Pacific Gas and Electric Company Chili Bar Project FERC Project No. 2155

# LIST OF APPLICABLE STUDY PLANS

### Description

• Channel Morphology Study Plan

#### 2.1 Channel Morphology Study Plan

This study is designed to provide information regarding the geomorphologic condition of river reaches downstream of Sacramento Municipal Utility District's (SMUD) Upper American River Project (UARP) and Pacific Gas and Electric Company's Chili Bar Project using the Rosgen methodology. The overall approach is to perform Rosgen Level I classification of all river reaches downstream of dams using available maps and photographs, and then to refine this typing by conducting Rosgen Level II classification and Level III condition assessment in sensitive reaches using site-specific measurements. Should any of the reaches seem impaired (e.g., excess sediment, lack of bedload sediment, excessive scouring or channel entrenchment, lack of or excess large woody debris (LWD), poor riparian vegetation, etc.), additional studies will be considered. Field data will only be collected in 2002 unless results indicate additional sampling is warranted.

#### 2.1.1 Pertinent Issue Questions

This Channel Morphology Study Plan addresses the following Aquatic/Water Issue Questions:

- 5. What effects do project features and operations have on fluvial geomorphology and stream habitat?
- 6. What are the physical attributes (i.e., available pools and presence of large debris) of the Project? How have they been affected by the Project? What habitat is provided by those attributes (habitat mapping)?
- 19. Do project features affect distribution of large wood in streams? Do they comply with Forest Service standards?
- 23. What Project flows affect recruitment and reproduction of riparian plants?
- 34. How are the Project operations affecting gravel recruitment (related to spawning and macroinvertebrate habitat)?
- 48. Does operation of the Project affect stream bank stability?
- 61. Does the existing minimum stream flow requirements adequately protect the fluvial geomorphological processes?

#### 2.1.2 Background

Effects of dams and flow regulation on channel morphology are expected to be more pronounced in alluvial reaches that have bed and banks composed of fluvially-derived sediment, as compared to bedrock channels that remain relatively unaltered due to high sediment transport capacities and resistant substrate (Montgomery and Buffington 1993). Alluvial reaches are characterized by fluvial transport of sediment over a variety of bed morphologies. At the reach-level, channel slope, sediment supply, transport capacity, and (LWD) loading are key determinants of channel form. Broad-level channel classification based on channel slope and confinement can be used to identify "sensitive reaches. "Sensitive reaches" are unconfined, low-gradient alluvial reaches where channel response to changes in sediment supply or transport dynamics is most likely to occur. Detailed field surveys in sensitive reaches downstream of the dams can be used to identify and quantify the effects of the dams and the altered flow regime on channel morphology.

#### 2.1.3 <u>Study Objectives</u>

The study objectives are to identify:

potential sensitive reaches downstream of the UARP's and Chili Bar Project's dams

effects of the projects on channel morphology, sediment transport, and LWD dynamics, loading, and function in sensitive downstream reaches

feasible measures to sustain geomorphic processes such as sediment transport and LWD loading that support aquatic and riparian habitat diversity in downstream reaches.

#### 2.1.4 <u>Study Area</u>

The study area will include all stream reaches identified by the Aquatics TWG. This includes the downstream reaches of all UARP dams and Chili Bar Dam.

#### 2.1.5 Information Needed From Other Relicensing Studies

Information needed from other studies includes: 1) the effects of flow regulation and diversion on flow conditions in the channel, which is necessary for developing hypotheses of anticipated effects of the projects on channel morphology and identifying potential field survey reaches, from the Hydrology Study; 2) results from water quality and turbidity studies from survey and existing data; and 3) the results of the Riparian Vegetation Study to assess linkages between geomorphic processes (and the effects of the Project on geomorphic process) and riparian vegetation. Bathymetric data from UARP reservoirs will also be made available for analysis. Information from the Channel Morphology Study may be useful in the Riparian Vegetation Study, Amphibians and Aquatic Reptiles Study, Aquatic Bioassessment Study, and the Water Quality Study. Information regarding blockage of connectivity of tributaries and side channels from the instream flow habitat mapping will be needed.

#### 2.1.6 <u>Study Methods And Schedule</u>

The study methods will include the following sequential steps:

<u>Rosgen Level I Classification</u> - The first phase will include a Rosgen Level I classification based on available topographic and geologic data. The purpose of the Level I classification is to provide a broad characterization that integrates the landform and fluvial features of valley morphology with channel relief, pattern, shape, and dimension for all stream reaches (Rosgen 1994). The initial evaluation will use material such as low-altitude video of channels in the area of the projects available from SMUD or other sources; USGS maps, historic and current aerial photographs, topographic and geologic maps as well as other available data for rivers affected by the projects to determine channel slope, approximate channel width and cross sectional form, and channel planform morphology (e.g., sinuosity and channel form, etc.). This information is needed to classify all reaches into Rosgen Level I types. The purpose of the Level I classification is to identify potential sensitive reaches and to predict anticipated reach-level morphology in alluvial (non-bedrock) reaches in all Rosgen channel types. Sensitive reaches will be delineated based upon their slope, channel confinement, and bed and bank sediment composition (e.g., alluvial versus bedrock). Using the Rosgen Level I classification, sensitive reaches could occur in type B, C, D, E, and F channels. Based on the results of the Level I effort, a recommendation will be made to the Aquatic TWG regarding the sampling locations for Level II surveys.

<u>Rosgen Level II Typing</u> - Locations for Rosgen Level II surveys will be determined based upon the Level I classification. While the number and distribution of potential sites is unknown at this time, at least one study site will be analyzed in each reach. A study site will be approximately 20 to 30 bankfull widths, where appropriate, in length with upper and lower boundaries geo-referenced. If there is more than one potential study site in each reach, the study site where channel response to operation of the projects is most likely will be analyzed. Additional sites (e.g., near recreation areas) may be considered. Interested parties from the Aquatics TWG and Plenary Group will be invited to visit the sites in the field to concur with or modify the selected survey sites. Level II field surveys will include, but not be limited to, measurements of 1) longitudinal profile (water surface and thalweg), 2) valley width, 3) approximately three monumented channel cross sections (including bankfull indicators, thalweg, water's edge, flood-prone area, where identifiable), and 4) pebble counts (Wolman 1954). Cross sections will be established with a sufficient number of verticals to clearly depict channel geometry (Harrelson, et al. 1994). Each transect will be photo-documented. Wherever possible, study sites for this effort will coincide with instream flow study sites. Based on the results of the Level II effort, a recommendation will be made to the Aquatic TWG regarding the sampling locations for Level III surveys.

<u>Rosgen Level III Condition</u> – It is anticipated that a Rosgen Level III condition analysis will be performed at a subset of the Level II study sites. The Level III analysis will include the following data collection elements: 1) bed surface texture based on facies mapping (stratification and delineation of channel bed features based on particle sizes and organization), 2) sediment deposition in pools will be assessed using an appropriate method (e.g., V\*, S\*, Q\*) (USFS 1997, Lisle and Hilton 1992, Hilton and Lisle 1993). In each reach examined as part of the Level III analysis, large woody debris (LWD) loading in the active channel will be measured and the geomorphic and ecological function of the LWD will be examined. For the purpose of this analysis, LWD is defined as in the USFS Region 5 Stream Condition Inventory (SCI) protocol: all pieces of wood lying within the bankfull width of the channel that measures one half bankfull width or longer. Wood must be both downed,

and with a portion lying within the bankfull channel, and dead or dying to be considered LWD. This will involve dividing the LWD into size classes and tallying the total number of LWD pieces in each size class in the reach. Because some LWD can be suspended over the channel or are too small to alter bed morphology, the interaction between LWD and the bed will be assessed. LWD, as a biological component, will be examined during the habitat mapping component of the instream flow study.

Additional Investigations – Depending upon the results of the above evaluations, additional studies may be conducted in some specific areas (e.g. Rosgen Level IV sediment budget).

It is expected that Rosgen Level I classification will occur in spring/early summer 2002. Selection of Rosgen Level II and III sampling sites and fieldwork will occur in summer 2002/2003. Note that interested parties from the Aquatics TWG and Plenary Group will be invited to visit the sites in the field to concur with or modify the selected survey sites before any fieldwork is conducted. Data analysis will occur in fall 2002/2003, and the results of the study will be presented to the Aquatic TWG in late 2002/2003. Should the data indicate that additional investigation is warranted in specific area (i.e., additional surveys, including identifying reference reaches to help isolate Project impacts, this study plan will be amended, in consultation with the Aquatics/Water TWG and Plenary Group, to include data gathering and analysis in these specific problem areas in 2003.

#### 2.1.7 <u>Analysis</u>

The results would be used to describe the existing channel conditions and to identify effects of the projects on channel morphology. The magnitude of sediment trapping by the reservoirs will be estimated. An incipient motion analysis will be performed using Shield's (and associated sensitivity analysis) equation (also perform sensitivity analyses in conjunction with opportunistic flow events) for each Level III study site. Potential problem areas (excess sediment, lack of bedload sediment, excessive scouring or channel entrenchment, lack or excess of LWD, poor riparian vegetation, etc.) will be identified, and potential mitigation measures will be evaluated.

#### 2.1.8 <u>Study Output</u>

A presentation on the preliminary results from the study will be made to the Aquatics TWG and the Plenary Group in late 2002. The ultimate study output will be a written report that includes the issues addressed, objectives, study area including sampling locations, methods, analysis, results, discussion and conclusions. The report will be prepared in a format so that it can easily be incorporated into SMUD's draft environmental assessment report that will be submitted to FERC with SMUD's application for a new license.

#### 2.1.9 <u>Preliminary Estimated Study Cost</u>

A preliminary study cost estimate will be prepared after the Plenary Group approves this study plan.

#### 2.1.10 <u>TWG Endorsement</u>

The Aquatics TWG approved this plan for the UARP on February 28, 2002. The participants at the meeting who said they could "live with" this study plan were BLM, PCWA, CSPA, SWRCB, USFS and SMUD. None of the participants at the meeting said they could not "live with" this study plan except for the PG&E participant who said PG&E would defer at this time since the plan did not include the Chili Bar Project and downstream. At the April 3, 2002 Plenary Group meeting, the plan was directed back to the Aquatic TWG to include the area below Chili Bar. At the April 11, 2002 Aquatic TWG meeting, the TWG approved the study plan. The participants at the meeting who said they could "live with" this study plan were BLM, SWRCB, USFS, PG&E, Camp Lotus, and SMUD. None of the participants at the meeting said they could not "live with" this study plan, except that PG&E said it needed management approval. PG&E obtained this approval as of April 30, 2002.

On May 1, 2002 the following participants gave Plenary Group approval to the plan: USFS, BLM, USFWS, Taxpayers of El Dorado County, Friends of El Dorado County, Camp Lotus, El Dorado County Water Agency, El Dorado County, Placer County Water Agency, California Department of Fish and Game, California State Water Resources Control Board, Pacific Gas and Electric and Friends of the River. None of the participants at the meeting said they could not "live with" this study plan.

### CHANNEL MORPHOLOGY TECHNICAL REPORT

#### SUMMARY

This technical report characterizes channel morphology and describes existing geomorphic functions in streams affected by the Sacramento Municipal Utility District's (SMUD) Upper American River Project (UARP) and Pacific Gas and Electric's (PG&E) Chili Bar Project.

Study results presented here reflect hierarchical studies conducted between 2002 and 2004. The initial studies involved a broad geomorphic characterization (Rosgen Level I) of the stream reaches affected by the two projects, including the Reach Downstream of Chili Bar. These results were used to identify potential response reaches. Response reaches are most likely to show effects from alterations to hydrology or sediment supply and are defined by Montgomery and Buffington (1998) as reaches with: 1) low slope (<4 percent); predominantly alluvial bed and banks (cobble-gravel facies or finer); and 3) plane bed or pool-riffle morphology.

Morphological description (Rosgen Level II) and channel condition assessment (Rosgen Level III) sites were selected in potential response reaches identified from the results of geomorphic characterization. In conjunction with the Aquatics Technical Work Group (TWG), 16 sites were selected for morphological description and/or channel condition assessment, including 4 sites in the Reach Downstream of Chili Bar. Low altitude aerial photographs and video footage taken during a helicopter flyover of the study area were used for site selection.

The channel morphological description and channel condition assessment revealed seven response sites in the UARP area, and one response site in the Reach Downstream of Chili Bar. Channels at these sites primarily exhibited pool-riffle morphology with well-developed floodplains. The following sites were designated response sites:

- Rubicon Dam Reach Site;
- Loon Lake Dam Reach Upper Site;
- Loon Lake Dam Reach Middle Site;
- Loon Lake Dam Reach Lower Site;
- Robbs Peak Dam Reach Site;
- Ice House Dam Reach Upper Site;
- Ice House Dam Reach Lower Site; and
- Upper Coloma Site in the Reach Downstream of Chili Bar.

The remaining five sites in the UARP and three sites in the Reach Downstream of Chili Bar were categorized as transport sites because they all occur in reaches where bedrock outcrops control channel morphology and sediment transport dynamics (Montgomery and Buffington 1993).

In order to evaluate the magnitude of flows that would mobilize the current bed material, Shields stress and bedload transport were evaluated for six response sites in the UARP and one response site in the Reach Downstream of Chili Bar, using the *EASI* (Enhanced Acronym Series with Interface) model. The results indicate that incipient bed mobility occurs between:

- 168-189 cubic feet per second (cfs) for the Rubicon Dam Reach Site;
- 86-326 cfs for the Loon Lake Dam Reach Middle Site;
- 940-1,241 cfs for the Loon Lake Dam Reach Lower Site;
- 917-1,568 cfs for the Robbs Peak Dam Site;
- 185-393 cfs for the Ice House Dam Reach Upper Site;
- 531-775 cfs for the Ice House Dam Reach Lower Site; and

• 1,703-4,317 cfs for the Lower Coloma Site in the Reach Downstream of Chili Bar.

The Loon Lake Dam Reach Upper Site was excluded from the Shields stress and bedload transport evaluation because dominant grain sizes in the channel bed are too small. Bedrock outcrops and boulders at all remaining project sites preclude an accurate assessment of Shields stress due to the influence of large flow obstructions on flow dynamics and sediment transport.

### **1.0 INTRODUCTION**

This technical report is one in a series of reports prepared by Devine Tarbell and Associates, Inc., and Stillwater Sciences for the Sacramento Municipal Utility District (SMUD) and Pacific Gas and Electric Company (PG&E) (jointly referred to as the Licensees) to support the relicensings of SMUD's Upper American River Project (UARP) and PG&E's Chili Bar Project. The Licensees intend to append this technical report to their respective applications to the Federal Energy Regulatory Commission (FERC) for new licenses. This report addresses the existing geomorphic form and function of streams in UARP reaches and the Reach Downstream of Chili Bar. This report includes the following sections:

- **BACKGROUND** Includes when the applicable study plan was approved by the UARP Relicensing Plenary Group; a brief description of the issue questions addressed, in part, by the study plan; the objectives of the study plan; and the study area. In addition, requests by resource agencies for additions to and modifications of this technical report are described in this section.
- **METHODS** A description of the methods used in the study, including a listing of study sites.
- **RESULTS** A description of the most important data results. Raw data, where copious and detailed model results are provided in a separate compact disc (CD) for additional data analysis and review by interested parties.
- SUMMARY A brief discussion of the results.
- LITERATURE CITED A listing of all literature cited in the report.

This technical report does not include a detailed description of the UARP Alternative Licensing Process (ALP) or the project, which can be found in the following sections of the Licensee's application for a new license: The UARP Relicensing Process, Exhibit A (Project Description), Exhibit B (Project Operations), and Exhibit C (Construction).

In addition, this technical report does not include a discussion regarding the effects of the projects on channel morphology or associated environmental resources, nor does the report include a discussion of appropriate protection, mitigation, and enhancement measures. An impacts discussion regarding the UARP is included in the applicant-prepared preliminary draft environmental assessment (PDEA) document, which is part of the Licensee's application for a new license. Development of resource measures will occur in settlement discussions, which will commence in 2004, and will be reported on in the PDEA.

### 2.0 BACKGROUND

### 2.1 Channel Morphology Study Plan

The Channel Morphology Study Plan was developed and approved by the Aquatic Technical Working Group (TWG) on April 11, 2002. The UARP Relicensing Plenary Group approved the study plan on May 1, 2002. This study plan was designed to address, in part, the following issue questions developed by the UARP Relicensing Plenary Group:

Issue Question 5.	What effects do project features and operations have on fluvial geomorphology and stream habitat?
Issue Question 6.	What are the physical attributes (e.g., available pools and presence of large debris) of the projects? How have they been affected by the projects? What habitat is provided by those attributes (habitat mapping)?
Issue Question 19.	Do project features affect distribution of large wood in streams? Do they comply with Forest Service standards?
Issue Question 23.	What project flows affect recruitment and reproduction of riparian plants?
Issue Question 34.	How are the project operations affecting gravel recruitment (related to spawning and macroinvertebrate habitat)?
Issue Question 48.	Does the operation of the projects affect stream bank stability?
Issue Question 61.	Do the existing minimum stream flow requirements adequately protect the fluvial geomorphologic processes?

Specifically, the objectives of the study plan were to identify:

- Potential response reaches within the UARP and in the Reach Downstream of Chili Bar.
- The effects of the projects on channel morphology: sediment transport and LWD dynamics, loading, and function in response downstream reaches.
- Feasible measures to sustain geomorphic processes (e.g., sediment transport and LWD loading) that support aquatic and riparian habitat diversity in downstream reaches.

As described above, this technical report does not include a comprehensive impacts assessment of the UARP and Chili Bar Project on channel morphology. This assessment will be done during settlement discussions. Therefore, the portions of the Issue Questions and objectives that pertain to impacts analysis are not addressed in detail in this report. The study area included all reaches affected by the two projects identified by the Aquatics TWG, including the Reach Downstream of Chili Bar.

In general, the methods approved by the UARP Relicensing Plenary Group included the application of channel morphology methods proposed by Rosgen (1996). Specifically, these methods included:

- Level I Geomorphic Characterization;
- Level II Morphological Description;
- Level III Channel Condition Assessment; and
- Additional Investigations depending on the results of the previous steps.

The results of the study would be used to describe the existing channel conditions and to identify potential problem areas (excess sediment, lack of bedload sediment, excessive scouring or channel entrenchment, lack or excess of LWD, poor riparian vegetation, etc.).

# 2.2 Water Year Type

The information in this subsection is provided for informational purposes, as requested by agencies. The derivation of water year types is described in the *Water Quality Technical Report*. Table 2.2-1 presents water year types for the period that is pertinent to this *Channel Morphology Technical Report*.

Table 2	<b>Gable 2.2-1.</b> Water year types applied to individual months of years 2001-2004.*											
Year	Jan	Feb	Mar	Apr	May	June	July	Aug	Sep	Oct	Nov	Dec
2001	AN	D	D	D	D	D	D	D	D	D	D	D

# 2.3 Agency Requested Information

In a letter dated December 17, 2003, the agencies requested that SMUD provide the following information with regard to channel morphology:

- Geographic Information Systems (GIS) map with validated channel classification of project-affected reaches, with the locations of Level II and III analysis sites delineated (This information is included in Appendix B of this *Channel Morphology Technical Report.*);
- Global Positioning System (GPS) coordinates of sites (Appendix F);
- Field survey methodology (Section 3.3);
- Level II and III data sheets with all survey information (Appendices G-L);
- Incipient motion analysis (Section 4.3);

Pacific Gas and Electric Company Chili Bar Project FERC Project No. 2155

- Field site visits to validate methods (e.g., bank full determination) (visits conducted to Ice House Dam Reach and Robbs Peak Dam Reach on June 23, 2004; to Loon Lake Dam Reach on July 12, 2004; to Slab Creek Dam Reach and Reach Downstream of Chili Bar on July 13, 2004);
- Field site photos (Appendix F);
- Aerial photography and videography conducted for the projects (previously provided on CD and DVD to TWG participants); and
- Review of this information to determine if additional field work is needed to complete Level III analysis and possibly Level IV analysis.

# 3.0 METHODS

The overall approach of this study involved geomorphic characterization (Rosgen Level I) of all river reaches downstream of dams using available maps and photographs, followed by morphological description (Rosgen Level II) and channel condition assessment (Rosgen Level III) in response reaches using site-specific measurements (Rosgen 1996). In addition, a bed incipient motion analysis is presented for each geomorphology site, where applicable, using Shields equation (Shields 1936).

Effects of dams and flow regulation on channel morphology are expected to be more pronounced in response reaches. Response reaches are reaches that are the most likely to show an impact from alterations to hydrology or sediment supply and are defined by Montgomery and Buffington (1998) as reaches with: 1) low slope (<4 percent); 2) predominantly alluvial bed and banks (cobble-gravel facies or finer); and 3) plane bed or pool-riffle morphology. Bedrock channels, or reaches with clasts comparable in size to depth of flow, remain relatively unaltered due to high sediment transport capacities and resistant substrate. Broad-level channel classification based on channel slope and confinement can be used to identify response reaches. Detailed field surveys are used to characterize channel morphology and describe existing geomorphic functions at response sites downstream of UARP and Chili Bar Project dams. These data may be used to identify and quantify the effects of changes in discharge and sediment regime on channel morphology.

### 3.1 Geomorphic Characterization

The first step in the channel morphology assessment included a geomorphic characterization (Level I) of stream reaches based on available data (Rosgen 1996). In this classification system, reaches are subdivided and assigned a letter designation based on the following channel attributes:

- Slope
- Planform (sinuosity)
- Entrenchment
- Valley type
- Landforms/soil type

Appendix A contains a schematic of the classification system (Rosgen 1996) depicting the channel form and associated metrics for each of the channel types in the Rosgen classification system.

Five primary data sources were used for the initial Level I channel characterization:

- United States Geological Survey (USGS) 1:24,000 topographic maps
- Channel slope data generated from a GIS
- Geologic maps
- Aerial photographs
- Video footage from helicopter aerial shoot.

Initially, USGS 1:24,000 topographic maps were evaluated to identify associations between topography and the processes that form them. These were used to determine the valley types within the study area, as defined by Rosgen (1996).

Next, channel slope data were generated from 1:24,000 USGS topographic maps and used as the basis for initial channel classification. Reach-scale gradients for all of the stream reaches were generated based on digitized and vectorized USGS 1:24,000 topographic separates. For this analysis, contour and stream network layers were used to generate the reach gradients at a 40-foot contour interval. The precision of the channel gradient data sets are the same as the USGS 1:24,000 topographic maps, which are generated from aerial photographic interpretation.

Geologic maps (Saucedo and Wagner 1992, Jenkins 1932) provided the locations of important changes in lithology, and provided an overall geologic context for analyzing field data.

Color aerial photographs taken in August 2002 at base flows for that season were orthorectified (1 foot = 1 pixel) and converted to a suitable format for use in GIS. Aerial photographs and low altitude (tree-top level) video coverage (August and October 2002) from a helicopter were used to define alluvial stream sections and to refine the slope-based channel geomorphic characterization.

In addition to these primary data sources, field data from coincidental habitat mapping, macroinvertebrate, and resident fish population surveys were used to determine the habitat type (low gradient riffle, run, pool, etc.) and the dominant bed material where these survey sites overlapped with the selected geomorphology study sites.

The purpose of the geomorphic characterization was to provide a broad classification that integrated valley morphology with channel relief, pattern, shape, and dimension for all stream reaches (Rosgen 1996). This information was used to identify potential response reaches. Potential response reaches were delineated based upon their slope, channel confinement, and bed and bank sediment composition (e.g., alluvial versus bedrock); these reaches occurred in Rosgen B, C, D, E, and F channel types.

### 3.2 Identify and Select Morphological Description and Channel Condition Assessment Sites

### 3.2.1 Identification of Potential Morphological Description and Channel Condition Assessment Sites

Morphological description (Level II) and channel condition assessment (Level III) sites were selected in consultation with the Aquatic TWG based on results of the geomorphic characterization (Level I). Wherever possible, sites were selected in response reaches. Survey sites were selected with the following characteristics:

- alluvial channel;
- slopes less than four percent (4%);
- well developed floodplains;
- accessible by field crews;
- coincide with the instream flow or other sites whenever possible; and
- sites where the channel is not confined by bedrock banks or valley walls.

In reaches where there was more than one potential survey site, the site where channel response to project operation is most likely to be evident was selected. The upstream-most response site in a stream reach was selected to measure potential scour below UARP or Chili Bar Project dams, and because effects of the projects can be more difficult to observe as new sources of sediment and water enter from tributaries downstream of a dam. Additional sites on some stream reaches were selected in the lower portion of the reach, where the combination of reduced peak flows and potentially increased sediment supply from tributaries can cause excess fine sediment deposition. In cases where the entire reach is confined by valley walls, survey sites were selected based on the presence of developed floodplains and continuous deposition of alluvial sediment.

### 3.2.2 <u>Selection of Morphological Description and Channel Condition Assessment Sites</u>

After geomorphic characterization (Level I), low altitude aerial photos and video footage conducted during a helicopter flyover of the study area were reviewed to confirm or reject potential sites.

### 3.2.2.1 Sites of the UARP

A total of 12 UARP sites were selected for morphological description (Level II) in conjunction with the Aquatics TWG on February 6, 2003. Each of these sites was also used for any channel condition assessment. UARP survey sites ranged from an elevation of 6,140 feet on the Rubicon River to 1,114 feet on the SFAR near the confluence of Rock Creek. Table 3.2-1 includes the list of Level II and III sites. Figure 3.2-1 is a summary map showing the locations of the Level II and III sites. Complete site maps are in Appendix B. Locations are also plotted on reach-scale longitudinal profile graphs in Appendix C.

# 3.2.2.2 Sites in the Reach Downstream of Chili Bar

In consultation with the Aquatics TWG on September 4, 2003, four sites were selected for morphological description (Level II) in the Reach Downstream of Chili Bar. Of these, only two were selected for channel condition assessment (Level III). Sites that were not chosen for channel condition assessment (Level III) were located in areas where the river is confined within a steep bedrock gorge with bedrock and large boulder channel substrate and few alluvial deposits. Survey sites in the Reach Downstream of Chili Bar ranged from an elevation of 840 feet to 502 feet on the SFAR. Table 3.2-1 includes the list of Level II and III sites. Figure 3.2-1 is a summary map showing the locations of the Level II and III sites. Complete site maps are in Appendix B. Locations are also plotted on reach-scale longitudinal profile graphs in Appendix C.

# 3.3 Morphological Description and Channel Condition Assessment

Morphological description (Level II) and channel condition assessment (Level III) data were collected following the survey methodologies and protocols listed below. During each visit, standardized Level II and Level III data sheets were completed. Appendix D includes sample datasheets.

