropriate receptacle, this service can be used very efficiently. However, vacuum disposal units are often used to pump oil layers directly off of water. This results in the intake of a significant amount free water along with the waste oil – and a significantly higher cost.

Additional Pay Item Notes :

The cooling and lubrication systems for the generator will be a combination of water and oil. These systems will be isolated from the water passages so that no contamination of passing water will occur. Used RS Means, a R13 Crew formed of 1 Forman, 3 Electricians, 1 Oiler, 0 .25 Equipment Crane. 5 Steelworkers to cut adjacent appurtenances and 1 Welder to cut pipes. Calculated 28 miles from Iron Gate Dam to Yreka Transfer Recycling (back and forth).

Additional Pay Item Notes :

Used 1 Forman, 3 Electrician, 2 laborer to haul with the crane in the truck. Assumed containing hazardous waste that will be disposed at 28 miles away from the construction site. In normal circumstances, decontaminated residual components could be accepted at landfill sites but Polychlorinated biphenyl, otherwise known as PCB, is a synthetic chemical that is widely used for industrial and commercial use as dielectric fluid in transformers and capacitors because of its high resistance to decomposition, low electrical conductivity, low flammability and high heat capacity. Transformer repair, reconditioning and retro-filling facilities are the major industry sectors that contributes to the spread of PCB contamination. Types of PCB Wastes:
PCB wastes are discarded materials that contain PCB or have been contaminated with PCBs and that are without any commercial, industrial, or economic use. For the purpose of this Code of Practice, PCBs wastes are classified as follows: Liquid PCB wastes
o PCB-based dielectric fluids removed from transformers and other equipment
o PCB-based heat transfer and hydraulic fluids Metallic solid wastes
o PCB equipment such as capacitors, transformers, switchgears, circuit breakers, heat transfer systems, etc.
o Contaminated components removed from electrical equipment such as windings; PCB-contaminated containers and equipment such as metal drums, tanks, pumps, metal filters, etc. Calculated 28 miles from Iron Gate Dam to Yreka Transfer Recycling

TOTAL COST for pay item $9,143

Additional Pay Item Notes :

Used 1 Forman, 3 Electrician, 2 laborer to haul with the loader in the truck. Assumed containing hazardous waste that will be disposed at 200 miles away from the construction site. In normal circumstances, decontaminated residual components could be accepted at landfill sites but Polychlorinated biphenyl, otherwise known as PCB, is a synthetic chemical that is widely used for industrial and commercial use as dielectric fluid in transformers and capacitors because of its high resistance to decomposition, low electrical conductivity, low flammability and high heat capacity. Transformer repair, reconditioning and retro-filling facilities are the major industry sectors that contributes to the spread of PCB contamination. Types of PCB Wastes:
PCB wastes are discarded materials that contain PCB or have been contaminated with PCBs and that are without any commercial, industrial, or economic use. For the purpose of this Code of Practice, PCBs wastes are classified as follows: Liquid PCB wastes
o PCB-based dielectric fluids removed from transformers and other equipment
o PCB-based heat transfer and hydraulic fluids Metallic solid wastes
o PCB equipment such as capacitors, transformers, switchgears, circuit breakers, heat transfer systems, etc.
o Contaminated components removed from electrical equipment such as windings; PCB-contaminated containers and equipment such as metal drums, tanks, pumps, metal filters, etc. Calculated 28 miles from Iron Gate Dam to Yreka Transfer Recycling

Additional Pay Item Notes :

Production is based off of RSMs using Crew formed of 1 Forman, 1 Electrician,1 Crane to load the transformer in the truck for disposal. In normal circumstances, decontaminated residual components could be accepted at landfill sites. Transformers of known PCB content over 50 ppm must be handled and disposed of in a manner that adheres to a strict code of Federal regulations (4O CFR Part 761).Transformers and other oil filled equipment that are known to be less than 50 ppm PCB are not regulated. Calculated 28 miles from Iron Gate Dam to Yreka Transfer Recycling.

Additional Pay Item Notes :

Weight and dimensions of the transformers have particular importance so transport vehicles must be adequate. A considerable proportion of the weight is due to the oil, so the direct consequence is that the big transformers have to be transported empty. During transport the transformers are filled either by dry air or nitrogen. Because of transportation, the auxiliaries have to be removed . For this reason the collaboration with all the people involved in the project is essential. AECOM best assumption - 2 crew R3 formed of 1 Forman, 1 Electricians, 1 utility man-bucket truck to work on the electrical line, 1 crane for disposal of each transformer in the truck and 2 laborers to remove the auxiliaries and the pad (1 excavator).

Additional Pay Item Notes :

Production is based off of RSMs using 3 Crew formed of 1 Forman, 1 Electrician,1 Articulated boom for each transformers. In normal circumstances, decontaminated residual components could be accepted at landfill sites. Transformers of known PCB content over 50 ppm must be handled and disposed of in a manner that adheres to a strict code of Federal regulations.Transformers and other oil filled equipment that are known to be less than 50 ppm PCB are not regulated. Calculated 28 miles from Iron Gate Dam to Yreka Transfer Recycling.

Additional Pay Item Notes :

The work is done by two 6-men crew (foreman, 4 laborers, and 1 equipment operator). Concrete hauling to disposal site - based on the current production rate, only 5 trips a day would be necessary. Demolition is done using hydraulic chipping hammers and excavator mounted claw. Allowance for saw cutting sub is included at one mobilization a week. Blasting method is not found to be feasible for this work. A check using RS Means was used: reference 03055110 ($224/CY, excludes hauling, sawing, and dumping) - Selective concrete demolition, reinforcing more than 2% cross-sectional area.

SUMMARY OF COSTS

Labor Cost	$74,191.02	Labor Burden @	0.0%	$0.00	Included in hourly labor rate.	$74,191.02
Material Cost	$3,709.55	Material Tax @	7.75%	$287.49		$3,997.04
Equipment Cost	$77,163.25	Equipment Tax @	7.75%	$5,980.15		$83,143.40
Subcontractors	$10,000.00					$10,000.00
DIRECT COST SUBTOTALS	$165,064			$6,268	DIRECT COST SUBTOTALS	$171,331

		Crew	Material	Subs	Cost Basis	
Installing Contractors Overhead@	15.0%				$161,331.47	$24,199.72
Installing Contractors Profit@	8.0%				$161,331.47	$12,906.52
GC Markup on Subs @	5.0%				$10,000.00	$500.00
					TOTAL MARKUP COSTS	$37,606.24
General Contractors Insurance @	1.0%			on	$208,937.71	$2,089
Bond @	1.0%			on	$208,937.71	$2,089
Contingency @	0.0%			on	$213,116.46	$0
					TOTAL COST for pay item	**$213,116**

Additional Pay Item Notes :

The work is done by two 6-men crew (foreman, 4 laborers, and 1 equipment operator). Concrete hauling to disposal site - based on the current production rate, only 5 trips a day would be necessary. Demolition is done using hydraulic chipping hammers and excavator mounted claw. Allowance for saw cutting sub is included at one mobilization a week. Blasting method is not found to be feasible for this work. A check using RS Means was used: reference 03055110 ($224/CY, excludes hauling, sawing, and dumping) - Selective concrete demolition, reinforcing more than 2% cross-sectional area.

Additional Pay Item Notes :

Assumed the process of removing and disposing of Bypass Outlet - 96" Dia, 0.25" Thick x 50' (weight: 256 LBS/LF)is done in around 1/2 day by 3 crew formed of 1 forman, 4 jouneymen, 4 steelworkers ;6 equipment operators 1 for each excavator, crane and loader. We dispose pipes with 1 trucks per day for each crew. Assumed contains paint with heavy metals 10% of the total lbs, 28 miles from Iron Gate to Yreka transfer recycling. Based on the current production rate, only 1 trips a day would be necessary. Demolition is done using one crawler crane, excavator and welding machine.

Additional Pay Item Notes :

The price of removing a building is based on several factors including the size of the space, structural additions on the property, required permits and waste material clearing. A complete demo of a house and its foundation or basement can cost much as $25,000.
The cost of removal can vary based on the area lived in and the typical wages in the region. Some estimates put a price tag of $18,000 on bulldozing a 1,500 square-foot house, while others show that the average estimate is around $4-$15 per square foot.
Hazardous waste can greatly impact the cost of clearing debris. Many older homes contain asbestos, and there are special fees and considerations associated with its removal and disposal. The national average cost to eliminate asbestos is about $200-$700 per hour. We take in consideration this aspect in our estimate assuming 3 Laborers working 3 days, 8 hours per day @$350

					TOTAL COST for pay item	$372,241

Additional Pay Item Notes :

The work is done by two 6-men crew (foreman, 4 laborers, and 1 equipment operator). Concrete hauling to disposal site - based on the current production rate, only 5 trips a day would be necessary. Demolition is done using hydraulic chipping hammers and excavator mounted claw. Allowance for saw cutting sub is included at one mobilization a week. Blasting method is not found to be feasible for this work. A check using RS Means was used: reference 03055110 ($224/CY, excludes hauling, sawing, and dumping) - Selective concrete demolition, reinforcing more than 2% cross-sectional area.

Additional Pay Item Notes :

Assumed the process of removing and disposing of Miscellaneous Metalwork in Fish Facilities (frames, grating, handrails, laddrs, mechanical sweeps) is done in around 1/2 day by 3 crew formed of 1 forman, 4 jouneymen, 4 steelworkers. We dispose metal with 1 trucks per day for each crew. Assumed contains paint with heavy metals 10% of the total lbs, 28 miles from Iron Gate to Yreka transfer recycling. Based on the current production rate, only 1 trips a day would be necessary. Demolition is done using one crawler crane, excavator and welding machine.

Additional Pay Item Notes :

Crew is built from B38 RSM which has a production of 53 SY an hour or 424 sy/ 3816 SF a day. Production was adjusted to show reaching 1/3 of the production from RSM's due to working in tight area, working around existing structures, and the haul route location/ turnaround time (which will not be fast). Also added an off-road dump truck and truck driver to haul asphalt waste to disposal area.

					TOTAL COST for pay item	$20,528

Additional Pay Item Notes :

The price of removing a building is based on several factors including the size of the space, structural additions on the property, required permits and waste material clearing. A complete demo of a house and its foundation or basement can cost much as $25,000.
The cost of removal can vary based on the area lived in and the typical wages in the region. Some estimates put a price tag of $18,000 on bulldozing a 1,500 square-foot house, while others show that the average estimate is around $4-$15 per square foot.
Hazardous waste can greatly impact the cost of clearing debris. Many older homes contain asbestos, and there are special fees and considerations associated with its removal and disposal. The national average cost to eliminate asbestos is about $200-$700 per hour. We take in consideration this aspect in our estimate assuming 3 Laborers working 2 days, 8 hours per day @$350

					TOTAL COST for pay item	$11,638

Additional Pay Item Notes :

The price of removing a building is based on several factors including the size of the space, structural additions on the property, required permits and waste material clearing. A complete demo of a house and its foundation or basement can cost much as $25,000.
The cost of removal can vary based on the area lived in and the typical wages in the region. Some estimates put a price tag of $18,000 on bulldozing a 1,500 square-foot house, while others show that the average estimate is around $4-$15 per square foot.
Hazardous waste can greatly impact the cost of clearing debris. Many older homes contain asbestos, and there are special fees and considerations associated with its removal and disposal. The national average cost to eliminate asbestos is about $200-$700 per hour. We take in consideration this aspect in our estimate assuming 3 Laborers working 1 days, 8 hours per day @$350

Additional Pay Item Notes :

The price of removing a building is based on several factors including the size of the space, structural additions on the property, required permits and waste material clearing. A complete demo of a house and its foundation or basement can cost much as $25,000.
The cost of removal can vary based on the area lived in and the typical wages in the region. Some estimates put a price tag of $18,000 on bulldozing a 1,500 square-foot house, while others show that the average estimate is around $4-$15 per square foot.
Hazardous waste can greatly impact the cost of clearing debris. Many older homes contain asbestos, and there are special fees and considerations associated with its removal and disposal. The national average cost to eliminate asbestos is about $200-$700 per hour. We take in consideration this aspect in our estimate assuming 3 Laborers working 1 days, 8 hours per day @$350

Additional Pay Item Notes :

When a transmission line is decommissioned and is not converted to another use, the decommissioning typically includes the removal of all infrastructure if it is no longer required, or has reached end-of-life conditions. Removed parts will be re-used, recycled or disposed. Production is based off of RSMs using Crew B-1C and B-3 (1 Forman, 2 laborer, 1 Excavator& 1 crane for lift, position and load in the truck, 1 Hydraulic rock-splitting/rock-drilling equipment to break equipment foundations and concrete) for demo :4 Electrician,, 1 utility truck access poles, string conductor, modify structure arms, provide guard structures, etc. Crews may be working simultaneously along the project alignment and substations, hydro plant and switchyard. .

			TOTAL COST for pay item	**$594,918**

Additional Pay Item Notes :

When a transmission line is decommissioned and is not converted to another use, the decommissioning typically includes the removal of all infrastructure if it is no longer required, or has reached end-of-life conditions. Removed parts will be re-used, recycled or disposed. Production is based off of RSMs using Crew B-1C and B-3 (1 Forman, 2 laborer, 1 Excavator & 1 crane for lift, position and load in the truck, 1 Hydraulic rock-splitting/rock-drilling equipment to break equipment foundations and concrete for demo :2 Electrician,, 1 utility truck to access poles, string conductor, modify structure arms, provide guard structures, etc. Crews may be working simultaneously along the project alignment and substations, hydro plant and switchyard. Transmission line poles or structures are commonly between 60 and 140 feet tall. There are several different kinds of transmission structures. Transmission structures can be constructed of metal or wood. They can be single-poled or multi-poled. They can be single-circuited, carrying one set of transmission lines or double-circuited with two sets of lines. Assumed based on RSMs we have "Communications transmission tower, radio towers self-supporting, wind load 70 mph basic wind speed, 120' high" (33811310). Pole height and load capacity limitations determine the distance between poles (span length) either on the basis of ground clearance or ability to support heavy wind and ice loads. Assumed average span between structures to be 275 feet so for 5 miles of overhead transmission we will have approximately 96 structures. In areas where single-pole structures are preferred, weak or wet soils may require concrete foundations for support. Where a transmission line must cross a street or slightly change direction, larger angle structures or guy wires may be required. Poles with guy wires impact a much larger area. Angle structures are usually more than double the diameter of other steel poles. They are made of steel, usually five to six feet in diameter, and have a large concrete base. The base may be buried ten or more feet below the ground surface. The diameter of the pole and the depth the base is buried depends on the condition of the soils and the voltage of the line. Assumed the structures are disposed to Yreka recycling, 34 miles away. This estimate is made as the best AECOM assumption, as actual pricing would occur during the detailed engineering and construction bid process.

PAY ITEM INFORMATION

PAY ITEM NUMBER	: 5.023		Project	: COPCO2		
Description	: Demolish transmission conductor from existing structure pole. Structures remain.					
Quantity	: 1.50 Miles

Additional Pay Item Notes :

Iron Gate Hatchery located near the Klamath River downstream of Iron Gate Dam will require a new connection from PacifiCorp's Hornbrook Substation (5G19). Details for connection requirements are unknown at this stage, this estimate is just an allowance for assumed 0.9 miles of overhead distribution line. Transmission line poles or structures are commonly between 60 and 140 feet tall. Distribution line structures are approximately 40 to 60 feet tall.

There are several different kinds of transmission structures. Transmission structures can be constructed of metal or wood. They can be single-poled or multi-poled. They can be single-circuited, carrying one set of transmission lines or double-circuited with two sets of lines. . A typical new 69 kV overhead single-circuit transmission line costs approximately $315,000 per mile as opposed to $1.6 million per mile for a new 69 kV underground line (without the terminals).

Additional Pay Item Notes :

Engineering and construction costs only. Environmental, Permitting, and Right of way Acquisition costs are not included. The following is a summary of anticipated equipment to be used for each construction activity. Survey work only requires the use of pickup trucks or ATVs. To dig holes and install the directly embedded structures or install 230-kV foundations it is anticipated that pickup trucks, 2-ton trucks, hole diggers, bulldozers, concrete trucks, carry alls, cranes, hydro crane, wagon drill, dump trucks, and front-end loaders will be used. Hauling lattice steel members, tubular poles, braces and hardware to the structure sites will require the use of steel haul trucks; carry all's, cranes, and forklifts. For assembly and erection of structures it is anticipated that pickup trucks, 2-ton trucks, carry all's, cranes, and a heavy lift helicopter may be used, not included here. Final cleanup, reclamation, and restoration will utilize pickups, 2-ton trucks, bulldozers, motor graders, dump trucks, front-end loaders.. The contractor will mobilize equipment and personnel to the construction site at various stages in the Project schedule depending on operational requirements. Assumed 230KV Single Circuit Tower. Estimate includes just towers and not included the transmission line to tie existing 230kV transmission line north and south of JC Boyle Substation together. The estimated costs can vary due to fluctuations in steel pricing, subsurface conditions, contractor availability and the time of year. Taking into account these fluctuations, the estimates are subject to a contingency of 20%. These are only estimates as actual pricing would occur during the detailed engineering and construction bid process.

Chapter 1: Introduction

This page intentionally left blank.

1. INTRODUCTION

KRRC developed this Draft Recreation Plan to provide information on the changes to existing recreation sites that will occur as part of the decommissioning and removal of the Lower Klamath Project consistent with the terms of the KHSA (the Project) and to provide a programmatic level of detail on proposed recreation opportunities and facilities that are consistent with pre-hydropower development conditions. KRRC developed this Draft Recreation Plan with input from a variety of stakeholders including tribes, state and federal agencies, county agencies and chambers of commerce, local residents, and public interest groups.

1.1 Existing Recreation Sites

Recreation sites are located throughout the project area from J.C. Boyle Reservoir to the Iron Gate fish hatchery. The existing recreation facilities and their planned disposition as part of the Project is presented in Tables 1-1 and 1-2.

Table 1-1 Existing PacifiCorp Recreation Facilities in the Project Area and Proposed Actions

Site	Property Type[1]	Facilities	Proposed Action	Estimated Annual Use[2]
J.C. Boyle Reservoir Recreation				40 – 65%
Pioneer Park (East and West)	Parcel A	Picnic areas, boat launches, shoreline fishing, interpretive signs, restrooms	Remove	
Stateline Take-out	Parcel A	Boat put-in/take-out, shoreline fishing access, restrooms. Upstream of Copco Lake	Unknown	
Fishing Access Sites 1-6	Parcel A	Shoreline fishing access, parking. Upstream of Copco Lake	Unknown	
Copco Lake Recreation				5 – 15%
Mallard Cove	Parcel B	Day use/picnic area, restrooms, boat launch with boarding dock, interpretive signs	Remove	
Copco Cove	Parcel B	Picnic area, restrooms, boat launch with boarding dock, interpretive signs	Remove	
Iron Gate Reservoir Recreation				5 – 25%

Site	Property Type[1]	Facilities	Proposed Action	Estimated Annual Use[2]
Fall Creek Day Use Area and Fall Creek Trail	Parcel B	Picnic areas, boat launch, restroom, hiking trail	Retain / modify	
Overlook Point	Parcel B	Picnic area, restrooms	Remove	
Wanaka Springs Day Use Area	Parcel B	Day use/ camping areas, fishing dock, restrooms, interpretive signs	Remove	
Jenny Creek Day Use Area and Campground	Parcel B	Campsites/day use areas (6), hiking trails, shoreline fishing, restrooms	Retain / modify	
Camp Creek Day Use Area and Campground (including Dutch or Scotch Creek)	Parcel B	Campsites (22), boat launch, boarding and fishing docks (3), swimming area, a RV dump station, interpretive display, restrooms	Remove	
Juniper Point Day Use Area and Campground	Parcel B	Campsites (9), a fishing dock, interpretive signs, restroom	Remove	
Mirror Cove Day Use Area and Campground	Parcel B	Campsites (10), a boat launch, fishing dock, interpretive signs, restroom	Remove	
Long Gulch Day Use Area and Campground	Parcel B	Picnic sites, boat launch, restrooms	Remove	
Iron Gate Fish Hatchery Day Use Area	Parcel B	Picnic areas, picnic shelter, visitor center, interpretive kiosks, restrooms, trail to river, fishing dock, boat launch (3)	Retain / Modify	

Notes

1. Parcel A lands will remain with PacifiCorp because these parcels are not directly related to the hydroelectric facilities to be transferred to KRRC (J.C. Boyle, Copco 1&2, and Iron Gate). Parcel B lands are directly related to these four hydroelectric facilities. According to the 2016 Amended KHSA, Parcel B lands are to be transferred to through KRRC to the states or other entities they designate and are intended for the public interest. There are over 8,000 acres of Parcel B land.
2. Data from 2015 PacifiCorp Licensed Hydropower Development Recreation Reports for J.C. Boyle, Copco 1, Copco 2, and Iron Gate.

Table 1-2 Other Existing Recreation Facilities in the Project Area and Proposed Actions

Site	Ownership	Facilities	Reservoir	Proposed Action
Topsy Campground	BLM	Campsites (15), an RV dump, day use areas (2), a boat launch with boarding dock, an accessible fishing pier, restrooms	J.C. Boyle	Modify / Retain
Sportsman's Park	Klamath County	Shooting ranges, dirt racetracks, archery courses, a model aircraft flying field, OHV area, restrooms	J.C. Boyle	Unchanged
Spring Island Boater Access	BLM	Boat launch, shoreline fishing access, interpretive signs, restrooms. Located downstream of J.C. Boyle	J.C. Boyle	Unknown
Klamath River Campground	BLM	Campsites (3), shoreline fishing and boating access, restrooms. Located downstream of J.C. Boyle	J.C. Boyle	Unknown
Turtle Camp	BLM	Primitive camping site downstream of J.C. Boyle	J.C. Boyle	Unknown
Dispersed Site	BLM	Primitive camping site downstream of J.C. Boyle	J.C. Boyle	Unknown

As shown in Tables 1-1 and 1-2, the Project will result in the removal of up to 9 recreation sites that are FERC license requirements along the Klamath River between J.C. Boyle Reservoir and Iron Gate Dam. This will include three separate recreation sites with campgrounds that provide a total of 41 campsites, 5 boat launches, 9 fishing docs, 9 recreation sites with restrooms, and 9 sites that support fishing access.

1.2 Existing Recreation Activities

The existing recreation sites described above primarily provide fishing, boating, and day use access to the three reservoirs. Some sites provide camping facilities for overnight use. In addition, whitewater rafting and associated put-ins, take-outs, and camping occurs in the Hell's Corner Reach between J.C. Boyle powerhouse and Copco Lake. Release flows from J.C. Boyle powerhouse supports whitewater rafting, which operates on a regular schedule and provides consistent flows during daylight hours.

The Project includes permanent removal of recreation sites associated with the reservoirs and the reduction in the number of days with acceptable flows associated with the FERC licensed hydropower facilities for whitewater boating in the Hell's Corner Reach, due to the removal of the J.C. Boyle development. Specifically, at the four developments, KRRC will completely remove a number of recreational facilities and the former recreation areas, parking areas, and access trails will be regraded and revegetated. In the Hell's Corner

Reach of the Klamath River, there will be a loss of flows acceptable for whitewater boating in the only Class IV+ rapids in the region that occur during the late summer.

1.3 Recreation Objectives

This Draft Recreation Plan seeks to identify recreation opportunities that will offset the removal of reservoir recreation sites and the reduction in whitewater boating days associated with the Project. The goal of the plan is to provide new riverine opportunities and facilities that are consistent with pre-hydropower development conditions. The recreation opportunities identified in this plan will need to be implementable by KRRC, offset the removal of reservoir recreation facilities and river access, and represent durable solutions – with parties responsible for maintenance and upkeep identified.

Chapter 2: Recreation Option Identification

This page intentionally left blank.

KLAMATH RIVER RENEWAL CORPORATION

2. RECREATION OPPORTUNITY IDENTIFICATION

2.1 Recreation Opportunity Identification Process

KRRC has implemented a comprehensive recreation opportunity survey to support development of a Recreation Plan that will be included in the Project. KRRC has considered opportunities identified in the 2011 *Detailed Plan for Dam Removal – Klamath River Dams* (Detailed Plan) by Reclamation. In addition, KRRC has started an on-going stakeholder outreach process seeking input from potentially impacted recreation users, operators, managers and administrators, including Tribes, state and federal agencies, county agencies and chambers of commerce, local residents, recreation businesses, and public interest groups. This stakeholder outreach process will continue through the development of the Final Recreation Plan scheduled for completion in June of 2019.

The recreation opportunities identified in this plan are all presented at a programmatic or planning level of detail with some opportunities including more detail than others depending on their level development as a part of earlier studies or review by stakeholders. The descriptions presented in Sections 2.2 and 2.3 provide at a minimum, sufficient detail to give reviewers an indication of the specific type of recreation condition they will offset or improve, their general location, the source that identified the opportunity, and in the case of new facilities, their future potential owner/operator if known and in the cases of existing facilities their current owner/operator.

2.1.1 Detailed Plan

The 2011 Detailed Plan was developed by staff from the Bureau of Reclamation's Technical Services Center consistent with the requirements outlined in the 2010 KHSA to inform the Secretarial Determination process with details on the proposed physical methods for removal of the four lower PacifiCorp dams, including plans for waste disposal, reservoir drawdown, reservoir restoration, existing recreation facility modification or removal, and recreation impact mitigation.

The Detailed Plan identified multiple new recreation facilities and river access points for camping and hiking, and river access for boating and fishing along the river channel between J.C. Boyle Reservoir and Iron Gate Dam to replace the function of the existing facilities to be removed or modified due to reservoir drawdown; these new facilities are detailed in Section 2.2.

2.1.2 Stakeholder Outreach

KRRC initiated a stakeholder outreach process to seek input on the recreation opportunities previously identified during development of the 2011 Detailed Plan as well as support with the identification of new opportunities that had not previously been identified. This ongoing outreach effort has included coordination with California and Oregon state officials, Siskiyou County, Klamath County, the Bureau of Land Management (BLM), PacifiCorp, economic development organizations including chambers of commerce, tourism organizations, recreation businesses, local communities (e.g., Copco, Hornbrook), and the general public. Section 2.3 presents recreation opportunities identified during this outreach effort. Table 2-1 identifies the stakeholders that participated in this outreach effort.

KRRC will continue the stakeholder outreach process through the development of the Final Recreation Plan. KRRC will also work with regulators to determine any requirements for the final plan.