# 3.3.1 <u>Morphological Description Surveys</u>

Morphological description (Level II) field surveys included, but were not limited to, the following site-scale measurements:

- longitudinal profile (water surface and thalweg);
- approximately three monumented channel cross-sections, each surveyed at intervals sufficient to clearly depict channel geometry (Harrelson *et al.* 1994);
- pebble counts of channel substrate at cross-sections (Wolman 1954); and
- bankfull indicators, thalweg, water's edge, and flood-prone areas were delineated where identifiable.

Each cross-section was photo-documented and any observations of potential anthropogenic influences on the channel were recorded, including excess fine sediment, excessively coarse channel bed, or channel incision. A site was approximately 20 to 30 bankfull widths in length, where appropriate, with upper and lower boundaries geo-referenced. Nine sites were less than 20 to 30 channel widths long. These sites were short (<20 bankfull widths long) alluvial sections with bedrock channels immediately upstream and downstream.

The elevation of bankfull discharge was estimated at each site. Bankfull discharge is the flow rate at which the water surface is at the floodplain level, or the elevation of the top of channel banks (Leopold 1994). This discharge is thought to have morphological significance because it represents the breakpoint between active channel formation and floodplain formation (Copeland *et al.* 2000). Much research has focused on the concept of a single representative discharge,

sometimes referred to as the channel-forming or dominant discharge, which may be used to determine stable channel geometry (Wolman and Miller 1960, Emmett 1975, Pickup and Warner 1976, Andrews 1980, Richards 1982, Ashmore and Day 1988, Leopold 1994, Nash 1994, Knighton 1998, Biedenharn *et al.* 2000, Copeland *et al.* 2000, Doyle *et al.* in review). Past research has shown that bankfull discharge ( $Q_{bf}$ ) may approximate the channel-forming discharge in stable, alluvial channels (Wolman and Miller 1960, Emmett 1975, Andrews 1980, Leopold 1994). In the context of the Rosgen approach, bankfull discharge is "the single most important parameter used in Level II classifications" (Rosgen 1996). Therefore, a meaningful evaluation of the delineative criteria set forth in the Rosgen stream classification system, and its implications for channel maintenance in the UARP and the Reach Downstream of Chili Bar, depends on the successful determination of bankfull discharge from field surveys. In the field component of this study, bankfull elevations were estimated from field indicators, including:

- topographic breaks;
- top of bar surfaces;
- distinct changes in vegetation; and
- obvious differences in grain size distributions at the surface (Leopold 1994).

Establishing "reference" sites upstream of the reservoirs is advised to compare delineative criteria and verify bankfull stage elevations between sites of the same type (Rosgen 1996). Few candidates for such sites exist in the UARP or the Reach Downstream of Chili Bar, because many of the upstream areas are bedrock dominated, non-alluvial transport reaches. Those that do exist are not comparable in character to the sites within the study areas. Thus, reference reaches were not established in the context of this study.

There are several important caveats concerning the definition and interpretation of bankfull discharge. First, field estimations of bankfull are generally difficult to make given the number of different criteria in common use to define bankfull stage, none of which appear to be universally applicable and/or free of subjectivity (Leopold *et al.* 1992, Leopold 1994, Copeland *et al.* 2000). Identification of bankfull indicators in the field should only be performed in stream channels that are stable and alluvial (Knighton 1998, Copeland *et al.* 2000). Thus, channels that are not stable, in the sense that they are adjusting to present or past human disturbance (e.g. dam construction, road building, instream mining), may not be good candidates for reliable bankfull estimation. Likewise, channels that deviate from the self-forming, alluvial channels typical of lowland, flat regions of a watershed, are also less likely to display clear bankfull indicators. As an alternative to bankfull, research has shown that the channel-forming discharge in alluvial channels may correlate best with the *effective* discharge (Q<sub>eff</sub>), or the discharge that transports the largest fraction of the average annual bed-material load (Pickup and Warner 1976, Richards 1982, Ashmore and Day 1988, Nash 1994, Biedenharn *et al.* 2000, Copeland *et al.* 2000, Doyle *et al.* in review).

Bedrock and boulder dominated mountain streams adjust according to a wide range of flows that mobilize both coarse and fine boundary sediments (Nolan *et al.* 1987, Wohl 2000, McBain and Trush 2004). Rapid variations in valley width, channel cross-sectional form, slope, substrate

composition, and other roughness elements, such as the presence or absence of vegetation or woody debris, contribute to the high variability of both velocity and channel dimensions in mountain environments (Wohl 2000). Therefore, indirect calculations of discharge (e.g., by Manning (1889) or Chezy (1769) equations (as presented in Knighton 1998)) may be imprecise given the complexity of grain, form, free-surface and boundary roughness in these environments. Further, the assumptions of downstream hydraulic geometry (e.g., empirical relations that assume that discharge (Q) is the dominant independent variable (Leopold and Maddock 1953)). on which the concept of a single channel forming discharge is based, may be less applicable in mountain rivers that are strongly influenced by non-fluvial processes (e.g., debris flows, landslides, glaciers), bedrock control, and/or large woody debris (McBain and Trush 2004, Wohl et al. 2004). Thus, field estimated bankfull elevations in these systems will naturally vary according to local controls over relatively short distances along a stream's longitudinal profile. There may also be few bankfull indicators along mountain streams: floodplain surfaces "are most prominent along low-gradient, meandering reaches..." and "are often hard or impossible to identify along steeper mountain streams" (Harrelson et al. 1994). This is because the rough channel boundaries and high transport capacity typical of these systems often leave little or no trace of a floodplain deposit.

Stream channels within the UARP and the Reach Downstream of Chili Bar are all strongly influenced by the underlying metamorphic and igneous complex that creates the Sierra Nevada range and foothills. Segments of these channels with alluvial deposits have been distinguished from those that are entirely bedrock controlled as potential "response" sites, where Level II and III channel morphology surveys were completed. Yet, as described by McBain and Trush (2004), these are "highly dynamic depositional environments" where large-scale geomorphic controls such as bedrock and boulders control the deposition of finer material as "nested" features. The significance of various flow thresholds and the existence of downstream hydraulic relationships are being studied in bedrock dominated and mountain channels, but show few significant correlations (Wohl et al. 2004, Wohl in review). In addition, it is important to note that the alluvial deposits that do occur in the UARP and Reach Downstream of Chili Bar may still be adjusting to changes to sediment and discharge regime under the recent 40-60 years of dam regulation. Considering all of the above, field estimates of bankfull level indicators may be expected to be highly variable over short reaches of channel, and potentially unreliable in some reaches. These factors combine to make estimates of bankfull discharge highly variable for most sites in the UARP and the Reach Downstream of Chili Bar. To obtain some understanding of the variability involved in the discharge estimates, and the meaningfulness of the field bankfull indicators, the study results are discussed in the context of current and pre-regulation hydrology in Section 4.4 of this report.

In some cases, field conditions precluded collecting cross-section survey data across the entire channel width at the flood-prone elevation, due to particularly wide floodplains, flood elevations above the upper terrace surfaces, thick vegetation, steep slopes, or other factors. In these cases, surveyor observations, extrapolated slope angle data, field notes, and/or site photographs were used to estimate the flood-prone width as accurately as possible. Slope extrapolations were typically based on the slope angles defined by the last few surveyed points. In most cases,

potential errors from flood-prone width estimates would not affect channel classification because cross-section survey data (or on-site observations) had already documented a sufficiently wide flood-prone width to place the cross-section in the highest entrenchment ratio category (floodplain width/bankfull width greater than 2.2). In a few cases where the calculated entrenchment ratio was less than 2.2, there was very high confidence in the flood-prone width estimate.

### 3.3.2 Channel Condition Assessment

Channel condition assessment (Level III) data were collected at all 12 sites in the UARP and two sites in the Reach Downstream of Chili Bar. The following data were collected:

- bed surface texture based on facies mapping (stratification and delineation of channel bed features based on surface particle sizes and organization);
- sediment deposition in pools using the V\* method (USFS 1997, Lisle and Hilton 1992, Hilton and Lisle 1993), where possible and applicable;
- streambank and channel condition and stability;
- riparian vegetation condition and potential;
- depositional features, meander pattern, and debris jam condition; and
- large woody debris (LWD) loading and function.

Pool selection for the V\* method is based on the process described by Hilton and Lisle (1992, 1993). Hilton and Lisle suggest that the usefulness of V\* is limited to channels with:

- a wide range in particle size between armor layers and fine sediment in pools;
- a single thread;
- pool-riffle morphology;
- stable banks;
- bed gradient less than 5%;
- pools that can be waded; and
- where significant volumes of fine sediment can be deposited in pools.

Field measurements should be taken during low-flow periods, when identifying the residual pool is easier. Pools should have a depth of at least 0.3 meters and a volume of at least  $0.3 \text{ m}^3$ . The size range of fine sediment varies by stream, but fine sediment typically consists of sand and small pebbles, but may include silt to medium pebbles. Fine sediments are distinguished from the coarser substrates in pools because fines are not armored, are distinctly finer than the rest of the bed, and easily penetrable with a metal rod (Lisle and Hilton 1993).

In practice, measurable fine sediment deposits were not observed in any pool for the sites in the UARP or the Reach Downstream of Chili Bar. In addition, several stream channels were planebedded, characterized by long stretches of relatively planar channel bed with a distinct lack of well-defined bedforms, and thus did not contain well-defined pools (as required for the V\* method). As such, V\* measurements were not taken at any site. Recognizing that the characterization of fine sediment accumulation in stream channels can be a useful guide in interpreting both geomorphic and biologic processes, field site visits were conducted with US Forest Service and SMUD personnel to determine an appropriate method to apply at response sites within the project areas. The effects of tributary inputs were discussed, yet it was determined that tributary influences were not easily identifiable at the channel surface, nor did an effective method exist to sufficiently address the balance between fine and coarse sediments in the main channel. Instead, it was proposed that surveys of riffle embeddedness would be performed at all but one response site, where a baseline quantification of fine sediment would be estimated. Embeddedness is the degree to which fine sediments surround coarse substrates on the surface of a streambed, and is often thought to indicate the level of substrate mobility as well as available habitat space for fish and macroinvertebrates. Embeddedness surveys require an appropriate method, as defined in the literature (Sylte and Fischenich 2002). Methods can include, but are not limited to, the following:

- 1. Visually estimate embeddedness to determine the percentage of surface area of the larger-sized particles covered by fine sediment.
- 2. A subset of relatively large particle sizes (site-specific) can be randomly selected and the percentage (to the nearest 10 percent) of each particle's height that is buried in the fine sediment can be noted by the extent of discoloration on the particle surface.
- 3. Fine sediment that is causing embeddedness can be characterized by visual estimation, or pebble count where possible.
- 4. Photographs of the substrate can be taken for further evaluation in the office.

The following methods are possible alternatives to V\* in the UARP and the Reach Downstream of Chili Bar:

- embeddedness surveys at riffle locations at response sites Rubicon Dam Reach, Loon Lake Dam Reach Middle and Lower sites, Robbs Peak Dam Reach, Ice House Dam Reach Upper and Lower sites, and the Upper Coloma Site in the Reach Downstream of Chili Bar; and
- sediment depth probing with a long metal rod or auger could be used to characterize overall fine sediment accumulation at the Loon Lake Dam Reach Upper Site.

At the remaining sites (Gerle Creek Dam, Junction Dam Reach, Camino Dam Reach, SFAR Reach, and Slab Creek Dam Reach in the UARP; and the Upper Canyon, Lower Coloma, and Gorge sites in the Reach Downstream of Chili Bar), the very low volumes of fine sediment present make alternative measurements of fine sediment accumulation unnecessary. Additional detail on the rationale for additional fine sediment assessment in each reach is provided in the results section.

LWD was defined according to the USFS Region 5 Stream Condition Inventory (SCI) protocol as all pieces of wood lying within the bankfull width of the channel that measured one half bankfull width or longer, with a minimum diameter of 6 inches. Only dead or dying, downed wood, with a portion lying within the bankfull channel was considered LWD. This involved

dividing the LWD into size classes and tallying the total number of LWD pieces in each size class at each site. Key pieces of LWD were determined using the following criteria:

- 1. All pieces with length greater than 1.2 times the bankfull channel width; or
- 2. Pieces meeting criterion 1 and with diameters > 24 inches.

Because some LWD was suspended over the channel or was too small to alter bed morphology, the interaction between LWD and the bed was qualitatively assessed. A more detailed assessment of LWD is presented in the *Stream Habitat Mapping Technical Report*.

## 3.4 Channel Bed Mobility

A bed incipient motion analysis is presented for each geomorphology site, where applicable, using Shields equation (Shields 1936). The *EASI* (Enhanced Acronym Series with Interface) model, which implements the surface-based bedload equation of Parker (1990a, b), was used to evaluate normalized Shields stress and bedload transport based on cross-section, channel gradient, surface grain size distribution, and discharge input parameters. A more detailed description of the model and assumptions is included in Appendix M.

## 4.0 **RESULTS**

Maps with the geomorphic characterization (Level I) results are in Appendix B. Reach-scale longitudinal profiles with slope graphs are in Appendix C. In addition, each site was photo-documented and GPS coordinates were recorded for each cross-section and longitudinal profile. One representative photograph for each of the three cross-sections at every site can be found in Appendix E, and a table of GPS coordinates and a complete photographic record, including index, are included in Appendix F (on separate CD). For some sites, an alphanumeric channel type could not be designated based on every metric of the delineative criteria (e.g., entrenchment ratio, width/depth ratio, and sinuosity), as proposed by Rosgen (1996) (Appendix A). In these cases, an appropriate channel type was assigned based on the preponderance of data.

### 4.1 Results for the UARP

Morphological description (Level II) and channel condition assessment (Level III) data were collected for 12 sites in the UARP. Table 4.1-1 presents a summary of channel characteristics and data analysis results for the UARP. Appendix G includes longitudinal profile data, cross-section data, and pebble count tables for each site. Longitudinal profiles, cross-sections, and pebble count plots for each site are located in Appendix H. Level III data can be found in Appendix I. Facies maps for the UARP reaches can be found in Appendix O. All UARP geological setting descriptions are based on those previously presented in the Project Operation and Resource Utilization Section of the Initial Information Package, or IIP (SMUD 2001).

### 4.1.1 <u>Rubicon Dam Reach Site (Geomorphology Site RD-G1)</u>

#### <u>Setting</u>

The 4.1-mile-long Rubicon Dam Reach on Rubicon River extends from the base of Rubicon Dam (elevation 6,548 feet) downstream to the confluence with Miller Creek (elevation 6,030 feet), and has a mean gradient of approximately 0.019 (1.9 percent). There is a 1.5-mile, low-gradient meadow (at Rubicon Springs) at the lower end of the reach and another short, lower gradient section of river just upstream of the meadow. No major tributaries enter this reach.

The Rubicon River drains a glaciated watershed, much of which is designated as wilderness, and flows through many sections of exposed granite and steep, confined bedrock chutes. Approximately 75 percent of the watershed is underlain by Mesozoic granitic and dioritic rocks. The remainder consists of the Miocene Mehrten Formation, glacial moraine deposits, and minor outcrops of the Jurassic metasedimentary rocks of the Sailor Canyon Formation.

### Morphological Description and Channel Condition Assessment

Morphological description (Level II) and channel condition assessment (Level III) data were collected along a 500-feet section of the Rubicon River located approximately 1.6 miles below Rubicon Reservoir at an approximate elevation of 6,140 feet (Figure 3.2-1). The site is located downstream of a narrow canyon, where the river enters a wide alluvial valley.

A mature conifer forest grows along the channel and on moderately steep (30-40 percent) valley slopes. The banks are well vegetated with thick grasses and deciduous understory. Survey measurements indicate that the channel at this site is an F4 channel type, with a moderate channel entrenchment (1.1-1.7), high width-to-depth ratio (41-125), local bed slope of 0.007 (0.7 percent), and a gravel-dominated substrate. This site is comprised of well vegetated, lateral and mid-channel gravel bars and has irregular meanders (S=1.12) with pool-riffle morphology. Raw banks of up to 12 inches were observed, but there was no evidence of recent sediment deposition or bar development. Woody debris was sparse in flood-prone areas. Key LWD pieces that span the channel were not observed at this site at the time of the survey.

V\* measurements were not taken because fine sediment deposits were not observed in the pools at the site. Between the pools, cross-section pebble counts indicate that small gravel (<8 mm along the middle axis) accounts for an estimated 3-10% of the surface bed material, while sand and smaller portions (<2 mm along the middle axis) account for 12-15%. The frequency of dominant and subdominant substrates over the entire length of the Rubicon Dam Reach, as reported in the Stream Habitat Technical Report (July 2004), indicate a low-to-moderate presence of gravel, sand, and silt (2-17%). These data indicate at least a moderate presence of fine material, despite observations that fines have not accumulated in discrete patches on top of the channel bed in pools. Following site visits to selected locations with SMUD and USFS representatives, it was agreed that embeddedness surveys at riffle locations were a possible alternative to the V\* method to better characterize the balance between fine and coarse sediment at this site.

#### 4.1.2 Loon Lake Dam Reach Sites (Geomorphology Sites LL-G1, LL-G2, LL-G3)

#### <u>Setting</u>

The 8.9-mile Loon Lake Dam Reach on Gerle Creek extends downstream from the base of Loon Lake Dam (elevation 6,310 feet) to the normal high water line of Gerle Reservoir (elevation 5,231 feet), and has a mean gradient of approximately 0.023 (2.3 percent). Major tributaries along this reach include Jerrett, Barts, Dellar, and Rocky Basin creeks.

The Gerle Creek watershed is underlain by Mesozoic granitic and dioritic rocks, glacial moraine deposits, and minor outcrops of the Jurassic metasedimentary rocks of the Sailor Canyon Formation. Gerle Creek drains Loon Lake Reservoir and flows initially to the west through a wide and swampy Holocene alluvial valley (Neck Meadow and Gerle Meadow) that is surrounded by moderately sloping and glaciated hillsides. This upper subreach meandering across the alluvial valley is approximately five miles long. Between Johnny's Hill and Gerle Creek Reservoir (located at the confluence of Angel and Gerle creeks), the river flows along a lithologic contact between granitic rocks and glacial till deposits. This lower subreach is approximately three miles long.

#### Morphological Description and Channel Condition Assessment

Morphological description (Level II) and channel condition assessment (Level III) data were collected at three sites (Upper, Middle, and Lower) along Gerle Creek downstream of Loon Lake Dam. The 400-feet-long Upper Site is located about 0.5 miles downstream of Loon Lake Dam at an approximate elevation of 6,150 feet (Figure 3.2-1). The 700-feet-long Middle Site is located approximately 2.7 miles downstream of Loon Lake Dam at an elevation of 5,900 feet. Physical Habitat Simulation (PHABSIM) sites are located approximately 0.5 miles up and downstream of this site. The 600-feet-long Lower Site is located about 7.5 miles downstream from Loon Lake Dam at an elevation of approximately 5,340 feet. A PHABSIM site is located approximately 0.25 miles downstream from this site.

<u>Upper Site (Geomorphology Site LL-G1)</u>: At this site, the valley is wide and the creek flows within a densely vegetated mountain meadow. Young and mature conifers grow together on low-lying banks along the channel and into the surrounding meadow. The floodplain is characterized by vegetated point and lateral bars, regular meanders (S=1.25), and subtle pool-riffle morphology. Survey measurements indicate that the channel at this site is an E5 channel type with very little entrenchment (5.4-14) and a low width-to-depth ratio (8-10). The average local bed slope is 0.007 (0.7 percent) and bed material is primarily fine to coarse sand. Thin silt deposits (0.04-0.20 inches) were observed over the entire channel bed. Several larger silt deposits of unknown thickness were noted behind flow obstructions and along the channel margins. Abundant medium to large sized woody debris occupies up to 30 percent of the active cross-sectional area. Several key pieces of LWD span the channel and act as velocity refuge, creating lateral scour pools. An estimated 30-50 percent of the active channel cross-section has been influenced by deposition and scour at obstructions, constrictions, and bends.

Although extensive fine sediment deposits were observed at this site, V\* is not an appropriate method to use at this site due to the lack of distinct pool-riffle control points and the contiguous nature of the fine sediments that make up the channel bed. Depth sounding via a long metal rod or auger to estimate and characterize overall fine sediment accumulation at this site is a possible alternative to V\*. Such data could be considered a baseline for comparison to future measurements and promote a better understanding of the balance between sediment supply and transport capacity at this location.

<u>Middle Site (Geomorphology Site LL-G2)</u>: This site is located immediately downstream of the confluence with Jerrett Creek at the head of a densely vegetated mountain meadow (Gerle Meadow), downstream of a steeper reach. A largely mature conifer forest grows on low-lying banks along the channel and into the surrounding meadow. The floodplain is characterized by a wide, straight channel with few meanders (S=1.05) and numerous lateral bars. Banks are well vegetated and low lying. Survey measurements indicate a C3 channel type with little entrenchment (5.4-9.3); high width-to-depth ratio (29-46); average local bed slope of 0.013 (1.3 percent); and bed material primarily comprised of small cobble. This site is characterized by plane-bed morphology with little bedform definition. Abundant medium to large sized woody debris was observed as single pieces and in jams. Many key pieces of LWD spanned the channel, although only a small number of these influenced channel morphology. Local scour, incision, fine sediment deposition, and/or enlargement of the channel were not observed. Many side channels were noted, commonly vegetated with grasses and herbaceous plants.

V\* measurements were not taken because fine sediment deposits were not observed in the pools at the site. Cross-section pebble counts indicate that fine gravel (<8 mm along the middle axis) accounts for an estimated 1-5% of the surface bed material, while sand and smaller portions (<2 mm along the middle axis) account for 1-5%. The frequency of dominant and subdominant substrates over the entire length of the Loon Lake Dam Reach, as reported in the Stream Habitat Technical Report (July 2004), indicate a moderate presence of gravel, sand, and silt (8-22%). These data indicate a at least a moderate presence of fine material, despite observations that fines are not located in discrete patches on top of the channel bed in pools. Following site visits to selected locations with SMUD and USFS representatives, it was agreed that embeddedness surveys at riffle locations were a possible alternative to the V\* method to better characterize the balance between fine and coarse sediment at this site.

<u>Lower Site (Geomorphology Site LL-G3)</u>: This site is located in a shallow valley downstream of the Ice House (Wentworth Springs) Road Bridge. Valley slopes are moderately steep (30-40 percent) with no evidence of historical or recent mass wasting episodes. A mature conifer forest with a moderately dense understory occupies the valley floor and side slopes at the site. Dense riparian vegetation, from large trees to small brush, covers the banks. The channel is characterized by pool-riffle morphology with point bar formation resulting in regular meanders (S=1.18). Survey measurements indicate a C3 channel type. The channel is slightly entrenched (2.9-8.5) with a high width-to-depth ratio (20-69), average local bed slope of 0.005 (0.5 percent), and bed material comprised primarily of cobble and gravel. Several high-flow side channels and debris jams were observed above the bankfull elevation along the right bank. Medium to large

sized woody debris is present in the bankfull channel. One key piece of large woody debris (LWD) created a plunge pool with reduced flow velocity. Isolated areas of recent scour and deposition were observed at the time of the survey, indicating that the channel is geomorphically active.

V\* measurements were not taken because fine sediment deposits were not observed in the pools at the site. Sand is present in low-velocity and less turbulent pockets along the channel margins. Cross-section pebble counts indicate that fine gravel (<8 mm along the middle axis) accounts for an estimated 0-4% of the surface bed material, while sand and smaller portions (<2 mm along the middle axis) account for 10-15%. The frequency of dominant and subdominant substrates over the entire length of the Loon Lake Dam Reach, as reported in the Stream Habitat Technical Report in July 2004, indicate a moderate presence of gravel, sand, and silt (8-22%). These data indicate a at least a moderate presence of fine material, despite observations that fines are not located in discrete patches on top of the channel bed in pools. Following site visits to selected locations with SMUD and USFS representatives, it was agreed that embeddedness surveys at riffle locations were a possible alternative to the V\* method to better characterize the balance between fine and coarse sediment at this site.

## 4.1.3 <u>Gerle Creek Dam Reach Site (Geomorphology Site GC-G1)</u>

### <u>Setting</u>

The 1.1-mile-long Gerle Creek Dam Reach on Gerle Creek extends from the base of Gerle Creek Dam (elevation 5,182 feet) to the confluence with the South Fork Rubicon River (SFRR) (elevation 4,980 feet), and has a mean gradient of approximately 0.035 (3.5 percent).

The Gerle Creek watershed is underlain by Mesozoic granitic and dioritic rocks, glacial moraine deposits, and minor outcrops of Jurassic metasedimentary rocks of the Sailor Canyon Formation. The creek is confined in a narrow canyon with vertical canyon walls near Gerle Creek Dam. The 0.5-mile section below Gerle Creek Dam is scoured to granitic bedrock and boulders. The channel in the lower portion of the reach is less confined and valley walls are less steep.

### Morphological Description and Channel Condition Assessment

Morphological description (Level II) and channel condition assessment data (Level III) were collected along an 800-feet section of Gerle Creek, approximately 0.8 mile below Gerle Creek Reservoir at an elevation of 5,020 feet (Figure 3.2-1). A PHABSIM site is located approximately 0.1 mile upstream from this site.

At this site, valley slopes are gentle (<30 percent) and there is no evidence of active or historical mass wasting along the channel margins. High brush, grass, and annual forbs densely occupy the banks of the low-water flow channel. Survey measurements indicate a B2c channel type at the upper cross-section and B3c channel types at the lower two cross-sections. The channel is moderately to slightly entrenched (1.9-12), has a moderate to high width-to-depth ratio (8-25) and a mean local bed slope of 0.008 (0.8 percent). Substrate is dominated by boulders at the upper cross-section and cobble at the two lower cross-sections. Bedrock and boulders form a straight, narrow channel (S=1.02) with discontinuous plane-bed morphology. Woody debris was

sparse within the bankfull channel and flood-prone areas. Key LWD pieces that span the channel were not observed along at this site.

Most of the medium grained and finer sediment fractions are absent, although one fine sediment deposit was observed in the tail end of a large pool near the lower cross-section. No fine sediment was observed deposited on the channel bed, suggesting that these grain size fractions are scoured and that transport capacity exceeds fine sediment supply. As a result, V\* measurements are not applicable at this site.

## 4.1.4 <u>Robbs Peak Dam Reach Site (Geomorphology Site RPD-G1)</u>

## <u>Setting</u>

The 5.6-mile-long Robbs Peak Dam Reach on SFRR extends from the base of Robbs Peak Forebay (elevation 5,205 feet) downstream to the confluence with Rubicon River (3,540 feet), and has a mean gradient of approximately 0.055 (5.5 percent). Major tributaries to this reach include Gerle and South creeks.