Table 2-1 Stakeholder Outreach Participants

Name	Name	Name
All-Outdoors	Hornbrook Residents[1]	Oregon Parks and Recreation Department
American Whitewater	Indigo Creek Outfitters[2]	PacifiCorp
Bruce Kinseth (R-Ranch)	Jack Trout[3]	Quartz Valley Indian Tribe
Bureau of Land Management	Jeff Stone	River Dancers
California Department of Fish and Wildlife	John Jacques (Klamathon Lodge)	Rogue Riverkeeper
California Natural Resources Agency	K. Bermel	Shasta Indian Nation
California Trout	Karuk Tribe	Shasta Nation
Carl and Linda Ebert (Copco Village Residents)	Klamath County Chamber of Commerce	Siskiyou Economic Development Council
Copco Village Residents[1]	Klamath County Economic Development	SWCA [4]
Discover Klamath	Momentum River Expeditions[2]	Trout Unlimited
Discover Siskiyou	Noah's Rafting Adventures[2]	
Fly Fishers International - Oregon Council	Oregon Fish and Wildlife	

Notes

1. Participants at public meetings held by KRRC in Copco Village and Hornbrook in June 2018 to seek input on recreation opportunities to be considered in the Recreation Plan
2. Member of the Upper Klamath Outfitters Association
3. Unaffiliated representatives from local (Klamath River Basin) recreational fishing industry
4. Consultant for Siskiyou County

The outreach effort also focused on the identification of evaluation criteria for these recreation opportunities to refine the list of opportunities identified for potential implementation by KRRC. The results of this feedback are described in greater detail in Section 3 of this plan.

2.2 Recreation Opportunities Identified in the Detailed Plan

This section presents descriptions of recreation features identified in the 2011 Detailed Plan. The Detailed Plan identified a list of potential recreation facilities and access areas that could be implemented under Mitigation Measure REC-1. These features were assumed to support cost estimates developed for the Detailed Plan. The Detailed Plan indicated that these opportunities were not assumed to be the only opportunities that would be considered. KRRC is presenting these opportunities from the Detailed Plan, along with stakeholder-suggested opportunities (see Section 2.3), as opportunities to consider in the development of the Final Recreation Plan. Like all opportunities presented in this draft, those described below will be subject to screening through the process described in Section 3.

Topsy Campground

Topsy Campground is an existing facility located on the southeastern shoreline of J.C. Boyle reservoir (shown on Figure 2-1 as Site 1). It is owned and operated by BLM. The Detailed Plan proposed modifications to accommodate river-based recreation as opposed to its current reservoir-based recreation use. This would include removal and replacement of the current boat ramp to support river access. In addition, the Detailed Plan proposed revegetation of the area around the existing campground. These modifications were identified to provide continued recreational access to the area for camping, hiking, boating, and fishing. BLM would continue to be the owner and operator of this modified facility. In addition to the proposed changes identified in the Detailed Plan, BLM suggested during initial stakeholder outreach completed during the development of this draft Recreation Plan that new camping areas and restrooms be developed next to the new water's edge. Development of additional campsites and parking would provide additional opportunities for camping, fishing, and hiking in this reach. The Detailed Plan proposed completion of these modifications for the year following dam removal and reservoir/river restoration.

Fall Creek Day Use Area

Fall Creek Day Use Area is an existing facility located on the far northeast shore of Iron Gate Reservoir (shown on Figure 2-1 as Site 14). The facility is currently owned and operated by PacifiCorp on Parcel B land. The Detailed Plan proposed that the site be retained and modified to support day use activities and hiking at Fall Creek. Upgrades identified in the plan included the reconstruction of the trail leading to the waterfall and other upgrades to support continued and improved recreational access in the area. The future owner and operator of the Fall Creek Facility is unknown. The Detailed Plan proposed completion of these modifications for the year following dam removal and reservoir/river restoration.

In addition to PacifiCorp's continued operations at Fall Creek, the Project includes development in close proximity to Fall Creek Day Use Area, including the Fall Creek Hatchery and changes to the Yreka water supply line. The area may become unsupportive of additional recreation opportunities.

Jenny Creek Day Use Area and Campground

The existing recreation site at Jenny Creek is located on the northern shoreline of Iron Gate Reservoir, between Copco Road and Jenny Creek (shown on Figure 2-1 as Site 15). This facility includes six campsite/day use sites and several user-defined trails. The Jenny Creek facilities are currently owned and operated by PacifiCorp on Parcel B land. The Detailed Plan proposed the site be expanded and upgraded to accommodate additional campsites and improved amenities. These modifications and upgrades to the Jenny Creek Day Use Area and Campground were proposed to increase recreation activities such as camping, hiking, and fishing at this location. The future owner and operator of the Jenny Creek Facility is unknown. The Detailed Plan proposed completion of these modifications for the year following dam removal and reservoir/river restoration.

Iron Gate Hatchery Day Use Area

The Iron Gate Hatchery Day Use Area is located just downstream of Iron Gate Dam, adjacent to Iron Gate Fish Hatchery (shown on Figure 2-1 as Site 16). The day use site is owned by PacifiCorp on Parcel B land and operated by California Fish and Wildlife (CDFW). The facility currently includes a covered picnic area, a visitor center/interpretive kiosk, and an ADA-accessible to the river shoreline. There is also a boat launch on the river shoreline across from the hatchery. The Detail Plan proposed that the site be retained and modified to provide additional facilities and a reconstructed boat ramp to support continued and improved recreational access in the area. The KHSA includes funding by PacifiCorp for the continued operation of the Iron Gate Fish Hatchery by CDFW for up to 8 years following facility removal, this included the transfer of ownership of the facility to CDFW. Future ownership and plans for operation of the recreation facilities at the Iron Gate Hatchery Day Use Area following facilities removal are however unknown. The Detailed Plan proposed completion of these modifications for the year following dam removal and reservoir/river restoration.

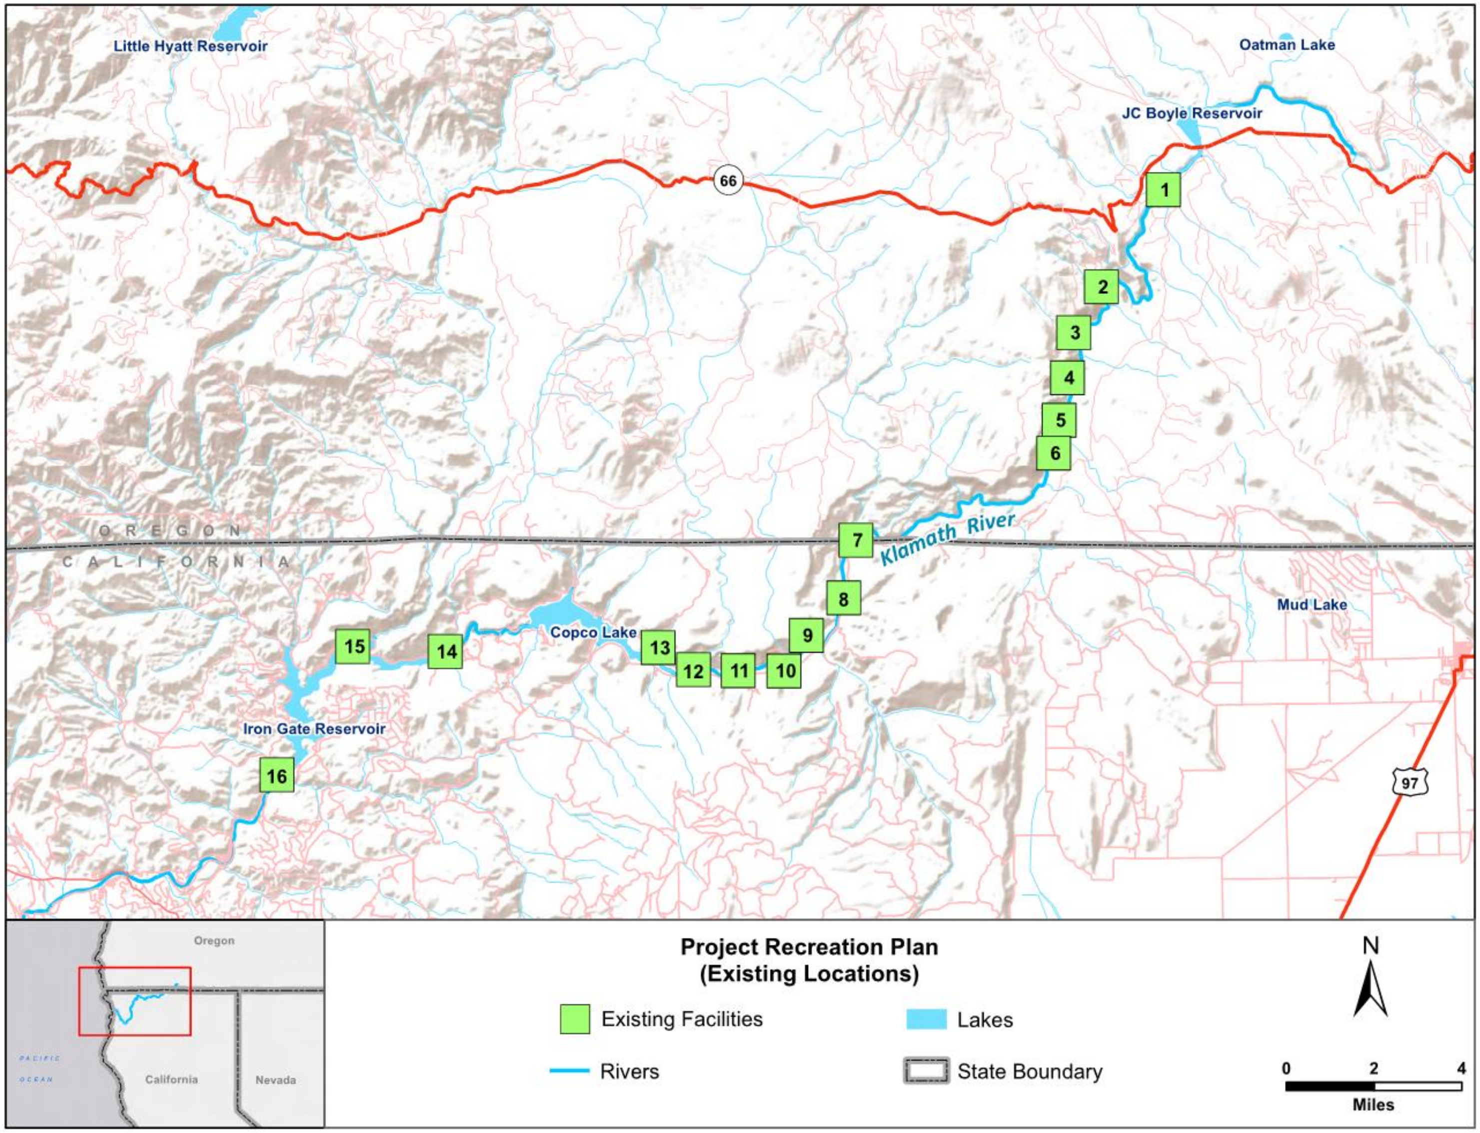

Figure 2-1 Existing Recreation Facility Locations That Could Be Retained or Modified

New Campgrounds

Two small to medium campgrounds were identified for development in the Detailed Plan. These campgrounds would accommodate a total of 20 campsites and include parking, day use facilities and a boat launch. If implemented, these newly developed campgrounds would provide river access, parking, day use amenities, essentially offsetting the loss of campgrounds at other locations post-dam removal. The specific location of these facilities was not identified in the Detailed Plan. The future owner and operator of these facilities is also unknown. The Detailed Plan proposed completion of these developments for the year following dam removal and reservoir/river restoration.

New Routes and Roads

The Detailed Plan identified as a potential recreation opportunity, the development of two potential routes/roads, with one route on each side of the river to provide public recreation access to existing and newly developed facilities on the river. These routes would be developed in coordination with the appropriate federal, state, and local agencies along with any private landowners because of their need to cross land held by multiple owners. These new roadways were identified in the Detailed Plan as permanent features. These roads were proposed in the Detailed Plan given their potential to improve access for recreational uses as well as improve law enforcement's ability to police the area. The specific configuration/layout of these proposed roadways was not provided in the Detailed Plan and no proposed owner/operator for the roadways was identified. The Detailed Plan proposed development of these new roadways would be incorporated into the overall reservoir/river restoration design as appropriate to complement its success.

Non-motorized Trail

The Detailed Plan also identified as a potential recreation opportunity, the development of a new non-motorized trail to provide fishing, biking, and hiking access along the river bank from the current J.C. Boyle dam site to Iron Gate Fish Hatchery. This new trail would be developed in coordination with the appropriate federal, state, and local agencies along with any private landowners because of its need to cross land held by multiple owners. This new trail was identified in the Detailed Plan as a permanent feature. The specific configuration/layout of this new trail was not provided in the Detailed Plan and no proposed owner/operator for the trail was identified. This trail would be developed in a way to be connected to any existing and developed recreation facilities developed as part of the Final Recreation Plan or in coordination with other regional efforts. The Detailed Plan proposed completion of this new trail for the year following dam removal and reservoir/river restoration.

2.3 Recreation Opportunities Identified through Stakeholder Outreach

This section presents descriptions of the recreation features identified during the initial stakeholder outreach effort described above in Section 2.1.2. The recreation opportunities identified during this process varied in levels of detail depending on what was provided by the stakeholders at the outreach meetings they participated in and in some cases in follow up submittals provided to KRRC in writing. In some cases, stakeholders identified opportunities that had already been evaluated as a part of the Detailed Plan effort described above in Section 2.2, those opportunities are not described again in this section. The opportunities identified ranged from the establishment of additional river access points, the funding of tourism campaigns, promoting regional recreation, and the development of commercial recreation establishments on the river. Suggestions were made the retention and/or improvement of existing facilities as well as the development of new facilities. KRRC is presenting these opportunities, along with those included in the Detailed Plan (see Section 2.2), as opportunities to consider in the development of the Final Recreation Plan. Like all opportunities presented in this draft, those described below would be subject to screening through the evaluation process described in Section 3.

2.3.1 Existing Facilities

Stakeholders suggested several potential recreation opportunities and features that could be developed at existing recreation sites in the project area that were not proposed for modification in the Detailed Plan.

Spring Island Boater Access

Spring Island Boater Access is located downstream of J.C. Boyle (shown on Figure 2-1 as Site 2). This site is owned and operated by BLM. The facility currently provides river access for boating. Stakeholders requested that the site be retained and enhanced to improve the site's conditions, if possible. Suggested enhancements could include an improved boat launch, access road, day use area, and/or restrooms and additional parking. Stakeholders indicated that Spring Island Boater Access is important to boaters as a location that would break up the whitewater rafting run upstream and downstream of the point where a clear shift in difficulty would occur. Retention of this site would allow the continued use of an established boater access site. BLM would continue to be the owner and operator of the access. If included in the Final Recreation Plan, completion of any enhancements to the site would be scheduled for the year following facility removal and reservoir/river restoration.

Campground South of J.C. Boyle Powerhouse

Stakeholders requested a campground be developed south of J.C. Boyle Powerhouse or enhancements be made to the campgrounds at one of the three existing river-side campgrounds operated by BLM (BLM Dispersed Site 1, Klamath River Campground, and Turtle Camp shown on Figure 2-1 as Sites 3, 4, 5). Klamath River Campground and Turtle Camp currently allow campfires and access for kayaks and small rafts. These existing sites could be enhanced to include defined campsites and improved boat launches, access roads, day use facilities, and/or restrooms. Enhancements to these sites or the development of a new site that would provide improved river access and river-side camping would provide additional opportunities for camping, boating, and hiking in this reach. BLM would continue to be the owner and operator of this modified facility. If included in the Final Recreation Plan, completion of these modifications would be scheduled for the year following facility removal and reservoir/river restoration.

Klamath River Campground and Turtle Camp

Klamath River Campground and Turtle Camp, shown on Figure 2-1 as Sites 4 and 5, are located south of J.C. Boyle Powerhouse. Klamath River Campground and Turtle Camp currently allow campfires and access for kayaks and small rafts. The sites are owned and operated by BLM. BLM suggested KRRC increase the number of camping sites and provide additional day use parking to accommodate additional users. Improvements to Copco Big Bend Road would be necessary. Development of additional campsites and parking would provide additional opportunities for camping, fishing, and hiking in this reach. BLM would continue to be the owner and operator of this modified facility. If included in the Final Recreation Plan, completion of these modifications would be scheduled for the year following facility removal and reservoir/river restoration.

Frain Ranch Campground

Frain Ranch is an existing dispersed recreation area and undeveloped campground in Oregon located between J.C. Boyle Reservoir and Copco (shown on Figure 2-1 as Site 6). Ownership of the land is divided between PacifiCorp (Parcel A) and BLM and is operated by the BLM. This site is mainly used by boaters, campers, and ATV users. Stakeholders requested that the site be enhanced to provide a developed campground on lands owned by the BLM with defined campsites, restrooms, picnic tables, and fire rings. Development at this site would require improvements to Topsy Grade Road, the main access road for the site. These enhancements were identified to provide additional opportunities for camping, boating, and hiking. BLM would continue to be the owner and operator of this modified facility. The entity responsible for long-term maintenance of the improved road has not yet been identified. If included in the Final Recreation Plan, completion of these modifications would be scheduled for the year following facility removal and reservoir/river restoration.

Stateline Boater Takeout

Stateline Boater Takeout is located between J.C. Boyle Reservoir and Copco Lake (shown on Figure 2-1 as Site 7), just below the state line. Ownership of the lands at this site is divided between BLM and PacifiCorp (Parcel A) and the site is currently operated by the BLM. Stakeholders requested that the site be retained and modified to allow future boating access and shoreline fishing. The portion of this access point owned by PacifiCorp is on Parcel A property, which would generally be retained by PacifiCorp after license surrender; however, the future ownership of this property is unknown. To improve river access following facility removal, stakeholders suggested the portion of the access point on BLM property could be upgraded to support additional use. Retention of and enhancements at this facility would allow the continued use of a recreation facility that offers river access for boating, fishing, and day use. BLM would continue to be the owner and operator of the modified facility. Completion of these modifications would be scheduled for the year following facility removal and reservoir/river restoration.

PacifiCorp Fishing Access Sites 1 through 6

PacifiCorp Fishing Access Sites 1-6 are located just upstream of Copco Lake (shown on Figure 2-1 as Sites 8 through 13). These sites are owned and operated by PacifiCorp (Parcel A), but they are not part of the FERC license for the hydroelectric developments. The facilities currently provide river access for fishing (and rafting at sites #1 and #6) along with some amenities for users. Stakeholders requested that access to these sites be maintained and if possible improved. PacifiCorp will retain ownership of these sites following license surrender for the hydroelectric developments and public access will no longer be available. It is unknown whether these sites would be sold to another entity or whether public access agreements could be granted in the future by PacifiCorp. If it is possible to maintain or enhance these sites, they could continue to provide river access for recreational fishing and boating uses. If included in the Final Recreation Plan, completion of any modifications at these sites would be scheduled for the year following facility removal and reservoir/river restoration.

R-Ranch

R-Ranch is located downstream of Iron Gate Reservoir in Hornbrook, California. The ranch currently supports camping, dirt bike and ATV riding, fishing, hiking, hunting, swimming, and horseback riding. Stakeholders suggested the ranch be expanded or enhanced to provide additional recreation opportunities. This expansion could include the development of a waterpark or similar attraction. R-Ranch is privately owned and operated. Future ownership and operations would remain unchanged. An expansion of R-Ranch would provide additional recreation, potentially reducing the impact from the loss of reservoir recreation. If included in the Final Recreation Plan, completion of any enhancements at R-Ranch would be scheduled for the year following facility removal and reservoir/river restoration.

2.3.2 New Facilities and Plans

This section presents descriptions of recreation opportunities stakeholders identified during outreach that were not directly linked to the retention of an existing facility.

Fishing Access Upstream of J.C. Boyle Powerhouse

Fishing access could be provided along the river approximately one mile upstream of the J.C. Boyle Powerhouse. The specific location of this access site was not however identified by the stakeholders that suggested it as a recreation opportunity for consideration. Currently, there is no trail next to river in this area, but there is the power canal access road that runs parallel to the river that could be connected to this new site. If the power canal access road would be closed to vehicles after dam removal, it could be converted to a trail and used for river access in this area. This new feature would provide river access for recreation uses such as fishing and walking. The future owner and operator of this facility is unknown. If included in the Final

Recreation Plan, completion of the development of these facilities would be scheduled for the year following facility removal/ river restoration.

Day Use and River Access at J.C. Boyle Powerhouse

Stakeholders recommended consideration of day use site to provide river access at the J.C. Boyle Powerhouse. The land directly surrounding J.C. Boyle Powerhouse and substation has been identified by stakeholders as a large and flat area that could serve as an effective location for a day use facility and/or campground. This land is currently owned by BLM, and BLM would continue to own the land following facilities removal and could potentially operate any new recreational facilities developed on this land. Development of a recreation facility at this site could increase recreational use and provide additional river access for hiking, fishing, and boating. If included in the Final Recreation Plan, completion of the development of these facilities would be scheduled for the year following facility removal/ river restoration.

New River Access Locations

Multiple whitewater rafting access locations were suggested by stakeholders between Keno Dam and the Iron Gate Hatchery. These locations were chosen based on known or expected changes in river conditions (rafting difficulty levels) and are shown in Figure 2-2. The site numbers identified for each access point in Figure 2-2 correspond to the site numbers listed for the descriptions of each access point presented in Table 2-2. Some of the locations identified were recommended for development prior to dam deconstruction to allow the continued use of existing river runs and to reduce the loss of boating access during dam decommissioning. No boating access will be allowed in the reservoirs themselves during drawdown and dam removal because conditions will constantly be changing, and it will be too risky to allow boating in the former reservoir areas due to the operation of the diversion facilities (e.g., large gates and tunnels at the dams) as well as the potential for mass movements of reservoir sediment into the river. Non-reservoir portions of the Klamath River system will remain accessible to boating during drawdown and dam removal. If included in the Final Recreation Plan, development of these pre-construction access sites needed during drawdown and dam decommissioning would need to be located outside of the existing reservoir footprints and scheduled for completion prior to the initiation of reservoir drawdown. The future owner and operator of these facilities is unknown. If included in the Final Recreation Plan, the remaining access sites would be completed the year following facility removal and reservoir/river restoration.

Table 2-2 Stakeholder Suggested Whitewater Rafting Access Points

Site ID	Location	Proposed Recreation Development
17	Keno Dam	Proposed access on river left. There is no existing facility for the run from Keno to J.C. Boyle. This would provide an additional river access point.
18	Highway 66 Bridge Crossing	Proposed access on river left. The current reservoir boat ramp could become a good location for rafting access point. This point could serve as a take-out for the Keno run and a put-in for the reach currently under J.C. Boyle Reservoir that would become available after dam removal.

Site ID	Location	Proposed Recreation Development
1*	Below J.C. Boyle Dam	Proposed on river left. Would serve as a put-in for the Boyle Bypass run during dam removal and future take-out for the extended Keno run post dam removal. Depending on river conditions post drawdown, this site might be exchangeable with access at Topsy Campground (if Topsy Campground is retained).
2	Spring Island Boater Access	Existing boater access site suggested for retention. This site is important to boaters as a location that breaks up the runs at a point where the difficulty changes. If this point is retained there would not be a need for a point at the J.C. Boyle Powerhouse.
19	Above Caldera	Proposed on river right, opposite to Frain Ranch. This would serve as an important location for rafters as the run changes from a class 3 to a class 4. The location opposite to the existing access site at Frain Ranch would provide boaters the opportunity to run the J.C. Boyle run and have shuttle access on the south side of the river. Currently boaters can only be shuttled on the north side, which restricts accessibility and reduces potential recreation use. This location would serve as a take-out for the J.C. Boyle Bypass run or put-in for Hell's Corner gorge. There is an existing road on the west side of the river that goes down to Caldera that could serve as an access road for this point.
7	Stateline Boater Takeout	Existing boater access site suggested for retention.
8	PacifiCorp Fishing Access Site 6	Existing boater access site suggested for retention. As noted above, this site is located on PacifiCorp Parcel A lands. Ability to obtain for future public access is uncertain.
13	PacifiCorp Fishing Access Site 1	Existing boater access site suggested for retention. As noted above, this site is located on PacifiCorp Parcel A lands. Ability to obtain for future public access is uncertain.
20	Above Copco 1 Dam	Proposed on river right. This point would serve as a take-out for the run currently under Copco Lake and a future put-in for the Copco 2 Bypass (Ward's Canyon) and Iron Gate runs. This area is anticipated to break up a Class 2 run (run under Copco Lake) and a Class 4 run (Ward's Canyon).
21	Copco 2 Dam (Ward's Canyon)	Proposed on river right, approximately 1,500 feet downstream of Copco 1 Dam. During drawdown and dam decommissioning activities, stakeholders indicated that this point could serve as an important access site for boaters, providing a put-in for the Ward's Canyon run. Given this facility's close proximity to Copco 1 Dam it would be located in an active construction area during dam removal. Stakeholders requested limited access to this site on a schedule coordinated with KRRC and contractors on-site. After dam removal has been completed, the site would serve as a put-in for the Iron Gate run. There is an existing dirt road that could provide access to this site.
22	Copco 2 Powerhouse	Proposed on river left. This site would serve as a take-out for the Ward's Canyon run or a put-in for the future Iron Gate run. It would represent a break in runs where there is a shift in difficulty.
14	Fall Creek	Proposed on river right. This point could serve as a take-out for upstream runs and a put-in for the run currently under Iron Gate Dam.
15	Jenny Creek Confluence	Proposed on river right. Stakeholders indicated that this site could allow boating during drawdown and serve as a take-out for the upper portion of the run currently under Iron Gate Reservoir and a future put-in for runs to Iron Gate and beyond. This site is interchangeable with the Camp Creek Confluence location.

Site ID	Location	Proposed Recreation Development
23	Camp Creek Confluence	Proposed on river right. Stakeholders indicated that this site could allow boating during drawdown and serve as a take-out for the upper portion of the run currently under Iron Gate Reservoir and a future put-in for runs to Iron Gate and beyond. This site is interchangeable with the Jenny Creek Confluence location, but may be a better location, based on bathymetry and pre-dam topographic maps.
16	Iron Gate Hatchery	Existing boater access site suggested for retention. Improvements to the existing facilities offered at Iron Gate Hatchery could provide needed access for boaters and serve as a take-out for the future Iron Gate run following dam removal.

*This site was proposed to be placed in close proximity to the existing Topsy Campground and is therefore represented in Figure 2-2 as site 1, Topsy Campground.