The SFRR watershed is underlain by Mesozoic granitic rocks, glacial moraine deposits, minor outcrops of the Miocene Mehrten Formation, Jurassic metasedimentary rocks of the Sailor Canyon Formation, and Paleozoic metasedimentary rocks. Upstream of the Gerle Creek confluence, the river flows through a glaciated, low relief granitic landscape. Downstream of the Gerle Creek confluence, the river is characterized by progressive entrenchment within the surrounding canyon. For the first two miles, the river is confined by moderate granitic canyon slopes. A contact between granitic and Paleozoic metasedimentary rocks marks a transition from the moderate canyon to a deep gorge with 1,500-feet walls.

### Morphological Description and Channel Condition Assessment

Morphological descriptions (Level II) and channel condition assessment data (Level III) were collected along a 900-foot section of the SFRR, approximately 0.5 mile below Robbs Peak Forebay at an elevation of 5,130 feet (Figure 3.2-1). In order to avoid effects from upstream project facilities on Gerle Creek, this site is located upstream of the SFRR/Gerle Creek confluence. A PHABSIM site is located approximately 0.1 mile downstream of the site.

At this site, valley slopes are gentle (<30 percent) with relatively high plant density and vigor, and there was evidence of infrequent mass wasting episodes. The floodplain is characterized by irregular meanders (S=1.00) with numerous mid-channel bars and overflow channels. The mid-channel cobble bars and streambanks are heavily vegetated with willows, and small conifers are growing on recently scoured surfaces. Survey measurements indicate a C4 channel type with slight entrenchment (2.1-4.1), high width-to-depth ratio (16-33), mean local bed slope of 0.002 (0.2 percent), and gravel-dominated substrate. Coarse sands also represent a moderate fraction of the surface grain size distribution. This site exhibits primarily plane-bed and pool-riffle morphology. Woody debris is absent from the low-flow channel, but medium to large sized woody debris (e.g., large limbs, branches, small logs, and/or portions of trees) occupied up to 10 to 30 percent of the active cross-sectional area above the low-flow wetted perimeter. Key LWD pieces that span the channel were not observed at this site.

V\* measurements were not taken because fine sediment deposits were not observed in the pools at the site. Cross-section pebble counts indicate that fine gravel (<8 mm along the middle axis) accounts for an estimated 1-4% of the surface bed material, while sand and smaller portions (<2 mm along the middle axis) account for 8-25%. On the ground habitat mapping was not performed for the Robbs Peak Dam Reach, so reach-long estimates of substrate composition are not available. The pebble count data indicate at least a moderate presence of fine material, despite observations that fines are not located in discrete patches on top of the channel bed in pools. Following site visits to selected locations with SMUD and USFS representatives, it was agreed that embeddedness surveys at riffle locations were a possible alternative to the V\* method to better characterize the balance between fine and coarse sediment at this site.

## 4.1.5 <u>Ice House Dam Reach Sites (Geomorphology Sites IH-G1, IH-G2)</u>

### <u>Setting</u>

The 11.5-miles-long Ice House Dam Reach on South Fork Silver Creek (SFSC) extends from the base of Ice House Dam (elevation 5,300 feet) to the normal high water line of Junction Reservoir (elevation 4,460 feet), and has a mean gradient of approximately 0.014 (1.4 percent). The reach is characterized by moderate valley walls that confine the channel to a narrow floodplain. Peavine Creek, Winmiller Ravine, and Big Hill Canyon are the three major tributaries in this reach.

SFSC is located in the southeastern portion of the project area and is underlain by Mesozoic granitic rocks, Paleozoic metasedimentary rocks, glacial moraine deposits, and Miocene Mehrten Formation rocks. Downstream of Ice House Reservoir, SFSC flows through a steep, granitic canyon that transitions into a deep gorge as the lithology shifts to Paleozoic metasedimentary rocks near the Silver Creek Campground. In 1992, the Cleveland Fire burned approximately 75 percent of the watershed (24,000 acres) downstream of Ice House Reservoir (USDA 1993).

### Morphological Description and Channel Condition Assessment

Morphological descriptions (Level II) and channel condition assessment data (Level II) were collected at two sites (Upper and Lower) along SFSC downstream of Ice House Reservoir. The 1,200-feet-long Upper Site is located approximately 1.5 miles downstream from the Ice House Reservoir at the Silver Creek Campground (Figure 3.2-1). PHABSIM studies were completed approximately 0.1 mile downstream of this site. The approximate elevation of the site is 5,190 feet. This site was not affected by the Cleveland Fire. The 1,300-feet-long Lower Site is located approximately 8.6 miles downstream of Ice House Reservoir at an elevation of approximately 4,665 feet. Again, a PHABSIM site is located approximately 0.1 mile downstream from this site. The Lower Site burned during the Cleveland Fire.

<u>Upper Site (Geomorphology Site IH-G1)</u>: At this site, valley slopes are gentle (<30 percent) with no evidence of recent major mass wasting episodes. The channel is characterized by planebed morphology, regular meander and point bar formation (S=1.03), banks stabilized by vegetation, and frequent terrace surfaces ranging from 10-16 feet above the estimated bankfull elevation. Survey measurements indicate a C4 channel type that is slightly entrenched (2.5-5) with high width-to-depth ratio (19-38) and an average local bed slope of 0.002 (0.2 percent). Bed material is primarily unconsolidated coarse sand and gravel that forms frequent bars along the channel margins. Local zones of bank scour and recent bar deposition suggest that sediment transport may occur regularly at moderate flows, and that the channel is likely sensitive to changes in discharge and sediment supply. Medium to small sized woody debris was present in moderate amounts, but has a limited effect on channel morphology. The lower section of this site contains several key LWD pieces that span the channel. These LWD pieces are firmly embedded, form backwater pools, act as instream cover, and effectively reduce flow velocity.

Fine sediment deposits were observed only on the floodplain surfaces, not in the base flow active channel. Residual pool filling measurements (V\*) were not taken at this site because of the dominant plane-bed morphology, which lack distinct bedforms required by V\*. Cross-section pebble counts indicate that fine gravel (<8 mm along the middle axis) accounts for an estimated 10-20% of the surface bed material, while sand and smaller portions (<2 mm along the middle axis) account for 15-27%. The frequency of dominant and subdominant substrates over the entire length of the Ice House Dam Reach, as reported in the Stream Habitat Technical Report in July 2004, indicate a low-to-moderate presence of gravel, sand, and silt (1-15%). These data indicate at least a moderate presence of fine material, despite observations that fines have not accumulated in discrete patches on top of the channel bed in well-defined pools. Following site visits to selected locations with SMUD and USFS representatives, it was agreed that embeddedness surveys at riffle locations were a possible alternative to the V\* method to better characterize the balance between fine and coarse sediment at this site.

*Lower Site (Geomorphology Site IH-G2):* This site is within the burned section of Ice House Dam Reach. The historically dominant conifer forest is slowly recovering on valley hillslopes that are primarily covered with dead wood and litter from the recent fires. The channel banks, which have been re-colonized by willow and alder, exhibit small amounts of erosion. This site exhibits primarily plane-bed morphology (S=1.18). Survey measurements indicate a C3 channel type that is slightly entrenched (2-3.3) with a high width-to-depth ratio (20-38) and an average local bed slope of 0.006 (0.6 percent). Although two medium-sized log jams and many pieces of LWD were observed at this site, most of the wood is only touching the wetted channel and is perched up on boulders and channel banks. There were no key pieces observed at this site.

Grain size distributions indicate that coarse gravel and small cobble are the dominant size classes in the main channel, although field observations suggest that the channel is highly embedded. Recent sand deposits are present on floodplains and terraces, and moderate deposition of new gravel and coarse sand was apparent on old and new bars. Thin silt deposits were observed over the entire bed within the active channel. More extensive silt deposits of unknown thickness were noted behind flow obstructions and along the channel margins. No discrete deep deposits were observed. Residual pool filling measurements (V\*) were not taken at this site because of the dominant plane-bed morphology, which lack distinct bedforms required by V\*. Cross-section pebble counts indicate that fine gravel (<8 mm along the middle axis) accounts for an estimated 2-8% of the surface bed material, while sand and smaller portions (<2 mm along the middle axis) account for 0-25%. The frequency of dominant and subdominant substrates over the entire length of the Ice House Dam Reach, as reported in the Stream Habitat Technical Report in July 2004, indicate a low-to-moderate presence of gravel, sand, and silt (1-15%). These data indicate a moderate presence of fine material, despite observations that fines have not accumulated in discrete patches on top of the channel bed in well-defined pools. Following site visits to selected locations with SMUD and USFS representatives, it was agreed that embeddedness surveys at riffle locations were a possible alternative to the V\* method to better characterize the balance between fine and coarse sediment at this site.

# 4.1.6 Junction Dam Reach Site (Geomorphology Site JD-G1)

## <u>Setting</u>

The 8.3-miles-long Junction Dam Reach on Silver Creek extends from the base of Junction Dam (elevation 4,300 feet) to the normal high water line of Camino Reservoir (elevation 2,195 feet), and the mean gradient is approximately 0.032 (3.2 percent). Major tributaries to this reach include Gray House Creek, Bear Creek, Davis Creek, and Onion Creek.

The watershed in the Junction Dam Reach is underlain by Paleozoic metasedimentary rocks and rocks of the Mehrten Formation. Silver Creek enters Paleozoic metasedimentary rocks just above Junction Dam and flows through a steep and highly confined gorge for most its course prior to the confluence with the SFAR.

### Morphological Description and Channel Condition Assessment

Morphological descriptions (Level II) and channel condition assessment data (Level III) were collected along an 820-feet section of Silver Creek about 1.5 miles downstream from the base of Junction Dam at an approximate elevation of 4,200 feet (Figure 3.2-1). PHABSIM studies were also completed at this site.

At this site, valley slopes are steep (>60 percent) with a mature conifer forest occupying steep bedrock banks. The valley lies perpendicular to the strike of a high-grade metamorphic complex, creating cascades and riffles where flow encounters more resistant bedrock layers (S=1.04). The riparian zone is relatively narrow, with a few alder saplings established on the low water shoreline and infrequent lateral bar deposits. Survey measurements indicate a B3c channel type, with moderate entrenchment (1.2-2.1), high width-to-depth ratio (20-42), mean local bed slope of 0.013 (1.3 percent), and a cobble-dominated substrate. This site is primarily bedrock controlled with discontinuous plane-bed morphology and little to no LWD in the active channel.

Gravel exists in the matrix beneath the cobble armor layer and pockets of gravel are deposited in the low velocity zones on the downstream sides of large flow obstructions and along the channel margins. No fine sediment (silt/sand) was observed deposited on the channel bed surface in the main flow paths or in pools, suggesting that these grain size fractions are scoured and that transport capacity exceeds fine sediment supply. As a result, V\* measurements are not applicable at this site.

### 4.1.7 <u>Camino Dam Reach Site (Geomorphology Site CD-G1)</u>

#### <u>Setting</u>

The 6.2-miles-long Camino Dam Reach on Silver Creek extends from the base of Camino Dam (elevation 2,810 feet) to the confluence of Silver Creek and the SFAR (elevation 2,055 feet), and has a mean gradient is approximately 0.023 (2.3 percent). The primary tributary to this reach is Round Tent Canyon.

Below Camino Dam, Silver Creek enters Paleozoic metasedimentary rocks of the Mehrten Formation and flows through a steep and highly confined gorge for most its course prior to the confluence with the SFAR. Camino Reservoir is located in the gorge area between the Jaybird and Round Tent canyon tributaries.

#### Morphological Description and Channel Condition Assessment

Morphological descriptions (Level II) and channel condition assessment data (Level III) were collected along a 700-feet section of Silver Creek about 3.5 miles downstream of Camino Reservoir and 2.75 miles upstream from the confluence with the SFAR (near the Camino Tunnel Adit) (Figure 3.2-1). The approximate elevation of the site is 2,380 feet.

At this site, valley slopes are moderately steep (40-60 percent), show evidence of infrequent episodes of mass wasting in the past, and confine the flow to a relatively narrow channel with low sinuosity (S=1.03). General vegetative vigor and density is low, suggesting a shallow, discontinuous root mass. The riparian zone is narrow, with low plant diversity and density. Channel character and hydraulics are primarily controlled by large flow obstructions created by frequent bedrock outcrops and large boulders. Survey measurements indicate a B3c channel type with moderate entrenchment (1.2-1.6), high width-to-depth ratio (22-26), average local bed slope of 0.016 (1.6 percent), and cobble-dominated substrate. This site is primarily bedrock controlled with steep riffles and intermittent pools. This site has coarse substrate with little LWD present within the active channel.

Gravel exists in the matrix beneath the cobble armor layer and pockets of gravel are deposited in the low velocity zones on the downstream sides of large flow obstructions and along the channel margins. No fine sediment (silt/sand) was observed deposited on the channel bed surface in the main flow paths or in pools, suggesting that these grain size fractions are scoured and that transport capacity exceeds fine sediment supply. As a result, V\* measurements are not applicable at this site.

### 4.1.8 <u>South Fork American River Reach Site (Geomorphology Site SFAR-G1)</u>

### <u>Setting</u>

The 2.8-miles-long SFAR Reach on SFAR extends from the confluence with Silver Creek (elevation 2,040 feet) to the normal high water line of Slab Creek Reservoir (elevation 1,850 feet), and has a mean gradient of 0.012 (1.2 percent). Bedrock walls confine the river in this narrow canyon and there are a few locations with floodplains on both sides of the channel. There are no major tributaries to the river in this reach.

The SFAR is underlain by Mesozoic granitic rocks, Paleozoic metasedimentary rocks, rocks of the Miocene Mehrten Formation, and glacial moraine deposits. From its confluence with Silver Creek to Slab Creek Dam, the river flows through a deep canyon composed of Paleozoic metasedimentary rocks. Steep valley slopes and bedrock walls confine the channel from bank to bank in many sections of the river in this area.

#### Morphological Description and Channel Condition Assessment

Morphological descriptions (Level II) and channel condition assessment data (Level III) were collected along a 520-feet section of the SFAR located approximately 2.2 miles upstream from the normal high water line of Slab Creek Reservoir at an elevation of 1,980 feet (Figure 3.2-1). The upstream portion of the SFAR above the Silver Creek confluence is out of the project area.

At this site, valley slopes are moderately steep (40-60 percent) and sparsely vegetated. Evidence of frequent or large mass wasting episodes that annually deliver sediment to the channel was observed. Bedrock and boulders form a straight, narrow channel (S=1.02) with coarse boulder and cobble point bars. Riparian vegetation is poorly established due to the lack of fine sediment deposition and steep bedrock banks. Survey measurements indicate a B3c channel type with high to moderate entrenchment (1.2-1.9), high width-to-depth ratio (14-26), average local bed slope of 0.009 (0.9 percent), and cobble-dominated substrate. Although the pebble counts indicate a cobble channel bed, field observations suggest this is only a thin layer covering boulders and bedrock. This site is primarily bedrock controlled with steep riffles and intermittent pools. There is little evidence of bank erosion. Little to no LWD is present within the active channel.

Gravel exists in the matrix beneath the cobble armor layer and pockets of gravel are deposited in the low velocity zones on the downstream sides of large flow obstructions and along the channel margins. No fine sediment (silt/sand) was observed deposited on the channel bed surface in the main flow paths or in pools, suggesting that these grain size fractions are scoured and that transport capacity exceeds fine sediment supply. As a result, V\* measurements are not applicable at this site.

### 4.1.9 <u>Slab Creek Dam Reach Site (Geomorphology Site SC-G1)</u>

### <u>Setting</u>

The 8.0-miles-long Slab Creek Dam Reach on the SFAR extends from the base of Slab Creek Dam (elevation 1,620 feet) to the normal high water line of Chili Bar Reservoir (elevation 990 feet), and has a mean gradient of approximately 0.015 (1.5 percent). Bedrock walls confine the river in this narrow canyon and there are few locations with floodplains on both sides of the channel. The largest alluvial deposits of sediments are located on the inside of meander bends or in pools forming isolated breaks in the steep river gradient. Tributaries to the SFAR along this reach include Redbird Creek, Iowa Canyon, South Canyon, Mosquito Creek, Jaybird Creek, Rock Creek, and White Rock Creek.

Pacific Gas and Electric Company Chili Bar Project FERC Project No. 2155

The lithology of the SFAR includes Mesozoic granitic rocks, Paleozoic metasedimentary rocks, Miocene debris deposits, and Pleistocene glacial moraine deposits. Downstream of the Slab Creek Dam, the lithology changes from Paleozoic metasedimentary rocks to Mesozoic granitic rocks, with lithology changing back to metasedimentary rocks at the Rock Creek confluence.

#### Morphological Description and Channel Condition Assessment

Morphological descriptions (Level II) and channel condition assessment data (Level III) were collected along a 650-feet section of the SFAR between the confluences of Jaybird Creek and Rock Creek, nearly 4.6 miles below Slab Creek Dam. The approximate elevation at the site is 1,114 feet (Figure 3.2-1). The site is approximately 0.1 mile upstream from the lower Slab Creek fish survey and PHABSIM sites and approximately 1.75 miles downstream of the benthic macroinvertebrate site. At the Slab Creek fish survey sites, only the upper segment had considerable gravel (30 percent) and cobble (40 percent) bed material. Neither of the macroinvertebrate sampling sites had continuous alluvial deposits in the Slab Creek Dam Reach.

At this site, valley slopes are steep (>60 percent), sparsely vegetated, and show evidence of infrequent mass wasting episodes. Bedrock and boulders form a straight, narrow channel (S=1.03) with coarse boulder and cobble point bars. Riparian vegetation is poorly established due to the lack of fine sediment deposition and steep bedrock banks. Survey measurements indicate that the channel at this site is a B3 channel type, with moderate to slight entrenchment (1.4-2.3), a high width-to-depth ratio (21-48), an average local bed slope of 0.028 (2.8 percent), and a cobble dominated substrate. Although the pebble counts indicate a cobble channel bed, field observations suggest this is only a thin layer covering boulders and bedrock. Local channel morphology includes bedrock and plane-bed environments, with little to no LWD present within the active channel. There is little evidence of bank erosion.

Gravel exists in the matrix beneath the cobble armor layer and pockets of gravel are deposited in the low velocity zones on the downstream sides of large flow obstructions and along the channel margins. No fine sediment (silt/sand) was observed deposited on the channel bed surface in the main flow paths or in pools, suggesting that these grain size fractions are scoured and that transport capacity exceeds fine sediment supply. As a result, V\* measurements are not applicable at this site.

#### 4.2 Results for the Reach Downstream of Chili Bar

Morphological description (Level II) surveys were conducted for four sites in the Reach Downstream of Chili Bar. Of these, channel condition assessment (Level III) data were collected for the two sites in the Middle Subreach. Table 4.2-1 presents a summary of channel characteristics and data analysis results for the Reach Downstream of Chili Bar. Appendix J includes longitudinal profile data, cross-section data, and pebble count tables for each site. Longitudinal profiles, cross-sections, and pebble count plots for each site are located in Appendix K. Level III data can be found in Appendix L. Facies maps for the Reach Downstream of Chili Bar can be found in Appendix P.

#### <u>Setting</u>

The 19.1-miles-long Reach Downstream of Chili Bar extends from the base of Chili Bar Dam (elevation 964 feet) to the normal high water line of Folsom Reservoir (elevation 466 feet), and has a mean channel gradient of approximately 0.005 (0.5 percent). The main tributaries to the SFAR along this reach, in the downstream direction, include Dutch Creek, Granite Creek, Jacobs Creek, Greenwood Creek, Hastings Creek, Norton Ravine, and Weber Creek.

This reach can be broken down into three distinct subreaches: Upper Subreach (Upper Canyon site), Middle Subreach (Upper and Lower Coloma sites), and Lower Subreach (Gorge site). The Upper Subreach is characterized by a higher channel gradient, long rapids, steep canyon walls, and few noteworthy alluvial deposits. The Middle Subreach lies in a broad, gently sloping valley and the channel is comparatively wider, more sinuous, and has more developed floodplains. Sections of the Middle Subreach have been mined for gold using suction dredges, which removed the original channel bottom and deposited dredger tailings in piles on the banks of the river. Suction dredging altered the channel morphology by removing coarse sediment and leaving behind large boulders, resulting in an artificially deepened channel. Portions of the Middle Subreach were excluded from consideration for a site because gold dredging greatly altered channel morphology. In the Lower Subreach, the regional slope increases again and the river enters a confining canyon. Here, the majority of the channel is formed in bedrock or boulders and depositional zones are typically found in areas where the canyon bottom widens.

NA = Not Applicable (see text)

\*Values based on estimated elevations (see text) Counts with <100 particles, or no counts performed (see text) The lithology of the SFAR from the confluence with Rock Creek (just upstream of Chili Bar Reservoir) to Folsom Lake includes Mesozoic granitic rocks and Paleozoic metasedimentary rocks. The lithology at the Rock Creek confluence is composed of late Silurian metasedimentary rocks of the Shoo Fly Complex. The lithology changes downstream to late-Permian to early-Triassic metasedimentary rocks of the Calaveras Complex. As the SFAR flows through the town of Coloma, it also passes through a Mesozoic granite inclusion from the Sierra Nevada batholith before changing back to the Calaveras Complex lithology. Downstream of Highway 50, the lithology changes to Jurassic metasedimentary rocks of the Western Jurassic terrane. Serpentine rock masses also occur where the SFAR enters into Folsom Lake (Alt and Hyndman 2000; Norris and Webb 1990).

### Morphological Description and Channel Condition Assessment Analysis

Level II Analysis: Channel morphology was described at four sites in the Reach Downstream of Chili Bar. The Upper Canyon Site was chosen as the representative channel type for the Upper Subreach. The 1,000-feet-long site is located about 2.2 miles downstream from the base of Chili Bar Dam at an elevation of approximately 840 feet above sea level (Figure 3.2-1). The "Flume" Flow Fluctuation Study Site is co-located at this site. Two representative sites were chosen for the long Middle Subreach. The Upper Coloma Site is located in the alluvial transition zone between the steep, confined Upper Subreach and low-gradient, less confined Middle Subreach. This 650-feet-long site is located about 5.1 miles downstream from the base of Chili Bar Dam, and lies at an elevation of 764 feet. The Lower Coloma Site is located in a broad valley downstream of the historical gold dredging activities. This 700-feet-long site is located about 9.3 miles downstream from the base of Chili Bar Dam, and lies at an elevation of about 680 feet. The "Camp Lotus" Flow Fluctuation Study Site is co-located at this site. Lastly, the Gorge Site is located in the Lower Subreach, where steep canyon walls confine the river into a narrow channel, high-gradient channel. This 600-feet-long site is approximately 17.5 miles downstream from the base of Chili Bar Dam and lies at an elevation of about 502 feet. The "Weber Creek" Flow Fluctuation Study Site is located approximately one mile downstream from this site.

<u>Level III Analysis:</u> Results of the geomorphic characterization (Level I) indicate that the Upper and Lower Subreaches of the Reach Downstream of Chili Bar cannot be classified as response reaches, as defined in Section 3.0 of this report. Therefore channel condition assessment (Level III) data were only collected at the Upper and Lower Coloma Sites in the Middle Subreach of the Reach Downstream of Chili Bar.

# 4.2.1 <u>Upper Canyon Site (Geomorphology Site CB-G1)</u>

At this site, the channel is deeply incised within gently rolling terrain of the Sierran foothills. Valley slopes are steep (>60 percent) with numerous bedrock outcrops. Portions of the hillslopes are un-vegetated and observational evidence suggests that the hillslopes are susceptible to occasional landslides and mass wasting. A thin forest occupies the surrounding hillslopes, although much of the ground below the trees is barren. Moderately vegetated banks consist of cobble, gravel, and sand. Survey measurements indicate a F3 channel type with a moderately entrenched channel (1.3-1.7), high width-to-depth ratio (30-51), average local bed slope of 0.01 (1.0 percent), and cobble-dominated substrate. Although the pebble counts

indicate a cobble channel bed, field observations suggest this is only a thin layer covering boulders and bedrock. The relatively coarse substrate is covered with black algae. Higher flows have created an overflow channel and cobble bar on the right bank. The channel at this site exhibits an irregular meander pattern (S=1.00) with little to no LWD present within the flood-prone area. Local channel morphology includes bedrock and plane-bed environments. There is little evidence of bank erosion.

Gravel exists in the matrix beneath the cobble armor layer and pockets of gravel are deposited in the low velocity zones on the downstream sides of large flow obstructions and along the channel margins. No fine sediment (silt/sand) was observed deposited on the channel bed surface in the main flow paths or in pools, suggesting that these grain size fractions are scoured and that transport capacity exceeds fine sediment supply. As a result, V\* measurements are not applicable at this site.

## 4.2.2 <u>Upper Coloma Site (Geomorphology Site CB-G2)</u>

At the Upper Coloma Site, valley slopes are moderately steep (40-60 percent) and exhibit evidence of episodic mass wasting. Vegetative vigor and density is largely controlled by aspect. The north facing slopes support greater floral density and diversity due to greater soil moisture retention during the summer and winter months. South facing slopes that are mostly dry throughout portions of the winter and the entire summer do not support a wide range or density of plant life. Survey measurements indicate a C3 channel type with a slightly entrenched channel (1.4-2.9), high width-to-depth ratio (35-57), average local bed slope of 0.007 (0.7 percent), and cobble-dominated substrate. This channel at this site is characterized by irregular meanders (S=1.20) and pool-riffle sequences with little signs of recent erosion or deposition. A vegetated, mid-channel bar divides the low flow into two channels at the upper end of the site. The channel bed, bar, and banks consist of cobble, boulders, gravel and sand (in order of dominance). Small bedrock outcrops occur along the banks at the upper and lower end of this site. The banks and tops of bars are moderately vegetated. The main channel lies as much as 7-10 feet below the level of surrounding alluvial fill at the downstream end of the site. All sizes of woody debris are essentially absent from within the bankfull channel and flood-prone areas.

A few small sand and silt deposits were observed in low-velocity, less turbulent pockets along the channel margins. No deposits were observed in the one pool evident at the site. Therefore, no V\* measurements were taken. Cross-section pebble counts indicate that small gravel (<8 mm along the middle axis) accounts for an estimated 0-2% of the surface bed material, and sand and smaller portions (<2 mm along the middle axis) similarly account for 0-2%. On-the-ground habitat mapping was not performed for the Reach Downstream of Chili Bar, so reach-long estimates of substrate composition are not available. Although field observations and survey data indicate that very little fine sediment is deposited on the channel bed at this site, fines were observed in the matrix of the coarse substrate. An embeddedness survey across the riffle located at this site may improve our understanding of the balance between fine and coarse sediment and, ultimately, the balance between sediment supply and transport capacity at this location.

## 4.2.3 Lower Coloma Site (Geomorphology Site CB-G3)

At the Lower Coloma Site, valley slopes are gentle (<30 percent) and do not appear to supply sediment to the channel through mass wasting processes. Numerous private, residential lots are located close to the banks on either side of the main channel. Hillsides are moderately vegetated with grasses, shrubs, and trees where human development has not modified the natural vegetation patterns. Riparian vegetation was sparse to dense along the channel margins, ranging from low lying grasses and shrubs to overhead bushes and trees. A dense wall of bramble (i.e., blackberry bushes) occupied the alluvial bar along the river right bank, and several private lawns extended down to or near the bankfull elevation on the left bank. Survey measurements indicate a C3 channel type with a slight entrenchment (1.7-2.0), high width-to-depth ratio (36-49), average local bed slope of 0.009 (0.9 percent), and cobble-dominated substrate. Bedrock outcrops occur along the banks at the upper and lower end of this site, and sparse boulders occur in the main channel. The channel at this site is characterized by regular meanders (S=1.20), point bars, and pool-riffle sequences with little signs of recent erosion. Similar bedrock outcrops exist throughout the channel at this site. The main channel lies as much as 10-16 feet below the level of surrounding boulder banks and alluvial fill at the downstream end of the site. Small to medium pieces of woody debris occur within the bankfull channel.

Gravel exists in the matrix beneath the cobble armor layer and pockets of gravel are deposited in the low velocity zones on the downstream sides of large flow obstructions and along the channel margins. Anecdotal evidence suggests that a large sand bar has formed in a pool at the upstream end of the site over recent years. This pool is created by flow separation around a large bedrock outcrop projecting into the channel from the left bank. No other fine sediment (silt/sand) deposits were observed on the channel bed surface in the main flow paths or in pools, suggesting that these grain size fractions are scoured and that transport capacity exceeds fine sediment supply. As a result, V\* measurements are not applicable at this site.

### 4.2.4 <u>Gorge Site (Geomorphology Site CB-G4)</u>

At this site, the channel is deeply incised within gently rolling terrain of the Sierra foothills. Valley slopes are moderately steep (40-60 percent) and exhibit evidence of mass wasting. This site is located in an alluvial depositional zone confined on the upstream and downstream ends by a narrow gorge (S=1.00). Hillslopes are moderately vegetated with grasses, shrubs, and trees. Willows, alders, and other riparian vegetation grow along the banks, but cobble bars surfaces are generally un-vegetated. Survey measurements indicate a F3 channel type with a moderate entrenchment (1.3-1.5), high width-to-depth ratio (51-81), average local bed slope of 0.006 (0.6 percent), and cobble-dominated substrate. A vegetated, mid-channel bar divides the low flow into two channels. The channel bed, bar, and banks consist of cobble, gravel, sand, and occasional boulders (in order of dominance). Sand beaches exist along the margins of the pools at the upper end of this site. Channel bed material is loosely packed and bright with little to no evidence of algal growth. The main channel lies as much as 10-16 feet below the level of surrounding alluvial fill at the downstream end of the site. All sizes of woody debris are essentially absent from within the bankfull channel and flood-prone areas. The Gorge Site is located in an alluvial section of the canyon, which is unusual for the Lower Subreach. Most of

the subreach is characterized by a bedrock gorge with large boulder riffles, small cascades, irregular meanders and pool-riffle morphology. Channel morphology and sediment dynamics within the gorge are very similar to the characteristics described for the Upper Canyon Site.

Gravel exists in the matrix beneath the cobble armor layer and pockets of gravel are deposited in the low velocity zones on the downstream sides of large flow obstructions and along the channel margins. No fine sediment (silt/sand) was observed deposited on the channel bed surface in the main flow paths or in pools, suggesting that these grain size fractions are scoured and that transport capacity exceeds fine sediment supply. As a result, V\* measurements are not applicable at this site.

## 4.3 Channel Bed Mobility

Channel survey data were used to evaluate Shields stress and sediment transport capacities at the geomorphology sites. The *EASI* (Enhanced Acronym Series with Interface) model was used to evaluate normalized Shields stress and bedload transport based on cross-section, channel gradient, surface grain size distribution, and discharge input parameters. A more detailed description of the model is included in Appendix M.

The *EASI* model was created primarily to address gravel transport. Grain size distributions in the UARP and the Reach Downstream of Chili Bar indicate that many grain size classes exist, outside the gravel range. Thus, transport flows must be considered carefully and as rough estimations rather than absolute values.

Although bed mobility and sediment transport rate is a topic of great interest to land managers, methods to determine the critical elements of incipient motion are still being developed for the wide range of channel types that occur in the stream reaches. Unfortunately, bed mobility is still difficult or impossible to accurately predict for many channel types using existing numerical modeling approaches, including channels with:

- steep gradient;
- rough, confined, thin or nonexistent alluvial cover over bedrock; and
- highly variable sediment sources.

In general, shear stress in the transport reaches within the UARP and in the Reach Downstream of Chili Bar dissipates over hydraulic jumps as flow encounters large boulders and/or bedrock. Pockets of sediment may be protected by these large flow obstructions despite a transport capacity that exceeds sediment supply. The dominant source of energy for sediment entrainment in these settings originates from random turbulence associated with flow separation that varies widely over short spatial and temporal scales. Predictions are further complicated by large variations in particle shape, size, and packing over small spatial scales. These conditions preclude an accurate evaluation of incipient motion using Shields stress equations (or any other available predictive numerical method) because existing models do not adequately address the extreme variability in hydraulic conditions near the stream bed, the bed material characteristics, or the size and availability of sediment supply. Field observations indicate that many of the

Sacramento Municipal Utility District Upper American River Project FERC Project No. 2101

study sites in the study area are comprised of these channel types. Study sites in the UARP where morphology precludes an accurate assessment of Shields stress include:

- Gerle Creek Dam Reach Site;
- Junction Dam Reach Site;
- Camino Dam Reach Site;
- S.F. American River Reach Site; and
- Slab Creek Dam Reach Site.

Study sites in the Reach Downstream of Chili Bar where morphology precludes an accurate assessment of Shields stress include:

- Upper Canyon Site;
- Lower Coloma Site; and
- Gorge Site.

The Loon Lake Dam Reach Upper Site was also considered for the analysis, but dominant channel particle size was too small for the model, a stipulation of the underlying Parker equations.

Normalized Shields stress and a bedload transport rating curve were determined for six response sites in the UARP and one response site in the Reach Downstream of Chili Bar (Tables 4.1-1 and 4.2-1). The longitudinal profiles, cross-sections, and grain size distributions for these sites are shown in Appendices G, H, J, and K. *EASI* modeling results for Shields stress and bedload transport rating curves are provided in Appendix N. Incipient bed mobility corresponds to a normalized Shields stress equaling unity (1). The corresponding discharge is the flow at which particles on the channel bed, large or small, begin to mobilize based on the concept of equal mobility (Parker *et al.* 1982, Andrews 1983). Particles of different sizes mobilize at the same discharge because they are inter-locked, and smaller particles are protected by the hiding and protrusion effects of the larger ones.

### 4.4 Bankfull Flow Analysis

Channel morphology survey results indicate that field measurements of the bankfull elevation, a measurement upon which much of the Rosgen analysis depends, showed large variability between sites and between cross-sections within sites. As already discussed in Section 3.3.1, this may be due to the problems encountered while attempting to estimate bankfull discharge, especially in bedrock dominated environments like those of the UARP and in the Reach Downstream of Chili Bar. In order to better understand the significance of bankfull flows in the vicinity of the UARP and Reach Downstream of Chili Bar, historic flow data were used from the Technical Report on Hydrology (February 2004) to compare both pre- and post-regulation 1.5-year floods with bankfull discharges calculated using field data at the 8 designated response sites. These comparisons were not made for the 8 designated transport sites due to the large influence of structural controls and their non-alluvial nature.

Assumptions regarding recurrence interval relations were used to compare field estimates of bankfull discharge with the hydrologic record. Annual maximum instantaneous flood peaks from regulated and unregulated periods of record were used to calculate the 1.5-year flood discharge for the response sites (Appendix Q). Where data were not available, unregulated discharge records from nearby watersheds with similar drainage areas and characteristics were used to estimate unregulated accretions downstream of reservoirs and/or pre-regulation flows. The 1.5-year recurrence interval has been shown to correspond to bankfull discharge for many stable, alluvial streams (Leopold 1994). However, it should be noted that recurrence intervals for bankfull discharge can be intrinsically different between channels, and often do not fall within the 1-2.5-year range that is commonly considered bankfull (Copeland *et al.* 2000).

Bankfull discharges and mean bankfull elevations measured in the field were compared to those based on recurrence intervals for both regulated and unregulated hydrology at each site (Appendix Q). The Manning equation was used to calculate a representative bankfull discharge for each cross-section using field data, and also to solve for the mean bankfull depth of each cross-section based on recurrence interval discharge estimates from each response site (Knighton 1998). Roughness coefficients, "n", were estimated using the results of five empirical relations and one additive equation (Cowan 1956) commonly used for mountain rivers (Wohl 2000). Estimates generated using the five empirical relations were averaged and compared to the additive method, or Cowan's method. In most cases, the roughness "n" value selected for use in the Manning equation represents the mean of the results obtained using Cowan's method and the average obtained using empirical relations. At sites or cross-sections where the influence of large flow obstructions (e.g.; LWD or in-channel vegetation) was great, the value estimated with Cowan's method was used.

Results of the comparison at each site suggest that field estimations of bankfull may be classified into three distinct groups (Table 4.4-1). The first group (1) consists of those cross-sections at a site where field estimated bankfull elevations primarily correspond with the estimated 1.5-year flood under the regulated hydrology. The second (2) consists of cross-sections at a site where bankfull elevations estimated in the field primarily correspond with the estimated 1.5-year flood under the pre-regulated hydrology. And, the third group (3) consists of those cross-sections at a site where there is little or no correspondence between field estimations of bankfull and the regulated or unregulated flows with 1.5-year recurrence interval. An interpretation is presented for each site below.

Group #3: Inconclusive

Group #2: Qbf corresponds with pre-regulated Q1.5

D<sub>bfmean</sub> = average bankfull depth

 $Q_{\rm bf}$  = bankfull discharge based on field measurements

At the Rubicon Dam Reach Site, field estimated bankfull discharge and elevation for the upper cross-section (Group #1) corresponds well with the 1.5-year flood under the regulated hydrology. Field measurements at both the middle and lower cross-sections (Group #3) underestimate mean bankfull elevations, and consequently discharge, when compared to those calculated using the regulated and unregulated hydrology. This may indicate that bankfull indicators are not well defined or entirely absent at these cross-sections because of the difficulties associated with measuring bankfull in mountainous and primarily bedrock controlled systems, as previously discussed in Section 3.3.1. Cross-section plots and the field photographs of both the middle and lower cross-sections suggest several explanations for the observed differences. The plot for the middle cross-section shows another possible slope break on the left bank that is slightly higher than the slope break on the right bank selected as the top-of-bank indicator. This higher slope break may be the true top-of-bank indicator, which would account for the underestimation. The cross-section plot at the lower cross-section shows a bar surface on the right bank that is much lower than other bars used as the top-of-bank indicator shown on either the upper or middle cross-sections. It is possible that this lower surface was mistaken for the top-of-bank indicator at the lower cross-section, which resulted in a bankfull discharge calculation that was too low.

At the Loon Lake Dam Reach Upper Site, field estimated bankfull discharges and elevations for both the upper and lower cross-sections (Group #2) correspond well with the 1.5-year flood under the unregulated hydrology. Field measurements at the middle cross-section (Group #3) overestimate mean bankfull elevation, and consequently discharge, when compared to those calculated using the regulated and unregulated hydrology. This may indicate that bankfull indicators are not well defined or entirely absent at this cross-section because of the difficulties associated with measuring bankfull in mountainous and primarily bedrock controlled systems, as previously discussed in Section 3.3.1. Cross-section plots suggest that field estimations of bankfull elevation occur at similar surfaces at all cross-section locations. Photographs of the middle cross-section show that large flow obstructions, such as large woody debris and vegetation, may locally influence channel dimensions. Scour associated with flow hydraulics around these obstructions may have created a pool at this cross-section and resulted in larger cross-sectional area and lower local slope, both of which may contribute to an overestimation of discharge.

At the Loon Lake Dam Reach Middle Site, field estimated bankfull discharges and elevations for both the upper and middle cross-sections (Groups #2 and #1) correspond well with the 1.5-year flood under the unregulated and regulated hydrology, respectively. Field measurements of bankfull elevation at the lower cross-section (Group #3) are between both regulated and unregulated bankfull calculations. This may indicate that bankfull indicators are not well defined or entirely absent at this cross-section because of the difficulties associated with measuring bankfull in mountainous and primarily bedrock controlled systems, as previously discussed in Section 3.3.1. Cross-section plots and photographs indicate that the meadow surface is highly irregular at this location. As a result, it is evident that there are several top-of-bank surfaces to select from in the field. In addition, as unregulated accretions occur along Gerle Creek, the hydrologic impact of Loon Lake Dam decreases. Accretion estimates confirm the diminishing effect of the dam, as the regulated and unregulated periods are similar. Thus, the geomorphic effects of floods during the regulated and unregulated periods are difficult to differentiate. This may also account for a field estimate that lies between the regulated and unregulated discharge estimates.

At the Loon Lake Dam Reach Lower Site, field estimated bankfull discharge and elevation for the lower cross-section (Group #1) corresponds well with the 1.5-year flood under the regulated hydrology. Field measurements at the upper and middle cross-sections (Group #3) underestimate bankfull elevation, and consequently discharge, when compared to those calculated using the regulated and unregulated hydrology. This may indicate that bankfull indicators are not well defined or entirely absent at these cross-sections because of the difficulties associated with measuring bankfull in mountainous and primarily bedrock controlled systems, as previously discussed in Section 3.3.1. Cross-section plots and photographs indicate that the floodplain surface is highly irregular at this location. As a result, it is evident that there are several top-of-bank elevations to select from in the field. Also, the effect of the estimated accretion is the highest of all sites on Gerle Creek below Loon Lake Dam. Accretion estimates are based on unregulated hydrology in nearby basins, and thus the effect of any discrepancies

between the estimate and the true accretion increases with drainage area below Loon Lake Dam. As such, the accretion estimates become less reliable for the lower site, and may contribute to the differences in mean bankfull depth and discharge calculations.

At the Robbs Peak Dam Reach Site, field estimated bankfull discharges and elevations for both the upper and middle cross-sections (Group #1) correspond well with the 1.5-year flood under the regulated hydrology, while the lower cross-section (Group #2) corresponds well with the 1.5-year flood under the unregulated regime. Cross-section plots indicate that the top-of-bank surface is above the estimated bankfull elevations at all cross-section locations, suggesting that the channel may have incised historically, although there are no significant indications of continuing channel incision. Photographs indicate that vegetation is growing well within the historic floodplain at the upper and middle cross-sections, which may have been more active during the pre-regulated period.

At the Ice House Dam Reach Upper Site, field estimated bankfull discharges and elevations for both the upper and lower cross-sections (Groups #1 and #2) correspond well with the 1.5-year flood under the regulated and unregulated hydrology, respectively. Field measurements of bankfull elevation at the middle cross-section (Group #3) are between both regulated and unregulated bankfull calculations. This may indicate that bankfull indicators are not well defined or entirely absent at this cross-section because of the difficulties associated with measuring bankfull in mountainous and primarily bedrock controlled systems, as previously discussed in Section 3.3.1. Cross-section plots and the field photographs of the middle cross-section suggest bankfull elevation was estimated below a primary slope break on the left bank. There are no noticeable slope breaks on the right bank. This may contribute to the difficulty in determining the field indicators of the 1.5-year flood at this cross-section.

At the Ice House Dam Reach Lower Site, field estimated bankfull discharges and elevations for both the middle and lower cross-sections (Groups #1 and #2) correspond well with the 1.5-year flood under the regulated and unregulated hydrology, respectively. Field measurements at the upper cross-section (Group #3) overestimate mean bankfull elevation, and consequently discharge, when compared to those calculated using the regulated and unregulated hydrology. This may indicate that bankfull indicators are not well defined or entirely absent at this crosssection because of the difficulties associated with measuring bankfull in mountainous and primarily bedrock controlled systems, as previously discussed in Section 3.3.1. Cross-section plots indicate that the bankfull indicators found at the lower two cross-sections were not found at the upper cross-section. A higher bankfull indicator was selected at the upper cross-section, which yielded a higher mean depth and cross-sectional area. Photographs confirm that there are few indicators along the relatively steep banks of the upper cross-section. Thus, discharge was probably overestimated because indicators of the 1.5-year flood were not clear at the upper cross-section.

The Upper Coloma Site was the only response site in the Reach Below Chili Bar. Because the difference between the estimated 1.5-year flood pre- and post regulation is relatively small, field estimated bankfull discharge and elevations at the middle and lower cross-sections (Groups #1

and #2) may correspond with either the 1.5-year flood under the regulated or unregulated hydrology. Field measurements at the upper cross-section (Group #3) overestimate mean bankfull elevation, and consequently discharge, when compared to those calculated using the regulated and unregulated hydrology. This may indicate that bankfull indicators are not well defined or entirely absent at this cross-section because of the difficulties associated with measuring bankfull in mountainous and primarily bedrock controlled systems, as previously discussed in Section 3.3.1. The conditions here are similar to those at the lower site of the Upper Ice House Dam Reach. Cross-section plots indicate that the top-of-bank bankfull indicators found at the lower two cross-sections were not found at the upper cross-section. A higher bankfull indicator was selected at the upper cross-section, which yielded a higher mean depth and cross-sectional area. Photographs confirm that there are few indicators along the relatively steep banks of the upper cross-section. Thus, discharge was probably overestimated because indicators of the 1.5-year flood were not clear at the upper cross-section.

In conclusion, the variability in the results of the comparisons of both pre- and post- regulation 1.5-year floods with bankfull discharges estimated using field data at the eight designated response sites demonstrates that a single channel forming discharge is difficult to define in bedrock controlled, mountainous settings. Furthermore, it supports the argument that channel form in these channels may not only reflect present hydrology and sediment regimes, but are also almost certainly shaped by sweeping large-scale controls that exist in these settings (e.g.; structural controls, infrequent hydrologic events and sediment input, and/or discharges that occurred under different climatic regimes). Many of effects of these influences are previously discussed in Section 3.3.1 of this report. The key elements of these are summarized below:

- Response channels in the UARP and the Reach Downstream of Chili Bar may not be self-forming and alluvial, as commonly defined (i.e., stream channels with mobile boundaries entirely composed of alluvium, where sediment supply equals or exceeds available transport capacity). Frequently occurring discharges may have less effect on modern channel form than episodic sediment delivery from mass wasting, infrequenthigh magnitude events caused by rain-on-snow events, and the influences of underlying bedrock geology. Many of the response channels are bedrock channels with relatively thin cover of alluvial material. The cover is thick enough to be show limited bedrock outcropping at the channel surface, but is not free of the influences of the underlying structure.
- 2) Large-scale controls effect local variations in valley width, channel cross-sectional form, slope, substrate composition, and other roughness elements, such as the presence or absence of vegetation or woody debris, and contribute to the high variability of both velocity and channel dimensions at the sites in the UARP and the Reach Downstream of Chili Bar. These effects are not easily quantified by many widely accepted geomorphic methods and tools, most of which were developed along stable, alluvial channels in lowland environments and provide the foundation for downstream hydraulic geometry relationships, indirect discharge calculations, and sediment transport models.

- 3) Channels that are regulated, such as those found in the UARP and the Reach Downstream of Chili Bar, may often show evidence of multiple geomorphic regimes and may not be stable. Pre- and post-regulation geomorphic indicators may be hard to differentiate in regulated systems, as shown in this analysis. Furthermore, the reaches at these sites may still be adjusting towards a new equilibrium based on the historic changes in the supply of sediment and water. As discussed in Section 3.3.1, channels that are not stable may not be good candidates for reliable bankfull estimation.
- 4) Finally, as McBain and Trush have highlighted in their 2004 article in Stream Notes, Sierra Nevadan streams, such as those found within the UARP and the Reach Downstream of Chili Bar, are complex and highly dynamic systems that may require a new approach in consideration of the underlying controls.

### 5.0 DISCUSSION

In this section, sites are discussed in the context of channel morphology and type (Tables 4.1-1 and 4.2-1). In order to permit a process-based discussion of each alphanumeric channel type observed in this study, each site was further sub-divided according to dominant channel morphology and type using the Montgomery and Buffington (1993, 1997, and 1998) system. Stream channels within a watershed can be divided into several categories according to the transport processes that dominate; a given reach may primarily generate, transport, or temporarily store sediment as it moves downstream. Channel response to changes in sediment supply and transport varies greatly depending on the dominant processes within a given reach. Although adjustments to alteration to flow and/or sediment supply may be complex, certain channel morphologies (e.g., colluvial, bedrock, cascade, and step-pool) are generally resilient and insensitive to these changes. These reaches are generally classified as source or supplylimited transport channel types. Along the same continuum, some channel morphologies (e.g., pool-riffle and regime morphologies) exhibit a wide range of potential responses to these changes and are most affected. These reaches are generally classified as transport-limited response channel types. Channels with plane-bed morphology are transitional in the spectrum and may either be transport or response type reaches depending on site-specific slope, confinement, and sediment supply. Plane-bed channels are characterized by long stretches of relatively planar channel bed with occasional channel spanning rapids, and a distinct lack of well-defined bedforms.

In this study, all observed B channel types were categorized as transport sites because they all occur in reaches where bedrock outcrops control channel morphology. Most observed C and all observed E channel types were categorized as response sites because these channels primarily exhibited pool-riffle morphology. Observed F channel types were either response or transport sites depending on local slope, bedrock influence, floodplain development, and bedform. Below, each channel type is discussed according to its relative sensitivity to changes in discharge and/or sediment supply, as either transport or response (Montgomery and Buffington 1993, 1998).

## 5.1 Transport Sites of the UARP

### 5.1.1 <u>B Channel Type</u>

All the designated transport sites within the UARP are classified as B channel types. This includes the Gerle Creek Dam Reach (B2c/B3c), Junction Dam Reach (B3c), Camino Dam Reach (B3c), SFAR Reach (B3c), and Slab Creek Dam Reach (B3) sites. All are moderately entrenched systems confined in structurally controlled, steep valleys. In most cases, narrow valleys form a narrow bedrock-controlled channel. Although pebble counts indicate a cobble channel bed, field observations show that numerous boulders and/or bedrock outcrops exist at each of these sites. Field observations also suggest that most of the boulders do not appear to be fluvially derived; rather, they were probably delivered to the mainstem by local slope failures, glacial processes, or glacial outwash floods. These large boulders essentially act as bedrock, as they appear to be stable even during extreme flow events. The hydraulics associated with flow around and over the top of large flow obstructions may control sediment transport and particle entrainment in these streams, particularly for sand and gravel. In most cases, the cobble substrate forms a veneer on top of a bedrock bed with gravel and finer material accumulating only in low-velocity pockets behind large flow obstructions and along the channel margins. Very little sediment is deposited in the riffles or pools, and lateral bar development is poor to nonexistent. Occasional alluvial deposits do occur where gradient or valley confinement decreases, and the channel widens (e.g., lower Gerle Creek). LWD was observed at the Gerle Creek Dam Reach Site (79 pieces/mile) and the Camino Dam Reach Site (8 pieces/mile), but did not appear to influence channel dynamics. LWD likely had a limited influence on channel morphology at these sites, as it was easily transported through these relatively, deep and straight sections. Fine sediment supply may have increased along the SFAR due to increased hillslope erosion following the 1992 Cleveland Fire (USDA 1993). No evidence of increased sediment supply was observed at the downstream SFAR Reach Site.

### 5.2 Transport Sites of the Reach Downstream of Chili Bar

### 5.2.1 <u>F Channel Type</u>

In general, F channel types are described as "deeply entrenched" within "highly weathered bedrock or depositional soils involving a combination of river downcutting and uplift of valley walls" (Rosgen 1996). Survey data and photographs confirm that the Upper Canyon (F3) and Gorge (F3) Sites are incised in the rolling terrain of the Sierra foothills and are structurally controlled by underlying bedrock lithology.

<u>Upper Canyon Site:</u> At the Upper Canyon Site (F3), a veneer of predominantly coarse cobble on the channel bed is covered with abundant, black algal growth. The lack of bright surfaces in the bed material at this site indicates that regular entrainment of the dominant substrate grain sizes does not occur under the current discharge regime. No major gravel or sand deposits were noted within the bankfull channel, suggesting that either supply in this size range is extremely low, or

fine bed material is quickly transported downstream. The only considerable depositional feature at this site is a large lateral cobble bar and overflow channel on the right bank, suggesting that the river is capable of transporting coarse material during high flows. Structural controls (e.g., slope, and channel confinement) have likely prevented alluvial deposition and floodplain development at this site since the last glaciation. No LWD was observed at this site. Due to the relatively high flows and a large upstream drainage area of this site, it is not likely that LWD historically played a large role in channel dynamics.

*Gorge Site:* Like the river channel at the Upper Canyon Site, the Gorge Site (F3) is deeply incised within the surrounding bedrock. This site is located where a temporary alluvial deposit has formed at a slope break within a narrow gorge where tributaries enter from both sides and the valley has widened. Like the Upper Coloma Site, a vegetated mid-channel bar divides the low flow into two channels, creating a riffle. Two small bedrock outcrops are located along the margins of the channel, and constrict flow at the tail of the riffle. No signs of rapid erosion or deposition were observed in the channel or along the banks. Few sand and silt deposits were observed in the low-velocity zones at the tail end of pools, although a large sand bar is located just above this site on the left bank. Grain size distributions are coarse and highly sorted, indicating that the finer portions may be transported downstream, including most classes of gravel. Cobble is loosely packed and surfaces are bright, indicating that the bed is mobilized on a regular basis. Flows under the current discharge regime may be incising into the cobble fill at this site, with as much as 10-13 feet of separation between the active channel and former floodplain at the downstream end of the site. No LWD was observed at this site. Due to the relatively high flows and a large upstream drainage area at the site, it is not likely that LWD has historically played a large role in channel dynamics. Although the site was established on alluvial fill, it is strongly influenced by the steep bedrock valley, which is representative of most of the Lower Subreach of the SFAR. The Lower Subreach is primarily characterized by a bedrock gorge with large boulder riffles, small cascades, irregular meanders and pool-riffle morphology. Channel morphology and sediment dynamics within the gorge are very similar to the characteristics described for the Upper Canyon Site.

# 5.2.2 <u>C Channel Type</u>

Although C channel types are often found in response reaches, bedrock control limits the ability of some channels within this class to act as a response reach. The Lower Coloma Site (C3) was categorized as a transport site because of local bedrock influence. Although the channel bed at this site is predominantly alluvial cobble deposits, several large bedrock outcrops protrude into the main flow from the left bank, strongly influencing channel flow hydraulics. In addition, many large boulders, which may be locally derived from bedrock sources, are located in the channel and along the banks. No signs of rapid erosion or deposition were observed in the channel or along the banks. A few small sand and silt deposits were observed in the low-velocity zones at the tail end of pools. Grain size distributions are highly sorted and very coarse, indicating that the finer portions may be preferentially transported downstream, including most classes of gravel. Cobble in the channel bed is slightly embedded and surfaces are mostly dull, indicating that the bed is stable and rarely mobilized. Survey evidence indicates that rare, high flows appear to be incising into the cobble fill at this site, with as much as 10-13 feet of

separation between the active channel and former floodplain at the downstream end of the site. Small amounts of LWD were observed at this site (23 pieces/mile). Due to the relatively high flows and a large upstream drainage area at this site, it is not likely that LWD has played a large role in channel dynamics throughout recent history.