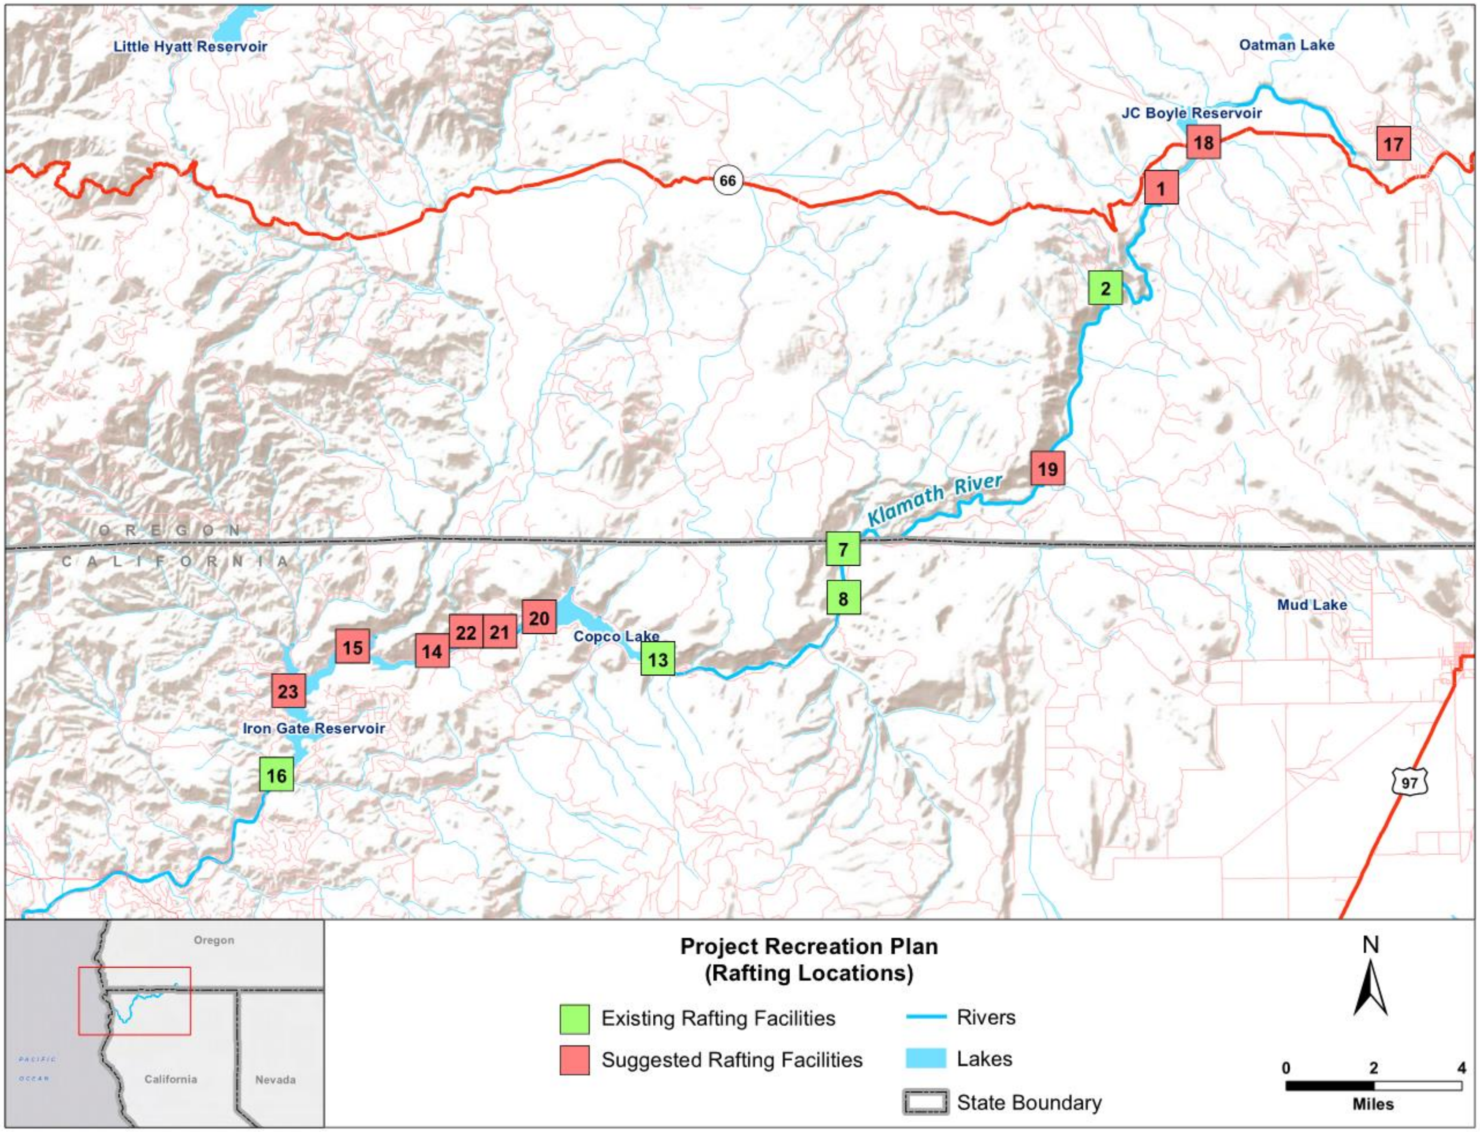

Figure 2-2 Potential Proposed River Access Sites

Copco 2 Bypass Reach

Stakeholders identified riparian vegetation that has grown into the historic river channel in the Copco 2 bypass reach due to low flows as a substantial safety hazard for future water-based recreation in that stretch of the river. The stakeholders indicated that the complete removal of this woody vegetation in the historic river channel prior to facilities removal would be most efficient to avoid complications generated by with vegetation removal attempted after the reach is inundated. Vegetation removal would make the reach navigable for boaters, providing an additional whitewater rafting run that would increase recreational boating use in the restored river. If included in the Final Recreation Plan, completion of vegetation removal would be scheduled for the year prior to reservoir drawdown.

Road Improvement

Stakeholders suggested that improvements could be made to some of the existing roadways that provide access to the Klamath River. The stakeholders indicated that many of the existing access roads in the area between Keno Dam and Iron Gate Dam are in need of improvement and long-term maintenance. Some of the roads have become unnavigable and inadequate for use to access recreation facilities. These poor road conditions also contribute to difficulties experienced by law enforcement personnel that need to access these areas. Stakeholders proposed that improvements be made to existing roads, such as Topsy Grade Road and Copco Big Bend Road, to improve accessibility and policing which could result in increased recreational use in the area. Specific stretches of roadways that need improvements have not been determined. It is assumed that roadways would continue to be owned and maintained by their current owners following any improvements. If included in the Final Recreation Plan, completion of roadway construction would be scheduled for the year following facility removal and reservoir/river restoration.

Access During Deconstruction

Stakeholders suggested that, where possible, access to roads currently used for river access be retained during the drawdown and deconstruction periods. These roads include but are not limited to the access road leading to J.C. Boyle Powerhouse and the dirt road near Copco 2 Dam, on river right. Road access could involve placing a flagger in established areas to direct traffic or establishing time intervals during which roads could be made open to the public. Providing road access that allows continued use for boaters and whitewater rafters during construction periods would reduce the impact made to boating in the Hell's Corner Reach during this time. Access requests would be coordinated with the contractor responsible for dam deconstruction activities. The terms of the access agreement would be determined and shared prior to facility removal and reservoir/river restoration.

Frain Ranch Bridge

Stakeholders suggested that a new bridge could be constructed to replace an old bridge that crossed the Klamath River at Frain Ranch. Reconstruction of this bridge would provide a point of access to either side of the river, increasing accessibility and recreational use in the area. The future owner and operator responsible for maintenance at the new bridge is unknown. If included in the Final Recreation Plan, completion of bridge reconstruction would be scheduled for the year following facility removal and reservoir/river restoration.

RV Park in Seiad Valley or Happy Camp

A RV park with full hookups and amenities to be developed in Seiad Valley or Happy Camp was identified as a potential recreation opportunity by stakeholders. The RV park could generate revenue and tourism within the county, potentially offsetting lost tax revenue due to dam removal. The location of this park and its proposed owner and operator were not identified. If included in the Final Recreation Plan, completion of the development of the RV park would be scheduled for the year following facility removal.

Walking Trails/Wildlife Viewing/ Interpretive Trails

The development of educational recreational use sites and interpretative exhibits in the area was identified by stakeholders as a potential recreation opportunity. It was suggested that instead of full removal of dam infrastructure, some infrastructure (e.g., fish ladders, powerhouses, etc.) could be retained and signage added to promote educational tourism. Trails could be developed and routed to take recreational users through or by some of these remaining structures (preferably those with historic backgrounds). Signage promoting wildlife viewing could also be provided along these trails.

Locations for these trails have not yet been determined but could include areas around Copco residential areas or in the reservoir footprints of JC Boyle, Copco, and Iron Gate reservoirs. Development of recreational activities close to residential areas at Copco could provide residents with beneficial uses to offset the loss of reservoir-based recreation opportunities. Interpretative trails could provide additional recreational uses and opportunities for walking and tourism and as well as utilize local services. Future owners and operators of the remaining infrastructure were not identified. If included in the Final Recreation Plan, completion of the proposed trails and educational sites would be scheduled for the year following facility removal and reservoir/river restoration.

Flatwater Recreation in Siskiyou County

New or enhanced day use and/or camping sites could be developed in Siskiyou County to replace lost flatwater recreation opportunities. Locations have not yet been determined but could include the enhancement of existing recreation facilities and/or the development of new facilities at Lake Shastina or Medicine Lake. Specific amenities that would be available at these sites were not specified. The future owner and operator of these facilities is unknown. The development of additional day use and/or camping sites could promote recreational use and potentially offset lost flatwater recreation opportunities due to facility removal. If included in the Final Recreation Plan, completion of the development of these facilities would be scheduled for the year following facility removal.

Fishing Access Upstream or Downstream of J.C. Boyle Powerhouse

Fishing access sites could be developed upstream or downstream of J.C. Boyle Powerhouse in the J.C. Boyle Powerhouse footprint and in the bypass reach. Stakeholders did not identify specific locations for these new access sites. With the removal of dam facilities an increase in steelhead fish is expected in this reach of the river. Development of fishing access sites in this area would promote increased fishing activity and recreational use in the hydroelectric reach. The future owner and operator of these facilities is unknown. If included in the Final Recreation Plan, completion of development of these access sites would be scheduled for the year following facility removal/ river restoration.

Whitewater Park

Stakeholders identified the development of an in-river or off-river whitewater park along the river as a potential facility that could help offset whitewater rafting impacts in the Hell's Corner Reach by facilities removal. The proposed facility could be established by diverting from the river to provide whitewater conditions for recreational users to practice whitewater boating. The site could include day use areas and various amenities. A whitewater park would provide additional recreational opportunities for boating and could be a newly established tourist attraction, which could provide economic benefits for the county. The location of this park has not yet been determined. The future owner and operator is also unknown. Initiation of construction of the whitewater park would be scheduled for the year following facility removal alongside ongoing river restoration activities.

Recreational Gold Mining

Recreational gold panning opportunities could be established in areas on the river in Siskiyou County where users could participate in the county's history and culture. Specific locations where gold panning might be supported have not yet been determined. These locations could provide interpretative signage for the activity, including information on the history of gold mining in the county. Stakeholders indicated that the establishment of gold panning opportunities along the river could attract tourists and contribute to recreational use and available activities in the area. The future owner and operator of these facilities is unknown. If included in the Final Recreation Plan, development of these access points would be scheduled for the year following facility removal/river restoration.

New ADA Facilities

The Detailed Plan identified Camp Creek as an existing facility that would be removed after dam removal. Camp Creek is one of the few ADA recreation facilities in Siskiyou County. The Detailed Plan proposed that at least one of the recreation facilities retained along the Klamath River between J.C. Boyle Dam and Iron Gate Dam be upgraded to an ADA facility to offset this lost facility. Stakeholders noted during outreach meetings that shifting demographics for recreational users in the area could warrant the development additional ADA-accessible facilities. These facilities could include, but are not limited to, fishing access sites, boat ramps, and restrooms. The specific location of this replacement facility was not determined in the Detailed Plan. The future owner and operator of this facility is unknown. If included in the Final Recreation Plan, development of the proposed facility would be scheduled for the year following facility removal and reservoir/river restoration.

Fishing Lodges

Stakeholders identified the development of two to five public fishing lodges to support fly fishing tourism along the hydroelectric reach as a recreation opportunity that should be considered. The fish lodges could provide year-round guided drift boat fishing, both fly and conventional fishing, for salmon, steelhead, and trout. Locations have not yet been determined but could be developed on Parcel B lands. Stakeholders suggested that these fishing lodges could be owned and operated under public/private partnerships, but the specific future owners and operators of these developments were not identified. Fees for facility use may be collected, but exclusive membership would not be permitted, and open access would be required. Fishing lodges could provide additional fishing access, increase recreational use in the area, additional jobs, and serve as a revenue generator to help offset lost tax revenue resulting from facilities removal. If included in the Final Recreation Plan, completion of development of these facilities would be scheduled for the year following facility removal and reservoir/river restoration.

River-side Commercial Recreational Development

Stakeholders suggested that commercial recreation facilities that could support recreational tourism could be developed on the river in the hydroelectric reach. The types of recreational uses for these developments were not specified. Potential locations were also not identified but facilities could be developed on Parcel B lands adjacent to the river. Similar to the fishing lodges described above, stakeholders suggested that these commercial developments could be owned and operated under public/private partnerships, but the specific future owners and operators of these developments were not identified. Fees for facility use may be collected, but exclusive membership would not be permitted, and open access would be required. River-side commercial recreation development could provide additional recreation opportunities such as fishing, hiking, boating, among other opportunities, as well as serve as a revenue generator to help offset lost tax revenue due to facilities removal. If included in the Final Recreation Plan, completion of development of these facilities would be scheduled for the year following facility removal and reservoir/river restoration.