## 5.3 Response Sites of the UARP

### 5.3.1 <u>F Channel Typ</u>e

The stream channel at the Rubicon Dam Reach Site (F4) is deeply incised within the surrounding terrain. Currently, the channel at this site has a well-defined pool-riffle sequence with stable, vegetated depositional bars. Banks are well vegetated and relatively stable, with few signs of erosion. Channel substrate exhibits a mixture of dull and bright surfaces, indicating that sediment transport of the bed material may occur regularly at moderate flows. Thus, unlike the F3 channel type at the Upper Canyon and Gorge Sites downstream of Chili Bar, this site has been designated a response site and is likely transport limited. Although a small amount of LWD was observed at this high elevation site at the time of the survey (11 pieces/mile), it did not appear to greatly affect channel morphology.

# 5.3.2 <u>E Channel Type</u>

E channel types are considered to be "hydraulically efficient" channel forms, typically maintaining high sediment transport capacities with stable beds (Rosgen 1996). Extensive riparian vegetation usually stabilizes the banks with dense root masses. These characteristics appear to hold true for the only E channel type in this study, the upper site (E5) in the Loon Lake Dam Reach. This is the only site within the study area where dominant grain size was sand or finer. Fine sediment is likely supplied by incision into the wide meadow fill that the channel is formed in, and surface erosion from surrounding granitic hillslopes. In addition, this site has the highest sinuosity of all the project sites. This is probably because the site lies in a large, unconfined valley with relatively flat topography, allowing the channel to meander freely. Bedrock confinement at the downstream end of the valley likely exerts limits on valley and channel gradient. Evidence of scour and deposition were observed in the field and it was estimated that as much as 50 percent of the active channel area has been influenced by deposits and scour from obstructions, constrictions, and bends. In addition, silt deposits over sandy substrate and signs of overbank flooding were observed. Medium and large woody debris may be an important influence on channel morphology and bank stability at this site. Observations indicate that there is a large build up of LWD in the active channel (832 pieces/mile), which adds roughness and affects sediment storage. This is the highest LWD loading of all the project sites. Large key pieces of woody debris are embedded in the channel and create habitat for fish and other aquatic organisms.

### 5.3.3 <u>C Channel Type</u>

All C channel types within the UARP were formed from alluvial deposition and were categorized as response sites. These sites were located along stream sections that typically had

well developed floodplains and primarily exhibited pool-riffle configuration. Alluvial channels exhibit a wide range of responses to changes in upstream watershed conditions, flow, and sediment supply (Rosgen 1996). For this reason, each response C channel type is discussed separately, including the Loon Lake Dam Reach Middle and Lower Sites (C3); the Robbs Peak Dam Reach Site (C4); and the Ice House Dam Reach Upper (C4) and Lower (C3) Sites.

<u>Loon Lake Dam Reach Middle Site:</u> While both the Loon Lake Dam Reach Middle Site and the Loon Lake Dam Reach Upper Site are located in meadow environments, the two sites are very different. The gradient at the middle site is about double the upper site, and sinuosity is markedly lower than the upstream site. Numerous lateral bars with bright surface grains indicate that sediment transport may occur regularly at moderate flows. In addition, many side channels were noted in the field, suggesting regular overbank flow and migration, or avulsion, of the main channel. Several debris jams and numerous key pieces of LWD created areas of scour and deposition in the channel (264 pieces/mile), suggesting that wood may affect channel morphology at this site.

<u>Loon Lake Dam Reach Lower Site</u>: Unlike the Loon Lake Dam Reach Middle Site, the Loon Lake Dam Reach Lower Site is located within a narrower valley and has distinct pool-riffle sequences. Evidence of sediment transport was more notable at this site. Sand deposits were observed in low velocity zones behind larger obstructions and along channel margins. Incision was also noted, with raw banks up to 12 inches high. An estimated 30-50 percent of the channel area is believed to be influenced by erosion and deposition at obstructions, around bends, or at constrictions. These observations may indicate that LWD has a greater effect on channel morphology at this site, despite having lower frequency (79 pieces/mile) than the two upstream sites.

<u>Robbs Peak Dam Reach Site:</u> At the Robbs Peak Dam Reach Site, dense willows grow on numerous bars within the bankfull channel area. Several small conifers were also noted growing on recently scoured surfaces and mid-channel bars. Field observations indicate that vegetation encroachment may be causing the channel to avulse between side channels at high flows. Bank erosion up to two feet high with exposed root mats and active sloughing were observed. Sand and gravel surfaces in the channel beds are mostly dull, suggesting gravel transport occurs only during higher flows. Although several debris jams with evidence of lateral channel erosion were observed upstream from the site, only a few pieces of LWD were noted at this site (12 pieces/mile).

<u>Ice House Dam Reach Upper Site:</u> At this site, lateral gravel bars are prevalent but sparsely vegetated. Several observed raw banks and bar deposits indicate that sediment transport occurs regularly, yet moderate to high levels of sand and fine gravel in the bars, stream banks, and channel bed suggest that supply from the banks and upstream sources may exceed transport capacity. Despite this, there were no signs of excessive incision and/or aggradation at the time of the survey. Moderate amounts of LWD were present at this site (57 pieces/mile).

Pacific Gas and Electric Company Chili Bar Project FERC Project No. 2155

<u>Ice House Dam Reach Lower Site:</u> The Ice House Dam Reach Lower Site is within the burned area from the 1992 Cleveland Fire. High fine sediment loads were expected to enter the main channel from the surrounding valley slopes (USDA 1993). Riparian vegetation recovered well along the banks, acting as a buffer between the barren hillslopes and the stream channel. Channel sediments are highly embedded, with mostly dull surfaces. A layer of sand covers the bed, with larger deposits noted behind flow obstructions and in the lower gradient portions at the site. Abundant sand deposits were also noted on the floodplains and terrace surfaces. Regulated spill from the upstream dam may not be sufficient to transport the additional sediment added from the effects of the fire. A few raw cut banks of up to 1 foot in height were observed in association with woody debris present in the channel. Two log jams and a great amount of LWD were seen at this site (236 pieces/mile). Although some local scour (1-1.5 feet) and sand deposits were seen associated with the wood, this did not appear to strongly affect channel morphology.

## 5.4 Response Sites of the Reach Downstream of Chili Bar

## 5.4.1 <u>C Channel Type</u>

The only C channel type in the Reach Downstream of Chili Bar that is formed from alluvial deposition is the Upper Coloma Site (C3). The SFAR at this site flows over cobble and small boulder alluvial fill. Two very small bedrock outcrops are located along the margins of the channel, but do not appear to affect flow dynamics at this site. No major signs of ongoing erosion or deposition were observed in the channel or along the banks. Few sand and silt deposits were observed in the low-velocity zones at the tail end of pools. Grain size distributions are well sorted, indicating that the finer portions may be transported downstream, including most classes of gravel. The cobble channel bed is slightly embedded and surfaces are mostly dull. indicating a stable bed that is rarely mobilized. Survey evidence indicates, however, that rare high flows cause incision into the cobble fill, with as much as 7-10 feet of separation between the active channel and former floodplain at the downstream end of the site. Interviews with a riverside property owner at this site confirm that the SFAR occasionally flows "brown" with sediment during "large floods," and that mid-channel bars have changed position "several times" (Haney, pers. comm., 2003). No LWD was observed at this site. Due to the relatively high flows and a large upstream drainage area, it is not likely that LWD has played a large role in channel dynamics throughout recent history.

		STREAM CHANNEL DEBRIS/BLOCKAGES (circle one)
D	••• /=	Materials, which upon placement into the active channel or floodprone area may cause and adjustment in
Descr	iption/Extent	channel dimensions or conditions, due to influences on the existing flow regime
D-1	None	Minor amounts of small, floatable material
D-2	Infrequent	Debris consists of small, easily moved, floatable material; i.e. leaves, needles, small limbs, twigs, etc
D-3	Moderate	Increasing frequency of small to medium sized material, i.e. large limbs, branches, small logs that when accumulated effect 10% or less of the active channel cross-sectional area.
D-4	Numerous	Significant buildup of medium to large sized materials, i.e. large limbs, branches, small logs, or portions of trees that may occupy 10 to 30% of the active cross-sectional area.
D-5	Extensive	Debris "dams" of predominantly larger materials, i.e. branches, logs, trees, etc., occupying 30 to 50% of the active channel cross-section, often extending across the width of the active channel.
D-6	Dominating	Large, somewhat continuous debris "dams," extensive in nature and occupying over 50% of the active channel cross-section. Such accumulations may divert water into floodprone areas and form fish migration barriers, even when flows are at less than bankfull.
D-7	Beaver Dams - Few	An infrequent number of dams spaced such that normal streamflow and expected channel conditions exist in the reaches between dams.
D-8	Beaver Dams - Frequent	Frequency of dams is such that backwater conditions exist for channel reaches between structures; where streamflow velocities are reduced and channel dimensions or conditions are influenced.
D-9	Beaver Dams - Abandoned	channel adjustments such as bank erosion, lateral migration, evulsion, aggradations and degradation.
D-10	Human Influences	Structures, facilities, or materials related to land uses or development located within the floodprone area, such as diversions or low-head dams, controlled by-pass channels, velocity control structures, and various transportation encroachments that have influence on the existing flow regime, such that significant channel

n	nonth	day year	(24-hour clock) (24-hour clock)					
		Category	(circle one for each of the four options for each category)					
Upper	1	Landform slope	Bank slope gradient <30%					
Banks		_	Bank slope gradient 30-40%					
During			Bank slope gradient 40-60%					
			Bank slope gradient 60+%					
	2	Mass wasting	No evidence of past or future mass wasting					
			Infrequent. Most likely healed over. Low future potential					
			Frequent or large, causing sediment nearly year long					
			Frequent or large causing sediment nearly year long or imminent danger of same					
	3	Debris jam potential	Essentially absent from immediate channel area					
			Present, but mostly small twigs and limbs					
			Moderate to heavy amounts, mostly larger sizes					

	2	wasting	no evidence of past of future mass wasting	5						
		_	Infrequent. Most likely healed over. Low future potential	6						
			Frequent or large, causing sediment nearly year long	9						
			Frequent or large causing sediment nearly year long or imminent danger of same	12						
	3	Debris jam potential	Essentially absent from immediate channel area	2						
			Present, but mostly small twigs and limbs	4						
			Moderate to heavy amounts, mostly larger sizes							
			Moderate to heavy amounts, predominately lager sizes	8						
	4	Vegetative bank protection	90%+ plant density. Vigor and variety suggest a deep, dense soil binding root mass	3						
			70-90% density. Fewer species or less vigor suggest less dense or deep root mass	6						
			<50-70% density. Lower vigor and fewer species from a shallow, discontinuous	9						
			root mass							
			<50% density, fewer species and less vigor indicate poor, discontinuous and shallow	12						
			root mass							
Lower	5	Channel capacity	Ample for present plus some increases. Peak flows contained. W/D ration <7	1						
Banks			Adequate. Bank overflows rare. W/D ratio 8-15	2						
			Barely contains present peaks. Occasional overbank floods. W/D ratio 15 to 25	3						
-			Inadequate. Overbank flows common. W/D ratio >25	4						
	6	Bank rock content	65%+ with large angular boulders. 12"+ common.	2						
			40-65%. Mostly small boulders to cobbles 6-12"	4						
			20-40%. With most in the 3-6" diameter class	6						
			20% rock fragments of gravel sizes, 1-3" or less	8						
	7	Obstructions to flow	Rocks and logs firmly embedded. Flow pattern w/out cutting or deposition. Stable	2						
			Bed							
			Some present causing erosive cross currents and minor pool filling. Obstructions	4						
			newer and less firm							
			Moderately frequent, unstable obstructions move with high flows causing bank	6						
			cutting and pool filling							
			Sediment traps full, channel migration occurring							
	8	Cutting	Little or none. Infrequent raw banks less than 6"	4						
			Some, intermittently at outcurves and constrictions. Raw banks may be up to 12"	6						
			Significant. Cuts 12-24" high. Root mat overhangs and sloughing evident	12						
			Almost continuous cuts, some over 24" high. Failure of overhangs frequent	16						
	9	Deposition	Little or no enlargement of channel or point bars	4						
			Some new bar increase, mostly from coarse gravel	8						
			Moderate deposition of new gravel and course sand on old and some new bars	12						
			Extensive deposits of predominately fine particles. Accelerated bar development	16

Comments:

No key pieces

### Rubicon Dam Reach Site (RD-G1) V Star

No Vstar measurements taken.

### Rubicon Dam Reach Site (RD-G1) Rosgen Level III

Rosgen Level III Data Sheet Study Reach Name: Rubicon Dam Reach Date: 8/26/03 Crew Initials: TNC, SRD Start time: End time:

Depositional Features (indicate one)

	B-1	point bars
	B-2	pt. bars w/ few mid channel bars
	B-3	many mid channel bars
x	B-4	side bars
	B-5	diagonal bars
	B-6	main branching w/ many mid channel bars and islands
	B-7	mixed side bar and mid channel bars exceeding 2-3X width
	B-8	delta bars

Description: straight reach with stable, vegetated gravel/cobble bars

Meander Pattern (indicate one)

Meanaci i attei	In (Intercence offic)	
	M-1	regular meander
	M-2	tortuous meander
x	M-3	irregular meander
	M-4	truncated meander
	M-5	unconfined me. scrolls
	M-6	confine me. scrolls
	M-7	distorted me. loops
	M-8	irregular with oxbows

Description: high mountain, bedrock controlled channel

#### STREAM CHANNEL DEBRIS/BLOCKAGES (indicate one)

Materials, which upon placement into the active channel or floodprone area may cause and adjustment in channel dimensions or conditions, due to influences on the existing flow regime

	Description/Exter	nt
x	D-1 (None)	Minor amounts of small, floatable material
	D-2 (Infrequent)	Debris consists of small, easily moved, floatable material; i.e. leaves, needles, small limbs, twigs, etc
	D-3 (Moderate)	Increasing frequency of small to medium sized material, i.e. large limbs, branches, small logs that when accumulated effect 10% or less of the active channel cross-sectional area.
	D-4 (Numerous)	Significant buildup of medium to large sized materials, i.e. large limbs, branches, small logs, or portions of trees that may occupy 10 to 30% of the active cross-sectional area.
	D-5 (Extensive)	Debris "dams" of predominantly larger materials, i.e. branches, logs, trees, etc., occupying 30 to 50% of the active channel cross-section, often extending across the width of the active channel.
	D-6 (Dominating)	Large, somewhat continuous debris "dams," extensive in nature and occupying over 50% of the active channel cross-section. Such accumulations may divert water into floodprone areas and form fish migration barriers, even when flows are at less than bankfull
	D-7 (Beaver Dams - Few)	An infrequent number of dams spaced such that normal streamflow and expected channel conditions exist in the reaches between dams.
	D-8 (Beaver Dams - Frequent)	Frequency of dams is such that backwater conditions exist for channel reaches between structures; where streamflow velocities are reduced and channel dimensions or conditions are influenced.
	D-9 (Beaver Dams - Abandoned)	Numerous abandoned dams, many of which have filled with sediment and/or breached, initiating a series of channel adjustments such as bank erosion, lateral migration, evulsion, aggradations and degradation.
	D-10 (Human Influences)	Structures, facilities, or materials related to land uses or development located within the floodprone area, such as diversions or low-head dams, controlled by-pass channels, velocity control structures, and various transportation encroachments that have

Notes: Fairly clean channel, with with monir amounts LWD on banks/bars

Comments:

### Loon Lake Dam Reach Upper Site (LL-G1) V Star

#### **V\* Measurements**

Study Reach Name:	Loon Lake Upper	
Date:	6/2/2003	Start time:

Crew Initials: JDS, MCM End time:

#### Comments:

No V\* measurements taken.

No pool-riffle morphology, so no true riffle control points.

The bed is comprised of silt and fine to coarse sand.

Silt patches overlay the unconsolidated sand, so Silvey road wouldn't stop after going through silt. There are a lot of silt deposits, but this method doesn't seem applicable.

### Loon Lake Dam Reach Upper Site (LL-G1) LWD Key Pieces

### Loon Lake Dam Reach Upper Site (LL-G1) Bank Erosion and Vegetation

#### **Bank Erosion and Vegetation**

Study Reach Name:	Upper Loon Lake	Crew Initials:	JDS, MCM
Date: 6/2/03	Start Time:	Stop Time:	

Bank material:

sand, silt/clay

BANK EROSION POTENTIAL							
(if banks are bedrock or composed of boulders, do not fill out this table)							
Bank a Bank b Bank c Bank							
Bank height	12-18"	12-18"					
Bankfull height	10"	10"					
Root depth	12-18"	12-18"					
Root density (%)	80-100%	80-100%					
Bank Angle (degrees)	60-90	1020					
Surface Protection (%)	80-100%	80-100%					
% of total study reach	80%	20%					

Notes

Stratification of unstable layers

in banks (below bankfull):

Sediment supply: High Vertical streambed stability: Aggrading

Bank and channel bed conditions notes:

Spalling of bedrock and prevasive overland flow during snowmelt leads to high rate of sand production to channel. Regulation of flow likely has led to lower transport and channel aggradation.

<b>VEGETATION NOTES (compositi</b>	on, vigor, density,	and potential):				

### Loon Lake Dam Reach Middle Site (LL-G2) **LWD** Frequency

#### LWD Frequency Data Sheet Study Reach Name: Middle Loon Lake Crew Initials: ZED, JLA, MCM Date:7/13/03 End time: 1145 Start time: 11:00 Diameter Class Length Class 3-10 ft (0.9-3.0 m) 10-25 ft (3.1-7.6 m) 25-50 ft (7.7-15.2 m) 50-75 ft (15.3-22.9 m) >75 ft (>23 m) 6-12 in (10-30 cm) 5 5 7 5 10 3 12-24 in (31-60 cm) 24-36 in (61-90 cm) >36 in (>90 cm)

"Tally as R if rootwad is attached."

Comments: There are many downed trees in the reach and large volume of LWD compared with other sites. Because of low banks, LWD and jams tend to push flows around, creating forced overflow channels. There are no pools in this reach caused by LWD with the exception of one area that is more like an aerction channel with stagnant water. Many of the forced overflow channels are well vegetated with grasses and herbaceous plants.

So many dead pine and cedar trees because they get inundated so often?

### Loon Lake Dam Reach Middle Site (LL-G2) V Star

No Vstar measurements taken.

### Loon Lake Dam Reach Middle Site (LL-G2) LWD Key Pieces

LWD Key Pieces Information Study Reach Name: Date:

Crew Initials: Start time:

End time:

Perform for 100 m of stream or reach length, whichever is greater. Criteria for Determining Key Pieces to be Measured (circle which used): (1) all pieces with length > 1.2 times bankfull channel width OR (2) pieces meeting criteria 1 and having diameters

constant on longitudinal profile         Images         Images <thimages< th="">         Images         <thimages<< th=""><th>KEY PIECE ATTRIBUTE</th><th></th><th></th><th></th><th></th><th></th><th></th><th></th><th></th><th></th><th></th><th></th><th></th></thimages<<></thimages<>	KEY PIECE ATTRIBUTE

### Loon Lake Dam Reach Middle Site (LL-G2) Rosgen Level III

#### Rosgen Level III Data Sheet

Study Reach Name: Middle Loon Lake Date:7/13/03 Crew Initials: JLA, MCM, ZED Start time: 1245 End time: 1250

#### Depositional Features (indicate one)

	B-1	point bars
	B-2	pt. bars w/ few mid channel bars
	B-3	many mid channel bars
x	B-4	side bars
	B-5	diagonal bars
	B-6	main branching w/ many mid channel bars and islands
	B-7	mixed side bar and mid channel bars exceeding 2-3X width
	B-8	delta bars

Description: very meager- one small mid-channel and one small point.

#### Meander Pattern (indicate one)

x	M-1	regular meander	
	M-2	tortuous meander	
	M-3	irregular meander	
	M-4	truncated meander	
	M-5	unconfined me. scrolls	
	M-6	confine me. scrolls	
	M-7	distorted me. loops	
	M-8	irregular with oxbows	

Description: almost no meander- flows go over bank and do not scour

#### STREAM CHANNEL DEBRIS/BLOCKAGES (indicate one)

Materials, which upon placement into the active channel or floodprone area may cause and adjustment in channel dimensions or conditions, due to influences on the existing flow regime

	Description/Extent					
	D-1 (None)	Minor amounts of small, floatable material				
	D-2 (Infrequent)	Debris consists of small, easily moved, floatable material; i.e. leaves,				
	D-2 (initequent)	needles, small limbs, twigs, etc				
		Increasing frequency of small to medium sized material, i.e. large limbs,				
	D-3 (Moderate)	branches, small logs that when accumulated effect 10% or less of the				
		active channel cross-sectional area.				
		Significant buildup of medium to large sized materials, i.e. large limbs,				
	D-4 (Numerous)	branches, small logs, or portions of trees that may occupy 10 to 30% of				
x		the active cross-sectional area.				
	D-5 (Extensive)	Debris "dams" of predominantly larger materials, i.e. branches, logs,				
		trees, etc., occupying 30 to 50% of the active channel cross-section,				
		often extending across the width of the active channel.				
		Large, somewhat continuous debris "dams," extensive in nature and				
	D.6 (Dominating)	occupying over 50% of the active channel cross-section. Such				
	D-6 (Dominating)	accumulations may divert water into floodprone areas and form fish				
		migration barriers, even when flows are at less than bankfull				
	D-7 (Beaver	An infrequent number of dams spaced such that normal streamflow and				
	Dams - Few)	expected channel conditions exist in the reaches between dams.				
		Frequency of dams is such that backwater conditions exist for channel				
	D-8 (Beaver	reaches between structures; where streamflow velocities are reduced				
	Dams - Frequent)	and channel dimensions or conditions are influenced.				
	D-9 (Beaver	Numerous abandoned dams, many of which have filled with sediment				
	Dams -	and/or breached, initiating a series of channel adjustments such as bank				
	Abandoned)	erosion, lateral migration, evulsion, aggradations and degradation.				
	,					
		Structures, facilities, or materials related to land uses or development				
	D-10 (Human	located within the floodprone area, such as diversions or low-head dams,				
	Influences)	controlled by-pass channels, velocity control structures, and various				
		transportation encroachments that have				
	1					

#### Notes: LWD plentiful in reach withseveral debris jams

### Loon Lake Dam Reach Middle Site (LL-G2) Pfankuch

Place X

Channel Stability (Pfankuch) Study Reach Name: Loon Lake Middle Crew Initials: MCM, JLA, ZED Date: 7/13/03 Start Time: 1230 Stop Time: 1245

Start Time: Stop Time:		Category	(choose one for each of the four options for each category)		Place 2 in this columr
Jpper	1	Landform	Bank slope gradient <30%	2	X
Banks		slope	Bank slope gradient 30-40%	4	
			Bank slope gradient 40-60%	6	
			Bank slope gradient 60+%	8	
	2	Mass wasting	No evidence of past or future mass wasting	3	x
	1	made madning	Infrequent. Most likely healed over. Low future potential	6	^
			Frequent or large, causing sediment nearly year long	9	
		Dahais isaa	Frequent or large causing sediment nearly year long or imminent danger of same	12	v
	3	Debris jam	Essentially absent from immediate channel area	2	Х
		potential	Present, but mostly small twigs and limbs	4	
			Moderate to heavy amounts, mostly larger sizes	6	
			Moderate to heavy amounts, predominately lager sizes	8	
	4	Vegetative	90%+ plant density. Vigor and variety suggest a deep, dense soil binding root mass	3	Х
		bank	70-90% density. Fewer species or less vigor suggest less dense or deep root mass	6	
		protection	<50-70% density. Lower vigor and fewer species from a shallow, discontinuous root mass	9	
		ľ	< 50% density, fewer species and less vigor indicate poor, discontinuous and shallow root mass	12	
ower	5	Channel	Ample for present plus some increases. Peak flows contained. W/D ration <7	1	
anks	Ŭ	capacity	Adequate. Bank overflows rare. W/D ratio 8-15	2	
alikə		capacity		3	v
			Barely contains present peaks. Occasional overbank floods. W/D ratio 15 to 25		X
	L		Inadequate. Overbank flows common. W/D ratio >25	4	
	6	Bank rock	65%+ with large angular boulders. 12"+ common.	2	
		content	40-65%. Mostly small boulders to cobbles 6-12"	4	Х
			20-40%. With most in the 3-6" diameter class	6	
			20% rock fragments of gravel sizes, 1-3" or less	8	
	7	Obstructions	Rocks and logs firmly embedded. Flow pattern w/out cutting or deposition. Stable bed	2	Х
		to flow	Some present causing erosive cross currents and minor pool filling. Obstructions newer and less	4	
			Moderately frequent, unstable obstructions move with high flows causing bank cutting and pool	6	
			Sediment traps full, channel migration occurring	8	
	8	Cutting	Little or none. Infrequent raw banks less than 6"	4	х
	ľ	Cutting	Some, intermittently at outcurves and constrictions. Raw banks may be up to 12"	6	^
				12	
			Significant. Cuts 12-24" high. Root mat overhangs and sloughing evident		
		<b>D</b>	Almost continuous cuts, some over 24" high. Failure of overhangs frequent	16	
	9	Deposition	Little or no enlargement of channel or point bars	4	Х
			Some new bar increase, mostly from coarse gravel	8	
			Moderate deposition of new gravel and course sand on old and some new bars	12	
			Extensive deposits of predominately fine particles. Accelerated bar development	16	
ottom	10	Rock	Sharp edges and corners. Plane surfaces rough.	1	
		angularity	Rounded corners and edges, surfaces smooth, flat	2	Х
			Corners and edges well rounded in two dimensions	3	
			Well rounded in all dimensions, surfaces smooth	4	
	11	Brightness	Surfaces dull, dark, or stained. Generally not bright	1	x
	''	Digititess		2	^
			Mostly dull, but may have <35% bright surfaces		
			Mixture dull and bright, ie 35-65% mixture range	3	
			Predominately bright, 65% exposed or scoured surfaces	4	Х
	12		Assorted sizes tightly packed or overlapping	2	
		of particles	Moderately packed with some overlapping	4	
			Mostly loose assortment with no apparent overlap	6	
			No packing evident. Loose assortment easily moved	8	
	13	Bottom size	No size change evident. Stable mater. 80-100%	4	Х
		distribution	Distribution shift light. Stable material 50-80%	8	
			Moderate changes in sizes. Stable materials 20-50%	12	
			Marked distribution change. Stable materials 0-20%	16	
	1 4	Soouring and			
	14	Scouring and	<5% of bottom affected by scour or deposition	6	<u> </u>
		deposition	5-30% affected. Scour at constrictions and where grades steepen. Some deposition in pools	12	Х
			30-50% affected. Deposits and scour at obstructions, constrictions, and bends. Some filling of pools	18	
			More than 50% of the bottom in a state of flux or change nearly year long	24	
	15	Aquatic	Abundant growth moss-like, dark green perennial. In swift water too.	1	
		vegetation	Common. Algae forms in low velocity and pool areas. Moss here too	2	
			Present but spotty, mostly in backwater. Seasonal algae growth makes rocks slick	3	X

Notes:

### Loon Lake Dam Reach Middle Site (LL-G2) Bank Erosion and Vegetation

#### **Bank Erosion and Vegetation**

Study Reach Name:Loon Lake - MiddleCrew Initials:ZED, MCM, JLADate:7/13/03Start Time:121:Stop Time:1230

BANK EROSION POTENTIAL							
(if banks are bedrock or composed of boulders, do not fill out this table)							
	Bank a	Bank b	Bank c	Bank d			
Bank height (ft)	2	0					
Bankfull height (ft)	3	3					
Root depth (ft)	2	<1					
Root density (%)	30%	50					
Bank Angle (degrees)	80	20					
Surface Protection (%)	95%	95					
% of total study reach	75%	25					

#### Notes

 Bank material:
 Cobble

 Stratification of unstable layers
 N/A - banks stable and almost totally vegetated with uniform layers

 in banks (below bankfull):
 V/A - banks stable and almost totally vegetated with uniform layers

Sediment supply: Low

Vertical streambed stability: Stable

Bank and channel bed conditions notes:

Channel and bank condition are extremely uniform throughout reach. Channel is wide and unconfined; banks are poorly defined - sometimes not at all.

	<b>RIPARIAN V</b>	EGETATION			
[	DENSITY (indic	ate all that apply)			
VEGETATION TYPE	LOW	MOD.	HIGH	NOTES	
Bare					
Forbs only					
Annual Grass w/ forbes					
Perennial grass					
Rhizomatous grasses					
(bluegrass, Grass like plants,					
sedges, rushes)					
Low brush					
High brush					
Combination grass/brush		8b			
Deciduous overstory	9a			some aspen	
Deciduous w/brush/grass		4.01		alders with grass	
understory		10b		& wildflower	
Perennial overstory				pines, cedars,	
		11b		firs - yong only (40-50 yrs)	
Wetland vegetation community			Marsh	valley floor in almost all	
			11/10/201	marsh/swampy	

VEGETATION NOTES (composition, vigor, density, and potential):

Site is entirely vegetated. Was likely marsh/swamp through entire valley floor. Conifers have stared establishing in last 40-50 years - likely from lower stream levels.

## Loon Lake Dam Reach Lower Site (LL-G3) LWD Frequency

Comments:

## Loon Lake Dam Reach Lower Site (LL-G3) V Star

### **V\* Measurements**

Study Reach Name: Lower Loon Lake Date: 7/14/03

Crew Initials: ZED, MCM, JLA Start time: 1430 End time: 1435

### Comments:

- 1. No Vstar measurments taken
- 2. Sand behind obstructions; deposited on banks by high flows
- 3. No sand filling pools; pools generally scarce and not filled with sand

## Loon Lake Dam Reach Lower Site (LL-G3) LWD Key Pieces

#### LWD Key Pieces Information

Study Reach Name: Loon Lake - Lower Date: 7/14/03

Crew Initials: MCM, ZED, JLA Start time: 0924 End time: 1200

Perform for 100 m of stream or reach length, whichever is greater. Criteria for Determining Key Pieces to be Measured (circle which used): (1) all pieces with length > 1.2 times bankfull channel width OR (2) pieces meeting criteria 1 and having diameters

KEY PIECE ATTRIBUTE												
	KEY PIECE NUMBER											
	1	2	3	4	5	6	7	8	9	10	11	12
Location on longitudinal profile	/											
Diameter (in)	12											
Length (ft)	70	)										
rootwad attached	No											
LOCATION IN BANKFULL

## Loon Lake Dam Reach Lower Site (LL-G3) **Rosgen Level III**

#### **Rosgen Level III Data Sheet**

Study Reach Name: Lower Loon Lake Date: 7/14/03 Crew Initials: ZED, MCM, JLA Start time: 1415

End time: 1420

#### Depositional Features (indicate one)

x	B-1	point bars
	B-2	pt. bars w/ few mid channel bars
	B-3	many mid channel bars
	B-4	side bars
	B-5	diagonal bars
	B-6	main branching w/ many mid channel bars and islands
	B-7	mixed side bar and mid channel bars exceeding 2-3X width
	B-8	delta bars

Description:

#### Meander Pattern (indicate one)

	in (inaloato ono)	
x	M-1	regular meander
	M-2	tortuous meander
	M-3	irregular meander
	M-4	truncated meander
	M-5	unconfined me. scrolls
	M-6	confine me. scrolls
	M-7	distorted me. loops
	M-8	irregular with oxbows

Description:

#### STREAM CHANNEL DEBRIS/BLOCKAGES (indicate one)

Materials, which upon placement into the active channel or floodprone area may cause and adjustment in channel dimensions or conditions, due to influences on the existing flow regime

	Description/Exter	nt
	D-1 (None)	Minor amounts of small, floatable material
	D-2 (Infrequent)	Debris consists of small, easily moved, floatable material; i.e. leaves,
x	D-2 (initequent)	needles, small limbs, twigs, etc
		Increasing frequency of small to medium sized material, i.e. large limbs,
		branches, small logs that when accumulated effect 10% or less of the
		active channel cross-sectional area.
		Significant buildup of medium to large sized materials, i.e. large limbs,
	D-4 (Numerous)	branches, small logs, or portions of trees that may occupy 10 to 30% of
		the active cross-sectional area.
		Debris "dams" of predominantly larger materials, i.e. branches, logs,
	D-5 (Extensive)	trees, etc., occupying 30 to 50% of the active channel cross-section,
		often extending across the width of the active channel.
		Large, somewhat continuous debris "dams," extensive in nature and
	D-6 (Dominating)	occupying over 50% of the active channel cross-section. Such
		accumulations may divert water into floodprone areas and form fish
		migration barriers, even when flows are at less than bankfull
	D-7 (Beaver	An infrequent number of dams spaced such that normal streamflow and
	Dams - Few)	expected channel conditions exist in the reaches between dams.
		Frequency of dams is such that backwater conditions exist for channel
	D-8 (Beaver	reaches between structures; where streamflow velocities are reduced
	Dams - Frequent)	and channel dimensions or conditions are influenced.
	D-9 (Beaver	Numerous abandoned dams, many of which have filled with sediment
	Dams -	and/or breached, initiating a series of channel adjustments such as bank
	Abandoned)	erosion, lateral migration, evulsion, aggradations and degradation.
		Other structures facilities on materials related to land uses an development
	D 10 (Human	Structures, facilities, or materials related to land uses or development
	D-10 (Human	located within the floodprone area, such as diversions or low-head dams,
	Influences)	controlled by-pass channels, velocity control structures, and various
		transportation encroachments that have

Description: Boulder bedrock channel. No meander pattern - straight.

#### STREAM CHANNEL DEBRIS/BLOCKAGES (indicate one)

Materials, which upon placement into the active channel or floodprone area may cause and adjustment in channel dimensions or conditions, due to influences on the existing flow regime

	Description/Extent					
Х	D-1 (None)	Minor amounts of small, floatable material				
	D-2 (Infrequent)	Debris consists of small, easily moved, floatable material; i.e. leaves,				
	D-2 (initequent)	needles, small limbs, twigs, etc				
		Increasing frequency of small to medium sized material, i.e. large limbs,				
	D-3 (Moderate)	branches, small logs that when accumulated effect 10% or less of the				
		active channel cross-sectional area.				
		Significant buildup of medium to large sized materials, i.e. large limbs,				
	D-4 (Numerous)	branches, small logs, or portions of trees that may occupy 10 to 30% of				
		the active cross-sectional area.				
		Debris "dams" of predominantly larger materials, i.e. branches, logs,				
	D-5 (Extensive)	trees, etc., occupying 30 to 50% of the active channel cross-section,				
		often extending across the width of the active channel.				
		Large, somewhat continuous debris "dams," extensive in nature and				
	D-6 (Dominating)	occupying over 50% of the active channel cross-section. Such				
	2 0 (20111100119)	accumulations may divert water into floodprone areas and form fish				
		migration barriers, even when flows are at less than bankfull.				
	D-7 (Beaver	An infrequent number of dams spaced such that normal streamflow and				
	Dams - Few)	expected channel conditions exist in the reaches between dams.				
	D-8 (Beaver	Frequency of dams is such that backwater conditions exist for channel				
	Dams - Frequent)	reaches between structures; where streamflow velocities are reduced				
	Dams - Hequent)	and channel dimensions or conditions are influenced.				
	D-9 (Beaver	Numerous abandoned dams, many of which have filled with sediment				
	Dams -	and/or breached, initiating a series of channel adjustments such as bank				
	Abandoned)	erosion, lateral migration, evulsion, aggradations and degradation.				
		Structures, facilities, or materials related to land uses or development				
	D 10 (Human	located within the floodprone area, such as diversions or low-head dams,				
	D-10 (Human	controlled by-pass channels, velocity control structures, and various				
	Influences)	transportation encroachments that have influence on the existing flow				
		regime, such that significant channel adjustments occur.				

#### Notes:

Pool tailout/riffle crest from station 515 to 625 on long profile. Comprised of cobble/gravel. Occupied by riparian scrub.

This section is the only pushable alluvial deposit in the study reach (remaining portions of reach are all boulder/ bedrock).

Thalweg through pool tailout/riffle crest impinges on LB. High flow channel/oxbow with ponded water on RB at the pool tailout/riffle crest.

From station 640 on (along long profile) channel is confined by a bedrock wall (RB) and narrows. Bed of channel from 640 on is all exposed bedrock.

LB from 640 on (long profile) is low gradient hillslope of soil material over boulders - stable, no signs of bank erosion.

## Gerle Creek Dam Reach Site (GC-G1) Pfankuch

"Tally as R if rootwad is attached."

Comments:

Almost no LWD in BF channel. There is lots of wood rafted during extreme events (>5-1R Good [?]) that provide little or no habitat. Approximately 5 LWD jams were observed in the low water channel between the dam and the upstream end of the site, most key pieces were locally derived, w/ some smaller logs floated in. No key pieces. CAB

Robbs Peak Dam Reach Site (RPD-G1) V Star

V star Measurements Study Reach Name: Robbs Peak Date: 5/19/03

Crew Initials: CAB, TNC, MCM Start time: ----; End time: ----

#### Comments:

No V\* measurements taken. No well defined residual pools, no discrete sand deposits.

## Robbs Peak Dam Reach Site (RPD-G1) Rosgen Level III

#### **Rosgen Level III Data Sheet**

Study Reach Name:		Robbs Peak
Date:		5/19/2003
Crew Initials:		CAB, TNC, MCM
Start time:	18:46	End time: 18:48

#### Depositional Features (indicate one)

	B-1	point bars
	B-2	pt. bars w/ few mid channel bars
x	B-3	many mid channel bars
	B-4	side bars
	B-5	diagonal bars
	B-6	main branching w/ many mid channel bars and islands
	B-7	mixed side bar and mid channel bars exceeding 2-3X width
	B-8	delta bars
Description:	mid channel hare	with willow

Description: mid-channel bars with willow

#### Meander Pattern (indicate one)

	M-1	regular meander
	M-2	tortuous meander
х	M-3	irregular meander
	M-4	truncated meander
	M-5	unconfined me. scrolls
	M-6	confine me. scrolls
	M-7	distorted me. loops
	M-8	irregular with oxbows
De e eninsti e re c	20	of usial abayment bayer and abayed and also abayered.

Description: it's a big mess of mid channel bars and abondoned side channels

#### STREAM CHANNEL DEBRIS/BLOCKAGES (indicate one)

Materials, which upon placement into the active channel or floodprone area may cause and adjustment in channel dimensions or conditions, due to influences on the existing flow regime

Description/Extent

			1
x	D-1 (None)	Minor amounts of small, floatable material	in low-water/bankful channel
	D-2 (Infrequent)	Debris consists of small, easily moved, floatable material; i.e. leaves,	
		needles, small limbs, twigs, etc	
		Increasing frequency of small to medium sized material, i.e. large limbs,	
	D-3 (Moderate)	branches, small logs that when accumulated effect 10% or less of the	
	· · · ·	active channel cross-sectional area.	
		Significant buildup of medium to large sized materials, i.e. large limbs,	
	D-4 (Numerous)	branches, small logs, or portions of trees that may occupy 10 to 30% of

Stop Time:					in this
		Category	(choose one for each of the four options for each category)		column:
Upper	1	Landform	Bank slope gradient <30%	2	x
Banks		slope	Bank slope gradient 30-40%	4	
			Bank slope gradient 40-60%	6	
			Bank slope gradient 60+%	8	
	2	Mass wasting	No evidence of past or future mass wasting	3	
			Infrequent. Most likely healed over. Low future potential	6	x
			Frequent or large, causing sediment nearly year long	9	
			Frequent or large causing sediment nearly year long or imminent danger of same	12	
	3	Debris jam	Essentially absent from immediate channel area	2	х
		potential	Present, but mostly small twigs and limbs	4	
			Moderate to heavy amounts, mostly larger sizes	6	
			Moderate to heavy amounts, predominately lager sizes	8	
	4	Vegetative	90%+ plant density. Vigor and variety suggest a deep, dense soil binding root mass	3	
		bank	70-90% density. Fewer species or less vigor suggest less dense or deep root mass	6	х
		protection	<50-70% density. Lower vigor and fewer species from a shallow, discontinuous root mass	9	
			<50% density, fewer species and less vigor indicate poor, discontinuous and shallow root mass	12	
Lower	5	Channel	Ample for present plus some increases. Peak flows contained. W/D ration <7	1	
Banks		capacity	Adequate. Bank overflows rare. W/D ratio 8-15	2	x
			Barely contains present peaks. Occasional overbank floods. W/D ratio 15 to 25	3	
			Inadequate. Overbank flows common. W/D ratio >25	4	
	6	Bank rock	65%+ with large angular boulders. 12"+ common.	2	
	Ŭ	content	40-65%. Mostly small boulders to cobbles 6-12"	4	
		oomon	20-40%. With most in the 3-6" diameter class	6	x
			20% rock fragments of gravel sizes, 1-3" or less	8	^
	7	Obstructions	Rocks and logs firmly embedded. Flow pattern w/out cutting or deposition. Stable bed	2	
	· '	to flow	Some present causing erosive cross currents and minor pool filling. Obstructions newer and less	4	
		10 11000		6	x
			Moderately frequent, unstable obstructions move with high flows causing bank cutting and pool		
	_	o	Sediment traps full, channel migration occurring	8	
	8	Cutting	Little or none. Infrequent raw banks less than 6"	4	
			Some, intermittently at outcurves and constrictions. Raw banks may be up to 12"	6	
			Significant. Cuts 12-24" high. Root mat overhangs and sloughing evident	12	x
			Almost continuous cuts, some over 24" high. Failure of overhangs frequent	16	
	9	Deposition	Little or no enlargement of channel or point bars	4	X
			Some new bar increase, mostly from coarse gravel	8	
			Moderate deposition of new gravel and course sand on old and some new bars	12	
			Extensive deposits of predominately fine particles. Accelerated bar development	16	
Bottom	10	Rock	Sharp edges and corners. Plane surfaces rough.	1	
		angularity	Rounded corners and edges, surfaces smooth, flat	2	х
			Corners and edges well rounded in two dimensions	3	
			Well rounded in all dimensions, surfaces smooth	4	
	11	Brightness	Surfaces dull, dark, or stained. Generally not bright	1	
			Mostly dull, but may have <35% bright surfaces	2	х
			Mixture dull and bright, ie 35-65% mixture range	3	
			Predominately bright, 65% exposed or scoured surfaces	4	
	12	Consolidation	Assorted sizes tightly packed or overlapping	2	
		of particles	Moderately packed with some overlapping	4	
			Mostly loose assortment with no apparent overlap	6	х
			No packing evident. Loose assortment easily moved	8	
	13	Bottom size	No size change evident. Stable mater. 80-100%	4	
		distribution	Distribution shift light. Stable material 50-80%	8	x
			Moderate changes in sizes. Stable materials 20-50%	12	
	1		Marked distribution change. Stable materials 0-20%	16	
	14	Scouring and	<5% of bottom affected by scour or deposition	6	x
	1.	deposition	5-30% affected. Scour at constrictions and where grades steepen. Some deposition in pools	12	Ê
	1		30-50% affected. Deposits and scour at obstructions, constrictions, and bends. Some filling of pools	18	
	1		More than 50% of the bottom in a state of flux or change nearly year long	24	
	15	Aquatic		 1	
	15	Aquatic	Abundant growth moss-like, dark green perennial. In swift water too.		x
	1	vegetation	Common. Algae forms in low velocity and pool areas. Moss here too	2	
	1		Present but spotty, mostly in backwater. Seasonal algae growth makes rocks slick Perennial types scare or absent. Yellow-green, short term bloom may be present	3	ļ

Notes:

**Channel Stability (Pfankuch)** 

The brightness is B.S. (bright where we walked). Rocks are bright but totally covered in algae. The size distribution doesn't work either. Bed poorly sorted. These categories do not apply here.

## Robbs Peak Dam Reach Site (RPD-G1) Bank Erosion and Vegetation

### **Bank Erosion and Vegetation**

Study Reach Name: Date: 5/19/2003 Robbs PeakCrew Initials:Start Time: 18:57Stop Time:

CAB, TNC, MCM 19:07

Bank material:

Gravel with high sand

<b>BANK EROSION POTENTIAL</b> (if banks are bedrock or composed of boulders, do not fill out this table)							
							Bank a Bank b Bank c Bank d
Bank height	2'	3'	BO	1'			
Bankfull height	1.5'	1.5'	BO	1'			
Root depth	2'	3'	BO	1'			
Root density (%)	70%	75	BO	75			
Bank Angle (degrees)	vertical	vertical	BO	20			
Surface Protection (%)	none	none	BO	20			
% of total study reach	20%	30	20	30			
Natao							

Notes

**Stratification of unstable layers** top of bank; there is no stratification **in banks (below bankfull):** 

Sediment supply:moderateVertical streambed stability:stable

Bank and channel bed conditions notes:

sediment supply is moderate, but high flows capable of tranporting gravel. Banks eroding because of veg encroachment. The river avulses between side channels during high flow.

RIPARIAN VEGETATION				
	<b>DENSITY</b> (indicate	e all that apply)		
VEGETATION TYPE	LOW	MOD.	HIGH	NOTES
Bare		1		high unvegetated bar
Forbs only				
Annual Grass w/ forbes				
Perennial grass				
Rhizomatous grasses

Perennial overstory		11b		lots of small pines
Wetland vegetation community				

**VEGETATION NOTES (composition, vigor, density, and potential):** Very dense willows

## Ice House Dam Reach Upper Site (IH-G1) **LWD Frequency**

### **LWD Frequency Data Sheet**

Study Reach Name: Upper Ice House Date:

5/15/2003

Start time:

Crew Initials: End time:

JDS, RAP

	Length Class				
Diameter Class	3-10 ft (0.9-3.0 m)	10-25 ft (3.1-7.6 m)	25-50 ft (7.7-15.2 m)	50-75 ft (15.3-22.9 m)	>75 ft (>23 m)
6-12 in (10-30 cm)	2	1	1		
12-24 in (31-60 cm)	3	4		2	
24-36 in (61-90 cm)					
>36 in (>90 cm)					

"Tally as R if rootwad is attached."

Comments:

All of the wood is stored in the channel downstream of XS2 where channel is steeper and narrower.

## Ice House Dam Reach Upper Site (IH-G1) V Star

### V\* Measurements

Study Reach Name: Upper Ice House Date: 5/15/2003 Start time: Crew Initials: JDS, RAP End time:

### Comments:

No V\* measurements taken.

- 1. Reach is predominantly gravel/sand facies.
- 2. Little or no evidence of material finer than sand except on floodplain/low bench surfaces.
- 3. Only one "pool" at upstream end of reach, and it's too deep and doesn't have evidence of fine sediment deposits.
- 4. No other well-defined pools.

### Ice House Dam Reach Upper Site (IH-G1) LWD Key Pieces

## Ice House Dam Reach Upper Site (IH-G1) Bank Erosion and Vegetation

### **Bank Erosion and Vegetation**

Study Reach Name:	Upper Ice House	Crew Initials:	JDS, RAP	
Date: 5/15/2003	Start Time:	Stop Time:		
Bank material:	gravel with high sa	and		
	BANK EROSIC	N POTENTIAL		
(if banks are bedrock or compo	osed of boulders, do not	fill out this table)		
	Bank a	Bank b	Bank c	Bank d
Bank height	3'	3'	2.5'	
Bankfull height	3'	2.5'	2.5'	
Root depth	2'	3'	2.5'	
Root density (%)	<10	40	50	
Bank Angle (degrees)	30	80	30	
Surface Protection (%)	10%	25	50	
% of total study reach	20%	10	70	

#### Notes

**Stratification of unstable layers** little stratification in bank profile **in banks (below bankfull):** 

Sediment supply:	moderate
Vertical streambed stability:	aggrading

loose bed material and sand/fine gravel in pools suggest a lot of bed mobilization

### Bank and channel bed conditions notes:

Moderately high supply of sand and gravel (from where?). Could be 1) passed through/over dam; 2) derived from banks (unlikely-no signs of bank erosion); 3) scoured from bed in upper part of reach

"Tally as R if rootwad is attached."

#### Comments:

Photo number 65 (digital card 64MB) looking upstream at Jay near cross-section 2. Note LWD on left bank. In reach, there were two medium-sized log jams (see photo), but wood appears to only cause local scour, and is not affecting the channel much. Some local scour (1-1.5 feet) and sand deposits around wood. Most of the wood is only touching the wetted channel and is perched up on boulders or channel banks. Photo number 67, looking upstream. Note that LWD is not in water - perched up on bedrock. NO KEY PIECES IN REACH.

### Ice House Dam Reach Lower Site (IH-G2) V Star

### **V\* Measurements**

Study Reach Name:	Lower Ice House	
Date:	5/18/2003	Start time:

Crew Initials: MCM/JDS End time:

### Comments:

Pool morphology not present in this reach (it's all plane bed runs and riffles) All fine sediment is draped in thin sheets over bed, except in only localized areas (e.g., behind a log or boulder). No deep sand deposits in reach.

## Ice House Dam Reach Lower Site (IH-G2) Rosgen Level III

### **Rosgen Level III Data Sheet**

Study Reach Nar	ne:	Lower Ice House Dam
Date:		5/18/2003
Crew Initials:		MCM/JDS
Start time:	9:30	End time: 9:50

**Depositional Features** (indicate one)

Bepeeldend		
	B-1	point bars
	B-2	pt. bars w/ few mid channel bars
	B-3	many mid channel bars
Х	B-4	side bars
	B-5	diagonal bars
	B-6	main branching w/ many mid channel bars and islands
	B-7	mixed side bar and mid channel bars exceeding 2-3X width
	B-8	delta bars

Description: Not really bars. Active terrace-plane bed channel with local deposits behind boulder obstructions.

#### Meander Pattern (indicate one)

Х	M-1	regular meander
	M-2	tortuous meander
	M-3	irregular meander
	M-4	truncated meander
	M-5	unconfined me. scrolls
	M-6	confine me. scrolls
	M-7	distorted me. loops
	M-8	irregular with oxbows

Description: Not much meandering; mostly 2 straight channel segments with active terraces separated by riffle at bend.

#### STREAM CHANNEL DEBRIS/BLOCKAGES (indicate one)

Materials, which upon placement into the active channel or floodprone area may cause and adjustment in channel dimensions or conditions, due to influences on the existing flow regime

	Description/Exter	
Х	D-1 (None)	Minor amounts of small, floatable material
	D-2 (Infrequent)	Debris consists of small, easily moved, floatable material; i.e. leaves, needles, small limbs, twigs, etc
	D-3 (Moderate)	Increasing frequency of small to medium sized material, i.e. large limbs, branches, small logs that when accumulated effect 10% or less of the active channel cross-sectional area
	D-4 (Numerous)	Significant buildup of medium to large sized materials, i.e. large limbs, branches, small logs, or portions of trees that may occupy 10 to 30% of the active cross-sectional area.
	D-5 (Extensive)	Debris "dams" of predominantly larger materials, i.e. branches, logs, trees, etc., occupying 30 to 50% of the active channel cross-section, often extending across the wid of the active channel.
	D-6 (Dominating)	Large, somewhat continuous debris "dams," extensive in nature and occupying over 50% of the active channel cross-section. Such accumulations may divert water into floodprom areas and form fish migration barriers, even when flows are at less than bankfull
	D-7 (Beaver Dams - Few)	An infrequent number of dams spaced such that normal streamflow and expected channel conditions exist in the reaches between dams.
	D-8 (Beaver Dams - Frequent)	Frequency of dams is such that backwater conditions exist for channel reaches between structures; where streamflow velocities are reduced and channel dimensions or conditions are influenced.
	D-9 (Beaver Dams - Abandoned)	Numerous abandoned dams, many of which have filled with sediment and/or breached, initiating a series of channel adjustments such as bank erosion, lateral migration, evulsion, aggradations and degradation.
	D-10 (Human Influences)	Structures, facilities, or materials related to land uses or development located within the floodprone area, such as diversions or low-head dams, controlled by-pass channels, velocity control structures, and various transportation encroachments that have
otes:		a sheet. Infrequent medium-sized wood occurs in channel but doesn't influence WD stored on terraces above bankfull elevations.

**VEGETATION NOTES** (composition, vigor, density, and potential): few alder saplings along low water shoreline. BLDR/BDRX substrate does not support veg.

## Camino Dam Reach Site (CD-G1) LWD Frequency

### LWD Frequency Data Sheet

Study Reach Name: Date:	Camino 8/13/2003	Start time:		Crew Initials: End time:	ACF, SRD
Diameter Class	Length Class 3-10 ft (0.9-3.0 m)	10-25 ft (3.1-7.6 m)	25-50 ft (7.7-15.2 m)	50-75 ft (15.3-22.9 m)	>75 ft (>23 m)
6-12 in (10-30 cm) 12-24 in (31-60 cm) 24-36 in (61-90 cm) >36 in (>90 cm)	1				

"Tally as R if rootwad is attached."