Siskiyou Tourism Plan

The Siskiyou County County-wide Tourism Marketing Plan (Siskiyou Tourism Plan) includes a variety of ideas intended to promote tourism within the county by reaching a broader audience. Stakeholders proposed that some elements in the Siskiyou Tourism Plan be implemented as part of the Final Recreation Plan. The Siskiyou Tourism Plan highlights a lack of available tourism promotion funding, which poses a significant challenge for the county. Through either direct funding or partnering to develop destination awareness for attractions and outdoor recreation opportunities within the county, this recreation opportunity could promote continued recreational uses such as hiking, fishing, hunting, biking, and boating which could help reduce the loss of recreation use due to reservoir removal. If included in the Final Recreation Plan, implementation of this plan could be scheduled to coincide with facility removal and continue for an undetermined period following completion of river and reservoir restoration.

Upgrade Private Campgrounds

Numerous private campgrounds were identified in the region by stakeholders as being important recreational resources. These facilities are owned and operated by a variety of private owners and operators. Modifications and/or upgrades to these facilities were suggested by stakeholders as a way to provide continued and improved recreational use in the area. The future owner and operator of these sites would be the current owners and operators. If included in the Final Recreation Plan, completion of the upgrades proposed to these sites would be scheduled for the year following facility removal/ river restoration.

Transportation Plan

Development of a Transportation Plan that identifies appropriate roads and trails that could provide access to existing and newly developed recreation facilities was identified by stakeholders as important for planning potential recreation facilities and road improvements. Stakeholders suggested that the plan also identify which lands the roads cross and the entity or entities with current and future responsibility for road maintenance. The Transportation Plan would help inform the identification of new access routes for development in the future along with potential existing roadways that could be repurposed for trail use. The timeline for the plan was not specified. If included in the Final Recreation Plan, efforts developing the plan could begin prior to reservoir drawdown.

Enhance Private Docks

Several homeowners use private docks to access the Klamath River for fishing. Stakeholders from the Copco Village community suggested these private docks be extended to the newly formed river. The extension of private docks post dam removal would provide continued access for residents. If included in the Final Recreation Plan, completion of these modifications would be scheduled for the year following facility removal and reservoir/river restoration.

Klamath Hot Springs

Stakeholders suggested that a recreation facility near the historic Klamath Hot Springs Resort could be developed as commercial recreation facility. Development of a structure with restrooms and shelter for visitors could increase access to the existing hot springs near Shovel Creek. The potential future owner and operator of this facility was not identified. If included in the Final Recreation Plan, completion of the development of this facility would be scheduled for the year following facility removal and reservoir/river restoration.

2.4 Summary of Identified Recreation Opportunities

Table 2-3 presents a summary of the recreation opportunities identified including details on the location, current and future ownership if known, and where the opportunity was identified.

Table 2-3 Identified Recreation Opportunities

Site ID	Feature	Proposed Recreation Development	Current Owner/Operator	Origin
1	Topsy Campground	Replace or redesign boat ramp for river access and revegetate the reservoir rim in the vicinity of the campground	Owned and operated by BLM on J.C. Boyle Reservoir	Detailed Plan
14	Fall Creek Day Use Area	Upgrade facilities and reconstruct trail leading to Fall Creek waterfall	Owned/operated by PacifiCorp (Parcel B); located on Copco Road which is maintained by PacifiCorp	Detailed Plan
15	Jenny Creek Campground	Expand campground and upgrade facilities to provide Jenny Creek and Klamath River recreation	Owned/operated by PacifiCorp (Parcel B) on the edge of Iron Gate Reservoir	Detailed Plan
16	Iron Gate Hatchery Day Use Area	Reconstruct day use site to provide additional facilities and a boat ramp	Owned by PacifiCorp (Parcel B) and operated by CDFW	Detailed Plan
--	New Campgrounds	Two small to medium campgrounds in TBD location	N/A	Detailed Plan
--	New Routes/Roads	Provide routes on each side of the river that could be retained permanently to provide public recreation access to the river at defined locations	N/A	Detailed Plan
--	Non-motorized Trail	Construct trail to provide fisherman, biking, and hiking access from JC Boyle dam site to Iron Gate fish hatchery	New trail would need to cross PacifiCorp (Parcel A and B), BLM, private lands and potentially USFS land	Detailed Plan
2	Spring Island Boater Access	Retain/Enhance existing Spring Island boater put in below JC Boyle Powerhouse on the Klamath River and provide additional parking	BLM owns land	American Whitewater and BLM
3, 4, 5	Campground South of JC Boyle Powerhouse	Enhance and develop a new campground near JC Boyle Powerhouse; Klamath River Campground (primitive), Dispersed Site 1 and Turtle Camp could be modified or improved	BLM operates Klamath River campground (primitive), Dispersed Site 1 and Turtle Camp	American Whitewater

Site ID	Feature	Proposed Recreation Development	Current Owner/Operator	Origin
6	Frain Ranch Campground	Enhance and develop campground and improve Topsy Grade Road to Frain Ranch; Frain Ranch is a dispersed recreation site used by boaters and campers	Operated by BLM on PacifiCorp (Parcel A) land between Copco and JC Boyle Powerhouse	American Whitewater
8 through 13	PacifiCorp Fishing Access Sites 1 through 6	Maintain or enhance fishing access sites on Parcel A land between Copco Lake and Stateline. Sites include signage, porta-johns, and trash receptacles	Owned/operated by PacifiCorp (Parcel A); these sites are part of the FERC Lower Klamath Project definition	American Whitewater & Fishing Interests
7	Stateline Boater Takeout	Retain/enhance existing boater takeout on the river at Stateline to accommodate multiple parties in the take-out area and provide additional camp sites	Operated by BLM on PacifiCorp (Parcel A) land	American Whitewater and BLM
--	Fishing Access Upstream of J.C. Boyle Powerhouse	Provide fishing access along the river near the powerhouse approximately 1 mile up stream	BLM owns land	BLM
--	Day Use and River Access at J.C. Boyle	Provide recreational use/access in the large flat area on the river by the powerhouse and substation	BLM owns land	BLM
1, 2, 7, 8, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23	New River Access Locations	Develop river boating access with amenities (restrooms, road access, parking) in areas where the difficulty of river navigation changes	BLM and PacifiCorp-owned land (Parcel A and B)	American Whitewater
--	Copco 2 Bypass Reach	Remove riverine vegetation to provide safe boating thoroughfare in the Copco bypass reach	Owned and operated by PacifiCorp (Parcel B)	American Whitewater
--	Road Improvement	Improvements to the existing roads, including but not limited to Topsy Grade Road and Copco Big Bend Road	Various	Multiple stakeholders

Site ID	Feature	Proposed Recreation Development	Current Owner/Operator	Origin
--	Access During Construction	Provide access to roads that lead to river access for boaters to use during drawdown and deconstruction periods. Access could be granted by flagger or established time intervals for public use.	N/A	Upper Klamath Outfitters Association and American Whitewater
--	Frain Ranch Bridge	Construct a replacement bridge that crosses the Klamath River at Frain Ranch to provide continuous access to both side of the river	N/A	BLM
--	RV Park in Seiad Valley or Happy Camp	Develop an RV park with full hookups that would be generate revenue and tourism	N/A	SWCA[1]
--	Walking Trails / Wildlife Viewing / Interpretive Trails	Retain portions of the dam structures, provide interpretive signage, and develop a walking trail around it. Trails could also incorporate wildlife viewing. Construct trails around Copco Village residential areas to provide recreation opportunities for residents.	PacifiCorp-owned land (Parcel B)	SWCA[1]
--	Flatwater Recreation in Siskiyou County	Develop day use and/or camping sites in TBD locations for public recreational use to replace lost flatwater recreation opportunities. Locations could include Lake Shastina and Medicine Lake.	N/A	SWCA[1]
--	Fishing Access Upstream or Downstream of J.C. Boyle Powerhouse	Develop fishing access sites in the J.C. Boyle Powerhouse footprint and in the bypass reach	BLM and PacifiCorp-owned land (Parcel A and B)	BLM and ODFW
--	Whitewater Park	Develop an in-river or off-river whitewater park	N/A	SWCA[1]

Site ID	Feature	Proposed Recreation Development	Current Owner/Operator	Origin
--	Recreational Gold Mining	Establish gold panning recreation opportunities in Siskiyou County	N/A	SWCA[1]
--	New ADA Facility	Provide at least one ADA facility to retain the current ratio of ADA opportunities in the area.	N/A	Detailed Plan, SWCA[1], Oregon Council, Copco Village Residents
--	Fishing Lodges	Provide up to five public fishing lodges that could support fly fishing tourism along the current hydroelectric reach. These could be developed on Parcel B land under public/private ownership	N/A	John Jacques
--	River-side Commercial Recreation Development	Develop commercial recreation uses at points along the river.	N/A	John Jacques
--	Siskiyou Tourism Plan	Provide funding to establish a tourism campaign that would point people to other recreation facilities within Siskiyou County. This could include strategically placed signage.	N/A	SWCA[1], Siskiyou Economic Development Council / Discover Siskiyou
--	Upgrade Private Campgrounds	Improve existing private campgrounds in the area	Unidentified private owners	Siskiyou Economic Development Council / Discover Siskiyou
--	Transportation Plan	Develop a transportation plan that identifies appropriate roads and trails that could provide access to recreation facilities	N/A	BLM
--	Expand R-Ranch	Expand the recreation opportunities provided at R-Ranch. This could include the development of a water park.	Bruce Kinseth	Bruce Kinseth
--	Enhance Private Docks	Enhance private docks that are currently on the reservoir to provide river access	Various private owners	Copco Village Resident

Site ID	Feature	Proposed Recreation Development	Current Owner/Operator	Origin
3,5	BLM Klamath River Campground and [Turtle] Camp	Increase the number of camping sites and increase the day use area parking and related infrastructure. Existing road will need to be enhanced.	BLM	BLM
1	Topsy Campground	Develop new camping areas and bathrooms next to the new water's edge. Remove and replace existing boat ramp and dock.	BLM	BLM
--	Klamath Hot Springs	Develop structure with restrooms and shelter at the Klamath Hot Springs near the Klamath River's confluence with Shovel Creek	N/A	K. Bermel

Notes

1. Consultant for Siskiyou County
2. Frain Ranch Bridge does not currently exist. Current ownership of the lands where the bridge could be developed is divided between PacifiCorp (Parcel A) and BLM.

Chapter 3: Recreation Opportunity Evaluation and Screening

This page intentionally left blank.

3. RECREATION OPPORTUNITY EVALUATION AND SCREENING

KRRC is developing evaluation and screening criteria that will be used to measure each recreation opportunity's consistency with the Recreation Objectives developed for this plan (Section 1.3). In addition, KRRC sought and continues to seek input on appropriate screening criteria as part of the stakeholder outreach effort that is underway in support of developing this plan. The preliminary criteria that have been identified, will be utilized during development of the Final Recreation Plan to measure whether each recreation opportunity will:

A. Directly address the recreation impacts generated by implementation of the KHSA.
B. Directly address or offset changes in the localized reservoir recreation or Hells Corner boating near where the impacts are occuring.
C. Improve access to or usability of an existing recreation resource on lands with a land manager/owner that will accept and agree to maintain the new or upgraded facility.
D. new or substantially increased O&M demands.
E. Not result in impacts to sensitive river and riparian habitats including important river spawning areas in and adjacent to any river channel.
F. Minimize and mitigate for any impacts to culturally sensitive areas.
G. Integrate into the existing communities and infrastructure.
H. Contribute to the regional recreation vision of Klamath River restoration
I. Be acceptible to law enforcement
J. Avoid impacts to local economics
K. Be implementable through available funding

Each opportunity that will be proposed for implementation by KRRC will need to support the criteria presented in the Final Recreation Plan. The preliminary criteria presented above are not final and may change in response to feedback received during the refinement and finalization of the plan. It is anticipated that the evaluation completed for the Final Recreation Plan will measure the degree to which each opportunity supports these criteria. Some of the recreation opportunities identified in this Draft Recreation Plan and others identified through continued stakeholder outreach may fully support some criteria and only partially support others. KRRC will use the screening process to identify in the Final Recreation Plan the proposed recreation facilities that are best able to support these criteria. The preliminary plans for how each screening criteria will be used to evaluate the recreation opportunities is presented below.

Criterion A will verify that each opportunity provides new or supports existing recreation activities or river access. Similarly, Criterion B tests whether a recreation opportunity will address, or offset, recreation impacts in the areas near where the impacts are occurring is measuring how well that the recreation facility or access point will improve conditions along the newly formed river channel between J.C. Boyle Reservoir and Iron Gate Dam. These criteria will evaluate recreation opportunities both qualitatively to verify the proposed location and type of facility and quantitatively to measure the amount of recreation access and use these facilities will provide to offset the removed facilities described in Section 1.2.1.

Criterion C was developed to ensure the durability of opportunities implemented as a result of this plan. Following the completion of facility removal and river restoration activities, KRRC will surrender its license for these facilities and will be unable to operate and maintain any new recreation features developed by this plan, jeopardizing their continued success in mitigating the impacts they were developed to address. For an opportunity to perform well under Criterion C, an entity responsible for its ownership, operation, and ongoing maintenance will need to be identified. Criterion D then evaluates whether each opportunity will generate new or substantially increased O&M demands given the need for this Recreation Plan to ensure the selection and implementation of durable solutions.

Criteria E and F utilized in this evaluation effort were identifed through stakeholder input. Participants in the outreach efforts detailed concerns that potential recreation facilities or river access points created by this Recreation Plan could potentially impact locations important for spawning and rearing along the newly formed river channel and could potentially be developed in areas at or nearby culturally significant resources. The evaluations under both of these criteria will rely on existing resource mapping, river restoration plans and input from the stakeholder groups that raised these concerns.

Criteria G and H were developed to ensure the seamless integration of recreation opportunities into the local communities as well as the entire region. These criteria evaluate each opportunity's potential to integrate into the communities and existing infrastructure and its consistency with the overall vision for a restored Klamath River. The evaluations under both criteria will rely heavily on stakeholder feedback received during outreach and the plans and objectives of local agencies.

Criterion I was developed to evaluate each opportunities acceptability to local law enforcement. During outreach, stakeholders indicated that recreation opportunities developed in the area will need to be accessible by law enforcement to minimize risk and vandalism. The existing access roads in several areas near the river need improvement and their current condition results in slower response times for law enforcement. This criterion will evaluate whether the option will be sufficiently accessible to law enforcement.

Criterion J was developed to assess each opportunity's impact to the local economies in Siskiyou and Klamath counties. This criterion will evaluate recreation opportunities both qualitatively and quantitatively to determine how the opportunity benefits the local economy and/or provides a means to offset lost tax revenue resulting from dam removal.

Criterion K was developed to determine whether available funding will be sufficient to support the development of each opportunity.

Chapter 4: Recreation Plan Implementation

This page intentionally left blank.

4. RECREATION PLAN FINALIZATION

This Draft Recreation Plan identifies the types of recreation opportunities and facilities consistent with pre-hydropower development conditions that will be developed to achieve the goals of the plan. This draft plan also describes the process envisioned by KRRC to evaluate these opportunities and identify the proposed facilities that will ultimately be recommended for implementation in the Final Recreation Plan.

Based on the anticipated removal of reservoir recreation sites and reduced whitewater rafting use under the Project, KRRC has identified the need to implement, in the Klamath River Basin, recreation facility upgrades and/or new facility developments to provide, at minimum, the types of facilities that are proposed in this Draft Recreation Plan. KRRC configured these proposed opportunities to offset the anticipated effects on recreation access associated with dam and associated reservoir removal. The proposed location of specific opportunity types identified below was driven by KRRC's desire to support continued recreation use and access throughout the project area. Under the Amended KHSA, the existing license for the four dams will be transferred to KRRC to implement their removal. Following their removal, KRRC will surrender this license. Ultimately, the ownership, operation, and ongoing maintenance of the recreation opportunities developed by this plan will be the responsibility of the parties that the lands are transferred to.

KRRC initiated a stakeholder outreach process to seek input on the recreation opportunities previously identified during development of the 2011 *Detailed Plan for Dam Removal – Klamath River Dams* (Detailed Plan) as well as support with the identification of new opportunities that had not previously been considered. This ongoing outreach effort has included coordination with California and Oregon state officials, Siskiyou County, Klamath County, the BLM, PacifiCorp, economic development organizations including chambers of commerce, tourism organizations, recreation businesses, local communities, and the broader public. The outreach effort will continue throughout the refinement of this draft plan into a Final Recreation Plan scheduled for completion in June of 2019.

4.1 Proposed Recreation Facilities

KRRC, through its review of the potential recreation facilities removed under the Project and through preliminary stakeholder outreach, has identified two types of recreation access facilities that if developed will offset recreation access that will be eliminated by implementation of the Project – whitewater boat put-in/take-out sites and fishing access sites. In addition, KRRC intends to continue to collect input from stakeholders on both the refinement of these options with the identification of specific locations for implementation and additional detail on the types of amenities developed at each site. KRRC also intends to collect input from these stakeholders on new recreation opportunities beyond the new and upgraded access sites identified in this draft plan.

4.1.1 River Access Sites – Whitewater Put-in/Take-out

To offset reductions in boating access on the Klamath River generated by both the removal of reservoir boating access locations and reductions in river flow conditions capable of supporting whitewater rafting and kayaking, KRRC has identified the development of river access sites that will support whitewater activities. This draft plan assumes the development of new or improved existing river access sites to allow for new whitewater boat access at or near the upstream and downstream ends of J.C. Boyle Reservoir, Copco Lake, and Iron Gate Reservoir. Developing put-in/take-out facilities at these locations will provide access to new sections of the river not currently accessible with the reservoirs in place.

These general locations will be refined during development of the Final Recreation Plan to incorporate input from stakeholders on site preferences, including input from future users on the specific locations anticipated to provide the best recreation experience. KRRC will also seek stakeholder input on any important in-river and river-adjacent habitat areas as well as sections of the river with specific cultural sensitivities to avoid and/or protect from future use. Preliminary feedback that has been provided by stakeholders on whitewater access preferences focused on identifying locations along the river with known or anticipated changes in future rafting/kayaking difficulty levels to better facilitate use of these sections by whitewater rafters and kayakers of varying skill levels.

KRRC will develop these river access sites to include at a minimum:

- An area near or along the adjacent roadway for the parking of trucks with trailers used to transport whitewater rafts, large passenger vans and buses for transporting commercial whitewater rafters,
- If necessary, an access road between any new parking areas and the adjacent existing roadway, and
- If necessary, developed paths from the area designated for parking to the river edge wide enough to support the portage of rafts.

Development of these whitewater access sites are assumed to require slope stabilization, drainage improvement, grading activities, and vegetation removal where necessary to develop parking areas, access roads and paths down to the river, if necessary, for raft portage.

4.1.2 River Access Sites – Fishing Access

To offset the loss of reservoir recreation sites that support flatwater recreation, KRRC has identified the development or improvement of access sites that will support fishing access on the river. This draft plan assumes the development of new or improved existing access sites to allow for access to the river for fishing and other active and passive recreation activities, including swimming. These sites could potentially be shared in some cases with the whitewater access sites identified above. KRRC will develop the sites to allow for new fishing access sites at locations along the river near or in the existing footprints of J.C. Boyle Reservoir, Copco Lake, Iron Gate Reservoir, and Copco No. 2.

Similar to the whitewater access sites described above, these general locations will be refined during development of the Final Recreation Plan to incorporate input from stakeholders on future user site preferences along with stakeholder concerns for biological and/or cultural resources. KRRC assumes that this will include input from stakeholders on preferred amenities at some or all of the sites. These amenities could potentially include fishing docks and Americans with Disabilities Act compliant features to support site accessibility.

KRRC will develop these river access sites to include at a minimum:

- An area near or on a road shoulder for the parking of personal vehicles,
- If necessary, an access road between any new parking areas and the adjacent existing roadway, and
- If necessary, developed trails from the area designated for parking to the river edge.

Similar to the whitewater access sites, development of these fishing access sites are assumed to require slope stabilization, drainage improvement, grading activities and vegetation removal where necessary to develop parking areas and access trails leading down to the river.

4.1.3 Other Recreation Facilities

KRRC intends to continue stakeholder outreach efforts during development of the Final Recreation Plan to refine the proposed recreation facilities identified above. KRRC intends this outreach effort to identify specific locations for recreation facility development and refine the site-specific details on the configuration of the preliminary amenities described above.

In addition to this refinement, KRRC intends to continue to collect input on other recreation facilities in the Klamath River Basin from stakeholders that could be developed in addition to or potentially in place of the facilities identified for implementation in this draft plan to offset impacts on reservoir recreation and whitewater recreation access in the Hell's Corner Reach associated with implementation of the Project.

4.2 Final Recreation Plan

As the Final Recreation Plan is developed, an evaluation and screening process will be implemented with input from stakeholders to identify the specific locations of, features developed for, and plans for operation and maintenance of the ultimate recreation opportunities. In addition, as was noted above, KRRC anticipates that additional recreation opportunities that have been identified during development of the final plan will perform well in this evaluation and screening process and could potentially be proposed by KRRC for implementation in the Final Recreation Plan alongside or in place of the facility types identified in this draft plan.

Subject: Proposed Update to Definite Plan – Appendix I - AR-7 Freshwater Mussels

Dear Mr. Thaler:

This correspondence follows recent discussions between the Klamath River Renewal Corporation (KRRC) and the State Water Resources Control Board (SWRCB) and California Department of Fish and Wildlife (CDFW) concerning KRRC's proposed revision to Aquatic Resource (AR-7), the measure to reduce project effects to freshwater mussels located between Iron Gate Dam and Cottonwood Creek. On a short-term basis, mussels located in this reach are expected to experience moderate to high mortality due to bedload burial associated with the sediment release during the removal of the Klamath River dams. The management objective of this measure during this period is to reduce this mortality by relocation of individual animals.

The three mussel taxa in the Klamath River include *Gonidea angulata* (Western ridged mussel), *Margaritifera falcata* (Western pearlshell mussel), and *Anodonta sp.* (floater mussel) (Davis et al. 2013). Mussels are abundant and widely distributed throughout the mainstem Klamath River and tributaries. *G. angulata* is more widely distributed and more abundant than the other species (Davis et al. 2013). *Anodonta sp.* are located immediately below Iron Gate Dam, but are uncommon elsewhere. *M. falcata* is most abundant between the Salmon River and Trinity River confluences, and are nearly equally common as *G. angulata* in the vicinity of the Trinity River (Davis et al. 2013). Mussel abundance also generally declines with increasing distance downstream from Iron Gate Dam, suggesting the effects of the increasing hydrologic variability of the Klamath River with distance from Iron Gate. Davis et al. (2013) concluded that habitats located further downstream had lower probabilities of supporting mussels due to more variable conditions.

During meetings in 2017, the Aquatic Technical Working Group (ATWG) reviewed relocation opportunities including moving mussels to the Keno to J.C. Boyle Reservoir reach. In June 2018, KRRC reviewed habitat conditions in the Keno to J.C. Boyle Reservoir reach and determined there is insufficient suitable freshwater mussel habitat in the reach. As there is insufficient habitat in the Keno to J.C. Boyle Reservoir reach, KRRC is now proposing to relocate mussels to the Klamath River downstream from the Trinity River confluence, or upstream of Copco Reservoir in the J.C. Boyle Dam to Copco Reservoir reach. In 2019, KRRC will be completing a more comprehensive freshwater mussel habitat reconnaissance to document existing freshwater mussel locations in the Iron Gate Dam to Cottonwood Creek reach, and to determine appropriate relocation sites in the two aforementioned reaches. *G. angulata* and *M. falcata* will mainly be targeted for relocation as there is appropriate habitat downstream from the Trinity River for both taxa (Davis et al. 2013). *G. angulata* have also been found upstream from Copco Reservoir (Byron and Tupen 2017). There are no recent published records of *M. falcata* upstream of Copco Reservoir.

The attached document summarizes the proposed updated language for the Detailed Plan – Appendix I. Narrative updates include the AR summary section, and Chapter 9 - Freshwater Mussels.

We appreciate your consideration of this proposed revision to measure AR-7. Please acknowledge receipt of this correspondence. If you have any questions on the application, please feel free to contact me at 510-679-6929 or mark@klamathrenewal.org.

encl: Appendix I – Freshwater Mussel Updated Language dated September 21, 2018.

Update for 20170929_krrc-tech_report.pdg

PDF p.262, report p. 7-8

First paragraph: “beds that will be salvaged and translocated is predicated on the available habitat in the Klamath River downstream from the Trinity River confluence (RM 43.4), and between J.C. Boyle Dam (RM 230.6) and Copco Reservoir (RM 209.0), and the abundance of mussels between Iron Gate Dam…”

9. FRESHWATER MUSSELS

The objective of the freshwater mussels measure is to address reservoir drawdown and project effects on freshwater mussels located in the Klamath River in the Hydroelectric Reach and downstream from Iron Gate Dam (RM 193.1). The 2012 EIS/R AR-7 focused conducting a freshwater mussel relocation pilot study followed by the salvage and relocation of freshwater mussels prior to reservoir drawdown. Salvaged mussels were to be held in a temporary location for later placement following reservoir drawdown, and placed in locations that will not be affected by the reservoir drawdown. Based on a review of the information discussed in greater detail below, KRRC and the ATWG concluded that a moderate scale freshwater mussel relocation effort is warranted. The proposed measure includes a freshwater mussel reconnaissance in 2019 followed by a limited freshwater mussel salvage prior to reservoir drawdown. Specifically, KRRC will salvage freshwater mussels from the 8-mile long Iron Gate Dam (RM 193.1) to Cottonwood Creek (RM 185.1) reach and translocate these mussels to one or more appropriate locations in the Klamath River downstream from the Trinity River confluence (RM 43.4), and between J.C. Boyle Dam (RM 230.6) and Copco Reservoir (RM 209.0). The translocation sites will be determined following the 2019 reconnaissance and discussion with the ATWG.

9.1 Proposed Measure

Based on a review of the 2012 EIS/R AR-7 presented in Section 9.2 below, input from the ATWG, and current freshwater mussels literature, the KRRC concluded that revisions to AR-7 are necessary to offset the anticipated short-term effects of the Project on freshwater mussels. The proposed measure includes a reconnaissance, salvage, and relocation of freshwater mussels from the 8-mile reach between Iron Gate Dam and the Cottonwood Creek confluence with the Klamath River. The monitoring and adaptive management plan has two specific actions.