Comments:

Very little LWD in channel or surrounding area. No key pieces.

## Camino Dam Reach Site (CD-G1) V Star

### **V\* Measurements**

Study Reach Name:CaminoDate:8/13/2003

Start time:

Crew Initials: ACF/SRD End time:

### Comments:

No V\* measurements taken (N/A).

Pools were too deep to measure and there didn't appear to be any fine sediment except for in the eddy of large boulders (and even that was rare).

## Camino Dam Reach Site (CD-G1) Rosgen Level III

### **Rosgen Level III Data Sheet**

Study Reach Name:	Camino
Date:	8/13/2003
Crew Initials:	ACF, SRD
Start time: 9:30 End time	:

#### Depositional Features (indicate one)

B-1	point bars
B-2	pt. bars w/ few mid channel bars
B-3	many mid channel bars
B-4	side bars
B-5	diagonal bars
B-6	main branching w/ many mid channel bars and islands
B-7	mixed side bar and mid channel bars exceeding 2-3X width
B-8	delta bars

Description: bedrock channel. gravel/cobble in channel; gravel on bank ledges

#### Meander Pattern (indicate one)

M-1	regular meander
M-2	tortuous meander
M-3	irregular meander
M-4	truncated meander
M-5	unconfined me. scrolls
M-6	confine me. scrolls
M-7	distorted me. loops
M-8	irregular with oxbows

Description: bedrock channel. cascade/step-pool sequencing; low frequency meandering

#### STREAM CHANNEL DEBRIS/BLOCKAGES (indicate one)

Materials, which upon placement into the active channel or floodprone area may cause and adjustment in channel dimensions or conditions, due to influences on the existing flow regime

Description/Extent					
	D-1 (None)	Minor amounts of small, floatable material			
	D-2 (Infrequent)	Debris consists of small, easily moved, floatable material; i.e. leaves, needles, small limbs, twigs, etc			
	D-3 (Moderate)	Increasing frequency of small to medium sized material, i.e. large limbs, branches, small logs that when accumulated effect 10% or less of the active channel cross-sectional area.			
	D-4 (Numerous)	Significant buildup of medium to large sized materials, i.e. large limbs, branches, small logs, or portions of trees that may occupy 10 to 30% of the active cross-sectional area.			
	D-5 (Extensive)	Debris "dams" of predominantly larger materials, i.e. branches, logs, trees, etc., occupying 30 to 50% of the active channel cross-section, often extending across the width of the active channel.			
	D-6 (Dominating)	Large, somewhat continuous debris "dams," extensive in nature and occupying over 50% of the active channel cross-section. Such accumulations may divert water into floodprone areas and form fish migration barriers, even when flows are at less than bankfull			
	D-7 (Beaver Dams - Few)	An infrequent number of dams spaced such that normal streamflow and expected channel conditions exist in the reaches between dams.			
	D-8 (Beaver Dams - Frequent)	Frequency of dams is such that backwater conditions exist for channel reaches between structures; where streamflow velocities are reduced and channel dimensions or conditions are influenced.			
	D-9 (Beaver Dams - Abandoned)	Numerous abandoned dams, many of which have filled with sediment and/or breached, initiating a series of channel adjustments such as bank erosion, lateral migration, evulsion, aggradations and degradation.			
x	D-10 (Human Influences)	Structures, facilities, or materials related to land uses or development located within the floodprone area, such as diversions or low-head dams, controlled by-pass channels, velocity control structures, and various transportation encroachments that have			

Notes: Sediment supply/flow affected by upstream dam

	7	Obstructions	Rocks and logs firmly embedded. Flow pattern w/out cutting or deposition. Stable bed	2	
	ľ	to flow	Some present causing erosive cross currents and minor pool filling. Obstructions newer and less	4	~
		10 11000	Moderately frequent, unstable obstructions move with high flows causing bank cutting and pool	6	x
			Sediment traps full, channel migration occurring	8	
	0	Cutting	Little or none. Infrequent raw banks less than 6"	0 4	
8 Cutting	Culling	Some, intermittently at outcurves and constrictions. Raw banks may be up to 12"	4 6	x	
				12	
			Significant. Cuts 12-24" high. Root mat overhangs and sloughing evident		
	0	Deperition	Almost continuous cuts, some over 24" high. Failure of overhangs frequent	16	
	9	Deposition	Little or no enlargement of channel or point bars	4	
			Some new bar increase, mostly from coarse gravel	8	
			Moderate deposition of new gravel and course sand on old and some new bars	12	x
-			Extensive deposits of predominately fine particles. Accelerated bar development	16	
Bottom	10	Rock	Sharp edges and corners. Plane surfaces rough.	1	
		angularity	Rounded corners and edges, surfaces smooth, flat	2	х
			Corners and edges well rounded in two dimensions	3	
			Well rounded in all dimensions, surfaces smooth	4	
	11	Brightness	Surfaces dull, dark, or stained. Generally not bright	1	х
			Mostly dull, but may have <35% bright surfaces	2	
			Mixture dull and bright, ie 35-65% mixture range	3	
			Predominately bright, 65% exposed or scoured surfaces	4	
	12	Consolidation	Assorted sizes tightly packed or overlapping	2	
		of particles	Moderately packed with some overlapping	4	х
			Mostly loose assortment with no apparent overlap	6	
			No packing evident. Loose assortment easily moved	8	
	13	Bottom size	No size change evident. Stable mater. 80-100%	4	
		distribution	Distribution shift light. Stable material 50-80%	8	
			Moderate changes in sizes. Stable materials 20-50%	12	х
	1		Marked distribution change. Stable materials 0-20%	16	1
	14	Scouring and	<5% of bottom affected by scour or deposition	6	1
	1	deposition	5-30% affected. Scour at constrictions and where grades steepen. Some deposition in pools	12	x
	1		30-50% affected. Deposits and scour at obstructions, constrictions, and bends. Some filling of	18	<u> </u>
	1		More than 50% of the bottom in a state of flux or change nearly year long	24	1
	15	Aquatic	Abundant growth moss-like, dark green perennial. In swift water too.	1	
	1.0	vegetation	Common. Algae forms in low velocity and pool areas. Moss here too	2	- v
	1	- Sectation		3	x
	1		Present but spotty, mostly in backwater. Seasonal algae growth makes rocks slick		───
	1		Perennial types scare or absent. Yellow-green, short term bloom may be present	4	

Notes:

Channel is characterized by steep valley walls with coniferous overstory on shallow soils. Large clasts make up majority of bed material, with some cobble/gravel/sand deposition on banks. LWD essentially absent from reach.

## Slab Creek Dam Reach Site (SC-G1) LWD Frequency

### LWD Frequency Data Sheet

Study Reach Name: Date:	Slab Creek Dam 5/23/2003	Start time:	15:10	Crew Initials: End time:	CAB, ZED 15:15
Diameter Class	Length Class 3-10 ft (0.9-3.0 m)	10-25 ft (3.1-7.6 m)	25-50 ft (7.7-15.2 m)	50-75 ft (15.3-22.9 m)	>75 ft (>23 m)
6-12 in (10-30 cm) 12-24 in (31-60 cm) 24-36 in (61-90 cm) >36 in (>90 cm)			20 00 k (() 10.2 h)		10 K ( 20 M)

"Tally as R if rootwad is attached."

Comments:

No LWD in or out of channel. Some very floatable small pieces outside bankfull. No key pieces.

## Slab Creek Dam Reach Site (SC-G1) V Star

V star Measurements			
Study Reach Name: Slab Creek Dam			
Date: 5/23/03			

**Crew Initials: CAB/ZED** Start time: 1520 End time: 1525

#### Comments:

No V\* measurements taken. No evidence of fine sediment in reach. Pools absent, generally glides. Pool/glide below end of reach too turbid and deep to measure V\*.

## Slab Creek Dam Reach Site (SC-G1) Rosgen Level III

### Rosgen Level III Data Sheet

Study Reach Name:		Slab Creek Dam
Date:		5/23/2003
Crew Initials:		CAB, ZED
Start time:	15:05	End time: 15:10

#### Depositional Features (indicate one)

x	B-1	point bars
	B-2	pt. bars w/ few mid channel bars
	B-3	many mid channel bars
	B-4	side bars
	B-5	diagonal bars
	B-6	main branching w/ many mid channel bars and islands
	B-7	mixed side bar and mid channel bars exceeding 2-3X width
	B-8	delta bars
Description	access CO/DO naint have	

Description: coarse CO/BO point bars

#### Meander Pattern (indicate one)

M-1	regular meander
M-2	tortuous meander
M-3	irregular meander
M-4	truncated meander
M-5	unconfined me. scrolls
M-6	confine me. scrolls
M-7	distorted me. loops
M-8	irregular with oxbows

Description: Meander pattern (nearly straight) determined by BR

#### STREAM CHANNEL DEBRIS/BLOCKAGES (indicate one)

Materials, which upon placement into the active channel or floodprone area may cause and adjustment in channel dimensions or conditions, due to influences on the existing flow regime

Description/Extent				
X	D-1 (None)	Minor amounts of small, floatable material		
	D-2 (Infrequent)	Debris consists of small, easily moved, floatable material; i.e. leaves, needles, small limbs, twigs, etc		
	D-3 (Moderate)	Increasing frequency of small to medium sized material, i.e. large limbs, branches, small logs that when accumulated effect 10% or less of the active channel cross-sectional area.		
	D-4 (Numerous)	Significant buildup of medium to large sized materials, i.e. large limbs, branches, small logs, or portions of trees that may occupy 10 to 30% of the active cross-sectional area.		
	D-5 (Extensive)	Debris "dams" of predominantly larger materials, i.e. branches, logs, trees, etc., occupying 30 to 50% of the active channel cross-section, often extending across the width of the active channel.		
	D-6 (Dominating)	Large, somewhat continuous debris "dams," extensive in nature and occupying over 50% of the active channel cross-section. Such accumulations may divert water into floodprone areas and form fish migration barriers, even when flows are at less than bankfull		
	D-7 (Beaver Dams - Few)	An infrequent number of dams spaced such that normal streamflow and expected channel conditions exist in the reaches between dams.		
	D-8 (Beaver Dams - Frequent)	Frequency of dams is such that backwater conditions exist for channel reaches between structures; where streamflow velocities are reduced and channel dimensions or conditions are influenced.		
	D-9 (Beaver Dams - Abandoned)	Numerous abandoned dams, many of which have filled with sediment and/or breached, initiating a series of channel adjustments such as bank erosion, lateral migration, evulsion, aggradations and degradation.		
	D-10 (Human Influences)	Structures, facilities, or materials related to land uses or development located within the floodprone area, such as diversions or low-head dams, controlled by-pass channels, velocity control structures, and various transportation encroachments that have

## LEVEL III DATA FOR THE REACH DOWNSTREAM OF CHILI BAR

# The Reach Downstream of Chili Bar: Upper Coloma Site (CB-G2) Lower Coloma Site (CB-G3)

## Upper Coloma Site (CB-G2) LWD Frequency

LWD Frequency Data Sheet

Study Reach Name: Chili Bar - Upper Coloma Date: 11/18/03 Start time: Crew Initials: CDJ, SKW End time:

Diameter Class	Length Class				
	3-10 ft (0.9-3.0 m)	10-25 ft (3.1-7.6 m)	25-50 ft (7.7-15.2 m)	50-75 ft (15.3-22.9 m)	>75 ft (>23 m)
6-12 in (10-30 cm)					
12-24 in (31-60 cm)					
24-36 in (61-90 cm)					
>36 in (>90 cm)					

"Tally as R if rootwad is attached."

Comments: No Key Pieces. No LWD in channel or along bank. Some present above bankfull elevation on left bank upper slope

## Upper Coloma Site (CB-G2) V Star

#### V\* Measurements

Study Reach Name: Chili Bar - Upper Coloma Date: 11/18/03 Start time: Crew Initials: CDJ, SDW End time:

**Comments:** No V\* taken - small patches of fine sediment present in residual pools, but wetted not applicable due to lack of fine sediment

## Upper Coloma Site (CB-G2) Rosgen Level III

#### Rosgen Level III Data Sheet

Study Reach Name:Chili Bar - Upper ColomaDate:11/18/2003Crew Initials:CDJ, SDW

Start time: End time:

#### Depositional Features (indicate one)

	B-1	point bars
Х	B-2	pt. bars w/ few mid channel bars
	B-3	many mid channel bars
	B-4	side bars
	B-5	diagonal bars
	B-6	main branching w/ many mid channel bars and islands
	B-7	mixed side bar and mid channel bars exceeding 2-3X width
	B-8	delta bars
Description:		C/B/G Bars

#### Meander Pattern (indicate one)

	M-1	regular meander
	M-2	tortuous meander
Х	M-3	irregular meander
	M-4	truncated meander
	M-5	unconfined me. scrolls
	M-6	confine me. scrolls
	M-7	distorted me. loops
	M-8	irregular with oxbows
Description:		Channel marked by occasional meanders and long runs with pool riffle sequences

#### STREAM CHANNEL DEBRIS/BLOCKAGES (indicate one)

Materials, which upon placement into the active channel or floodprone area may cause an adjustment in channel dimensions or conditions, due to influences on the existing flow regime

	Description/Exter	nt					
Х	D-1 (None)	Minor amounts of small, floatable material					
	D-2 (Infrequent)	Debris consists of small, easily moved, floatable material; i.e. leaves, needles, small limbs, twigs, etc					
	D-3 (Moderate)	Increasing frequency of small to medium sized material, i.e. large limbs, branches, small logs that when accumulated effect 10% or less of the active channel cross-sectional area.					
	D-4 (Numerous)	Significant buildup of medium to large sized materials, i.e. large limbs, branches, small logs, or portions of trees that may occupy 10 to 30% of the active cross-sectional area.					
	D-5 (Extensive)	Debris "dams" of predominantly larger materials, i.e. branches, logs, trees, etc., occupying 30 to 50% of the active channel cross-section, often extending across the width of the active channel.					
	D-6 (Dominating)	Large, somewhat continuous debris "dams," extensive in nature and occupying over 50% of the active channel cross-section. Such accumulations may divert water into floodprone areas and form fish migration barriers, even when flows are at less than bankfull					
	D-7 (Beaver Dams - Few)	An infrequent number of dams spaced such that normal streamflow and expected channel conditions exist in the reaches between dams.					
	D-8 (Beaver Dams - Frequent)	Frequency of dams is such that backwater conditions exist for channel reaches between structures; where streamflow velocities are reduced and channel dimensions or conditions are influenced.					
	D-9 (Beaver Dams - Abandoned)	Numerous abandoned dams, many of which have filled with sediment and/or breached, initiating a series of channel adjustments such as bank erosion, lateral migration, evulsion, aggradations and degradation.					
	D-10 (Human Influences)	Structures, facilities, or materials related to land uses or development located within the floodprone area, such as diversions or low-head dams, controlled by-pass channels, velocity control structures, and various transportation encroachments that have influence on the existing flow regime, such that significant channel adjustments occur.					

# Upper Coloma Site (CB-G2) Pfankuch

Place X in this

#### Channel Stability (Pfankuch)

Study Reach Name: Chili Bar - Upper Coloma

Crew Initials: CDJ, SDW Date: 11/18/2003

Start Time: Stop Time:

Stop Time:		Category	(choose one for each of the four options for each category)		in this columr
Upper	1	Landform	Bank slope gradient <30%	2	
Banks		slope	Bank slope gradient 30-40%	4	
			Bank slope gradient 40-60%	6	Х
			Bank slope gradient 60+%	8	
	2	Mass wasting	No evidence of past or future mass wasting	3	
	_		Infrequent. Most likely healed over. Low future potential	6	Х
			Frequent or large, causing sediment nearly year long	9	~
			Frequent or large causing sediment nearly year long or imminent danger of same	12	
	2	Debris jam	Essentially absent from immediate channel area	2	~
	3	potential		4	Х
		potential	Present, but mostly small twigs and limbs		
			Moderate to heavy amounts, mostly larger sizes	6	
			Moderate to heavy amounts, predominately lager sizes	8	
	4	Vegetative	90%+ plant density. Vigor and variety suggest a deep, dense soil binding root mass	3	
		bank	70-90% density. Fewer species or less vigor suggest less dense or deep root mass	6	
		protection	<50-70% density. Lower vigor and fewer species from a shallow, discontinuous root mass	9	Х
			<50% density, fewer species and less vigor indicate poor, discontinuous and shallow root mass	12	
.ower	5	Channel	Ample for present plus some increases. Peak flows contained. W/D ration <7	1	
Banks		capacity	Adequate. Bank overflows rare. W/D ratio 8-15	2	Х
			Barely contains present peaks. Occasional overbank floods. W/D ratio 15 to 25	3	
			Inadeguate. Overbank flows common. W/D ratio >25	4	
	6	Bank rock	65%+ with large angular boulders. 12"+ common.	2	
	Ŭ	content	40-65%. Mostly small boulders to cobbles 6-12"	4	х
		oomon	20-40%. With most in the 3-6" diameter class	6	~
				8	
		Obstantises	20% rock fragments of gravel sizes, 1-3" or less	-	
	7	Obstructions	Rocks and logs firmly embedded. Flow pattern w/out cutting or deposition. Stable bed	2	
		to flow	Some present causing erosive cross currents and minor pool filling. Obstructions newer and less firm	4	Х
			Moderately frequent, unstable obstructions move with high flows causing bank cutting and pool filling	6	
			Sediment traps full, channel migration occurring	8	
	8	Cutting	Little or none. Infrequent raw banks less than 6"	4	Х
			Some, intermittently at outcurves and constrictions. Raw banks may be up to 12"	6	
			Significant. Cuts 12-24" high. Root mat overhangs and sloughing evident	12	
			Almost continuous cuts, some over 24" high. Failure of overhangs frequent	16	
	9	Deposition	Little or no enlargement of channel or point bars	4	Х
			Some new bar increase, mostly from coarse gravel	8	
			Moderate deposition of new gravel and course sand on old and some new bars	12	
			Extensive deposits of predominately fine particles. Accelerated bar development	16	
Bottom	10	Rock	Sharp edges and corners. Plane surfaces rough.	1	
Jottom	10	angularity	Rounded corners and edges, surfaces smooth, flat	2	
		angularity	Corners and edges well rounded in two dimensions	3	v
			·	4	X
		D. S. L. L. S.	Well rounded in all dimensions, surfaces smooth		
	11	Brightness	Surfaces dull, dark, or stained. Generally not bright	1	X
			Mostly dull, but may have <35% bright surfaces	2	
			Mixture dull and bright, ie 35-65% mixture range	3	
			Predominately bright, 65% exposed or scoured surfaces	4	
	12	Consolidation	Assorted sizes tightly packed or overlapping	2	
		of particles	Moderately packed with some overlapping	4	
			Mostly loose assortment with no apparent overlap	6	Х
			No packing evident. Loose assortment easily moved	8	
	13	Bottom size	No size change evident. Stable mater. 80-100%	4	
		distribution	Distribution shift light. Stable material 50-80%	8	
			Moderate changes in sizes. Stable materials 20-50%	12	Х
			Marked distribution change. Stable materials 0-20%	16	~
	1.4	Scouring and	<5% of bottom affected by scour or deposition	6	
	14				~
		deposition	5-30% affected. Scour at constrictions and where grades steepen. Some deposition in pools	12	X
			30-50% affected. Deposits and scour at obstructions, constrictions, and bends. Some filling of pools	18	
			More than 50% of the bottom in a state of flux or change nearly year long	24	
	15	Aquatic	Abundant growth moss-like, dark green perennial. In swift water too.	1	
		vegetation	Common. Algae forms in low velocity and pool areas. Moss here too	2	Х
			Present but spotty, mostly in backwater. Seasonal algae growth makes rocks slick	3	
	1	1	Perennial types scare or absent. Yellow-green, short term bloom may be present	4	

## Upper Coloma Site (CB-G2) Bank Erosion and Vegetation

#### Bank Erosion and Vegetation

Study Reach Name:Chili Bar - Upper ColomaDate:11/18/03Start Time:

Crew Initials: CDJ, SKW Stop Time:

Bank material: Boulders, cobble

BANK EROSION POTENTIAL								
(if banks are bedrock or composed of boulders, do not fill out this table)								
	Bank a	Bank b	Bank c	Bank d				
Bank height (ft)	8.03-11.60	14.69-18.64						
Bankfull height (ft)	8.03	13.92						
Root depth (ft)	0.5-1.5	not visible						
Root density (%)	5-20%	not visible						
Bank Angle (degrees)	60-80	30-50						
Surface Protection (%)	75%	<5%						
% of total study reach	20-30%	60-80%						

Notes

Stratification of unstable layers in banks (below bankfull):

N/A No stratification present

Sediment supply: Moderat Vertical streambed stability: Degrading

**Bank and channel bed conditions notes:** Modern river is incising alluvial fill deposited during a prior period of aggradation. Thus, modern river banks are comprised of well rounded large cobble and small boulder. Modern river lies 5 - 15 feet below historical flow surface. Occasional high flows cover this historical surface (middle and lower cross-section).

RIPARIAN VEGETATION							
	<b>DENSITY</b> (indicate	e all that apply)

# ENHANCED ACRONYM SERIES (1 & 2) WITH INTERFACE (EASI): MODEL DOCUMENTATION

## **1 INTRODUCTION**

Sediment transport has been realized to be one of the most important processes in a fluvial ecosystem. Many recent channel rehabilitation projects and proposals have been focused on the remobilization or augmentation of gravel in heavily altered rivers in order to improve the quality of fish habitats. Suggestions on modifying channel cross sections (e.g., narrowing the main channel, lowering floodplain elevation, and lay back levees) are also proposed in certain rivers in order to increase the frequency of gravel transport and decrease the amount of gravel transported during extremely high flows. For example, gravel has been added below the Whiskeytown Reservoir in Clear Creek, California in hope of improving the existing salmonid spawning habitats. Similar practices are also documented at the Keswick Dam on the upper Sacramento River, California (Kondolf 1995). Larger scale gravel augmentations and flow alterations are also being considered in other rivers of California's Central Valley. A user-friendly tool for evaluation of such projects and proposals is, however, still unavailable to watershed managers, planners and practitioners. To fill in this void, Stillwater Sciences developed the EASI (Enhanced Acronym Series with Interface) program based on the surface based bedload equation and the Acronym1 and Acronym2 programs of Parker (Parker 1990a, b). In the EASI program, the *Acronym* programs are enhanced to allow for calculation of: (1) gravel transport rate and bedload grain size distribution with given surface gravel grain size distribution, channel geometry and water discharge; and (2) bedload transport rate and surface layer grain size distribution with given bedload grain size distribution, channel geometry and water discharge. The EASI program also allows for a river cross section and a duration curve as input parameters. In the case of a river cross section, the EASI program allows for the separation of floodplain and the main channel so that the hydraulics of the river can be evaluated more accurately. Table M-1 shows the similarities and differences between the EASI program and the Acronym Series (1 & 2) of Parker (1990b).

The most significant difference between *EASI* and the *Acronym* series is in the case of calculating surface layer grain size distribution. In this specific case, the *EASI* program uses bedload grain size distribution, water discharge or duration curve and channel width or channel cross section as input parameters, whereas *Acronym2* uses bedload transport rate and grain size distribution but not bedload transport rate as an input parameter can easily be seen in the case of gravel augmentation, in which the bedload grain size is readily available and bedload transport rate needs to be evaluated.

This report discusses how the surface based bedload equation of Parker (1990a) is implemented.

As is for any sediment modeling tools, the *EASI* program predicts certain parameters only as guidelines for management and engineering practice and thus, its results must be

Figure M-2. A typical cross section of a river.

Floodplain hydraulics and flow continuity are brought in to close the equations,

$$Q_{wf} = \frac{1}{n} A_f R_{hf}^{2/3} S^{1/2}$$
(17)

$$Q_{wf} + Q_{wc} = Q_w \tag{18}$$

$$R_{hf} = \frac{A_f}{P_f} \tag{19}$$

$$u_c = \frac{Q_{wc}}{A_c} \tag{20}$$

where n denotes Manning's n for floodplain;  $A_f$  denotes flow area in floodplain;  $P_f$  denotes the wet perimeter of the floodplain;  $R_{hf}$  denotes hydraulic radius of the floodplain;  $Q_{wf}$  and  $Q_{wc}$  denotes the discharge on floodplain and main channel respectively.

#### 3 CALCULATION OF BEDLOAD TRANSPORT RATE AND BEDLOAD GRAIN SIZE DISTRIBUTION

This part of the EASI program is designed for the following two cases:

interpreted by qualified hydraulic engineers or fluvial geomorphologists with field experience in the river to be modeled.

## 2 THE SURFACE BASED BEDLOAD EQUATION OF PARKER AND ITS MODIFICATION

The surface based bedload equation of Parker (1990a) is expressed for wide rectangular channel for which channel geometry can be expressed as a channel width. The equation is modified for the *EASI* program so that it can also handle a given cross section. Details of the surface based bedload equation of Parker can be found in the original references (Parker 1990a, b). Here only the most essential part of the Parker equation is presented so that we can discuss how the equation is modified and implemented in the *EASI* program.

The surface based bedload equation of Parker (1990a) for a wide rectangular channel is as follows,

$$\frac{RgQ_G p_i}{Bu_*^3} = \alpha F_i G \left[ \omega \phi_{sgo} \left( \frac{\overline{D_i}}{D_{sg}} \right)^{-\beta} \right]$$
(1)

where R denotes the submerged specific gravity of gravel; g denotes the acceleration of gravity;  $Q_G$  denotes volumetric bedload transport rate; B denotes channel width; u<sup>\*</sup> denotes shear velocity;  $\overline{D_i}$  denotes the mean grain size of the i-th subrange;  $p_i$  denotes the volumetric fraction of the i-th subrange in bedload;  $F_i$  denotes the volumetric fraction of the surface layer;  $D_{sg}$  denotes geometric mean grain size of the surface layer;  $\phi_{sgo}$  is normalized Shields stress;  $\omega$  is a function of the normalized Shields stress  $\phi_{sgo}$  and the arithmetic standard deviation of the surface layer. Coefficients  $\alpha$  and  $\beta$  are given as

$$\alpha = 0.00218; \quad \beta = 0.0951$$
 (2a, b)

Grain size is described both in diameter and in  $\Psi$ -scale, which is the negative of the more commonly used  $\phi$ -scale in geophysics community (Parker 1990b).

$$\psi_i = -\phi_i = \log_2(D_i) \tag{3}$$

The grain size is divided into N subgroups bounded by N+1 grain sizes  $\Psi_1$  (D<sub>1</sub>) to  $\Psi_{N+1}$  (D<sub>N+1</sub>). The mean grain size of the i-th subrange is then given as

$$\overline{\psi_i} = \frac{\psi_i + \psi_{i+1}}{2}, \quad \overline{D_i} = \sqrt{D_i D_{i+1}}$$
(4a, b)

The surface layer mean grain size  $\overline{\psi_s}$  and standard deviation  $\sigma_{s\psi}$  are as follows,

$$\overline{\psi_s} = \sum_{i=1}^{N} \overline{\psi_i} F_i , \quad \sigma_{s\psi}^2 = \sum \left( \overline{\psi_i} - \overline{\psi_s} \right)^2 F_i$$
(5a, b)

and the geometric mean grain size is given as

$$D_{sg} = 2^{\overline{\psi_s}} \tag{5c}$$

Note that the surface based bedload equation of Parker applies only to particles too coarse to be transported in suspension, and Parker further suggested that the finest grain size  $(D_1)$  be set as 2 mm as a common rule in field cases (Parker 1990a, b).

Figure M-1. Parameters  $\sigma_0$  and  $\omega_0$  as functions of  $\phi_{sgo}$  in Parker equation

Parameter  $\omega_{\rm i}$  is a function of the normalized Shields stress  $\phi_{\rm sgo}$ ,

$$\omega = 1 + \frac{\sigma_0}{\sigma_{s\psi}} (\omega_0 - 1) \tag{6}$$

where  $\sigma_0$  and  $\omega_0$  are functions of  $\phi_{sgo}$  given in Figure M-1 (Parker 1990a). The relations can also be found in tabulated form in Parker (1990b).

The normalized Shields stress  $\phi_{sgo}$  is acquired by dividing the surface based Shields stress  $\tau_{sg}^*$  by a reference stress  $\tau_{rsgo}^*$ ,

$$\phi_{sgo} = \frac{\tau_{sg}^*}{\tau_{rsgo}^*} \tag{7}$$

where the reference Shields stress  $\tau_{rsgo}^*$  is given by Parker (1990a) as 0.0386. The surface based Shields stress  $\tau_{sg}^*$  is defined as

$$\tau_{sg}^* = \frac{{u_*}^2}{RgD_{sg}} \tag{8}$$

Shear velocity u\* is assumed to obey the Keulegan resistance relation,

$$\frac{u}{u_*} = 2.5 \ln \left( 11 \frac{h}{k_s} \right) \tag{9}$$

in which u denotes flow velocity; h denotes water depth and  $k_s$  denotes roughness height. Roughness height is defined slightly differently from the original work of Parker (1990a, b) for simplicity,

$$k_s = 2D_{sg}\sigma_{sg}^{1.28} \tag{10}$$

where  $\sigma_{\rm sg}$  denotes surface layer geometric standard deviation,

$$\sigma_{sg} = 2^{\sigma_{s\psi}} \tag{11}$$

Note that the roughness height given by Equation (10) is an approximation of the original value given by Parker (1990a, b), in which the roughness height was defined as twice of surface layer  $D_{90}$ .

In case of a normal flow, shear velocity  $u_*$  can be expressed as

$$u_* = \sqrt{ghS} \tag{12}$$

in which S is channel bed slope.

Function G is given by Parker (1990a, b) as

$$G(\phi) = \begin{cases} 5474 \left(1 - \frac{0.853}{\phi}\right)^{4.5} & \phi > 1.59\\ \exp\left[14.2(\phi - 1) - 9.28(\phi - 1)^2\right] & 1 \le \phi \le 1.59\\ \phi^{14.2} & \phi < 1 \end{cases}$$
(13)

In case of an arbitrary cross section, the cross section is divided into the main channel and a floodplain as shown in Figure M-2. In this case the sediment transport over floodplain is assumed to be insignificant.

The surface based bedload equation of Parker (Equation 1) and the Keulegan resistance relation (Equation 9) are modified as follows,

$$\frac{RQ_G p_i}{A_c Su_*} = \alpha F_i G \left( \omega \phi_{sgo} \left( \overline{D_i} / D_{sg} \right)^{-\beta} \right)$$
(14)

$$\frac{u_c}{u_*} = 2.5 \ln \left( 11 \frac{R_{hc}}{k_s} \right) \tag{15}$$

where  $A_c$  denotes flow area in the main channel;  $R_{hc}$  denotes hydraulic radius of the flow in the main channel,

$$R_{hc} = \frac{A_c}{P_c} \tag{16}$$

and  $P_c$  denotes the wet perimeter of the main channel. Shear velocity, roughness height and grain size parameters in equations (14) and (15) all refer to those in the main channel.

- 1. To estimate current or historical gravel transport rate and bedload grain size distribution based on the existing or historical surface layer grain size distribution and the knowledge of channel geometry and water discharge information;
- 2. To estimate gravel transport rate and grain size distribution based on targeted surface layer grain size distribution, channel geometry and water discharge in case of gravel augmentation.

With the two cases, channel restoration practitioners and management can evaluate different restoration options or whether certain restoration practices are economically achievable. The procedure also allows for evaluation of channel cross section optimization such as channel narrowing, floodplain restoration and modification, etc.

## 4 CALCULATION OF BEDLOAD TRANSPORT RATE AND SURFACE LAYER GRAIN SIZE DISTRIBUTION

This part of the *EASI* program is designed for the purpose of estimating gravel transport rate and surface layer grain size distribution if a gravel augmentation with certain grain size distribution is given. Such an application allows restoration practitioners and management to evaluate whether the existing gravel for augmentation should be modified and if the practice is economically achievable. The procedure also allows for the evaluation of aforementioned channel cross section optimization.

## 5 APPLICATION EXAMPLE

The example is presented here to demonstrate what can be achieved from program *EASI*. The cross sections and grain size distributions used here are from an actual river. The scenarios to be simulated, however, are constructed only for demonstration purposes.

The scenario is as follows. A certain reach of a gravel bed river with salmon run is deprived of gravel because of a dam built not too far upstream. As a result, there are fewer areas available as salmonid spawning habitat and the quality of the available spawning habitat is degrading. The management is considering gravel augmentation as a way of improving the salmon habitat. The reach is fairly uniform with a typical cross section as shown in Figure M-3. The reach average channel slope is 0.003 based on water surface survey at a medium discharge. Post-dam flow duration curves are given in Figure M-4. The current reach average surface layer grain size distribution is given in Figure M-5.

Applying *EASI* program, it is found that the current post-dam gravel transport rate is only about 10 metric tons per annum (t/a) with bedload grain size distribution given in Figure M-5. Because the dam is capturing all the gravel and there are no tributaries between the dam and the reach, the 10 t/a gravel transport rate calculated by *EASI* program is probably not too far from reality. In some cases, however, the *EASI* program might over estimate the sediment transport rate because of the following conditions: (a) the reach could still be under going the post dam erosion process; and (b) there are bedrock controls that prevent further erosion of the current channel bed, banks or terraces. Under

either of the two conditions, the actual gravel transport rate could be lower than the value calculated with *EASI* program.

In order to increase gravel transport and improve salmonid spawning habitat, fish and wild life management is planning to have a gravel augmentation project implemented upstream of the reach in question. One of the concepts developed by McBain and Trush is to do a "gravel transfusion" before the augmentation. That is, to introduce massive amount of gravel into the reach before the augmentation so that the channel can be recovered quickly. The gravel transfusion will also prevent the possibility that gravel from augmentation will simply pass through the reach during high flows without leaving enough deposit.

Figure M-3. Channel cross sections to be used in the example

In this example, it is assumed that a gravel transfusion will be implemented with the grain size distribution given in Figure M-5. Applying *EASI* program, it is found that the long time average gravel transport rate will be increased to about 3660 t/a, or an annual gravel augmentation of about 3660 t/a.

Figure M-4. Pre- and post-dam duration curves to be used in the example.

Figure M-5. Grain size distributions presented in the example.

Figure M-6. Predicted gravel transport rate presented in the example.

Figure M-7. Predicted normalized Shields stress as presented in the example.

3,660 t/a of gravel transport is probably a very reasonable amount for augmentation. For demonstration purposes, however, let's assume that the management decided that the 3660 t/a gravel is too much to add and there is easy way to modify the channel so that a floodplain can be added as shown in Figure M-3. Applying *EASI* program it is found that the gravel transport rate dropped to about 1,270 t/a by adding the floodplain, which is about 35% of the amount without a floodplain. In this calculation the Manning's n for floodplain is assumed to be 0.035.

The grain size distributions, bedload rating curves and normalized Shields stresses in this example are given in Figures M-5, M-6, and M-7 respectively. One of the potentially most useful diagram is the normalized Shields stress given in Figure M-7. It is important to point out that normalized Shields stress equals to unity represents the incipient motion of bed material. Combine the rating curve given in Figure M-4 with the normalized Shields stress curves in Figure M-7, one can easily estimate at what percentage of time there is significant gravel transport in the river reach. For example, in the case of post gravel transfusion, the water discharge identified to correspond to normalized Shields stress equal to unit is about 19 m<sup>3</sup>/s, which corresponds to a non-exceedance probability of about 95%. In other word, there is only about 5% of the time during which the river is actively transporting gravel even with the gravel transfusion.

Possible measures to increase gravel transport duration include modification on the operation of the upstream reservoir, narrowing the main channel, further decrease the grain size of the transfusion gravel within the limitation for fish habitat, or a combination of those measures. All those measures could be evaluated with the *EASI* program. In the post transfusion case, for example, modifying the operation of the upstream reservoir so that there is more than 37 days every year to have discharge over 19 m<sup>3</sup>/s will increase the gravel transport period to 10%.

## 6 **DISCUSSIONS**

Program EASI stands for "Enhanced Acronym Series (1 & 2) with Interface", which is adopted from the Acronym series (Parker 1990b) and is simply a solution of the modified surface based bedload equation of Parker (1990a, b). It provides a tool for hydraulic engineers, fluvial geomorphologists, river restoration practitioners and management for a quantitative evaluation of gravel transport in a river reach. The program, however, cannot be blindly used to answer management questions. The practitioners must use their field experience in the river reach in question and in sediment transport in general in order to interpret the results. We strongly discourage any application of the program prior to a good understanding of the hydrology of the river and thorough field investigations of the river reach to be modeled. To reiterate, we would like to cite a sentence from Parker (1990b) while presenting his Acronym series: This program is "nothing more than tools for implementing calculation procedures published in the literature. The calculation of bedload transport in gravel rivers yields at best crude approximations of the actual observed numbers in field streams. Where engineering decisions are to be made, the results should be interpreted only by a competent hydraulic engineer or river geomorphologist with prior experience in the field of gravel rivers."

F. American Reach Site (SFAR-G1) Slab Creek Dam Reach Site (SC-G1)

# Rubicon Dam Reach Site (RD-G1)

The Rubicon Dam Reach Site is located in an "S" shaped meander. The channel is clear of debris, and lateral bars form the channel margins. At the upstream end of the site, cobble/gravel facies form a riffle, while bedrock forms the first outside river-right bend located just below the upper cross-section. The inside bend at the upper cross-section is a vegetated (small trees and shrubs) cobble/gravel bar with a high-flow channel behind it. Moving downstream, a pool has formed on the river-left outside bend with the start of a vegetated cobble/gravel bar on the inside river-right bend. At the middle cross-section, a second cobble/gravel riffle starts and continues to the end of the reach. The river-right bar continues to the lower cross-section, where a smaller vegetated (small trees and shrubs) cobble/gravel bar has formed on river-right. River banks and mid-channel gravel bars are well vegetated. Bank vegetation on river left consists of large trees with brushy under story, while vegetation on the right bank is composed of mainly small trees and shrubs on the cobble/gravel bars.

### Loon Lake Dam Reach Upper Site (LL-G1)

The Loon Lake Dam Reach Upper Site has vegetated point bars and subtle pool-riffle morphology (there are no true riffle control points). There were many fallen trees across the channel, with some spanning above the water surface elevation, while others are submerged. The reach bed is comprised of silt and fine to coarse sand. A number of down trees are found beginning just upstream of the middle cross-section and continuing to the end of the reach. Some sand and/or silt deposition has occurred in the low-velocity zones on the downstream side of each log and along the channel margins. River banks are well vegetated with trees and grass/shrub understory.

## Loon Lake Dam Reach Middle Site (LL-G2)

At the Loon Lake Dam Reach Middle Site, channel and bank conditions are extremely uniform. The channel is wide and unconfined, banks are poorly defined. The entire reach is well vegetated and LWD is plentiful in the reach with several debris jams. Because of the low banks, LWD and debris jams tend to create frequent overflow channels and mid-channel bars. The channel primarily consists of cobble/boulder facies with a meadow on the river-right bank and large trees on the river-left bank. The banks and floodplains on both sides of the channel also consist of cobbles and boulders in a soil matrix with dense vegetation. Many of the forced overflow channels are also well vegetated with grasses and herbaceous plants.

O-7

#### Approximate scale provided

#### Loon Lake Dam Reach Lower Site (LL-G3)

Pools at the Loon Lake Dam Reach Lower Site are scarce. Gravel, cobble, and sand form the channel bed downstream of the upper cross-section. Cobble with occasional boulders dominate as the river straightens out. The channel below the middle cross-section widens with several sand and gravel bars. Large cobbles and boulders, with small sand/fine gravel pockets, occur in the channel at the lower cross-section. Here, sand is deposited in high flow channels along the right bank and boulders form the moderately vegetated left bank, while the right bank is well vegetated.

### Gerle Creek Dam Reach Site (GC-G1)

The Gerle Creek Dam Reach Site is a straight, boulder and bedrock channel. Patches of gravel and small cobble are deposited behind obstructions. Boulder and bedrock facies continues downstream to just above the middle cross-section. Very little fine sediment is stored at this site, except in deepest parts of the big pool. Riparian vegetation grows only in the margin and tailout of a pool below the lower cross-section. There is little or no vegetation in other parts of reach.

## Robbs Peak Dam Reach Site (RPD-G1)

The channel substrate at the Robbs Peak Dam Reach Site is primarily coarse gravel, mixed with cobble and sand. Dense boulder deposits also exist, but are discontinuous. The active floodplain is wide with multiple flow paths, and sand is deposited on the margins and along the inside of the river meanders. Willows and some conifers grow in the channel, with frequent large woody debris piles observed above the low-flow wetted channel.

Facies Key\*:

GRCBSD = Mixed gravel, cobble, and sand. Algae covering rocks.

CB = Cobble sorted on outside of bend. Estimated d50 = 70mm.

CBGRSD = mixed cobble, gravel, and sand. Coarser than upstream unit. Estimated d50 = 60 mm.

Gravel w/ Sand = Unit of sand and gravel at downstream end of bar.

Willow 2 = Apex 5 ft above water surface elevation. Gravel and cobble with a veneer of sand, and relatively flat. Upstream end is grades to high gravel and cobble bar.

GRCB1 = Gravel and cobble bar, high and exposed with greater than 10% sand. Local sand patches associated with willow growth (>10 ft height) with conifer and minor aspen growing on sand.

Willow 4 = Tall, approximately 8-10 ft, willows along old channel was next to approximately 50 year old conifers and sand.

BOCBSD1 = Deposits of boulder, cobble, and sand with minor amounts of gravel. Estimated d50 without the sand = 120mm.

Mixed GRCBBOSD = Gravel, cobble, boulder, and sand mixed. Sand is in discrete patches. Estimated d50 = 100mm. Very high widely distributed . Sediment covered with algae. Channel boulders dense in some places, but not continuous.

GRCB2 = Cobble with pockets of gravel. Placed for road, no entrance visible from main channel.

\*Taken directly from field notes.

## Ice House Dam Reach Upper Site (IH-G1)

The active channel of the Ice House Dam Reach Upper Site is chiefly comprised of medium gravel and sand deposits with alternating bars and point bars. Large boulders lie in the channel and along the margins in several locations. Several channel-spanning pieces of LWD were found in the channel near the lower cross-section. Silt and sand are deposited in low-velocity zones on the margins and behind flow obstructions.

O-17

#### Ice House Dam Reach Lower Site (IH-G2)

Cobbly gravel facies dominate in most of the channel at the Ice House Dam Reach Lower Site, with intermittent boulder and bedrock outcrops. LWD is located on the river-left bank above and below the middle cross-section. Downstream of the middle cross-section, the boulder and cobble channel sweeps into a bedrock wall on the left. Here, a high flow side channel exists on the right bank. Boulder and cobble is deposited at the head of the overflow channel, gradually becoming cobble and gravel downstream. Terraces have formed on both banks. Vegetation is sparse throughout the reach.

## Junction Dam Reach Site (JD-G1)

At the Junction Dam Reach Site, cobble and gravel cover the channel and numerous boulders of various sizes occur over the entire length. Small patches of finer gravel and cobble exist behind large boulder obstructions, along the stream margins, and in the middle of the channel as lateral bar deposits. The channel is bedrock controlled, and outcrops occur on both banks throughout the site. Steep bedrock walls prevent vegetation growth, however trees and shrubs do begin to appear on top of the walls once they flatten out.

## Camino Dam Reach Site (CD-G1)

The Camino Dam Reach Site is bedrock controlled with a predominantly cobble and gravel bed. Bank ledges are composed of gravel. At the upper cross-section is a pool with a cobble bottom, bound at the bottom end by boulders and bedrock outcrops. The middle cross-section is a run with a boulder/gravel channel and bedrock banks. The lower cross-section is located near a pool with cobble bottom. Bedrock forms the banks at the downstream end of the site.

Approximate scale (1:1400)

# S. F. American Reach Site (SFAR-G1)

South Fork American River Reach Site (SFAR-G1)

The channel at the South Fork American River Reach Site is straight with intermittent lateral bars made of coarse material. Sand fills the interstitial spaces between the dominant cobble and boulder facies. Bedrock outcrops are prevalent on both banks, with a coarse cobble and boulder bar development on the left bank near the lower cross-section. The channel is characterized by steep valley walls, is sparsely vegetated with coniferous trees, with smaller trees and shrubs growing closer to the waters edge.

## Slab Creek Dam Reach Site (SC-G1)

Boulders and large cobble dominate substrate facies along the channel at the Slab Creek Dam Reach Site. The upper banks are characterized by moderate slopes with large boulders and bedrock outcrops. Primary channel flow meanders around two large boulder and cobble point bars. Minimal amounts of gravel are deposited in the low velocity areas behind boulders and bedrock flow obstructions. A thin veneer of silt is deposited along the margins of the low flow channel. Light shrubs and small trees are scattered in the boulder banks, but become denser up slope from the boulders.

Facies Key\*:

CO1 = Cobble with few boulders on downstream end of bar. Estimated d50 is 80mm. BOCO1 = Boulder field with cobbles and small patches of overbank gravel deposits. Estimated d50 is 500 mm.

BO1 = Boulder and bedrock steps in channel.

COBO1 = Channel cobbles and boulders, with very little gravel. Boulders arrangedon small steps. Estimate d50 = 200 mm.

COBO2 = Cobble and boulder bar on left bank, with some gravel. Boulders are not arranged as steps. Estimated d50 = 180mm.

BOCO2 = Channel coarse boulder and cobble deposit along bedrock margin.

Note: There is a thin veneer of silt on the channel margins from slow water effects.

\*Taken directly from field notes.

#### **APPENDIX P**

#### FACIES MAPS FOR THE REACH DOWNSTREAM OF CHILI BAR

•	Upper Canyon Site (CB-G1)	.P-2
	Upper Coloma Site (CB-G2)	
	Lower Coloma Site (CB-G3)	
	Gorge Site (CB-G4)	

Reach Downstream of Chili Bar: Upper Canyon Site (CB-G1) Upper Coloma Site (CB-G2) Lower Coloma Site (CB-G3) Gorge Site (CB-G4)

# Upper Canyon Site (CB-G1)

The channel at the Upper Canyon Site is straight with a gravel bar on the right bank. Boulder and bedrock facies dominate the banks and channel (50-60 % of the wetted channel). Cobble and small amounts of coarse gravel are deposited along the margins of the channel and behind large flow obstructions in the channel. Sparsely vegetated, steep hillslopes constrict the active channel, leaving little room for lateral movement or floodplain development. Despite this, wellestablished riparian plant communities were observed in some places along the waters edge, particularly on river-right. A thick layer of algae covers much of the substrate within the wetted channel.

# Upper Coloma Site (CB-G2)

The channel at the Upper Coloma Site is dominated by cobble, boulder, and gravel, with a small amount of fines in the tail end of the upstream pool. A densely vegetated, cobble and gravel mid-channel island exists near the upper cross-section, creating a riffle that ends upstream of the lower cross-section. Cobble, boulder, and gravel dominate the facies on both banks and a large lateral bar on river-right. Large trees are set back from the wetted channel on both banks, with smaller trees and shrubs growing close to the waters edge.

# Lower Coloma Site (CB-G3)

The channel at the Lower Coloma Site is dominated by cobble and boulder. Sand, gravel, and silt are deposited in a bar on the left bank below a large bedrock outcrop that obstructs the primary channel flow on the left bank above the upper cross-section. Both banks consist of cobble and boulder, with bedrock dominating near the end of the reach. Large trees are set back on a cobble and boulder terrace on both banks, with smaller trees and shrubs growing close to the waters edge.

# Gorge Site (CB-G4)

The flow splits around a lightly vegetated mid-channel bar, which extends from the upper cross-section to just upstream of the lower cross-section at the Gorge Site. A riffle exists at the tail end of this bar. A cobble and boulder lateral bar extends from upstream of the middle cross-section through the end of the reach on river left. The wetted channel is dominated by gravel and cobble for most of the site, coarsening in the downstream direction as the main flow runs through a riffle. Bedrock outcrops occur in several locations along the left bank. Sand beaches exist on both banks upstream of the upper cross-section.

## **References:**

Cowan, W.L. 1956. Estimating hydraulic roughness coefficients. Agricultural Engineering 37, 473-475. Hannaford, M. 2004. Pers. comm. with Chris Jaquette, Stillwater Sciences, September 2004. Wohl, E. 2000. Mountain Rivers. American Geophysical Union, Washington D.C.

Field Q<sub>bf</sub>. Solve for Q with known input parameters from field data. Use Manning's, because V needs to be calculated.

assumptions: A, S, and R are determined using XS data, n is determined using Cowan's method. w and d are from field data. equation :  $Q = 1.486/n * A * R^2/3 * S^1/2$ 

## Regulated Q<sub>recc</sub> (1.5-year return interval, hydro). Use known impaired or regulated Q1.5 to back out d, depth and

compare to what we saw in the field.

In Manning's, velocity is dependent on roughness (n) and slope (S). assumptions: assuming d approximates R (R may be more equivalent to d as width/depth ratio is greater than 20), all assumptions related to estimating n using Cowan's (1956) method, w and S from field data, Q determined with data directly from the USGS and the technical report on hydrology. Methods for estimating Q were either taken from hydrology report or from recommendations from Margaret Hannaford, primary author of the hydrology technical report for SMUD.

*equation* : Q = 1.486/n \* w \* d^5/3 \* S^1/2

## Unregulated Q<sub>recc</sub> (1.5-year return interval, hydro). Use known unimpaired or unregulated Q1.5 to back out d, depth

and compare to what we saw in the field.

assumptions : assuming d approximates R (R may be more equivalent to d as width/depth ratio is greater than 20), all assumptions related to estimating n using Cowan's (1956) method, w and S from field data, Q determined with data directly from the USGS and the technical report on hydrology. Methods for estimating Q were either taken from hydrology report or from recommendations from Margaret Hannaford, primary author of the hydrology technical report for SMUD.

*equation:* Q = 1.486/n \* w \* d^5/3 \* S^1/2

NOTE: Caution should be taken with calculations. They are "order-of-magnitude" estimates, and an adjustment for the appropriate number of significant figures has not been made.

## Robbs Peak Dam

No gauge Node Identification from Hydro Report none none Drainage Area 15.2 square miles Problematic because USGS Gauge # 11430000, South Fork Rubicon River below Gerle Creek near Georgetown, CA, is nearest gauge and is located below the confluence of Gerle Creek, a regulated drainage. Flow/drainage area was used for the gauge during the regulated period, which represents the spill of Robbs Peak Diversion Dam and Gerle Reservoir, and multiplied by the drainage area above Robbs Peak Diversion Dam. Record 1964 to 2001 Solution: Flow/Drainage Area for Gerle and South Fork Rubicon River drainages will be used to calculate Q1.5 for this location Flow/Area for Gerle/South Fork Rubicon drainages is 7.6 cfs/sqmi, thus multiply 7.6\*15.2 for solution Q1.5 (events with 1.5-year return period) 116 cfs cfs/square mile 7.6 cfs/square mile elevation 5130 ft

# Appendix Q. 1.5 Regulated

Ice House Dam Upper			
No gauge Node Identification from Hydro Report Drainage Area	Ice Hou 30	use 0.69 square miles	4
Use USGS gauge #11441500 and adjust for drainage area and climate Adjustment is from pers. comm. with Margaret Hannaford, hydrologist for SMUD who recommended using nearby unregulated watersheds to adjust for unregulated flow below Ice House Dam			
Record		, 1985 to 2001	
Q1.5 for gauge is a range 476 (and 93) cfs. 476 as example. 476 + (26*(30.69-27.5)) Q1.5 (events with 1.5-year return period, subsequent to SMUD UARP) Q1.5 (events with 1.5-year return period, subsequent to JFPH) cfs/square mile cfs/square mile elevation		559 cfs 176 cfs 18.2 cfs/square mile 5.7 cfs/square mile 190 ft	
<u>Ice House Dam Lower</u> No gauge			
Node Identification from Hydro Report Drainage Area Use USGS gauge #11441500 and adjust for drainage area and climate Adjustment is from pers. comm. with Margaret Hannaford, hydrologist for SMUD who recommended using nearby unregulated watersheds to adjust for unregulated flow below Ice House Dam Q1.5 for gauge is a range 476 (and 93) cfs. 476 as example. 476 + (26*(42.69-27.5))	Ice Hou 42	use 2.69 square miles	6
Q1.5 (events with 1.5-year return period, subsequent to SMUD UARP) Q1.5 (events with 1.5-year return period, subsequent to JFPH) cfs/square mile cfs/square mile elevation	2	871 cfs 488 cfs 20.4 cfs/square mile 11.4 cfs/square mile 665 ft	
<u>Chili Bar Upper Coloma Site</u> Gauge # 11444500, South Fork of the American near Placerville.			
Node Identification from Hydro Report	none	none	
Record Adjustment is made to values given location of site, estimated drainage area of 27 square miles greater than that at gauge (598 square miles), thus drainage area estimated at 625 square miles. To adjust for unregulated flow below Chili Bar Dam, use unregulated flow records from Placerville, Lotus, and Coloma gages Q1.5 for gauge is 5416 cfs. 5416+(9.3*(625-598))	1965 to	9 2001	
Drainage Area Q1.5 (events with 1.5-year return period) cfs/square mile elevation		625 square miles 667 cfs 9.1 cfs/square mile 764 ft	9

# Appendix Q. 1.5 Unregulated

<u>Rubicon Dam Reach</u> Gauge # 11428000 Record Drainage Area	1956 to 1963	31.4 square miles