- **Action 1:** KRRC will complete a reconnaissance in 2019 to assess the distribution and density of freshwater mussels in the 8-mile long bedload deposition reach from Iron Gate Dam (RM 193.1) downstream to the Cottonwood Creek confluence (RM 185.1). The reconnaissance effort will determine if the mussel beds identified in the 2007-2010 surveys are still present, and estimate abundance of a subset of the mussel beds in the reach.

- **Action 2**: Based on the reconnaissance and discussions with ATWG, KRRC will salvage and relocate a portion of the freshwater mussels located between Iron Gate Dam and Cottonwood Creek prior to drawdown to reduce project effects to the mussel community. Up to 20,000 mussels are planned for translocation to appropriate habitats in the Klamath River downstream from the Trinity River confluence (RM 43.4), and between J.C. Boyle Dam (RM 230.6) and Copco Reservoir (RM 209.0). Translocation sites will be located in areas that are anticipated by KRRC to experience minimal changes in channel bed elevation due to sediment deposition associated with the Project.

The proposed measure is intended to reduce project effects on freshwater mussels located downstream from Iron Gate Dam. The following sections provide additional detail on the proposed measure actions.

9.1.1 Action 1: Freshwater Mussel Reconnaissance

The KRRC will prepare a reconnaissance plan to assess freshwater mussels in the Iron Gate Dam to Cottonwood Creek reach in 2018. Habitat conditions will also be evaluated downstream from the Trinity River confluence, and between J.C. Boyle Dam and Copco Reservoir to determine the habitat capacity for translocated mussels. An existing freshwater mussel data set (base data for Davis et al. 2013), compiled by the Karuk Tribe, USFWS, and other collaborators from 2007 to 2010 for the Klamath River downstream from Iron Gate Dam, will be reviewed and used to plan the reconnaissance. The reconnaissance will confirm mussel beds identified in the 2007-2010 surveys and estimate abundance at a subset of the mussel beds locations. Habitat metrics in the potential translocation reach will be evaluated to maximize translocation success. The freshwater mussel reconnaissance and translocation reach habitat assessment are anticipated to take 5 days.

9.1.2 Action 2: Freshwater Mussel Salvage and Relocation

The KRRC will coordinate and implement a freshwater mussel salvage plan with freshwater mussel specialists. Based on the reconnaissance, a portion of the freshwater mussels located between Iron Gate Dam and Cottonwood Creek will be salvaged and relocated to reduce project effects to the freshwater mussel community. The freshwater mussel salvage and translocation effort is anticipated to require 10 days. The percentage of the existing mussel beds that will be salvaged and translocated is predicated on the available habitat in the Klamath River downstream from the Trinity River confluence, and between J.C. Boyle Dam and Copco Reservoir, and the abundance of mussels between Iron Gate Dam and Cottonwood Creek. Approximately 15,000 to 20,000 mussels are planned for translocation. During the course of these actions, it is not anticipated that the entire population of mussels residing below Iron Gate Dam will be recovered.

9.2 Summary of the Affected Species, Anticipated Project Benefits and Effects, Recent Literature, 2012 EIS/R AR-7, and Proposed Measure

The following sections review the components of the 2012 EIS/R AR-7, anticipated project effects and long-term benefits on freshwater mussels, and current freshwater mussel literature.

9.2.1 Affected Species

Species intended to be addressed in the 2012 EIS/R AR-7 include:

- Oregon floater *(Anodonta oregonensis)*
- California floater *(A. californiensis)*
- Western ridged mussel *(Gonidea angulata)*
- Western pearlshell mussel *(Margaritifera falcata)*

9.2.2 Anticipated Project Effects on Measure Species

Short-term effects of the Project (prolonged exposure to high suspended sediment levels and bedload movement) are predicted to be deleterious to freshwater mussels in the Hydroelectric Reach and in the lower Klamath River downstream from Iron Gate Dam (Reclamation and CDFG 2012). Substantial freshwater mussel population reductions are expected due to sediment effects and possibly low dissolved oxygen levels. The change in hydrological properties following project implementation may also disrupt the current distribution of freshwater mussels downstream from Iron Gate Dam (Davis et al. 2013). Table 9-1 includes the likely and worst-case effects on freshwater mussel species in the Klamath River.

Table 9-1 2012 EIS/R anticipated effects summary for freshwater mussels

Species	Life Stage	Likely Effects	Worst Effects
California Floater Oregon Floater Western Ridged Western Pearlshell	All	Substantial reduction in populations	Substantial reduction in populations

Source: USBR and CDFG 2012

The following sections include descriptions of anticipated effects to freshwater mussels based on information 2012 EIS/R (Reclamation and CDFG 2012; Vol. 1, pp. 3.3-173 to 3.3-175) as well as additional information from additional freshwater mussel studies, some of which were completed after the publication of the 2012 EIS/EIR.

Freshwater Mussels

Available studies have evaluated Klamath River Basin freshwater mussel age structure, growth rates, and size distribution (*G. angulata*; Tennant 2010); population distribution and habitat use (Krall 2010; Davis et al. 2013; May and Pryor 2015); and habitat associations (Westover 2010; Davis et al. 2013). Klamath River mussels are long lived (from 10 to more than 100 years, depending on species) and may not reach sexual maturity until 4 years of age or more. *Anodonta* species are found primarily downstream from Iron Gate Dam, and likely benefit from the stable hydrology and fine sediment deposits attributed to hydroregulation below the dam (Davis et al. 2013). *G. angulata* is the most abundant freshwater mussel in the Klamath River and the species is widely distributed between Iron Gate Dam and the Trinity River (Westover 2010;

Davis et al. 2013). *M. falcata* is the least abundant freshwater mussel found in the Klamath River and seems to be mostly found downstream from the confluence of the Salmon River (Westover 2010; Davis et al. 2013).

Freshwater mussel tolerance of high suspended sediment, low dissolved oxygen, and bedload deposition are not well understood. Vannote and Minshall (1982) evaluated freshwater mussels in an aggrading river system in Idaho and concluded that *G. angulata* appear to be better adapted for aggrading rivers based on siphon positions, shell morphology, and foot placement in the underlying substrate. *M. falcata* seemed to be less adapted for aggrading rivers due to a less developed siphon for filtering water. *M. falcata* also rarely burrow into substrate more than 25-40 percent of the valve length which may increase the mussel's susceptibility to scour (Vannote and Minshall 1982). *G. angulata* migrate vertically in the channel bed and are capable of maintaining position near the channel bed surface (Vannote and Minshall 1982). *M. falcata* are not known to migrate and are therefore more susceptible to sediment burial. *Anodonta* species are likewise susceptible to sediment scour and burial due to their thinner shells. Mussels that are dislodged from their normal vertical position and fall onto their sides may not regain the normal position and may perish (Vannote and Minshall 1982).

Mussels play important roles in aquatic ecosystems. Mussels influence water quality, nutrient cycling, and habitat and are also known as "ecosystem engineers" that actively modify their environment (Xerces Society 2009; Lopes-Lima et al. 2016; Lummer et al. 2016). They filter fine sediment and organic particles, create byproducts that are food items for macroinvertebrates, and comprise the greatest proportion of animal biomass in some waterbodies (Xerces Society 2009). In the Klamath River Basin, freshwater mussels filter and sequester toxins including toxigenic algae microsystins (Kann et al. 2010) and mercury (Bettaso and Goodman 2010). Filtration of waterborne toxins may result in bioaccumulation in freshwater mussels leading to human consumption risks (Bettaso and Goodman 2010; Kann et al. 2010).

The Project is anticipated to result in high suspended sediment levels and bedload deposition in the 8 miles of the Klamath River between Iron Gate Dam and Cottonwood Creek. Extremely poor water quality due to high suspended sediment concentrations is expected in the first 2 miles of the Klamath River downstream from Iron Gate Dam (Reclamation and CDFG 2012). Fine sediment effects on freshwater mussels include gill clogging, possible growth reduction, and impairment to mussel larval stages (Lummer et al. 2016). Due to both the anticipated deleterious high suspended sediment concentrations and low dissolved oxygen levels, freshwater mussels downstream from Iron Gate Dam may experience substantial mortality with the most significant impacts anticipated to mussels located immediately downstream from Iron Gate Dam.

Over the long-term, freshwater mussels are expected to benefit from the Project through the conversion of Hydroelectric Reach reservoirs to gravel bed rivers which will restore freshwater mussel habitat, reduce water quality and water temperature impairments related to the reservoirs, and restore access for anadromous and resident host fish species that will distribute freshwater mussel larvae throughout the Klamath River upstream from Iron Gate Dam. However, due to the long time freshwater mussels take to reach sexual maturity, the recolonization and/or growth of existing freshwater mussel populations upstream of Iron Gate Dam may be slow and may not be readily noticeable for some time.

9.2.3 2012 EIS/R AR-7

The 2012 EIS/R AR-1 (Vol. I, pp. 3.3-248 to 3.3-249) directed the salvage of freshwater mussels from the Hydroelectric Reach and downstream from Iron Gate Dam. Salvaged mussels were to be relocated to suitable instream habitat unaffected by high suspended sediment concentrations, or could be placed in temporary facilities and returned to the Klamath River following the Project. A salvage and relocation pilot study was also suggested to assess salvage feasibility and relocated mussel survival. Based on the pilot study results, a detailed salvage and relocation plan was to be developed.

9.2.4 KRRC's and the ATWG's Review of AR-7 for Feasibility and Appropriateness

The KRRC assessed the feasibility and appropriateness of AR-7 through multiple planning meetings held with the ATWG between May and August 2017. During these meetings, current information on Klamath River fisheries was presented and information on other dam removal projects conducted in the western United States was reviewed to understand how the aquatic ecosystem might respond, as discussed above. The ATWG's concerns regarding the 2012 AR-7 included:

- Unfamiliarity with successful freshwater mussel relocation efforts.
- Disease transmission concerns.

The following sections provide additional information regarding AR-7 feasibility and appropriateness, based on fisheries literature and ATWG input.

Unfamiliarity with Successful Freshwater Mussel Relocation Efforts

The ATWG was unfamiliar with successful freshwater mussel translocation efforts. Anecdotal information discussed during the ATWG planning meeting (Yreka, CA, May 23, 2017) alluded to low translocation success for the Elwha Dam Removal Project and highway construction projects. Additional information was acquired by the KRRC on the Elwha Dam Removal Project freshwater mussel (*M. falcata*) translocation. For that project, freshwater mussels were translocated to two sites and remained in one site prior to the dam removal project (P. Crain, U.S. Park Service, personal communication, 2017). The relocated freshwater mussels had high survival following the translocation and prior to the dam removals. Subsequent events that impacted the translocated mussels resulted in high mussel mortality. The events included raccoon predation due to shallow habitat at the first translocation site, and excessive sediment deposition at a side channel translocation site. The third monitored site was an artificial outfall channel from the water treatment facility that went dry due to inadvertent project operations. Mussels that remained in the Elwha River downstream from Elwha Dam are suspected to have experienced high mortality due to excessive sediment deposition following dam removal, followed by channel scour during the post-dam sediment sorting process.

Freshwater mussel translocation project monitoring results are not well represented in the fisheries literature. Unpublished freshwater mussel translocation monitoring manuscripts were reviewed to better understand the range of potential translocation success. Fernandez (2013) described the translocation success of 265 individual *M. falcata* in coastal southwest Washington. Between 55 percent and 95 percent of the transplanted *M. falcata* were accounted for in the translocation sites between one and three years following the translocation.

A review of translocation projects found mean mortality of relocated mussels was 49 percent based on an average recovery rate of 43 percent (Cope and Waller 1995). Cope and Waller (1995) found that survival of relocated mussels was generally poor and the factors influencing the survival of relocated mussels were poorly understood. For mussel relocation to be successful, more consideration must be given to habitat characterization at both the source and translocation sites. Olden et al. (2010) and Germano et al. (2015) offer considerations for successful freshwater organism and wildlife translocation efforts, respectively Luzier and Miller (2009) offer suggestions and considerations for freshwater mussel translocations.

Disease Transmission Concerns

The role of freshwater mussels in freshwater disease transmission is not well understood. Freshwater mussels are known to provide habitat for polychaete worms, one of the hosts in the life *C. shasta*. Polychaetes have been infrequently collected from freshwater mussel shells in the Hydroelectric Reach of the Klamath River (PacifiCorp 2004). Mussels may serve as a vector for other fish pathogens like *Flavobacterium columnare* and *Ichthyophthirius multifiliis* that are endemic to the Klamath River Basin (K. Kwak, CDFW, personal communication 2017).

Freshwater mussels inhabit the Klamath River upstream from Iron Gate Dam (Byron and Tupen 2017) and in tributaries upstream (Byron and Tupen 2017) and downstream from Iron Gate Dam (Davis et al. 2013; Howard et al. 2015; May and Pryor 2015), disease transmission may be less of a concern.

9.3 Summary

The Project is anticipated to have significant short-term effects, but long-term benefits for freshwater mussels. The 2012 EIS/R AR-7 included a freshwater mussel salvage and relocation pilot study followed by an informed salvage and relocation plan prior to the Project. The proposed measure includes completing a reconnaissance of existing freshwater mussels from Iron Gate Dam to Cottonwood Creek and potential translocation habitat on the Klamath River downstream from the Trinity River confluence, and between J.C. Boyle Dam and Copco Reservoir. KRRC will salvage and relocate freshwater mussels prior to the reservoir drawdown. It is not anticipated that the entire population of mussels residing below Iron Gate Dam will be recovered.
